TOXICOLOGICAL SCIENCES

An Official Journal of the Society of Toxicology

Published by Oxford University Press, Inc.

Abstracts of the
39th Annual Meeting
Volume 54, Number 1
March 2000

Preface

This issue of *The Toxicologist* is devoted to the abstracts of the presentations for the symposium, platform, poster / discussion, workshop, roundtable, and poster sessions of the 39th Annual Meeting of the Society of Toxicology, held at the Pennsylvania Convention Center, Philadelphia, Pennsylvania, March 19-23, 2000.

An alphabetical Author Index, cross referencing the corresponding abstract number (2), begins on page 423.

The issue also contains a Keyword Index (by subject or chemical) of all the presentations, beginning on page 448.

The abstracts are reproduced as accepted by the Program Committee of the Society of Toxicology and appear in numerical sequence.

Copies of *The Toxicologist* are available at $45 each plus $5 postage and handling (U.S. funds) from:

Society of Toxicology
1767 Business Center Drive, Suite 302
Reston, VA 20190-5332

This abstract book has been produced electronically by Coe-Truman Technologies, Inc. Every effort has been made to faithfully reproduce the abstracts as submitted. However, no responsibility is assumed by the organizers for any injury and/or damage to persons or property as a matter of products, instructions or ideas contained in the material herein. Because of the rapid advances in the medical sciences, we recommend that independent verification of diaganoses and drug dosage be made.

1 SUNRISE MINI-COURSE: INTRODUCTION TO PROTEOMICS.

D. C. Liebler. *University of Arizona, Tucson, AZ.*

The proteome consists of all of the expressed proteins in any particular cell and is thus the functional expression of the genome. Research in proteomics focuses on the expression of proteins and their post-translational modification by endogenous or exogenous agents. Proteomics approaches open new avenues to investigate mechanisms by which environmental chemicals affect living systems through identification of specific protein targets and characterization of effects on cellular protein expression and post-translational modification. Modern proteomics and genomics approaches offer an ability to observe changes in whole pathways and signalling networks as opposed to individual genes and proteins that code for single, cellular components. This short, basic course will introduce participants to methods used in proteomics, peptide sequence analysis and identification of proteins using databases. Applications of the techniques will also be discussed. This course should be useful to all toxicologists involved in mechanistic research.

2 SUNRISE MINI-COURSE: METABONOMICS—A NEW APPROACH TO DRUG TOXICITY SCREENING USING NMR SPECTROSCOPY, PATTERN RECOGNITION, AND EXPERT SYSTEMS.

D. G. Robertson[1] and J. K. Nicholson[2]. [1]*Parke-Davis Pharmaceutical Research, Ann Arbor, MI and* [2]*Imperial College, University of London, London, United Kingdom.*

The combination of NMR with computer pattern recognition, expert systems and other bioinformatic tools has given rise to a new "Metabonomics" approach to toxicological assessment. Metabonomics is complementary to genomic and proteomic approaches and also gives new biomarker or surrogate marker information on toxic effects of drugs, as well as providing insights into toxic mechanisms. New high throughput flow injection technology and expert system spectrometer control allows high throughput of biofluids for *in vivo* toxicological assessment at a much lower overall cost than other "rival" high technology screening tools. NMR spectroscopy of biofluids and intact tissues can be used to provide detailed biochemical information on the functional integrity of organisms following challenges with xenobiotics or other pathophysiological perturbations. This basic course on NMR spectroscopy and expert systems, and its application to toxicology, should appeal to those with interests in mechanistic problems, high throughput *in vivo* screening, and lead candidate selection.

3 ENVIRONMENTAL EPIDEMIOLOGY AND TOXICOLOGY: THE INTERFACE AND THE INTERACTIONS.

R. A. Parent[1], C. Schonwalder[2], I. Hertz-Picciotto[3], M. Longnecker[2], G. Matanoski[4] and R. Santella[5]. [1]*Consultox, Limited, Damariscotta, ME,* [2]*NIEH, Research Triangle Park, NC,* [3]*University of North Carolina School of Public Health, Chapel Hill, NC,* [4]*Johns Hopkins, School of Public Health, Baltimore, MD and* [5]*Columbia University, New York, NY.*

Assessing human health hazards from environmental exposures is the common goal of both epidemiology and toxicology. Few investigations have successfully blended these disciplines. Knowledge and understanding of exposures, associations with effects and mechanisms of toxicity are the underpinning of risk assessment and risk management. This course will outline several perspectives on the need for multidisciplinary cooperation between toxicologists and epidemiologists. The goal is to help toxicologists understand how their biological science can provide valuable tools for human population studies of health effects of environmental exposures. Environmental epidemiology basics will be presented and integrated with concepts and examples of how biologic understanding can strengthen the search for both association of exposure and disease and proof of cause/effect. Lectures will demonstrate the use of biomarkers of exposure and effect in epidemiology; the integration of toxicological understanding into epidemiological study design; and the importance of understanding exposure and dose/response. Participants will be better able to work with those planning population studies for chemical exposure risk discovery by understanding study design, exposure evaluation and outcome analysis.

4 PULMONARY IMMUNOTOXICOLOGY.

M. D. Cohen[1], J. T. Zelikoff[1], G. L. Finch[2], M. W. Frampton[3], M. H. Karol[4], R. B. Schlesinger[1] and R. L. Sherwood[5]. [1]*New York University School of Medicine, New York, NY,* [2]*Lovelace Respiratory Research Institute, Albuquerque, NM,* [3]*University of Rochester Medical Center, Rochester, NY,* [4]*University of Pittsburgh, Pittsburgh, PA and* [5]*IIT Research Institute, Chicago, IL.*

Pulmonary immunotoxicology has been active over the past decade in seeking to elucidate how environmental and workplace agents can modify immune function in the lungs so as to allow for indirect alterations in respiratory health and, subsequently, overall host health. This course will review recent advances in pulmonary immunotoxicology for investigators in the field as well as to those about to enter it. The first speaker will describe normal respiratory system structure, function, and immunology, as well as disposition of inhaled particles/gases. The second presenter will describe the major pathologies which may arise from immunomodulation. Each remaining presentation will deal with a major class of pulmonary immunomodulating agents and will provide an overview of exposure, mechanisms by which immunomodulation evolves, and the potential risk to human health from exposure to each class of agents. Because of the wide scope of agents to be discussed, this CE course will not only be of great interest to researchers in the fields of pulmonary toxicology and immunotoxicology, but it will be informative to scientists involved in regulatory matters and to those doing research in food safety, neurotoxicology, metals toxicology, and mechanisms.

5 MOLECULAR GENETICS, METABOLISM AND CELL SIGNALING IN RENAL CARCINOGENESIS: A LESSON IN SYNERGISTIC TOXICOLOGY.

M. A. Davis[1], G. Hard[2], S. S. Lau[3] and C. Walker[4]. [1]*University of Maryland, Baltimore, MD,* [2]*American Health Foundation, Vahalla, NY,* [3]*University of Texas, Austin, TX and* [4]*UTMD Anderson Cancer Center, Smithville, TX.*

Renal carcinogenesis provides an example of the synergetic relationship between metabolism, genetics, proliferation and cell death in mediating renal toxicity. The objective of this basic course is to provide a review of cellular responses and other physiologically relevant aspects of the kidney that are important in mediating renal carcinogenesis. The presentations will provide the attendees with a useful review of several currently emerging topics that are being integrated in mechanistic investigations. The information provided in this course will be of general use to individuals involved in safety evaluations, risk assessment and those that examine mechanisms of renal toxicity.

6 MOLECULAR APPROACHES TO A COMPREHENSIVE UNDERSTANDING OF CARDIOTOXICITY.

Y. J. Kang[1], J. P. Kehrer[2], J. Robbins[3] and K. B. Wallace[4]. [1]*University of Louisville, Louisville, KY,* [2]*University of Texas, Austin, TX,* [3]*University of Cincinnati, Cincinnati, OH and* [4]*University of Minnesota, Duluth, MN.*

Cardiotoxicity is a major environmental health problem and an important complication of clinical applications of a diversity of drugs including anticancer chemotherapeutics. However, we toxicologists have not explored this field to the same extent as we have in studying the toxicology of the liver, lungs, kidneys, or brain. As a result, cardiac toxicology research is extremely under-represented in the discipline of toxicology. Advances in molecular biology of the heart have provided tremendous opportunities to study molecular mechanisms of cardiotoxicity. Such studies are increasingly important for the molecular era of cardiac medicine. For example, myocardial gene therapy is likely to soon be in phase 1 trials and its associated cardiotoxicity must be studied. It is time for toxicologists to become more involved in this exciting field and to make our contributions to the advanced understanding of cardiovascular diseases. This CE course will provide: (1) an overview of toxic events in the heart; (2) a comprehensive discussion of myocardial energy metabolism and oxidative injury and the role of apoptosis in cardiotoxicity; (3) an overview of the most exciting advances in molecular biology of the heart; and, (4) a discussion of the molecular tools used to dissect cellular and molecular mechanisms of cardiotoxicity. The ultimate goal of this CE course is to promote cardiac toxicology research and teaching within our discipline.

7 ADVANCED NEUROTOXICOLOGY: BIOMARKERS AND MECHANISMS OF OXIDATIVE STRESS-INDUCED NEUROTOXICITY.

W. Slikker, Jr.[1], T. Guilarte[2], D. Cory-Slechta[3], S. G. Orrenius[4], T. Narahashi[5] and A. C. Scallet[1]. [1]*National Center for Toxicological Research, Jefferson, AR,* [2]*Johns Hopkins University, Baltimore, MD,* [3]*University of Rochester, Rochester, NY,* [4]*Karolinska Institute, Stockholm, Sweden and* [5]*Northwestern University, Chicago, IL.*

This advanced course will focus on oxidative stress-induced neurotoxicity and the several multidisciplinary approaches used to define this important mechanism of action of neurotoxicants. Researchers in the field of neurotoxicology rely on neuropathological, behavioral, neurochemical/molecular biological and electrophysiological approaches to define both the effects and mechanisms of neurotoxicity. The use of the multidisciplinary approaches to define a toxicological profile for an agent or class of agents is both a challenge and advantage to the practicing neurotoxicologist. The underlying theory and necessary techniques to define necrotic and apoptotic neural cell death will be presented. The behavioral consequences and neurochemical/molecular biological underpinnings of oxidative stress-induced toxicity will also be described. Toxicologists from academia, government and industry will all benefit from this in-depth description of oxidative stress-induced neurotoxicity and the multidisciplinary approaches used to unravel its mechanism.

8 RODENT TOXICITY AND NONGENOTOXIC CARCINOGENESIS: KNOWLEDGE-BASED HUMAN RISK ASSESSMENT FROM MOLECULAR MECHANISMS.

R. A. Roberts[1], W. H. Farland[2], T. Dalton[3], J. I. Goodman[4] and H. Shertzer[3]. [1]*AstraZeneca Ltd., Macclesfield, United Kingdom,* [2]*USEPA, Washington, DC,* [3]*University of Cincinnati, Cincinnati, OH and* [4]*Michigan State University, East Lansing, MI.*

It is necessary to determine whether chemicals or drugs have the potential to pose a threat to human health. Chemicals that can damage DNA are detected in short-term assays but the detection of nongenotoxic carcinogens relies upon bioassays in laboratory animals. However, there are marked rodent-human species differences in response to nongenotoxic carcinogens, questioning the relevance of rodent data for human risk assessment. This course aims to provide useful background on rodent nongenotoxic carcinogenesis, then to illustrate, by example, how knowledge of the molecular mechanisms of rodent nongenotoxic carcinogenesis coupled with an understanding of species differences can assist in knowledge-based human risk assessment. The ability of nongenotoxic carcinogens to cause oxidative stress, induce cell proliferation, suppress apoptosis and activate nuclear receptors will be discussed. Finally, consideration will be given to incorporating mechanism-based information into risk assessment for regulatory purposes.

9 ADVANCES IN NON-INVASIVE MICROMETER AND NANOMETER SCALE CELLULAR/TISSUE VITAL IMAGING.

R. C. Burghardt[1], M. A. Philbert[2], R. Barhoumi[1], D. Kawahara[3], C. R. Meyer[2] and D. Piston[4]. [1]*Texas A&M University, College Station, TX,* [2]*University of Michigan, Ann Arbor, MI,* [3]*Xenogen Corporation, Alameda, CA and* [4]*Vanderbilt University, Nashville, TN.*

Non-invasive, real-time imaging tools employing nano-optical/magnetic biosensors and biomarkers to define the function of living cells are among the most significant emerging technologies in the life sciences for toxicology applications. This basic course will identify these new technologies and provide examples of applications ranging from *in vivo* toxicokinetic monitoring in intact living cells to the detection of gene expression *in vivo* to increase understanding of the mechanisms of cellular toxicity. Speaker 1 will discuss nano-optochemical sensors that can be used to assess metabolic substrates and ions within cells following toxicant perturbation. Speaker 2 will discuss the real time analysis of cellular responses in cultured cells and describe instrumentation developed to integrate data acquisition and analysis of toxicant effects on Ca^{2+}-mediated signal transduction. Speaker 3 will discuss a significant microscopy advance, multi-photon microscopy, which uses ultrafast infrared laser pulses to image fluorescence signals for the study of sub-cellular responses within living tissue. Speaker 4 will describe new technology using a non-invasive, real-time imaging system to monitor intact living animals for specific gene induction by compounds. Speaker 5 will discuss a mechanism to obtain experimental results with low variance by production of imaging-induced changes in single animals used as their own controls, including testing for changes on volumetric data sets such as autoradiography and MRI.

10 TIPS FOR EFFECTIVE RISK COMMUNICATION.

M. J. Miller[1], G. Gray[2], J. Bus[3], D. Hyman[4] and B. Shurdut[5]. [1]*Exxon Biomedical Sciences, Inc., Annandale, NJ,* [2]*Harvard School of Public Health, Boston, MA,* [3]*Dow Chemical Company, Midland, MI,* [4]*SOT Public Affairs, Reston, VA and* [5]*SOT Congessional Fellow, Washington, DC.*

This basic course provides members with a practical understanding of the importance and necessity of effectively communicating health and environmental risks. Effective risk communication is an essential part of the risk assessment/risk management process. Misguided perceptions of risk by the public can have significant contrary impacts on regulatory priorities, research initiatives, business development and public health. The first speaker will discuss the changing nature of risk communication and the importance of providing scientific information in context. The next speaker will provide specific tips on how to communicate risk-related issues to reporters and give an overview of the elements of a great news story. The third speaker will discuss the importance of communicating scientific issues to Congress, give an overview of the political process, and provide advice to members when visiting Congress. The last speaker will discuss the importance and most effective means of providing accurate risk-based information to the public and provide tips on available tools/resources to assist members in speaking to schools, local communities and special interest groups. A discussion panel including the speakers and invited guests from the press, Congress and USEPA will summarize the key messages from the course and field questions from the floor. The course should be of broad interest to members involved in risk assessment and regulatory issues.

11 ANTIBODIES AS REAGENTS TO EVALUATE TOXICANT-MEDIATED SIGNAL TRANSDUCTION PATHWAYS.

R. S. Pollenz[1], B. Abbott[2], G. H. Perdew[3] and T. R. Sutter[4]. [1]*Medical University of South Carolina, Charleston, SC,* [2]*USEPA, Research Triangle Park, NC,* [3]*Penn State University, State Park, PA and* [4]*University of Memphis, Memphis, TN.*

Signal transduction pathways mediate the effects of many toxicologically important compounds (i.e., dioxins, estrogens, peroxisome proliferators, etc.). To understand how these compounds mediate biological effects, it is necessary to understand the expression, distribution and concentration of the signaling proteins, their interactions, and the gene products they regulate. One of the most effective ways to carry out such analyses is with specific antibodies to each of the component proteins. This course will provide a spring board for beginning and established investigators to learn state-of-the-art techniques and strategies involved in the analysis of proteins both *in vivo* and *in vitro*. Completion of this course should benefit those interested in establishing the use of antibodies within the laboratory and will also provide enough detail to allow individuals to better critique studies that utilize antibody reagents. Topics to be addressed include: analysis of protein domain structure and design of antibody regents, production and purification of antigens and antibodies, use of enzyme activity and expression, immunoprecipitation to assess protein expression and interaction, use of protein tags, quantitative Western blotting, and immunocytochemical methods to assess protein expression and subcellular localization in tissues. Each session will be technique-oriented and presented in a problem solving format based on real experimental successes and failures.

12 PHOTOTOXICOLOGY: BASIS PRINCIPLES OF LIGHT, PHOTOBIOLOGY, AND REGULATORY ISSUES.

P. D. Forbes[1], P. C. Howard[2], F. G. Gerberick[3], A. C. Jacobs[4] and J. F. Nash[3]. [1]*Argus Research Laboratories, Inc., Horsham, PA,* [2]*National Center for Toxicological Research, Jefferson, AR,* [3]*The Procter & Gamble Company, Cincinnati, OH and* [4]*USFDA, Rockville, MD.*

The dermatotoxic and carcinogenic properties of solar light have been documented for several years. Increased leisure time in outdoor activities, use of tanning beds, and the use of drugs that are photoactivated have resulted in increased interest in phototoxicology. This basic course will assist investigators in understanding fundamental issues and techniques in phototoxicology. The first presentation will focus on light characteristics, sources, methods of

detection, quantification, and photochemistry. The reaction of biological systems to light will be the focus of the second and third presentations. Characteristics of photodynamic reactions, phototoxicity, photoirritation, photoallergy, photoaging, photogenotoxicity, photomutagenesis, and photocarcinogenesis will be presented. Regulatory issues in phototoxicology will be outlined including U.S., European, and ICH guidelines and the use of animal models, transgenic animals, and *in vitro* studies. The design of methods and protocol to address phototoxicology issues will be presented from both the regulatory and industrial positions. Toxicologists from industry, government and academia will benefit from exposure to the basic principles, biology and application of phototoxicology.

13 TOXICOKINETICS AND PHYSIOLOGICALLY-BASED TOXICOKINETICS IN TOXICOLOGY AND RISK ASSESSMENT.

R. Dixit[1], M. E. Andersen[2], K. Krishnan[3] and J. E. Riviere[4]. [1]*Merck & Co., Inc., West Point, PA,* [2]*Colorado State University, Fort Collins, CO,* [3]*University of Montreal, Medicine du Travail er Hygiene du Milieu, Montreal, Quebec, Canada and* [4]*North Carolina State University, Raleigh, NC.*

With the implementation of the International Conference on Harmonization (ICH) Guidelines on Dose Selection for Carcinogenicity Studies and Systemic Exposure, the conventional toxicokinetics (TK) assessment has become an integral part of safety assessment. Toxicokinetic models have received increasing application in dose selection, trans-species comparison of toxicity and in assessing human safety margins of pharmaceutical agents. Physiologically-based toxicokinetic models represent the kinetic uptake and disposition of chemicals using the rates of biochemical reactions, as well as physiological and anatomical characteristics. In the absence of human pharmacokinetics data, these models have been successfully used for extrapolation of toxicokinetics from high dose to low dose and from animals to humans. The objective of this basic course is to describe and compare conventional compartmental toxicokinetics models and physiologically-based toxicokinetics models. Emphasis will be placed on the application of these models in dose selection, ICH guidelines, interpretation of toxicity data and human health risk assessment.

14 METAL EXPOSURE AND TOXICITY OF THE RESPIRATORY TRACT.

D. L. Morgan[1], M. P. Waalkes[2], J. M. Benson[3], J. C. Bonner[1], S. H. Gavett[4] and T. Gordon[5]. [1]*NIEHS, Research Triangle Park, NC,* [2]*National Cancer Institute at National Institute of Environmental Health Sciences, Research Triangle Park, NC,* [3]*Lovelace Respiratory Research Institute, Albuquerque, NM,* [4]*USEPA, Research Triangle Park, NC and* [5]*New York University Medical Center, New York, NY.*

Environmental and occupational inhalation exposures to metal vapors, fumes, and particulates are associated with a number of diverse and debilitating respiratory diseases. The diverse nature of metal-induced pulmonary diseases is due in part to the wide range of physiochemical properties of metals and metal compounds. The molecular mechanisms by which metals cause pulmonary disease are not clear, but metals can induce a variety of effects ranging from aberrant gene expression, inappropriate signal transduction to enhanced or perturbed apoptosis. This course will focus on the mechanisms by which inhaled metals cause acute inflammatory lung diseases, such as metal fume fever, as well as acute/chronic respiratory diseases such as asthma pulmonary fibrosis, and cancer of the respiratory tract. This course will have wide appeal for investigators in the fields of metal and inhalation toxicology, mechanisms carcinogenesis, occupational medicine and immunotoxicology.

15 SAFETY PHARMACOLOGY AND RISK ASSESSMENT.

L. B. Kinter[1], A. S. Bass[2], J. L. Mattsson[3], D. J. Murphy[4] and R. D. Sarazan[5]. [1]*AstraZeneca, Ltd., Wayne, PA,* [2]*Pharmacia & Upjohn, Inc., Kalamazoo, MI,* [3]*Dow AgroScience, Indianapolis, IN,* [4]*SmithKline Beecham Pharmaceuticals, King of Prussia, PA and* [5]*Eli Lily & Company, Greenfield, IN.*

Safety Pharmacology (SP) identifies unanticipated drug effects on critical organ functions. These studies contribute directly to risk assessment/management in human volunteers/patients, particularly in the design of initial (Phase I) clinical trials. Recognizing these contributions, the International Conference on Harmonization (ICH) accepted SP in 1998 for standardization of international guidelines defining basic (core) evaluations and points to consider for design and conduct of SP studies. The instructors will focus upon the impact of the proposed ICH Safety Pharmacology guidelines for toxicologists, and will address in detail the likely core cardiovascular, respiratory, and central nervous system evaluations. The course will be of broad interest to both academic and industrial scientists engaged in animal research and will present a timely overview of safety pharmacology for toxicologists.

16 TOXICOGENOMICS IN THE TRENCHES.

T. R. Zacharewski[1], P. Saama[1], W. B. Mattes[2] and E. Nuwaysir[3]. [1]*Michigan State University, East Lansing, MI,* [2]*Pharmacia & Upjohn, Inc., Kalamazoo, MI and* [3]*NIEHS, Research Triangle Park, NC.*

Toxicogenomics has emerged as a new discipline that integrates genomics (the study of all genes encoded by an organism's DNA) and bioinformatics with toxicology to assess and elucidate the mechanisms of action of known and suspected toxicants. The suite of bioinformatics tools and resources that are essential for this research will be covered in the first talk. Hybridization of mRNA to hundreds of complementary cDNAs/expressed sequence tags (ESTs) provides a method to monitor the totality of gene expression following chemical exposure; design, generation and use of such arrays of cDNAs on membrane filters and glass slides will be the topic of the second and third talk, respectively. The final presentation, which is more advanced, will examine the difficult nature of analyzing the data generated from such experiments in a rigorous statistical fashion. This course will be of particular interest to those investigators who are considering incorporating genomic technologies into their research programs.

17 THE APPLICATION OF PHILOSOPHY TO RISK ASSESSMENT, MANAGEMENT AND COMMUNICATION.

M. Saner[1] and M. Gillis[2]. [1]*Consultancy for Environmental Science and Policy, Ottawa, Ontario, Canada and* [2]*Department of Philosophy, University of Florida, Jacksonville, FL. Sponsor:* J. T. Zelikoff.

The debate generated by public concerns over modern science and technology has become increasingly polarized between "hard-core scientists" and the "hysterical public." Such polarization threatens the autonomy of science, as well as the development of useful technology. The ability to clearly conceptualize the relation between science and values and to systematically express this distinction in a dialogue are the best ways to address this problem. This basic course, using the context of human and environmental toxicology, will help participants influence and effectively participate in this important debate through better understanding of environmental ethics, a discipline within applied philosophy providing a systematic account of the moral relations between human beings and our natural environment. It incorporates topics ranging from animal welfare to the justification of environmental protection goals. The goal of this course is to provide the participants with a balanced assessment of the role of environmental ethics within risk evaluation, management, and communication. Participants will be provided with an overview of the interface between science and values (ethics), an introduction into environmental ethical theories, and examples of application of this material to concrete issues within risk evaluation, management and communication.

18 HUMAN HEALTH AND ECOLOGICAL IMPACT OF HARMFUL ALGAL BLOOMS.

R. C. MacPhail[1] and P. S. Spencer[2]. [1]*USEPA, Research Triangle Park, NC and* [2]*Oregon Health Sciences University, Portland, OR.*

Harmful algal blooms (HABs) refer to a broad array of toxic organisms that can attack both wildlife and humans. HABs can be found in ponds, lakes, streams, estuaries and oceans. Interest in HABs research has been sparked by the observation that HAB events are increasing world-wide in both frequency and spatial extent, thereby increasing exposure potential and risks to vertebrate and invertebrate species alike. HABs can produce toxins, of remarkable molecular complexity, that can damage a number of organ systems. Moreover, many HABs produce neurotoxins whose mode of action is so specific they have proved to be valuable research tools to probe the nervous system and its functions. Other HAB toxins (e.g., *Pfiesteria spp.*), on the other hand, are still poorly understood. Most of what is known about HAB toxicity has been derived from acute poisoning episodes and/or laboratory exposures; the pos-

sibility of chronic effects resulting from acute, episodic or long-term exposure is largely a matter of speculation. This symposium will elaborate our current understanding of HABs, the toxins they produce, their target organs, and their mode(s) of action in both humans and wildlife.

19 BREVETOXINS ARE HUMAN NEUROTOXINS THAT ARE ACTIVE ORALLY, BY INJECTION, AND BY INHALATION.

D. G. Baden. *University of North Carolina, Wilmington, NC.*

The polyether brevetoxins (PbTx) produced by the marine dinoflagellate *Gymnodinium breve* are amongst the most potent non-proteinaceous neurotoxins known. They interact with site 5 of voltage-gated sodium channels in neurons and produce a spectrum of effects including a shift of the activation potential to more negative values, prolonged mean open time of sodium channels, inhibition of channel inactivation, and induction or visualization of multiple subconductance states. These effects would appear to account for the signs and symptoms associated with massive fish kills, neurotoxic shellfish poisoning in humans, and other wildlife illnesses associated with Florida red tides. The respiratory effects of brevetoxins are less clearly understood and appear to represent a series of toxicologic signs and symptoms that do not always align with specific sodium channel depolarization. Following a large manatee epizootic event in 1996 associated with major Florida red tide, a series of maladies associated with phagocyte accumulation of toxin, and toxic shock syndrome-like events, pointed to a newly recognized type of toxicity associated with blooms of *G. breve*. These effects, and their significance in the context of other recognized deleterious brevetoxin effects, indicate that red tide poisoning may produce long-lasting or chronic effects on wildlife and human health.

20 HUMAN-HEALTH AND ECOLOGICAL IMPACT OF CYANOBACTERIA.

W. W. Carmichael. *Wright State University, Dayton, OH.*

Cyanobacteria are freshwater organisms responsible for algal blooms in lakes, ponds, rivers and reservoirs. The increasing prevalence of cyanobacteria blooms is due to nutrient overload (eutrophication) of waters, climate change, and enhanced scientific awareness. Many cyanobacteria, including Anabena, Aphanizomenon, Microcystis and Oscillatoria, produce toxins that can threaten the health of many forms of wildlife and humans. Toxins such as saxitoxin and anatoxin-a are well-known for their neurotoxic effects in a variety of species. In addition, the neurotoxin anatoxin-a(s) is a naturally occurring organophosphate (OP) whose toxic effects resemble those produced by many commercial OP insecticides. Cyanobacteria also produce microcystins and nodularins which have been shown to be hepatotoxic as well as hepatic carcinogen promoters. In addition, a recently identified alkaloid hepatotoxin, cylindrospermopsin, has been found in several Florida lakes undergoing incresed eutropliction. Reports of toxic cyanobacterial blooms date from at least the last century, and have killed numerous livestock and domestic pets in addition to many wildlife species. Human toxicity produced by cyanobacterial toxins has long been suspected, but never confirmed. Recently, however, microcystins have been implicated in the death of at least 52 humans, and liver failure in exposed survivors, undergoing renal dialysis in Brazil. While the risks of acute exposure to cyanobacteria have been well established, growing evidence suggests chronic effects may also result from contact with cyanobacteria blooms.

21 DOMOIC ACID (DA): ENVIRONMENTAL EXPOSURES, NEUROTOXIC EFFECTS AND MECHANISMS OF SUSCEPTIBILITY.

J. S. Ramsdell. *National Ocean Service, Charleston, SC.*

Domoic acid is a tricarboxylic acid produced by certain species of the diatom genus *Pseudo-nitzchia*. It was the causative agent of the amnesic shellfish poisoning in 1987. Since that time the toxic algae has been determined to have a worldwide distribution. Domoic acid binds competitively to kainic and AMPA-subtype glutamate receptors, and leads to rapid elevation of cytosolic free calcium in hippocampal pyramidal cells, which requires activation of NMDA receptors. Domoic acid adminstered to mice causes a dose-dependent sequel of acute signs, including hyperactivity, stereotypic scratching, seizures and status epiletictus. Domoic acid also causes a does-dependent induction of the calcium-sensitive immediate response gene c-fos in brain tissue primarily in hippocampus, olfactory bulb and area postrema/nucleus solitarius. Long-term effects of domoic acid in mice include decreased performance in working memory in the absence of apparent structural damage. Neonate mice are forty times more sensitive than adults to domoic acid due to poor clearance of the toxin. Increased prevalence of toxic species of *Pseudo-nitzchia* suggests that incidents of exposure of wildlife and humans will likely continue to occur.

22 HUMAN-HEALTH AND ECOLOGICAL IMPACT OF *PFIESTERIA* TOXIN(S).

J. Burkholder. *NCSU, Raleigh, NC.*

Pfiesteria piscicida is a recently discovered toxic dynoflagellate found in estuaries in North Carolina and Maryland. Current evidence also suggest there may be multiple species of *Pfiesteria* found throughout estuaries in the Southeast and Gulf of Mexico. Research on *Pfiesteria* has provided strong linkages between environmental deterioration, fish kills (that are sometimes massive), and subtle but serious adverse effects on human health. *Pfiesteria* displays: (1) a strong attraction to live fish; (2) production of toxin(s) that cause fish distress, disease and death; and (3) toxicity triggered by the presence of live fish. Laboratory research has shown that *Pfiesteria* will kill numerous species of fish and bivalved mollusks. *Pfiesteria* is also remarkable in its complex life cycle, with multiple amoeboid and flagellated stages and rapid transitions between these stages. Progress in toxin isolation indicates a hydrophilic fraction destroys certain mammalian tissues and the nervous system of fish, and a lipophilic fraction that produces edema in fish. Human-health effects of *Pfiesteria* toxin(s), from contact with water or by inhalation, include irritation, nausea and headaches, erratic behavior, and learning impairments. Evidence also suggests some signs of toxicity in humans may persist for years after exposure.

23 MOLECULAR MECHANISMS OF CHEMICAL TERATOGENESIS.

P. G. Wells. *University of Toronto, Toronto, Ontario, Canada.*

Although 50 years have passed since the thalidomide tragedy left thousands of infants born with severe malformations, only recently have a variety of biochemical and molecular biological approaches begun to reveal the underlying mechanisms and risk factors for chemical teratogenesis. This symposium provides a timely update of four approaches which, while diverse in technical repertoire and mechanistic thrust, all focus upon teratological mechanisms in the conceptus, providing both corroborating results and novel insights. First is the role of reactive oxygen species and oxidative macromolecular damage in teratogenesis, and the contribution of embryonic antioxidative enzymes and DNA repair in modulating teratologic risk. The second investigates the teratological significance of alterations in gene expression and signal transduction pathways regulating conceptal cell cycle checkpoint activation, DNA repair and apoptosis. A subsequent approach focuses on the signaling pathways modulating apoptotic cell death in the developing embryo, and how their perturbation by xenobiotics may lead to teratogenesis. Finally, recent comprehensive techniques in molecular biology, including DNA microarrays, are used to examine the complex pattern of changing gene expression in developing embryos, and the role that xenobiotic-initiated alterations in these expression patterns may play in teratogenesis.

24 REACTIVE OXYGEN SPECIES AND OXIDATIVE DAMAGE.

R. R. Laposa, P. G. Wells, C. J. Nicol and T. Parman. *University of Toronto. Ontario, Canada.*

We examined xenobiotic bioactivation and free radical-initiated, reactive oxygen species (ROS)-mediated oxidative molecular target damage, and DNA repair in mouse and rabbit models. Phenytoin and related teratogens were bioactivated by purified prostaglandin H synthases (PHSs) to free radical intermediates identified by electron spin resonance spectrometry. PHS-2 was high in mouse embryos, PHS-2 knockout mice were resistant to phenytoin teratogenicity, and PHS inhibitors (aspirin, etc.) reduced teratogenicity (phenytoin, thalidomide). Bioactivation, DNA/protein oxidation and embryotoxicity occurred in embryo culture (benzo[a]pyrene (B[a]P), phenytoin), indicating embryonic determinants. Treatment with antioxidative enzymes (superoxide dismutase (SOD), catalase) increased embryonic activities, blocked DNA oxidation and inhibited teratogenicity (phenytoin, B[a]P). Phenytoin- and

thalidomide-initiated oxidation of embryonic cellular macromolecules, glutathione (GSH) and teratogenicity were reduced by the free radical trapping agent phenylbutylnitrone and/or antioxidants (caffeic acid, vitamin E). ROS involvement *in vivo* was further implicated by hydroxyl radical formation (3-hydroxylation of salicylate), and increased teratologic susceptibility with mice deficient in glucose-6-phosphate dehydrogenase, or inhibition of GSH peroxidase or GSH reductase. PHS inhibitors or SOD inhibited micronucleus formation initiated in cultured fibroblasts by B[a]P and phenytoin. DNA may be an important target, since p53 knockout mice with deficient DNA repair were more susceptible to phenytoin and B[a]P embryotoxicity. (Support: Medical Research Council of Canada).

25 SIGNAL TRANSDUCTION PATHWAYS IN THE CONCEPTUS.

B. F. Hales and T. R. S. Ozolins. *McGill University, Montreal, Quebec, Canada.* Sponsor: P. G. Wells.

The signal transduction pathways mediating insult to the conceptus by most teratogens are unknown. The consequences of teratogen exposure depend on the ability of the embryo to respond as well as on the nature of the insult. Complex mechanisms, ranging from alterations in gene expression to DNA repair, cell cycle checkpoint activation, or apoptosis, detect an insult and trigger an embryo-protective response. Many stressors alter gene expression by perturbing regulation of the immediate early gene activator protein-1 (AP-1) transcription factor. To test the hypothesis that AP-1 is a significant determinant of embryonic susceptibility to insult, we investigated the regulation of AP-1 activity in rat embryos during organogenesis. AP-1 DNA binding activity is induced during transient oxidative stress in rat embryos *in vitro*. Supershift assays indicate that basal AP-1 binding in the embryo is due primarily to JunD, while in the yolk sac both c-Jun and JunD are important. Under oxidative stress, c-Fos and c-Jun contribute to AP-1 binding. Oxidative stress-induced changes in AP-1 activity in embryos are not due to activation of the extracellular signal-regulated kinases1,2 (ERKs-1,2) or stress activated protein kinases (SAPKs). Interestingly, UV irradiation and heat shock stimulate SAPKs in the yolk sac, but only heat shock is effective in the embryo, suggesting that SAPK pathways are poorly developed. Immunodepletion of redox factor 1 (Ref-1), a nuclear factor that promotes AP-1 binding, eliminates AP-1 activity from embryonic nuclear extracts. Therefore, in the conceptus, where AP-1 phosphorylation changes are not apparent, Ref-1 is a critical determinant of AP-1 activity. These data suggest that Ref-1 plays a pivotal role in the embryonic stress response. (Supported by the MRC of Canada.)

26 APOPTOTIC SIGNALING PATHWAYS.

P. E. Mirkes. *University of Washington, Seattle, WA.* Sponsor: P. G. Wells.

It is well recognized that environmental agents capable of disrupting normal development (i.e., teratogens) often induce excessive cell death as an early event in teratogenesis. Teratogen-induced cell death is also specific, i.e., some cells die while the majority survive, and those that die often are associated with areas of programmed cell death. I will present data showing that 4 different developmental toxicants, hyperthermia (43°C), cyclophosphamide (DNA alkylating agent), sodium arsenite (heavy metal), and staurosporine (protein kinase c inhibitor), induce activation of caspase-3, cleavage of poly (ADP-ribose) polymerase (PARP), and internucleosomal DNA fragmentation. These same agents also induce the release of cytochrome c from mitochondria coincident with the activation of caspase-3. These results suggest mitochondria serve as targets for these developmental toxicants. We have also shown that cells of the heart from early postimpalntation mouse embryos are completely resistant to the apoptotic stimulus initiated by these 4 developmental toxicants. The failure to undergo cell death in response to exposure to these teratogens is associated with a failure to release cytochrome c as well as the downstream events such as caspase-3 activation, PARP cleavage and DNA fragmentation. My laboratory has also begun to probe known signal transduction pathways in an effort to understand the mechanisms by which developmental toxicants trigger apoptosis in early postimplantation murine embryos. We have now shown that hyperthermia rapidly, but transiently, activates the mitogen-activated protein kinases (MAP Kinases) belonging to the ERK, JNK, and p38 pathways. The activation of the ERK and JNK pathways precedes by several hours the activation of caspase-3; therefore, these signaling pathways may be part of the upstream signaling events required for the activation of the apoptotic pathway. In contrast, cyclophosphamide and staurosporine activate the p38 but fail to activate the ERK, JNK pathways. Thus, activation of MAP kinase pathways is teratogen-specific.

27 ALTERED GENE EXPRESSION PATTERNS TO PREDICT AND UNDERSTAND CHEMICAL TERATOGENESIS.

R. Finnell, G. D. Bennett and J. G. van Waes. *University of Nebraska Medical Center, Omaha, NE.* Sponsor: P. G. Wells.

The Human Genome Project is progressing towards completion, providing a wealth of information in the form of expressed sequence tags (ESTs), single nucleotide polymorphisms (SNPs) and physically mapped genes to the research community. As a result, toxicologists are now able to incorporate this information into their research programs, enabling them to easily efficiently perform studies that were once regarded as possible only by molecular geneticists. These new technologies have created the situation where many long sought after interactions between environmental toxicants and their gene targets can finally be addressed. Perhaps the most important development is the existence of expression chips or DNA microarrays. With these DNA chips, investigators can detect and simultaneously monitor the expression of ordered sets of hundreds or thousands of genes from small biological samples. The application of these experimental approaches to understanding the mechanisms underlying teratogen-induced congenital defects will be the focus of this presentation. Experimental examples will include both pharmaceutical compounds (valproic acid and phenytoin) and environmental contaminants (arsenic). Specific target genes include: cell cycle checkpoint genes, folate biosynthesis pathway genes, and selected transcription factors. Efforts to understand the implications of the gene expression data will be fully explored, including experimental approaches to validate gene expression observations.

28 ARE THERE AUTOIMMUNE CONSEQUENCES OF TOXICANT EXPOSURE IN HUMAN POPULATIONS?

K. E. Rodgers[1] and M. A. Lynes[2]. [1]*University of Southern California, Los Angeles, CA and* [2]*University of Connecticut, Storrs, CT.*

Numerous studies have addressed the influence of environmental toxicants, medical devices, and ethical pharmaceuticals on the potentiation, initiation, and/or exacerbation of human autoimmune disease. While some pharmaceuticals have been shown to contribute to autoimmune-like disease that may be reversed when exposure to the drug is removed, the ability of environmental toxicants or medical devices to contribute to autoimmune disease is still a matter of considerable debate. Animal models of autoimmune disease have been successfully used as screens for the contribution of toxicants to the development of disease and to explore specific pathogenic mechanisms, but human epidemiological studies have been less successful in connecting toxicant exposure with autoimmune disease. This difficulty may arise from several facts. First, individual human autoimmune diseases are relatively rare, making the association of toxicant exposure with a specific disease more difficult. Symptoms associated with autoimmune disease also can vary widely between individuals, making diagnosis of a specific autoimmune disease less certain. Moreover, a variety of potential susceptibility genes segregate in the human population, adding an additional variable to this analysis. Finally, it is difficult to establish cohorts with consistent exposure for epidemiological evaluation. Panelists will address these issues from a variety of standpoints, providing insights into the methodologies used to assess these diseases, the types of ongoing studies that address elements of the issues described above, and the prospects for resolving these important areas of investigation. This roundtable should provide research scientists, clinicians, and epidemiologists with an opportunity to consider a range of issues related to toxicant-induced autoimmunity.

29 AUTOIMMUNE DISEASE AND ENVIRONMENTAL CHEMICALS.

N. R. Rose. *Johns Hopkins University, Baltimore, MD.* Sponsor: K. E. Rodgers.

Autoimmune disease results from an attack by the immune system on the host's own tissues. All of the human autoimmune disease show evidence of genetic predisposition. A number of heritable traits contribute to heightened susceptibility, but he best defined genes are members of the major histocompatibility complex, HLA. In toto, however, genetic predisposition accounts for less than half of the risk of developing and autoimmune disease. The remaining risk may reside in two factors. First are somatic variations in the immune system itself. Both T-cell and B-cell receptors are highly diverse in order to accommodate the large number of potential antigens. Second, external factors may contribute to the risk of developing an autoimmune disease. Infection and certain drugs are the most studied examples in human autoimmune disease, but circumstantial evidence and animal experiments have

implicated a number of environmental chemicals, such as mercury. The issue is in great need of careful epidemologic studies as well as experimental investigations of plausible cause-and-effect relationships between specific chemical and particular autoimmune disorders.

30 CONSEQUENCES OF OCCUPATIONAL AND ENVIRONMENTAL EXPOSURES IN THE DEVELOPMENT OF AUTOIMMUNE DISEASES.

D. M. Ozonoff. *Boston University, Boston, MA*. Sponsor: K. E. Rodgers.

It is well known that chemical agents (e.g., therapeutic drugs) can induce autoimmune disorders ("drug-induced lupus"). In addition, several workplace agents, especially organic solvents, have been implicated in autoimmune disorders (Goodpature's syndrome, Sevens-Johns syndrome, systemic sclerosis). This Roundtable presentation will discuss the extent to which we might expect autoimmune disorders to result from environmental/occupational exposures to chemical agents. The common chlorinated ethylenes trichloroethylene and percholorethylene (TCE and PCE) will be used as examples.

31 CRITICAL ISSUES FOR THE EVALUATION OF ENVIRONMENTALLY-RELATED AUTOIMMUNE DISEASES.

G. S. Cooper. *NIEHS, Research Triangle Park, NC*. Sponsor: K. E. Rodgers.

Some data from experimental and epidemiologic studies indicate that specific environmental exposures may contribute to the development of autoimmune diseases. However, the evidence for the most part can be described as somewhere between "scant" and "suggestive". Very few studies have been conducted, making it impossible to evaluate consistency between studies. First reports, even if they come from a well-conceived, well-conducted study, are often not confirmed by subsequent research. Another limitation is the difficulty in extrapolating from the high exposures typically found in certain occupational settings to the lower exposures that are more common in the general population. Although there is interest in silica dust as a cause of autoimmune disease, techniques for accurately assessing low-to-moderate levels of silica exposure, including likely sources of exposure in women, have not yet been validated and used in epidemiologic studies. A third limitation is the difficulty in generalizing across diseases: under what conditions or to what extent is what we learn about environmental associations with scleroderma applicable to systemic lupus erythematosus or rheumatoid arthritis or multiple sclerosis? Examples from the current literature will be discussed. It is important to build a case for the contribution of environmental or occupational exposures to the development or progression of autoimmune diseases, but this goal will be ill-served by premature judgements and by small, poorly-designed studies.

32 CHEMOPREVENTION OF TOBACCO SMOKE-INDUCED LUNG CANCER.

I. E. Espiritu, D. L. Uyeminami and H. P. Witschi. *ITEH, University of California, Davis, CA*.

In a series of experiments we investigated whether chemopreventive agents could inhibit the development of lung tumors in mice exposed to tobacco smoke. Male strain A/J mice were fed two chemopreventive agents: D-limonene at a concentration of 6.3 g/kg and XSC (1,4-phenylenebis (methylene) selenoisocyanate) at 20 mg/kg. They were exposed, 6 hours a day, 5 days a week for 5 months to a mixture of cigarette mainstream smoke (11%) and sidestream smoke (89%) at a concentration of 137 mg/m^3 total suspended particulate matter. After removing from smoke, they were allowed a 4 month recovery period in air before lung surface tumors were counted and multiplicity and incidence calculated. Animals exposed to tobacco smoke alone had an average of 2.8 tumors per lung, animals fed D-limonene 2.6 and animals fed XSC 2.4; the differences were statistically not significant. In a positive control experiment, animals injected with NNK had an average of 13 tumors/lung, animals fed D-limonene 7.8 and XSC 2.8 (differences highly significant), thus showing that the chemopreventive agents were effective against NNK. In addition to D-limonene and XSC, we have thus far evaluated the chemopreventive actions of green tea, phenethyl isothiocyanate (PEITC), aspirin, N-acetylcysteine and myo-inositol/dexamethasone. Of all these agents, only myo-inositol/dexamethasone successfully prevented smoke-induced lung tumor development. Chemopreventive agents effective against individual smoke constituents may thus often be not effective when evaluated against the real and complex mixture of full tobacco smoke (Supported by ES07908.)

33 A DIETARY ANTIOXIDANT PARADOXICALLY REDUCES TUMOR NUMBER BUT INCREASES MALIGNANCIES IN TRANSGENIC MICE TREATED TOPICALLY WITH BENZO(A)PYRENE.

K. R. Martin, C. Trempus, M. Saulnier, F. W. Kari, J. C. Barrett and J. E. French. *NIEHS/NIH, Research Triangle Park, NC*.

Epidemiological studies support the protective role of dietary antioxidants in preventing cancer. However, emerging evidence suggests that dietary antioxidants may also exacerbate carcinogenesis. To test this hypothesis in a model that possesses genotypic characteristics of human cancer, we selected the FVB/N Trp53 haploinsufficient Tg.AC (v-Ha-ras) mouse as a short-term cancer bioassay model, because it contains an activated, carcinogen-inducible ras oncogene and an inactivated p53 tumor suppressor gene, which are frequent genetic alterations in human cancers. These mice rapidly develop chemically-induced benign and fatal malignant skin tumors, which can easily be quantified. Mice were fed basal diets with or without 3% N-acetyl-L-cysteine (NAC), a well-recognized antioxidant, prior to, during, and after topical application of the carcinogen benzo(a)pyrene (64 µg/mouse, 2x/week, 7 weeks). Mice continuously fed NAC demonstrated a significant 43% reduction ($p<0.05$) in tumor multiplicity compared to controls (5.9 vs. 10.4). Tumor incidence (papillomas, keratoacanthomas and carcinomas) exceeded 90% for both groups. Although total tumors per mouse were reduced, skin malignancies (squamous cell and spindle cell carcinomas) were increased 70% (0.54 vs. 0.92 tumors/ animal at risk) in animals fed NAC (n=13) compared to basal-fed controls (n=13). Immunohistochemical analysis of tumors showed consistent and widespread expression of both the v-Ha-ras oncogene and p53 tumor suppressor protein. Southern analysis demonstrated no loss of p53 heterozygosity involving the Trp53 locus suggesting an alternate mechanism for inactivation of p53 or other critical genetic events leading to increased malignancies. In summary, these data demonstrate that the prototypic antioxidant NAC paradoxically decreases total tumor burden but increases progression to malignancy.

34 CHEMICAL INDUCTION OF LIVER TUMORS AND PRESTAGES IN THE AVIAN *IN OVO* CARCINOGENICITY ASSAY (IOCA) IN LESS THAN 24 DAYS.

H. Enzmann[1], K. D. Brunnemann[2], M. Rosenbruch[1], M. Iatropoulos[3], G. Schlüter[1] and G. M. Williams[3]. [1]*Bayer AG, Institute of Toxicology, Wuppertal, Germany,* [2]*American Health Foundation, Valhalla, NY and* [3]*New York Medical College, Valhalla, NY.*

Preneoplastic liver foci are widely accepted as reliable indicators of hepatocarcinogenesis. Our aim was to induce preneoplastic and neoplastic lesions in avian embryonic liver within the short time of embryonic development. To that end, turkey hatching eggs were injected with diethylnitrosamine or other hepatocarcinogens prior to incubation. After incubation for up to 24 days the embryos were removed from the eggs and liver samples were flash frozen or fixed for subsequent microscopic examination. Hepatocellular tumors were induced by the genotoxic carcinogen diethylnitrosamine at doses of or exceeding 4 mg per egg. Lower doses produced basophilic foci of altered hepatocytes that exhibit enzymatic alterations that have long been known as typical features of preneoplastic liver lesions in rat liver. These foci were closely associated with the occurrence of enlarged hepatocytes with karyomegallic atypical nuclei (KAN cells). Lower doses of genotoxic carcinogens that were insufficient for the induction of foci or tumors as well as non-genotoxic carcinogens like thioacetamide induced KAN cells, whereas toxic but not carcinogenic substances like KCN did not. There is histological evidence for a developmental sequence from KAN cells through foci to tumors. The IOCA is proposed as a rapid and inexpensive test for hepatocarcinogens.

35 THE USE OF A PHARMACOGENETIC MOUSE MODEL TO ASSESS MATERNAL AND FETAL SUSCEPTIBILITY TO THE CARCINOGENIC EFFECTS OF COMPLEX MIXTURES OF POLYCYCLIC AROMATIC HYDROCARBONS.

K. A. Rozett[1], M. D. Mitchell[2] and E. H. Weyand[1]. [1]*Joint Graduate Program in Toxicology, Rutgers University, Piscataway, NJ and* [2]*Searle, St. Louis, St. Louis, MO.*

Polycyclic aromatic hydrocarbons (PAH) have been demonstrated to effectively bind to the aryl hydrocarbon (Ah) receptor, thereby eliciting the expression of enzymes responsible for their metabolism. The development of mouse strains that differ genetically in their inducibility of these enzymes can be used to evaluate how differential enzyme expression can modulate PAH metabolism and therefore, their carcinogenic potency. Using the C57BL/6 X DBA/2 backcross model, both maternal and fetal susceptibility to the carcinogenic effects of a complex mixture of PAH was determined. B6D2F1/J females were mated with DBA/2J males and DBA/2J females with B6D2F1/J males. Pregnant females were given a gel diet adulterated with 0.3% coal tar beginning on day 13 of gestation (day 1 indicated by presence of a vaginal plug). Control females received an unadulterated gel diet. Dams and pups were sacrificed at the time of birth. Lung and liver tissues were removed from each pup and lung, liver, forestomach, intestine, and uterus from each dam. ^{32}P-postlabeling with multidimensional TLC was used to evaluate PAH:DNA adduct formation and RT-PCR utilizing a taqman fluorogenic probe was used to assess cytochrome (CYP) P4501A1 and P4501A2 expression. Total PAH:DNA adducts were relatively higher in the lung, forestomach, and uterus of B6D2F1/J dams when compared to DBA/2J dams, whereas the opposite was true of both liver and intestinal tissues. CYP1A1 induction was greatest in lung of both B6D2F1/J and DBA/2J dams, while CYP1A2 induction was greatest in liver tissue of both strains. Interestingly, no PAH:DNA adducts were detected in lung or liver tissues of pups born to dams of either strain, although induction of both CYP1A1 and CYP1A2 relative to controls was observed. This study shows that regardless of the genetic differences in maternal metabolism, both strains of dams were able to decrease the PAH burden on their pups to a level at which no detectable genotoxicity was observed. (EPRI Grant WO2963-06.)

36 ACTIVATION OF THE ARYL HYDROCARBON RECEPTOR BY PAH *ORTHO*-QUINONES.

M. E. Burczynski and T. M. Penning. *University of Pennsylvania, Philadelphia, PA.* Sponsor: T. Monks.

Polycyclic aromatic hydrocarbons (PAH) induce their own metabolic activation by binding to the cytosolic aryl hydrocarbon receptor (AhR) which then translocates to the nucleus to activate CYP1A1 gene transcription via xenobiotic response elements (XREs). Surprisingly, although the AhR demonstrates a strict specificity for planar aromatics, the nonplanar PAH metabolite trans-7,8-dihydroxy-7,8-dihydro-benzo[a]pyrene (B[a]P-diol) also induced CYP1A1 expression in HepG2 cells. Induction occurred over a delayed time-course (~6-12 h), suggesting a requirement for B[a]P-diol metabolism. Inhibition of dihydrodiol dehydrogenase (DD) members of the aldo-keto reductase (AKR) superfamily blocked this effect, suggesting that benzo[a]pyrene-7,8-dione (BPQ), a planar PAH ortho-quinone metabolite generated by DDs, was the actual inducer. BPQ was found to be a potent and rapid inducer of CYP1A1 mRNA, with an EC50 value in HepG2 cells identical to that of parent B[a]P. Multiple PAH o-quinones caused induction of CYP1A1, demonstrating that this was a general property of AKR-generated PAH o-quinones. HepG2101L cells stably transfected with an XRE-luciferase construct showed that BPQ activated CYP1A1 expression at the level of transcription via an XRE-dependent mechanism. BPQ failed to induce CYP1A1 in either AhR- or ARNT-deficient murine hepatoma cell lines and confirmed that induction of CYP1A1 was AhR-dependent. Electrophoretic mobility shift assays demonstrated the specific appearance of BPQ-activated AhR in the nucleus, and immunofluorescence studies confirmed that BPQ mediated nuclear translocation of the AhR. Previous studies have shown PAH o-quinones to be genotoxic both *in vitro* and in living cells. The cytosolic co-localization of the AKRs and AhR, and the subsequent hijacking of the AhR pathway by PAH o-quinones, provide a potential mechanism by which these genotoxic metabolites may be specifically targeted to the nucleus and may have significant consequences for PAH carcinogenesis. (Supported by grants CA39504 and CA55711 to TMP.)

37 INCREASED CELL PROLIFERATION AND HEPATOCELLULAR CANCER IN POLYCHLORINATED BIPHENYL-EXPOSED SPRAGUE-DAWLEY RATS.

J. Whysner. *American Health Foundation, Valhalla, NY.*

The objective of this research was to evaluate the histopathological sections of rat livers from a two year bioassay with polychlorinated biphenyls (PCBs) exposures using immunohistochemical staining for cell proliferation and other parameters related to the development of the hepatocellular carcinomas found in this study. Interim sacrifice groups of male and female rats exposed to different concentrations of four different commercially used PCB mixtures (Aroclors 1016, 1242, 1254, and 1260) for 26 or 52 weeks were evaluated and compared with the results of histological identification of tumors in the two year bioassay. Immunohistochemical staining for proliferating cell nuclear antigen (PCNA) among the various concentrations of Aroclors at 52 weeks showed dose-related increases and a correlation of increased cell proliferation with eventual tumor development. No increases in PCNA labeling were found at 26 weeks, and no increases in terminal deoxynucleotidyltransferase-mediated dUTP-biotin nick end labeling (TUNEL) were evident at either 26 or 52 weeks. Increases in glutathione S-transferase placental form (GSTP) positive foci were found at 52 but not at 26 weeks of PCB exposures. All altered foci that were identified by conventional staining also stained positive for GSTP. The results of this study show that increased cell proliferation was related to tumor development according to the potencies of the Aroclor types and dosages and that the time course of increased cell proliferation coincided with the development of GSTP positive foci.

38 BIOCHEMICAL BASIS FOR THRESHOLDS IN PCB-MEDIATED CARCINOGENESIS.

J. F. Brown, Jr., K. M. Fish, J. B. Silkworth and B. A. Mayes. *General Electric Corp R&D, Schenectady, NY.*

Parallel, multidose, chronic (2 yr) bioassays of Aroclors 1016, 1242, 1254 and 1260 in 35 groups of *ad libitum* fed male or female Sprague Dawley rats showed that PCBs could increase the incidence of liver tumors, except at the lower doses, and decrease those in other organs (Mayes *et al, Toxicol. Sci.* 41, 62-76, 1998). In order to identify the biochemical basis for the observed inhibitions and thresholds, we first determined the tissue accumulations (i.e., internal doses) of total PCBs (mostly non-coplanar), and total TEQ (mostly from coplanar PCBs). This showed that the hepatotumorigenesis could be induced by either the coplanars (in females only), the non-coplanars (in both sexes), or by non-PCB factors (especially in males). Determinations of other biochemical parameters then showed that regardless of mode of induction, hepato-tumorigenesis was closely correlated with cytosolic production of superoxide by redox cycling. This process, which became important in older animals, was found to be mediated by soluble, low molecular weight quinonoids. The resulting superoxide, or derived peroxide, is known to cause tumor promotion. The intracellular antioxidant found correlated with control of this route to tumor promotion, and hence production of the observed dose thresholds for hepatotumorigenesis, was glutathione. This is known to be upregulated by lipid oxidation products (increased even at the lower PCB doses), albeit not sufficiently to block rat liver tumorigenesis at high doses.

39 INFLUENCE OF NEONATAL STILBENE ESTROGEN EXPOSURE ON ESTROGEN RESPONSIVE GENES IN TESTIS OF HAMSTERS.

Q. Cai and D. Roy. *University of Alabama at Birmingham, Birmingham, AL.*

Exposure to stilbene estrogen (diethylstilbestrol, DES) to hamster neonates produces interstitial testicular cancer. However, the mechanism by which estrogen induces testicular cancer is not clear. In this study, we have examined the influence of neonatal stilbene estrogen exposure on estrogen responsive genes in testis. All neonates of Syrian golden hamsters received a single injection of DES (40 mg/kg) or corn oil (control) within 6 hours after birth. The animals were sacrificed at the age of 65 and 90 days. The testis was removed and total RNA was isolated. Using RT-PCR, the mRNA levels of estrogen receptor α (ER-α), estrogen receptor β (ER-β), aromatase, and inhibin/activin were determined. There was no difference in ER-α mRNA level between control and DES treated groups. The ER-β mRNA level was decreased after 65 days of DES treatment compared to control group, however there was no difference between control and 90 days DES treated groups. The aromatase mRNA level was decreased in the DES treated hamster testis after 65 days of DES treatment compared to control group, however there was no difference in aromatase level between control and DES treated groups after 90 days. We

also measured the levels of three subunits of inhibin/activin (α, β_A, β_B) in hamster testis. There was no difference between control and DES treated groups in all subunits. The results of this study indicate that neonatal DES treatment may result in the imbalance of intratesticular estrogen-androgen levels and their actions on the testis.

40 DRAMATIC SYNERGISM OF EXCESS SOYBEAN INTAKE WITH IODINE DEFICIENCY ON THE DEVELOPMENT OF RAT THYROID PROLIFERATIVE LESIONS.

A. Nishikawa[1], T. Ikeda[1], H. Nakamura[1], M. Miyauchi[1], T. Imazawa[1], H. Y. Son[1], F. Furukawa[1], S. Kimura[2] and M. Hirose[1]. [1]*Division of Pathology, National Institute of Health Sciences, Tokyo, Japan and* [2]*Showa Women's University, Tokyo, Japan.* Sponsor: T. Shirai.

High intake of soy-based products is inversely associated with relative risk of breast, prostate, and gastric cancers in human. On the other hand, thyroid enlargement by excessive soybean feeding especially in children and women has been known since previous half a century. In the present study, the effects of soybean protein feeding and the combined influence with deficient iodine were investigated in female F344 rats with special reference to the specificity and dose response. First, rats were fed basal diet, iodine-deficient (ID) diet, 20% defatted soybean (S) diet or ID + 20% S diet for up to 10 weeks. Dietary soybean dramatically induced thyroid follicular hyperplasias synergistically with ID. Secondly, rats were fed basal diet, ID diet, or ID + 0.2, 1.0, 5.0 or 25% S for 5 weeks. Soybean feeding showed synergistic effects on the development of thyroid hyperplasias with ID only at a dose as high as 25%. Thirdly, rats were fed basal diet, 20% S, 0.025% sulfadimethoxine (SDM), 20% S + 0.025% SDM, 0.05% phenobarbital (PB) or 20% S + 0.05% PB for 5 weeks. Soybean intake did not exert any synergistic effects with SDM or PB. Our results thus indicate that soybean intake specifically exerts synergistic effects with iodine deficiency on the development of thyroid hyperplasias in rats only at high doses. (This work was supported in part by a Grant-in-Aid for Research on Environmental Health from the Ministry of Health and Welfare of Japan.)

41 EFFECT OF PERINATAL/JUVENILE EXPOSURE TO HEPTACHLOR ON ADULT IMMUNE, REPRODUCTIVE AND NEURAL FUNCTION.

R. J. Smialowicz[1], W. C. Williams[1], C. B. Copeland[1], T. J. Shafer[1], C. A. Meacham[1], M. W. Harris[2], D. Overstreet[2], B. J. Davis[2] and R. E. Chapin[2]. [1]*NHEERL/EPA, Research Triangle Park, NC and* [2]*NTP/NIEHS, Research Triangle Park, NC.*

This study was performed to determine if persistent immunotoxic, reproductive toxic, and/or neurotoxic effects result from developmental exposure to heptachlor (HEP). Time-bred pregnant female Sprague-Dawley rats were dosed by gavage with HEP (0, 0.03, 0.3 or 3.0 mg/kg/d) from gestation day (GD) 12 to postnatal day (PND) 7, followed by direct dosing of the pups through PND 42. Separate groups of rats were used for testing immune, reproductive, and neurochemical parameters. The amount of HEP epoxide B found in milk, blood, fat and tissues was proportional to the dose of HEP administered. There were no untoward effects on the number or survival of pups born to HEP-exposed dams nor to pups exposed postnatally. There were no treatment effects for any of the reproductive endpoints examined. Gamma-aminobutyric acid (GABA)-stimulated ^{36}Cl flux was decreased in PND 21, but not PND 7 or 43 females, which suggests that HEP may transiently alter cortical $GABA_A$ function. The serum anti-SRBC IgM response of males, but not females, was significantly suppressed in a dose-dependent manner in rats 8-weeks-old. The percentage of $OX12^+OX19^-$ splenocytes (i.e., B cells and plasma cells) was reduced in the high dose males, suggesting that the suppressed anti-SRBC IgM response may be associated with the loss of these cells. The anti-SRBC IgM response was reduced only in males exposed to 0.3 mg HEP/kg/d in a second group of rats 21-weeks-old. At 25-weeks-old the anti-SRBC IgG response of these same rats was suppressed in all of the HEP-exposed males, but not females. These data indicate that perinatal exposure of male rats to HEP results in a persistent suppression of the primary (IgM) and secondary (IgG) anti-SRBC immune responses at a total dose of as little as 1.5 mg HEP/kg/rat. (This abstract does not reflect EPA policy. Partial support for this work came from the Hawaii Heptachlor Research and Education Foundation.)

42 DEVELOPMENTAL EXPOSURE TO TCDD AND MERCURIC CHLORIDE IN AUTOIMMUNE-PRONE MRL/*lpr* MICE.

D. A. Smith and D. R. Germolec. *Laboratory of Toxicology, NIEHS/NIH, Research Triangle Park, NC.*

Autoimmune diseases affect 5-7% of the human population in over 40 different forms, characterized by inappropriate immune responses to self. Certain environmental contaminants, particularly estrogenic endocrine disruptors, may contribute to this aberrant immune function. We have examined the potential for increased incidence and/or exacerbation of autoimmune disease in MRL/*lpr* autoimmune-prone mice exposed prenatally to either tetrachlorodibenzo-*p*-dioxin (TCDD) or mercuric chloride (HgCl2). MRL/*lpr* mice exhibit severe renal necrosis (glomerulonephritis) and increased levels of circulating autoantibodies similar to that observed in human systemic lupus erythematosis (SLE), and females present disease symptoms approximately six to eight weeks prior to males. Assessment of autoimmunity via quantitation of urinary protein and serum autoantibody levels was compared in female versus male mice to determine if there were differential chemical-induced effects. Results in female MRL/*lpr* mice indicate a significant, dose-dependent increase in urinary protein in animals prenatally exposed to TCDD as compared to controls at six weeks of age. Further, TCDD-induced urinary protein levels were significantly elevated when compared to positive control mice exposed to HgCl2. Autoantibodies to ss-DNA were significantly increased in a dose-dependent manner in TCDD-exposed animals as compared to controls at ten weeks of age. In males, there was a dose-related trend in urinary protein amongst TCDD-exposed animals compared to controls and HgCl2 at six weeks of age, becoming statistically significant at eight weeks of age. Significant dose-dependent increases in autoantibodies to ss-DNA were noted in the male animals exposed to TCDD compared to controls at ten weeks of age. These findings suggest that developmental exposure to TCDD may accelerate the onset of SLE in both male and female MRL mice. Furthermore, TCDD may be a stronger inducer of SLE than the prototypical control HgCl2 in neonatal mice.

43 PRENATAL DIETHYLSTILBESTROL EXPOSURE ALTERS γ-INTERFERON LEVELS.

B. Hissong, E. Sahin-Karpuzoglu, K. Donner, Y. Zhijun, N. Sriranganthan and S. A. Ahmed. *Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA.* Sponsor: S. D. Holladay.

Alterations in gamma-interferon, a T-helper 1-type cytokine, have been shown to have a profound impact on autoimmune and neoplastic diseases. In this study, we investigated whether gamma-interferon is modulated by estrogenic compounds. The levels of gamma-interferon mRNA and protein were increased in concanavalin-A-stimulated splenic lymphocytes from C57Bl/6 mice exposed to estrogen for 3-5 months. An estrogen-induced increase in gamma-interferon mRNA and protein was evident as early as 6 and 12 hours, respectively, after Con-A stimulation. Levels of gamma-interferon were also modulated by diethylstilbestrol (DES), a synthetic estrogen. The secretion of gamma-interferon by Con-A or anti-CD3 antibody-stimulated splenic lymphocytes from prenatal DES-exposed mice at 5-6 days of age was increased. This increase in gamma-interferon secretion was noticed despite decreased percentages of T cells. The increase in gamma-interferon in prenatal DES-exposed mice was transient, since by 2-3 months of age gamma-interferon levels approximated the controls. Preliminary studies on male mice show that secondary exposure to DES, 1 to 1.5 years after prenatal DES exposure, markedly increased the ability of splenic lymphocytes to secrete gamma-interferon after Con A stimulation. Our studies show that prenatal DES exposure alters the "cytokine programming" of lymphocytes and dysregulation of gamma-interferon-secretion may play a role in cancer and/or autoimmune diseases. (Supported by NIEHS:RO1 ES 08043-04.)

44 NEONATAL EXPOSURE TO PROPYLTHIOURACIL (PTU) INDUCES A SHIFT IN LYMPHOID CELL SUB-POPULATIONS IN THE DEVELOPING POSTNATAL MALE RAT SPLEEN AND THYMUS.

A. A. Rooney, S. De Bellefeuille, M. Fournier, J. Bernier and D. G. Cyr. *INRS-Institut Armand Frappier, Pointe-Claire, Quebec, Canada.*

It has been suggested that certain environmental toxicants can alter thyroid function in mammalian species. Such an effect may be particularly important in developing physiological systems involved in growth, reproduction, and immune function, all of which are influenced by thyroid hormones. The object of the present study was to determine the effects of PTU-induced hypothy-

roidism on the developing immune system by focussing on both the spleen and thymus gland. Male Sprague-Dawley rat pups were exposed to PTU through maternal milk by giving the mothers 0.02% PTU in their drinking water starting on the pups day of birth until weaning on day 28. Animals were sampled on days 14, 22, and 30. On days 22 and 30, PTU exposure increased the T-cells in the spleen as assessed by both the percentage of PanT positive and CD4 positive cells. PTU exposure also increased the percentage of CD8a positive cells in the spleen at d22, although no differences were detected at d14 or d30. PTU exposure decreased the percentage of CD45RA positive cells (B-cells) of splenocytes at d22 and d30 indicating that the relative B-cell population was decreased while the T-cell population was increased. PTU exposure decreased the NK lytic ability of cells at d22, but no functional differences were observed at d14 and d30, despite the increased percentage of CD161 positive cells (NK-cells) in PTU-exposed animals at each of the sampling points. PTU exposure increased the percentage of CD4+/CD8- in the thymus on d22 and caused a slight increase on d30. These data suggest that the effects of induced hypothyroidism on the cell populations in the spleen may result from changes in thymic T-cell development, although changes in B-cell development may also occur. The current data emphasize that thyroid hormones regulate not only the development of immune cells but also cell function and that both of these must be tested when investigating toxicological effects on the immune system.

45 NEONATAL EXPOSURE TO CADMIUM (CD) PRODUCES BOTH SHORT AND LONG TERM EFFECTS ON NK FUNCTION AND MITOGENIC RESPONSE OF RAT SPLENOCYTES AND THYMOCYTES.

A. A. Rooney, S. Pillet, D. G. Cyr and M. Fournier. *INRS-Institut Armand Frappier, Pointe-Claire, Quebec, Canada.*

Heavy metals, including Cd, have been shown to modulate immune measures including blastogenic response and NK activity. Little is currently known regarding the sensitivity of the immune system to heavy metals at different stages of development. The present objective was to determine the effects of low doses of Cd via the maternal milk on NK activity of splenocytes and blastogenic response of both splenocytes and thymocytes. Male and female Sprague-Dawley rat pups were exposed to Cd through maternal milk by giving the mothers either 0 (controls), 10 ppb or 5 ppm $CdCl_2$ in the drinking water (d1-24). Rat pups were weaned on day 24 and sampled on days 28 and 63. Shortly after weaning (d28), male rats from the high dose group exhibited a lowered NK response. The NK response of all Cd-exposed females and the low-dose, Cd-exposed males did not differ from that of controls. The blastogenic response of splenocytes from the high dose group rats to con A resulted in a decreased stimulation index (S.I.), although the blastogenic response to PHA and LPS were not different from control rats. There were no differences in the blastogenic response of thymocytes. In 63 day-old rats, the high dose Cd group displayed a decreased S.I. of thymocytes to con A. However, no differences were observed in blastogenic response of thymocytes to PHA and no differences in the blastogenic response of splenocytes to any of the mitogens was observed. There were no effects of Cd exposure on NK response. In conclusion, short-term exposure of relatively low doses of Cd via the maternal milk can alter aspects of immune function in young rats and can result in effects throughout the life of the animal.

46 HEMATOTOXIC EFFECTS OF PRENATAL EXPOSURE OF MICE TO CHLORDANE.

S. V. M. Dodson, K. S. Landreth, D. A. Piktel, W. Zhao, L. F. Gibson and J. B. Barnett. *West Virginia University, Morgantown, WV.*

Chlordane, a member of the organochlorine insecticides, was used for structural preservation against underground termites until as late as 1990 when the EPA banned production of chlordane. The toxicity of chlordane is essential because more than 30 million homes were treated, and the half-life of chlordane is estimated to be 20 to 30 years in soil. Chlordane is readily absorbed through the skin, airway, and gastrointestinal tract. We used a murine prenatal exposure model to examine the hypothesis that prenatal exposure to chlordane affects the development of hematopoietic tissues and results in lifelong failure of normal leukocyte development. Nine-week-old pregnant Balb/C mice were administered chlordane (18 mg/kg/day) from day 10 to 18 of gestation. Colony forming unit (CFU) assays show that single cell suspensions from the fetal livers of chlordane-treated mice *in utero* had decreased colony formation in both myeloid and lymphoid cell lineages by at least 50% as compared to controls with the largest decrease observed for IL-7 stimulated colonies. The conditioned medium from chlordane-treated fetal liver stromal cells supported IL-3, GM-CSF, and M-CSF dependent myeloid cell lines in bioassays. *In vitro* proliferation assays stimulated by hematopoietic cytokines revealed differences in proliferative capacity of fetal liver cells when compared to cells from vehicle-treated embryos. These results suggest that chlordane continues to pose a serious health threat to exposed individuals and that fetal development is a critical window of exposure to this compound.

47 REDUCTION OF SPLEEN CELLULARITY BY LOW-DOSE MATERNAL EXPOSURE TO 2,3,7,8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD) IN RATS.

K. Nohara[1], H. Fujimaki[1], H. Ushio[1], M. Kijima[2], T. Kobayashi[1], S. Tsukumo[2], Y. Miyabara[1], H. Sone[1], C. Tohyama[1] and J. Yonemoto[1]. [1]*National Institute for Environmental Studies, Tsukuba, Japan and* [2]*CREST, JST, Kawaguchi, Japan.*

TCDD exerts adverse effects on immune functions. Fetus is known to be much more sensitive to TCDD than adult. In order to obtain a clue to elucidate the mechanisms of immunotoxicity by maternally-exposed TCDD, pregnant Holtzman rats were administered a single oral dose of 0, 12.5, 50, 200 or 800 ng TCDD/kg body weight on gestation Day 15, and the thymus and spleen cells of male offspring were investigated on Day 21, 49, 63 and 120 after birth. Maternal exposure to TCDD did not cause any significant change in thymus weight, cell number/tissue weight (cellularity), thymocyte population in terms of the percentages of $CD4^-CD8^-$ (DN), $CD4^+CD8^+$ (DP), $CD4^+CD8^-$ (CD4-SP) and $CD4^-CD8^+$ (CD8-SP) cells in pups on Day 21. No alteration was observed in spleen weight and cellularity. The percentages of T cells and $CD4^+$ T cells in splenocytes were found to be significantly reduced by 200 ng TCDD/kg. On Day 49, pups maternally exposed to TCDD showed decreased spleen cellularity in a dose-dependent manner with the significant reductions at 200 and 800 ng TCDD/kg. Since percentages of T cells in splenocytes were not changed between control and exposed groups, the decreased cellularity appeared to be due to the reductions of both T and B cell numbers. Thymus weight, cellularity, thymocyte population and spleen weight were not changed by TCDD exposure. On Day 63, significant decrease in spleen cellularity was observed only at 200 ng TCDD/kg. On Day 120, the spleen cellularity did not differ between control and exposed groups. In summary, the present study revealed that a low-dose maternal exposure to TCDD significantly reduces spleen lymphocyte numbers with the most prominent effect around the age of puberty.

48 EMBRYONIC WINDOWS OF INCREASED VULNERABILITY TO PB-INDUCED IMMUNOTOXICITY DURING AVIAN DEVELOPMENT.

J. Lee, S. A. Naqi and R. R. Dietert. *Cornell University, Ithaca, NY.*

The developing immune system of rodents has been shown to exhibit increased sensitivity to Pb-induced immunotoxicity compared with that of adults. However, little is known about potential windows of increased vulnerability during discrete periods of embryonic development. To pinpoint differential embryonic sensitivity to Pb-induced immunotoxicity, sublethal doses of Pb were introduced in fertilized Cornell K Strain While Leghorn chicken eggs via the air sac at one of three different stages of embryonic development (7, 9, and 12 day of incubation, designated as E7, E9 and E12, respectively). Blood Pb levels were determined at hatching and Pb-induced immunotoxicity was evaluated in 5-6 week old young chickens using a delayed-type hypersensitivity reaction (DHR) against BSA, an anti-BSA antibody ELISA and macrophage production of nitric oxide as immune indicators. While juvenile levels of antibody responses to BSA were unaffected by the *in ovo* Pb exposure, macrophage production of nitric oxide (measured as nitrite production) was significantly depressed ($p<0.05$) following Pb-exposure (measured for E7 and E9 exposure only). In contrast with this pattern, the DHR function was unaltered following the E7 and E9 exposures, but was significantly depressed ($p<0.05$) after E12 exposure to Pb. Since the E9 and E12 sublethal exposures included overlapping doses of Pb with overlapping blood Pb levels, the capacity of Pb to influence the DHR function appears to emerge between days 9 and 12 of *in ovo* development. The stability of Pb-induced developmental immunotoxicity was examined using virus challenge. When chickens were exposed at E12 to Pb and then subjected to infection with infectious bronchitis virus (IBV), Pb-induced depression of the DHR was similar in severity to that observed in uninfected chickens. Based on these results, it is hypothesized that Pb exposure during different windows of embryonic development is likely to result in different immunotoxic outcomes in the juvenile. Furthermore, Pb-induced embryonic immune alterations are likely to remain evident during at least some juvenile disease challenges. (Supported in part by grants from the NIEHS-Superfund and the USDA.)

49 CHARACTERIZATION OF AN APPROACH TO DEVELOPMENTAL IMMUNOTOXICOLOGY ASSESSMENT IN THE RAT USING SRBC AS THEANTIGEN.

G. S. Ladics[1], S. C. Nicastro[1], C. Smith[1], T. L. Bunn[2], R. R. Dietert[2], P. K. Anderson[3], C. M. Wiescinski[3] and M. P. Holsapple[3]. [1]*The DuPont Co. Haskell Laboratory, Newark, DE,* [2]*Cornell University, College of Veterinary Medicine, Ithaca, NY and* [3]*Dow Chemical Company, Midland, MI.*

The objectives of this study were 1) to optimize and establish baseline values for the primary humoral immune response to SRBC using an ELISA or the plaque forming cell (PFC) assay and 2) to establish baseline values for splenic lymphocytes (B-cell, T-cell, T-helper and T-cytotoxic/suppressor cells) using flow cytometry for both 10- and 21-day old Crl:CD[1](SD)BR rats. Responses for each age group were compared both within and between litters. Due to the difficulty in administering SRBC by tail vein injection, 10-day old pups received SRBC intraperitoneally; but were still unable to generate an IgM response using either assay. The following mean absolute and relative (%) numbers of splenic lymphocytes were obtained for 10-day old rats, respectively: $0.18\pm0.08 \times 10^8$ (13 ± 5) $CD45^+$; $0.13\pm0.04 \times 10^8$ (9 ± 3) $OX12^+$; $0.07\pm0.01 \times 10^8$ (5 ± 1) $W3/25^+CD3^+$; $0.03\pm0.01 \times 10^8$ (2 ± 0.5) $OX8^-CD3^+$ cells. A splenic differential showed that ~80% of the 10-day old splenocytes were lymphocytes. Results with the ELISA showed that the SRBC-specific IgM antibody $\log_2$ titer for 21-day old rats was considerably less compared to young adult rats due to a high background response. Results with the PFC assay produced a response in 21-day old rats similar to that of adults. The following mean absolute and relative numbers of lymphocytes were obtained for 21-day old rats, respectively: $0.96\pm0.25 \times 10^8$ (48 ± 5) $CD45^+$; $0.77\pm0.16 \times 10^8$ (39 ± 3) $OX12^+$; $0.23\pm0.02 \times 10^8$ (12 ± 2) $W3/25^-CD3^+$; $0.14\pm0.02 \times 10^8$ (7 ± 1) $OX8^-CD3^+$ cells. Based on our data, the litter can be used as the unit of comparison for developmental immunotoxicology. Results suggest that it may not be possible to use a functional parameter in 10-day old rats; however, additional antigens need to be examined. Further studies are also needed to determine whether SRBC or other antigens can be integrated into studies with rat weanlings. (Supported by a grant from the Chemical Manufacturers Association.)

50 DEVELOPMENTAL IMMUNOTOXICOLOGY ASSESSMENT IN THE RAT: AGE, GENDER AND STRAIN CONSIDERATIONS.

T. L. Bunn[1], G. S. Ladics[2], M. P. Holsapple[3] and R. R. Dietert[1]. [1]*College of Veterinary Medicine, Cornell University, Ithaca, NY,* [2]*The DuPont Co., Haskell Laboratory, Newark, DE and* [3]*Dow Chemical Company, Midland, MI.*

A combined Delayed-type Hypersensitivity Response (DHR) to KLH and anti-KLH IgG antibody ELISA were assessed as potential biomarkers for developmental immunotoxicity with age, gender, site of antigenic challenge and strain as variables. The heavy metal, Pb, was used as a known developmental immunotoxin. Five-week old Sprague-Dawley (CD) rats produced lower levels of antibody and a decreased DHR compared with adults. In the age comparison, only adult males had a significantly increased DHR while both male and female adults produced higher levels of antibody than both genders of weanlings. When examining site of KLH challenge, the DHR was greater in young animals when challenged in the footpad vs. the earlobe and there were gender differences in antibody levels. Females had optimum antibody levels with a DHR challenge in the earlobe whereas males had optimum levels when challenged in the footpad. In a strain comparison between weanling rats exposed *in utero* to control acetate or Pb acetate (250 ppm lead acetate in drinking water) and pups examined at five weeks of age, the KLH immunization protocol produced a higher antibody response in CD vs. F344 rats; in contrast, F344 rats exhibited an elevated DHR. Pb exposure *in utero* via the pregnant dams produced differential gender effects in the juveniles of both strains. Females had a significantly decreased Pb-induced DHR ($p<0.05$) whereas males did not. These results suggest that the DHR and antibody ELISA against KLH are suitable as biomarkers of developmental immunotoxicity and, based on the Pb results, assessment can be performed in juvenile rats. Furthermore, at the KLH concentration utilized, the balance of cell-mediated vs. humoral response differed among the two strains examined. Further studies are needed to define the optimum concentrations of KLH for each strain when immunized as weanlings. (Supported by grants from the Chemical Manufacturers Association and the NIEHS-Superfund.)

51 THE INTERGRATION OF IMMUNOLOGICAL ASSESSMENTS AS PART OF THE RODENT DEVELOPMENTAL NEUROTOXICITY SCREEN.

R. P. Jones. *Covance, Harrogate, United Kingdom.* Sponsor: J. Norris.

Immunological assessments have in recent years become common additions to regulatory sub-chronic toxicity studies of 4 and 13 Weeks duration. However at our laboratory we have recently received requests to perform such evaluations as part of the established developmental neurotoxicology screen (EPA OPPTS 870.6300). This screen requires the oral administration of the test substance to female rats from Day 6 of gestation to Day 10 of lactation. The offspring are reared until they are at least 60 days of age. These offspring are used for a variety of neurological evaluations including neuropathology, a sub-group being destined for brain weight evaluation. Immunological assessments are added to this subgroup. The assessments included conventional histopathology together with image analysis and immunohistochemistry of select primary and secondary lymphatic organs. In addition, haematological assessments including differential white cell counts, red cell parameters and lymphocyte sub-sets are undertaken together with selected clinical chemistry parameters such as the immunoglobulins. Consequently, a broad assessment of immune competance of these Day 60 offspring can be made with out impinging on the primary design of the neurotoxicological screen.

52 IDENTIFICATION OF ESTROGEN RECEPTOR ISOFORMS IN MAMMARY CELLS: MODULATION BY 1,1-DICHLORO-2,2-*BIS*(CHLOROPHENYL) ETHYLENE (DDE).

L. M. Zipper and R. T. Mulcahy. *University of Wisconsin, Madison, WI.* Sponsor: A. A. Elfarra.

Mammary cell estrogen receptors (ER) play an important role in certain breast cancers. Environmental contaminants can modulate ER levels and/or activation. DDE, for which some studies have indicated higher levels in breast cancer patients, is an environmental contaminant which is thought to modulate the ER. Human cell models are pivotal tools to determine contaminant-induced changes in ER (e.g. TCDD effects in MCF-7 cells). We have observed that estradiol is mitogenic in the non tumorigenic MCF-10A cell line, defined in the literature as being ER-negative. Isoforms (α and β) of the ER have been identified in recent years; the functional role of these isoforms in carcinogenesis is still unknown. The present study aimed to assess the presence of ER-α and ER-β mRNA in cancerous (MCF-7A and T47-D) and normal (MCF-10A and MCF-12A) mammary cell lines by double PCR using nested primers. Both isoforms were present in each of the cell lines; levels for MCF-10A and MCF-12A were lower than those for MCF-7 and T47-D (highest amount) cells. In MCF-7 cells, treatment (24 h) with o,p'-DDE or p,p'-DDE increased ER-α mRNA level. Both the ER antagonist tamoxifen and ER agonist 16-α-OH-estrone decrease ER-α mRNA levels. This suggests that DDE isomers may magnify estrogenic activity in mammary cells by increasing ER levels through a mechanism independent of receptor occupancy. Future studies will look at the modulation of the ER-α/ER-β ratios following exposure to these compounds in MCF-10A cells.

53 TRANSCRIPTION OF THE HEAVY AND LIGHT SUBUNITS OF γ-GLUTAMYLCYSTEINE SYNTHETASE (γGCS) IS PARTIALLY REGULATED BY THE MAP KINASES ERK1 & 2.

L. M. Zipper and R. T. Mulcahy. *University of Wisconsin, Madison, WI.* Sponsor: A. A. Elfarra.

Transcription of both the heavy and light subunits of g-glutamylcysteine synthetase (γGCS), the rate limiting enzyme in glutathione synthesis, is induced by various xenobiotics including Pyrrolidinedithiocarbamate (PDTC). The potential involvement of the Mitogen Activated Protein kinases (MAPKs) in γGCS gene induction was investigated as these kinases are known to be important intermediate proteins in a variety signal transduction cascades. HepG2 cells were treated with 100mM PDTC and activation of JNK, p38, and ERK were assayed with western blots and *in-vitro* kinase assays. Results showed weak JNK activation at 1 and 2 hours after PDTC treatment, whereas ERK1/2 and p38 were activated by PDTC treatment as soon as 15 minutes (ERK1/2) and 30 minutes (p38) and remained active for as long as 4-6 hours. To determine if PDTC induced MAPK activation correlated with γGCS gene induction, HepG2 cells were treated with MAPK inhibitors and/or dominant negative MAPK constructs. Results show that such treatments decreased accumulation of γGCS RNA by 50% and also reduced transcription from promoter-reporter constructs. Binding of specific transcription factors to the EpREs that regulate γGCS were also altered by treatment with inhibitors as

assayed by gel shifts. Results from these studies suggest that MAPK family members, specifically ERK1/2, are at least partially involved in the regulation of γGCS gene transcription. Studies investigating the effect of p38 inhibitors and dominant negative p38 constructs on γGCS RNA accumulation and promoter activity are currently underway. (This work was supported by ES09749, CA57549, T32-CA09471.)

54 A CCAAT/ENHANCER BINDING PROTEIN (C/EBP) SITE ALONG WITH CREB BINDING PROTEIN (CBP) PARTICIPATE IN NEGATIVE REGULATION OF RAT *GST-Ya* IN VASCULAR SMOOTH MUSCLE CELLS BY BENZO(A)PYRENE.

Y. Chen and K. S. Ramos. *Texas A&M University, College Station, TX.*

Recent studies in this laboratory have established that a C/EBP-like site within the antioxidant/electrophile response element (ARE/EpRE) functions as a negative regulatory sequence in the rat GST-Ya promoter in vascular smooth muscle cells (vSMCs) and HepG2 cells. In the present study, electrophoretic mobility shift assays and transfection experiments were conducted to evaluate the influence of DNA/protein interactions on the ability of ARE/EpRE to function as a negative regulatory sequence in vSMCs. Evidence was obtained that C/EBP-β interacts with the C/EBP-like site of rat *GST-Ya*, and that the aryl hydrocarbon receptor (AhR) is present in the ARE/EpRE binding protein complex. To evaluate the role of these proteins in transactivation, expression vectors were co-tranfected with a rat *GST-Ya* reporter construct (1.6 CAT) in vSMCs. Overexpression of CBP nullified ARE/EpRE-mediated repression of rat GST-Ya in the presence of BaP. The specificity of this interaction was suggested by the finding that human adenovirus E1A protein abrogated co-transactivation potential of CBP, while an E1A mutant did not. In subsequent experiments we found that in the presence of CBP, overexpression of C/EBP-α or C/EBP-β decreased the expression of 1.6CAT, while AhR had the opposite effect. Collectively, our results suggest that negative regulation of rat *GST-Ya* in vSMCs by BaP results from limiting CBP protein levels, and that CBP serves as a mediator of functional interaction between C/EBPs and AhR in the regulation of this response. (Supported in part by NIH Grant ES 04849 and ES 09106.)

55 IDENTIFICATION OF A DOMAIN RESPONSIBLE FOR THE NEGATIVE FUNCTION OF RTARNTA IN AH RECEPTOR SIGNALING.

B. M. Necela and R. S. Pollenz. *Medical University of South Carolina, Charleston, SC.*

The secondary structure of the PST-rich COOH-end of rtARNTa was evaluated by computer analysis (Motif database). Computer analysis revealed that the sequence was dominated by β-sheets, numerous turn regions, and a lack of helices. In addition, the last 20 amino acids contained a region that appeared to be strongly hydrophobic. To assess the impact of these regions within the PST-rich COOH-end, the rtARNTa protein was truncated and function evaluated by electromobility shift assay and complementation of P4501A1 induction in ARNT deficient Hepa-1 cells. Complementation studies revealed that truncation of the hydrophobic domain that spanned the final 20-40 amino acids of rtARNTa restored the protein's ability to induce P4501A1. Gel shift analysis confirmed that these results were related to recovery of DNA binding of the rtARNT•AHR heterodimer. Addition of the hydrophobic domain to mARNT or rtARNT resulted in proteins with reduced DNA binding and the inability to complement AHR-mediated signal transduction. These findings indicate that the hydrophobic domain is primarily responsible for the negative function of rtARNTa, suggesting that it's repressor function may be related protein misfolding or masking of the DNA binding domain. In addition, the Gal4 fusion approach was employed to identify possible transactivation domains within the truncated rtARNTa proteins. Gal4 analysis revealed the lack of transactivation function in the truncated COOH terminal domains of rtARNTa, in contrast to the QN-rich COOH-end of rtARNTb. The lack of transcriptional activity was not related to DNA binding as the Gal4 fusion proteins bound DNA. Collectively, these studies narrow the negative function of rtARNTa to the presence of a C-terminal hydrophobic domain, and illustrates how changes in the C-terminal domain can affect protein function. (Supported by ES08980 and EPA STAR # U915218010.)

56 THE IMMUNOPHILIN HOMOLOG XAP2 SPECIFICALLY STABILIZES THE AH RECEPTOR AND IS ASSOCIATED WITH THE CYTOSKELETON.

J. R. Petrulis[1], B. K. Meyer[2] and G. H. Perdew[1]. [1]*Department of Veterinary Science, The Pennsylvania State University, University Park, PA and* [2]*Graduate Program in Biochemistry, Microbiology and Molecular Biology, The Pennsylvania State University, University Park, PA.*

The aryl hydrocarbon receptor (AhR) is a ligand-inducible transcription factor that mediates biological responses to halogenated aromatic hydrocarbons. The unliganded AhR is a cytoplasmic, tetrameric complex consisting of the AhR ligand binding subunit, a dimer of hsp90, and the hepatitis B virus X associated protein 2 (XAP2). The role of XAP2 as a member of the AhR core complex is poorly understood. XAP2 shares significant homology with the immunophilins FKBP12 and FKBP52, including a highly conserved, C-terminal, tetratricopeptide repeat (TPR) domain. XAP2 forms a complex with hsp90 and the AhR, but can also bind to both independently. This binding is mediated by the conserved TPR domain. Single point mutations in this region are sufficient to disrupt the association of XAP2 with both the AhR and hsp90 *in vitro* and in cells. Co-transfection of the AhR and XAP2 in COS-1 cells results in increased AhR levels compared with cells transfected with the AhR alone. Co-expression of the AhR with the TPR containing proteins FKBP52, PP5, or XAP2 TPR mutants deficient in binding to the AhR and hsp90, does not effect AhR levels. However co-expression of the AhR with the TPR domain of protein phosphatase 5 (PP5) results in AhR down-regulation. These results demonstrate that XAP2 is apparently unique among hsp90 binding proteins in its ability to enhance AhR levels. A yellow fluorescent protein (YFP)-XAP2-FLAG was constructed and biochemically characterized to demonstrate that no loss of function was detected. YFP-XAP2-FLAG was transiently transfected into primary human fibroblasts and was found to co-localize with cytoskeletal structures when visualized by fluorescence microscopy. Treatment of Hepa-1 cells with the hsp90 binding benzoquinone ansamycin geldanamycin (GA) and the macrocyclic anti-fungal radicicol resulted in AhR, but not XAP2 or FKBP52 turnover. These results suggest that XAP2/hsp90 and FKBP52/hsp90 complexes are similar yet exhibit unique functional specificity.

57 THE ARYL HYDROCARBON RECEPTOR/TRANSCRIPTION FACTOR (AHR) AND THE REL A NUCLEAR FACTOR-κB SUBUNIT COOPERATE TO TRANSACTIVATE THE c-*myc* PROMOTER.

S. A. Quadri, D. W. Kim, L. Gazourian, G. E. Sonenshein and D. H. Sherr. *Boston University Medical Center, Boston, MA.*

NF-κB/Rel is a family of dimeric transcription factors that regulates the promoter activities of many genes including those which control cellular proliferation, neoplastic transformation, and apoptosis. For example, the c-*myc* oncogene has two functional NF-κB elements. Rel factors have been found to interact, either as subunits or dimers, with other transcription factors. In particular, the RelA (or p65) subunit of NF-κB was shown to interact with the aryl hydrocarbon receptor/transcription factor (AhR), the latter mediating environmental carcinogen-induced malignant transformation. Recently, we have observed that AhR and NF-κB levels are highly elevated in breast cancer cells and that both transcription factors appear to be constitutively active. Herein, we demonstrate, with the help of co-immunoprecipitations that there is a physical association between RelA and AhR in breast cancer cells. Interestingly, the resulting complex activates c-*myc* gene transcription in these cells as detected by reporter gene analyses and electrophoretic mobility shift assays (EMSAs). Our results show that RelA and AhR proteins could be co-precipitated from the whole cell lysates of pre-malignant MCF-10F breast epithelial cells and from both cytoplasmic and nuclear extracts malignant Hs578T breast cancer cells. *AhR* and *RelA* gene co-transfection studies demonstrated cooperation between these respective gene products in transactivation of the c-*myc* promoter, and that this transactivation was dependent on NF-κB elements in the c-*myc* promoter. Furthermore, a novel AhR/RelA-containing NF-κB element binding complex was identified by EMSAs of nuclear extracts from *RelA* and *AhR* co-transfected Hs578T cells. Thus, the RelA and AhR proteins functionally cooperate to bind to NF-κB elements and transactivate the c-*myc* promoter, suggesting a new mecahnism whereby AhR/ NF-κB-dependent activation of the c-*myc* gene can promote proliferation and neoplastic transformation.

58 CROSSTALK BETWEEN THE PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR ALPHA AND PROTEIN KINASE C SIGNALING PATHWAYS.

J. P. Gray and J. P. Vanden Heuvel. *The Pennsylvania State University, University Park, PA.*

The peroxisome proliferator-activated receptors (PPARs) belong to the steroid hormone receptor superfamily, a group of transcription factors regulated through both ligand binding and phosphorylation events. Protein kinases may directly activate PPARs, affect their ability to bind ligands, or activate signaling in the absence of ligand. Preliminary work with protein kinase C inhibitors by other groups has shown decreases in both phenotypic and transcriptional responses of PPARα, although the reason for this "cross-talk" between signal transduction pathways is not clear. The goal of our research is to determine the mechanism of PKC cross-talk with PPARα. The phorbol esters, phorbol-12-myristate-13-acetate (PMA) and phorbol 12,13-dibutyrate (TPA), were shown to activate transcription from a peroxisome proliferator response element-driven luciferase construct (PPRE-Luc), generated using the upstream element of the rat ACO gene. When cells were co-treated with phorbol esters and Wy-14,643, a PPARα-specific activator, an additive effect was observed. Isotype-specific PKC inhibitors were used to show PKCα activity is necessary for Wy-mediated induction of the ACO gene. Rottlerin, a PKCδ-specific inhibitor, was able to inhibit activation by both Wy-14,643 and phorbol esters. In addition, an *in vitro* phosphorylation assay illustrated direct phosphorylation of PPARα by PKCα and PKCβ. These results suggest a direct interaction between PKC and PPARα. (Supported by NIH ES07799 and DK49009.)

59 OPPOSING ACTIONS OF p38- AND p44/p42-MAP KINASE INHIBITORS ON LPS-INDUCED NF-κB-MEDIATED GENE EXPRESSION IN NORMAL RAT KIDNEY EPITHELIAL (NRK52E) CELLS.

M. E. Ellis, J. Corral, J. Kushleika, F. J. Dieguez-Acuna and J. S. Woods. *University of Washington, Seattle, WA.*

MAP kinases play a central role in propagating stress signals mediated by lipopolysaccharide (LPS) and other toxicants in various cell types. We evaluated the role of p38- and p44/42-MAP kinase signaling pathways in LPS-induced NF-κB activation and NF-κB-mediated transcriptional gene expression in kidney epithelial (NRK) cells, employing SB203580 (SB), a specific inhibitor of p38, and PD98059 (PD), an inhibitor of MEK, the upstream activator of p44/p42 MAP kinases. LPS induces rapid activation and nuclear translocation of NF-κB in NRK cells (TAP 154:219-227, 1999). Neither SB nor PD pretreatment affected LPS-induced NF-κB activation or NF-κB-DNA binding in this cell line. However, SB (25-50 mM) caused a dose-related decrease in NF-κB-mediated transcriptional activity when administered to NRK cells transfected with a NF-κB-driven luciferase reporter gene (pLuc-4xNF-κB) prior to LPS treatment. Conversely, PD (10-30 mM) treatment enhanced LPS-induced luciferase activity by as much as 2-fold compared to treatment with LPS alone. These results indicate that p38 promotes, whereas p44/p42 MAPKs down-regulate, LPS-induced NF-κB-mediated gene expression at the level of transcriptional activation in NRK cells. These findings suggest the integrated regulation of NF-κB-mediated gene expression by MAP kinase pathways in kidney cells. (Supported by ES04696 and ES07033.)

60 A METHOD FOR HARVESTING RESPIRATORY/ TRANSITIONAL EPITHELIAL CELL RNA FROM THE ANTERIOR NASAL PASSAGES OF RATS.

S. D. Hester, D. C. Wolf, G. B. Benavides and K. T. Morgan. *US Environmental Protection Agency; East Carolina University, School of Medicine, Dep. Anatomy & Cell, Research Triangle Park, Durham, NC.*

The transitional and respiratory epithelia lining the lateral meatus and anterior septum of the rat nasal passages are a common site for injury from inhaled chemicals, including the rodent nasal carcinogen, formaldehyde. This anatomical target area is relatively small and presents a challenge when attempting to recover target cells for molecular biological studies. We developed a method for the isolation of airway lining epithelial cells from this site. Nine rats were euthanized and the head removed. Cells lining the nasal airway anterior to the septal window were separated from the underlying lamina propria by instilling 200μL (consistent with reported and our measured nasal volume for this region) of 2% type I collagenase into the anterior nares followed by incubation at 37°C for up to one hour. The head was maintained vertical with the nares down to confine collagenase to the anterior nose. The collagenase/cellular mixture was withdrawn, and the airways were flushed with an additional 200μL saline, and the cellular suspensions were pooled. Cell yield was quantitated microscopically by cytospin and differential stain, and total RNA was isolated from the remaining cellular extract. Approximately $1x10^5$ well preserved, ciliated, non-ciliated, and other epithelial cells were isolated per rat, with a yield of approximately 40μg of high quality total RNA. The heads were processed by routine methods for microscopic examination to verify the extent and success of the epithelial removal. This method of rat nasal epithelial cell isolation can be used to extract RNA, DNA, and proteins for molecular analyses within this important nasal epithelial cell target cell population.

61 MAGNETIC RESONANCE IMAGING (MRI), IMMUNOLOGY AND BIOCHEMISTRY OF MURINE NASAL AIRWAYS EXPOSED TO 2,4-TOLUENE DIISOCYANATE (TDI).

A. J. Wiethoff[1], S. R. Govil[1], W. E. Brown[1] and J. R. Harkema[2]. [1]*Carnegie Mellon University, Pittsburgh, PA and* [2]*Michigan State University, East Lansing, MI.*

Little is known about the effect of TDI inhalation, a known cause of occupational asthma, on the nasal passages. A MRI method for monitoring the morphological alterations in the upper airways due to irritant exposure has been developed and tested on mice exposed to chemicals with known pathophysiological changes in the nasal region. In the current study, we employed this technique, along with immunological and biochemical methods to determine the effectiveness of MRI as a technique to detect subtle changes in morphology resulting from TDI exposure and to gain insight into the mechanism of response. C57BL6 and Swiss Webster mice were exposed to 2,4-TDI for 2ppm hr and 1ppm hr, respectively. MR images were acquired before and at several time points after exposure. Nasal lavage, serum collection and fixation of the nasal passages were performed on subsets of mice at each time point. MRI detectable alterations were observed in C57BL6 mice after the 2ppm hr exposure while no detectable changes were seen in the Swiss Webster strain. Specific antibodies to a TDI-mouse serum albumin conjugate were found in sera from both strains at 2 and 4 weeks post exposure. Difference protein mapping of nasal lavage fluid as a function of time post exposure shows increases and decreases of a variety of proteins. Immunological and biochemical responses appear to occur at exposure levels where morphological changes are not detectable by MRI.

62 A SIMPLE MODEL FOR INTERSPECIES TISSUE DOSE COMPARISONS FOR VAPORS DEPOSITED IN THE NASAL CAVITY.

C. B. Frederick. *Rohm and Haas Co., Spring House, PA.*

A simple hybrid computational fluid dynamics (CFD) and physiologically based pharmacokinetic (PBPK) dosimetry model has been constructed to evaluate the tissue concentrations of a variety of vapors that may be deposited in the mammalian nasal cavity. The CFD-PBPK model incorporates a one-compartment description of the nasal cavity which serves as a portal of entry for inhaled vapors prior to distribution to systemic tissues. Although the model incorporates a dynamic description of mass transport across the air:mucus interface in the nasal cavity, it can also simulate 'C = 0' boundary conditions used for CFD simulations. Under these conditions, it accurately replicated CFD simulations conducted at a variety of flow rates with models of both the rat and human nasal cavity. In addition, the CFD-PBPK model accurately replicated experimental data on the nasal deposition of a wide variety of vapors under unidirectional flow in the rat nasal cavities. Comparison of the model predictions for the average rat and human nasal tissue concentrations following simulated inhalation exposures to a wide range of vapors (acid, alcohol, ketone, etc.) indicated that this ratio (often referred to as an 'interspecies extrapolation factor') was approximately one. Although the simple one-nasal-compartment CFD-PBPK model is useful for comparing average nasal and systemic tissue concentrations, the complex geometry of the mammalian nasal cavity may require more complex CFD-PBPK models to correlate regional tissue concentrations with the regional nasal lesions that often characterize inhalation exposure to toxic vapors.

63 BIOCHEMICAL AND PROLIFERATIVE CHANGES IN RESPIRATORY TISSUES OF RATS EXPOSED TO METHYL *tert*-BUTYL ETHER.

L. V. Radzius and R. A. Schatz. *Northeastern University, Boston, MA.*

Approximately 25% of gasoline sold in the United States is formulated with methyl tert-butyl ether (MTBE), a fuel oxygenate which is blended into gasoline at concentrations of 11-15% by volume. Health complaints suggestive of respiratory effects have been reported in areas where gasoline containing MTBE has been introduced. However, studies assessing MTBE's respiratory effects have been limited. Analysis of bronchoalveolar lavage fluid (BALF) and nasal lavage fluid (NLF) is considered to be a sensitive tool in assessing suspected respiratory toxicants. In this study, rats were exposed to MTBE (300 ppm for 6 hours) and sacrificed both immediately and 24 hours following cessation of exposure. Significant increases in sialic acid (231%), lactate dehydrogenase (106%), and acid phosphatase (246%) were seen in NLF of rats sacrificed 24 hours post-exposure to MTBE. No changes in gamma-glutamyl transferase or total protein were seen in NLF, either immediately following, or 24 hours post-exposure to MTBE. In addition, no changes in any of the above lavage fluid parameters were seen in BALF following exposure to MTBE at either time point, suggesting that toxicity is limited to the upper respiratory tract. Increased cell proliferation, as a repair mechanism, is also indicative of tissue injury. An increased level of proliferating cell nuclear antigen (PCNA) was also seen in respiratory mucosa of the nasal cavity, both immediately following (16%) and 24 hours following (61%) exposure to MTBE. No increases in PCNA were seen in the olfactory mucosa of the nasal cavity or the lung. The nose, especially the anterior respiratory mucosa, receives the highest dose of an inhaled xenobiotic. Biochemical changes in NLF suggestive of nasal irritation, mucous hypersecretion, cytotoxicity, and inflammation, and accompanying proliferative changes in respiratory mucosa indicate that MTBE may indeed be a nasal irritant and/or toxicant.

64 THE RELATIONSHIP OF PROTEIN CARBONYL LEVELS TO INFLAMMATORY RESPONSES IN BRONCHOALVEOLAR LAVAGE FLUID IN RATS, MICE, AND HAMSTERS FOLLOWING INHALED PIGMENTARY TITANIUM DIOXIDE.

E. E. Reverdy, E. Bermudez, J. B. Mangum, B. Asgharian and J. I. Everitt. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Protein carbonyls occur from the oxidative modification of amino acid residues and have been postulated to result from oxidants associated with inflammatory disease states. We hypothesized that elevated levels of protein carbonyl groups in the bronchoalveolar lavage fluid (BALF) may serve as a biomarker of oxidative stress in pulmonary disease. Exposures of laboratory rodents to high airborne concentrations of relatively noncytotoxic poorly soluble particles (PSP) leads to pulmonary inflammation, which may contribute to the production of protein carbonyls. The objective of the present study was to compare the BALF protein carbonyl levels in three rodent species following a subchronic particle exposure to pigmentary titanium dioxide (TiO_2), a well-studied PSP. Female Fischer 344 rats, B6C3F1 mice, and Syrian golden hamsters were exposed by whole-body inhalation to TiO_2 concentrations of 0, 10, 50, or 250 mg/m$_3$. Groups of animals were exposed for 6 h/d, 5 d/wk for 13 wk and allowed to recover for up to 26 wk. Inflammatory responses and protein carbonyl levels in BALF were determined at the termination of the 13-wk exposure then at 4, 13, and 26 wk postexposure. Carbonyl levels determined using an ELISA were significantly increased in rats exposed to 50 and 250 mg/m$_3$ of TiO_2, while mouse and hamster levels were elevated only following 250 mg/m$_3$. Elevation in carbonyl levels reflected similar patterns in BALF-associated cytologic and biochemical inflammatory indices. Inflammatory changes in all three species were limited to animals exposed to extremely high concentrations. These results suggest that the measurement of protein carbonyls in BALF may be a useful biomarker of particle-induced oxidant damage in conjunction with other oxidative end points. (Supported in part by the Chemical Manufacturers Association and the European Chemical Industry Council.)

65 CYTOTOXIC AND GENOTOXIC RESPONSES OF BUTADIENE SOOT DMSO EXTRACT (BSDE) IN CULTURED NORMAL HUMAN BRONCHIAL EPITHELIAL (NHBE) CELLS.

C. Kennedy[1], J. Catallo[1], W. Henk[2] and A. Penn[1]. [1]*LSU School Vet. Med., Physiol. Pharm. & Tox., Baton Rouge, LA and* [2]*LSU School Vet. Med., Anatomy, Baton Rouge, LA.*

Flaring of low molecular weight volatile organic compounds (e.g., 1,3-butadiene) at petrochemical plants produces soot containing a complex mixture of polycyclic aromatic hydrocarbons (PAHs). These include not only established carcinogens (e.g., benzo[a]pyrene) but also a range of cyclopenta-fused PAHs that are suspected carcinogens. The toxicological properties of these mixtures have not been well established. We are characterizing the cytoxicity and genotoxicity of BSDE *in vitro* using NHBE cells, the main target cell type for the development of lung cancer. Single-dose acute exposure of NHBE cells to BSDE for up to 72 hr resulted in the following effects that were not detected in vehicle-exposed control cells: 1)dose-dependent cytotoxicity as determined by clonal growth assays; 2)extranuclear cellular fluorescence (Ex.=365 nm; Em.>420 nm) presumably from the uptake of aromatic compounds and/or the formation of oxidized molecular complexes; 3)dose-dependent morphological changes including cell swelling and plasma membrane blebbing which are indicative of oncosis; 4)loss of cell organelles, an increased number of intracellular vacuoles and accumulation of membrane-limited extracellular material, as visualized by transmission electron microscopy; and 5)significantly elevated levels of binucleated cells, a marker of genotoxicity. These results suggest that inhalation exposure to industrially-generated soots may be significant from both the public and environmental health perspectives. It would seem that further toxicological studies on BSDE and related complex mixtures are warranted.

66 PULMONARY TOXICITY STUDY OF LUNAR AND MARTIAN DUST SIMULANTS INTRATRACHEALLY INSTILLED IN MICE.

C. Lam[1], J. T. James[2], J. A. Latch[3], A. Holian[4] and R. McCluskey[4]. [1]*Wyle Laboratories, Houston, TX,* [2]*Medical Operations, NASA Johnson Space Center, Houston, TX,* [3]*Pulmonary Dept., University of Texas, Houston, TX, Houston, TX and* [4]*Dept. of Environmental and Occupational Health, University of South Florida, Tampa, FL.*

NASA is contemplating sending humans to Mars and the Moon for further exploration. The properties of Hawaiian and Californian volcanic ashes allow them to be used to simulate Martian and lunar dusts, respectively. NASA laboratories use these dust simulants to test performance of hardware destined for Martian or lunar environments. Workers in these test facilities are exposed to low levels of these dusts. The present study was conducted to investigate the toxicity of these dust simulants. Particles of respirable-size ranges of lunar simulant (LS), Martian simulant (MS), TiO2 (negative control) and quartz (positive control) were each intratracheally instilled (saline as vehicle) to groups of 4 mice (C57BL, male, 2-3 month old) at a single treatment of 1 (Hi dose) or 0.1 (Lo dose) mg/mouse. The lungs were harvested at the end of 7 days or 90 days for histopathological examination. Lungs of the LS-Lo groups had no evidence of inflammation, edema or fibrosis. The LS-Hi-7d group had mild to moderate acute inflammation, and neutrophilic and lymphocytic infiltration; the LS-Hi-90d group showed signs of chronic inflammation and some fibrosis. Lungs of the MS-Lo-7d group revealed mild inflammation and neutrophilic and lymphocytic infiltration; the MS-Lo-90d group showed mild fibrosis and particle-laden macrophages (PLM). Lungs of the MS-Hi-7d group demonstrated mild to moderate inflammation and large foci of PLM; the MS-Hi-90d group showed chronic mild to moderate inflammation and fibrosis. To mimic the effects of the oxidative and reactive properties of Martian soil surface, groups of mice were exposed to ozone (3 hour at 0.5 ppm) prior to MS dust instillation. Lung lesions in the MS group were more severe with the pretreatment. The results for the negative and positive controls were consistent with the known pulmonary toxicity of these compounds. The overall severity of toxic insults to the lungs were TiO2< LS<MS<Quartz. For the mice in the 90-d study, blood samples were taken for immunotoxicity study. Antinuclear antibodies (such as those against Golgi, kinetichore, and centromere) were detected in serum in a greater extent in mice treated with LS than those with quartz, suggesting that LS, like quartz, has the potential of inducing antoimmune disease.

67 DEPOSITION AND DISPOSITION OF LARGE, HUMAN-RESPIRABLE PARTICLES IN THE LUNGS OF RATS.

J. R. Zanga and O. R. Moss. *Chemical Industry Institute of Toxicology, Reseach Triangle Park, NC.*

The predictions of a recently developed multiple-path computer model for lobar deposition of inhaled particles (S. Anjilvel and B. Asgharian, Fundam. Appl. Toxicol. 28, 41-50,1995) were evaluated in the rat for particles with an aerodynamic diameter larger than 2 μm. Two groups of 6 Long-Evans rats were exposed by endotracheal inhalation once for 30 min to an aerosol mixture of 3-, 6-, and 9-μm polystyrene latex beads. Approximately 24 hr after the exposure, the lungs were harvested, and each lobe was dissolved with strong base (TEAH) overnight. Particle counts were made using a hemacytometer viewed through a standard light microscope. The endotracheal inhalation exposure system was capable of delivering particles 3, 6, and 9 μm in diameter into the lungs of rats. The lobar distribution pattern of the 3-μm particles was fairly consistent among animals. The distribution of 3-μm particles in the alveolar region of the left lobe appeared to be underestimated by the dosimetry model with marginal significance. The model significantly overestimated the alveolar deposition of 3-μm particles in the right diaphragmatic and intercostal lobes. The 6-μm bead deposition pattern was very similar to the 3-μm bead deposition pattern. There were not enough 9-μm diameter particles present to compare among samples.

68 COMPARISON OF PULMONARY RESPONSE TO INHALED AND INTRATRACHEALLY INSTILLED DIESEL EXHAUST PARTICULATE.

N. H. Al-Humadi[1], P. D. Siegel[1], J. Y. C. Ma[1], W. G. Jones[2], M. W. Barger[1], D. M. Lewis[1] and J. K. H. Ma[3]. *[1]NIOSH/HELD, Morgantown, WV, [2]NIOSH/DRDS, Morgantown, WV and [3]The School of Pharmacy, West Virginia University, Morgantown, WV.*

Diesel exhaust particulate (DEP) is a complex mixture of polyaromatic hydrocarbons, ash, transition metals, and carbon core. Exposure levels of DEP up to 2 mg/m3 has been documented in underground mines, railroad, construction, and auto repair industries. Such exposures have been associated with pulmonary inflammation, fibrosis, lung cancer, increased rate of respiratory infections, and enhanced allergic sensitization. The purpose of this study was to compare the effect of the inhaled (4hr exposure, 17mg/m3) and intratracheally instilled (IT) DEP (5mg/kg b. wt.) and carbon black (CB, 34 mg/m3) particulate on pulmonary inflammation, pulmonary associated lymph node cells (LNC) and alveolar macrophages (AM) in a Brown Norway rat model. Carbon black was used as a surrogate of the non-extractable carbon core of DEP. Cellular Cysteine (CYS) and glutathione (GSH) levels were analyzed by conjugation to monobromobimane and subsequent HPLC-fluorescent analysis. Alveolar macrophage IL-1 and TNF- production were also assessed three days post exposure. Both, DEP and CB were generated by nebulizing suspended particles through a diffusion dryer into a nose-only chamber. Greater than 90% of the particles generated were in the submicron range. The microscopic evaluation of the DEP and CB particulate revealed similarities in shape and size between them. Inhaled DEP caused a significant increase in the levels of glutathione and cysteine in the LNC, but not AM. LNC thiols were unchanged following IT DEP, but AM GSH was elevated. A significant decrease of AM TNF- of DEP exposed rats after ex vivo endotoxin challenge was also observed in both IT and inhalation groups. Instillation of DEP caused pulmonary inflammation as noted by the increases in neutrophils count, and lavage protein and LDH levels. Inhaled DEP did not produce measurable pulmonary inflammation. The cause of the differences observed between acute inhalation vs IT DEP in pulmonary inflammation and thiol content is not known, but may be due to dose deposited in the lung.

69 CHRONIC INHALATION OF ROOM-AGED CIGARETTE SIDE-STREAM SMOKE (RASS) AND DIESEL ENGINE EXHAUST (DEE) IN RATS - EFFECTS ON LEUKOCYTE SUBPOPULATIONS IN BLOOD AND BRONCHOALVEOLAR LAVAGE FLUID (BALF).

B. Friedrichs, W. Stinn and H. J. Haussmann. *INBIFO, Cologne, Germany.*

The immuno-modulating effects of RASS, an experimental surrogate for environmental tobacco smoke (ETS), and DEE were investigated in a 24-month inhalation study in rats. The particulate matter concentrations chosen (3 and 10 μg/l) exceed the upper limit of typical ETS and DEE exposure concentrations for humans by approximately 100-fold. Leukocyte and lymphocyte subpopulations in blood and BALF were analyzed by microscopic and flow cytometric analysis. The following changes were observed in DEE-exposed, but not in RASS-exposed rats: In blood, there was a small increase in the (absolute and relative) number of neutrophils and a corresponding decrease in the percentage of lymphocytes, but no changes in blood lymphocyte subpopulations. In BALF, there was an increase in relative and absolute numbers of neutrophils from 1% or 1E5 cells in sham controls to up to 60% or 8E7 cells in the high DEE group. Corresponding lymphocyte numbers were 1.5% or 2E5 in sham controls, 8% or 3E6 in the low DEE group, and 5% or 6E6 in the high DEE group. These changes indicate a massive pulmonary inflammation. Within the BALF lymphocyte population, the T suppressor/cytotoxic cells were slightly increased. These results show that leukocyte subsets are more sensitive than lymphocyte subsets to chronic DEE inhalation. The major effects are restricted to the lungs as the port of entry and do not have relevant systemic consequences. RASS, which has an organic composition relatively similar to DEE, did not produce any immuno-modulating effects at the same particulate matter concentration. The immuno-modulating effects seen in DEE-exposed rats are considered as to be associated with the pulmonary accumulation of elemental carbon particles which was not seen in RASS-exposed rats. (Sponsored by Philip Morris USA.)

70 AHR AND PM10.

D. E. Arrieta, C. Hernandez and B. S. Washburn. *UTEP, El Paso, TX.*

Ah receptor mediated activity associated with PM10 extracts from the Paso del Norte airshed.The Paso del Norte airshed, which includes El Paso, TX, Ciudad Juarez, Mexico, and Las Cruces, NM, has historically high levels of PM10. The extensive use of wood and scrap material for fuel, an aged vehicular fleet, and rapid urban development associated with maquiladoras and NAFTA, have contributed to this problem, which is compounded by winter inversion layers. As a first step in an effort to identify biomarkers that reflect contaminants in this airshed, PM10 filters were collected from six monitoring sites located in El Paso and Ciudad Juarez. Filters from Jan. 1999 were extracted with dichloromethane for 24 hours in a Soxhlet apparatus and extracts were concentrated with a Kuderna-Danish per EPA method 3540C. To assess the biological effects of Ah receptor ligands associated with PM10, H4IIE rat hepatoma cells were exposed in 6-well plates to extracts containing the equivalent of 1 and 4 weeks of respirable air (air equivalents) for 24 hours and ethoxyresorufin-O-deethylase (EROD) activity was measured in the post-mitochondrial supernatant. Control activity was 1.55 pmol-1min-1mg prot; 1 μM b-naphthoflavone (BNF), the positive control, caused a 6½ fold increase. Variability in EROD activity was greatest in cells exposed to 1-week air equivalents from a brickmaking district, where as great as a 4 fold difference in enzyme activity (2.76-11.65 pmol -1min-1mg prot.) was observed on different dates. These differences are likely to be associated with varying patterns of activity in this cottage industry. Greater than 1-week air equivalents from this site inhibited enzyme activity by 50%. At sites primarily associated with car and truck traffic, EROD activity remained fairly constant (2.4-4.8 pmol-1min-1mg prot.) regardless of date. Filters from all winter months, are presently being analyzed for EROD activity and Ah receptor ligands with a luciferase reporter system.

71 DEPOSITION OF MONODISPERSE AEROSOLS IN YOUNG BEAGLE DOGS.

R. J. Hershman[2], S. J. Rothenberg[1], R. M. Beihn[3], W. J. Ehrhart[2], D. L. Dewees[2], S. D. Lief[1] and C. S. Godin[2]. *[1]Primedica Argus, Horsham, PA, [2]White Eagle Toxicology Laboratories, Doylestown, PA and [3]Scintiprox Inc., Indianapolis, IN.*

The effects of inhaled particles are determined by chemical composition and sites of deposition. The shape, density and size of the particles determine not only sites of deposition in the respiratory tract but also the fraction of inhaled particles that are deposited. Deposition of monodisperse aerosols (1 to 9 microns Mass Median Aerodynamic Diameter (MMAD)) was measured in young unsedated 4 and 7 month old Beagle dogs using mouth-breathing and nose-breathing models. Iron oxide aerosols, with ^{99m} Technetium tracer, were produced using a spinning top aerosol generator (STAG). Particle size was controlled by varying the concentration of the iron oxide suspension and the speed of the STAG rotor. Satellite particles were removed by adjusting the exhaust flow. Animals were acclimated to the mouth-breathing and nose-breathing masks prior to aerosol exposures and were exposed to aerosols of approximately 1, 3, 5, 7 or 9 microns MMAD for up to ten minutes. Deposition was determined using gamma camera scintigraphy. Scintography images were taken immediately after exposure. Areas of interest in the images were delineated and data reported for both total and regional deposition as a function of particle size. For the 7 month old Beagle dogs lung deposition was

greater at 3 microns than at 1 micron, whereas for the younger dogs lung deposition was greatest at 1 micron. The deposition over the one to three micron range in the 7 month old male Beagles was comparable to that previously published by Cuddihy (1973) for adult males. Deposition in the 4 month old dogs was lower at all particle sizes than in the 7 month old males; deposition in the 7 month old females was intermediate in value. Research Sponsored by: B Stuart, Shering-Plough; R Wolff, Eli Lilly; H Marchner, Astra; D Alexander, GlaxoWellcome and C Leach, 3M Pharmaceuticals.

71A CLEARANCE OF DEPOSITED AEROSOLS FROM YOUNG BEAGLE DOGS.

R. J. Hershman[1], S. J. Rothenberg[2], R. M. Beihn[3], W. J. Ehrhart[1], D. L. Dewees[1], S. D. Lief[2] and C. S. Godin[1]. [1]*White Eagle Toxicology Laboratories, Doylestown, PA,* [2]*Primedica Argus Research, Horsham, PA and* [3]*Scintiprox Incorporated, Indianapolis, IN.*

The effects of deposited particles are determined by the chemical composition of the particles, the sites of deposition and the rate of clearance from the respiratory tract. Measurements were made of deposition and clearance of monodisperse aerosols over the range 1 to 9 microns Mass Median Aerodynamic Diameter (MMAD) in young unsedated 4 months and 7 months old Beagle dogs using mouth-breathing and nose-breathing models. Iron oxide aerosols, with ^{99m}Technetium tracer, were produced using a spinning top aerosol generator (STAG). Animals were acclimated to the mouth-breathing and nose-breathing masks prior to aerosol exposures, and were exposed to aerosols of approximately 1, 3, 5, 7 or 9 microns MMAD for up to ten minutes. Deposition was determined using gamma camera scintigraphy. Scintigraphy images were taken immediately after exposure, and at approximately 1 hour, 2 hours and 4 hours post-exposure. Areas of interest in the images were delineated and clearance subsequent to deposition was monitored. All data were corrected for both attenuation by the body and radioactive decay during the measurements. Except for a peak in the gastrointestinal tract data for the nose-only exposed animals, presumed to reflect swallowing, the clearance data fell on a single curve for all animals. Thus the rate of clearance of the labeled iron oxide particles appeared to be independent not only of animal age and sex but also of particle size between 1 and 9 microns MMAD. (Research Sponsored by: B. Stuart, Shering-Plough; R. Wolff, Eli Lilly; H. Marchner, Astra; D. Alexander, Glaxo Wellcome; and C. Leaach, 3M Pharmaceuticals.)

72 AIR POLLUTION AND ELEMENTARY SCHOOL ABSENTEEISM.

L. Chen[1], B. L. Jennison[2], W. Yang[3] and S. T. Omaye[1]. [1]*University of Nevada, Environmental Sciences. & Health Grad. Program, Reno, NV,* [2]*Washoe County District Health Department, Reno, NV and* [3]*Bureau of Health Planning & Statistics, Nevada State Health Division, Carson City, NV.*

This study assessed the association between ambient air pollution and daily elementary school absenteeism in Washoe County, NV from 1996-1998. All 57 elementary schools in Washoe County were included. There was a total of 28,829 enrollments during the study period. The daily average absence rate was 5.09%. Air pollutant values including PM_{10}, O_3 and CO were obtained from seven air monitoring stations. Weather variables were collected from five of these stations and from the Western Regional Climate Center. The daily average concentration of PM_{10}, CO and O_3 was 32.44 μg/m^3, 2.73 ppm and 37.45 ppb respectively. The absence rate was regressed on the three air pollutants, weather variables and other confounding factors, using Autoregression analysis. Although the results showed that many factors could affect school absenteeism, after adjusting for the effects of weather variables, day-of-the-week, month and holiday indicators, and time trend, the results showed that CO and O_3 were statistically significant predictors of daily absenteeism in elementary schools. For every 1 ppm and 50 ppb increase in CO and O_3, the absence rate would increase 3.79% (95% CI 1.04-6.55%) and 13.01% (95% CI 3.41-22.61%) respectively. PM10 values, however, were negatively correlated with school absenteeism. (The support and cooperation of the Washoe County School District is gratefully acknowledged.)

73 PARTICULATE AIR POLLUTION AND HOSPITAL ADMISSIONS FOR CHRONIC OBSTRUCTIVE PULMONARY DISEASE IN RENO, NEVADA.

W. Yang[2], L. Chen[1], B. Jennison[3] and S. T. Omaye[1]. [1]*University of Nevada, Reno, NV,* [2]*Bureau of Health Planning and Statistics, Nevada State Health Division, Carson City, NV and* [3]*Air Quality Management Division, Washoe County District Health Dept., Reno, NV.*

This study assessed the association between ambient PM_{10} pollution and daily hospital admissions for Chronic Obstructive Pulmonary Disease (COPD) in Reno-Sparks, Nevada, for the period 1990-1994. All three hospitals in the region were included. There was a total of 3115 admissions for COPD during this period. Ambient PM_{10} values were obtained from one of seven air monitoring stations. Weather variables were also collected. The daily average concentration of PM_{10} was 36.55 μg/m^3. The Generalized Additive Model (GAM) was used in the analysis. After adjusting for the effects of weather variables, day-of-the-week, seasons and time trend, the results show that PM_{10} is a statistically significant predictor for daily hospital admissions for COPD. The relative risk (RR) of hospital admissions for COPD for an interquantile increase (26.6 μg/m^3) of the 24-h average level for PM_{10} is 1.049 (95% CI 1.011-1.087) which suggests that for every 26.6 μg/m^3 increase in the ambient PM_{10} level, there would be 31 more hospital admissions for COPD every year (95% CI: 7-55).

73A URBAN STRAY DOGS AS AN INDICATOR SPECIES FOR MONITORING CHRONIC EXPOSURES TO AIR POLLUTION: PREDICTIVE VALUE FOR CHILDREN? SHOULD WE BE CONCERNED?

L. Calderon-Garciduenas[1], R. Garcia[2], N. Osnaya[2], A. Jairo[2], H. Acuna[2], A. Villarreal-Calderon[2], J. Gallagher[3] and R. Devlin[4]. [1]*University North Carolina and Instituto Nacional Pediatria, Chapel Hill, NC,* [2]*Instituto Nacional de Pediatria, Mexico City, Mexico and* [3]*USEPA, Research Triangle Park, NC.*

A complex mixture of air pollutants is present in the ambient air in Mexico City. People and animals are exposed chronically and sequentially to outdoor pollutants. The principal objective of this study was to evaluate the lung histopathology and heavy and trace metal concentrations in Mexico City (MC) young (<1 y) and old (>5y) dogs from two different geographic areas with marked differences in the concentrations of criteria pollutants. Control dogs were included. Clinically healthy 94 stray dogs (49M/45F) including 19 controls and 75 from Southwest and Northeast MC were studied. Control dogs had unremarkable histological findings. Lung lesions were observed in all MC dogs regardless of age, gender and geographical source. Major findings included peribronchiolar and perivascular clusters of macrophages loaded with particulate material, increased numbers of intra-alveolar particle-laden macrophages, hyperplasia and hypertrophy of nonciliated bronchiolar cells with luminal accumulation of macrophages and decreases in luminal diameters, and replacement of type 1 alveolar cells with type 2 cells. Heavy and toxic trace metal lung analysis revealed significant differences in metals such as Pb between SW(residential area) and NE(industrial area) dogs and accumulation of metals in young vs older animals. Rb,Br,V,Cr and Co were detected in MC dogs. Chronic exposure to a polluted environment is causing significant lung damage in MC dogs. The lesions described in naturally exposed dogs may be a model for the early steps in human fibrotic/emphysematous/neoplasic lung diseases. Deep concern exist for similar lung lesions and metal deposition in children with a lifelong exposure to the same environment. This experiment was conducted on tissues obtained from pound dogs euthanatized for reasons other than this study. Euthanasia was conducted in accordanace with established guidelines of the American Veterinary Medical Association (J. Am. Vet. Med. Assoc. 202:229-249, 1993) and in accordance with applicable animal care and use regulations. [This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.]

74 ASBESTOS AND NON-ASBESTOS FIBER CONTENT IN LUNGS OF KOREAN SUBJECTS WITH NO KNOWN OCCUPATIONAL ASBESTOS EXPOSURE HISTORY.

I. J. Yu[1], K. Sakai[2], N. Hisanaga[3], J. D. Park[4], H. H. Chang[5], I. H. Kwon[6], J. H. Han[7], S. K. Yang[7] and H. K. Chung[7]. [1]*Industrial Safety and Health Research Institute, Taejon, Republic of Korea,* [2]*Nagoya City Public Health Institute, Nagoya, Japan,* [3]*Natl. Institute of Industrial Health, Kawasaki, Japan,* [4]*Chung-Ang University, Seoul, Republic of Korea,* [5]*Kosin University, Pusan, Republic of Korea,* [6]*Natl. Institute of Scientific Investigation, Pusan, Republic of Korea, and* [7]*Industrial Safety and Health Research Institute, Taejon, Republic of Korea.*

To provide an estimation of asbestos exposure among normal Koreans and a criterion for determining occupational asbestos exposed diseases, pulmonary fiber contents of both asbestos and non-asbestos types were evaluated in 25 Korean subjects with no known occupational history of asbestos exposure. Pulmonary fiber contents were analyzed by transmission electron microscopy with energy dispersive X-ray analysis after using the low temperature ashing procedure. Chrysotile fiber was the major fiber type found in the lungs of Korean subjects. Asbestos fiber concentrations found in males and females were 0.3×10^6 fibers/g of dry lungs and 0.15×10^6 fibers/g of dry lung tissue. Non-asbestos fiber contents found in males and females were 8.02×10^6 fibers/g of dry lungs and 7.85×10^6 fibers/g of dry lungs, respectively. There was no difference in asbestos content in lung among various age groups. Comparing these results with Japanese male (2.11×10^6 fibers/g of dry lung) and female subjects (1.38×10^6 fibers/g of dry lung), Korean male and female subjects had much less asbestos in their lungs.

75 DEVELOPMENT OF AEROSOL SAMPLING AND ANALYTICAL METHODS FOR MAN-MADE ORGANIC FIBERS.

K. L. Reed, G. L. Kennedy, Jr., M. A. Hartsky and D. B. Warheit. *DuPont Haskell Lab, Newark, DE.*

The purpose of this study was to compare the results of airborne organic fiber measurements using different collection modes and counting techniques. Atmospheres of p-aramid or cellulose respirable fiber-shaped particulates (RFP) were generated in an inhalation chamber. For each experiment, 30 filters (10 gold-coated polycarbonate filters, 10 methyl cellulose filters, and 10 methyl cellulose filters and corresponding cowls) were exposed to fibrous aerosols at concentrations ranging from 25 - 50 f/cc. Subsequently, attempts were made to count and compare each of the filters by three optical techniques, namely light microscopy (LM) (PCOM- NIOSH 7400) scanning electron microscopy (SEM), and transmission electron microscopy (TEM). Preliminary results demonstrated that the gold-coated polycarbonate filters were not appropriate for counting by LM and TEM. In addition, washing the cowl onto the same filter did not contribute greater numbers of fiber counts and seemed to facilitate clumping. When comparisons were made between LM, SEM, and TEM counts on the same filters, the fiber numbers were not significantly different when evaluated via the different analytical techniques. These findings are in contrast with the preliminary data of other investigators who have reported a 2-5 x increase in the numbers of organic fibers when counted by SEM vs. PCOM. Studies are ongoing to resolve the differences between analytical methods for counting organic fibers.

76 COMPARISON OF HISTOPATHOLOGY IN RATS SUBCHRONICALLY EXPOSED TO SMOKE FROM CIGARETTES THAT BURN OR PRIMARILY HEAT TOBACCO.

P. H. Ayres and A. T. Mosberg. *R J Reynolds Tobacco Co., Winston-Salem, NC.*

A subchronic nose-only inhalation study comparing the effects of smoke from a cigarette that primarily heats tobacco (Eclipse™ prototype 9-014), to that of smoke from a Kentucky 1R4F reference cigarette was conducted using Sprague-Dawley rats. Rats of each sex were exposed 1 hour a day, 5 days per week, for 13 weeks to mainstream smoke at 0, 0.16, 0.32, or 0.64 mg/liter of air. Endpoints were carboxyhemoglobin (HbCO), serum nicotine, clinical signs, body and organ weights, serum chemistry, hematology, and histopathology. Neither cigarette produced adverse changes in clinical signs, body and organ weights, serum chemistry, or hematology. HbCO and serum nicotine increased with both cigarettes in an exposure-dependent manner. Smoke related histologic changes were nasal chronic/active inflammation and epithelial hyperplasia, chronic/active inflammation of the larynx, squamous metaplasia of the ventral larynx, tracheal epithelial hyperplasia, increased goblet cells of the lung, and increased non-pigmented and brown/gold pigmented lung macrophages. Overall, the evaluation of histologic changes in rats exposed to smoke of Eclipse cigarettes indicated a reduction of biological activity compared to the smoke of the tobacco burning 1R4F cigarette.

77 EFFECTS OF THE ADDITION OF FLAVOR INGREDIENTS TO THE TOBACCO ON THE CHEMICAL COMPOSITION AND BIOLOGICAL ACTIVITY OF CIGARETTE SMOKE.

E. Roemer[1], K. Rustemeier[1], P. M. Vanscheeuwijck[2], T. J. Meisgen[1], D. J. Veltel[1], H. Haussmann[1] and E. L. Carmines[3]. [1]*INBIFO, Cologne, Germany,* [2]*CRC, Zaventem, Belgium and* [3]*Philip Morris USA, Richmond, VA.*

Cigarette mainstream smoke from American-blend test cigarettes with and without the addition of flavor ingredients was analyzed for its chemical composition. In total, more than 300 commonly used flavors were assigned to three different flavor mixtures. The flavors were incorporated into the cigarettes at two levels that exceed normal use levels. An unflavored cigarette served as control. The smoke constituents analyzed included those proposed by the US Consumer Product Safety Commission and additional smoke constituents classified as human or animal carcinogens by the International Agency for Research on Cancer. The results obtained for genotoxicity (Ames Assay), cytotoxicity (Neutral Red Assay), and inhalation toxicity (90 d, rat inhalation) of the smoke are compared relative to that of the control cigarette. The addition of the flavor ingredients caused an increase of approximately 20% in the yields of total particulate matter and tar per cigarette compared to the unflavored control. On a per mg TPM basis a general decrease was seen for most of the smoke constituents analyzed. This reduction was especially high for phenols (up to 70%), polycyclic aromatic hydrocarbons (50%), and N-nitrosamines (45%). Only a few constituents were increased: HCN, cadmium, formaldehyde, and resorcinol (approx. 30%). Neither the *in vitro* mutagenicity and cytotoxicity nor the *in vivo* inhalation toxicity were increased by the flavor ingredients added. The overall assessment suggests that the flavor ingredients do not increase the biological activity of the cigarette smoke, even at the exaggerated levels tested in the present series of studies.

78 THE INFLUENCE OF A MODIFIED PUFFING REGIMEN ON THE YIELDS OF SMOKE CONSTITUENTS FROM ELECTRICALLY HEATED AND CONVENTIONAL RESEARCH CIGARETTES.

K. Rustemeier[1], G. Patskan[2] and H. J. Haussmann[1]. [1]*INBIFO, Cologne, Germany and* [2]*Philip Morris USA, Richmond, VA.*

The influence of puff volume and frequency on the yields of a selection of toxicologically relevant constituents in the smoke of an electrically heated cigarette (EHC) was investigated and compared to that of the conventional reference cigarettes 1R4F (representative of the low-tar market segment) and 1R5F (ultra low-tar). For the reference cigarettes, the influence of vent blocking was also analyzed; the EHC has no vents. At a puff volume of 55 ml with 2 puffs/min, total particulate matter (TPM) yields increased 1.8-, 2.5-, and 3.5-fold over those obtained under ISO conditions (35 ml, 1 puff/min) for the EHC, 1R4F, and 1R5F, respectively. Very similar to these ratios are the median ratios (and 25th; 75th percentiles) obtained for the more than 20 smoke constituents determined, i.e., 1.5 (1.4; 1.6) for EHC, 1.9 (1.8; 2.1) for 1R4F, and 3.4 (3.2; 3.8) for 1R5F. Relative to the tar yield of these cigarettes, these median ratios were 0.92 (0.84; 0.96), 0.85 (0.82; 0.91), and 0.96 (0.90; 1.11). Additional complete vent blocking increased the TPM yields of the 1R4F by 3.1-fold and that of the 1R5F by 7.8-fold compared to ISO conditions. The corresponding median ratios of all smoke constituents analyzed were 2.3 (2.1; 2.6) and 5.4 (4.6; 7.5) and, relative to the tar yield, 0.90 (0.82; 1.03) and 0.83 (0.71; 1.19). There were only a few constituents that did not follow this general trend. The ratios obtained for the TPM and tar yields were generally higher than the median ratios for the individual smoke constituents. Thus, TPM and tar would seem to be critical and valid indicators of changes overall. Due to the construction principle of the EHC, the yields of almost all toxicologically relevant smoke constituents are relatively low compared to those of the reference cigarettes, and a modified puffing regimen can only result in limited changes.

79 COMPARISON OF TWO EXPOSURE REGIMENS IN RAT SUBCHRONIC INHALATION STUDIES WITH CIGARETTE SMOKE.

M. Kaegler[1], A. Teredesai[1], P. Vanscheeuwijck[2], P. Terpstra[2] and B. Gerstenberg[1]. [1]*INBIFO - Institut fuer Biologische Forschung, Koeln, Germany and* [2]*CRC Contract Research Center, Zaventem, Belgium.* Sponsor: S. P. Richard.

Part of the testing of cigarette modifications is an *in vivo* subchronic mainstream smoke inhalation study in rats often performed in basic accordance with OECD guideline 413. The testing entails the determination of relevant and sensitive endpoints and has been shown to be able to detect modification-induced differences in biological activity. The aim of this study was to compare two different exposure regimens: 6 hours, 7 days/week (proposed in guideline 413) vs. 2x1 hour, 5 days/week (new). In order to do this, the biological activity of mainstream smoke from the Reference Cigarette 1R4F (about 9mg tar) and the 1R5F (about 2mg tar) was determined. Qualitatively, there was no difference between the findings obtained with the different regimens. Furthermore, the findings were similar to those reported in the literature (e.g., reserve cell hyperplasia, squamous metaplasia, and atrophy at some sites in the upper respiratory tract). Both exposure regimens discriminated two reference cigarettes with the same 15% difference. For equal weekly Cxt, grading of histopathological findings for the two cigarettes were higher in the shorter exposure regimen. In addition, the number of statistically significant differences to sham-exposed control was also higher in the shorter exposure regimen. This shorter exposure regimen provides a better basis for discrimination between test cigarettes. These results indicate that exposure regimens other than the one proposed in guideline 413 are suitable options for cigarette smoke inhalation studies. (Sponsored by Philip Morris USA).

80 AGE RELATED ALTERATIONS IN PULMONARY FUNCTION AND PULMONARY LIPID PEROXIDATION AFTER EXPOSURE TO JP-8 + 100 BLEND JET FUEL.

R. S. Young and M. L. Witten. *University of Arizona, Tucson, AZ.*

The standard operation of military aircraft requires the use of several potentially hazardous chemicals. JP-8 + 100 blend jet fuel is an obvious necessity for aircraft function; however, chronic exposure to JP-8 + 100 blend jet fuel is common among personnel working on the flight line, engine mechanics, and pilots. The age range of these personnel can range from 18 years to 55 + years of age. We have demonstrated that exposure to JP-8 + 100 blend jet fuel induces significant alterations in lung permeability and pulmonary functions in our mouse exposure model. Our mouse model of JP-8 + 100 blend jet fuel exposure historically has ranged in age from 3-4 months. We therefore have conducted studies to determine the age-related effects of JP-8 + 100 blend jet fuel inhalation on the pulmonary microenvironment in aged animals. We exposed aged (12-14 months) and young (3-4 months) mice to 1000 mg/m^3 JP-8 + 100 blend jet fuel for seven days for one hour per day. Animals were sacrificed 24-30 hours after the final exposure and pulmonary functions (dynamic compliance and pulmonary resistance), lung permeability, histological analysis, and bronchoalveolar lavage fluid (BALF) were analyzed. Aged mice exposed to JP-8 + 100 blend jet fuel demonstrated significant alterations in pulmonary functions ($p<0.05$), lung permeability ($p<0.001$), and BALF levels of inflammatory mediators (TNF-alpha) and lipid peroxidation products (PGE_2 and 8-iso-PGF_2) ($p<0.0001$) compared to aged controls and young mice exposed to JP-8 + 100 blend. Histological analysis of lungs from aged animals exposed to JP-8 + 100 jet fuel demonstrate significantly increased alveolar epithelial injury compared to aged controls and young mice exposed to JP-8 + 100 blend jet fuel. We conclude that JP-8 + 100 blend jet fuel-induced lung injury is exacerbated in aged populations. (This work supported by the Air Force Office of Scientific Research Grant # F49620-94-1-0297 and by the U.S. Department of Defense Training Grant [AASERT].)

81 ACUTE INHALATION TOXICITY OF *CIS* AND *TRANS* ISOMERS OF 1,2-DICHLOROETHYLENE IN RATS.

D. P. Kelly[1], J. Hansen[1], W. Brock[1], J. Barter[2] and H. Burleigh-Flayer[2]. [1]*DuPont Co., Haskell Laboratory for Toxicology and Industrial Medicine, Newark, DE and* [2]*PPG Co., Pittsburgh, PA.*

Trans-1,2-Dichloroethylene (t-DCE) is used as an intermediate in the production of chlorinated chemicals and as a solvent, the cis isomer (c-DCE) occurs in some t-DCE processes. The acute toxicities of t-DCE and c-DCE were evaluated in Crl:CDBR male and female rats. The liver, kidney, heart, and lungs were evaluated histologically in rats that died during exposure or that survived a 14-day recovery period. The LC50s for the cis and trans isomers were 13,700 and 24,100, respectively. During exposures to each isomer above 12,000 ppm, the rats were prostrate and showed a lack of response to an alerting stimulus. Dose-related, centrilobular fatty changes were observed in the livers of male rats exposed to 13,500 and 15,700 ppm of c-DCE, but no compound-related effects were observed in the livers of rats exposed to t-DCE at concentrations up to 34,100 ppm. No effects were observed in the heart, kidney, or lung in rats exposed to either isomer. The lack of effects in the heart contrasts with an earlier report of cardiac effects with single exposures to DCE (unspecified isomers) in rats. It appears that c-DCE is approximately twice as toxic as t-DCE on an acute inhalation basis.

82 IS TOTAL MASS OR MASS OF ALVEOLAR-DEPOSITED AIRBORNE PARTICLES OF BERYLLIUM A BETTER PREDICTOR OF THE PREVALENCE OF DISEASE? A PRELIMINARY STUDY OF A BERYLLIUM PROCESSING FACILITY.

M. Kent[1], T. Robins[2], A. K. Madl[1], M. Goodman[4] and D. J. Paustenbach[5]. [1]*Brush Wellman Inc., Elmore, OH,* [2]*University of Michigan, School of Public Health, Department of Environmental Sciences, Ann Arbor, MI,* [3]*Exponent, Oakland, CA,* [4]*Exponent, Landover, MD and* [5]*Exponent, Menlo Park, CA.*

Cases of chronic beryllium disease (CBD) and beryllium (Be) sensitization continue to be identified among Be industry workers. The currently accepted method for measuring exposure, which involves measuring the total mass of airborne Be per cubic meter, shows an inconsistent dose-response relationship with the prevalence of CBD. This study was conducted to evaluate which Be aerosol characteristics other than total mass may be more informative in understanding the dose-response relationship between exposure to Be and disease. Personal samplers (n=53) using Andersen impactors and area samplers (n=55) using microorifice uniform deposit impactors (MOUDIs) were used to collect airborne Be samples were collected in five furnace areas at a Be manufacturing facility where prevalence rates of CBD and Be sensitization had been previously studied among 535 employees with significant Be exposure. The concentrations were expressed in terms of total mass per cubic meter, and in forms of mass, number, and surface area of particles per cubic meter that are predicted to deposit in the alveolar region of the lung. Tests for linear trend of the relationships of the various exposure metrics to prevalence of CBD and sensitization showed a highly significant association between mass, number and surface area concentration of particles predicted to deposit in the alveolar region of the lung and CBD and sensitization. However, no other exposure parameters showed significant relationships with CBD or Be sensitization. These results suggest that the concentration of alveolar-deposited particles is be a more relevant exposure metric for predicting the incidence of CBD or sensitization than the total mass concentration of airborne Be.

83 ASSESSMENT OF PERSONAL EXPOSURE OF GAS ATTENDANTS TO METHYLCYCLOPENTADIENYL MANGANESE TRICARBONYL (MMT).

M. Keiloun[1], F. Yang[2], Y. K. Chau[2], F. Gagnon[1], M. Rivard[1] and J. Zayed[1]. [1]*University of Montreal, Montreal, Quebec, Canada and* [2]*Environment Canada, Burlington, Ontario, Canada.* Sponsor: K. Krishnan.

Methylcyclopentadienyl manganese tricarbonyl (MMT) is an organic derivative of manganese (Mn) used in Canada as an antiknock agent and octane enhancer. In a recent study, we assessed the atmospheric concentrations of MMT at selected sites outdoor in Montreal. Results ranged from 1.8 ng/m^3 to 25 ng/m^3 (expressed as Mn) and do not reflect personal exposure levels. The highest values were obtained at a gas station (mean of 12 ng/m^3). Consequently, assessment of personal exposure of gas attendants constitute a promising research avenue. Moreover, the sampling method used in the previous study entails an uncertainty related to the possibility that the samples could include ultra fine particles which were able to pass through the filters used and the chemical analysis used (neutron activation) did not permit to discriminate Mn and MMT. The present study aims to assess personal exposure to MMT of gas attendants and to validate the sampling method as well as the chemical analysis. First, the average percentage of MMT recovery from spiked samples was 91.6% (SD=7.9). Then, exposure of 13 service station attendants was measured on 1 to 6 occasions each (n=32). The workers were asked to wear a portable pump for two hours. The air was pumped through two tubes in series filled with the absorbent Tenax® and glass wool plugs at both ends. The tubes were wrapped in aluminium foil and samples were analysed by GC-AED. The MMT concentrations, expressed as Mn, vary between 0.3 and 10.8 ng/m^3, with a mean of 3.8 ng/m^3, which is similar to the level of the environmental MMT contamination previously found.

84 ESTIMATING THE PROBABILITY OF SARIN VAPOR TOXICITY IN RATS AS A FUNCTION OF EXPOSURE CONCENTRATION AND DURATION.

R. Mioduszewski, J. Manthei, R. Way, D. Burnett, B. Gaviola, W. Muse, R. Crosier, D. Sommerville and S. Thomson. *U.S. Army ECBC, Aberdeen Proving Ground, MD.*

This study examined the effects of varying exposure concentration and duration on the probability of lethality occurring in rats exposed to Sarin (GB) vapor. Groups of male and female rats (Sprague-Dawley) were exposed to one of a series of GB vapor concentrations for 10, 30 90, or 240 minutes in a whole-body dynamic chamber. Separate concentration – exposure time values for lethality in 50% of the exposed population (LCt50) and corresponding dose-response slopes were determined for each exposure duration by the Bliss probit method. Contrary to that predicted by Haber's rule, LCt50 values increased with exposure duration (i.e., the CT for 50% lethality was not constant over time). Probability of lethality was approximated by a nonlinear function (toxic load model where C^(n)*t=constant). However, this approximation was only valid for a limited range of exposure duration in males as compared to females. Overall, female rats were more sensitive to GB vapor toxicity than male rats over the range of exposure concentration and duration studied. Miosis was the initial clinical sign noted following the start of GB vapor exposure. Pupil constriction was maximal at all concentration-duration combinations studied but progressed to mydriasis over several days before returning to pretreatment pupil diameters. Although blood cholinesterase activity was significantly inhibited by GB vapor exposure, no correlation between cholinesterase inhibition and exposure conditions or cholinesterase inhibition and severity of clinical signs was noted. No histopathological findings in surviving rats could be directly related to GB exposure.

85 LACK OF ADVERSE EFFECTS FROM SUBCHRONIC EXPOSURE OF RATS TO AEROSOLIZED PENTAERYTHRITOL ESTERS.

C. A. Schreiner and W. E. Dalbey. *Mobil Product Stewardship & Toxicology, Paulsboro, NJ.*

Groups of Sprague-Dawley rats (15/sex) were exposed to an aerosol of mixed pentaerythritol esters at concentrations of 0 (untreated controls), 0 (sham-exposed controls), 50, 150, and 500 mg/m^3. Exposures were 6 hr/day, 5 days/wk, for 90 days. The average mass median aerodynamic diameter was 1.0 µm for each concentration and geometric standard deviation was ~1.8. Particles were well within the respirable size range. Exposure did not adversely affect clinical signs, body weight, parameters of serum chemistry or hematology, sperm morphology, or the number of sperm or spermatids. Among the 12 organs weighed during the sacrifice following exposure, the lungs had a minimal increase in weight after exposure to 0.50 mg/L. Histological changes were also minimal; the number of macrophages in the pulmonary alveoli increased slightly. An additional 10 male rats were included in each group for pulmonary function tests and analysis of pulmonary hydroxyproline following exposure. No treatment-related changes were noted in any of the parameters measured in these animals. Overall, the effects of subchronic exposure of rats to an aerosolized of this sample of pentaerythritol esters at concentrations as high as 500 mg/m^3 were minimal.

86 FURTHER CHARACTERIZATION OF A RAT MODEL OF AMIODARONE-INDUCED PULMONARY TOXICITY (AIPT).

M. D. Taylor[1], K. Van Dyke[1], L. Bowman[2], P. R. Miles[2], V. Castranova[2] and M. J. Reasor[1]. [1]*West Virginia University, Morgantown, WV and* [2]*NIOSH/HELD, Morgantown, WV.*

The antiarrhythmic drug amiodarone (AD) is limited in use by its pulmonary toxicity involving inflammation and fibrosis. The goal of this study was to further characterize an animal model of AIPT and to examine the possible mechanisms involved in the progression of toxicity. Male F344 rats were instilled intratracheally with AD (6.25 mg/kg with a 3.125 mg/mL solution) in sterile water or the sterile water vehicle on day 0 and again on day 2, a protocol that leads to the development of pulmonary fibrosis on day 28 in the AD-treated animals. To study the initial events leading to this endpoint, animals were killed on days 3, 5, 6, 7, or 10 and bronchoalveolar lavage (BAL) was performed. Recovery of alveolar macrophages and eosinophils was increased on days 3 and 5, while neutrophil recovery was significantly elevated only on day 3. Potential oxidant production of BAL cells (total cells x PMA-stimulated luminol-dependent chemiluminescence [total counts/10^6 cells/20 min]) was markedly elevated in AD-treated rats on day 3. BAL cells recovered from AD-treated and control rats on day 3 were cultured overnight. Cells from AD-treated rats produced more nitric oxide (NO) breakdown products in the culture media than cells from control animals, indicating an increased cellular production of NO as a result of AD treatment. These findings indicate that this model exhibits a transient pulmonary inflammation soon after the administrations of the drug with the potential for elevated oxidant production in the lungs. Therefore, oxidant mechanisms may be involved in the development of AIPT in this model. (Supported by NIH 5 T32 GM07039.)

87 FIVE-DAY INHALATION EXPOSURE TO STYRENE HAS TOXIC AND PROLIFERATIVE EFFECTS IN THE LOWER RESPIRATORY TRACT OF THE SPRAGUE-DAWLEY RAT.

M. T. Sidel and R. A. Schatz. *Northeastern University, Boston, MA.*

Styrene exposure occurs primarily by inhalation and is associated with respiratory toxicity, which is attributed to the toxic metabolite, styrene oxide. Our lab has previously shown that a single (6 h) inhalation exposure to 50 ppm (TLV) styrene altered enzyme activities in the respiratory tissues to influence the formation and removal of styrene oxide. The nasal mucosa had a higher concentration of styrene oxide than the lung accompanied by an increase in toxicity and proliferation, not present in the lung. We examined whether inhalation exposure to 50 ppm styrene for five days influenced its own metabolism to the toxic metabolite, styrene oxide, and whether this resulted in tissue specific toxicity in the respiratory tissues. Styrene oxide is formed by the cytochrome P450 monooxygenase system and is then hydrolyzed or conjugated to less toxic metabolites by microsomal epoxide hydrolase (EH) and glutathione transferase (GST), respectively. In the respiratory tissues, there was a general decrease in P450 activity following styrene exposure while in the nasal mucosa GST activity was increased, but was decreased in the lung. There was no change in the activity of microsomal epoxide hydrolase in either tissue. Although styrene inhalation resulted in an inhibition of P450 activity in both tissues, the concentration of free styrene oxide in the nasal mucosa was 108 +/- 3 ng/g tissue, while in the lung, the concentration of styrene oxide was below the limit of detection (10 ng/g tissue). The activities of marker enzymes and the level of protein were measured in the bronchoalveolar (BALF) and nasal (NLF) lavage fluid. Proliferating cell nuclear antigen (PCNA) was determined following styrene exposure to measure proliferation. The concentration of the toxic metabolite, styrene oxide, was higher in the nasal mucosa than the lung after the five day exposure. However, there was no evidence of toxicity or proliferation in the nasal mucosa. In BALF, the activities of gamma-glutamyltranspeptidase (GGT), lactate dehydrogenase (LDH), acid phosphatase (ACP) and the level of protein as well as the level of PCNA in the lung were significantly increased following the five day exposure. The lung appears to be more sensitive to a five day inhalation exposure to styrene than the nasal mucosa. The free styrene oxide levels do not correlate with respiratory toxicity suggesting that styrene oxide may be bound to cellular macromolecules in the lung and not be detectable. Another explanation is that early production of styrene oxide during the five day exposure results in delayed pulmonary toxicity that is not evident until after the five day exposure. Cellular damage and proliferation occur in the lower respiratory tract after five days of exposure to levels of styrene equivalent to that experienced by occupational workers perhaps leading to potential respiratory problems.

88 CORRELATION OF *IN VITRO* AND *IN VIVO* PULMONARY RESPONSES TO DIFFERENT CELLULOSE MATERIALS.

J. M. Gearhart, L. E. Benton, J. M. Carter, G. M. Adamson and S. Y. Zhou. *The Procter & Gamble Company, Cincinnati, OH.*

In vitro studies were conducted with bleached cellulose pulp (BC), microcrystalline cellulose (MC) and cellulose insulation derived from recycled newsprint (CI). The *in vitro* responses were then compared to markers of pulmonary response for the same three materials after intratracheal instillation in rats. Immortalized rat alveolar type II epithelial cells (RLE-6TN) and alveolar macrophages (NR8383) were dosed with varying concentrations and for different periods of time, to create dose-response and time-response curves for the end points of LDH, pro-inflammatory and anti-inflammatory cytokines. TiO2, SiO2 and asbestos, were also studied in these two *in vitro* systems to provide comparisons with responses seen with nuisance and fibrogenic particulate materials. The *in vivo* studies in rats ranked the overall toxicity of these three cellulose materials as CI>MC>BC, as determined by analysis of biochemical markers, differential cell count and histopathology. Bronchial alveolar lavage samples (BAL) were analyzed for LDH, lysosomal acid hydrolases, alkaline phosphatase, total protein, and cell differentials at 3, 7, 14, and 28 days after dosing. The measures of response for the three dif-

7, 14, and 28 days after dosing. The measures of response for the three different cellulose materials as determined in the *in vitro* systems provided an accurate representation of the responses determined *in vivo*, with the strongest association between lung enzyme responses and proinflamatory cytokines. Conversion of *in vitro* doses of the three cellulose materials to that used in the *in vivo* studies, based on μg/m3, indicated the degree of response in the different measured parameters as being of similar magnitude at approximately the same *in vitro* versus *in vivo* doses. With further exploration of these *in vitro* techniques, the mechanisms of response for some materials depositing in the lung may be determined, as well as providing tools for the better design of *in vivo* pulmonary experiments.

89 XENOBIOTIC-METABOLIZING ENZYME ACTIVITIES IN PRIMARY CULTURES OF RAT TYPE II PNEUMOCYTES AND ALVEOLAR MACROPHAGES.

S. Dimova[1], P. H. M. Hoet[2], M. G. Demedts[2] and B. Nemery[2]. [1]*Institute of Physiology, Bulgarian Academy of Sciences, Sofia, Bulgaria and* [2]*Laboratorium voor Pneumologie, Longtoxicologie, K.U.Leuven, Leuven, Belgium.*

Because of the evidence for an involvement of xenobiotic bioactivation in pulmonary toxicity and carcinogenesis, it is important to improve our understanding of the xenobiotic-metabolizing enzymes in isolated and cultured specific pulmonary cell populations. Phase I and phase II xenobiotic-metabolizing enzyme activities and intracellular reduced glutathione (GSH) level were studied in primary cultures of rat type II pneumocytes (TII) and alveolar macrophages (AM). 7-Ethoxyresorufin (EROD), 7-pentoxyresorufin (PROD) and 7-benzyloxyresorufin (BROD) O-dealkylation, NADPH and NADH cytochrome c reductase, glutathione S-transferase (GST) and NAD(P)H:quinone oxidoreductase (QR) activities were assessed in sonicated cells, before plating (100% activity) and 24h and 48h after plating in TII, and 3h after plating in AM. In TII EROD activity was not detected at the protein concentrations used (0.2-0.5 mg cell protein per sample). In TII BROD and PROD activities decreased at 24h by 84% and 82%, respectively, and to lower levels at 48h. The activity of NADPH cytochrome c reductase, was stable but NADH cytochrome c reductase activity decreased at 24h (by 53%) and 48h (by 67%). The activity of GST decreased by 28% and 42% at 24h and 48h, respectively. GSH content increased with time in culture and at 48h was elevated by 130%. QR activity increased at 24h (by 55%), and then decreased to approximately the initial level at 48h. In freshly isolated AM, BROD activity was the only cytochrome P450-dependent alkoxyresorufin-O-dealkylase activity measured and it was 23 times lower than in freshly isolated TII. BROD activity decreased by 50% in attached AM. NADPH and NADH cytochrome c reductase activities decreased in the attached AM by 26% and 39%, respectively. No significant changes in GST and QR activities and GSH content were observed in attached AM. In conclusion, in conventional cultures of TII and AM, many of the metabolic capabilities of the cells were rapidly lost with time. Phase II-related enzyme activities were better kept than those of phase I.

90 THE EFFECTS OF AIRWAY CONSTRICTION ON AIRFLOW THROUGH THE UPPER HUMAN LUNG: A FLUID DYNAMICS MODEL.

P. F. Moyer[1] and M. J. Tobin[2]. [1]*ChemADVISOR, Inc., Pittsburgh, PA and* [2]*University of Pittsburgh, Pittsburgh, PA.*

A fluid dynamic model was designed to examine whether a constricted region of the upper human respiratory tract (simulating an insult to the airways) will significantly alter airflow in subsequent airway branches, that in turn may have physiologic relevance and public health importance. We constructed two-dimensional representations of the upper human respiratory system (generations 2-7) to model normal and constricted airways. Finite element fluid dynamic simulations of inspiratory air flow were calculated for both airway models, and the resultant flow solutions were analyzed using visualization software. The unobstructed airway model simulation predicted minimal airflow decrease through the primary path, with more notable decreases in the periphery. However, for the constricted airway simulation, there was a dramatic decrease in airflow for both the main pathway beyond the restriction site and the peripheral passages. These results suggest that areas of localized edema or bronchial constriction (where the passage narrows significantly) would cause a dramatic decrease in downstream airflow. This reduction of airflow could further compromise pulmonary function, and also alter the deposition pattern of particulate matter in the lung.

91 EFFECTS OF EXPIRED CARBON DIOXIDE ON VENTILATION AND AEROSOL DEPOSITION IN GUINEA PIGS UNDERGOING BAROMETRIC PLETHYSMOGRAPHY.

E. C. Kimmel, G. S. Whitehead and R. L. Carpenter. *NHRC/TD, Wright-Patterson AFB, OH.*

Barometric plethysmography is frequently used to evaluate changes in ventilation and breath structure in unrestrained (physically and chemically) animals in effort to determine the effect of inhaled pharmaceuticals or toxins on the airways. Discontinuous aerosol generation and delivery to the plethysmograph may require operation of the plethysmograph without a bias flow which is normally intended to refresh the plethysmograph air supply and remove expired CO_2. Continuation of the bias flow would artificially deplete aerosol concentration. However operation without bias flow results in CO_2 build up and subsequent stimulation of ventilation. Measurements of ventilation (f=breathing frequency, TV=tidal volume, and Ve=minute volume) and the flow-derived parameter Penh (enhanced pause) were performed on 11 guinea pigs using a commercially available 4.5 L (Buxco, Electronics) plethysmograph operating with and without a 900 mL/min bias flow. During these measurements a low flow (5 mL/min) microcapnometer was used to measure, continuously, CO_2 concentration in the plethysmograph. Without the bias flow CO_2 concentration in the plethysmograph increased steadily to an average 5.4% after 30 min, compared to 0.9% with bias flow. The buildup of CO_2 above 2% resulted in a moderate suppression of f, however TV, Ve, and Penh increased to 1.5, 1.4, and 1.7 of their baseline values, respectively. Theoretical changes in aerosol deposition in the extrathoracic, tracheobronchial, and pulmonary regions of the lung attributable to CO_2 induced elevation of TV were calculated for 300 mg/m3 concentration aerosols with MMAD's of 0.3, 1, 3, or 7 μm and sigma g's of 1.7.

92 SELENIUM-TREATED LUNG: VIBRATOME SECTIONING FACILITATION BY GELATIN INFILTRATION.

V. K. Nonavinakere[1], R. R. Bell[2], C. Brady, A. Yallapragada, N. Sheth and J. L. Early[1]. [1]*Medical University of S. C., Charleston, SC and* [2]*Searle, Skokie, IL.*

The lungs of guinea pigs (n=5) treated intratracheally (ITr) with selenium (Se) as selenomethionine (SEM) (0.06 mg Se/100g body weight) or saline were perfused with phosphate buffered saline via the right ventricle of the heart and fixed with ITr infusion of 10% buffered formalin. The formalin-fixed lungs were washed overnight with running water and infiltrated with gelatin (Gurusingie and Ehrlich, 1986). It was observed that infiltration of the lung lobe with 5% followed by 12% gelatin for three days each (6-8 hours per day) at 37°C was sufficient for easy sectioning using the Vibratome set at a speed of 8.5-9.and an amplitude of ≈10 with a blade angle, ≤25 degrees. Saline treated lung was sectioned in its collapsed state. The sections (30-40 microns) were stained with hematoxylin and eosin. Evaluation of stained sections revealed histological clarity. Light microscopic images of sections of Se-treated lungs showed cellular infiltration in the interalveolar septal area. Revisitation of the procedure corroborated that Vibratome is a useful tool to section tissues such as the lung in its inflated or collapsed state. (This was supported by the University research funds # 23030-CR10; NIH and SC Summer Undergraduate Research Programs.)

93 BIOCHEMICAL AND RESPIRATORY CHANGES CAUSED BY BRIEF EXPOSURE TO HIGH CONCENTRATION OF CARBON MONOXIDE AND CARBON DIOXIDE IN AWAKE RATS.

Z. Gu[1], A. Januszkiewicz[2], C. D. McKinley[2], M. A. Mayorga[2], L. M. Stuhmiller[1] and J. H. Stuhmiller[1]. [1]*JAYCOR, San Diego, CA and* [2]*Walter Reed Army Institute of Research, Washington, DC.* Sponsor: N. M. Elsayed.

Carbon monoxide (CO) inhalation can cause mental disorders, physical decrements and even death. Carbon dioxide (CO_2) is a respiratory stimulant. High concentrations of these combustion gases are of concern in military operations. This study addressed respiratory changes resulting from brief (5 min) exposures to high concentrations of CO and CO_2 (0-12000 ppm CO; 0-10% CO_2), alone or in combination, in awake male Sprague-Dawley rats (250-450g). Respiratory measurements were made using partial body flow plethysmographs attached to a static exposure chamber. Minute ventilation volume was found to increase approximately 1.5 times in rats exposed to 500, 1000, 3000, and 6000 ppm CO when also exposed to 5% CO_2, compared to corresponding CO-alone values for minute volume. At end-exposure, mean carboxy- hemoglobin (COHb) values were approximately 7.5, 14.5, 29.7, 57.2 and 63.0% in the 500, 1000, 3000, 6000, and 12000 ppm CO groups, respec-

tively. Post exposure COHb values increased to 10.8, 20.4, 47.3, 61.8 and 68.2% for these groups, respectively, when rats were coincidentally exposed to 5% CO_2. Blood chemistry returned to normal within 4h. No lethality was observed, up to 24h after exposure, likely attributed to the short exposure period. These results clearly demonstrate significant enhancement of CO poisoning by CO_2, an important toxicologic interaction between these two primary combustion gases. (Supported, in part, by DOT&E, Department of Defense, Washington, DC.)

94 INTRATRACHEAL ADMINISTRATION OF A RECOMBINANT SP-C LUNG SURFACTANT PREPARATION TO CYNOMOLGUS MONKEYS: A COMPARISON OF DIFFERENT TECHNIQUES.

B. Niggemann[1], J. Kemkowski[2], P. Nowak[2] and W. Mueller[1]. [1]*Covance Laboratories GmbH, Muenster, Germany and* [2]*Byk Gulden Institute of Pathology and Toxicology, Hamburg, Germany.* Sponsor: J. C. Norris.

The technique and procedure for the intratracheal administration of a rSP-C lung surfactant (Venticute®) preparation into the lung is a methodical challenge due to the requirements which have to be fulfilled: a) minimal animal burden, b) minimal influence of the administration technique and procedure on respiratory function, c) up to 4 administrations per day should be possible under comparable conditions, d) minimal artificial effects on the morphology of the respiratory tract. In order to comply with the above outlined requirements, two different administration techniques were established in a primate model: (1) administration via a pediatric bronchoscope and (2) administration via a surgically implanted intratracheal catheter. Both methods were used in 22 - 24 cynomolgus monkeys (Macaca fascicularis) weighing between 2.5 and 3 kg. For the administration via a bronchoscope, the monkeys were slightly sedated and additionally a local anesthesia was applied to the laryngeal region. For the administration via a surgically implanted catheter a specially constructed polyurethane tracheotomy spiral catheter was utilized. The implantation was performed 2-3 days before the first administration, the administration itself was done without prior sedation of the animals. The recombinant surfactant preparation was well tolerated. There were no serious complications by using both techniques up to 4 times a day. By comparing the behavior and appearance of the animals during and up to 30 minutes after the administration, it was evident that the procedure using a surgically implanted catheter offers substantial advantages over the alternative method of bronchoscopical application: i.e., minor bronchial irritation; undamaged tracheal mucous membranes; repeated anesthesia becomes unnecessary and the administration of a substance may be timed exactly eventually achieving continuous application.

95 INTRATRACHEAL ADMINISTRATION OF SYNTHETIC ZEOLITES AND ALUMINAS IN RATS.

W. E. Dalbey and C. Pulkowski. *Mobil Product Stewardship and Toxicology, Paulsboro, NJ.*

An intratracheal (IT) screening assay was performed on a series of synthetic aluminosilicate zeolites and alumina binders to compare their relative ability to cause pulmonary fibrosis (scarring) and related changes. Groups of 12 male rats were evaluated 6 months after instillation of 50 mg for lung volumes, pulmonary pressure-volume curves, pulmonary hydroxyproline (OHPro), lung weights, and histopathology. Negative controls were saline and glass beads; positive control was quartz. The test materials were organic-free ZSM-5 crystals, organic form of ZSM-5 crystals, alumina-bound ZSM-5, nickel/ZSM-5/Al_2O_3 binder, used nickel/ZSM-5/Al_2O_3 binder, nickel-tungsten/ZSM-5/Al_2O_3 binder, and Bayer pseudoboehmite. Particles were ground until at least 95% were less than 2.4 μm. Altered body weights or clinical signs were observed with nickel-tungsten/ZSM-5/Al_2O_3 binder, quartz, and alumina. At 6 months after dosing, quartz produced increased lung weight (wet and dry), increased pulmonary hydroxyproline, decreased lung volumes (total lung capacity and vital capacity), and microscopically observable granulomas with fibrosis. The severity of the pulmonary reactions was compared among the test materials. Based on these results, the effects of 4 aluminas (Bayer pseudoboehmite, Bayer γ-Al_2O_3, Ziegler pseudoboehmite, and Ziegler γ-Al_2O_3) were compared in additional groups. The IT assay proved to be a very useful tool for ranking the relative effects of this series of zeolites and aluminas.

96 APPLICATION OF STEPWISE DISCRIMINANT ANALYSIS PROCEDURE FOR THE EVALUATION OF TREATMENTS AGAINST PHOSGENE EXPOSURE IN ANESTHETIZED, VENTILATED, WEANLING SWINE.

N. A. Niemuth[1], F. M. Reid[1], C. M. Matthews[1], J. Nagaraja[1], A. M. Sciuto[2] and R. R. Stotts[2]. [1]*Medical Research and Evaluation Facility, Battelle, Columbus, OH and* [2]*United States Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

Phosgene (CG), a choking agent used during World War I, presents an industrial hazard today. CG induces pulmonary edema after an asymptomatic period of up to 24 hr. A 72 hr anesthetized, ventilated, weanling swine model was developed to assess the efficacy of treatments for respiratory casualties using blood gas, clinical chemistry, hematology, and respiratory parameters. Thirty-one pigs (sus scrofus) were anesthetized with isoflurane for surgical implantation of catheters into a femoral artery and vein. Following catheterization, anesthesia was maintained by slow infusion (~3 mL/hr) of pentobarbital sodium (65 mg/mL) and the animal was placed on a ventilator (Positive End Expiratory Pressure (PEEP) of 3-5 cm H2O; 30% O2). Animals were exposed to approximately 450 mg CG/m3 for 10 min, or 10 min of air. Three treatments were evaluated: 1) 2 ml of a 200 mg N-acetylcystiene (NAC)/ml solution administered intratracheally 30 min post-exposure and every 4 hr thereafter for 16 hr; 2) a loading dose of 45 mg ibuprofen (IBU)/kg administered intravenously 30 min post-exposure, followed by 22.5 mg IBU/kg every two hr for 24 hr; 3) O2 was increased to 45% immediately after exposure, along with incremental increases of 2-3 cm H2O PEEP every 30 min until the targeted level of 15 cm H2O PEEP was reached and maintained until end of study. A stepwise discriminant analysis procedure was used to select blood gas, clinical chemistry, and hematology parameters that explained the greatest variability between exposure/treatment groups and were also physiologically plausible. Parameters such as oxygen saturation, potassium, and blood urea nitrogen levels were identified as explanatory variables in the discriminant analysis. These parameters were consistent with respiratory damage and hyperkalemia associated with CG-exposure and possible renal effects associated with high IBU doses. (Supported by DAMD 17-89-C-9050.)

97 90 DAY INHALATION STUDY OF STAINLESS STEEL WELDING FUME IN SPRAGUE-DAWLEY RATS.

I. J. Yu[1], H. K. Chang[2], J. D. Park[3], K. H. Chung[4], J. S. Han[4], K. T. Han[4], K. S. Song[1], K. J. Kim[1] and H. K. Chung[1]. [1]*Industrial Safety and Health Research Institute, Taejon, Republic of Korea,* [2]*Kosin University, Taejon, Republic of Korea,* [3]*Chung-Ang University, Seoul, Republic of Korea and* [4]*Sung Kyun Kwan University, Suwon, Republic of Korea.*

In order to investigate welding fume exposure related occupational diseases such as nasal septum perforation, pneumoconiosis and manganese intoxication, welding fume exposure system including welding fume generator, exposure chamber and fume collector were built. Then the welding fume exposure system was monitored and validated. After an acute inhalation toxicity study, welding fume generated from stainless steel arc welding was exposed to male Sprague Dawley rats. The rats were exposed to the welding fume with approximately 70-80 mg/m^3 for 2 hrs in an inhalation chamber for 90 days. Animals were sacrificed at 0, 14, 30, 60 and 90 days after initial exposure. Upper respiratory tract including the nasal pathway, the conducting airway, and the gas exchange region including the +alveolar ducts, alveolar sacs and alveoli were investigated through histopathological examinations. The organ distribution of major metals in the welding fume including Mn, Cr, Fe, and Ni was measured in the blood, liver, testis, brain, kidneys, and lungs. The fume particles had various in their diameters ranging from 0.02-0.81μm and were distributed log normally with average diameter and geometric mean of 0.1±1.42. The average diameter 0.1μm resulted in fewer adsorption of the welding fume particles in the upper respiratory tract. The major sites for particle adsorption and deposition were the lower respiratory tracts including the bronchioles, alveolar ducts, alveolar sacs, and alveoli. No significant Mn increase was observed in the various organs during 90day exposure of welding fume. We could not find any significant welding fume exposure related pathological legion in the nasal region. The lower respiratory region, however, showed gradual mobilization and destruction of macrophages and marked interstitial infiltration of macrophages, and many granulomatous legions in interstitium and pluera. The histopathological examination of welding fume exposed lung suggests that the repeated exposure of welding fume may lead into progressive fibrotic changes.

98 GENERATION, SAMPLING AND ANALYSIS OF GB VAPOR FOR INHALATION TOXICOLOGY STUDIES.

W. T. Muse[1], L. C. Buettner[1], R. Mioduszewski[1], S. A. Thomson[1], C. L. Crouse[2] and L. C. Crouse[2]. [1]*U.S. Army, ECBC, Aberdeen Proving Ground, MD and* [2]*Geo-Centers, Inc., Newton Centre, MA.*

Generation, sampling and analytical techniques were developed to support inhalation studies on the lethal effects (LCt50) of varying exposure concentration and duration of sarine(GB)vapor in rats. This study tested and optimized various methodologies to generate, sample and characterize GB test atmospheres in an inhalation chamber. A syringe drive spray atomization system was used for GB vapor generation. Continuous chamber monitoring was accomplished using a phosphorus analyzer. Sampling methods included the traditional solvent bubbler technique as well as the development of an automated solid sorbent sampling system. All samples were quantitatively analyzed by gas chromatography for GB vapor. Concentrations derived from each sampling method were compared against each other and statistically evaluated. Results showed good correlation between the two methods (t-test >95%). In addition, stable GB test atmospheres (0.1–30 mg/m3) were generated over different exposure duration's (10, 30, 90, 240 min) with rapid monitoring capability. Future applications include the ability to generate and monitor GB levels approaching the TWA-TLV of 0.0001 mg/m3.

99 BENZENE EXPOSURE ASSESSMENT FOR USE OF A PETROLEUM NAPHTHA METAL PARTS CLEANER.

B. Kerger[1] and M. J. Fedoruk[2]. [1]*HSRI, Tallahasse, FL and* [2]*University of California, Irvine, CA.*

The OSHA Hazard Communication Standard requires that a product's Material Safety Data Sheet identify all carcinogenic agents whose concentrations are at least 0.1% (or 1,000 ppm). This study assesses benzene exposures associated with the operation of a small metal parts cleaner using virgin recycled petroleum naphtha solvents containing 9 and 58 ppm benzene. Benzene air concentrations (personal, area, and grab) were measured using NIOSH 1501 and USEPA TO-14 methods during one hour periods of vigorous parts cleaning. Airborne benzene concentrations associated with the 9 ppm solvent were ≤ 33 ppb in the worker breathing zone and above the parts cleaning tank. Peak concentrations adjacent to the metal parts during cleaning averaged 140 ppb. Area samples taken around the tank were less than 5 ppb. Cleaning with the 58 ppm benzene spiked solvent produced an average operator breathing zone concentration of 440 ppb. Peak concentrations measured adjacent to the metal parts cleaner averaged 490 ppb. Average concentrations around the tank were 63 ppb. These data indicate that operator exposures associated with aggressive parts washing using a naphtha solvent containing benzene at concentrations less than 58 ppm are associated with low level benzene exposures. Performing parts cleaning for long periods or use of naphtha solvents with higher benzene concentrations but still below the 0.1% criteria are likely associated with exposures that approach current workplace exposure limits.

100 SEASONAL CHANGE IN MITE NUMBERS AND INDOOR ALLERGEN CONTENT IN A FINNISH OFFICE ENVIRONMENT.

A. T. K. Harju[1], S. M. A. Pennanen[1], R. Merikoski[1] and J. Liesivuori[2]. [1]*Kuopio Regional Institute of Occupational Health, Kuopio, Finland and* [2]*University of Kuopio, Kuopio, Finland.* Sponsor: K. Heiskanen.

Allergy prevalence has been increasing over the last decades. House dust mites (HDM) together with cat and dog allergens have been considered very important indoor factors causing symptoms for affected individuals. The role of workplace as an exposure source has thus far been a minor consideration. This study was done in an office building. Desk chair and occasional floor samples were taken with a sampler connected to a vacuum cleaner. Mite samples were collected in May, August, November, and February, and the mites were identified microscopically. Indoor allergen samples (Der p 1, Fel d 1 and Can f 1) were collected in November and analyzed by two-site ELISA methods. Fourteen workers were tested with prick test for cat, dog, and mite (*Dermatophagoides pteronyssinus*, *D. farinae*, *Tyrophagus putrescentiae*, *Acarus siro* and *Lepidoglyphus destructor*) allergy. Out of 32 samples so far analyzed (May and August), 19 contained mites. Only one sample contained more than 100 mites/g dust. Majority of the mites were other than HDM, including Tarsonemus sp. and Mesostigmatids. No seasonal difference was obvious so far. Mite allergens were found only in two chairs out of the 14 studied and the concentrations were low (mean 0.009 μg/g). Cat and dog allergens, on the other hand, were found in every chair and in similar amounts (Can f 1 3.0-185.9 μg/g, geometric mean 24 μg/g, and Fel d 1 0.8-171.8 μg/g, geometric mean 22.7 μg/g). The allergen levels were relatively low compared to studies done at homes, but still in 50% of the samples allergen levels exceeded the proposed threshold levels for cat or dog sensitization. Six (43%) of the workers were prick positive to either cat (n=3, 21%), dog (n=4, 29%) and/or storage mites (n=3, 21%). No correlation between reported symptoms and positive skin reactions was found.

101 ASSESSMENT OF EPH A5 KNOCKOUT MICE FOLLOWING COCAINE ADMINISTRATION.

L. Michna[1], N. W. Gale[2], B. Liao[3], S. Chen[4], J. Lee[4], J. Rogove[4], G. D. Yancopoulus[2], R. Zhou[3] and G. Wagner[4]. [1]*Joint Graduate Program in Toxicology, Rutgers University/UMDNJ, Piscataway, NJ,* [2]*Regeneron Pharmaceuticals, Inc., Tarrytown, NY,* [3]*Rutgers University, Chemical Biology, Piscataway, NJ and* [4]*Rutgers University, Psychology, Piscataway, NJ.* Sponsor: K. R. Reuhl.

Eph A5 belongs to the Eph family of receptor tyrosine kinases. Eph receptors and their corresponding family of ligands, the ephrins, have been implicated in the guidance of axons and formation of topographic projection maps. Eph A5 receptor is most prominently expressed in the hippocampus and is critical during development. As Eph receptors appear to have distinct but overlapping patterns of expression, they possess unique, yet redundant functions. Previous studies in our labs using in situ hybridization have shown that ephrin-B2 ligand is up-regulated following cocaine, which suggests that the ligand may also play a role in drug-induced plasticity. To examine the behavioral toxicity of cocaine, Eph A5 knockout mice were evaluated in the place preference conditioning (PPC) and locomotor activity tests following cocaine 0.1-10 mg/kg (i.p.). To assess learning, the water maze was conducted without drug. Relative to controls, knockout mice were more sensitive to cocaine in the PPC test and exhibited less motor activity following saline or cocaine. Results from the water maze revealed no significant differences in acquisition ability, but retention time was increased for knockouts after two months. Neurochemical analysis revealed that compared to wild type, knockout mice had higher levels of dopamine and dihydroxyphenylacetic acid (DOPAC) in the striatum, yet this effect was reversed in the nucleus accumbens. In the hippocampus, there were no differences in monoamine concentrations. Knockout mice had slightly higher levels of dopamine, DOPAC, and homovanillic acid in the frontal cortex. These results indicate that Eph A5 receptor may play a role in plasticity involved in neural and behavioral toxicity.

102 VITAMIN E DEFICIENCY INCREASES SUSCEPTIBILITY OF THE BALB/C MOUSE TO MDMA-INDUCED DOPAMINERGIC NEUROTOXICITY.

E. A. Johnson[1], A. A. Shvedova[2], E. Kisin[2], J. P. O'Callaghan[1], C. Kommineni[2] and D. B. Miller[1]. [1]*Toxicology and Molecular Biology Branch, CDC-NIOSH and* [2]*Physiology and Pathology Research Branch, Health Effects Laboratory Division, CDC-NIOSH, Morgantown, WV.*

The mechanism of 3,4-methylenedioxymethamphetamine (MDMA)-induced neurotoxicity has been hypothesized to involve the formation of toxic free radical species. Since Vitamin E is a potent radical scavenger, we tested whether Vitamin E deficiency affects susceptibility to MDMA-induced dopaminergic neurotoxicity. Male BALB/c mice (3-4 weeks old) were kept on control (Vit. E, 50 IU/kg) and Vitamin E deficient (<10 IU/kg) diets for twenty weeks. Vitamin E levels in brain of deficient mice were reduced 75% compared to controls. Vitamin E deficient and control mice were randomly assigned to the following groups: saline 200 ul, (every 2 hrs X 4, s.c), or MDMA 5 mg/kg, (every 2 hrs X 4, s.c.) or 10 mg/kg (every 2 hrs X 4, s.c.). Rectal temperatures were assessed every 2 hours during the dose period. Vitamin E deficient animals exhibited MDMA-induced temperature modulation that was similar to control animals. Seventy-two hours following the first dose, animals were sacrificed and brains were dissected for determination of Vitamin E, glutathione, total antioxidant reserve, protein thiols, dopamine, DOPAC, HVA, and Glial Fibrillary Acidic Protein (GFAP), and livers were analyzed by histopathology. Animals given the Vitamin E deficient diet exhibited neurotoxic responses at the lowest dose of MDMA, while mice on the control diet were undamaged. Striatal dopamine was reduced by 47%, DOPAC by 44%, and HVA by 29%, while GFAP was elevated 3 fold. Neurotoxic responses were also observed at 72 hrs at the higher dose of MDMA, in both diet groups. In the Vitamin E deficient mice MDMA caused greater hepatic necrosis compared with controls. These data indicate that Vitamin E deficiency increases susceptibility to MDMA-induced neurotoxicity and hepatic necrosis and provide support for a free-radical mediated mechanism of toxicity.

103 NEUROPROTECTIVE ROLE OF SELENIUM IN METHAMPHETAMINE-INDUCED PEROXYNITRITE GENERATION AND DOPAMINERGIC NEUROTOXICITY.

S. Z. Imam[1], G. D. Newport[1], F. Islam[2], W. Slikker, Jr.[1] and S. F. Ali[1]. [1]*National Center for Toxicological Research/FDA, Jefferson, AR and* [2]*Department of Toxicology, Hamdard University, New Delhi, India.*

Methamphetamine (METH) has been known to produce neurotoxicity via generation of reactive oxygen and nitrogen species. In the present study, neuroprotective role of selenium (Se) in METH-induced dopaminergic neurotoxicity was evaluated using *in vitro* as well as *in vivo* system. For *in vitro* studies, PC12 cell cultures were exposed to 200 μM METH with or without 10 and 20 μM Se. METH exposure resulted in significant depletion of dopamine, and its metabolites DOPAC and HVA and significant formation of 3-nitrotyrosine (3-NT) in PC12 cell cultures. For *in vivo* studies, adult male C57BL/6N mice were supplemented with 0.5 mg Se/kg in the form of sodium selenite (Na_2SeO_3) in drinking water for one week. Animals received 4x10 mg/kg METH, i.p. at 2 hr. interval after one week of Se administration. Se supplementation continued for one more week before animals were humanely killed for the neurochemical analysis. Multiple injections of METH produced significant formation of 3-NT and depletion of dopamine and its metabolites in the caudate nucleus. Selenium supplementation attenuated the depletion of dopamine and its metabolites, DOPAC and HVA and the formation of 3-NT in PC12 cells as well as in mice caudate nucleus. These data suggest that METH-induced dopaminergic neurotoxicity is mediated by the production of peroxynitrite, and selenium plays a protective role in METH-induced neurotoxicity.

104 EFFECT OF *D*-AMPHETAMINE ON EXTRACELLULAR GLUTAMATE AND ASPARTATE LEVELS IN RAT AMYGDALOID MICRODIALYSATE.

J. Tor-Agbidye[1], B. K. Yamamoto[2] and J. F. Bowyer[1]. [1]*National Center for Toxicological Research/FDA, Jefferson, AR and* [2]*Case Western Reserve University School of Medicine, Cleveland, OH.*

Amphetamine related compounds are used in the treatment of attention deficit hyperactivity disorder, weight control/obesity and narcolepsy. In humans, it is known that seizures, as well as hyperthermia, result from overdose/poisoning from amphetamines and related compounds, and these seizures may contribute substantially to the lethality of amphetamines. Increased levels of extracellular glutamate are known to induce excessive neuronal stimulation, seizures and neuronal death. However, little is known about the effects of doses of d-amphetamine, ranging from those that produce stereotypic behaviors to those that induce seizures, on extracellular levels of glutamate in the amygdala. The goal of this study is to determine via brain microdialysis if extracellular glutamate levels are elevated in the amygdala after exposure to amphetamines. Male Sprague-Dawley rats (4 months old) were used. Extracellular brain levels of glutamate were determined after multiple doses (x3) 5.0mg/kg (elicits stereotypic behavior without seizures) or 15.0mg/kg (produce seizures) of d-amphetamine have been administered at 2 hr interval. Controls received ip injections of physiological saline. Glutamate concentration in the microdialysate averaged 1.84±1.1 μM prior to saline (basal level) and were 70% basal levels 2 hours after the 3rd saline dose. Glutamate levels were at about 90% of basal levels after the 3rd dose of 5.0mg/kg d-amphetamine. Robust increases in glutamate levels were also not observed after the 3rd dose in animals that received 15.0mg/kg d-amphetamine. In retrospect, glutamate increases in the amygdala were not as robust as those previously reported in the striatum. Extracellular amphetamine after the 3rd dose increased from 9 μM to over 40 μM in animals treated with 5 mg/kg and 15 mg/kg d-amphetamine, respectively. (Supported by NCTR/FDA and Intra Agency Agreement.)

105 INHIBITION OF γ-GLUTAMYLTRANSPEPTIDASE AT THE BLOOD-BRAIN BARRIER POTENTIATES METHYLENEDIOXYAMPHETAMINE NEUROTOXICITY.

F. Bai, S. S. Lau and T. J. Monks. *University of Texas at Austin, Austin, TX.*

Systemic metabolites play an important role in methylenedioxy-amphetamine (MDA) neurotoxicity, although the nature of the neurotoxic metabolite(s) remains unclear. We have shown that 5-(glutathion-*S*-yl)-α-methyldopamine (5-GSyl-α-MeDA), an *in vivo* metabolite of MDA, is a serotonergic neurotoxicant. Brain uptake of 5-GSyl-α-MeDA is decreased by glutathione (GSH) coadministration, but sharply increased by pretreatment with a γ-glutamyltranspeptidase (γ-GT) inhibitor [acivicin (AT-125)], suggesting competition of intact 5-GSyl-α-MeDA with GSH for the putative blood-brain barrier (BBB) GSH transporter. γ-GT is enriched in BBB endothelial cells. Inhibition of endothelial γ-GT may enhance the uptake of 5-GSyl-α-MeDA into brain by increasing the pool of 5-GSyl-α-MeDA available for the putative GSH transporter, thereby potentiating neurotoxicity. We now show that pretreatment of male Sprague-Dawley rats with AT-125 (18 mg/kg, ip) produces a 60% inhibition of γ-GT activity in rat brain microvessel endothelial cells. AT-125 pretreatment potentiates MDA-mediated depletions of serotonin (5-HT) and 5-hydroxyindole acetic acid (5-HIAA). Thus MDA (10 mg/kg, sc) decreases 5-HT in the cortex, hippocampus, striatum, and hypothalamus by 15%, 13%, 11%, and 29% of control values respectively. Following AT-125 treatment, MDA (10 mg/kg, sc) significantly decreases 5-HT concentrations to 60%, 56%, 73%, and 54% of control levels in cortex, hippocampus, striatum, and hypothalamus respectively. 5-HIAA levels in the forebrain are also decreased from 80-93% to 61-77% of control levels. In addition, glial fibrillary acidic protein (GFAP) is induced 1.6 fold in the striatum of AT-125 and MDA treated rats, but not in rats treated with MDA alone. The results indicate that 5-GSyl-α-MeDA, and perhaps other thioether conjugates of α-methyldopamine, play an important role in MDA-mediated serotonergic neurotoxicity. (DA 10832, ES 07784.)

106 PERIPHERAL BENZODIAZEPINE RECEPTORS ARE TRANSIENTLY INCREASED AFTER METHAMPHETAMINE ADMINISTRATION.

A. S. Howard, B. Cord, G. A. Ricaurte and T. R. Guilarte. *Johns Hopkins University, Baltimore, MD.*

The peripheral benzodiazepine receptor (PBR) has been demonstrated to be a sensitive marker of neurotoxicity and has been characterized in brain injury induced by neurotoxicants producing different types of cellular damage (Guilarte *et al.* NeuroToxicol. 16: 441, 1995; Kuhlmann and Guilarte Brain Res. 751: 281, 1997; Toxicol. Sci. 48: 107, 1999). Neurotoxicant-induced increases in PBR levels are the result of glial cell activation and the effect is specific to the region of damage. Methamphetamine (METH) is a drug of abuse known to result in protracted changes in dopamine (DA) and serotonin (5-HT) axonal markers in the brain. METH exposure (10 mg/kg, 4 times every 2 hrs) in rats induced approximately 50% depletions of DA and 5-HT. Increased expression of PBRs was measured in the hippocampus (91.8%), cingulate (89.5%) and striate (94.5%) cortex, thalamus (107%) and dorsal raphe (87.3%) but not in striatum 5 days after METH administration. At 14 days after drug administration, PBR levels in METH rat brains were no longer different from controls. These findings suggest that PBR expression in the brains of METH-treated rats is transiently increased. Striatal changes in PBR levels may be detected at an earlier time after METH administration (Escubedo et al., Brain Res. 814: 120, 1998). The relationship between regional changes in PBR expression and DA and 5-HT axonal markers as well as microglia and astrocytic markers are under investigation. (Supported by ES07062 to TRG.)

107 OBESITY AS A POTENTIAL RISK FACTOR FOR SUSCEPTIBILITY TO NEUROTOXIC INSULT.

K. Sriram and J. P. O'Callaghan. *CDC-NIOSH, Morgantown, WV.*

Obesity is a major risk factor associated with a variety of diseases including cardiovascular disorders, diabetes and certain cancers. Little information exists, however, as to whether obesity modifies the response of the central nervous system (CNS) to neural injury. The purpose of the present study was to determine if obesity serves as a predisposing factor in modifying/mediating a neurotoxic response. Leptin deficient (ob/ob) mice were used as a model of obesity and the dopaminergic neurotoxicants, 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) and methamphetamine (METH) were used as neurotoxic insults. Tyrosine hydroxylase (TH) was used as an index of dopaminergic nerve terminal integrity and was assessed by a novel fluorescence-based ELISA and by immunoblot. Glial fibrillary acidic protein (GFAP) was used as an index of the glial reaction to terminal damage and was assessed by sandwich ELISA. Both MPTP and METH significantly decreased striatal TH levels in a time-dependent fashion in the striatum of wild and ob/ob mice. Basal levels of TH were 25% lower in ob/ob mice compared to wild type mice. By 48 hours post-dosing, MPTP reduced TH by approximately 70-75% in both wild type and ob/ob mice. METH resulted in nearly a 90 % decrease in ob/ob mice in comparison to 75% decrements in wild type controls. These data were in agreement with immunoblot results on the same samples. While both MPTP and METH induced a large (>600%) increase in striatal GFAP of wild-type mice, this effect was attenuated (not exacerbated) in ob/ob mice. Basal levels of GFAP also were lower (25%) in ob/ob mice.

The data indicate that METH-induced dopaminergic neurotoxicity (based on TH decreases) is enhanced in the obese (ob/ob) and that the leptin-deficient condition decreases the basal levels of TH and GFAP. The ob/ob mouse may not serve as an appropriate model for assessing the effects of obesity on toxic responses of the CNS.

108 GENETIC POLYMORPHISMS OF SUPEROXIDE DISMUTASE (SOD1, SOD2) AND PARKINSON'S DISEASE.

Y. G. Hitosis, S. D. Quigley, J. Kushleika, F. M. Farin, J. S. Woods and H. Checkoway. *University of Washington, Seattle, WA.*

Oxidative stress caused by exposure to toxic agents may be associated with the pathogenesis of Parkinson's disease (PD). Superoxide dismutases are involved in reducing oxidative stress by catalyzing superoxide radicals which may damage DNA. We developed genomic DNA and cDNA-based sequencing assays to identify genetic variants in the copper/zinc superoxide dismutase (SOD1) and manganese superoxide dismutase (SOD2) genes. These assays involve PCR amplification of specific regions of DNA or cDNA followed by sequencing of the PCR amplicons on an ABI 377. DNA from 94 subjects from a case-control study of PD (45 cases and 49 controls) were analyzed and no genetic variants were detected in the gene encoding SOD1. However, a previously described polymorphism was identified consisting of a C47T in exon 2 of SOD2, which results in an alanine to valine substitution. We subsequently analyzed 386 PD subjects (155 cases and 231 controls) for this polymorphism using a fluorogenic 5' nuclease assay and an ABI 7700. The allelic frequencies for the cases were: CC (35, 22.6%), CT (77, 49.7%), TT (43, 27.7%). The allelic frequencies for controls were: CC (51, 22.1%), CT (125, 54.1%), TT (55, 23.8%). No statistically significant difference was found in the distribution of the mutant T allele among cases and controls (odds ratio, 0.97; 95% CI 0.60-1.58). These results indicate that there is no association between the presence of this SOD2 mutation and PD. (Supported by ES04696 and ES07033.)

109 IS NITRIC OXIDE INVOLVED IN NEURODEGENERATIVE PROCESSES?

D. A. Di Monte, J. E. Royland, M. Lavasani and J. W. Langston. *The Parkinson's Institute, Sunnyvale, CA.*

The role of nitric oxide in nigrostriatal degeneration, the pathological hallmark of Parkinson's disease, was investigated using two animal models, i.e. mice injected with either MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine) or methamphetamine. In MPTP-exposed animals, the nNOS (neuronal nitric oxide synthase) inhibitor 7-nitroindazole seemed to prevent neurotoxicity. However, additional experiments clarified that this neuroprotection was mostly due to inhibition of MAO-B (monoamine oxidase type B, the enzyme responsible for MPTP bioactivation) rather than NOS. Another NOS inhibitor, L-NG-nitroarginine, failed to exert any neuroprotective effect in the MPTP mouse model of nigrostriatal damage. In mice injected with methamphetamine, NOS inhibitors prevented both dopamine depletion and the loss of tyrosine hydroxylase-positive terminals in the striatum. The data indicate that the role of nitric oxide in nigrostriatal degeneration may vary depending upon the mechanisms involved in neuronal damage. Since NMDA (N-methyl-D-aspartate) receptor activation is thought to play an important role in methamphetamine neurotoxicity (but not that caused by MPTP), we postulate that the effects of nitric oxide may be an event downstream from excitotoxicity.

110 UPREGULATION OF PHOSPHORYLATED STAT3 PRECEDES GLIAL INDUCTION IN MPTP-MEDIATED NEUROTOXICITY.

M. A. Hebert and J. P. O'Callaghan. *Centers for Disease Control and Prevention/NIOSH, Morgantown, WV.*

STAT3 is a transcription factor that is activated by the JAK family of kinases or by the growth associated MAP kinase (MAPK). As recent studies have shown that Stat3 regulates gliogenesis in the central nervous system (CNS) and astrogliosis is a unifying effect of diverse injuries to the CNS, we are interested in elucidating the temporal relationship among alterations in Stat3, MAPK and gliosis following neurotoxic insult. At various timepoints following 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine- (MPTP, 12.5 mg/kg, s.c.) treatment, female C57BL/6J mice were sacrificed by focused microwave irradiation to preserve steady-state phosphorylation. Target (striatum) and non-target (hippocampus) tissue homogenates were assayed for levels of glial fibrillary acidic protein (GFAP) and dopamine (DA), as well as alterations in Stat3 and MAPK protein phosphorylation. A 2-fold increase in striatal GFAP was measured in MPTP-treated mice, 48 hours after dosing. Striatal DA depletion occurred within hours following treatment. Alterations in activated Stat3 and MAPK, as detected by phospho-state specific antibodies, were observed as early as one hour following neurotoxic insult and persisted for weeks. The most dramatic increase in the phosphorylated form of Stat3 and MAPK (500% and 100%, respectively) was measured prior to GFAP upregulation (12 hr post-MPTP). As MPTP-induced neurotoxicity requires uptake of MPP+ into DA terminals via the dopamine transporter (DAT), DAT inhibition should block phosphorylation events linked to dopamine terminal damage. Pretreatment with the DAT inhibitor nomifensine (25 mg/kg, s.c.) completely blocked the MPTP-induced increases in GFAP and phospho-Stat3, without altering these levels in saline-treated mice. These data suggest that the activation of Stat3 and MAPK are early events in toxicant-induced glial activation. These kinase/substrate pathways may serve as potential targets for modulation of degenerative and regenerative responses to neural damage.

111 ENVIRONMENTAL RISK FACTORS FOR PARKINSON'S DISEASE: POTENTIATED EFFECTS OF COMBINED PARAQUAT AND MANEB.

M. Thiruchelvam, B. J. Brockel and D. A. Cory-Slechta. *University of Rochester, Rochester, NY.*

Parkinson's disease (PD) is a neurological movement disorder resulting from a loss of dopamine (DA) neurons in the nigrostriatal dopaminergic pathway. The absence of any compelling data for a solely genetic etiology for this disease has focused attention on environmental exposures as causative agents, or as factors which act in conjunction with a genetic predisposition. The herbicide paraquat and the fungicide maneb have been shown to impact DA systems. These compounds show highly comparable patterns of geographical use, suggesting overlap in human exposure as well. This situation raises the possibility of a multi-hit environmental model for PD. C57BL/6 mice exposed to paraquat and maneb in combination show significant decreases in locomotor activity compared to when these agents are administered alone. Potentiated effects of levels of DA, its metabolites and DA turnover accompany combined relative to when administered alone. Furthermore, combined but not single compound exposure resulted in significant decreases in striatal but not nucleus accumbens tyrosine hydroxylase density. Thus these chemical mixtures may be important etiologic agents for PD. These findings also question the adequacy of current risk assessment guidelines for such chemicals based on effect levels derived from exposure to single agents. (Supported by ES05727, ES05017, ES05903, ES01247.)

112 THE CYCLODIENE INSECTICIDE HEPTACHLOR ALTERS DOPAMINE HOMEOSTASIS.

A. A. Garcia, S. E. Ethridge, J. Philhower and G. W. Miller. *University of Texas, Austin, TX.*

Epidemiological studies have demonstrated that exposure to pesticides is a risk factor for Parkinson's disease. We have previously shown that subchronic, repeated exposure to the cyclodiene insecticide heptachlor increases the expression of the plasma membrane dopamine transporter (DAT) and the vesicular monoamine transporter (VMAT2) in mouse striatum (Neurotoxicology. 20:631-638, 1999). The purpose of this study was to determine if a single dose of heptachlor has similar effects. 8-10 month old C57BL/6 mice were injected with a single dose of heptachlor (9 mg/kg, i.p.). 24, 48, and 72 hr later, striata were harvested and subjected to HPLC-EC analysis of dopamine (DA) and metabolites and western blot analysis of DAT and VMAT2 expression. Administration of heptachlor did not significantly affect striatal dopamine levels at any timepoint (-1.0%, -8.5%, +1.6 for 24,48, and 72 hr, respectively). Western blot analysis revealed that heptachlor altered DAT expression (-13.0%, -1.7%, and +13.0% for 24, 48, and 72 hour treated mice, respectively). We hypothesized that the trend of DAT upregulation would increase susceptibility to the dopaminergic toxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP); thus, MPTP was administered to mice that had been treated with heptachlor 72 hr earlier. HPLC and western blotting showed that the combination of heptachlor and MPTP was more toxic than either compound administered individually (DA +75% vs -28.6%; DAT -31.02% vs -51.9%; VMAT2 -19.4% vs -35.8% for MPTP vs heptachlor+MPTP, respectively). These results demonstrate that heptachlor increases susceptibility to MPTP and may be involved in the development of Parkinson's disease. (Supported by NIEHS 09248, 07784, and NINDS 37031.)

113 NIGROSTRIATAL DOPAMINERGIC TOXICITY INDUCED BY THE PYRETHROID INSECTICIDE DELTAMETHRIN.

S. E. Ethridge, A. A. Garcia, J. Philhower and G. W. Miller. *University of Texas, Austin, TX.*

Recent studies suggest that the majority of cases of idiopathic Parkinson's disease involve an environmental component. Epidemiological studies have demonstrated that exposure to pesticides is a risk factor for Parkinson's disease. In this study we show that the pyrethroid insecticide deltamethrin significantly alters the levels of dopamine (DA), its plasma membrane transporter (DAT), and the vesicular monoamine transporter (VMAT2) in the striata of treated mice. 8-10 month old C57BL/6 male mice were given a single injection of deltamethrin (9mg/kg, i.p.) and sacrificed either 24, 48, or 72 hr later. Striata were harvested and DA levels analyzed by HPLC-EC and expression of the DAT and VMAT2 by western blotting. By 72 hr DA levels were reduced, while DAT and VMAT2 levels were increased (DA -27.2%, DAT +58.3%; VMAT2 +39.9%, respectively). Since DAT is thought to be the molecular gateway by which the active metabolite of the dopaminergic toxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) enters the dopamine neuron, MPTP was administered to mice that had been treated with deltamethrin 72 hr prior. Results indicate that animals treated with deltamethrin were more sensitive to the toxic effects of MPTP than animals treated with MPTP alone (DA +75.9% vs. -25.2%; DAT -31.3% vs. -76.8%; VMAT2 -19.6% vs. -62.9%, for MPTP vs. deltamethrin+MPTP respectively). A similar upregulation of DAT by deltamethrin (10 nM) was seen in neuroblastoma cells stably expressing human DAT (43.2% increase in DA uptake). These results suggest that disruption of dopamine function by pesticides such as deltamethrin may contribute to the etiology of Parkinson's disease by altering dopamine transport. (Supported by NIEHS 09248, 07784 and NINDS 37031.)

114 HYPERTHERMIA-ENHANCED SEROTONIN (5-HT) DEPLETION RESULTING FROM *d*-FENFLURAMINE (*d*-FEN) EXPOSURE DOES NOT EVOKE A GLIAL-CELL RESPONSE IN THE CENTRAL NERVOUS SYSTEM OF RATS.

C. W. Stewart[1] and W. Slikker, Jr.[2]. [1]*University of Arkansas for Medical Sciences, Little Rock, AR and* [2]*National Center for Toxicological Research, Jefferson, AR.*

d-Fen-induced hyperthermia has been shown to coincide with an enhanced depletion of 5-HT and 5-hydroxyindole acetic acid (5-HIAA). Because these observations have relied on d-Fen exposure at multiple environmental temperatures, some have questioned the validity of the findings. Therefore, this experiment was designed to determined if the correlation between elevated body temperature and 5-HT depletion could be observed when d-Fen exposure occurred in one warm environment (28 degrees C) and to determined if a hyperthermia-enhanced glial-cell response could be evoked by d-Fen exposure. Hyperthermia-enhanced 5-HT and 5-HIAA depletion resulting from d-Fen exposure was dependent on body temperature during drug exposure. In the frontal cortex, 5-HT concentrations ranged from 3 to 45% of control values. Likewise, in the striatum and hippocampus, 5-HT concentrations ranged from 13 to 53% and 6 to 40%, respectively. The 5-HIAA concentrations had a wider range than the 5-HT concentrations for each brain region. In the frontal cortex, striatum and hippocampus, 5-HIAA ranged from 0 to 93%, 15 to 72% and 0 to 83% of control, respectively. In spite of the substantial reductions in 5-HT, there was no detectable glial-cell response. d-Fen-induced hyperthermia does not appear to cause generalized damage to neurons in the frontal cortex, striatum and hippocampus.

115 ACUTE EFFECTS OF METHYLPHENIDATE ON OPERANT BEHAVIOR IN THE RHESUS MONKEY II.

P. Morris, M. P. Gillam, C. McCarty and M. G. Paule. *Division of Neurotoxicology, NCTR, FDA, Jefferson, AR.*

In the present study, the stimulant methylphenidate (MPH) was administered to adult rhesus monkeys (N=8) previously trained on the five food-reinforced tasks of the NCTR non-human primate Operant Test Battery (OTB). Each task is designed to model a different aspect of brain function, including motivation (M), time estimation (TE), learning (L), color & position discrimination (CPD) and short-term memory (STM). MPH was administered acutely (i.v., 0.03 to 1.75 mg/kg, conducted over a 10 week interval) at 5.50 years of age and then again later at 9.25 years of age. Between these first and second acute administrations, MPH was also administered chronically (p.o., 2 times/day, 5 consecutive days/week, 0.1 - 2.0 mg/kg over 72 weeks and then 1.6 mg/kg for 81 weeks). Chronic administration of MPH produced no significant change in behavioral performance on any task of the OTB (The Toxicologist: 36, 63, 1997; 42, 304, 1998). However, when tested 15 minutes after acute MPH challenges, operant performance was significantly decreased on all tasks of the OTB (% task completed: for first acute administration, $F=14.23$ (M), 9.28 (TE), 9.59 (L), 5.55 (CPR) and 12.80 (STM), all $p<0.05$; for second acute administration, $F=16.83$ (M), 7.29 (TE), 26.56 (L), 12.16 (CPR) and 27.63 (STM), all $p<0.05$). Furthermore, the minimum dose for producing significant behavioral effects was lower for the second acute administration (% task completed, in mg/kg, first vs second: 1.0 vs 0.1 (L), 0.3 vs 0.1 (M, TE, STM); but 1.0 vs 1.0 (CPD)). It was concluded that, using a battery of operant behavior tests in a rhesus monkey model, the acute behavioral effects of the stimulant MPH can be modified by a preceding period of chronic MPH administration.

116 ROLE OF THE TSC-2 TUMOR SUPPRESSOR GENE IN QUINOL-THIOETHER MEDIATED NEPHROCARCINOGENICITY.

S. S. Lau[1], H. S. Yoon[1], M. N. Phan[1], C. L. Walker[2], J. I. Everitt[3] and T. J. Monks[1]. [1]*Div. of Pharmacol./Toxicol., College of Pharmacy, University of Texas at Austin, Austin, TX.* [2]*Univ. of Texas MD Anderson Cancer Center, Smithville, TX and* [3]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Sustained compensatory cell proliferation following toxic insult contributes to the mechanisms by which non- or weak genotoxicants exert their carcinogenic effects. 2,3,5-Tris-(glutathion-S-yl)hydroquinone (TGHQ), a potent nephrotoxic metabolite of HQ, markedly induces cell proliferation within the outer strip of the outer medulla (OSOM), and increases the incidence of renal cell carcinoma in Eker rats carrying the mutant Tsc-2 allele (Tsc-2EK/+). To identify factors involved in TGHQ-mediated renal carcinogenesis, Tsc-2EK/+ and wild type (Tsc-2+/+) Eker rats were treated with TGHQ (2.5 μmol/kg, i.p., 5X/wk) for 1, 2, or 4 months. TGHQ markedly increased cell proliferation within the OSOM in both Tsc-2EK/+ and Tsc-2+/+ rats in regions in which the tumors arose. Elevated cell proliferation became more pronounced as chemical treatment continued. TGHQ increased renal tumor incidence in Tsc-2EK/+ but not in Tsc-2+/+ rats, suggesting that cell proliferation was necessary but not sufficient for tumor development. Consistent with this hypothesis, loss of the wild type allele in the Tsc-2 gene was detected in early preneoplastic lesions (dysplastic tubules) isolated using laser capture microdissection, and in renal cell carcinomas that arose in TGHQ treated Tsc-2EK/+ rats. We hypothesize that loss of tuberin (the Tsc-2 gene product) may lead to tumor development due to a requirement for tuberin function during compensatory cell proliferation, consistent with its proposed role as a negative regulator of the cell cycle. Loss of the normal Tsc-2 allele in tumors is associated with elevated levels of cyclin D1 and ERK activity, suggesting that these genes may be down-stream effectors of tuberin which drive tumor growth following loss of tuberin function. (GM39338, ES07784).

117 THE USE OF VARIANT GLUTATHIONE S-TRANSFERASE GENES TO CONFER PROTECTION AGAINST ALKYLATING DRUGS TO HUMAN HEMATOPOIETIC STEM CELLS.

K. Murayama[1] and W. E. Fahl[2]. [1]*Environmental Toxicology Center, University of Wisconsin-Madison, Madison, WI and* [2]*Environmental Toxicology Center and McArdle Laboratory for Cancer Research, University of Wisconisn-Madison, Madison, WI.*

Past work in the field has shown that native glutathione S-transferase (GST) genes, when overexpressed in human cancer cells, can confer marked resistance to alkylating chemotherapy drugs as well as drugs known to generate reactive oxygen species. Previous work from our laboratory produced genetic variant GST genes with gain-of-function mutations that confer increased efficiency in conjugating and detoxifying nitrogen mustard derivatives. The current work presented here shows that expression of these gain-of-function mutants in human B-lymphocyte derivatives, Raji cells, results in greater resistance against the alkylating drug melphalan than that conferred by the wild-type GST. For these studies, both wild-type and gain-of-function GST variants were cloned into the pLg-IN retroviral expression vector. Retroviral particles containing these expression vectors were purified from PG13 packaging cells. In initial experiments, the retrovirus was used to infect Raji cells, and clones of GST-expressing cells were isolated. The initial experiments have shown that the gain-of-function GST variants, 11s1 and 11s4 confer greater resistance to these human B-lymphocyte derivatives than that conferred by the wild-type GSTs. Our current studies also include experiments to determine what limiting roles substrate availability, *i.e.* glutathione concentration, as well as reaction product concentration play in determining the over-

all GSH conjugation capacity of these B-lymphocytes. The concentration of GSH-conjugates formed in the cells is being modulated by expression of a recombinant MRP1 cDNA in the cells; this MRP1 membrane pump is responsible for exporting GSH-conjugates from mammalian cells. A full understanding of the role which GSH conjugation can play in modulating and controlling the toxicity of alkylating drugs in human cells is the underlying goal of all of these experiments. Such understanding will enable the use of these variant, gain-of-function GST proteins to protect human bone marrow cells in chemotherapy, and enable selection of bone marrow cells in routine gene therapy applications.

118 INACTIVATION OF PROTEIN DISULFIDE ISOMERASE WITH 1-CHLORO-2,4-DINITROBENZENE.

R. S. Kaetzel[1], T. S. Fraley[2], M. K. Brown[2] and D. J. Reed[2]. [1]*Department of Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR and* [2]*Department of Biochemistry and Biophysics, Oregon State University, Corvallis, OR.*

Protein disulfide isomerase (PDI) is a multifunctional protein with a number of diverse functional roles in the cell. In addition to thiol-disulfide exchange, PDI catalyzes the glutathione dependent reduction of dehydroascorbate, assists in the oxidative disulfide formation of protein folding, binds Ca^{2+}, estrogen, and thyroid hormones, and serves as a subunit of prolyl hydroxylase and triglyceride transferase found in the endoplasmic reticulum (ER). Protein disulfide isomerase, a 57-kDa ER resident is one of the most active and abundant oxidative folding catalysts isolated to date, with concentrations estimated at near mM in the ER. PDI is a member of the thioredoxin superfamily, having two functional domains with significant sequence homology of the redox cofactor, thioredoxin. These two domains are responsible for the disulfide isomerase activity. 1,2-Chloro-2,4-dinitrobenzene (DNCB, MW= 202.6) is an alkylating agent used for depleting intracellular GSH and has also shown distinct immunomodulatory properties. DNCB has been shown as an irreversible inhibitor of thioredoxin reductase which also contains the thioredoxin functional domain. In an effort to determine the relative reactivity of the thiols of the thioredoxin family of proteins, we incubated isolated recombinant rat PDI for 20 minutes at 20°C with increasing amounts of DNCB (0.1 to 1 mM). Our results show that a concentration of 1 mM DNCB decreases PDI activity by 70% within 5 minutes as measured by the GSH-dependent reduction of insulin. MALDI-MS analysis of PDI incubated with 0.5mM DNCB showed an increase in molecular weight by 462±156 g/mole. This increase corresponds to possibly three alkylation sites per molecule of PDI. Further analyses of the disulfide isomerase activity corresponding to these alkylation sites are currently underway. (This work was supported by grants from the NIH [ES00040 and ES00210].)

119 CHARACTERAZATION OF THE INTERACTION BETWEEN GLUTAMATE-CYSTEINE LIGASE SUBUNITS.

Y. Yang, T. P. Dalton, H. G. Shertzer and D. W. Nebert. *Center for Environmental Genetics, and Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.*

Glutamate-cysteine ligase (GCL) is the rate-limiting enzyme in the glutathione (GSH) biosynthesis pathway. This enzyme is a heterodimer comprising a structural subunit (GCLS) and a regulatory subunit (GCLR). Although GCLS alone can catalyze the formation of L-γ-glutamyl-L-cysteine, this activity is partially inhibited in the cell due to low affinity for glutamate and high sensitivity to GSH inhibition. The presence of GCLR enhances the enzyme activity by lowering the Km for glutamate and increasing the Ki to GSH inhibition. Therefore, GCLR plays a pivotal role in maintaining GSH homeostasis *in vivo*. To characterize further the interaction between GCLS and GCLR, we have developed a system to study heterodimer formation between purified His-6-GCLS (or GCLR) and ^{35}S-labeled GCLR (or GCLS) by means of Ni-6-Histidine tag affinity chromatography. When a mixture of His-6-GCLS and radiolabeled GCLR was applied to Ni-NTA resin, retention of GCLR was dependent on the presence of His-6-GCLS. Both GCLR and the heterodimer were present on the non-reducing SDS-PAGE gel, whereas under reducing conditions, only GCLR was seen on the gel, indicating that the GCLS/GCLR interaction involves both non-covalent binding and disulfide bond. Preliminary evidence revealed that the disulfide interaction is enhanced in the presence of oxidized GSH (GSSG) but not affected by L-glutamate, ATP, or L-α-aminobutyrate. GCLR contains six cysteine residues, two of them being consecutive. Each of the cysteine has been mutated to alanine by site-directed mutagenesis. The importance of each cysteine residue in the disulfide formation is currently under investigation. In addition, we have constructed a series of truncated GCLR proteins in order to map the region of non-covalent interaction. (Supported in part by NIH Grant R01 AG09235.)

120 GENETIC POLYMORPHISMS IN TWO GLUTATHIONE ASSOCIATED GENES AND SUSCEPTIBILITY TO IDIOPATHIC PULMONARY FIBROSIS.

J. Shao, C. L. Keener, J. Lurton, F. M. Farin, G. Raghu and T. J. Kavanagh. *University of Washington, Seattle, WA.*

Pulmonary fibrosis(PF) is characterized by excessive accumulation of connective tissue in the lung interstitium. Asbestos-related fibrosis has been suggested to be mediated by reactive oxygen species. Moreover, it has been shown that patients with idiopathic PF (IPF) have very low levels of glutathione(GSH) in their alveolar epithelial lining fluid. In addition, glutathione-S-transferase(GST) polymorphisms, especially class GSTM-1, have also been implicated in asbestos-related PF. Therefore we focused on two polymorphic enzymes which are crucial in detoxification of reactive oxygen species, the first and rate-limiting enzyme in GSH synthesis, glutamate-cysteine ligase(GLCL), and GSTM-1. GLCL is composed of two subunits, a catalytic subunit(GLCLc) and a regulatory subunit(GLCLr). GLCLc has a polymorphic trinucleotide repeat(TNR) in the 5'-untranslated region of its mRNA, just upstream of the GLCLc start codon. The GLCLc TNR genotypes of human fibroblast cell lines isolated from both normal (19) and IPF (21) lung tissue were characterized by PCR and automated DNA sequencing. We found 7, 8 and 9 TNR homozygosity, and 9/8, 9/7 and 8/7 TNR heterozygosity in both cell types. Although there was no significant difference in the frequency of any genotype, the 8 TNR was more frequent in fibrotic cells, whereas 9 and 9/7 TNR were more frequent in normal cells. Studies to determine the functional significance of those polymorphisms are being carried out. We also examined GSTM-1 genotypes. No significant difference between fibrotic and normal cells were found with respect to this genotype. (This work was supported by NIH grant ES 07033 and ES 04696.)

121 PCB-INDUCED EFFECTS ON GLUTATHIONE, AND GLUTATHIONE-RELATED ENZYMES AT SUBCHRONIC TIME POINTS.

T. P. Twaroski, M. L. O'Brien and L. W. Robertson. *University of Kentucky, Lexington, KY.*

Although polychlorinated biphenyls (PCBs) have been banned from production in many countries since the early 1970s, they persist in our environment and accumulate in target tissues, such as adipose and breast tissues. PCBs may induce drug-metabolism and may be substrates for the induced enzymes. Metabolism of PCBs may lead to oxidative events within the cell. The goal of this study was to determine the influence of PCBs on glutathione and glutathione-related enzymes. Male and female Sprague Dawley rats received two i.p. injections per week of PCBs 3, 28, 38, 77, 153 or both 77 & 153 (100μmol/kg/injection) and were sacrificed at the end of 1, 2, or 3 weeks. Livers were surgically removed, flash frozen in liquid nitrogen, and stored at –80. Whole liver homogenates, cytosol and microsomes were prepared and glutathione, glutathione peroxidase, glutathione reductase and glutathione transferase were determined. Both glutathione reductase and glutathione transferase activities were significantly increased in both male and female rats receiving PCB 77, a ligand for the Ah receptor, as well as both 77 & 153. No significant trend was observed in the total glutathione level data. Interestingly PCB 77, as well as the combination of PCB 77 & 153, decreased glutathione peroxidase activity levels in both male and female rats. Using northern analysis, we confirmed this decrease of activity, in male and female rats treated with PCB 77, was due to a decrease in GPx1 transcript. (P42 ES 07380, DAMD 17-96-1-6162, and T32 ES07266).

122 TISSUE SPECIFIC CHANGES IN GLUTATHIONE AND THE EXPRESSION OF THE CATALYTIC AND REGULATORY SUBUNIT OF GLUTAMATECYSTEINE LIGASE IN MICE EXPOSED TO METHYLMERCURY: A TIME-COURSE STUDY.

D. Diaz-Lopez, C. C. White, C. M. Krejsa, C. L. Keener, F. M. Farin and T. J. Kavanagh. *University of Washington, Seattle, WA.*

The tripeptide glutathione (GSH) plays a crucial role in protecting cells against oxidative stress. GSH is synthesized in a two-step process, the rate-limiting step being the binding of glutamate and cysteine, which is catalyzed

by the enzyme glutamate-cysteine ligase (GLCL). This enzyme is composed of two subunits, a large catalytic subunit (GLCLc) and a smaller regulatory subunit (GLCLr). The toxicity of methylmercury (MeHg) is known to be influenced by GSH status, and MeHg exposure often results in GSH depletion and induction of GLCL at the mRNA and protein levels. The objective of this study was to determine the effect of MeHg treatment (single dose of 6 mg/Kg by ip injection) on different mouse tissues. The experiment was designed as a time-course study in which 3 control and 4 treated C57 female mice were used for each time-point (6 h., 12 h. and 24 h.) and the tissues analyzed were liver, kidney, lung and small intestine. GSH levels were analyzed by Tietze assay, GLCL activity by HPLC, GLCLc and GLCLr protein levels by Western blot and GLCLc and GLCLr mRNA levels both by Northern blot and real-time fluorogenic 5' nuclease assay. There were no substantial changes in GSH levels or GLCL activity in the tissues examined. The more dramatic changes occurred at the mRNA level, with induction of both subunits in kidney, lung and small intestine at 12 h. Interestingly, the small intestine shows preferential upregulation of GLCLc, and the liver shows downregulation of both subunit mRNAs at 6 h. The changes in protein levels were not as substantial, but they reflect the changes in mRNA levels. These results show that different mouse tissues respond differently to MeHg treatment in regards to changes in GLCL, which suggests time- and tissue-specific regulation of the enzyme.

123 EFFECT OF INCREASING GSH SYNTHESIS ON RESISTANCE OF HEPA-1 CELLS TO DNA BREAKS CAUSED BY H_2O_2.

S. Shi, D. Botta, C. C. White and T. J. Kavanagh. *University of Washington, Seattle, WA.*

GSH is important in defending against oxidative stress. The rate limiting enzyme in GSH synthesis is glutamate-cysteine ligase (GLCL) which is composed of catalytic (GLCLC) and a regulatory (GLCLR) subunits. We developed cells with metallothionein promoter-regulatable overexpression of either GLCLC alone, GLCLR alone or the combination to test the hypothesis that increased GSH synthesis ability can protect cells from DNA breaks caused by H_2O_2 exposure. Microgel single cell electrophoresis assay (comet assay) was used to measure the DNA single-brand breaks after exposure to 100 mM H_2O_2 for one hour. The length of comet tails, and ratio of tail length to nuclear size were measured to quantitate DNA breaks. Compared with vector controls, cells overexpressing GLCLC and cells overexpressing GLCLR had significantly less DNA breaks as indicated by shorter tail length. Cells overexpressing GLCLC and cells overexpressing GLCLC + GLCLR were significantly lower in the ratio of tail length to nuclear size. These results show that increased synthesis of GSH helps to protect cells from DNA breaks caused by H_2O_2.

124 PREFERENTIAL INDUCTION OF THE G-GLUTAMYLCYSTEINE SYNTHETASE CATALYTIC SUBUNIT (GCSH) GENE BY DESFERRIOXAMINE OR HYPOXIA.

A. C. Wild, K. A. Gregg and R. T. Mulcahy. *University of Wisconsin, Madison, WI.* Sponsor: A. Elfarra.

The genes encoding the catalytic (GCSh) and regulatory (GCSl) subunits of g-glutamylcysteine synthetase, which catalyzes the rate limiting step in glutathione synthesis, can be induced by many agents including pro-oxidants and electrophiles. Typically both subunit genes are similarly induced in response to these agents. However, exposure of HepG2 cells to the iron-chelator, desferrioxamine (DFX), results in a robust induction of GCSh expression (~7x) accompanied by a relatively minor elevation (<2x) of GCSl mRNA levels. Induction by DFX is inhibited by both Actinomycin D and cycloheximide, suggesting that gene transcription and synthesis of new protein(s) are required. In contrast, catalase does not alter induction. DFX exposure also results in reduction of the GSH/GSSG ratio (decreased GSH; increased GSSG). DFX has been reported to activate gene expression via hypoxia responsive elements (HREs) by yet unknown mechanisms. Like DFX exposure, incubation of HepG2 cells under hypoxic (95% N2/5% CO2) conditions for 12 hours results in a significant elevation (>6x) of GCSh mRNA levels, but no change in GCSl expression. Differential induction persists following hypoxic incubation up to 24 hours. Consensus HREs have not been identified in the promoter of either subunit gene, but multiple potential HREs are present in the first intron of GCSh. In preliminary experiments DFX failed to induce expression of GCSh promoter/luciferae transgenes. Determination of enhancer activity in GCSh intron sequences is on-going. These results demonstrate that GCS subunit genes are not necessarily coordinately regulated and may be induced by independent mechanisms. (Supported by CA57549 and ES09749.)

125 EXPRESSION OF GLUTATHIONE REDUCTASE (GR), PEROXIDASE (GPX) AND TRANSFERASE (GST) ACTIVITIES IN NUCLEI AND NUCLEOLI OF LIVERS IN MALE AND FEMALE FISCHER 344 RATS.

S. Gupta and C. V. Smith. *Baylor College of Medicine, Houston, TX.*

GR is an important component of cellular antioxidant defenses, serving to sustain cellular supplies of glutathione (GSH) and to limit accumulation of glutathione disulfide (GSSG), thereby limiting the oxidation and S-thiolation of proteins. Increased expression of GR can significantly enhance cellular resistance to oxidants, particularly when expression is increased selectively in mitochondria. In the present studies, we isolated and purified nuclei from livers of male and female F344 rats using discontinuous sucrose gradient centrifugation, and assayed GR activities, which were 12 and 15 mU/mg pro, respectively. Nucleolar fractions showed GR activities of 30 and 51 mU/mg of pro, respectively, $P<0.05$ versus nuclear activities. Male F344 rats showed increases in GR activities in both nuclear and nucleolar fractions after giving 0.1 mmol/kg diquat; female F344 rats given 0.2 mmol/kg diquat showed increased GR activities in the nuclear fraction and decreased GR activities in the nucleolar fraction. GPX activities in nuclear and nucleolar fractions were between 200 and 300 mU/mg pro, but no differences in fractional activities were observed, although minor effects of diquat were observed in female rats. GST activities towards 1-chloro-2,4-dinitrobenzene (CDNB) in nuclei were 850 and 470 mU/mg pro in males and females, respectively; activities in nucleolar fractions were less than 40 mU/mg pro in all samples, indicating that the GR and GPX activities observed in the nucleolar fractions are not attributable to incomplete separation of nucleoplasm in isolation of the nucleoli. Some minor differences in activities of these enzymes were observed in nuclei and nucleoli, as were some changes in response to administration of diquat, but none of the differences or changes offer a reasonable explanation for the initiation of hepatic necrosis in diquat-treated rats, or the marked differences in susceptibilities between male and female F344 rats. The data indicate GR, GPX, and GST in nuclei contribute to cell defense functions, but the functions served by selective expression of GR and GPX in nucleoli are less evident. (Supported by NIH GM 44263.)

126 CLONING AND EXPRESSION OF RAT KIDNEY MITOCHONDRIAL DICARBOXYLATE CARRIER EXHIBITING GLUTATHIONE TRANSPORT ACTIVITY.

L. H. Lash, D. A. Putt and L. H. Matherly. *Wayne State University School of Medicine, Detroit, MI.*

Total rat kidney RNA was reverse transcribed and amplified with forward and reverse primers based on the published, complete cDNA sequence for the mitochondrial dicarboxylate carrier (DCC) from the Norway rat (*Rattus norvegicus*; GenBank accession number AJ223355). The expected PCR products were identified and a 1056-bp product was ligated into a T-A cloning vector (pGEM T-Easy) and its identity was confirmed by automated DNA sequencing. The amplified cDNA was then cloned into a bacterial expression vector (pRSET B) that adds an *N*-terminal $(His)_6$ tag to the translation product. The $(His)_6$-DCC fusion protein was overexpressed in *E. coli* and isolated from inclusion bodies. A time-dependent increase in expression of a 35.5-kDa protein, representing the fusion protein, was observed. Additional purification was attempted with a nickel-affinity column. The presence of the expressed protein was confirmed by immunoblot analysis using the RGS-His antibody, which only recognizes proteins with *N*-terminal $(His)_6$ tags. A single, immunoreactive protein at 35.5-kDa molecular weight, was observed. Before assessment of the function of the expressed carrier protein, liposomes were reconstituted with the solubilized inclusion body fraction and the presence of the DCC protein was confirmed by SDS-PAGE. The reconstituted proteoliposomes demonstrated rapid uptake of both [^{3}H]-glutathione and [^{14}C]-malonate. Furthermore, addition of 10 mM butylmalonate inhibited both transport processes, demonstrating function of the DCC. These results are consistent with properties of the DCC previously observed with intact rat kidney mitochondria and with partially purified and reconstituted protein. This approach will allow us to explore the molecular regulation of mitochondrial glutathione status and to better assess the function of this transport process in renal proximal tubular cells.

127 ELEVATED GLUTATHIONE (GSH) POOLS AND γ-GLUTAMYL TRANSPEPTIDASE (GGT) ACTIVITY IN COUMARIN-INDUCED CLARA CELL TOLERANCE.

J. Vassallo, S. Curry, M. Purdon, C. Lewis, A. Fix and L. Lehman-McKeeman. *Procter and Gamble Co., Cincinnati, OH.*

Coumarin is metabolized to epoxide and aldehyde intermediates which are acutely toxic to mouse lung Clara cells. However, with repeated dosing, Clara cells become resistant to coumarin-induced injury and demonstrate cross-resistance to other Clara cell toxicants. The purpose of the present work was to determine whether Clara cell tolerance is associated with changes in pulmonary glutathione regulation. Female B6C3F1 mice were dosed orally with coumarin (200 mg/kg) or vehicle for 1 or 10 days after which GSH levels and GGT activity were measured in whole lung. GGT and Clara cell secretory protein (CC10) were also evaluated with histochemical and immunohistochemical methods, respectively. Constitutive GSH levels increased from 1.3±0.1 μmol/g in control mice to 1.9±0.1 μmol/g in mice dosed for 10 days with coumarin. At 2 hr after a single dose of coumarin, whole lung GSH decreased by about 30% relative to control, whereas lung GSH was not significantly reduced at 2 hr after 10 daily doses. A single dose of coumarin did not alter lung GGT activity, but with repeat dosing, GGT activity was induced 7-times control values (26±3 and 182±13 pmol/min/mg, respectively). Histochemically, the increased GGT activity was localized to bronchiolar epithelium. Concurrent with changes in GGT and GSH regulation, the abundance of CC10 was markedly reduced in tolerant Clara cells. These results indicate that Clara cell tolerance is characterized by the maintenance of elevated GSH concentrations which is mediated at least in part by increased GGT activity. The loss of CC10 expression also suggests a change in the differentiation state of tolerant Clara cells.

128 *IN UTERO* ETHANOL EXPOSURE PRODUCES DIFFERENTIAL MITOCHONDRIAL GLUTATHIONE DEPLETION IN THE RAT CONCEPTUS.

M. J. Beck, C. Harris and M. A. Philbert. *University of Michigan, Ann Arbor, MI.*

Glutathione (GSH) is the most abundant low molecular weight thiol in the cell. Glutathione is synthesized and primarily located in the cytosol (85%) but is also found in the mitochondria (15%). Mitochondrial GSH content is critically dependent on uptake of cytosolic GSH. Alterations in mitochondrial GSH content have been shown to cause uncoupling of oxidative phosphorylation and opening of the redox-sensitive mitochondrial permeability transition pore. Ethanol (EtOH) causes teratogenicity in various animal models *in utero* and *in vitro* and modulates mitochondrial GSH content in adult tissues. This study was designed to determine the ability to deplete mitochondrial GSH in the early organogenesis stage rat conceptus following *in utero* exposure to EtOH. Dams were gavaged with 4.5 g/kg EtOH on the morning of gestational day 10. Purified mitochondria were prepared from embryos and visceral yolk sacs (VYS) harvested 12 and 24 hr later. Total cellular, mitochondrial, and cytosolic GSH content were measured by HPLC detection. Twelve hours after exposure to 4.5 g/kg EtOH, total cellular GSH content in the embryo was unchanged, yet embryonic mitochondrial GSH was depleted by 95% compared to control and cytosolic GSH was increased by 40%. At the 12 hr time point, VYS total cellular GSH content was depleted by 27%. Mitochondrial GSH content in the VYS decreased by 95%, and VYS cytosolic GSH was increased by 32%. After 24 hr, embryonic total cellular GSH was unchanged. Embryonic mitochondrial GSH showed a rebound recovery and cytosolic GSH was returned to control values. At the 24 hr time point, VYS total cellular GSH content was unchanged. However, VYS mitochondrial GSH was decreased by 43% compared to control, and cytosolic pools of GSH returned to control values. These results indicate that EtOH causes transient changes in total cellular GSH content while producing a dramatic redistribution of GSH from mitochondria to cytosol. These data suggest a mechanism of teratogenicity for EtOH through selective modulation of conceptal mitochondrial GSH status. (This research supported by ES07062, ES08846, and ES05235.)

129 *IN UTERO* AND *IN VITRO* COMPARISON OF ETHANOL EFFECTS ON THE ORGANOGENESIS STAGE RAT CONCEPTUS.

S. Akella, M. J. Beck, M. A. Philbert and C. Harris. *University of Michigan, Ann Arbor, MI.*

Ethanol (EtOH) produces neural tube and craniofacial defects and mental and growth retardation in the organogenesis stage rat conceptus. Teratogenic effects of EtOH have been suggested to result from oxidative stress which can alter reduced glutathione (GSH) status. Altered GSH and ATP concentrations are indices of oxidative stress and were evaluated in the gestational day 10 rat conceptus exposed to EtOH *in utero* and *in vitro*. Exposure of the dam to EtOH (4.5 g/kg) for 30 min did not affect GSH concentrations in the embryo or visceral yolk sac (VYS). After 3 hr, GSH content was decreased by 40% in the embryo and was unchanged in the VYS. By 6 hr, embryonic GSH content showed a rebound increase to 125% control and VYS GSH content remained unchanged. Exposure to EtOH *in vitro* (18 mg/ml) for 30 min did not affect GSH concentrations in the embryo or VYS. Beginning at 3 hr, embryonic and VYS GSH content decreased significantly over time until the end of the exposure period. Although GSH content was unchanged at 30 min, there was a 35% decrease in embryonic ATP levels following *in utero* exposure to EtOH. After 3 hr, embryonic ATP was still decreased by 35%. Cultured embryos showed a 55% depletion in ATP content, and after 3 hr, embryonic ATP levels remained depleted by 30%. ATP content in the VYS, however, showed only transient changes after EtOH exposure both *in utero* and *in vitro*. These results demonstrate clear differences in the *in utero* and *in vitro* effects of EtOH. Cultured embryos are more susceptible to changes in GSH and ATP content and do not show the adaptive response to EtOH-induced GSH depletion seen *in utero* at 6 hr. This rebound may provide a protective mechanism against EtOH toxicity *in utero*. Differences between *in utero* and *in vitro* responses to EtOH have important implications for the interpretation of *in vitro* developmental studies. (This research supported by ES08846, ES05235, and ES07062.)

130 EVALUATION OF CYTOPROTECTIVE PROPERTIES OF EBSELEN (2PHENYL-1,2 BENZISOSELENAZOL-3-(2H)-ONE) AGAINST CISPLATIN AND DIETHYLDITHIOCARBAMATE TOXICITY IN RAT HIPPOCAMPAL ASTROCYTES.

D. Hardej and L. D. Trombetta. *St. John's University, Jamaica, NY.*

Ebselen (2phenyl-1,2 benzisoselenazol-3(2H)-one), a seleno-organic compound, has been shown to have cytoprotective properties. This has been attributed to its ability to act as a glutathione peroxidase (GSH/PX) mimic. It has been implicated in increasing intracellular glutathione (GSH), as well as expressing antioxidant properties due to its ability to act as a scavenger of organic hydroperoxides. Cisplatin is a widely used chemotherapeutic agent that causes the generation of reactive oxygen species (ROS) which may interfere with cellular antioxidant defense systems. Diethyldithiocarbamate (DDC) is a compound commonly found in fungicides. It has been found to impose its toxic effect by disrupting cytoskeletal proteins and decreasing intracellular GSH pools. The purpose of this experiment was to evaluate the cytoprotective effects of ebselen pretreatment in cultures of rat hippocampal astrocytes exposed to cisplatin and diethyldithiocarbamate. Rat hippocampal astrocytes grown in DMEM/F-12 were pretreated with 30μM ebselen followed by exposure to 500, 250,125, 62.5, 31.25,15.625 and 7.8 μM cisplatin or 35 μg/ml DDC at subconfluency. Cell viability was determined using an MTT assay, a system that measures the activity of living cells via alterations in mitochondrial dehydrogenases. Dramatic increases in viability were seen in cells pretreated with ebselen and exposed to 500 and 250μM cisplatin. No protective effects were noted in cells pretreated with ebselen followed with DDC treatment. This poses questions on the mechanism of action of ebselen since GSH protects against DDC cytotoxicity.

131 IMPACT OF GSH DEPLETION ON HEPATIC COASH AND COASSG FOLLOWING TREATMENT WITH 4,4'-METHYLENE DIANILINE.

T. R. Dugas[1], V. Santa Cruz[1], H. Liu[1], L. K. Rogers[2], C. V. Smith[2] and M. F. Kanz[1]. [1]*University of Texas Medical Branch, Galveston, TX and* [2]*Baylor College of Medicine, Houston, TX.*

Methylene dianiline (DAPM) is an aromatic amine that specifically injures biliary epithelial cells (BEC). Previous studies indicate DAPM injury involves BEC, but not hepatic, mitochondria. DAPM also has only a minimal effect on hepatic glutathione (GSH) or glutathione disulfide (GSSG). Liver

Coenzyme A in its thiol form (CoASH) and as glutathione mixed disulfide (CoASSG), found predominately in mitochondria, equilibrates with GSH/GSSG and is used to indicate mitochondrial thiol/disulfide status. Our goal was to determine whether GSH depletion with both bromoheptane (BH, an alkylating agent) and butathionine sulfoximine (BSO, a GSH synthesis inhibitor) alters hepatic CoASH or CoASSG following DAPM treatment. Male SD rats were given BH (0.5 mmol/kg, po) at -1.5h, BSO (2.5 mmol/kg, ip) at -0.5h, and DAPM (50 mg/kg in 35% ethanol) at 0h. Liver was collected and freeze-clamped at 0, 3 and 6h. CoASH/CoASSG were determined by modification of an HPLC method developed by Rogers and Smith. BH/BSO treatment depleted GSH by 60-80% over 0-6h. While BH/BSO alone produced no evident injury, DAPM treatment alone produced moderate BEC injury. GSH depletion prior to DAPM treatment, however, caused pronounced BEC injury and mild hepatocellular injury. BH/BSO alone significantly increased CoASH and decreased CoASSG. DAPM alone decreased both CoASH and CoASSG at 3h, with no effect at 6h. Finally, treatment with both BH/BSO plus DAPM slightly decreased CoASH and dramatically increased CoASSG at 6h. Further, HPLC revealed a new peak eluting at a similar retention time as CoASH in samples from DAPM– and DAPM plus BH/BSO-treated rats. Identification of this component may indicate whether CoASH alkylation by DAPM/DAPM metabolite is occurring. Thus, GSH depletion enhanced the severity of DAPM toxicity while significantly increasing CoASSG. DAPM-induced changes in CoASH/CoASSG could be due to mitochondrial injury or to cell death. Nonetheless, this method provides a sensitive indication of mitochondrial involvement in DAPM toxicity. (Supported by NIEHS T32-ES 07254; NIEHS 06348.)

132 N-METHYLDITHIOCARBAMATE (NMDC) AND N,N-DIMETHYLDITHIOCARBAMATE (DMDC) DEPLETE GLUTATHIONE THROUGH INDEPENDENT MECHANISMS.

R. W. Thompson and W. M. Valentine. *Vanderbilt Univeristy, Department of Pathology, Nashville, TN.*

Dithiocarbamates are used in agriculture, medicine and industrial applications. NMDC has been reported to be two orders of magnitude more cytotoxic to CHO cells than the dialkyl analog, DMDC. The chemistry for these structurally related compounds is expected to be similar with the exception that NMDC can decompose at physiological pH to sulfhydryl ion (HS-), a potent inhibitor of cytochrome c oxidase, and methyl isothiocyanate (MITC), an electrophilic compound capable of covalently modifying cellular nucleophiles. The relative contribution of these two decomposition products to the cytotoxicity of NMDC was assessed using isolated rat liver mitochondria and suspension cultures of primary rat hepatocytes. Respiration of isolated rat liver mitochondria was assessed by monitoring oxygen consumption with an oxygen electrode and intracellular and extracellular reduced and oxidized glutathione from hepatocytes was measured by HPLC. Isolated rat liver mitochondria incubated with either NMDC or DMDC indicated that neither state 3 nor state 4 respiration was significantly different from controls for either dithiocarbamate. Incubation of hepatocytes with either NMDC or DMDC resulted in severely depleted intracellular levels of reduced glutathione. Prior depletion of intracellular GSH levels using diethylmaleate in cultured rat hepatocytes resulted in increased cytotoxicity for both NMDC and DMDC whereas a modest cytoprotective effect for NMDC and DMDC was observed upon supplementation of intracellular GSH levels with the membrane permeable ethyl ester of GSH. Extracellular samples from NMDC treated cells had significantly lower levels of oxidized glutathione than DMDC treated cells. LC/MS analysis of extracellular and intracellular samples from hepatocytes treated with NMDC indicated the presence of an S-(methyldithiocarbamoyl) glutathione conjugate and the mixed disulfide containing GSH and NMDC. The results obtained from the present study support the conclusion that NMDC and DMDC deplete GSH levels through independent mechanisms and that MITC plays a greater role in the cytotoxicity of NMDC than does HS-. (Supported by NIEHS grants ES06387, ES00267 and ES07028..

133 MECHANISTIC STUDY OF THE ACUTE TOXICITY OF 2-CHLOROACRYLONITRILE.

J. Mostowy and F. W. Fochtman. *Duquesne University School of Pharmacy, Pittsburgh, PA.*

The acute toxicity of 2-Chloroacrylonitrile (2-CAN) in Sprague Dawley rats as a function of cyanide generation and glutathione depletion was investigated. 2-CAN was administered through i.p. injection at doses of 10 mg/kg, 20 mg/kg and 40 mg/kg. Tissues (liver, kidney, heart and lung) were harvested at 15 minutes, 30 minutes, 1 hour, 2 hours and 4 hours after 2-CAN administration. Results show significant glutathione depletion in the liver after 1 hour. Depletion in the lungs was also observed but to a lesser amount. Detectable levels of cyanide increased as the dose increased. The cyanide level in blood after one hour was approximately 0.1 mcg/ ml. This data suggests that increased cyanide levels in the blood along with glutathione depletion may have a critical role in the mechanism of the acute toxicity of 2-CAN. Depletion of glutathione may allow the cyanogen to pass through oxidative metabolism and thereby cause increased cyanide levels in the blood.

134 THE PROTECTIVE ROLE OF THE ALPHA-CLASS GLUTATHIONE S-TRANSFERASE AGAINST OXIDATIVE STRESS.

Y. Yang[1], J. Cheng[1], U. Pandya[1], T. Hai[1], T. Zhao[2], S. S. Singhal[2], S. Awasthi[2] and Y. C. Awasthi[1]. [1]*The University of Texas Medical Branch, Galveston, TX.* [2]*University of Texas at Arlington, Arlington, TX and* [1]*Baylor College of Medicine, Houston, TX.*

Glutathione peroxidase (GPx) plays a major role in cellular defense against oxidative stress by reducing H_2O_2 and the lipid hydroperoxide (L-OOH) which propagate the autocatalytic chain of lipid peroxidation. Several Se-dependent GPx isozymes and the alpha class Glutathione S-transferases (GSTs) can reduce L-OOH through the GPx activity. However, the relative contributions of GSTs and the Se-dependent GPx isozymes in the reduction of L-OOH in cells is not known and needs to be investigated. During the present studies recombinant human alpha class GSTs A1-1 and A2-2 were prepared through their heterologous expression in *E. coli*. hGSTA1-1 and hGSTA2-2 catalyzed reduction of L-OOH and cumene hydroperoxide. The catalytic efficiency (k_{cat}/K_m) of hGSTA1-1 for phosphatidylcholine hydroperoxide (PC-OOH) and phosphatidylethanolamine hydroperoxide (PE-OOH) was found to be 181.3 and 199.6s^{-1} mM^{-1}, respectively, while the catalytic efficiency of hGSTA2-2 for PC-OOH and PE-OOH was 353 and 317.5 $s^{-1}mM^{-1}$, respectively. Immunotitration studies performed with the extracts of liver and testis from human and rat using the polyclonal antibodies against the alpha class GSTs showed that these antibodies immunoprecipitated about 75% and 46% of total GPx activities toward cumene hydroperoxide from human and rat liver, respectively. Likewise, about 64% and 56% of total GPx activities toward cumene hydroperoxide were immunoprecipitated by these antibodies from human and rat testis, respectively. Similar results were obtained when L-OOH were used as substrates in the place of cumene hydroperoxide. These results strongly suggest that the alpha class GSTs play an important role against oxidative stress in liver and testis through their Se-independent GPx activity. (CA27967)

135 GLUTATHIONE DEPLETION AND THE PRODUCTION OF REACTIVE OXYGEN SPECIES IN ISOLATED HEPATOCYTE SUSPENSIONS.

M. A. Tirmenstein, F. A. Nicholls-Grzemski[1], J. G. Zhang and M. W. Fariss. *Department of Pharmaceutical Sciences, College of Pharmacy, Washington State University, Pullman, WA.*

Freshly isolated suspensions of rat hepatocytes were exposed to the reduced gluathione (GSH) depleting agents *N*-ethylmaleimide (NEM), diethyl maleate (DEM) and ethyl methanesulfonate (EMS). These agents induced lipid peroxidation and cell death in a time-dependent manner. Dose response curves for DEM and EMS indicate that GSH must be depleted to below detectable levels (1 nmol/10^6 cells) in order for large increases in lipid peroxidation to occur. Concentrations of DEM and EMS that induced lipid peroxidation also increased reactive oxygen species (ROS) production as measured by increases in dichlorofluorescein (DCF) fluorescence. The addition of antioxidants prevented lipid peroxidation and protected against cell death, suggesting that lipid peroxidation is involved in the sequence of events leading to cell death induced by DEM and EMS. Mitochondrial electron transport inhibitors increased EMS and DEM-induced lipid peroxidation and cell death while the mitochondrial uncoupler, carbonyl cyanide m-chlorophenylhydrazone (CCCP), blocked lipid peroxidation but not cell death. Trifluoperazine (TFP), in contrast, decreased EMS and DEM-induced lipid peroxidation and cell death. Cyclosporin A provided no protection suggesting that TFP is not protecting solely through inhibition of the mitochondrial permeability transition. EMS-treatment resulted in the significant loss of mitochondrial α-tocopherol shortly after its addition, and this loss preceded losses in cellular α-tocopherol levels. Our results indicate that GSH depleting agents can induce large increases in lipid peroxidation and ROS production following the loss of GSH, and the mitochondria are the major source for this ROS generation. (This work was supported by NIEHS/NIH grant # R01ES 05452.)

136 INTRACELLULAR S-GLUTATHIONYL ADDUCTS IN HUMAN BRONCHOEPITHELIAL CELLS AFTER EXPOSURE TO TOLUENE DIISOCYANATE.

R. Clark Lantz[1], R. Lemus[2], R. W. Lange[2] and M. H. Karol[2]. [1]*Dept. of Cell Biology and Anatomy, Health Sciences Center, University of Arizona, Tucson, AZ and* [2]*Dept. of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

Toluene diisocyanate (TDI) is a recognized chemical asthmogen, yet the mechanism of this toxicity and the molecular reactions involved have not been elucidated. We have previously shown that TDI vapor forms adducts with the apical surface of the respiratory epithelium, and that it colocalizes with ciliary tubulin. *In vitro*, we have shown rapid reaction of TDI with glutathione (GSH) and transfer of the monoisocyanato-monoglutathionyl-TDI to a sulfhydryl-containing peptide. In addition, in culture we have evidence for TDI reacting with both low and high molecular weight intracellular thiols. GSH reactivity and transcarbamoylation could provide a mechanism for formation of TDI adducted hemoglobin which we have detected in circulating red blood cells. This study sought to identify intracellular GSH as the nucleophile reactant for TDI. We used the dye CellTracker Green (5-chloromethyl-fluorescein diacetate, CMFDA) for detection of glutathione. Dye activation and fluorescence requires functional intracellular esterases and glutathione S-transferase. Undifferentiated (1 day) and differentiated (6 day) air-liquid cultures of human bronchoepithelial cells were exposed to 100 ppb TDI vapor for 5, 15, or 30 min. Following exposure, cells were placed in medium containing 10 micromolar CMFDA. After 30 min, they were washed, then incubated for an additional 30 min with fresh medium prior to fixation with paraformaldehyde. Cells were subsequently imaged using a confocal microscope. Both one and six day cultures showed a decrease in intensity of the thiol staining as a function of the length of TDI exposure. For 1 day cultures, decrease in intensity was seen at the 30 min time period. For 6 day cultures, the decrease was evident in cultures exposed for only 5 min. This difference may be attributed to the difference in the amount of thiols in undifferentiated vs. differentiated cells. Differentiated cells contain 30-50% of the thiols found in undifferentiated cells. These results indicate that TDI enters pulmonary cells and reacts with intracellular GSH. This rapid reaction leading to the formation of S-glutathionyl adducts of TDI suggests the importance of cellular thiols in TDI-induced pulmonary disease. (Supported by Arizona Toxicology Center grant #ES06694 and NIEHS #05651).

137 2,3,5-TRIS-(GLUTATHION-S-YL) HYDROQUINONE INDUCES CELL TRANSFORMATION IN PRIMARY KIDNEY EPITHELIAL CELLS OF THE EKER RAT.

H. S. Yoon[1], C. L. Walker[2], T. J. Monks[1] and S. S. Lau[1]. [1]*Div. of Pharm./Toxicol., College of Pharmacy, University of Texas at Austin, Austin, TX and* [2]*University of Texas, MD Anderson Cancer Center, Smithville, TX.*

2,3,5-Tris-(glutathion-S-yl)hydroquinone (TGHQ) is a nephrotoxic and nephrocarcinogenic metabolite of the non-genotoxic carcinogen, hydroquinone (HQ) in the Eker rat. The Eker rat possesses a germline insertion in the Tsc-2 tumor suppressor gene, which predisposes these rats to renal cancer. In the present study, we report that TGHQ is capable of transforming renal epithelial cells from Eker rats after a single treatment (100 μM or 300 μM for 4hr). Cell lines were subsequently established (QT-RRE1, 2 and 3) from transformed colonies. QT-RREs exhibit characteristics of transformed cells, such as aneuploidy and anchorage-independent growth. G-banding analysis demonstrated a broad range of numerical chromosomal alterations among the cell lines. No Tsc-2 gene transcripts nor expression of tuberin, the protein encoded by Tsc-2, was observed in these cell lines as determined by RT-PCR and western blot analysis. Thus, the remaining functional allele of the Tsc-2 locus is inactivated by TGHQ treatment, which likely contributes to the development of the transformed phenotype. ERK (extracellular-signal-regulated kinase) may be one of the downstream effectors of tuberin, and high ERK activity may contribute to the disrupted growth signaling pathways caused by the loss of tuberin. Indeed, all three cell lines exhibit five fold higher ERK activity than untreated kidney epithelial cell lines. The results suggest that the Tsc-2 tumor suppressor gene is a target for TGHQ-mediated transformation. Moreover, inactivation of Tsc-2 by TGHQ appears to disrupt growth related signaling pathways via up-regulation of ERK activity. (GM39338, ES07784).

138 EFFECT OF DIETARY EXPOSURE OF 2,4,6-TRINIROTOLUENE (TNT) ON BIOCHEMICAL PARAMETERS IN NORTHERN BOBWHITE QUAILS (*COLINUS VIRGINIANUS*).

J. K. Vodela[1], R. M. Gogal[2], M. S. Johnson[3], G. J. Leach[3] and G. Reddy[3]. [1]*Dynamac Corporation Environmental Services, Aberdeen Proving Ground, Edgewood, MD,* [2]*Virginia Polytechnic Institute & State University, Blacksburg, VA and* [3]*US Army CHPPM, Aberdeen Proving Ground, MD.*

The widespread military use, manufacturing, loading, assembly and processing of TNT has resulted in regional contamination of soil, water and sediment at certain Army installations and waste disposal sites. This contamination has the potential of negatively impacting the wildlife. Currently, there are no toxicity data in birds to assess the ecological risk associated with the exposure to TNT. To address this issue, male and female birds weighing about 250-300 g (26-weeks) were fed on a diet containing 1047, 1660 and 2630 ppm TNT for 14 days, for which the calculated average consumed doses were approximately 75, 97 and 163 mg/kg/day, respectively. Upon completion of the feeding trial, liver samples were obtained and analyzed for microsomal cytochrome P450 and b5 content and the cytosolic glutathione antioxidant system. Dietary exposure of TNT in quail resulted in a significant increase in oxidized glutathione content in the 1660 and 2630 ppm diets, and a decrease in glutathione peroxidase activity in the 2630 ppm diet. However, there were no significant differences in reduced glutathione content, glutathione reductase and glutathione transferase activity or in cytochrome P-450 and b5 content. Results from this study show that none of the observed minimal treatment related changes had any toxicity relevance either on the glutathione antioxidant system or mixed-function oxidase components in birds. Therefore, these biochemical parameters may not be sensitive indicators for TNT exposure in birds. (Abstract does not reflect US Army policy).

139 DETERMINING OXIDIZED AND REDUCED GLUTATHIONE USING THE FLUOROMETRIC PROBE O-PHTHALALDEHYDE.

A. P. Senft, T. P. Dalton and H. G. Shertzer. *Department of Environmental Health and Center for Environmental Genetics, University of Cincinnati Medical Center, Cincinnati, OH.*

Due to the importance of GSH and GSSG in cellular signal transduction, gene regulation, redox regulation and biochemical homeostasis, accurate determination of cellular glutathione levels is critical. Several procedures have been developed, but many suffer from overestimating GSSG or from cellular substances interfering or competing with GSH determination. Assays based on HPLC, with enzymatic reduction of GSSG by glutathione reductase and NADPH appears to be valid, but are limited in sample throughput and availability of equipment. The fluorescence probe o-phthalaldehyde (OPA, phthalic dicarboxaldehyde) is semi-specific for GSH and has a high quantum yield, yet its use has been limited due to unidentified interfering and fluorescence quenching substances in liver. Assay conditions have been developed under which these limitations are avoided. By using a phosphate-buffered assay at lower pH, interference with non-specific reactants is minimal. Since enzymatic reduction is not possible due to the reaction of OPA with NAD(P)H, dithionite was used to reduce GSSG. Other stronger reducing agents lead to an overestimation of GSSG levels. High sample throughput combined with sensitive (20 pmol limit of detection) and accurate determination GSH and GSSG using OPA are achievable using any monochromatographic spectrofluorometer. Sample preparation and storage conditions are described that return the same levels of GSH and GSSG for at least 4 weeks. (Supported by NIH RO1-AG09235 and P30-ES06096.)

140 FLUORESCENCE-BASED ASSAY FOR GLUTAMATE-CYSTEINE LIGASE ACTIVITY IN MICROTITER PLATES.

C. C. White, H. A. Viernes, C. M. Krejsa, D. Neil and T. J. Kavanagh. *University of Washington, Seattle, WA.*

Glutamate-L-cysteine ligase (GLCL; also known as g-glutamylcysteine synthetase) is the rate limiting enzyme in glutathione (GSH) synthesis. Traditional assays for the activity of this enzyme are based either on coupled reactions with other enzymes, or on high performance liquid chromatography (HPLC) assessment of glutamylcysteine (GC) product formation. We took advantage of the reaction of naphthalene dicarboxaldehyde (NDA) with GSH or GC to form cyclized products that are highly fluorescent. Hepa-1 cells which were designed to overexpress mouse GLCL were used to evaluate and compare the utility of the NDA method with our standard assay based on

monobromobimane derivitization and HPLC analysis with fluorescence detection. Cell lysates from CR17 cells (overexpress both the catalytic and regulatory subunits of GLCL) and Hepa-V cells (contain plasmid vector alone) were incubated in reaction buffer and the resulting products were derivitized with either MBB for HPLC analysis, or with NDA for microplate reader analysis. Microplates were assessed for fluorescence of the NDA-GC + NDA-GSH adducts using a laser scanning cytometer. Good agreement was found between GLCL activities measured by MBB-HPLC and NDA microtiter analyses. However, high background GSH levels can limit the sensitivity of the assay, and in these cases, prior dialysis of cell lysates greatly improved the signal to noise. This assay should be useful for high-throughput GLCL activity analsyses. (Supported by NIH grants ES04696, ES07033, ES07032 and CA74184.)

141 QUANTITATION OF MOUSE GLCL-R AND GLCL-C MRNA AND OTHER GLUTATHIONE-RELATED ENZYMES USING FLUOROGENIC 5' NUCLEASE ASSAYS.

C. L. Keener, S. D. Quigley, D. Diaz-Lopez, F. M. Farin and T. Kavanagh. *Center for Ecogenetics and Environmental Health, Department of Environmental Health, University of Washington, Seattle, WA.*

Fluorogenic quantitation methods are becoming more important for completion of large-scale molecular studies. An ideal mRNA quantitation assay should be efficient, economical, automatable, and consistent with traditional Northern blot data. We have developed real-time fluorogenic 5' nuclease assays to quantitate mRNA expression levels of glutamate-cysteine ligase regulatory (GLCL-R) and catalytic (GLCL-C) subunits in mouse tissues. This fluorogenic assay employs 96-well microtiter plates that references the quantitation to a high expressing reference sample standard curve, and normalizes to GAPDH expression. Specific PCR primers and the fluorogenic probe were designed using PrimerExpressTM. The probe contains a fluorogenic reporter dye (6-FAM) on its 5' end, a quencher dye (TAMRA) on its 3' end. The probe is 100% homologous to the intron/exon boundary of the cDNA which was determined by sequence analysis from a genomic clone of GLCL-R. Our results corresponded to mRNA measurements derived from Northern blot data examining tissues from a case control study of mice exposed to methyl mercury. This procedure allows for precise quantitation of mRNA through real-time analyses of PCR amplification of cDNA. In addition, these types of assays are highly specific, non-radioactive, and cost-effective. Other assays are being developed for the quantitation of mouse glutathione reductase, glutathione peroxidase, glutathione synthetase, gamma-glutamyltransferase, and glutathione S-transferase genes. (Supported by NIEHS Center ES-07033 and ES-04696.)

142 FORMATION AND EXPORT OF THE GLUTATHIONE CONJUGATE OF 4-HYDROXYNONENAL (4-HNE) IN FRESHLY ISOLATED HEPATOCYTES.

J. F. Reichard, V. Vasiliou and D. R. Peterson. *University of Colorado Health Sciences Center, Denver, CO.* Sponsor:

Excessive alcohol consumption, iron overload and chlorinated hydrocarbons are believed to produce chronic hepatic liver injury as a consequence of uncontrolled membrane lipid peroxidation. The peroxidative destruction of polyunsaturated membrane lipids produces α-β unsaturated aldehydes including 4-hydroxynonenal (4-HNE). Aldehydic lipid peroxidation products readily form covalent adducts with cellular nucleophiles and accumulation produces diverse cytotoxic effects. Consequently, a number of enzyme systems have been characterized that detoxify these reactive aldehydes. Previous studies from our laboratory have characterized the hepatocellular capacity to oxidize, reduce and conjugate 4-HNE in suspensions of freshly isolated rat hepatocytes. Further, hepatoma cells have also been shown to rapidly conjugate and export the 4-HNE– glutathione (4-HNE– SG) adduct. In the current studies, suspensions of freshly isolated hepatocytes (10^6 cells/ml) were incubated with either low (25 μM) or high (250 μM) concentrations of 4-HNE and the formation of metabolites, including the 4-HNE– SG conjugate, quantified in the intra-and extracellular fractions by reverse-phase HPLC. Kinetic parameters of 4-HNE– SG formation and export were determined, as was the export of the reduced and oxidized metabolites. These studies demonstrate that suspensions of freshly isolated hepatocytes (10^6 cells/ml) rapidly eliminate 4-HNE. 4-Hydroxynonenoic acid (HNA), the oxidized metabolite of 4-HNE that is produced by aldehyde dehydrogenase (ALDH) appeared rapidly in the intracellular fraction and was rapidly exported. The glutathione S-transferase (GST) mediated conjugate, 4-HNE– SG, rapidly reached maximal intracellular concentrations and was eliminated by export to the extracellular fraction. Taken together these data demonstrate that oxidative and conjugative pathways are primarily responsible for elimination of 4-HNE in freshly isolated hepatocytes and that the metabolites are rapidly exported out of the cell. Further, transport of HNA and 4-HNE– SG appears to be an active process since both metabolites are exported against the concentration gradient. (Supported by NIH/NIAAH-09300.)

143 IMMUNOHISTOCHEMICAL STAINING OF LEAD BINDING PROTEIN IN HUMAN KIDNEY SECTIONS.

M. M. Schaekel[1], B. A. Fowler[1], E. F. Madden[1], M. M. Akkerman[1], S. Papciak[2] and S. Broedel[2]. [1]*Toxicology Program, University of Maryland, Baltimore, MD and* [2]*Athena Environmental Sciences, Inc., University of Maryland, Baltimore County, Tech. Enterprise Ctr., Baltimore, MD.*

Lead poisoning is a global problem that affects millions of persons. A number of studies have shown that individuals vary greatly in their susceptibility to lead toxicity suggesting intrinsic differences in the *in vivo* handling of this metal. Studies from this laboratory have demonstrated the presence of target tissue-specific lead-binding proteins (PbBP) in humans and other species. These proteins appear to markedly influence the intracellular bioavailability of Pb to sensitive cellular processes such as the heme biosynthetic and the renal gene expression pathways. The present studies were undertaken to examine the cellular distribution of diazepam binding inhibitor, one of the human PbBPs in renal tissue. To achieve this objective, polyclonal antibodies were prepared and purified from the serum of rabbits exposed to human PbBP. Immunohistochemical techniques were utilized to delineate which cell types in human kidney tissue contain the highest PbBP concentration. PbBP was detected in the cytoplasm of most of the proximal tubular cells of human kidney tissues. (Supported in part by USPHS training grant ES07299-05.)

144 CHRONIC POSTNATAL EXPOSURE TO LEAD (Pb) SIGNIFICANTLY ALTERS SERUM LEVELS OF TT4 AND TT3 IN RATS.

Q. Zhao, G. Tsao and W. Zheng. *Division of Environmental Health Sciences, Columbia University, New York, NY.*

Brain thyroxine is thought to be transported by transthyretin (TTR), a major CSF protein originated from the choroid plexus (CP). We have previously demonstrated that Pb accumulation in rat CP inhibits the synthesis and secretion of TTR. We further hypothesized that the depression of CP TTR production by Pb may impair brain development in young animals by depriving the CNS of thyroid hormones. This study was then designed to investigate thyroid hormone distribution in rat brain following postnatal Pb exposure. Male Sprague-Dawley rats, aged 21 days, were exposed to Pb in drinking water at doses of 0, 50, 100 or 250 μg Pb/ml (as Pb acetate) for 30 days. Total thyroxin (TT4) and total triiodothyronine (TT3) in frontal cortex, hippocampus, and cerebellum were partially purified by resin column and quantitated by radioimmunoassay (RIA). Serum TT4 and TT3 were determined directly by RIA. While the levels of TT4 and TT3 in tested brain regions did not seem to be significantly different in all dose groups, serum TT4 in the high-dose group (5.02±2.76SD, ng/ml) was significantly decreased compared to the controls (10.79±3.46 ng/ml) ($p<0.001$, $n=12$). Serum levels of TT3 in both mid-dose group (1.64±0.62 ng/ml) and high-dose group (1.60±0.42 ng/ml) were significantly lower than those in the control group (2.22±0.42 ng/ml) ($p<0.05$, $n=12$). The results suggest that chronic Pb exposure alters systemic homeostasis of thyroid hormones in postnatal rats. It would be interesting to know how this action may underlie Pb-induced toxicities in clinic. The study on the maternal Pb exposure and brain thyroxine status is currently under investigation. (Supported by NIEHS RO1 ES-08146.)

145 THE EFFECT OF PB^{2+} ON THE STRUCTURE AND FUNCTION OF OSTEOCALCIN.

T. L. Dowd[1], L. Mints[2], J. F. Rosen[1] and C. Gundberg[3]. [1]*Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY,* [2]*Albert Einstein College of Medicine, Bronx, NY and* [3]*Yale University School of Medicine, New Haven, CT.*

Lead toxicity is a major health problem in the U.S. Despite governmental regulations elevated blood Pb^{2+} levels have recently been found in younger children and older adults. Bone is the major reservoir of body Pb^{2+}. Lead has been shown to be detrimental to bone in studies with humans, animals and cells. The effect of Pb^{2+} at the molecular level is unknown. Osteocalcin is a noncollagenous bone protein which may play a role in bone turnover. We have used

Circular Dichroism, Nuclear Magnetic Resonance and a hydroxyapatite (bone mineral) binding assay to investigate the effect of Pb^{2+} on the structural and functional properties of osteocalcin. With circular dichroism (CD), we have shown that Pb^{2+} induces a similar percentage of a-helical structure in osteocalcin as Ca^{2+} but at 2 orders of magnitude lower concentration. To explain these results we have measured Kd's for both Pb^{2+}- and Ca^{2+}-osteocalcin using the CD titration data at physiological ionic strength. It was found that the Kd for Pb^{2+}-osteocalcin is .34uM which indicates more than 3 orders of magnitude tighter binding of Pb^{2+} than Ca^{2+} (Kd=1.25mM) to osteocalcin. The 1D NMR spectra show that much lower Pb^{2+} concentrations perturb the same resonances as Ca^{2+} indicating it binds at the same site and induces a similar conformational change but with some alterations. The hydroxyapatite binding assays show that Pb^{2+} causes an increased adsorption to hydroxyapatite, similar to Ca^{2+}, but also at 2-3 orders of magnitude lower concentration. Affinity constants for the protein-mineral complex as well as the number of sites occupied on the crystal were calculated for both Pb^{2+}- and Ca^{2+}-osteocalcin. The interaction of Pb^{2+} with osteocalcin may play a role in the observed low bone formation rates and decreased bone density observed in Pb^{2+}-intoxicated animals. Furthermore Pb^{2+} intoxication may exacerbate the bone loss observed in osteoporosis.

146 EFFECT OF ORAL SUCCIMER ON GASTROINTESTINAL LEAD ABSORPTION AND RETENTION IN MONKEYS.

J. D. Cremin, Jr.[1], M. L. Luck[2], N. K. Laughlin[2] and D. R. Smith[1]. [1]*Univ. of California, Santa Cruz, CA and* [2]*Harlow Center for Biological Psychology, University Wisconsin, Madison, WI.*

Out-patient succimer treatment of Pb-poisoned children may occur with ongoing Pb exposures, due to the scarcity of Pb-safe housing and uncertainties associated with identifying and remediating environmental exposures. The effects of succimer on the absorption and retention of Pb from exposures suffered concurrently with treatment are not well known. Here we utilized a juvenile non-human primate model of childhood Pb toxicity and a sensitive double stable Pb isotope tracer methodology to investigate the effects of oral succimer on GI Pb absorption and retention. Seventeen rhesus monkeys (*Macaca mulatta)* aged 15 months were fasted for 18h, and then dosed in rapid succession with ^{204}Pb (5 μg i.v.) and ^{206}Pb (72.6 μg orally), followed by treatment with vehicle (n=8) or succimer (n=9, 30mg/kg/day X 5 days). Blood and daily (24h) total fecal and urinary outputs were collected over treatment days -1 to 5, and analyzed for ^{204}Pb, ^{206}Pb, ^{207}Pb, and ^{208}Pb using magnetic - sector ICP-MS. Data were analyzed using an ANOVA ($P<0.05$ significance). Results indicate (i) GI Pb absorption was not measurably altered in the succimer group (51% +/- 5 SE of dose) compared to the vehicle (60% +/- 10 of dose); (ii) Succimer did significantly increase the urinary excretion of i.v. administered ^{204}Pb, but not ^{206}Pb that had been orally administered; (iii) Whole body retention of the orally administered Pb dose was not measurably different between treatments; and (iv) Succimer reduced fecal excretion of i.v. administered Pb, in favor of increased urinary excretion. Notably, only 11 and 16% (mean vehicle and control, respectively) of the i.v. ^{204}Pb dose was recovered in urine and feces over the 5 days of treatment (89 and 84% retained), while only 41and 49% of the orally administered ^{206}Pb dose was recovered (59 and 51% retained). (Supported in part by NIEHS R01 #ES06918 and F32 #ES05870.)

147 SALIVA MONITORING FOR EXPOSURE TO LEAD UTILIZING REAL-TIME MICROFLUIDICS/ ELECTROCHEMICAL ANALYSIS.

K. D. Thrall, T. S. Poet, Y. Lin, K. K. Weitz and C. Timchalk. *Pacific Northwest National Laboratory, Richland, WA.*

There is a growing need to develop reliable and portable analytical instruments for on-site monitoring of trace metals in individuals. Currently, such assays are carried out in central laboratories using separation techniques such as ion chromatography, atomic absorption spectroscopy, or inductively coupled plasma mass spectroscopy (ICP-MS). A portable microfluidics/electrochemical (MFE) system based on saliva analysis is being developed to more rapidly assess lead (Pb) levels in individuals. The MFE system detects Pb by utilizing Square Wave Anodic Stripping Voltammetry techniques. For Pb, saliva flows over an electrode surface. Pb+2 is reduced and accumulated, and the electric potential of the electrode is scanned. Results indicate a good linear response over a broad concentration range (1-200 ppb). Since the current Pb biological exposure indice (BEI) is based on measurements in blood (500 ng Pb/g blood), saliva Pb concentrations must be correlated with blood/plasma Pb concentrations. To evaluate the relationship between saliva Pb and blood Pb, F-344 rats were treated with a single oral dose of 0, 50, 100, 200, 500 or 1000 mg Pb/kg body weight, and 24 hours later were administered the muscarinic drug pilocarpine to induce salivation. Blood samples and approximately 1-2 ml of saliva were collected. Lead concentrations in saliva, whole blood, red blood cells (RBC) and plasma were quantitated by ICP-MS. A comparison of saliva Pb levels with blood Pb levels revealed a bi-phasic curve wherein the slope increased as RBC binding saturated and more Pb was available to be excreted in the saliva. The interpretation of this data indicates that a Pb level of 1 ng/g saliva corresponds with 500 ng Pb/g blood in the rat. ICP-MS analyses of the Pb samples (saliva and blood) were compared to analysis results using the portable MFE system and found to correlate well ($r2 = 0.87$). Ultimately, blood, saliva, and target tissue dosimetry will be evaluated using a physiologically based pharmacokinetic model for Pb that incorporates the salivary gland. It is anticipated that, once fully developed, this MFE device will be utilized as an important tool for real-time analyses of non-volatile environmental contaminants. (Supported by US DOE under Contract DE-AC06-76RLO 1830.)

148 BONE LEAD DRIVES CHANGE IN SERUM LEAD FROM PRENATAL TO POSTPARTUM PERIOD.

M. A. Manalo[1], S. J. Rothenberg[2], W. I. Manton[3], V. S. Kondrashov[1], R. Cuellar[1], S. Reyes[1], F. Khan[4] and A. C. Todd[4]. [1]*Drew University of Medicine and Science, Los Angeles, CA.* [2]*Drew University of Medicine and Science and National Institute of Public Health, Cuernavaca, Mexico, Los Angeles, CA,* [3]*University of Texas, Richardson, TX and* [4]*Mt. Sinai School of Medicine, New York, NY.* Sponsor: M. Soliman.

Maternal blood lead level rises significantly through the third trimester of pregnancy into the post-partum period. Investigators have noted that decreased blood volume, weight, and organ size, as well as removal of a significant sink for maternal lead, the fetus, after delivery might account for much of the increased post-partum blood lead concentration. Most (>99%) blood lead resides in erythrocytes. The remainder, found in serum, contains an unbound fraction that is likely to be the most bio-available. We measured serum lead in third trimester and post-partum by thermal ionization mass spectrometry, and *in vivo* cortical (tibia) and trabecular (calcaneus) bone lead concentration by K shell x-ray fluorescence post-partum. The range of prenatal and postnatal whole blood lead levels were 0.6-14.2 μg/dL and 0.8-25.4 μg/dL, respectively. Prenatal and postnatal serum lead ranged from 12-284 ng/L and 14-215 ng/L, respectively. Serum lead concentration was 0.22% (median) of whole blood lead level, with less than one percent of the sample showing greater than 1.0% concentration, consistent with data from other laboratories studying non-occupationally exposed groups. Tibia bone concentration ranged from -19.2 to 35.5 μg/g. Postnatal serum lead level was significantly higher than prenatal serum lead ($p<0.01$). After accounting for the highly significant correlation between change in whole blood lead pre and post delivery and change in serum lead over the same period, tibia lead concentration independently and significantly predicted increased postnatal serum lead ($p<0.01$), accounting for an additional 6% of variance in change of serum lead in a multiple regression model. There was no significant relationship between calcaneus lead and post-delivery change in serum lead level. As tibia lead has a half-life measured in decades, lead exposure years earlier can affect circulating serum lead in post-partum mothers, and thus play a role in postnatal lead exposure of nursing infants through breast milk.

149 LEAD AFFECTS FIBROBLAST PROLIFERATION AND BIOSYNTHESIS OF ARYLSULFATASE A.

X. G. Chen and R. D. Poretz. *Rutgers University, New Brunswick, NJ.* Sponsor: K. R. Cooper.

Lead exposure causes cognitive and behavioral deficits in some affected children. We had proposed that the combined effects of a single nucleotide polymorphisms (SNP) found in the human pseudodeficient arylsulfatase A (ASA) gene which results in reduced levels of the enzyme, and lead concentrations which decrease ASA activity culminate in cellular enzymic activity that is below a critical threshold required for the maintenance of normal nervous system function. Previously, we demonstrated that human fibroblasts grown in the presence of lead acetate exhibit a more than 60% decrease in steady-state levels of cellular ASA enzyme protein and that treatment of cells from individuals with the SNP(s) of pseudodeficient ASA, but not those from subjects with the normal gene, results in a significant decrease in ability of the cells to catabolize sulfatide, the substrate of ASA. The present study examines the potential of lead to affect the biosynthesis and turnover of ASA in human fibroblasts. Fibroblasts, grown in 20 μM lead, display a 30-40% increase in the rate of proliferation as determined by cell number, cellular protein and total mRNA. Metabolic labeling with 35-S-methionine demonstrates that lead

treatment causes a decrease of approximately 35% in the accumulation of newly synthesized intracellular ASA. This difference, in comparison to control cultures, is not due to differential rates of intracellular degradation of ASA or to levels of ASA specific mRNA. Though lead exposure results in increased cellular proliferation, it appears to cause decreased steady-state levels of ASA by affecting the protein translation or intracellular processing/trafficking pathways of ASA biosynthesis. (Supported in part by grants from NIEHS, R01-ES08373, and the March of Dimes Foundation.)

150 EVALUATION OF LEAD BIOKINETIC MODELS FOR ADULTS.

M. A. Maddaloni[1], M. A. Ballew[1], M. D. Johnson[1], G. A. Khoury[1], K. P. Koporec[1], P. A. Van Leeuwen[1], M. L. Stifelman[1], R. Troast[1], P. D. White[1], L. J. Zaragoza[1] and G. L. Diamond[2]. *[1]U.S. EPA, Washington, DC and [2]Syracuse Research Corporation, North Syracuse, NY.*

Responding to a need for a scientifically defensible approach for assessing human health lead risks at non-residential Superfund sites (where adults rather than children are the primary receptors), the U.S. EPA's Technical Review Workgroup for Lead (TRW) developed the Adult Lead Model (ALM) in 1996. Rather than incorporating a complex compartmental or PBPK type kinetic component, the ALM employs a simplified slope factor approach that relates lead uptake to blood lead. The need for immediate guidance limited the scope of the approach to a narrowly defined receptor population (i.e., adult worker at a commercial/industrial setting) and specific medium (i.e., soil/dust). Subsequently, the TRW committed to a more exhaustive effort to identify the most scientifically defensible methodology currently available to model non-residential lead exposures and risks. The TRW identified seven lead biokinetic models that have been used to assess the relationship between environmental lead exposures and blood lead concentration in adults. The models were evaluated and compared to the ALM based on the following general evaluation criteria: (1) completeness of exposure module, (2) kinetic performance, (3) utility of model output, and (4) ease of use and flexibility. Possible outcomes of the evaluation were: replace ALM with a superior model, modify ALM, or retain the existing ALM. Although no single model was judged to be a significant improvement over the ALM, various components from the different models were determined to be refinements in adult lead modeling. Specific model improvements included multimedia exposure modules, and highly versatile kinetic modules. Rather than invest in integrating beneficial components into a hybrid model, the TRW recommends retaining the ALM - while appreciating that certain site-specific risk assessments (e.g., short-term lead modeling) may benefit from analysis by alternative models - and supporting a research initiative to develop an all-ages biokinetic model that may adopt some of the more attractive features of existing models. It is noteworthy that the kinetic performance of the models evaluated produced similar estimates of quasi-steady-state blood lead when exposure parameters were normalized across models (i.e., all were set to approximate ALM inputs).

151 TOXICOSIS IMPACT OF LEAD ON OCCUPATIONALLY EXPOSED CHILDREN AND ADULTS.

M. M. Hussain. *Osmania University, Hyderabad, India.* Sponsor: S. M. Hussain.

27 Children and 28 Adults working as petrol sniffers, Printing Press workers and petty shop owners whose shops are stationed at the traffic junctions were chosen in this study. The workers are repeatedly exposed to lead emissions and the ambient air lead in their work environment ranged between 170-260 nanogram/cum. Blood samples from the test subjects and controls were assayed for blood lead, rbc and wbc count, haemoglobin, haemotocrit, mchc, delta aminolevulinic acid dehydratase, haemsynthatase, sgot, sgpt and bilirubin. 8 adults and 7 children showed blood lead more than 70 microgram / 100 ml blood and 50 microgram/ 100 ml blood respectively. Blood lead served reliable indicator reflecting adverse health effects. Decreased delta amino levulinic acid dehydratase was significant in all subjects. Subjects showed anemia with microcytic and hypochromic red blood cells. Reticulocytosis and basophilic stipling was also found. Genotoxicity of lead though uncommon was found in 2 adult cases as evident by scg test. 3 children showed blueish teeth, allergic dermatitis and greying of hairs. An attempt will be made to present and discuss certain markers more specific and suitable for assessing lead toxicity in occupationally exposed workers.

152 APPLICATION OF INDUCTIVELY COUPLED PLASMA MASS SPECTROMETRY TO ASSESS CELLULAR EXPOSURE TO TOXIC METALS.

S. Patierno[1], J. Singh[1], D. Pritchard[1], J. McLean[2] and A. Montaser[2]. *Departments of [1]Pharmacology, and [2]Chemistry, George Washington University, Washington, DC.*

Certain compounds of metals are implicated as environmental or occupational respiratory toxins or carcinogens. We have investigated the effects of soluble sodium chromate and particulate lead chromate in two relevant cultured cell types, normal human lung fibroblasts and normal human lung small airway epithelial cells. We have used inductively coupled plasma mass spectrometry (ICPMS) coupled with a specific method for assessing both the cellular uptake of chromium and observed in cells treated with either soluble sodium chromate or detected a dose-dependent increase in DNA-associated lead. This antioxidants such as melatonin affect the uptake and adduct formation of chromium. Whereas previous methods of assessing metal exposure often required large volumes of body fluids (such as urine or blood) and involved the use of hazardous radioactivity, the ICPMS analysis requires only microgram quantities of DNA and does not involve radioactivity. The ICPMS technique can readily be adapted to determine the exposure of humans and animals to different metals present in occupational and environmental settings. Sponsored by NIEHS grant ES05304 to S.R.P., NIEHS grant ES05844 to J.S., and USDE grant DF-FG02-93ER14320 and NSF grants CHE-9505726 and CHE-951244 to A.M.

153 TERATOGENIC EFFECT OF TRIVALENT AND HEXAVALENT CHROMIUM IN RABBITS.

O. S. El-Tawil and A. M. Morgan. *Forensic Medicine and Toxicology Department, Faculty of Veterinary Medicine, Cairo University, Giza, Egypt.*

Chromium is considered to be an essential nutrient that helps to maintain normal metabolism of glucose, cholesterol, and fat in humans. Studies in the literature indicate that hexavalent chromium (Cr-VI) is more toxic than trivalent chromium (Cr-III) as it is actively transported across the plasma membranes and is reduced via unstable reactive intermediate to Cr-III. Also, The published data indicate that exposure to Cr-VI decrease the number of viable fetuses and increase the number of dead ones. In the current investigation pregnant rabbits were exposed to Cr -III (chromium chloride) or Cr-IV (potassium dichromate) in drinking water at a dose of 500 ppm each during the organogenesis period. Exposure Cr-IV significantly increased the number of resorption sites and decreased the number of viable fetuses compared to Cr-III and control groups. Exposure to either chemicals induced dwarfism, kinky and short tails, lung hypoplasia, heart hypertrophy, intrathoracic hemorrhage and dilated nares and brain lateral ventricles. Furthermore, reduced ossification in parietal and inerparietal bones was significantly increased in the fetuses from the females exposed to Cr-VI. The results of the current investigation may indicate that both Cr-III and Cr-VI are teratogenic for the tested concentration. However, the severity of effects are higher with the exposure to Cr-VI.

154 ALLERGIC CONTACT DERMATITIS-BASED SOIL CRITERIA FOR HEXAVALENT CHROMIUM [CR(VI)].

T. Zewdie. *Massachusetts Department of Environmental Protection, Boston, MA.*

Cr(VI)-induced ACD has long been recognized as an adverse health effect in occupationally exposed people. However, such an effect from environmental exposure to chromium has not been systematically investigated nor used as an endpoint for setting soil exposure criteria. There are now data demonstrating the occurrence of ACD in people living in areas contaminated with chromium slag. Cr(VI)-induced ACD is a type IV, delayed, or cell mediated allergic reaction. Once sensitized to chromium, an individual is at risk of developing ACD whenever exposed to low concentrations of this chemical via the dermal, oral, or inhalation routes. Since the underlying mechanism for Cr(VI)-induced ACD involves the delicately balanced immune system, health-based cleanup goals for Cr(VI) in soil can be established using ACD as an endpoint. Cr(VI) has been clinically patch-tested at several varying concentrations by several groups in order to establish dose-response relationships and identify threshold concentrations. However, in all of these studies, the mass of Cr(VI) applied on a given area of skin (mg Cr(VI)/cm^2 skin) was not reported, thus prohibiting the use of these data for quantitative risk assessment purposes. A recent study based on a better dose delivery patch-test method determined the actual mass of Cr(VI) per square centimeter of skin that will illicit ACD in 10 %

of the Cr(VI) sensitized population. This applied dose (0.000089 mg/Cr (VI)/ cm^2 skin) was used with a skin soil adherence factor and a Cr(VI) dermal absorption efficiency to derive a Cr(VI) soil criteria of 175 mg Cr(VI)/kg of soil.

155 EFFECT OF SELENOCYSTINE METABOLITES ON METHIONINE ADENOSYLTRANSFERASE ACTIVITY *IN VITRO*.

T. Hasegawa[1], T. Okuno[2], K. Nakamuro[2] and Y. Seko[1]. [1]*Yamanashi Institute of Environmental Sciences, Fujiyoshida, Japan and* [2]*Faculty of Pharmaceutical Sciences, Setsunan University, Hirakata, Japan.*

Recent studies on metabolism of selenocystine (CySeSeCy) as selenium-containing amino acid showed that selenocysteine glutathione-selenenyl sulfide (CySeSG) was produced from reaction between CySeSeCy and reduced glutathione (GSH) in small intestine of mice receiving a single oral administration of CySeSeCy. In liver of animals, the CySeSG was reduced by GSH and/or glutathione reductase yielding selenocysteine, which is decomposed enzymatically to hydrogen selenide. The hydrogen selenide is subjected to sequential methylation with S-adenosylmethionine (SAM) as a mtthyl donner, resulting in the formation of mono-, di- and tri-methylated derivatives. The methylation process has been regarded as a detoxification mechanism of selenium compound. Our previous studies demonstrated that selenium methylation ability was depressed by inactivation of methionine adenosyltransferase, SAM synthesizing enzyme, in mice after repeated oral administration of CySeSeCy at a toxic dose. This study was carried out to elucidate a chemical form of selenium-containing metabolite which inhibited the methionine adenosyltransferase activity. Selenium-containing metabolite (CySeSeCy, CySeSG, sodium selenide, monomethylselenol, dimethyl selenide or trimethylselenonium ion) was incubated with liver cytosol supplemented methionine and ATP for 20 min, and SAM content was measured using HPLC method. The methionine adenosyltransferase activity was strongly inhibited by sodium selenide. In addition, inactivation of the enzyme was recovered by addition of a large amount of dithiothreitol. These results suggest that the selenide produced from CySeSeCy at a toxic level inhibits the methionine adenosyltransferase activity.

156 EFFECTS OF INORGANIC AND ORGANIC SELENIUM ON CYTOKINE PRODUCTION AFTER CONTINUOUS SHORT-TERM ORAL EXPOSURE IN MICE.

V. J. Johnson, M. Tsunoda and R. P. Sharma. *The University of Georgia, Athens, GA.*

Selenium (Se) is an essential as well as a toxic trace element. The immune system is a target of Se intoxication. We compared the effects of inorganic and organic forms of Se on the murine immune system following a short-term oral exposure. Male BALB/c mice, 6-7 weeks of age were continuously exposed to 0, 1, 3 or 9 ppm of Se as sodium selenite or seleno-L-methionine in the drinking water for 14 days. Following the treatment period mice were euthanized, trunk blood collected and spleen, thymus, liver and kidney were aseptically removed and weighed. Exposure to 9 ppm of Se as sodium selenite resulted in a marked decrease in body weight gain and relative organ weights. The thymus was significantly reduced in the 3 ppm of sodium selenite group. Sodium selenite at 9 ppm of Se reduced splenic cellularity and increased erythrocyte counts. The basal rate of splenocyte proliferation was increased in this group. Sodium selenite induced a dose-dependent increase in phytohemagglutinin-P-induced lymphocyte proliferation. Sodium selenite at 9 ppm of Se increased the production of pro-inflammatory cytokines, tumor necrosis factor α and interleukin-1β, in lipopolysaccharide-stimulated splenic macrophages. Seleno-L-methionine in drinking water did not produce any changes in the parameters examined. Results indicated a disparity in the immune system toxicity of inorganic vs. organic forms of Se administered via drinking water, inorganic Se being more toxic. Additionally, this study suggests that splenic macrophages and lymphocytes are targets of Se intoxication.

157 PULMONARY RESPONSES OF RATS IN VIVO AND IN VITRO FOLLOWING EXPOSURE TO VANADIUM PENTOXIDE.

K. M. Lee, K. H. Debban, D. L. Redetzke, L. A. Wisse, C. O. Romsos and R. A. Miller. *Battelle, Richland, WA.*

This study was to characterize the acute pulmonary responses of male F344 rats to vanadium pentoxide (V_2O_5) *in vivo* or *in vitro*. For *in vivo* exposure, rats (bw; 200-250g; n of 6/dose) were intratracheally instilled with V_2O_5 (0, 0.63, or 6.3 mgV/kg; 1mL/kg in saline). On days 1 and 3, the bronchoalveolar lavage (BAL; ~7 ml/wash) was performed. The BAL fluid from the first wash (BALF) was analyzed for LDH, NAG, protein, and cytokines (TNF-α, IL-6, and MIP-2). Cell pellets from all six washes were combined for cytological evaluation. The cells were resuspended and incubated (37°C, 95% RH, 5% CO_2) with endotoxin (LPS) *ex vivo* for 24 hrs. For *in vitro* exposure, BAL were performed on naïve rats (bw; 200-250g; n of 3/dose), the cell pellets were incubated with V_2O_5 (0, 1, 5, 25, and 125 µgV/ml; in RPMI 1640). At 2 and 24 hrs, culture medium was recovered and analyzed for LDH and cytokines. At 2 hrs, the cells were incubated with LPS for additional 24 hrs. Following instillation, increased lung weights and acute pulmonary inflammation were observed in a dose- and time-dependent manner. Concentrations of LDH, NAG, and protein increased in BALF from the high dose group up to day 3. The MIP-2 in BALF was highly responsive to vanadium exposure, whereas TNF-α was not. An increase in IL-6 was noted in BALF from the high dose on day 1. Following *in vitro* exposure, all three cytokines in the culture medium decreased in a dose-dependent manner at 2 hrs with minimal LDH leakage. When stimulated with LPS, the overall levels were increased but the relative reduction in cytokines persisted. Therefore, while vanadium exposure *in vivo* caused a clear acute inflammatory responses in the lungs accompanied by increases in enzymes and cytokines, vanadium *in vitro* appeared to suppress cytokine releases. The discrepancy between *in vivo* and *in vitro* cytokine responses was speculated to be related to differences in the microenvironments where vanadium particles interact with various cells involved.

158 THE ASSOCIATION BETWEEN GENETIC POLYMORPHISMS OF COPROPORPHYRINOGEN OXIDASE (CPOX) AND AN ATYPICAL PORPHYRINOGENIC RESPONSE TO MERCURY.

S. L. Srinouanprachanh, F. M. Farin, C. L. Keener, P. L. Simmonds and J. S. Woods. *University of Washington, Seattle, WA.*

Mercury (Hg) exposure poses a high risk of toxicity to humans. Previous studies have documented the efficacy of urinary porphyrin profile changes as a biomarker of low-level Hg exposure in human subjects and have defined the etiology of this effect as Hg-inhibition of the heme enzymes uroporphyrinogen decarboxylase and CPOX in the kidney. The objective of this study was to define the potential association between polymorphisms in the CPOX gene and an atypical porphyrinogenic response (APR) to Hg, characterized by excessively high urinary porphyrin excretion irrespective of level of Hg exposure, that is seen in 12-16% of Hg-exposed subjects. Automated DNA sequencing-based assays were developed to examine the 7 exons and flanking intron-exon boundries of the human CPOX gene in subjects with low-level occupational exposure to Hg as Hgo (mean urinary Hg=3.4 + 2.2 µg/l). Genetic analysis of exon 1 revealed a possible C39A encoding a cysteine to a termination codon change in 3 of 17 subjects. This change was not associated with the APR. In contrast, a polymorphism in exon 4 encoding a N272H substitution was found in 4 of 6 APR subjects in this group (mean urinary porphyins=129.6. + 38.2 µg/l vs. non-APR porphyrins=32.4 + 18 µg/l). Analysis of exon 5 revealed possible genetic polymorphisms that were also potentially associated with the APR to Hg. These findings indicate a possible genetic predisposition to an altered biological response to Hg that could affect Hg disposition and health risks. The APR might therefore serve as a biomarker of susceptibility to Hg toxicity. (Supported by ES04696 and ES07033.)

159 SPERMATOTOXICITY OF MERCURIC CHLORIDE IN RATS.

K. Ali, A. Atkinson, A. Khan, T. Graham and T. Bain. *Tuskegee University, College of Veterinary Medicine, Nursing & Allied Health, Tuskegee, AL.*
Sponsor: R. R. Dalvi.

Recently, we demonstrated in a reproductive and fertility study that mercuric chloride causes a dose dependent decrease in fertility, viability, pups per litter, and weaning indices in F_0 generation rats. The present study was undertaken to investigate the dose response and time course of alterations in semen quality. Samples were evaluated with a Hamilton-Thorne Toxicology Semen Analyzer (H-TTSA). Male rats were gavaged daily with 0.0, 0.5,1.0, and 1.5

mg $HgCl_2$/kg/day for up to 84 days. Interim measurements of semen quality were made at 14, 28, 56, and 84 days. Motile sperm percentages (MSP) were decreased in a dose dependent manner on Day 56. Also, MSP in the high dose group was significantly decreased when compared with the control on Day 56, and Day 84. Progressive motility was significantly decreased in the highest dose on Day 84. The parameters that described vigor of swimming sperm such as average path velocity (VAP), curvilinear velocity (VCL), and straight linear velocity (VSL) were significantly decreased in the mid and high treatment groups on Day 28. However, the parameters that described the sperm pattern such as lateral head displacement (ALH), beat cross frequency (BCF), and linearity (LIN) showed no dose response. The experimental results presented in this study suggest that mercuric chloride exposure in rats leads to significant reduction in motility and some velocity parameters. Therefore, reduction in reproductive and fertility indices in rats exposed to mercuric chloride may be related to alterations in semen quality.

160 DISTRIBUTION AND RETENTION OF MERCURY IN METALLOTHIONEIN-NULL MICE AFTER EXPOSURE TO MERCURY VAPOR.

M. Yoshida[1], M. Satoh[2], A. Yasutake[3], A. Shimada[4], Y. Sumi[1] and C. Tohyama[2]. [1]*St. Marianna University School of Medicine, Kawasaki, Japan.* [2]*National Institute for Environmental Studies, Tsukuba, Japan,* [3]*National Institute for Minamata Disease, Minamata, Japan and* [4]*Tottori University, Tottori, Japan.*

We studied the role of metallothionein (MT) in the distribution and retention of mercury in the brain, lung, liver and kidney of MT-null and wild-type mice after exposure to mercury (Hg)vapor. Mice were exposed to Hg vapor at 5.5 to 6.7 mg/cu m for 3 h and killed at 1, 24, 72, or 168 h after exposure. One hour after exposure to Hg vapor, there were no differences in mercury concentrations in these organs from MT-null and wild-type mice. However, the elimination rate of mercury from the organs, except the brain, were remarkably faster in MT-null mice than in wild-type mice. MT-I and -II levels in the lung and kidney were significantly increased in wild-type mice but not in MT-null mice at 24 h after exposure to Hg vapor. At this time point, over 65% of the mercury was retained in the MT fraction of the cytosol of organs from wild-type mice. In contrast, mercury appeared mainly in the high-molecular-weight protein fractions in the cytosol of organs from MT-null mice. In the brain, a large amount of mercury was bound to MT in both strains of mice immediately after exposure. No difference was observed in the elimination rate of mercury from brain between both strains of mice. Brain MT levels were elevated slightly in wild-type mice at 168 h after exposure but could not be detected in MT-null mice. These data suggest that no detectable MT-I and -II levels were found in the brains of MT-null mice and that mercury was apparently bound to MT-III. Using MT-null mice, we also showed that MT-III may play an important role in the retention of mercury in the brain.

161 ROLE OF GLUTATHIONE AND METALLOTHIONEIN IN RENAL TOXICITY OF INORGANIC MERCURY.

M. Satoh[1], A. Shimada[2], B. Zhang[1] and C. Tohyama[1]. [1]*National Institute for Environmental Studies, Tsukuba, Japan and* [2]*Tottori University, Tottori-shi, Japan.*

We examined the sensitivity of GSH-depleted MT-null mice to the renal toxicity of inorganic mercury. Eight-week-old male MT-null mice and wild-type mice were given s.c. injection of mercuric chloride (1.0 or 30 umol/kg). L-Buthionine-SR-sulfoximine (BSO, 2.5 mmol/kg), an inhibitor of GSH synthesis, was s.c. administered to these mice at 4 h prior to the mercury injection. Blood and kidney were removed from each mouse under ether anesthesia, at 24 h after the mercury injection. Blood urea nitrogen and creatinine values in the serum, and histopathological change in the kidney were utilized as indicators of renal toxicity. Injection of mercuric chloride at dose of 30 umol/kg did not induce the kidney damage in the wild-type mice. In the MT-null mice, the renal toxicity was induced by injection of a mercury dose of 30 umol/kg but not at 1.0 umol/kg. When renal GSH level was reduced by BSO pretreatment in the both strains of mice, injection of mercuric chloride at a dose of 1.0 umol/kg caused the kidney damage in the both strains of mice, and the nephrotoxicity was much severer in the MT-null mice than in the wild-type mice. In the present study, we found that GSH and MT play cooperatively an important role in detoxification of severe kidney damage caused by inorganic mercury. In addition, GSH may act as a primary protective factor against inorganic mercury-caused nephrotoxicity, because GSH-depleted mice were more sensitive to inorganic mercury than MT-null mice.

162 METHYLMERCURY'S EFFECTS ON MITOCHONDRIAL DNA IN DEVELOPING RODENT MIDBRAIN.

S. Lu, T. Kavanagh and E. M. Faustman. *University of Washington, Seattle, WA.*

Mitochondrial DNA damage is a significant target of oxidative stressors and has been shown to be more extensive and persists longer than nuclear DNA damage. Mitochondrial DNA damage leads to impaired electron transport chain function and results in decreased ATP production and formation of oxidative oxygen species (ROS). This can cause further damage to mitochondrial DNA, proteins and lipids and lead to opening of mitochondrial permeability transition pore and apoptosis. Research has shown that MeHg can induce formation of ROS by disrupting electron transport chain. In our present study, Extra-long PCR (XL-PCR) methods were conducted using two different DNA polymerases and in combination with automatic hot start techniques to detect mitochondrial DNA damage. Our results show that the amplification of a 5.7kb mtDNA fragment was decreased in MeHg-exposed primary rat embryonic CNS cells with a dose-response relationship over 0, 1, and 2 μM MeHg. This result suggests that MeHg induced mtDNA damage in rat embryonic CNS cells. However, in the rat kidney, exposure to 10 mM MeHg *in vivo*, the amplification of the 5.7kb mtDNA fragment was increased. Such an increase in mtDNA following *in vivo* MeHg exposure may result from changed mitochondrial replication as has been shown that MeHg induced a dose-response related increase in mitochondrial numbers in our preliminary studies. Further studies will detect the specific oxidative mtDNA damage (mutations, deletions) following MeHg exposure in primary rat embryonic CNS cells and relate these to MeHg's effects on cell kinetics and viability. (This research was supported by US EPA grant R825358.)

163 METHYLMERCURY-INDUCED APOPTOSIS IN NEURONAL AND NONNEURONAL CELL LINES THROUGH MICROTUBULAR DISRUPTION.

K. Miura[1], N. Koide[2], S. Himeno[2], I. Nakagawa[2] and N. Imura[2]. [1]*Wako University, Kitasato University, Tokyo, Japan and* [2]*Kitasato University, Tokyo, Japan.*

Methylmercury (MeHg) is known to interfere with cell cycle progression by disruption of microtubules. Depression of cell growth by MeHg eventually leads to cell death. Several studies have demonstrated MeHg-induced apoptosis, but the underlying mechanism has not yet been fully understood. In the present study, the relationship between the changes in cell cycle and the induction of apoptosis caused by MeHg was investigated in cultured mammalian cells. MeHg at growth inhibiting concentraions (3 to 5 microM) caused nuclear fragmentation and DNA ladder formation in rat pheochromocytoma (PC12) and mouse neuroblastoma cells exposed to MeHg for 48 h. Flow cytometric analysis revealed that the occurrence of apoptosis was preceded by the accumulation of cells in G2/M-phase after MeHg treatment. Exposure to colchicine, a well-characterized microtubule disruptor, also caused G2/M-phase arrest followed by the appearance of apoptotic cells. These results suggest that G2/M-phase arrest through the disruption of microtubules is an important event in the development of apoptosis by MeHg. Similarly, MeHg treatment led to G2/M-phase arrest followed by apoptosis in nonneuronal HeLa cells. p53 expression was not changed in either cell line. However, bcl-2 was phosphorylated by MeHg treatment in HeLa cells but not in PC12 cells. Thus, MeHg induces apoptosis via a p53-independent pathway in both cell lines, but different pathways may be activated after the disruption of microtubules in PC12 and HeLa cells.

164 ESTIMATION OF ALUMINUM BIOAVAILABILITY FROM DEGRADABLE CHAFF COUNTERMEASURES USING A PHYSIOLOGICALLY-BASED EXTRACTION TEST.

C. L. Wilson[1], H. M. Zhang[2], K. Lehman[1], T. Carpenter[1] and W. K. Alexander[1]. [1]*Naval Health Research Center Detachment (Toxicology), Wright-Patterson AFB, OH and* [2]*ManTech Environmental Technology, Inc., Wright-Patterson AFB, OH.*

Aluminum is the third most abundant element on earth and comprises roughly 8% of earth's crust. Few adverse human health effects resulting from aluminum exposure have been reported largely because this element is poorly absorbed from the human gastrointestinal tract. Aluminum has been implicated in the etiology of at least one neurodegenerative disease, although data supporting this hypothesis are inconclusive. United States military aircraft use aluminized glass chaff as a passive countermeasure to radar-guided threats. In an effort to assist in human health and ecological risk assessment of the geo-

graphical areas over which chaff is deployed, current studies are evaluating the effects of exposure to aluminized chaff. Results from an *in vitro* physiologically-based extraction test predict that intestinal absorption of aluminum derived from ingested chaff is minimal (5-10% bioaccessible). Validation of this experimental approach *in vivo* has been described elsewhere for both lead and arsenic and current efforts focus on validation of the technique for ingested aluminum. Preliminary results in male Fischer-344 rats dosed with aluminum lactate, aluminum hydroxide, or one of five different forms of chaff for five consecutive days suggest that aluminum from chaff is minimally absorbed via the gastrointestinal tract, as determined by blood and urine total aluminum concentration. No significant differences in body or organ weights were observed between control animals and animals dosed with any form of chaff. Results will be discussed within the context of application of the physiologically-based extraction test in human exposure assessment. Funding sponsor: Naval Air Warfare Center, Aircraft Division, Patuxent River, MD.

165 BRAIN ALUMINUM CLEARANCE IS SLOW.

R. A. Yokel[1], S. S. Rhineheimer[2], P. Sharma[3], D. Elmore[3] and P. J. McNamara[1]. [1]*College of Pharmacy and Graduate Center for Toxicology, University of Kentucky, Lexington, KY.* [2]*College of Pharmacy, University of Kentucky, Lexington, KY and* [3]*PRIME Lab, Department of Physics, Purdue University, W. Lafayette, IN.*

Objectives: To estimate the percentage of Al that enters the brain from the primary Al species in plasma (Al•transferrin, Al•Tf) and the duration of Al residence in the brain. **Experimental procedures:** Fischer 344 rats were given 1 ml of a ^{26}Al•Tf complex containing 14.9 ng (0.57 nmol) ^{26}Al bound to 37 nmol Tf. This was given i.v. over 1 h. Controls received identical treatment without ^{26}Al. Subjects received either saline or 0.15 mmol/kg desferrioxamine (DFO) thrice weekly i.p. beginning 1 day after the Al•Tf. Saline-injected subjects were terminated 1, 4, 16 and 32 days, whereas DFO-injected subjects were terminated 4, 16 and 32 days after ^{26}Al•Tf. Brain ^{26}Al was determined by accelerator mass spectrometry. **Results:** Approximately 0.007% of the ^{26}Al dose was in the brain 1 day after ^{26}Al•Tf. In the absence of DFO treatments, brain ^{26}Al concentration decreased by 30% from day 16 to 32. DFO treatments decreased brain ^{26}Al concentration 18 and 12% on days 16 and 32 when compared to that seen following saline treatments. **Discussion:** These results are consistent with previous studies suggesting that a small fraction of Al in blood is able to enter and be retained by the brain. Calculations suggest this Al could have entered the brain by transferrin receptor-mediated endocytosis. Al appears to be stored in a relatively non-mobile compartment in the brain within 1 day of brain entry, from which Al is slowly cleared. The small effect of DFO is consistent with the necessity of prolonged DFO therapy to significantly reduce Al-induced encephalopathy. These studies are being continued to better estimate the half-life of Al in the brain in the absence and presence of DFO treatment. (Supported by US-EPA R 825357.)

166 ALUMINUM BIOAVAILABILITY FROM DRINKING WATER IS NOT INFLUENCED BY STOMACH CONTENTS OR WATER HARDNESS.

P. J. McNamara[1], S. S. Rhineheimer[2], R. D. Brauer[2], P. Sharma[3], D. Elmore[3] and R. A. Yokel[1]. [1]*College of Pharmacy and Graduate Center for Toxicology, University of Kentucky, Lexington, KY.* [2]*College of Pharmacy, University of Kentucky, Lexington, KY and* [3]*PRIME Lab, Department of Physics, Purdue University, W. Lafayette, IN.*

Objectives: To estimate the bioavailability of Al from drinking water and the effects of water hardness and food in the stomach on this measure. **Experimental procedures:** Fischer 344 rats were acclimated to consumption 10 h/day of a 10% protein diet. This resulted in no appreciable stomach contents 14 h after diet and water removal when coprophagy was prevented by a fecal collection cup. All subjects had access to 2 ml of drinking water for 2 h. In a two × two design with n=5/group, subjects then had 2 h access to 0 or 1 g food prior to gastric (i.g.) administration of 50 ng ^{26}Al in soft water ($CaCO_3$ equivalent < 10 mg/l) or hard water ($CaCO_3$ equivalent 300 mg/l). All rats received a continuous i.v. infusion of 447 µg ^{27}Al/kg/hr, as $AlK(SO_4)_2$, from 2 h prior to 120 h after i.g. dosing. Blood was repeatedly obtained up to 120 h after i.g. dosing and analyzed to determine plasma ^{26}Al by accelerator mass spectrometry and ^{27}Al by electrothermal atomic absorption spectroscopy. Oral Al bioavailability was determined from the $AUC_{i.g.\ Al}/AUC_{i.v.\ Al} \times dose_{i.v.\ Al}/dose_{i.g.\ Al}$. The term $dose_{i.v.\ Al}/AUC_{i.v.\ Al}$ was replaced by the equivalent term clearance (Cl_s) which was determined from the ^{27}Al infusion rate/plasma ^{27}Al concentration. Therefore, oral Al bioavailability was determined in a model of drinking water consumption utilizing a physiologically-relevant oral Al dose and concurrent administration of two Al isotopes. **Results:** Overall bioavailability of Al averaged 1.5%. This was not significantly influenced by the presence of food in the stomach or high $CaCO_3$ concentration in the water. **Discussion:** The estimated oral bioavailability of Al from drinking water is higher than most reported estimates. Al bioavailability from drinking water appears to be independent of stomach contents or water hardness. (Supported by US-EPA R 825357.)

167 IRON-INDUCED HEPATOTOXICITY: EFFECTS ON NUCLEAR CALCIUM CONCENTRATION AND DNA FRAGMENTATION.

L. M. Milchak and J. D. Bricker. *Duquesne University, Pittsburgh, PA.*

Although it is well known that iron overdose can produce hepatotoxicity, the exact mechanism of cell death has yet to be determined. Previous research has suggested that the mechanism of iron toxicity involves an increase in nuclear calcium and an increase in DNA fragmentation. This study was performed to examine the time course of iron-induced DNA fragmentation and nuclear calcium disruption and also to examine methods of protecting against cytotoxicity. The study was performed using hepatocytes isolated from male Sprague-Dawley rats. Incubation of hepatocyte cultures with ferrous sulfate (3 µM or 5 µM) over the course of 20 hours produced concentration-dependent decreases in cell viability, as measured by Lactate Dehydrogenase (LDH) release and concentration-dependent increases in nuclear calcium concentrations, as measured by o-cresolphthalein complexation. DNA fragmentation was also shown to be increased in the hepatocytes as measured by agarose gel electrophoresis and by using an Enzyme-Linked Immunosorbent Assay (ELISA) for the detection of 5-Bromo-2-Deoxy-Uridine (Brd-U) labeled end fragments. Nuclear calcium levels and DNA fragmentation became elevated at approximately four hours into the incubation and cell viability became significantly lower at eight hours. Verapamil (25 µM), a calcium channel blocker, and 80 µM Aurinetricarboxylic acid (ATA), an endonuclease inhibitor, offered significant protection against iron-induced loss of viability and lessened DNA fragmentation. Verapamil decreased nuclear calcium accumulation while ATA did not. These results suggest that iron-induced hepatotoxicity may be mediated by increases in nuclear calcium, perhaps through the activation of calcium-dependent endonucleases resulting in DNA fragmentation and ultimately cell death.

168 PCR CLONING AND FUNCTIONAL CHARACTERIZATION OF ZEBRAFISH METALLOTHIONEIN GENE PROMOTER.

H. M. C. Yan and K. M. Chan. *The Chinese University of Hong Kong, Shatin, Hong Kong Special Administrative Region of China.*

Metallothioneins (MT) are metal binding proteins that are implicated in heavy metal ion detoxification processes and their quantitations are commonly used as biomarkers for heavy metal exposure. Zebrafish is a common tropical fish model for toxicity testings and developmental biology research. We are interested in using zebrafish as a model for our MT gene expression studies. To obtain MT gene promoter from zebrafish, two gene specific reverse primers designed from a published cDNA sequence (accession X97278) were applied for promoter finding using PCR, and a 859bp zebrafish MT promoter with 4 putative metal responsive elements, 3 AP1 sites and 1 Sp1 site was amplified and cloned for nucleotide sequence determination. A zebrafish MT gene with its promoter and coding region in a total of 1773kbp was further amplified by PCR. Deletion mutants of the promoter region lacking MRE sites were linked to luciferase gene and will be subjected to functional characterization in PLHC-1 cell line. For application as biomarker model fish, zebrafish MT promoter constructs will be transfected into various cell lineages and zebrafish embryos. The recombinant cell lines and transgenic zebrafish will thus be used in metal toxicity testings.

169 INHIBITION OF RECOMBINANT HUMAN SQUALENE MONOOXYGENASE (SQUALENE EPOXIDASE) BY TELLURIUM COMPOUNDS.

B. P. Laden and T. D. Porter. *University of Kentucky, Lexington, KY.* Sponsor: M. Vore.

Tellurium is an element with a number of industrial applications, including the manufacture of semiconductors, doping of metal alloys, and vulcanization of rubber; however, little is known about its toxicology. Weanling rats fed 1% elemental tellurium develop a transient peripheral demyelination due to the inhibition of squalene monooxygenase, a microsomal enzyme in the pathway

for cholesterol biosynthesis. The active metabolite responsible for this inhibition is not known. To study the potential mechanisms of tellurium toxicity in humans, a truncated human squalene monooxygenase (HSM) was cloned, expressed and purified. We previously reported that tellurite inhibits HSM with an IC50 of 17 μM. Kinetic analysis of the tellurite inhibition shows slope-parabolic and intercept-parabolic inhibition with respect to squalene, implicating more than one binding site for tellurite. To date, a wide variety of related compounds have been tested as inhibitors: dimethyltellurium dichloride is the most potent compound tested, having an IC50 of 1.5 μM. Because tellurite has been shown to bind sulfhydryl groups we hypothesized that the compounds bind to cysteine residues in HSM. Preliminary support for this hypothesis is provided by the observation that the sulfhydryl reagents glutathione, dithiothreitol, and beta-mercaptoethanol are able to protect against as well as reverse the inhibition. The presence of seven cysteine residues in HSM is consistent with the kinetic evidence for multiple tellurite binding sites on HSM. (Supported by a grant from the Ohio Valley Affiliate of the American Heart Association, NIEHS Training Grant ES-07266, and the UK Medical Center Research Fund.)

170 METAL INTERACTION WITH PHYSICAL AND CHEMICAL AGENTS IN THE INDUCTION OF CYTOGENETIC EFFECTS IN HUMAN LYMPHOCYTES.

S. P. Katsifis. *University of Bridgeport, Bridgeport, CT.*

Chromium and Nickel are widely spread environmental contaminants and known human carcinogens. Among the most frequently used cytogenetic endpoints to identify exposure to genotoxic agents are the induction of micronuclei (MN) and the induction of sister chromatid exchanges (SCE) in human lymphocytes.Treatment of human lymphocytes with NiSO4 (1-100 mM) or UV-light (200, 1000 ergs/mm2) induced micronuclei (MN) in a dose-dependent fashion. Statistical analysis of the interaction factor (IF), showed that combined treatments of Ni(II) (1-100 mM) with UV-light (200, or 1000 ergs/mm2) interacted antagonistically for the induction of MN. Furthermore Ni(II) [0.5-10 mM] with UV-light (200 or 1000ergs/mm2) or Cr(VI) interacted antagonistically for the induction of sister chromatid exchanges (SCE), in peripheral human lymphocytes. Based on the fact that Ni(II) alters DNA replication, we studied the toxicity of nickel in relation to the cell cycle of human lymphocytes. We also devised an index of cell cycle progression (ICCP) to quantitate the effect of Ni(II) treatments on the cell cycle. There was a delay of 2.1 h for the 5 and 10 mM Ni(II) treatments and a delay of 5.3 h for the 25 mM Ni(II) treatment. These observations has raised a concern that nickel present in complex mixtures may reduce the response, even in the presence of strong MN or SCE inducers, and may lead, therefore, to an underestimate of chemical exposure as assessed by these assays. Since metals affecting certain microsteps in the process of DNA replication or repair (eg. histones, polymerases, ligases) may have similar antagonistic effects, further studies, are recommended.

171 DIFFERENTIAL ABILITY OF TRANSITIONAL METALS TO INDUCE PULMONARY INFLAMMATION.

T. M. Rice[1], R. W. Clarke[1], R. Hauser[1], J. Antonini[2], J. J. Godleski[1] and J. D. Paulauskis[1]. [1]*Harvard School of Public Health, Department of Environmental Health, Boston, MA and* [2]*NIOSH, Morgantown, WV.*

Transition metals are components of airborne particles and have been implicated in adverse health effects. Relative toxicity and inflammatory potential of these metals are usually inferred from separate studies since little directly comparable data are available. The objective of this study was to compare the pulmonary effects of intratracheally-instilled, equimolar, soluble forms of six metal sulfates. Rats received either phosphate-buffered saline, 0.1 umol/kg, or 1.0 umol/kg of vanadium, nickel, iron (II), copper, manganese, or zinc. Bronchoalveolar lavage was performed at 0, 4, 16, or 48 hrs post-installation. At the 0.1 umol/kg dose, only Cu induced significant neutrophil influx at 16 and 48 hrs ($p<0.05$). For the 1.0 umol/kg dose at 4 hrs, Cu and Fe(II)-exposed animals had a significant increase in percent neutrophils compared to saline controls, and Cu had a significantly higher percentage than all other metals. After 16 hrs, each metal tested induced significant neutrophilia compared to controls, and Cu and Mn induced significantly higher neutrophilia than the other metals. At 48 hrs, neutrophilia was still increased in all metal exposures except Fe(II). Interestingly, Mn was the only metal to induce a significant increase in eosinophils (16 hr post-instillation, $p<0.05$). Additionally, Cu and Ni-exposed rats had significantly higher levels of lactate dehydrogenase in lavage supernatant compared to the other metals and controls. These results indicate that transition metals differ in their ability to induce pulmonary inflammation and toxicity. Cu appears to be the most pro-inflammatory metal, followed by Mn and Ni, while V, Fe(II), and Zn induced similar levels of neutrophila. We conclude that the extent and cellular nature of metal-induced pulmonary inflammation depends on the individual metal. (Supported by: ES00002, HL54958, HL07118, and HL05947.)

172 CARCINOGENIC NICKEL INDUCES GENES INVOLVED WITH HYPOXIC STRESS.

K. Salnikow[1], T. Kluz[1], M. Zoruddu[2] and M. Costa[1]. [1]*New York University School of Medicine, New York, NY and* [2]*University of Sassari, Sassari, Italy.*

Carcinogenic nickel compounds altered the program of gene expression in normal cells and induced a pattern of gene expression similar to that found in nickel-induced cancers. Here we have demonstrated that exposure of mouse normal fibroblasts, or human A549 cells to 1 mM nickel induced hypoxic signaling pathways by inducing hypoxia-inducible transcription factor (HIF-1) which mediated the induction of genes required by cells to survive hypoxia. We also showed that a new gene Cap43 was dependent upon HIF-1 since only HIF-1 proficient mouse cells induced Cap43 gene expression when exposed to either hypoxia (1%O2) or 1 mM nickel. We also showed that GAPDH, a gene induced by hypoxia through HIF-1, was similar to Cap43 in that it required HIF-1 mouse proficient cells to be induced by either 1 mM nickel or hypoxia (1%O2). These data demonstrated that nickel exposure turned on signaling for a hypoxic cascade that may be important in its carcinogenesis.

173 INHIBITION OF HISTONE ACETYLATION BY NICKEL COMPOUNDS IN *S. CEREVISIAE* AND MAMMALIAN CELLS.

W. Peng, L. Broday, M. Zorrodu and M. Costa. *New York University Medical Center, Tuxedo, NY.*

Environmental factors influence carcinogenesis by interfering with a variety of cellular targets. Carcinogenic nickel compounds are inactive in most gene mutation assays, but they induce chromosomal damage in heterochromatic regions and cause gene silencing on reporter genes located near heterochromatin in both yeast and mammalian cells. Here we studied nickel effects on the acetylation in the N-terminal region of histone H4. We demonstrate that *in vivo* nickel compounds decrease histone H4 acetylation levels in both yeast and mammalian cells. The effects of nickel on the lysine residue targets in the N-terminal region of histone H4 are distinct. In both yeast and A549 cells, lysine 12 is the most sensitive residue. While in yeast the acetylation levels of lysine residues at sites 16, 8 and 5 are also affected by nickel, in A549 cells the effect is limited mostly to lysine 12. Unlike in yeast cells, where acetylation levels are reduced by soluble nickel, the acetylation in A549 cells is inhibited only by non-soluble nickel particles (nickel subsulfide). Comparison among the yeast cells treated with a variety of metals shows that CuSO4 causes similar effect on histone acetylation as nickel, while CdCl2 or CoCl2 only slightly inhibits acetylation. In vitro inhibition of H4 acetylation by nickel is also observed using a purified acetyltransferase (GCN5).

174 NICKEL COMPOUND-INDUCED TOXICITY AND MORPHOLOGICAL TRANSFORMATION IN 10T1/2 CELLS.

K. N. Thakore, A. Verma, S. Ohshima, J. Ramnath, L. Kaspin, F. Clemens and J. R. Landolph, Jr. *USC/Norris Comprehensive Cancer Center, USC, Schools of Medicine, Los Angeles, CA.*

Certain insoluble nickel compounds are carcinogenic. We wanted to determine whether short-term *in vitro* assays could predict relative carcinogenic potentials of nickel compounds. We therefore examined abilities of these compounds to be phagocytosed by and induce cytotoxicity, micronuclei, chromosomal aberrations, and morphological transformation in 10T1/2 mouse embryo fibroblasts. The overall ranking for genotoxicity showed that Ni subsulfide and Ni oxides were most genotoxic; elemental nickel particles of <1 μM reported size had intermediate genotoxicity; and elemental nickel particles of 3-7 μM reported size together with soluble nickel sulfate had the lowest overall genotoxicity. Phagocytosis of insoluble nickel compounds and cell transformation endpoints correlated best with existing animal and human carcinogenicity data. Ni subsulfide and green Ni oxide, but not soluble nickel sulfate, were carcinogenic when inhaled by rats. Interestingly, both elemental nickel particles ranked the lowest in cell transformation, together with soluble nickel sulfate. Overall results indicate these *in vitro* assays can be used to prioritize nickel compounds for carcinogenicity in animals. We next induced ten foci in 10T1/2 with black nickel oxide and ten with green nickel oxide, derived transformed cell lines from the foci, and characterized these trans-

formed cell lines. These transformed cell lines all formed type II foci and had a stable focus-forming phenotype.

175 EFFECT OF THE HISTONE DEACETYLASE INHIBITOR TRICHOSTATIN A ON REACTIVATION OF A NICKEL-SILENCED GENE.

J. E. Sutherland and M. Costa. *New York University School of Medicine, New York, NY.*

We have previously reported that nickel (Ni) silenced the expression of the gpt transgene in the G12 hamster cell line. Silencing of the gpt gene involved increased chromatin condensation and cytosine methylation in the gpt promoter region and was assayed by assessing the cells' ability to grow in selective media containing 10 μg/ml 6-thio-guanine. Recently, our laboratory reported that nickel enhanced telomeric silencing and decreased histone acetylation in yeast cells. To determine if histone deacetylation participates in nickel-induced gpt gene silencing, we treated a Ni-induced 6-thio-guanine resistant (i.e. gpt -) G12 variant with 100 ng/ml trichostatin A (TSA, a histone deacetylase inhibitor) for 48 hr. We then assessed the reversion frequency back to gpt+ by selecting for growth in media containing 100 μM hypoxanthine, 1 μM aminopterin, and 100 μM thymidine (HAT). This treatment increased the gpt reversion frequency only slightly (1.5-3 times higher than the spontaneous reversion frequency) suggesting that by itself, histone acetylation was not sufficient to reactivate the gpt gene. We had previously found that treatment with 5 μM 5-azacytidine (5-azaC), an inhibitor of DNA methylation, resulted in gpt reversion. This effect was abolished when 100 ng/ml TSA was added concurrently with 5 μM 5-aza C probably because TSA slowed the cell cycle resulting in less 5-aza C incorporation into the DNA and hence less inhibition of DNA methylation. Interestingly, treatment of a gpt - clone that was non-responsive to 5 μM 5-aza C by itself with a combination of 5-aza C for 48 hr, followed by recovery for 48 hr, and then 100 ng/ml TSA for 48 hr resulted in a gpt reversion frequency that was 270 times higher than the spontaneous reversion rate. This result suggests that in some instances, perhaps depending upon the degree of chromatin condensation, DNA demethylation and histone acetylation were both involved in reactivation of the Ni-silenced gpt transgene.

176 EFFECT OF ORALLY-DOSED MANGANESE ON THE REPRODUCTIVE EFFICIENCY OF SD-RATS.

T. P. Ponnapakkam, K. Bailey, K. A. Graves, M. B. Iszard, G. A. Henry-Sam and T. P. Ponnapakkam. *College of Pharmacy, Xavier University, New Orleans, LA.*

The present study investigated the potential adverse effects of manganese on the reproductive systems in Sprauge-Dawley rats following oral exposure. Moreover, the purpose of this study was concerned with the dose-response of manganese and its toxicologic evaluation. Male and female SD rats (153-175g) were administered manganese acetate for 63 days. Studies were conducted in two phases. Phase I, used a single dose of 306 mgMn/kg. Significant decreases in ovary/uterus (55%) weight and insignificant increases in testicular (2.5%) weights were observed prior to mating. Following a mating period where Mn was discontinued, ovarian/uterus and testis weight decreased 22 and 9%, respectively. No significant changes in treated above control groups with respect to ovarian and uterine changes. Histopathology revealed focal mild prostatitis in treated males while controls remained unchanged. In phase II rats were dosed with 306, 612, 1225 and 1838 mgMn/kg. Prior to mating, decreases of 25, 29, 45, and 14%, respectively, of ovarian/uterine tissue weights were observed. Testicular weights for all treatment groups showed consistent decreases while histologically confirmed testicular degeneration was demonstrated in doses of 612 (33%), 1225 (50%) and 1838 (33%) mgMn/kg. Following mating when Mn administration was discontinued, decreases were observed in ovarian/uterine weights. Testicular weight were decreased in all groups. Affected animals had segmented degeneration of germinal epithelium within seminiferous tubules. This suggests that the male reproductive system is more sensitive than females to the effects of orally administered manganese. (Supported by ATSDR #U50/ATU398948-08.)

177 ACCUMULATION OF ZINC IN F_1 OFFSPRING OF ZINC CHLORIDE TREATED RATS.

M. Brownlow, A. T. Khan, A. Atkinson, T. C. Graham, M. Green, S. Ali and S. Thompson. *Tuskegee University, College of Veterinary Medicine, Nursing and Allied Health, Tuskegee, AL.* Sponsor: R. R. Dalvi.

The accumulation of zinc in the F_1 offspring of Zinc chloride (Zn) treated rats were analyzed to assist in determining the potential for Zn accumulation to influence reproductive performance and other systems in the second generation. Both male and female Fo rats were administered 0.0, 7.50, 15.0 and 30.0 mg/kg/day of Zn (oral gavage) during premating, mating, gestation and lactation periods. After weaning, one male and one female F_1 offspring were selected for Zn analysis The brain, thymus, testis, ovary, and stomach content were analyzed for Zn accumulation. In most instances, Zn accumulation in a dose dependent manner in the tissues that were analyzed. Zn accumulated in the ovary at the mid and high dose was significantly increase and almost twice the level noted their control. Also, Zn accumulation in the thymus of the mid and high dose rats of both sexes were significantly increased when compared to their controls. The pattern of Zn accumulation in the F_1 generation suggests the potential for effects upon immune system function in both sexes and upon reproduction in females. (Supported by MHPF/ATSDR Cooperative Agreement # U50/ATU398948-07.)

178 EFFECT OF SUBCHRONIC EXPOSURE OF RATS TO ZINC CHLORIDE DURING A BREEDING TRIAL ON HEMATOLOGY, BLOOD CHEMISTRY, ORGAN WEIGHTS, AND HISTOPATHOLOGY.

T. C. Graham, A. T. Khan, A. Atkinson, S. Ali, S. Thompson and M. Green. *College of Veterinary Medicine, Nursing & Allied Health, Tuskegee, AL.* Sponsor: R. R. Dalvi.

The effects of oral Zinc chloride (Zn) on reproductive performance are unknown. Therefore, the effects of 13 weeks of oral administration of Zn on hematology, blood chemistry, organ weights, and histopathology of rats were studied to determine their impact on breeding. Both male and female rats (45-50 days old at study initiation) were administered 0.0, 7.5, 15.0 and 30.0 mg/kg/day of Zn via oral gavage during premating, mating, gestation and lactation periods. Males were sacrificed after mating (13 weeks) and females were sacrificed after weaning (19 weeks). Clinical pathology assessment consisted of evaluations of the hemogram, leukogram, and selected chemistries. Organs from the nervous, urinary, endocrine, digestive, hematopoietic/lymphoreticular, and reproductive systems of both sexes were weighed and subsequently evaluated histopathologically. There were no significant Zn related changes observed in the clinical pathology parameters. Analysis of organ weight data showed Zn treatment related decreases in testicular and ovarian weights and an increase in the brain weights of males. Evaluation of histopathology revealed Zn treatment associated thymic atrophy, depletion of lymphoid tissue in lymph nodes, splenic hemosiderosis, and prostatic acinar atrophy. All effects related to treatment with the test compound were mild. However, those that were noted in reproductive organs could have had adverse effects upon reproduction. (Supported by MHPF/ATSDR Cooperative Agreement # U50/ATU398948-0.)

179 NITRIC OXIDE INDUCES METALLOTHIONEIN GENE EXPRESSION APPARENTLY BY DISPLACING ZINC BOUND TO MT.

K. Katakai[1], J. Liu[1], K. Nakajima[2], L. Keefer[3] and M. Waalkes[1]. [1]*NCI at NIEHS, Research Triangle Park, NC,* [2]*Otsuka Pharmaceutical, Rockville, MD and* [3]*NCI, FCRDC, Frederick, MD.*

The metal binding protein, metallothionein (MT), is probably involved in zinc homeostasis since it typically binds large amounts of zinc coordinated to its numerous cysteine groups. Zinc can control MT gene expression by interacting with metal-sensitive transcription factors and free zinc induces the accumulation of large amounts of zinc-containing MT protein. However, the precise factors governing intracellular release of metal ions from MT remain unknown. Aerobic nitric oxide (NO) can nitrosate thiol groups in proteins, and MT overexpression induces resistance to NO toxicity in certain cell lines, while MT-bound Cd is released by NO exposure. Based on these observations, we hypothesized that NO may also be effective at displacing zinc from MT, and that this could be an important physiological control mechanism in zinc homeostasis and utilization. Thus we studied the release of zinc from MT after NO exposure (using the diethylenetriamine nitric oxide adduct, DETA/NO, as the NO source) to help define this as a possible mechanism of

controlled zinc release from MT. In this study, we used TRL1215 cells (which are derived from fetal rat liver) and HUVECs (human umblical vein endothelial cells) as *in vitro* model systems. In these cell lines, MT protein levels and MT mRNA were induced by NO exposure following zinc treatment. Additionally, NO displaced MT-bound zinc, as assessed by gel-filtration chromatography. The released zinc probably then stimulated MT gene expression as assessed by MT mRNA and MT protein. These results suggest that NO may play an important role in regulation of zinc homeostasis in the cells by providing for a controlled release mechanism from metal stored in association with MT. The strong possibility exists that other genes could be activated by NO-induced release of MT-bound zinc.

180 DISTRIBUTION OF ZINC IN TARGET ORGANS OF ZINC CHLORIDE TREATED MICE.

M. Green, A. T. Khan, A. Atkinson, T. C. Graham, S. Thompson and S. Ali. *Tuskegee University, College of Veterinary Medicine, Tuskegee, AL.* Sponsor: R. R. Dalvi.

Male and female (CD) mice were administered either 0.0, 12.5, 25.0, 50.0, 100.0 or 200.0 mg/kg/day of zinc chloride via oral gavage to determine levels of zinc accumulation in various organs. Zinc accumulation in the brain, liver, kidney, pancreas, spleen, thymus, ovary, uterus, epididymis, seminal vesicle and testis were analyzed. Males showed 15.0, 13.0, and 16.0% reductions in body weight while females had 7.0, 9.0 and 8.0 % reductions in body weight gain at the 12.5, 25.0 and 50.0 mg/kg/day dose groups, respectively when compared to controls. The body weights of males in the 12.5, 25.0 and 50.0 mg/kg/day dose groups were significantly lower than their control group, but females had no significant differences in final body weight gain when compared to their control group. In males, Zinc accumulations in the kidney, pancreas, spleen, thymus, prostate and seminal vesicle, and in females, the pancreas, thymus, uterus, and ovary were significantly higher at 50.0 mg/kg/day when compared to control groups. Additionally, Zinc accumulation data showed a dose-dependent increase in all organs of both sexes. (Supported by MHPF/ATSDR Cooperative Agreement # U50/ATU398948-07.)

181 A PRELIMINARY STUDY ON THE TOXICITY OF ZINC ON RAT SPERMATOGENESIS AS DETERMINED BY FLOW CYTOMETRY.

N. K. Doyle, A. T. Han, A. Atkinson, T. C. Graham and J. Hudson. *Tuskegee University, College of Veterinary Medicine, Tuskegee, AL.* Sponsor: R. R. Dalvi.

The effects of zinc chloride (Zn) on the maturation of rat testicular germ cells are unknown. Therefore, Cell Flow Cytometry (CFC) was used to investigate the effects of Zn on rat testicular cell development. Male rats were administered either 0.0, 7.5, 15.0 or 30.0 mg/kg/day of Zn for 98 days. After the final exposure, rats were scarified and their testes were removed for CFC evaluation. The percentage of diploid, tetraploid and haploid cells were evaluated. All Zn treated groups appear to have a small dose dependent decrease in the percentage of haploid cells and consequently a small dose dependent increase in the percentage of diploid cells. Also, the mean percentage of round, elongating and elongated spermatids were evaluated. Exposure of rats to Zn resulted in a decrease in the percentage of elongated spermatids and an increase in round spermatids In summary, the pattern of all the changes noted may have been due to an arrest of maturation imposed upon an earlier cell stage that prevented the appearance of the next cell stage. (Supported by MHPF/ATSDR Cooperative Agreement #U50/ATU398948-07.)

182 NUCLEAR MAGNETIC RESONANCE (NMR) ANALYSIS OF THE INTERACTION OF EXOGENOUS DIVALENT METALS WITH ZINC FINGER MOTIFS IN THE SYNTHETIC ZINC FINGER MODEL.

M. Razmiafshari[1], D. A. D'Avignon[2], J. Kao[2] and N. H. Zawia[3]. [1]*University of California, Irvine, CA,* [2]*Washington University, St. Louis, MO and* [3]*University of Rhode Island, Kingston, RI.*

The Cys_2-His_2 family zinc finger motif is regarded as one of the major structural motifs in cellular proteins and is involved in eukaryotic protein-nucleic acid interactions. Zinc ions coordinate this finger-like structure through bonds created with cysteine and histidine amino acids. To determine whether these domains are potential targets for xenobiotic (Cd, Hg, and Pb) metals, we examined the interactions between several metals and a synthetic Cys_2-His_2 finger peptide (26-mer) corresponding to a single domain of the transcription factor Sp1. Recent studies conducted in our laboratory, have supported the ability of Pb(II), Hg(II), and Cd(II) to bind to the zinc finger region of this motif, but did not provide unequivocal interpretations in terms of the sites (residue) involved. Therefore, the metal-binding and structural properties of the synthetic peptide, in the presence or absence of zinc and a variety of other metals (Pb, Cd, Ca, and Hg) was investigated by one and two-Dimensional Nuclear Magnetic Resonance. Transition metals Zn(II), Cd(II) and Hg(II) and the non-transition metal Pb(II) demonstrated distinct signal changes in the aliphatic region, which could allow some structural inferences such as metal-cysteine binding to be drawn. Ca(II), on the other hand, did not exhibit any significant chemical shift of proton resonances in this region. All of the above metals, however, indicated major chemical shifts in the aromatic region of the spectra, which was indicative of metal-histidine binding. In addition, chemical shift assignment and sequential connectivity of the peptide were determined by 2D TOCSY and NOESY experiments. The interaction of the peptide with divalent metals, Zn(II), Pb(II) and Ca(II) were monitored by the cross peak in TOCSY and NOESY spectra. Cysteine and histidine residues show a distinct change in the amide and beta resonances region in the presence of Zn(II) and Pb(II) indicating the metal-ligand binding site are near these residues. However, Ca(II) was not actively involved in the binding site.

183 A ROLE FOR ZINC IN ANTI-APOPTOTIC ACTION.

M. Ishido, T. Adachi and M. Kunimoto. *National Institute for Environmental Studies, Tsukuba, Japan.* Sponsor: M. Satoh.

Cadmium, an environmental pollutant caused nephroptosis which was inhibitable by zinc. The mechanism of anti-apoptotic action of zinc is poorly understood. In this study, we found the stimulation of DNA synthesis, as assessed by BrdU incorporation during prevention by zinc of apoptosis, suggesting the proliferactive nature of zinc contributes to its inhibition of apoptosis. This finding was consistent with the result that the cells driven by dialyzed fetal bovine serum were resistant to apoptotic stimuli of cadmium. Furthermore, zinc activated the expression of endogenous Bcl-2 proteins. Overexpression of Bcl-2 proteins by transfection, however, did not facilitate zinc-mediated DNA synthesis. Thus, one possible role of zinc in prevention of apoptosis is to promote DNA synthesis , independently of activation of anti-apoptotic proteins Bcl-2.

184 MODULATION OF METALLOTHIONEIN MRNA BY ESTRADIOL IN PERIPHERAL BLOOD LEUKOCYTES FROM GREY SEALS.

S. Pillet[1], J. Bouquegneau[1], L. N. Measures[2], M. Fournier[3] and D. G. Cyr[1]. [1]*Université de Liège, Liège, Belgium,* [2]*Institut Maurice-Lamontagne, Mont-Joli, Quebec, Canada and* [3]*INRS-Institut Armand Frappier, Pointe-Claire, Quebec, Canada.*

Metallothioneins (MTs) are metal-binding proteins whose synthesis can be induced by heavy metals. MTs are synthesized in immune cells and can modulate several immune functions. Previous studies have reported gender differences in the sensitivity of seal macrophages to metals. The objective of this study was to determine which MT transcripts are present in peripheral blood leukocytes of grey seals and whether or not estradiol can modulate these. Using Northern blot analyses MTs (I, II, III) were undetectable in seal blood mononuclear cells. However, exposure of cells to $ZnCl_2$ (10^{-4} M, 10^{-5} M) increased MTI and II mRNA levels. MTIII mRNA was not detectable even in Zn-stimulated cells. To assess the time response of MT induction, cells were exposed to $ZnCl_2$ (10^{-4} M and 10^{-5} M) from 3 to 24 hours. MTI and MTII mRNA levels increased rapidly reaching maximum levels after 3 hrs of exposure. A dose-response relationship between MT mRNA levels and $ZnCl_2$ concentrations were observed. Exposure of cells to 10^{-4} M $ZnCl_2$ caused a 10-fold higher induction of both MT mRNA levels than 10^{-5} M $ZnCl_2$. To determine if estradiol could alter the response of the mononuclear cells to $ZnCl_2$, cells were exposed to physiological concentrations of $ZnCl_2$ and estradiol (0.05, 0.1, 0.5 nM). Our results show that estradiol can significantly increase MT I and II mRNA levels in the presence of $ZnCl_2$. Estradiol by itself had no effect. Together these results indicate that PBMNs can be stimulated by heavy metals to synthesize transcripts for both MT I and II and that estradiol can increase the sensitivity of these cells to heavy metals. These observations may have important implications in immunotoxicological risk assessment of heavy metal exposures due to male-female differences.

185 ROLE OF METALLOTHIONEIN AND GLUTATHIONE IN AGE-RELATED CHANGE IN CADMIUM-INDUCED LIVER INJURY IN MALE FISCHER 344 RATS.

L. E. Rikans[1] and T. Yamano[2]. [1]*University of Oklahoma Health Sciences Center, Oklahoma City, OK and* [2]*Osaka City Institute of Public Health and Environmental Sciences, Osaka, Japan.*

The influence of aging on the sensitivity of the liver to the acute toxicity of cadmium (Cd) has not been studied previously in adult rats. In this study hepatotoxicity caused by a single sc injection of CdCl2 was compared in 5-, 18-, and 28-month-old male Fisher 344 rats. Doses of Cd were adjusted on the basis of the mean lean body mass for each age group of rats, and liver injury was evaluated 24 hr after treatment. Cd treatment produced substantial increases in serum alanine aminotransferase (ALT) and sorbitol dehydrogenase (SDH) activities in 5- and 18-month-old rats, whereas no significant increases were observed in 28-month-old rats. Histological examination of r3qepresentative livers from each age group confirmed the findings for serum enzyme activity; hepatocellular necrosis was observed only in livers from 5- and 18-month-old rats. The attenuation of Cd hepatotoxicity in senescent rats did not appear to be related to pre-treatment levels of metallothionein or glutathione. Likewise, resistance to Cd could not be explained on the basis of metallothionein induction, which decreased as a function of aging. Thus, the mechanisms that account for the post-maturational decline in sensitivity to Cd do not appear to be associated with alterations in levels of the major factors that protect against Cd-induced hepatotoxicity.

186 ROLE OF KUPFFER CELLS AND INFLAMMATORY CYTOKINES IN THE ATTENUATION OF CADMIUM-INDUCED LIVER INJURY IN SENESCENT MALE FISCHER 344 RATS.

T. Yamano[1] and L. E. Rikans[2]. [1]*Osaka City Institute of Public Health and Environmental Sciences, Osaka, Japan and* [2]*University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Age of rats is one of the critical determinants of the degree of chemical-induced acute hepatotoxicity. In male Fischer 344 rats, subcutaneous cadmium (Cd) treatment (3 mg/kg) produced severe hepatotoxicity in young-adult rats (5 months old) but not in old rats (25 to 28 months old) 24 hr after treatment. We investigated this effect of aging from the aspect of the role of Kupffer cells and inflammatory cytokines. The phagocytic activity of Kupffer cells, determined as the rate of carbon clearance from blood, was stimulated by the administration of a hepatotoxic dose of Cd (3 mg/kg, sc) only in young-adult rats. Increases in hepatic concentrations of interleukin (IL)-1beta and cytokine-induced neutrophil chemoattractant (CINC) produced by Cd treatment were greater in young-adult rats compared to old rats. Pretreatment of young-adult rats with gadolinium chloride or cyclosporin A inhibited the elevations in hepatic cytokines and prevented Cd-induced liver damage. The results suggest that: (1) Kupffer cell activation is essential for inflammatory liver damage from Cd, (2) IL-1beta and CINC are important mediators of the inflammatory response induced by Cd, and (3) the attenuation of Cd-induced liver injury in senescent rats is caused by an impairment in Kupffer cell activation, leading to a lower production of CINC and less inflammatory liver injury.

187 THE INFLUENCE OF ADVANCED AGE ON THE HEPATOTOXICITY OF CHLOROFORM (CHCl3) AND BROMODICHLOROMETHANE (BDCM) IN MALE F-344 RATS.

T. McDonald, Y. M. Sey and J. E. Simmons. *NHEERL USEPA, Research Triangle Park, NC.*

Disinfection of water containing organic matter by chlorination or by ozonation followed by either chlorine or chloramine results in the production of a variety of halogenated byproducts, including trihalomethanes (THMs). CHC13 and BDCM are the two most prevalent THMs. Exposure to CHC13 and BDCM is virtually ubiquitous across all segments of the U.S. population, including the aged. Aged (22-23 month old) male F-344 rats are markedly more susceptible to carbon tetrachloride-induced hepatotoxicity than their younger counterparts (either 3- or 5- months old) (Schoeffner et al., 1999). Thus, the present objective was to investigate the influence of advanced age on susceptibility to the hepatotoxic effects of BDCM and CHC13. Each THM was evaluated in a separate experiment in which young (~90 day old) and aged male F-344 rats (22-24 months old) were administered 0, 0.5, 1.0 or 2.0 mmol THM/kg by oral gavage in an aqueous vehicle (10% Alkamuls) at a gavage volume of 5ml/kg at ~3 p. m (n=4/group). Hepatotoxicity was assessed 24 hr later by serum activities of sorbitol dehydrogenase (SDH) and alanine (ALT) and aspartate (AST) aminotransferases. In both young and old rats, the hepatotoxicity of CHC13 and BDCM was dose-dependent. The influence of age on THM hepatotoxicity was evaluated, in separate analyses for each THM, by two-way analysis of variance that included a THM*age interaction term as well as the main factors of THM and age. The THM*age interaction terms were significant for SDH, ALT and AST for both CHC13 and BDCM, indicating that the hepatotoxic effects of CHC13 and BDCM were dependent on rat age. For both CHC13 and BDCM, the differences between young and old rats were most apparent at the highest dosage. At 2.0 mmol CHC13/kg, relative to the young rats, mean ALT, AST and SDH values were between 4-and 7-fold greater in the old rats. At 2.0 mmol BDCM/kg, mean Alt, AST and SDH values were ~10-fold greater in old rats relative to young rats. In conclusion, advanced age increased the hepatotoxic response to both CHC13 and BDCM, indicating that the aged may be a susceptible subpopulation for THMs. (Abstract may not reflect EPA policy.)

188 DOSE RELATED INCREASE IN LIVER INJURY OF CHLOROFORM IS TEMPERED BY TISSUE REPAIR.

V. S. Vaidya[1], M. G. Soni[2], M. M. Mumtaz[3], H. Clewell[4], S. N. Murthy[1] and H. M. Mehendale[1]. [1]*Division of Toxicology and Louisiana Institute of Toxicology, The University of Louisiana at Monroe, Monroe, LA,* [2]*Burdock Associates, Inc., Vero Beach, FL,* [3]*ATSDR, CDC, Atlanta, GA and* [4]*ICF Kaiser International, Ruston, LA.*

Dose response assessment is a fundamental basis of quantitative relationships between exposure to an agent and the incidence of an adverse outcome versus the opposing compensatory response. Present studies were designed to investigate the dynamics of injury and tissue repair during chloroform toxicity. Male S-D rats were injected with ten-fold dose range of chloroform (0.05, 0.125, 0.25 and 0.5 ml/kg or 74, 184, 368 and 736 mg/kg ip in corn oil) and hepatotoxicity and tissue repair were assessed during a time course of 0-96 h. Blood levels of chloroform were estimated by gas chromatography after chloroform administration. Liver injury, as assessed by plasma alanine aminotransferase (ALT), peaked at 24 h and declined by 96 h for the lower three doses (74,184 and 368 mg/kg). A significant and progressive increase in plasma ALT was observed in the highest dose (736 mg/kg) treated group after 24 h. Tissue regeneration response as measured by 3H-thymidine incorporation into hepatonuclear DNA peaked by 36 h in rats treated with lower three doses of chloroform (74,184 and 368 mg/kg). This correlated with prompt recovery from liver injury without any mortality. However, with the highest dose of chloroform (736 mg/kg), tissue repair was delayed and attenuated allowing unrestrained progression of liver injury and 90% animal death. Histopathology of the liver samples correlated well with the biochemical parameters of liver injury. Chloroform concentrations in blood increased with dose reaching maximum at 1 h before declining to undetectable levels by 6 h after chloroform administration regardless of the dose. These results support the concept that quantifying tissue repair response along with injury inflicted by chloroform should yield a greater insight into the mechanism of toxicity on one hand and increase the usefulness of dose-response relationships on the other. (Supported by ATSDR # U61/ATD 681482.)

189 GAVAGE VEHICLE AND VOLUME MODULATION OF CHLOROFORM-INDUCED HEPATOTOXICITY IN MICE.

Y. M. Sey, A. McDonald and J. E. Simmons. *NHEERL USEPA, Research Triangle Park, NC.*

Digestible oils are frequently used as vehicles for oral administration of volatile lipophilic compounds. Previous research from our laboratory in the male F-344 rat has shown that chloroform (CHCl3) toxicity is modulated by both gavage vehicle and gavage volume. CHCl3 is a disinfection byproduct ubiquitously present in drinking water disinfected either by chlorination or by ozonation processes that involve post-treatment with chlorine or chloramine. In the rat, greater hepatic and renal toxicity is seen with oil administration, with increased toxicity at higher oil volumes. As less attention has been focused on the effects of gavage vehicle and volume in the mouse, the objective of the present study was to examine the influence of these factors on CHCl3-induced hepatotoxicity in this species. Female B6C3F1 mice (~70 days old) received a single oral gavage of 0, 238 or 477 mg CHCl3/kg (the NCI bioassay dosages). CHCl3 was administered in either 2.5, 5.0 or 10 ml corn oil/kg or 10 ml/kg of an aqueous-based vehicle (10% Alkamuls®). Toxicity was assessed at 24, 48 and 72 hr by serum activities of sorbitol dehydrogenase (SDH) and alanine (ALT) and aspartate (AST) aminotransferases. CHCl3 toxicity was dose- and time-dependent following delivery in either

vehicle. Under all conditions, toxicity was most severe at 24 hr. Vehicle differences were most apparent at 477 mg CHCl3/kg, with oil gavage resulting in greater toxicity than aqueous delivery. Enhancement of liver injury by oil delivery is consistent with previous findings in the male F-344 rat. At the high dose (477 mg/kg), the volume of oil had little or no apparent effect on CHCl3 hepatotoxicity. In contrast, at the low dose (238 mg/kg), CHCl3 toxicity was dependent on oil volume. Relative to the 10 ml/kg gavage volume, greater toxicity was observed at the 2.5 ml/kg gavage volume. This is in contrast to our findings in the rat, where compared to an oil gavage volume of 2.5 ml/kg, much greater toxicity was seen at 10 ml/kg. These data indicate that gavage vehicle and volume are significant modulators of CHCl3 hepatotoxicity in the mouse. In summary, while the effects of gavage vehicle appear to be consistent across species, the effects of gavage volume do not. Therefore, careful attention must be given to the experimental parameters of gavage vehicle and gavage volume when making toxic potency comparisons among chemicals and across species. (This abstract does not reflect EPA policy.)

190 DIFFERENCE IN RESPONSE OF LIVER AND KIDNEY TO HEPATIC DAMAGE.

Y. C. Kim and H. K. Yim. *Seoul National University, Seoul, Republic of Korea.*

We have examined the effects of preceding hepatic damage on response of liver and extrahepatic sites to a subsequent dose of xenobiotics. Adult male ICR mice were pretreated with a hepatotoxic dose of carbon tetrachloride (CCl_4; 0.05 ml/kg, ip) 24 hr prior to a challenging dose of either CCl_4 (0.02 ml/kg, ip), acetaminophen (APAP; 350 mg/kg, ip) or chloroform ($CHCl_3$; 0.025 or 1.0 ml/kg, ip). The CCl_4 pretreatment reduced the hepatotoxicity of challenging toxicants, but elevated the renal toxicity significantly as determined by changes in aspartate aminotransferase (AST), alanine aminotransferase (ALT), sorbitol dehydrogenase (SDH), and blood urea nitrogen (BUN) and creatinine levels in serum. Glutathione (GSH) level in the liver or in the renal cortex was not altered by the pretreatment. In mice pretreated with a 24 hr prior dose of CCl_4 the hepatic microsomal *p*-nitrophenol hydroxylase, *p*-nitroanisole demethylase, and aminopyrine demethylase activities were decreased, however, the renal microsomal drug metabolizing activities were all induced. In partially hepatectomized male mice there was a significant increase in the renal microsomal metabolizing activities, and the renal toxicity resulting from administration of CCl_4 or $CHCl_3$ was potentiated correspondingly. In female or castrated male mice, however, induction of the renal microsomal metabolizing activities by CCl_4 was diminished significantly. Also partial hepatectomy did not produce an increase in the renal metabolizing activities in female mice. But in female mice conditioned with testosterone a dose of CCl_4 induced the renal metabolizing activities to a level comparable to those of male mice. It is strongly suggested that testosterone play a critical role in the compensatory induction of the renal drug metabolizing enzyme activities in the male mice with preceding liver injury. The results obtained from this study emphasize the complexity of *in vivo* response problematical to predict in a limited test system.

191 EARLY ALCOHOL-INDUCED LIVER INJURY: SEX DIFFERENCES AND PYRUVATE INTERVENTION.

M. S. Elm, S. D. Tadic, V. M. Subbotin and P. K. Eagon. *University of Pittsburgh, Pittsburgh, PA.*

While chronic alcohol abusers of both sexes frequently experience disruption of sex hormone homeostasis, men and women differ in susceptibility to alcohol-induced liver injury, suggesting influence by sex hormones. This study determined if the sexes differ in early alcoholic liver injury and hepatic estrogen (E) metabolism, and if intervention with pyruvate, reputed to be hepatoprotective, might attenuate injury. Male and cycling female rats were fed standard alcohol-containing (36% alcohol, AF) or isocaloric (0% alcohol, IC) diets for 6 weeks. One-half of each group received pyruvate supplement equivalent to 10% of diet carbohydrate (AFP and ICP), the other half no addition. Liver injury was scored blindly using a 0 (none) to 4 (significant) scale in categories of fat drops, inflammation, and fibrosis. Compared to females, male rats had greater overall alcohol-induced injury ($p=.04$) regardless of intervention. In males, pyruvate treatment reduced inflammation ($p=.01$) and fibrosis ($p=.02$), and reduced overall injury ($p=.002$). In females, pyruvate reduced fat drops, inflammation and fibrosis slightly but not significantly, and reduced overall injury ($p=.01$). Alcohol-induced effects on E metabolism differed with sex. In males, E 2-hydroxylase (E2-OHase) activity was reduced 37% in AF ($p=.04$) with a 2.1-fold increased serum E ($p<.05$). Pyruvate normalized E2-OHase activity and serum E. In contrast, in females, E2-OHase activity was increased 14% in AF with 30% reduction in serum E; pyruvate treatment further enhanced E metabolism and reduced serum E levels, with E2-OHase activity increased 67% and serum E level reduced 33% in AFP. These data suggest that AF males sustain more early alcohol-induced injury than AF females; pyruvate intervention attenuates liver injury; and alcohol-induced effects of E metabolism differs between the sexes.

192 TNF-α AND TGF-α STIMULATE THE ENHANCED COMPENSATORY TISSUE REPAIR RESPONSE IN DIET RESTRICTED RATS AFTER THIOACETAMIDE-INDUCED LIVER INJURY.

U. M. Apte[1], S. K. Ramaiah[1], T. J. Bucci[2], A. Warbritton[2] and H. M. Mehendale[1]. [1]*Division of Toxicology, The University of Louisiana at Monroe, Monroe, LA and* [2]*Pathology Associates, Inc., National Center for Toxicological Research, Jefferson, AR.*

Studies have shown that 35% diet restriction (DR) protects rats from a lethal dose of thioacetamide (TA) due to enhanced compensatory tissue repair in DR rats. The objective was to investigate the role of TNF-α and TGF-α in hepatocyte proliferation after low (50 mg/kg) and a high (600 mg/kg) doses of TA in DR and *ad libitum* (AL) fed rats. TNF-α was estimated using rat-specific ELISA. DR itself did not change TNF-α expression. After low dose, TNF-α increased within 12 h in both AL and DR rats. Expression of TNF-α remained elevated until 96 h in DR rats while in AL rats it declined to control by 24 h. Similar results were obtained after high dose of TA. Regiospecific TGF-α expression was evaluated immunohistochemically in paraffin embedded rat liver sections during a time course after TA administrations. After high dose TGF-α expression in DR rats was sustained and 2-fold higher. The intensity of staining was much greater after high dose than low dose in DR rats. After low dose DR rat livers had higher TGF-α than AL rats. Staining pattern after low dose in DR rats paralleled the pattern in AL rats during 24-96 h. In both low dose and high dose studies, expression of TNF-α and TGF-α coincided with cell proliferation measured by ^{3}H-thymidine incorporation. TNF-α elevated during early time points while TGF-α increased during later time points indicating that TNF-α expression stimulates production of TGF-α, which in turn stimulates cell division. These results indicate that higher expression of TNF-α and TGF-α are responsible for the higher tissue repair in DR rats after TA-induced liver injury.

193 REGULATION OF INFLAMMATORY MEDIATOR PRODUCTION IN THE LIVER BY TUMOR NECROSIS FACTOR-α (TNF-α) IN CARBON TETRACHLORIDE (CCL_4)-INDUCED HEPATOTOXICITY.

L. A. Morio[1], K. A. Sprowles[1], H. Chiu[1], C. Desquitado[1], P. H. Zhang[1], M. W. Marino[2], D. M. Dambach[3], S. K. Durham[3], M. A. Gordon[1], J. D. Laskin[1] and D. L. Laskin[1]. [1]*Rutgers University, Piscataway, NJ,* [2]*Memorial Sloan Kettering Cancer Center, New York, NY and* [3]*Bristol-Myers Squibb, Princeton, NJ.*

Macrophages (MP) are known to release a number of cytotoxic mediators which have been implicated in the pathogenesis of liver injury. In the present studies we analyzed the role of MP-derived TNF-α in carbon tetrachloride (CCl_4)-induced hepatotoxicity. Treatment of mice with CCl_4 (0.3 ml/kg, i.p.) resulted in a time-dependent induction of centrilobular hepatic necrosis. This was associated with increases in hepatic lipid peroxidation and serum transaminase levels. CCl_4-induced toxicity was also correlated with increases in serum and hepatic TNF-α, as well as expression of several gene products thought to mediate liver inflammation, including inducible nitric oxide synthase (NOS II), cyclo-oxygenase-2 (COX-2), and heme oxygenase-1 (HO-1). To study the role of TNF-α in hepatotoxicity, we used TNF-α knockout mice. CCl_4 was less effective in inducing hepatotoxicity in these mice, suggesting that TNF-α contributes to hepatotoxicity in this model. Western blot analysis revealed that TNF-α knockouts treated with CCl_4 expressed greater quantities of hepatic COX-2 and HO-1 than wild-type mice, but less NOS II, demonstrating that TNF-α regulates production of these mediators. Many genes regulating production of inflammatory mediators contain binding sites for the transcription factor nuclear factor-kappa B (NF-κB). CCl_4 treatment of wild-type mice resulted in a time-dependent increase in NF-κB binding activity. Using knockout mice lacking the p50 subunit of NF-κB we analyzed the role of NF-κB in CCl_4-induced liver injury. CCl_4 was less effective in inducing injury in these mice. This was correlated with decreased TNF-α but increased hepatic COX-2 and HO-1. These data suggest that the hepatotoxic effects of TNF-α in CCl_4-induced liver injury may be mediated by altering expression of pro- and anti-inflammatory mediators and antioxidants. (NIH GM34310, ES06897; Burroughs Wellcome Fund).

194 INFLAMMATION AND APOPTOSIS IN RAT LIVER INDUCED BY MONOCROTALINE.

B. L. Copple, A. Banes, P. E. Ganey and R. A. Roth. *Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI.*

Monocrotaline (MCT) is a pyrrolizidine alkaloid that is hepatoxic, mutagenic and carcinogenic. Human exposure to MCT occurs from consumption of contaminated grains and herbal teas and medicines. MCT given intraperitoneally (i.p.) produced dose-dependent hepatocellular injury in rats that was significant at 200 mg/kg. Injection of 300 mg/kg MCT produced time-dependent hepatotoxicity beginning at 12 hours. Histologic examination of liver sections revealed widespread, panlobular hepatocellular necrosis and congestion, with injury being most pronounced in centrilobular regions. There was also an inflammatory infiltrate consisting of neutrophils (PMNs) and morphological evidence of apoptosis. This suggested that there might be both inflammatory and apoptotic components to MCT-induced liver injury. To quantify these, rats were treated with 300 mg/kg MCT (i.p.) for 4, 8, 12 and 18 hours, and liver sections were analyzed for PMN accumulation using immunohistochemistry. A time-dependent increase in the number of PMNs in areas of hepatocellular injury appeared as a trend by 4 hours and reached statistical significance by 18 hours. These same liver sections were analyzed using TUNEL staining (which identifies apoptotic cells by labeling DNA strand breaks, a hallmark of apoptosis). Only TUNEL-stained cells with apoptotic morphology were enumerated. MCT caused a statistically significant increase in TUNEL staining in the liver beginning at 8 hours. TUNEL staining was panlobular, with more extensive staining occurring in areas of hepatocellular necrosis. These studies revealed that MCT induces both inflammation and apoptosis in the rat liver. (Supported by NIH grant ES 04139.)

195 IMPORTANCE OF THE CXC CHEMOKINES MIP-2 AND KC FOR NEUTROPHIL-INDUCED LIVER INJURY DURING ENDOTOXEMIA.

H. Jaeschke[1], R. D. Hopper[1], J. A. Lawson[2], D. G. Remick[3] and A. Farhood[4]. [1]*University of Arkansas for Medical Sciences, Little Rock, AR,* [2]*Pharmacia & Upjohn, Inc., Kalamazoo, MI,* [3]*University of Michigan, Ann Arbor, MI and* [4]*University of Texas Health Science Center, Houston, TX.*

Neutrophils (PMNs) can cause parenchymal cell injury in the liver. Prerequisite for the attack on hepatocytes is the migration out of sinusoids, induced by a chemotactic signal. Thus, our objective was to evaluate the two murine chemokines MIP-2 and KC in a murine model of PMN-induced liver injury [700mg/kg galactosamine, 100μg/kg endotoxin (Gal/ET)]. Serum levels of MIP-2 and KC increased 950-fold and 380-fold, resp., within 90 min. Although the conc. declined 3 h after Gal/ET treatment, levels were significantly elevated during the entire observation period. RNase protection assays showed transcriptional activation of both chemokines in the liver. Gal/ET injection into ET-resistant strain C3H/HeJ did not result in MIP-2 or KC formation. However, i.v. injection of murine TNF-α, IL-1α, or IL-1β (2μg/kg) induced MIP-2 and KC formation. At 7 h after Gal/ET, large numbers of PMNs (262±9 PMN/50 high power fields) accumulated in sinusoids and partially extravasated into the parenchyma. High plasma ALT activities (2300±830 U/L) and histological evidence of necrosis (54±4% of hepatocytes) indicated severe liver injury. Administration of an antiserum against MIP-2 2 h before Gal/ET significantly reduced ALT activities and necrosis (20±4%). The number of hepatic PMNs was not affected, but less cells appeared to be in the parenchyma. Control serum or anti-KC antiserum were ineffective. **Conclusion:** Our data showed a cytokine-dependent transcriptional activation of CXC chemokine genes in the liver *in vivo*. MIP-2 appears to be the critical chemotactic signal for neutrophil-induced liver injury during endotoxemia. (Supported in part by 2 R01 NIEHS 06091.)

196 ROLE OF PEROXYNITRITE (PN) IN ACETAMINOPHEN (AA)-INDUCED HEPATOTOXICITY.

C. R. Gardner[1], D. M. Dambach[1], S. K. Durham[2], S. D. Cohen[3], M. K. Bruno[3], A. L. Salzman[4], G. J. Southan[4] and D. L. Laskin[1]. [1]*Rutgers University, Piscataway, NJ,* [2]*Bristol-Myers Squibb Research Institute, Princeton, NJ,* [3]*University of Connecticut, Storrs, CT and* [4]*Inotek, Boston, MA.*

Recent studies have shown that the toxicity of AA is mediated, in part, by inflammatory mediators produced by liver cells. In the present studies, we analyzed the role of reactive nitrogen intermediates in the pathogenic process. Treatment of mice with AA (100-300 mg/kg, ip) results in a dose and time dependent induction of centrilobular hepatic necrosis and increases in serum ALT which are evident within 6 hr. This was correlated with the appearance of inducible nitric oxide synthase (NOS II) in the liver. Immunohistochemistry also revealed PN-mediated injury which was identified by nitrotyrosine staining. This was observed in sinusoidal cells within 1 hr and was followed by hepatocyte staining by 6 hr. To study the role of nitric oxide and PN in AA-induced hepatotoxicity, we used aminoguanidine (AG, 100 mg/kg, 2x/day, ip), a selective NOS II inhibitor, and aminoethylselenourea (AEseU, 25 mg/kg, 2x/day, ip), a NOS II inhibitor and a PN scavenger. Both compounds were found to block AA-induced hepatotoxicity. AEseU was a more effective inhibitor of toxicity than AG. These findings suggest that reactive nitrogen intermediates, in particular PN, play a role in AA-induced liver injury. These data are supported by our observations that NOS II knockout mice are significantly less sensitive to AA-induced hepatotoxicity than control mice. These mice also do not exhibit evidence of PN-mediated tissue injury. To exclude the possibility that the reduced toxicity in NOS II knockouts was due to alterations in AA metabolism, we examined AA covalent binding to liver microsomal proteins by Western blotting. We found that the extent of covalent binding in microsomal proteins from wild type and NOS II knockout mice was similar. Moreover, although baseline hepatic glutathione (GSH) levels were 30% greater in NOS II knockouts, AA administration resulted in a 90% reduction in GSH in both genotypes. These data demonstrate that AA-induced toxicity involves both direct and indirect mechanisms. (Supported by NIH grants GM34310, ES06897and ES07163 and the Burroughs Wellcome Fund.)

197 RETINOL'S POTENTIATION OF ACETAMINOPHEN-INDUCED HEPATOTOXICITY DOES NOT INVOLVE THE DIRECT FORMATION OR CONJUGATION OF NAPQI.

B. J. Bray, R. I. Inder and R. J. Rosengren. *University of Otago, Dunedin, New Zealand.*

We have previously shown that retinol potentiates acetaminophen-induced hepatotoxicity in the BALB/C mouse. 4 days of retinol (75 mg/kg/d) was required to potentiate acetaminophen (400 mg/kg) hepatotoxicity (ALT activity; 3260±583 IU/L retinol + acetaminophen vs.1056±225 IU/L vehicle + acetaminophen, $p<0.05$). Retinol, alone and in combination with acetaminophen, decreased the catalytic activity and polypeptide levels of CYP3A as compared to the vehicle and untreated groups (catalytic activity; 0.72±0.08 nmol/mg/min retinol + acetaminophen vs. 1.21±0.07 nmol/mg/min untreated, $p<0.05$). However, no statistical difference has been demonstrated between any groups for the catalytic activity or polypeptide levels of CYP1A2 or CYP2E1. Furthermore, GSH concentrations in the liver were unaltered by the administration of retinol alone. However, our results demonstrate a significant decrease in the GSH content of retinol + acetaminophen treated animals, when compared to acetaminophen treated alone (0.36±0.11 vs. 0.87±0.19 respectively, $p<0.05$), which is consistent with an increase in the formation of the toxic metabolite, NAPQI. We can conclude that retinol's potentiation of acetaminophen-induced hepatotoxicity is not due to an induction of CYP450 isoforms or a reduction in available glutathione at the time of NAPQI formation. (Supported by a Laurenson Award from the Otago Medical Research Foundation and by a University of Otago Research Grant.)

198 MULTIDRUG RESISTANCE PROTEIN 2 (MRP2) MESSAGE RNA EXPRESSION IN MOUSE LIVER FOLLOWING CHEMICAL INDUCTION OF COMPENSATORY HEPATOCELLULAR PROLIFERATION *IN VIVO*.

G. E. Hennig[1], D. J. McCann[2], H. Whiteley[1] and J. E. Manautou[3]. [1]*Dept. Pathobiology, University Connecticut, Storrs, CT and* [2]*Drug Disp. & Metab. Department., AstraZeneca, Wilmington, DE and* [3]*Department Pharmaceutical Sciences, University Connecticut, Storrs, CT.*

Chemically induced compensatory hepatocellular proliferation can result in increased protection against hepatotoxicants. Enhanced expression of liver plasma membrane ATP-dependent transport proteins may contribute to this protection and, indeed, Mrp2 protein expression is elevated following acetaminophen treatment. Thus, the present studies were designed to investigate the relative abundance of Mrp2 mRNA. **Methods:** Male CD-1 mice received 350 mg acetaminophen/kg i.p. or 15 ul carbon tetrachloride/kg i.p. Control mice received vehicle only. Liver poly A+RNA was isolated at 12 and 24 hr after treatment, followed by reverse transcription-polymerase chain reaction (RT-PCR) using mouse Mrp2 specific primers, and agarose gel electrophoresis. Mrp2 cDNA bands were normalized to the housekeeping gene, hypoxanthine-guanine phosphoribosyltransferase (HPRT), cDNA bands. **Results:** No change in Mrp2 mRNA abundance was detected by image analysis at either

time point examined. **Conclusions:** The increase in Mrp2 protein induced by acetaminophen treatment cannot be accounted for by a concurrent change in mRNA levels. (Supported by grants from AstraZeneca and PhRMA Foundation.)

199 HIGH SENSITIVITY OF NRF2 KNOCKOUT MICE TO ACETAMINOPHEN HEPATOTOXICITY.

A. Enomoto[1], K. Itoh2, E. Nagyoshi[1], J. Haruta[1], T. Kimura[1], T. Harada[1] and M. Yamamoto[2]. [1]*Institute Of Environmental Toxicology, Ibaraki, Japan and* [2]*University Of Tsukuba, Ibaraki, Japan.* Sponsor: K. Ebino.

Nrf2 is a transcription factor that activates Antioxidant Response Element (ARE)-regulated genes including some members of Phase II drug metabolizing enzymes and those involved in oxidative stress defense mechanisms. In order to examine the effect of Nrf2 on xenobiotic metabolism *in vivo*, acetaminophen (APAP) hepatotoxicity was evaluated in Nrf2 knockout mice. When APAP was administered to 2 to 4-month-old male mice at dosage of 0, 150, 300 or 600 mg/kg (p.o., 4 mice/genotype/dose) after overnight fasting, 1 at 300 mg/kg and 3 at 600 mg/kg of homozygous knockout mice died within 24 hours, and those that survived for 24 hours showed higher plasma alanine aminotransferase activities, lower hepatic glutathione levels, and increased severity of centrilobular hepatocellular necrosis when compared to heterozygous knockout or wild-type mice. Time-course changes in blood biochemistry and histopathology at 0, 2, 8 and 24 hours after dosing of APAP at 300 mg/kg (4 mice/genotype/time point) indicated earlier development of hepatotoxicity in homozygous knockout mice than those of other genotypes. Hepatic glutathione levels were decreased markedly at 2 hours in all mice; at 8 hours, they remained lower than the pre-dose values in homozygous knockout mice while those in other mice recovered. These results clearly show Nrf2 affects sensitivity to APAP hepatotoxicity and suggest it plays an important role in xenobiotic detoxification *in vivo*.

200 INDUCTION OF HEME OXYGENASE (HSP 32) IN HEPATIC MACROPHAGES DURING ACETAMINOPHEN HEPATOTOXICITY.

H. Chiu and D. L. Laskin. *Rutgers University, Piscataway, NJ.*

Heme oxygenase (HO) is the rate-limiting enzyme for the physiological degradation of heme into biliverdin, iron, and carbon monoxide. Two isoforms have been identified, a constitutive form (HO-2) and an inducible form (HO-1). Both isozymes have been shown to be important in protecting against oxidant-induced injury. We have previously demonstrated that acetaminophen-induced hepatotoxicity is mediated in part by oxidants, in particular, nitric oxide, which is released by parenchymal and nonparenchymal liver cells. Macrophages are known to upregulate mediators which aid in antioxidant defense. In the present studies, we analyzed expression of HO-1 and HO-2 in hepatic macrophages during acetaminophen-induced toxicity. Treatment of male Long Evans Hooded rats with acetaminophen (1 g/kg, i.p.) caused a time-dependent induction of liver injury which was measured by increases in serum transaminase levels. This was observed within 3 hr of acetaminophen administration and reached maximal levels by 12 hr and was directly correlated with expression of inducible nitric oxide synthase (NOS II) protein in the liver. Hepatocytes, as well as macrophages isolated from acetaminophen treated rats also produced more nitric oxide in response to inflammatory mediators. We also found that acetaminophen treatment of rats resulted in a time-dependent induction of hepatic HO-1 expression which was maximum after 24 hr. Immunohistochemical analysis revealed that HO-1 expression was predominantly localized in hepatic macrophages, with weaker staining of hepatocytes. In contrast, no changes were observed in HO-2 expression. These data suggest that HO-1 may play a protective role in this model of hepatotoxicity. (Supported by GM34310 and the Burroughs Wellcome Fund.)

201 OVEREXPRESSION OF HEAT SHOCK PROTEINS IN HEPG2 CELLS USING ADENOVIRAL GENE DELIVERY.

J. K. Tolson[1], R. M. Voellmy[2] and S. M. Roberts[1]. [1]*University of Florida, Gainesville, FL and* [2]*University of Miami, Miami, FL.*

Increased expression of the heat shock proteins (hsps) is a highly conserved response to cellular stress in both eukaryotic and prokaryotic cells. In cultured cells, increased levels of hsps induced by mild hyperthermic treatment can result in tolerance to both severe hyperthermia and chemical stressors (e.g. tButylhydroperoxide, Cd, diethylnitrosamine, cyclophosphamide). Elucidation of the mechanism of cytoprotection afforded by hsps has been hampered by the induction of multiple hsps or concomitant physiological responses brought about by the inducing agents. In an effort to address these issues, replication deficient adenoviral vectors containing hsp25 (Ad25), hsp27 (Ad27), hsp70i (Ad70i), or a constitutively active heat shock factor (Ad-hsfB) were developed. HepG2 cells (ATCC - human liver cell line) were inoculated with adenovirus at levels of 1-200 multiplicity-of-infection (MOI) for 6-24 hours. Sub-lethal heat stress controls were incubated at 43°C for 60 min. Significant elevation of hsp protein levels was observed for an MOI of 10 or more. By 24 hours post-inoculation an MOI of 100 produced results most comparable to sub-lethal heat shock for the hsp70i and hsp27 adenovirus. Strong elevation of hsp25 was observed after Ad25 at an MOI of 10 or above. As anticipated, inoculation of HepG2 cells with Ad-hsfB at an MOI of 10 or more elevated the levels of all hsps tested. Elevated levels of hsps were specific to the inoculating strain of adenovirus (i.e. only the targeted hsp protein levels were elevated). The use of specific hsps delivered by adenoviral vectors will enable hypothesis testing of fundamental mechanisms for the role of hsps in hepatotoxicity. (Supported by ES-07213.)

202 GROWTH HORMONE DEPENDENT REGULATION OF THE PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR α.

A. J. Stauber, R. A. Staben, J. C. Coley and J. C. Corton. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Peroxisome proliferators (PP) are a structurally diverse group of rodent hepatocarcinogens. It is known that the peroxisome proliferator-activated receptor α (PPARα) plays an essential role in mediating the effects of PP. A recent study using Snell dwarf mice treated with the PP methylclofenapate showed increases in liver peroxisome proliferation but not hepatocellular proliferation (Styles *et al.*, 1990. *Carcinogenesis* **11**:387-91). Dwarf mice have very low levels of pituitary hormones, of which growth hormone (GH) is known to negatively regulate PPARα post transcriptionally. Based on these findings, we are using dwarf mice as a model to determine the role of peroxisome proliferation in carcinogenesis. PP-dependent gene and protein expression was examined in Snell (dw) and Ames (df) dwarf mice using our PP cDNA arrays and immunoblot analysis. These mice have mutations in the *pit*-1 and *prop*-1 genes, respectively, resulting in low levels of GH. To determine the effect of PP, dw mice were administered a single dose of the PP Wy-14,643 (50 mg/kg) and sacrificed 12 hr later. A number of PP-dependent genes (acyl-CoA oxidase, Cyp4a, fibrinogen) were constitutively altered in the absence of PP treatment in dw and df mice. However, some PP-dependent gene/protein expression was independent of dwarf status but altered by Wy-14,643 exposure (multi-functional protein-1, acyl-CoA thioesterase, Cu/Zn superoxide dismutase). Our results also indicate that PPARα is constitutively elevated in dw mice compared to their heterozygous counterparts. Because dwarf mice live 1.5-2.0 times as long as wild type mice, the markers of PP exposure that are constitutively activated in dwarf mice and thought to be important in hepatocarcinogenesis need to be reassessed as to their relevance for predicting liver cancer.

203 PPARα KNOCKOUT MICE ARE NOT PROTECTED AGAINST ACETAMINOPHEN (APAP) HEPATOTOXICITY BY CLOFIBRATE (CFB) PRETREATMENT.

C. Chen[1], V. M. Silva[1], J. C. Corton[2], H. Whiteley[3] and J. E. Manautou[1]. [1]*Dept. Pharmaceutical Sciences, University Connecticut, Storrs, CT,* [2]*Chemical Industry Institute of Toxicology, Research Traingle Park, NC and* [3]*Dept. Pathobiology, University Connecticut, Storrs, CT.*

The purpose of this study was to investigate whether the activation of the nuclear receptor PPARα mediates the protection against APAP hepatotoxicity by peroxisome proliferator pretreatment (T.A.P. 129:252, 1994). **Methods:** Female PPARα +/+ and PPARα -/- mice were given corn oil or 500 mg CFB/kg, i.p., daily for 10 days. They were then fasted overnight and either killed without challenge or at 4 or 24 hr after challenge with 600 mg APAP/kg, p.o. Controls were given 50% propylene glycol vehicle only. **Results:** At 24 hr, hepatotoxicity was evidenced by elevated plasma SDH and histopathology in corn oil pretreated PPARα +/+ and PPARα -/- mice receiving APAP. As expected, CFB pretreated PPAR +/+ mice were protected against APAP hepatotoxicity, while liver damage was present in CFB pretreated PPARα -/- mice. However, lesion severity in this group of mice was less than that of either group of corn oil pretreated mice receiving APAP. At 4 hr, hepatic glutathione depletion and selective arylation of 44 and 58 kDa cytosolic proteins by APAP were both greatly diminished in CFB pretreated PPARα +/+ mice, but unchanged in CFB pretreated PPARα -/- mice. **Conclusions:** These findings suggest that the protection against APAP hepa-

totoxicity by peroxisome proliferator pretreatment is in part mediated by the activation of PPARα receptor, which may lead to diminished net availability of reactive intermediate of APAP. (Supported by a grant from PhRMA Foundation.)

204 CHANGES IN THE EXPRESSION OF MOUSE LIVER PLASMA MEMBRANE PROTEINS INDUCED BY CLOFIBRATE.

E. C. Peterson[1], D. J. McCann[2] and J. E. Manautou[1]. *[1]Dept. Pharmaceutical Sciences, University Connecticut, Storrs, CT and [2]Drug Disp. & Metab. Department., AstraZeneca, Wilmington, DE.*

Dosing with the peroxisome proliferator clofibrate (CFB) protects mice against acetaminophen (APAP) hepatotoxicity. Previous studies showed that clearance of APAP from liver is significantly faster in mice receiving CFB. This rapid clearance occurs in the absence of noticeable changes in bioactivating or detoxifying pathways for APAP, suggesting a possible role for plasma membrane transport proteins in the hepatoprotection. In this study, changes in the expression of mouse liver plasma membrane proteins were analyzed by two-dimensional gel electrophoresis (2-D gel). **Methods:** Male CD-1 mice received 500 mg CFB/kg i.p., daily for 5 or 10 days. Controls were given corn oil vehicle only. Liver plasma membrane (mLPM), canalicular (cLPM) and basolateral (bLPM) membranes were prepared by sucrose density gradients, and then subjected to 2-D gel analysis. **Results:** The most prominent change observed in mLPM was an increased expression of a cluster of acidic proteins with an apparent Mr of 47,000. Further separation of cLPM and bLMP revealed that this cluster of proteins is native to the basolateral domain of the plasma membrane. No prominent changes in expression of canalicular proteins were detected. **Conclusion:** This studies suggests that pretreatment with CFB induces primarily bLPM proteins, with no noticeable changes in the profile of cLPM proteins (Supported by grants from PhRMA Foundation and AstraZeneca.)

205 THIAZOLIDINEDIONES PRODUCE SEVERE HEPATIC STEATOSIS IN MICE EXHIBITING INCREASED HEPATIC EXPRESSION OF THE PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR γ.

U. A. Boelsterli, E. A. Atzpodien and M. Bedoucha. *F. Hoffmann-La Roche AG, Basel, Switzerland.*

Background: Thiazolidinediones (TZDs), used to treat non-insulin-dependent diabetes mellitus (NIDDM), are selective ligands for the peroxisome proliferator-activated receptor γ (PPARγ>). This receptor, which is involved in the regulation of lipid homeostasis, is normally not abundantly expressed in the liver. **Aim:** We explored the hypothesis that PPARγ expression in the liver of obese mice exhibiting NIDDM is upregulated and that, therefore, treatment with TZDs produces increased hepatic lipid deposition. **Methods:** Basal hepatic PPARγ gene expression was analyzed by quantitative PCR both in genetically obese KKA^y mice, an animal model for NIDDM, and lean C57BL/6 control mice. KKA^y and lean controls were treated orally with vehicle or the TZDs, troglitazone (100 mg/kg/day) or rosiglitazone (2.5 mg/kg/day) for 4 weeks. At the end of the study, the extent of hepatocellular lipid accumulation and its distribution was evaluated histopathologically in liver sections. **Results:** Untreated KKA^y mice exhibited upregulated hepatic expression of both PPARγ1 and PPARγ2 (6-fold and 2-fold, respectively) mRNA, as compared to transcript levels in lean C57BL/6 mice. While, in lean mice, prolonged treatment with the TZDs had no apparent effect on hepatic lipid homeostasis, treatment of obese KKA^y mice with troglitazone or rosiglitazone resulted in severe hepatocellular steatosis. **Conclusions:** TZD treatment of diabetic mice exhibiting high expression levels of hepatic PPARγ results in increased lipid deposition in the liver. These augmented hepatocellular fat stores may not only be a reservoir for the accumulating lipophilic drug but also predispose for progressive liver injury.

206 EFFECT OF TROGLITAZONE ON THE LIVER OF THE ZDF RAT MODEL OF DIABETES MELLITUS.

T. Watanabe, T. Furukawa, S. Sharyo, S. Ogata, M. Takaoka and S. Manabe. *Sankyo Co., Ltd., Fukuroi, Japan.*

Troglitazone was developed as a curative medicine for type II diabetes mellitus. As troglitazone was clinically used, serious case of liver dysfunction, the cause of which was suggested to be the dosing of the agent, were reported. Based on analysis of the clinical data, these rare adverse effects were classified as idiosyncratic hepatocellular injury, however, it was not clear what kind of factor was involved in the idiosyncracy. In this study, we administered troglitazone to male ZDF rats, an animal model of diabetes mellitus, at dose levels of 0, 100 or 400 mg/kg for up to 3 months to investigate the possibility that liver dysfunction was induced by long term treatment of troglitazone under diabetic condition. The results indicated that no abnormalities were observed in general conditions or blood biochemical parameters, i.e., AST, ALT, ALP and total bilirubin, which are good indicators of liver dysfunction. Moreover, in liver histopathological examinations, although fatty change of hepatocyte was observed in one rat given 400 mg/kg, hepatocellular degeneration or necrosis was not observed in any rats given troglitazone. In summary, it was concluded that 3-month treatment of troglitazone did not induce liver dysfunction in ZDF rats. Thus, the liver dysfunction in humans was not reproducible in the ZDF model, suggesting that diabetic condition itself may not directly related to idiosyncracy reported in diabetes mellitus patients treated with troglitazone.

207 COMPARATIVE TOXICITY OF THIAZOLIDINEDIONES IN ISOLATED RAT HEPATOCYTES.

J. R. Haskins, P. E. Rowse, R. Rahbari and E. A. de la Iglesia. *Parke-Davis Pharmaceutical Research, Ann Arbor, MI.*

Thiazolidinediones, including troglitazone and rosiglitazone, are agents for the treatment of adult-onset insulin resistant diabetes. Thiazolidinediones have caused sporadic hepatic dysfunction, that led to hepatic failure in a small number of cases. The potential to induce toxicity was compared in isolated rat hepatocytes with troglitazone (TRO), its quinone (TRO-Q) and sulfate metabolite, the dione and tocopherol segments of TRO, and rosiglitazone (ROSI). Hepatocytes were exposed for 2 hours and evaluated for LDH, ALT and AST leakage (membrane integrity) by solid-phase assay, MTT activity changes (reductive metabolism) by spectrophotometry and for mitochondrial transmembrane potential alterations, $\Delta\psi_m$ (cell energetics) by flow cytometry. Increased LDH, ALT or AST leakage ranged from 2.0 and 6.5-fold with TRO at ≥300 μM concentrations. MTT activity decreased 47% to 90% with TRO at ≥300 μM. TRO-Q exposures caused 52% and 79% decreased MTT activity at 500 and 600 μM, respectively. Reductive metabolism decreased 46% with 600-μM ROSI. TRO, TRO-Q and ROSI caused significant $\Delta\psi_m$ decreases. The IC_{50} for effects on cell energetics was 277, 524 and 595 μM for TRO, TRO-Q and ROSI, respectively. No effects were seen with the sulfate metabolite or the dione or tocopherol segments of TRO. The results indicate a relative order of potency for hepatic effects where TRO > TRO-Q > ROSI. Based on the mechanism of liver cell effects, hepatotoxicity may be a class effect with thiazolidinediones.

208 KINETIC DIFFERENCES IN γ-GLUTAMYLTRANSFERASE (GGT) FROM LIVER OF DIABETIC RATS MAY BE DUE TO CHANGES IN CARBOHYDRATE STRUCTURE.

P. D. Cornwell, S. V. Pok, T. R. Bagwell and J. B. Watkins, III. *Indiana University School of Medicine, Bloomington, IN.*

Recent studies have shown that GGT activity is increased in the liver of insulin-dependent diabetic rats; however, this increased activity was not due to increased expression of the enzyme. In our current work, GGT was purified from the livers of male and female Sprague-Dawley rats after induction of diabetes with streptozotocin. Michaelis-Menten kinetic analysis of GGT from diabetic male rats versus controls showed an average increase of 360% in maximal GGT velocity (V_{max}), an average decrease of 8% in the Michaelis constant (K_m), and an average increase of 803% in the ratio V_{max}/K_m, using L-glutamic acid-p-nitroanilide as the γ-glutamyl donor and 6 different acceptors (glycyl-glycine, glycyl-alanine, methionine, glutamine, glutamate and alanine). Under the same conditions, female rats showed a 60% increase in V_{max}, an 18% increase in K_m and a 50% increase in the V_{max}/K_m ratio. Because GGT is glycosylated, these kinetic results indicate probable conformational changes due to differences in the carbohydrate structures attached to the enzyme. The activity of several glycosyltransferases from the livers of the diabetic rats were compared to controls. β1-4 Galactosyltransferase was increased 257% in diabetics versus controls (0.157 nmol NADH depleted/μg protein/minute vs. 0.044 nmol NADH depleted/μg protein/minute, $p<0.05$); however, no significant changes were found in the activities of α1-2 fucosyltransferase, α1-3 fucosyltransferase, N-acetylglucosaminyltransferase II or α2-3 sialyltransferase. These data indicate that glycosylation is altered in diabetic rat liver, which could alter GGT carbohydrate structure in such a way that the enzyme is more catalytically active.

209 DIABETES PROTECTS MICE FROM LETHAL EFFECT OF THIOACETAMIDE HEPATOTOXICITY.

K. Shankar, V. S. Vaidya, T. Wang and H. M. Mehendale. *The University of Louisiana at Monroe, Monroe, LA.*

The diabetic state has been shown to potentate hepatotoxicity of classical hepatotoxicants like thioacetamide (TA), CCl4 and chloroform in male Sprague-Dawley rats. Results from our laboratory have shown that TA liver injury in streptozotocin (STZ)-induced diabetic rats is highly exaggerated (~6-fold higher) and is also accompanied by decreased compensatory tissue repair. Higher liver injury further progressed owing to compromised tissue repair, leading to 90% mortality from an ordinarily non-lethal dose of TA. The objective of the present studies was to characterize the modulation of TA hepatotoxicity due to diabetes in male C57BL6 mice. Diabetes was induced by a single dose of STZ (200 mg/kg, i.p. in citrate buffer). Diabetes was confirmed by plasma glucose concentration (>350 mg/dl) prior to administration of TA or saline vehicle. Paradoxically, a dose of TA (1000 mg/kg i.p. in 1 ml saline/ kg) which caused 90% mortality in non-diabetic mice, caused only 10% mortality in diabetic mice. The diabetic state perplexingly protected from TA-induced liver injury and consequent lethality. A time-course of liver injury revealed ~5-fold higher liver injury in the non-diabetic mice as measured by alanine aminotransferase (ALT) activity. Liver injury was also confirmed by histopathology of liver sections by H & E staining. Tissue repair response as measured by 3H-thymidine incorporation into hepatonuclear DNA, was ~3-fold higher in the diabetic mice (at 48 hr) compared to non-diabetic mice. The present data indicate a striking species-difference in the way diabetes modulates the hepatotoxicity of TA. Our data also suggests that the tissue repair response in the normal mice is sluggish and appears at a later time (Supported by Board of Regents Support Fund.)

210 POTENTIATION OF THIOACETAMIDE-INDUCED LIVER INJURY IN STREPTOZOTOCIN-INDUCED DIABETIC RATS.

T. Wang[1], K. Shankar[1], M. J. J. Ronis[2] and H. M. Mehendale[1]. [1]*Division of Toxicology, College of Pharmacy and Health Sciences, The University of Louisiana at Monroe, Monroe, LA and* [2]*Arkansas Children's Hospital Research Institute, Department of Pediatrics, University of Arkansas for Medical Sciences, Little Rock, AR.*

Earlier studies revealed that enhanced liver injury accompanied by compromised liver tissue repair that leads to 90% lethality from a non-lethal dose of thioacetamide (TA, 300 mg/kg, ip) in streptozotocin-induced diabetic rats. The object of this study was to investigate underlying mechanisms for the increased liver injury and decreased liver tissue repair. We tested two hypotheses: (1) the increased TA liver injury is due to induction of CYP2E1 and FMO1 in diabetic condition; (2) the inhibition of tissue repair in diabetes is a function of diabetic condition rather than high liver injury of TA. Male Sprague-Dawley rats were pretreated with isoniazid (INH), a CYP2E1 inducer, or diallyl sulfide (DAS), a CYP2E1 inhibitor. Plasma ALT and SDH showed that TA liver injury was significantly increased in the INH-pretreated rats, whereas it was decreased 60% in DAS-pretreated rats. DAS pretreatment to the diabetic rats decreased a maximum of 75% TA liver injury. FMO1 is induced 1.8-fold in the diabetic rats. Paradoxically, after FMO1 was inhibited by dietary administration of indole-3-carbinol (0.25%, 10 days), TA liver injury was highly increased. Further, we compared tissue repair by employing equi-toxic doses of TA (30 mg/kg in the diabetic rats yields near equal liver injury as observed with 300 mg/kg in the non-diabetic rats). [^{3}H]-thymidine pulse labeling revealed DNA synthesis is delayed in the diabetic rats in spite of equal liver injury in diabetic and non-diabetic rats. We conclude that (1) CYP2E1 might primarily mediate bioactivation-based TA liver injury. (2) Compensatory tissue repair is delayed at low dose of TA, and delayed and decreased at higher dose of TA in the diabetic rats (Louisiana Board of Regents Support Fund).

211 MOLECULAR MECHANISMS OF CYTOPROTECTION AGAINST HYDROGEN SULFIDE TOXICITY.

M. A. Eghbal, B. Wu, P. S. Pennefather and P. J. O'Brien. *Faculty of Pharmacy, University of Toronto, Toronto, Ontario, Canada.* Sponsor: J. P. Uetrecht.

Hydrogen sulfide is a well known industrial toxin, yet it is produced in the body and has been postulated to have a physiological role. Therefore, metabolism may contribute to its biological effects. Glycine and alanine which block chloride ion channels in hepatocytes decreased NaHS cytotoxicty in freshly isolated hepatocytes suggesting that NaHS enters the cells via chloride ion channels. Hepatocyte GSH was depleted by NaHS although GSH did not react with NaHS in a cell free cystem. This suggests that an NaHS metabolite reacts with GSH. Furthermore GSH-depleted hepatocytes were more susceptible to NaHS than control cells, suggesting that GSH detoxifies this NaHS metabolite. Cytochrome P-450 inhibitors e.g. cimetidine, metyrapone and phenylimidazole were protective against NaHS toxicity, suggesting that cytochrome P-450 is involved in the metabolic activation of NaHS. Methionine was protective against NaHS and its protective effect was overcome by adenosine, an S-adenosyl-L-homocysteine hydrolase inhibitor. This suggests that intracellular methylation by S-adenosylmethionine detoxifies NaHS.

212 BETAINE - ITS ROLE IN METABOLISM OF GLUTATHIONE AND *S*-CONTAINING AMINO ACIDS.

S. K. Kim and Y. C. Kim. *Seoul National University, Seoul, Republic of Korea.*

We have examined the role of betaine in metabolism of glutathione (GSH) and *S*-containing amino acids to elucidate the mechanism of its dual action against chloroform hepatotoxicity previously observed in this laboratory (Kim *et al., Fd Chem Toxicol* 36: 655, 1998). Betaine (1000 mg/kg, ip) rapidly decreased the hepatic GSH level, but not the plasma GSH, in rats and mice. However, both hepatic and plasma GSH levels were elevated significantly 24 hr following the treatment. Hepatic efflux of GSH into plasma or the ratio of GSSG/GSH was not altered by betaine. Decreases in hepatic cysteine, glutamate and glycine were evident from t = 0.5 to 4 hr. Cysteine in plasma was increased from t = 0.5 hr. In liver, taurine and several amino acids, such as aspartate, tyrosine, isoleucine and leucine were declined whereas methionine was significantly increased. Hepatic *S*-adenosylhomocysteine (SAH) and *S*-adenosylmethionine (SAM) levels were also elevated, but cystathionine was decreased by a 4 hr prior dose of betaine. The activities of hepatic cystathionine β-synthase (CβS), cystathionine γ-lyase (CγL) and γ-glutamylcysteine synthetase (GCS) were all increased 24 hr after the betaine treatment. Hepatic uptake of cysteine was also decreased at t = 2 hr as determined by arterial-venous difference for cysteine in liver. In mice pretreated with propargylglycine (200 μmole/kg, ip), an irreversible inhibitor of CγL, betaine decreased the hepatic GSH and cysteine levels at t = 4 hr, however, betaine-induced increase of GSH in liver, kidney and plasma was diminished at 24 hr following the treatment. The results suggest that reduction of cysteine uptake from blood in conjunction with inhibition of the transsulfuration pathway be responsible for the rapid decrease in hepatic GSH, and that activation of the transsulfuration pathway and related enzymes play an important role in the elevation of this endogenous tripeptide in later time periods in animals treated with betaine.

213 IDENTIFICATION OF RAT HEPATIC PROTEINS ADDUCTED BY MALONDIALDEHYDE AND 4-HYDROXYNONENAL.

M. Panagiotidis[1], S. Luckey[1], D. Hartley[2] and D. Petersen[1]. [1]*University of Colorado Health Sciences Center, Denver, CO and* [2]*University of Kansas Medical Center, Kansas City, KS.*

Lipid peroxidation results in the production of α, β–unsaturated aldehydes, the most abundant products being malondialdehyde (MDA) and 4-hydroxynonenal (4-HNE). These aldehydes initiate cellular effects including dysregulation of Ca^{2+} homeostasis and signal transduction. In addition, their chemical reactivity facilitates adduction of cellular proteins possibly mediating cytotoxic events resulting from exposure to chemicals with prooxidative potential. The aim of this study is to identify hepatic aldehyde adducted proteins in rats following acute or chronic prooxidatvie challenge. Acute prooxidative challenge was by intragastric administration of CCl_4 (1ml/kg) after which the rats were sacrificed at 2.5 to 72 hrs following treatment. Chronic prooxidative challenge was by administration of an ethanol-containing diet for up to 120 days. Hepatic subcellular fractions were prepared and subjected to immunoprecipitation -immunoblotting using polyclonal antibodies specific for 4-HNE or MDA-protein epitopes. Immunoisolated proteins were subjected to tryptic digestion and HPLC separation of peptides for amino acid sequence analysis. MDA and 4-HNE adducted proteins with molecular weights of 205 and 170 kDa were isolated from either CCl_4 or alcohol-treated rats and identified as non-muscle myosin heavy chain A and carbamoyl phosphate synthetase I, respectively. 70 kDa and 35 kDa proteins adducted with wither 4-HNE or MDA were identified as urate oxidase. These results indicate that 4-HNE and MDA adduct common target proteins that are relatively abundant and have toxicologic significance with respect to disruption

of cytoskeletal function, urea cycle inhibition and uric acid oxidation. (Supported by NIAAA/NIH AA-09300.)

214 PROTEIN ADDUCT FORMATION BY NORCOCAINE NITROXIDE, AN N-OXIDATIVE METABOLITE OF COCAINE.

S. K. Ramaiah, J. W. Munson, J. K. Tolson and S. M. Roberts. *University of Florida, Gainesville, FL.*

Several lines of evidence indicate that N-oxidative metabolism of cocaine is required for its hepatotoxicity. It was demonstrated over 20 years ago that cocaine N-oxidative metabolism leads to formation of a reactive metabolite that binds irreversibly to proteins, and this binding correlates closely with cocaine-induced liver injury. The identity of the reactive metabolite has not been established with certainty. Early reports suggested that the stable nitroxide metabolite of cocaine (norcocaine nitroxide; NCNTX) was not sufficiently reactive to be responsible for protein binding. However, to test this more directly, 14C-labelled NCNTX was synthesized and incubated with mouse hepatic microsomes. Rapid, irreversible binding of radiolabel to protein was observed. The addition of NADPH to the incubation produced only a modest increase in radiolabel binding, indicating that oxidation of NCNTX is not required for protein-adduct formation. In subsequent experiments, incubation of unlabelled NCNTX with mouse whole liver homogenate was found to result in selective adduction of specific proteins as determined by Western blot analysis. Many of these proteins appear to have similar molecular masses as proteins adducted during cocaine hepatotoxicity *in vivo*. Two of the protein targets for cocaine binding *in vivo* have been identified recently as hsp60 and transferrin. Incubation of NCNTX with these proteins *in vitro* resulted in protein adduct formation. Incubation with cocaine under these conditions, in comparison, produced little or no protein adduct formation. These observations suggest that NCNTX formed from N-oxidative metabolism of cocaine is spontaneously reactive with proteins and that it could be responsible for much, if not all, of the protein adduct formation associated with cocaine hepatotoxicity. (Supported by DA-06601.)

215 COVALENT BINDING OF KETOCONAZOLE IN RAT HEPATIC TISSUE.

C. J. Buckholz and R. J. Rodriguez. *Oregon State University, College of Pharmacy, Corvallis, OR.*

It has been speculated that ketoconazole's (KT) hepatotoxicity may be a result of the parent compound and/or reactive metabolite(s) that covalently binds with hepatic macromolecules, thereby producing hepatic damage. Presently, mechanism(s) of toxicity or bioactivation of KT has not been investigated *in vivo*. The results of this study provide evidence that covalent binding to hepatic tissue is dose- and time-dependent. To determine whether covalent binding occurs, male Sprague-Dawley rats were injected with radiolabeled ^{3}H-KT (1.5 μCi/mg) at doses of 40 mg KT/kg and 90 mg KT/kg *i.p.* The liver was harvested at 0, 0.5, 1, 2, 4, 8, 12 and 24 hr after *i.p.* administration. Acute studies were performed because it is expected that formation of reactive metabolites will occur soon after KT administration. Liver tissues were homogenized and the protein was precipitated with 0.9 M TCA. The protein pellet was exhaustively washed with 80% methanol. Radioactivity was measured. The radioactivity was normalized to dpm/mg protein. Significant covalent binding occurred as early as 0.5 hr for both doses evaluated. The 40 mg KT/kg dose peaked at 2-hr (0.026 nmole KT/mg protein ± 0.005 nmole KT/mg protein) with a steady decline by 24 hr (0.018 nmole KT/mg protein ± 0.008 nmole KT/mg protein). The 90 mg KT/kg dose peaked at 8 hr (0.052 nmole KT/mg protein ± 0.001 nmole KT/mg protein) with a steady decline by 24 hr (0.030 nmole KT/mg protein ± 0.007 nmole KT/mg protein). The results represent three separate experiments. The binding of KT to hepatic tissue may be responsible for the hepatic injury and hepatic necrosis seen in the clinical literature. Moreover, the significant increase in covalent binding seen with the higher dose may warrant caution for those patients treated with higher doses of KT for prostate cancer. (Supported by Pharmaceutical Research and Manufactures of America Foundation.)

216 EFFECT OF DIMETHYLNITROSAMINE EXPOSURE IN MICE ON SELECTED MRNA TRANSCRIPTS FROM PERITONEAL, BONE MARROW, AND LIVER CELLS.

D. G. Fraser, T. L. Horn, V. R. Lappi, M. S. Rutherford and L. B. Schook. *University of Minnesota, St. Paul, MN.*

Dimethylnitrosamine (DMN) is a hepatotoxicant and a suspected carcinogen found in foods and in some industrial settings. We have studied the influence of murine macrophage heterogeneity and activation state by monitoring selected transcript expression following daily dimethylnitrosamine exposure. The purpose of this study was to determine whether expression of selected genes is altered during DMN exposure in the liver and peripheral tissue. Cells from the peritoneal cavity responded to 7 days of DMN exposure by increasing transcripts for the chemokine C10 and phosphoglycerate kinase in the latter part of the experimental period. Thioglycollate-elicited cells from the peritoneal cavity, however, responded to DMN exposure with an early increase in the relative amount of transcripts for the chemokine C10 and phosphoglycerate kinase and then a decrease in the latter days of the experiment. Cells recovered from the bone marrow showed little change in expression for these transcripts due to DMN exposure, whereas, these same cells from mice pretreated with thioglycollate responded with substantial increases in transcripts for the chemokine C10 and for mouse myeloid secondary granule protein. In the liver, the transcript for murine calcium binding protein pp52 increased coincidentally with an increase in pathology due to exposure to DMN. Thus, DMN exposure *in vivo* has both tissue-specific effects and can influence peripheral macrophage populations. (Supported by NIH grants 5F32 ES05745-03 and ES04348.)

217 HEPATIC ISCHEMIA/REPERFUSION INJURY REDUCED BY DIMETHYL SULFOXIDE.

J. B. Ulreich, Y. Ito, R. S. McCuskey, M. A. Levy, P. W. Johnson, R. Roy, J. J. Whitehead, J. R. Talley and P. Z. Nakazato. *University of Arizona, Tucson, AZ.*

Many potential transplant recipients die waiting for livers. Use of organs from non-heart-beating donors (NHBD) might reduce the current organ shortage. However, warm ischemia in NHBD produces damage that can lead to graft failure in recipients post-transplantation. The hepatic microvascular system is the target of ischemia/reperfusion (I/R) injury. Dimethyl sulfoxide (DMSO) has several well-known biological activities that may prevent or reduce such damage. Male Fischer 344 rats were pretreated with DMSO (2 ml/kg, ip) or saline (control) 30 minutes prior to the induction of ischemia. The rats were then subjected to 60 minutes of left lateral lobar ischemia and 60 minutes of reperfusion. Sham-operations were performed in an identical manner without vascular occlusion. The hepatic microvasculature of the left lateral lobe was observed using established high resolution *in vivo* microscopic methods. The numbers of leukocytes adhering to the sinusoidal wall, swollen endothelial cells (EC) and sinusoids containing blood flow (SCF) were counted. The phagocytic activity of Kupffer cells was assessed by counting the number of Kupffer cells that phagocytosed injected fluorescent latex particles in relation to the number of SCF. Results demonstrated that I/R caused significant increases in the numbers of adhering leukocytes, swollen EC, and phagocytic Kupffer cells as well as Kupffer cell phagocytic activity when compared to sham-operated animals. Pre-treatment with DMSO prevented these adverse events from occurring in the ischemic lobe. The number of SCF was significantly decreased by I/R, however, pre-treatment with DMSO restored SCF to sham-controls levels. Results indicate that pre-ischemic treatment of rats with DMSO reduced damage caused by warm ischemia. This suggests that pre-treatment with DMSO should prevent tissue damage in NHBD livers, thus providing additional organs suitable for transplantation. (Supported by the ADCRC [JU, PN], the AHA, AZ Affiliate [JU], the Richard Siegel Foundation and NIEHS Center Grant P30-ES-06694 [JU].)

218 EFFECT OF CRUCIFEROUS VEGETABLES (CV) ON CAFFEINE METABOLISM IN HUMAN VOLUNTEERS.

P. J. Young[1], D. G. Walters[1], C. Springall[1], F. A. Fairweather[1], E. A. Bowey[1], G. Williamson[2], N. J. Gooderham[3], A. R. Boobis[3] and B. G. Lake[1]. [1]*TNO BIBRA International Ltd., Carshalton, United Kingdom,* [2]*Institute of Food Research, Norwich, United Kingdom and* [3]*Imperial College School of Medicine, London, United Kingdom.*

In this study we have examined the effect of CV on the metabolism of caffeine (which reflects the activity of hepatic CYP1A2) in a group of 20 male, non-smoking, Caucasian volunteers. The study was conducted in three phas-

es, each of 12 days with 2 days between each phase. In phases 1 and 3 (washout periods) the subjects abstained from consumption of CV, whereas in phase 2 the subjects consumed 500 g per day of CV (250 g each of cooked Brussels sprouts and broccoli, eaten at breakfast and dinner). For the last 48 hr of each phase, the subjects refrained from consumption of caffeine and cooked and smoked meat and fish products. The morning after the end of each phase the subjects ingested a 2 mg/kg oral dose of caffeine. Saliva samples were collected at 0, 1, 2, 4, 6, 9, 12 and 22 hr and assayed by LC-MS-MS for caffeine content and at 6 hr for the paraxanthine/caffeine (17X/137X) ratio. Urine samples were collected from 2 hr before until 8 hr after the caffeine dose and were assayed by LC-MS-MS for caffeine and selected caffeine metabolites. Compared to phase 1, caffeine metabolism was significantly induced by CV consumption. Clearance values were 3356 and 3580 ml/hr, t½ values were 4.83 and 4.32 hr and $AUC_{0-\infty}$ were 58.7 and 50.0 μg-hr/ml for phases 1 and 2, respectively. No statistically significant differences were noted between phases 1 and 3. In contrast, CV treatment had no significant effect on various caffeine urinary metabolite ratios for CYP1A2, N-acetyltransferase 2 or xanthine oxidase activities, or on the 17X/137X saliva ratio after 6 hr. These results demonstrate that CV can induce CYP1A2-dependent caffeine metabolism in humans and that effects on caffeine metabolism are more reliably assessed by saliva kinetics than by the use of metabolite ratios. (Supported by UK MAFF.)

219 BENOXAPROFEN FORMS PROTEIN ADDUCTS IN THE BILE CANALICULI OF FEMALE CD1 MICE.

J. Caldwell, S. Fakurazi, L. A. Ramsay, N. Somchit and R. D. Goldin. *Imperial College School of Medicine, London, United Kingdom.*

The NSAID benoxaprofen (Oraflex; B) was withdrawn from use after a number of cases of fatal cholestatic jaundice in elderly patients receiving the drug. The formation of protein adducts of various NSAIDs has been associated with their hepatotoxicity in both animal and human studies (Pumford et al (1997) Drug Metab Rev 29, 39). We now report on an investigation of the mechanisms of the hepatotoxicity of benoxaprofen. Female CD1 mice were given single doses of benoxaprofen (5-200 mg/kg) or dose vehicle. The mice were sacrificed after 6 h, the livers excised and subcellular fractions prepared by differential centrifugation. The various fractions were subjected to SDS-PAGE and Western blotting with a rabbit anti-B-KLH antibody. There was a single major 110 kDa adduct concentrated in the 600 x g_{av} fraction. The amounts of this adduct increased in a dose-dependent manner. Adduct recognition was inhibited by B and B-RSA but not RSA. Immunohistochemical analysis showed these adducts to be localised in the bile canalicular plasma membrane. The molecular mass and intrahepatic location of these adducts, currently being characterised further, raises the possibility that they may be involved in the hepatotoxicity of B. We have shown with other hepatotoxic NSAIDs (diclofenac, sulindac) that the formation of 110 kDa adducts in the bile canalicular plasma membrane is associated with impairment of the active secretion of bile salts suggesting that the hepatotoxicity of these drugs is mediated by the intrahepatocytic accumulation of bile salts. 220 EFFECTS OF BILIRUBIN AND ARSENITE ON GLUTATHIONE S-TRANSFERASE AND NAD(P)H: QUINONE OXIDOREDUCTASE ACTIVITIES IN MOUSE HEPATOMA HEPA 1C1C7 CELLS.

A. O. S. El-Kadi, J. M. Seubert, L. V. Castro, C. D. Webb, C. K. Yaremko and J. R. Bend. *University of Western Ontario, London, Ontario, Canada.*

The current study evolved from recent results in our laboratory showing that bilirubin induces Cyp1a1 gene transcription through direct interaction with the aryl hydrocarbon receptor (AHR).The aims of this study were to; 1) determine if the increased expression of Cyp1a1 also occurs with other AHR battery genes such as glutathione s-transferase (GST) and NAD(P)H: quinone oxidoreductase (NAD(P)H:QOR), and 2) characterize the effects of arsenite, a potent inducer of heme oxygenase, on GST and NAD (P)H:QOR in the mouse hepatoma Hepa 1c1c7 wild-type (WT), AHR deficient (C12) and AHR nuclear translocator (ARNT) deficient (C4) cell lines. Bilirubin (1-250 μM) caused a concentration-dependent inhibition of GST and NAD(P)H:QOR in all cells with the largest inhibition in WT cells. Arsenite (5-20 μM) treatment resulted in a concentration-dependent decrease in GST and NAD(P)H:QOR activities in WT cells and to a lesser extent in C4 cells, whereas in C12 cells arsenite had no effect on GST but increased NAD(P)H:QOR activity. Co-administration of beta-naphthoflavone (10 μM) and arsenite (5-20 μM) further potentiated the inhibition of GST and NAD(P)H:QOR in WT cells with no changes in C4 cells while it further potentiated the increase of NAD(P)H:QOR activity in C12 cells. We conclude that the AHR mediated at least part of the inhibitory effect of bilirubin and arsenite on GST and NAD(P)H:QOR. Furthermore, ARNT appears to be required for the increase of NAD(P)H:QOR by arsenite and the AHR may prevent ARNT from fully participating in other ARNT-dependent pathways.

221 Mrp2 IS CRITICAL FOR CHOLESTASIS MEDIATED BY ESTRADIOL-17 β(β-D-GLUCURONIDE) ($E_2$17G).

M. Vore and L. Huang. *University of Kentucky, Lexington, KY.*

$E_2$17G is an endogenous metabolite of estradiol that decreases bile flow in the rat while estradiol-3-β-D-glucuronide ($E_2$3G) increases bile flow under the same experimental conditions. The present studies were designed to test the hypothesis that the accumulation of $E_2$17G in bile is essential for its cholestasis and whether direct inhibition of taurocholate (TC) transport is responsible for $E_2$17G cholestasis. Membrane vesicles from Sf9 cells expressing the bile salt export pump (Bsep) and rat canalicular membrane vesicles were used for transport studies. The single pass isolated perfused liver from male TR⁻ (mrp2-deficient Wistar rats) and control Wistar rats was used to monitor $E_2$17G cholestasis. In Sf9 membrane vesicles, Bsep-mediated ATP-dependent transport of TC (1 μM) was 110 ± 12.5 and 108 ± 17.3 % of control in the presence of 10 and 50 μM $E_2$17G, respectively. In rat canalicular membrane vesicles, 50 μM $E_2$17G and $E_2$3G inhibited ATP-dependent transport of 1 μM TC by 67 and 64% respectively. Infusion of 24 μmol ^{3}H-$E_2$17G was not able to induce cholestasis in TR⁻ rats, while 2 μmol ^{3}H-$E_2$17G inhibited bile flow by 51% in control rats. The peak biliary concentration of $E_2$17G, determined by HPLC, was 3.4 and 2.5 mM in male control and TR⁻ rats, respectively, whereas 2.5 mM $E_2$17G in bile is associated with cholestasis in control rats. Cumulative biliary excretion of $E_2$17G equivalents over 70 min was 1205 ± 136.5 and 908 ±15.8 nmol in control and TR⁻ rats, respectively. These data demonstrate that the accumulation of $E_2$17G in bile alone is not sufficient to induce cholestasis. Furthermore, direct inhibition of Bsep-mediated TC transport is not the mechanism by which $E_2$17G induces cholestasis. These data indicate that mrp2-mediated transport of $E_2$17G is critical to its ability to induce cholestasis. (GM55343)

222 BILE ACIDS AFFECT LIVER MITOCHONDRIAL BIOENERGETICS: POSSIBLE RELEVANCE FOR CHOLESTASIS THERAPY.

A. P. Rolo and C. M. Palmeira. *Center for Neurosciences, Department of Zoology, Portugal.*

Liver disease ranks as the third leading disease-related cause of death in the world. Two important but poorly understood manifestations of liver disease are cholestasis and steatosis, that can progress to primary billiary cirrhosis (a form of cholestatic liver disease). For years, several mechanisms are pointed out for this type of liver disease but they still poorly understood, like the exact therapy that should be prescribed to these patients, claiming our attention to this fact. The use of bile acid therapy, usually in the form of ursodeoxycholic acid (UDCA) and its conjugates (TUDC and GUDC) as increased, but the mode of action remains poorly understood. Several observations support the concept that bile acids may be cytotoxic by causing mitochondrial dysfunction. In this work we evaluate the toxicity of the bile acids cholic, ursodeoxycholic, deoxycholic, lithocholic and chenodeoxycholic on liver mitochondrial bioenergetic functions. Both cholic and ursodeoxycholic acids don't affect mitochondrial membrane potential nor the phosphorylative system in concentrations ranging from 10 to 200 μM. Opposingly, lithocholic and chenodeoxycholic acids decrease mitochondrial membrane potential for concentrations of 25 and 50 μM, respectively. Deoxycholic acid for concentrations ranging from 10 to 100 μM decrease mitochondrial membrane potential and additionally, at 100 μM the phosphorylative system is strongly affected, suggesting a strong effect at the ATP-synthase level. Furthermore, the hepatoprotective effects of UDCA and its conjugates were evaluated in terms of mitochondrial permeability transition pore (MPT) induction. UDCA, TUDC and GUDC decreases the susceptibillity of induction of MPT promoted by the toxic bile salts. These results claim attention for the fact that the impairment of mitochondrial function by bile acids can be clinically relevant for patients with cholestasis.

223 CYTOTOXIC EFFECTS OF METHYLENE DIANILINE TO PRIMARY CULTURED RAT BILIARY EPITHELIAL CELLS.

V. Santa Cruz, T. R. Dugas, H. Liu and M. F. Kanz. *The University of Texas Medical Branch, Galveston, TX.*

Methylene dianiline (4,4'-diaminodiphenylmethane, DAPM), a starting ingredient in the production of polyurethanes and epoxy resins, causes cholangitis and cholestasis in rats and humans by an unknown mechanism. DAPM initially targets biliary epithelial cells (BEC) in rats; early *in vivo* effects include increases in biliary levels of glucose and inorganic phosphate. *In vitro* studies using a primary BEC culture system could provide information regarding potential impairments in BEC structure/ function induced by DAPM. Our objectives were to 1) isolate, culture, and characterize primary rat BEC, and 2) perform dose-response and time-course studies of DAPM toxicity using these primary BEC cultures. BEC were isolated using a collagenase liver perfusion method (*Gastroenterology 104:840, 1993*) and cultured on collagen coated plates. Purity was assessed by specific markers for BEC: cytokeratin 19, OC.2 (a BEC-specific surface antigen), γ-glutamyl transpeptidase (GGT) activity and by ultrastructure. BEC cytotoxicity to xenobiotics was assessed by release of GGT, reduction in transepithelial resistance (TER), and formation of a formazan dye from the tetrazolium salt, XTT. The sensitivity of these assays was XTT > TER > GGT. The cytotoxicity of DAPM and α-naphthylisothiocyanate (ANIT) was assessed using BEC and HepG2 cells. BEC were more sensitive to ANIT (0.1 mM) and DAPM (2 mM) than HepG2 cells (0.2 mM and >10mM, respectively). BEC cytotoxicity was demonstrated at 2 mM DAPM, but this concentration is ~3X that found in bile. Thus, the toxic effects of DAPM *in vivo* may be due to 1) proximate metabolite(s) of DAPM, 2) synergistic effects of DAPM with biliary constituents, or 3) unknown phenotypic changes of cultured BEC. (Supported by NIEHS 06348; NIEHS T32-ES 07254; F31-ES 05831.)

224 NITRIC OXIDE ABOLISHES POST-NICOTINE DETRIMENTAL IMPACT ON STRESS-INDUCED GASTRIC ULCERS.

B. Qiu[1], Q. Mei[2], W. Wu[1], D. Qin[1] and C. J. Pfeiffer[3]. [1]*Shantou University Medical College, Shantou, China,* [2]*4th Military Medical University, Xian, China and* [3]*Department of Biomedical Sciences & Pathology, Virginia Tech, Blacksburg, VA.* Sponsor: M. Ehrich.

Chronic nicotine treatment or nitric oxide (NO) reduction intensifies stress-induced gastric ulcers. We tested whether a NO donor could prevent cold-restraint stress-induced gastric ulcers in chronic nicotine-treated rats. Nicotine 50μg/ml in drinking water was given ad lib for 20 days to male SD rats (160-180g, 8 rats/group). NO donor (Isosorbide dinitrite, 10mg/kg, PO) was given 1h and 10min before stress. Stress (2h) induced gastric ulcers, and nicotine treatment significantly intensified the ulcers. However, NO donor treatment failed to reduce this potentiated action. Ulcer index (mm): Water: 6.0±0.7; Nicotine: 19.0±1.7*; Nicotine+NO donor: 17.8±1.7*. Gastric mucus was measured (alcian blue). Mucus content (mg/g): Water: 200±17; Nicotine: 122±14*; Nicotine+NO donor: 143±15*. In another series of experiments, rats drank nicotine solution for 20 days, then the solution was replaced by water. Some ex-nicotine rats were treated a NO donor (10mg/kg, PO, tid). After 10 days, all animals were stressed. Ten-day nicotine cessation still remained a markedly intensifying action, and ten-day NO donor treatment completely abolished this detrimental impact. Ulcer index: Water: 6.3±0.7; Ex-nicotine: 11.0±0.9*; Ex-nicotine+NO donor: 5.8±0.7. Mucus content: Water: 190±18; Ex-nicotine: 142±16* Ex-nicotine+NO donor: 210±19. Conclusion: nicotine treatment reduced gastric mucus and intensified stress-induced gastric ulcers. Neither nicotine cessation alone nor acute NO donor treatment reversed nicotine worsening action on either mucus content or ulcers. However, nicotine cessation plus chronic NO donor treatment completely abolished the impact of nicotine on mucus reduction and ulcerogenic action. *$p<0.05$ vs water group.

225 DECREASE IN SERUM ACTIVITY OF INTESTINE-DERIVED ALKALINE PHOSPHATASE AS A POTENTIAL NON-INVASIVE INDICATOR OF DICLOFENAC-INDUCED ENTEROPATHY.

B. K. Shipp[1], W. E. Hoffmann[2], A. B. West[3], A. Balakumaran[1], C. R. Atchison[4] and M. T. Moslen[1]. [1]*University of Texas Medical Branch, Galveston, TX,* [2]*University of Illinois, College of Veterinary Medicine, Urbana, IL,* [3]*New York University Medical Center, New York, NY and* [4]*United States Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

Endoscopy of patients and volunteers receiving therapeutic doses of the non-steroidal anti-inflammatory drug diclofenac (Voltaren®) has revealed bleeding and ulcers in the proximal small intestine. In addition, post-mortem studies have linked NSAID use to ulcer formation in the distal small intestine [SI], a region difficult to evaluate by endoscopy. Our laboratory has observed decreases in serum activity of intestine-derived alkaline phosphatase [iALP] in rats given a single, large enteropathy-inducing dose of diclofenac (50 mg/kg). Determine if repeated treatment with diclofenac at the lower recommended therapeutic dosage (10 mg/kg for rodents) leads to decreases in serum iALP activity. Fed adult male Sprague-Dawley rats were treated by oral gavage for 5 days with 10 mg/kg diclofenac given once per 24 hr or in a divided dose of 5 mg every 12 hrs. Control animals were gavaged with the vehicle every 12 hr. Rats were sacrificed 12 hrs after the final dose, the gastrointestinal tract was examined for ulcer numbers and locations, and serum was analyzed for activities of ALP isozymes. Both the single and divided dosage regimens for diclofenac treatment resulted in a similar and appreciable number of ulcers in both the distal SI (15.6±10.2 and 17.8±12.3) and the cecum (10.8±7.9 and 5.0±6.5) without appreciable stomach lesions. Serum activities of iALP in the single and divided diclofenac dosage regimens were diminished by 32% and 51%, respectively. This observed decrease in serum activity of intestine-derived ALP after repeated treatment with a therapeutic dosage of diclofenac suggests that iALP might be used as a cost-effective non-invasive test for detecting NSAID-induced enteropathy in place of upper endoscopy. 226 ENZYME POLYMORPHISM IN COLON CANCER CASES.

K. Golka[1], H. C. Roemer[1], C. Roetzel[1], R. Thier[1], T. Reckwitz[2], F. Geller[1], U. Zorn[2] and D. Loehlein[2]. [1]*Institute of Occupational Physiology at the University of Dortmund, Dortmund, Germany and* [2]*Department of Surgery, Staedt. Kliniken Dortmund, Dortmund, Germany.*

Colon cancer is associated with genetic, occupational, and environmental factors. The polymorphic enzymes N-acetyltransferase 2 (NAT2), glutathione transferase M1 (GSTM1), and glutathione transferase T1 (GSTT1) are predisposing factors for several human cancers. Therefore, the study was carried out in an area of former coal, iron, and steel industries with a known elevated colon cancer mortality. The distribution of the genotypes of NAT2, GSTM1, and GSTT1 was investigated in 100 colon cancer cases and 150 controls (suffering from non-malignant diseases) from the same department. They were genotyped from leukocyte DNA by RFLP and PCR. Additionally, possible occupational and non-occupational risk factors were investigated using a questionnaire. In cancer cases 65% were "slow" acetylators, 53% were GSTM1 negative and 15% were GSTT1 negative. In controls 61% were "slow" acetylators, 51% were GSTM1 negative, and 14% were GSTT1 negative. In contrast to most studies on colon cancer cases, an overrepresentation of the "rapid" acetylator status was not observed in our study group from an area with known elevated colon cancer mortality. The impact of the "rapid" acetylator genotype as a risk factor for colon cancer may vary in different areas possible due to occupational and/or environmental factors. (Work was supported by Deutsche Forschungsgemeinschaft.)

227 EXPRESSION OF FLAVIN-CONTAINING MONOOXYGENASES IN HUMAN INTESTINE.

S. Kingkeohoi[1], R. J. Rodriguez[2], T. M. Filtz[2] and C. L. Miranda[1]. *Oregon State University* [1]*Dept. of Environment and Molecular Toxicology and* [2]*College of Pharmacy, Corvallis, OR.*

Drug metabolism in the small intestine can be considered an initial source of bioconversion of orally administered drugs resulting in decreased drug absorption. Thus, presystemic intestinal metabolism by cytochrome P-450 (CYP) and/or flavin-containing monooxygenases (FMO) may have significant effect on oral drug bioavailability. Exhaustive literature exists on intesti-

nal-CYP effect of drug absorption, while there is minimal research in the area of intestinal-FMO. The results of this study provide evidence that FMO isozymes are present in the GI tract. Western blotting techniques were used to determine the presence of FMO isozymes from microsomes prepared from human jejunal tissue and the human intestinal cell line, Caco-2. The results indicate that FMO1 was present in both the jejunal tissue as well as the Caco-2 cell line. FMO3 was present only in the jejunal tissue while FMO5 was present in the Caco-2 cells. These results are the first to demonstrate that a human intestinal cell line expresses various isozymes of FMO (FMO1 and FMO5). Moreover, the presence of FMO1 in the jejunal tissues and the Caco-2 cells correlate with published reports of FMO1 in rat and rabbit intestine. Lastly, these results demonstrate that the human jejunum expresses at least two forms of FMO (FMO1 and FMO3) which can result in presystemic metabolism of orally administered pharmaceuticals such as cimetidine thereby resulting in low bioavailability.

228 PEROXYNITRITE IN ACETAMINOPHEN (APAP)-INDUCED LIVER NECROSIS: DETOXIFICATION BY APAP.

J. A. Hinson[1], S. L. Michael[1], S. G. Ault[1], C. Gartner[2] and S. D. Nelson[2]. [1]*University of Arkansas for Medical Sciences, Little Rock, AR and* [2]*University of Washington, Seattle, WA.*

Metabolism of APAP by CYP450 to N-acetyl-*p*-benzoquinone imine is an initial step leading to toxicity. Recent data indicate that a second step may be important. We reported that in APAP intoxicated livers nitrotyrosine- and APAP-protein adducts co-localized in the hepatic centrilobular cells, the site of necrosis. Nitration of tyrosine is by peroxynitrite (PN), formed from NO with O_2^- by activated Kupffer cells. Nitration was directly proportional to toxicity. Since both tyrosine and APAP are phenols, we investigated the reaction of APAP with PN. GC-MS analysis of incubations of APAP with PN indicated formation of an APAP dimer, a product formed via the semiquinone imine, a free radical. The potential role of APAP in detoxification of PN was studied in mice. A time course/dose response for APAP toxicity was determined in mice. At 6 hrs following APAP serum ALT levels were inversely proportional to dose: 10,493 ± 981 IU/L for 300 mg/kg, 3,138 ± 91 IU/L for 450 mg/kg, and 1,961 ± 323 IU/L for 600 mg/kg; however, by 12 hrs ALT levels were directly proportional to dose. Tyrosine nitration was inversely proportional to dose at early times and directly proportional to dose at late times. APAP covalent binding was directly proportional to dose at all times. The APAP $t_{1/2}$ was 2 hrs and hepatic APAP levels were calculated to be 1 μmole/gm at 2.5, 7.0 and 9.8 hrs in the low, middle and high dose groups, respectively. These data support the hypothesis that PN is the toxic species, it may be detoxified by APAP, and APAP clearance is necessary for toxicity.

229 NITRATION OF TYROSINE IN THE 85 KDA REGULATORY SUBUNIT OF PHOSPHATIDYLINOSITOL 3-KINASE DURING ACETAMINOPHEN-INDUCED LIVER NECROSIS IN MICE.

S. L. Michael, S. G. Ault and J. A. Hinson. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Metabolism of acetaminophen (APAP) by CYP450 to N-acetyl-*p*-benzoquinone imine and covalent binding to proteins is a correlate of toxicity. We recently showed that a second step may be important. We reported that following a toxic dose of APAP, nitrotyrosine protein adducts and APAP-adducts co-localized in the hepatic centrilobular cells, the site of necrosis. Nitration is by peroxynitrite (PN), formed by reaction of NO with O_2^- from Kupffer cells. In this study we performed immunoblot analyses using an anti-nitrotyrosine antiserum. Immunoblot studies indicated three significant nitrated proteins in liver homogenates. These adducts were at low levels in hepatic homogenates from saline- and increased in livers of APAP-treated mice. Subsequently, we performed studies to determine if the major 85 kDa nitrated protein was the regulatory subunit of PI-3 kinase (P-85), a protein reported to be nitrated by PN *in vitro*. Proteins of the same molecular weights stained using anti-P-85 and anti-nitrotyrosine. A time course using anti-nitrotyrosine revealed that 4 hrs following APAP (300 mg/kg) to mice the nitrated 85 kDa hepatic protein increased 14X over saline controls. Similar analyses using anti-P-85 indicated a 19X increase. Serum ALT levels peaked at 8 hrs. Immunohistochemical analyses of liver sections indicated that P-85 was uniformly distributed in the lobule of saline-treated mice; however, in the livers from the APAP-treated mice P-85 was concentrated in the centrilobular areas, the site of necrosis. These data indicate that alterations of a signal transduction protein occur in APAP-induced hepatotoxicity.

230 PRODUCTION OF A RECOMBINANT 56-KDA SELENIUM BINDING PROTEIN ASSOCIATED WITH ACETAMINOPHEN (APAP) TOXICITY AND COVALENT BINDING.

A. M. Lucas[1], Y. H. Jung[1], M. K. Bruno[1], S. E. Shehin[2] and S. D. Cohen[1]. [1]*University of Connecticut, Storrs, CT and* [2]*Procter & Gamble Co., Cincinnati, OH.*

APAP toxicity has been highly correlated with covalent binding of APAP's reactive metabolite to a 58-kDa protein (58ABP) in murine liver. Sequence analysis of purified 58-ABP from liver cytosol revealed that this protein was homologous to a 56-kDa selenium binding protein (56SBP). Additional studies demonstrated that the 2 proteins were not products of the same gene and that 58ABP was expressed solely in the liver whereas the 56SBP was expressed in both liver and kidney. Interestingly, it appears that both cytosolic proteins are major targets for APAP binding. Therefore, to study additional aspects of APAP binding and toxicity a 56SBP recombinant protein was produced using the pET28b vector containing sequence for histidine and T7 tags (Novagen). 56SBP cDNA (from P. Harrison) was ligated into pET-28b (+) at the *HinD*III site and used to transform *E. coli* DH5α cells. Digestion with *HinD*III and *Apa*I confirmed the 56SBP insert was in frame with the T7 promoter (pSDC8). BL21(DE3)pLysS cells were transformed with pSDC8, a 60 kDa protein was expressed after IPTG induction. Western blot analysis showed that this protein reacted with 58-ABP antisera, T7 tag antisera, and a histidine conjugate confirming the protein was the recombinant 56SBP. The use of recombinant 56SBP will significantly enhance the ability to explore the mechanisms of covalent binding in APAP toxicity. (Supported by U. Conn. Res. Foundation, NIH ES07163, Boehringer Ingelheim Pharmaceutical, Inc.)

231 FORMAMIDINE, A NOVEL INHIBITOR OF NITRIC OXIDE PRODUCTION.

B. Billack[1], D. E. Heck[1], D. M. Porterfield[2], R. P. Malchow[3], P. J. S. Smith[2] and J. D. Laskin[4]. [1]*Rutgers University, Piscataway, NJ,* [2]*Marine Biological Laboratory, Woods Hole, MA,* [3]*University of Illinois at Chicago, Chicago, IL and* [4]*UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.*

The free radical gas nitric oxide is generated in biological systems by a family of oxidoreductases known as the nitric oxide synthases using arginine as the substrate. Elevated levels of nitric oxide have been observed in several inflammatory disorders. Our laboratory has been using substrate analogs to characterize mechanisms regulating production of nitric oxide in cell lines expressing either NOS 2, the calcium-independent cytokine inducible nitric oxide synthase (CX-1 and RAW 264.7 cells), or NOS 1, the calcium-dependent constitutively expressed isoform (GH3 cells). In both CX-1 and RAW 264.7 cells, nitric oxide production is induced by gamma-interferon. In GH3 cells, nitric oxide release is stimulated by potassium ionophores or high levels of KCl (25 mM), a process resulting in membrane depolarization and the opening of calcium channels. We found that in each cell type, formamidine, a compound structurally related to arginine, readily inhibits nitric oxide production. The effects were time- and dose-dependent (IC50 = 1-5 mM). In all cell types, the effects of formamidine were apparently not due to cytotoxicity, as determined by trypan blue dye exclusion. Using RAW 264.7 cells, we found that formamidine had no effect on expression of NOS 2 suggesting that the compound acts at the level of enzyme activity. Using a polarographic microsensor to measure real-time flux of nitric oxide release from RAW 264.7 cells, we found that formamidine required 2-4 hours to inhibit enzyme activity. This may be due to slow uptake of the drug. Taken together, our data suggests that formamidine acts to inhibit nitric oxide production by inhibiting the activity of both the NOS 1 and NOS 2 isoforms of nitric oxide synthase. (Supported by NIH grants ES 03647 and ES 06897.)

232 IDENTIFICATION OF OXIDATION PRODUCTS PRODUCED BY MAMMALIAN ALCOHOL DEHYDROGENASE FROM THIODIGLYCOL *IN VITRO*.

A. A. Brimfield[1], J. R. Smith[1] and M. J. Novak[2]. [1]*U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD and* [2]*Walter Reed Army Institute of Research, Silver Spring, MD.*

Sulfur mustard (2,2'-bis chloroethyl sulfide) is a chemical warfare agent causing delayed injury to epithelial tissue ranging from erythema to massive fluid-filled blisters and necrosis in a dose dependent manner. In aqueous media, sulfur mustard spontaneously rearranges to 2,2'-bis hydroxyethyl sulfide (thiodiglycol, TDG). Because TDG inhibited protein phosphatase activity in tissue cytosol but not in purified enzyme preparations, we hypothesized that

metabolic activation may be necessary for phosphatase inhibition. Using horse liver ADH, we isolated and instrumentally characterized two products arising from the enzymatic oxidation of TDG. One, with an Rf of 0.65- 0.70 by thin-layer chromatography (TLC)(silica gel, hexane:ethyl acetate 1:3, vol), gave a color consistent with an aldehyde when sprayed with 0.4% 2,4-dinitrophenyl hydrazine (DNPH) in 2.0 M HCl. The second, with an Rf of 0.74-0.78 in the same TLC system, did not react with DNPH. Electron impact (EI) GC-MS analysis of material isolated by preparative TLC indicated a small molecular ion peak at m/e 120 for the lower Rf compound with a base peak at m/e 46 and additional peaks at m/e 61 and 74. Methane chemical ionization GC-MS, which characteristically gives an unambiguous M+H+ peak, instead gave a peak at m/e 103 with this compound indicating the loss of H2O (120 + H+ - 18), behavior characteristic of an aldehyde. The higher Rf compound gave an EI mass spectrum with a base peak at m/e 46, additional peaks at m/e 59 and 74 and a molecular ion at m/e 118. This is consistent with published mass spectral data for the 1,4-oxathian-2-one. Methane chemical ionization produced an M+H+ at m/e 119. We conclude that the compound with Rf of 0.65-0.70, DNPH (+) and with a molecular ion at m/e 120 is the monoaldehyde of TDG. The compound with the higher Rf, DNPH (-), and a molecular ion at m/e 118 is the 1,4-oxathian-2-one.

233 MECHANISM OF INHIBITION OF LUNG CYP2E1 BY DIALLYL SULFONE.

P. G. Forkert and P. Premdas. *Queen's University, Kingston, Ontario, Canada.*

We have tested the hypothesis that lung CYP2E1 is inactivated by diallyl sulfone ($DASO_2$) through formation of the metabolite diallyl monoepoxide ($DASO_3$). $DASO_3$ was chemically synthesized and reacted with [^{3}H]glutathione (GSH) to produce the $DASO_3$-GSH standard. HPLC analysis of lung microsomal incubations with $DASO_2$ in the presence of [^{3}H]GSH and NADPH showed the formation of the $DASO_3$-GSH conjugate. This conjugate was not produced in incubations performed in the absence of $DASO_2$ or NADPH. The formation of the $DASO_3$-GSH conjugate in the incubations was time-dependent, peaking at 2 h. Conjugate formation was concentration-dependent; saturation was detected at 0.8 mM of $DASO_2$. Generation of $DASO_3$ in the microsomal incubations, as estimated by formation of a 4-nitrobenzyl pyridine derivative, peaked at 35 min. Levels of $DASO_3$ formed in the incubations were concentration-dependent, and were maximal at 1.0 mM of $DASO_2$. The $DASO_3$-GSH conjugate was also generated in incubations containing CYP2E1-expressed human lymphoblastoid microsomes. Furthermore, the formation of this conjugate was significantly inhibited in lung microsomes preincubated with an inhibitory CYP2E1 antibody. CYP2E1-mediated *p*-nitrophenol hydroxylase activity was significantly inhibited by $DASO_2$ in the microsomal incubations. This inhibitory effect was also observed in microsomes isolated from the lungs of mice treated with $DASO_2$. The loss in catalytic activity coincided with diminution of immunodetectable CYP2E1 protein in both the *in vitro* and *in vivo* systems, as assessed by protein immunoblotting. These results supported the conclusion that $DASO_3$ is responsible for the inactivation of lung CYP2E1. (Supported by NCI Grant RO1 CA73220-01.)

234 EFFECTS OF QUINONE METHIDES ON MOUSE LUNG EPITHELIAL CELL LINES.

Y. Sun, R. Kupfer, J. N. Lemercier and J. A. Thompson. *University of Colorado Health Sciences Center, Denver, CO.*

There is substantial evidence that butylated hydroxytoluene (BHT)-mediated mouse lung injury and tumor promotion are consequences of metabolic activation. BHT is oxidized by pulmonary cytochrome P450 forming two quinone methides, BHT-QM and BHTOH-QM. Both of these electrophiles readily form covalent adducts with cellular thiols but the latter is several-fold more reactive. In order to probe the targets of these metabolites possibly related to tumor promotion, cell lines derived from normal alveolar type II pneumocytes (C10 and E10) and the corresponding spontaneous transformants (A5 and E9) were incubated with quinone methides. Compared to the transformed cells, C10 and E10 cells had lower levels of glutathione S-transferase (GST) activity and greater sensitivity to quinone methide-induced toxicity. In all four cell lines, BHTOH-QM was substantially more toxic than BHT-QM in agreement with previous results using isolated bronchiolar Clara cells. The quinone methides irreversibly inhibited GST activity and both toxicity and GST inhibition were enhanced by depleting glutathione (GSH) levels. These results demonstrate that both GSH and GST are intracellular targets of BHT-derived quinone methides and suggest a possible mechanism for tumor promotion involving selective destruction of normal versus transformed cells. (Supported by NIH Grant CA41248.)

235 SUCCINYLACETONE ELICITS AN OXIDATIVE STRESS RESPONSE IN MOUSE HEPATOMA HEPA-1C1C7 CELLS.

M. Z. Dieter, G. G. Oakley and D. W. Nebert. *University of Cincinnati Medical Center, Center for Environmental Genetics and Department of Environmental Health, Cincinnati, OH.*

Succinylacetone is a tyrosine catabolite that accumulates in the absence of fumarylacetoacetate hydrolase (FAH), the final enzyme in the tyrosine catabolism pathway. Succinylacetone is a reactive oxygenated metabolite (yet a weak Michael reaction acceptor) found in the tissues, plasma, and urine of *Fah*(-/-) knockout and *14CoS/14CoS* mice, both of which lack a functional FAH enzyme. The presence of urinary succinylacetone is also used to screen patients for hereditary tyrosinemia type 1 (HT-1), an inherited deficiency of FAH. An oxidative stress response, characterized by the induction of stress-inducible genes and changes in glutathione status, has been observed in *Fah(-/-)* and *14CoS/14CoS* mice. We have tested the hypothesis that succinylacetone might cause an oxidative stress response. Northern blot analysis of succinylacetone-treated mouse hepatoma Hepa-1 cells demonstrates significant elevations in mRNA levels of the oxidative stress-responsive genes glutamate-cysteine ligase (catalytic and regulatory subunits, *Gcls* and *Gclr*), NAD(P)H: quinone reductase-1 (*Nqo1*) and heme oxygenase-1 (*Ho1*). Transient transfection of succinylacetone-treated cells with an electrophile response element (EPRE)-driven luciferase (*LUC*) construct generated a 3-fold increase in luciferase activity. Succinylacetone is a potent inhibitor of 5-aminolevulinic acid (ALA) dehydratase, the second enzyme in the heme synthesis pathway. Northern blot analysis and transient transfection of EPRE-*LUC* in ALA-treated cells demonstrate that an oxidative stress response is caused directly by ALA. We hypothesize that FAH deficiency leads to accumulation of succinylacetone, thus inhibiting ALA dehydratase, leading to build-up of ALA and resulting in the oxidative stress response. These findings may have clinical relevance for HT-1 patients as well as porphyria patients, and may partially explain the oxidative stress response observed in untreated *Fah(-/-)* and *14CoS/14CoS* mice. (Supported in part by NIH Grant R01 AG09235.)

236 ANTIOXIDANT BALANCE AND FREE RADICAL GENERATION IN VITAMIN E DEFICIENT MICE AFTER DERMAL EXPOSURE TO CUMENE HYDROPEROXIDE.

A. A. Shvedova[1], E. R. Kisin[1], C. Kommineni[1], R. P. Mason[2] and M. B. Kadiiska[2]. [1]*HELD/NIOSH, Morgantown, WV and* [2]*NIEHS/NIH, Research Triangle Park, NC.*

Organic peroxides are widely used in the chemical industry as initiators of oxidation for the production of polymers and fiber-reinforced plastics, in the manufacture of polyester resin coatings, and as antimicrobial agents in pharmaceuticals. Free radical production is considered to be one of the key factors contributing to skin tumor promotion by organic peroxides. *In vitro* experiments have demonstrated metal-catalyzed formation of alkoxyl, alkyl and aryl radicals in keratinocytes incubated with cumene hydroperoxide. The present study investigated *in vivo* free radical generation in lipid extracts of mouse skin exposed to cumene hydroperoxide. The electron spin resonance (ESR) spin-trapping technique was used to detect the formation of *alfa*-phenyl-*N*-*tert*-butylnitrone (PBN) radical adducts, following intradermal injection of 180 mg/kg PBN. It was found that 30 min after topical exposure, cumene hydroperoxide (12mmole/kg) induced free radical generation in the skin of female Balb/C mice (13-14 weeks old) kept for 10 weeks on vitamin E deficient diets. In contrast, no radical adducts were detected when cumene hydroperoxide was applied to the skin of mice fed a vitamin E sufficient diet. Importantly, levels of GSH and vitamin E in the skin of vitamin E deficient mice decreased 30% and 80%, respectively, compared to vitamin E sufficient controls. PBN adducts detected by ESR in vitamin E deficient mice provide direct evidence for *in vivo* free radical generation in the skin after exposure to cumene hydroperoxide.

236A THE ARYL HYDROCARBON RECEPTOR LIGANDS MODULATE MCF-10F BREAST EPITHELIAL CELL GROWTH.

A. F. Trombino[1], T. A. Jenkins[1], R. A. Matulka[2], R. I. Near[1] and D. H. Sherr[1]. [1]*Boston University School of Medicine and Public Health, Boston, MA and* [2]*USEPA, Research Triangle Park, NC.*

The aryl hydrocarbon receptor (AhR) is a ligand activated transcription factor implicated in the growth regulation of many cell types. Previous data have demonstrated that AhR mRNA levels correlated with the malignant state in human breast cancer cell lines. In addition, AhR protein expression correlated with the rate of cell growth. Analysis of AhR protein levels in MCF-10F breast epithelial cells determined that AhR protein expression decreased to undetectable levels when cells were grown in serum free media. However, when cells were rescued with media containing 5% serum, AhR protein expression increased in 6 hours. AhR ligands have been implicated in suppression of cell cycle. In order to determine if AhR can modulate cell growth, three AhR ligands (galangin, alpha-naphthoflavone, and indol-3-carbinol) were used. These compounds have been shown to be both AhR agonists and antagonists depending on concentration used. MCF-10F breast epithelial cells grown in media containing these compounds showed a decrease in both thymidine incorporation and cell number in a dose dependent manner. To determine if this decrease was due to cell cycle arrest, G0/G1 synchronized cells were grown in media containing serum and/or 10-5 to 10-6 M of AhR ligands for 24 hours. PI staining of MCF-10F cells grown with these inhibitors demonstrated that 60-80% of cells were arrested in G0/G1 ($p<0.05$) and that these cells did not progress into S-phase. These data demonstrate that the AhR can modulate malignant cell growth by suppressing cell cycle progression.

236B IDENTIFICATION OF A MEDIATOR OF THE CYTOSTATIC EFFECTS OF 12-0-TETRADECANOYLPHORBOL-13-ACETATE IN HUMAN BREAST MYOEPITHELIAL CELLS.

M. Guo, A. Joiakim and J. J. Reiners, Jr. *Institute of Chemical Toxicology, Wayne State University, Detroit, MI.*

The effects of 12-0-tetradecanoylphorbol-13-acetate (TPA) on cell cycle progression were examined in the human breast myoepithelial cell line MCF10A-Neo. Exposure of cultures to TPA induced a rapid but transient G_1 arrest (IC_{50}~0.5 nM). Cultures produced a conditioned media within one hr of TPA treatment that could totally account for the cytostatic effects of TPA. Conditioned media lost its cytostatic activity within 16-20 hr of TPA treatment. However, a cytostatic conditioned media was quickly generated by refeeding previously treated TPA cultures with new media. Removal of latent TGFβ from culture media, or supplementation of culture media with soluble $TGF\beta_{II}$ receptor, or preabsorption of conditioned media with an antibody to TGFβ, all reduced the cytostatic effects of TPA by ~50%. Cotreatment of cultures with the serine protease inhibitors aprotinin or plasminogen activator inhibitor 1 also suppressed (~50%) the cytostatic activity of TPA. Pretreatment with two cell permeable protein kinase C inhibitors (Ro-32-0432 and bisindolymaleimide) completely suppressed the cytostatic activity of TPA. In contrast, inhibitors of MEK (PD98059) and PI3 kinase (LY294002 and Wortmannin), two signaling pathways commonly activated by TPA, were without effect. These studies suggest that in MCF10A-Neo cells TPA activates protein kinase C-dependent processes which lead to the proteolytic activation of latent TGFβ being supplied by the serum in the culture media. However, TPA also stimulates the production of an additional cytostatic factor(s) which signals through a mechanism not involving the $TGF\beta_{II}$ receptor. (Supported by NIH Grant CA34469.)

236C EFFECTS OF DIETARY GENISTEIN ON UTERINE CELL CYCLE IN RATS: ANALYSIS BY FLOW CYTOMETRY.

M. H. Lu, N. Tang, C. C. Weis, C. Moland, S. L. Dial, W. S. Branham and S. A. Ferguson. *National Center for Toxicological Research, Jefferson, AR.*

The phytoestrogen genistein is a naturally occurring isoflavone consumed by humans mainly through the use of soy products. Genistein has been identified as an endocrine disrupting chemical affecting the growth and development of the reproductive tract and mammary glands in rats. This study is to evaluate the effects of dietary genistein on uterine tissue by flow cytometric cell cycle analysis. Genistein was fed in a soy-free casein-containing diet at 0, 25, 250, or 1250 ppm to F_0 dams beginning on gestation day (GD) 7 and continued to the weaning of F_1 pups. Exposure of F_0 dams to genistein continued until sacrifice at PND 120 or 154. Exposure of F_1 pups to genistein continued via lactation and after weaning by feed until sacrifice at PND 21, 25, 63, or 77. Uterine tissue was collected, preserved in citrate-sucrose-DMSO buffer, and frozen at -80°C until assayed using flow cytometry. The percentage (%) of cells in each cell cycle phase of the cell cycle was measured and analyzed by ModFit program. The results showed that 1250 ppm genistein did not cause cell cycle changes in uterus of the F_0 dams sacrificed at either ages. In the genistein-treated F_1 pups, no alterations of uterine cell cycle were observed at PND 77. However, in the PND 21 F_1 pups, significant decreases in the % of S- and G_0-cells were detected in the 25 and 1250 ppm groups, respectively. A significant increase in the S-cell was found in the 1250 ppm group of the PND 21 pups. In the PND 25 pups, exposure of dietary genistein at 1250 ppm caused an increase in the % of cells in both S- and G_2M-phases. At the same dose, the % of G_0-cells was significantly decreased. At PND 63, 1250 ppm genistein lowered the % of S-cells. However, a significant increase in the G_2M-cell was detected at all dosages evaluated. The results indicated that dietary exposure of genistein caused alterations in cell cycle in uterine tissue of the developing rats. Immature animals were found to be more sensitive to induction of changes in % S-cells inferring that the uterotrophic effect of genistein is more sensitive and detectable in early developmental age. The G_2M-arrest may occur after 3 weeks of age and appears obviously at PND 63. The effects may be age-dependent; younger animals may be more susceptible to the damage exerted by the compound.

236D INITIAL DEVELOPMENT OF A MULTISTAGE CANCER MODEL BASED ON SYRIAN HAMSTER EMBRYO (SHE) CELL TRANSFORMATION STUDIES.

K. H. Liao[1], D. L. Gustafson[2], M. H. Fox[3], L. S. Chubb[3], K. F. Reardon[1] and R. S. H. Yang[2]. [1]*Dept. of Chemical & Bioresource Engineering, Colorado State University, Fort Collins, CO,* [2]*Dept. of Environmental Health, Colorado State University, Fort Collins, CO and* [3]*Dept. of Radiological Health Sciences, Colorado State University, Fort Collins, CO.*

To better incorporate biologic information into quantitative cancer modeling, the two-stage MVK model has been modified for use with SHE cell neoplastic progression. Five phenotypic stages are included in this model: normal cells could either become senescent or mutate into immortal cells followed by anchorage-independent growth and tumorigenic stages. Cells in each stage have distinct division, death and mutation rates, and mutation is assumed to occur during cell division. Model development and related experiments are focused on studying the abilities of lead, arsenic, chromium and a mixture of these three metals to induce progression of SHE cells from one phenotype to the next. Cell division and death rates have been assessed using flow cytometric analysis for inclusion in the model. Cell division rates were measured using bromodeoxyuridine (BrdU) incorporation with propidium iodide staining, which allows for the calculation of potential doubling time, a measure of cell cycle time that takes growth fraction, but not cell loss, into account. Potential doubling times of normal SHE cells ranged from 12 to 59 hours, depending on the degree of confluence of cell cultures. Cell death was measured by a flow cytometry method based on propidium iodide staining specifically related to membrane damage. The individual metals and their mixture did not induce immortalization or further mutations of SHE cells in our laboratory. However, the growth of SHE cells were inhibited by 5.4 μM of arsenic and became senescent after only 16 population doublings, whereas normal cells and cells exposed to lower arsenic concentrations lasted for at least 30 population doublings. The model developed in our laboratory was proven to predict the growth of normal cells successfully. (This work was supported by ATSDR [Cooperative Agreement U61/ATU 881475] and NIEHS Superfund Basic Research Program [P42 ES05949].)

236E TRICHOSTATIN AFFECTS CELL PROLIFERATION AND DETOXIFICATION ENZYME ACTIVITY COMPARABLE TO THE DIFFERENTIATING AGENT BUTYRATE IN HUMAN HT29 COLON CARCINOMA CELLS.

R. Y. Odom[1], Y. G. Wirsiy[1], J. Cai[2], D. P. Jones[2] and W. G. Kirlin[1]. [1]*Morehouse School of Medicine, Atlanta, GA and* [2]*Emory University School of Medicine, Atlanta, GA.*

Chemoprevention of carcinogenic processes involve a variety of mechanisms. Previously, we have shown that compounds such as benzyl isothiocyanate (BIT), found in cruciferous vegetables and butyric acid, released from dietary fiber fermentation act to increase detoxification enzyme activity and decrease cell proliferation. Differentiation of the human colon adenocarcinoma cell line HT29 with sodium butyrate (NaB) results in increased activity of glutathione S-transferase (GST) and NAD(P)H:quinone reductase (N:QR), with a further increase in enzyme activities in response to 25 μM BIT. One proposed mechanism for the differentiating effect of NaB is inhibition of histone

deacetylase. We compared the effect of trichostatin, a histone deacetylase inhibitor, to that of NaB. HT29 cell proliferation, measured by [^{3}H]-thymidine incorporation, was dose-dependently decreased by trichostatin (TC) (0.25 - 2.0 μmol/l) and sodium butyrate (NaB) (1 - 5 mmol/l). Cell proliferation decreased by at least 90% with a 24 h exposure to 0.25 μM TC or 5 mM NaB. Both NaB and TC increased GST and NQR activities in response to BIT. NaB and TC, due to their affect on histone acetylation, may increase the susceptibility to enzyme inducers acting on promoter regions exposed by decreased contact between histone proteins and DNA. (Support: GM-08248, ES-09047.)

236F HEPATOMA CELL LINES FROM HUMAN, MOUSE AND RAT SHOW SIMILAR CELL CYCLE RESPONSES WHEN INCUBATED WITH CRUCIFEROUS VEGETABLE-DERIVED CRAMBENE.

A. S. Keck and E. H. Jeffery. *Nutritional Sciences, Urbana, IL.*

Cruciferous vegetables have cancer preventive effects in both animals and humans. These effects are believed to be due mainly to glucosinolates in crucifers. The glucosinolate breakdown product, crambene, is naturally produced when endogenous myrosinase hydrolyses the glucosinolate progoitrin. We earlier showed that crambene (1-cyano-2-hydroxy-3-butene) induces liver detoxification enzymes. Here we evaluated the effect of crambene (5mM) on the cell cycle in hepatoma cell lines from three different species: mouse (Hepa 1c1c7 cells), rat (H4IIEC3 cells) and human (HepG2 cells). By 24 hours, crambene caused cell cycle arrest in the G2-phase in all three cell lines. Cell viability was unaffected (>95%). The G2-population increased by 2-fold (HepG2), 2-4-fold (Hepa 1c1c7) or 1.5-2-fold (H4IIEC3) compared with control (0.1% DMSO). These findings indicate that cruciferous vegetables may protect after initiation of cancer by slowing the cell cycle, in addition to preventing initiation of carcinogenesis. (Supported by The Illinois council on Food & Agricultural Research.)

237 CELL-CYCLING EFFECTS FROM *IN VITRO* EXPOSURE TO SODIUM ARSENITE ON DEVELOPING RAT MIDBRAIN CELLS.

E. M. Schneider, R. A. Ponce and E. M. Faustman. *University of Washington, Seattle, WA.*

Arsenic and its metabolites distribute to all organs in the body, and can pass through the placental barrier as well as the blood brain barrier, which is not fully developed in the fetus. High-dose exposure to arsenic during development has resulted in neural tube defects, exencephaly, and other defects, while molecular mechanisms of lower-dose effects are undefined. In this study, gestation day 12 primary rat midbrain neuroepithelial cells were exposed to sodium arsenite (0, 2, 2.5, 4, and 5 μM, 0-48 hr) *in vitro*. Cell-cycling effects were determined by continuous BrdU labeling and bivariate flow cytometric Hoechst-ethidium bromide analysis. We observed a time- and concentration-dependent inhibition of cell proliferation in both G1 and G2/M as early as 12 hours after sodium arsenite exposure at the lowest concentration tested (2 μM), with no associated cytotoxicity at 24 hours as shown by the neutral red assay. Because of the observed G1- and G2/M-phase effects, fewer cells entered DNA synthesis or completing one round of cell division, respectively. The magnitude of this effect increased with increasing arsenic concentration. Although cell proliferation was inhibited, cell cycle progression was observed to occur under all exposure conditions. (Supported by Child Health Center Grant jointly funded by EPA and NIEHS.)

238 INVOLVEMENT OF P21$^{WAF1-CIP1}$ IN METHYLMERCURY-INDUCED CELL CYCLE INHIBITION.

M. A. Mendoza, R. A. Ponce, Y. C. Ou and E. M. Faustman. *University of Washington, Seattle, WA.*

Methylmercury (MeHg) has been recognized to exert toxicity particularly to developing central nervous system (CNS). To evaluate the role of p21, a cell cycle protein involved in the G1 and G2 phase checkpoints, in the cell cycle inhibition induced by MeHg we have utilized primary mouse embryonic fibroblasts (MEFs) of different p21 genotypes (wild type, heterozygous and null). MEFs were isolated at day 14 of gestation and treated at passage 4-6 with 2, 4 and 6 μM MeHg for 24 hr. Changes in cell cycle distribution after continuous MeHg treatment were analyzed by DNA content-based flow cytometry using DAPI. MeHg induced an increase in proportion of cells in G2/M at 2 and 4 μM MeHg irrespective of p21 genotype (p*0.05). Effects of MeHg on cell cycle progression were also evaluated using BrdU- Hoechst flow cytometric analysis. Inhibition of cell cycling was observed in all p21 genotypes after continuous exposure to MeHg for 24 and 48 hrs. p21 null (-/-) cells reached the second-round G1 at a higher fraction compared to the wild type (+/+) and heterozygous (+/-) cells (p> *0.05). The present study confirms previous observations that MeHg inhibits cell cycle progression through delayed G2-M transition. Furthermore, the G2/M accumulation induced by MeHg is independent of p21. Further studies on other cell cycle regulation pathways will provide further understanding of the effects of MeHg on cell proliferation. (This study was supported by EPA grant numbers R825358, R826886, R825358, and NIEHS grant number 5 P30 ES07033.)

239 ELEVATIONS IN MRNA LEVELS FOR CYCLINS FOLLOWING TRIMETHYLTIN-INDUCED HIPPOCAMPAL NEURODEGENERATION.

J. A. Kubik[1] and G. J. Harry[2]. [1]*NIEHS/Duke University, Research Triangle Park/Durham, NC and* [2]*NIEHS, Research Triangle Park, NC.* Sponsor: H. A. Tilson.

The interactions of glia and neurons during injury and subsequent neurodegeneration is a subject of interest in both disease and chemical-induced brain injury. One such model is the prototypical hippocampal toxicant trimethyltin (TMT). An acute injection of TMT (2.0 mg/kg, ip.) to postnatal day 20 CD-1 male mice produced neuronal necrosis and loss of dentate granule cells, astrocyte hypertrophy, and microglia activation in the hippocampus within 24 hours. While microglia show an early response to injury, their morphological progression to a phagocytic phenotype did not occur until 72 hours. The purpose of this study was to examine the role of microglia in the onset and progression of neurodegeneration and their differentiation to a phagocytic state. Based upon previous reports in the literature on the response of macrophages to injury, we examined both elevations in mRNA levels for pro-inflammatory cytokines and cell cycle control genes. TNFα, IL-1α, and IL-1β mRNA levels were significantly elevated in the hippocampus by 12 hrs. By 72 hrs, mRNA levels for cyclin A2 and cyclin B1 were elevated in the hippocampus by approximately 10-fold, decreasing to 2-fold at 10 days post-dosing. Immunohistochemistry showed a cellular localization of cyclins A2 and B1 to microglia in the region of neuronal necrosis. mRNA levels for cyclin C, cyclin D1, and cyclin D2 were elevated 2-fold by 72 hrs and remained elevated for 10 days. No changes were seen in cortex or cerebellar tissue from dosed animals. Immunohistochemistry for PCNA showed no evidence of cell proliferation, suggesting that the upregulation of these cell cycle genes is associated with cellular processes other than proliferation and may contribute to the differentiation of microglia to a phagocytic phenotype.

240 CELL CYCLE DEPENDENT NUCLEAR LOCALIZATION OF METALLOTHIONEIN IN 3T3-L1 FIBROBLAST.

M. Apostolova and G. Cherian. *University of Western Ontario, London, Ontario, Canada.*

Previous studies on human tumor cells have shown that metallothionein (MT) is expressed mainly in proliferating cells, and its nuclear localization occurs during the S-phase of cell cycle. The role of nuclear MT in cell proliferation was studied in 3T3-L1 fibroblasts using inhibitors of cell cycle and phosphorylation. The changes in localization of MT were followed by immunofluorescence using a polyclonal MT-antibody and anti rabbit IgG labelled with FITC. In these cells, MT was localized in the nucleus at late G1/early S-phase after blocking of the cell growth with Aphidicolin (0.25μg/ml), an inhibitor of DNA polymerase-α cell cycle with Aphidicolin (0.25μg/ml) treatment leads to relocation of MT to the cytoplasm at the end of M-phase. Flow cytometry analysis confirmed that the cell cycle was arrested at S-phase for most of the cells after treatment with Aphidicolin (4μg/ml), and MT was retained primarily in the nucleus. Rapamycin, an immunosuppressant drug can block progression of cell cycle at the G1 phase by inhibiting activation of serine/threonine p70S6 kinase. Addition of Rapamycin, PD98059 (an inhibitor of MAP kinase) or LY294092 (an inhibitor of PI3 kinase) blocked the translocation of MT in the nucleus of 3T3-L1 fibroblast, suggesting that the nuclear translocation of MT is dependant on MAP-kinase and PI3-kinase activity. The results show that the localization of MT in the nucleus occurs during G1/S-phase of the cell cycle, and it is transferred to the cytoplasm during M-phase. (Supported Medical Research Council of Canada.)

241 C-MYC ANTISENSE PHOSPHORODIAMIDATE MORPHOLINO OLIGOMERS LIMIT RAT LIVER REGENERATION AND CYTOCHROME P450 3A ACTIVITY.

V. Arora[1], D. Knapp[1], B. Smith[2], M. Reddy[1], D. Stein[1], M. Statdfield[1], D. Weller[1] and P. Iversen[1]. [1]*AVI Biopharma, Corvallis, OR and* [2]*Oregon State University, Corvallis, OR.*

Expression of c-myc protein is associated with cell proliferation. The present studies utilize antisense oligomers to inhibit c-myc expression in the regenerating rat liver following 70% partial hepatectomy (PH). Antisense phosphorodiamidate morpholino oligomers (PMO, novel DNA analogs) were administered intraperitoneally immediately after surgery to block expression of c-myc within the first 24 hours after PH. A 20-mer PMO complimentary to the c-myc mRNA at the translation start site was an effective sequence (AVI-4126: 5'-ACGTTGAGGGGCATCGTCGC-3'). A single intraperitoneal dose of 0.5 mg/kg AVI-4126 caused reduction of the regenerating liver c-myc protein in a sequence-specific and dose-dependent manner. Inhibition of c-myc expression resulted in reduction of proliferating cell nuclear antigen (PCNA) and arrested cells in the G0/G1 phase of the cell cycle. The ratio of G2:G0 cell populations in the regenerating liver twenty four hours after PH dropped from 29.1 in saline vehicle treated rats to 18.0 in rats treated with 2.5 mg/kg AVI-4126. Further, the expression of cell cycle checkpoint protein, p53 was inhibited with increasing doses of AVI-4126, but expression of p21(waf-1) was unaffected. The activity of cytochrome P-450 3A2 (CYP3A2) was evaluated by immunoblot analysis and erythromycin N-demethylation. AVI-4126 did not alter CYP3A activity in non hepatectamized animals but showed a dose dependent decrease in PH rats. We conclude that AVI-4126, antisense oligomer to c-myc, can reduce cell proliferation in the regenerating rat liver. Further, inhibition of c-myc may indirectly influence the expression of CYP3A.

242 EARLY INHIBITION OF HEPATOCYTE PROLIFERATION BY DICHLOROACETIC ACID (DCA) IN THE MALE B6C3F1 MOUSE AND F344 RAT.

A. DeAngelo. *US Environmental Protection Agency, Research Triangle Park, NC.*

DCA occurs in finished drinking water as a by-product of the chlorine disinfection process and was found to induce hepatocellular cancer in rats and mice. Mice were exposed to 0, 0.5, 1, 2, and 3.5 g/l and rats were exposed to 0, 0.05, 0.5, and 1.5 g/l DCA. Animals were euthanized at 5, 10 (rats), 15 and 30 days. Hepatocyte proliferation was measured by BRDU (mice) or PCNA (rats) immunohistochemical methods. DCA at 2 and 3.5 g/l depressed the hepatocyte labeling index (LI) in mice at 5 and 15 days; 0.5 and 1 g/l DCA depressed the Li at 15 days ($p<0.05$). The inhibitory effect was lost by 30 days. The inhibitory effect was not as marked in rats, as in mice. Treatment with 0.5 and 1.5 g/l DCA depressed the LI at 10 days ($p<0.05$); 1.5 g/l depressed the 30 day LI ($p<0.05$). At no time did DCA stimulate hepatocyte proliferation in mice or rats. To further investigate the effect of DCA on DNA synthesis, primary hepatocytes isolated from 28 day old male B6C3F1 mice and F-344 rats were exposed *in vitro* to 10^{-3} to 10^{-11} M DCA. DCA inhibited [3H]-thymidine incorporation into the DNA of mice, but not rats. The differential ability of DCA in mice and rats to inhibit hepatocyte proliferation in cell culture may be important in establishing the relationship between inhibition of cell proliferation and hepatocarcinogenesis. The early dose-dependent inhibition of hepatocyte proliferation *in vivo* correlated with DCA induction of hepatocellular carcinogenesis in male mice and rats. *This is an abstract of a proposed presentation and does not reflect EPA policy.*

243 26-WEEK DERMAL AND DOSED-FEED STUDIES OF DI(2-ETHYLHEXYL) PHTHALATE (DEHP) AND WY-14643 IN HOMOZYGOUS TG.AC TRANSGENIC MICE.

G. Freeman[1], J. Collins[1], P. Athey[1], S. Graves[1], M. Hejtmancik[1], M. Vallant[2] and W. Eastin[2]. [1]*Battelle, Columbus, OH and* [2]*NIEHS, Research Triangle Park, NC.*

DEHP and WY-14643 were used to study mechanisms of carcinogenesis in genetically altered mice. DEHP and WY-14643 were administered topically in acetone (DEHP-0, 100, 200, and 400 mg/kg; WY-14643-0, 2, 10, and 20 mg/kg) or in feed (DEHP-0, 1500, 3000, and 6000 ppm; WY-14643-0, 10, 50, and 100 ppm) to male and female homozygous Tg.AC mice for up to 28 weeks. The toxicity produced by topical and dosed-feed exposure to WY-14643 and dosed-feed exposure to DEHP (hepatomegaly, hepatocellular hypertrophy) were consistent with effects of peroxisome proliferating chemicals. Peroxisomal enzyme activity (β-oxidation and acyl CoA oxidase) and cell cycle biomarkers [proliferating cell nuclear antigen (PCNA) and cyclin-dependent kinase (CDK)] were included in these studies to assess oxidative effects and hyperplasia, respectively. Both administration routes of WY-14643 produced increases in β-oxidation and acyl CoA oxidase at all three dose levels and PCNA and CDK at the upper two dose levels. DEHP dosed-feed administration led to increases in peroxisomal enzyme activity (all three dose groups) and cell cycle biomarkers (high dose only). Topical administration of DEHP led to increases in β-oxidation and acyl CoA oxidase at the two highest dose groups but did not produce hepatocellular hyperplasia or any change in PCNA or CDK. Changes seen with DEHP were generally smaller in magnitude than those observed with WY-14643. Despite these increases, changes in enzymatic activity were not sensitive predictors of carcinogenic activity in this model as topical and dosed-feed exposure to DEHP and WY-14643 produced minimal to no treatment related proliferative lesions. In agreement with previous evaluations, the Tg.AC strain may not be responsive to non-genotoxic mouse liver carcinogens. (Supported by NIEHS Contract No. N01-ES-65406.)

244 DEXAMETHASONE SELECTIVELY INHIBITS WY-14,643 INDUCED CELL PROLIFERATION AND NOT PEROXISOME PROLIFERATION IN MICE.

S. J. Hall, G. Wollenburg, D. W. Alberts, J. D. Frank, C. L. McCoy, J. G. DeLuca and J. W. Lawrence. *Department of Safety, Merck and Co., West Point, PA.* Sponsor: R. Dixit.

It has been proposed that NFκB activation may be involved in the hepatocellular proliferation induced by peroxisome proliferators. We compared the induction of peroxisome proliferation and cell proliferation in C57Bl/6 mice treated with 100 mg/kg/day WY14,643 in the presence or absence of increasing doses of dexamethasone (DEX), an inhibitor of NFκB activation. Biochemical markers of peroxisome proliferation, including fatty acyl-CoA oxidase activity, CYP4A content, and liver to body weight ratios were markedly increased in the WY14,643 treated mice. DEX co-administration, up to the maximum dose of 50 mg/kg/day, did not prevent the induction of these parameters. Acyl-CoA oxidase mRNA levels increased 5-fold with WY14,643 treatment and 15-fold with DEX co-administration at 5 mg/kg/day. ApoCIII mRNA levels were decreased by 50% in WY14,643 treated mice. DEX alone at 5 mg/kg/day increased the ApoCIII mRNA 4-fold, but WY14,643 co adminstartion also inhibited this induction by greater than 50%. In addition, immunohistochemical detection of peroxisomes with anti-PMP-70 antibodies demonstrated marked proliferation of hepatocellular peroxisomes in WY14,643 treated mice regardless of DEX treatment. In contrast, co-administration of DEX at 2 mg/kg/day partially inhibited the cell proliferation response (measured by BrdU incorporation or Ki-67 immunohistochemical detection). Moreover, DEX at doses of 5 mg/kg/day or higher completely inhibited the induction of cell proliferation and, at the higher doses, reduced the cell proliferation rate to levels below the vehicle treated control mice. Our studies clearly demonstrate that the hepatocellular proliferation induced by a peroxisome proliferator can be modulated independently of the other pleiotropic effects usually induced by these agents, suggesting an indirect mechanism of hyperplasia.

245 PEROXISOME PROLIFERATOR-INDUCED CELL PROLIFERATION USING A PRECISION-CUT RAT LIVER SLICE MODEL.

D. W. Alberts, C. McCloud, M. Heimes, G. Wollenburg and J. W. Lawrence. *Department of Safety, Merck and Co., West Point, PA.* Sponsor: R. Dixit.

Precision-cut rat liver slices were evaluated for the ability to detect *in vitro* cell proliferation induced by the peroxisome proliferator WY14,643. No induction of S-phase DNA synthesis as measured by [^{3}H]-thymidine incorporation into DNA was observed after WY14,643 treatment when the media contained as little as 5 nM dexamethasone. However, when dexamethasone was omitted from the culture media, WY14,643 induced S-phase DNA synthesis. The presence of dexamethasone did not prevent the induction of DNA synthesis in slices treated with EGF or TNFα. The absence of dexamethasone in the culture media did not affect measures of viability such as protein synthesis, ATP, LDH leakage, or glutathione levels. In contrast to hepatocyte monolayer cultures, marked induction of peroxisomal β-oxidation was achieved in the absence of dexamethasone. The induction of [^{3}H]-thymidine incorporation by WY14,643 was inhibited by hydroxyurea suggesting the induction was due to replicative DNA synthesis and not DNA repair. WY14,643 induced cell proliferation and peroxisomal β-oxidation in a dose-

dependent manner with maximal effect at 3 μM at 48 hours of treatment. Bromodeoxyuridine labeling and immunohistochemistry demonstrated that cell proliferation was observed mainly in the bile duct epithelial cells in untreated liver slices, suggesting that the baseline labeling in this model can be further reduced if bile duct epithelial cell proliferation can be specifically suppressed. These data suggest that after careful consideration and optimization of culture conditions precision-cut rat liver slices are an effective *in vitro* model to measure hepatocellular proliferation in response to peroxisome proliferators.

246 THE EFFECT OF A DOMINANT-NEGATIVE CONNEXIN43 ON GAP JUNCTIONAL COMMUNICATION AND DIFFERENTIATION OF SEVERAL MAMMALIAL PROGENITOR CELL LINES.

J. E. Trosko[1], G. Chen[1], J. Suzuki, B. L. Upham[1], V. Krutovskikh[2], H. Yamasaki[2] and C. C. Chang[1]. [1]*Michigan State University, East Lansing, MI and* [2]*IARC, Lyon, France.*

Gap junctional intercellular communication (GJIC) has been associated with the regulation of cell proliferation, cell differentiation and synchronized electrotonic and metabolic functions of cells. To test the hypothesis that modulation of GJIC could affect differentiation of mouse osteoblast (MC3T3-E1), rat liver epithelial (WBF344), and human neural-glial (SVG) cell lines, we transfected these cells, which express normal Cx43 proteins, with either a plasmid containing the neo gene and the mutant Cx43 (Cx43delta, 7 residues deleted from the internal loop at positions 130-136). The wild type cells of each cell line, as well as those clones transfected with the control plasmid and the clones of each cell line transfected with Cx43delta were shown to have equivalent ability to transfer Lucifer yellow dye (MW=457), using the scrape loading/dye transfer technique to measure GJIC. The D/N Cx43 cell clones transferred Lucifer yellow iodoacetamide (MW=649) much slower (~50% less) than the control cells. The induction of differentiation in each cell type containing D/N Cx43 resulted in a large decrease in differentiated cells as compared to the wild-type controls. Phorbol ester blocked GJIC in all clones equally well. However, recovery of GJIC in the D/N Cx43 clones was significantly inhibited compared to the control cells. Results suggest a significant role of GJIC in the differentiation of these three progenitor cells. (Research supported by a grant from NCI [CA21104].)

247 PHENOLIC COMPONENTS OF CIGARETTE TAR INHIBIT DNA SYNTHESIS BY QUENCHING THE TYROSYL RADICAL IN RIBONUCLEOTIDE REDUCTASE.

J. M. McCue[1], K. L. Link[2], S. S. Eaton[2] and B. M. Freed[1]. [1]*University of Colorado Health Sciences Center, Denver, CO and* [2]*University of Denver, Denver, CO.*

Cigarette smoke is known to induce profound suppression of T cell responses in the lungs. We have found that the two major phenolic components of cigarette tar, hydroquinone (HQ) and catechol, block DNA synthesis in human T lymphocytes. The purpose of these experiments was to measure the effects of cigarette tar and its phenolic components on the tyrosyl radical in the M2 subunit of ribonucleotide reductase, a major rate-limiting enzyme in DNA synthesis. This radical is essential for enzyme activity and is the only stable tyrosyl radical in sufficient concentration to be detectable by electron paramagnetic resonance (EPR) in lymphocytes. The human Jurkat T cell line was cultured at 10^6 cells/ml in RPMI1640 + 10% FBS and treated for 5 min with cigarette tar extract, or 40μM HQ, catechol or phenol. Cigarette tar extracts were prepared by 'smoking' a single cigarette into 10 ml of medium via a vacuum pump at 125 ml/min. The cells were then centrifuged into quartz EPR tubes and frozen in liquid nitrogen. EPR spectra were obtained on a Varian E9 spectrometer with a TE_{102} resonator at 93K, 150mW and a frequency of 9.10 GHz (X-band). To improve spectra resolution, some samples also were analyzed on a Bruker E580 at 50K, 128mW. The tyrosyl radical was detected in Jurkat cells with an absolute signal intensity of 0.2 μM. Extracts from a low-tar cigarette (*Carlton*) quenched the M2 tyrosyl radical by <40%, while treatment with high-tar extracts (unfiltered *Camel*) resulted in >95% quenching. HQ and catechol quenched the tyrosyl radical by >99%, but phenol quenched only 25% of the radical. Nicotine (1mM) had no effect. The results indicate that the benzene derivatives, HQ and catechol, block DNA synthesis by quenching the M2 tyrosyl radical and thereby inhibiting ribonucleotide reductase. (Supported by NIH grants HL60538 and ES05673.)

248 EVALUATION OF THE UTILITY OF ACCELERATED INFUSIONS FOR THE DETERMINATION OF PHARMACOKINETIC LINEARITY.

K. W. Ward, R. Griffiths, M. A. Levy and B. R. Smith. *SmithKline Beecham Pharmaceuticals, King of Prussia, PA.*

Accelerated infusions are useful in the investigation of pharmacokinetic linearity. Little information, however, exists to validate this technique or to demonstrate its limitations. This investigation was performed (1) to determine whether accelerated infusion regimens reliably estimate the range of pharmacokinetic linearity for molecules of varying pharmacokinetic properties, (2) to evaluate the ability of accelerated infusions to identify pharmacokinetic nonlinearity, and (3) to compare results from the accelerated infusion technique to experimental values obtained independently with specific compounds. Simulations using accelerated infusions as the input function resulted in the anticipated profiles that contained an initial lag phase before reaching a linear slope. This lag phase increased with increasing half-life, and in some instances was sufficiently great to obscure the linear portion of the profile. These simulations also revealed that clearance estimated from the apparently linear portion of the concentration-time profile can be substantially overestimated (up to 2000% for the simulation conditions employed here) for compounds with long half-lives. Simulations of structured nonlinearity produced the predicted profiles for compounds with short to moderate half-lives, while demonstrating that compounds with longer half-lives produce acceleration profiles that do not allow distinction between linear and nonlinear pharmacokinetics. Finally, experiments employing accelerated infusions with 3 test compounds produced clearance estimates within 30% of those determined by independent means under linear conditions, and demonstrated the clear identification of nonlinearity for one compound. The data presented in this investigation indicate that accelerated infusions may be used to determine pharmacokinetic linearity for compounds within certain pharmacokinetic boundaries (i.e., for which half-life is sufficiently small), but that caution is required in the interpretation of such studies.

249 COMPARATIVE TOXICOKINETIC PROFILE OF HIGH AND LOW DOSE PROPANIL USING ACCELERATED MASS SPECTROSCOPY.

J. B. Barnett[1], R. Schafer[1] and J. Vogel[2]. [1]*West Virginia University, Morgantown, WV and* [2]*Lawrence Livermore National Laboratory, Livermore, CA.*

Toxicokinetic measurements using radiolabeled compounds are frequently hampered by lack of sensitive methods to measure low (environmentally relevant) levels of xenobiotics. This limitation can be overcome by using accelerator mass spectrometry (AMS). AMS can routinely measure low abundance ^{14}C accurately and reproducibly at 1 part in 10e12 to 10e15. This project was designed to measure the distribution and elimination of the aniline herbicide, propanil. Propanil was custom synthesized substituting ^{14}C for ^{12}C in the ring structure (Sp. Activity 12.3 mCi/mmol [Moravek Biochemicals]). C57Bl/6 mice were injected intraperitoneally with either a low dose of 0.88 ng/g ^{14}C-propanil or a high dose of 2 mg/g "cold" propanil-spiked with 0.88 ng/g 14 C-propanil dissolved in peanut oil. Starting 1 minute after injection the blood, spleens, and livers were removed from 3 animals per time point and flash frozen for shipment to the Center for AMS at LLNL. Additional samples were taken at 10, 20, 40, 80, 120, 240, 360, and 720 minutes after injection. The data profiles from the two dosing schemes differed substantially. Blood and tissue samples from animals receiving the low dose showed a sharp peak in activity at approximately 10 minutes after injection and activity dropped to a very low level by 40-80 minutes after injection. In contrast, samples from animals given the high concentration of propanil did not peak in activity until approximately 40 minutes and showed a substantial plateau of activity throughout the time course of the experiment. These differences may reflect saturation of the tissues by the high dose. Development of PBTK models of these data is continuing. (Supported by NIH grant, ES07512.)

250 THE DISTRIBUTION OF PULEGONE IN B6C3F1 MICE AND F-344 RATS.

E. H. Lebetkin, L. T. Burka and L. J. Chen. *NIEHS, Research Triangle Park, NC.* Sponsor: H. B. Matthews.

Pulegone is a monoterpene ketone found in the essential oils from many mint species. It is the major constituent of pennyroyal oil (*Mentha pulegium*, *Hedeoma pulegoides*, and others). It is used as a flavoring and fragrance and as an herbal to induce menstruation and abortion. Ingestion of pennyroyal oil

has caused human poisonings resulting in CNS toxicity, gastritis, hepatic and renal failure, pulmonary toxicity, and death. It has been nominated to the National Toxicology Program for toxicity and carcinogenicity studies. A distribution study of 14C-pulegone in B6C3F1 mice and F344 rats conducted to aid in the design of the NTP study has determined that pulegone is rapidly absorbed and excreted in urine and feces in both species. At doses from 0.8 to 80 mg/kg, male mice excrete about 73 to 85% in urine and 15 to 24% in feces in 24 hr. Rats take longer to excrete an oral dose, eliminating 44% in urine and 15 to 23% in feces in 24 hr. Tissue to blood ratios in male mice are highest in the liver and kidney (less than 9 at 2 hours) and in the gastrointestinal tract (up to 21 at 2 hr depending on tissue). These ratios drop at 24 hr to below 3 in the liver and kidney and to less than 2 in the G.I. tract. At 24 hr 0.6 to 0.9% of the radioactivity remains in the liver, a target tissue for pulegone toxicity. This data suggests that even though the majority of the pulegone is rapidly excreted, there may be bioaccumulation of pulegone-derived material in liver following multiple doses.

251 PRELIMINARY TOXICOKINETIC STUDIES OF METHYLEUGENOL (MEG) IN FEMALE FISCHER 344/N RATS AND B6C3F1 MICE.

R. J. Moore[1], R. L. Phelps[2], J. T. Pierce[1], S. R. Baum[1], J. A. Dill[1], J. D. Johnson[3], S. W. Graves[3], C. S. Smith[4] and A. F. Fuciarelli[1]. *[1]Battelle, Toxicology Northwest Operations, Richland, WA, [2]Allergan, Irvine, CA, [3]Battelle, Columbus Operations, Columbus, OH and [4]NIEHS/NTP, Research Triangle, NC.* Sponsor: R. A. Renne.

The National Toxicology Program is conducting toxicokinetic studies of methyleugenol (MEG) to correlate toxic effects with systemic availability and to improve the usefulness of toxicity study results in risk assessment. The primary purpose of this study was to determine plasma concentrations of MEG and to estimate toxicokinetic parameters to assist in the design of a definitive study. MEG disposition was assessed in female rats and mice dosed intravenously (37 mg/kg in ethanol:emulphor:water, 1:1:8) or by gavage (37 or 150 mg/kg in corn oil). Plasma concentration-versus-time profiles after IV dosing revealed that elimination of MEG was bi-phasic. Estimates of the terminal half-life, Cltot and AUC were 1.9 hr, 3100 mL/hr-kg and 12 µg-hr/mL for elimination of MEG from rat plasma. Estimates of the terminal half-life, Cltot and AUC were 1.3 hr, 13000 mL/hr-kg and 2.8 µg-hr/mL for elimination of MEG from mouse plasma. Vss for MEG in rat and mouse plasma were 1500 and 6100 mL/kg, respectively. Plasma concentration-versus-time profiles for animals dosed by gavage were characterized by an early absorption phase (~15-30 min post-dosing) followed by at least one secondary peak. These secondary peaks in the profiles were attributed to the use of corn oil as an administration vehicle and occurred at earlier time points in the higher dose groups. Bioavailability was 2.6% for rats and 2.4% for mice. Saturation of MEG metabolism occurred in gavaged animals as revealed by non-linear (dose-dependent) toxicokinetic behavior. Additionally, based on these results a GC/MS method ranging from 0.005 to 32 µg MEG/mL plasma was validated for use in the definitive MEG toxicokinetic study. (This work was supported by the NTP Chemistry Support Services Contract, N01-ES-55395.)

252 PRELIMINARY TOXICOKINETIC STUDIES OF ISOEUGENOL (IEG) IN FEMALE FISCHER 344/N RATS AND B6C3F1 MICE.

A. F. Fuciarelli[1], R. J. Moore[1], R. L. Phelps[2], J. T. Pierce[1], S. R. Baum[1], J. A. Dill[1], J. D. Johnson[3], S. W. Graves[3] and C. S. Smith[4]. *[1]Battelle, Toxicology Northwest Operations, Richland, WA, [2]Allergan, Irvine, CA, [3]Battelle, Columbus Operations, Columbus, OH and [4]NIEHS/NTP, Research Triangle Park, NC.* Sponsor: R. A. Renne.

The National Toxicology Program is conducting toxicokinetic studies of isoeugenol (IEG) to correlate toxic effects with systemic availability and to improve the usefulness of toxicity study results in risk assessment. The primary purpose of this study was to determine plasma concentrations of IEG and to estimate toxicokinetic parameters to assist in the design of a definitive study. IEG disposition was assessed in female rats and mice dosed intravenously (37 mg/kg in ethanol:emulphor:water, 1:1:8) or by gavage (37 or 150 mg/kg in corn oil). Plasma concentration-versus-time profiles after IV dosing revealed that elimination of IEG was bi-phasic. Estimates of the terminal half-life, Cltot and AUC were 2.4 hr, 4900 mL/hr-kg and 7.6 µg-hr/mL for elimination of IEG from rat plasma. Estimates of the terminal half-life, Cltot and AUC were 3.3 hr, 4000 mL/hr-kg and 9.2 µg-hr/mL for elimination of IEG from mouse plasma. Vss for IEG in rat and mouse plasma were 3910 and 2000 mL/kg, respectively. Plasma concentration-versus-time profiles for animals dosed by gavage were characterized by an early absorption phase occurring at ~15-20 min post-dosing followed by at least one secondary peak. These secondary peaks in the profiles were attributed to the use of corn oil as an administration vehicle and occurred at earlier time points in the higher dose groups. Bioavailability was ~20% for rats and mice. There was no evidence for saturation of IEG metabolism in gavaged animals. Additionally, based on these results a GC/MS method ranging from 0.015 to 32 µg IEG/mL plasma was validated for use in the definitive IEG toxicokinetic study. (This work was supported by the NTP Chemistry Support Services Contract, N01-ES-55395.)

253 PHARMACOKINETIC DATA FROM INTRAVENOUS HIGH DOSE IBUPROFEN IN ANESTHETIZED WEANLING SWINE.

F. M. Reid[1], J. W. Kohne[1], N. A. Niemuth[1], T. L. Hayes[1], A. M. Sciuto[2] and R. R. Stotts[2]. *[1]Battelle, Columbus, OH and [2]United States Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

A weanling swine model has been developed to assess the efficacy of treatments for phosgene (CG) intoxication. CG is a choking agent used during World War I and an industrial hazard today. CG produces pulmonary edema (PE) after an asymptomatic period of up to 24 hr. Pharmacokinetic data on ibuprofen (IBU) were collected using eleven pigs (sus scrofus, ~20 kg) that were initially anesthetized with isoflurane and catheters placed into a femoral artery and vein. Once catheterized, the anesthetized state was maintained by slow infusion (~3 mL/hr) of pentobarbital sodium (65 mg/mL) and ~45 mL/hr of Lactated Ringer's solution for 72 hr. Five ventilated, anesthetized test animals were exposed for 10 min to air, and 30 min later treated iv with a loading dose of 45 mg IBU/kg over 30 min. This was followed by a 22.5 mg IBU/kg maintenance dose over 30 min every two hours for the initial 24 hr. The remaining six anesthetized test animals were exposed for 10 min to a target concentration of 450 mg CG/m3 and received the same IBU treatment regimen. Heparinized blood samples were drawn from each animal every 30 min over the initial 26 hr and every 4 hr for 72 hr. Whole blood IBU concentration was determined using High Performance Liquid Chromatography (HPLC). Selected blood gases and electrolytes were analyzed using I-Stat System. The resultant data indicate that the elimination curve for IBU in anesthetized swine is rapid and similar to that reported for man. Similar IBU elimination curves were observed for air and CG-exposed animals, suggesting that CG exposure did not significantly affect IBU metabolism. IBU appears toxic at a total dose of ~6,300 mg when administered as described above. The anesthesia regimen used may alter liver metabolism of swine, increasing energy requirements and possibly IBU metabolism. When a high iv dose of IBU is used as treatment, electrolytes and glucose levels should be monitored. (Supported by DAMD 17-89-C-9050.)

254 BROMODICHLOROMETHANE AND DICHLOROACETIC ACID PLASMA PROFILES FOLLOWING DOSED-WATER EXPOSURE USING FVB/N MICE: PRELIMINARY TIME POINT COLLECTION STUDIES.

D. L. Reichelderfer[1], J. D. Johnson[1], B. L. Burback[1], S. W. Graves[1] and C. Smith[2]. *[1]Battelle, Columbus, OH and [2]NIEHS, Research Triangle Park, NC.* Sponsor: M. R. Hejtmancik.

Preliminary studies for bromodichloromethane (BDCM) and dichloroacetic acid (DCA) were performed to ascertain the feasibility of obtaining useful blood concentration data for toxicology studies being conducted by the National Toxicology Program (NTP) to evaluate water disinfectant by-products. Male and female FVB/N mice, 10 to 11 weeks old, were exposed to BDCM or DCA in drinking water (tap water vehicle) at concentrations of 175 or 700 mg/L (BDCM) and 500 or 2000 mg/L (DCA) for up to 9 days. Serial blood samples were collected over a 24-hr period on Days 3 (BDCM and DCA) and 8 (BDCM only). The plasma samples were analyzed for BDCM or DCA using gas chromatography methods, which utilized electron capture detection. The limit of quantitation (LOQ) values were 2.5 ng/mL for BDCM and 0.1 µg/mL for DCA. BDCM plasma concentrations for the 175 mg/L group (Days 3 and 8) or the 700 mg/L group (Day 3) were generally below the LOQ. On Day 8, the profile for the male 700 mg/L group had a C_{max} value of 4.4 ng/mL (T_{max} of 12:00 AM), whereas the female group's highest plasma concentration (2.3 ng/mL at 12:00 AM) was just below the LOQ. For DCA, plasma concentrations for the 500 mg/L group (Day 3) were generally below the LOQ. For the 2000 mg/L group, the C_{max} values were 0.96 µg/mL (males) and 2.1 µg/mL (females), which occurred at 1:00 AM (T_{max}). The males exhibited a second peak at 6:00 AM of 0.94 µg/mL. It was recommended that no blood samples be collected for the BDCM study based on these results. For the DCA study, times of 12 AM or 6 AM will provide an estimate of the peak plasma concentration after at least three days of exposure. (This work was supported by the NTP Chemistry Support Services Contract N01-ES-55395.)

255 DOSE-DEPENDENT TOXICOKINETICS OF MONOCHLOROACETIC ACID IN ADULT MALE SPRAGUE-DAWLEY RATS AFTER ORAL ADMINISTRATION.

S. A. Saghir[1], J. Siegrist[1] and K. K. Rozman[2]. [1]*Univ. of Kansas Med. Center, Kansas City, KS and* [2]*Univ. of Kansas Med. Center, Department of Pharmacology, Toxicology and Therapeutics: Kansas City, KS; Sect. Environ. Toxicol., GSF-Institut für Toxikologie, Neuherberg, Germany.*

Male rats were administered a nontoxic 10 mg/kg and a toxic 225 mg/kg dose (~$1.D_{20}$) of ^{14}C-MCA (2.5-3.0 µCi/kg) in saline by gavage at 2 ml/kg. They were housed individually in metabolism cages. Urine and feces were collected separately. Animals were euthanized 15, 45 min, 2, 4, 8, 16, and 32 h after dosing and tissues collected by gross dissection. Radioactivity in tissue aliquots and excreta was determined by scintillation counting after digestion. At the nontoxic dose, the administered dose rapidly disappeared from the stomach (absorption + gastric emptying) leaving only 34 and 10% of dose in stomach at 15 and 45 min after administration, respectively. Within 45 min after gavage, 45% of the dose appeared in the small intestine and was rapidly absorbed leaving only about 3% of dose in the small intestine at 4 h. Concentration of MCA in plasma peaked at 0.1% of dose by 2 h and declined thereafter. Most tissue profiles of MCA paralleled that of plasma with notable exceptions (liver, heart, brain, thymus). At the toxic dose much of the dose remained in the stomach due to edema which lasted about 8 h and led to extremely slow release of MCA into the small intestine (5% of dose at 2 h being the highest value). Most of dose was absorbed through the stomach as indicated by >54 and 17% of dose present in stomach 4 and 16 h after gavaging, respectively. Tissue concentrations remained below those seen after the nontoxic dose. Peak plasma concentration was reached within 15 min without an apparent subsequent uptake phase. About 70-80% of MCA recovered from the small intestine was parent compound at both doses. Fecal excretion was negligible (<1.5%) after either dose. The nontoxic dose was rapidly excreted in urine; 43% within 4 h and >56% within 8 h. However, at the toxic dose, urinary excretion was slow, especially at early time points (9% at 4 h and 18% at 8 h). Urinary excretion accelerated after the 8 h time point. A total of 72 and 66% of the dose was recovered in urine within 32 h after the nontoxic and toxic dose, respectively. Oral administration of MCA did not cause any overt toxicity up to 200 mg/kg. Doses ≥450 mg/kg caused 100% mortality.

256 TISSUE DISTRIBUTION AND EXCRETION STUDIES OF EMIVIRINE IN MONKEYS AND RATS.

T. B. Grizzle[1], L. H. Wang[1], M. R. Blum[1], C. P. Moxham[1], F. S. Rousseau[1], C. T. Whalen[2], D. G. Halverson[2] and G. M. Szczech[1]. [1]*Triangle Pharmaceuticals, Inc., Durham, NC and* [2]*Covance Laboratories, Inc., Madison, WI.*

Emivirine (EMV; Coactinon®; MKC-442) is a potent non-nucleoside reverse transcriptase inhibitor (NNRTI) for treatment of HIV-1 infection that is currently in Phase III clinical development. Tissue distribution and excretion of [^{14}C]EMV-derived radioactivity were studied in cynomolgus monkeys (CM), and in Sprague Dawley (SD; non-pigmented) and Long-Evans (LE; pigmented) rats. CM were orally dosed with 180 mg/kg/day (90 mg/kg x 2) EMV for 13 days, then given a single oral dose of 90 mg/kg containing 63 µCi/kg [^{14}C]EMV. Blood, urine and feces were collected at several intervals up to 96 hr post-dose. Dosing with EMV continued for 6 days to steady state, after which a second [^{14}C]EMV dose was given. Tissues were collected at 1 hr post-dose. Rats were given a single oral dose of 50 mg/kg containing 88 µCi/kg [^{14}C]EMV and blood and tissues were collected at 5 (LE rats) or 6 (SD rats) post-dose intervals. Blood and tissue samples were analyzed for [^{14}C]EMV-derived radioactivity ([^{14}C]EMV-RA) by liquid scintillation counting. In CM, [^{14}C]EMV-RA peaked at 2 hr post-dose in plasma, with detectable levels remaining at 96 hr. Highest [^{14}C]EMV-RA levels were found in liver, bile, kidneys, and plasma. Mean total dose recovery was 70% in urine and 19% in feces, with 81% of the dose recovered by 48 hr. [^{14}C]EMV-RA distributed well into aqueous humor, brain, CSF, and testes. In SD rats, distribution of [^{14}C]EMV-RA to tissues was rapid, with maximum levels occurring at 0.5 hr post-dose. Levels then declined rapidly, but remained detectable in all 23 tissues studied for >24 hours post-dose. The highest levels were found in (decreasing order) stomach, small intestine, large intestine, liver, adrenal gland, and kidneys. Terminal elimination half-lives ranged from 4.2 hr (abdominal fat) to 27.8 hr (liver). Distribution of [^{14}C]EMV-RA was similar in SD and LE rat tissues, indicating that there was no association of EMV with melanin. In both species, EMV was rapidly absorbed following oral administration and EMV and its metabolites were widely distributed to all tissues examined.

257 COMPARATIVE DISTRIBUTION BETWEEN URINE AND BIOLOGICAL TISSUES IN MICE EXPOSED TO ARSENITE. DOSE-DEPENDENT EFFECT.

L. M. Del Razo[1], E. M. Kenyon[2], M. F. Hughes[2] and D. J. Thomas[2]. [1]*CEMLB, UNC Chapel Hill, Chapel Hill, NC and* [2]*NHEERL, USEPA, Research Triangle Park, NC.*

The concentration of arsenicals in urine has been generally accepted as a good biological indicator of arsenic (As) exposure, because excretion via kidney is the major route for elimination of most As species. The efficiency of As methylation is often evaluated by the relative distribution of As species in the urine. However, urinary methylated As metabolites are excreted more quickly than inorganic arsenic (iAs), in consequence, relative amounts of As species in the urine might not reflect the methylation efficiency in the body. Comparative As distribution patterns between urine and biological tissues were made in adult female B6C3F1 mice exposed to a single oral dose of 0, 1, 10, 30 or 100 µmol/kg arsenite (AsIII). Concentrations of iAs, monomethylarsonic acid (MMA) and dimethylarsinic acid (DMA) were determined in urine collected during 6h postdosing and in blood, liver, lung, and kidney from mice sacrificed 6 h after AsIII exposure. Tissue distribution and concentration of arsenicals increased in a dose-dependent manner. The concentration of iAs and metabolites (%dose/g tissue) was greatest in the urine, followed by in descending order: liver, kidney, lung, and blood. The relative proportions of iAs and MMA were significantly higher in internal organs than in urine while the urinary relative proportion of DMA was higher than in biological tissues. At doses higher than 10µmol/kg AsIII, an increased percentage of iAs and decreased percentage of DMA were observed in biological tissues (kidney was the exception), which indicates that the metabolism of As was affected by the dose. With increased dose, urinary excretion of iAs and MMA increased and DMA decreased, suggesting inhibition or saturation of methylation of As. The urinary As metabolite profile was a sensitive indicator of the dose-effect alteration on As metabolism. (Disclaimer: This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.) (Supported in part by CR824915.)

258 TISSUE DISTRIBUTION OF ARSENITE (AsIII) AND ITS METHYLATED METABOLITES IN MICE.

E. M. Kenyon[1], L. M. Del Razo[2] and M. F. Hughes[1]. [1]*NHEERL, EPA, Research Triangle Park, NC and* [2]*CEMLB, University of North Carolina, Chapel Hill, NC.*

The relationship of exposure dose and tissue concentration of parent chemical and metabolites is a critical issue in cases where toxicity may be mediated by a metabolite or parent chemical and metabolite acting together. This has emerged as an issue for inorganic arsenic (IAs) because its principle methylated metabolite, dimethylarsinic acid (DMA), induces lung-specific DNA damage in multiple species, is a multiorgan tumor promotor in rats and mice, and a complete bladder carcinogen in rats. In this study, the time-course tissue distribution of IAs and its methylated metabolites was determined in blood, liver, lung and kidney of female B6C3F1 mice given a single oral dose of 0, 1, 10, 30 or 100 µmol/kg AsIII. Blood levels of IAs and its metabolites were uniformly lower across both dose levels and time points compared to other organs. IAs was the predominant form of arsenic (As) in liver at all doses at 6 hrs post dosing and at all times up to 24 hrs post dosing with 100 µmol/kg AsIII. DMA was the predominant form of As in kidney at all doses at 6 hrs post dosing and at all times from 2 to 24 hrs post dosing with 100 µmol/kg AsIII. Three- to 4-fold higher levels of IAs were achieved in liver compared to kidney, whereas the concentration of DMA occurring in kidney was and 2- to 3-fold higher compared to liver. Monomethyl-arsonic acid (MMA) was the least abundant form of As in all tissues, never exceeding more than 20% of the total As present. DMA was the predominant form of As in lung across all doses at 6 hrs post dosing and concentrations of DMA present were 3- to 4-fold higher than either IAs or DMA at doses of 10 µmol/kg and higher. The concentration of DMA in lung was significantly greater than other organs, except kidney, from 4 to 16 hrs post dosing with 100 µmol/kg AsIII. These data demonstrate distinct organ-specific differences in the distribution and methylation of IAs and its metabolites that will be important to consider when investigating mechanisms of arsenic-induced toxicity. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.)

259 STEADY-STATE DISPOSITION OF ARSENATE IN THE MOUSE.

M. F. Hughes[1], E. M. Kenyon[1], B. C. Edwards[1], C. T. Mitchell[1], K. L. Rust[1], L. Del Razo[2] and D. J. Thomas[1]. [1]*ETD/NHEERL US EPA, Research Triangle Park, NC and* [2]*Center For Environmental Medicine and Lung Biology, University of North Carolina, Chapel Hill, NC.*

Inorganic arsenic (iAs), a human carcinogen, is a common contaminant in air, food, soil, and water. Therefore, exposure to iAs occurs everyday. An unanswered toxicological question with iAs is the steady-steady tissue levels from continuous exposure to it. The objective of this study was to determine the steady-state disposition of arsenate after oral administration. Adult female B6C3F1 mice (N=10) were orally administered [^{73}As]-arsenate (0.5 mg As/kg) daily for nine days. Whole body [^{73}As] levels were determined before and immediately after dosing by whole body radioassay. Urine and feces were collected daily and assayed for [^{73}As]. Twenty-four hr after the last dose, all 10 animals were whole body radioassayed. Five mice were then killed and tissues were removed and analyzed for [^{73}As]. Whole body [^{73}As] levels were determined in the remaining mice for 9 more days. The mice were then killed and tissue levels of [^{73}As] were determined. Whole body retention of As 24 hr after the first dose was 2.2 μg; this increased to 7.1 μg 24 hr after the last dose. Nine days after the last dose, the levels of As decreased nonlinearly to 2.3 μg. [^{73}As] was excreted primarily in the urine, with approximately 76% of the daily dose was eliminated by this route. The daily dose excreted in feces was approximately 15%. Treatment did not affect urinary and fecal elimination of [^{73}As]. In mice killed 24 hr after the last dose, As tissue concentrations (μg As/gm tissue) were greatest in bladder (0.09), kidney (0.07), skin (0.07), and liver (0.05). Levels in blood, muscle, lung, and carcass ranged from 0.01-0.04 μg As/gm. Tissue concentrations of As decreased considerably in mice killed 9 days after the last dose. The concentrations were greatest in skin (0.04), bladder (0.01) and carcass (0.01). The other tissues had <0.01 μg As/gm. Accumulation of As in organs of the mouse correlates with the known human target organs for iAs-induced carcinogenicity. (Supported in part by CR824915.) (This abstract does not necessarily reflect EPA policy.)

260 METABOLISM AND PHARMACOKINETICS OF RODA IN ALBINO AND PIGMENTED RATS.

W. J. Fasano, R. Valentine and S. R. Frame. *The DuPont Company, Haskell Laboratory for Toxicology and Industrial Medicine, Newark, DE.*

1, 3-bis(4-aminophenoxy) benzene (RODA) is an aromatic ether diamine structurally similar to certain other aromatic diamines known to produce ocular lesions. Following a single oral administration to male and female Crl:CD®BR albino and male HsdBlu:LE pigmented rats, plasma kinetics of parent RODA for both sexes and strains were best described by an open one-compartment model ($t_{1/2}$ = 2-11 h) while total radioactivity in plasma was best described by an open two-compartment model ($t_{1/2}$ = 39-61 h); clearance of ^{14}C-residues associated with red blood cells was prolonged ($t_{1/2}$= 76-142 h). RODA was biotransformed primarily to *N,N'*-diacetylated monohydroxylated-RODA and excreted in the feces (83-93%). Urinary excretion was a minor elimination pathway for RODA metabolites (3.5 7.5%) which were excreted as sulfoconjugates of 4-acetamidophenol, 3-phenoxy-4-acetamidophenol, and *N,N'*-diacetylated-monohydroxylated RODA. At terminal sacrifice (120 h), most tissue ^{14}C-residue levels were comparable between albino and pigmented rats except for the amount in the skin and eyes. Samples of skin and whole eyes from pigmented rats contained ~3-fold higher ^{14}C-residues than albino rats at an equivalent dose. Histoautoradiography of eyes established that a greater abundance of radioactivity was sequestered within the choroid region of eyes from pigmented rats as evidenced by increased gain density in the pigmented uvea, and pigmented rats exhibited less severe retinotoxicity than albino rats. These data suggest that pigment may bind RODA or a metabolite, thereby affording some degree of protection from retinal injury.

261 DISTRIBUTION OF 2,4-DICHLOROPHENOXYACETIC ACID (2,4-D) IN THE RAT AFTER LOW-DOSE, CHRONIC ADMINISTRATION.

T. A. Patterson[1], W. Slikker, Jr.[1], Z. Binienda[1], H. Duhart[1], G. Lipe[1], G. Newport[1], J. A. Sandberg[1] and C. S. Kim[2]. [1]*Division of Neurotoxicology, National Center for Toxicological Research/FDA, Jefferson, AR and* [2]*Division of Toxicological Research, Center for Food Safety and Applied Nutrition/FDA, Laurel, MD.*

The tissue distribution of 2,4-D was examined in young adult rats after chronic dosing. Male Fisher-344 rats, approximately 12 weeks of age, were lightly anesthetized with isoflurane and kept at surgical anesthesia with 1.8% isoflurane/oxygen. Alzet osmotic pumps (Alza Corp., model 2ML) filled with [14C]2,4-D (12.5 uCi/kg/day) and unlabelled sodium 2,4-D (1 or 10 mg/kg/day) were implanted subcutaneously between the scapulae. The incision was closed with wound clips and the rats were returned to their cages. After 7, 14 or 27 days of 2,4-D infusion, the rats were sacrificed (n=7/dose/group) and blood, peripheral tissues and brain regions were collected. Tissues were analyzed for radioactivity by liquid scintillation spectrometry with automatic quench correction, and the concentration of 2,4-D was calculated from the known specific activity of the radioisotope in the infusate. The highest concentration of 2,4-D was observed in the kidney. This was consistent with both dosing groups (1 and 10 mg/kg/day) over time. The plasma levels of 2,4-D indicated that steady-state concentrations were reached between 7 and 14 days of dosing. Although the 2,4-D level in the kidney did not change over time, the levels in other peripheral tissues and all brain regions examined increased between 7 and 27 days, with brain concentrations of 2,4-D increasing dramatically between 14 and 27 days. These data suggest that 2,4-D levels accumulate in tissues over time with chronic dosing, and the primary route of elimination (kidney) becomes quickly saturated. These data will be used to validate the previously developed physiologically-based pharmacokinetic (PBPK) model for a single, high-dose of 2,4-D, for chronic exposure to low-doses of 2,4-D.

262 BIOTRANSFORMATION AND KINETICS OF EXCRETION OF *TERT.*-AMYL METHYL ETHER IN RATS AND HUMANS.

A. Amberg, E. Rosner and W. Dekant. *Institut fuer Toxikologie der Universitaet Wuerzburg, Wuerzburg, Germany.*

Tert.-Amyl methyl ether (TAME) may be widely used as an additive to gasoline in the future. Therefore, widespread human exposure to TAME may occur. To contribute to the characterisation of potential adverse effects of TAME, its biotransformation was compared in humans and rats after inhalation exposure. Human volunteers (3 males and 3 females) and rats (5 males and 5 females) were exposed to 4 (3.8±0.2) and 40 (38.4±1.7) ppm TAME for 4 hours in a dynamic exposure system. Urine samples were collected for 72 h in 6 h intervals and blood samples were taken in regular intervals for 48 h in humans. In urine, the TAME-metabolites tert.-amyl alcohol, 2-methyl-2,3-butane diol, 2-hydroxy-2-methylbutyric acid and 3-hydroxy-3-methylbutyric acid were quantified, TAME and tert.-amyl alcohol were determined in blood samples. After the end of the exposure period, blood concentrations of TAME were 4.4±1.7 μM in humans and 9.6±1.4 μM in rats after 40 ppm TAME and 0.6±0.1 μM in humans and 1.4±0.8 μM in rats after 4 ppm. TAME was rapidly cleared from blood in both rats and humans. The blood concentrations of tert.-amyl alcohol were 9.2±1.8 μM in humans and 8.1±1.5 μM in rats after 40 ppm TAME and 1.0 ± 0.3 μM in humans and 1.8±0.2 μM in rats after 4 ppm TAME. Tert.-amyl alcohol was also rapidly cleared from blood. In urine of humans, 2-methyl-2,3-butane diol, 2-hydroxy-2-methylbutyric acid and 3-hydroxy-3-methylbutyric acid were recovered as major excretory products in urine. In rats, 2-methyl-2,3-butane diol and its glucuronide were major TAME-metabolites. tert.-Amyl alcohol and its glucuronide were minor TAME-metabolites in both species. All metabolites of TAME excreted with urine in rats were rapidly eliminated. Metabolite excretion in humans was slower. The obtained data indicate differences in TAME-biotransformation and excretion between rats and humans. In rats, TAME-metabolites are rapidly excreted. In humans, metabolic pathways are different and metabolite excretion is slower. (Supported by the Health Effects Institute, agreement No. 96-3.)

263 THE EFFECT OF CO-EXPOSURE TO GASOLINE VAPOR ON THE TOXICOKINETICS OF METHYL-*TERT.* BUTYL ETHER.

J. M. Benson, B. M. Tibbetts and J. R. Krone. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

The purpose of these studies was to determine the effects of coinhalation of the volatile fraction of unleaded gasoline (LFG) on MTBE toxicokinetics. Groups of male F344/Crl rats were acutely exposed nose-only for 4 hr to 4, 40, or 400 ppm ^{14}C-MTBE and to 20 and 200 ppm LFG containing 4 and 40 ppm ^{14}C-MTBE, respectively. To evaluate the effects of repeated inhalation of LFG on MTBE toxicokinetics, rats were exposed for 7 d to 20 and 200 ppm LFG followed on the 8th day by a similar exposure to LFG containing ^{14}C-MTBE. Endpoints included respiratory parameters, initial body burdens, rates and routes of excretion, and tissue distribution and clearance. MTBE and its metabolite, tertiary butyl alcohol (TBA), were quantitated in blood, and 2-hydroxyisobutyric acid (IBA) and 2-methyl-1,2-propanediol (2MePD) quantified in urine. The rate of MTBE uptake (μmole/kg body weight/hr) was lin-

ear over the 4-400 ppm MTBE. Acute and repeated inhalation of 200 ppm LFG significantly decreased the rate of MTBE uptake. Exposure to the higher MTBE concentrations and to LFG altered the distribution of MTBE equivalents immediately after the exposure. Repeated inhalation of 200 ppm, but not 20 ppm, LFG increased the rate of clearance of MTBE equivalents from blood, lung, liver, kidney, and testes. Exhaled air and urine were the major routes of excretion of MTBE equivalents. Inhalation of 20 ppm LFG increased the relative percentages of MTBE equivalents excreted in exhaled air and decreased the percentage excreted in urine compared to that when 4 ppm MTBE was inhaled. Concentrations of TBA in blood were consistently higher than that of MTBE. TBA was cleared from blood more slowly than MTBE. TBA comprised 70-88 percent of the total urinary metabolite excretion. Results of our studies indicate that acute and repeated coexposure to 20 ppm LFG has similar effects on the toxicokinetics of MTBE compared to that when 4 ppm MTBE is inhaled alone. Repeated inhalation of 200 ppm LFG appears to increase the rate of clearance of MTBE compared to that occurring when 40 ppm MTBE was inhaled alone. This may be due to the induction of cytochrome P450s metabolizing MTBE and TBA. (Research funded under DOE Cooperative Agreement No. DE-FC04-96AL76406.)

264 UPTAKE AND ELIMINATION OF METHYL *TERT.* BUTYL ETHER (MTBE) AND *TERT.* BUTYL ALCOHOL (TBA) IN HUMAN SUBJECTS BY THE ORAL ROUTE OF EXPOSURE.

J. Prah[1], D. Ashley[2], T. Leavens[1], S. Borghoff[3] and M. Case[1]. [1]*USEPA, Research Triangle Park, NC,* [2]*CDC, Atlanta, GA and* [3]*CIIT, Research Triangle Park, NC.*

The production of MTBE, about 3 billion gallons in 1998, for use as an oxygenating fuel additive, has resulted in contamination of the ground and drinking water supplies in various parts of the country by leaks, spillage, and atmospheric deposition. As a result there is a potential for wide-spread exposure to MTBE by the oral route. In an effort to examine the pharmacokinetics of MTBE and one of its metabolites, TBA, human subjects rapidly drank 6.7 microliters of MTBE in 250 ml(20mg/L) lemon-lime Gatorade after fasting for at least 4 hr. The male subjects were selected to have a body mass index of 22-24 and be within the age range of 18-35. Over a 24-hr period 14 blood samples were obtained and analyzed for MTBE and TBA by a purge and trap technique coupled with GC/MS. The results show that MTBE was absorbed into the blood, but not as rapidly as via inhalation, and declined with an initial half life of about 1-3 hr. The peak levels of MTBE ranged from 5-15 ng/ml. Blood TBA rose more slowly, plateaued, and had a half life of about 13 hr. TBA exhibited peak blood concentrations of 15-20 ng/ml and were above baseline after 24 hr. Double exponential curves described the data well and had a correlation of greater than 0.95, implying that disposition was into two compartments. The AUCs for MTBE and TBA were ~1300-~1700 and ~13000-~17000 ng/ml*min, respectively. The residence time of TBA in the blood may be dependent on its water solubility or slow metabolism. These data demonstrated that MTBE was readily absorbed when administered orally and that TBA persisted with an extended half life. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

265 1,1,1,3,3,3-HEXACHLOROPROPANE: METABOLISM AND DISTRIBUTION IN MALE AND FEMALE SPRAGUE-DAWLEY RATS.

S. J. Sumner, B. Asghrian, K. Roberts, T. A. Moore and T. R. Fennel. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Short-term inhalation exposure of rodents to 1,1,1,3,3,3-hexachloropropane (HCP) results in adverse effects in multiple organs. These studies were conducted to determine the metabolism and disposition of HCP. Male and female Sprague Dawley rats were exposed for 6 hr to 25 or 100 ppm [14C/13C]HCP by inhalation or administered ip 150 mg/kg [14C/13C]HCP. Expired air, and excreta (collected for up to 24 hr following exposure termination), and tissues (collected at 24 hr) were evaluated for radioactivity distribution. Urinary metabolites and expired volatiles were characterized using 13C NMR spectroscopy. Most HCP-derived radioactivity (49-69%) remained in the rats 24 hr following termination of exposures. HCP was eliminated via metabolism to 14CO2 (15-24 %), urinary metabolites (10-17%), fecal metabolites (1-3%), or expired as volatiles (3-9%). A slightly greater urinary and fecal elimination occurred for males compared with females. Following inhalation exposure, the recovered dose (per kg body weight) was greater in females as compared with males. The greater retained dose for females is largely attributed to a greater accumulation of radioactivity in body fat. Both sexes had a relative decrease in the recovered dose with an increase in exposure concentration, suggesting saturation in the uptake or metabolism of HCP. The relative distribution was similar following inhalation exposure to HCP at 100 or 25 ppm. Evaluation of NMR spectra of urine indicated the presence of 3,3-dichloroacrylic acid (DCAA) and metabolites derived from glutathione replacement of one chlorine from DCAA. NMR spectra of extracted charcoal traps indicated the presence of pentachloropropene as an expired volatile. Mechanisms to produce DCAA may involve reductive dechlorination, hydroxylation, elimination of HCl, and acid chloride hydrolysis. (This study was funded by Vulcan Chemicals.)

266 TOXICOKINETICS OF HEXACHLOROBENZENE IN FEMALE RATS.

J. Little[1], R. Moore[1], R. Harris[1], T. Morton[1] and D. Overstreet[2]. [1]*Midwest Research Institute, Kansas City, MO and* [2]*NIEHS, Research Triangle Park, NC.* Sponsor: M. L. Cunningham.

Hexachlorobenzene (HCB) is a chlorine-saturated aromatic that is the parent compound in the substituted aromatic class of pesticides. It has been suggested that HCB could account for more dioxin-like activity in human milk than polychlorinated dibenzo-*p*-dioxins, dibenzofurans, and biphenyls together. The toxicokinetics (TK) of HCB were assessed after a single oral administration to female Sprague Dawley rats at two dose levels (0.03 or 30 mg/kg body weight). TK parameters estimated included maximum blood concentrations (C_{max}) and time-to-peak (T_{max}), absorption, distribution, and elimination rates (k_a, α, and β) and associated half-lives, systemic clearance (Cl_s/F), apparent volumes of distribution (V_c/F and V_β/F), and dose normalized areas under the concentration-time curves ($DNAUC_{0-\infty}$). Selected tissues (liver, fat, and lung) were also analyzed for HCB. Kinetic parameters estimated for tissues include mean residence time (MRT), C_{max}, T_{max}, $t_{1/2}$ and $AUC_{0-\infty}$. HCB was rapidly absorbed (mean absorption $t_{1/2}$=1.4 hr) and absorption was linear over the dose range. However, the terminal elimination half-life (β-$t_{1/2}$) decreased from 176 hr to 48 hr for rats in the 0.03 and 30 mg/kg dose groups, respectively, suggesting non-linear kinetics. Clearance and volume terms, Cl_s/F, V_c/F, and V_β/F, increased with increasing dose. This increase in systemic clearance was associated with a decrease in the $DNAUC_{0-\infty}$ from 0.65 to 0.14 (µgohr/mL)/dose for rats receiving 0.03 or 30 mg/kg of HCB, respectively. Tissue data indicated HCB is highly concentrated in fat, thus creating a deep compartment where the compound is released slowly into the systemic circulation. The observed C_{max} in fat was 0.23 and 168 µg/g of tissue for rats treated with 0.03 and 30 mg/kg of HCB. HCB kinetics in liver behaved in much the same way. Lung tissue contained significantly lower amounts of HCB than fat or liver, with linear kinetics. One possible explanation for dose-dependent or non-linear kinetics is that tissue retention may be saturated at the higher dose level. A disproportionate increase in the unretained (systemic) fraction of HCB could increase the rate of renal or biliary excretion. However, this can not explain the observed increase in V_c/F and V_β/F with increasing dose.

267 DISPOSITION OF OCTAMETHYLCYCLOTETRASILOXANE (D_4) IN FEMALE FISCHER 344 AND SPRAGUE-DAWLEY RATS FOLLOWING NOSE-ONLY INHALATION EXPOSURE.

K. P. Plotzke, J. M. Tobin, D. A. McNett, J. Durham, J. M. McMahon, R. H. Gallavan and R. G. Meeks. *Dow Corning Corporation, Midland, MI.*

Female Fischer 344 and Sprague-Dawley rats were exposed to 700 ppm ^{14}C-D_4 for a single 6 hr exposure. Immediately following exposure, body burden animals were solubilized and total ^{14}C body burden was determined. Excreta animals were placed in metabolism cages for 168 hr post exposure for collection of urine, feces and expired air. Additional animals were euthanized at predetermined time points for blood and tissue collection. Radioactivity was measured in all samples. Fischer 344 rats retained a significantly higher amount ($p<0.05$) of radioactivity (8.3±0.44%) than Sprague-Dawley rats (5.9±0.26%) at the end of the 6 hr exposure. Excretion of radioactivity was similar in both strains, with similar amounts being excreted in urine (~30%), feces (~20%), and expired volatiles (~30%). Concentration of radioactivity over time in blood, liver and lung was similar over the 168 hr post exposure period while differences were seen in fat (AUC in µg equivalent D_4/g•hr was 24164 and 15894) for Fischer 344 and Sprague-Dawley rats respectively. Analysis of blood, liver, lung and fat samples for parent D_4 demonstrated differences in the percent of radioactivity that could be attributed to metabolites in blood (60 vs. 80%), liver (30 vs 51%) and lung (84 vs. 91%) for Sprague-Dawley vs. Fischer 344 rats respectively. Fischer 344 rats consistently showed a higher amount of radioactivity present as metabolites as compared to D_4. Radioactivity present in the fat for both strains was predominately D_4. These kinetic differences between female Sprague-Dawley and Fischer 344 rats suggest that there may be important biochemical differences leading to a

decreased metabolism of D_4 in the female Sprague-Dawley rat. (Supported in part by the Silicones Environmental Health and Safety Council.)

268 USING PHARMACOKINETIC MODELING AND MONTE CARLO METHODS TO IMPROVE ESTIMATED BIOCONCENTRATION FACTORS AND HALF-LIVES FOR SUBSTITUTED DIPHENYL *P*-PHENYLENE DIAMINES IN CARP.

C. R. Kirman[1], T. F. Long[1], A. P. Leber[2], S. M. Hays[3] and M. L. Gargas[1]. [1]*McLaren-Hart/ChemRisk, Cleveland, OH,* [2]*Goodyear, Akron, OH and* [3]*Exponent, Boulder, CO.*

A one-compartment pharmacokinetic (PK) model was developed for three substituted diphenyl p-phenylene diamines (DPPDs). The PK model was fit simultaneously to fish tissue concentration and water concentration data collected at two test concentrations during bioaccumulation and depuration studies for each DPPD. Bioconcentration factors (BCFs) were calculated from steady state estimates of fish tissue concentrations as predicted by the PK model. BCFs were also calculated using each individual fish tissue data point, for comparison purposes. Similarly, half-lives were estimated for each DPPD using model predictions for the depuration phase based on: (1) the bioaccumulation and depuration data used together; and (2) the depuration data alone. Monte Carlo methods were used to assess how variability in the fish tissue and water concentration data impact the estimates for the BCFs and half-lives. For each DPPD, the BCF calculated using the maximum fish tissue concentration far exceeded the upper 95th percentile of the BCF distributions calculated from steady-state model predictions for the entire data set. Similarly, the maximum half-lives calculated using the depuration data alone far exceeded the upper 95th percentile of the half-live distributions calculated from the combined bioaccumulation/depuration data set. Because the shape of the bioaccumulation phase (i.e., time to reach steady-state) contains information important to half-life, the importance of including bioaccumulation data when determining half-lives is emphasized.

269 MATERNAL AND FETAL DISPOSITION OF A PHOSPHOROTHIOATE OLIGONUCLEOTIDE, ^{3}H-ISIS 2105, FOLLOWING 3-HOUR OR 7-DAY INTRAVENOUS INFUSION TO PREGNANT RATS.

N. V. Soucy[1], J. P. Riley[1], M. V. Templin[2], R. S. Geary[2], A. de Peyster[1] and O. G. Khatsenko[2]. [1]*San Diego State University, San Diego, CA and* [2]*Isis Pharmaceuticals, Inc., Carlsbad, CA.*

Fetal exposure was evaluated following i.v. dosing of ^{3}H-ISIS 2105 to timed-pregnant rats. ISIS 2105 is a 20-base phosphorothioate oligonucleotide (ODN); selected thymidine residues were nonexchangeable ^{3}H-labeled. To maximize the potential for fetal exposure, ^{3}H-ISIS 2105 was administered as either a 3-hr infusion of 6.6 mg/kg/hr, total dose 20 mg/kg, or as a continuous 7-day infusion at 0.3 mg/kg/hr, total dose 59 mg/kg. Infusions were delivered via jugular vein canula by syringe pump on GD 18/19 (3-hr) or by osmotic pumps implanted s.c. on GD 12 (7-day). Reported concentrations are based on measured radioactivity. Following a 3-hr infusion, maternal and fetal plasma conc of ^{3}H-ISIS 2105 were > 100 μg/ml and < 5 μg/ml, respectively. Maternal and fetal regions of the placenta had similar ODN conc (7 to 15 μg/g). Concentrations of ODN in fetal kidney were less than 1% of maternal kidney. Following a 7-day continuous infusion, maternal plasma levels were approx 12 μg/ml; fetal plasma levels were approx 10 μg/ml. Concentrations were similar for maternal and fetal placenta approx 3 μg/g. Fetal kidney concentrations were approx 2-3% of those in maternal kidney. Relative organ distribution in fetuses was similar following either dose regimen (kidney > GI ≈ brain > liver) and different from dams (kidney > liver > spleen). These data indicate a minimal transfer from dam to fetus, consistent with a limited ability for these relatively large polyanionic compounds to traverse the placenta.

270 GF120918 ENHANCES THE CNS PENETRATION OF AMPRENAVIR IN SPRAGUE-DAWLEY RATS.

J. E. Edwards[1], K. Brouwer[2] and P. J. McNamara[3]. [1]*University of Kentucky, Graduate Center for Toxicology, Lexington, KY,* [2]*Glaxo Wellcome, Inc., Research Triangle Park, NC and* [3]*University of Kentucky, College of Pharmacy, Graduate Center for Toxicology, Lexington, KY.* Sponsor: R. A. Yokel.

The HIV virus is able to survive in extravascular tissues even when protease and reverse transcriptase inhibitors are administered. It has recently been cited in literature that amprenavir, a relatively new protease inhibitor, is actively transported by mdr (P-glycoprotein). Mdr is expressed in normal tissues including the skin, testes, uterus, liver, kidney, intestine, and at the blood-brain barrier. Whole body autoradiograms have shown that the CNS concentration of amprenavir is significantly lower in wild type mice mdr1a/b +/+ when compared to double knock out mice mdr1a/b -/-. The purpose of this study is to determine the extent of mdr modulation in Sprague-Dawley rats treated with GF120918 (250 mg/kg for four days) using microdialysis. A microdialysis probe was placed in the jugular vein and in the frontal cortex of Sprague-Dawley rats. Amprenavir was infused (8.04 mg/hr) for 5.25 hours and samples were taken from the blood and brain to determine the unbound brain to blood concentration ratio (BBR). The BBR for rats in the absence of GF120918 was determined to be 0.10+0.03 (n=5). The BBR for amprenavir in Sprague-Dawley rats pretreated with GF120918 was 0.67+0.3 (n=5). It is clear from this study that GF120918 significantly increases the penetration of amprenavir into the CNS. The use of mdr inhibitors may offer a new strategy to increase the effectiveness of antiviral therapy directed at reducing the HIV load in the brain. (This work was supported by GlaxoWellcome and NIEHS training grant ES07266.)

271 DOSE DEPENDENT METABOLISM OF BENZOFLEX®2-45 PLASTICIZER IN RATS.

L. G. L. Knight[1], D. Shaw[1], B. C. Mayo[1] and J. P. McBriarty[2]. [1]*Huntingdon Life Sciences Limited, Huntingdon, United Kingdom and* [2]*Velsicol Chemical Corporation, Rosemont, IL.* Sponsor: R. J. Harling.

Benzoflex®2-45 (diethyleneglycol dibenzoate; [ring-U-^{14}C] labeled), a plasticizer, was administered orally to rats in corn oil at doses of 50 and 750 mg/kg. Both doses were rapidly absorbed and excreted. Within the first 24 hours, > 97% of the administered radioactivity was excreted in the urine, while < 1% was excreted in feces and no radioactivity was detected in the expired air. Plasma and whole-blood radioactivity measurements, as indicated by the total area under the curves (AUC_t; μg equivelents.h/g) suggested that the 750 mg/kg dose was disproportionately greater than the proportionate increase in dose (from 3 to 4x). Furthermore, the urinary metabolite profile changed from the low to high dose. At 50 mg/kg essentially all the urinary metabolite was composed of hippuric acid, the normal glycine conjugate of benzoic acid. At 750 mg/kg an additional metabolite was observed in the urine. Upon hydrolysis the second urinary metabolite was identified by radio-TLC to be consistent with the glucuronide conjugate of benzoic acid. Thus, doses within the range of 500 to 750 are suggestive of saturating the normal conjugation and excretion mechanism of diethyleneglycol dibenzoate. Any toxicity observed in this dose range or higher needs to be considered carefully since the normal metabolism of this substance is altered. The tissue distribution of the ^{14}C labeled substrate was variable but not remarkable at either dose. Most important was the dose dependent metabolism observed at a dose of 750 mg/kg; and that Benzoflex®2-45 plasticizer was rapidly absorbed and eliminated within 24 hours.

272 ROLE OF AH RECEPTOR ON HEPATIC SEQUESTRATION AND DISPOSITION OF DIOXIN—STUDIES USING THE AH RECEPTOR-KNOCKOUT MICE.

J. J. Diliberto[1], B. D. Abbott[2] and L. S. Birnbaum[1]. [1]*ETD,* [2]*RTD, NHEERL USEPA, Research Triangle Park, NC.*

Dioxin (TCDD, 2,3,7,8-tetrachlorodibenzo-π-dioxin)is the prototype and most potent member of the highly lipophilic polyhalogenated aromatic hydrocarbons (PHAHs) which are persistent and ubiquitous environmental contaminants. TCDD acts as a ligand and binds to the aryl hydrocarbon receptor (AhR which results in a wide range of adverse biological responses. Body burdens associated with these effects are dependent on the disposition of the ligand. Disposition of TCDD and dioxin-like compounds is influence by their lipophilicity, binding affinities to the AhR, and binding affinities to the CYP1A2 which is regulated by the AhR. In both acute and subchronic animal studies, there is a specific accumulation of TCDD in liver compared to adipose tissue. Hepatic sequestration is dose-dependent, and the inducible hepatic binding protein, CYP1A2, has been shown to be responsible for this hepatic sequestration. The objective of the present study was to investigate the role of the AhR on the hepatic sequestration and disposition of TCDD in homozygous AhR knockout (KO) mice (AhR-/-)compared to age-matched heterozygous (AhR+/-) mice (both groups were on the C57BL/6N lineage). The mice were dosed orally with 25 Mg [3H]TCDD/kg and at termination (four days after dosing), tissues were quantitated for TCDD-derived radioactivity. Results demonstrated differential effects on disposition within the two groups

of mice. These differences were reflected by liver-to-fat (L/F) concentration ratios (sensitive indicators for hepatic sequestration of TCDD). The L/F concentration ratios were <0.1 for AhR-/-mice. Previously, studies have demonstrated L/F concentration ratios of 0.2 in the CYP1A2 KO mice and 3.6 in the parental strains (C57BL/6N and 129/Sv) at the same dose and time. This study demonstrates the importance of the AhR on the pharmacokinetic behavior and mechanistic issues for TCDD and related compounds. (This abstract does not necessarily reflect EPA policy.)

273 DISTRIBUTION OF 2,2-BIS(4-CHOROPHENYL)-1,1,DICHLOROETHYLENE (p,p'-DDE) IN FETAL RATS.

B. R. Sparrow and M. J. Devito. *NHEERL USEPA, Research Triangle Park, NC.*

The environmental contaminant 2,2-bis(4-chlorophenyl)-1,1-dichloroethylene (p,p'-DDE) is a stable and persistent metabolite of DDT. p,p'-DDE acts as an antiandrogen in both *in vitro* and *in vivo* systems. Male rats exposed perinatally to high doses of p,p'-DDE display feminized external morphology in the form of reduced anogenitial distance and retained thoracic nipples. A recent study investigated the transplacental transfer of p,p'-DDE to the whole fetus, fetal liver, brain, and blood (You et. al., 1999). Here we investigate, in addition to the distribution of p,p'-DDE in fetal liver and blood tissue, the distribution of p,p'-DDE in maternal adipose, liver, blood, and placenta, and the distribution in various fetal urogential tissues including adrenals, kidneys, ovaries, testis, and the external sex papilla. Six time-pregnant Long Evans rats were dosed daily via gavage during GD14-18 with 100mg p,p'-DDE spiked with 3.19*u*Ci 4,4'-DDE-Ring-UL-^{14}C/ mL dosing solution /kg body weight. Each animal, on average, received approximately 2.7*u*Ci ^{14}C-DDE/day. On GD 19, the aforementioned tissues were harvested and the distribution of p,p'-DDE determined. Partitioning of p,p'-DDE in maternal tissues paralleled tissue lipid content with adipose containing approximately 1350 ppm followed by liver (79 ppm), placenta (34 ppm) and blood (22.9 ppm). p,p'-DDE distribution in fetal tissues were: adrenals (118.5 ppm), ovaries (61.9 ppm), liver (33.9 ppm), testis (21 ppm), external sex papilla (13.9 ppm), kidney (9.8 ppm), blood (7.9 ppm). The consequences of p,p'-DDE accumulation in fetal adrenals warrants further investigation. (Funded by a National Research Council-USEPA/NHEERL Research Associateship. This abstract does not reflect USEPA policy.)

274 COMPARATIVE DISPOSITION OF PROPARGYL ALCOHOL (PAL) IN MALE F-344 RATS AND B6C3F1 MICE.

K. J. Dix, D. P. Coleman, N. F. Gaudette, A. P. Stanley and A. R. Jeffcoat. *Research Triangle Institute, Research Triangle Park, NC.*

PAL, a moderately volatile acetylenic alcohol, is a high production volume chemical used as a chemical intermediate, a corrosion inhibitor, and a solvent stabilizer. There is potential human exposure to PAL in the occupational environment by inhalation and dermal contact. We have conducted a series of studies to compare the disposition of [^{14}C]PAL in male rats and mice after a single iv (1 mg/kg), oral (50 mg/kg), inhalation (1 ppm or 100 ppm for 6 h), or dermal (5 mg/kg) exposure. By 72 h following an iv or oral dose, 80-90% of the dose was excreted (urine, feces, volatile organics, and $^{14}CO_2$). The majority of the iv and oral doses was excreted in the first 24 h post-dosing, primarily in urine (40-60%) and as exhaled CO_2 (19-26%) by both species, with <1% of the dose exhaled as volatile organics. In the inhalation studies, 30-55% of the radioactivity to which animals were exposed was absorbed. The primary route of excretion of the absorbed dose was in urine (23-53%), and a significant portion was exhaled as volatile organics (15-20%) by 18 h after cessation of the inhalation exposure. In rats, elimination in bile (62% in 4 h) was much greater than elimination in feces (6% in 72 h), indicating that PAL metabolites undergo extensive enterohepatic recycling. Dermal exposure studies conducted in rats demonstrated that dermal absorption of PAL was minimal due to its inherent volatility; <5% of the applied dose was excreted in urine and feces or exhaled as CO_2. In summary, our studies show that after a single iv, oral, or inhalation exposure to PAL, the majority of the administered radioactivity is rapidly eliminated from the body. Further, systemic exposure after a brief dermal exposure to PAL is minimal due to its volatility, however significant absorption may occur with prolonged inhalation exposure or dermal contact.

275 PHARMACOKINETICS OF INHALED MANGANESE PHOSPHATE IN MALE SPRAGUE-DAWLEY RATS FOLLOWING SUBACUTE (14-DAY) EXPOSURE.

D. Vitarella, B. A. Wong, O. R. Moss and D. C. Dorman. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

The goal of this pilot study was to determine the exposure-response relationship for inhaled manganese phosphate in adult male CD rats. Manganese phosphate is the primary respirable ($PM_{2.5}$) tailpipe emission product arising from the combustion of methylcyclopentadienyl manganese tricarbonyl (MMT). Rats were exposed 6-hr/day for either 5 days/week (10 exposures) or 7 days/week (14 exposures) to manganese phosphate at 0, 0.03, 0.3, or 3 mg Mn/m^3 (MMAD=1.5 μm). The following tissues were collected following the last inhalation exposure: plasma, erythrocytes, olfactory bulb, striatum, cerebellum, lung, liver, femur, and skeletal muscle (n=6 rats/exposure group). Intravenous $^{54}MnCl_2$ tracer studies were also conducted following the 14th exposure (n=6 rats/concentration), and whole-body gamma spectrometry was performed immediately after injection and at 1, 2, 4, 8, 12, and 16 weeks after $^{54}MnCl_2$ administration. Increased olfactory bulb and lung manganese concentrations were observed only following exposure to 0.3 (14 exposures) or 3 mg Mn/m^3 (10 or 14 exposures). Increased manganese concentrations were observed in cerebellum, striatum, femur, and skeletal muscle only following exposure to 3 mg Mn/m^3 (10 or 14 exposures). Red blood cell manganese concentrations were increased only in rats exposed to 3 mg Mn/m^3 (10 exposures). Rats exposed to 3 mg Mn/m^3 also had faster initial and terminal manganese elimination rates when compared to air-exposed control animals. Our results suggest that the rat olfactory bulb may accumulate more manganese than other brain regions following inhalation exposure. (Funded by Ethyl Corporation in support of registration testing requirements arising under Section 211 (a, b) of the Clean Air Act.)

276 TOXICOKINETICS OF DOSE DEPENDENT THIOBENZAMIDE HEPATOTOXICITY AND TISSUE REPAIR RESPONSES.

H. M. Mehendale, V. S. Vaidya and R. A. Hill. *Division of Toxicology and Preclinical Sciences, College of Pharmacy and Health Sciences, The University of Louisiana at Monroe, Monroe, LA.*

Our recent mechanistic studies of thiobenzamide (TBZ) hepatotoxicity have demonstrated that at LD100 doses liver function returns to near normal prior to animal death. The lethal-dose repair, response is however, delayed and less robust than responses at sublethal but hepatotoxic doses. Accumulating evidence suggests that TBZ hepatotoxicity arises from the production of at least one reactive metabolite. In an attempt to further explain the observed differences in magnitude and time course of tissue repair response, plasma concentrations were quantitated for TBZ, TBZ-S-oxide (sulfine), and benzamide at various time intervals during 28 h after oral dosing. Preliminary results for 175-200 g (1.5-2 month old) Sprague Dawley rats indicate that at higher TBZ doses, S-oxide concentrations remain elevated for an extended period of time (30% of cmax at 10 h for a 1050 mg/kg dose vs. <1% of cmax at 10 h for 450 mg/kg; and <<1% of cmax at 6 h for 150 mg/kg). For benzamide, which is presumed to be formed from S-oxide via the reactive (sulfene) TBZ-S,S-dioxide, the differences were even more pronounced. At the highest dose, benzamide concentrations were 50% of cmax at 20 h, and still >25% cmax at 28 h. Although the benzamide AUCs increased roughly in proportions to the dose, cmax was approximately unchanged over all three dose levels. These data are consistent with either saturation or capacity reduction in the conversion of the S-oxide to benzamide at higher doses of TBZ, translating to much longer time frames during which tissues are being exposed to reactive intermediates. This scenario may partially account for the delayed onset and decreased aggressiveness of tissue repair at high doses, and therefore further explorations are in progress. (Board of Reagents Support Fund.)

277 HETEROLOGOUS EXPRESSION OF AND THE DEVELOPMENT OF ASSAYS FOR INTERACTION OF DRUGS WITH HUMAN P-GLYCOPROTEIN.

P. Stocker, L. Fox, D. T. Steimel and C. L. Crespi. *Gentest Corporation, Woburn, MA.*

P-Glycoprotein (PGP or MDR1) is a member of the ABC transporter superfamily and is expressed in the human intestine, liver and other tissues. Intestinal expression of PGP may affect the oral bioavailability of drug molecules and other xenobiotics that are substrates for this transporter. Interaction with PGP can be studied using either direct assays of drug transport in polar-

ized cell systems or with indirect assays such as drug-stimulated ATPase activity and inhibition of the transport of fluorescent substrates. We have expressed human PGP cDNA using both stable mammalian cell and baculovirus/insect cells expression systems. With the insect cell expressed material we have applied a colorometric assay for the ATPase activity to the detection of interaction of drugs with PGP. Known drug substrates stimulate vanadate-sensitive ATPase activity in PGP-containing insect cell membranes. These interactions typically demonstrated saturation kinetics. With the stable mammalian cell system we have examined the kinetics of drug transport across cell monolayers. Again, known drug substrates typically demonstrated saturation kinetics. Several xenobiotics stimulated ATPase activity but were not detectably transported in the mammalian cell system. In contrast, all xenobiotics that were transported also stimulated ATPase activity. For this latter class of xenobiotic, there was good agreement between the systems in the concentration that gave half maximal response. The ATPase assay is a useful screen for interaction with PGP. However, positive responses should be further investigated in transport assays. Concentration response data from the ATPase assay appears to be useful for the design of such transport assays.

278 EFFECTS OF PERCHLORATE ON THYROIDAL UPTAKE OF IODIDE & CORRESPONDING HORMONAL CHANGES.

K. Yu[1], L. Narayanan[2], R. Godfrey[3], P. Todd[1], T. Sterner[4], S. Young[1], T. Bausman[1], D. Mattie[1] and J. Fisher[1]. [1]*AFRL/HEST, Wright-Patterson AFB, OH,* [2]*Geo-Centers, Inc., Dayton, OH,* [3]*ManTech Environmental, Dayton, OH and* [4]*OpTech Corp, Dayton, OH.*

The production and storage of ammonium perchlorate (AP) has resulted in contamination of soil, ground and drinking water in a number of states. The perchlorate ion interferes with iodide uptake in the thyroid resulting in reduced thyroidal hormone synthesis. In rodents, this leads to lowered T_3 and T_4 blood levels and TSH activation to stimulate production of thyroid hormones. A series of experiments were conducted to investigate the temporal relationship between perchlorate-induced inhibition of iodide uptake in the thyroid and its effects on the synthesis of thyroid hormones. ^{125}I uptake inhibition studies were carried out in naïve rats given single intravenous perchlorate doses (0 - 3 mg/kg) and in rats given drinking water containing perchlorate for 2 weeks (0 -3 mg/kg/day). In other studies rats were given drinking water containing perchlorate for two weeks (0 - 10 mg/kg/day) and TSH, total T_3, total T_4, and free T_4 in serum were measured on days 1, 5, and 14 of treatment. TSH, T_3, T_4, and free T_4 time course data were collected in rats intravenously dosed with 3 mg/kg of perchlorate. Under conditions when iodide inhibition was about 70% (from 2-24 hours after a single 3 mg/kg intravenously dose of perchlorate), total T_4 serum level decreased and TSH serum level increased. TSH remained elevated for 48 hrs, while total T_4 returned to control levels by 48 hrs. In the drinking water studies, dose dependent thyroid activation was evident by temporal changes in inhibition of iodide uptake in the thyroid and accompanying thyroid hormone changes. TSH remained elevated for the 1, 3, and 10 mg/kg/day dose groups. In the 0.1 mg/kg/day dose group, TSH was elevated only on day 1 of treatment.

279 PREDICTION OF DOSE-RESPONSE FOR PERCHLORATE INHIBITION OF THYROIDAL IODIDE UPTAKE IN HUMANS USING A SIMPLIFIED PHARMACOKINETICS MODEL AND PERFUSED-ORGAN DATA FROM RATS.

G. Goodman. *Human Health Risk Resources, Inc.; Intertox, Inc., Seattle, WA.*

Recent improvement in measurement sensitivity has led to widespread detection of ppb perchlorate levels in groundwater. Populations throughout the Southwest potentially consume drinking water containing perchlorate at levels of approximately 10-20 ppb, leading to doses estimated as 0.0003-0.0006mg/kg-day. It is therefore of importance to determine a safe level of perchlorate exposure. The most sensitive site of perchlorate action is the sodium/iodide symporter. The concentration-dependence of perchlorate inhibition of iodide uptake by the symporter into the thyroid has been measured in perfused rat thyroid lobes (Greer *et al.* 1966. *Endocrinol.* 79: 237-247). On the assumption that the concentration-dependence in the isolated rat thyroid predicts that in the human thyroid *in vivo*, a model was developed for predicting the inhibition resulting from a given daily dose. Published perchlorate pharmacokinetics data in rats and humans were analyzed; assuming first-order kinetics, the elimination half-life ($t_{1/2}$) was estimated as 16-18 hr in humans and 20-24 hr in rats. Based on the model developed for estimating steady-state serum levels, a perchlorate dose of 0.03mg/kg-day (*e.g.*, consumption of drinking water containing 1 ppm perchlorate) was predicted to inhibit iodide uptake by about 50%. Recent data in humans suggest that inhibition of uptake by this amount requires a dose more than five-fold higher (Lawrence *et al.* 1999, ATA meeting abstract). Two hypotheses for this discrepancy can be put forward: (1) the rat symporter *in vivo* is more sensitive than the human symporter *in vivo*, and/or (2) the perfused thyroid is more sensitive than the thyroid *in vivo*.

280 HEPATIC SULFOTRANSFERASE ACTIVITY IN MALE RATS CHRONICALLY EXPOSED TO ETHANOL AS PART OF HIGH AND LOW CARBOHYDRATE DIETS INFUSED VIA TOTAL ENTERNAL NUTRITION (TEN).

M. J. J. Ronis, C. Mercado, D. Holder, C. Weatherford and T. M. Badger. *Arkansas Children's Hospital Research Institute, Little Rock, AR.*

There is good evidence that sexually dimorphic patterns of growth hormone (GH) secretion regulate the expression and activity of many sex-dependent hepatic enzymes in rat liver. We have shown that chronic ethanol exposure demasculinizes the pattern of GH secretion in male rats and as a consequence, significantly decreases expression and activity of the male specific hepatic P450 enzyme CYP2C11 (Badger et al. JPET 264: 438,1993). Moreover, the severity of CYP2C11 suppression increases as dietary carbohydrate is lowered. In addition to P450s, a number of rat hepatic phase II enzyme systems including the sulfotrasferases are sex-dependent and appear to be GH regulated. Therefore, the current study was designed to investigate the effects of ethanol and diet on hepatic sulfotransferase expression. Four groups of 250g male Sprague-Dawley rats (N=6-8) had IG cannulae surgically inserted and were placed on total enteral nutrition (TEN) using liquid diets. In two groups of rats, 36% of the carbohydrate calories were replaced with ethanol. The final carbohydrate content of one ethanol diet was 37.5% while the second was 3%. After 50 days of ethanol infusion, the rats were sacrificed, livers collected and cytosol prepared. Sulfotransferase activities towards the phenolic substrate b-napthol; the estrogens 17b-estradiol and estrone and hydroxysteroid substrate dehydroepiandrosterone (DHEA) were measured. No effects of either diet or ethanol were observed on b-naphthol sulfotransferase activity. In contrast, sulfotransferase activities towards both estrogens was increased 2-fold ($p<0.05$) and that towards DHEA was induced 2-4 fold ($p<0.05$) by chronic ethanol treatment. This effect of ethanol was independent of dietary carbohydrate concentration. These data are consistent with the predicted effects of suppressed and demasculinized GH secretion by ethanol. Phenolic sulfotransferase ST1A1 has been reported to be unaffected by GH manipulation. In contrast, the major estrogen sulfotransferase ST1E2 has been shown to be negatively regulated by GH, while the major hydroxysteroid sulfotransferase ST-40/41 has been reported to be selectively suppressed by the male pattern of GH secretion in rats. NIAAA08645.

281 ROLE OF PREGNENOLONE-16α-CARBONITRILE (PCN)-INDUCED EXPRESSION OF MRP2 IN THE ENHANCED PLASMA DISAPPEARANCE AND BILIARY EXCRETION OF DIBROMOSULFOPHTHALEIN (DBSP).

D. R. Johnson and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

Previous studies have shown that PCN increases the plasma disappearance and biliary excretion of DBSP in Sprague-Dawley (SD) rats. PCN also increases rat multidrug resistance protein 2 (Mrp2), a canalicular organic anion transporter protein responsible for excretion of DBSP. We hypothesize that up-regulation of Mrp2 by PCN is responsible for the enhanced plasma disappearance and biliary excretion of DBSP. This was resolved by measuring plasma disappearance and biliary excretion of DBSP in control and PCN-treated SD and Mrp2-deficient Eisai hyperbilirubinemic rats (EHBR). Male SD and EHBR rats were injected *ip* for four days with PCN (75 mg/kg/day) or vehicle control. On day five, DBSP (100 mg/kg) was injected *iv* and measured in blood and bile. Plasma DBSP disappearance was the same in non-induced SD and EHBR rats. PCN enhanced the plasma disappearance of DBSP in both SD and EHBR rats, but disappearance slowed at later time intervals in EHBR rats. The maximal rate of biliary excretion in non-induced EHBR rats was markedly reduced and delayed compared to non-induced SD rats. PCN increased DBSP biliary excretion in SD rats, but decreased the biliary excretion of DBSP in EHBR rats at later time intervals. These results suggest that the enhanced plasma DBSP disappearance produced by PCN is not due to Mrp2, as shown by the EHBR data. The low rate of biliary DBSP excretion in EHBR rats may to be due to an additional canalicular transporter. Furthermore, a PCN-inducible sinusoidal transporter may efflux DBSP into plasma. In conclusion, up-regulation of Mrp2 by PCN is not responsible for the increased uptake of DBSP, but is responsible for the enhanced biliary

excretion of DBSP. (Supported by NIH grants ES-03192 & ES-07079, and AHA grant KS-98-GS-11.)

282 DISPOSITION AND SEROTONERGIC EFFECTS OF CYHALOTHRIN IN CENTRAL NERVOUS SYSTEM.

M. R. Martinez-Larrañaga, M. Martinez, M. E. Morales, M. A. Martinez, M. J. Díaz, M. T. Frejo and A. Anadón. *Complutense University, Madrid, Spain.*

Cyhalothrin, type II pyrethroid insecticide, is used topically for the control of ectoparasites. It is also widely used in agriculture and in home desinsection. Pyrethroids are neurotoxic compounds. In humans, sensory facial irritation is a very common syndrome (paraesthesia and dysaesthesia). Cyhalothrin when injected peripherally to rat produced a severe syndrome characterized by tremor, salivation and choreoathetosis. The aim of this work was to determine cyhalothrin disposition and effects on the levels of 5-hydroxytrytamine (5-HT) and its metabolite 5-hydroxy-3-indole acetic acid (5-HIAA) in nervous tissues. Two experiments were carried out. Experiment 1: male Wistar rats were treated with cyhalothrin, single i.v. dose of 3 mg/kg and killed at different time periods. Plasma and nervous tissue samples were isolated, homogenized and extracted in acetonitrile to determine cyhalothrin concentrations by HPLC. Experiment 2: rats were divided into two groups. Group 1 rats received cyhalothrin (8 mg/kg for 6 days) orally. Group 2 rats (control group) received 0.5 ml corn oil/rat orally. All animals were killed 24 h after last dosing, brain regions were isolated and the contents of 5-HT and 5-HIAA quantified by HPLC-ED. The results indicated an accumulation and a slow final disappearance of cyhalothrin from tissues as well as a lower activity of the 5-HT-ergic system. (Work supported by Projects No. PB97-1236 (DGICYT), No. 08.8/0002/98 (CAM) and 99/0936 (FIS), Spain.)

283 ALTERATION OF METABOLISM FOR PERCHLOROETHYLENE AND 1,1,1,2-TETRACHLOROETHANE AFTER CARBON TETRACHLORIDE PRETREATMENT IN B6C3F1 MICE.

D. Mahle[1], R. Godfrey[1], G. Buttler[1] and J. Fisher[2]. [1]*ManTech Environmental Inc., Dayton, OH and* [2]*AFRL/HEST, Wright-Patterson AFB, OH.*

Perchloroethylene (PCE) and 1,1,1,2-tetrachloroethane (1,1,1,2-TC) are both metabolized by P450 2E1, ultimately yielding TCA as a major metabolite. Carbon tetrachloride (CT) has been shown to induce and inhibit P450 2E1 metabolism. To understand better the impact of CT on P450 2E1 mediated metabolism male B6C3F1 mice were dosed by bolus gavage with either 0, 0.1, 1, 5, 20, 50 or 100 mg/kg CT. Then, 1 hr later the mice were given a bolus gavage of 100 mg/kg PCE or 200 mg/kg 1,1,1,2-TC. At 4 hr after the challenge dose blood and liver were taken and analyzed for parent solvent concentration and for metabolites. TCA concentration in blood after the 0 mg/kg CT/ PCE challenge was 35.5±2.5 μg/g and decreased to 1.2±0.1 μg/g for the 100 mg/kg CT/ PCE challenge. TCA concentration in blood after the 0 mg/kg CT/ 1,1,1,2-TC challenge was 38.5±5.9 μg/g and decreased to 4.5±0.8 μg/g for the 50 mg/kg CT/ 1,1,1,2-TC challenge. Interestingly, the level of TCA increased in blood with a 0.1 mg/kg CT pre-treatment before both PCE and 1,1,1,2-TC as compared to the 0 mg/kg CT level, suggesting the possibility of induction of the P450 2E1 enzyme by CT at this dose. The pharmacokinetic data for these chlorinated solvents and their metabolites can be used to describe the possible interactions between solvents in a mixture that can alter toxicity.

284 INHIBITION OF FLAVIN-CONTAINING MONOOXYGENASE AND CYP1A2 ACTIVITIES IN HUMAN BY GRAPEFRUIT JUICE.

Y. N. Cha, J. H. Kang, C. S. Park and W. G. Chung. *Inha University, Inchon, Republic of Korea.*

CYP1A2 and flavin-containing monooxygenase (FMO) are known to oxidize various procarcinogens like aromatic and heterocyclic amines to cause colorectal and bladder cancers. Inhibition of these enzymes would lead to cancer prevention. Quercitrin, a flavonoid contained in grapefruit juice and red wine, is known to inhibit CYP1A2 and 3A4 activities *in vitro* and is considered to have cancer preventive effects. Thus, we have determined whether the administration of grapefruit juice would inhibit the CYP1A2 and FMO activities *in vivo* by assessing the molar concentration ratios of urinary caffeine (CA) metabolites after administering a cup of coffee. Intake of grapefruit juice inhibited the *in vivo* FMO activity (theobromine/CA) by 79% and the *in vivo* CYP1A2 activity (1,7-dimethylurate+paraxanthine/CA) by 32%, but not xanthine oxidase activity (1-methylurate/1-methylxanthine). Results of this study suggested that grapefruit juice would inhibit CYP1A2 and FMO activities *in vivo* and would prevent the metabolic activation of aromatic and heterocyclic environmental procarcinogens causing bladder and colo-rectal cancers. (Supported by an intramural grant from Inha University.)

285 INHIBITION OF LIVER MICROSOMAL FLAVIN-CONTAINING MONOOXYGENASE ACTIVITIES BY FLAVONOIDS.

W. G. Chung, S. D. Ryu, C. S. Park and Y. N. Cha. *Inha University, Inchon, Republic of Korea.*

Grapefruit juice, containing several flavonoids, has been known to inhibit the CYP3A4 and 1A2 activities *in vivo*. We found that intake of grapefruit juice inhibited also the flavin-containing monooxygenase (FMO) activity *in vivo*. Thus, we determined whether several bioflavonoids known to be contained in grapefruit juice would inhibit liver microsomal FMO activity *in vitro*. The thiobenzamide S-oxidation was inhibited in a dose dependent manner by flavonoids up to 80% (quercitrin), 64% (kaempferol) and 40% (naringin). The Ki values were 6.2, 12.0 and 13.9uM, respectively. Quercitrin (noncompetitive-uncompetitive type) and kaempferol (competitive-noncompetitive type) provide mixed inhibition pattern while naringin exhibited uncompetitive pattern. In addtion to the thiobenzamide S-oxidation, quercitrin, kaempferol and naringin inhibited the oxidation of N,N-dimethylaniline, another FMO assay, by 52-58%. This study indicated that quercitrin, kaempferol and naringin among bioflavonoids known to be contained in grapefruit juice are the ingredients responsible for the inhibition of *in vivo* FMO activity by intake of grapefruit juice in human. (Supported by an intramural grant from Inha University.)

286 TOXICOKINETIC-TOXICODYNAMIC RELATIONSHIPS IN TWO CASES OF CYANIDE POISONINGS.

F. J. Baud[1], S. W. Borron[2], M. Debray[3] and C. Bismuth[1]. [1]*Réanimation Médicale et Toxicologique, University Paris VII, Paris, France,* [2]*Réanimation Médicale et Toxicologique, George Washington University, Paris, France and* [3]*Laboratoire de Biomathématiques, University Paris V, Paris, France.*

The value of PK-PD relationships in clinical pharmacology is now well recognized. However, the potential interest of Toxicodynamic-Toxicokinetic (TK-TD) relationships in medical toxicology has been poorly investigated. The aim of this study was to correlate the plasma lactate concentrations and the corresponding blood cyanide concentrations. **Materials and Methods:** Plasma lactate concentrations (PLC) were measured using an enzymatic method. Blood cyanide concentrations (BCC) were measured using a colorimetric assay. Non-linear regression was used for modeling TK-TD relationships. **Results:** TK-TD relationships were studied in 2 cases of life-threatening cyanide poisonings (patients 1 and 2). The PLCs at the time of hospital admission were 53.0 and 47.7 mmol/L in patients 1 and 2, respectively (Nal < 2 mmol/L). The corresponding BCCs were 256 and 239 μmol/L, respectively. In patient 1, there was a plateau of PLCs corresponding to BCCs ranging from 256 to 100 μmol/L. Unfortunately, in patient 2 only one measurement was made at the highest PLC. In both cases supportive treatment was associated to the infusion of high doses of hydroxocobalamin. Both patients eventually died. The TK-TD relationships can be fitted with the sigmoidal Emax model in both patients (r2 = 0.946 and 0.824, respectively). The Hill coefficients (value + std error) were 3.15 + 0.95 and 4.75 − 3.06, respectively. The C50 (value + std error) were 60.0 + 5.3 and 46.2 + 7.5 μmol/L, respectively. **Discussion:** Our data showed that in patient 1 a plateau of PLCs was associated with a wide range of BCCs. During the course of severe cyanide poisoning, the relationship between the PLCs and the corresponding BCCs can be described by a sigmoidal model. The high value of the Hill coefficient showed that a small decrease in BCCs near the C50 was associated with a dramatic decrease in PLCs.

287 TOXICOLOGY IN THE NEXT MILLENNIUM: TOXICOGENOMICS AND PROTEOMICS.

I. Y. Rosenblum[1] and J. Barrett[2]. [1]*Schering-Plough Research Institute, Lafayette, NJ and* [2]*National Institutes of Environmental Health Sciences, Research Triangle Park, NC.*

Progress in the Human Genome Initiative has opened the doors to opportunities in toxicology never before imagined. The identification of large numbers of expressed genes has driven the development of technologies to investigate global changes in the expression patterns of both the messages and protein products from those genes. These emerging areas of genomics and proteomics, respectively, hold the promise of unraveling the complexity of the regulation of gene expression in normal tissues in normal states of growth and development, and differentiating those expression patterns from gene expression patterns found following exposures to various agents associated with specific mechanisms of cellular toxicity. The identification of such information could allow for truly powerful, rapid, high throughput *in vitro* screens for toxicity as well as identification of specific patterns diagnostic of specific mechanisms of toxicity associated with *in vivo* exposures to animals and humans. This rapidly emerging area of science is extremely timely for all toxicologists in all venues, academic, industrial, pharmacological, and regulatory, and should be of utmost interest to all the members of the Society of Toxicology.

288 MICROARRAY TECHNOLOGY IN MOLECULAR TOXICOLOGY.

R. Paules. *National Institute of Environmental Health, Research Triangle Park, NC.* Sponsor: J. C. Barrett.

One major challenge facing investigators in environmental health research is to assess exposures, and in doing so to identify intrinsic and extrinsic hazards and identify mechanisms of action underlying toxicity. Traditionally, toxicologists use rodent bioassays to evaluate potential hazards. These assays are expensive and take years to complete. cDNA microarray technology allows one to study changes in genome-wide patterns of gene expression, analyzing the expression of thousands of genes in one experiment. Assuming that exposures to different classes of toxicants result in distinct patterns of altered gene expression, in addition to common changes associated with the subsequent toxic response, microarray technology can be utilized to categorize and classify compound effects through the direct comparison of gene expression signatures in exposed and control samples. This approach may be useful to identify toxic substances individually or in mixtures, to determine whether toxic effects occur at low doses, to determine susceptible tissues and cell types, and to extrapolate effects from one species to another. We have developed a custom DNA microarray, ToxChip, that is a human cDNA clone array oriented toward the expression of genes involved in responses to toxic insult, including xenobiotic metabolizing enzymes, cell cycle components, oncogenes, tumor suppressor genes, DNA repair genes, estrogen-responsive genes, oxidative stress genes, and genes known to be involved in apoptotic cell death. Our initial efforts to build a toxic response data base include results from human cell culture systems exposed to representative agents from various classes of toxicants (including oxidant stressors, DNA damaging agents, and estrogenic compounds). Additional studies analyzing gene expression responses to toxicant exposures in mouse and yeast model systems are ongoing.

289 USE OF GENE EXPRESSION PROFILING IN PREDICTIVE TOXICOLOGY.

D. Mendrick. *Gene Logic, Inc., Gaitherburg, MD.*

Gene Logic is using the combined power of open and closed gene expression systems to develop large-scale expression databases. Working together with pharmaceutical companies we are building a ToxExpress™ reference database to identify patterns of toxicity from animal models that are predictive of human toxicity. The goal is to produce a high throughput assay to assist pharmaceutical companies in their prioritization of proprietary lead compounds. Gene Logic's closed system approach uses the GeneChip™ microarray technology to obtain quantified abundance data on known genes. Our open system, which confirms such markers and allows us to discover novel genes, is a proprietary differential display technique called READS™. Validation of both open and closed systems is performed with quantitative PCR. We are focusing initially on liver gene expression profiles using rat liver samples exposed *in vivo* to well-recognized, non-proprietary toxins and rat and human primary hepatocytes exposed *in vitro* to the same toxins. These studies will allow us to correlate the response between *in vivo* and *in vitro* exposure and across species. These expression profiles can be coupled to well-recognized pathways so that we can detect patterns of gene expression that are indicators of toxicity thus leading to the development of a higher throughput assay for the testing of proprietary compounds.

290 STRENGTHS AND WEAKNESSES IN THE CURRENT APPLICATIONS OF EXPRESSION PROFILING.

S. H. Friend. *Rosetta Inpharmatics, Kirkland, WA.* Sponsor: I. Y. Rosenblum.

Drug discovery rests upon an ability to identify effects of compounds on their intended targets, but it also requires an ability to monitor other activities of compounds that are unintended. Over the past several years, individuals have recognized that it is possible to use transcript arrays to follow the levels of expression for many of the genes within cells. The emphasis has been placed on monitoring transcriptional units to understand the transcriptome. This is quite helpful in understanding biology, but does not provide information regarding the activity or function of various proteins within the cell. This lecture will focus on the ability of expression profiling to follow protein function. The emphasis here is on using matrix approaches and pattern recognition to move beyond the analysis of transcript levels to being able to follow the function of intended and unintended targets within the cell. The strategy that we have employed involves building up large coherent sets of data and developing algorithms and other tools by which to successfully compare new profiles to those existing within libraries of profiles.

291 THE USE OF PROTEOMICS IN MOLECULAR TOXICOLOGY.

M. J. Cunningham[1], G. Holt[2], C. Moyses[2] and M. Egerton[1]. [1]*Incyte Pharmaceuticals, Palo Alto, CA and* [2]*Oxford GlycoSciences, Oxford, United Kingdom.*

Proteomics technology potentially offers a new approach to evaluating and prioritizing lead compound candidates. This technology involves high throughput separation, imaging and analysis of expressed proteins or Protein Expression Maps (PEMs). PEMs allow identification of known and novel proteins, analysis of posttranslational modifications and protein-protein interactions. Approximately 2000 proteins can be separated at the same time by MW and pI on a 2D gel, robotically excised and prepared for analysis and annotation by mass spectrometry. In a study of the rat liver proteome, the effects of compounds with known toxicities were analyzed resulting in over 58,000 curated features. More than 16,000 features have been identified from livers of clofibrate-treated Sprague-Dawley rats and of these, 600 features showed greater than 2-fold differential expression. Many enzymes including those involved in the beta-oxidation pathway were annotated, confirming decades of research. Analysis and management of the large volume of data which results from proteomics experiments has enabled the development of the powerful software tool, LifeProt™. Coupling proteomics technology with gene expression microarrays (GEMs) results in an integrated technology platform which may aid in prioritizing lead compounds.

292 PHARMACEUTICAL PROTEOMICS.

S. Steiner. *Large Scale Biology Corp., Rockville, MD.*

Recent progress in genomics and proteomics technologies has created a unique opportunity to significantly impact the pharmaceutical drug development processes. The perception that cells and whole organisms express specific inducible responses to stimuli such as drug treatment implies that unique expression patterns, molecular fingerprints, indicative of a drug's efficacy and potential toxicity are accessible. While genomic-based approaches capture fingerprints at the mRNA level, molecular analysis of drug effects by proteomics creates snapshots of gene regulation at the level of the protein and hence closer to ultimate cell function control. The integration into state-of-the-art toxicology of protein expression profiling promises new insights into mechanisms of drug action and toxicity. The benefits will be improved lead selection, and optimized monitoring of drug efficacy and safety in pre-clinical and clinical studies based on biologically relevant surrogate markers.

293 VALUES AND LIMITATIONS OF TRANSGENIC ANIMALS IN TOXICOLOGY.

D. L. Laskin[1] and A. E. Silverstone[2]. [1]*Rutgers University, Piscataway, NJ and* [2]*SUNY Health Science Center, Syracuse, NY.*

During the past few years there has been increasing use of transgenic animals in elucidating mechanisms of cellular function and more recently in evaluating the potential toxicity and/or carcinogenicity of xenobiotics. While the availability of these animals has advanced our understanding of a variety of biochemical, cellular, and physiological processes, the results need to be interpreted with caution. Null mice lacking particular genes or transgenics overexpressing genes often develop compensatory mechanisms that alter their responsiveness and confound the interpretation of normal function and response. This is particularly true in the immune system where there are multiple and cooperative pathways mediating host defense. Also important is the concept that the response of transgenic animals to a xenobiotic may vary with the genetic background of the animal. This symposium is focused on looking at diverse models of transgenic animals including mice lacking or overexpressing inflammatory and growth factor genes encoding for mediators such as tumor necrosis factor-α, nitric oxide synthase, superoxide dismutase, and transforming growth factor-βs that have been developed and utilized for evaluating tissue injury, apoptosis, receptor activity and carcinogenesis. In each of these systems the values and limitations of the technology will be discussed. Attempts will also be made to compare and contrast the results obtained with transgenic animals to those generated using pharmacologic antagonists, antisense expression, and monoclonal antibodies.

294 STUDIES ON THE ROLE OF INFLAMMATORY MEDIATORS IN CHEMICALLY-INDUCED TOXICITY, TRANSGENIC MODELS *VERSUS* PHARMACOLOGIC APPROACHES.

D. L. Laskin. *EOHSI, Rutgers University, Piscataway, NJ.*

Our research has focused on analyzing the role of macrophages and inflammatory mediators in chemically induced tissue injury. For these studies, two model systems are being used: the lung and the liver. In both of these tissues we have found that xenobiotic exposure is associated with localized accumulation of macrophages. We hypothesize that these cells become activated following toxicant exposure and release mediators that contribute to injury. In support of this hypothesis are our findings that macrophages isolated from the lung or liver of animals treated with toxicants such as ozone or acetaminophen, respectively, are "activated" to release increased amounts of tumor necrosis factor alpha (TNFα) and nitric oxide. To analyze the role of these cytotoxic mediators in toxicity, both pharmacologic inhibitors and knockout mice are being utilized. Whereas in some model systems, both approaches result in similar reductions in others such as hepatic necrosis induced by acetaminophen administration, opposing results are obtained. Thus, in this model, anti-TNFα antibody prevented toxicity, while TNFα knockout mice were more sensitive to acetaminophen. These data suggest that there are limitations in the use of transgenic animals which may be related to compensatory alterations in cytotoxic mediator production. (Supported by NIH Grants ES04738, GM34310 and the Burroughs Wellcome Fund.)

295 RADIATION CHIMERAS AND TRANSGENIC KNOCK-OUTS AS TOOLS TO DEFINE IMMUNE SYSTEM TARGETS FOR DIOXIN RECEPTOR AND ESTROGEN RECEPTOR ACTIVATION.

A. E. Silverstone. *SUNY Health Service Center, Syracuse, NY.*

The historical approach to determining how chemical agents affect the immune system was one of coincidence. For example, thymic epithelial (TE) cells were suggested to be the target for TCDD induced thymic atrophy because (1) levels of the AhR (TCDD receptor) in developing thymic lymphocytes was very low, but in TE cells was high; (2) exposure of TE cultures *in vitro* to TCDD made them less capable of supporting thymocyte proliferation in response to mitogen; (3) TE cell lines treated with TCDD produced IL-1,often associated with cell loss; and(4) TE cells *in vivo* demonstrated altered morphology after TCDD treatment. Our approach instead was to utilize AhR Knock-Out (KO) mice either as a source of hemopoietic stem cells or as recipients for normal stem cells in lethally irradiated recipients. Only in mice with AhR positive hemopoietic cells (even if all other tissues were AhR-KO) did TCDD cause thymic atrophy. While this result was particularly clear,studies with estrogen receptor (ER)a KO mice using a similar approach suggested both tissues were targets for estradiol induced thymic atrophy. However, these chimeras established a role for ERa in non hemopoeitic tissues as being essential for full thymic development. This approach leads to accurate understanding of the cellular targets for immunotoxic agents. Subsequently, one can determine which gene modulated products are actually produced to cause the observed effects. (Supported by ES07216 and ES04862 from NIEHS.)

296 USING TRANSGENICS AND OTHER APPROACHES TO STUDY REGULATION OF ANTIGEN-SPECIFIC T CELL APOPTOSIS BY GLUCOCORTICOIDS.

J. D. Ashwell. *Laboratory of Immune Cell Biology, NIH, Bethesda, MD.* Sponsor: A. Silverstone.

Activation-induced death of thymocytes (negative selection) and antigen-dependent rescue of thymocytes from a default death pathway (positive selection) determine the spectrum of antigenic specificities that T cells. Occupancy of the T cell antigen receptor (TCR) and the glucocorticoid receptor (GR) are potent means of inducing apoptosis in immature thymocytes. Surprisingly, T cells simultaneously signaled via the TCR and the glucocorticoid receptor survive, leading to the speculation that the balance between TCR and GR signaling might regulate antigen-specific T cell selection. Indeed, epithelial cells in the murine thymus were found to produce steroids. Using TCR transgenic mice and inhibitors of glucocorticoid biosynthesis, it was demonstrated in fetal thymic organ culture that thymocyte death caused by blockade of corticosterone biosynthesis requires TCR engagement. The role of glucocorticoids in thymocyte development was also explored in transgenic mice expressing antisense transcripts to the GR under the control of the proximal lck promoter. Data will be presented with these two model systems regarding the effect of inhibition of local glucocorticoid synthesis or responsiveness on murine models of autoimmune disease and the generation of the peripheral T cell antigen-specific repertoire.

297 IDENTIFYING CHEMICAL CARCINOGENS AND ASSESSING POTENTIAL RISK IN SHORT-TERM BIOASSAYS USING TRANSGENIC MOUSE MODELS.

R. W. Tennant, J. E. French, C. S. Trempus, R. E. Cannon and J. W. Spalding. *Laboratory of Environmental Carcinogenesis and Mutagenesis, NIEHS, USEPA, Research Triangle Park, NC.* Sponsor: A. E. Silverstone.

Significant progress in understanding human risk can be achieved by development of models in which the mechanistic process or sequence of events leading to malignant tumors can be studied.Several transgenic and knockout (haploinsufficient) mouse models have been developed and are being assessed for their responses to selected chemicals. Our laboratory has focused on the p53 haploinsufficient (p53±) and Tg.AC (zetaglobin promoted v-Ha-ras) models for carcinogen identification and mechanistic studies. Data will be presented that demonstrates the p53± model preferentially responds to mutagenic carcinogens via loss of function of the wildtype allele. Such loss can occur via deletion, as in the case of phenolphthalein induced thymic lymphomas or via a point mutation as seen in p-cresidine-induced bladder tumors. In addition, p53 function could be altered by an indirect mechanism involving over-expression of a regulatory protein such as mdm2. With the Tg.AC model, transcriptional activation of the transgene leads to papilloma development (reporter phenotype) by altering keratinocyte differentiation. This activation appears to depend upon a unique arrangement of two transgenes linked promoter to promoter. Spontaneous deletions that remove DNA sequences centered around the promoter junction of these transgenes completely eliminate transgene expression and papilloma development. Investigations into the role of this region in the tumorigenic process will be presented.

298 LESSONS FROM TGFβ1-DEFICIENT MICE: STRAIN DIFFERENCES AND GENETIC MODIFIERS OF RESPONSIVENESS.

T. Doetschman, S. Kallapur, S. Engle and I. Ormsby. *University of Cincinnati Medical Center, Cincinnati, OH.* Sponsor: A. E. Silverstone.

TGFβ1-/- mice have multiple defects that vary considerably with genetic background. Whether or not all null mice die of embryonic lethalities, as well as the type of embryonic lethality they die of, are all dependent on genetic background. On the C57BL/6 background, all TGFβ1-/- animals die before implantation. If the genetic background is a 50:50 mixture of 129 and C57BL/6, about half of the null mice survive to birth with no apparent abnormalities, but subsequently succumb to an autoimmune-like inflammatory dis-

ease around weaning age. On the other hand, if TGFβ1-/- mice are an equal mixture of 129 and CF-1 backgrounds, all null embryos undergo implantation, but about half of them die of hematopoietic and vascular defects at the yolk sac stage, and the other half die at weaning age of the inflammatory disease. Genetic background also determines the organs affected by inflammation, particularly in the gastrointestinal tract. Finally, if TGFβ1-/- mice are rescued from the inflammatory disease by genetic combination with mutations that eliminate functional T-cells, the null animals survive to 4-6 months of age, at which time they die of colon cancer. However, they develop colon cancer only if they are on a 129 background. The degree to which these phenotypes are the result of genetic modifiers will be discussed.

299 AIRBORNE PARTICULATE MATTER: PHYSICO-CHEMICAL CHARACTERISTICS AND HUMAN EXPOSURE ISSUES RELATED TO HEALTH EFFECTS RESEARCH AND ASSESSMENT.

J. A. Graham[1] and J. L. Mauderly[2]. [1]*USEPA, Research Triangle Park, NC and* [2]*Lovelace Respiratory Research Institute, Albuquerque, NM.*

Exposure to particulate matter (PM) is associated with excess mortality and morbidity, especially in individuals with cardiopulmonary disease. These epidemiologic findings are the cornerstone of EPA's revision of the PM National Ambient Quality Standards to include PM less than 2.5 microns. Uncertainties in the available information caused the US Congress to stimulate research by having the National Academy of Sciences identify key information needs and by significantly increasing research budgets. Of the several areas of research needed, the ones on mechanisms of the effect(s) and characterization of the causal PM (and perhaps co-occurring gases) are crucial. Key hypothesis for causative factors are: mass, size, number, surface area, chemistry, co-occurring gases, or some combination of them. Many toxicologists are engaging in research on these topics. One major difficulty is understanding the complex nature of PM as a prelude to designing the most effective studies. This workshop is designed to provide background on the nature of PM and exposures. Both aspects are important. Knowing the physico-chemical nature of key classes of PM is basic. For example, there are major differences between ultrafine, fine, and coarse mode particles in addition to size. Biological components might also have important influences. Information on co-occurring gasses is also a major element. Even if the ambient air were perfectly understood, it still is essential to characterize what fractions people are exposed to.

300 AIRBORNE PARTICULATE MATTER: WHAT DO WE KNOW ABOUT WHAT'S REALLY OUT THERE?

G. R. Cass. *California Institute of Technology, Pasadena, CA.* Sponsor: J. Graham.

Atmospheric particulate matter (PM) is distributed in size over the range from a few nanometers to hundreds of micrometers in diameter. Depending on their size, these particles will deposit in different parts of the respiratory system. Air pollutant particles also are chemically complex, and can act to transport strong acids, catalytic trace metals, allergenic proteins, and toxic organic compounds to various sites in the respiratory system. This presentation describes experimental methods that can be used to determine the size and chemical composition distribution of PM. Filter-based sampling systems have been used for more than 20 years to determine the bulk chemical composition of PM in serveral size ranges. These filter samples can be analysed for nearly all of the elements in the periodic chart, analysed for organic compounds for GC/MS, and be subjected to a variety of bioassay techniques to determine the presence of mutagens and allergens. Likewise, electrical aerosol analysers, differential mobility analysers and optical particle counters have provided much data on particle number counts as a function of particle size. Cascade impactors make it possible to simultaneously measure both the size and chemical composition distribution of a particle mixture. Time-of-flight MS now allow both particle size and chemical compostion to be mearsured in real time at the single particle level. Using these methods, considerable information has been acquired that describes atmospheric aerosol characteristics of possible importance to the community of toxicologists, including trace metals levels, the concentration of more than 100 organic compounds, mutagenic potency, allergenic protein concentrations, as well as the concentration and in some cases chemical composition of ultrafine PM. Examples of such data will be given based on measurements made in California and in the Northeastern US.

301 WHAT HAVE GASES GOT TO DO WITH IT?

E. Fujita. *Desert Research Institute, Reno, NV.* Sponsor: J. Graham.

Primary emissions from various combustion sources are very complex mixtures containing thousands of organic and inorganic constituents in the gas and particulate phases. Gases include criteria gases (e.g., CO, NO_2, SO_2), hazardous air pollutants (e.g., toxic volatile organic compounds [VOCs]), and VOCs and semi-volatile organic compounds that are precursors to both ozone and organic aerosols. Once released into the atmosphere, primary emissions are subjected to dispersion and transport and to various physical and chemical processes that determine their ultimate environmental fate. Many organic compounds are emitted at elevated temperatures as a result of combustion and condense rapidly upon cooling to ambient temperatures forming ultrafine and nuclei range particles. The "nuclei" range consists of particles less than 0.08 μm in aerodynamic diameter that are emitted directly from combustion sources. In polluted areas, the lifetimes of particles in the nuclei range is usually less than one hr because they rapidly coagulate with large particles or serve as nuclei for cloud or fog droplets. This size range is generally detected only when fresh emissions sources are close to the measurement site. Some of the gaseous species are converted into particles by series of chemical transformation, forming secondary aerosol. Sulfates and nitrates are the most common secondary particles, though a fraction of organic carbon can also result from VOCs via atmospheric reactions. This presentation will summarize recent findings pertaining to the composition of gases that co-occur with PM emitted from combustion sources. Because aerosols are particles suspended in gases and because gases are part of the formation processes for particles and have toxicity in their own right, it is important to understand the predominant classes of gases and how their presence may vary with PM.

302 BIOLOGICAL PARTICLES: TIME TO COME OUT OF THE CLOSET.

R. Jaenicke, S. Matthias-Maser and S. Gruber. *University of Mainz, Mainz, Germany.* Sponsor: J. Graham.

Atmospheric aerosol research has seen much progress in recent years; chemistry resolves particle sizes, vertical distributions emerge, inclusion in GCM is progressing, variability is realized, and so on. This research shows how important the understanding of the sources is: ocean and desert (soil) surfaces, gas-to-particle-conversion (i.e. hydrocarbon effluvia), cloud evaporation (particle transformation). However, it is hard to understand how the biosphere as a source for preformed particles has been so neglected. For example, the most recent monograph on clouds has not included the source strength of biological material. Scientists seem to be content with up to 50% of unidentified aerosol mass. Primary Biological Aerosol Particles (PBAP) consist of more than "classic" objects like pollen, spores, bacteria, and viruses. Broken parts of plants and insects as well as skin abrasion materials and hair are included. They might be important for the climatic system, acting as cloud condensation nuclei as well as ice nuclei, thus influencing cloud and rain formation. Knowledge about PBAP will be presented. The annual variation of the total concentration is rather small, mostly because resuspension seems to play a role. In the vertical, we see PBAP at elevated layers, mostly because they are prone to long range transport.

303 PERSONAL EXPOSURE TO PARTICULATE MATTER: WHAT DO WE REALLY BREATHE?

P. Lioy and J. Zhang. *Environmental & Occupational Health Sciences Institute, Piscataway, NJ.* Sponsor: J. Graham.

The presentation will provide basic information on exposures to PM and its size fractions that can occur among the general and selected subgroups of the general population. It will examine the quantitative information available on the actual or potential exposures to the coarse, fine and ultrafine fractions, and attempt to illustrate the complexity of the chemical composition in indoor, outdoor and personal air. Included will be the types of situations or activities that can lead to contacts which lead to high exposures. The analysis will use a mass balance approach to describe the current ambient exposure data base and indicate major areas of uncertainty. Specific examples will include well understood and poorly understood components of the PM mass fractions, e.g. sulfates and organic acids, respectively. All these information will be placed into a contextual framework that includes indoor and personal exposures to PM. The discussion will then be focused on illustrative examples of plausible

interaction of outdoor PM and gases with indoor and personal exposures, and the contributions that can be derived from each. Finally, the role of indoor air chemistry on the production of "fresh" particles from gaseous precursors that have both indoor and outdoor sources will be reviewed and placed into a context of daily variation in total exposure.

304 TOXICOLOGY FOR KIDS: THE CLASSROOM EXPERIENCE.

C. A. McQueen[1] and G. S. Yost[2]. [1]*The University of Arizona, Tucson, AZ and* [2]*University of Utah, Salt Lake City, UT.*

One of the long-range goals of the Society of Toxicology is to increase awareness and understanding of toxicology. One effective strategy is to encourage toxicologists to become involved in K-12 and community education. In 1999, the K-12 Education Subcommittee and the Education Committee sponsored a workshop on this topic. This year's workshop builds on the 1999 presentations by focusing on activities and materials that SOT members can use, giving concrete examples of educational do's and don'ts. The program is designed to give the perspective of scientists who have gone into the classroom or community and survived as well as to explore the powerful synergism of the scientist-teacher relationship. The purpose of the workshop is to provide examples of specific approaches, educational tools and demonstrations of proven techniques that will enable toxicologists to give effective presentations.

305 TOXICOLOGY: QUESTIONS AND ANSWERS.

C. A. McQueen and J. K. Norman. *The University of Arizona, Tucson, AZ.*

Toxicologists are becoming more involved in increasing public awareness and understanding of toxicology. This means going into the classroom or community and engaging the audience in a manner that facilitates learning science. One approach is to involve the audience by using an interactive presentation. Scientists are generally most comfortable with slide-based talks which can be easily modified to encourage audience participation. At the University of Arizona, Southwest Environmental Health Sciences Center, a question and answer format based on the web site "Chemicals and Human Health", www.biology.arizona.edu/chh, has been developed. In the oral presentation, a question is raised and the audience is presented with several possible answers. Choices are indicated by a show of hands. The scientific principle, rationale and correct answer are then discussed. Concepts taught in this way include the dose-response relationship, dose calculation, natural and synthetic chemicals as well as organ specific toxicity. This format has been successfully used with both children and adults. It is simple and can be readily adapted to fit the audience and the topic. (Supported by NIEHS, grant ES06694.)

306 GET THE LEAD OUT!

M. O. Dereski. *Wayne State University, Detroit, MI.*

Effective communication of environmental health issues to the public is a fertile ground for the toxicologist. One of the topics that many lay people do not realize still poses a significant health risk is exposure to lead. Lead poisoning remains a prevalent and serious disease for urban as well as suburban children throughout the country. This instructional lesson discusses the history of lead use and exposure, including a hands-on demonstration of qualitative lead testing of household items. The lesson also includes low cost preventative measures that can be taken by an at-risk homeowner to decrease exposure to the sources of lead. This presentation has been effectively given to large groups of school age children (grades 6-12) as well as adult community groups during the previous three years. Materials to supplement the lesson are available to toxicologists who plan classroom visits, or community group presentations. (Supported by grant ES06639-06.)

307 GOING TOXIC IN THE MIDDLE SCHOOL CLASSROOM.

M. L. Haasch. *University of Maryland, Solomons, MD.*

Bringing lessons in toxicology to the middle school classroom provides some excitement and added interest allowing the students to apply textbook knowledge to real-world situations. In order for trained toxicologists to infuse their unique knowledge into the middle school curriculum, two major things must happen. First, the toxicologist must be willing to break down the science into manageable bits that are economically feasible. Second, a mentor-teacher relationship must be established. A good approach for making a connection to a teacher is to use existing county- or statewide programs that provide teacher internships to the toxicology laboratory. The best mentor-teacher relationships require contact with an enthusiastic science teacher who is willing to work a little harder and take chances in order to liven up the classroom. Possible problems that can arise when bringing toxicology into the classroom include concerns for teachers about fitting the material into curricular standards, chaos in the classroom, encountering non-packaged results and vertebrate animal testing. For the toxicologist possible concerns include the demand on time and creative energies as well as facing and dealing with the middle school culture, but the rewards of engaging in these kinds of activities are boundless.

308 THE TEACHER—MENTOR RELATIONSHIP: HOW TO BRING TOXICOLOGY INTO THE MIDDLE SCHOOL CLASSROOM.

A. T. Williams. *Northern Middle School, Owings, MD.* Sponsor: M. L. Haasch.

This presentation will outline effective methods of translating "real world" laboratory experiences into classroom lessons. It details the 4-year collaboration between an 8th grade science teacher and a toxicologist. This connection utilizes the expertise of each partner – the toxicologist shares background knowledge and original ideas; the teacher addresses the state standards for lesson objectives and converts the information into a context suitable for 8th grade students. Both teacher and mentor work together to alter and refine the concepts to be taught. The students benefit because they are actively involved, the labs are meaningful and they learn by doing (hands on – minds on). They also have the experience of working with the toxicologist during class visits. The students develop a new appreciation for science and come to the classroom eager for the day's activities. Ongoing classroom projects include observation of developing Japanese medaka embryos, monitoring effects of runoff water, or fertilizers in ground-filtered water, to freshwater invertebrates. The inclusion of the topic of toxicology is appropriate in science classrooms because it provides a better understanding of experimental design. The use of the scientific method gives a framework for solving any problems in a logical manner.

309 SENSITIVITY OF NEURONAL NITRIC OXIDE SYNTHASE TO LINDANE.

D. Desaiah[1], A. Vann[2] and J. Cameron[2]. [1]*Univ. of Mississippi Medical Center, Jackson, MS and* [2]*Jackson State University, Jackson, MS.*

Organochlorine compounds, in general are neurotoxic chemicals and lindane is a known neurotoxic insecticide. The mechanism of action of lindane is suggested to be its ability to modulate (γ-amino-butyric acid receptor and intracellular calcium as well as calcium dependent enzymes. However, there is no information available on its effects on calcium-calmodulin dependent neuronal nitric oxide synthase (nNOS). nNOS is a constitutive enzyme involved in the synthesis of NO, a biologically important messenger molecule. Therefore, the present studies were undertaken to investigate the direct interaction of lindane with nNOS *in vitro*. The source of nNOS was from normal rat brain cerebral cortex and cerebellum. The tissue was homogenized in buffer (pH 7.2) containing 20mM Hepes, 0.32M sucrose, 0.5 mM EDTA and 1mM dithiothreitol. The homogenate was subjected to differential centrifugation and post 20,000 x g supernatant was used as enzyme source after removing endogenous arginine. The enzyme activity was measured by quantitation of ^{3}H-citrulline formed. Lindane (99.9% pure) dissolved in DMSO and further diluted in the reaction mixture to obtain 3-120μM concentrations. DMSO at 2μl had no effect on nNOS. The results obtained showed a concentration dependent inhibition of nNOS activity by lindane both in cerebral cortex and cerebellum. A 50% inhibition was obtained at less than 10μM lindane. These results clearly demonstrate that lindane is a potent inhibitor of nNOS. nNOS

may be one of the site of action for lindane through which many neurotransmitter pathways are altered including the well established GABAergic pathway. (Supported in part by grant NIH/T32 HL 07635.)

310 THE ROLE OF GLUTATHIONE S-TRANSFERASES IN THE METABOLISM OF METHYL PARATHION *IN VITRO*.

E. L. Abel, T. K. Bammler and D. L. Eaton. *University of Washington, Seattle, WA.*

The organophosphate esters are the most popular class of insecticides in use today because of their efficacy and lack of environmental persistence. However, organophosphate pesticides are highly toxic to mammals. Most organophosphates require activation via oxidative desulfuration in order to exert toxic effects by binding to acetylcholinesterase. The focus of this study was to investigate the ability of glutathione S-transferases (GSTs) to metabolize and detoxify the organophosphate pesticide, methyl parathion (MP), in several mammalian species prior to activation. Of particular interest are human GSTM1 and T1, both of which are polymorphic. If these metabolizing enzymes are shown to play a significant role in the delicate balance of activation and deactivation of MP, the polymorphisms could be useful in identifying individuals at heightened risk for MP poisoning. In order to ascertain the role of human GSTs in the metabolism of MP, liver cytosolic fractions from nine adults of known GST genotype and/or phenotype were incubated in the presence of MP. Metabolites of MP were analyzed by high performance liquid chromatography and UV absorbance detection. Rat, mouse, and non-human primate liver cytosolic fractions and recombinant GSTs were also tested. Of the cytosolic fractions tested, BHA-treated mice showed the highest activity (7.05 nmol desmethyl parathion /min/mg), followed by monkeys (2.47 nmol/min/mg), followed by rats (2.30 nmol/min/mg), with the human samples exhibiting the lowest activity (1.06 nmol/min/mg on average). Interindividual variation among the 9 human samples did not correlate with either the GSTM1 or T1 genotype/phenotype. In addition, of the recombinant GSTs tested (hGSTM1-1, hGSTM2-2, hGSTM3-3, hGSTM4-4, mGSTP1-1, mGSTP2-2, hGSTA1-1, rGSTA5-5, mGSTA3-3) only hGSTA1-1 and rGSTA5-5 showed significant activity (68.77 and 48.76 nmol/min/mg respectively). Our data suggest that neither hGSTM1-1 nor hGSTT1-1 is responsible for the majority of the activity seen in humans.

311 PESTICIDE TRANSPORT MEDIATED BY THE MULTIDRUG RESISTANCE-ASSOCIATED PROTEIN (MRP).

T. E. Tribull and L. J. Bain. *Clemson University, Department of Environmental Toxicology, Pendleton, SC.*

The multidrug resistance-associated protein (MRP) is a 190kD ATP-binding cassette protein involved in the active efflux of glutathione-, glucuronide-, and sulfate-conjugates from cells. It has been proposed that this transporter originated to protect cells and organisms from toxicity of many naturally-occurring compounds, including pesticides. Although the transport of pesticides in plant MRP homologues has been reported, no research has ever been published on pesticide transport by MRP in vertebrate systems. This is a particular deficit in toxicology as many environmentally relevant chemicals, such as pesticides, can be detoxified by conjugation. We have examined the toxicity of twelve different pesticides in human MRP-transfected NIH3T3 cells compared to mock-transfected control cells. Of the twelve, four of the pesticides, methoxychlor, alachlor, fenitrothion, and chlorpropham, all demonstrate between three- and four-fold greater toxicity to mock-transfected cells versus the MRP-transfected cells. This study suggests that MRP aids in protecting these cells from toxic effects of these pesticides. Future work will examine the actual transport of these pesticides as well as MRP's contribution to altering their toxicity to the organism.

312 CHARACTERIZATION OF OLFACTORY MUCOSAL TUMORS INDUCED IN RATS BY CHRONIC DIETARY ADMINISTRATION OF ALACHLOR.

M. B. Genter[1], D. M. Burman[1], M. W. Dingeldein[1] and B. Bolon[2]. [1]*Dept. of Environmental Health, University of Cincinnati, Cincinnati, OH and* [2]*Dept. of Pathology, Amgen, Thousand Oaks, CA.*

Chronic dietary exposure to the chloracetanilide (CA) herbicide alachlor (ALA) has been shown to induce nasal cavity tumors in rats (US EPA, Office of Pesticide Programs. PB85-175503, NTIS, Springfield, VA 1985). These CA-induced tumors had a distinctive distribution in the nasal cavity and apparently arose in the olfactory mucosa (Morgan *et al., Fundam Appl Toxicol* 36(Suppl. 1, pt. 2) 1997). The present studies were undertaken to identify the cell type of origin of ALA-induced olfactory mucosal tumors and to investigate the mechanism of ALA carcinogenicity. The current data are derived from interim 1 mo and 6 mo time points in an ongoing chronic feeding study. Male Long Evans rats (6 wk of age at the inception of the study) were administered ALA (>98% pure, Chem Service, West Chester, PA) in powdered diet at the dietary equivalent dose of 126 mg/kg/day. Following 1 mo of ALA exposure, neither histological abnormalities nor enhanced cell proliferation (by BrdU incorporation into S-phase nuclei) were observed in any region of the nasal cavity. However, six mo of ALA treatment resulted in increases in S-phase basal and non-basal cells in the olfactory mucosa. In addition, nasal masses ranging from small dysplastic plaques to adenomas (including one dysplastic variant) occurred in 6 of 15 ALA-treated rats after 6 mo of exposure. Age-matched control rats displayed no discernible nasal epithelial changes at either time point. The tumors appeared to originate in the olfactory regions of the nasal cavity; however, the masses consisted of low cuboidal epithelium, contained glands, and were associated with adjacent regions of respiratory metaplasia. Immunohistochemistry revealed that the tumors were negative for various olfactory mucosal markers, including olfactory marker protein (OMP, for mature olfactory neurons) and NMa (for cytochromes P450 CPY2A10/11 and 2G1), as well as p53. These data confirm that ALA is carcinogenic and support a metaplastic respiratory epithelial cell as the cell of origin.

313 CHANGES IN CAMP-DEPENDENT KINASE ACTIVITY AND EXPRESSION OF CA^{2+}/CAMP RESPONSE ELEMENT BINDING PROTEIN (CREB) IN THE BRAINS OF NEONATAL RATS EXPOSED TO CHLORPYRIFOS.

D. A. Jett, R. V. Navoa and R. Beckles. *Johns Hopkins University, Baltimore, MD.*

The alteration of cAMP-related cell signaling by organophosphate pesticides such as paraoxon and chlorpyrifos has been suggested by previous work in our laboratory and others. We report here on the activity of cAMP-dependent kinase (PKA) and the expression of the phosphorylated form of Ca^{2+}/cAMP response element binding protein (phospho-CREB) in the brains of developing rats exposed to chlorpyrifos. Increases in transcription of genes that are critical in neuronal plasticity and brain development are positively regulated synergistically by PKA and Ca^{2+}-mediated kinases which phosphorylate CREB. We injected rat pups subcutaneously with 40 mg/kg chlorpyrifos on postnatal days 7, 11, and 15, and collected their brains on day 16. The chlorpyrifos exposures did not result in any observable signs of cholinergic intoxication or weight loss, but caused moderate inhibition of brain acetylcholinesterase (55%). We developed a method for analyzing cytosolic PKA activity and phospho-CREB expression in nuclear extracts from the same tissue sample (cerebral cortex). PKA was determined by following the phosphorylation of Kemptide substrate; phospho-CREB was analyzed by Western blot using a specific antibody. We found that PKA activity, the expression of phospho-CREB, and the ratio of phospho-CREB to total CREB in treated pups were significantly decreased relative to rats treated only with corn oil vehicle. Expression of total CREB and the neuronal protein tubulin were not affected, indicating that the effects were specific and not related to a decrease in overall protein synthesis. These studies suggest that the reported changes in adenylyl cyclase activity and cAMP levels may produce effects downstream in the pathway. These effects may play a role in the developmental neurotoxicity of chlorpyrifos. (Supported by ES03819 JHU Center in Urban Environmental Health.)

314 NON-NEURONAL TARGETS FOR DEVELOPMENTAL EXPOSURE TO CHLORPYRIFOS: HEPATIC CELL SIGNALING.

J. T. Auman, F. J. Seidler and T. A. Slotkin. *Duke University Medical Center, Durham, NC.*

In addition to inhibition of cholinesterase, chlorpyrifos and its active metabolite, chlorpyrifos oxon, have been hypothesized to interact directly with constituents of cell signaling cascades, contributing to adverse effects on cell replication and differentiation. Among the putative targets are the receptors and transduction proteins involved in the production of cyclic AMP, one of the most important mediators of cell development. We studied the effects of neonatal chlorpyrifos exposure on hepatic adenylyl cyclase (AC), as the liver accumulates the highest concentrations of chlorpyrifos and is the site for generation of chlorpyrifos oxon. Newborn rats were given 1mg/kg of chlorpyrifos s.c. on PN1-4. Twenty-four h after the last dose, there was induction of AC

catalytic activity, measured with manganese, whereas activity requiring an interaction of AC with G-proteins (fluoride, forskolin) was impaired. In addition, the response of AC to hormonal signals was altered in a receptor-selective manner, with an enhanced response to glucagon but not a beta-adrenergic agonist. Treatment of older animals (PN11-14) did not impede G-protein-AC interactions, even when a higher dose of chlorpyrifos was used (5mg/kg/day); however, the response to glucagon was still enhanced in this later treatment group. These results indicate that chlorpyrifos targets the AC signaling cascade in non-neuronal tissues, leading to altered neonatal responses to hormonal input. (Supported by USPHS ES-07031.)

315 CHLORPYRIFOS AND CELL SIGNALING: EXPRESSION OF PHOSPHORYLATED CA^{2+}/CAMP RESPONSE ELEMENT BINDING PROTEIN (CREB) IN PC12 CELLS.

R. V. Navoa, R. Schuh and D. A. Jett. *Johns Hopkins University, Baltimore, MD.*

Phosphorylation of Ca^{2+}/cAMP response element binding protein (CREB) activates the transcription of genes known to be critical in brain plasticity and brain development. It is hypothesized that changes in the phosphorylation of CREB could be produced by changes we have previously observed in cAMP synthesis and cAMP-dependent kinase (PKA) activity after exposure to organophosphates. Thus, some of the developmental neurotoxicity of organophosphates could be explained by inhibitory effects on this pathway. In this study we used PC12 cells as an *in vitro* model for studying the effects of chlorpyrifos (CPF), and its more potent anticholinesterase metabolite chlorpyrifos-oxon (CPFO), on forskolin-stimulated expression of the phosphorylated form of CREB (phospho-CREB). Cells were incubated with various concentrations of CPF or CPFO for one hour prior to a 15 min stimulation with 25 μM forskolin. At the end of this period, cells were immediately lysed in 100°C lysis buffer, and the expression of phospho-CREB was determined by Western blot analysis using a specific antibody. We found that the expression of phospho-CREB was significantly reduced in cells treated with CPFO at low nanomolar concentrations, and these effects were not due to non-specific effects since the expression of the neuronal protein tubulin was not affected. We also found that CPF at low micromolar concentrations reduced forskolin-induced phospho-CREB expression, but a similar reduction was observed with tubulin. But surprisingly, nanomolar concentrations of CPF did appear to cause a specific reduction in phospho-CREB expression, and not in tubulin expression. The data suggest that nanomolar concentrations of CPF and CPFO caused a reduction in the expression of phospho-CREB, possibly through disruption of the cAMP-signaling pathway. Micromolar concentrations CPF also appeared to alter phospho-CREB expression, but it may have resulted from non-specific effects, e.g., cytotoxicity, decreased cell adhesion, or by the reported inhibitory effects of CPF on overall protein synthesis in this cell system. (Supported by ES03819, JHU Center in Urban Environmental Health.)

316 MECHANISM FOR DEVELOPMENTAL NEUROTOXICITY OF CHLORPYRIFOS: REACTIVE OXYGEN OR GENE TRANSCRIPTION?

T. L. Crumpton, F. J. Seidler and T. A. Slotkin. *Duke University Med Ctr, Durham, NC.*

Chlorpyrifos is rapidly replacing other organophosphate insecticides because of its relative safety and persistence. There is increasing concern about effects on brain development and studies suggest that targets other than cholinesterase inhibition could contribute to such effects. We used PC12 cells, a model for neuronal development which displays adverse effects of chlorpyrifos, to evaluate two proposed mechanisms: production of reactive oxygen species (ROS) and altered gene transcription. ROS production was measured in response to chlorpyrifos and its active metabolite, chlorpyrifos oxon, using an intracellular indicator. First, undifferentiated cells were treated for various times (10 min, 24, 48, 72 h). Next, differentiation was initiated with NGF and cells were examined at 72 h for ROS production. In neither case did chlorpyrifos (up to 50 μg/mL) or chlorpyrifos oxon (10 μg/mL) produce detectable levels of ROS. In contrast, much lower concentrations of chlorpyrifos directly interfered with the binding of AP-1 nuclear transcription proteins to their DNA recognition sites in a cell-free system; addition of chlorpyrifos to undifferentiated or differentiating PC12 cells also altered the expression/function of both AP-1 and Sp1 proteins. These results suggest that chlorpyrifos does not evoke ROS production in the PC12 model but does elicit effects on gene transcription factors that are likely to be involved in adverse effects on cell replication and differentiation. (Supported by USPHS ES-07031.)

317 CHLORPYRIFOS TARGETS MACROMOLECULE SYNTHESIS IN C6 GLIOMA CELLS.

S. J. Garcia, F. J. Seidler and T. A. Slotkin. *Duke University Medical Center, Durham, NC.*

The major mechanism for systemic toxicity of chlorpyrifos is inhibition of cholinesterase through the active metabolite, chlorpyrifos oxon. However, recent studies indicate that developmental neurotoxicity may also involve the direct targeting by chlorpyrifos itself, of events that are specific to cell replication and differentiation. Earlier, we found that chlorpyrifos exposure of neonatal rats led to delayed CNS cell loss during periods of synaptogenesis and gliogenesis. In the current study, we used cultured rat C6 glioma cells to determine whether chlorpyrifos itself affects cell replication in glial-type cells. DNA and protein synthesis were measured by incorporation of radiolabeled precursors into macromolecules during the log-phase of cell growth. With as little as 2h of exposure, chlorpyrifos caused a robust, concentration-dependent inhibition of DNA synthesis, with a threshold between 0.5 - 5 μg/mL; the effect in the glial line was greater in magnitude than had been seen previously using a neuronal cell line (PC12). Effects were selective for DNA synthesis, as much higher concentrations (50 μg/mL) were required to produce significant inhibition of protein synthesis. The reduction in DNA synthesis caused by chlorpyrifos exposure had an adverse effect on cell replication, as total cell number was significantly reduced in treated cells. Our results indicate that chlorpyrifos itself can exert adverse effects on neurodevelopment, targeting the proliferation of glial-type cells. (Supported by USPHS ES-07031 and the Ford Foundation.)

318 BEHAVIORAL DEFICITS AFTER EXPOSURE OF NEONATAL RATS TO THE INSECTICIDE, CHLORPYRIFOS.

K. Dam, F. J. Seidler and T. A. Slotkin. *Duke University Medical Center, Durham, NC.*

The widespread use of chlorpyrifos both agriculturally and in the home has led to increased concern over potential consequences of fetal and childhood exposures. Previous studies showed that apparently subtoxic doses of chlorpyrifos nevertheless target brain development, inhibiting mitosis, producing cell loss and altering synaptic activity. To determine whether these biochemical effects are associated with behavioral deficits, we evaluated locomotor activity and coordination skills in developing rats. Administration of 1 mg/kg of chlorpyrifos on postnatal days (PN) 1-4 elicited deficits in reflex righting on PN 3-4 and negative geotaxis on PN 5-8; the effect was gender-specific, with a greater effect on females. However, with the ontogeny of more complex behaviors, adverse effects of chlorpyrifos became more evident in males. Locomotor activity in an open field, measured on PN 21 and 30, was markedly reduced in male rats who had been exposed to chlorpyrifos on PN 1-4, whereas no differences were detected in females. These studies indicate that, even at levels below the threshold for overt toxicity, gender-selective behavioral abnormalities are present during and immediately after chlorpyrifos exposure, but also appear at later stages of development, well after the disappearance of chlorpyrifos from the body. (Supported by a STAR Fellowship from the US Environmental Protection Agency.)

319 ACTIVATION OF THE AH RECEPTOR SIGNAL TRANSDUCTION PATHWAY BY PROSTAGLANDINS.

M. S. Denison, W. J. Rogers, M. H. Ziccardi, G. M. Winters, V. Li, B. Keser and S. D. Seidel. *University of California, Davis, CA.*

The aryl hydrocarbon receptor (AhR) is a ligand-dependent transcription factor that mediates many of the biological and toxicological actions of a diverse range of chemicals, including 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). Although no endogenous physiological ligand for the AhR has yet been identified, numerous studies support the existence of such a ligand(s). Previous studies indicating an effect of TCDD and the AhR on arachidonic acid and prostaglandin synthetic and metabolic enzymes prompted us to examine whether these chemicals could activate the AhR signaling system. Using a recombinant cell bioassay system, we demonstrate that relatively high concentrations of several prostaglandins can activate a DRE-luciferase reporter gene in a dose- and AhR-dependent manner. In some cases, the magnitude of induction was several time greater than that produced by a maximal inducing dose of TCDD. Those prostaglandins which induced AhR-dependent gene expression also stimulated AhR transformation and DNA binding *in vitro*, suggesting that they are direct-acting. These data coupled with ligand binding analysis indicate that the prostaglandins are relatively weak AhR ligands. The

observed synergistic induction of AhR-dependent gene expression by selected prostaglandins is likely due to their ability to also activate other cell signaling systems which augment AhR signaling. Our results indicate that selected prostaglandins represent a structurally distinct and novel class of activators of the AhR signal transduction pathway (ES07685, ES07072, ES04699).

320 SYNERGISTIC ACTIVATION OF AH RECEPTOR-DEPENDENT GENE EXPRESSION BY ACTIVATORS OF PROTEIN KINASE C.

E. M. Khan and M. S. Denison. *University of California, Davis, CA.*

The aryl hydrocarbon receptor (AhR) is a ligand-dependent transcription factor which can be activated by a wide variety of structurally dissimilar chemicals. In addition to its role in modulating gene expression, the AhR mediates many of the toxic and biological effects of persistent AhR ligands, including 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD). Currently, no endogenous physiological AhR ligand has been identified. Using AhR ligand and DNA binding assays, we have identified several classes of bioactive lipids which can bind to and transform the AhR into its DNA binding form *in vitro*, albeit weakly. However, exposure of cell lines to some of these chemicals results in induction of AhR-dependent gene expression to levels equivalent to or several-fold greater than that produced by a maximally inducing dose of TCDD. The known ability of some of these compounds to activate second messenger systems suggests that the synergistic increase in gene expression is due to the concomitant activation of the AhR and second messenger signal pathways. Co-treatment or pretreatment of cells with the PKC activator, phorbol-12-myristate-13-acetate (PMA), synergistically increases the ability of AhR ligands (TCDD and β-naphthoflavone) to induce AhR-dependent gene expression; addition of PMA two hours after TCDD has no effect. Inhibitors of PKC activity block this induction. Not only do our results indicate that cross-talk between AhR and second messenger signaling pathways can synergistically enhance AhR-dependent gene expression, but they suggest a scenario in which AhR-dependent signaling by weak ligands (endogenous or exogenous) can be dramatically enhanced. (NIEHS ES07072)

321 ROLE OF THE ARYL HYDROCARBON RECEPTOR (AHR) IN THE ANTIESTROGENIC EFFECTS OF TCDD IN THE MOUSE UTERUS.

D. L. Buchanan[1], T. Sato[1], R. E. Peterson[2] and P. S. Cooke[1]. [1]*University of Illinois, Champaign-Urbana, IL and* [2]*University of Wisconsin, Madison, WI.*

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) causes a decrease in mouse uterine (Ut) weight. We determined previously that TCDD inhibits estrogen (E2)-induced Ut epithelial mitogenesis and that this effect requires AhR. The aim of this study was to further characterize the Ut epithelial response to TCDD and the role of AhR. To do this, ovariectomized wild-type (wt) and AhR knockout (AhRKO) mice received either oil, E2 (30 ng) or a combination of 5 μg/kg TCDD followed 24 h later by 30 ng E2. Northern blot analysis indicated that E2 stimulated similar large increases in Ut epithelial mRNA expression for the secretory protein lactoferrin (LF) in both wt and AhRKO mice compared to oil-treated controls. However, in wt mice, Ut LF mRNA was reduced 38% ($p<0.05$) by TCDD+E2, compared to E2 alone. In contrast, TCDD did not alter LF mRNA in E2-treated AhRKO mice. To investigate the tissue-specific role of AhR on TCDD-induced inhibition of epithelial mitogenesis, Ut stroma (S) and epithelium (E) from AhRKO and wt mice were enzymatically separated and recombined into four types of Ut tissue recombinants (wt-S + wt-E, wt-S + AhRKO-E, AhRKO-S + wt-E, AhRKO-S + AhRKO-E). Tissue recombinants were grafted into female nude mice, which were later ovariectomized and treated as above (oil, E2 or TCDD+E2); then epithelial labeling index (LI) was determined by thymidine autoradiography. Epithelial LI in wt-S +wt-E grafts from host animals given TCDD 24 h before E2 was reduced compared to those in E2-treated hosts. Similarly, LI in wt-S + AhRKO-E from hosts exposed to TCDD 24 h before E2 treatment, was reduced 33% ($p<0.05$) compared to E2 controls. Further, epithelial LI in AhRKO-S + wt-E and AhRKO-S + AhRKO-E was not affected by TCDD, even when epithelial AhR was present. We conclude that TCDD inhibits normal Ut epithelial secretory activity in response to E2 and that AhR is necessary for this inhibition. Also, TCDD inhibition of Ut epithelial mitogenesis appears to be mediated indirectly through stromal AhR, suggesting that activation of the AhR by TCDD disrupts the normal Ut stromal E2 signaling pathway. (Supported by an Interdisciplinary Environmental Toxicology Scholarship from Univ of IL to DLB and NIH Grant ES01332 to REP.)

322 THE ROLE OF RETINOIDS IN DIOXIN TOXICITY.

H. Håkansson. *National Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.*

Retinoids play a continuing role in many aspects of adult life. In addition, retinoids are critically involved in differentiation and embryonic development. An increasing amount of data suggest that retinoid disturbances, could be a general toxic mechanism for a large number of compounds, including environmental pollutants, pharmaceuticals, and alcohol. This study, which demonstrates structure-activity relationships and species and strain variations in the retinoid response, strongly suggest a role for retinoid disruption in dioxin toxicity, and a role for the Ah-receptor in retinoid disruption. 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) induces early, long-lasting, and marked increases in renal retinyl ester levels, renal retinol esterifying lecithin:retinol acyl transferase (LRAT) activity, and serum retinoic acid level in rat studies. Strongly correlating time- and dose-curves suggests a causal relationship between the three parameters. Increased whole body turnover and mobilization of retinoids from the liver by TCDD has been demonstrated by the use of model-based compartmental kinetic analysis. Hepatic retinoid reduction is a common response in all species investigated, which conforms to the assumed additive mechanism of action for dioxinlike compounds. In contrast, effects on serum and renal retinoid levels differ between species and strains. In addition, renal and serum retinoid responses show structure-related differences and non-additive interactions between different model PCB congeners, suggesting that disruption of the retinoid system can occur via different mechanisms. Together, these data strongly suggest a role for retinoid disruption in dioxin toxicity and a role for dioxins as specific tools to further clarify important steps in the regulation of retinoid metabolism.

323 MICROARRAY ANALYSIS OF IMMEDIATE EARLY GENE EXPRESSION IN RESPONSE TO 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN (TCDD).

D. E. Heck. *Rutgers University, Piscataway, NJ.*

Although numerous cellular and molecular processes altered by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) have been identified the sequella of events ultimately regulating toxicity of this compound remain undefined. In humans, an array of pathological responses ranging from teratogenic events to carcinogenesis have been attributed to exposure to TCDD. Although differential responses to TCDD exposure observed in humans have been attributed to potential genetic polymorphism, the acute chloracne response to high concentrations of TCDD is consistantly observed. Chloracne is believed to result from aberrant functioning within skin hair follicle and endothelial cells. To begin to address this issue we used mRNA isolated from primary cultures of human dermal microvascular endothelial cells in conjunction with microarray techniques to identify immediate early genes whose expression is altered by treatment with TCDD. Specific expression profiles of identified human genes as well as uncharacterized sequences were induced by TCDD. This distinct pattern of gene expression may be useful in determining processes critical for TCDD toxicity. (Supported by NIH grant ES 06897.)

324 DIOXIN INDUCED CHANGES IN GLOBAL EXPRESSION AS MEASURED USING EST FREQUENCY AND CDNA MICROARRAYS: IDENTIFICATION OF A SECOND GENE BATTERY.

R. S. Thomas[1], D. R. Rank[2], S. G. Penn[2], G. M. Zastrow[1], Y. Z. Gu[1], E. Glover[1], M. K. Bunger[1], S. Jovanovich[2] and C. A. Bradfield[1]. [1]*McArdle Cancer Research Laboratory, Madison, WI and* [2]*Molecular Dynamics, Sunnyvale, CA.*

2,3,7,8-Tetrachlorodibenzo-p-dioxin ("Dioxin") is a highly toxic environmental contaminant and one of the most potent liver tumor promoters ever described. Genetic and pharmacological evidence suggests that all of the biological effects of dioxins are mediated through binding to a ligand-activated transcription factor known as the aryl hydrocarbon receptor (AHR). The most widely studied AHR-regulated genes are xenobiotic metabolizing enzymes (XMEs), such as Cyp1a1, Cyp1a2, Cyp1b1 and Udpgt. Induction of the XME gene battery is thought to be part of an adaptive metabolic response to a family of structurally related toxicants and has not been shown to be related to any toxic endpoint. In an attempt to identify a responsive gene battery that might play a role in the hepatocarcinogenicity of dioxin, we initiated a comprehensive survey of dioxin-induced changes in liver gene expression using both expressed sequence tag (EST) frequencies and cDNA microarrays. Based on frequency analysis of nearly 5,000 ESTs derived from the livers of dioxin-

treated (10 mg/kg) and control mice, the overall inventory of liver mRNA transcripts was altered by approximately 30% following exposure to dioxin. In addition, significant changes were identified in a large number of genes not previously shown to be responsive to dioxin. In total, eleven genes were found to be significantly up-regulated by dioxin and nine genes were significantly down-regulated. Analysis of these changes using cDNA microarrays confirmed the EST results and revealed that a second battery of genes paralleled the XME response at all doses investigated (100, 10, 1, 0.3, and 0.05 mg/kg). Experiments in cell culture demonstrated that the changes in the second putative dioxin-inducible battery are mediated by more than one AHR-dependent mechanism. These studies provide molecular evidence that there exists a second battery of dioxin-inducible genes and that the transcriptional inventory of the liver as a whole is significantly altered following dioxin exposure.

325 MECHANISM OF INHIBITION OF TCDD-INDUCED GENE EXPRESSION BY ADENOVIRUS ONCOPROTEIN $E1A_{243}$: ROLE OF COADAPTOR PROTEINS IN AHR FUNCTION.

C. L. Jones and M. S. Denison. *University of California, Davis, CA.*

The aryl hydrocarbon receptor (AhR), a ligand-dependent transcription factor, activates gene expression via binding to the dioxin responsive element (DRE) adjacent to target genes such as CYP1A1. Recent *in vitro* evidence suggests that interactions between the AhR and/or Ah receptor nuclear translocator (Arnt) and coadaptor proteins within the nucleus modulate AhR-dependent signal transduction. Here we have investigated the functional significance of the reported interactions of AhR/Arnt with the retinoblastoma (Rb) and p300 coadaptor proteins using the adenovirus oncoprotein $E1A_{243}$ which is capable of binding both Rb and p300. Previously, $E1A_{243}$-dependent inhibition of TCDD-inducible CYP1A1 expression was solely attributed to inhibition of DRE function via disruption of Arnt:p300 complex formation. Using a combination of reporter and expression plasmid constructs containing discrete regions of the CYP1A1 gene as well as wild type and mutant $E1A_{243}$ proteins which vary in their ability to bind either Rb or p300 respectively, we show that high levels of $E1A_{243}$ directly inhibit CYP1A1 promoter function in a manner independent of $E1A_{243}$ binding to Rb or p300. However, low levels of $E1A_{243}$ expression have minimal effects on the promoter and appear to negatively regulate AhR-dependent signaling in a Rb- and p300-dependent manner. These studies suggest a functional role for both Rb and p300 in AhR-dependent gene transcription and demonstrate the importance of examining both enhancer and promoter function when evaluating the role of coadaptors in inducible gene transcription. (Support: NIEHS grant ES07072.)

326 TRANSIENT EXPRESSION OF CYP1A1 IN RAT EPITHELIAL CELLS CULTURED IN SUSPENSION.

S. A. Monk, M. S. Denison and R. H. Rice. *University of California, Davis, Davis, CA.*

CYP1A1 is known to be induced in human epidermal cells by suspension in methylcellulose-containing medium. The induction is Ah receptor-dependent, but other aspects of the mechanism remain to be elucidated. In present work, CYP1A1 was induced in cultured epithelial cells from a variety of rat epithelia (epidermis, esophagus, vagina, endometrium) upon suspension. The induction was dramatic but transient, where CYP1A1 mRNA reached substantial levels by 1 hr, was maximal by 4-5 hr, and disappeared by 8-10 hr. In addition, suspension induced transcription from a transfected luciferase reporter gene driven by a fragment containing the dioxin-response elements from the mouse CYP1A1 promoter. Although no exogenous Ah receptor ligand was added, induction was strongly inhibited by addition of alpha-naphthoflavone, consistent with generation of an endogenous ligand during suspension. Suspension resulted in activation of the Ah receptor as determined by mobility shift assay using nuclear extracts from suspended cells, but the methylcellulose medium itself failed to activate Ah receptor in cytosolic extracts of rat keratinocytes or mouse Hepa cells, indicating that this medium was not a source of ligand. Addition of TCDD to the suspension medium did not prolong the period of induction, but the protein synthesis inhibitor cycloheximide extended maximal induction beyond 12 hr. The kinetics of the induction process in cultured rat cells in suspension thus are consistent with generation first of an endogenous ligand and then of a relatively unstable protein acting to repress transcription.

327 MAXILLARY AND MANDIBULAR OSTEOINVASIVE PERIODONTAL SQUAMOUS PROLIFERATION IN MINK FED 3,3',4,4',5-PENTACHLOROBIPHENYL OR 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN.

J. A. Render[1], D. S. Rosenstein[2], S. J. Bursian[3] and R. J. Aulerich[3]. [1]*Department of Veterinary Pathology, Michigan State University, East Lansing, MI,* [2]*Department of Small Animal Clinical Sciences, Michigan State University, East Lansing, MI and* [3]*Department of Animal Science, Michigan State University, East Lansing, MI.*

Polychlorinated aromatic hydrocarbons, including polychlorinated biphenyls (PCBs), polychlorinated dibenzo-p-dioxins (PCDDs), and polychlorinated dibenzofurans (PCDFs), are persistent environmental contaminants. Mink (Mustela vison) are extremely sensitive to the toxic effects of these compounds and serve as sentinels of environmental contamination. In a study designed to examine the effects of 3,3',4,4',5-pentachlorobiphenyl (PCB 126) on growing mink, an unexpected lesion, maxillary and mandibular osteoinvasive periodontal squamous proliferation, was observed in all 20 animals that were fed 24 ppb PCB 126 beginning at 12 weeks of age. After receiving the PCB-treated diet for 31 days, the first mink was observed having difficulty chewing. Gross examination revealed mandibular and maxillary lesions consisting of swelling of the upper and lower jaws with nodular proliferation of the gingiva and loose teeth with increased gingival surface area. Radiographs indicated periodontal osteolysis of the maxilla and mandible. As the trial progressed, mink were euthanized as the clinical condition became apparent. The last mink was euthanized on day 69 of the trial. A subsequent trial was conducted to verify the lesion. Six-week-old and 12-week-old mink were administered either 24 ppb PCB 126 or 2.4 ppb 2,3,7,8,-tetrachlorodibenzo-p-dioxin (TCDD) via the feed. Within 2 weeks, maxillary and mandibular osteoinvasive periodontal squamous proliferation was detected histologically in both PCB 126- and TCDD-treated mink. These results document that certain polychlorinated aromatic hydrocarbons cause periodontal disease.

328 DIOXIN CONGENERS IN TISSUES OF VIETNAMESE LIVING IN THE NORTH AND SOUTH OF VIETNAM FROM 1970 THROUGH 1999 FROM AGENT ORANGE AND OTHER SOURCES.

A. Schecter[1], L. C. Dai[2], J. Constable[3], O. Paepke[4] and P. Fuerst[5]. [1]*University Texas School of Public Health, Dallas, TX,* [2]*Vietnam Red Cross and Hanoi Medical School, Hanoi, Viet Nam,* [3]*Harvard Medical School, Boston, MA,* [4]*ERGO Laboratory, Hamburg, Germany and* [5]*State Food Laboratory, Muenster, Germany.*

The largest dioxin (TCDD) contamination known was from spraying Agent Orange in Vietnam 1962-71. TCDD milk analyses in 1970 and 1973 showed extremely high TCDD levels, up to 1,850 and 400 parts per trillion (ppt) lipid respectively. Epidemiological studies have usually been conceptualized assuming most exposure was from the original spraying and that dose could be backcalculated using a half life of about 7-9 years. Blood dioxin levels from 1999 samples suggest elevated levels are still present and may sometimes be from new contamination. Blood TCDD levels of as high as 271 ppt (TEQ 300) have been found in blood from residents living near a US storage base in Binh Hoa which had known Agent Orange leakage. Also, a family of four which had moved from the north of Vietnam to the south after Agent Orange spraying ended was found to have TCDD blood levels of 65-85 ppt consistent with exposure from a recently contaminated food supply, especially fish from the Binh Hoa airbase potential TCDD contamination into nearby waterways. Average south Vietnamese blood TCDD is about 4 ppt and northerners have about 2 ppt. These recent finding complicate epidemiology studies because of the varying times of dose intake but uniquely provides large populations with recent as well as older TCDD exposures. This unfortunate set of circumstances may provide opportunity for toxicokinetic studies in addition to health studies of men, women, children, and of several generations.

329 MITOCHONDRIAL MECHANISMS OF DEVELOPMENTAL TOXICITY: CRITICAL EVENTS AND INTERVENTION.

T. B. Knudsen, M. F. O'Hara, J. H. Charlap, R. J. Donahue and R. C. Craig. *Jefferson Medical College, Philadelphia, PA.* Sponsor: P. Wier.

Mouse embryos lacking the *Trp53* gene (p53) are prone to spontaneous neural tube defects and altered teratogenicity. Differential display of p53-deficient mutant embryos revealed under-expression of 16S mitochondrial ribosomal RNA (16S rRNA), confirmed by metabolic profiling, as the early embryo

switches from anaerobic (glycolytic) to aerobic (oxidative) metabolism. In the present study, we tracked 16S rRNA during the critical period following teratogen exposure. Pregnant mice were injected intraperitoneally with 5 mg/kg 2-chloro-2'-deoxyadenosine (2CdA) on GD8 or 5 mg/kg methylmercury (MeHg) on GD9; expression PCR analysis used primers specific for 16S rRNA and β-actin to control for input RNA. Levels of 16S rRNA were significantly altered in either treatment scenario. 2CdA raised 16S rRNA levels by about 40% ($P < 0.01$) whereas MeHg lowered 16S rRNA by about 75% ($P < 0.01$) versus respective control embryos. Embryos were rescued from either teratogen-induced alteration in 16S rRNA when pregnant dams were injected with 4 mg/kg PK11195, an isoquinoline carboxamide specific for the mitochondrial peripheral-type benzodiazepine receptor (PBR). PK11195 protected embryos from developmental toxicity. For example, it protected fetuses from 2CdA-induced microphthalmia and fetal weight reduction. Rescued embryos did not display 2CdA-induced changes in p53 protein at 4.5h post-treatment, nor was therapy successful once p53 protein induction had occurred. These results suggest that: (1) deregulation of 16S rRNA expression represents a broad-based physiological response to chemical exposures; and (2) the mitochondrial peripheral-type benzodiazepine receptor may provide a critical link between toxicant effects and cellular responses. (Supported by grants RO1 ES09120 and T32 ES07282 from the NIEHS.)

330 ONTOGENY OF NAD KINASE IN THE RAT CONCEPTUS.

C. Harris and S. Akella. *University of Michigan, Ann Arbor, MI.*

NAD^+ kinase (NADK) is the only known enzyme in living systems to catalyze the formation of $NADP^+$ from NAD^+. The capacity to maintain an adequate supply of NADP(H) has important implications for developmental biosynthesis and embryonic biotransformation. Therefore, we believe it is important to determine the activity of this enzyme during development. No detectable activity was observed in GD 10 conceptuses. By GD 11 specific activities of 1.8 and 7.0 pmoles $NADP^+$/min/mg protein were measured in embryo and VYS, respectively. The VYS activity decreased thereafter with an increase in gestational age. By GD 18, the specific activity in the VYS had dropped to 0.5 pmoles $NADP^+$/min/mg protein. Developmental ontogeny profiles were generated for several other tissues at gestational times where adequate tissue amounts were available. The specific activity of NADK in the placenta increased from 1.3 pmoles $NADP^+$/min/mg protein on GD 11 to 32.7 pmoles $NADP^+$/min/mg protein on GD 15. Specific activities in the heart decreased with increasing gestational age (3.75 pmoles $NADP^+$/min/mg protein on GD 13 to 0.14 pmoles $NADP^+$/min/mg protein on GD 21). In contrast, the activity in the liver increased from 1.7 pmoles $NADP^+$/min/mg protein on GD 15 to 51.1 pmoles $NADP^+$/min/mg protein on GD 21. The specific activity was also determined in the brain where it peaked at 5.4 pmoles $NADP^+$/min/mg protein just before birth. In the lung, the activity increased from 0.9 pmoles $NADP^+$/min/mg protein on GD 17 to 5.9 pmoles $NADP^+$/min/mg protein on GD 21. However, it dropped in the kidney from 2 pmoles $NADP^+$/min/mg protein on GD 17 to 1.12 pmoles $NADP^+$/min/mg protein on GD 21. These results demonstrate time-dependent and tissue-specific variations in the activity of NAD^+ kinase. Variations in enzyme activities reflect alterations in functional needs for cofactors during differentiation and may reflect a cooperation between tissues to optimize detoxification capacity. This is of particular importance when chemical exposure during pregnancy disrupts the pyridine nucleotide redox status and the conceptus must then rely on NADK to provide additional NADP(H). (This research was supported by ES05235.)

331 ALTERATIONS IN ESTROGEN RECEPTOR (ER) ALPHA, ER BETA, AND LACTOFERRIN (LF) EXPRESSION IN REPRODUCTIVE TRACT TISSUES FOLLOWING TREATMENT WITH GENISTEIN OR DIETHYLSTILBESTROL (DES) DURING DEVELOPMENT.

R. R. Newbold[1], E. Padilla Banks[1], J. L. Hagelbarger[1], J. F. Couse[2] and W. N. Jefferson[1]. [1]*Laboratory of Toxicology, National Institute of Environmental Health Sciences, Research Triangle Park, NC and* [2]*Laboratory of Reproductive and Developmental Toxicology, National Institute of Environmental Health Sciences, Research Triangle Park, NC.* Sponsor: M. L. Cunningham.

Permanent alterations result in both male and female mice following developmental exposure to synthetic and natural occurring estrogenic compounds. Reports from our laboratory have shown that perinatal exposure of mice to DES results in impaired fertility and reproductive tract lesions. Long-term consequences of DES exposure on days 1-5 include a 95% incidence of uterine carcinoma. Similar long-term effects have been shown with other estrogens suggesting the developing reproductive tract is uniquely sensitive to compounds with estrogenic activity. To study the developmental effects of the phytoestrogen, genistein, we tested the possibility that neonatal exposure to this compound would alter estrogen signaling pathways in target tissues; these changes were compared to tissues similarly exposed to DES. The ontogeny of ERα, ERβ, and LF in differentiating reproductive tracts of control CD-1 mice (fetal day 14 through PND 26) was determined using a ribonuclease protection assay and immunohistochemical analysis. ERα was present in both ovary and reproductive tract; ERβ was in the ovary but not uterus. LF wasn't detected in uterine tissue until approximately postnatal day 19. Following neonatal treatment on days 1-5 with genistein (500-50,000 μg/kg) or DES (0.01-1,000 μg/kg), reproductive tract tissues were compared to controls to determine if treatment altered the expression of these proteins. Genistein or DES-exposed mice showed an increase in LF in the uterus on day 5, the last day of treatment. Further, data from genistein or DES neonatally exposed mice showed alterations in ERα and ERβ expression. The dose response and time course for ERα, ERβ, and LF expression is being determined, as well as, the relationship of altered protein expression to long-term adverse consequences.

332 MOLECULAR AND CELLULAR PATHOGENESIS OF 5-AZA-2'-DEOXCYTIDINE-INDUCED MURINE HINDLIMB DYSMORPHOGENESIS.

S. Branch[1] and G. Henry-Sam[2]. [1]*North Carolina State University, Department of Toxicology, Raleigh, NC and* [2]*Xavier University of Louisiana, College of Pharmacy, New Orleans, LA.*

5-AZA-2'-deoxycytidine (d-AZA) elicits defects and altered gene expression in mouse hindlimbs. Segmental formation of limb regions (stylopod, zeugopod, and autopod) is partially dependent upon Hox gene activation. The objective of this study was to understand the early pathogenesis and molecular etiology of d-AZA-induced hindlimb defects. Semi-quantitative RT-PCR was used to analyze hox gene expression (Hox A and D homologs, paralogs 9 - 13). Untreated and treated fore and hindlimb buds were collected 12 and 24 hrs after i.p. treatment (1mg/kg of d-AZA at 9 am on gestational day (GD) 10) and processed for RT-PCR. Other pregnant mice were treated similarly and whole embryos collected 12 and 24 hours post-treatment and processed for histopathological analysis. No changes in hox gene expression were detected in the forelimb tissue. There was a two-fold down-regulation of hox a-11 in the hindlimb bud tissue. No changes in the hoxd series were detected in the hindlimb bud tissue. The 12 and 24 hr. untreated mice exhibited findings consistent with physiological apoptosis. The treated mice exhibited necrosis and inflammation in most embryonic tissues. The hindlimb buds of the 12 hr. treated tissue exhibited axonal vacuolation. Thickening of the apical ectodermal ridge was evident in the 24 hr. treated limb buds (more severe in the hindlimb buds). Further, 6-aza-2'-deoxycytidine does not induce developmental toxicity at doses up to three times that of d-AZA. The data supports the hypothesis that altered gene expression via alterations in DNA methylation is associated with d-AZA-induced dysmorphogenesis. Further work is ongoing to determine the interplay of altered expression cascades and to better define the genotype/phenotype relationship in d-AZA-induced limb alterations.

333 MATERNAL IMMUNOSTIMULATION PROTECTS AGAINST URETHANE-INDUCED CLEFT PALATE.

L. V. Sharova, R. M. Gogal, P. Sura and S. D. Holladay. *Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA.*

Non-specific immunostimulation has reported efficacy in humans for reducing spontaneous early resorptions and abortions. This technique has further been reported to decrease malformations in mice caused by teratogenic chemicals. In the present study, ICR mice were exposed to urethane alone or together with Freund's complete adjuvant (FCA) or IFNγ. Urethane alone induced cleft palate in 70% of fetuses. Immunostimulation with IFNγ or FCA decreased cleft palate occurrence to 45% and 27%, respectively. Severity of the defect was reduced in fetuses from IFNγ-treated mothers compared to FCA-treated mothers. On gd 14, expression of genes bcl2, p53, and pkC was lower in fetal palate from urethane-exposed mothers compared to control. The bcl2/p53 ratio after urethane exposure was shifted in favor of p53. FCA immunization did not alter fetal bcl2 or pkC expression, but resulted in a further decrease in p53 expression which tended to normalize the bcl2/p53 expression ratio. Maternal IFNγ injection restored fetal palate bcl2 and pkC expression without changing p53 expression. Thus, with IFNγ treatment the bcl2/p53 expression ratio exceeded control. Urethane downregulated placental TGFα, TGFβ3, IGF II, wee-1 and bcl2 genes. However, FCA and IFNγ treatments normalized these gene expression profiles in placenta. These data

suggest that maternal immunostimulation may protect against urethane-induced cleft palate in rodents by normalization of critical gene expression during development. (Supported by NIH RO1-ES 09642-01.)

334 SECALONIC ACID D INHIBITS PROTEIN KINASE C ACTIVITY AND THE FORMATION OF AP-1 COMPLEX IN THE DEVELOPING MURINE PALATE.

G. Balasubramanian, U. Hanumegowda and C. S. Reddy. *University of Missouri, Columbia, MO.*

Secalonic acid D (SAD), a teratogenic mycotoxin, causes cleft palate (CP) in the offspring of exposed mice in association with inhibition, *in vitro*, of protein kinase C (PKC), an essential component in signaling pathways mediating cell proliferation and differentiation. In this study, we investigated whether the inhibition of PKC by SAD also occurs *in vivo* and if so what other down stream events are altered. Protein kinase C activity assays involving the transfer of g-phosphate from [32P] ATP to the substrate, using palatal tissue extracts from control and SAD-exposed litters, showed that SAD inhibited the activity of Ca^{2+}-dependent PKCs significantly more than the Ca^{2+}-independent ones. Activation of PKC is known to stimulate the formation of AP-1 (containing c-jun and c-fos in general and CREB/CREM in select tissues), which binds to the TPA responsive elements (TRE) on the DNA to influence gene transcription. Electrophoretic mobility shift assays performed with nuclear extracts from control and treated palatal tissues using the [32P] labeled AP-1 consensus oligonulceotide, demonstrated that the palatal AP-1 complex contains CREB but not CREM and that SAD inhibited the AP-1 complex formation at all time points tested compared to controls. These results suggest that SAD-induced PKC inhibition in the developing mouse palate affects downstream events and is likely to alter gene expression. (Supported by NIH grant # DE/OD 11822.)

335 EVALUATION OF THE PEROXYNITRITE PATHWAY IN PHENYTOIN EMBRYOTOXICITY USING INDUCIBLE NITRIC OXIDE SYNTHASE (INOS) KNOCKOUT MICE IN EMBRYO CULTURE.

S. Kasapinovic[1], M. J. Wiley[2] and P. G. Wells[3]. [1]*Faculty of Pharmacy, University of Toronto, Toronto, Ontario, Canada,* [2]*Department of Surgery, University of Toronto, Toronto, Ontario, Canada and* [3]*Faculty of Pharmacy and Department of Pharmacology, University of Toronto, Toronto, Ontario, Canada.*

Existing evidence indicates that teratogencity of the antiepileptic drug phenytoin involves reactive oxygen species (ROS), such as superoxide anion ($O_{2\cdot-}$), which oxidatively damage embryonic cellular macromolecules. $O_{2\cdot-}$ can react with nitric oxide generated by NOS forming peroxynitrite, which also causes macromolecular damage. To test whether the embryonic peroxynitrite pathway contributes to phenytoin embryotoxicity, B6129PF2 iNOS knockout and congenic wild-type mouse embryos were cultured on gestational day 9.5 (vaginal plug=day 1) for 24 hr with either a therapeutic concentration of phenytoin (20 μg/ml, 80 μM) or its vehicle (0.002N NaOH). Compared to wild-type controls, iNOS knockout embryos were partially protected from phenytoin embryopathies, with increases of 2.4-fold in anterior neuropore closure ($p<0.05$), 3.0-fold in turning ($p<0.05$), 4.4% in yolk sac diameter ($p=0.001$) and 15% in somite development ($p<0.001$). These results suggest that iNOS is constitutive during organogenesis, unlike in adult tissues where it is generally nonconstitutive, and that the embryonic peroxynitrite pathway interacts with ROS in the mechanism of phenytoin embryotoxicity. The partial nature of the protection may be due to peroxynitrite-independent ROS damage and/or induction of other embryonic NOSs. (Support: Medical Research Council of Canada.)

336 REACTIVE OXYGEN SPECIES IN DEVELOPMENTAL METHYLMERCURY NEUROTOXICITY.

M. A. Polunas and K. R. Reuhl. *Rutgers University, USA, NJ.*

The developmental neurotoxicity of methylmercury (MeHg) has been well studied, yet the underlying mechanisms remain largely unknown. In the developing brain, MeHg-induced injury involves both the forming cerebellum (CEL) and cerebral cortex, and can be ameliorated by vitamin E. Recent data suggest that MeHg increases the production of reactive oxygen species (ROS) in the brain of adult rodents, but the role of ROS in developmental MeHg neurotoxicity has not been determined. This study was undertaken to determine whether MeHg increases ROS production in the developing brain, and whether the effect varies according to brain region and/or subcellular fraction. Balb/c mouse pups were injected s.c. with 4.0 mg/kg MeHg or PBS on postnatal days (PND) 6, 8, and 10 and killed 24 hours after the final dose. CEL was separated from the rest of the brain (ROB); synaptosomes and mitochondria from both regions were prepared by differential centrifugation and ROS determined using the DCF assay. Dichlorofluoroscin diacetate (DCFH-DA), a stable non-fluorescent molecule, readily crosses cell membranes and is hydrolyzed by esterases to DCFH, which is trapped intracellularly. Subsequent oxidation to the fluorescent DCF was determined at excitation 488 nm and emission 525 nm. ROS production in brain was variable, with only moderate elevations in CEL mitochondria and ROB synaptosomes and no significant change in CEL synaptosomes or ROB mitochondria. Results suggest that acute MeHg treatment during the perinatal period does not yield marked and widespread production of ROS in the brain. Scavenging of ROS by antioxidant systems such as glutathione or ascorbate, or the immature pattern of lipids in the perinatal brain may also limit the detection of ROS. Assessment of antioxidant systems in these animals is currently under way. (Supported by NIH ES 04976 and ES-05022.)

337 ALTERED LEVELS OF APOPTOTIC AND NEUROTROPHIC FACTOR MRNA IN DEVELOPING RAT BRAIN FOLLOWING EXPOSURE TO MERCURY VAPOR OR LEAD ACETATE.

S. L. Chao[1], W. T. Haines[2], S. Barone, Jr.[1], H. A. Tilson[3], R. P. Beliles[4], D. L. Morgan[5] and G. J. Harry[5]. [1]*USEPA/NIEHS, Research Triangle Park, NC,* [2]*UNC-Chapel Hill/USEPA, Research Triangle Park, NC,* [3]*USEPA, Research Triangle Park, NC,* [4]*USEPA, Washington, DC and* [5]*NIEHS, Research Triangle Park, NC.*

Both apoptotic and neurotrophic factors play essential roles in the development of the brain and formation of the neural networks. Due to evidence suggesting apoptosis as a mode of action following developmental exposure to mercury and lead, we examined the temporal and regional profiles of mRNA levels for various pro- and anti- apoptotic factors following exposure to either mercury vapor or lead. The mRNA levels for bax, caspase 3, caspase2, bcl-x, and BDNF (brain derived neurotrophic factor) were examined in the postnatal rat brain following inhalation (nose-only) exposure to mercury vapor ($2mg/m^3$) at gestational days 6-15 or postnatal (PND 1-21) exposure to lead acetate (0.2%). Our results indicate an elevation in mRNA levels of both apoptotic factors and BDNF that were metal and brain region specific. Following exposure to mercury vapor, mRNA levels for the above factors increased in the cerebellum at PND 21while levels in the frontal lobe remained unchanged. Following lead acetate exposure, the hippocampus was most affected with significant elevations in caspase 3 and bax observed at PND 12 and post-weaning while bcl-x and BDNF were increased at PND12. In the cerebellum, mRNA levels for caspase 2, 3, and bax were elevated at PND 9. In the cortex, bcl-x and BDNF mRNA levels were decreased at PND 15. These data indicate both time and region specific responses of the developing nervous system following low level exposure to mercury vapor or lead acetate. This abstract does not necessarily reflect US EPA policy.

338 NEUROTOXIC HEAVY METALS LEAD AND MERCURY DISTURB N-CADHERIN EXPRESSION IN EMBRYONIC CHICK CORTICAL CELLS.

P. M. Dey and G. B. Grunwald. *Jefferson Medical College, Thomas Jefferson University, Philadelphia, PA.*

Exposure to heavy metals during embryogenesis disturbs brain development and results in decreased neurological potential. Morphogenesis of the central nervous system is mediated, in part, by the developmentally-regulated expression of the cell adhesion molecule N-cadherin. Appearance of this 130 kDa transmembrane glycoprotein and its associated cytoskeleton-linking proteins at neuronal cell surfaces mediates homophilic adhesion and bi-directional cell signaling during all stages of neurodevelopment. One prominent mechanism by which neural N-cadherin is turned over is by divalent-cation dependent proteolysis, resulting in the generation of truncated membrane-associated forms and soluble N-cadherin (NCAD90) fragments. Experiments were undertaken to determine whether the toxic metals lead and mercury disturb N-cadherin expression in chick cortical cells following exposure to metals using *in vitro* cell cultures and in purified synaptosomal membrane preparations. Incubation of cultured cortical cells with either 2 or 20 mM mercury chloride for 24 hours resulted in the dose-dependent increase in membrane-associated N-cadherin isoform expression, with significant elevation in levels of both the 130 kDa (at 20 mM) and 110 kDa isoforms (2 and 20 mM) and generation of

soluble NCAD90. Lead exposure of cortical cell cultures for one week in either 1 or 5 mM lead chloride resulted in reduced membrane-associated N-cadherin expression, along with significant loss of the N-cadherin cytoskeletal linker protein beta-catenin. Alteration in the developmentally-regulated expression of N-cadherin by lead and mercury may disturb N-cadherin-mediated brain morphogenesis, and could contribute to the neurological defects observed in developmental metal neurotoxicity. (Supported by NIH training grant T32 ES-07282.)

339 FEMALE PREDOMINANCE AMONG CD-1 MOUSE FETUSES WITH ARSENIC-INDUCED EXENCEPHALY.

C. A. Lammon and R. D. Hood. *University of Alabama, Tuscaloosa, AL.*

For comparison with the sex ratios of exencephalic fetuses reported by Machado *et al.* (Tox. Sci. 51:98-107, 1999) in arsenite treated C57BL/6J and SWV/Fnn mice, we examined exencephalic fetuses from both arsenite- and arsenate-exposed mice of a third strain (CD-1). These fetuses were derived from an ongoing study of the influence of methylation on arsenic teratogenicity. Groups of 20 female mice were mated (plug = gestation day 1) and given one of these treatments on GD 9: sodium arsenite (As III), 7.5 mg/kg, ip, with a 100 μM/kg dose of the methylation inhibitor periodate oxidized adenosine (PAD), ip, or with a 5, 10, or 20% protein diet; sodium arsenate (As V), 17.9 mg/kg (as Na_2HAsO_4), ip, with 100 μM/kg periodate oxidized adenosine (PAD), ip, or with a 5, 10, or 20% protein diet. The highest proportions of exencephalic female fetuses were from dams exposed to As(III) combined with PAD (34/21, 62%) or with the 10% protein diet (9/4, 69%) or to As(V) combined with PAD (21/14, 60%) or with the 10% protein diet (18/8, 69%). As(III) or As(V) plus the 20% diet was suggestive of a female preponderance, but the differences were smaller, while neither arsenical was associated with such an effect when given with the 20% protein diet. Due to the relatively low numbers of exencephalic fetuses, however, only the female preponderance of the total of As(III)-treated fetuses was statistically significant by the binomial test ($p \leq 0.02$), although the value for all As(V)-exposed fetuses closely approached significance ($p \leq 0.055$). These results thus support the findings of Machado *et al.* (1999), who reported a predominance of females among exencephalic fetuses from arsenite-exposed mice. (Supported by a grant from Sigma Theta Tau.)

340 RECENT TRENDS IN CHILDHOOD BLOOD LEAD LEVELS.

T. S. Bowers[1], R. L. Mattuck[1], B. D. Beck[1] and J. T. Cohen[2]. [1]*Gradient Corporation, Cambridge, MA and* [2]*Harvard Center for Risk Analysis, Cambridge, MA.*

Blood lead levels for children in the United States are known to have declined over the last few decades through at least 1994, the date of the most recent National Health and Nutrition Examination Survey (NHANES). The analysis presented here was performed to determine whether blood lead levels for children under age six have changed since 1994, and to quantify the magnitude of any change. This study evaluates blood lead levels from 12 longitudinal data sets from 11 states and one city. Geometric mean (GM) blood lead levels declined between four and 16 percent per year in ten of the 12 data sets. No differences in decline rates were observed between data sets from states that had universal screening or included repeat measures for an individual child, and those data sets from states that did not. Based on the quality of the data sets and the reproducibility of the decline rates, the average decline rate for blood lead levels since 1994 in children under age six is estimated as four to seven percent per year. This is comparable to the decline rate observed in earlier years of six to seven percent per year based on the NHANES II and III surveys. Using the decline rates estimated here, this analysis suggests that the GM blood lead level for U.S. children today is between approximately 2.0 and 2.3 μg/dL.

341 UPDATED VERSION OF CAL/EPA'S LEADSPREAD MODEL FOR PREDICTING BLOOD LEAD IN CHILDREN AND ADULTS.

J. C. Carlisle, J. P. Christopher, B. K. Davis, A. K. Klein, B. E. Renzi and M. J. Wade. *California Department of Toxic Substances Control, Sacramento, CA.*

The California Department of Toxic Substances Control has revised and updated its lead risk assessment spreadsheet model (LeadSpread) for predicting distributions of blood lead (PbB) for adults and for children 1-2 years old. Inputs to LeadSpread are central tendency values; output is converted to a lognormal distribution via an assumed geometric standard deviation. We increased this geometric standard deviation to 1.60, according to White et al. (1998). We decreased food consumption to 1.1 kg/day for children and 1.9 kg/day for adults (Bolger, 1996) and decreased our estimate of lead in the diet to 2.8 μg/kg of food for children and 1.6 μg/kg of food for adults (USFDA, 1996-97). Based on USEPA (1997), we increased soil ingestion rates to 100 mg/day for children and 50 mg/day for adults, decreased the ventilation rate for children to 6.8 m3/day, and changed exposed skin surface to 2,900 cm2 for children and 5,800 cm2 for adults. Using recent guidance on dermal risk assessment (USEPA, 1998), we decreased soil-to-skin adherence from 1 mg/cm2 for children and adults to 0.2 mg/cm2 for children and 0.07 mg/cm2 for adults. Using data from California Air Resource Board (Cal/EPA, 1999), we decreased our estimates of lead in air to 0.028 μg/m3 and airborne dust to 1.5 μg/m3. Assuming 20 mg Pb/kg in soil and 15 μg Pb/L in drinking water, these revised inputs to LeadSpread predict a geometric mean PbB of 1.7 μg/dL for children 1-2 years old, with a 99th percentile of 5.0 μg/dL. The National Health and Nutrition Examination Survey III, Phase 2 (NHANES III; USDHHS, 1996) found the geometric mean PbB in the Western U.S. to be 2.17 for children 1-6 years old and 2.64 in children 1-2 years old. Restricting the data from NHANES III to children living in post-1973 housing, geometric mean PbB decreases to 1.7 and 1.9 μg/dL for children 1-6 and 1-2 years old, respectively. Thus, LeadSpread with its revised inputs agrees well with NHANES III data for children either 1-2 or 1-6 years old in post-1974 housing. We also present predicted PbB using LeadSpread with various combinations of possible site-specific inputs.

342 COMPARISON OF UPDATED LEADSPREAD TO INTEGRATED UPTAKE, EXPOSURE, AND BIOKINETIC MODEL (IEUBK) FOR PREDICTING BLOOD LEAD IN CHILDREN.

J. P. Christopher, J. C. Carlisle, B. K. Davis, A. K. Klein, B. E. Renzi and M. J. Wade. *California Department of Toxic Substances Control, Sacramento, CA.*

California Department of Toxic Substances Control has revised LeadSpread, its spreadsheet model for predicting distributions of blood lead (PbB) in adults and children. Here we compare revised LeadSpread to USEPA's IEUBK model (ver. Lead99d). Structurally, the two models are very different. IEUBK is a multi-compartment, time-dependent model, while LeadSpread uses empirical relationships under steady-state assumptions. IEUBK allows a user-specified maternal blood lead concentration, indoor/outdoor ratios for dust, activity, and air, and optional inputs for additional sources of lead, such as paint. LeadSpread does not offer these features, but it has a plant uptake pathway. IEUBK estimates PbB for children up to 7 years old, while LeadSpread provides estimates for 1-2 year old children, with or without pica, and for adults. Operationally, IEUBK is a compiled model run in DOS, while LeadSpread is a spreadsheet model run in Microsoft Excel®. Slope factors describing change in PbB/unit of lead content in food, drinking water, or environmental media are explicit in LeadSpread, and they can be derived from IEUBK by running the model iteratively. For change in PbB vs. lead in air, LeadSpread has a discernible slope, while IEUBK does not. For drinking water and food, IEUBK shows faster rises in PbB per unit concentration of lead than does LeadSpread. For ingestion of soil, IEUBK includes a saturable and a non-saturable process. Because the saturable process is only slightly non-linear, we describe two slope factors for IEUBK, one for 0-700 and one for 0-7,000 mg Pb/kg soil. The one slope factor in LeadSpread for soil ingestion vs. change in PbB is about equal to the larger of the two for IEUBK. We compared outputs of the two models for children 1-2 years old. Using recommended defaults, 20 mg Pb/kg of soil, and 15 μg/L of drinking water, IEUBK predicted a geometric mean PbB of 1.9 μg/dL with a 99th percentile of 5.6 μg/dL, while LeadSpread predicted 1.7 and 5.1 μg/dL. A large national data base (NHANES III) reports a geometric mean PbB of 2.7 μg/dL for all children 1-6 years of age and 2.0 μg/dL for children 1-6 years of age living in post-1973 housing. The latter value is comparable to both models.

343 INVESTIGATION OF LEAD-BASED PAINT IN SOILS IN NON-RESIDENTIAL AREAS AT CLOSING MILITARY BASES.

D. Stralka, J. Hamill, D. Opalski and M. Work. *US Environmental Protection Agency, Region 9, San Francisco, CA.* Sponsor: J. Christopher.

Lead contamination in soils from the use of lead-based paints has been an environmental concern in residential areas for some time and has been the focus of legislation and various remediation efforts. This investigation was to

ascertain the extent of lead contamination around buildings in non-residential settings that had previously used leaded paints and have no operational history of lead usage. Several closing military bases in California representing the major branches of military service were investigated, affording a variety of building types, operational histories, construction materials, maintenance practices, and ages. Buildings were selected for investigation if they currently had lead-based paint, as indicated by hand held x-ray fluorescence, or were of the age that could have had leaded paint. Sampling was further based on the extent of painted surfaces and paint condition. Since the contribution of lead in soil from lead-based paint would be expected to be deposited in the near surface, soil samples were collected at 0 to 1 inch below ground surface at the building dripline and at distances of ½, 2 and 4 times. Samples were collected wherever there was soil at approximately 50-foot intervals around the selected buildings. There was no attempt to include or exclude paint chips from the sampling. Visible gravel, pebbles, and plant material were excluded from the samples. On selected sites that demonstrated lead in soil, composite samples to 6 inches were also collected to reveal lead impact with depth. Results yielded a few individual samples with percent-by-weight levels of lead in soil. In general, concentrations drastically decreased with distance from the building and with depth. The overall volume of soil impacted was small. Building material was weakly correlated with lead in soil with metal and wood structures having the highest burdens. Building age was also weakly correlated with soil burdens. High visibility buildings that receive more frequent maintenance had higher soil burdens. These results may be used to evaluate the risk from and risk management decisions needed for dealing with lead in soils in other then residential areas to effectively speed military base closure property transfers.

344 RECONSTRUCTION OF LIFETIME LEAD EXPOSURE FROM QUESTIONNAIRE, κ-XRF MEASUREMENTS, AND BIOKINETIC MODELING.

J. M. Gorell[1], E. L. Peterson[1], B. A. Rybicki[1], D. R. Chettle[2] and J. G. Pounds[3]. [1]*Henry Ford Health System, Detroit, MI,* [2]*McMaster University, Hamilton, Ontario, Canada and* [3]*Wayne State University, Detroit, MI.*

Exposure to lead is typically assessed by measurement of lead in blood, bone, or urine, and by use of risk factor questionnaires. In an effort to improve upon estimates of lifetime lead exposure, we sought to integrate historical exposure assessments and κ x-ray fluorescence (κ-XRF) bone lead measurements using biokinetic modeling. An algorithm was constructed to convert information derived from a Lead Exposure Questionnaire (LEQ) to a daily lead input to ICRP biokinetic model for lead to reconstruct the adult lifetime internal lead dose (blood and bone lead). All occupational and nonoccupational activities at risk for lead exposure were considered. The LEQ and κ-XRF measurement of tibial and calcaneal bone lead were assessed in 34 men and women, aged 62 to 86 yr, considering all potential lead exposures from age 18 yr onward. κ-XRF measured tibial and calcaneal lead was 17.6 +/- 15.1 and 19.8 +/- 17.5 microg Pb/g bone mineral, respectively. For all subjects considered together, the difference between bone lead stores predicted by biokinetic modeling at the time of κ-XRF measurement, and the κ-XRF measurement itself, was 2.9 +/- 2.2 microg Pb, weighted to cortical bone. This novel methodological approach provides the opportunity to construct and test hypotheses regarding the timing, duration, and intensity of adult lifetime lead exposure as a risk factor for chronic neurodegenerative, cardiovascular and skeletal diseases. (Supported by NIH ES06418 [JMG] and ES04040 [JGP].)

345 INCORPORATING SITE-SPECIFIC INFORMATION IN THE DETERMINATION OF LEAD REMEDIAL REQUIREMENTS AT CLOSED SMALL-ARMS FIRING RANGES.

L. G. Lund[1], L. B. Murray[1], K. A. Friesen[1] and M. Kankelfritz[2]. [1]*Parsons Engineering Science, Inc., Denver, CO and* [2]*Air Force Center for Environmental Excellence (AFCEE), San Antonio, TX.*

The Air Force Center for Environmental Excellence and Parsons Engineering Science have implemented a risk-based approach to determine remedial requirements at closed small-arms firing ranges on Air Force facilities. The purpose of this nationwide initiative was to establish a cost-effective, site-specific, technically sound, and unified approach to firing range site investigation, risk evaluation, and remediation. USEPA-approved biokinetic exposure models were used to assess site-specific risks from exposure to lead in soil and derive remediation goals. Bioavailability of lead has been shown to decrease with increasing particle size. There is evidence suggesting that soil particles <100 μm are more likely to be incidentally ingested because they adhere more readily to skin. Lead concentrations in the soil fraction containing particles with diameters ≤ 250 μm were used to estimate potential exposure. Lead bioavailability is expected to vary dependent on the chemical species. Lead carbonate and lead/metal oxides were the species most frequently encountered in soil samples. An *in vitro* method for estimating the relative bioavailability of lead in humans has been developed by researchers at Colorado University in Boulder and USEPA Region 8. *In vitro* relative bioavailability results for soil samples ranged from 70 to 100 percent. Site-specific information on particle size, chemical species, and *in vitro* bioavailability suggested that the bioavailability of lead in soils at small-arms firing ranges was not significantly different than the USEPA-recommended default. Results of exposure modeling incorporating the above site-specific information to assess potential risks and develop risk-based remediation goals in soils at small-arms firing ranges in Alaska, California, and Texas will be presented. In addition, lessons-learned in applying site-specific risk-based decision-making in the overall remedial process will be summarized.

346 SUBCHRONIC HEALTH EFFECT LEVELS FOR CHILDHOOD EXPOSURE TO ARSENIC.

J. S. Tsuji, R. A. Schoof and G. C. Hook. *Exponent, Bellevue, WA.*

The recent U.S. EPA policy to evaluate health risks to children has directed attention toward short-term exposures to chemicals in young children, even for chemicals regulated as long-term carcinogens. This paper reviews available data for a subchronic health effect level for arsenic exposure in ages 0-6, the focus of EPA assessments for children. A number of epidemiological studies have examined arsenic exposures primarily via drinking water. Studies noting health effects involving children in these populations were from Chile, China, Hungary, India, Japan, Mexico, Singapore, Thailand, and Taiwan. The following observations were noted: (1) dermatoses are consistently reported in both adults and children with hyper pigmentation reported at the lowest exposure levels (i.e., arsenic concentration in water); (2) the prevalence and severity of disease increase with age and exposure level; (3) studies tend to report mean exposure levels for the population rather than the level for those with health effects; (4) few studies give a detailed breakdown of disease prevalence with exposure level and age group. A study from West Bengal best documents prevalence of dermatoses by exposure level and age and indicates a no adverse effect level (NOAEL) below 100 ppb for children age 0-9 years. The other studies, although not as precise, are consistent with this level. Depending on drinking water intake rate and body weight assumed, this level would result in a subchronic NOAEL dose of approximately 0.008 mg/kg/day for hyperpigmentation. This dose is 10 times higher than the chronic NOAEL for skin and other effects used by EPA to develop the chronic reference dose for arsenic exposure.

347 DETERMINATION OF A HUMAN ACUTE NO OBSERVED ADVERSE EFFECT LEVEL (NOAEL) FOR COPPER.

K. A. Poirier[1], M. Araya[2], L. M. Klevay[3], J. J. Strain[4], F. H. Nielsen[3], P. Robson[4], M. C. McGoldrick[4] and S. R. Baker[5]. [1]*TERA, Cincinnati, OH,* [2]*Universidad de Chile, Santiago, Chile,* [3]*USDA, Grand Forks, ND,* [4]*University of Ulster, Coleraine, United Kingdom and* [5]*International Copper Association, New York, NY.*

This prospective, double blind controlled study was designed to determine the acute NOAEL of nausea in an apparently healthy population of individuals who drink copper containing water as the sulfate salt. Sixty adults, 30 of each sex and 18-60 years of age, were recruited at three different international sites (Coleraine, Santiago, and Grand Forks). Individuals with occupational copper exposure, at pregnancy or with gastrointestinal (GI) illness were excluded. Pharmaceutical grade copper was used to prepare testing solutions containing 0, 2, 4, 6, and 8 mg Cu/L (as copper sulfate) daily 30 minutes before administration by dissolving copper sulfate into freshly made room temperature, deionized water and maintained at the same temperature until dosing. Each subject was given a blind, randomly selected dose in a bolus of 200 ml (final total copper was equivalent to 0, 0.4, 0.8, 1.2, and 1.6 mg) over a consecutive 5 week period. Following dosing all subjects were monitored by health care personnel for 1 hour. All subjects completed questionnaires at 0 time, 15 minutes, 1 hour and 24 hours that screened for positive GI effects (nausea, vomiting, abdominal pain, and diarrhea). Nausea was the most frequently reported effect and was reported within the first 15 min. All other GI effects were reported within 1 hr. For the combined tri-site population (n = 180), 8, 9, 14, 25 and 44 subjects responded to one or more GI symptoms at 0, 2, 4, 6 and 8 mg Cu/L, respectively. Chi-square analysis of the data demonstrated a clear dose response to the combined positive GI effects and to nausea alone. Statistically significant greater reporting of effects occurred at 6 and 8 mg Cu/L. Therefore, an acute NOAEL and LOAEL of 4 and 6 mg Cu/L, respectively is determined in a combined international human population.

348 HOW USEFUL IS REGRESSION ANALYSIS IN DETECTING DOSE-RESPONSE IN EPIDEMIOLOGY STUDIES WHEN ONLY A FRACTION OF THE POPULATION IS SENSITIVE? THE CASE OF METHYLMERCURY.

A. H. Stern[1] and L. R. Korn[2]. [1]*New Jersey Department of Environmental Protection, Trenton, NJ and* [2]*Dept. of Environmental and Community Medicine, University of Medicine and Dentistry of New Jersey-Robert Wood Johnson Medical School, Piscataway, NJ.* Sponsor: G. B. Post.

The existence of a dose-response in epidemiologic studies is generally determined from the linear regression slope after controlling for covariates. This approach assumes the entire population is equally sensitive to the toxicant and that response is a function only of dose and a random error function. However, sensitive sub-populations have been identified for a variety of toxicants, possibly including the neurodevelopmental effects of methylmercury (MeHg). The study of MeHg exposure in the Seychelles Islands has failed to find significant effects (dose-response slope not significantly different from zero). Using data on the error function in developmental test scores and MeHg exposure distribution from that study, and assuming plausible dose-response relationships for sensitive subpopulations, we conducted Monte Carlo simulations of the power of linear regression analysis to detect a dose-response relationship in the total population (n = 700), and to compare dose-response slopes in the total and sensitive populations. Linear regression did not reliably detect a dose-response relationship for most scenarios when sensitives were 5% of the total and for some scenarios when sensitives were 10% of the total. We also found that the dose-response slope for the total population underestimated the sensitive dose-response slope in all cases by about an order of magnitude. These findings may have important implications for detection and quantification of dose-response relationships from epidemiologic studies.

349 NONCANCER RISK ASSESSMENT FOR ARSENIC BASED ON ITS VASCULAR EFFECTS.

K. Crump[1], H. Clewell[1] and J. Yager[2]. [1]*KS Crump Group, ICF Consulting, Inc., Ruston, LA and* [2]*EPRI, Palo Alto, CA.* Sponsor: J. M. Gearhart.

Considerable controversy has centered on whether there is epidemiological or mechanistic evidence for a "threshold" for the carcinogenic effects of arsenic (As), or at least for a highly nonlinear dose-response. If a nonlinear or MOE approach were to be chosen for the cancer risk assessment for As, a noncancer effect could well become the primary determinant of an acceptable water contamination limit for As. The current USEPA oral Reference Dose (RfD) for As is 0.0003 mg/kg/day, which equates to a drinking water concentration of approximately 0.01 mg/L, assuming a 70-kg person drinks 2 liters of water per day. Thus the current Maximum Contaminant Limit for As in drinking water, which is 0.05 mg/L, is roughly a factor of 5 higher than the concentration that would be consistent with the RfD. This RfD was based upon skin changes and possible vascular complications observed in a Taiwanese population exposed to a mean concentration of As in drinking water of 0.17 mg/L; these effects were not observed in a control population exposed to a mean concentration of 0.009 mg/L. Unfortunately, there is nearly a 20-fold difference between the control concentration, which was used as a No-Observed-Adverse-Effect-Level (NOAEL) in the derivation of the RfD, and the concentration at which the effects of As were observed. In order to provide a more precise estimate of the threshold for the noncancer effects of As, the Benchmark Dose method was applied to a number of published epidemiological studies investigating the vascular effects of As. Endpoints examined included cerebrovascular disease, ischemic heart disease, peripheral vascular disease, diabetes mellitus and hypertension. The Benchmark Doses obtained from these studies provide a robust basis for identifying a NOAEL for the noncancer effects of As.

350 IMMUNOCHEMICAL DETETCTION OF TRICHLOROACYLATED PROTEINS IN TETRACHLOROETHENE-TREATED AUTOIMMUNE-PRONE MICE.

S. M. Green, M. F. Khan, B. S. Kaphalia and G. A. S. Ansari. *University of Texas Medical Branch, Galveston, TX.*

The extensive use of perchloroethene (tetrachloroethene, PCE) combined with improper disposal has lead to it becoming a common environmental contaminant. Recent studies have linked PCE exposure to autoimmune diseases (ADs) such as lupus and scleroderma, which could be attributed to binding of PCE or its metabolites to cellular macromolecules, forming adducts which act as haptens and elicit an autoimmune response. Therefore, we determined the formation and distribution of protein adducts in tissues after PCE treatment as a basis for examining its potential to cause ADs. In the present study, we used MRL lpr and MRL +/+ mice as a model of a population susceptible to ADs, since both strains spontaneously develop a type of murine lupus; although the lpr strain develops ADs much faster then the +/+. Mice were given either acute (1 dose) or subacute (1 dose every third day for 8 weeks) treatments of PCE (5 mmol/kg in corn oil by gavage) and were sacrificed 24 hours after the last dose. Immunohistochemistry was done on paraffin embedded tissue sections using an antisera that was raised in rabbits to trichloroacylated keyhole limpet hemocyanin and recognizes trichloroacylated proteins. Very intense reactivity was seen in the hepatic centrilobular areas of both acutely and subacutely treated mice of both strains, while no staining was seen in vehicle-treated controls. No differences in apparent staining intensity or tissue distribution were observed in males compared to females and adducts were not found in any other tissue examined. We conclude that the formation of hepatic trichloroacylated protein adducts in PCE-treated mice is not dependent on duration of dosing, strain or sex of the subject animal.

351 TRICHLOROETHYLENE INDUCED FORMIC ACID EXCRETION LEADS TO KIDNEY DAMAGE IN THE MALE FISCHER RAT.

T. Green, J. L. Dow and J. R. Foster. *AstraZeneca Central Toxicology Laboratory, Macclesfield, United Kingdom.* Sponsor: E. A. Lock.

Trichloroethylene is both nephrotoxic and a weak renal carcinogen in rats in 2 year studies. Its two major metabolites, trichloroethanol and trichloroacetic acid, have been shown to induce the sustained excretion of large amounts of formic acid in urine which may account for the observations in the 2 year studies. The consequences of formic acid excretion on the rat kidney have been investigated in male Fischer rats given trichloroethanol in drinking water at concentrations of 0, 0.35 and 1.0 g/l for 52 weeks. The rats excreted large amounts of formic acid in urine reaching a maximum after 12 weeks (~65 mg/24hr at 1 g/l) and thereafter declining to reach an apparent steady state at 40 weeks (15-20 mg/24hr). Urine from treated rats was more acidic throughout the study and urinary methylmalonic acid and plasma N-methyltetrahydrofolate concentrations were increased, indicating an acidosis, vitamin B12 deficiency and impaired folate metabolism respectively. The rats treated with trichloroethanol developed kidney damage over the duration of the study which was characterised by increased urinary NAG and protein excretion (from 4 weeks), increased basophilia, protein accumulation and tubular damage (from 12 to 40 weeks), increased cell replication (at week 28) and evidence of focal proliferation of abnormal tubules at 52 weeks. Overall, these findings provide a potential explanation for the results of the two year chronic studies.

352 TRICHLOROETHYLENE INDUCED VITAMIN B12 AND FOLATE DEFICIENCY LEADS TO INCREASED FORMIC ACID EXCRETION IN THE RAT.

J. L. Dow and T. Green. *AstraZeneca Central Toxicology Laboratory, Macclesfield, United Kingdom.* Sponsor: E. A. Lock.

Trichloroethylene is both nephrotoxic and a weak renal carcinogen in rats in 2 year studies. Whilst investigating the mechanism(s) involved in the development of nephrotoxicity and renal cancer it was observed that trichloroethylene induced a sustained excretion of large amounts of formic acid in urine. Both of the major metabolites, trichloroethanol and trichloroacetic acid, were found to induce this response, but not the minor metabolite S-(1,2-dichlorovinyl) cysteine. Addition of folic acid either to diet or drinking water modulated the response indicating that these rats were folate deficient. Two markers of vitamin B12 deficiency, methylmalonic acid and 5-methyltetrahydrofolate, were also markedly increased in urine and plasma respectively. The

increase in 5-methyltetrahydrofolate is consistent with a folate deficiency caused by an inhibition of the vitamin B12 dependant methionine salvage pathway. Other polychlorinated solvents, including carbon tetrachloride and chloroform, also increased urinary formate excretion and since both vitamin B12 and polychlorinated carbon atoms readily form free radicals, it is suggested that trichloroacetic acid and trichloroethanol interact with vitamin B12 through a free radical mechanism inducing a B12 deficiency and, as a consequence, a folate deficiency. As a result of the folate deficiency, excess formic acid, which is normally utilised through this pathway, is excreted in urine.

353 TOXICOKINETICS OF MONOCHLOROACETIC ACID IN ADULT MALE SPRAGUE-DAWLEY RATS AFTER DERMAL APPLICATION.

J. Siegrist[1], S. A. Saghir[1] and K. K. Rozman[2]. [1]*Univ. of Kansas Med. Center, Department of Pharmacology, Toxicology and Therapeutics, Kansas City, KS and* [2]*Univ. of Kansas Med. Center, Department of Pharmacology, Toxicology and Therapeutics: Kansas City, KS; Section of Environmental Toxicology, GSF-Institut für Toxikologie, Neuherberg, Germany.*

Male Sprague-Dawley rats were dosed with a nontoxic dose of 10 mg/kg and a toxic dose of 125 mg/kg (~LD_{20}) dermally. An area of about 3-4 cm^2 was shaved slightly posterior to the scapulae of the rats and ^{14}C-MCA (2.5-3.0 μCi/kg) in acetone was applied onto the skin at 0.5 ml/kg. Acetone was allowed to evaporate. Thereafter, the dosing site was covered with parafilm which was then secured with masking tape. Three animals were euthanized at 15, 45 min, 2, 4, 8, 16, and 32 h after dosing and tissues collected by gross dissection. Radioactivity in tissue aliquots and excreta was determined by scintillation counting after digestion. Absorption was rapid through the skin (>50% within 45 min and about 80% within 4 h). About 93% dose penetrated through the skin within 32 h. Concentration of MCA in plasma and all other tissues peaked by 45 min after application (0.17% of absorbed dose), with the exception of thymus which peaked at 2 h. Radioactivity in brain and thymus declined very slowly from peak concentrations. Within 45 min, >10% of the absorbed dose was metabolized and cleared via bile followed by reabsorption. At the toxic dose, concentration in plasma peaked at 0.36% of the absorbed dose by 45 min and declined thereafter. Concentration in almost all of the other tissues peaked by 4 h with the exception of lung, muscle and skin where peak concentrations were found at 2 h after application. Again, similar to the nontoxic dose, 9% of the absorbed radioactivity appeared in small intestine within 45 min followed by reabsorption within 8 h. Fecal excretion was negligible. A total of 32 and 64% of the absorbed dose was recovered in urine by 32 h after the nontoxic and toxic dose, respectively. The plasma half-life of elimination of MCA after dermal application was about 2 h. Dermal application of MCA did not cause any overt toxicity (coma and/or death) up to 100 mg/kg. Doses 125, 150, and 175 mg/kg caused 20, 60, and 100% coma and death, respectively.

354 RENAL MITOCHONDRIAL ACONITASE FROM TETRAFLUOROETHYLCYSTEINE-TREATED RATS IS COVALENTLY MODIFIED BY DIFLUOROTHIOACETYL FLUORIDE AND POSSESSES DECREASED ACTIVITY.

E. A. James[1], S. P. Gygi[2], M. L. Adams[1], S. D. Nelson[1] and S. A. Bruschi[1]. [1]*Department of Medicinal Chemistry, University of Washington, Seattle, WA and* [2]*Department of Molecular Biotechnology, University of Washington, Seattle, WA.*

The site-selective nephrotoxicant tetrafluoroethylene (TFE) is bioactivated through sequential metabolism by glutathione-S-transferase, γ-glutamyl transpeptidase, cysteinylglycine dipeptidase, and cysteine-S-conjugate β-lyase. The ultimate toxicant, difluorothioacetyl fluoride (DFTAF), is a potent thioalkylating agent. In order to better understand the pathological sequalae of TFE-mediated toxicity, studies were performed to identify and characterize the DFTAF target previously designated P99. We utilized differential centrifugation, a DEAE anion exchange column, and SDS-PAGE with silver staining to isolate and visualize mitochondrial proteins from the renal proximal tubular epithelium of tetrafluoroethylcysteine (TFEC) -treated rats. Immunoblot analysis utilizing an anti-trifluoroacetyl antibody with confirmed selectivity for difluorothioamidyl lysine (DFTAL) moieties detected a DFTAL protein adduct with an apparent molecular mass of 99kD. Silver-stained bands containing this target protein were excised from polyacrylamide gels, destained, and subjected to in-gel digestion with trypsin. Tryptic peptides were analyzed by tandem mass spectrometry using a microcapillary liquid chromatography interface. The software Sequest™ was used to match collision-induced dissociation spectra against theoretical spectra of tryptic peptides in the OWL protein sequence database. The parent protein was found to possess a very high degree of sequence similarity to bovine mitochondrial aconitase (m-aconitase). (A sequence for rodent m-aconitase was not available.) Whole kidney homogenates from TFEC-treated rats were found to have significantly less aconitase activity than control tissue homogenates. We propose that DFTAF adduction of m-aconitase in the rat proximal tubular epithelium compromises turnover of citrate and constitutes an early event in the pathologic sequelae arising from exposure to TFE. (Supported by NIH GM51916 [SAB], P30 ES07033 [SDN], and the Merck Research Scholar Program [EAJ].)

355 POLYCHLORINATED BIPHENYLS ENHANCE INTRACELLULAR CALCIUM THROUGH PURINERGIC RECEPTOR ACTIVATION IN HUMAN MACROPHAGES.

M. Dehnhardt[1], D. Desaiah[2] and H. Wiegand[1]. [1]*Med. Inst. Envir. Hyg. Heinrich Heine University Duesseldorf, Duesseldorf, Germany and* [2]*Dept. Neurology, University Mississippi Medical Center, Jackson, MS.*

Polychlorinated biphenyl compounds (PCBs) are environmental neurotoxicants shown to exert their toxicity through increased intracellular calcium $[Ca^{2+}]_i$ in a number of cells. The mechanism of the disruption of calcium homeostatis by PCBs is not well understood. However, the non-planar but not co-planar PCBs were shown to disrupt calcium dependent signalling pathways. For many of the calcium homeostasis regulating purinergic receptor sub-types including P2X and P2Y adenosine trisphosphate (ATP) is a natural ligand. Human macrophages are known to express both $P2X_7$ and $P2Y_2$ receptors. Therefore, the objectives of this study were to determine whether PCBs enhance the $[Ca^{2+}]_i$ in human macrophages and, if so, is it due to the activation of purinergic receptors. Human monocyte derived macrophage cultures were treated with different concentrations of ATP, PCBs and iNOS modulators. The $[Ca^{2+}]_i$ imaging was conducted using Fura-2 as fluorescent probe. The results obtained showed that the $[Ca^{2+}]_i$ was increased as a function of ATP concentration with an EC_{50} of 7.1 μM. PCB 47, a non-planar PCB enhanced the ATP mediated $[Ca^{2+}]_i$ increase as evidenced by a shift of ATP dose-response curve to the left reducing the EC_{50} of ATP from 7.1 to 1.5μM. PCB 77, a co-planar PCB had no effect on purinergic receptor activity. N^G-amino-L- arginine (NAA), an inhibitor of iNOS increased the ATP mediated $[Ca^{2+}]_i$. SN-acetyl-L-,D-amino-pencillate (SNAP), a NO donor reduced the effects of both PCB 47 and NAA. Immunohistochemistry showed that PCB 47 induced iNOS. This effect was completely abolished by benzoyl-ATP, a specific $P2X_7$ agonist. These data clearly demonstrate for the first time that PCBs increase $[Ca^{2+}]_i$ by the modulation of purinergic receptors in human macrophages. These data further suggest that NO regulation depends on $P2X_7$ receptors in human macrophages. (This work was supported by Deutsche Forschungsgemeinschaft.)

356 COPLANAR PCB CONGENERS ARE UTEROTROPIC IN PRE-PUBERTAL RATS.

R. F. Seegal. *Wadsworth Center, NYSDOH, Albany, NY.*

There is considerable controversy whether dioxin-like coplanar polychlorinated biphenyl (PCB) congeners are estrogenic or anti-estrogenic. Determining the effects of these contaminants is important because, in addition to possible effects on reproduction, alterations in the hormonal milieu of the immature brain induced by these PCB congeners may negatively affect normal development leading to long-lasting changes in neurochemical function and behavior. We exposed prepubertal rats intra-peritoneally on postnatal days (PND) 21 and 22 to one of three coplanar PCB congeners: 3,4,3',4'-tetrachlorobiphenyl (TCB), at doses of 3 to 27 mg/kg; 3,4,5,3',4'-pentachlorobiphenyl (PtCB), at doses of 16 to 400 μg/kg or 3,4,5,3',4',5'-hexachlorobiphenyl (HCB), at doses from 100 to 800 μg/kg and measured uterine wet weight (UWW) in a blinded fashion on PND24. TCB, at doses ≥ 9 mg/kg and PtCB at doses ≥100 μg/kg significantly elevated UWW. HCB, a PCB congener highly resistant to metabolism, was not uterotropic at any of the doses. The anti-estrogen ICI 182,780 (0.5 mg/kg on PND21 and 22) completely blocked the uterotropic actions of TCB and PtCB, suggesting that these coplanar PCB congeners act through the estrogen receptor (ER). In additional experiments, we exposed prepubertal rats to PtCB and varying doses of 17β-estradiol (E_2). Concentrations of E_2 that did not alter UWW blocked the uterotropic actions of PtCB. These results suggest that coplanar congeners, capable of being metabolized to biphenylols, are uterotropic, act through the ER and appear to bind poorly to the ER. (Supported in part by NIEHS grant ES04913 to RFS.)

357 INSULIN RELEASE FROM RINM5F CELLS PRODUCED BY POLYBROMINATED AND POLYCHLORINATED BIPHENYLS (PBBS and PCBS).

M. A. Wagner and L. J. Fischer. *Michigan State University, East Lansing, MI.*

The structural similarities of PBBs and PCBs are consistent with published reports showing similar toxic actions produced by these two classes of environmental contaminants. However, differences in the physical properties of brominated and chlorinated organic molecules may result in quantitative, if not qualitative differences in their actions. Non-coplanar PCBs are known to stimulate insulin release from RINm5F cells by a calcium and kinase-dependent mechanism. The present study examines the potency of PBBs in producing the hormone-releasing effect. Experiments using a commercial PBB mixture (Firemaster-FF1) indicated that exposure of cells to 10 μg/ml in media produced a slight increase in insulin release compared to control (21.3 ng insulin/μg DNA vs 14.0 ng insulin/μg DNA)during a 120 min exposure period. A comparison of insulin release by identical pure congeners of PBBs and PCBs indicated striking differences. 2,2',4,4',5,5'-Hexabromobiphenyl (30μM) produced a 21% increase over control in media insulin whereas the identical chlorine-containing congener yielded a 342% increase in a 30 min exposure period. The 2,2'-dihalogenated congeners exhibited a different pattern as 30 μM of the dibromo congener provided a 274% increase in media insulin over control and the dichlobiphenyl congener produced a 189% increase. The shapes of the dose-response curves of the dibromo and dichloro biphenyl congeners were identical suggesting similar mechanisms of action. The results indicate that both PBBs and PCBs can elicit insulin release but the structure-activity relationships for this effect appear to be different. Based on results from the limited number of congeners studied, increasing the bromine content of PBBs attenuated activity whereas an increase in chlorine content of PCBs enhanced activity.

358 REACTIVITY OF HALOGENATED AND NON-HALOGENATED DIHYDROXY-BIPHENYLS *IN VITRO* AND IN CELLS IN CULTURE.

G. Ludewig[1], H. J. Lehmler[2], R. Boivin[2], A. Srinivasan[2] and L. W. Robertson[2]. [1]*Dept. Nutrition & Food Science, University of Kentucky, Lexington, KY and* [2]*Grad. Center for Toxicology, University of Kentucky, Lexington, KY.*

Several non-halogenated and halogenated biphenyls are suspected to be carcinogenic by being metabolized to dihydroxy-biphenyls or their quinones. For example, 2,5-dihydroxybiphenyl is a major metabolite of the fungicide orthophenylphenol that induces bladder cancer in rats. The leukemogene benzene is metabolized to phenol and further by peroxidases to 4,4'- and 2,2'-dihydroxybiphenyl, making both of them and their quinones possible candidates as the ultimate carcinogens of benzene. Also, chlorinated 4,4'-dihydroxybiphenyls are formed during industrial processes, but very little is known about these compounds. To learn more about the chemical and biological reactivity of such dihydroxy-biphenyls, and to determine structure activity relationships, we analyzed biphenyls with the hydroxyl groups in the positions 2,5- (2,5-BP), 3,4- (3,4-BP), 2,2'-(2,2-BP), and 4,4'- (4,4-BP), as well as 3,5,3',5'-tetrachloro-4,4' (TCBP), and 3,5,3',5'-tetrabromo-4,4'-biphenol (TBBP). We determined spectrophotometrically *in vitro* spontaneous and enzymatic oxidation and binding to glutathione, analyzed cytotoxicity by measuring 3H-thymidine incorporation and detected depletion of intracellular glutathione with the monobromobimane fluorescence assay. 2,5-BP was so reactive that it readily autoxidized in aqueous solution. The other biphenols were stable. All but 2,2'-BP were oxidized enzymatically by peroxidase/H2O2. The biphenols were cytotoxic at micromolar concentrations. The order of toxicity, 2,2'-BP < 4,4'-BP < TCBP < TBBP < 3,4-BP < 2,5-BP, paralleled the order of intracellular GSH depletion. We conclude that i. the position of the hydroxyl groups strongly influences the reactivity, ii. halogenation increases the cytotoxicity of 4,4'-BP, iii. cytotoxicity may be caused by oxidation to the quinone and binding to cellular sulfhydryl-containing compounds. Redox reactions, GSH depletion, and binding to cellular molecules may play a role in cancer initiation and promotion. (Supported by grants DAMD 17-96-1-6262 from DOD, P42 ES 07380 from NIEHS/EPA, and grant # 85-001-13-IRG from the American Cancer Society.)

359 RELATIVE POTENCY VALUES FOR INDIVIDUAL POLYCHLORINATED BIPHENYL CONGENERS FOLLOWING SUBCHRONIC DIETARY EXPOSURE.

E. Fattore[1], I. Chu[2], C. Trossvik[1] and H. Håkansson[1]. [1]*National Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden and* [2]*Health Protection Branch, Tunney's Pasture, Ottawa, Ontario, Canada.*

Polychlorinated biphenyls (PCBs) is a class of man-made chemicals consisting of 209 isomers with variable pattern of chlorine substitution. Although they were banned, they are still widely spread in the environment and many of them accumulate in fatty tissues of living organisms causing a broad range of adverse effects. In this study the potencies of individual chlorinated biphenyl (CB) congeners to modify vitamin A levels in liver and kidney and to increase liver 7-ethoxyresorufin-O-deethylase (EROD) activity, were investigated in Sprague-Dawley rats exposed to CB 126, CB 118, CB 77, CB 153, CB 128, CB 28, CB 105 and CB 156 for 13 weeks in their diets. The dose-response relationships were determined in order to calculate the relative potency (REP) values. Results showed almost the same order of potency of the congeners for the three investigated end points. EROD activity was the most sensitive end point followed by hepatic vitamin A reduction and by kidney vitamin A increase. The most powerful congeners, except CB 126, were CB 156 followed by CB 77 and CB 105. The REP values estimated for these congeners were in good agreement with the Toxic Equivalency Factors (TEFs) estimated for human risk assessment.

360 HEPATIC UPTAKE AND BIOLOGICAL ACTIVITY OF HALOGENATED AROMATIC HYDROCARBONS (HAHS) IN PRECISION-CUT RAT AND HUMAN LIVER SLICES.

J. R. Olson, B. P. McGarrigle, J. A. Hand, L. H. Chi, A. T. Drahushuk, H. B. Greizerstein and P. J. Kostyniak. *Department Pharmacology and Toxicology, SUNY at Buffalo, Buffalo, NY.*

Precision-cut rat and human liver slices in dynamic organ culture were utilized as an *in vitro* model to assess the hepatic uptake of HAHs and expression of dioxin responsive genes, including cytochrome P450 (CYP) 1A1, 1A2, and 1B1. Liver slices were incubated with medium containing HAHs, individually and in defined mixtures, or vehicle alone (0.1% DMSO) for 24 hrs and in HAH-free medium for an additional 72 hrs. The concentration of HAHs in culture medium and/or liver slices was determined at 24 hrs by GC with electron capture detection. The hepatic concentration of HAHs increased in direct proportion with the exposure and remained generally unchanged over the period form 24 to 96 hrs, when the slices were incubated in medium without HAHs. Similar hepatic concentrations of HAHs were also observed in rat and human liver slices following a given *in vitro* exposure. Dose response relationships for CYP1A1 mediated 7-ethoxyresorufin o-deethylase (EROD) activity in rat liver slices support a dioxin toxic equivalency factor (TEF) of 1.0 for 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), 0.5 for 2,3,4,7,8-pentachlorodibenzofuran (PeCDF), 0.1 for polychlorinated biphenyl (PCB) 126, 0.0001 for PCB 118 and 0 for PCB 153. Exposures to various binary mixtures of PCB 126 and 153 and tertiary mixtures of TCDD, PeCDF, and PCB 126 support the additive activity (based on EROD) of these HAHs. In general, human rat liver slices respond similarly to these HAHs (within a factor of 10), but exhibit a greater interindividual variability in the potency of a given HAH and the magnitude of EROD activity following *in vitro* exposure. Thus, this *in vitro* model not only provides a better means to extrapolate data to humans, but provides data on the range of responses observed in different individuals and a tool to investigate mechanisms which contribute to this variability. (Supported by US EPA R 825808.)

361 DEVELOPMENTAL EXPOSURE TO AROCLOR® 1254 ALTERS CALCIUM BUFFERING AND PROTEIN KINASE C ACTIVITY IN THE BRAIN.

P. R. S. Kodavanti, W. R. Mundy, E. C. Derr-Yellin and H. A. Tilson. *USEPA, Neurotox Div., Research Triangle Park, NC.*

Developmental exposure to polychlorinated biphenyls (PCBs) causes cognitive deficits in humans and animals; however, the underlying mode of action is not known. We have hypothesized that altered signal transduction may be associated with the neurotoxicity of PCBs, since second messengers such as Ca^{2+} and protein kinase C (PKC) play key roles in neuronal function and development. Our previous *in vitro* studies indicate that *ortho*-PCBs affected second messenger events at low micromolar concentrations while non-*ortho* PCBs did not. Subsequent repeated exposure studies with Aroclor 1254 in adult rats showed that *ortho*-PCBs preferentially accumulated in brain up to

13-15 ppm (equivalent to 40-50 μM) and decreased Ca^{2+} buffering as well as PKC activity which is in agreement with *in vitro* results. The present study was designed to determine if developmental exposure to Aroclor 1254 causes similar neurochemical changes. Pregnant dams were dosed orally with 0, 1 or 6 mg/kg/day Aroclor 1254 (Lot # 124-191, AccuStandard; contains mostly *ortho*-PCBs) from GD6 through PND21. The brains from pups at PND 4, 7, 14, 21, and 60 were assayed for Ca^{2+} buffering and PKC activity. Both microsomal and mitochondrial Ca^{2+}-uptake in frontal cortex increased during development reaching maximum at PND21, while total PKC activity increased from PND4 to PND14, and remained elevated until PND60. Developmental exposure to Aroclor 1254 increased microsomal Ca^{2+}-uptake from PND4 through PND21 with a decrease at PND60; however, mitochondrial Ca^{2+}-uptake was not altered. Exposure to Aroclor 1254 resulted in a dose-dependent decrease in PKC activity at PND14 and 21, which recovered to control levels by PND60. The distribution of PKC activity between the cytosol and membrane was not altered by Aroclor 1254. Total PCBs accumulated in frontal cortex of PND21 animals were 2.4 ppm and predominantly *ortho*-PCBs. These results suggest that developmental exposure to a PCB mixture altered second messengers in the brain and *ortho*-PCBs were accumulated in the brain at concentrations where significant *in vitro* effects were observed. (This abstract does not necessarily reflect USEPA policy.)

362 STRUCTURE ACTIVITY RELATIONSHIPS BETWEEN SELECTED POLYCHLORINATED BIPHENYL CONGENERS AND METABOLITES TOWARDS ACTIVATION OF RYANODINE RECEPTOR TYPE 1.

P. W. Wong[1], E. Mai[1], L. G. Hansen[2], C. E. Garner[3] and L. N. Pessah[1]. [1]*University of California, Davis, CA,* [2]*University of Illinois, Urbana, IL and* [3]*DuPont Pharmaceuticals Company, Newark, DE.*

We have previously reported that selected *ortho*-substituted polychlorinated biphenyl (PCBs) congeners alter Ca^{2+} regulation in both isolated microsomes and cultured PC12 cells. In order to further understand the mechanism(s) by which PCBs disrupt Ca^{2+} signaling, we performed a study detailing structure activity relationships between thirty-one PCB congeners and twelve PCB metabolites towards activation of ryanodine receptor type 1 (RyR1, a microsomal Ca^{2+} release channel expressed in skeletal muscle and $CD19^+$ B lymphocytes etc.). The activity of RyR1 with varying concentrations of selected PCB congeners was monitored by a radioligand binding assay using [^{3}H]ryanodine (the conformation selective probe specific for ryanodine receptors) and microsomal preparations enriched in RyR1 isolated from rabbit fast-twitch skeletal muscle. Our results revealed that the *ortho*- and *meta*-chloro-substitutions on the biphenyl structure of PCBs were the most determinants towards RyR1 activity. Among the thirty-one congeners tested, fourteen environmentally relevant congeners were examined. PCB 18, PCB 52 and PCB 187 are highly efficacious towards activation of RyR1, while PCB 41, PCB 101 and PCB 110 are with intermediate efficacy. Of all the tested congeners, PCB 136 (2,2',3,3',6,6'-hexachlorobiphenyl) is the most efficacious and potent congener (EC_{50} = 575 nM). These results enable us to predict the potency or efficacy of other environmentally relevant PCB congeners/metabolites on disruption of cellular Ca^{2+} signaling. Hence the study provides important information on further investigation of the mechanism(s) by which PCBs induce toxicity in humans. (Research is sponsored by NIEHS.)

363 MECHANISM OF INHIBITION OF STIMULATED NEUTROPHIL DEGRANULATION BY 2,2',4,4'-TETRACHLOROBIPHENYL.

P. E. Ganey[1], J. Olivero-Verbel[1] and B. V. Madhukar[2]. [1]*Dept. of Pharmacology and Toxicology, Institute for Environmental Toxicology and National Food Safety and Toxicology Center, Michigan State Univ., East Lansing, MI and* [2]*Dept. of Pediatrics and Institute for Environmental Toxicology, Michigan State Univ., East Lansing, MI.*

Ortho-substituted polychlorinated biphenyls (PCBs) like 2,2',4,4'-tetrachlorobiphenyl (2,2',4,4'-TCB) can activate neutrophils but also decrease activation in response to the peptide f-met-leu-phe (fmlp). The objective of this study was to examine mechanisms by which 2,2',4,4'-TCB inhibits degranulation. Degranulation of neutrophils exposed to fmlp was associated with activation of phospholipase A2 (PLA2). Degranulation and PLA2 activation were both inhibited by BEL, an inhibitor of calcium-independent PLA2 (iPLA2), suggesting that this isozyme is essential for degranulation. 2,2',4,4'-TCB also activated PLA2, but despite this, 2,2',4,4'-TCB abolished fmlp-induced degranulation. Calcium ionophores failed to restore the degranulation response in the presence of 2,2',4,4'-TCB and fmlp, suggesting that interference with intracellular calcium was not responsible for the inhibitory effect. Mitogen-activated protein kinases (MAPKs) are also important in fmlp-stimulated degranulation, but 2,2',4,4'-TCB increased phosphorylation of MAPK, indicating that this pathway was still functional. Electron microscopic examination of neutrophils revealed granules in close apposition to the membrane in fmlp-treated cells but not in neutrophils cotreated with 2,2',4,4'-TCB. These data suggest that the impairment of neutrophil degranulation observed with 2,2',4,4'-TCB may be related to the prevention of vesicle fusion with the plasma membrane. (Supported by ESO4911.)

364 A COMMON ELECTROTOPOLOGICAL MOTIF AMONG ORGANOCHLORINE COMPOUNDS THAT ACTIVATE NEUTROPHILS.

J. Olivero-Verbel and P. E. Ganey. *Department of Pharmacology and Toxicology, Inst. for Environmental Toxicology and National Food Safety and Toxicology Center, Michigan State Univ., East Lansing, MI.*

Organochlorine compounds (OCs) are some of the main toxicants present in the food web and target different cellular systems including the non-specific immune system. The objective of this study was to test the hypothesis that OCs that activate neutrophils share common structural features. Using activation of phospholipase A2 (PLA2) as a marker of neutrophil activation, isolated, rat neutrophils were exposed to a variety of OCs. The ortho-substituted polychlorinated biphenyl, 2,2',4,4'-tetrachlorobiphenyl, the alpha-, delta- and gamma-hexachlorocyclohexanes (HCCHs), dichlorodiphenyltrichloroethane (DDT), dieldrin, aldrin and chlordane, but not the non-orthochlorinated 3,3',4,4'-tetrachlorobiphenyl or beta-HCCH, induced activation of PLA2 in neutrophils. This activation of PLA2 was reduced by 60-80% by bromoenolactone (BEL), an inhibitor of Ca-independent PLA2 (iPLA2), and by the calmodulin inhibitors trifluoperazine and W7. These results suggest that all of the active OCs activate the same isoform of PLA2 and do so through Ca-calmodulin-dependent processes. Molecular modeling techniques were used to calculate molecular electrostatic potentials. Superimposing three-dimensional structures we have identified an electrotopological motif shared by all of the active OCs, as well as BEL. This motif was absent in the inactive OCs, beta-HCCH and the non-orthochlorinated PCBs. These results suggest that the bioactivity of OCs in neutrophils may be due to the presence of a specific substructure that fits into a receptor-like structure, allowing the activation of the neutrophil. (Supported by ESO4911.)

365 HEMOGLOBIN ADDUCTS OF POLYCHLORINATED BIPHENYLS AS POTENTIAL BIOMARKERS OF EXPOSURE.

N. Tampal[1], S. Myers[2], D. Pereg[1] and L. Robertson[1]. [1]*University of Kentucky, Lexington, KY and* [2]*University of Louisville, Louisville, KY.*

Lower polychlorinated biphenyls (PCBs) are known to form reactive metabolites. Proteins would be likely targets for attack by these electrophiles and covalent binding to the proteins would result in the accumulation of PCBs in both target and non-target tissues. This study investigates the formation of hemoglobin adducts using two PCBs. C57BL/6 mice (4 animals per group) were injected i.p. with phenobarbital (400 umol/kg) and B-naphthoflavone (100 umol/kg) for three consecutive days. On day 4, mice received i.p. either 14C 4-chlorobiphenyl, 14C 3,3',4,4'-tetrachlorobiphenyl, 14C benzo[a]pyrene (B[a]P) or vehicle. A second set of mice were treated with same doses of cold PCBs and B[a]P. Blood was collected at different time points from the tail vein. After removal of plasma, the red blood cells were lysed and the hemolysate was freed from the cellular debris by centrifugation. The total radioactivity in the hemolysate from both the hot PCB and B[a]P treated animals was found to be greater than the control group, suggesting adduct formation with hemoglobin. From the cold B[a]P/PCB treatments, globin was precipitated from the hemolysate using mild acidic conditions (0.1% HCl in acetone). LC-MS (electrospray) was then used to identify the adducts formed with globin. Our preliminary data showed an increase in mass corresponding to the adduct of the oxidized metabolite of at least one PCB. Detection of adducts of PCBs with hemoglobin could provide a valuable tool to evaluate exposure of a population. (Supported by P42 ES07380.)

366 COVALENT BINDING OF BENZO[A]PYRENE, 4-CHLOROBIPHENYL AND 3,3'4,4'-TETRACHLOROBIPHENYL TO NUCLEAR MACROMOLECULES IN FEMALE MICE.

D. Pereg, N. Tampal and L. W. Robertson. *University of Kentucky, Lexington, KY.*

Polychlorinated biphenyls (PCBs) are environmental pollutants and rodent carcinogens. Covalent binding of PCB metabolites to nucleophilic macromolecules was demonstrated *in vitro*, but few studies of such binding *in vivo* are available. The purpose of this study was to determine the binding affinity (carcinogen binding index, CBI) of benzo[a]pyrene, 4-chlorobiphenyl (4-CBP) and 3,3',4,4'-tetrachlorobiphenyl (3,3',4,4'-TCB) to nuclear macromolecules *in vivo*. C57/BL6 female mice were treated for three consecutive days with phenobarbital (400μmol/kg) and B-naphtoflavone (100μmol/kg), and on the fourth day, with 14C-labeled carcinogens. Mice were euthanized 24 hours later. DNA and chromatin proteins were extracted, separated and purified from whole livers by differential centrifugation and solvent extraction. DNA was further purified by hydroxylapatite chromatography. Radioactivity in DNA and nuclear proteins was determined by scintillation counting. Binding indexes were computed according to the concentration of chemical bound to macromolecules (umol chemical/mol amino acids or DNA) relative to the dose administered to the animals (mmol chem./kg body weight) or to the dose found in the liver (umol chem/g liver). Detection limits were computed based on the background readings of a corn oil-treated group. The protein binding index (PBI) was significantly lower for 3,3',4,4'-TCB (95% C.I.: 13.6±2.85) than for 4-CBP (95% C.I.: 29.6±9.65) and B[a]P (95% C.I.: 48.6±10.06) but all PBIs were significantly greater than detection limits (3.50, 4.85 and 3.09, respectively). Mean DNA binding indexes for B[a]P (95% C.I.: 1.81±1.5), 4-CBP (95% C.I.: 0.95±0.8) and 3,3',4,4'-TCB (95% C.I.: 0.77±1.1) were all greater than detection limits (0.63, 0.74 and 0.68, respectively) but these values were not statistically significant. This study shows that covalent binding of the tested compounds is significant for proteins. Binding to DNA is also suggested but not conclusive. (Supported P42 ES 07380.)

367 IDENTIFICATION AND CHARACTERIZATION OF ARYL HYDROCARBON RECEPTOR POLYMORPHISMS IN ATLANTIC TOMCOD (MICROGADUS TOMCOD) FROM ATLANTIC COAST POPULATIONS.

Z. Yuan, N. Roy, C. Sorrentino and I. Wirgin. *Department of Environmental Med., New York University School of Med., Tuxedo, NY.*

Cytochrome P4501A1 (CYP1A1) mRNA induction serves as an easily quantifiable surrogate marker for all biological responses to exposure to aromatic hydrocarbon (AHs), including halogenated AHs (HAHs) such as dioxins and PCBs, and polycyclic AHs (PAHs) such as B[a]P. Hepatic CYP1A1 mRNA induction was observed in adult tomcod from the Hudson River exposed to PAHs (B[a]P, b-NF, 3-MC), but induction was absent or at reduced levels in the Hudson River tomcod treated with HAHs (PCB congeners 77, 126, 169) even after fish were extensively depurinated in clean laboratory water. Both PAHs and HAHs induced hepatic CYP1A1 mRNA in fish from cleaner Canadian rivers (Margaree and Miramichi). We hypothesize that adaptation of the aryl hydrocarbon receptor (AhR) pathway has occurred in the Hudson River population due to chronic exposure to unusually high concentrations of AHs along with mixtures of other genotoxic xenobiotics. Restriction fragment length polymorphism (RFLP) analysis revealed high levels of structural diversity in AhR alleles among fish from four rivers. Four different exon-specific cDNA probes that spanned the entire AhR cDNA from exon 1 through exon 11 were developed to more precisely map the locations of these polymorphisms in tomcod AhR. One probe, which hybridized with fragments exclusively in exon 10, revealed two alleles, 0.86 kb and 0.67 kb. Three different genotypes, homozygotes for both alleles and a heterozygote, were observed. A second probe, which hybridizes with exon 11, revealed at least seven alleles among tomcod from these rivers. These polymorphisms were then characterized by direct sequencing of genomic DNA PCR products. Variation in exon 10 included a 6 nucleotide (nt) addition in Canadian fish starting after nt 3892 downstream of the transcription initiation site of the AhR genomic DNA sequence of tomcod from the Hudson River. These nucleotides are in frame and encode for two amino acids, phenylalanine (F) and leucine (L). Three other point mutations, two G-C transversions at nt 5174 and 5665 and a T-C transition at nt 5359 were found, but do not result in amino acid change. Characterization of exon 11 variation is ongoing.

368 ROLE OF CYTOCHROME P450 INDUCTION AND LIPID PEROXIDATION IN 3,3',4,4'-TETRACHLOROBIPHENYL (PCB-77) AND 2,2',4,4',5,5'-HEXACHLOROBIPHENYL (PCB-153)-INDUCED TOXICITY IN LIVER OF MALE RATS.

Z. A. Fadhel[1], Z. Lu[2], L. W. Robertson[2] and H. P. Glauert[2]. [1]*Jordan University for Women, Amman, Jordan and* [2]*University of Kentucky, Lexington, KY.*

Polychlorinated biphenyls (PCBs) are environmental contaminants that have been widely used for various industrial purposes. In spite of the numerous studies on PCBs, however, the mechanism of toxicity of PCBs remains unknown. The role of cytochrome P-450 in PCBs-induced hepatic lipid peroxidation is controversial. Therefore, the present study was undertaken to study the mechanism of action of two PCBs and their role in cytochrome P450 induction and lipid peroxidation. Two congeneric PCBs were studied: PCB-77, a non-ortho-substituted, coplanar PCB; and PCB-153, a di-ortho-substituted, nonplanar PCB. Groups of male Sprague-Dawley rats were given a single ip injection of one of the two PCBs (low and high doses), both PCBs at the low dose, or vehicle alone. Rats were killed after 2, 6, or 24 h; or 2, 6, or 10 days. Cytochrome P-450 induction occurred as early as 2 h with PCB-77 and 2 days with PCB-153. Significant increases of 1.4-, 2.3- and 2.3-fold and 1.8-, 3.1- and 2.3-fold in TBARS content in liver tissue occurred 2, 6 and 10 days after treatment with 150 umol/kg of PCB-77 and PCB-153, respectively. The results indicate that both PCBs induced cytochrome P-450 enzymes and enhanced lipid peroxidation in liver and subcellular fractions but with different potencies and onsets of action. The results also indicate a time difference between P-450 induction and lipid peroxidation. Thus, both PCB-77 and PCB-153 are toxic to cells, but may act via different mechanisms to induce their effects. (Supported by ES07380.)

369 PCB METABOLITES: CYTOTOXICITY, GLUTATHIONE DEPLETION AND INHIBITION OF TOPOISOMERASE II.

A. Srinivasan, L. W. Robertson and G. Ludewig. *University of Kentucky, Lexington, KY.*

PCBs are highly persistent contaminants in our environment. We have previously shown that lower halogenated PCBs can be metabolized to dihydroxy compounds that are further oxidized to (semi)-quinones, and this oxidation is associated with the formation of reactive intermediates, such as reactive oxygen species (ROS). In this study, we investigated the reactivity of these metabolites by analyzing 1. cytotoxicity to HL-60 human lymphoma cells 2. effect on GSH in cells & *in vitro* and 3. activity of topoisomerase II *in vitro*. Test compounds were dihydroxy- and quinone metabolites of mono-, di- and tri-chlorinated biphenyls. We found that the PCB metabolites are cytotoxic to HL-60 cells with LC50's ranging from 1 -15 μM. We hypothesized that the mechanisms of toxicity could be through GSH depletion. GSH depletion from HL-60 cells was measured using monobromobimane assay and GSH binding *in vitro* was measured using the method of Tietze. We found that PCB quinones bound to GSH in ratios of 1:2 *in vitro* and depleted GSH in HL-60 cells in a dose-dependent manner. The dihydroxy metabolites did not bind GSH *in vitro* and depleted GSH from cells only at higher concentrations than the quinones. To analyze the effect on other sulfhydryl-containing biological macromolecules, we measured topoisomerase II activity after exposure to the metabolites *in vitro*. The PCB quinones inhibited topoisomerase II while the PCB dihydroxy metabolites did not. Hence binding of the PCB quinones to cellular molecules, oxidation of the dihydroxy PCBs to the corresponding quinone, and oxidative stress may be the major causes for the cytotoxicity of these compounds. (Supported by DAMD 17-96-1-6262, NIEHS P42 ES 07380, and 85-001-12-IRG from the American Cancer Society.)

370 CONTRIBUTION OF RYANODINE-SENSITIVE Ca^{2+} POOL TO METHYLMERCURY (MeHg)-INDUCED CHANGES IN $[Ca^{2+}]_i$ IN RAT CEREBELLAR GRANULE NEURONS.

M. Sanchez, T. L. Stringfellow and W. D. Atchison. *Michigan State University, East Lansing, MI.*

Cerebellar granule cells are preferentially targeted during MeHg neurotoxicity, resulting in their death following both *in vivo* and *in vitro* exposure. In granule cells in culture, MeHg causes a multiphasic elevation of intracellular Ca^{2+} ($Ca^{2+}{}_i$) consisting of release of $Ca^{2+}{}_i$ stores ("first phase"), followed by influx of extracellular Ca^{2+} ("second phase") and subsequent cell death. The purpose of the present study was to identify the source of the first-phase Ca^{2+} elevation following MeHg exposure. We used the dye fura-2 and single cell microfluorimetry to monitor changes in $[Ca^{2+}]_i$ of neonatal rat cerebellar gran-

ule cells in culture. The presence of a ryanodine-sensitive Ca^{2+} pool was verified using 10 μM ryanodine to inhibit Ca^{2+}-induced Ca^{2+} release due to release of the IP_3-sensitive smooth endoplasmic reticulum (SER) Ca^{2+} pool. Subsequently we used 10 μM ryanodine to inhibit this Ca^{2+} pool during exposure to 0.5 μM MeHg. The time-to-onset of the two phases of Ca^{2+}_i elevations (intracellular and extracellular) in response to MeHg was measured, as was the amplitude of the first phase as a measure of the amount of Ca^{2+} released from intracellular pools. Inhibition of the ryanodine-sensitive Ca^{2+} pool resulted in delays of both the first phase (from 10.9±1.4 min to 20.2±3.6 min) and second phase (from 19.5±2.4 min to 28.0±4.3 min) Ca^{2+}_i elevations. Further experiments in a low Ca^{2+}, EGTA-containing buffer (to isolate the first phase) indicated a similar delay in the first Ca^{2+}_i phase as well as a 33% reduction in its amplitude, indicating the loss of a portion of the first phase during ryanodine pool inhibition. These results suggest that the SER ryanodine-sensitive Ca^{2+} pool contributes to the first phase elevation of Ca^{2+}_i induced by MeHg. (Supported by NIH grant ES03299.)

371 METHYLMERCURY (MEHG) ALTERS MITOCHONDRIAL CALCIUM HOMEOSTASIS IN RAT CEREBELLAR GRANULE NEURONS.

T. L. Stringfellow and W. D. Atchison. *Michigan State University, East Lansing, MI.*

The purpose of the present study was to test the effect of acute MeHg exposure on mitochondrial Ca^{2+} (Ca^{2+}_m) homeostasis using single cell microfluorimetry and the dyes fura-2 and rhod-2 to monitor changes in $[Ca^{2+}]_i$ and $[Ca^{2+}]_m$, respectively, in neonatal rat cerebellar granule cells in primary culture. Carbonyl cyanide *m*-chlorophenylhydrazone (CCCP) and oligomycin were used simultaneously to depolarize the mitochondria and prevent Ca^{2+}_m buffering. Treatment with CCCP+oligomycin followed by MeHg (0.5-1.0 μM) delayed significantly both the release of Ca^{2+}_i and influx of Ca^{2+}_e. The fluorescence due to Ca^{2+}_i release was almost completely abolished. Thus most of the Ca^{2+}_i released during early MeHg exposure originates in the mitochondria. Cells loaded with rhod-2 and exposed to 0.5 μM MeHg exhibited a multiphasic increase in fluorescence; the initial increase occurred at 7.9±1.5 min, which is before the onset of the first phase observed with fura-2. CCCP+oligomycin abolished this phase, suggesting that the fluorescence increase was from Ca^{2+}_m uptake. When CCCP+oligomycin was used with 0.5 μM MeHg in a low-Ca^{2+}, EGTA-containing media, only two increases in fluorescence were observed: the initial rise at 7.1±1.9 min, with an amplitude similar to that of physiological Ca^{2+}_m uptake; and a second increase several min later, when fluorescence increased above that seen with normal Ca^{2+}_m uptake. The early time-to-onset of the initial elevation suggests mitochondrial Ca^{2+} buffering from another Ca^{2+}_i source, possibly the smooth endoplasmic reticulum Ca^{2+} pools. The second elevation was associated with spreading of the dye from punctate mitochondrial staining to diffuse cytosolic staining, suggesting that the dye had leaked from the mitochondria, perhaps via opening of the permeability transition pore. These results suggest that mitochondria are an early target during low-concentration MeHg exposure, resulting in loss of Ca^{2+}_m buffering which occurs during the initial stages of altered Ca^{2+}_i homeostasis. (Supported by NIEHS grants R01 ES03299 and T32 ES07255.)

372 ASSESSMENT OF INTEGRIN PROTEIN EXPRESSION IN PC-12 CELLS AFTER METHYLMERCURY EXPOSURE.

J. E. Royland and S. Padilla. *USEPA, Research Triangle Park, NC.*

We are conducting a pilot project to investigate the use of integrins as early markers of developmental neuronal changes to neurotoxicants. Integrins serve to transduce signals bi-directionally between extra-cellular components such as extra-cellular matrix and cell adhesion proteins and intracellular components such as transduction pathway proteins and the cytoskeleton (Clark and Brugge, 1995). Formed from heterodimers of α and β protein subunits, the composition of the heterodimeric receptor is determined by tissue and cell type as well as specific cellular response (Huhtala et al., 1995). Integrins are intimately involved in a number of processes related to neuronal development, including cell migration (Georges-Labouesse, et al., 1998), maintenance or plasticity of synapses (Einherber et al., 1996), and axonal elongation (Murase and Hayashi, 1998). Currently our efforts are directed at identifying in *in vitro* studies profiles of integrin subunit protein expression using Western Blot analysis of PC-12 cells, which have been used extensively as a model of neurite outgrowth. We are monitoring changes in these profiles after exposure to the known neurotoxicant, methylmercury. PC-12 cells are converted to the neuronal phenotype by 7 days culture in nerve growth factor β (NGF) containing media. Cells are then detached, washed and replated in NGF free media ± 0.2 μM methylmercury and proteins extracted 1, 2, 4, 8, 12, 24 and 48 hrs post-treatment. Levels of integrin protein expression will be correlated with measurements of neurite outgrowth in control and experimental cultures. This abstract does not necessarily reflect US EPA policy.

373 TOXICITY OF THE CO-CONTAMINANTS 137CESIUM AND MERCURY ON THE DEVELOPING NEURON.

L. Fahey McGrath[1], K. G. Roberts[2] and K. R. Reuhl[2]. [1]*University of Medicine and Dentistry of New Jersey-Robert Wood Johnson Medical School, Environmental and Occupational Health Sciences Institute, Piscataway, NJ and* [2]*Joint Graduate Program in Toxicology, Rutgers University, Piscataway, NJ.*

137Cesium (137Cs) and mercury compounds, including methylmercury (MeHg), are co-contaminants found in fish from rivers and streams on and adjacent to several decommissioned nuclear processing facilities around the U.S. The present study explores the potential for both cesium (Cs) and radiocesium (137Cs) to modify MeHg toxicity. CsCl and 137CsCl alone and in combination with MeHg were added to cultures of developing neurons (derived from P19, embryonal carcinoma cells) during neuronal differentiation. After 2 days of differentiation in retinoic acid, P19 cells were exposed to MeHg, CsCl, or 137CsCl individually and in combination for 2 hrs. Cells were stained with an antibody to tyrosinated a-tubulin, and microtubules were examined by fluorescent microscopy as an index of toxicity during early differentiation. Data demonstrated a dose-dependent disruption of microtubules in cells treated exclusively with MeHg. Treatment with CsCl alone did not disrupt microtubules during neuronal differentiation. In addition, CsCl did not modify MeHg toxicity at concentrations up to 275 nM. Cells treated with 137 CsCl alone did not significantly alter microtubules at concentrations up to 10pCi. However, MeHg and 137CsCl treatment increased cell damage, characterized by cytoplasmic blebbing, complex membrane invaginations, and loss of membrane integrity at concentrations of 1.0 μM MeHg and 0.1 pCi 137 CsCl. This effect became more robust with increasing concentrations of radiocesium and mercury. The addition of 137CsCl did not alter the dose-response of microtubules to MeHg. Data suggest that 137Cs and MeHg are not acting through a common mechanism of microtubular disruption. These effects could have implications in established risk estimates associated with ingestion of mercury and 137Cs contaminated fish near Department of Energy sites. (Research funded in part by NIEHS #ES05022,ES04976, and DOE #DE-FC01-95EW550084.)

374 MICE WITH METALLOTHIONEIN-III OVER-EXPRESSION IN BRAIN: COMPARISON TO C57/BL6 MICE IN BEHAVIORAL EFFECTS OF METHYLMERCURY (MEHG).

C. Wang and H. L. Evans. *NYU School of Medicine, New York, NY.*

The MT-III isoform of Metallothionein, expressed primarily in neurons, may have important roles in protecting the nervous system from exposure to metals as well as a role in regulating neurobehavioral function. Mice with an over-expression of human MT-III (MT+/+) in brain were evaluated as potential models of the functional significance of MT in Neurotoxicology. Repetitive circling behavior was exhibited by 25% of the offspring of MT+/+ mice. This circling occurred in response to handling or other stimulation. MT+/+ mice which did not exhibit the circling were similar to mice of C57B6 and 129SV/LMT strains in growth and locomotor behavior. The mice were then exposed to MeHg in drinking water (8 or 32 ppm) for 14 days. Exposure to 32ppm caused the C57BL6 mice to begin losing weight and begin dragging the hind feet after 14 days of exposure. Early in the MeHg exposure, MT+/+ mice exhibited less habituation to an unfamiliar test cage, than did C57BL6 mice. The reduced habituation during exposure to MeHg was similar to that observed in rats during oral exposure to Pb (Gong & Evans, Toxicol. Appl. Pharmacol. 144:205, 1997). MT+/+ mice which exhibited repetitive circling became even more active during exposure to MeHg. There was no evidence that MT+/+ mice were much less sensitive to MeHg than other "normal" strains. These findings indicate the importance of determining the neurobehavioral baseline of genetic variants before one can interpret the effects of a toxicant. MT+/+ source mice provided by Dr. R. Palmiter (U. Wash.). (Supported by a Center Grant ES-00260.)

375 EFFECTS OF PROTEIN-DEFICIENT NUTRITION DURING PREGNANCY AND DEVELOPMENT ON DEVELOPMENTAL HINDLIMB CROSSING DUE TO METHYLMERCURY INTOXICATION.

S. K. Chakrabarti and C. Bai. *Université de Montréal, Montréal, Quebec, Canada.*

The effects of methyl mercury intoxication on the clinical neurological signs due to protein-calorie malnutrition in children are not known sufficiently. Timed pregnant Sprague-Dawley rats were fed either a control (20% protein) or low (3.5% protein) diet during gestation and lactation. The pups were separated from their mothers of each diet group on postnatal day 21, and were given the same diets as those of their corresponding mothers. The groups of pups from each diet group were treated either on postnatal day 21, or postnatal day 60 with 7.5mg methylmercury chloride (MeHgCl) per kg b.w. once daily by gavage for 10 consecutive days and the development of ataxia (hind limb crossing) was monitored. The offspring from protein-deficient diet were found to be more sensitive to MeHg-induced ataxia than those from protein-sufficient diet. Rats fed 3.5% casein diet accumulated more mercury in the different brain regions than those fed 20% casein diet. The rates of protein synthesis in different brain regions of offspring fed the protein-deficient diet were significantly reduced compared to those fed the protein-sufficient diet. However, MeHg treatment did not significantly modify further the rates of such protein synthesis in protein-deficient rats. Thus, increased inhibition of the rates of protein synthesis plus increased accumulation of mercury in different brain regions due to severe protein deficiency may result in increasing susceptibility of developing rats to MeHg-induced ataxia, or hind limb crossing. (Supported in part by FRSQ, Environmental Health.)

376 INHIBITORS OF ASTROCYTIC EXCITATORY AMINO ACID TRANSPORTER FUNCTION ALSO DECREASE MRNA LEVELS.

J. W. Allen and M. Aschner. *Wake Forest University School of Medicine, Winston-Salem, NC.*

Removal of the potentially neurotoxic excitatory amino acids (EAAs) aspartate and glutamate from the synaptic cleft is accomplished via a family of transporters localized on astrocytes (GLAST and GLT-1) and neurons (EAAC1 and EAAT4). Astrocytes are responsible for the majority of the EAA uptake, and are also responsible for the subsequent metabolism of glutamate to glutamine. Previous studies (Trotti et al, 1997) have shown EAA uptake induced current in astrocytes is decreased by oxidation of thiol-containing cysteine residues with 5,5'-ditho-bis-2-nitrobenzoic acid (DTNB) and increased by reduction of protein thiols with dithiothreitol (DTT). MeHg, a thiol reactive neurotoxicant, inhibits EAA uptake as does the non-thiol reactive competitive analog threo-β-hydroxy-aspartic acid (THA). This study examined if mRNA levels of GLAST, the only EAA transporter constitutively expressed in primary astrocyte cultures, were altered during inhibition or facilitation of EAA transport. Confluent cultures of primary neonatal rat cortical astrocytes were exposed for 6 hours to MeHg (10 μM), the EAA transport inhibitor THA (1 mM), the thiol oxidizing agent DTNB (500 μM), or the thiol reducing agent DTT (1 mM). Steady state levels of GLAST mRNA were assessed by northern analysis and standardized to 28S rRNA levels. Inhibitors of EAA transport, THA and DTNB, significantly decreased steady state levels of mRNA following 6 hours of exposure (-34% and -26% respectively). MeHg, a weaker inhibitor of EAA transport, produced a lesser decrease (-17%), while DTT produced an increase (+17%) in GLAST mRNA levels. In general, mRNA levels of GLAST reflected functional state of the transporter following 6 hours of inhibition or potentation. These data suggest GLAST mRNA levels may be regulated by the activity of the transporter. Conditions producing changes in the function of the transporter, such as over-production of free radicals, may cause not only acute inhibition of function, but also prolonged inhibition of uptake due to decreased mRNA transcription. (This study was supported by NIEHS 07331 to MA. JWA is a NIAAA trainee, T32 AA07565.)

377 FOREIGN METALLOTHIONEIN-I (MT-I) EXPRESSION BY TRANSIENT TRANSFECTION IN MT-I AND MT-II NULL ASTROCYTES CONFERS INCREASED PROTECTION AGAINST ACUTE METHYLMERCURY CYTOTOXICITY.

M. Aschner[1], C. P. Yao[1], J. W. Allen[1], L. A. Mutkus[1] and K. H. Tan[2]. [1]*Wake Forest University School of Medicine, Winston-Salem, NC and* [2]*Winston-Salem State University, Winston-Salem, NC.*

The mechanisms associated with metallothionein (MT) gene regulation are complex and poorly understood. Only a modest increase in brain MT expression levels is attained by exposure to metals, MT gene transfection, and MT gene knockin techniques. Accordingly, in the present study, MT null astrocytes isolated from transgenic mice deficient in MT-I and MT-II genes were introduced as a zero background model of MT expression. MT protein levels were determined by western blot analysis. MT proteins in MT-I and MT-II null astrocytes were undetectable. Transient MT-I gene transfection increased the levels of foreign MT expression in MT-I and -II null astrocytes by 2.3-fold above basal levels in wild type astrocytes. Intracellular Na251CrO4 efflux and D-[2,3-3H]-aspartate uptake were studied as indices of acute MeHg (5 mM) cytotoxicity. In MT-I and -II knockout astrocytes MeHg led to significant ($p<0.01$) increase in Na251CrO4 efflux and a significant ($p<0.05$) decrease in the initial rate (1 min) of D-[2,3-3H] aspartate uptake compared to MT-I and -II knockout controls. Transfection of the MT-I gene in MT-I and -II null mice significantly ($p<0.01$) decreased the effect of MeHg on Na251CrO4 efflux in MT null, as well as wild type astrocytes. MT-I gene transfection in MT-I and MT-II null astrocytes reversed the inhibitory effect of MeHg on D-[2,3-3H] aspartate uptake, such that initial rates of uptake in MT-I transfected cells in the presence and absence of MeHg (5 μM) were indistinguishable. These results demonstrate (1) that astrocytes lacking MTs are more sensitive to MeHg than those with basal MT protein levels, (2) that the MT-I gene can be overexpressed in MT-I and -II null astrocytes by transient MT-I gene transfection, and (3) that foreign MT expression endows astrocytes with increased resistance to MeHg. (Supported by NIEHS 07331. J.W.A. was supported by a NIAAA T32 AA07565.0.)

378 METAL AND RADIATION-INDUCED TOXIC NEUROPATHY (TN) IN TWO NAVAJO SISTERS.

J. F. Rosen and P. Mushak. *Albert Einstein College of Medicine and Children's Hospital at Montefiore, Bronx, NY.*

Introduction: "Navajo Neuropathy (NN)" was first reported in the 1970's in some Navajo. It was postulated to be a "genetic" disorder without any scientific proof. Thirty of 37 with this "syndrome" have died from fulminant liver disease or systemic infections. This "syndrome" includes progressive to static neuropathy, cataracts, and subcortical disease (by MRI) with an onset in early childhood. **Purpose and Methods:** Detailed clinical, genetic and environmental risk assessments of two Navajo sisters (27 and 28 years of age), presenting with "NN", were evaluated. **Results:** Extensive genetic testing was negative for both; but environmental health risk assessments revealed a toxic neuropathy from multiple toxicant exposures from abandoned surface mines during year-round herding. They had *in utero* and postnatal exposures to chemotoxic and radiotoxic levels of uranium (U) [and other radionuclides] and toxic levels of lead (Pb) in abandoned U mine pit waters, the exclusive source for drinking water and diluting infant formula. Additional fetal and postnatal toxicant exposures were to Pb, arsenic, and cadmium, in sheep meat from animals contaminated through vegetation and pit waters. The sisters had an *in utero* U/polonium radiation dose sufficient for CNS damage. Modeled *in utero* exposure to highly fetoneurotoxic Pb occurred via maternal blood lead level throughout pregnancy-embryonic and fetal stages of 40μg/dl. Further toxicity arose from other contaminant intakes during pregnancy in (μg/day): Cd, 656; As, 89. These toxic intakes of multiple contaminants continued postnatally. **Conclusion:** We conclude that there is no genetic basis for this disease. Its etiology is far more likely excessive exposure to metal toxicants and radionuclides *in utero* and postnatally thereby resulting in TN and subcortical CNS disease.

379 EFFECT OF NEONATAL LEAD EXPOSURE ON THE DEVELOPMENT OF CORTICAL COLUMNS IN THE RODENT BARREL FIELD.

M. A. Wilson, M. V. Johnston, G. W. Goldstein and M. E. Blue. *Kennedy Krieger Institute and Johns Hopkins University School of Medicine, Baltimore, MD.* Sponsor: J. Bressler.

To examine the effects of neonatal lead exposure on developing neuronal cir-

cuitry, this study utilized the rodent barrel field model. Rodent somatosensory cortex contains a topographic map of the whisker pad, called the barrel field. Columnar processing units in the barrel field have discrete clusters of neurons in layer IV that receive sensory information from a single whisker. In all areas of mammalian neocortex, less anatomically distinct cortical columns constitute the fundamental unit for information processing and storage. In this study, rat pups were exposed to 0, 0.02%, 0.1% or 0.2% lead acetate dissolved in their dam's drinking water from the day of birth through postnatal day 10. This treatment, which coincides with the development of the barrel field topographic map, produced blood lead levels ranging from 1 to 22 micrograms/dl. On postnatal day 10, barrel field area was measured using cytochrome oxidase histochemistry in sections tangential to the cortical surface. A dose-related reduction in barrel field area was observed (Pearson correlation -0.73, $p<0.01$), and the mean area of the barrel field in rats exposed to 0.2% lead acetate was reduced 13%, compared to controls. In contrast, there was no difference in total cortical area. These data support the hypothesis that childhood lead exposure may disrupt the development of columnar processing units in immature neocortex, leading to permanent impairment of cognition. (Support: NIEHS P01 ES 08131.)

380 TIME- AND REGION-SPECIFIC CHANGES IN AMINO ACID NEUROTRANSMITTERS IN RATS EXPOSED TO LOW LEVEL LEAD.

Y. Gedeon and A. L. Jadhav. *Texas Southern University, Houston, TX.*

The neurobiochemical mechanisms underlying lead(Pb)-induced behavioral alterations, learning/attention deficits and cognitive impairments are largely unknown. But evidence points to disruptions of monoamine and amino acid neurotransmitter function in the mesocorticolimbic system. Strictly from a quantitative standpoint, the amino acids are the major transmitters in the mammalian brain whereas the monoamines account for transmission at only a small percentage of central synaptic sites. This study sought to determine the temporal and regional pattern of amino acid neurotransmitter (i.e., glutamate, GLU, glutamine, GLN, gamma-aminobutyric acid, GABA, and glycine, GLY) level changes produced by subchronic postweaning low Pb exposure on the mesocorticolimbic system (i.e., nucleus accumbens, NA, hippocampus, HIP, and frontal cortex, FC). 21-day old male Long Evans rats exposed to 0 ppm (as sodium acetate in drinking water) and 50 ppm Pb (as lead acetate in drinking water) were sacrificed at 0, 30, 60 and 90 days. Blood lead (BPb) analysis by atomic absorption spectrophotometry showed a significant difference between the control and Pb-treated rats at each time point except at day 0. Moreover, there was no significant difference in BPb level between day 30, 60, and 90 within the control and Pb-treated groups. By day 30, BPb seems to stabilize around 11.8 microg/dl which is comparable to the Center for Disease Control and Prevention's threshold level for children. The evaluation of tissue amino acid contents by high performance liquid chromatography indicated significant decreases in GLU, GABA, and GLY in the FC at day 90 and in the HIP at day 60 whereas significant increases in GLN were observed in these regions at these time points. Moreover, GABA, GLY and GLN were increased in the NA at day 60 and 90. These data suggest that subchronic postweaning Pb produces time- and region-specific changes within the mesocorticolimbic amino acid transmitter system. 381 BLOCKADE OF NMDA RECEPTORS IN CORE BUT NOT SHELL OF NUCLEUS ACCUMBENS MIMICS LEAD (PB) EFFECTS ON LEARNING.

D. A. Cory-Slechta, M. Bauter and B. J. Brockel. *University of Rochester Medical School, Rochester, NY.*

Pb exposure selectively impairs learning on a multiple schedule of repeated learning and performance (Cohn et al., 1993). Since Pb inhibits NMDA receptors and nucleus accumbens (NAC; the terminal projection region for mesolimbic dopamine cell bodies) has been shown to be a target region for Pb-induced behavioral toxicity (Cory-Slechta et al., 1999), this study examined whether blockade of NMDA receptors in NAC could mimic Pb effects and if such effects would differ in core and shell subregions of NAC. Intra-NAC administration of the non-competitive NMDA antagonist MK-801 into surgically implanted bilateral guide cannulae, like Pb, decreased accuracy in the learning but not performance components of the schedule at 1.0 but not at 2.5 μg (total bilateral dose). This effect was not altered by chronic postweaning 100 ppm Pb acetate exposure of rats from weaning. Also, like Pb, this effect derived from increases in perseverative errors, while decreases in some skipping errors were detected. The accuracy reduction in the learning component could not be attributable to response rate changes, since rate increases occurred at 2.5 but not 1.0 μg MK-801 in all components. In shell, MK-801 decreased accuracy in both the learning and performance components in both control and Pb-exposed rats, and had no effect on response rates. These findings demonstrate a critical role for mesolimbic systems in the mediation of Pb-induced learning impairments. The relatively small magnitude of the accuracy decreases (10-15%), and their occurrence in core but not shell suggests the potential importance of hippocampal and prefrontal cortical afferent projections to NAC core as primary sites for these effects. ES01247, ES05017, ES05903.

382 SYNAPTIC TRANSMISSION MEDIATED BY GLUTAMATE AND GABA IS DECREASED IN RATS EXPOSED TO LEAD (PB^{2+}) *IN VIVO*.

M. D. Santos[1], E. F. R. Pereira[1], M. F. M. Braga[1], M. K. Nihei[2], M. Alkondon[1], E. X. Albuquerque[1] and T. R. Guilarte[2]. [1]*Department Pharmacol Exp Ther. University of Maryland School of Medicine, Baltimore, MD and* [2]*Dept Environmental Health Science, Johns Hopkins Univ, School Hygiene & Public Health, Baltimore, MD.*

The heavy metal, Pb^{2+}, has long been known to affect cognition in children, as well as learning and memory in experimental animals. To determine whether synaptic transmission is altered in rats exposed to Pb^{2+} during gestation and postnatally, we studied the hippocampus of rats chronically exposed to PbAc (0, 750 and 1500 ppm). Hippocampal slices were prepared from control and Pb^{2+} treated rats at 14 and 21 days of age, and whole-cell patch clamp recordings were performed on CA1 pyramidal neurons and interneurons. Currents were evoked either by applying agonists via a U-tube or by stimulating afferent fibers in the presence of selective receptor antagonists. In CA1 interneurons of Pb^{2+}-exposed rats, the peak amplitude of currents evoked by NMDA (50 μM) plus glycine (10 μM) was reduced by ~40% in 750 ppm-treated rats. In CA1 pyramidal neurons of 1500 ppm PbAc-treated rats, the amplitude of NMDA-evoked currents was decreased by ~50%. In addition, Pb^{2+} exposure (i) reduced the amplitude of pharmacologically isolated excitatory postsynaptic currents (PSCs) more than the inhibitory PSCs recorded from CA1 pyramidal neurons, (ii) caused a pronounced attenuation of ACh-evoked GABAergic PSCs, and (iii) enhanced the inhibitory effect of $PbCl_2$ (100 nM) on both glutamatergic and GABAergic synaptic transmission of hippocampal neurons. These findings suggest that multiple receptors associated with synaptic transmission are altered by *in vivo* exposure to Pb^{2+}. An imbalance of activity in different neurotransmitter systems may underlie the effects of Pb^{2+} on learning and memory in developing experimental animals and in humans. (Supported by ES05730 to EXA and ES06189 to TRG.)

383 [^{3}H]-MK-801 AND [^{3}H]-IFENPRODIL AUTORADIOGRAPHY SUGGEST N-METHYL-D- ASPARTATE RECEPTORS IN THE DENTATE GYRUS OF LEAD-EXPOSED RATS DIFFER IN THEIR PHARMACOLOGY.

T. R. Guilarte and J. L. McGlothan. *Johns Hopkins University, Baltimore, MD.*

We have previously shown that mRNA and protein expression for *N*-methyl-D-aspartate receptor subunit 1 (NMDAR1) are decreased in the hippocampus of rats exposed to 1500 ppm PbAc that exhibit deficits of long-term potentiation (LTP) and spatial learning. (Nihei *et al.*, Toxicol Sci. 48 1-S: 359, 1999). To determine the effect of Pb^{2+} on functional NMDARs in the hippocampus of littermates, we measured the binding of the NMDAR non-competitive antagonist [^{3}H]-MK-801, and the polyamine site antagonist [^{3}H]-ifenprodil. Levels of [^{3}H]-MK-801 binding were significantly higher ($F_{1,16}$=8.3, p=0.01) in Pb^{2+}-exposed dentate gyrus (DG) in the absence of exogenously added agonists (30 μM glutamate and glycine). [^{3}H]-MK-801 binding was significantly increased ($F_{1,16}$=8.3, p=0.01) in the DG of control rats by the addition of exogenous agonists. In Pb^{2+}-exposed rats, binding of [^{3}H]-MK-801 in the absence of agonists was equal to maximal binding in controls and could not be further increased by the addition of agonists. NMDARs composed of NR1/NR2B subunits have a greater sensitivity for both agonist and ifenprodil. [^{3}H]-ifenprodil binding was significantly greater ($F_{1,7}$=11.4, p=0.01) in the DG of Pb^{2+}-exposed rats. These findings suggest that in the DG of Pb^{2+}-exposed rats, either NMDARs are maximally stimulated by agonists under basal conditions, or a greater proportion of functional NR1/NR2B receptors exist in this brain region. (Supported by ES06189 to TRG.)

384 PKC-γ BUT NOT CA^{2+}-DEPENDENT PKC ACTIVITY IS REDUCED IN THE HIPPOCAMPUS OF RATS CHRONICALLY EXPOSED TO PB^{2+}.

M. K. Nihei, C. A. Prince, C. D. Toscano and T. R. Guilarte. *Johns Hopkins University, Baltimore, MD.*

The protein kinase C (PKC) family of serine/threonine kinases is comprised of at least 12 different isoforms. The brain-specific PKC-α requires Ca^{2+} and lipid cofactors for activity and has been shown to be involved in spatial learning and memory and is implicated in activity-dependent neuronal plasticity. In the present study, cytosolic and membrane fractions of hippocampus were prepared from postnatal day (PN) 50 rats exposed chronically to 0, 750, or 1500 ppm lead acetate (PbAc) in their diet. Western immunoblots showed reduction of PKC-α in both the cytosolic ($F_{2,17}=4.8$; $p<0.05$) and membrane ($F_{2,17}=3.3$; $p<0.064$) fractions. The alpha, beta-I, and beta-II isoenzymes were unchanged in either fraction. Ca^{2+}/lipid-dependent activity of PKC was not changed in either the cytosolic or membrane fractions in hippocampi of rats exposed to PbAc. Reductions in PKC expression were present at blood Pb^{2+} levels ranging from 25-35 μg/dl. Littermates to these rats demonstrate impaired spatial learning and *in vivo* long-term potentiation (LTP). Thus, reduced subcellular concentrations of PKC-gamma may be indicative of altered signal transduction and may be important in manifesting Pb^{2+}-induced impairments of learning and memory. (Supported by ES06189 to TRG and ES05869 to MKN.)

385 EFFECTS OF DIVALENT CATIONS ON [^{3}H]MK-801 BINDING TO THE N-METHYL-D-ASPARTATE (NMDA) RECEPTOR OF RAT BRAIN.

T. Ma and I. K. Ho. *University of Mississippi Medical Center, Department of Pharmacology & Toxicology, Jackson, MS.*

NMDA receptor, a subclass of glutamate receptor, plays an important role in a wide variety of physiological and pathophysiological processes. Our previous study have showed that subacute Pb-exposure of adult rats causes a decrease and that chronic Pb^{2+} exposure of developmental rats causes an increase in [^{3}H]MK-801 binding in the brain of rats. The present study investigated effects of several divalent cations on [^{3}H]MK-801 binding to rat brain sections and membrane preparations from adult rats *in vitro*. These cations (1-500 μM) were added into incubation system. Autoradiographic analysis of brain sections indicated that Pb^{2+} and Zn^{2+} enhanced [^{3}H]MK-801 binding at low concentrations (around 10 μM) and inhibited the ligand binding at high concentrations (>100 μM) in the cerebral cortex and hippocampus. However, Mg^{2+} and Ca^{2+} did not show such kind of biphasic effect. At high concentrations (>100 μM), Mg^{2+} induced decrease and Ca^{2+} induced increase in [^{3}H]MK-801 binding in the cortex and hippocampus. Similar effect of these cations on [^{3}H]MK-801 binding was also found in cortical membrane preparations. Hg^{2+} and Cd^{2+}, like Pb^{2+}, produced biphasic effect on [^{3}H]MK-801 binding to brain sections. When brain sections or membrane preparations were pre-treated with 0.8% Triton X-100, Pb^{2+} and Zn^{2+}-induced increase in [^{3}H]MK-801 binding was completely abolished. These results suggest that, besides Zn^{2+}, heavy metals Pb^{2+}, Hg^{2+} and Cd^{2+} may also act on modulatory site(s) on the NMDA receptor. The divalent cations-induced biphasic effects on [^{3}H]MK-801 binding to NMDA receptor rely on existence of the membrane lipids.

386 LEAD INDUCES PKC-MEDIATED PHOSPHORYLATION OF 45 KDA PROTEIN IN ISOLATED NERVE TERMINALS.

C. D. Toscano[1] and F. A. X. Schanne[2]. [1]*Johns Hopkins University, Baltimore, MD and* [2]*St. John's University, Jamaica, NY.*

Lead (Pb) is a well-known neurotoxicant. Exposure to relatively low levels of Pb is associated with deficits in cognitive function. The precise molecular mechanism underlying low level Pb toxicity is not understood. The highest affinity action of Pb yet described is its ability to activate calcium/phospholipid-dependent phosphotransferase, PKC. PKC is involved in many signal transduction processes in neurons and is essential for the induction of long-term potentiation, an electrophysiological model for learning. In the present study, we examined the ability of Pb^{2+} to activate PKC in presynaptic nerve terminals isolated from rat brain cortex, synaptosomes. The specific endogenous proteins phosphorylated were resolved by SDS-PAGE. PKC activity was determined in digitonin-permeabilized synaptosomes where the specific [Ca^{2+}] and [Pb^{2+}] were set using 5F-BAPTA as the chelator and the free metal ions confirmed using ^{19}F NMR. Experiments were performed in the presence and absence of the exogenous substrate [^{25}ser] PKC peptide 19-36, in the presence and absence of the PKC activator, PMA, and in the presence and absence of the PKC selective inhibitor, calphostin c. Increases in phosphorylation of exogenous substrate were seen at [Ca^{2+}] from 10^{-6} to 10^{-3} M. A marked increase in phosphorylation was observed at 10^{-9} M Pb^{2+}, corresponding to about 65% of maximal phosphorylation induced by Ca^{2+}. Phosphorylation was inhibited at higher [Pb^{2+}]. Ca^{2+}-induced increases in total phosphorylation of endogenous substrates were seen from 10^{-6} to 10^{-3} M with a specific increase in the phosphorylation of an 84 kDa protein. No significant increase in the total phosphorylation of endogenous substrates was seen with Pb^{2+}, but a specific significant increase in the phosphorylation of a 45 kDa protein was observed a 10^{-10} M Pb^{2+}. This protein corresponds to the localization of growth-associated protein 43 (GAP43, F1, B50), a well-documented PKC substrate whose phosphorylation is essential for the induction of LTP. These data begin to reveal how high affinity interactions of Pb^{2+} with PKC can alter specific molecular mechanisms involved in cognitive function.

387 CHRONIC DEVELOPMENTAL LEAD (PB) EXPOSURE INCREASES PHOSPHORYLATED FORMS OF RAT HIPPOCAMPAL PROTEIN KINASE C (PKC).

S. M. Lasley[1], M. A. Hebert[2], M. E. Gilbert[3] and J. P. O'Callaghan[2]. [1]*University of Illinois College of Medicine, Peoria, IL,* [2]*Centers for Disease Control - NIOSH, Morgantown, WV and* [3]*USEPA, Research Triangle Park, NC.*

Previous studies have demonstrated that chronic developmental Pb exposure impairs induction of long-term potentiation (LTP) and stimulation of glutamate release in rat hippocampus. Here we sought to identify mechanisms underlying these alterations by examining the expression of GAP-43–a PKC substrate linked to LTP development and transmitter release–and phosphorylation events related to PKC activation. Post-translational activation of PKC involves serial phosphorylation at three sites in order for the kinase to be responsive to stimulation (Dutil *et al.*, 1998). Pregnant Long-Evans dams were exposed to 0.2% Pb in drinking water beginning at gestational day 16 and exposure was continued throughout lactation with male offspring weaned to the same solution. At 60 days of age rats were sacrificed by focused microwave irradiation and dorsal hippocampi were dissected and sonicated. Proteins were separated by gel electrophoresis, transferred to nitrocellulose and immunoblots were probed with various primary antibodies (Ab); signal was detected by enhanced chemiluminescence. Hippocampal expression of GAP-43 did not differ between exposed and control animals. Moreover, an Ab that recognized an epitope common to the conventional α, β and γ isozymes of PKC also did not detect a Pb-related difference. However, blots probed with an Ab raised against a phosphorylated form of PKC (i.e., site 3 above) that recognized the conventional isozymes plus the novel δ isoform exhibited a band of phospho-PKC-like immunoreactivity that was significantly increased ($p < 0.05$) in Pb-exposed animals. Furthermore, blots probed with a phospho-PKCδ-specific Ab also displayed a band of significantly increased phospho-PKCδ-like immunoreactivity in exposed tissue ($p < 0.05$). The mechanism of the phosphorylation of GAP-43 by the δ isozyme has been described (Dekker and Parker, 1997). These results suggest an up-regulation in post-translational activation of some PKC isozymes. Future studies should examine these mechanisms in tissue tetanically stimulated to produce LTP or depolarized to induce glutamate release. (This abstract does not necessarily reflect U.S. EPA policy.)

388 PB EXPOSURE MODULATES EGR-1 DNA-BINDING BOTH *IN VIVO* AND *IN VITRO*.

R. Reddy[1] and N. H. Zawia[2]. [1]*Savannah State University, Savannah, GA and* [2]*University of Rhode Island, Kingston, RI.*

Zinc finger proteins (ZFPs) are essential components of developmental gene regulation and transcriptional activation and are the likely targets for disruption by heavy metals such as lead (Pb). We have previously reported alterations in the DNA-binding of ZFP transcriptional factors such as Sp1 and Egr-1 in rat cerebella, following developmental exposure to Pb. We further extended our studies to examine Pb induced alterations in the DNA-binding Egr-1 in different brain regions and in PC12 cells. Rats were lactationally - exposed to 0.2% Pb acetate from birth to weaning and their brain regions were obtained on postnatal days (PND) 3-30. Pheochromocytoma (PC12) cells were exposed to Pb acetate, nerve growth factor (NGF) in the presence or absence of staurosporine, a protein kinase C inhibitor. Nuclear extracts were prepared from brain tissues and PC12 cells and Egr-1 DNA-binding analysis were done using the gel shift mobility assay. Egr-1 DNA-binding in the control cerebellum and hippocampus was low on PND3 with a gradual increae to a peak at PND20. Egr-1 DNA-binding was relatively weak in the neocortex

and brainstem. In Pb-exposed animals, a preamture peak in Egr-1 DNA-binding was observed in the cerebellum and hippocampus. Egr-1 DNA-binding in PC12 cells increased in a dose dependent manner upon exposure to lower concentrations of Pb and NGF and was attenuated by the presence of staurosporine. These data suggest that Pb exposure alters gene expression through perturbations of ZFPs, and that such modulations may be mediated by protein kinase C.

389 INFLUENCE OF LEAD ON NITRIC OXIDE IN THE DEVELOPING RAT BRAIN.

B. Rajanna, R. Bell, S. Reddy, S. Swilley and S. Rajanna. *Alcorn State University, Alcorn State, MS.* Sponsor: D. Desaiah.

Nitric Oxide (NO), a neuronal messenger in the brain is synthesized by nitric oxide synthase during the conversion of L-arginine to citruline. Lead (Pb) is neurotoxic. This study was initiated to determine the effects of Pb on NO production in the developing rat brain. Pregnant Sprague Dawley rats in their 5th day of gestation were treated orally with 0.1% and 0.2% lead acetate. The control groups received saline. Treatments were continued during the pregnancy and until 21 post-natal days (PND). The pups were sacrificed at PND 5,10,15, 20 and 25, whole brain tissues were excised and separated into four regions: the cerebellum,the hippocampus, the frontal cortex and the brain stem. Nitrate and nitrite (NOx) levels were estimated by the chemiluminescent method using Sievers 280 - Nitric Oxide Analyzer (NOA). The effects of lead on NOx production were dose and age dependent and region specific. In the cerebellum of the brain at PND 25, 0.1% and 0.2% Pb reduced NOx by 428% and 328% respectively. In the hippocampus, both 0.1% and 0.2% Pb reduced NOx at all PND except PND 15. In the brain stem, there were significant reduction in NOx at PND 20 and 25. Lead (Pb) at both dose levels reduced NOx in the frontal cortex at PND 10, 15, 20 and 25. However, at 5 PND, there were no significant changes at both 0.1% and 0.2% Pb in the NOx of the frontal cortex. These results suggest that Pb reduces NO production in different regions of the rat brain leading to neuronal dysfunction. (Supported by NIH/NIGMS/MBRS #GM55356.)

390 OXIDATIVE STRESS IN EMBRYONIC RAT HIPPOCAMPAL NEURONS INDUCED BY LEAD IS REVERSED BY ASTROCYTE/NEURON INTERACTIONS.

C. A. Ferguson and G. A. Audesirk. *University of Colorado at Denver, Denver, CO.*

Inorganic lead is a very potent neurotoxicant that has profound effects on the development and function of the nervous system. This toxicant is very prevalent in the environment today and continues to affect individuals living primarily in urban settings. We performed experiments to evaluate 1)the effects of lead on reactive oxygen species (ROS) generation in both neurons and astrocytes, and 2) if astrocytes co-cultured with neurons conferred protection against the effects of lead on ROS generation in neurons. First, we exposed primary cell cultures of E-18 rat hippocampal neurons or astrocytes to 10μM lead chloride, 200μM hydrogen peroxide, or both lead and peroxide for 24 hours, after which the levels of ROS were measured using the fluorescent probe 2,7-dichlorofluorescine. Levels of ROS in neurons exposed to lead or peroxide increased to 150% of control values. ROS generation in neurons exposed to both lead and peroxide together increased to 210% of controls. Astrocytes showed no increase in ROS generation under any conditions. These data suggest that rat hippocampal neurons are unable to protect themselves against lead or peroxide induced oxidative stress, whereas astrocytes are. Previous studies have shown that heme oxygenase (HO-1, HO-2) is induced in other cell types undergoing oxidative stress. We evaluated the ability of both neurons and astrocytes to synthesize these proteins under lead and hydrogen peroxide induced oxidative stress. Neurons showed no significant increase in HO-1 or HO-2 with exposure to lead or peroxide. Astrocytes however showed a significant increase in HO-1 synthesis. These data suggest that HO-1 may play a role in protecting astrocytes from the effects of oxidative stress. Further experiments were performed to investigate whether or not astrocytes may confer protection to neurons under conditions of oxidative stress. Neurons were cultured both with astrocytes present and in astrocyte conditioned media. In both instances, the lead and peroxide-induced ROS generation seen in neurons alone was reversed. These data suggest a non-cell contact role of astrocytes in preventing oxidative stress in neurons.

391 LEAD (PB) TARGETS GRP78, A MOLECULAR CHAPERONE, IN C6 RAT GLIOMA CELLS.

Y. Qian, E. D. Harris, Y. Zheng and E. Tiffany-Castiglioni. *Texas A&M University, College Station, TX.*

Exposure to potentially neurotoxic levels of lead (Pb) occurs in about 9% of American children under six years of age. Astroglia in the brain serve as a Pb depot, sequestering Pb and preventing its contact with the more sensitive neurons. Astroglia have the capacity to adapt to Pb exposure, and as such are able to tolerate relatively high intracellular Pb accumulation. This tolerance mechanism has yet to be defined in biochemical terms. In the present study, we present evidence that glucose-regulated protein (GRP78), a molecular chaperone in the ER, participates directly or indirectly in the tolerance mechanism. Exposure of cultured C6 rat glioma cells, an astroglia-like cell line, to 1 μM Pb acetate for 1 week raised the intracellular levels of two proteins, one of which was identified by sequence analysis as GRP78. GRP78 accumulation started within one day and progressed with time of exposure. Studies *in vitro* showed further that GRP78 bound tightly to affinity columns with Pb^{2+} as the affinity ligand, and weakly when either Zn^{2+} or Ni^{2+} replaced the Pb^{2+}. GSH and BSA did not compete with GRP78 to chelate Pb^{2+}. However, the heavy metal binding domain (HMB) of Menkes protein competed with GRP78 for chelating Pb^{2+}. The data provide evidence that GRP78 may be a component of the Pb tolerance mechanism through its direct interaction with Pb^{2+}. Its increased synthesis could be part of the adaptive response to Pb exposure.

392 LEAD EXPOSURE ALTERS THE DEVELOPMENTAL EXPRESSION OF GALACTOLIPIDS AND CNPASE IN OLIGODENDROCYTES.

W. Deng and R. D. Poretz. *Rutgers University, New Brunswick, NJ.* Sponsor: D. Eaton.

Lead is known to cause myelin defects, although the mechanism is unclear. Our *in vivo* experiments indicate that lead exposure results in reduced cellular levels of enzymes in both the biosynthesis and degradation pathways of myelin-specific glycolipids in the developing rat brain. Myelin in the central nervous system is formed by oligodendrocytes, making these cells a possible target for lead. Development of the oligodendrocytes proceeds with a regulated temporal expression of specific glycolipids and glycoproteins which serve as markers of myelinogenesis. In the present study, rat oligodendroglial progenitor O2A cells and a CG-4-like cell line were used to examine the effect of lead on myelin-specific glycolipids and enzymes during developmental progression to mature oligodendrocytes. Lead acetate (5 μM) treatment, given prior to and during cell differentiation, altered the expression profile of cellular galactolipids during differentiation as detected by metabolic radiolabeling with 3-H-galactose. This exposure caused a decrease of approximately 50% in the ratio of galactocerebrosides/sulfatides in both undifferentiated and differentiated CG-4 cells. Lead treated CG-4 cells, as compared to appropriate controls, were found to possess 30% less activity for the oligodendrocyte marker, 2',3'-cyclic nucleotide 3'-phosphohydrolase (CNPase), in both the undifferentiated and differentiated stages. Surprisingly, undifferentiated CG-4 cells expressed high levels of this enzyme activity which, however, remained unchanged during cellular differentiation. This contrasts with O2A primary cells which express significant CNPase activity only after cell differentiation. It appears that the CG-4-like cell line differs from O2A primary cultures in regard to the degree of expression of some markers of differentiation, but may still serve as an appropriate experimental model for the examination of the effects of lead on oligodendrocyte development. (Supported in part by grants from NIEHS, R01-ES08373, and the March of Dimes Foundation.)

393 INHIBITORY EFFECT OF LEAD (PB) ON THE UPTAKE OF THYROXINE BY THE PERFUSED OVINE CHOROID PLEXUS (CP).

W. Zheng[1], R. Deane[2], J. E. Preston[3] and M. B. Segal[1]. [1]*Columbia University, New York, NY,* [2]*University of Greenwich, London, United Kingdom and* [3]*King's College London, London, United Kingdom.*

Lead exposure hinders brain development in children by a mechanism which remains unknown. Recent evidence shows that sequestration of Pb in the CP represses the production and secretion of transthyretin (TTR), a thyroxine transport protein, from the CP to CSF. This study was undertaken to determine if Pb treatment altered the unidirectional transport of T4 to the CSF in the isolated perfused CP. Sheep were injected subcutaneously with Pb acetate (6 mg Pb.kg-1; n=3) or Na acetate (control, n=3) every 48 hr for a period of 12 days. The CP was perfused with a modified Ringer via the internal carotid arteries.

The [125I]T4 uptake was determined by the paired-tracer method using the perfusate containing 0.5 Ci [125]T4 and 20 Ci [3H]mannitol at various concentrations of unlabeled T4 (trace to 15 M). While there was an increase in the [125I]T4 influx into the CP as the concentration of unlabelled T4 increased for both control and Pb treated animals, the actual influx was much reduced in the latter group. For example, the [125I]T4 influx into the CP at 15 M was 98.9 nmol.min-1.g-1+23.6SEM (n=7) and the mean value for the Pb-treated animals was 9.2 nmol.min-1.g-1+6.1, a reduction of 90% ($p<0.001$, by two-way ANOVA). The rate of vascular flow was also decreased by 67% from 2.6+0.13 to 0.87+0.08 ml.min-1.g-1 of CP (mean+SEM, $p<0.005$). The results suggest that Pb may reduce the uptake of T4 partially by decreasing the rate of vascular flow of the CP, an important factor in determining transport. (Supported by NIEHS RO1 ES08146.)

394 COMPARISON OF CYTOTOXICITIES INDUCED BY Mn(II) OR Mn(III) *IN VITRO*.

G. Tsao, Q. Zhao and W. Zheng. *Division of Environmental Health Sciences, Columbia University, New York, NY.*

The relationship between manganese (Mn) intoxication and Parkinsonism has long been established. However, the question as to what biological species of Mn is responsible for Mn-induced neurotoxicity remains unknown. This laboratory has previously demonstrated that Mn(II) inhibits aconitase, an enzyme possessing a [4Fe-4S] cubane cluster and regulating the cellular Fe homeostasis (Zheng, et al., Brain Res. 799:334, 1998). In the current study, we used cultured neuronal PC12 cells and purified mitochondrial aconitase to compare the *in vitro* cytotoxic effect of Mn(II) with Mn(III). When the aconitase was incubated with either Mn(II) as $MnCl_2$ (1 mM-2.5 mM) or Mn(III) as Mn acetate (125-700 μM), both Mn species decreased the rate of reaction catalyzed by aconitase. However, Mn(III) was evidently more effective than Mn(II) in enzyme inhibition. The ED_{10} (10% inhibition of aconitase activity) was 124 μM and 1164 μM for Mn(III) and Mn(II), respectively. Following exposure of cultured PC12 cells with 25-50 μM of either Mn(II) or Mn(III) in culture medium, both Mn species significantly retarded the cell growth compared to the controls by two-way ANOVA ($p<0.0001$). There was a significant statistical difference in the cell growth curves between Mn(II)- and Mn(III)-treated groups. For example, at day 5 after Mn treatment, the total viable cells in 50-μM Mn(II) group were 6.6% of the control, while it was 2.8% of the control values in 50-μM Mn(III) group. These *in vitro* results suggest that Mn(III) species seemed likely to be more cytotoxic than Mn(II) species. Whether the similar scenario also happens *in vivo* in animal models deserves further investigation.

395 COMPARATIVE TOXICOKINETICS OF MANGANESE CHLORIDE ($MnCl_2$) AND METHYLCYCLOPENTADIENYL MANGANESE TRICARBONYL (MMT) IN MALE SPRAGUE-DAWLEY RATS.

H. Kim[1], Q. Zhao[2] and W. Zheng[2]. [1]*Drug Met. & Pharmacokinetics, Smithkline Beecham, King of Prussia, PA and* [2]*Division of Environmental Health Sciences, Columbia University, New York, NY.*

The toxicokinetics of Mn was investigated in male and female rats either following a single intravenous (iv) or oral dose of $MnCl_2$ (6.0 mg Mn/kg), or following a single oral dose of MMT (20 mg MMT/kg or 5.6 mg Mn/kg). The plasma concentrations of Mn were quantified by AAS. Upon iv dose of $MnCl_2$, Mn rapidly disappeared from blood with a terminal elimination $t_{1/2}$ of 1.83 h and CL_s of 0.43 L/h/kg. The plasma concentration-time profiles of Mn could be described by C=41.9e-4.24t + 2.1e-0.44t. Following oral dose of $MnCl_2$, Mn rapidly entered the systemic circulation (T_{max}=0.25 h). The absolute oral bioavailability was 13%. Oral dose of MMT resulted in a delayed T_{max} (7.6 h), elevated C_{max} (0.93 μg/ml), and prolonged terminal $t_{1/2}$ (55.1 h). The rats receiving MMT had an apparent clearance (CL/F=0.09 L/hr.kg) about 37 fold less than did those who were dosed with $MnCl_2$. Accordingly, the AUC of Mn in MMT-treated rats was about 37 fold greater than that in $MnCl_2$-treated rats. A gender-dependent difference in toxicokinetic profiles of plasma Mn was also observed. Female rats displayed a greater AUC than that of male rats. Although the apparent Vd of Mn was similar in both sexes, the apparent CLs in males was about twice that observed in females. The results indicated that after oral dose, the MMT-derived Mn displayed a higher and more prolonged plasma concentration-time profile than $MnCl_2$-derived Mn. Thus, MMT-derived Mn appeared likely to accumulate in the body following repeated exposure.

396 MEDIA COMPOSITION AFFECTS MTT UPTAKE BY PRIMARY RAT ASTROCYTES IN RESPONSE TO MN EXPOSURE.

E. A. Malecki and J. R. Connor. *Penn State College of Medicine, Hershey, PA.*

The primary culture of glial cells from neonatal rats has proven to be a valuable model for studying neurotoxicity *in vitro*. Astrocytes perform supportive functions for neurons *in vivo*; therefore, effects of manganese (Mn) on astrocytes might contribute to its neurotoxicity. Primary rat astrocytes were obtained by shaking mixed glial cell cultures from various regions of brains of one day old pups and plated in 24-well poly-L-lysine coated plates. Cultures were maintained in DMEM/10%FBS until 48 hour exposure to varying concentrations of MnCl2 in either DMEM/10%FBS or OPTI-MEM/0.1%BSA. Manganese was found to have relatively little effect on astrocytes in DMEM/10%FBS media: uptake of MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide; as measured by absorbance at 570 nm) was consistently >50% of control cultures after 48 hours exposure to Mn concentrations up to 2 mM. There was little effect of brain region (cortical, striatal, mesencephalic) on the MTT uptake response to Mn exposure. In contrast, when astrocytes were exposed to Mn in OPTI-MEM/0.1%BSA, marked toxicity occurred at concentrations >250μM. We conclude that differences in nutrient and hormonal composition of the two media formulations affect astrocyte Mn toxicity. A systematic investigation of the factors affecting astrocyte Mn toxicity will yield valuable information about the mechanism of Mn neurotoxicity. (Supported by PHS/NIH NS10235 [EAM].)

397 OLFACTORY TRANSPORT OF INHALED ^{54}MANGANESE CHLORIDE TO THE BRAIN IN MALE CD RATS.

K. A. Brenneman, B. A. Wong, M. A. Buccellato, E. R. Costa, E. A. Gross and D. C. Dorman. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Inhalation exposure of humans to high concentrations of manganese (Mn) is associated with elevated striatal Mn levels and a Parkinson's-like motor disorder. Olfactory transport of Mn to the brain has been demonstrated in the rat following nasal instillation of $^{54}MnCl_2$; however, the significance of this route of delivery following inhalation is unknown. Our purpose was to determine if inhaled Mn could undergo olfactory transport to the brain in rats and the relative contributions of the direct olfactory and blood-borne routes to brain Mn levels. Male, 8-wk old, CD rats underwent a single, 90 minute, nose-only exposure to 0.55 mg Mn/m^3 in the form of aerosolized $^{54}MnCl_2$ (MMAD ~2.2 μm). Thirty rats had their right nostril occluded, preventing deposition of $^{54}MnCl_2$ in the right side of the nose and theoretically olfactory transport to the right side of the brain. Thirty positive control rats were exposed to $^{54}MnCl_2$ with both nostrils open to evaluate the symmetry of delivery. The left and right sides of the nose and brain including the olfactory bulb, tract/tubercle, and striatum were sampled from 6 rats/group (control and occluded) at 0, 1, 2, 4, and 8 days post-exposure. The mean sample activity/gram tissue wet weight for the left and right sides was compared to determine the relative contribution of olfactory uptake to brain Mn levels. High levels of activity in the olfactory bulb and tract/tubercle were observed following ^{54}Mn inhalation on the side with an open nostril within 1-2 days post-exposure. Brain and nose samples on the occluded side had negligible levels of activity. Control rats had equivalent ^{54}Mn concentrations on both sides of the nose and brain. These results demonstrated olfactory transport of inhaled ^{54}Mn to the olfactory pathway of the brain but not the striatum in the male CD rat. Furthermore, the olfactory route contributed the majority (up to 90%) of the Mn found in the olfactory pathway of the brain up to 8 days following a single inhalation exposure.

398 INFLUENCE OF SUBCHRONIC MANGANESE SULFATE ON THE NEUROBEHAVIOR OF MALE RATS.

H. L. Komiskey, X. F. Chen, T. D. Nguyen, M. D. Bradley, Q. Wu and D. Sarpong. *College of Pharmacy, Xavier University of Louisiana, New Orleans, LA.*

The potential of manganese sulfate to produce neurotoxicity following ninety days of daily gavage was studied in male rats. The rats were gavaged with suspensions containing 0.1, 1.0, 10, 30, or 100, mg/kg manganese or the vehicle each day. The functional observational battery, motor activity measurements, and the step-down task were used in an initial screen for neurotoxicity. In the functional observational battery, manganese sulfate only significantly affected weight gain. Male rats given 100 mg/kg manganese gained less weight

than those gavaged with 0.1 or 1.0 mg/kg manganese, or the vehicle. The locomotor activity of the rats was measured for 1 hour in a figure 8 maze. The rats gavaged with 30 mg/kg manganese had more motor activity during the hour in the maze, relative to rats gavaged with the vehicle. In addition, the rats gavaged with 30 mg/kg manganese had more motor activity in the final 20 min. in the maze, relative to rats gavaged with 100 mg/kg manganese. The gavaged doses of the trace metal salt did not significantly alter the performance of the rats on the step-down task. The behavioral effects produced by ninety days of daily gavage indicate that the higher doses of manganese sulfate may be toxic in male rats. (Support by ATSDR grant U50/ATU398948).

399 THE NEUROTOXIC EFFECTS OF MANGANESE IN A RAT MODEL OF PRE-PARKINSONISM.

R. H. Gwiazda, D. Lee, J. Sheridan and D. R. Smith. *Environmental Toxicology, University of California, Santa Cruz, CA.*

Elevated exposures to manganese (Mn) can induce neurologic impairments similar to those observed in Parkinson's disease (PD). Little is known about the toxic effects of low level chronic Mn exposure, particularly on sensitive sub-populations such as the aged. Here, a rat model of pre-parkinsonism was utilized to evaluate the hypothesis that Mn exposure can trigger the onset of parkinsonism. Different degrees of pre-parkinsonism were generated via unilateral intra-striatal injections of 6-hydroxydopamine (6-OHDA). In this model, dopamine (DA) depletion is considered to represent the extent of unilateral loss of substantia nigra dopaminergic neurons innervating the striatum. Treatment groups included: (T_1) saline intra-cranially (ic) + saline ip; (T_2) saline ic + $MnCl_2$ ip; (T_3) 3 µg 6-OHDA ic + saline ip; (T_4) 3 µg 6-OHDA ic + $MnCl_2$ ip; (T_5) 5.5 µg 6-OHDA ic + saline ip; and (T_6) 5.5 µg 6-OHDA ic + $MnCl_2$ ip. Manganese exposure (4.8 mg Mn/Kg body weight, 3 inj./wk X 5 weeks) started 4 weeks after performing the striatal lesions. Measured outcomes were striatal dopamine (DA) and its metabolites 3,4-dyhydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA). Results demonstrate predictable degrees of DA depletion in the three 6-OHDA treatment groups (0%, 50%, 70%, respectively) that are consistent with sub-threshold pre-parkinsonism. The DA/metabolite ratios varied across 6-OHDA treatments, indicating compensation for DA depletion through an increase in the rate of DA turnover. Notably, Mn exposure had no measurable effect on DA depletion, but did produce neuromotor impairments that were more severe in animals with existing high sub-threshold DA depletion (see Witholt et al., this volume). This indicates that the Mn exposures used here did not induce dopaminergic cell death, but did affect the nigro-stratial pathway in an as yet undetermined manner. This pre-parkinsonism rat model could prove highly useful to investigate the effects of environmental agents on the onset of Parkinsonism.

400 THE NEUROBIOLOGICAL EFFECTS OF MANGANESE EXPOSURE IN A RODENT MODEL OF PRE-PARKINSONISM.

R. D. Witholt, R. H. Gwiazda and D. R. Smith. *Environmental Toxicology, University of California, Santa Cruz, CA.*

Recent evidence has suggested that elevated exposures to manganese (Mn) and other metals is associated with the increased incidence of adult onset parkinsonism. Chronic elevated Mn exposure is known to cause neurotoxicity to the basal ganglia of mammals, resulting in neuromotor symptoms similar to those observed in parkinsonism. Here we utilized a rodent model of pre-parkinsonism (see Gwiazda et al., this volume) to investigate the effects of Mn exposure on neurotoxicity and the exacerbation of parkinsonism. A pre-parkinsonism state was induced using unilateral intra-striatal injection of 5.5µg 6-hydroxydopamine (6-OHDA). Mn exposure (4.8 mg $MnCl_2$/kg, i.p. 3 injections/week) was started four weeks after surgery and lasted five weeks. Female Sprague-Dawley rats (n=44) were divided among the following treatments (n=11/treatment): (A) Control, saline/vehicle; (B) Mn only; (C) 6-OHDA only; and (D) 6-OHDA + Mn. Neurobehavioral function was assessed following Mn exposure using a functional observational battery (FOB). Striatal dopamine concentrations and depletion (lesioned right vs. non-lesioned left striatum) were measured at sacrifice. Results indicated that the 6-OHDA lesion produced significant ($p<0.001$, ANOVA) depletion (60 - 70%) in striatal dopamine, but no measurable alteration of neurobehavioral function, thereby substantiating this pre-parkinsonism (i.e., sub-threshold) model. However, chronic Mn exposure resulted in significant ($p<0.05$) impairment of neurobehavioral function for eight of the ten FOB tests. No effects of Mn exposure on striatal dopamine depletion were detected. Notably, Mn exposure in the presence of a pre-parkinsonism state significantly exacerbated neurobehavioral impairment in the *reactivity to removal* and *hopping-left rear limb* (contralateral to lesion) FOB tests. These latter results suggest that chronic elevated Mn exposure may increase the risk of neurologic impairment in sub-populations that are in a pre-parkinsonism state.

401 INFLUENCE OF SUBACUTE MANGANESE SULFATE ON THE CHOICE ESCAPE LEARNING TASK IN MALE RATS.

H. L. Komiskey, X. F. Chen, M. D. Bradley, T. D. Nguyen and D. Sarpong. *Xavier University of Louisiana, New Orleans, LA.*

The choice escape learning task was used in rats to measure the effects of manganese sulfate on performance and on the acquisition of new information. Male Sprague-Dawley rats were given two weeks of daily gavage with suspensions containing 1.0, 10, 30, or 100, mg/kg manganese or vehicle each day. The vehicle contained 40% cornstarch, 10% sucrose, and 12% dextrinized cornstarch. After two weeks of daily gavage, each rat was given 100 Y-maze trials. The latency of escape (seconds) and errors (number of incorrect entries before the entry to correct arm) were analyzed. Rats gavaged with 1.0 or 100 mg/kg manganese, or the vehicle learned the correct choice for escape at a faster rate than rats given 30 mg manganese/kg ($p<.05$). Rats gavaged with 1.0 mg manganese/kg had a shorter latency of escape relative to rats given the vehicle or 30 mg manganese/kg ($p<.05$). In summary, the ability of manganese at 30 mg to impair the acquisition of new information, but not decrease the speed of responding, indicates that the trace metal at 30 mg/kg can decrease the learning processes of rats on the choice escape learning task. (Support by ATSDR grant U50/ATU398948.)

402 ASSESSMENT OF BIOACCUMULATION, HISTOPATHOLOGY AND NEURO-BEHAVIORAL DAMAGE IN PORTACAVAL ANASTOMOSIS RATS EXPOSED TO MANGANESE PHOSPHATE DUST: A PILOT STUDY.

L. Normandin[1], F. Salehi[1], R. F. Butterworth[2], S. Fadlallah[1], G. Kennedy[3], G. Carrier[1], D. Tapin[1] and J. Zayed[1]. [1]*University of Montreal, Montreal, Quebec, Canada,* [2]*Neuroscience Research Unit, Montreal, Quebec, Canada and* [3]*Mechanical Engineering Department, Montreal, Quebec, Canada.* Sponsor: K. Krishnan.

The addition of methylcyclopentadienyl manganese tricarbonyl (MMT) in unleaded gasoline, has resulted in increased attention of the effects of manganese (Mn). Hypothetically, people with chronic liver disease may be more sensitive to the adverse neurotoxic effects of Mn. Bioaccumulation of Mn in different organs/tissues, as well as histopathology and the neurobehavioral damage in end-to-side portacaval anastomosis (PCA) rats exposed to Mn phosphate via inhalation were investigated. The week before the PCA operation and four weeks after the PCA operation, the rats were investigated for a neurological evaluation (day-night activities). This neurological test was performed using a computerized autotrack system. Then a group of 8 PCA rats (E+) was exposed to 3000 mg m-3 (Mn phosphate) for 8 hr/day, 5 days/week for 13 consecutive weeks and compared to a control group (E-, n=8) of PCA rats exposed to the background level concentration of 0.03 mg m-3. At the end of the exposure period to Mn, another neurological evaluation was carried out. The rats were then sacrificed and Mn content in tissues and organs were determined by neutron activation analysis. The neuronal cell loss was assessed by neuronal cell counts, and the degree of Alzheimer type II astrocytosis was scored using a semiquantitative immunohistochemical procedure. Results show significant difference between E+ and E- rats. The results contribute to our understanding of the potential adverse effects of Mn in sensitive populations.

403 BIOACCUMULATION AND NEUROBEHAVIORAL EFFECTS OF INHALED MANGANESE DUST IN RATS.

A. St-Pierre[1], L. Normandin[1], G. Carrier[1], R. F. Butterworth[2], G. Kennedy[3], S. Fadlallah[1] and J. Zayed[1]. [1]*University of Montreal, Montreal, Quebec, Canada,* [2]*Neuroscience Research Unit, Montreal, Quebec, Canada and* [3]*Mechanical Engineering Department, Montreal, Quebec, Canada.* Sponsor: K. Krishnan.

The concern over environmental manganese (Mn) contamination has increased since the introduction of methylcyclopentadienyl manganese tricarbonyl (MMT) in unleaded gasoline. Many neurodegenerative disorders similar to Parkinson's disease have been related to chronic Mn exposure. The primary goal of this study was to determine the effects of Mn exposure via inhalation. More precisely, the bioaccumulation of Mn in different organs and tissues and the locomotor activity were assessed. A total of 26 rats (E+) were

exposed to 3709 mg/m3 Mn dust for 6 hr/day, 5 days/week for 13 consecutive weeks and compared to a control group of 12 rats (E-). After exposure, a neurological evaluation was carried out for 36 hours (a night-day-night cycle) using a computerised autotrack system. Rats were then sacrificed by exsanguination and Mn content in organs and tissues were determined by neutron activation analysis. Mn concentrations in lung, kidney and cerebellum were significantly higher in E+ than in E- (0.30 vs. 0.18, 1.15 vs. 0.96, 0.73 vs. 0.54 ppm; $p<0.01$) as well as for frontal and for the globus pallidus (1.69 vs. 0.86, 1.9 vs. 0.81 ppm; $p<0.05$). Locomotor activity indicate higher distance covered in the first 12 hour period for E+ ($p<0.05$) and lower resting time in the last 12 hour period for E+ ($p<0.05$). The results of this study contribute to an improved understanding of the health concerns associated with inhalation exposure to Mn.

404 UPTAKE OF SOLUBLE MANGANESE CHLORIDE VIA NOSE-ONLY INHALATION THROUGH THE OLFACTORY BULB.

P. G. Grant[1], G. Bench[1], J. L. Lewis[2] and K. K. Divine[3]. [1]*Lawrence Livermore National Laboratory, Livermore, CA,* [2]*University of New Mexico, Albuquerque, NM and* [3]*Inhalation Toxicology Research Institute, Albuquerque, NM.*

Proton Induced X-ray Emission (PIXE) has been used to study the uptake of soluble manganese chloride via nose-only inhalation through the olfactory bulb. Six Fisher 344 rats were exposed to manganese chloride, (0.53±.1 mg/m^3 of Mn, mass median aerodynamic diameter was 2.1±0.5 mm). The OSHA ceiling Threshold Limit Value for Mn is 5mg/mm^3. A vehicle control group of six rats was concurrently exposed to filtered air. Exposures were for 8 hours/day for 14 days. The brain and the olfactory bulbs were removed from euthanized rats, frozen in isopentane and cryosectioned into 10 micron thick sagittal sections. To date we have completed PIXE analysis of anterior portions of freeze dried sections (two per animal) obtained from three Mn dosed and two control animals. Two Mn dosed animals show uptake of Mn in both tissue sections while the third Mn dosed animal shows no evidence of Mn uptake from the exposure in either section and measured Mn contents are similar to levels measured in controls. As with uptake of soluble and insoluble forms of aluminum; nickel-63; and americium-241, the uptake of Mn occurs in only a subset of animals. In such animals Mn uptake occurs in the first mm of the olfactory bulb to levels of approximately 30mg/kg and subsequent deposition appears to occur at about 4mm. Pathology of nasal tissue and comparison of serial stained sections has not been completed and so we have not yet identified in what cell layer or nucleus the increase in Mn at 4mm occurs. However, the data indicates that Mn, once entering the bulb is moving transsynaptically beyond the olfactory glomeruli.

405 PROCONVULSANT EFFECT OF CHRONIC ARSENIC IN MICE.

D. De La Cruz[1], M. Gonsebatt[2], M. Perez[2] and C. Rios[1]. [1]*Institutio Nacional de Neurologia y Neurocirugia, Mexico,* [2]*Instituto de Investigaciones Biomedicas, UNAM, Mexico, and* [3]*Instituto de Fisiologia Celular, UNAM, Mexico.*

Arsenic (As) is a common pollutant of food and water. Human exposure to this element causes toxic effects in several organs. In humans (CNS) it produces convulsions, mental confusion, encephalopathy and coma. Studies in animals have shown that sodium arsenite ($NaAsO_2$) increases brain lipid peroxidation and alterates neurotransmitter levels. The present study was undertaken to investigate if arsenic has a proconvulsivant effect in mice chronically exposed to $NaAsO_2$ and to determine the brain lipid peroxidation in the same animals. Male BALB/c mice, weighing 25-30 gr were randomly allocated to each of groups (n = 6 - 10). Two independent groups of animals were intragastrically administered with either 2.5, 5.0 or 10 mg/kg $NaAsO_2$, or deionized water (Controls) daily during 30 days. At the end of treatments, all animals were injected with 3-mercaptopropionic acid (3-MPO) i.p., a known inhibitor of GAD (glutamate decarboxylase) in order to study the proconvulsant effect; another group of animals were used to quantify the lipid peroxidation in tissue homogenates from frontal cortex, corpus striatum and hippocampus. All the animals intoxicated with $NaAsO_2$ showed myoclonus and tonic-clonic convulsions generalized 2 minutes after injection of 3-MPO; whereas the animals of control group, presented myoclonus and tonic-clonic convulsions 4 minutes after administration of 3-MPO. Lipid peroxidation levels were higher ($p < 0.05$) in the frontal cortex (at doses 2.5 y 5.0 mg/kg) and corpus estriatum (at dose 2.5 mg/kg) in groups exposed to $NaAsO_2$. Sodium arsenite induced proconvulsivant effect in the animals exposed and it also increased the lipid peroxidation levels. Further studies are needed to elucidate the mechanisms for this As proconvulsivant effect in the brain.

406 MORPHOLOGICAL ALTERATIONS AND ENHANCED LIPID PEROXIDATION IN BRAIN REGIONS OF RAT AFTER PERINATAL COMBINED EXPOSURE TO CADMIUM AND DEXAMETHASONE.

M. Mendez-Armenta[1], R. Barroso-Moguel[1], C. Rios[2] and J. Villeda-Hernandez[1]. [1]*Lab Neuromorphology Cellular and* [2]*Dept. of Neurochemistry, Instituto Nacional de Neurologia y Neurocirugia, M.V.S., Mexico.*

Industrial and environmental exposure to cadmium (Cd) is well known to produce multiorgan toxicity in humans. Cd has been reported damage endothelial cells in several organs both adult or developing brain. On the other hand, metallothionein (MT) is an intracellular ligand for Cd. MT has been shown to protect against Cd-induced toxicity in many organs. We studied microscopical and lipid peroxidation changes in parietal cortex, striatum, hippocampus and cerebellum of rats following perinatal exposure to both Cd and dexamethasone (Dx), a drug known to induced MT synthesis in brain. Wistar rats of 13 days of age were treated for 5 days as follows: 1) saline solution, 2) $CdCl_2$ 1mg/kg/day, 3) Dx 2mg/kg/day 4)$CdCl_2$+Dx2mg/kg/day. Rats were killed on either 18 or 28 days of age. Their brains were included in paraffin and stained by Hematoxilin-Eosine and silver techniques. No lesions were observed in the brain of control rats. Rats treated with Dx at 28 days of age showed interstitial oedema in the four regions. Cd-treated rats at 28 days of age showed pyknotic cells, interstitial oedema in parietal cortex. Striatum shown initial congestion and oedema between nervous fibers. Hippocampus shown few pyknotic cells. Purkinje cells showed pyknosis and nuclear damage.The molecular and granular layers showed interstitial oedema. Lipid peroxidation increased in striatum of rats treated with Cd at 18 days of age. Rats treated with Cd+Dx showed decreased levels of lipid peroxidation in four regions at 18 days of age with respects to cd-treated rats. In general data suggest that Dx treatment attenuated cadmium-induced lesions.

407 THE EFFECTS OF ADRENALECTOMY ON TRIMETHYLTIN-INDUCED HIPPOCAMPAL INJURY IN RATS.

M. Sadamatsu[1], H. Imai[2], T. Nishimura[3], M. Kabuto[2] and N. Kato[4]. Sponsor: Y. Aoki.

Trimethyltin (TMT), an organic compound, is known to cause the hippocampal damage and also to show an transient increase of plasma corticosterone (CORT) level on day 3 and 4 after treatment, raising a question regarding the possible effects of CORT on the hippocampal damage. In our recent study, TMT was shown also to induce apoptotic cell death in hippocampal neurons. In the present study, therefore, the effects of adrenalectomy (ADX) on the TMT-induced hippocampal apoptotic cell death were investigated. Male adult Sprague-Dawley rats (aged 6 weeks) were assigned to the following treatment groups: sham+water (control), sham+TMT (9mg/kg, p.o.), ADX+water, and ADX+TMT. TMT or water vehicle were administered 7 days after ADX or sham operation. On 7 days after TMT (or water vehicle) treatment, rats were sacrificed and brain samples were collected. Brain samples were processed by TUNEL for detection and counting apoptotic cells. A higher number of apoptotic cell were found in the infrapyramidal blade, as compared with the suprapyramidal blade of the dentate gyrus in sham+TMT rats. In ADX+water rats, on the contrary, suprapyramidal blade exhibited a greater number of apoptotic cells then the infrapyramidal blade. TMT treatment to ADX rats increased apoptotic cells both in suprapyramidal blade and infrapyramidal blade. The present results may indicate that the topographical pattern of the granule cell degeneration induced by TMT treatment is different from that induced by ADX, and that the interaction of TMT treatment and ADX is greater than the sum of the individual effects.

408 TRIMETHYLTIN AND LPS INDUCE DISTINCT PATTERNS OF CYTOKINE AND CHEMOKINE EXPRESSION IN RAT HIPPOCAMPUS: LACK OF AN ASSOCIATION WITH INJURY-INDUCED GLIOSIS.

A. R. Little and J. P. O'Callaghan. *CDC/NIOSH, Morgantown, WV.*

Cytokines are proposed to play a role in the central nervous system (CNS) responses to injury and disease. One such response is neuronal damage-induced glial activation (gliosis). Here we examined the *in vivo* expression of cytokines and chemokines linked to CNS damage and gliosis. We used the

trimethyltin (TMT) model of neuronal injury (8mg/kg, i.p.) because the time-course of neuronal loss and glial activation have been characterized. Peripheral administration of lipopolysaccharide (LPS) (0.5 mg/kg), i.p.) was used as a positive control because it is known to elevate cytokines in the periphery and the CNS but does not itself induce neural damage. Using semi-quantitative RT-PCR, we found that cytokines (TNF-alpha, IL-1, TGF-beta) and chemokines (MIP-1, RANTES, and IFN-gamma) were elevated in liver, blood, and hippocampus following peripheral LPS at 2, 5, and/or 8 hours after administration, however, glial fibrillary acidic protein (GFAP) (a marker of gliosis) was not altered at any time point. In contrast, TMT-treated rats showed GFAP and GFAP mRNA increases in hippocampus by day 5 (300%). Analysis by Atlas Array of the most affected time point (day 5) corroborated RT-PCR results. This glial response was not accompanied by a significant elevation in TNF-alpha or IL-1alpha or beta. These results suggest that 1) pro-inflammatory mediators may be elevated within the CNS in the absence of neuronal damage and glial activation and 2) toxicant-induced neuronal damage and glial activation do not require upregulation of proinflammatory cytokines.

409 ORAL TREATMENT OF MICE WITH SODIUM SELENITE BUT NOT SELENOMETHIONINE INCREASES DOPAMINE METABOLITES IN THE STRIATUM.

M. Tsunoda, V. J. Johnson and R. P. Sharma. *The University of Georgia, Athens, GA.*

Selenium (Se) is an essential as well as a toxic trace element. The exposure to Se causes blind staggers in cattle, poliomyelomalacia in pigs, and nervous system disorders in people. In this study, groups of 5 male BALB/c mice each were administered sodium selenite or selenomethionine in drinking water *ad libitum* at 0, 1, 3, and 9 ppm as Se for 14 days. At the end of treatment, their brains were removed, dissected, and concentrations of norepinephrine (NE), dopamine (DA), dihydroxyphenylacetic acid (DOPAC), homovanillic acid (HVA), serotonin (5-HT), and 5-hydroxyindolacetic acid (5-HIAA) were determined in different brain regions. Food and water intake, and body weight gain were decreased in the group treated with the highest concentration of sodium selenite. In mice administered sodium selenite at 3 and 9 ppm, DOPAC was significantly higher in the striatum than in the control group. The striatal HVA was also increased in the group treated with 3 ppm Se; the DA showed a similar pattern but the increase was not statistically significant. No alterations of NE, 5-HT, and 5-HIAA levels were detected in any brain region of mice treated with sodium selenite. No significant differences in any parameter among the groups treated with selenomethionine were observed. The alterations of DA metabolites by inorganic Se in DA-rich striatum suggested a Se-specific increased neural activity of dopaminergic pathways. Results may be useful in elucidation of neurotoxicity of Se and in establishing a safe level of Se intake.

410 A *PRIORI* PREDICTION OF TISSUE:PLASMA PARTITION COEFFICIENTS OF DRUGS FOR PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) MODELS.

F. Theil and P. Poulin. *F. Hoffmann-La Roche Ltd., Pharma Research, Basel, Switzerland.*

The tissue:plasma ($P_{t:p}$) partition coefficients (PCs) are drug-specific input parameters in PBPK models. Until now the use of PBPK models in early stages of the drug discovery process was not possible, since the estimation of $P_{t:p}$ of new drug candidates by using conventional *in vitro*, *in vivo* and/or quantitative structure-property relationships (QSPR) methods is too time and cost intensive. The objectives of this study was to develop and validate two mechanistic equations for predicting *a priori* the rabbit, rat and mouse $P_{t:p}$ of eight non-fatty and non-excretory tissues for 67 structurally unrelated drugs. The first equation predicts $P_{t:p}$ at steady state, assuming a homogenous distribution and passive diffusion of drugs into tissues, from a ratio of solubility and macromolecular binding between tissues and plasma. The ratio of solubility was estimated from log vegetable oil:water PCs of drugs as well as lipid and water levels in tissues and plasma, whereas the ratio of macromolecular binding for drugs was estimated from tissue interstitial fluid-to-plasma concentration ratios of albumin, globulins and lipoproteins. The second equation predicts $P_{t:p}$ of drugs residing predominantly in the interstitial space of tissues. Therefore, the fractional volume content of interstitial space in each tissue replaced drug solubilities in the first equation. The average ratio of predicted-to-experimental $P_{t:p}$ values was 1.26 (S.D. = 1.40, r = 0.90, n = 269), and 85% of the 269 predicted values were within a factor of three of the corresponding literature values obtained under *in vivo* (most of the cases) and *in vitro* conditions. The major discrepancy observed between the predicted and experimental $P_{t:p}$, is for lung in the case of basic lipophilic drugs. It has been reported in the literature that the partitioning of these drugs into lung is principally governed by an lipophilic-ionic lysosomal trapping, which it has not been taken into account for predicting the $P_{t:p}$ of lung in the present study. The results indicate that our methodology for predicting $P_{t:p}$ is a valuable tool to aid the pharmacokinetic screening with PBPK models in early stages of drug discovery.

411 USING MUSCLE:PLASMA PARTITION COEFFICIENTS (PCS) AS SURROGATES FOR PCS OF OTHER TISSUES.

W. F. Richter, F. P. Theil and P. Poulin. *F. Hoffmann-La Roche Ltd., Pharma Research, Basel, Switzerland.*

The muscle is the most important organ for drug distribution on the basis of body mass (> 50% for mammalian species). Furthermore, for several mammalian species, the muscle contains similar levels of lipids, water and binding macromolecules (albumin, globulins, lipoproteins) as other tissues. Consequently, the muscle can potentially be used as a reference/surrogate organ for predicting the tissue:plasma partition coefficients ($P_{t:p}$) as drug-specific input parameters for physiologically-based pharmacokinetic (PBPK) models. The objective of this present study is to evaluate the adequacy of using $P_{t:p}$ of muscle as a surrogate for $P_{t:p}$ of other tissues for several structurally unrelated drugs. The method consists of performing regression analyses between $P_{t:p}$ of muscle and those of other non-fatty and non-excretory tissues (bone, brain, heart, intestine, lung, muscle, skin, spleen) to verify whether linear relationships can be obtained. Regression analyses were performed for experimental as well as predicted rabbit and rat $P_{t:p}$ of these above tissues. The experimental $P_{t:p}$ correspond to literature values determined under *in vivo* conditions, whereas those predicted correspond to optimized values obtained from PBPK modelling exercises, and calculated values presented in a companion poster. For predicted and experimental $P_{t:p}$, linear relationships ($r > 0.9$) were observed between muscle and other tissues, suggesting that $P_{t:p}$ of muscle is a good predictor for the $P_{t:p}$ of other tissues. This can be rationalized by the fact that the lipid, water and major binding macromolecule levels are not so different between these tissues. However, the correlation between $P_{t:p}$ of muscle and $P_{t:p}$ of brain, is less evident as for the other tissues. Therefore, it might possible that a permeability-limited process is present in brain under *in vivo* conditions in the case of some drugs, by contrast to the other tissues. The present study suggests that $P_{t:p}$ of muscle can be a good predictor for $P_{t:p}$ of non-fatty and non-excretory tissues for drugs distributing homogeneously or non-homogeneously into tissues predominantly by a passive process.

412 PREDICTION OF ADIPOSE TISSUE: PLASMA PARTITION COEFFICIENTS OF LIPOPHILIC IONIZED DRUGS.

O. Luttringer, F. P. Theil and P. Poulin. *F. Hoffmann-La Roche Ltd., Pharma Research, Basel, Switzerland.*

Adipose tissue is an important organ into which the lipophilic drugs can be distributed. The adipose tissue:plasma ($P_{at:p}$) partition coefficients (PCs) may be over-predicted by a factor more than three from *n*-octanol:water PCs ($P_{o:w}$) for lipophilic ionized drugs (LIDs). During the determination of $P_{o:w}$ with the conventional shake-vial method, the water phase may be partly solubilized in the *n*-octanol phase, which is also polar because of the presence of an hydroxyl group in molecules of *n*-octanol. Consequently, $P_{o:w}$ would increase if the drugs are soluble or substantially ionized in the water phase (which is the case for LIDs). The fact that $P_{o:w}$ are probably over-estimated in the experimental studies may explain why $P_{at:p}$ are over-predicted from $P_{o:w}$ for LIDs. Alternatively, vegetable oil (constituted of neutral lipids; triglycerides) has been recently suggested as a better surrogate than *n*-octanol for biotic neutral lipids in adipose tissue (constituted of 90% triglycerides and free fatty acids). The water phase is insoluble in the oil phase. Therefore, experimental vegetable oil:water PCs ($K_{vo:w}$) are observed to be lower than $P_{o:w}$ for LIDs. Hypothetically, $K_{vo:w}$ would better predict $P_{at:p}$ than $P_{o:w}$ do. The objective of the present study was to compare the predictability of rat and rabbit $P_{at:p}$ from $K_{vo:w}$ and $P_{o:w}$ for eighteen structurally unrelated LIDs. The $P_{at:p}$ were predicted using experimental $K_{vo:w}$ or $P_{o:w}$, and the unbound fraction in plasma as the only drug-specific input parameters in a tissue composition-based equation. The values of $P_{at:p}$ predicted with $K_{vo:w}$ are within a factor of two of their corresponding experimental $P_{at:p}$ values, whereas the values of $P_{at:p}$ predicted with $P_{o:w}$ are in most cases over a factor of three of their corresponding experimental $P_{at:p}$ values. The present study demonstrates that $K_{vo:w}$ is a better predictor of $P_{at:p}$ than $P_{o:w}$ for LIDs.

413 *IN VITRO-IN VIVO* EXTRAPOLATION OF TISSUE: PLASMA PARTITION COEFFICIENTS OF DRUGS.

A. Archer, F. P. Theil and P. Poulin. *F. Hoffmann-La Roche, Ltd., Pharma Research, Basel, Switzerland.*

The *in vitro* and *in vivo* tissue:plasma ($P_{t:p}$) partition coefficients (PCs) are used in physiologically-based pharmacokinetic (PBPK) models to estimate tissue distribution of drugs. Ideally, a value close to one is expected for the ratio of *in vitro* to *in vivo* $P_{t:p}$ ($P_{t:p\ in\ vitro/in\ vivo}$). However, this is not the case for several lipophilic ionized bases. The *in vitro-in vivo* extrapolation of $P_{t:p}$ is not well understood at the present time. *In vivo*, it is assumed that only the non-ionized form can cross the plasmatic membrane to be distributed into tissues. However, *in vitro* it is considered that the non-ionized and ionized forms can cross the artificial membrane used in the dialysis cells to separate the plasma and tissue homogenates. Consequently, the lipid:water PC in tissues, at steady state, would be different *in vivo* and *in vitro* especially for ionized drugs. This may principally explain the quantitative differences between the *in vitro* and *in vivo* $P_{t:p}$. The objective of this present study was to develop and validate a mechanistic method for predicting $P_{t:p\ in\ vitro/in\ vivo}$ for six non-fatty tissues and adipose tissue in rats. First, this is done for eleven drugs for which the distribution in a tissue is assumed to be homogeneous. Their $P_{t:p\ in\ vitro/in\ vivo}$ were predicted with a tissue composition-based equation as equal to the ratio between the *in vitro* and *in vivo* lipid:water PCs estimated for tissues. The predicted values of $P_{t:p\ in\ vitro/in\ vivo}$ differed to the experimental values obtained form the literature by an average factor of 1.07 (s.d. = 0.44, r = 0.90, n = 28). Specifically, for lipophilic ionized bases with a $pK_a > 8.1$, it is clearly demonstrated that values of $P_{t:p\ in\ vitro/in\ vivo}$ are lower than 0.5, whereas those for hydrophilic ionized bases with a $pK_a < 8.1$, acids with a pK_a between 7 and 8 as well as neutral compounds are close to one. For two drugs residing in interstitial space of tissues, their experimental $P_{t:p\ in\ vitro/in\ vivo}$ over than two were assumed to be principally governed by a difference in the tissue distribution between *in vitro* (homogenates) and *in vivo* (intact tissues). For these drugs, the predicted values of $P_{t:p\ in\ vitro/in\ vivo}$ differed to the experimental values by an average factor of 1.62 (s.d. = 0.85, r = 0.41, n = 9). The practical aim of this study is the *in vitro-in vivo* $P_{t:p}$ extrapolation.

414 ESTIMATING RAT BLOOD:AIR PARTITION COEFFICIENTS (PCs) OF VOLATILE ORGANIC CHEMICALS (VOCs) USING RECONSTITUTED MIXTURES OF *n*-OCTANOL, WATER, AND HEMOGLOBIN.

G. Charest-Tardif, M. Béliveau and K. Krishnan. *Université de Montréal, Montréal, Quebec, Canada.*

The rat blood:air PCs ($P_{b:a}$) of lipophilic VOCs cannot be predicted only with the consideration of their solubility in blood water and lipids, suggesting an important role of protein binding. Experimental evaluations of the contribution of hemoglobin (Hb) binding to the $P_{b:a}$ of VOCs, its possible dose-dependency and the quantitative nature of VOC-binding to hemoglobin [i.e., association constant (K_a), number of binding sites (n)] have not been performed. The objectives of this study were to: i) assess the contribution of hemoglobin to the $P_{b:a}$ of VOCs, and ii) estimate K_a and n for VOCs. *In vitro* vial equilibration studies were conducted using whole blood, or an equivalent mixture of water and *n*-octanol (with or without Hb) that were exposed to single (300 ppm) or varying concentrations of VOCs [bromoform (BF, 120-12725 ppm), chlorobenzene (CB, 125-27325 ppm), chloroform (CF, 125-207211 ppm), and ethylbenzene (EB, 125-22610 ppm)]. The PCs of VOCs determined using whole blood were comparable to those obtained using a reconstituted mixture of *n*-octanol, water and Hb (mean±SE, n=3-4) for BF (154±1.5), CB (55±6), CF (15±0.87), and EB (30±1.5). Also, the $P_{b:a}$ of all four VOCs decreased significantly at higher exposure concentrations, with no significant change in their octanol/water mixture:air PC. For each exposure concentration, the concentration of free chemical (C_{free}) in rat blood was calculated with the PC for the *n*-octanol/water mixture, whereas the concentration of bound plus free chemical (C_{tot}) was calculated from knowledge of the PC determined experimentally with whole blood. The values of K_a and n estimated by linear regression of a plot of C_{tot}/C_{free} vs $1/C_{free}$ were: BF (0.8, 4), CB (2.8, 1.4), CF (1.8, 1.2), and EB (2, 1.4). The results of this study confirm that a mixture of *n*-octanol, water and hemoglobin can adequatly predict the $P_{b:a}$, and that the dose-dependent nature of $P_{b:a}$ need not be considered for modeling inhalation exposures to VOCs for up to 2000-5000 ppm.

415 A QSAR-TYPE PBPK MODEL FOR INHALED CHLOROETHANES.

M. O. Fouchécourt and K. Krishnan. *Université de Montréal, Montréal, Quebec, Canada.*

The chemical-specific parameters required for PBPK models are either determined experimentally or predicted from the use of theoretical algorithms. The parameter values of related compounds may be useful for developing quantitative relationships that consistently describe the change in parameter values as a function of molecular structure. Such quantitative relationships between molecular structure information and V_{max}, K_m or partition coefficients (PCs) have not yet been developed. The purpose of this study was (i) to develop quantitative structure-activity relationship (QSAR)-type equations for associating the molecular structure of chloroethanes with the numerical values of parameters required for PBPK modeling (i.e., blood:air PC (P_b), tissue:blood PCs (P_t), V_{maxc} and K_m), in rats and humans, and (ii) to incorporate these QSAR-type equations within PBPK models such that molecular structure can be used as the sole input to simulate the pharmacokinetics of various chloroethanes in rats and humans. Experimental values of the parameters for monochloro-, 1,1- and 1,2-dichloro-, 1,1,2-trichloro, 1,1,2,2- and 1,1,1,2-tetrachloro, pentachloro- and hexachloro-ethanes were taken from the literature. Each molecule was described as the composite of a basic structure (C-C) and carbon substituent group (H_3, H_2Cl, HCl_2 or Cl_3). The quantitative relationships between structural features and the values of the parameters (P_i) were described by a Free-Wilson additive model: $P_i=A_i+\Sigma(f_s*C_{si})$ where A_i = contribution of the basic structure to the parameter P_i, f_s = frequency of occurrence of each substituent S and C_{si} = contribution of each S to P_i. The average ±SD (range) ratio of estimated/experimental values were 1.08±0.38 (0.64-1.57), 1.17±0.70 (0.5-4.18), 1.10±0.46 (0.6-2.12), 1.11±0.31 (0.79-1.8) for rat PCs, human PCs, V_{maxc} and K_m, respectively. The ratio of Ca_{ss} simulated using the QSAR-type PBPK models and the conventional PBPK models ranged from 0.78 to 1.21 (1.03 ±0.13) and from 0.76 to 1.55 (1.06±0.26), for rats and humans, respectively. The QSAR-type PBPK model as developed in the present study should be useful for examining the influence of change in number and nature of substituents on the kinetics of related chemicals.

416 PBPK MODELING OF ESTRADIOL DURING ESTROUS CYCLE AND ITS RELATIONSHIP TO UTEROTROPHIC EFFECTS IN RATS.

C. Émond and K. Krishnan. *Université de Montréal, Montréal, Quebec, Canada.*

A physiologically based pharmacokinetic (PBPK) model for 17β-estradiol (E2) has been developed by Plowchalk (Toxicologist, 42: 1180). This model simulates the kinetics of E2 without considering E2 variations during the normal estrous cycle. E2 concentrations in blood during the estrous cycle varies by about a factor of seven. At the present time, there are no published models that simulate the blood concentration profiles of E2 by accounting for both the endogenous cycle dependent production of E2 and exogenous E2. Further, only limited efforts have been made to evaluate linkage between tissue doses of E2 and health effects. The objectives of the present work were 1) to extend the Plowchalk PBPK model for E2 to include the cyclical hormone levels in the rat, and 2) to use this PBPK model to study the relationship between exogenous E2 exposure and uterotrophic effects. The PBPK model for estradiol contained seven compartments (blood, richly perfused tissues, slowly perfused tissues, pituitary, uterus, ovaries and liver). Data on blood E2 during estrous cycle, obtained from the literature, were used to develop a table function to incorporate into the rat E2 model written in ACSL®. Subsequently, the model simulated the blood concentration profiles of E2 following oral dosing, including the time-dependent changes in endogenous E2 levels. Dose-response data for E2-induced uterotrophic effects were obtained from the literature and their relationship to internal dose surrogates of E_2 examined. A non-linear relationship was observed between AUC for E2 concentration in uterus and uterus weight. The internal E2 dose response relationship established in rat may be useful as a basis for predicting the consequences of exposure to xenoestrogens that would cause specific changes in the circulating E2 levels.

417 PHYSIOLOGICAL MODELING OF HUMAN EXPOSURE TO CONTAMINANTS IN AMBIENT ENVIRONMENT AND FOOD CHAIN.

C. Blanchette and K. Krishnan. *Université de Montréal, Montréal, Quebec, Canada.*

Human exposure to environmental pollutants is evaluated with the knowledge of their concentration in the exposure media, consumption rate, and body weight. The concentration in food materials is sometimes considered equal to the average concentration and frequently calculated using a bioconcentration or bioaccumulation factor. The conventional approach also does not always account for the bioavailability and the kinetics of absorption of the chemicals in food materials. The objective of this study was to develop a physiologically-based modeling framework for evaluating human exposure to contaminants in the ambient environment and the food chain. The approach consisted of developing a set of physiologically-based pharmacokinetic (PBPK) models for humans and key animal species representative of the food chain such as fish, chicken and cow, and interconnecting them. All species are exposed to the same ambient environment or different environments. The output of the three animal models (such as tissue concentrations), along with the consumption patterns, served as input (via the gastro-intestinal tract) to the human PBPK model, which then simulated the internal dose of the specific chemicals modeled. The individual components of the PBPK model framework facilitate the simulation of the kinetics of chemical concentrations in tissues or other relevant compartments (e.g., egg, milk, muscle) in each of the species in the food chain. The three animal PBPK models have been validated by comparing the predictions with previously published experimental data on the concentrations of several PCBs following oral administration. The modeling framework developed in this study represents a biologically-based tool useful for improving our ability to assess accurately human exposure to contaminants present in the ambient environment and food chain.

418 PBPK MODELING AND EXTRAPOLATION OF PHARMACOKINETIC INTERACTIONS FROM SIMPLE TO COMPLEX CHEMICAL MIXTURES.

R. Tardif, S. Haddad, G. Charest-Tardif and K. Krishnan. *Université de Montréal, Montréal, Quebec, Canada.*

Methodologies for the health risk assessment of single chemicals are well developed but it is not the case with chemical mixtures. This situation is a result of our inability to predict the consequences of pharmacokinetic and pharmacodynamic interactions potentially occurring between mixture components. PBPK modeling provides a unique framework that can account for the higher order pharmacokinetic interactions in mixtures solely based on information obtained with binary mixtures. The ability to extrapolate pharmacokinetic interactions from simple to complex mixtures using PBPK models needs to be proven with increasingly complex chemical mixtures. The objective of the present study was to validate the PBPK modeling approach for extrapolation of pharmacokinetic interactions from binary to more complex mixtures of benzene (B), toluene (T), ethylbenzene (E) and *m*-xylene (X) and dichloromethane (D). The methodology consisted of initially obtaining and linking the single chemical PBPK model of each of these components at the level of the liver compartment on the basis of interaction mechanisms. Analysis of blood kinetic data from exposure to all binary combinations suggested that competitive metabolic inhibition was the most plausible interaction mechanism amongst all combinations. The metabolic inhibition constant (K_i) for each of these binary combinations was quantified and incorporated within the complex mixture PBPK model. The binary interaction-based mixture model was then used to predict the consequences of interactions occurring in more complex mixtures (4 or 5 components). The mixture PBPK model predicted adequately the blood kinetics of T, E, X, B and/or D present in mixtures of BTEX, DTEX and DBTEX. The results of the present study demonstrate that the pharmacokinetics of the components of complex mixtures can be described/predicted solely from mechanistic information on binary level interactions.

419 DERIVATION OF CHEMICAL-SPECIFIC ADULT-CHILDREN SAFETY FACTORS USING A PHYSIOLOGICAL MODELING APPROACH.

K. Price and K. Krishnan. *Université de Montréal, Montréal, Quebec, Canada.*

The adult-children differences in physiological and biochemical factors are thought to be responsible, in part, for the potential differences in pharmacokinetics and tissue dose of chemicals. The objective of this study was to derive chemical-specific safety factors for conducting adult-to- children extrapolation of safe exposure concentrations. Using a physiologically-based algebraic expression, the ratios of steady-state arterial blood concentrations (Cass) for several volatile organic chemicals (VOCs) (dichloromethane, toluene, trichloroethylene, chloroform, carbon tetrachloride, styrene, and m-xylene) in adults and 4-yr old children were obtained. This algebraic expression, derived from PBPK models, was used to calculate Cass as a function of inhaled concentration, alveolar ventilation rate (Qp), cardiac output (Qc), blood:air partition coefficient (Pb), fraction of cardiac blood flow to liver (Qlc) and hepatic extraction ratio (E). Based on literature data on adult-children differences in physiological parameters, it was found that the Cass slightly varied between adults and children of various age groups. The results indicate that the adult exposure concentration of VOCs should be divided by a factor ranging from 1.02 - 1.84 to obtain an equivalent Cass in 4-yr old children. For children of other age groups (5 - 17 years), the factor is even lower and closer to 1. The magnitude of difference in Cass between children and adults is a result of differences in uptake and metabolic clearance. The difference in uptake and the dose absorbed when adults and children are exposed to the same external concentration results from differences in Qp, Qc, Qlc, Pb and E. The factor accounting for differences in uptake between 4-yr old children and adults for dichloromethane, for example, is 1.2. The magnitude of difference in metabolic clearance, as determined by differences in body weight and liver blood flow rate, between 4 year old children and adults is in the order of 1.4. For older age groups (5-17 years), this factor is lower and closer to 1. This safety factor represents the default, which can be modified by the ratio of E in children and adults. The present study represents the first attempt of deriving a safety factor based on the differences in mechanistic determinants of pharmacokinetics between adults and children.

420 A SIMPLE METHOD FOR UNCERTAINTY ANALYSIS IN PBPK MODELS.

S. Said and K. Krishnan. *Université de Montréal, Montréal, Quebec, Canada.*

Methodologies for conducting uncertainty analysis in PBPK models have been developed by several authors. These methodologies in general use Monte Carlo method for sampling input parameters used in PBPK models written in programming or simulation languages. It is possible to solve differential equations and conduct PBPK simulations using spreadsheet programs such as Microsoft EXCEL®. EXCEL® also permits the use of add-in program such as Crystal Ball which facilitates Monte Carlo simulation. The objective of this study was to develop a simple method for conducting uncertainty analysis in PBPK models. The approach consisted of writing PBPK model equations in EXCEL® spreadsheets, and describing certain input parameters (physiological, biochemical) with a distribution function (normal, lognormal, uniform). Whereas the model equations were written and solved in EXCEL® spreadsheets, the input parameters were provided by Crystal Ball® based on the distribution and available parameter statistics. During the conduct of simulations, the investigator should specify the cell corresponding to the output for which the distribution should be graphically displayed. The distribution of the output is the result of the use of Monte Carlo method by Crystal Ball® to randomly generate parameter values. The PBPK model framework developed in Excel®/Crystall Ball® was used to conduct uncertainty analysis in simulations of pharmacokinetics of chloroform, methyl chloroform, trichloroethylene, benzene, carbon tetrachloride and methylene chloride in workers exposed for 8-hr to threshold limit values (TLVs) of these substances. Probability distributions of blood and tissue concentrations of these chemicals were generated for each sampling time. The results of the uncertainty analysis obtained using the simple method developed in the present study compared well with those obtained previously using simulation softwares such as Simusolv®.

421 AN ALGEBRAIC APPROACH FOR CONDUCTING SENSITIVITY AND VARIABILITY ANALYSES IN HUMAN PBPK MODELS.

K. Krishnan and M. O. Fouchécourt. *Université de Montréal, Montréal, Quebec, Canada.*

Sensitivity analysis in PBPK models facilitates the evaluation of the relative sensitivity of pharmacokinetic (PK) endpoints to changes in input parameters. Analysis of the impact of the variability of input parameters facilitates an evaluation of the possible magnitude of interindividual differences in pharmacokinetics. Health risk assessment approaches typically consider chronic exposure to contaminants, during which steady-state is attained. The steady-

state concentrations of chemicals in blood and tissues can be adequately determined using algebraic equations that use fewer parameters than full-blown PBPK models. The purpose of this study was to develop a simple algebraic approach for conducting sensitivity and variability analyses in human PBPK models of volatile organic chemicals (VOCs). Since the human models are used to simulate lifetime exposures, algebraic equations instead of full-blown PBPK models were used to obtain essentially the same results. Using the algebraic equation, the sensitivity of steady-state arterial blood concentration [$Ca_{ss} = 1/(1/P_b+Q_{lc}*E)$ where P_b = blood:air partition coefficient, Q_{lc} = fraction of blood flow to the liver and E = hepatic extraction ratio] of 17 volatile organic chemicals (VOCs) was determined for unit change in the numerical values of E, P_b and Q_{lc}. The percent change in Ca_{ss} for 1% change in P_b, E or Q_{lc} ranged from 0.04 to 0.99, 0.01 to 0.97, and 0.01 to 0.97, respectively. Given a 15 % and 22 % variability of P_b and Q_{lc} in a population, Ca_{ss} would vary by ±0.5-14.8% and ±0.27-26%, respectively. A 50% increase in E would lead to 0.6-29% decrease of Ca_{ss}, while a 50% decrease in E resulted in 0.6-92% increase in Ca_{ss}. This algebraic approach can provide the extreme values of PK endpoints (e.g., Ca_{ss}) for a given range of variability of input parameters in a population. Distributions of parameter values, if available, can also be used with this algorithm for assessing the probabilistic nature of the outcome.

422 IMPROVING THE RELIABILITY OF PARAMETERS IN PBTK MODELS USING MARKOV CHAIN MONTE CARLO SIMULATIONS.

F. Jonsson and G. Johanson. *National Institute for Working Life, Stockholm, Sweden.*

The kinetics of volatile substances can be described with the aid of physiologically based toxicokinetic (PBTK) models. However, such modeling is often performed without assessing the reliability of the parameters and their variability in the population. The aim of this study was to address these issues within a population PBTK framework using Markov chain Monte Carlo (MCMC) simulations. The MCMC method creates parameter estimates in the shape of distributions, incorporating existing data on the parameter distributions in the population. In a previous study (Carlsson, Scand J Work Environ Health. 8 (1982), 43-55), 6 male volunteers were exposed to toluene vapor for two hours at 80 ppm during various levels of exercise. Extensive physiological and kinetic data, such as toluene in arterial blood, subcutaneous adipose tissue and end-exhaled air, were collected up to one week postexposure. Thus, the Carlsson data were deemed sutiable for this study. The kinetic data were fit to a published PBTK model for toluene (Pierce et al., Toxicol Appl Pharmacol 139 (1995), 49-61). The results suggest that a separate compartment for perirenal fat should be added to the the model from Pierce et al. in order to describe the concentration-time profile in subcutaneous fat correctly. Furthermore, by using the information supplied by the experimental data it is possible to improve the reliability of the distributions of the fat-related physiological parameters. (The study was financially supported by the Swedish Council for Work Life Research.)

423 PROBABILISTIC DISTRIBUTIONS FOR PBPK MODEL PARAMETERS.

S. M. Hays[1], M. Butcher[2], G. C. Hook[1], Y. Lowney[1], C. R. Kirman[3] and D. J. Paustenbach[4]. [1]*Exponent, Boulder, CO,* [2]*Exponent, Bellevue, WA,* [3]*ChemRisk, Cleveland, OH and* [4]*Exponent, Menlo Park, CA.*

The most recent attempt by the regulatory agencies to use physiologically-based pharmacokinetic (PBPK) modeling for rulemaking (OSHA, 1997) has involved the use of probabilistic techniques to assess variability in population pharmacokinetics/toxicokinetics and to assess uncertainty in model predictions. Incorporation of probabilistic techniques into PBPK modeling is a significant technical challenge, and several key issues have been identified as a result of these efforts: 1.) How should model parameter distributions be defined? 2.) How should correlations between parameter distributions be defined (e.g., tissue blood flow should be from the upper end of the distribution when tissue volume is from the upper end of its distribution) and which parameters should be correlated? 3.) How should distributions be updated with new data or information? The application of probabilistic methods to PBPK modeling allows a more scientific representation of the uncertainty and variability in the model predictions of internal dose (kinetics) and response (dynamics). Fitting distributions and correlations to model parameters is the process of removing the uncertainty about - and capturing the variability inherent in - these physical systems. This work is the extension to the efforts by Brown et al. (1997) to provide distributions of model parameters. Specifically, distributions for most animal-specific PBPK model parameters are presented. Probabilistic bounds are also incorporated to assure the assumptions of the distribution are consistent with realistic bounds found in the data sets. In the same way, correlations between the parameters were estimated. The effect of these correlation estimates on the model output are compared to bounds on the output derived by alternative methods.

424 AN ADVANCED PBPK MODEL INPUT SYSTEM AND DATA REPOSITORY FOR COMPLEX MODELS WITH EXPORT FOR THE ACSL MODEL ENGINE.

F. W. Power[1], J. N. Blancato[2], A. Ruiz[1], J. Licitra[3] and J. Ventresca[2]. [1]*Anteon Corporation, Las Vegas, NV,* [2]*USEPA, Las Vegas, NV and* [3]*For the Anteon Corporation, Las Vegas, NV.*

As Physiologically Based Pharmacokinetic (PBPK) Models grow in complexity preparing inputs becomes more tedious and prone to mistakes. This comes after extensive research and literature searches to accumulate the required physiological inputs. In addition the user must often define very complex exposure scenarios. Often, even the most careful organization of inputs starts to break down under the pressures of preparing large numbers of inputs. An advanced input system has been developed for the Dose Estimating Exposure Model (DEEM) that incorporates a database of user generated data sets which can be exported to the specified model engine (currently ACSLTOX). The input screens are presented to demonstrate the scope of input choices. The user defines a new Model Data Set including units and model version. The subsystems and compartments active for the simulation are chosen. Then the exposure chemicals and their metabolites are specified with the type of metabolism and inhibitor if required. Inputs are then specified for each chemical. The compartments active for a chemical are specified. The binding, elimination and metabolism constants are input. The exposures are defined for one or more chemicals and one or more scenarios for each of eight exposure routes. Exposure time histories can be input for Inhalation, Rate Ingestion, and Skin Surface Water Exposures. NOTICE: The U.S. Environmental Protection Agency (EPA), through its Office of Research and Development (ORD), funded this research and approved this abstract as a basis for an oral presentation. The actual presentation has not been peer reviewed by the EPA. Mention of tradenames or commercial products does not constitute endorsement or recommendation for use.

425 APPLICATION AND USE OF DOSE ESTIMATING EXPOSURE MODEL (DEEM) FOR ROUTE TO ROUTE DOSE COMPARISONS AFTER EXPOSURE TO TRICHLOROETHYLENE (TCE).

C. S. Scott[1], J. N. Blancato[2], J. W. Power[3] and J. W. Fisher[4]. [1]*USEPA, Washington, DC,* [2]*USEPA, Las Vegas, NV,* [3]*Anteon Corporation, Las Vegas, NV and* [4]*Armstrong Laboratory Wright-Patterson AFB, Wright-Patterson AFB, OH.*

Route to route extrapolations are a crucial step in many risk assessments. Often the doses which result in toxicological end-points in one route must be compared with doses resulting from typical environmental exposures by another route. In this case we used EPA's Dose Estimating Exposure Model (DEEM) to examine the route comparisons of different measures of internal dose after exposure to TCE. DEEM is a physiologically based model architecture for estimating internal tissue doses resulting from actual or simulated exposures. Because of different kinetic rates in the body not each possible measure of dose has the same quantitative relationship with exposure. Modeling shows that for different choices of internal dose the "equivalent" exposures are different. For example, we first chose the dose of interest to be the area under the curve (AUC) of the metabolite, trichloroacetic acid (TCA). In this case and with this model set-up an 8-hour 30 ppm exposure via inhalation was equivalent to drinking water intake of 50mg per day. For other measures of dose the point of equivalent exposure is far different. Thus, information about the mode of action and selection of internal dose is crucial before route to route extrapolations can be rationally made. (NOTICE: The U.S. Environmental Protection Agency (EPA), through its Office of Research and Development, funded this research and approved this abstract as a basis for an oral presentation. The actual presentation has not been peer reviewed by the EPA.)

426 APPLICATION AND USE OF DOSE ESTIMATING EXPOSURE MODEL (DEEM) FOR DOSE COMPARISONS AFTER EXPOSURE TO TRICHLOROETHYLENE (TCE).

J. N. Blancato[1], F. W. Power[2] and J. W. Fisher[3]. [1]*USEPA, Las Vegas, NV,* [2]*Anteon Corporation, Las Vegas, NV and* [3]*Armstrong Laboratory, Wright-Patterson AFB, Wright-Patterson AFB, OH.*

DEEM, developed over the last few years, is a model architecture for estimating internal tissue doses resulting from actual or simulated exposures. Exposure profiles are inputted into DEEM through scenario-based modules or through time-histories of exposure concentration. The relationship of exposure to dose is complex and depends on many factors and is different for each choice of dose. In this example DEEM was specifically configured to simulate TCE pharmacokinetics in the human. The model was first tested against data taken from human volunteers (Fisher, et al.) Next we looked at the impact of different exposure regimens on various internal measures of dose for TCE. Our "base" exposure was 30 ppm for eight hours repeated for five days. The results of this exposure were compared to several profiles whose time-weighted average was 30 ppm over the 8-hour period. The profile concentrations ranged anywhere from 0 to 131 ppm to give the time-weighted 30 ppm average. The peak height of TCE concentration in the blood varied considerably upon exposure concentration, duration, and frequency as well as physiologic factors. In contrast, concentrations of the metabolites of TCE, trichloroacetic acid (TCA) and trichloroethanol (TCOH), were virtually the same regardless of which exposure profile was simulated. In some circumstances, for these measures of internal doses, an 8-hour average exposure suffices for their estimation. We present several different simulations to examine the impact of exposure on internal dose. Findings such as these could have impact on future exposure study designs. (NOTICE: The U.S. Environmental Protection Agency (EPA), through its Office of Research and Development, funded this research and approved this abstract as a basis for an oral presentation. The actual presentation has not been peer reviewed by the EPA.)

427 UNCERTAINTY ANALYSIS OF TCE USING THE DOSE ESTIMATING EXPOSURE MODEL (DEEM) IN ACSL.

A. M. Tseng[1], R. N. Brown[2], F. W. Power[1], J. N. Blancato[3] and C. W. Scott[1]. [1]*Anteon Corporation, Las Vegas, NV,* [2]*USEPA, Las Vegas, NV and* [3]*USEPA, Washington, DC.*

The ACSL based Dose Exposure Estimating Model (DEEM) under development by EPA is used to perform an uncertainty analysis of a physiologically based pharmacokinetic (PBPK) model of trichloroethylene (TCE). This model involves several circulating metabolites such as trichloroacetic acid (TCA) and trichloroethanol (TCOH) whose exact clearance parameter values are not always well known. A combined sensitivity and Monte Carlo analysis is presented. Some base model parameter values and associated experimental measurements were supplied by Fisher et. al. For imprecisely known parameters, sensitivity analyses use reasonable assumptions about parameter central tendency and natural variation. The natural variation is used in model runs to identify the most sensitive model parameters under various linear and nonlinear model concentration conditions. Using various sets of sensitive parameters, mixed normal and non-normal statistical distributional assumptions are used in Monte Carlo analyses under the assumption of independently varying parameters. Adjustments are made for correlated parameters. Central tendency and upper and lower percentile bounds are provided for time-dependent concentration curves of TCE, TCA, and TCOH, along with similar results for summary dose measures such as steady-state concentrations or area under the concentration curves. Experimental concentration measurements are plotted against predicted model variability. (NOTICE: The U.S. Environmental Protection Agency (EPA), through its Office of Research and Development (ORD), funded this research and approved this abstract as a basis for an oral presentation. The actual presentation has not been peer reviewed by the EPA. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.)

428 DOES CHLOROFORM CONFORM TO HABER'S INHALATION RULE FOR DIFFERENT RAT AGES? A PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBNK) MODELING APPROACH.

D. Litton, J. E. Simmons, W. Boyes, P. Bushnell and M. V. Evans. *EPA NHEERL, Research Triangle Park, NC.*

Chloroform ($CHCl_3$) is a disinfection by-product of water chlorination, for which there is a well established PBPK model. The objective of this study was to use this PBPK model for $CHCl_3$ to test Haber's rule, and evaluate how the predictions compared for young (2 month) and old (2 years) versus adult (3 month) rats. The default method for estimating inhalation toxicity makes use of Haber's rule, an empirical law that states that the inhalation concentration (C) times the exposure length (T) is a constant toxicological effect (k). For example, a 200 ppm, 2 hr length exposure would be theoretically toxicologically equivalent to a 400 ppm, 1 hr exposure, since their product is the same.Two sets of CxT scenarios were chosen to study higher concentrations with short durations and lower concentrations with longer durations. In the first scenario, C varied from 0.1 to 1600 ppm and length varied from 1600 to 0.1 hours. In the second scenario, C ranged from 0.1 to 48 ppm with exposures durating from 48 to 0.1 hours. The maximum rate of metabolism (rAM) in the liver and kidney were assumed to be directly related to toxicity for all simulations. When rAM for each organ was plotted versus concentration, these preliminary results were not a constant line, as would be expected from Haber's rule, but nonlinear results were observed. In addition, percent difference calculations using the adult values as the basis for comparison, showed the young rats to have 30% lower rAM, and the aged rats to have 27% higher rAM when compared to the adults for both types of scenarios tested. In summary, PBPK modeling was used as a tool to test the applicability of Haber's rule for inhalation exposures that vary in length and time. PBPK modeling suggested that $CHCl_3$ toxicity may not be described by Haber's rule. (This abstract does not refect EPA policy).

429 INCORPORATION OF STRAIN- AND AGE-SPECIFIC INPUT PARAMETERS INTO A PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) MODEL FOR CHLOROFORM ($CHCl_3$).

J. R. Morin[1], M. V. Evans[2] and J. E. Simmons[2]. [1]*ESE, UNC, Chapel Hill, NC and* [2]*NHEERL, USEPA, Research Triangle Park, NC.*

$CHCl_3$ is a trihalomethane (THM) present in drinking water disinfected either by chlorination or by ozonation processes that involve post-treatment with either chlorine or chloramine. PBPK models are available for $CHCl_3$, including one developed in our laboratory based on closed-chamber uptake curves for ~60-day-old male F-344 rats and Sprague-Dawley physiological input parameters (Yang et al., 1995). The objective of the present work was to determine the appropriateness of the 60-day-old $CHCl_3$ model for 90-day-old rats. This was prompted by the recent finding that a relatively small increase in age (2 months) resulted in an increase in the toxicity of another volatile organic solvent, carbon tetrachloride (Schoeffner et al., 1999). The existing $CHCl_3$ model was updated with physiological input parameters for F-344 rats (Delp et al., 1998) that have recently become available. Simple linear interpolation (between 60 and 180 days) was used to adjust the following: total cardiac output; fractional blood flow to liver, kidney, fat and muscle; and, fractional volume of the liver and kidney. Optimization (Simusolv®, Version 3.0, 1993) of the closed-chamber data obtained in ~60-day-old F-344 rats with input parameters specific for this age and strain resulted in a Vmaxc of 4.7 mg/kg/hr (compared to a Vmaxc of 4.1 mg/hr/kg in our previous model, with Km held constant). To evaluate the ability of the updated model to extrapolate across a small age range, ~90-day-old male F-344 rats were exposed to initial concentrations of 500 or 1000 ppm $CHCl_3$ for 6 hr by closed-chamber techniques. The uptake curves predicted by use of physiological input parameters for ~90-day-old rats closely matched the experimentally derived uptake curves. These results indicate that age extrapolation of physiological input parameters was successful in predicting uptake and metabolism of $CHCl_3$. The newly updated strain- and age-appropriate CHCl3 PBPK model is now available to investigate the pharmacokinetic interaction between the two most prevalent THMs, $CHCl_3$ and bromodichloromethane, using closed-chamber data being collected in ~90-day-old male F-344 rats. (This abstract may not reflect EPA policy. JR Morin supported by CT-826513.)

430 AN APPROACH TO OPTIMIZE GAS UPTAKE EXPERIMENTS TO IMPROVE PARAMETER ESTIMATION.

J. H. Overton and M. V. Evans. *USEPA, Research Triangle Park, NC.*

A non-invasive method of estimating metabolism parameters involves the use of the closed gas uptake chamber technique, PBPK models, and parameter estimation. This presentation deals theoretically with two questions: (1) What are some gas uptake chamber experimental designs that may reduce the uncertainty in estimated parameters? (2) Is there a method for choosing one design over another? In response to (1), three types of design are considered: (A) different initial chamber concentrations, (B) chamber volumes, and (C) time spans of pre exposure to a constant concentration prior to closing the chamber. For estimation of a rat metabolic rate, V_{max}, a PBPK model is used to sim-

ulate chamber concentrations (CI) and calculate sensitivity coefficients (SC, of CI to V_{max}) for all possible combinations of designs. Our approach to (2) is to assume that CI is approximately linear in V_{max} and treat the optimization as a linear regression in which SC is the independent variable. With assumptions about the error term and using all of the simulated "observations" for each design, the standard deviation (SD) of V_{max} for each design is estimated. The SDs represent the relative uncertainty of each experimental design and can be used to discriminate among the designs. For a "large" V_{max}, results generally indicate that the smaller the pre exposure times and the smaller the volumes the smaller the SD; but SD mainly decreases with increasing initial chamber concentration. With a V_{max} 1/50-th of the large V_{max}, SD behaves the same way as for the large V_{max} in relation to pre exposure time and chamber volume. In contrast to the large V_{max} results, the small V_{max} SD increases with increasing initial concentration. In conclusion, this method of discriminating among designs is an approach to developing more efficient experiments that reduce uncertainty in estimated parameters, and thus, should lead to improved risk assessments. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.)

431 COMPARATIVE ANALYSIS OF SOFTWARE FOR PHYSIOLOGICALLY BASED PHARMACOKINETIC MODELING: SIMULATION, OPTIMIZATION, AND SENSITIVITY ANALYSIS.

M. R. Easterling[1], M. V. Evans[2] and E. M. Kenyon[2]. [1]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC and* [2]*USEPA, Research Triangle Park, NC.*

SimuSolv® and the related ACSL® software packages have been widely used for development and application of physiologically based pharmacokinetic (PBPK) models. Due to the widespread use of PBPK modeling in toxicology and risk assessment and the cessation of further development and releases of SimuSolv®, evaluation of other packages with comparable capabilities is essential. A previously developed PBPK model for the environmental contaminant trichloroethylene (TCE) was used to compare the two software packages: SimuSolv® and Matlab®. The TCE model provides a framework for assessing common PBPK modeling activities in Matlab®, with an emphasis on comparisons to SimuSolv®. The model is flow-limited with 6 compartments (brain, liver, slowly perfused, fat tissue, kidney, and rapidly perfused). Matlab® provided a convenient framework for coding the model. Very similar results for model simulations were achieved using initial chamber concentrations from 10 to 1000 ppm. Differences between the two packages for predicted chamber and tissue concentrations were on the order of 10-4. Differences of these small magnitudes may be attributed to the different numerical methods used in simulating the models. Estimates of the Michaelis-Menten parameters for TCE metabolism in the liver (Vmaxc and Km) differed slightly due to the use of different optimization routines. SimuSolv® uses maximum likelihood and estimated Vmaxc as 4.4 while Matlab® uses least squares and had Vmaxc equal to 4.5. Both methods do yield parameter estimates that provide a good visual fit to the data. Sensitivity coefficients were calculated in SimuSolv® and code was written in Matlab® to calculate the sensitivity coefficients. Very similar results for sensitivity coefficients were achieved when using the same values of Vmaxc and Km in each package. In summary, Matlab® is an adequate replacement for SimuSolv® in this PBPK application. However Matlab® requires more programming by the user and it does not provide built in commands for parameter estimation or sensitivity analysis like SimuSolv®. (This is an abstract of a proposed presentation and does not reflect EPA policy.)

432 A FAMILY APPROACH FOR ESTIMATING REFERENCE DOSES/CONCENTRATIONS FOR SERIES OF RELATED ORGANIC CHEMICALS.

J. G. Teeguarden[1], T. Tyler[2], M. E. Andersen[3] and H. A. Barton[4]. [1]*K. S. Crump Group, Research Triangle Park, NC,* [2]*Union Carbide Corporation, Danbury, CT,* [3]*Colorado State University, Fort Collins, CO and* [4]*Health Effects Research Laboratory, USEPA, Research Triangle Park, NC.*

We developed pharmacokinetic (PK) methods to streamline development of Reference Concentrations (RfCs) and Reference Doses (RfDs) for compounds that are sequential metabolites of common precursor compounds. This approach is illustrated for the butyl series of chemicals: butyl acetate (BuAc), butanol (BuOH), butyraldehyde (BuCHO), and butyric acid (BuCOOH). These compounds are high volume industrial chemicals. Their major systemic effects are nonspecific. Administration of butyl acetate to test animals produces internal doses of the acetate and each of the subsequent metabolites - BuOH, BuCHO, and BuCOOH. It is possible to extrapolate from BuAc systemic toxicity studies to estimate potentially toxic levels of each of the metabolites. Using internal dose metrics simulated with a physiologically-based pharmacokinetic (PBPK) model, we developed methods to predict minimally toxic levels of each of the metabolites. The PBPK model combines submodels for each of the metabolites. The model describes intravenous, inhalation, and oral exposures. Using the PBPK analysis, we estimated the BuOH, BuCHO, and BuCOOH exposures that would result in the same blood AUC for these compounds as observed in the BuAC studies. The RfC or RfD of the metabolite can then be estimated from the study of the parent compound toxicity and the estimated tissue exposures of the various metabolites. This approach streamlines toxicity testing, and makes better use of the toxicity data and fiscal resources for risk and hazard characterization and risk assessment. This work was sponsored by the CMA Oxo Process Panel.

433 QUANTITATIVE EVALUATION OF THE PHARMACOKINETIC INTERACTIONS BETWEEN TRICHLOROETHYLENE (TCE), TETRACHLOROETHYLENE (PERC), AND 1,1,1-TRICHLOROETHANE (MC) USING GAS UPTAKE STUDIES AND PBPK MODELING.

I. Dobrev, M. E. Anderson and R. S. H. Yang. *Department of Environmental Health, Colorado State University, Fort Collins, CO.*

Volatile organic solvents are widely distributed environmental pollutants and common contaminants of many chemical waste sites. TCE, PERC, and MC are among the top ten 1997 ATSDR CERCLA high priority chemicals with 'Completed Exposure Pathway' and are frequently found in combination. To investigate the pharmacokinetic interactions among TCE, PERC and MC, gas uptake experiments were performed using a closed chamber exposure system. In each experiment, two rats (Fischer 344, male, 8-9 weeks old) were exposed to different initial concentration of TCE, PERC, and MC, applied singly or as a mixture, and their concentration in the gas phase of the chamber was monitored over a period of 6 h. A PBPK model was developed to test multiple mechanisms of inhibitory interactions, i.e. competitive, noncompetitive, or uncompetitive. The mixture exposure data were described by a system of equations in which a PBPK model was provided for each chemical and each was regarded as an inhibitor of the others' metabolism. At initial concentrations higher than 300 ppm, PERC and MC inhibit the metabolism of TCE. TCE kinetics were not visibly affected by co-exposure to PERC and MC at initial concentrations lower than 300 ppm. Model simulations indicated that among these three chemicals the inhibition was competitive. The metabolic rates of the three chemicals follow the order of TCE>PERC>MC. Results with binary combinations (TCE+PERC, TCE+MC, and PERC+MC) permit confirmation of the competitive interactions in the ternary mixture. Such interactive PBPK models will be of value in risk assessment of occupational and environmental exposure to solvent mixtures. (This study was supported by ATSDR [Cooperative Agreement U61/ATU881475], and NIEHS Superfund Basic Research Program [P42 ES05949].)

434 *IN-VITRO* TO *IN-VIVO* EXTRAPOLATION OF BENZENE (BZ) METABOLISM FOR PBPK MODELING OF BZ AND ITS METABOLITES IN MICE.

P. M. Schlosser[1], C. E. Cole[1,2] and H. T. Tran[2]. [1]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC and* [2]*Department of Mathematics, NCSU, Raleigh, NC, USA, Raleigh, NC.*

High-level BZ exposure to humans over extended periods has been shown to cause leukemia. There is considerable uncertainty in the risks of low-level BZ exposure from sources such as cigarette smoke, gasoline vapors, and automobile emissions. Conversion of BZ in the liver to benzene oxide (BO), phenol (PH), and/or hydroquinone (HQ) is thought to be an activating process for BZ-induced hematotoxicity. The higher sensitivity of mice than rats to BZ-induced hemato- and myelotoxicity corresponds to faster rates of BZ metabolism in mice relative to rats. Presuming that these endpoints are indicators of leukemogenic potential, the risk of BZ-induced leukemia in humans is expected to correlate with the levels of key BZ metabolites in human bone marrow. Biologically based, mathematical models describing BZ metabolism in rodent and human liver fractions have been previously developed. In order to predict dosimetry of BZ metabolites in humans, a PBPK model based on these *in vitro* models is now being developed. However, BZ dosimetry data in humans that could be used to validate this model are limited. Therefore, we have first developed such a model in mice, where more dosimetry data are available. The model tracks circulating levels of BZ, BO, PH, and HQ, as well as rates of conjugation and excretion of BO, PH, and HQ, and the rate of conversion of BO to muconic acid (MA). But even for mice, not all of the kinetic data needed for an extrapolation is available. The rate of conversion of BO to MA,

in particular, must be fit to *in vivo* data due to a lack of *in vitro* kinetic data. Likewise the rate of irreversible binding to macromolecules must be estimated from *in vivo* data in order to obtain reasonably good fits. Thus, it appears that complete *in vitro* to *in vivo* extrapolation of BZ metabolism is not possible with the existing set of *in vitro* kinetic data.

435 PRELIMINARY PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) MODELING FOR GENISTEIN DOSIMETRY IN RATS AND HUMANS.

M. G. Zager[1,2], P. M. Schlosser[1] and H. T. Tran[2]. [1]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC and* [2]*Department of Mathematics, North Carolina State University, Research Triangle Park, NC.*

A significant portion of total human exposure to endocrine-active compounds is through the diet. Phytoestrogens, such as genistein, found in soy-derived foods are a primary component of this dietary exposure. The National Toxicology Program (NTP) has initiated a multigeneration toxicity study on genistein in rats, and additional studies are underway to complement this work. In order to quantify and extrapolate any exposure-response relationships that may be observed in these studies, we seek to develop PBPK models that will estimate internal dosimetry of genistein in rats and humans. Existing pharmacokinetic data for genistein is not sufficient to accurately estimate all of the parameters of a PBPK model. Therefore we developed "preliminary" PBPK models that will serve to identify key data gaps and can be used in experimental design to fill these gaps. We initially developed PBPK models with a simple structure and few unknown parameters. After estimating those parameters we augmented the models to match existing data. The data include biliary excretion during a portal vein infusion of genistein (Sfakianos et al. 1997), biliary excretion during and after a duodenal infusion of genistein (Barnes et al. 1996), plasma concentration with urinary and fecal elimination after oral doses of genistein (King et al. 1996), and biliary and urinary excretion after oral doses of genistein (Yasuda et al. 1996). Augmentation of the models included compartments for GI tissue and bladder, and delayed variables to account for delays in both biliary and fecal elimination. Physiological parameters such as blood flows and tissue volumes were taken from the literature. The Mathworks' software package MATLAB was used to fit the unknown genistein-specific parameters to the published data. Given an infusion or initial oral dose, the preliminary PBPK models are now able to reasonably predict total concentrations of genistein and its metabolites in the blood and amounts in urine, bile and feces. For example, model predictions indicate that after an oral dose of 60 mg/kg genistein in the rat, the majority of genistein in circulation may be unconjugated for over 7 hours and biliary excretion rates are comparable to urinary excretion rates.

436 PHYSIOLOGICALLY-BASED PHARMACOKENETIC AND TWO STAGE CLONAL GROWTH MODELING OF CHLOROBENZENE-INDUCED PRENEOPLASTIC FOCI WITHIN THE ITO MEDIUM-TERM BIOASSAY.

Y. C. Ou[1], M. E. Andersen[1], R. B. Conolly[2], R. S. Thomas[3], Y. Xu[3], D. L. Gustafson[4] and R. S. H. Yang[1]. [1]*Environmental Health Department Colorado State Univ., Fort Collins, CO.* [2]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC,* [3]*McArdle Laboratory for Cancer Research, University of Wisconsin, Madison, WI and* [4]*School of Pharmacy, University of Colorado, Fort Collins, CO.*

ITO assay is a medium-term (8-week) liver bioassay involving sequential administration of initiating agent, test compound, and mitogenic stimulus. Comparative results from the ITO and two-year chronic bioassay show good correspondence. We describe here a quantitative description of glutathione-S-transferase π foci formation within the ITO framework, using PBPK and clonal growth model for tetra-, penta-, and hexachlorobenzene. To estimate parameters for the PBPK model, a single gavage study (0.1 mmol/kg) was conducted, and tissue concentrations at 7 time points over a 5-day period were collected. Two PBPK models were constructed to analyze the experimental data. The first model, which incorporated α-2μ binding in the kidney and diffusion-limited tissue uptake in the fat compartment, accurately described chlorobenzene levels in kidney and liver, but underestimated blood concentrations. The second model with protein binding in blood adequately described blood and tissue concentrations. To estimate parameters for the clonal growth model, several cell and biochemical parameters were collected, including 5-bromo-2'-deoxyuridine labeling index for analysis of cell division rate, and kinetic changes in foci size and number. The model successfully described the time-dependent changes in foci number, while underestimated the volume fraction of foci in the liver. To further improve model performance, observed time-dependent changes in hepatocyte density following penta- and hexachlorobenzene exposure were incorporated into the model. The application of PBPK and clonal growth modeling presented here provides a quantitative framework for the comparison of carcinogenic potential among chlorobenzene isomers. The approach may also serve as an example of biologically-based dose response modeling for other tumor promoters. (Supported by NIEHS P42 ES05949.)

437 PHYSIOLOGICAL PHARMACOKINETIC MODEL REDUCTION APPLIED TO HUMAN RISK ASSESSMENT.

X. Wang[1], M. J. DeVito[2], K. B. Bischoff[3] and L. S. Birnbaum[2]. [1]*InnaPhase Co., Philadelphia, PA,* [2]*USEPA, Research Triangle Park, NC and* [3]*University of Delaware, Newark, DE.*

Physiological pharmacokinetic models provide quantitative information between the exposure level and the biophase concentration of the xenobiotic based on physiological realities. However, it is difficult to apply physiological models directly to humans due to the limitation of data from humans. Similar problems occur in drug development where there is no information to validate a mechanistic model for humans. Therefore, a nonlinear mixed effect (NLME) pharmacokinetic (PK) approach is widely accepted in clinical trial data analysis. The NLME PK approach introduces covariates to the classical PK models to explain the interindividual variability that the classical PK models alone are unable to address. However, the NLME method is a purely statistical approach, where the covariates are determined through residual analysis. The present study combined both physiological modeling and the NLME approach to analyze human population data. This was done in three stages. First, a PBPK model was developed based on information from experimental animals. Second, model reduction was conducted and the physiological realities were expressed in the simplified model through well defined covariates. At stage three, a NLME modeling was conducted to establish the population PK model as well as individual PK models using sparse data. TCDD was used as an example since both a PBPK model for animals and sparse data from humans are available. This example demonstrates the potential use of this new approach for species extrapolation in human health risk assessments. (This study does not represent USEPA policy.)

438 INCORPORATING A VALIDATED PBPK PREGNANT RAT MODEL INTO A BBDR MODEL FOR THE EMBRYOTOXICITY OF 5-FLUOROURACIL.

R. W. Setzer and R. S. DeWoskin. *USEPA, Research Triangle Park, NC.*

5-Fluorouracil (5-FU) is a widely used antitumor agent that is embryotoxic in rats at maternal therapeutic levels. A biologically based dose-response model (BBDR) was developed that relates a single dose of 5-FU on gestation day 14 in rats to cell cycle effects in developing fetuses, specifically the inhibition of thymidylate synthetase (TS; due to formation of a FdUMP/TS/folate complex) with subsequent reduction in thymidylate (dTMP) levels, thymidine-5'-triphosphate (dTTP; a DNA precursor) and, ultimately, disruption of DNA synthesis. The initial modeling of the pharmacokinetic component of the BBDR model was based upon a two-compartment PBPK model (Collins et al., 1980) for the maternal kinetics with an added compartment for the fetal kinetics of 5-FU. This BBDR model described well the 5-FU concentration data from gestation day 19, but fetal compartment concentrations on day 14 and the time course of the inhibition were modeled empirically rather than mechanistically. To incorporate more physiological information, a pregnant rat PBPK model developed by O'Flaherty et al. (TAP 112:245-256, 1992) for the weak acid dimethloxazolidine-2,4-dione (DMO) was adapted for use in the 5-FU BBDR model. The O'Flaherty model adjusts for changes in the dam and fetal body weights, blood flows, and organ volumes as the gestation progresses. Metabolism of 5-FU and tissue partitioning was also added to the model. Sensitivity analysis and use of different data sets as the basis for the parameter estimates in this more detailed PBPK component provided insights into the importance of 5-FU pharmacokinetics to the resulting changes in thymidylate synthesis compared with other potential pharmacodynamic interactions. (This abstract does not necessarily reflect EPA policy.)

439 DEVELOPMENT OF A PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL FOR ANTHRAQUINONE IN MALE AND FEMALE RATS AFTER SINGLE INTRAVENOUS AND ORAL DOSES AND CHRONIC DOSING IN FEED.

G. M. Blumenthal, M. C. Kohn, F. M. Parham, R. L. Melnick, R. D. Irwin and C. J. Portier. *NIEHS, Research Triangle Park, NC.*

Anthraquinone (AQ) is an industrial chemical widely used in the production of dyes and paper products. It is a direct-acting mutagen in *Salmonella*. Toxicity and carcinogenicity tests performed by the National Toxicology Program (NTP) have shown AQ, when added to feed, to be carcinogenic to the female rat kidney and the male and female mouse liver. A physiologically based pharmacokinetic (PBPK) model for AQ was developed to characterize tissue concentrations of AQ in male and female rats resulting from intravenous and oral exposure. Plasma concentration and biliary secretion time-course data used to create the anthraquinone PBPK model were obtained from single administration intravenous and oral gavage toxicokinetic studies done as part of the NTP study, as well as from plasma samplings done at five intervals (8 days, and 13, 26, 52, and 78 weeks) during the chronic study. This PBPK model describes AQ as slowly and incompletely absorbed from the lower intestine into the blood via the lymph. AQ is represented as distributed slowly to tissues by a diffusion-limited transport process, stored in fatty tissues, and metabolized by both hepatic and extra-hepatic pathways. AQ secreted into the bile is reabsorbed from the intestine. The model reproduces plasma concentrations, which peak more than 8 hr after oral administration, and biliary secretion rates for anthraquinone as parent chemical after single intravenous and oral gavage exposures. The model was then used to simulate plasma concentrations for anthraquinone after chronic exposure in feed.

440 MODELING OF THE DISPOSITION OF GLYCYRRHIZIC ACID, A COMPOUND SUBJECT TO PRESYSTEMIC METABOLISM AND ENTEROHEPATIC CYCLING, IN HEALTHY VOLUNTEERS.

B. A. Ploeger[1], J. Meulenbelt[2] and J. DeJongh[3]. [1]*RITOX, Utrecht University, Utrecht, Netherlands,* [2]*National Institute of Public Health and the Enivornment, Bilthoven, Netherlands and* [3]*LAP&P Consultants, Leiden, Netherlands.* Sponsor: M. vandenBerg.

Glycyrrhizic acid (GD) is currently of clinical interest for treatment of chronic hepatitis. It is also applied as a sweetener in food products and chewing tobacco. In some highly exposed subgroups of the population, serious side effects like hypertension and electrolyte disturbances have been reported. For the health risk evaluation of GD exposure, a detailed insight into the kinetics of glycyrrhizic acid and its metabolites was obtained by the development of a kinetic model. Rat data show that after oral intake GD is hydrolyzed in the gastrointestinal tract by commensal bacteria and absorbed as its aglycon glycyrrhetic acid (GA). This compound is predominantly cleared from plasma by the liver after glucuronidation. Following biliary excretion commensal bacteria reconvert this GA-glucuronide to GA , which is reabsorbed by the gut. These kinetic processes were modeled in a biological motivated manner. Using the results of a clinical study, 5 of the 18 model parameters, having the most influence on the GA plasma concentration forecast, were successfully fitted to the data. In a 4-way cross over design, all volunteers consumed 4 different forms of liquorice. The model, parameterized with the mean of the fitted parameter values, successfully forecasted the GA plasma concentrations of another clinical study. The distribution of the individual parameters within the clinical study population was used to simulate the GA disposition within the general population by a Monte Carlo simulation. This simulation shows that especially in people having a prolonged gastrointestinal residence time, GA accumulates after repeated liquorice consumption, specifically increasing the health risk of this subgroup of individuals.

441 COMPARISON OF *IN VITRO* AND *IN VIVO* KINETICS OF TETRACHLOROBENZYLTOLUENES (UGILEC 141) AND PCBs.

H. J. Kramer[1], H. Drenth[1], R. H. L. Fleuren[1], M. VandenBerg[1] and J. DeJongh[2]. [1]*Ritox, Utrecht, Netherlands and* [2]*LAP&P Consultants, Leiden, Netherlands.*

Tetrachlorobenzyltoluenes (TCBTs) were introduced in Europe as a replacement for polychlorobiphenyl mixtures in hydraulic devices in the early 1980s. Since 1994 their use is prohibited. *In vitro* studies demonstrated that metabolism of TCBTs in mammalian species is relatively rapid compared to PCBs. However, *in vivo* studies showed that TCBT elimination was determined by their flow-limited release from the adipose tissues. It is therefore relevant to study the quantitative role of metabolism in the whole body elimination of TCBTs relative to that of PCBs. For this purpose, we determined *in vitro* metabolic rate constants for three TCBTs and seven PCBs using rat hepatic microsomes. In addition, we conducted an *in vivo* kinetic study in the rat. Rats were either fed with a mixture of TCBTs and PCBs or intravenously injected with the same mixture. Analysis of these *in vivo* results with a physiologically-based pharmacokinetic model confirms that the metabolism of TCBTs is limited by the perfusion of, and diffusion to, the adipose tissues.

441A ORGAN-SPECIFIC DIFFERENCES IN BASE-EXCISION REPAIR FOLLOWING ACUTE TREATMENT WITH BENZO[A]PYRENE.

T. J. Stedeford[1], F. Cardozo-Pelaez[2], C. G. Hover[1], R. D. Harbison[1] and J. Sanchez-Ramos[2]. [1]*Dept. of Environmental and Occupational Health, College of Public Health, University of South Florida, Tampa, FL and* [2]*Dept. of Neurology, College of Medicine, University of South Florida, James A. Haley Veteran's Hospital, Tampa, FL.*

Benzo[a]pyrene (B[a]P), a known carcinogen, is widely distributed in the environment. Studies suggest that the carcinogenic effect of B[a]P results from the formation of promutagenic DNA lesions, specifically 8-oxoguanosine and etheno-adducts. The lung is a target organ for B[a]P toxicity. Previous studies have demonstrated the presence of oxidatively modified bases in the lung compared with other tissues, following B[a]P treatment. The objective of this study was to determine the capacity of different organs to repair 8-oxoguanosine and etheno-adducts after treatment with B[a]P. Male Sprague-Dawley rats were treated with 20 mg/kg B[a]P i.p., 2 times/day for 5 days. At 24, 72, and 120 hours after the last treatment, lung, liver, and kidney were harvested. The capacity to repair 8-oxoguanosine and 3-methyladenosine were determined. Tissue extracts were incubated with a 32P-labelled oligonucleotide containing either 8-oxoguanosine or ethenoadenosine. Excision repair activity was determined by comparing cut and uncut DNA. The lung had a significant decrease in capacity to cleave 8-oxoguanosine at 72 hours following treatment, but recovered to above control values at 120 hours. The activities for liver and kidney remained at baseline for all times studied. 3-methyladenosine activity remained constant for all organs. This study suggests that organ-specific differences exist in base-excision repair activity in response to acute treatment with B[a]P. (Supported in part by NIOSH grant 416005-01 and VA Merit Review grant.)

442 DEVELOPMENT OF A PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL FOR ETHYLENE GLYCOL AND ITS MAJOR METABOLITE, GLYCOLIC ACID.

R. A. Corley, K. K. Weitz, R. A. Gies and K. D. Thrall. *Battelle, Pacific Northwest Division, Richland, WA.*

Ethylene Glycol (EG) is a major industrial chemical. An extensive database has been amassed on EG's toxicity and modes of action. At high oral bolus doses (≥500 mg/kg/day), EG causes renal and developmental toxicity. EG's toxicity has been primarily attributed to its major metabolite, glycolic acid (GA), which shows a high degree of dose-, route- and species-dependency. A physiologically based pharmacokinetic (PBPK) model was developed to describe the disposition of EG and GA in female rats, including pregnancy. Metabolic rate constants for EG and GA were estimated from liver slice kinetic studies. Partition coefficients for EG and GA were determined by vial equilibration and ultrafiltration methods. The PBPK model included inhalation, oral, dermal, intravenous and subcutaneous routes of administration. Metabolism of EG and GA were described in the liver with elimination via the kidneys. Several rat metabolism studies were simulated. Pregnancy had no effect on maternal EG and GA kinetics over a broad dose range. Simulations were consistent with studies indicating that metabolism of EG to GA was essentially first-order (linear) up to 2500 mg/kg/day while the metabolism of GA saturated between 200 and 1000 mg/kg/day. This resulted in non-linear increases in blood GA concentrations which correlate with the toxicity of EG. (Sponsored by the Ethylene Glycol Panel of the Chemical Manufacturers Association).

443 BIOLOGICALLY-BASED PHARMACOKINETIC MODELING OF UPTAKE AND INTRACELLULAR ACIDIFICATION OF ORAL EPITHELIAL CELLS INDUCED BY VINYL ACETATE EXPOSURE FROM DRINKING WATER.

R. Sarangapani[1], J. Teeguarden[1], A. Jarabek[2], J. Morris[3], R. Valentine[4], M. S. Bogdanffy[4] and M. E. Andersen[5]. [1]*K. S. Crump Group, ICF Consulting, Research Triangle Park, NC,* [2]*National Center for Environmental Assessment, Research Triangle Park, NC,* [3]*University of Connecticut, Storrs, CT,* [4]*DuPont Haskell Laboratory, Newark, DE and* [5]*Colorado State University, Fort Collins, CO.*

Recent two year drinking water studies with vinyl acetate (VA) in rats and mice have shown statistically significant increases in tumor incidences in several sites along the oral cavity, esophagus and fore-stomach at high doses (10000ppm) at terminal sacrifice, and not at lower doses (400, 2000 ppm). VA is extensively hydrolyzed by carboxylesterase (CE) to acetic acid (AA) and acetaldehyde (AAld). AAld is further rapidly oxidized to AA by a saturable aldehyde dehydrogenase (ADH). AAld is a potential clastogen and recent evidence suggests that an acidic intracellular pH is also clastogenic. It is proposed that intracellular accumulation (of VA and metabolism to) AA causes intracellular acidification resulting in cytotoxicity followed by reparative mucosal hyperplasia. At high doses, cell proliferation under conditions including high AAld concentration and lowered nonphysiological pH may lead to mutation, cellular transformation, and increased tumors. This same mode of action was used successfully to develop a biologically-based model for inhalation exposures in rats. A GI tract model was constructed to describe regional uptake and metabolism using information collected on (1) the temporal drinking water patterns in rodents, (2) the mucosal surface area and tissue thickness in different regions of the GI tract, (3) enzyme histochemical localization within the GI tract, and (4) regional enzyme kinetics for carboxylesterase in the GI tract of rodents. The resulting model describes diffusion-limited uptake of VA and intracellular pH changes in the epithelial tissue layer. Initial simulations of 24 hour exposure to 1000, 2000, 5000, and 10,000 ppm VA in drinking water yielded estimates of steady-state epithelial pH of 6.97, 6.88, 6.78, and 6.7, respectively. This model will be used for interspecies dose-response assessment in a harmonized approach to cancer and noncancer toxicity of oral VA exposures.

444 PRELIMINARY DEVELOPMENT OF A PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL FOR PERCHLORATE IN ADULT HUMANS.

E. Merrill[1], J. Fisher[2] and D. Mattie[2]. [1]*OpTech, Inc., Dayton, OH and* [2]*AFRL/HEST, Wright-Patterson AFB, OH.*

Perchlorate-contaminated groundwater presents a potential environmental health issue. Perchlorate is not metabolized and is almost completely excreted; however while in the body, it competitively inhibits iodide uptake in the thyroid and gut. Hence, there's concern that chronic exposure to low levels in drinking water could lead to hypothyroidism. A human physiologically-based pharmacokinetic (PBPK) model to predict the inhibition of thyroid iodine uptake and effect on thyroid hormones is under construction. The preliminary model, presented here, describes systemic clearance of perchlorate and simultaneous concentrations in the blood, lungs, slowly perfused tissue, rapidly perfused tissue, gut and thyroid. The gut and thyroid compartments are comprised of two compartments to describe non-linear uptake of perchlorate. Tissue/blood partition coefficient values were derived from published animal studies. Systemic clearance of perchlorate was established by fitting limited published human urinary excretion data. Urinary elimination rate constants ranged from 4 to 6 hr^{-1}- kg BW. The model adequately simulated the urinary excretion of perchlorate. Human studies are ongoing, which will provide data for further model development.

445 DEVELOPMENT OF A PHYSIOLOGICAL MODEL FOR PERCHLORATE INDUCED INHIBITION OF THYROIDAL UPTAKE OF IODIDE IN THE RAT.

J. Fisher[1], P. Todd[1], D. Mattie[1], D. Godfrey[2], L. Narayanan[3] and K. Yu[1]. [1]*AFRL/HEST, Wright-Patterson AFB, OH,* [2]*ManTech Environmental Inc., Dayton, OH and* [3]*Geo-Centers, Inc., Dayton, OH.*

NASA and DoD use ammonium perchlorate (NH_4ClO_4) salt as an oxidizer in solid rocket propellants. NH_4ClO_4 is highly soluble in water and completely dissociates to NH_4^+ and ClO_4^-. The ClO_4^- ion, because of its similarity in ionic size to I^- competes with I^- for uptake into the thyroid gland by the Na^+/I^- symporter. Consequently, the availability of I^- for thyroid hormone synthesis (thyroxine (T_4) and, 3,5,3'-triiodothyronine (T_3)) may be depleted leading to a state of hypothyroidism. A series of pharmacokinetic laboratory experiments were carried out using cold and radiolabeled perchlorate and ^{125}I in male Sprague-Dawley rats for development of a physiologically based pharmacokinetic (PBPK) model for perchlorate and ^{125}I in the rat. Subsequent pharmacokinetic experiments were conducted to examine the dose-response characteristics of perchlorate induced inhibition of uptake of ^{125}I in the thyroid. Perchlorate is excreted in urine (> 80% over 24 hrs). While in the body of naïve rats, perchlorate inhibits uptake of radiolabeled iodide. For perchlorate doses ranging from 0.01 to 3 mg/kg uptake of iodide in the thyroid gland was inhibited from about 20 to 80%. A rat PBPK model for perchlorate induced inhibition of uptake of iodide in the thyroid is presented.

446 TRICHLOROACETATE TISSUE DOSIMETRY AND PPARα-MEDIATED LIVER CANCER INDUCTION BY TRICHLOROETHYLENE AND PERCHLOROETHYLENE.

H. A. Barton[1], P. R. Gentry[2] and H. J. Clewell, III[2]. [1]*USEPA, NHEERL, Research Triangle Park, NC and* [2]*ICF Consulting/KS Crump Group, Ruston, LA.*

A biologically-motivated dose-response analysis was undertaken for liver cancer induction in mice by trichloroethylene (TCE) and perchloroethylene (PERC). The mechanistic hypothesis evaluated was whether tumors resulted from a peroxisome proliferator-activated receptor-alpha (PPARα)-mediated process initiated by formation of trichloroacetate (TCA) from the two volatile organics. Available mechanistic data for TCE, PERC, and TCA were compared with those for prototypical PPARα-ligands. Several early and late events were consistent: increased liver to body weight ratio (LW/BW) due to induction of peroxisomes, hypertrophy, and cell proliferation; the phenotype of induced foci; and reversibility of tumor response with cessation of exposure. One difference was hepatic accumulation of lipid with PERC, but not the other compounds. Use of precursor events for analyzing cancer dose response was evaluated; increased LW/BW was suggested as a useful indicator of the pleiotropic response necessary for PPARα-mediated liver carcinogenesis. Physiologically based pharmacokinetic models provided estimates of internal dose metrics for TCA. Oral and inhalation studies for LW/BW and cancer were evaluated to obtain points of departure. Low dose extrapolation used a margin of exposure approach for TCE; TCA and PERC were not evaluated. While there are difficulties in analyzing the hypothesis due to the variety of exposure protocols used in the studies with TCE, PERC, and TCA, this analysis indicated substantial consistencies in the database supporting a PPARα-mediated process for TCE- and TCA-induced liver carcinogenesis as a major causative process. (Abstract does not reflect EPA policy.)

447 DIALLYL SULFIDE PROTECTS AGAINST ALCOHOL ENHANCED ACETAMINOPHEN HEPATOTOXICITY IN *Cyp2e1(-/-)* MICE.

J. F. Sinclair[1,2,3], J. G. Szakacs[4], S. G. Wood[1], F. Gonzalez[5], E. H. Jeffery[6], S. A. Wrigthton[7], W. J. Bement[1] and P. R. Sinclair[1,2,3]. [1]*VA Medical Center, White River Junction, VT and* [2]*Salt Lake City, UT,* [3]*Biochem & Pharma./Tox., Dartmouth Medical School, Hanover, NH,* [4]*NIH, Bethesda, MD,* [6]*Dept. of Food Science/Human Nutrition, University of Illinois, Urbana, IL and* [7]*Dept. Drug Disp., Lilly Research Labs, Indianapolis, IN.*

One approach to determine the role of a particular form of CYP in drug toxicity involving bioactivation is to investigate whether treatment with a specific inhibitor of that CYP protects animals from the toxicity. A significant problem with this approach is that inhibitors administered *in vivo* may prove less specific than when used *in vitro*, due to the very high concentrations often achieved in the liver of the intact animal. Diallylsulfide is a chemical reported to specifically inhibit CYP2E. Protection against ethanol-mediated increases in acetaminophen (APAP) hepatotoxicity by diallyl sulfide is taken as evidence for a major role of CYP2E1. However, diallyl sulfone, a metabolite of diallyl sulfide, has been shown to also inhibit CYP3A and CYP1A2. Here we show that short-term treatment with diallyl sulfide protects *Cyp2e(-/-)* mice from APAP hepatotoxicity in animals pretreated with ethanol and isopentanol. Liver damage was assessed histochemically and by the elevation in serum levels of alanine aminotranferase. The absence of CYP2E1 in these mice was confirmed by immunochemical analyses of microsomes from all animals in the study. The results show that diallyl sulfide is not specific for CYP2E1 *in vivo*. (Supported by the Department of Veterans Affairs.)

448 HETEROLOGOUS EXPRESSION STRATEGIES OF THE CYTOCHROME P450 2F FAMILY ENZYMES.

K. W. Skordos and G. S. Yost. *University of Utah, Salt Lake City, UT.*

Cytochrome P450 enzymes 2F1 (human) and 2F3 (goat) have been shown to be selectively expressed in pulmonary tissues. Both of these enzymes are believed to participate in the biotransformation of pneumotoxic compounds to their respective reactive intermediates. 3-Methylindole is a pneumotoxin that requires P450-mediated dehydrogenation to elicit its toxic effects. Cytochrome P450 2F1 and 2F3 exclusively catalyze dehydrogenation of this substrate. To elucidate the biochemical parameters of this unique P450-mediated reaction, a system for the production of large amounts of pure enzyme is required. Bacteria remain the most preferred organism for the heterologous expression of mammalian P450 enzymes due to their lack of endogenous membrane-bound P450 enzymes and their ability to produce large quantities of the protein. Several strategies are currently being investigated for the expression of both 2F1 and 2F3 in a bacterial system. Cytochrome P450 2F3 has been expressed in a lac based expression system that co-expressed cytochrome P450-NADPH reductase. The maximal level of P450 expression was 24 nmols/liter of culture. Expression of cytochrome P450 2F1 has been attempted in this system, a lac based system without the reductase and a T7-based expression system. Heterologous expression of 2F1 in bacteria was not successful using these vectors, despite the greater than 85% sequence identity to 2F3. A chimeric construct of the cDNA encoding the N-terminal region of cytochrome P450 2F3 and C-terminal region of cytochrome P450 2F1 has recently been produced. Studies with this construct are currently being investigated. (Supported by USPHS Grant HL16345.)

449 DOES TCDD CAUSE PERINATAL IMPRINTING OF CYP4501A2 ACTIVITY IN THE HUMAN?

G. Lambert[1], P. Brambilla[2], H. Zhang[1], M. Cazzaniga[2], C. Dassi[2], L. Needham[3] and P. Mocarelli[2]. [1]*UMDNJ, Piscataway, NJ,* [2]*University of Milan, Hospital of Desio, Desio, Italy and* [3]*CDC, Atlanta, GA.* Sponsor: M. Iba.

This study addresses the question of whether high body burdens of TCDD during development may imprint the Ah receptor-Cytochrome P4501a2 system complex resulting in alteration of the adult's expression and /or inducibility of P450 1a2 activity. Study subjects were recruited during 1992 to 1995 from individuals who were exposed to very high levels of TCDD in 1976 following an industrial accident that released the TCDD into a residential environment. Thirty three females and 33 males were recruited into the study who were a few months to 54 years of age in 1976 when the exposure occurred. All subjects were healthy, none smokers, had a TCDD measure in serum in 1976 after the accident, and in 1992-1995. The [13]Caffeine breath test (CBT), to monitor P4501a2 activity, was conducted between 1992 and 1995. According to the subject's age at the time of the exposure, the subjects were divided into an Early Childhood Exposure Group (a few month to 5 years of age), a Late Childhood and Adolescence Exposure Group (6 to 16 years of age), and a Adult Only Exposure Group (16 years old and older). Comparison of CBTs between exposure groups was conducted using the Wilcoxon rank test. TCDD levels for the females ranged between 30 and 56,000 ppt in 1976, and 12 and 800 ppt in 1992;those for the males were between 50 to 11,000 ppt in 1976 and 1 to 700 ppt in 1992. The CBT, expressed as per cent of carbon thirteen label administered which is exhaled over two hours after the caffeine was taken, was significantly lower in the Early Childhood Exposure Group (median 3.8, range 1.3-4.8) as compared to the other two group (median 6, range 3.2-10; median 6.5, range 3.0-15 respectively, $p < 0.01$). This was observed even though the TCDD serum levels of all the groups were not different in 1976 or in 1992. The molecular mechanism by which apparent imprinting occured and the relative importance of the expression of P450s and their imprinting to the overall susceptibility of the human to the PAHs, and to normal development remains to be identified. The cooperation and understanding of the study subjects of Seveso are greatly appreciated. (Support: STAR grant from the USEPA and of Region Lombardia, Milano.)

450 NADPH- AND HYDROPEROXIDE-SUPPORTED 17BETA-ESTRADIOL (E2) HYDROXYLATION CATALYZED BY A VARIANT FORM (432L, 453S) OF HUMAN CYTOCHROME P450 1B1 (CYP1B1).

B. C. Spink, X. Zhuo, M. M. Hussain, J. F. Gierthy, X. Ding and D. C. Spink. *Wadsworth Center, New York State Department of Health, Albany, NY.*

Human CYP1B1 catalyzes the hydroxylation of E2 at C-4 with a lesser activity at C-2. The E2 4-hydroxylase activity of human CYP1B1 was first identified in MCF-7 breast cancer cells. Sequencing of polymerase chain reaction products revealed that CYP1B1 expressed in MCF-7 cells is not the previously characterized enzyme but a polymorphic form with leucine substituted for valine at position 432 and serine substituted for asparagine at position 453. To investigate the NADPH- and organic hydroperoxide-supported E2 hydroxylase activities of the 432L, 453S form of human CYP1B1, the MCF-7 CYP1B1 cDNA was cloned and the enzyme was expressed in Sf9 cells. In microsomal assays supplemented with human NADPH:cytochrome P450 oxidoreductase, the expressed 432L, 453S form catalyzed NADPH-supported E2 hydroxylation with a similar preference for 4-hydroxylation as the 432V, 453N form, with maximal rates of 1.97 and 0.37 nmol/min per nmol P450 for 4- and 2-hydroxylation. Cumene hydroperoxide efficiently supported E2 hydroxylation by both the 432V, 453N and 432L, 453S forms at several-fold higher rates than the NADPH-supported activities and lesser preference for E2 4- versus 2-hydroxylation (2:1). The hydroperoxide-supported activities of both forms were potently inhibited by the CYP1B1 inhibitor, 3,3',4,4',5,5'-hexachlorobiphenyl. These results indicate that the 432V, 453N and 432L, 453S forms of CYP1B1 have similar catalytic properties for E2 hydroxylation, and that human CYP1B1 is very efficient in catalyzing the hydroperoxide-dependent formation of catechol estrogens. (Supported by NIH Grants ES04913, ES03561 and DC02640.)

451 EFFECTS OF 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN AND DI-INDOLYLMETHANES ON CYTOCHROME P450 1A1, 1B1 AND 19 IN H295R HUMAN ADRENOCORTICAL CARCINOMA CELLS.

M. vandenBerg[1], L. Slobbe[1], *S. Safe*[2] and J. T. Sanderson[1]. [1]*RITOX, Utrecht, Netherlands and* [2]*Texas A&M, College Station, TX.*

Di-indolylmethane (DIM) is a condensation product of indole-3-carbinol, a consituent of cruciferous vegetables, and is formed in the stomach. DIM has been shown to have antiestrogenic properties; it alters estrogen metabolism and appears to antagonize breast tumor promotion. DIM is a weak agonist for the aryl hydrocarbon (Ah) receptor. DIM and four synthetic analogs (5,5'-dimethyl-, 5,5'-dimethoxy-, 5,5'-dibromo- and 1,11'-dimethoxy-C-methoxyphenyl-DIM) were examined in H295R cells for effects on three cytochrome P-450 (CYP) enzymes involved in estrogen synthesis and/or metabolism: CYP1A1, CYP1B1 and CYP19 (aromatase). Aromatase activity was measured by the conversion of [1β-^{3}H]-androstenedione to estrone and ^3H_2O. H295R cells were exposed to the test chemicals dissolved in dimethyl sulfoxide for 24 h prior to analyses. 2,3,7,8-Tetrachlorodibenzo-*p*-dioxin (TCDD) (0-30 nM) and DIM (0-10 μM) induced ethoxyresorufin O-deethylase (EROD) activity, as a measure of CYP1A1 and 1B1 activity, concentration-dependently with EC_{50} values of about 0.3 nM and 3 μM, respectively. DIM, but not TCDD, induced aromatase activity concentration-dependently to an apparent maximum of two-fold at 10 μM; greater concentrations of DIM and analogs were cytotoxic. TCDD (30 nM) increased levels of mRNA for CYP1A1 and 1B1 about 2 to 2.5 fold, but had no effect on mRNA for CYP19. DIM (3 μM) increased mRNA levels for all three CYPs between 1.8 and 2.5 fold. The DIM analogs (3 μM) induced aromatase and/or EROD activity, together with the corresponding mRNA levels. DIM and certain DIM analogs appear to induce CYPs via multiple pathways, including the Ah receptor-mediated pathway for CYP1A1 and 1B1 induction, and the protein kinase A-mediated pathway for the induction of aromatase.

452 DEVELOPMENTAL REGULATION OF ADIPOGENESIS, CYP1B1, AND THE ARYL-HYDROCARBON RECEPTOR IN MOUSE EMBRYO FIBROBLASTS.

P. R. Hanlon, L. G. Ganem, L. Zhang, W. Zheng and C. R. Jefcoate. *UW-Madison, Madison, WI.*

Mouse embryo fibroblasts (MEFs) are pluripotent cells that can be stimulated to differentiate into adipocytes, osteocytes, chondrocytes, or myocytes. We show that primary MEFs obtained from gestational day (gd) 14 are not responsive to hormonally-stimulated adipocyte differentiation, whereas gd16 MEFs are highly responsive. Primary MEFs derived from these days differ in the basal and induced expression of the peroxisome proliferator activated receptor γ (PPARγ), a key regulator of adipocyte differentiation, which has low expression in gd14 MEFs compared to gd 16 MEFs. Pretreatment with the DNA-hypomethylating agent 5-azacytidine for the two days preceding hormonal stimulation of adipocyte differentiation improved PPARγ expression in gd14 MEFs by threefold and allowed for differentiation to proceed in these cells. Adipocyte differentiation can be blocked by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) via activation of the aryl-hydrocarbon recep-

tor (AhR). We have shown that this corresponds to a prolongation of MAP kinase activation during the initial 24 hours following hormonal stimulation. The AhR controls constitutive and TCDD induced levels of CYP1B1 in gd16 MEFs. We have shown that gd16 MEFs, compared to gd14 MEFs, show ten-fold higher expression of cytochrome P450 (CYP) 1B1, the predominant P450 in mesenchymal cells. AhR protein expression and down regulation by TCDD were similar in gd14 and gd16 MEFs. In both gd14 and gd16 cells activation of AhR-responsive constructs was similar. CYP1B1 and AhR levels were not affected by 5-azacytidine treatment. Combined, these results suggest that: 1) the developmental pattern of CYP1B1 expression in MEFs does not stem from AhR levels or activity; 2) AhR and CYP1B1 do not control the developmental differences in adipogenic potential; 3) instead, these differences are due to PPARγ suppression in gd14 MEFs.

453 PAH/METAL MIXTURES: EFFECT ON PAH INDUCTION OF CYP1A2 IN CULTURED HUMAN HEPATOCYTES.

L. S. Kaminsky and D. D. Vakharia. *NY State Department of Health, Wadsworth Center, NY.*

The carcinogenicity of PAHs is potentiated by their CYP1-catalyzed bioactivation, and induction of the bioactivating enzymes by PAH facilitates this process. Metals (frequently environmental co- contaminants with PAHs) could affect PAH carcinogenicity by modifying PAH induction of CYP1A. The four most hazardous environmental metals (EPA and ATSR) were used to test this hypothesis in human hepatocyte cultures grown on collagen matrix. Studies were conducted in 96-well plates of hepatocyte cultures and extents of CYP1A2 induction by 10 μM benzo[a]pyrene (BAP), benzo[b]fluoranthene (BBF), dibenzo[a,h]anthracene (DBAHA), benzo[a]anthracene (BBA), or benzo[k]fluoranthene (BKF) were probed by ethoxyresorufin-O-deethylase activity. Cultures showed large interindividual variations and means of data from several individuals are reported. Induction efficiency (relative to dimethyl sulfoxide controls) was in the order of BKF (8±8-fold) > DBAHA (6±4-fold) > BAP (5±5-fold) > BAA (4±2-fold) > BBF (3±3-fold) (n=5-6), and was approximately 20% of that achieved by BKF or DBAHA and approximately the same for the other PAHs for CYP1A1 induction in HepG2 cells. At 1 μM concentrations of the metals, which did not produce cytotoxicity, CYP1A2 induction by the PAHs was diminished in a metal- and PAH-dependent manner: with BAP as inducer the inhibition was As (50±10%), Cd (24±11%), Pb (18±12%), and Hg (15±18%), n=3. HepG2 cells yielded similar data for CYP1A1 induction. Thus the metals in PAH/metal mixtures could diminish PAH carcinogenicity by decreasing induction of their bioactivation by CYP1A2. (Funded by EPA grant R827180010.)

454 IDENTIFICATION OF CYP2C9 AS THE MAJOR HUMAN LIVER MICROSOMAL LINOLEIC ACID EPOXYGENASE.

A. J. Draper[1] and B. D. Hammock[2]. [1]*Bucknell University, Lewisburg, PA and* [2]*University of California, Davis, CA.*

Leukotoxin (9,10-epoxy-12-octadecanoate) and isoleukotoxin (12,13-epoxy-9-octadecenoate) are monoepoxides of linoleic acid, synthesized by a cytochrome P450 monooxygenase and possibly by an oxidative burst of inflammatory cells. Recent experiments in this laboratory have indicated that the toxicity of leukotoxin and isoleukotoxin are not due to these epoxides, but to the 9,10- and 12,13-diol metabolites. These lipids may be involved in inflammation. This study used a combination of experimental approaches to identify the major cytochrome P450 enzyme in human liver involved in linoleic acid epoxidation. The kinetic paramenters were determined; the Km of linoleic acid epoxidation by pooled human liver microsomes was 170 μM and the Vmax was 58 pmol/mg/min. Correlation analysis was performed using individual samples of human liver microsomes, and the best correlation of linoleic acid epoxidation activity was with tolbutamide hydroxylase activity, CYP2C9. Experiments with inhibitory anti-cytochrome P450 antibodies also suggested that the major enzyme in linoleic acid epoxidation was a CYP2C enzyme. Incubations with chemical inhibitors had similar results; no chemical except tolbutamide, a competing substrate for CYP2C9, and sulfaphenazole, an inhibitor of CYP2C9, caused more than 20% inhibition of linoleic acid epoxidation. Both tolbutamide and sulfaphenazole caused greater than 80% inhibition. Finally, although many of the recombinant cytochrome P450 enzymes metabolized linoleic acid, only CYP2C9 had significant epoxidation activity. These results suggest that CYP2C9 is the predominant cytochrome P450 enzyme responsible for the epoxidation of linoleic acid in the human liver. This enzyme, therefore, may serve as a therapeutic target in the treatment of inflammation in order to reduce the amount of circulating leukotoxin and isoleukotoxin and their corresponding diols. (Supported by NIEHS postdoctoral fellowship ES05808, Amgen-American Liver Foundation Postdoctoral Fellowship, ES02710, ES05707 and ES04699.)

455 INDUCTION OF HEPATIC MICROSOMAL CYP1A ACTIVITY BY CYHALOTHRIN.

A. Anadón, M. R. Martinez-Larrañaga, M. Martinez, M. J. Díaz, M. A. Martinez, M. T. Frejo and M. Tafur. *Complutense University, Madrid, Spain.*

The effects of the pyrethroid type II cyhalothrin on hepatic cytochrome P450 (CYP) activities were investigated in male Wistar rats. Animals were divided into 3 groups of six animals each and received orally cyhalothrin dissolved in 0.5 ml corn oil at two dose leves of 4 and 8 mg/kg for 6 days. Control group rats received 0.5 ml corn oil orally. All animals were killed 24 h after last dosing, liver were removed and microsomal pellets prepared for enzyme determinations. Treatment with cyhalothrin enhanced the O-deethylation of ethoxyresorufin (EROD), an activity exclusively catalysed by CYP1A subfamily, and particularly CYP1A1 isoenzyme. Similar changes were observed in the O-demethylation of methoxyresorufin (MROD), an activity also associated with the CYP1A subfamily and particularly the CYP1A2 isoenzyme. Because of CYP1A subfamily has been implicated in the metabolic activation and toxicity of many chemicals, the induction of CYP1A1/2 by cyhalothrin raises the possibility that these enzymes may metabolically convert cyhalothrin to a 'reactive electrophile(s)' with toxicological consequences. (Work supported by Projects No. PB97-1236 (DGICYT), No. 08.8/0002/98 (CAM) and 99/0936 (FIS), Spain.)

456 CYP6L1 IS SPECIFICALLY EXPRESSED IN THE TESTIS AND ACCESSORY GLAND OF GERMAN COCKROACHES.

Z. Wen and J. G. Scott. *Cornell University, Ithaca, NY.*

Cytochrome P450s are a very important enzymatic system involved in the metabolism of endogenous compounds and xenobiotics. The multiplicity of P450 isoforms in every organism, the broad substrate spectra of some isoforms, and the difficulty in purification of isoforms make it challenging to study individual P450s. Using 3′ and 5′ RACE (rapid amplification of cDNA end) techniques, we have recently cloned full length cDNA of a new P450 gene, *CYP6L1*, from German cockroach, *Blattella germanica*. Using Northern Blot analysis, we found that CYP6L1 is only expressed in the abdomen of adult male German cockroaches. Further studies showed that it is specifically expressed in the testis and accessory gland of male adults. This is the first sex specifically expressed insect P450. Insect P450s are involved in the synthesis and degradation of insect hormones, including juvenile hormone and molting hormone, which are important for insect development and reproduction. The specific expression of CYP6L1 in the reproductive system suggests its possible involvement in the reproduction of German cockroaches. Understanding the role(s) of CYP6L1 will offer new insights into insect reproduction and may offer novel targets for the development of insect control agents.

457 EXPRESSION AND STEROID HYDROXYLATION ACTIVITY OF A CYP3A-LIKE PROTEIN IN CHANNEL CATFISH PROXIMAL AND DISTAL INTESTINE.

Z. Lou[1], M. Celander[2] and M. O. James[1]. [1]*University of Florida, Gainesville, FL and* [2]*Goteborg University, Goteborg, Sweden.*

An important cause of incomplete bioavailability is prehepatic metabolism in the GI tract, mainly by the CYP3A subfamily of enzymes. Our work examines the expression and activity of constitutive CYP3A proteins along the intestine of channel catfish, Ictalurus punctatus, fed commercial chow or semi-purified diets. Polyclonal antibodies (IgG) generated against trout CYP3A27 reacted strongly with catfish intestinal microsomes, showing a band with MW of 59 kDa. In catfish fed with chow, the expression of this protein was much higher in the proximal segment (0.101±0.031 nmole/mg protein) than in the distal part (0.032±0.023 nmole/mg protein). Gentest Supersomes human CYP3A4 was the CYP3A standard. Testosterone 6-beta-hydroxylation activity was monitored as the catalytic indicator of CYP3A. Washed catfish microsomes give 3 major metabolites, one unknown metabolite with relative Rf value 0.83, 6-beta-hydroxylated testosterone and androstenedione. Human CYP3A4 formed only 6-beta-hydroxy product under the same reaction conditions. Testosterone 6-beta-hydroxylation activity was higher in proximal than distal catfish intestine (263±80.3 and 88.6±15.6 pmol/min/mg protein for proximal and distal). The 6-beta-hydroxylation activities in the two segments correlated with the amount of CYP3A.

CYP3A amount and steroid-6beta-hydroxylation activities were lower in both segments of intestine from fish fed purified diet compared with commercial chow, but with the same trend along intestine. These results demonstrated that the expression of a CYP3A protein was higher in proximal than distal intestine. Testosterone 6-beta-hydroxylation was a good marker of CYP3A. (Supported by ES 05781 and 07375.)

458 PAH/METAL MIXTURES: EFFECT ON PAH INDUCTION OF HUMAN CYP1A1 IN HEPG2 CELLS.

D. D. Vakharia, L. Ning and L. S. Kaminsky. *NY State Departmentof Health, Wadsworth Center, Albany, NY.*

Environmental PAHs and metals coexist and such mixtures could affect the carcinogenicity of PAHs. One possible mechanism involves modification of PAH induction of the PAH-bioactivating CYP1A. The effect on PAH-mediated CYP1A induction of As, Pb, Hg, or Cd (ranked as the most hazardous environmental metals by EPA and ATSDR) has thus been investigated. Human, hepatic HepG2 tumor cells were selected as the model because of poor availability of human hepatocytes. Induction of CYP1A1 by 10 μM benzo[a]pyrene (BAP), benzo[b]fluoranthene (BBF), dibenzo[a,h]anthracene (DBAHA), benzo[a]anthracene (BBA), or benzo[k]fluoranthene (BKF) was probed by ethoxyresorufin-O-deethylase activity (EROD) in 96-well plates of HepG2 cells. Cells rapidly took up PAHs from medium; by 24 hr only 14% remained in the medium, and no detectable PAH bound to well walls. Induction efficiency (relative to dimethyl sulfoxide controls) was in the order DBAHA (29-fold) > BKF (19- fold) > BAA (7-fold) > BAP (6-fold) > BBF (1-fold), all at 10μM PAH. The metals did not affect cell viability up to concentrations of As, 5μM; Pb, 250μM; Hg, 5μM; and Cd, 2.5μM. At 1μM, all of the metals decreased levels of PAH-induced CYP1A1 activities (inhibition of EROD activity was excluded) by variable extents and in a PAH-dependent manner. With BAP as inducer decreases in induction were: As, 33%; Cd, 29%; Hg, 19%; and Pb 13%. Future studies will resolve the mechanism of metal-mediated decreases in PAH induction. We conclude that these metals in environmental PAH mixtures could diminish PAH carcinogenic potential by decreasing PAH-mediated induction of their bioactivation by CYP1A1. (Funded by EPA grant R827180010).

459 COMPARISON OF CYTOCHROMES P450 1B1, 1A1, AND 1A2 PROTEIN EXPRESSION IN LIVER AND LUNG MICROSOMES FROM SMOKERS AND NONSMOKERS.

J. Y. Ho, S. M. Bandiera, M. Kawai and T. K. H. Chang. *University of British Columbia, Vancouver, British Columbia, Canada.*

To investigate the inducibility of CYP1B1 by cigarette smoke, we determined the expression of this protein in lung and liver microsomes from smokers and nonsmokers. For comparison, we also measured CYP1A1 and CYP1A2 protein expression in the same samples. Anti-CYP1B1 antibody, which was raised in rabbits against a synthetic peptide corresponding to amino acids 280-295 of human CYP1B1, was specific for this CYP as assessed by immunoblot analysis with a panel of human recombinant CYP and purified rat CYP proteins. The levels of human CYP1A1 and CYP1A2, which can be resolved by SDS-PAGE as distinct bands, were determined using anti-rat CYP1A2 sera that reacted with both proteins. As expected, CYP1A2 was expressed constitutively in liver microsomes. In the same samples, CYP1A1 and CYP1B1 were also expressed, albeit at lower levels. The mean CYP1A1 and CYP1A2 levels were greater in liver microsomes from smokers, although a large inter-individual variability existed. In contrast, no apparent difference in CYP1B1 protein levels was found in liver microsomes from smokers and nonsmokers. In human lung microsomes, only CYP1A1 was detected reliably and the expression of this CYP appeared to be greater in smokers, but there were large inter-individual differences in CYP1A1 levels. In conclusion, based on our panel of human liver and lung microsomes, smoking does not appear to influence CYP1B1 protein expression, whereas it increases lung CYP1A1 and hepatic CYP1A1 and CYP1A2 levels.

460 SUPERIORITY OF MIDAZOLAM AS A PROBE FOR ASSESSING CYP 3A4 ACTIVITY IN THE HUMAN ENDOTOXIN MODEL.

S. I. Shedlofsky[1], R. T. Tosheva[1], K. T. Rockich[2], C. R. Cunningham[1], D. E. Goeger[3] and R. A. Blouin[2]. *[1]VA Hospital & University of Kentucky College of Medicine, Lexington, KY, [2]University of Kentucky College of Pharmacy, Lexington, KY and [3]University of Texas Medical Center, Galveston, TX.*

Critically ill septic patients receive many xenobiotics that require metabolism by P450s. The extent to which CYP3A4 activity in humans is altered during inflammation may have important clinical relevance. We compared results of midazolam pharmacokinetics (MDZ), erythromycin breath test (ERMBT) and urinary 6β-OH cortisol/cortisol ratio (6βC/C) as probes for CYP 3A4 in a human endotoxin model of sepsis. Ten healthy non-smoking male volunteers were studied twice receiving either two consecutive daily IV doses of LPS (4ng/kg) or saline in a balanced crossover design. ^{14}C-erythromycin (3μCi) and MDZ (20 μg/kg) were given IV after saline or the second dose of LPS. 6β-cortisol & cortisol were assayed in 24hr urines after saline and each dose of LPS. Pharmacokinetics of MDZ showed no statistically significant changes between control and LPS in clearance, volume of distribution, half-life or 30min serum 1-OH-MDZ/MDZ ratio. ERMBT, in contrast, showed a significant 19% decrease in the dose of $^{14}CO_2$ exhaled/h. However, CO_2 production after LPS is known to increase by 14% after LPS. Urinary 6βC/C ratio dropped 66% after the first LPS dose, but total urinary cortisol was markedly increased due to the adrenocortical response to LPS. Although ERMBT and urinary 6βC/C ratio did decrease after LPS, these changes are suspect because of the physiologic responses to inflammation. The lack of change in MDZ suggests CYP3A4 is not decreased in this model and MDZ is a more suitable probe.

461 INDUCTION OF CYP1A1 AND CYP1A2 IN THE HUMAN LUNG.

C. Wei[1], R. Caccavale[2], E. Weyand[1], P. Thomas[1] and M. M. Iba[1]. *[1]Rutgers University, Piscataway, NJ and [2]St. Peter's University Medical Center, New Brunswick, NJ.*

We examined the presence and inducibility of CYP1A1 and CYP1A2 in the human lung, using a tissue explant culture system and freshly resected lung specimens obtained from a population of patients undergoing therapeutic lobectomy. CYP1A1 and CYP1A2 were detected in the lung specimens at the level of protein (by western blot analysis), mRNA (by RT-PCR analysis), and activities (as measured by the (i) formation of adducts in pulmonary DNA by added benzo(a)pyrene (B[a]P) and (ii) pulmonary S9-catalyzed bioactivation of B[a]P and 4-aminobiphenyl to mutagens in S. typhimurium TA100 and TA98, respectively). The constitutive levels of CYP1A1 and CYP1A2 exhibited extensive inter-individual variability. The enzymes were induced to varying extents by TCDD, pyridine, and nicotine, with the induction exhibiting extensive inter-individual variability as well. Pyridine was a more effective inducer than TCDD in some subjects, and vice versa, whereas both compounds were effective inducers in other subjects. B[a]P and Omeprazole were also inducers of the enzymes. The results show that CYP1A2 is present and inducible in the human lung, and indicate the heterogeneity in individual sensitivity to pulmonary CYP1A induction, as well as in the compounds capable of effecting the induction. (Supported by ES06414 and ASPET SURF Program.)

462 PROTECTIVE ROLE OF EPOXIDE HYDROLASE AGAINST OLFACTORY TOXICITY OF COUMARIN AND 2,6 DICHLOROBENZONITRILE.

J. Gu, T. Su, X. Zhuo, Q. Y. Zhang, T. W. Lipinskas and X. Ding. *Wadsworth Center, New York State Department of Health; School of Public Health, State University of New York at Albany, Albany, NY.*

Coumarin and 2,6-dichlorobenzonitrile (DCBN) cause tissue-selective cytotoxicity and consequent depletion of P450 in the olfactory mucosa (OM). The reactive intermediates of DCBN and coumarin are epoxides, therefore, microsomal epoxide hydrolase (mEH) may play an important role in their detoxification. Since mEH is expressed only in specific zones in the OM while expression of OM P450s are not zonal, we speculated that cells expressing mEH would be selectively protected and mEH levels in OM would not be decreased, or not to the same extent as do the P450s following DCBN or coumarin treatment. We found that one or five weeks after a single ip injection of DCBN in C57BL/6 mice at 15 mg/kg, the levels of several P450s, such as CYP1A, 2A, and 2G1, but not of mEH, were significantly decreased in OM

microsomes. With a DCBN dose of 25 mg/kg, both P450 and mEH protein levels were decreased at 1 week following injection, but the extent of decrease was lower for mEH than for P450s. In Wistar rats, a single ip injection of DCBN at 25 mg/kg caused a modest decrease in the level of CYP2A/2G and an injection of coumarin at 50 mg/kg caused a dramatic depletion of P450 at 1 week following treatment, with no decrease in mEH level. These results support a protective function of mEH in the OM against DCBN and coumarin toxicity and call for further studies on the cell-specific regulation of mEH in rodent and human nasal mucosa. (Supported in part by NIH grant ES07462.)

463 DIFFERENTIAL INDUCTION OF MOUSE CYP2A5 AND CYP2J BY PYRAZOLE.

Q. Xie, Y. Zhang, Q. Y. Zhang, J. Gu, T. Su, L. S. Kaminsky and X. Ding. *Wadsworth Center, New York State Department of Health; School of Public Health, State University of New York at Albany, Albany, NY.*

We have recently shown that rat CYP2J4 is inducible by pyrazole in liver, intestine, and olfactory mucosa (Zhang et al., Drug Metab. Dispos., 1999, in press). The aim of the present study was to determine whether mouse CYP2J isoforms are also inducible by pyrazole, which was previously found to induce CYP2A5 in mouse liver but not the olfactory mucosa (Su et al., Drug Metab. Dispos. 26:822-824, 1998). CYP2J proteins were detected in mouse liver, lung, kidney, heart, eye, olfactory mucosa, and small intestine by immunoblot analysis with an anti-CYP2J4 antibody. Induction of CYP2J proteins was observed in liver, lung, kidney, olfactory mucosa, and small intestine following daily i.p. injection of pyrazole at 120 or 200 mg/kg for three consecutive days. CYP2J proteins were induced similarly in C57BL/6 and DBA-2 mice. In the same experiments, CYP2A5 was detected in the small intestine in addition to the liver and olfactory mucosa; however, treatment with pyrazole induced CYP2A5 in the liver, but not in the olfactory mucosa or the small intestine. Induction of CYP2J mRNAs was also observed by Northern blot analysis with a CYP2J4 cDNA probe. RNA-PCR analysis with isoform-specific primers showed that CYP2J5 was expressed in kidney and liver, but not in the other tissues examined, while CYP2J6 was detected in all tissues examined. These results indicate that CYP2Js are inducible by pyrazole in multiple mouse tissues at both protein and mRNA levels. However, the different tissue selectivities in CYP2A5 and CYP2J induction by pyrazole suggest involvement of different regulatory mechanisms. (Supported in part by NIH grants ES06256 and ES07462.)

464 IDENTIFICATION OF THE HEPATIC CYTOCHROMES P450 THAT CATALYZE COUMARIN 3,4-EPOXIDATION AND 3-HYDROXYLATION.

S. L. Born, D. Caudill, K. L. Fliter and M. P. Purdon. *The Procter & Gamble Company, Cincinnati, OH.*

Coumarin is a rat liver and mouse lung toxicant. Coumarin-mediated injury is metabolism- and species-dependent, resulting from the formation of coumarin 3,4-epoxide (CE) and its rearrangement product, o-hydroxyphenylacetaldehyde (o-HPA). o-HPA formation is greatest in mouse >> rat > man. 3-Hydroxycoumarin (3-HC) is a non-toxic product formed via a metabolic pathway distinct from that of CE. The goals of the current study were to identify the P450s involved in the formation of CE and 3-HC, and determine whether CE formation differs qualitatively in hepatic microsomes from mice, rats and man. Of a panel of 10 recombinant human P450 forms, 1A1, 1A2, and 2E1 catalyzed o-HPA formation. Rat recombinant 1A1 and 1A2 likewise formed o-HPA, but 1A2 produced o-HPA at a rate 11-times faster than the human form. In contrast, 3-HC formation was formed predominately by recombinant 3A4. Antibodies inhibitory to P450s 1A1/2 and 2E1 together blocked up to 87% of o-HPA activity in pooled F344 rat and individual human liver microsomes (n=3). In contrast, o-HPA formation in mouse liver was inhibited by only 42%, a result that suggests that additional enzymes may play an important role in mouse o-HPA production. Inhibition studies using naphthalene and 5-phenyl-1-pentyne suggest that this form may be P450 2F2. Thus, species differences in rat and human o-HPA production may result largely from differences in enzyme affinity, whereas high rates of CE formation in mouse liver may be attributed to a species-specific expression of additional high-capacity enzymes.

465 INHIBITION OF CYTOCHROME P450 6D1 BY ALKYNYLARENES, METHYLENE DIOXYARENES AND OTHER SUBSTITUTED AROMATICS.

J. G. Scott[1], M. Foroozesh[1], N. E. Hopkins[1], T. A. Alefantis[1] and W. L. Alworth[4]. [1]*Cornell University, Ithaca, NY,* [2]*Xavier University, New Orleans, LA,* [3]*Millsaps College, Jackson, MS and* [4]*Tulane University, New Orleans, LA.*

We evaluated 33 compounds, comprising 5 different structural groups (alkynylpyrenes, alkynylphenanthrenes, methylenedioxyarenes, flavones and miscellaneous), as inhibitors of house fly P450 6D1 (CYP6D1). In general, alkynylpyrenes were the most potent group of inhibitors, with maximum effectiveness noted when the substituent was in the 4 position. Substituted phenanthrenes were reasonable CYP6D1 inhibitors with the lowest IC50 observed for the analogue with the methylenedioxy substituent between the 9 and 10 positions. The ten methylenedioxyarenes varied considerably in their ability to inhibit CYP6D1. Piperonyl butoxide was the most potent inhibitor with increasing length of the alkyl substituent resulting in decreasing inhibition. Karinjin had the lowest IC50 of the four flavones that were tested. Overall, the most potent CYP6D1 inhibitors were large planar compounds. Four inhibitors were evaluated as permethrin synergists in the LPR strain of house fly (permethrin is detoxified via CYP6D1 in this strain) and they increased permethrin toxicity by 16- to 83-fold. The effect of structure on inhibition potency, as well as the mechanism of inhibition for seven representative inhibitors is discussed.

466 INSULIN DESTABILIZES CYP2E1, BUT NOT CYP2B OR CYP3A, MRNA IN PRIMARY CULTURED RAT HEPATOCYTES.

K. J. Woodcroft and R. F. Novak. *Institute of Chemical Toxicology, Wayne State University, Detroit, MI.*

The expression of CYP2E1 mRNA and protein is enhanced several-fold by experimental diabetes. CYP2B and CYP3A expression is also enhanced slightly under these conditions. We have previously demonstrated that insulin decreases CYP2E1 mRNA and protein levels in primary cultured rat hepatocytes, while having little effect on CYP2B or 3A expression. To examine whether insulin affects the stability of CYP2E1 mRNA, RNA degradation experiments were performed in primary cultured rat hepatocytes. Hepatocytes were cultured on Vitrogen in modified Chee's medium in the absence of insulin for the first 48 h of culture. Cells were then cultured in the presence or absence of 10 nM insulin for 2 h, followed by addition of 10 μg/ml Actinomycin D. Cells were harvested at 10, 13, 16, and 22 h after Actinomycin D addition, and CYP2E1, 2B, and 3A mRNA levels were monitored by Northern blot. The half-life of CYP2E1 mRNA was decreased from ~21 h in the absence of insulin to ~13 h in the presence of 10 nM insulin. In contrast, the half-life of CYP3A mRNA (~15 h) was unaffected by insulin treatment, while that of CYP2B mRNA appeared to be increased, from ~15 h to ~30 h, in the presence of insulin. In order to determine a possible mechanism for the destabilization of CYP2E1 mRNA by insulin, gel shift analysis for binding of cytosolic protein(s) to CYP2E1 mRNA was performed. A construct representing the 3'-portion of CYP2E1 mRNA (including the 3'UTR) formed two complexes following incubation with cytosolic extracts from hepatocytes cultured in the absence of insulin, or in the presence of 0.1-100 nM insulin for 24 h. The intensity of the CYP2E1 RNA-protein complexes decreased as insulin concentration increased. These data suggest that insulin decreases CYP2E1 mRNA levels in primary cultured rat hepatocytes by enhancing its degradation, possibly through reduced interaction with protective RNA binding protein(s). (Supported by NIH Grant ES03656 and NIEHS Center Grant P30 ES06639.)

467 CHARACTERIZATION OF THE RAT CYP1B1 GENE, INTERACTION BETWEEN CAMP AND AHR-RESPONSIVE SEQUENCES.

W. Zheng, L. Zhang, K. Bhattacharyya and C. R. Jefcoate. *University of Wisconsin, Madison, WI.*

CYP1B1 is appreciably expressed constitutively in multipotential mouse embryo fibroblasts and in steroidogenic cells, but is poorly expressed in hepatocytes even with TCDD induction. TCDD induces expression preferentially in mouse embryo fibroblasts while cAMP is more effective in steroidogenic cells. To understand the molecular mechanisms underlying the cAMP or TCDD regulated expressions, a 16kb rat genomic DNA was isolated and characterized, which contains DNA corresponding to the 7kb of 5'-flanking

sequence and the 9kb of three exons, two introns and 3'-flanking sequences. DNA sequence analysis revealed that rat, mouse and human CYP1B1 genes share similar gene structural organization and function motifs in the proximal promoter(PP) and a TCDD-responsive enhancer centered 1kb from the transcription start site. We used rat CYP1B1-luciferase reporter constructs (7kb of 5'-flanking and deletions) in mouse embryo fibroblast C3H10T1/2 cells, testicular Leydig MA10 cells and adrenal Y-1 cells. Luciferase activity responded in a cell selective manner in C3H10T1/2 (TCDD>>cAMP), MA10 (cAMP>>TCDD) and Y-1 (only cAMP). 1.2kb of 5'-flanking sequence allowed induction by cAMP only in MA10 cells but this was completely removed by a single mutation in the key XRE of the TCDD-responsive enhancer. This supports the involvement of this motif in the basal activity and cAMP-induction as well as TCDD-induction. We have also identified a sequence in the PP that is essential to all transcription. Deletion of a further PP sequence removed cAMP-induction but not TCDD-induction. The sequence only confers cAMP-inducibility in the presence of the upstream enhancer and apparently like basal transcription requires basal AhR-Arnt activity. cAMP inductions in both C3H10T1/2 and Y-1 cell lines are totally dependent on the second enhancer located within the region -5428/-5206. cAMP induction in MA10 cells also was potentiated two folds by inclusion of this region indicating regulation through both mechanisms. Several potential binding sites for transcription factors including STAT, CREB and RORA were identified in this region, which may be responsible for the cAMP regulation. These data demonstrate that multiple cAMP response sequences exist in CYP1B1 gene, which selectively function through AhR-dependent or independent pathways in different cells.

468 *IN VIVO* IH636 GRAPE SEED PROANTHOCYANIDIN EXTRACT (GSPE) EXPOSURE INHIBITS MOUSE LIVER MICROSOMAL CYP4502E1-DEPENDENT ANILINE HYDROXYLATION *IN VITRO*.

D. Bagchi[1], E. Hickey[2], H. Parikh[2] and S. D. Ray[2]. [1]*Creighton University Health Sciences Center, Omaha, NE and* [2]*AMS College of Pharmacy, Long Island University, Brooklyn, NY.*

Previous studies in our laboratories have demonstrated the protective abilities of a novel IH636 GSPE against oxygen free radicals, tobacco-induced programmed cell death in human oral keratinocytes, myocardial ischemia-reperfusion injury and infarction, and drug and chemically-induced multiorgan toxicity. This study compared the *in vitro* aniline hydroxylation patterns of *in vivo* GSPE pre-exposed hepatic microsomes with induced (1% acetone in drinking water for 3 days) and uninduced rat liver microsomes. Male B6C3F1 mice were fed GSPE containing diet (ADI 100 mg/kg body wt.) for 4 weeks. Liver microsomes were isolated from both control and GSPE-exposed mice, and aniline hydroxylation was assessed as a specific marker of CYP450-2E1 activity. Interestingly, GSPE supplementation for 4 weeks inhibited aniline hydroxylation by 40%, as compared to the control animals. Similar to *in vivo* GSPE preexposed mouse liver microsomes, rat liver microsomes when incubated with various concentrations of GSPE (100 and 250 μg/ml), inhibited aniline hydroxylation to various degrees (Uninduced: 40% and 60% and Induced: 25% and 50%, respectively). These data were compared with hydroxylation pattern of another hepatoprotective agent, such as 4-aminobenzamide (4-AB), which shows that 4-AB did not alter aniline hydroxylation at all. Collectively, these results may suggest that the ability of GSPE to inhibit CYP4502E1 is an additional cytoprotective attribute, in conjunction with its novel antioxidant efficacy.

469 INDUCTION OF CYTOCHROME P4501A1 IN HUMAN HEPATOMA HEPG2 CELLS BY 6-NITROCHRYSENE.

T. H. Ueng and R. M. Chen. *Institute of Toxicology, College of Medicine, National Taiwan University, Taipei, Taiwan Republic of China.*

The effects of 6-nitrochrysene (6-NC) on human cytochrome P450 (P450)-dependent monooxygenases were determined using human hepatoma HepG2 cells treated with the nitrated polycyclic aromatic hydrocarbon. Treatment with 6-NC caused concentration- and time-dependent increases of monooxygenase activity in HepG2 cells. Treatment with 100 μM 6-NC for 24 hr markedly increased benzo(a)pyrene hydroxylation, 7-ethoxycoumarin and 7-ethoxyresorufin O-deethylations activities in cell microsomes. The S9 fraction derived from 6-NC-treated HepG2 cells was more effective than the fraction from untreated cells in metabolic activation of 6-NC in the Salmonella typhimurium mutagenicity assay. Immunoblot analysis of microsomal proteins using mouse monoclonal antibody 1-12-3 to rat P450 1A1 revealed that 6-NC induced a P450 1A1-immunorelated protein in the hepatoma cells. RNA blot analysis of cellular total RNA using a human P450 1A1 3'-end cDNA probe showed that 6-NC increased the level of P450 1A1 mRNA. Nuclear transcription assay using the human P450 1A1 cDNA probe demonstrated that 6-NC increased the transcription rate of CYP1A1 gene in HepG2 cells. Similar to 6-NC, chrysene and 6-aminochrysene treatments increased P450 1A1 protein and mRNA in the hepatoma cells. Treatment of HepG2 cells with 6-NC increased cytosolic glutathione S-transferase and N-acetyltransferase activities. Treatment of lung carcinoma NCI-H322 cells with 6-NC resulted in induction of P450 1A1, similar to the inductive effects observed with the hepatoma cells. The present study demonstrates that 6-NC has the ability to induce catalytic activity, protein, and mRNA of human P450 1A1 in HepG2 cells and the induction mechanism involves a transcriptional event. Induction of the liver and lung P450 1A1 may be an important factor to consider in the assessment of 6-NC metabolism and toxicity in humans. (Supported by grant NSC88-2314-B002-047.)

470 TRANSIENT INDUCTION OF CYP1A1/CYP1B1- CATALYZED ESTROGEN METABOLISM IN T-47D CELLS BY BENZO[A]PYRENE IS DIMINISHED BY ARSINITE.

D. C. Spink, B. H. Katz, M. M. Hussain and L. S. Kaminsky. *New York State Department of Health, Wadsworth Center, Albany, NY.*

Polycyclic aromatic hydrocarbons (PAH) and metals are often co-contaminants in the environment, yet there have been relatively few studies of the combined effects of PAHs and metals on cytochrome P450 induction. In this study we examined the combined effects of metals and benzo[a]pyrene (BAP) on estrogen metabolism in T-47D human breast cancer cells. Exposure to BAP caused elevated rates of both the 2- and 4-hydroxylation pathways of estrogen metabolism, indicating induction of both CYP1A1 and CYP1B1. Induction of both pathways was transient, with metabolite formation peaking at 12 h after exposure and returning to near basal levels at 48 h. Dose-response studies showed maximal induction of both the 2- and 4- hydroxylation pathways at 3 mM BAP; higher levels of the PAH caused reduced rates of metabolism due to inhibition of CYP1A1 and CYP1B1. Experiments in which T-47D cultures were co-treated with 3 mM BAP and varying concentrations of Pb, Cd, Hg or As showed varying degrees of decreases in the induction of CYP1A1 and CYP1B1 by the metals. Arsenic in the form of arsinite caused the most pronounced decrease in the induction of CYP1A1 and CYP1B1 by BAP, with IC50s of approximately 3 mM for the 2- and 4-hydroxylation pathways. Hg and Pb were much less effective, causing only 50% decreases in induced metabolism at 30 and 300 mM, respectively. These effects could not be attributed to cytotoxicity as determined in cell viability assays. These results indicate a specific inhibitory effect of arsinite on the expression of CYP1A1 and CYP1B1 in T-47D human breast cancer cells. (Funded by EPA Grant R827180010 and NIH Grant ES03819.)

471 REAL-TIME FLUOROGENIC 5' NUCLEASE BASED ASSAYS FOR THE QUANTITATION OF RAT CYTOCHROME P450 MRNA.

S. D. Quigley, S. L. Srinouanprachanh, J. S. Sidhu, F. Lui, B. C. Krovat, F. M. Farin and C. J. Omiecinski. *University of Washington, Seattle, WA.*

Accurate and sensitive quantitation of mRNA expression profiles is becoming increasingly important in molecular toxicological studies. To address these issues, we developed real-time PCR 5' nuclease quantitation assays for CYP1A1, CYP1A2, CYP2B1, CYP2B2, CYP2E1, CYP3A1, CYP3A2, and albumin mRNA using the ABI Prism 7700 system and dual-labeled fluorogenic sequence specific probes. This real-time PCR technique eliminates the reliance on endpoint measurements and also the need for a competitor to be co-amplified along with the target. Rat CYP450 mRNA was reverse transcribed from 1μg total RNA which yielded enough cDNA for the quantitation of more than 15 different mRNA targets. Measurement of these CYP450 mRNAs showed highly reproducible values for triplicate reads (Coeff. of variation <0.05) and very precise standard curve values (R2 >0.995). Additionally, results were verified by comparison to previous data from both competitive RT-PCR (using a precisely constructed co-amplified competitor RNA molecule) and RNA slot blot analyses. This non-radioactive, non-intercalator based PCR product detection method is a substantial improvement over the previously established RNA analysis techniques and it allows for faster, more sensitive, and more accurate quantitation of very small amounts of mRNA. (Supported by NIEHS Center ES-07033 and ES-04696.)

472 DEVELOPMENT OF FLUORESCENT 5'-NUCLEASE ASSAYS FOR THE ALLELIC DISCRIMINATION OF SINGLE NUCLEOTIDE POLYMORPHISMS (SNPS) IN BIOTRANSFORMATION ENZYME GENES.

P. L. Stapleton, F. M. Farin, D. E. Abbott, Y. G. Hitosis, C. L. Keener, S. D. Quigley and C. J. Omiecinski. *Center for Ecogenetics and Environmental Health, Department of Environmental Health, University of Washington, Seattle, WA.*

Detection of single nucleotide polymorphisms (SNPs) provides the basis for most current molecular epidemiology studies. As studies have become more complex, however, cost-efficient, high-throughput methods for genotyping these polymorphisms have become a necessity. We have developed fluorescent 5'-nuclease assays to genotype specific SNPs in several biotransformation enzyme systems including cytochrome P450 (CYP) 1A1, CYP 2D6, CYP 2E1, catechol-o-methyltransferase, microsomal epoxide hydrolase, methyltetrahydrofolate reductase, N-acetyl transferase, and superoxide dismutase as well as those present in transforming growth factors, tumor necrosis factors and vitamin D receptors. The assay takes place in a single PCR reaction and utilizes the 5'-nuclease activity of Taq DNA polymerase to cleave allele-specific probes. These probes are labeled with two fluorescent dyes - a reporter and a quencher - and are added to the standard PCR assay. When both dyes are attached to the probe, the fluorescence of the reporter is quenched. During each extension cycle, however, the polymerase cleaves the reporter dye from the probe, thus separating it from the quencher, and the fluorescence is emitted. An ABI Prism® 7700 was used to collect and analyze the data. This procedure, combining the simplicity of PCR with the discrimination of allele-specific fluorescence, provides accurate results in an efficient, cost-effective format. (Supported by NIEHS Center ES-07033 and Superfund ES-04696.)

473 SEX DIFFERENCES IN HEPATIC CYP4A INDUCTION AND BIPHENYL METABOLISM IN BIPHENYL- ADMINISTERED BDF1 MICE.

M. Sunouchi, A. Miyajima, S. Ozawa and Y. Ohno. *National Institute of Health Sciences, Setagaya, Tokyo, Japan.* Sponsor: A. Takanaka.

In order to examine sex differences in the effects of biphenyl (BiP), we investigated effects of BiP on hepatic beta-oxidase activity, drug-metabolizing enzyme activities and BiP metabolism using in female and male BDF1 mice. BiP was orally administered at the dose of 1.3, 2.6 and 5.2 mmol/kg at 72, 48 and 12 hrs before sacrifice. In female mice, BiP significantly increased hepatic KCN-insensitive palmitoyl CoA (PCoA) oxidation (2.6 and 5.2 mmol/kg; 1.5-1.9 fold) and lauric acid (LA) 12-hydroxylation (1.3-5.2 mmol/kg; 2.1-3.8 fold). Furthermore, BiP markedly enhanced Cyp4a apoproteins in a dose-dependent manner. In male mice, BiP showed no significant increase of KCN-insensitive PCoA oxidation and LA 12-hydroxylation. In both the sexes, 7-pentoxyresorufin O-depentylation and level of Cyp2b apoprotein were elevated by BiP at the dose of 5.2 mmol/kg. On the other hand, the administration of BiP (5.2 mmol/kg) caused the increase of 4-hydroxybiphenyl, 4,4'- and 2,5-dihydroxybiphenyl production from BiP in the liver microsomes of female and male BDF1 mice. The increase in the rate of 4,4'-dihydroxybiphenyl production in females was 2-fold higher than that in males. These effects of the administration of BiP on BiP metabolism were qualitatively similar to that of phenobarbital but not clofibrate. These results indicated the possibility of sex differences in the toxicity of BiP.

474 MODULATION OF DRUG METABOLIZING ENZYMES FOLLOWING ADMINISTRATION OF BILIRUBIN IN RAT.

J. M. Seubert, A. O. S. El-Kadi, L. V. Castro, C. D. Webb, C. K. Yaremko and J. R. Bend. *Department of Pharmacology and Toxicology, University of Western Ontario, London, Ontario, Canada.*

Induction of stress proteins in liver, such as heme oxygenase 1 (HO-1), as a result of pathobiological stress, leads to the conversion of heme to its endogenous metabolite, bilirubin. Modulation of the cytochrome P450 (CYP) monooxygenase system (P450) by bilirubin was investigated using microsomes prepared from liver of male, adult Sprague-Dawley rats treated intraperitoneally (i.p.) with a single daily dose (0, 1, 2.5, 10, or 100 mg/kg) of bilirubin for 3 consecutive days. Animals were sacrificed 24 h after receiving the last dose of bilirubin. Hepatic total CYP content in microsomes decreased maximally to 50% of control values. P450-dependent 7-ethoxyresorufin O-deethylation (EROD) activities and 7-pentoxyresorufin O-deethylation (PROD) (CYP1A1/2 and 2B1/2, respectively) were minimally altered by bilirubin, decreasing to 70 and 80% of control values, respectively. Hepatic testosterone 2a-hydroxylase (T2aH), 6b-hydroxylase (T6bH) and 7a-hydroxylase (T7aH) activities (CYP2C11, 3A1/2 and 2A1 - dependent activities, respectively) were affected in a dose dependent manner. T2aH and T7aH activities were maximally reduced to 25 and 20% of control values and T6bH activity to 60%. A dose dependent decrease in total plasma bilirubin levels (~20 fold) occurred. Hepatic HO activity significantly increased to 240% of control values, which corresponded with maximum decreases of CYP content and P450 catalytic activities. Microsomal NAD(P)H:quinone oxidoreductase activity increased 210% above control levels, in the liver. Hepatic total glutatione S-transferase activity did not change but GST-Ya-dependent activity decreased 55% below control levels. No differences were observed in malondialdehdye (MDA) formation in either liver microsomes or serum, indicating little or no lipid peroxidation had occurred. The present findings demonstrate that bilirubin directly or indirectly is involved in the modulation of drug metabolizing enzymes in an isozyme selective manner.

475 CYTOCHROME P450 INHIBITION ASSAYS — THE CHALLENGES IN INTERPRETING DATA FOR CYP3A4.

D. M. Stresser, V. P. Miller, A. Blanchard, J. M. Ackermann, A. Dandeneau and C. L. Crespi. *GENTEST Corporation, Woburn, MA.*

We have developed microtiter plate-based, direct, fluorometric assays for the activities of the five principal human drug metabolizing enzymes, CYP1A2, CYP2C9, CYP2C19, CYP2D6 and CYP3A4. For individual CYP1, and CYP2 enzymes, the potency of enzyme inhibition (IC50) is generally maintained regardless of probe substrate or assay method employed. In contrast, CYP3A4 inhibition for a specific inhibitor shows significant differences in potency depending on the probe substrate being used. We have investigated these differences through the use of several structurally distinct fluorescent substrates for CYP3A4 and several classical substrate probes (for example, testosterone, nifedipine, and midazolam), with a panel of 20 chemicals about half were clinically significant CYP3A4 inhibitors. Under highly controlled test conditions the concordance among all 4 fluorometric probe substrates was only 70%. Several chemicals were found to inhibit the metabolism of some substrates while activating the metabolism of others. The mean range of nominal IC50 values was 27-fold [the range varied from 4.5-fold (ethynylestradiol) to 122-fold (cyclosporin A). Some of the differences can be rationalized with a more detailed interpretation of the inhibition curves. A prudent approach appears to be the use of multiple probe substrates to characterize the inhibition potential of xenobiotics for CYP3A4. However, even with this approach, there will always be uncertainty in predicting CYP3A4 inhibition.

476 SQUALESTATIN 1-INDUCIBLE CYP2B1 TRANSCRIPTION IS NOT MEDIATED THROUGH STEROL RESPONSIVE ELEMENT BINDING PROTEIN (SREBP).

T. A. Kocarek and N. A. Mercer. *Institute of Chemical Toxicology, Wayne State University, Detroit, MI.*

We previously demonstrated that squalestatin 1, an inhibitor of squalene synthase and sterol biosynthesis, is a potent and selective inducer of CYP2B in rat liver and primary cultured rat hepatocytes. Because cellular sterol depletion is known to regulate gene expression through the proteolytic activation of the SREBP class of transcription factors, we examined the abilities of transiently transfected SREBP-1a and SREBP-2 transcription factors to activate reporter gene expression from a 3-hydroxy-3-methylglutaryl coenzyme A synthase-luciferase construct (SYNSRE-Luc) or from a CYP2B1 5'-luciferase construct (CYP2B1-Luc), containing the phenobarbital-responsive unit, in primary cultured rat hepatocytes. Treatment of hepatocyte cultures with 10^{-7} M squalestatin 1 activated luciferase expression from SYNSRE-Luc and CYP2B1-Luc by ~4.5-fold and 7.3-fold, respectively, relative to untreated control cultures. As expected, co-transfection of hepatocytes with 1 or 2 ng of a plasmid expressing either the active SREBP-1a or SREBP-2 transcription factor increased luciferase expression from SYNSRE-Luc by 25- to 42-fold. However, co-transfection of hepatocytes with either of the SREBP expression plasmids had no effect on CYP2B1-Luc expression. These findings demonstrate that squalestatin 1-inducible CYP2B expression is not attributable to SREBP activation. We propose that squalestatin 1 inhibits the synthesis of an endogenous sterol that represses CYP2B1 transcription through an SREBP-independent mechanism. (Supported by NIH grant HL50710 and NIEHS Center grant ES06639.)

477 ESTRONE (E1) HYDROXYLATION CATALYZED BY HUMAN CYTOCHROMES P450 1A1 (CYP1A1) AND 1B1 (CYP1B1).

G. Oenga and D. C. Spink. *Wadsworth Center, New York State Department of Health, Albany, NY.*

Human CYP1A1 and CYP1B1 are expressed or are inducible in a number of extrahepatic, estrogen-responsive tissues including breast and uterus. Both enzymes catalyze the hydroxylation of 17beta-estradiol (E2); CYP1A1 is an E2 2-, 6alpha, and 15alpha-hydroxylase, whereas CYP1B1 is predominantly an E2 4-hydroxylase with a lesser activity at C-2. Metabolism of E1 by CYP1A1 and CYP1B1 is not well characterized, in part because of the difficulty in measuring E1 hydroxylase activity at low substrate concentrations. In this study we used gas chromatography/mass spectrometry (GC/MS) for the analysis of hydroxy-E1 metabolites produced in microsomal reactions with cDNA-expressed enzymes. Metabolites were recovered from microsomal reactions by solid-phase extraction and subjected to a conventional two-step derivatization procedure involving conversion of the 17-keto functions to methyl oximes and conversion of the hydroxyl groups to trimethylsilyl ethers. Analysis of these derivatives by GC/MS provided pmol sensitivity, appropriate for kinetic analyses of microsomal E1 metabolism. By using the GC/MS technique, human CYP1A1 expressed in Sf9 cells was found to catalyze 2- and 4-hydroxylation of E1 with Km values of 11.5 and 32.4 micromolar and Vmax values of 4.6 and 0.71 nmol/min per nmol P450, respectively. Human CYP1B1 catalyzed 2- and 4-hydroxylation with Km values of 6.8 and 4.0 micromolar and Vmax values of 0.30 and 0.53 nmol/min per nmol P450, respectively. Neither enzyme catalyzed detectable 16alpha-hydroxylation of E1. These results indicate that CYP1A1 and CYP1B1 catalyze E1 hydroxylation with significantly lower catalytic efficiencies with E1 as compared to E2 as substrate. (Supported by NIEHS Grant ES04913.)

478 RELATIVE ROLES OF CYP2E1 AND CYP1A2 IN MOUSE UROPORPHYRIA CAUSED BY ACETONE: IS THIS A MODEL OF PORPHYRIA CUTANEA TARDA.

N. Gorman[1,2], H. S. Walton[1,2], W. J. Bement[1], J. G. Szakacs[4], F. J. Gonzalez[5], D. W. Nebert[6], J. F. Sinclair[1,2,3] and P. R. Sinclair[1,2,3]. [1]*VA Medical Center, White River Junction, VT,* [2]*Biochem. and* [3]*Pharmacology/Toxicology, Dartmouth Medical School, Hanover, NH,* [4]*VA Medical Center, Salt Lake City, UT,* [5]*NCI, Bethesda, MD and* [6]*Dept. of Environmental Health, University of Cincinnati Med. Ctr., Cincinnati, OH.*

Porphyria cutanea tarda is a liver disease with skin lesions caused by hepatic overproduction of uroporphyrin (URO), and is associated with consumption of alcoholic beverages and moderate iron overload. Previously, we reported that acetone (AC), which, like ethanol, is an inducer of CYP2E1, stimulates the onset of hepatic URO accumulation in mice treated with iron dextran (Fe) and 5-aminolevulinic acid (ALA), the porphyrin precursor. Here we investigated whether CYP2E1 has an essential role in the AC stimulation using *Cyp2e1(-/-)* mice. Hepatic URO accumulation was stimulated by AC in *Cyp2e1(-/-)* mice to the same extent as in wild-type mice. In the absence of AC, there was less URO in the mutant mice treated with Fe and ALA than in the wild-type mice. URO accumulation caused by AC, Fe and ALA was completely prevented in *Cyp1a2(-/-)* mice. AC was not an inducer of CYP1A2 in the wild-type mice, as indicated by western blots of liver homogenates and microsomal methoxyresorufin demethylase activities. Increases in uroporphyrinogen oxidation activity were observed in hepatic microsomes from wild-type C57BL/6 mice treated with AC. We conclude that CYP2E1 is not required in AC stimulation of uroporphyria but CYP1A2 is required. CYP2E1 did contribute to uroporphyria in the absence of AC.

479 ALCOHOL CAUSES HEPATIC STEATOSIS AND ENHANCES ACETAMINOPHEN HEPATOTOXICITY IN *Cyp2e (-/-)* MICE.

J. F. Sinclair[1,2,3], J. G. Szakacs[4], S. G. Wood[1], H. S. Walton[2], F. Gonzalez[5], E. H. Jeffrey[6], S. A. Wrighton[7], W. J. Bement[1] and P. R. Sinclair[1,2,3]. [1]*VA Medical Center, White River Jct, VT and* [4]*Salt Lake City, UT, Depts.* [2]*Biochem. and* [3]*Pharma./Tox., Dartmouth Medical School, Hanover, NH,* [5]*National Institutes of Health, Bethesda, MD,* [6]*Dept. Food Science/Human Nutrition, University of Illinois, Urbana, IL, and* [7]*Dept. Drug Disp., Lilly Research Labs, Indianapolis, IN.*

Mice genetically engineered to delete expression of a particular CYP are being used to identify the role of that CYP in a toxicological response. Untreated *Cyp2e1(-/-)* mice were reported to be more resistant to APAP hepatotoxicity than wild type mice. Here we found that treatment with ethanol in combination with isopentanol increased steatosis and acetaminophen (APAP) hepatotoxicity in *Cyp2e(-/-)* and wild type mice. Steatosis from alcohol alone was similar in both strains. With APAP, maximal toxicity was observed at 300 mg APAP/kg in wild type mice and 400 mg/kg in *Cyp2e(-/-)* mice. Alcohol increased CYP2E and CYP3A in wild type mice and CYP3A in *Cyp2e(-/-)* mice. Although these findings suggest that CYP2E contributes to alcohol-mediated increases in APAP hepatotoxicity in wild type mice, the alcohol treatment caused greater apparent increases in CYP3A in these mice compared to the null strain. CYP3A and APAP activation activity were higher in female mice compared to male mice, yet the alcohol pretreatment was required to enhance APAP hepatotoxicity in both genders. The findings suggest that the alcohols have additional effects on the liver, other than increasing CYP3A, that contribute to the increase in APAP hepatotoxicity. The findings also indicate that CYP2E1 is not essential for alcohol-mediated increases in steatosis and APAP hepatotoxicity. (Supported by the Dept of Veterans Affairs.)

480 STUDIES WITH TRANSGENIC MICE ON THE ROLE OF CYP2E1 IN 1,1-DICHLOROETHYLENE- AND 1,2 DICHLOROETHANE-INDUCED TOXICITY IN MICE.

H. Lu, F. Bondoc, K. Reuhl and C. Yang. *College of Pharmacy, Rutgers, The State University of New Jersey, Piscataway, NJ.*

1,1-Dichloroethylene (1,1-DCE) and 1,2-dichloroethane (1,2-DCE) are of concern because of their demonstrated toxicity and carcinogenicity and their extensive use in the chemical industry. We investigated the role of CYP2E1 in 1,1-DCE- and 1,2-DCE-induced toxicity in CYP2E1-null and wild type mice. Male and female mice were given 1,1-DCE and 1,2-DCE (intragastrically, in corn oil) at 4-5 PM and then fasted overnight before sacrificing for analysis of toxicity. Knockout of CYP2E1 significantly prevented the 1,1-DCE (75 mg/kg)- and 1,2-DCE (400 mg/kg)-induced liver and kidney toxicity as reflected in the blood levels of GPT and urea nitrogen, respectively. No CYP2E1-null mice died, whereas 80% to 100% of wild type mice died after receiving 1,1-DCE at a dosage of 200 mg/kg or 1,2-DCE at a dosage of 600 mg/kg. 1,2-DCE-induced liver and kidney toxicity was completely prevented by knockout of CYP2E1 as indicated by biochemical and pathological analyses, suggesting that CYP2E1 is the enzyme responsible for 1,2-DCE-induced acute toxicity in mice. Nevertheless, liver and kidney toxicity was found in CYP2E1-null mice treated with 1,1-DCE, indicating that pathways other than CYP2E1 also contribute to 1,1-DCE-induced liver and kidney toxicity. The 1,1-DCE-induced toxicity was more severe in male mice than in female mice, possibly due to the higher CYP2E1 activity in male mouse kidney and the contribution of other male-specific P450 isozymes. (Supported by NIH grant ES03938 and facilities from the NIEHS Center Grant ES05022.)

481 PROTECTION AGAINST TCDD-INDUCED TOXICITY AND PORPHYRIA IN C57BL/6 CYP1A2 (-/-) KNOCKOUT MICE.

A. G. Smith[1], P. R. Sinclair[2], D. W. Nebert[3] and T. Dalton[3]. [1]*MRC Toxicology Unit, University Leicester, Leicester, United Kingdom,* [2]*VA Med. Center, White River Junction and Dartmouth Med. School, Hanover, NH and* [3]*Dept. Environmental Health, University Cincinnati Med. Center, Cincinnati, OH.*

We have previously shown that porphyria, characterised by hepatic accumulation of uroporphyrin, does not occur in C57BL/6 Cyp1a2 (-/-) knockout mice whereas it does occur in Cyp1a2 (+/+) wild type by combinations of iron, 5-aminolevulinic acid and the inducers of CYP1A2 3-methylcholanthrene and hexachlorobenzene. Here we have investigated the effects of TCDD the prototype AH receptor ligand and the most powerful CYP1A2 inducer and porphyrogenic agent, on both hepatic toxicity and porphyria. Mice received TCDD as an oral dose (75µg/kg) and were terminated after 5 weeks. Massive porphyria occurred in the wildtype but not in the -/- mice. Plasma ALT and AST levels were elevated 27- and 12- fold, respectively, in +/+ mice but elevations were <25% of that in the null mice. Histology of the liver confirmed considerably less toxicity (hepatocyte necrosis and biliary proliferation) in the -/- mice but there were no differences between genotypes in the degree of thymic atrophy caused by TCDD. CYP1A activities (EROD and MROD) and Western blotting confirmed absence of CYP1A2 induction but no depression of CYP1A1 expression. These results demonstrate that hepatic CYP1A2 expression has a profound influence on both porphyria and hepatic toxicity induced by TCDD supporting the proposal that the mechanisms are linked, probably by an oxidative mechanism.

482 EFFECTS OF HYPEROXIA ON LUNG INJURY AND CYTOCHROME P4501A1 EXPRESSION IN WILD TYPE AND AH RECEPTOR (AHR) KNOCKOUT MICE.

B. Moorthy, X. I. Couroucli and S. E. Welty. *Baylor College of Medicine, Houston, TX.*

We reported earlier that exposure of rats to 48 h of hyperoxia induces the activities and contents of hepatic CYP1A1 and 1A2, followed by a decline of induction at 60 h. In the present investigation, we tested the hypotheses that: (i) AHR (-/-) mice would be more susceptible to hyperoxic lung injury than wild type (C57BL/6J) mice; and (ii) hyperoxia would modulate CYP1A1 expression in lung by AHR-dependent mechanisms. AHR (+/+) and AHR (-/-) mice were maintained in room air (RA) or exposed to greater than 95% oxygen (hyperoxia) for 48 h, and lung weight/body weight ratios, pulmonary microsomal activities of ethoxyresorufin O-deethylase (EROD) (CYP1A1), and CYP1A1 apoprotein contents were determined. AHR (-/-) mice exposed to hyperoxia were more susceptible to hyperoxic lung injury, as indicated by significantly higher lung weight/body ratios than AHR (+/+) mice. Hyperoxia caused a 52% increase in pulmonary EROD activities in AHR (+/+) mice, and this was paralleled by enhancement in CYP1A1 apoprotein contents. However, hyperoxia altered neither EROD activities nor CYP1A1 apoprotein contents in AHR (-/-) mice, suggesting that AHR-dependent mechanisms contributed to CYP1A1 induction hy hyperoxia. In conclusion, our results showing increased susceptibility to hyperoxic lung injury of AHR (-/-) mice, which did not express lung CYP1A1, are consistent with the hypothesis that AHR-mediated pulmonary CYP1A1 induction by hyperoxia in the AHR (+/+) mice may play a protective role in hyperoxic lung injury. (Supported in part by NIH grant ES09132 and by ALA of Texas.)

483 CYTOCHROME P4501B1 MEDIATES INDUCTION OF BONE MARROW CYTOTOXICITY AND PRE-LEUKEMIA CELLS IN MICE TREATED WITH 7,12- DIMETHYLBENZ[A] ANTHRACENE.

S. M. Heidel[1], P. S. MacWilliams[1], W. M. Baird[2], W. M. Dashwood[1], J. T. M. Buters[3], F. J. Gonzalez[4], M. C. Larsen[1], N. Galvan[1], C. J. Czuprynski[1] and C. R. Jefcoate[1]. [1]*University of Wisconsin, Madison, WI,* [2]*Oregon State University, Corvalis, OR,* [3]*Technical University of Munich, Munich, Germany and* [4]*National Cancer Institute, Bethesda, MD.*

Humans are exposed to polycyclic aromatic hydrocarbons (PAH) through many environmental pollutants, especially the inhalation of cigarette smoke. These chemicals cause a variety of tumors and immunotoxic effects, as a consequence of bioactivation by P450 cytochromes to dihydrodiol epoxides. The recently identified cytochrome P4501B1 (CYP1B1) bioactivates PAHs, while CYP1B1 deficiency is linked to congenital human glaucoma. This investigation demonstrates that CYP1B1 null mice are almost completely protected from the acute bone marrow cytotoxic and preleukemic effects of the prototypic PAH 7,12-dimethylbenz[a]anthracene (DMBA). CYP1B1 null mice lacked the appreciable amounts of bone marrow DMBA-DNA adducts present in wild type mice, despite comparable hepatic levels of the predominant PAH-metabolizing cytochrome P450 CYP1A1. Wild type mice constitutively expressed CYP1B1 in bone marrow stromal cells, suggesting that local metabolism of PAHs initiates their cytotoxic and carcinogenic effects. Preliminary evidence suggests that benzo[a]pyrene, which exhibits greater binding to the AhR and induces a greater induction of hepatic CYP1A1 than DMBA, causes less bone marrow cytotoxicity than DMBA. This study substantiates the importance of local bioactivation of PAHs by CYP1B1 for bone marrow cytotoxicity. These findings, together with other recent reports, suggest that constitutive CYP1B1 expression may contribute to cancer susceptibility in specific tissues.

484 A THEORETICAL THERMODYNAMIC METHOD FOR IDENTIFYING POTENTIAL RATE-LIMITING STEPS IN CHEMICAL OXIDATIONS BY THE LIVER CYTOCHROME P4502E1.

P. Poulin. *F. Hoffmann-La Roche Ltd., Pharma Research, Basel, Switzerland.*

The rate-limiting steps determining the maximal velocity (V_{max}) of an enzymatic oxidation of low molecular weight volatile organic chemicals (LMVOCs) by the cytochrome (cyt) P-450, are hypothesized from the literature to be the formation of the monoatomic oxygen before the insertion into the substrate, and/or the insertion of the monoatomic oxygen into the substrate. Furthermore, for several structurally unrelated LMVOCs, for which it is assumed that their hepatic metabolism is predominantly governed by an oxidation involving the cyt P-450 2E1, similar values of V_{max} *in vivo* (in mole hr^{-1}) have been obtained in rats. This may be a consequence of rate-limiting steps determining chemical oxidations in rat livers under *in vivo* conditions. The objective of the present study was to develop a theoretical thermodynamic method for identifying potential rate limiting steps in LMVOC oxidations by the rat liver cyt P-450 2E1. The method consists of using a conventional thermodynamic equation of the transition state theory, to calculate the catalytic rate constant (K_{cat}) for the *in vitro* metabolism of LMVOCs in rat liver microsomes. This above theoretical exercise demonstrates that K_{cat} *in vitro* for LMVOCs are similar and well calculated, then, a rate-limiting step probably independent of the molecular structure could govern K_{cat} *in vitro* for chemical oxidations. The calculated K_{cat} *in vitro* was extrapolated to *in vivo* and used to predict a common value of V_{max} *in vivo* (= K_{cat} * [cyt P-450 $2E1_{liver}$] for twenty-fourth structurally unrelated LMVOCs. The experimentally determined V_{max} *in vivo* (avg.: $2.0x10^{-5}$ mole hr^{-1}, s.d. = $6.9x10^{-6}$, n = 24 LMVOCs) obtained from several experimental studies published in the literature, is in the range predicted for the common V_{max} *in vivo* (i.e., $1.5x10^{-5}$ to $9.5x10^{-5}$ mole hr^{-1} as a function of the concentration of cyt P-450 2E1 in rat livers). A practical aim of this present study is the use of the common V_{max} predicted for the *in vivo* situations in pharmacokinetic models instead of the experimentally determined V_{max} *in vitro* for first estimates of blood concentration-time profiles of each new/untested LMVOC.

485 ISOZYME-SELECTIVE INACTIVATION OF HEPATIC MICROSOMAL CYTOCHROME P450 BY REACTIVE OXYGEN SPECIES.

C. K. Yaremko, C. D. Webb and J. R. Bend. *University of Western Ontario, London, Ontario, Canada.*

The objective of this study was to test the hypothesis that cytochrome P450 (P450) isozymes vary in susceptibility to inactivation by reactive oxygen species (ROS), with the thinking that ROS-inactivated isozymes will be preferentially release heme substrate. Hepatic microsomes were incubated at 37°C for 15 min in the presence of hydrogen peroxide (H2O2, 0.1-1 M) or a FeCl3/H2O2/ascorbic acid free radical generating system (reagents 0.5-1.25 mM). CYP1A1 dependent ethoxyresorufin O-dealkylation (EROD), CYP1A2 dependent methoxyresorufin O-dealkylation (MROD) and CYP2B1 dependent pentoxyresorufin O-dealkylation (PROD) activities showed concentration-dependent, non isozyme-selective inactivation when treated with H2O2, culminating with total loss of activity at 0.5 M. CYP3A dependent erythromycin-N-demethylation activity showed considerable resistance to H2O2-induced inactivation and retained nearly 60% activity at 1 M H2O2. When incubated in the presence of FeCl3/H2O2/ascorbic acid, only PROD activity showed statistical decreases from control values at concentrations of 0.75 mM and 1.0 mM. Preliminary findings indicate that ROS selectively inactivate P450 isozymes which may preferentially release heme, the substrate for heme oxygenase-1 induced by elevated concentrations of ROS. (This work was supported by MRC grant #MT9972 to JRB.)

486 EPITOPE MAPPING OF CYP2B1 MONOCLONAL ANTIBODIES AND CONFIRMATION BY ELISA USING SYNTHETIC PEPTIDES.

B. Parimoo[1], R. Y. Cortes[2] and P. E. Thomas[1]. [1]*Laboratory of Cancer Research, College of Pharmacy, Rutgers University, Piscataway, NJ and* [2]*Department of Biochemistry and Microbiology, Cook College, Rutgers University, Piscataway, NJ.* Sponsor: M. M. Iba.

We have 12 monoclonal antibodies (MAbs) directed against rat CYP2B1 that recognize six spatially distinct epitopes. Our goal is to map the epitopes corresponding to these MAbs so that we can use this information to design antibodies for other P-450s. In our earlier studies we had made fourteen different constructs of CYP2B1, generated fusion proteins with glutathione S-transferase (GST), expressed them in E.coli and detected them by PAGE and Western blots. We narrowed down the epitopes for one group of inhibitory MAbs viz. BEA33, BE44, BE45 and BE28 to a region corresponding to amino acid sequence 250-261 in 2B1 protein. Other antibodies recognized amino acid sequences 262-272 in 2B1 (MAb 29) and 306-491 (BE46, B50 and BE49) in CYP2B1. Non-inhibitory MAbs BE26 and BE32 were mapped to a region 380-398 in 2B1 protein. However, BEA33 behaved differently from BE28, BE44 and BE45 in our earlier studies with inhibition. Our experiments with the fourteen constructs did not reflect a difference in the epitopes for these MAbs. We, therefore, made five new constructs covering nucleotide positions 463 to 801 of CYP2B1 to understand this further. Our results clearly indicate that there exists a subtle but noteworthy distinction between the

actual epitope positions of BEA33 and the others in this group viz. BE28, BE44 and BE45. The data collectively indicates that while the epitopes for BE28, BE44 and BE45 lie in the region corresponding to nucleotides 747-784 and BEF29 lies between nucleotides 784-801, that for BEA33 overlaps the junction of these two regions sharing a few amino acids that comprise the epitopes for the above mentioned MAbs. This difference may explain the data from the inhibition studies. The mapped epitopes for MAbs BE26/BE32 and MAb BEF29 have been confirmed by ELISA using synthetic peptides that were made in the same region. Identifying the sequence of amino acids composing these epitopes would aid in designing specific and inhibitory antibodies for this family and individual enzymes of other families of CYPs.

487 CLOTRIMAZOLE (CTMZ) AND KETOCONAZOLE (KTZ) AS POTENT AND SELECTIVE INHIBITORS OF RAT CYP 3A1/2 AND 2B1/2 ENZYMES.

V. K. Turan[1], V. M. Mishin[2] and P. E. Thomas[2]. [1]*Joint Graduate Program in Toxicology, Rutgers University / UMDNJ RWJ, Piscataway, NJ and* [2]*Laboratory for Cancer Research, College of Pharmacy, Rutgers University, Piscataway, NJ.* Sponsor: M. M. Iba.

In this study, CTMZ and KTZ were tested to determine their inhibitory potential towards CYP3A-mediated reactions, i.e., metabolism of testosterone to 6 beta-hydroxy-testosterone (6 beta-OH T), in rat liver microsomes. The particular objectives were to compare the inhibitory potencies (IC50 and ~90% inhibitory effect) using liver microsomes from adult female rats treated with dexamethasone (F-DEX) and untreated adult male rats (M-CTR), which are known to contain high levels of CYP isozymes 3A1 (3A23) and 3A2, respectively. The results demonstrated that CTMZ is a very potent and selective inhibitor of 6 beta-OH T production in all metabolic systems tested. Additionally, it was found that CTMZ is a potent inhibitor of CYP2B1/2-mediated reactions in liver microsomes from adult female rats treated with phenobarbital (F-PB). Indeed, the IC50 value for 6 beta-OH T formation was computed as 9.6 nM in F-DEX, 6.7 nM in M-CTR, and the IC50 for 16 beta-OH T formation as 12.4 nM in F-PB. The *in vitro* inhibitory potency for CTMZ was found to exceed significantly the same parameters for KTZ, a well-established specific inhibitor of CYP3A-mediated reactions *in vitro* and *in vivo*. In agreement, it was found that the IC50 for KTZ for 6 beta-OH T formation as 70 nM in F-DEX and 784 nM in M-CTR, which is more than 10-fold and 100-fold higher, respectively, than that for CTMZ. However, the inhibitory potency of KTZ for 16 beta-OH T formation was nearly equal to that of CTMZ, with the IC50 as 13.0 nM in F-PB. CTMZ and KTZ, at the concentrations that inhibit 90% and more 3A1/2- and 2B1/2-mediated reactions, has less or no effect on the activities of other major rat liver CYP isozymes, such as 1A1, 1A2, 2C11, and 2E1. In summary, CTMZ is a more potent and selective inhibitor of 3A1/2-mediated reactions than that of KTZ. However, KTZ is 10-fold more potent at inhibiting 3A1- than 3A2-mediated reactions.

488 EFFECTS OF ALBENDAZOLE TREATMENT ON HEPATIC CYTOCHROME P450 (CYP450) EXPRESSION IN THE RAT.

J. Asteinza[1], R. E. Reyes-Reyes[2], V. Dorado-González[2] and J. J. Espinosa-Aguirre[1]. [1]*Instituto de Investigaciones Biomédicas, Universidad Nacional Autónoma de México, México, D. F., Mexico and* [2]*Unidad de Investigación en Salud Infantil, Instituto Nacional de Pediatria, México, D. F., Mexico.* Sponsor: A. Albores.

The anthelmintic drug albendazole (ABZ) is a benzimidazole highly efficient in the treatment of neurocysticercosis. Its formula, methyl(5-(propylthio)-1H-benzimidazol-2-yl)carbamate, has been reported to act as a 3-methylcolanthrene-like CYP inducer. We looked at the effects of ABZ treatment (i.p. and p.o. administration) on the expression of some hepatic CYPs involved in the metabolism of environmental mutagens and carcinogens. Two different strategies were used: a) Immunoblots to specifically identify P450 proteins 1A1/2, 2B1/2 and 2E1; b) Quantification of alkoxyresorufin O-dealkylases (AROD) and p-nitrophenol hydroxylase (pNPH) activities in microsomal samples. Intraperitoneal administration of albendazole (50 mg/kg body weight/day/3 days in corn oil) to rats, caused an induction of hepatic CYP1A1 and CYP1A2 as well as a reduction of CYP2E1 expression as determined by western blot; AROD activities were increased and a slight decrease in pNPH catalytic activity occurred. When the two main metabolites of ABZ were used, results indicated that CYP1A1 induction was produced by the sulfoxide but not by the sulfone metabolite. Oral administration of ABZ at therapeutic dose (20 mg/kg body weight/day/3 days) produced an increase in CYP1A1 protein content 24 h after the first intake. The high protein level was maintained during the treatment and 24 h after the last administration. CYP1A1 basal protein levels were achieved 24 h later. Our results confirm and extend previous data on the inducing properties of ABZ. This CYP1A induction should be taken in to consideration to avoid exposure to other drugs and environmental mutagens/carcinogens that are putative substrates of this CYP subfamily like cigarette smoke, charcoal cooked meats or nitrite containing foods.

489 KINETICS OF 3-METHYLINDOLE OXYGENATION/DEHYDROGENATION BY CYTOCHROME P450 ENZYMES.

D. L. Lanza[1], C. L. Crespi[2] and G. S. Yost[1]. [1]*University of Utah, Salt Lake City, UT and* [2]*Gentest Corporation, Woburn, MA.*

3-Methylindole (3MI) is a selective pulmonary toxicant, and cytochrome P450 bioactivation of 3-methylindole is a prerequisite for toxicity. There are at least 3 pathways for 3MI bioactivation: hydroxylation, epoxidation and dehydrogenation. In metabolic/ kinetic studies using CYP2F1 and CYP2F3, it was shown that dehydrogenation of 3MI to 3-methyleneindolenine was catalyzed exclusively (V/K=72 and V/K=1.6, respectively). Dehydrogenation of 3MI appears to be the primary bioactivation pathway for these two enzymes, but it is not known if 3MI is simply a good substrate for dehydrogenation or if certain cytochrome P450s responsible for 3MI bioactivation have unique active sites that only catalyze the dehydrogenation of the molecule. Therefore, product formation and kinetics by the CYP2F1 and CYP2F3 enzymes were compared to other cytochrome P450 enzymes. The enzymes tested were CYP1A1, CYP1A2, CYP1B1 and CYP2E1. The CYP1A1 and CYP1A2 enzymes produced three 3MI metabolites: the dehydrogenation product, 3-methyleneindolenine (V/K=0.7 and V/K=24, respectively), the hydroxylation product, indole-3-carbinol (V/K=49 and V/K=111, respectively) and the epoxidation product, 3-methyloxindole (V/K=5 and V/K=91, respectively). For both enzymes, the maximum rate of 3-methyloxindole production was 3-4 fold higher than the dehydrogenation product. CYP1B1 produced indole-3-carbinol (V/K = 171) and 3-methyloxindole (V/K=5). CYP2E1 only produced 3-methyloxindole (V/K=100). The ability of the various CYP1 family enzymes to catalyze the formation of different 3MI metabolites, along with the specific oxygenation by CYP2E1, illustrate that dehydrogenation is not solely directed by the substrate, but that the members of the CYP2F family may possess unique active sites that control the dehydrogenation pathway. (Supported by USHPS grant number HL13645.)

490 THE EFFECT OF DEXAMETHASONE ON THE HALF-LIFE OF CYP2E1 MRNA IN PRIMARY CULTURED RAT HEPATOCYTES.

M. S. Hafner and R. F. Novak. *Wayne State University, Detroit, MI.*

Although the half-life of the CYP2E1 protein in the absence and presence of substrates and inducers has been examined in several systems, little is known regarding CYP2E1 mRNA turnover. The synthetic glucocorticoid, dexamethasone (Dex), is known to elevate the mRNA and protein levels of several P450s in cultured hepatocytes, including CYP2E1 mRNA. Since the mechanism of this elevation of CYP2E1 mRNA is unknown, the effect of Dex on CYP2E1 mRNA stability in primary cultured rat hepatocytes was examined. Hepatocytes were maintained for 48 h on Vitrogen-coated 60 mm dishes in fortified Chee's media supplemented with 0.1 nM insulin and 10^{-7} M Dex, with media changes every 24 h. Two hours prior to actinomycin D addition, the dishes were separated into two treatment groups: control (no Dex) and 10^{-7} M Dex. Media for each group was supplemented with 5 μg/ml of actinomycin D, and samples harvested immediately and at 2.0, 4.0, 6.0, and 8.0 h post-treatment for mRNA isolation and Northern blot analysis. CYP2E1 band densities were determined and the best fit line was obtained using linear regression analysis, which was then used to calculate CYP2E1 mRNA half-life values. The results reveal that the half-life of CYP2E1 mRNA isolated from Dex-treated cells was 11.0 h, whereas CYP2E1 mRNA isolated from control cells exhibited a half-life of 5.7 h. Thus a 2-fold difference exists in CYP2E1 mRNA half-lives between Dex-treated and untreated hepatocytes. This is consistent with CYP2E1 mRNA gel shift assays in which cytosol from Dex-treated hepatocytes yielded greater band intensities relative to untreated cells. This supports the hypothesis that the Dex-mediated increase in CYP2E1 mRNA is likely the result of enhanced mRNA stability associated with proteins bound to CYP2E1 mRNA. (Supported by grants ES 03656 and EHS Center Grant ES 06639.)

491 SPECIES, STRAIN AND TISSUE SPECIFIC CYP1A1 INDUCTION IN MICE EXPOSED TO TOBACCO SMOKE.

M. F. Wolfe, J. T. Thompson and H. R. Witschi. *University California Davis, Davis, CA.*

Induction of cytochrome P450 1A1 (CYP1A1) conventionally has been measured by the ethoxyresorufin-O-deethylase (EROD) assay. In order to assess differences among species and strains in CYP1A1 induction in various tissues, we exposed mice to tobacco smoke which contains several known inducers of CYP1A1. We also compared CYP1A1 activity as measured by the microsomal EROD assay with CYP1A1 activity measured by reverse transcriptase polymerase chain reaction (RT-PCR). We exposed two strains of laboratory mice (Mus musculus) AJ and C57; and a mouse species native to North America, (Peromyscus leucopus), to tobacco smoke in an enclosed chamber for six hours. Mice were sacrificed either immediately post-exposure or 24 hours post-exposure. CYP1A1 induction was measured in microsomal preparations of liver, lungs and kidneys via EROD assay, and in liver, lung and peripheral blood lymphocytes via RT-PCR. There was no significant difference in liver CYP1A1 activity among species/strains at either six or 24 hour sampling times. Peromyscus, but neither of the Mus strains, showed induction of CYP1A1 in the kidney at both 6- and 24-hour sampling times. Lung CYP1A1 activity was induced in both Mus strains and in Peromyscus.

492 MODULATION OF RAT PULMONARY CYTOCHROME P4501A1 (CYP1A1) EXPRESSION BY HYPEROXIA.

X. I. Couroucli, S. E. Welty, R. S. Geske, N. A. Patel and B. Moorthy. *Baylor College of Medicine, Houston, TX.*

We reported recently that exposure of rats to hyperoxia for 48 h leads to induction of hepatic CYP1A1/1A2 enzyme activities, followed by decline at 60 h. In this study we tested the hypotheses that: (i) Pulmonary CYP1A1 expression is modulated by hyperoxia, similar to the changes in hepatic CYP1A parameters; and (ii) hyperoxia-induced alterations in pulmonary CYP1A1 reflect cell-specific modulation of CYP1A1 expression, in relation to lung injury. Adult male Sprague-Dawley rats were maintained in room air (RA) or exposed to hyperoxia (> than 95% O2) for 24, 48, or 60 h, and lung microsomal ethoxyresofurin O-deethylase (EROD) (CYP1A1) activities, CYP1A1 apoprotein contents, and CYP1A1 mRNA levels were determined. Pulmonary EROD activities were enhanced 6.3-fold after 48 h of hyperoxia over RA controls, and this was accompanied by induction of CYP1A1 apoprotein. CYP1A1 enzyme activity and apoprotein content declined by 60 h. Hyperoxia exposure for 24 h showed a 58% increase in CYP1A1 mRNA over RA controls. CYP1A1 mRNA was no longer detectable after hyperoxia for 48 or 60 h. These results suggest that pre-translational mechanisms contributed to the modulation of CYP1A1 by hyperoxia. Lungs of hyperoxic animals showed an increase in CYP1A1 immunostaining in the bronchiolar epithelial cells, type II pneumocytes, and endothelial cells after 24-48 h. There was microscopic evidence of lung inflammation between 48 and 60 h. In conclusion, the early induction of CYP1A1 in the lungs in association with minimal lung injury in hyperoxia, followed by the terminal decline in CYP1A1 expression, which was temporally accompanied with severe lung inflammation, suggests that regulation of expression of pulmonary CYP1A1 by hyperoxia has mechanistic relationship(s) with hyperoxic lung injury. (Supported in part by NIH grant ES09132 and by ALA of Texas.)

493 SPECIFIC CYTOCHROME P450 INDUCTION IN FEMALE B6C3F1 MICE COMPARED TO FISCHER 344 RATS FOLLOWING PRETREATMENT OF 4-VINYLCYCLOHEXENE OR ITS TOXIC EPOXIDE METABOLITES.

S. M. Fontaine, P. B. Hoyer and I. G. Sipes. *The University of Arizona, Tucson, AZ.*

4-Vinylcyclohexene (VCH) is an intermediate in the production of rubber and styrene. Following repeated exposure, VCH is ovotoxic in B6C3F1 mice but not in F-344 rats. A crucial factor for the species differences in toxicity is the greater rate of formation of the toxic metabolites [1,2-vinylcyclohexene monoepoxide (1,2-VCHE), 7,8-vinylcyclohexene monoepoxide (7,8-VCHE), and ultimately, vinylcyclohexene diepoxide (VCD)], from VCH in mice as compared to rats. Hepatic microsomes isolated from mice or rats pretreated with VCH (7.5mmol/kg for 10d.) caused greater induction of bioactivation of VCH to epoxides in the mouse (3.5-fold in 1,2-VCHE formation, 2-fold in 7,8-VCHE formation, and detectable VCD formation) as compared to the rat (2.1-fold in 1,2-VCHE formation, 1.3-fold in 7,8-VCHE formation, and no detectable VCD formation). This parallels an induction of total cytochrome P450 levels in the mouse and not the rat. CYP2A and CYP2B protein immunoblots revealed induced expression of these isoforms following VCH pretreatment in mouse but not rat hepatic microsomes. Neither species pretreated with VCH demonstrated an induction of CYP2E1. To determine whether VCH and/or its epoxide metabolites were causing the inductions in CYP2A and CYP2B, mice and rats were dosed with either 7.5mmol/kg VCH, 1.4mmol/kg 1,2-VCHE, or 0.4mmol/kg VCD for 10 days (equitoxic doses of epoxides were used based on previous studies in the mouse). Microsomes from VCH-pretreated mice had elevated levels of CYP2A (2-fold) and CYP2B (3-fold), while those from 1,2-VCHE- and VCD-pretreated mice had only elevated levels of CYP2B (2.2-fold and 1.5-fold, respectively). CYP2E1 levels were not induced following pretreatment with VCH or the epoxide metabolites. Neither CYP2A, CYP2B, nor CYP2E1 levels were induced in rat microsomes following any of the pretreatments. In conclusion, at equitoxic doses in the mouse, the epoxide metabolites did not induce hepatic CYP levels to the same extent as VCH in the mouse, while neither VCH nor its epoxide metabolites induced any hepatic CYP levels in the rat. (This research was supported in part by NIEHS Training Grant (ES07091), Center Grant (ES06694) and Chemical Manufactures' Association.)

494 N-ALKYLPROTPORPHYRIN IX FORMATION IN RAT HEPATIC MICROSOMES AFTER INTERACTION WITH PORPHYRINOGENIC XENOBIOTICS.

S. G. W. Wong and G. S. Marks. *Department of Pharmacology and Toxicology, Queen's University, Kingston, Ontario, Canada.* Sponsor: T. E. Massey.

Several porphyrinogenic xenobiotics disrupt heme synthesis by eliciting mechanism-based inactivation of specific isozymes of cytochrome P450 (CYP). During inactivation, the CYP heme moiety is converted to an N-alkyprotoporphyrin IX (N-alkylPP), which is a potent inhibitor of the terminal enzyme in heme synthesis, ferrochelatase. We have already determined the major rat hepatic CYP isozyme sources of N-alkylPP after the administration of porphyrinogenic compounds *in vivo*. Previously we have determined the human CYP isozymes which undergo mechanism-based inactivation *in vitro* after interaction with several porphyrinogenic compounds. We did not, however, determine which of these isozymes were responsible for N-alkylPP formation. Thus, our objectives for the present study were to determine whether N-alkylPPs could be isolated from rat liver microsomes following interaction *in vitro* with porphyrinogenic xenobiotics, and if so, whether they are produced in amounts sufficient for studies utilizing microsomes containing human single cDNA-expressed CYP isozymes. The *in vitro* formation of N-alkylPP was observed following incubation of 3-[(arylthio)ethyl]sydnone (TTMS), allylisopropylacetamide (AIA), and 3,5-diethoxycarbonyl-1,4-dihydro-2,6-dimethyl-4-ethylpyridine (4-ethylDDC), but not 1-aminobenzotriazole (ABT), with rat hepatic microsomes. However the overall N-alkylPP yield per nmol CYP *in vitro* was much lower than previously observed *in vivo*. The N-alkylPP yield per nmol CYP was highest for TTMS, which elicited the formation of 0.043 nmol N-vinylPP/nmol CYP, and it was concluded that the use of microsomes containing single cDNA-expressed human CYP isozymes would be feasible for further study with TTMS, but not for AIA or 4-ethylDDC.

495 ALTERATION OF PARATHION AND CHLORPYRIFOS DESULFURATION BY METHOXYCHLOR *IN VITRO*.

L. A. Cook[1], H. W. Chambers[2] and J. E. Chambers[1]. [1]*Center for Environmental Health Sciences, College of Veterinary Med., Mississippi State University, MS and* [2]*Department of Entomology, Mississippi State University, MS.*

Methoxychlor (MXC), an organochlorine (OC) insecticide, was used to investigate the *in vitro* interaction of an OC insecticide with the desulfuration activity needed to activate the organophosphorus (OP) insecticides [chlorpyrifos (CPS) and parathion (PS)]. Adult rats were administered β-naphthoflavone (BNF) or phenobarbital (PB) to induce hepatic cytochrome P450s responsible for the activation of OP insecticides. Oil and saline (vehicle) controls and naive controls were also included. Microsomes were prepared from liver of male and female rats. Desulfuration activity was the same among control groups. Male rats treated with PB had 3.8- and 18-fold higher desulfuration activity of PS and CPS than the controls and when treated with BNF had 1.6- and 2.8-fold higher desulfuration activity of PS and CPS than controls. Female rats treated with PB had 3.6- and 13-fold higher desulfuration activity of PS and CPS than the controls and when treated with BNF had 1.2-and 2-fold higher desulfuration activity of PS and CPS than controls. MXC was added at an equimolar concentration concurrently with PS or CPS to initiate

desulfuration. In males, desulfuration of PS was decreased by 53%, 29%, and 39% for BNF, PB, and controls, respectively, and desulfuration of CPS was decreased by 74%, 26%, and 70% for BNF, PB, and controls, respectively. In females, desulfuration of PS was decreased by 50%, 29%, and 32% for BNF, PB, and controls, respectively, and desulfuration of CPS was decreased by 50%, 57%, and 51% for BNF, PB, and controls, respectively. MXC affected desulfuration in all groups and had the greatest effect on the desulfuration of CPS in BNF-treated and control males, and the least effect on PB-treated groups of both sexes.

496 EXPRESSION OF CYP2E1 IN ISOLATED OVARIAN FOLLICLES OBTAINED FROM B6C3F1 MICE.

E. A. Cannady, I. G. Sipes and P. B. Hoyer. *University of Arizona, Tucson, AZ.*

4-Vinylcyclohexene (VCH), an industrial chemical, causes ovarian toxicity in mice. Previous studies have shown that VCH is bioactivated to its ovotoxic metabolite, vinylcyclohexene diepoxide (VCD), by the cytochrome P450 (CYP450) enzyme system. In mice, VCD selectively destroys the smallest ovarian follicles (preantral; 25-100 mm). It is speculated that VCH is bioactivated in the liver, however, it is not known if the ovary also plays a role in the metabolism of VCH. The purposes of this study were to investigate a) whether the mouse ovary expresses mRNA encoding cyp2e1, b) the distribution of its expression in ovarian follicles, and c) the effect of VCD dosing on this expression. Female B6C3F1 mice (n=10) were dosed daily (15 d) with VCD (0.57 mmol/kg; ip) or control (sesame oil; ip), or 10 d with the cyp2e1 inducer, acetone (1% in drinking water; po). Following treatment, ovaries and livers were removed and ovarian follicles were separated into three distinct populations (fraction 1, small preantral, 25-100 mm; fraction 2, large preantral, 100-250 mm; and antral, >250 mm). Total RNA was isolated from these tissues. Expression of mRNA encoding cyp2e1 was visualized by reverse-transcriptase polymerase chain reaction (RT-PCR). Amplification products were detected in fraction 1, fraction 2, and liver, but not antral follicles, from control and acetone-treated mice. In VCD-treated mice, cyp2e1was detected in liver, but not in fraction 1 or fraction 2 ovarian follicles. These results demonstrate that expression of cyp2e1 in the mouse ovary is compartmentalized and expressed in preantral (25-250 mm) rather than antral (>250 mm) follicles. Furthermore, repeated dosing with VCD, known to be ovotoxic in those small follicles, may reduce ovarian expression of cyp2e1. This suggests that the ovotoxic metabolite, VCD, may affect expression of cyp450's in the ovary. (ADCRC 9809, ESO8979, ESO9246, NIEHS Center Grant 06694.)

497 AH RECEPTOR AND nf-κb INTERACTION: SUPPRESSION OF CYTOCHROME P4501A1 THROUGH ACTIVATION OF nf-κb.

Y. Tian[1], S. Ke[1], A. B. Rabson[2] and M. A. Gallo[1]. [1]*EOHSI, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ and* [2]*CABM, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.*

Inflammatory cytokines, such as TNF-α, IL-1β and bacterial endotoxin suppress the induction of cytochromes P450 1A1/1A2. However, the underlying mechanism(s) is not well understood. In an earlier study, we demonstrated a physical interaction and functional mutual modulation between the AhR and NF-κB signaling pathways. In the present studies, we showed that activation of NF-κB down-regulates the expression of cytochrome P450 1A1, thereby providing an underlying mechanism for the long-standing observations that inflammatory cytokines cause suppression of cytochromes P450 1A1/1A2. Specifically, NF-κB inducers, such as TNF-α and bacterial endotoxin, suppress *cyp1a1* gene expression in Hepa 1c1c7 cells, as determined by Western blot analysis, as well as transient transfection assays with a reporter gene whose expression is under the control of *cyp1a1* promoter. In transient transfection assays, we demonstrated that TNF-α-imposed repression of *cyp1a1* promoter activity is reversed by the NF-κB super repressor ΔIκBα, which is resistant to the TNF-induced degradation, thereby causing constitutive inhibition of NF-κB activation. These results suggest that the suppression of *cyp1a1* expression by cytokine TNF-α is mediated, at least in part, through the activation of NF-κB. Expression of RelA subunit of NF-κB through a tetracycline-regulated promoter also markedly suppresses the *cyp1a1* promoter activity in Hela cells; further strengthening the notion that NF-κB activation suppresses *cyp1a1* expression. (Supported in part by NIEHS Center Grant #ES05022.)

498 IMMUNOCHEMICAL CHARACTERIZATION OF RAT PREGNANE X RECEPTOR H.

H. Zhang, Y. Li, W. Zhu, L. Liu, L. Matoney and B. Yan. *University of Rhode Island, Kingston, RI.* Sponsor: Z. A. Shaikh.

An orphan nuclear receptor, termed the pregnane X receptor (PXR), has recently been cloned from several species. Transient cotransfection experiments demonstrate that the PXR responds to structurally dissimilar compounds and activates a reporter construct containing a *cis*-element from the gene encoding cytochrome P4503A (CYP3A). Northern blotting analyses show that several prototypical CYP inducers markedly increase the accumulation of rat PXR mRNA. This study was designed to immunochemically characterize the rat PXR. A peptide derived from this receptor was synthesized and conjugated with the keyhole limpet hemocyanin. An antibody was raised against the conjugated peptide and subjected to affinity chromatography. This antibody detected a protein only in the PXR-transfected COS-7 cells but not in the control cells. This immunoreactive protein had a molecular weight of 51-kDa, similar to that calculated from the cDNA. Consistent with the tissue distribution of PXR mRNA, this 51-kDa protein was abundant in liver, intestine, and to a lesser extent, in kidney and lung. The level of this protein were markedly increased in rats treated with isoniazid, clofibrate and perfluorodecanoic acid in both hepatic and extrahepatic tissues. The antibody also detected a testicular protein which had a higher electrophoretic mobility than the 51-kDa protein. The testicular protein was abundantly expressed and little change was observed in xenobiotic-treated rats. Compounds that increase PXR expression (inducers) and compounds that activate the PXR (ligands) likely have synergistic effects on CYP3A induction, providing a novel molecular explanation for drug-drug interactions. (Supported by a grant from the Rhode Island Foundation.)

499 THE NORDIC EXPERT GROUP FOR CRITERIA DOCUMENTATION OF HEALTH RISKS FROM CHEMICALS.

J. Jarnberg and G. Johanson. *Toxicology and Risk Assessment, National Institute for Working Life, Stockholm, Sweden.*

The main task of the Nordic expert group for criteria documentation of health risks from chemicals (NEG) is to produce criteria documents. These are used by the regulatory authorities in the Nordic countries as the scientific basis for setting occupational exposure limits (OELs) at the national level. Some of the NEG documents are also used internationally, e.g. by the European Union. NEG consists of scientific experts from the Nordic countries (Denmark, Finland, Iceland, Norway and Sweden). The project is financed by the Nordic Council of Ministers, an intergovernmental collaborative body for the five countries. The aim of the document is to establish dose-response /dose-effect relationships, to identify a NO(A)EL or LO(A)EL, and to define a critical effect based on the scientific literature. The draft document is reviewed and finally accepted by the NEG. The documents are written in English, and are printed and published by the National Institute for Working Life in Sweden in the scientific serial Arbete och Hälsa (http://www.niwl.se/ah/default_en.htm). In the near future, electronic short versions of the documents will be published on the web. During the past years NEG also had a bilateral cooperation with US NIOSH and the Dutch expert committee for occupational exposure standards (DECOS). The project started in 1978. Since then, approximately 130 criteria documents have been published. Recent documents include antimony, dichlorobenzenes and refractory ceramic fibers. The nordic collaboration in NEG is beneficial as it leads to a concordant view in risk assessment, a shared burden in producing documents and decreases duplication of work.

500 WORST-CASE BENZENE EXPOSURE SCENARIO FROM DIESEL LOCOMOTIVE EXHAUST IN A ROUNDHOUSE.

A. K. Madl[1] and D. J. Paustenbach[2]. [1]*Exponent, Oakland, CA and* [2]*Exponent, Menlo Park, CA.*

An exposure assessment of benzene was used to estimate the carcinogenic hazard posed by a possible worst-case exposure scenario to diesel locomotive exhaust in a roundhouse. To understand the upper bound risk to benzene from diesel exhaust, a locomotive was allowed to run for four 30-minute intervals during an 8-hour workshift in a roundhouse to simulate conditions that are beyond worst-case. Full-shift and one-hour airborne concentrations of benzene were measured in the breathing zone between and during the emission episodes on two consecutive days. Carbon monoxide, elemental carbon (surrogate for diesel exhaust), and nitrogen dioxide/nitric oxide area airborne measurements were used to characterize these conditions. Carbon monoxide was measured continuously; elemental carbon was sampled with full-shift

area samples; and nitrogen dioxide/nitric oxide was sampled using full-shift and 15-minute (nitrogen dioxide only) area samples. The benzene concentrations were compared to the current occupational exposure limits and to benzene concentrations associated with cigarette smoking and filling vehicle gas tanks at service stations. The one-hour airborne benzene concentrations range from 1-15ppb with 65% of the measurements below the limit of detection (2-4ppb). Results indicate that the 8-hour time-weighted average for benzene in the roundhouse is approximately 100 fold less than the current threshold limit value (TLV) of 0.5ppm. Under this worst-case exposure scenario, benzene concentrations from diesel exhaust are significantly less than those reported in cigarette smoke and those associated with filling vehicle gas tanks. These data are consistent with other studies, which have indicated that benzene concentrations due to diesel emissions in a relatively confined environment are low.

501 ESTIMATION OF LUNG CANCER RISK IN POPULATION LIVING IN THE VICINITY OF ALUMINIUM SMELTERS IN QUEBEC.

A. Vyskocil and C. Viau. *Université de Montréal, Dép. de Médecine du Travail et d'Hygiène du Milieu, Montréal, Quebec, Canada.*

Aluminium smelters using the older Horizontal Stud Söderberg process have long been recognised as significant contributors to PAH emissions. The lung is one of the target organs after PAH inhalation. Therefore, we focused our attention on estimation of lung cancer risk in population living in the vicinity of aluminium smelters in Quebec. For our calculations we used individual PAH concentrations measured at 11 different locations in Quebec between 1989 and 1994 . Two approaches in the risk assessment of PAH mixture were used. In the first approach, benzo[a]pyrene (B[a]P) toxic equivalent concentrations were used as estimates for exposure to the mixture of PAH. The relative potency factors proposed by Malcolm and Dobson (Department of the Environment. Her Majesty's Inspectorate of Pollution, London, 1994) were used. The lifetime unit risk values for continuous inhalation exposure to BaP obtained from the animal data sets ranging between 0.37 x 10-6 and 4.8 x 10-6 per ng/m3 of BaP were used. The calculated upper bound lung cancer risk values ranged between 1.2 x 10-7 and 4.7 x 10-5 . An alternative approach assumes that the potency of the PAH fraction of any environmental mixture is proportional to the BaP content of the mixture. Public lifetime lung cancer unit risk values of 0.3 - 9.5 x 10-5 per ng/m3 BaP , recalculated by Gibbs (Ann.Occup.Hyg. 41, Suppl. 1, 49-53, 1997) were used. The estimated excess probabilities of lung cancer ranged between 2 x 10-7 and 3.3 x 10-4. It should be noted that both estimates are based upon numerous assumptions such that the confidence in calculated values is evaluated as low-to-medium. (This study was supported by ALCAN ALUMINIUM Ltd., Canada.)

502 HEALTH RISK ASSESSMENT FOR A FORMER ARMY AMMUNITION PLANT.

N. Luke[1], L. J. Long[2], P. Amin[1], S. Muffler[1] and D. Boyadjian[1]. [1]*IT Corporation, Somerset, NJ and* [2]*U.S. Army Corps of Engineers, Nashville, TN.*

As part of a remedial investigation and feasibility study at an army facility which produced and stored trinitrotoluene during World War II, a comprehensive human health risk assessment was conducted to evaluate the cancer risk and health hazard for potentially exposed on-site workers, an off-site residential population and recreational users. Due to the large site area and different operational activities at the facility, six remedial sites and the entire site as a whole were evaluated. Risk analyses indicated that five of the six sites posed unacceptable risks and hazards to on-site workers. Nitroaromatic explosives, PCBs and metals contributed most to the risk and health hazards. However, the potential exposure pathway that presented the largest calculated risk and hazard for the on-site assessment was dietary consumption of fish caught in on-site ponds, a non-occupational, recreational exposure scenario. Upon further investigation of the aquatic monitoring program, it was concluded that this former army ammunition facility was not the single contributor to the PCBs in the fish caught from the ponds. The cleanup goals are being developed for the site.

503 RELATION BETWEEN WORKING CONDITIONS AND EXPOSURE TO DIOXINS IN A MUNICIPAL WASTE INCINERATOR.

Y. Ogawa[1], N. Hisanaga[1], H. Arito[1], X. Yu[1], R. Yoshida[1], A. Takata[1], H. Sakurai[1], S. Watanabe[2], I. Uchiyama[3], S. Asahi[4], I. Tanaka[4], M. Kudo[5] and T. Takata[5]. [1]*National Institute of Industrial Health, Kawasaki, Japan,* [2]*Tokyo University of Agriculture, Tokyo, Japan,* [3]*Institute of Public Health, Tokyo, Japan,* [4]*University of Environmental & Occupational Health, Kitakyusyu, Japan and* [5]*JISHA, Tokyo, Japan.*

The purpose of this paper is to report on the exposure assessment of MWI workers to dioxins. Subjects were 92 workers and were grouped to four categories. I; workers who did not work inside the facility. II; workers who had worked at the periphery of the facility and handled the non-flammable residues. III; workers who had worked inside the facility. IV; workers who had engaged in maintenance of the furnace, the electrical dust collector, and the smoke cleaning process. Total level of dioxins in I-TEQ (T-TEQ) of groups I, II, III, and IV were 34.2, 66.8, 93.3, and 323.3 pg I-TEQ/g blood-fat, respectively. The dioxin level of group IV was significantly higher than those of the rest of three groups and had a significant correlation between T-TEQ and working duration. Congener profiles of groups I, II, III, and IV expressed by PCDF/PCDD ratio were 0.3, 0.3, 0.7, and 1.6, respectively. From the high T-TEQ level and the positive correlation between T-TEQ and working duration, workers of group III and IV must have been exposed to dioxin emitted from the incinerator. PCDF rich congener profiles from excess exposure support this inference. Exposure to co-planer PCBs was also examined.

504 RISK ANALYSIS OF CANDLE EMISSIONS.

F. D. Stephen[1], C. H. Stineman[1], P. W. Jonmaire[1], D. W. Kelly[1] and R. D. Harbison[2]. [1]*Ecology & Environment, Inc., Lancaster, NY and* [2]*Center for Environmental/Occupational Risk Analysis & Management, College of Public Health, University of South Florida, Tampa, FL.*

Previous studies that reported significant public health risks from candle emissions have relied upon unsupported toxicity assumptions about candle soot and have based lifetime risk estimates on emissions from individual candles. Candle soot was assumed to exhibit the same cancer potency as diesel particulate matter (DPM). Carcinogenic PAHs, notable constituents of DPM, have not been detected, or are present only at low levels, in candle soot. Therefore, the assumption of equal potency is not warranted. The purpose of this study was to use generally accepted risk assessment methodology to evaluate the potential health risks associated with candle emissions. Probabilistic risk estimates were calculated using the fitted distribution of reported emissions as the source term and distributions from EPA's Exposure Factors Handbook for other exposure factors. A Monte Carlo analysis using Latin hyper cube sampling was performed. The 50th to 95th percentile risk estimates for benzene emissions ranged from about $2x10^{-8}$ to $1x10^{-6}$. Point estimates calculated using the 95% UCL emission rate, rather than individual candle emissions, resulted in risk estimates for benzene emissions ranging from $2x10^{-7}$ to $3x10^{-6}$. The potential risks estimated in this study are generally considered acceptable by USEPA, and are below the threshold (10-5) for California Proposition 65 listing and labeling. (Partially supported by NIOSH Grant T42/CCT412874.)

505 THE SCIENTIFIC BASIS FOR SETTING OCCUPATIONAL EXPOSURE LIMITS IN SWEDEN - THE SWEDISH CRITERIA GROUP.

J. Hogberg, G. Johanson and J. Montelius. *Toxicology and Risk Assessment, National Institute for Working Life, Stockholm, Sweden.*

The Swedish Criteria Group (SCG) is an expert committee at the Swedish National Institute for Working Life (NIWL) and consists of about 15 scientists from inside as well as outside the institute. They represent different areas in toxicology and occupational medicine. Observers from the trade unions and the Swedish National Board of Occupational Safety and Health (NBOSH) also participate in the group. The main task of the group is to gather and evaluate data, which are then used as a scientific basis for NBOSH in their setting of administrative occupational exposure limits. An appointed scientist writes a draft document that summarises toxicological and medical data. Only material published (preferably peer reviewed) in the scientific literature is accepted. After review in the Criteria Group the drafts are published as a consensus report from the group. The task of the Criteria Group is not to propose a numerical occupational exposure limit value but to present dose-effect and

dose-response relationships, define the critical effect for occupational exposure, and identify a NOAEL or LOAEL. The consensus reports are published yearly, both in English and in Swedish, by the NIWL in the scientific serial Arbete och Hälsa (http://www.niwl.se/ah/default_en.htm). Since the start of the Criteria Group in 1978, about 250 consensus reports and 39 comprehensive criteria documents have been published. Several of the criteria documents have been published in collaboration with the Dutch Committee on Occupational Standards (DECOS) or the US National Institute for Occupational Safety and Health (NIOSH). The Criteria Group also has a close collaboration with the Nordic Expert Group.

506 HUMAN HEALTH RISK ASSESSMENT OF TOLUENE DIAMINE ISOMERS FROM POLYURETHANE FOAM USED IN AN IMPLANTABLE MEDICAL DEVICE.

K. Kennepohl[1], D. Ridley[2], A. B. Kerr[1] and J. M. Daniels[1]. [1]*Cantox Health Sciences International, Mississauga, Ontario, Canada and* [2]*Cantox Health Sciences International, Bridgewater, NJ.*

The long term implantation of a new polyurethane foam-containing medical device could potentially result in exposure of recipients to low levels of the biodegradation products, 2,4- and 2,6-toluenediamine (TDA) over time. In animal studies, 2,4-TDA has been reported to be carcinogenic in rodents, and thus, a quantitative risk assessment of possible exposure to TDA from this novel medical device was undertaken.Based upon a considerable amount of published data related to the degradation of polyurethane-coated breast implants and the *in vivo* disposition of 2,4-TDA, the lifetime average daily exposure to 2,4-TDA from the polyurethane foam used in the current device was estimated to be 7.3x10-7 mg/kg body weight/day. A cancer potency estimate of 0.21 (mg/kg body weight/day)-1 for 2,4-TDA was derived based on a National Cancer Institute carcinogenicity study in rodents, in which it was concluded that 2,4-TDA, but not 2,6-TDA, was carcinogenic in rats and female mice. The resulting upper limit of risk was calculated to be 1.5x10-7, representing a theoretical lifetime risk (over 35 years) of 1.5 in 10 million for developing cancer from exposure to 2,4-TDA released from the polyurethane foam. Based upon this assessment, and the application of a number of conservative assumptions, it is concluded that the theoretical risk of developing cancer from exposure to 2,4-TDA, potentially released from polyurethane foam used in the medical device, is negligible. Furthermore, in humans industrially exposed to 2,4-TDA, there has been no evidence of an increased incidence of cancer.

507 ASSESSMENT OF RISK FROM DIOXIN IN TAMPONS.

L. W. Schroeder and T. H. Umbreit. *Center for Devices and Radiological Health, USFDA, Rockville, MD.*

We have examined claims originating on the Internet about potential harm from dioxin in tampons that have aroused concern in Congress. We have examined the potential for the processes used in the manufacture of tampons to generate dioxins and the available published analyses of dioxins in tampons. We have developed a likely exposure scenario based on typical useage patterns, and determined likely exposure levels. We compared these values to average daily doses and body burdens present in the US population. Tampons are made by mechanical means from rayon or cotton fibers. Cotton is bleached with hydrogen peroxide (or less commonly, with peracetic acid) and dioxins are not formed by this chlorine free process. Rayon is made from cellulose derived primarily from wood pulp which must be bleached to remove lignin. Chlorine gas bleaching generates a small amount of chlorinated dioxins; elemental chlorine free (ECF) bleaching can theoretically generate a very small amount of dioxin, but this amount is below the detection limit of current assay methods; totally chlorine free (TCF) bleaching generates no dioxins. Currently, ECF or TCF is used for all rayon in tampons sold in the US. Actual analyses in the literature report no TCDD (2,3,7,8-tetrachlorodibenzo-p-dioxin, the most toxic of the dioxin isomers) in tampons and very little TEQ (toxic equivalents, used to account for the relative toxicity of a mixture of dioxin isomers). Tampons are used ca. 4 days a month, and may be changed as often as every two hours. We calculate an average of 288 per year for 35 years or a lifetime usage of 10,080 tampons. Although both the theoretical assessment and actual measurements indicate that no TCDD is present in ECF or TCF bleached tampons, we assume as a worst case a dioxin (TEQ) content 2 times the maximum from actual measurements. We calculate that if dioxin were present at this amount, tampons would contribute, at a maximum, 3 thousandths of the average body burden and daily dose of dioxin found in the general US female population.

508 RISK ASSESSMENT-BASED APPROACH FOR THE BIOLOGICAL EVALUATION OF MEDICAL DEVICE MATERIALS.

M. E. Stratmeyer and R. P. Brown. *CDRH/FDA, Rockville, MD.* Sponsor: P. L. Goering.

Systemic toxicity tests of medical device materials are usually conducted using an extract obtained from the material. The use of relatively dilute extracts limits the ability of these tests to detect all but the most overt signs of toxicity. Further, these tests are often conducted with little or no knowledge of the chemical composition of the extract obtained from the device. As a result, it is not possible to anticipate the toxic effects that may be produced following exposure to the medical device material. To address these needs, a risk assessment-based approach has been developed to assess the potential for a medical device material to produce adverse systemic effects. The hallmarks of this approach are: 1) chemical characterization of the device, 2) estimation of the dose of each chemical constituent received by a patient, 3) derivation of a Tolerable Intake (TI) value for each constituent, and 4) comparison of the dose of each compound received by a patient to it's TI. While this proposed approach has not yet been formally accepted in CDRH as an alternative to systemic toxicity testing, it shows promise as a means to provide relevant data for regulatory decision making and should reduce the number of animals required for premarket testing. Further, this proposed approach is consistent with a number of regulatory initiatives currently underway in the FDA, including the use of knowledge bases and consensus standards for the biological evaluation of medical devices.

509 ESTIMATION OF MARGINS OF EXPOSURE: A PRELIMINARY RISK ASSESSMENT FOR OCTAMETHYLCYCLOTETRASILOXANE (D4) BASED ON REPRODUCTIVE TOXICITY STUDIES IN SPRAGUE DAWLEY RATS.

A. M. Shipp[1], C. Van Landingham[1] and R. Meeks[2]. [1]*The K S Crump Group, Inc., Ruston, LA and* [2]*Dow Corning Corporation, Midland, MI.*

The results for several endpoints evaluated in a reproductive toxicity study in which female Sprague-Dawley rats were exposed to D4 by whole body inhalation were selected for dose-response modeling using the Benchmark Dose (BMD) approach. Margins of Exposure (MOE), which are the ratio of the lowest lower bound on the BMD (BMDL) to the estimated intakes of D4, were calculated. Intake estimates were based on the exposure assessment conducted by Everest Consulting Assocates and differed only in the use of a more recently derived human dermal absorption value. These receptors included: 1) workers in the D4 manufacture, formulation of D4-containing products, or in the use of these products in professional settings; 2) consumers who use these personal care products; 3) consumers who may be exposed to silicone antifoams used in food processing; and 4) the general public living in the vicinity of a plant that produces or processes these materials. All MOEs calculated for the selected receptors were greater than 100 and with few exceptions were greater than 1000. When the impact of scientifically based assumptions regarding dermal absorption and route equivalence was considered, all MOEs for consumer use products were greater than 1000 and for many products, greater than 10,000. MOEs of even greater magnitude are expected when the species extrapolation uses the delivered dose at the target tissue rather than estimates of intake. MOEs may be further increased when the species- and strain-specific modes of action can be considered. (This work was supported in part by the Silicones Environmental Health and Safety Council.)

510 USE OF PBPK/PD MODELS AND FOLIAR TRANSFER COEFFICIENTS IN ASSESSING REENTRY INTO PESTICIDE TREATED CITRUS AND TURF.

J. B. Knaak[1], C. C. Dary[2], G. T. Patterson[3] and J. N. Blancato[2]. [1]*State University of New York at Buffalo, Buffalo, NY,* [2]*USEPA, Human Exposure and Atmospheric Sciences Division, Las Vegas, NV and* [3]*Medical Toxicology Branch, California Department of Pesticide Regulation, Sacramento, CA.*

Physiologically-based pharmacokinetic and pharmacodynamic (PB-PK/PD) models describing the fate of dermally applied 14C-ring labeled ethyl parathion and isofenphos and inhibition of B-esterases (acetylcholin-, butyrylcholin- and carboxyl-) by oxons in the rat were used in conjunction with foliar transfer coefficients to assess reentry levels/intervals into treated citrus (parathion) and turf (isofenphos) to harvest fruit or for recreational use, respectively. Michaelis-Menten kinetics were used to describe the desulfuration of parathion and isofenphos to their oxons and hydrolysis of parent chem-

icals and oxons. Bimolecular rate constants, ki (pM-1 hr-1) were used to describe inhibition. Rates for enzyme synthesis, reactivation and aging were considered. A foliar transfer coefficient (slope of the regression line relating exposure in µg/h and foliar dislodgeable residue in µg/cm2, two-sided residue) of 10000 cm2/h was used in both models. According to the PBPK/PD models, 3% of the parathion and isofenphos foliar residues transferred to human skin were dermally absorbed over an 8 h work day in citrus or 2 h on turf. Exposure to foliar residues of 0.09 µg/cm2 (two-sided leaf residue) of parathion on citrus and 0.6 µg/cm2 (two-sided leaf residue) of isofenphos on turf resulted in no red blood cell cholinesterase inhibition. On the basis of ChE NOELs of 0.05 mg/kg/day for parathion and isofenphos in chronic studies, margin of exposures (MOEs) of 16 and 10, respectively, were calculated.

511 A PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL FOR METHYL *TERT*-BUTYL ETHER IN HUMANS.

A. S. C. Licata[1], W. Dekant[2] and S. J. Borghoff[3]. [1]*Biomathematics Graduate Program, Research Triangle Park, NC,* [2]*University of Wurzburg, Wurzburg, Germany and* [3]*Chemical Industry Institute of Toxicolgy, Research Triangle Park, NC.*

The gasoline oxygenate methyl *tert*-butyl ether (MTBE) is the most frequently used additive to reduce carbon monoxide in automobile emissions. To evaluate recent concern that MTBE poses a health hazard to humans, pharmacokinetic information is needed. The objective of this study was to verify the ability of a physiologically based pharmacokinetic (PBPK) model to predict MTBE blood levels in humans following inhalation exposure. The model structure for MTBE was flow-limited and had 6 essential compartments: lung, liver, rapidly perfused tissues, slowly perfused tissues, fat, and kidney. In this model, metabolism occurred in the liver and followed Michaelis-Menten kinetics. The PBPK model used ordinary differential equations to explain the change in the amount of MTBE over time. The physiological and anatomical parameters were obtained from the literature. MTBE-specific parameter values such as partition coefficients for kidney and fat were experimentally measured in human tissue. The human MTBE blood:air partition coefficient was obtained from the literature. Metabolic rate constants were measured *in vitro* in human liver microsomes from 10 subjects and extrapolated to *in vivo* whole-body metabolism based on microsomal protein content, body weight, and liver weight as a percentage of body weight. This PBPK model was analyzed using MATLAB® and Simulink® software packages. Model simulations were compared with data on blood concentrations of MTBE taken from 6 individuals after a 4-hour inhalation exposure to 4 or 40 ppm MTBE. The PBPK model accurately predicted MTBE pharmacokinetics at the high MTBE exposure levels for all time points. However, the model underpredicted early time points while adequately predicting later time points at the low MTBE exposure level. The ability of this model to predict blood levels of MTBE given an external MTBE exposure concentration is important in determining dose estimates for risk assessment.

512 THE KINETIC-DYNAMIC RELATIONSHIP OF THE EFFECT OF REPEATED GLYCYRRHIZIC ACID EXPOSURE ON THE URINARY CORTISOL-CORTISONE RATIO IN HUMANS.

J. DeJongh[1], T. T. Mensinga[2] and B. A. Ploeger[3]. [1]*LAP&P Consultants, Leiden, Netherlands,* [2]*National Institute of Public Health and the Environment, Bilthoven, Netherlands and* [3]*RITOX, Utrecht University, Utrecht, Netherlands.* Sponsor: M. vandenBerg.

Glycyrrhizic acid (GD) is widely applied as a sweetener in food products and chewing tobacco and is also used clinically for treatment of chronic hepatitis. In some highly exposed subgroups of the population, side effects like hypertension and electrolyte disturbances have been reported. These clinical effects originate in the inhibition of 11-beta-hydroxysteroid dehydrogenase (HSD) by the main metabolite of GD, glycyrrhetic acid (GA). This renal enzyme converts the mineralcorticoid cortisol into the inactive compound cortisone. Long term elevation of renal cortisol induces symptoms of an apparent mineralocorticoid excess. For the health risk assessment of GD exposure, the toxicokinetic–dynamic relationship of GD was studied. An assay was developed for quantification of *in vivo* HSD inhibition by determining the ratio between cumulative urinary cortisol-cortisone levels in 24 hour urine samples. In a pilot study, in which two healthy volunteers consumed an aqueous suspension of 130 mg GA once daily for three days, a dose dependent increase of this ratio was found. The ratio returned to its basal level within 3 days after the GA exposure was stopped. The determined onset of the effect of GA on the urinary cortisol-cortisone ratio is consistent with the results of other clinical studies on this effect. Using both datasets, a relationship was found between the area under the GA plasma concentration-time curve, as forecasted by a previously reported human GA PBPK model, and the absolute change in the urinary cortisol-cortisone ratio. The PBPK/PD model shows that especially in people having a prolonged gastrointestinal residence time, the urinary cortisol-cortisone ratio will rise rapidly after daily liquorice consumption, indicating that this subgroup has a higher potential of developing liquorice induced hypertension.

513 DEVELOPMENT OF A PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PB-PK) MODEL AND HUMAN HEALTH RISK ASSESSMENT FOR COUMARIN.

H. J. Clewell[1], P. R. Gentry[1], J. M. Gearhart[2], S. L. Born[2], L. D. Lehman-McKeeman[2] and T. R. Covington[1]. [1]*KS Crump Group/ICF Consulting, Ruston, LA and* [2]*Miami Valley Laboratories, The Procter and Gamble Co., Cincinnati, OH.*

Coumarin, a fragrance ingredient, is a mouse lung and rat liver toxicant. Long-term administration of coumarin has been associated with an increased incidence of lung tumors in B6C3F1 mice in chronic oral gavage studies conducted by the NTP and liver tumors were observed in male Sprague-Dawley rats chronically fed coumarin in the diet. Species differences in the cytochrome P450-mediated metabolism of coumarin are profound, and are integrally linked to the toxicity of this chemical. In humans, coumarin is metabolized primarily to the non-toxic 7-hydroxycoumarin metabolite. In contrast, coumarin 3,4-epoxidation predominates in rodents. To better understand the relationship between coumarin bioactivation, toxicity, and carcinogenicity, a physiologically-based pharmacokinetic model for coumarin has been developed. Simulation of the pharmacokinetics of coumarin associated with administered doses from the animal toxicity and carcinogenicity data was conducted in order to derive dose metrics to identify the most likely metabolite associated with the observations in animals. This model was then extended in order to simulate dose metrics in the human following likely exposure situations. Mode of action of the carcinogenicity of coumarin was also determined, based on integration of the available qualitative and quantitative kinetic and toxicity information. The dose metrics were then used, in conjunction with the most appropriate dose-response model based on the proposed mode of action for coumarin, to conduct a human health risk assessment for coumarin.

514 INVESTIGATION OF THE IMPACT OF BENCHMARK AND PBPK MODELING ON THE DERIVATION OF MRLS.

R. Gentry[1], H. Clewell[1], T. Covington[1] and J. Wilson[2]. [1]*The K S Crump Group, Inc., ICF Consulting, Ruston, LA and* [2]*ATSDR, Atlanta, GA.* Sponsor: H. Mehendale.

This effort investigated the potential impact of physiologically based pharmacokinetic (PBPK) modeling and benchmark dose (BMD) modeling on the derivation of minimal risk levels (MRLs) for 10 chemicals: perchloroethylene, trichloroethylene, vinyl chloride, benzene, 1,1,1-trichloroethane, carbon tetrachloride, toluene, acetone, chromium, and lead. PBPK modeling was also used for route-to-route extrapolations in order to estimate MRLs for which no data appropriate for MRL derivation are currently available, or to compare the MRLs predicted across routes using the PBPK model versus current MRLs. The impact of drinking water patterns was also investigated, by incorporating a human drinking water profile into the PBPK models. There was no clear trend in terms of the direction of the impact of using these techniques; that is, both higher and lower MRLs were obtained. Twelve MRLs were estimated using route-to-route extrapolation for which no MRL currently existed. These included MRLs for perchloroethylene, trichloroethylene, vinyl chloride, benzene, cadmium, 1,1,1-trichloroethane, and toluene. The results of the comparison of predicted MRLs across routes demonstrated that for some chemicals, a more sensitive endpoint for one route of exposure could be used for the estimation of an MRL in place of a less sensitive endpoint by the other route. The incorporation of the drinking water profile had a significant impact on dose metrics that were representative of a peak target tissue concentration, but had relatively little impact on dose metrics that were representative of cumulative exposure. Because of the uncertainty in actual drinking water patterns in humans, deriving MRLs from dose metrics based on such patterns is not recommended at this time.

515 ASIAN & PACIFIC ISLAND SEAFOOD CONSUMPTION STUDY IN KING COUNTY, WASHINGTON.

R. M. Lorenzana[1], C. Nakano[2], S. Truong[3], R. Sechena[2], S. Liao[4], N. L. Polissar[5] and R. Fenske[2]. [1]*USEPA Region 10, Seattle, WA,* [2]*University of Washington, Seattle, WA,* [3]*Refugee Federation Service Center, Seattle, WA,* [4]*StatPro Consultants, Bothell, WA and* [5]*Mountain-Whisper-Light Statistical Consulting, Seattle, WA.* Sponsor: M. Watson.

Described are Asian and Pacific Islander (API) seafood consumption rates, species, and seafood parts commonly consumed and cooking methods. Phase I focused on identifying target ethnic groups and developing an appropriate questionnaire (see Asian and Pacific Islander Seafood Consumption Study, EPA 910/R-96-007, August 1996). Phase II, detailed in this report, was the characterization of seafood consumption patterns of ten API ethnic groups (Cambodian, Chinese, Filipino, Hmong, Japanese, Korean, Laotian, Mien, Samoan, and Vietnamese) within King County, Washington. Participants were first or second generation members, ≥ 18 years of age and were seafood consumers. A survey questionnaire was translated into the respondents' native languages. Surveys were administered by trained bilingual API community members. Phase III was the development of culturally appropriate health messages regarding seafood consumption risks and its dissemination to the API community. The majority of the 202 respondents (89%) were first generation (i.e., born outside the United States). There were slightly more women (53%) than men (47%), and 35% lived under the 1997 Federal Poverty Line. The average overall consumption rate for all seafood combined was 1.891 grams/per kilogram body weight/day (g/kg/day), with a median consumption rate of 1.439 g/kg/day. The predominant seafood consumed was shellfish (46% of all seafood). Seafood consumption based on gender, age, income, and "fishermen" status did not differ significantly.

516 ESTIMATES OF HUMAN EXPOSURE TO PCBS AND ASSOCIATED HEALTH RISKS FROM DIETARY SEAFOOD EXPOSURE.

N. L. Judd[1], D. A. Kalman[1], R. Sechena[1] and K. A. Toy[2]. [1]*University of Washington, Seattle, WA and* [2]*Tulalip Tribes, Marysville, WA.* Sponsor: E. M. Faustman.

PCBs have been detected in all species of fish monitored in the past ten years by the Puget Sound Ambient Monitoring Program. Recent surveys of Native Americans and Asian and Pacific Islanders (API) in the Puget Sound area have demonstrated seafood consumption rates far greater than the 6.5g/day adopted for use in the Clean Water Act. Median consumption rates are 53 to 66g/day for men and 25 to 34 g/day for women in the Tulalip and Squaxin Tribes and 89 g/person/day for API. There is concern about possible health risks from PCB exposure through seafood for these groups, but estimation of exposure is difficult due to inadequacies of environmental and consumption data. Our current study assesses confidence in available seafood PCB data for each species consumed as a percent of total seafood consumption and as a percent of estimated total seafood PCB exposure. A prioritization scheme based on species specificity, data quality, and location compatibility was developed to rate confidence in seafood PCB data. For API, 45.9% of total seafood consumed is shellfish; the geographic source of only 11% of this is known. 72-80% of anadromous fish, which dominate Tribal seafood diets, is harvested in Puget Sound. To explore the value of specific contaminant and consumption data for human health risk assessments, risk assessments based consumption of Puget Sound crab for the API and salmon for the Tribes were performed. These included consideration of cooking and preparation and use of Monte Carlo techniques. Results suggest that while PCB exposure from most seafood consumed by these groups cannot be well characterized, risk estimates based on consumption of species for which comprehensive environmental data exist still contain considerable variability and uncertainty.

517 ART MATERIALS RISK ASSESSMENT FOR DYED PAPER PRODUCTS.

I. S. Chaudhuri and M. Garcia. *ENSR Corporation, Acton, MA.*

A chronic human health risk assessment was conducted on six types of dyed paper products in order to comply with the requirements of the Labelling of Hazardous Art Materials Act (LHAMA; Public Law 100-695). LHAMA requires that certain types of art materials be reviewed to determine the potential for causing a chronic hazard, and that appropriate warning labels be put on those art materials found to pose a chronic hazard. The procedure for evaluating art materials is described in the American Society for Testing and Materials (ASTM D-4236). The first step involved collecting information on the composition of the paper products. Ingredients included pulp and various additives, such as corn starch, titanium dioxide, calcined clay, filter clay, aluminum sulfate, aluminum silicate, biocides, defoamers, dye fixatives, colored pigments and dyes. The suppliers of the additives provided Materials Safety Data Sheets (MSDSs) that listed individual ingredients and provided toxicity information. A list of the potentially most toxic compounds was developed and evaluated in a risk assessment. Two types of exposures were considered in the risk assessment – children using the paper for drawing in classrooms, and adult office workers using the paper for printing and copying. It was assumed that children and adults could be exposed to the paper products through incidental ingestion, dermal contact and inhalation of volatilized chemicals. Using these exposure assumptions and chemical-specific toxicity values, screening concentrations that represented safe levels of exposure were calculated for each of the chemicals. These screening concentrations were then compared to measured or predicted concentrations of these chemicals in the dyed paper products. The predicted concentrations were upper limits on the amount of chemical that could be present in the final paper product. The comparison showed that all of the measured and predicted levels were lower than the screening concentrations. These results showed that the paper products contained no materials in sufficient quantitities to cause health problems, and that no warning labels were required.

518 DEMOGRAPHICS OF CHRONIC DISEASES IN THE UNITED STATES.

J. M. Donohue[1], R. O'Day[2] and J. D. Rench[2]. [1]*USEPA, Washington, DC and* [2]*SRA Technologies, Falls Church, VA.* Sponsor: C. O. Abernathy.

Under the Safe Drinking Water Act amendments of 1996, the US EPA is directed to give increased attention to sensitive human populations. Individuals suffering from chronic diseases are, in some instances, more sensitive to the toxic effects of specific environmental contaminants. Accordingly, the US EPA Office of Water collected background demographic information on the prevalence of 12 chronic conditions in the US population. The National Health Interview Survey, National Health and Nutrition Examination Survey and Centers for Disease Control were the primary sources of this information. The data were compiled by age, gender, race, ethnicity, and geographic area. As expected, the prevalence of chronic diseases differed for children (<11 years) and adults (>20 years). Immunological hypersensitivity, including asthma and allergic disorders, were the leading chronic condition in both children and adults. Cardiovascular disease ranked third for both adults and children whereas hypertension ranked second for adults and fifth for children. Anemia ranked second among children but much lower in adults. The collected data provide useful background information in the risk assessment for any contaminant with an adverse impact on one or more of the populations characterized. (The opinions expressed in this abstract are those of the authors and not necessarily those of US EPA.)

519 ARE CONCENTRATIONS OF ARSENIC IN FILL SOILS AT MARE ISLAND ELEVATED?

V. Prilepin[1], C. Gorman[1], P. Wilson[1], K. Ryan[1], R. Pender[2] and J. Sinats[2]. [1]*Tetra Tech EM Inc., San Francisco, CA and* [2]*Engineering Field Activity West, Naval Facilities Engineering Command, San Bruno, CA.* Sponsor: J. P. Christopher.

Arsenic occurs naturally in soils and has industrial, agricultural, forensic, and medicinal uses. However, arsenic poses a human health risk at low concentrations in soils (0.38 ppm). An initial assessment of metals in soils at Mare Island Naval Shipyard (Vallejo, California) indicated that ambient concentrations of arsenic were 36 ppm in artificial fill and 16 ppm in materials native to the original island. Regulatory agencies were concerned that this disparity was due to Navy operations at Mare Island. To determine the sources of elevated arsenic we 1) re-evaluated the initial arsenic datasets for Mare Island, 2) reviewed the ambient arsenic literature for the Bay Area, and 3) conducted statistical comparison tests. Most of the Mare Island fill is composed of dredged estuarine deposits, so this study compared the fill and the native estuarine material. The initial datasets were expanded and compared statistically using the Wilcoxon Rank Sum (WRS) test. The study concluded that ambient arsenic concentrations in California consistently exceed the EPA's preliminary remediation goal by at least an order of magnitude and high ambient arsenic concentrations characterize much of the natural environment. The WRS test showed that fill and native arsenic concentrations at Mare Island are statistically indistinguishable. Average arsenic concentrations for fill and native data sets are 14.51 and 14.53 ppm, respectively; Z statistic equals 1.81, and double-sided p-value is 0.07. The elevated arsenic on Mare Island is likely a product of natural runoff from arsenic-bearing minerals exposed at the source

region of the Sacramento-San Joaquin and Napa River drainages. The data we present indicate a common origin for the arsenic present in soils at Mare Island and do not suggest that an environmental release due to Navy operations has occurred.

520 DETERMINATION OF ACUTE REFERENCE EXPOSURE LEVELS FOR AIRBORNE TOXICANTS.

G. V. Alexeeff, J. D. Budroe, J. F. Collins, R. H. Lam, D. C. Lewis, M. J. Lipsett and M. A. Marty. *State of California, Oakland, CA.*

We have developed acute inhalation reference exposure levels (RELs) applicable to the general public routinely exposed to hazardous substances released in the environment. The acute REL is an exposure that is not likely to cause adverse effects in a human population, including sensitive subgroups, exposed to that concentration on an intermittent basis. Acute RELs were developed for 51 compounds or classes of compounds, predominantly for one-hour exposures. The adverse effects were categorized as either mild (e.g., eye and respiratory irritation, mild cardiovascular or CNS effects, and immune responses) or severe (e.g., reproductive and developmental effects, hematological effects, and serious CNS effects). 34 of the RELs were based on human data. All acute exposure levels are designed to protect the most sensitive individuals in the population by identifying NOAELs and by inclusion of uncertainty factors (UFs). UFs ranged from 1 to 1000, although most of the UFs were 10 or less. Where the benchmark dose approach was applied, a log dose vs. probit response model identified the 95% LCL concentration expected to produce a 5% increase in toxic response, which was defined as a NOAEL. When the duration of experimental exposure (t) differed from the desired exposure duration, the concentration (C) was adjusted using $C^n \times t = K$, where K is a constant and $1 \leq n \leq 4.6$.

521 A PROPOSAL FOR INCORPORATING ORAL BIOAVAILABILITY IN HUMAN HEALTH RISK ASSESSMENTS.

L. J. Scarano[1], J. M. DeSesso[2] and C. F. Jacobson[2]. [1]*USEPA, Washington, DC and* [2]*Mitretek Systems, McLean, VA.*

Bioavailability is that fraction of the external dose of a substance that is available to contribute to the physiological or toxicological response of the substance. Oral bioavailability, a complex issue that impacts diverse scientific disciplines, can be conceptualized as three processes: (1) bioaccessibility (the fraction of the dose that is available for absorption), (2) absorption, and (3) distribution/metabolism. Once the substance reaches the target organ, toxicodynamic processes dominate. For each process, knowledge gained from experiments or literature searches can be used to modify the dose or exposure estimate (bioaccessibility) and/or the interspecies uncertainty factor (absorption, distribution/metabolism, toxicodynamics) normally used in non-cancer risk assessments. The accepted default value of the interspecies uncertainty factor is 10. Based on the literature examining bioavailability and uncertainty factors, we suggest that the interspecies uncertainty factor comprises three components: absorption (1.0 - 2.24), distribution/metabolism (1.0 - 2.24), and species sensitivity (1.0 - 2.0). The product of the maxima of these components is 10. When good-quality data exist for any component, they should be used in the risk assessment, and the numerical value of the corresponding uncertainty factor component can be reduced. Incorporating bioavailability data will likely have a small impact on the numerical outcome of risk assessments, but the confidence in the output will be strengthened because scientifically defensible values rather than default assumptions were used. (This presentation is an extension of a U.S. EPA, Office of Water project funded through the ILSI Risk Science Institute. These views do not reflect the policy or opinions of the USEPA or the Risk Science Institute.)

522 CHEMICAL POLLUTANTS PRESENT IN YOUNG BODY, RISK FOR CANCER DISEASE.

C. Hura, M. Leanca and B. A. Hura. *Institute of Public Health, Iassy, Romania, Romania.*

The authors present the research results obtained in 1998-1999 period of some chemical pollutants with risk for cancer disease [nitrates/nitrites, pesticide residues, metals] in human body, in relation with these chemical pollutants from foods [vegetables, meat, fish, milk, bread] and in total diets from Iassy, Bacau and Botosani districts. The investigation were carried on urine samples from 120 children (2-16 years old) and 120 young (17-20 years old) which living in Iassy, Bacau and Botosani districts. The pesticide residues in urine and foods were analyzed by gas-chromatographic method, nitrates/nitrites were analyzed by colorimetric method and metals by atomic absorbtion spectrophotometric method. In all analyzed samples these chemical pollutants were found. The mean levels of organochlorine pesticide residues in urine varied between 0.57μg/l (3-5 years old) and 0.92 μg/l (6-10 years old). The mean levels of nitrite in urine varied between 0.72 mg/l (3-5 years old) and 1.2 mg/l (11-16 years old). The mean levels of zinc in urine varied between 0.7 μg/l (11-16 years old) and 1.51 μg/l (6-10 years old). The mean levels of copper in urine varied between 0.08 μg/l (3-5 years old) and 0.34 μg/l (11-16 years old). We haven't found correlation between the levels of these chemical pollutants present in urine with the levels of foods used in these districts. Determination of these pollutants in young body are important in clinical routine analysis and environmental monitoring for the prevention, control and reduction of pollution as well as for occupational health and epidemiology.

523 CHARACTERIZATION OF FURAN-MEDIATED APOPTOTIC AND NECROTIC CELL DEATH IN ISOLATED RAT HEPATOCYTES.

S. A. Ploch, T. Melhuish, V. Wong and G. L. Kedderis. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Furan is a nonmutagenic, hepatotoxic compound that induces hepatocellular carcinomas in rats and mice through mechanisms involving cell death and proliferation. Previous studies in our laboratory have shown that exposure of isolated F-344 rat hepatocytes to furan produced concentration- and time-dependent increases in endonuclease-mediated DNA double-strand breaks (dsbs) prior to cell death. To characterize the role of apoptosis in cell death, F-344 rat hepatocytes were treated with 100 μM furan or 50 μg/ml cycloheximide for 4 hr in suspension and analyzed for evidence of apoptotic and necrotic cell death using flow cytometry (Annexin V binding/propidium iodide staining) and with morphological techniques (Hoechst staining). While cycloheximide produced a 3-fold increase in apoptosis over controls (6 ± 3% vs. 18 ± 2%) at the four hr time period, 100 μM furan did not cause a significant increase in apoptosis or necrosis, despite causing a significant increase in DNA dsbs. After 24 hr culture of furan exposed cells, predominantly necrotic cell death with some apoptosis was observed with 100 μM furan, while 10 μM furan did not produce these effects. These data are consistent with *in vivo* studies in mice demonstrating that necrosis is the predominant mode of cell death induced by furan. The dose-dependence of these effects in isolated hepatocytes is consistent with prior data showing DNA dsbs induced by low concentrations of furan (10 μM) were repaired after 24 hr in culture. Erroneous repair of DNA dsbs may be involved in the induction of mutations leading to furan-induced liver cancer.

524 PROTECTIVE EFFECTS OF D-TAGATOSE AND D-FRUCTOSE AGAINST CYCLOSPORINE A-INDUCED APOPTOSIS IN RAT HEPATOCYTES.

S. Grub[1], U. A. Boelsterli[2], W. E. Trommer[1] and A. Wolf[3]. [1]*Novartis Pharma AG, Experimental Toxicology, Basel, Switzerland,* [2]*F. Hoffmann-La Roche Pharma AG, Nonclinical Drug Safety, Basel, Switzerland and* [3]*University of Kaiserslautern, Kaiserslautern, Germany.*

Lipid peroxidation, a general cytotoxicity mechanism of many xenobiotics is dependent on the presence of catalytic amounts of iron ions. Since cyclosporine A (CsA) induces an oxidative stress in rat hepatocytes, it was the purpose of the present study to investigate the role of iron-mediated lipid peroxidation in the cell damaging process by means of potential cytoprotective ketohexose- and desferrioxamine-type iron chelators. Rat hepatocytes were cultured for 4 and 20 hours with 0, 10, 25 and 50 μM CsA in the absence or presence of 4 mM D-tagatose, D-fructose, D-glucose or 5 mM desferrioxamine. Whereas the ketohexoses D-tagatose and D-fructose significantly attenuated CsA-induced LDH release, as well as inhibited caspase-3 activation and chromatin condensation and fragmentation, the aldohexose D-glucose did not have any inhibitory effect. The iron chelator desferrioxamine did not protect against CsA-induced LDH release and apoptosis. These data indicate that iron catalyzed lipid peroxidation is not directly involved in the cyclosporine cytotoxicity and apoptosis, and that the cytoprotective and anti-apoptotic effect of the ketohexoses are probably mediated by inhibition of caspase-3.

525 ENHANCED PANLOBULAR HEPATOTOXICITY TO ACETAMINOPHEN IN BCL-2 OVEREXPRESSING TRANSGENIC MICE.

M. L. Adams[1], R. H. Pierce[2], N. Fausto[3], S. D. Nelson[1] and S. A. Bruschi[1]. [1]*Department of Medicinal Chemistry, University of Washington, Seattle, WA,* [2]*Department of Pathology, Wright-Patterson Medical Center, Wright-Patterson AFB, OH and* [3]*Department of Pathology, University of Washington, Seattle, WA.*

The mitochondria play an important role in apoptosis and drug-induced cell death. Previously, we have shown that acetaminophen (APAP)-mediated hepatotoxicity and cell death is associated with translocation to mitochondria of the BCL-2 family member, BAX. Mitochondrial translocation of BAX is consistent with its proapoptotic role initiating collapse of the mitochondrial inner membrane potential. Based on the antiapoptotic characteristics of the intracellular regulator protein BCL-2, we hypothesized that BCL-2 overexpression in transgenic mice would be hepatoprotective. Mice with a human BCL-2 transgene (-/+) and wild type (WT: -/-) were dosed with 500 mg/kg (ip) APAP or N-acetyl-m-aminophenol (AMAP). Early pathological evidence for APAP-induced zone 3 necrosis was seen at 6 hours in BCL-2 (-/+) mice while AMAP-treated BCL-2 (-/+) mice showed only microvesicular steatosis without progression to extensive necrosis. By 24 hours, APAP-treated BLC-2 (-/+) mice demonstrated severe panlobular necrosis with hemorrhagic infiltration. In contrast, WT mice dosed with APAP showed characteristic centrilobular necrosis. AMAP-treated BCL-2 (-/+) mice demonstrated only scattered necro-inflammatory foci. The evaluation of plasma transaminase activities was also consistent with the enhanced hepatotoxicity of APAP in BCL-2 (-/+) animals. To further evaluate the role of mitochondria in APAP-mediated hepatotoxicity, Complex III activity was assessed. In BCL-2 (-/+) mice only APAP led to decreased Complex III activity which correlated strongly with plasma enzyme activities. The specificity of the correlation between Complex III and hepatic damage is being examined. In conclusion, BCL-2 overexpression unexpectedly enhances APAP-associated hepatotoxicity in mice but has no effect on the toxicity of AMAP. (Supported by NIH grants #GM25418 to SDN, #GM51916 to SAB, NIEHS Center Grant P30-ES07033, and #CA74131 to NF.) The views expressed in this article are those of the author(s) and do not reflect the official policy or position of the United States Air Force, Department of Defense, or the US Government.

526 THE ROLE OF APOPTOSIS IN PHENOBARBITAL MODULATION OF COCAINE-INDUCED LIVER DAMAGE.

D. J. Price[1], C. A. Muro-Cacho[2] and R. D. Harbison[1]. [1]*Department of Environmental and Occupational Health, College of Public Health, Tampa, FL and* [2]*Department of Pathology, College of Medicine, University of South Florida, Tampa, FL.*

Liver damage, following cocaine administration, has been generally attributed to necrosis. The purpose of this study was to evaluate a possible apoptotic component in cocaine hepatotoxicity. Male ICR mice were either pretreated with phenobarbital (80 mg/kg, i.p.) for three days and subsequently administered cocaine (60 mg/kg, i.p.), or treated with cocaine (60 mg/kg, i.p.) alone. Blood and liver were harvested at 0.5, 1, 2, 4, 6, 12, 24, 48, 72 hours and 7 days following cocaine treatment. Serum alanine aminotransferase activity was used to verify hepatotoxicity and liver tissue from treated and control mice was analyzed to determine amount and area of apoptosis. The histopathological evaluation of cocaine-induced damage revealed patterns of necrosis similar to those reported in previous studies. However, using the TUNEL method, apoptotic cells were observed in the same hepatic compartments in which necrosis was identified. Thus, in mice treated with cocaine alone apoptosis was observed in midzonal and centrilobular regions, while in mice treated with cocaine following phenobarbital pretreatment, apoptosis was observed exclusively in midzonal and periportal areas. Treatment with phenobarbital protected the centrilobular region from both apoptosis and necrosis. Also, histopathological evaluation suggested that cocaine altered the normal trafficking pattern of hepatocytes. Thus, hyperplastic hepatocytes, originating in midzonal regions, appeared to migrate to adjacent regions where significant cell loss had occurred. Together these results indicate that apoptosis contributes significantly to cocaine-induced liver damage, that hepatocyte traffic may play an important role in restoring liver function, and that phenobarbital treatment may alter the type, the intensity and the course of cocaine-induced hepatic injury. (Supported in part by NIOSH Grant 412874-03.)

527 EFFECTS OF GALACTOSAMINE AND TNF-α ON CASPASE-MEDIATED APOPTOSIS IN ISOLATED RAT HEPATOCYTES.

T. K. Baker and M. A. Carfagna. *Eli Lilly and Company, Greenfield, IN.*

Release of tumor necrosis factor (TNFα) alpha following lipopolysaccharide treatment has been shown to induce apoptosis in galactosamine (GalN)- sensitized mice leading to hepatic failure. GalN's ability to inhibit mRNA and protein synthesis sensitizes hepatocytes to the apoptotic process by depleting uridine. The objective of this study was to evaluate the role of caspases 3 and 8 in cell killing by GalN and TNFα alone and in combination. Primary isolated F344 rat hepatocytes were pretreated with varying amounts of GalN (0.5 - 7.5 mM) for 30 minutes followed by 40 ng/mL TNFα treatment. TNFα and/or GalN treatment was given for 4, 24 or 48 hours. Endpoints evaluated were caspases 3 and 8 activity along with LDH leakage. Rat hepatocytes sensitized with GalN displayed increased caspase 3 activity 24 hours after treatment with 40 ng/mL TNFα. TNFα alone had no effect on caspase 3 activity. N-acetyl cysteine (NAC) treatment enhanced the activity of caspase 3 in GalN sensitized hepatocytes following 24 hour 40 ng/mL TNFα treatment. Caspase 8 activity was unaffected by GalN and TNFα treatment. Caspase 3 activity was elevated following 48 hours of treatment with GalN alone. This study suggests that GalN sensitized TNFα treated hepatocytes undergo apoptosis through a caspase 3 mediated pathway that does not appear to involve caspase 8 activation. Treatment with NAC potentiated the caspase 3 activity. These data are in contrast to effects seen in monocytic cell lines where NAC offers protection against apoptosis via its anti-oxidant properties. In addition, previous studies with actinomycin-sensitized hepatocytes have described an apoptotic pathway that includes caspase 8 activation.

528 EFFECT OF P53 STATUS ON 7H-DIBENZO[C,G]CARBAZOLE-INDUCED APOPTOSIS AND CLONOGENIC SURVIVAL.

T. J. O'Brien, J. R. Schneider, K. R. Mitchell and D. Warshawsky. *University of Cincinnati Medical Center, Cincinnati, OH.*

7H-Dibenzo[c,g]carbazole (DBC) is a potent hepatotoxin and liver carcinogen in rodents following various routes of exposure. While p53 mutations have been observed in DBC-induced murine liver tumors, the biological consequences of these mutations are unknown. The aim of this study was to determine the effects of p53 status on DBC-induced apoptosis and cell survival, *in vitro*. Hepatoma cells harboring point mutations in the p53 gene (HLF, Mahlavu) were markedly resistant to DBC-induced apoptosis relative to wild-type cells (HepG2) measured by DNA laddering, DNA content and TUNEL analyses. In contrast, colorectal carcinoma cells (RKO) overexpressing the HPV16 E6 protein underwent p53-independent apoptosis following exposure to DBC. In the HLF, Mahlavu and RKO-E6 cells, significant increases in clonogenic survival were measured following exposure to DBC. Additional factors were examined that could contribute to the marked differences observed in the hepatoma cell lines. There were no differences in 14C-DBC uptake or ROS generation by DBC in any of the cell lines. However, high concentrations of DBC (80 microM) were found to maximally deplete intracellular ATP levels within 6 hours in HepG2 cells (<50% of controls) en route to membrane leakage and necrosis. HPLC analysis of 14C-DBC-exposed cultures revealed the greatest quantity of DBC species detected in HepG2 cells suggesting that differential metabolism may be a contributing factor. While these results suggest that the role of p53 in DBC-induced apoptosis is cell type specific, the clonogenic survival following DBC exposure is dependent upon p53 status.

529 SUPPRESSION BY ZINC OF DOXORUBICIN-INDUCED APOPTOSIS: INHIBITION OF CASPASE-3 ACTIVATION.

J. C. Lambert, G. W. Wang and Y. J. Kang. *University of Louisville, Louisville, KY.*

The prevention of apoptosis by zinc has been observed in several cultured cell systems. The anti-apoptotic action has generally been attributed to its effects on late events of caspase-3-mediated apoptotic pathway, including inhibition of caspase-3 action and endonuclease activities. In this study we investigated the effect of zinc on activation of caspase-3 by doxorubicin, an effective anti-cancer agent, in HeLa cells. Cultured cells were treated with ZnC_{l2} prior to exposure to one μM doxorubicin for 12 hrs. DOX caused massive apoptosis and zinc significantly inhibited the apoptotic effect as determined by TUNEL assay and Annexin V-FITC staining. Examination by a laser confocal microscope using an antibody against the active form of caspase-3 revealed that zinc dramatically diminished DOX-activated caspase-3 activities. The effect of zinc on the processing of pro-caspase-3 by DOX was then examined by

Western blot. This process was also significantly inhibited by zinc. The results obtained from this study thus demonstrates that zinc specifically inhibits caspase-3 activation, suggesting its anti-apoptotic effect is mediated by multiple actions on the mitochondrion-controled apoptotic pathway. (Supported in part by NIH grants CA68125 and HL59225.)

530 DOXORUBICIN-INDUCED HEPATOTOXICITY MAY INVOLVE APOPTOTIC CELL DEATH BY MODULATING EXPRESSION OF BCL-XL AND P53.

S. D. Ray[1], G. Balasubramanian[2], W. N. Ratna[1], R. R. Raje[1], V. R. Reid[1], C. S. Reddy[3] and D. Bagchi[1]. [1]*Div. of Pharmacology & Toxicology, Long Island University, Brooklyn, NY.* [2]*Div. of Vet. Biomedical Sciences, University of Missouri, Columbia, MO and* [3]*Creighton University College of Pharmacy & Allied Health Professions, Omaha, NE.*

The cytotoxic effect of Doxorubicin (DOX) on malignant cells and its toxic effects on various target organs such as liver, heart, and kidney are well known. This study examined the potential of DOX to induce or enhance apoptotic cell death, and to influence the expression of apoptosis-regulatory genes such as bcl-XL and p53 in the liver. Male ICR mice, fed ad libitum, were treated ip with single doses of DOX (20, 40, 60, 80 and 120 mg/kg) and sacrificed 36 hours later. Blood was collected for analysis of serum chemistry, and liver samples for histopathology and Western blot analysis. DOX produced liver injury (>ALT levels) and DNA fragmentation in a dose-dependent manner. Higher doses of DOX (80 and 120 mg/kg) were lethal to mice. Lower doses (0, 20, 40, 60 mg/kg) inhibited bcl-XL expression in a dose-dependent manner (nearly blocking it at 40 and 60 mg/kg), and increased apoptotic death, whereas the same doses of DOX enhanced p53 gene expression. Although p53 is known to induce either cell cycle arrest or apoptosis, these findings suggest that p53 facilitates apoptotic death. (Supported by Div. of Pharmacol. & Toxicol., AMS Coll. of Pharm. & Hlth. Scs.)

531 OXIDATIVE STRESS IN KERATINOCYTES: ROLE IN APOPTOTIC SIGNALING.

V. E. Kagan[1], Y. Y. Tyurina[1], V. A. Tyurin[1], K. Kawai[1], J. P. Fabisiak[1], C. Kommineni[2], V. Castranova[3] and A. A. Shvedova[2]. [1]*Dept. of EOH & Pharmacology, University of Pittsburgh, Pittsburgh, PA and* [2]*HELD/NIOSH, Morgantown, WV.*

We studied the mechanism(s) through which oxidative stress participates in apoptotic signaling in keratinocytes. We exposed normal human keratinocytes (NHEKs) to cumene hydroperoxide (Cu-OOH, 50-200μM) for 1 h and found significant and dose-dependent depletion of antioxidant reserves, oxidation of GSH and protein sulfhydryls. We metabolically labeled membrane phospholipids in NHEKs with oxidation-sensitive cis-parinaric acid (PnA) to detect selective oxidation of specific phospholipid classes. We found that incubation of NHEKs with Cu-OOH resulted in dose-dependent oxidation of PnA-phospholipids: phosphatidylinositol (PI), phosphatidylserine (PS), phosphatidylethanolamine (PE) and phosphatidylcholine (PC). Most importantly, PS was significantly more sensitive to Cu-OOH oxidation than other phospholipids. This selective oxidation of PS did not occur in liposomes prepared from PnA-labeled keratinocytes phospholipids. Exposure to Cu-OOH induced externalization of PS in NHEKs, as evidenced by its chemical labeling with fluorescamine. These oxidative modifications of NHEK phospholipids were not accompanied by gross changes of the phospholipid composition as evidenced by our HPTLC determinations. Together with other assays of apoptosis (caspase-3 activation and DNA laddering), our results suggest that Cu-OOH-induced selective PS oxidation may represent a signaling pathway linked to PS externalization in keratinocytes undergoing apoptosis.

532 ENHANCED GLUTATHIONE BIOSYNTHESIS RETARDS APOPTOSIS IN SPITE OF CASPASE-3 ACTIVATION IN HEPA-1 CELLS OVEREXPRESSING GLUTAMATE-CYSTEINE LIGASE.

D. Botta, C. C. White, C. M. Krejsa and T. J. Kavanagh. *University of Washington, Seattle, WA.*

Glutathione is a major antioxidant that is responsible for maintaining thiol redox potential. Glutamate-Cysteine Ligase (GLCL) is the rate limiting enzyme in glutathione biosynthesis. Increased glutathione has been implicated in the resistance of certain cell types to apoptotic stimuli. We have stably transfected mouse liver Hepa-1 cells (CR17) which overexpress both the catalytic (GLCLc) and regulatory (GLCLr) subunits of GLCL, to test the hypothesis that increased glutathione synthesis is important in preventing apoptosis. Previously we have shown that CR17 cells when treated with TNF plus actinomycin D conserve their glutathione levels, NADPH levels and mitochondrial membrane potential, whereas plasmid vector alone transfectants (Hepa-V cells) did not. Caspase-3 is activated in both Hepa-V and CR17 cells with TNF+ActD treatment at 12 hrs. Western blot analysis shows substantial cleavage of GLCLc in Hepa-V cells, whereas only minimal cleavage of GLCLc was seen in CR17 cells at 22 hr. The increased glutathione biosynthesis capacity of CR17 cells not only allows them to resist TNF+ActD induced glutathione depletion, but may also inhibit apoptotic events secondary to caspase-3 activation. (This work was supported by NIH Grants ES04696, ES07033 and ES07032.)

533 COMPARATIVE *IN VITRO* STUDIES OF CADMIUM AND ARSENIC-INDUCED APOPTOSIS IN RENAL TUBULE EPITHELIAL CELLS.

B. A. Fowler, K. S. Squibb, M. Akkerman and E. Madden. *Program in Toxicology, University of Maryland, Baltimore, MD.*

Cadmium and arsenic are nephrotoxic elements which frequently occur together in Superfund sites. The mechanism(s) by which these elements produce cell death are not completely understood. The present studies were undertaken to examine differences in the inter-species induction of apoptosis in renal tubule epithelial cells from rats, hamsters and humans following *in vitro* exposures to Cd^{2+} or As^{3+} over concentration ranges between 10-7M to 10-4M. The TUNEL assay was utilized to examine the induction of apoptosis in relation to cell injury as monitored by changes in ALAMAR Blue fluorescence. Results of these studies indicated that both elements were capable of producing apoptosis in cells from all 3 species but that the cellular mechanisms appear different for Cd^{2+} and As^{3+} since there were marked morphological response differences for each element. Arsenic (As^{3+}) exposure also produced necrosis in some cells so that both necrosis and apoptosis mechanisms were operating. The results of the ALAMAR Blue assay showed a dose-related decreases in cell metabolism following both cadmium and arsenic exposure. Overall the results of these studies indicate that renal tubule epithelial cells from all 3 species are susceptible in a similar manner to apoptosis induced by Cd^{2+} and As^{3+} exposure. It is hypothesized that the As^{3+} is operating via mitochondrial apoptotic inducing factors while the mechanism for cadmium is presently unclear. (Supported by USEPA STAR Grant ER 827161-01-0.)

534 ACROLEIN ENHANCES MECHLORETHAMINE-INDUCED APOPTOSIS.

J. C. Kern and J. P. Kehrer. *The University of Texas at Austin, Austin, TX.*

Acrolein, a highly electrophilic α,β-unsaturated aldehyde is, along with phosphoramide mustard, a metabolic product of cyclophosphamide (CP). Although acrolein is generally considered to be a toxic metabolite, at low concentrations it may enhance the activity of CP by sensitizing cells to apoptosis. To test this theory, B lymphocytic FL5.12 cells were incubated for 0.5 h with 2.5 μM acrolein followed by 150 or 250 nM mechlorethamine. Acrolein depleted GSH by ~80% at 0.5 h. Apoptosis was morphologically distinguished from necrosis by the acridine orange/ethidium bromide assay. At 24 h post-treatment, acrolein alone caused 15% apoptosis and 6% necrosis, whereas mechlorethamine alone caused 23 and 33% apoptosis and 5 and 2% necrosis at 150 and 250 nM, respectively. When acrolein and 150 nM mechlorethamine were combined there was 44% apoptosis and 4% necrosis. Acrolein with 250 nM mechlorethamine caused 60% apoptosis and 5% necrosis. Enhanced apoptosis was more evident using an ELISA to assess nucleosomes in the cytoplasm. To test the possibility this sensitization effect was working through GSH depletion, FL5.12 cells were treated with 1 mM diethyl maleate (DEM) (lowering GSH by ~70%). Surprisingly, DEM alone caused a significant amount of necrosis, making it impossible to assess the effect of co-treatment with mechlorethamine. These data demonstrate that acrolein enhances apoptosis induced by subsequent treatment with an alklyating agent. At comparable levels of GSH depletion, the effects of acrolein and DEM differ suggesting mechanistic differences. The ability of acrolein to inhibit NF-κB activation at 4 h may be a factor in the observed apoptosis. (Supported by HL48035, ES09791 and ES07784.)

535 DIFFERENTIAL VINCRISTINE-INDUCED ENGAGEMENT OF APOPTOSIS IN DRUG RESISTANT AND SENSITIVE LYMPHOMA CELL LINES.

K. A. O'Brien and S. E. Bloom. *Department of Microboilogy & Immunology, Cornell University, Ithaca, NY.* Sponsor: R. R. Dietert.

Resistance of cancer cells to chemotherapeutic drug treatments can involve several different mechanisms. Although most drug treatments induce apoptosis, it is less clear in what cases differential triggering of this process plays a prominent role in drug resistance. We used a panel of drug resistant and sensitive cell lines to assess the role of apoptosis induction in cellular responses to the lymphoma drug and spindle poison vincristine (VCR). Avian and human lymphoma cell lines were exposed to graded concentrations of VCR and studied for the extent of mitotic inhibition and apoptosis at 6, 12, 24, and 48 hours using a combination DNA and viability fluorescence assay. Drug resistant and sensitive lymphoma cell lines were shown to be arrested in mitosis to a similar extent, about 50% blocked cells at 6 hours. VCR induced apoptosis quickly and extensively in the avian DT40 B lymphoma cells, 80% apoptosis at 12 hours, but only modestly (less than 10%) in the CU159 T lymphoma cells. CU159 cells persisted in a mitotically blocked state without entering an apoptotic cascade. The Burkitt's lymphoma cell lines also showed differential sensitivity to VCR-induced apoptosis. The ST486 cell line underwent apoptosis readily whereas the CA46 cell line survived in a mitotically blocked condition without engaging in apoptosis. The EW36 cell line showed intermediate sensitivity to VCR-induced apoptosis. Caspase-3 activation was found to be coincident with the engagement of apoptosis observed morphologically. These results suggest a prominent role for differential triggering of apoptosis, associated with caspase-3 activation, underlying drug resistance. In lymphoma cells, regulation of differential apoptosis induction by VCR appears to be upstream of caspase-3 activation.

536 CELLULAR GLUTATHIONE STATUS MODULATES PCB-INDUCED STRESS RESPONSE AND APOPTOSIS IN PORCINE ENDOTHELIAL CELLS.

R. M. Slim, M. Toborek, L. W. Robertson, H. J. Lehmler and B. Hennig. *Department of Nutrition and Food Science, Graduate Center for Toxicology and Department of Surgery; University of Kentucky, Lexington, KY.*

Exposure to environmental contaminants, such as polychlorinated biphenyls (PCBs), may severely compromise normal function of vascular endothelial cells (EC). We have previously shown that PCB 77 (3,3'4,4'-tetrachlorobiphenyl), an arylhydrocarbon receptor (AhR) agonist, can induce oxidative stress in cultured EC. We now show that PCB 77 can activate EC and induce a cellular stress response which is reflected by the activation of c-Jun amino-terminal kinase/stress-activated protein kinase (JNK/SAPK). Our data suggest that this PCB 77-mediated stress response can be modulated by the intracellular glutathione (GSH) content, which was initially decreased in cells exposed to PCB 77. EC pretreated with buthionine-sulphoximine (BSO), an inhibitor of GSH synthesis, delayed the late recovery of PCB-induced JNK/SAPK activity. In contrast, media supplementation with the glutathione precursor N-acetyl-cysteine (NAC) was sufficient to inhibit PCB 77-induced JNK/SAPK. Although PCB 77 alone did not induce apoptosis, combined treatment with PCB 77 and BSO induced the activation of caspase 3, annexin V and DNA fragmentation. The caspase-3-specific inhibitor DEVD-CHO protected cells against PCB 77/BSO mediated-apoptosis and inhibited the caspase activity without affecting JNK/SAPK activation or cellular glutathione levels. These results suggest that AhR ligands, such as PCB 77 cause vascular EC dysfunction by modulating intracellular GSH, which subsequently leads to activation of stress-specific kinases. Furthermore, inhibition of glutathione synthesis by BSO or possibly other prooxidants can further potentiate the PCB 77-induced stress response, and ultimately lead to apoptotic cell death. (Supported in part by grants from NIEHS/EPA, and the KY Agr. Exp. Station.)

537 3-METHYLINDOLE (3MI) CAUSES BOTH APOPTOSIS AND NECROSIS IN CULTURED HUMAN LUNG CELLS.

W. K. Nichols, J. I. Bossio and G. S. Yost. *University of Utah, Salt Lake City, UT.*

The immortalized lung cell line (BEAS-2B) is susceptible to cytotoxic effects of the pneumotoxicant 3MI. Bioactivation of 3MI by cytochrome P450 enzymes is required to produce a reactive metabolite that is responsible for the formation of protein and DNA adducts. Earlier studies by our laboratory have shown that 3MI can cause cytotoxicity based on the release of lactic dehydrogenase into the media during incubations of human and rabbit lung cells with this toxicant. Evidence of apoptosis as well as necrosis has been demonstrated by fluorescence microscopy using acridine orange and ethidium bromide. An increase in apoptotic nuclei has been observed within 18 hr for BEAS-2B cells incubated with 3MI. In addition, an increase in DNA damage is observed within 24 hr by terminal deoxynucleotidyl transferase (TdT)-mediated dUTP nick end labeling. Although most cells appear to undergo necrosis, there is a significant degree of cells induced to undergo apoptosis in the presence of 3MI. These studies indicate that some cellular injury induced by 3MI promotes both apoptosis and primary necrosis in cultured human lung cells incubated with this toxicant. (Supported by USPHS grant HL13645 from NHLBI.)

538 THE JNK AND P38MAPK ARE NOT ACTIVATED IN BREAST CANCER CELLS MCF-7 BY GENISTEIN.

S. Nomoto and F. Kayama. *Jichi Medical School, Kawachi, Japan.* Sponsor: T. Yoshida.

Breast cancer is the most common cancer among American women, whereas Asian women, particularly Chinese and Japanese, have a relatively low incidence. It is believed that genistein, a prominent isoflavonoid contained in soy products, may be responsible for reducing the rate of breast cancer in Asian women, due to high rate of soy products in Asian diet. Genistein was shown to arrest cell cycle at the G2-M phase and induce apoptosis in breast cancer cell lines. However the signal transduction pathway(s) activated by the treatment of genistein has not been clearly identified. We investigated the effects of genistein on the MAP kinase cascades, the JNK and p38MAPK pathways. When we treat the cells with 30μM of genistein, the rate of cell death reached 65% after 24 h and 81% after 48 h, indicating that genistein treatment at this concentration causes apoptosis. Under the same condition, we performed Western blotting analysis using phospho-specific antibodies against JNK and p38MAPK that recognize the kinases phosphorylated as the result of activation of upstream kinases. The phosphorylated forms of JNK and p38MAPK were not identified after genistein treatment, suggesting that the JNK and p38MAPK pathways were not activated by genistein in MCF-7 cells. The involvement of other possible signaling pathways is currently under investigation.

539 EFFECT OF METALLOTHIONEIN ON DOXORUBICIN-INDUCED APOPTOSIS IN CARDIOMYOCYTES: ROLE OF CYTOCHROME C-ACTIVATED CASPASE-3.

G. W. Wang, Z. X. Zhou and Y. J. Kang. *University of Louisville, Louisville, KY.*

In previous studies, we have demonstrated that metallothionein (MT), a potent antioxidant, functions in cardiac protection against doxorubicin (DOX)-induced injury. The present study was undertaken to investigate possible mechanisms by which MT functions in this cardioprotection. Because apoptosis is a constant feature of myocardial damage following oxidative stress and reactive oxygen radicals generated from DOX are highly responsible for the drug's cardiotoxicity, this study focused on effects of MT on DOX-induced myocardial apoptosis using primary neonatal cardiomyocyte cultures. Cardiomyocytes isolated from MT-overexpressing transgenic neonatal mice and non-transgenic controls were treated with DOX at different concentrations for varying periods of time. Cardiomyocyte apoptosis was detected by a TUNEL assay and an Annexin V-fluorescein isothiocyanate binding. To investigate cellular and molecular mechanisms leading to DOX-induced apoptosis, the activation of mitochondrion-controlled apoptotic pathway was examined, including Western blot analysis of mitochondrial release of cytochrome c and caspase-3 activation, the latter was further confirmed by laser confocal microscope using an antibody against the active form of caspase-3. DOX markedly induced apoptosis in non-transgenic cardiomyocyte cultures as a function of time in a dose-dependent fashion. This apoptotic effect was significantly suppressed in the MT-overexpressing transgenic cardiomyocyte cultures. Corresponding to the apoptotic effect of DOX and the inhibitory effect of MT, increased mitochondrial release of cytochrome c and activation of caspase-3 were observed in the non-transgenic cardiomyocytes following DOX treatment. The activation of this mitochondrion-controlled apoptotic pathway was almost completely blocked in MT-overexpressing transgenic cardiomyocytes. These results demonstrate that MT suppresses DOX-induced apoptosis in cardiomyocytes through at least in part inhibition of mitochondrion-controlled apoptotic pathway. (Supported in part by NIH grants CA68125 and HL59225, American Heart Association EI award (9640091N) and Jewish Hospital Foundation, Louisville, Kentucky.)

540 CHARACTERIZATION OF THE ARSENITE DOSE RESPONSE CURVE ON PROMYELOCYTIC LEUKEMIA CELLS (U-937).

K. P. Singh, S. A. Reddy and M. J. McCabe, Jr. *Wayne State University, Detroit, MI.*

Arsenic is a known environmental toxicant and carcinogen. Chronic arsenicism leads to several cancers, yet arsenic trioxide treatment has been found recently to induce clinical remission in patients with acute promyelocytic leukemia (APL). While some data suggest that the potential therapeutic value of arsenicals may lie in triggering apoptosis, it has not been established that cytotoxicity is the sole mechanism of action. We have used a promyelocytic leukemia cell line (U-937) to characterize the dose dependent effects of arsenite on cell growth, viability, apoptosis and differentiation. Arsenite has diverse effects on U937 cells that are dependent on concentration. Low concentrations of arsenite (i.e., 1μM) potentiate the vitamin-D3-induced differentiation of U937 cells towards monocytic maturation. Both Mac-1 expression and NBT reduction, markers of monocyte differentiation, are increased in arsenite-exposed, D3-co-stimulated cells. Intermediate concentrations of arsenite (i.e., 5 to 10 μM) are cytostatic but not cytotoxic. Cell cycle analysis using elutriated, synchronous cell populations revealed that arsenite delays cell cycle transit by affecting both the G1 and G2phases of the cell cycle. Higher concentrations (i.e., >10 μM) or prolonged (i.e., 24 hr) incubation with intermediate concentrations of arsenite induced apoptotic cell death based on both morphological and biochemical criteria. Arsenite-induced apoptosis was caspase-3 dependent, as caspase-3 was activated in a time- and concentration-dependent fashion. Moreover, arsenite induced cell death was prevented in the presence of the broad caspase inhibitor, z-vad-fmk. The caspase inhibitor did not reverse arsenite-induced cytostasis, suggesting that the cell cycle and apoptotic effects of arsenite are separable. Our studies show that arsenite has a differential dose effect on promyelocytic leukemia cells, and that cell cycle control and differentiation are more sensitive parameters than is cell death. (Supported by P30-ES06639.)

541 ROLE OF BCL-2 AND BCL-X_L IN MITOCHONDRIAL PERMEABILITY TRANSITION INDUCED BY THE RADIOSENSITIZER CI-1010.

T. J. Miller[1], M. L. Hann[1], R. B. Tjalkens[1], L. Dethloff[2] and M. A. Philbert[1]. [1]*University of Michigan, Ann Arbor, MI and* [2]*Parke-Davis Pharmaceutical Research, Ann Arbor, MI.*

The mitochondrial permeability transition (MPT) is a high conductance transmembrane pore that opens prior to apoptosis *in vitro*. Expression of antiapoptotic proteins such as Bcl-2 and Bcl- X_L stabilize the pore in the closed conformation, conferring protection against neurotoxicants. CI-1010 ((R)-α [(2-bromoethyl)-amino]methyl]-2-nitro-1H-imidazole-1-ethanol monohydrobromide), is a nitroimidazole that produces progressive retinal neuronal degeneration with sparing of adjacent glial cells. Differential cellular susceptibility to CI-1010 is mediated by opening of the MPT and correlates with differential expression of Bcl-2 and Bcl-X_L in astrocytes and neurons. The present study uses human SY5Y neuroblastoma and rat C6 glioma cells as a model of retinal astrocytes and neurons: CI-1010 treated SY5Y cells undergo apoptosis in culture. Following exposure to 750 μM CI-1010 at 1, 2, 4, and 24 hours, expression of Bcl-2 and Bcl-X_L was monitored using western blot analysis and opening of the MPT imaged by confocal microscopy (TMRM, calcein AM, propidium iodide). Loss of mitochondrial reducing potential was determined by the MTT cytotoxicity assay. C6 glioma cells express high constitutive levels of Bcl-2 and Bcl-X_L, however, increased expression of both proteins was detected in both cell types 24h after exposure to CI-1010. CI-1010 also induced rapid mitochondrial depolarization in SY5Y neuroblastoma cells and C6 glioma cells within 10 min. Viability assays revealed a lower LC_{50} for SY5Y approximately half that of C6 treated with CI-1010. The precise role of Bcl-2 and Bcl-X_L in the regulation of MPT-induced cell death remains to be determined. However, these results suggest that constitutive expression of Bcl proteins may confer increased protection against nitrocompound-induced neurotoxicity.

542 DYSREGULATION OF CD95-MEDIATED APOPTOSIS BY MERCURY.

M. J. Whitekus, B. S. Chelladurai, A. J. Rosenspire and M. J. McCabe, Jr. *Wayne State University, Institute of Chemical Toxicology, Detroit, MI.*

Exposure to inorganic mercury (Hg^{2+}) has been associated with autoimmune disease; however, the underlying mechanisms are poorly understood. Since dysregulation of CD95/Fas-mediated apoptosis has been implicated in autoimmune disorders, we have hypothesized that Hg^{2+} could contribute to autoimmunity by dysregulating apoptosis in autoreactive lymphocytes. Using Jurkat T cells we have established that 5-10 μM $HgCl_2$ attenuates CD95-mediated apoptosis by targeting a molecular component upstream of caspase3 or caspase3, itself. Hg^{2+} does not appear to block the activation of caspase9 or caspase8, suggesting that mercury does not dysregulate the CD95 pathway by direct interaction with caspases. Furthermore, using a caspase3 enzyme activity assay we have ruled-out the possibility that caspase3 is directly targeted by mercury. Hg^{2+} loses its ability to block caspase3 activity when added after anti-CD95 in a time dependent fashion. Moreover, Hg^{2+} does not block TNF-mediated activation of caspase3 indicating that the molecular component responsible for the inhibition of caspase3 by Hg^{2+} in the CD95 pathway is not present in the TNF pathway. Experiments using human peripheral blood lymphoblasts are being conducted to corroborate the above findings. This study is the first to correlate Hg^{2+}exposure with dysregulation of the CD95 death pathway. It represents a model to test the hypothesis that modulation of the CD95 pathway by Hg^{2+} contributes to a breakdown in peripheral tolerance leading to autoimmunity. (Supported by P30-ES06639 and R21-ES10351.)

543 METHYLMERCURY AND MERCURIC CHLORIDE AFFECT NEURONAL APOPTOSIS IN PC12 CELLS IN A DOSE- AND NGF-DEPENDENT FASHION.

D. K. Parran[1], L. D. White[2] and S. Barone, Jr.[2]. [1]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC and* [2]*Neurotoxicology Division, NHEERL, USEPA, Research Triangle Park, NC.*

Methylmercury (CH3Hg), an ubiquitous environmental toxicant, has a profound effect on the developing central nervous system. Gestational exposure to CH3Hg has led to neurological abnormalities resulting from death of neurons and altered cytoarchitecture in the developing CNS. We examined the effects CH3HgCl and HgCl2 on cell death in rat pheochromocytoma (PC12) cells. PC12 cells were exposed to 0, 0.01, 0.03, 0.1, 0.3, 1, 3 and 10 mM of either CH3Hg or HgCl2 in the presence or absence of 50 ng/ml NGF for 24 hours. Following exposure, fragmented DNA, an endpoint of apoptosis, was quantified by ELISA. Determinations of alterations in cell size and morphology were also made. In the presence of NGF, CH3Hg caused increased levels of fragmented DNA at concentrations of 1, 3 and 10 mM, while HgCl2 had no significant effect on fragmented DNA at any of the concentrations tested. In the absence of NGF, control levels of fragmented DNA were approximately 8-12 times higher than in the presence of NGF and both mercury compounds increased fragmented DNA at the higher concentrations (3 and 10 mM). Effects on cell size were also observed following exposure to CH3Hg. In the presence of NGF, a significant decrease in cell size was observed at 0.3-10 mM of CH3Hg, while no significant change in cell body size was seen following exposure to HgCl2. These data suggest that, in the presence of NGF, CH3Hg but not HgCl2, induces apoptotic cell death. (This abstract does not necessarily reflect EPA policy.)

544 PARP EXPRESSION AND CLEAVAGE PRECEDE NEURONAL DEATH FOLLOWING OXIDATIVE INJURY IN NEONATAL RATS.

S. M. Schmura-Martin and M. R. Grafe. *University of Texas Medical Branch, Galveston, TX.* Sponsor: M. Treinen-Moslen.

Background: Nitric oxide (NO) and peroxynitrite have been implicated as mediators of neuronal death following focal brain ischemia. Studies in adult human and rat brain have implicated DNA damage and the activation of poly (ADP-ribose) polymerase (PARP) in this pathway to neuronal death. Neuronal vulnerability to insult peaks at post-natal day 7 in the rat, a period associated with rapid brain growth and the formation of synaptic connections. Death of neurons during the comparable period in humans is known to have long-term consequences, for example Cerebral Palsy. PARP expression in neonatal rats following oxidative injury has not been previously examined and, if present, may be a target for therapeutic intervention. **Objective:** We tested the hypothesis that PARP expression is rapidly increased in response to a hypoxic/ischemic NO-mediated insult, and that the cleavage of PARP would precede the onset of morphological changes consistent with cell death. **Experimental Design:** Hypoxic-ischemic injury was induced by left common carotid artery ligation of 7 day old rats and was followed by a 90 or 120 minute exposure to 7.6% oxygen. Extent of injury and expression of PARP were examined 1, 2, 6 and 12 hrs post-hypoxia. Hematoxylin and eosin stained coronal brain sections were examined for morphological changes and TUNEL staining was employed to identify neuronal death. PARP cleavage was detected with anti-PARP antibodies by Western blot. **Results:** Significant morphological changes such as vacuolization of the neuropil, cell shrinkage,

pyknotic nuclei and increased cytoplasmic eosinophilia were observed primarily in the ipsilateral neocortex in rats with a 12-hr survival period but not in brains of rats who survived <12 hrs. PARP cleavage was detectable in rats surviving 6 hrs post-hypoxia. **Conclusions:** Our observations of PARP expression prior to the appearance of morphological changes suggest a window in which PARP inhibitors could be administered to block subsequent neuronal death and minimize brain damage. (Supported by NIEHS T32 ES07254.)

545 INVOLVEMENT OF NMDA-RESPONSIVE NEURONS IN STAUROSPORINE AND OXYGEN/GLUCOSE DEPRIVATION-INDUCED CELL DEATH.

C. E. Thomas and D. A. Mayle. *Lilly Research Labs, Greenfield, IN.*

Cell death in primary rat cortical neuronal cultures was investigated using the excitotoxin N-methyl-D-aspartate (NMDA) or the pro-apoptotic agent staurosporine (STS). The mode of cell death was compared/contrasted to an *in vitro* model of ischemia which utilized 5 hr of oxygen and glucose deprivation (OGD) followed by re-oxygenation. Cultures exposed to NMDA undergo necrotic cell death typified by lactate dehydrogenase (LDH) leakage with little caspase-3 activation or oligonucleosome formation. Cells exposed to STS exhibit rapid, extensive activation of caspase-3 with coincident LDH leakage and generation of oligonucleosomes. Both LDH leakage and oligonucleosome content were significantly greater at 48 hr than at 20 hr with STS treatment. Pretreatment of the cultures with NMDA for 4 days prior to STS effectively killed NMDA-responsive neurons, prevented caspase-3 activation and diminished LDH leakage and oligonucleosome formation. Following OGD with re-oxygenation, extensive oligonucleosome formation and LDH leakage is observed in the absence of caspase-3 activation. Depletion of NMDA-responsive neurons prevented OGD-induced LDH leakage and oligonucleosome formation. Partial protection was provided by the NMDA channel blocker MK-801 which also restored sensitivity to STS-induced caspase-3 activation. The data with OGD are consistent with 1) a non-apoptotic cell death in NMDA-responsive neurons which resembles excitotoxicity and 2) a caspase-3 insensitive apoptosis in remaining neurons. Thus, OGD induces both necrotic and apoptotic cell injury and the modality of cell death in NMDA-sensitive neurons is dependent upon the initiating event and the time over which the phenomenon is studied.

546 EXPRESSION OF THE MITOCHONDRIAL PROTEIN SM-20 PROMOTES DEATH IN NERVE GROWTH FACTOR-DEPENDENT SYMPATHETIC NEURONS.

E. A. Lipscomb, P. D. Sarmiere, R. J. Crowder and R. S. Freeman. *University of Rochester, Rochester, NY.* Sponsor: N. Ballatori.

The withdrawal of nerve growth factor (NGF) from sympathetic neurons results in cell death. Since the death of these neurons is blocked by inhibitors of RNA and protein synthesis, we hypothesize that genes specifically expressed following NGF withdrawal are likely to be important in the apoptotic pathway. Using the technique of differential display, we identified a gene called SM-20 that is preferentially expressed in NGF-deprived (dying) versus NGF-maintained (healthy) sympathetic neurons. To begin characterization of the SM-20 protein, we performed subcellular localization studies. In immunofluorescent experiments, SM-20 colocalized with Mitotracker Green FM, a mitochondria-selective dye, and cytochrome oxidase I, a mitochondrial protein. We found that the first 25 amino acids of SM-20 are sufficient to target dihydrofolate reductase (DHFR), a cytosolic protein, to the mitochondria. To explore the significance of SM-20 in the apoptotic pathway, we overexpressed SM-20 in sympathetic neurons maintained in the presence of NGF. Microinjection of SM-20 expression vectors resulted in decreased cell survival as compared with b-galactosidase injected controls. These results suggest that increased SM-20 protein may contribute to neuronal death by affecting mitochondrial function. Recent microinjection studies have demonstrated that SM-20(51-355), a truncated form of SM-20 lacking the first 50 amino acids, can elicit cell death comparable to full-length SM-20 when overexpressed in sympathetic neurons. Thus, it is conceivable that localization of SM-20 to the mitochondria is not necessary for its death-promoting activity. Currently, we are investigating the effects of tetracycline-inducible expression of SM-20 on the survival of rat PC12 cells. (Supported in part by NIH Grant NS34400 and NIH Toxicology Training Grant ES07026.)

547 ROLE OF CYTOCHROME C IN CYANIDE-INDUCED APOPTOTIC CELL DEATH.

P. G. Gunasekar[1], G. T. Ramesh[2], J. L. Borowitz[1] and G. E. Isom[1]. [1]*Purdue University, West Lafayette, IN and* [2]*Texas Southern University, Houston, TX.*

Previous studies show that cyanide (KCN) can induce neuronal apoptotic cell death, which is mediated by oxidative stress following NMDA receptor activation and involves the caspase-3-like proteinase. Release of the apoptotic factor cytochrome C from mitochondria into the cytosol is an early signaling factor for a variety of apoptotic stimuli. In the present study, cerebellar granule cells were used to investigate the early signaling events responsible for the induction of apoptosis in cyanide-induced cell death. In this cell model, exposure to cyanide at different concentrations (100-500 μM) for 24 hrs induced maximum release of cytochrome C into the cytosolic fraction as assessed by western blot. This was associated with enhanced caspase 3-like proteinase expression, followed by apoptosis as determined by western blot and TUNEL staining, respectively. It was found that induction of cytochrome C release into the cytosol occurred as early as 3 hrs of cyanide exposure, which proceeded the initiation of caspase activation. Elevation cytosolic cytochrome C was blocked by pretreatment with uric acid, a scavenger of peroxinitrite, indicating that oxidative stress plays a role in the release of cytochrome C from the mitochondria. This process was initiated by NMDA receptor activation since MK-801 blocked the elevation of cytosolic cytochrome C. However, the caspase-3 inhibitor, Ac-DEVD, did not prevent cytochrome C release, indicating the induction of cytochrome C release is upstream to caspase activation in cyanide- induced cell death. (Supported by NIH grant ESO4140.)

548 DIETHYLDITHIOCARBAMATE INDUCES APOPTOSIS IN RAT HIPPOCAMPAL ASTROCYTES.

J. A. Mlockier-Audrain and L. D. Trombetta. *St. John's University, Jamaica, NY.*

Diethyldithiocarbamate (DDC), a potent metal chelator and pro-oxidant has been shown to be neurotoxic. This may be due to its chelating ability resulting in an increase of intracellular metal concentration or by forming disulfide linkages with essential proteins. The pathogenesis of thiocarbamate toxicity is not clearly understood. Mammalian cells have evolved numerous responses to toxicity. Apoptosis, a form of cell death, is an important regulatory elimination pathway in the development of many animal cell types. The purpose of this experiment was to determine if DDC caused apoptosis in rat hippocampal astrocytes. Astrocytes grown in Dulbecco's modified Eagle's essential media were treated with 35 and 350 μg/ml DDC at subconfluency for 1 hr, washed and refed with normal media. Cells were collected at 24, 48 and 72 hr following DDC post-treatment. Apoptosis was detected using an *in situ* staining method for DNA strand breaks detected by TUNEL and visualized by light microscopy. Apoptosis was observed at 48 and 72 hr post-treatment at the 35 μg/ml DDC dose and observations were dramatically increased at the 350 μg/ml dose. No apoptotic cells were seen at the 24 hr post-treatment time period regardless of dose. This investigation suggests that cell death resulting from DDC toxicity may be due to an apoptotic event and not solely due to necrosis.

549 DOPAMINE AND CYANIDE-INDUCED NEURONAL APOPTOSIS IN RAT MESENCEPHALON CULTURES.

D. C. Jones, P. G. Gunasekar, J. L. Borowitz and G. E. Isom. *MCMP, Purdue University, West Lafayette, IN.*

Dopamine (DA) neurotoxicity has been implicated in the degeneration of dopaminergic neurons. The goal of the present study was to examine DA toxicity in rat mesencephalon cells. Since neurons may be more susceptible to injury under energy impaired conditions, cyanide (KCN) was use to inhibit mitochondrial respiration. Cells were incubated with DA (300 mM) and/or KCN (100 mM) for 24 hrs. TUNEL staining revealed that DA-induces apoptosis and KCN increased this effect, suggesting that impaired energy metabolism potentiates DA toxicity. Intracellular generation of reactive oxygen species (ROS) increased significantly in DA-treated cells and was potentiated by KCN. This effect was attenuated with glutathione and uric acid, indicating involvement of ROS and NO in DA toxicity. Furthermore, DA and DA + KCN produced an immediate increase in Ca++. The increase in intracellular ROS and Ca++ preceded depolarization of the mitochondrial membrane. Cells exposed to DA and/or KCN for 1, 2, and 4 hrs exhibited mitochondrial depolarization. Western blot analysis demonstrated that cells incubated with DA had increased levels of cytosolic cytochrome c. Cytochrome c release was potentiated by KCN and blocked by pre-treatment with glutathione and uric

acid. Exposure of cells to DA, and/or KCN resulted in caspase 3 activation, which was maximal at 12-18 hrs. It was concluded that mesencephalon cells incubated with DA undergo apoptosis, which is potentiated by compromised neuronal energetics. DA-induced apoptosis is mediated by ROS and involves the initiation of an intracellular cascade characterized by; a rise in intracellular Ca++, depolarization of the mitochondrial membrane, the release of cytochrome c and activation of caspase 3. (Supported by NIH grant ESO4140.)

550 PYRIDOSTIGMINE-INDUCED CEREBELLA GRANULE CELL DNA FRAGMENTATION VIA LOSS OF MITOCHONDRIAL MEMBRANE POTENTIAL AND ACTIVATION OF CASPASE-LIKE PROTEASES.

L. Li, P. G. Gunasekar, J. L. Borowitz and G. E. Isom. *MCMP, Purdue University, West Lafayette, IN.*

Pyridostigmine bromide (PB) is a reversible cholinesterase inhibitor that has been used for treatment of myasthenia gravis and for prophylactic protection against organophosphate nerve agent. We have previously shown that PB can induce apoptotic cell death in the rat brain. In this study we investigated the role of loss of mitochondrial membrane potential and caspase-like protease activity in PB-induced DNA fragmentation in rat cerebellar granule cell. DNA fragmentation was determined by gel electrophoresis of extracted DNA and TUNEL staining cerebella granule cells. Exposure of cerebellar granule cells to PB(250 μM) for 24 hr caused apoptotic cell death. Pretreatment of the cells with the caspase inhibitor Z-Val-Ala-DL-Asp-Fluoromethyl keton (zVAD-flk 100 μM) and the muscarinic receptor antagonist atropine (10 μM) blocked cellular chromatin condensation and the DNA fragmentation induced by PB. To confirm whether caspase-like proteases were involved in the apoptotic events, we treated granule cells with varying concentrations of PB (50-500 μM) for 24 hr. PB caused a dose-dependent increase in the activity of caspase-like proteases. Time studies showed that caspase-like protease activity was first elevated at 4 hr and was markedly increased at 16-24 hr. Both zVAD-flk and atropine blocked caspase-like protease activity induced by PB exposure. Using RH123 as a probe to determine the changes of mitochondrial membrane potential, PB induced a dose-dependent loss of mitochondrial membrane potential in the cells, which was blocked by atropine. These results show that PB-induced cerebellar granule cell DNA framentation involves loss of mitochondrial membrane potential and activation of caspase-like proteases. (Supported by U.S. Army grant DAM 17-97-71354.)

551 METABOLITES OF CHLORPYRIFOS INDUCE APOPTOSIS IN PC12 CELLS.

K. P. Das[1], S. Barone, Jr.[2] and L. D. White[2]. [1]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC and* [2]*Neurotoxicology Division, NHEERL, USEPA, Research Triangle Park, NC.*

Previously we reported that neurite outgrowth was inhibited by the cholinesterase-inhibiting pesticide chlorpyrifos (CPF) and its metabolites, CPF-oxon and trichlorpyridinol (TCP) in differentiated PC12 cells. These effects of CPF and TCP were observed in the absence of cholinesterase inhibition. In the present study, we evaluated the effects of CPF, CPF-oxon and TCP on apoptosis in differentiated and undifferentiated PC12 cells. PC12 cells were differentiated for one week with 50 ng/ml of hrNGF followed by replating cells at 1x105 cells in 24 well plates. Following NGF withdrawal, 5 ng/ml of hrNGF prevented 50% of the cell death in differentiated cells, and 0.1 ng/ml was equally effective in undifferentiated cells. Apoptosis was examined in the presence or absence of different doses (0.1, 1, 10, 100 μM or nM) of CPF, TCP, or CPF-oxon with or without hrNGF at 37 C for 24 h. Cells were lysed and fragmented DNA was assessed using a cell death ELISA. Our results show that, i) TCP (1 μM) or CPF-oxon (1 nM) alone induced apoptotic death, ii) in the absence of NGF, CPF-oxon or TCP showed a dose-dependent induction of apoptotic death, and iii) exposure to NGF (10 ng/ml) protected against cell death at all doses of TCP and CPF-oxon used except at 100 μM and 100 nM, respectively. These results suggest that differentiated PC12 cells are more vulnerable to apoptotic cell death following NGF withdrawal than undifferentiated cells and that NGF under certain conditions can protect against this pesticide-induced apoptosis. (This abstract does not necessarily reflect EPA policy.)

552 INDUCTION OF MUTATION AND APOPTOSIS IN MOUSE PRIMORDIAL GERM CELLS BY ENU.

T. Shibuya, T. Kashima, Y. Saito, T. Nagao, K. Imai and H. Ono. *Hatano Research Institute, Food and Drug Safety Center, Hadano, Japan.*

Primordial germ cells (PGC) are the ancestor cells of both male and female gamete. If a mutation is induced in a PGC, all germ cells derived from it possess the same mutation (cluster mutations). We have found that N-ethyl-N-nitrosourea (ENU) induces recessive mutations at a relatively high rate in male mice primordial germ cells (PGC) at 8.5, 10.5 and 13.5 days of development (G8.5, G10.5 and G13.5) using a specific locus test (Shibuya et al., 1993 and 1996). An apparent stage-specificity have been observed on the induction of mutations, i.e., G10.5 is the highest, followed by G8.5 and then G13.5. The cluster mutations have been easily obtained in G8.5 and G10.5 PGC. The high mutation rate in G8.5 and G10.5 are resulted from incidences of cluster mutations. Furthermore, a dose-dependent induction of mutations was also observed in both G8.5 and G10.5 PGC. It is known that the numbers of PGC at these developmental stages are very small and PGC proliferate rapidly with a doubling time of about 16 hr at these developmental stages. Therefore, the induction of cluster mutation by ENU might result from complex phenomena. Furthermore, the cell killing effect may modify the induced mutation rate. To elucidate the cell kinetics on mutation induction in PGC by ENU, we studied on apoptosis of PGC G13.5 in genital ridge of male treated with ENU at G10.5. ENU induced apoptosis dose-dependently in PGC. Therefore, apoptosis induced by ENU is one of an important factor to induce cluster mutations.

553 PARTICIPATION OF THE P53 PROTEIN ON THE MEMBRANE EXPRESSION OF FAS IN THE GC-2SPD(TS) GERM CELL LINE.

J. H. Richburg and H. Gao. *College of Pharmacy, University of Texas, Austin, TX.*

The tumor suppressore p53 is a transcription factor that is involved in the regulation of cell growth and apoptosis. Recent observations suggest that the p53 protein can influence the re-distribution of the Fas receptor (Fas) from a cytosolic location to the cell membrane by a transcription-independent mechanism. The Fas-system has been previously shown participate in the regulation of testicular germ cell apoptosis. In this study, we evaluate the influence of p53 activation on the membrane expression of Fas in a p53-termperature-sensitive germ cell line (GC-2spd). In these cells, p53 is activated and found exclusively in the nucleus at the permissive temperature of 32°C, Both western blot analysis and immunocytochemistry were used to examine the membrane expression of Fas in these cells. In cells maintained at 32°C, significant increase in the membrane expression of Fas was observed compared to those maintained at 37°C. The sensitivity of GC-2spd cells to Fas-mediated apoptosis was assessed by the addition of a Fas-activating antibody (5ug/ml, Jo-2, PharMigen) to the culture media. Apoptosis was assessed by erminal deoxynucleotide transferase-mediated dUTP nick end labeling (TUNEL). In GC-2spd cells maintained at 32°C, a large increase in TUNEL-positive cells was observed after 24 h and few viable cells remained attached to the culture matrix after 48 h. Taken together, these data indicate the involvement of p53 in the localization of Fas to the germ cell membrane. (Supported by NIEHS grants ES09145 & ES07784.)

554 DIFFERENTIAL SENSITIVITY OF YOUNG AND ADULT FASml MUTANT *GLD* MIDE TO MONO-(2-ETHYLHEXYL) PHTHALATE (MEHP)-INDUCED TESTICULAR GERM CELL APOPTOSIS.

C. J. Giammona, J. H. Richburg and A. Nanez. *College of Pharmacy, University of Texas, Austin, TX.*

Apoptosis of testicular germ cells is essential for functinonal spermatogenesis. The Fas-signaling system has been proposed as a mechanism by which Fas ligand (FasL)-expressing Sertoli cells initiate apoptosis of Fas receptor (Fas)-positive germ cells. Exposure of C57/b16 mice to the Sertoli cell toxicant MEHP (1 g/kg, p.o.) induces a rapid increase in the incidence of germ cell apoptosis. Previous work of our group revealed the insensitivity of prepubertal gld mice, which express a non-functional form of FasL, to MEHP-induced germ cell apoptosis for up to 24 h after exposure. Regardless of this insensitivity, the gld mice exhibit no significant testicular-related abnormalities (e.g.,m massive hyperplasia, infertility, etc) compared to the parent strain. Therefore, we tested whether the decreased sensitivity of germ cells to MEHP-induced apoptosis extends beyone 24 h and if it is dependent upon the

age of the gld mice. Young 28-day-old gld and wild-type mice wer given an acute oral dose of MEHP (1 g/kg) and testes collected aftger 48, 72, 96 and 120 h. Adult mice were given a single dose of MEHP (2 g/kg) and testes collected after 6, 12, 24 and 48 h. Characteristic apoptotic DNA collected after 6, 12, 24, and 48 h (slightly elevated compared to 24 h) whereas a 3-fold increase was seen in wild-type mice (similar to 24 h level). In adult gld and wild-type mice an identical 3-fold increase in TUNEL-positive cells was observed 24 h aftger MEHP exposure. These data suggest that germ cell was observed 24 h after MEHP exposure. These data suggest that germ cell apoptosis occurs in adult, and to a lesser degree in young, gld mice via a Fas-independent signaling mechanism. This mouse model may be useful in providing new insights into additional signaling pathways regulating testicular germ cell apoptosis. (Supported by NIEHS grants ES089145 and ES07784.)

555 SALICYLIC ACID AND CHLOROFORM-INDUCED NEPHROTOXICITIES MAY INVOLVE GENOMIC DNA FRAGMENTATION AND CELL DEATH BY APOPTOSIS.

R. R. Raje, E. J. Hickey[1], V. R. Reid[1], W. N. Ratna[1] and S. D. Ray[1]. 1*Dept. of Pharmacology, Toxicology and Med. Chem., College of Pharmacy and Health Sciences, Long Island University, Brooklyn, NY.*

Chloroform (Chfm) and salicylic Acid (SA), two well known nephrotoxins, show apoptogenicity towards the liver. The objectives of the present investigation were to determine whether Chfm and SA have the potential to induce genomic DNA fragmentation in kidneys, and if so, whether they turn on apoptotic cell death in addition to necrosis *in vivo*. In order to assess these events, male ICR mice (25-45g) were treated with nephrotoxic doses of Chfm (200-550 mg/Kg, i.p.) and SA (200-500 mg/Kg i.p.) for 24 hours. Blood was collected for the determination of plasma BUN (nephrotoxicity) and malondialdehyde levels (MDA: malondialdehyde, a marker of lipid peroxidation), and superoxide dismutase activity (SOD: a marker of oxidative damage). Kidney tissues were histopathologically evaluated for apoptotic/necrotic deaths and analyzed for DNA fragmentation. Results show that both Chfm and SA induce significant DNA fragmentation and cause cell death by apoptosis. Although, Chfm and SA both were equally effective in inducing nephrotoxicity, SA was slightly more potent in causing DNA damage. In addition, both these agents showed increased levels of MDA and SOD activity indicating possible involvement of oxidative stress. Collectively, these studies establish links between oxidative-stress-mediated nephrotoxicity, DNA fragmentation, and apoptotic cell death in kidneys.

556 DICLOFENAC-INDUCED NEPHROTOXICITY MAY INVOLVE OXIDATIVE STRESS AND MASSIVE GENOMIC DNA FRAGMENTATION *IN VIVO*.

E. J. Hichey, V. R. Reid[1], W. N. Ratna[1], R. R. Raje[1] and S. D. Ray[1]. *Division of Pharmacology, Toxicology and Medical College of Pharmacy & Health Sciences, Long Island University, Brooklyn, NY.*

Diclofenac (DCLF) is a nonsteroidal anti-inflammatory drug, that is widely used for the treatment of osteoarthritis, rheumatoid arthritis, ankylosing spondylitis, and acute muscle pain conditions. The goals of this investigation were to determine: (i) potential of DCLF to induce nephrotoxicity, (ii) its power to induce oxidative stress and genomic DNA damage, and (iii) its ability to induce apoptotic cell death in addition to necrosis. Male ICR mice (25-45 g),*fed adlibitum*, were administered nephrotoxic doses of DCLF (100 & 300 mg/Kg, orally) and sacrificed 24 h later. Blood was collected to evaluate renal injury (BUN), lipid peroxidation (MDA: malondialdehyde levels), and superoxide dismutase (SOD) activity (a marker of oxidative stress). Kidney tissues were examined histopathologically, and analyzed for DNA damage. Results show that diclofenac is a potent nephrotoxin (at 100 and 300 mg/kg: 4 and 5 fold increase in BUN respectively) and a powerful inducer of oxidative stress (significant increase in MDA levels) leading to massive DNA fragmentation (100 and 300 mg/kg: 3 and 10 fold increases compared to control) coupled with apoptotic and necrotic cell deaths. A dose-dependent increase in MDA level and SOD activity were also observed. Collectively, these data suggest that, in addition to its nephrotoxic potential, DCLF at toxic doses, may induce genomic instability *in vivo*.

557 HPLC ANALYSIS OF CYTOCHROME C USING 393NM DETECTION.

M. J. Picklo, V. Q. Nguyen, J. Zhang, T. J. Montine and D. G. Graham. *Vanderbilt University Medical Center, Nashville, TN.*

The release of cytochrome c from the mitochondria can induce apoptotic cell death. Previous methods to detect cytochrome c release from mitochondria have relied upon immunoblotting, a procedure that can be limited by non-linearity of signal, epitope masking, and impracticality for large numbers of samples. In order to circumvent these limitations, we have developed a reverse-phase HPLC method for cytochrome c detection and quantitation by taking advantage of a novel acid-induced absorbance maximum at 393 nanometers for cytochrome c in buffer containing 0.1% trifluoroacetic acid. With a C4 reverse-phase analytical column, this assay had a limit of quantitation of 10 ng (0.8 pmoles) of cytochrome c. HPLC detection of cytochrome c was then compared against immunoblot detection of cytochrome c. Both methods demonstrated a good linearity between signal response and cytochrome c loaded (10 ng to 100 ng). However, in contrast to the HPLC method, the immunoblotting signal plateaued at 150 ng of cytochrome c. We demonstrated the detection and quantitation of cytochrome c from isolated mitochondria. HPLC quantitation of cytochrome c is rapid and can be performed on the raw sample. This method of cytochrome c analysis may be useful for the study of agents that cause mitochondrial dysfunction and apoptotic cell death.

558 DIFFERENTIAL INHIBITION OF RIBOSOMAL RNA SYNTHESIS BY TOPOISOMERASE INHIBITORS.

D. Muscarella and S. Bloom. *Cornell University, Ithaca, NY.* Sponsor: R. R. Dietert.

The genes encoding ribosomal RNA (rRNA) are highly sensitive to the inhibition of transcription by topoisomerase inhibitors compared to genes encoding mRNA transcripts. Because transcription of rRNA accounts for a significant proportion (~50%) of total RNA synthesis in growing cells, such preferential drug interactions may be a potentially important determinant of drug-induced cell death. We examined rRNA transcriptional inhibition by several topoisomerase inhibitors, including camptothecin and actinomycin D, in B- and T-lymphoma cells that are highly sensitive and resistant to the induction of apoptosis by these agents, respectively. We found that the mode of rRNA synthesis inhibition varied among the particular agents used and, in some cases, was concentration-dependent. At relatively low concentrations of actinomycin D, and at all concentrations of camptothecin tested, premature termination of rRNA transcription was detected, resulting in the accumulation of small, truncated transcripts. The sites of termination of transcription were localized within the 5'external transcribed region of the pre-rRNA and corresponded to a region in the gene that containes several topoisomerase I sites. In contrast, exposure of cells to higher concentrations of actinomycin D, which were required to inhibit mRNA synthesis, resulted in the inhibition of initiation of rRNA transcription. We also found that the mode of inhibition of rRNA transcription correlated with different forms of cell death. For example, concentrations of actinomycin D that lead to premature termination of transcription resulted in the induction of apoptosis whereas cells exposed to higher concentrations of this drug, in which transcriptional initiation was blocked, were unable to execute an apoptotic pathway but instead underwent delayed cell death by necrosis. Thus, topoisomerase inhibitors show interactions with rDNA that may influence the mode and extent of cell death.

559 EVALUATION OF THIOBARBITURIC ACID REACTIVE SPECIES INDUCTION AND MEASURES OF APOPTOSIS FOLLOWING ACUTE AND REPEATED ORAL EXPOSURE TO METHYLMERCURY.

D. J. Mason, Jr., M. Vernon, L. D. white, S. Barone, Jr. and P. R. S. Kodavanti. *Neurotoxicology, USEPA, NHEERL, Research Triangle Park, NC.*

The purpose of this research is to develop a battery of end points to be used in neurotoxicological hazard identification. Putative mechanisms of methylmercury-induced neurotoxicity include the induction of reactive oxygen species and apoptosis. In this study, an attempt was made to determine if oral administration of methylmercury induced such responses. Male Long-Evans rats were administered dosages of methylmercury known to induce neuropathology. Areas of the central nervous system associated with methylmercury-induced dysfunction, spinal cord, cerebellum, and neocortex, were assayed for lipid peroxidation at selected time points after acute oral

administration (0, 0.12, 0.37, 1.11, 3.33, and 10 mg/kg) or after a seven day repeated oral regimen. Lipid peroxidation was determined measuring thiobarbituric reactive species (TBARS). To characterize the generation of TBARS and assay sensitivity, lipid peroxidation was induced, in a dose-dependent manner, via ex vivo addition of ferrous ammonium sulfate. In addition, tissues from these regions were assayed for DNA fragmentation with an enzyme linked immuno-sorbant assay (ELISA). Acute and repeated exposure regimens resulted in some lethality and decreased body weight gain. In contrast to previous studies involving subcutaneous and intraperitoneal administration of methylmercury, significant increases in TBARS were not observed. DNA fragmentation following acute administration of methylmercury chloride resulted in a suggested increase in apoptosis. These results may indicate that oral administration of methylmercury chloride does not induce lipid peroxidation. However, given the trends observed with DNA fragmentation, further studies concerning the time course and potential for methylmercury-induced apoptosis might be justified. (This abstract does not necessarily reflect EPA policy.)

560 DELAYED-TYPE HYPERSENSITIVITY TO SULFAMETHOXAZOLE IN MICE: ROLE OF METABOLITES.

N. Santolaria[1], G. Choquet-Kastylevsky[1], R. Tedone[2], M. Aujoulat[3] and J. Descotes[1]. [1]*Poison Center and INSERM U503, Lyon, France,* [2]*INSERM U503, Lyon, France and* [3]*Phœnix International Preclinical Services, L'Arbresle, France.*

Little is known of the mechanisms involved in delayed-type hypersensitivity (DTH) to drugs. The skin adverse effects of sulfamethoxazole (SMX) are probably immune mediated and caused by metabolites. A murine model combining *in vivo* and *in vitro* endpoints was used in an attempt to predict DTH reactions to SMX. Mice injected intra-dermally with SMX for 3 days were challenged at day 7 with SMX alone or incubated with a microsomal enzymic activation system (S9mix). No *in vivo* positive DTH responses were obtained using several mouse strains, varying SMX and S9mix dose levels, challenge sites, or phenobarbitone pretreatment. In contrast, the secondary proliferation of spleen cells *in vitro* from SMX- or SMX/S9mix-treated mice evidenced SMX-specific lymphocytes, which could be stimulated only after incubation of SMX with S9mix. As no proliferation was obtained after incubation with S9mix alone, a mitogenic effect or sensitization to microsomal proteins can be excluded. In addition, *in vitro* cell proliferation only occurred following prior metabolite production, whereas sensitization of mice was achieved after treatment with either SMX alone or SMX/S9mix. These results confirm the crucial role of metabolites in SMX hypersensitivity in mice as already shown in human patients. It remains to test whether similar ex vivo findings can be obtained in mice to predict DTH reactions to other medicinal products.

561 REACTIVITY OF T CELLS TO DRUGS AND THEIR METABOLITES.

C. Burkhart[1], B. Schnyder[1], S. von Greyerz[1], K. Schnyder-Frutig[1], D. J. Naisbitt[2], M. Pirmohamed[2], B. K. Park[2] and W. J. Pichler[1]. [1]*Inselspital, University of Bern, Bern, Switzerland and* [2]*University of Liverpool, Liverpool, United Kingdom.* Sponsor: F. Gerberick.

Drugs represent a group of low molecular weight non-peptide antigens which can be recognized by alpha beta TCR-positive T cells. Over the past years, specific T cell clones have been generated from patients allergic to the antibiotic sulfamethoxazole (SMX) suggesting an important role for T cells in the manifestation of drug hypersensitivity. Allergic reactions to SMX are usually thought to be a consequence of bioactivation to the hydroxylamine metabolite (SMX-NHOH) and further oxidation to the ultimative reactive metabolite, nitroso-sulfomethoxazole (SMX-NO). SMX-NO is then able to covalently modify self proteins which in turn might be recognized as neo-antigens by the immune system. Recent investigations, however, revealed additionally a MHC-restricted but processing- and metabolism-independent pathway of drug presentation. Antigen-presenting cells (APCs) preincubated with the drug over night and subsequently washed were not able to activate SMX-specific alpha beta TCR+ T cells. The drug could, however, be efficiently presented even by glutaraldehyde-fixed APC when it was continuously present in the culture. Moreover, T cell clones responded to non-covalently presented SMX by a rapid downregulation of their T cell receptors. These observations were best explained by a labile, low-affinity binding of SMX to MHC-peptide complexes on APCs and a processing-independent antigen presentation. In order to study the role of covalent versus non-covalent drug presentation in SMX-allergy, a) we analyzed whether T cells from allergic and non-allergic individuals react with SMX and the metabolites SMX-NO or SMX-NHOH; b) we generated T cell clones to SMX and the chemically reactive metabolites and investigated the crossreactivity in detail; and c) we assessed the kinetics of TCR downregulation in T cell clones crossreactive with SMX/SMX-NO. Our data indicate, that crossreactive T cells can be detected in and isolated from the peripheral T cell pool of drug-allergic individuals but that their appearance differ between individuals. The overall pattern of antigen-reactivity suggests that in SMX-hypersensitivity already the primary stimulation can be directed to the non-covalently bound SMX.

562 IMMUNOMODULATION BY MEDICINAL DRUGS ASSOCIATED WITH ANAPHYLAXIS IN HUMANS: SELECTIVE INDUCTION OF TH-2 RESPONSES DURING PRIMARY IMMUNE STIMULATION IN MICE.

D. E. Amacher, B. W. Gutting, R. Lariviere and L. W. Updyke. *Pfizer, Inc., Groton, CT.*

Hypersensitivity reactions involving the immune system may be the most frequent adverse effects associated with pharmaceutical agents. Anaphylaxis, immediate-type hypersensitivity, is a relatively rare adverse drug-reaction but is one of concern due to its potential severity. Current pre-clinical animal models have little value, if any, in predicting drug-induced anaphylaxis. Anaphylaxis is a type 2 IgE mediated reaction. In the mouse IgE production is regulated by the availability of IL-4, which is produced by Th-2 cells (T-helper cell type 2) and is antagonized by INFγ. This study was conducted in BALB/c mice and used the conjugate TNP-OVA (trinitrophenyl-ovalbumin) in the reporter antigen popliteal lymph node assay (RA-PLNA) to test the following hypothesis: pharmaceutical agents associated with anaphylaxis in humans produce a positive response in the RA-PLNA and selectively induce type 2 antibody (IgE and IgG_1) to TNP. The analgesic glafenine (GF), the NSAID zomepirac (ZO) (both withdrawn from the market due to anaphylaxis) and the NSAID diclofenac (DF), which is associated with anaphylaxis, were tested. Phenobarbital (PB) was used as a negative control, and streptozotocin, which selectively induces a type 1 (INFγ, IgG_{2a}) response in the TNP-OVA RA-PLNA, was used as an isotype control. GF, ZO, DF and STZ produced dose-dependent increases in the lymph node diameter and cellularity while PB failed to produce a response. The four immunostimulating compounds also significantly increased TNP-specific IgM production. However, GF, ZO and DF selectively induced IgE and IgG_1 TNP-antibody production while STZ selectively induced IgG_{2a}. Although it is unrealistic to suggest that one assay based on a limited number of test compounds can independently identify all drugs with the potential to induce anaphylaxis in humans, this study does suggest the mouse RA-PLNA should be further investigated.

562A PRIMARY AND SECONDARY IMMUNE RESPONSES TO THE NSAID DICLOFENAC IN BALB/C MICE: EVIDENCE FOR DRUG-SPECIFIC SENSITIZATION.

B. W. Gutting[1], L. W. Updyke[1], S. De Guise[2], R. Lariviere[1] and D. E. Amacher[1]. [1]*Pfizer, Inc., Groton, CT and* [2]*University of Connecticut, Department of Pathobiology, Storrs, CT.*

The NSAID diclofenac (DF) is associated with idiosyncratic hepatotoxicity and several distinct hypersensitivity reactions. The mechanism(s) are unknown but evidence suggests both cell-mediated and antibody-mediated immune effector systems may be involved. This suggests DF can haptenize protein *in vivo* and can be recognized as an immunogen/antigen. This study tested the hypothesis that a single dose of DF, unconjugated and administered without adjuvant, can sensitize BALB/c mice. It used the reporter antigen popliteal lymph node assay (RA-PLNA) with the conjugate TNP-Ficoll (trinitrophenyl-Ficoll) to characterize a DF primary and secondary immune response. The specificity of the secondary immune response was determined by injecting the irrelevant hapten D-Penicillamine (D-PEN). Following a footpad injection, the primary RA-PLNA reaction using DF produced a dose- and time-dependent increase in cellularity and was dominated by TNP-specific IgM antibody production on days 4-8 with minimal IgG (IgG_1, IgG_3, IgG_{2a} and IgG_{2b}) produced on days 5-8. Next, mice were divided into 2 groups and gavaged (1x) with either 1.0 mg DF or vehicle (ddH_2O). Then 21 days later all animals were injected with DF - TNP-Ficoll. Compared with vehicle treated controls, animals gavaged with DF produced a secondary response that was significantly increased both in magnitude on day 4 (based on cellularity and TNP-specific IgM production) and kinetics on day 4 (based on IgG_1 production). Additionally, the secondary response was dominated by IgG_1 and IgG_3 isotype production, relative to IgM, on day 7. In separate groups of animals, the oral dosing with DF or vehicle was repeated. Then 21 days later all groups were injected with D-PEN. Based on cellularity, IgM and IgG antibody production the RA-PLNA response to D-Pen on days 4 and 7 did not differ between treatment and control groups. These results suggest that a single

oral dose of DF can sensitize BALB/c mice. Additionally, this data demonstrates the potential of the mouse RA-PLNA in detecting drug-specific immunomodulation without the need to generate drug-conjugates or identify relevant *in vivo* carrier proteins.

563 CYTOKINE LEVELS AND CELL POPULATION CHANGES AS PREDICTIVE MEASURES OF IMMUNOSTIMULATORY EFFECTS OF PHOSPHOROTHIOATE OLIGONUCLEOTIDES (PS ODN) IN MICE.

K. M. Lemonidis, M. V. Templin, M. J. Graham and R. M. Crooke. *Isis Pharmaceuticals, Inc., Carlsbad, CA.*

Female B6C3F1 mice were used to develop more predictive measures for distinguishing between stimulatory and non-stimulatory PS ODNs. Previous estimates had been based on splenomegaly and *in vitro* B cell assays. In addition to spleen weight, serum cytokine levels, spleen cytokine mRNA levels, ODN concentrations in spleen, and splenocyte population identification were investigated. With a single iv dose of 20 mg/kg ISIS 12449 (high stimulator), spleen weights increased approximately 2-fold. Cytokines including MIP-1α, MIP-2, MCP-1, IL-10, IL-12, IFN-γ, IL-1β, IL-6, IL-1Ra, TNF-α/β, MIF, and RANTES were increased in serum or splenocyte mRNA. Relative numbers of macrophages and endothelial cells were increased; B and T cells were unaffected. In comparison, an equal dose of ISIS 12450 (low stimulator) had no effect on spleen weight, cytokines were unchanged for serum or mRNA, and spleen cell populations were similar to saline dosed mice. The concentration of ISIS 12449 in spleen, as determined by CGE analysis, was slightly greater at early time points (< 1h) but not at the later experimental time points (2 - 144 h). Thus, a stimulatory ODN induced a spectrum of cytokine and cell population changes consistent with non-specific systemic immune stimulation. These end points will provide a comparative baseline by which the immune stimulation of other ODNs can be assessed.

564 ANALYSIS OF IMMUNE-RELATED ADVERSE EVENTS ASSOCIATED WITH THERAPEUTIC USE OF DRUGS.

J. L. Weaver[1], A. de Saint-Denis[2], J. Swann[1], G. Armstrong[1] and K. L. Hastings[1]. [1]*Center for Drug Evaluation and Research, USFDA, Rockville, MD and* [2]*Universite Paris XI, Faculte de Pharmacie de Chatenay-Malabry, Paris, France.*

Immune-related adverse responses to therapeutic drugs make up approximately 10% of all adverse events reported to the FDA. Existing nonclinical assays appear to be poorly predictive of drug-induced immune-related systemic hypersensitivity. We extracted immune-related adverse event data from the FDA database and obtained usage data for up to the first five years of actual sales for ~380 drugs approved for marketing between 1978 and 1997. The selected drugs included only small, organic, single active ingredient formulations. Proteins, salts, metals, combination products and polymers were excluded. We calculated incidence of reported adverse events per million shipping units of drug. The data were then ranked by individual incidences and groups of related incidences. The incidence values ranged from over 1000 to 0 events per million units. Over 75% of reported adverse events were in two categories: rash and urticaria. The remaining events were mostly anaphylaxis, angioedema, Stevens-Johnson syndrome, photosensitivity, vasculitis, and eosinophilia. A plot of the ranked incidence values demonstrated a multi-exponential shape with <5% of the drugs being "highly positive". The data could be used to select drugs for evaluation of assays proposed to predict systemic drug allergy.

565 INVESTIGATION OF IMMUNOSTIMULATORY POTENTIAL WITH A MODIFIED MURINE POPLITEAL LYMPH NODE ASSAY.

J. Medina, P. Ulrich, A. Wolf, R. Kammermann and J. Streich. *Novartis Pharma AG, Basel, Switzerland.*

The suitability of a modified murine popliteal lymph node assay (PLNA) to investigate the immunostimulatory potential of test compounds was investigated. Groups of six female BALB/c mice received a s.c. injection of either Oxazolone (0.25%), D-Penicillamine (0.2, 2 and 20%), Carbamazepine (0.2, 2 and 10%), Procainamide (0.2, 2 and 20%), Procainamide (20%) + S-9 mix, or Diphenylhydantoin (3%), into the left foot pad. The popliteal lymph nodes (LN) draining the site of application were excised 5 days later (peak of response). The evaluation consisted of assessing LN weights and cell counts, LN macrophage activity and cell surface marker expression (CD4 T cells, CD8 T cells, B cells, antigen presenting cells and CD4 T cells with an enhanced expression of IL-2 receptor). The immunostimulatory substances induced LN hyperplasia (increased LN weights and cell counts), as well as an augmented macrophage activity (oxidative burst) upon PMA-restimulation *in vitro* in LN cell suspensions, reflecting the onset of an inflammatory process. The specificity of the immune responses was confirmed through the characterization of the immune cell activation pattern: an increased CD4 blastocytosis, as well as an upregulation of IL-2R expression on CD4 T cells could be observed. The monitorization of multiple endpoints in the present system represents an advantage with respect to the standard PLNA, which determines only LN cellularity: the specificity and the potential to identify weak immunostimulatory responses are enhanced. In conclusion, these results support the suitability of the modified PLNA to assess the immunostimulatory potential of test substances.

566 ALLERGENICITY OF HAZELNUT PROTEINS IN THE BROWN NORWAY RAT MODEL OF FOOD ALLERGY.

J. Laugée and C. Meredith. *TNO BIBRA International Ltd., Carshalton, United Kingdom.* Sponsor: B. G. Lake.

Food induced pollen-associated oral allergy syndrome (OAS) has become a well established clinical entity. At present there is limited information on the nature of food proteins responsible. We have employed the Brown Norway (BN) rat model of food allergy to study the potential of selected food allergen extracts to induce sensitization with the production of specific IgE. We have measured the potential of the same food extracts to induce mediator release in a mast cell surrogate (the rat basophil cell line RBL-2H3) when passively sensitised with specific rat IgE. RBL-2H3 cells were sensitised using an optimal dilution of sera (1:50) containing IgE raised in BN rats against hazelnut proteins. We found that sensitized cells respond to challenge with native hazelnut protein in a dose-dependent manner, releasing up to 75% of total β-hexosaminidase. Challenge with hazelnut protein heated for 40 min at 140°C also elicited a comparable response, suggesting that certain allergenic epitopes within hazelnut proteins can survive high temperature. Challenge with both birch pollen extract and purified Bet v1 also elicited a significant response, signifying cross reactivity between the hazelnut and birch pollen allergens, observations that were confirmed by inhibition immunoblotting studies. These results suggest that the BN rat model would be a suitable surrogate for man in the investigation of the sensitisation phase of OAS and that the RBL-2H3 cell line is suitable for studying cross reactivity of food protein allergens. (Supported by MAFF, UK and EU FAIR contract CT97-3224.)

567 EVALUATION OF HUMAN CONTACT ALLERGENS IN THE MURINE LOCAL LYMPH NODE ASSAY.

C. A. Ryan[1], G. F. Gerberick[1], L. W. Cruse[1], D. A. Basketter[2], L. J. Lea[2], L. Blaikie[2], R. J. Dearman[3], E. V. Warbrick[3] and I. Kimber[3]. ICCVAM (Interagency Coordinating Committee on the Validation of Alternative Methods) has recently endorsed the murine local lymph node assay (LLNA) as a stand-alone method for skin sensitization hazard identification. The investigations described here were designed to explore further the ability of the LLNA to identify accurately those chemicals that cause allergic contact dermatitis in humans. To that end we have measured, in three laboratories, LLNA responses induced by 18 test chemicals, 11 of which are known to cause skin sensitization and 7 of which are not associated to a significant extent with allergic contact dermatitis in humans. Three concentrations of each material were tested and were chosen to provide the highest possible concentration based on either solubility in the selected vehicle or lack of systemic toxicity. The LLNA correctly classified 16 of the 18 materials. All of the 11 chemicals tested which are associated with allergic contact dermatitis in humans were found to be positive in the LLNA. Of the seven materials believed to be non-sensitizers, five were negative in the LLNA and two elicited weakly positive results at relatively high test concentrations (50 and 100%). In a comparison of the LLNA and human classification with this data set, the LLNA was found to have an accuracy of prediction of 89%. This is consistent with the 72% accuracy derived by ICCVAM in their independent analysis of the performance of the LLNA using a data set of 74 chemicals. Collectively these data provide additional evidence that the LLNA is able to discriminate skin sensitizers from those chemicals which do not possess a significant skin sensitization potential and thus provides a stand-alone method for hazard identification that offers important animal welfare benefits.

568 PREDICTING THE SKIN SENSITIZING POTENTIAL OF PHARMACEUTICALS AND PHARMACEUTICAL INTERMEDIATES USING THE LOCAL LYMPH NODE ASSAY.

T. A. Kimmel[1], F. J. Guerriero[2], C. W. Seaman[3], S. J. Binks[4], J. E. Billitti[5] and R. G. Sussman[1]. [1]*Warner-Lambert Company, Morris Plains, NJ,* [2]*SmithKline Beecham, King of Prussia, PA,* [3]*SmithKline Beecham, Welwyn, United Kingdom,* [4]*GlaxoWellcome Research and Development Ltd., Ware, United Kingdom and* [5]*Agouron Pharmaceuticals, Inc., San Diego, CA.*

The murine Local Lymph Node Assay (LLNA) was recently recommended by a US interagency peer review panel for regulatory acceptance as a stand-alone alternative to guinea pig skin sensitization tests. The purpose of this collaborative study was to evaluate more extensively the performance of the LLNA, as a predictor of the skin sensitization potential of pharmaceuticals and pharmaceutical intermediates. Over 65 compounds belonging to highly diverse chemical classes were tested using both the LLNA and a guinea pig test method, and the results were compared for each compound. LLNA performance was also compared with compound molecular weight (MW), as well as with the choice of vehicle used in the assay. For most compounds, the presence or absence of positive structural alerts for skin sensitization, as identified by a commercially-available SAR modeling program, was investigated. Overall, the LLNA did not demonstrate strong agreement with either guinea pig test, due to a high incidence of false negative results. No overt relationships were observed between LLNA performance and either MW or vehicle, and no key structural alerts were identified. The results suggest that the LLNA might not be effective as a stand-alone alternative to guinea pig test methods, particularly when used to predict the skin sensitizing potential of pharmaceuticals and pharmaceutical intermediates. Further investigation is recommended in order to evaluate this assay for use in the pharmaceutical industry.

569 UTILITY OF THE LLNA FOR THE INVESTIGATION OF THE IMPACT OF VEHICLE MATRIX ON SKIN SENSITIZATION POTENCY.

L. Blaikie[1], D. A. Basketter[1], E. V. Warbrick[2], R. J. Dearman[2] and I. Kimber[2]. [1]*SEAC Toxicology Unit, Unilever Research Colworth, Sharnbrook, United Kingdom and* [2]*AstraZeneca Central Toxicology Laboratory, Macclesfield, United Kingdom.*

The identification of chemicals with contact allergenic activity is often followed by estimation of the potency of that hazard, so that a risk assessment for a defined use situation can be made. However, methods for quantitative assessment of skin sensitizing potency are not widely available. Recently, it has been proposed that the murine local lymph node assay (LLNA) may provide such information via interpolation of dose response information to give an estimate of the quantity of a chemical necessary to generate a threshold positive response (the EC3 value). It is recognized that the perceived potency of a chemical sensitizer may be influenced to a considerable degree by the vehicle matrix/formulation in which skin exposure occurs. Using the LLNA, EC3 values can be used to assess the impact of vehicle upon sensitizing potency. Dihydroquinone (HQ), ethyleneglycol dimethacrylate (EGDMA), dibromodicyanobutane, cinnamic aldehyde, isoeugenol, dimethylaminopropylamine and chloromethylisothiazolinone (CMI) were tested in the standard range of vehicles proposed for the LLNA (acetone/olive oil [4/1 v/v], dimethyl formamide, methylethylketone, propylene glycol and dimethylsulfoxide). The results revealed substantial vehicle related variations in potency; eg EC3 values for HQ ranged from 0.08%->1.0%; for EGDMA the range was 15%-36%; for CMI the range was 0.0049%-0.048%. Chemical dependent effects of vehicle on potency were observed. In summary, these results demonstrate that the matrix in which a chemical contacts skin can have a substantial impact on its sensitization potential. This effect can be quantitated successfully by estimation of the EC3 value in the LLNA.

570 QUANTITATIVE ESTIMATION OF SKIN SENSITIZING POTENCY USING THE LOCAL LYMPH NODE ASSAY.

D. A. Basketter[1], L. Blaikie[1], C. A. Ryan[2], G. F. Gerberick[2], R. J. Dearman[3] and I. Kimber[3]. [1]*SEAC Toxicology Unit, Unilever Research Colworth, Sharnbrook, United Kingdom,* [2]*Procter & Gamble, Cincinnati, OH and* [3]*AstraZeneca Central Toxicology Laboratory, Macclesfield, United Kingdom.*

Risk assessment in skin sensitization demands that information on the relative potency of the chemical under evaluation is available. Until recently, this has been assessed only in a qualitative or semi-quantitative manner using guinea pig data and/or limited information from predictive human testing. The development of the murine local lymph node assay (LLNA) has afforded an opportunity to derive a quantitative estimate of sensitizing potency via a mathematical interpolation of dose response data. In this way, the concentration of a test chemical necessary to stimulate a 3-fold increase in activity in lymph nodes draining the site of chemical application is obtained; the EC3 value. This parameter has been calculated for a range of substances and compared with what is understood of the relative sensitizing activity of these chemicals in humans. Twenty chemicals were placed into 5 categories on the basis of their human sensitizing potency. LLNA dose response data for these chemicals (in a standard vehicle) were used to derive EC3 values. The strongest 4 allergens (Class 1) had EC3 values in the region of 0.001%-0.01%, while for the weakest 8 allergens, EC3 values were typically >25%. The LLNA provided a rank order comparable to that in humans. All the strongest sensitizers and non-sensitizers were identified correctly. Of the remaining 8 chemicals with significant sensitizing activity, the LLNA assessment of relative potency was of the correct order for 7 when an EC3 value of 10% was used to distinguish between Classes 2 and 3. As expected, the LLNA was not able to assign a potency estimate for the weakest sensitizers (Class 4). In conclusion, derivation of an EC3 value for a skin sensitizer may provide an objective and quantitative estimate of its relative potency.

571 PRIMARY EAR IRRITATION AND LYMPH NODE HYPERPLASIA INDUCED BY CONTACT ALLERGENS AND IRRITANTS IN THE MURINE LOCAL LYMPH NODE ASSAY.

J. Bluemel[1], P. Ulrich[2], J. Streich[2], M. Buchs[2] and H. W. Vohr[1]. [1]*Bayer AG, Wuppertal, Germany and* [2]*Novartis Pharma AG, Basel, Switzerland.*
Sponsor: A. Wolf.

To improve the predictive differentiation of contact allergy (CA) and photoallergy (CPA) from irritancy (IR) and photoirritancy (PI), induced by low molecular weight compounds, we established a murine local lymph node assay (LLNA) with two endpoints in different tissues: ear-draining lymph node (LN) hyperplasia and primary ear irritation. Groups of female BALB/c or NMRI mice received compound solution or vehicle (40% Dimethylacetamid, 30% Acetone, 30% Ethanol) alone on the dorsum of both ears on three consecutive days. Immediately after compound application indicated groups of mice were exposed to a UVA light-dose of 10J/cm². Ear swelling was determined before treatment and immediately before necropsy. Weights of the apical area (0.5 cm²) of the right ear as well weights and cell counts of the auricular lymph nodes draining the ear tissue were determined at necropsy 24 hr following the last exposure. Tested chemicals were oxazolone, dinitrochlorobenzene, dinitrofluorobenzene, eugenol, isoeugenol, mercaptobenzothiazol as CA, tetrachlorosalicylanilide, chlorpromazine as CPA, croton oil, sodium dodecyl sulfate as IR and 8-methoxypsoralen as well as anthracene as PI. The principle findings of this study were: (I) both CA and CPA as well as IR and PI induce hyperplasia of draining LN, (II) irritants predominantly induce skin irritation, which in turn increases draining LN hyperplasia, (III) some CA and CPA induce only marginal skin irritation, but a vigorous LN hyperplasia. The ratio of relative increases in ear thickness/weight and LN hyperplasia were used to differentiate between (photo)allergic and (photo)irritant reactions (IMDS: integrated model for the differentiation of chemical-induced allergic and irritant skin reactions). A ratio fare above 1, obtained with a certain concentration of the test chemical, indicate a (photo)allergic reaction, whereas a ratio below 1 points to (photo)irritation. Values around 1 indicate that the test chemical is likely to possess both considerable irritative and allergenic potential and, thus has to be evaluated in further testing. Our results show that this model contributes to the differentiation of CP/CPA from IR/PI by investigating simple endpoints in a short study conduct.

572 ROLE OF GLUTATHIONE IN CONTACT SENSITIZATION: APPLICATION OF A FLOW CYTOMETRY-BASED LOCAL LYMPH NODE ASSAY.

E. J. Yurkow, D. R. Cerven, D. Hall, K. B. Graver, T. Hoff and G. L. DeGeorge. *MB Research Laboratories, Spinnerstown, PA.*

The Local Lymph Node Assay (LLNA) is an animal-based test employed throughout the cosmetic and pharmaceutical industries to screen and characterize the immunotoxic properties of chemicals. Although the LLNA is effective at detecting chemical irritants and sensitizers, it has limited discriminating power to differentiate distinct subclasses of sensitizing agents (i.e., irritants vs. contact allergens). To improve the specificity and sensitivity of this important screening test, we have applied flow cytometry to the standard assay. Using this modified LLNA, we examined the role of glutathione levels in the induction of contact sensitization. In these studies, dinitrochloroben-

zene (DNCB, a known sensitizer), Vitamin E or vehicle were applied to the dorsum of both ears of mice for three consecutive days. Subsets of each treatment group were co-treated without or with the glutathione synthesis inhibitor, buthionine sulfoximine (BSO), dosed in the drinking water. Prior to sacrifice the mice were injected with bromodeoxyuridine (BrdU, i.p.) and the number of proliferating (BrdU-positive) cells of the auricular lymph nodes was determined using flow cytometry. Both DNCB and Vitamin E were found to induce lymphocyte proliferation (> 3 fold over vehicle control) and thus were positive as sensitizers in this modified LLNA. These agents were also found to increase cellular levels of reduced glutathione in the epidermal keratinocytes of mouse skin. BSO was found to dramatically inhibit agent-induced increases in cellular glutathione as determined using flow cytometry and the (fluorescent) glutathione-specific dye, monochlorobimane. Interestingly, the ability of these sensitizers to induce proliferation of lymphocytes was dramatically inhibited by treatment with BSO, and both DNCB and Vitamin E failed to function as sensitizers in BSO-treated mice. Results of these studies indicate that cellular levels of reduced glutathione may play a critical role during the induction phase of contact sensitization.

573 UTILIZATION OF SAR AND THE MURINE LOCAL LYMPH NODE ASSAY (LLNA) TO ASSESS THE SENSITIZATION POTENTIAL OF HAIR COLORANTS.

R. S. Grabarz[1], W. E. Dressler[1], O. T. Macina[2] and R. K. Sharma[1]. [1]*Bristol-Myers Squibb Worldwide Beauty Care Group Research and Development, Stamford, CT and* [2]*Dept. of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

Both oxidative (permanent) and direct (semi-permanent) dyes have an acknowledged potential to cause contact sensitization, however, this is regarded as a manageable health issue for the general population. The use of computational toxicology and the local lymph node assay (LLNA) allows us to evaluate the sensitization potential of new dye candidates "upstream" of the more traditional guinea pig assays (i.e., Buehler or GPMT methods). A number of aromatic/nitro-aromatic amines used commercially as oxidative or direct hair dyes were evaluated for allergic contact sensitization potential using the LLNA. Test materials included 10 direct and 2 oxidative dyes. The application vehicle for all materials was dimethyl sulphoxide (DMSO). Relative potency was compared to para-phenylenediamine, a more relevant although less potent allergen as compared to other OECD recommended positive controls, such as 2,4-dinitrochlorobenzene (DNCB), oxazolone, or hexyl-cinnamic aldehyde (HCA). Using a Computer Automated Structure Evaluation (CASE/MultiCASE) customized database constructed of aromatic and nitro-aromatic amines, SAR predictions and LLNA data were compared with historical data obtained with traditional guinea pig methods. In addition, the data generated from the LLNA was also used to derive a quantitative SAR model for predicting sensitization. When comparing actual LLNA and guinea pig data, an overall concordance of 77% (10/13) was achieved. Sensitivity and specificity were 92% (12/13) and 85% (11/13) respectively. These results indicate the LLNA may be successfully used to evaluate the contact sensitization potential of new and existing hair colorants.

574 A TWO-TIERED MURINE LOCAL LYMPH NODE ASSAY TO IDENTIFY CONTACT (PHOTO)ALLERGENIC POTENTIAL.

P. Ulrich[1], J. Bluemel[2], J. Streich[1], M. Buchs[1] and H. W. Vohr[2]. [1]*Novartis Pharma AG, Basel, Switzerland and* [2]*Bayer AG, Wuppertal, Germany.*
Sponsor: A. Wolf.

To improve the predictive differentiation of contact allergy (CA) and photoallergy (CPA) from irritancy (IR) and photoirritancy (PI), induced by low molecular weight compounds, we developed a non-radioactive, two-tiered protocol of the murine local lymph node assay (LLNA). Tier I testing covering a broad concentration range of the test chemical consists of two endpoints: primary ear skin irritation and lymph node (LN) hyperplasia. The ratio of the relative changes in the ear-draining LN and in the ear skin provides information about the preferential mode of action the tested chemical. A ratio fare above 1, obtained with a certain concentration of the test chemical, indicate a (photo)allergic reaction, whereas a ratio below 1 points to (photo)irritation. Values around 1 indicate that the test chemical is likely to possess both considerable irritative and allergenic potential and, thus has to be evaluated in a tier II test schedule. For tier II testing mice were sensitised with selected tier I concentrations of chemicals or treated with vehicle (40% Dimethylacetamid, 30% Acetone, 30% Ethanol) on the shaved back on 3 consecutive days with subsequent UVA exposure in case of CPA and PI studies. Challenge was performed 12 days later on the ears on 3 consecutive days in order to reveal a possible allergy-related increase in ear swelling and ear weight as well as to investigate the expression of relevant cytokines at two stages of the evolution of an allergic response, the induction and the challenge phase. Tested chemicals were oxazolone, dinitrochlorobenzene, dinitrofluorobenzene, eugenol, isoeugenol as CA, tetrachlorosalicylanilide, chlorpromazine as CPA, croton oil as IR and 8-methoxypsoralen as well as anthracene as PI. Exclusively in case of CA and CPA, allergy-related ear swelling and ear weight increase as well as a marked increase in IL-4 and IL-10 expression by ex vivo restimulated LN CD4 T cells was observed in the challenge groups. These results were in line with the finding of high ratios between LN hyperplasia and primary skin irritation. Ratios around 1, which do not precisely indicate the mode of action of a chemical - CA/CPA or IR/PI, can occurr at high concentrations of chemicals with CA/CPA potential, but also with compounds like croton oil consisting of different ingredients. One of these ingredients of croton oil are phorbol esters affecting lymphocytes in a non-specific manner, and thus, causing LN hyperplasia. Especially in the latter case tier II testing provided the necessary information to predict or deny a CA or CPA potential.

575 ASSESSMENT OF THE SUBCUTANEOUS ROUTE OF TEST ARTICLE ADMINISTRATION USING THE MOUSE LOCAL LYMPH NODE ASSAY.

B. A. Olenchock[1], K. P. Baran[2] and B. J. Meade[1]. [1]*National Institute of Occupational Safety and Health, Morgantown, WV and* [2]*3M Corporation, St. Paul, MN.*

The mouse local lymph node assay (LLNA) measures lymphocyte proliferation in draining lymph nodes of mice after topical application of a test material to the intact, non-occluded skin of both ears. There is a need to develop methods to evaluate the sensitization potential of chemicals and/or materials that are implanted or injected into the body (e.g. drugs, implanted medical devices, biologics), for which topical application in not a relevant route. In addition, it is important to distinguish between IgE mediated and cell mediated sensitizers. To evaluate the sensitization potential of implanted/injected materials, the LLNA was conducted using the subcutaneous route rather than the topical route. Two irritants (sodium lauryl sulfate (SLS), nonanoic acid), a T-cell mediated sensitizer (oxazolone), and a protein that is foreign to the mouse (human albumin) were evaluated using the subcutaneous route of administration. An IgE-mediated sensitizer (toluene diisocyanate; TDI) and a T-cell mediated sensitizer (DNFB) were used as positive controls. The irritant nonanoic acid did not induce lymphocyte proliferation compared to the vehicle control group. However, as seen with topical administration, SLS induced low level, significant lymph node cell proliferation at the two highest concentrations. Oxazolone and human albumin caused a significant concentration-dependent increase in lymphocyte proliferation versus the vehicle control. Both DNFB and TDI were associated with significant lymphocyte proliferation compared to the vehicle control. Phenotypic analysis conducted for groups of mice treated subcutaneously with vehicle (polyvinyl pyrrolidone; PVP), nonanoic acid, oxazolone, DNFB and TDI revealed a significant increases in the percent B220+ lymphocytes for the oxazolone, DNFB and TDI groups, whereas the nonanoic acid group was similar to the control. The percent IgE+B220+ lymphocytes increased from least to greatest in the oxazolone, DNFB and TDI groups, respectively whereas the nonanoic acid group was similar to the vehicle control group. TDI was associated with a 2-8 fold increase in the percent IgE+B220+ lymphocytes as compared to oxazolone or DNFB.

576 ASSESSMENT OF A MODIFIED LOCAL LYMPH NODE ASSAY TO EVALUATE THE IRRITANCY/SENSITIZATION POTENTIAL OF CHEMICALS EXPOSED TO BREACHED SKIN.

H. L. Glass[1], K. P. Baran[2] and B. J. Meade[1]. [1]*National Institute for Occupational Safety and Health, Morgantown, WV and* [2]*3M Corporation, St. Paul, MN.*

There is a need to develop methods to evaluate the sensitization potential of chemicals and/or materials that contact breached skin (e.g. polymeric tissue adhesives, wound dressings, occupational exposure to chemicals through wounded or irritated skin). For this purpose a modified local lymph node assay (LLNA) was conducted using standardized methods for breaching the skin at the dose application site. Female BALB/C mice were exposed for three consecutive days on the ear to vehicle (.9% sterile saline) or a foreign protein (25% human albumin) via the topical route, breached skin route utilizing either a Simplate (Organon Teknika, Corp., Durham, NC) or a Multi-Test (Lincoln Diagnostics, Inc., Decatur, IL) device, or injected in the subcutaneous tissue between the ears. In order to investigate the potential for enhanced sensitivity of the assay by occlusion, for each test condition

(excluding the subcutaneous group) the exposure site was occluded using Blenderm (3M Corp., St. Paul, MN) tape in one group of animals and left unoccluded in a second group. Two days following the final exposure animals were injected intravenously with 3H thymidine, sacrificed five hours later and the draining lymph nodes excised and processed as for a standard LLNA. When unoccluded, no difference in proliferation occurred following topical application to intact skin. However, an increased proliferative response (>5 fold) was seen following both methods of breached skin with no significant differences between methods. With occlusion, exposure by all routes induced significant proliferation, however breaching with the Multi-Test device induced significantly higher (>3 fold over topical and >2 fold over Simplate) proliferation than by the other routes and induced proliferation similar to that observed following subcutaneous administration. Results indicate that the Multi-Test may provide a useful method for breaching the skin in testing compounds where exposure is anticipated to occur to compromised skin.

577 DERMAL SENSITIZATION EVALUATION OF MALEIC ANHYDRIDE AND SUBSEQUENT REACTION MATERIALS USED IN THE DEVELOPMENT OF A NOVEL SYNTHETIC FIBER.

S. M. Glaza[1], R. W. Kapp, Jr.[2] and D. E. Strother[3]. [1]*Covance Laboratories Inc., Madison, WI,* [2]*BioTox, Richmond, VA and* [3]*BP Amoco Chemicals Inc., Arlington, VA.*

Maleic anhydride is a highly reactive chemical intermediate that has widespread use in the manufacture of polyester resins in the textile industry. The irritation properties of this material are well known, however the dermal sensitization potential has not been well documented. As part of a worker safety monitoring program, the dermal sensitization potential of maleic anhydride and that of several downstream synthesis materials used in the manufacture of a novel high nitrile content fiber were evaluated in a series of guinea pig dermal sensitization studies utilizing a standard closed-patch test method. Rechallenge techniques were used to selectively determine cross-reactivity between materials. The starting reaction material, maleic anhydride, was shown to be a dermal sensitizer. Reaction products of maleic anhydride and alcohols used as a stabilizer in the polymer formulation were also determined to be dermal sensitizers. The latex precursor of the novel high nitrile content polymer (before final stripping and addition of the maleate stabilizing agent) was also determined to be a weak dermal sensitizer. The polymer products (raw polymer with stabilizer prior to pellet formation, in pellet form, and in spun fiber form) were all shown to be non-sensitizers. Rechallenge applications determined that 1) animals previously sensitized to maleic anhydride were not cross-reactive to the maleate polymer stabilizer; 2) animals previously sensitized to the maleate polymer stabilizer were not cross-reactive to the final polymer; and 3) animals sensitized to the high nitrile polymer prior to addition of the maleate stabilizer were not cross-reactive to the raw polymer (with stabilizer prior to pelleting). Animals that had been previously sensitized to the stabilizer had equivocal responses when rechallenged with the raw polymer (with stabilizer prior to pelleting) indicating potential cross-reactivity. We conclude that maleic anhydride, the reaction product of maleic anhydride and alcohols and the raw nitrile polymer latex are dermal sensitizers, but no evidence of sensitization potential by the finished polymer was detected in these assays.

578 TOPICAL EXPOSURE OF MICE TO RESPIRATORY SENSITIZING ACID ANHYDRIDES STIMULATES THE EXPRESSION OF INTERLEUKIN 5.

I. R. Humphreys, R. J. Dearman and I. Kimber. *AstraZeneca Central Toxicology Laboratory, Macclesfield, United Kingdom.*

We have shown previously that prolonged topical exposure of BALB/c strain mice to chemical contact or respiratory allergens such as 2,4-dinitrochlorobenzene (DNCB) or trimellitic anhydride (TMA) elicits cytokine secretion patterns consistent with the selective activation of type 1 and type 2 T lymphocytes, respectively. Certain respiratory sensitizing acid anhydrides including phthalic anhydride (PA) and maleic anhydride (MA) stimulate comparable levels of the type 2 cytokine interleukin (IL)-10 to those provoked by TMA, but induce somewhat lower levels of the type 2 product IL-4. We have therefore examined the production by allergen-activated lymph node cells (LNC) of IL-5, a type 2 cytokine which plays an important role in the differentiation and recruitment of eosinophils. Exposure to TMA, PA or MA resulted in each case in the expression by LNC of relatively high levels of IL-5, with peak production ranging from 50 to 200pg/ml. In contrast, LNC derived from DNCB-treated animals failed to elaborate detectable amounts of this cytokine (<20pg/ml) under conditions where vigorous secretion of the type 1 cytokine interferon γ was observed. Furthermore, negative selection (by complement depletion) of $CD4^+$ or $CD8^+$ lymphocytes revealed that $CD4^+$ T helper (Th) 2 type cells were the exclusive source of IL-5, in addition to the other type 2 cytokines. These data demonstrate that exposure to respiratory sensitizing acid anhydrides activates predominantly Th2 type cells, resulting in the expression of IL-5, which presumably plays a central role in the lung eosinophilia which is a key feature of chemical respiratory allergy.

579 CYTOKINES FROM BRONCHOALVEOLAR LAVAGES AND THEIR *IN VITRO* PRODUCTIONS IN ASTHMATIC RATS INDUCED BY TOLUENE DIISOCYANATE.

K. Zheng[2], M. Ariizumi[1], H. Todoriki[2], D. Nong[2], T. Morioka[3] and H. Yamamoto[1]. [1]*University of the Ryukyus School of Medicine Department of Preventive Medicine, Nishihara, Japan,* [2]*University of the Ryukyus School of Medicine Department of Otorhinolaryngology, Nishihara, Japan and* [3]*University of the Ryukyus School of Medicine First Department of Pathology, Nishihara, Japan.* Sponsor: T. Yoshida.

To investigate the status and the role of cytokines in occupational asthma induced by toluene diisocyanate (TDI), we carried out a quantitative determination of cytokine profiles from bronchalveolar lavages (BAL) and their *in vitro* productions, as well as from splenocytes and sera in an asthmatic murine model induced by TDI. Male rats were sensitized with two courses of intranasal application of 5% TDI in ethyl acetate for seven consecutive days each time separated by a one week rest. The control group of rats were similarly treated with vehicle. A week after second sensitization, both groups of rats were provoked by applying 2.5% of TDI in vehicle. BAL fluids and sera from all rats were collected, and BAL-adherent cells and splenocytes were cultured for determination the levels of IL-2, IL-4, IL-5 and IFN-r. After lavation, the lungs were intratracheally fixed and removed for histologic examination. Differential cell counts were performed on BAL fluids and peripheral bloods. The results showed that the TDI-sensitized group of rats exhibited the asthmatic symptoms. TDI exposure resulted in elevated IL-4, IL-6 in BAL fluids, IL-4, IL-6 and IFN-r in BAL-adherent cells and splenocytes, and IL-6 in sera. A marked infiltration of the peribronchial regions with eosinophils was observed in lung sections from TDI-exposed rats. The cell counts revealed that the increases of the numbers of neutrophils and eosinophils were found in BAL fluids and peripheral bloods from asthmatic rats. These findings indicate that IL-4, IL-6 and IFN-r may play an important role in the pathogenesis of TDI-induced occupational allergic asthma.

580 CYTOKINE REGULATION OF T CELL DIFFERENTIATION AND ANTIBODY ISOTYPE PRODUCTION IN A MOUSE MODEL OF OVALBUMIN SENSITIZATION.

G. W. Lulham. *ClinTrials BioResearch Ltd., Senneville, Quebec, Canada.*

A mouse model featuring key components of human allergic asthma, including eosinophil recruitment into airwalls and Th2 pathway predominant antibody production has been validated. Intraperitoneal sensitization to ovalbumin followed by inhalation challenge resulted in eosinophil infiltration into peribronchial regions of the lung at 48h post-challenge. Levels of Th2 pathway antibodies (IgE, IgG1 and anti-ovalbumin antibodies AntiOVS IgE and AntiOVS IgG1) increased following sensitization, or sensitization and challenge, while Th1 pathway antibodies (IgG2a/b and anti-ovalbumin antibody AntiOVA IgG2a/b) were unchanged. This pattern of cellular and humoral change is characteristic of Th2 cell predominance leading to release of cytokines which are chemoattractant to eosinophils and stimulate B-cell switching to IgE and IgG1 isotype production.Preventive treatment of naïve mice with IFNy, Anti IL 4 (low and high doses), Anti IL 5 (low and high doses), or IL 12 (low and high doses) was performed both before the sensitization injections and before the ovalbumin aerosol challenge, to examine their preventive effect on Th2-cell pathway commitment caused by sensitization. Anti IL 5 significantly decreased peribronchial eosinophil infiltration at 12 and 48h post aerosol challenge, however it had no effect on altering antibody production even when given before sensitization. Both IFNy and Anti IL 4 pretreatment had little effect on preventing inflammatory eosinophil infiltration following aerosol challenge, but caused a dose-related switching of T-cell differentiation away from Th2 predominant B-cell AntiOVA IgE production to Th1 predominant B-cell AntiOVA IgG2a/b production. IL 12 treatment before sensitization caused both a consistent trend to decreased eosinophil infiltration and a dose-related B-cell isotype switching from AntiOVA IgE to AntiOVA IgG2a/b.In conclusion, it appears that IFNy, Anti IL 4 and IL 12, when given preventively before antigen exposure, can regulate the direction of T-cell differentiation and B-cell antibody isotype production from Th2 predominance to Th1 predominance. IL 12 appears to have additional benefit in

amelioration inflammatory cell infiltration when given preventively before sensitization. These cytokines or anti-cytokine antibodies therefore are potentially strong tools to modify cellular events and/or alter the direction of immune-mediated responses in allergic asthma.

581 THE ROLE OF TUMOR NECROSIS FACTOR (TNF) IN AIRWAY REACTIVITY TO TOLUENE DIISOCYANATE (TDI).

J. M. Matheson[1], R. W. Lange[2], R. Lemus[3], M. H. Karol[3] and M. I. Luster[1]. [1]*NIOSH, Morgantown, WV,* [2]*3M Pharmaceuticals, St. Paul, MN and* [3]*University of Pittsburgh, Pittsburgh, PA.*

Nearly 9 million workers are exposed to chemical agents associated with asthma; and, isocyanates represent the most common cause of occupationally-induced asthma. We hypothesize that inflammation is a pre-requisite of TDI-induced asthma and that the regulation of this inflammation by TNF is important in isocyanate-asthma development. To explore this hypothesis, TNF receptor knockout (TNFR) and anti-TNF (x-TNF) treated C57BL/6J mice were sensitized (s.c., 20µl, Day 1), boosted (s.c., 5µl, Days 4 and 11), and challenged (inhalation, 100ppb, Days 21, 23 and 25) with TDI (80:20, 2,4:2,6 TDI). Twenty-four hours following the last challenge, non-specific airway reactivity to methacholine challenge was reduced to baseline levels in x-TNF treated mice. Serum titers of TDI-specific IgG antibody were significantly reduced in TNFR and x-TNF mice compared to exposed wild-type mice and these antibodies were primarily of the IgG_1 isotype. Airway inflammation, goblet metaplasia and epithelial damage were reduced in the TNFR and x-TNF treated mice. In addition, x-TNF treatment modulated IL-4 and IFNγ message levels in airway tissues, while significantly decreasing TNF, IL-4 and IFNγ levels in splenic supernatants. Furthermore, TNF neutralization markedly reduced the number of FITC containing cells in local draining lymph nodes in an intratracheal instillation model. These results suggest that TNF plays a role in the airway inflammatory response to an irritant such as TDI and that one of the controlling steps may be modulation of the migration of antigen presenting cells to the local lymph node.

582 FURTHER EXPERIENCE WITH THE ASSESSMENT OF THE RESPIRATORY SENSITIZING POTENTIAL OF PROTEINS USING THE MOUSE INTRANASAL TEST.

R. W. R. Crevel[1], L. Blaikie[1], D. A. Basketter[1] and K. L. White[2]. [1]*SEAC Toxicology Unit, Unilever Research Colworth, Sharnbrook, United Kingdom and* [2]*Medical College of Virginia, Richmond, VA.*

Certain proteins are capable of driving the immune system to form antigen specific immunoglobulin E (IgE) as part of a type-I hypersensitivity response. Thus if such proteins become airborne they can act as human respiratory allergens. Toxicologists have used a variety of protocols to model the relative ability of different proteins to induce respiratory sensitisation. The mouse intranasal test (MINT) has been proposed recently as an alternative to the hisorical guinea pig models, which although producing results predictive for man suffer from a number of limitations. The MINT has proven quite robust in interlaboratory evaluation of a positive control allergen (Alcalase) and a number of other proteins. However, it has been our experience that this method has produced estimates of relative sensitizing potency, compared to Alcalase, which in some instances have been substantially different to those assessed in the guinea pig. Proteins demonstrated to be approximately an order of magnitude more potent than Alcalase in guinea pig models have proven less allergenic than Alcalase in the MINT. Further MINT evaluation of a number of proteins in another laboratory has confirmed the differential between the guinea pig and mouse models for some proteins. The present studies have therefore provided additional data indicating that the MINT has limitations as a reliable predictive tool for the assessment of relative respiratory sensitizing potency and thus requires further evaluation. In particular, discrepancies in the potency assessments mean that occupational exposure guidelines established on the basis of MINT data may be flawed.

583 ALLERGIC INFLAMMATION AND ENZYME SPECIFIC IGG1, IGE ANTIBODY TO VARIOUS ENZYMES IN THE MOUSE INTRANASAL TEST (MINT).

J. S. Parris[1], E. D. Clark[1], A. S. Fix[1], K. Sarlo[1], J. A. McCay[2], V. L. Peachee[2], Y. L. Veloso[2] and K. L. White, Jr.[2]. [1]*The Procter and Gamble Company, Cincinnati, OH and* [2]*ImmunoTox, Inc., Richmond, VA.*

The MINT has been proposed for use for the assessment of immunogenic potential of enzymes. BDF1 mice receive an intranasal dose of enzyme protein on days 1, 3, 10 with serology on day 15. IgG1 antibody (AB) response to several enzymes has been well characterized in this model. IgG1 has been used as a surrogate marker for IgE antibody. The goal of the present work was to characterize allergic inflammation, IgG1 and IgE AB after exposure to various enzyme allergens following an extended dose schedule. Mice were exposed to Alcalase, Savinase, Termamyl and an endocellulase in detergent matrix on days 1, 3, 10, 17 and 24. Sera and nasal tissue were collected on day 29. Since exposure guidelines exist for Alcalase, this enzyme was used as the reference in all studies. From the IgG1 antibody response, endocellulase and Termamyl were estimated to be 3.8x to ~5x more potent than Alcalase. This is consistent with the potency estimates made from the regular dose regimen (Robinson, 1998 ToxSci, 43:39). Savinase and Alcalase were considered equipotent following both dose regimens. A dose-dependent increase in eosinophil infiltrate was noted in the nasal tissue of animals exposed to the enzymes. The infiltrates were noted in the front, mid and posterior sections of the nasal cavity. Mild eosinophilia was noted in the nasal cavity of control animals (detergent matrix). Enzyme specific IgE AB was detected by the rat passive cutaneous anaphylaxis test. IgE antibody to Termamyl was present at protein doses that did not induce IgG1 or IgE antibody to Alcalase or Savinase. The IgE antibody response to endocellulase was greater than the IgE antibody response to Alcalase. Based on the IgE antibody response, Termamyl and endocellulase were judged to be more potent than Alcalase. Therefore, the IgE and IgG1 responses were consistent in their ability to rank enzymes as more potent than Alcalase. These data support the use of IgG1 antibody as a surrogate marker for IgE when making immunogenic or allergenic assessments of enzymes in the MINT.

584 ASPIRATION (ASP) *VS.* INTRANASAL (IN) INSTILLATION LEAD TO COMPARABLE IMMUNE RESPONSES TO ALCALASE IN BDF1 MICE.

E. D. Clark, J. S. Parris, P. A. Horn, M. K. Robinson and K. Sarlo. *The Procter and Gamble Company, Cincinnati, OH.*

The mouse intranasal test (MINT) has been proposed for use for the assessment of immunogenic potential of enzymes. IN instillation of protein led to little exposure to the lung (Robinson, etal, FAAT 1996, 34:15) yet led to a robust IgG1 and IgE antibody (AB) response to the enzyme allergen Alcalase. Early work by Kawabata, etal (1996, FAAT 29:238) showed that IgG1 and IgE AB could be induced in mice after 6 weeks of intratracheal exposure to Alcalase. The objective of this study was to compare the immune response to Alcalase following IN and direct lung exposure (ASP). Aspiration was used instead if intratracheal instillation due to the ease of the technique. BDF1 mice were exposed to Alcalase protein in saline or detergent (3mg/ml) on days 1, 3, 10 with serology on day 15. The IgG1 AB response to Alcalase was potentiated by the detergent 3.4x after ASP exposure. The same degree of potentiation (3.5x) was observed after IN exposure (Robinson, 1996). The response to Alcalase in detergent following ASP was similar to the response obtained after IN instillation (ASP ED50=0.18µg, IN ED50=0.22µg where ED50 is defined as the effective dose to generate ½ the maximum AB repsonse). Extension of the dose schedule to days 1, 3, 10, 17 and 24 with serology on day 29 led to higher IgG1 titers and AB responses to lower doses of Alcalase in both the IN and ASP exposed animals. The dose-IgG1 AB response was very similar between IN and ASP exposed animals. Alcalase specific IgE AB was detected by the rat passive cutaneous anaphylaxis test. Extension of ASP exposures to days 1, 3, 10, 17 and 24 induced IgE antibody to Alcalase. The extended dose schedule also allowed us to detect IgE antibody to Alcalase following IN instillation. These data show that exposure to enzyme allergen via the nasal mucosa or the lung will lead to similar IgG1 and IgE antibody responses in the BDF1 mouse.

585 STUDY ON THE ALLERGENIC POTENTIAL OF A FIRE-EXTINGUISHER POWDER AT TWO TIME POINTS IN BROWN NORWAY RATS.

H. G. Hoymann, M. Hecht, A. Emmendörffer and H. Muhle. *Fraunhofer Institute of Toxicology and Aerosol Research, Hannover, Germany.*

This study was performed to evaluate the respiratory allergenicity of a fire-extinguisher powder (FEP; siliconized powder on ammonium phosphate/ammonium sulfate basis). Male Brown Norway rats were given s.c. either FEP, ovalbumin (OA) plus alum, or vehicle on days 0, 2, and 7 to induce hypersensitivity. An antigen challenge was performed under anesthesia on day 14 or 21, respectively, during simultaneous recording of lung function. The FEP-treated animals were challenged with either 14 or 290 µg deposited FEP aerosol (low FEP, high FEP), or they were not challenged (neg-

ative control, NEG). The OA-sensitized animals were challenged with OA aerosol (40 μg; POS). The vehicle-treated group was exposed to the high FEP aerosol dose to assess non-specific reactivity (NFEP). A novel dose control system was used which processes data on respiratory minute volume and aerosol concentration. Airway hyperreactivity was assessed 22-24 h after OA challenge using acetylcholine provocations with evaluation of the inhalational dose causing 150 % increase in lung resistance. Bronchoalveolar lavage (BAL) was performed and blood withdrawn for later IgE analysis 44-48 h after challenge. At both time points (14/21 days), the early reaction after OA aerosol challenge was determined as a marked increase in airway resistance, and a marked hyperreactivity was found in the OA vs. NEG animals 24 h after challenge. In the FEP groups as well as in the NFEP group only a moderate increase in resistance and a slight to moderate hyperreactivity were detected. Significant eosinophilia was only detected in the POS group. The OA-effects were more pronounced after 21 than after 14 days. We conclude: the tested FEP did not induce respiratory allergenicity but moderate non-specific airway reactions in a rat model of allergic asthma. The OA-results indicate that allergenicity should be assessed after 21 days.

586 DEVELOPMENT AND VALIDATION OF AN IMMUNOENZYMOMETRIC ASSAY FOR TOTAL MURINE IGE: APPLICATION TO THE IDENTIFICATION OF RESPIRATORY HYPERSENSITIVITY POTENTIAL IN C57BL/6J AND BALB/C MICE.

J. A. Little, L. McLoughlin, P. R. Ryle and S. A. Allan. *Huntingdon Life Sciences, Huntingdon, United Kingdom.* Sponsor: R. J. Harling.

The aim of this study was to: (1) refine and validate assay methodology for total serum IgE in mice and (2) assess possible strain differences in detection of respiratory sensitisers using this assay. The immunoassay methodology has been redeveloped with substitution of immunoreagents, optimisation of assay conditions and selection of suitable standard matrix. The method has been validated to GLP standards with regard to precision, accuracy, matrix effects, specificity and analyte stability. The assay has a lower and upper limit of quantification of 9 ng/ml and 1000 ng/ml respectively (CV and relative error ≤ 20%). Untreated BALB/c mice showed a 7-fold higher baseline level of IgE than the C57BL/6J strain (266.5 compared with 36.2 ng/ml). Proportional, dose-dependent, statistically significant ($P<0.001$) increases in IgE occurred in both strains in response to the administration of moderate (TMA) and strong (HDI) respiratory sensitisers. Greater proportional increases, over the vehicle control group level, were observed with C57BL/6J mice in comparison with BALB/c (55-fold versus 8-fold, elicited by HDI at a high-dose). Although the variability in IgE levels within each dose group was similar for both strains, the use of C57BL/6J may allow greater potential for detection of weak or moderate respiratory sensitisers, in view of the low baseline control IgE values in this strain.

587 INFLUENCE OF TOPICAL EXPOSURE TO RESPIRATORY AND CONTACT ALLERGENS ON SERUM IGE LEVELS IN THE BROWN NORWAY RAT.

E. V. Warbrick, R. J. Dearman and I. Kimber. *AstraZeneca Central Toxicology Laboratory, Macclesfield, United Kingdom.*

Topical exposure to chemical respiratory allergens such as trimellitic anhydride (TMA) has been shown previously to induce increases in the total serum concentration of IgE in BALB/c strain mice. Contact allergens such as 2,4-dinitrochlorobenzene (DNCB), which apparently lack respiratory sensitizing potential, fail to provoke similar changes. We have now examined the influence of topical exposure to TMA and DNCB on serum IgE levels in the Brown Norway (BN) rat. Such animals can be bled serially and thus it is possible to perform longitudinal analyses of changes in serum IgE concentration. The kinetics of IgE responses can therefore be followed on an individual animal basis, allowing discrimination between transient and sustained increases in serum IgE concentration and in addition the exclusion of those animals with pre-existing high IgE levels. Rats (n=5) were exposed on shaved flanks to 50% TMA, to 1% DNCB or to vehicle (acetone: olive oil; 4:1) alone on day 0 and received a repeat dose at half the initial concentration on day 7 on the dorsum of each ear. Total IgE was measured by enzyme-linked immunosorbent assay (ELISA) in serum samples taken prior to, and from 14 to 28 days following, initial exposure. Pre-exposure IgE levels ranged from 0.18-0.7μg/ml. The levels of serum IgE in the majority of rats exposed to DNCB or vehicle alone remained relatively stable throughout the duration of all experiments conducted (0.18-0.87μg/ml), although some animals displayed transient increases in serum IgE. In each study exposure only to TMA resulted in a marked and persistent elevation in serum IgE with levels peaking between days 21 to 28 (1.11-2.69μg/ml). These data suggest that the measurement of induced changes in serum IgE concentration in the BN strain of rat is able to differentiate between different classes of chemical allergen and support the use of DNCB and TMA as controls against which to assess the activity of other test materials.

588 TRIMELLITIC ANHYDRIDE (TMA) INDUCED RESPIRATORY HYPERSENSITIVITY IN THE GUINEA PIG DOES NOT DIFFER IN SEXUALLY IMMATURE OR MATURE ANIMALS OF EITHER GENDER.

C. P. Larsen and J. F. Regal. *University of Minnesota, Duluth, Duluth, MN.*

The prevalence of asthma in humans is higher in children than in adults, and higher in males than in females until the age of puberty. We determined if TMA-induced cellular infiltration into the lung differed among four groups of Hartley guinea pigs (Charles River Lab.): sexually immature females (n=24; 274 ± 4 g at sensitization) and males (n=23; 300 ± 4 g), and sexually mature females (n=12; 435 ± 5 g) and males (n=12; 587 ± 5 g). Animals sensitized with 0.3% TMA were intratracheally challenged 21 d later with 4 mg of either TMA conjugated to guinea pig serum albumin (TMA-GPSA) or GPSA. Twenty-four hr after GPSA challenge, numbers of eosinophils in both the bronchoalveolar lavage fluid (BAL) and lung tissue were greater in mature females than in mature males, while numbers of neutrophils in lung tissue were greater in mature males. Twenty-four hr after TMA-GPSA challenge, numbers of eosinophils, neutrophils and mononuclear cells in the BAL, eosinophils and neutrophils in lung tissue, microvascular leakage of protein and lung hemorrhage increased significantly over GPSA challenged animals in all four groups. The magnitude of the TMA-GPSA induced response did not significantly differ due to sexual maturity or gender ($p<0.05$, three-way ANOVA). Thus, TMA-induced respiratory hypersensitivity is similar in guinea pigs of either gender regardless of sexual maturation. (Supported by NIH ES 07406.)

589 EVALUATION OF ANTIGENS IN THE ELISA INHIBITION ESSAY FOR NATURAL RUBBER LATEX PROTEINS.

V. J. Tomazic-Jezic and A. D. Lucas. *USFDA, CDRH/OST/DLS/HSB, Rockville, MD.* Sponsor: P. L. Goering.

In the process of development of a ELISA Inhibition assay for the quantitation of the natural rubber latex (NRL) proteins, we investigated properties of proteins from ammoniated (AL) and non-ammoniated (NAL) raw latex, as coating antigens, immunizing antigens and reference antigens. The anti-NRL sera were produced by immunizing rabbits with AL, NAL and a mix of both antigens. Determination of affinity of rabbit antisera for binding to these antigens indicated strong preference of both anti-AL and anti-NAL antibodies to bind the immunizing antigen, while anti-Mix antiserum bound similarly to both antigens. Evaluation of the three sera in the ELISA inhibition assay with AL and NAL proteins as coating and reference antigens, further confirmed this finding. Anti-AL serum demonstrated a strong preference in inhibiting and binding to AL antigen, as compared to either NAL antigen or mix. In the case where NAL was a coating antigen, standard curves for both inhibition antigens (AL and NAL) with all three sera were more linear and uniform. Next we investigated the capacity of different anti-sera to inhibit proteins in glove extracts, comparing two coating antigens, AL and NAL. We observed a significant difference in the appearance of the inhibition curves of glove extracts with these two coat antigens. When NAL was used as a coat antigen, the inhibition curves by all three sera were similar. The results indicate that the selection of an appropriate combination of anti-serum, inhibiting and coating antigen is critical for the accurate measurements of the NRL proteins in the finished products.

590 A STUDY OF LATEX ALLERGY USING THE NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY.

A. Exuzides[1], B. Finley[2] and D. Cher[1]. [1]*Exponent, Menlo Park, CA and* [2]*Exponent, Oakland, CA.*

Some researchers have suggested that, as a result of latex glove use, latex sensitization rates in health care workers (HCW) may be far higher than in the general population. However, measurements of latex sensitization rates in HCW have varied considerably and are difficult to interpret because of biases. These include methodological problems (biased and low recruitment rates), not controlling for important confounders (atopy), combining different

latex exposures (powdered and non-powdered), and failure to include a control group. The National Health and Nutrition Examination Survey (NHANES) is periodically conducted by the National Center for Health Statistics to provide estimates of the health and nutritional status of the US population. In this paper, we analyze data on latex allergy from NHANES III for the period of 1988-91. Demographic and socioeconomic factors along with complete medical and dietary history are available for the surveyed subjects. In addition, spirometry, fundoscopy, and laboratory data on blood and urine are also available. We analyzed the prevalence of elevated (at least 0.35 IU/ml) IgE levels specific for latex, as determined by the AlaSTAT assay results reported in NHANES III. We found that the prevalence of elevated anti-latex IgE among HCW and non-HCW was not statistically significantly different. Odds ratios computed for current HCW vs non-HCW, and historically longest job HCW vs. non-HCW were 1.24 and 0.98, respectively (p-values>.05). Adjustments for age and sex did not significantly affect the results. Based upon the results of allergy skin tests reported in NHANES III, HCW were more likely to show positive responses to common allergens. In summary, the NHANES data suggest that the prevalence of latex sensitization in HCW is no greater than in the general population.

591 RETINOID BINDING PROTEINS AND RETINOID TOXICITY.

E. Li. *University of Washington School of Medicine, St. Louis, MO.* Sponsor: D. Acosta.

Vitamin A is indispensable for growth, reproduction, differentiation and vision of vertebrates. Vitamin A deficiency is a major cause of childhood morbidity and mortality worldwide. On the other hand, the pharmacological use of retinoids can result in severe fetal malformations and in the adult most commonly causes hyperlipidemia. Two classes of non-steroid nuclear hormone receptors mediate retinoid signaling, the retinoic acid receptor and retinoid x receptor. In addition, the retinoid x receptors play a central role in regulating gene transcription through formation of homodimers and formation of heterodimers with other nuclear receptors other than the retinoic acid receptors, such as the peroxisome proliferator-activated receptors, vitamin D3 receptors, the thyroid hormone receptors. Intracellular trafficking of retinoids is mediated by specific cytoplasmic carrier proteins, which influence ligand availability for binding with the nuclear retinoids. Retinoid signaling involves a complex interplay between the nuclear receptors, cytoplasmic carrier proteins and sites of metabolic processing. Our laboratory has been interested in studying the structural basis of ligand protein interactions and in modeling intracellular trafficking of retinoids between various retinoid binding proteins. We have purified fully functional bacterially expressed nuclear retinoid receptors and cytoplasmic retinoid binding proteins and analyzed the interactions of these proteins with retinoids in solution using a number of biophysical techniques, most notably nuclear magnetic resonance. Using this approach we have modeled how the physical properties of these binding proteins affect vitamin A homeostasis and toxicity.

592 ASSESSING THE SAFETY OF GENE THERAPY.

J. E. Sanders[1] and M. E. I. Leibbrandt[2]. [1]*Rhône-Poulenc Rorer, Collegeville, PA and* [2]*Chiron Corp., Emeryville, CA.*

The ability to add a gene to a specific cell type is of great potential for the practice of medicine since it provides the opportunity to alter cellular function or structure. Doing so allows us to treat disease from the "inside out." Genes can be delivered by many routes of administration in viral or non-viral vectors; the individual characteristics of the vector transgene combination create unique challenges for the science of toxicology. For example, all viral vectors have the potential to become replication-competent and thus the molecular structure of the gene therapy should be chosen to minimize this risk. The potential for toxicity due to insertion into the host genome should be evaluated when integrating vectors are used (retroviral, adeno-associated viral) to confer long term expression of the transgene. Host immune responses associated with adenoviral vectors, on the other hand, create different challenges for toxicologists. The acute toxicity of the vector particle should be assessed in concert with the toxicity of the expressed transgene. Since there is currently limited ability to target gene therapies to individual cell types, the consequences of inappropriate transduction and expression should be evaluated with reference to biodistribution *in vivo*. The level and localization of such inadvertent transduction in tissues such as the testis and ovary must be closely examined in order to ensure negligible risk of germline transmission.

593 OVERVIEW OF GENE THERAPY.

P. Delaere. *Rhône-Poulenc, Vitry-Sur-Seine, France.* Sponsor: J. E. Sanders.

Gene Therapy is a great opportunity for the Pharmaceutical Industry since it is a new way to deliver new drugs which are produced locally and can act either locally or systemically. Viral and non viral vectors can transfer genes into various tissues (tumor cells, skeletal and cardiac muscles, vascular wall, brain tissue...). Currently different types of vectors are used in clinical trials: retrovirus, adenovirus, lentivirus, AAV, Poxvirus, naked DNA combined or not with lipofection or electroporation. The genes are transferred and expressed; they can evoke biologic responses that are relevant to human diseases. Adverse events have been rare and have been related mostly to the dose and the manner in which the vectors were administered. Improvements of vectors reside in the efficiency of gene delivery, the selective physical and/or genetic targeting, the decrease in the inflammation associated with some viral vectors, and the control and the stability of expression. A broad survey of gene therapy will be presented with the aim of answering the questions: What is gene therapy, how is it being used in clinical and in preclinical studies? What are some of the generic and specific safety, issues associated with gene therapy? Regarding the type of vectors, how do they achieve therapeutic effect? What are the vector specific advantages and issues. The potential side effects of specific delivery systems will also be discussed. Although different types of vectors will be presented with their advantages and limitations, a focus will be provided on adenovirus as viral vectors and on non viral approaches which exhibit complementary advantages. This presentation will also provide the audience with an appreciation of the technical challenges to measure and localize vector tissue distribution and gene expression using state-of-the-art assays.

594 PRE-CLINICAL EVALUATION OF THE HUMAN FACTOR VIII RETROVIRAL VECTOR.

M. E. I. Leibbrandt, H. Roehl, J. Greengard and M. Giedlin. *Chiron Corp., Emeryville, CA.*

Hemophilia A, characterized by absent or low levels of circulating functional factor VIII, occurs in 1 of every 10,000 live male births. Currently, this disease is treated by exogenous replacement of the deficient protein through administration of recombinant factor VIII or plasma-derived factor VIII. Successful gene therapy would confer long term, endogenous expression of factor VIII at levels sufficient to provide prophylaxis from spontaneous joint bleeds. A retroviral vector expressing human factor VIII (hFVIII(V)) has been developed for the treatment of patients with hemophilia A. Intravenous administration of hFVIII(V) to adult or juvenile rabbits at doses of $0.6–21 \times 10^8$ cfu-eq/kg was well-tolerated and led to the expression of therapeutic levels (=14 ng/ml) of factor VIII. Factor VIII levels varied widely between individual animals, possibly due to the presence of anti-human factor VIII antibodies. Expression followed a lag phase of 2-3 weeks and continued until animals were sacrificed between 3 months and 2 years post-treatment. There was a correlation between the dose of hFVIII(V) and circulating levels of FVIII. Acute toxicology studies in mice and rabbits showed no effects of hFVIII(V) treatment on hematology or clinical chemistry parameters, body weights, food consumption or macroscopic observations at necropsy at doses up to 96×10^8 cfu-eq/kg. Hemophilic dogs treated with hFVIII(V) showed shortened whole blood clotting time although response was highly variable between individual animals. Biodistribution of hFVIII(V) by PCR showed that vector- specific sequences localized primarily to the liver and spleen with occasional signal in other tissues including testis. A 16-week study is underway in rabbits to determine whether localization of hFVIII(V) to testis is associated with the presence of vector-specific sequences in semen.

595 PRE-CLINICAL STUDIES ON DNA PLASMID DISTRIBUTION AND INTEGRATION.

W. Nichols, B. Ledwith, S. Manam, P. J. Troilo, A. B. Barnum, C. J. Pauley, T. G. Griffiths II, L. B. Ludlow, H. B. Schock, H. Zhang, J. E. Faris, P. A. Way, C. M. Beare and W. J. Bagdon. *Merck Research Labs, West Point, PA.* Sponsor: J. E. Sanders.

The primary safety concerns for DNA plasmids being used for vaccines or gene therapy are integration into the genome of the recipient, the induction of chromosomal aberrations, autoimmune effects and the induction of anti-DNA antibodies. Today this discussion will be limited to integration into the host cell genome and the tissue distribution of plasmids after Intramuscular injection. Integration is of concern because by definition this produces insertional

mutagenesis and this in turn has the potential to activate oncogenes or inactivate tumor suppressor genes and could therefore play a role in tumorigenesis. A test system utilized for integration should have a sensitivity that permits comparisons to the spontaneous mutation rate in order to make risk evaluations. This can be achieved by electrophretic methods that can separate free plasmid from genomic DNA followed by PCR techniques to detect plasmid in the purified genomic DNA. This methodology is capable of detecting one plasmid integration in 150,000 nuclei. In studies of several different plasmids at 6 weeks and 6 months after injection, plasmids are detected at the site of injection. At time points of 1 to 7 days after injection plasmid is detected in small numbers in blood and many of the 14 tissues that are examined for tissue distribution. There has been no evidence of integration at the sensitivity of approximately one copy per microgram of DNA which, assuming that each integration would produce a significant mutation, is at least 3 orders of magnitude less than the sponteneous mutation frequency.

596 REGULATORY CONSIDERATIONS FOR GENE THERAPY CLINICAL TRIALS.

A. M. Pilaro. *FDA/CBER, Rockville, MD.* Sponsor: J. E. Sanders.

Gene therapy is one of the fastest growing areas in biotechnology, with over 300 clinical protocols currently active. Initially, gene therapy agents were used to "replace" defective genes in diseases such as cystic fibrosis, in which the underlying disease could contribute to the toxicity of the agent employed. Developing a toxicology program to determine the safety of these agents, therefore, requires a modified approach which encompasses both the pharmacology and toxicity of the gene product itself, as well as the vector system used for delivery, in the context of the application for the clinical trial. The issues involved in designing and developing appropriate preclinical safety testing for these agents, and the regulatory guidances currently in practice in the United States will be presented. An overview of the safety issues novel to gene therapies, and the strategies for designing preclinical studies to address these concerns will be discussed. The effects of the route of administration, frequency and duration of exposure, as well as the type of vector employed on the safety and clinical activity will be identified. Other safety considerations to be discussed include biodistribution, duration and degree of vector expression in target and other tissues, the effects of gene expression on organ pathology and/or histology, and interactions of the host immune system with the transduced cell population. Current recommendations for preclinical studies in support of future licensing of gene therapeutic agents will also be discussed.

597 ADVANCES IN THE USE OF MECHANISM-BASED BIOMARKERS IN RISK ASSESSMENT.

L. L. Smith[1], E. A. Lock[1] and J. A. Swenberg[2]. [1]*AstraZeneca CTL, Alderley Park, United Kingdom and* [2]*University of North Carolina, Chapel Hill, NC.*

Understanding the biochemical and molecular mechanisms whereby foreign compounds interact with and perturb biological systems is fundamental to toxicology. The use of molecular mechanistic data from whole animal studies, human exposure and *in vitro* studies with animal and human tissues is pivotal to assessing the likely risk to humans. Recent advances in molecular techniques and the use of biomarkers has enabled more accurate assessment of risk following exposure to chemicals. It is now well established that human susceptibility to tissue injury and cancer can in part be attributed to genetic polymorphisms. The symposium will focus on the application of molecular markers to determine exposure, early effects and susceptibility to benzene, butadiene, polycyclic aromatic and heterocyclic amines, nitrosamines, and polycyclic aromatic hydrocarbons found in cigarette smoke and polluted air. The utility of molecular markers causally related to the mechanism of toxicity of a novel herbicide will be presented. Emerging evidence on the role of gene environmental interaction associated with DNA damage, that may contribute to the etiology of human cancer will also be discussed.

598 MOLECULAR BIOMARKERS OF BENZENE EXPOSURE AND RISK.

M. T. Smith[1], L. Zhang[1], R. Hayes[2], G. L. Li[3] and N. Rothman[2]. [1]*University of California, Berkeley, CA,* [2]*National Cancer Institute, Bethesda, MD and* [3]*Chinese Academy Preventive Medicine, Beijing, China.*

Benzene is an established cause of leukemia at high doses, but the risk it poses at exposures of <1ppm in air is difficult to quantify. Molecular biomarkers may improve the accuracy of this risk assessment. We have therefore attempted to develop and validate biomarkers of exposure, early effect and susceptibilty to benzene. We have shown that NQO1 genotype and cytochrome P4502E1 phenotype are important biomarkers of susceptibility. Further, since chromosomal aberrations (CA) have been shown to be predictive of future cancer risk and specific CA are found in leukemias, we have proposed that specific CA may be excellent biomarkers of early effect. Leukemia-specific CA were found at elevated rates in the blood of 43 workers exposed to high levels of benzene (median, 31ppm). A larger study is planned for the year 2000 that will use these validated markers in biological samples from a substantially larger number of workers exposed to lower levels of benzene. The design of this new study will be presented together with a summary of data generated from our original cross-sectional study in highly exposed workers.

599 ADVANCES IN THE USE OF MECHANISM-BASED BIOMARKERS IN RISK ASSESSMENT.

J. Swenberg, H. Koc, A. Ranasinghe, N. Christove-Gueorguieva and P. Upton. *University of North Carolina, Chapel Hill, NC.*

Butadiene (BD) is a potent carcinogen in mice, a weak carcinogen in rats and a probable carcinogen in humans. Recent molecular dosimetry studies in these species have greatly increased our understanding of the metabolism of BD. It is clear that the major electrophile (>95%) in all three species is the epoxybutane diol (EBD). This is the result of metabolism of BD in the endoplasmic reticulum to BDO, then to BDO2, and finally to EBD. EBD is 1/200th as mutagenic as BDO2. BDO2 and EBD form trihydroxybutane adducts in DNA and hemoglobin. The DNA adducts of BDO show a linear response, while the trihydroxybutane adducts show a supralinear response due to saturation of metabolic activation. Molecular epidemiology studies on BD workers have shown clear evidence of exposure, based on hemoglobin adducts, but no evidence of genotoxicity following a battery of evaluations. Furthermore, lymphocytes from GSTT1 null individuals have been shown to to be at greater risk for SCE formation following *in vitro* exposure to BDO2, but no such increased susceptibility was observed for any biomarker in studies of exposed workers. Thus, the increased susceptibility of the GSTT1 null genotype appears to be associated with saturation of this detoxication pathway following high *in vitro* exposures.

600 TYROSINEMIA AS A MARKER OF EXPOSURE TO HPPD INHIBITORS.

W. M. Provan, J. Botham, J. E. Doe, R. W. Lewis and M. Robinson. *AstraZeneca, Macclesfield, United Kingdom.* Sponsor: E. A. Lock.

In mammals, the single mechanism of action of mesotrione, a selective herbicide, is inhibition of the hepatic enzyme, 4-hydroxyphenyl pyruvate dioxygenase (HPPD), a key enzyme in the catabolism of tyrosine. Prolonged inhibition of this enzyme increases plasma tyrosine levels, the extent of which is dependent on the efficiency of a second hepatic catabolic enzyme, tyrosine aminotransferase, (TAT). TAT activity is species and sex dependent in the rat, male rats having particularly little activity while humans and mice have high activity. Consequently, on prolonged exposure to mesotrione, rats develop a severe tyrosinemia with associated toxicological symptoms: ocular lesions, increased liver and kidney weight, reduced body weight and reduced pup survival. In contrast, high hepatic TAT activity in the mouse precludes extreme elevation of plasma tyrosine levels, yielding no significant toxicological effects in this species after exposure to mesotrione. The activity of TAT in mice and humans is similar. Thus, humans, like mice, are unlikely to develop the severe tyrosinemia and associated toxicity expressed in rats. This is confirmed by results in humans patients being treated for hereditary tyrosinemia type I with high doses of a more potent structurally related triketone. It is concluded that high levels of tyrosine mediate the species specific toxicity associated with exposure to mesotrione and tyrosine elevation is a function of the HPPD inhibition and innate TAT activity. Thus, the plasma concentration of tyrosine, and TAT activity levels are mechanism-based biomarkers which accurately reflect the species/sex-specific toxicity associated with exposure to mesotrione and are key to accurate human risk assessment.

601 RELATION BETWEEN GENETIC SUSCEPTIBILITY AND DNA ADDUCT FORMATION.

F. F. Kadlubar[1], P. H. Thompson[1], C. B. Ambrosone[1], M. Yang[1], B. F. Coles[1], N. P. Lang[2] and K. E. Anderson[3]. [1]*Division of Molecular Epidemiology, NCTR, FDA, Jefferson, AR,* [2]*Arkansas Cancer Research Center, Little Rock, AR and* [3]*University of Minnesota, Minneapolis, MN.* Sponsor: E. A. Lock.

Carcinogen exposure and carcinogen-DNA damage occur sequentially as necessary though not always sufficient events in the initiation of the cancer process. In humans, there is now unequivocal evidence that both exogenous and endogenous DNA adducts are present in carcinogen-target tissues. However, differences in human cancer susceptibility can also be attributed to genetic polymorphisms in carcinogen-metabolizing enzymes, in DNA repair mechanisms, and in genes that control cell growth and differentiation. Accordingly, a combined approach is now needed in order to the assess the relevance of these findings to cancer etiology, to identify high-risk individuals, and to provide better health monitoring, earlier diagnosis, and cancer prevention. Our recent efforts have focussed on aromatic and heterocyclic amines, nitrosamines, and polycyclic hydrocarbons found in cigarette smoke, polluted air, and in cooked foods and on the role of such gene-environmental interactions associated with DNA damage that may contribute to the etiology of human colon, pancreas, breast, prostate, and lung cancers.

602 THE ROLE OF ENDOTOXIN IN OCCUPATIONAL AND ENVIRONMENTAL LUNG DISEASE: EXPOSURE-RESPONSE RELATIONSHIPS AND SUSCEPTIBILITY FACTORS.

P. S. Thorne[1] and I. Glimour[2]. [1]*The University of Iowa, Iowa City, IA and* [2]*USEPA, Research Triangle Park, NC.*

Endotoxins (lipopolysaccharides, LPS) are integral components of the outer membrane of Gram-negative bacteria and are ubiquitous throughout our environment. They are comprised of a conserved lipid region (lipid A) which imparts toxicity, and a species-specific long chain polysaccharide moiety that binds host receptors such as LPS binding protein (LBP) and CD14. Inhalation exposures to endotoxin occur in complaint buildings, agricultural settings and in a variety of industrial operations. Epidemiologic studies consistently demonstrate that endotoxin exposure is a significant risk factor for the development of respiratory symptoms and decrements in lung function, and may be an important factor in the pathogenesis or progression of lung diseases such as byssinosis, organic dust toxics syndrome, asthma, and cystic fibrosis. After inhalation, endotoxin triggers the upregulation of an array of cytokines leading to neutrophil recruitment and lung injury. This symposium will present recent studies of the chemical and toxicological properties of endotoxin, report exposure concentrations from a variety of occupational environments, and describe current analytical methods for endotoxin measurement. Exposure-response data from epidemiology studies and recent inhalation experiments in humans and animals will then show the role of endotoxin in causing or promoting lung disease, and highlight differences in genetic susceptibility. Finally, the role of endotoxin exposure as a co-factor in asthma and its interaction with other forms of air-pollutant exposure will be described.

603 STRUCTURE AND FUNCTION OF ENDOTOXIN AND MOLECULAR RESPONSES IN THE LUNG.

M. I. Gilmour. *USEPA, Research Triangle Park, NC.*

Lipopolysaccharide (LPS) is the active component of endotoxin in the walls of all Gram-negative bacteria, and is capable of eliciting a febrile response and inflammation in a variety of tissues. LPS molecules comprise a conserved lipid region (lipid A), and a long chain polysaccharide moiety that displays high diversity across bacterial species. The polysaccharide component facilitates binding to serum proteins and cellular structures, while phosphorylated D–glucosamine residues, fatty acids, and acyl chains on the lipid A portion impart biological activity. Although almost any mammalian cell will respond to LPS, monocytes, leukocytes, and endothelial and epithelial cells are most often associated with its activation and subsequent effects. A number of different binding proteins have been shown to enhance the activational properties of LPS. LPS binding protein (LBP) is a serum factor that catalyzes the interaction between LPS and CD14 on the surface of monocytes, resulting in increased calcium flux, tyrosine phosphorylation and activation of nuclear transcription factors. In cells lacking CD14 receptors (e.g. smooth muscle and endothelial cells), LPS stimulation may occur through other receptors (CD11 and CD18). Following these various activational signals, cells produce an array of potent endogenous mediators including IL-1α, IL-6, IL-8, TNFα, IFN-γ; and prostaglandins. Depending on the concentration of LPS exposure, symptoms may range from a mild fever and myalgia to severe leukopenia, tachycardia, hypotension, and multi–organ failure (septic shock syndrome). While mild symptoms will resolve within hours, more severe illness can be treated with receptor antagonists of the various mediators or by competitive inhibition with less toxic forms of LPS. (This abstract does not reflect EPA policy.)

604 ENDOTOXIN AS A CAUSATIVE AGENT FOR OCCUPATIONAL AND ENVIRONMENTAL LUNG DISEASE.

P. S. Thorne. *College of Public Health, The University of Iowa, Iowa City, IA.*

Inhaled endotoxins are bioactive components of aerosols found in both occupational and non-occupational settings. Exposures to airborne endotoxins are generally quantified from air samples using a bioactivity assay, the Limulus amebocyte lysate (LAL) assay. Assay validation studies in our laboratory and others have demonstrated acceptable within-lab reproducibility but generally poor between-lab reproducibility. Research is underway to improve or replace the LAL assay. We have used the LAL assay to assess endotoxin exposures in a variety of occupational and domestic environments. Exposures to endotoxins occur at high levels in agricultural settings such as livestock barns and during crop harvesting, transfer and processing. Exposures in agriculture can exceed 35,000 EU/m3 of air but generally range from 100 to 10,000 EU/m3. Endotoxin exposures usually occur at lower levels (1-2,500 EU/m3) in industrial settings such as metals machining plants, composting facilities, and sawmills. Our analyses of dust samples from homes across the U.S. indicate dust concentrations ranging from 102 to 106 EU/m2 of vacuumed surface with presence of carpeting, geographic location, and indoor storage of kitchen waste as important determinants. Epidemiologic studies have linked endotoxin exposure with a variety of pulmonary conditions including chronic nose and throat irritation, organic dust toxics syndrome, grain fever, asthma-like syndromes and exacerbation of asthma. Inhalation toxicology studies using susceptible mouse strains have demonstrated production of pro-inflammatory cytokines (e.g. IL-1, IL-6, TNFα, and MIP-2) and neutrophil recruitment to the airways leading to airway remodeling. Recognition of endotoxin-induced pulmonary toxicity has led to proposals to establish occupational exposure limits, although currently none exist in the U.S.

605 THE GENETICS OF ENDOTOXIN-INDUCED AIRWAY DISEASE.

D. A. Schwartz. *University of Iowa, Iowa City, IA.* Sponsor: P. S. Thorne.

Despite the tremendous inter-individual variability in the response to inhaled toxins, we simply do not understand why certain people develop disease when challenged with environ-mental agents and others remain healthy. Although asthma is a complex disease, it appears to occur in genetically susceptible individuals who are primed to respond to a limited number of specific agents, such as endotoxin. Focusing on the airway response to inhaled endotoxin has permitted us to determine that humans and different strains of mice have a broad physio-logic and biologic response to this very common agent that is known to cause and exacerbate acute and chronic forms of airway disease. Moreover, our studies in humans indicate that a common missense mutation in the extracellular domain of the TLR4 receptor, a gene that has been shown to affect endotoxin responsiveness in mice, is associated with a significantly blunted response to inhaled endotoxin in humans. In vitro functional studies confirm the biological importance of this mutation in the TLR4 receptor. Moreover, the wild type allele of TLR4 rescues the endotoxin hyporesponsive phenotype in either primary airway epithelial cells or alveolar macrophages obtained from individuals with the TLR4 mutation. Our findings provide the first genetic evidence that a common mutation causes differences in endotoxin responsiveness, and demonstrate that gene sequence changes alter the ability of the host to respond to environmental stress.

606 INFLAMMATORY AND EPITHELIAL RESPONSES IN AIRWAYS EXPOSED TO ENDOTOXIN AND OZONE.

J. R. Harkema. *Michigan State University, East Lansing, MI.*

People are exposed daily to a combination of air pollutants (e.g. ozone) and airborne biogenic substances (e.g. bacterial, antigenic). Ozone is the principal oxidant pollutant in photochemical smog and a potent airway irritant. Millions of people live in urban environments (e.g. Mexico City) with high ambient

concentrations of both ozone and bacterial endotoxin. This lecture will focus on the results of studies designed to test the hypotheses that 1) co–exposure to ozone and endotoxin cause greater alterations to the airway epithelium than exposure to either toxicant alone and 2) that the magnitudes of these epithelial changes are dependent on the preceding or concurrent airway inflammatory response. F344 rats were exposed to 0 or 0.5 ppm ozone, 8 h/day, for 3 days and intranasally instilled with endotoxin (100μg) prior to each daily exposure. Nasal tissues were processed for light microscopy and image analysis, or for mucin–specific mRNA analysis. Ozone alone caused nasal airway alterations that included neutrophilic inflammation, increased mucin gene expression, and nasal epithelial proliferation (hyperplasia) and differentiation (mucous cell metaplasia). Endotoxin alone caused nasal inflammation, mucin–gene overexpression, and epithelial hyperplasia, but no mucous cell metaplasia. Rats exposed to both toxicants had greater inflammatory and epithelial responses than either toxicant alone, and endotoxin potentiated the ozone–induced mucous cell metaplasia. Subsequent studies have suggested that this potentiation is dependent on the neutrophilic inflammation. Our findings suggest that endotoxin exposure can magnify some, but not all of the epithelial lesions caused by ozone, and this augmentation may be mediated through inflammatory mechanisms. (Funded by NIH grant HL59391.)

607 THE ROLE OF ENDOTOXIN IN ASTHMA AND ALLERGY.

D. Peden. *UNC Chapel Hill, Chapel Hill, NC.* Sponsor: M. I. Gilmour.

Endotoxin is a commonly encountered air contaminant in a number of occupational settings, with high concentrations being reported in ambient air. Such levels are associated with acute reductions in lung function, respiratory symptoms and nasal inflammation in exposed persons. LPS levels in the range of 0.25 μg/m3 have been associated with increased reports of ocular and nasal symptoms by office workers, suggesting that even low levels of LPS may cause airway symptoms and inflammation. Furthermore, disease severity of mite-sensitive asthmatics has also been shown to correlate better with levels of endotoxin than mite allergen in samples of house dust collected from their homes. These observations suggest that lower levels of LPS may cause morbidity in sensitive subgroups, such as atopic asthmatics. In human challenge studies, allergic asthmatics have been reported to have increased responses (decreased lung function and increased non-specific airway reactivity) to LPS challenge than non-asthmatic subjects. Exposure of asthmatics to low levels of LPS enhances immediate and late phase responses to inhaled allergen. Likewise, nasal LPS challenge in atopic asthmatics induces eosinophil influx in asthmatics that have increased constitutive levels of GM-CSF. Allergen challenge of allergic asthmatics also causes increased levels of CD14 (the LPS receptor) in BAL fluid from these subjects, suggesting that allergen challenge could enhance inflammatory responses to LPS. Preliminary data from our group reveals that allergen challenge prior to LPS exposure yields greater PMN and eosinophil numbers in the nasal airway than either LPS or allergen alone. Taken together, these data support the hypothesis that asthmatics, especially atopic asthmatics, may be at increased risk for respiratory tract morbidity associated with low level LPS exposure.

608 FRITZ HABER AND HIS IMPACT ON TOXICOLOGY.

H. Witschi. *University of California, Davis, CA.*

Fritz Haber (1868-1934) was a German physical chemist, Nobel prizewinner and foreign member of the US Academy of Science. His greatest accomplishment in science was the development of a practical method to prepare nitrogen from air (nitrogen fixation or Haber-Bosch process). While working on the toxicity of war gases, he formulated "Haber's rule" [CxT = constant] in order to characterize the toxicity of a toxic inhalant. Between 1919 and 1933, he was one of the leading figures in revitalizing science in Germany. At his institute in Berlin, he worked with such luminaries as Albert Einstein, Lise Meitner and Otto Hahn. His last paper described what became know as the Haber-Weiss reaction. After his death he became for a long time forgotten by the Nazis because he was Jewish and after World War II by the Allies because they never forgave him for his work on war gases in World War I. And yet he was one of the truly great modern scientists, not only because of his science, but also because of his role in science politics and policies. Haber's rule can actually be rewritten as a special case of the family of power law curves and may be used in standard setting and risk assessment. Some newer experimenters show that the rule also applies to chronic toxicity, provided that exposure occurs under conditions of a steady state of exposure.

609 HABER'S RULE (CT=K): A SPECIAL CASE IN A FAMILY OF CURVES RELATING CONCENTRATION AND DURATION OF EXPOSURE TO A FIXED LEVEL OF RESPONSE.

F. Miller. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

In the early 1900s, Haber expounded that the acute lethality of war gases could be assessed by the concentration of the gas in a cubic meter of air multiplied by the time in minutes that the animal had to breathe the air before death ensued (i.e., Ct=k). This concept was not original with Haber. In 1900, Warren used the equation T(X-8) = constant, where T was the time of killing and X was the strength of salt solution that killed Daphnia magna. Both Warren and Haber recognized that Ct=k was applicable only under certain conditions. However, many toxicologists have used this relationship to analyze experimental data whether or not their chemicals, biological endpoints, and exposure scenarios were suitable candidates for Haber's Rule. Since the relationship between C and t is linear on a log-log scale and was, therefore, relatively easy to solve by hand, Haber's Rule gained early acceptance among toxicologists. In 1940, Bliss provided an elegant treatment on the relationship between exposure time, concentration, and toxicity of insecticides. Bliss examined various situations involving the equation (C–C0)nt=k, where the constant, C0, represents a threshold concentration or physiologic zero for a given mode of toxic action. Haber's Rule has been applied to latency data from cancer studies, but enough exceptions were found that Ctn=k was proposed as a general rule for such data. Some argue that various aspects of concentration and duration of exposure leading to a fixed level of response have surfaced so frequently in toxicology that this relationship may be generalizable to the whole field. The family of power law curves represented by $(C-C_0)\alpha\ t^0=k$ allows for such a generalization and encompasses the full range of toxicokinetic and toxicodynamic conceptual considerations that will be discussed by others at this workshop.

610 THE USE OF HABER'S RULE IN STANDARD SETTING AND RISK ASSESSMENT.

D. Gaylor. *USFDA, Jefferson, AR.* Sponsor: H. R. Witschi.

Haber's Rule simply states that the incidence and/or severity of a toxic effect depends on the total exposure, i.e., exposure concentration (c) rate times the duration time (t) of exposure (cxt). This rule, within constraints, often is used in setting exposure guidelines for toxic substances. Establishing reference doses (acceptable daily intakes) for long-term exposures when only the results of short-term studies are available requires the use of an uncertainty (safety) factor. The value of this uncertainty factor often approximates a value comparable to Haber's Rule for extrapolation from short-term to long-term exposure durations. As a default procedure, cancer risk estimates generally are based on the average lifetime daily dose which is derived from the total cumulative exposure, i.e., Haber's (CxT). This has been shown both theoretically and empirically to be valid within a factor of 10 for carcinogens. This provides some credence for the use of an additional safety factor of 10, in some instances, for exposures of children to carcinogens. Finally, a generalization of Haber's Rule, exposure concentration raised to a power times exposure duration, will be discussed.

611 THE HABER-WEISS REACTION AND MECHANISMS OF TOXICITY.

J. P. Kehrer. *The University of Texas at Austin, Austin, TX.*

The concept that the highly reactive hydroxyl radical (HO•) could be generated from an interaction between superoxide ($O_2^{\bullet-}$) and hydrogen peroxide (H_2O_2) was proposed (with Joseph Weiss) in Professor Haber's final paper published in 1934. Until it was recognized that free radicals are produced in biological systems, this finding seemed to have no relevance to biology. However, following the discovery that $O_2^{\bullet-}$ was a normal cellular metabolite, it was quickly recognized that the Haber-Weiss reaction ($O_2^{\bullet-} + H_2O_2 \rightarrow HO^{\bullet} + O_2 + HO^-$) might provide a means to generate more toxic radicals. Although the basic reaction has a second order rate constant of zero in aqueous solution and thus cannot occur in biological systems, the ability of iron salts to serve as catalysts was discussed by these authors. Because transition metal ions, particularly iron, are present at low levels in biological systems, this pathway (commonly referred to as the iron-catalyzed Haber-Weiss reaction) has been widely postulated to account for the *in vivo* generation of the highly reactive

HO•. Recent data documenting the importance or redox regulation of various cellular signaling pathways makes it clear that free radicals are essential for normal cellular function. However, this also makes it obvious that disruptions of free radical production or defenses at many different levels can lead to adverse effects on cells. While the generation of HO•, which is by far the most reactive oxygen species, is generally indicative of an overtly toxic event, it is through studies at this level that we have reached a better understanding of free radicals as both signaling molecules and toxic species.

612 THE ROLE OF TIME IN TOXICOLOGY OR HABER'S CXT PRODUCT.

K. K. Rozman. *University of Kansas Medical Center, Kansas City, KS.*

It happened exactly 100 years ago that Warren established for the first time a quantitative link between dose and time while studying the toxicity of sodium chloride in Daphnia magna (Straus). During this century many toxicologists in different contexts returned to this idea, which has become known as Haber's Rule of inhalation toxicology. Every attempt to explore this relationship ended in frustration because of the supposed occurrence of exceptions. Thus, toxicologists concentrated on the quantitative relationship between dose and effect under mostly isotemporal conditions while time took a back seat and was assigned such arbitrary, semiquantitative designations as acute, subacute, subchronic and chronic. Time itself as a quantifiable variable of toxicity was seldom studied and when it was done, it was often not under isodosic (steady state) conditions as required by theory. A recent analysis of toxicological time indicated the impact of 3 independent time scales (toxicokinetic, toxicodynamic, exposure frequency) in toxicological studies, which interact with dose and effect to yield the enormous complexity known to every toxicologist. Based on prototypical examples when toxicokinetic (dioxins), toxicodynamic (nitrosamines, benzene) or exposure frequency (methylene chloride, chloroacetic acid, HgCl2, CdCl2 etc.) represent the critical time scale, the general validity of the cxt=k concept will be discussed as a starting point for a theory of toxicology. As endpoints of toxicity, (delayed) acute toxicity, blood dyscrasias and cancer will be used to illustrate the critical conditions needed to demonstrate the validity of this theory.

613 ETHANOL SIGNALING APOPTOSIS IN NORMAL HUMAN HEPATOCYTES, ROLE OF TUMOR NECROSIS FACTOR α, FAS LIGAND AND CASPASE-3 INHIBITOR.

G. G. Katz[1], N. H. Shear[1], K. Valentino[2], I. Malkiewicz[1] and M. G. Neuman[1]. [1]*Sunnybrook & Women's College Health Sciences Centre, Toronto, Ontario, Canada and* [2]*IDUN Pharmaceuticals, La Jolla, CA.* Sponsor: J. Utercht.

Aims: 1-To assess the mechanism by which ethanol (EtOH) is signaling for apoptosis in a normal human primary hepatocyte (NHPH) culture. 2-To delineate the role of tumor necrosis factor alpha (TNF) antibody (anti-TNF) and caspase-3 inhibitor (CAPI) in cell protection against apoptosis. **Methods:** In a culture of NHPH treated for 24 hours, either with 80 mM EtOH or 30 pg/mL TNF, apoptosis was assessed by ELISA, which quantitates histones associated with DNA cleavage at the internucleosomal linker region, and by transmission electron microscopy. In a second set of experiments, prior to the same treatment, cells were exposed to 5 nM CAPI or 30 pg/mL anti-TNF. For each set of experiments, apoptosis was assessed in 6 flasks (6000 cells/flask) and 30 wells. We also measured the cytochrome oxidase activity with the diaminobenzidine immunochemnistry technique. Fas(APO-1, CD95) molecules on the plasma membrane of hepatocytes increased and were represented immunohistochemically in cells without chromatin condensation. **Results:** ANOVA was used for statistical analysis and the values are given as mean % apoptotic cells or bodies ± SD. The value for control was 6±0.5; for EtOH, 26±1*; for TNF, 53±5*; for EtOH and anti-TNF, 16± 8#@; for TNF and anti-TNF, 4±2; and for EtOH and CAPI, 10±6@ (@p<0.05 lower than the EtOH value; #p<0.05; *p<0.001 higher than the control value). As shown by this data, apoptosis in TNF treated cells is abolished by anti-TNF. Hepatocytes are protected against EtOH-induced apoptosis by pre-treatment with anti-TNF and CAPI. In early stage of apoptosis was al rupture of the outer mitochondrial membrane. Parts of the inner membrane extended through the gap of the outer membrane, whereas the rest of the inner membrane still formed the cristae. This feature appeared in hepatocytes before chromatin condensation. Taking all the apoptotic hepatocytes we may characterized them by being apoptotic with condensed chromatin and high enzyme activity (10%), pre-apoptotic, without chromatin condensation but high enzyme activity (35%), and neither condensed chromatin nor a remarkable reaction product of cytochrome oxidase activity(55%) Fas(APO-1, CD95) molecules on the plasma membrane of hepatocytes increased in cells without chromatin condensation. **Conclusions:** EtOH-induced apoptosis is initiated by TNF and Fas ligand. Therefore, both anti-TNF and CAPI might inhibit hepatic apoptosis. Mitochondria play a pivotal role in pre-apoptotic stages.

614 ROLE OF TNFα- AND NFκB- MEDIATED CELLULAR SIGNALLING IN THE SUPPRESSION OF RAT HEPATOCYTE APOPTOSIS BY PEROXISOME PROLIFERATORS.

S. C. Cosulich[1], P. R. Holden[1], M. R. C. Needham[2], P. P. Newham[2] and R. A. Roberts[1]. [1]*AstraZeneca CTL, Macclesfield, United Kingdom and* [2]*AstraZeneca Pharmaceuticals, Macclesfield, United Kingdom.*

Peroxisome proliferators (PPs) cause rodent liver enlargement and tumors. *In vitro*, PPs induce rat and mouse hepatocyte DNA synthesis and suppress both spontaneous apoptosis and that induced by the physiological negative liver growth regulator, transforming growth factor β1 (TGFβ1). Previously, we have shown that exogenous tumour necrosis factor α (TNFα) perturbs growth control in rat or mouse hepatocytes, implicating this cytokine in the mechanism of action of PPs. In addition, antibodies to TNFα receptor type 1 (TNFR1) abrogated completely the response of mouse hepatocytes to nafenopin whereas anti-TNFα receptor 2 blocking antibodies were without effect. Since TNFα signalling to the transcription factor nuclear factor κB (NFκB) is thought to be responsible for many of the effects elicited by this cytokine, we investigated activation of NFkB by nafenopin and by TNFα. Nafenopin shared the ability of TNFα to cause activation of NFκB as determined by electrophoretic mobility gel shift assay (EMSA). NFκB activation requires the successive action of NFκB inducing kinase (NIK), and the phosphorylation of NFκB inhibitory proteins (IκB) by an IkB kinase (IKK) complex. The IKK2 subunit of IkB kinase is thought to be essential for NFκB activation and prevention of apoptosis. To determine whether IKK2 played a role in the suppression of apoptosis by PPs, we expressed a dominant negative form of IKK2 (IKK2dn) in primary rat hepatocyte cultures. Expression of IKK2dn caused apoptosis in primary rat hepatocytes in the absence of addition of TNFα. Moreover, IKK2dn-induced apoptosis could not be rescued by addition of TNFα or nafenopin. These results demonstrate a requirement for TNFα signalling via TNFR1 and NFκB in the suppression of apoptosis by the PP class of hepatocarcinogens.

615 THE MITOCHONDRIAL PERMEABILITY TRANSITION STIMULATES LYSOSOMAL PROLIFERATION AFTER NUTRIENT WITHDRAWAL PLUS GLUCAGON IN RAT HEPATOCYTES.

S. P. Elmore, T. Qian and J. J. Lemasters. *University of North Carolina, Curriculum in Toxicology and Department of Cell Biology & Anatomy, Chapel Hill, NC.*

Autophagy rids cells of excess and dysfunctional organelles, liberates nutrients and may be involved in apoptosis. Mitochondrial depolarization indicates loss of function and suggests onset of the mitochondrial permeability transition (MPT). Previously, we showed that autophagic stimulation by nutrient withdrawal and glucagon causes depolarization of individual mitochondria, which then move into autophagic vacuoles. Cyclosporin A (CsA), a specific inhibitor of the MPT, blocks mitochondrial depolarization after autophagic stimulation. Here, we aimed to test the hypothesis that nutrient deprivation plus glucagon promotes proliferation of acidic lysosomal autophagic vacuoles in a CsA-dependent manner. Overnight cultured rat hepatocytes were co-loaded with MitoTracker Green-FM (MTG, 500 nM) and tetramethylrhodamine methylester (TMRM, 1 μM). Green-fluorescing MTG is retained covalently by mitochondria, whereas red-fluorescing TMRM is released after mitochondrial depolarization. TMRM quenches MTG fluorescence, and thus the recovery of green MTG fluorescence signifies individual mitochondrial depolarization. In other experiments, lysosomes were labeled with LysoTracker Red (200 nM). Switching from serum- and insulin containing growth medium to Krebs-Ringer-HEPES buffer containing 1 μM glucagon increased the number of individually depolarized mitochondria by196 and 358% after 20 and 40 min, respectively, and the number of lysosomes by 45, 208 and 430% after 20, 40 and 60 min. Lysosomal proliferation after autophagic stimulation lagged behind mitochondrial depolarization by 20 min. CsA (5 μM) blocked both depolarization and lysosomal proliferation. In conclusion, the MPT causes mitochondrial depolarization and promotes lysosomal proliferation after autophagic stimulation.

616 iNOS-DEPENDENT, p53-MEDIATED SUPPRESSION OF APOPTOSIS IN ALVEOLAR MACROPHAGES EXPOSED TO BLEOMYCIN *IN VIVO*.

D. W. Davis[1], D. A. Weidner[1], A. Holian[2] and D. J. McConkey[1]. [1]*MD Anderson Cancer Center, Houston, TX and* [2]*University of Texas Medical School, Houston, TX.*

Chronic inflammation in the lung leading to the development of pulmonary fibrosis is a common response to environmental pollutants and cancer chemotherapeutics such as bleomycin. We speculate that pulmonary fibrosis may be initiated by bleomycin-induced apoptosis of alveolar macrophages resulting in impaired clearance of apoptotic cells and/or release of inflammatory cytokines. Here we report that bleomycin stimulated apoptosis in alveolar macrophages from C57/Bl6 mice exposed to bleomycin *in vivo* or *in vitro*. Cell death was associated with oligonucleosomal DNA fragmentation and was inhibited by the caspase inhibitor ZVAD-fmk. Analysis of p53 localization demonstrated translocation of wild-type p53 into the nucleus following exposure to bleomycin *in vivo* but not *in vitro*. Strikingly, alveolar macrophages from homozygous p53-deficient mice were 2 fold more sensitive to bleomycin than those obtained from wild-type mice following exposure *in vivo*. Similarly, TUNEL analysis demonstrated that lung epithelial cells were 4-5 fold more sensitive to bleomycin-induced apoptosis than were wild-type cells. However, there was no difference in levels of apoptosis in wild-type and p53-/- macrophages exposed to bleomycin *in vitro*. Furthermore, levels of apoptosis were significantly higher in iNOS-/- mice than wild-type mice treated with bleomycin *in vivo*. In addition, bleomycin upregulated iNOS expression in wild-type mice. Our results strongly suggest that nitric oxide activates p53 to suppress bleomycin-induced apoptosis within the lung.

617 TNF-α STIMULATES CARDIOMYOCYTE APOPTOSIS BY A p38 MAPK-DEPENDENT PATHWAY REQUIRING REACTIVE OXYGEN SPECIES.

J. B. Klein, G. Wang, Z. Zhou, A. Buridi and Y. J. Kang. *University of Louisville, Louisville, KY.*

The molecular mechanisms of TNF-α (TNF) dependent apoptosis are incompletely understood. We have established a primary neonatal mouse cardiomyocyte culture system to study the mechanisms of cardiomyocyte apoptosis. This system was used to culture cardiomyocytes from cardiac specific metallothionein (MT) overexpressing transgenic mice produced in our laboratory. MT is a potent antioxidant that scavenges many reactive oxygen species (ROS). Using this model, we addressed the hypothesis that TNF stimulates cardiomyocyte apoptosis by a p38 mitogen activated protein kinase (MAPK) dependent pathway. p38 MAPK activation was determined by immunofluorescent staining with anti-phospho-p38 MAPK antibody and visualization by confocal microscopy. Apoptosis was measured by Annexin V binding and TUNEL assay. TNF rapidly activated p38 MAPK and induced myocyte apoptosis. Pharmacologic p38 MAPK inhibition by SB203580 (an inhibitor of p38 MAPK alpha and beta, but not gamma and delta) blocked TNF-dependent apoptosis. Furthermore, MT cardiomyocytes were resistant to TNF-stimulated p38 MAPK activation and apoptosis. However, p38 MAPK is functional in MT-overexpressing cells as evidenced by the finding lipopolysaccharide (LPS) stimulated apoptosis and activated p38 MAPK in wild-type cardiomyocytes. SB203580 inhibited LPS-induced apoptosis. Interestingly, LPS activated p38 MAPK, but did not induce apoptosis in MT-overexpressing cardiomyocytes. These observations indicate that: 1.) Not all activated p38 MAPK isoforms cause apoptosis; 2.) TNF activates a specific p38 MAPK isoform that propogates the apoptotic pathway; 3.) ROS, through an unknown mechanism, activate a p38 MAPK isoform that is essential to apoptotic signalling.

618 ROLE OF FAS AND FAS LIGAND IN METHYLCHOLANTHRENE-INDUCED TUMORIGENESIS.

A. Zeytun[1], M. Nagarkatti[2] and P. S. Nagarkatti[1]. [1]*Dept. of Biology, Virginia Polytechnic and State University, Blacksburg, VA and* [2]*Dept. of Biomedical Sciences and Pathobiology, VA-MD Regional College of Veterinary Medicine, Blacksburg, VA.*

Methylcholanthrene (MCA) is a member of the polycyclic aromatic hydrocarbons and a potent chemical carcinogen. In the current study, we investigated the role played Fas and Fas ligand(L) in the induction of tumors by MCA. Injection of MCA subcutaneously or intraperitoneally induced tumors more rapidly in two month-old C57BL6 lpr/lpr (Fas-deficient) and C57BL6 gld/gld (FasL-defective) mice when compared to age-matched C57BL6 +/+ mice. Also, in lpr and gld mice, the tumors grew at a faster rate than in wild-type mice. When the above mice were challenged with a LSA, a syngeneic tumor followed by treatment with BCNU, a nitrosourea, 100% of the mice could reject the tumor. However, upon rechallenge with the same tumor, 100% of the wild-type mice but not lpr or gld mice, were able to reject the LSA tumor. The lpr and gld mice but nor wild-type mice, exhibited increased levels of TGF-b and IL-10, particularly with increasing age. These studies demonstrate that lpr and gld mice are more susceptible to MCA-induced tumors because of the inability of the tumor cells to undergo Fas-based apoptosis and due to a defect in antitumor immunity. Recently, humans with defect in Fas have been identified and have been shown to develop lymphoproliferative disease. Our studies demonstrate that individuals with a defect in Fas and/or FasL may be more susceptible to tumors induced by chemical carcinogens (Supported in part by grants from NIH ES 09098, HL 058641 and AI 01392 and EPA.)

619 GLUTAMATE CYSTEINE LIGASE CATALYTIC SUBUNIT IS CLEAVED DURING APOPTOTIC CELL DEATH.

C. M. Krejsa[1], C. C. Franklin[2], R. H. Pierce[2], C. C. White[1], N. Fausto[2] and T. J. Kavanagh[1]. [1]*Department of Environmental Health, University of Washington, Seattle, WA and* [2]*Department of Pathology, University of Washington, Seattle, WA.*

Apoptosis is a highly regulated form of cell death which occurs following growth factor withdrawl and engagement of cell surface "death" receptors. Many chemical toxicants and chemotherapeutic agents exert their toxicity through the induction of apoptotic pathways. A common feature in numerous models of apoptosis is the disregulation of intracellular redox status. In particular, glutathione (GSH) levels often decline rapidly following apoptotic stimuli, and supplementation with GSH precursors has been shown to promote resistance to apoptosis in many models. The rate limiting step in GSH biosynthesis is catalyzed by glutamate cysteine ligase, (GLCL, aka. γ-glutamyl cysteine synthetase). We have found that during apoptosis the catalytic subunit (GLCL-C) is cleaved in a caspase-3 dependent manner. This cleavage occurs in a variety of cells undergoing receptor-mediated and chemically induced apoptosis, and also *in vivo*, in livers of mice treated with anti-Fas antibody. Purified recombinant GLCL-C treated *in vitro* with apoptotic cell lysates or with recombinant caspase-3 is cleaved to a stable, lower molecular weight product. In vitro cleavage is blocked by peptide inhibitors of caspase-3. GLCL-C cleavage is not observed in MCF-7 cells which do not express caspase-3; however MCF-7 cells transfected with caspase-3 do cleave GLCL-C during apoptosis. Furthermore, cleavage is specific to GLCL-C, and does not affect the molecular weight of the GLCL regulatory subunit. Recombinant mouse GLCL-C which has been mutated at the cleavage site is not cleaved *in vitro* or in transfected cells undergoing apoptosis. We are currently investigating the functional effects of GLCL-C cleavage on enzyme activity. (This work was supported by NIH grants CA75316, ES04696, and ES07033.)

620 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN (TCDD) INHIBITS GROWTH FACTOR WITHDRAWAL-INDUCED APOPTOSIS IN THE HUMAN MAMMARY EPITHELIAL CELL LINE, MCF-10A.

J. W. Davis, II, K. Melendez, V. M. Salas and S. W. Burchiel. *University of New Mexico College of Pharmacy Toxicology Program, Albuquerque, NM.*

Previous studies have demonstrated that under growth factor-restricted conditions 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) stimulates growth, the tyrosine phosphorylation of numerous effector molecules, and increases phosphatidylinositol 3-kinase (PI3K) activity in MCF-10A cells. In the present studies TCDD (3-30 nM) was found to increase cell recovery on days 2-6 by as much as 80% when insulin or epidermal growth factor (EGF) were removed from the media. In addition, TCDD inhibited apoptosis stimulated by EGF or EGF and insulin withdrawal by almost 80% as determined by annexin V binding and poly(ADP-ribose) polymerase (PARP) cleavage. However, withdrawal of insulin alone did not induce apoptosis even though TCDD did increase cell number in its absence. The phosphorylation status of Akt, a serine/threonine kinase that mediates PI3K-dependent inhibition of apoptosis, was examined. Immunoblot analysis revealed that TCDD treatment resulted in a transient increase in Akt phosphorylation that disappears within 18 hr. It appears that EGF stimulates an anti-apoptotic pathway, whereas insulin signals a pro-mitogenic pathway. TCDD seems to mimic both of these pathways. These data shed light on a potential mechanism whereby TCDD may act as a human breast carcinogen and a tumor-promoting agent. (NIEHS R01-ES-07259.)

621 DEXAMETHASONE INDUCES APOPTOSIS IN ALL SUBSETS OF T LYMPHOCYTES IN THE THYMUS AND PERIPHERY.

M. Nagarkatti[1], A. Kamath[1] and P. S. Nagarkatti[2]. [1]*Dept. of Biomedical Sciences and Pathobiology, VA-MD Regional College of Veterinary Medicine, Blacksburg, VA and* [2]*Dept. of Biology, Virginia Polytechnic and State University, Blacksburg, VA.*

It is well established that dexamethasone induces thymic atrophy by triggering apoptosis in immature CD4+ CD8+ T cells. In the current study, we investigated the effect of dexamethasone on induction of apoptosis in other T cell subsets in the thymus and spleen. C57BL/6 mice were injected with 100 mg/kg body weight of dexamethasone by the i.p. route. The control mice received the vehicle alone. Twelve hours later, the thymus and spleen were harvested and stained with antibodies against CD4 and CD8, and FITC-dUTP and analyzed flow cytometrically for triple color staining. The results demonstrated that dexamethasone induced apoptosis in all 4 subsets of T cells(CD4+, CD8+, CD4+CD8+ and CD4-CD8-). This was demonstrable both immediately and after *in vitro* culture. In the spleen, apoptosis was not detected immediately upon isolation, however, following *in vitro* culture, apoptosis could be detected in both CD4+ and CD8+ T cells as well as in B lymphocytes. Dexamethasone treatment induced upregulation of caspase-3 activity in the thymus but not in the spleen. The current study demonstrates that dexamethasone can not only induce apoptosis in immature cortical T cells in the thymus but also in mature lymphocyte subpopulations both in the thymus and periphery (Supported in part by grants from NIH ES 09098, HL 058641 and AI 01392 and EPA.)

622 TCDD-INDUCED APOPTOSIS IN THE THYMOCYTES OF PERINATALLY-EXPOSED NEONATES.

L. M. Hudson[1], M. Nagarkatti[2] and P. S. Nagarkatti[1]. [1]*Department of Biology, Virginia Tech, Blacksburg, VA and* [2]*Department of Biomedical Sciences and Pathobiology, Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA.*

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) is a highly toxic environmental contaminant. The immune system is highly sensitive to TCDD and therefore this contaminant has raised significant health concerns. Recent studies from our laboratory demonstrated that TCDD treatment triggers apoptosis in thymocytes of adult C57BL/6 mice. Also, prenatal administration of TCDD has been shown to have profound immunotoxic effects. In the current study we tested the hypothesis that prenatal administration of TCDD results in immunotoxicity due to induction of apoptosis in thymocytes of the neonate. To this end, pregnant female C57BL/6 mice were given a single intraperitoneal injection on gestational day 14 with 0.1, 1, or 5mg/kg body weight TCDD or the vehicle, as a control. On postnatal days 2, 4, 7, 14, and 21, the thymocytes were isolated and studied for apoptosis using terminal deoxynucleotidyl transferase (TdT) and fluorescein isothiocynate (FITC-dUTP). We found that thymic cellularity and percent viability of the thymocytes was decreased in the pups exposed to the highest dose of TCDD, when compared to the control. On postnatal days 2 and 4, but not subsequently, thymocytes from TCDD-exposed pups showed increased apoptosis upon *in vitro* culture, when compared to the control. These results indicate that TCDD-induced toxicity in perinatally-exposed neonates is due to induction of apoptosis in the thymocytes (Supported in part by grants from NIH ES 09098, HL 058641 and AI 01392 and EPA.)

623 EFFECT OF ALACHLOR ON MOUSE SPLENOCYTE APOPTOSIS.

H. P. Misra[1], J. Bard[1], F. Adeshina[2] and H. Choudhury[2]. [1]*Virginia Tech, Blacksburg, VA and* [2]*USEPA NCEA, Cincinnati, OH.*

Alachlor, a class II carcinogen, is widely used as a herbicide. The precise mechanism of carcinogenesis and an effective biomarker for monitoring alachlor exposure have not been defined. We studied the effects of alachlor on mouse splenocytes to assess programmed cell death (apoptosis). Splenocytes were treated with 0, 10, 50, 100, or 500 μM alachlor for 16hrs and a DNA ladder assay as a marker of cellular apoptosis and a flow cytometric TUNEL assay for quantitation of DNA breaks in single cells were utilized to assess apoptosis in these cells. The DNA ladder assay showed increased DNA breaks in cells treated with alachlor in a dose-dependent manner. A significant increase in laddering was observed exposing cells with as little as 10 μM alachlor. Treatment of cells with 100 μM alachlor resulted in a very intense DNA ladder with little intact genomic DNA remaining in the cell population. The results of TUNEL assay supported the results obtained from the DNA ladder assay. Thus, cells treated with 0, 10, 50, 100 and 500 μM alachlor showed 28, 56, 62, 74, and 93% FITC (an indicator of 3' DNA breaks) incorporation, respectively. These findings could be useful for the development of biomarkers to assess the safety of this chemical in the environment. (This work was supported in part by the US EPA under a cooperative agreement.)

624 FLUORIDE INDUCES APOPTOSIS BY CASPASE-3 ACTIVATION IN HL-60 CELLS.

C. D. Anuradha, S. Hirano and S. Kanno. *Regional Environment Division, National Institute for Environmental Studies, Tsukuba, Japan.* Sponsor: G. E. Hatch.

Fluoride is well known as a specific and effective caries prophylactic agent and its systemic or local application was therefore recommended during the past decades. However several problems resulting from fluoride toxicity like dental and skeletal fluorosis have been recognised. Fluoride toxicity is gaining increasing importance, but still very little is known on the mechanism of action of fluoride. In the present study the toxicity of fluoride on human leukemia (HL-60) cells were investigated. **Material and Methods:** HL-60 cells were cultured in RPMI 1640 medium containing 10% FBS at 37°C and 5% CO_2 atmosphere. The cells were exposed to fluoride and FITC-Annexin-V binding, DNA laddering, Western blotting using polyclonal anti-caspase-3 and PARP (poly ADP-ribose polymerase) activity were investigated. **Results and Discussion:** HL-60 cells underwent apoptosis on exposure to 2 mM fluoride. When fluoride treated cells were incubated with FITC-Annexin V, binding of FITC-Annexin to surface of cells were observed. Agarose gel of extracted DNA from fluoride treated cells showed DNA ladder which is a typical feature of apoptosis. Western blot reveals a 17 kd subunit of active caspase-3 in fluoride treated cells along with 32 kd unprocessed pro-caspase 3 seen in untreated cells suggesting that fluoride triggers apoptotic cell death by caspase-3 activation in HL-60 cells. The treated cells showed a cleaved 85 Kd fragment and complete loss of the intact 116 kd form of PARP as compared to untreated cells. The results clearly suggest that fluoride is toxic to HL 60 cells by triggering a apoptotic pathway,in the process activating caspase-3 which in turn cleaves PARP leading to DNA damage and ultimately cell death.

625 VARIABILITY IN HUMAN SENSITIVITY TO ARSENIC: AN INTERNATIONAL STUDY OF POPULATION RESPONSE TO ARSENIC IN DRINKING WATER.

C. A. Loffredo[1], H. V. Aposhian[2], M. E. Cebrian[3], H. Yamauchi[4] and E. K. Silbergeld[1]. [1]*University of Maryland, Baltimore, MD,* [2]*University of Arizona, Tucson, AZ,* [3]*CINVESTAV, Mexico DV, Mexico and* [4]*Marianna School of Medicine, Kawasaki, Japan.*

Estimating the nature and extent of human cancer risks due to arsenic (As) in drinking water is currently of great concern, since millions of persons worldwide are exposed to arsenic primarily through natural enrichment of drinking water drawn from deep wells. Humans metabolize and eliminate As through oxidative methylation and subsequent urinary excretion. Variations in arsenic metabolism may therefore affect individual risks of intoxication and carcinogenesis. Using data from three populations, from Mexico, China, and Chile, we have analyzed the distribution in urine of total arsenic and arsenic species (inorganic arsenic (InAs), monomethyl arsenic (MMA), and dimethyl arsenic (DMA)). Arsenic species were separated by ion exchange chromatography and measured by atomic absorption spectrophotometry. Data were analyzed in terms of total amounts of each species and by evaluating each species as a ratio to each species and to total As. In each population we examined male-female differences in urinary levels of the three forms of As within areas of high and low As exposure via drinking water. In all persons most of the urinary As was present as DMA. Male-female differences were discernible in both high and low exposure groups from all three populations, but the gender differences varied by population. The data also indicated bimodal distributions in the ratios of DMA to InAs and to MMA. While the gene or genes responsible for arsenic methylation are still unknown, the results of our studies among the ethnic groups in this study are consistent with the presence of functionally genetic polymorphisms in arsenic methylation leading to measurable differences in toxicity. The metabolic differences among these populations are consistent with reported differences in population risks of arsenic-induced cancer. These studies highlight the need for continuing research on the health effects of As in humans using molecular epidemiologic methods.

626 CYTOTOXICITY AND MITOGENICITY OF ARSENICALS ON RAT AND HUMAN UROTHELIAL CELLS.

S. Yamamoto, L. L. Arnold, P. Ryder, E. Uzvolgyi and S. M. Cohen. *Pathology/Microbiology, University of Nebraska Med. Ctr., Omaha, NE.*

Dimethylarsinic acid (DMA) chronically fed to F344 rats produced urothelial tumors. We showed that it leads to urothelial cytotoxicity with consequent regeneration. Various arsenicals are present in the urine of DMA-treated rats [9.9 μM AsIII and 78.8 μM DMA, (Wanibuchi et al., Carcinogenesis, 1996)]. To evaluate the cytotoxicity and mitogenicity of arsenic compounds, we added them to cultured non-tumorigenic rat bladder urothelial cell lines S6 and MYP3. The cells were treated with sodium arsenite (AsIII), sodium arsenate (AsV), DMA, and monomethylarsonic acid (MMA) for 7 days and then cell viability was evaluated using Trypan blue. The LC50 was 0.5 μM AsIII and 5 μM AsV in both S6 and MYP3 cells, but was 0.2 mM for DMA and 1 mM for MMA in S6 cells and 0.5 mM for DMA and 5 mM for MMA in MYP3 cells. The effect of DMA on the cell cycle of MYP3 cells was examined by flow cytometry. After 7 days treatment with 1 mM DMA, most cells arrested in the G2 phase and many multinucleated cells were present. These results indicate that urothelial cell lines are more sensitive to arsenic compounds compared with other cell lines previously reported. However, as with other cell lines, inorganic arsenicals are considerably more cytotoxic than organic arsenicals. Cytotoxicity *in vitro* of AsIII occurred at concentrations comparable to those produced in urine of rats fed cytotoxic and carcinogenic doses (100 ppm of the diet or drinking water) of DMA.

627 GENETIC EVENTS ASSOCIATED WITH ARSENITE-INDUCED MALIGNANT TRANSFORMATION: APPLICATION OF cDNA MICROARRAY TECHNOLOGY.

H. Chen[1], J. Liu[1], A. Merrick[2] and M. Waalkes[1]. [1]*NCI and* [2]*Lab of Molecular Carcinogenesis at NIEH/NIH, Research Triangle Park, NC.*

Arsenic is a human carcinogen. Epidemiological studies link arsenic exposure to cancers of the skin, lung, liver and other internal. However, inorganic arsenic has never been unequivocally shown to be carcinogenic in animals, and its mechanism remains unknown. Our previous showed that chronic (>18 weeks), low level exposure (125 to 500 nM) to arsenite induces malignant transformation in a liver epithelial cell line (PNAS 94: 10907, 1997). DNA methylation is significantly reduced and aberrant expression of the oncogene, c-*myc*, is increased with transformation. To further examine aberrant gene expression associated with arsenic carcinogenesis, the Clontech cDNA expression microarray was used. Our results show that the expression of more than 50 genes were altered in arsenite-transformed cells. For example, many oncogenes (c-*myc*, c-*jun* and c-*met*, etc.) were increased, while the tumor suppressor gene P53 was decreased. IGFII and insulin receptor were downregulated. Expression of the cell cycle related genes CyclinD1, and PCNA were increased while CDK4 was decreased in transformed cells. Expression of GST gene and several transporter protein genes were increased. The results of Western Blot analysis of c-Myc, CyclinD1, PCNA, P53 and GST agree with the analysis of gene expression. These results revealed for the first time important aberrant gene expression patterns occurring in arsenite-induced malignant transformation. These initial studies could be critical in future studies designed to more fully elucidate the molecular mechanisms of arsenic carcinogenesis.

628 SODIUM ARSENITE INDUCES DNA-PROTEIN CROSSLINKS IN WRL HUMAN HEPATIC CELLS IN MOUSE LIVER.

P. Ramirez[1], L. M. Del Razo[2], D. L. de la Cruz[3], C. Rios[1], L. Galvan[1] and M. E. Gonsebatt[1]. [1]*Ins Inv Biomed, UNAM, Mexico DF, Mexico,* [2]*CINVESTAV, IPN, Mexico DF, Mexico and* [3]*Ins Nal de Neurologia, Mexico DF, Mexico.*

The induction of DNA-protein crosslinks (DPC) have been proposed as indicators of early biological effects due to the fact that known or suspected carcinogens induce an increased proportion of proteins tightly bound to DNA. Arsenic is a human carcinogen metabolized in liver cells through series of oxi-reduction reactions that could potentiate the formation of DNA-protein crosslinks. To investigate if arsenite could induce DPC we decided to use a human hepatic cell line (WRL-68). After treatment of confluent cells with different concentrations of As 3+, they were lysed and DPC precipitated and isolated with a solution of 2% SDS solution and KCl. Trivalent arsenic induced DNA-protein crosslinks linearly related with dose. Thus, we decided to test the induction of DPC in whole animals. 25-30 mg Balb C male mice, were treated with different concentrations of sodium arsenite i.p.(4.5, 9 and 12 mg/kg) and orally during 30 days (4, 8 and 10 ppm in drinking water). Mice were killed by cervical dislocation, livers where extracted and homogenized in PBS pH 7.4 three hours after i.p. treatments and on the 30th day in oral treatments. A significant increase of DPC was observed in mice receiving 12 mg/kg i.p. and in those receiving 8 ppm in drinking water. Since DPC are also induced by other known or suspected carcinogens, they could represent a early manifestation of liver damage by arsenite.

629 SODIUM ARSENITE-INDUCED DYSREGULATION OF PROTEINS INVOLVED IN PROLIFERATIVE SIGNALING.

K. J. Trouba, E. M. Wauson and R. L. Vorce. *University of Nebraska Medical Center, Omaha, NE.*

It is well accepted that arsenic is a human carcinogen, yet its mechanism of action is not defined. Arsenic cannot be classified as an initiating agent or as a promoter, although altered proliferative reponsiveness has been proposed as a mechanism by which arsenic exerts its carcinogenic effects. Based on the hypothesis that arsenic exposure results in modulation of both positive and negative regulators of cell proliferation, this study examined physiological and biochemical changes in the proliferative response of murine fibroblasts grown long-term in the maximum tolerated concentration of sodium arsenite. In response to EGF stimulation, DNA synthesis and the proportion of cells entering S phase of the cell cycle both were increased in cells grown long-term in arsenic as compared to arsenic-naive cells. Analysis of positive proliferative regulators revealed an increase in the expression of c-myc and E2F-1, thereby supporting the hypothesis that arsenic increases activity of positive growth modulators. In contrast, the activity of ERK-2 was decreased, and expression of EGF-receptor and mSOS were unchanged. When negative regulators of proliferation were examined, expression levels of MAP kinase phosphatase-1 and p27Kip1 were found to be lower in arsenic treated cells as compared to control cells; this result supports a model in which arsenic disinhibits normal regulation of cell proliferation. Taken together, these data indicate that long-term exposure to sodium arsenite creates conditions within the cell consistent with sensitization to mitogenic stimulation. It is further postulated that the observed changes in mitogenic signaling proteins contribute to the carcinogenic property of arsenic.

630 ARSENIC(III) ALTERS GLUCOCORTICOID RECEPTOR (GR) FUNCTION AND GR-DEPENDENT GENE REGULATION IN H4IIE CELLS.

R. C. Kaltreider, R. A. Green and J. W. Hamilton. *Dartmouth Medical School, Hanover, NH.*

Chronic human exposure to non-overtly toxic doses of arsenic is associated with an increased risk of cancer. Although its carcinogenic mechanism is still unknown, arsenic is not directly genotoxic and is therefore thought to act principally as a tumor promoter. Previous studies in our laboratory demonstrated that low dose As(III) had profound effects on expression of several inducible genes, including the hormone-regulated phosphoenolpyruvate carboxykinase (PEPCK) gene, in whole animal and cell culture systems. The effects of As(III) on both basal and hormone-inducible PEPCK expression were strongly associated with the glucocorticoid receptor (GR)-mediated regulatory pathway. We therefore specifically examined the effects of As(III) on the biochemical function of GR in hormone-responsive cells. Non-cytotoxic As(III) treatments 1.0-3.3 μM) of rat hepatoma H4IIE cells significantly decreased both basal and dexamethasone (Dex)-inducible expression of transiently transfected luciferase constructs under the transcriptional control of either two tandem glucocorticoid response elements (GREs) or 600 bp of the proximal rat PEPCK promoter which contains two GREs. The decreases in Dex induction following As(III) were As(III) dose-dependent but not time-dependent, occurring even after simultaneous administration of As(III) and Dex. Gel mobility shift assays demonstrated no significant effect of As(III) treatment on basal GR-DNA binding in nuclear extracts from As(III)-treated cells. However, As(III) had little or no effect on cellular GR protein levels as measured by western blot assays. In addition, As(III) caused the translocation of a green fluorescent protein (GFP)-tagged GR fusion protein to the nucleus, as measured by confocal microscopy, whereas As(III) pre-treatment had no effect on Dex-induced translocation. These results suggest that As(III) is altering GR function and GR-dependent gene regulation principally by altering its function as a transcription factor. (NIH-NIEHS ES07373.)

631 ISOLATION OF P53-REPRESSOR PROTEINS INDUCED BY EXPOSURE OF HUMAN KERATINOCYTES TO LOW LEVELS OF ARSENITE.

H. Hamadeh[1], K. Hayes[1], E. Nuaysir[1], J. C. Barrett[1], D. B. Menzel[2] and C. Afshari[1]. [1]*NIEHS, Research Triangle Park, NC and* [2]*UCI, Irvine, CA.*

The skin is considered a major target of arsenic carcinogenesis. However, there is little known of the mechanism of arsenic carcinogenesis. We previously reported on the ability of environmentally-relevant levels of arsenite (As III) to modulate levels of p53 and mdm2 in human keratinocytes (HaCaT). The decrease in p53 levels was attributed to the concomitant increase in mdm2 levels. We investigated whether p53 modulation was due to factors other than mdm2 binding to p53 thereby increasing rate of degradation. We employed affinity chromatography by using a DNA sequence from the promoter region of the p53 gene to isolate proteins that might help modulate the levels of p53 due to arsenite exposure by binding to this region of the promoter. We isolated several proteins that were induced by arsenite treatment (0, 100, 500, 1000 nM) of human keratinocytes (HaCaT) for 14 days, and would tentatively act as repressors of the p53 gene by binding to its promoter region. We also report on using microarray technology to observe induction of a suite of genes representing a unique footprint for arsenic exposure. These genes might be useful for the screening of compounds for their potential effects that are related to those of arsenic.

632 ELEVATED LEVELS OF INDUCIBLE HEAT SHOCK PROTEIN (HSP70-1) PROTECT MCF-7 CELLS FROM ARSENITE TOXICITY.

J. A. Barnes[1], D. J. Dix[2], B. W. Collins[3], J. B. Garges[2] and J. W. Allen[3]. [1]*National Research Council, Environmental Carcinogenesis Division, USEPA, Research Triangle Park, NC,* [2]*Reproductive Toxicology Division, USEPA, Research Triangle Park, NC and* [3]*Environmental Carcinogenesis Division, USEPA, Research Triangle Park, NC.* Sponsor: I. W. Smoak.

Elevated HSPs protect against cellular damage from heat but it is unclear whether HSP induction alters the damaging effects of chemical contaminants. This study was designed to investigate the effects of sodium arsenite (As) in MCF-7 cells that overexpress inducible HSP70. A tetracycline-controlled expression system was developed to regulate HSP70 levels. Clone14 (C14) exhibited the highest induction of HSP70 in the absence of doxycycline ("ON") and HSP70 could be down-regulated to control levels in the presence of doxycycline ("OFF"). In order to examine the cytotoxic and genotoxic effects of sodium arsenite, C14ON and C14OFF cells were exposed to either 0 (control), 5 μM or 10μM As. For cytotoxicity studies, cells were exposed for 24 hours and assayed for viability and apoptosis using acridine orange and ethidium bromide staining. Both C14ON and C14OFF cells showed a dose-dependent decrease in cell viability and increase in apoptosis in response to arsenite. Cells expressing elevated HSP70 were significantly less affected (i.e. higher viability, lower apoptosis) than cells that did not overexpress HSP70. The genotoxicity of arsenite was evaluated using a cytokinesis-block micronucleus (MN) assay. MN were induced in both C14ON and C14OFF cells in response to As. However, induction levels of MN were significantly lower in HSP70 overexpressing cells as compared to cells that expressed control levels of HSP70 ($p< 0.05$). Collectively, these data demonstrate a protective effect of HSP70 expression on the cytotoxic and genotoxic effects of arsenite in MCF-7 cells. (This abstract does not necessarily reflect EPA policy.)

633 CARCINOGENICITY AND CO-CARCINOGENICITY OF SODIUMARSENITE IN p53+/- MALE MICE.

J. Popovicova[1], G. J. Moser[2], T. L. Goldsworthy[2] and R. R. Tice[2]. [1]*AWWARF, Denver, CO and* [2]*ILS, Research Triangle Park, NC.*

Arsenic is a human carcinogen for which there are presently no rodent model systems. Methylation is the proposed mechanism for thedetoxification of arsenicals. Hepatic methyl donor status in rodents can be decreased by maintenance on a choline deficient (CD) diet compared to a choline sufficient (CS) diet. This study evaluated the carcinogenicity and co-carcinogenicity of arsenic in male p53+/- mice as a function of hepatic methyl donor status. Co-carcinogenicity for bladder and skin, two human tumor sites for arsenic, was tested usingp-cresidine and 4-vinyl-1-cyclohexene diepoxide (VCD), respectively. Over a 26-week period, groups of =20 male p53+/- mice were exposed tosodium arsenite (0.005%) in drinking water, p-cresidine (0.2%) in the diet, VCD (25 mg/week) administered dermally, both sodium arseniteand p-cresidine, or both sodium arsenite and VCD. At the completion of the 26-week treatment period, mice treated with VCD or VCD and arsenic were maintained for an additional 22 weeks on arsenic alone. In terms of hepatic methyl donor status, levels of s-adenoysl-methionine and s-adenoysl-homocysteine in liver were independent of diet while CD mice exhibited reduced hepatic levels of phosphocholine. CD mice on arsenic excreted lower levels of arsenicals in urine. Treatment with arsenic alone did not induce a significant tumor response in mice on either diet. The incidence of skin tumors was increased in CS but not CD mice treated with VCD; the incidence was not modulated by exposure to arsenic. Both the CD diet and arsenic enhanced the extent of bladder hyperplasia and the incidence of carcinomas in p-cresidine-exposed mice. Under these conditions, arsenic was not carcinogenic inmale p53+/- mice. However, concomitant exposure to arsenic appeared to increase the incidence of bladder carcinomas in CD mice exposed top-cresidine. (This work was supported by AWWARF.)

634 ROLE OF MAP KINASES (MAPKs) AND APOPTOSIS IN ARSENIC-INDUCED MALIGNANT TRANSFORMATION AND SELF-TOLERANCE.

W. Qu, C. Bortner, M. Hobson, J. Liu, T. Knowles and M. P. Waalkes. *NIEHS, Research Triangle Park, NC.*

Arsenic is a human carcinogen. Our prior work showed that chronic arsenite (As^{+3}) exposure induced malignant transformation in a rat liver epithelial cell line (TRL 1215) and that self tolerance to As^{+3} occurs concurrently with transformation in these cells. This study examined the role of signal transduction in malignant transformation induced by As^{+3} and in the concurrent development of self-tolerance to acute As^{+3} toxicity. Transformation was induced in TRL 1215 cells by continuous exposure to 0.5 μM As^{+3} for 18 or more weeks, and these cells were then compared to passage matched control cells. Other TRL 1215 cells were treated subchronically (2-3 weeks) with As^{+3} to define events occurring prior to transformation. The various treatment groups and controls were subjected to an acute high dose As^{+3} exposure and levels of phosphorylated MAPKs, ERK1/2, JNK and P38, were determined by Western blot analysis. After acute As^{+3} exposure, all three MAPKs were phosphorylated in a time-dependent and dose-dependent fashion in all treatment groups. However, the levels of phosphorylated ERK1/2 and JNK were decreased in the As- transformed cells compared to control, while the levels of phosphorylated ERK1/2, JNK and P38 remained the same as control in cells treated subchronically with As^{+3}. Flow cytometry analysis using Annexin/FITC revealed that As^{+3}-induced apoptosis was markedly reduced in As-transformed cells compared to control cells, while As^{+3}-induced apoptosis was increased in cells exposed subchronically to As^{+3} compared to control. These results indicate that As^{+3} induces apoptosis in the early stages of exposure prior to transformation but that after As^{+3}-induced transformation has occurred, cells show resistance to As^{+3}-induced apoptosis, a finding which might be due to down-regulation of MAPKs pathways. This resistance to apoptosis may play a critical role in As^{+3}-induced self tolerance and, if generalized, has potential implications for As-induced malignancies.

635 FURTHER TRANSFORMATION OF IMMORTALIZED HUMAN KERATINOCYTE FOLLOWING TREATMENT OF MNNG, ARSENIC, OR AN ARSENIC-CONTAINING MIXTURE.

D. Bae, J. A. Campain and R. S. H. Yang. *Center for Enviromental Toxicology and Technology, Department of Environmental Health, Colorado State University, Fort Collins, CO.*

As an initial phase of a project exploring the carcinogenic potential of arsenic (As) and an As-containing metal mixture in human keratinocytes, cell transformation studies were conducted. To generate a positive control for chemical transformation of immortalized human keratinocytes, we chose the RHEK-1 cell line and a known human carcinogen, 1-methyl-3-nitro-1-nitrosoguanidine (MNNG). In parallel, RHEK-1 cells were exposed to MNNG (one 24hr exp.), or to low doses (0.12 - 0.18μM) of As or to an As, Cr, Cd, Pb mixture; the latter two treatments were carried out chronically for 6 mos. At passage 13 after treatment with 0.1μg/ml MNNG, the exposed cells (OM3) gained the ability to grow in methylcellulose (MC); at passage 25 the culture tested highly positive for tumorigenicity in immunocompromised mice. Interestingly and in contrast to what we observed with OM3, we saw no conversion of RHEK-1 to the anchorage independent phenotype at any dose of As tested. As-treated cultures had an altered morphology from control cells, showed altered growth characteristics in MC, and exhibited decreased differentiation when confluent. Our findings support the idea that As is not capable of transforming immortalized keratinocytes when administered alone, but does have substantial effects on cell growth and differentiation. Cultures treated with the 4-metal mixture showed very similar behavior to As-treated cultures. We are

currently analyzing the tumorigenicity of both the As- and mixture-treated cultures in nude mice. Establishment of a malignant cell line (OM3) is crucial for all of our carcinogenesis studies, as it will enable us to identify distinct transformation-associated end points in human keratinocytes. (This study was supported by ATSDR [Cooperative Agreement U61/ATU881475], and NIEHS Superfund Basic Research Program [P42 ES05949].)

636 ARSENIC, ALONE AND IN CHEMICAL MIXTURES, ANTAGONIZES THE DEVELOPMENT OF GLUTATHIONE S-TRANSFERASE π (GST-P) POSITIVE FOCI IN THE RAT LIVER.

W. A. Pott, S. A. Benjamin and R. S. H. Yang. *Center for Environmental Toxicology & Technology, Fort Collins, CO.*

Using Ito's Medium-Term Liver Foci Bioassay, we implemented a "top-down" approach to further investigate the antagonistic effects of a 4-chemical mixture (Pott *et al.*, *Cancer Letters* 133:185-190, 1998) containing arsenic (As), 1,2-dichloroethane (DCE), trichloroethylene (TCE), and vinyl chloride (VC) on the development of glutathione S-transferase π (GST-P) positive hepatic foci in the rat. On day 1, adult male Fischer 344 rats were administered diethylnitrosamine (DEN; 200 mg/kg intraperitoneally) or saline as a negative control. During weeks 3-8, the 4-chemical mixture (75 ppm As, 300 ppm DCE, 1900 ppm TCE, 15 ppm VC), or a 3- (As, DCE, TCE) or 2-chemical submixture (As, DCE), or As alone was orally administered to rats. An additional treatment group received the 4-chemical mixture with a higher dose level of As (300 ppm weeks 3-4, 150 ppm weeks 5-8). Arsenic and DCE were administered in the drinking water, TCE and VC via once daily corn oil gavage, 5 days/week. DEN positive controls received deionized water and corn oil gavage. Rats underwent partial hepatectomy on day 22 and were sacrificed at the end of week 8. Preliminary morphometric analysis revealed a significant decrease in the total area of GST-P positive foci associated with exposure to As alone (75 ppm) compared to DEN positive controls ($p < 0.05$). Exposure to the 4-chemical mixture (300/150 ppm As) significantly decreased the total area of GST-P positive foci and the number of large foci (> 0.2 mm in diameter) compared to DEN positive controls ($p < 0.05$). These results suggest that As is responsible for the observed antagonistic effect. Experiments to further validate these findings and enhance comparisons among treatment groups are currently underway. (This project is funded by the ATSDR [Cooperative Agreement No. U61/ATU881475], NIEHS Superfund Basic Research Program [P42 ES05949], and NCI [K08 CA72396-03].)

637 EFFECTS OF 2,3,7,8-TETRACHLORODIBENZO-P-DIOXIN ON SP1 ABUNDANCE IN THE NEOCORTEX AND CEREBELLUM IN RATS.

T. Nayyar and D. B. Hood. *Meharry Medical College, Nashville, TN.*

Gestational exposure to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) has been strongly implicated to produce fetotoxic responses that consist of thymic hypoplasia, decreased fetal growth, prenatal and postnatal mortality along with developmental toxicity in male and female reproductive systems, in laboratory mammals. We have studied the effects of three single low dose exposures of TCDD in timed-pregnant rats on the developmental expression profile of Sp1 in different brain regions. Differential gene expression is partially regulated by transcription factors which may be targets for perturbations by TCDD. Single oral doses of 0.25, 0.5 and 1.0 μg TCDD/kg, respectively, were given on gestational day 15 to three groups of Harlan Sprague Dawley rats. Electrophoretic mobility shift analysis using nuclear extracts from the cerebral cortex and cerebellum of the offspring on postnatal days (PND) 3, 5, 10, 15, 20 and 30 revealed a dose dependent leftward shift in the developmental expression profile of Sp1 as compared to controls. There were little no statistically significant differences observed with regard to birthrate, body weight gain, and gross brain weight over the PND period. These observations suggest that *in utero* and lactational exposure to TCDD alters the developmental regulation of gene expression in the rat cortex and cerebellum through the modulation of the transcription factor Sp1. (Supported by NIH G12 RRO 3032 and NIEHS ES00287.)

637A GESTATIONAL EXPOSURE OF LONG EVANS RATS TO 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD) LEADS TO STUNTED MAMMARY EPITHELIAL DEVELOPMENT IN FEMALE OFFSPRING.

G. L. Youngblood[1], J. T. Hamm[2], L. S. Birnbaum[2] and S. E. Fenton[1]. [2]*US EPA, Reproductive Toxicology and* [2]*Experimental Toxicology Divisions, Research Triangle Park, NC.*

The effects of exposure of pregnant rats to TCDD on mammary gland development of resulting offspring was examined. Time-pregnant Long Evans rats were exposed to 1μg/kg TCDD or vehicle on gestation day 15. On postnatal day (PND) 4, litters were culled to 8 pups each. Female offspring were sacrificed on PND4, 33, 37, 45, 68 and 110 to examine mammary gland morphology. Treated animaals from all early time points were significantly smaller than control litter mates and displayed delayed vaginal opening. TCDD exposed offspring displayed vaginal threads when examined on PND33, 37, and 45. Mammary glands taken from treated animals on PND4 had severely stunted epithelial development. They displayed fewer primary branches (2.5 vs 3.5 for control), and dramatically fewer terminal end structures per gland (45 vs. 107 for control). This phenomenon was subsequently observed in glands of 33 and 37 day old females. Furthermore, unlike fully developed glands of control 45 day old females, all of those previously exposed to TCDD retained prominent terminal end buds. Although end buds were differentiated in glands of 68 and 110 day old animals, the spindly nature of the glands from treated dams was still prominent. In mammary transplantation studies, involving the addition of epithelium taken from the nipple area of a donor animal into the cleared fat pad of the recipient, the epithelium taken from a TCDD exposed 25 day old female grew and appeared normal in the fat pad of control animals after 5 weeks. However, the epithelium of control animals transplanted into TCDD exposed fat pads grew at a slow rate and appeared underdeveloped. We conclude from these studies that prenatal exposure to TCDD adversely alters mammary gland development in resulting female offspring and that the hormonal milieu or mammary stroma may play a critical role in this development. (This abstract does not reflect EPA policy.)

638 TRANSFER OF 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN IN RATS THROUGHOUT PREGNANCY AND LACTATION.

Y. Miyabara, N. Nishimura, S. Ohsako, R. Ishimura, K. Nohara, H. Sone, C. Tohyama and J. Yonemoto. *National Institute for Environmental Studies, Tsukuba, Japan.*

The transplacental exposure to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) during developmental stage of fetuses causes reproductive disorders. We have shown that a relatively low dose of TCDD caused a significant decrease of anogenital distance in male rats. To determine the exact level of fetal body burden, we utilized high-resolution GC/MS (HP6890, Hewlett Packard, US/JMS-700, JEOL, Japan) and measured the amounts of TCDD. Pregnant Holtzman rats were given a single oral dose of 0, 200, 800 or 1600 ng TCDD/kg body weight on Gestation Day (GD) 15. Dams were killed on GD 16 and GD 20, and fetuses and placentas were removed. On Day 21 after birth, the other dams and pups were sacrificed, and liver, fat and serum were collected. On GD 16 at an 800 ng TCDD/kg dose, 145, 135 and 111 pg TCDD/g wet-tissue were found in maternal serum, placenta and fetus, respectively. On GD 20, 221, 114 and 59.6 pg TCDD/g wet-tissue were found in maternal serum, placenta and fetus, respectively. Whereas the TCDD concentration in fetus was declined, the TCDD amount transferred from dam to fetuses was increased 0.8 ng/litter (GD 16) to 2.6 ng/litter (GD 20). At weaning, each individual pup had 4.1-4.5% of the administrated TCDD. The present results support the earlier findings in which the TCDD exposure level via placenta was lower than that via lactation.

639 ABRUPTION OF PLACENTAL MATURATION BY MID-PREGNANT EXPOSURE TO 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN IN RAT.

R. Ishimura, M. Ohmura, Y. Miyabara, S. Ohsako, Y. Aoki, N. Nishimura, K. Nohara, H. Sone, J. Yonemoto and C. Tohyama. *National Institute for Environmental Studies, Tsukuba, Japan.*

The haemochorial placenta is unique in that the fetal-derived trophoblast cells contact directly to maternal blood. Transplacental exposure to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) causes disorder of fetal and postnatal development, but nearly no reports on the possible involvement of TCDD in placental growth and development are available. In the present study, pregnant

Holtzman rats (CR) were given a single oral dose of 0, 800 or 1600 ng TCDD/kg body weight on gestation Day (GD) 15 and placental tissue was collected on GD 20. TCDD treatment resulted in intrauterine fetal death in a dose-dependent manner by GD 20. The weight of placenta showed no significant difference between control and TCDD-treated rats. However, in TCDD-treated rats, the junctional zone that consists of glycogen cell, spongiotrophoblast cell and tropholbast giant cell was found disorganized and vacuolized at spongiotrophoblast cells layer. In addition, northern blot analysis of placental total RNA showed down-regulation of spongiotrophoblast cell marker proteins such as prolactin-like protein-D and spongiotrophoblast cell-specific protein, which was consistent with the histological observation. The present results suggest that TCDD affects the fetal development by altering placental growth and function.

640 HEMATOPOIETIC TOXICITY OF TCDD IN DEVELOPING ZEBRA FISH.

C. D. Belair, W. Heideman and R. E. Peterson. *University of Wisconsin, Madison, WI.*

The initial signs of toxicity exhibited by zebrafish larvae exposed to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) as newly fertilized eggs are cardiovascular. To determine whether TCDD affected vascularization, expression of the endothelial cell marker flk-1 was analyzed by *in situ* hybridization. The spatial-temporal expression of flk-1 in TCDD-treated embryos did not vary from control embryos suggesting that the vascular network was initiated correctly. TCDD-induced reduction in blood flow was analyzed by differential interference contrast microscopy and quantified using transgenic embryos expressing GFP from the GATA-1 promoter specifically in hematopoietic cells. As early as 60 hours post fertilization (hpf) the blood flow rate was reduced 20% in TCDD exposed embryos and continued to decline thereafter until no flow was observed. A new observation was that the number of circulating blood cells was also reduced by TCDD treatment. While TCDD did not appear to alter the number of hematopoietic progenitor cells present at 22-26hpf before the onset of circulation, the number of cells circulating in the blood of TCDD-treated embryos was less than controls as early as 48hpf and continued to decline until blood flow was undetectable. GFP protein levels from whole embryo extracts was analyzed by Western blot, and confirmed the microscopic observations that TCDD-treated embryos had fewer GFP-labeled blood cells than control embryos. These preliminary data suggest that a primary embryotoxic effect of TCDD is on hematopoiesis. Ongoing studies are addressing whether TCDD treatment alters the differentiation and/or the proliferation of hematopoietic cells using a variety of histologic and molecular analyses. (Supported by NIEHS F32-ES05862-02 to CDB and UW SeaGrant R/BT-12.)

641 DEVELOPMENTAL EXPRESSION OF THE ARYL HYDROCARBON RECEPTOR (AHR) IN THE AVIAN EMBRYO.

M. K. Walker[1], S. E. Heid[2], S. M. Smith[3] and H. I. Swanson[2]. [1]*University of New Mexico, Albuquerque, NM,* [2]*University of Kentucky Medical School, Lexington, KY and* [3]*University of Wisconsin, Madison, WI.*

To elucidate tissues in which the AhR may play a role during embryogenesis, we investigated AhR expression in the chick embryo by immunohistochemistry. On incubation days 1.7-5, chick embryos were preserved in Bouin's fixative, dehydrated, paraffin-embedded, and sectioned. Sections were stained with rabbit anti-mouse AhR polyclonal antibody (3 μg/ml), washed, incubated with goat anti-rabbit IgG-biotin, washed, incubated with streptavidin-B-galactosidase, and developed using X-gal. Western blot analysis of the *in vitro* expressed chicken AhR cDNA confirmed that the AhR antibody specifically recognized the chicken AhR. AhR expression was not detected on incubation day 1.7. On day 2.2, AhR expression was detected in ectoderm: skin, diencephalon, otic vesicle, myelencephalon, and mandibular arch mesenchyme; mesoderm: somitic myotome and myocardium; and endoderm: pharyngeal and foregut epithelium. From incubation days 3-5, AhR expression became more restricted in the brain and expanded in neural-crest cell derivatives including to the dorsal root, sympathetic, and cranial ganglia. AhR expression was also present in the smooth muscle of dorsal aorta and carotid arteries, in the dorsal mesentery, limb muscle masses, and epithelium of the mesonephric ducts, while expression was also detected in a variety of endodermal derivatives such as thyroid rudiment, Rathke's pouch, liver, lung bud epithelium, pancreatic rudiment, and the entire gastrointestinal epithelium. In general, the AhR tended to be expressed in the epithelial component, or responding tissue, at many sites of tissue induction. The role of the AhR in the epithelium at these sites of tissue interaction is not known; however, the AhR may function to maintain epithelial competence to respond to the mesenchymal signals or may participate in the epithelial response to the inductive signals. (Supported, in part, by NCI IRG #192, NIH #BH953016, and AHA WI # 96-GB-77.)

642 AH RECEPTOR (AHR) IN MOUSE PROSTATE GROWTH AND DEVELOPMENT: PHYSIOLOGICAL ROLE AND ROLE IN MEDIATING TCDD EFFECTS.

T. M. Lin, K. Ko, S. Ohtani and R. E. Peterson. *University of Wisconsin, Madison, WI.*

To determine if inhibitory effects of TCDD on prostate development are AhR-dependent and if AhR might play a physiological role in regulating prostate development, heterozygous ($Ahr^{\pm}$) male and female mice (provided by Dr. Chris Bradfield) were mated and pregnant females treated with 5 μg TCDD/kg or vehicle on Gestation Day (GD) 13. Pups were weaned on postnatal day (PND) 21. Tissue was obtained from GD 18 fetuses and PND 10-16 pups for genotypic analysis by PCR. *In utero* and lactational TCDD exposure of wild-type ($Ahr^{+/+}$) males inhibited ventral prostate (VP) growth to such an extent that on PND 21 the VP resembled that typically seen in control fetuses on GD 18. Ductal development was impaired and only 50% of the luminal epithelial cells expressed androgen receptor (AR) compared to almost 100% of luminal epithelial cells in control. By PND 35 VP, anterior prostate (AP), dorsal lateral prostate (DLP), and seminal vesicle (SV) weights were 12, 28, 47, and 50% of control, respectively. By PND 90, DLP and SV weights had recovered somewhat (to 68 and 71% of control values) but VP and AP weights were still only 15 and 27% of control. Significantly, TCDD failed to reduce prostate or SV weights in null mutant ($Ahr^{-/-}$) males, demonstrating that the above effects of TCDD were AhR-dependent. The inhibitory effect of TCDD was also detected in the GD 18 fetus by a complete blockade of ventral prostatic bud formation, the initial step in ventral prostate development. Scanning EM examination of urogenital complexes on GD 18 revealed agenesis of ventral prostate buds in TCDD-exposed $Ahr^{+/-}$ fetuses but no effect in their $Ahr^{-/-}$ littermates. To determine if AhR has a physiological role in male accessory sex organ growth, VP, DLP, AP, and SV weights were compared on PND 35 and PND 90 for males with different AhR genotypes from the same litter. There were 13-26% reductions in the weights of these organs in vehicle-exposed $Ahr^{-/-}$ males compared to $Ahr^{+/+}$ males, suggesting that AhR signaling may be involved, physiologically, in modulating prostate growth. (Supported by NIH Grant ES01332.)

643 EFFECTS OF *IN UTERO* AND LACTATIONAL TCDD EXPOSURE ON DIHYDROTESTOSTERONE (DHT) FORMING ENZYMES IN RAT VENTRAL PROSTATE.

H. M. Theobald, T. M. Lin and R. E. Peterson. *University of Wisconsin, Madison, WI.*

In utero and lactational (IUL) exposure of rats to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) inhibits prostate growth without reducing fetal and postnatal plasma androgen concentrations. However, it is not known if TCDD affects formation of the most biologically active androgen, dihydrotestosterone (DHT), in rat prostate. Since a reduction in prostatic DHT formation could impair prostate growth and development, we determined effects of IUL TCDD exposure on DHT-forming enzymes and on the expression of prostatic binding protein subunit C3 (PBP-C3) mRNA, which is androgen-regulated. The activities of 3α-hydroxysteroid dehydrogenase (3α-HSD) and 5α-reductase type 2 (5α-R) were evaluated in ventral prostate homogenates after exposure to a single maternal dose of vehicle or 1 μg TCDD/kg on gestation day 15. During the postnatal period (PNDs 14, 21, and 32) 3α-HSD activity in the ventral prostate was 70-200 times greater than 5α-R activity in vehicle-exposed rats. TCDD exposure reduced 3α-HSD activity to 38 and 82% of control on postnatal days (PNDs) 14 and 21, respectively, but did not affect it on PND 32. On the other hand, the activity of 5α-R was *increased* 2.5-, 3.6-, and 5.1-fold, respectively, on these same PNDs. In a separate experiment androgen responsiveness was assessed in ventral prostates removed from TCDD- and vehicle-exposed males on PND 11 and 18. These organs were cultured for 1 day without androgen exposure, then for 2 days with graded concentrations of testosterone, DHT, or 5α-androstane-3α,17ß-diol, and harvested at the equivalent of PND 14 and 21. Androgen-induced increases in PBP-C3 mRNA abundance were significantly inhibited by TCDD exposure. In addition, immunohistochemical PBP-C3 and androgen receptor protein expression were reduced in TCDD-exposed prostates. Thus, IUL TCDD exposure caused substantial effects on androgen responsiveness of prostate luminal epithelial cells with far less effect on androgen metabolism. One possible interpretation for these results is that IUL TCDD exposure reduces androgen responsiveness by inhibiting luminal epithelial cell development. (Supported by NIH Grant ES01332.)

644 THE MECHANISM OF RETARDATION OF JAW GROWTH BY TCDD IN EARLY ZEBRA FISH EMBRYOS.

H. Teraoka[1], S. Ogawa[1], W. Dong[1], H. Hiraga[1] and N. Ueno[2]. [1]*School of Veterinary Medicine, Rakuno Gakuen University, Ebetsu, Japan and* [2]*National Institute for Basic Biology, Okazaki, Japan.* Sponsor: S. Fukushima.

Naturally fertilized zebrafish embryos were exposed to various concentrations of TCDD (2,3,7,8-tetrachloro-p-dibenzodioxin, 0.1-1ppb) dissolved in water solution from 30% epiboly to the end of experiments (usually 84 hrs after fertilization) at 28.5 degrees centigrade. TCDD caused a dose-dependent inhibition of lower jaw development other than edema or fish death, although it little affected the total body length. Movement of neural crest cells into jaw primordia did not seem involved in these actions. Delay in blood circulation became prominent just after 60 hrs after fertilization, when lower jaw was developing. Beta-Naphthoflavone, another AhR agonist and CYP1A (one of cytochrome P450) inducer, caused toxic effects on zebrafish embryos very similar to TCDD. These toxic effects by AhR agonists were effectively recovered by proadifen, general inhibitor for P450. Expressions of mRNA like goosecoid, bone morphogenetic proteins (2 and 4) or distal-less homeoboxes (2-4) at jaw primordia were not markedly decreased by TCDD before or at the beginning of jaw growth, as revealed by in situ hybridization. These results suggest the correlation between circulation failure and jaw growth retardation, and the involvement of P450 in TCDD-induced toxicity.

645 PHYSIOLOGICAL ROLE OF THE ARYL HYDROCARBON RECEPTOR (AhR) IN MURINE OVARIAN DEVELOPMENT.

J. C. Benedict[1], T. M. Lin[2], I. K. Loeffler[2], R. E. Peterson[2] and J. A. Flaws[1]. [1]*University of Maryland, Baltimore, MD and* [2]*School of Pharmacy, University of Wisconsin, Madison, WI.*

The AhR is a cytosolic ligand activated transcription factor that regulates the response to structurally related environmental contaminants such as 2,3,7,8 tetrachlorodibenzo-p-dioxin (TCDD). However, the physiological role of the AhR is not well understood. Thus, the purpose of this study was to investigate whether it played a role in murine ovarian development. In the mouse, ovarian development begins in prenatal life, continues through neonatal life, and results in formation of the primordial follicle pool. This pool is required for ovarian function throughout the reproductive life span. By embryonic day 18 (E 18), germ cells are present in the developing ovary. By postnatal days 2-3 (P 2-3), most germ cells are surrounded by granulosa cells to form primordial follicles. By postnatal day 8 (P 8), all germ cells are surrounded by granulosa cells, resulting in complete formation of the primordial follicle pool. Thus, to determine the effect of the AhR during ovarian development, ovaries were harvested from AhR knockout (AhRKO) and wildtype (WT) mice on E 18, P 2-3, and P 8, and complete serial sections were prepared for histological evaluation of germ cell and follicle numbers. At E 18, there were no significant differences in germ cell numbers between WT and AhRKO mice, suggesting that the AhR is not required for germ cell development. At P 2-3, WT ovaries had fewer fully formed primordial follicles than AhRKO mice (21,120±2688 vs. 38,440±3632, n=4-7, p=0.008). WT ovaries also had more naked germ cells than AhRKO mice (18,160±720 vs. 12,696±1192, n=3, p=0.05). At P 8, WT and AhRKO ovaries had similar numbers of primordial follicles (39,960±4400 vs. 33,504±3000, n=8-9, p=0.25). These results suggest that the AhR slows formation of primordial follicles during neonatal life. (Supported by the Heinz Family Foundation and the Veteran's Administration [JF] and NIH grant ES01332 [RP].)

646 *IN UTERO* AND LACTATIONAL TCDD EXPOSURE ALTERS ESTROGEN RECEPTOR-ALPHA EXPRESSION IN THE RAT MAMMARY GLAND.

B. C. Lewis[1], S. Hudgins[1], A. Lewis[1], K. Schorr[1], R. Sommer[2], R. E. Peterson[2], J. Flaws[3] and P. A. Furth[1]. [1]*Institute of Human Virology, Medicine & Physiology, UMMed School, Baltimore, MD,* [2]*Environmental Toxicology Center, University of Wisconsin, Madison, WI and* [3]*Epidemiology & Preventive Medicine, UMMed, Baltimore, MD.*

In the mammary gland, estrogen triggers ductal cell proliferation. Intact estrogen signaling pathways are required for normal ductal elongation and development. This study was initiated to determine whether *in utero* and lactational (IUL) 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) exposure alters estrogen receptor-alpha (ERα) expression and response in the rat mammary gland. Pregnant Holtzman rats were administered a single oral dose of 1Fg/kg TCDD, or vehicle, on gestation day 15 and offspring were weaned on postnatal day 21. TCDD exposed and control non-exposed rats were oophorectomized at 9 weeks of age. Two weeks later both the TCDD and control rats were divided into three groups, receiving either placebo, 0.025, or 0.1 mg 17b-estradiol pellet implants. After 48 hours all rats were euthanized and the mammary tissue removed for analysis. Whole mount studies revealed baseline morphological abnormalities as well as enhanced ductal growth in TCDD exposed rats as compared to control rats. Ki67 immunohistochemistry demonstrated a higher rate of ductal cell proliferation at the 0.025 mg 17b-estradiol dose in the TCDD treated groups as compared to the non-exposed control groups. In the absence of exogenous estrogen, both Northern and Western blot analysis showed an increase in ER-α expression levels in the TCDD exposed group as compared to the control. RT-PCR of progesterone receptor (PR) mRNA demonstrated little PR expression in either control or TCDD baseline groups, indicating that the ERα was not activating PR transcription despite its higher expression in the TCDD treated group. PR expression was induced by estrogen exposure in both groups. These results demonstrate that *in utero* and lactational TCDD exposure increases steady-state levels of ER-α in the rat mammary gland.

647 INFLAMMATORY MEDIATORS IN NASAL LAVAGE FLUID OF NON-SYMPTOMATIC VOLUNTEERS: ONE-YEAR FOLLOW-UP STUDY.

M. H. Roponen[1], M. Seuri[2], A. Nevalainen[1] and M. R. Hirvonen[1]. [1]*National Public Health Institute, Kuopio, Finland and* [2]*Kuopio Regional Institute of Occupational Health, Kuopio, Finland.* Sponsor: M. Viluksela.

There has been intense interest in developing noninvasive methods to detect airway inflammation in different respiratory disorders induced by exposure to bioaerosols. The measurement of inflammatory mediators in nasal lavage (NAL) fluid represents a direct method to investigate upper airway inflammation. We aimed to confirm the validity of this technique using one-year follow-up study with 9 non-symptomatic volunteers. NAL was performed every other week altogether 27 times. Production of inflammatory mediators in the nasal lavage fluid was studied ie. interleukin-1 (IL-1), interleukin-6 (IL-6) and tumor necrosis factor alpha (TNF) by immunoassay, and nitric oxide (NO) as nitrite by Griess reaction. After NAL subjects filled in a one-page questionnaire concerning their health and use of medicine during the preceding week. The highest 5% of the measurements were excluded as outlayers. Most of these peak values can be explained with the questionnaire data. The mean value of nitrite concentration for the remaining 95% of the measurements was 1,502±0,109μM. The respective figures for TNF were 4,117±0,306 pg/ml, for IL-1 28,365±2,150 pg/ml and for IL-6 9,160±0,683 pg/ml. Individual and seasonal variations were low. These results suggest that nasal lavage technique is a valid method for the assessment of upper of airway inflammation.

648 ENVIRONMENTAL MYCOBACTERIA INDUCE INFLAMMATORY RESPONSES IN HUMAN 28SC MACROPHAGES.

K. J. Huttunen, E. Iivanainen, M. H. Roponen and M. R. Hirvonen. *National Public Health Institute, Kuopio, Finland.* Sponsor: M. Viluksela.

Excess moisture in building structures enables the growth of various fungi and bacteria. Some of these bioaerosols may be able to cause respiratory tract disorders and other inflammatory symptoms, typically associated with exposure to indoor air of moldy houses. The identification of most potent microbes and mechanisms of diseases are still under investigation. In the present study the ability of four different environmental mycobacteria strains to induce the production of inflammatory mediators and cause cytotoxicity in human 28SC macrophage cell line was investigated. The macrophages were primed with IFN-gamma (1 ng/ml) for 24 h and exposed for 24 h (exp5, exp6, exp7 spores/ml) to two strains of Mycobacterium avium and Mycobacterium terrae which were isolated from a mouldy building. Production of inflammatory mediators were measured from the culture medium; cytokines IL-6 and TNF-alpha immunochemically, nitric oxide (NO) as nitrite by Griess reaction and Western Blot analysis. In addition, the induced cytotoxicity in the macrophages was measured with MTT-test. The nitrite and IL-6 concentrations in the culture medium of the control cells were 1,6 μM and 0,2 pg/ml, respectively. Mycobacteria exposure induced dose dependent production of nitrite (up to 2,4 μM), and IL-6 (up to 3,6 pg/ml) in human macrophages, whereas no TNF-alpha production was detected. However, the potency of the mycobacteria to induce these responses differed between the two tested species. Apathogenic environmental Mycobacteria terrae was more effective than potentially pathogenic Mycobacterium avium. Moreover, mycobacteria exposure did not cause cytotoxicity in human 28SC macrophages.

649 INFLAMMATORY RESPONSES AFTER INTRATRACHEAL INSTILLATION OF SPORES OF *STREPTOMYCES CALIFORNICUS* IN MICE.

J. Jussila, H. Komulainen, K. Huttunen, M. Roponen, A. Nevalainen and M. R. Hirvonen. *National Public Health Institute, Kuopio, Finland.* Sponsor: M. Viluksela.

Moisture related microbial growth in buildings is associated with respiratory symptoms and inflammatory reactions, but the mechanisms of the effects leading to clinical manifestations are not known. We studied the effects of a single dose of intratracheally instilled spores of Streptomyces californicus (1,1x10E8 spores/animal), isolated from a moldy building, on inflammatory mediators i.e., interleukin-6 (IL-6) and tumour necrosis factor alpha (TNF alpha) in bronchoalveolar lavage fluid (BALF) of male NIH/S mice. Moreover, the total cell numbers, total protein, cell differentials and expression of inducible nitric oxide synthase (iNOS) in BALF cells were analysed. The mice were exsanguinated by cardiac puncture under pentobarbital anesthesia at time points 3 h, 6 h, 24 h, 3 days or 7 days. The tracheas were cannulated and the lungs were lavaged with HBSS. The cell suspensions were spun for cell differentials. IL-6 and TNF alpha concentrations were analysed by ELISA and total protein by modified Lowry method from the BALF supernatant. Total cell numbers were defined from cell pellets resuspended to medium by Trypan blue exclusion method. Expression of iNOS were analysed from the combined cell pellets by Western Blotting. The highest concentrations of TNF alpha and IL-6 in BALF were reached at 6 hours of exposure but only IL-6 was significantly increased at 24 hrs. Expression of iNOS was seen 24 hrs after exposure. The maximum levels of total protein concentrations in BALF were measured at 24 hrs. Total cell number was increased after 6 hours and reached the maximum after 24 hrs. Neutrophil number reached the highest level after 24 hrs. The highest number of macrophages was detected after 3 days of exposure and that of lymphocytes after 7 days of exposure. Altogether, these results show clearly that the spores of S. californicus from moldy houses caused an acute inflammation in mice lungs. The acute phase was over in 3 days after a single dose but abnormal numbers of macrophages and lymphocytes were detectable in airways even after 7 days.

650 INFLAMMATORY RESPONSES AND CYTOTOXICITY INDUCED BY *STREPTOMYCES ANULATUS* IN MICE MACROPHAGES ARE DEPENDENT ON NUTRIENTS AND PH LEVEL IN THE GROWTH MEDIA.

M. R. Hirvonen, M. Ruotsalainen, M. Suutari and A. Nevalainen. *National Public Health Institute, Kuopio, Finland.* Sponsor: M. Viluksela.

Epidemiological data indicate that living or working in a moldy building is associated with increased risk of respiratory diseases related to inflammatory reactions, but the specific causes and the cellular mechanisms of the illnesses are not clear. The effect of pH level and nutrients in the growth media on the ability of Streptomyces anulatus, to induce inflammatory responses and to cause cell death in RAW264.7 macrophages was studied. The macrophages were exposed 24 h (10exp5, 10exp6, 10exp7 spores/10exp6 cells) to S. anulatus, which was isolated from a mouldy building and grown on six media at pH 4, 5.5, 7, 8.5, 10 or 11.5. Production of inflammatory mediators i.e., IL-6 and TNFalpha by immunoassay, nitric oxide (NO) by Griess reaction and Western Blot analysis and reactive oxygen species (ROS) by luminometric method in RAW264.7 cells were assayed. The cell viability was measured by MTT-test. Significant dose dependent NO (up to 30.4 µM), TNFalpha (up to 2900 pg/ml) and IL-6 (up to 4800 pg/ml) production was induced in RAW264.7 cells by the spores of S.anulatus. However, the potency of the spores to induce these responses was dependent on both nutrients and pH in the growth media. The spores grown on media containing glycerol were the most cytotoxic (up to 96%) whereas the percentage of dead cells was from 52 to 3% when the spores were grown on the other media. Only the spores grown on media with glycerol also significantly increased ROS production (up to 320% of controls). These results suggest that both pH and nutrients play an important role in the ability of S.anulatus to induce inflammatory responses and cytotoxicity in mammalian cells.

651 COMPARISON OF THE INFLAMMATORY POTENCY OF BACTERIA AND THEIR CELL-WALL COMPONENTS IN THE LUNG.

J. M. Gassman[1], M. E. O'Neill[1], J. Phipps[1], K. Kulhankova[1], C. Duchaine[2] and P. S. Thorne[1]. [1]*University of Iowa, College of Public Health, Iowa City, IA and* [2]*Hopital Laval, Ste-Foy, Quebec, Canada.*

Bacteria are components of aerosols found at high concentrations in a variety of occupational settings, especially agriculture. Inhaled non-pathogenic organisms may induce potent inflammatory responses in the lung. We have previously shown that pulmonary exposures to certain components of bacteria (e.g., lipopolysaccharides {LPS}) and fungi (e.g., glucans) induce production of inflammatory cytokines (e.g., IL-6, TNFalpha, MIP-2) and monocyte and neutrophil recruitment to the airways. In recent studies, we explored the hypothesis that inhaled Gram-negative (Gm-) bacteria and their cell-wall components are more potent inducers of inflammation than Gram-positive (Gm+) organisms and their cell-wall components. BALB/cJ mice were exposed acutely to inhaled bacteria (Gm-: Enterobacter agglomerans, Pseudomonas aeruginosa; Gm+: Micrococcus luteus, Bacillus megaterium) in post log-phase growth; to LPS, peptidoglycan, or lipoteichoic acid by inhalation or instillation; or to inhaled or instilled sterile, pyrogen-free saline (sham exposure). Exposure-response relationships for inflammation were studied at 5 and 24 hours post exposure. For both time points, inhalation of Gm- bacteria resulted in a dose-dependent increase in inflammatory cells and cytokines when exposure was quantified by either concentration of bacteria or concentration of LPS associated with the bacteria. Exposure to Gm+ organisms, peptidoglycan, or lipoteichoic acid resulted in significantly lower inflammatory responses at both 5 and 24 hr. Our studies add evidence to the hypothesis that organic dust-induced acute lung inflammation is primarily associated with Gm- bacteria and less so with Gm+ organisms or their cell-wall components. (Supported by CDC/NIOSH U07CCU706145.)

652 DEVELOPMENT OF A RAT MODEL TO INVESTIGATE INFLAMMATORY REACTIONS OF THE LUNG.

M. Hecht, R. Baelder, W. Bartsch, A. Emmendoerffer and H. Muhle. *Fraunhofer Institute for Toxicology and Aerosol Research, Hannover, Germany.*

Inflammatory reactions of the lung play an important role in clinics under conditions like e. g. ARDS or hemorrhagic shock. These reactions are mainly associated with bacterial infections. But inflammatory reactions of the lung can also be induced by by other agents like particles or fibres which are deposited in the lung in aereas with high environmental polution. Irrespective of the causative agent the underlying mechanisms are very similar. After an activation of macrophages and epithelial cells these cells produce inflammatory mediators with cell activating, cytotoxic, and chemotactic potential. In a second step infiltrating neutrophils contribute to the reaction with the production and release of different mediators finally leading to the damage of lung tissue. Because there is a need for animal models which can be used to study inflammatory reactions of the lung we treated Spraque Dawley rats intratracheally with two concentrations of LPS and monitored the course of the reaction from 3 to 48 h. We investigated changes in the differential cell counts in the lung and measured the concentration of different cytokines like interleukin-1, interleukin-6, and tumor-necrosis factor-a in the bronchoalveolar lavage fluid (BAL). The tissue and cell damage was evaluated by measuring the concentration of total protein, ß-glucuronidase, and g-glutamyltransferase (g-GT) in the BAL. We found an increase in the neutrophils and total cell number and elevated levels of the soluble mediators in the BAL. These changes were time and concentration dependent with a maximum between 6 and 18 h and a decline at 48 h. Our data show that this model displays the characteristic features of an inflammatory reaction in the lung. It can be used to investigate the effect of drugs on the inflammatory reaction of the lung and may therefore be usefull to study new approaches in the treatment of the inflammatory reaction.

653 TIME COURSE AND KINETICS OF EOSINOPHILIC INFLAMMATION AND CORRESPONDING LUNG TOXICITY EFFECTS IN AN ALLERGIC ASTHMA MODEL IN BROWN NORWAY RATS.

D. B. Warheit, T. R. Webb and K. L. Reed. *DuPont Haskell Laboratory, Newark, DE.*

Allergic Asthma is a pulmonary disease characterized by antigen-induced pulmonary eosinophilia, airway hyperresponsiveness, antigen-specific IgE anti-

body responses and bronchoconstriction. In attempting to elucidate mechanisms associated with the pathogenesis of this disease, a number of animal models have been developed. The current studies were undertaken to develop a model of allergic asthma model in Brown Norway rats. Unlike the neutrophilic inflammatory response to inhaled particles in most strains of rats, inhalation of antigens in sensitized Brown Norway rats results in a complex cellular response which is characterized by a variety of inflammatory cell-types, and is dependent on the time course of inflammatory cell recruitment. In characterizing this ovalbumin-challenged model of allergic asthma, it was important to assess the time course of pulmonary inflammation, cell proliferation and apoptosis. Male Brown Norway rats were sensitized and boosted with intraperitoneal injections of ovalbumin in aluminum hydroxide on experimental days 1 and 8. On days 15-17, rats were challenged by an inhalation exposure to 5% ovalbumin, and evaluated by bronchoalveolar lavage and BrdU cell proliferation assessments at 24 or 48 hrs postexposure. Control rats were similarly treated to ovalbumin aerosol exposures, however, these animals had been sensitized and boosted with aluminum hydroxide (minus the ovalbumin). Cell differential evaluations demonstrated that the rats exposed for 3 days/24 hrs postexposure and for 2 days/48 hrs postexposure produced the greatest numbers of BAL eosinophils and corresponding indicators of pulmonary toxicity. It was interesting to note that earlier exposure time periods (i.e., 1 day/24 hrs) generated a predominantly neutrophilic inflammatory response, while longer exposure/postexposure time periods (i.e., 3 day/48 hrs) produced a predominant mononuclear inflammatory reponse. Subsequent studies demonstrated that the 2 day/48 hr protocol produced the optimum eosinophilic, cytotoxic, cell proliferative and apoptotic response. Histopathological evaluations demonstrated a chronically active alveolitis and bronchiolitis, characterized by epithelial cell proliferation in the airways and inflammatory cell proliferation in the alveoli. Studies are ongoing to assess the cell-types undergoing apoptosis in both the airway and parenchymal regions to fully characterize this model in order to assess it relevance/utility for humans.

654 SUBSTANCE P AND OTHER MEDIATORS IN A RABBIT MODEL OF ACUTE RESPIRATORY DISTRESS SYNDROME (ARDS).

S. Wang[1], R. C. Lantz[2] and M. L. Witten[1]. [1]*Department of Pediatrics, Center for Toxicology, University of Arizona, Tucson, AZ and* [2]*Department of Cell Biology & Anatomy, Center for Toxicology, University of Arizona, Tucson, AZ.*

Mortality due to acute respiratory distress syndrome (ARDS) remains unacceptably high at greater than 50% because there is still much to be learned concerning its primary pathogenesis. Little information is known about the mechanisms of neurogenic inflammation relating to ARDS. It is our objective to determine that afferent neural response was involved in the pathogenesis of acute smoke-induced ARDS. New Zealand rabbits were exposed to a 60 tidal volume of diesel fuel-polycarbonate plastic smoke and ventilated for 30 minute post-smoke. Smoke exposure induced significant increases in bronchoalveolar lavage concentrations of substance P (SP), tumor necrosis factor-a (TNF-a), and 6-keto-prostaglandin F1-a, when compared to sham smoke control. Changes of SP were paralleled with alterations of lung morphological and gas exchange function. It is speculated that highly sustained SP levels may activate preinflammatory cytokines and/or -eicosanoids cross-talks due to affected affinity of neurokinin (NK) receptors and decreased activity of neural endopeptidase (NEP) following acute smoke inhalation. These data suggest that afferent neural response to smoke inhalation may be a key primary contributor to the cascade that establishes ARDS. (Supported by ALA of Arizona 12734 and DAMD 17-94-J4001.)

655 EFFECTS OF QUINOLINEDIONE DERIVATIVES ON THE EXPRESSION OF INDUCIBLE CYCLOOXYGENASE AND NITRIC OXIDE SYNTHASE IN LPS-ACTIVATED MACROPHAGES.

J. Y. Lee[1], S. M. Chung[1], H. J. Kim[2], C. K. Ryu[2] and J. H. Chung[1]. [1]*Seoul National University, Seoul, Republic of Korea and* [2]*Ewha Womans University, Seoul, Republic of Korea.*

Newly synthesized quinolinedione derivatives, 6-(4-fluorophenyl) amino-5,8-quinolinedione (OQ1) and 6-(2,3,4-trifluorophenyl) amino-5,8-quinolinedione (OQ21) have been tested for the ability as anti-inflammatory and antiseptic drugs using lipopolysaccharide (LPS)-stimulated macrophage cell line (RAW 264.7 cell). Both OQ1 and OQ21 suppressed *de novo* synthesis and cellular accumulation of prostaglandin E_2 in a dose-dependent manner, suggesting that these compounds blocked inducible cyclooxygenase (COX-2) activity. In addition, OQ1 and OQ21 inhibited the LPS-stimulated expression of inducible cyclooxygenase (COX-2) and inducible nitric oxide synthase (iNOS). In order to investigate the mechanism for this inhibition, LPS-stimulated protein tyrosine phosphorylation was determined. OQ1 and OQ21 suppressed tyrosine phosphorylation of mitogen-activated protein kinases (MAPKs) suggesting that OQ1 and OQ21 inhibited LPS-induced MAPK activation resulting in the decrease of COX-2 and iNOS expression. These results suggest the possibility that quinolinedione derivatives, OQ1 and OQ21, may be effective therapeutic agents for septic shock and other inflammatory diseases.

656 POLYCHLORINATED BIPHENYLS INCREASE PRO-INFLAMMATORY CYTOKINE PRODUCTION AND MODIFY THE INFLAMMATORY RESPONSE TO LIPOPOLYSACCHARIDE.

N. M. Filipov, D. A. Lawrence and R. F. Seegal. *Wadsworth Center, New York State Department of Health, Albany, NY.*

Polychlorinated biphenyls (PCBs) alter immune and nervous system functions while lipopolysaccharide (LPS) stimulates both systems. The objectives of this research were to assess whether PCBs alter tissue and circulating pro-inflammatory cytokine production either alone or after LPS challenge. Mice were fed 0, 25, 50, or 100ppm of Aroclor 1254 for 2 or 6wk. Following PCB exposure, mice received either 1 mg/kg/BW LPS or saline, and were analyzed 3h later. LPS-induced plasma cytokine levels were not altered by PCBs. However, PCBs elevated splenic IL-1β levels at 2wk (100ppm) and at 6wk (50 and 100ppm), but did not alter the LPS-induced splenic IL-1β increase. At 6wk, but not at 2wk, PCBs enhanced LPS-stimulated levels of splenic IL-6. In the brain, 50ppm PCBs enhanced the LPS-induced IL-1β increase at 2 wk, but the effect was lost with 100ppm. Interestingly, brain IL-6 levels were increased by 50ppm PCBs (2 and 6wk) with the magnitude of the increase being lower at 6wk than at 2wk. As with brain IL-1β, brain IL-6 levels were not affected by 100ppm PCBs; this lack of a response at 100ppm was not due to toxicity since the LPS-induced brain IL-6 was not altered. It is concluded that PCBs induce pro-inflammatory cytokines in the brain and the spleen and modify the inflammatory response to LPS. Therefore, PCB-induced inflammation in the CNS and periphery could potentially be a causative factor for previously reorted PCB-related neurotransmitter and behavioral alterations. (Supported by NIEHS ES07251 and ES05879.)

657 HEPARIN OR NEUTROPHIL DEPLETION ATTENUATES ENDOTOXIN-INDUCED POTENTIATION OF ALLYL ALCOHOL HEPATOTOXICITY.

S. Kinser, R. A. Sneed, R. A. Roth and P. E. Ganey. *Michigan State University, East Lansing, MI.*

Noninjurious doses of endotoxin (LPS) enhance liver damage in rats from a variety of chemicals including allyl alcohol. The potentiation of allyl alcohol hepatotoxicity could not be reproduced in the isolated, buffer-perfused liver, suggesting that extrahepatic factors are necessary. The coagulation system, and particularly thrombin, is a critical factor in liver injury resulting from large doses of LPS (10^8 EU/kg). Accordingly, the purpose of these studies was to test the hypothesis that thrombin is involved in the potentiation of allyl alcohol hepatotoxicity by LPS. Rats were treated with heparin (2000 U/kg body weight, i.v.), an inhibitor of thrombin, one hour before treatment with LPS (1.2×10^5 EU/kg body weight, i.v.). Two hours later, allyl alcohol (30 mg/kg body weight, i.p.) was administered. Liver and blood samples were taken at three, four, and nine hours after heparin. Four hours after cotreatment with LPS/allyl alcohol, plasma fibrinogen concentration was decreased, suggesting activation of coagulation, and plasma concentration of tumor necrosis factor α (TNF-α) was increased. At nine hours, liver injury in rats cotreated with LPS/allyl alcohol was evident from elevations in plasma activities of alanine aminotransferase (ALT) and aspartate aminotransferase (AST). Heparin attenuated the changes in TNF-α, fibrinogen, ALT, and AST induced by treament with LPS/allyl alcohol. Evaluation of tissue sections stained immunohistochemically for neutrophils revealed increased staining in livers from rats treated with LPS. The contribution of neutrophils to hepatotoxicity was tested in rats treated with an anti-neutrophil immunoglobulin G fraction and then given the LPS/allyl alcohol cotreatment described above. Depletion of circulating neutrophils decreased the accumulation of neutrophils in the liver and reduced liver injury in the LPS/allyl alcohol cotreatment group. In summary, both the coagulation system and neutrophils are involved in allyl alcohol liver injury potentiated by endotoxin. (Supported by ES08789.)

658 ENDOTOXIN POTENTIATES AFLATOXIN B_1-INDUCED HEPATOTOXICITY THROUGH A TN-α-DEPENDENT MECHANISM.

C. C. Barton, E. X. Barton, P. E. Ganey and R. A. Roth. *Michigan State University, East Lansing, MI.*

Exposure to a small, nontoxic dose of bacterial endotoxin (LPS) potentiates the hepatotoxicity of aflatoxin B_1 (AFB_1), characterized by periportal necrosis, inflammation and cholestasis. Some of the pathophysiological effects associated with LPS are mediated through tumor necrosis factor-α (TNF-α). This study was conducted to explore the role of TNF-α in the AFB_1/LPS model. Male, Sprague-Dawley rats (250-300 g) were treated with either 1 mg AFB_1/kg, ip, or its vehicle (0.5% DMSO/water) and with either E. coli LPS (7.4 X 10^6 EU/kg, iv) or its saline vehicle 4 hours later. Serum TNF-α was measured by ELISA at 6, 12, 24, 48, 72 and 96 hr after AFB_1 administration. LPS administration resulted in a marked rise in TNF-α at 6 hr that preceded the onset of liver injury. TNF-α mRNA in liver was measured by semi-quantitative RT-PCR and was increased by LPS. The mRNA of receptors (R1 and R2) for TNF-α was also examined. R1 mRNA levels were not altered; however, R2 mRNA was increased by either AFB_1 or LPS. To determine if TNF-α plays a causal role in the development of liver injury, the increase in TNF-α was attenuated by administration of either pentoxifylline or anti-TNF-α serum, and liver injury was assessed from alterations in the concentration of bile acids and the activities of alanine aminotransferase, aspartate aminotransferase, alkaline phosphatase, γ-glutamyltransferase and 5'-nucleotidase in serum and from histopathologic examination of liver. Administration of either of these TNF-α inhibitors resulted in protection. These data support the hypothesis that LPS-induction of TNF-α plays a causal role in the potentiation of AFB_1-induced hepatotoxicity. (Supported by NIH grant ES04139.)

659 ACUTE ENDOTOXEMIA IS ASSOCIATED WITH INCREASED STAT1 AND NFKB NUCLEAR BINDING ACTIVITY IN HEPATIC MACROPHAGES AND ENDOTHELIAL CELLS.

N. Ahmad, L. C. Chen, C. A. Martey, S. G. Ricketts, J. D. Laskin and D. L. Laskin. *Rutgers University, Piscataway, NJ.*

Acute endotoxemia induces the accumulation and activation of macrophages in the liver. This is associated with priming of these cells to produce increased quantities of nitric oxide (NO) and prostaglandin E2 (PGE2) in response to inflammatory mediators such as lipopolysaccharide (LPS) and g-interferon (g-IFN). In the present studies we analyzed mechanisms regulating increased mediator production by macrophages and endothelial cells during acute endotoxemia. The promotor regions of the inducible nitric oxide synthase (NOSII) and cyclooxygenase-2 (COX-2) genes which regulate NO and PGE2 production respectively, contain binding sites for several transcription factors including signal transducers and activators of transcription-1 (STAT1) and nuclear factor kB (NFkB). Whereas, STAT1 is activated by g-IFN, NFkB activation occurs in response to LPS. We speculated that increased NO and PGE2 production in response to g-IFN and LPS during acute endotoxemia is due to altered transcription factor activity. Acute endotoxemia was induced by injecting rats with Escherichia coli LPS (5 mg/kg i.v.). We found that macrophages and endothelial cells from control rats expressed low levels of activated STAT1 as determined by electrophoretic mobility shift assays and Western blotting. Treatment of the cells with g-IFN for 30 min resulted in a marked increase in STAT1 binding activity and phosphorylated STAT1 protein. Induction of acute endotoxemia caused a time-dependent increase in STAT1 binding to the g-IFN activation site (GAS) on DNA and an increase in phosphorylated STAT1 protein. These effects were most pronounced in cells isolated 24 hours after endotoxin administration to animals. The addition of g-IFN to hepatic macrophage and endothelial cell cultures further increased STAT1 binding activity and phosphorylated STAT1 levels when compared to cells from control animals. In contrast to STAT1, constitutive NFkB binding activity was not observed in macrophages and endothelial cells from control animals. However, these cells were responsive to *in vivo* endotoxin. Thus, treatment of rats with endotoxin resulted in a time dependent increase in NFkB binding activity. Taken together these data suggest that increased mediator production by liver nonparenchymal cells during acute endotoxemia may be due to increased activity of STAT1 and NFkB. (Supported by NIH GM34310, ES06897 and The Burroughs Wellcome Fund.)

660 HEPATOTOXICITY FROM COADMINISTRATION OF SMALL, SYNERGISTIC DOSES OF MONOCROTALINE AND BACTERIAL ENDOTOXIN IS ATTENUATED BY HEPARIN.

S. B. Yee, P. E. Ganey and R. A. Roth. *Michigan State University, East Lansing, MI.*

Coadministration of small, noninjurious doses of the food-borne toxin monocrotaline (MCT) and bacterial endotoxin (LPS) to male, Sprague-Dawley rats results in pronounced hepatotoxicity. Histopathologic analysis of livers demonstrated both midzonal (i.e., LPS-like) and centrilobular (i.e., MCT-like) lesions. Endothelial cell injury in central veins and decreased plasma fibrinogen concentration observed in these animals suggested that the coagulation system might play a causative role in the hepatocellular injury. Accordingly, we treated animals with the anticoagulant, heparin (HEP), to determine if the coagulation system might be involved in liver injury in this model. MCT (100 mg/kg, i.p.) was given to rats 4 hours before LPS (7.4 x 10^6 EU/kg, i.v.), and then HEP (2000U/kg; i.v.) or saline (SAL) vehicle was administered 5.5 hours after MCT. A significant decrease in hepatocellular injury, as marked by plasma alanine aminotransferase (ALT) and aspartate aminotransferase (AST) activities and by histopathologic examination, was observed in animals that received the MCT/LPS/HEP combination in comparison to animals that received MCT/LPS/SAL. Liver histopathological analysis revealed that lesion size and frequency were less in animals that received HEP, but the qualitative nature of the lesions remained unchanged. These results are consistent with a causative role for the coagulation system in this MCT/LPS model of liver injury. (Supported by NIH Grants ES 04139 and ES08789.)

661 LIVER INFLAMMATION AFTER ACETAMINOPHEN OVERDOSE: ROLE OF NEUTROPHILS.

J. A. Lawson[1], A. Farhood[2], R. D. Hopper[3], M. L. Bajt[3] and H. Jaeschke[3]. [1]*Pharmacia & Upjohn, Inc., Kalamazoo, MI,* [2]*University of Texas Health Science Center, Houston, TX and* [3]*University of Arkansas for Medical Sciences, Little Rock, AR.*

Acetaminophen overdose induces severe liver injury and hepatic failure. There is evidence that inflammatory cells may be involved in the pathophysiology. Thus, the aim of this investigation was to characterize the neutrophilic inflammatory response after treatment of C3Heb/FeJ mice with 300 mg/kg acetaminophen. A time course study showed that neutrophils accumulate in the liver parallel to or slightly after the development of liver injury. The number of neutrophils in the liver was substantial (209±64 PMN/50 high power fields at 12 h) compared to baseline levels (7±1). Serum levels of TNF-α and the C-X-C chemokines KC and MIP-2 increased by 28-, 14-, and 295-fold, respectively, over levels found in controls during the injury process. In addition, mRNA expression of MIP-2 and KC were upregulated in livers of acetaminophen-treated animals as determined by Ribonuclease Protection Assay. However, none of these mediators was generated in large enough quantities to account for neutrophil sequestration in the liver. There was no upregulation of Mac-1 (CD11b/CD18) or shedding of L-selectin on circulating neutrophils. Moreover, an anti-CD18 antibody had no protective effect against acetaminophen overdose during the first 24 h. These results indicate that there is a local inflammatory response after acetaminophen overdose including a substantial accumulation of neutrophils in the liver. However, neutrophils do not contribute to the injury. The inflammation observed after acetaminophen overdose may be characteristic for a response sufficient to recruit neutrophils for the purpose of removing necrotic cells but is not severe enough to cause additional damage.

662 MECHANISMS OF MUTUAL ANTAGONISM BETWEEN NF-κB AND THE GLUCOCORTICOID RECEPTOR.

L. I. McKay and J. A. Cidlowski. *NIEHS, Research Triangle Park, NC.* Sponsor: M. Gomez-Angelats.

The transcription factors NF-κ B (NF-κB) and glucocorticoid receptor (GR) have diametricially opposed roles in the modulation of immune/inflammatory responses. NF-κB induces the expression of pro-inflammatory genes, while GR suppresses immune function in part by suppressing expression of these same genes. We have demonstrated that physiological antagonism between NF-κB and GR is due to a mutual transcriptional antagonism requiring the presence of specific domains of each transcription factor. By *in vitro* coimmunoprecipitation (co-IP), we show that the p65 subunit of NF-κB physically interacts with GR, and that this interaction is enhanced by the transcriptional cointegrator CREB Binding Protein (CBP). To clarify the mechanism

by which p65 and GR interact to antagonize each other's function we employed p65 RHD, a dominant negative regulator of p65 transactivation, in transient cotransfection assays. Interestingly, p65 RHD efficiently blocks p65 transactivation of an NF-κB responsive reporter, yet cannot interfere with p65 mediated repression of GR transactivation and has no direct effect on GR transactivation (despite the fact that GR and p65 RHD co-IP). This indicates that the transactivation domain of p65 is required for repression of GR transactivation, but that NF-κB need not be transcriptionally active to repress GR. Cotransfection studies in which CBP is overexpressed indicate that both GR-mediated repression of p65 transactivation and p65 mediated repression of GR transactivation are dose-dependently enhanced by CBP, suggesting that the mechanism of p65-GR antagonism is not a simple competition for a limiting pool of CBP, but rather that CBP might serve as an integrator for p65 and GR which facilitates physical interaction between the DNA-bound transcription factors. Studies using the glucocorticoid antagonist RU 486 indicate that antagonist-bound GR, though transcriptionally inactive, retains the ability to interact with p65 and repress its transactivation. However, antagonist bound GR does not co-IP with CBP. Consequently, CBP cannot enhance the physical interaction of GR with, or the repressive effect of antagonist-bound GR on, NF-κB.

663 PROTECTIVE EFFECT OF RECOMBINANT INTERLEUKIN-6 ON SKIN INFLAMMATION CAUSED BY 7,12-DIMETHYLBENZ[A]ANTHRACENE IN INTERLEUKIN-6 NULL MICE.

M. Murata, B. Zhang, N. Nishimura, M. Satoh and C. Tohyama. *National Institute for Environmental Studies, Tsukuba, Japan.*

Interleukin-6 (IL-6) is a multifunctional cytokine, which regulates essential physiological functions such as acute phase reaction, immune response, hematopoiesis and bone metabolism. In order to examine the protective effect of IL-6 on skin damage caused by 7,12-dimethylbenz[*a*]anthracene (DMBA), we have conducted administration of IL-6 extracorporeally to the IL-6 null (IL-6-/-) mice. Female IL-6-/- mice and wild type B6J129Sv mice were topically applied a single dose of DMBA (500μg /mouse) on dorsal skin. Osmotic pumps with a delivery rate of 0. 5 μl/h were filled with recombinant human IL-6 (rhIL-6) (10 or 25μg/day) and then implanted subcutaneously on the ventral side of the mice (IL-6-/- + rhIL-6 mice). In control mice, PBS was filled instead of rhIL-6. Tissue samples were collected 5 days after DMBA administration, and subjected to histopathological examination. A severe skin damage was observed in IL-6-/- mice characterized by lymphocyte infiltration and keratinocyte hyperproliferation, whereas only epidermal hyperplasia was observed in the wild-type mice. Recombinant hIL-6 treatment to DMBA-treated IL-6 null mice suppressed the ocurrence of the above-mentioned skin damage. The present results suggest that IL-6 plays an important role in defense mechanism for cutaneous inflammation caused by DMBA.

664 ELEVATED OXIDATIVE STRESS IN SKIN OF B6C3FL MICE AFFECTS DERMAL EXPOSURE TO MACHINE WORKING FLUID.

C. V. Kommineni, E. Kisin, N. Al-Humadi, V. Castranova and A. A. Shvedova. *HELD/NIOSH, Morgantown, WV.*

Metal Working Fluids (MWFs) are widely used for metal cutting, drilling, shaping, lubricating and milling in the industrial world. Potential for dermal and inhalation exposure to MWFs exists in a large number of workers via aerosols, splashing during the machining process, and other industrial operations. Both females and males are involved in these industrial operations. It has been reported earlier that occupational exposure to MWFs causes health problems, e.g. allergic and irritant contact dermatitis. Previously, we have shown that dermal exposure of B6C3F1 mice (female and male) to 5% MWFs for 3 months resulted in an increase in skin histamine and mast cell counts. Topical exposure to MWF also resulted in depletion of two major water soluble antioxidants, e.g. ascorbate and glutathione in the liver of both genders. The level of lipid peroxidation (MDA) in the liver of both sexes and the testes in males was concomitantly increased. The goal of this study was to evaluate interaction between oxidative stress in the skin and topical application of MWF. To create acute skin inflammation, an H_2O_2 producing enzyme, glucose oxidase conjugated to polyethylene glycol (GOD-PEG), was injected intradermally. Intradermal administration of GOD-PEG to B6C3F1 mice (female and male, 8-12 weeks old) resulted in inflammation and muscle fiber necrosis in the skin. The level of GSH in skin was reduced after GOD-PEG treatment of B6C3F1 mice. To determine whether oxidative stress influences the dermal response to MWF, mice were injected with GOD-PEG 24 h prior to topical exposure to unused MWF (200 μl 30%). This resulted in an increased inflammatory response in skin, reduced GSH and protein thiols, and an increased level of peroxidative products. Further study is necessary to delineate the role of oxidative stress in enhancing contact/irritant dermatitis triggered by occupational exposures to MWF.

665 GLUTATHIONE (GSH) QUENCHES PEROXYNITRITE - MEDIATED NITRATION OF PROSTAGLANDIN H SYNTHASE FORM-2 (PGHS-2).

C. K. Kim[1], E. S. Roberts-Kirchhoff[2], K. N. Barton[1], J. Perterson[2], D. Kaplan[1], D. A. Putt[1] and H. Kim[1,3]. [1]*Detroit R&D, Inc.*, [2]*University of Detroit Mercy and* [3]*Institute of Chemical Toxicology, Wayne State University, Detroit, MI.*

Increased expression of both inducible nitric oxide (NO) synthase and PGHS-2 has been reported in intestinal inflammation. Overexpression of PGHS-2 induces cellular oxidative stress. NO reacts with superoxide produce under oxidative stress to form peroxynitrite, a potent toxic oxidant. To investigate whether, PGHS-2 isolated from sheep placenta was treated with peroxynitrite and nitration of PGHS-2 was analyzed by Western blot analysis using antibodies against nitrotyrosine. Nitrotyrosine levels of PGHS-2 dramatically increased after treatment with 300μM peroxynitrite. Surprisingly, addition of 30μM GSH to the reaction mixture prevented nitration of PGHS-2 by peroxynitrite. This result suggests that GSH prevents peroxynitritemediated nitration of PGHS-2 by formation of nitrosoglutathione and that nitration of GSH futher increases oxidative stress by lowering cellular GSH levels. 666 DIGESTIBILITY OF PROTEINS IN SIMULATED GASTRIC FLUID.

J. G. Kenna and R. M. Evans. *AstraZeneca CTL, Macclesfield, United Kingdom.* Sponsor: E. A. Lock.

Previous investigators have reported that 16 purified food protein allergens exhibited markedly greater stability in simulated gastric fluid (SGF) *in vitro* than 9 common plant proteins, and have concluded that stability in SGF distinguishes food allergens from nonallergens (Astwood et al., Nature Biotechnology 14: 1269, 1996). In the present study, the stability of 17 food protein allergens in SGF (0.08% (w/v) pepsin, 0.2% NaCl, 0.7% HCl) at 37°C has been compared with the stability of 24 proteins not associated with food allergy (17 plant food proteins and 7 animal proteins). Protein stability was assessed by SDS-polyacrylamide gel electrophoresis, using a gel system that resolved polypeptides with molecular masses that exceeded approximately 2 kDa. 13 food protein allergens were partially or completely stable for at least 60 min and/or were cleaved to polypeptide fragments that persisted for at least 60 min. 2 food allergens were degraded to peptides that were stable for 15 min and 2 were degraded to peptides that were stable for 5 min. Of the 17 plant food proteins that were tested, 8 were degraded completely within 5 min, as was 1 of the animal proteins. In contrast, 3 plant proteins resisted digestion for at least 60 min (e.g. potato tuber carboxypeptidase inhibitor), while 3 yielded polypeptide fragments that persisted for at least 60min (e.g. turnip cytochrome f). Peptide fragments that persisted for at least 60 min were also observed with 4 of the animal proteins (e.g. horse heart myoglobin). These results confirm that stability in SGF is a general feature of many food protein allergens. However, it is clear that similar stability is exhibited by other plant and animal proteins not suspected to be allergens. The implication is that resistance of food proteins to digestion in SGF is not a defining characteristic of allergenic potential.

667 SOY DIETS CONTAINING GENISTEIN STIMULATE GROWTH OF ESTROGEN-DEPENDENT TUMORS IN A DOSE DEPENDENT MANNER.

C. D. Allred, K. F. Allred, Y. H. Ju, S. M. Virant and W. G. Helferich. *Department of Food Science and Human Nutrition, University of Illinois, Urbana, IL.*

We have demonstrated that genistein and the glycoside form, genistin, stimulate estrogen (E)-dependent human breast cancer (MCF-7) cells *in vivo* (Cancer Research 58:3833, FASEB J. 13(4) A370). Genistin which is metabolized to genistein after consumption is the predominant isoflavone in soy protein commercially available. Depending on processing, soy isolates can contain different concentrations of genistein. We hypothesize that soy protein

isolates containing different concentrations of genistein will stimulate the growth of E-dependent cells *in vivo* in a dose dependent manner. We conducted experiments in which these soy protein isolates were fed to athymic mice implanted subcutaneously with E-dependent tumors. Genistein content of the soy isolate diets were 15ppm, 150ppm, or 300ppm. Positive (+E) and negative (-E) control groups received casein based diets. Tumor size was measured weekly. At completion of the study animals were killed and tumors collected for BrdU incorporation and pS2 expression. Incorporation of BrdU into cellular DNA was utilized as an indicator of cell proliferation whereas pS2 is an E-responsive gene. Soy protein diets containing genistein increased E-dependent tumor growth in a dose dependent manner. Cell proliferation was greatest in tumors of animals given E or dietary genistein (150 and 300ppm). Expression of pS2 was increased in tumors from animals consuming dietary genistein. (Supported by NIH grant (CA77355) to WGH.)

668 DEVELOPMENT OF A DOSE RESPONSE MODEL FOR EXPOSURE TO *LISTERIA MONOCYTOGENES* DURING PREGNANCY.

M. A. Smith[1], R. E. Brackett[1], H. M. McClure[2] and M. P. Doyle[1]. [1]*University of Georgia, Athens, GA and* [2]*Yerkes Primate Research Center, Atlanta, GA.*

Listeriosis is a foodborne illness resulting in an estimated 1850 cases and over 400 deaths per year in the U.S., about 1/4 of which are stillbirths, spontaneous abortions or neonatal deaths. Both human and non-human primates are susceptible to listeriosis when pregnant, with the same maternal and fetal reactions and pathological lesions. The objective of this study is to establish a dose response model for *Listeria monocytogenes* (*Lm*) using a the pregnant rhesus monkey as an animal surrogate for humans. The study was designed as a Phase I clinical trial using guidelines developed for testing anti-cancer drugs in humans. Initially, 3 animals were given a cocktail of 6 strains of *Lm* which were isolated from either human or primate outbreaks. Based on adverse pregnancy outcomes, two strains were identified for further testing. Nine rhesus monkeys were given oral doses ranging between 10^6 to 10^{11} cfu *Lm*/ml of whipping cream at approximately 110 days gestation. Animals were observed for outward signs of illness, and fecal and blood samples were collected and cultured to determine presence of *Lm*. Out of nine treated animals, four resulted in stillbirths. *Lm* was isolated from fetal tissue, and pathology indicated *Lm* as the cause of pregnancy loss. In pregnancies resulting in stillbirths, *Lm* was isolated from feces 3 or more days post-treatment indicating that *Lm* had survived and probably colonized the GI tract. (This work was supported by FDA grant FDU001622-01.)

669 DOES THE INCREASED CORN INTAKE BY MEXICAN-AMERICANS LOWER THEIR BLOOD FOLATE LEVELS?

L. M. Barraj[1], B. J. Petersen[1] and S. Saunders[2]. [1]*Novigen Sciences, Inc., Washington, DC and* [2]*Frito-Lay, Inc., Dallas, TX.*

Several studies have explored potential associations between incidence of neural tube defects (NTD) and folate deficiency, maternal chemical exposures, including environmental pesticides and water disinfection by-products, or exposures to fumonisins in corn. A recent publication has made the assumption that an apparent NTD cluster among Mexican-Americans living in South Texas is related to the high intakes of corn based foods and to the potential contamination of these foods with fumonisin. We used data collected by the National Health and Nutrition Examination Survey III (NHANES III) and USDA's Continuing Survey of Food Intakes by Individuals (CSFII) and examined the frequency of intake of corn-based foods by the US population, specifically Mexican-Americans, as well as folic acid intakes and folate blood levels. The results of these analyses showed significantly higher frequency of consumption of corn-based foods as well as significantly lower blood folate levels among Mexican-Americans. However, no significant associations were detected between the frequency of consumption of corn-based foods among Mexican-Americans and their blood folate levels. In fact, blood folate levels of Mexican-Americans who reported not consuming corn-based foods in the previous months were similar to those observed among Mexican-Americans who consumed corn-based foods daily. Furthermore, blood folate levels of Mexican-Americans who reported not consuming corn-based foods were significantly lower than those observed among non-Hispanics who also reported not consuming corn-based foods. These results suggest that factors other than corn intake are related to the lower blood folate levels observed among Mexican-Americans and the NTD cluster observed in South Texas.

670 PRELIMINARY STUDIES ON THE FATE OF FUMONISINS DURING THE MANUFACTURE OF TORTILLA CHIPS.

K. A. Voss[1], D. S. Saunders[2] and F. I. Meredith[1]. [1]*Russell Research Center, USDA/ARS, Athens, GA and* [2]*Department of Food Safety, Frito-Lay, Inc., Plano, TX.*

Fumonisins are mycotoxins produced by *Fusarium moniliforme* (= *F. verticillioides*) and *F. proliferatum*, fungi commonly found on corn. They cause fatal diseases in farm animals, are hepato- and nephrotoxic, and are rodent liver and kidney carcinogens. Human health effects of fumonisins are unclear, although survey data suggest that consumption of fumonisin contaminated corn as a dietary staple is correlated with high esophageal cancer rates in areas of southern Africa and China. Little information on how cooking affects fumonisins is available. Therefore, the fate of fumonisins during commercial scale production of fried tortilla chips, a popular snack food, was studied by determining the fumonisin concentrations of the corn, the process intermediates, and the chips using HPLC. Measurable fumonisin B_1 (FB_1) and B_2 (FB_2) concentrations in the chips varied, but were 40-80 percent lower than in the raw corn (n=4 batches) from which they were made. Cooking and steeping the corn in alkaline water, the first step in the process, was critical for lowering fumonisin concentrations. The intermediate steps of grinding the cooked corn into masa, baking, and frying the masa had little effect. Hydrolyzed FB_1 (HFB_1) was formed during cooking and steeping. HFB_1 concentrations in the fried chips were, however, relatively low compared to FB_1, suggesting that most HFB_1 remained in the steep liquid and other waste byproducts. These findings suggest that steeping and rinsing cooked corn in water effectively reduces fumonisin concentrations in food products manufactured from corn.

671 COMPARISON OF SPHINGOLIPID CHANGES IN TWO STRAINS OF MICE DOSED WITH FUMONISIN B1 (FB1) BY TWO DIFFERENT ROUTES.

E. N. Enongene[1], R. T. Sharma[2], K. A. Voss[1] and R. T. Riley[1]. [1]*USDA, Athens, GA and* [2]*College of Veterinary Medicine, University of Georgia, Athens, GA.*

Fumonisins are fungal toxins produced by Fusarium moniliforme which occurs on corn worldwide.The fumonisins are potent inhibitors of ceramide synthase. Inhibition of ceramide synthase causes a rapid increase in free sphinganine. We determined the time course of changes (0 to 48 h) in levels of free sphingoid bases, complex sphingolipids, and ganglioside GM1 (based on Cholera toxin binding) in intestinal epithelial cells, liver, and kidney from male NIH Swiss mice and male BALB/C mice treated with a single gavage or subcutaneous dose, respectively, of FB1 (25 mg/kg body wt). The subcutaneous and gavage routes of exposure in male BALB/C mice and male NIH Swiss mice produced similar results: a rapid (maximal at 4 -12 h) and reversible (return to control at 24 -48 h) increase in free sphinganine in intestinal epithelial cells (~300 to 400%) and liver (~200 to 300%), and an equally rapid but more slowly reversible (return to control >48 h) increase in kidney (~2000 to 2500%). There was no change in concentration or expression of complex sphingolipids or GM1, respectively. Thus, strain and route of exposure had no effect on the time course of sphingoid base accumulation, complex sphingolipids, or expression of GM1. (Supported in part by NIH Grant # ES09403.)

672 THE EFFECT OF FUMONISIN PRODUCING *FUSARIUM MONILIFORME* ON SELECTED IMMUNE RESPONSES OF MICE TO *TRYPANOSOMA CRUZI*.

C. Dresden-Osborne[1], G. P. Noblet[1], E. N. Enongene[2], R. T. Riley[2], C. W. Bacon[2] and K. A. Voss[2]. [1]*Clemson University, Clemson, SC and* [2]*Russel Research Center, ARS-USDA, Athens, GA.*

Fumonisins, produced by *Fusarium moniliforme* (=*F. verticilloides*) and related fungi, occur naturally on corn. Although known to elicit various species- and organ-specific toxicities, fumonisins are largely unstudied with respect to effects on immune function. *Trypanosoma cruzi*, the causative agent of Chagas' disease in humans, has a complex life cycle that includes both bloodstream and tissue stages in the mammalian host. The host immune response to *T. cruzi* includes macrophages phagocytizing and killing the parasite (partially mediated by the production and release of nitric oxide) or serving as host cells for parasite replication. BALB/c mice (3 groups, 20/group) were fed diets containing 0, 50 or 150 ppm fumonisins (fumonisins B_1+B_2 provided by *F. moniliforme* culture material) for one week prior to intraperitoneal injection with *T. cruzi*. Blood parasites were counted every 5-6 days, and 5 mice/group were euthanized on days 0, 14, 26 and 36 post-infection. Although body and

organ weight effects were minimal, fumonisin doses did cause significant dose-related increases in tissue sphinganine concentrations, a biomarker of fumonisin exposure. No differences among groups in blood parasite counts were found on days 8, 14, 20 or 36. Parasite counts of the controls, but not the fumonisin-fed groups, increased sharply on day 26. Control parasite counts decreased again on day 31, but remained significantly ($p<0.05$) higher than those of the high dose group. Differences in nitric oxide (NO) production were not found among groups before day 14 or on day 36. NO production of high dose mice peaked and was significantly increased ($p<0.05$) compared to controls on day 14, whereas NO production in controls peaked on day 26, simultaneously with peak blood parasite counts. These findings suggest that fumonisins affected immune response to *T. cruzi* and that *T. cruzi*-infected mice may be a good *in vivo* model for further studying the immunotoxic effects of fumonisins.

673 APPLICATION OF AN *IN VITRO* GASTROINTESTINAL MODEL FOR THE PREDICTION OF MYCOTOXIN ENTEROSORBENT EFFICACY.

S. L. Lemke[1], K. Mayura[1], S. E. Ottinger[1], C. A. Ake[1], H. J. Huebner[1], K. Pimpudkee[1], N. Wang[2], L. F. Kubena[3] and T. D. Phillips[1]. [1]*College of Veterinary Medicine, Texas A&M University, College Station, TX,* [2]*Dept. of Statistics, Texas A&M University, College Station, TX and* [3]*USDA ARS, College Station, TX.*

The successful inclusion of NovaSil clay in diets for the prevention of aflatoxicosis in animals has created an interest in the investigation of other potential enterosorbents for mycotoxins. Since *in vitro* studies are not always predictive of *in vivo* results, our objectives in this study were to compare three rapid *in vitro* methods, i.e., single point adsorption (SPA), adsorption isotherm (Q_{max}), and chemisorption index (C_α) with a recently established gastrointestinal (GI) model. These four methods were used to delineate the efficacy of binding of aflatoxin B_1 (AfB_1) to five sorbents: NovaSil, sand, charcoal, clinoptilolite and organoclay. Additionally, a corn-based feed matrix was included in modified isotherm and GI studies to examine potential interactions. As expected, NovaSil proved efficacious in all test methods (SPA and GI = >99% AfB_1 bound; $C_\alpha = 0.89$; and $Q_{max} = 0.461$mol/kg). Clinoptilolite did not effectively bind AfB_1, but had a C_α equal to 0.54. Also, under GI conditions, this clay demonstrated catalytic activity that was not observed in the other methods. Binding of AfB_1 by charcoal was higher than, or comparable to, NovaSil (SPA and GI = >99% AfB_1, $C_\alpha = 0.78$; and $Q_{max} = 0.889$ mol/kg) but was hindered in the presence of a corn matrix as seen by a decrease in the distribution coefficient ($K_d = 1.19 \times 10^6$ vs 1.11×10^5). To further test the predictive power of the GI model, studies were conducted with zearalenone (ZEN) and fumonisin B_1 (FB_1) and compared with *in vivo* results. The GI model was shown to be an efficient method of screening potential mycotoxin sorbents that includes physiologically relevant parameters and allows a more confident prediction of *in vivo* efficacy (Supported by USDA 9703230, NIEHS P42-ES04917, NCI CA-74552 and TAES H6215.)

674 THIN FILM CLAY-BASED COMPOSITES AS AFFINITY PROBES FOR AFLATOXINS.

H. J. Huebner, K. Mayura, C. Ake, S. L. Lemke and T. D. Phillips. *Texas A&M University, College Station, TX.*

The self-assembly of thin montmorillonite films on solid substrates has enabled the formation of advanced hybrid materials that possess unique properties. Stepwise film self-assembly is based on electrostatic attraction between oppositely charged components. It offers a novel strategy for building ordered organic/inorganic films on substrates while maintaining systematic control over film composition, structure and thickness. Our objectives were to utilize thin film technology to construct clay-quartz composites for the selective cleanup and analysis of aflatoxins from a variety of contaminated samples. In this study, a calcium montmorillonite clay (CMC), with high affinity and enthalpy of adsorption for aflatoxins, was electrostatically anchored onto the surface of quartz particles (212-300 μm) using poly(diallyldimethylammonium chloride) (P). Self-assembly of CMC films was accomplished by the sequential treatment of substrate in aqueous cationic solutions of P (1% w/v) and aqueous dispersions of CMC. Particle sizes of CMC and the number of deposition cycles of P and CMC on quartz were controlled experimentally. Composites (1.0 g) were tested for aflatoxin B_1 (AfB_1) capacity by eluting an aqueous AfB_1 solution (4 μg/ml) through prototypical glass affinity columns. Results showed that 50% breakthrough capacities for AfB_1 were highest with composites formulated with the largest CMC particle sizes and multilayer film depositions. Breakthrough capacities (50%) for AfB_1 ranged from 13-77 μg for monolayer composites and 15-140 μg for multilayer composites. Composites (0.5 g) were also tested for their ability to recover intact AfB_1 (12 μg) from aqueous solution. Results indicated that the highest AfB_1 recoveries were achieved using composites hybridized with the largest CMC particle sizes. Recoveries ranged from 1.7±0.1 to 7.5±0.4 μg AfB_1. Preliminary results suggest that thin film CMC composites may provide an alternative and cost-effective method for cleanup and analysis of aflatoxin contaminated media. (Supported by USDA 9703230, NIEHS P42-ES04917 and TAES H6215.)

675 HIGH AFFINITY SORPTION OF AFLATOXIN B1 BY HECTORITE CLAY.

K. Pimpukdee, C. Ake, S. L. Lemke, K. Mayura and T. D. Phillips. *Texas A&M University, College Station, TX.*

In the present study a variety of clays, differing in their chemical and structural characteristics, were tested for their ability to sorb aflatoxin B1 (AfB1) from aqueous solution. Results indicated maximal binding of AfB1to sorbents possessing high surface area, high cation exchange capacity (CEC) and intact interlayers. Based on these initial screening studies, hectorite (a trioctahedral smectite clay) was selected for further characterization and comparison with NovaSil (a dioctahedral smectite clay mineral). Equilibrium adsorption isotherms were run for each sorbent using methods previously established in our laboratory. The maximal capacities (Qmax) and affinity constants (Kd) for the adsorption of AfB1 were determined. At 25°C, the Qmax derived from a fitted Langmuir equation for hectorite was 0.919 ± 0.25 mol/kg vs 0.302 ± 0.01 mol/kg for NovaSil. The Kd was equal to 6.46 x 104 and 2.44 x 105 for hectorite and NovaSil,respectively. These findings suggest that the trioctahedral clay (hectorite) is an effective sorbent for AfB1 *in vitro*. A sensitive bioassaywas also used to confirm the detoxification of aflatoxins following sorption to hectorite. However, further *in vivo* studies in animals arerequired to determine the efficacy and safety of this clay before it can be used as a dietary enterosorbent. (Supported by USDA 9703230, NIEHSP42-ES04917 and TAES H6215.)

676 MODULATION OF BARRIER FUNCTION OF SMALL INTESTINAL EPITHELIAL CELLS BY TRICHOTHECENE MYCOTOXIN, DEOXYNIVALENOL.

Y. Sugita-Konishi, Y. Itoh, F. Kasuga and S. Kumagai. *National Institute of Infectious Diseases, Tokyo, Japan.* Sponsor: R. T. Riley.

The trichothecenes are known immunomodulators in animals. In mice, repeated oral dosing of deoxynivalenol (DON) altered cell-mediated and humoral immune responses and thereby reduced the host resistance to infectious diseases. However, the effect of oral exposure to trichothecenes on intestinal structure and function is still unknown. We used the human intestinal cell line (Caco-2) to study the effects of DON on the structure and differentiation of the intestinal epithelium and the secretion of proinflammatory cytokines. When Caco-2 cells were exposed to DON at concentrations that did not inhibit protein synthesis, the structure of the apical surface was altered and permeability of mannitol increased. DON suppressed the development of brush border membrane associated enzymes. The secretion of IL-8 from intestinal epithelial cell, a proinflammatory cytokine, was enhanced by DON. These results show that DON can modulate intestinal epithelium structure and function. Therefore the DON modulation of barrier function *in vivo* may influence the susceptibility to enteropathogens.

677 MODULATION OF GLUTATHIONE *S*-TRANSFERASES BY DIETARY BUTYLATED HYDROXYTOLUENE IN TURKEYS.

P. J. Klein, R. E. Buckner and R. A. Coulombe, Jr. *Utah State University, Logan, UT.*

Poultry are the most susceptible food animal species to the toxic effects of the mycotoxin aflatoxin B_1 (AFB_1). We previously showed that the extreme sensitivity of turkeys to AFB_1 is due to a combination of efficient AFB_1 activation by cytochrome P450s (CYPs) 1A2 and 3A4 and deficient detoxification by glutathione *S*-transferases (GSTs). As a strategy to induce GSTs relevant to AFB_1-detoxication, we pretreated male turkey poults of varying ages with 0.01 and 0.04 % (w/w) butylated hydroxytoluene (BHT) in the diet for 10 d. Liver cytosol from these animals showed increased general GST activity in the high BHT groups of all ages. BHT also significantly induced μ class GST activity in all age groups. Western immunoblots showed that immunoreactive proteins corresponding to α, μ, π and σ-class GSTs were significantly increased by BHT treatment. There was, however, no measurable AFB_1-8,9-

epoxide conjugation activity *in vitro* using liver cytosol from either control or BHT-treated poults of any age. While turkeys appear to possess inducible elements for GST expression, BHT apparently did not induce a GST isoform specific to AFB_1 detoxification. (Supported by USDA-NRI grants 97-3081 and 98-3754.)

678 TOXICITY OF COPPER SULFATE SUPPLEMENT IN OHIO FEEDER LAMBS.

I. S. Kim[1], M. K. Hoffman[1], A. M. Kadry[1], S. I. Hafner[2], A. J. Skowronek[3], W. M. Hockman[3] and P. T. Brisker[3]. [1]*Emerging Issue Branch, Chemistry and Toxicology Division, Food Safety and Inspection Service, United States Department of Agriculture, Washington, DC,* [2]*Eastern Laboratory, Food Safety and Inspection Service, United States Department of Agriculture, Athens, GA and* [3]*Animal Disease Diagnostic Laboratory and Division of Meat Inspection, Ohio Department of Agriculture, Reynoldsburg, OH.* Sponsor: R. S. Nair.

Copper sulfate has wide use as an agricultural poison and as an algicide in water purification. It has been used as a growth promotant for food animals, although documentation for such use is minimal. An investigation was carried out subsequent to an outbreak of copper sulfate toxicity in a group of Ohio feeder lambs. Sixty lambs were orally exposed to as high daily dose of 1339 ppm of copper sulfate in feed. A miscalculation was made in the formulae by the owner. Thirteen percent of the exposed animals died within a few weeks of daily exposure. Clinically, the lambs exhibited signs of depression, weakness and anorexia prior to death. Gross postmortem examination revealed hepatomegaly and splenomegaly. Histopathologic examination of tissues was typical of ovine copper toxicosis. The liver showed diffuse hepatocellular degeneration with multifocal necrosis in association with an abundance of cytoplasmic brown pigment. The kidneys exhibited diffuse interstitial edema and luminal hemoglobin pigment in association with tubular epithelial necrosis and regeneration. The level of copper in the liver (298 +/-34.59 ppm) was 300 times higher than that of muscle and 75 times that found in the kidneys. The findings of this investigation indicate the need to establish regulatory limits of copper in order to limit producer usage and to ensure that the U.S. consumer is not exposed to meat and poultry products adulterated with metals of toxicological concern.

679 TOXICITY PROFILE OF DIFFERENT IRON COMPOUNDS IN THE DEVELOPING RAT.

S. F. Ali[1], S. Z. Imam[1], G. W. Lipe[1], W. Slikker, Jr.[1], V. C. Dunkel[2] and P. Whittaker[2]. [1]*National Center for Toxicological Research/FDA, Jefferson, AR and* [2]*CFSAN/FDA, Washington, DC.*

Iron is the most abundant metal in the human body and is essential for normal neurological development. Iron deficiency during development can cause behavioral alterations including deficits in learning and memory. A high level of iron in the cell is capable of producing reactive oxygen species such as hydroxyl radicals. The present study was designed to evaluate the toxicity of three different iron compounds in developing rats. One month old male Sprague-Dawley rats were dosed orally with an acute dose of ferrous sulfate ($FeSO_4$; 1 g/kg), carbonyl iron (Fe; 30 g/kg) or sodium iron ethylenediaminetetracetate (NaFeEDTA, 2 g/kg) and were humanely killed after 15 min, 30 min, 1 hr, 2 hr, 4 hr and 24 hr. Trunk blood was collected for serum iron determination and brain tissue was removed and quickly dissected into different regions for analysis of dopamine and its metabolites. Acute administration of all three-iron compounds increased blood iron concentration that reached peak level at 4 hrs. $FeSO_4$ produced a significant decrease in the concentration of dopamine and its metabolites DOPAC and HVA at 4 hrs. After the administration of Fe and NaFeEDTA, dopamine or its metabolites showed no significant alterations. Brain and liver iron concentrations were also evaluated by atomic absorption spectrophotometry after $FeSO_4$ administration. Iron levels increased significantly in the brain at 15 and 30 min, whereas the liver iron concentrations increased at 2 hr. At these doses, these data demonstrate that $FeSO_4$ is capable of altering dopamine levels when compared to Fe and NaFeEDTA.

680 PHENYLBUTAZONE: A NEW CHALLENGE TO THE SAFETY OF US MEAT.

M. K. Hoffman[1], I. S. Kim[1], R. A. Sams[2], N. E. Weber[3] and A. M. Kadry[1]. [1]*Emerging Issue Branch, Chemistry and Toxicology Division, Food Safety and Inspection Service, United States Department of Agriculture, Washington, DC,* [2]*Animal Disease Diagnostic Laboratory and Division of Meat Inspection, Ohio Department of Agriculture, Reynildburg, OH and* [3]*Center of Veterinary Medicine, FDA, Rockville, MD.*

Phenylbutazone is a nonsteroidal anti-inflammatory drug. For humans the drug is usually prescribed as a last resort, because of serious idiosyncratic side effects. Blood dyscrasia and anaphylaxis are the main side effects, which are usually accompanied with difficulty in swallowing, gasping for breath, dizziness, or fainting. The drug could cause liver and kidney failure. Phenylbutazone is approved for relief of inflammatory conditions associated with the musculoskeletal system in dogs and horses (21 CFR 520.1720), but, because of its potential human health impacts, the Food and Drug Administration prohibits its use in all food animals. Most recently, residues of phenylbutazone were detected in the tissues of several food animals, including a "Grand Champion Steer" at an Ohio County Fair, and a horse. In the first case, both phenylbutazone and its metabolite oxyphenylbutazone were extracted from urine before being quantified and confirmed by gas chromatography/mass spectrometry. In the latter case, phenylbutazone was found in fat adjacent to muscle tissue. In the last two years, FSIS has found ten instances of illegal usage of phenylbutazone. These findings of phenylbutazone residues may warrant investigation of the compliance of food animal veterinarians and animal owners to Federal regulations as well as education regarding use of this drug in food animals. Use of this banned drug in food producing animals compromises the health of the American public and jeopardizes the safety of the American food supply. Any finding of phenylbutazone in a food producing animal renders that animal carcass, as well as all other carcasses that are "mixed" with that carcass, as "adulterated," leading to an economic loss to food animal producers. Cooperation between Federal Agencies and Veterinary Associations is required to prevent future occurrence of this problem.

681 SAFETY ASSESSMENT OF *BETA*-HYDROXY-*BETA*-METHYLBUTYRATE.

S. Im[1], R. J. Rose[2], T. E. Shaw[2], V. M. Tai[3] and J. M. Daniels[2]. [1]*Cantox Health Sciences International, Calgary, Alberta, Canada,* [2]*Cantox Health Sciences International, Mississauga, Ontario, Canada and* [3]*Cantox Health Sciences International, Vancouver, British Columbia, Canada.*

Beta-Hydroxy-Beta-methylbutyrate (HMB), also called 3-hydroxy-3-methylbutyrate, or beta-hydroxyisovalerate, is a metabolite of the amino acid leucine, and is purported to enhance muscle development in humans and animals through a decrease in the breakdown of protein. Despite the fact that HMB is a normal component of human metabolism and is also obtained from dietary sources, the safety of this compound was assessed given that relatively high doses are ingested to provide the desired effects.A series of studies have been performed which have examined the potential for adverse effects of HMB in male and female human volunteers at doses of up to 3,000 mg HMB (as the calcium salt)/day (equivalent to 43 mg Ca-HMB/kg body weight/day or 17 mg of HMB free base/kg body weight/day in a 70 kg human) for up to 7 weeks, and up to 5,000 mg Ca-HMB/kg/day for 1 week in pigs or 200 mg Ca-HMB/kg/day for 4 weeks in hamsters. No adverse effects have been observed, although there were some decreases in serum cholesterol levels noted in both humans and animals. The lack of reported adverse effects of HMB ingestion in animals or humans, coupled with the endogenous role of HMB, supports the safety of ingesting doses of up to 3,000 mg per day by non-pregnant adults. There is no available evidence to suggest any increased risk of adverse effects from use of HMB, although the effects of long-term supplementation with high doses of HMB have not been investigated.

682 DEVELOPMENT OF MODELS TO PREDICT THE ALLERGENIC POTENTIAL OF FOOD PROTEINS.

C. Meredith and H. A. C. Atkinson. *TNO BIBRA International Ltd., Carshalton, United Kingdom.* Sponsor: B. G. Lake.

Introduction of novel proteins into the human diet following GM strategies has led to concerns of allergenicity. Although cross-reactivity of novel protein with existing allergens can be demonstrated, there are no techniques to determine the capacity of novel proteins to induce sensitization. We developed three interlinked models to assess inherent allergenic potential of food pro-

teins; these are based on the response of the BN rat (a high IgE responder strain) to (a) i.p. or (b) p.o. administration of protein together with the specific adjuvant carrageenan (1 mg/ml i.p.), and (c) analysis for allergenic fragments following *in vitro* digestion by immunoblot using PCA-positive sera from day 28 i.p. and day 42 p.o. The quantity of protein required to induce a 50% response (ED50) was calculated. We found that a protein of low allergenic potential, such as bovine serum albumin (BSA), produced an ED50 level of 10 μg i.p., whereas proteins of higher allergenic potential such as bovine lactoferrin (LF) or ovalbumin (OA) exhibited significantly lower ED50s of 50 ng and 6 μg respectively. For oral exposure, ED75s of 5.0, 50 and 100 mg/kg were observed for OA, LF and BSA respectively. These differences were reflected in the persistence of IgE binding epitopes following *in vitro* digestion. We have used these dose-response curves to rank food proteins in terms of their inherent allergenic potential both i.p. and p.o. and we are now integrating this data into a risk assessment analysis for novel proteins. (Supported by MAFF UK.)

683 ANTIBACTERIAL ACTIVITY OF IMMOBILIZED ORGANOCLAY FILTRATION BEDS.

P. Herrera, H. J. Heubner, C. Ake and T. D. Phillips. *Texas A&M University, College Station, TX.*

Previous research has shown that phyllosilicate clays modified with cationic surfactants cetylpyridinium (CP), hexadecyltrimethylammonium (HDTMA), and cetyldimethylethylammonium (CDEA) were effective in reducing *Salmonella enteritidis* (*SE*) colony counts in bulk antibacterial assays. In order to increase the hydraulic conductivity of these materials for use in filtration beds, the organoclays were immobilized onto sand. Various chemical agents were tested for adhesive ability, water insolubility and inherent antimicrobial activity. From the promising candidates a polyvinyl adhesive was chosen as the primary adhesive agent. Bulk antibacterial assays performed with 10 mg of the immobilized organoclays (IOC) showed that the these materials retained their antibacterial activity after processing. Reductions in plate colony counts ranged from 16.5% for CP-exchanged sodium montomorillonite (MS:CP*SWy-2) to 83.9% for CDEA-exchanged low pH montmorillonite (MS:CDEA*LpHM). The sand matrix (MS) and immobilized activated charcoal (MS:AC) failed to produce any significant decreases. Pilot studies with columns containing 1.0 g of IOC showed that maximal filtration efficiency was obtained at a filtration rate of 1.0 ml/min. Initial column studies with *SE* suspensions with concentrations of 3.0×10^8 CFU/ml produced reductions in colony plate counts varying from 28.5% for CP-exchanged calcium montmorillonite (MS:CP*STx-1) to 59.5% for MS:CDEA*LpHM. MS and MS:AC yielded much lower reductions (7.6% and 10.4%, respectively). Studies with *Escherichia coli* suspensions (3.0×10^7 CFU/ml) exhibited reductions varying from 59.3% for MS:CP*STx-1 to 99.9% for MS:CDEA*LpHM. These intial results suggest that these immobilized organoclays would be effective in reducting microbial numbers in wastewater. (Supported by NIH P42 ES04917, USDA 9703230, and TAES H6215.)

684 A RANDOM WALK MODEL OF STRATUM CORNEUM PENETRATION.

H. F. Frasch. *National Institute for Occupational Safety and Health, Morgantown, WV.* Sponsor: A. Shvedova.

Penetration of chemicals through skin is governed by its specific morphological structure and biochemical composition. In order to account for the complex "brick-and-mortar" structure of the stratum corneum, a mathematical model has been devised that explicitly incorporates this non-uniform structure. Diffusion is modeled as a random walk of particles through an asymmetrical 2-phase system of corneocytes bounded by continuous lipid bilayers. The model accounts for partitioning between the phases and relative diffusivity within both phases. Model results permit the calculation of effective diffusivity (D^*), effective path length (l^*), and lag time (τ). Thus results can be compared with experimentally determined permeation coefficients and lag times. Non-steady state permeation vs. time of methyl parathion was modeled, and the result corresponds closely (R^2=0.98) with measured data. Model results demonstrate the strong dependence of D^*, l^* and τ on both partitioning and relative diffusivity. In its current implementation, lipid-corneocyte partitioning and diffusivities within the phases are model input parameters. In future refinements, we will incorporate quantitative structure-activity relationships to model partitioning and diffusivity. This will permit individual chemicals to be used explicitly as inputs. Phenomena such as tissue adsorption and cutaneous metabolism can also be incorporated. Because it accounts for biophysical phenomena at the elementary molecular level, the model is comprehensive yet fairly simple.

685 PHOTOTOXICOLOGY: PHOTOCARCINOGENESIS HISTORICAL CONTROL DATA AS A KEY INTERPRETIVE ELEMENT.

D. B. Learn, C. P. Sambuco, P. D. Forbes and A. M. Hoberman. *Primedica Argus, Horsham, PA.*

Studies have been conducted over the past two decades to assess the ability of compounds to modify skin tumor development elicited by exposure to simulated sunlight in Crl:SKH1-*hr*BR hairless mice (photocarcinogenesis). Low and high ultraviolet radiation dose calibration groups (i.e., mice exposed to 600 or 1200 Robertson Berger Units/week) have been included in these studies to permit determination of test article or vehicle effects. The skin tumor endpoints evaluated have been prevalence (i.e., the proportion of mice in a group exhibiting one or more qualifying tumors, as a function of time, and adjusted for the effects of competing mortality), median onset (i.e., the time at which one-half of the members of the groups have acquired one or more qualifying tumors) and yield (i.e., the number of tumors present, divided by the number of surviving mice). Examination of the prevalence and median data for seven studies conducted in the past four years revealed good interstudy reproducibility. Skin tumors tended to occur slightly earlier in female mice, as compared with male mice. Some topically administered vehicle products enhanced photocarcinogenesis, but oral (gavage) vehicles did not. Examination of the tumor yield data confirmed the gender difference and vehicle effect, but as compared with the prevalence and median data, more variability was seen with this endpoint. The inclusion of these calibration groups in photocarcinogenesis studies has provided useful information on the homogeneity of skin tumor responses in this test system and can provide valuable assistance with respect to assessment of product effects and detection of sources of variability.

686 INVESTIGATION OF SKIN PHOTOTOXICITY POTENTIAL USING AN *IN VITRO* HUMAN EPIDERMIS MODEL (SKINETHIC).

J. Medina, A. De Brugerolle De Fraissinette, C. Elsaesser, V. Picarles, N. Hartmann, O. Grenet, S. Chibout and M. Kolopp. *Novartis Pharma AG, Basel, Switzerland.*

The present study evaluated the suitability of the human reconstituted epidermis model SkinEthic® for the assessment of the *in vitro* phototoxic potential of topical products. The phototoxic compounds 8-Methoxypsoralen, Tetracycline, Promethazine and 6-methylcoumarine (weak phototoxicity), and the non-phototoxic compound Sodium lauryl sulphate were tested. The response of the tissue to the application of the test articles in the presence and absence of UV light, was analyzed in terms of viability (LDH release), pro-inflammatory activity (IL-8 and IL-1-alpha release and mRNA expression) and morphology (histopathological analysis). Two different prediction models were used: the Photo-Irritancy Factor (PIF) and the Mean Photo Effect (MPE). All the non-phototoxic and phototoxic products tested were correctly classified. Due to poor skin penetration, Tetracycline was identified as phototoxic only after application in the culture medium, and not via the topical route. These results indicate that the method is appropriate for the investigation of the phototoxic potential of products intended for topical administration. A simplified version based on the determination of LDH release is recommended for high throughput screening purposes (simple differentiation between phototoxic and non-phototoxic products). On the other hand, the complete version of the protocol, including all parameters, seems to be necessary for the evaluation of weak phototoxic products.

687 PREDICTIVE VALUE OF A HUMAN SKIN EQUIVALENT (APLIGRAF) FOR THE EVALUATION OF SKIN IRRITATION POTENTIAL.

J. Medina, A. De Brugerolle De Fraissinette, C. Elsaesser, V. Picarles, O. Grenet, S. Chibout, M. Kolopp, U. Junker, M. E. Ebelin, P. Burtin, B. Vogel and A. Cordier. *Novartis Pharma AG, Basel, Switzerland.*

The present study was designed to investigate the response of the human skin equivalent Apligraf *in vitro* to the application of irritant substances, and its predictivity as a screening tool for skin irritant potential in humans. Sodium Lauryl Sulfate, Calcipotriol and Trans-Retinoic acid were applied to Apligraf *in vitro* for 24 hours. Cell viability (lactate dehydrogenase leakage, MTT mitochondrial reduction), release and mRNA expression of the pro-inflammatory cytokines IL-1-α and IL-8, and morphological changes were assessed. The same products were applied to 30 healthy volunteers in a double-blind, randomized, vehicle-controlled within-subject study. The skin reactions after

repeated 24-h applications over 3 weeks under Finn chamber patches were monitored by visual scoring and biophysical methods (TEWL, chromametry and blood flow). The sensitivity, specificity and predictivity of Apligraf for assessing skin irritation were evaluated. Sodium Lauryl Sulphate was cytotoxic to Apligraf, and increased the release and expression of cytokines at low (0.2%, 0.4%), but not at high (0.8%, 1%) concentrations. It induced severe irritancy *in vivo*. Trans-Retinoic acid increased the expression and release of cytokines with no detectable cytotoxicity, and showed moderate irritancy in humans. Calcipotriol did not affect cell viability, but it increased the production of cytokines, and was mild to moderate for healthy volunteers. Apligraf, used for *in vitro* testing showed a good predictive value for the substances under investigation. In conclusion, the irritation potential of the tested products could be predicted with Apligraf, by monitoring cytotoxicity, the profile of proinflammatory cytokines and morphological changes.

688 HIGHLY DIFFERENTIATED *IN VITRO* SKIN MODEL FOR HIGH THROUGHPUT SCREENING OF TOPICAL THERAPEUTICS.

P. J. Hayden, G. R. Jackson, Jr., M. Klausner and J. Kubilus. *MatTek Corporation, Ashland, MA.*

EpiDerm™ is an *in vitro* organotypic human skin model cultured at the air/liquid interface to produce a three-dimensional tissue with a stratum corneum possessing a barrier function similar to native epidermis. The model is suitable for topical application of creams or lotions, and has found use in applications including cytotoxicity, irritation, and/or efficacy screening of topical pharmaceutical or cosmetic products and ingredients. EpiDerm is presently produced on cell culture inserts, which can be handled and manipulated individually. The current abstract describes two experimental formats in which the tissues are cultured on one-piece 24-well or 96-well plates suitable for high-throughput applications. Histological evaluations show the experimental formats produce tissues which are indistinguishable from the standard format. To demonstrate the utility of the model, TNF-α secretion in response to topically applied phorbol ester (PMA) was measured by ELISA. PMA is a powerful tumor promoter which acts primarily via interaction with protein kinase C and has been shown to upregulate TNF-α expression. PMA treatment resulted in a 1.7-2.4 fold increase in TNF-α secretion but had no effect on tissue viability, as indicated by the MTT assay. In addition, high quality total RNA (absorbance ratio at 260/280 nm were 1.8 - 2.1; agarose gel electrophoresis ribosomal RNA bands were distinct and well defined) was extracted and purified from the tissues utilizing a procedure based on GSCN lysis and immobilization on glass-fiber filters. RNA yields averaged 46.2 $\mu g/cm^2$ tissue. These data indicate that the new experimental EpiDerm formats may find utility in high-throughput screening applications such as in monitoring mRNA levels or the effects of PKC inhibitors and/or similar pharmaceutically important cellular targets.

689 A CLINICAL SKIN SAMPLING APPROACH TO ASSESS SENSORY SKIN IRRITATION.

M. A. Perkins, M. A. Osterhues, S. Vogelpohl and M. K. Robinson. *Procter & Gamble Company, Cincinnati, OH.*

We have developed a noninvasive Sebutape sampling procedure to adsorb and quantify molecular mediators of skin inflammation. This procedure has been used to distinguish inflamed from normal skin or mucosa, where the inflammation is caused by chemical irritants or existing dermatoses such as diaper dermatitis or gingivitis. Recently, we have applied this methodology to attempt to define quantitative markers for neurosensory skin irritation. Sensory skin irritation refers to the myriad of symptomatic complaints (including itch, sting, and burn) frequently associated with inflammatory skin conditions or skin intolerance to various products. Often, sensory skin irritation occurs in the absence of visual skin reactions. The use of our Sebutape procedure was introduced to provide potential means for quantitative assessment of these responses. Study subjects were first introduced to a clinical assessment scale (the labeled magnitude scale or LMS) used to evaluate chemosensory skin reactions to chemical agents. They were then treated with escalating concentrations of chemical stimuli (lactic acid, capsaicin) on the face or arm. After each treatment, they rated the intensity of the reaction on the LMS scale. Applications continued until a moderate degree of intensity was noted. At different times, Sebutape samples were collected from the treatment sites and frozen until analyzed. The clinical results showed a clear dose response pattern in the LMS to the chemical treatments, with most subjects achieving a moderate intensity of response. The Sebutape samples were extracted in buffer and analyzed (via chemical or immunoassay methods) for recoveries of various neuro and inflammatory mediators. Precise correlations between incidence and/or severity of sensory skin irritation must await large scale subject evaluations; however, clear indications of elevation or decline in specific mediator recoveries (e.g., interleukin-1α, interleukin-1 receptor antagonist, IL-1ra/IL-1α ratios, interleukin-8, nitric oxide) have been observed and continue to drive this research effort.

690 COMPARISON OF CHEMICAL-INDUCED SKIN IRRITATION RESPONSES BETWEEN CAUCASIAN AND ASIAN POPULATIONS.

M. K. Robinson. *The Procter & Gamble Co., Cincinnati, OH.*

There is considerable speculation that certain human populations (particulary ethnic subpopulations) are more prone to developing adverse skin reactions than others. In particular, a heightened sensitivity among Asian subjects (vs. Caucasians) has been suggested. This has implications for the procedures used for skin safety assessment of new ingredients and products, especially those marketed globally. However, there is little published data to support the speculation (M.K. Robinson, Contact Dermatitis 41:65-79, 1999). The focus of this investigation was to directly compare skin irritation responses between Caucasian subjects and different subpopulations of Asian subjects (Chinese, Japanese) to determine if significant differences in response patterns would emerge. The studies used 2 different skin irritation test methods concurrently in the same subjects. The first was a cumulative response (14 day repeated occluded patch exposure) to several dilute concentrations of the anionic surfactant, sodium dodecyl sulfate (SDS). The second was an acute response (up to 4 hr occluded patch exposures) to several materials (20% SDS, 10% acetic acid, 100% octanoic acid, 100% decanol, and water) with diverse skin irritation potentials. In an initial study among Caucasian and Japanese subjects, the Japanese subjects responded faster than the Caucasian subjects in both the acute and cumulative irritation tests. A repeat of this exact study protocol was then conducted among Caucasian, Japanese, and Chinese subjects. In this second study, no differences were seen in the acute or cumulative irritation responses between the Japanese and Caucasian subjects. Minimal differences were seen between the Chinese subjects and the other populations. These divergent results underscore the difficulty in ascribing true population differences in skin reactivity based upon studies in limited subject populations. These findings may be indicative of the wide variation in skin responsiveness across human subjects in general.

691 HUMAN ACUTE SKIN IRRITATION POTENTIAL, *IN VIVO*: GLUCOWATCH® BIOGRAPHER.

D. R. Wilson and S. J. Fermi. *Cygnus, Inc., Redwood City, CA.* Sponsor: W. G. Reifenrath.

The GlucoWatch® biographer, developed by Cygnus, Inc., is a frequent, automatic, and non-invasive glucose monitor intended to provide diabetics with the information needed to control their glucose levels. Sponsored by Cygnus, Hill Top Research, Inc. (Miamiville, OH) performed a clinical trial evaluating the acute irritation potential of the GlucoWatch® biographer in 51 diabetic and 52 non-diabetic subjects following a single 15hr wear period. The irritation recovery process was also evaluated. Two test systems delivering iontophoretic current (up to $0.32 mA/cm^2$ for 6min during each 20min glucose measurement cycle) were placed on each forearm. Following removal, the skin sites were evaluated and scored on Day 1 (15min post removal) and on Days 2, 3, 4, 6, and 8 utilizing modified Draize erythema and edema scales (0 to 4). There were no serious or unexpected adverse events, and no subjects were discontinued from the study. Day 2 erythema scores (most sensitive evaluation uninfluenced by transient skin responses) for the 198 active devices applied to diabetics revealed these levels of irritation at glucose collection sites: 16% none, 72% mild, & 12% moderate; the 204 applied to non-diabetics produced: 14% none, 78% mild, & 8% moderate. Irritation responses began to resolve on Day 2; most resolved by Day 8; all were resolved by Day 15. No clinically meaningful differences existed in irritation rates between diabetic and non-diabetic subjects. Analyzing age and gender variables within the two groups, no clinically meaningful differences were observed.

692 A NOVEL USE OF AN *IN VITRO* PERCUTANEOUS ABSORPTION PROCEDURE TO ASSESS ABSORPTION POTENTIAL OF HUMAN VAGINAL TISSUE.

E. C. Lonardo[1] and T. A. Roy[2]. [1]*Advanced Care Products, Johnson & Johnson Corporation, North Brunswick, NJ and* [2]*Petrotec, Inc., Langhorne, PA.*

Vaginal epithelium is permeable to a wide variety of compounds. Unfortunately, quantitative data on the extent of absorption are often lacking. The *in vitro* percutaneous absorption procedure is valuable in developmental stages of vaginal drug delivery systems. It allows for direct risk assessment and eliminates ethical and safety concerns associated with human *in vivo* testing. By using an *in vitro* technique, the absorption potential of polydimethylsiloxane (PDMS) was assessed through human vaginal tissue. In vitro percutaneous absorption experiments (96 hr) were performed with two PDMS samples (350 cSt and 10 cSt). Infinite doses (10 mg/cm2) were applied to the donor side of split thickness human abdominal skin sections (reference standard) and full-thickness human vaginal tissue mounted in Franz *in vitro* diffusion cells. In order to facilitate the measurement of percutaneous absorption, doses were spiked with the respective 14C-PDMS (350 cSt or 10 cSt) prior to the study. Based on 14C-PDMS, the dermal flux rate for the infinite dose of 350 cSt PDMS was 0.31 and 1.98 ng/cm2/hr for the abdominal skin and vaginal tissue respectively. For the 10 cSt PDMS, flux rates were 0.52 and 5.52 ng/cm2/hr for the abdominal skin and vaginal tissue respectively. Although vaginal absorption of 350 and 10 cSt PDMS is 6 and 10 times greater respectively, than through abdominal tissue, less than 0.01% of the PDMS was absorbed through the dermal barrier regardless of tissue or viscosity of PDMS. This novel *in vitro* approach allows for direct determination of vaginal bioavailability of drug products or vehicles either intended or not intended to be absorbed into the blood stream and is a promising tool for vaginal therapeutic drug development.

693 SKIN PENETRATION OF ORGANIC COMPOUNDS FROM SOILS.

W. Reifenrath[1], H. Kammen[1], W. Palmer[2], M. Major[2] and G. Leach[2]. [1]*Stratacor, Inc., Richmond, CA and* [2]*US Army CHPPM, Aberdeen Proving Ground, MD.*

Nine C-14 labeled organic compounds were mixed with soils or acetone and applied to the epidermal surface of viable excised pig skin mounted in evaporation/penetration chambers. Skin penetration of the compounds was measured by assay of radiolabel in the dermis and receptor fluid. The compounds tested were 2,4-dinitrotoluene (2,4-DNT), 2,6-DNT, 2-amino-4,6-dinitrotoluene (2-ADNT), 4-ADNT, 2,4-diamino-6-nitrotoluene (2,4-DANT), 2,6-DANT, trinitrobenzene (TNB), thiodiglycol (TDG), and hexahydro-1,3,5-trinitro-1,3,5-triazine (RDX). A low carbon soil (Yolo) and a high carbon soil (Tinker) were used. Applications were made at a chemical dose of 10 µg/cm2 and a soil dose of 10 mg/cm2. Selected samples of dermis and receptor fluid were analyzed for radiochemical identity; non-parent compounds were detected for RDX, TDG, TNB and 2,4-DANT. Mean penetration from low carbon soil was generally higher than for high carbon soil; however, the effect was significant only for 2,4-DNT and 2,6-DNT (ANOVA, Newman-Keuls test, $p = 0.05$). Mean penetration from acetone solution was always higher than from soils; however, the effect was not significant ($p = 0.05$) for all combinations of compound and soil. These results demonstrated that incorporation of a compound into soil or incorporation into soil with a higher carbon content did not necessarily result in a significant reduction of skin absorption.

694 THE EFFECT OF SURFACE CONTACT ON DERMAL ABSORPTION OF PESTICIDES FROM HOUSE DUST.

G. A. Keating[1], S. B. DuTeaux[2] and K. T. Bogen[1]. [1]*Lawrence Livermore National Laboratory, Livermore, CA and* [2]*University of California, Davis, CA.* Sponsor: H. I. Maibach.

The effect of surface contact on the dermal absorption of pesticides was examined by comparing uptake in human skin *in vitro* using two application methods. House dust (<150 µm, 40% organic carbon) spiked with either 14C-pentachlorophenol (PCP, 260 ng/g) or 14C-2,4-dichlorophenoxyacetic acid (2,4-D, 435 ng/g) was deposited on or pressed into the skin under mild pressure (0.5 psi) in flow-through diffusion cells for 8 hrs. Applied dust loads for the two application methods ranged from 0.12 - 3.0 mg/cm2 skin. PCP uptakes, normalized for dust load, with the press and deposition methods were 1.04±0.88 and 0.65±0.47 fmol 14C/cm2, respectively. 2,4-D uptakes with the press and deposition methods were 0.31±0.49 and 0.43±0.67 fmol 14C/cm2, respectively. Normalized uptake did not vary with the applied dust load or the percent transferred to the skin for either chemical. When normalized by the applicator dust load, uptake increased markedly at applied dust loads below 0.2 mg/cm2, suggesting enhanced skin-dust contact at lower applicator loads. (Work performed under the auspices of the U.S. Environmental Protection Agency, IAG #DW89937390-01-0 and under the auspices of the U.S. Department of Energy at Lawrence Livermore National Laboratory under Contract W-7405-ENG-48.)

695 EFFECT OF SOIL LOADING AND SOIL SEQUESTRATION ON DERMAL BIOAVAILABILITY OF POLYNUCLEAR AROMATIC COMPOUNDS.

T. A. Roy[1], R. Singh[2] and D. P. Weyand[3]. [1]*Petrotec, Inc., Langhorne, PA,* [2]*College of Pharmacy, Rutgers, The State University of New Jersey, Piscataway, NJ and* [3]*Maple City Research, Hornell, NY.*

Literature reports show that sorption of polynuclear aromatic compounds (PAC) on soil can significantly impede their penetration through the skin. Studies conducted in our laboratory with PAC-contaminated soils from industrial sites show reductions in PAC dermal flux of 1-3 orders of magnitude compared to the neat PAC-containing contaminant. The dermal flux values are used to calculate site-specific dermally absorbed dose (DAD) values that are essential for estimating risk associated with human exposure. Two criticisms of the *in vitro* procedure used in our earlier studies are 1) the "infinite dose" soil loading used (10 mg/cm^2) is well above what some consider the actual soil adherence factor (AF) of 0.2 mg/cm^2 and, 2) the procedure does not account for the effect of contaminant aging or soil sequestration phenomena. To address these concerns, *in vitro* experiments were carried out using human skin sections and PAC-spiked soil at 10, 5, 2.5 and 1 mg/cm^2 to evaluate the effect of soil loading on dermal flux and percent of dose absorbed (PADA). Additionally, dermal experiments were conducted with the freshly spiked (PAC) soil (day 1) and with aliquots of the same soil following 45 and 110 days of laboratory aging. Dermal flux of benzo[a]pyrene (BaP) was measured using liquid scintillation counting and a newly developed HPLC-fluorescence assay for monitoring aged PAC in soils. Results from the soil loading study show that flux is not affected by loading above "monolayer" (~3 mg/cm^2) coverage and that flux decreases in proportion to soil loading below monolayer coverage. Further, the results show that PADA decreases proportionately with increased soil loading above monolayer and remains constant at sub-monolayer coverage. Results from the soil sequestration study show a 50% reduction in BaP dermal bioavailability following 110 days of aging.

696 EXHALED BREATH ANALYSIS AND PBPK MODELING OF THE DERMAL ABSORPTION OF TRICHLOROETHYLENE IN RATS.

T. S. Poet[1], R. A. Corley[1], K. D. Thrall[1], J. A. Edwards[1] and R. C. Wester[2]. [1]*Battelle, Richland, WA and* [2]*University of California, San Francisco, CA.*

Due to the large surface area of the skin, the percutaneous absorption of chemicals from contaminated water or soil is potentially a problem. The amount of chemical absorbed through the skin is dependent upon the permeability coefficient (kp), exposure media, concentration gradient, surface area exposed, and the length of exposure. At steady state, dermal absorption is calculated using Fick's law. Physiologically based pharmacokinetic (PBPK) modeling was used to describe the kp of trichloroethylene (TCE) under non-steady state conditions based on exhaled breath data acquired from rats following dermal exposure to TCE in water or soil matrices. A patch (occluded or non-occluded) was applied to the clipper-shaved back of F-344 rats. Rats were placed in off-gassing chambers and the chamber air TCE concentration was quantitated for 4-5 hr using an ion trap mass spectrometer. Patch components and dosing solutions were analyzed to determine TCE concentrations before and after the exposures. Target water TCE concentrations were 0.05 and 0.15% (w/v). Target soil TCE concentrations were 0.5, 1.5, and 3%. The rate of loss of TCE (Kloss) from the non-occluded patch and kp were estimated for each individual animal by optimization of the least-squares fit of the model to the patch component and exhaled breath data using Simusolv™ (Mitchell & Gathier). The average kp for all water exposures was independent of concentration, at 0.28 ± 0.018 cm/hr. The uptake of TCE from a soil matrix was lower than from a water matrix, with the occluded soil exosures, the kp was estimated at 0.14 + 0.012 cm/hr and the non-occluded soil exposures kp was 0.053 ± 0.0041. The rate of loss from non-occluded systems was 0.74 ± 0.068 hr-1. The assessment of matrix effects on apparent kp will aid in addressing dermal risk assessments. (Supported by US DOE grant No. DE-FG07-97ER62509.)

697 HUMAN DERMAL ABSORPTION OF TRICHLOROETHYLENE FROM SOIL AND WATER.

R. C. Wester[1], T. S. Poet[2], K. K. Weitz[2], J. A. Edwards[2], R. A. Corley[2], H. Tanojo[1], X. Hui[1], H. I. Maibach[1] and K. D. Thrall[2]. [1]*Department of Dermatology, University of California at San Francisco, San Francisco, CA and* [2]*Pacific Northwest National Laboratory, Richland, WA.*

The study objective was to determine trichloroethylene (TCE) human dermal absorption in real time for risk assessment. The amount of chemical absorbed through the skin is dependent upon the permeability coefficient (kp), exposure media, concentration gradient, surface area exposed, and the length of exposure. At steady-state, dermal absorption can be calculated using Fick's law. For non steady-state conditions, physiologically based pharmacokinetic (PBPK) modeling is well-suited to determining kp. PBPK modeling was used to assess the percutaneous absorption parameters for TCE based on exhaled breath concentrations in human volunteers. Volunteers were exposed to 0.1% TCE in water or 0.5% TCE in soil either by placing a hand in 4 kg of soil or water or to 80 g of soil or water in patches placed on their forearm. Subjects were provided breathing air via a facemask to eliminate inhalation exposure. The subject's exhaled breath was analyzed using an ion trap mass spectrometer, which can quantitate TCE in the breath stream in the 1-5 ppb range. The pre- and post-exposure concentrations of TCE in the exposure media were analyzed to track changing exposure conditions. The percentage absorbed and kp were estimated for each individual subject by optimization of the least-squares fit of the PBPK model to the media concentrations and the exhaled breath data using Simusolv™ (Mitchell & Gathier). In the occluded water and soil patch studies, 4.0±0.20 and 0.90±0.32% of the total available TCE was absorbed over 8 hr, respectively. The kp for water exposures was 0.019±0.001 cm/hr for the patch system and 0.016±0.003 cm/hr for the hand immersion studies. The kp optimized from soil exposures was less than half that for dermal exposures to TCE in water. Determination of kp specific for exposure matrices will aid in the dermal risk assessments for real-life scenarios. (Supported by US DOE grant No. DE-FG07-97ER62509.)

698 PHARMACOKINETIC MODELING OF DERMAL EXPOSURE TO BROMODICHLOROMETHANE (BDCM) IN HUMAN VOLUNTEERS.

J. L. Valentine[1], R. A. Pegram[1], J. D. Prah[1], M. W. Case[1], D. L. Ashley[2], M. V. Evans[1] and V. Benignus[1]. [1]*USEPA, NHEERL, Research Triangle Park, NC and* [2]*Centers for Disease Control and Prevention, NCEH/EHLS, Atlanta, GA.*

Bromodichloromethane (BDCM) is a disinfection by-product commonly found in many U.S. finished water sources after chlorination of water that contains bromide and organic precursors. Routes of significant BDCM exposure include oral ingestion and absorption through the skin during showering and bathing activities. Epidemiological studies suggest a correlation between exposures to chlorinated drinking water and cancers of the urinary bladder and lower intestinal tracts. High-dose BDCM exposures produce tumors in the liver, kidneys and large intestines of rodents. The purpose of this research was to adapt a previously published physiologically based pharmacokinetic (PBPK) model for rats to predict the pharmacokinetics of BDCM in humans. Model compartments included alveolar space, venous and arterial blood, fat, liver, skin, and rapidly and slowly perfused tissues. A dermal absorption component was added to the model, that considered skin surface area exposed and thickness; where the skin mass transfer coefficient was assumed to be similar to chloroform, another trihalomethane. Tissue/blood partition coefficients were assumed to be constant across species. Average human organ volumes and blood flow rates to tissues were obtained from the literature. Metabolic parameters were allometrically scaled from rodents to humans. Healthy male subjects were exposed arm-only to Chapel Hill, NC drinking water that contained BDCM and other constituents. Blood was collected prior to each drinking water exposure and for predetermined time points until 24 hours following initiation of exposure for quantitation of BDCM. The scaled BDCM PBPK model simulations were in good agreement with experimental blood BDCM concentration-time data. Sensitive model parameters included skin permeability, hepatic metabolism, and blood flow to the liver and fat. The PBPK model will be valuable in evaluating target tissue BDCM dosimetry in humans after dermal exposure, and aid in quantitating the carcinogenic risk of BDCM in humans. (This abstract does not reflect official U.S. EPA policy.)

699 PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL FOR DERMAL ABSORPTION OF METHYL *TERTIARY*-BUTYL ETHER.

T. L. Leavens[1], J. D. Pleil[2], M. W. Case[1], D. L. Ashley[3] and J. D. Prah[1]. [1]*NHEERL, USEPA, Chapel Hill, NC,* [2]*NERL, USEPA, Research Triangle Park, NC and* [3]*Center for Disease Control and Prevention, NCEH/EHLS, Atlanta, GA.*

Dermal exposure to the oxygenated fuel additive methyl tertiary-butyl ether (MTBE) occurs from contact with contaminated groundwater sources during daily activities such as bathing and showering. The purpose of this research was to develop a physiologically based pharmacokinetic model for dermal absorption of MTBE. Compartments in the model included alveolar space, arterial and venous blood, brain, fat, gastrointestinal tract, kidney, liver, rapidly perfused tissues, skin, and slowly perfused tissues. Metabolism of MTBE to tertiary butyl alcohol (TBA) was assumed to occur only in the liver, and elimination was assumed to occur via exhalation of MTBE and TBA and urinary elimination of TBA. Absorption of MTBE through skin was described by well-stirred compartments for exposure media, skin, and blood that perfused the skin, with equilibrium between the media and skin compartments and the skin and blood compartments. Predictions from the model were compared with data on blood and exhaled breath concentrations of MTBE and TBA in male subjects whose arms were submerged in water containing MTBE for one hour. The model overpredicted the absorption of MTBE from water into blood, shown by predictions of a more rapid increase in blood concentrations and higher peak concentrations of MTBE than experimentally observed values. The parameters to which the peak blood concentration of MTBE was most sensitive included permeability, thickness, and surface area of skin; blood flow to skin; and alveolar ventilation. In addition the predicted blood concentrations versus time indicated the compartmental model for dermal absorption is not appropriate for MTBE, and a distributed model may more accurately predict dermal absorption of MTBE into the blood. Ultimately the dermal model will be used to predict the relative contributions of various routes of exposure to total body burden of MTBE and TBA in humans exposed environmentally to MTBE. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.)

700 *IN VIVO* PERCUTANEOUS ABSORPTION OF ^{14}C-OCTAMETHYLCYCLOTETRASILOXANE IN FISCHER 344 RATS.

M. L. Jovanovic, J. M. McMahon, D. A. McNett, J. M. Tobin, R. H. Gallavan and K. P. Plotzke. *Dow Corning Coorporation, Midland, MI.*

The percutaneous absorption of neat ^{14}C-octamethylcyclotetrasiloxane (D_4) was evaluated in female Fischer 344 rats when applied topically at 10, 5 and 2 mg/cm^2 of skin. Each dose level was represented by twelve animals (4 rats/group) that were exposed for 1, 6, or 24 hr and two 24 hr controls. An additional 24 hr exposure group (N=4) was added to evaluate disposition of the residual D_4 following a soap and water wash. All rats were exposed in a semi-occluded manner using an aluminum skin depot with charcoal basket for collection of volatilized test material. During exposure, rats were housed in Roth-style metabolism cages to enable collection of urine, feces, and expired air. Rats in the wash group were removed from the cages after 24 hr of exposure, dose sites were washed, charcoal baskets were replaced, and the animals were returned to the cages for continued collection (168 hr) of excreta and expired air. At the termination of exposure or at 168 hr post exposure, blood was collected via cardiac puncture, the charcoal baskets were removed and extracted, skin was washed, tape stripped, excised and solubilized. Remaining carcasses were also solubilized. Radioactivity content in each sample was measured by liquid scintillation counting (LSC). In addition, six jugular vein cannulated females were exposed to the highest dose and blood samples were collected up to 10 hr after exposure. The samples were extracted and analyzed by LSC and GC/MS. Concentrations of D_4 in all blood samples were below limits of quantification. The percent dose absorbed was determined as the amount of radioactivity in expired air, carcasses, excreta, skin and cage rinses. The percent of absorption did not differ across the groups compared by dose levels ($p>0.05$). However, D_4 absorption in the wash group after 168 hr (0.350±0.009%, 0.494±0.015% and 0.513±0.084% dose absorbed at high, medium and low dose, respectively) was significantly lower ($p<0.01$) than that seen after 24 hr of exposure (0.609±0.086%, 0.599±0.056% and 0.756±0.081%, respectively). The percent of applied dose recovered from all the animals was >91%. Funded in part by the Silicones Environmental, Health and Safety Council.

701 *IN VITRO* ABSORPTION OF DECAMETHYLCYCLOPENTASILOXANE (D_5) IN HUMAN SKIN: A COMPARISON TO OCTAMETHYLCYCLOTETRASILOXANE (D_4).

J. M. McMahon, K. P. Plotzke, M. L. Jovanovic, D. A. McNett, R. H. Gallavan and R. G. Meeks. *Dow Corning Corporation, Midland, MI.*

The absorption of ^{14}C-decamethylcyclopentasiloxane (D_5) was evaluated when applied to human skin using a flow-through diffusion cell. Human epidermis was prepared from intact abdominal skin. Skin discs from six donors were mounted in replicate in the flow-through chambers. A physiological receptor fluid was pumped underneath the skin samples for 24 hr and collected in a fraction collector. Barrier integrity of the skin was initially screened with ^3H-H_2O. Skin samples were evaluated on two separate days. On day one, skin samples from each of the three donors were dosed with neat D_5 and three were dosed with a generic anti-perspirant formulation containing D_5. On day two, new skin samples from the same six donors were dosed with the opposite test material. Immediately after dosing, charcoal baskets were placed above the skin and secured into a custom designed cap to capture volatilized material. At the end of 24 hr, the charcoal baskets were removed and extracted, skin was washed and solubilized, and the receptor fluid was collected. The radioactivity content in each sample was measured by liquid scintillation counting. The percent dose absorbed was determined as the amount of radioactivity in the receptor fluid combined with the amount remained in the skin after washing. This was compared with another siloxane octamethylcyclotetrasiloxane (D_4) which was evaluated under a similar protocol and reported previously. Data analysis indicated that 0.04±0.01% and 0.50±0.07% of the applied dose of neat D_5 and D_4, respectively was absorbed at the end of the assay and that this was not significantly different from that seen with formulated D_5 or D_4 (0.02±0.01% and 0.49±0.18%, respectively). The percent of applied dose recovered from all analyzed samples for neat D_5 and D_4 was >91%, and for D_5 and D_4 formulated in an antiperspirant was >98%. (Funded in part by the Silicones Environmental, Health and Safety Council.)

702 PARTICLE PENETRATION OF THE SKIN AS A ROUTE OF SENSITIZATION IN OCCUPATIONAL LUNG DISEASE.

S. S. Tinkle[1], J. M. Antonini[1], B. A. Abrigo[1], E. J. Adkins[2] and J. R. Roberts[1]. [1]*CDC/NIOSH, Morgantown, WV and* [2]*West Virginia University, Morgantown, WV.*

Chronic Beryllium Disease (CBD) is an occupationally-acquired lung disease that begins as a cell-mediated immune response to beryllium particulates that, over time, results in development of non-caseating granulomas. During the last ten years, the beryllium industry has made major improvements in respiratory protection and engineering control technology design, however, the rate of disease has not declined. We hypothesized that dermal exposure to beryllium particulates, coupled with joint motion, as at the wrist, would provide an alternative route for sensitization to beryllium. To test this hypothesis, 400 - 600 micron thick sections of human skin (n = 8) were applied to a flexing device with surgical glue. The integrity of the stratum corneum was verified with the NOVA DPM, and 100 µl of 0.5, 1 or 4 micron FITC-conjugated dextran beads were applied to the surface of the skin. The skin was subjected to repeated 30 degree flexure for 0, 15, 30 or 60 minutes. Control tissues were not flexed. Following treatment, tissues were fixed, cut in 20 micron thick sections, and mounted on slides in cross-section. Penetration of beads into the skin was evaluated at 1 micron intervals by laser scanning confocal microscopy. To verify that bead penetration occurred through the stratum corneum, we evaluated data between 5 and 15 microns only. We documented 0.5 and 1 micron bead penetration into the epidermis and the dermis in flexed samples, but not non-flexed tissues. Although not quantitative, only a very small percentage of beads was observed in the skin, and there was no clear time-dependence associated with penetration. Four micron beads did not penetrate the skin These data suggest that particle penetration of the skin is a potential route of exposure in dusty work environments.

703 PERCUTANEOUS ABSORPTION AND METABOLISM OF 7-(2H-NAPHTHO[1,2-D] TRIAZOL-2-YL)-3-PHENYLCOUMARIN IN HUMAN SKIN.

J. Yourick[1], M. Koenig[2], D. Yourick[2], H. Matthews[3] and R. Bronaugh[1]. [1]*USFDA, Office of Cosmetics and Colors, Laurel, MD,* [2]*WRAIR, Division of Neurosciences, Washington, DC and* [3]*NIEHS, Research Triangle Park, NC.*

The fluorescent brightening agent, 7-(2H-naphtho[1,2-d]triazol-2-yl)-3-phenylcoumarin (7NTPC), is a compound of moderately high production level (1 million pounds per year) that is used in several different industrial applications. Little toxicity data exist for 7NTPC and given the potential for occupational exposure, skin absorption and metabolism studies of 7NTPC were initiated in human skin. Confocal laser cytometry was used to visualize 7NTPC absorption across a section of human skin. Absorption was measured over 24 hr by using flow-through diffusion cells. The percent of total (receptor fluid + skin) applied dose absorbed was 16.2±2.08 for 10µg/cm²; and 5.4±0.40 for 50µg/cm². 7NTPC remaining in the skin after 24 hr was 14.7±1.67 percent of the applied dose absorbed for 10µg/cm²; and 5.1±0.41 for 50µg/cm². The upper stratum corneum (SC) was stripped with tape at the end of the study. Skin content was not reduced and indicates that 7NTPC remaining in skin was not on or near the skin surface. 7NTPC metabolism in skin was examined by HPLC, but no metabolites were found. Confocal laser cytometry revealed that fluorescence due to 7NTPC was present across the skin section in the SC, epidermis, and dermis. An intense fluorescence (a high concentration of 7NTPC) was associated with a section of a hair follicle present in the dermis. The majority of absorbed 7NTPC remains in the skin after 24 hr. Fluorescence studies show that 7NTPC diffuses from the SC down to the dermis to be absorbed. 7NTPC is a lipophilic chemical that probably forms a skin reservoir resulting in slow diffusion through skin. (Supported by Interagency Agreement No. Y1-ES-8056-01with NIEHS.)

704 PERCUTANEOUS ABSORPTION AND METABOLISM OF THE SELF-TANNING AGENT DIHYROXYACETONE IN HUMAN SKIN.

R. L. Bronaugh[1], H. B. Matthews[2] and J. J. Yourick[1]. [1]*Office of Cosmetics and Colors, USFDA, Laurel, MD and* [2]*NIEHS, Research Triangle Park, NC.*

The self-tanning agent which colors skin, dihydroxyacetone (DHA), is being increasingly used by the public because of the growing awareness about the dangers of sun exposure. Due to a lack of DHA absorption studies, we initiated skin absorption and metabolism studies of DHA in viable human skin. Absorption was measured over 24 hr by using flow-through diffusion cells. The percent of total (receptor fluid + skin) applied dose absorbed was 23.9±10.6 for 2.5% DHA in water; 21.7±9.9 for 5% DHA in water; and 22.3±5.7 for 5% DHA in an emulsion. DHA diffusing through the skin and into the receptor fluid was approximately 0.5% of the applied dose for both the water and emulsion dosing vehicles. The absorption of DHA into the receptor fluid was relatively slow with about 0.1% of the applied dose absorbed during each 6-hr collection fraction. Stratum corneum (SC) stripped with tape at the end of the study revealed that approximately 5% of the applied dose was found in each of the first five and the second five tape strips. No matter whether DHA was applied to skin in water or the emulsion, approximately 12% of the applied DHA dose was found in the viable epidermis and dermis. DHA metabolism in skin was examined by HPLC, but no metabolites were found. The majority of absorbed DHA remains in the skin after 24 hr. Preliminary covalent binding studies indicate that about 5% of the radioactivity found in the skin after 24 hr is covalently bound to protein. We conclude that even though DHA absorption is over 20%, little of the DHA passes through skin. (Supported by Interagency Agreement No. Y1-ES-8056-01 with NIEHS.)

705 COMPARATIVE *IN VITRO* PERCUTANEOUS ABSORPTION OF NONYLPHENOL AND NONYLPHENOL ETHOXYLATES (NPE-4 AND NPE-9) THROUGH HUMAN, PORCINE AND RAT SKIN.

J. D. Brooks[1], N. A. Monteiro-Riviere[1], G. Simon[2], R. L. Joiner[3], J. P. Van Miller[4] and J. E. Riviere[1]. [1]*Center for Cutaneous Toxicology and Residue Pharmacology, North Carolina State University, Raleigh, NC,* [2]*Rhodia, Inc., Raleigh, NC,* [3]*General Electric Corporation, Pittsfield, MA and* [4]*Union Carbide Corporation, Danbury, CT.*

The purpose of this study was to assess the percutaneous absorption of 14C ring-labeled nonylphenol (NP) and the nonylphenol ethoxylates NPE-4 and NPE-9 in human, porcine and rat skin. In vitro studies were conducted for 8 hr in flow-through diffusion cells using topical solutions of 0.1, 1.0 and 10% in PEG-400 or 1% in water (NPE-9 only). NP absorption was assessed as a 1% solution in PEG-400. Perfusate fluxes over time and skin deposition at the end of perfusion was assessed. Absorption of NPE-4, NPE-9 and NP was similar across all species at less than 1% of the applied dose over 8 hr. Penetration (absorption + skin deposition) was generally below 5% of applied dose, the majority located in the stratum corneum. In all species and for both NPEs, the fraction of dose absorbed was highest for the lowest applied dose. Absorption expressed as actual mass absorbed over 8 hr was similar (approximately 0.3 mg/cm2) across all concentrations. Penetration, but not absorption, was

greater from a water vehicle compared to PEG-400, particularly in rat skin. These studies suggest that NP, NPE-4 and NPE-9 were minimally absorbed across skin from all three species. (Supported by the Alkylphenols and Ethoxylates Research Council.)

706 MIXTURE COMPONENT EFFECTS ON THE PERCUTANEOUS ABSORPTION OF TCB, PCB, AND PCP.

J. R. Pirone[1], R. E. Baynes[1], M. Mumtaz[2], G. L. Qiao[3] and J. E. Riviere[1]. [1]*Center for Cutaneous Toxicology and Residue Pharmacology, North Carolina State University, Raleigh, NC.* [2]*Agency for Toxic Substances and Disease Registry (ATSDR), Atlanta, GA and* [3]*EAB/HELD, National Institute for Occupational Safety and Health (NIOSH), Morgantown, WV.*

Interactions between chemicals in a mixture and interactions of mixture components with the skin, can significantly alter the rate and extent of percutaneous absorption, as well as the cutaneous diposition of a xenobiotic. The predictive ability of dermal absorption models, and consequently, the dermal risk assessment process would be greatly improved through the elucidation and characterization of these interactions. As a first step, the effects of several generalized mixture components on the percutaneous absorption of 3,3',4,4',5-pentachloro biphenyl(PCB), 3,3',4,4'-tetrachloro biphenyl (3,3',4,4'-TCB), and pentachlorophenol (PCP) were examined using isolated perfused porcine skin flap (IPPSF) and porcine skin flow through (PSFT) diffusion cell systems. Mixtures containing combinations of the surfactant sodium lauryl sulfate (SLS), the vasodilator methyl nicotinate (MNA), ethanol, and water were studied. With all mixtures studied, PCB, and TCB absorption was negligible (~0.1% of the applied dose) as quantified using both radiolabel and an HPLC method. In contrast, the absorption of PCP occurred to a much greater extent (~14% of the applied dose), and showed significant mixture effects. Not only was the magnitude of PCP absorption altered, but the absorption profiles, and the disposition within the stratum corneum, dermis, epidermis, and subcutaneous fat were highly dependent on mixture components. The contrast of the results obtained for PCB and PCP, illustrate an area of interaction between the structural and chemical parameters that dictate the amount of chemical absorbed into the systemic circulation. (Supported by ATSDR U61/ATU484504.)

707 APPLICATION OF A HUMAN SKIN TISSUE CULTURE MODEL IN DERMAL ABSORPTION STUDIES OF 3,3',4,4'-TETRACHLOROBIPHENYL (TCB).

G. L. Qiao[1] and J. E. Riviere[2]. [1]*National Institute for Occupational Safety and Health, Morgantown, WV and* [2]*North Carolina State University, Raleigh, NC.*

TCB, one of the dioxin-like PCBs, demands much research and regulatory attention. To evaluate an *in vitro* generated human skin tissue culture model, cutaneous disposition of TCB under different exposure scenarios was investigated. Occlusive or non-occlusive doses of ^{14}C-TCB were applied at 4 or 40 μg/cm^2 in different vehicles including acetone, methylene chloride, a water-acetone mixture, and a soil-based mixture in flow-through diffusion cell studies (n=6~7/exposure condition). Significant exposure-dependent dermal absorption and disposition were observed. *In vitro* 8-hr absorption varied from 0.04% to 1.46% depending on vehicle, dosage, and occlusion. Much more TCB was absorbed into perfusate from soil than from liquid (organic or water-organic mixture) vehicles although the total penetration amount was less. Surprisingly, TCB dermal absorption/penetration ratios, which can reflect dermal absorption efficiency, were decreased by occlusion (soil dose, 0.45→0.13) or by adding water to the acetone vehicle (0.06→0.02). A lower (1/10) TCB dose in soil or in acetone showed a 3-5X higher fractional dose absorption, but a lower (1/3~1/2) transdermal flux (μg/cm^2/hr), than the higher dose in each vehicle. In conclusion, this human skin tissue culture model showed similar dermal absorption and disposition characteristics for TCB when compared to an *in vitro* porcine skin model. Dermal absorption data from liquid TCB doses might underestimate the risk of TCB from contaminated soil. Such observed exposure-dependent dermal disposition profiles need to be considered while assessing TCB dermal risk. (Supported by EPA-CR 824007.)

708 CHEMOMORPHIC ANALYSIS OF MALATHION IN SKIN LAYERS: IMPLICATIONS FOR THE USE OF DERMATOPHARMACOKINETIC (DPK) TAPE STRIPPING IN EXPOSURE ASSESSMENT TO PESTICIDES.

C. C. Dary[1] and M. A. Saleh[2]. [1]*USEPA, Las Vegas, NV and* [2]*Texas Southern University, Houston, TX.*

The dermatopharmacokinetic (DPK) method of dermal tape stripping may prove to be a valuable addition to risk assessment protocols for toxic substances. To examine this possibility, the dermal penetration and absorption characteristics of [^{14}C]-malathion in the Sprague-Dawley rat was examined by three analytical techniques. [^{14}C]-malathion was applied in different vehicles for 30-minute and one-hour periods of exposure. Penetration into the stratum corneum (SC) was assessed by tape stripping followed by Instant Electronic Autoradiography (IEA). Also, the [^{14}C]-activity retained in three successive 16μm sections of the skin application site was determined by IEA and malathion was identified by Fourier Transform Infrared Microscopy (FTIR microscopy). Absorbed [^{14}C]-malathion was measured in selected tissues, organs, and the residual carcass by Liquid Scintillation Counting (LSC). Penetration into the SC followed a linear trend. The capacity of the SC reservoir for malathion amounted to approximately 1% of the dermal dose, while approximately 6% of the dose was absorbed. Results from this study support the view that LSC remains the method of choice to efficiently and reliably quantify absorption of a radiolabelled test substance. IEA offers the ability of the user to visualize the extent and profile of dermal absorption. When IEA is combined with FTIR microscopy, an effectual tool for studying the penetration of chemicals into layers of the skin emerges. The combined use of the three analytical techniques can be used to test the validity of the DPK method in hazard evaluation and exposure assessment of the organophosphorus insecticides. The U.S. Environmental Protection Agency (EPA), through its Office of Research and Development, participated in this research and approved this abstract as a basis for an oral presentation. The actual presentation has not been peer reviewed by the EPA.

709 ASSESSMENT OF SKIN ABSORPTION AND PENETRATION OF JP-8 JET FUEL AND ITS COMPONENTS.

J. McDougal[1], W. Weisman[2], D. Pollard[3], C. Garrett[1], R. Davis[2] and T. Miller[2]. [1]*Geo-Centers, Inc., Dayton, OH,* [2]*AFRL/HEST, Wright-Patterson AFB, OH and* [3]*ManTech Environmental Inc., Dayton, OH.*

The dermal pharmacokinetics of jet fuels in general and JP-8 in particular is not well understood, even though the use by government and industry, worldwide, is over 59 billion gallons per year. JP-8, which is similar to kerosene, is composed of hundreds of hydrocarbon chemicals and their isomers. Exposures to JP-8 can occur from vapor, liquid or aerosol. Inhalation and dermal are the most prevalent routes of exposure. JP-8 may cause irritation when the skin is exposed repeatedly or for prolonged periods. The purpose of this investigation was to measure JP-8 and its major constituents in rodent skin and the flux through rodent skin to assess the potential for toxic effects with human exposures. Static diffusion cells containing dermatomed rodent skin were used in these 4-hour experiments. The absorption time course for six individual components (all aliphatic) of JP-8 was determined in the skin. All components appeared to be at a maximum by four hours. The chemical with the highest concentration in the skin was undecane (0.27 μg/mg skin) and the chemical with the lowest concentration was tetradecane (0.05 μg/mg skin). The penetration time course of thirteen individual components was determined from the receptor solution. The flux from this JP-8 fuel ranged from a high of 82.4 nanograms/cm^2/hr (the additive DIEGME) to a low of 0.5 nanograms/cm^2/hr (tridecane). The concentrations of chemicals in the skin suggest that it may be possible to determine which components are responsible for irritation. The fluxes suggest that JP-8 penetration through the skin will not cause systemic toxicity because fluxes are too low to cause significant body burden. (Supported by AFOSR 92HE05COR.)

710 CORRELATION APPROACHES FOR ESTIMATING SKIN PERMEABILITY OF HYDROCARBON COMPONENTS OF JP-8.

P. Robinson[1] and J. McDougal[2]. [1]*ManTech Environmental Inc., Dayton, OH and* [2]*Geo-Centers, Inc., Dayton, OH.*

The jet fuel, JP-8, consists of a complex mixture of hundreds of components. Component classes include straight chain alkanes, branched chain alkanes, cycloalkanes, diaromatics, n-alkanes and napthalenes. In a series of *in vitro* dermal penetration experiments using rat skin, dermal penetration coefficients

K_p (cm/h) were measured for the 13 most rapidly penetrating components. Several correlation approaches for predicting K_p for chemicals in water are found in the literature, based on molecular weight MW and the octanol/water partition coefficient $K_{o/w}$. Application of this approach for hydrocarbon components in JP-8 gave the following equation: Log K_p = -5.47 - 0.365 log $K_{o/w}$ + 0.00343 MW. The correlation coefficient (R^2) for this relationship is 0.876, which is higher than most of the published correlation approaches. (This value is further increased to 0.919 if the additive diethylene glycol is also included). Penetration into the skin was inversely related to log $K_{o/w}$, suggesting that the JP-8 vehicle is an even more lipophilic environment than the stratum corneum (insofar as it is adequately represented by octanol). In contrast to our study, correlations from studies in which water is the vehicle characteristically show a positive impact of $K_{o/w}$ and a negative impact of the molecular weight on the permeability coefficient. Since JP-8 is more lipid-like than the skin, as $K_{o/w}$ goes up the chemical would have a greater tendency to stay in the lipid vehicle and in the lipid layers of the skin, primarily stratum corneum, and not enter the receptor solution. Consistent with this, the log octanol/water partition coefficient has a much larger impact on the permeability than the molecular weight. Indeed, statistically log K_p alone appears to account for the variability in log K_p. Thus, for such lipophilic compounds, penetration through the skin is in this case likely limited by partitioning out of the lipid phase into the aqueous layers of the skin (and not by a molecular weight-dependent diffusion process). (Supported by AFOSR 92HE05COR.)

711 INFLUENCE OF JET FUEL MIXTURES ON DERMAL ABSORPTION OF AROMATIC AND ALIPHATIC COMPONENTS.

R. E. Baynes, J. D. Brooks, A. R. Abdullahi, R. Wilkes and J. E. Riviere. *Center for Cutaneous Toxicology and Residue Pharmacology, North Carolina State University, Raleigh, NC.*

Jet fuels are formulated with numerous aliphatic and aromatic components and performance additives. Jet fuel formulations can cause dermal irritation, but dermal absorption of these components in a jet fuel mixture is unknown. The purpose of this study is to evaluate the physicochemical properties of these mixtures in context of how they influence the absorption and permeability of an aromatic (14C-naphthalene) and aliphatic (3H-dodecane) marker in porcine skin and silastic membranes. In these 5-hour *in vitro* flow-through studies, JetA, JP-8, and JP-8(100) fuels, JP-8 evaporated (JP-8(puddle)), and JetA+DIEGME, JetA+8Q21, and JetA+Stadis450 were tested. These 3 additives are formulated with JetA to form JP-8. Naphthalene absorption (1.29 - 2.39%dose) was greater than dodecane absorption (0.1 - 0.28%dose). Stadis450 and JP-8(puddle) increased dodecane absorption, while DIEGME increased naphthalene absorption as well as diffusivity from JetA. These latter effects were not observed in silastic membranes suggesting that these interactions may involve the lipid pathway in skin. More dodecane was deposited in the stratum corneum (4.2 - 7.7%dose) at 5 hours than naphthalene (1.4 - 4.1%dose) and the 3 jet fuel additives enhanced deposition of naphthalene and not dodecane in JetA. These studies suggest that absorption and deposition of aromatic, aliphatic and jet fuel components can be influenced by specific performance additives and these interactions may be related to the unique chemistry of these components. (Supported by USAFOSR#FQ8671-98.)

712 CUTANEOUS IRRITATION OF TOPICALLY APPLIED JET FUELS IN THE PIG.

N. A. Monteiro-Riviere, A. O. Inman, B. N. Rhyne and J. E. Riviere. *Center for Cutaneous Toxicology and Residue Pharmacology, North Carolina State University, Raleigh, NC.*

Occupational exposure to jet fuel has recently become a source of concern. This study investigates the cutaneous exposure of 3 fuels by quantitating erythema, edema, transepidermal water loss (TEWL), and epidermal thickness of exposed pig skin. Yorkshire pigs were exposed to Jet A, JP8, and JP8-100 under occluded (Hill Top chamber or cotton fabric) and nonoccluded conditions for 5 hr, 24 hr, and 5 days. In the fabric sites, slight erythema was present within 5 hr, with moderate erythema present after 5 days. No erythema was noted in Hill Top sites after 5 days. Slight edema was observed in the fabric sites at 5 days. An increase in change in TEWL (DTEWL) was present in 5 day fabric sites, 24 hr and 5 day fabric-associated open sites, 24 hr and 5 day Hill Top sites, and 5 hr and 24 hr Hill Top-associated open sites. In general the mean DTEWL of the fabric and Hill Top sites was lower than the associated open sites. Epidermal thickness was greater in fabric than in open sites with little difference between the 5 day Hill Top and open sites. The epidermal peg thickness increased at 24 hr and 5 days with Jet A, JP8, and JP8-100 in the fabric sites. At 5 days the peg thickness was greater in the fabric than the Hill Top sites. In conclusion, the fabric treated with fuel caused the greatest increase in cutaneous erythema and epidermal thickness. (Supported by USAFOSR FQ8671.)

713 CYTOKINE RELEASE FROM KERATINOCYTES EXPOSED TO JET A, JP-8, AND JP8-100 JET FUELS.

D. G. Allen, N. A. Monteiro-Riviere and J. E. Riviere. *Center for Cutaneous Toxicology and Residue Pharmacology, North Carolina State University, Raleigh, NC.*

The toxicity of jet fuels has primarily centered on damage due to pulmonary exposure. Airway inflammation, immune disfunction, and memory disturbances are among the adverse effects associated with aerosolized fuels. However, there are few studies that have focused on the dermatotoxicity of jet fuels. These studies, primarily involving skin painting with middle distillates such as kerosene, have shown that they cause edema, erythema, blisters, and burning sensations indicative of a severe inflammatory response. With the recent advances in fuel mixtures that include an expanding number of compounds, increased concern is being given to the potential dermatotoxicology of jet fuels. The purpose of this study was to identify biomarkers of inflammation in normal human epidermal keratinocytes (NHEK) exposed to three jet fuel mixtures, Jet A, JP8, and JP8-100. Using an enzyme-linked immunosorbent assay (ELISA), NHEK were found to release the pro-inflammatory cytokines TNF-α and IL-8 in response to exposure to all three jet fuels within 8 hr and continuing to rise through 24 hr compared to controls. mRNA for both cytokines was also transcribed throughout exposure to the fuels which was detected via a quantitative reverse transcriptase polymerase chain reaction (RT-PCR) method as early as 15 min following exposure. These results demonstrate that jet fuels induce the production and release of proinflammatory cytokines in NHEK, and thus create the potential for chronic inflammation which may contribute to the development or progression of disease states in the skin. (Supported by USAFOSR FQ 8671.)

714 CUTANEOUS ENZYME HISTOCHEMISTRY OF TOPICALLY APPLIED JET FUELS IN THE PIG.

B. N. Rhyne, J. E. Riviere and N. A. Monteiro-Riviere. *Center for Cutaneous Toxicology and Residue Pharmacology, North Carolina State University, Raleigh, NC.*

The purpose of this study was to assess cutaneous enzyme activity in response to topical jet fuel exposure using enzyme histochemistry for alkaline phosphatase (ALK), acid phosphatase (ACP), and non-specific esterase (NSE) in the skin of pigs. Yorkshire pigs were exposed to Jet A, JP8, and JP8-100 for 5 hr, 24 hr, and 5 days under occluded fabric (335 ml), occluded Hill Top chamber (25 ml) and nonoccluded (25ml) conditions. The stratum basale layer (SB) showed a jet fuel treatment response and overall increase in ALK activity in the 5 day fabric sites. The SB layer had the greatest ACP staining in the 5 day Hill Top sites. With NSE, no differences were noted in the SB layer. In the stratum spinosum (SS) layer, ALK staining was the greatest in the 5 day fabric and 5 day Hill Top sites. Staining of ACP in the SS layer was highest in the 5 day Hill Top. NSE stained greatest in the 5 day fabric sites of the SS layer. In the stratum granulosum (SG) layer, the ALK staining was greatest at 24 hr in both the fabric and Hill Top sites. No differences were noted in the ACP of the SG layer. The intensity of NSE in the SG layer was greatest in the 5 day exposure fabric sites. In conclusion, the 5 day jet fuel treatments generally showed an increase in ALK, ACP, and NSE activity within each layer in response to JetA, JP8, and JP8-100. (Supported by USAFOSR FQ8671.)

715 USE OF METHYL SALICYLATE AS A SIMULANT TO PREDICT THE PERCUTANEOUS ABSORPTION OF SULFUR MUSTARD.

J. E. Riviere[1], C. E. Smith[2], K. Budsaba[3], J. D. Brooks[1], E. J. Olajos[3], H. Salem[3] and N. A. Monteiro-Riviere[1]. [1]*Center for Cutaneous Toxicology and Residue Pharmacology, North Carolina State University, Raleigh, NC,* [2]*Department of Statistics, North Carolina State University, Raleigh, NC and* [3]*U.S. Army Chemical and Biological Defense Command, Aberdeen Proving Ground, MD.*

Exposure to chemical vesicants such as sulfur mustard (HD) continue to be a threat to military forces which requires that protectant strategies to exposure

be evaluated. Methyl salicylate (MS) has historically been the simulant of choice to assess HD exposure. The purpose of this study was to compare the percutaneous absorption and skin deposition of MS to HD in the isolated perfused porcine skin flap (IPPSF). HD data were obtained from a previously published study in this model (Toxicol. Appl. Pharmacol 135: 25-34, 1995). 400 mg/cm 2 of 14C-MS or 14C-HD in ethanol were topically applied to 16 IPPSFs and experiments terminated at 2 hrs, 4 hrs or 8 hrs. Perfusate was collected at increasing time intervals throughout perfusion. Radioactivity was determined in perfusate and skin samples. Perfusate flux profiles were fitted to a bi-exponential model Y(t)=A (e-bt - e-dt) and AUC, peak flux and time to peak flux were determined. HD had more pronounced and rapid initial flux parameters ($p<0.05$). AUC determined from observed and model-predicted parameters were not statistically different, although mean HD AUC was 40 to 50% greater than MS. HD skin and fat levels were up to twice those seen with MS, but had lower stratum corneum and residual skin surface concentrations ($p<0.05$). Compared to other chemicals studied in this model, HD and MS cutaneous disposition were very similar, supporting the use of MS as a dermal simulant for HD exposure. (Supported by USACBDC #DAAD13-98-D-0014.)

716 EFFECTS OF LOW DOSE SULFUR MUSTARD ON GROWTH AND DNA DAMAGE IN HUMAN CELLS IN CULTURE.

W. J. Smith, B. S. Toliver, E. W. Nealley, J. J. Guzman and C. L. Gross. *US Army Med. Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.* Sponsor: A. A. Brimfield.

Sulfur mustard (HD) is a potent cytotoxic chemical agent with vesicating (blistering) properties when applied to the skin of humans. Development of medical countermeasures to protect individuals from injury following attack by this chemical warfare weapon requires an understanding of the mechanisms by which the pathology is generated. DNA is believed to be a major macromolecular target of HD in the epidermis. Using human epidermal keratinocytes (HEK) and human lymphocytes (PBL) in culture, we evaluated the effects of HD on DNA as assessed by the comet single cell electrophoresis assay. In addition we evaluated survival and growth through the measurement of viable cell number, metabolic fluorescence of alamar blue and membrane integrity assessment by calcein-AM at various times after exposure to low doses (0.01-5.0 μM) of HD. At 5 μM HD growth of HEK is retarded for 72 hours but then returns to control levels. Below 5 μM no inhibition of growth is detected. At 5 μM HD cross-links formed in PBL DNA inhibit the expression of H_2O_2 induced single strand breaks in the comet assay. Below 5 μM inhibition of single strand breaks is not observed. Most research with mustard toxicity is conducted at significantly higher dose ranges, around 100 μM, because these are believed to be equivalent to the vesicating doses on skin. At those high doses it is difficult to assess the genotoxicity or growth potential of HEK exposed to HD *in vitro*. These studies suggest that cells can be exposed to a concentration of HD (1-5 μM) that should generate significant DNA damage and survive the insult. Understanding the biochemical effects at this level may lead to medical countermeasures against the higher, injurious levels seen in battlefield conditions.

717 NEW INFORMATION DEBUNKS BLEACH FOR PATIENT DECONTAMINATION IN CHEMICAL/BIOLOGICAL WARFARE INCIDENTS.

T. Garland. *Texas Engineering Extension Service & College of Veterinary Medicine, Texas A&M University, College Station, TX.* Sponsor: J. W. Spoo.

Threats of chemical and biological warfare and terrorism have spawned several national research and management initiatives, and the U.S. government is spending millions of dollars to educate first responders and cities on dealing with these critical issues. The United States is a recent arrival to this lethal field, as personnel in Israel, the Middle Eastern countries and the European Union have long been versed in prevention and treatment injuries and illnesses caused by these agents. However, there is a history of research conducted on these issues in the United States. The majority of this research was performed by, or for, the military, and most of it was classified and therefore unavailable to scientists, medical care givers, and emergency first responders. Recently (early 1999) several of these documents were declassified, revealing what appears to be new information. A 1953 study, classified as secret until early 1999, revealed that bleach solutions and slurries of sodium hypochlorite are more harmful to the skin of patients exposed to nerve agents, such as GB (sarin), than is the agent itself, and is less effective than washing with soap and water. This study compared the effectiveness of removal of the agents by bleach solutions, sodium hypochlorite, an ointment M5, and soap and water. This study evaluated the amount of damage to the skin caused by these agents in the presence of each method of decontamination and the subsequent lethality of the agent. Later reports on the topic seem to have been ignored by the military and the scientific community until the declassification of the above study. Additional studies have examined chemical warfare agents other than nerve agents and the effectiveness of various methods of decontamination, skin damage and lethality following the treatments. Bleach solutions, bleach slurries, and sodium hypochlorite may not be the "gold standards" as had been reported for the past forty years. In light of these declassified studies, it appears that first responders, city planners and medical personnel may need to reformulate their thinking, planning and protocols for dealing with these agents.

718 DIPHOTERINE® DECONTAMINATION OF C^{14}-SULFUR MUSTARD CONTAMINATED HUMAN SKIN FRAGMENTS *IN VITRO*.

P. Gerasimo[1], J. Blomet[2], L. Mathieu[2] and A. H. Hall[3]. [1]*Service de Protection Radiologiques des Armees, Ministry of Defense, France.* [2]*Laboratoire Prevor, Moulin de Verville, France and* [3]*Toxicology Consulting and Medical Translating Services, Elk Mountain, WY.*

As about 70% of skin-deposited sulfur mustard is retained in the *stratum corneum*, various decontamination methods were studied *in vitro* on human skin *stratum corneum* fragments. Skin specimens were obtained from patients undergoing elective abdominoplasty who gave written consent after full disclosure. Skin fragments prepared according to a previously described method[1,2] were exposed to C^{14}-labelled sulfur mustard in methylene chloride solution with a specific activity of 1.66 GBq/mmol (CEN SACLAY, Molecules Marques, Gif sur Yvette, France). After a 5 minute exposure, skin fragments were immersed in one of 3 solutions: water+soap; physiologic saline; or Diphoterine® (Laboratoire Prevor, Valmondois, France - an hypertonic, amphoteric chelating agent). Three decontamination protocols were utilized: 3 minutes; 10 minutes; or 3 successive decontaminations of 10 minutes each. Residual decontamination solution radioactivity was measured as previously described[2]. With all 3 decontamination protocols, Diphoterine® resulted in more residual C^{14}-sulfur mustard in the decontamination solution, and this was significantly greater ($p<.05$) as compared to water+soap with either a single 10 minute or 3 successive 10 minute decontaminations. Diphoterine® deserves further study as a skin decontamination solution for sulfur mustard.

719 POST EXPOSURE TREATMENT WITH IODINE PROTECTS AGAINST SULFUR MUSTARD-INDUCED SKIN LESIONS.

U. Wormser[1], B. Brodsky[1], A. Sintov[2] and A. Nyska[3]. [1]*The Hebrew University, Jerusalem, Israel,* [2]*Ben Gurion University of the Negev, Beer Sheva, Israel and* [3]*National Institute of Environmental Health and Sciences, NIH, Research Triangle Park, NC.* Sponsor: E. Hoffer.

Sulfur mustard (SM) is a powerful vesicant employed as a chemical warfare. The currently available antidotes against this blisterogen are of limited use. The present study demonstrates the protective effect of topical iodine preparation as post exposure treatment against SM (1.2mg net liquid) -induced lesions using the fur-covered guinea pig skin model. Iodine treatment 15 min after SM exposure resulted in statistically significant reduction of 48%, 50% and 55% in dermal acute inflammation, hemorrhage and necrosis, respectively, whereas the epidermal healing markers, hyperkerathosis and acanthosis were significantly elevated by 72% and 67%, respectively (skin analyzed 2 days after treatment). These healing parameters are the most reliable histological proof for the effectiveness of iodine. At longer interval of 30 min between SM exposure and iodine treatment there was significant degree of protection albeit to a lesser extent than that observed in the shorter interval. Although the epidermal healing markers were not elevated, the degenerative parameters such as epidermal microblisters and ulceration, and dermal acute inflammation, hemorrhage and necrosis were significantly reduced by 35%, 67%, 43%, 39% and 45%, respectively. At 45 min interval between exposure and treatment there was also certain degree of protection expressed by significant reduction in dermal acute inflammation and necrosis although the epidermal acanthosis and hyperkerathosis were reduced, indicating for low healing potential. At interval of 60 min between exposure and treatment, iodine was less efficient, nevertheless, significant reduction in epidermal microblisters and elevated acanthotic area were observed even at this long interval. Gross pathology analysis showed strong protective effect at intervals of 15 and 30 min and to a lesser extent at 45 and 60 min. The present findings suggest the iodine preparation as a potential antidote against skin lesions induced

by SM. (Supported by USAMRMC Cooperative Agreement No. DAMD17-98-2-8009.)

720 NONINVASIVE DETERMINATION OF SKIN SURFACE ASPARTIC PROTEINASE ACTIVITY IN THE LIVING ANIMAL-EFFECT OF NITROGEN MUSTARD.

B. Brodsky[1], A. Nyska[2], R. Kohen[1], E. Moor[3], A. Eldad[3], R. Gal[4] and U. Wormser[1]. [1]*The Hebrew University, Jerusalem, Israel,* [2]*National Institute of Environmental Health and Sciences, NIH, Research Triangle Park, NC,* [3]*Hadassah University Hospital, Jerusalem, Israel and* [4]*Rabin Medical Center, Petah Tiqva, Israel.* Sponsor: E. Hoffer.

The present research demonstrates a method for *in situ* determination of stratum corneum aspartic proteinase in the living animal. A non-leaky well, containing [^{125}I]S-carboxymethylated insulin B-chain as a substrate, was constructed on the shaved back of anesthetized guinea pigs and rats. The enzymatic activity was determined by measuring the radiolabled trichloroacetic acid soluble material. We show pepstatin-sensitive proteinase activity bound to skin surface indicating the involvement of aspartic proteinase(s) such as cathepsin D and/or E. Aged rats had about 6 fold lower activity than young animal. The proteinase activity was inhibited by the alkylating agent mechlorethamine and by the cosmetic propylene glycol. Similar procedure was carried out with intact human skin pieces obtained from plastic surgeries. This activity was inhibited by anti human cathepsin D antibodies. Cathepsin D was immunohistochemically localized in the corneal and granular layers of the epidermis. Skin surface aspartic proteinase/cathepsin D activity may serve as a marker for skin toxicity or for certain skin disorders leading to new approach in their medical treatments.

721 COMPARISON OF THE EFFECT OF ALLERGEN AND IRRITANT TREATMENT ON PROLIFERATION AND SUBPOPULATION OF THE DRAINING LYMPH NODE CELLS IN MICE AND GUINEA PIGS.

Y. Yoshida, Y. Oyake, H. Sakaguchi, M. Okuda and H. Suzuki. *Kao Corporation, Tochigi, Japan.* Sponsor: J. J. Mertens.

False positive results (Stimulation Index [SI]>3) have been reported for certain irritants in the murine local lymph node assay (LLNA). The purpose of this study was to distinguish allergenic responses from irritant responses using the murine LLNA and the guinea pig lymph node cell proliferation assay (GPLNA, R. Kashima et al., 1994). LLNA was conducted according to the conventional method. The GPLNA employed a single 24-hour occlusive patch, which causes well-defined erythema. Five days after application of occlusive patch, suspensions of superficial dorsal cervical lymph node cells (LNC) were individually prepared and the 3H-TdR incorporation was measured. In addition to LNC proliferative responses, we examined the phenotypic characteristics of LNC both in mice and in guinea pigs. In the LLNA, a maximum non-irritating concentration gave positive results for SLS (5%, SI=4.2) and Tween 80 (5%, SI=5.3). In GPLNA, 0.5% DNCB and 25% aniline gave positive responses. Conversely, negative results were obtained for the irritants (0.3% SLS and 50% Tween 80). Based on these results, the GPLNA was considered a useful method because no false positive results were generated. Phenotypic characterization of the LNC from mice following application of 0.25% DNCB showed a 30% decrease in the percentage of CD4+ cells and a 2.1-fold increase in the percentage of B220+ cells. Small changes in the opposite direction were observed with the irritants. Thus, these allergens and irritants could be distinguished by analyzing phenotypic characteristics of LNC in mice. Phenotypic characterization of the LNC from guinea pigs following 0.5% DNCB application gave similar changes to those observed in mice. These data suggest a possibility that analysis of surface markers may differentiate between allergen and irritant responses in guinea pigs.

722 COMPARISON OF THE GUINEA PIG MAXIMIZATION TEST (GPMT), THE MURINE LOCAL LYMPH NODE ASSAY (LLNA) AND STRUCTURE-ACTIVITY RELATIONSHIP MODELS TO PREDICT THE POTENTIAL OF CHEMICALS TO CAUSE OF ALLERGIC CONTACT DERMATITIS.

I. Fishman, A. R. Cunningham and M. H. Karol. *Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

Allergic contact dermatitis (ACD) is a delayed-type hypersensitivity response of the skin to a chemical. The prevalence of the disease in the general population is about 10%. Traditionally, guinea pigs have been used to test chemicals for their potential to cause ACD. We have developed a structure-activity relationship (SAR) model of ACD based upon the guinea pig data, and more recently have developed a SAR model based exclusively on human data. In the current study, we sought to compare the data from testing of the same chemicals in guinea pigs, humans and mice. We also examined the prediction of ACD activity by both SAR models with the test results reported for the LLNA. Based on 40 chemicals that were common to the LLNA and human ACD test sets, the sensitivity of the LLNA was 0.83, the specificity was 0.27. Comparison of data from the LLNA with that from the GPMT yielded a sensitivity of 0.83 and specificity of 0.57. The SAR model based on human data correctly predicted the activity of 65% of the LLNA-positive chemicals, and 40% of the inactive chemicals. The data are being examined to determine the ability of the models to predict strong, moderate and weak sensitizers as identified by the animal and clinical test results, as well as the ability of each model to identify structural features associated with activity. It is anticipated that such analyses will result in greater understanding of the appropriate use of animal tests and SAR models as well as greater understanding of the mechanism underlying ACD.

723 REGULATION BY VERAPAMIL OF DENDRITIC CELL MIGRATION IN MICE.

M. Cumberbatch, R. J. Dearman and I. Kimber. *AstraZeneca Central Toxicology Laboratory, Macclesfield, United Kingdom.*

It has been reported previously that p-glycoprotein (MDR-1), expressed by human Langerhans cells (LC), regulates the trafficking of LC from the epidermis. Thus, anti-MDR-1 antibodies or verapamil (a drug that antagonizes MDR-1 transport) was found to inhibit the migration of LC from the epidermis in human skin explant cultures. The interpretation was that MDR-1 function is necessary for the secretion by LC of a physiological substrate required for migration. To investigate the contribution of MDR-1 to LC migration *in vivo*, the influence of verapamil on contact allergen- and cytokine-induced dendritic cell (DC) migration in mice has been examined. Groups of mice (BALB/c strain) were exposed on the dorsum of both ears to 1% verapamil dissolved in methanol, or to methanol alone, 2 hours prior to application to the same site of the contact sensitizing chemical oxazolone (Ox; 0.5%). Under these conditions of exposure verapamil was found to inhibit, by approximately 80%, the accumulation of DC in draining lymph nodes measured 18 hours later. In subsequent experiments, the influence of verapamil on LC migration stimulated by intradermal administration of either tumor necrosis factor α (TNF-α) or interleukin 1β (IL-1β) was investigated. Prior exposure of mice to verapamil caused a marked inhibition (85%) of draining lymph node DC accumulation measured 4 hours following TNF-α injection. In contrast, verapamil was without effect on DC migration stimulated by exogenous IL-1β. Since Ox- and TNF-α-induced DC migration in mice are both IL-1β-dependent, it is proposed that one function of MDR-1 is to regulate the secretion by LC of IL-1β.

724 SUBACUTE INTRADERMAL CIS-UROCANIC ACID SUPPRESSES THYMIC CELLULARITY IN TWO STRAINS OF MICE.

M. R. Prater, R. M. Gogal and S. D. Holladay. *Virginia-Maryland Regional College Of Veterinary Medicine, Viginia Tech, Blacksburg, VA.*

Urocanic acid predominates in the strateum corneum of mammals in the trans isomer form. Exposure to ultraviolet light causes isomerization to the cis isomer, which is then partially absorbed systemically. Excessive cis-urocanic acid (cis-UCA) has been suggested to be involved in sunlight-induced local and systemic immunosuppression. In this study, cis-UCA was administered intradermally in two strains of 6 week-old female mice (C3H-HEN and C57Bl/6) for one day, five consecutive days, or three times a week for four weeks. The following parameters were measured 48 hours after administra-

tion of the final dose of cis-UCA as indicators of alterations in immune function: thymic and splenic organ weights, total cellularity and leukocyte cellularity of the thymus and spleen, splenic macrophage phagocytosis, and splenic leukocyte production of hydrogen peroxide (chemiluminescence assay). Significant decreases in thymic leukocyte cellularity were seen in both strains of mice in the four-week dosing regime, supporting previous observations of thymic effects in mice exposed subacutely to cis-UCA. (Supported by NIH RO1-ES 09642-01.)

725 ROLE OF METABOLISM IN ARSENIC-INDUCED CYTOKINE PRODUCTION IN MURINE KERATINOCYTES.

E. Corsini, M. Marinovich and C. L. Galli. *University of Milan, Milan, Italy.*

Inorganic arsenicals are skin carcinogens both in humans and rodents. It has recently been demonstrated that arsenic induces overexpression of keratinocyte-derived growth factors, which are likely to have a significant role in arsenic-induced skin hyperkeratoses and cancer. The mechanism(s) involved in this induction are, however, still elusive as the role of arsenic valence. The purposes of this study were to investigate the early intracellular events that follow *in vitro* treatment with sodium arsenate in a murine keratinocyte cell line (HEL30), which leads to interleukin-1α (IL-1α) production, and second, to characterize the role of the cell metabolism in arsenic toxicity. It has been known for some years that arsenic affects mitochondrial enzymes and impairs tissue respiration. We demonstrated by electron microscopy analysis that arseniate induced a dramatic alteration in keratinocyte mitochondria, that could be prevented by rotenone pretreatment, suggesting the possible involvement of mitochondria-derived reactive oxygen species (ROS). The first intracellular event following the binding of As to mitochondria is reactive oxygen species generation, followed by activation of transcription factors (NF-κB and AP-1), production of IL-1α and proliferation of keratinocytes. In mammals, the biotransformation of arsenic is based on several steps: arsenate species must be reduced to arsenite, through glutathione consumption. Arsenite is sequentially methylated, first to form monomethylarsonic acid and subsequently dimethylarsinic acid (DMA), which are less reactive and are rapidly excreted in urine. In our cells, DMA up to 1mM did not induce IL-1α production, confirming that the methylation of inorganic arsenic is indeed a detoxification mechanism. Regarding the effect of As valency on IL-1α production, we found that As(III) is five times more potent then As(V). However, this is due to a difference in cell uptake between As(III) and As(V), in particular, to a competition of phosphate anions with As(V) uptake. In medium without phosphates, As(V) shows the same potency of As(III). On the contrary the phosphates content does not influence the effect of As(III) on IL-1α production. Glutathione deprivation exacerbates both As(III) and As(V)-induced IL-1α production. Thus, it still remains to be elucitated the role of intracellular reduction of As(V), in order to identify the species responsible for IL-1α neosynthesis. (Acknowledgement: this study was partially supported by a grant from UNIPRO.)

726 QUENCHING OF CITRAL SENSITIZATION DEMONSTRATED IN A HUMAN REPEATED INSULT PATCH TEST.

A. M. Api and D. Isola. *Research Institute for Fragrance Materials, Inc., Hackensack, NJ.*

Quenching is the term used to describe the phenomenon of inhibition of sensitization. Citral is a fragrance ingredient that has a powerful lemon scent. It has been demonstrated that although citral produces sensitization reactions when applied alone, it does not produce any reactions in a human maximization test when combined with d-limonene (Opdyke, 1976). In this study, a solution of 4% citral and 1% d-limonene in diethyl phthalate was tested in a repeated insult patch test with a total of 118 human subjects. The test method was an adaptation of the Draize Patch Test that included an induction phase consisting of nine repetitive 24-hour occluded applications on the same skin site for three weeks. This was followed by a two-week rest period. The challenge phase consisted of a 24-hour occluded application to a naive site. No sensitization reactions were observed. In summary, quenching has been clearly demonstrated for citral with d-limonene in two different human sensitization tests (a human maximization test and a human repeated insult patch test).

727 SKIN PENETRATION BY THE NATURAL RUBBER LATEX PROTEINS, HEVEIN, AND RUBBER ELONGATION FACTOR.

M. D. Howell[1], B. B. Hayes[1], H. Alenius[2] and B. J. Meade[1]. [1]*National Institute for Occupational Safety and Health, West Virginia University, Morgantown, WV, and* [2]*National Institute for Occupational Safety and Health, Helsinki, Finland.*

Differences in IgE antibody patterns have been demonstrated in latex allergic individuals who have undergone multiple surgeries and those with limited surgical exposure to natural rubber latex (NRL). Adult health care workers show a higher prevalence of antibody towards hevein (Hev b 6.02) whereas children requiring multiple surgeries have shown a higher prevalence of recognition of Rubber Elongation Factor (REF, Hev b 1). The mechanisms underlying the differences in protein recognition by these risk groups is presently not known. These studies were designed to examine the extent of dermal penetration of hevein and REF using hairless guinea pig skin in an *in vitro* flow through dermal penetration model. Proteins were radiolabeled with 125-I using a modified chloramine-T method and applied to dermatomed skin sections (250 μm) that were unaltered or abraded via tape stripping to remove the stratum corneum. In comparing the penetration of hevein and REF into intact and abraded skin samples (n=6), no significant differences were observed between the two proteins. For intact skin, 0.34% and 0.57% of the total applied radiolabeled proteins were recovered for hevein and REF, respectively. Dermal abrasion increased the penetration into the skin with 5.22% of hevein and 3.32% of REF being retained. For both hevein and REF, less than 2% of the proteins penetrated through the intact skin while greater than 20% was able to penetrate through abraded skin. Mass balance for all penetration studies was greater than 94%. Immunohistochemistry of skin sections revealed localization of proteins in the stratum corneum of intact samples with more intense staining in the viable layers of the epidermis in abraded samples. Based on the results of these studies, the differences in sera recognition of hevein and REF between HCW and multiple surgery patients does not appear to be related to the ability of the proteins at equal concentrations to penetrate the skin. (These studies were supported in part by the NIOSH/NIEHS interagency agreement #Y02ES10189.)

728 DERMAL AND SYSTEMIC TOLERABILITY OF TOPICALLY APPLIED ISIS 2105, A PHOSPHOROTHIOATE OLIGODEOXYNUCLEOTIDE (PS ODN), IN SPRAGUE-DAWLEY RATS.

R. E. Morgan, K. Lemonidis, A. Chappell and M. V. Templin. *Isis Pharmaceuticals, Inc., Carlsbad, CA.*

A topical formulation has been developed for dermal delivery of antisense ODNs. Local and systemic tolerability has been characterized using ISIS 2105, a representative 20-base P=S ODN, at concentrations of 0.2%, 0.5%, 2.0% and 10% (w/w). Vehicle absent ODN or formulated with ISIS 2105 was applied to the dorsal region of rats and an occlusion barrier placed over application sites for 6 hours per day. Local tolerability of ISIS 2105 was assessed following daily treatments for 14 days. Dermal tolerability was dose (conc)-dependent with moderate erythema and mild ulcerations at 10%; mild erythema and minimal ulcerations at 2.0%; minimal erythema at 0.5%; and no apparent effects at either 0.2% or in vehicle controls. Evidence of immune stimulation, e.g. a mononuclear cell infiltrate at the epidermal/dermal junction, was found at 10% and to a lesser extent at 2.0%. Immunohistochemical localization illustrated deposition of ODN in both dermis and epidermis. Quantitation of ODN in treated skin revealed non-linear, dose-dependent uptake; 5.8, 20.3, 51.1, and 362.0 μg/g in skin treated with 0.2%, 0.5%, 2.0% and 10%, respectively. Metabolism in skin was minimal, with 40% to 90% of total ODN measured as parent compound. Systemic exposure was low and dose-dependent. There was no evidence (hematology, serum chemistry, histology) of systemic toxicity. Most importantly, these studies verify epidermal and dermal uptake of ODN in intact skin. Dermal alterations were dose-dependent and correlated to significant local exposure. Systemic exposure was nominal, consistent with minimal toxicity. This suggests therapeutic dose regimens may be developed for safe/effective topical ODN delivery.

729 DERMAL TOLERABILITY AND IMMUNOSTIMULATORY EFFECTS OF PHOSPHOROTHIOATE OLIGODEOXYNUCLEOTIDES (PS ODN) FOLLOWING INTRAVENOUS, INTRADERMAL AND TOPICAL ADMINISTRATION IN RATS.

J. P. Riley[1], N. V. Soucy[1], P. Davison[2], K. York-Defalco[2], A. de Peyster[1] and M. V. Templin[2]. [1]*San Diego State University, San Diego, CA and* [2]*Isis Pharmaceuticals, Inc., Carlsbad, CA.*

ISIS 12450, ISIS 2105, and ISIS 12449 have low, medium, and high potential for inducing immune stimulation, respectively. The role of immune stimulation in inducing dermal irritation was assessed by comparing responses to these PS ODNs. Doses were given as 10 mg/kg i.v., 10 mg/kg i.d., or in a 10% (w/w) topical formulation. Topical and i.d. doses were given at the dorsal scapular region; dermal tolerability following all three routes was evaluated at this site. Following i.v. dosing, no dermal effects were noted; spleen weights were increased approx. 1.3, 1.6-, and 1.9-fold over control with ISIS 12450, ISIS 2105, and ISIS 12449. ID administration resulted in localized erythema, edema, and focal eschar. Mean severity scores (0 to 5 scale) were 2.0, 2.2, and 3.4 with ISIS 12450, ISIS 2105, and ISIS 12449. For ISIS 2105 and ISIS 12449 a minimal mononuclear cell infiltrate was noted at the epidermal/dermal junction. Spleen weights were increased approx. 1.1-, 1.4-, and 1.7-fold over control. Topical administration resulted in similar dermal alterations as noted above (mean scores 1.6, 2.8, and 3.8); a mononuclear cell infiltrate was noted for ISIS 12450 (minimal), ISIS 2105 (mild), and ISIS 12449 (mild to moderate); splenomegaly was minimal with all three compounds (1.0-, 1.1-, and 1.2-fold over control). Thus, relative potency for inducing immune stimulation correlated to relative potency for inducing dermal alterations. This suggests immune stimulation is likely to be a significant factor in the induction of dermal effects, particularly with routes of administration that provide extensive dermal exposure.

730 IMMUNE MODULATION BY AN ANTISENSE OLIGODEOXYNUCLEOTIDE DESIGNED TO INHIBIT ICAM-1 EXPRESSION.

S. P. Henry[1], K. White[2], M. V. Templin[1] and A. A. Levin[1]. [1]*Isis Pharmaceuticals, Inc., Carlsbad, CA and* [2]*Immunotox, Inc., Richmond, VA.*

ISIS 2302 is a phosphorothioate oligonucleotide designed to inhibit human ICAM-1, and is intended for treatment of inflammatory diseases. Although this compound is able to inhibit inflammation, one of the potential toxicities associated with phosphorothioate oligodeoxynucleotides is immune stimulation. Immunotoxicity studies were performed in mice to fully understand the modulatory capability of ISIS 2302 and a murine analog, ISIS 3082. Effects of ISIS 3082 were limited to decreases in contact hypersensitivity and a 2-way MLR at doses of 1 to 20 mg/kg, consistent with anti-inflammatory properties. There was no other effect on cellular immunity, indicating selective modulation of immune function. These effects were consistent with selective inhibition of ICAM-1 expression. By comparison, immunostimulatory properties of ISIS 2302 were seen at doses ≥ 20 mg/kg. Dose-dependent increase in spleen weight was associated with increased number of B cells at 50 mg/kg. Mitogenic response to LPS was also increased, but there was no increase in total IgM or IgG, and no specific antibody response to the oligonucleotide. Increases in IL-6, IL-12, and MCP-1 were observed at 20 and 50 mg/kg, along with increased NK cell activity. There were no other changes in cellular immune function. Thus, anti-inflammatory activity occurs at doses 5 to 10-fold lower than required for toxicity. Effects on immune suppression or stimulation appear to be limited in mice. Furthermore, monkeys are less sensitive to immune stimulation than mice indicating even greater therapeutic margin. ISIS 2302 has a very low potency for immune stimulation relative to other compounds in this chemical class.

731 RECOVERY OF IMMUNE RESPONSE FOLLOWING ADMINISTRATION OF AN ANTI-CD154 MONOCLONAL ANTIBODY (HU5C8) TO CYNOMOLGUS MONKEYS.

A. Vick[1], C. TenHoor[1], M. Lerner[2], W. Hall[2], M. Butt[2], N. Gillett[3] and D. Frazier[4]. [1]*Biogen, Inc., Cambridge, MA,* [2]*Pathology Associates, Inc., Frederick, MD,* [3]*Sierra Biomedical, Inc., Sparks, NV and* [4]*Pfizer, Inc., Groton, CT.*

Hu5C8 is a humanized monoclonal antibody that binds CD40 ligand (CD154) on activated CD4+ T cells and inhibits its interaction with CD40. Inhibition of the CD40:CD40L interaction has been shown to block the development of specific antibodies, down-regulate the activation of T cells, and interfere with the maintenance of germinal centers (GC) within lymphoid follicles. Studies to examine the toxicity and pharmacologic activity of hu5C8 were conducted in cynomolgus monkeys. Pharmacologic activity was assessed by measuring the immune response to exogenous protein antigens including tetanus toxoid (TT) and Keyhole Limpet Hemocyanin (KLH). A dose-dependent inhibition of primary and secondary immune responses was observed following the administration of hu5C8. Test article-related changes observed at necropsy were limited to GC hypoplasia in the spleen and lymph nodes. The extent of these changes showed a clear dose-dependency and correlated with the extent of immune response following antigen challenge. The duration of treatment had a limited effect on the extent of GC effects. Animals that received similar doses of hu5C8 for 4 or 26 weeks displayed a similar extent of hypoplasia. Functional recovery, defined as the ability to achieve immune responses comparable to untreated animals, was observed in all hu5C8-treated animals. The time-period in which animals achieved functional recovery was dependent on the dose of hu5C8. Recovery at the tissue level was observed in all animals following the demonstration of functional immune recovery.

732 IMMUNOCHEMOTHERAPY ON TUMOR GROWTH AND METASTASIS BY POLYSACCHARIDES ISOLATED FROM *PHELLINUS LINTEUS.*

S. B. Han, H. M. Kim, C. W. Lee and D. H. Hong. *Korea Research Institute of Bioscience and Biotechnology, Taejon, Republic of Korea.*

It was previously reported that polysaccharides (PL) isolated from Phellinus linteus strongly stimulated cell-mediated and humoral immunity. This study was undertaken to investigate the immunochemotherapeutic activity of PL against tumor growth and metastasis. PL alone significantly prolonged the survival rate of B16F10-implanted mice, inhibited tumor growth in NCI-H23-implanted nude mice, and reduced the frequency of pulmonary metastasis of B16F10 melanoma. Adriamycin significantly inhibited tumor growth, but only slightly inhibited metastasis. The combination therapy with PL and adriamycin was more effective in inhibiting tumor growth, but not metastasis. PL did not induce direct toxicity in cancer cells, which is characteristic of immunotherapeutics. In conclusion, PL might be of use in immunochemotherapy of cancer because of its effective activities on tumor growth and metastasis through the immunopotentiation of the patients without toxicity.

733 IMMUNOTOXIC EFFECT OF INORGANIC LEAD (PB) ON HOST-RESISTANCE OF MICE ASSOCIATES WITH MOUSE SIDED-TURNING BEHAVIOR.

D. Kim[1] and D. A. Lawrence[2]. [1]*SUNY at Albany, Albany, NY and* [2]*Wadsworth Center, NYDOH, Albany, NY.*

Differential immune reactivities of mice were associated with behavioral sidedness; mice with left-turning preference had lower *in vivo* humoral and cell-mediated immune responses than mice with right-turning preference. The immune, endocrine, and nervous systems closely interact to maintain homeostasis, which is sensitive to environmental factors. In this study, we have investigated the influence of inorganic lead (Pb) on neuroimmune interactions. Pb reduced host-resistance of BALB/c mice to Listeria monocytogenes infection. Pb increased the susceptibility to Listeria in mice with both left- and right-turning preference; however, Pb did not alter host-resistance of mice with no turning preference. In contrast to mice with no turning preference, the spleens of Pb-exposed mice with turning preference were smaller than those of non-Pb-exposed mice 3 days after infection. The lower host-resistance of Pb-exposed mice with turning preference correlated with elevated serum gamma IFN and IL-6 levels, indicators of disease severity. Although the basal serum gamma IFN levels were lower in all groups after Pb exposure, the relative levels correlated with host-resistance. Reduction of basal serum gamma IFN levels by Pb weakened defense mechanisms early in infection and may inhibit effective proliferation of splenocytes. We suggest that the observed differential susceptibility to Listeria can be reordered by environmental stressors, in that the more resistant right-turners became more susceptible than no preference mice after Pb exposure. The differential effects of Pb based on behavioral differences suggest that neuroimmune circuitry may be involved in the processes described. (Funded by NIH ES03179.)

734 INVESTIGATIONS ON THE IMMUNOSTIMULATING POTENTIAL OF A COMBINATION OF OCTAMETHYLCYCLOTETRA- AND DECAMETHYLCYCLOPENTASILOXANE IN RATS AND MICE.

H. W. Vohr and E. M. Bomhard. *Bayer AG, Wuppertal, Germany.*

Octamethylcyclotetrasiloxane (D4) and decamethylcyclopentasiloxane (D5) are low molecular weight cyclic polydimethylsiloxanes often used in combination e.g. in personal and health care product formulations. Previous studies with D4 did not indicate a suppressing/modulating effect on the immune system of Fischer 344 rats (Munson et al., The Toxicologist 36, 1997, 265). In B6C3F1 female mice subchronic oral exposure to D4 induced suppression of T-dependent humoral immune response (Le and Munson, The Toxicologist 36, 1997, 265). D5 had no immunosuppressing effects on Fischer 344 rats after inhalation exposure to concentrations up to 160 ppm (Burns-Naas et al., Toxicol. Sci. 43, 1998, 28-38). Our investigations aimed to study the combination of D4 (ca. 75%) and D5 (25%) with regard to a potential of an immunostimulating interaction with immunocompetent cells in NMRI mice and Wistar rats. As positive control, 2,4-dinitrofluoro-benzene (DNFB) was used. The D4/D5 mixture (in sesame oil) was injected subcutaneously into the pad of the left paw at doses of 3 and 10 mg/kg body weight (bw). DNFB was likewise administered at dose levels of 0.6 and 2 mg/kg bw. Popliteal lymph nodes were weighed and the cells counted, cells were stained with antibodies to mice and rat T- or B-cell surface markers and analyzed in a fluorescense-activated cell scanner (FACScan). Macrophage analyses was done after stimulation with 4,3-phorbol-12-myristate-13-acetate (PMA). Altogether there was no indication of a test substance specific activation of the cells of the immune system. DNFB, in contrast, led to a specific stimulation of lymphocytes (memory T-cell increase).

735 COMPARED EFFECTS OF MORPHINE AND NICKEL CHLORIDE ON NK CELL ACTIVITY IN RATS AND MONKEYS.

F. Condevaux[1], A. Forichon[1], M. Aujoulat[1] and J. Descotes[2]. [1]*Phoenix International Preclinical Services, L'Arbresle, France and* [2]*Poison Centre & Inserm U503, Lyon, France.*

Natural Killer (NK) cell activity is often recommended as a critical endpoint in the immunotoxicity evaluation of environmental chemicals. However, this assay is usually performed in rodents and rarely in monkeys so that no interspecies comparison of results is available. This study was conducted to compare the effects of *in vitro* exposure to 1, 10 and 100 µg nickel chloride and 0.01 nmol, 1 nmol and 1000 nmol morphine sulfate in rats and monkeys. NK cell activity was measured from ^{51}Cr release by YAC (rats) and K562 (monkeys) cells using three different ratios of target:effector cells, namely 1:25, 1:50 and 1:100. Nickel chloride and morphine sulfate induced a marked decrease in NK cell activity which was statistically significant only at the higher concentration. As a similar trend was noted in both species, these results suggest that similar results can be expected from NK cell measurement during immunotoxicity evaluation in monkeys and in rats. In addition, this assay prove useful for immunotoxicity evaluation of medicinal products.

736 IMMUNE, THYROID, AND HEMATOLOGICAL EVALUATION OF AMMONIUM PERCHLORATE IN B6C3F1 MICE.

D. E. Keil[1], M. Jenny[1], D. A. Warren[2], J. EuDaly[1] and R. Bullard-Dillard[3]. [1]*Medical University of South Carolina, Charleston, SC,* [2]*TERRA, Inc., Tallahassee, FL and* [3]*Claflin College, Orangeburg, SC.*

Studies were undertaken in female B6C3F1 mice to assess thyroid, hematological, and immunological effects of ammonium perchlorate (AP) (0, 0.1, 1.0, 3.0, and 30 mg/kg/day). Several immunological and hematological parameters were not significantly affected after exposure to AP for 14 or 90 days including: total white (WBC) and red blood cell number; hematocrit; hemoglobin; red blood cell indices; bone marrow cellularity and proliferative function; spleen and thymus weight and cellularity; kidney, liver, and body weights; cytotoxic T cell activity; thymic and splenic CD4/8 lymphocyte subpopulations; *in vivo* antibody responses to sheep red blood cells; macrophage nitrite production; and serum autoantibody production. However, an enhanced proliferative response to soluble listerial antigen was observed in a classical delayed type hypersensitivity assay; hypertrophy and/or colloid depletion were observed in thyroid tissue; and serum T4 levels were significantly decreased with no change in T3 or TSH. Decreased phagocytosis function by peritoneal macrophages was detected and this was reversible upon 30-day cessation of AP exposure. Despite decreases in phagocytic function of nearly 50% in some AP treatment groups, host resistance to Listeria monocytogenes challenge (2700 CFU) was normal. Increased natural killer cell activity was also detected but resistance to B16F10 tumor challenge was not correspondingly affected. In light of the normal host responses to tumor and listeria challenges after exposure to AP, it is apparent that the altered immunological, hematological, and thyroid parameters were not sufficient to alter host resistance under these experimental conditions. (This study was funded by the Department of Defense [DSWA01-97-1-0008].)

737 EFFECTS OF N,N,-DIETHYL-M-TOLUAMIDE (DEET) ON IMMUNE FUNCTION PARAMETERS IN B6C3F1 MICE.

G. S. Gilkeson, A. C. Dudley, J. G. EuDaly, M. M. Peden-Adams and D. E. Keil. *Medical University of South Carolina, Charleston, SC.*

It has been suggested that DEET, in combination with a variety of environmental agents relevant to the Gulf War, may have contributed to the manifestations reported by veterans. Since some of the reported symptoms suggest a link to immune dysfunction, it is important to assess the immunological effects of DEET independently and in combination with other environmental agents. To determine the immune effects of DEET exposure singly, adult female B6C3F1 mice were injected subcutaneously for 14 days with DEET only at either 6.25,12.5, 25, or 50 mg/kg. Effects on lymphoproliferation, natural killer cell activity, thymus and spleen weight and cellularity, and thymic and splenic CD4/CD8 lymphocyte subpopulations were assessed 24 hours after the last dose. No effect was observed in lymphoproliferation, natural killer cell activity, thymic weight, splenic weight, thymic cellularity, or splenic cellularity. Significant decreases were, however, observed in the percentage of thymic CD4-/CD8- lymphocytes at the 12.5, 25, and 50 mg/kg treatment levels and in splenic CD4+ lymphocytes at the 50 mg/kg treatment level. These results suggest that DEET alone does not profoundly affect immune function. Future studies in our laboratory will investigate the immunological and autoimmune effects of DEET in combination with other agents to include JP-8 jet fuel, pyridostigmine bromide, and exercise stress.

738 DIETARY IODINE MODULATES AMMONIUM PERCHLORATE INDUCED IMMUNOTOXICITY.

M. Jenny[1], D. E. Keil[1], D. A. Warren[2] and J. EuDaly[1]. [1]*Medical University of South Carolina, Charleston, SC and* [2]*TERRA, Inc., Tallahassee, FL.*

The use of ammonium perchlorate (AP) as an oxidant in solid propellants has resulted in groundwater contamination and the potential for human exposure via ingestion. Previous studies revealed that the administration of 30 mg/kg/day AP in drinking water to adult, female B6C3F1 mice resulted in the enhancement of natural killer cell activity and suppression of serum total T4 levels and phagocytic activity by peritoneal macrophages. Since AP alters thyroid function by competitively inhibiting the trapping mechanism that incorporates free iodine into T3 and T4, it was hypothesized that a reduction in dietary iodine would enhance the effects of AP consumption. AP (0 and 30 mg/kg/day) was administered to two groups of female B6C3F1 mice via drinking water. In addition to AP exposure, mice within each group were fed a diet containing 1.89 ppm or 0.15 ppm of iodine (Tek Lab Sterilizable Rodent Diet, formula no. 8656). After 14 days of AP exposure, the mice fed 1.89 ppm iodine had a 25% reduction in serum total T4 levels but no significant changes in peritoneal macrophage or splenic total cellularity, nitrite production by peritoneal macrophages, or natural killer cell activity. In contrast, mice fed 0.15 ppm iodine had a 50% reduction in total T4 levels, a 50% reduction in peritoneal macrophage cellularity, reduced nitrite production by peritoneal macrophages, and a 2-fold increase in natural killer cell activity. Thyroid hormone and immune parameters in control mice were not affected regardless of iodine diet. These findings suggest that dietary iodine may modulate the toxicity of AP. (This study was funded by MUSC internal research funds.)

739 EXPOSURE TO SODIUM BROMATE IN DRINKING WATER FOR 28 DAYS PRODUCED MINIMAL IMMUNOTOXIC EFFECTS IN FEMALE B6C3F1 MICE.

T. L. Guo[1], J. A. McCay[1], N. A. Karrow[1], G. W. Johnson[1], R. D. Brown[1], D. L. Musgrove[1], D. R. Germolec[2] and K. L. White, Jr.[1]. [1]*Virginia Commonwealth University, Richmond, VA and* [2]*NIEHS, Research Triangle Park, NC.*

Sodium bromate (SBM) is one of the disinfection by-products (DBPs) found

in drinking water. To evaluate the immunotoxic potential of SBM in female B6C3F1 mice, SBM (80-800 mg/l) was administered in the drinking water for 28 days. Exposure to SBM did not produce any signs of overt toxicity; no gross pathological lesions were observed. There were no significant differences in drinking water consumption, body weight, body weight gain, or weights of thymus, liver, kidneys and lung between animals exposed to SBM and controls. However, animals exposed to SBM had a significant increase in absolute (28%) and relative (26%) spleen weights. The erythrocyte count, hemoglobin, hematocrit, mean corpuscular volume, platelet count, total leukocyte count, and counts of differential leukocytes were unaffected by SBM. A dose-related increase in reticulocytes was observed following exposure to SBM with the greatest increase (78%) observed at the highest dose level. Overall there were no changes in the absolute number of total T cells, CD4+ T cells, CD8+ T cells, natural killer (NK) cells and macrophages after exposure to SBM. There was no alteration in the IgM antibody-forming cell response, mixed leukocyte reaction and NK activity while the activity of peritoneal macrophages was decreased after exposure to SBM. In conclusion, SBM produced minimal toxicological and immunotoxic effects in female B6C3F1 mice. (This work was supported in part by the EPA and NIEHS Contract ES55387. This abstract does not represent EPA policy.)

740 EXPOSURE TO DISINFECTION BY-PRODUCT DIBROMOACETIC ACID DOES NOT ALTER IMMUNE FUNCTION OR HOST RESISTANCE.

J. A. McCay[1], D. L. Musgrove[1], R. D. Brown[1], G. W. Johnson[1], N. A. Karrow[1], T. L. Guo[1], D. R. Germolec[2] and K. L. White, Jr.[1]. [1]*Virginia Commonwealth University, Richmond, VA and* [2]*NIEHS, Research Triangle Park, NC.*

Dibromoacetic acid (DBA) is a disinfection by-product contaminant found in drinking water. The purpose of these studies was to determine the potential effects of DBA on the immune system when administered in the drinking water. Female B6C3F1 mice were exposed daily, ad libitum, to DBA in the drinking water at dose levels of 250, 500, and 1000 mg/l for 28 days. Body weight and change in body weight were unaffected. While the high and middle doses produced a decrease in absolute thymus weight (19%), an increase was observed in absolute liver weight (25%) at the high dose. The mid and high doses produced significant increases in relative liver weight 11% and 23% respectively. Hematological parameters were not affected. No alteration was observed after exposure to DBA in the antibody forming cell response to sRBC. In the NK assay, both basal and augmented, no affect was demonstrated. No effect was observed on the mixed leukocyte response (MLR). Previous range finding studies showed modulation at the high dose of 2000 mg/L in several measured immune parameters. Hence, host resistance studies were conducted. No change was demonstrated in the B16F10 melanoma tumor model using 2 challenge levels, no alteration in immune susceptibility to S pneumoniae was seen with three challenge levels and no change was observed in the parasitemia with the Plasmodium yoelii challenge. These studies demonstrate that in female B6C3F1 mice the immune system is not a target for DBA at doses of 1000 mg/l or less. (This work was supported in part by the EPA and NIEHS Contract ES 55387. This abstract does not represent EPA policy.)

741 EXPOSURE TO SODIUM CHLORITE IN DRINKING WATER FOR 28 DAYS PRODUCED MINIMAL IMMUNOMODULATORY EFFECTS IN FEMALE B6C3F1 MICE WITH THE EXCEPTION OF INCREASED NK CELL ACTIVITY.

N. A. Karrow[1], J. A. McCay[1], T. L. Guo[1], G. W. Johnson[1], R. D. Brown[1], D. L. Musgrove[1], D. R. Germolec[2] and K. L. White, Jr.[1]. [1]*Virginia Commonwealth University, Richmond, VA and* [2]*NIEHS, Research Triangle Park, NC.*

Sodium chlorite (SCl) is one of many chlorination by-products found in drinking water. Its immunomodulatory properties were evaluated by exposing female B6C3F1 mice to SCl in their drinking water (0.1, 1, 5, 15, 30 mg/l) for 28 days. In addition to a routine toxicological evaluation of the mice, a panel of immune assays was used to assess immunomodulation. Other than a significant dose-related increase in the percent of reticulocytes, peaking at 34% in the 15 mg/l treatment group, no change in hematological or toxicological parameters was measured. A dose-related increase in splenic natural killer cell activity was observed in SCl-treated mice when data were expressed as lytic units/107 cells and lytic units/spleen. Peak NK activity was greater than 260% in the 30 mg/l treated mice for both parameters. Spleen antibody-forming cell response and mixed leukocyte response, and peritoneal macrophage activating factor were not affected by SCl exposure. Phenotypic analysis of the splenocytes revealed a 30% and 26% increase in the percent and absolute number of CD8+ cells in the 30 mg/l treatment group; no significant change in Ig+ B cells, CD3+ and CD4+ T cells, NK cells, and macrophages was detected. These results indicate that SCl enhances NK activity and slightly alters CD8+ spleen cell numbers. (This work was supported in part by the EPA and NIEHS Contract ES55387. This abstract does not represent EPA policy.)

742 EXAMINATION OF THE MECHANISM FOR RAPID LOSS OF MURINE NK CELL LYTIC FUNCTION IN CELL CULTURES.

P. Hébert and S. B. Pruett. *LSU Health Sciences Center, Shreveport, LA.*

A number of immunotoxicants affect NK cells, and cell culture systems are often required to investigate the mechanisms responsible for these effects. Unfortunately, rodent NK cells rapidly lose their cytolytic function in culture. It is not known if preferential death of NK cells (as compared to other splenocytes) or loss of activity of viable NK cells is primarily responsible for the observed loss of lytic function. The present study addressed this matter using flow cytometry. Splenocytes were cultured for 12 hr in 48-well plates with an initial cell density of 10^8/ml. Cells were then washed and labeled with anti-NK1.1-phycoerythrin and 7-amino actinomycin D (7-AAD, which labels only dead cells). Gates were set using cells labeled with isotype control antibody or 7-AAD alone. Results from three experiments indicate that cells in control splenocyte cultures had an overall viability of 84±1% after 12 hr. In contrast to the total cell population, NK cell viability in control cultures was 36±3%. Cultures in which IL-2 (125 or 2000U/ml), polyinosinic polycytidylic acid (25μg/ml or 200μg/ml), or mouse growth hormone (5 ng/ml or 40 ng/ml) was added at the initiation of culture had significantly increased NK cell viability (78±2, 77±1, 56±3, 62±1, 48±1, and 49±3%, respectively). None of the agents added to these cultures significantly affected overall cell viability. This is not surprising, because NK cells constitute less than 5% of the cells in the spleen. These results suggest that part of the loss of NK cell activity is due to rapid and relatively selective loss of NK cell viability in culture systems. (Supported by NIEHS grant ES09158 and NIAAA grant AA09505.)

743 MERCURY: EFFECTS OF EXPOSURE ON *SCHISTOSOMA JAPONICUM* INFECTION IN MICE.

B. L. Ramirez[1], R. Rubite[2], J. Catapia[2], J. Cuevas[2] and E. K. Silbergeld[3]. [1]*National Institues of Health, Bethesda, MD,* [2]*University of the Philippines, Manila, Philippines and* [3]*University of Maryland, Baltimore, MD.*

Mercury (Hg) is a well described immunotoxin, with effects on both autoimmunity and host resistance to infection. We have previously reported that low level Hg exposure in mice can impair host resistance to murine malaria infection by *P yoelli*. In these studies, we extend our evaluation of Hg immunotoxicity to study the response of mice to infection by the trematode parasite *Schistosoma japonicum*. Schistosomiasis is a serious chronic parasitic disease that affects 150 to 200 million people worldwide. Cases of mercury poisoning have been reported in *S. japonicum* endemic areas in the Philippines. Mercury toxicity was induced in ICR mice by subcutaneous injections of $HgCl_2$ (100 μg/kg) every other day for 11 days. Following exposure to Hg, mice were infected with *S. japonicum* in two models: the acute infection model and the sensitized lung granuloma model, each with a control group. All infected mice developed hepatosplenomegaly. In both the sensitized lung granuloma model and the acute infection model, Hg exposure resulted in a significant reduction of granuloma area around *S. japonicum* eggs in either liver or lung tissue. These results are consistent with an inhibition of cell mediated immune response, as was described in our model of murine malaria infection. In the acute infection model we measured IgG antibody responses against soluble worm antigen preparations (SWAP) from *S. japonicum* using indirect ELISA. IgG antibodies to SWAP increased over the course of infection in all mice, but in male mice IgG levels were significantly lower in Hg treated mice as compared to controls. These results indicate that Hg exposure can also interfere with humoral immune responses in the schistosomal model. This is the first study of potential interactions between mercury and schistosomiasis infection. These findings have implications for the clinical treatment of schistosomiasis with praziquantel, acquired resistance to infection, and strategies for vaccine development. (Research supported in part by an NIH Fogarty ITREOH grant to EKS.)

744 MHC CLASS II EXPRESSION AND PROTEIN SYNTHESIS ARE NOT ALTERED IN EPIDERMAL LANGERHANS CELLS OF FEMALE BALB/C MICE FOLLOWING *IN VITRO* EXPOSURE TO 2-BUTOXYETHANOL.

P. Singh and B. L. Blaylock. *Division of Toxicology, College of Pharmacy and Health Sciences, University of Louisiana at Monroe, Monroe, LA.*

We have previously reported that topical exposure to 2-butoxyethanol (BE) significantly suppresses the local contact hypersensitivity response (CHR) in female BALB/c mice. As the primary antigen presenting cells in the skin, epidermal Langerhans cells (LC) play a key role in the CHR. Other studies have indicated that decreased MHC class II expression and/or protein synthesis in epidermal LC are ways in which chemical exposure can lead to suppression of the CHR. In order to uncover a potential mechanism for the observed immunosuppression following topical exposure to BE, we investigated the effects of BE exposure on MHC class II expression, protein synthesis and viability in epidermal LC. Freshly isolated epidermal cells were exposed *in vitro* to 10-10, 10-8 and 10-6 M BE for 48 hrs, then LC were assayed for MHC class II expression and viability using flow cytometric analysis. To study the effects of BE on protein synthesis, freshly isolated epidermal cells were exposed *in vitro* to 10-12, 10-10, 10-8, 10-6 and 10-4 M BE and pulsed with 1 microCi 3H-Leu/1 x 106 cells for 48 hrs. Uptake of 3H-Leu was then measured in a liquid scintillation counter. BE did not significantly alter viability, MHC class II expression or protein synthesis in epidermal LC of female BALB/c mice. We conclude that BE-induced immunosuppression of the CHR following topical exposure to BE is not due to reduced MHC class II expression, protein synthesis or viability of epidermal LC.

745 SUPPRESSION OF HUMAN CYTOKINE SECRETION BY CIGARETTE SMOKE.

Y. Ouyang, M. T. Aubrey and B. M. Freed. *University of Colorado Health Sciences Center, Denver, CO.*

Although cigarette smoke is known to have detrimental effects on the immune system, the nature of this immune suppression is poorly understood. We have previously shown that two tar components, hydroquinone (HQ) and catechol, are potent inhibitors of lymphocyte proliferation. The purpose of the current study was to measure the effects of cigarette tar, HQ and catechol, on the production of proinflammatory cytokines. Cigarette smoke extracts were prepared by 'smoking' single cigarettes via a mechanically vacuum pump at 125 ml/min through 10 mls of RPMI1640. The levels of HQ and catechol in these extracts were quantitated by C18 reverse phase HPLC using an electrochemical detector set a 0.7 mV. Cytokine production was measured by pretreating 10^6 human lymphocytes/ml in RPMI1640 + 10% FBS with the tar extract, HQ or catechol, and then stimulating the cells with αCD3 + PMA for 24 hrs. Quantitation of the cytokines was performed by ELISA using standard curves with purified recombinant human cytokines. The levels of HQ and catechol were similar and directly proportion to the tar content of the individual cigarette; they ranged from 30-40μM (unfiltered *Camel*) to 15-20μM (*Marlboro*) to <1μM (*Carleton 100s*). Extracts from these three cigarettes blocked production of IL-1β, TNF-α, IL-2 and IFN-γ in a dose-dependent fashion, exhibiting >90% suppression even at 1:100 dilutions. HQ and catechol also blocked production of these cytokines by >90% at 40-50μM (IC_{50} ranged from 10-40μM for the different cytokines). Thus, level of HQ and catechol in 2-3 cigarettes is sufficient to induce near complete suppression of IL-1β, TNF-α, IL-2 and IFN-γ production. However, the potent inhibitory effects of the unfractionated cigarette tar cannot be accounted for by HQ and catechol alone. These experiments suggest that there may be additional immunosuppressive compounds present in tar that are even more potent than HQ and catechol, or there may be synergistic immunosuppression between several different compounds in cigarette tar. (Supported by NIH grants HL60538 and ES05673.)

746 AN ARYL HYDROCARBON RECEPTOR INDEPENDENT MECHANISM OF JP-8 JET FUEL IMMUNOTOXICITY IN TWO STRAINS OF MICE.

A. C. Dudley, J. G. EuDaly, M. M. Peden-Adams and D. E. Keil. *Medical University of South Carolina, Charleston, SC.*

JP-8 jet fuel is a kerosene-based, complex mixture of aliphatic and aromatic hydrocarbons with a high flash point and low vapor pressure. It is used extensively by both the military and commercial airlines and is the desired alternative to other fuel sources due to its resistance to crash-induced fires and evaporative losses. However, recent reports have shown that acute, relatively low dose exposures to aerosolized JP-8 vapors can overtly and persistently impair immune function in B6C3F1 mice. Thus far, no mechanism has been put forth to account for such immunotoxicity. Given the evidence that polycyclic aromatic hydrocarbons (PAHs) possess the ability to affect many aspects of the immune system through a putatively described mechanism which involves the aryl hydrocarbon receptor (AhR), it was hypothesized that JP-8 may exert toxicity through AhR-mediated signal transduction. To test this hypothesis, JP-8 was administered by oral gavage for 7-days to either a hydrocarbon 'responsive' strain of mice (B6C3F1) or a classically 'non-responsive' strain (DBA/2). The results show that each strain was equally sensitive at several endpoints when evaluated for spleen and thymus weight and cellularity, liver weight, B and T- cell lymphocyte proliferation, the plaque forming cell response, and western blots for CYP1A1/2 and AhR. Additionally, *in vitro* JP-8 administration in the murine Hepa – 1 and human THP-1 monocytic cell lines did not induce CYP1A1/2 or promote downregulation of the AhR protein. These results support a new hypothesis that JP-8 may exert its toxicity via an AhR independent mechanism.

747 HALOTHANE-INDUCED LIVER DAMAGE IN GUINEA PIGS: ROLE OF PROTEIN ADDUCTS AND ANTI-INFLAMMATORY CYTOKINES.

M. Bourdi[1], J. L. Martin[2] and L. R. Pohl[1]. [1]*National Institutes of Health, Bethesda, MD and* [2]*The Johns Hopkins Medical Institutions, Baltimore, MD.*

The guinea pig model of halothane-induced liver injury resembles the mild acute toxicity produced by halothane in about 10 to 20% of humans and not the severe form of halothane hepatitis that appears to have an immunopathological basis. For example, in contrast to halothane hepatitis in humans, the severity of liver injury in susceptible guinea pigs does not increase after multiple exposures to halothane suggesting that immunopathological mechanisms are unlikely to be involved in the guinea pig model. The basis for susceptibility to halothane-induced hepatotoxicity and the mechanisms preventing immunological responses against trifluoroacetyl (TFA)-protein adducts were investigated. Male outbred Hartley guinea pigs were administered halothane (10 mmol/kg, i.p.) and livers and blood were collected after 48 and 72 hours. Immunoblot and immunohistochemistry studies indicated that the metabolism of halothane in livers of susceptible guinea pigs resulted in the formation of much higher levels of TFA-protein adducts than the resistant animals. Susceptible guinea pigs also had much higher levels of TFA-protein adducts in the sera than the resistant animals. These adducts were likely derived from damaged hepatocytes. At 48 hours and 72 hours after halothane treatment, we also found a high correlation between serum ALT levels and anti-inflammatory cytokines IL-10 and IL-4. These results indicate a role of TFA-protein adducts in the susceptibility of guinea pigs to halothane hepatotoxicity and suggest a pathway by which the liver TFA-protein adducts may come into contact with cells of the immune system to induce immune reactions. They also suggest that IL-10 and IL-4 may have a protective role in preventing immune reactions against TFA-protein adducts. Similar mechanisms may be important in the development of halothane hepatitis in humans.

748 TCDD SUPPRESSION OF IL-12 INHIBITS THE GENERATION OF THE TH1-MEDIATED IMMUNE RESPONSE TO OVALBUMIN.

D. M. Shepherd, E. A. Dearstyne and N. I. Kerkvliet. *Oregon State University, Corvallis, OR.*

Interleukin (IL)-12 is a heterodimeric cytokine produced by antigen presenting cells (APC) which promotes the development of TH1-mediated immune responses. We have previously reported that TCDD exposure suppresses the TH1 response to ovalbumin (OVA) in the DO11.10 adoptive transfer model. TCDD suppressed the production of OVA-specific IgG2a antibodies and the production of IL-2 and IFN-from OVA-specific T cell receptor (TCR) transgenic (Tg) CD4+ T cells. These results led us to hypothesize that TCDD inhibits the generation of the TH1-mediated immune response to OVA via suppressed IL-12 production. To test this hypothesis, we measured splenic IL-12 production from adoptively-transferred mice following immunization with OVA. Results indicated that IL-12 levels from TCDD-treated mice were significantly suppressed over the course of the immune response to OVA when compared to vehicle-treated mice. Furthermore, the administration of recombinant IL-12 to TCDD exposed mice elevated anti-OVA IgG2a titers to levels normally detected in vehicle treated, OVA-immunized mice. Although adoptively-transferred OVA-specific T cells from TCDD-treated mice administered IL-12 produced greater amounts of IFN- not IL-2) upon restimulation, this effect did not appear significant enough to account for the restoration of anti-OVA IgG2a production in these animals. Recently, we have found that

TCDD enhances the deletion of OVA-specific TCR Tg+ CD4+ T cells in adoptively-transferred mice on days 4-7 post-immunization which could underlie the anti-OVA antibody suppression. However, IL-12 treatment of TCDD-exposed mice did not increase the frequency of OVA-specific CD4+ T cells when compared to vehicle treated mice suggesting that TCDD-induced deletion of CD4+ T cells is not responsible for the suppression of OVA-specific antibody production. These data indicate that TCDD may be inhibiting the generation of antigen-specific immunity by directly affecting APC functions such as IL-12 production. (This work was supported by NIEHS grants ES03966 and ES00040.)

749 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN (TCDD) EXPOSURE INCREASES A NOVEL CELL POPULATION IN THE SPLEEN OF P815 TUMOR INJECTED MICE: CHARACTERIZATION OF MAC1+GR-1+ CELLS.

J. Y. Choi and N. I. Kerkvliet. *Department of Environmental and Molecular Toxicology and Environmental Health Sciences Center, Oregon State University, Corvallis, OR.*

We have previously shown that TCDD caused a significant increase in Mac1+ cells in the spleen of C57Bl/6 mice in the P815 tumor allograft model. In the present studies, we report a similar increase in Mac1+ cells in the blood, and that these Mac1+ cells co-express Gr-1 antigen, a myeloid differentiation marker. Experiments were conducted to characterize the Mac1+Gr-1+ cells using flow-cytometric and immunohistochemical techniques. Mice were gavaged with vehicle or TCDD (15μg/kg), injected ip with P815 tumor cells and sacrificed on days 1 through 9 after P815 injection. The absolute number and percent of Mac1+Gr-1+ cells in the blood and the spleen gradually increased over time in both TCDD and vehicle groups, however, both the number and percent of the Mac1+Gr-1+ cells were consistently greater in TCDD-treated mice. For example, in the blood on day 9, we observed that 72% of the white blood cells were Mac1+Gr-1+ in the TCDD-treated mice, compared to 42% in the vehicle-treated mice. Likewise in the spleen, TCDD treatment resulted in 25% Mac1+Gr-1+ cells compared to 13% in vehicle-treated mice. Morphological analysis identified the Mac1+Gr-1+ cells in the blood as neutrophils. Immunohistochemical analysis showed that the Mac1+Gr-1+ cells were localized in the red pulp in the spleen. Flow cytometric analysis of the Mac1+Gr-1+ cells in the spleen on day 9 showed that these cells did not express the lymphocyte markers, CD4, CD8 or B220, or the dendritic cell marker, CD11c. Several costimulatory and adhesion molecules including ICAM, LFA-1, MHC Class I, CD40, F4/80 and B7-2 were expressed at various levels on the Mac1+Gr-1+ cells. TCDD exposure down-regulated the expression of B7-2 and ICAM on these cells. The possible immuno-regulatory role of Mac1+Gr-1+ cells in this model is currently under investigation. (Supported by NIEHS grant ES03966 and ES00210.)

750 CHARACTERIZATION OF MICE TRANSGENIC FOR A CONSTITUTIVELY ACTIVE MUTANT OF THE AH RECEPTOR SHOWS ALTERATIONS IN IMMUNE SYSTEM DEVELOPMENT.

P. Andersson[1], A. Ridderstad-Wollberg[2], J. McGuire[1], L. Poellinger[1] and A. Hanberg[1]. [1]*Karolinska Institute, Stockholm, Sweden and* [2]*Astra Zeneca, Stockholm, Sweden.* Sponsor: H. Vainio.

The Aryl Hydrocarbon Receptor (AhR) is generally assumed to mediate most toxic effects of dioxins such as 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) and planar polychlorinated biphenyls (PCBs). This has been determined in several ways, most recently by using mice lacking a functional Ah receptor, which are resistant to the lethal wasting syndrome and cleft palate that is usually found after relatively high doses of TCDD. We have chosen an alternative transgenic strategy to study the toxic effects and mechanisms mediated by the AhR. A mutant form of the AhR which is constitutively active was defined and transgenic animals expressing this mutant AhR were created. The expression was targeted to the immune system where increased expression of CYP1A1 compared to wild type animals indicates that the mutant AhR is activated in the absence of exogenous AhR ligands. The immune system is affected in several ways in these mice. Relative thymus weights are decreased, which is considered to be a hallmark effect of dioxin exposure. The distribution of CD4/CD8-positive T-cells is not affected in the thymus but the CD4-positive T-cells are slightly increased in peripheral lymph nodes. The development of B-cells is skewed to a larger fraction of mature B-cells in both bone marrow and spleen. However, the most striking finding is the absence of a B-cell population in the peritoneum, belonging to the CD5-positive B1-cells. These transgenic mice clearly show that an activated Ah receptor can disturb the development of the immune system.

751 TCDD SUPPRESSES T CELL EXPANSION AND CYTOKINE PRODUCTION IN LYMPH NODES OF MICE INFECTED WITH INFLUENZA VIRUS.

K. A. Mitchell[1], T. K. Warren[2] and B. P. Lawrence[1]. [1]*Pharmacology/Toxicology Graduate Program, Washington State University, Pullman, WA and* [2]*Department of Pharmaceutical Sciences, College of Pharmacy, Washington State University, Pullman, WA.*

Halogenated aromatic hydrocarbons, such as 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD), are prevalent and highly toxic environmental contaminants. It is well established that TCDD-mediated immunosuppression includes impairment of antibody and cell-mediated immune responses. Suppression of immunity is attributed in part to the effects of TCDD on T cell function, although the underlying mechanism has not been determined. To examine the mechanisms of TCDD immunosuppression, we are using a murine model of human influenza A virus infection. During infection with influenza virus, antibody production and cell-mediated immunity depend on the activation and differentiation of T cells in the mediastinal lymph nodes (MLN). Specifically, viral clearance requires the differentiation of naive CD8+ T cells into cytotoxic T lymphocytes (CTL), which migrate to the lung and kill infected cells. We have previously shown that exposure to TCDD impairs antibody production and decreases recruitment of CTL to the lung during influenza virus infection. We hypothesize that these effects of TCDD are due to impaired T cell responses in the MLN. To test this, C57Bl/6 mice were gavaged with TCDD (10 μg/kg) one day prior to i.n. infection with influenza virus. After 1 to 9 days, mice were sacrificed and MLN cells were stained with fluorochrome-conjugated antibodies for flow cytometry. Our findings indicate that exposure to TCDD results in a two-fold decrease in CD4+ and CD8+ cell number in the MLN and a 50% decrease in the percentage of CD8+ T cells bearing the CTL phenotype ($CD44^{hi}CD62L^{lo}$). Cytokine analysis of *in vitro* restimulated MLN cells indicates that exposure to TCDD reduces IFN-γ and IL-2 production by 50%. These findings suggest that TCDD-mediated suppression of host resistance to influenza virus may be due in part to impaired activation and expansion of T lymphocytes in the regional lymph nodes.

752 SINGLE-DOSE ADMINISTRATION OF 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN PRODUCES A TIME- AND DOSE-DEPENDENT ALTERATION IN THE MURINE BONE MARROW B LYMPHOCYTE MATURATION PROFILE.

T. S. Thurmond, F. G. Murante and T. A. Gasiewicz. *University of Rochester, Rochester, NY.*

The halogenated aromatic hydrocarbon, 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is a ubiquitous, highly toxic environmental contaminant that has been shown to produce immunotoxic effects in mammals. Although its immunotoxicity has been widely reported, little is known regarding its effect upon the development of immune system cells, especially the B lymphocyte. The present study's purpose was to assess the effect that single-dose administration of TCDD has over time upon bone marrow B cell progenitors and pro/pre-B, immature B and mature B cell subpopulations. Results showed that the mature B lymphocyte subpopulation varied in a cyclic manner with a significant increase one day following TCDD treatment (30 μg/kg bw) followed by a significant decrease at day nine, and a return to near vehicle levels by day thirty-one. Pro/pre-B and immature B cell subpopulations were significantly decreased at days six and nine. The earliest B cell progenitor subpopulation increased until day nine and then decreased to vehicle-treated levels. We have shown that TCDD produces a rapid alteration in the B cell maturation profile which affects both less mature and mature subpopulations and is cyclical over time. This change correlates with increased numbers of B cell progenitors at the time at which the mature B subpopulation is at its lowest.

753 INVESTIGATION OF REYES-LIKE SYNDROME AND INFLUENZA MORTALITY IN DIOXIN-EXPOSED MICE.

R. W. Luebke, C. B. Copeland, L. R. Bishop, M. J. Daniels and M. I. Gilmour. *USEPA, Research Triangle Park, NC.*

Mortality is increased in B6C3F1 mice exposed to 0.1μg TCDD/ kg before infection with influenza A virus. But, viral titers were not elevated and antiviral antibody titers were only suppressed at 10μg TCDD/kg, suggesting that viral overgrowth, secondary to immunosuppression, was not the proximate cause of death. We tested the hypothesis that a Reye's-like syndrome (RLS, mito- chondrial toxicity and dysfunction) was responsible for increased mortality in exposed, infected mice, based on similarities between biochemical and immunological events in RLS and TCDD-exposed animals. B6C3F1

mice were given a single i.p. injection of 0, 0.25, 0.5 or 10μg TCDD/kg 7 d before infection by intranasal instillation of 25 PFU of influenza A Hong Kong/8/68 (H3N2). Sub-groups of noninfected control and high dose group were evaluated for baseline values. Five days after infection, 7 mice were killed from each dose group; serum, lung lavage fluid (BALF) and lung tissue were collected for clinical chemistries, cell counts, cytokine analysis and viral titers. Viral titers were similar in all treatment groups. There was no effect on serum NH_3 or glucose concentrations, two prominent indicators of the altered mitochondrial oxidative metabolism typically observed in RLS. Total cell counts in the BALF were increased by TCDD exposure alone and to a greater extent in combined exposure/infected groups. An increased percentage of neutrophils relative to macrophages was found in the infected/high dose group, possibly due to an observed increase in BALF levels of MIP-2. The remaining 20 animals/group were followed for mortality; increased mortality was only observed at the highest dose. These results suggest that RLS is an unlikely explanation for increased influenza mortality in TCDD-exposed mice. (This abstract does not represent EPA policy.)

754 EXPOSURE TO TCDD CAUSES DELETION OF ACTIVATED ANTIGEN-SPECIFIC CD4+T CELLS.

E. A. Dearstyne and N. I. Kerkvliet. *Oregon State University, Corvallis, OR.*

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) is a ubiquitous environmental contaminant that suppresses both cell mediated and humoral immune responses. The mechanism by which TCDD exerts its immunosuppressive properties is not completely understood. In addition, the cellular target(s) of TCDD is not known. T helper (CD4+) cell-mediated immune responses are particularly sensitive to the effects of TCDD. We hypothesize that one potential mechanism by which TCDD causes immune suppression is by augmented apoptosis in the antigen- responsive CD4+ population. Apoptosis plays a crucial role in immune function during lymphocyte maturation, activation, effector function, and down regulation of immune responses. In order to test our hypothesis, we used the DO11.10 transgenic T cell receptor (Tg-TCR) adoptive transfer model. This model allows us to track a small population of transgenic DO11.10 CD4+ T cells in syngenic Balb/c mice using a monoclonal antibody (KJ1-26) that recognizes the Tg TCR. Maximal expansion of the splenic antigen-specific CD4+ T cells (CD4+KJ1-26+) occurs 3 days after immunization with 2 mg of ovalbumin in complete Freund's adjuvant (OVA/CFA). Exposure to TCDD (15 μg/kg) did not affect the maximal expansion of the CD4+KJ1-26+ T cells. However, TCDD significantly decreased the percentage and number of CD4+KJ1-26+ T cells on days 5-7 post OVA/CFA administration in a dose responsive manner. This decrease correlated with a significant increase in the level of phosphatidylserine (PS) exposure, an early marker of apoptosis. These results suggest that TCDD is enhancing the deletion of the activated antigen-specific CD4+ T cells, at least in part through an induction of apoptosis of those cells. We also examined the expression of Fas, a molecule important in the induction of apoptosis which is upregulated upon activation. Surprisingly, Fas expression was decreased on the CD4+KJ1-26+ T cells from TCDD-treated animals 3-7 days after antigen administration. Additional studies are necessary to determine the mechanism by which TCDD causes the deletion of the antigen-specific T helper cells. (Supported by NIH grant ES00040.)

755 AHR KNOCKOUT MICE AND 2,3,7,8 TETRACHLORODIBENZO-*P*-DIOXIN (TCDD) IMMUNOTOXICITY: IMMUNE SUPPRESSION INDUCED BY TCDD IS DEPENDENT ON EXPRESSION OF AHR IN BONE MARROW-DERIVED CELLS.

B. A. Vorderstrasse[1], L. Baecher-Steppan[1], A. E. Silverstone[2] and N. I. Kerkvliet[1]. [1]*Dept. of Environmental & Molecular Toxicology, & Environmental Health Sciences Center, Oregon State University, Corvallis, OR and* [2]*Dept. of Microbiology & Immonology, State University of New York, Syracuse, NY.*

TCDD, a highly toxic environmental contaminant, suppresses both humoral and cell-mediated immune responses in the mouse. Many of TCDD's toxic effects are known to be dependent on the AhR, a cytoplasmic receptor which binds TCDD, translocates to the nucleus, and induces gene transcription. Although the AhR is implicated in the immune dysfunction caused by TCDD, some controversy exists as to its obligatory role. Data generated from *in vivo* studies have collectively supported the hypothesis that TCDD suppresses the immune response in an AhR-dependent manner. However, results from some *in vitro* studies have suggested that the suppression is AhR-independent. In order to resolve this issue, we examined the immune response of AhR knockout mice treated with an immunosuppressive dose of TCDD (15μg/kg). We found that TCDD exposure did not suppress the ability of AhR-/- mice to generate an antibody response to sheep red blood cells (SRBC) or a cytotoxic T cell (CTL) response to allogeneic tumor cells, while these responses were significantly suppressed in AhR+/+ mice. These results are consistent with previous *in vivo* studies and provide compelling evidence that the AhR is required for TCDD-induced immune suppression. Additional experiments using chimeric animals were performed to test the hypothesis that the immune suppression induced by TCDD results from a direct effect on hematopoietic cells. In these experiments, AhR+/+ mice were lethally irradiated and then reconstituted with bone marrow cells from either AhR+/+ or AhR-/- animals. When the chimeric animals were treated with TCDD, only those reconstituted with AhR+/+ bone marrow were sensitive to TCDD-induced suppression of the SRBC and CTL response to allogeneic tumor. Taken together, these results support the hypothesis that TCDD-induced immune suppression is AhR-dependent and results from a direct effect on hematopoietic cells. (Supported by NIH #ES03966 and ES00040.)

756 SENSITIVITY OF THE SRBC PFC ASSAY VS ELISA FOR DETECTION OF IMMUNOSUPPRESSION BY TCDD AND TCDD-LIKE CONGENERS.

C. W. Johnson[1], W. C. Williams[2], C. B. Copeland[2], M. J. DeVito[2] and R. J. Smialowicz[2]. [1]*Curriculum in Toxicology-UNC, Chapel Hill, NC and* [2]*USEPA, NHEERL, Research Triangle Park, NC.*

The antibody plaque-forming cell (PFC) assay to sheep red blood cells (SRBC) is considered to be one of the most sensitive assays for detection of immunosuppression, and traditionally has been used in immunotoxicity testing. However, an enzyme-linked immunosorbent assay (ELISA) (Temple et al., 1993), is gaining popularity as a more convenient and less expensive alternative. The PFC assay quantifies the number of anti-SRBC producing plasma cells in the spleen, while the ELISA measures SRBC-specific IgM antibody in the serum. This study was performed to compare the sensitivity of these two assays to detect immunosuppression by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and TCDD-like congeners. Two sets of 6-7 groups of female B6C3F1 mice (6-7 mice/grp, 8-weeks-old) were given a single oral exposure to corn oil or different doses of TCDD or congeners. Seven days later, mice were immunized i.v. with SRBC. The first set of mice was evaluated using the PFC assay and the second using the ELISA, on day 4 or 5 post-immunization, respectively. The four TCDD congeners tested were: 1,2,3,7,8-pentachlorodibenzo-p-dioxin (PeCDD), 2,3,4,7,-pentachlorodibenzofuran (4PCDF), 3,3',4,4',5-pentochlorobiphenyl (PCB126) and 2,3',4,4',5-pentachlorobiphenyl (PCB118). The ED50s for TCDD and each congener were determined from the PFC and ELISA data. For all the chemicals tested the ED50s for the ELISA were lower than the ED50s for the PFC, with percent differences ranging from 33 to 84%. These results indicate that the ELISA is a more sensitive assay for detecting suppression of the SRBC-specific IgM response of dioxin-like chemicals in this rodent model and supports its use as a sensitive alternative to the PFC assay. (This abstract does not reflect EPA policy. This work was supported in part by The Dow Chemical Co. and The DuPont Co.)

757 EFFECTS OF TCDD ON PRIMARY TOXOPLASMOSIS IN C57/BL6 MICE.

M. D. King, M. Ehrich, M. Nagarkatti and D. S. Lindsay. *Virginia-Maryland Regional College of Veterinary Medicine, Blacksburg, VA.*

In the current study, the effect of of 2,3,7.8-tetrachlorodibenzo-p-dioxin (TCDD) on infection caused by *Toxoplasma gondii*, a protozoan parasite was studied. C57BL/6 mice were fed 25 tissue cysts of *T. gondii* and treated with sodium sulfadiazine to prevent death from acute disease. Six weeks later, mice were treated with 50μg/kg body weight TCDD and the extent of infection and immune status was determined. TCDD treatment of chronically infected mice did not cause differences in brain lesions or *T. gondii* tissue cyst numbers. It was, however, observed that there was a significant decrease in the thymic cellularity in uninfected or *T. gondii*-infected mice treated with TCDD but not the vehicle. Furthermore, alterations in the percentage and absolute numbers of CD4+, CD8+, CD4+CD8+and CD4-CD8- T cells were observed in *T. gondii*-infected mice following TCDD treatment. However, there were no changes in the splenic cellularity and T cell subsets in all groups of mice. Next, whether prior treatment with TCDD would influence the course of an acute infection with *T. gondii* in C57/BL6 mice was investigated. The results demonstrated that 50% of the vehicle-treated *T. gondii* infected mice and 100% of TCDD-treated *T. gondii* infected mice died from acute toxoplasmosis 11 to 13 days post-infection as indicated by the presence of tachyzoites in liver and lung impression smears. Results of the present study

indicate that prior exposure to TCDD can exacerbate a primary *T. gondii* infection in C57/BL6 mice.

758 MODELING THE CORTICOSTERONE AND STRESS-INDUCED SUPPRESSION OF TH1 AND TH2-RELATED ANTIBODY RESPONSES AND CYTOKINE RESPONSES IN B6C3F1 MICE.

R. Fan and S. B. Pruett. *LSU Health Sciences Center, Shreveport, LA.*

This work is part of project investigating the role of chemical-induced stress responses in immunosuppression. The goal of this study was to develop mathematical models relating an important stress mediator, corticosterone, and suppression of humoral immune responses and related cytokine responses. Female B6C3F1 mice were treated with corticosterone or restraint stress and the area under the corticosterone vs. time curve (AUC) was determined (*Tox. Sci.* 49:272). This parameter is an important part of these modeling studies, because it reflects cumulative corticosterone exposure over time, and it is a better predictor of immunological outcome than corticosterone concentration at any single time point. In separate experiments, mice were treated with the same regimen of corticosterone or restraint at an optimum time before immunization with keyhole limpet hemocyanin (KLH, 100 μg/mouse, i.p.). Two weeks later IgG1 and IgG2a antibodies specific for KLH were measured by ELISA. The results demonstrate similar patterns of suppression of the anti-KLH responses (both IgG1 and IgG2a) by restraint and by exogenous corticosterone, when the data are plotted as relative antibody response vs. corticosterone AUC. The slopes of the restraint and corticosterone lines were not significantly different, but the elevations of the restraint lines were significantly lower than those obtained with corticosterone, indicating greater suppression of the antibody response (at equivalent cumulative corticosterone exposure) in restrained mice. Similar patterns of suppression were noted for a Th1 cytokine (IL-2) and a Th2 cytokine (IL-4), except that restraint did not significantly decrease IL-2 production. Linear models from these studies should permit the prediction of at least the minimum expected suppression of antibody and IL-4 responses to KLH on the basis of the corticosterone AUC. In addition, the data demonstrate that the widely accepted view that glucocorticoids selectively suppress Th1 responses is not correct under all circumstances. (Supported by NIEHS grant ES09158.)

759 QUANTITATIVE ASSESSMENT OF CHANGES IN CYTOKINE GENE EXPRESSION AND I KAPPA B AND NF-KAPPA B PROTEINS INDUCED BY CORTICOSTERONE IN B6C3F1 MICE.

Q. Zheng and S. B. Pruett. *LSU Health Sciences Center, Shreveport, LA.*

Cytokines contribute to the toxicity of a number of drugs and chemicals. A number of these pro-inflammatory cytokines activate the hypothalamic-pituitary-adrenal axis, and the resultant increase in glucocorticoids is important in regulating cytokine production and preventing or diminishing adverse effects. However, the concentration and duration of endogenous glucocorticoids required to prevent or decrease cytokine synthesis has not been systematically investigated. In the present study, the major endogenous glucocorticoid of mice, corticosterone, was administered subcutaneously in a suspension of 2% beta-cyclodextrin in Hanks' Balanced Salt Solution. In a previous study, we determined the area under the corticosterone vs. time curve (AUC) produced by selected dosages of corticosterone (*Tox. Sci.* 49:272). This parameter is an effective measure of cumulative corticosterone exposure, and several corticosterone dosages have been identified that yield corticosterone AUC values similar to those induced by chemical or psychological stressors. In the present study these dosages of corticosterone were evaluated for their effect on the production of cytokines, using an RNAse protection assay with probes for 10 cytokines (Pharmingen, Inc.). Preliminary experiments indicated that the experimental design allowing the greatest sensitivity was as follows: Corticosterone (or dexamethasone as a positive control) was administered subcutaneously, then cytokine production was stimulated three hours later by intravenous administration of anti-CD3 antibody (50 μg). The spleen was removed 1.5 hr after anti-CD3 administration, and RNA was isolated. The RNAse protection assay indicated dose-dependent suppression of Interleukins 2, 4, 6, 13, and 15 as well as Interferon-gamma. In addition, there was a dose responsive increase in IL-10. It has been suggested that glucocorticoids suppress the expression of some cytokine genes by upregulating IkB gene expression and thereby preventing the activation of NF-kB. Initial experiments to determine the effects of corticosterone and dexamethasone *in vivo* on basal levels of these molecules indicate that there was a significant increase in IkB and a decrease in NF-kB, but these changes were transient, and further work is needed to demonstrate that they are responsible for changes in expression of IL-2 or other cytokines. These results quantify the corticosterone exposure required to regulate potentially harmful cytokine responses. (Supported by NIEHS grant ES09158.)

760 CPG DNA MOTIFS DO NOT ACTIVATE THE HYPOTHALAMIC-PITUITARY-ADRENAL (HPA) AXIS OR AFFECT ITS ACTIVATION BY OTHER MEANS.

L. P. Myers and S. B. Pruett. *LSU Health Sciences Center, Shreveport, LA.*

Bacterial DNA containing unmethylated CpG motifs (CpG DNA) has adjuvant effects. Clinical trials are underway to evaluate the effectiveness of CpG DNA as an adjuvant in human vaccines. The adjuvant-associated increase in cytokines, however, has not been completely studied. Some cytokines activate the HPA axis and could lead to subsequent immunosuppression. Alternatively, if CpG DNA suppressed activation of the HPA axis, this could increase the probability of cytokine-induced shock syndrome. Therefore, this study was done to examine the effects of CpG DNA on activation of the HPA axis. Administration of CPG DNA (30-300 μg, kindly provided by Dr. Art Krieg) alone did not significantly increase serum corticosterone concentrations 1-4 hr after administration, nor did calf thymus DNA which was used as a control. Administration of CpG DNA (30 μg/mouse) prior to endotoxin (LPS) caused an increase in tumor necrosis factor-alpha (TNF-α) indicative of an adjuvant effect (7590 pg/ml by ELISA) compared to LPS alone (822 pg/ml). LPS, however, induced similar levels of corticosterone with (726 ng/ml by RIA) or without (676 ng/ml) CpG DNA, and these values were roughly half of the maximal stress-induced level. LPS alone over a broad range of dosages caused peak corticosterone levels similar to LPS plus CpG DNA. Exogenous TNF-α administered *in vivo* induced comparable peak levels of corticosterone with (560 ng/ml) or without (527 ng/ml) CpG DNA. An alternative stressor (restraint) yielded similar peak levels of corticosterone with (649 ng/ml) or without (660 ng/ml) CpG DNA. These results suggest that CpG DNA does not activate the HPA axis or alter its normal activation by other stimuli. Although it remains possible that such effects may occur under other circumstances, the present results do not indicate that alterations of the HPA axis will adversely affect the safety of CpG DNA adjuvants.(Supported by NIH grants ES09158 and AA09505.)

761 ROLE OF CORTICOSTERONE IN ETHYL CARBAMATE-INDUCED SUPPRESSION OF ANTIBODY RESPONSE TO SHEEP RED BLOOD CELLS IN FEMALE BALB/C MICE.

S. W. Cha[1], M. H. Lee[2], K. H. Kim[1], E. J. Kim[1], S. S. Han[1] and T. C. Jeong[1]. [1]*Toxicology Research Center, KRICT, Taejon, Republic of Korea and* [2]*College of Veterinary Sciences, Seoul National University, Suwon, Republic of Korea.*

A possible role of corticosterone in ethyl carbamate-induced immunosuppression was investigated in female BALB/c mice using the antibody response to a T-cell dependent antigen, sheep red blood cells, and/or subpopulation changes of thymocytes and splenocytes. When mice were treated with ethyl carbamate ip for 7 consecutive days at 100, 200 and 400 mg/kg, the antibody response was significantly suppressed and the weights of thymus and spleen were reduced. In addition, the level of serum corticosterone was increased. Flow cytometric analyses demonstrated that the numbers of splenic macrophages, B- and T-cells and thymic CD4+CD8- and CD4-CD8+ cells were significantly decreased by ethyl carbamate. Ethyl carbamate-induced suppression of antibody response was partially recovered when adrenalectomized (ADX) mice were treated with ethyl carbamate. In addition, the decrease in splenic numbers of B- and T-cells and macrophages by ethyl carbamate was partially blocked in the ADX mice. Moreover, a single dosing of corticosterone at 25 mg/kg to ADX mice caused a significant suppression of antibody response. These results indicate that ethyl carbamate-induced increase in corticosterone level may closely be related with ethyl carbamate-induced immunosuppression in female BALB/c mice. (Supported by a grant from the Ministry of Science and Technology, Korea.)

762 RESTRAINT STRESS MODIFIES DNCB-INDUCED LYMPH NODE CYTOKINE PRODUCTION, BUT NOT T CELL PROLIFERATION.

M. S. Flint, B. A. Abrigo and S. S. Tinkle. *CDC/NIOSH, Morgantown, WV.* Sponsor: M. I. Luster.

The timing of a stressful event with respect to antigen exposure affects the development of the immune response. We have demonstrated that restraint applied prior to sensitization alters the ear swelling response and the pattern of cytokine production differently than restraint applied prior to challenge. We hypothesized that restraint would also modify the immune response to chemical in the draining lymph nodes. Male BALB/c mice were exposed on the dorsum of both ears on days 1, 2 and 3 with 1% or 0.5% di-nitrochlorobenzene (DNCB; n = 5) or vehicle only (n = 10), and restrained for 2 hours prior to chemical application on day 1 or day 3. We assessed T lymphocyte proliferation on day 5. To evaluate lymph node cytokine production, lymph nodes were removed on day 5 and cultured for 24, 48 and 72 hours. To assess these parameters following chemical challenge, we sensitized mice on the flank on days 1 and 2, challenged on day 6 immediately following restraint, and assessed T lymphocyte proliferation on day 8. We determined that, for all treatment paradigms, DNCB stimulated significant T cell proliferation which was not altered by restraint. Furthermore, we determined that DNCB-activated lymph node cells (LNCs) produced IL-6 and IFN-γ and that restraint enhanced both cytokines at all timepoints. For example, at 48 hours, the concentration of IFN-γ in non-restrained mice measured 83.5 pg/ml, whereas restrained mice produced 232 pg/ml. IL-6 production at 48 hours measured 87.5 pg/ml in non-restrained mice and 289 pg/ml in restrained mice. These data suggest that restraint stress modulates the lymph node immune response to chemical through changes in cytokine production that do not alter significantly T cell proliferation.

763 MECHANISMS OF METALLOTHIONEIN-MEDIATED IMMUNE SUPPRESSION: EFFECTS ON ANTIGEN PRESENTATION.

K. C. Crowthers and M. A. Lynes. *University of Connecticut, Storrs, CT.*

Metallothionein (MT) is a stress-induced protein that can modulate the consequences of exposure to heavy metals and to reactive oxygen intermediates. MT can be induced by toxicants such as metal cations and acute phase cytokines. Recent work from a number of laboratories has suggested that metallothionein also plays an integral part in cellular mechanisms that are part of the signal transduction cascade. Metallothionein can serve as an essential reservoir of trace metals, regulate the activity of Zn-dependent transcription factors, and can act to maintain a reduced cytoplasmic environment. These roles are essential to normal cellular processes, including those that are part of an effective immune response. Previous work from our laboratory has demonstrated that exogenous MT can downregulate the developing immune response, reducing levels of antigen-specific humoral and cellular immune responses. In contrast, MT-null mice display increases in mitogen-responses and in antigen-specific humoral responses. This enhanced immune function in MT-null animals correlates with an increased NF-kB activity that is associated with the metallothionein-null phenotype. The experiments described here show that metallothionein can interfere with antigen processing and presentation, a hallmark of an effective immune response. By utilizing OVA-specific TH cell clones, we have shown that metallothionein interferes with IL-2 secretion from T cells after activation with antigen. For instance, Do11.10 T cells have a 20-30% decrease in IL-2 secretion when MT is added to cultures utilized in antigen presentation assays. This decrease in T cell function may be due to changes in lymphocyte apoptosis that occur in the presence of extracellular metallothionein. The observation that antigen-specific T cells isolated from MT-null mouse spleens have an approximate 30% increase in IL-2 secretion in antigen presentation assays further extends the idea that metallothionein synthesis is important in determining the effectiveness of an immune response. These results may imply that toxicants which upregulate metallothionein levels can modulate immune capacity through alterations in T cell survival, antigen processing and presentation. This would suggest a novel therapeutic avenue that might lead to clinical manipulations of toxicant-induced immune.

764 CHARACTERIZATION OF THREE ANTIBODY RESPONSE MODELS IN THE MOUSE: KINETICS AND SENSITIVITY TO CLASSICAL IMMUNOSUPPRESSANTS.

C. M. Wiescinski, P. K. Anderson and M. P. Holsapple. *Dow Chemical, Midland, MI.*

The primary component of the Environmental Protection Agency (EPA) immunotoxicity guidelines (OPPTS 870.7800), is the antibody response to a T-dependent antigen; sheep red blood cells (SRBC). The selection of this functional endpoint was based in part on the results of the National Toxicology Program (NTP) validation studies that included an intralaboratory comparison and the characterization of over 50 different compounds. The EPA guidelines also indicate that the antibody response can be measured by either a plaque-forming cell (PFC) assay or an enzyme-linked immunosorbent assay (ELISA). The selection of the PFC assay was based on the substantial database generated by the NTP studies. The ELISA is not nearly so well characterized, but it is an attractive alternative because of numerous technical and methodological advantages. The overall goal of this investigation was to compare the sensitivity of the antibody response models to the classical immunosuppressants cyclophosphamide (CY) and benzo(a)pyrene (B(a)P). In addition to comparing the anti-SRBC response in the PFC assay, we included the antibody response to a second T-dependent antigen, Keyhole limpet hemocyanin (KLH), which was also measured by an ELISA. The selection of KLH was based on the observation that it appears to be the second most prevalent antigen in previous immunotoxicity studies and on the fact that it has been used in humans to assess immunocompetence. The three antibody response models were initially optimized as to the antigen concentration and the kinetics of the response. The results indicated a comparable sensitivity with the anti-SRBC PFC assay and the anti-SRBC ELISA in agreement with a previous study (Temple et al., 1993). In contrast, the anti-KLH ELISA was less sensitive to treatment with either cyclophosphamide or B(a)P. It is premature to conclude that KLH is an inappropriate choice as a second T-dependent antigen in immunotoxicology studies. Future studies will compare the sensitivity of these three antibody response models to additional chemicals.

765 EFFECTS OF EXERCISE STRESS OR PYRIDOSTIGMINE BROMIDE (PSB) ON IMMUNE FUNCTION PARAMETERS IN B6C3F1 MICE.

M. M. Peden-Adams, A. C. Dudley, J. G. EuDaly, G. S. Gilkeson and D. E. Keil. *Medical University of South Carolina, Charleston, SC.*

Pyridostigmine bromide (PSB) and physiological stress have been identified as potential agents that contributed to symptoms reported by Gulf War veterans. These exposures in combination with other compounds may result in toxicity to the neuro-endocrine-immune axis thereby leading to the reported manifestations of the Gulf War veterans. To assess the immune effects of these exposures independently, adult female B6C3F1 mice were either gavaged daily for 14 days with PSB (0, 1, 5, 10, or 20 mg/kg) or were challenged daily for 14 days to physiological stress via forced exercise on a treadmill (0, 20, 40, or 60 minutes). Immune parameters assessed were lymphoproliferation, natural killer cell activity, the plaque-forming cell (PFC) response, thymus and spleen weight and cellularity, and thymic and splenic CD4/CD8 lymphocyte subpopulations. No effect was observed in lymphoproliferation or natural killer cell activity following either treatment. Exposure to PSB had no effect on thymic or splenic weights but exercise stress resulted in significant decreases in both spleen and thymus weight at the 40 and 60 minute time points. Both agents significantly decreased the PFC-response (at 1, 5, and 20 mg PSB/kg and at 40 and 60 minutes of exercise, respectively) and altered splenic and thymic CD4/CD8 subpopulations. These studies are a result of our intial efforts to determine the immunological effects due to combined exposure to exercise stress and PSB. Additionally, exposure to these agents will be assessed concurrently with other Gulf War relevant environmental agents such as JP-8 jet fuel and n,n,-diethyl-m-toluamide.

766 α-TOCOPHERYL SUCCINATE (TS) PREVENTS MITOCHONDRIAL COMPLEX I INHIBITOR-INDUCED HEPATOCYTE TOXICITY.

J. G. Zhang, M. A. Tirmenstein, F. A. Nicholls-Grzenski and M. W. Fariss. *College of Pharmacy, Washington State University, Pullman, WA.*

Our laboratory has demonstrated that the exposure of rat hepatocytes to the glutathione (GSH) depleting agents, diethyl maleate (DEM) and ethyl methane sulfonate (EMS) results in mitochondria-mediated oxidative damage and cell death, that are prevented by TS (25 μM) treatment. Here we exam-

ined the role of GSH depletion (using a non-toxic concentration of DEM) and TS treatment in the toxicity induced by four specific mitochondrial complex inhibitors using freshly isolated rat hepatocyte suspensions. The inhibitors of mitochondrial complex I, rotenone (ROT, 100 μM) and complex II, thenoyltrifluoroacetone (TTFA, 100 μM), caused oxidative damage, as evidenced by the increase in lipid peroxidation and LDH leakage (an indicator of cell death) as well as the decrease of mitochondrial membrane potential (MMP). The depletion of GSH with 1 mM DEM dramatically potentiated both ROT and TTFA-induced oxidative damage to hepatocytes. TS (25 μM) totally prevented oxidative damage induced by either ROT or ROT + DEM but did not prevent TTFA or TTFA + DEM-mediated oxidative damage. Blockade of complex III by antimycin A (AA, 50 μM) and IV by cyanide (CN, 1 mM) collapsed MMP and caused cell death but did not increase lipid peroxidation. DEM or TS, however, had little effect on both AA and CN-induced toxicity. Our findings demonstrate that complex III and IV-induced cell death is not mediated by oxidative stress. In contrast, cell death caused by the inhibition of mitochondrial complexes I and II is related to oxidative stress and modulated by the depletion of GSH. TS treatment protects hepatocytes from oxidative damage resulting from the inhibition of mitochondrial complex I. Interestingly, the oxidative damage induced by mitochondrial complex II inhibitor was not prevented by TS, suggesting that TS cytoprotection may be associated with complex II activity. (Supported by NIH grant #R01ES05452.)

767 PHOSPHATIDYLCHOLINE HYDROPEROXIDE DECREASES MITOCHONDRIAL MEMBRANE POTENTIAL AND OXIDIZES CARDIOLIPIN.

M. R. Garry, T. J. Kavanagh and E. M. Faustman. *University of Washington, Seattle, WA.*

Phospholipid hydroperoxide glutathione peroxidase (PHGPx) is a member of the family of selenium dependent enzymes that catalyze the reduction of hydroperoxides, using glutathione or other thiols as reducing substrates. Unlike the three other members of the family, PHGPx can directly reduce membrane phospholipid hydroperoxides. A mitochondrial-targeted form resides in the contact sites between the inner and outer mitochondrial membrane. A previous study using guinea pig cells showed that treatment with phosphatidylcholine hydroperoxide (PCOOH) induces loss of mitochondrial membrane potential ($\Delta\Psi m$) and that overexpression of PHGPx protects against this loss. The present study investigates whether the PCOOH-induced loss of $\Delta\Psi m$ is associated with oxidation of cardiolipin, a mitochondrial membrane phospholipid that is required for function of adenine nucleotide translocator (ANT), a component of the permeability transition pore. Mouse embyronic fibroblasts treated with PCOOH (0, 5, and 50 μM) showed a loss of $\Delta\Psi m$ ($p<0.01$), as indicated by a decrease in CMX-rosamine fluorescence analyzed by confocal imaging. In addition, the loss in $\Delta\Psi m$ was correlated with cardiolipin oxidation, indicated by a decrease in 10-nonyl acridine orange (NAO) fluorescence ($p<0.05$). Cytotoxicity also increased in a dose-dependent manner with PCOOH treatment ($p<0.01$). These results support the hypothesis that PHGPx protects against the loss of $\Delta\Psi m$, at least in part, by protecting mitochondrial membrane cardiolipin. Further studies will examine the interaction between PHGPx, ANT, and formation of the permeability transition pore, with which PHGPx is co-located. (Supported by NIH Grants ES07033 and ES07032.)

768 DOXORUBICIN-INDUCED CUMULATIVE AND IRREVERSIBLE MITOCHONDRIAL DYSFUNCTION.

S. Zhou, A. Starkov and K. Wallace. *Department of Biochemistry and Molecular Biology, and Toxicology Graduate Program, University of Minnesota School of Medicine, Duluth, MN.*

Interference with mitochondrial calcium regulation has been proposed to be a primary causative event to explain doxorubicin-induced cardiotoxicity. We previously reported disruption of mitochondrial calcium homeostasis following chronic doxorubicin administration. The present study was designed to characterize the dose-dependent and cumulative mitochondrial calcium regulation and to assess the reversibility of this functional lesion. Sprague-Dawley rats were treated with 2 mg/kg/wk doxorubicin s.c. for 4-8 weeks. With succinate as substrate cardiac mitochondria isolated from rats after 4 weeks of treatment with doxorubicin expressed a lower calcium loading capacity compared to control. This suppression of calcium loading capacity increased with successive doses to 8 weeks of treatment ($p<0.05$), and persisted for 5 weeks after discontinuation of doxorubicin treatment. The decrease in cardiac mitochondrial calcium loading capacity was not due to bioenergetic changes in the electron transport chain, as the mitochondrial coupling efficiency was not altered by doxorubicin treatment. Preincubation of mitochondria from treated rats with tamoxifen, dithiothreitol, amifostine, or monobromobimane did not reverse the diminished calcium loading capacity. In contrast, incubation with cyclosporin A abolished any discernible difference in mitochondrial calcium loading capacity between doxorubicin-treated and saline-treated rats. Furthermore, it was found that the ADP/ATP translocase content was significantly diminished in mitochondria from rats receiving 8 weeks of doxorubicin treatment. These data indicate that doxorubicin treatment *in vivo* causes an irreversible and dose-dependent decrease in mitochondrial calcium loading capacity. The suppression of adenine nucleotide translocase content is possibly a critical factor responsible for the decreased mitochondrial calcium loading capacity, which in turn may account for the clinically observed cumulative and irreversible loss of myocardial contractility in patients receiving doxorubicin chemotherapy (Supported by NIH grant HL-58016.)

769 EFFECTS OF HYPEROXIA ON LUNG COASH AND COASSG CONCENTRATIONS IN THE RAT.

D. J. O'Donovan, L. K. Rogers, S. E. Welty, P. L. Ramsey and C. V. Smith. *Baylor College of Medicine, Houston, TX.*

CoASH is compartmentalized preferentially in the mitochondria and CoASH and its mixed disulfide with GSH (CoASSG) undergo thiol/disulfide exchange reactions with GSH and GSSG *in vitro*. We measured CoASH and CoASSG in freeze-clamped lung tissues from Fischer-344 (F344) and Sprague-Dawley (SD) rats exposed to >95% O2 or maintained in room air for 48 h to test the hypothesis that oxidant stresses on lung thiol status would be expressed predominantly in the mitochondria. Lung tissue concentrations of CoASH and CoASSG were not different in F-344 or SD rats, but CoASH levels were decreased following hyperoxia (example: F-344 declined from 6.4+/-0.8 to 3.0+/-0.6 nmol/g). The decline in CoASH levels was not accompanied by increases in CoASSG contents, which also declined from 0.9+/-0.15 to 0.5+/-0.13 nmol/g of lung; AcCoA levels were also lower in the lungs of rats exposed to hyperoxia. Lung mitochondrial SDH activities were not diminished in hyperoxia, indicating that the decreases in CoASH are not attributable to general mitochondrial destruction. Pulmonary edema was observed in hyperoxic rats and accounted for some of the declines in CoASH, per g of tissue or per mg of protein, but CoASH contents per total lung also declined. Total lung CoASSG contents were not lower in the rats exposed to hyperoxia, and CoASH/CoASSG ratios were lower in animals exposed to hyperoxia, consistent with an oxidant stress on this thiol/disulfide redox couple. In contrast, lung GSH/GSSG ratios did not decrease, which suggests a mitochondrially compartmentalized oxidant stress response to hyperoxia in the lungs of the rats is consistent with some form of compartmentalization or selectivity in the oxidant stress responses. The mechanisms and pathophysiological consequences of the decreases in lung CoASH levels are not evident from these studies, but the loss of more than half of the tissue contents of this critical biochemical intermediate is likely to generate additional effects.

770 INDUCTION OF THE MITOCHONDRIAL PERMEABILITY TRANSITION *IN VITRO* BY CARBOXYLIC ACIDS.

K. B. Wallace[1] and C. B. Frederick[2]. [1]*University of Minnesota, Duluth, MN and* [2]*Rohm & Haas Co., Spring House, PA.*

Induction of the mitochondrial permeability transition (MPT) has been implicated in the mechanism of tissue injury for a variety of foreign chemicals, including oxidants and weak acids. We recently reported that acrylic acid induces the MPT *in vitro*, which we suggested might be a critical event in the acute inflammatory and hyperplastic response of the olfactory epithelium. The purpose of the present investigation was to determine if induction of the MPT is a general response to short chain carboxylic acids or if there are critical physical chemical parameters for this response. Freshly isolated rat liver mitochondria were incubated in the presence of varying concentrations of selected carboxylic acids. Induction and progression of the MPT was monitored spectrophotometrically. All of the acids that we tested caused a concentration-dependent induction of the MPT, which was blocked by cyclosporine A. Although the C5 carboxylic acids were slightly more potent than the C4 acids, there was no correlation with the degree of saturation, the octanol/water coefficient (logP) or the dissociation constant (pKa) of the acids that we tested. We conclude that induction of the MPT *in vitro* is a general response to short chain carboxylic acids having a pKa of 4-5 and that induction of the MPT may be an important causative factor in the acute inflammatory and/or hyperplastic response to this important class of compounds.

771 DIBROMOACETONITRILE (DBAN), A DRINKING WATER CONTAMINANT, INDUCES OXIDATIVE DAMAGE AND BASE EXCISION REPAIR IN MOUSE FIBROBLASTS.

A. E. Ahmed, K. H. Chen, T. Ngyuen and S. Jacob. *University of Texas Medical Branch, Galveston, TX.*

DBAN, a water chlorination byproduct detected in drinking water is a direct acting genotoxic agent. The mechanisms of DBAN adverse effects are not known. This study examines the mechanism of DBAN effects in mouse fibroblasts (Mβ16tsA) as these cells are widely distributed and participate in several repair processes *in vivo*. Fibroblasts were exposed to various concentrations (5 μM- 40 μM) of DBAN for 10- 240 min. Phase contrast microscopic and morphologic evaluation of DBAN-treated cells indicated features of apoptosis at low exposure levels and severe membrane damages at higher concentrations of DBAN. The data indicate a concentration and time dependent depletion (up to 80%) of total GSH, until 40 min. At later times, however, GSH concentrations were rebound. Malondialdehyde (MDA), was significantly increased (up to 5 fold). Increase in membrane damage was indicated by leakage of lactate dehydrogenase (up to 250% of control) and decreased viability (18% of control). The ability of fibroblasts to undergo DNA repair was studied using base excision repair assay (BER). BER was up regulated in cells exposed to 5μm DBAN for 10 min. and was inhibited at higher concentrations and longer time periods. These studies indicate that DBAN causes oxidative stress leading to membrane and nuclear damage in fibroblasts.

772 THE COMPARABILITY OF THE AMOUNTS OF 8-OXODG ON ISOLATED DNA DETECTED BY THE METHODS USING ELECTROPHORESIS AND HPLC-ECD.

R. Yoshida and Y. Ogawa. *National Institute of Industrial Health, Kawasaki, Japan.*

Quantitative detection of oxidative DNA damage in tissues is an important factor for risk assessment, especially of tumor development. First, 8-oxodG was produced on lambda DNA by methylene blue and visible light. Second, 8-oxodG was cut off by fpg protein enzymatically. And then we measured the number of fpg protein sensitive sites as oxidative DNA damage maker on isolated DNA using electrophoresis developed by Sutherland et al. and compared with the number of damaged DNA, especially 8-oxodG, measured by HPLC-ECD. When we define X as the number of 8-oxodG / 10 to the fifth dG measured by HPLC-ECD method and Y as the number of 8-oxodG / 10 to the fifth dG measured by electrophoresis method, Y and X were fitted to Y=1.19X+0.91 by simple regression analysis. Correlation coefficient was 0.93. Even though the specificity of the electrophoresis method is lower than that of the HPLC-ECD method, the values by two methods were similar. Furthermore, it is considered that this electrophoresis method is more useful than HPLC-ECD method when we measure several oxidative DNA damages at the same time, because we could measure other oxidative DNA damages by changing only DNA glycosylase. We are now planing to establish the measurement of oxidative DNA damages in living cells using electrophoresis method.

773 LIPID PEROXIDATION FORMS N^2,3-ETHENOGUANINE BY DIRECT ALKYLATION: STUDIES USING [$^{13}C_{18}$]-ETHYL LINOLEATE.

A. J. L. Ham[1] and J. A. Swenberg[2]. [1]*Department of Pathology, University of North Carolina, Chapel Hill, NC and* [2]*Department of Environmental Sciences and Engineering and Department of Pathology, University of North Carolina, Chapel Hill, NC.*

Recently, a number of endogenous DNA adducts have been attributed to the reaction of DNA with products of lipid peroxidation. Here we demonstrate that N^2,3-ethenodeoxyguanosine (εG) is formed from the reaction of either deoxyguanosine (dGuo) or calf thymus DNA (ctDNA) with [$^{13}C_{18}$]-ethyl linoleate ([$^{13}C_{18}$]-EtLA) under peroxidizing conditions. [$^{13}C_{18}$]-EtLA was reacted with 200 nmol dGuo in the presence of *tert*-butyl hydroperoxide (t-BuOOH) at 50°C for 24 hr. εG was analyzed by immunoaffinity chromatography-gas chromatography-high resolution mass spectrometry (IA/GC/HRMS) of the pentafluorobenzyl derivative of its base. This reaction, using a 10-fold molar excess of [$^{13}C_{18}$]-EtLA, resulted in a 5700- and 400-fold increase in [$^{13}C_2$]-εG and unlabeled εG, respectively, compared to controls. This same reaction with [$^{13}C_{18}$]-EtLA in equimolar concentration resulted in a 1000- and 130-fold increase in [$^{13}C_2$]-εG and unlabeled εG, respectively, compared to controls. dGuo incubated in the presence of t-BuOOH, but no lipid, resulted in a 60-fold increase in εG, compared to controls. Increases in unlabeled εG suggested an alternative mechanism to direct alkylation by EtLA. To test the hypothesis that deoxyribose oxidation products form εG, dGuo was reacted with equimolar concentrations of [$^{13}C_{18}$]-EtLA and a 10-fold molar excess of thymidine, a source of deoxyribose. This reaction resulted in a 840- and 110-fold increase in [$^{13}C_2$]-εG and unlabeled εG, respectively, compared to controls. The amount of εG formed in the presence or absence of thymidine was comparable suggesting that dGuo was the source of unlabeled εG. In addition, [$^{13}C_{18}$]-EtLA was reacted with 300 μg ctDNA in the presence of t-BuOOH at 37°C for 24 hr. This reaction, using a 10-fold molar excess of [$^{13}C_{18}$]-EtLA, resulted in a 27- and 4-fold increase in [$^{13}C_2$]-εG and unlabeled εG, respectively, compared to controls. These data show εG is formed primarily from direct alkylation by ethyl linoleate under peroxidizing conditions. These data also show εG is formed from an alternative mechanism that may result from dGuo oxidation. (Supported by NIH grants ES07017, ES05779 and ES05948.)

774 REDUCTION OF WHITE BLOOD CELL DNA DAMAGE (COMET ASSAY) BY BLACK TEA CONSUMPTION IN SMOKERS AND NON-SMOKERS.

J. Meng, Y. Xu, B. Ren, L. M. Kamendulis, N. Dum and J. E. Klaunig. *Indiana University School of Medicine, Indianapolis, IN.*

DNA damage can occur in humans following exposure to endogenous and exogenous agents. DNA damage may lead to gene mutation, conformational changes in chromosomes and modulation of gene expression. Since DNA damage has been implicated in the process of tumorigenesis, aging, and other diseases, a reduction of DNA damage is an important strategy for chemoprevention agents. Black tea has been shown to possess antioxidant and anticarcinogenic properties. Using the Comet assay (single cell gel electrophoresis) we examined whether black tea consumption prevented DNA damage in smokers and non-smokers. Volunteers (males and females, 25-35 years of age; cigarette smokers (20 + /day) and nonsmokers) were provided a black tea beverage (2.4~4.8g tea solids) for 2 weeks and a placebo for 2 weeks. After treatment, blood was collected, white blood cells were separated, and assayed for DNA damage using the alkaline comet assay. While variation was seen between individuals, in general, smokers exhibited an increase in the Comet tail length and moment compared to nonsmokers. Consumption of black tea resulted in a significant decrease in Comet tail length and moment in smokers and in nonsmokers. In addition, oxidized purines in the WBC nuclei were also determined by using Fpg (formamidopyrimidine-DNA glycolase) enzyme pretreatment. Smokers showed a significant increase Comet tail length and moment in Fpg treated cells which was reduced following black tea consumption. Similar trends were seen in nonsmokers. These results suggest that black tea consumption had a protective effect against DNA damage (as measured by the Comet Assay) in smokers and non-smokers.

775 THE ROLE OF RAT PLASMA IN MANIFESTING TOXICITY OF ERYTHROCYTES BY MENADIONE: INVOLVEMENT OF REACTIVE OXYGEN SPECIES GENERATION.

S. M. Chung, J. Y. Lee and J. H. Chung. *Seoul National University, Seoul, Republic of Korea.*

Our previous studies have demonstrated that nonenzymatic reaction of menadione with thiols in plasma generated reactive oxygen species, resulting in potentiation of the menadione-induced platelet toxicity. Since menadione, one of the representative quinone compounds, has been reported to cause hemolytic anemia *in vivo*, we hypothesized that erythrocytes could be one of the potential target tissues to menadione in the presence of plasma. To investigate the role of plasma in the erythrocyte toxicity by menadione and to identify reactive oxygen species derived from the reaction of menadione with plasma, rat plasma was treated with menadione sodium bisulfite (MSB), water soluble menadione. Treatment with MSB increased oxygen consumption rate as well as luminol- and lucigenin-amplified chemiluminescence in a dose-dependent manner. The chemiluminescence enhanced by luminol or lucigenin was inhibited by superoxide dismutase (SOD) addition, suggesting that superoxide anions were generated. When erythrocytes were suspended in plasma or buffer, MSB-induced chemiluminescence in plasma was larger than that in buffer, indicating that erythrocytes suspended in plasma were exposed to greater extent of free radicals than those in buffer. Consistent with these findings, we observed MSB-induced hemolysis only in erythrocytes suspended in plasma while not in those suspended in buffer. In order to identify the reactive oxygen species associated with cytotoxicity, various radical scavengers were tested to inhibit MSB-induced hemolysis. Addition with catalase or mannitol resulted in significant inhibition of hemolysis, while SOD had no effect. These results suggest that hydrogen peroxide and hydroxyl radical

rather than superoxide appeared to be involved in erythrocyte cytotoxicity although the reaction of plasma thiols with MSB was accompanied by superoxide generation.

776 PEROXIDATION AND EXTERNALIZATION OF PHOSPHATIDYLSERINE IN PLASMA MEMBRANE OF HL-60 CELLS DURING *TERT*-BUTYL HYDROPEROXIDE-INDUCED APOPTOSIS: ROLE OF CYTOCHROME *C*.

K. Kawai, Y. Tyurina, V. Tyurin, V.E. Kagan and J. Fabisiak. *Dept of Environmental & Occupational Health, Pittsburgh, PA.*

We have previously identified selective phosphatidylserine (PS) oxidation as a potential signaling pathway preceding PS externalization in apoptotic cells following oxidant exposure. Here we address the subcellular localization and potential mechanism of PS oxidation during oxidant-induced apoptosis. We found that 20 min exposure of HL-60 cells to 150 μM *tert*-butyl hydroperoxide (*t*-BuOOH) was sufficient to induce apoptosis as shown by DNA fragmentation and changes in nuclear morphology. Apoptosis was accompanied by the translocation of cytochrome *c* from mitochondria to cytosol, as well as, activation of caspase-3. Lipid peroxidation in individual phospholipid classes was monitored using the oxidation-sensitive fluorescent fatty acid, *cis*-parinaric acid, metabolically incorporated in cellular phospholipids. Oxidation of major phospholipids, including phosphatidylcholine (PC) and phosphatidylethanolamine, was also observed 40 min after the 20-min *t*-BuOOH treatment. PS oxidation, however, was significantly greater than in other phospholipids and was accompanied by PS externalization determined by fluorescamine labeling of externalized aminophospholipids. Analysis of phospholipid oxidation in various subcellular fractions obtained after *t*-BuOOH treatment revealed that PS in plasma membrane was oxidized to a greater extent than PS contained in other cell organelles. HL-60 cells were "loaded" with exogenous cytochrome c in the presence of mild sonication. Selective oxidation of PS was observed after cytochrome *c* loading alone and was especially marked when "loaded" cells were challenged with *t*-BuOOH. Using a cell-free model system we observed that cytochrome c/H_2O_2 could effectively oxidize arachidonyl residues in purified PS but not in PC. Thus, selective PS oxidation during oxidant-induced apoptosis occurs in plasma membrane and may, in part, be mediated through the redox activity of cytochrome *c* released into the cytosol. PS oxidation may be a component of apoptotic signaling pathways serving to modulate PS externalization within the plasma membrane.

777 LIPID PEROXIDATION CAUSED BY SELENOCYSTINE AND ITS ENHANCEMENT BY INHIBITOR OF SELENIUM METHYLATION IN MICE.

Y. Seko[1], H. Hosaka[1], K. Takahashi[2] and T. Hasegawa[1]. [1]*Yamanashi Institute of Environmental Sciences, Fujiyoshida, Japan and* [2]*Japan Animal Care, Meguro, Japan.* Sponsor: K. Nakamuro.

Selenocystine can be decomposed to selenide, and then selenide can be methylated to dimethyl selenide or trimethylselenonium ion *in vivo*. The methylation is regarded as detoxification process, because these methylated selenium compounds are excreted into exhalation and urine, respectively. On the other hand, selenide has the potency to generate active oxygen species if selenide reacts with oxygen molecule, and the lipid peroxidation is one of possible mechanisms of selenium toxicity. The effects of a methylation inhibitior, periodate-oxidized adenosine (PAD), on the lipid peroxidation and toxicity by selenocystine were examined in the present investigation in mice. Serum glutamate oxaloacetate transaminase (GOT), hepatic lipid peroxide (thiobarbituric acid reactive substances; TBA-RS), and content of selenium in the liver increased in a dose dependent manner six hours after the administration of selenocystine at a dose of 0, 10, 20, or 40 micromole/kg orally. Co-administration PAD with selenocystine increased GOT, TBA-RS, and the content of selenium in the liver significantly as compared with those of mice treated with selenocystine alone. Selenocystine also increased blood urea nitrogen (BUN), but not TBA-RS in the kidney; co-administration of PAD did not increase BUN nor TBA-RS. These results suggest that lipid peroxidation, possibly caused by selenide, is involved in the manifestation of toxicity of selenocystine in the liver.

778 METABOLISM OF 4-HNE BY RAT KUPFFER CELLS.

S. W. Luckey and D. R. Petersen. *University of Colorado Health Sciences Center, Denver, CO.*

The importance of Kupffer cells in CCl_4 and ethanol-induced liver damage has recently been demonstrated. Common to both of these animal models of hepatotoxicity is the cytotoxic process of lipid peroxidation. Lipid peroxidation is a cellular process that releases aldehydic products such as *trans*-4-hydroxy-2-nonenal (4-HNE), and is believed to play a major role in liver damage. 4-HNE is believed to directly activate Kupffer cells, resulting in production of biologically active products that modulate inflammatory responses, tissue and matrix remodeling, and regulate hepatocyte function. In order to determine whether freshly isolated rat Kupffer cells have the capacity to metabolize 4-HNE, we analyzed this cell type for alcohol dehydrogenase (ADH), aldehyde dehydrogenase (ALDH), and glutathione-*S*-transferase (GST) enzyme systems. Spectrophotometric analysis of ADH and ALDH enzyme activity determined that activity in Kupffer cells is difficult to quantitate through this particular method. Total GST enzyme activity was also determined spectrophotometrically using 1-chloro-2, 4-dinitrobenzene as a substrate. GST activity observed was 103±5.4 μmol/min/mg protein. Immunoblots demonstrate that Kupffer cells contain GST classes Ya, Yb, and P1-1, as well as ADH Class I and Class II ALDH. HPLC measurements of 4-HNE metabolism studies were conducted in freshly isolated Kupffer cells in which the cells were treated with 25μM 4-HNE. These studies indicate that 4-HNE is metabolized in a biphasic manner with a production of 4-hydroxy-2-nonenoic acid suggesting involvement of the ALDH enzyme system. These data suggest that Kupffer cells may have the capacity to metabolize and detoxify 4-HNE. (Supported by NIAAA F31 AA05536-02.)

779 EFFECT OF THE OXIDATIVE STRESS PRODUCED BY ETHANOL, ACETALDEHYDE AND ENDOTOXIN ON INTERLEUKIN-8 SECRETION BY HEPG2 CELLS.

L. Gómez-Quiroz, B. Farfán, M. C. Escobar and M. C. Gutiérrez-Ruiz. *Universidad Autónoma Metropolitana-Iztapalapa, México, D.F., Mexico.*

Chronic inflammatory responses, associated with large neutrophil influxes, occur following acute or chronic liver injury in response to a variety of hepatotoxic chemicals and infectious agents. Oxidative stress play an important role in these events. Cytokines, particularly tumor necrosis factor-α (TNF-α), and chemokines, such as interleukin-8 (IL-8), are important regulators of hepatic injury and repair following the insult. The objetive of the present work was to study the effect of oxidative stress produced by ethanol (EtOH), acetaldehyde (Ac) and LPS on IL-8 secretion by HepG2 cells. Cells were treated during 24 h with 50 mM EtOH, 175 μM Ac or 1μg/ml of LPS. Neutral red probe and MTT assay were performed to study the physiological damage produced by the toxics. Lipid peroxidation damage was determined by MDA production in the presence of thiobarbituric acid. GSH content was determined by Ellman's reaction and SOD activity by Winterbourn method. IL-8 secretion was determined by ELISA. Lisosomal damage, determined by neutral red probe, showed that EtOH treatment produced a 17% and Ac 41% decrease of OD comparing with control values. MTT assay resulted in an increase of 15% in EtOH and 43% in Ac of OD in control values. Lipid peroxidation damage increased 30% in EtOH, 43% in Ac and 33% in LPS comparing with control cells. GSH content decreased in 31% with EtOH, 42% with Ac and 21% with LPS. SOD activity diminished in all treatments, presenting the lower value the Ac treated cells. IL-8 secretion was determined in presence of the toxics, and the effect 10 mM of antioxidant N-acetyl-L-cysteine (NAC) and 1,1,3,3-tetramethyl-2-thiourea (TMTU) and policlonal anti-human TNF-α were also studied. IL-8 secretion increased 38% in EtOH, 41% in Ac and 38% in LPS treated cells. Both antioxidant treatments showed a decrease under control values in IL-8 secretion. Anti TNF-α treatment produced also a decrease in IL-8 secretion. GSH protects against oxidative damage, and oxidative stress has been associated with a decrease in these levels. In our study GSH content decreased while lipid peroxidative damage increased. SOD activity was also diminished as a result of hepatotoxic damage. HepG2 cells readily responded to antioxidant agents and anti TNF-α to control IL-8 secretion, an evidence that oxidative stress is a mediator in IL-8 production. An indirect participation of TNF-α in this process was also evaluated showing that is an important mediator of damage in this process.

780 EFFECTS OF BLEOMYCIN (BLM) ON LIVER ANTIOXIDANT ENZYMES AND THE ELECTRON TRANSPORT SYSTEM FROM *AD LIBITUM* AND DIETARY RESTRICTED FEMALE AND MALE FISCHER 344 RATS.

V. G. Desai, A. Aidoo, J. Li, L. E. Lyn-Cook and R. J. Feuers. *National Center for Toxicological Research/FDA, Jefferson, AR*. Sponsor: W. Slikker, Jr.

Dietary Restriction (DR) is the only known intervention that delays aging and age-related diseases. Among the proposed mechanisms are: lowering free radical production, increased free radical detoxification and/or removal of oxidatively damaged macromolecules. In the present study, the effect of BLM on antioxidant enzymes and the electron transport system (ETS) complexes has been evaluated in different cellular fractions of liver in female and male Fischer 344 rats. Animals were fed *ad libitum* (AL, n=5) or 60% of the AL intake (DR, n=5) for 6 weeks. A single intra peritoneal injection of either 2.5, 5 or 10 mg BLM/kg body weight was given to rats at 20 weeks of age and they were sacrificed 4 weeks after a drug treatment. BLM significantly increased glutathione peroxidase and lactate dehydrogenase activities in liver cytosol of male AL rats more than in females. Similar changes were also noted for glutathione reductase and glucose 6-phosphate dehydrogenase activities in BLM-treated AL rats. Drug treatment had no significant effect on these enzyme activities in DR animals. In liver mitochondria, glutathione peroxidase was increased in female and male AL rats, but more so in females. Profound effects of BLM were noted in activities of complexes I, III and IV of ETS, in both AL and DR female and male rats; however, complex II demonstrated no significant diet or treatment effect. Induced antioxidant enzyme activities in BLM-treated AL rats may be a response to excessive free radical generation due to BLM metabolism in AL animals that is mitigated by DR. Further, dysfunction of ETS due to altered complexes I, III and IV (but not complex II) might suggest its role in a secondary mechanism for generation of free radicals during BLM metabolism contributing to its toxicity in AL animals which was modulated by DR.

781 *IN SITU* DETECTION OF QUINONE-INDUCED REACTIVE OXYGEN SPECIES PRODUCTION IN INTACT CULTURED HEPATOCYTES USING LUMINOL CHEMILUMINESCENCE.

F. Boess and U. A. Boelsterli. *F. Hoffmann-La Roche Ltd., Nonclinical Drug Safety, Basel, Switzerland.*

Luminol-enhanced chemiluminescence (LCL) has been widely used to measure the production of reactive oxygen species (ROS) in cell-free systems or in subcellular fractions. Quantitative determination of drug-induced increased ROS production in intact cells has, however, remained difficult. We adapted the LCL method for measurement of ROS production in intact cultured hepatocytes because increased ROS production has been implicated in cell signaling and hepatic toxicity of numerous drugs. Short-term cultured murine hepatocytes were incubated with the redox-cycling agent menadione (2-methyl-1,4-naphthoquinone, MNQ). In the presence of luminol (10 μM) and horseradish peroxidase (13 U/ml) LCL was quantitated on-line with a thermostated chemiluminescence plate reader. MNQ-induced LCL increased non-linearly in a concentration- and temperature-dependent manner. Both catalase and dimethylthiourea strongly attenuated the signal, indicating that the signal is largely dependent on the presence of hydrogen peroxide. To further validate the method, other quinones, including 1,4-benzoquinone (BQ), 1,4-naphthoquinone (NQ), and 2,3-dimethoxy-1,4-naphthoquinone (DMNQ), were used. As expected, ROS production was most pronounced in the presence of MNQ and DMNQ followed by NQ, whereas exposure of hepatocytes to BQ exhibited no detectable ROS production. These findings are in accordance with the known redox-cycling activities of DMNQ and MNQ and the increasingly prevailing arylating capacities of NQ and BQ. The data demonstrate that different quinones can be differentiated with respect to their ROS-producing capacities and that LCL measurements allow for a reliable detection and quantitation of drug-induced ROS production in intact cultured hepatocytes.

782 OXIDANT STRESS IN RAT LIVER FOLLOWING LIPOPOLYSACCHARIDE ADMINISTRATION: ROLE OF NITRIC OXIDE.

C. Zhang, L. M. Walker and P. R. Mayeux. *University Arkansas Medical Sciences, Little, AR.*

The role of inducible nitric oxide synthase (iNOS) in LPS-induced hepatic injury was evaluated using the iNOS inhibitor L-iminoethyl-lysine (L-NIL). Male rats (250 g) were divided into three groups. One group received LPS (S. minnesota) 2 mg/kg i.v. A second group received LPS plus L-NIL (3 mg/kg i.p.) at the time of LPS administration followed by a second dose 3 hr later. A third group received saline i.v. At 6 hr, the rats were killed by an overdose of pentobarbital. Blood and liver were collected. Serum nitrate/nitrite (metabolic products of NO) levels (n=5) were increased from 5.4±1.5 nmole/ml in the saline group to 360±48 nmole/ml in the LPS group. Values for the LPS+L-NIL group was significantly reduced to 35±7 nmole/ml. Tissue malondialdehyde levels were increased from 0.20±0.02 nmole/mg (n=4) in the saline group to 0.41±0.03 (n=4) in the LPS group. L-NIL significantly reduced the values to 0.29±0.02 nmole/mg (n=4). 4-Hydroxylnonenal protein adducts levels were increased 3.6 fold by LPS treatment as compared to saline. L-NIL significantly reversed the levels to 1.6 fold (n=4). Intracellular glutathione levels were decreased from 8.49±0.64 nmole/mg (n=4) in the saline group to 5.63±0.51 nmole/mg in the LPS group (n=7). L-NIL significantly increased the levels to 7.04±0.46 nmole/mg (n=7). These data indicate that LPS-induced NO generation can result in oxidant stress in the liver and that inhibitors of iNOS may offer some protection in LPS-induced hepatic toxicity.

783 EFFECT OF N-ACETYLCYSTEINE AND α-TOCOPHEROL IN OXIDATIVE STRESS INDUCED BY LIPOPOLYSACCHARIDE AND ACETAMINOPHEN IN MICE.

J. H. Cho, S. H. Jeong and J. M. Park. *National Veterinary Research & Quarantine Service, Anyang, Republic of Korea*. Sponsor: J. Chung.

Lipopolysaccharide, an endotoxin produced by gram negative bacteria, has been known to induce endotoxemia in human and animals. Hyperthermia, anorexia, fatigue and tachycardia, etc. are well known symptoms observed in the case of endotoxemia.Acetaminophen is widely used as an antipyretic drug but its side effects of hepatotoxicity and oxidative damage are concerned.In this study, we investigated the profile of oxdative stress induced by lipopolysaccharide (LPS) and acetaminophen (AC) in mice with the indices of glutathione (GSH), glutathione disulfide (GSSG), malondialdehyde (MDA), superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPX) in serum or in liver of mice. And then, the anti-oxidative effects of N-acetylcysteine (NAC) or α-tocopherol (TC) on the oxidative stress induced by LPS or AC single or combined treatment.GSH and GSSG in serum and liver were decreased but MDA in liver was increased at 48 hours after the second treatment of LPS(5, 10 mg/kg B.W., ip). GSH in serum was decreased but GSSG in serum and GSH and GSSG in liver were decreased at 4hours after the 8th treatment of clinical dosage of AC(35 or 105mg/kg B.W., 2times per day for 4days orally). NAC(2 or 5 mmol/kg, ip) inhibited the GSH decrement and MDA increment induced by LPS and the decrement of GSH induced by AC. TC inhibited the increment of GSSG and MDA induced by LPS but showed none effect on the oxidative stress induced by AC. Finally, the decrease of GSH induced by LPS was inhibited more effectively by the combined treatment of AC and NAC than single treatment of AC and the increase of MDA induced by LPS was inhibited more effectively by the combined treatment of AC and TC than single treatment of AC.These results show oxidative stress induced by LPS can be alleviated by combined treatment of NAC or TC with the common antipyretic agent, AC.

784 PEROXYNITRITE CONTRIBUTES TO OZONE-INDUCED LUNG INJURY.

L. Fakhrzadeh[1], C. R. Gardner[1], A. L. Salzman[2], G. J. Southan[2], J. D. Laskin[1] and D. L. Laskin[1]. [1]*Rutgers University, Piscataway, NJ and* [2]*Inotek, Boston, MA.*

Inhalation of ozone (O_3) causes epithelial cell damage and Type II cell hyperplasia. This is associated with the accumulation of macrophages in the lower lungs which have been shown to contribute to toxicity. Alveolar macrophages (AM) release a number of mediators with cytotoxic potential including nitric oxide and superoxide anion. These can react leading to the formation of peroxynitrite, an even more potent oxidant. To analyze the role of these mediators in O_3 toxicity we used transgenic animals lacking the gene for inducible nitric oxide synthase (NOSII) or overexpressing the gene for superoxide dismutase (SOD). Treatment of wild type control animals with O_3 (0.8-1 ppm) for 3 hr resulted in an increase in bronchoalveolar lavage (BAL) fluid protein reaching a maximum 24-48 hr after exposure. This was correlated with increased expression of NOSII protein and mRNA by alveolar macrophages and increased production of nitric oxide as well as peroxynitrite. O_3 inhalation also resulted in the appearance of nitrotyrosine staining in the lungs, a marker of peroxynitrite damage. In contrast, BAL protein was not increased in NOSII knockout mice or SOD overexpressors demonstrating that these mice were protected from O_3 induced epithelial injury. Moreover, AM from the transgenic mice did not produce increased amounts of nitric oxide or perox-

ynitrite even after O_3 inhalation. There was also no evidence of nitrotyrosine staining in the lungs. These data suggest that O_3 induced lung injury is mediated by peroxynitrite. To test this possibility directly we used a peroxynitrite scavenger, aminoethylselenourea (AESeU). AM from wild type control mice pretreated with AESeU (10-30 mg/kg) twice daily for three days produced significantly less nitric oxide than cells from ozone treated mice, and produced negligible quantities of peroxynitrite. Mice pretreated with AESeU were also protected from O_3 induced tissue injury as evidenced by reduced BAL fluid protein and the absence of nitrotyrosine staining. Taken together these data demonstrate that peroxynitrite contributes to O_3 toxicity. (Supported by ES04738, ES06897& Burroughs Wellcome Fund.)

785 NITRIC OXIDE-INDUCED COPPER DELIVERY BY METALLOTHIONEINS TO APO-SUPEROXIDE DISMUTASE.

S. Liu[1], J. Fabisiak[1], V. Tyurin[1], G. Borisenko[1], B. Pitt[2], J. Lazo[2] and V. Kagan[1]. [1]*University of Pittsburgh, Department of Environmental & Occupational Health, Pittsburgh, PA and* [2]*University of Pittsburgh, Depart. of Pharmacology, Graduate School of Medicine, Pittsburgh, PA.*

In mammalian metabolic pathways, toxicity of excess copper is prevented by its sequestration in: (i) the metal-binding metallothioneins (MT), or (ii) export via the copper-translocating ATPases. How effective are metallothioneins in these copper sequestration mechanisms and how are they linked to other mechanisms of copper regulation is unknown. We studied Cu transfer from Cu-MT to apo/Zn-SOD in cell-free model system and found that Cu_5-MT and Cu_{10}-MT were able to reconstitute SOD activity only in the presence of a nitric oxide donor, (Z)-[N-(3-ammoniopropyl)-amino]-diazen-1-ium-1,2-diolate (NOC-15). The percentage of reconstitution by Cu_5-MT and Cu_{10}-MT was 34% and 83% respectively, compared with that reconstituted by free Cu. Non-denaturing PAGE staining for SOD activity and protein showed that reconstitution of enzymatically active protein and shift from non-Cu containing band to 2-Cu containing bands only occurred in the presence of NOC-15 for both Cu_5-MT and Cu_{10}-MT. 2, 2'-Dithiodipyridine titration of MT SH-groups showed a 70% decrease after incubation with NOC-15. The transfer of Cu from Cu-MT to apo/Zn-SOD was not accompanied by enhanced Cu-dependent generation of ascorbate radicals or hydroxyl radicals as measured by EPR spectroscopy. Cu chelation assay using bathocuproine sulfonate (BCS) showed that NOC-15 induced reconstitution of apo/Zn-SOD did not require release of free Cu (from Cu_5-MT). Overall, our results suggest Cu-MT may function in a nitric oxide-dependent physiologic pathway for delivery of Cu to apo-SOD.

786 FREE RADICAL MEDIATED MECHANISMS OF METHYLCYCLOPENTADIENYL MANGANESE TRICARBONYL (MMT)-INDUCED DOPAMINERGIC TOXICITY IN PC12 CELLS.

J. R. Wagner[1], V. Anantharam[1], P. G. Gunasekar[2] and A. G. Kanthasamy[1]. [1]*UC Irvine, Irvine, CA and* [2]*Purdue University, W. Lafayette, IN.*

Despite the known neurotoxic effects of manganese on the dopaminergic system, methylcyclopentadienyl manganese tricarbonyl (MMT) has recently been legalized for use as a fuel additive in the United States. Data regarding the mechanism of action of this organic manganese compound on the CNS is greatly needed for appropriate risk assessment. It has been shown that MMT is a mitochondrial toxin, and inhibits aerobic respiration at Complex I in isolated mitochondria. Previously, we have shown that MMT dose-dependently increases cytotoxicity, extracellular dopamine (DA), and reactive oxygen species (ROS) in PC12 cells, an *in vitro* model of dopaminergic neurotoxicity. In order to further understand the causal factor in this toxicity, these endpoints were examined after 15 min pretreatment with antioxidants followed by MMT challenge. After exposure to MMT for 1 hr, cytotoxicity was measured by either the Trypan Blue Dye Exclusion Assay or by the LDH release method, DA was measured by HPLC-EC, and ROS were measured by the 2,7-dichlorofluorescin method. It was determined that Trolox, a Vitamin E analogue, prevents ROS formation, and also protects the cells against MMT-induced cytotoxicity. Further mechanistic studies in our lab have shown that MMT treatment causes NF-κB translocation, caspase activation, PKC translocation/cleavage and cytochrome C release within 2 hours of exposure, and these changes are consistent with mitochondrial damage and ROS mediated cell death. These data indicate that free radical-mediated mechanisms may be operative in MMT-induced dopaminergic toxicity, and further studies are being undertaken to determine if exposure could initiate or accelerate neurodegenerative processes that lead to dopaminergic disorders such as Parkinson's disease.

787 EXPOSURE OF H441 CELLS, A PULMONARY-DERIVED CELL LINE, TO 7-KETOCHOLESTEROL LEADS TO CYTOTOXICITY, WHICH IS PRECEDED BY INCREASES IN INTRACELLULAR GLUTATHIONE DISULFIDE (GSSG) CONTENTS.

S. E. Welty, K. T. Hougland, L. K. Rogers, H. W. McMicken and C. V. Smith. *Baylor College of Medicine, Houston, TX.*

Premature infants commonly develop severe chronic lung disease, which is called bronchopulmonary dysplasia (BPD). The histological characteristics of BPD are arrested lung growth, lung cell damage and fibrosis. There is abundant evidence that BPD develops, in part, as a consequence of oxidant stress to the lung. However, the mechanisms by which oxidant stresses mediate cell injury and altered cell growth are unknown. Oxysterols, which are products of oxidation of cholesterol, have been studied in the context of atherogenesis and have been found to lead to cytotoxicity that was associated with alterations in cellular glutathione (GSH) contents and increased formation of reactive oxygen species. In preliminary studies, we detected oxysterols in the tracheal aspirate samples of intubated newborn infants. The purpose of the present study was to test the hypotheses that a specific oxysterol, 7-ketochosterol, mediates cytotoxicity in a pulmonary-derived cell line, and that the cytotoxicity is preceded by alterations in cellular GSH and/or GSSG contents. We exposed H441 cells, a transformed human lung cell line with characteristics of Clara cells, to 0, 5, 10 or 50 nmol/ml of 7-ketocholesterol for up to 48 h. At each time point, cell and media LDH activities were determined, as well as cellular contents of GSH and GSSG. We found that media LDH activities doubled in the plates of cells exposed to 50 nmol/ml for 24 h and in the plates of cells exposed to 10 nmol/ml for 48 h, suggesting that these two doses of 7-ketocholesterol lead to significant cytotoxicity. Cellular LDH activities were also diminished in plates of cells exposed to the two highest doses of 7-ketocholesterol. Surprisingly, there was no effect of 7-ketocholesterol on cellular GSH contents in any of the plates of cells. However, cellular GSSG contents showed a marked dose response to 7-ketocholesterol as early as 12 h of exposure (1.91±0.03 vs. 2.46±0.12, vs. 3.26±0.58, vs. 4.40±0.73 in cells exposed to 0, 5, 10 and 50 nmol/ml respectively, $P<0.05$). These surprising early increases in cellular GSSG contents in cells exposed to 7-ketocholesterol suggest that the compound's cytotoxicity is mediated through a rapid increase in cellular peroxide production, or by attenuating the reduction or export of GSSG from the cells. Studies to determine mechanisms for the increases in cellular GSSG levels mediated by 7-ketocholesterol are warranted and may lead to important mechanistic insights into the cellular basis for cytotoxicity mediated by 7-ketocholesterol.

788 A PRELIMINARY STUDY ON THE EFFECTS OF DIETARY VITAMIN E AND C SUPPLEMENTATION ON ANTIOXIDATIVE ENZYMES IN RATS.

K. F. Shireen[1], R. D. Pace[1], A. Atkinson[2], T. C. Graham[2], M. Green[2] and A. T. Khan[2]. [1]*CAENS and* [2]*CVMNA, Tuskegee University, Tuskegee, AL.*
Sponsor: R. R. Dalvi.

The aim of this study was to evaluate the effect of high levels of dietary supplementation of vitamin E and C on the antioxidant status of rat tissues [pectoralis major (PM), sartorius (S) and Liver (L)]. Male rats were fed either Control (rodent diet), vitamin C (VC) supplemented, vitamin E (VE) supplemented or combination of vitamin E and C (CVEC) supplemented diets for 28 days. At the end of experiment, all rats were sacrificed and PM, S and L tissues were analyzed for selected antioxidative enzymes, catalase (Cat) and gluthathione peroxidase (GPx) levels were assayed. GPx activity was lower in PM with VC, VE, and CVEC supplementation when compared to control. GPx activity was lower in S with both VC and VE and was higher with the CVEC. GPx activity was lower in L with VE and showed no changes when compared to other diets or with control. Cat activity in PM was higher with all vitamin supplementations when compared to control. Cat activity in S was higher in both VC and CVEC. However, VE increased Cat activity in S compared to control. This preliminary data indicates that dietary supplementation of VC and CVEC increased Cat activity. Whereas the supplementation of VC, VE and the CVEC reduced the activity of GPx in both Pm and S.

789 ANTIOXIDANT LOADING PROTECTS FROM BLAST OVERPRESSURE-INDUCED OXIDATIVE STRESS.

N. M. Elsayed, K. L. Armstrong, M. T. Williams and M. F. Cooper. *Walter Reed Army Institute of Research, Washington, DC.*

Detonation of explosives or firing of large caliber weapons during military operations or training and occupational high energy impulse noise, produce blast overpressure (BOP) waves characterized by rapid rise in atmospheric pressure above ambient. Exposure to BOP waves can cause injury, predominantly to the hollow organs accompanied by hemorrhage, edema, and hypoxia. We observed in rats that BOP induces free radical-mediated oxidative stress characterized by antioxidant depletion, increased lipid peroxidation, and decreased hemoglobin (Hb) oxygenation. We examined whether loading the rats with pharmacological doses of antioxidants can protect from BOP. Sprague-Dawley rats weighing 300-350 g were loaded with vitamin E (vE), vitamin C (vC) or lipoic acid (LA) for 3 consecutive days before a BOP exposure. Antioxidants were administered by gavage using 2-ml vehicle (corn oil or distilled water) alone or containing 800 IU vE, 25 mg LA or 1000 mg vC. Each regimen was subdivided into 4 groups (6 rats/group): vehicle control and exposed, and antioxidant control and exposed. After the 3-day loading, all rats were deeply anesthetized with sodium pentobarbital, then the exposed groups were subjected to a low-level BOP at 62±2 kPa peak pressure of 5 msec duration. One hour after exposure, the rats were euthanized then blood and lungs were analyzed for biochemical alterations. We found that antioxidant loading resulted in elevated Hb oxygenation, decreased lipid peroxidation, and smaller lung weight increases. These observations suggest that preloading with pharmacological doses of antioxidants for only three days can alleviate BOP-induced oxidative stress. The order of antioxidant efficacy was vE>LA>vC. These observations have clinical and occupational implications.

790 FREE RADICAL SCAVENGING *VS* BCL-2 INDUCTION IN ANTIAPOPTOTIC EFFECT OF ESTROGENS IN MCF-7 BREAST CANCER CELLS.

Y. Y. Tyurina, V. A. Tyurin, N. F. Schor and V. E. Kagan. *Department of Environmental & Occupational Health, Pediatrics and Pharmacology, University of Pittsburgh, Pittsburgh, PA.*

Since estrogens are known to act as radical scavengers their antiapoptotic activity may be related the antioxidant effects. Alternatively, this activity may be due to estrogen receptor- and estradiol-induced overexpression of the antiapoptotic gene, *bcl-2*. To experimentally resolve these alternative pathways we studied long-term and acute effects of estrogens on phospholipid peroxidation induced in MCF-7 human breast cancer cells by a lipid-soluble azo initiator of peroxyl radicals 2,2'-azobis(2,2-dimethylvaleronitrile), AMVN (addition of 10^{-8}-$5x10^{-7}$M estradiol to the medium immediately or for 14 days preceding AMVN treatment). Incubation of control MCF-7 cells with AMVN resulted in oxidation of major phospholipid classes: phosphatidylinositol (PI), phosphatidylserine (PS), phosphatidylethanolamine (PE) and phosphatidylcholine (PC). Acute exposure of MCF-7 cells to estradiol resulted in protection against AMVN-induced oxidation of PI and PS, and a trend towards such protection of PE and PC. Long-term exposure to estradiol caused selective protection of PS, whose oxidation is a critical component of the final common pathway for apoptosis. Not surprisingly, protection of PS was accompanied by a 2-fold decrease in the percentage of cells demonstrating apoptotic morphology after a 24 h exposure to AMVN. Additionally, long-term exposure to estradiol yielded an increase in GSH level in MCF-7 cells while short-term incubation had no effect of GSH content. Our results indicate that estrogens may act as both free radical scavengers and antiapoptotic agents in breast cancer cells.

791 MYELOPEROXIDASE-CATALYZED ONE-ELECTRON GENERATION OF ETOPOSIDE PHENOXYL RADICALS IN VIABLE HL60 CELLS.

A. A. Kuzmenko[1,2,3], J. C. Yalowich[1], W. P. Allan[1] and V. E. Kagan[2]. [1]*Environmental & Occupational Health, Universisty Of Pittsburgh, Pittsburgh, PA,* [2]*Pharmacology Department, University Of Pittsburgh, Pittsburgh, PA and* [3]*A.V. Palladin Institute of Biochemistry, Ukranian National Academy of Sciences, Kiev, Ukrain.*

Etoposide (VP-16), a widely used phenolic antitumor drug, is also known to cause secondary acute myeloid leukemias. We hypothesized that VP-16 genotoxicity is associated with its one-electron oxidative metabolism to its phenoxyl radical catalyzed by myeloperoxidase (MPO) in bone marrow progenitor cells. Our previous work demonstrated that both purified MPO and MPO activity in homogenates of human leukemia HL60 cells were able to catalyze formation of VP-16 phenoxyl radicals in the presence of H_2O_2. In the present study, we attempted to identify conditions compatible with the detection of VP-16 phenoxyl radicals in viable HL60 cells. We found that VP-16 phenoxyl radical could be directly observed in HL60 cells by EPR spectroscopy if: (i) MPO activity was sufficiently high (≥ 10 nmol quaiacol/min/10^6 cells), (ii) endogenous GSH was substantially depleted (> 75% by 5 min preincubation with a maleimide SH reagent, ThioGlo™-1), and (iii) endogenous catalase was inhibited (by pretreatment with 3-amino-1,2,4-triazole). In HL60 cells grown in the presence of an inhibitor of heme synthesis, succinyl acetone (SA, 500 μM), both decreased MPO activity and VP-16 phenoxyl radical production was observed. Importantly, a significantly enhanced VP-16-induced formation of DNA/topoisomerase II complexes was found in HL60 cells under conditions where GSH concentration was depleted by 54% as a result of ThiolGlo™-1 treatment (1.0 μM, 5 min) and VP-16 phenoxyl radical was immediately detectable by EPR. We conclude that VP-16 phenoxyl radical formation may be essential for VP-16-induced geno- and cytotoxicity through either their direct effects on topoisomerase II and/or indirectly on intracellular GSH.

792 REDOX-CYCLING OF PHENOLS CAUSES DEPLETION OF GSH, OXIDATIVE STRESS AND CYTOTOXICITY IN NORMAL HUMAN EPIDERMAL KERATINOCYTES (NHEKS).

E. R. Kisin[1], C. Kommineni[1], Y. Y. Tyurina[2], V. A. Tyurin[2], D. Schwegler-Berry[1], V. Castranova[1], V. E. Kagan[2] and A. A. Shvedova[1]. [1]*HELD/NIOSH, Morgantown, WV and* [2]*Departments of EOH & Pharmacology, University of Pittsburgh, Pittsburgh, PA.*

Exposure to phenolic compounds is associated with neuro-, myelo-, immuno-, geno-, and dermotoxicity. In skin, phenols cause rash and inflammation, contact and irritant dermatitis, leucoderma and cancer promotion. The biochemical mechanisms responsible for cytotoxicity of phenolic compounds are not well understood. We hypothesized that the cytotoxic effects of phenolic compounds are due, at least in part, to the generation of phenoxyl radicals via their enzymatic one-electron oxidation which alters the intracellular pool of GSH and protein sulfhydryls. To test this hypothesis, we measured cell viability, intracellular levels of GSH and protein SH-groups, as well as lipid peroxidation in NHEKs exposed to twelve different phenolic compounds. We found that an 18 h incubation of cultured NHEKs in the presence of 100-500 μM 1,4-benzenediol (hydroquinone), *o*-hydroxybiphenyl (2-phenylphenol), bis-(4-glycidyloxyphenyl)-methane, bis (4-hydroxyphenyl)-dimethylmethane (bisphenol A), 4-*tert*-butylcatechol, 1,2-benzenediol (catechol), *iso*-eugenol (2-methoxy-4-propenylphenol), eugenol (4-allyl-2-methoxyphenol) or phenol caused pronounced cytotoxicity and significant depletion of GSH. In addition, concentration-dependent cell detachment, loss of cell-cell contacts, and disruption of the cellular membrane were observed. Importantly, the phenolic compounds that did not decrease thiol levels, such as 3-n-pentadecylphenol, 4-*tert*-butylphenol, or bis (4-hydroxyphenyl) methane, did not induce cytotoxicity after a 18 h treatment. Incubation of ascorbate-preloaded keratinocytes with phenols produced an EPR-detectable signal of ascorbate radicals indicating that redox-cycling of the one-electron oxidation product of phenol, its phenoxyl radical, is likely involved in these oxidative effects. While phenolics are known to act as radical scavengers, their enzymatically formed metabolites, phenoxyl radicals, can react with vital thiol reductants and cause cytotoxic effects.

793 OXIDATIVE STRESS FOLLOWING TRAUMATIC BRAIN INJURY IN RATS: ASCORBATE RADICAL AS A TOOL TO DETECT FREE RADICAL ACTIVITY.

V. A. Tyurin, Y. Y. Tyurina, G. G. Borisenko, M. Rose, D. Bonislawski, S. Graham and V. E. Kagan. *Departments of Environmental and Occupational Health, Pharmacology and Neurology, University of Pittsburgh, Pittsburgh, PA.*

Several studies failed to detect generation of oxygen radicals following traumatic brain injury (TBI) using ESR of spin traps. We attempted to detect any spin adducts of oxygen radicals in the ESR spectra of brain samples taken at different times after TBI (1.0, 2.5, and 6 hr) from animals injected with high doses of DMPO (ip, 80 mmol/kg). We found that the concentration of DMPO in the brain 1 h after injection was ≈10.0 mmol/kg and declined by 6h to ≈2.0 mmol/kg. We demonstrated that endogenous ascorbate was able to outcompete DMPO as the radical scavenger, hence prevent any detection of DMPO adducts with oxygen radicals. We used a catalytic system to generate hydroxyl radicals (H_2O_2/Fe^{2+}) in brain homogenates in which we manipulated concentrations of DMPO and endogenous ascorbate (using ascorbate oxidase).

The formation of DMPO-OH adducts was detectable after elimination of ascorbate by ascorbate oxidase. In all other conditions, only ESR signal of ascorbate radical was readily discernable in the spectra. We further utilized ascorbate as an endogenous spin trap in the brain. We found that 1.5, 4 and 6 h after trauma brain homogenates produced higher steady-state concentrations of ascorbate radicals than controls. Accordingly, the content of ascorbate was significantly lower in the samples of traumatized brain than in the controls (53.9 in control vs 34.8 nmol ascorbate/mg protein vs 6 hr after trauma, respectively). We conclude that monitoring ascorbate radical formation in oxidatively challenged brain is instrumental for detection of free radical activity.

794 PHOSPHINE-INDUCED OXIDATIVE DAMAGE IN RATS.

C. Hsu. *Taipai Medical College, Taipei, Taiwan, Republic of China.*

Phosphine (PH_3), from hydrolysis of aluminum, magnesium and zinc phosphide, is an insecticide and rodenticide. Earlier observations on PH_3-poisoned insects, mammalian cell lines and humans led to the proposed involvement of oxidative damage in the toxic mechanism. This investigation focused on PH_3-induced oxidative damage in rats and antioxidants as candidate protective agents. Male Wistar rats were treated ip with PH_3 at 2 mg/kg. Thirty min later the brain, liver, and lung were analyzed for glutathione (GSH) levels and lipid peroxidation (as malondialdehyde and 4-hydroxyalkenals) and brain and lung for 8-hydroxydeoxyguanosine (8-OH-dG). PH_3 caused a significant decrease in GSH concentration and elevation in lipid peroxidation in brain (36-42%), lung (32-38%) and liver (19-25%) and significant increase in 8-OH-dG in brain (70%) and liver (39%). Antioxidants administered ip 30 min before PH_3 were melatonin, vitamin C and β-carotene at 10, 30 and 6 mg/kg, respectively. The PH_3-induced changes were significantly or completely blocked by melatonin while vitamin C and β-carotene were less effective or inactive. These findings establish that PH_3 induces and melatonin protects against oxidative damage in the brain, lung and liver of rats and suggest the involvement of reactive oxygen species in the genotoxicity of PH_3.

795 6-HYDROXYDOPAMINE RELEASES IRON FROM SERUM TRANSFERRIN: OXYGEN RADICAL PRODUCTION AND TOXICITY.

V. E. Kagan[1], G. E. Borisenko[1], C. J. Hsia[4] and N. Schor[3]. *University of Pittsburgh, Department of [1]Environmental & Occupational Health, [2]Pharmacology, [3]Pediatrics and Neurology, Pittsburgh, PA and [4]University of Pittsburgh and Synzyme Technology, Pittsburgh, PA.*

The dopamine analogue, 6-hydroxydopamine (6-OHDA), is selectively toxic to catecholaminergic neurons. Because of its selectivity for neuroblastic cells in the sympathetic nervous system, 6-OHDA has been suggested as a chemotherapeutic agent for targeted treatment of patients with neuroblastoma. We tested the hypothesis that toxicity of 6-OHDA is caused by its interaction with serum ferric-transferrin (Fe-TF) resulting in release of iron, that through its redox-cycling by 6-OHDA triggers generation of reactive oxygen species. 6-OHDA-induced release of iron from Fe-TF was demonstrated by: 1) Decay of the characteristic low-temperature EPR signal of Fe-TF (g=4.3) and appearance of the high-spin signal from iron chelated by 6-OHDA oxidation products. 2) Spectrophoto-metrically-detectable complex of iron with Fe^{2+} chelator, ferrozine. 3) Redox-cycling of ascorbate yielding EPR-detectable ascorbate radical formation. 4) Generation of hydroxyl radicals as evidenced by EPR of its adduct with a spin trap, DMPO. In human plasma, 6-OHDA caused iron release only under nitrogen but not under air or oxygen. The absence of 6-OHDA effect in plasma under aerobic conditions was due to its ferroxidase activity (hence, reuptake of Fe(III) by apo-TF) and catalytic oxidation of 6-OHDA by ceruloplasmin. Modeling of these plasma activities by a stable nitroxide radicals, TEMPOL, resulted in protection of plasma Fe-TF against iron release under nitrogen. Parenteral administration of 6-OHDA to mice resulted in iron release from Fe-TF as evidenced by transformation of the Fe-TF EPR signal that was indistinguishable from that seen *in vitro*. Administration of the iron chelator, deferoxamine, to mice prior to administration of toxic doses of 6-OHDA resulted in a decrease in activity impairment of mice as compared to that seen with 6-OHDA alone. These findings suggest that iron-chelators may be used for prevention of 6-OHDA toxicity.

796 SUPEROXIDE RADICALS ARE INVOLVED DURING REDUCTION OF ALAMAR BLUE.

C. L. Rabideau and H. P. Misra. *Virginia-Maryland Regional College of Veterinary Medicine, VA Tech, Blacksburg, VA.*

AlamarBlue (AB; Alamar Biosciences, Inc.), a fluorogenic compound, is used to assess cell proliferation and cell-mediated cytotoxicity in various mammalian and bacterial cells. Because the AB assay offers the advantages of technical simplicity, freedom from radioisotopes and reproducibility and sensitivity, it is now the method of choice for assessing cellular phenomena. However, the mechanism(s) of such reduction by cellular activity has not been elucidated. We found that superoxide radicals (O_2-), generated by xanthine oxidase (X.O.) acting on xanthine, were able to reduce AB and this reduction was found to be susceptible to inhibition by superoxide dismutase (SOD) at pH 6.0, as well as at pH 7.0. The rate of reduction of AB by xanthine + X.O., and sensitivity of this reduction to inhibition by SOD were both pH-dependent. The iron-chelator desferoxamine (10^{-4}M), hydroxyl radical scavenger mannitol (6 mM), and catalase (1,000 units), all had trivial effects on the rate of AB reduction. EPR spectroscopy in combination with spin trapping techniques, using the X.O. system in the presence of DMSO to generate O_2- and DMPO as a spin trapping agent, was used to monitor the O_2- scavenging ability of AB. In this assay, AB was found to inhibit DMPO-O_2- adduct formation in a dose-dependent manner. These data clearly demonstrate that AB is a potent scavenger of O_2- and assays utilizing AB, to assess the metabolic activity of cells, may actually be monitoring the intracellular production of O_2-.

797 TOCOPHERYL SUCCINATE CYTOPROTECTION IS ASSOCIATED WITH A UNIQUE UPTAKE ADVANTAGE IN ISOLATED RAT HEPATOCYTES.

F. A. Nicholls-Grzemski, M. A. Tirmenstein, J. G. Zhang, N. M. Naslund and M. W. Fariss. *Department of Pharmaceutical Sciences, Washington State University, Pullman, WA.*

Previous studies from our laboratory have demonstrated that administration of 25 μM tocopheryl succinate (TS) completely protects hepatocyte suspensions from the toxic effects of ethyl methanesulfonate (EMS). EMS is an alkylating agent that depletes cellular glutathione resulting in lipid peroxidation and cell death and has an onset of action approximately 90 minutes after exposure. In contrast to TS, protection toward EMS was not observed with administration of equimolar tocopherol (T) or tocopheryl acetate (TA). We propose that the selective cytoprotection afforded by TS is associated with the rapid uptake and subsequent hydrolysis of TS to T in mitochondria, the subcellular source of reactive oxygen species in EMS toxicity. To test this hypothesis, we measured cellular and mitochondrial T levels by HPLC in hepatocytes exposed to TS, T and TA. Unfortunately, the lipophilic nature of vitamin E prevented an accurate assessment of these compounds in cell homogenate and subcellular fractions. We therefore determined the cellular and mitochondrial antioxidant capacity as a measure of active T incorporation using a novel fluorimetric lipid peroxidation assay which examines the susceptibility of membranes to ferrous/ADP:ascorbate (FeAs) prooxidant stress. Results from these studies showed that hepatocytes incubated with TS were completely protected against FeAs-induced lipid peroxidation within 1 h, as were the mitochondria isolated from these cells. In contrast, hepatocytes required over 2 h incubations with T and TA to provide significant resistance to FeAs-induced lipid peroxidation. Thus the antioxidant capacity of hepatocytes and mitochondria from incubations with T, TS or TA correlated with the relative protective abilities of these compounds toward EMS toxicity. We conclude that the rapid uptake and hydrolysis of TS in mitochondria results in enhanced antioxidant protection of mitochondria and hepatocytes against the acute toxic effects of EMS. (This work was supported by NIEHS/NIH grant # R01ES 05452.)

798 FREE RADICAL INVOLVEMENT IN THE POTENTIATION OF NOISE INDUCED HEARING LOSS (NIHL) BY CARBON MONOXIDE (CO).

D. B. Rao and L. D. Fechter. *University of Oklahoma-Health Sciences Center, Oklahoma City, OK.*

Potential hypotheses for cochlear toxicity following simultaneous exposure to noise and carbon monoxide (CO) includes free radical involvement. Simultaneous exposure to noise and CO results in potentiation of noise induced hearing loss (NIHL) by CO. In this study, protective effects of phenyl-*N-tert*-butylnitrone (PBN - a known free radical scavenger) against potentiation of NIHL by CO has been demonstrated. In addition, electroparamagnetic spectroscopy (EPR) was used to demonstrate the presence of free

radicals in the cochlea. Auditory sensitivity was evaluated in Long Evans hooded rats exposed to conditions that show optimum potentiation. Treatment groups included rats administered PBN(ip) pre- *and* post-combined exposure to noise and CO. In addition, protective effects seen with this pre- *and* post-combined exposure treatment were compared to protective effects of PBN when administered only post combined exposure versus repeated administration post combined exposure. End-points evaluating auditory sensitivity included compound action potential (CAP) and cochlear microphonic (CM). Results demonstrate effective protection of PBN when administered pre and post combined exposure. Partial protection was obtained with post administration of PBN and with repeated post administration of PBN. EPR spectra revealed PBN adducts with trapped free radicals in animals exposed to noise and CO. These results show that toxic pathways involved in the potentiation of noise induced hearing loss (NIHL) by CO includes free radicals which are generated early in the process of combined exposure. Occupational exposure to noise and CO is common in work environments of fire-fighters and automobile/aircraft workers Elucidation of these mechanisms is relevant not only to set exposure limits in work environments, but also in order to develop effective preventive and protective regimens. (This study was supported by NIOSH grant #03481 and NIEHS grant ES 08082 to L D Fechter. Additional support was obtained through a cooperative agreement with NSF EPSCoR program [EPS9550478].)

799 EFFECTS OF *PLUCHEA SYMPHYTIFOLIA* IN CHOLESTEROL AND TRIGLYCERIDES BLOOD LEVELS.

M. Morales-Gonzalez and L. Santos. *Pontifical Catholic University of Puerto Rico, Ponce, PR.*

Pluchea symphytifolia is a common plant around the world. It has been used as stimulant, diuretic, tonic and digestion helper. This investigation studied the effect of Pluchea symphytifolia in cholesterol and triglycerides levels in blood samples taken from CF-1 mice. Thirty five (35) male mice from the species CF-1 were divided in seven groups with 5 mice in each group. Group Control I had a diet based on rabbit food with 2% of cholesterol and was treated with 12.5% plant extract. Control II-A had a normal diet and water. Control II-B had food elevated in lipids and drink only water. Experimental groups were divided in two groups of 10 mice (I and II). One group received a normal diet (I) and the other group a diet elevated in lipids (II). Each group was then subdivided in two groups (IA, IB, IIA and IIB). Experimental Groups IA and IIA were treated with 12.5% extract and Experimental Groups IB and IIB with 7.5% extract. Food and treatment was ad libitum. Blood samples from the eyes were taken initially(before starting the treatment), two weeks and four weeks after the treatment. The experiment duration was six weeks. Results indicate a significant decrease on triglycerides levels after the treatment. Also, they suggest some decrease an cholesterol levels. Further studies in relation to cholesterol levels will be performed in order to established blood levels decrease.

800 COMPARISON OF CYTOTOXIC EFFECTS OF OCHRATOXIN A AND B ON HUMAN, RAT AND PORCINE RENAL CELLS.

A. Heussner[1], M. Stack[2], K. Hochberg[3] and D. R. Dietrich[1]. [1]*Environmental Toxicology, University of Konstanz, Konstanz, Germany,* [2]*Food and Drug Administration, Washington, DC and* [3]*Urology, Klinikum Konstanz, Konstanz, Germany.*

Chronic dietary intake of ochratoxin A (OTA) via contaminated food (bread, beer, coffee, wine, meat) has been associated with increased incidences of urothelial tumors and nephropathy in humans (e.g., Balkan Endemic Nephropathy, BEN). It has also been demonstrated to be carcinogenic in rodents, with distinct species- and sex-differences in susceptibility. The mechanism(s) leading to these sensitivity differences have yet to be elucidated. This study investigated the cytotoxic effects of OTA and its structural analogue OTB on primary renal cortex cells from humans (biopsy material), both sexes of F344 rats, and from improved German hybrid pigs. Furthermore, a porcine renal cell line, LLCPK-1, was used for comparison. Cells were exposed to OTA and OTB at concentrations ranging from 1 nM to 100 μM for 24 to 96 hours. Following incubation several cytotoxicity endpoints were assessed: Neutral red uptake, MTT reduction and cell number analyses (Coulter counter) to show differences in proliferation. Supravital fluorescent staining techniques as well as electron microscopy were employed to detect toxin induced morphological changes. A range of fluorescent labeled antibodies to cytoskeletal proteins (e.g., vimentin, cytokeratins, actin, talin, tubulin) were used to demonstrate OTA- and OTB-induced morphological changes. Although all cells showed similar toxin induced morphological changes, distinct species-differences were observed in respective sensitivities: porcine kidney cells > human kidney cells > rat kidney cells/ LLCPK-1.

801 INTER-SPECIES VARIATIONS IN OCHRATOXIN A PROTEIN BINDING AND UPTAKE.

D. R. Dietrich[1], E. O'Brien[1], A. Heussner[1], M. Stack[2], K. Hochberg[3] and B. W. Day[4]. [1]*Environmental Toxicology, University of Konstanz, Konstanz, Germany,* [2]*Food and Drug Administration, Washington, DC,* [3]*Urology, Klinikum Konstanz, Konstanz, Germany and* [4]*Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

Chronic dietary intake of ochratoxin A (OTA) via contaminated food (bread, beer, coffee, wine, meat) has been associated with increased incidences of urothelial tumors and nephropathy in humans (e.g., Balkan Endemic Nephropathy, BEN). It has also been demonstrated to be carcinogenic in rodents, with distinct species- and sex-differences in susceptibility. The mechanism(s) leading to these sensitivity differences have yet to be elucidated. The aims of this study were to investigate the possibility that such differences could arise due to variations in OTA protein binding and/or uptake. Protein binding studies were carried out with a classical competitive assay using [3H]OTA and homogenates from human, porcine, rat and mouse renal cortex tissue. Species-specific binding capacities were observed: human >> rat > pig > mouse. OTA bound human and porcine homogenates with higher affinity than rat and mouse with regard to competition with bromosulftophthalein (BSP). Concentration-dependent inhibition of [3H]OTA binding was also seen with piroxicam, indomethacin, nalidixic acid, ethacrynic acid, furosemide and probenecid, but not with fumonisin B1, para-amminohippurate (PAH) and several bile acids. [3H]-OTA uptake was measured over 60 min in human (HKC) and porcine (PKC) primary renal epithelial cells and in NRK52E and LLCPK-1 cell lines. Uptake over time remained relatively constant, however, distinct differences were observed in the amount of [3H]-OTA taken up by the different cell types. Both HKC and PKC displayed a 10-15 fold higher uptake than that observed in LLCPK-1 and NRK-52E cells.

802 ANTIPROLIFERATIVE AND CELL CYCLE SPECIFIC EFFECTS OF OCHRATOXIN A IN LLCPK-1, NRK-52E AND PORCINE PRIMARY PROXIMAL KIDNEY CELLS.

S. B. Dreger[1], E. O'Brien[1], M. Stack[2] and D. R. Dietrich[1]. [1]*Environmental Toxicology, University of Konstanz, Konstanz, Germany and* [2]*Food and Drug Administration, Washington, DC.*

Ochratoxin A (OTA) is a mycotoxin produced as a secondary metabolite by certain Aspergillus and Penicillium species. It is commonly found as a contaminant of both human and animal foodstuffs. All human blood samples tested to date have proved positive for OTA. Average daily intake in humans is estimated to be approximately 5–10ng/kg. OTA has been demonstrated to induce nephropathy as well as to be immunotoxic in pigs (antiproliferative effect in T-cells) and teratogenic in several species including rat, mouse, hamster and chick. Although little is known about its potential for human teratogenesis, OTA displays similarities in animal models to other well-characterized human teratogens e.g., valproate and thalidomide, especially with respect to dose-dependency and gestational sensitivity periods. A disruption in the normal cellular proliferation control could contribute to the observed induction of nephropathy, immunotoxicity and teratogenicity of OTA. Therefore, the effect of OTA on proliferation rates of LLCPK-1, NRK-52E and porcine primary proximal kidney cells (PKC) following acute exposure was investigated. Cells were exposed to increasing concentrations of OTA over 24, 48 and 72hrs. Antiproliferative effects were determined using a Coulter counter. The concentration producing a 50% proliferative arrest (GI50) in LLCPK-1 and NRK-53E cells lines was 21mM, with PKCs displaying a GI50 of 15mM. Standard flow cytometric analysis of propidium iodide stained DNA was used to investigate the nature of this growth inhibitory effect. OTA was found to increase the percentage of cells residing in the G2/M phases of the cell cycle. More detailed analysis, (fluorescence-microscopic mitotic index of Hoechst-stained DNA) demonstrated no increased numbers of cells in M-phase thus suggesting an OTA mediated specific blockade of the cell cycle located to the G2 phase in all three cell types.

803 A COMPARISON OF RECONSTITUTION TIMES FOR CROTAB AND ANTIVENIN (*CROTALIDAE*) POLYVALENT [WYETH].

R. E. Hill[1], G. M. Bogdan[2] and R. C. Dart[2]. [1]*University of Colorado Health Sciences Center, Denver, CO and* [2]*Rocky Mountain Poison and Drug Center-Denver Health, Denver, CO.*

Background: Both antivenom products have been shown to be effective in patients with crotalid snake envenomation. It is generally believed that the less purified Wyeth antivenom requires more time to dissolve in its diluent than the CroTAb antivenom, but there is no literature available to support or dispute this perception. **Objective:** To compare the reconstitution times for CroTAb and Wyeth antivenom by randomized analytical and blinded observational methodology. Methods: In the first phase, three vials of each antivenom were injected with 10 ml of recommended diluent, and then 10 ul aliquots of antivenom were taken from all vials at 5 minute intervals from 0 to 90 minutes. The samples were diluted, randomized and spectrophotometrically analyzed according to the method of Bradford (1976) as modified by Pierce using the Coomassie Plus Protein Assay Reagent. In the second phase, time required for complete dissolution of five vials of each antivenom was empirically judged by three medical professionals at 5-minute intervals for a 90-minute duration. **Results:** Two Factor ANOVA indicated there was a statistically significant difference over time ($p<0.001$) and between each group ($p<0.002$) based on the reconstitution/time curves for each antivenom in the analytical phase. In the observational phase the average time to reconstitution for CroTAb was 38 minutes (SD+12 min.), but none of the Wyeth vials were determined to be reconstituted at the end of the 90-minute trial. The higher proportion of CroTAb vials reconstituted within 90 minutes was statistically significant (two-tailed Fisher?s Exact test, $p=0.008$). **Conclusions:** CroTAb had a significantly shorter reconstitution time by both analytical determination and clinical observation. Since the time required for each product to dissolve into solution delays treatment, a significant difference in reconstitution time would be clinically useful in determining antivenom selection.

804 EXPRESSION OF INDUCIBLE NITRIC OXIDE SYNTHASE AND INFLAMMATORY CYTOKINES BY α-HEDERIN IN MACROPHAGES.

C. Y. Choi[1], H. K. Kim[1], K. H. Yang[2] and H. G. Jeong[1]. [1]*Chosun University, Kwangju, Republic of Korea and* [2]*KAIST, Taejon, Republic of Korea.*

α-Hederin, a triterpenoid saponin which exists in some oriental herbs, was known to decrease the hepatotoxicity of cadmium by inducing expression of metallothionein. However, the mechanism(s) by which α-Hederin induces metallothionein is not well investigated. Inflammatory cytokines, such as TNF-α, IL-1β, and IL-6, and nitric oxide were suggested as mediators of up-regulation of metallothionein. In the present study, we investigate the role of inflammatory cytokines and iNOS in α-Hederin-induced up-regulation of the metallothionein in murine peritoneal macrophages. The induced expression of metallothionein in α-Hederin-treated cells was accompanied by increase of transcripts for IL-1β, IL-6, TNF-α, and iNOS in a dose-dependent manner by RT-PCR analysis. The increase in NO, as demonstrated by measurement of nitrite was found to correlate well with an increase in transcripts of iNOS. Since the promoter in IL-1β, TNF-α, and iNOS gene contains binding motifs for NF-κB/Rel, the effect of α-Hederin on the activation of this transcription factor where determined. Using DNA fragments containing the NF-κB/Rel binding sequence, α-Hederin was shown to activate the protein/DNA binding of NF-κB/Rel to its cognate site as measured by electrophoretic mobility shift assay. Collectively, the results of these experiments indicate that expression of IL-1β, IL-6, TNF-α, and iNOS were induced by α-Hederin and these results show that the inflammatory cytokines and iNOS that are induced by α-Hederin may play an important role in the α-Hederin-induced up-regulation of metallothionein. (Supported by KOSEF Grant 981-0505-028-2 and 1999-2-214-002-5.)

805 EFFECTS OF HEPATIC CYTOCHROME P450 BY GLYCYRRHIZIN AND GLYCYRRHETINIC ACID.

H. G. Jeong[1], H. K. Kim[1], C. Y. Choi[1] and K. H. Yang[2]. [1]*Chosun University, Kwangju, Republic of Korea and* [2]*KAIST, Taejon, Republic of Korea.*

There have been numerous reports of the antihepatotoxic activity of glycyrrhizin, a triterpenoid saponin of Glycyrrhiza glabra L. as well as its genuine aglycon, 18beta-glycyrrhetinic acid, but little attention has been paid to regarding to its effects of cytochrome P450 (P450). Therefore, in this study, we investigate the effects of glycyrrhizin and 18beta-glycyrrhetinic acid on the constitutive and inducible microsomal activities and expression of P450 in rat. The administration of glycyrrhizin and 18beta-glycyrrhetinic acid to rats significantly decreased the activities of microsomal pentoxyresorufin O-dealkylase and aniline hydroxylase, representative activities of P4502B1/2 and P4502E1, respectively, in a dose- and time-dependent manner. However, ethoxyresorufin O-deethylase and methoxyresorufin O-demethylase, a representative activity of P4501A1 and P4501A2, respectively, was decreased to a lesser extent. Glycyrrhizin and 18 beta-glycyrrhetinic acid also decreased inducible monooxygenase activities in the same manner. Suppressions of P450 isozyme expression occurred in glycyrrhizin and 18beta-glycyrrhetinic acid treated hepatic microsomes, as determined by immunoblot analysis in a manner consistent with that of the enzyme activity levels. These results suggest that glycyrrhizin and 18beta-glycyrrhetinic acid may act as a more specific suppressor for P4502B1/2 and P4502E1 than P4501A/2. (upported by KOSEF Grant 981-0505-028-2 and 1999-2-214-002-5.)

806 COUMARIN DOES NOT INDUCE UNSCHEDULED DNA SYNTHESIS (UDS) IN THE *IN VIVO* RAT HEPATOCYTE DNA REPAIR ASSAY.

A. J. Edwards, R. J. Price, A. R. Renwick and B. G. Lake. *TNO BIBRA International Ltd., Carshalton, United Kingdom.*

In this study we have examined the ability of coumarin to induce UDS in hepatocytes after *in vivo* administration to male Sprague-Dawley CD rats. From a preliminary toxicity study, the oral maximum tolerated dose (MTD) of coumarin was determined to be 320 mg/kg body weight. In the UDS study rats (n=3 per group) were treated with single oral 32, 107 and 320 mg/kg (i.e., $^1/_{10}$, $^1/_3$ and $^1/_1$ MTD) doses of coumarin. Negative controls were treated with corn oil and positive controls with either 20 mg/kg dimethylnitrosamine (DMN, for the 2-4hr expression of UDS) or 50 mg/kg 2-acetylaminofluorene (2-AAF, for the 12-16 hr expression of UDS). Hepatocytes were isolated by liver perfusion either 2-4 hr or 12-16 hr after treatment. The cells (viability 85-91%) were cultured in medium containing [^{3}H]thymidine for 4 hr and then in medium containing unlabelled thymidine for 12-24 hr. UDS was quantified by grain counting of autoradiographs. Coumarin at doses of 32, 107 and 320 mg/kg had no significant effect on UDS in rat hepatocytes either 2-4 hr or 12-16 hr after dosing. In contrast, significant increases in UDS were observed in hepatocytes from rats treated with either DMN for 2-4 hr or 2-AAF for 12-16 hr. Net grain counts were significantly increased from -0.33 to 5.69 and from -0.03 to 11.44 by treatment with DMN and 2-AAF, respectively. Both genotoxins also increased the percentage of hepatocyte nuclei with >5 and >10 net grains. These results demonstrate that coumarin does not induce UDS in hepatocytes of male Sprague-Dawley CD rats after oral administration at doses up to the MTD of 320 mg/kg. (Conducted as part of a Coumarin Research Program and supported by RIFM, Inc., IFRA (Geneva, Switzerland), IOFI (Geneva, Switzerland) and Rhodia Inc.)

807 SAFETY RISK ASSESSMENT OF THE MYCOTOXIN PATULIN IN APPLE JUICE AND APPLE JUICE PRODUCTS.

S. H. Henry, M. J. DiNovi and P. M. Bolger. *FDA, Washington, DC.*

Patulin is a highly toxic heterocyclic lactone, produced by a variety of molds including *Penicillium* and *Aspergillus*. Patulin can be found in various apple products, and is associated with moldy apples used for juice production. Patulin inhibits protein synthesis and impairs several enzymes, including alcohol dehydrogenases, and mixed function oxidases. Rodent carcinogenicity studies have yielded inconclusive results. No documented cases of human illness associated with patulin have been observed. However, the FDA has estimated a Tolerable Daily Intake (TDI) of 0.43 μg/kg bw based upon application of a 100-fold safety factor to the No Observed Adverse Effect Level observed in a 109 week gastric intubation patulin study in the rat. Because of patulin's toxicity and the large consumption of apple juice and apple juice products by U.S. children particularly in relation to their body weight, the FDA has proposed setting a limit of 50 ppb for patulin. To estimate this limit, apple juice consumption data from the 1987-88 USDA National Food Consumption Survey (NFCS), and patulin levels from 1660 samples of apple juice were used to estimate exposure. At the 50 ppb limit, all age categories, including infants and young children, are adequately protected, *i.e.*, are exposed to levels of patulin equal to or below the TDI, even a two year-old 90th percentile consumer.

808 SAFETY/RISK ASSESSMENT OF THE CONSUMPTION OF PEAR BRANDIES CONTAINING METHANOL.

S. A. Assimon[1], S. M. Dugar[2] and P. M. Bolger[1]. [1]*Food and Drug Administration, Washington, DC and* [2]*Bureau of Alcohol, Tobacco and Firearms, Rockville, MD.*

Some pear brandies can contain methanol (MeOH), a compound associated with pronounced visual and central nervous system toxicity. This assessment addresses the potential health hazards of acute and chronic consumption of pear brandy due to MeOH exposure. Various pear brandy products (n=134) were analyzed for MeOH content by gas chromatography with a flame ionization detector. The MeOH content of these products ranged from 0.03 to 0.87 (mean = 0.41) % volume. The estimate of exposure to MeOH from brandy consumption was based on brandy MeOH content and point estimates of brandy intake (USDA, CFSII, 1989-1992). Mean and 90-99th percentiles of the average MeOH exposures were estimated for one-day and chronic consumption of brandy. The tolerable daily intake (TDI, mg/kg/day) for MeOH for one-day exposure is 7.1 (human NOAEL, FDA, 1984) and for chronic exposure is 0.5 (RfD, IRIS, EPA, 1993). The average single-day exposure to MeOH from ingestion of pear brandy was at or below the TDI for the mean, 90th and 95th percentile brandy intake levels, but exceeded it at the 99th percentile level. One-day MeOH exposure for the 134 individual pear brandies exceeds the one-day TDI 7.5, 46.3, 51.5, 85.1% of the time at the mean, 90th, 95th and 99th percentile intake levels, respectively. The average chronic exposure to MeOH from pear brandies exceeds the chronic TDI at several intake percentiles (mean, 90-99th). Thus, the possibility exists that some pear brandy products at some exposure levels of varying duration may represent a hazard to human health.

809 DETERMINATION OF AD50 AND LD50 OF *CLERODENDRON SIPHONANTHUS* LEAF EXTRACT FOR ANTIFERTILITY AND MORTALITY OF *CALLOSOBRUCHUS CHINENSIS* (L.) BY TOPICAL, DIPPING AND INJECTION METHODS.

S. K. Pandey[1] and M. B. Khan[2]. 1*C.S.J.M. University, Rae-bareli-229001, India.* Sponsor: D. Acosta, Jr.

AD50 with the effect of *Clerodendron siphonanthus* leaf extract on hatchability has been noted. These median antifertility doses are 0.7828ug./weevil, 0.4682% per weevil and 0.5346% per weevil in topical, dipping and injection (12ug/weevil) methods respectively. Probit analysis for dose response data for *Clerodendron siphonanthus* showed that linear relation ship existed between the concentration (Log X) and percentage antifertitlity induced (Probit Y). LD50 was observed with effect of antifertility agent *Clerodendron siphonanthus* leaf extract during hatchability i.e. 0.8217 µg per weevil, 0.5164 percent per weevil 0.4813 percent per weevil in topical, dipping and injection (12ul per weevil method respectively). Probit analysis showed that a linear relation ship existed in between the concentration (Log X) and percentage mortality induced (Probit Y), AD50-Antifertility dose, LD50-Lethal dose.

810 DISTURBANCES IN CA^{2+} SIGNALING FOLLOWING AROCLOR® 1254 INVOLVE INTRA- AND EXTRACELLULAR CA^{2+} POOLS IN A TEMPORALLY DISTINCT SEQUENCE.

J. R. Inglefield, W. R. Mundy and T. J. Shafer. *USEPA, Research Triangle Park, NC.*

Polychlorinated biphenyls (PCBs) are ubiquitous, persistent bio-accumulative toxicants (PBTs) that affect many types of cells and for which alterations of intracellular Ca^{2+} homeostasis is a recurring theme. Using single cell, fura-2 ratio fluorescence imaging we recently reported that addition of Aroclor 1254 (A1254; UltraScientific Inc.) to developing neocortical cells (maintained in culture < 8 days) resulted in an immediate, transient increase of intracellular Ca^{2+} (latency < 0.5 min, duration 3.9 ± 0.3 min) followed 3-16 min later by the onset of recurring Ca^{2+} oscillations (duration, 10-30 sec each). These later disturbances were dependent on extracellular Ca^{2+} and blocked by the L type voltage-gated Ca^{2+} channel (VGCC) antagonist, nifedipine (1 µM) (Soc. Neurosci. Abstr. 25, 500.17). Here, the initial Ca^{2+} transient was studied and found to be concentration-dependent (1- 25 µM), reaching 1 -1.5 µM intracellular [Ca^{2+}] with 20 µM A1254 from a basal level of 0.1 µM. The source of Ca^{2+} during the initial transient (intra- vs. extracellular) was localized to intracellular pools since neither Ca^{2+}-depleted buffer (in presence of 1 mM EGTA) nor pre-treatment with nifedipine (1 µM) prevented the initial increase of intracellular [Ca^{2+}] by A1254 (20 µM). Following administration of thapsigargin (10 µM for 10 min) to deplete intracellular Ca^{2+} stores, both carbachol-stimulated intracellular Ca^{2+} release and the A1254 -induced Ca^{2+} transient were blocked. Current studies are focused on determining the involvement of specific intracellular stores (e.g. ryanodine- or IP_3- sensitive). Effects of PCB congeners were structure-dependent wherein addition of ortho-substituted PCB 4 and PCB 138, but not the non-ortho substituted PCB 15, PCB 77, or PCB 126 (10 µM each), also caused this initial Ca^{2+} transient. These observations are consistent with A1254 causing an initial transient which is dependent on intracellular Ca^{2+} stores, followed by Ca^{2+} oscillations which are dependent on extracellular Ca^{2+} and mediated by L-type VGCC. (This abstract does not necessarily reflect US EPA policy.)

811 ACUTE EXPOSURE TO PCB153 AND PCB28 SUPPRESSES LONG-TERM POTENTIATION IN HIPPOCAMPAL SLICES.

M. E. Gilbert. *USEPA, Research Triangle Park, NC.*

Long-term potentiation (LTP) is a model of synaptic plasticity that encompasses the physiological changes associated with memory. We have demonstrated a reduction in hippocampal LTP in adult rodents whose exposure to PCBs was restricted to the perinatal period (Gilbert and Crofton, 1999). LTP has also been shown to be involved in activity-dependent synapse formation at very early stages of hippocampal development (Durand et al., 1996). The present study examined the effects of acute exposure to two ortho-substituted congeners (PCB28, PCB153) on synaptic plasticity *in vitro*. Hippocampal slices were prepared from adult male rats and maintained in physiological buffer for 2 hrs prior to recording. Stimulating electrodes were placed in stratum radiatum of area CA1. Evoked field potentials were recorded from the CA1 pyramidal cell layer and the stratum radiatum. No change in population spike (PS) amplitude recorded from pyramidal cells was evident in slices maintained in 0.2% DMSO vehicle, PCB 153 (3 and 10µM) or PCB28 (10µM) over a 60 min recording period. LTP (15 100 Hz 4-pulse bursts) was induced 1-2 hrs after exposure to PCB-containing medium. Potentiation of the PS was reduced by 10µM PCB28. PCB153 also demonstrated a trend for reduced PS LTP at concentrations of 3 and 10µM. To the extent that functional synapse induction and LTP are mechanistically similar processes (Durand et al., 1996), the acute action of PCBs to suppress LTP may disturb synaptogenesis when PCBs are present during hippocampal development following *in vivo* dosing. Altered synaptic networks may contribute to a reduced capacity to support LTP in the adult offspring of PCB-exposed dams. (This abstract does not necessarily reflect US EPA policy.)

812 DEVELOPMENTAL EXPOSURE TO A1254 ALTERS SYNAPTIC TRANSMISSION IN THE DENTATE GYRUS *IN VIVO*.

J. L. Blanton, M. M. Taylor, K. M. Crofton and M. E. Gilbert. *USEPA, Research Triangle Park, NC.*

Previous work has demonstrated a reduced capacity to support long-term potentiation (LTP) in animals exposed to a PCB mixture, Aroclor 1254 (A1254) (Gilbert and Crofton, 1999). Assessment of "normalized" input/output (I/O) functions collected prior to LTP induction failed to reveal differences in baseline synaptic transmission between control and PCB-exposed groups. The present study was designed to systematically evaluate excitatory and inhibitory synaptic transmission using a more extensive I/O analysis and tests of paired pulse depression. Pregnant dams were exposed to 6 mg/kg/day of A1254 from GD6 to PND21. This dosage of A1254 produces perinatal hypothyroxenemia, hearing loss, and impaired LTP in offspring. Adult male offspring were anesthetized with urethane and stimulating and recording electrodes placed in the perforant path and dentate gyrus. An ascending series of 15 stimulus intensities was delivered (100-1500µA) to the perforant path. Population spike (PS) amplitudes recorded in the dentate gyrus were slightly but significantly enhanced in PCB-exposed animals relative to controls only in the midrange intensities. No group differences were observed in EPSP slope amplitudes. Inhibitory synaptic transmission was assessed by delivering pairs of stimulus pulses at 5 intervals (IPI=10-70 msec) and 3 intensities (50, 80,100% maximum). Paired pulse depression was decreased at the intermediate IPIs (20 and 30ms), a change restricted to the lowest stimulus intensity. These data demonstrate subtle alterations in synaptic function in hippocampus as a result of early PCB exposure. These data support previous conclusions that PCB-induced LTP deficits are not readily attributable to reductions in synaptic excitability. (This abstract does not necessarily reflect US EPA policy.)

813 DEVELOPMENTAL EXPOSURE TO THE 2,2',4,4',5,5'-HEXACHLOROBIPHENYL (PCB153): THYROID HORMONES AND NEUROBEHAVIORAL EFFECTS.

M. M. Taylor, J. M. Hedge, K. A. Jarema and K. M. Crofton. *USEPA, Research Triangle Park, NC.*

Polychlorinated biphenyls (PCBs) are pervasive environmental contaminants that have been shown to detrimentally affect somatic and behavioral endpoints. Primiparous Long-Evans rats were exposed to 0, 1, 5, 20 or 60 mg/kg/day PCB153 via oral gavage from Gestation Day 6 through Postnatal Day 21. Offspring were evaluated at various ages for circulating thyroid hormone concentrations [total serum triiodothyronine (T3) and thyroxin (T4)], survival, body weight, eye opening, motor activity development, auditory startle response and auditory thresholds. A dose-dependent moderate reduction in T4 concentrations was apparent from PND4 to PND21, with a maximal effect at 60 mg/kg (52% decrease at PND21). T4 in dams on PND22 was deceased up to 32% at 60 mg/kg. Concentrations of T3 did not differ from controls for pups or dams. There was no body weight gain reduction in either the dams or the offspring. There was no alteration in eye opening or survival. There was an age- but not dose-dependent increase in motor activity from PND7 to 14. Further, auditory startle amplitudes were not affected on PND24. These data suggest that PCB153 is much less potent as a thyroid hormone disruptor during development compared to Aroclor 1254. Furthermore, PCB153 at the doses tested does not seem to alter many of the endpoints previously shown to be sensitive to Aroclor 1254 exposure. (This abstract does not necessarily reflect US EPA policy.)

814 SEX-DEPENDENT BEHAVIORS AND STEROID HORMONE CONCENTRATIONS IN RATS AFTER MATERNAL EXPOSURE TO A RECONSTITUTED MIXTURE OF PCBS.

H. Lilienthal, J. Hany, H. Kaya, A. Fastabend, A. Roth-Haerer and G. Winneke. *Medical Institute of Environmental Hygiene, Duesseldorf, Germany.* Sponsor: H. Wiegand.

Previous work from our group indicated reduced serum testosterone concentrations and feminized saccharin preference in adult male rats and decreased aromatase (CYP19) activity in the hypothalamus of newborn male rat pups maternally exposed to a PCB-mixture which was reconstituted according to the congener pattern found in human breast milk. Effects of the reconstituted mixture were more pronounced than effects of Aroclor 1254. In the present study the dose-response relationship for the reconstituted PCB-mixture was examined. Female rats were fed PCB-loaded diets resulting in an average daily intake of about 0, 0.5, 2 or 4 mg/kg b.wt. Exposure started 50 days prior to mating and was continued throughout mating and gestation until parturition. Adult male, but not female offspring exhibited dose-dependent elevations of saccharin preference indicating a feminization of this sexually dimorphic behavior. Evaluation of conditioned place preference revealed a preference for the testosterone-paired side in adult male rats of the highest exposure group (4 mg/kg b.wt.). In addition, there were dose-dependent reductions in serum testosterone levels in female pups on postnatal day (PND) 21 and in adult male rats. Serum levels of the secosteroid 1,25-$(OH)_2$-vitamin D_3 were decreased in dams on 0 and PND 21 and on PND 21 in offspring in a dose-related manner. Taken together, maternal exposure to a reconstituted PCB-mixture resulted in dose-dependent and long-lasting alterations of sex-specific behaviors and sex hormone levels in male rats. (Grant PUG 97004, State of Baden-Wuerttemberg, Germany, to H.L.).

815 GENDER-SPECIFIC CORTICAL ASYMMETRY OF RAT BRAIN FOLLOWING PRENATAL EXPOSURE TO TCDD.

K. M. Zareba[1], R. Hojo[1], V. P. Markowski[2], S. Stern[1], R. B. Baggs[1], C. Cox[1], G. Zareba[1] and B. Weiss[1]. [1]*University of Rochester School of Medicine and Dentistry, Rochester, NY and* [2]*Salem State University, Salem, MA.*

Sexually dimorphic patterns of cortical asymmetry in rats show that males exhibit pronounced right hemisphere dominance while females exhibit more diffuse lateralization patterns but tend to greater left hemisphere dominance. Prenatal TCDD (2,3,7,8 tetrachlorodibenzo-p-dioxin) exposure produces demasculation of offspring sexual behavior. This study aimed to determine gender-specific differences in cortical lateralization in Holtzman rats exposed prenatally to TCDD. Pregnant females were given a single p.o. dose of 180 ng/kg on gestational day 18 (GD 18). Cortical depth measurements were taken in selected brain regions in offspring 300 days of age. Areas 2, 3, 17, and 18a, at bregmas -1.8, -3.8, and -5.8, were chosen for analysis. Morphometric indices were collected using digitized, enhanced images produced by a photomicroscope fitted with a special color camera. In several brain areas of male offspring, a marked reversal from right hemispheric dominance or symmetry to left hemispheric dominance was observed. Female offspring brains tended to show a contrary but less pronounced tendency to deviate from symmetry to right hemisphere dominance. In general, prenatal exposure of males to TCDD produced a change in the pattern of cortical asymmetry consistent with the behavioral demasculation reported in the literature. (Supported by grants ES 08958 and ES 01247 from NIEHS.)

816 MOTOR ACTIVITY OF RAT OFFSPRING AFTER A SINGLE PRENATAL EXPOSURE TO 2,3,7,8-TCDD.

C. Watanabe[1], V. P. Markowski[2], G. Zareba[3], C. Cox[3], S. Stern[3] and B. Weiss[3]. [1]*University of Tokyo, Tokyo, Japan,* [2]*Salem State University, Salem, MA and* [3]*University of Rochester School of Medicine and Dentistry, Rochester, NY.*

Altered neurobehavioral development is becoming recognized as one of the most sensitive consequences of prenatal TCDD exposure. Still to be elucidated, however, are such issues as dose-response relationships, critical periods of exposure, and the types of neurobehavioral functions susceptible to exposure. In one phase of a program to evaluate the offspring of Holtzman rats born to TCDD-exposed females, we measured motor activity at various times during postnatal development. On gestational day 18 (GD18), pregnant rats were given single p.o. doses of 0, 20, 60, or 180 ng/kg TCDD. Motor activity (one male and one female per litter) was assessed during 15-min periods in a small chamber equipped with a Doppler effect-detection device on postnatal days (PND) 30, 38, 90, and 150. Onset and termination of movements were recorded and analyzed for each session to capture the episodic nature of activity. Results obtained on PND30 were analyzed separately because a different size activity chamber was used at that time. All the groups followed a similar developmental pattern of activity. At PND90, the number and duration of episodes were smallest and the intervals (IRTs) between episodes the longest of any of the test ages. TCDD exerted little influence on this developmental pattern, except that TCDD-exposed males at PND90 tended to exhibit fewer movements and longer IRTs than controls ($p=0.051$, and 0.052, respectively, based on Kruskal-Wallis tests). These results suggest that maternal exposure to TCDD on GD18 may influence one aspect of motor activity in the offspring. (Supported by grants ES 08958 and ES 01247 from NIEHS.)

817 LOW LEVEL PRENATAL TCDD AFFECTS OPERANT RESPONDING FOR MOTOR REINFORCEMENT IN FEMALE RATS.

V. P. Markowski[1], G. Zareba[2], C. Cox[2] and B. Weiss[2]. [1]*Salem State University, Salem, MA and* [2]*University of Rochester School of Medicine and Dentistry, Rochester, NY.*

Wheel-running behavior, and other measures of activity in sexually mature female rats are linked to the 4-5 day estrus cycle. Such behaviors are sensitive to acute exposure to estrogenic substances or to developmental exposure to substances that disturb the organization of the brain regions that mediate incentive motivation or motor output. Operant responding for food is also linked to the estrus cycle. During behavioral estrus, females resemble males in that they respond at higher rates on certain reinforcement schedules. In the current procedure, both wheel running and operant responding for food were examined in rats that were exposed to a single, low prenatal dose of 2,3,7,8, tetrachlorodibenzo-p-dioxin (TCDD). Pregnant Holtzman rats were administered 20, 60, or 180 ng/kg TCDD p.o. on gestational day 18. Beginning on postnatal day 80, male-female pairs of littermates were trained to lever press for food on a random ratio schedule. A separate group of female offspring were trained to lever press on a fixed-ratio schedule for a brief opportunity to run in specially-designed wheels. Both random ratio and fixed-ratio requirements were increased across sessions. Vaginal lavage data were also collected to monitor cyclicity and were later compared to the behavioral data. In the wheel procedure, TCDD reduced the number of completed fixed-ratio schedules, reduced the lever response rate, and reduced the number of wheel revolutions per session in correspondence with dose. These data indicate that TCDD can induce subtle motor or motivational decrements in adult female rats responding for other primary reinforcers and extend previous findings on the effects of TCDD on male sexual behavior. (Supported by grants ES 08958 and ES 01247 from NIEHS.)

817A EFFICACY OF RECOMBINANT C FRAGMENT OF HEAVY CHAIN BOTULINUM NEUROTOXIN SEROTYPE B AGAINST LETHAL AEROSOL CHALLENGE OF BOTULINUM B TOXIN IN RHESUS MONKEYS.

J. W. Boles, M. W. West, V .A. Montgomery, R. F. Tammariello, L. A. Smith and L. M. Pitt. *Toixcology Division, US Army Medical Research Institute of Infectious Diseases, Fort Detrick, MD.*

Botulinum neurotoxin B (BoNTB) is a distinct protein subtype of neurotoxins normally considered to be foodborne pathogens. These neurotoxins cause flaccid paralysis at the motor endplate by inhibiting the function of proteins associated with the release of vesicles containing acetylcholine. Similarly, aerosolized botulinum B causes flaccid muscle paralysis with loss of funtion of the muscles of respiration ultimately causing death in both routes. Because adjunctive and therapeutic methods are limited by their need of logistical support and recognition of exposure respectively, prophylaxis is the current method to combat deliberate, aerosol exposure of BoNT. The current study is part of a series of studies evaluating the toxicity of the different serotypes of BoNT in rhesus monkeys and the efficacy of their corresponding recombinantly derived C fragment of the H_c chain (carboxy terminus of the heavy chain, receptor binding domain) to protect against effects of aerosolized toxin. Specifically this study was to determine the efficacy of rBoNTB H_c to protect against aerosolized BoNTB in the rhesus monkey and whether a difference exists between two candidate dosages. Animals were given three inoculations of either 1 or 5 µg rBoNTB Hc (4 weeks apart, IM, Alhydrogel adsorbed). Serial serum neutralization assays (SNA) and enzyme-linked immunosorbant assays (ELISA) were performed at various time points before aerosol challenge. Monkeys were then challenged with an aerosol concentration of BoNTB 50 times the BoNTB LCT_{50} at 6 weeks after the last inoculation. All vaccinated animals produced a detectable SNA and ELISA titer and survived the aerosol challenge while the vaccine controls did not indicating that rBoNTB is both immunogenic and protective in this model.

818 TESTOSTERONE REVERSES ETHANOL-INDUCED DEFICIT IN SPATIAL REFERENCE MEMORY IN CASTRATED RATS.

R. Khalil and M. R. I. Soliman. *College of Pharmacy, Florida A&M University, Tallahassee, FL.*

The present study was designed to evaluate the effects of ethanol, testosterone and combination of ethanol and testosterone, on spatial reference memory in castrated rats. Male Sprague-Dawley rats (120-150g), were adapted to 12-hour light: 12-hour dark illumination cycle for 7 days. After the adaptation period, animals were castrated bilaterally under pentobarbital anesthesia. Animals were monitored for a recovery period of 10-14 days. Ethanol (3g/kg as 22.5% solution in saline, i.p.), testosterone (2.5 mg/ rat in 0.2ml olive oil S.C. in the dorsal region) and combination of the drugs were administered to rats at 9:00 h. Control animals were injected i.p. with 2 ml saline. After a training period of 4 days, spatial reference memory was evaluated in treated and control rats for 7 days using the Morris water maize. The time to find the platform (latency) was significantly increased in ethanol treated rats as compared to control, indicating that ethanol induces deficit in spatial reference memory. On the other hand, testosterone administration improved spatial reference memory by significantly decreasing the latency period. In addition, there was a significant decrease in latency period in the animals treated with combination of ethanol and testosterone. These findings clearly indicate that administration of testosterone not only improved the reference memory but also reversed the spatial memory deficit induced by ethanol in castrated rats. (Supported by NIH grant RR03020.)

819 NEUROPROTECTION OF ALCOHOL AGAINST HIV-1 GP120 NEUROTOXICITY.

A. Belmadani, M. A. Collins and E. J. Neafsey. *Loyola University Medical Center, Maywood, IL.* Sponsor: E. E. Creppy.

Human Immunodeficiency Virus type 1 (HIV-1) induces brain damage leading to dementia. A large number of individuals with AIDS consume alcohol. However, the effects of alcohol on neurodegeneration associated with HIV are still unstudied. Many reports indicate that the HIV glycoprotein gp120, is a potential mediator of HIV neurotoxicity. Its toxicity is mediated, at least, by excitotoxicity mechanisms including stimulation of glia to release factors (particularly arachidonic acid, AA) which increase extracellular glutamate and activation of NMDA receptors which involve excessive Ca++ influx. Likewise NMDA receptors and glia are alcohol targets. Our recent study shows a neuroprotection effect of alcohol, which mediated by astrocytes dependent-function. In this study, we examine the effects of alcohol pretreatment on gp120 induced neurotoxicity, in rat brain organotypic slice cultures (HEC), in term of AA release and LDH leakage. Our results show that gp120 (100 pM) induces an increase of AA release (150%) after 15 min, accompanied by increase of NO liberation and IL6 production. In parallel, LDH release increased by 209% after 24 h of treatment as compared to control. After 6 days of pretreatment with alcohol (30 mM), the increase of AA and LDH significantly prevented. However, the increase of IL6 and NO remained strongly correlated. Our finding suggests that the neuroprotective effect of alcohol, is in part, mediated by the following: 1- Modulation of AA cascade, 2- activation and/or proliferation of astrocytes, which occurred in presence of gp120, leading to increase the glutamate uptake.

820 NICOTINE-ETHANOL INTERACTIONS ARE ALTERED IN ADOLESCENT *VS.* ADULT RATS.

A. H. Rezvani and E. D. Levin. *Duke University Medical Center, Durham, NC.*

Nicotine and ethanol are two of the most widely used drugs in the world. They are often used together, but their interactive effects are not well understood. Both nicotine and ethanol use often begins during adolescence. It is not known whether the interaction of these drugs differs in adolescence vs. adulthood. The current study was conducted to determine the interactive effects of nicotine and ethanol in adolescent and adult rats. Forty-two female Sprague-Dawley rats (18 adolescents 49 days old and 24 adults 69 days old) were injected with vehicle, nicotine (0.2 mg/kg SC), ethanol (2.5 g/kg, IP) or ethanol + nicotine (N=4-7/age/treatment). Effects on body temperature (15 minutes after injection) and locomotor activity (20-80 minutes after injection) were measured. Locomotor activity was measured in the figure-8 apparatus. Unique interactions of ethanol and nicotine were seen in adolescents vs. adults with both measures. Body temperature was lowered by both ethanol and nicotine to a similar extent when given alone to adolescent and adult rats. However, the combination of nicotine and ethanol caused a significantly greater decrease in body temperature of adolescent rats than adults ($p<0.005$). In the locomotor activity test, ethanol caused a similar degree of sedation in adolescents and adults. Nicotine did not cause a discernable effect in either age group. When nicotine was given in combination with ethanol, there was a substantial reversal of the ethanol-induced hypoactivity in adults, but not in adolescents ($p<0.05$). Adolescence appears to be a unique period for vulnerability to the effects of nicotine and ethanol. (This research was supported by NIDA grant DA11943.)

821 ADOLESCENT NICOTINE EXPOSURE CAUSES PERSISTENT CHANGES IN RAT BRAIN.

J. A. Trauth, F. J. Seidler, E. C. McCook and T. A. Slotkin. *Duke University Medical Center, Durham, NC.*

Whereas numerous studies have examined fetal or adult nicotine exposure, few studies have concentrated on exposure during adolescence, the period in which tobacco use typically begins. We gave nicotine to adolescent rats on postnatal days 30-47 via minipump infusions that achieve plasma nicotine levels found in smokers, and compared the results with similar infusions in adult rats. There were major differences in the regional specificity and persistence of nicotinic cholinergic receptor upregulation. In adolescents, upregulation was uniform across all regions during the infusion period, whereas in adults, there was a distinct regional hierarchy, hippocampus > cerebral cortex > midbrain; accordingly, receptors in the adolescent midbrain were upregulated far more than in adults. With adolescent nicotine treatment, significant increases were still apparent in male rats one month after the termination of exposure. We also obtained evidence for cell damage in nicotine-exposed adolescents. There were statistically significant changes in cell number (DNA content) and size (protein/DNA) in cortex and midbrain. In female hippocampus, nicotine evoked increases in expression of p53 mRNA, accompanied by increases in the cell membrane protein concentration, again suggestive of cell damage. Adolescent nicotine exposure thus elicits persistent changes in the brain, effects that may contribute to increased addictive properties and behavioral deficits. (Supported by a STAR fellowship from the US Environmental Protection Agency and by a grant from the Smokeless Tobacco Research Council.)

822 ADAPTATION OF THE 2-DEOXYGLUCOSE METHOD TO FISH FOR CHARACTERIZING KNOWN AND UNKNOWN AQUATIC NEUROTOXINS.

J. B. Sass, J. A. Choich and E. K. Silbergeld. *Program in Human Health & the Environment, University of Maryland, Baltimore, MD.*

We have developed a unique and much needed system to aid in the characterization of neurotoxins, and contribute to human and environmental risk assessment studies. This method is based on the pioneering work of L. Sokoloff (1977), which shows a direct relationship between glucose metabolism and regional brain activity. The product of the breakdown of 2-deoxyglucose (2-DG) is deoxyglucose-6-phosphate, which lacks the necessary oxygen for further enzyme recognition and metabolism, and thus remains trapped in the tissue, indicative of regional neural activity. Living, healthy fish (10-20g body weight) are injected intramuscularly with 1uCi of ^{14}C 2-DG and immediately allowed to swim freely in water with dissolved neurotoxins, mimicking real-life environmental exposure. At completion of the experimental time-course (20 minutes), the fish are sacrificed with a lethal dose (0.5g/L) of MS222, and brains are removed and fixed in 10% NBF overnight. Brains are then cryopreserved in 20% sucrose overnight and stored frozen at -20°C. Brains are cryosectioned (10-20μm) and the sections are analyzed by LM autoradiography and H & E staining. A microscope fitted with both dark and bright field optics is used to facilitate visualization of both cytoarchitecture and 2-DG localization within the same field. Preliminary data using goldfish and known optic lobe stimuli (strobe-light and dark exposure) shows a 10-30% regional redistribution of glucose in the brain in response to the stimuli. Our system is intended to aid in defining the mechanisms of action of neurotoxins and supply vital information regarding neural targets. More importantly, assessment of toxins can be done prior to identification and/or purification. It is a novel approach to the characterization of environmental toxins, which is an increasingly important part of today's research. (Supported by NIEHS grants P01ES09563-01 and 5-T32ES07263.)

823 A RAT MODEL OF THE COGNITIVE IMPAIRMENT CAUSED BY *PFIESTERIA PISCICIDA*.

E. D. Levin[1], H. B. Glasgow, Jr.[2], N. J. Deamer-Melia[2], J. M. Burkholder[2], A. H. Rezvani[1], N. C. Christopher[1], V. C. Moser[3], K. Jensen[3], G. J. Harry[4] and D. Schmechel[1]. [1]*Duke University Medical Center, Durham, NC,* [2]*North Carolina State University, Raleigh, NC,* [3]*USEPA, Research Triangle Park, NC and* [4]*NIEHS, Research Triangle Park, NC.*

Pfiesteria piscicida, a dinoflagellate found in estuaries along the east coast of the United States has been associated with cognitive deficits in humans. We have developed a rat model of this cognitive deficit using the radial-arm maze to demonstrate the causal relationship between exposure to Pfiesteria-containing waters and cognitive impairment. Sprague-Dawley rats injected once (sc) with Pfiesteria-containing water (35,600 or 106,800 cells/kg of rat body weight) showed a significant deficit in radial-arm maze choice accuracy during the learning phase of training. Learning deficits have been seen ten weeks after a single exposure to Pfiesteria. Three different types of Pfiesteria culture samples have been found to cause radial-arm maze choice accuracy deficits. Juvenile male and female as well as adult female rats showed significant Pfiesteria-induced deficits. Locomotor activity was not as sensitive as radial-arm maze choice accuracy to the Pfiesteria-induced effects. Measures of the functional observational battery were largely unaffected by Pfiesteria exposure. Radial-arm maze choice accuracy deficits caused by exposure to Pfiesteria-containing water may be useful in helping to identify the critical toxin(s) of Pfiesteria piscicida. (This research was supported by the US-EPA, NOAA, NIEHS and the State of North Carolina.)

824 BREVETOXIN-INDUCED AUTOCRINE EXCITOTOXICITY IS ASSOCIATED WITH MANIFOLD ROUTES OF CA^{2+} INFLUX.

T. F. Murray and F. W. Berman. *Department of Physiology and Pharmacology, University of Georgia, College of Veterinary Medicine, Athens, GA.* Sponsor: R. P. Sharma.

A fluorescence imaging plate reader (FLIPR&Oχιρχ;, Molecular Devices, Sunnyvale, CA) was used to monitor real-time alterations in intracellular Ca^{2+} ($[Ca^{2+}]_i$) in fluo-3-loaded cerebellar granule neurons (CGNs) exposed to the brevetoxin, PbTx-1. PbTx-1 produced rapid and concentration-dependent increases in neuronal $[Ca^{2+}]_i$ with a potency nearly identical to that determined previously for PbTx-1-induced neurotoxicity. The N-methyl-D-aspartate (NMDA) receptor antagonists MK-801, dextrorphan and D-AP5, and tetanus toxin (TT), an inhibitor of Ca^{2+}-dependent exocytotic neurotransmitter release, effected significant reductions in both the integrated fluo-3 fluorescence response and excitatory amino acid (EAS) release, and protected CGNs against PbTx-1 neurotoxicity. The L-type Ca^{2+} channel antagonist nifedipine produced a modest reduction in the fluo-3 response, but reduced substantially the plateau phase of the PbTx-1 increment in $[Ca^{2+}]_i$ when combined with MK-801. When nifedipine and MK-801 were combined with the Na^+/Ca^{2+} exchange inhibitor, KB-R7943, the PbTx-1 increment in $[Ca^{2+}]_i$ was nearly completely attenuated. These data show that Ca^{2+} entry into PbTx-1-exposed CGNs occurs through three primary routes: NMDA receptor ion channels, L-type Ca^{2+} channels, and reversal of the Na^+/Ca^{2+} exchanger. There was a close correlation between reduction of the integrated fluo-3 fluorescence response and level of neuroprotection against PbTx-1 challenge afforded by blockers of each Ca^{2+} entry pathway; however, simultaneous blockage of L-type Ca^{2+} channels and the Na^+/Ca^{2+} exchanger, while reducing the integrated $[Ca^{2+}]_i$ response to a level below that provided by NMDA receptor blockage alone, failed to completely attenuate PbTx-1 neurotoxicity. This finding suggests that in addition to total $[Ca^{2+}]_i$ load, neuronal vulnerability is governed selectively by the NMDA receptor Ca^{2+} influx pathway.

825 A RECEPTOR SCREEN TO IDENTIFY TOXICANTS AND TOXINS OF BRAIN NEUROTRANSMITTER RECEPTORS.

A. M. El-Nabawi, M. E. Eldefrawi and A. T. Eldefrawi. *University of Maryland, Sch. of Medicine, Baltimore, MD.*

A protocol was developed to identify neurotransmitter receptor targets of neurotoxic agent(s) that mediate cognitive function. Current radioactive ligand binding assays for acetylcholine (nicotinic and muscarinic), glutamate (AMPA and NMDA), dopamine (D1 and D2) and GABAA receptors vary greatly in tissue preparation, temperature, incubation time, volume and buffer. This protocol uses a single membrane preparation, isolated from a rat brain homogenate in 20 mM Tris-HCl buffered modified Krebs Ringer, by centrifugation at 40,000xg for 20 min. The pellet is washed by recentrifugation four times and then suspended in 50 mM Tris-HCl, pH 7.4 to yield 1 mg protein/ml. This tissue preparation is divided into 25 mL samples, each of which is incubated for 60 min at 23°C with a specific radioactive ligand for each receptor, in a final volume of 250 mL; at a concentration that produces <5% receptor occupancy. Bound radioactive ligand is separated from unbound by vacuum filtration on GF/B filter and quantitated by liquid scintillation counting. Nonspecific binding is determined in presence of a saturating concentration of the selective receptor antagonist. One rat brain is sufficient for >300 assays. This assay is applicable for high throughput screening (Supported by NIEHS grant No. PO1 ES09563.)

826 CONVULSANT ACTIVITY OF NOVEL 6-HYDRO-8-METHOXYQUINOLONE ANTIBIOTICS.

J. L. Hannah-Hardy[1], V. A. Murphy[1], B. R. Kuzmak[1] and K. Sealover[2]. [1]*P&G Pharmaceuticals, Mason, OH and* [2]*Novascreen, Baltimore, MD.*

Most quinolone antibiotics are known to have convulsant activity. This activity has been related to inhibition of γ-aminobutyric acid, subtype A ($GABA_A$) receptors and is enhanced in the presence of nonsteroidal antiinflammatory agents such as 4-biphenylacetic acid (4BPA). Novel 6-hydro, 8-methoxy-quinolone antibiotics (PGE-9262932, PGE-4175997, PGE-9509924 and PGE-510629) were compared to benchmark quinolone antibiotics (gatifloxacin, trovafloxacin, ciprofloxacin) using the following assays: $GABA_A$ receptor binding in the absence or presence of 4BPA and proconvulsant activity in mice using pentylenetetrazole (PTZ) as the convulsant. For the $GABA_A$ receptor assay, bovine cerebellum suspension (4 mg/ml), [^{3}H]-GABA (5 nM), quinolone (1 μM to 6 mM) with or without 4BPA (1 mM) were incubated at 0°C for 60 min, cold vacuum filtered and assayed by liquid scintillation. An IC_{50} was determined from percent specific binding vs. the logarithm of the concentration. For the proconvulsant assay, CD-1 mice (21 per group) were dosed with 200 mg/kg IP of a quinolone or vehicle and 1 hr later given PTZ, 50 mg/kg IP, and observed for convulsions for 15 min. All of the compounds had IC_{50}s at the $GABA_A$ receptor of ≥ 800 μM, except for PGE-9509924 where it was 120 μM. The poor binding of ciprofloxacin and trovafloxacin to the $GABA_A$ receptor in the absence of 4BPA suggests this assay does not provide a reliable estimate of quinolone convulsant potential. $GABA_A$ receptor binding in the presence of 4BPA was only slightly increased (< 5-fold) with all compounds except trovafloxacin and ciprofloxacin (>200-fold). None of the 6-hydro-8-methoxy-quinolones enhanced the convulsant activity of PTZ, but activity was enhanced by gatifloxacin, trovafloxacin and ciprofloxacin. The 6-hydro-8-methoxy-quinolones appear to have lower convulsant activity than gatifloxacin, trovafloxacin and ciprofloxacin.

827 THE N-METHYL-D-ASPARTATE (NMDA) RECEPTOR ANTAGONIST, CP-101,606, DOES NOT PRODUCE NEURONAL VACUOLATION OR NECROSIS IN THE POSTERIOR CINGULATE/RETROSPLENIAL (PC/RS) CORTEX OF RATS: A MAJOR POINT OF DIFFERENTIATION FROM COMPETITOR NMDA RECEPTOR ANTAGONISTS.

B. A. Pettersen and L. A. Chatman. *Pfizer, Groton, CT.*

CP-101,606, the dextrorotatory enantiomer of (1S, 2S)-1-(4-hydroxyphenyl)-2-(4-hydroxy-4-phenylpiperidino)-1-propanol, is a NR2B subunit antagonist of the NMDA receptor under clinical development as a neuroprotectant in head trauma and stroke. The potential of CP-101,606 to produce morphological changes in cerebrocortical neurons of rats was evaluated since other NMDA receptor antagonists (e.g., MK-801, CGS 19755) produce neuronal vacuolation and necrosis in the PC/RS cortex of rodents in a dose-, time- and age-dependent manner. Sprague-Dawley rats (5/sex/dose/time point) received a single i.v. bolus dose of 0, 2, 10 or 50 mg/kg CP-101,606, followed 20 minutes later by a 3.67 hour i.v. infusion dose of 0, 1, 6, or 30 mg/kg/hr CP-101,606, respectively, or 4.4 mg/kg MK-801 (s.c., positive control, females only) prior to necropsy/perfusion fixation at 4, 12 and 24 hours after the start of dosing. The age of animals and time points selected for histologic examination in this study are most appropriate for assessing pathomorphologic changes with other NMDA receptor antagonists such as MK-801. Neuronal vacuolation and necrosis were observed in the PC/RS cortex of rats treated with the positive control agent, MK-801 within 4 and 24 hours after dosing, respectively. In contrast, CP-101,606 did not affect neuronal morphology. Steady-state plasma CP-101,606 levels at the low dose were equivalent to the efficacious level in rat head trauma models (~0.2 μg/ml) and at the high dose were within the maximum tolerated range (~8 μg/ml) based on previous rat studies. These data suggest that blockade of the NMDA receptor is not necessarily associated with pathomorphologic changes in the PC/RS cortex and that a critical factor may be the site of interaction of the antagonist within the receptor complex.

828 FLUOROCARBONS CFC-12 (DICHLORODIFLUOROMETHANE) AND HFC-134A(1,1,1,2-TETRAFLUOROETHANE) INDUCE DEPOLARIZATION OF BRAINSTEM AND HIPPOCAMPAL NEURONS.

J. Lin[1], J. B. Dean[2], G. D. Ritchie[3], J. Rossi, III[4] and A. F. Nordholm[4]. [1]*ManTech Environmental Technology, Inc., Dayton, OH,* [2]*Dept. of Physiology and Biophysics, Wright State Univ., Dayton, OH,* [3]*Geo-Centers, Inc., Dayton, OH and* [4]*Naval Health Research Center, Detachment-Toxicology, Wright-Patterson Air Force Base, OH.* Sponsor: D. E. Dodd.

Replacement of the chlorofluorocarbon refrigerant CFC-12 by HFC-134a has led to concerns about the comparative toxicity that is especially related to cardiorespiratory control. The actions of CFC-12 and HFC-134a were tested on neurons in cardiorespiratory areas of the brainstem (dorsal motor nucleus, DMN; nucleus tractus solitarius, NTS; locus coeruleus, LC) and a non-cardiorespiratory area (hippocampus CA1). Perforated patch recordings were made in slices (rat, 200-350 μm, P1-14) visualized using infrared video microscopy. Both chemicals were saturated at the slice after 15 min (72.5 mg/l and 438.6 mg/l for CFC-12 and HFC-134a, respectively). Bath application of HFC-134a or CFC-12 (20 min) induced depolarization, increased firing rate, and decreased input resistance (R_{in}) in all brainstem neurons tested (8.6± 2.5 mV; R_{in} -32%). 30% of brainstem neurons tested depolarized suddenly (>Δ20 mV) and became swollen after 2-15 min of exposure to CFC-12 (12.1-72.5 mg/l) or HFC-134a (35.7-438.6 mg/l). The majority of brainstem neurons survived, 40% of which recovered from 20 min of exposure. There were no significant differences among the neurons from LC, DMN and NTS in response to either HFC-134a or CFC-12 exposure. When concentrations for both HFC-134a and CFC-12 were reduced to 0.38-1.6 mg/l at the slice, both chemicals induced slight depolarization associated with decreased R_{in} in 40% of neurons tested. No neuronal damage or death was observed. All CA1 neurons tested survived 20 min exposure of either chemicals. HFC-134a induced depolarization associated with decreased R_{in} in CA1 neurons. CFC-12, however, induced a 5% decrease in R_{in} but no significant membrane potential change. Thus, HFC-134a depolarized neurons in both brainstem and hippocampus, but only neurons in the brainstem were irreversibly depolarized. CFC-12 affected neurons in the brainstem only (ONR, NIH HL56683).

829 NEUROLOGIC, MORPHOMETRIC AND PATHOLOGIC EVALUATION OF NERVE FUNCTION AND ULTRASTRUCTURE IN BEAGLE DOGS ADMINISTERED THALOMID (THALIDOMIDE) OVER 53 WEEKS.

M. Morgan[1], S. Thomas[2], M. Evans[3], M. Brockman[3], J. Ehrhart[4] and S. Teo[2]. [1]*TherImmune Corporation, Gaithersburg, MD,* [2]*Celgene Corporation, Warren, NJ,* [3]*Pathology Associates International, Frederick, MD and* [4]*White Eagle Laboratories, Doylestown, PA.*

Thalidomide has been approved in the US. A potential adverse event in humans is the development of peripheral neuropathy after prolonged use. Evaluations of nerve function and ultrastructure were performed as part of a 53-week toxicity study in Beagle dogs. 28 male and 28 female dogs were orally dosed with thalidomide capsules at 0, 43, 200 or 1000 mg/kg/day for 53 weeks with subsequent recovery for 5 weeks. All dogs were neurologically examined at weeks -2, 13, 26, 38, 51 and 58. Nerve function was assessed by measuring sensory nerve action potential (SNAP), action potential amplitude, duration and latency from the tibial nerve of the gastrocnemius muscle. Sensory nerve conduction velocity (SNCV) was also determined. Dogs were sacrificed at interim (26 weeks), end of dosing (53) and recovery (58) time points. Mean myelin thickness and mean axonal diameter of sural nerve fibers were determined using light microscopy at each sacrifice. Morphometric and pathologic evaluations were performed using electron microscopy. The distal spinal cord was also evaluated using light and electron microscopy at weeks 53 and 58. Distal spinal cord measurements included average thickness of myelin sheath, area of entire nerve fiber (myelin sheath plus axon), area of each axon cylinder and area of each myelin sheath. Thalidomide did not induce any neurological deficits. It had no effect on nerve function. There were no thalidomide-related ultrastructural morphometric and pathologic changes in sural nerve and distal spinal cord at all 3 sacrifice time points. The Beagle dog is therefore not predisposed to develop thalidomide-induced peripheral neuropathy.

830 MYELINOPATHY FOLLOWING SUBCHRONIC ADMINISTRATION OF ETHYL METHACRYLATE IN THE RAT.

K. F. Jensen[1], A. A. Abdel-Rahman[2], A. M. Kishk[2], J. K. Olin[1] and M. B. Abou-Donia[2]. [1]*NHEERL, USEPA, Division of Neurotoxicology, Research Triangle Park, NC and* [2]*Duke University Medical Center, Department of Pharmacology and Cancer Biology, Durham, NC.*

To identify potential morphological alterations in the nervous system resulting from exposure to ethyl methacrylate (EMA), sections were examined from the forebrain, brainstem, spinal cord and sciatic nerve of rats exposed to 0.1, 0.2, 0.5% EMA in drinking water for 60 days. While a decrease in the density of neurons was apparent in regions of the forebrain, brainstem and spinal cord, more striking were spongiform-like alterations in major fiber tracts. In the spinal cord, clusters of enlarged axons were equally distributed throughout the dorsal, lateral and ventral columns. These clusters of enlargements involved internodal portions of adjacent axons, and there was no evidence of more than one enlargement along the trajectory a single axon. In the sciatic nerve, cytoskeletal aberrations were apparent in sparsely distributed axons and some large caliber axons exhibited relatively thin myelin sheaths indicative of remyelination. This pattern of alterations is consistent with a central-peripheral myelinopathy, rather than the primary axonopathy typically associated with the structurally related neurotoxicants, acrylamide and glycidamide.

831 GAMMA-DIKETONE NEUROPATHY: ULTRASTRUCTURAL CHARACTERIZATION OF PERIPHERAL NERVE FIBERS.

E. J. Lehning[1], B. S. Jortner[2], J. Fox[2], S. Perkins[2], J. Hinckley[2] and R. M. LoPachin[1]. [1]*Montefiore Medical Center, Bronx, NY and* [2]*Virginia Tech, Blacksburg, VA.*

We have shown that exposure to neurotoxic doses of the gamma-diketone, 2,5-hexanedione (HD), produces axonal swellings and atrophy in rat peripheral nerves (Lehning et al. Toxicol. Appl. Pharmacol. 135:58, 1995). In the present study, we used transmission electron microscopy to characterize the morphologic and ultrastructural appearance of swollen and atrophic fibers in proximal sciatic and posterior tibial nerves. Rats (250-275 gm) were given daily gavage doses of 250 mg/kg HD and were sacrificed at slight, moderate or severe levels of hindlimb weakness. Tibial and sciatic nerves exhibited occasional swollen myelinated axons which were distended by excess, abnormally arrayed neurofilaments. Atrophic myelinated axons, however, were

abundant in both nerve regions but were more prominent in distal tibial when compared to proximal sciatic nerve. In addition, the magnitude and frequency of atrophy progressed as a function of HD exposure duration. Atrophied fibers displayed shrunken linear or irregular profiles which were correlated to reductions in ultrastructurally evident neurofilaments and increases in microtubule density. These morphologic observations were corroborated by immunoblot analyses demonstrating a decrement in neurofilament protein subunits with no change in tubulin content (See companion abstract by Opanashuk et al.). This study provides ultrastructural morphologic evidence that axon atrophy associated with gamma-diketone peripheral neuropathy results in cytoskeletal simplification where a selective decrease in neurofilament content occurs in conjunction with microtubule conservation. (Supported by ES07912.)

832 HEXANEDIONE NEUROPATHY: RELATIONSHIP OF AXONAL ATROPHY WITH ALTERATIONS IN NEUROFILAMENT GENE EXPRESSION.

L. A. Opanashuk, F. C. Chiu, D. K. He, E. J. Lehning and R. M. LoPachin. *Albert Einstein College of Medicine, Bronx, NY.*

We have previously used quantitative morphometric analysis to demonstrate that axonal atrophy is the primary neuropathic feature associated with 2,5 hexanedione (HD) peripheral distal axonopathy. In this study, we tested the hypothesis that alterations in neurofilament content is the mechanism of HD-induced axonal atrophy. Rats were exposed by gavage to 3 dosing rates (100, 250, or 400 mg/kg/d) of HD until moderate changes in gait were observed (99,69, and 22 days, respectively). Dorsal root ganglia were removed and processed for isolation of total RNA. Alterations in neurofilament (NF) subunit (NF-H, -M, and -L) gene expression were assessed by northern blot. Proximal sciatic and distal tibial nerve proteins were subjected to immunoblot analysis for NF-H, -M, -L and tubulin content. HD exposure resulted in decreased levels of NF-H, -M, and -L mRNA at all dosing rates. Changes in RNA expression were paralleled by dose-rate dependent reductions in NF protein content, which were more prominent in distal tibial nerves. The greatest decrement in NF protein levels were detected in the long-exposure/low-dose (175 mg/kg/d) treatment groups. Slower-migrating NF-H immunoreactive bands were detected in nerves following 400mg/kg/d HD exposure. However, the presence of these higher molecular weight species do not account for the decline in neurofilament content because they were inconsistently detected on a spatiotemporal basis. Alterations in tubulin expression were not found in response to HD exposure. These findings indicate that reduced NF gene expression is a selective cytoskeletal effect, which could be related to the mechanism of HD-induced axonal atrophy. (Supported by NIH grant ES07912.)

833 FORMATION OF ACRYLAMIDE (ACR) AND GLYCIDAMIDE (GLY) HEMOGLOBIN ADDUCTS IN ACR-EXPOSED RATS.

D. S. Barber[1], J. Hunt[1], M. Ehrich[1], E. J. Lehning[2] and R. M. LoPachin[2]. [1]*Virginia-Maryland Regional College of Veterinary Medicine, Blacksburg, VA and* [2]*Montefiore Medical Center, Bronx, NY.*

We have shown previously that oral ACR exposure produced abundant peripheral nerve axon degeneration whereas ip injection was not associated with fiber loss (Lehning et al., Toxicol. Appl. Pharmacol. 151:211-221, 1998). The basis for this differential expression of axon degeneration is uncertain but could involve exposure-dependent differences in metabolite production. GLY is an epoxide metabolite of ACR which may contribute to neurotoxicity (J. Toxicol. Env. Health 39:447-464, 1993). Both ACR and GLY readily adduct hemoglobin. Evidence suggests the extent of hemoglobin adduction in blood correlates positively with development of neurotoxicity and reflects concentrations of ACR and GLY protein adducts in tissue. Therefore, in the present study, ACR and GLY hemoglobin adducts were quantified as methyl ester derivatives by GC-MS. Adducts were determined in rats at several times during exposure to ACR by ip injection (50 mg ACR/kg/day) or in drinking water (2.8mM ACR). At times of equivalent neurobehavioral toxicity, ACR adduct contents were approximately equal for both exposure routes. However, GLY adduct levels were 4-7 times greater in rats exposed to ACR by drinking water than by ip injection ($p < 0.05$). These results indicate more GLY is formed in rats receiving ACR in drinking water than by ip injection and suggest GLY might be involved in peripheral nerve axon degeneration. (This research is supported by NIH grant ES03830.)

834 THE XENOESTROGEN 4-OCTYLPHENOL (4-OP) INCREASES THE EXPRESSION OF AMYLOID PRECURSOR-LIKE PROTEIN-2 (APLP-2) MRNA IN THE HYPOTHALAMUS OF THE SNAPPING TURTLE.

V. L. Trudeau[1], S. Chiu[1], S. W. Kennedy[2] and R. J. Brooks[3]. [1]*University of Ottawa, Department of Biology, Ottawa, Ontario, Canada,* [2]*Environment Canada, NWRC, Hull, Quebec, Canada and* [3]*University of Guelph, Department of Zoology, Guelph, Ontario, Canada.* Sponsor: M. E. Hahn.

The gonadal steroid estradiol (E2) is important for the development and regulation of hypothalamic function and many aspects of reproduction in vertebrates. Pollutants, such as 4-OP, that mimic the actions of estrogens are therefore candidate endocrine disrupting chemicals. We employed a differential display strategy (RNA-arbitrarily primed PCR) to isolate partial cDNA sequences of neurotransmitter, developmental and disease-related genes that may be regulated by 4-OP or E2 in the turtle hypothalamus. Hatchling and year-old male snapping turtles (Chelydra serpentina) were exposed to 10 ppb waterborne 4-OP or E2 for 17 days. One transcript (421 bp) regulated by 4-OP and E2 was 83% identical to human APLP-2. APLP-2 and the amyloid precursor protein (APP) regulate neuronal differentiation and are also implicated in the genesis of Alzheimer's disease in humans. Northern blot analysis determined that the turtle hyothalamus contains a single APLP-2 transcript of 3.75 kb in length. Exposure to 4-OP upregulated hypothalamic APLP-2 ($p<0.05$) mRNA levels 2-3 fold in month old and yearling turtles. E2 did not affect APLP-2 in hatchlings but in contrast stimulated a 3-fold increase ($p<0.05$) in APLP-2 mRNA levels in yearling males. The protein beta-amyloid, a selectively processed peptide derived from APP is also involved in neuronal differentiation, and accumulation of this neurotoxic molecule results in neuronal degeneration in the Alzheimer brain. Therefore, we wished also to determine the effects of estrogens on its expression. Using homology cloning based on known sequences, we isolated a cDNA fragment (474 bp) from turtle brain with 88% identity to human APP. Northern blot analysis determined that a single 3.5 kb transcript was expressed in the turtle hypothalamus. In contrast to APLP-2, waterborne 4-OP and E2 did not affect the expression of APP. Our results indicate that low levels of 4-OP are bioactive and can specifically alter the expression of APLP-2. Given that APLP-2 is involved in neuronal development, we hypothesize that 4-OP exposure may disrupt hypothalamic development in young turtles. (Supported by CNTC.)

835 ABILITY OF AG AND NAC TO ACT AS SCAVENGERS OF 4-HYDROXY-2(E)-NONENAL.

L. J. Zimmerman, V. Amarnath, T. J. Montine and W. M. Valentine. *Vanderbilt University, Nashville, TN.*

Oxidative degradation of polyunsaturated lipids leads to the formation of α, β-unsaturated aldehydes, such as 4-hydroxy-nonenal (HNE), which have been linked to the progression of several age-related diseases including atherosclerosis and Alzheimer's Disease. Recent efforts in our laboratory have focused on the abilities of *N*-acetylcysteine (NAC) and aminoguanidine (AG) to prevent the reaction between HNE and proteins and mitigate subsequent tissue damaging effects from HNE. Using ^{13}C NMR spectroscopy and ^{13}C-labeled HNE, we found both NAC and AG can effectively compete with BSA for scavenging HNE. Although NAC had little effect on Michael adducts already formed on BSA, AG was able to substantially reverse the adduction and effectively remove HNE from the protein. Neither scavenger had any effect on pyrrole adducts once formed on the protein. Gel electrophoresis techniques showed that AG can effectively compete with β-lactoglobin (LG) for HNE to reduce and partially reverse protein cross-linking over time when pretreated with AG. AG, known to interfere with advanced glycation chemistry, may also act *in vivo* to effectively scavenge α, β-unsaturated aldehydes that arise from lipid peroxidation. (Supported by NIEHS Grants ES06387 and ES07028.)

836 DISULFIRAM IS A SELECTIVE SCHWANN CELL TOXICANT THAT PRODUCES S-(N,N-DIETHYLCARBAMOYL)-CYSTEINE PROTEIN ADDUCTS.

E. G. Tonkin, J. C. L. Erve, K. Amarnath and W. M. Valentine. *Vanderbilt University, Nashville, TN.*

Disulfiram (tetraethylthiuram disulfide or Antabuse®) is a dithiocarbamate drug used clinically for alcohol aversion therapy. In certain individuals, disulfiram administration produces a sensorimotor peripheral neuropathy. Disulfiram metabolism produces carbon disulfide (CS_2), but previous investigations have demonstrated minimal CS_2-mediated protein cross-linking to result from disulfiram administration, arguing against CS_2 as the proximate

neurotoxic metabolite of disulfiram. Identification of an S-(N,N-diethylcarbamoyl) glutathione metabolite of disulfiram suggested that covalent protein modification resulting from the electrophilic metabolites methyl N,N-diethylthiocarbamoyl sulfoxide or sulfone may contribute to disulfiram neurotoxicity. In the current study, male Sprague-Dawley rats were administered 1% w/w disulfiram in their diet. Hemoglobin and spinal cord axonal proteins were isolated at 2-, 4- and 7-week intervals, and separate animals were used to obtain spinal cord and peripheral nerve sections for light and electron microscopy. Protein samples were either hydrolyzed and analyzed by LC-MS/MS or examined intact by MALDI-MS for the presence of S-(N,N-diethylcarbamoyl) cysteine. Modified cysteine was detected at all time points and reached maximum levels at 2 and 4 weeks for hemoglobin and axonal proteins, respectively. A unique peak was identified in globin preparations analyzed by RP-HPLC that exhibited a mass consistent with the formation of an S-diethylthiocarbamoyl adduct on the beta3-globin chain. Elimination of modified beta3-globin obeyed first order kinetics with a half-life on the order of 11 days. Morphological changes detected in the peripheral nerves of disulfiram-exposed animals initiated with vacuole formation in the Schwann cell cytoplasm and progressed to segmental demyelination with little change observed within the axon. The formation of S-(N,N-diethylcarbamoyl) cysteine proteins adducts presents a potential mechanism through which disulfiram may target Schwann cells. (Supported by NIEH grants ES06387, ES07028, ES05764, & ES00267.)

837 FUMONISIN B1-INDUCED PRODUCTION OF REACTIVE OXYGEN SPECIES IN HUMAN NEUROBLASTOMA CELLS UNDER GLUTATHIONE DEPLETION.

H. Stockmann and K. M. Savolainen. *Finnish Institute of Occupational Health, Helsinki, Finland.*

Fungal growth in moisture problem houses often leads to exposure to large number of microbes many of which produce microbial toxins. They may cause deleterious health effects in animals and man. The typical symptoms of exposure to indoor air bioaerosols are fatigue and respiratory tract disorders such as infections, irritation of respiratory airways and the lungs, and febrile reactions, if the concentrations of the bioaerosols are sufficiently high. Recent findings also suggest that microbial toxins, e.g., fumonisin B1 (FB1), produced by Fusarium moniliforme, frequently present in mold problem houses, may cause serious effects in the CNS of animals and man. We have studied the effects of FB1 on the production of reactive oxygen species (ROS), levels of intracellular glutathione (GSH), and cell viability in human SH-SY5Y neuroblastoma cells. The cells were exposed to FB1 at concentrations of 0.01, 0.1, 1, 10, and 100 μM up to 36 h in 48-well plates. The production of ROS, the levels of GSH, and cell viability were measured at 0, 0.5, 1, 2, 3, 4, 5, 12, 24, and 36 h by using fluorescent probes, dichlorofluorescein, monochlorobimane, and propidium iodide, respectively. The exposures were carried out in the presence and absence of diethyl maleate (DEM) that effectively depletes intracellular GSH and thereby renders the cells more susceptible to oxidative stress. Exposure of the cells to FB1 induced a transient dose-dependent increase of ROS production from 0 to 5 hours, both in the presence and absence of DEM, that was not apparent at 12, 24, or 36 h. FB1 did not affect the GSH levels or cell viability at any time point. Number of studies have shown that these cell are resistant to oxidative stress. It is also tempting to speculate that the initial and transient ROS production may have lead to activation of transcription factors and subsequent alterations in gene expression that may have rendered the cells resistant to deleterious effects of FB1. (Supported by the Academy of Finland.)

838 NEURODEGENERATIVE DISEASE IN GLUCOSE-6-PHOSPHATE DEHYDROGENASE (G6PD)-DEFICIENT MICE.

W. Jeng[1] and P. G. Wells[2]. [1]*Faculty of Pharmacy, University of Toronto, Toronto, Ontario, Canada and* [2]*Faculty of Pharmacy and Department of Pharmacology, University of Toronto, Toronto, Ontario, Canada.*

During pregnancy, the antioxidative enzyme G6PD protects the embryo from endogenous and xenobiotic-initiated DNA oxidation and teratogenicity mediated by reactive oxygen species (ROS) (Nicol et al., FASEB J. [in press] 1999). Here we determined if G6PD also might protect against endogenous ROS-mediated neurodegeneration in aged G6PD-deficient mice. Six normal (+/+) and 5 heterozygous G6PD-deficient (+/-) male and female mice, about 2 years of age, were killed by cervical dislocation and the brains were isolated for subsequent histological sectioning and H&E staining. Morphological observations were examined in a blinded fashion by a certified veterinary pathologist. In addition to the typical changes relating to aging in all animals, significant degenerative changes were observed in the brains of +/- G6PD-deficient mice compared to age-matched G6PD-normal controls. In the deficient mice, there was prominent cerebellar vacuolation of the white matter and increased pathological loss of Purkinje cells with concurrent astrocyte proliferation. In the frontal cortex, an increase in the glia-to-neuron ratio in the mid- to outer regions and an increased number of chromatolytic or pyknotic (dead or dying) neurons were observed, along with numerous condensed and pyknotic centrally chromatolytic neurons at the lateral border of the hippocampus. There were also scattered examples of large vacuolated mononuclear cells adjacent to blood vessels in the hippocampus. Lipofuscin accumulation was more pronounced in +/- G6PD-deficient mice. These results are consistent with an endogenous ROS-mediated mechanism of neurodegeneration, and suggest that G6PD-deficient mice may be a useful model for these diseases. Furthermore, G6PD appears to be an importanat neuroprotective enzyme, and hereditary G6PD deficiencies, which are the most common human enzymopathies, may constitute an important risk factor for some neurodegenerative diseases. (Support: Medical Research Council of Canada.)

839 EFFETS OF SDZ PSC 833 ON GLUCOSE METABOLISM IN PRIMARY CULTURES OF RAT NEURONAL AND RAT GLIAL CELLS.

F. Cruz and A. Wolf. *Novartis Pharma AG, Experimental Toxicology, Basel, Switzerland.*

Impaired glucose metabolism plays a fundamental role in many heriditary and drug-induced neurological disorders. It was the purpose of the present study to evaluate, whether disturbances of the glucose metabolism in neural cells might also contribute to the reversible neurological side effects of PSC833 in rats. PSC833 and cyclosporine A (CsA) were investigated in primary cultures of rat neuronal and glial cells at the concentration of 0, 0.1, 1, 10 and 20 μM for 24 and 48 hours. Lactate dehydrogenase (LDH) was determined as a marker of cytotoxicity. Proliferation was determined in astrocytes. Glucose metabolism was investigated in cells by 13C-NMR using (1-13C)-glucose as a substrate. Glucose and lactate concentrations were determined spectrophotometrically in the cell culture supernatants. PSC833 at the concentrations of 10 μM PSC833 was neither cytotoxic in neuronal and glial cells, nor did it inhibite proliferation in astrocytes 24 hours after incubation. Under the same conditions, the determination of the (1-13C)-glucose metabolism revealed in both cell types, significantly increased glucose consumption by the formation of (3-13C)-lactate, as well as decreased levels of Krebs cycle intermediates in comparison to controls. In the cell culture medium 10 μM PSC833 treatment resulted from both cell types in increased glucose consumption and lactate production, same as CsA at 20 μM. The non-neurotoxic PSC833 metabolite M9 did not cause significant changes in glucose consumption and lactate formation not even at concentrations of 20 μM. The present results suggest, that PSC833-mediated impairment of the neuronal and glial glucose metabolism and the impaired TCA (tricarboxylic acid) cycle flux, resulting in decreased Krebs cycle metabolite formation, can cause energy depletion and acidosis, which might contribute to the reversible neurological symptoms of PSC833. The relevance of the present findings is strongly supported by the similar concentrations applied *in vitro* and those found *in vivo* in the brain in rats and by the finding, that the non-neurotoxic PSC833 metbolite M9 did not cause significant changes in all glucose metabolism parameters.

840 THE MITOCHONDRIAL PERMEABILITY TRANSITION: ROLE IN DIFFERENTIAL SUSCEPTIBILITY OF SY5Y NEUROBLASTOMA AND C6 GLIOMA CELLS AS A MODEL FOR 1,3-DINITROBENZENE-INDUCED ENCEPHALOPATHY.

R. B. Tjalkens, M. M. Ewing and M. A. Philbert. *Toxicology Program, Department of Environmental Health Sciences, University of Michigan, Ann Arbor, MI.*

1,3-Dinitrobenzene (DNB)-induced encephalopathy is mediated by oxidative stress and mitochondrial dysfunction. The ability of DNB to induce mitochondrial permeability transition (MPT) was investigated in SY5Y neuroblastoma and C6 glioma cells. The present studies evaluate the differential susceptibility to induction of MPT following exposure to DNB. Neuroblastoma cells were more sensitive to the cytotoxic effects of DNB than glioma cells, as measured by the capacity of mitochondria to reduce the tetrazolium compound, 3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide (MTT). The IC_{50} values for inhibition of MTT reduction by DNB were 107±25 μM in SY5Y cells and 1047±101 μM in C6 cells. DNB induced abrupt depolarization of mitochondria in both neuroblastoma and glioma cells that was inhibited by trifluoperazine. Onset of MPT occurred at ten-fold lower concentration of DNB in SY5Y cells than in C6 cells, consistent with the observed differential sensitivity to DNB-induced mitochondrial dysfunction.

Antioxidants, deferoxamine and α-toxopherol acid-succinate, prevented DNB-induced MPT in C6 and SY5Y cells, indicating that oxidative stress was involved in the induction of MPT by DNB. Exposure to DNB also caused a decrease in mitochondrial calcium in SY5Y and C6 cells, concurrent with onset of MPT. Mitochondrial calcium release was blocked by trifluoperazine, deferoxamine, and α-toxopherol, suggesting that DNB-induced mitochondrial calcium efflux requires induction of oxidative stress and opening of the permeability transition pore. These data demonstrate that SY5Y neuroblastoma and C6 glioma cells are differentially susceptible to DNB-induced MPT and suggest that differences in regulation of MPT may contribute to cell-specific oxidative injury in the central nervous system. (Supported by PHS-NIH grants ES08846 and ES06103.)

841 BCL-2-FAMILY PROTEIN EXPRESSION IN DIFFERENTIAL SENSITIVITY OF SY5Y NEUROBLASTOMA AND C6 GLIOMA CELLS TO 1,3-DINITROBENZENE-INDUCED MITOCHONDRIAL PERMEABILITY TRANSITION.

M. A. Philbert and R. B. Tjalkens. *Toxicology Program, Department of Environmental Health Sciences, University of Michigan, Ann Arbor, MI.*

In brain, regional and cellular differences in regulation of the mitochondrial permeability transition (MPT) may mediate sensitivity to endogenous and exogenous oxidants. The correlation between expression of Bcl-2-family proteins and sensitivity to 1,3-dinitrobenzene (DNB)-induced MPT was examined in C6 glioma and SY5Y neuroblastoma cells. C6 glioma and SY5Y neuroblastoma cells were exposed to DNB and evaluated by laser scanning confocal microscopy for loss of mitochondrial membrane potential, measured using the fluorescent cationic dye, tetramethylrhodamine (TMRM). DNB caused a rapid decrease in mitochondrial membrane potential in both C6 and SY5Y cells. By 40 min, membrane potential in SY5Y cells exposed to 50 μM DNB was reduced similarly to that in C6 cells exposed to 500 μM DNB. The first order rate constants for mitochondrial depolarization were: C6, $k = 0.31 \pm 0.02$ min^{-1}; SY5Y, $k = 0.14 \pm 0.01$ min^{-1}. Loss of mitochondrial membrane potential was inhibited in both cell lines by pretreatment with trifluoperazine, indicating onset of MPT. The antioxidants desferoxamine and α-tocopherol prevented DNB-induced loss of mitochondrial membrane potential, suggesting that oxidative stress from DNB exposure induced opening of the PTP. Following 60 min exposure to DNB, cellular ATP levels were reduced to 63% and 22% of control in C6 and SY5Y cells, respectively. The expression of Bcl-2, Bcl-X_L, and Bax was evaluated in C6 and SY5Y cells by western immunoblotting. C6 cells strongly expressed Bcl-X_L and only weakly expressed Bcl-2 and Bax, whereas SY5Y cells expressed lower levels of Bcl-X_L and higher levels of both Bcl-2 and Bax. These results suggest that higher constitutive expression of Bcl-X_L, rather than Bcl-2, correlates with resistance to DNB-induced MPT. (Supported by PHS-NIH grants ES08846 and ES06103.)

842 THE EFFECT OF PHENYLALANINE AND ITS METABOLITES ON ASTROCYTE PROLIFERATION: A POTENTIAL MECHANISM FOR PHENYLKETONURIA?

J. Oberdoerster, M. Wei and L. G. Costa. *University of Washington, Seattle, WA.*

Phenylketonuria (PKU) is a genetic defect that, without strict dietary control, results in the accumulation of phenylalanine (Phe) in body fluids. If the proper diet is not maintained during pregnancy, the offspring of phenylketonuric women are born with mental retardation and microcephaly (i.e., maternal PKU (mPKU)). Primary cultures of rat astrocytes and human astrocytoma (132 1N1) cells were used to test the hypothesis that the smaller brain size of individuals with mPKU is a result of reduced astrocyte proliferation. A 24 hr exposure to Phe or to six Phe metabolites (phenylacetic acid (PAA), phenyllactic acid, hydroxyphenylacetic acid, phenylpyruvic acid, methyl phenylalanine, and phenylethylamine (PEA), mandelic acid) did not result in cytotoxicity measured by the release of lactate dehydrogenase. Exposure to Phe, however, decreased cell proliferation measured by the incorporation of [3H]thymidine into cellular DNA. This effect was concentration dependent, and flow cytometry revealed that Phe exposure results in the accumulation of cells in the Go/G1 phase of the cell cycle. In addition, in 132 1N1 cells, exposure to PAA, and in rat astrocytes, exposure to PEA inhibited cell proliferation. Membrane localization is critical for the activation of Ras and RhoA, two small G-proteins that are involved in cell cycle progression. Immunoblot analysis revealed that treatment of both rat astrocytes and 132 1N1 cells with Phe analogs that inhibit proliferation results in an accumulation of Ras and RhoA in the cytoplasm. These results suggest that the central nervous system dysfunction associated with PKU, at least in part, may be due to reduced astrocyte proliferation, and that this effect may involve diminished translocation of Ras and RhoA to the cell membrane. (Supported by T32 ES07032 and P30 ES07030.)

843 COMPARISON OF A DYNAMIC, THREE-DIMENSIONAL, *IN VITRO* BLOOD BARRIER MODEL TO THE TWO-DIMENSIONAL CULTURE INSERT SYSTEM TO STUDY DRUG PASSAGE ACROSS THE BRAIN ENDOTHELIAL MONOLAYER.

S. B. Munro and S. G. Gilbert. *SNBL USA, Ltd., Redmond, WA.*

Promising therapeutics aimed at the CNS often fail in clinical trials, since many drugs are excluded by the blood-brain barrier (BBB). An *in vitro* model of the BBB is therefore an invaluable tool for researchers studying drug passage across the brain endothelial monolayer. The purpose of this study was to compare two configurations of an *in vitro* barrier model for use in assaying the ability of compounds to cross the BBB. The first model consisted of a two-dimensional system using bovine endothelial cells seeded onto the apical side of culture insert filters, which were placed into the wells of a 6-well plate. The permeability of the endothelial cell monolayers were measured by adding permeate (14C-Diazepam) and impermeate (3H-Sucrose) compounds. Aliquots were removed from the insert chambers and wells at several time intervals, and permeability values were calculated from the measured 14C and 3H levels. The results show that while the cells did establish a barrier to the compounds relative to blank inserts, the permeability values obtained for diazepam versus sucrose were not found to be significantly different. We then tested a model of the BBB consisting of a three dimensional co-culture system, using several artificial capillaries supported inside a sealed chamber. Bovine endothelial cells were seeded intraluminally, while rat glial cells were seeded in the extraluminal space. 3H-Sucrose and 14C-Diazepam were applied to the *in vitro* BBB intraluminally. Aliquots of media were taken from the extraluminal space and the intraluminal space at several time intervals and assayed for the presence of each compound. The permeability values obtained for diazepam were found to be on the order of 100-fold greater than those obtained for sucrose. This data demonstrates that the dynamic, three-dimensional model is much more sensitive in assessing the ability of compounds to cross the blood brain barrier, and more closely resembles the *in vivo* BBB.

844 POSITIVE MODULATION OF AMPA RECEPTORS PROMOTES CELLULAR REPAIR FOLLOWING EXCITOTOXIC INJURY TO BRAIN TISSUE *IN VITRO* AND *IN VIVO*.

B. A. Bahr[1], J. Bendiske[1], G. Rogers[2], M. Rudin[3], S. Urwyler[3] and A. Sauter[3]. [1]*University of Connecticut, Storrs, CT,* [2]*Cortex Pharmaceuticals, Irvine, CA and* [3]*Novartis Pharma AG, Basel, Switzerland.*

Ampakines are compounds developed for the treatment of neurological disorders. They enhance the ionotropic activity of AMPA receptors, glutamate-gated channels also known to function as cell-surface signal transducers by interacting with and/or regulating G-proteins, Src-family kinases, and MAP kinase pathways involving CREB and the neurotrophic factor BDNF (Nature 389:502, 1997; ibid. 397:72, 1999; J. Neuroscience 19:2954&5861, 1999). This study tested whether Ampakines can promote cellular viability by augmenting such metabotropic actions. Accordingly, CX516 (1-(quinoxalin-6-ylcarbonyl)piperidine) and other Ampakines were screened for protective effects in hippocampal slice cultures and adult rats treated with excitotoxic levels of AMPA (15-min infusion vs. intrastriatal injection). In the slices, the selective loss of CA1 neurons evident 24 h later was reduced 75% by 100 μM CX516; all subfields exhibited normal cell density and morphology 10 days post-insult when the Ampakine was administered. In the rats, CX516 co-injected with AMPA attenuated the MRI-measured lesion extent by 65% in a dose-dependent manner. Effects on changes in neuronal markers (CAT and GAD) also indicated protection. Persistent injury in the slice model, measured as calpain-induced cytoskeletal breakdown, exhibited Ampakine-mediated recovery in pyramidal and dendritic zones. Such cellular recovery was evident when Ampakines were administered before or after the excitotoxic episode. These data indicate that Ampakines promote signaling cascade(s) underlying neuroprotection. Close correspondence between protective action and electrophysiological influences among micromolar- and nanomolar-potent analogs will be discussed.

845 POTENTIATION OF OCTAVE-BAND NOISE INDUCED AUDITORY IMPAIRMENT BY HYDROGEN CYANIDE INHALATION.

J. Kong, G. Chen, W. Tawackoli and L. D. Fechter. *University of Oklahoma, Health Sciences Center, Oklahoma City, OK.*

It is known that noise, hydrogen cyanide (HCN) and carbon monoxide (CO) are present in various environmental situations and can cause serious hazards with neurotoxicological effects. In previous studies from our lab, broadband and octave-band noise induced hearing loss has been found to be potentiated by simultaneous CO exposure. In the present study, octave-band noise induced auditory impairment was studied with the presence of HCN gas at levels of 10, 30 and 50 ppm. The American Conference of Governmental Industrial Hygienists (ACGIH) threshold limit value (TLV) is 10 ppm or 11 mg/m3 as a ceiling value, also with a "skin" notation. The octave-band noise had a center frequency of 13.6 kHz and the intensity of noise used was 100 dB (Ln). Experimental animals (rats) were exposed to noise, HCN and their combinations in the chamber for 2 hours. The compound action potential (CAP) and cochlear microphonics (CM) were recorded 4 weeks after the exposure to assess permanent auditory impairment. Noise induced elevation of the CAP threshold and the CM iso-amplitude curve were potentiated by the simultaneous HCN exposure of 10 ppm or higher. HCN potentiation seems dosage-dependent. HCN exposure alone had no effect on CAP and CM. The size of the potentiation shown by CAP and CM was similar, indicating a possible origin of HCN potentiation from damage to the outer hair cells. (This project was funded by NIOSH grant OH03481 to L.D. Fechter and by NSF EPSCoR Cooperative Agreement OSR-9550478.)

846 INTERMITTENT NOISE INDUCED HEARING LOSS AND THE INFLUENCE OF CARBON MONOXIDE.

G. D. Chen, M. L. McWilliams and L. D. Fechter. *University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Intermittent noise causes less hearing loss than continuous noise of equal intensity. The reduction in damage observed with intermittent noise may be explained by the fact that the auditory system has time to recover between the noise phases. Simultaneous carbon monoxide (CO) exposure produces greater noise-induced hearing loss than does noise alone. In the present study, intermittent noise (octave-band with center frequency of 13.6 kHz, 100 dBLin) of 2-hours total duration, but with different noise duty cycle (% of noise during exposure) was used. The intermittent exposure that had shorter noise duty cycle (more rest periods in noise) induced less permanent threshold shift (PTS) than those that had longer noise duty cycle (or fewer rest periods). This relation between the loss in compound action potential (CAP) sensitivity and the noise duty cycle (or rest period) was abolished by the presence of CO. That is, all noise exposures produced equivalent threshold shifts if CO was present. Cochlear microphonic (CM) amplitude revealed similar results to those seen using the CAP. While intermittent noise did not cause hair cell loss by itself, the combined exposure to noise and CO (1200 ppm) caused remarkable OHC loss in the basal turn. (This work was supported by NIOSH grant OH03481 to L.D. Fechter and by NSF EPSCoR Cooperative Agreement OSR-9550478. The authors thank Dr. D.L. Ding for the helpful technical advice.)

847 COCHLEAR HISTOCHEMICAL CHANGES AFTER LOW MODERATE LEVEL TOLUENE EXPOSURE.

G. D. Chen, M. L. McWilliams, J. Kong and L. D. Fechter. *University of Oklahoma Health Science Center, Oklahoma City, OK.*

Toluene is known as an ototoxic agent. However, permanent hearing loss has been reported in rats only after toluene exposure of 1000 ppm for 16 h/d for 5 days. Current permissible exposure limit (PEL) of toluene for human is 100 ppm. The current study evaluated cochlear function succinate dehydrogenase activity and apoptosis acutely following toluene exposure. Changes in succinate dehydrogenase (SDH) activity in auditory hair cells serve as an early marker of cellular stress in cochlear hair cells. In this study guinea pigs were exposed to low level toluene (1000 ppm, 500 ppm and 250 ppm) 8h/d, 5d/w for 4 weeks and distortion product testing was undertaken to assess outer hair cell function. Cochleae were removed immediately after the last exposure and incubated with SDH incubation solution. Reduced SDH activity in hair cells was observed in the basal turn in the animals exposed to 500-ppm and 1000-ppm toluene. However, this change was not seen in the animals with 3-day recovery period after exposure. Interestingly, the changes are comparable to the measurements of distortion product otoacoustic emmission (DPOAE). A few outer hair cells in the very base turn (corresponding to frequencies higher than 24 kHz) also showed signs of programmed cell death (apoptosis) suggesting the development of limited cellular damage undetectable using functional testing. The data show a clear low-level toluene-induced impairment of auditory hair cells. Some impairment may develop into a permanent injury. (Supported by NIEHS grant ES08082 and NIOSH grant OH03481 to L.D. Fechter and by NSF EPSCoR Cooperative Agreement OSR-9550478.)

848 LOW-MODERATE LEVELS OF TOLUENE INFLUENCE ON AUDITORY FUNCTION AND RELATED BLOOD CONCENTRATIONS IN THE GUINEA PIG.

M. L. McWilliams, D. P. Wang, G. D. Chen, T. A. Hall and L. D. Fechter. *University of Oklahoma Health Science Center, Oklahoma City, OK.*

Toluene is a widely used organic solvent has adverse effects on the human auditory system, the mechanism of which is unclear. The current permissible exposure limit (PEL) for inhalation by humans is 100 ppm, which is also the lowest-observed-adverse-effect level (LOAEL) for acute neurological effects in humans. Recently, our studies in the guinea pig found that an acute disruption of otoacoustic emissions occurs for 8 hr/day, 5 day/wk inhalation exposures as low as 250 ppm. Interestingly, after 4 weeks of exposure, the disruption did not develop into a permanent hearing loss but an acute decrease in succinate dehydrogenase activity was seen. Published data suggest that 50% of toluene is metabolized within the first 60 min post-exposure. This rapid elimination of toluene may be related to the lack of a permanent hearing loss at low toluene concentrations. Subjects were exposed to 500 ppm for 8 hr/day and monitored for auditory disruption and succinate dehydrogenase activity at multiple points during the exposure. Additional subjects were exposed concurrently for determination of blood concentration. Data shows the low-moderate toluene inhalation effects on acute DPOAE shift, toluene blood concentrations, and succinate dehydrogenase activity. (This work was supported in part by NIEHS grant ES08082 and NIOSH grant OH03481 to L.D. Fechter and by NSF EPSCoR Cooperative Agreement OSR-9550478.)

849 DOSE RESPONSE OF CARBOPLATIN-INDUCED OTOTOXICITY IN RATS.

K. Husain, R. B. Scott, S. M. Somani and L. P. Rybak. *Southern Illinois University School of Medicine, Springfield, IL.*

Carboplatin, a platinum containing anticancer drug, currently being used against sarcomas of head and neck. However, a single high dose of carboplatin is ototoxic in cancer patients. This is the first study to show the ototoxic potential of carboplatin in a rat model. Male Wistar rats were divided into five groups and treated as follows: 1) control (saline, i.p.); 2) carboplatin (64 mg/kg, i.p.); 3) carboplatin (128 mg/kg i.p.); 4) carboplatin (192 mg/kg, i.p.) and 5) carboplatin (256 mg/kg, i.p.). Animals in all groups were sedated with ketamine/xylazine and auditory brain-evoked responses (ABER) were recorded then they were treated as above protocol. Post treatment ABER were measured four days after dosing. The animals were sacrificed on the fourth day and cochleae were harvested and analyzed. Carboplatin dose dependently decreased body weight (82%, 75%, 70% and 54% of control) respectively. No significant changes were noted on ABER threshold at 64 mg/kg and 128 mg/kg dose of carboplatin. However, at higher doses of carboplatin (192 mg/kg and 256 mg/kg), there was a significant elevation of hearing threshold shifts at clicks, 4, 8, 16, and 32 KHz tone burst stimuli. The cochlear antioxidant enzyme activities (SOD, CAT, GSH-Px, GR and GST) were decreased (90%-51% of control) with increasing dose of carboplatin. Cochlear lipid peroxidation was significantly increased (111-146% of control) in a dose dependent manner. The data suggest that higher dose of carboplatin induces oxtotoxicity as evidenced by a significant elevation of hearing threshold shifts, enhanced cochlear lipid peroxidation and depletion of cochlear antioxidant defense system in rats. (Supported by SIU School of Medicine and National Organization of Hearing Research.)

850 TOPOGRAPHIC ANALYSIS OF FLASH VISUAL EVOKED POTENTIALS IN DOGS.

T. Okamoto and M. Yasuda. *Medicinal Safety Research Laboratories, Sankyo Co., Ltd., Shizuoka, Japan.* Sponsor: S. Manabe.

A visual evoked potential by flash stimulation (flash VEP) indicates an electrophysiological response from the retina to the visual cortex and is expected to be applied in the evaluation of neurotoxicity. Although flash VEPs have

been recorded in dogs, the relation between waves and the visual pathway is not well known. We analyzed the flash VEPs in dogs using a topographic method. On the topographic mapping, a negative response area indicated that evoked potentials were observed in the frontal region of the brain in the stimulated site followed by the shifting of the area to the contralateral frontal region and occipital region, during the first 100 msec. The negative response area in the frontal region in the stimulated site, contralateral frontal and/or temporal region, and occipital region were observed at latencies of N1, P2 and N2 of the flash VEP, respectively. On the ERG, the latencies of a- and b-waves were 12 and 30 msec, respectively. The latencies of a- and b-waves on the ERG were coincident with the latencies of P1 and N1 on the flash VEP. In the dogs with experimentally impaired right lateral geniculate bodies, the latency of P2 was prolonged and the N2 and P3 components of the flash VEPs disappeared after stimulation in the left eye. Only the early negative response area was detected at the stimulated site of the frontal region on the topographic mapping. Therefore, it is concluded that P1 and N1 are referred to ERG, P2 is referred to the potentials from the retina to the brainstem and N2 is referred to those from the brainstem to the visual cortex, respectively.

851 MORPHOMETRIC MEASUREMENT VALIDATION STUDY COMPARING DAY 9 AND DAY 11 SPRAGUE-DAWLEY RATS.

R. M. Parker[1], R. H. Garmen[2], A. M. Hoberman[1], R. G. York[1] and J. F. Barnett, Jr.[1]. [1]*Primedica Argus Research Laboratories, Inc., Horsham, PA and* [2]*Consultants in Veterinary Pathology, Monroeville, PA.*

This study validates an approach to the morphometric component for the US EPA OPPTS 870.6300 Developmental Neurotoxicity Study. Rather than subjecting pregnant rats to a variety of neurotoxic agents, the decision was made to initially perform the morphometric measurements on Day 9 and 11 Sprague Dawley (Crl:CD®BR VAF/Plus®) rat pups. Days 9 and 11 were chosen to demonstrate that the measurement data from the selected neuroanatomic areas would reveal age-related developmental difference and might, therefore, be predictive of either an *in utero* neurotoxic effect or a delay in brain development. Nine gross and microscopic morphometric measurements were made on the five brains/sex/timepoint: anterior-posterior length of the cerebrum and cerebellum; thickness of the frontal and parietal cortex, corpus callosum, hippocampal gyrus and external granular layer (cerebellum); width of the caudate/putamen; and height of the cerebellar cortex. As expected, the mean values for all of the neuroanatomic measurements were greater for the 11 day-old rat pups than for the 9 day-old pups, but there was overlap between the Day 9 and Day 11 rat pup data with the greatest measurement for at least one 9 day-old pup being greater than the lowest measurement for one of the 11 day-old pups. However, in spite of moderate data overlap between the two age groups and the presence of moderate intra-age group variability in the measurements for each neuroanatomic location, statistically significant increases were found for the following brain regions: anterior-posterior length of the cerebrum and cerebellum, thickness of the frontal cortex, width of the caudate/putamen, and height of the cerebellar cortex. Control morphometric data from six Developmental Neurotoxicology Studies will also be presented.

852 NEUROBEHAVIORAL EVALUATION OF RESIDUAL EFFECTS OF ACUTE CHLORINE INGESTION.

R. M. Singer. *Raymond Singer, Ph.D. - A Professional Association, Santa Fe, NM.*

Rationale: Chlorine exposure can lead to respiratory dysfunction resulting in brain cell hypoxia, injury and neurobehavioral disorders. **Assessment Approach:** Comprehensive neurobehavioral toxicity evaluations were performed on 2 cases, including WAIS, Neurotoxicity Screening Survey, Trailmaking (TT), and memory tests including Benton Visual Retention test (BVRT), Expanded Paired Associates Tests (EPAT), a logical memory test (LM), Selective Reminding Test (SRT), and tests for malingering and distortion. **Summary of Findings:** Case 1, 59 year old Ph.D., pre-exposure IQ 95th %, was served water contaminated with chlorine disinfectant, went into respiratory distress and treated at the local emergency room. He was examined 3 years post-exposure, and found to have vocal cord dysfunction and sleep apnea, central-type. BVRT showed 9 errors (strong indication of brain impairment); EPAT was at 34th and 17th %; *Neurotoxicity Screening Survey* was elevated at 236; SRT was at the 8th %; TT was at the 50th and 31st %; and LM < 1st %. Case 2, 40 year old male nurse, pre-exposure IQ at the 63rd%, was examined 1.5 years post-exposure to iced tea contaminated with chlorine. He developed reactive airway disease. Current IQ was at the 32nd %, with specific deficits in immediate memory, visual logic and psychomotor speed, all at the 16th %. BVRT showed 14 errors; EPAT was at 5th and 1st%; *Neurotoxicity Screening Survey* was elevated at 332; SRT was at 2nd %; TT was at 2nd and 24th %; LM < 1st. Follow-up interviews at 1 and 2 years post-exam indicated continued symptoms. In both cases, all test results of malingering were negative, and medical record review found no other explanations for the declines. **Conclusion:** Chlorine ingestion neurotoxicity was found which lasted many years after exposure.

853 USE OF TWO AROCLOR* LOTS TO EVALUATE TEQ AND OXIDATIVE STRESS PREDICTORS.

D. E. Burgin[1], J. J. Diliberto[2], P. R. S. Kodavanti[3] and L. S. Birnbaum[2]. [1]*UNC Curriculum in Toxicology/USEPA, Research Triangle Park, NC,* [2]*USEPA/NHEERL/ETD, Research Triangle Park, NC, and* [3]*USEPA/NHEERL/NTD, Research Triangle Park, NC.*

In order to characterize risk associated with exposure to polyhalogenated aromatic hydrocarbons (PHAHs), the toxic equivalency factor (TEF) approach was created. Mixtures of polychlorinated biphenyls (PCBs) can thus be compared against dioxin. Two commercial mixtures of Aroclor 1254, Lot 6024 and Lot 124-191, were analyzed and Lot 6024 has approximately ten times the dioxin toxic equivalents (TEQ) of Lot 124-191. The purpose of this study was to determine if the TEQ for the two lots is predictive of any oxidative responses seen on a weight basis. Previous studies in our laboratory indicate that the TEQ is not predictive of all induced enzyme levels in lots with high non-dioxin like congeners. The TEQ works for EROD and MROD, not for PROD or T4 tests. Cytochrome c reduction, a measure of superoxide anion production, was in evidence only at the highest dose of Lot 124-191. Ascorbic acid, an antioxidant, was elevated at the highest doses for both lots. Uric acid, an antioxidant, showed a significant decrease over control at the highest dose for Lot 124-191. This suggests that multiple mechanisms that can lead to higher than expected levels of oxidative stress. In the present study, it is apparent that TEQs for mixtures can explain the variances in dioxin-like effects, but non-dioxin like congeners cause other responses that are not associated with the Ah receptor. The TEQ approach works well when only dioxin-like PHAHs are present. However, when non dioxin-like PCBs are present, application of the TEF approach must be used with caution. This is due to both synergistic and antagonistic interactions that have been observed with PCB mixtures. For antagonism, the TEF approach would overestimate the toxicity of a PCB mixture. For synergism, the TEF approach could significantly underestimate the toxicity of a mixture. For protection of human health and the environment, current regulations rely on the toxicity of individual congeners and do not take into account possible interactions. (This abstract does not necessarily represent EPA policy. DEB supported by EPA CT902908.)

854 HUMAN INTERINDIVIDUAL VARIABILITY IN THE EXPRESSION OF CYTOCHROME P450 FORMS CRITICAL TO XENOBIOTIC METABOLISM.

J. C. Lipscomb[1], C. A. F. Striley[2] and J. E. Snawder[2]. [1]*U.S. Environmental Protection Agency, NCEA, Cincinnati, OH and* [2]*National Institute for Occupational Safety and Health, Cincinnati, OH.*

Estimates of human interindividual differences in susceptibility to toxic insult may have their basis in pharmacokinetic (PK) and/or pharmacodynamic (PD) variations. Although the US EPA does consider separating uncertainty factors into PK and PD components, as done for perchlorate, there are no guidelines to inform such a process, and critical data are often absent. However, other agencies have separated the animal to human uncertainty factor (UF_A) into PK and PD components. To quantify human interindividual differences and produce results which might be used to support data-derived uncertainty factors for human interindividual variability (UF_H) with respect to the PK component, we have quantified and determined the distribution of several cytochrome P-450 (CYP) forms in a group of 141 human hepatic microsome samples. Mean and SD values (pmol CYP/mg microsomal protein) of CYP1A, CYP2E1 and CYP3A forms were 33.6±28.1, 59.4±18.2, and 141.9±104.5, respectively. Further, activity (pmol/min/pmol microsomal protein) towards substrates characteristic for a total of 7 CYP forms demonstrated standard deviations of 46 to 111% of mean values and normal distributions.Immunologically-detected CYP1A, CYP2E1 and CYP3A forms were also normally distributed. When data on enzyme selectivity for a given chemical exist, the specific activity of that enzyme can be combined with data describing the varaibility of enzyme expression to determine the extent of human interindividual variability in the intrinsic metabolism of the chemcial. Variations in intrinsic metabolism can be included in physiologically based PK models as has been done for trichloroethylene (*Toxicol Appl Pharmacol* 152:376-387, 1998). This improves estimates of human PK variability by including physiologic constraints such as solubility in blood and delivery to the liver.

855 PROSPECTS FOR IMPROVING RISK ASSESSMENT USING DNA-BASED MUTATION DETECTION.

B. L. Parsons and R. H. Heflich. *National Center for Toxicological Research, Jefferson, AR*. Sponsor: W. Slikker.

The sensitivity associated with the DNA-based detection of specific, somatic mutations, termed genotypic selection, continues to improve. We have developed an assay, MutEx/ACB-PCR with a sensitivity of 10-7 in reconstruction experiments. Application of MutEx/ACB-PCR to the detection of specific point mutations in genomic DNA requires isolation of genomic DNA fractions enriched for particular DNA sequences and this methodology is currently being developed. Extrapolation from other mutational targets suggests that the frequency of spontaneous basepair substitution mutation is on the order of 10-7 per basepair. Thus, a genotypic selection with a sensitivity of 10-7 may be sufficient to detect spontaneous mutation as well as any chemically induced mutations at particular oncogene and tumor suppressor gene sites. The potential to use genotypic selection to improve chemical risk assessment should now be explored. We propose that specific mutations known to predominate the human tumor spectrum (i.e., ras and p53 hotspot mutations) be developed as targets for genotypic selection. With such assays, induced mutant frequencies could be measured in situations of known mutagen/carcinogen exposure. For example, tissues of patients who had received chemotherapeutics could be analyzed and compared to those of untreated individuals and similar analyses, using equivalent doses, could be performed in rodent models. In so doing, the relevance of the rodent model for human risk assessment could be established in a quantitative manner with regard to a particularly relevant endpoint for cancer risk assessment, oncogene and tumor suppressor gene mutation. Replacing the default safety margins used to account for uncertainty in species extrapolation with precise measures of chemical-specific, cancer gene mutation induction is an example of how mechanistic data could be incorporated into and improve chemical risk assessment. (Sponsored by the SOT Regulatory and Safety Evaluation Specialty Section.)

856 ESTIMATION OF ACUTE INHALATION THRESHOLD CONCENTRATIONS FOR HUMAN EXPOSURE FROM LIMITED ANIMAL DATA.

T. L. Long, H. T. Borges, C. B. Bast, K. A. Davidson, C. S. Forsyth, S. Milanez, C. M. Troxel, R. A. Young and S. S. Talmage. *Oak Ridge National Laboratory, Oak Ridge, TN.*

Data on safe concentrations for human exposure are lacking for many potentially hazardous chemicals that may be accidentally released to the atmosphere. We reviewed available sublethal and lethal animal and human toxicity data on 50 chemicals that are produced and transported within the United States. Inhalation exposure limits were derived for 30 min to 8 hr timepoints representing airborne concentrations 1) at or above which most individuals would experience irreversible or disabling effects and 2) which represent a threshold for lethality among humans. These concentration limits were based on the toxicity data and use of appropriate uncertainty factors. Ratios between these levels were generally 10 (92%), and most were 5 (80%). Only four chemicals had ratios that were >10 (8%). The mean ratio for the fifty chemicals analyzed was 5.04±6.22, the median was 3, and the range was 1.7-40. The 95% confidence limits were 3.27-6.80. An analysis of toxicity data utilized for development of these levels revealed a significant difference between ratios for chemical-specific values that were based on human and animal data, values based on animal data from different species ($p<0.05$), or values derived from data using the same animal species (n.s., but an obvious difference). Independent t-tests were used to determine statistical significance between groups of ratios. In summary, when data are lacking for determination of exposure concentrations associated with disabling or irreversible effects of a chemical in humans, a five-fold reduction of the lethality threshold from animal data would encompass ~ 80% of these situations, and a ten-fold reduction would encompass ~92% of these cases.

857 GUIDELINES FOR APPLICATION OF DATA-DERIVED UNCERTAINTY FACTORS IN RISK ASSESSMENT.

B. Meek[3], E. Ohanian[5], A. Renwick[6], B. Naumann[4], B. Lake[2], V. Vu[5], L. Haber[1] and M. Dourson[1]. [1]*Toxicology Excellence for Risk Assessment, Cincinnati, OH,* [2]*BIBRA International, Surrey, United Kingdom,* [3]*Health Canada, Ottawa, Canada,* [4]*Merck & Co., White House Station, NJ,* [5]*U.S. EPA, Washington, DC and* [6]*University of Southampton, Southampton, United Kingdom.*

A meeting of investigators of the data-derived uncertainty factor approach for estimating tolerable intakes, acceptable daily intakes or reference doses/concentrations is described. This meeting was designed to move beyond the default uncertainty factors of the IPCS (1994) scheme, by providing an initial description of criteria for the sufficiency of data for use as the basis of data-derived uncertainty factors. The results of this meeting are that animal and human data must be compared on the basis of the measurement of similar endpoints that are relevant to the critical effect. This comparison should consider all available toxicity studies, including all available studies on potential mechanisms of toxicity, modes of action, and biological plausibility. One should recognize that *in vivo* toxicity studies can often give results that reflect both kinetic and dynamic differences, and that some information on either, or both, can be wrought from such studies. Specifically, for consideration of adequacy of data to replace the default value for the toxicokinetic component of data within humans, or between humans and animals, a good PBPK model was considered the best basis for a quantitative interspecies comparison, followed by a good kinetic study in both experimental animals and humans where issues of chemical species, route of administration, amount of dose or concentration, and length of exposure are all carefully evaluated. Specifically, for dynamics comparison of animal to human or within human data, the basis of dynamic comparison must be relevant to the critical endpoint used as a basis of the RfD or TI. The quantitative determination of human toxicodynamic (and perhaps toxicokinetic) data-derived factors should compare mean values to 2 or 3 standard deviations away (as appropriate for endpoint). Comparison with sensitive subgroups should compare mean values in general population with 2 or 3 standard deviations away from the sensitive population mean value. Means values between these populations should not be used as the data-derived factor.

858 COMPARISON OF A SINGLE POINT ESTIMATE METHOD TO BENCHMARK DOSE RESPONSE MODELING FOR ESTIMATING POTENCY OF CARCINOGENS.

C. B. Van Landingham, A. M. Shipp and K. S. Crump. *The K S Crump Group, ICF Consulting, Ruston, LA*. Sponsor: M. A. Friedman.

The T25 method of evaluating the carcinogenic potency of a chemical, which is currently used by the European Economic Council, is based on the selection of a single dose in a chronic bioassay with an incidence rate that is significantly higher than the background rate. The T25 is determined from that single point by a linear extrapolation or interpolation to the chronic dose, in mg/kg/day, at which it is expected that there would be a 25% increase in the incidence of the specified tumor type above the background rate. Another method of deriving a carcinogenic potency value based on a 25% increase in incidence above the background rate is the estimation of an ED25 derived from a benchmark dose response model fit to the chronic bioassay data for the specified tumor type. A detailed comparison was made between the two methods using more than 250 chronic bioassays conducted by the National Toxicology Program. In each of the two-year bioassays, a tumor type was selected based on statistical and biological significance, and both T25 and ED25 benchmark estimates were determined for that endpoint. In addition, simulations were done using underlying cumulative probability distributions to examine the effect of dose spacing, number of animals per dose group, the possibility of a dose threshold, and variation in the background incidence rates on the T25 and ED25 estimates. The simulations showed that in the majority of cases the T25 method underestimates the true T25 dose and overestimates the carcinogenic potency. The ED25 benchmark estimate is generally less biased and has less variation about the true T25 value.

859 DEVELOPMENT OF A PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODEL FOR A BIOLOGICALLY-BASED DOSE-RESPONSE ASSESSMENT FOR DIMETHYL SULFATE.

M. S. Bogdanffy[1], R. Sarangapani[2], J. Teegaurden[2] and H. A. Barton[3]. [1]*DuPont Haskell Laboratory, Newark, DE.* [2]*K.S. Crump Group, ICF Consulting, Research Triangle Park, NC and* [3]*NHEERL USEPA, Research Triangle Park, NC.*

A biologically based dose response analysis was developed to derive appropriate control strategies for dimethyl sulfate (DMS). Dimethyl sulfate is an oily, colorless liquid with a wide variety of industrial applications. Inhalation studies have shown that repeated exposure to DMS leads to upper and lower respiratory tract tumors in rats and mice. The weight of experimental evidence suggests that DMS possesses genotoxic and carcinogenic potential. Here we present a quantitative dose-response assessment for inhaled DMS using a physiologically based pharmacokinetic (PBPK) model which is used to complete the necessary interspecies (rat-human) dosimetry extrapolation. The model is designed to predict the number of DNA adducts in the nasal mucosa following DMS exposure. The model predictions are compared to experimentally measured N7-methyl guanine (N7mG) DNA adduct levels in the respiratory and olfactory mucosa of rats following repeated daily exposures. The model predicts a steady increase in adduct levels during exposure and a rapid removal of adducts following cessation of exposure, similar to what is seen experimentally. The existing cancer bioassay data on DMS was modeled to determine the point of departure for low dose extrapolation using N7mG DNA adducts as the dose metric. Using the LED10 value from the rat cancer bioassay analysis and the pharmacokinetic model, human equivalent concentrations (HEC) were determined for various risks and exposure scenarios. These HECs were used to support development of appropriate control strategies for DMS exposure.

860 A TEST FOR REASONABLENESS OF DEFAULT VALUES FOR ENVIRONMENTAL CHEMICALS USING MONTE-CARLO SIMULATIONS AND PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODELS.

H. A. El-Masri and M. M. Mumtaz. *Computational Toxicology Laboratory, Division of Toxicology, Agency for Toxic Substances and Disease Registry, Atlanta, GA.*

Often the toxicity of environmental chemicals has to be estimated, based on certain assumptions. Some assumptions such as uncertainty factors are well recognized while others are not. Uncertainty factors (UF) of 10 have been routinely used for various types of extrapolations by governmental agencies, advisory bodies, and the private sector, and have been widely accepted by the scientific community. This study was undertaken to evaluate the appropriateness of using of such UFs for two key areas of uncertainties namely, intra- and inter- species extrapolations. This was achieved through the application of advances in computational techniques linking Monte-Carlo simulations with physiologically based pharmacokinetic (PBPK) animal and human models. Simulations were run for dichloromethane (DCM), a major environmental pollutant, at a NOAEL level to derive a distribution for total amount metabolized in animals. The output of these simulations were then applied to the human PBPK model to obtain a distribution for human equivalent NOAELs. The MRL value of 6x10-2 mg/kg/day, derived by applying the UFs approach to the DCM NOAEL, is about the 95 percentile of the simulated exposure distribution in humans. These results show that the use of the default values of 10 for DCM are reasonable. We are in the process of studying other environmental chemicals such as trichloroethylene and vinyl chloride to understand the universality of this trend and determine that the use of these values provide adequate protection to the public.

861 BIOLOGICALLY BASED DOSE-RESPONSE (BBDR) MODELS AS A MECHANISTIC FRAMEWORK FOR ORGANIZING THE EXTANT LITERATURE AND DATA.

R. S. DeWoskin[1], C. Mueller[2], D. Crawford-Brown[2] and R. W. Setzer[1]. [1]*USEPA, Research Triangle Park, NC and* [2]*University of North Carolina, Chapel Hill, NC.*

Biologically based dose-response (BBDR) models integrate what is known about a toxicant into a simulation of the toxicant's kinetics and dynamics. Constructing a BBDR model requires a review and organization of the literature and data needed to estimate parameters and to mathematically describe interactions among biologically relevant compartments. As the BBDR model begins to take shape, the model itself provides a useful mechanistic-based framework for further organizing the literature and the supporting data. Recent advances in web-site and database software support this approach and are particularly helpful with two key challenges in constructing BBDR models: 1) an efficient means by which to identify, extract, and organize data especially for compounds with an extensive literature base; and 2) access to the information needed to perform quality assessments. Presented here is an example of a hypertext web-site based upon a BBDR model for the developmental effects of 5-fluorouracil (5-FU). The 5-FU BBDR framework provides an efficient template for organizing and accessing the relevant abstracts, articles, and extracted information from the literature as well as access to a full audit trail of the data used to develop and validate the model. This audit trail provides the information needed to perform quality assessments of the model and the parameter estimates. With appropriate quality controls and peer review for incorporated information, wide-spread access to such a web-site would reduce duplication of effort among researchers and agencies needing to summarize the extant literature, would facilitate collaboration in the construction of a BBDR model, and would provide a mechanistic framework for identifying data needs. (This abstract does not necessarily reflect EPA policy.)

862 PROPOSED NEW RISK ASSESSMENT FOR ACETALDEHYDE.

M. Osier[1], M. Odin[1], P. McGinnis[1] and B. Boutin[2]. [1]*Syracuse Research Corporation, North Syracuse, NY and* [2]*National Center for Environmental Assessment, USEPA, Cincinnati, OH.*

EPA is in the process of updating the risk assessment for acetaldehyde. Animal studies have demonstrated irritant effects of acetaldehyde following both oral and inhalation exposure, with the critical effect for both routes of exposure being hyper- and metaplasia of the tissues along the portal of entry. While oral carcinogenicity data are unavailable, chronic inhalation studies have demonstrated tumor formation in the nasal cavity, with tumors being located in the same areas that the noncancer effects are seen. The proposed RfD (Oral Reference Dose) is based on a published NOAEL of 125 mg/kg-day for hyper- and metaplastic responses in the forestomach of male Wistar rats. An uncertainty factor (UF) of 3000, (10 for intraspecies variation; 10 for interspecies extrapolation; 10 for use of a subchronic study; 3 for database insufficiencies), was applied to derive an RfD of 4x10-2 mg/kg-day. The proposed RfC (Inhalation Reference Concentration) is based on a published NOAEL of 390 ppm for hyper- and metaplastic responses in the posterior nasal region of male and female Syrian golden hamsters. Following conversion to a NOAEL[HEC] of 5.45 mg/m3, an UF of 1000 (3 for interspecies variation; 10 for intraspecies variation; 10 for the use of a subchronic study; 3 for database insufficiencies) was applied to derive a proposed RfC of 5x10-3 mg/m3. Oral carcinogenicity data are unavailable. The inhalation unit risk was based on the incidence of upper respiratory tract tumors in male Wistar rats following a 28-month exposure to acetaldehyde. An LEC10 of 7.43 mg/m3 was calculated from the incidence data using a polynomial curve-fitting program (Global86), and used to derive an inhalation unit risk of 1.3x10-5 (µg/m3)-1. Acetaldehyde is presently classified as a group B2 chemical (probable human carcinogen) under EPA's 1986 guidelines for carcinogen risk assessment. (This abstract does not necessarily reflect EPA policy.)

863 CARCINOGENIC POTENCY OF ENVIRONMENTAL TOBACCO SMOKE (ETS) IN STRAIN A/J MICE.

H. P. Witschi[1] and K. T. Bogen[2]. [1]*ITEH, University of California, Davis, CA and* [2]*University of California, HEA Division L-396, Lawrence Livermore National Laboratory, Livermore, CA.*

While directly inhaled tobacco smoke has long been recognized as a human carcinogen, concerns about environmental tobacco-smoke exposure (ETS) as a human cancer risk factor have mounted considerably over the last 15 y. Epidemiological studies suggest a relative risk of about 1.3 for the incidence of lung cancer among nonsmoking spouses, but the statistical and biological significance of this risk remains contested. Recent studies involving exposure of strain A/J mice to well defined ETS atmospheres examined various toxic endpoints, including 5 independent 10-month studies in which rates of lung-tumor occurrence in groups of mice exposed to ETS alone were compared to those of groups kept in filtered air. Detailed data obtained on chamber concentrations of TSP (total suspended particulate matter) throughout exposure allowed traditional multistage estimates of ETS carcinogenic potency in A/J mice using combined sex-specific data sets indicating statistically significant ETS-related elevations in either animals with lung tumor(s) or total lung tumors per animal. Best estimates of ETS potency based on these data range from 0.4 to 1 per (mg TSP per kg body weight per d), implying a corresponding increased lifetime lung-tumor risk of 0.3% to 0.7% in humans

chronically exposed to typical ETS concentrations in U.S. smoking households (assuming ETS is equally potent in A/J mice and humans). The mouse-based ETS risk estimates overestimate lung-cancer mortality risk in human smokers by a factor of ~20 to ~60, which is consistent with A/J-mouse hypersusceptibility to lung tumorigenesis

864 ALTITUDE AS A FACTOR IN CARBON MONOXIDE RISK ASSESSMENT.

J. J. McGrath. *Texas Tech University Health Sciences Center, Lubbock, TX.*

The National Ambient Air Quality Standard for carbon monoxide (CO) is set at 9 ppm for 8 hrs based on studies in subjects with exercise-induced angina exposed to CO during exercise at sea level. It has been estimated that over 35 million people live or visit at altitudes above 5,000 ft in the United States; worldwide, the figure is closer to 80 million. Estimates indicate that nearly 60% of those going to altitude are older than age 40 and 15% are older than age 60. In addition to a higher prevalence of cardiopulmonary disease, older people may have reductions in ventilatory capacity, efficiency and hypoxic ventilatory drive that impair the normal adaptive response to altitude. The population at altitude comprises both residents, fully adapted to altitude, and short-term visitors or sojourners. It is the sojourner at altitude who is at greater risk from exposure to CO. The decreased oxygen tension (hypoxia) in the inspired air, the most prominent feature of the altitude environment, causes physiological changes that affect dosimetry and the potential toxicity of CO. The hypoxemia resulting from ascent to altitude increases with increasing elevation and could be expected to intensify the pre-existing hypoxemia in cardiopulmonary impaired patients. Thus, the increasing altitude would affect dosimetry as well as exacerbate the pathophysiological effects produced by CO in subjects with cardiopulmonary disease. Therefore, cardiopulmonary impaired subjects exposed to CO in the more stressful altitude environment could be expected to suffer adverse health outcomes at lower ambient CO concentrations than subjects exposed at sea level.

865 NONCANCER ASSESSMENTS OF PHENOL.

L. T. Haber, Q. Zhao, A. M. Maier and M. L. Dourson. *Toxicology Excellence for Risk Assessment, Cincinnati, OH.*

Phenol is a component of several consumer products, including analgesics, ointments, throat lozenges, and tobacco smoke, and has been reported as a contaminant in drinking water and at Superfund sites. The current phenol RfD on IRIS was adopted in 1989, based on reduced fetal weight in a gavage developmental toxicity study in rats. A 1986 review found the data inadequate for the development of a RfC. A number of new studies have been conducted since those assessments. New oral studies include a 13-week neurotoxicity study, a 2-generation reproductive study, and a rat developmental toxicity study, as well as a study comparing toxicokinetics via different routes and a number of other toxicokinetics studies. These studies improve the quality of the database, although no database uncertainty factor was used for the RfD currently on IRIS, despite the problematic nature of some of the studies. In light of the new studies, no database uncertainty factor would be required now. A 2-week inhalation study in rats is newly available, and supplements the earlier database of low-quality 2-week and 90-day studies, including a 2-week study that evaluated some neurotoxicity endpoints. The adequacy of the overall inhalation database for develop of a RfC is questionable. The hazard identification of this chemical is focussing on decreased fetal body weight, neural effects, hematological effects, and immune effects; the critical effect is chosen from these endpoints. In addition to the new data, EPA methods for noncancer risk assessment have been updated. An updated RfD and an evaluation of the appropriateness of deriving an RfC, will be presented, based on current EPA methods. (This work was conducted under contract to EPA, but the opinions expressed in this abstract are those of the authors and do not necessarily represent EPA policy.)

866 CALIFORNIA PUBLIC HEALTH GOALS FOR CARBOFURAN, DIQUAT, SIMAZINE, AND THIOBENCARB.

J. Bankowska[1], R. A. Howd[1], L. Jowa[2], R. S. Tomar[1] and M. J. DiBartolomeis[1]. [1]*Cal/EPA, OEHHA, Oakland, CA and* [2]*Cal/EPA, OEHHA, Sacramento, CA.*

The California Office of Environmental Health Hazard Assessment conducts risk assessments, based exclusively on public health considerations, for chemicals in drinking water in support of Public Health Goals (PHGs). PHGs are concentrations of chemicals in water that are not expected to produce adverse effects in humans consuming water over a lifetime. The development of PHGs for the pesticides carbofuran, diquat, simazine, and thiobencarb involved a critical review of the available data submitted in support of pesticide registration as well as from the open scientific literature, and the use of state-of-the-art risk assessment methods. The proposed PHG of 1.7 ppb for carbofuran is based on a no-observed-adverse-effect-level (NOAEL) of 0.1 mg/kg-day for observed changes to the testes, particularly to the sperm itself, at higher doses in male rats. For diquat, the proposed PHG of 15 ppb is based on an estimated NOAEL of 0.22 mg/kg-day for lens opacities from a chronic dietary study in male and female rats. The proposed PHG for thiobencarb is 70 ppb, which is based on a NOAEL of 1 mg/kg-day for noncarcinogenic effects in rats. The proposed PHG of 0.4 ppb for simazine is based on mammary gland carcinomas observed in female rats in a chronic dietary study. The cancer slope factor was derived by linear extrapolation from the lower 95% confidence limit on the dose associated with a 10% increased risk of cancer (LED_{10}). Once adopted, PHGs are intended to guide California risk managers in establishing and interpreting state drinking water standards.

867 ENVIRONMENTAL CONTAMINANTS AND POTENTIAL HUMAN RISK ASSOCIATED WITH SELECTED BOTANICAL DIETARY SUPPLEMENTS.

D. B. Huggett, D. S. Block, J. C. Allgood, I. A. Khan, D. Schlenk and W. H. Benson. *University of Mississippi, University, MS.*

Botanical dietary supplements have a long history of use in Europe and China, but they are becoming increasingly popular in the United States. However, little data is available regarding environmental contaminants in botanical dietary supplements and the health risk posed to those ingesting contaminated supplements. To investigate this data gap, Ginseng, St. Johns Wart, Passion Flower, Echinacea, and Valarian were purchased from the United States, Europe and China. Samples were analyzed for metals (arsenic, cadmium, nickel, chromium, and lead) and chlorinated pesticides (PCNB, DDT and metabolites, aldrin, etc.). Flame and furnace atomic absorption spectrophotometry were utilized for analysis of metals, while gas chromatography was utilized for analysis of chlorinated pesticides. Since no formalized guidelines exist for the determination of risk and hazard in botanical dietary supplements, U.S. Environmental Protection Agency guidelines for the protection of human health were utilized. Metals and chlorinated organics were present in all samples analyzed, but these concentrations pose a low noncarcinogenic hazard (<0.2); however, chlorinated pesticides presented 1x10-6 risk in Ginseng (24%), Passion Flower (40%), Valarian (45%), Echinacea (29%) and St. John's Wart (58%) samples at a dose of 1000mg/day (a medium to high dose depending on the supplement). If a low dose of supplement is taken daily (100 mg), then only one of the samples exceeded 1x10-6 risk. In addition, a reduction in exposure duration (from 350 d to 42 d) significantly reduced the calculated risk.

868 CORRELATION OF THE UTEROTROPHIC ACTIVITY AND THE EXPRESSION OF ESTROGEN SENSITIVE GENES IN THE RAT UTERUS IN RESPONSE TO XENO- AND PHYTOESTROGENS.

P. Diel[1], T. Schulz[1], K. Smolnikar[1], G. Vollmer[2] and H. Michna[1]. [1]*DSHS, Cologne, Germany and* [2]*TU Dresden, Dresden, Germany.* Sponsor: B. Stahl.

Uterine response to estrogens involves the activation of a large number of estrogen sensitive genes. We have investigated the estrogenic potency of xeno- and phytoestrogens and the mechanisms of their molecular action by a correlation of the uterotrophic activity and their ability to modulate the expression of estrogen sensitive genes. The expression of androgen receptor (AR), progesterone receptor (PR), estrogen receptor (ER), clusterin (CLU), complement C3 (C3), and GAPDH mRNA in the rat uterus following oral administration of ethinylestradiol (EE), bisphenol A (BPA), o,p'-DDT (DDT), tert-octylphenol (OCT) and daidzein (DAI) was analysed. A significant stimulation of the uterine wet weight could be observed in response to high doses of all substances. Their overall potency was low compared to EE. DDT exhibited a comparatively high potency to stimulate uterine weight whereas BPA and DAI were less potent. The analysis of gene expression revealed a very specific profile of molecular responses which are unpredictable from the uterotrophic response alone. A dose dependent analysis revealed that C3 mRNA is already modulated at doses where no uterotrophic response was detectable. Although DAI and BPA only weakly stimulate uterine growth these substances led to a strong alteration of the expression of AR, ER and C3. In conclusion, according to their response pattern the analyzed compounds can be subdivided into distinct classes of substances, characterized by their

potency to induce a compound specific fingerprint of uterine gene expression. This in turn represents a very sensitive tool to investigate estrogenicity of natural and synthetic compounds and to get information in regard to their molecular mechanisms.

869 TRANSFERABLE FUR RESIDUES AND CHOLINESTERASE INHIBITION OF DOGS TREATED WITH FLEA CONTROL COLLARS CONTAINING ORGANOPHOSPHORUS INSECTICIDES.

S. Boone, J. Tyler and J. Chambers. *Mississippi State University, Mississippi State, MS.*

Dogs were treated with a commercial over the counter flea and tick control collar containing chlorpyrifos (Dursban® - 8.0%, 2.54 g) or tetrachlorvinphos (Rabon® - 14.55%, 4.8 g) using the recommended guidelines. The residues available for transfer to humans from the fur of the dogs and inhibition of plasma cholinesterase in the dogs was determined over the study as a biomarker. Twenty-four dogs were used for each study and the fur was sampled by rubbing with cotton gloves for 5 minutes in three 10 x 4 inch areas: along the lower back (back), along the neck without the collar in place (neck), and along the neck with the collar in place (collar). Gloves were extracted by the Accelerated Solvent Extractor. Tetrachlorvinphos and chlorpyrifos residues were analyzed by GC/ECD. The residue and blood samples were taken at 8 time points after placement of the collar: 4 hrs, and 3, 7, 14, 28, 56, 84, and 112 days (and also 140 and 168 days for chlorpyrifos). For tetrachlorvinphos, the average values for these eight time points for the collar were 14, 24, 24, 19, 13, 13, 4, and 3 mg; for the neck were 4, 8, 8, 6, 4, 3, 1, and 1mg; for the back were 0.2, 0.3, 0.2, 0.2, 0.1, 0.1, 0.03, and 0.02 mg. Preliminary results (12 dogs) of the chlorpyrifos samples through 140 days averaged 0.2-0.5 mg for the collar, 0.1-0.25 mg for the neck, and 0.003-0.005 mg for the back. Plasma cholinesterase levels were measured as butyrylcholinesterase using butyrylthiocholine and as acetylcholinesterase using acetylthiocholine. In the preliminary results, chlorpyrifos inhibited the dog plasma butyrylcholinesterase and acetylcholinesterase but tetrachlorvinphos did not. Tetrachlorvinphos showed a peak at 3 to 7 days and decreased throughout the study. In contrast, chlorpyrifos showed constant and significantly lower transferable residue levels throughout the study. (Supported by EPA R 825170.)

870 CHRONIC PATHOLOGICAL EFFECTS FROM EXPOSURE OF JAPANESE MEDAKA (*ORYZIAS LATIPES*) EMBRYOS TO BROMOFORM.

A. Thiyagarajah[1], L. K. Teuschler[2], J. C. Lipscomb[2], C. Gennings[3] and W. R. Hartley[1]. [1]*Tulane University Medical Center, New Orleans, LA,* [2]*NCEA, USEPA, Cincinnati, OH and* [3]*MCV, VCU, Richmond, VA.*

The purpose of this study was to determine the chronic toxicity of bromoform in an alternative test species, Japanese medaka (Oryzias latipes). In this study, we exposed medaka embryos at 64-cell stage (early high blastula) to 0, 5, 10, 25 and 50 mg bromoform /L (nominal concentrations) and DMSO (solvent carrier) for 10 days. The embryos then transferred to clean embryo-rearing solution until they hatch, followed by six to twelve month grow-out in spring water. At 6 and 12 months post hatch, up to 60 fish were killed by overdose of anesthesia, fixed in 10% neutral buffered formalin, and evaluated histologically. Immature gonads and cystic ovaries were found in all groups, but the incidence was higher in bromoform-exposed fish. The incidence of thyroid follicular hyperplasia was higher at twelve months in bromform-exposed fish. A low incidence of a variety of renal degenerative lesions occurred in both control and bromoform- exposed fish. However, the incidence of renal cystic tubules was higher in bromoform-exposed fish. A low incidence of degenerative and non -neoplastic proliferative lesions were observed in the livers of both control and bromoform- exposed fish. There was an increased incidence of hepatic cysts in the six-month old medaka exposed to bromoform. Dose-response of histopathological endpoints will be discussed. Critical endpoints from this study will be compared to the chronic toxicity of bromoform in rodent risk assessment models. (Abstract may not reflect USEPA policy. Funded in part by USEPA Cooperative Agreement.)

871 CHRONIC TOXICITY OF CHLOROFORM IN THE JAPANESE MEDAKA (*ORYZIAS LATIPES*).

W. R. Hartley[1], J. C. Lipscomb[2], L. K. Teuschler[2], C. Gennings[3] and A. Thiyagarajah[1]. [1]*Tulane University Medical Center, New Orleans, LA.* [2]*NCEA, USEPA, Cincinnati, OH and* [3]*MCV, VCU, Richmond, VA.*

Short-term *in vivo* toxicological methods are needed to provide data for the assessment of health risk of disinfection by-products such as chloroform. Japanese medaka embryos (N=500) at early high blastula stage were exposed to nominal concentrations of 25, 50 or 100 mg/L chloroform for 10 days, transferred to embryo-rearing solution until they hatched, and then were grown-out for six to twelve months in spring water. Sixty fish were killed at 6 months post hatch and the remaining were killed at 12 months post hatch, and histologically evaluated. Hepatic, renal, gonadal , and thyroid lesions were associated with chemical exposure. A low incidence of hepatic neoplasms [cholangioma (25 and 50 mg/L) and lipoma (50mg/L)] was observed in chloroform-exposed fish. The hepatic non-neoplastic proliferative lesions were clear cell foci, vacuolated cell foci and altered hepatocellular foci. The hepatic degenerative lesions observed were excessive accumulation of substances (glycogen and or lipid), fatty change, necrosis, hepatic cysts, and spongiosis hepatis. Renal lesions were primarily degenerative in nature except one case of a neoplasm, renal lipoma, in one 12-month-old fish exposed to 25 mg/L chloroform. Ectopic ovarian follicles were found in one fish exposed to 100 mg/L chloroform and a female control fish had ectopic testis in the anterior abdominal cavity. Immature ovaries were found in fish exposed to 25 (16/46) and 50 mg/L (10/47) chloroform and one control fish examined after 12 months. Thyroid follicular hyperplasia was observed in all groups of fish including controls but the incidence was higher in fish exposed to 25 and 50 mg/L chloroform. Higher mortalities in the 100 mg/L group probably resulted in a lack of expected dose-response. Potential utilization of this research for risk assessment is presented. (Abstract may not reflect U.S. EPA policy. Funded in part by USEPA Cooperative Agreement.)

872 SAR ANALYSES AS PART OF THE HIGH PRODUCTION VOLUME CHEMICAL CHALLENGE INITIATIVE.

A. R. Cunningham[1], H. S. Rosenkranz[1], E. P. Copelin[1] and G. Klopman[2]. [1]*University of Pittsburgh, Pittsburgh, PA and* [2]*Case Western Reserve University, Cleveland, OH.*

Within the next five years chemical manufactures are required, as part of the EPA's High Production Volume (HPV) Chemical Challenge Initiative, to make available basic toxicological information on approximately 2800 chemicals. These chemicals are all produced or imported into the US in over 1 million pound quantities per year. The data required consist of the Organisation for Economic Cooperation and Development Screening Information Data Set (SIDS). These data are designed to provide an initial minimal set of information for hazard identification. The purpose of our experiment is to assess the utility of structure-activity relationship (SAR) modeling as a prescreening technique for hazard identification. This will allow chemicals to be rationally prioritized for more comprehensive testing. We used the MCASE SAR program and its contingent of approximately 60 validated SAR models for a variety of toxicological endpoints. For analysis, we randomly chose two sets of 100 organic chemicals (i.e, inorganic and chemical mixtures were excluded) from the HPV list. These chemicals have been assigned to undergo SIDS testing in the early phase of the program. This will allow us to assess and improve our methods as the HPV Initiative progresses. Based upon SAR models of *Salmonella* mutagenicity and the *in vivo* micronuclei assay, 8% of HPV chemicals have the potential for being *in vivo* genotoxicants and therefore represent a cancer risk to humans. On the other hand, between 11-31% (depending upon protocol) of the chemicals were predicted to be rodent carcinogens providing that the protocol included testing at the maximum tolerated dose. Also, 3% of HPV chemicals may be developmental toxicants. Our results so far indicate that SAR approaches to hazard identification of widely used chemicals represent a viable alternative to traditional methods.

873 DERIVATION OF A SPECIFIC DERMAL CANCER POTENCY FACTOR FOR BENZO(A)PYRENE.

M. A. Katona, T. F. Long, C. R. Kirman, M. L. Gargas and W. R. Rish. *McLaren/Hart, Inc., Cleveland, OH.*

A review of recent site-specific risk assessments revealed that in many cases much of the risk was due to dermal exposure to polynuclear aromatic hydrocarbons (PNAs), especially benzo(a)pyrene (B[a]P), in soil. For B(a)P, a dermal cancer potency factor (CPF) is normally derived from an oral CPF adjust-

ed for absorption. This common practice introduces uncertainties due to inherent differences in the absorption, pharmacokinetics, and target organ specificity of chemicals following different routes of exposure. Little or no consideration is given to the bioavailability and degradation of B(a)P in soil. These conservative and arguably erroneous assumptions give disproportionate weight to PNAs at or near urban soil background levels. Using B(a)P as an example, published data from several dermal carcinogenicity studies of B(a)P were evaluated in combination with pharmacokinetic parameters to derive a specific dermal CPF for exposure to B(a)P. Soil, weather, and time also influence the amount of B(a)P that is available to be absorbed from the skin and need to be considered. The major target organ for B(a)P following dermal exposure is the skin. Numerous rodent dermal toxicity studies show that B(a)P absorption into the epidermis produces tumors. Published literature on dermal absorption of B(a)P, skin permeability, the influence of a soil matrix, and aging was used to derive a refined estimate of the amount absorbed through the skin from soil. A comparison of the risks derived from the default and the refined approach demonstrates that the risks associated with dermal exposure to soil bound B(a)P are likely lower than previously assumed.

874 ORGANIC TIN EXTRACTION RESULTS FROM POLYVINYL CHLORIDE (PVC) AND CHLORINATED POLYVINYL CHLORIDE (CPVC).

C. J. McLellan, K. D. Cox and L. L. Bestervelt. *NSF International, Ann Arbor, MI.* Sponsor: M. L. Dourson.

NSF International is a third party, independent, not-for-profit organization, which is dedicated to public health safety and protection of the environment. Since 1944, NSF International has developed product standards and provided third party conformity assessment services to government, users, and manufacturers/providers of products and systems. NSF has been developing standards for the testing and certification of plastics plumbing components since 1965. ANSI/NSF Standard 61: Drinking Water System Components-Health Effects establishes requirements for the testing and evaluation of contaminants that are extracted from water, which has been exposed to a material or product that is intended to convey drinking water. Dimethyl and dibutyl organotin stabilizers are added to PVC/CPVC formulations to protect the resin from thermal degradation during processing and usage. Stabilizers protect the PVC/CPVC by inhibiting the dehydrochlorination reaction by exchanging their anionic group, X, with the allylic chlorine atoms in the polymer. In addition, stabilizers can react with the HCl produced, producing compounds which may inhibit other side reactions. There are more than 595 PVC/CPVC products produced by 88 companies at 148 manufacturing sites currently certified by NSF International to the health-effects requirements of ANSI/NSF Standard 61. NSF tests approximately 350-500 samples annually based upon the protocol described in ANSI/NSF Standard 61, Appendix B. The samples tested at NSF are new products which are tested at pH 5, pH8 and pH 10. Before testing, the samples are conditioned for 14 days at 30°C in water. Immediately following conditioning, the samples are exposed for one final 16-hour exposure. The quantitative measurement of organo-tin is an indirect measurement. Our laboratory analyzes the extractant water for total tin content, which is mathematically adjusted for molecular weight to reflect the maximum potential organo-tin extraction value. The lab results are then normalized for the pipe size based on its intended end use. NSF began collecting extraction results from PVC/CPVC material products testing in 1992. The normalized concentrations of organic tin averages 6.4 μg/L with a range from 0.0005 to 46 μg/L for PVC. The normalized concentrations for CPVC averages 11 μg/L with a range from 0.00013 to 140 μg/L. There are occasions when the concentration extracted of organotin exceed the Maximum Drinking Water Level (MDWL) for chronic exposure based on a single time point analysis. In those cases, a follow up multiple time point analysis is performed, followed by a regression analysis of the data to evaluate the decay of tin overtime. The day 1 normalized concentration (acute exposure) is compared to the Short Term Exposure Level (STEL) and the extrapolated Day 90 concentration (chronic exposure) is compared to the MDWL. Based on our current database, more than 99% of the products tested with a multiple time point analysis have met the pass/fail criteria for acute and chronic exposure as defined under ANSI/ NSF Standard 61, Annex A.

875 BIOAVAILABILITY OF CAPTAN IN HUMAN BLOOD.

E. B. Gordon[1], S. A. Mobley[2], S. Lee[2] and M. Williams[3]. [1]*Makhteshim-Agan of North America Inc., New York, NY.* [2]*Tomen Agro, Inc., San Francisco, CA and* [3]*Horizon Laboratories, Inc., Columbia, MO.*

Captan is a broad-spectrum fungicide that is commonly used throughout the world to protect food crops and other plants from fungal diseases. Chronic feeding studies have shown captan to cause duodenal tumors in mice (but not rats) at high doses (>800ppm). Mechanistic data suggest that duodenal tumor formation is a result of chemical irritation to the intestinal villi, a non-genotoxic event. The risk of developing duodenal cancer from captan depends upon an "irritation-producing" concentration of captan to the duodenum. The bioavailability of captan to the duodenum is crucial for the formation of tumors. For oral exposure, the extrapolation from mouse bioassays to humans is direct; for dermal exposure, however, the stability of captan in blood becomes an important factor. A freshly drawn human blood sample was used in an *in vitro* degradation study at 37°C with ^{14}C-captan. It demonstrated that captan degrades rapidly in human blood with a measured half-life as short as one second. Evolution of the imide ring, tetrahydrophthalimide, was measured, confirming captan's degradation versus its possible loss through absorption to blood constituents. Following dermal exposure, captan will not be available at the target organ (duodenum) since multiple half-lives would have taken place during the systemic transit time (averaging one minute). This finding is relevant in the risk characterization of captan via dermal route. Farm workers such as strawberry harvesters who contact captan are without measurable risk of duodenal cancer. Current regulatory paradigms do not consider this degradation and thus overestimate the risk to farm workers. The addition of this blood degradation factor to the USEPA and California DPR human risk assessments for dermal exposure will eliminate the cancer risk concern following worker exposure.

876 DERMAL EXPOSURE TO BENZO[A]PYRENE (BAP): COMPARATIVE DOSIMETRY IN THE MOUSE AND HUMANS.

J. Bounds and A. Shipp. *The K S Crump Group, Inc., ICF Consulting, Ruston, LA.* Sponsor: J. M. Gearhart.

Chronic rodent bioassays, by either the oral or inhalation routes of exposure, have been used to derive cancer potency values. For dermal exposures, route to route extrapolation is done either by adjusting the orally-derived potency value by the comparative absorption (oral versus dermal) or, less frequently, by pharmacokinetic models that include the skin as an active compartment. When the skin is the target tissue, it may appear preferable to use a chronic dermal study, e.g., mouse skin painting study, to derive a dermal cancer potency factor. In the absence of a kinetic model, significant adjustments to the applied dose are required when the chemical of interest is a PAH. Extrapolations must consider differences in absorption of the compound, metabolism to the active component, and the sensitivity of the tissue to that active component. The human equivalent dose of BaP applied to the skin that would result in the same tissue dose, is more than a 1000 times greater than the dose applied in the mouse skin painting study. Using the applied dose from a mouse skin painting study without dosimetric adjustments will result in a significant overestimation of the dermal cancer potency for BaP.

877 EVALUATION OF THE DERMAL BIOAVAILABILITY OF SOIL-AGED NAPHTHALENE.

G. A. Skowronski, R. M. Turkall and M. S. Abdel-Rahman. *UMDNJ - New Jersey Medical School, Netwark, NJ.*

Assessment of health risk and the establishment of remediation levels for chemicals in soil can be improved significantly by determining the effects of chemical "aging" on bioavailability. Studies were conducted on ^{14}C-labeled naphthalene (NAP) administered to dermatomed male pig skin in flow-through diffusion cells. A comparison of dermal penetration was made between pure chemical, NAP added immediately to soil, and aged for 3 months in sandy and clay soils. After aging, the bioavailability of NAP was decreased by 96-99% compared to chemical without soil. However, the bioavailability of NAP in newly contaminated soil was similar to pure compound. Decreased NAP bioavailability with aging indicates that the potential risk to health and the environment will also be reduced. (Supported in part through funding from the Hazardous Substance Management Research Center and the New Jersey Commission on Science and Technology.)

878 COMPARATIVE ABSORPTION OF ALUMINUM NITRATE IN SOIL AND AQUEOUS SOLUTIONS.

J. Reed[1], R. Garipay[2], G. Hahn[1] and R. Harbison[1]. [1]*University of South Florida, Tampa, FL,* [2]*United States Navy, Norfolk, VA and* [1]*Ecology & Environment, Inc., Buffalo, NY.*

There is little data available concerning the effect of soil on the bioavailability of aluminum. Therefore, complete absorption is usually a default assumption used for assessing environmental exposure. The purpose of this study was to evaluate the possible attenuating effects of soil on the bioavailability of aluminum. The effects of soil and aqueous matrices on the oral absorption of aluminum were compared. An animal model using Sprague-Dawley rats was developed. Test groups were gavaged daily with 300 and 600 mg/kg of aluminum in soil or water for fifteen days. Blood, liver, brain, and bone samples were collected. All samples were digested and analyzed for aluminum using Inductively Coupled Plasma-Atomic Emission Spectroscopy. No clinical signs of adverse effects were observed during this study. Mean body weights of all treated groups were within five percent of the controls for each matrix. Bone aluminum levels were significantly lower for the group exposed to aluminum mixed with soil. However, there were no significant differences in aluminum levels in blood, liver, kidney and brain. Thus, soil may affect the levels of aluminum in some tissues but not others. Therefore, in assessing environmental exposures associated with aluminum in soil, the target organ level should be considered and may be affected by soil adsorption. (Supported in part by NIOSH grant 412874-03.)

879 FACTORS AFFECTING THE ACTIVITY AND EXPRESSION OF HUMAN CYTOSOLIC GLUTATHIONE S-TRANSFERASE (GST) ISOFORMS.

M. K. Manibusan[1], M. Follansbee[2] and C. Abernathy[1]. [1]*USEPA, OW, Washington, DC and* [2]*ISSI Consulting Group, Yarmouth, ME.*

Understanding the factors that influence the levels of expression of GST enzymes in humans is important to identifying sensitive subpopulations who may be at risk for adverse health effects when exposed to certain environmental contaminants. The GSTs are phase II enzymes involved in the detoxification of many chemicals in mammals. Alterations in the levels of GST alpha, mu, pi and theta isoform expression have been associated with differential susceptibility to some toxic contaminants, such as polycyclic aromatic hydrocarbons, aflatoxin B1, and heterocyclic amines. GST isoforms expression is determined by an interplay between many genetic and environmental factors, which is important in understanding their detoxification activities. Generally, higher levels of the GST isoforms are associated with an increased tolerance to some chemical insults. Conversely, the loss or reduced expression of most GSTs is often associated with an increased susceptibility. For example, research has shown that individuals with the GSTM1 null genotype and greater than 50-pack years of cigarette smoking had a two-fold greater risk of bladder cancer when compared to equivalent smokers who were not homozygous for the GSTM1 null allele. In addition, those individuals with no identified exposure to toxicants, who are deficient in GST theta are more likely to have chromosomal abnormalities than those who are heterozygous. (The scientific views expressed are solely those of the authors and do not necessarily reflect those of the U.S. EPA.)

880 DNA REPAIR GENES-POTENTIAL CANCER SUSCEPTIBILITY GENES.

T. R. Smith, M. S. Miller, K. Lohman and J. J. Hu. *Wake Forest University School of Medicine, Winston - Salem, NC.*

In 1999, approximately 175,000 US women will be diagnosed with breast cancer. About 60% of breast malignancies do not have identifiable risk factors such as a first-degree relative with breast cancer. Studies suggest an association between deficient DNA repair and breast cancer with odds ratios (ORs) ranging from 1.6 to 10.0. Therefore, suboptimal DNA repair is hypothesized to be an important breast cancer susceptibility factor. DNA repair systems maintain a cell's genetic integrity and prevent DNA lesions from being replicated during DNA synthesis. DNA repair genetic polymorphisms have been identified in a normal human population. Some of the variant alleles may affect DNA repair capacity as the sites of polymorphism lead to amino acid substitutions. Thus, DNA repair genotypes have the potential to be classified as cancer susceptibility genes and may be associated with individual's risk for cancer. We have completed a breast cancer case-control study to evaluate the role of genetic polymorphisms of DNA repair genes in breast cancer risk. The study population consisted of 123 cases and 185 controls recruited at Georgetown University Medical Center from 8/95 to 11/96. The genotypes examined include 5 polymorphisms in 4 DNA repair genes: XRCC1, XRCC3, APE, and XPD. Genomic DNA isolated from whole blood was used for PCR-RFLP genotype analysis. The allele frequency of individual genotypes was not significantly different between cases and controls. However, a potential association was observed between breast cancer risk and XRCC1 (exon 6) and XRCC3 (exon 7) variants with age-adjusted ORs of 1.6 (95% confidence interval (CI)=0.8,3.3) and 1.3 (95% CI=0.8,2.2), respectively. For both cases and controls, the data suggested a possible linkage between the variant allele of XRCC1 (exon 10) and the wild-type allele of XRCC1 (exon 6). The most interesting finding of this study is that women with both XRCC1 (exon 6) and XRCC3 (exon 7) variant alleles have a 4.5-fold increased risk for breast cancer (95% CI=1.4,16.0). This study supports the hypothesis that DNA repair genetic polymorphisms may serve as potential biomarkers for human breast cancer risk. (Supported by grants from ACS and NCI.)

881 USE OF PHARMACOKINETIC MODELING TO RELATE HYDRAZINE LUNG CANCER POTENCY ACROSS GAVAGE AND DRINKING WATER BIOASSAYS.

S. K. Chute[1], G. L. Ginsberg[1] and W. E. Pepelko[2]. [1]*State of Connecticut, Hartford, CT and* [2]*USEPA, Washington, DC.*

Gavage dosing has frequently been used in cancer bioassays, but questions exist regarding how best to apply gavage results to human risk assessment. Carcinogenic potency was compared across gavage and drinking water routes of administration using a variety of dose-metrics as derived from a pharmacokinetic model of hydrazine (HZ). HZ was selected because adequate bioassay data exist by relevant dose routes in mice. The cancer database encompassed eleven gavage and eight drinking water (DW) studies conducted in mice of various strains. Dose-response relationships for lung cancer frequency suggest that the rate of nitrogen exhalation is a predictive biomarker of exposure to carcinogenic metabolites of HZ, while other dosemetrics (e.g.; total amount of nitrogen exhaled, or AUC or peak HZ in blood) are not. Use of nitrogen exhalation rate to extrapolate cancer potency across dose routes is consistent with evidence that metabolic pathways leading to nitrogen exhalation involve oxidation to radical species. Results with HZ indicate that gavage and DW cancer potency is similar when dosemetrics are expressed in terms of peak rate nitrogen exhalation. To determine if the results of the HZ analysis also pertain to the structurally similar carcinogen, isoniazid (INH), the gavage and drinking water bioassay INH database was evaluated. This comparison indicates that on an administered dose basis, INH is equi-potent to HZ for gavage exposure. However, for DW exposure INH was considerably less potent than HZ. This larger gavage/DW differential for INH is due to the lower DW potency of INH as compared to HZ. This difference can be explained by INH having detoxification pathways not available to HZ that are saturated during gavage dosing.

882 DEVELOPMENT OF PROPOSED OCCUPATIONAL EXPOSURE LIMITS FOR SELECTED GLYCOL ETHERS USING PBPK MODELING AND MONTE CARLO SIMULATION.

L. M. Sweeney[1], C. R. Kirman[1], T. Tyler[2] and M. L. Gargas[1]. [1]*McLaren-Hart/ChemRisk, Cleveland, OH and* [2]*Union Carbide, Co., Danbury, CT.*

Certain glycol ethers are known to be teratogenic in rodents. A safe working environment may be assured by establishing and achieving appropriate occupational exposure limits for these compounds. Physiologically based pharmacokinetic models for methyoxyethanol, ethoxyethanol and ethoxyethyl acetate in pregnant rats and humans have been developed. The models were used to calculate human-equivalent no observed effect levels (NOELs), based on internal concentrations in rats exposed at previously determined NOELs for developmental toxicity. The human-equivalent NOELs were derived from modeling using average values for physiological, thermodynamic, and metabolic parameters. The uncertainty in the point estimates for the NOELs was estimated from the distribution of internal dose estimates obtained by varying key parameter values over expected ranges and probability distributions. Key parameters were determined through sensitivity analysis. Distributions of the values of key parameters were sampled using Monte Carlo techniques and internal doses calculated for 1200-2000 parameter sets. The 95th percentile was used to calculate interindivual uncertainty factors (UFs). NOELs were divided by these UFs to calculate proposed occupational exposure limits.

883 COLGATE-PALMOLIVE'S PROGRAM - VALIDATE THE EPIOCULAR™ HUMAN TISSUE CONSTRUCT MODEL (OCL-200).

M. E. Blazka[1], J. W. Harbell[2], M. Klausner[3], H. Raabe[2], J. Kubilus[3], F. Hsia[4], B. Minerath[5] and D. M. Bagley[1]. [1]*Colgate-Palmolive Co., Piscataway, NJ,* [2]*Institute for in vitro Sciences, Gaithersburg, MD,* [3]*MatTek Corp., Ashland, MA,* [4]*3M Co., St. Paul, MN and* [5]*Kimberly Clark, Neenah, WI.*

The objective of this corporate-based program was to formally validate the EpiOcular™ model's ability to predict the eye irritation potential of surfactants and surfactant-based formulations. As defined by the Interagency Coordinating Committee on the Validation of Alternative Methods (NIH Publication No. 97-3981), a validated method is one for which the reliability and relevance for a specific purpose have been established. EpiOcular™ is a commercially available three-dimensional *in vitro* model of the human corneal epithelium composed of normal human-derived epidermal keratinocytes. Four laboratories (Institute for In Vitro Sciences, MatTek, 3M and Kimberly Clark) conducted a range finding and three definitive assays on each of 20 blinded materials (6 formulations, 14 surfactants) in compliance with FDA GLPs using a formal and detailed test protocol. EpiOcular results for the test materials were compared to previously published eye irritation studies in animals. In terms of reliability, the results were reproducible within and between the laboratories. In terms of relevance, the EpiOcular™ model correctly predicted the Draize score for a majority of the samples tested. Results from five of six formulations were in agreement with the *in vivo* data. In addition, the eye irritation potential for anionic and cationic surfactants was correctly predicted. For those materials not predicted, the majority seemed to be alcohol ethoxylate surfactants that were under-estimated or amphoteric surfactants that were over-estimated for eye irritation. A complete statistical analysis of the data will be presented. These data indicate that, for certain classes of surfactant and surfactant-based formulations, the EpiOcular™ model has met the critical validation criteria for assessing ocular irritation.

884 THE EPIOCULAR TISSUE MODEL: *IN VIVO* VERSUS *IN VITRO* DRAIZE SCORES FOR CONSUMER PRODUCTS.

M. Klausner[1], M. Osborn[1], K. Bellavance[1], B. Breyfogle[1], J. Kubilus[1], D. R. Cerven[2] and G. DeGeorge[2]. [1]*MatTek Corporation, Ashland, MA and* [2]*MB Research Laboratories, Spinnerstown, PA.*

EpiOcular™ (OCL-200) is an organotypic tissue model of the human corneal epithelium (HCE) cultured from normal human keratinocytes using serum free medium. H&E stained histological cross-sections show that the structure of EpiOcular closely parallels that of the HCE. Previously, a prediction equation for eye irritation, Draize score (MMAS) = $-4.74 + 101.7/\sqrt{ET\text{-}50}$, was developed by correlating the *in vitro* ET-50 with Draize rabbit eye scores for 19 water-soluble chemicals from the ECETOC database and 41 cosmetic or personal care products/ingredients (ET-50 refers to the time of exposure which reduces the tissue viability to 50%, as determined by the MTT assay, in minutes). The current study reports *in vitro* results for an additional 24 consumer products, including shampoos, hand soaps, laundry detergents, dishwashing liquids, and skin lotions. A plot of the *in vivo* and calculated *in vitro* Draize scores, when correlated to the line *In Vivo Draize (MMAS) = In Vitro Calculated Draize*, gave the correlation coefficient, $r = 0.85$; when a single outlier was excluded $r = 0.93$. The useful range of the EpiOcular test was evaluated by testing surfactants at concentrations at which the Draize test is insensitive (MMAS scores < 2.0). EpiOcular was able to distinguish between surfactants at concentrations 3-10 fold below this point. Thus, the EpiOcular tissue model appears to be a sensitive, accurate *in vitro* means of predicting *in vivo* ocular irritancy for a range of consumer products and raw materials.

885 AN HISTOPATHOLOGICAL ANALYSIS OF DAMAGE TO BOVINE CORNEAS IN VITRO BY SELECTED OCULAR TOXICANTS.

R. D. Curren[1], M. G. Evans[2], H. A. Raabe[1], R. R. Ruppalt[1] and J. W. Harbell[1]. [1]*Institute for in vitro Sciences, Inc., Gaithersburg, MD and* [2]*Pathology Associates International, Frederick, MD.*

The Bovine Corneal Opacity and Permeability (BCOP) assay has proved a useful tool for the *in vitro* assessment of potential ocular irritation of various chemicals and formulations. In this assay viable corneas excised from normally discarded bovine eyes are directly exposed to test materials for various lengths of time and then monitored for changes in corneal opacity and permeability. However, analysis of a major validation program jointly sponsored by the European Commission and the British Home Office (EC/HO Study) indicated that, although the BCOP assay was arguably the best performing assay in the study, the ocular irritation potential of several materials in that study was not correctly predicted. We investigated whether histopathological evaluation of the bovine corneas would reveal damage that was not suggested by the traditional *in vitro* endpoints of opacity and permeability. We found that the three most severely underpredicted materials, parafluoroaniline, quinacrine, and sodium oxalate, showed diverse cellular damage throughout the epithelium and extending into the stroma. This was also true of a fourth underpredicted material, aspartic acid, although after exposure in a non-buffered medium opacity and permeability increased to the point where they were also predictive of the *in vivo* injury. Three moderately underpredicted materials, potassium cyanate, methyl cyanoacetate and 2-ethyl-1-hexanol, showed multi-focal separation of the basal epithelial cells from the basal lamina, as well as other changes which were more reflective of the *in vivo* scores than were the *in vitro* opacity and permeability measurements. It is clear that the excised bovine cornea does respond appropriately *in vitro* to the above test materials and that it may be possible to develop a histopathological scoring scale which extends the utility and further optimizes the BCOP assay beyond its current capacity.

886 THE CORNEAL ENDOTHELIUM IN THE BOVINE CORNEA OPACITY AND PERMEABILITY (BCOP) ASSAY.

P. L. Casterton[1], J. L. Ubels[2] and J. T. Sybesma[2]. [1]*Amway Corporation, Ada, MI and* [2]*Calvin College, Grand Rapids, MI.*

The corneal endothelium is essential for maintenance of corneal transparency. Damage can result in corneal opacity and may be irreversible since corneal endothelial cells do not proliferate. Examination of the corneal endothelium has not been included in the BCOP assay. The purpose of this study was to evaluate effects of irritants on the corneal endothelium. Corneas were treated according to the BCOP protocol following exposure to acetone, isopropanol, 1% NaOH, 30% sodium lauryl sulfate (SLS), or 30% trichloroacetic acid (TCA). The endothelium was stained with alizarin red S and trypan blue, and analyzed by light microscopy and image analysis. Exposure to acetone, SLS, isopropanol or NaOH for 1 min caused damage to 10-15% of endothelial cells. Exposure to TCA for 1 min caused death of up to 50% of endothelial cells. Corneas treated with acetone for 10 min had extensive areas of damage and isopropanol treatment for 10 min caused death of 50-100% of endothelial cells. A 10 min exposure to NaOH or TCA, caused death of all endothelial cells. Interpretation of these data is complicated, however, by the observation that simply mounting the cornea in the BCOP assay holders without further treatment damaged to 15-20% of the endothelial cells. This damage corresponded to folds in the cornea caused by clamping the aspherical bovine cornea into the circular chamber of the corneal holder. Examination of the corneal endothelium should be added to the BCOP assay; however, optimization will require modification of the cornea holders.

887 EVALUATING THE EYE IRRITANCY POTENTIAL OF ETHANOLIC TEST MATERIALS WITH THE BOVINE CORNEAL OPACITY AND PERMEABILITY ASSAY.

J. E. Swanson[1] and J. W. Harbell[2]. [1]*SC Johnson, Racine, WI and* [2]*Institute for in vitro Sciences, Inc., Gaithersburg, MD.* Sponsor: R. D. Curren.

Organic solvents can play a vital role in consumer product formulation. They can solubilize and deliver ingredients as well as provide desirable product attributes such as skin feel or fragrance. Experience has shown that the actual irritation induced by such formulations *in vivo* can be quite different than what might be expected on the basis of individual ingredient concentrations. This study was undertaken to evaluate the role of ethanol, as a formulation vehicle, in the ocular irritancy of insect repellent formulations. The concentration of the active repellent ingredient was held constant while the type and concentrations of organic solvents including ethanol, were varied. Ocular irritation potential was measured was measured using the Bovine Corneal Opacity and Permeability Assay. Abattoir-derived corneas were exposed to test materials for ten minutes and opacity and permeability end points measured. Selected tissues were fixed for histological evaluation. Concurrent positive and negative controls were tested along with a severely irritating benchmark formulation. Limited *in vivo* data were also available. Experience showed that the permeability endpoint of the assay, which measures disruption of the corneal epithelium, correlated better with the *in vivo* results than did the combined opacity and permeability scores. It proved useful to normalize the permeability scores against the established benchmark, thus yielding a P-ratio and enabling the rank-ordering of the test formulations for ocular irritation potential. Ethanol concentration alone was not predictive of irritation potential. However, certain non-irritating formulations could be ren-

dered irritating by the addition of low levels of ethanol. Histopathology and judicious use of *in vivo* testing confirm the utility of this *in vitro* approach as a product development tool.

888 OPTICAL DETERMINATION OF CORNEAL OCULAR IRRITANCY AND POTENTIAL FOR RECOVERY.

N. L. C. Laycock[1], R. Munger[1], R. Osborne[2] and M. Griffith[1]. [1]*University of Ottawa Eye Institute, Ottawa, Ontario, Canada and* [2]*The Proctor and Gamble Company, Cincinnati, OH.* Sponsor: L. D. Lehman-McKeeman.

As the function of the cornea is to focus light entering the eye, corneal transparency is a clinically well-established indicator of its health. Disease or injury leads to opacification. In this study, light transmission through the cornea was used to predict ocular irritancy potential of chemicals. We examined differential changes in transparency of ex vivo rabbit corneas, human eye bank corneas and human corneal equivalents constructed from cell lines, in response to different classes of potentially irritating and/or toxic chemicals. We measured transmission of light through each cornea on a custom-designed instrument. Then each cornea was treated with 100 µL of test substance for 5 min, washed and transmission was re-measured. At 30 sec post treatment, all three types of corneas showed similar changes in transmission in response to the culture medium control and the different test substances. However, rabbit corneas (the current standard for animal toxicity testing) and corneal equivalents showed greater sensitivity to chemical exposure than human eye bank corneas. The latter was most likely due to the poorer conditions of human corneas available for research. At 3 and 7 days post-treatment, decreased levels of light transmission were maintained, indicating a lack of recovery of corneal transparency in this time period. These results indicate that the custom-designed instrument was able to reliably and quantitatively measure responses of *in vitro* rabbit, human and reconstructed corneas to surfactant-based substances. The ability to measure responses up to at least one week also indicates potential of the approach to assess recovery following chemical exposure.

889 USE OF CONFOCAL MICROSCOPY TO MEASURE CORNEAL RESPONSES TO SURFACTANTS IN AN *EX VIVO* RABBIT EYE MODEL.

D. A. Roberts, G. L. Rutschilling, G. M. Ridder, J. K. Maurer and R. M. Osborne. *The Procter & Gamble Company, Cincinnati, OH.* Sponsor: L. D. Lehman-McKeeman.

An *ex vivo* method was developed to assess the area and depth of injury to rabbit corneas following application of surfactant based substances to the corneal surface of abattoir-derived rabbit eyes. Previous *in vivo* confocal microscopic analysis indicated area and depth of injury are quantitative measures of corneal response to surfactant-based substances *in vivo*. In the current work, surfactants and surfactant-based product formulations previously characterized *in vivo* were applied to the corneal surface of *ex vivo* rabbit eyes for 30 seconds. Then, the corneas were washed and incubated with Syto10 and Dead Red, fluorescent nucleic acid stains which differentiate live and dead cells. These dyes provided clear visualization of individual cell status by laser scanning confocal microscopy in serial images. Depth of injury was determined to be the focal plane of the cornea where no further staining of dead cells was seen, and live cells were present. The endpoint of the test, the normalized depth of injury (NDI), was expressed as a percent of overall corneal thickness. These methods were developed based on responses to 4 prototype anionic and cationic surfactant-based formulations and ingredients, demonstrating it was possible to distinguish substances and test conditions producing slight (epithelium alone), mild to moderate (epithelium and superficial stroma), and severe (deep stroma to full-thickness) damage to the corneas based on comparison to *in vivo* confocal measurements. Following methods development, 7 additional coded nonionic, anionic and cationic surfactants previously characterized *in vivo* were used to further validate the *ex vivo* test. The *ex vivo* NDI results agreed quantitatively with previous *in vivo* measurements, and agreed also with *in vivo* classification of responses as slight, mild to moderate, and severe. Thus, measurement of area and depth of injury in *ex vivo* rabbit corneas provides mechanistically-based quantitative data to assess the eye irritation of surfactant-based substances.

890 MÜLLER CELL CULTURES IN EVALUATIONS OF RETINAL TOXICITY.

T. A. Toimela, H. Mäenpää and H. Tähti. *University of Tampere, Medical School, Tampere, Finland.* Sponsor: K. Savolainen.

Retina is one of the most metabolically active tissues in the body, and maintaining the neuronal microenvironment by Müller cells is of vital importance to vision. Müller cells are predominant glial cells in the neural retina. They regulate the ion balance and e.g. glutamate concentration in the retina. Too high glutamate concentrations have been shown to cause excitotoxic neuronal damage and death. Pure Müller cell cultures would serve a good model for studies of the regulatory functions of Müller cells, and for evaluations of glutamate toxicity in the neural retina. There are several methods for culturing Müller cells. Many of them use avascular retinas like that of a rabbit. The advantage is that relatively pure cultures free of astrocytes, endothelial cells and pericytes can be obtained, if the area near the medullary ray is not used. In vascular retina, blood vessels cover the whole retina area, and cultures free of contaminating cell types are not easy to set up. The retina can be dissociated by enzymatic digestion (e.g. with trypsin or papain), and then cultured for definite times. Neurons do not survive long in this type of coculture, but other cell types from blood vessels can survive. A more refined method uses additional gradient centrifuging steps in order to separate purer Müller cells. Another method, where Müller cell cultures are initiated from floating pieces of retina, from which Müller cells drop out, has also been presented. These methods rely on the fact that activated Müller cells are highly viable, and degenerating or necrotic retinas trigger the activation. We have used the above methods for initiating Müller cell cultures from porcine retinas. In characterization of Müller cells antibodies to glial fibrillary acidic protein (GFAP), cellular retinaldehyde binding protein (CRALBP), carbonic anhydrase II and glutamine synthetase have been used. The usual problem with all these methods seems to be that pure cultures cannot be obtained or cultures do not survive many subcultures. Some Müller cell lines have been presented, but they are not freely available. A continuous cell line would be necessary for toxicological large-scale evaluations.

891 SAFETY EVALUATION OF INTRAVITREAL ADMINISTRATION OF RHUFAB VEGF IN CYNOMOLGUS MONKEYS FOR 1 MONTH.

D. B. Eppler[1], B. Christian[2], C. Murphy[3], G. Leatherberry[2], J. Miller[2], P. Miller[1], J. VerHoeve[3], R. Dubielzig[3], D. Albert[3], T. M. Nork[3] and C. A. O'Neill[1]. [1]*Genentech, Inc., South San Francisco, CA.* [2]*Covance Laboratories, Madison, WI and* [3]*Comparative Ophthalmic Research Laboratories, University of Wisconsin, Madison, WI.*

A recombinant antigen binding fragment of a humanized monoclonal antibody to VEGF (rhuFab VEGF) is being developed as a therapeutic for age-related macular degeneration. The toxicity of intravitreal administration of rhuFab VEGF to cynomolgus monkeys, given once every two weeks for 1 month, was assessed. Monkeys (n=16) were assigned to 3 groups and received either: Vehicle, (n=4); 500 µg/eye, (n=4); or 2000 µg/eye, (n=8) rhuFab VEGF, in a 50 µL volume. The 4 additional animals in the high-dose group were designated recovery animals and were observed for 1 month after cessation of dosing. The first intravitreal administration of rhuFab VEGF produced a dose-dependent anterior chamber (AC) inflammation consisting of only flare and cell observed 24-hours after dosing. Inflammation was transient with only anterior vitreal cell persisting at 7 days postdose. After the third dose, AC inflammation in 500 and 2000 µg treated eyes was equivalent to that of vehicle treated eyes. Repeated administration in the same location resulted in scleral weakening. Two high-dose treated animals developed transient retinal perivenular infiltrates that were reversible during the recovery period. rhuFab VEGF administration did not alter posterior segment as evidenced by changes in electrodiagnostics, fundus imaging or ocular histopathology. Additionally, rhuFab VEGF induced no changes on any systemic parameters evaluated. Intravitreal administration of rhuFab VEGF once every two weeks was well tolerated at doses up to 500 µg/eye and produced no lasting effect on ophthalmic parameters.

892 A NOVEL APPROACH FOR IRIS COLORIMETRY DETERMINATIONS.

B. Niggemann[1], D. McGee[2], W. Mueller[1], F. Vogel[1] and R. Korte[1]. [1]*Covance Laboratories GmbH, Muenster, Germany and* [2]*Alcon Research Limited, Fort Worth, TX.* Sponsor: J. C. Norris.

Prostaglandin derivatives are used as promising agents for glaucoma in eye drops because of their ocular hypotensive activity. With Latanoprost, the phenyl-substituted prostaglandin F2a, iris color changes were observed in cynomolgus monkeys (Macaca fascicularis) and in multi-center clinical trials. To document these changes, the standard approach up to now was that photographs were taken and compared with color plates. The disadvantage of this method is that the color intensity varies between the measurements of different months due to changes in the developer and experimental conditions. Furthermore, one person has to judge if there are any changes or not which includes the subjective opinion of this person.Therefore, a computerized method (patent pending) using a video camera (3-CCD) attached to the slit lamp was developed. The signals are transferred to a computer and single frames which are "frozen" by means of a "grabber card" can be stored. In advance the equipment is calibrated and color plates are measured to check the standard conditions. The pictures are evaluated by a software program which displays the average color (as red, green and blue values) of the selected area as a basis for statistical evaluation. This inexpensive method provides a fast and accurate means to quantify color changes in the iris of experimental animals and humans. In addition the stored photographs could be evaluated visually.This is the first time that iris color changes are demonstrated in a publication based on this new method which produces objective values.

893 A METHOD FOR ASSESSING VISUAL ACUITY IN UNANESTHETIZED RATS USING THE OPTICOKINETIC REFLEX.

M. J. Nolt, D. N. Beyus and W. P. Weisenburger. *Pfizer Inc., Groton, CT.*

An efficient, noninvasive procedure to assess visual function in adult and developmental rodent toxicity studies would enhance the safety evaluation of drugs and the hazard identification of chemicals. We are developing a technique that utilizes the opticokinetic reflex (OKR) that has been used successfully in the past for measurement of visual function in several species including rodents and children, but has only rarely been applied to toxicological assessment. For assessment of visual acuity, the method involves observation of a reflexive lateral nystagmus (OKR) in response to vertical black and white stripes of equal width that move across the visual field of an unanesthetized subject. An acuity threshold is determined by varying the widths of the stripes until the OKR is no longer elicited and then calculating the threshold in minutes of visual angle. Male Long Evans rats were restrained individually on a stationary platform inside of a rotating cylinder (45.7 cm diameter, 29.2 cm high) with the eyes unobstructed 20cm from the inside surface of the cylinder. Stimulus sheets of black and white stripes were placed sequentially inside of the cylinder which was then rotated between 1-1.5 rpm. The eyes were observed with an illuminated magnifier for the presence or absence of the OKR. In initial experiments, stripes 10mm wide were presented to confirm the presence of OKR and then stimulus stripes from 5-1mm were presented in 0.5mm increments by a psychophysical tracking procedure. A threshold was considered to be midway between a stimulus that elicited the OKR and a narrower stimulus that did not. The presumed threshold was crossed at least twice. Later experiments used stimulus width increments of 0.25 mm to provide finer resolution. Test-retest and interobservor reliabilities were found to be high with this method and the time required to test a rat was usually less than 20 minutes. Automation of stimulus presentations and objective recording of the OKR would improve efficiency and are being pursued. Visual acuity of male Long Evans rats weighing 300-400 grams under bright illumination was determined to be in the range of 37 to 54 minutes of visual angle, which agrees very well with reported findings from other laboratories using behavioral and electrophysiological methods.

894 HUMAN SENSORY IRRITATION AND ODOR TESTING ON A COMPLEX AROMATIC HYDROCARBON.

A. M. Medeiros[1], W. C. Daughtrey[1], B. M. Jarnot[2], R. Schmidt[3] and W. Cain[3]. [1]*Exxon Biomedical Sciences, Annandale, NJ, and* [2]*Exxon Chemical Company, University of California, San Diego, CA..*

A complex aromatic hydrocarbon (CAH) is a C10-C12, high boiling hydrocarbon composed predominantly of alkylated naphthalenes, with < 0.4 ppm benzene and is used primarily as a carrier solvent for agricultural pesticide spray applications. Previous studies in the mouse suggested that CAH fluid might be a potent sensory irritant. Therefore, we initiated testing to determine human odor and sensory (nasal and ocular) irritation response thresholds on CAH and its major vapor phase constituents.Serial dilutions of CAH, naphthalene, 1-methylnaphthalene (1-MN), 2-methylnaphthalene (2-MN) and a low naphthalene CAH product (CAH-LN) were placed in 2L glass vessels equipped with portals for the eye or nose. Using a 2- or 3-alternative forced-choice test to detect nasal and ocular response, respectively, headspace vapors from dilution series of each material were presented to subjects (n=22) in 14 trials with a 2-min. rest period between trials. The respective mean detection thresholds for ocular and nasal responses in ppm were 39 and 54 for CAH, 37 and 50 for CAH-LN, 88 and 90 for naphthalene, 66 and 85 for 1-MN, and 109 and 149 for 2-MN. Odor detection thresholds for these materials were < 3.0 ppb. Results from this study showed, in humans, CAH and CAH-LN do not appear to be potent sensory irritants as previously suggested by the mouse studies. These materials have odor thresholds well below sensory irritation thresholds. The eyes appear to be more sensitive than the nose. These results contribute to the database on CAH.

895 FROM EPIDEMIOLOGY TO THE GENE: MECHANISMS BY WHICH PARTICULATE MATTER (PM) INDUCES ADVERSE EFFECTS.

D. L. Costa and R. Devlin. *USEPA, Research Triangle Park, NC.*

Epidemiology studies have shown a relatively consistent association between outdoor PM concentrations and various adverse health effects, including premature mortality, exacerbation of asthma and other respiratory diseases, and decreased lung function. The biological basis of these associations is unknown, although epidemiology, toxicology, and clinical studies suggest asthmatics, young children, elderly people, and those with pre-existing cardiopulmonary conditions might be particularly susceptible. Little is known of the contributory factors specific to PM or the host. Consequently, several laboratories are earnestly examining the pathophysiology and toxicological mechanisms that underlie PM effects. The attention being focused on understanding potential physiological linkages between PM and acute mortality has led to the perception that PM may directly or indirectly (via inflammation of the lung) affect the heart. The sequence of biological steps from target dose of PM within the lung to cardiac alterations are likely to be complex. This symposium will provide an update attempting to link the latest cross-discipline research on PM addressing the importance of altered intrapulmonary target dose in those with lung disease, the correlative evidence from field study cardiac monitoring to new findings in experimental animals, and the fundamental molecular signaling events that may well trigger the biological cascade from the cell to the whole organism. The attendee will gain an appreciation for the complexity of the PM response, the role of target tissue dose, responses from the cellular to organismic level, and the potential for cardio-pulmonary interactions in the clinical impact of PM on health.

896 POPULATION STUDIES EXAMINING PM-INDUCED CHANGES IN CARDIAC FUNCTION.

D. W. Dockery. *Harvard Public Health, Boston, MA.* Sponsor: D. Costa.

A large and growing body of epidemiologic studies have reported that daily mortality increases following acute increases in particulate (PM) air pollution. Although the relative increase is greatest for respiratory deaths, the increase in numbers is greatest for cardiovascular associated deaths. Analysis by location shows that most of these acute deaths occurred out of hospital, suggesting sudden cardiac deaths. Time series studies of hospital admissions have also consistently shown increased daily admissions for cardiovascular disease (ischemia, coronary heart failure, and dysrhythmias) associated with increased PM concentrations. The mechanisms underlying these associations are not understood. A recent study assessed the potential linkage through acute hypoxemia in a panel of elderly subjects. No association was found between PM exposures and twice daily pulse-oximetry measurements. However, heart rate was observed to increase with increasing PM concentrations. In addition in a subset of these subjects with ambulatory electrocardiographic monitoring, heart rate variability was found to decrease with increasing PM concentrations. Decreased heart rate variability, a measure of impaired autonomic control, is associated with a poor cardiovascular prognosis. In another recent study, the incidence of cardiac arrhythmias in patients with implanted cardioverter defibrillators have been reported to increase with air pollution exposures. This rapidly developing body of epidemiologic studies of cardiovascular effects of PM exposures will be reviewed with particular attention to possible mechanisms.

897 DOSIMETRY OF INHALED PARTICLES IN SUSCEPTIBLE POPULATIONS.

W. D. Bennett, K. L. Zeman, J. S. Brown and C. S. Kim. *CEMLB/UNC & HSD/USEPA, Chapel Hill, NC.* Sponsor: D. Costa.

Particulate air pollution has been linked to acute increases in mortality/morbidity primarily in the elderly, children and those with preexisting cardiorespiratory disease. While these individuals may be predisposed to acute toxic effects, they may also receive an increased dose of particles to their lungs compared to healthy, young adults. In a series of studies we have been measuring deposition (both total and regional) and clearance of inhaled particles in these susceptible subpopulations for comparison to healthy young adults. While healthy elderly subjects appear not to receive enhanced deposited doses of fine particles compared to younger individuals, those with chronic obstructive pulmonary disease (COPD) receive 2.5 times on average the deposited dose at rest of their age-matched healthy cohort. The deposited dose in COPD increases (as much as 5 times normal) with increasing airway obstruction. Furthermore, the deposited dose in COPD is very nonuniform in the lung, i.e. "hotspots" associated with airway deposition, and the insoluble particle clearance from the airways in COPD is about half the rate of normal. These effects greatly enhance the airway tissue dose in COPD to >> 10 times normal. Similar studies are being conducted in children. It's likely that children also receive an increased dose to their bronchial airways relative to healthy adults. Much of this effect may be associated with children's higher activity levels and ventilation rates that shift deposition of particles to proximal, airway surfaces. Exercise is also associated with a shift from nasal to oral breathing, thereby diminishing the filter capacity of the nose and exposing the lung to higher particle concentrations. Studies are currently ongoing to compare oronasal switching patterns in children vs. adults. Results from these dosimetry studies in susceptible populations may prove useful in determining relative risks associated with the inhalation of airborne particulates. (Supported by USEPA Cooperative Agreement CR817643.)

898 CARDIAC AND THERMOREGULATORY EFFECTS FOLLOWING EXPOSURE TO PARTICULATE MATTER IN HEALTHY AND COMPROMISED RATS.

W. P. Watkinson[1], M. J. Campen[2], J. P. Nolan[2], U. P. Kodavanti[2], K. L. Dreher[2] and D. L. Costa[2]. [1]*UNC SPH, Chapel Hill, NC and* [2]*PTB, ETD, NHEERL, USEPA, Research Triangle Park, NC.*

Extensive epidemiological evidence suggests that exposure to ambient particulate matter (PM) may be responsible for an increased incidence of cardiopulmonary-related morbidity and mortality. A series of animal studies conducted in our laboratory examined this reported association. All studies used male rats (60d) implanted with radiotelemetry transmitters to monitor electrocardiogram (ECG), heart rate (HR), and core body temperature (Tco) throughout the experimental time period (48h pre-exposure–96h postexposure). In the first study, healthy Sprague-Dawley rats (SD) were intratracheally instilled (IT) with one of four doses of residual oil fly ash (ROFA; 0.0, 0.25, 1.0, or 2.5 mg). These rats demonstrated a biphasic, dose-related response consisting of an acute and delayed bradycardia, accompanied by an increase in cardiac arrhythmias, profound hypothermia, and pulmonary inflammation. This protocol was repeated in three models of cardiopulmonary stress/disease, induced by subjecting rats to 1) cold-stress (10°C), 2) ozone-induced (1 ppm×6h) pulmonary inflammation, and 3) monocrotaline-induced (MCT; 60 mg/kg) pulmonary vasculitis/hypertension. Compromised rats exhibited an exaggerated response with lethality observed only in the MCT-treated group. Subsequent studies examined the effects of inhaled (IH) ROFA (15 mg/m3×6h/d×3d) in both MCT-treated SD and Spontaneously Hypertensive (SH) rats. These animals demonstrated similar effects as above (SH>SD) but of lower magnitude with no lethalities. Studies using aged SH rats (15m) investigated the differential responses to prototypical ambient (OTT; Ottawa dust; 2.5 mg), combustion (ROFA; 0.5 mg), and natural source (MSH; Mt. St. Helens volcanic ash; 2.5 mg) particles. Adverse effects, as measured by changes in ECG, HR, and arrhythmia incidence, in order of severity were OTT>ROFA>MSH. Other studies examined the effects of the specific metal constituents of PM (e.g., Fe, V, and Ni), either alone or in combination, in awake MCT-treated SD rats. These studies showed significant acute and delayed decreases in HR and Tco, and increased arrhythmogenesis and lethality. In sum, these results demonstrate substantial cardiotoxicity in rats after both IT and IH exposure to PM or its acidic metal constituents and suggest that the adverse health effects observed following PM exposure may represent a summation of effects of individual metals, as modulated by host susceptibility. (This abstract has been internally cleared and does not reflect EPA Policy.)

899 THE ROLE OF CALCIUM AND ANTIOXIDANTS IN ULTRAFINE PARTICLE-MEDIATED PULMONARY INFLAMMATION.

K. Donaldson, W. MacNee and V. Stone. *Biomedicine Research Group, Napier University & ELEGI Laboratory, Edinburgh, United Kingdom.* Sponsor: D. L. Costa.

Evidence to support the hypothesis that ultrafine particles mediate adverse health effects of PM is still limited. However, toxicological studies support the contention that ultrafine particles have the potential to cause lung inflammation. We have utilised a number of surrogate particles to investigate the generality and mechanism of the pro-inflammatory effects of ultrafine particles. In inhalation studies, exposure to ultrafine carbon black (ufCB, 14nm primary particle diameter; 1000μg/m3 for 7 hours) we detected low level inflammatory change plus evidence of oxidative stress; no such effects were seen with fine carbon black (CB, primary diameter 260nm) at identical exposure. Instillation studies at low dose (<125μg) confirmed that ufCB is substantially more inflammogenic that CB and that antioxidants blunted ufCB inflammation. Monodispersed latex particles with primary particle diameters 525, 202 and 64nm (ufLatex) show a distinct size-related ability to cause inflammation following instillation with ufLatex particles being substantially more inflammogenic than the other size particles. In vitro studies have highlighted the oxidative stress-inducing properties of ufCB and the ability of both ufCB and ufLatex to cause rapid alterations in intracellular Ca^{2+} in a macrophage cell line. These effects appear to involve the plasma membrane Ca^{2+} channels. These allow rapid ingress of extracellular Ca^{2+} in response to a signalled release of endoplasmic reticulum stores of Ca^{2+} within the cell, leading to cell activation for gene expression. could lead to cell activation and gene expression. Enhanced cytokine secretion by macrophages and other target cells in the lungs of compromised individuals where the Ca^{2+} signalling pathways are already 'primed' may therefore be anticipated and this may help in understanding susceptibility.

900 DIFFERENTIAL ACTIVATION OF MITOGEN ACTIVATED PROTEIN KINASE (MAPK) PATHWAYS AND TRANSCRIPTION FACTORS BY SPECIFIC PARTICULATE (PM) COMPONENTS.

J. M. Samet[1], W. Wu[2], R. Silbajoris[1], L. M. Graves[2], W. Reed[2], I. Jaspers[2] and R. B. Devlin[1]. [1]*NHEERL, Research Triangle Park, NC and* [2]*University of North Carolina, Chapel Hill, NC.* Sponsor: D. L. Costa.

Numerous epidemiological studies have shown associations between ambient levels of PM and respiratory-related morbidity and mortality. The mechanisms responsible for these effects are not understood, but may involve an inflammatory response to metallic compounds present in PM. Our studies have sought to identify signaling mechanisms through which combustion-derived metals associated with PM, such as As, Cu, V and Zn, induce the expression of inflammatory proteins in human airway epithelial cells (HAEC). Specifically, we have examined the effect of metal exposure on protein phosphotyrosine metabolism and the activation of the phosphorylation-dependent MAPK cascades. Western blotting and activity assays showed that acute, non-cytotoxic exposures to As, Cu, V or Zn result in rapid activations of the MAPKs ERK, JNK and P38, as well as the MAPK kinase MEK-1, the EGF receptor tyrosine kinase, and the MAPK-dependent transcription factors Elk-1, JNK and ATF-2 in the human bronchial epithelial cell line BEAS. In addition, we have obtained evidence suggesting activation of Ras in BEAS cells treated with As, V or Zn ions. Phosphotyrosine accumulation and MAPK activation is also evident immunohistochemically in rats intratracheally instilled with the metallic mixture residual oil fly ash. In order to identify possible mechanisms that account for the activation of intracellular signaling elements in HAEC, we studied the effect of metal exposure on tyrosine phosphatase activity in whole and fractionated HAEC homogenates. These results showed that V and Zn ions, but not As ions, are potent inhibitors of tyrosine phosphatases, such as PTP1B, present in HAEC. Taken together, these studies demonstrate that ambient PM metals differentially activate intracellular signaling in HAEC.

901 INTERACTION WITH IONOTROPIC NEUROTRANSMITTER RECEPTORS BY ENVIRONMENTAL TOXICANTS: CONSEQUENCES FOR NEURONAL FUNCTION.

J. B. Suszkiw[1] and W. D. Atchison[2]. [1]*University of Cincinnati, Cincinnati, OH and* [2]*Michigan State University, East Lansing, MI.*

Ionotropic receptors comprise one of two major classes of ligand-gated ion channels. The ligand binding site(s) are directly coupled to the ion conductance pathway in these macromolecules, as opposed to being coupled to a GTP-binding protein or intracellular second messenger. As such, ionotropic receptors provide the simplest and fastest way of transducing an extracellular stimulus into a change in neuronal excitability. Ionotropic receptors comprise the major class of transmitter receptors involved in "fast neurotransmission," and mediate both excitatory and inhibitory synaptic function. Neurotransmitter receptors of the ionotropic class comprise a major gene family which is unrelated to the specific class of neurotransmitter, but rather to the mechanism of signal transduction. Included in this class are the nicotinic receptors for acetylcholine, gamma amino butyric acid (GABA) A-subclass, several types of glutamate receptors (kainate/AMPA, NMDA) glycine and serotonin ($5HT_3$) receptors. This class of receptors shares common structural characteristics, typically consisting of multimeric macromolecules, with similar overall hydrophobicity of the subunits, and significant homology in their primary structure. The receptors play crucial roles in functions such as learning and memory, nervous system development and synaptogenesis, and regulation of overall neuronal excitability. Additionally, these receptors collectively serve as targets of a number of important therapeutic agents, natural toxins and xenobiotics. As such, these receptors serve as important targets of some major classes of toxicants. Mechanisms by which toxicants may act include direct block of the binding sites for the stimulating ligand, direct effects on the ion channel itself, or effects on the modulatory processes associated with these receptors. (Supported by NIEHS grants ES03299 [wda] and ES06365 [jbs].)

902 PERTURBATION OF EXCITATORY AND INHIBITORY GABAA RECEPTOR RESPONSES IN CORTICAL NEURONS *IN VITRO* BY POLYCHLORINATED BIPHENYLS (PCBS).

J. R. Ingelfield[1] and T. J. Shafer[2]. [1]*NHEERL, Research Triangle Park, NC and* [2]*USEPA NHEERL, Research Triangle Park, NC.*

$GABA_A$ receptors are the major inhibitory receptor in the central nervous system of mature animals and mediate excitatory responses which underlie trophic actions of the neurotransmitter GABA in the developing nervous system. Because $GABA_A$ receptors are important to nervous system development and are substrates for steroids, hormones and chlorinated chemical pollutants, we examined the hypothesis that disruption of $GABA_A$ receptor function in neurons contributes to the developmental neurotoxicity of PCBs. In cortical neurons maintained in culture, Aroclor 1254 (A1254, 2-20 μM, 1hr) initiated (within 5min) sustained Ca^{2+} oscillations, suggestive of action potential generation. These oscillations in $[Ca^{2+}]_i$ were dependent on Ca^{2+} entry via voltage-sensitive Ca^{2+} channels as they were blocked by 1 μM nifedipine. A1254 (10 and 20 μM) increased basal $[Ca^{2+}]_i$ significantly after 1 hr and reduced significantly (2-20 μM, 1hr) both excitatory and inhibitory responses to GABAA receptor stimulation. In addition, both *ortho-* (2,2'-dichlorobiphenyl, 2,2',3,4,4',5-hexachlorobiphenyl) and non-*ortho-* (4,4'-dichlorobiphenyl, 3,3',4,4',5-pentachlorobiphenyl) substituted PCB congeners (5-10μM, 1hr) inhibited $GABA_A$ responses. Thus, effects of PCB congeners on $GABA_A$ receptors appear to have a different structure-activity relationship than reported previously for other endpoints of neuronal function. In addition, only 4,4'-dichlorobiphenyl and 2,2',3,4,4',5-hexachlorobiphenyl significantly increased basal $[Ca^{2+}]_i$. Thus, perturbation by PCBs of $GABA_A$ receptor-mediated responses occurred in the absence of or after only slight PCB-induced increases (2 μM A1254) in basal $[Ca^{2+}]_i$, suggesting that PCB effects on $GABA_A$ receptors may not depend on changes in $[Ca^{2+}]_i$+]. These results demonstrate that GABAA receptor responses are sensitive to PCB effects. Such effects may contribute to the developmental neurotoxicity of PCBs.

903 DISRUPTION OF CEREBELLAR GRANULE CELL GABAA FUNCTION BY METHYLMERCURY INDUCES EARLY ONSET SYNAPTIC EXCITATION.

W. D. Atchison, Y. F. Xu and Y. Yuan. *Michigan State University, East Lansing, MI.*

Methylmercury (MeHg) has wide-ranging neurological effects including disturbances of motor coordination, an effect mediated primarily in the cerebellum. In both developing and mature organisms, cerebellar granule neurons are primary targets of MeHg-induced neurotoxicity. Studies of effects of acute administration of MeHg to isolated slices of rat brain reveal a striking disruption of synaptic transmission in both hippocampal CA1 region and cerebellar parallel and climbing fiber pathways. A common effect which precedes this block of excitatory transmission is a transient enhancement of synaptic transmission- reflected as increases in amplitude of excitatory postsynaptic potentials (EPSPs). This action, which is most pronounced with low concentrations of MeHg could be due either to direct facilitation of glutamatergic function, or indirectly to disruption of tonic inhibitory synaptic transmission at these synapses. Analysis of $GABA_A$ receptor-mediated inhibitory postsynaptic potential amplitudes revealed that they were blocked with a timecourse which preceded block of EPSPs, but which was consistent with the observed increase in EPSP amplitude. In isolated cerebellar granule cells in culture, MeHg at 1 μM completely blocked $GABA_A$ activated current within 6-10 min and generated an inactivating inward current which persisted in the presence of TTX, TEA and Cd^{2+}. When the MeHg-induced effect on GABA-mediated nonspecific current was maximal, GABA no longer induced an inward current, but rather an outward current, which was blocked by bicuculline and activated by muscimol. Thus $GABA_A$ receptor responses are sensitive targets for MeHg. Due to the importance of synaptic inhibition to neuronal function, these effects of MeHg could have important implications for cerebellar function in both developing and mature organisms by inappropriately activating certain neuronal circuits. (Supported by NIEHS grant ES03299.)

904 NEURONAL NICOTINE ACETYLCHOLINE RECEPTORS: A NOVEL TARGET OF INSECTICIDES.

T. Narahashi. *Northwestern University, Chicago, IL.*

The development of insect resistance to insecticides is one of the most serious problems in pest control since insects could not only gain resistance to any insecticides but also gain cross resistance to a new insecticide that shares the same target site with the existing insecticides. Therefore, the development of insecticides that act on a new and novel target site is urgently required, and neuronal nicotinic acetylcholine receptors (nnAChRs) hold promise as a new target. Nitromethylene heterocycle insecticides such as imidacloprid and the oxadiazine insecticide indoxacarb (DPX-MP062) have recently been demonstrated to act on nnAChRs. Imidacloprid and cartap suppressed the activity of nnAChRs of PC12 cells, yet significant differences in their mechanisms of action could be unveiled only by single-channel analyses. Indoxacarb suppressed the α7 type ACh-induced current in rat cortical neurons while augmenting the α4β2 type current. On the contrary, the metabolite DCJW had little or no effect on both types of current. Thus indoxacarb's action is subunit specific. (Supported by NIH grant R01NS14143.)

905 INTERACTIONS OF PB^{2+} WITH NICOTINIC RECEPTORS AND WITH GABAERGIC AND GLUTAMATERGIC SYNAPSES: IMPLICATIONS FOR SYNAPTIC PLASTICITY IN THE DEVELOPING HIPPOCAMPUS.

E. X. Albuquerque. *University of MD, Baltimore, MD.*

Recently we demonstrated that Pb^{2+} (≥100 nM), by interacting with targets within presynaptic terminals, facilitates the action potential-independent release of GABA and glutamate from hippocampal neurons in culture. With an IC50 of approximately 65 nM, Pb^{2+} was also shown to block the action potential-dependent release of both GABA and glutamate. This Pb^{2+}-induced inhibition of evoked transmitter release was likely due to block of voltage-gated Ca^{2+} channels. Further, Pb^{2+} causes a Ca^{2+}-dependent, biphasic block of whole-cell currents mediated by activation of α7-like neuronal nicotinic receptors (nAChRs) in hippocampal neurons in culture. In the subsecond time scale Pb^{2+}(≥1 μM) associates with a site on the extracellular domain of α7-like nAChRs to cause a reversible block of the receptors. This is evidenced by reduction of the amplitude and acceleration of the decay phase of the α7-nAChR mediated type IA currents, and by shortening of the open time and reduction of frequency of openings of α7 nAChR channels. Within 1-2 min, Pb^{2+}, via an intracellular mechanism, causes an additional irreversible reduction of the amplitude of type IA currents. It is noteworthy, that at lower concentrations (10-100 nM), Pb^{2+}, by activating protein kinase C (PKC) in hippocampal neurons, effectively blocks the ability of acetylcholine to control, via nAChRs, release of GABA and glutamate. Thus, given that synaptic activity is critical for the establishment of stable synaptic connections early in development, Pb^{2+}-induced long-lasting effects on neuronal maturation and plasticity could be accounted for by changes in mechanisms that control transmitter release. Support: USPHS grant ES05730.

906 LATEX ALLERGY IN THE WORKPLACE.

M. Toraason and D. Germolec. *NIOSH, Cincinnati, OH.*

The United States Occupational Safety and Health Administration (OSHA) estimates that 8-12% of healthcare workers are sensitized to natural-rubber latex. In addition, approximately 0.5-1% of the general population is reported to be sensitized. Clinical signs and symptoms of latex induced disease range from simple irritation to immunologic manifestations such as urticaria, asthma, and anaphylaxis. The mechanisms of latex allergy are complex, and are induced by exposure to numerous allergenic proteins found in natural-rubber latex as well as other chemicals used in latex products manufacturing. For example, there are 250+ proteins containing multiple epitopes in latex of which at least 30 have allergenic potential. Several latex proteins have been epitope mapped. Sequencing demonstrates both unique epitopes and sequences commonly found in other plant proteins. These common epitopes result in cross-reactivity to other plant allergens found in pollens and foods. A further complication arises from the ability of latex proteins to associate with glove powder. This enhances the potential for respiratory sensitization from aerosolized powder associated proteins, and both humans and experimental animals have demonstrated hypersensitivity following exposure to latex via the respiratory route. The diagnosis of latex allergy is complicated by these variables, which in turn hinders the development of intervention strategies. Further epidemiological assessment can more explicitly define the scope, trends, and demographics of latex allergy. Diagnostic accuracy can be improved through greater knowledge of proteins involved in the development of latex allergy, and factors analysis of presently available diagnostic tests. *In vivo* and *in vitro* models can elucidate mechanisms of sensitization and provide an understanding of the role of exposure route in latex associated diseases. Combined, these efforts can lead to intervention strategies for reducing latex allergy in the workplace.

907 LATEX ALLERGY: CLINICAL AND EPIDEMIOLOGICAL DATA.

G. Sussman. *University of Toronto, Toronto, Ontario, Canada.* Sponsor: M. Toraason.

Natural rubber latex (NRL) allergy has become an important occupational health concern particularly among healthcare workers (HCWs). Clinical manifestations include irritant contact dermatitis, allergic contact dermatitis (type 4), and type 1 immediate hypersensitivity responses. Type 1 (IgE mediated) NRL allergy includes contact urticaria, systemic urticaria, angioedema, rhinitis, conjunctivitis, bronchospasm and anaphylaxis. Diagnosis of type 1 latex allergy is made by accurate history including questions on atopic status, food allergy, reactions to latex devices (gloves, balloons, condoms), and reactions during medical and dental procedures. To confirm a diagnosis either *in vivo* skin prick testing (SPT) or *in vitro* assays for latex specific IgE are performed. The major source of workplace exposure has been the powdered NRL gloves used by HCWs. Surveys of HCWs have demonstrated that the prevalence of sensitization to latex ranges from 2.9% in Finland to 4.7% in Belgium among hospital workers as a group, and from 6.2% in operating room staff in Finland to 9-10% in Canada and France. We recently observed that the prevalence of latex sensitization based on SPT was 12.1% with a minimum prevalence of 9.5% among 1351 HCWs in two hospitals. There were significant associations with atopic status, positive SPT to certain foods, work related symptoms, and departmental use of gloves per HCW. In this study about 60% of the latex SPT positive participants had work related symptoms. It has been reported that 2.5% of HCWs have latex induced occupational asthma confirmed by specific inhalational challenge. Sensitization to latex has extensive cross-reactivity with certain foods and leads to clinical allergic reactions. Positive food SPTs occurred in our patients with the following frequency: avocado (53%), potato (40%), banana (38%), tomato (28%), chestnut (28%), and kiwi (17%). As well we reported that dental school students were at high risk for latex sensitization with prevalence rates of 0% for year one and two students, 6% of year 2 students, and 10% of year four students having a positive latex SPT. The prevalence of latex sensitization in occupationally unexposed groups is quite low, generally less than 1%.

908 MOLECULAR CHARACTERIZATION OF LATEX ALLERGENS.

D. Beezhold. *Guthrie Research Institute, Sayre, PA.* Sponsor: M. Toraason.

Type 1 latex allergy is an IgE mediated response to antigenic proteins found on products made from natural rubber latex. Natural rubber latex is harvested from trees and ammoniated to prevent coagulation resulting in the hydrolysis of the latex proteins. Prior to use in manufacturing, the latex is formulated by the addition of multiple chemicals. Thus, human exposure is to a mixture of residual chemicals and hydrolyzed latex peptides. The hydrolyzed nature of the allergens has complicated identification of major allergens and the development of reagents for *in vivo* and *in vitro* diagnostic tests. Multiple investigators, using a variety of methodologies, have succeeded in identifying the major IgE binding allergens (Hev b 1-8). More recently, these proteins have been cloned, sequenced and expressed as recombinant proteins. Skin testing with recombinant Hev b 2, 3, 5, 6, 7, and 8 revealed Hev b 5, 6 and 7 to be the most common allergens for healthcare workers. Using overlapping synthetic peptides, IgE binding epitopes have been determined for these allergens. Hev b 5 contained at least 6 epitopes, while Hev b 7 contained 12 epitopes all with limited sequence homology to other known plant proteins. Hev b 6 however, contained six epitopes with sequence homology to defense proteins common to many different plants. Sequence homology helps to explain the cross reactivity to a variety of foods experienced by latex allergic individuals. The development of recombinant allergens provides reagents which should greatly improve the diagnostic accuracy of tests for latex allergy.

909 COMPLICATIONS IN INTERPRETATION OF DIAGNOSTIC TESTS FOR LATEX ALLERGY.

R. Biagini. *NIOSH, Cincinnati, OH.*

The diagnosis of natural rubber latex allergy begins with a clinical history and often involves a confirmatory test. While the puncture skin test (PST) has been regarded as a primary confirmatory test for the assessment of patients for IgE-mediated disease, the absence of an FDA-licensed Hevea brasiliensis latex extract in the USA has restricted its use in the diagnosis of latex allergy. Serological tests have therefore become critically important as alternative diagnostic tools. Three manufacturers have currently obtained 510K clearance from the FDA for their latex *in vitro* reagents: the CAP System (Pharmacia-UpJohn); the AlaSTAT, (Diagnostic Products Corporation) and the HY-TEC assay (HYCOR Biomedical). Although all of these commercial assays are based on non-ammoniated latex (NAL) as their primary allergen, there are differences in their solid or soluble supports and detector systems. Paired-comparisons of the three assays indicates that they disagree on the antibody status of an individual serum. This leads to patient's sera being "positive" by one or two tests and negative in (an)other(s). It is speculated that the disagreement among tests is due to IgE antibody assays detecting different subsets of IgE antibody of a given specificity, possibly as a result of differential specificities of their allergen-containing reagents. Reasons for this include variability in allergen content in different batches of source latex; sensitized individuals producing specific IgE antibody to at least 8 *Hevea* allergens, Hev b 1-Hev b 8, each of which differs in its structure, size, net charge (pI), relative allergenicity and abundance in natural rubber latex. The relative content and ratios of Hevs in the final allergen preparation most probably could enhance the diagnostic accuracy of a specific test. Other potential causes of allergen-containing reagent heterogeneity include variable stability during storage and variable binding of allergen to labels (e.g., biotinylated co-polymer in AlaSTAT) or solid supports (sponge in CAP; cellulose disc in HYTEC). Using receiver operating characteristic (ROC) curve analysis, and positive PST to NAL as the discriminator, the HY-TEC system has significantly greater ($P<0.01$) area under the curve (AUC, 0.924 + 0.017, standard error) than CAP (0.869 + 0.024) or AlaSTAT (0.858 + 0.024), suggesting it may be more accurate under the comparison conditions evaluated.

910 ANIMAL MODELS AND MECHANISMS OF LATEX ALLERGY.

B. J. Meade. *NIOSH, Morgantown, WV.*

Animal models are frequently used to conduct mechanistic studies that due to test article toxicity or sensitization potential would be unethical to perform in humans. Several laboratories have developed models to study latex allergy and although these include rabbit and guinea pig models, most animal research has been conducted in murine models. Although clinical and exposure data have been gathered on the factors affecting the elicitation of responses in latex allergic individuals, less is known regarding the development of sensitization. Coupled with *in vitro* dermal penetration studies, murine models were established to investigate the role of the route of exposure in the development of latex sensitization. Time course and dose response

studies have shown multiple subcutaneous (s.c.) administrations of as little as 0.19μg non-ammoniated latex proteins (NAL) elicited IgE production in 5 weeks. Animals exposed s.c., intratracheally (i.t.) or topically to 12.5μg NAL demonstrated IgE production within 2, 3 and 5 weeks, respectively. Although elevations in total and latex specific IgE have been observed following topical, intranasal (i.n.), i.t. and s.c. exposures, pulmonary responses (as measured by plethysmography) following respiratory challenge was only seen in mice sensitized by the topical or respiratory routes. Both *in vitro* penetration and *in vivo* studies highlight the importance of skin condition in the development of latex allergy with enhanced penetration and earlier onset of IgE production seen with experimentaly abraded skin. These models are also being used to investigate the role of concurrent exposure to other chemicals and agents in the workplace on the development of latex allergy. I.n. co-exposure to endotoxin with recombinant Hev b 5 was reported to increase the Hev b 5 specific IgE response without altering total IgE. In our model, i.n. co-exposure of endotoxin with a mixture of NAL proteins was found to suppress the elevation in total IgE seen in response to NAL alone. These observations underscore the complexity of the mechanisms involved in the development of an allergic response to a complex mixture.

911 HARMONIZATION OF CANCER AND NON-CANCER RISK ASSESSMENT: MOVING BEYOND THE NRC BOOK.

H. Zenick[1] and M. S. Bogdanffy[2]. [1]*NHEERL, Research Triangle Park, NC and* [2]*E.I. Du pont de Nemours & Co., Newark, DE.*

The publication of the 1983 NRC report, Risk Assessment in the Federal Government: Managing the Process established the framework and principles for risk assessment that are still applied today, essentially unmodified. At that time, the primary focus was on cancer risk assessment with the consequence being the emergence of a somewhat dichotomous approach to assessing cancer and non-cancer risks. The rapid increase in our understanding of toxicokinetic and toxicodynamic mechanisms is now challenging the validity of these assumptions and the value of retaining such a disparate approach. Evidence suggests that carcinogens may work initially through a variety of less direct targets/processes, some of which may have thresholds. Similarly, because of factors such as differences in individual susceptibility and existing background rates, certain non-cancer effects may not exhibit a threshold. In this workshop, a more consistent and integrated approach to human health risk assessment will be discussed. In exploring the future directions that risk assessments will take, mechanistic commonalties between cancer and non-cancer effects will be examined as well as issues related to differences in disease expression (e.g. exposure parameters, disease latency). Discussions in this workshop will include an historical perspective, the central roles of mode of action and tissue dosimetry, and stochastic vs. tolerance distribution models in integrated approaches to cancer and non-cancer risk assessment.

912 HARMONIZATION IN RISK ASSESSMENT—OVERVIEW HISTORICAL ASSUMPTIONS AND PRACTICES.

G. Kimmel and V. Vu. *USEPA, Washington, DC.* Sponsor: H. Zenick.

In 1983, the National Research Council published Risk Assessment in the Federal Government: Managing the Process. Since then, much has been done in the way of producing guidance for carrying out risk assessments, as well as developing new approaches. Recently, the risk assessment field has begun to challenge the traditional approaches to risk assessment. This is especially true in the separation of cancer and non-cancer risk assessments. Historically, cancer has been considered a non-threshold response, while other health endpoints were considered threshold effects. However, in 1994 NRC, in Science and Judgement in Risk Assessment, noted the importance of an approach that is less fragmented, more consistent in applications of similar concepts, and more holistic than endpoint-specified guidelines. The report questions the application of a non-threshold quantitative approach as a default in all cancer risk assessments. Conversely, the use of a threshold concept as a default for agents that cause nerve, reproductive and developmental toxicity or that act on various systems through receptor-medicated events is also questioned. The EPA has begun to address this changing philosophy, and its revised cancer risk assessment guidance has proposed departing from the assumption that all cancer effects show linear dose-response relationships. The Agency is also developing an over-arching framework for human health risk assessment. The Agency is seeking the input of the risk assessment community as evidenced by a recent SOT Contemporary Concepts in Toxicology workshop, cosponsored by several governmental and non-governmental groups, on the harmonization of risk assessment approaches including incorporation of mechanistic information. The present talk will briefly review the historic assumptions underlying current approaches to health risk assessment and will summarize EPA's current interest in a more integrated approach to risk assessment in the future.

913 MODE OF ACTION AND TISSUE DOSIMETRY—LINCHPINS OF HARMONIZATION OF CHEMICAL RISK ASSESSMENT.

M. E. Anderson[1] and H. A. Barton[2]. [1]*Colorado State University, Fort Collins, CO and* [2]*NHREEL, Research Triangle Park, NC.*

Chemical risk assessments have evolved as knowledge of toxicological and biological processes has matured. However, there is divergence of risk assessment practices among agencies and offices within the same agencies. As chemical risk assessments become more objective, there is increasing emphasis on more consistent guidelines for these assessments. Increasingly, the emphasis has been on how the chemical interacts with the biological system to produce the adverse outcome, the so-called mode of action. Mode of action is especially helpful in defining approaches for low dose extrapolation. Comprehensive mode of action statements, however, should convey both the biological consequence of the exposure and the form of chemical that initiates changes in the biological system. The form of chemical relates to proper tissue dosimetry. Quantitative integration of dosimetry and mode of action occurs through pharmacokinetic (PK) and pharmacodynamic (PD) models. Biologically based dose response (BBDR) models link dosimetry from PK models quantitatively to adverse response through mode of action. Presently and perhaps well into the future, our confidence in PK and precursor effect models will be much higher than that in complete BBDR models. Harmonization will be accelerated by consistent use of mode of action data to infer the nature of low dose curves and dosimetry/precursor effect models that allow more confident prediction of the shape of dose response curves over a wide range of exposure conditions. This talk illustrates mode of action and dosimetry concepts qualitatively and quantitatively by reference to harmonization of cancer and non-cancer risk assessment and efforts to create BBDR models for carcinogens.

914 MODE OF ACTION AS A GUIDE TO QUANTITATIVE ANALYTICAL APPROACHES.

L. Rhomberg. *Gradient Corporation, Cambridge, MA.* Sponsor: H. Zenick.

Harmonization of quantitative risk assessment methodologies should aim at achieving logical consistency among methods. Mere imposition of similarity in the operational steps of calculation can actually work against this more fundamental harmony by hiding important differences in interpretation. The same growing insight into underlying mechanisms of toxicity that suggests some commonalities between cancer and noncancer toxicities also reveals an impressive diversity of fundamental mechanisms within these two classes. Some aspects of underlying modes of action relevant to choosing quantitative analytical approaches are discussed, including action at different levels of biological organization, functional redundancy of targets, and the distinction between stochastic processes and tolerance distributions as a basis for the existence of a dose-response relationship. The pursuit of biologically based mechanistic models for characterizing dose-response relationships will engender more diversity as each endpoint comes to be analyzed in a way appropriate to its underlying biology. Too rigid a notion of what "harmonization" means, therefore, may stultify development of models yielding deeper and more reliable insight into toxicity and may cloud proper interpretation of risk analysis results.

915 INTEGRATIVE APPROACHES TO RISK ASSESSMENT BASED ON MODE OF ACTION: CANCER AND NON-CANCER ENDPOINTS.

W. Farland, A. Jarabek and V. Vu. *USEPA, Washington, DC.*

There is general agreement in the scientific community that increased use of more and different information will be required to improve our understanding of risks from environmental toxicants. Recent advances in approaches to risk assessment are designed to accommodate such information. Among other things, these advances focus on breaking down the traditional dichotomy between approaches to evaluating cancer and non-cancer endpoints. The focus on better metrics for dose, understanding the basis for outcomes within

the range of observation and use of these improvements to inform judgment below the range of observation (extrapolation) will result in better characterizations of hazard and risk. To be most valuable in risk assessment, incorporation of more information should allow the identification of hazards by providing data on measurable biochemical or cellular endpoints which can serve as biomarkers of response for more complex adverse biological effects such as cancer, or developmental disorders. Ideally, these measurable endpoints should be mechanistically linked to the effect of concern rather than simply being correlated with it. Identification of key events leading to toxicity can provide insights into the conditions necessary for response, and the shape of the dose-response relationship for effects of concern as one goes from high to low dose. Developing means for the incorporation of such *in vitro* and *in vivo* data should allow the extension of the dose response relationship established by more traditional toxicology studies to lower levels, based on increased ability to detect responses in individual cells or using more sensitive biochemical or molecular biolological techniques. The determination of an appropriate exposure or dose metric to link these data will be critical. Incorporation of such information into risk assessments may also suggest targets of opportunity for further study in human populations by identifying potentially sensitive populations based on molecular or cellular characteristics or on sensitive stages in development and aging. Several examples including recent assessments of perchlorate and vinyl acetate will be used to illustrate the positive direction of the field of risk science and the role of new methods and data in improving assessments.

916 FINDING OUR WAY THROUGH THE GENE EXPRESSION DATA MAZE USING A DYNAMICAL MODEL OF OXIDATIVE STRESS.

K. T. Morgan[1], R. Reynolds[1], L. M. Crosby[2], G. Benavides[3], H. R. Brown[1], B. Gaskill[1], D. Sprenger[1], G. Conner[1], K. Gottschalk[1], T. Fox[1], C. Merrill[3], C. Qualls[1], L. Yoon[1] and P. Fink[4]. [1]*GlaxoWellcome, Inc., Research Triangle Park, NC,* [2]*North Carolina State University and USEPA, Research Triangle Park, NC,* [3]*North Carolina State University and GlaxoWellcome, Inc., Research Triangle Park, NC and* [4]*Interleukin Genetics, San Antonio, TX.*

Gene expression array technology is creating a flood of data on gene expression responses by cells and tissues exposed to toxicants. Oxidative stressors, such as GSH depletion, oxidation, or exposure to oxidants, underlie many disease states and oxidative mechanisms have been demonstrated for a wide range of chemicals. Computer modeling provides a means to integrate our understanding of cellular biochemistry, signal transduction pathways, gene expression and transcriptional regulation in 'normal' cells and cells undergoing oxidative stress. Such models also provide a means to investigate the dynamics of interactions between these factors. Exposure of HepG2 cells to diethyl maleate, paraquat, and potassium bromate altered gene expression, detected using Clontech Expression Arrays and TaqMan, and GSH:GSSG values. Our experimental data and published literature were used as a basis for the development of a dynamical model (Biofusion Modeling on an Extend software platform) to study gene expression responses to oxidative stress. The model simulated aspects of energy metabolism (ATP:ADP), redox balance (GSH:GSSG), generation of superoxide and hydroxyl radicals, antioxidant responses (SOD, CAT, gammaGCS, GPX1, GR, HO-1), and transcription regulation (AP-1, NF-κB, p53) over 24 hrs in 1 min time steps. The model was found to (1) assist in the storage, integration and interpretation of these complex information/data sets while providing a dynamic rendition of their interrelationships, (2) permit hypothesis development and 'in silico' testing, and (3) provide a basis for interpretation of data derived from gene expression array technology. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.)

917 TOXICOGENOMICS: UNDERSTANDING THE USE OF MICROARRAYS FOR TOXICOLOGY STUDIES *IN VIVO*.

K. T. Blanchard[1], O. DiSorbo[1], R. Burris[2], R. T. Dunn, II[2], S. B. Farr[2] and R. E. Stoll[1]. [1]*Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT and* [2]*Phase-1 Molecular Toxicology, Inc., Santa Fe, NM.*

Toxicogenomics has recently emerged as the science of interpreting gene expression patterns elicited by toxicants. However, it is critical to define the usefulness and potential limitations of any new technology before it is applied as part of a human safety assessment in drug development. The current study focused on these types of issues; 1) defining the assay reproducibility, 2) understanding the heterogeneity between samples, and 3) the ability to identify similarities or differences in gene expression patterns obtained from animals treated with several different toxicants. Groups of Sprague-Dawley rats were treated with either peroxisomal proliferators (clofibrate, gemfibrozil, or Wyeth-14,643) or an enzyme inducer (phenobarbital) for 2 weeks by oral gavage. After treatment the animals were sacrificed, hepatic RNA was isolated, and low-density gene array analysis (about 200 genes/slide) was conducted by a dual labeling technique using the Cy3 and Cy5 fluorescent probes. A pooled sample of RNA, isolated from the liver of untreated rats, served as the control for normalization between arrays. Results indicate that the assay is highly reproducible. When each RNA sample was assayed on 2 separate arrays, there was a high correlation in the gene expression profiles ($r > 0.900$). Likewise, when groups of rats were treated with the same compound, animals responded uniformly with correlations in the gene expression pattern again greater than 0.900. Since these initial data clearly established that the assay was reproducible and animals responded uniformly, comparisons were made between different compounds. As expected, similarities in gene expression were obtained when comparing the clofibrate, gemfibrozil, and Wyeth-14,643 whereas, phenobarbital produced a pattern dissimilar to that obtained by the peroxisomal proliferators. Together these data provide an early indication for the reproducibility and potential usefulness of Toxicogenomics in the field of Safety Assessment.

918 DIFFERENTIAL GENE EXPRESSION IN RATS FOLLOWING CHRONIC SODIUM VALPROATE EXPOSURE.

N. J. Plant[1], G. G. Gibson[1], T. Bertram[2], P. Bugelski[2] and P. Lord[1]. [1]*School of Biological Sciences, Universtiy of Surrey, Guildford, United Kingdom and* [2]*Safety Assessment, SmithKline Beecham Pharmaceuticals, Welwyn, United Kingdom.*

Sodium valproate (SV) is clinically employed as an anti-convulsant and, recently in the USA, as a mood stabiliser in manic-depressive illness (bipolar disorder). While the incidence of toxicity associated with the clinical use of valproate is lower than with many other anticonvulsant/mood stabilising drugs, it is becoming increasingly clear that serious hepatotoxicity makes up a significant percentage of these adverse effects. Jeavons1 reported 60 cases of death due to hepatic failure within the first six months of multidrug treatment, including valproate, with fatalities occurring mainly in children. Previous studies have highlighted the different pharmacological effects of acute SV exposure, a combination of which are likely to underpin its observed broad-spectrum anticonvulsant efficacy. However, limited studies have been undertaken to study the chronic effects of this compound, and how genomic effects may underlie the observed mood stabilising and hepatotoxic effects. Suppression PCR Subtractive Hybridisation (SSH) is a PCR-based method for isolating differentially expressed genes, enabling the identification of genes implicated in the modes of action of drugs. This study uses SSH, along with RT-PCR, to identify and quantitate mRNA species regulated in response to chronic SV exposure in rats. Male Sprague Dawley rats were dosed with vehicle (saline), 250 or 500mg/kg/day sodium valproate i.p. for four days, a dose previously shown to elicit similar effects to those seen in humans (e.g. microvesicular steatosis, mitochondrial damage). Twenty-four hours after the final dose, (Day 5) animals were killed, mRNA extracted from control and treated livers and subjected to SSH. Resultant regulated species were screened to remove false positives, sequenced and changes quantified using RT-PCR. 10 up-regulated and 15 down-regulated mRNA species were identified. Six novel mRNA species were identified, for which no functional data is known, and these provide new lines of investigation which we are currently under investigation. Several mRNA species were identified that may play a role in the observed hepatotoxicity. These include a down regulation of species involved in cellular energetics (i.e. succinate dehydrogenase, aldolase B) which may be involved in the mitochondrial damage, possibly leading to the observed loss of Acyl CoA (Ponchaut et al., 1992). Cellular proliferation (i.e. NAP4) and protein synthesis (i.e. ribophorin II) were also down-regulated, suggesting a general loss of cell viability. Such data forms the basis for further studies into the genomic changes associated with chronic SV exposure.

919 THE GENE EXPRESSION SIGNATURE OF TCDD IN HUMAN HEPG2 CELLS.

A. Puga, A. Maier and M. Medvedovic. *Department of Environmental Health, University of Cincinnati, Cincinnati, OH.*

One of the most puzzling aspects of the biological impact of *2,3,7,8*-tetrachlorodibenzo-p-dioxin (TCDD), the prototype dioxin, is that it causes a profusion of apparently unrelated biological effects. In humans, exposure to TCDD and to many other chlorinated phenolic agents causes chloracne, a long-lasting skin disease characterized by the hyperkeratinization of follicular sebocytes. Long-term epidemiologic studies have also established a strong

link between exposure to high doses of TCDD and certain types of cancers and cardiovascular disease. TCDD exposure during mouse embryogenesis causes hydronephrosis and craniofacial anomalies, whereas in adult rodents, TCDD causes an elevated incidence of hepatic carcinoma and pulmonary and skin tumors. Other consequences of TCDD exposure include disturbances of lipid metabolism, cardiovascular and craniofacial abnormalities during fish development, and immunotoxic, reproductive and endocrine effects, some of which appear to be present also in exposed humans. The effects of TCDD at the cellular level are just as diverse and often contradictory. In human keratinocytes, dioxin induces proliferation as well as terminal differentiation. Immature thymocytes from rats and mice treated with TCDD *in vivo*, but not *in vitro*, show increased apoptosis. In rat hepatocytes, TCDD has also been reported to induce apoptosis as well as to inhibit uv-induced apoptosis and to increase, in some reports, and to decrease, in others, proliferation rates. TCDD also abrogates the estrogen-dependent proliferation of human breast cancer cells. Many of the effects of TCDD exposure have been known for many years to result from the activation of the Ah receptor, a ligand activated transcription factor that, through dimerization with ARNT, is responsible for the up-regulation of several well-characterized genes; however, a more complete signature of regulatory mechanisms affected by TCDD, which might shed light on the mechanisms responsible for its many biological effects, has never been obtained. We have used a microarray hybridization approach to characterize the response of the human HepG2 hepatoma cell line to TCDD exposure. We find that TCDD disregulates by at least a factor of 2 the expression of 412 known genes in addition to that of several hundred more expressed sequence tags (ESTs). Treatment with TCDD in the presence of cycloheximide (CX), allowed us to distinguish primary effects of exposure from secondary effects, which are blocked by inhibition of protein synthesis. Of the 412 known genes, 25 are up-regulated regardless of CX treatment, and 125 other are up-regulated only when protein synthesis is allowed to proceed. Similarly, 80 genes are down-regulated independently of CX treatment, whereas down-regulation of an additional 137 is blocked by CX. The remaining 46 genes are either induced (10) or repressed (36) by TCDD only when protein synthesis is blocked. Regulatory patterns induced or repressed in the presence of CX by benzo(a)pyrene, another Ah receptor ligand, are by and large the same as those resulting from TCDD exposure. These results suggest that the development of a sound understanding of the molecular mechanisms governing the outcome of TCDD exposure promises to be orders of magnitude more complicated than might have been previously imagined. (Supported by NIH P30 ES06096 and R01 ES06273.)

920 THE USE OF MICROARRAYS TO IDENTIFY AND CHARACTERIZE POTENTIAL HEPATOTOXICANTS BY PATTERN RECOGNITION.

P. R. Holden[1], J. D. Tugwood[2], J. Kimber[1] and W. D. Pennie[1]. [1]*AstraZeneca CTL, Macclesfield, United Kingdom and* [2]*Safety Assessment AstraZeneca, Macclesfield, United Kingdom.*

Transcript profiling using microarray technology provides new approaches to hazard characterization and determination of modes of action. Here we describe the use of transcript profiling to determine changes in gene expression associated with compounds that cause hepatotoxicity. A custom designed nylon microarray comprising of 2400 cDNA clones representing 600 genes, selected to represent pathways related to cell growth, differentiation or death, has been employed to investigate gene expression in the human HepG2 cell line exposed to hepatotoxicants. Cells in replicate flasks were exposed to high or a low toxic doses, as determined by LDH release, of ethanol (EtOH: 500mM, 300mM), carbon tetrachloride (CCl4: 20mM, 5mM), hydrogen peroxide (H_2O_2: 10mM, 1mM) and acetaminophen (APAP: 10mM, 2.5mM) for 24 h. Preliminary data reveal that a number of genes with roles in many cellular functions including apoptosis, cell cycle, transcription and stress were upregulated (up to 6.5 fold) or downregulated (up to 7.2 fold) by treatment with selected hepatotoxicants. In addition, the regulation of certain genes was common to more than one treatment, for example; prolactin was induced and p27Kip1 was repressed in both low EtOH and low H_2O_2 treatments. These results suggest that it may be possible to associate gene expression patterns with specific forms of hepatotoxicity.

921 GENE EXPRESSION PROFILE OF PRIMARY HUMAN HEPATOCYTES TREATED WITH A PEROXISOME PROLIFERATOR, WY-14,643.

M. P. Lawton, J. Jeffries-Griffor, L. F. Nelms and J. T. Mayne. *Pfizer, Inc., Groton, CT.*

Peroxisome proliferator-activated receptor alpha (PPAR-α) is a nuclear hormone receptor thought to mediate the generation of peroxisome proliferation and non-genotoxic hepatocarcingenesis in rodents. In humans, however, clofibrate and other PPAR-α ligands are used safely for the treatment of hyperlipoproteinemias. The mechanisms underlying the differences in species responsiveness to peroxisome proliferators are not clear, but could involve different expression levels of the receptors or differences in the regulatory sequence of PPAR-α target genes. To help understand this species difference we have used oligonucleotide arrays (Affymetrix GeneChip probe arrays) to generate gene expression profiles of primary human hepatocytes exposed to the PPAR-α ligand Wy-14,643. Primary human hepatocytes treated for 24 hours with up to 100 mM of Wy-14,643 showed many changes in gene expression when compared to vehicle-treated cells. In addition to increasing the expression of certain stress-associated and growth-regulated genes, Wy-14,643 decreased the expression of a variety of drug- and fatty acid-metabolizing genes. These results provide insight into previously reported findings regarding the responses of human hepatocytes to peroxisome proliferators and demonstrate the utility of gene expression profiling for characterizing cellular responses to xenobiotics.

922 ANALYSIS OF THE DRUG PHARMACOLOGY TOWARDS PREDICTING DRUG BEHAVIOR BY EXPRESSION PROFILING USING HIGH-DENSITY OLIGONUCLEOTIDE ARRAYS.

M. Durst[1], R. Kerb[2], J. T. Ma[1], V. B. Truong[1], E. Khurgin[1], T. R. Gingeras[1], B. B. Hoffman[2] and J. S. Hu[1]. [1]*Affymetrix, Santa Clara, CA and* [2]*Stanford Univ., Palo Alto, CA.* Sponsor: D. Acosta, Jr.

An important aspect of the drug development process is prediction of efficacious and toxic side effects. Many lead compounds for drugs fail due to unexpected toxicity or lack of efficacy in late stage of the expensive and lengthy drug development process. We hypothesize that pharmaceutical compounds targeted to cells will induce characteristic changes in mRNA expression patterns, as a result of affecting specific pathways downstream to the molecular targets of the compounds. Thus, the mode of action and efficacious or toxic side effects of the compounds may be reflected in these characteristic changes in mRNA expression. We attempt to explore the approach of using expression profiling to identify patterns or fingerprints that can help predicting specific drug effects or behaviors. Specifically, we aimed to correlate known drug effects and properties with expression patterns that are likely to be the signature for a specific drug effect or property. A large-scale experimental study was performed to discover if there are changes in expression levels and patterns that can be correlated with drug activation mode and target specificity. We treated human aortic smooth muscle cells with a large number of agonists and antagonists targeted at adrenergic receptors to produce 100 expression profiles from 50 treatments. The resulting data sets were analyzed by two statistical analysis methods. The hierarchical clustering analysis based on the behavior of the most variable genes showed that these compounds can be classified into separate groups correlated with their activation mode and target specificity as well. By principal component analysis, a set of genes have been identified whose expression changes correlated with the activation properties of the compounds targeted at adrenergic receptors. Agonists and antagonists can be classified primarily into two different groups based on the behavior of this set of genes. These two sets of genes can be potentially used as fingerprints for predicting the activation or target specificity properties of the compounds. This approach may be extended to identifying expression patterns correlated with specific toxic property of compounds, which may be used as fingerprints for prediction of drug toxicity. This study suggests that specific gene expression patterns correlated with certain drug effect and behavior can be identified through expression profiling.

923 USING TRANSCRIPT PROFILING TECHNOLOGY TO GAIN A BETTER UNDERSTANDING OF TOXIC MECHANISMS.

H. J. Townsley and G. J. Moffat. *AstraZeneca Central Toxicology Laboratory, Alderley Park, Macclesfield, United Kingdom.* Sponsor: E. A. Lock.

Microarray technology would appear to offer great potential for toxicology - in either a predictive context or helping to unravel mechanisms of toxicity at the molecular level. As a first step in evaluating the true potential of toxicogenomics, we have utilised an *in vivo* approach to gain new perspectives on the molecular events triggered by a range of liver toxicants, including peroxisome proliferators (PPs). The key objective of these experiments has been to identify important gene expression changes associated with toxic events ie. which genes are switched on/off and what is the magnitude of induction/repression? To enable such meaningful data interpretation, it is

important to recognise the challenges presented by adopting an *in vivo* approach, in particular the extent of background variability in gene expression patterns between animals, as well as examining dose response and time course effects. In this regard, we have conducted experiments to gauge the extent of blot to blot, probe to probe and animal to animal variability. These data have clearly shown that variability decreases with increasing intensity of hybridisation signal. However, our data have confirmed that it is important to characterise the degree of variability within each *in vivo* experiment. Our data have also shown marked differences in gene expression patterns dependent on dose and/or time. Set against this background however, we have shown that administration of compounds such as DEHP to male rats have not only altered the hepatic expression of genes known to be induced by PPs (e.g., CYP4A1) but have induced a number of unexpected changes that may provide important mechanistic information.

924 CONSTITUTIVE AND INDUCIBLE EXPRESSION OF CYP1B1 IN VASCULAR SMOOTH MUSCLE CELLS: DIRECT INVOLVEMENT OF THE ARYL HYDROCARBON RECEPTOR IN BENZO[A]PYRENE-MEDIATED DEREGULATION OF *C-HA-RAS*.

J. K. Kerzee[1] and K. S. Ramos[1]. [1]*Faculty of Toxicology and Center for Environmental and Rural Health, Texas A&M University, College Station, TX.*

Previous studies in this laboratory have found that transcriptional deregulation of *c-Ha-ras* in vascular smooth muscle cells (vSMCs) by benzo(a)pyrene (BaP) involves oxidative metabolism to intermediates that generate reactive oxygen species. Interestingly, *c-Ha-ras* gene activation by BaP (3μM) is absent in aryl hydrocarbon receptor (AhR) null ($AhR^{-/-}$) vSMCs, suggesting that the AhR participates in the regulation of cytochrome P450-mediated metabolism of BaP, or is directly involved in the transactivation response. The present studies were conducted to examine constitutive and inducible mRNA expression of cytochromes P4501A1 (*CyP1A1*) and 1B1 (*CyP1B1*) in vSMCs from $AhR^{+/+}$ and $AhR^{-/-}$ C57/Bl6J mice. Constitutive *CyP1B1*, but not *CyP1A1*, expression was observed in $AhR^{+/+}$ and $AhR^{-/-}$ vSMCs, while inducible expression of both genes was only seen in $AhR^{+/+}$ vSMCs challenged with BaP (3μM). Aryl hydrocarbon hydroxylase (AHH) activity was upregulated to comparable levels in $AhR^{+/+}$ and $AhR^{-/-}$ vSMCs challenged with BaP (3μM). This response, however, was not mediated by *CyP1A1* since ethoxyresorufin-o-deethylase activity (EROD) activity was not detected. Actinomycin D (2μg/ml) or cycloheximide (10μM) did not block BaP-induced AHH activity, indicating that increased transcription, or de novo protein synthesis, were not responsible for AHH induction. Modulation of growth-related signaling in vSMCs was not dependent on the AhR phenotype since BaP (3μM) inhibited DNA synthesis in both $AhR^{+/+}$ and $AhR^{-/-}$ vSMCs. Collectively, these data suggest that AhR is directly involved in the deregulation of *c-Ha-ras* gene by BaP in vSMCs, but that this role is independent of *CyP1B1*-associated AHH activity. (Supported by NIH Grants ES 04849 and ES 09106.)

925 FURTHER CHARACTERIZATION OF OXIDANT-ACTIVATED PROTEIN BINDING TO THE ANTIOXIDANT/ELECTROPHILE RESPONSE ELEMENT IN VASCULAR SMOOTH MUSCLE CELLS.

M. T. Holderman and K. Ramos. *Center for Environmental & Rural Health, Texas A&M University, College Station, TX.*

Previous reports from this laboratory have established that xenobiotic-induced deregulation of gene expression in vascular smooth muscle cells (vSMCs) involves binding of nuclear proteins to the antioxidant/electrophile response element (ARE/EpRE). Studies using mutant *c-Ha-ras* oligonucleotides have shown that maximal protein binding in response to oxidant challenge requires a TMA box 5' of the ARE/EpRE core region, as found in the mouse *GST-Ya* ARE/EpRE (5'TAATGGTGACAAAGCAACTT3'). Our first experiment was conducted to determine if the length of chemical treatment influences *GST-Ya* ARE/EpRE protein binding in intact cells. Randomly cycling vSMCs were tested for ARE/EpRE protein binding following challenge with hydrogen peroxide (25μM) for 0.25-48 hr. Increased binding in response to oxidant challenge was observed as early as 15 minutes, and remained elevated for up to 48 hr. We next evaluated ARE/EpRE protein binding in isolated nuclei or intact murine vSMCs challenged with hydrogen peroxide (25 or 40μM) to determine if direct macromolecular oxidation, or cellular coupling of a stress response, is required for activation of protein binding. Enhanced binding to the ARE/EpRE was observed in both intact cells and isolated nuclei, suggesting that direct chemical modification of macromolecular structures is sufficient for activation of protein binding to the ARE/EpRE. Addition of hydrogen peroxide (25 or 40μM) to nuclear preparations isolated from peroxide-treated cells (25μM) did not modify the binding response profile. On the basis of these findings we conclude that activation of ARE/EpRE protein binding by hydrogen peroxide is a rapid and sustained response which does not appear to require intracellular coupling of a stress signal. (Supported by NIH Grants ES 04849 and ES 09106.)

926 ACTIVATION OF *L1MD* RETROTRANSPOSON IN MOUSE VASCULAR SMOOTH MUSCLE CELLS BY BENZO[A]PYRENE METABOLITES AND HYDROGEN PEROXIDE: IMPLICATIONS IN CHEMICAL ATHEROGENESIS.

K. P. Lu and K. Ramos. *Texas A&M University, College Station, TX.*

We have previously shown that the *L1Md* retrotransposon is activated by acute exposure of vascular smooth muscle cells (vSMCs) to benzo(a)pyrene (BaP). Retrotransposons are mobile DNA elements that propagate through the genome by the process of transcription, reverse transcription, and reintegration. The mechanism of *L1Md* retrotransposon activation by BaP is currently unknown and therefore, the present studies were conducted to determine if BaP metabolites (7, 8-diol, 3-hydroxy, 3, 6-quinone) and/or hydrogen peroxide mimic the ability of the parent compound to activate retrotransposons in mouse vSMCs. RT-PCR and Northern analyses were used to evaluate *L1Md* expression in murine vSMCs following an 8 hr chemical challenge. Our results showed that BaP 7, 8-diol was the strongest inducer of L1Md retrotransposon activation relative to BaP itself, or the other metabolites examined. A low concentration (25μM) of hydrogen peroxide also activated *L1Md*. These results demonstrate that BaP induces activation of retrotransposons and that activation is mediated, at least in part, by cytochrome P450-derived metabolites and reactive oxygen species. Because retrotransposon activation is associated with genomic instability, our results implicate *L1Md* in the acquisition of proliferative vSMC phenotypes during the course of the BaP-induced atherogenic response. (Supported by NIH Grants ES 04849 and ES 09106.)

927 CHARACTERIZATION OF THE NZB/NZWF1 MOUSE MODEL FOR IDENTIFICATION OF DRUG INDUCED AUTOIMMUNE DISEASE.

G. C. Llewellyn and D. Wierda. *Eli Lilly and Company, Greenfield, IN.*

The female NZB/NZWF1 mouse is a well recognized model of human systemic lupus erythematosus (SLE). Autoimmune parameters such as anti-DNA antibody formation occur spontaneously and progress with increasing age. The goal of these studies is to identify drugs with the potential to induce autoimmune disease. An autoimmune syndrome can be induced in NZB/NZWF1 mice at a young age following an acute exposure to mercuric chloride. Following exposure to mercuric chloride (1.0mg/kg), total serum IgG (mg/ml) was increased 67% and the anti-DNA IgG titer was increased by 87%. Spleen cells were obtained from mice exposed to mercury and treated *in vitro* with concanavalin A (Con A) or lipopolysaccharide (LPS). The Con A induced production of IL-2, IL-4, and IL-6 was increased by 46%, 39%, and 36% respectively in spleen cells from mercury treated mice. The LPS stimulated production of IgG was increased by 77% in splenocytes from mercury treated mice. Additionally, splenocytes from naïve NZB/NZWF1 mice were treated *in vitro* with mercuric chloride. IL-2 and IL-4 production were increased by 10mM mercuric chloride by 70% and 77% respectively. Further experiments with drugs known to induce a lupus like symptoms will determine the ability of this model to detect compounds that may induce autoimmune disease.

928 A COMPREHENSIVE MODEL TO TEST FOR IMMUNOMODULATION: THE LISTERIA IMMUNIZATION CHALLENGE ASSAY (ICA).

S. Spanhaak, A. Pachot and A. H. Penninks. *TNO Nutrition and Food Research Institute, Zeist, Netherlands.* Sponsor: B. M. Kulig.

Because of the complexity of the immune system a large battery of different assays has been developed over the years to test its functionality. To investigate 'overall' effects of immunomodulating compounds on the immune system varying numbers of experiments are necessary to demonstrate wanted (modulation of the immune functions by drugs or nutrients) or unwanted

(toxic or sensitizing compounds) effects. A good example is the tiered approach that has been developed to test for immunotoxic properties of xenobiotics. Although on itself a sensible approach, it requires often more than one study to allow a proper evaluation with regard to possible immunomodulating characteristics of the test compound. The development of the immunization Challenge Assay enables the evaluation of various aspects of the specific and non-specific immune response in one study. The Listeria Immunization Challenge Assay (Listeria ICA) is divided into two phases: an immunization phase with Listeria monocytogenes bacteria followed by a challenge phase in which the animals will be intravenously infected with the live, virulent bacterium. This approach offers the possibility to investigate (possible) effects on various compartments of the immune system. It may be adapted for either a broad general screening of compounds or to investigate in more detail the mechanism behind already established immunomodulating effects. Compound interactions with the immune system are tested during the immunization phase i.e., during a time-period the immune system is forced to respond to a stimulus and is expected to be more sensitive for interference. Effects on one or more immune parameters measured may be related to effects on the overall response of the animals during the challenge (infection) phase, i.e., the overall protection of the animals. In this way, the relevance of the observed immunomodulating effects with respect to the ultimate susceptibility for infection can be evaluated. By applying just one antigen, effects measured on all separate parameters may be evaluated within the same context, i.e., a comprehensive test model is used. The choice of the intracellular surviving Listeria monocytogenes bacterium as an antigen not only enables the investigation of humoral responses but also, and especially, cellular specific and non-specific responses. In the first set of experiments an optimal immunization procedure has been developed. It was found that (sc) immunization with viable bacteria, but not dead (irradiated) bacteria, resulted in a dose-dependent protection against the experimentally (iv) induced listeria infection. Depending on the immunization dose up to 100% protection was obtained. In contrast, immunization with dead, irradiated, bacteria did not result in a measurable protection against the listeria infection. However, when using an adjuvants (aluminium hydroxide) the responses induced by the immunization with dead bacteria could be enhanced sufficiently to obtain some level of protection. Parameters which were amongst others measured in these studies were antigen specific delayed type hypersensitivity responses, *in vitro* proliferative responses and antibody levels, lymphocyte subpopulations and cytokine m-RNA transcription. The level of protection was assessed by determining the number of remaining Listeria monocytogenes bacteria in liver and spleen two or four days after infection. So far the model has been developed to a stage that immunomodulating effects of compounds can be tested. A sub-optimal immunization procedure, i.e., resulting in a level of protection which may be influenced by the test compound in either a positive or a negative way, has now been defined. The next step will be the application of known immunomodulating compounds to validate the immunization challenge assay (ICA) and to determine the sensitivity of this approach.The use of dead bacteria for the immunization procedure offers special application possibilities with respect to the investigation of new adjuvants.

929 USE OF DENDRITIC CELLS FOR IMMUNOTOXICOLOGICAL SCREENING: EFFECTS OF IL-16 AND RSV-INFECTION.

A. Emmendoerffer, E. Kniep, B. Zickler, J. Jiao, C. Norden and T. Boeker. *Fraunhofer Institute for Toxicology and Aerosol Research, Hannover, Germany*. Sponsor: H. Muhle.

Dendritic cells (DC) are the most important cells in regulating the cellular immune response by recruiting and activating naive T-cells. Therefore, they play an important role in allergic inflammation and viral infections. The aim of our studies was to generate human dendritic cells and to use these cells as tool for immunotoxicological screening. Human dendritic cells were generated from monocytes by cultivation in IL-4 and GM-CSF. Having characterized optimal serum-free culture conditions by measuring T cells responses (MLR) and surface phenotype (flow cytometry) the effects of recombinant IL-16 (mediator of the late phase of allergic reactions) and the effect of an infection with the respiratory syncytial virus on DC function were assessed. IL-16 induces the expression of different chemokines/ cytokines both on protein and on mRNA level (e.g. MIP-1a, RANTES, IL-8 and IL-10) and accelerates the maturation of DC as measured by increased expression of surface antigens e.g. CD83, CD86. In the case of RSV infection it could be shown that the virus infects DC and induces maturation, production of IL-10 and at higher MOI apoptosis. These studies demonstrate that DC are a suitable target for immunotoxicological screening *in vitro*.

930 UTILITY OF THE LOCAL LYMPH NODE ASSAY FOR THE IDENTIFICATION OF IMMUNOSUPPRESSIVE DRUGS.

G. C. Llewellyn, J. F. Lockwood and D. Wierda. *Eli Lilly and Company, Greenfield, IN.*

The Local Lymph Node Assay (LLNA) is a robust tool for the identification of compounds producing contact sensitization. Some investigators have suggested that the popliteal LLNA could be used to identify immunosuppressive drugs. The purpose of these studies was to explore this possibility by using one model immunosuppressive agent and several test compounds with known or suspected immunosuppressive effects to inhibit the LLNA response elicited following exposure to the contact sensitizer oxazolone. Female CBA/J mice were exposed dermally to test compound or oxazlone (0.05% and 0.1%) alone or the combination of the two. Following the exposures, radiolabeled thymidine incorporation into lymph node cells was determined or lymph node phentotypic analysis was performed. Dermal exposure to dexamethasone (0.05%) was capable of attenuating the radiolabel incorporation induced by oxazolone by 80% (0.05%) and 86% (0.1%). Dexamethasone reduced the oxazolone induced increases in the number of lymph node T-cells by 92% and B-cells by 97%. The oxazolone induced alterations in lymph node percentage of T-cell and B-cells was inhibited by approximately 70%. In contrast, dermal exposure to indomethacin, thalidomide, pentoxifylline, or chelerythrine were unable to alter the effects of oxazolone on proliferation and lymph node cell phenotypes. The absence of activity of these compounds may be dependent on the route of exposure. Parenteral exposure to these compounds is under evaluation. These results suggest that the LLNA is not a sensitive model for detecting compounds with weak to moderate immunosuppressive activity.

931 SUBERYTHEMAL UVB EXPOSURE AFFECTS AIRWAY HYPERRESPONSIVENESS INDUCED BY TH1 AND TH2 MEDIATED PULMONARY HYPERSENSITIVITY.

H. Van Loveren[1], A. Boonstra[2], H. Van Der Vliet[1], M. E. A. Van Dijk[1], A. Fluitman[1], H. F. J. Savelkoul[2] and J. Garssen[1]. [1]*National Institute Public Health and Environment, Bilthoven, Netherlands and* [2]*Erasmus University, Rotterdam, Netherlands.*

One of the major immunomodulatory effects of UV exposure is suppression of cellular immune responses that can be evoked by skin contact with contact sensitizers (e.g., picryl chloride, DNCB, and oxazalone). The Th1 mediated contact hypersensitivity response was suppressed by low doses of UV exposure if the animals or human volunteers were exposed to UV prior to skin sensitization. This immunosuppressive effect was detectable if mice were exposed to UV at the site of first contact with the chemical or even at a distant site; the first referred to as local and the latter as systemic immunosuppression. We demonstrated that in a model for contact hypersensitivity in mice the Th1 associated cytokine IFN-γ production was impaired whereas the Th2 cytokine interleukin 4 remained unaffected after exposure to low doses of UV light prior to skin-sensitization. Based on these observations, the hypothesis was put foreward, that UV exposure could have an influence on respiratory allergy. For this reason, the effect of UV exposure was studied in two different murine models, i.e., for type I (IgE mediated) and type IV (delayed type) pulmonary hypersensitivity, respectively. In both animal models inflammatory reactions were present in the lungs of mice that were challenged with the specific antigen via the airways. In the picryl chloride type IV allergy model, inflammatory reactions consist of especially mononuclear cells, whereas in the ovalbumin type I allergy model also eosinophylic granulocytes were present. In both models non-specific airway hyperreactivity to bronchoconstricting stimuli such as acetylcholine was induced. Prior studies have indicated that IFN-γ is involved in the induction of airway hyperreactivity both in models for Th1 mediated and Th2 mediated pulmonary hypersensitivity. If mice were exposed to UV light for 5 consecutive days prior to sensitization with picryl chloride or ovalbumin, airway hyperreactivity to cholinergic stimuli was significantly impaired. In the picryl chloride model, IFN-γ production was suppressed; in the ovalbumin model, specific IgE production was suppressed. This study indicates that immunomodulation induced by exposure to low doses of UV might have consequences for respiratory allergy.

932 ACTIVATION OF GUINEA PIG COMPLEMENT BY TRIMELLITIC ANHYDRIDE CONJUGATED TO GUINEA PIG SERUM ALBUMIN (TMA-GPSA).

J. F. Regal, C. P. Larsen and T. M. Kane. *University of Minnesota Duluth, Duluth, MN.*

Actively sensitized guinea pigs challenged intratracheally with TMA-GPSA

respond with eosinophil, neutrophil and mononuclear cell infiltration into the lungs and lung hemorrhage. Previously, using Cobra venom factor to deplete complement, we demonstrated a role for the complement system in TMA-induced cell infiltration into the lung and lung hemorrhage (J Pharmacol Exp Ther 273:793-801, 1995). In addition, we detected the complement activation product C3a in the bronchoalveolar lavage fluid of these animals. To determine if TMA GPSA could cause complement activation *in vitro*, varying concentrations of TMA-GPSA and GPSA (0.5 to 500 μg/ml) were incubated at 37°C for 15 min with complement from either unsensitized guinea pigs or guinea pigs sensitized with TMA. Complement activation was assessed by measuring cleavage of the third component of complement (C3 conversion). After agarose gel electrophoresis of samples, C3 conversion products were visualized in the gel by immunoprecipitation with antibody to guinea pig C3 and Coomassie blue staining. TMA-GPSA caused significant C3 conversion when incubated with complement from unsensitized animals. This is the first demonstration that TMA-GPSA can activate the complement system in the absence of specific antibody. Significantly more C3 conversion occurred when TMA-GPSA was incubated with complement in the presence of TMA specific antibody than without antibody. GPSA itself caused minimal C3 conversion. Thus, TMA-GPSA causes cleavage of C3 *in vitro*, consistent with previous evidence that TMA induced respiratory hypersensitivity in the guinea pig is, in part, dependent on the complement system. (Supported by NIH ES 07406.)

933 IMMUNOLOGIC AND BIOCHEMICAL ABNORMALITIES IN WORKERS EXPOSED TO POLLUTANTS AT AN EGYPTIAN COPPER COMPANY.

L. H. El-Sayed[1], H. Ghoneim[1], M. H. El-Sayed[1], S. R. Demian[1], A. I. Adam[1], P. Urso[2] and N. Abou Rawash[1]. [1]*Medical Research Institute, Alexandria University, Alexandria, Egypt and* [2]*Clark Atlanta University, Atlanta, GA.*

For this project we studied: a) biochemical changes; b) serum immunoglobulin (Ig) levels, and c) mitogenicity of peripheral blood lymphocytes (PBL) in workers (experimentals) **directly** exposed to high concentrations of pollutants in several sectors of a major copper company in Alexandria. These sectors included the aluminum utensils area, semicontinuous aluminum casting, brass foundries and steel furnaces. Toxicants in these sectors included aluminum hexachloroethan, silica, cadmium, copper, mercury, lead, asbestos, nickel, zinc, silver, carbon, iron and sulphite detected in high concentrations in the sectors where workers are directly exposed. Administrative personnel in the plant not directly exposed were included as positive controls; negative controls were people living in areas of Alexandria where the concentration of these toxicants was relatively low. Significant variations occurred in liver and lung functions, in lipid profiles, vitamins E and C, glucose-6-phosphate dehydrogenase and other enzymes including superoxide dismutase, glutathione, and anti-oxidants. All personnel of the aluminum utensils area showed reduction in the Ig's gamma, mu, and alpha assayed by ELISA, while workers directly exposed in the other sectors showed elevated Ig's. Mitogenic activity in cultured PBL assayed by ^{3}H-thymidine uptake was impaired in all plant personnel. However, experimentals showed increases in the cytokines IL-2, IL-6, IFN-gamma, TNF-alpha and beta assayed by ELISA, but not in IL-4. Changes were directly related to duration of exposure. Some workers (16.2%) showed symptoms of arthritis and spondylitis. Thus, abnormalities were greatest in directly exposed workers, while other plant personnel showed some form of toxicity in the parameters studied. Clinical significance of the immunologic abnormalities seen is under further study.

934 AFB_1-INDUCED SUPPRESSION OF MACROPHAGE-DERIVED CYTOKINE PRODUCTION IS DUE TO INCREASES IN PGE_2.

K. E. Jordan, M. Wills-Karp and G. J. Jakab. *Division of Toxicological Sciences, Johns Hopkins University School of Hygiene, Baltimore, MD.*

Previously, we showed that male F344 rats given a single, acute intratracheal dose of Aflatoxin B_1 (AFB_1) and subsequently challenged with *Listeria monocytogenes*, demonstrated impaired clearance of bacteria from the lung, liver and spleen. In these animals, splenic macrophage phagocytic activity and TNFα production were suppressed whereas T cell derived cytokine (IFNγ) production was not altered. As TNFα and IL-12 are required for host resistance against *L. monocytogenes*, the mechanisms by which AFB_1 impairs macrophage-derived cytokine production was investigated *in vitro* by exposing RAW 264.7 macrophages to AFB_1 and quantitating cytokine production. LPS-inducible TNFα and IL-12 production was significantly suppressed (50 and 60% of controls respectively) in cells exposed to 30 μM AFB_1. In contrast, IL-1 production was not affected, thereby suggesting a specificity for cytokines targeted by AFB_1. In addition, AFB_1 exposure increased LPS-inducible PGE_2 4-fold as compared to cells treated with medium alone. TNFα levels were restored in AFB_1-exposed cells treated with 1 nM indomethacin, thus blocking the AFB_1-induced increase in PGE_2. Therefore, it appears that AFB_1 is increasing COX2 activity. This finding is significant, as the likely mechanism by which AFB_1 is suppressing TNFα and IL-12 is through increased production of PGE_2, as PGE_2 is known to downregulate macrophage-derived TNFα and IL-12 production. In conclusion, the data provide a potential mechanism by which *in vivo* exposure to AFB_1 may be suppressing host resistance against *L. monocytogenes*.

935 ALTERATIONS IN THE PRE-B CELL POPULATION OF THE BONE MARROW AFTER *IN VIVO* EXPOSURE TO A MIXTURE OF HERBICIDES.

P. de la Rosa, J. B. Barnett and R. Schafer. *West Virginia University, Morgantown, WV.*

Chemical mixture risk-assessment extrapolated from single treatment data does not account for interactions between mixture components. Previous research has demonstrated that the herbicide propanil (3,4-dichloropropionanilide) is immunotoxic to the thymus, spleen and bone marrow affecting specific T and B cell responses and progenitor differentiation. Propanil is sold as a mixture with the herbicide 2,4-D (2,4-dichlorophenoxyacetic acid) in commercial preparations such as Nox-D and Herbanil. The goal of our research is to determine the immunotoxic effects of *in vivo* intraperitoneal exposure to a mixture of propanil and 2,4-D in C57Bl/6 mice. Single herbicide treatments include 50 mg/kg or 200 mg/kg doses. Mixtures were composed of either 50 mg/kg + 50 mg/kg or 50 mg/kg + 200 mg/kg combinations of the two herbicides. In the bone marrow, exposure to propanil, 2,4-D, or a mixture of the two herbicides specifically decreased the pre-B cell population as assessed by flow cytometric analysis of B220+ lymphocytes. Mixtures of 50 mg/kg propanil and 50 mg/kg 2,4-D did not cause additive decreases. However, a 50 mg/kg propanil + 200 mg/kg 2,4-D mixture synergistically decreased the percent of pre-B cells as compared to the 200 mg/kg 2,4-D component alone. All mixture concentrations caused significant decreases in pre-B total cellularity. Preliminary experiments indicate that the mechanism of selective lymphocyte depletion by propanil or 2,4-D may be through the release of glucocorticoids in response to chemical stress. This study demonstrates that propanil and 2,4-D are immunotoxic to a developmental immune organ and that exposure to a mixture of the two herbicides can potentiate immune cell loss. (Supported by NIEHS grants ES07460 and ES07512.)

936 DYNAMICS OF THE IMMUNE SYSTEM OF THE RAT IN AN INTERMITTENT DOSING STUDY WITH AFLATOXIN B1 (AFB_1).

D. M. Hinton[1], M. J. Myers[2], R. Raybourne[1], R. E. Sotomayor[1], J. Shaddock[3], A. Warbritton[3] and M. Chou[3]. [1]*CFSAN, USFDA, Laurel, MD,* [2]*CVM, USFDA, Laurel, MD and* [3]*NCTR, USFDA, Jefferson, AR.*

AFB_1 is a known carcinogen and affects immune function in animals. We were interested in the immunotoxic mechanisms relevant to low doses and to intermittent exposure. Fisher-344 male rats were fed intermittently for 40 weeks (4 weeks-"on" and 4 weeks-"off" diet) doses of 0.01, 0.04, 0.4 and 1.6 ppm of AFB_1 and for 40 weeks continuously at the 1.6 ppm level. Groups of animals were sacrificed at 4 week intervals up to 20 weeks and then at 40 weeks. Lymphoid tissues were removed and processed for histopathology and imaging. Splenic cell suspensions were analyzed by flow cytometry for % T (CD3) and % B (CD45R) cells and % helper (CD4) and % suppressor (CD8). Portions of the suspension were stimulated in culture for analysis of the productive capacity for cytokines IL-2 (Con-A), IL-1 and IL-6 [LPS, LPS + γ interferon (INF) and γINF + NGMA, a nitric oxide synthetase inhibitor]. Hematologic and other endpoints were measured also. Animals were 6 weeks of age at the start of dosing and were in growth phase during the 20 weeks of dosing. Dynamic changes were seen in both T-and B-cells for controls, e.g., % T increasing from 27 to 58% and B-cells decreasing from 50 to 28%, both reaching a plateau at approx. 20 weeks of age. The %CD4 and CD8 cells as well as IL-2 increased with time, (CD4, 24 to 50%, and CD8, from 10 to 20% at 14 weeks of age.) A 7-fold increase for IL-2 was seen at 18 weeks of age. After the first 4 weeks of dosing, B-cells decreased from 50 to 32% while T-cells increased from 27 to 43% at 0 to 0.4 and 1.6 ppm AFB_1. Increases in both CD4 and CD8 populations were seen. IL-2 was increased only at lower doses. After the first "off" cycle the trends for %T, %B and %CD4 were not reversed while %CD8 was reversed. After the 2nd "on" cycle shifts in the various cell populations were seen again. Dynamic changes were seen also for IL-1 and IL-6 after the 2nd "on" cycle suggesting a pro-inflammatory response. The significance of these changes in immune parameters in relation

to functional responses and carcinogenicity is of interest and need to be determined.

937 ACUTE *IN VIVO* EXPOSURE TO THE MAMMALIAN IMMUNOTOXICANT, BENZO[A]PYRENE ALTERS IMMUNE RESPONSES OF FISH.

E. A. Carlson and J. T. Zelikoff. *New York University School of Medicine, Tuxedo, NY.*

Increasing public concerns regarding the use of mammals in toxicological studies have led researchers to seek "alternative models" to investigate the biological effects of xenobiotics. Due to its small size and adaptability to a laboratory environment, the Japanese medaka (Oryzias latipes) lends itself well to such studies. Although medaka are used routinely for carcinogenicity testing, little emphasis has been placed upon this species for assessing the immunotoxic effects of chemicals. Given the known effects of benzo(a)pyrene (BP) on the immune system of mammals, studies were conducted using medaka to examine the effects and cellular mechanisms by which exposure to BP might alter the immune status of this laboratory fish model. A single IP injection of BP at doses ranging between 2 and 600μg/g BW had no effect upon medaka survival for up to 7d post-injection. Forty-eight hr after injection of either BP or the vehicle control, fish were sacrificed, and appropriate organs/cells used to assess effects upon: lymphocyte proliferation, oxyradical production, antibody forming cell (AFC) numbers, thymic cellularity and apoptosis, and CYP1A protein level/activity. Results demonstrated that a single, relatively low dose of BP (2μg/g BW) suppressed stimulated T- and B-lymphocyte proliferation and kidney phagocyte intracellular superoxide production, in the absence of increased levels of hepatic CYP1A expression/activity. At higher BP concentrations, suppressive effects were also observed upon AFC numbers and kidney phagocyte extracellular superoxide and hydrogen peroxide production. Thus, similar to that observed in mammalian species, the immune responses of medaka appear sensitive to the immunotoxic effects of BP exposure. The observation that both mammalian and piscine models respond similarly to BP helps to solidify the applicability of the medaka model for use in immunotoxicological research. (Research supported by U.S. Army Augmentation Award.)

938 NON-GENOTOXIC CARCINOGENS (NGC) CAUSE MUTATIONS *IN VIVO* BY OXIDATIVE STRESS.

B. S. Shane[1] and M. L. Cunningham[2]. [1]*Louisiana State University, Baton Rouge, LA and* [2]*National Institutes for Environmental Health Sciences, Research Triangle Park, NC.*

The mechanism by which non-genotoxic carcinogens such as oxazepam (OX), phenobarbital (PHE) or Wyeth 14,643 (WY) cause hepatocarcinogenesis is unknown. These compounds do not form DNA adducts, are weak mutagens in bacterial systems and weak clastogens in mammalian cells. One mechanism that has been proposed for tumorigenesis is replication of cells with oxidative lesions. Since chronic feeding of PHE, OX and WY induce specific cytochrome P450's and cause hepatomegaly, we hypothesize that increased oxidative stress could result from enhanced production of superoxide radicals following induction of these enzymes and the resulting lesions could be fixed during hyperplasia. To investigate the role of oxidative stress *in vivo*, Big Blue® transgenic mice were fed carcinogenic doses of OX, PHE or WY for six months. The mutant frequency of the lacI transgene was determined in the liver of the mice and a representative sample of mutants was sequenced. After clonal correction, the MF of lacI in the treated groups receiving OX and WY was significantly increased ($p<0.05$) compared to the control. An intriguing finding was the observation that the mutation spectra recovered from the three treated groups were virtually identical to one another but significantly different ($p<0.02$-0.008) from that of a historic control spectrum. A 2-5-fold increase in the mutation frequency of transversions at guanines, (both G:C>T:A and G:C>C:G) was observed in all the spectra. Although hypertrophy was evident after six months of feeding, clonal expansion of mutations was less than 10% in all the spectra. Our findings suggest that the lesions were caused by oxidative stress and that most of the mutations were unique and did not arise from clonal expansion. (Supported by NIH CA72534.)

939 A ROLE FOR OXIDATIVE STRESS IN THE PROMOTION OF INITIATED CELLS.

Y. Xu, B. Ren and J. E. Klaunig. *Division of Toxicology, Department of Pharmacology & Toxicology, Indiana Univsersity School of Medicine, Indianapolis, IN.*

During the process of cancer formation, normal cells appear to exert some control on the growth and/or apoptotic death of preneoplastic initiated cells. The selective clonal growth of initiated cells can occur following stimulatory pressures from endogenous or exogenous agents. This results in an increase in the growth (or decreased death) in the initiated cells compared to surrounding normal cells. This response of initiated cells appears to be an epigenetic process (tumor promotion). In the present study, the promotion effect of oxidative stress on 'initiated' Syrian Hamster Embryo (SHE) cells was investigated. A cell line from a morphological transformed clone (via benzo(a)pyrene treatment) of SHE cells was selected as the 'initiated' cells. Some of the cells were transfected with pEYFP-mito plasmid to develop a cell line with green fluorescence protein (GFP). The cells with GFP were co-cultured with normal SHE cells. The growth of 'initiated' cells was studied following the treatment of t-butyl hydroperoxide (tBH). Without treatment, the growth of the 'initiated' cells was slower than normal SHE cells and appeared to be influenced by the number and proliferation status of the surrounding normal cells. Low concentrations of tBH (0.05-0.1 μM) increased the clonal growth of the 'initiated' cells. The 'initiated' cells were found to be more resistant than normal cells to the toxicity of tBH treatment. This resistance in 'initiated' cells could be explained by increased cellular defenses in the cells. Therefore, the growth of 'initiated' cells following tBH treatment could result from relative growth inhibition of surrounding normal cells. Interestingly, Tea antioxidants (EGCG and tea pigments) suppressed the growth of 'initiated' cells, but had no effect on normal cells. The results suggested that oxidative stress functions during the promotion stage of the cancer process by selectively inducing the growth of initiated cells.

940 ROLE OF ACRYLONITRILE METABOLISM IN THE INDUCTION OF OXIDATIVE STRESS AND MORPHOLOGICAL TRANSFORMATION OF SYRIAN HAMSTER EMBRYO (SHE) CELLS.

L. M. Kamendulis, H. Zhang and J. E. Klaunig. *Indiana University School of Medicine, Division of Toxicology, Indianapolis, IN.*

Acrylonitrile (ACN), a chemical used in the manufacture of plastics, rubber and acrylic fibers, produces tumors of the brain in rats following chronic oral exposure. The mechanism(s) for ACN carcinogenicity appears to involve the induction of oxidative damage. ACN is detoxified primarily through conjugation with GSH, while oxidative metabolism by cytochrome P450 produces cyanoethylene oxide (CEO), a reactive epoxide metabolite. CEO can be further metabolized to cyanide (CN). In the present study, SHE cell morphological transformation (MT), an assay system that has been shown to be predictive of carcinogenicity *in vivo*, was utilized to further examine ACN metabolism and oxidative stress induction in the transformation process. ACN treatment produced MT in a dose-dependent manner in SHE cells at 50 and 75 μg/ml that was accompanied by increased hydroxyl radical and 8-hydroxydeoxyguonosine (8OHdG) formation after 1 and 3 days of treatment. Similar increases in hydroxyl radical and 8OHdG production were observed following treatment with 500 μM CN. Additionally, the MT induced by CN was blocked by addition of the antioxidant vitamin E. Modulation of GSH by chemical depletion with buthionine sulfoxamine enhanced and co-incubation with the sulfhydryl donor N-acetylcysteine protected ACN-induced MT. These results indicate that ACN induces oxidative stress during metabolism that appears to contribute to SHE cell transformation and further substantiates a role for oxidative stress in the induction of glial cell tumors in the rat.

941 MECHANISMS FOR THE INDUCTION OF OXIDATIVE STRESS IN SYRIAN HAMSTER EMBRYO (SHE) CELLS BY ACRYLONITRILE.

H. Zhang, L. M. Kamendulis and J. E. Klaunig. *Division of Toxicology, Department of Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

Chronic administration of acrylonitrile (ACN) to rats resulted in an increased incidence of neoplasms of the brain. Recent evidence from our group and others has suggested that acrylonitrile induces oxidative stress in rat brain and cultured rat glial cells. Additionally, our group has shown that acrylonitrile induces morphological transformation concomitant with an increase in the

formation of oxidized DNA in Syrian Hamster Embryo (SHE) cells in a dose dependent manner. The mechanism of the induction of oxidative stress in SHE and glial cells remains unresolved. The present study examined the effect of acrylonitrile on both enzymatic and nonenzymatic antioxidants in SHE cells. SHE cells were treated with sublethal doses of acrylonitrile (0, 25, 50, and 75μg/ml) for 1hr, 4hrs, 1 day, 2 days, and 7 days. Acrylonitrile (50μg/ml and 75μg/ml) increased the amount of reactive oxygen species in SHE cells. GSH was depleted and catalase and superoxide dismutase was significantly decreased in SHE cells after 4 hours of treatment. The inhibition of this antioxidants was temporal, returning to control values after 1 day of treatment. In the absence of metabolic enzymes acrylonitrile had no inhibitory effect on antioxidant enzymes. In additional experiments, cyanide (a possible metabolite of acrylonitrile) produced a similar inhibition of catalase and superoxide dismutase in the SHE cells. These studies suggest that the induction of oxidative stress by acrylonitrile involves a temporal decrease in antioxidants in the cells possibly through the metabolism of acrylonitrile to cyanide.

942 MODULATION OF FOCAL AND NON-FOCAL HEPATOCYTE DNA SYNTHESIS IN 2-BUTOXYETHANOL TREATED MICE.

B. C. Gottschling, L. M. Kamendulis and J. E. Klaunig. *Division of Toxicology, Department of Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

2-Butoxyethanol (2-BE) has been reported to induce liver neoplasia in B6C3F1 liver following chronic treatment. While the mechanism for the observed tumor induction has not been defined, 2-BE induces hemolysis and subsequent hemosiderin deposition in the liver. This has led to a hypothesis that the resulting iron deposition in the liver contributes (via an oxidative stress mechanism) to the formation of the liver tumors. The current study examined the effects of 2-BE treatment on the induction of cell growth in focal lesions and non-focal hepatocytes. Male B6C3F1 mice that contained focal lesions (induced by DEN) were treated with 2-BE (400mg/kg/day; gavage) for 7 and 30 days. Additional mice received 2-BE plus Vitamin E-supplemented diet (450mg/kg diet). Controls included vitamin E supplementation only and untreated mice. Seven days prior to sampling, mice received an osmotic minipump containing BrdU. At sampling livers were harvested and examined for DNA synthesis in focal and non-focal hepatocytes. 2-BE treatment resulted in a decreased hematocrit of 15% in both 2-BE only and 2-BE plus Vitamin E supplementation. A 2 - 4 fold increase in DNA synthesis was seen in non-focal hepatocytes after 7 and 30 days. Supplementation with Vitamin E in the diet ablated this 2-BE induced increase. While no increase in focal labeling index was seen after 7 days of treatment, a 2-BE related increase in DNA synthesis was seen after 30 days of treatment. This increase in focal lesion DNA synthesis was prevented by vitamin E supplementation. These results suggest that the 2-BE produces its carcinogenic effect through indirect means (via iron deposition and resulting oxidative stress).

943 EFFECTS OF 2-BUTOXYETHANOL, 2-BUTOXYACETIC ACID, AND FERROUS SULFATE ON THE MORPHOLOGICAL TRANSFORMATION OF SYRIAN HAMSTER EMBRYO (SHE) CELLS.

J. Park, L. M. Kamendulis and J. E. Klaunig. *Division of Toxicology, Department of Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

The compound 2-butoxyethanol (2-BE), a component in many industrial and consumer cleaning products, has been recently reported to induce an increase in liver tumors in B6C3F1 mice following chronic treatment. Previous studies by our group showed that 2-BE *in vivo* treatment induced oxidative stress in the mouse liver. This effect appears to be through the induction of hemolysis and the resulting increase in iron deposition rather than via the compound or a metabolite of the compound directly. Based on this previous study, we questioned whether 2-BE, its primary metabolite (2-BAA) or iron (ferrous sulfate) was responsible for the observed hepatic carcinogenicity. To help address this issue we used the Syrian Hamster Embryo (SHE) cell morphological transformation assay, an *in vitro* assay with a good correlation to the chronic bioassay results for screening carcinogenic agents. SHE cell was treated with 2-BE (1 - 20 mM), 2-BAA (0.5 - 20mM), and ferrous sulfate (0.5 - 50 μg/ml) for 7 days. The treatments of 2-BE and 2-BAA did not induce any significant morphological transformation in the SHE cells. In contrast, treatment with ferrous sulfate (2.5 and 5 μg/ml) induced a significant increase in SHE cell morphological transformation. Co-treatment of ferrous sulfate with alpha tocopherol or EGCG (green tea antioxidant) resulted in a prevention of ferrous sulfate induction of morphological transformation. These data support the hypothesis that the observed induction of hepatic tumors by 2-BE is through an indirect mechanism via iron deposition which results in oxidative stress in the mouse liver.

944 ROLE OF OXYGEN FREE RADICALS IN PCB AND DIOXIN CARCINOGENESIS.

J. T. Painter, K. D. Pinella, J. D. Tessari, G. N. Cosma and S. A. Benjamin. *Colorado State University, Fort Collins, CO.*

In order to explore a role for reactive oxygen species in the carcinogenesis of dioxin-like agents, female Sprague-Dawley rats were exposed to PCB126, PCB153, dioxin (TCDD), and an environmentally relevant mixture of PCBs 126 and 153. Liver microsomes were analyzed for estrogen catechol metabolites by gas chromatography-electron capture and cytochrome P450 1A1 enzyme induction by 7-ethoxyresorufin-O-deethylase (EROD) assay. Experimental groups received control, low, or high doses of each of the chemical groups in corn oil gavage and were sacrificed at 13 or 30 weeks. EROD activity increased in dose-responsive fashion in rats treated with Ah-receptor binding TCDD and PCB126. No changes in CYP1A activities were observed with the non-Ah-receptor binding PCB153. The PCB153/126 mixture produced an unexpected greater-than-additive elevation in EROD activity. Analyses of catechol estrogen metabolites demonstrated a dose-responsive decrease in 2/4-hydroxyestradiol ratio after TCDD and PCB126 exposures (2.2 and 2.4-fold, respectively), while PCB153 exposures resulted in an increased ratio (1.5-fold). PCB126/153 exposures resulted in a 1.7-fold decline in the 2/4-hydroxyestradiol ratio. 4-Hydroxylated catechol estrogens may be metabolized via cytochrome P450 reactions to quinones that undergo redox cycling reactions, producing oxygen radical species that can cause oxidative DNA damage. When combined with the higher levels of endogenous estrogen in females, this may provide an explanation of gender differences seen in carcinogenesis. These results suggest that carcinogenic effects of complex mixtures of chlorinated hydrocarbons are difficult to predict based on their separate effects on P450 enzyme induction and subsequent estrogen metabolism. (This work is supported by NIEHS Grant #E5-97-003.)

945 ANTICARCINOGENIC ROLE OF METALLOTHIONEIN IN THE DMBA/TPA-CAUSED SKIN CARCINOGENESIS.

J. S. Suzuki[1], N. Nishimura[1], B. Zhang[1], S. Kobayashi[2], M. Satoh[1] and C. Tohyama[1]. [1]*National Institute for Environmental Studies, Tsukuba, Japan and* [2]*Kyoritsu College of Pharmacy, Minato-ku, Japan.*

Metallothioneins (MTs) are a family of cysteine-rich proteins, inducible by endo- and exogenous stimuli, such as heavy metals and cytokines. They are evolutionally highly conserved, but the full physiological nature of these proteins are largely unknown. As a possible physiological role, MTs are thought to scavenge active oxygen species, mainly hydroxyl radicals *in vivo* and *in vitro*. Utilizing MT-null mice, whose MT-I and -II genes are knocked out by homologous recombination, we studied susceptibility of MT-null mice in the DMBA (7,12-dimethylbenz[a]anthracene) /TPA (12-O-teradecanoylphorbol-13-acetae)-caused two stage carcinogenesis model. Mice on a 129/Ola x C57BL/6J background were subjected to a single topical application of carcinogen (50 or 100 μg DMBA/mouse) and, 1 week later, to promotion with 10 μg TPA twice a week for 20 weeks. At week 20, 90-100% of MT-null mice developed papillomas in the skin whereas only 10-40% of wild-type mice had the tumor. No tumor was observed in wild-type or MT-null mice receiving TPA alone. These results indicate that MT-null mice are extremely susceptible to the two-stage carcinogenesis caused by DMBA/TPA. Investigating mutations, by PCR-RFLP and PCR-SSCP methods, in c-Ha-ras, c-Ki-ras and c-N-ras genes in the papilloma tissue of the wild-type and MT-null mice, we detected transversion of A182 to T of the codon 61 of c-Ha-ras, showing that MT is preventing the occurrence of ras mutation that is activated by DMBA/TPA. We here show that MT, constitutively expressed in the skin, is acting as an anticarcinogenic factor in the chemical carcinogenesis, which is a novel physiological function of MT.

946 EFFECT OF DIETARY VITAMIN E ON OTHER CELLULAR ANTIOXIDANT DEFENSE SYSTEMS IN PHENOBARBITAL-TREATED RATS.

K. G. Calfee-Mason, B. T. Spear and H. P. Glauert. *University of Kentucky, Lexington, KY.*

The purpose of this study was to determine the effect of vitamin E on other cellular defense systems when rats are treated with phenobarbital, a liver

tumor promoter. Upon phenobarbital treatment in rodents, hyperplasia and increased cytochrome P-450 2B1/2B2 activities occur. Since hydrogen peroxide may be released as a by-product of cytochrome P-450, a reactive oxygen environment may be important in tumor promotion by phenobarbital. The oxidative stress-activated transcription factor nuclear factor-κB (NF-κB) is activated in phenobarbital-treated rats, but when dietary vitamin E is increased, NF-κB activation is decreased. In this study thirty-nine male Sprague-Dawley rats were fed a purified diet with varying levels of dietary vitamin E (10, 50, 250 ppm of alpha-tocopherol acetate). After 28 days, 0.05% phenobarbital was added to the diets of half the rats for 10 days. Liver homogenates were made and used to determine catalase activity, and liver cytosol was used to assay total glutathione, glutathione peroxidase, glutathione reductase, and glutathione transferase. The results demonstrate that higher dietary vitamin E levels increase total glutathione and glutathione peroxidase activity and slightly elevate catalase and glutathione transferase activities in both phenobarbital treated and control animals. This study shows that vitamin E does not act solely to scavenge free radicals, but also influences other cellular antioxidant defenses. (Supported by CA74147 and CA01688.)

947 ANALYSIS OF RAT BONE MARROW BY FLOW CYTOMETRY FOLLOWING IN VIVO EXPOSURE TO CYCLOHEXANONE OXIME (CHO) OR DAUNOMYCIN HCL (DAUN).

S. J. Schomaker, D. E. Amacher and F. A. Clemo. *Pfizer Inc., Groton, CT.*

The purpose of these studies was to evaluate bone marrow from male CD rats following exposure to known hematotoxins using flow cytometry and a monoclonal antibody to the cell surface antigen CD71. Male rats, 12 per dose group, were treated with either CHO at 300 mg/kg for 10 days or DAUN at 10 mg/kg for 1 day. Corresponding control groups received equivalent volumes of the appropriate vehicle. Half of the animals from each treatment group were sacrificed at the end of the dosing schedule while the remaining animals were sacrificed after a recovery period. Hematology analyses were completed prior to the onset of each study and on the day of necropsy. Marrow was isolated from the tibia of each rat, stained with R-phycoerythrin-conjugated mouse anti-rat CD71 (transferrin receptor on proliferating cells) monoclonal antibody and then analyzed on the flow cytometer for myeloid:erythroid (M:E) ratios. Flow cytometric determinations of myeloid and erythroid population percentages and M:E ratios from untreated rats were confirmed by microscopic examination of marrow cytospins and flow cell sorts. M:E ratios for control animals determined by flow cytometry were not significantly different between the two studies (1.83 vs. 1.89). CHO treated rats showed a significant ($p < 0.01$) decrease in M:E ratios (0.96 - CHO vs. 1.48 - control) at day 11 as a result of an increase in erythroid cells. M:E ratios were significantly increased ($p < 0.05$) for rats treated with DAUN at day 3 (5.07 - DAUN vs. 1.70 - control) and corresponded to generalized depletion of all marrow cell lines with greater loss occurring in erythroid cells. At the end of the recovery period, M:E ratios of CHO and DAUN rats were similar to controls. Hematological values corroborated changes in marrow myeloid and erythroid populations evaluated by this flow cytometric technique. Using flow cytometry and a monoclonal antibody to the cell surface antigen CD71, this study demonstrated the reversible selective toxicity on myeloid and erythroid populations of the marrow following *in vivo* exposure to CHO or DAUN.

948 A PROPOSED APPROACH FOR THE VALIDATION OF A RADIOTELEMETRIC DEVICE TO MEASURE CARDIOVASCULAR PARAMETERS IN THE RAT.

J. Zeiders, G. J. Gromelski, V. B. Ciofalo and C. B. Spainhour. *Chrysalis Preclincial Sevices Corporation, Olyphant, PA.*

The measurement of various cardiovascular parameters in laboratory animals can play a very important role in pharmacology and toxicology evaluations. The data from such studies are commonly used as predictors of the safety and efficacy of new chemical entities in humans. Parameters of interest typically include blood pressure, heart rate and an electrocardiogram. Historically, this type of data has been obtained from chemically restrained animals. However, anesthesia affects normal cardiovascular physiology and data from conscious and unrestrained animals is more desirable and relevant. Radiotelemetry provides a method to obtain measurements of various cardiovascular parameters from unrestrained and conscious animals. Before such instrumentation can be used though, a series of procedures must be completed ensuring that the instrument conforms to the defined needs of the user and that the designed output meets the designed input. Testing is conducted under very specifically defined conditions simulating actual use. The validation process is composed of two arms: electronic and physiologic validation. What is reported here is the detailed step-wise electronic and physiologic validation of a Data Sciences International (DSI) remote monitoring system. Six to eight week old, male, Sprague Dawley rats weighing 300 - 350 gm apiece were surgically implanted with type TL11M2-C50 (DSI) transducers. Standards were selected to test the ability of the system to clearly define changes in blood pressure and other cardiovascular parameters in a measurable and interpretable fashion. The agents used were: hydralazine (H; 5 mg/kg), a vasodilator; propranolol (P; 30 mg/kg), a β-blocker, isoproterenol (I; 0.1 mg/kg), a β-agonist and epinephrine (E; 0.25 - 3.0 μg/kg), an α,β-agonist. The vehicle was 0.25% methylcellulose (M). Animals were dosed with M on days 1, 8 & 15; H on days 2 & 5, P on days 9 & 12; I on days 16 & 19 and I + E on days 22 & 23. Days 3, 4, 10, 11, 17 & 18 were washout days. The complete package of electronic and physiologic data represent a regulatorily defensible validation package.

949 RATIOMETRIC ANALYSIS OF NONYL ACRIDINE ORANGE (NAO) FLUORESCENCE IS A SENSITIVE INDEX OF OXIDATIVE LOSS OF MITOCHONDRIAL CARDIOLIPIN.

R. H. Pierce[1], M. Poot[2], T. J. Kavanagh[3] and N. Fausto[2]. [1]*USAF, Wright-Patterson Medical Center, Wright-Patterson AFB, OH,* [2]*Department of Pathology, University of Washington, Seattle, WA and* [3]*Department of Environmental Health, University of Washington, Seattle, WA.*

Nonyl acridine orange (NAO) is a lipophilic acridine orange derivative with high affinity for cardiolipin, the chief lipid comprising the mitochondrial inner membrane. Because binding of NAO to cardiolipin is membrane potential insensitive, it has been used to measure total cellular mitochondrial mass. NAO fluorescence is usually measured in the green as unbound NAO in solution has an excitation and emission maximum of 495 nm and 519 nm respectively. Petit[1] *et al* have shown, however, that NAO binds cardiolipin with a stoichiometry of 2 dye molecules to 1 cardiolipin, dependent on the diacidic structure of cardiolipin. When bound to cardiolipin in this 2:1 ratio, a red NAO emission fluorescence is detected, presumably from excimer formation. Red NAO fluorescence is more specific for cardiolipin than the green fluorescence. Green NAO fluorescence is lost as a consequence of mitochondrial oxidative stress produced by menadione[2]. We have recently demonstrated that AML12 hepatocytes exposed to actinomycin D and TNF undergo apoptosis which involves oxidative stress, including the loss of cardiolipin (measured as red fluorescence). Coincubation with α-lipoic acid, a potent antioxidant, blocks the loss of NAO fluorescence[3]. We show here that this loss of NAO staining cannot be attributed to a change in cellular pH. Furthermore, we report a method for analyzing NAO fluorescence as the ratio of red:green fluorescence. Cells undergoing oxidative stress-induced loss of cardiolipin can be identified by the fluorescence shift from red to green. This ratiometric approach is useful for both flow cytometric and confocal microscopic analyses and has several distinct advantages over single color fluorescence techniques. Chief among these benefits is that ratiometric data is independent of cell size and cellular variability in dye loading. In addition, for confocal microscopy studies, ratiometric analyses allow one to perform real-time identification of cells undergoing oxidative stress, and to assess heterogeneity among mitochondrial cardiolipin oxidation within individual cells. 950 RELATING MELANIN DEGRADATION PRODUCTS TO ACTUAL MELANIN CONTENT: APPLICATION TO HUMAN HAIR.

C. R. Borges, D. G. Wilkins and D. E. Rollins. *University of Utah, Salt Lake City, UT.*

Numerous studies have confirmed that melanin pigments play an important role in the incorporation of drugs into hair. This may lead to a bias in the interpretation of hair testing results. To develop non-biased testing procedures, the role of specific subtypes of melanin in drug incorporation should be characterized. Methods for characterizing and quantitating melanin subtypes from the two types of melanin found in hair-eumelanin and pheomelanin, have been established. 5,6-Dihydroxyindole (DHI) and 5,6-Dihydroxyindole-2-carboxylic acid (DHICA) make up the majority of the eumelanin polymer while benzothiazene units derived from 2-Cysteinyl-S-DOPA (2-CysDOPA)

and 5-Cysteinyl-S-DOPA (5-CysDOPA) comprise the majority of the pheomelanin polymer. To ascertain the true nature of a melanin pigment, the contribution from each of the above monomer units must be determined. Procedures that allow for quantitation of eumelanin and pheomelanin subtypes by HPLC methods have been developed. Our results show that: 1) Pyrrole-2,3-dicarboxylic acid (PDCA) and Pyrrole-2,3,5-tricaboxylic acid (PTCA), markers for DHI and DHICA units, respectively, are produced in 0.37% and 4.5% yields, respectively, when melanins are subjected to alkaline hydrogen peroxide degradation, 2) 3-Aminotyrosine (3AT) and 4-Amino-3-hydroxyphenylalanine (AHP), markers for 2-CysDOPA and 5-CysDOPA, respectively, are produced in 15% and 22% yield, respectively, when subjected to hydriodic acid hydrolysis, and 3) PDCA and PTCA are not specific markers of eumelanin, and that PTCA can be produced from DHI derived units. In spite of these facts, production of degradation products from unexpected sources is consistent and thus can be accounted for. The degradation products PDCA, PTCA, 3AT, and AHP are used to quantitate the amounts of eumelanin and pheomelanin subtypes in hair. These assays will allow deeper investigation into the relationship between melanin composition and drug incorporation into hair. (Supported by NIH grant DA07820.)

951 THE USE OF FLUORO-JADE B AND BLACK-GOLD TO DETECT NEURONAL AND MYELIN DEGENERATION IN THE RAT FOREBRAIN.

K. J. Hopkins and L. C. Schmued. *National Center for Toxicological Research, Jefferson, AR.* Sponsor: W. Slikker, Jr.

Neurological disease and exposure to certain chemical compounds can result in neuronal degeneration and myelin changes in the central nervous system. Two novel compounds, Fluoro-Jade B (FJ B) and Black-Gold (BG), have been developed to histochemically identify such brain lesions. The first compound, FJ B, is the second generation green fluorescent marker specific for degenerating neurons. It is sensitive, simpler and more reliable than traditional supressed silver techniques. Exposure to excitotoxins, like kainic acid, or the electron transport inhibitor 3-nitropropionic acid, results in extensive, neuronal labeling with FJ B, while treatment with ibogaine, MK801, MPTP, d-fenfluramine, or methamphetamine results in a more restricted pattern of cell staining. FJ B has also been used to detect amyloid plaques in human brain tissue and astrocytosis following semi-chronic chemical treatments. The second compound, Black-Gold, is a haloaurophosphate complex used to visualize normal and pathological myelin. Exposure to compounds such as kainic acid or 3-nitropropionic acid results in myelin damage characterized by fragmentation and "bead-like" varicosities. The use of these dyes individually, or in combination with other specialized stains, allows for a rapid, reliable evaluation of disease and chemically induced brain damage. (Supported by FDA protocol #7013.01.)

952 DEVELOPMENT OF AN *IN VIVO* METHOD TO ASSESS SINGLE FIBER ELECTROMYOGRAPHIC JITTER IN JUVENILE AND ADULT RATS.

D. B. Finley[1] and D. W. Herr[2]. [1]*University of North Carolina, Chapel Hill, NC and* [2]*USEPA, Research Triangle Park, NC.*

A novel *in vivo* technique is presented that uses single fiber electromyography (SFEMG) to measure muscle action potentials elicited by electrical stimulation of the sciatic nerve in rats. The variability in latency from the stimulus to a point on the rising phase of the muscle action potential (MAP) at a selected percent of the MAP amplitude is called the neuromuscular jitter. Although the clinical usefulness of jitter measurement as an electrodiagnostic tool for the study of neuromuscular transmission disorders has been well established, it has only recently been used as an early endpoint to assess the effects of toxicants. In anesthetized animals, stimulating needle electrodes delivered a 50 μsec cathodal pulse near the sciatic nerve. The stimulus intensity was adjusted to produce small twitches in the rat's toes and a MAP greater than -1 mV. The SFEMG recording electrode was inserted into the subject's gastrocnemius muscle. The SFEMG jitter was computed as the mean consecutive difference (MCD) of latencies from a series of 50 consecutive discharges. The variability of the MCD was assessed by recording from 3 different SFEMG electrode placements within the gastrocnemius muscle of each rat and calculating the MCD at 3 different percent amplitude points (10, 25, and 50) of the MAP. There were no significant differences in the jitter from recordings made at the different SFEMG electrode placements within each subject, or at any of the percent amplitude criterion points. Results indicate that using this *in vivo* technique the overall median (and 25-75 percentiles) for SFEMG jitter within the gastrocnemius muscle of juvenile rats was 21.3 μsec (16.7-34.3) and in adult rats was 15.9 μsec (9.0-25.2). These results indicate that direct axonal stimulation and subsequent SFEMG jitter measurements may prove to be a sensitive endpoint for examining xenobiotic effects on neuromuscular transmission. (Funded by the EPA/UNC Toxicology Research Program, Training Agreement CT902908. This abstract does not necessarily reflect US EPA policy.)

953 DEVELOPMENT OF A NEW MECHANICAL IRRITATION TEST.

M. A. Farage. *The Procter and Gamble Company, Cincinnati, OH.* Sponsor: R. S. Nair.

Certain consumer products worn in close proximity to the skin, such as feminine hygiene products and diapers, are sometimes tested for the potential to cause mechanical irritation as part of the overall safety assessment. Historically, this test has been performed using the wrist as the test site. However, a more sensitive test was needed to detect subtle differences in current product candidates. We chose to investigate the behind the knee as an alternative body site. The negative (satin) or the positive (burlap) control materials were covered by either an athletic band on the wrist, or an Ace* band/brace on the knee. Twelve panelists wore the positive control material on one wrist and one knee, and the negative control material on the alternate wrist and knee. The bands were worn 6 hours/day for 4 days. Test sites were scored for irritation on a visual scale twice each day; prior to wrist or knee band application and 30 minutes after removal. The mechanical irritation caused by the positive and negative control materials was significantly different after the first day of wear at both test sites (knee and wrist). However, at the behind the knee these differences were greater, and the effects more prolonged. Based on this initial study we concluded that this protocol, i.e., using the behind the knee as a test site, 4 days of material wear for 6 hours/day, and materials applied using a knee band/brace, is a sensitive test system for evaluating mechanical irritation. Further, satin and burlap are effective negative and positive controls to use in future experiments.

954 EVALUATION OF NMR ANALYSIS OF URINE FOR SCREENING LIVER AND KIDNEY TOXINS.

D. G. Robertson, M. D. Reily, R. E. Sigler, D. F. Wells and D. Paterson. *Parke-Davis Pharmaceutical Research, Ann Arbor, MI.*

The combination of NMR and pattern recognition analysis of urine, "metabanomics", has been successfully used to characterize *in vivo* toxicity. The utility of this technology was assessed by administering Wistar rats (4/dose) single doses of 2 known hepatotoxins, 0.1 and 0.5 ml/kg carbon tetrachloride (CCL4) and 10 and 100 mg/kg α-napthylisothiocyanate (ANIT); 2 known nephrotoxins, 15 and 150 mg/kg 2-bromoethylamine (BEA) and 15 and 150 mg/kg para aminophenol (PAP), and 1 and 5 mg/kg of the diuretic furosemide (FURO). 24-hour urine samples were collected (0°C.) pretest and daily for 4 days postdose. Animals were sacrificed on Day 4 with a control and high dose CCl4 and BEA treated animals maintained for 10 days to assess reversal. Clinical pathology samples were obtained on Days 1, 2 and 4 or Days 1, 4 and 10 (reversal groups). Target organ pathology was evaluated at termination. Standard urinalysis, including urine volume, quantitative protein, creatinine clearance, and electrolyte excretion were also conducted on BEA, PAP and FURO samples. Urine was subjected to 600 MHZ ^{1}H NMR analyses with spectra further evaluated using principal component analyses (PCA). Results indicated that high doses of all toxins produced the anticipated lesions, while the low doses produced minimal if any pathology. PCA data were in agreement with clinical chemical indices of toxicity but were more consistent with regard to onset, duration and reversal of toxicity and potentially more sensitive. Pharmacological doses of FURO had no effect on NMR/PCA. These data suggest that NMR/PCA can serve as a powerful tool for the rapid evaluation of onset, severity and reversal of *in vivo* toxicity using a peripheral sample.

955 EVALUATION OF RESPIRATORY PARAMETERS OBTAINED FROM CONSCIOUS PRIMATES DURING INHALATION EXPOSURE.

P. McDonald and K. McInally. *Inveresk Research, Tranent, United Kingdom.* Sponsor: S. B. Wilson.

During the course of inhalation toxicology experiments it is essential to quantify the volume of aerosol inhaled by the test animal. There is currently limited information in the literature regarding respiratory data for non-human pri-

mates. Published data available tends to be focused on sedated or anaesthetised animals which may not be reflective of the breathing patterns of a fully conscious restrained animal. During the course of a repeat 90 day inhalation toxicity study with a nebulised protein, respiratory frequency, tidal volume, minute volume, expiratory and inspiratory flow times were recorded in 52 cynomolgus monkeys (Macaca fascicularis) using a pneumotachograph and differential pressure transducer incorporated into the face mask dosing system. Animals were fully conscious under light restraint during all procedures. Measurements were obtained from all animals prior to and during inhalation exposure on 5 occasions over the study duration. The results obtained showed a wide degree of variability in both respiratory frequency, tidal volume and minute volume. A significant degree of inter and intra animal variation was noted which was not related to any adverse behavioural events during the dosing procedures. The results indicate that careful appraisal of in situ respiratory measurements are required if the volumetric data is to be used for dosimetry purposes.

956 A STUDY OF THE EFFECTS OF RESTRAINT DURATION FOR NOSE-ONLY INHALATION EXPOSURE ON EMBRYO/FETAL DEVELOPMENT IN RATS.

B. J. Varsho, G. D. Cappon, D. T. Kirkpatrick, D. C. Welter, J. C. Obrecht and T. D. Feikert. *WIL Research Laboratories, Inc., Ashland, OH.*

The current study assessed the effects of various nose-only (N-O) inhalation exposure restraint durations on pregnancy, maternal body weight, food consumption, clinical condition, and embryo/fetal development in Crl:CD®(SD)IGS BR rats. Animals were incrementally acclimatized to restraint tubes for at least 4 days prior to mating. The maximum acclimatization time for each animal matched its designated exposure duration. Following acclimatization, 25 mated female rats per group were exposed to filtered air using N-O exposure techniques for 1, 2, or 6 hours on gestation days (GD) 6 through 17. The control group was exposed to filtered air for 6 hours using whole-body exposure techniques. Acclimatization to N-O restraint had no effects on mating, ovulation, or nidation. N-O restraint from GD 6-17 had no effects on clinical condition or food consumption. Slight, statistically significant reduced mean body weight gains or body weight losses were induced in all N-O groups on the first day of restraint (GD 6). These reductions were sufficiently minor as to create no statistically significant difference in mean body weight throughout the study. The reductions were transient, because much if not all of the differences from the weight gain in the whole-body group was recovered following the last day of restraint (GD 18-20). Net mean body weight (GD 20 weight minus gravid uterine weight) and net mean body weight gains were unaffected by any restraint duration. Gravid uterine weights and fetal viability and weights were comparable across groups. No N-O restraint-related malformations were observed. No significant changes were observed in biological endpoints using these three N-O exposure paradigms; therefore; N-O exposure in a suitable approach for prenatal developmental toxicity studies.

957 USE OF JUVENILE DOGS IN PRECLINICAL INHALATION TOXICITY TESTING.

R. Salame, A. Viau and C. M. Banks. *ClinTrials BioResearch Ltd., Senneville, Quebec, Canada.* Sponsor: G. W. Lulham.

The dog is a standard large animal species used in inhalation toxicity studies. Recent changes in the approach taken in toxicity testing of drugs intended for pediatric population necessitate the use of an animal model at a correspondingly young age. The feasibility of using young dogs in inhalation toxicity studies and the environmental modifications required were investigated in this experiment. Animals were received at approximately 2 to 3 months of age. A period of acclimation to the laboratory environment was allowed before commencement of acclimation to the exposure apparatus. Modifications to the housing units, environmental conditions, watering and feeding regimens as well as additional exercise periods were required. The inhalation exposure mask and restraint systems were modified to accommodate the smaller size of the animals and to ensure efficient containment of the atmosphere. In conclusion, with minimal modifications to the current husbandry and exposure procedures, animals as young as 4 months old can be utilized on inhalation toxicity studies.

958 ELECTRORETINOGRAM (ERG) RECORDING IN THE BEAGLE DOG.

P. Mansell, M. Vezina and G. Washer. *ClinTrials BioResearch Ltd., Senneville, Quebec, Canada.* Sponsor: G. W. Lulham.

Electroretinography is becoming increasingly recognised as an aid in assessing retinal changes in toxicology studies in conjunction with ophthalmology and histopathology. Background ERG data for beagle dogs was obtained using an EPIC 2000 ERG recorder, Grass flash stimulus and Ganzfeld dome. Under ketamine and xylazine anesthesia, following dark adaptation, ERG's were performed to verify the range of scotopic response. The ERG protocol consisted of a series of tests to assess scotopic response utilising neutral density wratten filters to regulate light transmission. Following the filter sequence, the dogs were adapted to background light and exposed white flicker light at 31 Hz to assess photopic cone response. Parameters recorded were a-wave implicit time and amplitude and b-wave implicit time and amplitude for the single flash ERG, and b-wave amplitude and latency for the 31 Hz white flicker. Small differences were observed between left and right eyes in the mean values although occasional, larger variations were noted in certain individual animals. A-wave amplitude and implict time for descending light log units varied between 0 and -65 uV (sd 0.1-23) and 23 and 16 ms (sd 7.3-1.5) respectively. B-wave amplitude and implict time varied between 0 and 165 uV (sd 0.01-56) and 73 and 50 ms (sd 1.8-9.5) respectively. B-wave amplitude and latency for the 31 Hz white flicker were 25 uV (sd 12.7) and 27 ms (sd 0.9) respectively. It is concluded that the reproducibility of ERG data in the beagle dog using this GLP validated method is acceptable and suitable for use as an aid in the overall evaluation of change in the retina.

959 DETERMINATION OF TAMOXIFEN AND METABOLITES IN MOUSE FETAL TISSUE USING CAPILLARY ELECTROPHORESIS (CE) CHROMATOGRAPHY.

J. M. Sanders, K. L. Alford, P. J. Schupp, R. R. Newbold and M. L. Cunningham. *NIEHS, Research Triangle Park, NC.*

Tamoxifen (TAM), an antiestrogen, has been approved for use by women at risk for developing hormone-dependent breast cancer. Although transplacental exposure of TAM has been linked to reproductive tract toxicity in female offspring of CD-1 mice, there is little or no data describing potential TAM-induced fetal toxicity to women who may become pregnant while receiving prophylactic TAM treatment. In support of the National Toxicology Program's characterization of reproductive and developmental effects of TAM, the present work describes a CE-based analytical technique used for detection of TAM and two of its major metabolites, N-desmethyltamoxifen (DMT), and 4-hydroxytamoxifen (4-HT) in CD-1 mouse fetal tissue. Hexane/isoamyl alcohol (98:2, v/v) was used to extract TAM-derived material from CD-1 mouse fetuses 2-12 hr following administration of 100 mg TAM/kg to dams on gestation day 16. The presence of TAM, DMT, and 4-HT was confirmed in fetal extracts by CE chromatography utilizing a 57 cm x 50 μm capillary with a nonaqueous buffer system of 1:1 (v/v) methanol/acetonitrile containing 50 mM ammonium acetate and 1.5% acetic acid. Voltage and temperature were optimized at 15 kV and 40°C, respectively. The limit of detection by UV absorption of TAM was approximately 675 attomoles at a signal to noise ratio of 2:1. This work demonstrates transplacental transport of TAM following exposure to CD-1 mice and a sensitive analytical technique for detecting low concentrations of TAM and similar compounds in biological tissues.

960 THE YEAST DEL ASSAY DETECTS CARCINOGENS.

R. J. Brennan[1] and R. H. Schiestl[2]. [1]*OSI Pharmaceuticals Inc., Uniondale, NY and* [2]*Harvard School of Public Health, Boston, MA.*

We have constructed and used DEL assays, which quantify potentially carcinogenic DNA deletion events in yeast, human cells and *in vivo* in mice. DEL events in all three assay formats are induced by a wide variety of carcinogens, many of which, such as benzene and PCBs, are negative in most other short-term genotoxicity tests. The yeast DEL assay also differentiates correctly between problematic carcinogen/non-carcinogen structural analogs. Of 62 chemicals of known carcinogenicity tested, the yeast DEL assay correctly identifies 85%. In comparison, the widely used Salmonella reverse mutation assay correctly classifies only 33%. The yeast DEL assay is now under development as a fully automated, robotic screen. We have adapted the assay to a liquid, microtiter plate format using optical density growth detection. Pilot studies, focused on the parameters of cell density and growth kinetics in microtiter plates, showed the feasibility of such a format. Refinement and fur-

ther development have allowed the detection of two-fold differences in DEL frequency, and significant, dose-dependent effects of carcinogens on deletion frequency have been detected. Further assay development (including the addition of cytotoxicity compensation) and full robotic automation is underway. Ultimately we will validate the automated assay with 500 chemicals of known carcinogenic activity. Automated, higher throughput and highly predictive genotoxicity screens like the DEL assay will assist in the identification of undesirable compound characteristics earlier in the drug discovery process, improving pharmaceutical companies' ability to make fast, scientifically-based decisions on early drug leads. More widespread adoption of a validated DEL assay may reduce the number of animals used in carcinogenicity testing of novel pharmaceuticals, and its high predictive value may reduce the failure rate of promising drug candidates due to unanticipated carcinogenic potential.

961 A YEAST ASSAY FOR CHROMOSOME GAIN.

N. G. Howlett and R. H. Schiestl. *Harvard School of Public Health, Boston, MA.*

Aneuploidy is defined as a deviation in chromosome number from an exact multiple of the haploid state. Aneuploidy in germ cells is a significant contributor to genetic disease in man, e.g., Down's and Klinefelter's syndrome. Furthermore, an increased susceptibility to neoplasia has been observed with many congenital aneuploidies, an observation consistent with the increased levels of genomic instability characteristic of tumor cells. Currently there is a notable absence of information on the mechanism and genetic control of both spontaneous and induced aneuploidy. The yeast DEL assay selects for deletion events removing the LEU2 gene that is flanked by his3 repeats. Cells positive for His+ and Leu+ occur after duplication of the chromosome and deletion on one of the duplicated chromosomes. Spontaneous frequencies of chromosomal gain were approximately 2.3 x 10-3 and 1.6 x 10-2 for the haploid strain RSY6 and the diploid strain RS112, respectively. We have also assessed the ability of the yeast DEL assay to accurately detect the known aneugens benomyl, MMS, EMS, and actinomycin D. All chemicals increased the frequency of chromosome gain in a dose-dependent manner. For example the alkylating agent EMS, and actinomycin D induced aneuploidy approximately 8.8-fold and 5.2-fold in RSY6, respectively. FACS-analysis of propidium iodide-stained spontaneous and methotrexate-induced HIS+LEU+ revertants confirmed deviation in chromosome number. Most interestingly, 100% of haploid HIS+LEU+ revertants were hyperdiploid, while 90% of diploid HIS+LEU+ revertants were indeed aneuploid, indicating different mechanisms of chromosomal non-disjunction in the haploid and diploid strains. In addition, data on spontaneous levels of chromosome gain will be presented for yeast strains deficient in various components of DNA repair pathways. Thus the yeast DEL assay can be employed to detect chromosome gain, and will provide valuable information on the genetic and/or epigenetic mechanisms underlying chromosome gain.

962 DEVELOPMENT OF A WHOLE BODY PERFUSION FIXATION SYSTEM FOR CYNOMOLGUS MONKEYS.

A. C. Gibbs and J. Wilkins. *Covance Laboratories Ltd., Harrogate, United Kingdom.* Sponsor: J. Norris.

Whole body perfusion fixation avoids many of the artefactual changes observed microscopically in a variety of tissues following immersion fixation. Whole body perfusion is the preferred method of fixation for toxicology studies that require a detailed evaluation of, amongst other tissues, the central or peripheral nervous system. At Covance, we developed a system for whole body perfusion of primates in response to a Sponsor request for the technique to be performed on a chronic toxicity study where evidence of peripheral neuronal budding was required. The practical considerations involved in the perfusion of a large animal are numerous; the relatively large size of cynomolgus monkeys means that adequate perfusion of the extremities without causing tissue damage due to the perfusion pressure required is a difficult balancing act. The method used involves the introduction of an initial perfusate of heparinised saline containing sodium nitrite via the left ventricle; the right atrium is incised to allow the replacement of the blood in the circulatory system with the initial perfusate. Once the blood is replaced, the animal is perfused with 10% neutral buffered formalin until full fixation of all tissues is achieved. The system developed is very successful and excellent preservation of the cellular architecture was achieved in all tissues.

963 CONTINUOUS SUBCUTANEOUS INFUSION IN THE CYNOMOLGUS MONKEY.

S. N. Groom and G. Washer. *ClinTrials BioResearch Ltd., Senneville, Quebec, Canada.* Sponsor: G. W. Lulham.

The subcutaneous route is an important method of drug administration in humans. Continuous subcutaneous infusion was developed at CBTR to provide an alternative to subcutaneous injection. The feasibility of drug delivery by continuous subcutaneous infusion in the Cynomolgus monkey was investigated over a period of 28 days. Six Cynomolgus monkeys were surgically prepared with an indwelling subcutaneous lumbar catheter, fitted with CTBR's standard intravenous infusion jacket and tether assembly and infused subcutaneously with 0.9% Sodium Chloride, U.S.P via an in-line 0.22mm filter for 24 hours/day for 28 consecutive days. Infusion rates were selected to deliver daily dose volumes of 1 or 6 mL/kg/day (0.04 or 0.25 mL/kg/h). Dosimetry data for the 28-day period demonstrated all animals received within ± 10% of the nominal volume. Continuous 24 hour/day subcutaneous infusion of 0.9% Sodium Chloride, U.S.P. in the monkey at rates equivalent to 1 and 6 mL/kg/day for 28 days resulted no toxicologically significant effects upon clinical condition, body weight, hematology or clinical chemistry parameters. Treatment-related gross findings were confined to swelling at the infusion site (associated with mild edema and/or hemorrhage) in 2/3 high rate (6 mL/kg/day) animals. In light of these findings, 6 mL/kg/day was considered to represent the upper limit for subcutaneous infusion for 28-day studies.Subsequent to the conduct of the feasibility study a 13-Week continuous subcutaneous infusion toxicity study was successfully performed in Cynomolgus monkeys using infusion rates selected to deliver 3 mL/kg/day. The control data from this study confirmed the findings of the initial 28-day study and are presented.

964 CONNEX IN-LIFE DATA CAPTURE SYSTEM: A SYSTEM OVERVIEW.

T. J. Jameson and A. J. Little. *Covance Laboratories Europe, Harrogate, United Kingdom.* Sponsor: J. Norris.

The Connex data capture system has been developed at Covance Harrogate, England to record In-life Toxicology Data from a diverse range of species. The initial version of Connex was designed to record Food/9Water Consumption, bodyweights, clinical observations and tissue masses with the aim of replacing the Toxdata system or the manual data records used for more complex study designs. Subsequent developments have now extended this range to include test article administration. The existing Toxdata system relies upon data being recorded on to pre programmed magnetic discs. These discs are taken into animal rooms for data recording after which they are returned to a central "link room" where the information is uploaded on to a main frame computer and the data printed, this process is controlled using paper records. Connex excels over the existing systems in many ways, the first of which is the scheduling of data recording which is monitored by a dedicated program. This "Connex Console" program shows the current status of all studies being run on Connex and is available within the Animal Houses, Study Director group and Quality Assurance Department. Data generated using Connex is stored electronically and an interface has been designed permitting data to be reviewed in a safe environment. To ensure data is secure at all times extensive power failure, data transfer (network) failure and computer security/failure procedures have also been incorporated into the system. This poster provides an overview of both systems demonstrating how data collection is scheduled, stored, accessed and protected.

965 ASSESSMENT OF MURINE MICTURITION PATTERN AND UROTHELIAL PERMEABILITY AFTER CYCLOPHOSPHAMIDE ADMINISTRATION.

R. W. Wood, L. Eichel, E. M. Schwarz, E. M. Messing and J. S. Shojaie. *University of Rochester Medical Center, Rochester, NY.* Sponsor: R. K. Miller.

Toxicants can have adverse effects on the structure and function of the urinary bladder, resulting in elevated frequency of urination, changes in the functional capacity of the bladder, and in its ability to act as a barrier to intravesical resorption of xenobiotics. Noninvasive techniques have been developed that permit the evaluation of urinary frequency and void volume, as well as to describe the elimination of marker substances in urine that may undergo intravesical reuptake and hence prolongation of excretion with impairment of bladder mucosal barrier function. Cyclophosphamide (300 mg/kg IP) produces hematuria that persists for up to two weeks and is associated with

delayed clearance of fluorescein (1mg/kg IP), decreased urine production, reduced void volume, and increased voiding frequency. The resultant irritative voiding syndrome demonstrated the ability to measure syndromes characterized by overactive bladder, and may be useful in acute and chronic toxicity evaluations, medication development, and in the investigation of the molecular determinants of bladder structure and function. To produce elevated urine production, mice (female CRL CD-1) were offered a drinking solution of 0.125% saccharin and 3.0% glucose stabilized with parabens; this mixture results in at least a ten-fold elevation in urine production. Void volumes typically ranged from 150 to 300 µl, and occurred about 12 per hour. Thus measurable amounts of urine could be collected with a conventional fraction collector placed under a Nalgene mouse diuresis cage. For the measurement of void volume and frequency, the collection funnel was removed from the diuresis cage and replaced with a stainless screen. A urine pan sits on a balance configured to report changes of 15 mg and the resultant stable weight to a resolution of 1 mg. Character strings were sent via a terminal server to a remote networked computer that provided evaporation correction and event characterization. The system can measure many balances simultaneously, and provides descriptive statistics within- and across sessions. (Acknowledgments: DA05080, Departments of Urology, OB/GYN, Medicine.)

966 THE DESIGN OF A USER FRIENDLY DATA RECORDING SYSTEM.

A. J. Little and T. J. Jameson. *Covance Laboratories Europe, Harrogate, United Kingdom.* Sponsor: J. Norris.

End user involvement has been the key to the successful design and implementation of the Connex In-life data capture system both in terms of the programming and the computer workstations used in the laboratory environment. By consultation with end user departments the dedicated Covance Information Systems Department have been able to incorporate many excellent features into the Connex capture system. This poster will show the ease with which laboratory data can be recorded, demonstrating how external devices for electronic identification of animals and test substances are integrated in to the recording process. Many control measures have also been built in to the Connex system to prevent data entry errors and ensure data integrity. These measures include the comparison of every weight (animal, food or water) against background data at the time of recording. The system also forces balance calibration, audit trails any data changes and automatically records when animals have been electronically identified to perform procedures. To assist data entry purpose designed computer workstations have been developed for both the Rodent and Non-Rodent areas. The challenge when designing these workstations has been to provide a durable protection system for the integrated electronic components whilst maintaining the highest possible levels of ergonomics. The two very different solutions will be detailed together a new prototype "touch screen" workstation intended to further aid data capture.

967 ELECTRON PARAMAGNETIC RESONANCE (EPR) MEASUREMENTS OF MANGANESE OXIDATION STATE IN BIOLOGICAL SAMPLES: IMPLICATIONS OF THE ROLE OF OXIDATION STATE IN TOXICITY.

S. H. Reaney, R. H. Gwiazda and D. R. Smith. *University of California, Santa Cruz, Santa Cruz, CA.*

Elevated exposures to manganese (Mn) and other metals have been associated with the increased incidence of Parkinsonism. This raises concern over the pending use of the antiknock gasoline additive methylcyclo-pentadienyl manganese tricarbonyl (MMT), which upon combustion may yield particles with Mn in a mixture of oxidation states. Mn oxidation state may play an important role in neurotoxicity, since studies have shown that Mn can impair dopaminergic systems via direct oxidation of dopamine, or through the generation of ROS via other redox processes. Here, we are developing an *in situ* method for the measurement of Mn oxidation state in biological tissues (blood and brain), in which divalent Mn (d^5) is quantified via electron paramagnetic resonance (EPR), total Mn is determined using magnetic-sector ICP-MS, and inferred trivalent Mn is determined by difference. We then conducted an *in vitro* study in fresh whole blood to determine the effects of Mn exposure of different oxidation states on the kinetic and steady state balance between Mn(II) and Mn(III). Since the complex matrix of biological samples and inherent Mn-binding can preclude the utility of simple aqueous EPR standards, we have investigated standards of aqueous Mn(II) (as "free" or hexa-aquo Mn(II)), Mn(II) + lysozyme (non-specific Mn binding), and Mn(II)-glutamine synthetase (specific Mn binding) to demonstrate quantifiable EPR spectra. Results to date have: (i) Established a detection limit of 30ppb for the measurement of Mn(II) by EPR; (ii) Suggested that the steady-state Mn(II):Mn(III) ratio of the redox reaction Mn(II)$\leftrightarrow$Mn(III) in whole blood differs, depending on whether the added (spiked) Mn was as Mn(II) or Mn(III), and; (iii) Suggested that the steady-state Mn(II):Mn(III) ratio is different in blood compared to brain tissues of $Mn(II)Cl_2$ exposed rats. These preliminary data suggest that the oxidation state of introduced Mn could influence the potency by which excessive Mn exposure exerts toxicity.

968 COMPARISON OF *AD LIBITUM* AND RESTRICTED FEEDING REGIMENS FOR CHRONIC STUDIES USING THE SPRAGUE-DAWLEY RAT.

M. Boyer, L. J. Kangas, P. Batham and C. M. Banks. *ClinTrials BioResearch Ltd., Senneville, Quebec, Canada.* Sponsor: G. W. Lulham.

In recent years, there has been a trend towards restricting the amount of food provided to rats during chronic studies in an attempt to increase overall health of the animals and therefore, enhance survival. In the past few years CTBR has performed a number of studies with various types of diet restriction. Some of the long term carcinogenicity studies have been completed and the survival data at Week 104 was compared with survival data for some studies fed ad libitum. Other parameters, such as body weight and incidence and onset of masses were also compared. The data shows that the average survivability of in the males and the females with restricted feeding when compared to those fed ad libitum was higher. The amount of food given per day (ie.: 21g vs. 25g) also had an influence the survival in of the males. The overall health of the animals for which the diet was restricted was better (i.e.: reduced number of palpable masses and fewer age-related changes) and the body weights lower. In conclusion, the survival at completion of carcinogenicity studies can be improved by restricting the amount of food provided to the animals. The observed reduction in bodyweights can also be beneficial as it results in reducing the total amount of test article required to complete the studies.

969 A HIGH THROUGHPUT SCREENING ASSAY FOR HEPATOTOXICITY USING CRYOPRESERVED ANIMAL AND HUMAN HEPATOCYTES.

C. Lu, P. M. Silber, C. Ruegg and A. P. Li. *In vitro Technologies, Inc., Baltimore, MD.*

Recently, we have developed a procedure for the successful cryopreservation of animal and human hepatocytes. We report here a high throughput screening procedure for hepatotoxicity using the cryopreserved cells. Cryopreserved hepatocytes were thawed and plated in 96-well plates preplated with test chemicals at the appropriate concentrations. After an incubation of 4 hrs, cytotoxicity was evaluated using two procedures: 1. Measurement of mitochondrial functions using the MTT assay. 2. Measurement of cellular ATP. The MTT assay was performed by adding the MTT reagent directly into the wells after the 4-hr incubation period, allowing an additional 3-hr incubation period for the metabolism of the reagent, addition of acidified isopropanol to extract the blue color metabolite, and quantification of absorbance at 650 nm. ATP quantification was performed by the addition of a cell lysis buffer after the incubation period followed by the quantification of ATP via chemoluminescence. The ability of the assays to distinguish hepatotoxic and nonhepatotoxic compounds was evaluated using the known hepatotoxicants tamoxifen, ethynyl estradiol, and the nontoxic analogue estradiol. Tamoxifen and ethynyl estradiol consistently yielded dose-dependent cytotoxicity using both MTT and ATP endpoints, while no significant cytotoxicity was observed with estradiol. The cytotoxicity measurement based on ATP quantification was found to be superior to the MTT assay because of the decreased cost and time required. We believe that this assay with cryopreserved hepatocytes and ATP cytotoxicity endpoint can be automated and used routinely for the screening of chemical libraries to allow rank-ordering of product candidates based on hepatotoxic potential.

970 EXTENDED DURATION POWDER DELIVERY SYSTEM USED IN PRE-CLINICAL STUDIES IN RODENTS.

W. Lee, A. Viau and C. M. Banks. *ClinTrials BioResearch Ltd., Senneville, Quebec, Canada.* Sponsor: G. W. Lulham.

The Extended Duration Powder Delivery System (EDPDS) was developed at CTBR in order to fulfill a pharmaceutical industry demand for testing of dry powder formulations in an automated and reproducible manner, with minimal

intervention and at wide ranges of aerosol concentration.The EDPDS is sufficiently versatile to establish stable powder aerosol concentrations of different magnitudes (ie. 5 mg/L to 2000 mg/L) and for different lengths of time (ie. 10 minutes to 4 hours) without having to replenish the supply of test article and interrupt the exposure. Its modular design allows the system to be easily adapted by changing the size of the feed components and by controlling the feed rate with a variable speed motor which can be set to as low as 1 RPM to aerosolize minute quantities of test powder into the exposure chamber. The EDPDS has been used successfully on 5-day, 14-day and 28-day rodent inhalation toxicity studies. The system proved to be an efficient and highly reproducible means of delivering a range of powder concentrations on subacute studies that could be readily applied to subchronic, chronic and carcinogenicity inhalation studies.

971 SPECIES COMPARISON OF METHEMOGLOBIN REDUCTASE.

G. A. Rockwood[1], K. R. Armstrong[2], E. J. Machholz[2], C. B. Carpenter[4] and S. I. Baskin[3]. [1]*Drug Assessment,* [2]*Comparative Medicine and* [3]*Pharmacology Divisions, USAMRICD, Aberdeen Proving Ground, MD and* [4]*Division of Veterinary Medicine, WRAIR, Washington, DC.*

Methemoglobin (MHb) formation is an effective strategy for treating cyanide (CN) poisoning. Methemoglobin reductase (MR) is the enzyme that reduces MHb back to hemoglobin (Hb). The endogenous, circulating, normal level of MR reflects the capacity to reduce MHb and is therefore an important factor in evaluating the anti-CN efficacy of MHb formers. To help determine which animal species would most accurately predict the human response to MHb formers, the activity of MR was measured (mean±SEM) in whole blood of several species following established analytical methods. The animals employed included rhesus monkeys (Macaca mulatta; samples collected at USAMRICD), African green monkeys (Chlorocebus aethiops; samples collected at USAMRICD), and beagle dogs (Canis familiaris; samples collected at WRAIR). The MR values in these animal species were compared with normal human values. The human range for MR (n = 30) was 12.6 - 24.2 IU/g Hb, with a mean of 16.6±0.44 IU/g Hb (Mayo Medical Laboratories, Rochester, MN). The mean MR level in rhesus monkeys (n = 15) was 20.2±0.74 IU/g Hb, falling within the normal human range. For African green monkeys (n = 19) the mean was 26.0±0.76 IU/g Hb, slightly higher than the normal human upper limit. For beagle dogs (n = 15) the mean MR level was 9.5±0.22 IU/g Hb, approximately 25% lower than the normal human lower limit. Although the beagle dog has been used extensively in the study of MHb formers, these data suggest that the rhesus monkey may also be an appropriate model.

972 COMPARISON OF RESULTS FROM CROSS-SITE VALIDATION OF CONTINUOUS INFUSION PROCEDURES, EVALUATING TWO ROUTES OF INTRAVENOUS ADMINISTRATION AND PRECANNULATED CRL:CD(SD)IGS BR AND FISHER CDF (F-344)CRLBR RATS.

M. D. Walker[1], J. M. Kleeman[2], M. E. McKeon[1], S. H. Cyrek[1], R. E. Kerl[2] and B. A. Wunderlin[1]. [1]*Covance Laboratories, Inc., Vienna, VA and* [2]*Covance Laboratories, Inc., Madison, WI.* Sponsor: L. E. Beebe.

Identical validation studies were conducted at our Vienna, VA and Madison, WI laboratories, to determine the feasibility of using vendor-supplied precannulated rats, to compare the use and manageability of Fisher-344 and CD® rats, to evaluate the jugular and femoral routes of intravenous infusion, and to assess survival when a known vascular irritant is infused. The results of the two studies were compared to determine the similarities and differences between sites when a common protocol is followed and a harmonized technology is utilized. The rats were precannulated by the supplier (Charles River Laboratories) and eighty animals (10/sex/strain/route) were assigned to each study. Saline (0.9%) was administered to all rats at a rate of 15 mL/kg/1 hour daily, for Days 1-15; from Days 16-30 a 7.5% solution of Solutol HS was infused at the same rate to equal numbers of each sex/strain/route. A standard battery of ante- and post-mortem evaluations were performed, to include mortality, clinical signs, body weights, food consumption, clinical pathology, necropsy findings, and histopathology. Ten rats died, were sacrificed moribund due to sepsis and inflammation of the infusion site, or were removed from each study; the majority (70%) were male CD® rats exposed to Solutol with no predilection for route. Clinical observations included swelling at the cannulation site, primarily in the jugular CD® rats exposed to Solutol. Males of both strains exposed to Solutol had a slight decrease in body weights and food consumption with a less apparent effect in females during Weeks 3 and 4 of treatment. Clinical pathology changes were similar between studies and were primarily related to chronic cannulation (decreased red blood cell mass, increased neutrophil count, and increased globulin). In addition, lower cholesterol values were found in both strains of rats given Solutol. Microscopic evidence of catheter-site abcessation were more frequent in jugular CD® rats at the Vienna site, with no appreciable difference in lesion incidence among groups at the Madison site. These data indicate that similar results were obtained for both studies, precannulated rats are acceptable for use, femoral intravenous infusion is preferred for irritating formulations, and the Fisher rat is a superior model for chronic infusion.

973 ELECTROSPRAY IONIZATION TANDEM MASS SPECTROMETRY (ESI-MS/MS) ANALYSIS OF URINARY METABOLITES OF 1,1,2,2-TETRACHLOROETHYLENE USING AN AUTOMATED SPE SAMPLE PREPARATION SYSTEM.

K. L. Cheever, K. L. Marlow, M. A. Butler, M. A. Torrason and D. G. DeBord. *NIOSH, ETB, Cincinnati, OH.*

1,1,2,2-Tetrachloroethylene [Perchloroethylene] (*PERC*, CAS 127-18-4), used extensively as a dry cleaning agent and in industrial degreasing processes, has been reported to increase the incidence of liver tumors in mice or of nephrotoxicity and renal tumors in male rats. Bioactivation of *PERC* is reported to occur by two pathways, oxidation by CYP2E1 and glutathione *S*-conjugation. Trichloroacetic acid (*TCA*, CAS 76-03-9) and dichloroacetic acid (*DCA*, CAS 79-43-6) are reported urinary metabolites of *PERC* oxidation whereas the glutathione conjugate, *S*-(1,2,2-trichlorovinyl) -L-glutathione (*TCVG*) is further cleaved to *S*-(1,2,2-trichlorovinyl)-L-cysteine (*TCVC*) and acetylated to N-acetyl-*S*-(1,2,2-trichlorovinyl)-L-cysteine (N-ac-*TCVC*). A potential biomonitoring method was developed to measure urinary levels of *TCA*, *DCA*, *TCVC* and N-ac-*TCVC*. Stable isotope-labeled analogs of *TCVC* and N-ac-*TCVC* were prepared (Bartles and Miner, 1989) and deuterated *DCA* was purchased as internal standards. A BenchMate® II robotic workstation was used to automate sample preparation. *PERC* metabolites (>90%recovery) were analyzed using a ThermoQuest Finnegan LCQ tandem mass spectrometer. Chromatographic standards *TCVC* and N-ac-*TCVC* were synthesized as above. Compounds of interest were eluted within 12 min and detected using ESI-MS/MS in multiple segments, initially in the negative ion mode for detection of *TCA* and *DCA*, and subsequently in the positive ion mode for *TCVC* and N-ac-*TCVC*. Urine samples from rats exposed to 100, 500, or 1000 mg/kg *PERC* contained detectable amounts of *PERC* metabolites in urine over a 48-hr period. The LOD per injection was 30 fmol for *TCVC*, 800 fmol for N-ac-*TCVC*, 10 pmol for *DCA*, and 75 pmol for *TCA*. This procedure appears to offer significant advantages over typical extraction and derivatization methods for the same compounds by GC-MS. Thus, *PERC* internal dose for various exposures can be rapidly quantified using metabolites in a single assay using an automated sample preparation system.

974 INDUSTRIAL COMBUSTOR VALIDATION TEST MEASURING AIR EMISSIONS OF DIOXINS AND FURANS ON A TEQ BASIS USING EPA METHOD 23 AND HRGC/HRMS VERSUS THE AMBSTACK SAMPLER AND CALUX BIOASSAY.

G. C. Clark[1], M. Chu[1], D. Touati[2], B. Rayfield[3], J. Stone[4] and M. Cooke[5]. [1]*Xenobiotic Detection Systems, Durham, NC,* [2]*Aceadis, Durham, NC,* [3]*Kilkelly Associates, Raleigh, NC,* [4]*URG Chapel Hill, NC and* [5]*Cooke Companies International, Chapel Hill, NC.*

The analysis of polychlorinated dibenzo-p-dioxin (PCDD) and polychlorinted dibenzofuran (PCDF) in gaseous samples by EPA method 23 and analysis by high resolution gas chromatography/ high resolution mass spectrometry (HRGC/HRMS) is expensive and complex. We have designed a low cost unitized sampling system, the (AmbStack Sampler) and combined it with a reporter gene bioassay system, the Chemical Activated Luciferase Expression method (CALUX), to provide direct TEQ estimates of PCDD/PCDF contamination in air. The current study was designed to compare PCDD/PCDF determinations on a toxic equivalency (TEQ) basis by EPA method 23 and HRGC/HRMS and the AmbStack/CALUX system. In the current experiments simultaneous sampling by both methods were performed on a North American Package Boiler (NAPB) combusting a dopant (a mixture of 1,2 dichlorobenzene and copper naphthenate) at a flow rate adjusted to yield a HCl concentration at the stack of approximately 500 ppm at 7% O_2. The flue gas stream for this experiment was stable at a temperature of 140°C with a moisture level of about 11%. Samples were collected for three hours at a flow rate of 3.58 M^3 and analyzed by both HRGC/HRMS and CALUX analysis. HRGC/HRMS results were 2.75 ng TEQ/dscm (7% O2) versus 3.4 ng

TEQ/dscm (7% O2) by AmbStack/CALUX. EPA method 23 and HRGC/HRMS and AmbStack/CALUX provided similar estimates of TEQ contamination of combustion effluents. The AmbStack/CALUX system is useful as a low cost diagnostic tool to quickly measure PCDD/PCDF emissions from thermal combustion systems allowing optimization of conditions to minimize emissions of these toxic environmental contaminants.

975 DEVELOPMENT OF A HETEROPLASMIC MITOCHONDRIAL DNA STANDARD REFERENCE MATERIAL FOR DETECTION OF HETEROPLASMY AND LOW FREQUENCY MUTATIONS.

L. A. Tully, F. P. Schwarz and B. C. Levin. *National Institute of Standards and Technology, Gaithersburg, MD.*

A heteroplasmic human mitochondrial DNA (mtDNA) standard reference material (SRM) is being developed to provide quality control to medical, forensic and toxicological scientists who wish to determine their detection limits when examining low frequency mutations or heteroplasmic sites in DNA. While the detection of a mutation present in every mtDNA molecule is routine, it is extremely difficult to detect mutations present in only a low proportion of the molecules. In mtDNA diseases, the proportion with the mutation appears to increase with age (i.e., the mutation becomes more predominant in older individuals, who then exhibit the disease symptoms). To address these concerns, mtDNA mixtures containing a polymorphic/wild type site in different percentages (1, 2.5, 5, 10, 20, 30, 40 and 50%) have been constructed. With automated sequencing techniques (ABI 373 or 310), we were able to unambiguously detect the polymorphism present at the 30% level. With Denaturing Gradient Gel Electrophoresis (DGGE), resolution at the 5% level was feasible. With the addition of a Peptide Nucleic Acid (PNA) complementary to the wild type sequence, PCR of the wild type decreased, the mutant DNA selectively amplified, and detection became possible at the 5% level. This SRM can be employed to test and perfect more sensitive mutation detection techniques. Pre-symptomatic mtDNA diseases, once detectable, may become treatable, and perhaps even preventable. These more sensitive techniques may permit toxicologists to detect the effects of chemical and physical mutagens before they cause adverse health and environmental problems.

976 HISTORICAL CONTROL DATA FROM TOXICOLOGY STUDIES IN THE CAT.

L. Bonnet[1], M. Gregoire[1], B. Regnier[1] and J. Descotes[2]. [1]*Phoenix International Preclinical Services, L'Arbresle, France and* [2]*Poison Centre & Inserm U 503, Lyon, France.*

Reference data were compiled from laboratory cats comprising the control groups in experiments performed in our laboratories since 1995. In total, approximately 500 cats were used for various types of study of up to 71 weeks in duration, including: efficacy studies for vaccines or drugs, safety, pharmacokinetics and toxicology. The experimental protocol must take into account the particular environmental needs of the species. Group housing is advisable for long term studies, as are rest areas, scratching planks and toys. Single caging is sometimes necessary for toxicology investigations, but socialisation should be allowed for as long as possible each day. This species is well known for being difficult to handle. Technicians must be well trained, quiet and gentle; moreover, they must like cats! Some types of sophisticated examination routinely performed in other species, such as the dog, require an adaptation when applied to cats (e.g. Doppler-shift sphygmomanometry for blood pressure measurement and vascular access ports for repeated blood sampling in non-anaesthetised animals). The precautions necessary for the purchase, transportation and handling of SPF cats are similar to those used with other species. Physiological, biochemical (blood and urine), haematological and pathology data will be presented.

977 DETERMINATION OF TREMOROGENIC HARMANE AND HARMINE IN HUMAN BLOOD BY A SIMPLE AND RAPID LIQUID CHROMATOGRAPHY METHOD.

Y. Guan[1], W. Zheng[1,2] and E. D. Louis[3]. [1]*Division of Environmental Health Sciences,* [2]*Depts. of Pharmacology &* [3]*Neurology, College of Physicians & Surgeons, Columbia University, New York, NY.*

A number of tremorogenic β-carboline alkaloids such as harmane, harmine, and harmaline have been found in common plant-derived foodstuffs, beverages, and inhaled substances. Because of their natural presence in the food chain, there is a growing concern regarding the potential risks of certain essential tremors associated with the long-term, low-level dietary exposure to these alkaloids. However, the lack of a sensitive quantitative method has rendered it impractical for the risk assessment. The purpose of this study was therefore to develop a simple and rapid analytical method to determine blood levels of two major β-carboline derivatives, harmane and harmine. Human blood was extracted with ethyl acetate and methyl-*t*-butyl ether (2:98) in an alkaline condition. After solvent evaporation, the samples were reconstructed in methanol. The samples were fractionated on a 250x4.6 mm C18 reversed-phase column with an isocratic mobile system consisting of 17.5 mM potassium phosphate buffer (pH 6.5) and methanol (30:70), followed by an on-line fluorescence detection. The method had the detection limit to determine 206 pg/ml and 81 pg/ml of harmane and harmine, respectively, in human blood. The intra-day precision (C.V.) at 25 ng/ml was less than 6.7% and 3.4% for harmane and harmine, respectively. The inter-day precision was 7.3% for harmane and 5.4% for harmine. The method is sensitive and reproducible and has proved useful for both laboratory and clinical studies of β-carboline toxicities. (Supported by NIEHS P30-ES09089.)

978 USING HISTORICAL CONTROL DATA TO QUANTIFY VARIABILITY INHERENT IN STANDARD NEUROTOXICITY MEASURES: FORE- AND HIND-LIMB GRIP STRENGTH AND HIND LIMB FOOT SPLAY.

R. L. Williams[1], M. R. Riggs[1], R. Mandella[2] and B. J. Henry[3]. [1]*Research Triangle Institute, Research Triangle Park, NC.* [2]*Huntingdon Life Science, East Millstone, NJ and* [3]*Rhone Poulenc Ag Company, Research Triangle Park, NC.*

The EPA intends to require registrants of conventional "food use" pesticides, as well as neurotoxic registered pesticides, to submit data from acute, subchronic, and developmental neurotoxicity studies in rats. EPA will use this data in the implementation of the Food Quality Protection Act. To provide a basis for interpretation of neurotoxicity data by the scientific and regulatory communities, historical control data on fore and hind limb grip strength and hind limb foot splay from Huntingdon Life Sciences (HLS) were analyzed by Research Triangle Institute statisticians to identify and quantify all sources of variability inherent in these tests.The control data set was comprised of 31 studies conducted between 1993 and 1999, with 10 animals/sex/study. Evaluations were performed at Days 1,8 and 15 for acute studies, at Weeks 5, 9 and 13 for subchronic studies, and at Week 4 for 28-day studies. There were 2 replicates per evaluation at each time point. The quality assurance-reviewed data set was divided into one subset for each test. The continuous variables were: Body weight, testing interval, digital measure of grip strength or manual measure of landing foot splay. The categorical variables were: rat strain, gender, technician performing the test, equipment number, and study number. The reproducibility of the digital output for fore or hind limb grip strength and the manually measured hind limb landing foot splay was analyzed. Measurement error models were fit to the data to study possible sources of variability; such as, animals, trials, time points, technician, equipment, and studies. The relationships between fore and hind limb grip strength, hind limb grip strength and hind limb landing foot splay, and all three measures were also quantified.

979 ISOLATION OF HUMAN HEMOGLOBIN ADDUCTS AS BIOMARKERS OF EXPOSURE TO ACRYLAMIDE.

C. A. Lanteri and C. J. Bonaventura. *Duke University Marine Laboratory, Beaufort, NC.* Sponsor: M. B. Abou-Donia.

Acrylamide is a commercially important chemical that is used in the drinking water purification process, production of grouting materials, and gel electrophoresis. The Environmental Protection Agency classifies acrylamide as a neurotoxin and a probable human carcinogen. Acrylamide readily and irreversibly forms hemoglobin adducts. Because hemoglobin adducts are not subject to physiological repair mechanisms, acrylamide adducts of hemoglobin may be efficient biomarkers for human exposure. Presently, the exact location of acrylamide adduct formation on the human hemoglobin molecule is unknown. The purpose of the present study is two-fold. First, the extent of acrylamide adduction occurring in oxygenated, deoxygenated, carbon monoxide bound, met, and β-93 cysteine residue blocked purified human hemoglobin (Hb A_0) samples shall be determined. Second, the specific site of adduction on the hemoglobin molecule will be identified. Fulfilling these two goals will provide insight into using human hemoglobin adducts as biomarkers for exposure to acrylamide. Reverse phase high-performance liquid chromatography (HPLC), mass spectrometry, and tryptic peptide maps will aid in the location of acrylamide adducts. Preliminary experiments using spectrophotometry and gel electrophoresis suggest that some aspect of the adduction

process is more available or reactive when Hb A_0 is deoxygenated. β-93 cysteine residues, which have been suggested as possible sites of acrylamide adduction, are much less accessible in deoxygenated Hb A_0. Since deoxygenated Hb A_0 appears to show the greatest amount of adduction, the β-93 cysteine residue site is probably not involved in acrylamide adduct formation.

980 NEITHER DIRECT CHEMICAL NOR CYANIDE ANTAGONISM CAN FULLY EXPLAIN THE ANTIDOTAL EFFECT OF N-ACETYL-L-CYSTEINE ON ACUTE ACRYLONITRILE INTOXICATION.

F. W. Benz, J. Li, D. Corbett and D. E. Nerland. *Department Pharmacology & Toxicology, University of Louisville, Louisville, KY.*

Acrylonitrile (AN) is acutely toxic. Candidate mechanisms for toxicity include metabolism to cyanide (CN), covalent binding (CB) to proteins and depletion of glutathione (GSH). We have previously characterized the dose-dependent toxicokinetics of AN and the biomarkers CN, CB and GSH. We have now studied the effect of three mechanism-based antidotes on these parameters. Benzylimidazole (BI, 1mg/kg) blocks metabolism to CN. Thiosulfate (TS, 1g/kg) serves as a sulfur donor in CN detoxification. N-acetyl-L-cysteine (LNAC, 2mmol/kg) may 1.) decrease AN body burden by direct chemical antagonism, 2.) serve as a GSH precursor and 3.) serve as a sulfur donor like TS. Rats were given AN sc in the scruff of the neck and antidotes were administered ip simultaneously. Following AN-LD90 (2.2mmol/kg), all antidotes abolished the area under the curve (AUC) for CN in blood and brain but only LNAC decreased the AUC for AN in blood. However, this AUC for AN was much greater than that seen following AN-LD50 (1.5mmol/kg) alone. Tissue CB was not markedly changed by any antidote and only LNAC attenuated AN-induced GSH depletion. In rats treated with AN-LD90 + LNAC, blood levels of AN, LNAC and GSH were comparable (~1mM) and steady for the first 30 min. However, during this same time interval, liver GSH decreased over 90%. Mortality in rats given AN-LD90 + antidotes was 100% for saline, BI and TS but 10% for LNAC. We conclude that, although CN undoubtedly contributes to AN toxicity, abolishing the acutely toxic AUC for CN is not sufficient to preserve life. In addition, direct chemical antagonism of AN by LNAC in blood does not occur to any significant extent. (Supported by NIEHS ES 06141.)

981 IDENTIFICATION OF SITES OF HUMAN SERUM ALBUMIN MODIFICATION BY 2,4- AND 2,6-TOLUENE DIISOCYANATE.

R. Lemus, B. W. Day and M. H. Karol. *Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA, PA.*

Toluene diisocyanate (TDI), a 4:1 mixture of 2,4- and 2,6- isomers used in the preparation of polyurethanes, is a recognized cause of occupational asthma. We have previously shown that the TDI isomers react readily with thiolated molecules. Clinical and experimental evidence indicates that serum albumin is adducted by TDI following inhalation of the chemical. We have in order to determine the site(s) of TDI binding to the protein and the significance of the adduct(s) to sensitization and asthma, we utilized radiolabelled TDI. Twenty fold molar excess human serum albumin was dissolved in PBS, pH 7.4 and reacted separately with custom prepared [14C]- 2,4 and [14C]- 2,6 TDI. The adducted protein was then subjected to four different proteolysis conditions without prior disulfide bond reduction: pronase E, trypsin, V8 and cyanogen bromide (CNBr) cleavage. Samples of both the digest and control where reduced with dithiothreitol (DTT) and analyzed by SDS-PAGE. The CNBr induced cleavage reaction was potentially the most informative regarding elucidation of site(s) of reaction by gel electrophoresis. CNBr cleavage bands, stained with Coomassie Blue, were excised from the gel, the proteins were eluted and evaluated for 14C content by liquid scintillation spectrometry. For 2,4-TDI, the majority of the 14C label, in non-reduced samples, was located in bands having apparent molecular weights of 49, 29, and 15 Kda. For non-reduced samples of 2,6-TDI, the label was located in bands of 29 and 15 Kda. Autoradiography confirmed the results for both isomers. Interestingly, fragments treated with DTT prior to SDS-PAGE retained little radiolabel suggesting that TDI was bound to thiol labile site(s). Two such sites of thiol lability on HSA are the free thiol (cysteine-34) and carboxylate residues. Further purification and analysis of the adducted peptides will provide information of the nature of the adducts and of the amino acids adducted. Such information will be invaluable for elucidation of the antigens involved in TDI hypersensitivity and asthma. (Supported by NIEHS 05651.)

982 EVIDENCE FOR THE PRESENCE OF A PUTATIVE AH RECEPTOR LIGAND IN CV-1 CELLS.

C. R. Chiaro[1], C. Marcus[2] and G. H. Perdew[3]. [1]*Graduate Program in Genetics, The Pennsylvania State University, University Park, PA,* [2]*College of Pharmacy, University of New Mexico, Albuquerque, NM and* [3]*Department of Veterinary Science, The Pennsylvania State University, University Park, PA.*

The Ah receptor is a ligand activated transcription factor which has been shown to be largely responsible for mediating the cellular response to numerous environmental compounds such as 2,3,7,8-tetrachlorodibenzo-p-dioxin. A role for the AhR in normal cellular biology has been previously postulated, but no endogenous ligand has yet been identified. The presence of a putative endogenous ligand has been determined by transient transfection of cultured CV-1 cells with various cytochrome P450 isoforms. CYP1A1, CYP1A2, CYP1B1, CYP2E1 and CYP3A4 expression vectors were transiently co-transfected into cultured CV-1 cells along with an AhR expression vector (pcDNA3/bmAhR) and the DRE-driven reporter (pGudLuc6.1). The subsequent effect of P450 expression on DRE-driven luciferase reporter activity was assayed. Expression of either CYP1A1, CYP1A2 or CYP1B1 in CV-1 cells reduced DRE-driven reporter activity in a concentration dependent fashion with the highest level of expression essentially abolishing reporter activity. Neither CYP2E1 nor CYP3A4 expression demonstrated any significant reduction in endogenous ligand levels as assayed through DRE-driven reporter activity. A stable CV-1 cell line was generated through stable co-transfection of CV-1 cells with CYP1B1 (pRc/CMV/1B1) along with a hygromycin resistance encoding vector (pRep). This resulted in a clone which displays an approximate 16-fold reduction in DRE-driven luciferase reporter activity when compared to control CV-1 cells co-transfected with pcDNA3/bmAhR and pGudLuc6.1. Cytosolic extracts generated from these two cell lines were fractionated on a C-18 microbore HPLC column using a 70% MeOH isocratic gradient. Fractions were collected, dried and then further analyzed for ligand activity in HepG2 40/6 cells which contain a stably integrated DRE-driven reporter construct. Many of the strong induction peaks identified in the CV-1 cytosolic extracts were absent in the CV-1/1B1 Clone-7 control cell line confirming the presence of putative AhR ligands which are capable of undergoing CYP1B1 metabolism to a less active product.

983 FUNCTIONALY IMPORTANT PHOSPHORYLATION SITES IN XAP2, A MEMBER OF THE UNLIGANDED ARYL HYDROCARBON RECEPTOR COMPLEX.

A. B. Dull[1] and G. H. Perdew[2]. [1]*Graduate Program in Genetics, Pennsylvania State University, University Park, PA and* [2]*Department of Veterinary Science, Pennsylvania State University, University Park, PA.*

Exposure to Xenobiotics such as 2,3,7,8 tetrachlorodibenzo(p)dioxin (TCDD) may result in a myriad of deleterious effects such as tumor promotion, wasting syndrome, and immunotoxicity all of which are mediated by the aryl hydrocarbon receptor (AhR) pathway. AhR is a ligand activated transcription factor that prior to exposure to dioxin, exists as a cytosolic 9S heterocomplex consisting of one molecule of AhR, a hsp90 dimer, and a immunophilin-like protein known as the Hepatitis B virus X-associated protein 2 (XAP2). The regulatory role of XAP2 in the AhR signal transduction pathway is being studied through examination of phosphorylation status. Two-dimensional phosphoamino acid analysis has demonstrated that this protein is primarily phosphorylated on serine residues. Identification of important phosphorylation sites was facilitated by the creation of serine to alanine mutations in XAP2-FLAG using site-directed mutagenesis. Loss of phosphorylation with these S to A mutations was identified through the following techniques: 32 P-orthophosphate labeling of COS-1 cells that were transiently transfected with XAP2-FLAG and S to A XAP2-FLAG expression vectors, anti-FLAG immunoprecipitations, tricine polyacrylamide gel electrophoresis, transfer to membrane, tryptic digestion of the radiolabeled protein, followed by peptide mapping techniques. Four S to A XAP2-FLAG mutants (43, 53, 131-2) exhibited loss of phosphorylation. Western blot analysis has determined that the S43A XAP2-FLAG mutant was unable to complex with hsp90 in COS-1 cells, while the S53A XAP2-FLAG mutant had decreased affinity for hsp90 COS-1 cells. The S43A XAP2-FLAG mutant would not radiolabel upon use of high levels of 32 P-orthophosphate, even though Western blot analysis determined that the protein was being expressed well. This data suggests that 43 could be a major phosphorylation site that may possibly influence phosphorylation of other serine residues in XAP2-FLAG. In conclusion, these results suggest that phosphorylation is essential for XAP2-FLAG to function properly in the cell.

984 PHOSPHORYLATION OF A PAS-REGION ARNT SERINE RESIDUE DOES NOT MODULATE ARNT:AHR OR ARNT:ARNT ACTIVITY.

S. L. Levine, D. B. Carlson and G. H. Perdew. *Department of Veterinary Science, Pennsylvania State University, University Park, PA.*

The ARNT protein belongs to the family of bHLH-PAS transcription factors and regulates a range of cellular processes by either homodimerizing or heterodimerizing with other bHLH-PAS proteins. Previously, the human ARNT protein was shown to be a phosphoprotein, but regulation of ARNT with respect to its phosphorylation status is poorly understood. Phosphoaminoacid analysis of [32P]-orthophosphate labeled human ARNT in COS-1 cells demonstrated that ARNT is predominantly phosphorylated on serine residues and several serine/threonine protein kinases phosphorylated bacterially expressed ARNT truncations *in vitro*. Solid-phase radio-sequencing of a tryptic phosphopeptide predicted one of the serine residues within the PAS-region as a probable phosphorylation site. Site-directed mutagenesis was used to change this serine residue to alanine and then two-dimensional phosphopeptide maps were generated to demonstrate the loss of the predicted PAS-region phosphorylation site. Both alanine and glutamic acid mutants were compared with the wild-type in an ARNT deficient cell line for their capacity to either (i) modulate activation of aryl hydrocarbon receptor (AhR) mediated reporter-vector expression in the presence and absence of tetrachlorodibenzo-p-dioxin or (ii) modulate an ARNT homodimer activated class B E-box reporter-vector expression. Changing this PAS-region serine residue to either an alanine or a glutamic acid did not influence AhR mediated or class B E-box-driven reporter activity. Although phosphorylation of this PAS-region serine does not modulate AhR:ARNT or ARNT:ARNT activity, this phosphorylation site may be important in other ARNT mediated expression systems.

985 NUCLEAR RECEPTOR COACTIVATOR, SRC-1 INTERACTS WITH Q-RICH SUB-DOMAIN OF THE AHR AND MODULATES ITS TRANSACTIVATION POTENTIAL.

M. B. Kumar[1] and G. H. Perdew[2]. [1]*Graduate Program in Biochemistry, Microbiology and Molecular Biology, The Pennsylvania State University, University Park, PA and* [2]*Department of Veterinary Science, The Pennsylvania State University, University Park, PA.*

The Aryl hydrocarbon Receptor (AhR), a soluble cytosolic protein, mediates many of the toxic effects of TCDD and related chemicals. The toxic effects are largely cell-, tissue-, and promoter context dependent. Although many details of the overall dioxin signal transduction have been elucidated, the transcriptional regulation of dioxin induced genes like cyp1A1 is not completely understood. Previously, we have shown that the co-regulator RIP140 is a potential AhR coactivator. The role of coactivator, SRC-1 in AhR-mediated transcriptional regulation was examined. SRC-1 increased AhR-mediated, TCDD-dependent, reporter gene activity 3.2- and 3-fold in Hepa-1 and COS-1 cells, respectively. In *in vitro* interaction assays, SRC-1 was found to interact with AhR and not with ARNT. Although SRC-1 interacted with AhR even in the absence of TCDD, the addition of ligand further increased SRC-1 binding to AhR. Deletional mapping studies of the AhR domain that interacts with SRC-1 revealed that SRC-1 binds to the AhR transactivation domain. Finer mapping of the SRC-1-interacting sub-domains in the AhR transactivation domain suggested that the Q-rich sub-domain was necessary and sufficient for interaction, similar to that seen with RIP140 and the AhR. Using GFP-tagged constructs and co-immunoprecipitation assays, SRC-1 was shown to interact with AhR in cells. Unlike RIP140, LXXLL motifs in SRC-1 were necessary for interaction with AhR *in vitro* and for co-activation in Hepa-1 cells. This study demonstrates the potential role of SRC-1 in AhR transactivation, as well as possible differences in the mechanisms of RIP140 and SRC-1 recruitment to the AhR transactivation domain.

986 ACTIVATION OF EXTRACELLULAR SIGNAL-REGULATED KINASES (ERKS) BY 2,2',4,4'-TETRACHLOROBIPHENYL IN RAT LIVER CELLS: ROLE OF CALCIUM.

B. V. Madhukar, X. Y. Zeng and O. M. Hernandez. *Michigan State University, East Lansing, MI.*

Polychlorinated biphenyls (PCBs) are widespread environmental contaminants. Much evidence indicates that exposure to PCBs can cause a number of toxic effects such as heptoxicity, reproductive and immunotoxicty etc. Although PCBs occur as mixtures in the environment, the various congeners present in the mixtures can be broadly grouped as coplanar, non-coplanar and mixed type congeners. Unlike the coplanar PCBs that exert their toxic effects by binding to the Ah-receptor, the non-coplanar PCBs do not bind with the Ah-receptor. The tumor promoting and neurotoxic effects of this group of PCBs suggest their interaction with other cellular components. In this study we investigated the effects of 2,2',4,4'-tetrachlorobiphenyl (TCB) and other PCB congeners on mitogen activated protein kinase (MAPK) signal transduction pathway involving ERK 1 and 2 in WB rat liver epithelial cells as a mechanism of their epigenetic effects. Activation of ERKs in PCB treated WB cells under various conditions was assessed by immunoblotting with phosphorylation (activated) state specific ERK antibodies. The results suggested that 2,2'4,4'-TCB activated ERKs 1 and 2 in a dose-dependent manner. Activation of ERKs sustained for up to at least 6 hrs. At 24 hrs after treatment there was a loss of activated ERKs. In contrast 3,3,',4,4'-TCB a coplanar PCB congener did not activate ERKs even at 20 μM. Activation of ERK by 2,2,4,4'-TCB was not inhibited by genistein (50 mM) a tyrosine kinase inhibitor, bisindoloylmaleimide (5 mM) a protein kinase C inhibitor, suggesting that two kinase families were not involved in ERK activation by 2,2',4,4'-TCB. ERK activation by TCB was not inhibited by manumycin a ras protein inhibitor, radicicol an inhibitor of raf-1 kinase or KN-93 an inhibitor of CaM kinase II. However, when the extracellular calcium was removed from the medium ERK activation by this agent was significantly decreased. Taken together, our results suggest that extracellular calcium-dependent cellular processes were involved in ERK activation by 2,2',4,4'-TCB. (Supported by NIEHS grant ES-04911.)

987 EXPRESSION OF TYPE XII COLLAGEN AND EMMPRIN IN NORMAL AND HYPOXIC PULMONARY ARTERIES.

M. K. Gordon[1], R. Hahn[1], P. Zhou[1], P. Bhatt[1], M. Goyal[1], L. Sharma[1], D. Heck[1], J. D. Laskin[1], D. Laskin[1], G. Chen[2], N. A. McHugh[2], C. A. Tozzi[2], D. J. Riley[2] and D. R. Gerecke[1]. [1]*Rutgers University, Piscataway, NJ and* [2]*UMDNJ, Robert Wood Johnson Medical School, Piscataway, NJ.*

Pulmonary hypertension causes an increase in deposition of extracellular matrix material, particularly fibrillar collagen, in the adventitial tunic of the arteries. In a rat model, pulmonary vessels can be made hypertensive by hypoxia. If the animal is returned to ambient air within a couple of weeks, the condition is reversible, as long as the endothelium is intact. Type XII collagen is a molecule associated with collagen fibrils. Lying on the surface of the fibrils, it bridges, organizes and stabilizes fibrillar collagen arrangement. We have examined the expression of the mRNA for type XII collagen in normal, hypertensive and restored pulmonary vessels. We have also examined the expression of mRNA for EMMPRIN, an endothelial product that is a matrix metalloproteinase inducing molecule. As vessels produce excessive matrix and become hypertensive in response to anoxia, type XII collagen mRNA increases and EMMPRIN decreases. The MMP-inducing EMMPRIN mRNA increases in amount when the animal is returned to ambient oxygen, beginning the matrix degradation and the vessel structure remodelling that occurs in the return to a more normal phenotype. Once remodeling has occurred, the EMMPRIN mRNA amounts return to normal. These results give some insight into how the deposition of excessive amounts of fibrillar collagen may be stabilized in the hypertensive adventitia, and what may trigger the matrix metalloproteinases to remove it, to restore the vessel to a normal phenotype.

988 DIFFERENTIAL ACTIVATION OF C-HA-RAS ARE/EpRE BINDING PROTEINS BY BENZO[A]PYRENE AND THAPSIGARGIN IN VASCULAR SMOOTH MUSCLE CELLS.

K. P. Miller and K. S. Ramos. *Faculty of Toxicology & Center for Environmental and Rural Health, Texas A&M University, College Station, TX.*

Efforts in this laboratory have focused on the characterization of vascular smooth muscle cell (vSMC) proteins that interact with the antioxidant/electrophile response element (ARE/EpRE) of *c-Ha-ras*. UV crosslinking studies have shown that multiple proteins of comparable molecular weights bind to *c-Ha-ras*, r*GSTYa* and *NQO$_1$* ARE/EpREs, though several unique proteins recognize the *c-Ha-ras* sequence. The present studies were conducted to gain further insight into the cellular localization of *c-Ha-ras* ARE/EpRE binding proteins, and their relative contribution to formation of specific DNA/protein complexes in response to benzo(a)pyrene (BaP) and thapsigargin. Our results showed that both nuclear and cytosolic vSMC proteins bind to the *c-Ha-ras* ARE/EpRE in BaP (3uM) -treated cells, yielding two complexes of comparable migration and apparent composition. Under more stringent nuclear protein extraction conditions, we also identified a third ARE/EpRE complex that was inducible by BaP (3uM) within 0.5 hours, and reached maximal induction by 2 hours. A fourth BaP-inducible ARE/EpRE complex was also identified, though it represented a minor component of total DNA binding activity.

Treatment of vSMCs with thapsigargin to release intracellular Ca^{2+}stores markedly induced the minor ARE/EpRE complex, along with two of the complexes observed in BaP-treated cells. Although the predominance of BaP- and thapsigargin- inducible complexes differed, the relative protein composition profiles in UV crosslinking gels was comparable for both treatments. Thus, inducible *c-Ha-ras* ARE/EpRE binding in vSMCs involves unique proteins that contribute to differences in complex formation in response to BaP and thapsigargin. (Supported by NIH Grants ES04849 and ES 09106.)

989 MECHANISMS OF C-HA-RAS ACTIVATION IN VASCULAR SMOOTH MUSCLE CELLS BY BENZO[A]PYRENE.

R. P. Metz, Y. Zhang and K. S. Ramos. *Faculty of Toxicology & Center for Environmental and Rural Health, Texas A&M University, College Station, TX.*

Increased vascular smooth muscle cell (vSMC) proliferation and migration to the intima are early events in atherogenesis. Benzo[a]pyrene (BaP), a known carcinogen and atherogen, increases *c-Ha-ras* mRNA levels in vSMCs, and this response is believed to contribute to the appearance of proliferative (i.e. atherogenic) phenotypes. The purpose of these studies was to evaluate the mechanism of increased *ras* expression following BaP exposure in vSMCs. Multiple putative BaP-responsive regulatory DNA elements are discernable in the mouse ras promoter (i.e. electrophile and aryl hydrocarbon response elements), suggesting a transcriptional activation mechanism. Nuclear run-off experiments using vSMC nuclei demonstrated that BaP causes an increase in the rate of *c-Ha-ras* transcription. BaP-induced ras expression was not associated with mutations in the IDX alternative splice site- a mutation known to effect ras expression. Treatment of vSMCs with actinomycin D prior to BaP exposure resulted in decreased ras mRNA levels indicating that increased mRNA stability did not contribute to increased steady state mRNA levels. The mouse ras gene has been shown to utilize at least three different transcription start points located at -1045, -1030 and -1012 with respect to the first codon. Primer extension analysis was performed to determine if BaP alters transcription start point utilization during *ras* expression. Several novel transcription start sites were detected between bases -999 and -1284, however, the pattern of start sites was the same in vehicle- and BaP-treated vSMCs. Taken together, these results confirm that BaP increases expression of the *ras* gene in vSMCs through a transcriptional activation mechanism. (Supported by NIH Grants ES 04849 and ES 09106.)

990 GENERATION OF MUTANT GLUTATHIONE S-TRANSFERASE P1 CDNAS BY RANDOM MUTAGENESIS OF GSTP1C.

S. Gullung and F. Ali-Osman. *UT M.D. Anderson Cancer Center, Houston, TX.*

Glutathione S-transferase P1, a major drug and electrophile metabolizing and detoxifying enzyme was shown recently to be encoded by a polymorphic gene locus, a result of nucleotide transitions in the region encoding the active site of the peptide. The resulting variant GSTP1 proteins exhibit significant functional differences. We propose that the active site of the GSTP1 peptide can be mutated to generate other GSTP1 cDNAs that encode GSTP1 peptides with more potent drug metabolizing activity. Such mutants can be used to confer resistance to otherwise toxic compounds including, mutagens, carcinogens, and anticancer agents. In this study, we describe the use of the technique of Degenerate Oligonucleotide Mediated Random Mutagenesis (DOMRM) to create mutant GSTP1 cDNAs. Since Try108 is a critical amino acid in the GSTP1 active site and AA104 is involved in the GSTP1 polymorphism, the degenerate primers were designed to facilitate amino acid substitutions at codons 104 and 108. The primers ranged between 20 to 100 nucleotides in length to improve template annealing. The degenerate primers spanned nucleotides of codons 103 to 110 with a change rate of 2 nucleotide per oligonucleotide, which should allow for the creation of mutant cDNAs, each coding a polypeptide whose primary structures differ by at least one amino acid. A nucleotide sequence (6 bases) with a mutation rate of zero was added to the 5' and 3' ends of the oligonucleotides to protect the integrity of the mutation rate throughout the primer. Using this strategy, we successfully generated random mutant GSTP1 cDNAs, which were subsequently ligated into the expression vector pBK-CMV. Structural and functional characterizations of the novel mutants are presently ongoing.

991 VIMENTIN GENE EXPRESSION IS ALTERED IN THE CENTRAL NERVOUS SYSTEM (CNS) OF HENS TREATED WITH DIISOPROPYLPHO-SPHOROFLUORIDATE (DFP).

T. R. Damodaran and M. B. Abou-Donia. *Duke University Medical Center, Department of Pharmacology and Cancer Biology, Durham, NC.*

A single dose of DFP (1.7 mg/kg/s.c.) produces delayed neurotoxicity in hens in 7-14 days. DFP produces OPIDN by altering the levels and functions of serveral cytoskeletal proteins including enzymes. Vimentin plays an important role in the maintenance of brain homeostasis vital for neuronal survival after injury. Hence, we carried out a time course study in which hens were sacrificed at different time points; 1,2,5,10,20 days after intramuscular administration of DFP. Total RNA was extracted from brain regions, cerebrum, cerebellum, and brainstem as well as the spinal cord. Northern blots were prepared and hybridized to vimentin c-DNA probe. The results indicate that vimentin levels were down-regulated in spinal cord at 1 and 2 days to 47% and 50 % respectively. There was a moderate increase to 65% at 5 days and the levels remained at 58% and 61 % for 10 and 20 days, respectively. In brainstem the mRNA levels were down-regulated to 55% and 53% at 1 and 2 days, respectively and stayed at 62% and 65% during 5 and 10 days. At 20 days the levels decreased further to 53%. Hence the mRNA levels in susceptible tissues (brainstem and spinal cord) never recovered to control levels at 20 days. In contrast there was no decline in the transcript level in cerebrum(non-susceptible tissue) at 1 day (98%) and levels were up-regulated to 134%, 123% at 2 and 5 days respectively. On the other hand, the message levels returned to near control values at 10 and 20 days (105% and 97% respectively). In cerebellum (which is also a susceptible tissue) after an initial decline at 1 and 2 days (77% and 46% respectively), vimentin levels were re-induced rapidly (128%) at 5 days and stayed at the same levels (128%) until 10 days. The transcript levels came down to control vaules (101%) at 20 days. The differential and distinctive expression pattern of vimentin in DFP-induced OPIDN indicate its possible role in the astroglial pathology leading to CNS injury and axonal degeneration. 992 IMPACT OF CHEMICALLY-INDUCED OXIDATIVE STRESS ON CADHERIN/CATENIN COMPLEXES.

V. J. Schmid[1], M. Schmelz[2] and A. R. Parrish[1]. [1]*Texas A&M University System Health Sciences Center, College Station, TX,* [2]*University of Arizona College of Medicine, College Station, TX.*

Previous work has shown that chemically-induced oxidative stress disrupts the protein interactions of the E-cadherin/β-catenin/α-catenin complex in precision-cut mouse liver slices. Although these data suggest a role for oxidative stress in disruption of cell-cell adhesion mediated by cadherin/catenin complexes, our understanding of these effects are confounded by the fact that the composition of cadherin/catenin complexes is not homogenous in the liver. Both E- and N- cadherin are expressed in the liver, as well as β- and γ-catenin; thus four distinct complexes mediate cell-cell adhesion in the liver: E-cadherin/β-catenin/α-catenin; E-cadherin/γ-catenin/α-catenin: N-cadherin/β-catenin/α-catenin; N-cadherin/γ-catenin/α-catenin. Taking advantage of the retention of normal cellular heterogeneity offered by precision-cut mouse liver slices, the current study was designed to examine the impact of chemically-induced oxidative stress on cadherin/catenin complexes. Precision-cut mouse liver slices were challenged with diamide [25-250 μM; 6 hr] or tert-butylhydroperoxide [5-50 μM; 6 hr]. A polyclonal antibody against γ-catenin was used to immunoprecipitate proteins prior to Western blot analysis with monoclonal antibodies to E- or N-cadherin. Interestingly, no effect on protein interactions of γ-catenin with either cadherin was observed. Indirect immunofluorescence was used to co-localize catenins and cadherins following chemical challenge. A heterogeneous reduction in co-localization was seen in precision-cut liver slices. Taken together, these data suggest that oxidative stress selectively disrupts cadherin/catenin complexes in the liver. This response is dictated, in part, by the protein composition of the cell adhesion complex. (Supported by NIEHS center grant 09106.)

993 THIOL DISULFIDE REDOX IN GROWTH CONTROL OF HT29 CELLS.

L. T. Miller, J. Cai, W. H. Watson, P. Sternberg and D. P. Jones. *Emory University, Atlanta, GA.*

Redox sensitive proteins have been shown to effect changes in cell proliferation. To determine whether extracellular redox conditions affect cell proliferation in HT29 cells, we grew cells in cysteine-containing medium with additions of either cystine or GSSG to shift redox potential (Eh) to a more oxi-

dized condition. Cell proliferation rates were measured by both tritiated thymidine incorporation and BrdU incorporation. Results show that cell proliferation rate varied as a function of thiol-disulfide redox state. Over the range of Eh found for GSSG/GSH and cysteine/cystine pools in human plasma (-50mV to -130mV), the rate approximately doubled. As a model system to determine whether changes in the redox state of intracellular proteins occurred under these conditions, we examined the redox state of thioredoxin *in vivo*. Protein extracts were carboxymethylated, and modified proteins were separated by polyacrylamide gel electrophoresis under native conditions. Bands corresponding to varying redox states of thioredoxin were identified by western blot. Results show that thioredoxin is more oxidized in cells cultured in a more oxidized condition. These experiments demonstrate that changes in extracellular redox conditions induce changes in cell proliferation, and that corresponding changes in the state of an intracellular protein can be assessed by western blot of carboxymethylated cell lysates. 994 TOXICANT- & PROSTAGLANDIN-MEDIATED INDUCTION OF ELONGATION FACTOR 1α.

K. M. Towndrow, H. H. Lo, T. J. Monks and S. S. Lau. *The University of Texas at Austin, Austin, TX.*

Prostaglandins (PGs) have many diverse, and often opposing, roles in cellular signaling pathways. In a model of toxicant-induced nephrotoxicity, PGE_2 and its stable synthetic analog, 11-deoxy-16,16-dimethyl PGE_2 (DDM-PGE_2), protect renal epithelial cells (LLC-PK_1) against 2,3,5-*tris*-(glutathion-*S*-yl)hydroquinone [TGHQ]-induced cytotoxicity via an unknown receptor-mediated mechanism(s). ^{35}S-methionine labeling of newly synthesized proteins following treatment of LLC-PK_1 cells with DDM-PGE_2 revealed the induction of a number of proteins. Electrospray mass spectrometric analysis identified in-gel tryptic digests of two ^{35}S-methionine labeled proteins to be elongation factor 1α (EF-1α) and actin. EF-1α is a critical actin-binding protein involved in peptide elongation during protein synthesis, which is also found in close association with the cytoskeleton. DDM-PGE_2 (1 μM, 24 h) induced EF-1α synthesis 12 fold as indicated by western blot analysis. The role of EF-1α, if any, in the cytoprotective mechanism(s) of DDM-PGE_2 remains to be determined. However, it is possible that elevated EF-1α levels may protect kidney cells from acute toxicity by facilitating the synthesis of additional cytoprotective proteins. Indeed, EK-3 cells (a TGHQ-transformed Eker rat-derived renal epithelial cell line) exhibit elevated constitutive EF-1α levels, which were further increased following additional exposure to TGHQ (300 μM; 1h). TGHQ also induced EF-1α synthesis in LLC-PK_1 cells (4 fold; 300 μM, 2 h). Moreover, TGHQ-induced tumors in Eker rats express elevated EF-1α levels. The ability of TGHQ to increase EF-1α synthesis, and elevated EF-1α expression in TGHQ-induced tumors, may indicate a role for EF-1α and PGs in TGHQ-mediated nephrocarcinogenicity. 995 CHANGES IN HISTONE PHOSPHORYLATION IN RESPONSE TO QUINOL THIOETHER INDUCED ONCOTIC AND APOPTOTIC CELL DEATH.

K. Tikoo, S. S. Lau and T. J. Monks. *Division of Pharmacology & Toxicology, College of Pharmacy, University of Texas at Austin, Austin, TX.*

Chromatin structure plays an important role in regulating gene expression. Histones are essential for maintaining chromatin structure and are therefore intimately involved in modulating gene expression. A role for the post-translational modification of histones in apoptosis has been proposed, but remains a subject for debate. In contrast, little information is available on histone modification during oncotic cell death. We have previously shown that 2,3,5-tris-(glutathion-S-yl)hydroquinone (TGHQ) induces growth arrest and cell death in human leukemia cells (HL-60) and porcine renal proximal tubular epithelial cells (LLC-PK1). We therefore compared histone phosphorylation patterns during TGHQ induced apoptosis of HL-60 cells and TGHQ induced oncosis of LLC-PK1 cells. TGHQ induced apoptosis in HL-60 cells is preceded by dephosphorylation of histone H2A. Because phosphorylation of histone H2A occurs throughout the cell cycle the results suggest that dephosphorylation of H2A may be due to growth arrest, which precedes apoptosis. In contrast, although TGHQ induced LLC-PK1 cell oncosis is also preceded by dephosphorylation of histone H2A, this is followed by the subsequent phosphorylation of histone H3. Phosphorylation of histone H3 at Ser-10 and Ser-28 plays an important role in chromatin condensation during mitosis and during premature chromosome condensation (PCC). Consistent with this, chromatin sensitivity to micrococcal nuclease, which preferentially cleaves active chromatin, decreases in response to TGHQ in LLC-PK1cells. Collectively, these results suggest that during oncosis LLC-PK1cells attempt to engage PCC, which leads to mitotic catastrophe and cell death (ES 07359, ES 07784).

996 POTENTIAL INVOLVEMENT OF PROTEIN PHOSPHATASE 2B AND ROTAMASE IN NORMALIZATION OF GAP JUNCTIONAL COMMUNICATION AND CONNEXIN43 PHOSPHORYLATION AFTER EXPOSURE OF V79 FIBROBLASTS TO A PHORBOL ESTER.

T. Sanner, V. Cruciani and S. O. Mikalsen. *Department of Environmental and Occupational Cancer, Norwegian Radium Hospital, Oslo, Norway.* Sponsor: E. Dybing.

Several kinases have been implicated in the regulation of gap junctional intercellular communication (GJIC), presumably through phosphorylation of the gap junction proteins. Connexin43 (Cx43) is one of the major gap junction proteins in the body. In many cell types, including V79 Chinese hamster lung fibroblasts, the Cx43 phosphorylation status may profoundly change concurrently with a strong inhibition of GJIC after activation of protein kinase C by 12-*O*-tetradecanoylphorbol 13-acetate (TPA). After removal of TPA, both parameters normalize within 3-4 hours, even in the presence of cycloheximide, indicating independence of protein synthesis. We have here studied the potential involvement of phosphatases in the normalization process. Protein phosphatase (PP) 1 and 2A inhibitors (okadaic acid, calyculin A) had no effect, while PP2B inhibitors (cyclosporin A, FK506) delayed the normalizations by about 1 hour. Cyclosporin A and FK506 are dependent on accessory proteins called cyclophilins and FK506-binding proteins (FKBPs) for the inhibition of PP2B. These proteins possess rotamase activity. The rotamase activity of FKBPs is also inhibited by rapamycin, an agent that does not inhibit PP2B. Rapamycin had no effect of the normalization of GJIC after TPA exposure, but surprisingly, it delayed the normalization of Cx43 phosphorylation status even more than cyclosporin A and FK506. Furthermore, TPA causes disappearance of gap junction plaques in immunofluorescence experiments. Cyclosporin A, FK506 and rapamycin delayed the normalization of reappearance of Cx43-containing gap junction plaques. These results may suggest that PP2B is involved in the normalization of GJIC after TPA exposure, while rotamase activity is involved in the normalization of Cx43 phosphorylation status.

997 ROLES OF MITOGEN-ACTIVATED PROTEIN KINASES IN OXIDATIVE STRESS MEDIATED CELL DEATH SIGNALING IN LLC-PK1 CELLS.

Q. Huang, S. S. Lau and T. J. Monks. *University of Texas at Austin, Austin, TX.*

The mitogen-activated protein (MAP) kinase family mediates important signal transduction pathways in response to diverse external signals. 2,3,5-*tris*-(glutathion-*S*-yl)hydroquinone (TGHQ) is a potent nephrotoxicant and nephrocarcinogen causing cell death in a reactive oxygen species (ROS) dependent manner. The extracellular signal-regulated kinases (ERKs) and c-Jun N-terminal kinases (JNK/SAPK) are rapidly phosphorylated in renal proximal tubule epithelial cells (LLC-PK_1) following treatment with TGHQ, which also depends upon the generation of ROS. We now report that the activity of ERKs is elevated 4 fold 30 min after TGHQ treatment. Consistent with their phosphorylation pattern, activation of ERKs is transient and returns to constitutive levels by 5 hr. Moreover, the phosphorylation of p38 also increases in response to TGHQ treatment as evidenced by western blot analysis. We have previously shown that activated ERKs and p38 appear to contribute to cell death signaling, as inhibition of ERKs or p38 by PD098059 and SB202190 protected cells against TGHQ mediated cell death. In addition, TGHQ strongly activates the AP-1 and NFκB transcription factors. The DNA binding activity of AP-1 is abrogated by PD098059 and SB202190, presumably as a consequence of the decreased stress signaling. However, both kinase inhibitors potentiated TGHQ mediated NFκB activation. Furthermore, a NFκB inhibitory peptide partially reverses PD098059 mediated protection against cell death, suggesting that NFκB activation is an important element of the stress response. Taken together, the activation of MAP kinases, especially ERKs, plays a key role in cell death signaling in response to TGHQ induced oxidative stress in LLC-PK1 cells, and suppression of NFκB by MAP kinases may be involved in this cascade. (ES 07359, ES07784.)

998 THE EFFECTS OF MAP EXPRESSION ON METHYLMERCURY-INDUCED MICROTUBULE DISASSEMBLY.
