The sensitivity of microtubules (MTs) to methylmercury- (MeHg) induced disassembly was compared in undifferentiated, MAP1A- and MAP2C-transfected, and neuronally-differentiated P19 Embyronal Carcinoma (EC) cells. The extent of MT disassembly was examined qualitatively by mmunofluorescence microscopy and Western blotting and quantitatively by dot blotting of polymer and soluble proteins extracts. Immunofluorescence microscopy showed that MeHg disassembled MTs in a time- and dose-dependent manner and that MTs in both MAP2C-transfected and neuronally differentiated cells, but not those in MAP1A-transfected cells, were significantly more resistant to MeHg-induced MT depolymerization than those in undifferentiated cells. These results suggest that MAP2C has a greater ability to stabilize MTs against MeHg-induced disassembly than MAP1A. Surprisingly, however, when the extent of MT disassembly was assessed by Western blotting and by quantitative dot blotting no change was observed in the amounts of tubulin, MAP2, or MAP1A, in the polymer and soluble fractions in MeHg-treated samples, compared to the control cells that were not treated. These data indicate that although MeHg treatment results in the disassembly of Mts they were not depolymerized as detergent-soluble subunits. (Supported by NSERC Canada.)

999 PROTEIN-KINASE C (PKC) INHIBITS THE ACTIVITY OF ORGANIC ANION TRANSPORTING POLYPEPTIDE OATP1 AND OATP2 BY DIRECT PHOSPHORYLATION, BUT NOT BY INTERFERENCE WITH INTRACELLULAR VESICLE TRAFFICKING.

G. L. Guo and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

Oatp1 and Oatp2 are expressed in hepatic sinusoidal membranes as well as apical membranes of kidney proximal tubules and choroid plexus in brain. Transport mediated by Oatp1 and Oatp2 is sodium-independent, ATP-independent and temperature-sensitive. They transport a wide spectrum of substrates with diverse structures. The substrate spectrum and tissue distribution indicate that Oatp1 and Oatp2 may play important roles in chemical disposition and drug-drug interactions. Several potential PKC phosphorylation sites in Oatp1 and Oatp2 have been revealed by amino acid sequence analysis. Therefore, the purpose of this study was to determine the effects of PKC on the transport activities of Oatp1 and Oatp2 by uptake assays in Oatp1- or Oatp2-cRNA injected Xenopus laevis oocytes. The present study demonstrated that the transport activities of Oatp1 ([3H]estrone-3-sulfate uptake) and Oatp2 ([3H]digoxin uptake) were inhibited by phorbol-12-myristate-13-acetate (PMA), a potent activator of PKC, in a dose- (1 nM to 10 mM) and time-dependent (5 to 60 min) manner. This inhibition is PKC specific in that an inactive PMA analogue, 4α-phorbol-12,13-didecanoate, had no effect on Oatp1- and Oatp2-mediated transport. In addition, the effect of PMA was blocked by a specific PKC inhibitor, bisindolylmaleimide (1 microM). PMA treatment increased phosphorylation of serine and threonine, but not tyrosine amino acid residues of the transporters. In contrast, pretreatment of oocytes with the microtubular inhibitor colchicine (1 mM for 8 hrs) did not prevent the decrease in transport elicited by PMA. Therefore, this study suggests that activation of PKC inhibits the function of Oatp1 and Oatp2, and that the mechanism by which PKC inhibits the transport of these transporters appears to be via direct phosphorylation, rather than interference with intracellular vesicle trafficking. (Supported by NIH grant ES-01142 and American Heart Grant KS-98-GS-11.)

1000 GENE EXPRESSION ARRAY ANALYSES OF SULFUR MUSTARD-INDUCED PROINFLAMMATORY MEDIATOR RESPONSE IN MOUSE EARS.

M. M. Danne[1], M. C. Babin[2], M. Y. Gazaway[2], K. M. Ricketts[2], J. J. Schlager[2] and K. L. Buxton[1]. [1]*Battelle Memorial Institute, Columbus, OH and* [2]*U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

Nucleic acid array technology is poised to become a principal technique in biomarker research. As part of the Chemical and Biological Weapons Defense Program, the United States Army Medical Research Institute of Chemical Defense is interested in identifying biomarkers predictive of exposure to vesicating agents such as sulfur mustard [bis(2-chloroethyl) sulfide; HD]. Studies were undertaken to profile gene expression patterns in RNA populations isolated from ear tissue of CD1 mice either treated or not treated with a candidate antivesicant compound prior to HD exposure. Adult, male mice were treated topically with either HD (0.16 mg/ear), indomethacin (IND), or IND followed by HD, on the medial ear surface. At approximately 6 hr or 24 hr following exposure, biopsies were taken, snap frozen in liquid nitrogen, and stored ≤ -70C. Messenger ribonucleic acid (mRNA) was isolated and a complementary deoxyribonucleic acid (cDNA) probe was radioactively labeled using gene-specific primers. After hybridizing the labeled cDNA probe to a 588-gene expression array (Atlas Mouse cDNA Expression Array, Clontech, Palo Alto, CA), data were analyzed using AtlasImage™ 1.0 (Clontech). Normalization was performed with two housekeeping genes, ubiquitin and ribosomal protein S29, by comparing expression on arrays probed with IND-, HD-, and HD/IND-treated samples to an array probed with a naïve sample. Genes indicative of tissue damage, stress, and inflammation have been identified from HD-exposed tissue, while HD/IND-treated tissue shows increased expression of genes involved in repair of damaged tissue. These data contribute to the understanding of the early events associated with HD-induced skin injury. (Supported by Contract No. DAMD17-89-C-9050 and by Battelle Memorial Institute.)

1001 CHARACTERIZATION OF SULFUR MUSTARD-INDUCED PROINFLAMMATORY MEDIATOR RESPONSE IN MOUSE EARS.

K. L. Buxton[1], M. C. Babin[2], K. M. Ricketts[2], M. Y. Gazaway[2], J. A. Blank[1] and M. M. Danne[1]. [1]*Battelle Memorial Institute, Columbus, OH and* [2]*U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

Sulfur mustard, [bis(2-chloroethyl) sulfide; HD] is an alkylating agent that produces incapacitating blisters in exposed tissue. Recent reports suggest that proinflammatory genes may be useful biomarkers of vesicant-induced injury. Studies were undertaken to characterize levels of gene expression in animals exposed to HD using the mouse ear vesicant model (MEVM). Adult, male CD1 mice, housed under AAALAC guidelines, were exposed topically to HD (0.16 mg/ear), or a pre-treatment of either hydrocortisone (HC), indomethacin (IND), olvanil (OLV), or dexamethasone (DEX) and HD, on the inner surface of the right ear using established procedures. The left ear served as a vehicle (dichloromethane) control. At approximately 2 hr, 6 hr, and 24 hr following exposure, skin biopsies were taken, snap frozen in liquid nitrogen, and stored ≤ -70 C. Skin samples were analyzed for levels of mRNA using a Ribonuclease Protection Assay (RPA). There was an elevation of mRNA coding for Macrophage Inflammatory Protein-2 (MIP-2) at HD-exposed sites relative to control tissue at each timepoint, with peak-levels occuring at 24 hr. Without pre-treatments, Monocyte Chemoattractant Protein-1 (MCP-1) gene expression increased two-fold at 2 hr, peaked at 6 hr, and returned to a two-fold increase at 24 hr, and Interleukin-1β (IL-1β) message levels increased dramatically at 6 hr then decreased at 24 hr. Significant reduction in mRNA coding for MIP-2 was evident with DEX and IND pre-treatments at 24 hr compared to samples that had no pre-treatment. Pre-treatment with DEX decreased MCP-1 gene expression at 6 hr. Production of mRNA coding for IL-1β was significantly decreased at 6 hr with HC and DEX pre-treatments. These data contribute to the understanding of the early events associated with HD-induced skin injury. (Supported by Contract No. DAMD17-89-C-9050.)

1002 EFFECT OF PENTOXIPHYLLINE ON COLLAGEN SECRETION BY RAT HEPATIC STELLATE CELLS EXPOSED TO ACETALDEHYDE.

A. Correa-Ramírez, E. Hernández-Pérez, L. Gómez-Quiroz, V. Souza, L. Bucio and M. C. Gutiérrez-Ruiz. *Universidad Autónoma Metropolitana-Iztapalap, México, D.F., Mexico.*

Physiopathology of liver fibrosis is far from being completely understood, and the efficacy of the avaliable therapeutic strategies is disappointing. Increased evidence has so far implicated TNF-α as a pivotal molecule involved in liver damage. Pentoxiphylline (PTX) has been reported to inhibit TNF-α production as well as to decrease collagen deposition. Activated stellate cells are responsible for increased collagen deposition in liver fibrosis and cytokines are recognized as important mediators in this process. The aim of this study was to determine the effect of PTX on oxidative stress, collagen and TNF-α secretion by rat hepatic stellate cells (CFSC-2G) pretreated with acetaldehyde. Media containing 175μg/ml of acetaldehyde were added to rat hepatic stellate cells 24 hours after seed and replaced 48 hours later with media containing 200μM/ml of PTX which was collected after 24 hours. Cells

were counted and used to determine lipid peroxidation by malondialdehyde production. Collagen secretion was measured by the hydroxiproline micromethod in culture media. TNF-α secretion was quantified by ELISA. Neutral red and MTT assays were performed in presence of different concentrations of PTX to select the one that did not alter cellular function. A concentration above 250μM/ml decreased substantially cell function. PTX did not alter collagen secretion (0.3731 ± 0.035μmol/10^6 cells) in rat hepatic stellate cells. Acetaldehyde treated cells increased 2.6 times collagen secretion (1.264±0.22μmol/10^6 cells) while lipid peroxidation values enhanced by four times compared with control cells. In presence of PTX, acetaldehyde treated cells diminished by 3.1 times collagen secretion (0.3951±0.049∝mol/10^6 cells) compared to those not exposed to this drug, the concentration of collagen in the media was similar to that of control cells (0.4847±0.058∝mol/10^6cells). Similar results were obtained when anti-TNF-α was added. A slight increment in TNF-α was observed after acetaldehyde treatment which decreased with PTX treatment. The present study demonstrates that rat hepatic stellate cells increase collagen secretion as a result of acetaldehyde treatment. PTX brings collagen secretion levels to normal values probably by suppressing TNF-α secretion.

1003 THE ATM PROTEIN IS INVOLVED IN REPAIRING DNA DOUBLE STRAND BREAKS WITH SPECIFIC ENDS.

Y. Li and K. Dixon. *University of Cincinnati, Cincinnati, OH.*

Ataxia telangiectasia (A-T) is a human genetic disease characterized by progressive cerebellar degeneration, hypersensitivity to ionizing radiation (IR), and high cancer risk. The hallmarks of A-T cells are IR sensitivity and abnormally high rates of spontaneous and IR-induced chromosomal breakage and rearrangement. Compared to normal cells, A-T cells have slower kinetics and lower fidelity of repairing IR-induced DNA double strand breaks (DSB), indicating that there is a primary defect in DSB repair in A-T cells. The ATM (Ataxia telangiectasia mutated) gene encodes a 350 KD protein kinase that belongs to a PI-3 kinase family that includes proteins involved in DNA repair and cell cycle regulation, such as DNA-PK. The recent discovery that the ATM protein is able to bind to DSB, independent of DNA-PK, further supports a distinctive role of the ATM in DSB repair. We are investigating the role of ATM in DSB repair by measuring the capacity of nuclear extracts prepared from ataxia telangiectasia (A-T) fibroblasts to rejoin restriction endonuclease cleaved plasmid DNA. A reversion vector, SupF22 (a generous gift of M. Seidman), which was constructed to detect small deletions, was used in our experiments. SupF22 was linearized with 7 different endonucleases that cut between the two microhomologies. SupF22 reverts to an active SupF gene through precise deletion of 53 base pairs of DNA between two copies of the microhomology sequence GGGT and can be scored as blue colonies in the indicator bacterial strain. We found that DSB repair efficiency in both normal and A-T extracts decreased in the order: 4 bp 5' overhang > 2 bp 5' overhang > 3 bp 3' overhang or blunt ends. DSB repair fidelity in normal extracts ranged from 0 to 0.26%, regardless of the nature of DSB ends. Meanwhile, the repair fidelity of DSB with 5' overhang in A-T extracts was close to that in normal extracts. However, the repair fidelity was dramatically decreased in A-T extracts when SupF22 carrying DSB with blunt or 3' overhang ends was incubated in A-T extracts, a difference as much as 10 folds was observed in our experiments. These results indicated that the ATM protein might be involved in repairing DSB with blunt or 3' overhang ends.

1004 INDUCTION OF XPA BY CISPLATIN IN CISPLATIN-RESISTANT OVARIAN CARCINOMA CELLS.

J. C. States[1] and D. J. Kaplan[2]. [1]*University of Louisville, Louisville, KY and* [2]*Wayne State University, Detroit, MI.*

Purpose: Recent evidence suggests that DNA repair gene expression is regulated. Increased DNA repair gene expression has been implicated as a mechanism for resistance to cytotoxic chemotherapy. The role that regulation of DNA repair plays in cell survival is of great significance to our understanding molecular events associated with the response of metastatic cancer cells to cytotoxic chemotherapy. XPA is an essential part of the nucleotide excision repair pathway which removes the majority of DNA damage induced by the cytotoxic chemotherapeutic agent cisplatin (CP). XPA mediates the assembly of the excision complex at the site of DNA damage. We have investigated XPA regulation in response to CP treatment in CP-resistant and CP-sensitive ovarian carcinoma cells to test the hypothesis that CP-resistance is associated with DNA repair gene inducibility. **Methods:** Paired CP-sensitive (A2780) and CP-resistant (A2780/CP70) cells were treated with CP at their respective LC50 (3 μM and 40 μM) for 1 h. XPA expression was analyzed by Western blot of whole cell lysates. XPA promoter regulation was analyzed in reporter gene assays using XPA promoter/reporter gene constructs containing XPA promoter fragments of different lengths. Transcription factor binding to XPA promoter fragments was determined by electrophoretic mobility shift and super-shift analyses. **Results:** Preliminary data indicate that CP treatment induces XPA expression and XPA promoter activity in the CP-resistant cells but not in the CP-sensitive cells. XPA promoter induction was dependent on the presence of an upstream region of the XPA promoter. Electrophoretic mobility shift analyses indicated that multiple factors in both CP-sensitive and CP-resistant cells bind this upstream promoter fragment essential for CP induction. However, CP-sensitive cells contain an additional factor not found in CP-resistant cells. **Conclusions:** These data support the hypothesis that XPA expression is induced in response to CP treatment in CP-resistant tumor cells but not in CP-sensitive tumor cells. The results suggest the hypothesis that induction is inhibited by a negative acting XPA promoter binding factor in CP-sensitive cells. Current efforts are aimed at determining whether increased XPA expression is also associated with increased DNA repair capacity in CP-resistant cells and at identifying the putative negative acting factor present in CP-sensitive cells. (Supported by NIEHS grant R01 ES06460 and a Pilot Project award from NIEHS Center grant P30 ES06639.)

1005 EVALUATION OF LESION BYPASS IN *XERODERMA PIGMENTOSUM* VARIANTS CELL EXTRACTS.

B. R. Johnson and M. P. Carty. *University of Cincinnati, Cincinnati, OH.*
Sponsor: A. Puga.

The conversion of unrepaired DNA damage in the genome to mutations during DNA replication is a critical step in the initiation of carcinogenesis. A number of specialized DNA polymerases that are involved in replication and mutagenesis at DNA damage site in mammalian cells have recently been identified. These polymerases are products of a gene superfamily with homology to the bacterial SOS response gene *umuC*, which includes the *RAD30*, *RAD30B*, *REV3* and *DinB* genes. The human *RAD30* gene, which is mutated in the skin cancer prone disease Xeroderma Pigmentosum Variant (XPV), encodes a novel DNA polymerase, eta [η], required for error-free bypass of UV-induced pyrimidine dimers in DNA. To further investigate the DNA polymerase requirements for lesion bypass in normal and XPV lymphoblasts, we have developed an *in vitro* primer extension assay utilizing cell-free extracts. Primed oligonucleotides, 55-56 bases in length, containing known mutagenic lesions including an abasic (tetrahydrafuran) residue, pyrimidine dimer, or a (6-4) photoproduct at nucleotide 39 from the 5'terminus, were used as templates for DNA synthesis in these cell extracts. Replicated products were separated and analyzed by 15% PAGE. Our results show that replication is arrested at an abasic site following DNA synthesis in all extracts tested, as shown by the formation of synthesis products which are 38nt and 39nt in length. However some bypass of the abasic lesion was also observed, demonstrating that these cell extracts contain the polymerase activities required for lesion bypass. We have also performed experiments using aphidicolin, an inhibitor of the replicative DNA polymerases, α, δ and ε. Consistent with a requirement for additional DNA polymerase activities for replication at an abasic site, replication on damaged and undamaged DNA is differentially inhibited by aphidicolin. This *in vitro* assay can be used to investigate the biochemical requirements for bypass of a variety of lesions, including single benzo(a)pyrene-7,8-dihydrodiol-9,10-epoxide [BPDE] adducts, in human cell extracts. (Supported by NIH ES08079 [MPC] and ES07250-11 [BRJ/P.Stambrook, PI].)

1006 HIGH FREQUENCY OF LOSS OF HETEROZYGOSITY AT CHROMOSOME 11 IN BENZENE-INDUCED THYMIC LYMPHOMAS IN P53+/- TRANSGENIC MICE.

S. E. Boley[1], E. Anderson[1], J. E. French[2], L. Donehower[3], D. Walker[4] and L. Recio[1]. [1]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC,* [2]*National Institute for Environmental Health Sciences, Research Triangle Park, NC,* [3]*Baylor College of Medicine, Houston, TX and* [4]*USEPA, Research Triangle Park, NC.*

In an ongoing study, benzene inhalation exposure has induced a high frequency (>80%) of thymic lymphomas in p53+/- mice beginning at six months of exposure. To characterize the presence and extent of loss of heterozygosity (LOH) on chromosome 11, we have examined the status of seven microsatellite markers in 27 benzene-induced and six spontaneous thymic lymphomas. LOH at microsatellite markers is an indication of large genetic alterations such as gross deletions, recombination or chromosomal loss. Benzene-induced thymic lymphomas exhibited six patterns of LOH and 59% (16/27) of induced lymphomas exhibited the same pattern. Each of the six spontaneous thymic lymphomas analyzed showed a unique pattern of LOH,

only one of which was exhibited by the benzene-induced thymic lymphomas. Over 90% (25/27) of the benzene-induced thymic lymphomas exhibited loss of the functional p53 allele, and the loss of p53 was accompanied by LOH at other microsatellite markers suggesting the LOH was a result of gross alteration of chromosome 11. The results indicate that benzene treatment is inducing a high frequency of LOH on chromosome 11 in p53+/- mice, and that loss of the functional p53 allele or some other gene on chromosome 11 is a key event in the induction of thymic lymphomas in these mice.

1007 FURTHER EVIDENCE FOR A PALINDROMIC ORIENTATION OF TRANSGENE PROMOTER SEQUENCE CRITICAL FOR TUMORIGENIC RESPONSIVENESS IN TG.AC MICE.

B. A. Rosenzweig[1], R. Honchel[1], K. L. Thompson[1], C. Strupczewski[1], K. T. Blanchard[2], S. M. Furst[2], R. E. Stoll[2] and F. D. Sistare[1]. [1]*Center for Drug Evaluation and Research, FDA, Laurel, MD and* [2]*Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT.*

Tg.AC mice have been shown to develop skin papillomas when exposed to carcinogens and this transgenic mouse model is being used in a short-term carcinogenesis assay for safety testing of pharmaceuticals. A subset of hemizygous Tg.AC mice were found to be refractory to carcinogens. We have previously shown that hemizygous Tg.AC mice (both responders and nonresponders) contain about 40 copies of transgene but the nonresponders had lost a 2 kb BamHI fragment containing z-globin promoter sequence (Thompson et al., 1998). Restriction enzyme and S1 nuclease digestion experiments strongly suggested that the 2 kb BamHI fragment results from a palindromic orientation of the transgene, though alternative interpretations could not be ruled out. Ongoing attempts to PCR and/or clone the "head-to-head" juncture have been unsuccessful, probably due to the symmetrical structure of the palindrome. Restriction enzyme and S1 nuclease digestion experiments indicated two subsets of nonresponder Tg.AC mice, one with a large, slightly asymmetric deletion across the "head-to-head" juncture of the palindrome and another with only a small asymmetric deletion in the same 2 kb BamHI fragment. Prompted by evidence for asymmetric deletions in the palindromic structure, we attempted to PCR across the "head-to-head" junction of transgene in nonresponder DNA using a strategy where one of the PCR primers was designed based on sequence thought to be deleted on only one side of the palindrome. The resulting PCR products were cloned and sequencing results confirmed the suspected palindromic orientation of transgene in Tg.AC mice. Furthermore, the deletions seen in nonresponder mice resulted in the loss of z-globin symmetry in the "head-to-head' region of the palindrome. Although a large number of full-length copies of transgene are present in Tg.AC mice, loss of "head-to-head" symmetry in palindromic structure, even by deletions as small as 75 bp, result in complete loss of ability of carcinogen to activate transgene expression.

1008 SELECTION OF DRUGS TO TEST THE SPECIFICITY OF THE TG.AC ASSAY BY SCREENING FOR INDUCTION OF THE *GADD153* PROMOTER *IN VITRO*.

K. L. Thompson, D. D. Broud and F. D. Sistare. *FDA, Laurel, MD.*

Increased experience with short-term carcinogenicity assays that use genetically altered mouse models, such as the Tg.AC assay, is required for understanding the strengths and limitations of these assays. To help select pharmaceuticals to test the limits of specificity of the Tg.AC assay, a rapid throughput *in vitro* assay was developed that is predictive of *in vivo* activity in the Tg.AC assay. This assay measures activation of a hamster *gadd153* promoter construct that is stably expressed in HepG2 cells. The *gadd153* promoter is responsive to DNA damage, oxidative stress, and endoplasmic reticulum impairment. 100 noncarcinogenic pharmaceuticals were screened in the *gadd*153 assay, along with two other gene induction assays less predictive of Tg.AC activity (zeta-globin promoter induction in K562 cells and fos promoter induction in HepG2 cells). About 20% of the drugs we screened induced the *gadd153* promoter. Several criteria were used to select the three best candidates for subsequent *in vivo* testing in a Tg.AC assay: whether drug solubility in acetone or ethanol was sufficient to elicit systemic toxicity, the level of *gadd153*, zeta-globin, and fos promoter inductions by the drug, the potency of the drug in the *in vitro* assays, and the cost of the drug required for a 6-month study. Testing whether noncarcinogenic pharmaceuticals that activate select stress response pathways *in vitro* can elicit papillomas in the Tg.AC skin paint assay will accelerate the evaluation of the specificity of the Tg.AC assay and assist in defining its appropriate usage in the safety testing of pharmaceuticals.

1009 CLONING AND DEXAMETHASONE REGULATION OF THE RAT ARYL SULFOTRANSFERASE (SULT1A1) GENE.

Z. Duanmu and M. Runge-Morris. *Institute of Chemical Toxicology, Wayne State University, Detroit, MI.*

Aryl sulfotransferase (SULT1A1) catalyzes the sulfation of phenols, acetaminophen, minoxidil and other substrates. Previous reports demonstrated that rat hepatic SULT1A1 mRNA levels are induced by glucocorticoid treatment. In the present study, a 1921 bp fragment of the 5' flanking region of the SULT1A1 gene was isolated from a rat genomic library using the GenomeWalker kit (Clontech Laboratories, Inc.). A computerized analysis of the sequence for potential transcription factor binding sites indicated that the SULT1A1 gene does not contain a consensus glucocorticoid response element (GRE). In order to examine the regulation of SULT1A1 gene transcription by glucocorticoids, luciferase reporter constructs containing either the intact 1921 bp SULT1A1-5'flanking region or SULT1A1-5' deletion fragments were prepared and transiently transfected into primary cultured rat hepatocytes. Transfectants containing the intact SULT1A1-5':luceriferase construct displayed substantial increases in luceriferase activity (of~30-fold) in response to 24h treatment with dexamethasone (DEX, 10^{-7}M) relative to DMSO-treated controls. In hepatocytes transfected with either of two deletion constructs prepared from the SULT1A1-5' flanking region (beginning -768 bp and -477 bp relative to the transcription start site), DEX (10^{-7}M) produced ~17- and ~14-fold increases in luceriferase activity, respectively. The results suggest that a functional *cis*-acting DEX-responsive element is located within ~477 bp of the SULT1A1 core promoter. (Supported by NIH Grant ES05823 and NIEHS Center Grant ES06639.)

1010 TISSUE DISTRIBUTION OF ALCOHOL DEHYDROGENASE, ALDEHYDE DEHYDROGENASE AND CYTOCHROME P450-2E1 IN CHRONIC ETHANOL-TREATED SPRAGUE-DAWLEY RATS.

J. A. Walisser, M. Panagiotidis, D. R. Petersen and V. Vasiliou. *University of Colorado Health Sciences Center, Denver, CO.*

The class I alcohol dehydrogenase (ADH) is the major mammalian enzyme involved in ethanol oxidation. The ethanol-inducible cytochrome P450-2E1 (CYP2E1) and the catalase-H2O2 system also metabolize ethanol to acetaldehyde. Acetaldehyde is further metabolized to acetate principally by the mitochondrial aldehyde dehydrogenase (ALDH2), as well as the cytosolic aldehyde dehydrogenase (ALDH1). Many of the toxic and pathologic effects associated with chronic alcohol consumption are attributed to increased formation of acetaldehyde and reactive oxygen species. In order to characterize the effect of chronic ethanol treatment on protein levels of ADH, ALDH and CYP2E1, the tissue distribution of these enzymes was examined by Western blot analysis. Male Sprague-Dawley rats were fed a low-carbohydrate liquid diet containing 35% ethanol-derived calories for 100 days. Pair-fed control rats received the liquid diet containing dextrose isocaloric to the ethanol calories consumed by the ethanol-fed rats. Tissue homogenates were prepared from 12 tissues including liver, kidney, heart, lung, stomach, intestine, pancreas, spleen, bladder, testis, muscle and brain. The CYP2E1 protein levels were increased in liver and kidney of ethanol-treated rats compared to control animals. In contrast, chronic ethanol treatment did not alter the class I ADH protein levels in any of the tissues where the protein was detected. Similarly, ALDH2 protein levels were not altered by the ethanol treatment when compared to controls. These results suggest that chronic ethanol treatment increases CYP2E1 protein in rat liver and kidney, but does not influence class I ADH or ALDH2 protein levels in rat tissues. The induction of CYP2E1 by ethanol, and the consequent increase in acetaldehyde formation and oxidative stress, may partially explain the fatty accumulation in the liver and kidney that is associated with chronic alcohol abuse. (Supported by R01 AA11885 [VV] and R01 AA09300 [DRP].)

1011 METABOLISM OF THE NICOTINE BY-PRODUCT NNAL BY HUMAN UDP-GLUCURONOSYLTRANSFERASES (UGTS).

N. Nguyen[1], C. P. Strassburg[2], G. Kuehl[3], S. Murphy[3] and R. H. Tukey[1]. [1]*University of California, San Diego, La Jolla, CA,* [2]*Hannover Medical School, Hannover, Germany and* [3]*University of Minnesota, Minneapolis, MN.*

The tobacco-specific and carcinogenic nitrosomine 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanol (NNAL) is the major metabolite formed from the carbonyl reduction of NNK, a nitrosation product of nicotine. The major detoxification step of NNAL is felt to be the formation of NNAL-beta-O-D-glu-

cosiduronic acid (NNAL-Gluc) catalyzed by the superfamily of UGTs. In humans, we have demonstrated that the UGT1 and UGT2B genes are differentially expressed in different tissues of the gastrointestinal tract. This work has led to the cloning of twelve of the fifteen known human UGT cDNAs, each being characterized for substrate specificity following expression in V79, HK293 or insect SF-9 cells. Highly purified NNAL was incubated with total cellular extracts expressing the different UGTs to examine the ability of the expressed enzymes to form NNAL-Gluc. Two forms of the glucuronide are generated with human liver microsomes as detected by TLC, NNAL-Gluc-a (rf=0.68) and NNAL-Gluc-b (rf=0.74). Expression of UGT2B4, 2B7, 2B10 and 2B15 does not support glucuronidation of NNAL. UGT1A7, expressed in biliary and gastric epithelium as well esophageal tissue, formed approximately ten fold more NNAL-Gluc-a than NNAL-Gluc-b. On a comparable level, UGT1A9, which is expressed in liver, intestine and esophagus, formed similar ratios of NNAL-Gluc as found with UGT1A7. UGT1A10, found in all extrahepatic tissues, catalyzed only NNAL-Gluc-a. UGT1A6, not found in the esophagus but in most other tissues, also generated only NNAL-Gluc-a. There was no detectable activity for UGT1A1, 1A3, 1A4 or 1A8. It is worth noting that three of the active proteins, UGT1A7, 1A9 and 1A10 are expressed in esophagus, a tissue that is susceptible to the carcinogenic actions of tobacco smoke adducts. (Supported by USPHS grants CA79834 [RHT], and DFG STR493/3-1 [CPS].)

1012 ETHANOL METABOLISM AND SENSITIVITY IN MICE WHICH LACK CYP2E1 EXPRESSION.

T. L. Ziegler, Z. Kiebler, D. R. Petersen and V. Vasiliou. *University of Colorado Heath Sciences Center, Denver, CO.*

Ethanol is metabolized to acetaldehyde mainly by the alcohol dehydrogenase pathway (ADHs) and to a lesser extent by microsomal oxidization (CYP2E1) and the catalase-H2O2 system. Acetaldehyde, which is responsible for some of the ethanol-induced effects, is further oxidized to acetate by aldehyde dehydrogenases (ALDHs). In this study, a transgenic Cyp2e1(-/-) mouse line was used to elucidate the role of this enzyme in ethanol metabolism and sensitivity. Ethanol was administered to both male and female Cyp2e1(-/-) and 129/sv wt mouse lines and comparisons of the pharmacokinetic parameters and sleep times were evaluated. Differences were evaluated by quantitating the concentrations of ethanol and acetaldehyde in whole blood at 15, 30, 60, 120, and 180 minutes following a single i.p. dose of ethanol (2.0, 3.0, 4.0, or 5.0 g/kg) by gas chromatography-headspace analysis. Differences in sleep time were determined for each genetic stock and sex following a single i.p. dose at 3.0, 4.0, or 5.0 g/kg of ethanol. Following i.p. administration, the rates of ethanol elimination from whole blood were similar regardless of dose or genetic stock. However, the blood acetaldehyde levels were higher in wt mice than in Cyp2e1(-/-) mice. Interestingly, female mice achieved higher ethanol blood levels than the males following equivalent dosing. In contrast, acetaldehyde was found to reach higher levels in male animals yet not in females. Male mice exhibited a longer sleep time than females. The Cyp2e1(-/-) mice yielded longer sleep times than the control animals in both sexes. These data suggest that although the contribution of CYP2E1 in ethanol oxidation may be limited, this enzyme may play a role in ethanol sensitivity in the brain. In vitro metabolic studies will be performed on microsomal enzymes isolated from the brain and liver of both genetic mouse lines. (Supported by R01 AA11885 [VV] and NIAAA Training Grant 5T32AA07464 [TLZ].)

1013 ISOLATION AND SEQUENCING OF CYP1A CDNAS FROM FIVE SPECIES OF BUTTERFLYFISH: A CASE FOR DIET-DRIVEN EVOLUTION IN A CRITICAL BIOTRANSFORMATION ENZYME.

B. C. DeBusk, M. Slattery and D. Schlenk. *University of Mississippi, University, MS.*

Complementary DNAs of cytochrome P450 1A (CYP1A) have been cloned and sequenced from the livers of five butterflyfish species (*Chaetodon auriga, C. citrinellus, C. melannotus, C. plebius,* and *C. vagabundus*) collected at Lizard Island, Australia. The cDNAs were obtained by reverse-transcriptase polymerase chain reaction using primers derived from conserved codons in the amino acid coding region of teleost CYP1A. The 1186-1188 base pair products are within the open reading frame encoding 395 amino acid proteins containing the I-helix and heme binding regions typical of CYP proteins. The nucleotide and derived amino acid sequences are most closely related to the butterflyfish, *C. capistratus*. A rooted genetic distance tree was obtained using these sequences and sequences from ten teleost sequences. Based on parsimony analysis, *C. vagabundus* and *C. auriga* group together, *C. plebius* and *C. melannotus* group separately, and these form separate branches from *C. capistratus*. *C. citrinellus*, a phenotypically distinct member of the genus, does not group with the other butterflyfish. Interestingly, *C. vagabundus*, *C. auriga*, and *C. citrinellus* maintain generalist feeding patterns, while *C. plebius* and *C. melannotus* display highly specialized feeding preferences for chemically defended hard and soft corals, respectively. This evidence suggests that diet-related factors may have driven the molecular changes exhibited in CYP1A among butterflyfishes and provides a basis for the differential expression of this enzyme among the species.

1014 SODIUM AZIDE-INDUCED THERMOTOLERANCE AND STRESS PROTEIN INDUCTION IN WILD-TYPE AND MUTANT STRAINS OF *C. ELEGANS*.

M. M. Massie, E. M. Lapoczka, K. D. Boggs, N. D. Smith, G. E. White and K. E. Stine. *Department of Biology/Toxicology, Ashland University, Ashland, OH.*

Sodium azide, a mitochondrial toxicant, has long been used to anesthetize the nematode *C. elegans*, but the mechanism by which this organism can survive this exposure is not known. We hypothesized that survival may involve cellular stress response mechanisms, and as such may produce cross-tolerance to thermal stress. Worms pre-exposed to 10 mM azide showed significantly increased thermotolerance to 37°C, with a 0.68 survival probability (SP) compared with 0.07 SP for control worms taken directly to 37°C without prior azide exposure ($p<0.05$). This is, however, less than the 0.92 SP for worms pre-exposed to 33°C (the classic heat shock phenomenon). Using SDS-PAGE, Coomassie Brilliant Blue staining, and Western Blot analysis, we observed induction of hsp70 and hsp16 following azide exposure, although levels of induction were low compared to the worms pre-exposed to 33°C. Under unfavorable conditions, *C. elegans* enters a non-feeding, non-aging life cycle stage known as the dauer stage. We tested *daf-21*, a constitutive dauer-forming hsp90 mutant, and were able to demonstrate azide-induced thermotolerance, indicating that hsp90 may not be critical to the worm's response to stress. Azide-induced thermotolerance was also displayed by several other constitutive dauer-forming mutants (*daf-2*, *daf-7*, and *daf-14*). Also, by selecting for individual worms that survived 37°C without prior exposure to azide or elevated temperatures we have identified and characterized several intrinsically thermotolerant substrains of the N2 wild type *C. elegans* strain.

1015 IDENTIFICATION AND CHARACTERIZATION OF AN E3 UBIQUITIN- PROTEIN LIGASE IN THE SOFT SHELL CLAM (MYA ARENARIA).

M. L. Kelley and R. J. Van Beneden. *University of Maine, Orono, ME.* Sponsor: M. E. Hahn.

Certain softshell clam (Mya arenaria) populations in eastern Maine have a high prevalence of gonadal tumors; the cause of these tumors is unknown. A significant contaminant found in these environments is dioxin, a known carcinogen. A cDNA fragment with sequence similarity to the E3 family of ubiquitin-protein ligases was first identified from gill mRNA of dioxin-exposed clams. E3 enzymes are responsible for ligating ubiquitin molecule(s) onto a protein, targeting it for degradation. E6-AP is the best studied member of the E3 ubiquitin-protein ligase family defined by a conserved region of approximately 350 amino acids termed the "homologous to the E6-AP carboxyl terminus" (hect) domain. The hect domain includes several highly conserved residues. This includes an absolutely conserved cysteine residue 30-40 amino acids from the carboxyl terminus which is the site of ubiquitin thioester bond formation. E6-AP targets the tumor suppressor p53 for degradation; a decrease in p53 protein is known to affect cell cycling, thus promoting cell proliferation. This pathway has been observed in human cervical cancer. The cDNA sequence of clam E3 has been determined and is structurally similar to the vertebrate E6-AP at the predicted amino acid level (47-48% and 49% identical to mouse and human E6-AP, respectively). We are exploring whether the clam E3 protein is functionally similar to other E3 proteins by determining if it covalently binds ubiquitin, a hallmark of this protein-degradation pathway. We will also identify proteins targeted for degradation by clam E3. Results of these studies may contribute to an understanding of gonadal tumor progression in this invertebrate model system.

1016 ANALYSIS OF GENE EXPRESSION IN F-344 RATS FOLLOWING DERMAL EXPOSURE TO FUELS AND SOLVENTS.

C. Garrett, K. Geiss and J. McDougal. *Geo-Centers, Inc., Dayton, OH.*

In an effort to establish safe exposure scenarios for military personnel coming into contact with fuels and solvents, we proposed to develop a predictive mathematical model of early cellular responses of the skin. Several components of jet fuels are considered to be dermal irritants. Cellular responses to irritants are complex and not completely understood. Cellular damage releases cytokines and chemokines, which are involved in the initial inflammatory response. One such chemokine, nitric oxide (NO), causes dilation of the vasculature. NO is produced by inducible nitric oxide synthase (iNOS). The iNOS gene is upregulated during the inflammatory response. Therefore, the analysis of iNOS mRNA may be useful for studying the process of dermal irritation. Isolation of high quality, undegraded RNA is crucial to the analysis of gene expression patterns. However, the isolation process becomes particularly challenging in the skin. Skin is tough, difficult to homogenize, and is abundant in RNAses. We developed a technique of harvesting rodent skin which minimizes the degradative effects of RNAse, while providing a sample that is easily homogenized in the isolation reagent. Our technique involves immediately submersing the freshly harvested skin sample in a solution of 10mM vanadium chloride to inhibit RNAse, then mincing the tissue and flash freezing with liquid nitrogen. Frozen, minced tissue is then pulverized with a stainless steel mortar and pestle and homogenized in a commercial isolation reagent containing phenol and guanidine thiocyanate. We were able to obtain RNA with an average yield of 1.0 - 5.0 μg RNA/mg skin and a OD_{260}:OD_{280} ratio of 1.6 to 1.8. Gel electrophoresis and northern analysis with 28S and actin cDNA probes confirm the quality of the RNA that we obtained by this method. (Supported by CDC/NIOSH RO1 OH03654-01 and AFOSR 92HE05COR.)

1017 EFFECTS OF ADENOVIRAL VECTORS ON MOUSE LIVER PROTEIN PATTERNS.

R. M. Lyons[1], S. Steiner[2], S. Houy[3], M. Kolopp[3], S. D. Chibout[3], E. Otto[1], M. Gorziglia[1], M. Kadan[1] and M. Kaleko[1]. [1]*Genetic Therapy, Inc, Gaithersburg, MD,* [2]*Large Scale Biology Corp, Rockville, MD and* [3]*Novartis Pharma AG, Basel, Switzerland.*

Adenoviral vectors, when administered intravenously, are associated with acute hepatotoxicity and transient vector expression. It has been suggested that continued viral gene expression may limit the duration of vector expression due to cellular immune responses and may also contribute to the hepatotoxicity observed. To further decrease viral gene expression, two vectors were constructed to eliminate E4 viral gene expression. One vector, Av4dlP, contained the E4 coding region but was deleted in the E4 promoter; another vector Av4orf3, was deleted in the E4 coding region except for orf3. The parental vector Av3, contained the complete E4 gene and its promoter. Each of these three vectors also contained the nuclear localized β-galactosidase gene (nBg) as a reporter. A one week comparison study was performed in C57BL/6 mice. Mice were treated with a single intravenous administration of one adenoviral vector at a dose of 5 x 10^9 particles/mouse and were sacrificed 1 week after vector administration. Liver function tests (LFTs) were performed the day after vector administration and every other day until termination. Liver samples were collected at necropsy for immunohistochemistry to evaluate gene transfer and vector expression, histopathology and proteome analysis. There was a clear ranking of the adenoviral vectors with regard to the severity of the effects on liver protein patterns. The Av4dlP vector was the least hepatotoxic when all parameters, including liver protein pattern, liver function tests and histopathological investigation were taken into consideration. A large set of liver proteins was altered by the vectors of which 12 have been identified. The proteins thus far identified indicate impairment of mitochodrial function and effects on the cytoskeleton. While the mechanism of adenoviral vector hepatotoxicity remains unclear, proteome analysis is a sensitive tool for comparisons of cellular effects of vector modifications and may aid in the selection of less toxic vectors.

1018 PROTEOMIC ANALYSIS IN RENAL TOXICITY.

M. D. Kelly[1], S. J. Kennedy[1], R. Parekh[2], C. Moyses[2], R. Amess[2], N. Downes[1] and R. Hill[1]. [1]*Quintiles England Ltd., Ledbury, United Kingdom and* [2]*Oxford GlycoSciences, Abingdon, United Kingdom.* Sponsor: P. McAnulty.

Proteomic analysis involves the systematic separation, identification and characterisation of proteins present in a tissue or other biological sample. By comparing the proteins present in samples from animals given a test material with those present in samples from control animals, it is possible to identify directly those proteins that are potentially related to target organ toxicity. In molecular investigations, proteomic analysis is often regarded as equivalent to genomic analysis. In toxicity studies, although the pattern of gene activity will be abnormal in a tissue with a pathological lesion, there can be a poor correlation between the level of activity of different genes and the relative abundance within the tissue of the corresponding proteins. This is especially true where the mode of action of the test material interferes with protein synthesis and/or post-translational modification. Consequently, the information about a pathological process that can be derived from analysis at the level of gene activity is incomplete. Unlike genes, until very recently it was not technically possible to subject proteins to high throughput, automated analysis. Proteomics technology has now bridged that gap, making it possible to analyse proteins using high throughput, automated techniques. This paper describes the results obtained when proteomes were analysed from a rat repeat-dose toxicity study using the known nephrotoxin, Gentamicin. A treatment related response was obtained for the kidney cortex proteomes that was evident at dose levels lower than those which had elicited changes in conventional toxicopathological endpoints. 40mg/kg/day gentamicin produced only minor changes by histopathological investigation and no changes in clinical pathology parameters. Preliminary proteomic analysis showed changes in >100 expressed proteins in the kidney cortex at doses of 0.1, 1, 10 and 40mg/kg/day. Ongoing work to be presented includes identification of affected proteins and proteomic analysis of urine and plasma from the treated animals.

1019 ARYL HYDROCARBON RECEPTOR-MEDIATED INHIBITION OF MAMMARY TUMOR GROWTH IN AN ATHYMIC NUDE MOUSE MODEL BEARING MCF-7 CELL XENOGRAFTS.

A. J. McDougal and S. Safe. *Texas A&M University, Department of Veterinary Physiology & Pharmacology, College Station, TX.*

6-Methyl-1,3,8-trichlorodibenzofuran (6-MCDF) binds to the aryl hydrocarbon receptor (AhR) and exhibits partial AhR antagonist activity for several receptor-mediated toxic responses. In contrast, 6-MCDF induces AhR-mediated antiestrogenic activity in the rodent uterus and human breast cancer cell lines. The role of the AhR in mediating the antiestrogenic/antitumorigenic activity of 6-MCDF was further investigated in athymic nude mice implanted with an estrogen pellet and bearing MCF-7 human breast cell xenografts. MCF-7 cells express a functional AhR and estrogen receptor α (ERα), and 10^7 cells in a Matrigel suspension were transplanted on both sides of the mammary fat pad. After allowing 1 week for tumor formation, one group received corn oil (vehicle control) and a second group was treated with 25 mg/kg/day 6-MCDF by oral gavage. A 7-fold increase in tumor volume was noted in the control over a period of 5 weeks; however, in animals treated with 6-MCDF, no significant induction of tumor volume was observed over the same time period. Postmortem analysis showed no significant differences in body and organ weights between the two treatment groups, and CYP1A1-dependent hepatic microsomal ethoxyresorufin *O*-deethylase was not significantly induced by the dose of 6-MCDF used in this study. Results of preliminary studies using other breast cancer cell lines including Ah-nonresponsive benzo[a]pyrene-resistant MCF-7 cells confirm the role of the AhR in mediating the antitumorigenic response of 6-MCDF. (CA64801 and ES09106)

1020 METHYLENE-SUBSTITUTED 1,1'-DIMETHYLDIINDOLYLMETHANE ANALOGS AS INHIBITORS OF CARCINOGEN-INDUCED MAMMARY TUMOR GROWTH IN RODENTS.

M. D. Morrow, A. J. McDougal and S. Safe. *Texas A&M University, Department of Veterinary Physiology & Pharmacology, College Station, TX.*

Diindolylmethane (DIM) is an aryl hydrocarbon receptor (AhR) agonist and inhibits estrogen-induced responses in the rodent uterus and carcinogen-induced mammary tumor growth in female Sprague-Dawley rats. A number of new methylene-substituted analogs of DIM have been synthesized and investigated for their antiestrogenic and antitumorigenic activities in rodent models. Initial studies examined 1,1'-dimethyldiindolylmethane analogs substituted at the CH_2 bridge with 4-hydroxyphenyl, 4-methoxyphenyl and 1-naphthyl substituents. All of these compounds were only weakly active in AhR binding or transformation assays, and at doses as high as 100 mg/kg/day (X3), no induction of hepatic microsomal CYP1A1-dependent ethoxyresorufin *O*-deethylase (EROD) activity was observed in C6B3F1 mice. Additionally, treatments do not induce estrogenic responses in the mouse

uterus. Despite the apparent lack of AhR agonist activity, the C-substituted DIM analogs inhibited growth of 7,12-dimethylbenz[a]anthracene-induced mammary tumors at doses as low as 1.0 mg/kg/every second day. At this dose, there was no significant tumor growth throughout 21 days of treatment, whereas in vehicle control animals, tumor volumes increased >3.5-fold. Thus, these analogs are more potent inhibitors of mammary tumor growth than DIM, and preliminary results suggest that their mechanisms of antitumorigenic action are at least, in part, through AhR-independent pathways. (CA64081 and ES09106)

1021 ABERRANT METHYLATION OF THE *p16INK4a* PROMOTER AND ALTERED PROTEIN EXPRESSION IN AFLATOXIN B_1 (AFB_1)-INDUCED MOUSE LUNG TUMORS.

A. S. Tam[1], J. F. Foley[2], A. C. Patel[2], T. R. Devereux[2], R. R. Maronpot[2] and T. E. Massey[1]. [1]*Department of Pharmacology and Toxicology, Queen's University, Kingston, Ontario, Canada and* [2]*National Institute of Environmental Health Sciences, Research Triangle Park, NC.*

The *p16INK4a* tumor suppressor gene is a cyclin-dependent kinase inhibitor, and inactivation of the gene by an accumulation of methylated cytosine-guanine (CpG) sites is a common occurrence in human and animal primary tumors. Carcinogen exposure can induce the activity of DNA methyltransferases, the enzymes responsible for methylation of CpG sites; thus, *de novo* methylation of the *p16INK4a* promoter might be induced by aflatoxin B_1 (AFB_1). In this study, female AC3F1 (A/J x C3H/HeJ) mice were treated with AFB_1. Six to fourteen months after dosing, mice were killed and tumors collected. Analysis of DNA samples from 61 AFB_1-induced whole AC3F1 mouse lung tumors was performed to assess methylation status. Direct sequencing of sodium bisulfite modified DNA revealed that 66% (40/61) of the samples were partially methylated at 30% or more of the CpG sites analyzed. Twenty AFB_1-induced tumor sections were examined for altered expression of the *p16INK4a* protein by immunohistochemical staining. In comparison to normal lung tissue, where greater than 90% of nuclei stained positively, decreased expression was observed in 39% (7/20) of tumor samples with 0-60%, of the cells staining positive for p16. In the 7 samples with decreased expression, 5 showed methylation of greater than 30% of the CpG sites examined. The correlation between p16 immunohistochemical and methylation of at least 30% of the CpG sites was 56%. This suggests that methylation of the *p16INK4a* promoter plays a role in, but is not absolutely required for AFB_1-induced mouse lung tumorigenesis. (Supported by Medical Research Council of Canada Grant # MT-10382.)

1022 POTENTIAL MECHANISMS OF TUMORIGENIC ACTION OF DIETHANOLAMINE IN MICE.

W. T. Stott[1], M. J. Bartels[1], K. A. Brzak[1], M. Mar[2], D. A. Markham[1], C. M. Thornton[1], L. Kan[1], S. Curry[3], M. Purdon[3] and S. H. Zeisel[2]. [1]*Dow Chemical Company, Midland, MI,* [2]*University of North Carolina at Chapel Hill, Chapel Hill, NC and* [3]*Procter & Gamble Company, Cincinnati, OH.*

Diethanolamine (DEA), a secondary amine found in a number of consumer products, has been reported to induce liver tumors in mice. The lack of genotoxicity in short-term assays and a Tg.AC bioassay, suggests a nongenotoxic mechanism of action. In an attempt to define the latter, the potential nitrosation of DEA to form N-nitrosodiethanolamine (NDELA) *in vivo* and the consequences of the known metabolic incorporation of DEA into phospholipids were examined. A tumorigenic dosage of DEA (160 mg/kg/day) was administered with or without supplemental sodium nitrite (170 ppm in drinking water) to B6C3F1 mice via dermal application (with or without access to the application site) or oral gavage for 2-4 weeks. Blood levels of DEA reflected the dosing method used; oral>dermal with access>dermal without access. No NDELA was observed in the urine, blood or gastric contents of any group of treated mice at levels of ≥1.5 ppb. Liver choline and phosphocholine were decreased 62-84% in an inverse relation to blood DEA levels. In a separate group of orally dosed mice, elevations in diacylglycerol and protein kinase C isoforms (PKC) and decreased S-adenosylmethionine (SAM) levels occurred. It was concluded that DEA induced choline deficiency, a known carcinogenic nutritional state. Subsequent chronic induction of PKC activity and decreased SAM levels may underlie DEA tumorigenesis in mice.

1023 CHOLINE INHIBITS DIETHANOLAMINE (DEA)-INDUCED MORPHOLOGICAL TRANSFORMATION IN SYRIAN HAMSTER EMBRYO (SHE) CELLS.

L. Lehman-McKeeman and E. Gamsky. *Procter and Gamble Co., Cincinnati, OH.*

DEA and its fatty acid condensates are widely used in commerce. DEA is hepatocarcinogenic in mice, and although negative in a standard battery of genetic toxicity tests, it was positive in the SHE cell morphological transformation assay. The goal of this work was to determine whether the carcinogenic effects of DEA may be caused by altered choline homeostasis. SHE cells were cultured in medium containing DEA (0, 10, 50, 100, 250, and 500 μg/ml) and [33P]-phosphorus was used to label phospholipid pools. After 7 days, cells were harvested, lipids extracted and [33P]-labeled phospholipids were quantified by autoradiography after thin layer chromatographic separation. In control cells, phosphatidylcholine (PC) accounted for 43±1% of total phospholipid synthesis. DEA treatment decreased PC synthesis at concentrations >50 μg/ml, with PC reduced to 14±2% of cell phospholipids at 500 μg/ml. DEA inhibited choline uptake into SHE cells at concentrations >50 μg DEA/ml, reaching a maximum 80% inhibition at 250-500 μg/ml. Additionally, [14C]-DEA was detected in phospholipid head groups. The concentration-dependent reduction in PC synthesis and incorporation of [14C]-DEA into phospholipids was inhibited when DEA-treated cells were cultured with excess choline (30 mM). Similarly, DEA (10-500 μg/ml) transformed the SHE cells in a concentration-dependent manner, whereas choline supplementation inhibited DEA-induced morphological transformation. Thus, DEA disrupts intracellular choline homeostasis by inhibiting choline uptake and altering phospholipid synthesis. Since excess choline blocks these effects and inhibits cell transformation, the results suggest that the cell transformation and carcinogenicity of DEA are secondary to biochemical changes consistent with intracellular choline deficiency.

1024 MODULATION OF MITOMYCIN C CYTOTOXICITY BY OLTIPRAZ.

D. A. Sachs and R. Fleming. *Wake Forest University School of Medicine, Winston-Salem, NC.* Sponsor: M. Miller.

The phase II detoxification enzyme, NAD(P)H: quinone oxidoreductase 1 (NQO1), has been shown to be induced by the dithiolthione oltipraz. Oltipraz may be able to modulate greater intracellular cytotoxicity of mitomycin C through the induction of NQO1. A single base pair polymorphism in exon 6 of the NQO1 protein has been shown to significantly reduce NQO1 enzymatic activity. To determine whether an unfavorable NQO1 genotype may be phenotypically altered by pharmacologic modulation to increase mitomycin C efficacy, two human cancer cell lines (MCF-7 and Lovo) were studied using an optimal oltipraz dose of 100uM. Effects on NQO1 enzyme activity after treatment with oltipraz were assayed using a spectrophotometric method and compared to baseline enzymatic activities in non-treated cells. NQO1 activity in oltipraz-treated cells increased two- to three-fold. In additional studies where pre-treatment of the cells with 100μM oltipraz over an optimal induction time course of 48 hours was followed by a 24-hour treatment with 0.5μg/mL mitomycin C, the number of colonies counted in flasks containing MCF-7 cells was reduced by 50% when compared to cells treated with mitomycin C alone. Lovo cells undergoing the combined oltipraz/mitomycin C treatment had colony numbers reduced by nearly 100% compared to treatment with mitomycin C alone. The human cancer cell lines, MCF-7 and Lovo, appear to exhibit an increased mitomycin C cytotoxicity when pre-treated with oltipraz. This may translate for cancer patients with an at-risk NQO1 genotype as an opportunity to increase mitomycin C sensitivity and produce therapeutic improvement in mitomycin C cytotoxicity.

1025 POTASSIUM BROMATE-INDUCED RAT CLEAR CELL RENAL TUMOR IS INDEPENDENT OF CODING REGION MUTATIONS IN THE VON HIPPEL-LINDAU GENE.

Y. H. Shiao[1], M. Hooth[2], L. M. Li[1], A. B. DeAngleo[2], L. M. Anderson[1] and D. C. Wolf[2]. [1]*Laboratory of Comparative Carcinogenesis, NCI-FCRDC, Frederick, MD and* [2]*Environmental Carcinogenesis Division, NHEERL/USEPA, Research Triangle Park, NC.*

Potassium bromate (KBrO3) is a rat renal carcinogen and a major drinking water disinfection by-product from ozonization. While KBrO3 is a human nephro- and neuro-toxicant, its carcinogenicity in humans is unknown. Clear cell renal tumors, the common form of human renal carcinomas, are rare in animals but can be induced by KBrO3 in Fischer 344 rats. Alteration of the

von Hippel-Lindau (VHL) gene is frequently observed in clear cell renal carcinomas in humans and has been associated with the same tumor type induced by N-nitrosodimethylamine in Wistar rats. Detection of VHL mutations in KBrO3-induced rat renal tumors would allow direct comparison of mutation spectra with those in humans, providing an indication of relevance for carcinogenicity of KBrO3 in human kidney. Formalin-fixed paraffin-embedded clear cell renal tumors from male Fischer 344 rats treated with KBrO3 for 2 years in the drinking water and kidney samples from untreated control were microdissected for DNA extraction. The coding region and exon-intron boundaries of the VHL gene were examined by polymerase chain reaction, which was optimized to amplify fragmented DNA from archived tissues, and direct DNA sequencing. More than 90% of the DNA sequencing has been completed. No mutations were detected in any of 9 selected kidney tumors and 1 control. This suggests that induction of clear cell renal tumor by KBrO3 in Fischer 344 rats is not associated with mutations in the coding region of the VHL gene. Other VHL alterations, such as allele loss and methylation in the promoter region, have been reported in human clear cell renal carcinomas and are under investigation in these rat tumors in order to clarify the role of VHL in KBrO3-induced rat renal tumorigenesis. (This abstract does not reflect EPA policy.)

1026 IMPROVED METHODOLOGY FOR THE SIMULTANEOUS DETERMINATION OF ENDOGENOUS ESTROGENS AND THEIR METABOLITES USING HIGH-PERFORMANCE LIQUID CHROMATOGRAPHY WITH ELECTROCHEMICAL AND ULTRAVIOLET DETECTION (HPLC/EC/UV).

W. Davis, D. R. Doerge and D. W. Roberts. *National Center for Toxicological Research, Jefferson, AR.*

A major risk factor in the etiology of breast cancer is the length of women's exposure to endogenous estrogens. Early menarche, early first pregnancy and late menopause have all been shown to increase the risk of breast cancer development. Several metabolites of endogenous estrogens including 4-hydroxyestradiol and 16-alphahydroxyestrone have been shown to be genotoxic in various experimental systems. However, the relative importance of these metabolites in breast cancer etiology remains unclear. In order to prove any hypothesis regarding a relationship between these metabolites (and others) and breast cancer development assays that are rugged, rapid, sensitive, and reproducible are needed for the analysis of biological samples collected during epidemiological studies. Taking as a point of departure methodology described in personal communications with P Gamache and J Lavigne, we have developed a HPLC/EC/UV method that separates 12 estrogens/metabolites (estriol, 16-alphahydroxyestrone, 4-hydroxyestradiol, 2-hydroxyestradiol, 2-hydroxyestrone, 4-hydroxyestrone, estradiol, 4-methoxyestradiol, 2-methoxyestradiol, estrone, 4-methoxyestrone and 2-methoxyestrone) in less than half the time of previous methods. After solid phase extraction of the analytes from human samples, a binary gradient reverse-phase (C18) HPLC separation with a mobile phase system of ammonium acetate / citric acid buffer (pH 3) and acetonitrile was used to baseline resolve these components in 20 minutes. Detection at the low pmol level was obtained using 8 coulometric sensors. This method, because of its speed and sensitivity, will facilitate the routine analysis of estrogen metabolites. (Supported by grants from Arkansas Breast Cancer Research program and Office of Women's Health, FDA.)

1027 THE TEMPORAL LOSS OF DNA REPIAR CAPACITY BY ESTROGEN EXPOSURE.

J. W. DuMond, Jr. and D. Roy. *University of Alabama, Birmingham, AL.*

In this study we report the effects of both natural and stilbene estrogen exposures on the DNA repair capacity of the normalized mouse Leydig cell line, TM3, using the host cell reactivation assay. We have used 17β-estradiol, 17α-estradiol, diethylstilbestrol (DES) and Bisphenol A as test compounds. Cells were exposed to ether a sub-chronic 12 day treatment (100-ng DES only) or an acute 72 hour treatment. A significant ($p < 0.05$) dose dependent decrease in the DNA repair of the Leydig cells was observed when exposed to DES (1 pg, 1 ng, and 100 ng/ml). A non-significant decrease in DNA repair was observed with 1 pg/ml Bisphenol A. The DES concentration of 100 ng/ml resulted in the maximum decrease of DNA repair (53.57%), followed by DES, 1 ng/ml (53.27%), Bisphenol A, 1 pg/ml (43.51%), and DES, 1 pg/ml (24.28%). 17β-estradiol and 17α-estradiol treatment resulted in a non-significant increase of DNA repair, 32.10% and 54.37% respectively. Sub-chronic treatment with 100 ng/ml DES resulted in a non-significant decrease in DNA repair activity (26.15%). The data presented here is novel and intriguing as it provides direct evidence for a mechanism for the induction of genomic instability by DES and Bisphenol A. However, whether the observed attenuation in DNA repair capacity by estrogen exposure leads to accumulation of DNA damage remains to be ascertained.

1028 AN INDUCIBLE DNA REPAIR PROCESS IS INDEPENDENT OF NON-HOMOLOGOUS END-JOINING (NHEJ).

N. Whisnant-Hurst[1], T. D. Stamato[2] and S. A. Leadon[1]. [1]*University of North Carolina, Chapel Hill, NC and* [2]*The Lankenau Medical Research Center, Wynnewood, PA.*

DNA repair is vital for maintaining genomic stability. The role of DNA repair in assuring normal development and preventing carcinogenesis is demonstrated in individuals with DNA repair disorders such as Xeroderma Pigmentosum and Cockayne syndrome. We have discovered a novel, inducible DNA repair response in cells treated with ionizing radiation (IR) at the G1/S border of the cell cycle. This process differs from constitutive repair processes by producing very long repair patches (VLRP) of at least 150 nucleotides in addition to constitutive repair patches of 3-5 nucleotides. One signal for the induction of VLRP is double-strand breaks produced by ionizing radiation and bleomycin. In the current study, we examined whether several components of the non-homologous end joining pathway that rejoins double-strand breaks are involved in this inducible repair process. Cells with mutations in the XRCC4 gene, as well as the p86 subunit of Ku and the catalytic subunit of the DNA-dependent protein kinase (DNA-PK) were irradiated at the G1/S border of the cell cycle and repair patch size was analyzed by alkaline cesium chloride density gradients. XR-1 cells which lack the XRCC4 gene were able to produce VLRP of 150 bases, and the VLRP were produced at a higher level than seen in normal human fibroblasts. Two cell lines with mutant Ku86, xrs6 and MEF Ku86 -/-, were also able to produce long patches of 200 and 150 bases. These cell lines also produced a higher level of VLRP than is seen in normal fibroblasts. Finally, we examined two cell lines with a deficiency in the catalytic subunit of the DNA-PK. Hamster V3 cells and MO59J human glioblastoma cells both produced long patches of 175 bases, while the V3 cells produced VLRP at normal levels and the MO59J cells overproduced the long patches. These results indicate that neither the XRCC4 gene product nor the components of the DNA-PK are required for the production of long patches. The overproduction of long patches in several of the cell lines appears to be the result of a mutation in the p53 gene in these cells because the overproduction is also seen in the corresponding control cell lines and in fibroblasts that are p53 deficient. Further investigation will focus on whether components of the double-strand break repair process of homologous recombination are responsible for producing VLRP. (Supported by NCI CA62059.)

1029 DNA-DAMAGE BY HYDROXYLAMINE O-SULFATE AND METHYL ETHYL KETOXIME O-SULFATE.

U. Schauer[1], M. Friedewald[1], M. Derelanko[2] and W. Dekant[1]. [1]*Institut fuer Toxikologie der Universitaet Wuerzburg, Wuerzburg, Germany and* [2]*Allied Signal, Inc., Morristown, NJ.*

Long term inhalation of methyl ethyl ketoxime (MEKO) causes a dose-dependent induction of liver tumors in male rats and male mice. The mechanistic basis for the sex-specific tumor induction is not known. Oxime O-sulfates have been implicated as toxic metabolites involved in the induction of DNA-damage by oximes and sec. nitroalkanes. We compared the ability of synthetic MEKO O-sulfate (purity > 98%) and hydroxylamine O-sulfate to induce DNA-damage (8-oxo-deoxyguanosine and 8-amino-deoxyguanosine) in calf thymus DNA and mutagenicity in Salmonella typhimurium TA100. MEKO O-sulfate was stable in aqueous solution at pH 7.4; less than 5% decomposition was noted after 48 h at 37°C. To study DNA-damage, MEKO O-sulfate and hydroxylamine O-sulfate were incubated with DNA in buffer at pH 7.5 for 4 h at 37°C, DNA was isolated, hydrolysed and 8-oxo-deoxyguanosine and 8-amino-deoxyguanosine were quantified by HPLC with electrochemical detection. At concentrations of 0.72 mM, MEKO O-sulfate did not induce detectable levels of 8-amino-deoxyguanosine and caused only a minor increase in the concentration of 8-oxo-deoxyguanosine. At 7.2 mM MEKO O-sulfate, 8-oxo-deoxyguanosine was increased from 63±28 pml/mg DNA to 280±52 pmol/mg DNA and 8-amino-deoxyguanosine was formed (57±30 pg/mg DNA). Hydroxylamine O-sulfate in identical concentrations induced large increases in 8-oxo-deoxyguanosine (up to 13 732±4 306 pg/mg DNA) and induced formation of 8-amino-deoxyguanosine in concentrations of 30 012±1745 pmol/mg DNA. In agreement with the DNA damage studies, only hydroxylamine O-sulfate caused mutations in Salmonella typhimurium. The results suggest that oxime O-sulfates are stable in aqueous solution and

that reactive intermediates from oxime O-sulfates *in vivo* should only be formed after further enzymatic activation to yield hydroxylamine O-sulfate.

1030 MOLECULAR DOSIMETRY AND REPAIR STUDIES ON N^2,3-ETHENOGUANINE IN HEPATOCYTES AND NONPARENCHYMAL CELLS FROM RATS EXPOSED TO VINYL CHLORIDE.

E. J. Morinello[1] and J. A. Swenberg[2]. [1]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC and* [2]*Curriculum in Toxicology and Department of Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC.*

Exposure to vinyl chloride (VC) monomer causes hepatic angiosarcomas, tumors that originate from endothelial cells lining the hepatic sinusoids, in rats and humans. This study investigated the molecular dosimetry of the VC-induced, promutagenic DNA adduct N^2,3-ethenoguanine (N^2,3-εGua) in hepatocytes and nonparenchymal cells (NPC). Based on evidence that NPC (a population enriched in endothelial cells) were deficient in base excision repair relative to hepatocytes, it was hypothesized that higher concentrations of N^2,3-εGua would be present in NPC DNA following VC exposure. 12 wk-old male Sprague-Dawley rats were exposed to 0, 10, 100, or 1100 ppm VC for 1 or 4 wk (6 hr/d, 5 d/wk). A recovery group was similarly exposed for 4 wk and maintained 1 wk before being killed. The liver of each animal (n=3-5) was perfused with collagenase *in situ*, and hepatocytes were separated from NPC by differential centrifugation. DNA from each population was hydrolyzed in 0.1*N* HCl, and N^2,3-εGua was isolated with immunoaffinity chromatography. The adduct was quantitated with gas chromatography-high resolution mass spectrometry, and the guanine content of each sample was determined by HPLC. The exposure-response curve with respect to N^2,3-εGua was supralinear with a plateau between 100-1100 ppm, and there was a 2-4 fold accumulation of the adduct between 1 and 4 wk in both hepatocytes and NPC. However, no significant cell type-specific differences in adduct concentrations were observed in controls or rats exposed to any VC concentration. Surprisingly, there were no significant adduct concentration differences between the 4 wk and recovery groups with either cell type, suggesting that N^2,3-εGua is poorly repaired *in vivo*. The persistence of this adduct may increase its mutagenic potential, although it appears that factors in addition to relative adduct concentrations are important determinants of the susceptibility of NPC to VC-induced carcinogenesis. (This work was supported in part by NIH grants ES07126 and ES05948.)

1031 DEOXYADENOSINE (dAdo) ADDUCTS FORMED BY THE SYN- AND ANTI-DIOL-EPOXIDES OF 7,12-DIMETHYLBENZ[A] ANTHRACENE (DMBA) ACCOUNT FOR ITS TUMOR INITIATION ACTIVITY IN MOUSE SKIN.

S. V. Vulimiri[1], M. S. Tang[2], A. Viaje[3], J. X. Chen[2], D. S. Bilolikar[2], R. Morris[4], R. G. Harvey[5], T. J. Slaga[3] and J. DiGiovanni[1]. [1]*The University of Texas MDACC, Smithville, TX,* [2]*NYU, Tuxedo, NY,* [3]*AMC-CRC, Denver, CO,* [4]*LMRC, Wynnewood, PA and* [5]*Ben May Institue, UC, Chicago, IL.*

The current study was designed to explore the possibility that the dAdo adducts formed by the bay-region diol-epoxides of DMBA (syn- and anti-DMBADE) account for the tumor initiation activity of DMBA. Groups of SENCAR mice (4/group) were topically treated with 10 nmol of DMBA, 50 and 100 nmol of both syn- and anti-DMBADE and were sacrificed at 3, 6 and 24 h after the treatment. DNA adduct formation in epidermis was analyzed by nuclease P1-enhanced 32P-postlabeling assay. Tumor initiation activity was assessed by a two-stage initiation-promotion protocol and formation of specific mutations in codons 12, 13 and 61 of the Ha-ras gene in skin tumors was assessed by a PCR-RFLP protocol. Results from these experiments showed that both syn- and anti-DMBADE formed stable dAdo adducts in mouse epidermis, most of which co-migrated with the stable dAdo adducts formed by the parent compound. In addition, both the syn- and anti-DMBADEs possessed tumor initiation activity. Essentially all (100, 96 and 94%, respectively) of the papillomas produced by syn- and anti-DMBADE contained a -CAA- to -CTA- mutation in codon 61 of Ha-ras gene similar to the parent compound DMBA. Collectively, these results indicate that the dAdo adducts induced by both bay-region diol-epoxides of DMBA lead to the mutations in codon 61 of Ha-ras gene and consequently initiate tumorigenesis in mouse skin (Supported by NIEHS ES 03124, ES 08389, and from The Council for Tobacco Research 3995 [M.-s.T.]; NIEHS Center grant ES 07784 and CA 79442 [J.D.].)

1032 EXPOSURE-DEPENDENT ACCUMULATION OF N7-(2-HYDROXYPROPYL)GUANINE (7-HPG) IN DNA OF TISSUES OF F-344 RATS AFTER INHALATION EXPOSURE TO PROPYLENE OXIDE (PO).

M. N. Ríos-Blanco[1], A. Ranasinghe[1], J. Nakamura[1], M. S. Lee[2], M. Dhawan-Robl[2], J. G. Filser[2] and J. A. Swenberg[1]. [1]*University of North Carolina, Chapel Hill, NC and* [2]*GSF Inst. of Toxicology, Neuherberg, Germany.*

PO is an industrial chemical shown to induce tumor formation (2-3% incidence) in nasal passages of rodents in the high exposure groups (≥ 300 ppm) in carcinogenicity bioassays. Nasal tumors were accompanied by nonneoplastic changes suggesting that cytotoxicity and compensatory cell proliferation may be involved in PO carcinogenesis. In the present study, exposure-dependent accumulation of 7-HPG in nasal respiratory epithelium (NRE), lung and liver was determined in male F344 rats exposed to PO (0, 5, 25, 50, 300 or 500 ppm) by the inhalation route for 3 days (6 hr/day) or 20 days (6 hr/day; 5 days/week). The exposures studied ranged from low concentrations, such as those potentially occurring in the workplace, to high concentrations that were carcinogenic in rodents, thus providing valuable information for biologically based risk assessment for PO. Preliminary results (n=3) showed a linear response in 7-HPG accumulation for all three tissues and both lengths of exposure. The nose had the highest concentration of adducts followed by lung and liver, with linear regression slopes 1/6 and 1/15 that of the nose, respectively. These differences are thought to be due to greater amounts of PO reacting with nasal tissue and a combination of direct and systemic exposure in the lung. We have previously shown an increase in cell proliferation in the NRE only at carcinogenic exposures. While 7-HPG is not promutagenic, loss of the adduct by chemical depurination and base excision repair can produce abasic sites. Abasic sites were measured in these three tissues and testis using the ARP method and showed no increase in rats exposed to 500 ppm PO for 20 days, suggesting that this is not a mechanism of mutagenesis for 7-HPG. Thus, the modest increase in nasal tumors may be related more to increased cell proliferation than to the very high number of 7-HPG adducts. (Supported in part by CMA and CEFIC.)

1033 ASSOCIATION BETWEEN THE XRCC1 399 GLN POLYMORPHISM AND ADENOCARCINOMA OF THE LUNG.

K. K. Divine[1], F. Gilliland[2], R. E. Crowell[3], M. G. Menache[1] and S. A. Belinsky[1]. [1]*Lovelace Respiratory Research Institute, Albuquerque, NM,* [2]*University of Southern California, Norris Comprehensive Cancer Center, Los Angeles, CA and* [3]*Veterans Affairs Medical Center, University of New Mexico School of Medicine, Albuquerque, NM.*

Genetic predisposition to cancer has been associated with hereditary genetic defects in DNA repair. Maintenance of genomic integrity is critical in the protection against mutations that lead to cancer. XRCC1 is a DNA repair enzyme involved in the base excision pathway. Three polymorphisms have been identified in the XRCC1 gene that code for nonconservative amino acid changes at codons 194 (Arg to Trp), 280 (Arg to His) and 399 (Arg to Gln). Significant associations have been reported between the 399 Gln allele and higher levels of both AFB_1-adducts and GPA somatic mutations. We conducted a case control study to test the hypothesis that the 399 Gln allele is positively associated with adenocarcinoma of the lung. In this study, 74 lung adenocarcinoma samples and 68 control samples were genotyped at position 399. Polymorphic frequencies in the adenocarcinoma samples were 43% for Arg/Arg, 37% for Arg/Gln and 20% for Gln/Gln. In the control samples, XRCC1 polymorphic frequencies were 46% for Arg/Arg, 47% for Arg/Gln and 7% for Gln/Gln. A marginal significance (p=0.07) was noted between lung adenocarcinoma and presence of the 399 Gln/Gln allele. Additional samples are being analyzed to determine if this association is significant ($p \leq 0.05$). (Supported by NIH Grants 1 F32 ES05836-01 and CA70190 from NIEHS under the U.S. DOE cooperative agreement No. DE-FC04-96AL-76406.)

1034 ANALYSIS OF MUTATION IN LUNG OF BIG BLUE RAT INDUCED BY EXPOSURE TO DIESEL EXHAUST.

H. Sato[1], H. Sone[1], M. Sagai[2], K. T. Suzuki[3] and Y. Aoki[1]. [1]*National Institute for Environmental Studies, Tsukuba, Japan,* [2]*Aomori University of Health and Welfare, Aomori, Japan and* [3]*Chiba University, Chiba, Japan.*

Exposure to diesel exhaust (DE) is known to cause lung tumors in rats. To clarify the mutagenicity of DE, we estimated mutant frequency (MF) and determined the mutation spectra in rat lung after exposure to DE using lambda/lacI transgenic rats (Big Blue system). Male Big Blue rats were exposed for 4 weeks to 1 or 6 mg/m3 of DE, which contains suspended particulate mat-

ter. Control rats were maintained in filtered air. After exposure to 6 mg/m3 DE, MF in lung was 4.8-fold higher than in control rats ($p<0.01$), Sixty-nine mutants were identified after exposure to 6 mg/m3 DE. The major mutations were A:T to G:C and G:C to A:T transitions. Remarkably, G to T transversion of the lacI gene at site 221 was a hot spot induced by exposure to DE. DNA adducts formed by DE were analyzed using a 32P-postlabel-TLC method and the amount of 8-hydroxydeoxyguanosine (8-OHdG) was measured using HPLC. Relative adduct level and amount of 8-OHdG were significantly increased in the rats exposed to DE. The level of cytochrome P450 1A1 mRNA was shown by northern blot analysis to be significantly increased in the rats exposed to 6 mg/m3 DE. These results indicate that DE causes lesions in genomic DNA and acts as a mutagen in rat lung.

1035 INFREQUENT P53 MUTATIONS IN LIVER TUMOURS INDUCED BY 3-CHLORO-4-(DICHLOROMETHYL)-5-HYDROXY-2[5H]-FURANONE (MX) IN RATS.

P. Hakulinen[1], V. M. Kosma[2], K. Makkonen[3], K. Servomaa[4], R. Vasara[4], J. Mäki-Paakkanen[1] and H. Komulainen[1]. [1]*Division of Environmental Health, National Public Health Institute, Kuopio, Finland,* [2]*Department of Pathology and Forensic Medicine, University of Kuopio, Kuopio, Finland,* [3]*STUK-Radiation and Nuclear Safety Authority, Helsinki, Finland and* [4]*North Savo Regional Environment Centre, Kuopio, Finland.* Sponsor: M. Vilukselą.

MX, a disinfection by-product in chlorinated drinking water, is mutagenic in bacteria and in mammalian cells. In a recent carcinogenicity study with Wistar rats [Komulainen H. et al., J. Natl. Cancer Inst. 89:848-856, 1997], MX caused tumours at multiple sites, including the liver. In order to evaluate the molecular mechanisms of the MX-induced carcinogenesis, we analyzed mutations in p53 gene (exons 4-7) and expression of p53 gene in formalin-fixed, paraffin-embedded liver tumours of the rats (altogether 16 adenomas, 8 carcinomas, 23 cholangiomas, 3 cholangiocarcinomas). Mutations were investigated by polymerase chain reaction-single strand conformation polymorphism (PCR-SSCP) followed by direct sequencing. Four mutations (3 G:C->A:T transitions, one A:T->T:A transversion) were detected in 2/16 adenomas and 1/3 cholangiocarcinomas, all in high dose females of the study. An immunohistochemical overexpression of the p53 gene was detected in all cholangiomas and cholangiocarcinomas, but in none of the adenomas or carcinomas. The results suggest, that p53 mutations are not involved in MX-induced liver carcinogenesis in Wistar rats. (Supported by Academy of Finland, Finnish Research Programme on Environmental Health.)

1036 CHRONIC TOXICITY OF DIETHYLNITROSAMINE, MANNITOL AND CAPROLACTAM IN HETEROZYGOUS *p53*-DEFICIENT (+/-) AND WILD (+/+) TYPE MICE.

M. J. Iatropoulos[1], A. M. Jeffrey[1], G. M. Williams[1], G. Schlueter[2] and H. G. Enzmann[2]. [1]*New York Medical College, Valhalla, NY and* [2]*Bayer AG, Wuppertal, Germany.*

This study compares the carcinogenicity of diethylnitrosamine (DEN) in conventional mice to that in *p53*-deficient mice, chiefly to assess the potential of DEN to induce DNA adducts in the liver of transgenic mice. Mannitol (MAN) and caprolactam (CAP) were also tested. Sixty male wild type mice (+/+), 8 weeks old, and 60 heterozygous (+/-) C57BL/6 (*p53*-deficient) mice, 8 weeks old, were used. Of the 6 experimental groups, groups 1(wild type, (+/+) and 2 (*p53*-deficient heterozygous; (+/-) served as room controls. Groups 3 (+/+) and 4(+/-) were exposed orally (gavage) to 50 μmoles/kg bw DEN weekly for a total of 10 doses. Group 5 (+/-) was exposed to 15,000 ppm of CAP in the diet for up to 26 weeks. Group 6 (+/-) was exposed to 50,000 ppm of MAN in the diet for up to 26 weeks. At 10 weeks, part of the liver was removed for DNA adduct analysis by the immunoslot blot method which measures O^4-EtT (O^4-ethylthymidine) adducts. Absolute and relative liver weights were measured, and liver microscopy (H&E) was performed. The liver was also evaluated immuno-histochemically by staining for proliferating cell nuclear antigen (PCNA) and by measuring the replicating fraction (RF). No significant or consistent body or liver weight changes were present in any of the groups. No consistent and pertinent changes in RF values were present in any of the groups and no other pertinent and consistent morphologic changes were evident in the livers. The O^4-EtT modified bases of liver DNA indicated a significant increase in both groups 3 and 4 mice, when compared to their respective controls, although not significantly different from each other. None of the tested substances produced neoplasms in p53 (+/-) mice. This was unexpected for DEN, especially since it produced DNA adducts in the liver.

1037 TOXICITY OF INHALED BROMODICHLOROMETHANE IN p53+/- TRANSGENIC MICE.

V. R. Torti[1], A. J. Cobb[1], J. I. Everitt[1], M. Marshall[1], G. Boorman[2] and B. E. Butterworth[1]. [1]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC and* [2]*National Institute of Environmental Health Sciences, Research Triangle Park, NC.*

The purpose of this study was to determine the dose response curves and target organ toxicity for the water disinfection by-product bromodichloromethane (BDCM) as the basis for selecting doses for long term cancer studies in the p53 +/- mouse model. Wild type and p53+/- mice on the FVB/N and C57BL/6 backgrounds were exposed to BDCM vapor daily for 6 hr/day at concentrations of 0, 1, 10, 30, 100, and 150 ppm for 1 week and at 0, 0.3, 1, 3, 10, and 30 ppm for 3 weeks. In the 1-week exposure study dose-dependent mortality and morbidity were observed at concentrations of 30 ppm and above and were as high as 100% at 150 ppm. In the 3-week exposure study mortality and morbidity was only found in the 30 ppm exposure groups and was 0, 17, 50, and 33% for the wild type C57BL/6, p53+/-C57BL/6, wild type FVB/N, and the p53+/- FVB/N mice, respectively. Dose-dependent tubular degeneration, necrosis, and associated regenerative cell proliferation (greater than 10 fold over controls) were seen at concentrations as low as 10 ppm in the kidneys of all strains at 1 week. Pathological changes were more severe in the FVB/N compared to the C57BL/6 and were more severe in the heterozygotes compared to the wild type. However, recovery and return of the percentage of cells in S-phase to control levels was seen at 3 weeks. Similar dose-dependent increases in hepatic necrosis and regenerative cell proliferation were observed, but were induced only at concentrations of 30 ppm and higher. The maximum tolerated dose for longer-term studies with these mice is on the order of 10 ppm. Differences in toxicity indicate that the exact strain and genotype should be used when doing range finding studies to select doses for p53+/- cancer studies.

1038 TUMORIGENIC POTENTIAL OF CARBARYL IN THE P53 KNOCKOUT MOUSE MODEL.

D. Bigot-Lasserre, F. Chuzel, E. Debruyne, M. Urtizberea and N. Carmichael. *Rhône-Poulenc Agro, Sophia Antipolis, France.*

Using the genotoxic compound urethane, we have previously shown the heterozygous p53 knockout mice to be sensitive to the development of vascular tumors within a short period of time. The essentially zero level of vascular tumors in control p53 knockout mice made this system particularly suitable for studying low potency compounds suspected of being vascular carcinogens. Therefore, this model was used to assess the significance of vascular tumors noted in a long term study in CD-1 mice with carbaryl. Although increased incidences of vascular tumors were observed in male mice at 100, 1000 and 8000 ppm, no clear dose-effect relationship was obtained. In previous studies, carbaryl had shown clastogenic activity in an *in vitro* CHO assay with S9 activation but was negative in an *in vivo* chromosomal aberration test (rat bone marrow). Metabolism data obtained in the rat had suggested the possible formation of epoxide metabolites. In order to investigate whether Carbaryl might induce vascular tumors by a genotoxic mechanism it was administered continuously via the diet to groups of 20 male heterozygous p53 knockout mice at concentrations of 0, 10, 30, 100, 300, 1000 and 4000 ppm for 180 days (8000 ppm exceeding the MTD in CD-1 mice). Carbaryl induced no neoplastic or preneoplastic changes in the vascular tissue of any of the organs examined (nor in any other tissue). Neoplasms, recognized as those which typically occur spontaneously in untreated mice of this strain, were sporadically observed in a few animals from the intermediate dose groups with no evidence of a dose or treatment relationship. Under the conditions of this study Carbaryl did not show any carcinogenic potential in the p53 heterozygous mouse. In particular there was no evidence that the apparent increase in vascular tumors in the previous lifetime mouse study reflect a genotoxic mechanism.

1039 SUBACUTE EXPOSURE OF P53-HEMIZYGOUS (+/-) MICE TO 4-(N-METYHL-N-NITROSAMINO)-1-(3-PYRIDYL)-1-BUTANONE (NNK).

U. Wirnitzer, M. Rinke, E. Hartmann, V. Geiss, H. Enzmann and G. Schlüter. *Bayer AG, Wuppertal, Germany.*

We investigated the sensitivity of the p53-hemizygous (+/-) mouse to exposure to 4-(N-Methyl-N-nitrosamino)-1-(3-pyridyl)-1-Butanone (NNK). A single exposure of A/J or (A/J x TSG-p53)F1 mice to NNK results in 100% or 97% of multiple lung adenomas within 16/17 weeks. In our study NNK was

administered at a dose, that is cumulative comparable to the exposure levels occuring in life-long smokers. NNK was administered to 26 male and 26 female p53-hemizygous (p53 +/-) C57BL mice intraperitoneally 5 times once a week during 5 consecutive weeks in a dose of 1 mg/kg body weight. Half of these animals were then kept for a subsequent 9 week and the other half for a 22 week treatment-free period. The animals were regularly observed, body (weekly) and organ weights as well as feed intake (weekly) were determined. Organs and tissues were subjected to gross and histopathological investigations. Treatment with NNK did not induce any effects on general condition, species-specific behavior, mortality, body weight development and food consumption. Liver weights were significantly reduced in females after 27 study weeks. Histopathologically no indications of neoplasia or pre-neoplasia were seen in liver and lungs. It is concluded, that within a period of 27 weeks the p53-hemizygous (p53 +/-) C57BL mice is insensitive to the carcinogenic effect of NNK seen in A/J mice and Syrian golden hamsters at a cumulative dose comparable to the lifetime-exposure of smokers.

1040 TUMORIGENIC POTENTIAL OF COMPLEX MIXTURES IN p53 DEF. MICE.

R. Singh, K. A. Rozett, N. Modi, T. Stakhiv and E. H. Weyand. *College of Pharmacy, Rutgers University, Piscataway, NJ.*

Previous studies have demonstrated that manufactured gas plant tar (MGP tar) is highly tumorigenic in mouse lung following ingestion. The present study evaluates the potential tumorigenic activity of manufactured gas plant tar, pharmaceutical grade coal tar (PG tar) and benzo[a]pyrene B[a]P in $p53^{def}$ mice. Diets containing MGP tar (0.3%), PG tar (0.3%) or B[a]P (100 ppm) were fed to $p53^{def}$ mice for 26 weeks. A negative control group was maintained on a non-adulterated basal gel diet. Mice dosed with a single ip injection of 2.1 mg of B[a]P in a tricaprylin vehicle and maintained on a non-adulterated basal gel diet were positive controls. Animal body weights and diet consumption were monitored throughout the study. Ingestion of a 100 ppm B[a]P diet resulted in 55% of the mice developing forestomach tumors with a multiplicity of 2.9 tumors/mouse. Mice injected with 2.1 mg B[a]P had a 29% forestomach tumor incidence with a multiplicity of 1 tumor/mouse. In contrast, a much lower tumorigenic response was observed in mice ingesting MGP tar and PG tar. In these animals, 5 and 18% of the mice developed forestomach tumors with a multiplicity of 0.36 and 0.15 tumors/mouse, respectively. Interestingly, no lung or liver tumors were observed in any of the treated groups. These results are in contrast to the results of previous studies that demonstrated MGP tar to be highly tumorigenic in mouse lung. The lack of lung tumorigenicity may be due to the dose of each mixture administered and/or the exposure time given to animals. These results also suggest that the lung and liver tumorigenicity previously observed with other strains of mice may not involve p53 gene mutations. (EPRI Grant WO2963-06)

1041 CANCER BIOASSAY AND GENOTOXICITY OF INHALED BENZENE IN P53+/- AND C57BL/6 MICE.

L. Recio[1], S. Boley[1], J. Everitt[1], R. A. James[1], D. Janszen[1], L. Healy[1], K. Roberts[1], D. Walker[2], L. Pluta[1] and J. E. French[3]. [1]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC,* [2]*USEPA, HERL, Research Triangle Park, NC and* [3]*NIEHS, Research Triangle Park, NC.*

P53+/- and wildtype C57B1/6 mice have been exposed to benzene by chronic inhalation to assess tumorigenic and genotoxic responses. To determine the time to maximum tumor induction, the length of exposure was for 36 weeks or until the survival in the benzene exposed groups reached 20% of unexposed controls. Mice were exposed to either 0 ppm or 3000 ppm x hr/week of benzene using three exposure regimens: 100 ppm (6 hrs/day 5 days/week); 100 ppm (10 hrs/day 3 days/week; MWF) or 200 ppm (5 hrs/day 3 days/week; MWF). The frequency of micronuclei in peripheral blood was determined at 1, 5, 13 and at 33-38 weeks of exposure. At 26 weeks of exposure to benzene the incidence of thymic lymphomas was: 22% in the 100 ppm exposure groups, 2% in the 200 ppm exposure group and 0% in the air controls. In the 100 ppm exposure groups, 36 weeks of benzene exposure induced a high frequency of thymic lymphomas in p53+/- mice, >80% incidence compared to 2% in unexposed controls. In the 200 ppm exposure group, the incidence of thymic lymphomas in p53+/- mice at 36 weeks was 17%. The incidence of thymic lymphomas in C57B1/6 mice at 36 weeks at all levels of benzene exposure was less than 5%. The frequency of micronuclei was elevated in all exposure groups at all time points examined. The increased frequency of micronuclei in peripheral blood was equivalent or greater in the C57B1/6 mice than in the p53+/- mice. These data indicate that benzene inhalation exposure is carcinogenic in p53+/- mice, but at these levels of benzene exposure p53+/- mice are not more sensitive to the genotoxic effects of benzene than wild type mice.

1042 SPONTANEOUS TUMOR PROFILE IN THE P53 DEFICIENT TG.AC (V-HA-RAS) BIGENIC MOUSE MODEL.

G. J. Moser[1], T. L. Goldsworthy[1], R. R. Tice[1], G. E. French[2], J. F. Mahler[2], J. W. Spalding[2] and R. W. Tennant[2]. [1]*Integrated Laboratory Systems, Research Triangle Park, NC and* [2]*NIEHS, Research Triangle Park, NC.*

The p53+/- and Tg.AC transgenic mouse models are under consideration as adjuncts or alternatives for carcinogen identification. A p53+/- mouse with a Tg.AC hemizygous alteration was generated as another possible short-term bioassay model and to provide a mechanistic understanding of carcinogen induced neoplasia. Male (92) and female (100) bigenic mice were observed under normal husbandry conditions. Mean survival time in humane- and moribund-euthanized mice was greater in male than female mice with 50% mortality occurring at 37.3 and 30.6 weeks of age respectively. Seventy-one percent of female mice died prior to when 50% mortality was attained in male mice and only 5 female mice survived to the terminal sacrifice at 49 weeks of age (after 43 weeks on study). Jaw masses (presumably odontogenic tumors) and enlarged spleens were the most frequent necropsy findings (70% of animals). At 20, 25, 30, and 49 weeks of age, jaw masses were found in 2, 7, 9, and 19% of male mice, respectively, and 3, 11, 14, and 29% of female mice, respectively. Surprisingly, uterine masses (presumably leiomyosarcomas) were first found as early as 12 weeks. At 15, 20, and 25 weeks, uterine masses were found in 13, 15, and 19%, respectively, of female mice. The bigenic model permits comparison to sporadic tumor incidence in p53+/- or Tg.AC mice. Inherent genetic susceptibilities for tumor formation were suggest that there are tissue specific interactions between p53 and v-Ha -ras. Since both ras and p53 are detected in many human cancers, a mechanistic understanding of critical gene events and interactions occurring in neoplasia may help in defining carcinogen specific mechanisms of cancer using this model. (This work was sponsored by NIEHS [N01-ES-65399].)

1043 ANALYSIS OF RESPONDER STATUS ACROSS MULTIPLE GENERATIONS OF TG.AC TRANSGENIC MICE.

T. L. Goldsworthy[1], G. J. Moser[1], J. J. Clancy[1], D. K. Kantz[1], R. R. Tice[1], J. W. Spalding[2], R. E. Cannon[2], G. N. Rao[2] and R. W. Tennant[2]. [1]*Integrated Laboratory Systems, Inc., Research Triangle Park, NC and* [2]*NIEHS, Research Triangle Park, NC.*

The v-Ha-ras transgenic Tg.AC mouse model has been proposed as an alternative short term *in vivo* model to the conventional two-year bioassay for the identification of carcinogens. When exposed to 12-0-tetradecanoyl-phorbol-13-acetate (TPA), Tg.AC mice respond with skin papillomas as a reporter phenotype. During the last several years, an increased incidence in TPA-exposed non-responder Tg.AC mice has been observed. The present study monitored the response of male and female homozygous Tg.AC mice from six different generations to 2.5 µg TPA applied topically either two or three times per week for 12-21 weeks. The incidence and multiplicity of papillomas from three studies initiated in late 1997 through mid 1998 was decreased as compared to three studies using mice from a colony founded in late 1998. Between these two sets of experiments, the incidence of mice exhibiting at least 20 papillomas increased from 30% to 90%. Genomic DNA blots have conclusively linked an altered genotype to the non-responder phenotype. The latter studies exhibited remarkable consistency in regard to tumor incidence, multiplicity, and latency following TPA exposure, with no difference noted between sexes. These studies demonstrate the robustness of the papilloma response in recent multiple generations of Tg.AC mice and the utility of TPA as an appropriate positive control. (This work was sponsored by NIEHS [N01-ES-95442].)

1044 CARCINOGENIC ENDPOINT EVALUATION IN TG. AC TRANSGENIC MICE GIVEN CYCLOSPORIN A DERMALLY FOR 26 WEEKS.

A. M. Hoberman[1], L. G. Lomax[2] and J. H. Wedig[1]. [1]*Primedica Redfield, Redfield, AR and* [2]*Pathology Consultant, Little Rock, AR.*

The purpose of this study was to assess the potential carcinogenicity of cyclosporin A when applied topically to homozygous TG. AC mice for 26 weeks. Groups of 15 male and 15 female mice approximately 10 weeks old were given 200 µl/mouse topical doses daily of the following for 26 weeks:

acetone vehicle, 2.5 µg of 12-0-tetradecanoly phorbol-13-acetate (positive control), 0.05, 0.4 or 0.8 µg of cyclosporin A dissolved in acetone. Visual observation for papillomas began after 4 weeks and tumor palpation began after 12 weeks. Clinical observations were done daily. Each mouse was necropsied and a complete set of tissues was evaluated histologically. No treatment-related effect was noted on weekly body weight or feed consumption. Papillomas were noted grossly and microscopically at the application site in all but two of the positive control mice. There was no significant difference in the survival rates of the three cyclosporin A treated groups when compared to the control group. The number of squamous papillomas at the application site was statistically ($p < 0.05$) increased in the females given 0.8 µg cyclosporin A compared to the controls (3/14 vs 0/14, respectively) but was not statistically increased in the males (2/15 vs. 0/15, respectively). The incidence of all other tumors among cyclosporin A treated animals was comparable to control animals.

1045 POINT MUTATIONS OF THE TRANSGENE IN FORESTOMACH AND SKIN TUMORS OF RASH2 TRANSGENIC MICE INDUCED BY N-METHYL-N NITROSOUREA (MNU) OR N-ETHYL-N-NITROSOUREA (ENU).

K. Mitsumori[1], S. Wakana[2], K. Urano[2], C. Maruyama[2], T. Usui[2], K. Yasuhara[1], T. Koujitani[1], M. Hirose[1] and N. Tamaoki[2]. [1]*National Institute of Health Sciences, Tokyo, Japan and* [2]*Central Institute for Laboratory Animals, Tokyo, Japan.*

It has been reported that forestomach and skin squamous cell tumors are induced by a single injection MNU in transgenic mice carrying the human proto-type c-Ha-ras gene (rasH2 mice) with an extremely high incidence of point mutations of the transgene. On the other hand, our previous studies in which rasH2 mice received a single injection of vinyl carbamate revealed that the transgene mutations were extremely low in the lung tumors induced. To examine the frequency of the transgene mutation, rasH2 mice received an intraperitoneal injection of 37.5 mg/kg MNU or 120 mg/kg ENU, and were reared until 26 weeks. In the MNU group, squamous cell tumors of the forestomach were found in 16/16 males and 20/20 females, and skin papillomas in 70% of these mice. In the ENU group, the forestomach tumors were found in 14/20 males and 7/20 females, and skin papillomas in 15%. The incidences of the transgene mutation of the forestomach tumors and skin tumors in the MNU group were 87% and 82%, respectively, those in the ENU group being 15 and 50%, respectively. Real-time RT-PCR analysis showed that the human c-Ha-ras gene expression level elevated in both MNU- and ENU-induced tumors. Our results suggest that the transgene mutation is not always related to the inductions of the forestomach and skin tumors.

1046 A 26-WEEK STUDY IN TRANSGENIC RASH2 MICE WITH ETHYLENE THIOUREA.

B. R. Dudek[1], S. W. Curtiss[1], D. L. Morris[1], R. T. Bunch[1], C. E. Wilker[1], J. E. Sagartz[1], D. E. Morton[1], K. L. Kolaja[1], T. Usui[2] and C. A. Alden[1]. [1]*G.D. Searle, Metabolism and Safety Evaluation, St. Louis, MO and* [2]*Central Institute for Experimental Animals, Kawasaki, Japan.*

Male and female transgenic rasH2 (TgrasH2) mice (15/sex), which are being evaluated by ILSI as a more rapid alternative to lifetime mouse bioassays, were given ETU in their diets at 0.6% (6000 ppm) for 26 weeks. ETU is a nonmutagenic carcinogen which was positive for thyroid and liver neoplasm's in a chronic mouse (B6C3F1) bioassay. After 26 weeks, male and female mice had lower body weights compared to controls: 76% and 85%, respectively ($p<0.01$). There were no moratalities. There were no significant clinical signs of toxicity during the study. 14/15 males and 15/15 females had enlarged thyroids at final sacrifice and liver weights were significantly increased over controls: males and females 134% and 120%, respectively ($p<0.01$). Histopathology results in treated mice included thyroid tumors in males (8/15) and females (11/15). No thyroid tumors were seen in controls. Additionally 6 male mice and 2 female mice had liver adenomas, versus none in the respective control groups; 1 treated male and 2 treated females had lung adenomas. In conclusion, ethylene thiourea, a nongenotoxic carcinogen, administered in the diet of TgrasH2 male and female mice at 0.6% for 26 weeks, induced thyroid and liver tumors. These results provide support for the TgrasH2 model as a rapid alternative carcinogenicity test system for nongenotoxic agents.

1047 A 26-WEEK STUDY IN TRANSGENIC RASH2 MICE WITH SULFISOXAZOLE.

B. R. Dudek[1], S. W. Curtiss[1], D. L. Morris[1], R. T. Bunch[1], C. E. Wilker[1], J. E. Sagartz[1], D. G. Morton[1], K. L. Kolaja[1], T. Usui[2] and C. L. Alden[1]. [1]*G.D. Searle, Metabolism and Safety Evaluation, St. Louis, MO and* [2]*Central Institute for Experimental Animals, Kawasaki, Japan.*

Male and female transgenic rasH2 (TgrasH2) mice (15/sex), which are being evaluated by ILSI as a more rapid alternative to lifetime mouse bioassays, were given the antimicrobial sulfisoxazole (non-carcinogenic in a chronic study in B6C3F1 mice) in their diets at levels of 0.5%, 2% and 3% for 26 weeks. A 4-week range-finding study in wild-type mice (CB6F1) at 5% caused 50% mortality in males. At 26 weeks male mice at 2 and 3% had lower mean body weights compared to controls: 89%, and 85%, respectively ($p<0.01$) . Male body weights at 0.5% were comparable to controls and females at 0.5% were greater (109%, $p<0.01$) than controls. Females at 2 and 3% were comparable to controls. Male/female mortality was: 1/1, 0/1 and 5/0 in the 0.5, 2 and 3% groups, respectively. There were no significant clinical signs of toxicity. Gross and histopathology findings were unremarkable. In conclusion, sulfisoxazole, a non-carcinogen, administered in the diet of TgrasH2 male and female mice for 26 weeks, induced no false positive neoplastic or pre-neoplastic lesions. These results provide support for theTgrasH2 model as an alternative rapid carcinogenicity test system for nongenotoxic test agents.

1048 DOSE-DEPENDENT SUPRA-ADDITIVITY FOR THE INDUCTION OF MOUSE SKIN PAPILLOMA BY CHRONIC TREATMENT WITH VARIOUS DOSE COMBINATIONS OF 7,12-DIMETHYLBENZ[A]ANTHRACENE (DMBA) AND 12-O-TETRADECANOYLPHORBOL-13-ACETATE (TPA).

W. K. Lutz[1], A. Kopp-Schneider[2], T. Fekete[1] and S. Vamvakas[3]. [1]*University of Wuerzburg, Wuerzburg, Germany.* [2]*German Cancer Research Center, Heidelberg, Germany and* [3]*The European Medicines Evaluation Agency, London, United Kingdom.*

Toxicity testing is usually performed on single chemicals and includes high dose levels. In contrast, humans are exposed to a multitude of substances at low dose. One question therefore is whether supra-additive effects of mixtures can be observed also with doses around the no-observed-adverse-effect levels (NOAEL) of the single chemicals. Using the wellknown example of a synergistic tumorigenic effect on mouse skin of a combination of the DNA-reactive carcinogen DMBA with the tumor-promoting agent TPA, deviation from additivity was investigated as a function of dose. Twentyfive groups of 16 female NMRI mice were treated on the back twice weekly for up to two years with 100 µl acetone containing various dose combinations of DMBA and TPA (0, 0.1, 0.3, 1, 3 nmol per application; full 5x5 dose matrix). Papilloma formation was recorded weekly. Kaplan-Meier estimators for censored observations of time-to-the-first-papilloma were derived for all groups. DMBA and TPA alone increased the papilloma incidence at and above dose levels of 0.3 and 1 nmol, respectively. For the statistical analysis of combination effects, logrank tests for interaction were performed in a 2x2 design. Combinations of equipotent doses of the single chemicals (DMBA+TPA at 0.3+1 and 1+3 nmol), resulted in significant supra-additivity ($p=0.014$ and 0.045, respectively). In contrast, synergism was not observed when the combined treatment was carried out with the two components at their NOAEL (0.1+0.3 nmol ; $p=0.98$). The observed dose dependence for supra-additivity may have an impact on the risk assessment of environmental mixtures.

1049 PAH AND METAL MIXTURES IN METROPOLITAN SOILS OF NEW ORLEANS.

H. Mielke, G. Wang, C. Gonzales, M. K. Smith, L. Binh and N. Quach. *Xavier University, New Orleans, LA.*

Evaluating the quantities and associations of mixtures of metals and organic compounds is an important step in toxicological assessment. This study compares mixtures of polycyclic aromatic hydrocarbons (PAHs) and selected metals (Pb, Zn, Cd, Mn, Ni, Cu, Cr, V) of New Orleans (n=28) soil samples and Mississippi River alluvium (n=6), parent material of the lower delta. Surface (2.5 cm deep) soil samples were air-dried and sieved (2 mm screen). Accelerated solvent extraction (ASE) was applied to soil extraction for analysis with gas chromatography-mass spectrometry (GC-MS). Metals were extracted using a 5:1 ratio of 1 mol L^{-1} nitric acid (room temperature) to soil, shaken for 2 hours, centrifuged (1000 x g - 15 min.), and filtered. Metal ions in the extracts were determined using inductively coupled plasma-atomic

emission spectrometry (ICP-AES). Mann-Whitney tests show the differences ($p < 0.001$) between urban soils and alluvium. Pearson product moment correlation reveals that urban soils collected from inner to suburban New Orleans generally exhibit a strong association (correlation coefficient = 0.78, $p = 10^{-6}$) between PAHs and metals. Specific compounds, Acenaphthylene, Benzo(a)pyrene, and Benzo[g,h,I]perylene exhibit a correlation coefficient of > 0.88 and $p < 10^{-9}$. The results suggest that the distribution of mixtures of PAHs and metals are similar and that they are predicted by the soil metal maps of metropolitan New Orleans. (Acknowledgements: Research on soil metals funded by the ATSDR/MHPF cooperative agreement # U50/ATU398948, and on soil PAHs by DOD Grant # DSWA01-97-1-0028.)

1050 METAL MIXTURES OF MODERN ALLUVIUM: BASELINE DATA FOR MISSISSIPPI RIVER DELTA SOILS.

C. R. Gonzales, H. W. Mielke, M. K. Smith and A. L. Sturghill. *Xavier University of LA, New Orleans, LA.*

Establishing baseline data is essential for comparative research on the concentrations and associations of metals of various sample collections. This study evaluates the mixtures of metals (Pb, Zn, Cd, Mn, Ni, Cu, Co, Cr and V) in alluvium samples of the lower Mississippi River delta that originate from the entire watershed. Surface (2.5 cm deep) soil samples were air-dried and sieved (2 mm screen). Metals were extracted using a 5:1 ratio of 1 mol L^{-1} nitric acid (room temperature) to soil, shaken for 2 hours, centrifuged (1000 x g - 15 min.), and filtered. Metals were determined with inductively coupled plasma-atomic emission spectrometry (ICP-AES). Samples were stratified into groups according to location a) along the riverbank (n=42), b) distant to roads and railroad tracks (n=58), and c) next to roadways and railroad tracks (n=41). Mann Whitney rank sum tests show that metal concentrations in group b < group a < group c ($p < 0.001$). The respective medians for groups b, a, and c are: Pb 4.0, 4.0, 8.8; Zn, 9.5, 10.3, 22.5; Cd 0.8, 0.8, 1.0; Mn 81, 155, 324; Ni 3.4, 3.8, 6; Cu 1.8, 2.6, 9; Co 2.5, 2.6, 3.7; Cr 0.6, 0.8, 1.1; and V 1.8, 2.3, 7.0. Pearson product moment correlation shows closest associations for metals within groups a and b (correlation coefficients >0.80 and $p < 10^{-15}$). In group c, Pb, Mn, Ni, Cu, Co and V, exhibit strongest associations (correlation coefficient >0.80, $p < 10^{-12}$). These baseline data apply to modern alluvium of the Mississippi River delta. (Acknowledgements: ATSDR/MHPF cooperative agreement #U50/ATU398948.)

1051 PAH AND METAL MIXTURES IN BAYOU ST. JOHN SEDIMENTS.

G. Wang, H. W. Mielke, C. R. Gonzales, M. K. Smith, L. Binh and N. N. Quach. *Xavier University of Louisiana, New Orleans, LA.*

Bayou St John (BSJ) is an historic waterway and location of the first settlement (~1700) of New Orleans. This study evaluates the quantities and associations of mixtures of polycyclic aromatic hydrocarbons (PAHs) and selected metals (Pb, Zn, Cd, Mn, Ni, Cu, Cr, & V) of the bayou (n=10) and compares them with Mississippi River delta (MRD) alluvium (n=6) and New Orleans (n=28) soil samples. Sediments were collected with a Wildco-Ekman bottom dredge. The samples were air dried and ground to a fine powder. Accelerated solvent extraction (ASE) was applied to sediment extraction for analysis with gas chromatography-mass spectrometry (GC-MS). Metals were extracted using a 5:1 ratio of 1 mol L^{-1} nitric acid (room temperature) to soil, shaken for 2 hours, centrifuged (1000 x g - 15 min.), and filtered. Metal ions in the extracts were determined using inductively coupled plasma-atomic emission spectrometry (ICP-AES). Mann-Whitney tests show differences ($p < 0.001$), with PAH in BSJ sediments > urban soils > MRD alluvium (PAH index ratio of 11k:3.6k:0.2k). No difference appears between metal content of sediments and urban soils. Pearson product moment correlation reveals that metals and PAH are not significantly associated. Several metals show significant associations, Pb-Cr, Mn; Zn-Cd, Ni; Cd -Ni, V; and Mn-Cr. Most PAHs are significantly associated. PAHs accumulate in Bayou Saint John sediments and, in contrast to urban soils, are mixed with, but not associated with metals. (Acknowledgements: Research on soil metals funded by the ATSDR/MHPF cooperative agreement # U50/ATU398948, and on soil PAHs by DOD Grant # DSWA01-97-1-0028.)

1052 ADDRESSING CONCERNS ABOUT TOXIC INTERACTIONS AT HAZARDOUS WASTE SITES.

J. A. Freedman, F. Schnell, W. H. Taylor and M. D. Brooks. *Agency for Toxic Substances and Disease Registry, Atlanta, GA.*

Traditionally, potential for harm from exposure to chemicals and radiation at hazardous waste sites is assessed one substance at a time. People concerned about "synergism" among pollutants find traditional assessment disconcerting. "Hanford Downwinders", concerned about releases from Hanford (south-central Washington), asked the Agency for Toxic Substances and Disease Registry (ATSDR) to discuss toxic interactions in general, and interactions between radioactive and nonradioactive substances in particular. In response, we reviewed literature on interactions among noncarcinogens and among carcinogens, mechanisms of interactions, and doses of interactions. Doses are critical. People often equate thresholds for toxic effects with conservative screening levels typically hundreds to tens of thousands of times below their lowest toxic doses (or doses that might result in measurable increases in non-threshold effects). For interactions between chemical and radioactive substances, we reviewed literature on combinations of tobacco smoke with (1) occupational and environmental exposures to radon progeny and (2) occupational exposures to plutonium oxide. The databases for these combinations were, respectively, the most plentiful and the most relevant to Hanford. Because non-additivity commonly results from saturation of shared elements in overlapping mechanisms, neither harmful nor protective interactions are likely from environmental exposures to mixtures of substances at levels orders of magnitude below their thresholds. However, ATSDR continues to evaluate the possibility interactions among chemicals with overlapping mechanisms of action might, in the event of massive releases, produce synergistic or antagonistic effects of public health significance. (The opinions expressed are those of the authors and may not necessarily represent ATSDR policy.)

1053 ANALYSIS OF A MIXTURE OF ESTROGEN AGONISTS IN AN ER-α REPORTER GENE ASSAY.

C. Gennings[1], G. D. Charles[2], B. B. Gollapudi[2], T. R. Zacharewski[3] and E. W. Carney[2]. [1]*Virginia Commonwealth University, Richmond, VA,* [2]*The Dow Chemical Company, Midland, MI and* [3]*Michigan State University, East Lansing, MI.*

Response surface methodology has been successfully applied to the analysis of a wide range of chemical mixtures in order to describe interactions among the chemicals while accounting for biological variability. One objective of our work is to apply similar techniques to the analysis of mixtures of endocrine-active compounds. A full 4x4x4 factorial design (64 groups) was used where each chemical (17β-estradiol at 0, 0.01, 0.1, 1.0 nM; ethinylestradiol at 0, 0.001, 0.01, 0.1 nM; diethylstilbestrol at 0, 0.01, 0.1, 1.0 nM) was assessed individually and in all possible combinations in an MCF-7 cell ER-α Environ Sci Technol 29:2140-6, 1995). A response surface was estimated using a non-linear mixed (population-averaged) model, as a sigmoid-shaped relationship was expected. The model was parameterized to allow for within-replicate correlated responses while assuming data across replicates were independent. The definition of additivity used was that given by Berenbaum (J Theoretical Biology 114:413-31, 1985). The overall test for additivity was rejected indicating a complex interaction among the three chemicals. At the highest concentrations, an antagonistic interaction was apparent, presumably due to competition for a common receptor. However, a similar analysis was performed using a 3x3x3 design in which the highest concentration of each chemical was omitted. In this region of the dose response, the overall test for additivity was not rejected, indicating an additive relationship among the three chemicals. This finding demonstrates the successful application of response surface approaches to ER-α agonists, and illustrates that interactions can differ greatly between different regions of the dose response. Funded by The Chemical Manufacturers Assoc. (Arlington, VA).

1054 REINVENTING MIXTOX: PRIORITY CHEMICAL MIXTURES AND THE INTERACTIONS-ADJUSTED HAZARD INDEX.

J. Colman[1], R. Hertzberg[2], P. McClure[1], M. Odin[1], F. Llados[1], W. Stiteler[1] and D. A. Gray[1]. [1]*Syracuse Research Corporation, North Syracuse, NY and* [2]*National Center for Environmental Assessment (NCEA), USEPA, Cincinnati, OH.* Sponsor: P. McGinnis.

Feedback from Regional Superfund risk assessors indicated that EPA's original Mixtox interactions data base was only marginally useful; it provided no indication of the numerical change in the Hazard Index due to interactions, and thus no quantitative alterations were being made in the site assessments.

This pilot project initiates the transformation of EPA's Mixtox data base into a tool directly useful for Superfund baseline risk assessment. Binary chemical mixtures (chemical pairs) were prioritized by screening analytical results from final National Priority List (NPL) sites using RfD-based screening concentrations, followed by application of an algorithm to rank the frequency of toxicologically significant binary mixtures at NPL sites. Priority inorganic and organic chemical pairs were selected from the top-ranking pairs. Trichloroethylene and lead were the predominant chemicals in the organic and inorganic priority pairs, respectively. Binary weight-of-evidence (WOE) determinations for interactions were then developed for 12 priority pairs using the current EPA mixture risk methodology. Of the 24 WOE classifications of joint toxic action for these 12 pairs, three were "greater than additive," four were "less than additive," one was "adequate evidence of additivity," and the rest were default classifications of additivity (due to conflicting or inadequate information). The WOE classifications, converted to numerical scores, are used to estimate an interactions-adjusted hazard index, as demonstrated in a software mock-up. (This abstract does not necessarily reflect EPA policy.)

1055 A MECHANISTIC ANIMAL-REPLACEMENT APPROACH FOR PREDICTING THE MEDIAN LETHAL CONCENTRATION (LC_{50}) OF MIXTURES OF NARCOTIC CHEMICALS IN THE RAT.

M. Béliveau and K. Krishnan. *Université de Montréal, Montréal, Quebec, Canada.*

The acute median lethal concentration (LC_{50}) in several aquatic species is associated with a relatively constant lipoid chemical concentration (C_{lipid}) of 40-160 mM. Recent studies suggest that these lipoid concentrations could be associated with the occurrence of non-specific chemical narcosis in mammals as well. In the case of chemical mixtures, if the exposure concentration of each component contributing towards the lipoid concentration can be calculated, then they can be added together to determine the set of ambient concentrations of chemicals in a mixture corresponding to LC_{50}. Further, the contribution of each chemical to the lipoid concentration can be predicted on the basis of its lipid:air partition coefficient (P_{la}). These observations provide a unique opportunity for exploring the development of animal-replacement algorithms for predicting LC_{50} of mixtures of narcotic chemicals in mammalian species, more specifically the rat. The objective of the present study was to develop an algorithm for predicting the LC_{50} of narcotic chemical mixtures based on knowledge of the P_{la} and the molar fraction (F_i) of each mixture component. An algorithm that considers C_{lipid} (40 - 160 mM), fraction of blood flowing through the metabolizing tissue, hepatic extraction ratio, and oil:air partition coefficient was developed. Results show that the above algorithm adequately predicted the rat LC_{50} of over 20 non-specific narcosis-inducing organic chemical mixtures containing alcohols, ketones, esters, alkanes, haloalkanes, and aromatics. The average ratio of the predicted mixture LC_{50} values to the experimental values was 1.1 (sd=0.45, n=22). The algorithm developed and validated in this study represents the first mechanistic animal-replacement tool ever developed for predicting the rat LC_{50} of narcotic chemical mixtures.

1056 PHYSIOLOGICAL MODEL-BASED ESTIMATION OF AN UNCERTAINTY FACTOR (UF) ACCOUNTING FOR PHARMACOKINETIC INTERACTIONS IN MIXTURES.

S. Haddad, G. Charest-Tardif and K. Krishnan. *Université de Montréal, Montréal, Quebec, Canada.*

While it may be difficult to obtain the necessary information to model the pharmacokinetics of chemicals in mixtures, it should be feasible to predict the maximal effect of interactions on the kinetics of each mixture component on the basis of theoretical and mechanistic considerations. The objectives of the present study were to: (i) predict and validate the theoretically-possible, maximal impact of interacting chemicals on the blood concentration profile of each component in mixtures of 10 volatile organic chemicals in the rat, and (ii) derive an UF by comparing the kinetics of chemicals obtained during single exposure to those obtained during mixture exposure. With the hepatic extraction ratio (E) set equal to zero or one, the physiologically-based pharmacokinetic (PBPK) model yielded an envelope demarked by the maximal and minimal blood concentration vs time profiles for each component of the chemical mixtures. The experimental data on blood concentrations of parent chemicals collected during exposure to increasingly complex mixtures (2, 4, 5, 8 or 10 components) approached but did not exceed the simulated envelope. The ratio of the area under the concentration of parent chemical vs time curve between the maximal interaction effect (i.e., while E=0 or E=1) and single exposures provides a factor that quantifies the theoretically-possible change in kinetics of components during mixed exposures. Mechanistically-based algebraic expressions, based on PBPK model equations, were developed to quantify UF which ranges between 1.2 and 10.1 in rats and 1.3 and 11.9 in humans at steady-state, for chemicals investigated in this study. This UF, in fact, is conceptually similar to the inter-individual UF for pharmacokinetic differences currently used in health risk assessment.

1057 TARGET ORGAN VARIABILITY IN THE TOXICITY OF CHEMICAL MIXTURES.

J. G. Pounds[1], P. L. Pokorksi[1], D. G. Chen[2] and M. Mumtaz[3]. [1]*Wayne State University, Detroit, MI,* [2]*Pacific Biological Station, Nanaimo, British Columbia, Canada and* [3]*Agency for Toxic Substances and Disease Registry, Atlanta, GA.*

To estimate the toxic action of chemical mixtures it is often assumed that the interactive toxicity of a chemical mixture is consistent across target organs, such as brain, liver, and kidney. To test this assumption a series of parallel experiments were performed to compare the phenotype-dependent interactive toxicity of simple mixtures of toxic metals in primary cultures of rat hepatocytes, rat osteoblastic bone cells (ROS17/2.8), and in Rhesus renal cortical cells (LLC-MK2). To minimize the differences between culture conditions and maximize the ability to make distinctions based on cell type alone, Ham's F12 medium supplemented with 5% FBS, glutamine, and gentamicin was used for all cultures. Cells were treated for 24 hr with 0-30 μM CdCl2, 0-60 μM HgCl2, or a 1:2 molar ratio of the mixture. Cytotoxicity was determined at 24 hr by lactate dehydrogenase release. The data were analyzed statistically and graphically by the linear model of null interaction of Kodell and Pounds. The hepatocytes were most sensitive, and the osteoblastic bone cells were least sensitive, to both metals. The Cd LC50s were ~5, 15 and 18 μM for the hepatocytes, LLCMK2 and ROS cells respectively. The cell type-dependent response to Hg was similar with LC50s of 19, 38, and 42 μM respectively. In contrast, the cytotoxicity of mixture was response additive in all three cell types tested. However, cell and tissue dose is an important determinant of toxicity. Variability in multiple target organ toxicity must be considered and a systems approach must be pursued when integrating and estimating the joint toxic action from exposures to multiple chemicals. (Supported by ATSDR U61/ATU581481.)

1058 EFFECT OF ETHYLBENZENE CO-EXPOSURE ON STYRENE'S NASAL TOXICITY IN RATS.

D. C. Pedersen. *Northeastern University, Boston, MA.*

Styrene is widely used in the production of plastics and resins. It is manufactured from ethylbenzene and thus co-exposure to both compounds is likely. While both compounds are respiratory irritants, styrene exposure results in damage to tissues of the nasal passages. Studies in this laboratory (Sidel and Schatz, 1998,1999) have demonstrated the toxic and proliferative effects of exposure to 50 ppm styrene. In this study, we characterized the effects of co-exposure with 300 ppm ethylbenzene. The co-exposure prevented the nasal toxicity (indicated by elevated levels of LDH and GGT in nasal lavage fluid) seen with styrene exposure alone. Acid phosphatase activity was increased by both styrene and ethylbenzene exposures alone and the response to the co-exposure was additive. It is possible that an inflamatory response (vs. toxicity) is involved with these solvents. The co-exposure also prevented styrene's proliferative effects in both olfactory and respiratory epithelia of the nose. Styrene is metabolized by CYP P450s to the reactive epoxide styrene 7,8-oxide, which is thought to be responsible for its toxicity. The co-exposure caused greater reductions in the activity of CYP P450s involved in styrene metabolism (CYP 2B1, CYP 4B1 and CYP 2E1) in nasal microsomes than caused by styrene alone. Activity of microsomal epoxide hydrolase was unchanged while GST activity was decreased with the co-exposure compared to styrene exposure alone. These data indicate that the reduction in activity of CYP P450s is a major factor in the alteration in toxicity.

1059 *IN VITRO* EVALUATION OF THE WEIGHT OF EVIDENCE METHOD FOR TOXICOLOGIC INTERACTIONS OF CHEMICAL MIXTURES.

M. M. Mumtaz[1], C. T. De Rosa[1], J. P. Groten[2], V. J. Feron[2], H. Hansen[1] and P. R. Durkin[3]. [1]*Agency for Toxic Substances and Disease Registry, Atlanta, GA,* [2]*TNO, Zeist, Netherlands and* [3]*Syracuse Environmental Research Associates, Syracuse, NY.*

ATSDR, in collaboration with TNO, is conducting studies to evaluate the weight of evidence (WOE) method to estimate joint toxic action of chemical mixtures [Environ. Health. Perspect. 106: 1353-1360. (1998)]. An *in vitro* study, which measured the formation of MTT-formazan, was undertaken to evaluate the predictive capability of the WOE method. Rat kidney slices were used in two series of experiments, one with a quaternary mixture of similarly acting chemicals and the other with a binary mixture of dissimilarly acting chemicals. The quaternary mixture consisted of the cysteine conjugates of trichloroethylene (TCE), tetrachloroethylene (PCE), hexachlorobutadiene (HCBD), and 1,1,2-trichloro-3,3,3-trifluoropropene (TCTFP). The binary mixture consisted of $HgCl_2$ and the cysteine conjugate of HCBD. In each series, 120 kidney slices were assayed concurrently. For the binary mixture, the experimental design consisted of a complete factorial design, whereas for the quaternary mixture it consisted of 20 different combinations of varying doses. The results of the experimental studies agreed with the WOE assessment-based predictions which showed that, in the dose range tested, the quaternary mixture evidenced dose-additive toxicity. Additional agreements with the WOE assessment indicated that the HCBD conjugate had no impact on the toxicity of $HgCl_2$, but $HgCl_2$ antagonized the toxicity of the HCBD conjugate. The results of this *in vitro* study suggest that (1) the WOE method can be used for assessing joint toxic action across a range of doses and, (2) it can be used to screen/prioritize mixtures for experimental and follow up studies for multiple toxicity end points.

1060 STUDY DESIGNS FOR ASSESSING INTERACTIONS IN CHEMICAL MIXTURES.

B. Price[1], C. J. Borgert[2], C. Wells[1], T. S. Gross[3], P. D. Guiney[4] and T. G. Osimitz[4]. [1]*Price Associates, Washington, DC,* [2]*Applied Pharmacology and Toxicology, Inc., and Department of Physiological Sciences, University of Florida College of Veterinary Medicine, Alachua, FL,* [3]*USGS BRD Caribbean Science Center and Department of Physiological Sciences, University of Florida College of Veterinary Medicine, Gainesville, FL and* [4]*S.C. Johnson & Son, Inc., Racine, WI.*

A study design for assessing interactions between chemicals in mixtures should have well-defined objectives and should answer three general questions. How many different dose combinations should be tested? Which mixture combinations should be tested? How many replicates of each selected mixture combination should be tested? We have developed a sequential approach for identifying appropriate chemicals combinations to test interactions. Our approach maximizes efficiency by focusing on local rather than global characterization of chemical interactions. To demonstrate our approach, we characterized concentration-response relationships for six compounds (Aminog, Atrazine, Flavone, MCanthrene, Naphthoflavone, and Quercetin) on 11-ketotestosterone and estradiol production in gonadal tissue cultures. Gonadal tissue was harvested from female bass (2-3 years of age) during the peak reproductive season (February - April) to maximize steroidogenic activity and available gonadal mass. Tissue was minced and incubated in culture medium with or without test agents for 48 hours in the absence or presence of exogenous testosterone to control for substrate limitation of steroidal aromatase activity. Duplicates of each treatment were performed in two experiments using tissue from a different female. Estradiol and 11-ketotestosterone in culture medium were measured by validated RIA procedures. Concentration-response curves were used to evaluate the magnitude of response necessary to detect departure from additivity in combination experiments and to identify important chemical combinations for testing. The results indicate advantages over full factorial and block designs with respect to efficiency and for conformity with criteria for reliable interaction analysis.

1061 EVIDENCE FOR DOSE ADDITIVITY OF CHLOROFORM (CHC13) AND BROMODICHLOROMETHANE (BDCM) IN MICE.

J. E. Simmons[1], C. Gennings[2], L. K. Teuschler[3], Y. M. Sey[1] and A. McDonald[1]. [1]*NHEERL USEPA, Research Triangle Park, NC, and* [2]*MCV Richmond, VA and* [3]*NCEA, Cincinnati, OH.*

Chemical disinfection of drinking water, while one of the public health triumphs of the 20th century, results in the production of a variety of disinfection byproducts (DBPs), including CHc13 and BDCM. The objective of the present study was evaluation of the nature (additive, nonadditive) of the hepatotoxic interaction between CHC13 and BDCM. Female CD-1 mice, ~65-70 days old, were gavaged daily for 14 days witheither CHC13, BDCM or binary combinations of CHC13 and BDCM in an aqueous vehicle (10% Alkamuls®) at a constant volume of 10 ml/kg. Dosing solutions were made fresh daily. On day 15, hepatotoxicity was assessed by serum sorbitol dehydrogenase (SDH). The experiment consisted of 12 treatment groups: one vehicle control group; three of CHC13 alone, 0.1, 1.0 and 3.0 mmol CHC13/kg/day; three of BDCM alone, 0.1, 1.0 and 3.0 BDCM/kg/day; three mixture groups at a 1:1 mixing ratio of CHC13:BDCM and total mixture dosages of 0.1, 1.0 and 3.0 mmol/kg/day: and, two mixture groups at a 2.7:1 mixing ratio of CHC13:BDCM and total mixture dosages of 1.0 and 3.0 mmol/kg/day. The 2.7:1 mixing ratio of CHC13:BDCM was based on their average seasonal proportions at 35 water treatment facilities (Krasner et al., 1989). The data were analyzed with a threshold additivity model (Gennings et at., 1997); the null hypothesis is dose additivity. An overall test for additivity of these 5 mixtures was not rejected (p=0.798). For the 1:1 mixing ratio, the mean experimental SDH values (IU/l) vs the means (95% prediction intervals) predicted by the threshold additivity model were: at 0.1 mmol/kg-14.5 vs 13.4 (6.6, 20.3); at 1.0 mmol/kg-24.1 vs 27.7 (13.5, 41.8); and, at 3.0 mmol/kg-155.7 vs 118.5 (17.5, 219.6). For the 2.7:1 CHC13:BDCM mixing ratio, the mean experimental vs predicted (95% prediction interval) SDH levels were:at 1.0 mmol/kg-26.4 vs 26.4 (12.1, 40.8); and, at 3.0 mmol/kg- 141.9 vs 111.0 (41.7, 180.2). The closeness of the predicted and observed mixture responses indicates that CHC13 and BDCM were dose additive for hepato

toxicity at these mixture doses and combinations. (This abstract may not reflect EPA policy.)

1062 TOXICOLOGICAL INTERACTIONS AMONG ARSENIC, CADMIUM, CHROMIUM, AND LEAD IN HUMAN KERATINOCYTES.

J. A. Campain[1], D. Bae[1], C. Gennings[2], W. H. Carter, Jr.[2] and R. S. H. Yang[1]. [1]*Center for Environmental Toxicology, Department of Enviromental Health, Colorado State University., Ft. Collins, CO and* [2]*Dept. of Biostatistics, Virginia Commonwealth University, Richmond, VA.*

The objective of this study was to characterize potential interactions among arsenic (As), chromium (Cr; 1:1 mixture of Cr^{3+} and Cr^{6+}), cadmium (Cd), and lead (Pb) with respect to cytotoxicity at a mixing ratios of interest in human keratinocytes. Three immortal keratinocyte cell lines (RHEK-1, HaCaT, and NM1) and normal human epidermal keratinocytes (NHEK) were exposed to increasing concentrations of the individual metals or to a mixture of the four metals. Cell viability was determined by MTT (thiazolyl blue) assay after 24 hr treatment. The overall range of concentrations studied for the individual metals was from 0.3 to 300μM. A 4-metal mixture (1X) was prepared at the concentrations of LD_{50}s of As, Cr, and Cd; but 100μM of Pb was utilized, as we were unable to get substantial cell killing at any dose used. Thorough statistical analyses of the cytotoxicity data were carried out to test for deviations from additivity and discern the nature of interactions among the four metals. An approach using an "additivity response surface", permits testing the hypothesis that metals in a mixture act in an additive fashion. In RHEK-1 and HaCaT, the responses were antagonistic at high concentration (0.3X). However, at the middle concentration (0.1X and 0.03X), there was a significant synergistic interaction. A synergistic response predominated at the middle concentration groups (0.3X and 0.1X) in NHEK and NM1. These findings suggest that the metals studied might exhibit different mechanism of toxicity in NHEK and NM1, which has very similar growth characteristics to normal cells, as compared to the other immortal keratinocyte cell lines. (This study was supported by ATSDR [Cooperative Agreement U61/ATU881475], and NIEHS Superfund Basic Research Program [P42 ES05949].)

1063 BIOCHEMICAL EFFECTS OF MANUFACTURED GAS PLANT TAR IN RATS.

N. Modi[1], D. Mauro[1], S. Emsbo-Mattingly[1], B. Taylor[1] and E. H. Weyand[1]. [1]*Rutgers University, Piscataway, NJ and* [2]*Meta Environmental, Watertown, MA.*

Previous studies have demonstrated that mouse lung is a target organ for the genotoxic effects of manufactured gas plant tar (MGP tar) following ingestion. In addition, the chemicals primarily responsible for these effects appear to be benzo[b]flouranthene, benzo[a]pyrene (B[a]P) and an unidentified component of MGP tar. The genotoxic effect of MGP tar in species other than mice has not been fully evaluated. Therefore, the present study evaluated the genotoxic effects of MGP tar in rats following ingestion. Powder diets containing neat MGP tar, soil contaminated with MGP tar, and organic extracts of these soils were fed to CD rats for 13 days. In addition, diets containing B[a]P ranging from 0.5 to 100 ppm were also evaluated. Metabolites of polycyclic aromatic hydrocarbons in urine and chemical: DNA adduct formation in lung, liver, forestomach and mammary tissues were evaluated. Ingestion of soil adulterated with MGP tar resulted in two major DNA adducts in lung tissue. One of the these adducts is derived from B[a]P while the second is formed from the unidentified component of MGP tar. Ingestion of diets containing neat MGP tar and an extract of contaminated soil also resulted in the unidentified DNA adduct being formed in lung and forestomach tissue. However, no DNA adducts were detected in liver and mammary tissues. In the case of rats ingesting 0.5 to 100 ppm B[a]P a single major adduct was only detected in tissues of rats receiving 50 and 100 ppm of B[a]P. These results indicate that the PAH component of MGP tar is readily bioavailable following ingestion similar to the results observed with mice. In addition, the unknown compound within the mixture may also play a key role in the formation of chemical:DNA adduct in rat tissue. (EPRI Grant WO2963-06.)

1064 REPRODUCTIVE AND DEVELOPMENTAL TOXICITY OF AIDS COMBINATION THERAPIES IN SWISS (CD-1®) MICE.

G. N. Rao[1] and H. D. Giles[2]. [1]*NIEHS, Research Triangle Park, NC and* [2]*Southern Research Institute, Birmingham, AL.*

Combination therapy with anti-HIV and opportunistic infection drugs is a common practice in treatment of AIDS patients including pregnant women. Reproductive and developmental toxicity of most individual drugs is known but not the effects of combination therapies. To understand the reproductive and developmental consequences of combination therapies, commonly used anti-HIV drug AZT and opportunistic infection therapies pyrazinamide, rifabutin and clarithromycin were evaluated by 10 to 30 day gavage studies in Swiss (CD-1®) mice either alone or AZT with one of the opportunistic infection drghugs. The doses include AZT 200 and 400; pyrazinamide 300, 1500 and 3000, rifabutin 80, 320 and 640 and clarithromycin 250, 500 and 1000 mg/kg/day. AZT alone caused an increase in resorptions and decrease in litter size. Pyrazinamide alone caused slight declines in fetal weights and slight increases in the duration of gestation and resorptions. Rifabutin alone decreased the pregnancy rate and fetal weights. Clarithromycin alone decreased the pregnancy rate and reduced the litter size. Pyrazinamide, rifabutin or clarithromycin when given in combination with AZT increased the reproductive and developmental toxicity far greater than any one drug. Combination therapies caused decreases in pregnancy rates and litter sizes and increased the number of resorptions, stillborn pups and pup deaths. Significant numbers of gross external alterations in pups were not observed following administration of any drug alone or in combination. Clarithromycin appears to be the most toxic and pyrazinamide the least toxic of the three opportunistic infection therapies with regard to enhancement of reproductive and developmental toxicity of AZT. Results of these studies indicate that the reproductive and developmental toxicity of combination therapies could be more severe and possibly different from the individual drugs.

1065 BACKGROUND DNA MODIFICATIONS (I-COMPOUNDS) IN LIVER AND COLON OF FEMALE F-344 RATS FED WITH DIETS SUPPLEMENTED WITH SUNFLOWER, RAPESEED, OLIVE, OR COCONUT OIL.

U. Lutz[1], R. C. Gupta[2] and W. K. Lutz[1]. [1]*University of Wuerzburg, Wuerzburg, Germany and* [2]*University of Kentucky, Lexington, KY.*

I-compounds are bulky covalent DNA modifications formed in tissues of untreated laboratory animals detectable by the ^{32}P-postlabeling method. They appear to be derived mainly from DNA-reactive intermediates of nutrient and oxygen metabolism. In this study, the postlabeling method was adapted for the analysis of DNA of rat colon, a target organ for fat-associated carcinogenesis, and the effect of various types of fat supplements was investigated. Groups of 5 female F344 rats were fed for 4 weeks diets containing 17 percent sunflower, rapeseed, olive, or coconut oil. DNA adducts were analyzed by the nuclease P1-enhanced version of the ^{32}P-postlabeling assay. Chromatography on 'home-made' tlc sheets was in 2 directions/2 solvents for the liver samples and 2 directions/3 solvents for the colon. Concentrations of sodium phosphate, urea, and ammonia (colon only) were optimized for the resolution of the respective adduct spots. In the liver, which is not a target organ, 5 spots could be clearly distinguished. All were present in all animals. Mean adduct levels of the individual spots ranged from 5 to 58 per 10E^9 nucleotides (RAL-values). Between the groups, there was a significant difference in only one spot, with RAL-values 2.5 times higher in the rapeseed group as compared with all others. In the colon, 7 spots were seen consistently. Mean adduct levels ranged from 3 to 89 per 10E^9 nucleotides. No difference between the groups was significant, primarily because of large variabilities within the groups. Epidemiological evidence suggests that various types of fats modulate the process of colorectal carcinogenesis differently. In a human biomonitoring study, DNA adducts associated with lipid peroxidation were higher in white blood cells of humans set on a sunflower oil-based diet compared to rapeseed oil. The present data derived from a target organ of an animal model do not confirm such differences for other DNA modifications of so far unknown structure. (Supported by the Swiss Federal Office of Public Health No.316.98.0677.)

1066 EVALUATION OF THE ORAL SUBACUTE TOXICITY AND GENOTOXIC POTENTIAL OF TRICHLOROMETHYL PHENYL CARBINYL ACETATE (TPCA).

G. A. Wellington, J. Cocchiara and D. Isola. *Research Institute for Fragrance Materials, Hackensack, NJ.* Sponsor: A. M. Api.

To evaluate the acute systemic toxicity of trichloromethyl phenyl carbinyl acetate (TPCA), 60 rats (10/sex/group) were dosed with 100, 300 or 1000 mg/kg/day, via gavage, for 14 days. Clinical signs included decreased food consumption and fecal volume, labored breathing, moribundity, and yellow anogenital staining. Hypertrophy of centrilobular hepatocytes was observed in males and females at 300 and 1000 mg/kg, and eosinophilic cytoplasmic inclusions were observed in male kidneys at all dose levels. The presence of eosinophilic cytoplasmic inclusions is unique to male rats and is compatible with the diagnosis of alpha 2-i-globulin nephropathy. According to an EPA Policy Statement, the male rat kidney response to chemicals that induce alpha 2-micro-globulin accumulation is probably not relevant to human risk assessment. Based on the effects seen in the liver of rats treated with 300 and 1000 mg/kg per day, the no-observed-effect-level (NOEL) was 100 mg/kg per day. TPCA was also tested in the bacterial reverse mutation assay using Escherichia coli tester strain WP2 uvrA in the presence and absence of Aroclor-induced rat liver S9 and in Salmonella typhimurium tester strains TA98, TA100, TA1535 and TA1537. TPCA did not cause a positive response in any of the tester strains in the presence or absence of S9. The clastogenic potential of TPCA was also evaluated using Chinese hamster ovary (CHO) cells, both in the presence and absence of an Aroclor-induced S9-activated test system. In the S9-activated test system, CHO cells were exposed to TPCA for 4 hours; in the non-activated test system, treatment was for 4 and 20 hours. No evidence of a clastogenic potential of TPCA was observed. TPCA did not show genotoxic potential based on negative results in both Ames and cytogenetic assays.

1067 DNA ADDUCTS IN LIVER, LUNG AND ISOLATED LUNG CELLS OF RATS AND MICE EXPOSED TO 160 PPM [RING-U-^{14}C]-STYRENE BY NOSE-ONLY INHALATION FOR 6 HOURS.

K. P. de Kloe[1], P. J. Boogaard[1], B. Wong[2], S. C. J. Sumner[2] and N. J. van Sittert[1]. [1]*Shell Research & Technology Centre Amsterdam, Amsterdam, Netherlands and* [2]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Clara cells are predominant in mouse but almost absent in rat and human lung and contain various CYPs, which may oxidize styrene to the rodent carcinogen styrene-7,8-oxide (SO). SO or other reactive metabolites might form DNA adducts and cause the bronchioalveolar tumors seen in mice exposed to 150 ppm styrene. In rats no tumors were seen at 1000 ppm. 12 Rats and 60 mice were exposed to 160 ppm ^{14}C-styrene (52 mCi/mmol) for 6 h by nose-only inhalation in a recirculating exposure system. Liver and lungs were isolated 0 and 42 h after exposure. Type II cells and Clara cells were isolated from rat and mouse lungs, respectively. DNA adduct profiles in mice and rats differed quantitatively and qualitatively in liver, total lung and lung cells. At

0 and 42 h after exposure, the 2 isomeric N7-guanine adducts of SO (GS) were present in liver at 3.0±0.2 and 1.9±0.3 (rat) and 1.2±0.2 and 3.2±0.5 (mouse) per 10^8 bases. Several unidentified adducts were present at 2-3 times higher concentrations than GS in mouse, but not rat liver. In both rat and mouse lung GS was the major adduct at ~1 per 10^8 bases at 0 h and these levels halved at 42 h. In both rat Type II and non-Type II cells, GS was the major adduct and was ~3 times higher in Type II cells than in total lung. DNA adduct levels in Clara cells and non-Clara cells were similar to total lung. The hepatic covalent binding index (CBI) at 0 and 42 h was 0.19±0.06 and 0.14±0.03 (rat) and 0.25±0.11 and 0.44±0.23 (mouse), respectively. The pulmonary CBIs were 0.17±0.04 (rat) and 0.24±0.04 (mouse). Compared to CBIs for other genotoxicants, these values indicate that styrene has only very weak genotoxic potency. The overall results of this study suggest that a non-genotoxic or epigenetic mechanism, possibly caused by a cytotoxic metabolite, is involved in the tumorigenicity in chronically exposed mice. (This study was supported by the Styrene Information and Research Center and Shell International Chemicals.)

1068 FURFURAL DOES NOT INDUCE UNSCHEDULED DNA SYNTHESIS (UDS) IN THE *IN VIVO* B6C3F1 MALE AND FEMALE MOUSE HEPATOCYTE DNA REPAIR ASSAY.

A. J. Edwards[1], T. B. Adams[2] and B. G. Lake[1]. [1]*BIBRA International, Carshalton, United Kingdom and* [2]*FEMA, Washington, DC.* Sponsor: R. Ford.

In this study, the ability of furfural to induce UDS in hepatocytes after *in vivo* administration to male and female B6C3F1 mice was examined. From a preliminary toxicity study, the oral maximum tolerated dose (MTD) of furfural was determined to be 320mg/kg body weight. In the UDS study rats were treated with single oral 50, 175 and 320mg/kg doses of furfural. Negative controls were treated with distilled water and positive controls with either 20mg/kg dimethylnitrosamine (DMN, for 2 to 4 hr expression of UDS) or 200mg/kg *o*-aminoazotoluene (OAT, for 12-16 hr expression of UDS). Hepatocytes were isolated by liver perfusion either 2-4 hr (3 mice per furfural treatment level, 3 negative and 3 positive controls) or 12-16 hr (3 rats per furfural treatment level) after treatment. Hepatocytes were cultured in medium containing [^{3}H]thymidine for 4 hr and UDS assessed by grain counting of autoradiographs. Furfural, at doses of 50, 175 and 320mg/kg, did not produce any statistically significant increase in the net nuclear grain count after either 2-4 or 12-16 hr of treatment. In contrast, significant increases in net nuclear grain counts were observed in hepatocytes from male and female mice treated with either DMN for 2-4 hr or OAT for 12-16 hr. Net grain counts were significantly increased from -1.26 to +38.8 ($p<0.01$, pooled t-test) for male mice treated with DMN; from -2.41 to 30.78 ($p<0.001$, pooled t-test) for female mice treated with DMN; -2.79 to 17.23 ($p<0.001$, pooled t-test) for male mice treated with OAT; and -2.57 to 28.78 ($p<0.001$, pooled t-test) for female mice treated with OAT. The percentage of hepatocytes with net grain counts >5 was significantly increased for both positive controls while those for furfural-treated groups and controls were similar. These results demonstrate that furfural does not produce DNA damage in male or female mice hepatocytes *in vivo* at doses up to the MTD of 320 mg/kg. (Supported by FEMA.)

1069 CARCINOGEN INDUCED DNA DELETIONS IN MICE.

R. H. Schiestl, A. J. R. Bishop and J. Aubrecht. *Harvard School of Public Health, Boston, MA.*

Genetic instability and deletions are involved in carcinogenesis. We have used the mouse pink-eyed unstable (pun) reversion assay to detect DNA deletion events *in vivo* in the mouse. The pun phenotype is a dilute fur coat and pink eyes resultant from a lack of pigmentation. Spontaneous reversion of the mutation produces mice pigmented with spots in either tissue. Such reversions are the result of homologous recombination deleting one copy of a tandem duplication that interrupts the p gene. Deletion during embryogenesis results in a visible fur spot or an eyespot in the offspring.Induced pun reversion can be detected by the furspot assay following exposure to various carcinogens such as X-rays, cis-platinum(II)diamine dichloride (cisplatin), EMS, MMS, ENU, benzo(a)pyrene (B(a)P), trichloroethylene, benzene, sodium arsenate, polychlorinated biphenyls, dioxin and cigarette smoke. Eyespots are induced in this study by X-ray, cisplatin and B(a)P. As the position of an eyespot indicates the time during embryo development at which the deletion event occurred, examining the eyespots within the region of the retinal pigment epithelium (rpe) that correlates to the time of induction allows an increased sensitivity. Pregnant dams are induced 10 days post coitum and the pups examined for furspots 10 days post partum. Eyes are taken 30 days post partum and the rpe is recovered and examined. The eyespot assay requires less than 15 mice per chemical, substantial less than the furspot assay or many other phenotypic *in vivo* assays. These results further substantiate carcinogen induced genomic instability due to an increased level of homologous recombination. Since 25% of our genome consists of repeated elements, deletion between such repeats may be a significant step in carcinogenesis.

1070 EFFECT OF DIETARY FOLATE DEFICIENCY ON ARSENIC GENOTOXICITY IN MICE.

E. W. McDorman[1], B. W. Collins[2] and J. W. Allen[2]. [1]*Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC and* [2]*Environmental Carcinogenesis Division, NHEERL, USEPA, Research Triangle Park, NC.* Sponsor: D. J. Holbrook.

Arsenic, a human carcinogen found in drinking water supplies throughout the world, is clastogenic in human and rodent cells. An estimated ten percent of Americans are deficient in folate, a methyl donor necessary for normal nucleotide metabolism, DNA synthesis, and DNA methylation. Folate deficiency has been shown to enhance the activity of several mutagens, and may also increase arsenic genotoxicity. We are evaluating induction of micronuclei (MN) in peripheral blood erythrocytes of male C57Bl/6J mice fed folate-deficient (FD; 0 mg/kg diet) or folate-replete (FR; 5 mg/kg) diets for 7 weeks. During week 7, mice on each diet (n=4 per group) were given 4 consecutive daily doses of sodium arsenite (0, 2.5, 5, or 10 mg/kg in water) or acrylamide (positive control; 50 mg/kg in water) via oral gavage. Kinetochore immunostaining was employed to help distinguish between MN resulting from chromosome breakage and MN resulting from chromosome loss. Statistically significant increases in MN were observed in both FD and FR mice at 5 and 10 mg/kg arsenite in polychromatic erythrocytes (PCEs), but not normochromatic erythrocytes (NCEs). At 10 mg/kg, MN-PCE levels in FD mice were 4-fold higher than control levels (16.1±3.9/1000 vs. 4.1±0.8/1000), while increases in FR mice were 1.6-fold higher (5.6±1.3/1000 vs. 3.4±0.7/1000). For all dose groups, MN-NCE levels were higher in FD mice than in FR mice. The observed MN were of the negative kinetochore staining type, suggesting that they derived from chromosome breakage rather than whole chromosome loss. Our results indicate that dietary folate deficiency increases arsenic-induced clastogenesis in mice at high doses. Since both arsenic and folate deficiency interfere with DNA repair, dysregulation of this process may contribute to the high MN levels observed. (This abstract does not necessarily represent US EPA policy.)

1071 GENOTOXICITY OF METHYLPHENIDATE HYDROCHLORIDE IN THE *IN VIVO* MOUSE MICRONUCLEUS ASSAY.

B. E. Stewart[1], P. T. Curry[2], G. Ng[1], N. B. Modi[1] and M. E. Prevo[1]. [1]*ALZA Corporation, Mountain View, CA and* [2]*Covance Laboratories, Vienna, VA.*

The potential of methylphenidate HCl (MPH) to induce micronuclei in bone marrow polychromatic erythrocytes (PCEs) of mice was evaluated *in vivo*. Male and female Crl:CD-1®(ICR)BR mice were gavaged with single doses of MPH; the positive control, cyclophosphamide (CP); or the MPH vehicle control (phosphate buffer). Based on preliminary toxicity assessments, MPH doses used were 87.5, 175, and 350 mg/kg for males and 75, 150, and 300 mg/kg for females. MPH-treated animals were individually housed. Animals (n=5/sex) in the MPH and vehicle treatment groups were euthanized and bone marrow harvested at 24 and 48 hours post-treatment; positive control animals were evaluated only at 24 hours. Coded bone marrow preparations were evaluated for cytotoxicity by calculating the PCE to red blood cell ratio for at least 200 erythrocytes. At least 2000 PCEs per animal were scored for micronuclei, and the frequency of micronuclei was expressed as the percent micronucleated cells. One male in the high-dose group died within the first hour after treatment; no other animals died. Dose-related transient clinical signs (eg, hyperactivity, licking, and/or chewing), consistent with the known pharmacological activity of MPH, were observed at all dose levels in both sexes, primarily on the day of dosing. Plasma data from MPH-treated satellite animals confirmed exposure to methylphenidate and the primary human metabolite. At the dose levels used, MPH was not cytotoxic to the bone marrow. MPH did not induce increases in the frequency of micronucleated PCEs over levels observed in vehicle control animals. The positive control, CP, induced a significant increase in micronucleated PCEs in both males and females. MPH was negative in the mouse bone marrow micronucleus assay.

1072 N7-(1-(HYDROXYMETHYL)-2,3-DIHYDROXYPROPYL) GUANINE IS THE MAJOR DNA ADDUCT AFTER EXPOSURE TO 1,3-BUTADIENE BUT NOT 1,2-EPOXY-3-BUTENE.

P. J. Boogaard, K. P. De Kloe and N. J. van Sittert. *Shell Research & Technology Centre Amsterdam, Amsterdam, Netherlands.*

Mice are more susceptible to the rodent carcinogen 1,3-butadiene (Bd) than rats. Genotoxic epoxides of Bd, 1,2-epoxy-3-butene (BMO), 1,2-epoxy-3,4-butanediol (EBD) and 1,2:3,4-diepoxybutane (DEB), have been suggested as the ultimate carcinogens. Reaction of DNA or guanosine (dG) with BMO gives equal amounts of *N*7-(2-hydroxy-3-butenyl)guanine (**G1**) and *N*7-(1-(hydroxymethyl)-2-propenyl)guanine (**G2**). When DEB was reacted with DNA or dG mainly *N*7-2,3,4-trihydroxybutylguanine (**G3**) was formed. EBD exists as different stereo-isomers. Racemic EBD reacted with dG gave equal amounts of **G3** and *N*7-(1-(hydroxymethyl)-2,3-dihydroxypropyl)guanine (**G4**), but when S-EBD was reacted with dG **G4** was the predominant adduct (> 90%) with only traces of **G3** (~5%). In rats and mice exposed to [4-^{14}C]-BMO by i.p. administration (1-50 mg/ kg) DNA adduct profiles in rat and mouse were similar in liver and lung with **G1** and **G2** as main adducts (857 and 368 per 10^8 bases in rat and mouse liver, respectively, after 20 mg/kg) and **G4** as minor adduct (101 and 50 per 10^8 bases). In rats and mice exposed to 200 ppm [2,3-^{14}C]-Bd by nose-only inhalation for 6 h, **G1** and **G2** were only minor adducts in liver (1.9 and 8.0 per 10^8 bases for rats and mice, respectively) and lung (1.6 and 6.6 per 10^8 bases). **G3** was present in mouse, but not rat, liver and lung at levels of 20 and 12 adducts/10^8 bases. The major adduct was **G4** which accounted for 13 and 90 (liver) and 11 and 139 (lung) adducts/10^8 bases in rats and mice, respectively. These results indicate that the major DNA adduct following exposure to Bd is from EBD, and not from BMO or DEB. In addition, the results suggest that there is a strong stereospecific preference for the formation of S-EBD in mice. These findings have important implications for the understanding of the mechanism of carcinogenicity of Bd.

1073 THE PRODUCTION OF MICRONUCLEI BY DI-*N*-BUTYL PHTHALATE IN MALE F-344 RATS.

R. D. Thomas, M. McDaniel and T. Womble. *Florida A & M University, Tallahassee, FL.*

Di-n-Butyl phthalate (DPB) is an odorless and colorless liquid used in the manufactoring of plastics. The annual global production is estimated to be in the billions of pounds. These compounds have been found in sugar, salt, dairy products, meat, fish, shell fish, instant soups, cereal, and edible plant products. Due to the ubiquitous nature of DBP and the enormous potential of human exposure, it is of utmost importance to investigate the toxic potential of DBP. Although there is little carcinogenic and genotoxic data for DBP, other phthalate esters such as di (2-ethylhexyl) phthalate (DEHP)have been shown to be carcinogenic and genotoxic. Based on this data we hypothesize that DBP is genotoxic. To test this hypothesis male F344 rats were dosed with various doses of DBP (10g/kg, 5g/kg, & 1g/kg) by gavage. Twenty-four hours after dosing, the rats were sacrificed and the testes removed. Slides were prepared from the testes, stained with 33258 Hoechest, and analyzed by fluorescence microscopy. One-thousand cells from each group were analyzed for micronuclei formation. The results revealed that DBP produced micronuclei in a dose dependent fashion. The high dose (10g/kg) produced micronuclei in 174 cells, the 5g/kg dose produced mironuclei in 133 cells, and the 1g/kg dose produced micronuclei in 56 cells. Eight cells in the control group that recieved only corn oil formed micronuclei. The formation of micronuclei indicates that chromosome breakage has occurred. This is direct evidence that DBP is genotoxic *in vivo*. This genotoxicity can lead to cancer or other adverse effects.

1074 COMPARISON OF THE MUTAGENICITY OF METHYLEUGENOL (ME) *IN VIVO* IN THE LIVER OF BIG BLUE® TRANSGENIC RATS AND MICE.

S. P. Tyrrell[1], X. Zhang[1], M. L. Cunningham[2] and B. S. Shane[1]. [1]*Institute for Environmental Studies, Louisiana State University, Baton Rouge, LA and* [2]*Laboratory of Pharmacology and Chemistry, NIEHS, Research Triangle Park, NC.*

Methyleugenol (ME) is a naturally occurring allylbenzene found in some foods and spices and is also used as a flavoring agent. A primary metabolite of ME, 1'-hydroxymethyleugenol, forms protein and DNA adducts. Although ME is hepatocarcinogenic in rodents, it is not mutagenic in most standard assays. To explore whether ME is mutagenicity *in vivo*, it was administered by gavage for 90 days at a carcinogenic dose to transgenic Big Blue® male mice (300mg/kg/day, 5 days/week) and Big Blue® female rats (1,000mg/kg/day 5 days/week), harboring the lacI target transgene. Despite the finding that the mutant frequency (MF) of lacI in the liver of ME-treated mice ($4.27\pm1.09\times10^{-5}$) was the same as that recorded in control mice ($4.20\pm2.15\times10^{-5}$), the mutation spectrum from the ME-treated group was significantly different ($p<0.034$) from that in controls. In contrast to the findings in mice, the MF of lacI was significantly higher ($p<0.05$) in the liver of ME-treated female rats ($8.69\pm3.09\times10^{-5}$) compared to controls ($1.20\pm0.73\times10^{-5}$). These results illustrate the importance of interspecies comparisons in evaluating the mutagenic potency of a compound. This species difference for ME is most likely due to metabolic differences between rats and mice, an important consideration in the extrapolation of risk of ME to man.

1075 FREQUENCY AND SPECTRUM OF MUTATIONS INDUCED IN THE LAC I GENE OF TRANSGENIC MICE AFTER COMPLEX EXPOSURES TO GENOTOXIC CARCINOGENS.

D. A. Delker, K. M. Jackson and B. B. Gollapudi. *The Dow Chemical Company, Midland, MI.*

Transgenic rodents harboring shuttle vectors allow mutation analyses in any tissue of interest. These models also enabled the characterization of mutational spectra for several individual carcinogens. However, there is limited mutational data on agents given in combination. We have determined the mutant frequency of benzo[a]pyrene (BaP, 250 mg/kg/day), nitrosodimethylamine (NDMA, 7 mg/kg/day), and ethylnitrosourea (ENU, 50 mg/kg/day) in 12 week-old male Big Blue B6C3F1 mice administered either singly (3 daily oral doses) or in combination (BaP-day 1, NDMA-day 2, and ENU-day 3). All genotoxic agents, alone or in combination, increased mutant frequencies in the liver (3- to 6-fold) and kidney (2- to 4-fold). ENU alone and in combination increased mutant frequencies in the brain (1.5 fold) while BaP and NDMA alone had no effect. None of the treatments increased mutant frequencies in the testes. Mutational spectrum analyses of liver DNA revealed a high percentage of G:C to A:T transitions in the negative control (88%) and the NDMA (64%) groups. In contrast, BaP, ENU and the combination treatment induced a high percentage (>50%) of transversions. G:C to C:G (3 out of 4), A:T to T:A (3 out of 5), and G:C to T:A (10 out of 24) were the most common type of transversions induced by BaP, ENU, and the combination treatment, respectively. Finally, 46% (19 out of 41) of the mutations in the combination treatment group occurred at CpG islands compared to less than 22% in the other treatment groups. These results suggest that high doses of genotoxic agents in combination vs. singly while not affecting mutant frequency may change mutational spectrum.

1076 APPLICATION OF BIG BLUE® (BB) TRANSGENIC RAT FOR THE STUDY OF MUTATION INDUCTION IN NASAL MUCOSA: AN INHALATION STUDY WITH GLYCIDYL METHACRYLATE.

B. B. Gollapudi, K. M. Jackson, R. J. McGuirk, S. J. Day, D. A. Delker and J. M. Waechter, Jr. *The Dow Chemical Company, Midland, MI.*

The introduction of transgenic technology enhanced our ability to study mutagenicity in virtually every tissue of rats and mice. We have utilized the transgenic BB Fischer-344 rat model for the study of *in vivo* mutagenic potential of inhaled glycidyl methacrylate (GMA) - a chemical used in a variety of industrial polymer chemistry applications. Previous studies have shown that GMA is mutagenic *in vitro* in the Ames and CHO/HGPRT assays but was negative in a bone marrow micronucleus assay for cytogenetic damage following i.p. doses of up to 300 mg/kg bw. In order to evaluate its mutagenicity in a target tissue relevant to potential occupational exposure, respiratory and olfactory mucosa of GMA-exposed BB rats (1, 10, and 25 ppm; 6 h/d, 5 d/wk for 2 wks followed by a 4-wk manifestation period) were analyzed for lacI mutations. The highest concentration induced significant body weight depression and histopathological changes in both olfactory and respiratory mucosa. However, there were no significant increases in lacI mutant frequency (per 100,000 plaque forming units) vs. negative control either in the olfactory (15.7 vs. 15.1) or the respiratory (18.1 vs. 12.6) mucosa of rats (N=5) exposed to 25 ppm GMA. The positive control dimethylnitrosamine (p.o., 6 mg/kg/d, 5d/wk for 2 wks followed by 3 wks manifestation) induced a significant elevation in mutant frequency (194.3) in the olfactory mucosa. These results are suggestive of a critical role for metabolic processes in affording a significant level of protection against the potential *in vivo* genotoxicity of GMA.

1077 INVESTIGATION OF THE RADIOADAPTIVE RESPONSE IN BRAIN AND LIVER OF PUR288 *LacZ* TRANSGENIC MICE.

J. A. Kind[1], R. N. Winn[1], C. H. Jagoe[2], M. E. Boerrigter[3] and C. E. Dallas[1]. [1]*University of Georgia, Athens, GA,* [2]*Savannah River Ecology Laboratory, Aiken, SC and* [3]*Leven, Inc., Bogart, GA.*

The radioadaptive response (RA), where a small priming dose of ionizing radiation can lessen the effects of subsequent exposure to a higher radiation challenge dose, was investigated in multiple tissues within a transgenic organism. Well characterized in *in-vitro* models, current RA research has focused on particular cell types (i.e., lymphocytes), and does not provide comparative data for responses of multiple tissues within an organism. Transgenic animals are useful for such comparisons, because the transgene is integrated into all cells in the body. The pUR288 *LacZ* plasmid based transgenic mouse model utilizes a plasmid vector allowing highly efficient recovery of mutation targets, and is robust to large size change mutations that result from radiation exposure. Female C57Bl/6 pUR288 *LacZ* mice were exposed to priming doses ranging from 7.5 to 37.5 R x-rays over a three day period. After three weeks they received an acute challenge dose of 250 R x-rays. Animals were euthanized three weeks post-challenge, and brain and liver were flash frozen in liquid nitrogen, and stored at -80°C until analysis. Spontaneous mutant frequencies (MF) were significantly higher in liver than in brain (6.62×10^{-5} vs. 3.51×10^{-5}). In the absence of a priming dose, the 250 R challenge doubled the MF of both liver and brain (13.38×10^{-5} and 7.63×10^{-5} respectively). There were no apparent radio-protective effects from any priming dose in liver, while priming doses of 15, 22.5, and 37.5 R significantly reduced (by 40%) the mutagenic effects of the 250 R challenge in brain. Restriction analysis of mutants revealed a significant decrease in large size-change mutations at the three priming doses in brain. This study demonstrates the utility of this model for the investigation of radiological processes of large size-change mutations, as well as demonstrating a radioadaptive response in brains, but not livers of mice *in vivo*. (Supported by U.S. DOE DE-AC09-756R000 and the American Foundation for Pharmaceutical Education.)

1078 MUTATION FREQUENCIES OF MINISATELLITE REPEAT NUMBERS IN HUMAN SPERM BEFORE AND AFTER CANCER CHEMOTHERAPY WITH ALKYLATING AGENTS.

N. Zheng[1], D. G. Monckton[1], G. Wilson[1], F. Hagemeister[1], R. Chakraborty[2], T. H. Connor[2], M. J. Siciliano[1] and M. L. Meistrich[1]. [1]*The University of Texas, M. D. Anderson Cancer Center, Houston, TX and* [2]*The University of Texas, School of Public Health, Houston, TX.*

The spontaneous frequency of minisatellite repeat number changes in the human germline is relatively high. We chose minisatellites as mutation targets to determine whether they can be used as sensitive indicators of heritable genetic damage caused by chemical mutagens. We compared the mutation frequencies in sperm of the same Hodgkin's disease patients pre- and post-treatment with alkylating agents. Small pool polymerase chain reaction (SP-PCR) (PCR on DNA equivalent to approximately 100 sperm) and Southern blotting techniques were used to detect mutations and quantify the frequency of repeat number changes at the minisatellite MS205 locus. At least 7900 sperm in each sample were screened. The mutation frequencies of pre- and post-treatment for the two patients treated with 3 to 4 cycles of Cytoxan, Vinblastine, Procarbazine, and Prednisone (CVPP) / Adriamycin, Bleomycin, Dacarbazine, CCNU, and Prednisone (ABDIC) were 0.22 and 0.23%; and 0.94 and 0.98%. The mutation frequencies for one patient treated with 6 cycles of Mechlorethamine, Oncovin, Procarbazine, and Prednisone (MOPP) were 0.79 and 1.14%. The mutation frequency of the patient after MOPP treatment was 1.44 times as high as that before treatment, which was statistically significant. Since the samples were collected 9 to 15 years after receiving alkylating agent chemotherapy, we conclude that there is no effect of CVPP/ABDIC regimens on the mutation frequency in spermatogonia. However, the higher doses of the alkylating agent procarbazine in the MOPP treatment may increase the mutation frequency at the MS205 locus in spermatogonia.

1079 ASSESSMENT OF DNA DAMAGE IN WORKERS EXPOSED TO ROOFING ASPHALT.

T. Reid[1], C. Hayden[1], D. Marlow[1], R. Rinehart[2], J. Mierz[2], D. Werren, M. Toraason[1] and D. G. DeBord[1]. [1]*NIOSH, Cincinnati, OH and* [2]*Harvard School of Public Health, Boston, MA.*

To determine the potential for increased genetic damage due to asphalt-fume exposure, the single cell gel electrophoresis (comet) assay was used to measure DNA strand breaks in peripheral blood leukocytes at the start and end of a work week that involved exposure to asphalt fume, and in some cases coal-tar pitch. The study population consisted of 25 roofers exposed to hot asphalt and 12 construction workers not exposed to asphalt during the past 5 years. Air monitoring and urinary 1-OH-pyrene levels were used to assess PAH exposure. DNA damage is expressed as %Tail DNA (±S.E.M.). The average %Tail DNA at the start of the week was 15.1±0.6 among all roofers and 14.3±1.1 among controls. The average %Tail DNA at the end of the week was 16.7±0.6 among roofers and 14.5±1.0 among controls. In some cases roofers (n=18) were exposed to coal tar pitch during removal of existing roofing materials prior to applying hot asphalt. These roofers had higher air levels of total particulates and benzene solubles as well as urinary 1-OH-pyrene than a subset of roofers (n=7) not exposed to coal-tar pitch for at least 3 months. Start of the week levels of DNA damage were lower in the non-pitch exposed group of roofers (13.7±0.7) than in the pitch exposed group (16.1±0.6). End of the week levels of DNA damage were somewhat higher in the pitch-exposed roofers (16.9±0.8) compared to the group of roofers who were not exposed to pitch (16.1±0.6). Coal-tar pitch may contribute to higher basal levels of DNA damage than exposure to asphalt fume alone.

1080 ANALYSIS OF THE COMPONENTS OF EDIBLE OIL FUMES IN THE KITCHEN AND THEIR GENOTOXCITY IN *DROSOPHILA*.

S. Li, J. Zhang, X. Zhao and S. Xu. *Shanghai Tiedao University Medical College, Shanghai, China.* Sponsor: K. G. Hofer.

The objective of this study was to test the components of the condensation of edible oil kitchen fumes and their genotoxicity in Drosophila. Analytic method of the components was carried out by gas chromatography and mass spectra (GC/MS) and the genotoxicity of the condensate was detected using the sex-linked recessive lethal (SLRL) test in Drosophila. Results of GC/MS analysis showed that 74 kinds of organic compounds were detected out in the organic extracts of condensed oil from kitchen fumes. The compounds included hydroxylic acids, hydrocarbons, alcohols, esters, aldehydes, ketones, aromatic compounds, and steroids, etc. The total frequency rates of SLRL induced at the concentrations of 110, 320 and 960μg/ml were 1.732%, 4.306% and 1.707%, respectively. Meanwhile, their sterility rates of the first broods were 2.6%, 2.1% and 2.8%, respectively ($p<0.05$ as compared with the control). The frequency of SLRL in the second brood was 0.5% at 320μg/ml and 0.5% at 110μg/ml ($p<0.001$). We conclude that condensates of edible oil fume have many kinds of organic components which include hydroxylic acids, hydrocarbons, alcohols, esters, aldehydes, ketones, aromatic compounds, and steroids, and that the condensate of edible oil fume has genotoxic activity in Drosophila.

1081 SINGLE-STRAND DNA BREAKS FOLLOWING EXPOSURE TO COMBINED THERAPEUTIC HIV/AIDS AGENTS.

J. T. Chen and B. C. Levin. *National Institute of Standards and Technology, Gaithersburg, MD.*

The Single Cell Gel Assay (Comet Assay) was used to measure DNA single-strand breaks occurring in human lymphoblast cells (GM03798, NIGMS Human Genetic Mutant Cell Repository, Coriell Institute for Medical Research, Camden, NJ) exposed to therapeutic HIV/AIDS agents either individually or in combination. Azidothymidine (AZT) had been noted to cause such DNA damage by other detection methods. We wished to determine if the Comet Assay would also detect the damage by AZT and if more damage would occur with combined therapeutic agents. Therefore, we also examined zalcitabine (ddC) and didanosine (ddI) individually, in binary combinations with AZT, and as mixtures of all three chemicals. All three compounds are nucleoside analogs used to treat HIV/AIDS. Viability of the cell cultures was determined with trypan blue. For the Comet Assay, the cells were treated with each of the compounds for various times and concentrations to determine the optimal concentrations and times for testing. AZT caused increasing amounts of cell death and DNA single-strand breaks as the concentration was increased from 100 to 800 μM. The maximum loss of viability occurred at 48 hrs. When individually tested at 200 to 800 μM, neither ddC nor ddI caused the loss of cell viability or the DN single-strand breaks noted with AZT. Combinations of ddC at the highest concentration tested (800 μM) with AZT at 200 μM (a concentration producing minimal comets) increased the size of the comets noted with AZT alone indicating additional DNA damage. Similar combinations of ddI and AZT showed the same effect. Mixtures of ddC (800 μM), ddI (800 μM) and AZT (200 μM) produced the greatest amount of damage.

1082 A GENOTOXICITY STUDY WITH P-ARAMID RFP (RESPIRABLE-SIZED, FIBER-SHAPED PARTICULATES).

D. B. Warheit[1] and H. Murli[2]. [1]*DuPont Haskell Laboratory, Newark, DE and* [2]*Covance Labs. Inc., Vienna, VA.*

The objective of this *in vitro* assay was to assess the potential for p-Aramid RFP (respirable-sized, fiber-shaped particulates) to induce chromosomal aberrations in cultured human peripheral blood lymphocytes without metabolic activation. The highest concentration tested in this assay was limited by the physical characteristics of p-Aramid RFP. The test article was suspended in fully supplemented RPMI culture medium with 1% Pluronic F68. All dosing was achieved using a dosing volume of 90% (900 µL/mL) and the vehicle control cultures were treated with 900 µL/mL of fully supplemented RPMI culture medium with 1% Pluronic F68.In the chromosomal aberrations assay, the treatment period was for 3.0 hours and 19.0 hours without metabolic activation, and cultures were harvested 22.0 hours from the initiation of treatment. Replicated cultures of human whole blood lymphocytes were incubated with 6.30, 12.6, 25.2, 50.4, 101, 201, and 401 µg/mL. Cultures treated with concentrations of 6.30, 12.6, 25.2, and 50.4 µg/mL for 3.0 hours and 6.30, 12.6, 25.2, and 201 µg/mL for 19.0 hours were analyzed for chromosomal aberrations. No significant increase in cells with chromosomal aberrations, polyploidy, or endoreduplication was observed in the cultures analyzed. The results demonstrated that p-Aramid RFP was negative for inducing chromosomal aberrations in cultured human peripheral blood lymphocytes without metabolic activation.

1083 SPONTANEOUS HYDROLYSIS AND AN ACTIVE REPAIR PROCESS DETERMINE THE OVERALL RATE OF REMOVAL OF DNA-PROTEIN CROSSLINKS FROM FORMALDEHYDE-EXPOSED CELLS.

G. Quievryn and A. Zhitkovich. *Brown University, Department of Pathology and Lab Medicine, Providence, RI.*

Formaldehyde is an ubiquitous chemical with numerous sources of human exposure in both environmental and occupational settings. Formaldehyde is also a rodent carcinogen and it forms DNA-protein crosslinks (DPC) as the dominant form of DNA damage in exposed cells. Neither the mutagenic potential nor repair mechanisms of these important lesions are known at this time. In this study, we conducted detailed analysis of the stability of formaldehyde-induced DPC *in vitro* and in cultured cells. Both DNA-histone crosslinks formed *in vitro* and DPC induced *in vivo* exhibited a similarly high rate of spontaneous hydrolysis with the average half-life of 26.3 hr at 37°C and physiological pH/ionic conditions. The rate of the DPC removal from intact cells was even more rapid and was similar among three different human cell lines (HF/SV fibroblasts, Ad293 kidney and A549 lung cells). The average half-life was 12.5 hr; range 11.6-13 hr. After adjustment for the spontaneous loss, an active repair process was calculated to eliminate DPC from cells with the average t1/2=23.3 hr. Nucleotide-excision repair appears to play no significant role in the removal of DPC since repair-deficient XP fibroblasts had kinetics of the adduct elimination similar to other cells. Depletion of intracellular glutathione had no effect on the initial levels of DPC or the rate of their repair. A rapid loss of DPC from exposed cells determined in part by hydrolytic instability of these lesions suggests that application of DPC measurements as a biological dosimeter of formaldehyde exposure could be limited to situations with very recent exposures.

1084 MECHANISM OF METHYLENE DI-PHENYL DIISOCYANATE GLUTATHIONE CONJUGATE MICRONUCLEI INDUCTION DISTINGUISHABLE FROM THAT OF METHYLENEDINALINE.

B. Z. Zhong and P. D. Siegel. *NIOSH/HELD, Morgantown, WV.*

Methlyene di-phenyl diisocyanate (MDI) is widely used in the production of polyurethane products, such as wood binders and foams. Diisocyanates are very reactive compounds that can undergo nonenzymatic hydrolysis to form methylenedianiline (MDA), or react under physiological conditions with primary amines to form ureas and/or with thiols to form labile thiol acid esters. MDA is a carcinogen in animals and a suspected carcinogen in humans. We have previously reported that exposure of Brown Norway rats (BNR) to MDI induces micronuclei (MN) in bone marrow polychromatic erythrocytes. In vitro studies suggested that both MDI glutathione (MDI-GSH) conjugates and MDA are potential genotoxic metabolites of MDI. Addition of MDI directly to cell cultures did not induce micronuclei. The mechanism of micronuclei induction of these metabolites was explored in the present study. Chinese hamster lung fibroblasts were incubated with MDA or MDI-GSH. Micronuclei kinetichore from cytokinesis-blocked cells were labeled by immunofluorescent staining. Cells were washed, methanol fixed, treated with Tween 20 buffer, then labeled with antikineticore and fluoresceinated goat anti-human IgG antibodies to discern the presence of centromere within the micronuclei. Vincristine, DMSO and glutathone were used as positive, solvent and negative controls, respectively. MDA induced MN were negative with respect to anti-kineticore antibody binding. This is consistent with induction of chromosomal fragments by MDA binding to DNA. MDI-GSH induced MN had a significant increase in the number of anti-kineticore antibody labeled MN. MDI-GSH also increased the number of cells in metaphase. These results suggest that MDI-GSH MN induction was mediated through disruption of microtubules, whereas MDA MN induction was by a DNA-binding mechanism.

1085 *IN VIVO* DETECTION OF CHEMICALLY-INDUCED MUTATIONS IN TRANSGENIC FISH CARRYING CII/CI MUTATIONAL TARGETS.

R. N. Winn, M. B. Norris and K. J. Brayer. *University of Georgia, Athens, GA.* Sponsor: C. E. Dallas.

We examined the responses of the cII/cI transgenes in fish (medaka, *Oryzias latipes*) following treatment with either, the model mutagen, ethylnitrosourea (ENU), or a drinking water disinfectant by-product, potassium bromate ($KBrO_3$). The assay consisted of recovering the bacteriophage lambda vector which harbors the cII/cI target genes using *in vitro* packaging, followed by plating phage-infected indicator bacteria to quantify the frequency of cII/cI mutants. The assay is based on the role that the cII protein plays in the ability of the bacteriophage lambda to commit to either the lytic or lysogenic cycle using specialized E. coli hosts. The lysogens produced by the lambda phage with the wild-type cII/cI are favored, and indistinguishable in the E. coli lawn, while lambda phage that carry a cII/cI mutation are selected by forming plaques on the bacterial lawn when incubated at 24°C. Despite the small size of the fish, the vector was recovered with high efficiency (>0.3-2 $X10^6$ PFUs/reaction) which facilitated practical analyses of cII/cI mutant frequencies (MF) in whole fish, as well as in liver, and testes. Exposure-dependent inductions in MF (minimum two-fold induction above 2.9 $X\ 10^{-5}$) were observed in whole fish, testes, and liver after 15 days following 1 h exposures to 80 mg/L and 120 mg/L ENU. A ~two-fold induction of cII/cI mutants was observed in fish following a 28 day chronic exposure to 400 mg/L $KBrO_3$. These results further support the practical viability of transgenic fish as models for mutation detection in genotoxicity, and with distinct relevance to aquatic environmental health hazard assessment.

1086 RADICAL GENERATION CAPACITIES OF AMBIENT PARTICULATE MATTER IN RELATION TO ITS GENOTOXICITY.

P. J. A. Borm, R. P. S. Schins, A. M. Knaapen, D. Hohr and L. Dunemann. *Medical Institute for Environmental Hygiene, Düsseldorf, Germany.* Sponsor: K. E. Driscoll.

The purpose of this study was to investigate the generation of radicals by ambient particulate matter and to relate these data to (oxidative) DNA damage in alveolar type II cells. Particle morphology and chemical composition was determined by TEM/EDX and AAS analysis of transition metals. Fenton-driven radical formation by particles was evaluated by electron spin resonance (ESR) and by unwinding of supercoiled f X 174 RF1 DNA. DNA damage was measured by single cell gel electrophoresis and immunohistochemical analysis of 8-hydroxydeoxyguanosine. In line with previous observations, PM as well as PM supernatant cause depletion of supercoiled plasmid DNA. Both particles and supernatant produced hydroxyl radical-DMPO adducts in the presence of hydrogen peroxide, and this effect was completely abrogated upon pre-incubation with desferrioxamine (5 mM). PM supernatants also caused DNA damage in type II cells, and this damge was reduced upon pretreatment with desferrioxamine. Our data provide evidence that airborne particulate matter generates hydroxyl radicals in acellular systems, and that this may result in enhanced DNA damage in lung cells.

1087 SUPRA-ADDITIVE GENOTOXICITY OF A COMBINATION OF GAMMA-IRRADIATION AND ETHYL ETHANESULFONATE IN MOUSE LYMPHOMA L5178Y CELLS.

S. O. Mueller[1], H. Stopper[2] and W. K. Lutz[2]. [1]*NIEHS, LRDT, Research Triangle Park, NC and* [2]*Department of Toxicology, University of Wuerzburg, Wuerzburg, Germany.*

While testing for genotoxicity is usually performed on single chemicals, exposure of humans always comprises a number of genotoxic agents. The investigation of potentially synergistic effects of combinations therefore is an important issue in toxicology. Combinations of a 511 keV gamma-radiation with the chemical alkylating agent ethyl methanesulfonate were investigated in the *in vitro* micronucleus test in mouse lymphoma L5178Y cells. With combinations in the low-dose-linear effect range for the individual agents (0.25-2 Gy and 0.8-3.2 mM, respectively), supra-additivity by 34-86% was seen. The synergism was more pronounced at the higher dose levels. Supra-additivity was confirmed in experiments using cytochalasin B and analyzing binucleate cells only, to control for putative effects on the cell cycle. Statistical significance was shown by a 2-factor analysis of variance with interaction. The results indicate that damage to DNA by gamma-radiation and alkylation could affect different rate-limiting steps in the formation of micronuclei. Further investigations will have to show whether the observations are of general validity, in particular, whether other endpoints of genotoxicity produce the same results and whether the degree of supra-additivity is always dose-dependent. The latter would have a strong impact on the risk assessment for mixtures at low dose.

1088 SATURATION OF BASE EXCISION REPAIR RESULTS IN PERSISTENT 5'-NICKED AP SITES IN HUMAN CULTURED CELLS EXPOSED TO METHYL METHANESULFONATE.

J. Nakamura, B. F. Pachkowski and J. A. Swenberg. *Department of Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC.*

It has been demonstrated that significant numbers of mutagenic apurinic/apyrimidinic (AP) sites are generated under physiological conditions in genomic DNA through spontaneous depurination. In addition, DNA glycosylases enzymatically introduce AP sites from a wide range of base adducts. We previously demonstrated that methyl methanesulfonate (MMS) induced an accumulation of AP sites in human cultured cells. We further hypothesized that this increase in AP sites may be derived from saturation of the deoxyribose 5-phosphate (dRp) lyase activity of DNA polymerase β (β-pol). In this study, we quantitated and characterized AP sites and heat-labile bases in H2E1 cells exposed to MMS for up to 24 hr. To measure heat-labile lesions such as N7-methylguanine (7MG) and N3-methyladenine, a depurination assay was further optimized by incubating the DNA at 70°C for 24 hr in PBS. The number of heat-labile lesions detected by the Aldehyde Reactive Probe-Slot-Blot method was slightly higher than the number of 7MG adducts. These heat-labile lesions increased in a time-dependent manner and reached a plateau at 4-h exposure. Based on the number of AP sites and heat-labile lesions, we estimated that ~700 heat-labile lesions/1,000,000 nucleotides induced an imbalance of base excision repair, resulting in an increase in the number of AP sites in cells. The AP sites were predominantly cleaved 5' to the lesions, as expected following AP endonuclease activity. These results suggest that dRp lyase activity of b-pol, the next enzyme in base excision repair, may be the rate-limiting step. (Supported in part by NIEHS Superfund Basic Research Program Grant P42-ES05948.)

1089 EVALUATION OF MUTAGENICITY OF BENZO[A]PYRENE, DIBENZOTHIOPHENE, ISOQUINOLINE AND CARBAZOLE USING A NEWLY IMPROVED A_L MUTAGENICITY ASSAY.

C. J. Belfiore[1], Y. C. Ou[1], D. L. Gustafson[2] and R. S. H. Yang[1]. [1]*Center for Environmental Toxicology and Technology, Department of Environmental Health, Colorado State University, Fort Collins, CO and* [2]*University of Colorado, Health Sciences Center, School of Pharmacy, Denver, CO.*

The A_L mutagenicity assay has been shown to be highly sensitive compared to Ames and HPRT assays. The A_L human/hamster hybrid cell line (Jones *et al.*, 1975) contains one copy of human chromosome 11, encoding several cell surface antigens useful as markers for mutation. We have extended this assay by introducing a metabolic activation system. In the initial phase of studies exploring mutagenicity of benzo[a]pyrene (BaP), dibenzothiophene (DBT), isoquinoline (IQ) and carbazole (CZ), toxicity studies were conducted. Cell viability was determined by clonogenicity assay after 20 or 24 hr exposure to increasing concentrations of individual chemicals. Range of concentrations studied was from 1.25μM to 80μM; 6 or 7 concentrations were used for each dose-response curve. Chemical exposures were conducted with and without activation using Aroclor-induced rat liver S9 fraction. Optimal S9 concentration was 100μg/ml. In the absence of S9, CZ, IQ and BaP exhibited no toxicity toward A_L cells. IQ exhibited no toxicity with S9 activation. DBT exhibited toxicity both with and without metabolic activation; with addition of S9, a "rebound" dose-response curve at a lower dose range was consistently observed. Estimated LD_{50} for both BaP and CZ following activation was 5μM. Mutation rates at the S1 locus were determined in A_L cells exposed to each chemical. Consistent with previous findings, BaP exposure induced a dose-dependent increase in mutant fraction (M_f) with S9 activation only. At LD_{50} of BaP with S9, M_f was approximately $100/10^5$ surviving cells, a 7 to 12 fold increase above background. Preliminary results suggest that neither IQ nor CZ induce appreciable mutation at this locus. Following conclusive quantitation of mutagenicity, derivatives of those chemicals resulting in significant M_f will be examined in the same system to elucidate pathways leading to toxic and mutagenic interactions. (Supported by NIEHS 1 R01 ES09655.)

1090 *IN VITRO* STUDIES ON THE INDUCTION OF APOPTOSIS-RELATED DNA STRAND BREAKS (AR-DNASB) BY THE BENZENE METABOLITES MUCONALDEHYDE (MUC) AND HYDROQUINONE (HQ), SINGLY AND IN COMBINATION.

R. P. Amin and G. Witz. *Joint Graduate Program in Toxicology, Rutgers University/UMDNJ-RWJ Medical School, Piscataway, NJ.*

The biological effects of benzene, a clastogen and human leukemogen, are mediated, in part, by ring-hydroxylated metabolites including hydroquinone (HQ) and ring-opened metabolites including trans,trans-muconaldehyde (muconaldehyde, MUC), a 6-carbon diene dialdehyde. We hypothesize that benzene hematotoxicity involves interactive effects by muconaldehyde and hydroquinone with respect to DNA. In the present studies, we used the TUNEL assay to study the effect of MUC and HQ, singly and in combination, on AR-DNASB in HL-60 cells and bone marrow cells of male CD-1 mice and transgenic mice overexpressing SOD (TgSOD). HL-60 cells treated with 5, 10 and 25 μM MUC had a TUNEL index (% labeled cells) of 4.3±0.6%, 56.5±15.3% and 95.0±1.0%, respectively, compared to 1.7±0.5% for control, while treatment with 5-25 μM HQ for 1hr resulted in no significant increase in TUNEL labeling. Co-treatment with MUC and HQ resulted in significant decreases in TUNEL labeling relative to treatment with MUC alone i.e. 48% for the 25 μM MUC/HQ combination compared with 95% for MUC alone. MUC was more effective than HQ in inducing AR- DNASB in bone marrow cells of CD-1 or SOD transgenic mice, i.e. the TUNEL index was 32.8±2.0% and 22.2±4.0% for 10 μM MUC or 10 μM HQ, respectively at the 18 hr time point in TgSOD mice. SOD overexpression appeared not to affect AR-DNASB levels in response to MUC or HQ. Treatment with binary mixtures of 5 μM MUC and 1-10 μM HQ (8-18 hr incubation) resulted in less than additive increases in AR-DNA strand break levels. These results indicate that interactions at low benzene metabolite concentrations can alter genotoxic outcome observed for individual metabolites. The relevance of our findings to benzene hematotoxicity remains to be determined. (Supported by NIH grants ESO2558 and ESO9676 from the National Institute of Environmental Health Sciences, and NIEHS Center grant ESO5022.)

1091 ASSESSMENT OF THE GENOTOXICITY OF THALOMID (THALIDOMIDE).

S. Teo[1], M. Morgan[2] and S. Thomas[1]. [1]*Celgene Corporation, Warren, NJ and* [2]*TherImmune Corporation, Gaithersburg, MD.*

Thalidomide has been approved for use in the US. The genotoxicity of Celgene's formulation of thalidomide, Thalomid, was determined in 3 *in vitro* assays. In the Ames assay, reverse mutations at the histidine loci of 5 strains of *S. typhimurium* (TA1535, 1537, 98, 100, 102) and the tryptophan locus of one strain of *E. Coli* (WP2 uvrA) were determined. The assay was performed in the presence and absence of Arochlor 1254-induced S9 using both liquid pre-incubation and plate incorporation methods. Concentrations of 50 - 10,000 mg Thalomid/plate were used. In the gene mutation assay, the xanthine-guanine phosphoribosyl transferase (XPRT) locus was examined for forward mutation in cultured AS52 Chinese hamster ovary (CHO) cells. Cells were incubated with Thalomid and S9 at 0.017 - 1000 mg/ml and without S9 at 0.50 - 1000 mg/ml. In the *in vivo* micronucleus assay, the potential for Thalomid to induce micronuclei in newly formed polychromatic erythrocytes (PCEs) in mouse bone marrow was determined. Mice were dosed ip with 0, 500, 2500 and 5000 mg/kg Thalomid in 1% carboxymethylcellulose (CMC)

and sacrificed at 24, 48 or 72 hours. Femur bone marrows were scored for micronucleated PCEs. A positive response is obtained if Thalomid induces a statistically significant dose-dependent increase for a single sacrifice time or sex in the frequency of PCEs at one or more concentration. There was no significant increase in revertant frequencies in the Ames assay. Thalomid did not produce any significant dose-dependent increase in the forward gene mutation frequencies. It was also negative in the micronucleus test. Celgene's formulation of thalidomide is therefore considered non-genotoxic in the assays used.

1092 THE INDUCTION OF BASE-SUBSTITUTION MUTATIONS BY DAUNOMYCIN IN *SALMONELLA TYPHIMURIUM*.

W. J. Mackay[1] and A. A. Cauchi[2]. [1]*Edinboro University of Pennsylvania, Edinboro, PA and* [2]*Texas Tech Health Sciences Center, Lubbock, TX.*

Anthracyclines (primarily daunorubicin and adoxrubicin) are mutagenic antibiotics that are widely used in chemotherapy procedures for the treatment against a variety of malignant tumors, and these compounds arrest tumor cell growth by interacting with cellular DNA. However, clinical use of anthracyclines is hindered by tumor resistance and the adverse effects of these compounds (acute myelosuppression and cardiotoxicity) to healthy tissues. In spite of intensive investigations, the events leading to cell death and differential cytotoxicity in the presence of these antineoplastic compounds are not totally understood. A great many short term tests have been developed that allow compounds to be screened for potential gentotoxicity. The first such assay to be optimized for convenience and sensitivity is called the Ames test. Previous studies showed that daunomycin induced frameshift mutations in prokaryotic (*e.g.* TA98 in the Ames Test) and eukaryotic cells. More recently, a set of *Salmonella* strains (TA7001 to TA7006) was generated to easily identify base-substitution events by reversion of *his* point mutations. In this study, we show that daunomycin can also induce base-substitution mutations in *Salmonella*. Specifically, AT to GC transition mutations (TA7001) were induced 6-fold, GC to AT transition events (TA7004) were induced 11-fold, and GC to TA transversion mutations (TA7005) were induced 8-fold above spontaneous levels. Thus, it appears that daunomycin can induce a wide array of mutational events which include frameshifts and base-substitution mutations.

1093 INDUCTION OF MUTAGENIC DNA DAMAGE DURING REDUCTION OF CHROMATE BY CYSTEINE IS DEPENDENT ON FORMATION OF CHROMIUM(III)-DNA ADDUCTS.

Y. Song, G. Quievryn, V. Voitkun, A. DeLucia, M. Goldfarb and A. Zhitkovich. *Brown University, Dep. of Pathology and Lab Medicine, Providence, RI.*

Mutagenic activity of carcinogenic chromium(VI) arises from its intracellular metabolism, a process which ultimately yields Cr(III). Cysteine (Cys) is considered to be one of the potential reducers of Cr(VI) *in vivo*, and this amino acid also forms crosslinks with DNA in Cr(VI)-exposed cells. In this work, we studied formation of mutagenic DNA damage during reduction of Cr(VI) by Cys with the aim of identifing types of lesions responsible for the genotoxic effects of Cr(VI). The mammalian pSP189 shuttle-vector was utilized for detection of mutagenic activity following replication of the plasmids in human diploid fibroblasts. Reduction of Cr(VI) by Cys led to an extensive Cr(III)-DNA binding which could be prevented either by occupation of DNA phosphates with Mg ions or by blocking Cr(III) reactions by addition of EDTA or inorganic phosphate. Incubation of Cr(VI)/Cys with DNA resulted in the formation of Cr(III)-DNA monoadducts, Cys-Cr(III)-DNA and DNA-DNA crosslinks. Reductive metabolism of Cr(VI) did not lead to the production DNA strand breaks or apurinic sites when trace amounts of iron were removed from all reagents. Reduction of Cr(VI) by Cys was found to lead to the dose-dependent formation of mutagenic DNA damage. Mutations were undetectable when Cr(III) binding to DNA was blocked. A substantial increase in the fluorescence of the oxidant-sensitive dye DCF was observed in Cr(VI)/Cys reactions, however, DCF fluorescence was not affected by conditions that eliminated mutagenic DNA damage. We concluded that the formation of mutagenic DNA lesions during reduction of Cr(VI) by Cys is determined by binding of Cr(III) to DNA.

1094 *SALMONELLA TYPHIMURIUM* YG7104 AND YG7108 CO-EXPRESSING HUMAN CYP2E1 AND NADPH-P450 REDUCTASE ARE SENSITIVE TO PROMUTAGENIC CYP2E1 SUBSTRATES IN THE AMES ASSAY.

M. T. Cooper and T. D. Porter. *University of Kentucky, Lexington, KY.* Sponsor: M. Vore.

We have developed an Ames mutagenicity test that utilizes cloned human cytochrome P450 2E1, rather than a rat liver homogenate (S9 fraction), to activate promutagenic CYP2E1 substrates, including nitrosamines, to their reactive forms. Nitrosamines can cause mutagenicity by alkylating DNA at the O^6 position on guanine residues. Nitrosamines are not mutagenic, *per se*, but must be activated by liver enzymes, namely CYP2E1, in order to react with the DNA. Nitrosamines have been categorized as human mutagens, yet yield poor results in the traditional Ames assay. We postulated this lack of sensitivity in the Ames assay to nitrosamine mutagenicity might be due to the DNA repair capabilities in the commonly used Ames bacterial strains such as TA1535. TA1535 is capable of repairing alkylation damage to DNA via two native O^6-methylguanine methyltransferases. These two enzymes are encoded by genes *ogt* and *ada*. Deletions derivatives of TA1535 have been developed: YG7104 (*ogt*) and YG7108 (*ogt* and *ada*). To examine the role of these methyltransferases in mutagenicity we co-expressed human CYP2E1 and P450 reductase in strains TA1535, YG7104 and YG7108. CYP2E1 and reductase expression was verified using Western blot, cytochrome *c* reduction and CO-difference spectra. The non-expressing TA1535, YG7104 and YG7108 strains yield no increase over spontaneous revertants when exposed to nitrosamines, chloroform or CCl_4. TA1535 co-expressing CYP2E1 and reductase shows no increase in sensitivity to nitrosamines, chloroform or CCl_4; however, both YG7104 and YG7108 co-expressing strains show increased sensitivity to various nitrosamines (dimethyl-, diethyl-, dipropyl-, dibutyl-), chloroform and CCl_4. The increased sensitivity in these strains was blocked by ethanol, an inhibitor of CYP2E1. (Supported by NIH grant ES-06420 and fellowship ES-05852.)

1095 UTILITY OF AN AMES SCREENING ASSAY FOR THE EARLY EVALUATION OF PHARMACEUTICAL COMPOUNDS FROM A COMBINATORIAL LIBRARY.

M. D. Todd[1] and L. F. Stankowski, Jr.[2]. [1]*Chiron Corporation, Emeryville, CA and* [2]*Chrysalis Preclincal Services, Olyphant, PA.*

Genotoxicity testing of pharmaceutical compounds traditionally has been performed once a drug development candidate is selected. An Ames screening assay that requires only 13 mg of compound, compared to 1 to 2 gms for a FDA/OECD-compliant Ames assay (full Ames), has been developed. Therefore, genotoxicity testing can be performed much earlier in the drug selection process. Five Salmonella typhimurium strains (TA98, TA100, TA102, TA1535 and TA1537) are used in the screening assay in a liquid preincubation format with and without S9 metabolic activation. Strains TA98 and TA100, and strains TA1535 and TA1537 are evaluated as mixed cultures. Approximately 50 substituted heterocyclic compounds from a combinatorial chemistry library were evaluated in the screening assay. Compounds were tested at six dose levels up to 500 mg/plate with TA98/TA100, TA1535/TA1537 and TA102. Significant structure-activity relationships were observed. Compounds containing a nitropyridyl substituent induced a statistically significant, dose-dependent, at least two-fold increase in revertant frequencies (positive) in strains TA98/TA100 and in strains TA1535/TA1537. In contrast, compounds with an aminonitropyridyl or a cyano substituent at the same position on the molecule were negative or equivocal in the same strains. A change from an imidazole to a pyridone substituent at a different position on the scaffold also was associated with positive test results. Selected molecules that were tested in the screening assay also were tested in a full Ames assay. Compounds with the nitropyridyl substituent also were positive in the full Ames, and increased the revertant frequencies of strains TA98 and TA1537. The screening Ames assay showed good concordance with the full Ames assay. Only one compound gave a different result, being equivocal in the screening Ames assay and negative in the full Ames assay. Thus, the screening Ames assay is predictive for the full Ames assay and has been an invaluable tool in directing medicinal chemistry efforts.

1096 GENOTOXIC INTERACTIONS OF MODEL COMPOUNDS AND BINARY MIXTURES.

S. S. Garcia[1], M. G. Mumtaz[2] and K. C. Donnelly[3]. [1]*Texas A&M, College Station, TX,* [2]*Agency for Toxic Substances & Disease Registry, Atlanta, GA and* [3]*Texas A&M University, College Station, TX.*

Although human exposure typically occurs to complex mixtures, the vast majority of toxicology literature has been developed for individual compounds. Information is needed to describe potential chemical interactions to facilitate the preparation of human health risk assessments for complex mixture exposures. This study investigated the genotoxic interactions of model compounds and binary mixtures representing two classes of compounds. The model chemicals included the polycyclic aromatic hydrocarbons benzo(a)pyrene (BAP), chrysene and anthracene; and the chlorinated aromatic hydrocarbons pentachlorophenol (PCP) and tetrachlorophenol. Genotoxicity was measured using either the Salmonella/microsome mutagenicity assay, or the *E. coli* prophage induction assay. Generally, the Salmonella assay is more sensitive to benzo(a)pyrene, while *E.coli* responds to chlorinated phenols. Chemicals were dissolved in DMSO and tested as individual compounds, as well as binary, and in some cases tertiary mixtures. Individual chemicals were tested at a minimum of five concentrations and the concentration of each component of the binary mixtures was the same as was used with the individual chemcials. For all mixtures, the response appeared to be very dose dependent. Some inhibition of BAP mutagenicity was observed at higher concentrations of chrysene. In the first experiment with BAP and PCP, BAP induced a 9.5 fold increase in plaques at a concentration of 0.95 mM, while PCP induced an 18.3 fold increase and the BAP-PCP mixture induced an 87 fold increase in plaque formation. In a second experiment, BAP induced a 9.3 fold increase, PCP induced a 14.5 fold increase, and the BAP-PCP mixture induced a 60.4 fold increase in plaque formation. The enhanced genotoxic response was highly dose dependent, and some inhibition was observed at the highest dose tested. Additional studies are planned to investigate the effect of the mixture on metabolite formation.

1097 PRETREATMENT OF *SALMONELLA TYPHIMURIUM* WITH INTERCALATORS INCREASES THE MUTAGENICITY OF N-ACETOXY-2-ACETYLAMINOFLUORENE.

B. F. Said, D. C. Matsumoto, A. Hamade and R. C. Shank. *University of California, Irvine, Irvine, CA.*

Exposure of DNA to a genotoxin can result in non-additive damage by subsequent exposure to a second genotoxin. An on-going study has examined effects of DNA intercalators, benzo(a)pyrene diol epoxide (BPDE) and ethidium bromide (EB) on the mutagenicity of N-acetoxy-2-acetylaminofluorene (AcO-AAF) in the T98 frameshift strain of Salmonella typhimurium. T98 was incubated with BPDE (0.075 microgram/plate) for 15 min, then with AcO-AAF (0.25 microgram/plate); the mutagenic potency of AcO-AAF was increased 4-6 fold above the theoretical additive effect. In a parallel experiment EB (0.02 microgram/plate) increased the mutagenic potency of AcO-AAF 5-fold. Increases were a linear function of concentration of BPDE and EB. Pretreatment with increasing concentrations of BPDE (up to 0.3 microgram/plate) or EB (up to 3 microgram/plate) alone did not produce significant numbers of revertants, indicating enhancement was due to an increase in AcO-AAF mutagenic potency. Enhancement was not observed when treatment order was reversed. Pretreatment of T98 with DNA cross-linking agent, cis-platin, before EB treatment blocked the EB-dependent enhancement of AcO-AAF mutagenicity. Pretreatment of cells with BPDE, EB, or aflatoxin B1-8,9-epoxide enhanced primarily -2 frameshift mutations induced by AcO-AAF in the his D3052 allele. The results are discussed in terms of modulation of DNA damage by carcinogenic mixtures potentially due to changes in helix conformation by the first genotoxin followed by non-additive damage by subsequent exposure to a second genotoxin. (Supported by EPA grant R825809.)

1098 OXIDATIVE DNA DAMAGE AND MUTAGENICITY OF CYANOETHYLENE OXIDE.

A. M. Jeffrey, T. Spratt and J. Whysner. *American Health Foundation, Valhalla, NY.*

Cyanoethylene oxide (CNEO), the epoxide of acrylonitrile (ACN), has been prepared and tested for its mutagenicity in the Ames assay using *S. typhimurium* strains TA1535 and the TA7000 series. These effects are being investigated to provide an understanding of the reports of genotoxicity of ACN with metabolic activation. Mutants from strain TA1535, capable of growing in the absence of histidine, have been reported to occur most commonly with GC®AT transitions or GC®TA transversions. In the TA7000 series, only one type of base substitution can produce mutants capable of growing in the absence of histidine. CNEO exposures produced dose-related increases in mutants in both TA1535 and TA7004, which corresponds to a GC®TA transversion. This mutation is consistent with base mispairing of 5-hydroxycytosine or the formation of apurinic sites resulting from repair of 8-oxodeoxyguanosine. A dose-related positive response was also obtained in one of two experiments with TA7002, which may reflect AT®TA transversions. Other strains did not give a positive response, including TA7001, which is consistent with negative results for TA102. In a parallel experiment exposing TA1535 to CNEO, DNA was extracted and the levels of 8-oxodeoxyguanosine and 5-hydroxycytosine were determined by HPLC with electrochemical detection. Both oxidized DNA nucleosides increased in a dose-dependent manner. Since no increases were seen in calf thymus DNA treated with CNEO, the oxidative damage seen in the bacteria appear to result from stimulation of reactive oxygen species or inhibition of DNA repair.

1099 COMPARATIVE MECHANISMS OF ACTIVATION OF ESTROGEN RECEPTOR α BY ESTROGEN AND 4'-HYDROXYTAMOXIFEN.

E. Castro-Rivera and S. Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Seventeen β-Estradiol (E2) and 4'-hydroxytamoxifen (4-OHT) exhibit estrogen receptor α (ERα) agonist and antagonist activities in mammary cancer cells, whereas both compounds exhibit agonist activity in the endometrium. This study compared the estrogenic effects of E2 and 4-OHT in ECC-1 and HEC1A endometrial cancer cells and other cell lines using constructs containing E2-responsive inserts from the creatine kinase B (pCKB), cathepsin D (pCATH) and complement C3 (pC3) gene promoters linked to luciferase (luc) or chloramphenicol acetyltransferase (CAT) reporter genes. Cells were also cotransfected with wild-type ERα variants expressing activation function 1 (ERα-AF1) or AF2 (ERα-AF2). Using pCKB as a model construct, E2 significantly induced CAT activity (15- to 30-fold) in both endometrial cell lines as well as HepG2 (liver) and ER-negative MDA-MB-231 (breast) cancer cell lines cotransfected with wild-type ERα expression plasmid. 4-OHT also acted as an ERα agonist in the four cell lines cotransfected with ERα; however, the magnitude of the induction response (4- to 14-fold) was lower. Similar results were obtained using pC3 and wild-type ERα in the same cell lines. In contrast, using the pCKB construct, E2 but not 4-OHT activated reporter gene expression in cells cotransfected with ERα-AF1 or ERα-AF2, and results obtained with pC3-luc varied with different cell lines, wild-type or variant ERα. The data indicate that the ERα-AF1-dependent activation by 4-OHT is cell context- and gene promoter-dependent, and this is consistent with the increasingly complex interactions associated with ligand-mediated activation of ERα. (ES04917 and ES09106.)

1100 EVALUATION OF AGONISTIC AND ANTAGONISTIC EFFECTS OF SEVERAL CHEMICALS, MAINLY PYRETHROID INSECTICIDES, USING THREE *IN VITRO* ASSAYS WITH HUMAN ESTROGEN, ANDROGEN OR PROGESTERONE RECEPTOR MEDIATED MECHANISMS.

K. Saito, K. Sumida, N. Ohe, Y. Tomigahara, N. Isobe, I. Nakatsuka and H. Kaneko. *Environmental Health Science Laboratory, Sumitomo Chemical Co., Ltd., Osaka, Japan.*

Agonistic or antagonistic effects of xenoestrogens (BisphenolA, *p*-nonylphenol and *o,p'*-DDT), putative antagonists (4-hydroxytamoxifen, hydroxyflutamide and RU486) and pyrethroid insecticides (*d-trans*-allethrin, cypermethrin, empenthrin, fenvalerate, imiprothrin, permethrin, *d*-phenothrin and prallethrin) were evaluated using three *in vitro* assays with human estrogen α(ERα),androgen (AR) or progesterone (PR) receptor mediated mechanisms. Mammalian cell-based luciferase reporter gene assays were developed for analyzing the effects on receptor-mediated gene activation. Receptor-independent effects on consutitutive luciferase activation in control cells were examined for determining the appropriate dose levels of chemicals. Effects on ligand-dependent interaction between receptors and a coactivator (TIF2: Transcriptional Intermediary Factor 2) were examined by yeast two-hybrid assays. Moreover, binding capacity of test chemicals was investigated by competitive ligand binding assays. Significant ($p0.05$) positive effects of cognate hormones (E2:17β-estradiol, DHT:dihydrotestosterone and progesterone) were detected in all assays. Xenoestrogens showed significant agonistic effects in ERα assays. Putative antagonists inhibited the cognate hormone-mediated transactivation and interaction between the receptors and TIF2 through the receptor binding. However, none of pyrethroids tested showed

significant agonistic or antagonistic effects (100nM-10μ) in the present assays, suggesting that pyrethroids tested do not exert hormonal or anti-hormonal effects through human ERα, AR or PR-mediated mechanisms.

1101 ESTROGEN-MEDIATED ACTIVATION OF c-*Fos* PROTO-ONCOGENE THROUGH PROTEIN BINDING THE SERUM RESPONSE ELEMENT.

R. Duan and S. Safe. *Texas A&M University, Department of Veterinary Physiology & Pharmacology, College Station, TX.*

Analysis of the c-fos protooncogene promoter has identified a distal GC-rich element (-1168 to -1161) required for estrogen (E2)-responsiveness in MCF-7 breast cancer cells. More proximal downstream sequences (-354 to -296) contain a *sis*-inducible element (SIE) and a serum response element (SRE) required for transactivation by growth factors. Surprisingly, in MCF-7 cells transfected with constructs containing the -354 to -296 (pSS) or SRE (pSRE) from the fos gene promoter, E2 induced a 2- to 4-fold increase of chloramphenicol acetyltransferase (CAT) (reporter gene) activity, and this response was dependent on cotransfection with estrogen receptor α (ERα). Hormone-dependent induction was inhibited by cotransfection with dominant negative ras or MAPK expression plasmids; the response was also inhibited by the MAPKK inhibitor PD 98059 and the pure antiestrogen ICI 182,780. Analysis of proteins interacting with SRE was determined by gel electophoretic mobility shift assays using MCF-7 cell nuclear extracts, and both the serum response factor and Elk-1 transcription factor were identified as SRE-bound proteins. Retarded band intensities were enhanced after treatment with E2 or growth factors. Thus, results of this study show that ligand-activated ERα mediates the ras → MAPK signaling pathway in MCF-7 cells and activates c-fos expression through the SRE. This represents a unique mechanism of ERα in which E2 and growth factors activate proteins binding the same response elements. (ES09253 and ES09106)

1102 EFFECTS OF LIGAND-STRUCTURE ON ESTROGEN/ANTIESTROGEN INDUCTION VIA ESTROGEN RECEPTOR/SP1 INTERACTIONS WITH GC-RICH PROMOTER ELEMENTS.

X. Li, W. Porter, E. Castro-Rivera, Q. Chin, R. Duan, B. Saville, G. Sun, W. Xie and S. Safe. *Texas A&M University, Department Veterinary Physiology & Pharmacology, College Station, TX.*

Estrogen receptor (ER)-mediated transactivation is dependent on ER-subtype, gene promoter, cell context and ligand structure. In ER-positive human breast cancer cells, 17β-estradiol (E2) induces several genes through ERα/Sp1 interactions that involve interactions with GC-rich sites, and for some genes, other DNA-bound factors may also be required. Ligand-dependent ERα activation of heat shock protein 27 gene expression gave a unique induction response; 10 nM E2 and 1000 nM of the steroidal pure antiestrogen ICI 164,384 induced heat shock protein (Hsp) 27 mRNA levels (3.2- and 2.3-fold), whereas the structurally-related steroidal antiestrogen ICI 182,780 did not affect mRNA levels. E2 and both steroidal antiestrogens caused a 2- to 5-fold increase in reporter gene activity using constructs containing E2-responsive inserts from the Hsp 27 gene promoter (pHsp27) or a consensus GC-rich Sp1-binding site (pSp1). Estrogen/antiestrogen-induced gene expression was observed in cells cotransfected with wild-type human ERα expression plasmid; however, only E2 induced reporter gene activity in cells cotransfected with a DNA-binding domain-deficient ERα mutant (HE11). In contrast, other Sp1-dependent constructs from the c-fos and adenosine-deaminase gene promoter were responsive to E2 but not the steroidal antiestrogens suggesting that specific promoter elements may contribute to antiestrogen-dependent activation, and this is currently being investigated. (CA76637 and ES09106).

1103 CELL AND PROMOTER-SPECIFIC INTERACTIONS OF STEROID RECEPTOR COACTIVATORS WITH ESTROGEN RECEPTOR α (ER_α) AND ER_α/SP1.

T. A. Nguyen and S. Safe. *Texas A&M University, Department of Veterinary Physiology & Pharmacology, College Station, TX.*

Steroid receptor coactivators (SRCs) are a family of proteins that interact with steroid hormone receptors and other members of the nuclear receptor family resulting in enhanced ligand-induced transactivation. SRC family members are expressed in multiple tissue and cancer cell lines, and their coactivator effects have primarily been characterized in non-mammary cancer cell lines. This study investigates the effects of SRCs on estrogen receptor α (ER_α) activation of estrogen response element-dependent constructs (pERE) and GC-rich elements (pSp1) that bind ER_α/Sp1. Initial results show that in CHO-1 and COS-1 cells treated with E2 and transfected with pERE and ER_α, there was a 4- to 8-fold induction of reporter gene activity. Cotransfection with SRC-1 and SRC-3 enhanced (30-50%) the induction response as previously reported. In contrast, enhancement of ER_α action by SRCs was not significant in MCF-7 human breast cancer cells. In a parallel study, MCF-7 cells were transfected with ER_α and pSp1, and estrogen induced a 2- to 3-fold increase in reporter gene activity; however, after cotransfection with SRC-3, there was a subsequent 100% decrease in ER_α/Sp1-dependent transactivation. In gel mobility shift and coimmunoprecipitation assays, SRC-3 decreased ER_α/Sp1 binding to [^{32}P]Sp1 oligonucleotide, and both ER and Sp1 antibodies coimmunoprecipitated [^{35}S]SRC-1 incubated with ER or Sp1 alone or in combination, respectively. These data reveal complex cell-specific functional differences in ER_α and ER_α/Sp1 interactions with SRC family members. Results of a systematic study in different cell lines with SRC-1, SRC-2, SRC-3 and other coactivators will also be described. (CA76637 and ES09106).

1104 CELL CONTEXT-DEPENDENT ESTROGEN RECEPTOR α (ERα) AGONIST AND ERβ ANTAGONIST ACTIVITIES OF METHOXYCHLOR METABOLITES.

L. Pallaroni[1], B. Saville[1], J. E. Lee[1], M. Stoner[1], K. Gaido[2], S. C. Maness[2] and S. Safe[1]. [1]*Texas A&M University, Department of Veterinary Physiology & Pharmacology, College Station, TX and* [2]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Structure-activity relationships among a series of methoxychlor metabolites have identified four congeners that exhibit estrogen receptor α (ERα) agonist activity but partial ERβ antagonist responses in Hep G2 cells using the C3-luc construct containing an estrogen (E2)-responsive insert from the complement C3 gene promoter. Using the C3-luc assay system (cotransfected with ERα or ERβ), the effects of cell context on the ERα (agonist) and ERβ (antagonist) activities were determined for 2,2-bis(*p*-hydroxyphenyl)-1,1,1-trichloroethane (HPTE), 2,2-bis(*p*-hydroxyphenyl)-1,1-dichloroethylene (HPDE), 2-(*p*-hydroxyphenyl)-2-(*p*-methoxyphenyl)-1,1,1-trichloroethane (HPTE-OMe), and 2-(*p*-hydroxyphenyl)-2-(*p*-methoxyphenyl)-1,1-dichloroethylene (HPDE-OMe). Initial studies utilizing HPTE as a prototype showed that this methoxychlor metabolite exhibits ERα agonist and ERβ antagonist activities in several cell lines transfected with C3-luc and ERα or ERβ including PE06 and PE04 human ovarian cancer cells, HeLa cells (cervical cancer) and SAOS human osteosarcoma cancer cells. Although HPTE was an ERα agonist in MDA-MB-231 breast cancer cells, no inhibition of E2-activated ERβ-dependent luciferase activity was observed at HPTE concentrations as high as 10 ∝M. The comparative ERα (agonist)/ERβ (antagonist) activities of the four methoxychlor metabolites were investigated in SAOS cells, and all compounds inhibited (100%) ERβ activation of C3-luc. The ERα agonist activities of these compounds were variable; only HPTE was a full agonist at the highest concentration (10 ∝M); however, potencies were cell context-dependent. (ES09106 and ES04917)

1105 TRANSCRIPTIONAL ACTIVATION OF ORNITHINE DECARBOXYLASE GENE EXPRESSION BY ESTROGENS IN MCF-7 BREAST CANCER CELLS.

C. Qin and S. Safe. *Texas A&M University, Department of Veterinary Physiology & Pharmacology, College Station, TX.*

Ornithine decarboxylase (ODC) is a key enzyme in the biosynthesis of polyamines and important for cell proliferation and growth of cancer cell lines, including MCF-7 human breast cancer cells. 17β-Estradiol (E2) induces proliferation and ODC gene expression in estrogen receptor (ER)-positive MCF-7 cells, and this study investigated the molecular mechanisms of ODC induction by E2. A series of constructs containing -164 to +29 (pODC1), -122 to +29 (pOCD2), -93 to +29 (pODC3), and -74 to +29 (pODC4) ODC gene promoter inserts were transiently transfected into MCF-7 cells, cotransfected with ERα expression plasmid, and treated with 10nM E2. Luciferase (reporter gene) activities were induced 2- to 3-fold with constructs pOCD1, pOCD2 and pODC3, but not pODC4, suggesting that the -93 to -74 region of the promoter was required for ERα-mediated transactivation. This region contains a CCAAT motif, and in transient transfection studies using a construct (pODC5) containing this site and upstream sequences (-164 to -71), E2 did not induce luciferase activity suggesting that the CCAAT binding site was required but not sufficient for hormone-mediated induction. The -164 to +29 region of the ODC gene promoter multiple (5) recognition sites for nuclear transcription factors and the requirement for each motif was determined by

site-directed mutagenesis followed by transfection of the mutant constructs, and the results showed that both a CCAAT and an adjacent CP2 binding site were required for E2-mediated transactivation. This response did not require direct ERα protein-promoter interactions, and the mechanisms of transcription factor activation via ERα-induced kinase-dependent and -independent pathways will be discussed. (CA76636 and ES09106)

1106 LIGAND-ACTIVATED ESTROGEN RECEPTOR α (ERα)/Sp1 ACTION IN BREAST CANCER CELLS IS DEPENDENT ON THE ACTIVATION FUNCTION 1 DOMAIN OF ERα.

B. Saville, M. Wormke and S. Safe. *Texas A&M University, Department of Veterinary Physiology & Pharmacology, College Station, TX.*

Estrogen receptor α (ERα)/Sp1 is an estrogen-inducible transcription factor complex that interacts with specific GC-rich sites in several target genes. In contrast, ERβ/Sp1 exhibits minimal ligand-induced activity, and using a series of chimeric proteins containing activation function-1 (AF-1) of ERα fused to AF-2 of ERβ ($ERα_{/β}$) and AF-1 of ERβ fused to AF-2 of ERα ($ERβ_{/α}$), it was shown that E2-induced transactivation via ER/Sp1 was dependent on the AF-1 domain of ERα. Deletion mutants of the AF-1 domain of wild-type human ERα and chimeric $ERα_{/β}$ were generated, and E2-induced transactivation was determined in MDA-MB-231 breast cancer cells cotransfected with deletion mutants and constructs contain consensus GC-rich (pSp1) or estrogen response element ($pERE_3$) inserts. Induction of reporter gene activity was observed for cells transfected with $pERE_3$ and wild-type ERα (3.4-fold) or $ERα_{/β}$ (3.90-fold) and significant induction was observed for all deletion mutants. In cells transfected with pSp1 and wild-type ERα or $ERα_{/β}$, there was a 2.6- and 4.4-fold induction of reporter gene activity, respectively, and the loss of induction in cells transfected with ERα-AF-1 deletion mutants was associated with aa 79 to 117. Subsequent studies with a newly reported p68 (helicase) AF-1-dependent coactivator of ER and other ligand-activated nuclear receptors showed that coexpression of this protein decreased ERα/Sp1 action in breast cancer cells. (CA76636 and ES09106)

1107 DOWNREGULATION OF VASCULAR ENDOTHELIAL GROWTH FACTOR EXPRESSION IN HEC1A ENDOMETRIAL CANCER CELLS THROUGH INTERACTIONS OF ESTROGEN RECEPTOR α AND Sp3 PROTEINS.

M. Stoner[1], F. Wang[1], I. Samudio[1], C. Vyhlidal[1], M. Kladde[2], T. Nguyen[1] and S. Safe[1]. [1]*Texas A&M University, Department of Veterinary Physiology & Pharmacology, College Station, TX and* [2]*Texas A&M University, Department of Biochemistry & Biophysics, College Station, TX.*

Vascular endothelial growth factor (VEGF), a potent angiogenic factor, is downregulated by 17β-estradiol (E2) in HEC1A endometrial cancer cells, and initial studies identified a region of the VEGF gene promoter (-131 to +54) required for hormone-decreased expression. Subsequent deletion analysis identified a minimal active construct (pVEGF6) that contained the -66 to +54 promoter region, and the E2 response was subsequently lost by mutation of a G-rich -66 to -52 sequence. Nuclear extracts from HEC1A cells bound the G-rich sequence in gel mobility shift and footprinting assays, and results of oligonucleotide competition and antibody supershifts confirmed that both Sp1 and Sp3 proteins, but not early growth response-1 (Egr-1) protein, bound this critical promoter sequence. The mechanism of estrogen receptor α (ERα)-mediated downregulation of pVEGF6 was investigated in *Drosophila* Schneider SL-2 cells that do not express endogenous Sp1, Sp3 or ERα proteins. In SL-2 cells transiently transfected with pVEGF and Sp1 expression plasmids, cotransfection with ERα (and treatment with E2) significantly increased the reporter gene activity. In contrast, cotransfection with ERα decreased transactivation in SL2 cells transfected with pVEGF6 and Sp3 expression plasmids. These data, coupled with preliminary results of coimmunoprecipitation and other Sp3-ERα interaction studies, suggest a unique mechanism of E2-decreased gene expression through ERα-Sp3 interactions. (CA76636 and ES09106)

1108 REGULATION OF TRANSFERRIN GENE EXPRESSION BY 17β-ESTRADIOL IN HUMAN BREAST CANCER CELLS.

C. Vyhlidal, C. Mach and S. Safe. *Texas A&M University, Department of Veterinary Physiology & Pharmacology, College Station, TX.*

Transferrin is an iron binding protein that transports ferric iron between sites of absorption, storage, and utilization in vertebrate serum. Transferrin is an essential growth factor involved in growth regulation and differentiation. Transferrin is predominately synthesized in the liver; however, its expression has been identified in several cell types including the MCF-7 human breast cancer cell line. Secretion of transferrin by MCF-7 cells is induced in response to 17β-estradiol (E2). Treatment with 10 nM E2 of MCF-7 cells transfected with 3.6 Kb of the transferrin 5'-promoter sequence (Tf-3600/+39-CAT) linked to a chloramphenicol acetyltransferase (CAT) reporter resulted in a 20-fold increase in CAT activity. However, E2 had no effect on CAT activity from cells transfected with a reporter construct containing only 620 bases (Tf-620/+39-CAT) of the 5'-regulatory region of transferrin. Transfection of MCF-7 cells with a CAT reporter containing bases -1600 to -620 resulted in a 6-fold increase in CAT activity in response to E2. Sequence analysis of the 1000 bases between -1600 and -620 did not reveal any perfect, palindromic estrogen response elements (EREs); however, there is one imperfect palindromic ERE at -795 as well as several half palindromic ERE sites (ERE1/2). Putative binding sites for AP-1, CREB, and Sp1 also are found within this region, and previous studies have shown E2 responsiveness through direct or indirect interactions of estrogen receptor α with proteins bound to similar sequence motifs. Current studies are focused on identifying the sequence elements within the -1600 to -620 region of the transferrin gene promoter responsible for induction of transcription by E2. (CA76636 and ES09106)

1109 TRANSCRIPTIONAL ACTIVATION OF CATHEPSIN D GENE EXPRESSION BY GROWTH FACTORS.

F. Wang, R. Duan and S. Safe. *Texas A&M University, Department of Veterinary Physiology & Pharmacology, College Station, TX.*

Insulin growth factor I (IGF-I), transforming growth factor α (TGFα) and epidermal growth factor (EGF) induced cathepsin D gene expression and reporter gene activity in MCF-7 human breast cancer cells transiently transfected with a construct (pCD1) containing a -2576 to -124 cathepsin D gene promoter insert. In contrast, IGF-I, but not TGFα or EGF, induced reporter gene activity in cells cotransfected with wild-type estrogen receptor (ER) expression plasmid and a construct (pCD2) containing estrogen-responsive downstream elements from -208 to -101. Promoter deletion and mutational analysis experiments identified four GC-rich sites and an imperfect palindromic estrogen responsive element required for IGF-I activation of the ER (ligand-independent). Subsequent studies with the mitogen-activated protein kinase (MAPK) inhibitor, PD98059, and a $serine^{118}$-ER mutant confirmed the role of the MAPK pathway for IGF-I activation of the ER in MCF-7 cells. Thus, growth factor activation of ER can mediate transactivation vs. ER/Sp1 binding to GC-rich sites and represents a novel pathway for ligand-independent ER action. The divergent pathways for IGF-I and TGFα/EGF activation of the ER observed in MCF-7 cells contrast with previous data indicating that pathways for growth factor activation of the ER are dependent on the gene and/or gene promoter and on cell context. (ES09106 and ES09253)

1110 INSULIN-LIKE GROWTH FACTOR-1 INDUCES ADENOSINE DEAMINASE IN MCF-7 HUMAN BREAST CANCER CELLS THROUGH ESTROGEN RECEPTOR-SP1 INTERACTIONS.

W. Xie, R. Duan and S. Safe. *Texas A&M University, Department of Veterinary Physiology & Pharmacology, College Station, TX.*

Adenosine deaminase (ADA) catalyzes the deamination of adenosine and deoxyadenosine, and 17β-estradiol (E2) induces ADA gene expression in MCF-7 human breast cancer cells. Analysis of the ADA gene promoter has shown that only one of six proximal (-211 to +11) GC-rich Sp1 binding sites in the promoter at -79 to -73 is responsible for E2-inducibility via estrogen receptor α (ERα)/Sp1 interactions. In transient transfection studies with pADA211, which contains the -211 to +11 ADA gene promoter linked to a bacterial chloramphenicol acetyltransferase (CAT) reporter gene, E2 and insulin-like growth factor 1 (IGF-1) induced a 3.2- and 2.5-fold increase in CAT activity, whereas transforming growth factor α and epidermal growth factor were not active. The induction response was only observed in cells cotransfected with ERα expression plasmid suggesting a unique ligand-independent ERα/Sp1 activation by IGF-1. The mechanism of this response was further investigated in MCF-7 cells treated with 10 nM IGF-1 cotransfected

with pADA211, ERα expression plasmid, and dominant negative expression plasmids for ras or MAPK. The 2.5-fold induction response by IGF-1 was totally blocked by both dominant negative plasmids; moreover, in cells cotransfected with variant ER expression plasmids mutated in key phosphorylation sites (serine 118 or 167), IGF-1 activation of ERα was not observed. These results demonstrate that IGF-1 activates ERα through the ras-MAPK pathway and ERα/Sp1 induces ADA through interaction with GC-rich sites in the promoter. The failure of other growth factors to activate ERα/Sp1 is being investigated. (ES09253 and ES09106)

1111 LIGAND STRUCTURE-DEPENDENT DIFFERENCES IN ACTIVATION OF ESTROGEN RECEPTOR α IN HUMAN HepG2 LIVER AND U2 OSTEOGENIC CANCER CELL LINES.

K. Yoon[1], L. Pallaroni[1], K. Ramamoorthy[1], K. Gaido[2] and S. Safe[1]. [1]*Texas A&M University, Department of Veterinary Physiology & Pharmacology, College Station, TX and* [2]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Differences in ligand-activation of estrogen receptor α (ERα) were investigated in human HepG2 liver carcinoma and U2 osteogenic sarcoma cells transfected with wild-type ER (ER-wt) and variants expressing only activation function 1 (ER-AF1) or AF2 (ER-AF2). The estrogen-responsive C3-luc construct containing the complement C3 gene promoter linked to a bacterial luciferase reporter gene was used to determine ligand-induced transactivation by wild-type or variant ERα. The qualitative pattern of ER-dependent responses was similar in both cell lines for a series of weakly estrogenic hydroxy and dihydroxyaromatic compounds including *p*-octylphenol, *p*-nonylphenol, 2′,4′,6′-trichloro-4-biphenylol, 2′,3′,4′,5′-tetrachloro-4-biphenylol, bisphenol A and 2,2′-bis(*p*-hydroxyphenyl)-1,1,1-trichloroethane. The weakly estrogenic pesticide, kepone, and the phytoestrogens, resveratrol (a trihydroxystilbene) and naringenin (a flavanone), induced distinctly different patterns of responses; induction by these compounds was not observed in either cell line cotransfected with ER-wt or ER-AF2. In contrast, naringenin activated ER-AF1 in HepG2 cells and resveratrol activated ER-AF1 in U2 cells. In HepG2 cells cotreated with E2 plus the estrogenic compounds, only BPA and resveratrol exhibited ERα antagonist activity. Structure-dependent differences in ERα activation and inhibition are consistent with the increasingly complex tissue-specific patterns of ERα action indicating that the estrogenic activity of an individual compound can only be determined using an extensive testing protocol. (ES09106 and ES04917)

1112 ACTIVITY OF BENZO[A]PYRENE AND ITS HYDROXYLATED METABOLITES IN AN ER-α REPORTER GENE ASSAY.

E. W. Carney[1], G. D. Charles[1], M. J. Bartels[1], T. R. Zacharewski[2], N. L. Freshour[1] and B. B. Gollapudi[1]. [1]*The Dow Chemical Company, Midland, MI and* [2]*Michigan State University, East Lansing, MI.*

This study investigated benzo(a)pyrene (B[a]P), a substrate for CYP1A, 2C and 3A, to characterize the metabolic competence of an ER-α transactivation system and to explore potential interactions of cellular metabolism with ER-mediated responses. In a system utilizing MCF-7 cells transiently transfected with a chimeric estrogen receptor (Gal4-HEG0) and a luciferase reporter (17m5-G-Luc), B[a]P (>1 μM) produced responses comparable to that of 0.1 nM 17-β estradiol (E2). Metabolic profiles of B[a]P-treated MCF-7 cultures showed endogenous formation of the 3- and 9-hydroxy (3-OH and 9-OH) and the 7,8- and 9,10-dihydroxy (7,8-OH and 9,10-OH) B[a]P metabolites. Alpha-Napthoflavone (NF), an Ah receptor antagonist and P450 inhibitor, also decreased the response to B[a]P but not to E2. In the ER-α reporter assay, the 3-OH and 9-OH, but not the 7,8-OH and 9,10-OH metabolites produced maximal responses comparable to E2 with EC50 values of 1.2 and 0.7 μM, respectively. ICI inhibited responses to the 3-OH and the 9-OH species, while NF inhibited the response to the 9-OH, but not the 3-OH metabolite. These results suggest that MCF-7 cells are capable of metabolically activating BaP to an estrogenic substance in an *in vitro* gene expression assay. Funded by The Chemical Manufacturers Association (Arlington, VA).

1113 INCORPORATION OF S-9 ACTIVATION INTO AN ER-α REPORTER GENE ASSAY.

G. D. Charles[1], M. J. Bartels[1], C. Gennings[2], T. R. Zacharewski[3], N. L. Freshour[1], B. B. Gollapudi[1] and E. W. Carney[1]. [1]*The Dow Chemical Company, Midland, MI,* [2]*Virginia Commonwealth University, Richmond, VA and* [3]*Michigan State University, East Lansing, MI.*

The Endocrine Disrupter Screening and Testing Advisory Committee (EDSTAC) recommended that the evaluation of chemicals in the *in vitro* transcriptional activation assays be performed in the presence and absence of metabolic activation in order to enhance the ability to detect compounds with pro-hormonal activity. Therefore, the feasibility of incorporating an exogenous metabolic activating system into an estrogen receptor-α (ER-α) transactivation assay was investigated. 17βide methoxychlor (MXC), were evaluated in the presence and absence of Aroclor-1254 induced rat liver S-9 fractions. In the absence of S9, both E2 and MXC responded consistently, with average EC50 values of 9.6 x 10E-11 M and 1.2 x 10E-5 M, respectively. Following 24h exposures to 0.1% S-9 fractions with NADP and isocitrate cofactors, the EC50 value for E2 increased to 1.4 x 10E-9 M. By comparison, the EC50 value for MXC decreased to 4.9 x 10E-7 M. In the presence of S-9, both E2 and MXC demonstrated increased secondary metabolite formation as evidenced by HPLC analysis. Consistent with these data, E2 metabolites evaluated in the ER-α reporter assay exhibited decreased potencies and the MXC metabolite HPTE, increased potency, relative to parent. These results show that S-9 is not required for detection of the pro-estrogen, MXC, apparently due to low, but sufficient, intrinsic metabolic activity of MCF-7 cells. However, 0.1% S9 was shown to be compatible with the MCF-7 cell reporter gene assay and has the potential to enhance detection of pro-estrogenic materials. (Funded by The Chemical Manufacturers Association, Arlington, VA.)

1114 A COMPARISON OF (ANTI-) ESTROGENICITY AMONG TEN POLYCHLORINATED BIPHENYL (PCB) METHYLSULFONES AND THEIR PRECURSOR PCBs IN TWO HUMAN CELL LINE-BASED ER-CALUX ASSAYS.

R. J. Letcher[1], J. Lemmen[2], A. Brouwer[3], B. van der Burg[2] and M. van den Berg[1]. [1]*Research Institute for Toxicology, Utrecht University, Utrecht, Netherlands,* [2]*Hubrecht Laboratory, Netherlands Institute for Developmental Biology, Utrecht, Netherlands and* [3]*Institute of Environmental Studies, Free University of Amsterdam, Amsterdam, Netherlands.*

Polychlorinated biphenyls (PCBs) with *meta-para* chlorine-unsubstitution are biotransformed to persistent 3- and 4-methylsulfone ($MeSO_2$-) metabolites in humans. The potential for $MeSO_2$-PCBs to modulate estrogen receptor- (ER-) mediated induction of luciferase activity *in vitro* was investigated using two ER-CALUX assays with stably transfected human breast T47D.luc adenocarcinoma cells (T47D-ER) and 293 human embryonal kidney cells (293HEK-ERα). (Anti-) estrogenic activity was determined for ten 3- and 4-$MeSO_2$-PCBs (i.e., of CB-49, -52, -70, -87 and -101), their precursor PCBs, the analog $MeSO_2$-2,5-Cl_2benzene (2,5-Cl_2Bz), 4′-OH-CB30 (2,4,6-Cl_3), and anti-estrogenic tamoxifen and ICI 182,780. In both assays 4′-OH-CB30 (10 μM) was the only estrogenic compound, resulting in a 50- to 60-fold induction. 17β-estradiol (E_2) had a similar efficacy, but with much greater potency (EC_{50}, 10 pM). In the T47D-ER, PCBs and 2,5-Cl_2Bz were not (anti-) estrogenic up to 10 μM. The $MeSO_2$-PCBs were not estrogenic up to 10 μM. The 3-$MeSO_2$-PCBs did not antagonize of E_2-induced activity (EC_{50}, 10 pM) up to 10 μM;, except for 3-$MeSO_2$-CB70 and -CB-101. $MeSO_2$-PCBs having a 4-$MeSO_2$-group, mono-*ortho*-chlorination and 3,4-dichloro-substitution on the non-$MeSO_2$-containing phenyl ring were the most potent antagonists. Inhibition was as great as 80% at concentrations as low as 1.0 μM;. Inhibition by tamoxifen (EC_{50}, 0.1 μM) and ICI 182,780 (EC_{50}, < 0.01 μM) was essentially 100%. Similar compound- and concentration -dependent trends for (anti-) estrogenicity were observed in the 293HEK-ERα assay. Anti-estrogenicity was not due to cytotoxic or cell proliferation effects. The present results suggest that depending on the structure, persistent $MeSO_2$-PCBs are anti-estrogenic *in vitro* via interaction of the ER.

1115 ESTABLISHMENT OF *XENOPUS LAEVIS* AS A MODEL FOR INVESTIGATING *IN VITRO* AND *IN VIVO* ENDOCRINE DISRUPTION IN AMPHIBIANS.

Y. W. Huang, J. B. Mattews and T. R. Zacharewski. *Department of Biochemistry and the National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI.*

In this study, *in vitro* estrogen receptor (ER) competitive binding and gene expression assays, and the induction of vitellogenin mRNA *in vivo* were used to assess *Xenopus laevis* as an amphibian model for examining potential endocrine disruptors. Competitive binding to *Xenopus* ER was investigated using a bacterially expressed fusion protein consisting of glutathione-S-transferase (GST) linked to the ER ligand binding domain (LBD) of *Xenopus* (GST-xER). Equilibrium analysis revealed saturation was reached at a concentration of 10 nM [^{3}H]17β-estradiol (E2) with a dissociation constant (K_d) of 6.4±1.3 nM. In a competitive binding assay, the IC_{50} value for E2 was 12.2±0.34 nM. The ability of E2 to induce *Xenopus* ER-regulated gene expression was assessed in MCF-7 human breast cancer cells transiently transfected with a chimeric receptor consisting of the Gal4 DNA binding domain linked to the *Xenopus* ER LBD (Gal4-xER) and a Gal4-regulated luciferase reporter gene, 17m5-G-Luc. Treatment of E2 resulted in approximately 30-50 fold maximal induction of reporter gene activity with an EC_{50} of 0.67±0.31 nM. Adult male *Xenopus* were intraperitoneally treated for 3 consecutive days with E2 at 0, 0.05, 0.1, 0.5, 1, and 5 mg/kg for a period of 12 days. The level of vitellogenin induction was determined using semiquantitative RT-PCR. E2 treatment showed a dose response increase in vitellogenin mRNA with the maximal induction at an accumulative dose of 3 mg/kg E2 ($p < 0.001$, $n = 35$). In summary, we have developed three complementary methods to detect estrogenic effects of E2 using *Xenopus* as a model. These methods can be used to assess the estrogenicity of a substance in *Xenopus* as a model amphibian species.

1116 *IN VITRO* ESTROGENIC POTENCY OF POLYBROMINATED DIPHENYL ETHERS.

S. Hoving[1], I. A. T. Meerts[1], R. Letcher[2], A. Bergman[3], B. van der Burg[4] and A. Brouwer[5]. [1]*Wageningen University, Wageningen, Netherlands,* [2]*Research Institute of Toxicology (RITOX), Utrecht, Netherlands,* [3]*Stockholm University, Stockholm, Sweden,* [4]*Netherlands Institute for Developmental Biology, Utrecht, Netherlands and* [5]*Institute of Environmental Studies, Free University of Amsterdam, Amsterdam, Netherlands.*

Polybrominated diphenyl ethers (PBDEs) are used in large quantities as additive flame retardants in e.g. plastics and textile materials. PBDEs have been detected in biota, human adipose tissue and plasma samples. The present study investigated the possible (anti-)estrogenic potency of PBDEs in an estrogen receptor mediated, chemical activated luciferase reporter gene assay (ER-CALUX). Human T47D breast cancer cells, stably transfected with an estrogen responsive luciferase reporter gene construct (T47D.luc), were exposed to 17 different PBDEs and 3 hydroxylated PBDEs (concentrations varied from 0.01 to 50 μM) in present or absence of 10 pM estradiol (E2). In total 8 PBDEs showed estrogenic potencies, with EC50 values varying from 2.5 to 7.3 μM. The EC50 value of the most potent hydroxylated PBDE (2-bromo-4-(2,4,6-tribromophenoxy)phenol) was 0.5 μM, with a maximum fold induction of luciferase activity exceeding that of E2, though at concentrations 50,000 times higher. In an ER-α transfected human embryonic kidney cell line (293 HEK.luc), 4-(2,4,6-tribromophenoxy)phenol was a highly potent estrogen (EC50 < 0.1 μM and a maximum 35- to 40-fold induction similar to E2) relative to the estrogenic 2,4,6-tribromodiphenyl ether and 2,2',4,4',6-pentadiphenyl ether (EC50 < 5.0 μM, maximum < 15 fold induction). These results indicate that several pure PBDE congeners, but especially hydroxylated PBDEs are inducers of the estrogen receptor signal transduction pathway *in vitro*. (This study was supported by the commission of the European Communities [grant ENV-CT96-0170].)

1117 DIFFERENCES IN (ANTI) ESTROGENICITY BETWEEN TECHNICAL TOXAPHENE AND FOUR OF ITS ENVIRONMENTALLY IMPORTANT CONGENERS IN THE ER-CALUX ASSAY.

H. Drenth[1], R. Letcher[1], J. Legler[2], M. Oehme[3], A. Brouwer[4] and M. VandenBerg[1]. [1]*Ritox, Utrecht University, Utrecht, Netherlands,* [2]*Dept. Toxicology, Wageningen University and Research Centre/Netherlands Institute for Developmental Biology, Utrecht, Netherlands,* [3]*Organic Analytical Chemistry, University of Basel, Basel, Switzerland and* [4]*Institute for Environmental Studies, Amsterdam, Netherlands.*

Among the endocrine disrupting contaminants, the organochlorine pesticide toxaphene has been identified as a chemical class possessing estrogenic activity. Toxaphene is a mixture consisting of at least 670 constituents which has mainly been used on a large scale in the US. Due to aerial and aquatic transport, toxaphene is an ubiquitous contaminant, thus relatively high concentrations are found in the environment and human foodstuffs. Because of selective degradation and transport, the congener pattern of the technical mixture is changed markedly in environmental matrices and biota. Three congeners CHB26, CHB50, and CHB62, according to the Parlar nomenclature, are detected in almost every sample. Together with CHB32, which is readily degraded, these comprise the four toxaphene indicator compounds. Until now, only the technical mixture has been used to assess estrogenic effects. However, in the present study we also used the four pure congeners in the ER-CALUX assay. In this *in vitro* assay, luciferase activity can be induced in stably transfected human breast cancer cells via the estrogen receptor pathway. Estradiol (positive control) and technical toxaphene induced luciferase activity maximally 49- and 22-fold, respectively. The calculated EC50 values are 4.81 pM for estradiol, and 18.7 μM for technical toxaphene. None of the four pure congeners showed any effect on luciferase activity in the same concentration range as the technical mixture. Based on these observations, it can be concluded that most probably other constituents are responsible for the observed effects of technical toxaphene. The present results show that the estrogenic risk of toxaphene exposure in humans is possibly overestimated if the technical mixture is solely used in *in vitro* assays.

1118 *IN VITRO* STUDIES OF POTENTIAL DEVELOPMENTAL TOXICITY OF SOME AGROCHEMICALS COMMONLY USED IN RED RIVER VALLEY, MN.

N. Lin[1] and V. F. Garry[2]. [1]*Toxicology Graduate Program, University of Minnesota, Minneapolis, MN and* [2]*Environmental Medicine and Pathology, University of Minnesota, Minneapolis, MN.*

Epidemiologic studies by our group show increased frequency of birth defects in the pesticide applicators and general population of the Red River Valley, Minnesota. Based on frequency of use and known biology, certain herbicides, pesticide additives, fungicides, and mycotoxins are suspect agents. To define whether these agents affect certain developmental endpoints *in vitro*, we examined twelve selected agrochemicals using MCF-7 breast cancer cell line. In the flow cytometric assay we used, cell proliferation in this estrogen-responsive cell line indicates xenobiotic-mediated estrogenic effects. Cell viability, morphology, ploidy and apoptosis were incorporated in this assay. The data showed that adjuvants X-77 and Activate Plus induced significant cell proliferation at 0.1 and 1 μg/ml. Commercial grade herbicides 2,4-D LV4 and 2,4-D Amine induced cell proliferation at 1 and 10μg/ml. The reagent grade 2,4-D products failed to induce proliferation over the same concentration range, suggesting that other ingredients in the commercial products, presumably adjuvants, could be a factor in these results. Fungicide triphenyltin and mancozeb provoked apoptosis that peaks at 4.1μg/ml (10^{-5}M) and 50μg/ml, respectively. Triphenyltin also induced aneuploidy at 0.41μg/ml (10^{-6}M). These data suggest potential developmental toxicity of several test agrochemicals, and are a first step in assessments of human effects and *in vivo* studies.

1119 ACETAMINOPHEN ALTERS ESTROGEN RECEPTOR-REGULATED PROCESSES IN DIFFERENT CELLS IN A LIGAND-BINDING-INDEPENDENT MANNER.

J. Dowdy, S. Gadd, S. Rhodes and M. R. Miller. *West Virginia University, Morgantown, WV.*

Previous studies demonstrated that acetaminophen stimulates proliferation of estrogen receptor (ER) positive breast cancer cells, and this acetaminophen-induced proliferation is inhibited by anti-estrogens. These studies indicate acetaminophen alters breast cancer cell proliferation by an ER-mediated pathway. The next goal was to determine if acetaminophen binds ERα or ERβ and

to determine the extent to which acetaminophen alters expression of specific ER-regulated genes in different cells. The ability of acetaminophen to compete with binding of 3H-estradiol to purified ERα or ERβ was determined. Acetaminophen (106-fold molar excess) did not compete with 3H-estradiol binding ERα or ERβ, indicating this drug does not bind ER in the same manner as E2. The effect of acetaminophen on expression of specific genes was determined in ER + breast cancer cells (MCF-7) and endometrial carcinoma cells (Ishikawa). In MCF-7 cells, c-myc is induced by estradiol. Ribonuclease protection assays were used to examine c-myc gene expression in MCF-7 cells; c-myc expression was normalized to expression of 18S rRNA. Estradiol induced an ~3-fold increase in c-myc expression 1 hr after addition to cells, and acetaminophen induced c-myc RNA ~2-fold 2 hr after addition to cells. In Ishikawa cells, estradiol induces alkaline phosphatase activity, which is measured spectrophotometrically. Acetaminophen did not induce alkaline phosphatase activity; rather, acetaminophen inhibited estradiol-induced alkaline phosphatase activity in a dose dependent manner. The acetaminophen-mediated reduction of estradiol-induced alkaline phosphatase activity was not due to direct inhibition of this enzyme activity or to general toxicity. These findings demonstrate that acetaminophen can exhibit estrogenic or anti-estrogenic activity on different ER-regulated processes in different cells in a manner that appears to be independent of ligand binding to ER.

1120 INVESTIGATING THE MECHANISM OF METHOXYCHLOR TOXICITY THROUGH ESTROGEN RECEPTORS ALPHA AND BETA USING CDNA ARRAY TECHNOLOGY.

K. M. Waters[1], S. Safe[2], K. S. Korach[3] and K. W. Gaido[4]. [1]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC,* [2]*Texas A & M University, College Station, Texas, College Station, TX,* [3]*NIEHS, Research Traingle Park, NC and* [4]*CIIT, Research Triangle Park, NC.*

The reproductive effects of the pesticide methoxychlor during utero exposure is similar to, but not identical to that observed for the sex steriod estrogen. The dissimilarities may be due to distinct patterns of estrogen receptor α (ERα and estrogen receptor β (ERβ expression in selected targer tissues. We have shown previously that the *in vivo* metabolite of methoxychlor, 2,2-bis (p-hydroxyphenyl)-1,1,1-trichloroethane (HPTE), has selective agonist activity through ERα and antagonist activity through ERβ and androgen receptor. To investigate the mechanism of methoxychlor-induced toxicity, we subcutaneously dosed C57BL/6 male and female weanling mice daily with either vehicle (corn oil), 17β-estradiol (E2) (50μg/kg), HPTE (500mg/kg), E2+HPTE, or flutamide (45mg/kg) for three days. On day 4, several target organs were harvested. We observed an increase in uterine wet weight of 3.8-fold with E2, 2.6-fold with HPTE, and 8.9-fold with E2+HPTE. Flutamide treatment had no effect on uterine wet weight, and neither E2, HPTE, nor flutamide significantly altered ovarian or testicular wet weights. RNA from prostates, testes, uteri and ovaries was isolated and used to probe Clontech Atlas Mouse cDNA expression arrays. HPTE altered the expression of several of the same genes as E2, such as glutathione peroxidase, insulin-like growth factor binding protein-6, and cathespin D, while other genes were differentially regulated, such as interleukin-11, insulin-like growth factor binding protein-4, and integrin beta. Quantitation of gene changes will be required using standard molecular techniques. These data will provide a better understanding of the roles of ERα and ERβ in both normal endocrine function and its alteration by environmental chemicals. (ES09106 & ES04917)

1121 EFFECTS OF OCTYLPHENOL ON TESTOSTERONE BIOSYNTHESIS BY CULTURED PRECURSOR CELLS (PC) AND IMMATURE LEYDIG CELLS (ILC) FROM RAT TESTES.

E. P. Murono, R. C. Derk and J. H. deLeon. *NIOSH, HELD, Morgantown, WV.* Sponsor: V. Castranova.

4-Tert-octylphenol (octylphenol, OP) is a degradation product of alkylphenol ethoxylates, widely used as a surfactant additive in the manufacture of detergents, plastics and pesticides. OP has been reported to mimic estrogen in many cellular systems and, thus, to potentially alter normal sexual growth/maturation. In the present studies, the direct effects of OP on 10 mIU/ml human chorionic gonadotropin (hCG)- stimulated testosterone (T) biosynthesis by cultured PC and ILC were examined. PC are mesenchymal cells that differentiate into ILC, mainly through the actions of luteinizing hormone, between ~ 14 to 28 d after birth, and ILC are converted to adult Leydig cells during the next 4 to 5 weeks of maturation. PC and ILC were isolated by elutriation and Percoll gradient centrifugation of collagenase-dispersed testes from 23-day-old Sprague-Dawley rats. Increasing concentrations of OP (1-2000 nM) progressively decreased hCG-stimulated T starting at 100 or 500 nM, to maximal declines of 30 to 70% below control at the highest concentration in both PC and ILC following exposure for 24 h. OP, similarly, decreased 1 mM 8-Br-cAMP-stimulated T in both PC and ILC, suggesting that the main site(s) of action occur after cAMP formation. To further localize the site(s) of action of OP, the conversion of 1 μM 22 (R) hydroxycholesterol, pregnenolone, progesterone or androstenedione to T after exposure to increasing OP concentrations and hCG was evaluated. Progressive declines in 22 (R) hydroxycholesterol, pregnenolone and progesterone conversion to T were observed, but not androstenedione, suggesting that P450c17 activity, which converts progesterone to androstenedione, is inhibited by OP but not 17β-hydroxysteroid dehydrogenase activity, which converts androstenedione to T. OP also may inhibit cholesterol side-chain cleavage and 3β-hydroxysteroid dehydrogenase-isomerase activities, but additional studies are necessary to confirm this possibility. Interestingly, 17β-estradiol (1-1000 nM) had no effect on hCG-stimulated T formation in both PC and ILC, and concomitant exposure to 100 nM ICI 182,780, a pure estrogen antagonist, did not alter the inhibitive effects of OP. These results suggest that OP effects on both PC and ILC do not mimic the actions of estrogen and are not mediated through the classic estrogen receptor -α or -β pathway.

1122 MONO-(2-ETHYLHEXYL) PHTHALATE SUPPRESSES ESTRADIOL BY DECREASING AROMATASE MRNA EXPRESSION LEVEL AS SHOWN BY REAL TIME RT-PCR.

T. N. Lovekamp[1] and B. J. Davis[2]. [1]*North Carolina State University, Raleigh, NC and* [2]*NIEHS, Research Triangle Park, NC.*

Di-(2-ethylhexyl) phthalate (DEHP) is a commercially important plasticizer that is ubiquitous in the environment. DEHP and its active metabolite mono-(2-ethylhexyl) phthalate (MEHP) are reproductive and endocrine toxicants in animal models. MEHP has a direct effect on the granulosa cells of the rat ovary to suppress estradiol production by affecting aromatase, the rate limiting enzyme for the conversion of testosterone to estradiol. To better understand the mechanism of action of MEHP, we tested the hypothesis that MEHP decreases transcription of the aromatase gene. Granulosa cells were obtained from 28 day old Fisher 344 rats that had been treated with PMSG either 24 or 48 hours earlier to induce follicle development. Cells were cultured for 48 hours with FSH (2.5 ng/mL) and testosterone (500nM) and 0mM, 0.001mM, or 100mM MEHP (in DMSO). As previously found, 100mM MEHP significantly decreased mean estradiol levels in media compared to control and low dose with $p<0.0001$. Moreover, MEHP had a greater effect on estradiol production from cells obtained 24 hours after PMSG treatment compared to cells obtained 48 hours after PMSG treatment. This is consistent with the understanding that MEHP affects the differentiating granulosa cell. RNA was analyzed using the TaqMan real-time PCR assay to measure aromatase message. In 4 separate experiments, samples treated with 100mM MEHP had half ($p<0.005$) as much aromatase message compared to control samples when normalized to GAPDH. The 0.001mM treatment group was not statistically different from controls. This was the case for both the 24 hour and 48 hour post-PMSG treatment. These results indicate that the suppression of estradiol by MEHP may occur at a transcriptional level. Future experiments will examine the effects of MEHP on the aromatase protein. We anticipate that these studies will uncover the molecular mechanisms by which MEHP inhibits granulosa cell differentiation and ovulation.

1123 OXIDATIVE STRESS BY SODIUM ARSENITE INHIBITS ADRENAL CHOLESTEROL METABOLISM WHILE SHOWING BOTH STIMULATION AND SUPPRESSION STEROIDOGENIC ACUTE REGULATORY OF PROTEIN.

D. Zhao, I. Artemenko and C. R. Jefcoate. *University of Wisconsin-Madison, Madison, WI.*

The steroidogenic acute regulatory protein (StAR) is a key participant in the hormonally activated transfer of cholesterol to cytochrome P450scc. Here we show that two activators of stress activated protein kinase pathways (SAPK), arsenite and anisomycin, each potentiate the maximum stimulation of StAR mRNA (3.5 kb) by Br-cAMP at low concentrations (respectively, 20 μM, 2.5 fold and 0.2 μM, 5 fold). Hydrogen peroxide (100 μM), a strong activator of NFκB, was ineffective in this stimulation. At higher concentrations (>40 μM) of each activator StAR mRNA and protein expression was reduced sharply, reaching almost complete suppression by arsenite. None of these agents changed basal StAR expression indicating potentiation and suppression of the protein kinase A stimulation as opposed to a direct effect on transcription. Time courses for StAR stimulation by Br-cAMP indicated that at low concentrations of arsenite rates of transcription were elevated after a 1 hr lag. At higher concentrations an early increase was followed after 2 hr by a rapid decrease indicating onset of increased degradation of StAR mRNA. Hydrogen

peroxide was only weakly inhibitory even at high concentrations (500 μM). StAR protein levels were elevated at low levels of anisomycin and arsenite and decreased at higher levels in parallel with the changes in mRNA. Arsenite substantially changed the distribution of StAR forms. Notably there was an elevation of the p37 metabolism in both Y-1 and MA10 cells was inhibited by arsenite at high concentrations. Cholesterol metabolism in both Y-1 and MA10 cells was inhibited by arsenite at high concentrations. There was no significant stimulation of pregnenolone production at low concentrations of arsenite where StAR mRNA and protein expression were potentiated. Stimulation of StAR expression by arsenite and anisomycin corresponded to enhanced activation of p38 kinase. Inhibition by arsenite corresponded in dose and time to a threshold for activation of JNK. Anisomycin at higher levels directly inhibit protein translation. Arsenite potentiated 20α-hydroxycholesterol metabolism by P450scc indicating that mitochondrial function and cytochrome turnover are not compromised. In vivo studies indicates that ACTH-stimulated blood corticosterone (60 min/ACTH) were lowered by two-fold after intragastric administration of sodium arsenite (20 mg/kg body weight, 24 hr prior to stimulation with ACTH). This inhibition is remarkably similar to what we have seen in cultured adrenal cells. These studies show that StAR expression is highly sensitive to activation of these SAPK by both arsenite and anisomycin through effect at multiple levels of regulation.

1124 EFFECTS OF CHLORO-S-TRIAZINE HERBICIDES AND METABOLITES ON AROMATASE (CYP19) ACTIVITY IN VARIOUS HUMAN CELL LINES AND ON VITELLOGENIN PRODUCTION IN MALE CARP HEPATOCYTES.

J. T. Sanderson, R. J. Letcher, M. Heneweer and M. van den Berg. *RITOX, Utrecht, Netherlands.*

A potential mechanism for the estrogenic properties of the chloro-*s*-triazine herbicides was investigated *in vitro* in several cell systems. Effects on aromatase, the enzyme that converts androgens to estrogens, were determined in H295R (adrenocortical carcinoma), JEG-3 (placental choriocarcinoma) and MCF-7 (breast cancer) cells; effects on the estrogen receptor-mediated induction of vitellogenin were determined in freshly isolated hepatocytes of a genetically uniform strain of adult male carp (*Cyprinus carpio*). Aromatase activity was measured by the conversion of [1β-^{3}H]-androstenedione to estrone and ^3H_2O; both the release of ^3H_2O and the formation of estrone were quantified as measures of catalytic activity. Atrazine, simazine, propazine and two of the six tested common metabolites of these herbicides induced aromatase activity in H295R cells concentration- (0-30 μM) and time- (0-72 h) dependently. At a 30 μM concentration an apparent maximum induction of about 2 to 2.5 fold was achieved after exposure to the triazines for 24 h. The induction responses were confirmed by similar increases in CYP19 mRNA levels, determined by reverse-transcriptase polymerase chain reaction. In JEG-3 cells the induction responses were less pronounced, while aromatase expression in MCF-7 cells was not detectable under our culture conditions. None of the triazine herbicides or their metabolites (0-30 μM) were capable of inducing vitellogenin production in carp hepatocytes. They were also not capable of antagonizing the induction of vitellogenin by 20 nM (EC_{50}) 17β-estradiol. These findings together with those of other investigators indicate that the estrogenic effects associated with the triazine herbicides *in vivo*, are not estrogen receptor-mediated, but may be partly explained by their ability to induce aromatase.

1125 DIETHYLSTILBESTEROL REGULATES COX-2 EXPRESSION IN VAGINAL EPITHELIAL CELLS.

D. Davison, P. Patal and D. E. Heck. *Rutgers University, Piscataway, NJ.*

Exposure of the human fetus to the synthetic estrogen diethylstilbesterol (DES) is associated with a high incidence of vaginal adenosis later in life. This condition, characterized by the appearance of glandular tissue within the vagina, has been attributed to altered differentiation of vaginal epithelial cells (VEC). However, the molecular events leading to this condition are poorly understood. To explore this process we exposed primary cultures of human vaginal ectodermal epithelial cells to DES. These cells proliferate in medium containing low levels of calcium (<0.05 mM). The addition of calcium (1.2 mM) to the cells causes the cells to flatten, elongate and take on characteristics of differentiating vaginal epithelial cells. In low calcium conditions these cells constitutively express cyclooxygenase 2 (Cox-2), an immediate early mediator of inflammation expressed in secretory tissues including gastrointestinal mucosa and kidney. Calcium-mediated differentiation downregulates Cox-2 expression in VEC. We found that treatment of undifferentiated, but not differentiated VEC, with DES (1 nM) dramatically upregulates Cox-2 expression. These findings suggest that regulation of Cox-2 is differentiation-dependent. We hypothesize that regulation of Cox-2 expression in undifferentiated VEC may reflect events important in DES-mediated pathology.

1126 8-BROMO CYCLIC-AMP AND DEXAMETHASONE (DEX) FAIL TO REVERSE THE DECREASE IN CATECHOLAMINES (CA) INDUCED BY ATRAZINE (ATZ) AND SIMAZINE (SIM) IN PC12 CELLS.

P. C. Das[1], W. K. McElroy[2] and R. L. Cooper[2]. [1]*Curriculum In Toxicology, UNC-CH, Chapel Hill, NC and* [2]*Repro. Tox. Division, NHEERL, EPA, Research Triangle Park, NC.* Sponsor: R. J. Kavlock.

Previously we reported that the chlorotriazines (CTZs), in particular ATZ, disrupt ovarian function, suppress luteinizing hormone release and decrease hypothalamic norepinephrine concentration in the rat. Using PC12 cells, we also showed that the CTZs reduce catecholamines concentration and release *in vitro*. The present study was designed to verify i) the altered intracellular concentration and pattern of release of CA by ATZ and SIM in PC12 cells and ii) whether cAMP and DEX, which are known to regulate the enzymes invovled in CA synthesis, can reverse the effects of ATZ and SIM. PC12 cells were incubated with ATZ or SIM alone or in combination with 8-bromo cAMP (1 mM) or DEX (1 μM) for up to 36 h. Both ATZ and SIM (12.5, 25, 50, 100, and 200 μM) significantly inhibited intracellular dopamine in a dose-dependent manner. ATZ (100, 200 μM) and SIM (200 μM) significantly inhibited intracellular norepinephrine and caused a dose-dependent decrease in norepinephrine release at 6-24 h. Cell viability was not altered by any treatment. Both 8b-cAMP and Dex stimulated intracellular dopamine and norepinephrine concentrations and norepinephrine release over time, however these activators failed to reverse the decreases in catecholamines induced by the CTZs. These data suggest that both ATZ and SIM suppress catecholamines synthesis in PC12 cells but not through the same regulatory pathways effected by 8b-cAMP or Dex. (This abstract does not reflect U.S. EPA policy.)

1127 GENE INDUCTION BY PHENOBARBITAL AND CELL SIGNALING IN THE HEPATOCYTE.

C. Omiecinski. *University of Washington, Seattle, WA.*

The induction of biotransformation processes has substantial impact on an individual's response to pharmaceutical and toxicant exposures. Phenobarbital (PB) is a prototypical inducing agent for a variety of drugs and other xenobiotic compounds that exhibit pleiotropic effects in the liver of mammalian organisms. Biotransformation genes that are markedly up regulated by this "class" of compounds include certain glutathione transferases, UDP-glucuronosyl transferases, aldehyde dehydrogenases, and cytochrome P450 monooxygenases. The molecular mechanisms and signaling pathways responsible for the transcriptional activation effects of PB inducers remain poorly defined. To further investigate the induction paradigm, one research thrust of our laboratory has focused on the development of transgenic mouse and primary hepatocyte *in vitro* models enabling investigation of the biology of PB induction together with that of liver-specific gene expression. Initially, results form our transgenic models largely pointed the way to the subsequent discovery of a PB responsive unit or module (PBREM) localized ~2200 bp upstream of the transcriptional initiation site for the rat CYP2B2 and mouse Cyp2b10 genes. This module is centered on a nuclear factor 1 site and is flanked by sequence motifs for putative nuclear receptor interactions. Further transgenic mouse studies by our laboratory indicated that NR1 is not the key regulator of PB responsiveness within the PBREM; rather, a CAR nuclear receptor protein was identified recently by Dr. Negishi's group as a critical modulator of PB transcription. Since this transcriptional response is largely lost in transformed cell lines, we have developed a defined primary hepatocyte culture model and investigated liver specific signaling cascades required for maintaining the highly differentiated cell phenotype. Using this model, we demonstrated that de novo protein synthesis is not required for PB induction. Arrays of pharmacological agents have been evaluated for their effects on hepatocyte signaling networks and potential modulation of the PB induction process. PKC, MAPK, CAMKII and P13K pathways have been largely ruled out as PB signaling mediators. In contrast, important roles were established for protein kinase A (PKA) and protein phosphatase pathways (PP2A) as regulators of the induction response, although recent experiments have established that PB exposures per se do not increase cAMP levels or PKA activity in hepatocytes. Further experiments with the developed transgenic and *in vitro* models are poised to delineate the cell signaling networks and associated extracellular matrix interactions that define the hepatic phenotype, regulate genetic induction, and modulate the toxicological responses characteristic of this organ.

1128 ROLE OF CO-REPRESSORS AND CO-ACTIVATORS IN REGULATION OF SOLUBLE RECEPTOR MEDIATED TRANSCRIPTION.

G. H. Perdew. *Penn State University, University Park, PA.*

One of the primary areas of interest to toxicologists is to understand the mechanisms underlying tissue-, cell-, and species-specific expression of genes involved in a given toxic response. Recently it has become increasingly apparent that a major contributing factor to transcriptional activation and repression of target genes is the recruitment of co-activators and co-repressors. In addition, there are several examples of tissue-specific expression of co-activators (e.g. ARA70) that may contribute to a unique pattern of gene expression. Transcriptional regulation by co-activators/co-repressors has been predominantly studied in the context of steroid receptors, such as Estrogen and PPARg γ receptors. Many of the coactivators such as p300 and SRC-1, which have been extensively characterized, bind to a growing list of enhancer binding transcription factors, this may indicate that these factors compete for a limiting pool of available coactivators. It has also been shown that even small differences in expression of transcription factors and coactivators can lead to threshold effects during growth and development. In addition to affecting steroid hormone receptors, recent studies revealed that co-activators play a role in regulating transcriptional activation by the Ah receptor/ARNT heterodimer. Studies presented in this symposium will examine the ability of co-activators/co-repressors to alter expression of enzymes by the Ah receptor and several steroid receptors in a tissue- and ligand-specific manner.

1129 HORMONES, TRANSCRIPTIONAL REPRESSION, AND THE ROLE OF CO-FACTORS IN THE FUNCTION OF NUCLEAR HORMONE RECEPTORS.

Z. Yang, S. H. Hong and M. Privalsky. *University of California, Davis, CA.*
Sponsor: G. H. Perdew.

The nuclear hormone receptors, such as the estrogen, androgen, retinoid, vitamin D3, and thyroid hormone receptors, play many crucial roles in vertebrate physiology and development. Nuclear hormone receptors have also been implicated as targets of endocrine disrupters, such as environmental estrogens, and it is clear that aberrant receptor activity can play a causal role in a variety of human endocrine and neoplastic diseases. Nuclear hormone receptors function by regulating the expression of specific target genes in response to binding of cognate hormone. These transcriptional properties are mediated through the ability of these nuclear hormone receptors to physically associate with coactivator and corepressor proteins. In this presentation, we will describe our studies elucidating how different hormone-derivatives, natural and artificial, regulate the interaction of thyroid hormone and retinoid receptors with the SMRT/N-CoR corepressors, and with the SRC-1 coactivators. We will also describe our recent results demonstrating how other signal transduction systems operating within target cells, such as the MAP kinase cascade, can modulate the actions of these nuclear hormone receptors and thereby modify the actions of the hormone ligand itself. We also will report our newest studies that detail how aberrant cofactor/receptor interactions can contribute to several human endocrine and neoplastic disorders.

1130 A PHARMACOLOGICAL DISSECTION OF RXR SIGNALING PATHWAYS WITH REXINOIDS.

R. A. Heyman[1], M. F. Boehm[2], D. Crombie[2] and I. Schulman[2]. [1]*X-Ceptor Therapeutics, San Diego, CA and* [2]*Ligand Pharmaceuticals, San Diego, CA.*
Sponsor: G. H. Perdew.

Receptor X receptor (RXR) plays a central role in the regulation of many intracellular receptor signaling pathways. To examine signaling pathways mediated by RXR and its partners we have designed and characterized a series of synthetic ligands that bind RXR and modulate its transcriptional properties. These RXR ligands, referred to as rexinoids, are dimer selective in that they can function as agonists and/or antagonists depending upon the context of the homodimer or heterodimer partner. These rexinoids have been used as pharmacological tools in a multitude of molecular cellular and animal models. In animal models of non-insulin dependent diabetes mellitus (NIDDM) and obesity, RXR agonists function as insulin sensitizers significantly decreasing hyperglycemia and hyperinsulinemia. At the molecular level, these activities are mediated by the RXR: PPARγ heterodimer. Binding of agonists to these nuclear receptors results in a conformational change in receptor structure that promotes interaction between activated receptors and co-activators. Analysis of RXR: PPARγ heterodimers and cofactors suggests that RXR and PPARγ can distinguish among co-activators by recognizing distinct structural features of nuclear receptors. RXR ligands selectively recruits SRC-1 to the dimer whereas, CBP selectively recruits CBP. These differences may account for the gene and tissue selectivity of these pharmacological agents. Thus, the ability of RXR to dimerize with distinct receptors allows rexinoids to alter transcriptional signaling of distinct endocrine signaling pathways and offers new opportunities for the effective treatment of certain pathophysiological states.

1131 ROLE OF TRANSCRIPTIONAL CO-ACTIVATOR PROTEINS IN FUNCTIONING OF THE Aryl HYDROCARBON RECEPTOR/ARYL HYDROCARBON RECEPTOR NUCLEAR TRANSLOCATOR (AHR/ARNT) DIMER.

T. V. Beischlag, K. Muhammad, W. E. Nelson and O. Hankinson. *University of California, Los Angeles, CA.*

AHR binds a variety of pollutants, including 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and benzo(a)pyrene, and mediates the carcinogenic and toxic effects of these compounds. After binding ligand, AHR dimerizes with the ARNT protein. The AHR/ARNT dimer activates transcription of CYP1A1 and certain other genes. Induction of CYP1A1 is involved in carcinogenesis by benzo(a)pyrene. In contrast, the mechanisms of TCDD carcinogenesis and toxicity is obscure. However, they probably depend (at least in part) upon transcriptional activation of certain other (perhaps unidentified) genes. We are studying the role that know coactivator proteins play in transcriptional activation by the AHR/ARNT dimer. We are particularly interested in the three members of the Steroid Receptor Cactivator (SRC) family, SRC-1 (also called NCoA-1), SRC-2 (NCoA-2, TIF-2, GRIP-1), and SRC-3 (p/CIP, ACTR, AIB1, TRAM1) because they contain bHLH-PAS (basic helix-loop-helix-per/arnt/sim homology region) domains towards their amino termini. Each of the SRC proteins stimulates TCDD-dependent induction of a luciferase reporter gene by the AHR/ARNT dimer. SRC-1 and SRC-2 bind ARNT *in vitro* and in mammalian cells *in vivo*. Thus the SRC proteins appear to act as transcriptional coactivators for the AHR/ARNT dimer. Thyroid receptor/retinoblastoma protein interacting protein (Trip230), another coactivator protein, was also found to stimulate transcriptional activation by the AHR/ARNT dimer and associate with ARNT in mammalian cells *in vivo*. Trip230 therefore may be another coactivator for AHR/ARNT. Finally, we have isolated several novel ARNT interacting proteins, some of which may represent transcriptional coactivators. Future studies will probe the mechanism of activation of the various coactivator proteins.

1132 NUCLEAR RECEPTOR CO-ACTIVATORS RIP140 AND SRC-1 INTERACT WITH GLUTAMINE-RICH DOMAIN OF THE Aryl HYDROCARBON RECEPTOR AND MODULATE ITS TRANSCRIPTIONAL ACTIVITY.

M. B. Kumar and G. H. Perdew. *The Pennsylvania State University, State College, PA.*

The Aryl hydrocarbon Receptor (AhR), a soluble cytosolic protein mediates many of the toxic effects of TCDD and related chemicals. The toxic effects are both cell-, tissue-, and species dependent. Although the mechanism of action of ligand-mediated AhR has been elucidated, the sequence of events following the binding of AhR/Arnt to DRE has yet to be understood. The possible role of Nuclear Receptor (NR) coactivators RIP140 and SRC-1 in the modulation of transcriptional activity of AhR/Arnt was examined. RIP140 and SRC-1 enhanced TCDD-mediated, dioxin response element-driven reporter gene activity in three cell lines. Co-immunoprecipitation and co-localization assays revealed that RIP140 and SRC-1 interacted with AhR has a complex transactivation domain composed of an acidic, Q-rich, and P/S/T subdomains. Mapping of the interaction sites revealed that RIP140 and SRC-1 were recruited by the AhR was mapped to a location between amino acid residues 154-350, which is distinct from those involved in Estrogen Receptor binding. The signature motif, LXXLL, which is responsible for binding of several coactivators to NR, is not required for RIP140 binding to the AhR. These results suggest that the AhR may be capable competing with steroid receptors for a common coactivator pool.

1133 INTRODUCTION.

S. B. Pruett[1] and T. R. Jerrells[2]. [1]*LSU Medical Center, Shreevport, LA and* [2]*Omaha VA Medical Center, Omaha, NE.*

Excessive ethanol (EtOH) consumption is a pervasive problem, and it is associated with an increased risk of infectious disease and cancer. Recent studies in animal models and human subjects have revealed a number of mechanisms by which EtOH decreases immune function. A mouse model of acute EtOH exposure has revealed decreases in NK cell function (and in resistance to B16F10 melanoma cells) and decreases in MHC class II proteins on B cells. These actions are mediated at least partly by an EtOH-induced stress response. Results from a mouse model of chronic EtOH consumption demonstrate a delayed suppression of antibody responses that is not mediated by direct action of EtOH, but by an indirect mechanism. Results from a similar mouse model indicate that early suppression of innate immunity to intracellular bacterial or viral infections contributes to a subsequent over production of proinflammatory cytokines. These cytokines represent a major pathogenic mechanism. A potential molecular mechanism for suppressed innate immunity has been identified in human subjects following acute exposure to EtOH in a controlled experimental setting. Monocytes from these subjects exhibit diminished NFκB activation associated with preferential induction of inhibitory p50/p50 homodimers. Human alcoholics have increased numbers of activated T cells, and this may result from upregulation of CD40L. There also seem to be alterations in the Th1/Th2 balance. Thus, EtOH alters a number of immune functions through several different mechanisms. Some common effects and mechanisms of action have been identified in acute and chronic studies in rodents and humans, but additional comparisons are needed. Completion of the *in vitro/in vivo*, human/animal parallelogram seems feasible and could provide valuable information for risk assessment in immunotoxicology.

1134 SUPPRESSION OF NK CELL ACTIVATION AND MHC CLASS II EXPRESSION ON B CELLS BY ACUTE ETHANOL EXPOSURE IN MICE: MECHANISMS OF ACTION AND INVOLVEMENT OF ENDOGENOUS CORTICOSTERONE.

S. B. Pruett. *LSU Medical Center, Shreveport, LA.*

In a mouse model of acute EtOH exposure, among the most striking immunological changes are a decrease in NK cell lytic function (with a consequent decrease in resistance to B16F10 melanoma metastases) and a decrease in the expression of MHC class II proteins on B cells. The glucocorticoid antagonist RU 486 partially prevents suppression of NK cell function and completely prevents the loss of MHC II proteins. This suggests that corticosterone produced as part of the EtOH-induced stress response is involved in suppression of NK cell function and completely responsible for the decrease in MHC class II expression. Administration of exogenous corticosterone and evaluation of the area under the corticosterone vs. time curve in EtOH and corticosterone-treated mice support these conclusions. Furthermore, similar blood EtOH levels are required to increase glucocorticoid levels in mice and in humans. The mechanism of suppression of NK cell activation and resistance to B16F10 tumor cells seems to involve decreased upregulation of type I interferon and granzyme B and decreased perforin levels. The mechanism by which MHC class II expression on B cells is suppressed involves down regulation of transcription of the MHC class II gene. In addition, *in vitro* studies at relevant corticosterone levels indicate a novel mechanism that is mediated by caspase activation and is associated with apoptosis of B cells. These results indicate that the importance of the EtOH-induced neuroendocrine stress response depends on the immune parameter evaluated and that EtOH acts by different mechanisms to alter different immune parameters within the same experimental model. (This work was supported by grants from NIAAA [AA09505] and NIEHS [ES09158], and the author is supported by a Career Development Award from NIAAA [AA00201].)

1135 THE EFFECTS OF SUB-CHRONIC ETHANOL FEEDING ON IMMUNE-MEDIATED HOST DEFENSES TO INTRACELLULAR BACTERIA AND VIRUSES.

T. R. Jerrells. *Omaha VA Medical Center & University of Nebraska Medical Center, Omaha, NE.*

Human beings who consume large amounts of alcohol have been shown to have a significantly higher incidence of infections. Of interest is the incidence of tuberculosis and hepatitis C virus infections in populations of human beings who chronically consume large amounts of alcohol. With the use of a mouse feeding model my laboratory has investigated the effects of ethanol (ETOH) consumption on parameters of immunocompetence, especially cellular immune responses to intracellular bacteria and a murine virus that causes a hepatitis. The studies have been done with a pair-feeding protocol where C57B1/6 mice were fed a liquid diet containing ETOH to supply 37% of the calories from ETOH, an isocaloric control liquid diet, or laboratory chow. The results of these studies have shown that animals that consume the ETOH diet are significantly more susceptible to a systemic infection with Listeria monocytogenes and an oral infection with Salmonella typhimurium. We have also shown that a more severe hepatitis following infection with murine cytomegalovirus is associated with consumption of ETOH in this model. Interestingly, data have been collected that support the suggestion that a more robust inflammation is the major mechanism of pathogenic effects following infection in the ETOH-consuming animals. This apparently is the result of over production of proinflammatory cytokines. The common mechanism of susceptibility seems to be an inability of the early, innate immune response to control the initial replication of the infectious organism. (Supported by AA07731 and AA12450.)

1136 RESULTS FROM A CHRONIC LIQUID DIET MODEL—INDIRECT, TIME-DEPENDENT EFFECTS ON THE HUMORAL IMMUNE RESPONSE.

M. P. Holsapple. *Dow Chemical Co., Midland, MI.*

The overall objective of these studies was to characterize the effects of chronic exposure to ethanol using a pair-feeding regimen. Adult female B6C3F1 mice were exposed to a liquid diet containing 5% ethanol (v/v) that provided 36% of the caloric intake. There was a definite temporal relationship to the consequent suppression of the antibody response to a T-dependent antigen with no suppression observed after 14 days of exposure. The magnitude of suppression increased from 18% after 21 days to 70% after 42 days. In contrast with our results with the *in vivo* antibody response, we saw no suppression of the *in vitro* antibody responses by splenocytes from ethanol-treated mice to a variety of antigens after any length of exposure. We speculated that the basis of the suppression of the *in vivo* antibody response was an indirect consequence of exposure to ethanol. We subsequently determined that when splenocytes from untreated mice were cultured in 5% serum from ethanol-exposed mice (42-day group), there was a >80% suppression of the *in vitro* antibody response relative to the serum from the pair-fed controls. As an important comparative control, we showed that there was no difference between the responses of splenocytes from untreated mice when cultured in either 5% normal mouse serum or 5% serum taken from the pair-fed controls. A determination of the ethanol content in the serum from the treated mice (42-day group) indicated that the amount of ethanol present in the cultures (<0.003%) could not account for the observed suppression. These results will provide the framework for the discussion of a model which is centered around an indirect mechanism of ethanol-induced immunosuppression, which is mediated in part by a serum factor.

1137 ROLE OF NF-κB IN INHIBITION OF INFLAMMATORY MEDIATOR PRODUCTION BY ALCOHOL IN HUMAN MONOCYTES.

G. Szabo and P. Mandrekar. *UMass Medical School, Worcester, MA.*
Sponsor: S. B. Pruett.

Chronic alcohol use is associated with impaired immunity and host defense. We showed that even *in vitro* acute ethanol treatment results in decreased production of inflammatory cytokines that are major contributors to host defense including tumor necrosis factor-α (TNFα), IL-1β, and chemokines IL-8 and MCP-1. Here we show that acute consumption of alcohol (2 ml vodka/kg body weight; BAL:.1g/dl) by non-alcoholic healthy individuals significantly decreases TNFα and IL-1β production in ex vivo challenged isolated blood monocytes ($P<0.01$). SEB-induced IL-8 and MCP-1 levels were also reduced in whole blood obtained 18 hrs after alcohol consumption ($p<.01$). However, the intracellular mechanisms for down-regulation of bacterial stimulation-induced inflammatory cytokine production in MØ after acute alcohol treatment are yet to be dissected. Here, NF-κB/Rel was tested as a potential target of ethanol in regulation of inflammatory cytokine gene expression. We have previously reported a rapid decrease in mRNA and protein levels of the NF-κB-regulated inflammatory cytokines in MØ after acute ethanol treatment. Minimal NF-κB binding was seen in unstimulated MØ from non-alcoholic donors. MØ activation with 1μg/ml LPS or SEB substantially increased NF-κB binding of both the p65/p50 and p50/p50 dimers as early as 30 min and as late as 24 hrs after stimulation. However, ethanol (25mM) prevented p65/p50

heterodimer induction by LPS or SEB in MØ. NF-κB inhibitor by ethanol required de novo protein synthesis and was not mediated by inhibition of SEB or LPS-induced IkB degradation. Finally, preferential induction of p50/p50 homodimer was seen by ethanol in MØ. These results imply that inhibition of NF-κB activation is likely to be one of the intracellular mechanisms for the ethanol-induced inhibition of inflammatory mediator production in monocytes. (Supported by NIH AA08577 and A11576 grants.)

1138 CHRONIC ETHANOL EXPOSURE—COMPARISONS OF HUMAN AND EXPERIMENTAL DATA.

R. T. Cook. *University of Iowa & Veterans Administration Medical Center, Iowa City, IA.* Sponsor: S. B. Pruett.

Chronic alcoholism is associated with signs of immune deficiency; there are significant increases in serious infections such as bacterial pneumonia, septicemia, tuberculosis and others. It is unknown whether alcohol congeners influence any of the immune alterations, but animal models of alcohol abuse demonstrate that pure dietary ethanol at 25+% of total calories is immunosuppressive, with increased mortality from experimental bacterial pneumonia, more extensive infections by Listeria and Salmonella, and increased numbers of Mycobacterium avium in chronic ethanol animals. Evaluation of lymphocyte immunophenotype and function in human alcoholics has shown persistent activation of CD8+ T-cells both in alcoholics with and those without liver disease, and very substantial activation of both CD8+ and CD4+ T-cells in alcoholics with liver disease. The concept has arisen that the immune deficiency in alcoholics may result from an increase in TH2 type lymphocyte function. Recent work in the author's laboratory has demonstrated that most alcoholics have an increase in a phenotype (CD57+ T-cells) that show a rapid TH1 response after *in vitro* stimulation through the T-cell receptor (TCR). These cells are end-stage effectors which produce significant IFNγ and TNFα, and are thought to then rapidly undergo apoptosis. Cytoplasmic IL-4 can also be demonstrated in the fresh CD4+ T-cells of some alcoholics, so the balance of TH1/TH2 may be altered. Stimulation through the TCR rapidly upregulates CD40 ligand (CD40L) on CD4+ T-cells *in vitro*, and there is some data suggesting its persistent upregulation in the alcoholic, consistent with an increase in T-dependent B-cell activation, and an increase in T-cell-monocyte interactions. These data and that of the previous speakers will be summarized and an integrated view of current questions in the field will be offered.

1139 MYCOTOXINS: RECENT ADVANCES AND THEIR RELEVANCE TO CARCINOGENESIS AND TOXICOLOGY.

K. Voss[1], Y. Dragan[2] and W. M. Haschek[3]. [1]*USDA ARS Russell Research Center, Athens, GA,* [2]*Ohio State University, Columbus, OH and* [3]*College of Veterinary Medicine, University of Illinois, Urbana, IL.*

Fumonisins are produced by *Fusarium moniliforme* (recently reclassified as *F. verticillioides*) and *F. proliferatum*, fungi commonly found on corn. They are suspected human carcinogens which affect populations utilizing contaminated corn as a dietary staple. Fumonisin B_1 (FB_1), the most thoroughly studied fumonisin, causes the species-specific toxicities elicited by *F. verticillioides* in farm and laboratory animals. On the molecular level, fumonisins disrupt sphingolipid metabolism by inhibiting ceramide synthase. Apoptosis is an early cytotoxic event following fumonisin exposure. These findings are significant not only for mycotoxicology, but also for understanding fundamental toxicological principles. The aim of this symposium is to explore how fumonisins can be used to investigate connections between carcinogenicity, cytotoxicity and apoptosis, and specific biomolecular events. Specific topics to be covered are: (a) the liver and kidney tumorigenic effects of FB_1 in rats and mice; (b) the role of apoptosis as an early event in fumonisin toxicity; (c) the use of FB_1 as a model for the role of apoptosis in nongenotoxic carcinogenesis and its implications for evaluating risk; (d) the use of fumonisins as research tools for studying sphingolipid-mediated cell regulatory functions, including those governing apoptosis and mitosis; and (e) to show how an integrated strategy combining biochemical, physiological and pathological approaches can be used to study *in vivo* mechanisms of toxicity and interspecies differences.

1140 CARCINOGENICITY OF FUMONISIN B_1 IN F-344 RATS AND B6C3F1 MICE.

P. C. Howard[1], R. J. Lorentzen[2], K. A. Voss[3], R. Kovach[4] and T. J. Bucci[1]. [1]*FDA NCTR, Jefferson, AR,* [2]*FDA Food Safety & Applied Nutrition, Washington, DC,* [3]*USDA ARS, Athens, GA and* [4]*Pathology Associates International, Jefferson, AR.*

Fumonisin B_1 (FB_1) is a toxin produced by Fusaria fungi that contaminate crops worldwide. The tumorigenicity of FB_1 was determined in male and female F344/Nctr rats and B6C3F1/Nctr mice. The highest concentration of FB_1 in the diets (NIH-31) were 100 and 150 ppm for female and male rats, and 80 and 150 ppm for female and male mice, respectively. FB_1 induced renal tubule adenomas and carcinomas in male rats (50 and 150 ppm), and did not induce tumors in female rats. FB_1 increased hepatocellular carcinoma formation in female mice (50 and 80 ppm), while no increase in tumor formation was observed in male mice. FB_1-induced changes in cell proliferation, apoptosis, and sphingoid bases were consistent with the observed target tissues. These results support the conclusion that FB_1 is a rodent carcinogen. This data is currently being used for human cancer risk estimations.

1141 APOPTOSIS AND ITS IMPLICATIONS FOR TOXICITY, CARCINOGENICITY AND RISK: FUMONISIN B_1 AS AN EXAMPLE.

S. M. Cohen. *University of Nebraska Medical Center, Omaha, NE.*

The balance between the rates of cell proliferation and cell loss in conjunction with the differentiation status of the tissue are among the many factors contributing to carcinogenesis. Nongenotoxic (non-DNA reactive) chemicals may affect this balance by increasing proliferation through direct mitogenesis or through a regenerative response following loss of cells through cytotoxic (oncotic) or apoptotic necrosis. In male rats, the mycotoxin fumonisin B_1 (FB_1) caused hepatic toxicosis and hepatocellular carcinomas in one study but caused renal carcinomas in a second. It has also been shown to cause liver cancer in female mice. An early effect of FB_1 exposure in these target organs is apoptosis. Induction of apoptosis may be a consequence of ceramide synthase inhibition and disruption of sphingolipid metabolism by FB_1. FB_1 is not genotoxic in bacterial mutagenesis screens or in the rat liver unscheduled DNA synthesis assay. Thus, FB_1 may be the first example of an apparently nongenotoxic carcinogen which exerts its effects through apoptotic necrosis, atrophy, and consequent regeneration. If so, selection of damaged cells which are resistant to apoptosis, but susceptible to cancer development, would have important implications for neoplastic development and evaluation of cancer risk.

1142 INHIBITORS OF SPHINGOLIPID BIOSYNTHESIS AS RESEARCH TOOLS FOR UNDERSTANDING THE MECHANISM OF ACTION.

R. T. Riley[1] and A. H. Merrill, Jr.[2]. [1]*USDA/ARS, Athens, GA and* [2]*Dept. of Biochemistry, Emory University, Athens, GA.*

The first reported fungal inhibitor of *de novo* sphingolipid biosynthesis was fumonisin B_1 (FB_1). Since this discovery, 40 known or suspected microbial inhibitors of sphingolipid biosynthesis have been reported. These include metabolites that inhibit serine palmitoyltransferase, ceramide synthase (including FB_1), and inositol phosphoceramide synthase. In addition to the microbial inhibitors, there are also inhibitors of glycosylceramide synthase, ceramidase, and sphingosine kinase. These inhibitors are used to reveal the role of sphingolipids in cellular regulation and the importance of ceramide synthase inhibition in the diseases associated with fumonisins. FB_1-inhibition of ceramide synthase increases the intracellular concentration of free sphingoid bases and their 1-phosphates, and decreases the *de novo* biosynthesis of ceramide and more complex sphingolipids. Free sphingoid bases, sphingoid base metabolites, ceramide, and glycosphingolipids are known modulators of cell function, survival, and growth. In short-term experiments, inhibition of ceramide synthase by fumonisins can inhibit cellular effects induced by ceramide generated *de novo* or increased glycosylceramide synthesis. In longer term experiments, ceramide synthase inhibition promotes the effects induced by free sphingoid bases/metabolites, and inhibits the processes that require more complex sphingolipids. Inhibitors of other enzymes in the *de novo* sphingolipid biosynthetic pathway have proven useful in dissecting the contribution of the changes in specific sphingolipid pools in the cellular effects of fumonisins. These studies have revealed new information about the mechanisms of action of fumonisins and the importance of sphingolipids in cellular regulation.

1143 RELATING MOLECULAR MECHANISMS TO PATHOPHYSIOLOGICAL EFFECTS: FUMONISIN AS A CASE STUDY.

P. D. Constable[1], L. A. Gumprecht[1], G. W. Smith[1], M. E. Tumbleson[1], R. M. Eppley[2], S. Mathur[1] and W. M. Haschek[1]. [1]*University of Illinois, Urbana, IL and* [2]*USFDA, Washington, DC.*

Fumonisins, mycotoxins produced by *Fusarium verticillioides* (= *F. moniliforme*) and *F. proliferatum*, inhibit sphingosine N- acyltransferase, a key enzyme in the pathway of *de novo* sphingolipid biosynthesis, resulting in increased concentrations of sphingosine (So) and sphinganine (Sa) in serum and tissues of all species. Fumonisins cause lethal pulmonary edema in pigs and leukoencephalomalacia in horses; renal injury in rabbits, sheep, and rats; and liver injury in all species. Our recent studies have focused on the pathogenesis of fumonisin B_1 induced pulmonary edema, which is unique to swine, taking into consideration pathological, physiological and biochemical alterations. Interstitial pulmonary edema was accompanied by membranous accumulations in the pulmonary capillary endothelial cells which appear specific to this cell type and to swine. Fumonisin B_1 increased mean pulmonary arterial pressure and decreased heart rate, cardiac output and mixed venous oxygen tension. Additionally fumonisin B_1 decreased cardiac contractility as assessed by left ventricular end-systolic elastance and maximal rate of change of pressure. However, the permeability of the alveolar-capillary membrane was not altered. Fumonisin increased the concentrations of So and Sa in the kidney>liver>lung>heart, as well as in serum. Neither pulmonary edema nor cardiovascular physiologic alterations occurred in calves given purified fumonisin B_1 intravenously at the same dose; however, the increases in serum Sa and So in calves were much lower than in pigs. The changes in pigs are compatible with the inhibition of L-type calcium channels by increased So and/or Sa concentration. Therefore, fumonisin-induced pulmonary edema in swine presumably results from acute left-sided heart failure mediated by inhibition of sphingolipid biosynthesis.

1144 THE INFLUENCE OF CO-POLLUTANTS ON THE TOXICITY OF AIRBORNE PARTICULATE MATTER.

M. C. Madden[1] and K. E. Pinkerton[2]. [1]*USEPA, Research Triangle Park, NC and* [2]*University of California, Davis, CA.*

Recent epidemiological reports have shown an association between ambient air particulate matter (PM) concentrations and human mortality and morbidity, such as increased hospitalizations. PM coexists in the ambient air with many other pollutants, and therefore complicates the assessment of the contribution of PM to the affected health endpoints. In the National Research Council's Report in 1998 that concerned Airborne PM Research Priorities, one of the research aspects emphasized was performance of controlled toxicological studies and epidemiological studies related to examining effects of co-pollutants on possible PM-induced health endpoints. In this session, evidence of the support for co-pollutant influences on PM-associated health effects will be examined from epidemiological studies. Evidence of co-pollutants affecting PM-induced responses will be will drawn from findings of controlled *in vivo* and *in vitro* exposure studies that examine cardiopulmonary effects of PM. These controlled co-pollutant studies can potentially suggest which pollutants are likely to influence PM-induced lung and extrapulmonary toxicity, and potential mechanisms for these interactions. Additionally, the characteristics and components of PM likely to be influenced by other ambient pollutants can be identified in these studies. Oxidants including ozone, inorganic components such as sulfates, organic constituents such as aromatic compounds, and biological substances (i.e., endotoxin) can all play an important role in modifying PM-induced effects by allowing co-pollutant interactions. Data presented from gaseous pollutant interaction with cigarette smoke, more typically an indoor pollutant, will compliment the understanding of outdoor PM toxicology.

1145 EPIDEMIOLOGIC EVIDENCE OF CO-POLLUTANT INFLUENCE ON PARTICULATE-INDUCED TOXICITY.

C. A. Pope. *Brigham Young University, Provo, UT.* Sponsor: M. C. Madden.

Epidemiologic evidence suggests that airborne particulate matter (PM), especially primary and secondary combustion-related PM, is a risk factor for cardiopulmonary disease and mortality. Most epidemiological studies have focused on effects of acute exposure. Chronic exposure, however, may be more important in terms of overall public health relevance. Chronic exposure likely increases the risk of cardiopulmonary disease and mortality. Acute exposure can exacerbate existing cardiopulmonary disease and increase the number of persons in a population who become symptomatic, require medical attention, or die. There is also evidence of health effects due to exposure to other air pollutants-including O_3, CO, SO_2, and NO_2. Basic approaches to evaluating the contributions of co-pollutants to PM-induced toxicity include: 1) estimate regression models with multiple pollutants as covariates and use statistical criteria such as significance levels or coefficient size and stability to evaluate the relative impact; 2) evaluate estimated pollution effects in areas with different levels and combinations of co-pollutants. These epidemiologic approaches reveal evidence of combustion-source PM toxicity that is independent of co-exposure to SO_2, NO_1, or O_3. It remains unclear if the relative toxicity of combustion-related PM is due to the relative small size of the particles, their chemical composition, or their associations with other combustion related pollutants. Epidemiologic studies are limited due to the use of people living in uncontrolled environments with complex mixtures of air pollution. An improved understanding of the influence of co-pollutants on PM-toxicity requires continued contributions from toxicological studies.

1146 EFFECT OF CO-POLLUTANTS (SO_2, NO_2, AND NH_3) ON THE ACUTE PULMONARY TOXICITY OF PARTICLES AND PARTICULATE MATTER (PM)—ASSOCIATED METALS.

K. L. Dreher. *USEPA, Research Triangle Park, NC.* Sponsor: D. L. Costa.

Exposure to ambient air PM occurs in the presence of a complex and dynamic mixture of gaseous air pollutants. The ability of co-pollutants to influence the adverse health effects associated with ambient air PM exposure represents a critical risk assessment issue. Toxicology studies have employed surrogate aerosols and mixtures to examined the extent to which co-pollutants (SO_2, NO_2, and NH_3) may influence the ability of particles to alter lung physiology, immune function and injury or modulate the toxicities of causal PM components. Exposure of animals to aerosol mixtures containing SO_2 and soluble metal salts or insoluble metal oxides was found to enhance the ability of SO_2 to induce alterations in pulmonary function through the formation of H_2SO_4. Additional studies involving the exposure of animals to carbon black (CB) particles in the presence of sulfuric acid or SO_2 with high relative humidity were found to produce immunotoxic and cellular cytotoxic effects that were not induced by individual exposures to these substances. Similar studies have detected increased cell proliferation in epithelial cells at airway bifurcations in rats exposed to a mixture of NH_4NO_3 and CB particles. Surrogate mixture studies have examined the potential interactions between PM-associated metals (Fe and Zn) and other PM co-constituents (H_2SO_4, NO_3-, and NH_4+) resulting from the transformation of gaseous air pollutants (SO_2, NO_2 and NH_3). Dilute sulfuric acid was found to dramatically increase ZnO bioavailability and pulmonary toxicity. Nitrate and ammonium were found to enhance Fe and attenuate Zn pulmonary toxicities. Metal bioavailability could account for some but not all of the observed effects of NO_3-, and NH_4+ on either Fe or Zn pulmonary toxicities. These results demonstrate the ability of SO_2, NO_2 and NH_3 co-pollutants to influence PM toxicity through: (i) the surface formation and/or deposition and enhanced pulmonary delivery of toxic substances such as acids; and (ii) the surface formation and/or deposition of acids, NO_3-, and/or NH_4+ which can modify the toxicity of other PM constituents such as metals by enhancing their bioavailability or biopotency, and/or altering their cellular specificity.

1147 EXPOSURE TO ENVIRONMENTAL TOBACCO SMOKE (ETS) ENHANCES THE SENSITIVITY OF THE LUNGS TO OZONE-INDUCED INJURY.

K. E. Pinkerton, M. Yu and H. P. Witschi. *University of California, Davis, CA.*

To examine the effects of ETS on the sensitivity of the lungs to ozone, A/J and B6C3F1 mice were exposed to filtered air, ETS, ozone or ETS followed by ozone. ETS exposure was for 6 hr/day for 3 days at a total particulate concentration of 30 mg/m³; ozone exposure was for 24 hrs at 0.5 ppm. Proliferating cells were identified by bromodeoxyuridine (BrdU) immunolabeling. The percent of BrdU labeled cells within the centriacinar regions of the lungs was found to be significantly elevated in both strains of mice following exposure to ozone (3-fold above control) and further augmented in mice exposed to ETS and ozone (4-fold above control). In contrast, exposure to ETS alone did not change BrdU labeling compared with filtered air control mice. Cytokine release *in vitro* from alveolar macrophages obtained from the lungs by bronchoalveolar lavage was also examined. In both strains of mice, there was a significant decrease in IL-6 production with or without

lipopolysaccharide (LPS) stimulation following exposure to ozone alone or to ETS plus ozone. There was also a significant elevation in LPS-stimulated TNF-α release following exposure to ETS plus ozone. We conclude that (1) ETS exposure enhances the sensitivity of mice to ozone-induced lung injury and (2) the increase in susceptibility to ozone injury observed may be associated with a reduction in the levels of IL-6 and concomitant enhancement in LPS-stimulated release of TNF-α from alveolar macrophages. (Supported by TRDRP and NIH ES00628.)

1148 THE EFFECTS OF OXIDANTS ON MODIFYING THE TOXICITY OF AMBIENT PM.

A. J. Ghio, J. H. Richards, L. A. Dailey, G. E. Hatch and M. C. Madden. *USEPA, Research Triangle Park, NC.*

Exposure to ambient air particulate matter (PM) is associated with increased human morbidity and mortality due to cardiopulmonary toxicity. It has been proposed that PM presents an oxidative stress to the lower respiratory tract. Interactions between PM and oxidants such as ozone (O_3) are possible as a result of a chemical reaction and/or shared mechanism of biological effect. We used diesel exhaust particles (DEP) to examine for an interaction between PM and O_3 in inducing lung toxicity. The effects of ozonation on DEP-induced lung toxicity were examined. Rats were intratracheally instilled with saline vehicle, DEP, or DEP previously exposed *in vitro* to O_3. At 24 hr post instillation, lungs were lavaged, and total protein (TP) levels, LDH activity, and cell differential counts determined. With up to 500 μg instilled, both particle types induced significant dose-dependent increases in TP, LDH, and neutrophils (compared to vehicle). However, OzDEP was more potent at 10 μg than DEP in the induction of neutrophilia and an LDH increase. The increased toxicity of the OzDEP was not due to oxidation by air, as air-exposed DEP had the same activity as unexposed DEP. These data suggest that low, ambient concentrations of O_3 can react with DEP to produce an altered, stable particle that is more toxic in a rat model than the unexposed DEP. O_3 and at least some PM may therefore chemically react, and play a role in PM-induced morbidity and mortality.

1149 INTERACTION OF ENDOTOXIN, OZONE, AND ULTRAFINE PARTICLES.

G. Oberdörster, A. Elder, J. N. Finkelstein and C. Cox. *University of Rochester, Rochester, NY.*

Exposure to endotoxin (LPS) can occur by multiple routes including inhalation of ambient particles contaminated with LPS, respiratory tract infection with gram negative bacteria, and from gastrointestinal sources via increased mucosal permeability. LPS induces the LPS exposures the response of the organism to other subsequent stimuli could be significantly altered, resulting in a greater susceptibility towards experiencing adverse effects. Thus, depending on the sequence and mode of exposure. LPS can be viewed both as a co-pollutant and as a priming agent of target cells. Epidemiological observations of an association of increased morbidity with low urban particulate levels still require proof of causality. There is some controversy as to whether particles alone at low environmental concentrations can cause significant adverse effects. Several hypotheses have been proposed and are currently being tested to examine causality including the suggestion that the presence of host susceptibility factors such as age in addition to co-pollutants is essential for inducing health effects related to low particulate levels. Our hypothesis that particle size also plays a crucial role in that ultrafine particles have a greater toxic potential than larger particles has been supported by results from several laboratories in the past. Subsequent studies in rats and mice with inhaled low-level carbonaceous ultrafine particles in combination with ozone and priming of the respiratory tract with LPS showed that ultrafine particle-induced pulmonary inflammation can be amplified by prior LPS and by simultaneous ozone exposure. Age also plays an important role since an oxidative stress response appears to be more likely in the aged organism.

1150 ARE DIETARY SUPPLEMENTS SAFE?

R. E. Osterberg. *USFDA, Rockville, MD.*

Most dietary supplements are regulated under the Dietary Supplement Health and Education Act (DSHEA) and are not subjected to the same standards and labeling requirements as medicines and foods. With over half of the U.S. public now consuming dietary supplements, (Americans spent almost $4 billion in 1998 on herbal remedies), more are turning to "natural" products than ever before for many reasons. They want something less toxic than prescription drugs and/or they want to prevent sickness and/or improve their quality of life. The demand for dietary supplements necessitates that the industry makes efforts to ensure that its products are safe and that its claims are substantiated. Manufacturers must also become more vigilant because international groups (i.e., Codex Alimentarius Commission) and federal and state regulators are becoming more concerned about product safety and standards. Although most dietary supplements have extensive marketing histories, the published literature contains relatively few documented safety studies in humans, including information on supplement-drug or supplement-food interactions. This roundtable will discuss the concerns that regulators have with dietary supplements and the steps that the dietary industry is taking to address those concerns within the context of DSHEA. Also discussed will be the information that is known and assumed about the safety/toxicities of selected dietary supplements.

1151 DIETARY SUPPLEMENT SAFETY—IMPROPER USE OF THE ADVERSE EFFECTS REPORTING SYSTEM.

T. M. Farber. *ToxaChemica, International, Rockville, MD.*

A proposed rule has been issued by the FDA, which would have a detrimental effect on the marketing and use of ephedra-containing dietary supplements. The proposed rule was issued primarily on the basis of a large number of Adverse Event Reports (AERs) gathered by the FDA.The FDA and the Texas Department of Health, through intensive multimedia warnings and manipulation, have turned a passive alerting system into an active data-gathering process through the active recruitment of cases and the exaggeration of the possible hazards of ephedra products. The AER database is flawed to a significant degree; lacking critical information in almost 90% of the cases. In spite of the fact that a causality analysis could not be performed on this poor database, the FDA has made invalid epidemiological projections based on this information. The AER system for dietary supplements needs to be significantly improved so that causality can be demonstrated before actions are taken against dietary supplements. The proposed rule on ephedra-containing dietary supplements should be withdrawn.

1152 DIETARY SUPPLEMENTS—HUMAN HEALTH RISK STANDARDS AND METHODS OF ASSESSMENT.

M. Bolger. *USFDA, Washington, DC.*

The statutory mandate for assessing the safety/risk of dietary supplements is contained in the federal Dietary Supplement Health and Education Act of 1994. A dietary supplement is intended for ingestion and is a vitamin, mineral, herb or botanical or amino acid. It is used to supplement the diet by increasing the intake of a concentrate, metabolite, constituent, extract or combination of any of the aforementioned ingredients. If a dietary supplement (A) presents a significant or unreasonable health risk under conditions of use or (B) is a new dietary ingredient for which there is inadequate information to provide reasonable assurance of safety, it is deemed to pose an imminent hazard to public health or safety. The burden of proof to satisfy these safety/risk standards reside with the FDA. Current approaches for quantifying the hazards/risks of dietary supplements will be described through several case studies. The types of information/issues considered in the safety/risk assessment of dietary supplements include product identification (e.g. botanicals plant identification), history of use, dietary supplement mixtures and interactive effects (additive, synergistic, antagonistic), patterns of animal and human intoxications (e.g., differences in routes and frequency of exposure, retrospective, case-control, prospective studies), use of adverse reporting information (e.g., passive vs active reporting systems), uncertainty in extrapolation (route to route, species to species, duration and frequency of exposure), uncertainty in dose-response information (e.g. laboratory animal vs. veterinary and human case reports), severity of response and adverse effect, and risk characterization-safety assessment versus quantitative risk assessment.

1153 BOTANICAL DIETARY SUPPLEMENTS—ISSUES OF SAFETY.

J. Cardellina. *Council for Responsible Nutrition, Washington, DC.* Sponsor: R. E. Osterberg.

Questions about the safety of botanical dietary supplements have garnered increasing attention in the past two years. While most herbs with a well-documented historical use are generally regarded as safe, based on sustained human consumption over a long period of time, little is known about the interaction of today's dietary supplements with other herbs or with prescription and over the counter medications.At a minimum, a functional, effective adverse effect reporting system is required. It is insufficient merely to collect and collate reports of potential adverse effects; it is necessary that follow up investigation and evaluation of such reports take place, so that causality can be established or negated. This would be a critical step in developing meaningful data about the safety of such products.

1154 DIETARY SUPPLEMENT SAFETY.

L. C. Totman. *Consumer Healthcare Products Association, Washington, DC.*

The U.S. market for dietary supplements has greatly expanded in recent years. Dietary supplements do, however, have an extensive history of use. They are marketed with reasonable expectation that no harm will occur, as are other regulated food products. The largest segment of the dietary supplement market comprises vitamins, minerals, and a few botanicals. Concerns about safety mostly involve products outside that core of the market. FDA has authority to take action against any dietary supplement product that is found to be unsafe or that makes unsubstantiated claims or unapproved drug claims. FDA also has legal authority to move against any dietary supplement that presents a significant or unreasonable risk of injury or illness. The agency can prevent a product from being marketed if insufficient information is submitted to show the basis for determining it is "reasonably expected to be safe". Adverse event reports (AERs) on marketed products can signal safety problems that warrant further investigation and perhaps action to assure public safety. FDA's AER system for dietary supplements should be strengthened. Good manufacturing practices (GMPs) are critically important for dietary supplement product safety. FDA needs to have strong, practical GMP regulations and enforcement. Dietary supplement safety depends on responsible manufacturers and FDA's use of its enforcement powers.

1155 EFFECTS OF CO-EXPOSURE OF TIMOTHY GRASS POLLEN AND DIESEL EXHAUST PARTICLES ON SPECIFIC POLLEN ANTIBODY PRODUCTION (IGE AND IGG1) AFTER INTRANASAL AND INTRATRACHEAL APPLICATION IN BROWN NORWAY RATS.

P. A. Steerenberg, J. A. M. Dormans, C. C. M. Van Doorn, S. Middendorp, J. G. Vos and H. van Loveren. *National Institute Public Health and Environment, Bilthoven, Netherlands.*

During the last decades, the prevalence of allergy has increased world-wide. To investigate the adjuvant effect of DEP in pollen allergy, Brown Norway (BN) rats were sensitized intranasally or intratracheally with timothy grass pollen (Phleum pratense) with or without DEP (3 mg/ml). Intranasal sensitization (200 µl, 10 mg/ml) was performed daily for 5 consecutive days and intratracheal sensitization (200 µl, 10 mg/ml) was performed once. Challenge with pollen was performed at day 21 similarly to the sensitization protocol. Blood samples were taken at day 28 after the first sensitization. The binding of DEP to pollen grains was studied by scanning electron microscopy and the inflammatory response in the lung was studied by light microscopy. IgE and IgG1 responses against pollen grains were measured by digoxigenin (DIG)-ELISA. Scanning electron microscopy revealed a mixture of free DEP and DEP associated with pollen grains. Both intranasal and intratracheal routes of administration of pollen grains induced inflammatory reactions in the lung with an influx of macrophages, eosinophilic granulocytes and granuloma formation. Pollen grains were localized in the alveoli both after intranasal and intratracheal administration and were surrounded by macrophages. The number and localization of pollen grains were similar for both routes of administration. After co-exposure with DEP, DEP loaded macrophages were found around the pollen. Localization, inflammatory reaction and integrity of pollen were similar as seen without DEP. At day 28 specific IgE and IgG1 antibodies were found in serum of rats immunized intranasally or intratracheally. IgE antibody response was higher in rats immunized with pollen grains and DEP than in rats immunized with pollen only. The IgG1 antibody response was much higher compared to the IgE response, but the level of IgG1 antibodies was slightly affected by DEP.

1156 THE ADJUVANT ACTIVITY OF PARTICULATE POLLUTANTS IN AN INTRANASAL MODEL.

M. van Zijverden[1], M. Bol[1], A. van der Pijl[1], A. H. Penninks[2], H. van Loveren[3] and R. H. H. Pieters[1]. [1]*RITOX Immunotoxicology, Utrecht, Netherlands,* [2]*TNO Nutrition and Food Research Institute, Zeist, Netherlands and* [3]*RIVM National Institute of Public Health, Bilthoven, Netherlands.* Sponsor: M. van den Berg.

The prevalence of respiratory allergy is increasing. Particulate pollutants like diesel exhaust particles (DEP) may play a role by acting as adjuvants, stimulating Thelper 2 (Th2) immune responses to common allergens. We studied the influence of particulate pollutants *on the sensibilisation process* in an intranasal model. The defined reporter antigen TNP-OVA (2,4,6 trinitrophenylphosphate-ovalbumin) (10µg) was given intranasally on 3 consecutive days together with DEP, carbon black particles (CBP) or amorphous silica particles (SIP) (total dose: 200µg) to female BALB/C mice (6-8 weeks). At day 10 an intranasal challenge with TNP-OVA alone was given and at day 15 ELISPOT (on draining lymph nodes of the lung (PBLN), spleen and bone marrow) and ELISA (on serum) were performed. Data on IL-4 and IFNγ were obtained by flowcytometry on PBLN cells and ELISA on supernatant of overnight culture. After CBP exposure an increase in number of T cells and B cells, the latter producing increased levels of IgG1, was observed in the PBLN. The ratio of IL-4+ over IFNγ+ T cells increased, as well as overnight IL-4 production. In serum elevated levels of IgG1 and IgE were observed, IgG2a levels did not change. DEP exposure caused elevation of IgG1 levels, while IgE levels and IL-4 production showed a trend to be increased. SIP administration induced no significant changes. No effects were observed in spleen and bone marrow. CBP adjuvate the immune response most clearly, skewing the response in Th2 direction. The adjuvating activity of DEP is less strong but also shows some Th2 characteristics. SIP do not adjuvate in this model. Findings are in accordance with epidemiological studies showing that DEP and fine particles in general are involved in respiratory allergy.

1157 BETA-1,3-GLUCAN ADJUVATES THE ALLERGIC RESPONSE TO OVALBUMIN IN MICE.

H. Ormstad[1], M. Løvik[1], N. Ohno[2], E. C. Groeng[1] and G. Hetland[1]. [1]*National Institute of Public Health, Oslo, Norway and* [2]*Tokyo University of Pharmacy & Life Science, Tokyo, Japan.* Sponsor: E. Dybing.

The polyglucose beta-1,3-D-glucan is a major structural component of the cell wall of yeasts and fungi. There is an association between exposure of the airways to β-1,3-glucan and increased prevalence of atopy and decreased expiratory capacity. We have investigated the effect of the soluble beta-1,3-glucan SSG from Sclerotinia sclerotiorum on the allergic immune response to the model allergen ovalbumin (OA) by using the popliteal lymph node assay (PLNA)in mice. In PLNA allergens and adjuvants are injected repeatedly into one hind footpad. End point measurements are PLN weight and cell number and proliferation, and serum levels of IgE, IgG1 and IgG2a anti-OA. The mice were given SSG+OA, SSG or OA alone and either sacrificed on D20, or reinjected with OA on D21 before sacrifice on D26 or D33. SSG+OA increased PLN weight and cell number ($p \leq 0.023$) compared with OA or SSG alone on D26. On D26 and D33, SSG+OA strongly increased IgE and IgG1, but not IgG2a, anti-OA IgE levels ($p<0.001$)compared with OA or SSG alone on. Our results show that β-1,3-glucan has an adjuvant activity on the allergic immune response in a mouse model. This supports the reported observations of inhaled β-1,3-glucan as an enhancer and inducer of allergic disease in humans.

1158 SYSTEMIC ADMINISTRATION OF *BORDETELLA PERTUSSIS* ENHANCES PULMONARY SENSITIZATION TO DUST MITE IN JUVENILE RATS.

W. Dong[1], L. Gregg[2], M. J. Selgrade[1] and M. I. Gilmour[1]. [1]*Immunotoxicology Branch, USEPA, Research Triangle Park, NC and* [2]*Dept. of Immunology, North Carolina State University, Raleigh, NC.*

Studies have shown that the incidence of allergy and asthma has increased significantly, especially in children, in the past few decades. Inactivated *B. pertussis*, which has been routinely given to children as a vaccine component, has also been used as an adjuvant for enhancing IgE production in experimental models of allergy. The objective of this study was to establish an aller-

gy model in young rats and address the hypothesis that systemic administration of *B. pertussis* could augment allergic immune responses after intra-pulmonary house dust mite (HDM) sensitization. Three-week old female Brown Norway rats were sensitized with 10 µg HDM intratracheally or intraperitoneally with or without intraperitoneal injection with 10^8 whole killed *B. pertussis* organisms. Ten days later, the rats were challenged with 5 µg HDM intratracheally. Bronchial lymph nodes and bronchoalveolar lavage fluid (BAL) were collected 0, 2, and 4 days post challenge. For both systemically and locally sensitized rats, co-administration of pertussis enhanced HDM-specific lymphoproliferative responses in cells from the pulmonary lymph nodes and eosinophil, total protein, lactate dehydrogenase, and HDM-specific IgE and IgG levels in BAL. These responses in the locally sensitized rats given pertussis were comparable to those in systemically sensitized rats given pertussis. Regardless of adjuvant, local lymphoproliferative responses and eosinophilia were greater in locally sensitized rats, whereas BAL IgE and IgG were greater in systemically sensitized rats. Unlike studies of adult rats, we were unable to demonstrate immediate airway hyperreactivity to HDM challenge in any of the treatment groups. The data show that intratracheal instillation of HDM induces a mild allergic sensitization in juvenile rats and that co-administration of *B. pertussis* enhances this sensitization process to levels seen in animals immunized with antigen and *B pertussis*. These results suggest that simultaneous exposure to Th2 type vaccines and common antigens may be a risk factor for allergic sensitization and asthma. (This abstract does not necessarily reflect EPA policy.)

1159 RESPONSES OF BALB/C MICE TO RESPIRATORY SENSITIZATION WITH THE BIOPESTICIDE, *METARHIZIUM ANISOPLIAE*.

M. D. W. Ward, S. L. Madison, D. L. Andrews, C. A. Manuel, D. M. Sailstad, S. H. Gavett and M. K. Selgrade. *NHEERL, USEPA, Research Triangle Park, NC.*

Metarhizium anisopliae, an entomopathogenic fungus licensed for indoor use, has been shown to elicit allergic responses in BALB/C mice intraperitoneally (IP) sensitized and intratracheally (IT) challenged with a *M. anisopliae* crude antigen (MACA) preparation. In this study the IT route of sensitization is compared to IP sensitization and to an IT vehicle control. The IT route consisted of 4 IT exposures of 10 µg MACA in 50 µl HBSS over a four-week period (vehicle controls received HBSS only). While the IP route consisted of IP sensitization with 25 µg MACA in 0.2 ml of 1.3% alhydrogel followed 14 days later with an IT challenge (10 µg MACA/50 µl HBSS). Mouse airway reactivity was assessed by methacholine challenge and serum and bronchoalveolar lavage fluid (BALF) samples were collected and the lungs fixed in 10% formalin at 1, 3, and 8 days following the MACA IT challenge (DPIT). Both total BALF cellularity and differential cell counts were significantly greater in IT sensitized mice compared to both IP and vehicle controls at 1 DPIT with total cellularity and eosinophilia still significant at 3 DPIT. Both IT and IP mice had significantly elevated levels of IL-5 (1 and 3 DPIT) but only IP mice had significant IL-4 (1 DPIT). Airway reactivity was significantly increased for both IP and IT mice (1 and 8 DPIT). However, IT mice also demonstrated significant airway reactivity at day 3 compared to both IP and vehicle controls. Analysis of lung pathology showed that the types of lesions in both IP and IT mice were similar in nature but more severe in IT mice. Additionally, 4 protein bands have been identified by serum IgE on western blots. These proteins compromise ~12.3% of the MACA proteins. In summary, sensitization to MACA was achieved with the IT protocol. Local lung responses including total IgE, inflammation and airway hyperreactivity were greater in the IT sensitized mice whereas the systemic total IgE response was greatest in the IP sensitized mice. (This abstract does not reflect EPA policy.)

1160 NATURAL RUBBER LATEX ALLERGY: A CRITICAL REVIEW.

B. L. Finley[1], D. J. Cher[1] and S. M. Hays[2]. [1]*Exponent, Menlo Park, CA and* [2]*Exponent, Boulder, CO.*

Several researchers have suggested that occupational contact with natural rubber latex (NRL) gloves caused an epidemic of type I NRL allergic responses, especially among health care workers. However, the risk factors, temporal trends, and natural history of the illness have not been well described. We critically reviewed the published epidemiologic literature on NRL allergy, summarizing the weight of evidence supporting latex gloves as a cause of NRL allergy. We excluded over 200 case reports of individual subjects (mostly health care workers) as they contained little epidemiologic information that related disease to exposure. The remaining studies (approximately 20) were assessed using standard epidemiologic criteria for study quality, bias, validity and causation. None met all of these criteria. Limitations included: lack of control groups, lack of blinded outcome assessment, the potential for selection bias, comparison of risks based upon prevalence rather than incidence differences, lack of control for duration of exposure and atopy (the genetic tendency for allergic reactions), and lack of a standardized method for diagnosis. Four studies (Gryzbowski, 1996; Ownby, 1996; NHANES III; NIOSH, 1999) showed the least potential for the biases mentioned above. Most notably, the study by NIOSH (NIOSH, 1999) satisfied most of the criteria for a well conducted epidemiology study, comparing current health-care workers with a matched control population. Overall, these studies indicated that the prevalence of latex sensitization in health care workers is not significantly higher than in the general population that has far less contact with latex gloves. In summary, the weight of evidence is inconsistent with the occurrence of an epidemic in health care workers. Further studies that improve upon the quality of previous work should be performed.

1161 ORAL SENSITIZATION TO PEANUT PROTEINS; A BROWN NORWAY RAT FOOD ALLERGY MODEL.

L. M. J. Knippels, S. Spanhaak and A. H. Penninks. *TNO Nutrition and Food Research Institute, Zeist, Netherlands*. Sponsor: B. Kulig.

We developed an oral sensitization protocol for food proteins for the rat. To further validate this model rats were exposed to various concentrations of peanut protein-extracts and immune-mediated effects after an oral and respiratory challenge were investigated.Young Brown Norway (BN) rats (n=8) were exposed to different doses of a crude peanut extract (CPE; 0.1, 1, 10 or 20 mg protein/ml/rat/day) or roasted (RPE; 1 mg protein/ml/rat/day) peanut-protein extract by daily gavage dosing during 42 days without the use of an adjuvant. Blood samples were obtained from the orbital plexus at weekly intervals. Peanut-specific IgE and IgG responses were determined by PCA and ELISA, respectively. After a resting period the animals received first an oral (100 mg protein) and one week later a respiratory (0.6% or 1% protein) challenge with peanut proteins and effects on the breathing frequency were studied. Preliminary results show that animals orally exposed to the different doses of both peanut-protein extracts developed specific antibodies. Almost all animals developed specific IgG antibodies against peanut-proteins except some animals exposed to RPE. The responses observed in the animals dosed with 1 mg of raw-peanut-protein extract were higher compared to the animals exposed to 1 mg of roasted peanut extract. Although not all PCA measurements have been performed yet, preliminary results show a more variable specific IgE response between the different treatments. Both oral and respiratory challenges with peanut proteins resulted in a temporary decrease in breathing frequency in a minority of animals. We show that Brown Norway rats develop specific IgG and IgE responses upon daily intra gastric dosing of peanut proteins without the use of an adjuvant. In this model, CPE seem to induce better antibody responses compared to RPE. Moreover, systemic immune-mediated effects after an oral and respiratory challenge are observed in a few animals. Additional analyses will be performed to compare the induced immune responses observed in this study with studies performed previously at our laboratory with other food allergens (hen's egg white and cow's milk) to obtain information on the relative allergenicity of these products to support that the BN rat may provide a suitable animal model to study the allergenicity of (novel) food proteins.

1162 DIVERGENT ANTIBODY RESPONSES INDUCED IN MICE BY FOOD PROTEINS.

I. Kimber[1], D. A. Basketter[2] and R. J. Dearman[1]. [1]*AstraZeneca Central Toxicology Laboratory, Macclesfield, United Kingdom and* [2]*Unilever Safety and Environmental Assurance Centre, Sharnbrook, United Kingdom.*

We have shown previously that systemic (intraperitoneal; ip) exposure of BALB/c strain mice to the protein allergen ovalbumin stimulates the production of both specific IgG and IgE. Treatment under identical conditions with bovine serum albumin, a food protein considered to have a relatively limited allergenic potential, elicits vigorous IgG but no, or only low titer, IgE antibody. We have now examined antibody responses provoked in mice following exposure to other food proteins: acid phosphatase derived from the potato, a common food protein which is suspected of having only very low allergenic potential, and the non-mitogenic agglutinin peanut lectin, an important allergenic constituent of peanut extracts. Mice received ip or intradermal (id) injections of protein in phosphate buffered saline on days 0 and 7. Fourteen days after the initiation of exposure, serum samples were prepared and analyzed for IgG antibody by enzyme-linked immunosorbent assay and for IgE content by homologous passive cutaneous anaphylaxis assay. Administration of potato acid phosphatase by id or ip routes stimulated IgG antibody pro-

duction but failed, even at doses of 10%, to elicit detectable IgE. In contrast, treatment with as little as 0.2% peanut lectin via either route of exposure provoked vigorous IgG and IgE antibody responses. The ability of peanut lectin to induce IgE antibody was not a general property of lectins, as administration of equivalent amounts of the agglutinin derived from potato, a non-mitogenic lectin with comparable molecular weight to peanut lectin, failed to stimulate detectable IgE. Taken together these data suggest that these proteins display in mice a divergent ability to stimulate IgE antibody following id or ip exposure to native protein which is consistent with their varying allergenic potential in man.

1163 THE ROLE OF THE LIVER IN THE MECHANISM OF ORAL TOLERANCE.

C. Ju and L. R. Pohl. *NIH, Bethesda, MD.*

It is currently believed that most drug-induced allergic reactions (DIARS) are caused by immunogenic conjugates formed from the reaction of a reactive metabolite of a drug with cellular proteins. However, it is not clear why more people do not develop immune reactions against protein adducts of drugs. One possible mechanism that may explain the low incidence of DIARS in many cases is oral tolerance, an antigen-specific immunological hyporesponsiveness induced by the oral administration of antigens. Although recent evidence suggests that the liver may have a role in the induction of oral tolerance against protein antigens, relatively little work has been done to explore the role of the liver in tolerance caused by the oral administration of drugs and other sensitizing chemicals. As an initial step to address this problem we fed the skin-sensitizing agent 2,4-dinitrochlorobenzene (DNCB) (250 mg/kg) to mice prior to sensitizing and challenging them by painting DNCB on the skin of the abdomen and ears, respectively. In another set of animals, DNCB was fed to mice and protein adducts were measured in the liver immunohistochemically and by immunoblotting with the use of polyclonal antibodies raised against the dinitrophenyl (DNP) hapten. It was found that the feeding of DNCB to mice inhibited the ear swelling effects of DNCB and led to the formation of protein adducts in hepatocytes, Kupffer cells and endothelial cells of the liver. Since these cells have been suggested to have a role in the induction of oral tolerance against protein antigens, they may also inhibit immune reactions against protein adducts of xenobiotics that are either transported to liver from other sites or are formed in the liver.

1164 LACK OF ALLERGENICITY OF RECOMBINANT LACTOFERRIN: ROLE OF GLYCOSYLATION.

R. J. Dearman[1], D. R. Headon[2] and I. Kimber[1]. [1]*AstraZeneca Central Toxicology Laboratory, Macclesfield, United Kingdom and* [2]*Agennix, Inc., Houston, TX.*

It has been shown previously that recombinant allergenic proteins such as the profilins are less allergenic than native proteins with respect to IgE binding and that such may be as a result of differential glycosylation of the recombinant and native materials. In the current experiments we have compared the ability of human native and recombinant forms of the iron-binding protein lactoferrin (LF) to induce IgE responses following systemic (intraperitoneal; ip) exposure of BALB/c strain mice. Mice received 250 µl of 1% w/v of protein by ip injection on days 0 and 7 and were exsanguinated 14 days after the initiation of exposure. Pooled sera were analyzed for IgE content by homologous passive cutaneous anaphylaxis assay and IgG antibody was measured by enzyme-linked immunosorbent assay. Administration to mice of native LF provoked vigorous anti-LF IgG and IgE antibody responses. Identical exposure to the recombinant material failed to elicit detectable IgE antibody and resulted in somewhat less vigorous IgG antibody responses. The failure of recombinant LF to induce IgE was not due to a loss of allergenic epitopes, since IgE antibody raised against native LF recognized equally both forms of LF. The ability of native, but not recombinant, LF to provoke IgE production was independent of the degree of iron saturation, with apo and iron-saturated forms of native LF stimulating high titer IgE responses. It was demonstrated that native and recombinant LF have identical amino acid sequences and 3D X ray crystallographic structure. Thus, the divergent IgE responses stimulated by the two forms of LF are likely to be a function of their differential glycosylation status.

1165 THE INVOLVEMENT OF EPIDERMAL GAMMA DELTA T CELLS IN THE INITIATION PHASE OF A CONTACT HYPERSENSITIVITY.

R. H. H. Pieters, R. Bleumink, M. Bol, C. de Heer and E. van 't Erve. *RITOX, Utrecht, Netherlands.* Sponsor: M. vandenBerg.

Components of the natural immune system are crucial in immunosensitization to allergic and autoimmunogenic chemicals, because they deliver both adjuvant as well as immunodeviating signals. In contact hypersensitivity, epidermal gamma delta T cells may play a role in this respect. Previously, we have shown that epidermal application of the contact allergen 2,4-dinitro-1-fluorobenzene (DNFB) induces migration of murine gamma delta T cells from the epidermis of the ear to the local auricular lymph node (ALN). In this study, the kinetics of the migration, cytokine production and localization in the lymph node of gamma delta T cells were characterized in C57Bl6 mice that were ear-painted with 1% (w/v) DNFB in a mixture of acetone and olive oil (AOO, 4:1). In a separate study, the BrdU staining method was used to detect proliferating cells in the epidermis. Earsheets and lymph node cryosections were prepared and stained for gamma delta T (mAb GL3). Lymph node cells were used for cytokine detection in gamma delta T cells by flowcytometry. Results show that gd T cells: -home to the medullary region of the ALN; -localize in the vicinity of antibody forming B cells; -produce IFNgamma and hardly if any IL4; -reappear in the epidermis from day 10 to form a normal staining pattern again by day 20. The reappearance is not accompanied by BrdU+ gamma delta T cells in the epidermis. Combined with findings of others that epidermal gamma delta T cells are formed only during prenatal phase of murine life we suggest that reappearing gamma delta T cells remigrate back from the lymph node. Results together indicate that gamma delta T cells, by producing the type-1 cytokine IFNgamma, may be involved in skewing of the contact hypersensitivity response towards a type 1-dependent DTH-reaction. In concordance, C57Bl6 are Th1-responding mice and Th2-responding BALB/c mice contain very few gamma delta T cells in the epidermis.

1166 CHEMICAL STRUCTURE ACTIVITY RELATIONSHIPS IN SKIN SENSITIZATION.

D. W. Roberts[1], G. F. Gerberick[2], L. Blaikie[3] and D. A. Basketter[3]. [1]*Unilever Research, Port Sunlight, United Kingdom.* [2]*Procter & Gamble Company, Cincinnati, OH and* [3]*SEAC Toxicology Unit, Unilever Research Colworth, Sharnbrook, United Kingdom.*

Knowledge of the underlying mechanisms of skin sensitization has enabled the development of (quantitative) structure activity relationships {(Q)SARS} for skin sensitizing chemicals. Typically these are based on physicochemical parameters representing the ability of the chemical to partition into the skin and its ability to react with skin proteins. In our most recent studies, fragrance chemicals containing aromatic and aldehydic groups and a series of diketones have been evaluated using a range of SAR techniques. Assessment of the "aromatic aldehydes" demonstrated that sensitizing ability was not related to the dipole across the aldehydic carbonyl group. This indicated that Schiff's base formation was less important than other reaction mechanisms, such as Michael addition. With the family of diketones, initial development of a QSAR suggested that an electrophilicity parameter based on Taft substituent constants derived for hard electrophiles having a reactive carbonyl group could be used as a measure of their chemical reactivity. Quantitative estimates of the skin sensitisation potential of these reactive hard electrophilic carbonyl compounds in the local lymph node assay (LLNA) showed a good correlation with their relative alkylation index (RAI) - an expression incorporating terms related to chemical reactivity, skin permeation and dose. Overall the findings reaffirm our view that physical organic chemistry is the key to understanding why some chemicals sensitise more strongly than others, while some do not sensitise at all, and provide further evidence of the value of the LLNA for SAR studies.

1167 COMPARATIVE SAR MODELING OF THE MOUSE LYMPHOMA ASSAY: THE NTP AND GENE-TOX DATABASES.

S. G. Grant[1], Y. P. Zhang[1], B. Henry[1], G. Klopman[2] and H. S. Rosenkranz[1]. [1]*University of Pittsburgh, Pittsburgh, PA and* [2]*Case Western University, Cleveland, OH.*

The *in vitro* mouse lymphoma assay (MLA) measures somatic mutation at an autosomal diploid locus heterozygous for a drug resistance marker. This assay has been evaluated as a possible short-term assay for identification of carcinogens. We have constructed structure-activity relationship (SAR) models

of MLA data from two sources, the U.S. National Toxicity Program (NTP), and the Gene-Tox working group (GT), using the CASE/MultiCASE expert system. The two models differed significantly in predictivity, complexity, inferred mechanisms and in concordance with carcinogenicity. Based on an evaluation of the different criteria used to 'accept' data into the two data sets, it was expected that the NTP assay was measuring primarily gene-specific mutation, which would result in a fairly simple model with high concordance with other mutational assays. The GT data, on the other hand, were expected to be measuring somatic segregation, or 'loss of heterozygosity', which is known to occur by a variety of mechanisms. We therefore expected this model to be more complex, and perhaps less predictive, owing to potential antagonism between chemicals acting by distinct molecular mechanisms. Instead, we found the GT MLA model to be the simpler and more predictive of the two, and to have a very high concordance with carcinogenicity. These data suggest that loss of heterozygosity is the most important event in the carcinogenic process, and that, despite the wide variety of mechanisms that have been shown to be possible for this step in carcinogenesis, in reality only one or a very few commonly occur.

1168 THE ROLE OF OUTDOOR DUST IN EXPOSURES TO CHEMICALS IN SOIL: CASE STUDIES FOR ARSENIC.

R. A. Schoof and J. S. Tsuji. *Exponent, Bellevue, WA.*

The development of risk-based remediation goals for contaminated soils is generally based on the assumption that human exposures are driven by direct contact with soil in the upper 3 to 6 inches. In the case of lead, exposures to the chemical in indoor dust are also considered. Less attention has been focused on the role of outdoor dust in such exposures. At most contaminated sites chemical concentrations in dust will reflect the concentrations in the underlying soil, and the relative contributions of outdoor dust and soil will be difficult to discern. However, at sites with active deposition of chemicals to soil from air, a marked concentration gradient may arise. Studies of arsenic exposures in children from two communities affected by copper smelters were used to examine the relative contribution of outdoor dust to the exposures. The arsenic concentrations in soil in Anaconda, MT and Ruston, WA were similar at the time of the studies; however, outdoor dust concentrations were approximately 10 times higher in Ruston due to the recent operation of the smelter. Urinary arsenic concentrations in Ruston children were also much higher. Prediction of urinary arsenic concentrations based on soil ingestion rates, and fractional arsenic absorption and urinary excretion indicated that only the outdoor dust could account for the observed urine concentrations in the Ruston children. This finding has significant implications for the design of studies of soil ingestion, and for remediation of contaminated soils.

1169 NONMONOTONIC DOSE RESPONSE TUMOR INCIDENCES USING STANDARD MODELS RESULTING FROM THE COMPENSATION OF INDUCED INCREASED MUTATION RATES BY CHANGES IN PARAMETERS INDUCED BY BODY WEIGHT DECREASES.

A. Turturro, Q. Zheng, B. S. Hass and R. W. Hart. *National Center for Toxicological Research, Jefferson, AR.*

Nonmonotonic dose-response curves, especially U- or J-shaped curves, are common results in tumor bioassays. There are a number of mechanisms that have been postulated to explain this, e.g., induced delays in proliferation rates resulting from DNA damage; induced DNA repair. However, the most common observation associated with these nonmonotonic curves is a loss in body weight (BW). The loss in BW results in a decrease in proliferation and an increase in apoptosis in organs that change their size with BW, such as liver. Using standard models for carcinogenesis, such as the Moolgavkar-Venzon-Knudson two-stage model, the impact of these changes on the tumor risk associated with agents that increase mutation rates (such as genotoxic agents) was evaluated. It was found that a 10% BW loss would compensate for at least a ten-fold increase in mutation rate, a 20% BW loss for at least a sixty-fold increase in mutation rate, and a forty percent BW loss for over a 500-fold increase in mutation rate. The competing effects on proliferation and mutation rates can result in U- or J-curves when mutagenic agents are administered, especially at the lower doses. Also, given the relative impact of the effects of BW and any mutagenic effect, these results also suggest that it is the effects of mutagens on proliferative parameters, not a direct effect on mutagenesis, that are most important in inducing tumors by these agents.

1170 ENHANCING THE RISK ASSESMENT PEER REVIEW PROCESS THROUGH STAKEHOLDER CONTRIBUTIONS.

D. A. Canter. *USEPA, Washington, DC.*

The EPA hazardous waste program has implemented a mechanism which enables stakeholders to highly controversial issues to contribute to the peer review process of associated risk assessment activities. All identified stakeholders are requested to submit nominations of highly qualified experts in the scientific disciplines identified in a notice published in the Federal Register. An independent peer review contractor selects from among the nominated scientists, making sure that none of the selected scientists has any real or perceived conflicts of interest. The peer review is in the form of a workshop open to the public at which stakeholders have the opportunity to make brief opening remarks and submit written comments. Depending on the complexity of the risk assessment issues to be addressed, the reviewers may then break into smaller discipline-specific subgroups. Following the meeting, the peer reviewers prepare a final report. To date, this mechanism has been used for four peer reviews of contentious risk assessment issues. Two of the peer reviews evaluated draft risk assessments of emissions from two facilites that burn hazardous waste, one evaluated the draft toxicity review document and proposed reference dose for a groundwater contaminant at a number of sites, and the fourth, which is still in process, will evaluate the toxicity testing strategy and associated protocols for a wastestream contaminant at one Superfund site. Stakeholder participation to date has been significant, both in terms of nominating experts and participating in the peer review workshops. Most stakeholders have supported the peer review process regardless of their positions on the risk assessment issues. This paper evaluates the lessons learned thus far and makes recommendations for future improvements. Such a model could be adopted by other governmental and private organizations for controversial risk assessment issues.

1171 CONSIDERATION OF ALTERNATE EXPOSURE PATHWAYS IN THE POSSIBLE RELATION TO PREVALENCE CHRONIC BERYLLIUM DISEASE.

D. Paustenbach[1], D. Deubner[2], M. Kelsh[1], Y. Lowney[3] and M. Kolanz[4]. [1]*Exponent, Menlo Park, CA,* [2]*Brush Wellman Inc., Elmore, OH.* [3]*Exponent, Boulder, CO and* [4]*Brush Wellman Inc., Cleveland, OH.*

The association between airborne beryllium concentrations and prevalence of chronic beryllium disease (CBD) has not shown a clear dose-response relationship. It is recognized that individuals become sensitized to beryllium (Be) before developing CBD. Studies have primarily focused on the respiratory route, although prior skin patch tests have shown that individuals can be sensitized by Be exposure to the skin. Therefore, the purpose of this study is to evaluate whether evidence exists for a multiple Be exposure pathway model. Our proposed model integrates inhalation, dermal and oral Be exposure pathways associated with the worker task, clothes, hands, gloves, workplace surfaces and ambient air. The study design considered alternative exposure pathways that may contribute to Be sensitization by comparing potential routes of exposure in two different Be manufacturing facilities. In a qualitative evaluation, worker activity and personal protective equipment use in a Be manufacturing facility in Elmore, Ohio (which have reported cases of CBD) were compared to a Be processing facility in Cardiff, United Kingdom (which have not reported cases of CBD). It was found that the worker activities and protective control measures varied significantly between the two Be manufacturing facilities. Skin exposures were likely higher at the Elmore facility compared to the Cardiff facility since workers in the Elmore facility had frequent skin contact and clothing contamination with Be. These observations suggest that if an extrapulmonary route of exposure can cause sensitization, less than complete controls on skin contact and ingestion can be the reason why attempts to control Be respiratory exposure do not alone reduce the occurrence of sensitization and disease. Once sensitization is achieved, inflammation in the lung may occur with very small incremental lung burdens of Be. Other factors such as size distribution of airborne particles and Be form may also explain the differences in CBD prevalence between the two facilities, but air levels alone may not be an adequate measure of dose.

1172 THE PERSISTENT, BIOACCUMLATIVE TOXICS (PBT) PROJECT: RISK-BASED INTENTIONS—TOXICOLOGICAL LIMITATIONS.

D. J. Paustenbach[1], H. Estreicher[2] and K. T. Connor[3]. [1]*Exponent, Menlo Park, CA,* [2]*Covington&Burling, Washington, DC and* [3]*Exponent, Landover, MD.*

US EPA has established the Multimedia PBT Strategy with the intention of making persistent, bioaccumulative toxics (PBTs) a regulatory priority. In addition, several other programs in the U.S. and abroad are in the process of establishing criteria by which additional compounds can be added to a PBT list. These programs have generally recognized the need for risk-based goals, i.e., global actions to restrict or ban specific compounds should be based on an expected benefit to human health; yet, there is currently no unified plan for the consideration of toxicology in establishing PBT criteria. We assert that formulae are needed that can be used to derive a combined measure of persistence (P), bioaccumulation (B), and toxicity (T) in order to establish criteria for identifying new PBTs. These formulae should be based on a matrix of the three P, B, and T parameters wherein a range of criteria values are available for each parameter, varying in accordance with the values of the other two parameters. However, a key limitation in the consideration of toxicity information in the categorization scheme is the dearth of available data for assessing human health risks from very low-level, long-term exposures to environmental chemicals. Animal studies using high doses are clearly uninformative and epidemiological studies rarely have the power to detect effects from very low-level exposures. Therefore, while the consideration of human health risks is essential in developing PBT regulations, it is currently hindered by the current state of the science. We conclude that the existing epidemiological database should be used to examine how any human health effects from known PBTs could have been predicted by other toxicological data; and that such an evaluation should be considered a prerequisite to the use of toxicity data in a PBT categorization scheme.

1173 A PROBABILISTIC HUMAN HEALTH RISK ASSESSMENT FOR THE INTAKE OF POLYCHLORINATED BIPHENYLS (PCBS) IN ANGLERS OF THE LOWER FOX RIVER, WISCONSIN.

K. Connor[1], V. Craven[2], N. Wilson[2], T. Iannuzzi[1], D. Ludwig[1] and B. Finley[3]. [1]*Exponent, Landover, MD,* [2]*Exponent, Farmington Hills, MI and* [3]*Exponent, Oakland, CA.*

Sediments and biota in the Lower Fox River (Wisconsin) have been shown to contain PCBs and, as a result, fish consumption advisories (FCAs) have been in place for the last several years. We recently conducted an assessment of the PCB-related health risks to recreational anglers of the Lower Fox River. Fish consumption rates were estimated from the recent Wisconsin Fishing and Outdoor Recreation Survey (WFORS) (TER 1999). A site-specific distribution of species-weighted, representative fish tissue PCB concentrations was derived based on the species that are caught and consumed by local anglers. Probabilistic risk estimates from this study suggest that fish consumption risks at the mean level of exposure are below applicable Wisconsin regulatory benchmarks— the incremental cancer risk was 1E-6, and the hazard index was 0.3. At the 95th percentile of exposure, the incremental cancer risk was 2E-5, and the hazard index was 3. The lack of a significant health risk might appear to conflict with the presence of the FCAs, particularly since a portion of our consumption rate distribution exceeds the FCA-recommended value. However, the FCA is based on assumptions regarding species-specific PCB concentrations and consumption rates that may not reflect the actual conditions measured in the WFORS survey and the biota analyses. Furthermore, the use of a probabilistic analysis minimizes the conservatism that is inherent in the point estimate assumptions used to establish the FCA. In summary, we conclude that the presence of an FCA does not necessarily imply that normal angler activities are associated with a health risk.

1174 IS SULFATE IN DRINKING WATER A HAZARD FOR INFANTS?

M. Goodman and J. S. Tsuji. *Exponent Health Group, Landover, MD.*

Health advisories related to U.S. drinking water regulations for sulfate have focused on its laxative effects in infants and unacclimated travelers. Of greatest concern is whether this effect would cause serious dehydration in infants. Early, limited studies indicated that sulfate levels in water in excess of 500 ppm might cause diarrhea in infants. Recent data from ecological studies in areas of high sulfate in water, experiments with human volunteers, and animal studies indicate that higher levels may be tolerated without adverse effects. Studies of infants in areas of high sulfate in water have not shown an increased prevalence of diarrhea with increasing levels of sulfate in water; although, sample sizes at higher sulfate levels are small and mothers are reluctant to use water containing higher sulfate levels due to potentially unpleasant odor and taste. Adult human volunteers similarly showed no increase in diarrhea incidence with sulfate levels up to 1,200 ppm (the highest level tested). Newborn swine fed sulfate in water mixed with formula did not show signs of loose stools until levels reached 1,600 ppm and higher and displayed no adverse effects on growth or development. Evaluations of whether sulfate levels are harmful should also consider that (1) The osmotic laxative effect of sulfate is not known to cause significant dehydration or loss of salt, and (2) normal laxative effects of breast milk exceed those of sulfate at the levels that occur naturally in water supplies. Thus, an advisory for sulfate in water, especially as low as 500 ppm, seems unnecessary.

1175 TRANSLATING THE RESULTS OF RISK CHARACTERIZATION INTO HUMAN HEALTH CONDITIONS (HHC) IN USEPA'S COMPARATIVE RISK FRAMEWORK METHODOLOGY (CRFM).

G. E. Rice[1], J. C. Lipscomb[1], B. Boutin[1], M. Brown[1], R. Clark[2], J. Cohen[3], T. Harvey[1], D. Miltner[2], P. Murphy[1], L. K. Teuschler[1], R. Rheingans[4] and L. R. Papa[1]. [1]*USEPA, NCEA, Cincinnati, OH,* [2]*USEPA, NRMRL, Cincinnati, OH,* [3]*Harvard Ctr Risk Analysis, Boston, MA and* [4]*CDC, ATSDR, Atlanta, GA.*

U.S. EPA's 1998 draft CRFM and Case Study (http://www.epa.gov/ncea/new.htm) combines elements of human health risk assessment and prevention effectiveness analysis to aid decisions about environmental health interventions posing disparate health risks. The CRFM compares the health consequences (e.g., cancer, microbial illness) and the financial costs associated with each intervention. The likelihood of human health effects and the general nature of the human health effects are estimated through evaluation of both experimental toxic endpoints and epidemiologic data. This effort focuses on one CRFM component, translating the health effects, as determined in the risk characterization step of the risk assessment paradigm, into incrementally-measurable HHC (e.g., a developmental effect, a clinical infection). The HHCs are the anatomic/physiologic properties that comprise the structure and functioning of the human body, defining the health-related quality of life. Differences in HHC's latency, duration and severity necessitate that they be represented using a common metric. A CRFM approach is to assess confidence in the accuracy of the translation into HHC based on the underlying data. In the Case Study, this translation allowed quantification of the impact on human health for two different drinking water treatment options: chlorination +/- pre-ozonation. Pre-ozonation greatly reduced the health impact of microbial illnesses, slightly reduced the health impact of both reproductive and developmental toxicity, and slightly increased the health impact of cancer-related effects, for an overall 68% reduction in combined health impact compared to chlorination alone.

1176 INDEPENDENT PEER REVIEW AND RISK VALUES DATABASE.

J. Patterson, A. Maier and M. L. Dourson. *Toxicology Excellence for Risk Assessment, Cincinnati, OH.*

Risk values developed by various organizations often differ due to scientific judgments, the mission of the organization, or because of the use of more recently published data. Toxicology Excellence for Risk Assessment (TERA) initiated an independent program to help validate the soundness of these risk values by making peer review available to all organizations. This process has resulted in the review of independently derived risk values for several dozen substances such as acrylonitrile, methylmercury, hexavalent chromium, Telone II, barium, arsenic, ethylene oxide, and soluble nickel salts (see http://www.tera.org/peer). A database of risk values, International Toxicity Estimates for Risk (ITER), provides a side-by-side comparison of values from government agencies and private organizations and makes the results of these peer review meetings widely available (see http://www.tera.org/iter on the Internet). To verify the utility of the program, we analyzed the ITER entries for 13 substances from the ATSDR/EPA 1997 list of top 20 priority substances. Of these, the noncancer risk values were the same for two chemicals between ATSDR and EPA, were different for 5 substances, and no value was published for the remainder. It is also important to provide a resource for compilation of risk values from multiple organizations to ensure identification of all available risk values. For example, we compared the cancer risk values for these same 13 priority substances and found that both EPA and Health Canada had published values for four substances, EPA but not Health Canada had a

risk value for four substances, and Health Canada but not EPA had a value for one substance. These comparisons demonstrate that the Peer Review program and ITER database are valuable tools for ensuring that risk assessors have ready access to the most current risk values.

1177 RESULTS OF QA/QC TESTING OF EPA BENCHMARK DOSE SOFTWARE VERSION 1.2.

J. Gift[1], W. Wheeler[2], R. Subramaniam[3], J. Caldwell[1], E. Yount[1], A. Mendoza[2] and R. W. Setzer[4]. [1]*USEPA NCEA, Research Triangle Park, NC.* [2]*Environmental Careers Organization, Boston, MA.* [3]*Sciences International, Alexandria, VA and* [4]*USEPA NHEERL, Research Triangle Park, NC.*

EPA is developing benchmark dose software (BMDS) to support cancer and non-cancer dose-response assessments. Following the recent public review of BMDS version 1.1b, EPA developed a Hill model for evaluating continuous data, and improved the user interface and Multistage, Polynomial and Power models. The BMDS system was subjected to an extensive QA/QC program, which included the independent verification of 7 dichotomous, 3 continuous and 3 developmental models. Each BMDS model was compared to an equivalent non-EPA model using data sets obtained from EPA cancer and non-cancer data bases. Many different configurations (combinations of options) for each of the EPA and non-EPA models were applied to 100 dichotomous or continuous dose-response data sets, resulting in well over 1,000 runs per model. Textual and graphical results of the model runs (e.g., maximum likelihood values, p-values, shape of the fitted curve) were collected and evaluated to determine strengths and weaknesses of each model. Preliminary results indicate that the BMDS dichotomous models calculate a BMD over 99% of the time, and fitted parameters such as benchmark dose and likelihood values from the BMDS Multistage model agree with values obtained from the THRESH model developed by Crump, Inc. The only deviations between the BMDS Multistage and THRESH were degrees of freedom differences for the chi-squared goodness-of-fit statistic resulting from a philosophical divergence on the appropriate approach for background estimates that reach the zero lower bound constraint. EPA will initiate a similar QA/QC analysis of several new BMDS models, including the Agency's new cancer model, a dichotomous Hill model and additional continuous (e.g., Hybrid) models in 2000.

1178 IMPROVING UNDERSTANDING OF WATER QUALITY AND HUMAN HEALTH ISSUES IN STUDENTS, TEACHERS, AND COMMUNITY MEMBERS IN RURAL OREGON.

E. Davis-Butts[1], M. M. Bloomfield[1], C. L. Dahl[2], H. Sherburne[3] and N. I. Kerkvliet[3]. [1]*SMILE Program, Oregon State University, Corvallis, OR,* [2]*CH2M Hill, Corvallis, OR and* [3]*Environmental Health Sciences Center, Oregon State University, Corvallis, OR.*

In 1996, a collaborative group at Oregon State University consisting of the Environmental Health Sciences Center, the Science and Math Investigative Learning Experiences (SMILE) program, and the Department of Public Health, was awarded a 4-year grant from the National Institutes of Environmental Health Sciences (NIEHS) to improve understanding of environmental health science by students, teachers, and community members in rural Oregon. The project makes use of the existing network of 75 teachers and over 700 minority and disadvantaged students in the pre-college SMILE program. Environmental health science activities are conducted at three main events: teacher development workshops, family science nights, and high school Challenge Weekends. Each year a different environmental health theme is addressed: chemical hazards in the home, indoor air quality, water quality, and food safety and human health. Year three of this grant focused on water quality and human health. Educational activities included visiting scientists laboratories, testing well-water for nitrates, and learning about risk assessment and major sources of water pollution This presentation describes the types of hands-on science activities conducted to educate teachers, students, and community members about water quality and human health.

1179 ENVIROHEALTH LINK SUMMER INSTITUTE AND WEB SITE-http://www.mpt.org/chl/home.html.

C. Mutryn. *Maryland Public Television, Owings Mills, MD.* Sponsor: M. A. Truch.

Maryland Public Television and the Johns Hopkins School of Hygiene and Public Health maintain a professional development program to provide middle and high school teachers with new scientific information and technology skills, so they can better incorporate environmental health science topics into their classroom curricula. The program keeps teachers up-to-date with current information on this science and offers strategies to transfer complex scientific information to their students in an understandable and usable way. The program consists of: 1) an annual week-long professional development Institute to provide "Master Teacher"-led environmental health lesson planning workshops, Internet and multimedia software workshops, lectures and panel discussions by Hopkins scientists, and hands-on laboratory and field experiences. 2) the resource-rich EnviroHealth Link web site, which (http://www.mpt.org/chl/home.html) provides teachers a place where they can get immediate answers to questions, updated environmental health information, Internet resources, and feedback from other teachers about environmental health-based classroom activities.

1180 HEALTH AND ENVIRONMENTAL RESOURCES AT THE UNIVERSITY OF WASHINGTON (HERE@UW).

J. F. Sharpe. *University of Washington, Seattle, WA.* Sponsor: D. L. Eaton.

HEALTH AND ENVIRONMENTAL RESOURCES AT THE UNIVERSITY OF WASHINTON (HERE@UW).Since 1994, the HERE@UW (Health and Environmental Resources for Educators at the University of Washington) programs has been working with K-12 teachers and students to make environmental health concepts a part of every child's early educational experience. This program includes an "Environmental Health for Educators" workshop that provides middle and high school teachers from all subject areas the content knowledge necessary to make environmental health (EH) a part of what they already do in the classroom. Participants learn about EH issues from community and university health professionals, share with us lesson plans they have developed and used in their classrooms, and earn continuing education credits for their participation. We have also developed two computer-based curricula. The first, Essentials of Cell Biology: Toxicology in Action, is an interactive CD-ROM that shows how cell biology connects with the principles of toxicology and risk. Resources in a virtual toxicology office allow the user to learn about cell biology and its direct link to human and environmental health. The second curriculum, Project Greenskate, is a web-based program that asks students to investigate the potential health concerns surrounding the development of a city park on a former industrial site contaminated with certain common environmental pollutants (lead, PCB, and TPHs). Using an engaging, game-like format, Greenskate introduces basic toxicology concepts such as dose-response, routes of exposure, thresholds for toxic effects, biotransformation, and risk assessment. HERE@UW has developed and is distributing "Tox in a Box," a resource kit that prepares EH professionals to visit K-12 classrooms by providing them with the materials and confidence they need to be a success. This presentation will emphasize how Tox-in-a-Box can help all SOT members become active in k-12 outreach.

1181 ENVIRONMENTAL AND RURAL HEALTH EDUCATION PARTNERSHIP.

L. Johnson, J. J. Denton, T. Davis, K. C. Donnelly, N. Ing and I. Ramos. *Center for Environmental and Rural Health, Texas A&M University, College Station, TX.*

The long-term goal is to develop an engaging model for enhancing environmental and health science education of grade levels 6-8 in rural settings. Environmental health in the rural setting is emphasized because of public concern for increased numbers of environmentally health-related diseases in rural Texas (birth defects, lead poisoning, etc.). Further, the Center for Environmental and Rural Health (CERH) provides knowledge and research experiences for outreach. Middle school grade levels are chosen to focus the application on the prime developmental period for social skills of public school students. Rural schools are least likely to receive information on environmental health issues, but may need it most. Specific aims are: 1) to develop engaging multimedia learning materials tailored for rural middle school students (develop a health science curriculum transmitted to public schools via currently established and popular Internet Web sites); 2) to provide professional staff development programs (develop/execute short courses for teachers that integrate implementing Web-based environmental and health science curriculum units that describe distant education design options with current state of knowledge in environmental health, and that enhance teachers' awareness of rural health problems and potential solutions); and 3) to provide a human interface and online interaction to establish partnerships between public middle school students and scientists directly (faculty and graduate students visit and present scientific findings and excitement of doing research to students directly and on-line). These specific aims will improve the public understanding of health sciences and encourage a large number of

students to enter and remain in science academic tracks to produce the nation's needed workforce for future scientists and related workers in biomedical and health-related sciences.

1182 ENVIRONMENTAL CYBER SCHOOLHOUSE.

M. O. Dereski and L. Pietrantoni. *Wayne State University, Detroit, MI.*

"Health Quest" is the first lesson of the Environmental Cyber Schoolhouse Curriculum. The Cyber Schoolhouse is a World Wide Web-based series of interactive, multimedia environmental health lessons geared toward seventh, eighth, and ninth grade students. The goals of the lesson are to: increase student's understanding of how basic scientific research provides information necessary to identify risk factors and safeguard human health; introduce students to science related careers; allow for virtual as well as hands on experimentation in the classroom. The focal point of the lesson is the main character Maria, a young child who has a mildly elevated blood lead level (15μg/dL) that has been detected through routine screening at a local health fair. The students will collect information about lead poisoning and prevention by joining Maria at the health fair and at her subsequent visit to her pediatrician's office. The students will gather enough information to allow them to outline a protocol to decrease Maria's exposure to lead by providing a lead safe environment and subsequently lowering her blood lead level. Field testing of the site is currently being carried out with two urban schools, one suburban school, and two urban community youth centers programs. This projected is supported by Grant 5 25 ES09881-02.

1183 THE TOXRAP™ NETWORK: A SUCCESSFUL MODEL FOR BRINGING TOXICOLOGY TO SCHOOLS.

J. K. Norman[1], B. D. Steinberg[2], A. R. Gotsch[2], B. Schlegel[2], B. L. Weidner[2] and C. A. McQueen[1]. [1]*University of Arizona, Tucson, AZ and* [2]*University of Medicine and Dentistry, Piscataway, NJ.*

In recent years the Society of Toxicology has placed increased emphasis on the need to communicate basic toxicological principles to the general public. The ToxRAP™ Network is an example of an outreach program that has successfully trained teachers to include toxicology concepts in their K-9 classrooms. This program, offered by the Environmental and Occupational Health Sciences Institute (EOHSI) and the Southwest Environmental Health Sciences Center (SWEHSC), used a train-the-trainer model to create local teacher expertise in environmental health sciences. Leadership Teams, made up of teachers and administrators, were brought to campus for a series of workshops focused on the award-winning ToxRAP™ curriculum series. As part of the training program, EOHSI and SWEHSC developed innovative methods for helping teachers understand scientific materials, develop regional implementation plans, and share program successes. The Teams returned to their school district or geographic area and trained other teachers to use ToxRAP™ curriculum. Twenty-seven teams from 11 states participated in the program. In turn, they trained approximately 750 teachers. All workshops were rated highly by participants. Formal and informal evaluations indicated that Leadership Teams successfully trained local educators to teach toxicology and related principles to their students. Several participating districts adopted the curriculum for district-wide implementation. Several projects demonstrating students' knowledge of environmental health risk assessment resulted, including a student-authored book about an environmental health investigation they conducted in their school. A train-the-trainer model is an effective method of integrating toxicology into K-9 curricula and helping students utilize scientific information to make decisions. This model can be used by universities and organizations such as local SOT chapters who wish to support environmental health sciences education for classroom teachers. (This project was supported by NIEHS, NIH [ES08221, ES05022 & ES06694].)

1184 SCHOOL LIFE SCIENCE LABORATORY: CLASS PROJECTS CENTERED ON THE EFFECTS OF TOXIC AGENTS ON AQUATIC MODEL ORGANISMS.

C. Aguilar[1], D. H. Petering[1] and R. Ryder[2]. [1]*Marine Freshwater Biom Sci Center, University Wisconsin-Milwaukee, Milwaukee, WI and* [2]*School of Education University Wisconsin-Milwaukee, Milwaukee, WI.* Sponsor: D. Eaton.

Scientists and educators have collaborated in creating a set of experiment modules that provide students with intensive problem based instruction focusing on the scaffolding of critical thinking skills to understand basic science and environmental health science concepts. These concepts are addressed within the context of hands-on classroom experiments with aquatic organisms—fish, frogs, and lower life forms-to participate in experiments related to bioaccumulation of chemicals and the developmental and neurobehavioral effects of toxic agents such as lead and ethanol. A one-week intensive summer workshop prepares teachers to implement the modules in their curriculum by combining a short course in central concepts of environmental health with extensive laboratory experience. Center scientists lead the experiments in the modules and the presentation of educational strategies to promote collaborative learning, higher order thinking, and strategic learning. Teachers also acquire training in the integration of instructional technology in the science curriculum and the use of multimedia and Internet communications tools to provide contact between students, teachers, scientists, and educators.Full support during the school year to implement the modules is provided. The results have been dramatic; many teachers consider work with the modules to be the highlight of their year, parents and school staff acquire a better understanding of environmental health concepts and students understand that they are engaged in authentic scientific learning. (Supported by NIEHS grant ES-08271.)

1185 RISKS & CHOICES: TEACHING ENVIRONMENTAL HEALTH SCIENCE.

B. W. Lloyd[1], A. M. Sarquis[1], J. C. Loper[2] and M. W. Tabor[2]. [1]*Miami University, Middletown, OH and* [2]*University of Cincinnati Medical Center, Cincinnati, OH.*

Built as a collaborative effort between Miami University's Center for Chemical Education and the University of Cincinnati Medical Center's Department of Environmental Health, *Risks and Choices* is a four-year, multifaceted teacher enhancement project for middle and high school teachers. In Year One 40 master science teachers participated in an intensive course in environmental health science principles held at Miami University and taught collaboratively by environmental health scientists from the University of Cincinnati and instructional staff from the Center for Chemical Education. These participants developed classroom environmental health science lessons for their students based upon their experience. During the 1997-98 academic year, these Facilitators tested these materials with over 3000 students. The revised instructional materials serve as the basis of instructional units for subsequent implementation workshops for teachers, grades 5-12. These workshops are taught by Teacher Leaders selected from the original master teachers. The workshop content includes investigating environmental and genetic factors affecting the interaction of environmental toxins and human health, principles of toxicology, risk assessment and communication, and the issues of ethics and environmental justice that impinge on decisions concerning environmental health issues. As a result of these workshops, we have a group of teachers throughout the country who are experienced in integrating environmental health issues into their regular curriculum. The final phase of our present program includes a series of one and two-day Academies that focus on important *Risks & Choices* topics. Academies are also being conducted by our affiliates in Texas, Connecticut, and California. Academy Resource Guides are being prepared for distribution.

1186 EATING FOR YOUR HEALTH.

H. Losey and M. O. Dereski. *Wayne State University, Detroit, MI.*

As part of the "Chemicals in My World" curriculum series, the lesson "Eating for Your Health" has been developed to deal with the nutritional and exercise concerns of today's youth. The goals of this lesson intended for students in grades six through eight, are to introduce them to the influence of good nutrition and exercise on human health and disease. The following topics are included in the lesson: the definition of a calorie with a hands on calorimetry experiment; testing of various foods for their chemical components (protein, sugar, starch and vitamin C); a fat extraction experiment; and demonstration of the energy (calories) expended in various forms of exercise. The topics covered in this lesson have been aligned with the national science education standards. The Eating for Your Health lesson has been presented to several groups of students and teachers around the Metropolitan Detroit area, with positive reviews and feedback. This lesson is currently available for use by educators in their own classrooms. (This work is supported by NIEHS Grant P30 ES06639.)

1187 AN ELECTROPHILE RESPONSE ELEMENT (EpRE) MEDIATES INDUCTION OF THE γ-GLUTAMYLCYSTEINE SYNTHETASE REGULATORY SUBUNIT (GCSl) GENE.

A. M. Erickson, H. R. Moinova and R. T. Mulcahy. *University of Wisconsin, Madison, WI.* Sponsor: A. Elfarra.

γ-Glutamylcysteine synthetase, the rate-limiting enzyme in glutathione synthesis, consists of a catalytic (GCSh) and a regulatory (GCSl) subunit. Two cis-elements, an AP-1 site (-340:-334) and an Electrophile Response Element (EpRE) (-301:-290), have been implicated in the regulation of GCSl expression in response to pro-oxidants. The AP-1 element has been shown to regulate the basal expression of GCSl gene. However, regulation of GCSl inducible expression is complex (see Moinova and Mulcahy. (1998) JBC 273:14683-14689 and Galloway and McLellan. (1998) Biochem. J. 336:535-539). The function of the EpRE in GCSl inducibility was further investigated by transient transfection of mutant and synthetic constructs. Mutation of the AP-1 site results in reduced basal expression, while mutation of both the AP-1 and EpRE sites leads to the elimination of induction by both tert-butylhydroquinone (tBHQ) and b-naphthoflavone (b-NF), confirming our earlier report. While deletion of the 3' sequences flanking the EpRE reduces both basal and inducible expression, retention of the core EpRE sequence still supports induction by tBHQ. Further analysis of potential cis-elements near the EpRE and AP-1 site is currently under investigation. Nevertheless, current studies support a functional role for the EpRE in mediating inducible gene expression by tBHQ and b-NF. (Funded by grants ES09749 and CA57549.)

1188 MOUSE GLUTAMATE-CYSTEINE LIGASE REGULATORY SUBUNIT: GENE STRUCTURE AND REGULATION BY OXIDATIVE STRESS.

W. A. Solis, D. W. Nebert, M. Z. Dieter, S. Freshwater and T. P. Dalton. *Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.*

The abundant cellular thiol, glutathione (GSH), maintains cellular redox homeostasis. Glutamate is first ligated to cysteine to form γ-glutamylcysteine by glutamate-cysteine ligase (GCL), the first and rate-limiting step in *de novo* GSH synthesis. GCL is an heterodimer composed of a 70-kD structural subunit (GCLS) having the catalytic activity and a 30-kD regulatory subunit (GCLR) that modifies the Km for the GCL substrate. We have cloned and characterized the structure of the mouse *Gclr* gene (spanning ~22 kb). An 8-fold induction of GCLR mRNA was observed after *tert*-butylhydroquinone (tBHQ) cell treatment. Nuclear run-on assays showed that GCLR mRNA accumulation is due to a higher rate of *Gclr* transcription (6- to 8-fold), compared to the 2- to 3-fold increase in *Gcls* transcription rate by tBHQ. RNase-protection analysis revealed two major and several minor transcription start sites within the proximal 300-bp adjacent to the start of translation. Transient transfection analysis with luciferase reporter constructs containing progressive promoter deletions (5 to 0.3 kb) show high basal and 2-fold-inducible expression. Nonetheless, a construct containing 0.3 kb of promoter that omits the 5' distal transcription start site shows a striking decrease in basal activity and no tBHQ-inducibility. In contrast, a construct in which the proximal transcription start site has been ablated gave low basal activity with no effect on tBHQ-inducibility. A putative electrophile response element (EPRE) is located within 0.3 kb of the 5'-most transcription start site. Site-directed mutagenesis demonstrated that this EPRE is not required, however, for tBHQ-induction. Robust expression of the *Gclr* gene is thus up-regulated by oxidative stress, at least in part, by *cis*-acting elements within 0.5 kb of the proximal promoter. (Supported by NIH Grant R01 AG09235.)

1189 GENE EXPRESSION ANALYSIS OF MOUSE LIVER AND MOUSE HEPATOCYTES FOLLOWING EXPOSURE TO OXIDATIVE STRESS AGENTS MENADIONE AND DIQUAT.

V. I. C. Oreffo, S. L. Doughty, T. Goodall, T. G. Hammond and C. N. Kind. *AstraZeneca R&D Charnwood, Loughborough, United Kingdom.*

Transcription profiling following compound exposure may be predictive for specific toxicity processes. Changes in gene expression were determined in livers from CD-1 mice given single (s.c.) dose treatments of menadione (40, 100 mg/kg) or diquat dibromide (50 mg/kg), two mechanistically related oxidative stress compounds. Animals were killed at 6,12, 24 and 48h following dosing. In addition, primary cultures of hepatocytes from untreated mice were exposed to 40μM menadione or 50μM diquat for 6 and 24h *in vitro*. The pattern of gene expression was compared between treatment groups and controls. Affymetrix GeneChip analysis was used to monitor the relative abundance of approximately 6,500 murine genes and ESTs. Approx. 3% to 6% of sequences on the GeneChip exhibited 2-fold or greater change in expression in treated groups compared to controls for both *in vivo* and *in vitro* studies. 32-41% and 24-31% of sequences showing 2 fold or greater change in expression were common to both chemical treatments *in vivo* after 6h and 24h respectively. Similarly, 32-51% and 13-37% of genes showing 2 fold or greater change in expression were common to both chemical treatments *in vitro* after 6h and 24h respectively. These results suggest a substantial percentage of genes are similarly affected following exposure to two related redox cyclers. Up-regulation of acute phase proteins and down-regulation of metabolic enzymes were found to be a consistent feature of *in vivo* toxicity. Analysis of *in vitro* samples revealed a markedly different pattern of gene expression, although there was a high concordance between the two oxidative stress compounds. This probably reflects differences in complexities of toxic responses *in vivo* versus *in vitro*.

1190 1,2-DICHLOROBENZENE ACTIVATES THE NUCLEAR TRANSLOCATION OF ACTIVATOR PROTEIN-1, NUCLEAR FACTOR-κ B AND ELECTROPHILE RESPONSIVE ELEMENT IN HEPATOCYTES ISOLATED FROM MALE FISCHER 344 RATS.

H. S. Younis[1], A. R. Parrish[2] and I. G. Sipes[1]. [1]*University of Arizona, Tucson, AZ and* [2]*Texas A&M University, College Station, TX.*

1,2-Dichlorobenzene (1,2-DCB), an industrial solvent, is a known hepatotoxicant. Work done by our group and others suggests that two oxidative events that mediate liver injury occur following 1,2-DCB treatment. The first oxidative phase is caused by the bioactivation of 1,2-DCB to reactive intermediates, while activation of inflammatory cells (i.e. Kupffer cells) mediates a second oxidative stress. To investigate the molecular and cellular processes of hepatocellular oxidative stress, hepatocytes were isolated from male Fischer-344 rats, and examined for glutathione disulfide (GSSG), a marker of oxidative stress, and enhanced nuclear translocation of activator protein-1 (AP-1), nuclear factor κB (NF-κB) and electrophile responsive element (EpRE) transcription factors following incubation with 1,2-DCB (3.55 or 7.12 nmol). Oxidative stress occurred in hepatocytes incubated with 1,2-DCB as concentrations of GSSG were maximally elevated (15% above control) by 1 hr, while glutathione concentrations progressively decreased to 78% of control by 6.5 hr. The activities of AP-1 and NF-κB were increased by as much as 3-fold by 6 hr of 1,2-DCB treatment as compared to control. Nuclear translocation of EpRE was also enhanced by 3-fold but occurred earlier (2 hr) following 1,2-DCB treatment. Moreover, jun N-terminal kinase was activated in 1,2-DCB treated hepatocytes by 0.5 hr and was maintained for up to 2 hr. These data suggest that 1,2-DCB induced oxidative stress triggers a cascade of molecular processes that promote the nuclear translocation of transcription factors involved in regulating the expression of oxidant sensitive genes in hepatocytes. (Supported by Center Grant P30-ES06694 and an AFPE Fellowship.)

1191 OXIDATIVE INJURY MODULATES EXTRACELLULAR MATRIX-REGULATED NFκB BINDING ACTIVITY IN VASCULAR SMOOTH MUSCLE CELLS.

E. E. Williams, E. Wilson and K. S. Ramos. *Faculty of Toxicology and Center for Environmental and Rural Health, Texas A&M Univ., College Station, TX.*

Repeated exposure of rats to allylamine induces proliferative (i.e. atherogenic) phenotypes in vascular smooth muscle cells (vSMCs). This atherogenic response is mediated by permanent changes in signaling pathways associated with integrin-coupled extracellular matrix interactions. The present study investigated the relationship between increased proliferative capacity and extracellular matrix signaling in vSMCs derived from rats subjected *in vivo* to an atherogenic allylamine regimen. Because extracellular matrix signaling is coupled to integrin-mediated activation of NF-κB binding, electrophoretic mobility shift assays and measurements of cell proliferation were conducted to compare cells seeded on plastic, collagen, fibronectin, and laminin. Allylamine cells displayed a proliferative advantage when seeded on plastic, fibronectin and laminin, but not when seeded on collagen. Five major NF-κB complexes were resolved on 7% non-denaturing polyacrylamide gels. The predominance of individual complexes was substrate-dependent with complexes 2, 3, 4 and 5 being prominently induced on plastic, laminin and fibronectin, and complexes 3 and 5 on collagen. Allylamine cells exhibited increased NF-κB binding relative to controls when seeded on plastic, laminin and fibronectin, but not on collagen, indicating that NF-κB binding activity correlates with the occurrence of proliferative phenotypes in vSMCs. These results implicate integrin-coupled NF-κB signaling in the induction of athero-

genic phenotypes by allylamine. (Supported in part by NIH Grant ES 09106 and a TAMU Interdisciplinary Grant.)

1192 ACTIVATION OF HEPATIC NF-κB BY POLYCHLORINATED BIPHENYLS (PCBS) *IN VIVO* AND IN CULTURED RAT HEPATOCYTES.

Z. Lu, B. T. Spear, L. W. Robertson and H. P. Glauert. *University of Kentucky, Lexington, KY.*

Polychlorinated biphenyls (PCBs) are environmental pollutants that, due to their persistence and biomagnification, raise concerns about the health consequences of long-term exposure. The mechanism of the promoting activity of PCBs has not yet been determined. Previous studies show that oxidative stress occurs during metabolism of PCBs, with the formation of free radicals and oxidative DNA damage, which may contribute to their promoting activity. In this study, we examined whether oxidative stress-sensitive transcription factors NF-κB or AP-1 would be induced by PCBs *in vivo* or in primary hepatocyte culture. Male Sprague-Dawley rats were injected i.p. with corn oil, 2,2',4,4',5,5'-hexachlorobiphenyl (PCB-153, 30, 150 or 300 umol/kg), 3,3',4,4'-tetrachloro-biphenyl (PCB-77, 30, 150 or 300 umol/kg) or both PCBs (30 or 150 umol/kg each). Rats were killed 2, 6, or 24 hours, or 2, 6, and 10 days after the PCB injection. Electrophoretic mobility shift assays were performed to determine the DNA binding activities of NF-κB and AP-1. The highest NF-κB DNA binding activity was observed in rats receiving higher doses of PCB-153 (150 and 300 umol/kg), with a peak occurring 2 days after injection. NF-κB activity was also increased in rats receiving both PCBs to a lesser extent, but no effect was seen in rats treated with PCB-77. Primary rat hepatocytes were cultured on collagen gels in serum-free L-15 medium with or without PCBs. NF-κB binding activity in hepatocytes culture was increased after a 48 hour exposure to PCB-153 (20 μM). These results show that hepatic NF-κB binding activity can be activated by specific PCBs *in vivo* and in cultured rat hepatocyte culture, indicating hepatic oxidative stress induced by PCBs. (Supported by ES 07380.)

1193 BCL-X1 AND BCL-2 EXPRESSION IN RAT VESTIBULAR AND AUDITORY BRAINSTEM NUCLEI FOLLOWING *IN VIVO* EXPOSURE TO *m*-DINITROBENZENE.

M. L. Hann and M. A. Philbert. *University of Michigan, Ann Arbor, MI.*

m-Dinitrobenzene (DNB) induces dose-dependent gliovascular lesions in auditory and vestibular brainstem nuclei with secondary damage to neurons. This study investigates Bcl-2 and Bcl-X_L expression in rat brainstem nuclei during DNB-induced neurotoxicity *in vivo*. Male Fisher 344 rats were given either 7 mg/kg (mild lesion) or 10 mg/kg (severe lesion) DNB in DMSO twice daily via intraperitoneal injection for 1-3 days and sacrificed at 24, 48, 54 and 72 h after the first dose. Immunohistochemistry and western immunoblotting were used to examine expression of Bcl-X_L and Bcl-2 in affected regions such as inferior colliculi, deep cerebellar roof, vestibular, and cochlear nuclei. Regions resistant to DNB-induced neurotoxicity, such as cerebellum and hippocampus, were also examined. Positive staining for Bcl-X_L and Bcl-2 was noted in neuronal somata, dendrites and proximal axons of brainstem neurons in rats given 60 mg/kg DNB at 10 mg/kg twice daily for three days. No expression of Bcl-X_L and Bcl-2 was observed in neurons and astrocytes of control brains. Western blotting revealed moderate basal expression of Bcl-X_L and Bcl-2 in the inferior colliculi, deep cerebellar roof and cochlear nuclei of all control and DNB-exposed animals. A time-dependent increase in Bcl-X_L and Bcl-2 expression was observed in cerebellum and hippocampus in animals exposed to 10 mg/kg DNB, but not in controls at any timepoint. DNB-related induction of both proteins began at 24 h and was maximal at 72 h. Increased levels of Bcl-X_L and Bcl-2 were observed by immunohistochemical analysis in all brainstem nuclei examined from animals exposed to 7 mg/kg DNB twice daily for three days. No increase in expression of Bcl-X_L and Bcl-2 was observed by western blot analysis with the 7 mg/kg DNB dosing regimen. These results suggest that differential expression of Bcl-X_L and Bcl-2 correlates with lack of susceptibility to DNB neurotoxicity. (This research is supported by PHS-NIH Grants ES08846 & ES06103.)

1194 DIFFERENTIAL EXPRESSION AND ACTIVITY OF *Nrf2* IN LUNGS OF HYPEROXIA-SUSCEPTIBLE AND -RESISTANT MICE.

H. Cho, S. P. M. Reddy, L. Zhang, A. E. Jedlicka and S. R. Kleeberger. *Johns Hopkins University, Baltimore, MD.*

Acute respiratory distress syndrome (ARDS) is a major lung disease mediated by reactive oxygen species. An *in vivo* model of acute lung injury with similar features of ARDS has been produced by administration of hyperoxia (>95% oxygen) to animals. Among inbred mouse strains mice, C57BL/6J (B6) have greater sensitivity to hyperoxia than other inbred strains, including C3H/HeJ (C3). We recently identified significant hyperoxia-susceptibility quantitative trait locus (QTL) on mouse chromosome 2. A strong candidate gene within this QTL is *Nrf2*, an essential transcriptional regulator of antioxidant enzymes that play key roles in protecting cells against carcinogenicity and oxidative stress. To test the hypothesis that *Nrf2* confers differential susceptibility to oxygen toxicity, *Nrf2* mRNA expression (by reverse transcriptase-polymerase chain reaction) and DNA binding activity (by gel shift/supershift analyses) were evaluated in the lungs of C3 and B6 mice exposed to hyperoxia. Exposure markedly and similarly induced *Nrf2* mRNA expression at 90 min and 6 hr in both strains, compared to strain-matched air-controls. The mRNA levels returned to basal levels at 24 hr in both strains. A second increase in *Nrf2* mRNA expression occurred after 48 hr in C3 mice; in B6 mice, the mRNA level did not increase again until after 72 hr. The basal NRF-2 activity was greater in B6 mice compared to C3. After 90 min exposure, NRF-2 activity increased in C3 mice proportional to gene expression and remained elevated until 48 hr. In contrast, NRF-2 activity was markedly decreased in B6 mice by 6 hr and continued to decrease during the exposure. These results indicate that there is a significant strain-specific variation in *Nrf2* expression and activity after hyperoxia exposure. The results also suggest the early increase in NRF-2 activity conferred greater protection against oxidant injury in resistant C3 mice, while decreased NRF-2 activity may enhance susceptibility in B6 mice. (Support: ES 09606, HL 57142.)

1195 ACTIVATION OF ACTIVATOR PROTEIN-1 BY REACTIVE OXYGEN SPECIES ASSOCIATED WITH ASBESTOS.

V. Vallyathan, M. Ding, X. Shi and V. Castranova. *NIOSH, Morgantown, WV.* Sponsor: D. Jones.

Inhalation of asbestos causes alterations in cell signaling cascades, gene expression, cell injury and cell proliferation which may lead to pulmonary fibrosis, lung cancer, or mesothelioma. Asbestos-mediated free radical reactions are believed to trigger a number of cellular and molecular events that may promote fibrogenesis and carcinogenesis. Because activator protein 1 (AP-1) plays an important role in pre-neoplastic-to-neoplastic transformation, tumor promotion and metastasis, we studied the possible activation of AP-1 *in vitro* in cultured JB6 cells and *in vivo* using transgenic mice after exposure to crocidolite asbestos. *In vitro* exposure to asbestos, caused a dose- and time-dependent activation of AP-1 in cultured JB6 cells. Exposure of mice to crocidolite asbestos caused a significant (22-fold) activation of AP-1 in bronchiolar tissue compared to a moderate 10-fold increase in the lung tissue. The induction of AP-1 in asbestos exposure appears to be mediated through the phosphorylation of mitogen-activated protein kinases, Erk 1 and Erk2. Hydroxyl radical scavengers inhibited asbestos-induced AP-1 activation. These data support the hypothesis that oxygen radical mechanisms may be associated with pulmonary fibrosis and carcinogenesis.

1196 METHODS FOR MEASURING EXPRESSION OF IL-1 ALPHA, NITRIC OXIDE SYNTHASE, AND NITRIC OXIDE IN F-344 RAT SKIN IN RESPONSE TO DERMAL EXPOSURES TO FUELS OR SOLVENTS.

M. Kabbur[1], C. Garrett[2], K. Geiss[2], W. Brinkley[1] and J. McDougal[2]. [1]*AFRL/HEST, Wright-Patterson AFB, OH and* [2]*Geo-Centers, Inc., Dayton, OH.*

Organic chemicals such as jet fuels and solvents are recognized to cause skin irritation after dermal exposures. The molecular responses to these chemicals that result in acute irritation are not understood well enough to allow the establishment and choice of safe exposure limits. We conducted studies to determine the feasibility of measuring various inflammatory factors, including IL-1 alpha, nitric oxide synthase, and nitric oxide. Male F-344 rats were exposed to organic chemicals for one hour using Hill Top Chambers®. Three hours after the exposures treated and control skin samples (1 to 1.5g) were collected. Light microscopy evaluation was performed on formalin-fixed and

paraffin embedded skin sections using anti-rat IL-1 alpha and anti-rabbit nitric oxide synthase polyclonal antibodies. Minced skin was placed in liquid nitrogen and pulverized with a stainless steel mortar and pestle, and then homogenized in Tris buffer solution using an ultrasonic homogenizer. After centrifugation, the supernatant was utilized for measurement of IL-1 alpha using commercial ELISA kit. Spectrophotometry was used to measure nitric oxide production using the Griess reagent. Treated skin showed nitric oxide levels increased 1.5- to 2-fold. Immunohistochemical staining indicated increased (two-fold) expression of IL-1 alpha and nitric oxide synthase compared to control. These methods will be appropriate to determine the time profile of irritant changes with solvent and fuel exposures. (Supported by CDC/NIOSH RO1 OH03654-01 and AFOSR 92HE05COR.)

1197 INDUCTION OF TRANSFORMING GROWTH FACTOR-BETA1 IN SPLENOCYTES OF ANILINE-TREATED RATS.

M. F. Khan, X. Wu and G. A. S. Ansari. *University of Texas Medical Branch, Galveston, TX.*

Fibrosis appears to be an important preneoplastic event in the splenic toxicity of aniline. We have shown that aniline exposure in rats causes oxidative stress in the spleen and hypothesize that this oxidative stress may cause the induction of fibrogenic cytokines leading to splenic fibrosis. To demonstrate the role of cytokines in the aniline-induced splenic fibrosis, male SD rats were given 1 mmol/kg/day aniline hydrochloride (by gavage in 0.5 ml water) for 7 days and euthanized 24 hr following the last dose. Aniline exposure caused significant increases in spleen weights (97%), splenocyte cell counts (25%) and malondialdehyde-protein adducts (56%) as compared to controls. Transforming growth factor-beta1 (TGF-b1), which is considered one of the most fibrogenic cytokines, was quantitated in the splenic cells and culture supernatants by an ELISA. Total TGF-b1 content in the freshly isolated splenocytes from aniline-treated rats showed a 30% increase ($p<0.01$) as compared to the controls. The culture supernatants (from splenocytes cultured for 24 hrs) from aniline-treated rats showed a 60% increase in total TGF-b1 ($p<0.01$) as compared to controls. Our results show that aniline exposure causes induction of TGF-b1 in splenocytes and support the role of cytokines in the aniline-induced splenic fibrosis.

1198 HYPEROXIA DIMINISHES GLUTATHIONE REDUCTASE (GR) ACTIVITIES IN MURINE LUNG AND LIVER MITOCHONDRIA BUT NOT IN NUCLEI.

Y. L. Wong, C. V. Smith, H. W. McMicken and S. E. Welty. *Baylor College of Medicine, Houston, TX.*

Underdeveloped antioxidant systems in premature infants contribute to many of the diseases that are common in these individuals. Glutathione (GSH) serves in reduction of oxidants, with concomitant formation of glutathione disulfide (GSSG), which is reduced back to GSH by GR. Plasma GSH levels are low and GSSG levels are high in premature infants, suggesting deficiencies in GSH synthesis and/or GR activities. In the present studies, we exposed C57/BL6 mice to FiO_2>95% for 0, 24, 48 and 72h and prepared liver and lung subcellular fractions by differential centrifugation, purifying the nuclei using a discontinuous sucrose gradient. At all time points, GR activities were higher in nuclei than in either cytosol or mitochondria. Hyperoxia did not affect nuclear GR activities prior to onset of lung injury. In room air (RA), nuclear GR activities were 16.7 (0.9) [mU/mg protein (SEM)] in livers and 80.1 (3.2) in lungs. Mitochondrial GR activities decreased as a function of time in hyperoxia, from 10.5 (0.6) in RA to 6.6 (0.7) at 48h in livers and from 14.7 (0.8) to 11.2 (0.4) in lungs ($p<0.05$ in both). The decreases in mitochondrial GR activities in the lungs and livers of animals exposed to hyperoxia preceded increases in lung weights, suggesting that diminished mitochondrial GR activities may have contributed to the development of hyperoxic lung injury. Therapeutic strategies based on augmenting GR activities in lung and/or liver mitochondria to maintain highly reduced GSH/GSSG ratios in these compartments may attenuate or delay the development of hyperoxic lung injury. The consistently high nuclear GR activities suggest that GR is essential for normal functioning in this critical cellular compartment, although the exact roles are yet to be defined. 1199 ESTROGEN AND PROGESTERONE RECEPTOR EXPRESSION AND LOCALIZATION IN THE RAT UTERUS AFTER ADMINISTRATION OF THE XENO-ESTROGENS BISPHENOL A, P-*TERT*-OCTYLPHENOL AND *O,P'*-DDT.

P. Diel, K. Smolnikar, T. Schulz, U. Laudenbach and H. Michna. *DSHS, Cologne, Germany.* Sponsor: B. Stahl.

The potential impact of xenoestrogens on human health is currently under debate, also due to the lack of data. To analyze molecular mechanisms of the action of xenoestrogens we have investigated the expression and localization of the estrogen receptor (ER) and the progesterone receptor (PR), after administration of bisphenol A (BPA), p-tert-octylphenol (OCT) and o,p'-DDT (DDT) in comparison to ethinylestradiol (EE) in the uterus of ovariectomized female DA/HAN rats. The animals were treated for 3 days p.o. with the xenoestrogens BPA (5, 50 and 200 mg/kg/day), OCT (5, 50 and 200 mg/kg/day), DDT (20, 100 and 500 mg/kg/d) and EE (0.1 mg/kg/day). Expression and localization of ER and PR protein was analyzed using immunohistochemistry. The wet weight of the uterus was dose dependently stimulated after administration of DDT (100 and 500 mg/kg/day) and after administration of 200 mg/kg/day OCT. A slight but significant stimulation was detectable after administration of 200 mg/kg/day BPA. Immunohistochemical analysis revealed estrogen like reactions in ER and PR expression and localization after dose dependent administration of OCT and DDT at doses 1000 to 10000 times higher than EE. No changes could be detected after administration of BPA at any dose administered. A comparison of these data to the uterotrophic response revealed that estrogen like changes in ER and PR expression and localisation after administration of OCT and DDT occurred at doses where no uterotrophic response was detectable. Interestingly, the tiny increase of uterine wet weight after administration of BPA does not correlate with an alteration of the expression pattern of ER and PR in the uterus. In summary, our data provide evidence that in regard to ER and PR expression and localization OCT and DDT act in the uterus in a typical estrogen like manner but with a low potency. The uterotrophic effect of BPA seems to be very tiny even if compared to OCT and DDT. Further investigations to elucidate potential alternative molecular mechanisms, e.g., (anti-) androgen-like action, are ongoing.

1200 THE EFFECTS OF LOW AND HIGH DOSE PRENATAL EXPOSURE TO BISPHENOL A ON FEMALE RAT OFFSPRING.

X. Wu and I. Chahoud. *Institute of Clinical Pharmacology and Toxicology, Berlin, Germany.* Sponsor: D. Acosta, Jr.

Bisphenol A (BPA) is a monomer of polycarbonate plastics used in many consumer products. Many studies have shown that BPA has estrogenic activity both *in vitro* and *in vivo* experimental test systems. It has been reported that a low dose of BPA may affect male offspring in mice differently from a high dose. As effects on female offspring have been neglected, the aim of the present study was to investigate the effects of high and low doses of BPA on the reproductive function in female offspring after prenatal exposure. Pregnant Sprague Dawley rats were randomly assigned to 4 groups (20 rats per group), housed singly, and maintained under standard conditions. Two groups were treated by gavage with doses of 0.1 and 50 mg Bisphenol A/kg b.w. on day 6-21 post conception. The third group received 0.2 mg/kg b.w. of 17-alpha-estradiol as positive control, and the control group was given the vehicle on the same days. In the female offspring the following endpoints were investigated: mean age at vaginal opening, length of estrous stage, organ weight, histological examination, sexual hormone level, and expression of c-fos and estrogen receptor genes in uterus. The results show that the mean age at vaginal opening (in days) was higher in the low dose group of BPA (49.4±2.7) and the estradiol treatment group (46.2±1.7) compared to the control (44.0±4.0); in contrary, it was lower in the high dose group of BPA (41.8±2.9 day). The length of the estrous stage was longer than 1 day only in 17% of the control females. In all estradiol females the length fasted more than 1 day. This effect was more pronounced in the lower dose of BPA (74%) than in the high dose (60%). Relative uterine weight was measured in estrous (ES) and diestrous (DS) stage. It decreased in the estradiol group in both stages (ES=0.160±0.024, DS=0.118±0.003) when compared to the control group (ES=0.256±0.055, DS=0.192±0.024). Such changes could not be confirmed in BPA treatment groups. The gene expression, given as median, of the estrogen receptor alpha was up-regulated in the high BPA dose level in ES and DS (ES=81.7%, control: 54.0%; DS=117.7%, control: 42.7%). In the estradiol group the effect occurred only in DS (66.4%). In the low dose of BPA this effect was not observed. Generally, it can be concluded that different doses of BPA may induce different effects in different tissues. Additionally, effects observed in one dose cannot always be used to be extrapolated to others. (Support: BMBF.)

1201 AN ESTROGEN EQUIVALENTS COMPARISON OF DAILY DOSES OF BISPHENOL A FROM POLYCARBONATE BABY BOTTLES VS. NATURALLY-OCCURRING COMPOUNDS.

T. Bernhardt[1], B. Finley[1], M. Goodman[2] and K. Connor[2]. [1]*Exponent, Oakland, CA and* [2]*Exponent, Landover, MD.*

It has recently been suggested that potential migration of residual bisphenol-A (BPA) from polycarbonate baby bottles may pose an endocrine disruptive health threat to infants. Although high doses of BPA in animals can cause estrogenic effects, such as increased uterine wet weight, conflicting evidence exists as to whether such effects occur in animals at the much lower doses that might be experienced by bottle-fed infants. To date, there have been no studies to determine whether estrogenic effects might occur in infants exposed to BPA through product use. In order to accurately assess whether such effects might occur, it is important to account for the daily estrogenic dose associated with the presence of natural estrogens and other "estrogen-like" hormones in breast milk and cow's milk. In addition, most vegetable-based baby foods contain high levels of phytoestrogens that are more potent as estrogens than BPA. We present a comparative analysis of the daily infant estrogenic dose associated with the presence of BPA in consumed liquids (breast and cow's milk, juices, etc.) vs. the dose associated with the consumption of naturally occurring estrogenic compounds in an infant's diet. Data from recent extraction studies conducted with polycarbonate bottles were used to derive estimates of BPA concentrations that might exist in liquids that are contained in the bottles under a variety of food preparation conditions. Measured concentrations of naturally occurring estrogenic compounds in baby foods were taken from the primary literature. Published estimates of the volume and composition of the daily infant diet were used to derive plausible estimates of daily doses of BPA and naturally occurring estrogenic compounds for a variety of conditions. These doses were then normalized to "estrogenic equivalent" doses using published estimates of the relative estrogenic potency of BPA and the naturally occurring compounds. Our findings indicate that the maximally plausible estrogenic dose of BPA that might be experienced by an infant is several hundred times lower than the estrogenic equivalence of isoflavones consumed with soy-based infant formulas. Moreover, this dose of BPA would have less than 2 percent of the estrogen equivalence of naturally occurring estradiol in human breast milk. Based on these findings, we conclude that migration of BPA from polycarbonate bottles poses no endocrine disruptive health risk to infants.

1202 THE EFFECT OF SAMPLING DESIGN ON THE OUTCOME OF ENDOCRINE, REPRODUCTIVE AND DEVELOPMENTAL TOXICITY STUDIES.

D. B. Janszen, B. A. Elswick and F. Welsch. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

A common experimental design in endocrine and reproductive toxicity evaluations is to expose the pregnant dam to a test chemical, and then to measure the response of interest in littermates at subsequent points in time. Litter sizes may be standardized soon after birth, or only a single randomly selected offspring per sex from each litter may be examined at each time point or become a parental animal for the next generation. In a study of the weak xenoestrogen bisphenol A (BPA) [see preceding abstract], possible treatment-related effects on ventral prostate (VP) fresh weights were found in rat offspring at six months of age using a study design in which one or two male pups per litter were randomly selected. However, in subsequent BPA and di-n-butyl phthalate studies, where VP weights of entire litter complements were examined, large intralitter variability of this specific end point became apparent. These data led us to believe that the earlier VP BPA results were likely due to selecting one or two males per litter where intralitter variability was large. This hypothesis was tested by simulating the effects of sampling design (one, two, or three male pups randomly selected from the full litter complement). These simulations used data from actual experiments as well as data created for the simulation. After 1000 simulations, the measure of the combined iterations was the percentage of correctly predicted results, defined as to whether there was a treatment effect at the significance level of $p<0.05$. False positive (Type I) or false negative (Type II) interpretations about treatment effects may be made more than 50% of the time when only one pup per litter is randomly selected. These statistical power considerations raise concern about selection of one pup per litter for highly variable end points.

1203 EFFECTS OF PERINATAL EXPOSURE TO LOW DOSES OF BISPHENOL A IN MALE OFFSPRING OF SPRAGUE-DAWLEY RATS.

B. A. Elswick, D. B. Janszen, J. C. Gould, D. B. Stedman and F. Welsch. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Bisphenol A (BPA) is a constituent of epxoy resins and polycarbonate plastics used in the packaging of canned foods and beverages. Leaching of BPA into the contents may result in ingestion of small quantities. BPA is a relatively weak estrogen receptor agonist and is suspected of perturbing endocrine homeostasis. Here we describe reproductive and developmental effects of BPA on male F1 offspring from birth to adulthood. Two replicate blocks of 8 dams/treatment group (resulting in an overall sample size of 13-16 pregnancies/group) consumed drinking water with 0, 0.005, 0.05, 0.5, 5 or 50 mg BPA/L from gestation day 2 through postnatal day (PND) 21. Estimated daily intakes ranged from ~0.001 to ~10 mg/kg/day. BPA treatment neither affected anogenital distance nor body weights on PND 2, or body weight gains up to PND 21. Additionally, BPA did not affect preputial separation, a developmental landmark. On PND 21, 41, and 177, one or two randomly selected male pups were necropsied. BPA treatment did not alter either fresh organ weights or hormone levels on PND 21 and 41. Additionally, Western blot analysis for androgen receptor in ventral prostates (VP) from PND 41 males did not display BPA related changes. At PND 177, BPA exposed rats did not display significant differences in hormone levels, sperm counts, or immunohistochemical VP AR levels. No significant alterations emerged when fresh organ weights were compared to concurrent controls except for a significant increase in VP weights in the 0.05, 5 and 50 mg BPA/L dosing groups. The apparent weight increase was not dose-related and occurred without concomitant histological changes. Large intralitter variability of VP fresh weights may be a confounding factor in these results. In a mating study, the males displayed no detectable changes in fertility. Aside from the equivocal VP effect, the data indicate that under the indirect pre- and postnatal BPA exposure conditions (drinking water of the dam and lactation) the differentiation and function of the reproductive system in male rats appeared to be unimpaired.

1204 EFFECTS OF PERINATAL EXPOSURE TO LOW DOSES OF BISPHENOL A ON FEMALE OFFSPRING OF SPRAGUE-DAWLEY RATS.

F. Welsch, B. A. Elswick, and D. B. Stedman. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Bisphenol A (BPA) is a constituent of polycarbonate materials used in packaging canned foods and beverages. Leaching into the contents may result in human ingestion of small quantities of BPA. BPA is a weak estrogen agonist suspected of being able to perturb endocrine homeostasis. The study design consisted of two replicate blocks of 8 dams/treatment group (resulting in an overall sample size of 13-16 pregnancies per treatment). Dams consumed drinking water with 0, 0.005, 0.05, 0.5, 5 or 50 mg BPA/L from gestation day 2 through postnatal day (PND) 21 with estimated daily intakes ranging from ~0.001 to 10 mg/kg/day. Diethylstilbestrol (DES; 0.05 mg/L) was used as an estrogenic reference chemical. The present report describes the reproductive development and function of female F1 offspring randomly selected from each litter for specific end points in comprehensive postnatal assessments. The observations extended from PND 2 to ~10 months of age. There were no differences in anogenital distance and body weights on PND 2 among BPA treatments compared to control, nor were there any differences in body weight gains up to PND 21. However, there were significant reductions in body weights from age-matched concurrent controls in DES exposed offspring. This body weight reduction was later recovered in the adult. DES females were younger than control offspring when achieving the developmental landmarks of vaginal opening and first estrus, but the BPA-treated rats were unaffected. Estrous cyclicity up to ~7 months and ovarian follicle counts at 4 months of age were not different between control and any of the DES or BPA treated females. Neither fertility and fecundity in continuous breeding evaluations nor lordosis behavior were affected in any treatment groups. No meaningful differences were found in the organ weights at various ages. Overall, the data indicate that under the indirect pre- and postnatal BPA exposure conditions (drinking water of the dam and lactation) the differentiation and function of the reproductive system in female rats appeared to be unimpaired.

1205 ENDOCRINE DISRUPTION ACTIVITY OF ENDOSULFAL IN YEAST TRANSFORMANTS AND IN MICE.

S. H. Jeong, J. H. Cho and J. M. Park. *National Veterinary Research & Quarantine Service, Anyang, Republic of Korea.* Sponsor: J. Chung.

Recently, the concern for chemicals suspected as one having steroid-like activity is increased higher than ever. Endosulfan, an organochlorine pesticide of the cyclodiene group, widely used for control of insects in crops, is known as a mutagen and reproductive toxicant. Human health risk can be affected in the case of ingestion of livestock product or crops contaminated with this hazardous chemical.We studied the endocrine disruption activity of endosulfan in yeast transformants contained the human estrogen, androgen or progesterone receptor along with the appropriate steroid responsive elements upstream of the β-galactosidase activity. We also compared the endocrine disruption activities in yeast transformants to those in mice to know if the yeast transformants are reliable tool for screening the endocrine disrupters.Endosulfan induced increase of β-galactosidase activity 2-3times more than control in estrogen receptor gene transformed yeast at the doses of more than $2.5x10^{-4}$M and androgen receptor gene transformed yeast at the doses of more than $2.5x10^{-5}$M. In progesterone receptor gene transformed yeast, β-galactosidase activity was increased 5-6 times more than control at the doses of more than $5x10^{-6}$M. The relative weight of adrenal gland was increased and estrus cycle was delayed in female mice treated with endosulfan(10mg/kg B.W.) via gavage once per day for 14 days. The contents of estrogen and progesterone in serum were decreased significantly in endosulfan-treated female mice at pre-estrous stage. The sperm motility was decreased significantly in male mice exposed orally with 10mg/kg B.W. of endosulfan once per day for 48 days.These results suggested that endosulfan could react with progesterone receptor moderately and with estrogen and androgen receptor weakly and be an endocrine disrupter in both of yeast transformants and mice. In addition, yeast transformants contained the human estrogen, androgen and progesterone receptor combinated with the steroid responsive elements can be simple and reliable screening tools for the investigation of endocrine disrupters.

1206 LOCALIZATION OF GLUTAMATE CYSTEINE LIGASE (GLCL) SUBUNIT MRNAS WITHIN THE RAT OVARY.

U. Luderer[1], D. Diaz[2], T. J. Kavanagh[2] and E. M. Faustman[2]. [1]*University of California at Irvine, Irvine, CA and* [2]*University of Washington, Seattle, WA.*

GLCL, the rate-limiting enzyme in glutathione (GSH) synthesis (also known as gamma-glutamylcysteine synthetase), is expressed in most tissues, including the ovary. We have previously observed that ovarian reduced GSH and GLCL catalytic (GLCL-c) and regulatory (GLCL-r) subunit mRNA levels fluctuate significantly during the rat estrous cycle. Such fluctuations suggest that ovarian GSH synthesis may be hormonally regulated and that GSH may play a role in normal follicular development. In order to begin to delineate the role of GSH in follicular development we used in situ hybridization to study GLCL-c and GLCL-r mRNA expression in the rat ovary during the 4-day estrous cycle. Three rats were sacrificed on each day of the cycle, ovaries were removed, and sections were hybridized with ^{35}S-labeled antisense riboprobes for GLCL-c and GLCL-r. Sense riboprobes served as negative controls. Mouse kidney sections were run as positive controls with each experiment. Visualization was done by autoradiography and dark-field microscopy. We observed high GLCL-r expression in the granulosa cells and oocytes of healthy growing and antral follicles, but not in primary or atretic follicles or in other cell types. In contrast, GLCL-c was expressed rather homogeneously throughout the ovaries. High GLCL-r expression in growing follicles, but not in atretic follicles, supports the hypothesis that GSH plays a role in protecting developing follicles from reactive oxygen species which are produced during normal follicular development. (Supported by NIEHS Center for Ecogenetics and Environmental Health [1 P30 ES07033-03] and by US EPA #R-825358-01-0 [to E.F.].)

1207 *IN UTERO* ANTI-ANDROGEN (FLUTAMIDE) EXPOSURE INCREASES LEYDIG CELL ACTIVITY IN ADULT RATS.

F. Chuzel[1], F. Berniaud[1], C. Try[1] and M. Benahmed[2]. [1]*Rhône-Poulenc Agro, Sophia Antipolis, France and* [2]*Inserm, Lyon, France.* Sponsor: A. Blacker.

In the testis, the main function of Leydig cells is to produce steroids under the control of gonadotropins. Studies have clearly shown that androgens are absolutely required to maintain normal testicular function. In the present study we assessed by semi quantitative RT-PCR whether prenatal exposure to the anti-androgen flutamide affects post natal Leydig cell functions. Pregnant Sprague Dawley rats were treated with flutamide (at 0, 2, 10, 50 mg/kg/day, from day 6 up to delivery). At post-natal day 90 (PND 90), male offspring were sacrificed, blood samples were taken for testosterone and LH levels and testes were collected for extraction of total mRNA. Exposure to flutamide during the fetal period resulted in an increase of testosterone production by Leydig cells as evidenced by higher testosterone levels in mature males (PND 90) from all treatment groups. This effect was maximal at 10 mg/kg/day (137% of control). In an attempt to explain this increase and to determine the level of action, we studied the expression of genes implicated in the production of testosterone by Leydig cells. The expression of CYP Side Chain Cleavage (CYP SCC) and CYP 17alpha hydroxylase (CYP 17alpha) messenger were only slightly increased (about 10%) at 10 and 50 mg/kg/day. In contrast, the level of the Steroidogenic Acute Regulatory protein (stAR) mRNA was increased in a dose-related manner (30% and 56% at respectively 10 and 50mg/kg/day). At 2 mg/kg/day, no effects were observed on CYP SCC, CYP 17alpha and StAR gene expression. In conclusion, it appears that Leydig cell activity in the adult testis is affected after a fetal androgen disruption. Assessment of the expression of these genes at different critical periods of Leydig cell maturation is in progress to better define the impact of prenatal exposure to an anti-androgen.

1208 LONG-TERM GENISTEIN EXPOSURE HAS MINIMAL EFFECTS ON SEX BEHAVIOR IN FEMALE RATS.

K. M. Flynn[1], S. A. Ferguson[1], K. B. Delclos[1] and R. R. Newbold[2]. [1]*FDA/National Center for Toxicological Research, Jefferson, AR and* [2]*National Institute for Environmental Health Sciences, Research Triangle Park, NC.*

The estrogen mimic genistein occurs naturally in several plants including soybeans; human exposure is via consumption of soy-based products (e.g., tofu and soy milk), dietary supplements, or infant formula. Adult human exposure estimates range from 0.1 mg/kg/day for the typical Western diet to 1.4 mg/kg/day for a typical Asian diet. There are little data on the developmental effects of genistein exposure. Here, pregnant rats consumed soy-free diets containing 0, 5, 100, or 500 ppm genistein, approximately equivalent to 0, 0.4, 8, and 40 mg/kg/day beginning on postnatal day (PND) 42 (prior to mating). Their offspring continued on the same diets throughout this study. F1 females were tested for sex behavior between PNDs 65-95 by rating their lordosis response on a scale of 0-3 following handling. Intact animals (n=40, 10 per dose) were tested for 5 consecutive days and ovariectomized animals (n=40, 10 per dose) received estradiol and progesterone before a single day of testing. Mean lordosis ratings (LR) and lordosis quotients (LQ) were calculated and analyzed using 1 way ANOVA with $p<0.05$ required for significance. The ranges for mean LR were 1.54 to 2.19 in intact animals in estrus (i.e., their highest score) and 0.64 to 1.39 in hormone-primed ovariectomized animals. The ranges for LQ were 7.00 to 9.00 in intact females and 3.44 to 6.71 in ovariectomized. There were no significant genistein-related effects. These results suggest that long-term genistein exposure in rats, at doses approximating human exposures, does not cause gross alterations in female sex behavior. There may be, however, genistein-induced alterations not observable in this type of sex behavior assessment. Additional studies are underway to identify changes in other behaviors that may be altered after multiple generations of genistein exposure. (Supported by Interagency Agreement #224-93-0001 between the FDA and the NIEHS.)

1209 EVALUATION OF THE EDSTAC MALE PUBERTAL ASSAY IN CD RATS USING TESTOSTERONE, STEROID BIOSYNTHESIS INHIBITORS, DOPAMINERGIC (DA) AGENTS AND THYROID INHIBITORS.

M. S. Marty, J. W. Crissman and E. W. Carney. *The Dow Chemical Company, Midland, MI.*

The Endocrine Disrupter Screening and Testing Advisory Committee (EDSTAC) has designated the male pubertal assay as an alternate Tier I screening test to detect potential endocrine disrupting (ED) chemicals. We began evaluating the ability of this assay to detect EDs acting through a variety of mechanisms. Weanling male rat pups were dosed for 30 d by gavage with vehicle (0.5% methocel) or the following test compounds (mg/kg/d): testosterone (T, 0.1, or 0.4), ketoconazole (KETO, 24), finasteride (FIN, 20 or 80), testolactone (TL, 220), fadrozole (FAD, 0.6 or 6.0), haloperidol (HALO, 2 or 4), bromocryptine (BRC, 10 or 50), phenobarbital (PB, 50 or 100) or 6-propylthiouracil (PTU, 240). In vehicle-treated males, age at pubertal onset, as evidenced by preputial separation (PPS), was 44.4±2.0 d. Only TL, PTU, and high dose BRC significantly delayed the age at PPS (α=0.05). Considerable interanimal variability within the control population (± 2 d) suggests that age at PPS may be a relatively insensitive endpoint for assessing

endocrine function. Conversely, significant reductions in body weight (~10% at PPS) did not alter age at PPS spuriously. Additional endpoints enhanced assay sensitivity. Epididymal weights were significantly reduced by KETO, a broad spectrum steroid biosynthesis inhibitor, FIN, a 5α-reductase inhibitor, and TL, an aromatase inhibitor. TL's effects were consistent with antiandrogenic activity by this compound. FAD, a more specific aromatase inhibitor, did not alter any assay parameters. PTU, a thyroid inhibitor, and HALO, a DA receptor antagonist, altered thyroid weight. PTU also altered thyroid histology and hormone levels. Thus, this assay was capable of detecting EDs operating through a variety of mechanisms; however, it failed to detect T or FAD. Hypothetically, higher doses of T should be detectable with this assay, but its capacity to detect aromatase inhibitors remains in question.

1210 *IN UTERO* FLUTAMIDE AND DIETHYSTILBESTROL TREATMENTS DECREASE OSP/CLAUDIN11 EXPRESSION IN ADULT TESTIS.

I. Goddard[1], A. Hellani[1], F. Chuzel[2], P. Contard[3], R. Bars[2] and M. Benahmed[1]. [1]*Inserm U407, Lyon, France,* [2]*Rhône-Poulenc Agro, Sophia Antipolis, France and* [3]*Rhône-Poulenc Agro, Lyon, France.* Sponsor: A. Blacker.

In the testis, OSP (Oligodendrocyte Specific Protein)/Claudin 11 is expressed specifically by Sertoli cells and is involved in the formation of the hemato-testicular barrier. In the present study we assessed by semi-quantitative RT-PCR whether the prenatal exposure to endocrine modulators such as anti-androgen flutamide or estrogen diethylstilbestrol affect the postnatal OSP/Claudin 11 expression. Pregnant Sprague Dawley rats were treated with flutamide (0, 2, 10 mg/kg/day) or with DES (0, 1, 5, 10 μg/kg/day) from day 6 to delivery. After sacrifice, testes were either processed for RNA extraction immediately (PND 90) or enzymatically digested to obtain Sertoli cells (PND 15) from which RNA was extracted after culture. These two different experimental protocols were used since at PND 15 but not at PND 90, Sertoli cells can be easily separated and purified from other testicular cell types. Treatment of dams by all doses studied of either flutamide or DES was associated with a decrease in OSP mRNA level (with a maximum of about 80% and 50% for all concentrations of flutamide and DES, respectively) in whole testes from PND 90 offspring. In order to assure that a decrease in OSP expression was not simply due to the treatment-associated reduction of the Sertoli cell number at PND 15, Sertoli cells originating from either control or treated groups (flutamide or DES) were cultured at the same density. In this experimental setup, as with PND 90, we also observed a decrease in OSP/Claudin 11 expression. Thus, a decrease (45%) in OSP/Claudin 11 mRNA was observed in rats born by mothers treated with 10 mg/kg/day of flutamide. Pre-natal treatment with DES (5 and 10 μg/kg/day) decreased OSP/Claudin 11 expression about 30% and 50%, respectively. In conclusion, OSP/Claudin 11 mRNA expression in adult testis is reduced in animals exposed *in utero* to flutamide or to DES. Since OSP/Claudin 11 is the major constituent of tight junction strands of Sertoli cells, it is possible that adult testicular compartmentalization is affected by the decrease in OSP/Claudin 11 in rats exposed to flutamide or DES during the fetal life.

1211 COMPARATIVE ENDOCRINOLOGY STUDY OF DEHYDROEPIANDROSTERONE (DHEA) AND A FLUORINATED ANALOGUE IN BEAGLE DOGS.

B. S. Levine[1], A. P. Brown[1], R. L. Morrissey[2], S. Das[3] and J. A. Crowell[4]. [1]*University of Illinois, Chicago, Chicago, IL,* [2]*Pathology Associates Intl., Chicago, IL,* [3]*AniLytics Inc., Gaithersburg, MD and* [4]*National Cancer Institute, Rockville, MD.*

DHEA and its sulfated metabolite, DHEA-S, are major endogenous adrenal steroids. DHEA is under development as a potential cancer chemopreventive agent. However, due to DHEA's endocrine effects, a fluorinated analogue (fluasterone; fl-DHEA) was synthesized as a potential alternate agent. This study evaluated the endocrine effects of DHEA and fl-DHEA in adult male and female Beagle dogs following 4 weeks of daily oral (capsule) treatment. Dose levels studied were 0, 10 and 100 mg/kg/day for each drug (3 dogs/sex/group). Neither administration of DHEA nor fl-DHEA resulted in mortalities, clinical signs of toxicity, histologic lesions or changes in body weights, food consumption or organ weights. Administration of DHEA resulted in dose-dependent increases in plasma DHEA and DHEA-S 1 hr after dosing, with the highest values in the males. fl-DHEA produced dose-dependent increases in plasma DHEA and fl-DHEA levels at 1 hr. Female dogs treated at 100 mg/kg/day DHEA had significant increases in plasma dihydrotestosterone and androstenedione, and nonsignificant increases in mammary tissue levels of DHEA and estradiol. These changes were not seen in DHEA-treated males or in the fl-DHEA dose groups, and indicate that DHEA can be converted to androgenic steroids by female dogs. Administration of either 10 or 100 mg/kg/day fl-DHEA to male and female dogs did not result in treatment-related effects. (Supported by NCI Contract No. NO1-CN-75127-MAO.)

1212 A MORPHOMETRICAL ANALYSIS OF EFFECTS OF FEMALE SEX HORMONES ON HAMSTER PANCREATIC ISLETS.

F. Furukawa, A. Nishikawa, M. Miyauchi, H. Nakamura, H. Y. Son and M. Hirose. *National Institute of Health Science, Tokyo, Japan.* Sponsor: T. Shirai.

It is known that sex hormones, including estrogen, can stimulate the release of insulin. Therefore, the modulating effects of female sex hormones, ethinylestradiol (EE) and levonorgestrel (LN), on the hamster pancreatic islets were investigated by morphometrical analysis. A total of 30, 9-week-old female Syrian hamsters were used in this experiment. Animals in groups 1-3 (each consisting of 10 hamsters) were respectively fed diet supplemented with 1 ppm EE (group 1) and 10 ppm LN (group 2), and without supplementation (group 3) for 26 weeks. At the end of the experiment, all animals were sacrificed and the pancreatic tissues were collected and processed for histological examination. Areas and diameters of the pancreatic islets were significantly increased, and their roundness significantly decreased by the EE or LN treatment. Thus histopathologically, the EE and LN groups showed telangiectasia and irregularity in form of the islets. Positive rates for insulin producing cells in the islet were significantly higher in the EE and LN groups than in the control group, although those for glucagon and somatostatin were lowered. Cell proliferative activity in both islets and acini was significantly increased in the EE and LN groups as compared to the control values. The results in the present experiment demonstrate that synthetic estrogen and progestins can affect hamster pancreatic islets when administrated in the diet.

1213 DETECTION OF DOPAMINERGIC MODULATORS IN A TIER I SCREENING BATTERY FOR IDENTIFYING ENDOCRINE-ACTIVE COMPOUNDS (EACs).

J. C. Cook[1], L. G. Davis[2], S. R. Frame[2] and J. C. O'Conner[2]. [1]*Pfizer, Inc., Groton, CT and* [2]*Dupont Haskell Laboratory, Newark, DE.*

Apomorphine (APO; D_2 receptor agonist), haloperidol (HAL; D_2 receptor antagonist), and reserpine (RES; dopamine depletor) have been examined in a Tier I screening battery, which has been designed to detect endocrine-active compounds (EACs). The Tier I battery incorporates two short-term *in vivo* tests (5-day ovariectomized female battery and 15-day intact male battery using Sprague-Dawley rats) and an *in vitro* yeast transactivation system (YTS). In the *in vivo* female battery, both HAL and RES increased serum PRL concentrations as expected. Increases in serum PRL levels are enhanced when daily dosages are administered via multiple-daily dosing of the test compound, which results in higher sustained blood levels of the test compounds. APO failed to decrease serum PRL concentrations in the female battery. In the *in vivo* male battery, HAL increased serum PRL concentrations as expected. However, APO and RES failed to effect serum PRL concentrations. In summary, HAL-like compounds would be identified in the Tier I male and female battery primarily via increased serum PRL concentrations. RES-like compounds would be identified in the Tier I male battery via decreased gonadotropins and steroids and possibly in the Tier I female battery by a minimal increase in serum PRL concentrations. Compounds which produce a marginal increase in serum PRL when administered using single daily dosing can also be confirmed in an *in vivo* female battery with multiple dosing since this regiment increases the magnitude of the PRL increase. APO, a D_2 receptor agonist, was not detected in the *in vivo* male or female batteries, but in both instances the top dosage produced minimal decreases in body weight (99-96% of control). Hence, the proposed Tier I battery needs to be further evaluated with higher dosages of APO and other D_2 receptor agonists to determine whether it is capable of detecting such agents.

1214 EFFECTS OF AFLATOXIN-B_1 (AFB_1) AND ITS METABOLITES AFLATOXICOL (AFLO) AND AFLATOXIN M_1 (AFM_1) ON THE RODENT UTERUS.

C. F. Brownie. *North Carolina State University, College of Veterinary Medicine, Raleigh, NC.*

Reproductive associated problems in bovine and avian species have been attributed to dietary AFB_1 exposure. AFB_1-induced hypovitaminosis - A,

and/or structural similarities of AFB_1 to estradiol-17β are thought to be possible mechanism (s) by which reproductive problems in these species develop. Evaluating the role of AFB_1 in rodent reproduction in terms of its estrogenic and antiestrogenic potential on uterine growth *in vivo*; and its binding to uterine estrogenic receptors seems prudent. Immature (21 day old) CD rats were treated with increasing doses of AFB_1 (1.0 μg/kg-4.0 mg/kg) alone or in combination with estradiol -17β (fixed dose 0.016 μg/kg) subcutaneously for three days. All rats were sacrificed 24 hrs. following the last injection, the uteri excised, cleared free of fat and other tissues, and weighed. Kidney, liver, ovarian, and adrenal weights were also recorded. Uterine weights increased in a dose - dependent fashion with estradiol-17β alone but not with AFB_1 alone, even when administered at doses as high as 4 mg/kg. AFB_1 in combination with estradiol-17β had little or no effect on estrogen-stimulated increase in uterine weights. Kidney weights appeared to be increased at high doses "2.0 and 4.0 mg/kg" of AFB_1, in the presence of estradiol - 17β. Body weight gains were decreased significantly in rats treated with high levels of AFB_1(1.0, 2.0, and 4.0 mg/kg). Utilizing *in vitro* methods (Korach et al. J. Biol.Chem. 254: 8963-8968, 1979) Aflatoxicol (AFL0), but not AFB_1 or AFM_1 appeared to compete, with diethylstilbestrol (DES) for uterine estrogenic receptors. Further studies are required to delineate AFB_1- induced reproductive associated problems in bovine and avian species.

1215 THE HERSHBERGER ASSAY FOR (ANTI)- ANDROGENS: AN INTERLABORATORY COMPARISON.

L. A. Albin[1], M. L. Kinnett[1], J. Ostby[2], L. E. Gray, Jr.[2], A. G. E. Wilson[1] and W. R. Kelce[1]. [1]*Monsanto, St. Louis, MO and* [2]*USEPA, Research Triangle Park, NC.*

The rat 7-day Hershberger assay has been recommended by the US EPA's Endocrine Disruptor Screening Program to identify substances with androgenic and anti-androgenic activity. Here we assess the ability of two laboratories to independently use this assay to correctly identify chemicals with known (anti)-androgen activity. Immature 28-34 day old rats castrated at day 21 (10 rats/group) were dosed by gavage with vehicle (corn oil), flutamide (100 mg/kg/day), 1,1-dichloro-2,2-bis(p-chlorophenyl) ethylene (p,p'-DDE; 100 mg/kg/day) or dibutylphthalate (DBP; 1000 mg/kg/day) with (to assess antiandrogenic activity) and without (to assess androgenic activity) a subcutaneous injection of testosterone propionate (TP; 50 μg/day) for seven consecutive days. In both laboratories, TP injections alone increased ventral prostate (VP; ~ 4-fold), seminal vesicle (SV; ~5-fold) and levator ani/bulbocavernosus (LABC; ~ 2-fold) weights compared to vehicle treated controls. The potent androgen receptor antagonist flutamide completely blocked the androgenic effects of TP in all tissues, while the weak androgen receptor antagonist p,p'-DDE reduced VP, SV and LABC weights in TP injected rats by approximately 50 percent; similar results were obtained in both laboratories. Neither laboratory was able to detect the non-receptor mediated antiandrogenic effects reported for DBP. Neither flutamide, p,p'-DDE nor DBP increased VP, SV or LABC weights over vehicle treated controls suggesting that these chemicals lack androgenic activity. Taken together, the results suggest that the Hershberger assay is effective to assess (anti)-androgenic activity of substances acting through the androgen receptor and is repeatable among independent laboratories.

1216 EVALUATION OF A TIER I SCREENING BATTERY FOR DETECTING ENDOCRINE-ACTIVE COMPOUNDS (EACS) USING THE POSITIVE CONTROLS TESTOSTERONE, COUMESTROL, PROGESTERONE, AND RU486.

L. G. Davis[1], S. R. Frame[1], J. C. Cook[2] and J. C. O'Connor[1]. [1]*DuPont Haskell Laboratory, Newark, DE and* [2]*Pfizer, Inc., Groton, CT.*

Coumestrol (COUM; estrogen receptor (ER) agonist), testosterone (TEST; androgen receptor (AR) agonist), progesterone (PROG; progesterone receptor (PR) agonist), and mifepristone (RU486; PR antagonist) have been examined in a Tier I screening battery designed to detect EACs. The Tier I battery incorporates two short-term *in vivo* tests using CD rats (5-day ovariectomized female and 15-day intact male batteries) and an *in vitro* yeast transactivation system (YTS). In the female battery, TEST increased uterine weight, uterine stromal cell proliferation (CP), and altered serum hormone concentrations; in the male battery, TEST increased accessory sex gland weights, altered serum hormone concentrations, and produced microscopic changes of the testis; and, in the YTS, TEST activated gene transcription in the yeast containing the AR or PR. In the female battery, COUM increased uterine weight, uterine stromal CP, uterine epithelial cell height, and increased serum PRL; in the male battery, COUM altered serum hormone concentrations; and, in the YTS, COUM activated gene transcription in the yeast containing the ER. In the female battery, PROG increased uterine weight, uterine stromal CP, uterine epithelial cell height, and altered serum hormone concentrations; in the male battery, PROG decreased epididymis and accessory sex gland weights, altered serum hormone concentrations, and produced microscopic changes of the testis; and, in the YTS, PROG activated gene transcription in the yeast containing the AR or PR. In the female battery, RU486 increased uterine weight and decreased uterine stromal CP; in the male battery, RU486 decreased epididymis and accessory sex gland weights, and increased serum FSH and LH; and, in the YTS, RU486 activated gene transcription in the yeast containing the ER, AR, or PR. Using the responses obtained for the Tier I battery, a distinct "fingerprint" was produced for each type of endocrine activity against which compounds with unknown activity can be compared.

1217 PHYSIOLOGICALLY BASED MODELING OF THE RAT ESTRUS CYCLE AND HUMAN MENSTRUAL CYCLE INCLUDING A LINK TO BREAST CANCER INCIDENCE RATES.

B. A. T. Willems, B. J. Davis and C. J. Portier. *NIEHS, Research Triangle Park, NC.*

Physiologically based models for both the human menstrual cycle and rat estrus cycle have been developed, and are presented as autonomous hormonal circuits in which no forced triggers, like fixed cycle length or day of ovulation, are incorporated. These models incorporate six organ systems belonging to the endocrine system: the brain/hypothalamus, the hypophysial portal system, the pituitary gland, the ovaries, the liver and the gastro-intestinal tract. Serum hormone levels in cycling women (estrogen, progesterone, LH, FSH, Inhibin) and in female rats (estrogen, progesterone, LH, FSH, prolactin) are used for model optimization. Developing such models has several advantages. Physiologically based models which describe the production of and interaction between the numerous hormones involved in the menstrual and estrus cycle are useful in studying the effects of exogenous compounds or endocrine disrupters on hormonal equilibrium. Furthermore, even though endogenous estrogen levels are already related with e.g. breast cancer in women, the response to an exogenous impact is still very much unknown. By linking the changes in simulated estrogen levels with changes in parameters used in cancer models (e.g., two-stage model), an exploration of changes in dose-response curve shapes, as a result of the exposure, is feasible.

1218 DISTURBANCE OF THYROID HORMONE HOMEOSTASIS FOLLOWING CONTINUOUS INTRAVENOUS INFUSION OF PROBENECID IN RATS.

D. A. Manca, R. M. Walker, S. G. Groom, L. E. Lillie and P. V. Turner. *Parke-Davis Pharmaceutical Division, Warner-Lambert Co., Mississauga, Ontario, Canada.*

The goitrogenic potential of probenecid, a widely used renal tubular transport blocking agent, was investigated following continuous intravenous infusion. Groups of 10 rats/sex were administered the vehicle, or 5, 10, and 20 mg/kg/hr for 2 weeks (dose-response phase). In addition, 5 males received 20 mg/kg/hr for 3, 7, or 14 days (time-course phase). **Dose-Response Phase:** Probenecid plasma concentrations were below the limit of quantification at 5 mg/kg/hr, and within the intended therapeutic range (30-150 μg/mL) at 10 mg/kg/hr. At 20 mg/kg/hr concentrations ranged from 279 to 658 μg/mL. Serum levels of thyroxine (T_4) and triiodothyronine (T_3) were significantly lower in both sexes at 10 mg/kg/hr (T_4: 25% to 50% of controls; T_3: 84%) and 20 mg/kg/hr (T_4: 27% to 51%; T_3: 82%). Increases in absolute (16% to 21%) and relative (20% to 22%) liver weight, and an increased incidence of minimal-to-mild follicular cell hypertrophy in males were noted at 10 and/or 20 mg/kg/hr. **Time-Course Phase:** Levels of T_3 (24% to 32% of controls) and reverse T_3 (58% to 73%) decreased on days 3-14 and 7-14, respectively. T_3 was minimally affected on Day 14 (83%). Levels of thyroid stimulating hormone (TSH) increased 53% on Day 7, and were paralleled by an increase in absolute (91%) and relative (75%) thyroid weights, and by minimal-to-mild follicular cell hypertrophy (Day 7-14). Hepatic microsomal UDP-glucuronosyltransferase activity increased 75% to 96% on Day 3 and 14, and was inversely correlated with serum T_4 concentrations (r^2:0.47-0.69; $P<0.01$-0.05). Significant increases were also noted in CYP450, EROD, PROD, and erythromycin n-demethylase. These results suggest that thyroid changes associated with probenecid result from disturbances of the hypothalamic-pituitary-thyroid (HPT) axis consequent to increased biliary clearance of T_4-UDPGT. However, direct effects on the HPT axis cannot be excluded based on TSH and T_4 profiles, and structural similarities between probenecid and known inhibitors of thyroxine peroxidase.

1219 ATRAZINE DISRUPTION OF THE HYPOTHALAMIC-PITUITARY AXIS: CONSEQUENCES FOR REPRODUCTIVE FUNCTION.

M. M. Ford and J. C. Eldridge. *Department of Physiology & Pharmacology, Wake Forest University School of Medicine, Winston-Salem, NC.*

The triazine herbicide atrazine (ATR) has been reported capable of disrupting endocrine processes that govern reproductive function in rodents. Prior studies have pointed to an anti-estrogenic profile for ATR, and it was observed that high dose ATR treatment to ovariectomized (ovex), estrogen-primed Sprague Dawley (SD) rats led to an attenuated LH surge response. In this study the effects of ATR on the hypothalamic-pituitary axis in the presence and absence of estrogen were examined. Ovex SD rats were administered a control vehicle (carboxymethylcellulose; CMC) or ATR (300 mg/kg BW via gavage) for 6 days. On days 3-6 subgroups of the vehicle and ATR-treated animals received either peanut oil (100 µl s.c.) or beta-estradiol-3-benzoate (EB; 15 µg/100 µl oil s.c.). Trunk plasma and hypothalamus were collected from each animal between 14.00-15.00 hours on day 7. A significant main effect of EB was detected in the reduction of plasma gonadotropins and body weights, and in the augmentation of hypothalamic GnRH content. ATR exhibited an overall effect in the increase of plasma FSH and in the decrease of animal body weights. In addition, a trend was found toward a decrement in plasma LH and an augmentation of hypothalamic GnRH content. Interactions between EB and ATR were undetectable in any of the parameters measured, although an interaction did approach significance with plasma FSH. These results suggest that ATR does not likely alter estrogen regulation of the reproductive neuroendocrine axis, but that it can disrupt the normal processes taking place at the hypothalamic-pituitary level. It is possible that ATR interferes with the synthesis/release of GnRH or the activity of this peptide with its receptor. (Supported in part by Novartis Crop Protection.)

1220 MODULATION OF SERUM TESTOSTERONE AND PROSTATE ESTROGEN RECEPTORS α AND β BY DIETARY GENISTEIN.

A. Dalu[1], B. Blaydes[1], C. Bryant[1], J. Latendresse[2], C. Weis[1], R. Newbold[3] and K. B. Delclos[1]. [1]*National Center for Toxicological Research, Jefferson, AR,* [2]*Pathology Associates International, Jefferson, AR and* [3]*National Institute for Environmental Health Sciences, Research Triangle Park, NC.*

Genistein, a naturally occurring isoflavonoid, is primarily found in soybeans. It exerts its estrogenic/antiestrogenic effects primarily through binding to estrogen receptors α and β (ERα and β), and thereby may affect the growth and development of prostate. In addition, genistein has been reported to affect enzymes involved in steroid synthesis and metabolism. Here we report genistein's effects on ERα and β in prostate and on serum testosterone. Genistein was fed to F_0 male and female CD rats 28 days before mating at 0, 5, 100, 500 ppm. Exposure of F_1 pups continued throughout lactation. At weaning, the male pups from genistein dosed diet were either switched to control diet (designated as G/C, n=12) or continued to be on the same dose of dietary genistein (designated as G/G, n=12). At sacrifice (PND140), ventral prostate (VP) and dorsolateral prostate (DLP) were removed for histopathological evaluation (n=6-8 per treatment group) and measurement of ERα & β levels by Western blot (n=6 per treatment group). Radioimmunoassay analysis indicated that serum testosterone (T) and dihydrotestosterone (DHT) levels exhibit an increasing linear trend ($p \leq 0.05$) in G/G treated groups, but not in G/C groups. Serum T levels differed significantly from controls in the 500 ppm G/G group. Patterns of ER proteins, as detected by Western blot analysis, varied depending upon receptor type, tissue (DLP or VP), and dosing regimen. ERα was increased in DLP at 5 ppm (~50% over control) and in VP at 5 and 100 ppm (~25 and 31% over control, respectively) with the G/C treatment. In G/G groups, ERα was decreased in DLP at 100 ppm (~59% of control). ERβ was generally decreased in the DLP at all doses (46-89% of control) in both G/C and G/G groups. There were mixed results in the expression of ERβ in VP. These preliminary results suggest that genistein may alter serum T levels and act in dose- and tissue-dependent manner in modulating the expression of ERα and β. While the mechanisms whereby genistein alters hormone and receptor levels remain to be elucidated, the observed effects may have important implications in male reproductive tract function and susceptibility to or prevention of prostatic carcinogenesis.

1221 EFFECT OF 3,3',4,4',5,5'-HEXACHLOROBIPHENYL (PCB 169) ON FREE AND TOTAL THYROXINE IN RATS.

J. M. Hedge, M. J. DeVito and K. M. Crofton. *USEPA, Research Triangle Park, NC.*

Hypothyroxenemia in rats has been well documented as a result of either developmental or adult exposure to polychlorinated biphenyls (PCBs). PCBs may cause these effects through induction of catabolic enzymes or interference with plasma transport proteins. Transthyretine is the major thyroid hormone transport protein in rats. This preliminary study investigates the effects of a single oral dose of PCB 169 (concentration of 1 mg/kg given at 0.5, 1, 2, 4, 8, 24, or 48 prior to sampling), in 27 d old female Hooded Long-Evans rats. We hypothesized that displacement of thyroxine (T4) from transthyretine by PCB169 would result in an increase in the free concentration of T4. Serum total and free thyroxine concentrations (TT4 and FT4, respectively) were determined by radioimmunoassay kits. No significant increase in TT4 or FT4 concentrations was seen at any time point as a result of PCB 169 exposure. However, both TT4 and FT4 decreased about 20% after 24 to 48 hours. Based on these results it would appear that PCB 169 does not disrupt the free/bound ratio of thyroxine in young rats. The decrease in FT4 and TT4 at the later time periods is probably due to induction of catabolic enzymes in the liver. The lack of effect on FT4 during the early time points may result from either a minimal role for transthyretine binding in the PCB mediated decreases in T4 or to binding of T4 to alternative transport proteins. Young rats are known to have significant concentrations of thyroid binding globulin (TBG) up to eight weeks of age and PCBs do not displace T4 from TBG. Future studies will investigate this issue with older rats and other PCB congeners. (This abstract does not necessarily reflect the policy of the US Environmental Protection Agency.)

1222 EFFECT OF NONYLPHENOL ON SERUM TESTOSTERONE LEVELS AND TESTICULAR STEROIDOGENIC ENZYME ACTIVITY IN NEONATAL AND PUBERTAL RATS.

E. M. Laurenzana[1], C. C. Weis[1], B. B. Blaydes[1], R. R. Newbold[2] and K. B. Delclos[1]. [1]*NCTR, Jefferson, AR and* [2]*NIEHS, Research Triangle Park, NC.*

Nonylphenol is an environmentally persistent degradative product of alkylphenol polyethoxylates, which are widely used in a variety of household and commercial applications. Perinatal administration of nonylphenol and other alkylphenols has suggested that these compounds may interfere with male reproductive tract development. Therefore, these studies examined the effects of nonylphenol on serum testosterone levels and testicular steroidogenic enzyme activities at critical developmental stages. Male rats were dietarily exposed to various doses of nonylphenol (0, 25, 200 and 750 ppm) throughout gestation and until sacrifice at either postnatal day 2 (PND2) or PND50. At PND2, serum testosterone levels were significantly decreased in all groups exposed to nonylphenol. The activity of 17 alpha-hydroxylase/C17-20 lyase (P450c17) in PND2 testicular homogenates was not affected by nonylphenol treatment. However, the addition of nonylphenol (0.1-100 micromolar) to the metabolic incubation resulted in a dose-dependent decrease in enzyme activity. In PND50 rats, nonylphenol treatment did not affect serum testosterone levels. The dorsal prostate weight was increased in the 200 and 750 ppm dose groups; no effects were observed in other male reproductive organs. Nonylphenol treatment did not affect P450c17 activity in microsomes prepared from testes of PND50 rats. However, the presence of 100 micromolar nonylphenol in the incubation resulted in a significant decrease in enzyme activity. These results suggest that nonylphenol exposure results in decreased serum testosterone levels in neonatal rats, and that inhibition of steroidogenic enzymes may be a contributing factor.

1223 THYROID HORMONE DISRUPTIVE EFFECTS OF BROMINATED DIPHENYL ETHERS FOLLOWING DEVELOPMENTAL EXPOSURE.

T. Zhou[1], M. M. Taylor[2], M. J. DeVito[2] and K. M. Crofton[2]. [1]*University of North Carolina, Chapel Hill, NC and* [2]*USEPA, Research Triangle Park, NC.*

Our previous work has demonstrated that short-term *in vivo* DE-71 (mostly tetra- and penta-bromodiphenyl ethers, a commercial polybrominated diphenyl ether mixture) exposure induces hypothyroxenemia via induction of uridinediphosphate-glucuronosyltransferases (UDPGTs). In this study, we examined thyroid hormones and thyroxine glucuronidation in rats following perinatal maternal exposure to DE-71. Primiparous rats were orally administered DE-71 (0, 1, 10 and 30mg/kg/day) in corn oil from gestation day (GD) 6 to postnatal day (PND) 21. Serum and liver samples obtained from dams

(GD21 and PND22), fetuses (GD21) and offspring (PND4, 14, 36 and 90) were analyzed for circulating total serum thyroxine (T4), triiodothyronine (T3), thyroid-stimulating hormone (TSH) or hepatic microsomal ethoxy- and pentoxy-resorufin-O-deethylase (EROD and PROD) and UDPGT activities. Serum T4 was reduced in a dose dependent manner in fetuses on GD21 (maximal 41%) and offspring on PND4 and PND14 (25, 50, and 70% maximal in the 1, 10, and 30 mg/kg/day groups, respect-ively), but recovered to control levels by PND36 and 90. Reduction in serum T4 was also noted in GD21 dams (44% at highest dose), as well as PND22 dams (49% at highest dose). There was no significant effect of DE-71 on T3 concentrations at any time in the dams or the offspring. Increased liver/body weight ratios were consistent with induction of EROD (100-fold) and PROD (20-30 fold) in offspring. These data support the conclusion that DE71, a commercial mixture of brominated diphenyl ethers, is an endocrine disruptor in rats during development. (This abstract does not necessarily reflect the policy of the US Environmental Protection Agency.)

1224 PURE POLYCHLORINATED BIPHENYL (PCB) METABOLITES CROSS THE PLACENTA IN THE RAT AND MAY REDUCE FETAL THYROID HORMONE LEVELS.

I. A. T. Meerts[1], Y. Assink[1], P. H. Cenijn[1], B. M. Weijers[1], A. Bergman[2], J. Koeman[1] and A. Brouwer[3]. [1]*Wageningen University, Wageningen, Netherlands,* [2]*Stockholm University, Stockholm, Sweden and* [3]*Free University of Amsterdam, Amsterdam, Netherlands.*

This study was designed to determine the maternal to fetal transport of the polychlorinated biphenyl (PCB) PCB-metabolite 4-OH-2,3,3',4',5-pentaCB (PCB-OH) and the effects on maternal and fetal thyroid hormone homeostasis. Pregnant Wistar rats were orally exposed to 0 or 5 mg PCB-OH per kg body weight per day from gestation day (GD) 10 to 16. A separate group of rats received 4.2 mg/kg bw/day of a radiolabelled [14C] PCB-OH from GD10-16. On GD17 and GD20 maternal and fetal blood and a wide range of tissues were collected. Tracer analyses showed that most (approx. 88%) of the total administered PCB-OH was excreted in the faeces; maternal and fetal organs contained only 5% and 2.3%, respectively. Fetal brain contained 2-4 times more PCB-OH compared to maternal brain. Maternal plasma T3 and T4 levels were unaffected. Fetal T4 levels were decreased dose-dependently (maximal decrease of 91% on GD20, in high dose group). Fetal plasma TSH levels were significantly increased by 124% (5 mg/kg). No effects on maternal or fetal liver T4 UDP-glucuronyltransferase activity were detected. The PCB-OH in plasma was bound to fetal transthyretin. These data demonstrate that pure PCB-metabolites are able to cross the placenta and reduce fetal thyroid hormone levels by binding to transthyretin. (This study was supported by the commission of the European Communities [grant ENV-CT96-0170].)

1225 COMPARISON OF THE ORAL (GAVAGE) AND INTRAPERITONEAL ROUTES OF ADMINISTRATION FOR IDENTIFYING ENDOCRINE-ACTIVE COMPOUNDS (EACS) USING AN *IN VIVO* MALE BATTERY, AND EVALUATION OF IMMUNE SYSTEM ENDPOINTS.

J. C. O'Conner, S. R. Frame, C. Smith and G. Ladics. *Dupont Haskell Laboratory, Newark, DE.*

An *in vivo* screening battery using intact adult male rats has been evaluated for its ability to detect four EACs using two different routes of administration, oral gavage and intraperitoneal (IP) injection. The test compounds included the antiandrogens flutamide (FLUT) and *p,p'*-DDE (DDE), the steroid biosynthesis inhibitor ketoconazole (KETO), and the thyroid toxicant phenobarbital (PB). Male rats were dosed for 14 days via oral or IP administration and euthanized on the morning of test day 15. The endpoints evaluated included: final body and organ weights, serum hormone concentrations, histopathology of the testis and thyroid gland, and evaluation of immune system endpoints (humoral immune function, spleen and thymus weights, and spleen cell number). After IP compound administration, all four test compounds were identified as expected based on their specific mode of action. FLUT and DDE decreased the weights for the androgen-dependent tissues (ASG, epididymis, prostate, and seminal vesicles), caused hormonal alterations (increased serum T, E2, DHT, FSH, and LH), and caused histopathologic changes of the testis (Leydig cell hyperplasia). KETO decreased the weights for the androgen-dependent tissues (ASG, epididymis, prostate, and seminal vesicles) and caused hormonal alterations (decreased serum T and DHT; increased serum FSH, and LH). PB did not effect organ weights; however, serum hormone levels were effected (decreased serum T, DHT, PRL, FSH, LH, T_3, T_4; increased serum TSH and E2) and thyroid follicular cell hypertrophy was observed. After oral compound administration, FLUT and PB displayed the same pattern of altered endocrine and reproductive responses that were observed by the IP route. Also, orally administered FLUT and PB did not alter the primary humoral immune response to SRBC. PB increased spleen weight at the highest dose. DDE and KETO are currently being evaluated by the oral route.

1226 EVALUATION OF OESTROGENIC POTENTIAL OF BISPHENOL A IN THE UTEROTROPHIC ASSAY BY ORAL AND PARENTERAL ROUTE AT EXTENDED DOSE RANGES.

F. W. Jekat[1], K. Twomey[2], J. H. Butala[3], S. Z. Cagen[4], S. S. Dimond[5], R. L. Joiner[5], R. N. Shiotsuka[6], G. Stropp[1], G. E. Veenstra[7] and J. M. Waechter[8]. [1]*Bayer AG, Wuppertal, Germany,* [2]*AstraZeneca CTL, Macclesfield, United Kingdom,* [3]*Consultant to Aristech, Pittsburgh, PA,* [4]*Shell Chemical Co, Houston, TX,* [5]*General Electric Co, Pittsfield, PA,* [6]*Bayer Corp., Stilwell, KS,* [7]*Shell Chemicals Ltd., London, United Kingdom and* [8]*The Dow Chemical Co., Midland, MI.*

The objective of this study was to evaluate the oestrogenic potential of bisphenol A (BPA) at both conventional doses and (ultra) low doses by different routes of administration using the current short-term *in vivo* model for oestrogenicity, the uterotrophic assay. Groups of 10 immature Wistar strain derived female rats were given doses of 0, 0.002, 0.02, 0.2, 1, 10, 100, 200, and 800mg/kg/d orally or 0, 0.002, 0.02, 0.2, 1, 10, 100, and 800mg/kg/d subcutaneously (s.c.) for 3 consecutive days. 17beta-oestradiol at a dose of 0.4mg/kg/d served as a positive control. In addition to determining wet and dry uterus weights, histopathology was carried out for elucidating more discreet oestrogenic responses. These detailed investigations revealed indications of oestrogenicity at oral doses of 200 and 800mg/kg/d, and at s.c. doses of 10, 100 and 800mg/kg/d. The responses were dose-related, with no indication of oestrogenic activity at lower doses. Differences in kinetics and bioavailability of the parent compound (Pottenger et al., The Toxicologist 1998; 42 (1S): 282) provide an explanation for the different response thresholds seen between the two routes. In our uterotrophic assays the oestrogenic potential of BPA revealed a monotonic dose response with thresholds above the NOELs of toxicity that have been previously established in conventional studies. The absence of an oestrogenic response at (ultra) low doses corroborate the absence of reproductive toxicity (including reproductive organ weight effects) of BPA at these dose levels (Cagen et al., Toxicol Sci 1999; 50: 36-44; and Dimond et al., The Toxicologist 1999; 48: 45-46). These results do not support the hypothesis of a non-monotonic dose response of BPA-related oestrogenic potential *in vivo*. (Studies were sponsored by The Bisphenol A Global Industry Group.)

1227 DEMONSTRATION OF DOSE-RESPONSE OF THE 3-DAY UTEROTROPHIC ASSAY IN IMMATURE CRL:CD(SD)IGS BR RATS WITH ETHINYL ESTRADIOL AND COMPARISONS OF ROUTES OF ADMINISTRATION.

L. B. Biegel[1], M. W. Turner[2], K. D. Lane[2] and B. R. Fisher[2]. [1]*Covance Laboratories, Inc., Madison, WI and* [2]*Covance Laboratories, Inc., Vienna, VA.*

The purpose of this study was to validate and demonstrate the dose-responsiveness of the rodent uterotrophic assay with ethinyl estradiol, in 18 day old rats. Recent attention is focused on assay conduct and validation for regulatory purposes. In the current study, ethinyl estradiol (EE) was administered to weaned, immature female rats on postnatal days (PND) 18, 19, and 20 at concentrations of 0, 0.01, 0.03, 0.1, 0.3, 1.0, 3.0, and 10 µg/kg. Two additional groups of rats were treated with 0.1 or 1.0 mg/kg of the estrogen antagonist, ICI-182,780 (ICI) immediately followed by administration of 3.0 µg EE/kg. Untreated control groups were also included in the study design. Administration of EE or ICI was by oral gavage (PO) or by subcutaneous injection (SC). There were no clinical signs of toxicity or alterations in body weights or food consumption detected. On PND 21 the animals were sacrificed. The uterus, ovaries, and vagina were examined, and the uteri were weighed with and without fluid. Administration by PO or SC at concentrations of 3.0 and 10.0 µg EE/kg produced significant increases (2 to 4.4 fold) in absolute uterine wet weight and increased uterine fluid imbibition. Administration of 1.0 µg EE/kg (by SC) also produced a statistically significant increase in uterine wet weight (160% of control). By contrast, concentrations of 0.01 to 0.3 µg EE/kg (by SC) or 0.01 to 1.0 µg EE/kg (by PO) produced no alterations on any of the parameters measured. ICI (0.1 or 1.0 mg/kg) did not antagonize the uterotrophic effects of 3.0 µg/kg EE when administered PO, but produced an approximate 30% reduction in the estrogenic increase in uterine weight and the EE-induced uterine fluid imbibition was ablated when administered SC. These results support previous reports

that the SC is a more sensitive route than PO and demonstrate the feasibility of using weaned 18 day old rats.

1228 THE *IN VIVO* AND *IN VITRO* ESTROGENICITY OF PENTACHLOROPHENOL AND ACETAMINOPHEN.

R. Patel and R. J. Rosengren. *University of Otago, Dunedin, New Zealand.*

The identification of increasing numbers of xenoestrogens in our environment has been the source of much concern in recent years. Recently, Harnagea-Theophilus and Miller (1998) hypothesized that the presence of a substituted phenol in the structure of a compound may be indicative of its estrogenic potential. Based on this hypothesis, two phenol group containing compounds were selected and assessed for estrogenic potential. Acetaminophen (APAP) is a frequently used analgesic and previous studies have demonstrated evidence of estrogenic activity in estrogen-responsive human breast cancer cell lines. Pentachlorophenol (PCP) was once extensively used as a timber-treatment product and there is only limited data investigating its potential for xenoestrogen activity. The present study used uterine wet weight, estrogen receptor binding and estrogen and progesterone receptor quantification to evaluate the estrogenic capabilities of these compounds. Uterine wet weight was measured in 23 day old female C57Bl/6 mice dosed with vehicle, 17ß-estradiol (10 µg/kg/day), APAP (100, 200, 250 mg/kg/day) or PCP (20, 30 mg/kg/day) for 3 days and sacrificed 24 hours after the last dose. The ability to compete with 17ß-estradiol for binding to estrogen receptors was assessed in hepatic and uterine cytosolic and nuclear extracts. Extracts were prepared from 21 day old female C57Bl/6 mice, and saturation and competitive binding experiments were carried out using the hydroxyapatite method. Cytosolic and nuclear extracts from the treated animals were used to quantify progesterone and estrogen receptor status. The results indicated that there was no evidence of estrogenic activity for APAP (0.03-2.5 mM) in either nuclear or cytosolic hepatic or uterine extracts, the uterotrophic assay or as indicated by progesterone or estrogen receptor quantification. However, PCP (75-115 µM) consistently exhibited evidence of weak competition with 17ß-estradiol, in both uterine and hepatic extracts, yielding IC50 values of 95.14 and 71.20 µM, for hepatic cytosolic and nuclear extract, respectively and 91.07 and 98.53 µM for uterine cytosolic and uterine nuclear extracts. Furthermore, PCP (20 mg/kg/day) induced a significant increase in uterine wet weight (0.56 ±.02) relative to control (0.31±.06, $p<0.05$). Therefore acetaminophen displayed no estrogenic potential in these experiments, while PCP was weakly estrogenic.

1229 EVALUATION OF THE UTEROTROPHIC ASSAY IN THE IMMATURE FEMALE SPRAGUE-DAWLEY RAT USING OESTRADIOL BENZOATE (OB), BISPHENOL A (BPA) AND OCTYL PHENOL (OP).

D. R. Chubb and A. G. Richardson. *Quintiles England Limited, Ledbury, United Kingdom.* Sponsor: T. Palmer.

OB, BPA and OP were used in a series of experiments to evaluate the uterotrophic assay in the immature female Sprague Dawley rat. Animals were 21 days old on the first day of dosing and were dosed once a day for up to three days. On the fourth day, surviving animals were euthanased and the uterus was excised, blotted dry and weighed. Mean uterus weight was analysed using Students or Williams 2-sided t-Tests. Oral administration of 0.4mg/kg/day OB produced highly significant increases ($p<0.001$) in uterine weight compared with controls. BPA failed to produce an increase in uterine weight when administered orally (400mg/kg/day) but did produce a significant increase in uterine weight ($p<0.05$) when administered subcutaneously (150mg/kg/day). When this experiment was repeated using an increased group size no significant increase was detected. Oral administration of OP produced very significant increases ($p<0.01$) in uterine weight at a toxic dose level (800mg/kg/day) but no increase at a lower non-toxic dose (400mg/kg/day). Subcutaneous administration of OP produced a significant increase ($p<0.05$) in uterine weight at a toxic dose level (600mg/kg/day) and a very significant increase ($p<0.01$) at a non-toxic dose (300mg/kg/day). The assay clearly demonstrated the uterotrophic effect of a known oestrogen (OB) in the Sprague Dawley strain. The results obtained with BPA and OP indicate that the route of administration and group size are important factors in the detection of weak responses. Uterotrophic activity has been reported for BPA in Alpk:AP rats (Ashby and Tindell 1998) but the doses used could not be achieved in our facility in Sprague Dawleys due to toxicity, therefore the strain of rat may also be important. Further work on OP is ongoing to assess the enhanced uterotrophic response observed at non-toxic doses.

1230 ASSESSMENT OF THE OESTROGENIC ACTIVITY OF BENZOPHENONE SUNSCREEN AGENTS.

V. A. Baker, P. A. Jones and L. J. Lea. *SEAC Toxicology Unit, Unilever Research, Colworth House, Sharnbrook, United Kingdom.* Sponsor: J. W. Hamilton.

Over the last few years, lists of chemicals described as "known or suspected endocrine disrupters" have been produced from numerous sources. Benzophenone, a chemical used as a fixative in perfumes and cosmetics for it's UV absorbing properties, has been listed among "chemicals suspected of having endocrine disrupting effects" by the Japanese Environment Agency. However, there is currently only one report from an *in vitro* study (Jobling, et al 1995) suggesting weak oestrogenic activity. Therefore, using a combination of *in vivo* and *in vitro* assays, the possible oestrogenic effects of benzophenone and benzophenone-3 (2-hydroxy-4-methoxybenzophenone), used as a sunscreen agent, have been investigated. Competitive binding *in vitro* with the immature rat uterine oestrogen receptor (ER) was used to measure the ability of benzophenones to bind to the ER and in addition an oestrogen-inducible yeast screen, expressing the human ER, was used to examine the transcriptional activation of oestrogen responsive genes. Benzophenone and benzophenone-3 did not display any oestrogenic activity in these *in vitro* assays tested up to a concentration of 10^{-3}M. Uterotrophic assays have been conducted to investigate the potential for benzophenones to elicit an oestrogenic response when administered orally to immature female rats at doses of 50, 150 or 500 mg/kg/day for three consecutive days. Benzophenone and benzophenone-3 did not exhibit oestrogenic activity in the immature female rat using uterine wet weight as the endpoint, whereas 17beta-oestradiol (0.4mg/kg/day) consistently produced a significant increase in uterine weights over vehicle control. In conclusion, we have shown that the suggestion of endocrine disruption for benzophnones is not supported when tested in a combination of *in vivo* and *in vitro* assays for oestrogenic activity.

1231 ASSESSMENT OF ESTROGENIC AND ANTIESTROGENIC ACTIVITY OF D4 IN IMMATURE RATS USING THE UTEROTROPHIC ASSAY.

J. M. McKim, Jr.[1], W. J. Breslin[2], P. C. Wilga[1], E. Stanton[1], K. P. Plotzke[1], R. H. Gallavan[1] and R. G. Meeks[1]. [1]*Dow Corning Corporation, Midland, MI and* [2]*MPI Research, LLC, Mattawan, MI.*

The estrogenic and antiestrogenic effects of D4 were evaluated by measuring changes in uterine weight and epithelial cell morphology in immature Sprague Dawley (SD) rats. These data were compared to data obtained for ethinyl estradiol (EE), diethylstilbesterol (DES) and coumestrol (CE). Beginning on postnatal day 18, the pups (12/group) received a single oral dose of either D4 (0, 10, 50, 100, 250, 500,and 1000 mg/kg/day), EE (1, 3, 10, and 30 mg/kg/day), DES (0.5, 1.5, 5, and 15 mg/kg/day), or CE (10, 35, 75, and 150 mg/kg/day) in sesame oil once daily for 4 consecutive days. Antiestrogenic effects were determined by coadministering D4 (500 mg/kg/day) with varying amounts of EE. ICI 182,780, a potent antiestrogen, was coadministered (3 mg/kg/day) with EE as a positive control. On the morning following the last dose, animals were euthanized and their uteri removed, weighed, and processed for histological examination. Uterine weight versus log dose was analyzed by linear regression analysis. The coefficients obtained were used to calculate relative potency. Absolute and relative uterine weights and epithelial cell height were statistically increased at all doses of D4 above 100 mg/kg/day. When D4 was coadministered with EE there was a statistically significant reduction in uterine weight compared to EE alone. The results indicate the following ranking based on estrogenic potency: EE > DES >>>>CE >> D4. Relative to the weak phytoestrogen CE, D4 was 83 times less estrogenic. Strain sensitivity was determined by testing Fischer rats under a similar experimental design. In conclusion, D4 showed weak estrogenic and antiestrogenic activity in both rat strains. Based on potency, SD rats were more sensitive to EE, DES, and D4 than Fischer rats. Thus, strain may play a role in the risk characterization of estrogenic or antiestrogenic compounds. (Supported in part by the Silicones Environmental Health and Safety Council.)

1232 BISPHENOL A- INDUCED INCREASES IN UTERINE WEIGHT AND STRESS PROTEIN LEVELS IN OVARIECTOMIZED B6C3F1 MICE ARE MEDIATED THROUGH THE ESTROGEN RECEPTOR.

A. D. Papaconstantinou[1], T. H. Umbreit[2], B. R. Fisher[3], P. L. Goering[2] and K. M. Brown[1]. [1]*Department of Biological Sciences, The George Washington University, Washington, DC,* [2]*Health Sciences Branch, Center for Devices and Radiological Health, USFDA, Rockville, MD and* [3]*Covance Laboratories, Inc., Vienna, VA.*

We have previously shown that bisphenol A (BPA), a ubiquitous and abundant contaminant of the environment and food products, increased uterine weights and altered uterine morphology and stress protein levels in ovariectomized mice. From these *in vivo* studies we concluded that BPA was weakly estrogenic. In the present study we examined the effects of the estrogen receptor antagonist ICI 182,780 (ICI), on BPA-induced increases in uterine weight and stress protein levels. Ovariectomized B6C3F1 mice were injected subcutaneously daily for 4 days with corn oil, 40 ng beta-estradiol, 2 mg BPA, or a low (20 μg) or high (200 μg) dose of ICI alone or in combination with 2 mg of BPA. Uterine wet weights were taken, and levels of the stress proteins, hsp90alpha, hsp72, hsc73, and grp94 in uterine homogenates were evaluated by Western blot analysis. BPA increased uterine weights and levels of hsp90alpha and grp94, and these effects were partially reversed by the high dose of ICI. The results of this study suggest that the BPA-induced increases in both uterine weight and stress protein levels are at least partially mediated through the estrogen receptor.

1233 IMPOSEX INDUCTION BY NEUROHORMONES.

E. Oberdörster[1] and P. McClellan-Green[2]. [1]*Clemson University, Pendleton, SC and* [2]*Duke University Marine Laboratory, Beaufort, NC.*

The peptide hormone APGWamide induces imposex more effectively than either tributyltin or testosterone in *Ilyanassa obsoleta*. Imposex, the imposition of male characteristcs on female snails, is caused by exposure to tributyltin (TBT) at concentrations as low as 2 ng/L. The mechanism of imposex induction has been proposed to be the inhibition of aromatase. However, the role of vertebrate steroid hormones in sexual development of molluscs has been questioned since only peptide hormones play a significant role in sexual development in most invertebrate phyla. Mud snails, *Ilyanassa obsoleta*, were injected (i. p.) every other day with either TBT (2 or 20 ng), testosterone (5 or 50 ng), or one of four peptide hormones: APGWamide, conopressin, LSSFVRIamide, or FMRFamide (1 or 100 picomoles). Control snails were injected with either PBS (for peptides) or ethanol (TBT and testosterone). Twenty snails were sacrificed after 7 and 14 days for each exposure group, sexed, and percent imposex and penis length measured. Imposex in control snails ranged from 7-11%, with an average penis length of 0.16 mm. Both TBT and testosterone significantly induced imposex at the 20 ng level and 50 and 500 ng levels, respectively. Maximal induction was by 500 ng testosterone on day 14 at 39%/0.25 mm. APGWamide significantly induced imposex at both doses. The 1 pmol dose imposex levels were 69%/0.32 mm after 7 days, and 80%/0.49 mm after 14 days. The 100 pmol dose imposex levels were 65%/0.24 mm after 7 days and 81%/0.28 mm after 14 days. The other neurohormones did not significantly induce imposex. From this data, it is clear that APGWamide induces imposex much more rapidly and results in longer penis length than either TBT or testosterone.

1234 MOLECULAR CLONING OF ESTROGEN RECEPTOR ISOTYPES IN LARGEMOUTH BASS, *MICROPTERUS SALMOIDES*.

T. L. Sabo-Attwood, C. J. Bowman and N. D. Denslow. *University of Florida Department of Pharmacology & Therapeutics, Gainesville, FL.*

Environmental endocrine disruptors have caused a variety of adverse biological effects in wildlife species. Many of these compounds have been shown to mimic estrogens and mediate their effects via the estrogen receptor (ER). The discovery of estrogen receptor isotypes raises questions regarding the mechanisms of action of estrogen and related environmental contaminants. We have recently cloned portions of both ERα and ERβ cDNA from largemouth bass liver tissue. A third sequence with mixed homology to ERα and ERβ has yet to be characterized. Using alpha-specific primers, 553bp and 900bp sequences were amplified that contain as high as 93% homology to the ERα ligand and DNA binding domains of other fish species. Overall, a 1.4kb sequence can be pieced together representing domains C,D, and E of ERα. A portion of ERβ cDNA spanning the DNA binding domain and following loop region was amplified using primers that were specific at the 3' end. With these primers, two sequences were produced with approximate sizes of 500 bp each. Cloning and sequencing showed that one fragment shared 90% homology with ERβ of other aquatic species including gilthead and tilapia, while the other insert showed high but mixed homology to ERα and ERβ. These fragments can be used as probes in the further characterization of the receptors while concurrent work ensues to obtain the entire coding sequences. The availability of receptor isotypes will allow for determination of how xenobiotic contaminants interact with the ER's to illicit their effects.

1235 COMPARATIVE ENDOCRINOLOGY STUDY OF DEHYDROEPIANDROSTERONE (DHEA) AND A FLUORINATED ANALOGUE IN RATS.

A. P. Brown[1], R. L. Morrissey[2], S. Das[3], J. A. Crowell[4] and B. S. Levine[1]. [1]*University of Illinois, Toxicology Research Laboratory, Chicago, IL,* [2]*Pathology Associates International, Chicago, IL,* [3]*AniLytics, Inc., Gaithersburg, MD and* [4]*National Cancer Institute, Rockville, MD.*

This study compared the endocrinologic effects of DHEA and fluasterone (fl-DHEA) in male and female rats following four weeks of daily oral (gavage) administration. DHEA is an adrenal steroid that is under development as a potential cancer chemopreventive agent. However, due to DHEA's endocrine effects, a fluorinated analogue (fl-DHEA) was synthesized as an alternate agent. Initial dose levels studied were 0, 30 and 300 mg/kg/day for each compound (N = 12/sex/group). However, due to weight loss at the high dose level for each drug, dose levels were lowered to 150 mg/kg/day for DHEA and fl-DHEA. DHEA at 30 or 300/150 mg/kg/day produced an estrogenic effect in female rats expressed as decreased plasma FSH and LH, inhibition of ovulation, prolonged estrus and increased uterine estrogen receptors. DHEA also increased plasma levels of androstenedione in both sexes. fl-DHEA decreased plasma FSH, LH and tissue estradiol, and increased plasma dihydrotestosterone levels in both sexes. fl-DHEA at 30 or 300/150 mg/kg/day increased the diestrus II phase, while 300/150 mg/kg/day fl-DHEA decreased the weights of the uterus, prostate, seminal vesicles and testes, and decreased the occurrence of estrus. Qualitatively different endocrinologic effects were produced by the compounds; DHEA produced an estrogenic response in female rats, while fl-DHEA produced complex endocrinologic effects in both sexes. (Supported by NCI Contract No. NO1-CN-75127-MAO.)

1236 CALPAIN ACTIVITY, AND CALPAIN INHIBITORS IN DELAYED NEUROPATHY INDUCED BY ORGANOPHOSPHATES (OP): MONITORING USING AUTOANTIBODIES.

H. El-Fawal and A. DeFeo. *Mercy College, Dobbs Ferry, NY.* Sponsor: J. P. O'Callaghan.

Previous studies demonstrated the attenuating effects of calcium channel blockers or calpain inhibitors on the development of OP-induced delayed neuropathy (OPIDN) in hens. This modifying effect by calcium channel blockers extended to the attenuated activity of the calcium-dependent protease calpain. Therefore, selective calpain inhibitors I (CaI) and II (CaII) were used to modify the development of OPIDN following a single dose of phenyl saligenin phosphate (PSP, 3 mg/kg, im). CaI and CaII (5 mg/kg, im) were administered immediately before PSP and 24h after PSP. Quantification of clinical signs was by measurement of stride width and length. This indicated that functional impairment was greatest in hens treated with PSP only. CaI and CaII did not attenuate the inhibition of neuropathy target esterase (NTE) produced by PSP at 24h, nor did they themselves inhibit NTE. Calpain activity in brain, spinal cord, and sciatic nerve were 140%, 130%, and 175%, respectively, compared to controls at 14 days post-PSP exposure. The amelioration of the degree of OPIDN development was confirmed by histological examination of the biventer cervicis nerve, and by assay for serum autoantibodies to neurofilaments (Nfs), and myelin basic protein (MBP). Autoantibodies to Nfs were detected as early as 6 days post-PSP exposure and predominated in hens not receiving calpain inhibitors. Autoantibody levels significantly correlated with the decline in gait length at 14 and 21 days. This data further implicates calpain in development of OPIDN, and suggests that calpain inhibitors can modify OPIDN. Furthermore, serum autoantibodies to nervous system proteins may be used to monitor neuropathy development and intervention. (Supported by NIH HD35965.)

1237 NEUROPATHY IN ORGANOPHOSPHOSPHORUS PESTICIDE (OP)-EXPOSED WORKERS: MONITORING USING AUTOANTIBODY (AAB) TO NERVOUS SYSTEM AND MUSCLE PROTEINS.

A. De Feo and H. A. N. El-Fawal. *Mercy College, Dobbs Ferry, NY.*
Sponsor: J. P. O'Callaghan.

Human exposed to pesticides or heavy metals have been shown to have serum AAb to nervous system (NS) proteins that may be indicative of subclinical neurotoxicity. Some OP pesticides are suspected of causing neuropathy and/or myopathy. Agricultural workers exposed to OP for a period exceeding 5 years (n=65) and a reference population from a food processing plant (n=50, no direct exposure) were assessed for possible neuropathy and/or myopathy using serum AAb detection against neurofilaments (NF), myelin basic protein (MBP), desmin (D), choline acetyl transferase (ChAT), and acetylcholinesterase (AChE). OP pesticides included metamidophos, and chlorpyrifos, both suspected of causing neuropathy. IgG to NF, neuronal intermediate filaments, and MBP predominated in pesticide workers. IgG to ChAT, a presynaptic enzyme of motor neurons, was found only in pesticide-exposed workers. IgG to D, a muscle intermediate filament, and to AChE were detected in 45% of the pesticide-exposed group. AChE activity was 40-60% of normal (24 IU/g Hb). In contrast, few of the reference population had detectable IgG levels, only IgM to NF. None had either IgG or IgM to MBP, D, ChAT, or AChE. IgG levels to NF correlated with exposure duration. In addition, IgG levels to NF and D correlated with peripheral sensorimotor deficits (muscle tremor and reflexes). The detection of AAb to NF, and MBP suggests neuronal involvement, while those to ChAT suggest α-motorneurons. Neuromuscular damage is further supported by detection of AAb to D, possibly due to AChE inhibition. OPs are known to produce neuropathy resulting in AAb. This study suggests that AAb detection may be useful in monitoring pesticide neurotoxicity in the field. (Supported by NIH HD35965.)

1238 THE EFFECT OF REPEATED ORAL EXPOSURES TO CHLORPYRIFOS OR METHYL PARATHION ON BRAIN CHOLINERGIC AND DOPAMINERGIC SYSTEMS IN DEVELOPING RATS.

J. Tang and J. E. Chambers. *Center for Environmental Health Science, College of Veterinary Medicine, Mississippi State University, Mississippi State, MS.*

The wide use of chlorpyrifos (CPS) and methyl parathion (MPS) is of great public health concern, particularly because juveniles are more sensitive to these compounds. The effect of CPS or MPS on cholinesterase (ChE) activity, muscarinic acetylcholine receptor (mAChR) subtypes (M1 and M2) densities, choline acetyltransferase (ChAT) activity, and dopamine (DA) receptors (D1 and D2) densities in cortex and/or striatum was studied in early postnatal rats gavaged daily with CPS or MPS in corn oil from postnatal day (PND)1 through PND 21. Rats in the low dosage groups received CPS and MPS at 1.5 and 0.3 mg/kg, respectively, for all treatments. Rats in the high dosage groups received incremental dosages from 1.5 to 6 mg/kg for CPS or from 0.3 to 0.9 mg/kg for MPS. This dosing protocol resulted in about 32% and 62% ChE inhibition in cortex and striatum, respectively, in the low dosage groups of both compounds, and about 70% and 80% ChE inhibition in cortex and striatum, respectively, in the high dosage groups of both compounds on PND 22. M1 and M2 mAChR densities in cortex were about 73% and 79% of control levels in the high CPS and MPS dosage groups, respectively, and in striatum about 59% and 76% of control levels in the high CPS and MPS dosage groups, respectively, on PND 22. ChAT activity in the high MPS dosage group was 82% of control levels on PND 22. D1 DA receptor density in striatum decreased (about 61% of control levels in both compounds) on PND 6 and increased (about 120% and 133% of control levels in the CPS and MPS groups, respectively) on PND 14. D2 DA receptor density in striatum was about 72% of control levels in all treated groups on PND 22. The results indicate that changes in cholinergic and dopaminergic systems were induced by repeated oral exposure to CPS or MPS in developing rats. (Supported by NIH RO1 ES04394.)

1239 ANALYSIS OF THE ADDITIVITY OF *IN VITRO* INHIBITION OF AChE BY MIXTURES OF CHLORPYRIFOS-OXON AND AZINPHOS-METHYL-OXON.

J. R. Richardson[1], H. W. Chambers[2] and J. E. Chambers[1]. [1]*Center for Environmental Health Sciences, College of Veterinary Medicine, Mississippi State University, MS and* [2]*Dept. of Entomology and Plant Pathology, Mississippi State University, MS.*

Organophosphorus (OP) insecticides act through a common mechanism of toxicity, the inhibition of acetylcholinesterase (AChE) by their active metabolites. The effects of *in vitro* exposure of AChE to chlorpyrifos-oxon (C=O) and azinphos-methyl-oxon (AZM=O), was investigated to determine if concurrent exposure to these two OP compounds results in purely additive effects. Inhibition values (concentrations of inhibitor required to elicit 10-90% inhibition of AChE) were determined individually for C=O and AZM=O in increments of 10% for AChE in a rat brain membrane preparation. Then, percentage inhibition for various mixtures of the two compounds was determined by the addition of a defined concentration of C=O (110, 120, or 130) along with various defined concentrations (110-170) of AZM=O, and repeated with AZM=O held constant and C=O varied at the same concentrations. The theoretically calculated percent inhibition, which takes into account the fraction of AChE molecules assumed to be available for inhibition by the second compound following inhibition by the first compound, was calculated for the various mixtures and compared to the experimentally observed percentage inhibition. Theoretical calculations determined that the inhibition of AChE by mixtures of AZM=O and C=O would result in less than simple mathematical summation of percent inhibitions, and was confirmed by experimental results. For example, an 120 of C=O and an 140 of AZM=O yielded a theoretical inhibition of 49.35% and experimental results yielded a value of 49.4% inhibition, not the 60% which is calculated by simple summation of the individual percent inhibitions. These data suggest that simple mathematical summation of percent inhibitions is not the appropriate method for describing the combined effects of C=O and AZM=O on AChE *in vitro*.

1240 BRAIN ACETYLCHOLINESTERASE SENSITIVITY TO INHIBITION BY ORGANOPHOSPHATES IN JUVENILE AND ADULT RATS.

A. Kachroo, J. E. Chambers and H. W. Chambers. *Mississippi State University, Starkville, MS.*

Juvenile rats are more sensitive to the acute toxicity of organophosphate (OP) insecticides than are adults. Brain acetylcholinesterase (AChE) sensitivity, as measured by IC50 analysis, has been shown to be the same in both juvenile and adult rats for paraoxon (Atterberry et al., TAP 147:2, 1997) and chlorpyrifos-oxon (Padilla et al., TAP 148:1, 1998). Based on these data alone, it could be assumed that no age-related differences in AChE sensitivity occurs. AChE was assayed in whole brain homogenates spectrophotometrically using acetylthiocholine as the substrate and 5,5'-dithio-bis(2-nitrobenzoic acid) as the chromogen. IC50 values for diazoxon, azinphosmethyl-oxon, O-methoate, coroxon, paraoxon, chlorpyrifos-oxon, methyl paraoxon, fenitrooxon, malaoxon and phoxim-oxon were determined in 12 and 70 day old male rats. IC50 values for these 10 compounds ranged from 2 nM to 15,867 nM. Similar IC50's for coroxon, paraoxon, chlorpyrifos-oxon, methyl paraoxon, fenitrooxon and malaoxon were observed for both ages. However, diazoxon, azinphosmethyl-oxon, O-methoate, and phoxim-oxon exhibited 1.3-, 1.3-, 1.2-, and 1.2- fold lower IC50 values, respectively, for juveniles than adults ($p<0.05$). These data suggest that the sensitivity of brain AChE to inhibition by OP compounds may not always be the same for juveniles and adults, and that these differences are compound specific. The greater sensitivity of the AChE to inhibition by some OP compounds could contribute to the greater vulnerability of juveniles to OP insecticide toxicity.

1241 EFFECTS OF PCB EXPOSURE ON THE TOXIC IMPACT OF ORGANOPHOSPHORUS INSECTICIDES.

R. L. Carr, J. E. Chamber, T. A. Couch, G. C. Durunna, J. A. Guarisco, A. Kachroo, E. C. Meek and J. R. Richardson. *Center for Environmental Health Sciences, College of Veterinary Medicine, Mississippi State University, Mississippi State, MS.*

Exposure to polychlorinated biphenyls (PCBs) can alter the metabolism of organophosphorus (OP) insecticides. PCB exposure not only increases cytochrome P450 levels but also increases levels of A-esterases and carboxylesterases which can detoxify the insecticides' active metabolites (oxons). Following administration of 4 mg/kg-day Aroclor 1254 in safflower

oil p.o. to female rats for 50 days, rats were injected i.p. with high sublethal dosages of the parent insecticides, parathion (P=S), methyl parathion (MP=S), or chlorpyrifos (C=S), or their respective oxons, paraoxon (P=O), methyl paraoxon (MP=O), or chlorpyrifos-oxon (C=O). Acetylcholinesterase (AChE) activity was determined in the medulla-pons, hippocampus, corpus striatum, and cerebral cortex at 2 and 24 hrs post exposure. There was induction of the protective esterases in the PCB rats. At 2 hrs, few differences in the amount of AChE inhibition were observed between control and PCB rats exposed to C=S, P=S, and MP=S. In control rats, the inhibition was higher at 24 hrs than at 2 hrs with C=S and P=S but not with MP=S. The P=S and C=S treated PCB rats had lower levels of AChE inhibition than did the controls suggesting that preexposure to PCBs has a protective effect against the acute toxicity of these two compounds but not MP=S. At 2 hrs with the oxons, no differences in the amount of AChE inhibition were observed between control and PCB rats suggesting that PCB-induction of esterases does not have a protective effect. Substantial recovery of AChE activity had occurred by 24 hrs with all three oxons. However, unlike the other oxons, AChE activity in the P=O treated PCB rats had recovered to a greater extent than had the P=O treated controls suggesting a possible PCB-mediated mechanism which allows faster recovery from P=O exposure. Thus, PCB exposure can attenuate the toxic effects of C=S and P=S but not MP=S or the respective oxons of the insecticides.

1242 ELECTROENCEPHALOGRAM (EEG), CORE TEMPERATURE (T_C) AND MOTOR ACTIVITY (MA) IN THE RAT EXPOSED TO CHLORPYRIFOS (CHP).

O. A. Timofeeva[1,2] and C. J. Gordon[1]. [1]*USEPA NHEERL at Chapel Hill, Research Triangle Park, NC and* [2]*UNC, Chapel Hill, NC.* Sponsor: R. C. MacPhail.

There are reports of acute and chronic changes in the EEG of humans exposed to organophosphate (OP) pesticides. However, little has been done to correlate EEG changes in humans to that of experimental animals exposed to OPs such as CHP. Our study used radio telemetry to monitor cortical EEG, T_c and MA in undisturbed, unrestrained rats exposed to CHP. Transmitters (Data Sciences, St. Paul, MN; model TA10ETA-F40) were implanted intraperitoneally. EEG leads were threaded under the skin and fixed to the skull. EEG power spectra were computed in all vigilance states and averaged hourly at least a day before and after the administration of CHP (25 mg/kg; p.o.). CHP led to a significant decrease in EEG power in the 7-8, 9-13 and 14-27 Hz ranges and increases in the 1-2 and 4-6 Hz ranges. Power shifts were greatest ~4 hr after CHP and were associated with reductions in T_c and MA. The muscarinic agonist oxotremorine (OX) (0.2 mg/kg; s.c.) led to similar marked reductions of EEG power in the 7-27 Hz range. However, OX had no effect on EEG power at the low frequencies. OX also led to a significant reduction in T_c and MA. We propose that the changes in the EEG following CHP are partly attributed to stimulation of muscarinic receptors in the CNS. However, the increase in slow wave activity following CHP is apparently unrelated to muscarinic stimulation. (This abstract does not necessarily reflect US EPA policy.)

1243 COMPARISON OF NEUROLOGICAL AND COGNITIVE EFFECTS FOLLOWING SUBCUTANEOUSLY-ADMINISTERED CHLORPYRIFOS.

V. C. Moser, K. L. McDaniel, T. E. Samsam and P. J. Bushnell. *NHEERL/USEPA, Research Triangle Park, NC.*

Chlorpyrifos, a widely used organophosphorus pesticide, produces in rats alterations in several cognitive tasks, including delayed match-to-position and sustained attention. A profile of lowered activity, ataxia, and decreased sensory responsiveness has also been characterized using a functional observational battery (FOB) and motor activity. This study was conducted to compare the relative sensitivity of neurological and cognitive measures in detecting effects of chlorpyrifos. Adult Long-Evans rats (n=8/dose) were trained to perform an appetitive signal detection task (SDT) designed to assess sustained attention. When performance was stable, rats received a single subcutaneous dose of either 0, 60, 125, or 250 mg/kg chlorpyrifos. SDT testing continued daily after dosing. These rats were also evaluated using the FOB and motor activity before dosing, and 3, 7, and 17 days after the dose. For both types of tests, significant effects were observed only in the high dose group (250 mg/kg). In the SDT, chlorpyrifos produced an increase in the proportion of false alarms for 4 weeks after dosing, and reduced the proportion of hits at high signal intensities during week 1 only. A few behavioral effects were observed with the FOB in the same dose group. These changes included decreased rearing in the open field at all test times, and decreased response to the tail-pinch stimulus at the 3-day test only. These data reflect impaired sustained attention after administration of subcutaneous chlorpyrifos, at a dose that also produced neurobehavioral alterations. (This abstract does not necessarily reflect US EPA policy.)

1244 NEUROLOGIC ASSESSMENT OF RATS FOLLOWING LOW DOSES OF SARIN, PYRIDOSTIGMINE, CHLORPYRIFOS, AND DEET.

C. T. Olson, J. A. Blank, P. H. Kinney, A. W. Singer, G. B. Freeman and R. A. Lordo. *Battelle, Columbus, OH.*

Potential neurobehavioral and neuropathologic effects in rats due to exposure to low levels of Sarin (GB), alone or in combination with other compounds to which soldiers may have been exposed during the Persian Gulf War, were assessed. Doses of pyridostigmine bromide (PB) im, Sarin (GB) sc, and chlorpyrifos (CPF) topically which produced approximately 20-30, 5-10, and 5-10 percent whole blood cholinesterase inhibition (ChE-I), respectively, were used along with 15 μL N,N-diethyl-m-toluamide (DEET;≥ 97%) topically, either separately or combined, in adult Sprague-Dawley rats. Compounds were given either once a day (PB,GB) or twice a day (CPF, DEET) for four days. Blood samples were taken prior to initial dosing, the day following the last dose, and 30 days after the start of dosing to measure ChE-I. Neurobehavioral assessments were accomplished prior to dosing, the day after the last dose, and the 15th and 30th day after the start of dosing using a Functional Observational Battery (FOB) and a Figure 8 Activity Monitor. Rats were then sacrificed and selected tissues from the central and peripheral nervous systems were collected and examined microscopically. No neurobehavioral or neuropathologic effects could be attributed to dosing with GB, alone or in any combination, or to the other compounds. (This research was supported by the Department of the Army under Contract No. DAMD17-97-C-7067.)

1245 ACUTE SARIN EXPOSURE LEADS TO CHOLINERGIC DYSREGULATION IN CENTRAL NERVOUS SYSTEM OF RATS.

W. A. Khan, A. Dechkovskaia, K. H. Jones and M. B. Abou-Donia. *Duke University Medical Center, Department of Pharmacology and Cancer Biology, Durham, NC.*

The neurotoxic effects of the nerve agent sarin (isopropyl methyl phosphonoflouridate are mediated, primarily by inhibition of acetylcholinesterase (AChE). Other biological targets of sarin that are linked to acetylcholine metabolism, however, have not been evaluated in detail. In the present study, we evaluated the enzymes involved in the biosynthesis and degradation of acetylcholine after acute exposure to sarin. Male Sprague-Dawley rats were exposed to a single LD50 dose (100μg/kg, i.m.) of sarin for various time periods and their brain AChE, choline acetyl transferase (ChAT) and plasma butyrylcholinesterase (BChE) activities were studied. Brain AChE activity was significantly inhibited in cortex, mid brain, brain stem and cerebellum and plasma BChE by 1 hr and remained inhibited for extended period following single exposure. In contrast, ChAT activity registered an increase in cortex and brain stem at 1 and 3 hr post exposure, but remained unchanged in mid brain. Also, we detected only minimal activity in the cerebellum that remained unchanged after sarin exposure. These data suggest that acute sarin exposure may modulate the biosynthesis and degradation of acetylcholine differentially and thereby cause dysregulation in excitatory neurotransmission. (Supported in part by a DOD Grant DAMD 17-98-C-8027.)

1246 TOXICITIES OF ORGANOPHOSPHORUS COMPOUNDS IN A HUMAN NEUROBLASTOMA (SH-SY5Y) CELL LINE.

T. Cho and E. Tiffany-Castiglioni. *Texas A&M University, College Station, TX.*

Organophosphorus compounds (OPs) are widely used for the purpose of pest control. A major portion of military chemical warfare agents is also comprised of OP compounds. OP toxicity is primarily associated with the inhibition of cholinesterase activity, resulting in over-stimulation of acetylcholine that in turn could lead to death of exposed organism by suffocation. Unlike OP compounds such as paraoxon that inhibit cholinesterase activity acutely, some OP compounds, such as mipafox and DFP, can induce organophosphate induced delayed neuropathy (OPIDN) which is characterized by a 10-14 day delayed onset of symptoms such as ataxia and muscle paralysis. This study reports on

the evaluation of acetylcholinesterase inhibition of paraoxon, dementon-S, mipafox, and methyl parathion with the human neuroblastoma cell line, SH-SY5Y. Mipafox and paraoxon exhibited the highest and the lowest apparent IC_{50}s at 8.91 and 0.0084 μ M, respectively. Methyl parathion and dementon-S exhibited IC_{50}s in μ M range, 4.35 and 1.45 μ M, respectively. These findings indicate that oxidized compounds such as paraoxon have more potent anticholinesterase activity. In an amino acid incorporation assay, mipafox induced a significant reduction of [^{3}H]-leucine incorporation into protein at doses at or above 0.5 and 5 μ M for 4 and 7 day incubation, respectively. The SY5Y cell line responds to nerve growth factor (NGF) to express adrenergic activity and neurite growth. Among many proteins comprising the neurite, neurofilament (NF) is one of the major structural proteins. It was reported that NF-H is expressed much later in development than NF-L and NF-M. This study reports that NGF induced the increase of NF-H expression approximately 2 times over the control based on western analysis. It is expected that this protein can be one of the prospective tools to detect neuronal deformation related to OPIDN.

1247 DELAYED INTERACTIVE EFFECTS OF SARIN, PYRIDOSTIGMINE AND EXERCISE ON THE BIOCHEMICAL AND HISTOPATHOLOGICAL CHANGES IN MICE.

T. Asha, K. Husain, R. Helfert, S. Verhulst and S. M. Somani. *Southern Illinois University School of Medicine, Springfield, IL.*

Pyridostigmine (PYR), a reversible cholinesterase inhibitor, was used as a pretreatment drug for possible nerve agent exposure during the Gulf War. Military personnel were under physical stress and might have been exposed to low dose sarin. Hence, this study investigated the interactive effects of low-dose sarin, PYR and exercise training in mice. Male NIH Swiss mice were divided into five groups and treated as follows: (1) Control; (2) Sarin [0.01 mg /kg, s.c.]; 3) Sarin + exercise; (4) Sarin + PYR [1.2 mg/kg, p.o.]; (5) Sarin + PYR + exercise. Exercise was given for 10 weeks; however, PYR and sarin were administered daily during 5th and 6th weeks. The animals were sacrificed 24 hours after the last treatments. Tissues were dissected and processed for biochemical analysis and light and electron microscopy. Mild patchy lesions, small angulated fibers, central nucleation and foci of myonecrosis were observed only in the muscle of exercise + sarin or PYR + sarin groups. Sarin significantly decreased plasma BuChE activity, platelet, triceps muscle, and striatal AChE activity (81%, 71%, 68% and 63% of control, respectively); NTE activity in platelets, spinal cord, cortex and striatum (55%, 82%, 63% and 75% of control, respectively). Sarin significantly increased MDA levels in sciatic nerve and spinal cord (122% and 126% of control, respectively). Exercise + sarin group showed a significant reduction in plasma BuChE activity, platelets, triceps muscle, sciatic nerve and striatal AChE activity (79%, 58%, 56%, 76% and 71% of control, respectively). NTE activity in platelets, spinal cord, cortex and striatum (42%, 69%, 58% and 72% of control, respectively). Exercise + sarin group also showed a significant increase in plasma CPK activity and MDA in spinal cord (112% and 132% of control, respectively). PYR + sarin + exercise group significantly altered muscle AChE activity, MDA level, platelets, sciatic nerve spinal cord and cortical NTE activity. The data suggest that exercise potentiated the biochemical and histopathological changes in tissues of mice treated with sarin and sarin + PYR. (Supported by US Army contract # DMAD17-97-C-7066.)

1248 EFFECT OF LOW LEVEL SARIN EXPOSURE ON PHYSIOLOGICAL PARAMETERS IN RATS.

R. F. Henderson[1], C. A. Conn[1], E. B. Barr[1], T. H. March[1], J. R. Krone[1], M. L. Sopori[1], Y. Tesfaigzi[1], M. Wachulec[1] and D. B. Mash[2]. [1]*Lovelace Respiratory Research Institute, Albuquerque, NM and* [2]*University of Miami, Miami, FL.*

Since the conclusion of the Persian Gulf War in 1991, some veterans have complained of diverse symptoms. This has increased interest in the potential long-term effects of single or repeated exposure to subclinical levels of nerve gas. As a part of this research effort, male F344 rats are being exposed singly (1 hour) or repeatedly (1 hour each day for 5 days or for 10 days) under normal and heat-stressed (core body temperature elevated by 1°C) conditions to 0, 0.2 or 0.4 mg/m^3 of sarin. The exposure levels represent literature values for the EC_{50} and one-half the EC_{50} for rats. Preliminary studies indicated that the exposures caused no overt symptoms of neurotoxicity (tremors) under non-heat stress conditions. Studies on temperature regulation indicated that 32°C was the ambient temperature required to raise the core body temperature of the rats (normally held at 25°C) by approximately one degree. When the rats were confined in nose-only exposure tubes, ambient temperatures of 17 and 22°C were required to maintain normal and heat-stressed core body temperatures, respectively. Analysis of changes in brain cytokine levels indicated that the cytokines (IL-1, IL-6), peaked after 3 days of heat stress; based on this information, animals were placed under heat-stress conditions for 3 days prior to exposure. During the study, the core body temperatures, as well as the motor activity of the rats, were monitored from 3 days before the beginning of the exposures until one month after the end of the exposures. Respiratory parameters were measured during the exposure. At 1 day and at 1 month after the end of the exposures, groups of rats were sacrificed and brains analyzed for total cytokines by RT-PCR and by *in situ* immunohistochemistry techniques. Brains were also analyzed for histopathology, including apoptosis and for concentration of cholinergic receptor sites. This is a report of the initial findings of the physiological response of the rats to inhaled sarin. Changes in respiration rate, core body temperature and motor activity were noted. (Research was funded by the US Army under Contract DAMD17-97-C-7054.)

1249 PERSISTENT NEUROBEHAVIORAL EFFECTS IN SPRAGUE-DAWLEY RATS FOLLOWING PRENATAL EXPOSURE TO THE ENVIRONMENTAL ESTROGEN, CHLORDECONE.

S. A. Laessig, A. P. Auger, M. M. McCarthy and E. K. Silbergeld. *University of Maryland, Baltimore, Baltimore, MD.*

The chlorinated pesticide, chlordecone, was banned in the USA because of its relatively strong estrogenic and neurotoxic activity. It is now useful as a model for estrogenic endocrine disruptors. Perinatal exposure of female rats to high doses of chlordecone results in altered vaginal opening, estrous cycling, and behavior. Because the developing brain is extremely sensitive to gonadal steroids, we examined the effect of prenatal chlordecone exposure on sexually dimorphic adult behaviors. We examined spontaneous activity and sex behavior in adult rats of both sexes to test if prenatal chlordecone (CD) exposure altered central nervous system function in adults. Chlordecone (5 mg/kg) was administered to pregnant rats on gestation day 16. At 50 days of age, body weight did not differ, but testis weight was significantly increased in males prenatally exposed to CD compared to controls ($p<0.001$). Behavioral tests were performed at 60-120 days of age following gonadectomy. Females prenatally exposed to CD displayed an increased ratio of inside/total crossings in an open field ($p<0.02$) with no change in total ambulation compared to controls. Males exposed to CD were not different from controls in the open field test. However, both males and females prenatally exposed to CD displayed increased levels of lordosis (female sex behavior) compared to controls when primed with estradiol benzoate and progesterone ($p<0.05$). After implanting with testosterone, a greater proportion of naïve males prenatally exposed to CD mounted stimulus females than naïve control males ($p<0.05$). These results suggest that prenatal exposure to the environmental estrogen chlordecone persistently altered sexually dimorphic behaviors in adult male and female rats. (Supported by a VA Merit Award to MMM and EKS and an American Fellowship from the American Association of University Women to SAL.)

1250 LINDANE *PER OS* INHIBITS ITS OWN ABSORPTION; PK 1195 EXACERBATES AND DEVAZEPIDE ANTAGONIZES THIS.

D. Woolley, E. Garcia, L. Drummer and K. Dai. *University of California, Davis, CA.*

Lindane is a neurotoxicant with antiGABAergic effects which include seizures, hypothermia and anorexia when given p.o. in the rat. PK 11195 (a 2-phenyl isoquinoline carboxamide) exacerbated lindane-induced hypothermia when both were given i.p., perhaps because of synergistic interaction between the 2 compounds at GABA-A receptors in temperature-regulating centers. When lindane was given p.o. and PK 11195 i.p., the effects of lindane were reduced. *In vitro* studies using intestinal strips revealed that both PK 11195 and lindane reduced the amplitude of intestinal contractions. A synergistic interaction in reducing G.I. motility, and therefore absorption of lindane, was hypothesized to account for the reduction of the effects of lindane by PK 11195. The direct effects of lindane in decreasing intestinal motility probably result from antagonizing the GABA-A receptor in the myenteric plexus. Devazepide, which is a cholecystokinin (CCK) -A receptor antagonist, given i.p. worsened the convulsant effects of lindane given p.o., at least in part by preventing constriction of the pyloric sphincter caused by lindane. This allowed more lindane to leave the stomach and be absorbed in the intestine. It is hypothesized that, when given p.o., lindane reduces its own absorption by antagonizing the GABA-A receptor and thus slowing intestinal motility. In the same way, gastric motility and the probability that the pyloric sphincter is open are also reduced. This would slow emptying of the stomach and also reduce toxicity.

1251 CHRONIC GAVAGE TOXICITY/CARCINOGENICITY STUDY OF METHYLEUGENOL IN F-344/N RATS.

J. D. Johnson[1], M. J. Ryan[1], S. W. Graves[1], M. R. Hejtmancik[1], R. Herbert[2] and K. M. Abdo[2]. [1]*Battelle, Columbus, OH and* [2]*NIEHS, Research Triangle Park, NC.*

Methyleugenol (MEG) is used as a flavoring agent and to impart fragrance in cosmetic products. MEG was selected for testing because of its widespread use and structural resemblance to known carcinogens, eg. safrole. Male and female F-344/N rats (50/sex/group) were administered MEG (99% purity) in 0.5% methylcellulose by gavage at doses of 37, 75 or 150mg/Kg, 5 days/week, for 105 weeks; a control group (60 rats/sex) received only the vehicle and a stop-exposure group (60 rats/sex) received 300mg/Kg for 53 weeks followed by the vehicle only for the remaining 52 weeks. MEG decreased survival (≥150mg/Kg) and body weight (≥37mg/Kg). MEG induced liver, glandular stomach and kidney neoplasms. The overall incidence of hepatocellular adenomas or carcinomas was 7/50, 14/50, 28/50, 43/50 and 45/50 (males) and 1/50, 8/50, 14/49, 34/49 and 43/50 (females) for the control, 37, 75, 150 and 300 mg/Kg groups, respectively. The incidence of hepatocholangioma and hepatocholangiocarcinoma was increased at 300mg/Kg. The overall incidence of benign or malignant stomach neuroendocrine tumors was increased at doses of ≥150mg/Kg (males) or ≥75mg/Kg (females) and of renal tubule adenomas at doses of ≥75mg/Kg (males only). Also, a positive trend in the incidence of malignant mesotheliomas, mammary gland fibroadenomas, subcutaneous fibromas and fibrosarcomas was observed for higher dose groups of male rats. MEG caused a dose-dependent increase in the incidence of non-neoplastic lesions in the liver (eosinophilic/mixed cell foci, hypertrophy, oval cell/bile duct hyperplasia and cystic degeneration), glandular stomach (mucosal atrophy/neuroendocrine cell hyperplasia) and kidney (renal tubule hyperplasia). Under the conditions of this study, MEG produced clear evidence of carcinogenic activity in both sexes of F-344/N rats. (Supported by N01-ES-25337.)

1252 CHRONIC GAVAGE TOXICITY/CARCINOGENICITY STUDY OF METHYLEUGENOL IN B6C3F$_1$ MICE.

M. R. Hejtmancik[1], J. D. Johnson[1], J. D. Toft II[1], S. W. Graves[1], R. Herbert[2] and K. M. Abdo[2]. [1]*Battelle, Columbus, OH and* [2]*NIEHS, Research Triangle Park, NC.*

Methyleugenol (MEG) is used as a flavoring agent in foods and beverages, as well as to impart a fragrance in cosmetic products. MEG was selected for testing because of its widespread use and structural resemblance to known carcinogens, eg. safrole. Male and female B6C3F$_1$ mice (50/sex/group) were administered MEG (99% purity) in 0.5% methylcellulose by gavage at doses of 0 (control), 37, 75 or 150mg/Kg, 5 days/week, for 104 weeks. Survival was similar to control for males but decreased to 37, 33 and 4%, respectively, for females. At termination, group mean body weights decreased 11 to 17% (males) and 40 to 47% (females) relative to controls. MEG induced liver and glandular stomach neoplasms. The overall incidence of hepatocellular adenoma, carcinoma or hepatoblastoma was 31/49, 47/50, 46/50 and 41/50 (males) and 25/50, 50/50, 49/49 and 49/50 (females) for the control, 37, 75 and 150mg/Kg groups, respectively. In addition, the 150mg/Kg group exhibited malignant neuroendocrine tumors of the glandular stomach (2/50 males) and hepatochol-angiocarcinomas (2/50 females). MEG caused a dose-dependent increase in the incidence of non-neoplastic liver lesions (eosinophilic foci, hypertrophy, necrosis, oval cell and bile duct hyperplasia, hemosiderin pigmentation, chronic active inflammation and hematopoietic cell proliferation) and glandular stomach lesions (glandular ectasia, mucosal atrophy, chronic active inflammation and epithelial and neuroendocrine cell hyperplasia). Under the conditions of this study, MEG produced clear evidence of carcinogenic activity in both sexes of B6C3F$_1$ mice. (Supported by N01-ES-25337.)

1253 SUBCHRONIC TOXICITY OF METHYLEUGENOL ADMINISTERED BY GAVAGE TO F-344 RATS AND B6C3F1 MICE.

M. L. Snell[1], K. M. Abdo[1], R. A. Herbert[1], S. Eldridge[2] and M. L. Cunningham[1]. [1]*NIEHS, Research Triangle Park, NC and* [2]*PAI, Frederick, MD.*

Methyleugenol (MEG) is used as a flavoring agent in foods and as a fragrance in perfumes. It is similar in chemical structure to the carcinogen safrole and was found to induce neuroendocrine (ECL cell) tumors of the glandular stomach and liver tumors in a recent NTP bioassay. MEG was administered to F344 female rats at 0, 37, 75, 150, 300 and 1000 mg/kg/day and to B6C3F1 male mice at 0, 9, 18.5, 37, 75, 150 and 300 mg/kg/day for 30 and 90 days. Stomach pH and serum gastrin levels were measured. Cell proliferation and histopathology were analyzed in the squamous epithelium of the forestomach, gastric pits and fundic glands of the glandular portion of the stomach, pyloric region and the liver. Male mice demonstrated significantly increased serum gastrin levels at 150 and 300 mg/kg/day at 30 days as did female rats at 300 and 1000 mg/kg/day and 150, 300 and 1000 mg/kg/day at 90 days. A significant increase in stomach pH was also observed in female rats at 300 and 1000 mg/kg/day at 30 and 90 days. Treatment related increases in cell proliferation were observed in the fundic glands of mice and rats and liver of rats. These data support the hypothesis that the stomach tumors are secondary to parietal cell necrosis causing a rise in stomach pH resulting in chronic gastrin release which is trophic for ECL cell proliferation. Increased cell proliferation may contribute to liver tumors.

1254 CHEMOPREVENTION OF B[A]P-INDUCED MORPHOLOGICAL TRANSFORMATION IN SYRIAN HAMSTER EMBRYO CELLS BY STRAWBERRY EXTRACTS.

H. Xue[1], R. M. Aziz[2], N. Sun[2], L. M. Kamendulis[1], Y. Xu[1], G. D. Stoner[2] and J. E. Klaunig[1]. [1]*Division of Toxicology, Department of Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN and* [2]*Division of Environmental Health Sciences, Ohio State University School of Public Health, Columbus, OH.*

Recent studies have demonstrated potential cancer chemopreventive activity of berry derivatives including strawberries. To date the exact chemical agent(s) responsible for the chemopreventive activity in the strawberries has not been defined. In the present study, we utilized the Syrian Hamster Embryo (SHE) cell Transformation model to examine the potential activity of several strawberry extracts. For strawberry extract preparation, freeze-dried strawberries were combined with methanol and either extracted with water (FA003), dichloromethane and methanol (FA-DM) or methanol only (FA-ME). These extracts were analyzed for anti-transformation activity in the SHE cell assay. Benzo(a)pyrene (B(a)P) was used as the positive carcinogen. In initial studies, the relative toxicity and transformation ability of the extracts was examined. The maximum subtoxic concentration for all extracts was found to be 100 μg/ml. None of the extracts by themselves produced an increase in morphological transformation. For chemopreventive activity assessment, SHE cells were treated with each extract and B(a)P for 7 days. FA-ME (5-100 μg/ml) produced a dose dependent decrease (60-84%) in transformation compared with B(a)P treatment only, while FA-003 and FA-DM did not induce a significant decrease in transformation. In a separate study, the FA-ME was examined for chemopreventive activity after a 24 hr co-treatment with B(a)P and for 6 days after a 24 hr treatment with B(a)P. Under this protocol, FA-ME reduced the transformation rate in a dose dependent manner when coincubated with B(a)P for 24 hrs but failed to prevent transformation when incubated for 6 days following the B(a)P treatment. These results suggest that several fractions of the strawberry extract are potentially chemopreventive with the FA-ME extract having the most potency. The FA-ME fraction was also shown to function during metabolism, activation and/or DNA binding of B(a)P.

1255 REVERSIBILITY OF PRENEOPLASTIC NODULES INDUCED IN RAT PANCREAS BY SOY FLOUR.

R. E. Sigler, L. A. Dethloff, M. S. LaGattuta and F. A. de la Iglesia. *Parke-Davis Pharmaceutical Research, Ann Arbor, MI.*

Rodents fed soy flour (SF) diet develop numerous pancreatic nodules and represent a model for the study of pancreatic tumorigenesis. This work presents data on the putative reversibility of rodent pancreatic nodules. Groups of rats were fed SF diet for 45 weeks. Progression of pancreatic nodules was assessed thereafter by serial laparotomy at 3-month intervals. Post-laparotomy at Week 45, one group (A) was maintained on SF and a second group (B) was on regular rodent chow. At Week 45, SF-fed rats averaged 6 nodules ranging from 2 to 10 mm per pancreas. By Week 58, the number and size of nodules increased in 80% of the rats in Group A. In contrast, Group B rats averaged 3 nodules ranging from 2 to 5 mm. BrdU-containing osmotic pumps were implanted SC 4 days after discontinuing SF diet and acinar and duct cell proliferation were assessed by morphometry. Apoptotic cell death was quantitated in sections stained by terminal nucleotidyl transferase. Acinar cell proliferation decreased in nodules from rats in Group B relative to nodules from rats in Group A. Duct cell proliferation also decreased in nodules from rats from Group B. Increased apoptotic acinar cells were observed concurrently with decreased BrdU labeling in nodules from Group B rats, suggesting that cell proliferation and nodule development, may be reversed or arrested.

1256 EFFECT OF GREEN AND BLACK TEA POLYPHENOLS ON CYCLOOXYGENASE (COX)- AND LIPOXYGENASE (LOX)-DEPENDENT METABOLISM OF ARACHIDONIC ACID IN HUMAN COLON TISSUES.

J. I. Hong[1], T. J. Smith[1], C. T. Ho[2], D. A. August[3] and C. S. Yang[1]. [1]*Lab. for Cancer Research, Rutgers Univ., Piscataway, NJ,* [2]*Dept. of Food Sci., Rutgers Univ., New Brunswick, NJ and* [3]*Robert Wood Johnson Medical School-UMDNJ, Piscataway, NJ.* Sponsor: K. Reuhl.

Ingestion of green tea has been shown to rapidly decrease prostaglandin E_2 (PGE_2) levels in human colorectum, suggesting that tea polyphenols might modulate arachidonic acid metabolism. In this study, we investigated the effects of green and black tea polyphenols on COX- and LOX- dependent arachidonic acid metabolism in normal human colon mucosa and colon cancers. At 30 μg/ml, (-)-epigallocatechin-3-gallate(EGCG), (-)-epigallocatechin (EGC), and (-)-epicatechin-3-gallate (ECG) from green tea and theaflavins (TFs) from black tea inhibited LOX-dependent activity by 35 - 75%. The green tea polyphenols are stronger inhibitors of LOX compared to TFs. The formation of different LOX metabolites was affected evenly by tea polyphenols. Tea polyphenols inhibited COX-dependent arachidonic acid metabolism in normal colon by 37 - 62%, at 30 μg/ml. ECG showed the strongest inhibition. It also inhibited ovine COX-1 in a non-competitive manner with a Ki of 16.9±1.3 μM. Compared to other metabolites, thromboxane (TBX) and 12-hydroxyheptadecatrienoic acid (HHT) formation was more severely inhibited by EGCG, ECG, and TFs. The inhibitory effects of EGCG and TFs on the metabolism were, however, less pronounced in tumors. TFs increased the production of PGE_2 and decreased the formation of TBX and HHT. Among TF mixtures, purified TF showed the most potent increase of PGE_2. The effect was related to COX-2 activity and its expression level in microsomes. The results suggest that inhibition of arachidonic acid metabolism may be one of the possible anticarcinogenic mechanisms of green tea in the prevention of human colon cancer. (Supported by NIH grant CA56673.)

1257 EVALUATION OF THE TUMORIGENIC ACTIVITY OF A CRUCIFEROUS VEGETABLE JUICE IN A SHORT-TERM BIOASSAY USING TRANSGENIC MICE.

P. J. Spencer[1] and B. B. Gollapudi[2]. [1]*University of Michigan, Environmental Health Sciences/Toxicology Program, Ann Arbor, MI and* [2]*The Dow Chemical Company, Toxicology & Environmental Research and Consulting, Midland, MI.*

Cruciferous vegetables such as broccoli are generally believed to be a beneficial component of the human diet by virtue of their protective activity in carcinogenesis. However, recent studies indicated that juices and extracts of these vegetables have genotoxic activity in some *in vitro* test systems (Gupta et al., Reg. Toxicol., 23, 14, 1996; Kassie et al., Chemico-Biol. Interact., 102, 1, 1996). We have previously demonstrated that broccoli juice/extracts, while not mutagenic in the Ames test, exhibited considerable cytotoxicity and genotoxicity in the mouse lymphoma forward mutation assay and the CHO chromosomal aberration test. Since a causal relationship between genotoxicity and carcinogenicity is generally assumed, we have investigated the tumorigenic potential of broccoli juice in a short-term bioassay using the transgenic Tg.AC mouse model. Homo- and hemizygous female Tg.AC mice (15 mice/group/zygosity) were dosed dermally (200 ul/mouse, 5 days/week, 26 weeks) either with acetone; or crude broccoli juice (1:1 ratio in acetone). Mice treated with the phorbal ester TPA (2.5 μg/mouse, 3 days/week for up to 26 weeks) were used as positive controls. No papillomas were observed at the dermal test site of mice treated with broccoli juice or acetone for 26-weeks. However, mice treated with TPA began to develop tumors at approximately 5 weeks after the start of treatment with 100% of genotypically responder mice developing papillomas by the end of the 26-week study. These data suggest that the genotoxic agent(s) present in broccoli juice were efficiently detoxified *in vivo*, a result consistent with the abrogation of broccoli-induced genotoxicity *in vitro* in the presence of S9. Current efforts are underway to examine the antitumorigenic effects of broccoli in Tg.AC mice treated with benzo(a)pyrene or TPA.

1258 RESVERATROL, AN ANTIOXIDANT FOUND IN RED WINE, PREVENTED THE INHIBITION OF GAP JUNCTION INTERCELLULAR COMMUNICATION BY THE TUMOR PROMOTING AGENTS DICUMYL AND BENZOYL PEROXIDES.

J. M. Carbone, T. Lee, L. L. Li, A. M. Rummel, J. E. Trosko and B. L. Upham. *Michigan State University, East Lansing, MI.*

Dicumyl and benzoyl peroxides act as tumor promoters in SENCAR mice, while di-tert-butyl-peroxide does not have tumor promoting activity. Tumor promotion requires the removal of growth suppression by decreasing gap junction intercellular communication (GJIC) and the induction of mitogenic intracellular pathways. We showed that dicumyl and benzoyl peroxides both reversibly inhibited GJIC at noncytotoxic doses in WB-F344 rat liver epithelial cells, while the non-tumor promoting di-tert-butyl peroxide did not inhibit GJIC. Both dicumyl peroxide and benzoyl peroxide also transiently activated mitogen-activated protein kinase, specifically extracellular receptor kinase. The consumption of red wine is believed to be responsible for the low incidence of cancer and heart disease among the French population and the active component of red wine is thought to be the antioxidant resveratrol. We found that pretreating WB cells with resveratrol prevented the GJIC-inhibitory effects by dicumyl and benzoyl peroxides. (This research was supported by the NIEHS Superfund grant #P42 ES04911-07and USAFOSR grant no. F49620-97-1-0022.)

1259 CHEMOPREVENTIVE EFFECTS OF ORALLY ADMINISTERED IMPERATORIN AND ISOPIMPINELLIN.

H. E. Kleiner[1], L. L. Miller[1], S. V. Vulimiri[1], W. H. Johnson[2], C. P. Whitman[2] and J. DiGiovanni[1]. [1]*University of Texas MD Anderson Cancer Center, Smithville, TX and* [2]*University of Texas at Austin, Austin, TX.*

Several naturally occurring coumarins, to which humans are routinely exposed in the diet, were previously found to inhibit P450-mediated metabolism of benzo[a]pyrene (B[a]P) and 7,12-dimethylbenz[a]anthracene (DMBA) *in vitro*, block DNA adduct formation, and inhibit skin tumor initiation by B[a]P and/or DMBA when applied topically to SENCAR mice. The present study was designed to investigate the effects of orally administered naturally occurring coumarins (70 mg/kg, p.o., 4 successive daily doses) on phase I and II enzyme activities, and DNA adduct formation by B[a]P and DMBA in various SENCAR mouse tissues. Orally administered imperatorin and isopimpinellin inhibited both P450 1A1-mediated 7-ethoxyresorufin O-dealkylase and P450 2B1/2-mediated pentoxyresorufin O-dealkylase activities (except in liver) at 1 hr after the last of 4 consecutive doses in forestomach, liver, lung and skin epidermis. Hepatic glutathione S-transferase (using 1-chloro-2,4-dinitrobenzene as substrate) was elevated at both 1 and 24 hr after the last oral dose of both imperatorin and isopimpinellin. Orally administered imperatorin inhibited DMBA DNA adduct formation in epidermis and forestomach. Orally administered isopimpinellin inhibited B[a]P DNA adduct formation in forestomach, liver, and lung. Certain naturally occurring coumarins may be effective anticarcinogens in several tissues when administered orally. (CA79442)

1260 EFFECTS OF INTERMITTENT EXPOSURE TO AFLATOXIN B1 (AFB1) ON DNA AND RNA ADDUCT FORMATION IN RAT LIVER.

R. E. Sotomayor[1], D. M. Hinton[1], M. Washington[1], L. Nguyen[2], R. Nyang'anyi[2] and M. Chou[3]. [1]*CFSAN, USFDA, Laurel, MD,* [2]*JIFSAN, University Maryland, College Park, MD and* [3]*NCTR, USFDA, Jefferson, AR.*

Little is known about the health risks posed by intermittent exposure to chemical carcinogens. AFB_1, a known animal carcinogen, was chosen as the chemical model to assess the effects of intermittent exposure. Fisher-344 male rats were intermittently fed 0.01, 0.04, 0.4, and 1.6 ppm of AFB_1 for 8, 12, 16, 20, and 40 weeks with alternate 4-week dosing periods and 4-weeks no-dosing periods. Other groups of rats were continuously fed 1.6 ppm of AFB_1 for 4, 8, 12, 16 and 40 weeks. DNA and RNA adducts were measured at 4-week intervals for up to 20 weeks of intermittent exposure and for up to 16 weeks of continuous exposure. DNA and RNA were extracted from the liver, purified, and acid hydrolyzed. The hydrolyzed DNA and RNA were extracted by solid-phase extraction before being injected into a Waters HPLC system equipped with fluorescence and photo-diode array detection. Under the HPLC conditions used, AFB_1-N^7-Gua did not separate well from AFB_1-FAPyr1 but AFB_1-FAPyr2 did. Therefore, the terms AFB_1-DNA or -RNA adducts are used here to include both AFB_1-N^7-Gua and AFB_1-FAPyr1 adducts. The extent of AFB_1-

DNA adducts was dose-dependent from 0.01 to 1.6 ppm regardless of the exposure regime. AFB_1-DNA adducts increased 1.5- to 2-fold from 4 to 20 weeks of intermittent exposure only when the rats were dosed the last 4 weeks before sacrifice. When the rats were off-treatment for the last 4 weeks, the levels of AFB_1-DNA adducts decreased but remained significantly above control levels. In comparison, the levels of DNA adducts increased markedly from 4 to 16 weeks of continuous feeding with 1.6 ppm AFB_1 and did not appear to reach a steady-state at 16 weeks of treatment. The extent of AFB_1-RNA adducts was also dose-dependent from 0.01 to 1.6 ppm regardless of the exposure regime. While these results appear significant, further research is needed to determine the overall implications for health risk assessment.

1260A COMPARATIVE ANALYSIS OF CHEMICAL:DNA ADDUCT FORMATION IN MOUSE LUNG FOLLOWING DERMAL APPLICATION OF COAL TAR SHAMPOO AND MGP TAR.

B. L. Ma, A. Yarborough, B. Frimpong and K. Rozett. *Rutgers University, Piscataway, NJ.*

Recent studies have demonstrated that manufactured gas plant (MGP) tar is a potent lung tumorigen when ingested by animals. In addition, lung tissue has been determined to be particularly susceptible to chemical:DNA adduct formation following the ingestion or dermal application of MGP tar. The similarity in the chemical composition of MGP tar and pharmaceutical grade coal tar suggests that coal tar containing shampoos would exhibit similar properties. Thus, the present study evaluated the potential of over-the-counter coal tar containing shampoos to induce chemical:DNA adduct formation in mouse lung following dermal application. Six coal tar shampoos along with shampoo mixtures prepared with pharmaceutical grade coal tar or MGP tar were evaluated. Shampoos were applied to the shaved backs of CD-1 mice fitted with Elizabethan collars to prevent shampoo ingestion. Mice were housed individually for 24 hrs in metabolism cages and urine was collected for 1-hydroxypyrene analysis while chemical:DNA adduct formation was evaluated in lung and skin tissue. In the case of DNA adduct formation, all of the shampoos evaluated produced easily detectable levels of adducts in skin and lung tissue. Adduct levels varied according to the tar content of each shampoo. In some instances, the over-the-counter coal tar shampoos produced lung DNA adduct levels comparable to those observed with mice treated with a similar dose of a shampoo prepared with MGP tar. These results demonstrate that coal tar containing shampoos produce significant levels of chemical:DNA adducts in lung tissue following topical application. In addition, the similarity in the ability to produce lung DNA adducts between MGP tar and coal tar containing shampoos also suggests that these shampoos may exhibit similar biological properties. (EPRI Grant WO2963-06.)

1261 INDOLE-3-CARBINOL DEMONSTRATES ESTROGENIC PROPERTIES IN THE RAINBOW TROUT: CONTRIBUTION OF 3,3'-DIINDOLYLMETHANE.

A. D. Shilling, D. B. Carlson and D. E. Williams. *Department of Environmental & Molecular Toxicology & Marine/Freshwater Biomedical Sciences Center, Oregon State University, Corvallis, OR.*

Indole-3-carbinol (I3C), a compound found in *Brassica* vegetables has been widely studied for its chemopreventive properties. In previous studies, I3C blocked tumor initiation and promotion; however, it can also act as a tumor promoter. I3C and some of its acid condensation products have been shown to be antiestrogenic, particularly 3,3'diindolylmethane (I33'), in several cell line assays. We report that I33' acts as an estrogen in the rainbow trout liver *in vitro* and *in vivo* by inducing vitellogenin (Vg), a well-characterized biomarker for estrogens. Precision-cut liver slices from male rainbow trout, *Oncorhynchus mykiss*, 8 mm x 250 μm, were incubated in Hank's media of 25% fetal bovine serum supplemented with HEPES, $NaHCO_3$ and 1% bovine serum albumin at 14°C for 96 hr. I3C, I33' and a mixture of I3C acid condensation products (RXN) (0-250 μM) were added to the medium with DMSO as the vehicle. I33' and RXN increased Vg levels in rainbow trout liver slices by over 100 and 10 fold, respectively, vs vehicle. The efficacy of I33' induction of Vg was comparable to 17β-estradiol with 500 fold less potency. *In vivo*, juvenile male rainbow trout were fed I3C, RXN (0- 2000 mg/kg) or I33' (0-250 mg/kg) for two weeks. At 2000 mg/kg, I3C induced Vg by over 100,000 fold compared to controls, which was comparable to 5 mg/kg 17β-estradiol (the dose resulting in maximum induction). Compared to I3C, RXN was one-tenth as potent, but I33' was three times as potent. I33' may account for Vg increases observed in trout fed I3C as it is present in liver after oral dosing, at concentrations (70 μM) expected to maximally induce Vg. In trout, results *in vitro* and *in vivo* document that I33' is estrogenic, consistent with our hypothesis that I3C promotes liver cancer in trout by estrogenic pathways. I33' apparently functions as a pro- or antiestrogen in a tissue- and/or species-specific manner. (Supported by ES03850, ES04766 and ES07060.)

1262 EFFECTS OF COMBINED TREATMENT WITH ANTIOXIDANTS AND SODIUM NITRITE ON THE RAT FORESTOMACH.

M. Miyauchi, A. Nishikawa, F. Furukawa, H. Nakamura, H. Y. Son, T. Ikeda, T. Imazawa and M. Hirose. *National Institute of Health Sciences, Tokyo, Japan.* Sponsor: T. Shirai.

It has been shown that the combined administration of ascorbic acid or phenolic compounds with sodium nitrite ($NaNO_2$) induces cell injury and hyperplasia in the rat forestomach epithelium, which subsequently leads to squamous cell tumor development. We have investigated the effects of $NaNO_2$ in combination with nine environmental antioxidants, *i.e.* α-tocopherol, sodium erythorbate (SE), β-carotene, quercetin, green tea catechins (GTC), hydroquinone (HQ), *o*-phenylphenol (OPP), curcumin and bisphenol A on the rat forestomach. Five-week old male F344 rats were fed diet containing the antioxidants at 1% or basal diet with or without 0.2% $NaNO_2$ in the drinking water for 4 weeks. Using ELISA, urinary 8-hydroxydeoxyguanosine (8-OHdG) levels were measured. We also investigated the expression of 8-OHdG, inducible nitric oxide synthase (iNOS), cyclooxygenase-2 (COX-2) and nitrotyrosine (N-Tyr) by immunohistochemistry. Microscopically, no changes were seen in any of the antioxidant or $NaNO_2$ alone group. However, combined treatment with α-tocopherol, SE, GTC, HQ or OPP with $NaNO_2$ induced squamous cell hyperplasia with inflammation and erosion in the forestomach. Most remarkable changes were observed in the groups receiving SE or HQ with $NaNO_2$. PCNA-labeling indices were significantly increased by the combination of SE, GTC, HQ or OPP with $NaNO_2$ as compared with the $NaNO_2$ alone value. However, no variation in 8-OHdG levels was detected among the groups. Immunohistochemical analysis showed positive expression of iNOS, COX-2 and N-Tyr in the inflammatory cells but not in the forestomach epithelium. These results indicate that co-administration of a-tocopherol, SE, GTC, HQ or OPP with $NaNO_2$ induces forestomach hyperplasia, and suggest that production of NO and COX-2 in the inflammatory cells may be secondarily involved in this process.

1263 INDUCTION OF TUMORS IN THE COLONS AND LIVERS OF FEMALE SCID MICE BY 2-AMINO-3-METHYLIMIDAZO[4,5-*f*]QUINOLINE (IQ), AND THEIR MODULATION BY FATTY ACIDS.

E. I. Salim, H. Wanibuchi, K. Morimura, S. Yamamoto and S. Fukushima. *Osaka City University Medical School, First Department of Pathology, Osaka, Japan.*

2-Amino-3-methylimidazo[4,5-*f*]quinoline (IQ), one of the most potent mutagenic heterocyclic aromatic amines, was found to be carcinogenic to several organs including the liver in various mammals, however, the colon has not been shown to be a target for IQ carcinogenicity in any mouse strain tested. We recently reported the sensitivity of mice with severe combined immunodeficiency (SCID) to a low-dose site-specific induction of aberrant crypt foci (ACF), preneoplastic lesions, in the colon by IQ. In the present experiment we tested the carcinogenic effect of dietary administration of 300 ppm IQ alone and the modifying effects of fatty acids in combination with IQ for 32 weeks on SCID mice. A total of 75 female SCID mice were divided into 5 groups. Group 1 received IQ mixed with the basal diet. Groups 2-4 received 20% corn oil, perilla oil or olive oil respectively mixed with the basal diet and IQ, while group 5 received the basal diet only as control. Treatment with IQ only (group 1) caused mainly 50% incidence of colonic adenomas and 58% incidence of liver adenomas and adenocarcinomas in the mice in addition to 100% incidence of preneoplastic lesions in both organs. Treatment with corn oil and perilla oil inhibited significantly the incidence of colon tumours into 9% and 0% and liver tumours into 0% and 8% respectively along with a significant reduction in the tumoricidal activities in the two organs such as cell proliferation, mitotic indices and colonic crypts heights. Olive oil treatment didn't show similar inhibitory effects. Colonic tumours were mainly induced in the distal colons. These results support the carcinogenic potential of IQ in the colon of SCID mice and that corn oil and perilla oil, but not olive oil, perform strong suppressing effects on the tumoricidal activity of IQ in the colon and liver of SCID mouse.

1264 A REVIEW OF MORTALITY IN TUMORIGENICITY STUDIES, COMPLETED OVER THE PERIOD 1987 TO 1999, USING THE CHARLES RIVER ORIGINAL OR INTERNATIONAL GENETIC STANDARD SPRAGUE-DAWLEY RAT.

W. N. Hooks and R. J. Harling. *Huntingdon Life Sciences, Huntingdon, United Kingdom.*

At Huntingdon Life Sciences, the mortality data have been analysed from the control groups of 81 tumorigenicity studies using the original or International Genetic Standard (IGS) strain designations of Sprague-Dawley rat, Crl:CD®BR (VAF). The data obtained from the IGS rat have been closely monitored since the introduction of this new strain designation in 1996 and 11 studies completed in 1998 or 1999 have been compared against up to 70 studies using the original strain designation (completed over 1985 to 1997). Low protein maintenance diet was used in these dietary and oral gavage studies. The analyses have indicated that the IGS rat is showing a similarly high mortality pattern to that seen in the original strain studies completed over the period 1996-97, but an increased pattern when compared with studies completed 1993-95. In the original rat studies, review of the terminal mortality against time has demonstrated an increasing trend towards higher values over the period of 1987 to 1997, particularly in females. The 11 completed IGS rat studies show a similar trend to the original rat studies. From the results currently available, it can be concluded that the IGS rat is not remarkably different from the original strain of rat, showing the same high mortality pattern, particularly in female rats.

1265 A REVIEW OF THE IN-LIFE PARAMETERS AND TUMOUR DATA IN TEN GANG-HOUSED DIETARY TUMORIGENICITY STUDIES USING THE CHARLES RIVER INTERNATIONAL GENETIC STANDARD OR ORIGINAL STRAIN DESIGNATIONS OF SPRAGUE-DAWLEY RAT.

R. J. Harling, W. N. Hooks, S. M. Harling and C. Gopinath. *Huntingdon Life Sciences, Huntingdon, United Kingdom.*

At Huntingdon Life Sciences, data obtained from the Charles River International Genetic Standard (IGS) strain of Sprague-Dawley rat have been closely monitored since the introduction of this new strain designation in 1996. The in-life and tumour data from the control groups of ten gang-housed dietary tumorigenicity studies (using low protein maintenance diet) have been assessed, with five IGS rat studies (completed 1998-99) compared against five studies (completed 1994-97) using the original strain of Sprague-Dawley rat. These comparisons have shown that the IGS rat is showing a similarly high mortality pattern to that seen in the original strain studies. The bodyweight growth pattern, bodyweight gain and food consumption data analysed over the first year, have only shown minor differences between the IGS rat and the original strain of rat. Assessment of the tumour profile (tumour incidence, number of tumour bearing rats and factors contributory to death) has not shown any major differences between the two groups. From the results available, it can be concluded that the IGS rat is not remarkably different from the original strain of rat.

1266 MECHANISM OF NEPHROCARCINOGENICITY OF A SHORT CHAIN CHLORINATED PARAFFIN.

G. D. Warnasuriya[1], J. R. Foster[2], B. M. Elcombe[1] and C. R. Elcombe[1]. [1]*University of Dundee, Dundee, United Kingdom and* [2]*AstraZeneca Central Toxicology Laboratory, Alderley Park, Macclesfield, United Kingdom.*

Short-chain chlorinated paraffins cause kidney tumours in male rats but not in female rats or mice of either sex. To investigate whether the tumours were caused via the accumulation of a male rat specific protein, alpha 2u globulin, groups of male and female Fischer 344 rats were dosed by gavage for 28 consecutive days with Chlorowax 500C (C12:60Cl%,C500) or 1,4-dichlorobenzene (DCB), dissolved in corn oil, at doses of 625 and 300 mg/kg of body weight respectively. Control animals received corn oil vehicle alone. DCB is known to cause male rat specific kidney tumours via the accumulation of alpha 2u globulin. All animals were implanted with osmotic pumps containing BrdU to label proliferating cells. On termination, kidneys were removed and sections were immunohistochemically stained for alpha 2u globulin and BrdU. The remainder was homogenised and analysed by polyacrylamide gel electrophoresis (PAGE) and two dimensional PAGE (2D-PAGE). Western blots were performed using anti-alpha 2u globulin antibody on both PAGE and 2D-PAGE gels. The immunohistochemical staining showed an increase in alpha 2u globulin and cell proliferation in both C500- and DCB-treated male rats. The increases were greater in the DCB-treated male rats. No changes in these parameters were seen in the treated female rats. Analysis of data from individual rats indicated that the increase in cell proliferation was directly correlated with the increase in alpha 2u globulin. Western blotting showed five different isoelectric isoforms of alpha 2u globulin in control male rat kidney. Increases in all five isoforms were observed in the C500-treated male group. The increase in total alpha 2u globulin was greater in the DCB males and a specific increase in the more basic isoform was observed. Thus, alpha 2u globulin appears to be involved in the nephrocarcinogenicity of C500, however, there appears to be both a quantitative and qualitative difference between the C500- and the DCB-induced renal responses.

1267 EKER RAT MODEL CHARACTERIZATION, PHASE II-THE RESPONSE TO A GENOTOXIC CARCINOGEN AND TWO NON-CARCINOGENIC NEPHROTOXINS FOLLOWING FOUR OR SIX MONTHS OF DOSING.

A. F. Youssef[1], L. D. Morton[1], E. Lloyd[1], A. Kiorpes[2] and F. L. Fort[1]. [1]*TAP Holdings, Inc., Deerfield, IL and* [2]*Redfield Laboratories, Redfield, AR.*

The Eker rat carries a germline mutation in the Tsc-2 tumor suppressor gene, which predisposes it to the development of renal carcinoma (RC). In phase I, 4 months treatment with 2,4-Diaminotoluene or 2-Nitropropane (genotoxic non-renal carcinogens) increased renal hyperplastic tubules (HT) and RC or increased total tumor count (TT), respectively (Youssef et al., Toxicol. Sci. 43:233, 1999). Phase II characterized the responses of the Eker rat after 4 or 6 months exposure to another genotoxic non-renal carcinogen (furan) and two non-carcinogenic nephrotoxins (aluminum nitrilotriacetate (Al-NTA) and cyclosporine A (CsA)). Three groups were treated with either furan, 8 mg/kg/day orally (p.o.) 5x/week, CsA, 30 mg/kg/day p.o. 7x/week or Al-NTA, 2 mg/kg/day intraperitoneally (i.p.) 3x/week, for 4 or 6 months. Three control groups received either no treatment or vehicle (sterile water, i.p. for Al-NTA or olive oil p.o. for furan and CsA) daily for 4 or 6 months. Histopathology included: counting of all renal proliferative lesions (i.e., HT, RA and RC), and TT in all animals. Statistical analysis (two-tailed) showed increased HT, RA and TT after Al-NTA or CsA compared to their controls, and increased RA and TT after 6 months vs. 4 months. There was no change in incidence of RC. Furan did not result in renal proliferative lesions or in biliary neoplasms. The model did not show promise as an alternative for screening of compounds for carcinogenic potential (Sponsored by TAP Holdings, Inc.).

1268 EFFECT OF CHLOROFORM WITH DICHLOROACETIC ACID OR TRICHLOROACETIC ACID ON N-METHYL-N-NITROSO-UREA-INITIATED LIVER AND KIDNEY TUMORS IN FEMALE AND MALE B6C3F1 MICE.

M. A. Pereira, P. B. Conran and P. M. Kramer. *Medical College of Ohio, Toledo, OH.*

Chloroform, dichloroacetic acid (DCA) and trichloroacetic acid (TCA) are common byproducts found in chlorinated drinking water. All three chemicals have been shown to induce liver tumors in B6C3F1 mice. Therefore, we evaluated mixtures containing chloroform with either DCA or TCA in the drinking water. Male and female B6C3F1 mice were administered 30 mg/kg *N*-methyl-*N*-nitrosourea on day 15 of age. At four weeks of age, the mice started to receive in their drinking water 3.2 gm/l DCA or 4.0 gm/l TCA with 0, 800 or 1,600 mg/l chloroform. The mice were sacrificed at 44 weeks of age and their livers and kidneys evaluated for tumors. Both DCA and TCA promoted liver tumors in female and male mice. The presence of chloroform greatly reduced the level of yield of liver tumors promoted by DCA but not TCA. In contrast, chloroform greatly enhanced the yield of kidney tumors in DCA-treated male mice. The kidney tumors were mainly solid and papillary cystic adenomas. Chloroform did not effect the yield of kidney tumors in TCA-treated mice. Kidney tumors were not found in female mice. Hence, in DCA-treated mice chloroform prevented liver tumors and promoted kidney tumors male, while in TCA-treated mice chloroform did not affect the tumor yield in either organ. Funded in part by the US Environmental Protection Agency Grant R 825384 and not subjected to the Agency's review nor necessarily reflects the views of the Agency.

1269 A MULTISTAGE BIOLOGICALLY BASED MODEL FOR MOUSE LIVER TUMORS RESULTING FROM EXPOSURE TO DICHLOROACETIC ACID.

J. R. Rabinowitz[1], M. O. Schonwalder[2], A. B. DeAngelo[1], M. J. Mass[1], J. Ross[1], H. W. Carter[3], J. H. Carter[3], R. E. Richmond[3] and S. Nesnow[1]. *[1]USEPA NHEERL/ECD, Research Triangle Park, NC, [2]ESE/UNC, Chapel Hill, NC and [3]Wood Hudson Cancer Research Laboratory, Newport, KY.*

Dichloroacetic Acid (DCA) is a major byproduct of the chlorine disinfection of humic acid containing drinking water sources. It is a hepatocarcinogen in mice and rats at exposure concentrations in drinking water that are at least 4 orders of magnitude above the concentrations in drinking water to which humans are exposed. Under the dosing regime that results in the formation of tumors in B6C3F1 male mice, DCA causes a spectrum of benign, premalignant and malignant lesions of the liver that changes during the lifetime of the subjects. To aid in the extrapolation from these exposure conditions to drinking water exposures a biological based model for DCA carcinogenesis has been developed. Histopathologic analysis of the livers of exposed mice suggests that following chronic exposure to DCA, carcinomas can arise directly from single initiated cells in the liver as well as within hyperplastic nodules and adenomas. Based on these studies, a biologically based model for DCA carcinogenesis that contains at least 3 precancerous stages and 6 transitions was developed. With the large number of parameters in this model, it is clear that any method for numerical parameter estimation would not provide meaningful results. The PCNA and TUNEL assays were used to obtain birth and death rates for cells in each precancerous stage. A general transition rate was obtained from the mutation frequency induced in the livers of lacI B6C3F1 transgenic mice. Many of these parameters were a function of DCA exposure. Using the experimentally determined parameters and the Kolmogorov backwards equations, there is agreement with the time-to-tumor data for mice exposed through their drinking water for two years. It is more difficult to obtain agreement with the experimental determination of the number of tumors/animal as a function of time in that study. Dose related extrapolation of the model may be obtained from extrapolation of the parameters. (This abstract does not necessarily reflect US EPA policy).

1270 SODIUM CHLORATE TREATMENT RESULTS IN A DOSE-DEPENDENT INCREASE IN RAT THYROID FOLLICULAR CELL HYPERPLASIA FOLLOWING SUBCHRONIC EXPOSURE IN DRINKING WATER.

M. J. Hooth[1], A. B. De Angelo[1], M. H. George[1], G. A. Boorman[2] and D. C. Wolf[1]. *[1]USEPA/NHEERL, Research Triangle Park, NC and [2]NIEHS/NTP, Research Triangle Park, NC.*

Chlorine dioxide treatment is an effective water disinfection method but sodium chlorate has been identified as a potentially harmful disinfection by-product. Subchronic toxicity tests have identified the rat thyroid as the primary target organ. Studies were performed at EPA or sponsored by the National Toxicology Program (NTP) to describe the development of thyroid lesions in animals exposed to various doses of sodium chlorate in the drinking water. Under the NTP dosing regimen, male and female F344 rats and B6C3F1 mice were exposed to 0, 0.125, 1.0, or 2.0 g/L sodium chlorate for 21 or 90 days. Under the EPA dosing regimen, male F344 rats were exposed to 0, 0.001, 0.01, 0.1, 1.0, or 2.0 g/L sodium chlorate for 90 days. Female F344 rats were exposed to 0, 0.5, 1.0, 2.0, 4.0, or 6.0 g/L of sodium chlorate for 105 days. Thyroid follicular cell hyperplasia and significant colloid depletion were present in all male and female F344 rats at doses of 1.0 g/L or greater of sodium chlorate following 21 days and 90 days of treatment in the NTP study. While serum T_3 and T_4 levels were not altered in male or female rats after 90 days, TSH levels increased slightly in a dose-dependent manner. Thyroid follicular cell hyperplasia was present in female F344 rats at doses of 1.0 g/L or greater and in male F344 rats at all treatment doses in the EPA study. Significant thyroid colloid depletion was present in female F344 rats at doses of 2.0 g/L or greater. Increased cell proliferation was not evident in male rats but female rats had a 5-19 fold increase in positively stained S-phase cells compared to concurrent controls. Follicular cell hyperplasia was not present in male or female B6C3F1 mice. Sodium chlorate treatment induced a dose-dependent increase in the incidence and severity of thyroid follicular hyperplasia associated with colloid depletion and increased serum TSH levels. Male rats appear to be more sensitive to the effects of sodium chlorate treatment than females. (This abstract does not reflect EPA policy.)

1271 EFFECT OF 2,2',4,4',5,5'-HEXACHLOROBIPHENYL (PCB-153) AND 3,3',4,4'-TETRACHLOROBIPHENYL (PCB-77) ON NF-KB AND AP-1 ACTIVATION, ALTERED HEPATIC FOCI FORMATION, CELL PROLIFERATION AND APOPTOSIS IN RATS.

J. C. Tharappel, L. W. Robertson, E. Y. Lee, B. T. Spear and H. P. Glauert. *University of Kentucky, Lexington, KY.*

PCBs are environmental pollutants that have been withdrawn from use but still persist in nature. They have been shown to be complete carcinogens and tumor promoters in rodent liver. In this study we investigated the mechanisms of tumor promoting activity of two different PCB congeners. After initiation with diethylnitrosamine (DEN), rats were injected biweekly with either PCB-153 or PCB-77 (100 or 300 μmol) or with both PCBs (100 μmol each). All animals were sacrificed ten days after the fourth injection; three days before sacrifice all animals were implanted with osmotic pumps containing 5-bromo-2'-deoxyuridine (BrdU). NF-kB and AP-1 were found to be strongly activated by both PCBs and by their combination. While the number of placental glutathione S-transferase-positve foci was increased in all PCB treated animals, the mean focal volume in all groups remained unchanged. The cell proliferation index showed a significant increase only in high-dose PCB-77 treated animals. The apoptotic index (measured using the TUNEL assay) was increased by PCB-77 but decreased by PCB-153. These results show that NF-kB and AP-1 activation is increased following the application of PCBs as tumor promoters. (Supported by ES 07380 and ES 07266.)

1272 COMPARATIVE 30-WEEK DERMAL TUMOR PROMOTION EVALUATION OF CIGARETTE SMOKE CONDENSATE FROM A REFERENCE CIGARETTE AND AN ECLIPSE PROTOTYPE (9-014) TEST CIGARETTE IN FEMALE SENCAR MICE.

D. R. Meckley[1], K. R. Van Kampen[2], J. D. deBethizy[1] and A. T. Mosberg[1]. *[1]R.J. Reynolds Tobacco Company, Winston-Salem, NC and [2]The Van Kampen Group, Inc., Ogden, UT.*

A 30-week dermal tumor promotion assay was conducted to compare the potential dermal tumor promotion activity of mainstream cigarette smoke condensate (CSC) collected from an ECLIPSE prototype cigarette (9-014), which primarily heats tobacco, and a 1R4F (University of Kentucky) reference cigarette. Mainstream CSC's were collected by cold trap from smoke generators using the Federal Trade Commission puffing regimen. Female SENCAR mice were "initiated" with a single 75 μg application of DMBA to the shaved dorsal skin. The CSC's were then applied to the skin three times per week for 29 weeks. Each CSC was administered at 9, 18, or 36 mg tar/application to groups of 40 animals. End-points included body weights, clinical observations, organ weights, dermal tumor development data and histopathology. The numbers of dermal tumors and the numbers of dermal tumor-bearing animals for the 1R4F reference CSC were statistically different from the "DMBA-initiated" control group and increased with increasing exposure. When corresponding doses of 1R4F reference and 9-014 CSC were compared, the 9-014 CSC groups had significantly fewer dermal tumors and tumor-bearing animals. In this assay, the dermal tumor-promotion potential of the 9-014 CSC was, therefore, substantially reduced when compared to the 1R4F reference CSC.

1273 REVERSIBILITY STUDY OF THE HEPATIC AND PULMONARY EFFECTS OF PERMETHRIN IN MICE.

W. H. Butler[1], M. A. Morelli[2], J. D. McCarty[2], J. M. Finch[3] and S. J. Barton[3]. *[1]Bletchingley, Surrey, United Kingdom, [2]FMC Corp., Princeton, NJ and [3]Inveresk Research, Tranent, United Kingdom.*

The study was designed to investigate the autonomous growth of permethrin-induced hepatic eosinophilic adenomas and pulmonary adenomas in mice. Groups of 50-100 female mice were fed control diet or 5000 ppm permethrin for 9, 12, 15, or 18 months and sacrificed. Additional groups receiving treatment for these intervals received untreated diet following the treatment interval and then were sacrificed at 18 or 24 months to monitor for recovery/reversal of effects. All groups of mice were examined for the incidence of hepatic and pulmonary lesions. At each of the interim kills following treatment with permethrin, the mice had increased liver weights, centrilobular hypertrophy and karyomegaly. Eosinophilic adenomas were seen at 12 months, with the highest incidence at 18 months. Satellite groups at 12 months showed increases of hepatic P450, CYP1A, CYP2E1, CYP3A, and CYP4A. Following withdrawal of treatment the centrilobular hypertrophy and karyomegaly reversed. No progression or increase in hepatic eosinophilic adenomas was seen. The

number of basophilic adenomas increased with age. PCNA immunocytochemistry showed that the labeling of eosinophilic nodules was less than basophilic nodules with a different distribution within the nodule. These data show eosinophilic adenomas in the liver are not associated with hepatocarcinomas, suggest adenomas are end-stage lesions, and do not satisfy the requirement for autonomous growth. The lungs showed consistent Clara Cell hypertrophy and hyperplasia at all times on treatment which reversed in the recovery groups. Pulmonary adenomas were seen at 9 months but only increased at the 18-month interim kill. Following withdrawal of treatment there was no progression of pulmonary adenoma to carcinoma at the final kills at 18 and 24 months.

1274 PROMOTING ACTIVITY OF XYLAZINE ON RAT THYROID CARCINOGENESIS AND ITS MECHANISM OF ACTION.

K. Yasuhara, K. Mitsumori, K. Takegawa, T. Koujitani, H. Onodera, H. Takagi, M. Hirose and M. Hirose. *National Institutes of Health Science, Tokyo, Japan.* Sponsor: T. Shirai.

We have reported that thyroid hypertrophy was induced in rats given xylazine hydrochloride (XZ), an alpha-2-adrenoceptor agonist which is used for food-producing animals as a sedative agent, for 28 days. In order to examine the thyroid tumor promoting potential of XZ, male F344 rats received diet containing 0 or 1000 ppm XZ for 52 weeks after initiation with 2400 mg/kg N-bis(2-hydroxypropyl)nitrosamine (DHPN). Focal follicular cell hyperplasias, adenomas and carcinomas were observed in 100, 60 and 25% of the animals of the DHPN+XZ group, respectively, and these incidences were significantly increased as compared to the DHPN alone group. As a second experiment to clarify the mechanism of the promotion effects, male F344 rats received diet containing 0 or 1000 ppm XZ for 1-4 weeks to examine serum levels of T3, T4 and TSH as well as thyroid iodine uptake and organification. In the XZ group, a significant increase in thyroid weights and decreases in serum T3/T4 were observed from week 1, and inhibition of thyroid iodine uptake and organification from week 2. These results indicate that XZ exerts a tumor-promoting effect on the thyroid follicular cells, and suggest that alterations of thyroid-related hormone levels in the XZ group are due to inhibition of thyroid iodine uptake and organification, the thyroid tumor-promoting effects being probably secondary to prolonged serum TSH stimulation resulting from negative feedback through the pituitary-thyroid axis.

1275 4-CHLOROBIPHENYL HAS CANCER-INITIATING ACTIVITY.

P. Espandiari, T. Twaroski, M. Festag, E. Y. Lee, H. P. Glauert and L. W. Robertson. *University of Kentucky, Lexington, KY.*

A modified Solt-Farber protocol was selected to investigate the initiating activity of several lower chlorinated PCBs including PCBs 3, 12, 38, and 77 in male Fischer 344 rats. Rats received a standard 2/3 partial hepatectomy followed by a single bolus dose of the suspected initiating agent, or vehicle. Two weeks later all selection groups received 3 daily doses of 2-acetylaminofluorene then a single dose of carbon tetrachloride via gavage, followed by 3 additional daily treatments of 2-AAF. Only PCB 3 induced grossly visible nodules as well as induced gamma-glutamyltranspeptidase (GGT) positive foci per cm3 and per liver in treated rats. Histological staining of liver sections further revealed the presence of foci and nodules in hematoxylin and eosin-stained sections in all DEN treated animals and in 80% of 4-CBP treated animals. The number of GGT-positive foci (expressed per liver and per cm3) and focal volume of these foci (in % of liver volume) in DEN-treated animals were 5500 foci/liver, 425 foci/cm3, and 34%, respectively, while 4-CBP treated animals had 1500 GGT-positive foci/liver, 200 foci/cm3, and 3% of the total liver. No GGT-positive foci were detected in vehicle or non-selected groups, and all rats that were administered PCB 77 failed to survive the selection portion of the experimental treatments. We must conclude that under the conditions and time course of this experiment, PCB 3 has initiating activity in male Fischer 344 rats.

1276 CONSIDERATION OF THE POTENCY CLASSIFICATION OF ACRYLAMIDE (ACR) BASED ON THE INCIDENCE OF TUNICA VAGINALIS MESOTHELIOMAS (TVMS) IN MALE FISCHER 344 RATS.

G. Lawrence, R. Gentry, H. J. Clewell and A. M. Shipp. *The K S Crump Group, Inc., ICF Consulting, Ruston, LA.* Sponsor: M. A. Friedman.

The T25 approach is used by the European Community to classify cancer potency as low, medium or high. Using TVM incidence data in male F344 rats, the T25 for ACR was "borderline" between the high and medium categories. For borderline chemicals, modifying factors (dose-response, species/strain activity, genotoxicity, mechanistic relevance to humans and toxicokinetics) are considered qualitatively to determine if the chemical should be in the lower or higher potency category. To recommend placement of ACR into the appropriate category, a weight-of-evidence evaluation of all of the relevant data for ACR was conducted. The T25 calculated using the Benchmark approach, an alternative to the T25 approach, indicated that ACR should be classified as medium. An evaluation of the mode of action strongly indicated that the presence of Leydig cell tumors (LCTs) was an obligatory, precursor step in the production of TVMs. The formation of LCTs was related to changes in normal hormone levels and alterations in Leydig cell feedback loops, conditions unique to the aging male F344 rat. ACR likely exacerbates this process via dopamine-mediated decreases in prolactin levels, resulting in a down-regulation of LH receptors on the testes, a mechanism not operative in man. The down-regulation of LH receptors is followed by a compensatory increase in LH Leydig cell stimulation, and eventually more metabolically active LCTs. LCTs further alter hormonal balances triggering alterations in growth factor receptors leading to autocrine stimulation of mesothelial cells and TVMs. Based on these data, ACR should remain in the medium potency category.

1277 THE U.S. HIGH PRODUCTION VOLUME (HPV) CHEMICAL VOLUNTARY CHALLENGE PROGRAM.

R. H. Hefter, L. J. Scarano and D. Sawhney. *USEPA, Washington, DC.*

On Earth Day, 1998, Vice President Al Gore challenged the U.S. chemical industry to provide a minimum set of hazard data on the approximately 2800 U.S. HPV chemicals (manufactured or imported at > 1 million pounds per year) and make the information publicly available. The "Challenge Program" is unique because: 1) it is based on a cooperative effort among government, industry, and environmental groups; 2) chemical manufacturers are volunteering to make hazard data publicly available; and 3) the data will be placed on the internet for right-to-know purposes. The program is based upon the Screening Information Data Set (SIDS) which has been a mainstay of the Organization for Economic Cooperation and Development's (OECD) existing chemicals testing program. The SIDS includes tests for physicochemical properties (melting point, boiling point, vapor pressure, partition coefficient, and water solubility); environmental fate (photodegradation, biodegradation, stability in water, and transport/distribution estimates); ecotoxicity (acute toxicity to fish, daphnids and aquatic plants); and human health effects (acute and repeat dose toxicity, genotoxicity, and reproductive/developmental effects). Discussions about determining the adequacy of existing data, the use of structure-activity relationships primarily through their use in chemical categories, and developing appropriate summaries of test reports which will be placed on the worldwide web will be presented. If available, the first round of data will be presented and discussed. (The views expressed are those of the authors and do not represent EPA policy. Visit the Challenge homepage at http://www.epa.gov/chemrtk/volchall.htm.)

1278 THE FDA PROCESS IN ADDRESSING ACCEPTANCE AND IMPLEMENTATION OF ICCVAM-RECOMMENDED TOXICOLOGICAL TESTS.

L. M. Schechtman and B. A. Schwetz. *USFDA, Rockville, MD.*

ICCVAM (the Interagency Coordinating Committee on the Validation of Alternative Methods), established in 1997, is charged with establishing criteria and processes for the validation and regulatory acceptance of sponsored toxicological test methods. In response to that mandate, 14 federal regulatory and research agencies and programs that would consider utilizing such methods or the data derived from them participate in trans-agency efforts associated with the validation, acceptance and harmonization of toxicological test methods. The FDA initiative in responding to ICCVAM issues involves input from ORA (Office of Regulatory Affairs) and all FDA research and product-based centers, i.e., NCTR (National Center for Toxicological Research), CDER (Center for Drug Evaluation and Research), CBER (Center for Biologics Evaluation and Research), CDRH (Center for Devices and Radiological Health), CFSAN (Center for Food Safety and Applied Nutrition, and CVM (Center for Veterinary Medicine), coordinated through CDER's Office of Testing and Research (OTR). FDA product Centers function as distinct units regulating different products and responding to different regulatory directives. ICCVAM-validated methods are reviewed by each Center for applicability regarding research potential, intended use, and relevance to products regulated within their purview. The organization and nature of the

FDA is such that the diversity of regulated products necessitates that each product Center (and not the Agency as a whole), in its mission to ensure product safety, determines which new ICCVAM-recommended test(s) are appropriate for implementation to achieve their regulatory obligations. Centers promote internal and external awareness of ICCVAM information, pending ICCVAM-recommended procedures, and their anticipated application to the Center's safety assessment processes. Upon adoption of a test by a given Center, relevant staff scientists are informed and educated regarding the availability and utility of the test and data interpretation. Sponsored by the SOT Regulatory and Safety Subspecialty Committee.

1279 THE ROLE OF THE INTERAGENCY COORDINATING COMMITTEE ON THE VALIDATION OF ALTERNATIVE METHODS IN THE REGULATORY ACCEPTANCE OF NEW TOXICOLOGICAL TESTING METHODS.

W. S. Stokes[1] and R. N. Hill[2]. [1]*Environmental Toxicology Program, National Institute of Environmental Health Sciences, Research Triangle Park, NC and* [2]*Office of Prevention, Pesticides and Toxic Substances, Environmental Protection Agency, Washington, DC.* Sponsor: J. R. Bucher.

New toxicological test methods offer benefits of improved safety assessments and potential cost and time savings, and the refinement, reduction, and replacement of animal use. Before new test methods are used to generate information to support regulatory decisions, validation studies must be conducted to determine their performance characteristics, limitations, and usefulness for specific proposed uses. The Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM) and the National Toxicology Program Interagency Center for the Evaluation of Alternative Toxicological Methods (NICEATM) were established by the U.S. government to work with test developers and Federal agencies to facilitate the evaluation and adoption of new test methods. Test developers are encouraged to interact with ICCVAM/NICEATM throughout test method development, pre-validation, and validation to maximize the likelihood of generating information needed by agencies to assess the usefulness and limitations of new test methods. Test method submission guidelines have been established and are periodically updated to assist developers in designing test method protocols and validation studies that will adequately address established validation and acceptance criteria. Following validation, ICCVAM and NICEATM coordinate the independent peer review of test methods by an independent international panel of expert scientists. The review process provides for stakeholder participation through public meetings and the opportunity for public comments. The peer review report and ICCVAM recommendations are then provided to Federal agencies for regulatory acceptance consideration. These initiatives seek to facilitate the development, validation, and acceptance of new methods that will provide enhanced protection of public health and the environment and benefit animal welfare whenever feasible. Sponsored by the SOT Regulatory and Safety Subspecialty Committee.

1280 GOOD RESEARCH SCIENCE: CRITICAL TO EFFECTIVE REGULATORY DECISION-MAKING.

S. C. Fitzpatrick and B. Schwetz. *USFDA, Rockville, MD.*

One of FDA's highest priorities is to ensure that the strongest, most up-to-date science underpins all of its decision-making. From the reviewer to the inspector, FDA can only be effective if it has a strong, scientifically skilled workforce. FDA faces many challenges that demand the development and application of sound scientific regulatory principles. For example, FDA must continually identify and respond to an ever-changing array of public health hazards. FDA is also called upon to review products that result from cutting-edge science. FDA must constantly evaluate the public health impact of its prevention and control measures. If FDA has to respond on the basis of incomplete information, it may be forced to compensate for uncertainty by requiring more regulation. More regulation is not only costly to the agency in terms of time and personnel, but it imposes additional financial burdens on industry, and ultimately increases the price to the consumer. To meet this challenge, FDA has developed many innovative regulatory research programs. FDA believes that good laboratory science and research builds a strong foundation for its scientists to anticipate and comprehend new technologies, detect and address risks, and find science-based strategies for their regulatory decisions. FDA has achieved many of its research goals through the strong partnerships it has forged with its sister regulatory agencies. These partnerships have resulted in collaborative research projects on the cutting edge of toxicological science. (Supported by the SOT Regulatory and Safety Evaluation Specialty Section.)

1281 INCORPORATING CHILDREN'S HEALTH CONCERNS INTO STATE ENVIRONMENTAL REGULATIONS: THE MICHIGAN PERSPECTIVE.

M. A. Kamrin[1], M. DeVito[2], R. Etzel[3], J. Gracki[4], W. Weil[5], G. Wolff[6] and K. Harrison[6]. [1]*Michigan State University, East Lansing, MI,* [2]*U.S. Environmental Protection Agency, Research Triangle Park, NC,* [3]*U.S. FDA, Washington, DC,* [4]*Grand Valley State University, Allendale, MI,* [5]*General Motors, Detroit, MI and* [6]*Michigan Environmental Science Board, Lansing, MI.*

President Clinton issued an Executive Order in 1997 mandating that federal agencies ensure that environmental standards are protective of children's health although federal guidance has been slow in coming. Michigan has taken the lack of guidance as an opportunity to develop innovative approaches to achieving the Order's goals. In December,1998, the Governor convened a Panel to evaluate the protectiveness of current environmental standards, administered by the Michigan Department of Environmental Quality, for children's health and to identify and prioritize standards that may need to be reevaluated. The Panel found that the standards of one state agency could not be evaluated in the absence of consideration of standards of other state agencies as well as consideration of unregulated exposures. It was also clear that there are far too many regulations for the Panel to realistically evaluate and the Panel concluded that it could best fulfill its charge by developing an approach for identifying the most significant exposures and thus for selecting for re-evaluation those regulations having the greatest impacts on children's health. This approach is based on the sensitivity analysis concept. Exposures to the same chemical (or class of chemical) by different exposure routes are semi-quantitatively assessed to determine if one or a small number of routes are responsible for the majority of the risk. Once the largest risk contributors for each chemical are identified, risk comparisons between chemicals or chemical groups can be made and used in assigning priorities for re-assessments.

1282 OCCUPATIONAL EXPOSURE LIMITS (OELS) FOR 30 ORGANOPHOSPHATE PESTICIDES (OPS) AND SUPPORTING RATIONALE.

J. E. Storm[1], K. K. Rozman[2] and J. Doull[1]. [1]*Univ. Kansas Medical Center, Kansas City, KS, and* [2]*Univ. Kansas Medical Center, Kansas City KS; GSF Institut fur Toxikologie, Neuherberg, Germany.*

Dose- and time-dependent red blood cell (RBC) acetylcholinesterase (AChE) inhibition was evaluated for 30 OPs to clarify the dose-time-response relationship in general; and, to recommend inhalation OELs (mg/m3). Data from 1400+ studies indicated departures from equivalent toxicity across species (humans, rats, dogs), exposure routes (oral, inhalation) and exposure duration (suchronic, chronic) for specific OPs were common, but were readily explained by consideration of OP-specific rates of toxicokinetic (TK; e.g., toxification or detoxification rates) and toxicodynamic (TD; e.g., rates of binding, aging, etc.) processes in relation to exposure duration and observation period. OELs based on peak RBC AChE inhibition were derived using a weight-of-evidence NOEL approach which considered data from all pertinent oral and inhalation studies as well as pertinent TK and TD processes. Overall, OELs were poorly correlated with inhalation NOELs derived from oral NOELs in dogs, rats or humans using species-specific physiologic parameters, consistent with the observation that oral studies often failed to consider OP-specific TK and TD processes in their design. OELs were better correlated with inhalation NOELs from rat inhalation studies which tended to minimize the confounding influence of TK and TD processes by appproaching constant dose. (Not enough dog or human inhalation studies were available for analysis.) Thus, although more readily available, oral studies are a poor basis for OELs unless relevant TK and TD processes are incorporated into their design. (JES current address: NY State Dept. of Health).

1283 VARIATION IN CANCER CLASSIFICATION BETWEEN EUROPEAN COUNTRIES AND ORGANIZATIONS.

B. D. Beck[1], M. R. Seeley[1], L. E. Tonner-Navarro[2] and R. Deskin[2]. [1]*Gradient Corporation, Cambridge, MA and* [2]*CYTEC Industries, West Paterson, NJ.*

This study a) compared cancer classification systems and their use in different European countries and agencies and b) identified reasons for differences in classifications for the same chemical. Countries and agencies considered were: the International Agency for Research on Cancer (IARC), the European Union (EU), the German MAK (maximum workplace concentration) Commission (German MAK), the Netherlands, Norway, and Sweden. We

evaluated 14 chemicals. IARC, the EU, and the German MAK classify carcinogens according to potential for carcinogenicity in humans, which may affect labeling, use restrictions, and occupational exposure levels (OELs). Norway classifies carcinogens according to potency, for labeling and establishing use restrictions, without distinguishing between animal and human carcinogens. The Netherlands classifies carcinogens according to genotoxicity, for specifying risk assessment approaches and deriving OELs. Different countries and agencies place different weight on data from epidemiological and animal studies, and mechanistic studies. There is general agreement on classification for chemicals with good evidence of carcinogenicity in humans (e.g. asbestos, benzene, and vinyl chloride) and less agreement for chemicals with positive animal data and inadequate or limited human data (e.g. 1,2-dichloroethylene, tetrachloroethylene, and trichloroethylene). Differences appear to be due to consideration of mechanisms, consideration of negative epidemiology data, and date of the classification (i.e., data availability). For example IARC recently downgraded its classification of acrylonitrile from probably to possibly carcinogenic to humans (2A to 2B) based on epidemiology data, but the classification of acrylonitrile has not been adjusted by either the EU or the German MAK.

1284 EUROPEAN DIFFERENCES IN DERIVATION OF OCCUPATIONAL EXPOSURE LEVELS.

M. R. Seeley[1], B. D. Beck[1], L. E. Tonner-Navarro[2] and R. Deskin[2]. [1]*Gradient Corporation, Cambridge, MA and* [2]*CYTEC Industries, West Paterson, NJ.*

This study a) compared derivation of occupational exposure levels (OELs) in European countries and agencies, and b) identified reasons why OELs may differ for the same chemical. Countries and agencies considered were: the European Union (EU), the United Kingdom (UK), the German MAK (maximum workplace concentration) Commission (German MAK), the Netherlands, Sweden, Denmark, Norway, and Ireland. Most countries and the EU use separate committees for evaluating scientific criteria, and technical and socioeconomic factors. Composition of the committee evaluating scientific data consists of: independent scientific experts (EU, German MAK); scientists representing employers, labor, and trade organizations (UK, Sweden); or scientists appointed by government, or a governmental organization (Netherlands, Denmark, Norway). OELs for genotoxic carcinogens consider: technological feasibility (UK, German MAK); cost-benefit analysis (UK); and acceptable risk level with consideration of socioeconomic factors (Netherlands, EU). OELs for non-carcinogens and non-genotoxic carcinogens are generally health-based, using a No-Observed-Adverse-Effect-Level (NOAEL) or Lowest-Observed-Adverse-Effect-Level (LOAEL) and uncertainty factor (UF) approach. The EU uses unique species-specific UFs, and UFs to account for the nature of the dose-response relationship. The UK uses UFs that consider severity of the critical effect. OELs for respiratory sensitizers may be based on feasibility (UK) or acceptable risk (EU). The selection of critical endpoint varies among countries and agencies. For example, Sweden is more likely to select irritation as a critical effect, which may be the basis for the lower OEL for trichloroethylene in Sweden (10 ppm) vs. other countries (30 - 100 ppm). Other differences in OELs reflect differences in both risk assessment and risk management approaches. For example, the difference in the OEL for ethylene oxide between the UK (5 ppm) and the German MAK (1 ppm) appears to reflect differences in risk management rather than risk assessment.

1285 JOURNAL ARTICLES: IMPROVING THE USEFULNESS FOR RISK AND REGULATORY ASSESSMENTS.

S. M. Taulbee. *SkeleTech, Inc., Bothell, WA.* Sponsor: R. W. Tyl.

Risk and health affects assessment professionals rely on published literature for primary and supporting documentation in evaluating compounds. In performing assessments, the usefulness of a journal article is first effected by the quality of the data and completeness of information and second by the value of the research results. A review of 97 reproductive and developmental toxicology articles was performed to evaluate the completeness of data presentation. The evaluation used regulatory and Institute for Evaluating Health Risk (IEHS) criteria to review presentation of materials and methods, results and discussion. The review showed that ~99% of the articles lacked at least one of the evaluation criteria. Results showed that ~4 to 8% of the articles did not adequately describe the test, control or reference substance; and ~40% did not describe characterization analyses. Approximately 30% of the articles did not fully describe the number of animals on study. While these results are dramatic, they must be tempered with an understanding that many articles are written to describe research results of in a certain context unrelated to risk evaluations. However, data are potentially used in other than the intended context, e.g., risk assessment, and journal instructions and editors encourage condensation and summarization. The primary purpose of this poster is to demonstrate the need for, and to present a list of, key criteria to be used by authors and journal reviewers as a checklist, thereby improving the availability of useful data.

1286 PROPOSED GUIDELINES FOR THE GLOBAL PRECLINICAL DEVELOPMENT OF VARIOUS NUTRACEUTICALS.

C. B. Spainhour and V. B. Ciofalo. *Chrysalis Preclinical Services Corporation, Olyphant, PA.*

Nutraceuticals have been defined by Stephen DeFelice as food, or parts of food, that provide medical or health benefits, including the prevention and treatment of disease. While there is still some debate about what a nutraceutical is, medical foods, functional foods and dietary supplements are all considered to be specific types of nutraceuticals. Due to a variety of socio-economic pressures, there is a rapidly growing popularity and prevalence of nutraceuticals, especially dietary supplements. Companies have perceived a significant market opportunity with these products because of attractive economic returns and an extremely lax global regulatory environment. As the lines of demarcation begin to pale between these new types of products and foods, food additives and traditional drugs, the need for regulatory guidance is becoming increasing more profound. Proposed here the details of preclinical development packages for a variety of different types of nutraceuticals. Before proceeding with the development of any potential nutraceutical, it is important to ascertain whether the potential product is a food, a drug or a dietary supplement. It is the intended use of a proposed nutraceutical rather than the type of ingredient in the nutraceutical that determines the applicable review process. Drugs must be proven to be safe and effective for a particular indication before marketing according to well-known guidelines. In parallel fashion, food additives incur a FDA premarket review of ingredient safety. Specific programs are outlined for medical and functional foods. Dietary supplements have no FDA premarket review of ingredients or finished products. They also incur no regulations concerning good manufacturing practice, identification, characterization or standardization of ingredients, efficacy or safety. From a regulatory viewpoint, the treatment of a dietary supplement is dependent on how it is labeled and what claims are stated on the label or in the course of marketing the material. In order to market dietary supplements, testing included in a developmental package can range from a basic pharmacology profile, acute toxicology data, antigenicity and hypesensitivity testing results and other specific tests as indicated to complex programs similar to those for pure pharmaceuticals. The proposed programs attempt to achieve balance between regulation, safety, cost and liability.

1287 RISK ASSESSMENT-BASED APPROACH FOR THE BIOLOGICAL EVALUATION OF MEDICAL DEVICE MATERIALS.

M. E. Stratmeyer and R. P. Brown. *Health Sciences Branch, CDRH/USFDA, Rockville, MD.* Sponsor: P. L. Goering.

Systemic toxicity tests of medical device materials are usually conducted using an extract obtained from the material. The use of relatively dilute extracts limits the ability of these tests to detect all but the most overt signs of toxicity. Further, these tests are often conducted with little or no knowledge of the chemical composition of the extract obtained from the device. As a result, it is not possible to anticipate the toxic effects that may be produced following exposure to the medical device material. To address these needs, a risk assessment-based approach has been developed to assess the potential for a medical device material to produce adverse systemic effects. The hallmarks of this approach are: 1) chemical characterization of the device, 2) estimation of the dose of each chemical constituent received by a patient, 3) derivation of a Tolerable Intake (TI) value for each constituent, and 4) comparison of the dose of each compound received by a patient to it's TI. While this proposed approach has not yet been formally accepted in CDRH as an alternative to systemic toxicity testing, it shows promise as a means to provide relevant data for regulatory decision making and should reduce the number of animals required for premarket testing. Further, this proposed approach is consistent with a number of regulatory initiatives currently underway in the FDA, including the use of knowledge bases and consensus standards for the biological evaluation of medical devices.

1288 DOSE-DEPENDENT HYPOTHYROXINEMIA IN FEMALE SD RATS FOLLOWING A SINGLE ORAL DOSE OF 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN.

M. Sato[1], Y. Miyabara[1], J. Yonemoto[1], Y. Matsuzaki[2], Y. Aoki[1], C. Tohyama[1] and N. Nishimura[1]. [1]*National Institute for Environmental Studies, Tsukuba, Japan and* [2]*Institute of Clinical Medicine, University of Tsukuba, Tsukuba, Japan.*

In order to assess the effects of 2,3,7,8-tetrachlorodibenso-p-dioxin (TCDD) on thyroid function, low doses of TCDD, just sufficient to affect hormonal status were employed in this study. Female Sprague-Dawley (SD) rats (6-week old) were given a single oral dose of TCDD ranging from 1.0 to 4.0 μg/kg bw, and serum and tissue samples were collected 7 days after dosing. Serum levels of thyroxine (T4) were decreased significantly at doses of 2.0 and 4.0 μg TCDD/kg, but triiodothyronine (T3) levels were not changed. Serum thyroid stimulating hormone (TSH) levels and thyroid weights were significantly increased at dose of 4.0 μg TCDD/kg bw. A marked increase of hepatic TCDD-responsive genes, UDP-glucuronosyltransferase-1 (UGT1) and cytochrome P4501A1 (CYP1A1), were found at as low as 1.0 μg TCDD/kg bw in a dose-related fashion. TCDD concentrations in the serum and adipose tissues were detected dose-dependently by gas chromatography-mass spectrometry. Interestingly, we found the intensive immunostaining of TSH by TCDD in the βcells of the pituitary anterior lobe. These results show that the induction of TCDD-response gene UGT1 (1.0 μg/kg bw) via aryl hydrocarbon (Ah) receptor may cause an enhancement of biliary excretion of T4. The subsequent depression in serum T4 levels results in an elevation of TSH production. The present studies demonstrate for the first time that a single low dose of TCDD induce hypothyroxinemia as a result of liver-pituitary-thyroid axis in a dose-dependent manner.

1289 MODIFICATION OF 2,3,7,8-TETRACHLORO-DIBENZO-*P*-DIOXIN INDUCED CYTOCHROME P-4501A1 BY ESTROGEN IN LIVER OF FEMALE LONG-EVANS RATS.

J. Yonemoto[1], S. Sarkar[1], N. R. Jana[1], C. Tohyama[1], T. Kusumegi[2] and H. Sone[1]. [1]*National Institute for Environmental Studies, Tsukuba, Japan and* [2]*Crest, Kawaguchi, Japan.*

2,3,7,8-Tetrachlorodibenzo-*p*-dioxin (TCDD) induces liver tumors in female rat liver and is classified as a potential human carcinogen. In the present study, we examined the effects of estrogen (E2) on TCDD-induced CYP1A1 gene expression in the liver of female Long Evans rat. Induction of CYP1A1 by TCDD was observed following oral administration of single doses of 100, 300 and 1000ng/kg body weight. The induction of CYP1A1, determined as EROD activity, was significantly increased by E2 (17b-estradiol, 5μg/kg body weight) treatment to both intact and ovariectomized rats. Immunoblot analysis of liver cytosol showed no apparent change in arylhydrocarbon receptor (AhR) levels by treatment of E2 or TCDD alone or both compounds. While there was an increase in nuclear AhR by E2 or TCDD alone or both, no difference between TCDD alone and E2 plus TCDD treatment was observed. Additionally, immunoblot analysis also showed that treatments by E2 alone and E2 plus TCDD, but not TCDD alone, significantly increased E2 receptor (ER) levels in the nucleus of ovariectomized rat liver. These observations suggest that the liganded ER in the nucleus may be involved in the activation of CYP1A1 gene expression after the formation of Ah receptor TCDD complex. In conclusion, estrogen *in vivo* can enhance the TCCD induced CYP1A1 expression.

1290 DIFFERENTIAL EFFECTS OF ESTRADIOL CONGENERS ON THE EXPRESSION OF CYP1A1 INDUCED BY 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN IN A MOUSE OVARIAN EPITHELIAL CANCER CELL LINE.

D. Son[1], K. F. Roby[2], K. K. Rozman[3] and P. F. Terranova[4]. [1]*Univ. of Kansas Medical Center, Center Reproductive Sci., Depts. Mol. & Integ. Physiology, Kansas City, KS,* [2]*Univ. of Kansas Medical Center, Department of Anatomy & Cell Biology, Kansas City, KS,* [3]*Univ. of Kansas Medical Center, Department Pharmacology, Toxicology, & Therapeutics, Kansas City, KS; Sect. Physiology, Obstetrics & Gynecology, Kansas City, KS.*

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) is a well known environmental pollutant, promoter of carcinogenesis and reproductive toxicant. TCDD induced ethoxyresorufin-o-deethylase (EROD) activity dose-dependently in a mouse ovarian epithelial cancer cell line (ID8). Induction of EROD by TCDD was inhibited by a-naphthoflavone, an aryl hydrocarbon receptor (AhR) antagonist. Interestingly, estradiol (E2) congeners increased dose-dependently the induction of EROD by TCDD in order of estrone (E1) > 17b-estradiol (E2) > 4-hydroxyestradiol (4-OHE2) @ 2-hydroxyestradiol (2-OHE2), whereas estriol (E3) decreased EROD activity. E2 congeners did not affect the number of ID8 cells, as shown by similar DNA and protein concentrations during 48hr in culture. Based on Western and Northern blots, E2 increased CYP1A1 protein and mRNA dose-dependently whereas E3 decreased these parameters. Transfection with a dioxin response element (DRE)-containing a luciferase reporter revealed that E2 did not alter the luciferase activity induced by TCDD whereas E3 decreased luciferase activity dose-dependently, indicating differential mechanisms between E2 and E3. RT-PCR revealed that CYP1A1 mRNA was induced by TCDD in ID8 cells whereas CYP1B1 mRNA was constitutively expressed and was not affected by TCDD. Progesterone and gonadotropins had no effect on the induction of EROD by TCDD. Based on RT-PCR, estrogen receptor (ER) a is constitutively expressed in ID8 cells, but ERb and progesterone receptors were not detectable. These results indicate that most of the E2 congeners tested in this study enhanced induction of EROD by TCDD wherease estriol reduced its ability to do so. This differential effect may provide insight into the mechanism(s) of how estrogens interact with TCDD.

1291 INCREASED OXIDATIVE DNA DAMAGE IN FEMALE SPRAGUE-DAWLEY RATS CHRONICALLY TREATED WITH 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN AND 17 β-ESTRADIOL.

M. E. Wyde[1], G. W. Lucier[2] and N. J. Walker[2]. [1]*UNC, Chapel Hill, NC and* [2]*NIEHS, Research Triangle Park, NC.*

Hepatocarcinogenesis induced by 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) is influenced by ovarian hormones. The induction of cell proliferation and the formation of oxidative DNA damage by TCDD are ovarian hormone-dependent. Estrogen is hypothesized to contribute to the mechanism of TCDD-induced hepatocarcinogenesis through multiple mechanisms, including the increased production of reactive oxygen species from the redox cycling of catechol estrogen metabolites. The aim of this current study was to test the hypothesis that estrogen enhances TCDD-induced formation of oxidative DNA damage. Diethylnitrosamine-initiated intact and ovariectomized female Sprague-Dawley rats were co-treated with 17β-estradiol and TCDD for 30 weeks and 8-hydroxydeoxyguanosine (8-OHdG) adduct formation in hepatic nuclear DNA was measured by HPLC with electrochemical detection. Preliminary analyses demonstrated an increase in 8-OHdG adduct formation in TCDD-treated intact, but not ovariectomized rats. The formation of 8-OHdG was increased in TCDD-treated ovariectomized rats supplemented with continuous 17β-estradiol and equivalent to levels observed in TCDD-treated intact rats. These data support previous observations of the dependency of TCDD-induced 8-OHdG adduct formation on ovarian hormones and suggest that 17β-estradiol is a key factor in TCDD-induced oxidative DNA damage.

1292 INHIBITION OF ESTROGEN-INDUCED RETINOIC ACID RECEPTOR α1 GENE EXPRESSION BY TCDD MECHANISMS OF ACTION.

G. Sun, I. Samudio and S. Safe. *Texas A&M University, Department of Veterinary Physiology & Pharmacology, College Station, TX.*

17β-Estradiol (E2) induces retinoic acid receptor α1 (RARα1) mRNA levels (2-fold) in MCF-7 human breast cancer cell lines, and after cotreatment with 10 nM 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD), the E2-induced response was completely inhibited in these cells. pRARA12 is an estrogen-responsive construct containing an insert from the -509 to +105 region of RARα1 gene promoter linked to a bacterial chloramphenicol acetyltransferase (CAT) reporter gene. In MCF-7 cells transiently transfected with pRARA12 and an estrogen receptor α (ERα) expression plasmid, treatment with 1 nM E2 resulted in a 4-fold induction of CAT activity. Cotreatment with 1 nM E2 + 10 nM TCDD significantly decreased (> 50%) the hormone-induced response. Promoter deletion and mutation analysis was further used for identifying functional inhibitory dioxin-responsive elements (iDREs) (GCGTG) that interact with the Ah receptor complex and mediate inhibitory effects of TCDD for other E2-induced genes including cathepsin D, c-*fos* and *pS2*. Results showed that a potential iDRE at -110 was not functional; however, inhibition of E2-induced transactivation using several constructs was dependent on the Ah receptor. The mechanisms associated with inhibition of ERα/Sp1-dependent activation of RARα1 gene promoter-derived constructs by TCDD were investigated and shown not to be related to modulation of kinase-dependent

activation of Sp1 or alteration of cellular Sp1/Sp3 ratios. The results suggest that Ah receptor-mediated downregulation of ERα levels may be a possible mechanism, and this was supported by DNA footprinting studies showing that the Ah receptor complex partially blocked ERα/Sp1 interactions with E2-responsive GC-rich sites. (ES04176 and ES09106)

1293 3',4'-DIMETHOXYFLAVONE AS AN ARYL HYDROCARBON RECEPTOR ANTAGONIST IN BREAST CANCER CELLS.

J. E. Lee, M. Sethi-Gupta and S. Safe. *Texas A&M University, Department of Veterinary Physiology & Pharmacology, College Station, TX.*

Previous studies have shown that several substituted flavonoids, including some 3'-substituted flavones, exhibit aryl hydrocarbon receptor (AhR) antagonist activities. The AhR antagonist activity of substituted flavones can be both structure- and cell context-dependent, and interpretation of results can be difficult due to other activities of these compounds. We have been investigating the AhR agonist/antagonist activities of 3',4'-dimethoxyflavone (DMF) in estrogen receptor (ER)-positive MCF-7 and T47D breast cancer cell lines. 2,3,7,8-Tetrachlorodibenzo-*p*-dioxin (TCDD) (1 nM) induced a 20- to 40-fold increase in CYP1A1-dependent ethoxyresorufin *O*-deethylase (EROD) activity in MCF-7 and T47D cells, whereas 0.1 to 10 μM 3',4'-DMF alone did not induce EROD activity. In cells cotreated with 1 nM TCDD plus 0.1 to 10 μM 3',4'-DMF, there was a concentration-dependent decrease in the induced response, with total inhibition at the 10 μM concentration. In parallel experiments; 3',4'-DMF (10 μM) also inhibited chloramphenicol acetyltransferase (CAT) activity in breast cancer cells treated with 1 nM TCDD and cotransfected with pRNH11c, an Ah-responsive construct containing a human CYP1A1 gene promoter insert (-1142 to +2434) linked to a CAT reporter gene. 3',4'-DMF alone did not induce CAT activity in this transfection assay. 3',4'-DMF did not significantly inhibit estrogen-induced growth of breast cancer cells, and ongoing studies are further investigating the AhR antagonist activities of 3',4'-DMF and the effects of this compound in blocking AhR-mediated antiestrogenic responses in breast cancer cells. (ES04176 and ES09106)

1294 TESTICULAR TOXICITY OF TCDD IN A TCDD- SENSITIVE AND A TCDD-RESISTANT RAT STRAIN: A STEREOLOGICAL ANALYSIS.

J. T. Tuomisto[1], C. Celebi[2], U. Simanainen[1], A. M. Haavisto[3], N. E. Skakkebæk[2], J. Tuomisto[1], J. Toppari[3] and M. Viluksela[1]. *[1]National Public Health Institute, Kuopio, Finland, [2]Department of Growth and Reproduction, Juliane Marie Center, National University Hospital, Copenhagen, Denmark and [3]Department of Physiology, University of Turku, Turku, Finland.*

Testicular toxicity of TCDD was studied in the sensitive Long-Evans (Turku/AB; L-E) and the resistant Han/Wistar (Kuopio; H/W) rats, differing >1000-fold in their sensitivity to the acute lethality of TCDD. Adult male rats were given a single oral dose of TCDD at 0, 0.1, 2 or 20 μg/kg (L-E), and 0, 0.1, 20 or 1000 μg/kg (H/W). The study was terminated and samples collected 4 or 17 days after dosing. Testes were fixed in Bouin's solution and examined using a stereological optical disector/fractionator method. Sertoli cells, Leydig cells and spermatogenic cells at stages VII and VIII of the seminiferous epithelial cycle were quantified. Serum testosterone, estradiol, LH and FSH levels were analyzed using RIA/FIA. Neither strain showed any changes in seminiferous epithelial cell types 4 days after dosing. On day 17, the number of Sertoli cells and all spermatogenic cell types (spermatogonias, preleptotene and pachytene spermatocytes, round spermatides) at stages VII and VIII were significantly decreased at 20 μg/kg in L-E rats. The number of Leydig cells was not significantly affected. In H/W rats no changes were observed at 1000 μg/kg on day 17. Decreases were observed in serum testosterone, estradiol and LH concentrations in L-E rats at 20 μg/kg on day 17 (estradiol and LH levels showed some decrease already on day 4), but not at all in H/W rats. It is concluded that H/W rats that are resistant to acute lethality of TCDD are also resistant to the toxic effects of TCDD to the seminiferous epithelium. (Supported by the Academy of Finland, the Finnish Research Programme on Environmental Health.)

1295 TUMOR PROMOTION IN THE LIVERS OF MALE RATS CHRONICALLY EXPOSED TO 2,3,7,8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD).

N. J. Walker, M. E. Wyde, M. S. Lebetkin, T. E. Cambre and G. W. Lucier. *National Institute of Environmental Health Sciences, Research Triangle Park, NC.*

Chronic exposure to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) induces the formation of liver tumors in female but not male rats. The aim of this study was to investigate the mechanism of the gender-specific hepatocarcinogenicity of TCDD. The development of putatively preneoplastic altered hepatocellular foci (AHF) was analyzed in the livers of diethylnitrosamine-initiated male Sprague-Dawley rats that were treated weekly with 700 ng TCDD/kg, or corn oil vehicle, for 30 weeks. Mean hepatic TCDD levels (ppt wet weight), measured by GC/MS, were 35 ± 26 ppt and 12595 ± 4225 ppt in control and TCDD-treated male rats, respectively. AHF expressing the placental form of glutathione-S-transferase (PGST) were measured immunohistochemically. The mean number of PGST AHF/cm^3 in TCDD-treated male rats (4921±1074) was significantly higher than that observed in control animals (2559±1904) ($P<0.01$ Fisher PLSD test). These levels were significantly higher than those observed in similarly treated female rats. In contrast there was no significant difference in mean PGST AHF liver volume fraction between corn oil-treated (0.84±0.81) and TCDD-treated (1.63±1.08) animals. Furthermore these volume fractions were similar to that observed in similarly treated female rats. These data suggest that in males, TCDD is able to promote the formation of these putatively preneoplastic AHF but is unable to promote the growth of them. The increase in number of AHF by TCDD may be due to an increase in mutation of normal cells to an initiated phenotype and/or due to a suppression of apoptosis of initiated cells.

1296 LIVER TUMOR PROMOTING ACTIVITY OF TCDD IN A TCDD-SENSITIVE AND A TCDD-RESISTANT RAT STRAIN.

M. Viluksela[1], Y. Bager[2], J. T. Tuomisto[1], G. Scheu[2], M. Unkila[1], R. Pohjanvirta[1], S. Flodström[2], L. Wärngård[2], V. M. Kosma[3], J. Mäki-Paakkanen[1], C. Klimm[4], K. W. Schramm[4], T. Vartiainen[1] and J. Tuomisto[1]. *[1]National Public Health Institute, Kuopio, Finland, [2]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Department of Clinical Pathology and Forensic Medicine, University of Kuopio, Kuopio, Finland and [4]GSF-Institut für Ökologische Chemie, Neuherberg, Germany.*

Liver tumor promoting activity of TCDD was studied in the sensitive Long-Evans (Turku/AB; L-E) and the resistant Han/Wistar (Kuopio; H/W) rats differing >1000-fold in their sensitivity to the acute lethality of TCDD. Female rats were partially hepatectomized, initiated with nitrosodiethylamine and, after 5 weeks, treated with weekly s.c. doses of TCDD (total doses 0, 0.17, 1.7, 17 (both strains), 170 and 1700 (H/W only) μg/kg) for 20 weeks. Liver TCDD concentrations at the end of the study reflected accurately the doses administered. Dose-responses for liver EROD activity were largely similar in both strains. Liver tumor promoting activity, measured as glutathione S-transferase P (GST-P) positive foci, was significantly and dose-dependently increased in L-E rats at 1.7 and 17 μg/kg, but in H/W rats only at 170 μg/kg. Histopathological findings and elevation of plasma transaminase activities followed the same pattern, suggesting an association between liver tumor promotion and hepatotoxicity in these rat strains. Frequency of micronucleated erythrocytes in bone marrow and peripheral blood were increased in L-E rats at 17 μg/kg and in H/W rats at 170 and 1700 μg/kg. The results demonstrate that although H/W rats are extremely resistant to the acute lethality of TCDD, they are relatively sensitive to liver tumor promotion by the same compound, and the sensitivity difference between L-E and H/W rats in liver tumor promotion (about 100-fold) is clearly smaller than that in lethality. (Supported by the European Commission, Contract No. ENV-CT96-0336.)

1297 ANEMIA AND LUNG CANCER IN 1,2,3,4,6,7,8-HEPTACHLORODIBENZO-*P*-DIOXIN (HPCDD)-TREATED FEMALE SPRAGUE-DAWLEY RATS AFTER VARIOUS SINGLE AND MULTIPLE ORAL DOSES.

K. K. Rozman[1], M. Lebofsky[2] and D. M. Pinson[3]. [1]*Section of Environmental Toxicology, GSF-Institut für Toxikologie: Neuherberg, Germany; University of Kansas Med. Center, Department Pharmacology, Toxicology & Therapeutics, Kansas City, KS,* [2]*Univ. of Kansas Med. Center, Department Pharmacology, Toxicology and Therapeutics, Kansas City, KS and* [3]*Univ. of Kansas Med. Center, Department Pathology and Lab. Medicine, Kansas City, KS.*

Groups of 30 to 60 adult female Sprague Dawley rats were administered single doses of HpCDD ranging from 2.8 to 3.4 mg/kg in corn oil (4 ml/kg) by gavage. Another group of 30 females received a loading dose of 2.8 mg/kg HpCDD followed by biweekly maintenance doses of 0.086 mg/kg also by gavage. Body weight and feed intake were monitored at least 5 times a week. Animals were monitored for signs of wasting/hemorrhage (25% or more body weight loss/bleeding around nose or in intestine), anemia (exceptional paleness) and lung cancer (visible only as an abscess upon death) by daily observations. The different effects were allowed to run their time course unless rats were in severe distress (e.g., large or bleeding [mainly mammary] tumors) in which case they were euthanized. Upon death heart, lungs, kidneys, upper GI tract, sternum and femur, liver and any macroscopically observable tumor were harvested, embedded, sectioned and stained with H & E. Microscopic examination confirmed in every instance macroscopic observations regarding anemia in that bone marrow cellularity was always less than 20% in exceptionally pale rats. Additional, macroscopically not identifiable squamous cell carcinomas of the lungs were also detected by light microscopy. Times to first wasting/ hemorrhage (70.3±8.5 mg/kg x day) and to first anemia (435.8±15.4 mg/kg x day) and to first lung cancer (544.9±66 mg/kg x day) were in reasonably good agreement with c x t=k. Steady state vs. single dose exposure resulted in a steepening of the dose response for wasting/hemorrhage and for anemia with an increase in incidence approximately proportionate to the AUC. More time will be needed to obtain corresponding information for lung cancer.

1298 2,3,7,8- TETRACHLORODIBENZO-*P*-DIOXIN (TCDD) ACCELERATES DIFFERENTIATION, BUT NOT APOPTOSIS, OF HUMAN KERATINOCYTES IN ORGANOTYPIC CULTURE.

J. A. Loertscher, C. A. Sattler and B. L. Allen-Hoffmann. *University of Wisconsin-Madison, Madison, WI.*

Human exposure to the environmental toxin TCDD produces a severe skin pathology known as chloracne. Historically the primary tool employed to explore the molecular basis of TCDD's effect upon skin has been monolayer culture of keratinocytes. Because monolayer culture cannot recapitulate the three dimensional architecture or epithelial-mesenchymal interactions found in skin, organotypic culture, which accounts for these factors, would be an ideal system in which to investigate the effect of TCDD on intact skin. In new experiments we have shown that TCDD causes accelerated differentiation in a three dimensional, organotypic skin model. Analysis at both the light and electron microscope levels reveals a fully differentiated cornified layer in TCDD-treated organotypic cultures at earlier time points than observed in vehicle (DMSO)-treated controls. In situ 3' end labeling reveals no increase in nucleosomal fragmentation, a characteristic of apoptosis, in TCDD-treated organotypic cultures. Furthermore, basal cells in TCDD- and DMSO-treated organotypic cultures show no differences in proliferation as measured by quantification of BrdU positive nuclei. We hypothesize that TCDD exerts its effects upon intact skin through transcriptional modification of a mesenchymally-produced growth factor, which in turn could produce changes in the differentiation program of the epithelial layer. The described *in vitro* organotypic skin model will be used to test both the validity of this hypothesis and the cell type-specific role that the aryl hydrocarbon receptor (AhR) plays in TCDD toxicity in skin.

1299 TCDD INDUCES EXPRESSION OF MATRIX REMODELING PROTEASES.

L. A. White, C. D. Capperino and B. L. Allen-Hoffmann. *University of Wisconsin, Madison, WI.*

Exposure to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) results in a number of pathological conditions including chloracne, a hyperkeratinization of the skin, as well as an increased incidence of liver and skin cancer. It is generally accepted that the pathological effects of TCDD are mediated through its binding to the aryl hydrocarbon receptor (AhR). TCDD binding to AhR results in translocation into the nucleus, where it dimerizes with ARNT and becomes an active transcription factor binding to specific sequences known as xenobiotic response elements (XRE). How this pathway results in the pathological effects of TCDD in target tissues is unclear. Using human skin as a model, we have focused on the effect of TCDD on a family of matrix proteases, the matrix metalloproteinases (MMP). These enzymes are responsible for the majority of extracellular matrix degradation, and their expression is required for processes involving tissue remodeling such as wound healing and development. We identified two potential XRE elements in the promoter of the human MMP-1 (collagenase) gene, suggesting a role for the AhR/ARNT pathway in regulation of this gene. Northern analysis demonstrates that expression of MMP-1, as well as other MMPs, is increased in TCDD-treated keratinocytes, but not in TCDD-treated dermal fibroblasts. Mobility shift analysis shows binding to both the putative XRE elements in the MMP-1 promoter. Our findings have identified a new class of target genes that may be involved in mediating the pathological response of human skin to TCDD exposure.

1300 DERMAL AND ORAL EXPOSURE OF TCDD IN TG.AC MICE: DOSE- AND TIME-RESPONSE STUDIES.

A. P. J. van Birgelen[1], J. D. Johnson[2], A. F. Fuciarelli[3], J. D. Toft[2], M. Hejtmancik[2], J. Mahler[1] and J. R. Bucher[1]. [1]*NIEHS, Research Triangle Park, NC,* [2]*Battelle Memorial Laboratories, Columbus, OH and* [3]*Battelle-Toxicology Northwest, Richland, WA.*

Dose-response and exposure route studies were performed with the ubiquitous, bioaccumulative, and carcinogenic agent-2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD)-using the Tg.AC transgenic mouse model in order to evaluate the development of papillomas over time. Female hemizygous Tg.AC mice (20/group) received 0, 5, 17, 36, 76, 121, 166, 355, or 760ng TCDD/kg in acetone three times a week, for 26 weeks, by dermal application or 0, 105, 450, or 1250ng TCDD/kg in corn oil five times a week, for 26 weeks, by gavage administration. With either route of exposure, TCDD caused neoplastic lesions that were confined to the skin and included squamous cell papillomas and carcinomas. The average number of papillomas per animal and the time to papilloma occurrence were dose-dependent. An increase in the number of papillomas was observed at doses ≥17ng TCDD/kg (dermal) or 1250ng TCDD/kg (oral) by study termination. A dose-dependent increase in hepatic and pulmonary cytochrome P4501A activities was observed. TCDD significantly increased hepatic CYP1A1 and CYP1A2 activities in all dose groups (dermal and oral). Pulmonary CYP1A1 activities were significantly increased at doses ≥36ng TCDD/kg in the dermal study and at all dose levels in the oral study. A remarkable finding in the gavage study was the absence of neoplastic lesions in organs other than the skin.

1301 IDENTIFICATION AND CHARACTERIZATION OF TIG1, A NOVEL TCDD-INDUCIBLE GENE.

Q. Ma[1] and K. Baldwin[2]. [1]*HELD/NIOSH, Morgantown, WV and* [2]*TMBB/HELD/NIOSH, Morgantown, WV.*

TCDD (2,3,7,8-tetrachlorodibenzo-p-dioxin) is a prototype of a class of halogenated aromatic hydrocarbons, which are mostly byproducts of industrial processes and combustion of fuels. Many of the chemicals are persistent environmental contaminants. TCDD elicits a wide range of toxic responses in animals and impose a threat to human health. The aryl hydrocarbon receptor is a ligand-activated receptor/transcription factor, which, together with other factors, mediates the biological effects of TCDD and related chemicals. The mechanism of action of AhR involves transcriptional regulation of gene expression of target genes. However, current knowledge on the target genes and their roles in TCDD toxicity is limited and does not adequately explain the wide spectrum of TCDD toxicity. To gain new insights into the mechanism of TCDD action, we have utilized the mRNA differential display technique to identify new genes that are regulated by TCDD. We report here the identification of a new TCDD-inducible gene (TIG1) in mouse cell lines. Analyses of the partial sequence of TIG1 suggest that it represents a novel gene product. The induction of TIG1 by TCDD is both time- and dose-dependent. Cycloheximide, an inhibitor of protein synthesis, superinduces TIG1 in the presence of TCDD. Cell genetic analyses of the induction reveal that it requires AhR and Arnt. Furthermore, these analyses demonstrate that the transcription activation functions of both AhR and Arnt are required for the induction of the gene. Finally, treatment of C57BL/6 mice with low doses of TCDD induces TIG1 mRNA expression in liver. Thus, TIG1 is a novel target gene of

TCDD in both cultured cell and intact animal; the induction of the gene by TCDD is mediated through the AhR/Arnt signaling process. These findings provide new insights into the mechanism of gene regulation by AhR. Current research is aimed at analyses of the sequence and cellular function(s) of TIG1.

1302 INDUCTION OF METALLOTHIONEIN IN LIVER OF FEMALE RATS TREATED WITH 2,3,7,8-TETRACHLORODIBENZO-*p*-DIOXIN.

N. Nishimura[1], J. S. Suzuki[1], M. Sato[1], M. Ohmura[2], M. Satoh[1], Y. Aoki[1] and C. Tohyama[1]. [1]*National Institute for Environmental Studies, Tsukuba, Japan and* [2]*CREST, JST, Kawaguchi, Japan.*

Metallothioneins (MTs) are cysteine-rich metal-binding proteins that exert cytoprotective effects against metal toxicity and oxidative stress. Since 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) is known to cause an exaggerated oxidative stress response in the rats and mice, we have thus studied a possible involvement of MT in oxidative responses induced by TCDD. Female Sprague-Dawley (SD) rats (6-week old) were administered a single oral dose of TCDD varying from 1.0 to 4.0 μg/kg and the serum and tissues were collected 7 days after dosing. In the liver MT protein as well as mRNAs of MT-I and MT-II, the major forms of MT, were dose-dependently induced at as low as 1.0 μg TCDD/kg bw. Significant increases in serum 8-OHdG levels, a biomarker for DNA oxidation, were observed in the rats dosed at 2.0 and 4.0 μg TCDD/kg bw. TCDD administration resulted in a significant increase in metal concentrations (Cu, Fe, Zn and Ca) in the liver. Serum cytokines (TNF-α, IL-1β, IL-6 and IL-10), GOT and GPT were not affected at any doses of TCDD. These results indicate that a single low dose of TCDD caused an oxidative stress response as shown by an increase in serum 8-OHdG levels, and suggest that induced MT in the liver may be responsible for the reduction of the toxicity for an oxidative stress caused by TCDD. (This work was supported in part by STA Special Fellowship to N. Nishimura.)

1303 MECHANISTIC MODELING OF TCDD-INDUCED CYTOCHROME P450 GENE EXPRESSION IN RAT LIVER.

A. H. Kim[1], M. C. Kohn[2], C. J. Portier[2], G. W. Lucier[2] and N. J. Walker[2]. [1]*University of North Carolina, Chapel Hill, NC and* [2]*NIEHS, Research Triangle Park, NC.*

The dose-response relationships of cytochromes (CYP) P450 1A1, 1A2, and 1B1 in the livers of female Sprague-Dawley rats chronically exposed to 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) have been characterized. The aim of this study was to evaluate CYP P450 gene expression across several chronic tumor initiation/promotion studies in a mechanistic model and to use the model to identify possible mechanisms for the previously observed differences in the dose-dependent expression of CYP1A1, CYP1A2, and CYP1B1. In the two continuous studies, rats were treated with either low or high doses of TCDD via biweekly gavage for 30 continuous weeks. In the "discontinuous" study, rats were treated with the same approximate daily dose of TCDD via biweekly gavage but for varying exposure durations. TCDD-induced gene expression was modeled using biochemically realistic parameters such as multiple binding sites for the TCDD/aryl hydrocarbon receptor (AhR) ligand/AhR nuclear translocating protein (ARNT) complex at dioxin responsive elements (DREs) on DNA, stabilization of mRNA by a poly(A) tail, a lag time for mRNA translation, and saturation kinetics of protein synthesis. The best fit of the model to the observed data predicted: (1) the TCDD/AhR/ARNT complex had a higher affinity to DREs of CYP1A1 and CYP1A2 compared to CYP1B1, (2) CYP1B1 mRNA was less stable due to its estimated shorter poly(A) tail, and (3) saturation kinetics was due to the limited number of ribosomes available for binding to RNA. The ability of this model to reproduce the observed TCDD-induced responses demonstrates its utility for providing mechanistic insights into receptor-mediated gene induction.

1304 MARKERS OF EXPOSURE AND EFFECT IN REPRODUCTIVE AND NON-REPRODUCTIVE TISSUES OF FEMALE CHICKENS FOLLOWING *IN VIVO* TCDD TREATMENT.

B. J. Stanton, F. El-Sabeawy, E. Enan, B. L. Lasley and D. M. Fry. *University of California, Davis, CA.*

While the overt toxicity of TCDD to avian species has been clearly demonstrated, the associated biochemical and molecular changes have been much less studied. To address this issue, twenty-one week old Rhode Island Red - White Feather F1 hybrid hens were treated with 10 (low dose) or 100 (high dose) μg/kg body weight TCDD or an equal volume of the corn oil vehicle and sacrificed after 24 hours to determine the effect of exposure on cellular function and signal transduction pathways. Liver, adipose, and ovarian tissues were collected and analyzed for glutathione-S-transferase, lipoprotein lipase, glucose transporter, and cellular signaling protein kinases that are well-characterized as targets for TCDD in mammals. The kinases we specifically focused on are two important components of signaling protein pathways: -tyrosine kinase, an upstream signaling protein that mediates cytosolic signals in response to changes in epidermal growth factor receptor (EGFR)-ERK2, one of the MAPK family members that can transduce from cytosolic to nuclear signal, activates the transcriptional activity of several transcription factors including early response genes and their protein complex AP-1, and phosphorylates and activates the estrogen receptor. Glutathione-S-transferase (GST) activity was increased in adipose tissue, not effected in the liver, and decreased in the ovarian tissue of birds exposed to the high dose of TCDD, but was not changed in either tissue with 10 μg/kg TCDD. Lipoprotein lipase activity in adipose tissue was decreased in birds treated with 100 μg/kg TCDD but not with 10 μg/kg exposure. Glucose transporters in liver (GLUT2) of birds in the high dose group bound more cytochalasin B than the respective controls, while glucose transporter binding in adipose tissue (GLUT4) decreased in TCDD-treated birds. Finally, tyrosine phosphorylation of a currently unidentified protein with M_r between 116 and 97 consistently increased in liver, ovarian, and adipose tissue of 100 μg/kg TCDD-treated birds. Future experiments will also measure ethoxyresorufin-O-demethylase (EROD) activity as classical marker of exposure, and lipid peroxidation and epidermal growth factor receptor binding as additional indicators of biochemical effects.

1305 AGONIST ACTIVATION OF THE ARYL HYDROCARBON RECEPTOR COMPARED TO AVIAN CARDIOTOXICITY MEDIATED BY TCDD.

S. E. Heid[1], M. K. Walker[2] and H. I. Swanson[1]. [1]*Department of Pharmacology, College of Medicine, University of Kentucky, Lexington, KY and* [2]*College of Pharmacy, University of New Mexico, Albuquerque, NM.*

Polyhalogenated aromatic hydrocarbons, such as 2,3,7,8 tetrachlorodibenzo-p-dioxin, (TCDD) are ubiquitous environmental contaminants whose toxicity has been correlated with their ability to bind and activate the aryl hydrocarbon receptor (AHR). The AHR activates specific genes such as cytochrome p450 1A1 and 1A2 (CYP1A1 and CYP1A2) by binding to specific DNA response elements. Avian species are especially sensitive to TCDD exposure which results in a myriad of toxic effects including edema disease and cardiotoxicity, as well as increased levels of CYP1A4 and CYP1A5, the avian homologues to mammalian CYP1A1 and CYP1A2. However, the direct activation of the avian AHR has yet to be characterized or correlated with observed physiological effects of TCDD exposure in avian systems such as cardiotoxicity. Therefore we have designed a model to determine the relative affinity of five well-defined AHR agonists, including TCDD, for the chicken AHR by comparing the ability of each compound to induce DNA binding of the AHR complex in either LMH (chicken liver carcinoma) cells or HepG2 (human liver carcinoma) cells by electrophoretic mobility shift assay. These results were quantitated by phosphorimaging analysis to determine the toxic equivalency factors from the apparent EC50 of each of these compounds between the chicken and human AHR. Our initial results indicated no dramatic difference between the binding affinities for the chicken and human AHR. To correlate activation of the DNA binding form of the AHR to cardiotoxicity, the chicken AHR cell culture data were compared to the ability of the same compounds to increase heart wet weight in chick embryos. Our initial results indicate that the rank/order for these compounds may differ between the *in vitro* and *in vivo* models for AHR mediated toxicity in the developing chicken. These data suggest that factors, in addition to AHR activation, may contribute to the cardiotoxicity induced by AHR agonists *in vivo*.

1306 TCDD INDUCED NF-KB BINDING TO THE KB CONSENSUS MOTIF IN MURINE B-CELL LINES.

S. B. K. Stoughton. *Michigan State University, East Lansing, MI.* Sponsor: D. Eaton.

2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is a prominent environmental toxicant with effects including lymphoid involution, chloracne, teratogenesis, cancer, and immunosuppression. The mechanism which are responsible for these effects is thought to be mediated by the aryl hydrocarbon receptor (AhR). However, previous studies in our laboratory demonstrated an AhR-independent effect of TCDD on NF-kB binding in the 3'a-hs4 enhancer

region of the 3'a immunoglobulin heavy chain enhancer. NF-kB is a transcription factor that is involved in the regulation of genes participating in immune and inflammatory responses, many of which have been shown to be affected by TCDD. The aim of the present study was to further characterize TCDD-mediated induction of kB binding using a kB consensus probe. kB binding was evaluated, by an electrophoretic mobility shift assay, in two B-cell lines, the AhR-expressing CH12.LX cell line and the AhR-deficient BCL-1 cell line. TCDD induced kB binding in a concentration-dependent manner in the CH12.LX cells. TCDD- inducible binding to the kB consensus probe was competed away with both the unlabeled kB consensus probe, as well as, the unlabeled 3'a-hs4 probe, indicating that the binding observed at the 3'a hs4 enhancer was specific for the kB motif identified within the enhancer. Since LPS is a polyclonal stimulator for B-cells and is known to induce kB binding, the effect of LPS stimulation on kB binding alone or in costimulation with TCDD were also evaluated. In the CH12.LX cells, LPS induced kB binding; however, a 30nM TCDD treatment resulted in greater kB binding as compared to that induced by LPS alone. Interestingly, costimulation with both TCDD and LPS resulted in reduced binding to the kB motif as compared to TCDD alone. TCDD-induced kB binding was also observed in the BCL-1 cells. These results demonstrate a concentration dependent induction of kB binding by TCDD that is AhR-independent. (This work was supported by NIEHS Grant ES02520.)

1307 ANTAGONISTIC EFFECTS OF DI-*ORTHO* POLY CHLORINATED BIPHENYLS ON ARYL HYDROCARBON RECEPTOR-DEPENDENT CYP1A1 AND IGM GENE EXPRESSIONS IN CH12.LX B CELLS.

J. Suh[1], J. Kang[2], K. Yang[1] and N. E. Kaminski[2]. [1]*Korea Advanced Institute of Science and Technology, Taejon, Republic of Korea and* [2]*Michigan State University, E. Lansing, MI.*

Halogenated aromatic hydrocarbons (HAHs) are ubiquitous contaminants in our environment. Many of the toxic effects produced by HAHs are believed to be elicited by binding to aryl hydrocarbon receptor (AhR). However, several recent investigations have demonstrated that certain HAH congeners, primarily di-orthosubstituted polychlorinated biphenyls (PCB), inhibited the AhR-mediated responses induced by other toxic HAHs. The mechanism responsible for this inhibition by certain PCBs is presently unknown. Here we present the antagonistic effects of di-orthosubstituted PCBs on AhR-mediated biological responses in the murine B cell line, CH12.LX. CYP1A1 mRNA expression induced by TCDD or coplanar PCBs [PCB77 (3,3',4,4'-tetrachlorobiphenyl) and PCB126 (3,3',4,4',5-pentachlorobiphenyl)]was inhibited by PCB153 (2,2',4,4',5,5'-hexachlorobiphenyl) and another di-orthosubstituted PCB congeners [PCB47 (2,2',4,4'-tetrachlorobiphenyl), PCB52 (2,2',5,5'-tetrachlorobiphenyl), and PCB128 (2,2',3,3',4,4'-hexachlorobiphenyl)] also antagonized CYP1A1 mRNA induction in co-treatment with TCDD. Di-orthosubstituted PCB52 antagonized TCDD- or PCB126-mediated inhibition of IgM secretion in LPS-activated cells. This inhibition of IgM secretion by PCB52 was found to correlate well with a change in mRNA expression level of IgM heavy chain. Furthermore, in TCDD-treated CH12.LX cells, PCB52 inhibited nuclear translocation of AhR from cytosol and subsequent DNA binding of AhR to the dioxin responsive element (DRE) in the nucleus. Collectively, these results suggest that certain di-orthosubstituted PCBs inhibit AhR ligand-modulated CYP1A1 and IgM heavy chain gene expression in B cells through the inhibition of AhR activation. (This work was supported in part by NIH grant PO1 P42ES04911-08.)

1308 THE AHR SIGNALING PATHWAY AND TRANSCRIPTIONAL REGULATION OF IGM EXPRESSION BY 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN.

C. E. W. Sulentic[1], N. E. Kaminski[1] and M. P. Holsapple[2]. [1]*Michigan State University, East Lansing, MI and* [2]*Dow Chemical, Midland, MI.*

The immune system has been identified as a sensitive target for the toxic effects produced by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). Furthermore, the B-cell has been identified as a sensitive cellular target of TCDD by previous cell-type fractionation studies from this laboratory. The actual molecular mechanism responsible for the immunotoxic effects produced by TCDD is unclear; however, many of the biological effects produced by TCDD are thought to be mediated by the aryl hydrocarbon receptor (AhR). Our previous results describing the CH12.LX and BCL-1 B-cell lines, which differ markedly in their expression of the AhR and in their sensitivity to TCDD, have implicated a role for the AhR in TCDD-induced inhibition of B-cell function. The purpose of the present studies was to further investigate this role of the AhR through a characterization of the structure activity relationship (SAR) of several polychlorinated dibenzo-p-dioxin (PCDD) congeners on three endpoints, inhibition of both IgM secretion and μ heavy chain expression and AhR-mediated CYP1A1 induction, in the CH12.LX cells. The effects of the PCDD congeners followed a SAR for each endpoint with the following rank order potency, TCDD > 1,2,3,4,7,8-hexachlorodibenzo-p-dioxin (HxCDD) > 2,3,7-trichlorodibenzo-p-dioxin (TriCDD) > > 1-monochlorodibenzo-p-dioxin (MCDD). Among the three endpoints, there was also a general concordance between the EC_{50} and IC_{50}'s for a particular congener. In addition, TCDD, HxCDD, TriCDD and MCDD had no effect on IgM secretion from the AhR-deficient BCL-1 cells. These results further support an AhR-dependent mechanism for the inhibition of IgM secretion and of μ expression. Furthermore, two dioxin responsive enhancer (DRE)-like sites were identified within the Ig heavy chain 3'α enhancer which might mediate the PCDD-induced inhibition of μ heavy chain expression and thus of IgM secretion. EMSA-Western analysis with the CH12.LX cells demonstrated TCDD-induced binding of the AhR nuclear complex to both DRE-like sites as well as TCDD-induced binding of several NF-κB/Rel proteins to a κB site which overlaps one of the DRE-like sites. Interestingly, κB binding in the BCL-1 cells was also induced by TCDD demonstrating an AhR-independent effect of TCDD on κB binding. These results support an AhR/DRE-mediated mechanism for TCDD-induced inhibition of μ heavy chain expression. Although the effect on κB binding may not contribute to this effect, induction of κB binding by TCDD may have profound effects on the vast number of genes that are regulated by NF-κB/Rel proteins. (These studies were supported by the NIH grant ES02520.)

1309 MODULATION OF MOUSE IgH 3'α-HS4 ENHANCER ACTIVITY BY 2,3,7,8-TETRACHLORODIBENZO-p-DIOXIN AND LPS.

J. Kang[1], K. Yang[2] and N. E. Kaminski[1]. [1]*Michigan State University, E. Lansing, MI and* [2]*Korea Advanced Institute of Science and Technology, Taejon, Republic of Korea.*

Immunoglobulin heavy chain (IgH) gene expression is controlled by a variable region promoter, intronic enhancer and additional regulatory region recently identified in the 3' end of the IgH locus. 3' regulatory region of IgH locus includes several enhancer elements and these enhancer elements function as a locus control region which shows tissue-specific and position-independent activity. All of these promoter and enhancer elements are B lymphoid-specific and regulation of IgH gene expression by these elements is extremely complex. 3'α-hs4 is one of the important enhancer elements of IgH 3' regulatory region and shows enhancer activity throughout B cell development. Here, we demonstrate the effect of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and LPS on 3'α-hs4 enhancer activity in CH12.LX B cells using transient transfection and luciferase reporter gene assay. We amplified IgH variable region promoter and 3'α-hs4 enhancer element from B6C3F1 mouse genomic DNA and subcloned to upstream and downstream multicloning site of luciferase structural gene, respectively. Transient transfection of 3'α-hs4 to CH12.LX cells showed relatively high basal level activity and this 3'α-hs4 activity was enhanced by TCDD and LPS treatment. Furthermore, the enhancement of 3'α-hs4 activity by TCDD was partially blocked by alpha-naphthoflavone which is known as partial blocker of AhR activation. These results show that TCDD and LPS modulate 3'α-hs4 enhancer activity and suggest that IgH gene expression may be regulated by TCDD in an AhR-dependent manner. (This work was supported in part by NIH grant ES02520.)

1310 EXOGENOUS GONADOTROPIN RELEASING HORMONE (GNRH) INDUCES LUTEINIZING HORMONE (LH) AND FOLLICLE STIMULATING HORMONE (FSH) SURGES AND PARTIALLY RESTORES OVULATION IN AN ECG-PRIMED IMMATURE RAT MODEL TREATED WITH 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN (TCDD).

Center, Department Pharmacology Toxicology & Therapeutics: Kansas City, KS; Section of Environ. Toxicology, GSF-Institut für Toxikologie, Neuherberg, Germany.*

Immature (23 day old) female Sprague-Dawley rats were dosed with TCDD (32 mg/kg) in corn oil or vehicle alone. Equine chorionic gonadotropin (eCG) was injected (5 IU, sc) 24-h later to induce follicular development. 54-h after

eCG injection, half of TCDD- or corn oil-treated rats were injected with GnRH (2 mg/rat, sc) to induce LH and FSH surges. TCDD (32 mg/kg) inhibited ovulation by ~75% (2 to 3 ova/rat) when compared with vehicle-treated control rats (~10 ova/rat). GnRH (2 mg/rat) increased the number of ova shed to ~7 ova/rat in TCDD-treated rats, although this was lower than vehicle-treated control rats receiving GnRH (~15 ova/rat). The LH and FSH surges triggered by exogenous eCG in controls was abolished by TCDD (32 mg/kg) at 54 to 60-h after eCG injection and the gonadotropin surges were restored when GnRH was given. GnRH alone increased serum concentrations of estradiol (E2) and progesterone (P4) at 56 to 58-h after eCG injection, but in rats treated with both TCDD and GnRH, serum concentrations of E2 and P4 were reduced. Because TCDD blocks ovulation by preventing the LH surge and through direct inhibitory action on follicular rupture, GnRH could only partially restore the blockade of ovulation induced by TCDD. In addition, it appears that a lack of hypothalamic GnRH secretion may account for the absence of an LH surge in TCDD-treated rats through mechanisms not yet identified.

1311 BLOCKAGE OF OVULATION BY POLYCHLORINATED DIBENZOFURANS (PCDFS), BIPHENYLS (PCBS) AND THEIR MIXTURE WITH DIBENZO-*P*-DIOXINS (PCDDS)SUPPORTS THE TOXIC EQUIVALENCY (TEQ) CONCEPT.

X. Gao[1], P. F. Terranova[2] and K. K. Rozman[3]. [1]*Kansas University Med. Center, Department of Pharmacology Toxicology & Therapeutics, Kansas City, KS,* [2]*Kansas University Medical Center, Depts. of Molecular & Integ. Physiology, Obstetrics & Gynecology, Center Reproductive Science, Kansas City, KS and* [3]*Section of Environmental Toxicology; GSF-Institut für Toxikologie: Neuherberg, Germany; University of Kansas Med. Center, Department Pharmacology, Toxicology & Therapeutics, Kansas City, KS.*

Immature female rats were administered various doses of 2,3,4,7,8-pentachlorodibenzofuran (PeCDF), 3,3',4,4',5-pentachlorobiphenyl (PeCB) or 2,2',5,5' tetrachlorobiphenyl (TCB) and their mixture with polychlorinated dibenzo-p-dioxins (PCDDs) including 2,3,7,8 tetrachlorodibenzo-p-dioxin (TCDD), 2,3,4,7,8-pentachlorodibenzo-p-dioxin (PeCDD) and 2,3,4,6,7,8-hexachlorodibenzo-p-dioxin (HxCDD). Equine chorionic gonadotropin (eCG; 5IU) was injected 24-h later to induce follicular development. Blood and ovaries were harvested, ovarian weights and the number of ova shed were determined at various times after eCG. Serum concentrations of 17ß-estradiol (E2), progesterone (P4), luteinizing hormone (LH), and follicle stimulating hormone (FSH) were determined by radioimmunoassay. PeCDF, PeCB, TCB and their mixture with PCDDs blocked ovulation dose dependently. The slopes of the dose responses for inhibition of ovulation generated by the individual PeCDF, PeCB and/or their mixture with PCDDs were similar. PeCDF, PeCB and the mixture increased serum concentrations of E2 at 72-h after eCG injection, the day of expected ovulation; in contrast, serum P4 and FSH were decreased at that same time point. Only the high doses of TCDD, PeCDF, PeCB and the mixture blocked LH and FSH surges at 58-h after eCG. The ovarian histology revealed that the effect of PeCDF, PeCB and the mixture was very similar to that of PCDDs, consisting of ova trapped in preovulatory follicles and a lack of or reduced number of corpora lutea. These results provide further support of the TEQ concept and indicate a similar mechanism of action among PCDDs, PCDFs, and PCBs in this ovulation model.

1312 INTERACTION OF ESTRADIOL AND 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN IN AN OVULATION MODEL: EVIDENCE FOR SYSTEMIC AND LOCAL EFFECTS.

B. K. Petroff[1], X. Gao[2], K. K. Rozman[3] and P. F. Terranova[4]. [1]*Univ. of Kansas Medical Center, Department of Mol. and Integ. Physiol., Kansas City, KS,* [2]*Univ. of Kansas Medical Center, Department of Pharmacol., Toxicol. and Therap., Kansas City, KS,* [3]*Univ. of Kansas Medical Center, Department of Pharmacology, Toxicology & Therapeutics, Section of Environmental Toxicology, GSF-Institut für Toxikologie. Neuherberg, Germany and* [4]*Univ. of Kansas Medical Center, Department of Mol. & Integ. Physiology, of Obstetrics & Gynecology, Center for Reprod. Sci., Kansas City, KS.*

Immature (day 25) hypophysectomized or intact rats were treated subcutaneously with a long acting estrogen (estradiol cypionate, ECP, 0-2 mg/kg, s.c.) followed 24 hours later by TCDD (0 or 10 mg/kg, p.o.). On the next day, follicular development was induced with equine chorionic gonadotropin (eCG, 5 or 10 IU, s.c.) followed by an ovulatory dose of human chorionic gonadotropin (hCG, 10 IU, s.c.). Systemic exposure to TCDD alone tended to retard weight gain in hypophysectomized rats. The inhibition of ovulation by systemic TCDD was potentiated by systemic pretreatment with ECP (2 mg/kg) in hypophysectomized but not in intact rats. Furthermore, only hypophysectomized rats exposed systemically to TCDD and ECP exhibited actual weight loss. Pair feeding mimicked the combined effects of TCDD and ECP on ovarian function in hypophysectomized rats. In another experiment, rats received ECP subcutaneously (0 or 2 mg/kg) and TCDD into the ovarian bursa (0 or 250 ng). Still another group of rats received TCDD orally (10 mg/kg) and ECP into the ovarian bursa (0 or 1.5 mg). In contrast to systemic TCDD exposure, for which ECP pretreatment potentiated the effect on ovulation, blockade of ovulation by intrabursal treatment with TCDD was alleviated by local or systemic ECP pretreatment. Overall, the results indicate that estrogens increase the systemic toxicity of TCDD in hypophysectomized rats while antagonizing direct effects of TCDD in the ovary.

1313 A MAJOR HUMAN ARSENIC METABOLITE, DIMETHYLARSINIC ACID (DMA), REQUIRES REDUCED GLUTATHIONE (GSH) TO INDUCE APOPTOTIC CELL DEATH.

T. Sakurai and M. P. Waalkes. *NCI at NIEHS, Research Triangle Park, NC.*

Inorganic arsenicals are potent toxicans and carcinogens in humans. In mammals, including humans, inorganic arsenicals often undergo methylation, forming compounds such as dimethyarsinic acid (DMA). Some evidence indicates DMA is carcinogenic in rodents, possibly through formation of radical species. Thus, in this study we examined the role of reduced glutathione (GSH) in the *in vitro* cytotoxicity of DMA compared to that of the inorganic arsenical, arsenite, using murine TRL 1215 liver cells. Arsenite was very cytotoxic in these cells (IC_{50} ~ 35 :M after 48 hours of exposure). With arsenite about 20% of dead cells were apoptotic while 80% were necrotic. Arsenite cytotoxicity increased when GSH was depleted with the glutathione synthase inhibitor, buthionine-sulfoximine (BSO). In contrast, DMA was much less cytotoxic (IC_{50} ~ 1.5 mM) than arsenite and most cells died through apoptosis. BSO actually decreased the DMA-induced cell death. The glutathione reductase inhibitor, carmustine, and a glutathione peroxidase activator, sodium selenite, also prevented DMA-induced cytolethality. Conversely, the addition of GSH or a GSH precursor, N-acetyl-cysteine, enhanced DMA-induced cell death. These data imply that DMA requires GSH to induce apoptosis *in vitro*. Furthermore, DMA markedly increased cellular GSH levels, but, despite this, DMA also induced lipid peroxidation. Ethacrynic acid, an inhibitor of glutathione S-transferase that catalyses GSH-substrate conjugation, and acivicin, an inhibitor of (-glutamyltranspeptidase which catalyses the initial breakdown of GSH-substrate conjugates, also suppressed DMA-induced cell death. These findings indicate that DMA induces apoptosis *via* conjugation with GSH and DMA enhances the cellular accumulation of GSH. Increased apoptosis can be associated with development of proliferative lesion but further study is required to define any such role in DMA-induced neoplasia.

1314 ACUTE ARSENIC-INDUCED FREE RADICAL PRODUCTION AND OXIDATIVE STRESS-RELATED GENE EXPRESSION IN MICE.

J. Liu[1], M. Kadiiska[2], Y. Liu[3], W. Qu[1], R. P. Mason[2] and M. P. Waalkes[1]. [1]*Lab of Comparative Carcinogenesis, NCI at NIEHS, Research Triangle Park, NC,* [2]*Lab of Pharmacology & Chemistry, NIEHS, Research Triangle Park, NC,* [3]*University of Kansas Medical Center, Kansas City, KS.*

This study determined free radical production and oxidative stress-related aberrant gene expression in mice acutely treated with inorganic arsenicals. Mice were treated with a high dose of arsenite (As^{+3}, 100 : mol/kg, sc) or arsenate (As^{+5}, 500 : mol/kg, sc). To evaluate free radical production, mice were simultaneously given the spin trap agent, *N-tert*-butyl-A-phenylnitrone (PBN, 250 mg/kg, ip, in DMSO) with the arsenicals, and livers were removed 30 minutes later. The PBN-trapped free radicals were extracted with methanol:chloroform (1:2), and detected with electron spin resonance (ESR). Arsenical treatment resulted in the appearance of free radicals, with stronger signals seen in As^{+3}-treated mice than in As^{+5}-treated mice. To examine oxidative stress-related aberrant gene expression, livers were removed 3 hours after arsenic treatment, and total RNA was extracted. The Clontech Atlas Toxicology/Stress array indicated that acute arsenic treatment markedly induced heme oxygenase 1 (HO-1; 6-fold), heat-shock protein (HSP60; 3-fold), the DNA damage-induced protein gadd45 (20-fold), along with DNA excision repair proteins such as ERCC-1 (7-fold). In contrast, DNA mismatch repair protein MSH3, MHR23, MmRad51, 8-oxy-quanine DNA glycosylase and breast cancer susceptibility locus 2 product (BRCA2) were down-regulated 50-90%. Expression of many cytochrome P450 enzymes and NADPH-cytochrome P450 reductase were reduced, while CYP3A25 was slightly

increased. Arsenic-induced HO-1, HSP70, and nuclear factor 6 B were observed by Western-blot analysis. Thus, a variety of aberrant gene expressions are associated with acute arsenic-induced oxidative stress and these could play a critical role in acute toxicity.

1315 THE ROLE OF TRANSPORT PROTEINS AND GLUTATHIONE *S*-TRANSFERASE Pi IN ARSENIC TOLERANCE SEEN IN CELLS CHRONICALLY EXPOSED TO LOW LEVELS OF ARSENITE.

Y. Qi, J. Liu[1], H. Chen[1], D. Johnson[2] and M. Waalkes[1]. [1]*NCI at NIEHS, Research Triangle Park, NC and* [2]*University of Kansas Medical Center, Kansas City, KS.*

Arsenic (As) is a known human carcinogen. Our recent work showed that chronic (>18 week) low level (500 nM) arsenite (As^{+3}) exposure induced malignant transformation in a rat liver epithelial cell line (TRL 1215). These cells also developed self-tolerance to As, with a significant reduction in the accumulation of cellular As. The purpose of this study was to examine the role of transport proteins and glutathione *S*-transferases (GST) in decreased As accumulation in these chronic As exposed (CAsE) cells. The Clontech Atlas cDNA microarray analysis indicated that the expression of GST-pi was markedly increased in CAsE cells. The expression of multidrug resistance gene (MDR1) that codes for the transporter P-glycoprotein (P-gp) and multidrug resistance protein (Mrp2) was also increased in CAsE cells, but to a lesser extent than the GST-pi gene. Increased protein levels of GST, Mrp2 and P-gp in CAsE cells were confirmed by Western-Blot analysis. The increased levels of GST suggest that an As-glutathione complex may be formed and effluxed by Mrp2 and/or P-gp transporter. Furthermore, the CAsE cells showed cross-resistance to several anticancer drugs, such as cisplatin, vinblastine, adriamycin, and actinomycin D. Resistance to these anticancer drugs is known to be associated with the increased GST and efflux via Mrp2 or P-gp transporter. These results indicate that chronic As exposure induces GST, which may facilitate the formation of an As-glutathione conjugate for efflux by increased Mrp2 and/or P-gp transporter, thus decreasing As accumulation in the CAsE cells.

1316 EARLY MOLECULAR AND CELLULAR EFFECTS OF ARSENIC IN SKIN CULTURES.

L. Bernstam, C. H. Lan, J. Lee and J. Nriagu. *University of Michigan, Ann Arbor, MI.* Sponsor: F. L. Vaughan.

The effects of topically applied As(V) and As(III) in Earle's balanced salt solution on cytotoxicity, apoptosis, morphology, permeation rate, biosynthesis of DNA, RNA and protein were studied in human pseudoepidermis (PSED) grown on Puropore® nylon membranes at the air-liquid interface and in submerged cultures of human keratinocytes (HK). Topical exposure of PSED to 100 -250μg/L of As(V) results in the focal disruption of the basal layer with occasional karyopyknotic cells 24 hours later. With 500-1000 μg/L, cells progressively deteriorate with disintegration of the basal layer pyknotic nuclei and abundant mitotic figures. Cornified layers remain intact. Marked DNA fragmentation consistent with apoptotic changes are seen in lifted cultures at 250-1000μg/L exposure starting at 24hr. HK grown in submerged culture for 24 hr and exposed to 500 and 1000μg/L As(V) for the following 4 days developed the most pronounced changes involving striking stratification and differentiation of HK. As(III) exposure produced marked, dose dependent cytotoxicity as early as 24 hours. Permeation of arsenic was used to evaluate the degree of barrier function in PSED. Most of the applied As(V) was adsorbed at concentrations of <500μg/L; at 1000μg/L As(V) ~30% was retained by the culture. LDH leakage in PSED (determined in the aliquots of the same effluent) increased during 2hr exposure to 250μg/L As(III) and 500μg/L As(V). In contrast, the submerged 24hr old cultures of human keratinocytes (HK) revealed LDH release at 10μg/L As(V) after 2hr exposure. 3H-thymidine incorporation in PSED exposed to 10-1000μg/L As(V) revealed a biphasic response with an initial decrease (ca 50%) with subsequent stimulation (ca 2.5-fold) of the incorporation at 24hr exposure. Variability of 3H-uridine and 14C-leucine incorporation in short-term exposures was not statistically significant. Long-term exposure experiments are under way. (This research is funded by AWWA.)

1317 MONOMETHYLARSONOUS ACID (MMA^{III}) IS MORE TOXIC THAN ARSENITE IN CHANG HUMAN HEPATOCYTES.

J. S. Petrick[1], F. Ayala-Fierro[1], W. R. Cullen[2], D. E. Carter[1] and H. V. Aposhian[1]. [1]*The University of Arizona, Tucson, AZ and* [2]*The University of British Columbia, Vancouver, British Columbia, Canada.*

Methylation has been considered by many to be the primary detoxication pathway of inorganic arsenic. Inorganic arsenic is methylated by many, but not all animal species to monomethylarsonic acid (MMA^{V}), monomethylarsonous acid (MMA^{III}) and dimethylarsinic acid (DMA^{V}). Yet the relative toxicity of MMA^{III} has remained unknown. *In vitro* toxicities of arsenate, arsenite, MMA^{V}, MMA^{III} and DMA^{V} were determined in Chang human hepatocytes. Leakage of lactate dehydrogenase (LDH) and intracellular potassium (K^+) and mitochondrial metabolism of the tetrazolium salt XTT were used to assess cytotoxicity due to arsenic exposure. The mean LC_{50} based on LDH leakage in phosphate media was 6.0 μM for MMA^{III} and 68.0 μM for arsenite; for K^+ leakage in phosphate media, it was 6.3 μM for MMA^{III} and 19.8 μM for arsenite. The mean LC_{50} based on XTT metabolism in phosphate media was 13.6 μM for MMA^{III} and 164 μM for arsenite. LC_{50}'s were also determined in phosphate-free media. The results of the three cytotoxicity assays (LDH, K^+ and XTT) using phosphate media reveal the following order of toxicity in Chang human hepatocytes: MMA^{III}>Arsenite>Arsenate>MMA^{V}= DMA^{V}. The results demonstrate that MMA^{III} is a highly toxic intermediate in inorganic arsenic methylation and again raises the question as to whether methylation of inorganic arsenic is a detoxication process. (Supported in part by the NIEHS Superfund Basic Research Program Grant ES-04940 and NIEHS Center Grant ES-06694.)

1318 METHYLATED ARSENIC IN URINE AS A FUNCTION OF EXPOSURE TO INORGANIC ARSENIC IN DRINKING WATER.

D. Schreinemachers[1], E. E. Hudgens[1], X. C. Le[2], R. L. Calderon[1] and D. J. Thomas[3]. [1]*EPA, Chapel Hill, NC,* [2]*University of Alberta, Edmonton, Canada and* [3]*NHEERL, EPA, Research Triangle Park, NC.*

A salient feature of inorganic arsenic (iAs) metabolism is its conversion to monomethyl (MAs) and dimethylated (DMA) forms. Although methylation is often considered a means of detoxification of iAs, methylated arsenicals exert distinct adverse effects, including tumor initiation and promotion. Hence, methylation might also be regarded as a means of activation of iAs to more toxic forms. Here, we examined the profiles of iAs, MAs, DMA in urines collected from 96 individuals residing in Millard County, Utah, who used drinking water supplies that contained from 2 to 600 μg of iAs/L. The percentage of As in urine that was accounted for by MAs and DMA was stable for repeated urine samples collected on a single day and also stable across a five-day experimental period. A strong correlation between the concentration of iAs in the drinking water supplies used by participants and the concentration of MAs and DMA in urine suggested that in this population ingestion of iAs-containing drinking water was the major determinant of the amount of methylated As excreted in urine. The percentage of As in urine that was present as MAs or DMA ranged from 74 to 94 percent among study participants. The ratio of the concentration s of DMA to MAs in urine ranged from about 2 to 14 and was not strongly correlated with the concentration of all forms of As (iAs+MAs+DMA) in urine. Hence, factors other than the concentration of As in the drinking water supply or intake of As from drinking water likely determines the interindividual differences in the capacity for the methylation of iAs or for the retention of these arsenicals. These differences may be genetically determined or related to differences in other environmental factors that determine metabolic capacity. (This abstract does not necessarily reflect EPA policy.)

1319 POTENTIATION OF AGONIST-INDUCED PLATELET AGGREGATION BY ARSENIC.

M. Y. Lee, J. Y. Lee and J. H. Chung. *Seoul National University, Seoul, Republic of Korea.*

Chronic ingestions of arsenic by drinking water have been reported to induce cardiovascular disease such as blackfoot disease, atherosclerosis and hypertension, but the exact mechanism has not been elucidated yet. In order to investigate the possible causes of cardiovascular disease by arsenic, we examined the effects of arsenic on platelets which play an important role in development of cardiovascular disease. Sodium arsenite (iAsIII), trivalent inorganic arsenic, did not induce either aggregation or cytotoxicity to rat platelets directly, whereas iAsIII potentiated platelet aggregations induced by various

agonists, such as thrombin, collagen, ADP and arachidonic acid in concentration- and time-dependent manners. Thrombin-induced platelet aggregation was also enhanced by sodium arsenate (iAsV) or monomethylarsonic acid (MMA) in relatively higher concentrations compared to iAsIII. Treatment of iAsIII resulted in a dose-dependent increase of thrombin-induced serotonin secretion from platelets, while the formation of thromboxane A_2 from platelets did not altered significantly. Consistent with these findings, the *in vivo* studies revealed that ingestion of drinking water containing iAsIII in mouse elevated blood serotonin levels significantly, which is indicative of platelet aggregation *in vivo*. These results suggest that arsenic exposure makes platelets more susceptible to aggregatory stimulus and readily enhance the serotonin secretion from platelets and thus these effects by arsenic may contribute to the pathogenesis of cardiovascular disease.

1320 INDUCTION OF C-MYC PROTEIN BY ARSENITE IN PRECISION-CUT MOUSE KIDNEY SLICES.

C. Gudman and A. R. Parrish. *Texas A&M University System Health Science Center, College Station, TX.*

Arsenic [As] is a ubiquitous environmental contaminant with many adverse human health effects, including cancer, cardiovascular diseases and nephrotoxicity. Although the mechanism(s) underlying the acute toxicological response of the kidney to arsenite [As(III)] and arsenate [As(V)] has been elucidated over the past three decades, our understanding of the potential molecular effects of lower, non-cytotoxic levels of As remains sparse. Previous studies have shown that nanomolar levels of both As(III) and As(V) enhance c-myc gene expression in precision-cut rabbit renal cortical slices following 6 hr of exposure. In the current study, experiments were designed to further characterize the effect of As(III) on expression of c-myc. There is a well-established relationship between overexpression of c-myc and renal diseases, including cancer and polycystic kidney disease, suggesting that c-myc may be a critical mediator of the nephrotoxicity of As(III). Precision-cut kidney slices were prepared from male CD-1 mice and following a 1 hr pre-incubation, As(III) [0-5μM] was added for 6-24 hr. Nuclear extracts were prepared from kidney slices and c-myc protein expression was examined by Western blot analysis. Following 6 hr of exposure, 5μM As(III) enhanced c-myc protein expression, however, 8 hr of As(III) challenge resulted in a concentration-dependent increase in c-myc protein, with the peak effect observed at 1μM. Although c-myc protein levels were elevated in As(III)-challenged renal slices following 10 hr of exposure, by 12 hr no effect of As(III) on c-myc protein was seen. These data suggest that induction of c-myc protein may be a critical target of As(III) in the kidney.

1321 ALTERATIONS IN THE UBIQUITIN-DEPENDENT PROTEOLYTIC PATHWAY CAUSED BY LOW-LEVEL ARSENITE EXPOSURE IN RABBIT RENAL CORTICAL SLICES.

D. S. Kirkpatrick[1], J. M. Catania[1], F. M. Bautista[1], A. R. Parrish[2] and A. J. Gandolfi[1]. [1]*University of Arizona, Tucson, AZ and* [2]*Texas A & M University, College Station, TX.*

Our recent studies have shown low-level arsenite concentrations to affect several genes in the ubiquitin-dependent proteolytic pathway in rabbit renal cortical slices. Other studies suggest that disruption of ubiquitin-dependent protein degradation by arsenite may contribute to both its genotoxicity and carcinogenicity. While changes in the ubiquitin pathway following chemical and oxidative stresses are well documented, effects of low-level arsenite exposure on the ubiquitin-dependent proteolytic pathway remain unclear. Thus, cortical slices from the rabbit kidney were incubated in concentrations of As(III) between 100nM and 10μM. One hr prior to collecting slices for protein analysis, a peptide-aldehyde proteosome inhibitor (Z-Leu-Leu-Leu-al, 50μM) was introduced to allow the cellular accumulation of ubiquitin-tagged proteins for analysis. Slices were collected at timepoints 0, 4, 8 and 24 hr. Using an antibody recognizing ubiquitin in the free and conjugated forms, protein homogenates from control and As(III) treated kidney slices were analyzed by Western blot. Renal cortical slices exposed to As(III) in levels as low as 1μM show detectable decreases in the accumulation of ubiquitin-conjugated proteins in the cell at early timepoints. At the later time points, accumulation of ubiquitin-tagged proteins appears to be elevated in slices exposed to arsenic at all concentrations, possibly as a recovery mechanism that degrades proteins damaged by arsenite treatment. Ongoing studies seek to understand if alterations in ubiquitin-dependent proteolysis represent response to and recovery from subtoxic levels of arsenite, or a precursory response signaling the onset of toxicity. (NIH ES04946.)

1322 ARSINE TOXICITY IN THE PERFUSED RAT KIDNEY AND CORTICAL EPITHELIAL CELLS.

F. Ayala-Fierro, A. L. Baldwin, L. M. Wilson, J. E. Valeski and D. E. Carter. *University of Arizona, Tucson, AZ.*

Arsine (AsH_3) is the most toxic form of arsenic. It is used extensively in the semiconductor industry for epitaxial growth of gallium arsenide and as a dopant for silicon-based electronic devices. In these situations accidental exposure to AsH_3 may occur. Exposure to AsH_3 is fatal in 25% of the reported human cases, and usually results in acute oliguric renal failure. The mechanism of renal toxicity is unknown. This study investigated acute AsH_3 toxicity in the rat perfused kidney and in the renal cortical epithelial cells. The hypothesis was that early AsH_3 toxicity is caused by unchanged AsH_3, but at later time points, it requires the formation of hemolysate containing arsenite (AsIII) as a metabolite. Perfusion for 10 minutes with AsH_3, but not with the hemolysate, produced toxicity in the isolated kidney. The main AsH_3 target was the glomerular and peritubular microvasculature as determined by electron microscopy. AsH_3 toxicity in the cortical epithelial cells required 24 hours to appear. However, the AsH_3-produced hemolysate and the AsIII-spiked hemolysate produced toxicity in these cells as early as 1 hour. Toxicity in these cells was investigated by XTT bioreduction (mitochondrial marker), intracellular potassium (early toxicity) and LDH leakage (cell death). It was concluded that unchanged AsH_3 damages the renal microvessels at an early time compromising renal filtration. The extent of damage will determine the delay time for the symptoms to appear (2-24 hours). At a later time, the hemolysate products along with As(III), will further compromise renal function leading to oliguric renal failure. (Supported by NIEHS Grant ES06644, and Center Grant P30 ES06694.)

1323 INTERACTIONS OF DIMETHYLARSINIC ACID WITH RAT ERYTHROCYTES.

M. A. Peraza-Lopez and D. E. Carter. *University of Arizona, Tucson, AZ.*

Unlike other mammalian animal models, rats demonstrated significant accumulation of dimethylarsinic acid (DMA) in blood over time. However, the actual binding site of DMA in the rat erythrocyte is not clear. Our laboratory has shown that, in spectral studies of oxyhemoglobin (oxyHb), DMA did not bind oxyHb on the iron or the porphyrin ring of heme, nor to the globin chains in a manner that denatured the protein. In this study, it is hypothesized that hemoglobin reduced DMA(V) to DMA(III), which could bind hemoglobin at sulfhydryl groups on its globin chains. This investigation examined the binding of DMA with rat oxyHb in solution and the distribution and binding of DMA in the Sprague Dawley rat erythrocyte. Rat oxyHb solutions, dosed with DMA (1 to 10mM), were incubated for up to 60 minutes at 37°C. Free and bound DMA were separated by ultrafiltration, and DMA was measured by hydride generation atomic fluorescence spectroscopy. Little binding occurred (1-3% of the total DMA dose), and no significant changes in binding were observed with increasing dose or time. Uptake and cellular distribution of DMA were examined by exposing rat erythrocytes to 1 and 10mM DMA at 37°C for 30 minutes or 24 hours. DMA uptake was slow, with 30-40% of the dose taken up by 30 minutes, increasing to 40-65% by 24 hours. Most of the intracellular DMA was localized to the intracellular side of the membrane and bound to high molecular weight cytosolic proteins. The percent of the DMA dose found in these two cellular compartments significantly increased over time. Levels of glutathione (GSH) and glutathione disulfide (GSSG) were measured in erythrocytes dosed with DMA to determine if GSH was reducing DMA(V). GSH depletion was observed but was not accounted for by increases in GSSG, indicating the formation of another product of GSH oxidation. (Supported by NIH Grant ES06644, NIEHS Grant ES07091, and Center Grant P30 ES06694.)

1324 STUDY ON METABOLISM OF ARSENIC AND DNA DAMAGE IN THE PATIENTS WITH ACUTE ARSENIC POISONING.

H. Yamauchi. *St. Marianna University School Medicine, Kawasaki, Japan.* Sponsor: T. Yoshida.

The presentation is results of toxicology area concerning mass acute arsenic poisoning in Japan on 1998. The patients were 67 people and 32 men and 35 women. The age was from 1 to 67 years old. Four people died around half a day after intake of the arsenic trioxide. The curry was contaminating with the arsenic trioxide. The patients ate several items of the curry with the teaspoon. Arsenic trioxide intake dose in 63 patients was presumed to be 20-140mg. The mean of the urinary arsenic (inorganic arsenic; iAs + methylated arsenic; MA

+ dimethylated arsenic; DMA) levels after intake of the arsenic trioxide at 1, 10 and 30 days, 9029, 1148 and 160 μg As/g creatine, respectively. In the arsenic ratio in the urine after intake of the arsenic trioxide during a day, iAs 86%, MA 9% and DMA 3%, respectively. The concentration of arsenic in urine recovered at the level of normality two or three months later. The methylation capacity in the acute arsenic-poisoning patients was compared. The 2-nd methylation (MA to DMA) was observed in the age difference. The low age person of the methylation capacity was higher than the senior persons. On the other hand, the sex difference was not indicated. The DNA damage by the exposure of arsenic trioxide in the acute arsenic-poisoning patients was evaluated. DNA damage in the body was caused by arsenic trioxide intake, and 8-hydroxy-2-deoxyguanosine (8-HOdG) levels in urine increased remarkably. The determination of 8HOdG levels in urine was effective to the evaluation of DNA damage by the arsenic exposure.

1325 ROLE OF METALLOTHIONEIN IN ORGAN DISTRIBUTION AND EXCRETION OF CADMIUM COMPLEXES.

K. Slamka and G. Cherian. *University of Western Ontario, London, Ontario, Canada.*

The role of metallothionein (MT) in the distribution and excretion of cadmium (Cd) was studied in MT-I/II knockout (null) mice after a single i.p. injection of one of four different Cd-complexes: Cadmium chloride, Cd- cysteine (1:2), Cd- glutathione (1:2), and Cd-MT. Each of these compounds was injected (0.9mg/kg) to wild type (control) and knockout mice, and mice were killed after 24 hours. The amount of cadmium was measured in blood, liver, kidney, pancreas, spleen, heart, lung, stomach and intestine; and MT content determined by Cd-hem assay. There was no detectable MT in any organs of MT-null mice. The tissue distribution (%) of cadmium was similar between control and MT-null mice within each treatment group, although the concentration of cadmium was low in MT-null mice. There was a greater excretion of cadmium into the intestine of MT-null mice as compared to the control, suggesting an increased bilary excretion of cadmium. In mice injected with Cd-MT, most of the Cd was detected in the kidney (53-66%) while in all other treatment groups most of the cadmium was accumulated in the liver (46-62%). Injection of Cd-MT caused renal damage in both control and MT-null mice. The results suggest that the intracellular MT plays only a minor role in the initial organ distribution of Cd. However, in the absence of two major isoforms of MT, more cadmium is excreted into the intestine, and less Cd is retained in the body. (Supported by MRC, Canada.)

1326 EXPRESSION OF IMMEDIATE EARLY GENES IN CULTURED HUMAN PROXIMAL TUBULE CELLS AND THE DERIVED CELL LINE, HK-2, EXPOSED TO CADMIUM.

R. Dutta, V. L. Phillips, S. Somji, S. H. Garrett, J. H. Todd, M. A. Sens and D. A. Sens. *Department of Pathology, West Virginia University, Morgantown, WV.*

Many of the immediate early genes, such as c-fos, c-jun and c-myc, are induced in response to cellular stress. The expression of these three genes was assessed in cultures of human proximal tubule (HPT) cells and an immortalized human proximal tubule cell line, HK-2, exposed to lethal and sublethal concentrations of cadmium for durations of several hours to 16 days. HK-2 cells required lower levels of cadmium to elicit similar toxicities compared to HPT cells. It was determined that the expression of c-fos was induced at 1-2 hr and returned to near control levels by 24 hr. For c-jun the expression profile was similar; however, in the case of c-myc, there was no induction observed. The response in the HK-2 cell line was similar to that of the HPT cells except that induced c-fos and c-jun levels were attained with lower levels of cadmium. During long term cadmium exposure there was cell death in both culture systems without induction of any of these genes.

1327 CADMIUM-INDUCED ALTERATIONS IN CHRONICALLY EXPOSED HUMAN PROSTATE EPITHELIAL CELLS.

W. E. Achanzer, M. M. Webber and M. P. Waalkes. *NCI at NIEHS, Research Triangle Park, NC.*

Human prostate is a presumptive target of cadmium (Cd) carcinogenesis, although the mechanisms involved remain elusive. To define the molecular events associated with chronic Cd exposure in the prostate, the normal human prostate epithelial cell line RWPE-1 was continuously exposed to 10 μM Cd *in vitro* for 8 weeks and compared to passage-matched control cells. The Cd-treated prostate epithelial (CTPE) cells showed altered morphology, increased Cd resistance and decreased dependence on growth factors compared to controls. Specifically, the CTPE cells grew more efficiently in growth factor-free medium and, unlike control RWPE-1 cells, were unresponsive to epidermal growth factor (EGF). The latter is significant since EGF receptor levels also appear to be reduced in prostate tumors. In addition, CTPE cells showed a propensity to form foci of piled-up cells in culture, which is often seen with malignantly transformed cells. Data from cDNA array experiments indicated altered expression of a variety of genes in CTPE, including down-regulation of several pro-apoptotic genes, such as those coding for several caspases, as well as retinoic acid receptor γ and retinoid X receptor β. As predicted from the array data, CTPE cells were more resistant than RWPE-1 cells to the apoptosis inducer, etoposide (ETS). This resistance was accompanied by a decrease in caspase-3 enzymatic activity in ETS-treated CTPE cells compared to similarly treated RWPE-1 cells. CTPE cells also showed resistance to the growth inhibitory effects of all-trans retinoic acid. Retinoids are important regulators of prostate growth *in vivo* and are being investigated as chemopreventative and chemotherapeutic agents. In summary, chronic Cd exposure induces growth and gene expression alterations in human prostate epithelial cells indicative of transformation and loss of growth regulation that could be important in the development of prostate malignancies.

1328 EFFECT OF CADMIUM ON PANCREATIC PROTEASE ACTIVITIES IN MICE.

S. Hide[1], T. Funakoshi[2] and M. P. Waalkes[3]. [1]*Kumamoto University, Research Triangle Park, NC,* [2]*Kyushu University, Research Triangle Park, NC and* [3]*NCI at NIEHS, Research Triangle Park, NC.*

The pancreatic effects of cadmium (Cd) in mice were studied. A single sc injection of 1 mg Cd/kg had no obvious toxic effects on the liver, kidney, and pancreas at both 1 and 5 days after Cd treatment. However, within the pancreas the activities of trypsin, chymotrypsin, and carboxypeptidase A were significantly decreased at 1 day after Cd treatment, while the activity of carboxypeptidase B was not changed. The concentrations of Cd in the pancreas were very similar at 1 and 5 days after Cd treatment, indicating a stable deposition of the metal. Metallothionein levels in the pancreas were increased but only at 5 days after Cd treatment. In order to more fully examine the inhibitory effects of Cd on these protease activities in the pancreas, the direct effects of Cd on purified proteases were also studied *in vitro*. Contrary to the results *in vivo*, Cd increased the activity of purified trypsin in a concentration-dependent manner. Consistent with the *in vivo* results, the activity of purified carboxypeptidase A was decreased by *in vitro* Cd treatment in a concentration-dependent fashion. The activities of chymotrypsin and carboxypeptidase B did not change with *in vitro* Cd exposure. The enhanced activity of trypsin by Cd was returned to the control levels by subsequent treatment with EDTA, indicating that this effect was reversible. In addition, the zinc normally contained in purified carboxypeptidase A and carboxypeptidase B was released by the Cd exposure. These results indicate that Cd inhibits protease activities within the pancreas *in vivo* at doses which do not induce overt hepatic, renal, or pancreatic toxicity. Based on additional *in vitro* study, the decreases seen in trypsin and chymotrypsin activities might be due to indirect effects of Cd while the decreases in carboxypeptidase A activity are probably due to a direct inhibition of the enzyme by the metal.

1329 CADMIUM-INDUCED HEPATOTOXICITY IN TUMOR NECROSIS FACTOR-α KNOCKOUT MICE.

E. B. Harstad and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

Cadmium (Cd) is an environmental pollutant that causes hepatotoxicity. Recent reports indicate that Kupffer cells, the resident macrophages of the liver, participate in the manifestation of chemical-induced hepatotoxicity. Tumor necrosis factor-alpha (TNF) is a proinflammatory cytokine that is a major product of Kupffer cells and mediates the hepatotoxic effects of bacterial endotoxin (LPS). LPS, in combination with d-galactosamine (LPS/Gln), causes severe hepatic necrosis and apoptosis. Mice deficient in TNF have been shown to be less sensitive to the hepatotoxic effects of several hepatotoxicants, including carbon tetrachloride and acetaminophen and resistant to LPS and LPS/Gln. It has been speculated that cadmium also may exert its hepatotoxicity, in part, via the production of TNF by the Kupffer cells. Therefore, this study was undertaken to determine whether mice deficient in TNF are resistant to Cd-induced hepatotoxicity. TNF knockout (TNF-KO) and wildtype (TNF-WT) mice were dosed ip with saline, LPS (0.1 mg/kg)/Gln (700 mg/kg), or CdCl2 (2.2, 2.8, 3.4, 3.9, and 4.5 mg Cd/kg). Serum alanine aminotransferase (ALT) and sorbitol dehydrogenase (SDH)

activities were quantified to assess liver injury. Caspase-3 activity was quantified to assess hepatocellular apoptosis. LPS/Gln-treatment increased ALT (17 fold) and SDH (21 fold) in TNF-WT mice. In contrast, LPS/Gln-treatment did not significantly increase ALT or SDH in TNF-KO mice. LPS/Gln-treatment caused a 7.8-fold increase in caspase-3 activity in TNF-WT mice, but did not increase caspase-3 in TNF-KO mice. Cd caused a dose-dependent increase in liver injury in both TNF-WT and TNF-KO mice. However, the liver injury produced by Cd in the TNF-KO mice was not different from that in TNF-WT at any dose. No significant increase in caspase-3 activity was detected in any of the Cd- treated mice. These data indicate that, in contrast to LPS/Gln-induced hepatotoxicity, TNF does not appear to mediate Cd-induced hepatotoxicity. (Supported by NIH grants ES-01142 and ES-07079.)

1330 THE MECHANISM OF GLYCINE PROTECTION AGAINST CADMIUM-INDUCED CYTOTOXICITY IN LLC-PK_1 CELLS.

Z. A. Shaikh and W. Tang. *Department of Biomedical Sciences, College of Pharmacy, University of Rhode Island, Kingston, RI.*

We have reported previously that glycine protects against chronic cadmium (Cd)-induced nephrotoxicity *in vivo*. The purpose of the present study was to examine the mechanism of glycine protection. Confluent monolayers of LLC-PK_1 cells were treated with 30 μM $CdCl_2$ in DME medium, with or without pretreatment with 10-100 mM glycine for 16 hr, and/or cotreatment with glycine. Treatment with Cd alone was toxic and caused 56% LDH leakage over 24 hr. Pretreatment and cotreatment with 10 mM glycine offered no protection, however, 25, 50, and 100 mM glycine decreased LDH leakage to 26, 22, and 23%, respectively. Pretreatment or cotreatment with 50 mM glycine also reduced LDH leakage to 28 and 25%, respectively. The cells accumulated 0.55 μg Cd/mg protein after incubation with 30 μM Cd for 4 hr. Pretreatment, cotreatment, or a combination at 50 mM glycine decreased Cd accumulation by 25, 51, and 63%, respectively. This suggested that glycine protected against Cd cytotoxicity by reducing Cd accumulation. The reduction in Cd accumulation could be due to either reduced uptake because of complex formation between glycine and Cd or increased efflux in the presence of glycine. The complex formation was examined by incubating 50 mM glycine with 30 μM Cd in Tris-HCl buffer (pH 8.4) at room temperature for 20 min and chromatography on a Sephadex G-10 column. Cd formed a stable complex with glycine as all of the Cd co-eluted with glycine. To examine the effect of pretreatment with 50 mM glycine on the efflux of Cd, the cells were exposed to 30 μM radiolabeled Cd for 30 min followed by incubation in Hank's buffered salt solution containing 30 μM non-radiolabeled Cd. Glycine pretreatment increased the efflux of Cd. As compared to the non-pretreated cells, 17% more Cd was released into the medium by glycine pretreatment in 5 min. Thus, glycine appears to protect against Cd-induced cytotoxicity in LLC-PK_1 cells not only by reducing Cd uptake but also by increasing its efflux. (Supported by PHS grant # ES 03187.)

1331 MITOCHONDRIAL DAMAGE UPON CADMIUM-METALLOTHIONEIN ADMINISTRATION IS CAUSED BY CD^{++}.

W. Tang and Z. A. Shaikh. *Department of Biomedical Sciences, College of Pharmacy, University of Rhode Island, Kingston, RI.*

Acute cadmium-metallothionein (CdMT) injection causes renal proximal tubular damage and mitochondria are considered the earliest target. The purpose of the present study was to examine whether the mitochondrial damage *in vivo* was due to Cd^{++} released upon CdMT degradation. Sprague-Dawley rats were injected ip with 0.3 μmol Cd as CdMT/kg. Urine was collected at 4°C and the animals were sacrificed after 8 and 12 hr. Mitochondria were isolated from renal cortex and respiratory function was measured. Urinary protein, a marker of renal function, increased 2.5- and 11.4-fold after 8 and 12 hr of CdMT injection, respectively. Similarly, urinary LDH, a marker of cytotoxicity, increased 2- and 29-fold. At these time points, mitochondrial respiratory control ratio decreased 16.5 and 51%. State 3 oxygen consumption rate also decreased by 23 and 52% suggesting that Cd inhibited mitochondrial electron transfer. As compared to the controls, the P/O ratio decreased 8 and 24% indicating that mitochondrial oxidative phosphorylation was uncoupled. In a parallel study, mitochondria were isolated from untreated Sprague-Dawley rats and incubated with 0.1-2 μM $CdCl_2$ for 1 min. Cd treatment caused a dose-dependent decrease in respiratory control ratio, state 3 oxygen consumption, and an increase in state 4 oxygen consumption. Treatment with 2 μM Cd decreased the respiratory control ratio by 67% and state 3 oxygen consumption by 25%, suggesting that mitochondrial respiratory function and electron transfer were inhibited. In comparison, state 4 oxygen consumption rate was 129% of controls, indicating that mitochondrial oxidative phosphorylation was uncoupled. The similarity of the mitochondrial damage caused by CdMT administration *in vivo* and $CdCl_2$ treatment *in vitro* suggests that it is the Cd^{++} liberated from CdMT degradation that is responsible for the renal toxicity. (Supported by PHS grant # ES03187.)

1332 CADMIUM (CD)-INDUCED ACUTE HEPATIC INJURY IS EXACERBATED IN HUMAN INTERLEUKIN-8 TRANSGENIC MICE (HIL-8TG).

H. Horiguchi[1], A. Harada[2], E. Oguma[3], M. Sato[4], Y. Homma[3], F. Kayama[1], M. Fukushima[3] and K. Matsushima[5]. [1]*Jichi Medical School and CREST, Tochigi, Japan.* [2]*Kanazawa University, Kanazawa, Japan.* [3]*Fukushima Medical University, Fukushima, Japan,* [4]*Tokushima Bunri University, Tokushima, Japan and* [5]*Tokyo University and CREST, Tokyo, Japan.*

It is generally accepted that severe hepatocellular necrosis along with infiltration of neutrophils occurs after acute Cd exposure. In order to investigate the role of neutrophils in Cd-induced liver injury, we first prepared hIL-8Tg which overexpressed IL-8 and displayed an inability of neutrophil migration due to the lack of chemotactic gradient and the downregulation of L-selectin on the surface, and then examined Cd-induced hepatotoxic effects in these mice. A significantly lower survival rate was observed in hIL-8Tg compared with wild-type mice after subcutaneous administration of Cd. Evident liver injury characterized by abrupt increases in plasma GOT and GPT levels was found in hIL-8Tg at 18 hours after Cd administration. Histological examinations including H-E staining and esterase staining revealed the infiltration of numerous neutrophils into the damaged liver tissues in wild-type mice, and the inhibition of the neutrophil migration into the liver as well as enhanced hepatocellular necrosis in hIL-8Tg. Peripheral white blood cell and polymorphonuclear cell counts increased in wild-type mice, whereas the increase in those blood leukocyte counts was delayed in hIL-8Tg. There was no significant difference in the amounts of Cd accumulated in liver and kidneys between wild-type mice and hIL-8Tg. Metallothionein expression was not suppressed in the liver of hIL-8Tg, although the initial synthesis was a little delayed. In conclusion, an acute Cd hepatotoxic effect was exacerbated in hIL-8Tg, suggesting that neutrophils play a protective role in an acute Cd-induced liver injury.

1333 DIETARY EXPOSURES OF CADMIUM IN THE UNITED STATES.

S. Tao and P. M. Bolger. *FDA, Washington, DC.*

The Total Dietary Study (TDS), FDA's yearly market basket program, monitors levels of toxic chemical contaminants and nutrients in the U.S. food supply. It provides information on trends in concentrations in the food supply and dietary exposures for the general population. Retail food samples are collected 4 times a year, once each from 4 geographic areas of the U.S., and are analyzed either after preparation/cooking or as ready-to-eat. The latest TDS (1991-1997, 18 baskets) data show that mean cadmium concentrations range from below detection (≤0.002 ppm) to 0.125 ppm, with very low levels detected in most foods. Only 15% of the 264 foods/mixed dishes had a cadmium concentration ≥ 0.02, and 21% between 0.01 and 0.02 ppm. The highest concentrations (0.05 to 0.125 ppm) are found in leafy vegetables, liver, peanuts, and grain cereals. Based on the United States Department of Agriculture's 1987-1988 Nationwide Food Consumption Survey, the estimated daily cadmium average intakes are (μg/day):6-11 month-old, 1.3; 2 year-old, 4.8; 6 year-old, 7.5; 10 year-old, 8.6; 14-16 year-old boys, 10.6; 14-16 year-old girls, 8.3; 25-30 year-old men, 11.2; 25-30 year-old women, 8.7; 40-45 year-old men, 12.2; 40-45 year-old women, 8.9; 60-65 year-old men, 11.5; 60-65 year-old women, 8.9; 70+ year-old men, 10.8; and 70+ year-old women, 8.1. Major sources of cadmium exposure are vegetables, especially lettuce, spinach and potatoes, and grain products. The estimated average cadmium exposures over this period have remained low and are well within the World Health Organization's provisional tolerable weekly intake of 7 μg/kg body weight/week for cadmium.

1334 HIGHLY SENSITIVE MINIATURIZED ASSAY FOR CADMIUM IN BLOOD OR URINE.

M. H. Bhattacharyya and E. A. Cerny. *Argonne National Laboratory, Argonne, IL.*

Cadmium is a toxic metal with widespread use in batteries, pigments for plastics and paints, and as coatings on metal products. Cadmium workers are

monitored for elevated cadmium levels in blood and/or urine to ensure that they are not receiving excessive doses. In some areas where mining or smelting is carried out, food, water and air may contain elevated levels of cadmium that is unknowingly ingested or inhaled by the human population. A highly sensitive assay (detection limit=0.02μg/L) for blood/urine cadmium has been published (Peterson et al., Anal. Biochem., **192**, 434-40, 1991). Its main drawback is the relatively large amount of blood needed, up to 8mL. We report here a miniaturized version that uses only 1mL. Blood is deproteinated directly with hydrochloric acid (HCl), converting cadmium to the anionic hexachloride form, which immediately binds to AG1-X8 anion-exchange resin. Use of 15mg resin in a centrifugeable column greatly simplifies eluate collection. Other blood ions are washed out with a small HCl volume. Conversion from the anionic cadmium hexachloride to the cationic cadmium nitrate is begun by a 1N HNO_3 wash. The final sample treatment step involves extraction of resin-bound cadmium into 100μL of 1N HNO_3 with 70% cadmium recovery, affording a 7-fold concentration of the sample cadmium. Cadmium in the final acid extract is quantitated by graphite furnace atomic absorption spectrophotometry. This miniaturized assay is simplified, retains the high sensitivity of the original assay, and, with its small sample volume (1mL), can be applied to pediatric studies. (Work supported by NIEHS grant ES04816.)

1335 CADMIUM-INDUCED LUNG INJURY: EVIDENCE FOR A SPECIFIC INCREASE IN THE PERMEABILITY OF E CADHERIN AND VE-CADHERIN DEPENDENT CELL-CELL JUNCTIONS.

C. A. Pearson, P. C. Lamar, R. J. Niewenhuis and W. C. Prozialeck. *Midwestern University, Downers Grove, IL.*

Although it is well-known that respiratory exposure to Cd^{2+} results in pulmonary edema, the specific mechanisms underlying this effect have yet to be elucidated. Studies from our laboratory have shown that Cd^{2+} can disrupt the tight junctions between epithelial cells in culture by interfering with the normal function of the Ca^{2+}-dependent cell adhesion molecule E-cadherin. The objective of the present study was to determine if the early pneumotoxic effects of Cd^{2+} might result from specific changes in the permeability of E- and VE-cadherin-dependent cell-cell junctions in the lung. Male CF1 mice were given either saline or $CdCl_2$ (65 nmoles) via intratracheal instillation. After 24 hours, the animals were euthanized, and the lungs were removed and either subjected to bronchoalveolar lavage or analyzed for histopathologic changes. The results showed that Cd^{2+} caused an increase in lung weight and in the protein content of the lavage fluid. The microscopic analyses showed evidence of edema and capillary congestion but little evidence of injury to the alveolar epithelial cells or the capillary endothelial cells. In addition, the samples from the Cd^{2+}-treated mice showed a decrease in the amount of E-cadherin in the epithelial cells of the alveoli and small bronchioles and of VE-cadherin in vascular endothelial cells. These findings suggest that Cd^{2+}-induced pulmonary edema may be a consequence of relatively specific increases in the permeability of the cadherin-dependent cell-cell junctions in the alveolar epithelium and the vascular endothelium. (Supported by Grant #R01 ES06478 from the NIEHS.)

1336 CADMIUM DISRUPTS VE-CADHERIN-DEPENDENT CELL-CELL JUNCTIONS IN HUMAN UMBILICAL VEIN ENDOTHELIAL CELLS.

P. C. Lamar, C. A. Pearson and W. C. Prozialeck. *Midwestern University, Downers Grove, IL.*

Many of the acute toxic effects of cadmium (Cd^{2+}) *in vivo* seem to involve an increase in microvascular permeability. However, the mechanisms by which Cd^{2+} increases endothelial permeability are not well understood. The recent finding that Cd^{2+} can selectively damage cadherin-dependent cell-cell junctions in many types of epithelial cells lead us to examine the effects of $Cd2^{2+}$ on the vascular endothelial (VE)-cadherin-dependent cell-cell junctions in human umbilical vein endothelial cells (HUVEC's). Primary cultures of HUVEC's were grown to confluence on glass coverslips and then exposed to Cd^{2+} (0-180 microM in serum-free medium) for up to 24 hours. The results showed that exposure to Cd^{2+} for 2-8 hours caused the cells to separate from each other without detaching from the growing surface. This effect coincided with the loss of vascular endothelial (VE) cadherin from the cell borders, the reorganization of the actin cytoskeleton, and the appearance of the gaps between the cells. Additional results showed that the cells were still viable and were not in metabolic distress at the time in which these changes were occurring. These results are similar in many respects to those we have recently observed in several other types of epithelial cells, and they suggest that VE-cadherin-dependent intercellular junctions may be specific targets for Cd^{2+} toxicity in endothelial cells. (Supported by Grant # R01 ES06478 from the NIEHS.)

1337 CADMIUM DISRUPTS CADHERIN-DEPENDENT CELL-CELL JUNCTIONS IN ROS 17/28 CELLS.

W. C. Prozialeck, P. C. Lamar and C. A. Pearson. *Midwestern University, Downers Grove, IL.*

While the osteotoxic effects of Cd^{2+} have long been recognized, the mechanisms by which Cd^{2+} affects bone are not well-understood. Recent studies from our laboratory have shown that Cd^{2+} can selectively damage the E-cadherin-dependent junctions between many types of epithelial cells in culture. At the same time, studies from other laboratories have shown that E-cadherin and related cadherins are present in osteoblast-like cells and play a key role in the differentiation of the cells into their epithelial phenotype. The objective of the present study was to determine if $Cd2^{2+}$ could disrupt cadherin-dependent cell-cell junctions in the rat osteoblast-like cell line, ROS 17/28. The cells were grown to confluence on glass coverslips in DMEM and then exposed to 0-20 microM Cd^{2+} in a physiological saline solution. The integrity of cell-cell junctions was assessed morphologically, and cadherin-like cell adhesion molecules were visualized by immunofluorescence using a pan-cadherin primary antibody. Exposure to Cd^{2+} for 2-4 hours caused the cells to separate and retract from each other without detaching from the growing surface. This effect coincided with the loss of pan-cadherin immunoreactive material from the cell borders and a reorganization of the actin cytoskeleton, but occurred well before the cells showed evidence of serious injury or the loss of membrane integrity. These results indicate that Cd^{2+} can disrupt the cadherin-dependent cell-cell junctions in ROS 17/28 cells, raising the possibility that some of the osteotoxic effects of Cd^{2+} might result from the disruption of cadherin dependent cell-cell junctions in bone. (Supported by Grant RO1 ES06478 from the NIEHS.)

1338 CADMIUM CHLORIDE ($CdCl_2$) INDUCES REGIONAL EXPRESSION OF HEAT SHOCK PROTEIN-72 (hsp72) IN RAT LIVER.

P. L. Goering[1], R. R. Dugvala[1], B. R. Fisher[2] and R. J. Marler[2]. [1]*Center for Devices and Radiological Health, FDA, Rockville, MD and* [2]*Covance Laboratories, Vienna, VA.*

Many proteotoxic agents enhance the expression of hsps, a response that may constitute a cellular defense mechanism. $CdCl_2$ is a well-known hepatotoxicant after acute exposure and produces a general necrotic response across the liver acinus. We have shown previously that, in response to acute $CdCl_2$ exposure, the *de novo* synthesis of hsp72 (an inducible member of the hsp70 family) is induced in rat liver prior to detection of hepatic injury using classical functional and clinical indices. The objective of this study was to determine the cell-specific localization of hsp72 within the liver acinus in response to $CdCl_2$. Male SD rats were injected with $CdCl_2$ (0.5, 1, and 2 mg Cd/kg, iv), and livers were removed at 4, 8, 16, and 24 hr after injection. Tissue sections were fixed and prepared for histopathological and immunohistochemical analyses. No treatment-related histopathological changes were observed. A monoclonal antibody specific to hsp72 was used for immunohistochemical analyses. No immunostaining signal specific for hsp72 was observed in untreated controls. In rats receiving 2 mg Cd/kg, no signal was observed after 4 hr; however, a low-intensity signal was first detected after 8 hr. At 16 after exposure, no signal was observed in rats injected with 0.5 mg Cd/kg, but a low-intensity signal was detected at the 1 mg/kg dose. The most intense hsp72 signal was observed 16 hr after exposure to 2 mg Cd/kg. Hsp72 accumulation was predominantly localized in the cytoplasm of centrolobular hepatocytes, primarily around venules. At 24 hr after exposure, the hsp72-specific signal was less intense. These results demonstrated that hsp72 expression in response to acute Cd exposure occurs in hepatocytes located in centrolobular areas and adjacent to larger intrahepatic venules prior to the onset of overt cytotoxicity.

1339 SUPPRESSION OF A HIGH-AFFINITY MANGANESE TRANSPORT PATHWAY IN CADMIUM-RESISTANT METALLOTHIONEIN NULL FIBROBLASTS.

S. Himeno[1], T. Yanagiya[2], S. Enomoto[3], Y. Kondo[4] and N. Imura[1]. [1]*Kitasato University, Tokyo, Japan,* [2]*Kitasato University, RIKEN, Tokyo, Saitama, Japan,* [3]*RIKEN, Saitama, Japan and* [4]*Nippon Medical School, Tokyo, Japan.*

We have established a Cd-resistant cell line (Cd-rB5) from immortalized metallothionein null fibroblasts, and found that Cd-rB5 cells exhibited a marked decrease in cadmium (Cd) uptake. This cell line may be useful in elucidating the mechanism of Cd transport in mammalian cells. A multitracer technique developed at RIKEN, Japan, was applied to examine whether the incorporation of other metals than Cd was also altered in Cd-rB5 cells. Among 20 elements added to the medium, incorporation of Mn(II) into Cd-rB5 cells was approximately 10% of that of parental cells. However, the reduced uptake of Mn(II) in Cd-rB5 cells was observed only at low manganese concentration, suggesting that a high-affinity component of manganese transport system is suppressed in Cd-rB5 cells. Competition experiments revealed that Mn(II) inhibited Cd(II) uptake competitively with an apparent Ki of 140 nM in parental cells, but not in Cd-rB5 cells. The mutual inhibition of the uptake of Cd(II) and Mn(II) was also observed in other mammalian cells such as HeLa, PC12 and Caco-2 cells. The optimal pH for the uptake of both Cd(II) and Mn(II) was 7.4, suggesting the existence of a novel transporter for these metals distinct from already reported divalent metal transporter (DMT1) having an optimal pH at 5.5. These results demonstrate that Cd(II) utilizes a high-affinity Mn(II) transport pathway for the entry into mammalian cells, and that the suppression of this pathway resulted in a reduced accumulation of Cd in Cd-rB5 cells.

1340 INTERLEUKIN-6 AS A CO-STIMULATOR FOR METALLOTHIONEIN INDUCTION BY CADMIUM.

A. O. Molotkov, M. Satoh and C. Tohyama. *National Institute for Environmental Studies, Tsukuba, Japan.*

Some cytokines as well as metals have capability of inducing metallothionein (MT) in various tissues. Previously we found that IL-6 played a pivotal role in the induction of MT in the remaining liver after partial hepatectomy. Using IL-6 GKO mice we have studied the possible association of IL-6 in induction of MT by Cd. Cd was injected sc at a dose of 0.5, 1.0 or 2.0 mg/kg, 2 times with a 24 h interval. At 24 h after the last injection, liver and blood were collected. Tissue MT and serum IL-6 were determined by using MT RIA and ELISA, respectively. Liver damage was estimated by GPT and GOT activities. We found that Cd induced MT in the liver and kidney in both IL-6 GKO and B6J129Sv (wild-type control) mice. Nevertheless, Cd treatment at dose of 2.0 mg/kg resulted in 1.8 and 1.4 times larger amounts of liver and kidney MT levels, respectively, in B6J129Sv mice compared to IL-6 GKO mice. Cd treatment at doses of 1.0 and 2.0 mg/kg tended to increase serum IL-6 level in the wild-type mice. GOT and GPT activities were increased in the serum of both strains of mice treated at 2.0 mg Cd/kg. We speculate that an increase in serum IL-6 level acts as a co-stimulator for the induction of MT in the liver and kidney in B6J129Sv mice. (This work was supported in part by STA Fellowship to A. Molotkov.)

1341 CHRONIC CADMIUM TOXICOSIS IN PRIMATES: RENAL TUBULAR ATROPHY AND OSTEOMALACIC OSTEOPENIA INDUCED IN OVARIECTOMIZED CYNOMOLGUS MONKEYS.

Y. Kurata[1], T. Doi[1], T. Kawasuso[1], O. Katsuta[1], H. Hiratsuka[1], M. Tsuchitani[1] and T. Umemura[2]. [1]*Mitsubishi Chemical Safety Institute Ltd., Kashima, Japan and* [2]*Hokkaido Univ., Sapporo, Japan.*

To develop an experimental model of chronic cadmium toxicosis in primates, repeated intravenous injections (2 - 3 times per week for 13 - 15 months) of 0 (n=4), 1.0 (3), and 2.5 mg/kg (2) cadmium chloride (Cd) was performed in ovariectomized cynomolgus monkeys. Cd treatment induced normocytic-normochromic anemia, and distinctive kidney and bone lesions. In regard to the kidney, histopathological examination revealed interstitial fibrosis, dilatation and degeneration of tubules, and atrophy of tubular epithelium in the renal cortex. The renal tubular dysfunction appeared to be produced from the early stage of the treatment period (4 or 5th month and later) as indicated by increases of urinary enzyme activities such as ALP, gamma-GT, LAP, LDH, and NAG. In regard to the bone, mineral densities (by DXA method) of the lumbar vertebrae and femur showed 26 - 27 or 20 - 22% decrease. Histomorphometrically, the osteoid volume against the bone volume of the lumbar vertebrae and femur cortex were 12 - 15 or 5 - 12 times higher than those of the control specimens. Moreover, decreases in bone volume of the trabeculae in the lumbar vertebrae, femur, and sternum were also obvious. A significant decrease in the plasma inorganic phosphorus level was almost simultaneous with leakages of tubular marker enzymes in urine. Moreover, a decrease in the plasma calcium level and an increase in the urine deoxypyridinoline level appeared later. In conclusion, chronic cadmium toxicosis is reproducible in primates by repeated intravenous injections of Cd following ovariectomy, and is characterized by renal anemia, tubular atrophy with interstitial fibrosis in the renal cortex, and osteomalacic osteopenia, which closely resemble human itai-itai disease.

1342 THE DEVELOPMENT OF THE CADMIUM DIETARY EXPOSURE MODEL (CDEM).

G. L. Diamond[1], W. C. Thayer[1], H. Choudhury[2], T. F. Lockwood[1], W. M. Stiteler[1], P. E. Goodrum[1] and J. M. Hassett[3]. [1]*Syracuse Research Corporation, North Syracuse, NY,* [2]*National Center for Environmental Assessment, USEPA, Cincinnati, OH and* [3]*State University of New York College of Environmental Science and Forestry, Syracuse, NY.*

The Cadmium Dietary Exposure Model (CDEM), utilizes national survey data on food cadmium concentrations and food consumption patterns to estimate dietary intakes in the U.S. population. The CDEM has been linked to a modification of the cadmium biokinetic model of Kjellström and Nordberg (KNM) to derive estimates of kidney and urinary cadmium that reflect U.S. dietary cadmium intake and related variability. Variability in dietary cadmium intake was propagated through the KNM using a Monte Carlo approach. The model predicts a mean peak kidney cadmium burden of approximately 3.5 mg and a 5th-95th percentile range of 2.2-5.1 mg in males. The corresponding peak renal cortex cadmium concentration in males is 15 (10-22, 5th-95th %) mg/g wet cortex. Predicted kidney cadmium levels in females were higher than males: 5.1 (3.3-7.6) mg total kidney; 29 (19-43) mg/g wet cortex. Predicted urinary cadmium in males and females agreed with empirical estimates based on the NHANES III, with females predicted and observed to excrete approximately twice the amount of cadmium in urine than males. The predicted 95th percentile values for peak kidney cadmium burden are approximately 60% of the peak kidney burden predicted for a chronic intake at the U.S. EPA Reference Dose of 1 mg/kg-day (8.2 mg). (Supported in part by EPA Cooperative Agreement CR822761 and EPA Contract 68-C6-0024. Statements in this report do not reflect opinions or policies of the U.S.EPA.)

1343 CONTRASTING ROLE OF NA+ IONS IN MODULATING CU+2 VERSUS CD+2 INDUCED HEPATOCYTE TOXICITY.

J. Pourahmad and P. J. O'Brien. *University of Toronto, Toronto, Ontario, Canada.* Sponsor: D. M. Templeton.

Cu^{+2} induced hepatocyte cytotoxicity involved membrane lipid peroxidation and "ROS" formation and was prevented by antioxidants. No increase in cellular Na^+ was observed although cytotoxicity was markedly enhanced by Na^+ omission from the media. Omission of Na^+ from the incubation medium however greatly increased Ca^{+2} accumulation in Cu^{+2} treated hepatocytes. This was partially reverted upon transferring the cells to a Na^+ containing medium Removing media Ca^{+2} with EGTA also prevented Cu^{+2} induced hepatocyte cytotoxicity. This suggests that a Na^+-dependent Ca^{+2} transporter is involved in controlling excessive accumulation of Ca^{+2} caused by the Cu^{+2} induced membrane lipid peroxidation. On the otherhand Cd^{+2} induced hepatocyte cytotoxicity involved mitochondrial toxicity and ATP depletion but not lipid peroxidation. Omission of Na^+ or Cl^- from the medium ameliorated Cd^{+2} induced hepatocyte toxicity. Furthermore the Na^+/H^+ exchange inhibitor amiloride or the Cl^- channel blocker glycine also prevented Cd^{+2} induced hepatocyte toxicity. Cd^{+2} but not Cu^{+2} treated hepatocytes were also much more suseptible to a hypotonic media. This suggests that Cd^{+2} cytotoxicity could be attributed to disruption of cell volume regulation mechanisms. The increased osmotic load caused by uncontrolled accumulation of intracellular Na^+ likely resulted from the activation of Na^+/H^+ exchanger and the Na^+/HCO_3^- cotransporter by acidosis caused by the ATP depletion induced by Cd^{+2}.

1344 PROTECTIVE EFFECTS OF ZINC ON RAT HEPATIC STELLATE CELLS TO CADMIUM.

M. C. Escobar, M. C. Gutiérrez-Ruiz, L. Bucio, E. Hernández-Pérez and V. Souza. *Universidad Autónoma Metropolitana-Iztapalapa, México, D.F. Mexico.*

Zinc (Zn) is an essential trace element that protects against hepatotoxicity produced by a variety of chemicals, among them Cadmium (Cd). The mechanism of Zn protection has been attributed to the following: 1-stabilization of lysosomal, mitochondrial and microsomal membranes; 2-inhibition of P-450-dependent mono-oxygenase activity; 3-stabilization of cellular thiol and activation of glutathione-associated enzymes and 4-sequestration of reactive moieties, free radicals and Cd by the Zn-induced metallothionein. The aim of the present study was to evaluate the protective effect of Zn on Cd toxicity in a rat hepatic stellate cell line (CFSC-2G). Cells were pretreated during 24 h with 60μM $ZnCl_2$, and then 3 or 5 μM $CdCl_2$ were added for another 24 h. MTT assay showed that mitochondrial function diminished 15 and 30% with 3 and 5 μM respectively, and this damage was reversed with Zn pretreatment. Lipid peroxidation damage increased approximately 103% with both Cd concentrations. This effect was not observe in Zn pretreated cells. Catalase activity was inhibited 21% in Cd-treated cells. Zn-pretreated cells presented catalase activity values similar to the control ones. Glutathione (GSH) content was diminished in 33% and 42.8% with 3 and 5 μM $CdCl_2$ respectively while no change, compared to control cells, was observed in Zn-pretreated hepatic stellate cells. No change in glutathione reductase activity was observed in any treatment. Metallothionein-I (MT) induction was determined. MT-I mRNA was presented in all treatments. However, Cd treated cells presented higher MT-I mRNA content than Zn pretreated cells. In conclusion, the present study suggests that Zn reduces Cd toxicity in rat hepatic stellate cells by controlling lipid peroxidative damage and GSH levels rather than by inducing MT-I.

1345 EFFECTS OF CADMIUM ON THE EXPRESSION OF CYCLIN D1 AND CYCLIN DEPENDENT KINASE (CDK4), TUMOR SUPPRESSOR GENES P27 AND P53, AND ONCOGENE C-MYC IN *IN VITRO* TWO STAGE TRANSFORMATION PROCESS.

M. Z. Fang and M. H. Cho. *Laboratory of Toxicology, College of Veterinary Medicine, Seoul National University, Suwon, Republic of Korea.*

In vitro two stage transformation of BALB/3T3 cells is a well-known neoplastic process similarly with *in vivo* two stage carcinogenesis process. To determine the effects of cadmium in *in vitro* two stage transformation and elucidate cellular/molecular mechanisms of two stage transformation, we transformed BALB/3T3 mouse embryo cells with MNNG as a initiator and $CdCl_2$ as a promoter at high transformation frequency, and detected the alterations of the protein and/or mRNA expression levels of cyclin D1, cyclin dependent kinase 4 (CDK4), PCNA, tumor suppressor gene p27 and p53, and oncogene c-myc. Whole cell protein and total RNA were extracted from Control, MNNG, and MNNG+$CdCl_2$ (forming morphologic transformation focus at high frequency). Western blot analysis revealed that: [1] the expression levels of cyclin D1, CDK4, and PCNA were higher in MNNG+$CdCl_2$ group than in the other two groups.; [2] wild-type p53 protein was strongly expressed in MNNG group, but not expressed in MNNG+$CdCl_2$ group; [3] In MNNG+$CdCl_2$ group, the expression level of p27 was reduced significantly compared to Control and MNNG groups; [4] c-myc protein was highly expressed in MNNG+$CdCl_2$ group among three groups. In addition, quantitative RT-PCR and Northern blot showed that: [1] cyclin D1 and PCNA mRNA expression levels were highest in MNNG+$CdCl_2$ group; [2] mutant-p53 mRNA was apparently expressed in MNNG+$CdCl_2$ group, while slightly expressed in MNNG group; [4] p27 mRNA expression pattern was quite similar with that of protein. These results indicates that transformed cells express higher levels of cyclin D1, CDK4, and PCNA than nontransformed cells, while tumor suppressor genes p53 and p27 were strongly inhibited and oncogene c-myc was highly activated in transformed cells. Our data also elucidates that cadmium enhances the transformation process of MNNG-treated cells by inhibiting the tumor suppressor gene and accelerating the proliferation of initiated cells.

1346 THE EFFECT OF DIOXIN ON VASCULAR ENDOTHELIAL GROWTH FACTOR EXPRESSION AS ASSAYED BY TWO PCR-BASED METHODS.

H. M. Handley[1], J. J. Stegeman[1], D. Tillitt[2] and D. Papoulias[2]. [1]*Woods Hole Oceanographic Institution, Woods Hole, MA and* [2]*Columbia Environmental Research Center, Columbia, MO.*

Cardiovascular abnormalities are among the earliest and most striking teratogenic effects of TCDD (tetrachlorodibenzo-p-dioxin). Vascular endothelial growth factor (VEGF) is an endothelial cell-specific mitogen crucial in normal cardiovascular development. However, its role in abnormal development in animals exposed to environmental contaminants has not been determined. We examined whether VEGF expression in fish embryos is influenced by exposure to TCDD. Pre-gastrula zebrafish were injected with TCDD in triolein or triolein alone (control). Embryos from each treatment group were harvested at 12 and 24 hours post fertilization (hpf), and total RNA was isolated for use in two RT-PCR methods. Semi-quantitative RT-PCR involves normalizing signals from a target gene(s) to those of beta-actin. In competitive RT-PCR, recombinant DNAs with binding sites for gene-specific primers are used as internal standards, allowing quantification of the number of copies of a given sequence per unit RNA. Repetitions of semi-quantitative RT-PCR yielded similar patterns but large variation in the magnitude of observed differences. The data show no change in VEGF or CYP1A mRNA at 12hpf, but suggest slight induction of both genes by triolein and further induction by TCDD when expression is assayed at 24hpf. Competitive RT-PCR revealed a different scenario, indicating an increase in VEGF expression associated with triolein injection, but no TCDD-specific response by VEGF. At present, the discrepancies in the data make it difficult to draw firm conclusions as to the effect of TCDD on embryonic VEGF expression.

1347 TCDD CHANGES GROWTH FACTOR AND MATRIX PROTEIN EXPRESSION IN FETAL RAT VAGINAL TRACT.

B. D. Abbott[1], L. S. Birnbaum[1] and C. H. Hurst[2]. [1]*RTD, NHEERL, USEPA, Research Triangle Park, NC and* [2]*University North Carolina, Curr. Toxicol., Chapel Hill, NC.*

TCDD exposure induces reproductive and developmental effects. In rats, *in utero* exposure causes abnormalities in the female rat reproductive system, including reduced fecundity and a vaginal thread. The vaginal thread is manifested prenatally and altered morphology is detected as early as GD18. Fusion of the Mullerian ducts (MD) in the lower vaginal tract does not progress in treated fetuses, resulting in a residual mesenchyme surrounded by epithelial cells. The etiology of this defect may include disruptions in growth factor-mediated cellular proliferation, differentiation, and/or migration, as well as basement membrane remodeling. In this study, the expression of epidermal growth factor receptor (EGFR), transforming growth factor β-3 (TGF-β3), aryl hydrocarbon receptor (AHR), and laminin was examined immunohistochemically. Time-pregnant Long Evans rats (Charles River, Raleigh, NC) received on GD15 a single, oral dose of 1 microgram TCDD/kg or vehicle (5 ml corn oil/kg). Dams were sacrificed on GD 18 or 19 and reproductive tracts of female fetuses were dissected. Tissues were fixed in 3% paraformaldehyde, dehydrated and embedded in paraffin. Sections were prepared with control and treated tissues placed on each slide. Antibodies to EGFR, TGF-β3, and AHR (Santa Cruz Biotechnology) and laminin (Sigma) were incubated with sections overnight and detected with the Vector ABC Kit (Vector Labs, Burlingame, CA). TCDD elevated TGF-β3 in reproductive tract epithelium and mesenchyme. AHR expression increased in the MD luminal epithelium, but EGFR appeared to be unaffected by TCDD exposure. Laminin in basement membrane of Wolfian duct and urethra was expressed more strongly in TCDD-treated fetuses. It is not clear which cellular processes are required for fusion of MD in the lower reproductive tract of rodents, however the effects of TCDD suggest that growth factors and matrix remodeling may be important in removal of cells from between the ducts and fusion of the ductal epithelia. (Disclaimer: This abstract does not necessarily reflect EPA policy.)

1348 EARLY MORPHOGENETIC EVENTS ARE ALTERED IN THE FORMATION OF THE LOWER REPRODUCTIVE TRACT IN FEMALE RAT FETUSES GESTATIONALLY EXPOSED TO 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN (TCDD).

C. H. Hurst[1], B. D. Abbott[2] and L. S. Birnbaum[2]. [1]*University of North Carolina-Chapel Hill, Chapel Hill, NC and* [2]*USEPA, Research Triangle Park, NC.*

Exposure to TCDD and dioxin-like compounds results in a wide variety of effects in experimental animals, including a wasting syndrome, immunosuppression, thymic atrophy, chloracne, teratogenicity, carcinogenicity, as well as other toxic and biochemical effects. In rats, a single oral dose of 1.0μg TCDD/kg on gestation day (GD) 8 or GD15 caused structural and functional abnormalities in the female rat reproductive system, including reduced fecundity and the presence of a vaginal thread. The vaginal thread in TCDD-exposed rats consists of mesenchyme surrounded by epithelial cells and is clearly visible in histological sections as early as PND2. The objective of this study was to investigate TCDD-induced alterations during embryogenesis to better understand vaginal thread formation. Time-pregnant Long Evans rats received a single, oral dose of 1.0μg TCDD/kg on GD15. Dams were sacrificed on GD17, 18, 19, and 21 and the reproductive tracts from female fetuses were examined histologically. Subtle differences in the spatial orientation of the Mullerian ducts (MD) were present as early as GD17. Abnormalities in Mullerian duct fusion (a process critical to vaginal morphogenesis) were detected as early as GD18 and these effects constitute the origin of the vaginal thread. Furthermore, on GD19 the length of unfused MD was significantly greater in TCDD-treated fetuses than in controls. This information may help elucidate the mechanism of action of TCDD-induced effects on vaginal development in the rat. (This abstract does not necessarily reflect EPA policy. CHH supported by EPA, CT 902908.)

1349 TCDD DOSE RESPONSIVENESS AND EARLY GESTATIONAL EXPRESSION OF A TCDD RESPONSIVE LACZ REPORTER TRANSGENE IN MICE.

D. A. Nazarenko, S. D. Dertinger and T. A. Gasiewicz. *University of Rochester, Rochester, NY.*

The Aryl-hydrocarbon Receptor (AhR) is a ligand-dependent transcription factor that mediates the toxicity of halogenated aromatic hydrocarbons including 2,3,7,8-tetra-chlorodibenzo-p-dioxin (TCDD). These compounds are potent reproductive and developmental toxicants due to their ability to modulate gene expression and cellular differentiation and proliferation. The determination of the tissue-specific transcriptional activity of the AhR complex *in vivo* will allow the identification of tissues where the AhR may have some functional role that is susceptible to disruption by exposure to TCDD. A transgenic mouse model has been developed in our lab that can delineate the temporal and spatial context of active AhR in a cell- and region-specific manner. This model has previously identified several target tissues during mid gestation (gestational day [GD] 13-16) including the genital tubercle and paws. Longer TCDD exposures (48 and 72h) showed a similar pattern of expression. Embryos exposed to TCDD (30μg/kg) for 24h beginning on GD 6 to 12 have also been evaluated. Results indicate that the transgene is expressed in individual cells particularly in the developing ear. A dose response study was completed to evaluate responsiveness of the transgene at lower doses. Mice were exposed to 30, 15, 3, and 1.5μg/kg TCDD for 24h. Analysis of transgene induction was completed on an organ-by-organ basis. A 2.6 fold induction above vehicle was noted in the liver at the lowest TCDD dose and a 2.2 fold induction in the lung at the 3μg/kg dose. These results indicate that the model is capable of detecting low dose activation of the reporter, thus allowing the sensitive detection of developmental targets of TCDD. (Supported in part by NIEHS Grant ES09430, Center Grant ES01247, and Training Grant ES07026.)

1350 POLYBROMINATED BIPHENYL EXPOSURE *IN UTERO*: POSSIBLE EFFECTS ON BEHAVIOR IN THE MOUSE.

K. A. Miller, C. V. Vorhees, H. G. Shertzer and D. W. Nebert. *Department of Environmental Health, Department of Pediatrics, University of Cincinnati Medical Center, Cincinnati, OH.*

In Southern Michigan in 1973, livestock were heavily contaminated with polybrominated biphenyls (PBBs) due to accidental ingestion of the flame retardant "Firemaster"; humans eating these livestock suffered numerous health problems-somnolence and amnesia, mental confusion, leukocytopenia, chloracne [sentinel sign of aryl hydrocarbon receptor (AHR)-mediated toxicity in dioxin-exposed workers], and low-birth-weight and lowered I.Q. in children exposed to PBBs *in utero*. To investigate any correlation between neurobehavioral toxicity caused by PBBs and the involvement of the AHR, we are comparing 3,4,5,3',4',5'- (coplanar, cHBB) with 2,4,6,2',4',6'-hexabromobiphenyl (non-coplanar, ncHBB) treatment of pregnant C57BL/6J (B6, high-affinity-AHR) inbred mice and B6.D2-Ahr^d (low-affinity-AHR) congenic mice. In utero treatment was given at gestational day 5, and the offspring were tested 60 days post partum for locomotor activity plus four behavioral tests: the delayed spatial alternation (DSA) T-maze, latent-learning, Morris water maze, and step-down passive-avoidance (SDPA) tasks. There were no striking differences among groups in the DSA T-maze or SDPA endeavors. In contrast, using a water-finding task we found that cHBB-treated B6 mice show a trend in a deficit in latent learning-compared with that in cHBB-treated B6.D2-Ahr^d mice or either control group. cHBB-treated B6 mice also weighed significantly less than cHBB-treated B6.D2-Ahr^d mice or either control group. These data are consistent with the possibility that the AHR might be involved in the onset of cognitive deficits seen following *in utero* exposure to cHBB. Dopamine is known to play a key role in cognitive and emotional states, including latent learning. Although the underlying molecular mechanisms of these behaviors have not been determined, we postulate that CNS developmental expression of the AHR may predispose those areas of the CNS where the AHR is expressed to a greater risk of cHBB toxicity-perhaps by local disruption of dopamine signaling. (Supported in part by NIH Grant P30 ES06096.)

1351 EFFECTS OF DIETARY *p,p'*-DDE ADMINISTERED MATERNALLY ON REPRODUCTIVE DEVELOPMENT OF ADULT MALE RATS.

S. L. Archibeque-Engle, L. You, M. Casanova and H. D. A. Heck. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

To test the hypothesis that exposure to endocrine-active compounds during development results in permanent alterations in sexual development, we examined sexual behavioral responses and luteinizing hormone (LH) secretion patterns in adult male rats following their exposure to the environmental antiandrogen *p,p'*-DDE at early developmental stages. Twenty-eight day-old female rats were fed NIH-07 diet containing 0, 2.5, 25, or 250 ppm DDE for eight weeks before breeding with untreated males and during pregnancy and lactation. Male offspring were placed on standard NIH-07 diet at weaning. LH levels in serum samples collected from four-month-old male rats were 4.56 ± .41 (n=14), 3.59 ± .32 (n=14), 4.25 ± .59 (n=13), and 1.93 ± .77 (n=14) ng/mL for the 0, 2.5, 25, and 250 ppm DDE groups, respectively ($p<0.01$, with 2.5 and 250 ppm groups being significantly different from the 0 ppm group). When additional male rats were evaluated for masculine sexual behavior at approximately five months of age, no change was found in the number of mounts, number of intromissions, latency of ejaculation, and postejaculatory interval for the DDE-treated rats. However, the 2.5 ppm group showed significantly prolonged latency of mount and latency of intromission ($p< 0.05$). All male rats were then castrated and estrogen-plus-progesterone (E+P) conditioned before being tested for the potential of displaying E+P elicited feminine sexual behavior. In the 0, 2.5, 25, and 250 ppm groups, 8 (n=13), 42 (n=12), 20 (n=10), and 55% (n=11) of the respective males showing various degree of lordosis when mounted by untreated stud males. In addition, when canulated and stimulated with an E+P injection regime, the rats in the 250 ppm group exhibited a time-dependent elevation in the circulating LH level. The results suggest a substantial degree of variability in the evaluation of adult rat sexual behavior. Further research and analysis are needed to ascertain whether neonatal DDE can exert long-term effects on adult sexual behavior. Such effects, particularly when associated with low-dose DDE exposures, need to be assessed for potential human relevance.

1352 DEVELOPMENTAL EFFECTS OF AROCLOR* 1242 ON MALE OFFSPRING AFTER GESTATIONAL AND LACTATIONAL EXPOSURE.

M. R. Fielden, R. G. Halgren, K. Chou and T. R. Zacharewski. *Michigan State University, East Lansing, MI.*

Developmental effects of PCBs on male reproduction in rodents have been studied previously in several laboratories, however, with inconsistent results. The effects on testicular weights and fertility depend on the test congener or mixture, the dosage, the developmental stage during exposure, and the age of the animals when examined. We have previously reported an increase in testis weight and a decrease in sperm fertilizing ability in 3,3',4,4'-tetrachlorobiphenyl treated young males. The effect of Aroclor 1254 on sperm fertilizing ability after neonatal exposure, however, was not observed until 45 weeks of

age. The objective of this study is to examine the effects of gestational and lactational exposure of Aroclor 1242 (0, 10, 25, 50 and 100 mg/kg/2 days) on testicular development and sperm quality in 16-week old male mice. Sperm concentration and quality were examined using *in vitro* fertilization and computer-assisted sperm motion analysis. Testicular gene expression in mice from 25mg/kg treatment group was examined using a commercial cDNA array. There was no effect on maternal body weight, fecundity, litter size, litter weight, sex ratio or 21-day survival index. There was a dose-dependent increase in liver weights in 21 day old male offspring ($p<0.04$), but no observable change in testis and thymus weights at 3 weeks of age. There was, however, an increase in anogenital distance in the male offspring in the 25 mg/kg treatment group on day 21 ($p<0.002$). At 16 weeks of age, there were no detectable changes in sperm count or fertilizing ability. There were no changes in liver or thymus weight, however, there was a dose-dependent trend of increased testes weight. cDNA array analysis did not reveal any changes in gene expression. (Sponsored by the Michigan Great Lakes Protection Fund.)

1353 INSULIN-LIKE GROWTH FACTOR EXPRESSION IN MURINE EMBRYOS EXPOSED *IN VITRO* TO *o,p'*-DDT.

A. R. Greenlee, C. A. Quail, L. M. Misner and K. Liu. *Marshfield Medical Research Foundation, Marshfield, WI.*

During pregnancy, insulin-like growth factors (Igf) are synthesized by both mother and embryo and are thought essential for implantation and fetal development. Because the appearance of Igf ligands and receptors coincides with the expression of estrogen receptors in preimplantation embryos, it is possible that the events are closely linked and subject to perturbation by environmental estrogens that may accumulate in fluids of the reproductive tract. The goal of this study was to determine the effects of an estrogenic pesticide o,p'-DDT on the expression of Igfs in murine embryos at the 2-cell, 8-cell and blastocyst stages using immunocytochemistry. Pronuclear embryos were obtained from superovulated CD-1 mice and cultured for 24, 72 and 114 h in 25 microliter drops of Earle's balanced salt solution (EMG) under oil, containing 0.1% ethanol (control) or 0.1 microg/ml o,p'-DDT. Development of embryos to stage was scored before the embryos were fixed in paraformaldehyde. Embryos were incubated overnight with 6 microg/ml polyclonal anti-Igf-1R, -Igf-II or –actin, rinsed, and incubated 1h with FITC-labeled anti-IgG of appropriate specificity. DNA was stained with propidium iodide before the embryos were placed in mounting medium and examined with a Nikon Optiphot-microscope. Fluorescence intensity was scored for reactions blocked with the peptide of interest and statistically compared to results for unblocked reactions. Three immunocytochemistry experiments were completed in which all three stages of development were analyzed. A total of 193 stage-appropriate exposed embryos were compared to 194 control embryos. ANOVA was used to analyze the data. The model included the variables: pesticide, blocked vs unblocked reactions, antibody and stage of development. In comparison to control treatment, o,p'-DDT significantly reduced embryo development to the 2-cell, 8-cell and blastocyst stages ($p=0.0167$). Overall, antibody activity was reduced by pre-incubation with the relevant protein ($p=0.0001$). Immunocytochemistry data suggest that *in vitro* exposure to o,p'-DDT did not significantly alter expression of Igf-1R, Igf-II or actin proteins for embryos at the 2-cell, 8-cell or blastocyst stages ($p=0.1174$). Further research will include RT-PCR for more quantitative comparisons of growth factor expression. (Financial support was provided by the WD Connor Trust and MMRF.)

1354 RABBIT ORAL DEVELOPMENTAL TOXICITY STUDIES WITH TWO PERFLUORINATED COMPOUNDS.

R. G. York[1] and M. T. Case[2]. [1]*Primedica Argus Research Laboratories, Inc., Horsham, PA and* [2]*3M Corporate Toxicology, Saint Paul, MN.*

Rabbit developmental toxicology studies were conducted on two perfluoronated compounds – perfluorooctanesulfonate (PFOS) and 2-(N-ethyl perfluoro-octanesulfonamido)-ethyl alcohol (N-EtFOSE). Dosages of 0, 0.1, 1.0, 2.5 and 3.75 mg/kg/day in 0.5% Tween 80 were used for both studies. Although no compound related deaths occurred, maternal toxicity (reduced body weight gain and feed consumption values) was present at the higher dosage levels of both studies. On the basis of these data, the maternal no-observable-effect-level (NOEL) of N-EtFOSE and PFOS was 0.1 mg/kg/day (the 1.0 mg/kg/day and higher dosages caused statistically significant reductions in body weight gains or weight losses and the 2.5 and 3.75 mg/kg/day dosages also significantly reduced absolute and relative feed consumption values). The developmental NOEL was 1.0 mg/kg/day for both compounds (the 2.5 and 3.75 mg/kg/day dosages of N-EtFOSE caused increased incidences of late resorptions and abortions and the 2.5 and 3.75 mg/kg/day dosages of PFOS caused reductions in fetal body weights and delays in ossification). Detailed fetal external gross, soft tissue and skeletal examinations failed to reveal any malformations related to treatment. It was concluded that these perfluoronated compounds were not selective developmental toxicants in rabbits.

1355 EMBRYOTOXICITY OF 3-CHLORO-4-(DICHLOROMETHYL)-5-HYDROXY-2(5*H*)-FURANONE (MX) AND FOUR HALOACETIC ACIDS IN MICROMASS *IN VITRO* TEST.

H. Huuskonen, M. Jokela and T. Vartiainen. *National Public Health Institute, Kuopio, Finland.* Sponsor: J. Tuomisto.

3-Chloro-4-(dichloromethyl)-5-hydroxy-2(5*H*)-furanone (MX) and other halocompounds, such as trichloroacetic acid (TCA), dichloroacetic acid (DCA), tribromoacetic acid (TBA) and dibromoacetic acid (DBA) are drinking water disinfection by-products (DBPs). They are created when water with naturally occuring organic compounds and bromine is chlorinated or ozonated. These compounds are known or suspected to cause cancer and reproductive effects at high concentrations. The embryotoxic potential of MX, TCA, DCA, TBA and DBA was evaluated using rat limb bud (LB) micromass test. Following dissociation of LB tissues with trypsin, single-cell suspensions were prepared in Ham's F-12 culture medium containing 5% fetal calf serum (pH 7.0-7.4). The cell suspensions were filtered and adjusted to give 2×10^7 cells per ml. Aliquots of 5 µl were delivered to 96-well tissue plates and incubated for 2 hours at 37°C in a humidified air containing 5% CO_2. Eight concentrations of MX, TCA, DCA, TBA or DBA were added in a final volume of 300 µl culture medium per well. At the end of the 5-day culture period, cells were stained with Neutral Red and Alcian Blue for determination of concentrations that produced a 50% inhibition of cell proliferation (IP_{50}) and differentiation (ID_{50}) The embryotoxic potential of MX was high in the micromass test and decreased in the following order: MX >> DBA> >TBA >DCA >TCA. The IP_{50}-and ID_{50}-values for MX were 7.1 µg/ml and 6.5 µg/ml, respectively.

1356 EVALUATING THE ROLE OF GAVAGE TREATMENT OF TRICHLOROETHYLENE, TRICHLOROACETIC ACID, AND DICHLOROACETIC ACID ON THE DEVELOPING SPRAGUE-DAWLEY RAT FETUS.

L. J. Graeter[1], S. R. Channel[1], J. S. Eggers[1], C. D. Goodyear[1], P. D. Johnson[2], K. MacMahon[1], G. L. Sudberry[1], D. A. Warren[1], J. W. Fisher[1] and J. R. Latendresse[1]. [1]*Air Force Research Laboratory, Wright-Patterson AFB, OH and* [2]*University of Arizona, Tucson, AZ.*

Trichloroethylene (TCE) and its metabolites are commonly found in finished drinking water and as groundwater contaminants in many regions of the United States. Therefore, it is important that the health effects of TCE and its metabolites be assessed, both epidemiologically and experimentally. Epidemiological studies have shown a correlation between drinking water that contains halogenated hydrocarbons and an increased incidence of congenital cardiac malformations in children born to mothers residing in these areas. Follow-up studies in avian and rodent models have also shown an increased incidence of cardiac malformations at varying dose levels of these compounds. However issues have been raised with these studies regarding data gaps, the lack of a dose-response relationship, and the use of different evaluation techniques. The objective of this study was to validate previous reports of cardiac teratogenicity following maternal administration of TCE, trichloroacetic acid (TCA), and dichloroacetic acid (DCA) to Sprague-Dawley rats via gavage on gestation days six through fifteen. All-trans retinoic acid (RA) was used as a positive control. Maternal and fetal examinations were performed on gestation day twenty-one. Fetal hearts were examined in situ, removed, and formalin-fixed for later microscopic/dissection examination. The mean uterine weights of the TCA group were significantly lower than the vehicle control group. Fetal body weights in the TCA and DCA groups were significantly decreased. A significant number of external malformations were observed in the DCA-treated fetuses. No significant differences in cardiac malformation incidence were observed in the TCE-, TCA-, or DCA-treated groups. Expected incidence levels of both maternal and fetal lesions were observed in the retinoic acid positive control group.

1357 ALTERED GENE EXPRESSION IN THE DEVELOPING MALE REPRODUCTIVE TRACT FOLLOWING *IN UTERO* EXPOSURE TO DI-*N*-BUTYLPHTHALATE.

V. D. Shultz, S. L. Phillips, K. P. Reischmann, K. W. Gaido and P. M. D. Foster. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Developmental exposure to di-*n*-butyl phthalate (DBP), a ubiquitous plasticizer and solvent, alters male rodent reproductive function and sexual differentiation. Although the reproductive effects are similar to that of flutamide, a classical androgen receptor antagonist, DBP does not directly interact with the androgen receptor. The objective of this study was to explore the potential mechanisms of DBP-induced reproductive malformations by examining the expression of critical regulatory genes during reproductive development and determining their association with cellular proliferation and differentiation. Pregnant Sprague-Dawley rats were administered 500mg/kg/day of DBP or 50mg/kg/day of flutamide in corn oil by gavage from gestation days (gd) 12 to 21, the period of male reproductive tract development. Steady-state levels of androgen receptor (AR), steroidogenic factor (SF-1), epidermal growth factor (EGF), and its cognate receptor EGF-R mRNAs were analyzed by semi-quantitative RT-PCR using RNA from treated and control fetal testes. At gd 21, SF-1 gene expression was decreased by 20% in DBP treated testes, while a similar increase occurred with flutamide exposure. AR message and protein levels increased by 20% in DBP treated testes, while flutamide exposure resulted in a similar increase in message levels but did not translate into a similar increase in the level of protein. EGF mRNA was unaltered by DBP exposure but its cognate receptor mRNA was elevated by 40%. EGF-R mRNA levels were increased by nearly 20% by flutamide exposure. While the average change in the level of gene expression among treatment dams was not statistically significant, the greatest degree of change in mRNA levels occurred in fetuses most severely affected by DBP exposure as assessed by decreased anogenital distance. The rat Clontech Atlas cDNA array is currently being used to identify more global changes in gene expression with DBP exposure throughout the time course of reproductive development. These studies demonstrate that the gene expression profile associated with DBP exposure differs from that of flutamide and occurs by a yet to be defined mechanism.

1358 NONYLPHENOLS DIFFERENTIALLY AFFECT γ-GLUTAMYL TRANSPEPTIDASE IN TESTIS AND MALE ACCESSORY ORGANS IN RATS DURING DEVELOPMENT.

P. C. Lee, B. H. Jelinek, P. Ho and M. Struve. *Medical College of Wisconsin, Milwaukee, WI.*

We have previously shown that administration of nonylphenols (NPs) to neonatal male rat pups impair their subsequent reproductive development. Gamma-gluctamyl-transpeptidase (GTP), present in the testis and seminal vesicle, exhibits developmental maturation in these tissues. In this study, we examined the effect of NPs on GTP activities in the testis and male accessory organs to see whether NP perturbs GTP development in these tissues. Newborn male pups were given NPs at (8.0 mg/Kg body wt.) or vehicle (dimethylsulfoxide) for 15 days. They were sacrificed at 25 days of age. NP treated pups showed decrease level of GTP in their epididymus. GTP activity in the testis, seminal vesicle or prostate was minimally affected. To study the kinetic parameters, NPs were also given as a single injection to pups at ~22 days of age (8.0 mg/Kg body wt.) and sacrificed at 24 and 48 hours post-injection. GTP activity was not affected in the testis, seminal vesicle and prostate at both time points. The epididymus, however, showed a reduction in GTP activity at 24 hours post-treatment and decreased further at 48 hours. The degree of decrease in GTP activity was dose dependent and was detectable at NP concentration of 6.0 mg/Kg body wt. Though the exact function of GTP on reproductive development is not clearly understood, GTP knock out mice are found to be infertile. The adverse effects of NPs on male reproductive development might be at least in part through its action on GTP development in some of these male accessory tissues.

1359 EXPOSURE TO 2,4,5-TRICHLOROPHENYL-4'-NITROPHENYL ETHER INHIBITS DEVELOPMENT OF OTOLITHS IN CD-1 MICE.

B. M. Francis. *University of Illinois at Urbana-Champaign, Urbana, IL.*

Certain nitrodiphenyl ethers, including the herbicide nitrofen (2,4-dichlorophenyl 4'-nitrophenyl ether), are potent developmental toxicants that not only cause perinatal mortality, but also induce subtle malformations in surviving offspring. These malformations, including diaphragmatic hernias and small or absent Harderian glands, are more readily detected postnatally than in prenatal screens. We have also observed that a small percentage of pups which survive prenatal exposure to the nitrofen analog, 245-TCN (2,4,5-trichlorophenyl 4'-nitrophenyl ether), engage in compulsive circling when disturbed. In earlier studies, 245-TCN was the only one of 30 diphenyl ethers to cause circling, and did so only at doses that induced a high frequency of perinatal mortality. Because circling may result from defective development of otoliths, we collected term fetuses exposed to either nitrofen or 245-TCN and processed them for examination of otoliths. When pregnant mice were exposed to 20 mg/kg/day 245-TCN on gestation days (GD) 6-15 (day of semen plug=GD 0), some offspring in each litter lacked one or more otoliths, and most otoliths were decreased in size even when present. Single doses of 50 mg/kg on GD 8, 9, 10 or 11 also decreased otolith size. Preliminary data from such single day dosing studies demonstrate that the highest incidence of otolith damage occurs on or after GD 11. This is in contrast to other diphenyl ether-induced malformations, for which the most sensitive day is GD 8 (in mice). Single-day dosing on GD 8, 9, 10 or 11,with up to 700 mg/kg technical nitrofen, (a dose causing nearly 100% perinatal mortality on GD 8), did not significantly decrease otolith size.

1360 DEVELOPMENTAL NEUROTOXIC EFFECTS OF 2,2',4,4',5-PENTABROMODIPHENYL ETHER (PBDE 99) IN THE NEONATAL MOUSE.

H. Viberg[1], A. Fredriksson[1], E. Jacobsson[2], U. Öhrn[2] and P. Eriksson[1]. [1]*Dept. Environmental Toxicology, Uppsala University, Uppsala, Sweden and* [2]*Dept. Environmental Chemistry, Stockholm University, Stockholm, Sweden.*
Sponsor: K. M. Crofton.

Polybrominated diphenyl ethers (PBDEs) are used in large quantities as flame-retardant additatives. In a recent study we have seen that neonatal exposure to some brominated flame-retardants can cause permanent aberrations in spontaneous behavior that seem to worsen with age. In view of an increasing amount of PBDEs in mothers milk and in the environment, the present study was undertaken to investigate whether there is a critical and limited phase for induction of persistent neurotoxic effects of PBDE 99. Mice were exposed neonatally on day 3, 10 or 19, to 8 mg PBDE 99/kg body weight. Uptake and retention of [^{14}C]PBDE was studied in the mouse brain after exposure to 1.5 MBq [^{14}C]PBDE 99/kg body weight, on postnatal day 3, 10 or 19. Spontaneous behavior was observed in 4-month-old mice. Mice exposed to PBDE 99 on day 3 or 10 showed significantly impaired spontaneous motor behavior. Neonatal mice, exposed to [^{14}C]PBDE 99 on postnatal day 3, 10 or 19, were sacrificed 24 h or 7 days post-treatment and the amount of radioactivity in the brain was measured. [^{14}C]PBDE 99 was detected in the brain but no significant difference was evident between the age categories after 24 h. On day 7, [^{14}C]PBDE 99 was still present in the brain, though radioactivity had decreased significantly in all age categories. Nicotine-induced behavior in adult mice has also been tested after neonatal exposure to PBDE 99. The nicotine-induced behavior test revealed a hypoactive response in contrast to the hyperactive response shown in the control animals, indicating effects on the cholinergic system. In conclusion, the behavioral disturbances observed in adult mice following neonatal exposure to PBDE 99 are induced during a defined period of neonatal life and the adult response to nicotine is significantly changed.

1361 EFFECT OF ETHANE DIMETHANESULPHONATE (EDS) AND MOLINATE ON THE DEVELOPMENT OF THE PRENATAL MURINE REPRODUCTIVE TRACT.

D. K. Tarka[1], G. R. Klinefelter[2], J. Suarez[2], N. Roberts[2] and J. M. Rogers[1]. [1]*USEPA/University of North Carolina, Research Triangle Park, NC and* [2]*USEPA, Research Triangle Park, NC.*

Endocrine disrupting compounds that disturb Leydig cell steroidogenesis may reduce testosterone biosynthesis and subsequently result in dysgenesis of the male reproductive tract. The effect of ethane dimethanesulphonate (EDS) and molinate on reproductive tract development in CD-1 mice exposed *in utero* was investigated based on reported reproductive damage in adult male rats. EDS is a model compound specifically cytotoxic to the Leydig cells and molinate is a thiocarbamate herbicide that is reported to inhibit esterase activity and thus prevent the assembly of cholesterol esters, a necessary precursor to testosterone biosynthesis. Timed pregnant CD-1 dams were dosed i.p. with 0, 25 or 50 mg/kg/d EDS, or 0, 50 or 100 mg/kg/d molinate on gestation days 11 thru 16. On gestation day 18, mouse fetuses were removed via caesarian section; anogenital distance (AGD) was measured and fetuses were examined for reproductive tract malformations. No reproductive tract malformations were

detected but a significant dose-dependent decrease in AGD was observed with both treatments in both male and female pups. AGD is an androgen-dependent endpoint and, thus, the results of these gestational exposures suggest that the disruption of fetal Leydig cell steroidogenesis yields reduced testosterone levels. Current studies are underway to examine testis histology and to measure whole body testosterone throughout the dosing regimen via radioimmunoassay. Potentially, this mechanism could result in a delay in puberty and decreased fertility. (This abstract does not necessarily reflect EPA policy DKT; Training Agreement T901915.)

1362 EARLY EMBRYONIC LOSS INDUCED BY DIBUTYLTIN DICHLORIDE (DBTCl) IN RATS.

M. Ema, A. Harazono and K. Kawashima. *National Institute of Health Sciences, Osaka, Japan.*

Dibutyltins are extensively used as heat and light stabilizers for poly(vinyl chloride) plastic products. The present study was conducted to evaluate the adverse effects of dibutyltin on initiation and maintenance of pregnancy after administration during early pregnancy in rats. Following successful mating, female rats were given DBTCl by gastric intubation at 0,3.8,7.6, or 15.2 mg/kg on days 0-3 or days 4-7 of pregnancy (sperm day = day 0 of pregnancy). Female rats were sacrificed on day 20 of pregnancy and pregnancy outcome was determined. In females successfully mated, DBTCl caused complete failure in implantation, which was evidenced by total absence of any implantation site, and the pregnancy rate was significantly decreased after administration of DBTCl on days 0-3 at 7.6 and 15.2 mg/kg. The incidence of postimplantation embryonic loss per litter in the groups give DBTCl on days 0-3 were comparable to those in the control group. No decrease in the pregnancy rate was found after administration of DBTCl on days 4-7 of pregnancy. The incidence of postimplantation embryonic loss per litter was significantly increased after administration of DBTCl on days 4-7 at 3.8 mg/kg and above. It could be concluded that DBTCl causes pre-and postimplantation embryonic loss when administered during early pregnancy.

1363 ALTERATION OF PALATAL CYCLIC AMP SIGNALING COMPONENTS BY SECALONIC ACID D.

U. Hanumegowda, G. Balasubramanian and C. S. Reddy. *University of Missouri, Columbia, MO.*

Cyclic AMP (cAMP), known to play an important role during normal palate development, relays its signals via protein kinase A (PKA) and the transcription factors such as cAMP response element binding protein (CREB) and modulator (CREM). Secalonic acid D (SAD), a cleft-palate-causing mycotoxin, is known to affect palatal cAMP levels. In the present study, the effect of SAD on the downstream components of cAMP-PKA pathway was investigated. Western blots of palate samples collected from control and SAD-treated mice showed that, despite no effects on CREB, level of phosphorylated CREB (pCREB) increased soon after SAD treatment (GD 12) but was reduced below that of controls later (GD 14). Electrophoretic mobility shift assays using nuclear extracts from the control and SAD treated tissues and [32P] labeled consensus oligonucleotide of CRE (cAMP response element) revealed similar level of the complex formed between CRE and CREB/CREM. Interestingly, the gel supershift assays with the antibodies against CREB and CREM, showed that the proportion of CREM binding to CRE increased whereas that of CREB decreased at the earlier time point following SAD treatment. This correlated well with an increase in CREM protein following SAD treatment. These results suggest that early increase in pCREB by SAD leads to induction of CREM which results in increased CREM binding to CRE. Since CREM is a repressor protein, these results indicate that SAD may downregulate genes involved in cell proliferation. (Supported by NIH grant # DE/OD 11822.)

1364 EFFECTS OF LINURON ON ANDROGEN-DEPENDENT REPRODUCTIVE DEVELOPMENT IN THE MALE SPRAGUE-DAWLEY RAT.

B. S. McIntyre, N. J. Barlow, D. G. Wallace, S. C. Maness, K. W. Gaido and P. M. D. Foster. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Linuron (3-(3,4-dichlorophenyl)-1-methoxy-1-methylurea) is an herbicide known to block androgen action in the male rat. Studies were undertaken to characterize the ability of linuron to activate transcription through the androgen receptor (AR) *in vitro* and to determine whether *in utero* exposure to linuron alters androgen-dependent male rat reproductive development. In the *in vitro* HepG2 system, linuron did not stimulate transcriptional activity of the AR in the absence of dihydrotestosterone (DHT). However, linuron competitively antagonized DHT-induced transcriptional activity of the AR in a dose-responsive manner with an IC_{50} of 15μM. Pregnant rats were given linuron by gavage at 0, 12.5, 25, or 50 mg/kg/day (n=11/group) from gestation day 12 to 21. Anogenital distance, birth weight, and pup weight gain were unaffected. Male thoracic areola and/or nipple retention was observed in 11/58 rats (5/10 litters), 19/57 rats (6/10 litters), 27/69 rats (9/11 litters), and 32/44 rats (8/8 litters) in the 0, 12.5, 25, and 50 mg/kg/day dose groups, respectively. Prenatal linuron exposure did not affect preputial separation, testicular descent, or gross morphology of the external genitalia. Reproductive organ weights and hormone levels were unaltered in the adult male offspring. However, reproductive tract lesions were observed in all linuron-exposed groups. Atrophic testes in adult offspring were seen in 2/56 rats (2/10 litters), 8/69 rats (4/11 litters), and 5/44 rats (3/8 litters), while atrophic epididymides occurred in 1/56 rats (1/10 litters), 8/69 rats (4/11 litters), and 2/44 rats (1/8 litters), in the 12.5, 25, and 50 mg/kg/day dose groups, respectively. Partial or absent epididymides and vasa deferentia were observed in 3/44 rats (2/8 litters) only in the 50 mg/kg/day dose group. The primary histologic lesion in grossly abnormal testes was germ cell degeneration with spermatogenic arrest. These data demonstrate that *in utero* exposure to linuron results in testicular toxicity and malformations of the epididymides and vasa deferentia, indicating that linuron selectively impairs testosterone-, rather than DHT-mediated, reproductive development. These findings are distinctly different from the effects induced by flutamide, an AR antagonist that shares structural similarities with linuron.

1365 DEVELOPMENTAL TOXICITY OF OCTYLTIN STABILIZER IN MICE.

A. S. Faqi[1], H. Schweinfurth[2] and I. Chahoud[1]. [1]*Institute of Clinical Pharmacology and Toxicology, Berlin, Germany and* [2]*Schering Institute for Experimental Toxicology, Berlin, Germany.* Sponsor: R. Stahlmann.

The Octyltin stabilizer ZK 30.434 is a mixture of 80% dioctyltin diisooctylthioglycolate (DOTTG) and 20% of monooctyltin triiosooctyl thioglycolate (MOTTG) which is used as stabilizer for rigid polyvinylchloride (PVC) materials. One of the application of such stabilized films is the packaging of foodstuffs. Exposure to humans occur via migration of DOTTG/MOTTG from PVC materials. The purpose of the study was to investigate the development toxicity of the mixture DOTTG/MOTTG and determine the no-observed adverse effect level (NOAEL) dose. For this purpose 2 developmental toxicity studies were conducted using different doses. In the first study pregnant mice were treated orally with 0, 20, 30 or 45mg DOTTG/MOTTG/kg b/w. In the second study the pregnant mice recieved 0, 67 and 100mg DOTTG/MOTTG/kg b/w. The control groups received oral daily doses of 5 ml Arachis/kg b/w. by gavage for the entire treatment period. All the animals were treated daily on days 6-17 of gestation and sacrificed on day 18 of gestation. The number of implantation sites and viable fetuses showed no substance-related effects. The resorption rates (resorption/implantation) were significantly increased and fetal weight significantly reduced in the 2 higher dose groups. External anomalies including bent forelimbs, cleft palate and exencephaly were found in fetuses treated with 100mg DOTTG/MOTTG/kg b/w. A significant increase in cleft palate, however, was also found in the fetuses of 67mg/kg dose group when compared to the control fetuses. Moreover, in the 2 higher doses a dose-dependent increase in skeletal anomalies was observed. A part from a significant increase in supernumerary lumbar ribs observed at the dose level of 20mg/kg b.w., no other developmental effects were reported on the fetuses treated with low doses of DOTTG/MOTTG. It can be concluded that DOTTG/MOTTG is embryo-fetotoxic and induces developmental effects. The highest dose used (100mg/kg) is maternally toxic.

1366 DEVELOPMENTAL TOXICITY IN RATS TREATED ORALLY WITH 2-(2-IODOETHYL)-1,3-PROPANEDIOL DIACETATE.

F. J. Guerriero[1], C. W. Seaman[2], G. L. Sprague[1], T. J. Sutton[2] and C. D. N. Toseland[2]. [1]*SmithKline Beecham Pharmaceuticals, King of Prussia, PA and* [2]*SmithKline Beecham Pharmaceuticals, Welwyn, United Kingdom.*

The transport of new chemicals around the European Union must be preceded by their registration with the Competent Authorities, a process which involves both hazard and risk assessment. In order to comply with this Notification of New Substances directive, the research chemical 2-(2-iodoethyl)-1,3-propanediol diacetate (CAS RN 127047-77-2) was examined in, among other tests, a 28-day rat oral toxicity study at doses of 15, 150 and

350 mg/kg/day. The male rats receiving 350 mg/kg/day of this material exhibited specific organ toxicity in the form of decreased testis weight and moderate seminiferous tubular atrophy. A dose of 150 mg/kg/day had no effect on the testes. A reproductive toxicity study was therefore undertaken to determine whether the tubule degeneration was of sufficient magnitude to impact on male fertility. To maximise the amount of information available from the additional study, an assessment of female fertility and general reproductive performance was performed and the offspring were examined for gross abnormalities. Male fertility was not influenced by oral treatment at doses up to 350 mg/kg/day, in spite of the re-appearance of a similar degree of degeneration of the seminiferous tubules; and female fertility was also unaffected at this dose. However, many of the offspring born from females treated at doses of 150 and 350 mg/kg/day died by Day 1 post partum and in 13 of the decedent offspring there was a treatment-related abnormality in the form of disruption of palatal fusion and mineralisation. The 13 affected offspring also showed delayed respiratory epithelial development. This abnormality was distinct from the typical cleft palate which occurs spontaneously and was in fact seen in three offspring from the control rats in the study. Based on these findings, 2-(2-iodoethyl)-1,3-propanediol diacetate was classified as a rat developmental toxin and, in the present absence of an understanding of the mechanism of this effect, a potential human developmental toxin.

1367 SUBCRONIC AND DEVELOPMENTAL TOXICITY STUDIES OF *N*-BUTYL PROPIONATE VAPOR IN RATS.

C. E. Ulrich[1], M. D. Nemec[1], M. I. Banton[2], T. R. Tyler[3] and R. H. Garmon[4]. [1]*WIL Research Laboratories, Ashland, OH,* [2]*Shell Chemical Company, Houston, TX,* [3]*Union Carbide Corporation, Danbury, CT and* [4]*Consultants in Veterinary Pathology, Murrysville, PA.*

Two inhalation studies ere conducted to evaluate the possible subchronic and developmental toxic effects of n-butyl propionate (NBP). In the subchronic study, Sprague-Dawley rats (15/sex)were exposed to 0, 250, 750, or 1500 ppm vapor for 6hr/day, 5 days/wk for 13 wks. Five of the rats/sex/group were held after the final exposure for an 8 week recovery period. Clinical signs, body weights, food consumption, hematology and clinical chemistry evaluations were conducted. At the end of exposure and recovery periods, necropsies were preformed, organs weighed, and tissues processed for microscopic examination. Exposure did not produce deaths or adversely affect clinical signs, hematology, clinical chemistries, organ weights, or the histology of major visceral organs. The only systemic toxic effects were decreases in body weight, body weight gain, and feed consumption in the 1500 ppm group rats. Morphologic changes were limited to the nasal cavity as evidenced by a concentration-related increased incidence and severity of olfactory epithelium degeneration in rats of the 750 and 1500 ppm groups. Both the systemic and nasal cavity efects appeared reversible after exposure ceased. In the developmental toxicity study, pregnant Sprague-Dawley rats (24/group) were exposed to 0, 500, 1000, or 2000 ppm vapor for 6 hr/day on gestation days (gd) 6-15 and euthanized on gd 20. All exposed dams exhibited reductions in body weight, body weight gain, and feed consumption. Intrauterine growth and survival were equivalent across all groups and there were no treatment-related developmental or teratogenic effects. The NOAELs determined for NBP were 250 ppm for subchronic toxicity (based on the olfactory epithelium degeneration) and 2000 ppm for developmental toxicity (no developmental effects at highest exposure level tested). Under the conditions of the latter study, a NOAEL was not determined for maternal toxicity.

1368 DEVELOPMENT TOXICITY OF 3-NITROBENZOIC ACID (NBA) IN WISTAR RATS.

K. K. Kabirov and A. V. Lyubimov. *Center of Ecology and Biotesting, PERM, Russian Federation.*

Pregant Wistar rats were exposed to NBA by whole body inhalation at concentrations of 0, 0.4, 1.0 or 2.9 mg/m3 for 4 hr/day 7 days/week throughout gestation. In pregnant dams exposed to NBA at the concentration of 2.9 mg/m3, a significant increase in the level of aspartate aminotransferase and alanine aminotransferase in blood and a significant increase of the liver lipid peroxidation were observed. Relative liver weights of pregnant dams were significantly decreased at concentrations of 1.0 and 2.9 mg/m3. NBA treatment significantly increased embryolethality at the concentrations of 1.0 and 2.9 mg/m3. The number of metacarpal bones and the number of ribs were significantly decreased at the same concentrations. Upper and lower incisor eruption was significantly delayed in the 2.9 mg/m3 experimental offspring group. A non-significant delay in eye opening and hair appearance were observed also at the maximal tested concentration. A dose-dependent retardation of the body weight was more evident in female progeny. Offspring prenatally exposed to NBA at the concentrations of 1 and 2.9 showed significant changes in behavior in the open field test. The relative weights of the pups' liver, heart, lungs and adrenal gland were significantly decreased in the 1.0 and 2.9 mg/m3 experimental groups. Thus, the LOELs (Lowest Observed Effect Level) and NOELs (No Observed Effect Level) of NBA were 1 and 0.4 mg/m3 both for the maternal and developmental toxicity, respectively.

1369 ASSESSMENT OF THE TERATOGENICITY OF TRIVALENT AND HEXAVALENT CHROMIUM COMPOUNDS IN FEMALE RABBITS.

O. S. Z. El-Tawil and A. M. Morgan. *Cairo University, Faculty of Veterinary Medicine, Forensic Medicine and Toxicology Department, Giza, Egypt.*

The exposure of pregnant female rabbits to trivalent (chromium chloride) or hexavalent (potassium dichromate) chromium compounds in drinking water (500ppm) during the organogensis period (6-18th day of gestation) revealed embryotoxic - and fetotoxic effects.Both trivalent and hexavalent compounds induced dwarfism, kinky and short tail and a significant reduction in the number of implantation sites and in the number of viable fetuses. The number of females with resorption was significantly increased in the hexavalent-exposed group.Visceral abnormalities in the form of lung hypoplasia, heart hypertrophy, intrathoracic hemorhage and dilated nares and brain lateral ventricles were found in the fetuses of both chromium (III, VI) treated mothers. Skeletal anomalies (reduced number of sternal and caudal bones) were also recorded in both chromium groups. Furthermore, reduced ossification in parietal and inerparietal bones was significantly increased in the hexavalent chromium exposed females. Chromium levels in blood, placenta and fetuses significantly increased in both chromium groups. In conclusion, the exposure of pregnant rabbits to trivalent and hexavalent chromium compounds would have adverse effects on the embryonic and fetal development.

1370 BIOLOGICALLY-BASED DOSE-RESPONSE MODEL FOR METHYL MERCURY DEVELOPMENTAL TOXICITY INCORPORATING NOVEL *IN VIVO* CELL CYCLING DATA.

T. A. Lewandowski, R. A. Ponce, S. Hong, S. M. Bartell and E. M. Faustman. *Department of Environmental Health, Institute for Risk Analysis and Risk Communication, University of Washington, Seattle, WA.*

We are developing a biologically-based dose response model that describes the developmental toxicity of methyl mercury (MeHg) in the developing embryonic rat brain. Key components of the model include biologically-derived rate constants for proliferation of neuroepithelial cells. We are using 5-bromo-2'-deoxyuridine (BrdU) DNA labeling *in vivo* and flow cytometry to obtain these parameters. We found that in the untreated animal, the fraction of cycling midbrain cells declines from 73 (±4) percent on gestational day (gd) 12 to 10 (±4) percent on gd 16. The estimated cell cycle time increases from 16 hours on gd 12 to 20 hours on gd 16, while the estimated S phase duration increases from 8 hours on gd 12 to 10 hours on gd 16. Similar values were obtained *in vitro* for rat midbrain cells cultured from gd 12 to gd 14 (Ponce et al., 1994). We are now evaluating the effects of MeHg on cell cycle kinetics *in vivo*. Preliminary data indicate that dosing on gd12 to achieve a gd14 brain concentration of approximately 3 μg/g, results in a significant increase in the fraction of BrdU labeled cells (labeling time=1.5 hr), suggestive of a slowing of S-phase progression. We are now collecting data on the effect of MeHg on the overall fraction of cycling cells and the cell cycle time. This data will be incorporated into our model and compared to fetal midbrain cell number data being collected in parallel. This will allow us to describe the effect of MeHg on cell cycle progression *in vivo* and its effects on neural development. We will also assess the utility of *in vitro*-derived data for modeling, thus improving our knowledge of the uncertainty associated with *in vitro* to *in vivo* extrapolation. (Supported by NIEHS T32ESO-7032, USEPA CR825173, USEPA R825358 and USEPA/NIEHS R826886.)

1371 DEVELOPMENTAL TOXICITY OF LEAD IN SMOOTH MUSCLE.

K. M. McHugh and V. Gabetta. *Thomas Jefferson University, Philadelphia, PA.* Sponsor: P. Wier.

Exposure to heavy metals has been shown to permanently alter the growth state of smooth muscle cells. Prior studies in our lab have characterized an *in vitro* model of normal smooth muscle differentiation based upon differential isoactin gene expression. In an effort to determine what effect lead exposure

has on normal intestinal smooth muscle cell (ISMC) differentiation, primary cultures of ISMC's were grown in the presence of lead at a concentration corresponding to 13.75 micrograms/deciliter blood lead level. Morphologic analysis showed that prolonged lead exposure has the potential to disorganize/disrupt the highly characterized "hills and valley" phenotype routinely observed in cultured ISMCs. Northern blot analysis using the γ-smooth muscle, α-smooth muscle, β-cytoplasmic, and γ-cytoplasmic isoactin-specific cDNAs indicated that cultured ISMCs grown in the presence of lead displayed dramatic alterations in isoactin gene expression versus control cells. Lead-exposed ISMC's possessed a γ-smooth muscle:alpha smooth muscle isoactin ratio of 0.19±0.08. This smooth muscle isoactin ratio does not correspond to any of the previously characterized ISMC phenotype-specific smooth muscle isoactin ratios. Rather, lead-exposed ISMCs display a unique smooth muscle isoactin ratio suggesting a possible altered cellular phenotype that is intermediate to those previously described. These studies demonstrate that lead exposure has a profound effect of ISMC differentiation *in vitro* providing a basis for future studies designed to identify the complex transcriptional endpoints that are susceptible to heavy metal-induced developmental toxicity.

1372 TERATOGENICITY SCREENING OF ANTISENSE PHOSPHORODIAMIDATE MORPHOLINO OLIGOMERS IN ZEBRAFISH EMBRYO MODEL.

C. Ghosh and P. L. Iversen. *AVI BioPharma Inc., Corvallis, OR.*

Antisense technology holds great promise for therapeutic applications. Phosphorodiamidate morpholino oligomers (PMOs) are a new class of antisense agents that inhibit gene expression by hybrid arrest of translation. We examined the teratogenic potential of antisense PMOs in zebrafish embryogenesis model. AVI-4126, a 20-mer PMO targeted to c-myc, was used for these studies. Zebrafish have become a popular model for studies of vertebrate development and toxicology. They grow rapidly, reach sexual maturity in approximately three months and produce transparent embryos that complete development in 96 hr. Blastula stage zebrafish embryos were exposed to different concentrations (0.1-100 μM) of AVI-4126 and were morphologically evaluated for any developmental abnormality and subsequent lethality. Uptake of PMO in embryos was studied by fluorescent microscopy and histology. We observed fluorescence in a wide variety of embryonic tissues including muscle and cartilage structures. The zebrafish embryos (up to N=60 per dose group) treated with AVI-4126 during blastula stage of development did not show any teratogenic effect at any dose. Information obtained from such studies will be useful for further assessment of teratogenic potential of these antisense agents in more complicated whole animal models.

1373 A DEVELOPMENTAL NEUROTOXICITY STUDY OF PROPYLTHIOURACIL IN RATS.

G. D. Cappon, M. Bowen, K. Rhodes, C. Kopp and A. E. Radovsky. *WIL Research Laboratories, Inc., Ashland, OH.* Sponsor: D. G. Stump.

In humans, hypothyroidism causes irreversible mental retardation and various neuromotor disabilities. Propylthiouracil (PTU) administration to pregnant rats is a commonly used experimental model of human congenital hypothyroidism. The objective of this study was to evaluate the sensitivity of the experimental design described by U.S. EPA OPPTS Guideline 870.6300 (Developmental Neurotoxicity) to predict the adverse effects in rats of a known human developmental neurotoxicant. Propylthiouracil was administered at dosage levels of 3.8, 19 and 38 mg/kg/day by oral gavage once daily from gestation day 6 through lactation day 10. Offspring were evaluated by use of an observational battery and evaluated for motor activity, acoustic startle response and learning and memory in the Biel water maze. Live litter size was reduced in the 38 mg/kg/day group. Pup viability from birth to PND 4 was reduced in the 19 and 38 mg/kg/day groups. Pup weights were reduced by 10% at birth for all dosage levels, and remained reduced for the duration of the study. The observational battery demonstrated delays in pupillary response, startle reactivity, mobility and neuromuscular development on postanal day (PND) 20. Neuromuscular measures continued to be impaired at the PND 35 and 45 observations. Motor activity was not affected. Acoustic startle response was reduced at all dosage levels when evaluated on PND 22. When evaluated on PND 60, an augmented acoustic startle response was noted at all dosage levels. Latency to escape the Biel maze was increased for all dosage levels at the PND 22 evaluation; however, swimming ability was markedly reduced for all treatment groups. When assessed at PND 62 swimming ability was comparable between all groups. However, time to escape the Biel maze was increased for males and females at all dosage levels by approximately 60%; there was no dose response relationship. The experimental design used in this study is sensitive to the effects of PTU, a known developmental neurotoxicant.

1374 BRAIN MORPHOMETRY IN A DEVELOPMENTAL NEUROTOXICITY STUDY OF PROPYLTHIOURACIL.

A. E. Radovsky, J. T. Yarrington, G. D. Cappon, K. S. Regan and R. E. Wilson. *WIL Research Laboratories, Inc., Ashland, OH.* Sponsor: D. G. Stump.

Morphometric evaluation of the brains of postnatal day 11 rat pups from an oral gavage study of the developmental neurotoxicity of propylthiouracil in Sprague Dawley Crl:CD®(SD) IGS BR rats was done in accordance with OPPTS 870.6300. Linear measurements were made of 35 regions from 5 levels of the brain of 6 pups/sex from the vehicle (0.5% methylcellulose) control group and from the high dose group whose mothers had been given 38 mg/kg/day of propylthiouracil from gestation day 6 through lactation day 10, inclusively. Four coronal sections were made that included the cerebral cortex, basal ganglia, hippocampus, and the thalamus and midbrain. These levels corresponded to Plates 11, 14, 21, and 26; and the midsagittally-sectioned cerebellum and pons corresponded to Plate 44, of The Rat Brain by Paxinos & Watson (1982). Systematic computer-assisted (PAX-It, MIS, Inc., Franklin Park, IL) measurements were made from images acquired with an Optronics model S6067 digital camera at total magnifications of 10X, 16X, 25X, or 40X. Measurements included the lengths and widths of the most rostral hemisphere, the thalamus, and the cerebellum; the widths of the caudoputamen, fornix, and midbrain; and the thickness of the entire hippocampal formation; the thickness of the cortex at 12 defined sites; the hippocampal formation (height and length of the dentate hilus and of layers of pyramidal neurons); and specific cell layers (the external and internal granular cell layers of lobule 9 of the cerebellum; and the marginal zone and the most superficial neuronal layer of the cingulate cortex at the midline). Measurements that had more than 20% standard deviation in the control group were considered unreliable. A t-test gave a p-value of less than .05 for measurement means of the decreased thickness of the frontoparietal cortex in the brains of exposed male and female rat pups; the increased distance between the layers of pyramidal neurons of the hippocampus in exposed male pups; and the increased height of the dentate hilus and decreased thicknesses of the base of cerebellar lobule 9 and the pons in exposed female pups in comparison to the measurement means of controls. A subset of the 35 measurements was selected as sensitive and reliable for brain morphometry in developmental neurotoxicity studies.

1375 VALIDATION OF TEST PROCEDURES FOR A DEVELOPMENTAL NEUROTOXICITY SCREEN USING METHIMAZOLE.

L. P. Sheets, H. E. Hoss, R. G. Gilmore and S. G. Lake. *Bayer Corporation, Stilwell, KS.*

The U.S. EPA guideline for a developmental neurotoxicity study (OPPTS 870.6300) includes a standardized test battery (e.g., developmental landmarks, automated motor activity, auditory startle habituation, tests of associative learning and memory, and neuropathology, including brain measurements) that are administered at specific ages. This guideline requires that labs validate their test procedures by establishing test norms for the appropriate age groups, demonstrating competence in evaluating effects in neonatal animals perinatally exposed to chemicals, and providing positive control data that demonstrate the sensitivity of the procedures being used. The antithyroid drug methimazole has been recommended for use as a positive control for such a developmental test battery (Comer and Norton, 1982). This paper discusses the results of a study with methimazole that was conducted in accordance with these guideline requirements and discusses how those results contribute toward satisfying the aforementioned requirements. In this study, methimazole was administered in the drinking water (0 or 0.1 mg/ml) to pregnant female Wistar rats (25/dose group) on gestation day 16 through lactation day 10 (Comer and Norton, 1982). The offspring were then tested in accordance with OPPTS 870.6300, with additional measurements of circulating [T3 and T4] and thyroid morphology. This treatment produced a number of effects in male and female offspring, including an average 16% and 84% decrease in blood [T3] and [T4], respectively, a modest decrease in body weight, developmental delays, including delayed preputial separation and vaginal patency, effects on motor activity and startle response amplitude, and reductions in brain measurements. These results support the use of this treatment in validating the test procedures in this developmental test battery.

1376 EFFECTS OF 5-AZA-2-DEOXYCYTIDINE (D-AZA) ON REPRODUCTIVE CAPACITY AND POST-NATAL DEVELOPMENT OF CD-1 MICE.

F. J. Cisneros and S. Branch. *North Carolina State University, Department of Toxicology, Raleigh, NC.*

It has been reported that d-AZA induces DNA hypomethylation and can therefore alter gene expression. The embryonic developmental toxicity of d-AZA may be mediated by this mechanism. In addition, body weight gain and post-natal development is gene dependant. It has been shown that here is a correlation between reproductive ability and body weight. The objective of this study was to evaluate the effects of 5-aza-2'-deoxycytidine (d-AZA) on reproductive capacity and post-natal development of CD-1 mice. Pregnant CD-1 mice were administered 1.0 mg/kg of d-AZA at gestation day (GD) 10. Controls were left untreated. The mice were allowed to give birth. The body weights of the resulting F1 control and treated pups were recorded at three different times points (3, 5 and 6 months of age). To evaluate the reproductive capacity, 5 month old treated F1 males and females were mated with normal females and males (Groups 1 and 2, respectively). The control group consisted of mated control males and females (Group 3). Mating pairs were housed separately for four days and the presence of plugs were recorded (plug day designated as GD 0). At gestational day 17, pregnant females were killed. Dam, uterine, and litter weights were recorded. Fecundity and teratological data were also recorded. Our data suggest that body weight differences between treated and control parents are statistically significant and were more pronounced with increased age ($p>0.01$). There was a significant difference ($p>0.01$) in number of plugs and pregnancy rates between each group compared to controls. Ten percent of group 1 females had plugs, but no pregnancies were observed. 100% of group 2 females had plugs resulting in a 75% of pregnancy rate. Forty-five percent of group 3 females presented plugs resulting in a 18.18% pregnancy rate. The reproductive data obtained suggests that reproductive capacity of d-AZA treated males is more adversely affected than that of treated females. Detailed reproductive analyses are ongoing to better characterize the male reproductive toxicity of d-AZA.

1377 TOMUDEX-INDUCED MAMMALIAN DEVELOPMENTAL TOXICITY IS PREVENTED BY CO-TREATMENT WITH FOLINIC ACID.

J. E. Andrews, J. M. Rogers, H. P. Nichols, C. S. Lau and J. E. Schmidt. *US Environmental Protection Agency, Research Triangle Park, NC.*

The thymidylate synthase (TS) inhibitor, Tomudex (TM), is a structural analogue of folate. TS inhibition has been shown to result in impaired embryonic development. We evaluated the developmental toxicity of TM in a rodent whole embryo culture (WEC) system and tested the ability of folinic acid to rescue embryos from TM toxicity. Gestational day (GD) 9.5 rat embryos were cultured for 48 hours in the presence of 0, 50, 100, 150, 250, 350 or 500 ng TM/4ml culture medium(CM). Following culture, embryos were evaluated for growth and development. Embryos exposed to ≥150 ng TM had a concentration dependent increase in incidence of open neural tubes, rotational defects, eye defects and abnormal caudal appendages, and a concentration dependent decrease in developmental score. Significant embryo lethality was observed at concentrations ≥ 350 ng TM /4ml CM. Additional embryos were cultured with 0-1100 ng TM/4ml CM and co-treated with 10 μg folinic acid/4ml CM. At the end of 48 hours, embryos were evaluated as above. All TM exposed embryos co-treated with folinic acid developed similarly to control embryos. Folinic acid co-treatment completely prevented the occurrence of malformations resulting from exposure to TM. Folinic acid alone (10 μg folinic acid /4ml CM) had no impact on embryonic development. Preliminary studies have been conducted on GD 9.5 embryos cultured with 0-950 ng TM/4ml CM for 2 hours and then transferred to CM with no TM. At the end of 48 hours of culture, TM exposed embryos were evaluated and found to be indistinguishable from control embryos suggesting that embryos can recover from short term exposure to as much as 950 ng TM/4ml CM. These data suggest that TM is developmentally toxic to the midgestational embryo and that folinic acid can competitively inhibit TM toxicity.

1378 DEVELOPMENTAL TOXICITY OF AMINOPTERIN IN *DROSOPHILA*.

D. W. Lynch. *NIOSH, Experimental Toxicology Branch, Cincinnati, OH.*

To further characterize the *Drosophila*-based prescreen to detect developmental toxicants, aminopterin (4-aminofolic acid [APN]; CAS No. 54-62-6), was studied. APN, a documented developmental toxicant and teratogen, was formerly used clinically as an antineoplastic agent. APN inhibits dihydrofolate reductase preventing the formation of folinic acid and stopping one carbon metabolism needed for the synthesis of DNA in rapidly dividing cells. Initially, 7 APN concentrations ranging from 4 - 80 μg/vial were evaluated. In a second experiment, 6 concentrations ranging from 0.01 - 2 μg/vial were utilized to determine if a threshold of developmental toxicity could be observed. Each experiment included a concurrent control. *Drosophila* were exposed throughout development (egg through third instar larva) in culture vials to medium containing APN. Each vial contained 1g of powdered medium and 5ml of distilled deionized water or a solution of test chemical in water. A mated, untreated, Oregon-R wild-type female (Mid-American *Drosophila* Stock Center, Bowling Green State University, Ohio) was added to each vial and allowed to oviposit for 20 hours, then removed. Emerging offspring were collected over 10 days, and examined microscopically (25x) for bent humeral bristles and wing blade notches; morphological defects shown to occur with an increased incidence in flies exposed to developmental toxicants. In each experiment, the incidence of the two defects at each concentration was compared to the controls using chi-square. The incidence of wing blade notches was significantly increased (all $p< 0.001$) at 2 μg/vial, 17/138; 4 μg/vial, 20/170; 10 μg/vial, 25/96; 14.1 μg/vial, 9/81; 20 μg/vial 13/82; 28.3 μg/vial 9/43; 40 μg/vial 18/61; and at 80 μg/vial, 10/25. One wing blade notch was observed among 414 control flies. Bristle defects were not increased by APN. Mortality of the offspring was increased and the first day of emergence was delayed at the two highest APN concentrations. The results with APN parallel the developmental toxicity reported in mammals and replicate and expand published *Drosophila* data. These findings provide additional support for increased utilization of this assay as a prescreen for the detection of developmental toxicants.

1379 AMPHETAMINE-STIMULATED DOPAMINE (DA) RELEASE IN F_1 AND F_2 MALE RATS EXPOSED TO THE ESTROGENIC COMPOUND, GENISTEIN.

B. J. Gough[1], S. A. Ferguson[1], K. M. Flynn[1], K. B. Delclos[1] and R. R. Newbold[2]. [1]*National Center for Toxicological Research/FDA, Jefferson, AR* and [2]*NIEHS, Research Triangle Park, NC.*

Developmental steroid hormone treatment causes adverse effects; however, the potential effects of developmental exposure to endocrine disruptors such as the phytoestrogen genistein are relatively unknown. Because estradiol affects striatal DA release, it is plausible that genistein might have similar effects. Here, Sprague-Dawley rats (F_0 generation) were exposed to 0, 100, or 500 ppm genistein in a soy-free diet. Genistein treatment continued throughout the F_1 and F_2 generations. Between postnatal days (PND) 100-175, striatal microdialysis samples (DA, DOPAC, HVA, and 5-HIAA) were collected from awake males of the F_1 (n=10 for 0 ppm; n=9 for 500 ppm) and F_2 (n=7 for 0 ppm; n=4 for 100 ppm; n=7 for 500 ppm) generations for 2 hr at 20 min intervals. After the baseline period, 2 mg/kg d-amphetamine was injected ip and sample collection continued for the subsequent 3.7 hr. There were no statistically significant effects of genistein treatment on any measure. Results indicated that all rats responded similarly to amphetamine with increased DA levels, decreased DOPAC and HVA levels and only minor changes in 5-HIAA levels. These results would indicate that developmental/chronic genistein exposure has few effects on striatal DA release. (Supported by Interagency Agreement #224-93-001 between the FDA and the NIEHS.)

1380 TERATOGENIC EFFECTS OF VALPROIC ACID IN THE FETAX SYSTEM: SIMILARITIES TO EFFECTS OBSERVED IN HUMANS.

E. O'Brien, A. Prietz and D. R. Dietrich. *Environmental Toxicology, University of Konstanz, Konstanz, Germany.*

The vast number of new chemicals and pharmaceuticals which requiring safety evaluation and teratogenicity testing has lead to renewed interest from regulatory and industrial communities in the development and licensing of alternative *in vitro* teratogenesis assays. The FETAX assay has a number of advantages to offer in this respect. It is a high-throughput, rapid assay system (96h), allowing large numbers of samples to be screened for morphological, histological and biochemical effects. The assay in-corporates all the major stages of embryonic development. Since development occurs ex utero very specific interventions are possible. The relevance of the assay with regard to the detection of compounds teratogenic to mammals, specifically humans, may, however, be questioned due to species differences. Therefore, further investigation of this testing system requires using several known mammalian teratogens and non-teratogens in addition to the comparison of the results with published human epidemio-logical studies. One good candidate for such an investiga-

tion is valproic acid (VPA), a well characterized human teratogen inducing spina bifida as well as craniofacial and cardiac malformations in humans and laboratory species following *in utero* exposure of the embryos. Following standard range-finding experiments, stage 8-11 X enopus laevis embryos were selected and exposed to mM concentrations of VPA (corresponding to serum therapeutic VPA levels in epilepsy treatment) for 96h, i.e., in accordance with the ASTM standard static renewal protocol. Embryos were fixed and mortality, malformation and growth inhibition were assessed. Dose-response curves for mortality and malformation were steep. LC50 and LC100 values of 0.27 mM and 0.4 mM respectively were noted and VPA-exposed embryos displayed a specific and reproducible craniofacial narrowing (EC50 0.15 mM). Embryo death at concentrations of *0.3 mM was preceded by axial malformations and pronounced cardiac edema. Embryos surviving exposure to 0.5 mM VPA displayed severe notochord anomalies, cardiac edema and microcephaly, which closely mimic the malformations characteristic in human valproate syndrome.

1381 ASSESSMENT OF THE EFFECTS OF PEGVISOMANT ADMINISTERED SUBCUTANEOUSLY ON EMBRYO-FETAL DEVELOPMENT, FERTILITY AND IGF-I CONCENTRATIONS IN RABBITS.

P. Frank[1], D. G. Stump[2], T. Kern[2] and R. J. Davis[3]. [1]*Patricia Frank & Associates, Evanston, IL,* [2]*WIL Research Laboratories, Inc., Ashland, OH and* [3]*Sensus Drug Development Corp., Austin, TX.*

Pegvisomant is an injectable recombinant human growth hormone receptor antagonist for treatment of acromegaly. Pegvisomant reversibly binds to the human growth hormone receptor leading to a block of signal transduction and to a reduction in circulating insulin-like growth factor I (IGF-I). In a preliminary study, nonpregnant rabbits were administered subcutaneous (sc) injections of 3 mg/kg/day pegvisomant for three consecutive days. Two hours following the third dose, the mean serum IGF-I concentration was reduced 55% relative to the control group value. In a dose range-finding study in pregnant rabbits administered sc injections of pegvisomant at 0.3, 1, 3 and 10 mg/kg/day from gestation days (GD) 7-20, the mean serum IGF-I concentration in the 10 mg/kg/day group was reduced by 48% compared to the control group value two hours following dosing on GD 20, and mean serum growth hormone concentrations were increased 71 and 830% in the 3 and 10 mg/kg/day groups, respectively. These results demonstrated that pegvisomant is able to produce a pharmacologic effect in rabbits at 3 and 10 mg/kg/day. In a definitive embryo-fetal development study in rabbits administered pegvisomant sc at 1, 3 and 10 mg/kg/day from GD 7-20, no maternal or developmental toxicity was observed. In a study of the effects of pegvisomant on early embryonic development in rabbits following sc injection at 1, 3 and 10 mg/kg/day from GD 0-7, postimplantation loss was increased in the 10 mg/kg/day group (33.0% compared to 21.3% in the control group). No other embryo toxicity and no maternal toxicity were observed. Because the therapeutic intent of pegvisomant is to return IGF-I concentrations to normal in individuals with elevated IGF-I concentrations, the failure to sustain pregnancy in the 10 mg/kg/day group at a dose that has been demonstrated to reduce rabbit IGF-I concentrations below normal may not be indicative of results in humans under therapeutic conditions. To our knowledge, this is the first report of IGF-I concentrations in pregnant rabbits.

1382 STREPTOZOCIN TREATED DAMS:F_1 GESTATIONAL THROUGH POST-LACTATIONAL EXPOSURE TO CADMIUM CHLORIDE.

B. A. Gentles, K. Burge and E. E. Smith. *Texas Tech University, Lubbock, TX.*

Depending on the route and duration of exposure, cadmium can induce toxicity in several tissues including the lung, liver, kidney and gonads. Mature female nulliparous rats were exposed to $CdCl_2$ in drinking water two weeks after a single IP injection of streptozocin (SZ), and bred to non-treated males. Cadmium exposure in the F_1 pups, continued through post-lactation to postnatal day (PND) 45. At PND 45 F_1 animals were euthanized, plasma and selected organs were collected weighed and quickly frozen or placed in formalin for histological analysis. Cadmium chloride at 200μM significantly reduced the body weight and spleen weight of pups from SZ treated dams. At 100 μM $CdCl_2$ increased the heart weight and spleen while it decreased weight of the pancreas of pups of SZ treated dams. The lung, kidney, and testis weights of pups in this treatment group were similar to the control. Only the weight of the pancreas of pups from SZ-alone treated dams was found to be significantly less than the control. The data indicate that gestational, lactational and post-lactational exposure to the diabetogenic streptozocin and cadmium results in signs of general toxicity at PND 45. Further evaluation is required to determine the long-term reproductive and developmental implication at the cellular and molecular level.

1383 GENETIC DIFFERENCES IN SENSITIVITY TO ETHANOL TERATOGENESIS IN ZEBRA FISH.

M. J. Carvan, III and D. W. Nebert. *Center for Environmental Genetics and Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.*

Fetal Alcohol Syndrome (FAS) is a constellation of congenital anomalies seen in some newborns of alcoholic women that is characterized by prenatal and postnatal failure-to-thrive, central nervous system disorders, and a distinctive set of patterning defects that affect the cardiovascular system, facial structures and limbs. Data from clinical twin studies and animal models argue strongly for a robust genetic component to FAS. The long-range goal of this project is to elucidate the molecular mechanisms by which ethanol perturbs embryonic and fetal development and to identify genes that play a role in sensitivity to ethanol-induced teratogenesis. We first examined ethanol teratogenesis by exposing eight genetically-isolated lines of zebrafish to a series of ethanol concentrations. Indeed, these lines displayed striking variability in their sensitivity to the embryolethal effects of ethanol, the LD50 ranging between 17 and 240 mM. We also analyzed ethanol-induced growth retardation effects by measuring embryo length 6 days post-fertilization; ethanol delayed the growth in both the sensitive and resistant lines, but with a greater reduction of mean length in the sensitive lines. These data are consistent with a genetic basis for ethanol sensitivity. These preliminary results also suggest that the zebrafish, which develops outside the mother, might offer an excellent model system for studying directly the contribution of fetal genes to ethanol-induced teratogenesis. The zebrafish vertebrate model system has proven to be very powerful for the purpose of identifying genes that play a role in specific physiological and developmental events. Comparing ethanol-sensitive and -resistant zebrafish will elucidate the genetic and molecular mechanisms behind the sensitivity of vertebrate embryos to alcohol toxicity, and may apply directly to alcohol sensitivity in humans. (Supported in part by NIH Grants RO1 ES07058 and P30 ES06096.)

1384 COMPARISON OF AUDITORY STARTLE REFLEX AND MOTOR ACTIVITY IN RATS DOSED WITH AMPHETAMINE AND CHLORPROMAZINE.

H. M. O'Meara and M. Watson. *Ricerca, Inc., Painesville, OH.*

As part of the Environmental Protection Agency's developmental neurotoxicity study, Health Effects Test Guidelines OPPTS 870.6300, positive control data are required to demonstrate the sensitivity of the procedure being used. Two of the tests required by this guideline are assessment of motor activity and auditory startle reflex. As part of a positive control validation study, groups of 4 male and 4 female Sprague Dawley rats were injected intraperitoneally (1 ml/kg) with amphetamine (1 mg/kg) or chlorpromazine (6mg/kg). An additional group was dosed with saline (1 ml/kg) to serve as controls. Approximately 30-60 minutes post-dose, each animal's activity was monitored in an Opto-Varimex motor activity box over a fifteen minute testing period. Results showed an increase in animal activity for amphetamine and a decrease for chlorpromazine as expected. The study was repeated with the exception that animals were placed in sound-attenuated chambers to measure habituation of the startle reflex response. Animals were acclimated for 5 minutes and then presented with 20 msec, 120 dB burst of noise at 8 second intervals for 50 trials. The peak amplitude of the response and latency to startle was averaged over 5 blocks of 10 trials. A decrease was noted in the startle amplitude for chlorpromazine, but the latency to startle for chlorpromazine and amphetamine and the startle response for amphetamine were similar to the saline control group. Amphetamine and Chlorpromazine would appear to be suitable positive control agents for motor activity testing, but not appropriate for positive control testing in the startle reflex system.

1385 CHARACTERIZATION OF URINARY METABOLITES OF [1, 2, 3-^{13}C] ACRYLAMIDE IN MALE F-344 RATS FOLLOWING DERMAL APPLICATION OR IP INJECTION.

M. Friedman[1], S. J. Sumner[2], C. Williams[2] and T. R. Fennell[2]. [1]*UMDNJ, Netwark, NJ and* [2]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Acrylamide(AM) is used in the manufacture of polymers and is a known neurological toxicant. Glycidamide (GA), an epoxide metabolite of AM, is a known mutagen. In this study the metabolism of AM was evaluated following intraperitoneal (ip) and dermal routes of administration. Male F344 rats were administered a 47 mg/kg ip dose or a 138 mg/kg dermal application of [1, 2, 3-^{13}C]AM. Urine was collected for 24 hr. Signals in the ^{13}C -NMR spectra of urine were assigned to previously identified AM-derived metabolites. Assignments included metabolites derived from direct AM conjugation with glutathione (AM-GSH)and metabolites derived following conversion of AM to GA. Following ip administration of [^{13}C]AM to F344 rats, ~62% of the dose was excreted in the urine. AM-GSH were excreted in the highest concentration (~69% of excreted metabolites). Similar results were previously obtained in our laboratory following a 50 mg/kg gavage administration to F344 rats. In both the ip and gavage studies, the remainder of the excreted metabolites (~30%) were derived following conversion of AM to GA. A small fraction of the applied dose was excreted in the urine (~1.5%) following dermal application of [^{13}C]AM, indicating that AM did not rapidly penetrate the skin. For dermal application, the AM-GSH deried metabolites accounted for ~52% of the excreted urinary metabolites, while GA-derived metabolites accounted for the remainder (48%). These data are important for development and validation of physiological-based pharmacokinetic models for AM. (This study was funded by the Acrylamide Monomer Producers Association.)

1386 GESTATIONAL THROUGH POST-LACTATIONAL EXPOSURE OF AMMONIUM PERCHLORATE TO DEER MICE (*PEROMYSCUS MANICULATUS*).

E. H. Roots, K. A. Thuett, B. A. Gentles, R. J. Kendall and E. E. Smith. *Texas Tech University, Lubbock, TX.*

Ammonium Perchlorate (AP) has recently been recognized as a pervasive and lingering water contaminant. AP is known to inhibit iodide uptake in the thyroid. AP's biological effects were evaluated in deer mice, a sentinel wildlife species. Ten mated pairs per dose group were exposed to AP in drinking water (1nM, 1microM, 1mM and control), starting at cohabitation and continuing through post-lactation. The first litters (F1a) were examined for differences in body weight, water consumption, survival indices, time of cohabitation to parturition and litter size. Body weights were observed at postnatal day (PND) 1, 5 and every 5 days thereafter up to PND 70. Body weights on PND 1 were not significantly different. PND 5 were found to differ significantly between the 1mM and control groups. The 1mM treatment group was significantly different from the control for all observation days excluding PND 15. It is interesting to note that body weights appeared dose-dependent. The F1a body weights indicate that growth and development may be affected by AP exposure. There was no significant difference for water consumption or survival indices for postnatal days 1, 5, 10 and 20. The mean number of days for cohabitation to parturition showed a dose-dependent change (control=30 days; treatment groups ranged from 31-38). In addition, while there was 100% conception in the control group, there was a 10% reduction in the treatment groups. These preliminary data indicate that AP dosage does appear to affect impregnation or ability to maintain pregnancy. However, litter size did not show significance among dose groups. Furthermore, in preliminary behavioral observations, it appears that treatment groups exposed to higher concentrations of AP are less active. The views and conclusions contained herein are those of the authors and should not be interpreted as necessarily representing the official policies or endorsements, either expressed or implied, of the 311 HSW/IERA or the U.S. Government.

1387 DEVELOPMENTAL TOXICITY OF AMMONIUM PERCHLORATE ADMINISTERED ORALLY IN DRINKING WATER TO DEER MICE (*PEROMYSCUS MANICULATUS*).

K. A. Thuett, E. H. Roots, B. A. Gentles, R. J. Kendall and E. E. Smith. *Texas Tech University, Lubbock, TX.*

Ammonium perchlorate (AP) is manufactured for use as an oxidizer in solid fuel propellant for rockets, missiles, and fireworks. Environmental concerns include contamination of surface and ground water, and its ability to affect the thyroid gland, which may affect growth and development. In this study, male and female deer mice (10 pair per treatment group) were given continual access to control, 1nM, 1microM, or 1mM AP dissolved in drinking water, from the first day of cohabitation. Body weights of second litter ($F2_b$) pups were recorded beginning on day 1 and taken every 5 days thereafter. Pups were then weaned and necropsied at post-natal day (PND) 21. Gonads, kidneys, adrenals, liver, and heart were collected and evaluated for indication of general toxicity. Selected organs were fixed and processed for histopathology, which is in progress. Body weights and weights for ovaries, testes, and adrenals showed no significant difference between treatment groups. Kidney ($p=0.0001$), liver ($p=0.0001$), and heart ($p=0.0020$) weights, all showed significant differences between treatment groups. Mean kidney weight (0.1389 g) of the 1mM group was higher than that of the control (0.1209 g), while the 1microM group weight (0.0995 g) was lower than controls. The mean liver weight (0.4775 g) of the 1mM group was higher than that of the control (0.3964 g), while the 1microM group weight (0.3112 g,) was lower than controls. The same pattern occurred for the heart with the 1mM group weight (0.0713 g) being higher, and the 1microM group weight (0.0562 g) being lower than control (0.0704 g). The lack of significance in body weight, in contrast to the significance seen in organ weights, indicates that AP effects may be due to organ-specific developmental toxicity. Based on the preliminary data, further developmental toxicological characterization of *in utero* and lactational exposure to AP is needed to fully determine a dose-dependent response. (This research was supported in part by the U.S. Department of Defense, through the Strategic Environmental Research and Development Program (SERDP) under a Cooperative Agreement with the USAF, Institute for Environment, Safety, and Occupational Health, Brooks AFB, TX.)

1388 POSTNATALLY ADMINISTERED α-DIFLUOROMETHYLORNITHINE (DFMO) HAS MINIMAL EFFECTS ON SPATIAL LEARNING AND MEMORY IN ADULT RATS.

A. M. Cada and S. A. Ferguson. *National Center for Toxicological Research/FDA, Jefferson, AR.* Sponsor: W. Slikker.

Postnatal treatment with α-difluoromethylornithine (DFMO), a potent inhibitor of ornithine decarboxylase, has been shown to stunt growth measures such as body and brain weight, eye opening, and fur growth in rats and delay development of complex integrated behaviors such as swimming ontogeny when given from birth to weaning (20-21 days). Shorter courses of treatment (e.g., PND 5-10) affect growth measures to a lesser degree (cerebellar stunting and delay of eye opening) but do not alter various reflex, motor coordination or spontaneous activity indices measured up to postnatal day 28 (Cada et al., in press). In the present study, 29 Sprague-Dawley litters (4 female, 4 male each) were injected subcutaneously with 500 mg/kg DFMO or saline vehicle daily on postnatal days 5-12. Measures of spatial learning and memory were conducted in adulthood: complex maze for water reward on postnatal days 71-75 and Morris water maze on postnatal days 93-96. DFMO treatment did not significantly affect learning or retention in the complex maze. Number of rewards earned increased across the five days of testing in both treated and control groups. In the Morris water maze, males were more accurate and swam faster irrespective of treatment group. DFMO treatment did not affect measures of accuracy, speed, distance or proximity. Improvement across days was seen on latency, path length, and proximity measures for both groups. These results indicate that multiple measures of spatial learning and memory are not affected by early postnatal DFMO treatment.

1389 EVALUATION OF RAT EPIDIDYMAL SPERM MOTION PARAMETERS GENERATED BY THE HAMILTON-THORNE SPERM ANALYZER (IVOS) FOR USE IN TOXICOLOGICAL ASSESSMENT.

M. Horimoto[1], S. Ito[2] and M. Kato[3]. [1]*Pfizer Pharmaceuticals Inc., Taketoyo, Japan,* [2]*Yamanouchi Pharmaceutical Co. Ltd., Tokyo, Japan and* [3]*Nihon Bioresearch Inc., Hashima, Japan.* Sponsor: M. S. Tassinari.

To determine which parameters provide utility in toxicological assessment for male reproductive function, a collaborative working group evaluated epididymal sperm motion using the Hamilton-Thorne Sperm analyzer (IVOS). Male rats were treated with 6 known toxicants, adriamycin (ADM), α-chlorohydrin (ACH), ethylene glycol monoethyl ether (EGEE), 2,5-hexandione (2,5-HD), ornidazole (OZ) and sulfasalazine (SASP). The males were evaluated for body weight, testicular and epididymal weight, epididymal sperm count, sperm motion and fertility outcome. The sperm motion parameters included percentage of motile sperm (total motility), percentage of progressively motile sperm (progressive motility), curvilinear velocity (VCL), average path

velocity (VAP), straight line velocity (VSL), amplitude of lateral head displacement (ALH), beat cross frequency (BCF), linearity (LIN) and straightness (STR). Decreases in testicular and epididymal weights were observed in the ADM, EGEE and OZ studies. Impaired fertility of the males treated with ACH, EGEE, SASP and OZ was indicated by decreases in pregnancy index, number of implantation sites and/or number of live fetuses. For all toxicants, abnormal epididymal sperm motion was detected at the lowest observed effect level by the IVOS parameters. Progressive motility was consistently reduced and the most sensitive parameter for all toxicants. Velocity parameters (VAP, VSL, VCL) responded sensitively to abnormal sperm motion for all toxicants except EGEE. In conclusion, among the parameters generated by the IVOS, progressive motility and velocities are considered to be sensitive and valuable parameters for detecting adverse effects on sperm motion and should be considered for inclusion in analyses of sperm function.

1390 MATERNAL IMMUNOSTIMULATION AND PREVENTION OF TERATOGENESIS.

R. M. Gogal, L. V. Sharova, P. Sura, M. R. Prater and S. D. Holladay. *Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA.*

Activation of the maternal immune system during early gestation via exogenous, non-specific immunostimulants has been reported to protect against certain fetal defects (i.e., resorption, cleft palate, digit and tail anomalies). The mechanism(s) behind such protection remain unclear. In this study, female C57Bl/6 and ICR mice were pre-treated with immunostimulants from two weeks prior to mating up to day 3 of gestation. Urethane, a known teratogen and immunotoxicant, was then administered at various time points during gestation. The maternal thymus and spleen were evaluated for changes in organ weight, cellularity, leukocyte subpopulation differentials, apoptosis, and cell proliferation. These data were then compared to fetal outcome in respective litters. Immune stimulation did not affect the maternal thymic effects of urethane. Further, no changes in maternal thymic or splenic T-cell profiles were detected which correlated with reduced teratology in litters from immunostimulated mothers. Adrenal weights were unchanged for all treatment groups suggesting no significant corticosteroid involvement. Immunostimulation increased the percentage of macrophages in the maternal spleen. (Supported by NIH RO1-ES 09642-01.)

1391 GLUCOSE-DEPENDENT EXPRESSION OF EXTRACELLULAR MATRIX PROTEINS IN EMBRYONIC MOUSE HEART.

J. Joyner and I. W. Smoak. *North Carolina State University College of Veterinary Medicine, Raleigh, NC.*

Glucose is critical to the organogenesis-stage embryo and its excess or deficiency interferes with normal development. The early embryonic heart depends on glucose and glycolysis and is particularly sensitive to glucose availability. Elevated glucose produces increased synthesis of extracellular matrix (ECM) proteins in adult cells, including renal and endothelial, and may contribute to diabetic complications. The relationship between glycemic exposure and ECM proteins was therefore examined in the embryonic heart. CD-1 mouse embryos were exposed on gd 9.5 (plug = gd 0.5) for 24 hr in whole-embryo culture (WEC) to 40 mg/dl glucose (hypoglycemia), 150 mg/dl glucose (normoglycemia), or 600 mg/dl glucose (hyperglycemia). Embryos were fixed, embedded in paraffin, and sectioned at 5μm. Sections were evaluated by immunohistochemistry (IHC) using a rat monoclocal antibody for laminin (Lam) and a goat polyclonal antibody for fibronectin (FN). Hearts were isolated from embryos and pooled, sonicated, and 5μg resolved and evaluated for FN by SDS-PAGE/Western analysis. Results of IHC studies demonstrated strong expression of both Lam and FN in the embryonic heart, which appeared to increase with increasing level of glycemic exposure. Similarly, FN level, as detected by SDS-PAGE/Western analysis, was low in hearts after embryonic exposure to hypoglycemia, moderate after normoglycemia, and highest after hyperglycemia. Thus, glucose excess appears to increase ECM protein expression in embryonic heart as in other tissues. The underlying mechanism is still under investigation.

1392 A STUDY OF VEHICLES FOR DOSING CULTURED RODENT EMBRYOS WITH NON-AQUEOUS SOLUBLE COMPOUNDS.

K. A. Augustine[1], Q. Zhang[1] and M. J. Welsh[2]. [1]*SmithKline Beecham Pharmaceuticals, King of Prussia, PA and* [2]*University of Michigan, Ann Arbor, MI.*

Rodent whole embryo culture is a valuable approach for studying compound-induced teratogenicity during early organogenesis. Finding vehicles for non aqueous-soluble compounds has been problematic due to developmental toxicity associated with many solvents, including dimethylsulfoxide (DMSO) and ethanol. The purpose of this study was to identify alternative vehicles for non-water soluble compounds. We tested carrier solutions containing bovine serum albumin (BSA) and glycerol as well as the solvents, formamide, dimethylformamide, DMSO and two fractions of DMSO. Based upon the fact that DMSO has a higher freezing point than its degradation products, parent DMSO was fractionated from these products by freezing point differences. Our results indicate that at dose concentrations of 0.08% and 0.04%, respectively, the BSA carrier solution and the solvents, formamide, dimethylformamide and low freezing point fraction of DMSO (lofp-DMSO) exhibited no significant toxicity when compared to untreated cultured rat embryos. All-trans retinoic acid (RA), a non-aqueous soluble compound and potent teratogen, was diluted in the various solutions and a dose response study was undertaken in embryo culture to determine the delivery efficiency of the vehicle. Varying degrees of RA embryopathy were observed at different dose ranges when RA was diluted in the different vehicles. Although RA completely solubilized in DMSO and DMF, RA solubilized in DMSO produced a higher incidence of embryolethality at 1uM and a greater severity in malformations at the 0.1μM dose, indicating that DMSO may enhance teratogenicity. RA suspended in the glycerol carrier solution produced malformations at the 1 and 10 μM dose, whereas when suspended in the BSA carrier solution, RA produced malformations only at the high dose. These results suggest that the carrier solutions had varying influences on RA toxicity. Based upon these studies, we suggest that dimethylformamide and formamide, at 0.04% dose concentrations, are non-embryo-toxic and may serve as good alternative vehicles for the delivery of non-water soluble compounds in rodent whole embryo culture.

1393 THE EFFECT OF TIME OF CESAREAN SECTION ON FETAL BODY WEIGHTS IN RATS ON DEVELOPMENTAL TOXICITY STUDIES.

D. E. Rodwell. *Huntingdon Life Sciences, East Millstone, NJ.*

Cesarean sections in rat developmental toxicity studies are generally performed on Gestation Day 20 and, depending on the facility, can be performed between 0800-1700 hrs. The effects of litter size on individual fetal weights has been well documented, however, the effects of time of cesarean section on individual fetal body weights have not been appropriately examined. In order to examine time related effects on fetal body weights at cesarean section, forty-two time-mated Sprague-Dawley IGS rats were received on Gestation Day (GD) 2 and cesarean section were performed on GD 20. On GD 20, female rats received a cesarean section during three intervals: 0800-0900 hrs. (Group I), 1130-1230 hrs. (Group II) and 1500-1600 hrs. (Group III). Mean litter size was unaffected by the time of cesarean section. Mean litter sizes for Groups I, II, and III were 12.8, 11.7, and 12.6, respectively. A significant increase in fetal body weight for Groups II and III was observed when compared to Group I. The mean fetal body weights for the combined sexes (male and female) for Groups I, II, and III were 3.8, 4.2 and 4.5 grams, respectively. Fetuses in this study exhibited an increase in body weight of approximately 0.1 grams per hour on Gestation Day 20. In addition, there was a greater incidence of decreased ossification of the 5 and/or 6 sternebra (e) unossified in fetuses when cesarean sections were performed between 0800-0900 hrs on Gestation Day 20. Based on these results, it is imperative that cesarean sections be performed at the same time each day, in as short a period of time as possible. More importantly, equal numbers of dams from each group should be cesarean sectioned during the same time interval to reduce variations in fetal body weights.

1394 COMPUTATIONAL EVALUATION OF HAZARDOUS AIR POLLUTANTS FOR DEVELOPMENTAL TOXICITY USING A STRUCTURE ACTIVITY APPROACH.

O. T. Macina[1], N. B. Sussman[1], S. G. Grant[1], C. A. Thomas[1], D. R. Mattison[1], T. Woodruff[2], J. Caldwell[2] and R. Smith[2]. [1]*University of Pittsburgh, Pittsburgh, PA and* [2]*USEPA, Research Triangle Park, NC.*

Birth defects cause significant infant mortality and morbidity, resulting in great emotional and economic burden in the United States as well as in the rest of the world. In the United States alone, during 1993, developmental abnormalities were the underlying cause of death for 21.3% of infants less than one year of age. There is concern that exposure to air pollutants may effect the integrity of human health within industrialized countries. The United States Environmental Protection Agency's list of Hazardous Air Pollutants were screened against Structure Activity Relationship models derived from a machine learning algorithm for predictions regarding risk of human developmental toxicity. Multiple random sampling was employed in order to derive 10 structurally based models which were utilized to screen individual and representative mixture Hazardous Air Pollutants. The results of the computational screen were pooled in the form of a cumulative index (indicating high, moderate, and low potential) and evaluated according to their level of confidence. Air pollutants such as 2-acetylaminofluorene, 4-aminobiphenyl, biphenyl, 4-nitrobiphenyl, 3,3'-dimethylbenzidine, and 3,3'-dichlorobiphenyl have been identified by the structural models to pose a high risk to the developing human fetus. An additional screen against a mutagenicity data base has identified additional compounds that may be suspect due to their genotoxic risk.

1395 APPLICATION OF CLONAL GROWTH MODELS TO CANCER RISK ASSESSMENT.

R. B. Conolly and F. Miller. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

The 2-stage clonal growth model, a mechanistically-motivated model for cancer dose-response assessment, offers significant theoretical advantages over alternatives such as the linearized multistage model (LMS) or the low dose linear extrapolation approach proposed under the US EPA's new Guidelines for Carcinogen Risk Assessment. These advantages include a model structure that incorporates rates of cellular death, division and mutation in a manner consistent with the generally accepted pathway by which critical mutations accumulate and clinically detectable tumors are formed. The main focus of the symposium will be on a new cancer risk assessment for formaldehyde based on a clonal growth model. The historical development of quantitative models for cancer risk assessment, including the multistage and LMS models and the 2-stage clonal growth model will be presented. The key technical features of the new formaldehyde assessment, including advanced dosimetry modeling, identification of target cell populations, and incorporation of mode of action information will be covered. Finally, the issues that regulatory agencies such as the US EPA must consider in deciding when a new cancer risk assessment, such as the formaldehyde assessment, is appropriate for use in regulatory activities will be discussed.

1396 MULTISTAGE CANCER MODELS AND QUANTITATIVE ASSESSMENT.

S. H. Moolgavkar. *Fred Hutchinson Cancer Research Center Biostatistics, Seattle, WA.* Sponsor: R. B. Conolly.

A historical survey of stochastic models of carcinogenesis will be given and the use of these models for risk assessment discussed. The first multistage models were proposed in the 1950s to explain the regularity of the age-specific incidence curves of common human carcinomas. The current default procedure for quantitative risk assessment is the linearized multistage procedure, which is based on an early model proposed by Armitage and Doll. This procedure makes a number of approximations that will be discussed in non-technical terms. These approximations are not valid when tumor probabilities are high as in experimental studies. The Armitage-Doll model did not consider cell proliferation kinetics. Models explicitly incorporating cell proliferation kinetics were introduced in the 1970s. These models, the best known of which is the two-stage clonal expansion model, can be used to investigate the effects of both genotoxic and non-genotoxic carcinogens. The use of these clonal growth models for risk assessment will be discussed and illustrated by means of an example. This example will set the stage for the discussion of the formaldehyde risk assessment to follow.

1397 REGIONAL DOSIMETRY OF FORMALDEHYDE IN RAT AND RHESUS MONKEY NASAL PASSAGES AND HUMAN RESPIRATORY TRACT.

J. S. Kimbell, R. Subramaniam, P. M. Schlosser, E. A. Gross, R. B. Conolly and K. T. Morgan. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Rates of cell death, division, and mutation are determinants of tumor incidence and are affected by formaldehyde in a dose-dependent manner. Exposure of tissue lining the respiratory tract to inhaled formaldehyde varies by location and these site-specific patterns vary among species. Formaldehyde-induced lesions observed at the carina of the rhesus monkey lower respiratory tract (LRT) suggested that both the upper respiratory tract (URT) and LRT might be at risk in humans. Regional uptake in rat and monkey nasal passages and in the entire human respiratory tract was needed for a new human health cancer risk assessment using a clonal growth model. Three-dimensional computational fluid dynamics (CFD) models of inspiratory nasal airflow and uptake in the rat, rhesus monkey, and human, and a typical-path model of uptake in the human URT and LRT incorporating oronasal and cyclic breathing were developed. Local formaldehyde flux (mass/area/time) was estimated for activity patterns of breathing rates in humans using both CFD and typical-path models. The amount of surface area affected by specific ranges of flux (flux intervals or "bins") was estimated. The rat nasal surface area was partitioned into 20 flux bins while 45 bins were used for the entire human respiratory tract. Sensitivity analyses showed that cancer risk predicted by the clonal growth model was sensitive to the number of flux bins but did not change when more than 20 or 45 bins were used for the rat nose and human respiratory tract, respectively. The use of anatomically-accurate CFD models and a human typical-path model accounts for interspecies differences in inspiratory airflow and formaldehyde uptake patterns and thus contributes to a reduction in uncertainty in cancer risk estimates. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.)

1398 NEED FOR IDENTIFICATION OF TARGET CELL POPULATIONS WHEN DEVELOPING CLONAL GROWTH MODELS OF CARCINOGENICITY.

F. J. Miller. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Independent of the number of mutational stages included in a clonal growth model of a carcinogenic process, identifying the target cells of interest is a critical aspect of model development. Most investigators determine the cell division rate (α) based on the fraction of cells labeled (LI) in the organ of interest over the time interval (t) during which the cells were exposed to the label. This approach assumes that all the cells are capable of entering into the initiated pool and does not take into account the fact that only a fraction (f) of the cells are not terminally differentiated. Thus, f affects the calculated cell division rate since $\alpha=(2t)^{-1} \ln(1-LI/f)^{-1}$, where ln stands for natural logarithm. More accurate knowledge of the number of cells at risk means that the statistical estimation of other parameter values will also be more accurate. Since the fraction of terminally differentiated cells can vary between animals and humans, incorporating data on the number of cells at risk will tend to increase the accuracy of a clonal growth model and decrease the level of uncertainty associated with risk estimates derived from the model. Determining the fraction of cells at risk is not necessarily a straightforward task. If the clonal growth model has dose-response information for specific locations, such as for particular anatomical regions in the nose or airway generations in the lower respiratory tract built into it, then this level of resolution must also be determined for the cells at risk. In addition, anatomical and morphometric data must typically be synthesized from a number of sources to calculate the fraction or number of cells at risk. The kind of data and types of calculations needed to account for cells at risk in a clonal growth model of carcinogenesis will be illustrated for formaldehyde carcinogenicity in the respiratory tracts of rats and humans.

1399 FORMALDEHYDE CANCER DOSE-RESPONSE ASSESSMENT USING A 2-STAGE CLONAL GROWTH MODEL.

R. B. Conolly. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Two modes of action, direct mutagenicity and cytotoxicity/regenerative cellular proliferation (RCP), have been implicated in the carcinogenicity of

formaldehyde in rat nasal epithelium. The biologically-motivated, two-stage clonal growth model readily incorporates data on these modes of action and thereby facilitates reduction of uncertainty in cancer risk assessment through increased used of relevant mechanistic data. Dose-response data on DNA-protein cross-links (DPX), representing direct mutagenicity, and on RCP were used to define effects of formaldehyde on parameters of the clonal growth model. The dose-response for DPX is linear in the low dose region, below about 1 ppm, and supralinear at higher concentrations. The dose-response for RCP is U-shaped, below control at 0.7 and 2 ppm and above control at 6, 10 and 15 ppm. However, since the U-shape was not significantly different from a hockey stick-shaped curve, cancer risk predictions were developed using both dose-response shapes for RCP. With U-shaped RCP, no additional human cancer risk was predicted below 1 ppm. This result, obtained in the presence of the low-dose linear, directly mutagenic effect mediated by DPX, illustrates the strong influence of cell kinetics in clonal growth models. Using hockey stick-shaped RCP, 40-year occupational exposure starting at age 18, 8 hr/day, 5 days week, to 0.1 or 1.0 ppm with a continuous 80 year lifetime background environmental exposure level of 4 ppb, human additional risks were predicted to be $2x10^{-8}$ and $1x10^{-5}$, respectively. The model predicts considerably lower risks than previous formaldehyde cancer risk assessments, which is consistent with the greater use of conservative default assumptions in the previous assessments and the use of more mechanistic data in the current assessment. This work also illustrates the pivotal role of dose response data for RCP in cancer risk assessments using clonal growth models.

1400 RISK ASSESSMENT WITH MECHANISTIC MODELS: ISSUES FOR ACCEPTANCE IN REGULATORY APPLICATIONS.

A. M. Jarabek. *National Center for Enviromental Assessment, Research Triangle Park, NC.* Sponsor: F. J. Miller.

To keep contemporary with the evolving science of toxicology, various U.S. EPA guidance expands the role of mechanistic data in risk assessment. Emphasis is placed on evaluating the mode of action (MOA) for a chemical, defined as its influence on molecular, cellular and physiological functions. "Precursor lesions" may be more accessible data to obtain, as well as more proximate to the relevant exposure than historical outcomes such as tumors, but establishing their biologic linkage requires integration of data based on different levels of organization (e.g., cellular to population) and incorporation of all relevant mechanistic data on dosimetry, toxicant-target interactions, and responses. Effective application of these principles requires new approaches that are outside routine testing paradigms and aimed at elucidating MOA through hypothesis-generated research and modeling. Refining future risk assessment lies in providing a framework to formalize an understanding of the reduced uncertainty due to the increase in accuracy of the MOA description, versus historical approaches that are presumed to be protective (conservative) when essential MOA elements are unknown. Attributes of the formaldehyde clonal growth model approach will be contrasted with historical default assumptions to illustrate challenging issues between development of MOA data and its acceptance in risk assessment applications.

1401 MOLECULAR APPROACHES TO STUDIES OF GLUTATHIONE METABOLISM AND FUNCTION.

C. V. Smith. *Ohio State University, Columbus, OH.*

Glutathione (γ-glutamylcysteinylglycine; GSH) is a critical participant in many biochemical and physiological processes, serving as a key metabolic intermediate and cofactor, and functioning in cellular protection mechanisms against many chemically reactive intermediates and xenobiotics that would otherwise alkylate or oxidize critical biological molecules. In part because of these multiple primary functions in cellular protective mechanisms, GSH has served as something of a toxicological Rosetta stone, providing important clues to mechanisms of metabolism of many xenobiotic and endogenous substances and insights to the mechanisms of action of many toxicants and disease processes. Modulations of GSH status and function, principally through the use of pharmacological agents or through dietary manipulations, have been utilized extensively in studies of tissue damage. Although much has been learned from such investigations, the pharmacological agents employed frequently manifest multiple effects, the contributions to outcome assessments of which have often been overlooked or underestimated. More recently, the tools of modern molecular biology have made available new experimental models that avoid the confounding secondary effects of pharmacological agents and are well suited for testing important fundamental hypotheses regarding GSH function. The major objective of the symposium is to present and discuss recent advances in the development of new experimental models of GSH function made possible by modern molecular biological approaches, with emphasis on the application of these experimental models to testing toxicologically important hypotheses.

1402 GLUTHIONE AND APOPTOSIS IN γ-GLUTAMYL TRANSPEPTIDASE-DEFICIENT MICE.

D. J. Reed and Y. Will. *Oregon State University, Corvallis, OR.*

Metabolic conversion of glutathione (GSH), glutathione disulfide (GSSG), and glutathione conjugates to constituent amino acids is initiated by γ-glutamyl transpeptidase (GGT). GGT is in high concentration in the brush border of the kidney, with lesser amounts in the biliary tree and elsewhere. Inhibition or elimination of this enzyme results in glutathionuria and levels of GSH increasing from micro- to millimolar in urine. GGT-deficient (GGT-KO) mice are severely limited in growth and life span due to the lack of ability to maintain GSH homeostasis and a chronic tissue-specific GSH deficiency. Although the cause of death of these mice 10-12 weeks after birth remains uncertain, they are useful models to elucidate aspects of the role of GSH in mechanisms of cell death. Thymocytes treated with dexamethasone (DEX) undergo a step-wise dysregulation of mitochondrial function involving mitochondrial permeability transition (MPT). Depolarization and uncoupling of MPT have been discussed as the "point of no return" in apoptosis and are strongly influenced by thiol status. We characterized the GSH status of splenocytes and thymocytes obtained from GGT-KO mice and found a significant decrease in cells obtained from GGT-KO when compared to cells obtained from GGT-WT. Since little is known about the role of mitochondrial GSH in splenocytes, we further elucidated how mitochondrial and cytosolic GSH relate to apoptotic events. Thymocytes were subjected to cytofluorometric analysis to examine apoptotic events. Thymocytes obtained from GGT-KO mice were more susceptible to apoptosis than were thymocytes obtained from wildtype mice. Supplementation of GGT-KO mice with the GSH precursors, N-acetylcysteine (NAC) and 2-oxo-4-thiazolidine-carboxylic acid (OTC) showed complete reversal of increased susceptibility. These and other findings with the GGT-KO mice will be discussed in terms of the usefulness of this model to address questions about the role of GSH and GGT in the toxicity of various chemicals.

1403 THE EFFECTS OF OVEREXPRESSION OF GLUTAMATE-CYSTEINE LIGASE ON CELL SURVIVAL, CELL GROWTH AND APOPTOSIS.

T. J. Kavanagh. *University of Washington, Seattle, WA.*

The tripeptide thiol glutathione (GSH) is important in free radical scavenging, xenobiotic conjugation and maintenance of cellular redox status. Glutamate-cysteine ligase (GLCL; also known as γ-glutamylcysteine synthetase) is the rate limiting enzyme in GSH synthesis. GLCL is composed of catalytic (GLCLC) and regulatory (GLCLR) subunits. We transfected the mouse cDNAs for these subunits driven by a metallothionein promoter into Hepa-1 cells, and derived lines which stably overexpress GLCLC and GLCLR alone or in combination. Cells which highly overexpress GLCLC+GLCLR have slightly higher GSH levels in the presence of Zn when compared to controls, are resistant to oxidants, and to TNF+ActD-induced GSH depletion, loss of mitochondrial membrane potential, and apoptosis. These findings imply that upregulation of GLCL activity contributes to resistance to oxidative stress and drug-induced apoptosis in cancer cells.

1404 GLUTATHIONE PEROXIDASE-1 REGULATION AND FUNCTION.

M. J. Kelner. *UC San Diego, San Diego, CA.*

The cytosolic selenium-dependent glutathione peroxidase (GPX1) is one of the most extensively characterized selenoproteins. The enzyme catalyzes the conversion of hydrogen peroxide and hydroperoxides to water and the corresponding alcohols, respectively, using reduced GSH as a hydrogen donor. The post-transcriptional regulation of GPX1 *in vitro* by selenium has been well defined. Most multicellular organisms, however, are not deficient in selenium. This implies that redox-controlled transcriptional regulation of GPX1 may be more physiologically relevant in humans. Studies in our laboratory have identified several regulatory mechanisms and elements in the human GPX1 gene. [1] There exist in the 5'-nontranslated region (promoter) of the human GPX1 gene both positive and negative regulatory elements. There exists at least one positive or oxidative responsive regulatory element (ORE) capable of tran-

scriptionally responding to stress induced by paraquat, peroxides and some agents not traditionally considered oxidizing agents. The consensus sequence of this element is being defined and its homology to similar oxidative responsive elements in other glutathione peroxidases determined. [2] Negative regulatory elements (NREs), capable of binding to nuclear proteins, were also identified in the GPX1 gene. Sequences similar to these two NREs have been identified in other antioxidant enzymes, suggesting a common regulatory mechanism. [3] The ability of the 5'-untranslated region in GPX1 mRNA to specifically bind to a regulatory protein has been documented and 3 nucleotides critical for protein/mRNA binding identified. [4] Null or "knock-out" GPX1 mice have been generated to further investigate the tissue-specific distribution of GPX1. These findings will be discussed in terms of the role of GPX1 in protecting cells against general oxidative damage from a variety of toxins.

1405 GLUTATHIONE REDUCTASE MODULATION BY MODER MOLECULAR METHODS.

C. V. Smith. *Ohio State University, Columbus, OH.*

Glutathione disulfide (GSSG) is produced when glutathione (GSH) reduces hydroperoxides and other oxidants. Glutathione reductase (GR) catalyzes the NADPH-dependent reduction of GSSG back to GSH, thus coupling the antioxidative capabilities of GSH to the substantial eductive capacity afforded by cellular NADPH. A very few humans have been identified with unusually low GR activities, apparently resulting from production of an unstable protein. Much of the toxicological relevance of GR is attributed from studies of the effects of 1,3-bis(2-chloroethyl)-1-nitrosourea (BCNU), which irreversibly inhibits GR *in vitro* and *in vivo*. However, BCNU also alkylates and crosslinks DNA and large and variable fractions of the effects of BCNU on cytotoxicities are more closely correlated with the effects on DNA than on inhibition of GR. We have used a cDNA for human GR to transfect Chinese hamster ovary (CHO) cells. By transfection with hGR in the antisense orientation we have generated a stable CHO-derived cell line that exhibits 50% of the normal cell GR activity and is more susceptible to oxidant injury. Transfection of CHO cells with hGR in the sense orientation has been used to generate cells with increased GR activities and resistance to oxidant challenge, especially if the transgene product is directed to the mitochondria by attachment of a functional mitochondrial targeting signal 5' to the hGR cDNA. This transgene construct has been used with an adenoviral transfection system to enhance GR activities and augment oxidant resistance in human-derived H441 cells. GR functions as an antiparallel (head-to-tail) homodimer with two active sites per dimer, each site formed with critical residues from each monomer. We have generated several dominant negative mutant constructs that attenuate the activity of the human gene product, but are less effective in inhibition of endogenous CHO cell GR activities, despite the high interspecies identities of the GR primary sequence. The most remarkable observation thus far has been the substantial enhancement of cellular resistance to oxidant injury provided by increased GR activities in the mitochondrial compartment. (Supported by GM44263 from the National Institutes of Health.)

1406 HUMAN IMMUNOTOXICITY: EXAMPLES & STRATEGIES FOR DETERMINIG RISK: INTRODUCTION.

M. J. K. Selgrade. *USEPA NHEERL, Research Triangle Park, NC.*

Laboratory rodent studies indicate that a number of chemicals are immunotoxic. Human data has been more difficult to obtain. In some cases parallel effects have been demonstrated in humans and rodents following exposure to immunosuppressive chemicals. However, for many chemicals, different endpoints have been assessed in humans and rodents making comparisons across species difficult. Rodent studies often assess antigen-driven responses, whereas human studies usually assess less invasive, static indicators of immune competence. Examples of human studies that assessed antigen-driven responses will be presented in this workshop as well as attempts to relate immune suppression to enhanced disease susceptibility in humans. Because data from human *in vivo* exposures is difficult to obtain, studies on *in vitro* exposure of human cells will be described as a tool for assessing human immunoxicity. Evidence for a common mechanism underlying rodent and human effects will also be presented. Human data has been more readily available for protein allergens. The use of this data along with animal data to understand how magnitude, frequency, and duration of exposure affect risk of sensitization will be described. The workshop will conclude with a discussion of the best approaches and designs for human immonotoxicity studies, use of animal data in assessing human risk, and research needed to improve assessment of immunotoxicity in humans.

1407 IMMUNOLOGIC EFFECTS OF POLYOCHLORINATED BIPHENYL (PCB) AND DIOXIN EXPOSURE IN DUTCH TODDLERS.

N. Weisglas-Kuperus. *Sophia Children's Hospital, Rotterdam, Netherlands.*
Sponsor: M. J. Selgrade.

Prenatal exposure to PCBs and dioxins is associated with changes in the T-cell lymphocyte populations in healthy Dutch infants. We investigated whether these changes persisted into later childhood and whether this exposure was associated with the prevalence of infectious or allergic diseases and humoral immunity in toddlers. 207 healthy mother-infant pairs were studied. Prenatal exposure to PCBs and dioxins was estimated by the sum of PCBs 118, 138, 153 and 180 (SPCB) in maternal and cord plasma and in breast-fed infants by the dioxin, planar and mono-ortho PCB toxic equivalent (TEQ) levels in milk. At 42 months of age, body burden was estimated by the SPCB in plasma. Prevalence of infectious and allergic diseases was assessed by parent questionnaire. Anti-body levels after mumps, measles & rubella vaccination were assessed. In some cases lymphocyte phenotypic markers were analyzed. In toddlers prenatal PCB exposure was associated with increased T cell numbers and lower antibody levels. Adjusted for confounders (gender, parity, maternal education breast feeding, parental occupation, smoking by parents, family history of atopy, day care or nursery attendance), prenatal PCB exposure was associated with less shortness of breath with wheeze. Current PCB body burden was associated with a higher prevalence of recurrent middle ear infections and chickenpox and a lower prevalence of allergic reactions.

1408 THE HEALTH CONSEQUENCES OF STRESS INDUCED IMMUNE MODULATION.

R. Glaser and J. Kiecolt-Glaser. *The Ohio State University, Columbus, OH.*
Sponsor: M. J. Selgrade.

In a series of studies, we examined the impact of academic stress on different aspects of the cellular immune response in medical students. The results of these studies showed significant down-regulation/dysregulation of several aspects of the cellular immune response. In order to explore whether these statistically significant differences were biologically significant, we performed a study in which medical students were inoculated with a recombinant Hepatitis-B (Hep-B) vaccine. Each vaccination was administered to coincide with the third day of a three day examination series. Students who reported greater social support and lower anxiety and stress had higher antibody levels to the vaccine and a more vigorous T-cell response at the end of the third inoculation (6 months). In a second series of studies with caregivers of Alzheimer's Disease (AD) patients, similar down-regulation of several aspects of the cellular immune response was observed in caregivers as compared to well-matched control subjects. Once again, we explored the possibility that these changes were significant enough to effect how a person responds to a vaccine; we used the influenza virus vaccine. AD caregivers showed a poorer antibody response and virus-specific T-cell response following vaccination with the flu vaccine as compared to the control subjects. The differences in antibody and T-cell responses to these two virus vaccines provide a demonstration of how psychological stress may be able to alter a person's immune response to a vaccine and therefore risk for infection. We believe that the data obtained in these studies provide a clue for how stress can affect how a person would respond to infection with a live virus.

1409 MECHANISMS OF HUMAN IMMUNOTOXICITY INDUCED BY POLYCYCLIC AROMATIC HYDROCARBONS (PAHs): LESSONS FROM MURINE *IN VITRO/INVIVO* AND HUMAN *IN VITRO* STUDIES.

S. W. Burchiel. *University of New Mexico, Albuquerque, NM.*

Polycyclic aromatic hydrocarbons (PAHs), such as 7,12-dimethylbenz(a)anthracene (DMBA) and benzo(a)pyrene (BaP), are well known immunotoxicants in animals and likely in humans. Human B and T lymphocytes appear to be sensitive to DMBA, resulting in altered antigen receptor signaling and disruption of Ca^{2+} homeostasis. Prolonged elevation of Ca^{2+} in lymphocytes induces apoptosis. There appear to be several mechanisms responsible for elevation of Ca^{2+} in B and T cells. PAHs produce a somewhat

nonspecific and rapid mobilization of Ca^{2+} from intracellular stores via an IP3-dependent and protein tyrosine kinase (PTK)-associated pathway. In human lymphocytes, the src and src-like PTKs that are rapidly (5-10 min) activated by PAHs include Lck, Fyn, and Zap-70 in T cells; Lyn and Syk are activated in human B cells. These kinases are also activated following prolonged (18 hr) exposures to BaP, through a mechanism that requires P4501A or 1B metabolism. Extracellular Ca^{2+} is required for these prolonged effects. Alpha-naphthoflavone (ANF) was found to prevent the inhibition of T cell proliferation produced by BaP, as well as to prevent B cell apoptosis, and Ca^{2+} elevation. BaP metabolites appear to produce immunotoxicity by both oxidative (N-acetylcysteine, NAC-sensitive) and electrophilic mechanisms. Since the mechanism (s) of immunotoxicity appear to be similar in mice and humans, and there seems to be good agreement between *in vivo* and *in vitro* studies, PAHs may be excellent candidates for developing models for mechanism-based risk assessment. (Supported by ES-05495.)

1410 ALLERGY TO ENZYMES: USE OF PRE-CLINICAL AND CLINICAL DATA TO ASSESS THE RISK TO MAN.

K. Sarlo. *Procter & Gamble Company, Cincinnati, OH.*

Detergent enzymes are well known occupational allergens. Exposure guidelines and safe handling practices have minimized sensitizations (allergic antibody) and greatly reduced the incidence of allergy and asthma among the detergent workforce. After many years of medical and environmental monitoring, we can conclude that allergic symptoms are elicited mainly by high, peak exposures to enzyme dust. Sensitizations develop also via exposure to lower levels of enzyme dust. The prevalence of sensitization to protease in our detergent manufacturing facilities is between 11%-16%. There have been no asthma cases in the past 7 years. Allergy to enzymes among consumers of detergent products is a rare event. In 1970, there were a few cases of enzyme allergy after exposure to high levels (~200 ng/m3) of enzyme in a dusty detergent product. Current laundry exposures are lower with no sensitizations. Effect and no-effect exposure conditions are known for enzymes used or misused in laundry products and personal cleansing applications. Exposure to protease levels of 11 ng/m3 (range: 3-29 ng/m3) in a shower via use of an enzyme-containing beauty bar led to 6% sensitizations in a 6-month clinical trial. In comparison, exposure to less than 0.1 ng/m3 via hand laundry or personal cleansing with an enzyme synthetic laundry bar did not sensitize several hundred atopic Filipino study subjects after 2 years of use. Via retrospective and prospective clinical evaluations of exposed populations, we are beginning to understand how magnitude, frequency and duration of exposure relate to sensitization to enzymes. The use of animal models to assess the relative allergenic potential of enzymes has been used to establish exposure guidelines for the detergent industry. Animal models can also be used to understand how different "patterns" of exposure relate to the induction of allergy. Taken together, the pre-clinical/clinical data on enzyme allergy will allow us to identify thresholds for sensitization and to accurately calculate risk of developing sensitization to enzymes among exposed populations.

1411 CURRENT STATUS OF MODEL DEVELOPMENT FOR PHOTOBIOLOGY RISK ASSESSMENT WITH RELEVANCE TO HUMANS.

G. F. Gerberick. *Procter & Gamble Company, Cincinnati, OH.*

Acute and chronic exposure to ultraviolet radiation (UVR) produces damage to human skin. Such damage is a human health concern and believed to play a role in several diseases including development of human skin cancers. Chemicals—including drugs—which absorb UVR may directly affect acute and chronic photobiological responses. More controversial is the view that some pharmacological/toxicological effects of a chemical may increase human health risk by exacerbating UVR-induced damage indirectly viz a viz a secondary mechanism. Efforts are ongoing to develop and/or refine acute and chronic phototoxicological models, and both *in vitro* and *in vivo* models have been used successfully to assess human risk of direct phototoxicological effects of chemicals. The conduct of clinical studies measuring well-defined photobiological endpoints represents an important alternative. The methods and endpoints of human clinical photobiological studies will be presented. The overall issue of public health and chemical safety with regard to phototoxicological concerns will be discussed by US FDA representatives.

1412 EFFECTS OF ULTRAVIOLET (UV) LIGHT ON BIOLOGICAL SYSTEMS.

I. E. Kochevar. *Harvard, Boston, MA.* Sponsor: G. F. Gerberick.

Humans are exposed to solar UVB (290-320 nm) and UVA (320-400 nm) light which has both deleterious and beneficial effects. For photobiological responses to occur, the UV light must be absorbed by molecules that are termed "chromophores". Endogenous tissue chromophores include DNA, proteins, urocanic acid, porphyrins, nicotinamide adenine dinucleotide (NADH) and flavins. Exogenous chromophores may be present in drugs or topically applied preparations. Biological responses to UV light vary with the wavelength of the light since each chromophore has a distinct absorption spectrum and because the penetration depth of light into tissue varies with the wavelength. For example, 10% of 300 nm radiation reaches approximately 15 μm into fair human skin whereas 10% of 365 nm radiation penetrates about 150 μm. Absorption of UV light by molecules produces very short lived excited state molecules which may undergo chemical reactions with cellular molecules that initiate cellular responses. Other processes of excited state molecules, such as production of heat or light (fluorescence) do not cause biological responses. The chemical reactions include formation of reactive oxygen species, conversion of 7-dehydrocholesterol to cholesterol, and production of dimers between thymines in DNA. The cellular responses, which include initiation of new gene expression, mutagenesis, and apoptosis, lead to observable responses in skin such as erythema, melanogenesis, hyperproliferation of the epidermis and tumorigenesis.

1413 PHOTOTOXICOLOGICAL RISK ASSESSMENT: LIMITATIONS OF CURRENT MODELS.

J. F. Nash. *Procter & Gamble Company, Cincinnati, OH.* Sponsor: G. F. Gerberick.

Determination of the phototoxicological potential of a chemical or product is a specialized subset of the human safety assessment. The decision to initiate such an assessment is based on the principle that the compound of interest absorbs ultraviolet (UV) light in the solar spectrum, i.e., 290-760 nm. Because many molecules absorb UV in this range, such information provides little insight about the potential biological consequences of the absorbed UV energy. To this end, the *in vitro* 3T3 Neutral Red Uptake (NRU) phototoxicity-screening assay may be used to determine the relative toxicological potential of a chromophore. The 3T3 NRU screening assay has undergone a rigorous validation demonstrating the sensitivity and specificity of the results. As with other *in vitro* assays, system incompatibility and establishment of a no observed effect level (NOEL) or dose threshold are potential limitations. There are animal models to evaluate phototoxicity as well as the photoallergenicity potential of a chemical. Importantly, the animal models have been evaluated with established human positive and negative controls. In this regard, human assays of phototoxicity and photoallergenicity exist and are used primarily as confirmatory tests or for establishing a NOEL. Up to this point, the tests address the acute phototoxicological potential of a chemical. The long-term phototoxicological concern, mainly photocarcinogenicity, may be evaluated using modifications of genotoxic and rodent carcinogenicity assays. Specifically, the photogenotoxic potential of a compound may be evaluated using photomutagenic, photoclastogenic and/or photo-comet assays. These approaches are adaptations of existing genotoxic models with the addition of UV light. The *in vivo* model most commonly used to evaluate photocarcinogenicity is the SKH1 (hr/hr) albino hairless mouse. For both photogenotoxicity and photocarcinogenicity, the absence of known human positive controls is problematic. Moreover, the use of the hairless mouse to investigate secondary mechanisms of photocarcinogenicity is complex and of unknown relevance in evaluating human health risk.

1414 THE USFDA/NIEHS PHOTOTOXICOLOGY RESEARCH CENTER: UNDERSTANDING AND DEVELOPING ANIMAL MODELS FOR PHOTOCARCINOGENESIS TESTING.

P. C. Howard[1], R. L. Sams[1], B. J. Miller[1], W. G. Wamer[2] and J. Z. Beer[3]. [1]*NCTR/FDA, Jefferson, AR.* [2]*Center for Food Safety and Applied Nutrition, FDA, Washington, DC and* [3]*Center for Devices and Radiological Health, FDA, Washington, DC.* Sponsor: G. F. Gerberick.

The Phototoxicology Center was developed in response to the need for mechanistic and tumorigenicity testing of products of interest to the FDA and

NIEHS. Mice are exposed to simulated solar light using a 6.5 kWatt xenon arc solar simulator, or any combination of fluorescent tube generated light (e.g. UVA + UVB). Mechanistic studies on the rates of cell proliferation and apoptosis, DNA damage formation, and expression of mutations in specific cell types will be used to understand the effects of compounds with or without light on skin cells and tumor development. Tumor studies will be conducted using the SKH-1 hairless mouse. Future utilization of this facility will include evaluating the tumorigenic response of new rodent models (e.g. TgAC transgenic mice) to simulated solar light, and comparison to the SKH-1 mouse. Our current studies are focused on the effects of alpha-hydroxy acids on induction of skin tumors in SKH-1 mice with simulated solar light.

1415 REGULATORY CONSIDERATIONS ON PHOTOBIOLOGY RISKS.

A. Jacobs. *FDA/CDER, Rockville, MD.*

The U.S. Food and Drug Administration is charged with evaluating the safety of drug products, including photosafety. At present, with a few exceptions, only drugs applied to sun-exposed areas of the skin are assessed for photosensitivity (i.e., photoirritation and photoallergy) or for the potential to enhance ultraviolet (UV)-associated skin cancer. However, some systemically administered drugs, such as fluoroquinolone antibiotics, have been shown to be photosensitizing. Regulatory photobiology questions for dermatologic products include when and how to test, risk/benefit and approvability, and appropriate risk communication. For example, a new UV filter, which is intended for protection of skin from sunlight, should always be tested for possible adverse effects due to concurrent sunlight exposure. For some photosensitizing drug products, a warning to avoid exposure to sunlight may be sufficient and additional phototesting may not be necessary. Considerations for phototesting of nonphotosensitizing drugs include duration of use, whether the skin receives a large exposure, effects on the skin, and pharmacological activity.

1416 PHOTOCARCINOGENICITY OF DRUGS—HUMAN EXPERIENCE.

R. S. Stern. *Beth Israel Deaconess Medical Center, Boston, MA.* Sponsor: G. F. Gerberick.

Photocarcinogenicity of Drugs—Human Experience.A number of commonly used medications including quinolone antibiotics, psoralens and various tetracycline derivatives are photosensitizers. These chemicals enhance the erythema response to sunlight and sunlight exposure. Drugs might increase the risk of skin cancer by one or more of a variety of mechanisms including direct genotoxic effects, effects on the immune system, increasing penetration of UV light, and stimulating cellular proliferation. The effect of such exposures on cancer risk has been best quantified in humans for oral psoralen photochemotherapy (PUVA). The experience of a cohort of 1380 patients followed for more than 20 years who received PUVA therapy for the treatment of psoriasis documents that long-term high dose exposure to PUVA greatly increases the risk of squamous cell carcinoma. After 15 years, the risk of melanoma is also increased among high dose patients. PUVA therapy is immunosuppressive in the skin, induces psoralen DNA adducts, is genotoxic and mutagenic. Substantially increased risk is only observed after many purposeful exposures to ultraviolet and this drug. These data suggest that at least some photosensitizing chemicals can substantially increase the risk of skin cancer in humans, but with this drug when used in adults, long-term multiple exposures appear to be necessary for a clinical meaningful increase of risk. The photocarcinogenic risk of drugs is likely to be a function of their photobiologic effects, frequency of use, and perhaps age of the user.

1417 AUGMENTED HUMORAL IMMUNE FUNCTION IN METALLOTHIONEIN-NULL MICE: POSSIBLE INTERACTIONS WITH METALLOTHIONEIN AND THE SIGNAL TRANSDUCTION PATHWAY.

K. C. Crowthers, V. Kline, C. Giardina and M. A. Lynes. *University of Connecticut, Storrs, CT.*

Infection, inflammation, autoimmune disease, and neoplasia are all associated with stressful conditions that can result in increased metallothionein (MT) synthesis. MT is a small, thiol-rich protein which can act as a reservoir of essential heavy metals, scavenge free radicals, and provide a homeostatic mechanism that regulates damage caused by toxic heavy metals. In previous work, we have shown that exogenous MT can suppress the developing humoral immune response. This finding suggested that endogenous MT might similarly alter immune function, and that there would be substantial changes in humoral immune function in mice that have a targeted deletion in the MT-1 and -2 genes. Here we show that MT-null (MTKO) animals display a significant enhancement in their ability to mount a T-cell dependent antibody response. This augmented *in vivo* response is paralleled by increases in the proliferation response to mitogenic stimulation and enhanced differentiation of antigen-specific B cells to plasma cells. Moreover, we have found that cells from MT-null animals display significantly elevated levels of NF-κB activity when compared to wildtype controls. Taken together, these results suggest that both metal- and stress-induced immune suppression may be mediated by increased expression of MT, as well as serve as a negative regulator of the immune response in unstressed conditons.

1418 SUSCEPTIBILITY TO ULTRAVIOLET B RADIATION-INDUCED SYSTEMIC IMMUNOSUPPRESSION IN FOUR DIFFERENT TRANSGENIC MOUSE STRAINS WITH SPECIFIC DEFECTS IN NUCLEOTIDE EXCISION REPAIR: XPA, XPC, TTD/XPD AND CSB NULL MICE.

J. Garssen[1], H. Van Steeg[1], F. De Gruijl[2], J. De Boer[1], B. Van Der Horst[3], H. Van Kranen[1], G. Weeda[3], J. Hoeijemakers[3] and H. Van Loveren[1]. [1]*National Institute Public Health and Environment, Bilthoven, Netherlands,* [2]*Utrecht University, Utrecht, Netherlands and* [3]*Erasmus University, Rotterdam, Netherlands.*

Exposure to ultraviolet light, especially wavelengths in the UVB band present in sunlight, can impair immune responses in animal and man. UVB exposure appears to inhibit most specifically Th1-mediated immune responses as both contact hypersensitivity (CHS) and delayed type hypersensitivity (DTH) are very sensitive to suppression by UVB irradiation. It is remarkable that this immunomodulation is not restricted to the exposed skin but is also found at (distant) sites, i.e., a systemically mediated immunosuppression can be induced. As UVB radiation is not able to penetrate much deeper than the viable cell layers of the epidermis, the immunosuppression is likely to be mediated by these exposed cells, their products or photoactivated factors present in the superficial layers. Various processes have been found to contribute to the UV-induced immunosuppression: e.g., urocanic acid isomerization, release of neuropeptides, and membrane damage through which signalling pathways (e.g. NF-kB) become activated. Amidst all these processess, DNA damage appears to play a paramount role in UV-induced suppression of many cellular immune responses. Enhanced (enzyme-mediated) clearance of this damage counteracts the immunosuppression dramatically. Conversely, persistence of the damage by a lack of DNA repair would plausibly lead to the enhancement of the immunosuppression. The aim of the present study is to determine what type of DNA damage, i.e., in which part of the genome, contributes most to the UV-induced immunosuppression and the acute skin reactions (such as edema and erythema, i.e. "sunburn"). To this end, 4 different strains of transgenic mice with specific defects in nucleotide excision repair (NER) were used: CSB mice with defective transcription coupled repair (TCR), XPC mice with defective global genome repair (GGR), and XPA and TTD/XPD mice with TCR and defective GGR. The immunomodulation was assessed in a DTH reaction against an infectious agent, Listeria monocytogenes, and a CHS reaction against picrylchloride. Our results indicate and confirm that UV-induced damage in the transcribed DNA strand clearly plays a major role in the acute sunburn reaction. However, the UV-induced immunosuppression is not evidently related to this DNA damage and the related sunburn reaction, nor specifically to the DNA damage in the non-transcribed DNA. The only genotype that appears to be extremely sensitive to the UV-induced immunosuppression is XPA-/-, the only one with a complete lack of both TCR and GGR. A slight increase in susceptibility to UV-induced suppression of CHS in TTD/XPD-/- mice suggests that persistence of pyrimidine (6-4)pyrimidone photoproducts in the transcribed strand may contribute most specifically to the immunosuppression.

1419 MECHANISM OF MACROPHAGE ACTIVATION BY ANGELAN ISOLATED FROM ANGELICA GIGAS NAKAI, TRADITIONAL ORIENTAL DRUGS.

H. M. Kim, Y. J. Jeon, K. S. Ahn and S. B. Han. *Kor Res Inst Biosci Biotech, Taejon, Republic of Korea.*

In our previous studies we showed that the primary target cell of angelan, a polysaccharide purified from Angelica gigas Nakai, is a macrophage (Han et

al., 1998). In the present study we examined the effect of angelan on iNOS, IL-1b, and TNF-a transcription in mouse macrophage line RAW 264.7. We show that angelan produces a marked induction of iNOS, IL-1b, and TNF-a transcription by RAW 264.7 cells. Since these gene transcriptions have been recently shown to be under the control of NF-κB/Rel family of transcription factors, we assessed the effect of angelan on NF-κB/Rel using a electrophoretic mobility shift assay. Treatment of RAW 264.7 cells with angelan produced strong induction of NF-κB/Rel binding. Treatment of RAW 264.7 cells with angelan slightly induced AP-1 binding activity, whereas Oct binding was not affected by angelan. Angelan stimulated macrophages to activate NF-κB/Rel, whereas neither B-cells nor T-cells were affected by the angelan. In conclusion, we demonstrate that the stimulation effect of angelan on macrophage is mediated by specific activation of NF-κB/Rel.

1420 EVIDENCE FOR A ROLE BY SMADS IN TGF-β1-INDUCED MODULATION OF T-CELL EFFECTOR FUNCTION.

S. C. McKarns and N. E. Kaminski. *Michigan State University, Department of Pharmacology and Toxicology, East Lansing, MI.*

TGF-β1 is the most potent known immune suppressive factor. Elevated levels of TGF-β1 have been associated with xenobiotic-induced liver injury, e.g. carbon tetrachloride (CCl4) and acetaminophen. We have previously established that a profound TGF-β1-mediated, T-cell dependent transient immune suppression accompanies modest CCl4-induced liver injury. More recently, we have demonstrated that TGF-beta1 modulates interleukin-2 (IL-2) expression in CD3 and CD28-activated splenic T-cells. The mechanisms underlying TGF-β1-mediated suppression of T-cell function are currently unknown. The objective of the present studies was to test the hypothesis that TGF-β1-induced immune modulation of T-cell effector function is mediated, at least in part, through serine/threonine TGF-β receptor activation of Smad transcription factors. Towards this end, we have identified several CAGA Smad response elements within the 5' minimal essential promoter region of the IL-2 gene. Western blot analysis indicates that Smad3 nuclear expression increases in a concentration- and time-dependent manner following TGF-β1 exposure. The most robust increase in Smad3 nuclear expression was observed following low TGF-β1 exposure; this observation correlates with low concentration TGF-β1-mediated augmentation of IL-2 expression. Additionally, TGF-β1- and CD3 and CD28-induced protein binding at the proximal phorbal ester DNA response element in the IL-2 promoter is abrogated with mutation of the 5' and 3' flanking CAGA Smad response elements. In summary, these data support the hypothesis that Smads may play a mechanistic role in hepatoxicant-induced immune suppression. (This work was supported by NIEHS Grant P01P42ES04911-08C.)

1421 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN (TCDD) ALTERS DENDRITIC CELL MATURATION AND INTERFERES WITH NF-κB/REL SIGNALING.

C. E. Ruby and N. I. Kerkvliet. *Oregon State University, Corvallis, OR.*

TCDD, the prototypic ligand for the Ah receptor, causes a host of immunomodulatory phenomena, including suppression of cell-mediated and humoral immune responses. Dendritic cells (DC) are professional antigen presenting cells that induce and maintain the adaptive immune response. DC develop from stem cells found in bone marrow and become fully mature upon the uptake of antigen, exposure to cytokines such as TNFα, and following cell-cell interactions. Studies were undertaken to determine if TCDD disrupts the process of DC maturation. Bone marrow cells from C57Bl/6 mice were exposed to 10^{-9} M TCDD and cultured with a DC growth factor, GM-CSF, for 7 days inducing a population of cells to express characteristic DC markers including CD11c, CD80, CD86, major histocompatibility class II protein (MHC II), CD40 and Dec205. These cells were then treated with TNFα for two days and maturation was evaluated by the level of expression of MHC II and CD86 on $CD11c^+$ cells. TNFα treatment increased the expression of MHC II and CD86 in vehicle-treated cells; TCDD significantly attenuated this expression indicating a suppression of DC maturation. Maturation of DC is dependent on the NF-κB/Rel family of transcription factors. Since TCDD was shown to interfere with DC maturation, we investigated the effects of TCDD on NF-κB/Rel signaling in DC. DC 2.4 cells, a murine bone marrow derived DC cell line, were treated with 10^{-9}M TCDD for 24 hours prior to activation with TNFα. Translocation of NF-κB/Rel to the nucleus as visualized by immunoblotting was blocked in TCDD exposed cells after TNFα activation when compared to vehicle-treated cells. These findings suggest that exposure to TCDD alters maturation of DC which could be a consequence of TCDD altering NF-κB/Rel signaling. (Supported by NIH #ES00040.)

1422 THE EFFECTS OF PCBS AND ESTROGENS ON PHAGOCYTE INOS, COX-2, NRAMP, AND CYP1A EXPRESSION IN THE CHANNEL CATFISH MONOCYTE/MACROPHAGE CELL LINE 42TA.

C. D. Rice and Y. Xiang. *Clemson University, Pendleton, SC.* Sponsor: D. Schlenk.

Recent studies suggest that environmental estrogens may negatively impact the reproductive physiology of fish and wildlife, and possibly humans, while planar halogenated aromatic hydrocarbons (HAHs) may antagonize this effect. However, the interactive effects of estrogens and HAHs in mixtures on immunophysiology remain uncharacterized. In mammals, both HAHs and environmental estrogens modulate phagocyte-associated proinflammatory responses. The effects of environmental estrogens and HAHs on inflammatory responses in fish are unknown. We treated cytokine/LPS-stimulated 42TA cells, a channel catfish monocyte cell line, with 17b-estradiol (E2), nonylphenol (NP), PCB-126, PCB-104, and PCB-126 + NP, PCB-104 + NP, PCB-126 + E2, and PCB-126 + PCB-104. Cell lysates were probed by SDS-PAGE/western blotting for inducible prostaglandin endoperoxide H synthase-2 (cyclooxygenase-2; COX-2), nitric oxide synthase II (iNOS), natural resistance associated membrane protein (nRAMP), and CYP1A. The mAbs used for western blotting were developed from peptide sequences chosen upon cloning and sequencing each of the above fish phagocyte proteins. Nitric oxide synthase II and nRAMP were generally unaffected by treatment. However, E2 suppressed, while the weak estrogen NP enhanced COX-2 and CYP1A expression. In comparison, PCB-126 enhanced COX-2 and CYP1A, while PCB-104 mimicked the effect of E2 by suppressing COX-2 and CYP1A. Our results are similar to those from published studies using rodents. Therefore, we suggest that the channel catfish monocyte/macrophage cell line 42TA may be a good model for understanding the effects of xenobiotic mixtures containing both Ahr- and ER-active compounds. Current efforts are underway to determine if inducible CYP1A and COX-2 in 42TA cells have enzymatic activity. Although the relative roles of macrophage monooxidation reactions (CYP?) and peroxidiation reactions (COX-2?) in metabolizing certain xenobiotics to reactive metabolites are still unclear, the 42TA cell line may provide some answers.

1423 ROLE OF NF-κB IN THALIDOMIDE AND DEXAMETHASONE INDUCED TUMOR NECROSIS FACTOR α EXPRESSION.

T. R. Rowland[1], S. M. McHugh[2], J. Deighton[2], P. W. Ewan[2], R. J. Dearman[3] and I. Kimber[1]. [1]*GlaxoWellcome, Stevenage, United Kingdom,* [2]*Addenbrooke's Hospital, Cambridge, United Kingdom and* [3]*AstraZeneca Central Toxicology Laboratory, Macclesfield, United Kingdom.*

Thalidomide, withdrawn from use as a sedative during pregnancy due to its teratogenic effects, has been recognized recently as having immunomodulatory activity, specifically the inhibition of proinflammatory cytokines such as tumor necrosis factor α (TNF-α) and interleukin 6. We have demonstrated previously that culture with thalidomide inhibits TNF-α mRNA expression and protein production by mitogen-stimulated human peripheral blood mononuclear cells (PBMC). We have now investigated the influence of this drug on nuclear levels of NF-κB in mitogen-activated PBMC, using dexamethasone as positive control due to its well characterized and NF-κB mediated effects on TNF-α expression. PBMC were stimulated optimally with mitogen (phytohemagglutinin or phorbol myristate acetate and ionophore) in the presence of 10^{-1}-10^{-5} mM thalidomide or dexamethasone, concentrations which caused a dose-dependent inhibition of TNF-α production. Cells were harvested at 0 to 8 hours and levels of NF-κB measured in nuclear extracts by electrophoretic mobility shift assays using a radiolabeled DNA probe specific for NF-κB and analyzed by optical densitometry. Nuclear levels of NF-κB were unaffected by thalidomide at all concentrations tested, including those (10^{-1}-10^{-3} mM) which resulted in significant inhibition of TNF-α mRNA and protein expression. In concurrent experiments, dexamethasone was found to reduce NF-κB levels in a dose-dependent manner. TNF-α gene expression is controlled by at least three separate transcription factors that are involved in binding to the promoter region. These observations suggest that thalidomide does not act directly upon NF-κB and therefore inhibits TNF-α production through another independent mechanism.

1424 SUPPRESSIVE EFFECTS ON LYMPHOCYTES FUNCTION BY MICROCYSTIN COMPOUNDS.

S. S. Yea[1], H. M. Kim[2], H. M. Oh[2] and K. H. Yang[1]. [1]*Korea Advanced Institute of Science and Technology, Taejon, Republic of Korea and* [2]*Korea Research Institute of Bioscience and Biotechnology, Taejon, Republic of Korea.*

Microcystin and nodularin are cyclic peptides produced by cyanobacteria. In the present study, we studied immunosuppressive effect of microcystin and nodularin. Microcystin-LR and -YR form and nodularin produced a dose-dependent inhibition of *in vitro* polyclonal antibody response and lymphoproliferative response to LPS. Microcystin-YR and nodularin also decreased lymphoproliferative response to ConA, but microcystin-LR showed no significant effect. Intraperitoneal administration of nodularin produced an inhibition of primary humoral immune responses to the T-cell dependent antigen, sRBC. Microcystin-LR, -YR, and nodularin also reduced IL-2 mRNA expression in murine splenocytes and thymocytes. When IL-2 mRNA stability was evaluated using quantitative/competitive RT-PCR, nodularin treatment led to rapid decline of IL-2 mRNA levels if actinomycin D was treated to PMA plus ionomycin (Io)-stimulated splenocyte culture. To further characterize the mechanisms for the reduced IL-2 mRNA level, the binding activity of transcription factors for IL-2 gene expression was measured by electrophoretic mobility shift assay. Nodularin reduced the NF-AT binding activity in PMA/Io-induced splenocytes, but no significant effect was observed on AP-1, NF-κB, and Oct binding activity. These results suggested that immunosuppressive effect of microcystin compounds might be due to the decreased IL-2 gene expression which was mediated by the inhibition of NF-AT binding activity. (Supported by the grant from the Ministry of Science and Technology, 97-N1-05-03-A-01.)

1425 *IN VIVO* INDUCTION OF TRANSCRIPTION FACTORS BY LIPOPOLYSACCHARIDE (LPS) THAT CONTROL SPLENIC PROINFLAMMATORY CYTOKINE TRANSCRIPTION.

H. R. Zhou and J. J. Pestka. *Michigan State University, East Lansing, MI.*

The effect of *in vivo* LPS exposure on the binding of transcription factors responsible for controlling gene expression of the proinflammatory cytokines TNF-α, IL-6 and IL-1β was assessed. The kinetics of AP-1, NF-IL6, NF-κβ, CREB, AP-2α and SP1 binding was measured in spleens of mice exposed ip to LPS (4 mg/kg BW) over an 8 hr period. AP-1 binding activity was elevated to 34- to 54-fold between 0.5 and 4 hr in LPS-treated mice. LPS increased NF-IL6 binding 108-fold within 0.5 hr with full recovery being observed by 4 hr. NF-κβ binding was unaffected. In LPS -treated mice, CREB, AP-2α and SP1 binding increased slightly after 0.5 hr but decreased markedly below control values up to 8 hr. Specificities of the transcription factors were verified by competition assays with unlabeled consensus and mutant oligonucleotides. Supershift and Western blot analysis were used to identify the LPS-inducible DNA binding proteins for AP-1(c-Jun[KM-1], Jun B, Jun D, and c-Jun AP-1 at 30 min; c-Jun/AP-1 at 4 hr), NF-IL6(c/EBPβ), NF-κβ(P65, P50 and c-rel at 30 min; p50 at 4 hr) and CREB(ATF-2 and CREB-1 at 30 min; CREB 2 at 4 hr). Taken together, the results indicate that LPS can modulate *in vivo* binding activities of transcription factors specific for regulatory motifs in TNF-α, IL-6 and IL-1β promoter regions. (Supported by PHS Grants ES 03358 and ES 09521.)

1426 INDUCTION OF MONOCYTE CHEMOTACTIC PROTEIN-1 (MCP-1) AND C-C CHEMOKINE RECEPTOR 2B (CCR2B) EXPRESSION IN THE LIVER DURING ACETAMINOPHEN-INDUCED HEPATOTOXICITY: ROLE OF TUMOR NECROSIS FACTOR-ALPHA (TNF-α).

D. M. Dambach[1], K. Gray[1], S. K. Durham[1] and D. L. Laskin[2]. [1]*Bristol-Myers Squibb, Pharm. Res. Inst., Princeton, NJ and* [2]*Rutgers Univ., Piscataway, NJ.*

Macrophages have been shown to play a critical role in acetaminophen-induced hepatotoxicity. These cells release cytotoxic mediators such as nitric oxide and peroxynitrate which contribute to the pathogenic process. Macrophage accumulation at injured sites is mediated by chemotactic cytokines. One of the most active members of this cytokine family is MCP-1 which acts by binding to a highly specific receptor, CCR2b. We speculated that MCP-1 may be involved in the recruitment of macrophages into the liver during acetaminophen-induced hepatotoxicity. To test this theory, we analyzed MCP-1 and CCR2b expression in the liver. Male C57BL6/129Sv mice were injected with acetaminophen (300mg/kg, i.p.) or PBS control. Animals were sacrificed 1-24 hr later and liver tissue collected and processed for RT-PCR. Acetaminophen administration was associated with a time dependent induction of MCP-1 mRNA in the liver which was evident within 6 hr of treatment of the mice and reached a maximum by 24 hr. This was correlated with increased serum MCP-1. Acetaminophen treatment also induced CCR2b mRNA expression which reached maximum levels after 12-24 hr. TNFα has been reported to upregulate MCP-1 expression. To analyze the role TNFα in chemokine expression in the liver following acetaminophen administration, we used mice with a targeted deletion of the gene for the TNFα p55 receptor. MCP-1 and CCR2b mRNA expression were significantly reduced in p55-/- mice treated with acetaminophen, when compared to wild type controls. Serum MCP-1 levels were also decreased. These data suggest that TNFα regulates the expression of MCP-1 and CCR2b in the liver in this model of hepatotoxicity. Moreover, this chemokine may be involved in macrophage infiltration into the liver after acetaminophen administration. (Supported by NIH grant GM34310 and the Burroughs Wellcome Fund.)

1427 CANNABINOL ENHANCEMENT OF ANTI-CD3/CD28-INDUCED INTERLEUKIN-2 PRODUCTION IS MEDIATED THROUGH THE PKC/MAPK PATHWAY.

T. Jan and N. Kaminski. *Michigan State University, East Lansing, MI.*

One of the key features of cannabinoid-mediated biological effects on the immune system is the modulation of cytokine expression by T cells. Full activation of T cells requires dual stimulatory signals through the T cell receptor/CD3 complex and CD28. In the present studies, the effects of cannabinol on IL-2 production induced by soluble anti-CD3 and anti-CD28 mAb (CD3/CD28) in murine splenocytes was studied. CD3/CD28 induced only modest IL-2 production as compared to PMA/ionomycin. Although PMA alone was incapable of inducing IL-2, it synergized with ionomycin, CD3 or CD3/CD28 to dramatically enhance the production of IL-2 which was all significantly attenuated by PD098059, an inhibitor of MEK-1. These results suggest that PMA-activated PKC/MAPK pathway plays a key role in IL-2 regulation and that CD3/CD28 does not fully activate the MAPK pathway. Among the different stimuli examined, only CD3/CD28-induced IL-2 was markedly enhanced by cannabinol pretreatment, whereas the others were all suppressed. The cannabinol-mediated enhancement of IL-2 production was abrogated by staurosporine (a PKC inhibitor), but not by dibutyryl-cAMP, pertussis toxin or cannabinoid receptor antagonists (SR141716A and SR144528). Western blot analysis revealed that cannabinol up-regulated the MAPK signaling pathway as evidenced by the elevation of phosphorylated extracellular signal-regulated kinase-1 (ERK-1) and ERK-2 in the nucleus of cannabinol-pretreated and CD3/CD28-activated splenocytes. Alike IL-2 production, the increase in ERK-1 and ERK-2 was also abrogated by PD098059. Taken together, the present studies demonstrate that cannabinol enhances CD3/CD28-induced IL-2 production by up-regulating the PKC/MAPK pathway in murine splenocytes, which is not mediated through the cannabinoid receptor and cAMP pathway. A second important observation is that cannabinol can differentially modulate IL-2 production by primary T cells depending on the activation stimulus. (This work was supported by NIDA Grant DA07908.)

1428 DISSECTION OF THE EFFECTS OF PROPANIL ON T CELL SIGNALING PROCESSES USING DNA ARRAY TECHNOLOGY.

K. Brundage, R. Schafer and J. B. Barnett. *West Virginia University, Morgantown, WV.*

Propanil (3',4'-dichloropropionanilide), a post-emergence amide class herbicide, is used extensively during the cultivation of rice and wheat. Previous work in our laboratory has demonstrated that mice exposed to propanil have decreased T cell-dependent responses, decreased NK activity, and thymic atrophy with a decrease in the $CD4^+CD8^+$ immature thymocyte population. Analysis of cytokine production *in vivo* demonstrated a decreased production of interleukin (IL)-2, IL-6, Granulocyte/ Macrophage-Colony stimulating factor and interferon-gamma two days after exposure to propanil. In vitro, the mouse T cell line, EL-4, when stimulated with PMA and ionomycin in the presence of propanil (50 μM or less) had decreased IL-2 secretion, mRNA levels and stability but normal IL-2 mRNA kinetics. Recently, we have begun to dissect the steps in the signal transduction pathway that leads to IL2 production using the human T cell line, Jurkat. Preliminary data suggest that expression of some immediate early genes of the mitogenic and CREB signal pathways, in particular egr-1, are decreased by exposure to propanil. In addition, a marked increase in mRNA levels of several stress-induced and apoptotic pathway proteins including hsf-1, hsp90, inducible-nitric oxide synthase (iNOS), ATF-2 and Bax was observed. Many other genes, e.g., c-*fos* and I-

kappaBalpha, showed no change in expression levels. Taken together, these results suggest that exposure to low doses of propanil affects a multitude of important signal transduction proteins involved in T cell activation and IL-2 production. (Supported by NIH grant ES07512.)

1429 MICROARRAY ANALYSIS OF GENE EXPRESSION PATTERNS INDUCED BY IRRITANT AND SENSITIZING CHEMICALS.

B. He, A. E. Munson and B. J. Meade. *National Institute for Occupational Safety and Health, Morgantown, WV.*

Chemical-induced dermatitis continues to be an important occupational health problem. Despite decades of investigation, the molecular mechanisms underlying chemical induced hypersensitivity and irritation remain unclear due to the complicated interplay between properties of different chemicals and the immune system. In this study gene expression patterns induced by Toluene Diisocyanate (TDI, IgE-inducing sensitizer), Oxazolone (OXA, cell-mediated hypersensitivity inducing sensitizer) or Nonanoic acid (non-sensitizing irritant) were investigated using gene microarrays. Female BALB/c mice were dermally exposed on the ears once daily for 4 consecutive days. On day 5 the lymph nodes draining the exposure sites were collected and used for mRNA extraction. For TDI and OXA exposures, the concentrations used induced similar quantities of mRNA in the draining lymph nodes. The extracted mRNAs were reverse transcribed into cDNAs and then *in vitro* transcribed into biotin-labeled cRNAs. The hybridization of labeled cRNAs to GeneChip Mu6500 oligonucleotide arrays (Affymetrix,CA) and scanning were conducted by Research Genetics, Inc. AL. Of the 6,500 genes on the arrays, there were 19 genes whose expression levels were significantly different between TDI- and nonanoic acid-treated samples, 18 genes between OXA and nonanoic acid samples and 33 genes between TDI and OXA samples. These include immune response-related genes, transcriptional factors, signal transducing molecules and Expressed Sequence Tags. Microarray analysis identified differentially expressed genes which can be further investigated by conventional methods. Candidate genes will be chosen for further evaluation following exposure to a panel of chemical sensitizers and irritants. Further studies will be conducted to define the functional roles of these genes.

1430 A STUDY ON AN EXPOSURE MARKER FOR SAFROLE.

M. J. W. Chang and C. Y. Ko. *Chang Gung University, Tao-Yuan, Taiwan Republic of China.*

Safrole is a known animal carcinogen. It exists in sassafras oil, black pepper, ginger, and *Piper* betle inflorescence, etc. The latter is an unique ingredient of the Taiwanese betel quid. To assess the contribution of safrole in the induction of oral and liver cancer among the Taiwanese betel quid chewers, it is desirable to have an assessable biomarker for exposure. It has been shown that the main urinary metabolite of safrole is the glucuronide conjugate of 1,2-dihydroxy-4-allylbenzene (DHAB). DHAB standard was synthesized via a demethylation of eugenol. Its structure was confirmed by NMR and a ≥95% purity by NMR, TLC, and HPLC analyses. Urine sample preparation involved a 16-hour anaerobic hydrolysis with β-glucuronidase and extraction with ethylacetate. Quantitative analysis was accomplished by an isocratic HPLC on an ODC column with UV detection. The linearity of the standard curve (3.5 to 28 μg/mL) was good (r≥0.997), all relative errors were <±12%, and recovery was 70.2±6.7% (n=4). When male Wistar rats were given safrole in corn oil, at 0, 75, 150, and 300 mg/kg, both the first and second day urines showed a linear dose-response relationship of r=0.90 and 0.99, respectively. The method was then applied to 11 human subjects, 7 betel quid non-chewers and 4 chewers. The results showed that DHAB of the non-chewers ranged from 0.75 to 17.75 μg/mg creatinine (crn) with a median of 1.64. For the chewers, it was 1.47~12.16 with a median of 4.17 μg/mg crn, which was ~2.54 times of the non-chewer's. Thus, it is concluded that DHAB can be the biomarker of exposure to safrole. (Supported by grant DOH88-HR-802, ROC.)

1431 EFFECT OF GENETIC POLYMORPHISMS OF CYP2A6 AND 2E1 ON URINARY COTININE LEVELS IN JAPANESE.

T. Kawamoto. *University of Occupational and Environmental Health, Kitakyushu, Japan.* Sponsor: K. Toshihiro.

Among nicotine metabolites, urinary cotinine has been popularly used as an exposure biomarker for cigarette smoking. However, it is well known that there are individual differences in nicotine kinetics and metabolism. In order to clarify the effects of the genetic polymorphims of drug metabolizing enzymes on nicotine metabolism, urinary cotinine levels in Japanese students and office workers were studied in the relation with cytochrome P4501A1 (CYP1A1), CYP2A6, CYP2E1, aldehyde dehydrogenase 2 (ALDH2), N-acetyltransferase 2 (NAT2) and glutathione S-transferase M1 (GSTM1). As a result, cigarette consumption and homozygous CYP2A6 deletion significantly affect urinary cotinine levels. The genetic polymorpshim in 5'-flanking region of CYP2E1 can be also considered as a clue of individual differences in nicotine metabolism. In a smoking challenge test, cumulated urinary cotinine excretion in the homozygously CYP2A6 deleted individuals was about one seventh as compared to the controls that have CYP2A6*1 allele.

1432 HUMAN SKIN SENSITIZATION POTENTIAL, *IN VIVO*: GLUCOWATCH® BIOGRAPHER.

D. R. Wilson and S. J. Fermi. *Cygnus, Inc., Redwood City, CA.* Sponsor: W. G. Reifenrath.

The GlucoWatch® biographer, developed by Cygnus, Inc., is a frequent, automatic, and non-invasive glucose monitor intended to provide diabetics with the information needed to control their glucose levels. Sponsored by Cygnus, Hill Top Research, Inc. (Miamiville, OH) performed a clinical trial evaluating the potential of the active GlucoWatch® biographer to induce contact sensitization (allergic skin response) in 31 diabetic and 56 non-diabetic subjects via Repeat Insult Patch Test. The active test system delivered iontophoretic current (up to 0.32 mA/cm^2 for 6 minutes during each 20 minute glucose measurement cycle). When worn, the following components of the biographer contacted the skin surface at distinctly different regions; i.e., device edge, active glucose collection gel pad (with glucose oxidase), blank gel pad (without glucose oxidase), skin contact adhesive area, and sweat sensors. These skin regions were evaluated separately. There were nine 14-hour biographer applications in the induction phase, and (after a 13 to 16-day break) a single 8-hour application in the challenge. 99 subjects initially enrolled in the study; 12 subjects dropped out, (9 diabetics and 3 non-diabetics). None of the diabetics dropped out for reasons related to diabetes. There were no serious or unexpected adverse events during the study. No subject scored greater than a 2 (moderate) for erythema or a 2 (light) for edema during the Induction or Challenge Period. Conclusion: There was no indication of contact sensitization in either diabetic or non-diabetic subjects.

1433 BIOMARKERS OF INTERNAL DOSE IN WORKERS EXPOSED TO CHLORONITROBENZENE.

C. R. Jones[1], G. Sabbioni[2] and O. Sepai[1]. [1]*Department of Environmental & Occupational Medicine, Newcastle University, Newcastle Upon Tyne, United Kingdom and* [2]*Walther-Straub Institut für Pharmakologie und Toxikologie, Ludwig-Maximilians Universitat, München, Germany.*

Para-chloronitrobenzene (p-CNB) has multiple pharmaceutical and agrochemical applications. P-CNB acts as a haematotoxic agent following metabolic activation to the phenylhydroxylamine. The aim of this study was to determine the occupational exposure level, and the internal dose, of p-CNB in exposed factory workers, from the Peoples Republic of China. Eight hour time weighted average (TWA) workplace exposure levels (n=21) ranged from 1.604 - 78.26mg/m^3 (mean: 7.97mg/m^3, UK 8hr TWA limit=1mg/m^3). Urine samples were collected from workers for the determination of recent exposure. HPLC-UV analysis of spot urines from exposed workers (n=43) revealed three metabolites; p-chloroaniline (p-CA), 2-chloro-5-nitrophenol (CNP) and N-acetyl-S-(4-nitrophenyl)-L-cysteine (NANPC). P-CA was detected in 30 (mean: 0.470μ mol/mmol creatinine, range: 0.140-2.47μ mol/mmol creatinine); CNP was detected in 41 (0.620μ mol/mmol, 0.006-4.779μ mol/mmol) and NANPC was detected in 42 (0.819μ mol/mmol, 0.158-2.574μ mol/mmol) of the exposed samples. Metabolites were not detected in non-exposed controls (n=10), within the detection limits of the assay (0.167μ mol on column). Blood samples were collected for the determination of cumulative exposure dose. Haemoglobin (Hb) was hydrolysed in base. The released p-CA was derivatised with pentafluoropropionic anhydride and quantified by GC-MS using single ion monitoring and negative chemical ionisation. The mean adduct levels from exposed (n=43) and factory controls (n=17) were 8.09pmol/mg Hb (range: 0.15-17.06pmol/mg Hb) and 1.70pmol/mg Hb (0.14-8.22pmol/mg Hb) respectively. The presence of p-CA was confirmed by GC-MS electron impact ionisation. No significant correlation was found between external exposure and markers of internal dose, or between urinary metabolite and Hb adduct levels. The urinary metabolites provided markers of short-term exposure, reflecting the inter-day variability in external exposure dose. The presence of Hb adducts and absence of urinary

metabolites in factory controls confirmed exposure had occurred in these workers over the life-span of the erythrocytes. Therefore Hb adducts are markers of the integrated body burden following exposure over a longer time period. In conclusion, it is important to quantify both short and long-term markers of exposure to detect variability in exposure levels with time.

1434 BIOMARKERS OF OXIDATIVE STRESS STUDY I. ARE PLASMA ANTIOXIDANTS MARKERS OF CC14 POISONING?

M. B. Kadiiska[1], B. C. Gladen[1], D. D. Baird[1], G. E. Hatch[2], D. P. Jones[3], R. P. Mason[1] and J. C. Barrett[1]. [1]*NIEHS, Research Triangle Park, NC,* [2]*EPA, Research Triangle Park, NC and* [3]*Emory University, Atlanta, GA.*

Antioxidants in the blood plasma of rats were measured as part of a comprehensive, multilaboratory validation study searching for non-invasive biomarkers of oxidative stress. For this initial study an animal model of CCl4 poisoning was studied. The time-(2, 7 and 16 h) and dose-(120 mg/kg and 1200 mg/kg, i.p.) dependent effects of CCl4 on plasma levels of alfa-tocopherol, ascorbic acid, glutathione (GSH and GSSG), uric acid and total antioxidant capacity were investigated to determine whether the oxidative effects of CCl4 would result in losses of antioxidants from plasma. The alfa-tocopherol concentration was decreased in CCl4-treated rats. However, due to concomitant decreases in cholesterol and triglycerides, it was impossible to dissociate oxidation of a-tocopherol from generalized lipid changes. Ascorbic acid levels were higher with treatment at the earliest time point; the ratio of GSH to GSSG generally declined, and uric acid remained unchanged. Total antioxidant capacity showed no significant change except for 16 h after the high dose, when it was increased. These results suggest that plasma changes due to liver malfunction and rupture of liver cells impede detection of any potential changes in the antioxidant status of the plasma.

1435 DETERMINING AN OCCUPATIONAL DERMAL EXPOSURE BIOMARKERS FOR ATRAZINE THROUGH MEASUREMENT OF METABOLITES IN HUMAN URINE BY HPLC ACCELERATOR MS.

B. A. Buchholz[1], S. J. Gee[2], S. D. Gilman[3], B. D. Hammock[2], X. Hui[4], H. J. Maibach[4], J. S. Vogel[1] and R. C. Wester[4]. [1]*LLNL, Center for Accelerator Mass Spectrometry, Livermore, CA,* [2]*UC-Davis, Department of Entomology, Davis, CA,* [3]*University of Tennessee, Department of Chemistry, Knoxville, TN and* [4]*UCSF, Department of Dermatology, San Francisco, CA.* Sponsor: B. Hammock.

Metabolites of atrazine were measured in human urine after dermal exposure using HPLC to separate and identify metabolites and accelerator mass spectrometry (AMS) to quantify them. Ring labeled 14C-atrazine was applied for 24 h to the forearms of human volunteers at low (0.167 mg, 6.45 microCi) and high (1.98 mg, 24.7 microCi) doses. The effective radiation doses to the subjects were in the 1-30 microSv range, similar to that delivered in a dental X-ray. Urine was collected for seven days. The urine was centrifuged to remove solids and the supernatant was measured by liquid scintillation counting prior to injection on the HPLC to insure that <0.17 Bq (4.5 pCi) was injected on the column. Peaks were identified by co-elution with known standards. Elution fractions were collected in 1 min increments, half of each fraction was analyzed by AMS to obtain limits of quantitation of 14 amol. Mercapturate metabolites of atrazine and dealkylated atrazine dominated the early metabolic time points, accounting for approximately 90% of the 14C in the urine. No parent compound was detected. The excreted atrazine metabolites became more polar with increasing time, and an unidentified polar metabolite that was present in all samples became as prevalent as any of the known ring metabolites several days after the dose was delivered. The mercapturate metabolites of atrazine appear to be the best class of biomarkers of dermal exposure. Knowledge of metabolite dynamics is crucial to developing useful assays for monitoring atrazine exposure in agricultural workers. (Work was performed under the auspices of the U.S. Department of Energy at Lawrence Livermore National Laboratory under contract W-7405-ENG-48.)

1436 PMN FUNCTION AS BIOMARKER OF OXIDANT EXPOSURE.

E. Hoffer[1], Y. Baum[1], T. Machamid[2], A. Aloufi[3], A. Tamir[4] and A. Tabak[1]. [1]*Israel Poison Information Center, Haifa, Israel,* [2]*Kupat Holim Clalit, Afula, Israel,* [3]*Ministry of Health, Haifa, Israel and* [4]*Technion, Haifa, Israel.*

Welders are exposed in their work to oxidizing air pollutants like ozone and nitric oxide, as well as to metal oxides. Peripheral blood neutrophils of welders and of an age and smoking habits matched group were tested for PMA-stimulated release of superoxide anions. We found that the stimulated release of superoxide anions from PMN isolated from welders was significantly lower (p=0.021) than that of the matched group. Smokers and older workers had a lower PMN function as compared to that of non- smokers and younger workers. In order to elucidate this effect, another set of experiments were carried out in which PMN from healthy volunteers were also tested for the stimulated release of superoxide anions after being incubated with plasma of welders and of a matched (age and smoking habits) control group. These experiments showed that stimulated superoxide production was inhibited ($p<0.05$) by: 1) incubation with plasma from welders as compared to that of a matched group; 2) plasma from elderly individuals as compared to that of younger ones; 3) plasma from smokers as compared to that of non-smokers. These findings indicate that age and exposure to oxidants and cigarettes smoke induce the appearance in plasma of factors which affect neutrophil function. Determination of these factors could potentially be used to detect the exposure level of individuals to environmental pollutants. There is a definite advantage of analyzing plasma instead of PMN from exposed individuals.

1437 PHYSICOCHEMISTRY AND PULMONARY TOXICOLOGICAL PROPERTIES OF ORIMULSION FLY ASH.

A. Mallett[1], A. Miller[2], W. Linak[2], J. Richards[2], J. McGee[2], J. Lehmann[2] and K. Dreher[2]. [1]*University of North Carolina at Chapel Hill, School of Public Health, Chapel Hill, NC and* [2]*Environmental Protection Agency, Research Triangle Park, NC.* Sponsor: D. L. Costa.

Orimulsion® is a fuel source that could be an economical substitute for coal and heavy oil currently used in utility and other types of commercial boilers. The environmental and public health risks associated with the combustion of Orimulsion® are unknown. This study compares the physicochemical and acute pulmonary toxicological properties of Orimulsion fly ash (OFA-100 and OFA-400) derived from the combustion of two forms of Orimulsion with similar properties of fly ash obtained from the combustion of a conventional fuel source, residual oil #6 (ROFA #6). Fuels were burned in a Package Boiler Simulator under identical combustion conditions and oil fly ash particles (<2.5μm MMAD)were collected on filters. Collected OFA-100, OFA-400 and ROFA #6 were analyzed for: particle acidity; 1MHCl and water soluble metal (V, Ni, Fe, Cu, Zn, Pb, Cd); and sulfate content. Particle acidty, sulfate level, as well as acid and water soluble total metal content were comparatively similar for all oil fly ash samples examined. OFA-100 and OFA-400 filters had considerably less water soluble metals when compared to the ROFA #6 filter, with the exception of elevated Ni and V levels in the OFA-400 filter. Male, 60 - 70 day old, Sprague-Dawley rats were exposed by intratracheal instillation to water extracts of each oil fly ash filter. Animals were examined for biomarkers of injury by bronchoalveolar lavage at 24h post-exposure. The measurements of edema and inflammation for all oil fly ashes were comparable at low dose levels. However, OFA particles were found to elicit significantly greater inflammatory responses at higher doses when compared to ROFA #6. ROFA #6 particles were found to induce more pulmonary edema when compared to animals exposed to either OFA sample. These results demonstrate that OFA-100 and OFA-400 particles display similar physicochemical properties when compared to ROFA #6. However, OFA-100 and OFA-400 particles led to a pro-inflammatory response, whereas the ROFA particles caused more lung edema. (This abstract has been reviewed and does not necessarily reflect EPA policy or endorsement. Research was support by the USEPA-UNC-CH Training Agreement #CT 826513.)

1438 NITROUS OXIDE EXPOSURE ASSESSMENT IN OPERATING-ROOM PERSONNEL: METHIONINE SYNTHASE AND HOMOCYSTEINE MONITORING.

A. Tabak[1], Y. Katz[2] and E. Hoffer[1]. [1]*Israel Poison Information Center, Haifa, Israel and* [2]*Haemek Medical Center, Afula, Israel.*

Prolonged exposure to nitrous oxide may cause adverse effects on both the hematologic and nervous system in humans; the clinical symptoms resemble those observed in vitamin B12 deficiency. In patients receiving nitrous oxide anesthesia, a considerable inactivation of methionine synthase in mononuclear white blood cells, as well as an increase in plasma homocysteine were observed. The present research focuses on the relationship between the extent of occupational exposure to the anesthetic gas nitrous oxide (N2O) and the behavior of methionine synthase in lymphocytes and homocysteine in plasma Three groups of humans, 30 in each group were evaluated: medical doctors, mainly anesthetists, operating room nurses and non-exposed matched subjects. Homocysteine levels in plasma were determined by HPLC with a fluo-

rescent detector. The method is based on the pre-column derivatization of homocysteine with ABDF. The activity of methionine synthase (holo and apo-enzyme) in lymphocytes was determined by measuring the production of 14C- methionine from 14C- methionine tetrahydrofolate with and without addition of methyl cobalamine.The obtained results (mean±SD) were: Homocysteine (microg/ml): 1.18±0.32, 1.14±0.28 and 1.25±0.44 for M.D.'s, nurses and control group respectively. Methionine synthase holo-enzyme asp-mol/hr/million cells was 99.8±29.8, 76.3±9.7 and 100.4±22.3, while methionine synthase holo and apo-enzyme was 158.2±33.7, 153.1±60.7 and 150.0±29.9 for the same study groups respectively. One can see that there is no significant difference between the levels of homocysteine and of methionine synthase of the three groups considered. Thus, it appears that the levels of nitrous oxide in the operating rooms of the hospitals included in this study are sufficiently low and therefore do not affect the biochemical parameters evaluated.

1439 FUMONISIN B1-INDUCED LIVER TOXICITY, LIVER FREE SPHINGANINE, AND LIPID PEROXIDATION COMPARED IN SIX DIFFERENT STRAINS OF MALE MICE.

R. T. Riley[1], J. L. Showker[1], K. A. Voss[1], E. N. Enongene[1], F. I. Meredith[1] and R. P. Sharma[2]. [1]*Russell Research Center, USDA/ARS, Athens, GA and* [2]*College of Veterinary Medicine, University of Georgia, Athens, GA.*

Fumonisin B1(FB1) is a fungal toxin that inhibits ceramide synthase, a key enzyme in the de novo sphingolipid biosynthesis pathway. In Sprague Dawley and Fischer 344 rat, New Zealand white rabbit, and BALB/c and other mouse strains, disruption of sphingolipid metabolism has been hypothesized to be an important mechanism of action of FB1-induced liver toxicity. However, there is one report that liver toxicity in rodents is not related to ceramide synthase inhibition based on the fact that the IC50 for ceramide synthase inhibition in primary rat hepatocytes is ~0.1 micromolar, whereas, evidence of cytotoxicity first occurs at ~75 micromolar FB1. This retrospective study was conducted to determine the relationship between liver toxicity based on blind pathology scores from H&E stained liver sections, serum alanine aminotransferase (ALT), liver free sphinganine, and lipid peroxidation (TBARS) in liver from six mouse strains dosed subcutaneously with 2.25 mg FB1/kg body weight/day for 5 days. The results show that there is a close correlation between the liver toxicity scores and liver free sphinganine (an indicator of ceramide synthase inhibition), and between the serum ALT and free sphinganine. There was no increase in lipid peroxidation based on the total thiobarbituric acid positive substances. Thus, in male mice, when liver pathology is observed, there is a close correlation between the incidence and severity of the pathology, increased serum liver enzymes and free sphinganine indicative of disrupted sphingolipid metabolism. (Supported in part by NIH ES09403.)

1440 ASSESSING THE STABILITY OF HEMOGLOBIN ADDUCTS AFTER ADMINISTRATION OF BENZENE TO MALE F-344 RATS.

M. A. Troester[1], L. L. Kupper[2] and S. M. Rappaport[1]. [1]*Dept. of Environmental Sciences and Engineering, School of Public Health, University of North Carolina, Chapel Hill, NC and* [2]*Dept. of Biostatistics, School of Public Health, University of North Carolina, Chapel Hill, NC.*
Sponsor: J. A. Swenberg.

Hemoglobin (Hb) adducts have potential for use in estimating the blood dose of electrophilic benzene metabolites. To relate adduct formation with dose, knowledge of adduct stability is necessary. The constant, predetermined lifespan of the red blood cell leads to zero-order kinetics of adduct removal if Hb adducts are stable. For unstable adducts, mixed zero- and first-order kinetics describe the loss of adduct by simultaneous hemoglobin turnover and chemical instability. The stability of total radiobound adducts ([^{14}C]R-Hb) and cysteinyl adducts of benzene oxide ([$^{13}C_6$]BO-Hb) was investigated in Hb of male F344 rats following administration of a single oral dose of 400 mg [U-^{14}C/$^{13}C_6$] benzene/kg body weight. The decay trends of both [^{14}C]R-Hb and [$^{13}C_6$]BO-Hb were best described by a zero-order process, with lifetimes for [^{14}C]R-Hb and [$^{13}C_6$]BO-Hb (47 and 55 days, respectively) that were consistent with the lifetime of rat erythrocytes (45-65 days). Based on these findings, BO-Hb can be used in human populations to estimate the average daily dose over the ~120 day lifetime of the erythrocyte.

1441 ARSENIC AND LEAD EXPOSURE IN CHILDREN LIVING IN SMELTER AREAS OF MEXICO AND BOLIVIA.

L. Carrizales[1], L. Yáñez[1], J. Calderon[1], E. Paz[2] and E. Diaz-Barriga[1]. [1]*Autonomous University of San Luis Potosi, School of Medicine, San Luis Potosi, Mexico and* [2]*Pan American Health Organization, El Paso, TEXAS.*

The objective of this study was to compare the levels of environmental contamination and children exposure in areas next to primary and small scale secondary smelters (S-smelters). The primary smelter was a copper metallurgical located in the community of Morales in San Luis Potosi, Mexico, and the S-smelters were located in the Bolivian site of El Alto Lima. In El Alto Lima and Morales, arsenic and lead contamination was found in soil and dust (concentrations in soil were above the guidelines recomended by the United States Environmental Protection Agency). In Morales, the arsenic concentration in airborne particulate was 0.56 µg/m3. Children in Morales and in El Alto Lima, had similar geometric means of arsenic in urine; and in El Alto Lima, an inverse correlation was found for age and urinary arsenic ($r = -0.28$, $p<0.01$). Also, an inverse correlation was registered for age and blood lead levels (PbB) in children living in El Alto Lima ($r = -0.29$, $p<0.01$). Children aged 5-7 years presented the highest PbB and 44% of them had levels higher than 10 µg/dl. In Morales, a direct correlation between age and PbB was found at this site, ($r=0.29$, $p<0.01$). In the age group of 7-9 years, 56% of the children had PbB higher than 10 µg/dl and 8% had levels above 20 µg/dl. It is evident that studies are needed in order to identify adverse health effects in children living in the smelter sites; nevertheless, it is more important to develop risk reduction programs. (This work was supported by a grant from the Consejo Nacional de Ciencia y Tecnología, Sistema de Investigación Miguel Hidalgo [RN-27/96].)

1442 FORMATION OF HEMOGLOBIN ADDUCTS IN FEMALE RATS AND MICE EXPOSED TO BUTADIENE.

P. B. Upton[1], A. Ranasinghe[1], V. E. Walker[2] and J. A. Swenberg[1]. [1]*Department of Environmental Sciences & Engineering, University of North Carolina, Chapel Hill, NC and* [2]*New York State Department of Health, Wadsworth Center, Albany, NY.*

1,3-Butadiene (BD) is an important industrial chemical that is carcinogenic in mice and rats. The present study was conducted to compare the formation of N-terminal valine adducts, hydroxybutenylvaline (HBVal) and trihydroxybutylvaline (THBVal), in hemoglobin from female F344 rats and B6C3F1 mice exposed to 0 or 1250 ppm BD for 1, 5 or 10 days. Briefly, globin was extracted from washed red blood cells, subjected to a modified Edman degradation and washed on C_{18} columns. An aliquot was removed for HBVal-pentafluorophenylthiohydantion (PFPTH) quantitation while the remainder was acetylated for quantitation of THBVal-PFPTH. Synthesized external standards for both HBVal-PFPTH and THBVal-PFPTH were used after Edman degradation. Gas chromatography/tandem mass spectrometry (GC/MS-MS) was used to quantitate HBVal-PFPTH, while THBVal-PFPTH was measured by either GC/high resolution mass spectrometry (GC/HRMS) or GC/MS-MS. The use of GC/MS-MS has improved the sensitivity and resolution for THBVal-PFPTH over GC/HRMS. Results show a linear increase in the formation of N-terminal valine hemoglobin adducts. Female mice had HBVal values of 0.4, 1100, 4410, and 7360 pmol/g globin at 0 ppm exposure and 1250 ppm BD for 1, 5, or 10 days, respectively. The THBVal values in female mice were 540, 4200, 19800, and 35900 pmol/g globin at 0 ppm exposure and 1250 ppm BD for 1, 5, or 10 days, respectively. Female rats had HBVal levels at 0.04, 180, 830, 1390 pmol/g globin at 0 ppm exposure and 1250 ppm BD for 1, 5, or 10 days, respectively. The THBVal levels in these same rats were 200, 1227, 4720, and 8020 pmol/g globin at 0 ppm exposure and 1250 ppm BD for 1, 5, or 10 days, respectively. These data clearly show that hemoglobin adducts accumulate in a linear fashion in both rats and mice, that THBVal is found in greater amounts than HBVal, and that mice form more adducts than rats. (Supported in part by the Chemical Manufacturers Association.)

1443 PROTEOMIC ANALYSIS OF RENAL AND HEPATIC PROTEIN EXPRESSION IN RATS EXPOSED REPEATEDLY TO JET FUEL VAPOR.

F. Witzmann[1], G. D. Ritchie[2], R. L. Carpenter[2], A. F. Nordholm[2], C. L. Wilson[2] and J. Rossi, III[2]. [1]*Molecular Anatomy Laboratory, Indiana University, Purdue University, Columbus, IN and* [2]*Neurobehavioral Effects Laboratory, Naval Medical Health Research Center Detachment-Toxicology (NHRC-TD), Wright-Patterson Air Force Base, OH.*

Male Sprague-Dawley rats were exposed by whole body inhalation to JP-8 jet fuel vapor (1000 mg/m3 + 10%) or room air control conditions for 6 hr/day, 5 days/wk for 6 consecutive weeks (180 hr). Following an 82-day recovery period, rats were sacrificed and tissues evaluated for altered expression of 500+ proteins. Tissues were examined for both total protein abundance and protein charge modification. Kidney and liver samples were solubilized and separated via large scale, high resolution two-dimensional electrophoresis (2-DE) and gel patterns scanned, digitized and processed for statistical analysis. Through the use of peptide mass fingerprinting, confirmed by sequence tag analysis, three altered proteins were identified and quantified. Numerically, but not statistically significant increases were found in total abundance of lamin A (NCBI accession no. 1346413) in the liver, and of 10-formyltetrahydrofolate dehydrogenase (10-FDH; #1346044) and glutathione-S-transferase (GST; #2393724) in the kidneys of vapor exposed subjects. Protein charge modification index (CMI) analysis indicated significant alterations ($p<0.001$) in expressed lamin A and 10-FDH.

1444 ANTIOXIDANT EFFECTS OF BLACK TEA IN SMOKERS AND NON-SMOKERS.

B. Ren, Y. Xu, L. M. Kamendulis, N. Dum, J. Meng and J. E. Klaunig. *Division of Toxicology, Department of Pharmacology & Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

While the chemopreventive effects of green tea in humans have been examined, less information is aviliable on black tea (the most commonly consumed form of tea in Europe and North America). Both black tea and green tea have been shown to reduce carcinogen-induced tumorigenesis and mutagenesis in *in vivo* and *in vitro* systems. This chemopreventive activity appears to be based, in part, on the antioxidant properties of tea. Oxidative stress has been implicated as a causative or participating factor in several human diseases including cancer, neurodegenerative diseases, and heart disease. Increased oxidative stress with resulting oxidative damage has been associated with certain lifestyle behaviors, including smoking. We have previously reported a decrease of oxidative stress in an Asia study population and a American study population after consuming green tea. The present investigation examined the effects of black consumption on selected oxidative stress endpoints in an American study group. Study participants (50 males and females; 25-35 years of age; smokers and non-smokers) were given black tea for 2 weeks or placebo for 2 weeks. Blood and urine were sampled after each treatment. Biomarkers of oxidative stress, including oh8dG and MDA in urine and antioxidants, were measured. The relative level of reactive oxygen species (ROS) were evaluated in individuals by determining urinary 2,3-DHBA 6 hours after administrated 1 gram of aspirin. The relationship of oxidative stress biomarkers, dietary intake and tea consumption was analyzed. The results showed that black tea consumption decreased oxidative stress in most individuals, (decreased levels of oh8dG, MDA, and 2,3-DHBA). Cigarette smoke for the most part increased oxidative damage (oh8dG and MDA). These results showed that similar to green tea, black tea also function as an antioxidant in humans.

1445 CRITICAL END - POINTS SELECTED IN A REPORT SYSTEM FOR AFLATOXIN-OCCUPATIONAL EXPOSED POPULATION IN THAILAND.

P. Sinhaseni, T. Suramana and N. Dusitsin. *The Institute of Health Research, Chulalongkorn University, Bangkok, Thailand.*

In recent years, a wide range of structurally dissimilar xenobiotics appears to be involved in toxicant-initiated oxidative stress. Aflatoxin B1 has previously been shown to alter mitochondrial function by inhibiting the electron transport chain as well as by uncoupling of oxidative phosphorylation. It has been proposed that the involvement of cytokine released from macrophage may inhibit RNA polymerase action and play a role to modify phosphodiester bond in white blood cells of spleen. Recently, prevention of aflatoxicosis and aflatoxin residues with hydrated sodium calcium aluminosilicate have been studied by Philips and colleagues. However, Jakab et al. (1994) reported that respirable particle of dust in animal feed may inhibit alveolar macrophage phagocytosis. We investigated different aluminosilicate as well as zeolite (clinoptilolite) formulations normally used in Thailand as feed adsorbants for their bulk density and particle size distribution. These adsorbants' effects to reduce aflatoxicosis were examined. It is found that clinoptilolite which is a non-selective aflatoxin binder can modulate aflatoxicosis in rats but may present occupational hazard in users. Health surveillance program which provide oxidative-stress toxicants related information were set up for exposed workers. The critical end-points selected are general reproductive health of exposed workers which are routinely monitored in public health report system (congenital malformation of offsprings, fertility and disorder of thyroid gland).

1446 CYP1A1, CYP1A2 AND CYP1B1 MRNA EXPRESSION LEVELS IN HUMAN BLOOD USING A REAL-TIME REVERSE TRANSCRIPTION-PCR SYSTEM.

H. Sone[1], C. Tohyama[1], C. Suzuki[2], M. Kabuto[1] and J. Yonemoto[1]. [1]*National Institute for Environmental Studies, Tsukuba, Japan and* [2]*CREST, Kawaguchi, Japan.*

Environmental pollutants such as dioxin and related compounds induce CYP1A1, CYP1A2 and CYP1B1 via aryl hydrocarbon receptor-mediated mechanism. EROD activity is a very useful marker for exposure level of those environmental pollutants particularly in experimental settings, but has a demerit of low detection sensitivity in the human subjects in epidemiological studies. To quantify the CYP1A1, CYP1A2 and CYP1B1 mRNA in blood, we have thus developed a real-time quantitative reverse transcription-PCR assay based on TaqMan fluorescence methodology. By applying as little as 1 ng of total RNA from the blood, we could determine CYP1A1, CYP1A2 and CYP1B1 mRNA in the blood from 71 volunteers living in two different areas. Expressed levels of CYP1A1, CYP1A2 and CYP1B1 genes varied among individual participates, the difference of which was thought to reflect in part the exposure levels of TCDD and other environmental pollutants. The quantification by TaqMan fluorescence method of CYP1A1, CYP1A2 and CYP1B1 genes expression level in blood would be a sensitive and accurate method to monitor environmental contamination of analyzing large numbers of samples in a minimized time.

1447 A NEW APPROACH FOR EVALUATION OF EXPOSURE TO ENVIRONMENTAL HAZARDOUS AGENTS.

J. S. Kritzler[1], B. Brodsky[1], A. Nyska[2], Y. Weisman[3], I. Shatz[1], M. Furth[4], E. Ashash[5] and U. Wormser[1]. [1]*The Hebrew University, Jerusalem, Israel,* [2]*National Institute of Environmental Health and Sciences, NIH, Research Triangle Park, NC,* [3]*Kimron Veterinary Institute, Beit Dagan, Israel,* [4]*The General Health Insurance Fund, Jerusalem, Israel and* [5]*Ashdot-Yaacov, Ashdot-Yaacov, Israel.* Sponsor: E. Hoffer.

The conventional procedures for biological monitoring are not always suitable for the current public health requirements. In this study we propose a unique approach for exposure detection. We have developed a bioassay system based on the sensitivity of *in vitro* cell culture to toxic agents present in the circulation. We have used two systems: a) the animal model in which human Y79 retinoblastoma cells were exposed to serum samples of paralyzed ostriches; b) the human model in which these cells were exposed to sera of males, non smokers, industry workers dealing with production of cholinesterase inhibitors. The assay was performed by exposure of Y79 human retinoblastoma cells to 1.5% human serum or 2% ostrich serum for 3 days and cell viability was measured by the neutral red assay. In the ostrich system, the sera of paralyzed birds caused a statistically significant reduction of 63% in cell viability in comparison to samples of healthy ostriches. Heat-treatment did not reverse the cell killing effect of the specimens obtained from the paralyzed ostriches, indicating that complement was not involved in this phenomenon. In the human system, although the workers were well protected and asymptomatic, there was 32% reduction in cell viability in comparison to that caused by sera of office workers. The present findings may offer a unique approach for diagnosis of latent exposure to hazardous environmental chemicals and to a mixture of harmful agents.

1448 DNA ADDUCT FORMATION IN THE LUNGS OF FEMALE SPRAGUE-DAWLEY RATS TREATED WITH THE ENVIRONMENTAL CARCINOGEN 1-NITROPYRENE.

M. R. Santiago[1], I. Vargas[1], L. S. Von-Tungeln[2], P. P. Fu[2] and D. Herreno-Saenz[1]. [1]*Pharmacology and Toxicology, School of Medicine, University of Puerto Rico, San Juan, Puerto Rico and* [2]*Division of Biochemical Toxicology, National Center for Toxicological Research, Jefferson, AR.*

DNA adducts are useful biomarkers of exposure and assist in determining the absorption, metabolic activation/detoxification pathways, and DNA repair mechanisms following exposure to genotoxic chemicals. 1-Nitropyrene (1-NP), a well-known tumorigen and carcinogen, is a widespread environmental contaminant from a number of sources the foremost being diesel exhaust. The principal metabolic activation pathway leading to mutation and tumor induction of 1-NP is nitroreduction. Three DNA adducts [*N*-(deoxyguanosin-8-yl)-1-aminopyrene, 6-(deoxyguanosin-N^2-yl)-1-aminopyrene, and 8-(deoxyguanosin-N^2-yl)-1-aminopyrene] have been identified from the nitroreduction of 1-NP and may be responsible for the mutagenicity and carcinogenicity of this nitropolycyclic aromatic hydrocarbon. Each of these adducts have been detected in mammary tissue, a tumor target tissue in rats treated with 1-NP. Since diesel exhaust is a lung carcinogen in rats, we investigated if 1-NP would form DNA adducts in the tissue. Female Sprague Dawley rats were treated with 1-NP by i.p. injection at doses of 25, 50, and 100 mg/kg. The lungs were removed at 12, 24, and 48 hrs and 7, 14, and 28 days after the treatment. Lung nuclei were prepared, DNA was isolated, and DNA adduct formation analyzed by ^{32}P-postlabeling/HPLC. At the 100 mg/kg dose, all three adducts were detected in the lungs at 48 hrs and 7 days. These data suggest that 1-NP is activated by nitroreduction in rat lung and may contribute to the tumorigenicity observed with diesel exhaust.

1449 THE USE OF AN ANDROGEN RECEPTOR-ACTIVATED LUCIFERASE EXPRESSION (AR-CALUX) ASSAY FOR SCREENING OF STEROID GROWTH PROMOTERS IN CATTLE.

B. M. G. Blankvoort[1], E. M. de Groene[1], D. C. Timmer[1], A. Brouwer[2], R. F. Witkamp[1] and J. M. M. Aarts[3]. [1]*TNO Nutrition, Zeist, Netherlands,* [2]*Free University, Amsterdam, Netherlands and* [3]*Wageningen University Research Center, Wageningen, Netherlands.*

Steroid growth promoters (Gps) are substances that are administered to farm animals in order to enhance the efficiency of meat production. The use of these compounds is prohibited in the European Union (EU). However, GPs are frequently detected in random samples from butchers, stressing the need for reliable, cheap and fast detection methods. Therefore, an androgen receptor mediated chemical-activated luciferase expression (AR-CALUX) assay was developed. In this assay, androgen receptor agonistic potential is quantified by measuring luciferase activity, using a 96 well format. A dose-dependent increase in luciferase induction, up to three-fold, was found with 1 nM R1881, a potent synthetic androgen. Due to a high background signal we expect to find a higher fold induction after improving assay conditions. The natural androgen receptor (AR) ligand dihydrotestosterone as well as the synthetic androgens 17-β-trenbolone and 17-α-trenbolone were less potent inducers in accordance with their lower AR binding and activating potency. Progesterone also induced luciferase expression. However flutamide, an anti-androgen, was able to suppress this response indicating that the response induced by progesterone is AR-mediated. 17-β-Estradiol and dexamethasone did not induce luciferase expression, strongly suggesting that the assay is specific for androgen receptor agonists.

1450 ANALYSIS OF ENVIRONMENTAL AND BIOLOGICAL EXTRACTS FOR DIOXIN-LIKE ACTIVITY UTILIZING A LUCIFERASE REPORTER GENE BIOASSAY.

D. E. Shubert[1], F. D. Stephen[1], P. J. Kostyniak[1], H. B. Greizerstein[1], J. E. Vena[2], T. A. Gasiewicz[3], P. F. Dehn[4] and J. R. Olson[1]. [1]*Dept. Pharm. and Tox., SUNY at Buffalo, Buffalo, NY,* [2]*Dept. of Social Preventive Medicine, SUNY at Buffalo, Buffalo, NY,* [3]*Dept. of Environmental Medicine, University of Rochester, Rochester, NY and* [4]*Dept. of Biology, Canisius College, Buffalo, NY.*

Most of the biological and toxicological effects of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and related compounds are mediated by binding to the aryl hydrocarbon receptor (AhR) and the subsequent interaction of the ligand-activated AhR with dioxin response elements (DREs). A murine hepatoma cell line (hepa 1c1c7) was stably transfected with the p2Dluc plasmid containing two DREs upstream from the luciferase gene. A 96-well plate format has been optimized for this reporter gene bioassay system to assess TCDD/AhR-responsive luciferase activity of dioxin-like chemicals and complex mixtures. The transfected cell line is exceptionally sensitive, detecting levels of TCDD as low as 1 pM (0.06 pg/200 µl/well). The bioassay also exhibits good specificity, with agents having the following relative potencies: TCDD > 2,3,4,7,8, pentachlorodibenzofuran (PeCDF) > PCB 126 > PCB 118 ~ benzo(a)pyrene > omeprazole > PCB 153. A similar maximal signal was obtained with TCDD, PeCDF, and PCB 126. In contrast, PCB 153 (1000 nM) did not show any significant response. This model is currently being utilized as a screening tool to assess the relative dioxin-like activity of defined chemical mixtures and complex mixtures of chemically analyzed extracts from Great Lakes sediments, human milk, and human serum. (Supported in part by ATSDR H75-ATH298338.)

1451 THE TK+/- MOUSE: AN IN VIVO MUTATION MODEL THAT DETECTS LOSS OF HETEROZYGOSITY.

V. N. Dobrovolsky and R. H. Heflich. *National Center for Toxicological Research, Jefferson, AR.* Sponsor: W. T. Allaben.

Loss of heterozygosity (LOH) is a major mechanism by which cells loose tumor suppressor gene function and become cancerous. Until recently, there were no *in vivo* reporter gene systems capable of detecting spontaneous and treatment-induced LOH. Using gene targeting, we have developed mice heterozygous for the endogenous thymidine kinase (Tk) gene in which the wild-type (WT) allele of the Tk gene serves as a target for mutation. The Tk+/- mouse is an *in vivo* analog of Tk+/- mouse lymphoma cells, which are widely used in mutagenicity studies and are highly sensitive to LOH mutation. Tk mutant lymphocytes from Tk+/- mice are identified by their ability to form clones in the presence of the toxic thymidine analog 5-bromodeoxyuridine (BU). Results indicate that the Tk gene of Tk+/- mice detects mutants containing loss of the entire WT Tk allele (LOH), as well as point mutation and intragenic deletion and insertion. We found that more than 50% of the Tk mutants from untreated Tk+/- mice are caused by LOH. Also, LOH occurs frequently in the Tk gene of mice treated with carcinogens that produce mainly point mutation in the endogenous X-linked Hprt gene or in transgenic shuttle-vector genes. The results indicate that Tk+/- mice detect a greater range of the mutations involved in carcinogenesis than do other *in vivo* mutation models. Thus, Tk+/- mice may be a useful tool for assessing risks associated with exposure to potential carcinogens. (Sponsored by the SOT Regulatory and Safety Evaluation Specialty Section.)

1452 CELLULAR AND SUBCELLULAR LOCALIZATION OF PERIPHERAL BENZODIAZEPINE RECEPTORS FOLLOWING TRIMETHYLTIN-INDUCED BRAIN INJURY.

A. C. Kuhlmann and T. R. Guilarte. *Johns Hopkins University, Balitmore, MD.*

The peripheral benzodiazepine receptor (PBR) is currently used as a marker of inflammation and gliosis following brain injury. Previous reports have suggested that elevated PBR levels in injured brain tissue are specific to activated microglia and infiltrating macrophages. We have produced hippocampal lesions using the neurotoxicant trimethyltin (TMT) to determine the cellular and subcellular nature of the PBR response. Degenerating, argyrophilic pyramidal neurons were observed in the hippocampus at 2 and 14 days after TMT exposure (8 mg/kg, single injection). Reactive microglia were evident at both time points with a maximal response occurring at 14 days and subsiding by 6 weeks. Astrocytosis was observed at 14 days and 6 weeks after exposure but not at 2 days suggesting a delayed onset but protracted astrocytic response relative to microglia. Morphological evidence from PBR immunohistochemistry and [^{3}H]-PK11195 microautoradiography indicated that both microglia and astrocytes are capable of expressing high levels of PBR after TMT brain injury. This was confirmed by double labeling of either *Griffonia simplicifolia* isolectin B_4 binding, a microglia-specific marker, or glial fibrillary acidic protein (GFAP) immunohistochemistry, an astrocyte-specific marker with PBR fluorescence immunohistochemistry. These results demonstrate that PBR expression is increased after brain injury in both activated microglia and astrocytes. Our findings also suggest the first evidence for nuclear localization of PBR in glial cells. (Supported by ES07062 to TRG.)

1453 BERYLLIUM BLOOD LYMPHOCYTE PROLIFERATION TEST (BLPT): VARIABILITY AND POSITIVE PREDICTIVE VALUE.

D. Deubner[1], M. Goodman[2], J. Ianuzzi[2], P. Chapman[3] and M. Kelsh[3]. [1]*Brush Wellman Inc., Elmore, OH,* [2]*Exponent, Landover, MD and* [3]*Exponent, Menlo Park, CA.* Sponsor: D. J. Paustenbach.

Lymphocyte proliferation assays are widely used as biomarkers for exposures to various metals including beryllium. Results are typically categorized as: abnormal (positive), normal (negative) or borderline. This study evaluated nearly 5000 blood lymphocyte proliferation test (BLPT) results collected since 1992 from three labs during periodic surveys at two beryllium plants in Tucson, AZ and Elmore, OH. Single split blood samples were sent to two independent laboratories. If both labs report negative BLPT-the person is considered not sensitized. Discrepancies between the two labs or uninterpretable results warrant a repeated testing. Two positive BLPTs, either from the two independent labs or from repeat testing at the same lab are sufficient to consider a person beryllium sensitized. Analysis included examination of inter- and intra-laboratory variability by calculating a kappa statistic, and assessment of positive predictive value of BLPT with respect to forecasting chronic beryllium disease (CBD). The level of agreement between the first and the second test for all three labs (intra-lab variability) was fair to moderate with kappa ranging between 0.3 and 0.5. The inter-lab agreement depended on the survey site ranging from poor (kappa=0.1) in Elmore to good (kappa=0.8) in Tucson. An abnormal BLPT test was approximately 50% predictive of CBD as detected on subsequent bronchoscopy. The BLPT has a high degree of variability, its positive predictive value is acceptable, but the sensitivity and specificity are still unknown. BLPT may serve as a useful medical surveillance tool, however it does not meet the criteria for a screening test.

1454 BIOMONITORING FOR BERYLLIUM: EXPERIENCE WITH A U.S. WORK FORCE.

Y. Lowney[1], D. Deubner[2], S. M. Hays[1], P. Chapman[3], B. Kerger[4], W. Shields[5] and D. J. Paustenbach[3]. [1]*Exponent, Boulder, CO,* [2]*Brush Wellman Inc., Elmore, OH,* [3]*Exponent, Menlo Park, CA,* [4]*Health Science Resource Integration, Tallahassee, FL and* [5]*Exponent, Bellevue, WA.*

Experiments in animals indicate that beryllium (Be) has a very low bioavailability, a moderate to long half-life, and that urine is the primary route of excretion for absorbed Be. The feces is the primary route of excretion of unabsorbed Be following oral or inhalation exposure (via mucocilliary escalator). Studies conducted in the 1960s indicated that Be workers had elevated levels of urinary Be but a correlation between levels of Be in urine or blood and airborne concentrations of Be in work areas could not be established. There have been suggestions that workers may be absorbing Be by routes other than inhalation. Therefore, the purpose of this study was to determine whether a biomarker approach (using urine or blood) could be used to evaluate the extent and route of exposure using more modern analytical techniques. If so, the method would be useful in assessing whether workplace behaviors or exposure interventions are effective in limiting human exposures to beryllium in the workplace. The population evaluated consisted of individuals working with beryllium metal, beryllium oxide, and alloys. A control population of administrative personnel from buildings that are separate from the manufacturing facility were included in the survey. Of the193 urine samples collected, only 18 had detectable levels of Be (detection limit of 0.2 μg/L). Based on a comparison to nationwide data collected as part of the National Health and Nutrition Examination Survey (NHANES III), the data indicated that workers exposed to different forms of beryllium in the workplace had urinary levels that were indistinguishable from background levels in the United States. These preliminary results suggest that a more sensitive method for detecting beryllium in biological media is needed. Therefore, studying blood or urine to identify Be exposure will only be appropriate when the quantitative technique is sensitive enough to distinguish Be concentrations in exposed and unexposed populations.

1455 DEVELOPMENT OF METHODS FOR ANALYSIS OF BIOMARKERS OF BENZENE EXPOSURE USING GAS CHROMATOGRAPHY/MASS SPECTROMETRY (GC/MS) AND MATRIX ASSISTED LASER DESORPTION IONIZATION (MALDI).

J. M. Starr, J. R. Krone, M. G. Menache and R. F. Henderson. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

Because benzene is used extensively in industry and is a widespread industrial pollutant, it is important that biological monitoring accurately reflect the history of exposure. To provide more information on previous exposures than a single biomarker can provide, it is desirable that a battery of biomarkers be used. This work describes the development of assays for longer and shorter-term biomarkers of benzene exposure. Recent biomonitoring studies have focused on assessment of urinary levels of S-phenylmercapturic acid (S-PMA) and trans,trans-muconic acid (t,tMA) as they are specific to benzene and are biomarkers of recent exposure. Methods to assay a specific longer lived biomarker, S-phenylcysteine adducts, in albumin and hemoglobin have also been published, but require extensive preparatory work. Previous studies of the urinary metabolites have largely extracted and analyzed S-PMA and t,tMA separately, by splitting the samples prior to analysis. In this study, methods were developed for the combined extraction, derivatization and analysis of S-PMA and t,tMA from urine via liquid extraction, followed by derivatization using hydrochloric acid/methanol and GC/MS analysis. Recoveries were 90% for S-PMA and 78% for t,tMA from spiked water samples. The limit of detection for t,tMA was 10 ηg/mL and 20 ηg/mL for S-PMA. The best sensitivity for the combined analytes was obtained using positive ionization, although negative ionization was more sensitive for t,tMA alone. MALDI analysis of S-phenylcysteine adducts in albumin was accomplished using tryptic digests and provided sensitivity comparable to current literature methods. (Supported by U.S. EPA Assistance Number R826249-01-0.)

1456 ANALYSIS OF URINARY METABOLITES OF BUTADIENE.

J. R. Krone[1], M. R. Bish[1], D. A. Kracko[1], R. W. Nelson[2] and R. F. Henderson[1]. [1]*Lovelace Respiratory Research Institute, Albuquerque, NM and* [2]*Intrinsic Bioprobes, Inc., Phoenix, AZ.*

The toxicity of 1,3-butadiene (BD) varies greatly in rodent species and raises the question of whether the risk of BD exposure in humans is more like that of the sensitive species, the mouse, or more like that of the resistant species, the rat. Numerous studies have indicated that one reason for the species differences in response to BD is that the blood and tissues of BD-exposed mice contain high levels of both the mono- and the diepoxide metabolite of BD, while the tissues and blood of exposed rats contain very little of the diepoxide. The diepoxide is far more mutagenic than the monoepoxide, and it is reasonable that the diepoxide plays a major role in tumor induction in the mouse. A major question is the extent to which humans metabolize BD to the diepoxide, but evidence for diepoxide formation in humans is difficult to obtain. The diepoxide would be expected to clear rapidly from the blood, as is seen in BD-exposed mice. Currently we are testing the hypothesis that the diepoxide along with MI and MII, which are water soluble, would be excreted in the urine and could be used as markers of exposure. To extend this research to humans, diepoxide, MI and MII were assayed for in urine. Diepoxide was studied by monitoring diepoxide protein-binding in urine using a matrix assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF MS) method. Briefly, the method involves a protein affinity capture step followed by mass spectrometric detection. The protein that we chose to assay for was β_2-microglobulin (B2M) which is a urinary protein common to primates and rodents and contains many possible adduct sites for diepoxide. Agarose beads are crosslinked with an antibody towards the B2M and this then becomes our affinity column. Results from rat and mouse exposures indicate the presence of diepoxide in the urine of mice but not rats. Urines from workers exposed to BD are being analyzed by electrospray ionization mass spectrometry (LC/MS/MS) for MI and MII. The urine was first cleaned-up by a solid phase extraction method, then simultaneously analyzed for the two metabolites by LC/MS/MS. (Research supported by HEI 97-1, NIH Grants ES-06015 and ES-09401, and CMA Research Agreement OLF-16.0-RES-LRRI.)

1457 AN EMPIRICAL MODEL OF BENZENE EXPOSURE BASED ON MULTIPLE BIOMARKERS.

M. G. Menache[1], N. Lian[2], J. M. Starr[1] and R. F. Henderson[1]. [1]*Lovelace Respiratory Research Institute, Albuquerque, NM and* [2]*Medical & Scientific Research Services, Albuquerque, NM.*

To improve human health risk assessment for benzene exposure, an empirically based model using a battery of biomarkers from blood, exhaled air, and urine samples is being developed. For development, testing and validation, the model is being formulated based on experimental measurements from controlled exposure conditions in mice. The critical factors in the development of the model are the use of biomarkers that: 1) can be measured non-invasively, 2) have different clearance patterns, and 3) are relatively specific to benzene. Benzene in exhaled breath, benzene in blood, and phenylcysteine adducts on albumin and on hemoglobin will be used in the model. Although

not necessarily specific to benzene exposure, chromosomal aberrations will also be incorporated as a long-term marker of damage. The logic of the model is as follows: Consider two biomarkers, each with a simple negative exponential clearance as a function of time. Generally, such curves are fit with the fraction or percent of the biomarker as the dependent variable so that all curves are normalized to describe clearance relative to deposition. Because the model should predict exposure, not deposition, this formulation will not provide enough information. The total deposition must be described by some other equation that is a function of the exposure concentration. With two biomarkers, then, there are two equations which can be solved to predict the two unknowns-exposure concentration and time since exposure. The model is being developed for benzene, but if it can be applied successfully to quantifying human doses, the conceptual framework may readily be extended to other compounds. (Supported by U.S. EPA Assistance Number R826249-01-0.)

1458 3-NO_2-ACETAMINOPHEN FORMATION BY REACTIVE NITROGEN SPECIES.

T. V. Zenser[1], V. J. Lakshmi[1], F. Hsu[2] and B. B. Davis[1]. [1]*VA Medical Center, Saint Louis Universtity, St. Louis, MO and* [2]*Washington University, St. Louis, MO.*

Reactive nitrogen species (RNS) play a role in a number of physiological and pathological processes. Identifying specific RNS involved in this process is difficult to assess. The reaction of some RNS with acetaminophen (APAP) was evaluated. ^{14}C-APAP (0.06 mM) was incubated with 1 mM spermine-NONO; 1μg/ml myeloperoxidase, 0.05 mM H_2O_2, and 0.1 mM $NaNO_2$; 0.1 mM $NaNO_2$ and 0.1 mM HOCl; 0.1 mM $ONOO^-$; 2 mM Sin-1. Incubations contained 0.1 mM DETAPAC, and were at pH 7.4, 37°C, and for 30 min. Metabolism was assessed by HPLC. Incubations with myeloperoxidase, $ONOO^-$, and Sin-1 yielded a new product representing 7, 3.3, and 1% of the total radioactivity recovered by HPLC. The final pH of these incubations did not change by more than ±0.1 pH unit. The myeloperoxidase reaction was completely prevented with 1 mM NaCN, while the $ONOO^-$ reaction was prevented by preincubation of $ONOO^-$ for 10 min. The new product was identified by ^{1}H NMR and EI/ESI mass spectrometry as 3-NO_2-acetaminophen. Human polymorphonuclear neutrophils incubated with APAP and phorbol ester also synthesized 3-NO_2-acetaminophen. These results suggest that 3-NO_2-acetaminophen may be useful as a marker for certain RNS.

1459 APPLICATION OF SOLID PHASE MICROEXTRACTION TO THE MEASUREMENT OF URINARY BENZENE IN WORKERS EXPOSED TO BENZENE.

S. Waidyanatha[1], N. Rothman[2], S. Fustinoni[3], M. T. Smith[4], R. B. Hayes[2], W. Bechtold[5], M. Dosemeci[2], G. Li[6], S. Yin[6] and S. M. Rappaport[1]. Barnaba 8, Italy,* [4]*School of Public Health, University of California, Berkeley, CA,* [5]*Lovelace Respiratory Research Institute, Albuquerque, NM and* [6]*Chinese Acadamy of Preventative Medicine, Beijing, China.*

The application of solid-phase microextraction to the determination of urinary benzene (UB) levels and the utility of UB as a short-term biomarker of exposure to benzene was investigated in urine samples collected from 42-exposed workers and 41 controls from Shanghai, China as a part of a cross-sectional study of benzene biomarkers. The mean UB levels in exposed workers (28.3 μg/L) were statistically higher than the controls (0.145 μg/L) ($p=0.0001$). When the log-transformed UB levels were regressed on log-transformed individual benzene exposure (8-h TWA) and other urinary metabolites, significant correlations were observed (UB vs. exposure: $r = 0.80$: UB vs. phenol: $r = 0.83$; UB vs. catechol: $r = 0.85$; UB vs. hydroquinone; $r = 0.87$; UB vs. muconic acid: $r = 0.87$) with $p<0.001$. The use of UB at low levels of benzene exposure will be investigated. (Supported in part by NIH grant P42ES05948.)

1460 SPECTROPHOTOMETRIC ANALYSIS OF SOLUBILIZED RAT HAIR PROTEINS FOLLOWING INTRAPERITONEAL INJECTION OF 2,5-HEXANEDIONE.

C. F. Brownie[1], L. Lack[2], T. J. Ribar[1] and M. B. Abou-Donia[2]. [1]*North Carolina State Univ., College of Veterinary Medecine, Raleigh, NC and* [2]*Dept. of Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.*

Neurotoxic industrial solvents n-hexane and methyl n-butyl ketone are toxic by virtue of their common metabolite 2,5-hexanedione (2,5-HD). Our previous work (Johnson, et al., J. Toxicol. Env. Health, 1995) has shown that pyrrole-like substances in solubilized rat hair proteins from rats injected ip) daily with 2,5-HD were maximally absorbed in the 530 nm spectral region following reaction with the Ehrlichs reagent (p-dimethylaminobenzaldehyde). Modification of current analytical methods to achieve high specificity and lower detection limits with small sample quantities could have important implications for monitoring human populations. Adult male Sprague-Dawley rats weighing approximately 350 g were housed in individual metabolic cages with food and water provided ad libitum. Individual rats were injected (ip) daily with either 50 mg/kg 2,5-HD or physiologic buffered saline (PBS). Plucked hair samples (dorsal, right flank, and left flank) were obtained from each rat before and at seven-day intervals post 2,5-HD or PBS exposure for 28 days. Hair protein solubilization and extraction procedures were adapted from Marshall and Gillespie (J. of Forensic Sci. Soc.1982). One ml of dialyzed hair protein solution (2,5-HD or PBS control) was read against a reference cuvette containing water or reagent blanks. Analyses were done utilizing Shimadzu UV 160 V recording spectrophotometer at an absorbance spectral range of 450-600 nm. In all spectral tracings absorbance (530 nm) of pyrrole-like substances were only detected in samples from 2,5-HD treated rats. Absorbance at 530 nm was detected starting from 7-14 days post exposure. Further studies utilizing solubilized human hair proteins devoid of pigmentation, with the goal of developing a technique to detect exposure to neurotoxic solvents in human populations occupationally at risk are being carried out.

1461 METALLOTHIONEIN ISOFORM 3 AS A POTENTIAL BIOMARKER FOR HUMAN BLADDER CANCER.

D. A. Sens, S. Somji, D. L. Lamm[2], S. H. Garrett, F. Slovinsky, J. H. Todd and M. A. Sens. *Department of* [1]*Pathology &* [2]*Urology, West Virginia University, Morgantown, WV.*

Bladder cancer is the fifth most common cancer in the United States. Currently, there are no widely accepted tumor markers that allow screening for the early presence of bladder cancer or for the detection and monitoring of advanced metastatic disease. The goal of the present study was to determine if the expression of MT-3 may serve as a biomarker for human bladder cancer. Immunohistochemistry, immuno-blot and RT-PCR analysis were used to define the localization and expression of MT-3 protein and mRNA in fresh and archival biopsy specimens. Immunohistochemical analysis disclosed no immunoreactivity for MT-3 in cells comprising normal bladder. MT-3 mRNA and protein could not be detected in normal bladder using RT-PCR or immuno-blot respectively. Immunohistochemical analysis demonstrated that MT-3 was expressed in *carcinoma in situ* (CIS), high grade bladder cancer, low grade bladder cancer and dysplastic lesions. MT-3 immunostaining was intense in both CIS and high grade bladder cancer, and low to moderate in low grade and dysplastic lesions. The cDNA from the RT-PCR primed for MT-3 was demonstrated to contain a *Fok I* restriction site, a site unique to MT-3. This study demonstrates that MT-3 is up-regulated in human bladder cancer and that this up-regulation increases with increasing tumor grade. The finding that MT-3 expression is minimal in normal bladder suggests that MT-3 could be developed into an effective biomarker for bladder cancer.

1462 METALLOTHIONEIN ISOFORM 1 AND 2 GENE EXPRESSION IN THE HUMAN BLADDER: EVIDENCE FOR UPREGULATION OF MT-1X AND DOWN REGULATION OF MT-1E mRNA IN BLADDER CANCER.

M. A. Sens[1], S. A. Somji[1], D. L. Lamm[2], D. A. Sens[1], S. H. Garrett[1], F. Slovinsky[1] and J. H. Todd[1]. *Department of* [1]*Pathology &* [2]*Urology, West Virginia University, Morgantown, WV.*

Metallothioneins (MT) are a family of low molecular weight, cysteine-rich intracellular proteins that bind transition metals. There is a family of genes that underlies the expression of these proteins. Studies have shown an association of metallothionein (MT) over-expression with tumor type and grade. The goal of this study was to define the expression of MT-1 and MT-2 genes

and protein in normal bladder and to demonstrate that the expression of MT-1 and 2 isoforms are altered in bladder cancer. Immunohistochemistry was used to localize MT-1/2 protein and RT-PCR to determine expression of the MT-1 and MT-2 isoform-specific mRNAs. Normal bladder was not immunoreactive for the MT-1/2 protein but did express mRNA for the MT-2A, MT-1E and MT-1X genes. In contrast, bladder cancers were immunoreactive for the MT-1/2 protein with reactivity localized to the cytoplasm in all MT positive tumors and to the nucleus in a small sub-set of these tumors. In general, the intensity of MT immunoreactivity increased with tumor grade, with *carcinoma in situ* having pronounced reactivity. RT-PCR analysis of tumor specimens demonstrated a constant expression of MT-2A mRNA, down regulation of MT-1E mRNA and an upregulation of MT-1X mRNA in bladder cancers. This study demonstrates that there is a variation in MT expression in bladder cancer.

1463 CLONING OF ZONA RADIATA PROTEINS FROM RAINBOW TROUT (*ONCORHYNCHUS MYKISS*): A MARKER FOR INVESTIGATING ESTROGENIC ENDOCRINE MODULATORS IN FISH.

T. Celius, J. B. Matthews[1], T. R. Zacharewski[1] and J. Giessy[1,2]. [1]*Department of Biochemistry & Zoology and* [2]*National Food Safety & Toxicology Ctr., Michigan State University, East Lansing, MI.*

We have investigated induction of vitellogenin and zr-proteins in rainbow trout (*Oncorhynchus mykiss*) liver and plasma, after *in vivo* treatment with estradiol-17β (E2) and alpha-zearalenol (α-ZEA). A method for quantification of zr-proteins and vitellogenin PCR products has been developed using flourescent labeled probes (TaqMan assay). A partial sequence of rainbow trout zr-protein has been cloned (GenBank accession number AF185274) by alignment of available zr-protein sequences from four different fish species. The cloning was performed using reverse transcriptase polymerase chain reaction (RT-PCR) with an oligo dT primer followed by rapid amplification of cDNA ends (RACE) PCR and two degenerate zr-protein primers designed from a conserved region of the aligned sequences. This strategy resulted in a 700 bp long fragment that showed high amino acid sequence identity to that of salmon (77%), winter flounder (64%), carp (63%) and medaka (61%) zr-proteins. For the *in vivo* experiment juvenile rainbow trout (50-100 g) were kept 10 fish per 370 liter tank at 15°C (± 1) and acclimatized for 7 days prior to treatment, following a single intraperitoneal injection with E2 (0.01, 0.1, 1.0 or 10 mg/kg fish) or α-ZEA (0.1, 1.0 or 10 mg/kg fish). Enzyme-linked immunosorbent assay (ELISA) showed induction for both proteins in blood plasma from fish treated with E2 or α-ZEA. The potency of α-ZEA was approximately 10-fold less when compared to E2. Furthermore, preliminary data using the TaqMan assay indicate a dose-dependent induction of vitellogenin and zr-proteins after treatment with E2 and α-ZEA.

1464 INDUCTION OF CYTOCHROME B_5 BY CCl_4 IN RAINBOW TROUT LIVER.

M. W. Roomi. *Linus Pauling Institute, Oregon State University, Corvallis, OR.*

Several reports suggest that fish are a valuable model for testing environmental and occupational xenobiotics and also serve as nonmammalian vertebrate surrogates for understanding drug metabolism in humans. The present study was undertaken to investigate what effect if any CCl_4 will have in rainbow trout (RT) liver on cytochrome b_5. For comparative purposes cytochrome P-450 was also determined. RTs were given ip corn oil and CCl_4 (0.3 and 0.5 ml/100 g body weight, in 1:1 corn oil). The livers were excised after 24 hrs. Microsomes were prepared for determination of cytochrome b_5 and cytochrome P-450. Administration of CCl_4 showed a significant decrease in cytochrome P-450 content compared to the control. There was no difference between the two CCl_4 treated groups. However CCl_4 treatment showed a gradual but significant increase in the 0.3 ml group whereas the 0.5 ml CCl_4 treated showed a four fold increase compared to the control. These results suggest that cytochrome b_5 and cytochrome P-450 are differently regulated by CCl_4 in RT liver. Cytochrome b_5 is upregulated and cytochrome P-450 is down regulated. Exactly how CCl_4 is modifying the expression of cytochrome b_5 remains to be elucidated. The increase in cytochrome b_5 could be used as a useful marker for monitoring various environmental chemicals. (Supported by the Linus Pauling Institute.)

1465 DETERMINATION OF TOPICALLY APPLIED ANTIBIOTICS AND OTHER ENVIRONMENTAL CHEMICALS BY USING A TRANSDERMAL SWEAT PATCH AND GC/MS ANALYSIS.

V. F. Kalasinsky, C. J. Corso, D. M. Wong-Verelle and S. C. Cordero. *Armed Forces Institute of Pathology, Washington, DC.* Sponsor: B. Levin.

Sweat analysis is being evaluated as a minimally invasive means of testing patients for therapeutic drugs and drugs of abuse. Sweat can be collected in a transdermal patch for periods of up to seven days and subsequently analyzed by a variety of methods after the components of the sweat is extracted from the patch. In the present study, gas chromatography-mass spectrometry (GC/MS) was used to evaluate the possibility that airborne or topically-applied chemicals or their metabolites could be collected in a transdermal patch. Volatile laboratory solvents and topical creams containing bacterial or fungal antibiotics or insect repellents were chosen for the study. Subjects exposed to these materials because of occupational or medical reasons wore patches for one to seven days. Blood specimens were drawn at the end of this period to allow data for the patch to be compared to the more traditional sampling methodology. The results indicate that antibiotics and insecticides can be detected after dermal application, and the lower volatility organic compounds were detected presumably after inhalation. The utility of transdermal patches for detecting environmental and consumer chemicals will be demonstrated. These results suggest applications in occupational settings whereby environmental exposures for individuals can be monitored.

1466 SENSORY NERVE-MEDIATED NASAL VASODILATORY RESPONSE TO ETHYL ACRYLATE.

J. B. Morris, G. Gianutsos and J. Stanek. *University of Connecticut, Storrs, CT.*

Ethyl acrylate is a sensory irritant with an RD50 of roughly 1000 ppm in the rat. Our previous studies have characterized the immediate nasal vascular response to acrolein and acetaldehyde. The current study was aimed at characterizing this response to the ethyl acrylate. Nasal vascular responses were assessed by continuously monitoring the nasal uptake of an inert vapor (acetone) in an anesthetized F344 rat model. Ethyl acrylate exposure produced an immediate concentration dependent vasodilatory response. The response occurred in the absence of change in nasal air flow resistance. The LOEL for this response was 100 ppm; the NOEL 25 ppm. Pretreatment of rats with capsaicin (50 mg/kg, 1 week prior) to defunctionalize sensory nerves abolished the response to 200 ppm ethyl acrylate providing strong evidence that it was sensory nerve-mediated. The response was significantly diminished by treatment with the CGRP antagonist hCGRP 8-37 suggesting an important role for the sensory nerve-derived neuropeptide CGRP. Pretreatment with the nNOS selective inhibitor 7-nitroindazole also significantly diminished the response. Thus, at concentrations of 100 ppm or above ethyl acrylate induces an immediate sensory neuronal nasal vasodilatory response that appears to be mediat ed via release of CGRP and activation of nNOS and release of NO.(This work supported by NIEHS R01-08765.)

1467 CORRELATION OF REGIONAL HYDROGEN SULFIDE FLUX PREDICTION WITH THE DISTRIBUTION OF NASAL OLFACTORY LESIONS IN SUBCHRONICALLY EXPOSED RATS.

F. J. Moulin, K. A. Brenneman, J. S. Kimbell, D. C. Doman and R. A. James. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Hydrogen sulfide (H_2S) is a toxic gas generated by natural and industrial sources. At high concentrations (>1000 ppm), it induces rapid respiratory paralysis and sudden death but at lower concentrations usually encountered in the environment H_2S appears to target primarily the olfactory system. Rats acutely exposed to H_2S exhibit dose-dependent necrosis of the olfactory mucosa. To test the hypothesis that the flux of inspired H_2S to the airway walls determines the distribution of tissue damage within the olfactory region of the rat nose, the nasal lesions of adult, male CD rats exposed by inhalation to 30 or 80 ppm H_2S (6 hrs/day for 70 consecutive days) were mapped. Neuronal loss and basal cell hyperplasia evaluated by the change in thickness and cellular composition of the olfactory neuronal cell layer were used as markers of damage to the olfactory epithelium. The incidence of the lesions was determined regionally at two cross-section levels of the nose corresponding to the mid-point of the nasal cavity (section 1) and the middle portion of the ethmoid recess (section 2). A three-dimensional, anatomically accurate, computational fluid dynamic model of the rat nasal passages was used to predict regional

H_2S flux. Four regions on the first section and 39 regions on the second section were ranked separately by lesion incidence and predicted H_2S flux, and the rankings were compared. Statistical analysis showed that H_2S flux and lesion incidence were correlated ($p<0.005$) within the olfactory epithelium for both 30 and 80 ppm exposure. These results indicate that airflow-driven patterns of H_2S uptake play an important role in the distribution of olfactory lesions and suggest that species-specific regional airflow in the nasal cavity must be taken into consideration when extrapolating rat lesions to human risk estimates.

1468 POTENTIATION OF OZONE-INDUCED MUCOUS CELL METAPLASIA BY ENDOTOXIN IS NEUTROPHIL-DEPENDENT.

J. G. Wagner, J. A. Hotchkiss and J. R. Harkema. *Michigan State University, East Lansing, MI.*

Exposure of laboratory animals to ozone, the primary oxidant gas in photochemical smog, causes neutrophilic inflammation and mucous cell metaplasia (MCM) in the nasal transitional epithelium (NTE) of rats and monkeys. Bacterial endotoxin is a common airborne biogenic agent that induces acute neutrophilic inflammation, but not MCM, in NTE. It does, however, potentiate ozone-induced MCM in rat nasal airways (Fanucchi et. al., *Toxicol. Appl. Pharmacol.* 152:1-9, 1998). In the present study, F344 rats exposed to 0 or 0.5 ppm ozone (8 h/d x 3 d) were intranasally instilled with 0 or 100 μg endotoxin 24 h and 48 h after the third ozone exposure. To determine the role of neutrophilic inflammation in endotoxin-induced potentiation of the MCM caused by ozone, half of the rats were depleted of circulating neutrophils prior to saline or endotoxin instillations. Rats were killed 6 h or 3 d after the last intranasal instillation and nasal tissues were processed for 1) light microscopy and morphometric analysis to determine the number of infiltrating neutrophils and the volume density (amount) of stored mucosubstances in the NTE, and 2) for quantitative RT-PCR analysis of steady-state mucin gene (rMuc-5AC) mRNA levels in the NTE. Endotoxin induced a transient influx of neutrophils in both air and ozone exposed rats that was completely blocked by neutrophil depletion. Endotoxin increased rMuc-5AC mRNA levels in the NTE of ozone-exposed rats, however, neutrophil depletion had no effect on endotoxin-induced upregulation of mucin gene mRNA levels. Endotoxin potentiated (4x) the ozone-induced increase in stored mucosubstances, but only in neutrophil sufficient rats with endotoxin-induced inflammation. These data indicate that endotoxin's potentiation of ozone-induced upregulation of mucin gene (rMuc-5AC) mRNA levels is neutrophil-independent while it's effects on intraepithelial production and storage of mucous glycoproteins is dependent on the presence of neutrophils. (Research funded by NIH/NHLBI grant HL59391-01.)

1469 NEWBORN MICE DIFFER FROM ADULT MICE IN CHEMOKINE AND CYTOKINE EXPRESSION AFTER OZONE EXPOSURE BUT NOT ENDOTOXIN.

J. N. Finkelstein, C. J. Johnston, R. Gelein and G. Oberdorster. *University of Rochester, Rochester, NY.*

Neonatal animals of many mammalian species are more tolerant to pulmonary oxidative stress-inducing toxicants than are adults. Previous studies using exposure to acute hyperoxia demonstrated a rapid increase in the abundance of inflammatory chemokine and cytokine mRNA species early in the injury process, while the adult response was not seen until lethal exposure levels were achieved. Our current hypothesis is that such differential response is due to differences in specific cellular injury and not a consequence of altered regulation of inflammatory responses. To test this hypothesis we utilized two distinct models of pulmonary injury and inflammation: ozone (O_3) which causes epithelial injury and bacterial endotoxin which causes inflammation independent of direct epithelial injury. Mice (C57BL/6J) either 36 hours or 8 weeks of age were exposed to varying concentrations of ozone for 4 through 24 hours or to an LPS aerosol (total estimated deposited dose 10 ng) and examined at 2, 6, or 24 hours post inhalation. Adult mice displayed enhanced sensitivity to ozone as demonstrated by increased abundance of mRNA encoding eotaxin, macrophage inflammatory protein (MIP)-1α, MIP2, interleukin (IL)-6 and metallothionein (Mt). In newborn mice only Mt was increased. In contrast, 2 hours after exposure to endotoxin, mRNA for tumor necrosis factor (TNF) α, eotaxin, MIP-1α/β, MIP-2, interferon γ inducible protein (IP)-10 and monocyte chemoattractant protein (MCP)-1 were all increased in both adults and newborns. In this model, IL-6 and interferon-γ mRNA were increased acutely only in adults. The ability of neonatal animals to increase abundance of multiple inflammatory mediator mRNAs following endotoxin suggests that the lack of response of these genes following ozone is not due to the inability to mount an inflammatory response but is secondary to enhanced epithelial injury in the adult lung and a role for the epithelium in regulating the expression of certain inflammatory mediators. (Supported by grants from the CIAR, EPA STAR grant R826784, EPA PM Center R827354, and ES 01247.)

1470 COMBINED EFFECTS OF CIGARETTE SMOKE AND OZONE IN A MOUSE MODEL OF SMOKE-INDUCED EMPHYSEMA.

K. J. Nikula, J. C. Seagrave, E. B. Barr, J. A. Berger, G. L. Finch, T. H. March and M. G. Menache. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

Both cigarette smoke (CS) and ozone (O_3) cause pulmonary inflammation in humans and experimental animals, and cigarette smoking is the main risk factor for emphysema in humans. In this study we are examining the effects of combined exposures to CS and O_3 on antioxidant status, inflammatory responses, proteases, and development of emphysema in a mouse model of CS-induced emphysema. Female $B6C3F_1$ mice are exposed in whole-body chambers to 250 mg CS particulate matter/m³ or filtered air, 6 hours/day, 5 days to week and to O_3 at either 0, 0.08 (low O_3), or 0.3 (high O_3) ppm 8 hours/night, 5 nights/week. Mice were sacrificed at scheduled intervals to collect bronchoalveolar lavage (BAL) supernatant and cells and lung tissue for antioxidant status, histopathology, and stereology. O_3 caused an exposure-related increase in BAL supernatant total glutathione that was comparable to, and additive with, the effects of CS. The effect at 4 weeks was considerably greater than at 1 week. O_3 alone had little effect on BAL inflammatory cells at 1 week, but caused a dose-related increase in neutrophils and macrophages at 4 weeks. In combination with CS, which caused a marked, progressive increase in BAL neutrophils and macrophages, low O_3 did not affect BAL inflammatory cell numbers, but high O_3 suppressed the CS-induced increase in neutrophils at 1 week, and the CS-induced increase in both neutrophils and macrophages at 4 weeks. BAL protein was increased by both CS and O_3 at 1 and 4 weeks. Gelatinolytic activity in BAL was increased slightly by high O_3 and markedly by CS at both 1 and 4 weeks. However, at 1 week, the combination of CS and high O_3 induced markedly less activity than CS alone, whereas at 4 weeks, the combination induced activity comparable to that of CS alone. These results indicate complex interactions between the effects of CS and O_3 that may be additive or inhibitory depending on the endpoint and exposure concentration. (This research was conducted by the National Environmental Respiratory Center with support from the U.S. Environmental Protection Agency under Cooperative Agreement CR826442-01-1 with the Lovelace Respiratory Research Institute. This report has not been subjected to the Agency's peer or policy reviews and therefore does not necessarily reflect the views of the Agency and no official endorsement should be inferred.)

1471 LONG-TERM OZONE EXPOSURE INCREASES CYP2B ACTIVITY AND WORSENS INJURY TO THE CENTRAL ACINUS BY 1-NITRONAPHTHALENE.

R. C. Paige, F. H. Royce, A. R. Buckpitt and C. G. Plopper. *University of California, Davis, CA.*

It is well recognized that repeated exposure to ozone at concentrations resulting in acute injury and inflammation render the centriacinar epithelium resistant to further oxidant injury. However, human populations exposed to oxidant gases like ozone are also exposed to a variety of environmental contaminants that require bioactivation for their toxicity. Whether changes that render the lung resistant to injury by an oxidant gas alter the metabolic activity required for bioactivation of other toxicants is not known. We tested the hypothesis that the tolerance produced by long-term exposure to ozone (O3) does not apply to bioactivated lung toxicants. Rats were exposed to 0.8 or 1 ppm O3 or filtered air (FA) for 90 days. On the morning following the 90th exposure, rats were administered the bioactivated lung toxicant 1-nitronaphthalene (1-NN) at 0, 50, or 100 mg/kg or were euthanized immediately for P450 measurements. We compared the level of toxicity in centriacinar areas with activity of CYP1A1, CYP2B and NADPH cytochrome P450 reductase in airway compartments isolated by microdissection. Based on high resolution histopathology and morphometry, there was significantly greater cell necrosis and epithelial exfoliation in O3-exposed rats administered 50 or 100 mg/kg 1-NN, compared to FA-exposed rats administered the same dose. In O3-exposed rats, CYP2B activity was elevated 3-fold ($p<0.02$) in samples containing the centriacinar region. Immunohistochemically detectable CYP2B protein was elevated in nonciliated terminal bronchiolar epithelium. In centriacinar epithelium, long-term exposure to ozone elevates: 1) CYP2B activity; 2) immunoreactive CYP2B protein; 3) 1-NN toxicity. We conclude that repeated, long-term exposure of human populations to trophospheric ozone elevates

the risk of pulmonary injury by contaminants activated by the cytochrome P450 monooxygenase system. (This work was supported by NIEHS ES 00628, ES 09681, ES 04311, and T32 ES 07059.)

1472 MECHANISMS OF AGE-RELATED SENSITIVITY TO OZONE IN WISTAR RATS.

K. L. Kraft[1], M. C. Madden[2], D. L. Costa[3], J. D. Carter[2] and R. B. Devlin[2]. [1]*University of North Carolina, Chapel Hill, NC,* [2]*USEPA/NHEERL/HSD/CRB, Chapel Hill, NC and* [3]*USEPA/NHEERL/ETD/PTB, Research Triangle Park, NC.*

Ozone (O3) induces lung inflammation in humans and rodents. Evidence suggests age-related sensitivities to O3-induced lung responses in humans and rodents as well. These studies examined age-related O3-sensitivity in 14, 21, 28 and 60 day old Wistar rats exposed to 0.0, 1.0 or 2.0 ppm O3 for 2 hours. Polymorphonucleocytes (PMNs) in bronchoalveolar lavage fluid (BALF) increased in all age-groups after 1.0 and 2.0 ppm O3. Viable cells decreased after 2.00 ppm O3, most severely (87% to 48%) in 14 day olds, and epithelial cells increased 7.6X in 14 and 3X in 21 day olds. Total Protein (TP) increased 312% in adults at 2.0 ppm O3 but showed non-concentration related changes in 14 and 21 day olds with baselines elevated compared to adults. PGE2 recovered from 14 day olds increased 5 fold after 1.0 and 2.0 ppm O3 whereas 21 and 28 day olds increased only at 2.0 ppm O3. Mechanisms of altered arachidonic acid (AA) metabolism after O3 exposure *in vivo* were examined in 14 and 60 day old rats. Compared to age-matched controls, secretory PLA2 in lavage fluid showed no change in activity. Cyclooxygenases I & II showed no change in protein or mRNA in macrophages or tracheal epithelium. AA re-esterification was examined in tracheas and macrophages by incubation with 3H-AA alone, 3H-AA with 10uM non-radioactive AA or 3H-AA with Triacsin C pretreatment. In all studies, O3 decreased incorporation of 3H into phospholipids, with only increased recovery of unesterified AA in 14 day old tracheas. Adult tracheas and macrophages from both age groups showed increased incorporation of 3H into triglycerides. Epithelia of 14 and 60 day olds may have different capacities for redirecting storage of AA after alteration of esterification pathways. These biochemical alterations may contribute to increased PGE2 in BALF from 14 day olds. These findings support earlier studies which suggest younger Wistar rats are more sensitive to O3 than adults. (Supported by CT902908. This abstract does not represent EPA policy.)

1473 PRODUCTION OF EXHALED BREATH CARBONYLS IN HUMAN SUBJECTS EXPOSED TO OZONE.

M. C. Madden, L. A. Dailey and J. M. Samet. *USEPA, NHEERL, Research Triangle Park, NC.*

Responses to ozone (O_3) exposure such as lung inflammation are postulated to be mediated through secondary reaction products of O_3 with lung biomolecules. Carbonyls and peroxides are believed to be the main reaction products. Additionally, carbonyls may also be derived from lipid peroxidation and be indicative of the level of oxidative stress in a tissue. We have previously shown hydrogen peroxide to be increased in the exhaled breath of O_3-exposed human subjects. In this study we examined the production of exhaled breath carbonyls (as a measurement of lung carbonyl content) induced by O_3 exposure, and the effect of dietary anti-oxidant supplementation on carbonyl formation. Subjects were exposed to air or 0.4 ppm O_3 for 2 hr with intermittent exercise. Subjects had their diet supplemented with anti-oxidants (vitamins C and E, and V-8 juice) or placebo (orange soda and sugar pills) for 2 wk prior to the O_3 exposure . Breath was collected just prior to exposure and immediately after the last exercise period into inert Tedlar bags, passed through cartridges coated with the carbonyl derivatizing agent 2,4-dinitrophenylhydrazine (DNPH); the derivatives eluted with acetonitrile, and quantitated by HPLC-UV. The data suggested: 1) in placebo-treated subjects, total carbonyls (i.e., defined as the total amount of 3 to 11 carbon straight chain carbonyls) significantly increased after O_3 exposure, but not air exposure (relative to pre-exposure values) ($p<0.05$; $n=5$); 2) subjects pretreated with anti-oxidants did not have an increase in total carbonyls after air or O_3 exposures. Therefore lung carbonyls were increased in response to O_3 exposure, and may be markers of an exposure to this pollutant as well as mediators of lung responses. Anti-oxidant pretreatment attenuated the O_3-induced increase in carbonyls. (This is an abstract of a proposed presentation, and does not necessarily reflect US EPA policy.)

1474 INHALED NAPHTHALENE (NA) CAUSES DOSE DEPENDENT CLARA CELL CYTOTOXICITY IN MICE.

J. A. A. West, G. Pakenham, D. Morin, C. A. Fleschner, C. G. Plopper and A. R. Buckpitt. *University of California, Davis, CA.*

Current OSHA standards for human NA exposure are set at 10ppm (TWA) with a STEC of 15ppm. While several studies have addressed the dose dependence of NA injury by intraperitoneal (i.p.) administration, the pattern and severity of injury by inhalation exposure is unknown. To determine the regio-specific and dose dependent differences with inhalation exposure, mice were exposed (4 hrs) to a range of NA concentrations (0-100ppm). Mice were killed and lungs were fixed via tracheal infusion for high-resolution histopathology 24 hours after the completion of NA exposure. NA (≤200mg/kg) administered i.p. causes Clara cell cytotoxicity which is limited to distal airways. Higher doses (>300mg/kg) extend the injury pattern toward the lobar bronchus. In contrast, NA inhalation exposure causes injury to lobar bronchus epithelium at 2ppm; injury increases in severity and in a dose dependent fashion up to 75ppm. Terminal airways of exposed mice exhibited little or no injury at low doses (2-10 ppm); doses exceeding 10ppm were required to produce injury to Clara cells in the terminal airways. We conclude: 1) Clara cells of mouse airways are exquisitely sensitive to inhaled NA at concentrations well below the current OSHA standard; 2) by inhalation exposure the pattern of NA injury moves proximal to distal with increasing severity in a dose dependent fashion and; 3) susceptibility to NA injury in naive animals is not related to airway level but to dose distribution. (Research funded by ES04311, ES00628, ES06700, ES05707, ES04699, ES09681.)

1475 LUNG TUMORIGENICITY FROM EXPOSURES OF F-344 RATS TO COMBINATIONS OF BERYLLIUM AND PLUTONIUM.

G. L. Finch, F. F. Hahn, L. F. Blair, M. D. Hoover and C. H. Hobbs. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

Beryllium is classified as either a demonstrated or probable carcinogen in humans, whereas radiation is a known carcinogen. We have shown that inhaled beryllium metal caused a high incidence of rat lung tumors. This study was conducted to examine (1) dose-response relationships between beryllium exposure and lung tumor induction in rats at lower doses than those previously studied, and (2) potential interactions between beryllium and plutonium in producing lung tumors. Equal numbers of male and female F344 rats received single, nose-only inhalation exposures to either filtered air, beryllium metal (target initial lung burdens [ILBs] of either 0.3, 1, 3, 10, or 50 μg), or 239PuO2 (target ILBs of either 230 or 450 Bq). The 230 Bq ILB of plutonium was combined with either the 1 or 10 μg ILB of beryllium. Animals were held for life-span observation. Neither exposure-related mortality nor life-span shortening was observed. Because histopathological evaluations are not complete, we estimated lung tumor incidence from necropsy findings of lung masses or nodules in apparently non-leukemic rats on study for at least 1 yr. Estimated incidences of 4, 4, 12, 50, 61, and 91% were observed for the 0, 0.3, 1, 3, 10, and 50 μg ILBs of beryllium, respectively, and 28 and 46% for the 230 and 450 Bq ILBs of plutonium, respectively. Incidences of 62 and 89% were seen in the groups receiving ILBs of 230 Bq plutonium and either 1 or 10 μg of beryllium, respectively. These data demonstrate a no-effect level and dose-response relationship for the induction of beryllium-induced lung tumors in rats; and suggest an additive to super-additive effect of combined exposure. However, definitive conclusions must await completion of the histopathology and statistical evaluations. (Research supported by the US Department of Energy under Cooperative Agreement DE-FC04-96AL76406.)

1476 PULMONARY RESPONSES OF RATS, MICE, AND HAMSTERS TO INHALED TITANIUM DIOXIDE (TiO_2).

E. Bermudez[1], J. B. Mangum[1], E. E. Reverdy[1], B. A. Wong[1], B. Asgharian[1], P. M. Hext[2], D. B. Warheit[3], and J. I. Everitt[1]. [1]*CIIT, Research Triangle Park, NC,* [2]*Zeneca Central Toxicology Lab, Macclesfield Cheshire, United Kingdom and* [3]*Dupont Haskell Lab, Newark, DE.*

Rats are unique in that the inhalation of high concentrations of poorly soluble, relatively noncytotoxic particles, can result in an "overload" of clearance mechanisms and ultimately can lead to pulmonary tumors. The objective of the present study was to examine the pulmonary responses of rodents to inhaled pigmentary TiO_2 to elucidate the basis for the species-differences in the long-term outcome of chronic exposure. Female mice, rats, and hamsters were exposed to 10 (L), 50 (M), or 250 (H) mg/m3 TiO_2 for 6 h/d, 5 d/wk, for 13 wk with recovery groups held for an additional 4, 13, 26 or 52 wk period.

Following exposure and at each recovery time the TiO_2 burden in the lung was determined. The inflammatory response of the lung (LDH, total protein, and cytologic parameters in bronchoalveolar lavage fluid) was assessed at each time point. Burdens (mg/g) of TiO_2 in the lung following exposure to L, M, or H TiO_2 were; (mouse) 5.2, 53.5, 170.2; (rat) 7.1, 45.1, 120.4; and (hamster) 2.6, 14.9, 120.3. Lung burdens decreased with time after exposure; the decline was more rapid in hamsters than in mice or rats. Increases in macrophage and neutrophil numbers and in soluble indices of inflammation were observed in all three species following exposure to M and H TiO_2 (rats > mice, hamsters) and remained elevated, relative to controls, at 26 weeks post exposure. Histopathologic examination of lungs showed a concentration dependent distribution pattern of particles which tended to be species specific at the L and M exposure concentrations. Hypertrophy and hyperplasia of alveolar epithelium and fibrotic changes were observed in rats exposed to H TiO_2. These data suggest that rats exposed to concentrations likely to induce overload differ from mice and hamsters in their cellular responses and in the way they clear and sequester particles. (Supported in part by Chemical Manufactures Association and European Chemical Industry Council.)

1477 SEVERITY OF PULMONARY EPITHELIAL AND INFLAMMATORY RESPONSES IN CARBON BLACK-EXPOSED RATS IS DEPENDENT ON PARTICLE SURFACE AREA.

J. R. Harkema[1], J. A. Hotchkiss[1], C. B. Bennett[1], A. C. P. Elder[2] and G. Oberdorster[2]. [1]*Michigan State University, East Lansing, MI,* [2]*University of Rochester, Rochester, NY.*

Rats chronically exposed to high levels of carbon black particles (Cb) develop lung tumors in association with chronic active inflammation and epithelial cell proliferation. The purpose of the present study was to determine the relationship of the particle surface area with the severity of the induced epithelial proliferation and inflammation in the lungs of rats exposed to Cb. F344 rats were exposed to three concentrations (1, 7, 50 mg/m3) of high surface area Cb particles (HSCb) and one concentration (50 mg/m3) of low surface area Cb particles (LSCb) for 6 h/day, 5 days/wk for 13 wks. The retained particle burden of LSCb was the same as that of the mid dose HSCb in terms of surface area, but was 1.6 times greater than the high dose HSCb in terms of particle mass. Rats were sacrificed one day after the end of exposure. The left lung lobe of each rat was intratracheally fixed at a constant pressure and further processed for light microscopy and morphometric analysis. Numeric densities of alveolar macrophages, neutrophils, and type 2 cells in the alveolar parenchyma, and epithelial cells in terminal bronchioles were morphometrically determined. Compared to controls, rats exposed to HSCb had a dose-dependent increase in the numeric densities of all cell types. For example, there was a 40, 75 and 128%, increase in the numeric density of type 2 cells in rats exposed to 1, 7, and 50 mg/m3 of HSCb, respectively. Numeric cell densities in the lungs of rats exposed to 50 mg/m3 LSCb were consistently lower than those in rats exposed to 50 mg/m3 HSCb. In addition, more necrosis of alveolar macrophages was observed in rats exposed to HSCb as compared to rats exposed to LSCb. These results suggest that the magnitude of the pulmonary proliferative and inflammatory lesions induced by Cb exposure is dependent, in part, on particle surface area. (Research funded by the International Carbon Black Association.)

1478 CYTOKINE, OXIDANT, AND MUTATIONAL RESPONSES AFTER LUNG OVERLOAD TO INHALED CARBON BLACK.

J. M. Carter[1], G. Oberdorster[2] and K. E. Driscoll[1]. [1]*Procter & Gamble Company, Cincinnati, OH and* [2]*University of Rochester, Rochester, NY.*

Complex interactions between humoral and cellular mediators orchestrate the pathogenic effects of inhaled toxins leading to pulmonary inflammation, fibrosis and tumorigenicity. Chronic inhalation of poorly soluble particles at levels that cause persistent, marked inflammation has been associated with increased levels of adenomas and carcinomas in the rat lung. This response seems to be unique to the rat and has not been observed in mice, or hamsters. At present, the mechanisms underlying the development of particle-induced rat lung tumors are not completely understood, but increasing evidence indicates the rat lung tumor response is due to a secondary, non-genotoxic mechanism such as inflammation. Hence, the recruitment of neutrophils during the inflammatory response and subsequent release of oxidants from these cells may play an important role in the pathogenesis of lung tumors. To investigate this hypothesis rats were exposed to air, 1, 7, 50 mg/m3 of a high surface area carbon black (HSCB) and 50 mg/m3 of a low surface area carbon black (LSCB) for 13 weeks. Immediately following inhalation exposure and 3 months post exposure animals were sacrificed, bronchoalveolar lavage (BAL) was performed and characterized for cell number, type, oxidant and antioxidant levels. Ex vivo mutational analysis of inflammatory cells was evaluated by co-incubating with a rat lung epithlial cell line (RLE). Additionally, lung tissue was evaluated for pro- and anti-inflammatory cytokines. There was a dose and time related effects with all the parameters evaluated as well as a particle size effect. LSCB at both time points was similar to mid dose HSCB. Particle surface area appears to be an important determinant for particle overload-induced oxidant generation and associated mutational events in the lung. (Sponsored by the ICBA.)

1479 PARTICLE SURFACE AREA-ASSOCIATED PULMONARY EFFECTS FOLLOWING OVERLOADING WITH CARBON BLACK.

A. C. P. Elder[1], N. Corson[2], R. Gelein[1], P. Mercer[1], K. Nguyen[1], C. Cox[2], P. Keng[3], J. N. Finkelstein[4] and G. Oberdorster[1]. [1]*University of Rochester - Department of Environmental Medicine, Rochester, NY,* [2]*University of Rochester - Department of Biostatistics, Rochester, NY,* [3]*University of Rochester - Department of Radiation Oncology, Rochester, NY and* [4]*University of Rochester - Department of Pediatrics, Rochester, NY.*

Rats, but not mice or hamsters, exposed to high levels of carbon black develop lung tumors in association with lung overload. This and the lack of direct genotoxicity suggest a mechanism of tumor formation based on inflammatory and proliferative processes. To evaluate mechanistic aspects of this response, female F-344 rats (8 wks) were exposed to three concentrations (1, 7, 50 mg/m^3) of high surface area carbon black (HSCb) and one concentration (50 mg/m^3) of low surface area carbon (LSCb) for 13 weeks; serial sacrifices were performed during and post-exposure. There was a dose-dependent increase in the lung burden of HSCb. The LSCb mass lung burden was about 1.6 times higher than the high dose of HSCb at the end of exposure. In terms of retained particle surface area, however, the LSCb was the same as the mid-dose HSCb. Cellular and biochemical parameters and the concentration of cytokines/chemokines increased in bronchoalveolar lavage (BAL) fluid with the dose of HSCb. For the LSCb, these parameters were either the same as mid-dose HSCb or in between the mid- and high-dose HSCb. These elevations persisted in the mid- and high-dose HSCb groups and for LSCb; however, there was some regression of response for the mid-dose HSCb. Strand break analyses revealed DNA damage in BAL cells from the HSCb groups, whereas this response appeared to be lower in the LSCb group; DNA damage was less in lung tissue cells of all groups. These results indicate that retained particle surface area plays an important role in particle-induced inflammatory processes. (This research was funded by the International Carbon Black Association.)

1480 TUMOR NECROSIS FACTOR-α (TNF-α) ADMINISTRATION MIMICS ALLERGIC ADJUVANT EFFECT OF RESIDUAL OIL FLY ASH (ROFA) PARTICLES.

A. L. Lambert[1], M. J. K. Selgrade[2] and M. I. Gilmour[2]. [1]*University of North Carolina, Chapel Hill, Chapel Hill, NC and* [2]*USEPA, NHEERL, Research Triangle Park, NC.*

We have previously demonstrated that pulmonary exposure to ROFA results in enhanced sensitization to house dust mite (HDM) and promotes allergic lung disease after allergen challenge. This effect was associated with increased TNF-α and Th2 cytokines in the lung. TNF-α is a macrophage- and bronchial epithelial cell-derived cytokine which has been shown to upregulate the expression of adhesion molecules on endothlial cells, promoting granulocyte migration to the lung, and to influence B cell isotype switching to IgE antibody formation. The present study examined whether enhanced sensitization to HDM could be achieved by instillation of TNF-α. One day prior to pulmonary sensitization with 10μg HDM, BN rats (56 days old, female) were instilled via the trachea with either 2.0μg recombinant rat TNF-α, 2.0μg bovine serum albumin (BSA), or 1000μg ROFA, and were challenged with 10μg HDM 14 days later. Antigen-induced immediate bronchoconstriction responses were significantly elevated in the TNF and ROFA groups compared with BSA control. Antigen-specific IgE titers, lymphocyte proliferation to HDM, as well as bronchoalveolar lavage fluid biochemicals, cytokines (TNF-α and IL-6), and eosinophil numbers were also elevated in rats treated with ROFA or TNF compared with BSA-treated control rats after HDM challenge. This study demonstrates that TNF-α has the same activity as ROFA in the enhancement of allergic sensitization. (This abstract does not reflect US EPA policy.)

1481 *IN VIVO* AND *IN VITRO* CORRELATION OF PULMONARY MAP KINASE ACTIVATION FOLLOWING METALLIC EXPOSURE.

R. Silbajoris[1], A. J. Ghio[1], R. Jaskot[2], K. L. Dreher[2], L. E. Brighton[3] and J. M. Samet[1]. [1]*Human Studies Div., National Health and Environmental Effects Research Lab., USEPA, Research Triangle Park, NC,* [2]*Experimental Toxicology Div., National Health and Environmental Effects Research Lab., USEPA, Research Triangle Park, NC and* [3]*Center for Environmental Med. and Lung Biology, University of North Carolina, Chapel Hill, NC.* Sponsor: M. C. Madden.

Residual oil fly ash (ROFA) is a particulate pollutant produced in the combustion of fuel oil. Exposure to ROFA is associated with adverse respiratory effects in humans, induces lung inflammation in animals, and induces inflammatory mediator expression in cultured human airway epithelial cells (HAEC). ROFA has a high content of transition metals, including vanadium, a potent tyrosine phosphatase inhibitor which we have previously shown to disregulate phosphotyrosine metabolism and activate mitogen-activated protein kinase (MAPK) signaling cascades in HAEC. In order to study MAPK activation in response to *in vivo* metal exposure, we used immunohistochemical methods to detect levels of phosphorylated protein tyrosines (P-Tyr) and the MAPKs ERK1/2, JNK, and P38, in lung sections from rats intratracheally exposed to ROFA. After a 1 h exposure to 500μg ROFA, rat lungs showed no histological changes and no significant increases in immunostaining for either P-Tyr or phospho (P)-MAPKs compared to saline-instilled controls. At 4 hs of exposure, there was mild and variable inflammation in the lung which was accompanied by an increase in specific immunostaining for P-Tyr and P-MAPKs in airway and alveolar epithelial cells and resident macrophages. By 24 hs of exposure, there was a pronounced inflammatory response to ROFA instillation and a marked increase in levels of P-Tyr and P-MAPKs present within the alveolar epithelium and in the inflammatory cells, while the airway epithelium showed a continued increase in the expression of P-ERK1/2. By comparison, HAEC cultures exposed to 100μg/ml ROFA for 20 min resulted in marked increases in P-Tyr and P-MAPKs, which persisted after 24 hs of exposure. P-Tyr levels continued to accumulate for up to 24 h in HAEC exposed to ROFA. These results demonstrate *in vivo* activation in cell signaling pathways in response to pulmonary exposure to particulate matter, and support the relevance of *in vitro* studies in the identification of mechanisms of lung injury induced by pollutant inhalation. This abstract of a proposed presentation does not necessarily reflect EPA policy.

1482 RESIDUAL OIL FLY ASH SLOWS THE CLEARANCE OF *LISTERIA MONOCYTOGENES* FROM RAT LUNGS.

J. M. Antonini[1], M. R. Jernigan[1], H. M. Yang[1], J. Y. C. Ma[1], J. R. Roberts[1], M. W. Barger[1], L. Butterworth[1] and R. W. Clarke[2]. [1]*NIOSH, Morgantown, WV and* [2]*Harvard School of Public Health, Boston, MA.*

Inhalation of residual oil fly ash (ROFA) has been shown to increase pulmonary morbidity and impair lung defense mechanisms. The objective of this study was to evaluate the effect of ROFA exposure on the clearance of a bacterial pathogen from the lungs. Elemental analysis revealed the ROFA particles to be comprised of Al, Si, S, Ca, V, Fe, and Ni. Young adult male Sprague-Dawley rats were dosed intratracheally with saline (control) or ROFA at a dose of 1 mg/100 g b wt. Three days later, ~500,000 *Listeria monocytogenes* were intratracheally instilled into the ROFA-treated and saline control rats. Bronchoalveolar lavage was performed on the right lungs at 3, 5, and 7 days after exposure to *L. monocytogenes*. The cells recovered were differentiated, and chemiluminescence, an index of macrophage activation, was measured. At the same time points, the left lung and spleen were removed, homogenized, and cultured on brain heart infusion agar at 37°C. Colony forming units were counted after an overnight incubation. Pre-exposure to ROFA significantly ($p<0.05$) delayed the pulmonary clearance of *L. monocytogenes* as compared to the saline control rats. ROFA had no effect on the influx of neutrophils into the lungs but caused a significant ($p<0.05$) decrease in macrophage chemiluminescence as compared to saline control rats. We have demonstrated that acute exposure to ROFA slowed the pulmonary clearance of *L. monocytogenes*. This is most likely due to a ROFA-induced suppression of macrophage activation, perhaps related to the elemental composition of the particles. Therefore, in an occupational setting, inhalation of ROFA may lead to increased susceptibility to pulmonary infection.

1483 METAL-CONTAINING PARTICULATE MATTER-INDUCED AUTOXIDATION OF SYNTHETIC LUNG EPITHELIAL LINING FLUID.

G. Sun[1] and G. E. Hatch[2]. [1]*Curriculum in Toxicology, University of NC, Chapel Hill, NC and* [2]*NHEERL, USEPA, Research Triangle Park, NC.*

Oxidative stress has been implicated in the toxicity of metal-rich particulate matter (PM). Lung epithelial lining fluid (ELF) contains several antioxidants and serves as the first line of defense against inhaled toxins and infective agents. We used synthetic ELF (sELF) as a model system to study the role of residual oil fly ash (ROFA, an ambient PM containing soluble transition metals) in autoxidation of ELF constituents and the effects of antioxidants on this process. sELF was formulated based on literature data and our own measured values of human bronchoalveolar lavage. Oxygen-18 labeling was used to trace the extent of oxidation by measuring ^{18}O incorporated into sELF components after exposure of sELF (200 μL, pH 7.4) containing ROFA (0-200 μg/mL) to 20% $^{18}O_2$ (24°C, 4 h). Ascorbate, urate, total glutathione, and non-protein sulfhydryls were also measured. ROFA induced autoxidation of sELF significantly in the presence of ascorbate and this effect was slightly enhanced by glutathione. Ascorbate became inhibitory at high concentrations. Catalase, superoxide dismutase, and glutathione peroxidase had no significant effect on the autoxidation at normal and 2X reported physiological concentrations. The consumption of ascorbate was ROFA-dose-dependent, while urate, total glutathione, and non-protein sulfhydryls were not depleted under any condition studied. Compared with maximum possible binding of ROFA metals to sELF components, oxygen incorporation was 2-9X higher (on a nmol/mL basis). These results suggest that ROFA-induced oxidative stress might be a significant contributor to toxicity and that ascorbate and glutathione act as pro-oxidants in this process. (Supported by EPA/UNC CT #902908. This abstract does not represent EPA policy.)

1484 SURFACE CHARGE AND SIZE AS CONTRIBUTING FACTORS TO PARTICULATE MATTER (PM) TOXICITY.

M. Oortgiesen[1], S. A. Simon[1], L. Lee[2] and B. Veronesi[2]. [1]*Duke Univiersity Medical Center, Department Anesthesiology and Neurobiology, Durham, NC and* [2]*USEPA, NHEERL, NTD, Research Triangle Park, NC.*

The heterogeneous composition of PMs has complicated identifying which physicochemical component(s) contribute to their inflammatory effects. In vitro exposure of airway cell targets to various urban and industrial PM pollutants results in differential inflammatory changes (e.g., cytokine release, oxidative burst). In this study, nine PMs from various urban, natural and industrial sources (e.g., urban air particles, diesel, woodstove, oil fly ash) were described in terms of their surface charge (i.e., zeta potential) and particle size. The different PMs were examined in field suspension (fine and course particles) and after 0.22 um filtration (ultrafine particles). The zeta potentials of suspended field PMs (1-30 um in diameter) did not differ significantly across sources, but were dependent on the vehicle milieu. For example, zeta potential values of PM suspended in 1 mM KCl (pH 7.4) ranged from averaged values of -27 to -42 mV, whereas, when suspended in serum-supplemented culture media, their zeta potentials ranged from -6 to -12 mV. In contrast, the zeta potentials of the ultrafine particles (i.e., after 0.22 um filtration) were highly variable, ranging from averaged values of +13 mV to -109 mV in 1 mM KCl (pH 7.4). Exposure of mouse sensory neurons and human bronchial epithelial cells (i.e., BEAS-2B) to the individual suspended field PM or to their filtrates produced a differential release of the proinflammatory cytokine IL-6. Collectively, these data suggest that both surface charge and particle size are contributing factors to the inflammatory effects of PMs seen in cultured airway target cells. Although charge appears not to be the discriminative factor for the differential inflammatory effects of PM >1 um, it may be relevant for the ultrafine PM fraction.(This abstract has been reviewed by NHEERL and does not necessarily reflect EPA policy).

1485 CHANGES IN HEART RATE VARIABILITY IN YOUNG AND ELDERLY HUMANS EXPOSED TO CONCENTRATED AMBIENT AIR PARTICLES.

R. B. Devlin[1], W. Cascio[2], H. Kehrl[1] and A. Ghio[1]. [1]*Environmental Protection Agency, Research Triangle Park, NC and* [2]*University of North Carolina, Chapel Hill, NC.* Sponsor: M. Madden.

Epidemiology studies have shown an association between ambient air particles (PM) and mortality in the elderly related to cardiovascular causes. In addition, a recent study has shown an association between PM and decreased heart rate variability in elderly residents of a retirement village. The purpose

of this study was to determine if exposure of young and elderly volunteers to moderate levels of PM under controlled conditions results in decreased heart rate variability. Fourteen healthy young volunteers (aged 18-35) and 14 healthy elderly volunteers (aged 65-80) were exposed to concentrated Chapel Hill ambient air particles (CAPS) for two hours. Heart rate variability was determined before, immediately after, and 24 hrs after exposure. Changes in both time (SSDN, PNN50) and frequency (LF, HF, LF/HF) domain were measured. There were no statistically significant changes in heart rate variability in young subjects. In contrast, elderly subjects developed significant decrements in both time and frequency domain immediately after exposure. Changes in some of these parameters persisted for at least 24 hrs. These data demonstrate that PM can induce decreased heart rate variability in the elderly, which can persist for many hours, suggesting a possible mechanism that may contribute to the epidemiology findings. (This abstract of a proposed presentation does not necessarily reflect EPA policy.)

1486 LUNG INJURY FROM EXPOSURE TO RESIDUAL OIL FLY ASH (ROFA), OTTAWA DUST (OTT), OR MT. ST. HELENS ASH (MSH) IN A RAT MODEL OF HYPOXIA-INDUCED PULMONARY HYPERTENSION (PHT).

W. J. Burke[1], J. R. Lehmann[2], U. P. Kodavanti[2], M. J. Schladweiler[2], D. Winsett[2], T. Krantz[2], J. Richards[2] and D. L. Costa[2]. [1]*North Carolina Central University, Durham, NC and* [2]*US EPA, Research Triangle Park, NC.*

Previous studies to assess PHT as a susceptibility factor for particulate matter (PM) have used monocrotaline (MCT) to induce the impairment. While causing damage to pulmonary blood vessels, MCT also gives rise to substantial coexistent lung inflammation. The hypoxia model in the rat has virtually no inflammatory component while exhibiting considerable PHT and cardiomegaly. We hypothesized that PHT alone without coexistent inflammation would result in increased lung injury induced by PM exposure. Male, 60-day old SD rats (260-290 g) were subjected to 12 days of either normobaric normoxia or hypoxia (10% O2). Subgroups of normoxic and hypoxic rats were then intratracheally (IT) instilled with saline suspension of 3.3 mg/kg MSH (inert PM), OTT (ambient PM), or ROFA(oil combustion PM). At 24 hrs post IT, bronchoalveolar lavage fluid (BALF), blood and heart weights were analyzed. Hypoxic animals exhibited PHT (RV/LV+S: normoxia = 0.35±0.04, hypoxia 0.60±0.07; hematocrit: normoxia = 46.4±2.0, hypoxia = 56.0±2.9). PM exposure caused increases in BALF protein, albumin and LDH (ROFA>OTT>MSH) in both normoxic and hypoxic animals. BALF total cells and neutrophils also increased following exposure (ROFA>OTT>MSH). While hypoxia was associated with exacerbated ROFA and OTT-induced increases in BALF protein and total cells, neutrophilic inflammation remained similar in both normoxic and hypoxic rats. Exposure to ROFA and OTT caused plasma fibrinogen levels to increase slightly in normoxic but significantly in hypoxic rats. This study shows that preexistent PHT without pulmonary inflammation is associated with some degree of exacerbation of PM-induced pulmonary injury and systemic changes. (This abstract does reflect EPA policy; Supported in part by NCCU #CT827262.)

1487 1, N2 PROPANODEOXYGUANOSINE-DNA ADDUCTS AND ARTERIOSCLEROTIC PLAQUES IN COCKERELS EXPOSED TO ACROLEIN.

A. Penn[1], R. Nath[2], J. Pan[2], L. C. Chen[3], K. Widmer[1], W. Henk[4] and F. L. Chung[2]. *LSU* [1]*Physiol., Pharm., Tox., and* [4]*Anat., School of Veterinary Medicine, Baton Rouge, LA.* [2]*American Health Foundation, Valhalla, NY and* [3]*Nelson Institute, NYU School of Medicine, Tuxedo, NY.*

Inhalation of 1.3 butadiene, a vapor phase component of second-hand tobacco smoke (SS) accelerates development of arteriosclerotic plaques. We asked whether inhaled acrolein (ACR), a reactive aldehyde that is also a prominent vapor phase component of SS, damages artery wall DNA and also accelerates plaque development. Cockerels inhaled 0, 1, or 10 ppm ACR mixed with HEPA-filtered air for 6 hr. Half were sacrificed immediately for detection of the stable, premutagenic 1, N2 propandeoxyguanosine ACR-adduct in aortic DNA via a 32P-postlabeling/HPLC method and half were sacrificed after 10 days for assessment of adduct repair. After 1 day, ACR-DNA adducts were 5x higher in the 1 & 10 ppm groups than in HEPA-filtered air controls. However, after 10 days, adduct levels in the 1 & 10 ppm ACR groups were reduced to the control adduct level. For the plaque studies, cockerels inhaled 1 ppm ACR (6 hr/day, 8 wk) mixed with the same HEPA-filtered air inhaled by controls. Plaque development was measured blind by computerized morphometry. Unlike the case with butadiene, ACR inhalation did not accelerate plaque development. Thus, even though repeated exposure to ACR alone has no effect on plaque size under the exposure conditions used here, a single, brief inhalation exposure to ACR elicits repairable DNA damage to the artery wall. These results suggest that frequent exposure to SS may lead to persistent artery wall DNA damage and thus provide sites on which other SS plaque accelerants can act. (Supported by NIEHS # 08624.)

1488 THE RESPONSE OF HUMAN AIRWAY EPITHELIAL CELLS TREATED WITH DIESEL PARTICULATES IN VITRO WILL VARY ACCORDING TO THE COMPOSITION OF THE PARTICULATES.

L. A. Dailey[1], D. B. Harris[2] and M. C. Madden[1]. [1]*USEPA, NHEERL, Human Studies Division, Research Triangle Park, NC and* [2]*USEPA, NRMRL, Emissions Characterization & Prevention Branch, Research Triangle Park, NC.*

Strong epidemiologic evidence suggests that increased morbidity and mortality are associated with pollution episodes. These studies further suggest that particulate matter (PM), a major constituent of ambient pollution, is an important player in the adverse pulmonary effects observed. Many sources contribute to the particulate fraction of ambient pollution, including diesel exhaust particulates (DEP). The composition of diesel exhaust particulates varies greatly dependent upon multiple factors, including the engine driving cycle conditions. We have examined the effect of DEP components derived from different driving cycles on the responses of normal human bronchial epithelial cells (NHBE) *in vitro*. Specifically, we have looked at NIST standard references materials DEP 1650 and 2975 (parent), an idling workload at KW~0 (extract 2A) and a high workload at KW~85 (extract 5A). NHBE cells were treated for 2 hrs at 37C, 5% CO2 with 0 to 500µg/0.5ml of each DEP in HBSS + 0.005% BSA. Cell culture medium was then added to the cells. Cell supernatants were collected for measurement of cytotoxicity and inflammatory mediators at 24 hrs. Preliminary findings show that all 3 DEPs have a slightly cytotoxic effect on NHBE cells at 500µg compared to untreated controls as measured by LDH release. The release of the inflammatory cytokine IL-8 was decreased 2.3-fold and 4.7-fold in cells treated with 500µg parent and extract 2A, respectively, whereas cells treated with 500µg extract 5A showed a 2.4-fold increase in IL-8 release. Basal release of PGE2, another marker of inflammatory responses, did not appear to differ from controls in cells treated with extract 2A but was increased as much as 2.5-fold in cells treated with parent and extract 5A. Melittin stimulation of the cells showed that parent and extract 2A had an inhibitory effect on PGE2 release at 500µg, but all 3 compounds showed increased melittin stimulated PGE2 production at 50 and 100µg. The data suggests that the response of NHBE cells to treatment with diesel exhaust will vary dependent upon the engine load which affects the exhaust components. (This is an abstract of a proposed presentation, and does not necessarily reflect US EPA policy.)

1489 EFFECTS OF LUNAR AND MARTIAN SOIL SIMULANTS ON HUMAN ALVEOLAR MACROPHAGES (HAM).

J. A. Latch, R. F. Hamilton, Jr., T. Y. Gots and A. Holian. *University of Texas Houston Health Science Center, Houston, TX.*

In this study the potential toxicity of JSC-Mars 1, a Martian regolith simulant, and JSC-1, a lunar mare soil simulant, were considered in preparation for long-term space missions. HAM were treated with the Martian or lunar dust simulant *in vitro* for 24 h. Cells were examined for viability by Trypan blue exclusion and for apoptosis by morphological and cell death ELISA assays. Treatment with either particulate resulted in significant HAM apoptosis. To elucidate a possible mechanism, by which these particles induce apoptosis, we investigated the involvement of scavenger receptors (SR) in this process. Cells were pretreated with polyinosinic acid (poly I; 0 or 250 µg/ml) 15 min prior to treatment with one of these particulates; poly I competitively inhibits binding to SR. Pretreatment with poly I significantly inhibited apoptosis. Therefore, HAM apoptosis induced by these particulates may be due to the interaction with SR resulting in initiation of one or more signaling pathways leading to apoptosis. Furthermore, treatment of HAMs with either particulate resulted in a shift in the RFD1+:RFD1+7+ HAM subpopulation ratio toward RFD1+. This shift suggests particle-induced activation of the immune system.

1490 LUNG INFLAMMATION AND DAMAGE AFTER SILICA INHALATION IN RATS: IS THERE RECOVERY?

D. W. Porter[1], V. A. Robinson[1], D. Ramsey[2], A. Khan[2], J. McLaurin[2], A. Teass[2], R. Mercer[1] and V. Castranova[1]. [1]*HELD NIOSH, Morgantown, WV and* [2]*DBBS NIOSH, Cincinnati, OH.*

Crystalline silica (quartz) is a well established lung inflammatory and fibrogenic occupational dust. Although the pulmonary effects of silica exposure in animal models has been well studied, the relationships between silica exposure and clearance (recovery) on lung inflammation and damage has not been investigated. To investigate these relationships, rats were exposed to filtered air (control) or 15 mg/m^3 silica aerosol (6 hours/day,5 days/week). Rats were exposed for 20, 40 or 60 days and each exposure group had a corresponding exposure plus 36 day recovery group. Rat lungs were lavaged to isolate bronchoalveolar lavage (BAL) cells and acellular BAL fluid, while samples of whole blood were collected to monitor peripheral leukocytes. Pulmonary inflammation was monitored by measuring BAL polymorphonuclear leukocytes (PMN). BAL PMN cell counts were elevated in silica-exposed versus control rats, and PMN counts increased further during recovery. Blood leukocyte counts displayed a pattern similar to the BAL PMN counts. Silica cytotoxicity was measured by analyses of BAL fluid lactate dehydrogenase (LDH) activity and albumin (ALB) concentration. BAL fluid LDH activities and ALB concentrations were higher in silica-exposed versus control rats, and these parameters continued to increase during recovery. These data indicate that progressively severe silica-induced lung inflammation and damage occurs in response to the duration of silica inhalation and these processes continue after silica exposure has ended.

1491 EXPOSURE TO SILICA ACTIVATES MACROPHAGES AND INCREASES THE PULMONARY CLEARANCE OF *LISTERIA MONOCYTOGENES* IN RATS.

H. Yang, J. Y. C. Ma, J. R. Roberts, M. W. Barger, L. Butterworth, V. Castranova and J. M. Antonini. *NIOSH, Morgantown, WV.*

Alveolar macrophages (AM) play a crucial role in protecting the lungs from infectious agents. In this study, we evaluated the effect of silica on macrophage function using a rat *Listeria monocytogenes* (LM) infection model. Male Sprague-Dawley rats were instilled intratracheally with saline or silica (20 mg/rat). Thirty-five days later, the rats were then inoculated intratracheally with either ~5,000 or 500,000 LM. At 3, 5 and 7 days post-infection, the left lung was removed, homogenized and cultured on brain heart infusion agar at 37°C. The numbers of viable LM were counted after an overnight incubation. Bronchoalveolar lavage (BAL) was performed on the right lungs and BAL cell differentials, acellular LDH activity and acellular albumin content were determined. Macrophage chemiluminescence (CL) and nitric oxide (NO) production were assessed as a measure of macrophage function. Pre-exposure to silica significantly increased the pulmonary clearance of LM as compared to saline controls. Exposure to silica caused significant increases in BAL neutrophils, LDH and albumin in non-infected rats. The generation of CL by AM was also enhanced in silica-treated rats. In summary, the results demonstrated that subchronic exposure of rats to silica increased neutrophil infiltration and macrophage activation. These enhanced activities may be responsible for increasing the pulmonary clearance of LM.

1492 LUNG FLUID ACTIVATION OF INHALED P-ARAMID RFP IS A PREREQUISITE FOR BIODEGRADABILITY: DEVELOPMENT OF *IN VITRO* CELLULAR AND NONCELLULAR MECHANISTIC STUDIES.

T. R. Webb, M. A. Hartsky and D. B. Warheit. *DuPont Haskell Lab., Newark, DE.*

Numerous inhalation toxicity studies have demonstrated that inhaled p-aramid RFP are biodegradable, i.e., break down transversely into smaller fragments in the lungs of exposed rats and hamster. The finding of p-aramid RFP shortening in the lungs of two rodent species and the lack of lung tumors in rats have been considered by IARC in 1997 as evidence supporting a Category 3 classification (Inadequate evidence for carcinogenicity). In the current study, we have investigated the mechanisms of p-aramid RFP biodegradation in the lungs of animals. We have hypothesized that lung fluids interact with and activate the inhaled p-aramid RFP following deposition in the lung; subsequently, the RFP become vulnerable to enzymatic attack in the lungs. To test the hypothesis, p-aramid RFP and a biopersistent control organic fiber-type, cellulose RFP were instilled into the lungs of rats and the lungs digested 24 hrs post-instillation, using two different digestion techniques, 1) a conventional ethanolic KOH method, and 2) an enzyme method (designed to simulate pulmonary enzymes). Following tissue processing, the RFP lengths were assessed by scanning electron microscopy. The results demonstrated that the enzyme method but not the KOH method artificially cleaved the p-aramid RFP recovered from rat lungs. In contrast, neither the enzyme or KOH method affected the length dimensions of cellulose RFP. Additional *in vitro* studies were conducted wherein p-aramid or cellulose RFP were incubated with lavaged fluids from a normal rat and then underwent simulated digestion procedures with either KOH or enzyme methods. The lengths of p-aramid RFP were shortened when incubated with BAL fluids and then "digested" with the enzyme method but not with KOH, thus confirming the *in vivo* results. In contrast, no change in fiber lengths were measured in the cellulose RFP following incubation with BAL fluids and subsequent "digestion" with either KOH or enzyme method. Additional studies are ongoing, wherein saline and BAL-treated p-aramid and cellulose RFP have been incubated with alveolar macrophages and with macrophage/epithelial cell co-cultures for one or two weeks. Preliminary data generated from these experiments demonstrate that macrophages phagocytize the BAL-treated p-aramid RFP, and this could account, in part, for the biodegradability of inhaled p-aramid measured in the lungs of exposed rats. To summarize our findings, these data suggest that components of lung fluids coat and catalyze the p-aramid, rendering the RFP vulnerable to enzymatic attack by macrophages or other pulmonary cell-types. This could represent a mechanism through which inhaled p-aramid RFP are shortened in the lungs of exposed rats and hamsters. Cellular studies are ongoing to assess the contribution of pulmonary macrophages to the clearance and shortening of p-aramid RFP.

1493 BIOSOLUBILITY AND SHORT-TERM LUNG INFLAMMATION CAN BE USED TO ASSESS THE TOXIC POTENTIAL OF SYNTHETIC VITREOUS FIBERS.

T. W. Hesterberg and G. A. Hart. *Johns Manville Corp., Littleton, CO.*

A new bio-soluble fiber glass (JM 902) was developed for specialty insulation and filtration. JM 902 was tested for *in vitro* dissolution, biopersistence in rats, and early effects on bronchoalveolar (BAL) and pleural (PL) lavage fluid in rats. In vitro dissolution of JM 902 (kdis at pH 7.4=150 ng/cm2/hr) was faster than that of another fiber glass (kdis=100) that was innocuous in a rat chronic inhalation study. JM 902 also cleared rapidly from the lungs of rats: following 5 d fiber inhalation, lung clearance weighted half-time for fibers >20 mm in length was 6.8 days (satisfies the EU criterion for Category 0, non-carcinogen); following intratracheal instillation, JM 902 demonstrated a clearance half-time for fibers >5 mm in length of 20 days (satisfies the German criterion for a non-hazardous fiber). BAL and PL inflammatory indicators were measured in rats 1, 14, and 30 days after 5 d of fiber inhalation. Results for JM 902 were compared with those for 2 other fiber glasses (JM 901 standard insulation and JM 475 special application fiber) and amosite asbestos. (In previous rodent chronic inhalation studies, JM 901 was non-pathogenic, while JM 475 and amosite were pathogenic.) All 4 fibers induced elevated cellular and biochemical markers for inflammation in BAL at d 1 and in PL at d 14. However, only JM 475 and amosite asbestos continued to induce BAL/PL elevations through d 30, indicating sustained inflammation. In rats exposed to JM 901 and 902, BAL/PL parameters returned to normal levels by d 30. Thus, bio-solubility as well as short-term measures of sustained inflammation can be used to assess the potential toxicity of SVFs.

1494 THE INHALATION BIOPERSISTENCE AND MORPHOLOGIC LUNG DISPOSITION OF PURE CHRYSOTILE SERPENTINE ASBESTOS IN COMPARISON TO TREMOLITE AMPHIBOLE ASBESTOS IN RATS.

D. M. Bernstein[1], R. A. Rogers[2] and P. Thevenaz[3]. [1]*Consultant in Toxicology, Geneva, Switzerland,* [2]*Rogers Imaging Corporation, Needham, MA and* [3]*Research & Consulting Company Ltd., Füllinsdorf, Switzerland.*

Chrysotile is a serpentine composed of many fine fibrils which have an exposed layer of magnesium. Amphiboles (e.g tremolite) are rod-like fibers in which magnesium is sandwiched within the silicon matrix. McDonald (1997) has postulated that the presence of tremolite which occurs in many chrysotile mines, may account for much of the excess mortality found in chrysotile workers. **Design:** Pure chrysotile from the Cana-Brava Mine was investigated to determine the kinetics without amphiboles/tremolite. The study determined lung clearance (biopersistence), translocation and distribution within the lung. Chrysotile exposure aerosol had 465 fibers/cm^3 longer than 20μm. **Clearance:** Through 12-months post inhalation exposure (5 day, 6 hrs/day), lungs were analysed by TEM for total fiber number and size. This procedure digests the entire lung with no possibility of localising fibers in the lung.

Distribution: Confocal microscopy was used to determine the anatomic fate, orientation and distribution of fibers in airways, alveoli and lymphatics. **Results:** Pure chrysotile is rapidly removed from the lung. Fibers L>20 μm are cleared with a $T_{1/2}$=1.3 days. Fibers 5-20μm had a $T_{1/2}$=2.4 days. Fibers were never found clumped together but appeared as fibrils in corners of alveolar septa and within macrophages. In lymphatics, they appeared free or within lymphocytes. **Conclusion:** Pure chrysotile has been found to clear rapidly from the lung. The remaining short fibers were found in alveoli and lymphatics. These results support the evidence that the carcinogenicity of commercial chrysotile largely depends on its tremolite content.

1495 CRITICAL ROLE OF FIBER LENGTH IN THE BIOACTIVITY AND CYTOTOXICITY OF GLASS FIBERS.

V. Castranova[1], W. Jones[2], T. Blake[1], J. Ye[1], X. Shi[1], G. Deye[3] and P. Baron[3]. [1]*HELD or* [2]*DRDS, NIOSH, Morgantown, WV and* [3]*DPSE, NIOSH, Cincinnati, OH.*

A critical question in fiber research is the relative contribution of chemical properties vs physical dimensions to the potential pathogenicity of an inhaled fibrous particle. To address this question, it is essential to obtain fiber samples of discrete lengths for investigation. Recently our laboratory has developed a method, which utilized a dielectrophoretic classifier, to separate fiber fractions of narrowly defined lengths. The objective of the present study was to analyze the effects of fiber length on the ability of macrophages to phagocytize these fibers and to determine the potency of fibers of various lengths to activate nuclear transcription and cytokine production and to elicit cytotoxicity. Glass fibers (JM-100) were separated into five discrete size fractions (lengths of 3, 4, 7, 17, and 33 μm). Fibers ≤ 7 μm long were phagocytized by macrophages *in vitro*, while fibers ≥ 17 μm in length were too long to be completely engulfed, resulting in frustrated phagocytosis. There was a clear distinction in the bioactivity and cytotoxicity of fibers too long to be completely engulfed compared to shorter fibers. Glass fiber fractions having 17 μm or 33 μm lengths exhibited similar cytotoxicity on macrophages *in vitro*, measured as lactate dehydrogenase release or inhibition of zymosan-stimulated chemiluminescence. However, these long fibers had a toxic potency nearly two orders of magnitude greater than fiber fractions of 3, 4, and 7 μm lengths. Bioactivity was measured as the ability of glass fiber fractions to activate the DNA binding of the transcription factor, nuclear factor kappa B (NFkB), to activate the gene promoter for tumor necrosis factor alpha (TNFα), and to increase TNFα production by macrophages *in vitro*. Long fibers (17 μm) were significantly more potent bioactivators than short fibers (7 μm). This bioactivation was inhibited by N-acetyl-L-cysteine, an antioxidant, indicating that the generation of oxidants contributed to this induction. These results suggest that length plays an important role in the potential pathogenicity of fibrous particles with effects being magnified when fibers are too long to be phagocytized completely.

1496 DIETARY VITAMIN E SUPPLEMENTATION DOES NOT PREVENT LUNG MITOCHONDRIAL DYSFUNCTION INDUCED BY *IN VITRO* AMIODARONE AND N-DESETHYLAMIODARONE.

J. W. Card, M. J. Steenbakkers, K. M. Beard, W. J. Racz, J. F. Brien, B. M. Bennett and T. E. Massey. *Department of Pharmacology & Toxicology, Queen's University, Kingston, Ontario, Canada.*

We have previously shown that mitochondrial dysfunction may be an initiating mechanism of amiodarone (AM)-induced pulmonary toxicity, and that dietary vitamin E supplementation decreases pulmonary injury resulting from intratracheal administration of AM to the hamster. In whole lung mitochondria isolated from hamsters maintained on a control diet, complex I-supported state 4 (resting) respiration was inhibited to a similar extent (by 72-89%) by equimolar concentrations (100, 200 or 400 μM) of AM or *N*-desethylamiodarone (DEA). In mitochondria from vitamin E-supplemented hamsters (500 IU d,l-α-tocopherol acetate / kg chow for 6 weeks), 400 μM DEA inhibited state 4 respiration more than 400 μM AM did (95% vs. 72%) ($p<0.05$), whereas 100 or 200 μM AM and DEA produced inhibition of the same magnitude (by 63-91%). For complex II, all concentrations of both drugs (50-400 μM) inhibited state 4 respiration in mitochondria from both diet groups, but 100, 200 and 400 μM DEA (by 90-100%) had greater effects than equimolar concentrations of AM (by 60-78%) ($p<0.05$). In addition, inhibition by DEA at both complexes occurred more rapidly than did inhibition by AM. For both diet groups, mitochondrial membrane potential (measured by safranine dye fluorescence) was decreased to the same degree by equimolar concentrations of both drugs, but at 200 and 400 μM, the rate of decrease was greater (by 229-600%) for DEA than for AM ($p<0.05$). Lipid peroxidation in mitochondria from the control diet group, measured as thiobarbituric acid-reactive substance (TBARS) production, was not increased by either drug (50-400 μM) in incubations lasting up to one hour. While differential effects of AM and DEA with respect to respiration and membrane potential were observed, the minimal effect of dietary vitamin E supplementation in this study suggests that the protective mechanism(s) of vitamin E against AM-induced pulmonary toxicity is not exerted at the level of the mitochondrion. (Supported by Medical Research Council of Canada grant No. MT-13257.)

1497 AMIODARONE (AM) DISRUPTS MITOCHONDRIAL MEMBRANE POTENTIAL IN ISOLATED LUNG CELLS: POTENTIAL MECHANISM OF AN INDUCED PULMONARY TOXICITY.

M. W. Bolt, W. J. Racz, J. F. Brien, B. M. Bennett and T. E. Massey. *Departments of Pharmacology and Toxicology and Medicine, Queen's Univ., Kingston, Ontario, Canada.*

Amiodarone (AM), a commonly prescribed antidysrhythmic agent, causes potentially fatal pulmonary fibrosis. In the present study, we investigated perturbation of mitochondrial function as a possible initiating mechanism of AM induced cytotoxicity in hamster lung cells. Preparations enriched with alveolar macrophages (95=98%), alveolar type II cells (75-85%) and non-ciliated bronchiolar epithelial (Clara) cells (35-50%), were isolated from male golden Syrian hamsters by protease digestion followed by centrifugal elutriation and density gradient centrifugation. In intact cells, mitochondrial membrane potential was measured cytofluorometrically with the 5,5',6,6'-tetrachloro 1,1',3,3'-tetraethylbenzimidazolcarbocyanine iodide (JC-1)probe (argon laser excitation 488nm). Following incubation for 2 h, the ratio of mean red (high membrane potential) to mean green (low membrane potential) fluorescence (i.e. mean 575nm fluorescence intensity/mean 525nm fluorescence intensity SD) of vehicle treated (0.1% ethanol) alveolar macrophages (1.19 0.3) alveolar type II cells (1.00 0.4) and Clara cells (1.14 0.3) was significantly higher ($p<0.01$, n=5) than in the 100 M AM treated cells (0.69 0.2), (0.49 0.2), and (0.52 0.2) respectively. Following preloading with [3 H] adenosine for 1 h, and subsequent incubation with 100 & M AM or vehicle for 2 h, [3 H] ATP, [3 H] ADP and [3 H] AMP were separated by reverse phase HPLC and quantitated by scintillation counting. In contrast to the membrane potential results, no significant differences in the amounts of [3 H] ATP, [3 H] ADP or [3 H] AMP were observed between control and AM treated cells. Although we have previously demonstrated significant AM-induced cytotoxicity within these enriched fractions at 24h, cell viability (measured by 0.5% trypan blue exclusion) was not altered by 100 M AM at 2h. This demonstrates that AM disrupts mitochondrial membrane potential early during AM exposure, at a time when effects on ATP content and cell viability are not apparent. Hence, the initiating mechanism of AM-induced cytotoxicity may be perturbation of mitochondrial function. (Supported by MRC of Canada Grant# MT-13257.)

1498 ASSESSMENT OF ACUTE LUNG INJURY IN RATS EXPOSED TO DIPHENYLMETHANE-4,4'- DIISOCYANATE (MDI): ANALYSIS OF BREATHING PATTERNS AND LUNG LAVAGE.

J. Pauluhn. *Bayer AG, Wuppertal, Germany.*

The early acute pulmonary response of Wistar rats exposed nose-only to diphenyl-methane-4,4'-diisocyanate (MDI) aerosol was examined to investigate both the relationship between acute pulmonary irritation and ensuing disturbances of the air-blood barrier. The first was addressed by analysis of changes in breathing patterns, the second was addressed in rats exposed for 1 x 6-hr to 0.6 to 20 mg MDI/m³, including analysis of the time-response relationship of MDI-induced acute lung injury during a postexposure period of 1-week. Bronchoalveolar lavage fluid and cells were analyzed for markers indicative of injury and changes in surfactant homeostasis. The analysis of breathing patterns demonstrated that respirable MDI aerosol caused a concentration-dependent apneic pause with minor changes on respiratory rate which is suggestive of stimulation of J-receptors. Serial sacrifices of rats exposed for 6-hr to 0.6-20 mg MDI/m³ revealed that most endpoints were maximal on postexposure day 1 and changes returned to the level of the control group on day 7. The analysis did not reveal a time-dependent exacerbation of effects. The relative comparison of effects suggests that a dysfunction of the air-blood barrier was characterized the increase in BAL-ACE (ACE: angiotensin-converting enzyme) activity and marked increase of intracellular phospha-tidyl-choline. In summary, this study suggests that respirable MDI aerosol appears to stimulate extravasation of plasma proteins via stimulation of J-receptors rather than cytotoxicity. It is believed that the increase of intracellular phospholipids indicates the involvement of pulmonary surfactant.

Thus, it appears that changes in pulmonary surfactant function is important for the understanding of the pathomechanism of respirable MDI aerosol.

1499 FATE OF DIESEL SOOT-ADSORBED BENZO[A]PYRENE FOLLOWING DEPOSITION AND RETENTION IN THE LUNGS OF DOGS.

P. Gerde[1], B. A. Muggenburg[2], M. Lundborg[1] and A. R. Dahl[3]. [1]*Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden,* [2]*Lovelace Respiratory Research Institute, Albuquerque, NM and* [3]*Battelle Pulmonary Therapeutics, Columbus, OH.*

The rate and extent to which carcinogenic hydrocarbons on diesel soot particles are released in the lungs may contribute to the suspected activity of diesel emissions as lung carcinogens in humans. The alveolar absorption of tritiated benzo(a)pyrene (BaP) adsorbed on the carbonaceous core of diesel soot particles was measured in the Beagle dog. The concentration of BaP was 0.015 μg/μg soot, which corresponds to 25% of a monomolecular coating of BaP on the particle surface. The dogs were exposed to a bolus of resuspended diesel soot in a single deep breath, and the subsequent appearance of BaP in the systemic circulation was monitored by repeatedly sampling blood from the ascending aorta and the posterior vena cava. At 5.6 months after the exposure, diesel soot was recovered from peripheral lung tissue and the tracheobronchial lymph nodes through ultracentrifugation. The release rate of BaP from the soot was highest at the moment of deposition, but decreased rapidly with time. Soot recovered from lung and lymph nodes 5.6 months after the exposure had 16% and 10%, respectively, of a monomolecular layer of BaP-equivalent activity remaining. The bioavailability of BaP from soot particles was, thus, significantly higher in lymph nodes than in lung parenchyma. Of the radioactivity extracted into toluene from the recovered soot particles, ~30% was BaP parent compound, and the rest was metabolites/decay products of BaP. After toluene extraction, 7% of a BaP monolayer remained on the soot. A substantial fraction of soot-adsorbed BaP was extracted in the lung, but still was less than that extractable into organic solvents. (Research sponsored by the Health Effects Institute and the Swedish Council for Working Life Research, under Cooperative Agreement DE-FC04-96AL76406 with the US DOE.)

1500 GENETIC MODELING OF TOLERANCE TO ZINC OXIDE INHALATION IN INBRED MICE.

S. Wesselkamper, L. C. Chen and T. Gordon. *New York University, Tuxedo, NY.*

In a variety of occupational settings, workers are exposed to inhaled toxicants such as zinc oxide (ZnO) fumes generated from welding processes. Inhalation exposure to ZnO can induce a variety of rapidly onsetting adverse pulmonary effects including inflammatory cellular influx, and can also give rise to systemic effects such as "inhalation fever." As a result of frequent and repeated exposures to various inhaled toxicants, many workers develop tolerance (or tachyphylaxis) to the exposures and exhibit reduced symptoms. The implications of tolerance to health risks in humans are numerous. We hypothesize that inter-individual variability in the development of tolerance to inhaled toxicants is controlled by host genetic factors. Studies were conducted using inbred strains of mice to begin identifying genes controlling the development of tolerance. Ten inbred mouse strains were exposed to 1.0 mg/m^3 for 3 h a single time (1X) or on 5 successive days (5X). Pulmonary inflammation was assessed after 1X and 5X exposures by inflammatory cell counts and total protein content in bronchoalveolar (BAL) lavage. Results demonstrated marked inter-strain variation exists in the ability to develop tolerance to ZnO-induced pulmonary inflammation, as well as in the initial pulmonary response to inhaled ZnO. In general, only a tolerant and a non-tolerant phenotype was displayed among the inbred strains which suggests that a single gene may be responsible for a significant amount of variance in the tolerance phenotype. BALB/cBy and DBA/2 mice were identified as tolerant and non-tolerant strains, respectively. Inflammatory cell and protein concentrations in BAL fluid from F1 offspring of these two strains exposed to ZnO were like that of the tolerant BALB/cBy progenitor. This is indicative that the ZnO-induced pulmonary tolerance phenotype is an inheritable dominant trait. This genetic model provides a unique opportunity to investigate mechanisms and regulation of pulmonary tolerance. The observations from this research will allow for the identification of genes that control the development of tolerance through the use of linkage analysis and oligonucleotide microarray techniques in future studies.

1501 DNA SEQUENCE POLYMORPHISMS OF INTERLEUKIN-1 AND TUMOR NECROSIS FACTOR-α IN SILICOSIS.

B. Yucesoy, J. M. Matheson, V. Vallyathan, D. S. Sharp, A. Weston and M. I. Luster. *NIOSH, Morgantown, WV.*

Silicosis is an inflammatory /fibrotic lung disease and represents a major health problem worldwide. Many gene products which include inflammatory and fibrotic mediators are involved in the progression of this disease. Since IL-1 and TNF-α promote inflammation and fibrosis and play a central role in the pathogenesis of many chronic inflammatory diseases, it is now believed that the polymorphisms of these cytokines play an important role in silicosis. To investigate the relationship between severity of silicosis and the genetic variations associated with interleukin-1(IL-1) and tumor necrosis factor-α (TNF-α) production, we examined DNA collected from lung autopsy tissues from 150 miners diagnosed with silicosis as well as in 150 control miners with no disease. We analysed functional SNPs at the TNF- α (-308 and -238), IL-1β (+3953), IL-1α (+4845) and IL-1 receptor antagonist (RA) (+2016) loci by RT-PCR to determine each genotype. Our preliminary results suggest that IL-1RA (+2016) and TNF-α (-238) may have a role in the pathogenesis of silicosis. These findings provide new insight into the possible role of IL-1 and TNF-α polymorphisms in the severity of this disease.

1502 EFFECTS OF SULFUR DIOXIDE EXPOSURE ON NEUTROPHIL RESPIRATORY RESPONSE IN CATTLE.

L. Komarnisky[1], A. A. Khan[2], R. J. Christopherson[1] and R. W. Coppock[2]. [1]*Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada and* [2]*Toxicology Unit, Alberta Research Council, Vegreville, Alberta, Canada.*

Sulfur dioxide (SO_2) is one of the pollutants that is suspected in affecting the health and productivity of cattle raised on pastures located in close proximity to sour gas and petroleum processing operations in Alberta, Canada. The objective of this investigation was to assess the effects of SO_2 on cell-specific respiratory responses in peripheral neutrophils of cattle. For inhalation exposures to SO_2, two steers were sequentially exposed to atmospheres containing 0, 5, and 20 ppm of SO_2 for 6 hr/day for a period of 6-7 days per exposure in a controlled environmental system. Blood from each animal was collected before, during and after exposure to SO_2. The respiratory rates of neutrophils were measured in non-stimulated cells (basal rate) and in phorbol myristate acetate (PMA)-stimulated cells (respiratory burst or stimulated rate). A flow cytometric procedure involving the oxidation of dihydrorhodamine to rhodamine was used to measure the respiratory responses in neutrophils. Exposure to SO_2 did not cause any significant change in the basal rates; however, the respiratory burst response was lowered by 25-30% after exposure to 5 ppm, and by 60% after exposure to 20 ppm SO_2 concentrations. In experiments conducted *in vitro*, the direct treatment of isolated neutrophils with sulfite ($SO_3^=$), a primary hydrated form of SO_2 at physiological pH, caused inhibition of cellular respiration and superoxide anion production in PMA-stimulated neutrophils. The sensitivity of these cell-specific responses was dependent on $SO_3^=$ concentration and duration of treatment. The stimulus-dependent respiratory responses were severely inhibited (> 80%) after a 24 hr treatment of cells with fairly low concentrations of $SO_3^=$ (e.g., 1 mM). This research will ascertain the exposure sensitivity, its nature, and associated implications for cattle health.

1503 CHANGES IN GENE EXPRESSION IN NHBE CELLS EXPOSED TO TRANSITION METALS.

J. Stonehuerner[1], I. Jaspers[2], S. Nierkens[2] and R. Devlin[1]. [1]*National Health & Environmental Effects Research Laboroatory, USEPA, Research Triangle Park, NC and* [2]*Center for Environmental Medicine and Lung Biology, University of North Carolina, Chapel Hill, NC.* Sponsor: M. Madden.

Metals (Cu, Fe, Zn, As, V) present in particulate pollution have been shown to cause lung injury and inflammation in animals and in cultured human lung epithelial cells. Earlier work demonstrated that individual metals did not all activate the same signal transduction pathways or transcription factors, suggesting that metals may exert their effects by different mechanisms. In order to better understand differences in mode of action of individual metals, we have employed gene array technology to compare patterns of gene expression after exposer of human lung primary epithelial cells to Ni(II), Fe(II), V(IV), Zn(II), or As(III). Cells were exposed to these metals for 4 hours and mRNA levels of 588 genes were quantified using the Atlas Human cDNA Expression Array (Clontech). The expression of mRNAs coding for nearly 100 different genes was significantly altered by these metals; both increased and decreased

amounts of mRNA were observed. Preliminary analysis indicates that Fe and Zn followed similar gene expression patterns as did V and Ni while As-induced gene expression was most closely related to that of V and Ni. Specifically, V, Ni, and As upregulated genes such as cyclic-AMP-dependent transcription factor ATF-4, RANTES, and calgranulin A and B generally associated with increases in inflammation and down-regulated genes such as IL-13 associated with decreases in inflammation whereas Fe and Zn upregulated more genes associated with apoptosis such as UV excision repair protein RAD23 and c-myc transcription factor (puf) as well as certain glutathione transferases. In order to facilitate analysis of the large data set, we chose to focus on the changes in expression in inflammatory genes. Metal-induces changes in expression of the subset of inflammatory-associate genes were confirmed by RT-PCR analysis of mRNAs present after 4, 8, and 24 hour exposures. These data should provide new insights into transition metal toxicity as well as illustrating the utility of gene array technology in identifying patterns of gene expression. (This abstract of a proposed presentation does not necessarily reflect EPA policy.)

1504 EFFECT OF CRF RECEPTOR-1 INHIBITION ON LEYDIG CELL TESTOSTERONE PRODUCTION.

P. J. Ciaccio, S. I. Wert, B. Gemzik and B. D. Car. *Dupont Pharmaceuticals, Newark, DE.*

A role for the corticotrophin releasing factor (CRF) in androgen biosynthesis by testicular Leydig cells has been proposed. We evaluated the potential effects of a series of selective CRF receptor-1 (R1) antagonists (SK696, SP904, and SP397) on testosterone production in primary cultures of rat, dog and monkey Leydig cells. Cells were isolated by differential density gradient separation of enzymatically digested testicle. Enrichment for Leydig cells was confirmed by 3-b hydroxysteroid dehydrogenase staining and cytology. Cells were cultured for 1 to 3 hours in the presence or absence of 2 IU/mL (rat, monkey) or 5 IU/mL (dog) of human chorionic gonadotrophin (hCG) after which time testosterone was assayed in supernatant by radioimmunoassay. Ketoconazole, used as a positive control, produced an expected dose-dependent decrease in basal and hCG-stimulated testosterone production in all species. CRF itself did not alter baseline testosterone production and R1 antagonists did not modify basal or hCG-stimulated testosterone production in any species. A role for CRF R1 in Leydig cell testosterone biosynthesis was not demonstrated. Therefore, pharmacologic inhibition of CRF R1 is not expected to alter Leydig cell function in humans.

1505 INTERACTION OF METHOXYCHLOR AND RELATED COMPOUNDS WITH ESTROGEN RECEPTOR ALPHA AND BETA, AND ANDROGEN RECEPTOR: STRUCTURE-ACTIVITY STUDIES.

K. W. Gaido[1], S. C. Maness[1], D. P. McDonnell[2], D. Kupfer[3], S, Dehal[3] and S. Safe[4]. [1]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC,* [2]*Duke University Medical Center, Durham, NC,* [3]*University of Massachussets Medical Center, Worcester, MA and* [4]*Texas A & M University, College Station, TX.*

We have previously demonstrated the differential activity of the methoxychlor metabolite 2,2-bis(p-hydroxyphenyl)-1,1,1-trichloroethane (HPTE) with estrogen receptor alpha (ERα), beta (ERβ), and androgen receptor (AR). In this study we characterize the ERα, ERβ, and AR activity of structurally related Methoxychlor metabolites. Human hepatoma cells (HepG2) transfected with human ERα, ERβ, or AR expression plasmids plus and a steroid-responsive reporter gene, were dosed with various concentrations of HPTE or structurally related compounds in the presence (for detecting antagonism) or absence (for detecting agonism) of 17β-estradiol or dihydrotestosterone. The monohydroxy analog of methoxychlor as well as mono- and dihydroxy analogs of 2,2-bis(p-hydroxyphenyl)-1,1-dichloroethylene had ERα agonist activity and ERβ and AR antagonist activities similar to that observed for HPTE. The trihydroxy analog of methoxychlor displayed only weak ERα agonist activity and did not alter ERβ or AR activity. Replacement of the trichloro- or dichloroethane with a methyl group resulted in a compound with agonist ERα and ERβ activity while retaining AR antagonist activity. This study identifies some of the structural requirements for differential ERα, ERβ, and AR activity and demonstrates the complexity involved in determining the mechanism of action of endocrine active chemicals that may act as agonists or antagonists through one or more hormone receptors. (ES09106 and ES04917)

1506 ANDROGEN RECEPTOR AGONIST DIHYDROTESTOSTERONE REDUCES ESTROGENIC RESPONSES IN RAINBOW TROUT.

D. E. Williams and A. E. Shilling. *Oregon State University, Corvallis, OR.*

We investigated the capacity of dihydrotestosterone (DHT), a potent, non-aromatizable androgen, to act as an endocrine disruptor in rainbow trout, *Oncorhynchus mykiss*, by altering vitellogenin (Vg), 17β-estradiol (E_2) and total cytochrome P450 levels. DHT (0, 50 or 100 mg/kg/day) and flutamide (0 - 1250 mg/kg/day), an androgen receptor antagonist, were fed to juvenile rainbow trout for 2 weeks. No toxicity was observed between groups as observed grossly and measured by body weight and liver somatic index. Vg and E_2 levels were suppressed by over 80% and 50%, respectively, in trout fed DHT. In trout fed DHT and flutamide, Vg levels were similar to groups fed DHT alone, suggesting that the DHT effects on Vg were not mediated through direct androgen receptor binding. Flutamide alone, however, was as effective as DHT in decreasing E_2 in both sexes, but decreased Vg significantly in males only. This observed difference in Vg production in response to E_2 decreases may represent sex differences in crosstalk between the androgen and estrogen receptor pathways regarding Vg production. Cytochrome P450 repression was quantified to explore possible indirect effects of DHT. DHT reduced total P450 content to less than 20% of controls in both sexes. Co-treatment with flutamide somewhat inhibited these decreases in males, suggesting that DHT induced P450 decreases may be partially mediated through androgen receptor binding. In females fed DHT, flutamide did not increase P450 levels suggesting a sex difference in the sensitivities to androgen receptor mediated effects by DHT. The antiestrogenic and P450 effects of DHT may or may not be related. These studies indicate that androgen receptor agonists/ antagonists can elicit significant antiestrogenic effects that may not necessarily be mediated through receptor binding. (Supported by ES03850 and ES07060.)

1507 THE CONSTITUTIVE ANDROSTANE RECEPTOR BETA MEDIATES THE TRANSCRIPTIONAL REGULATION OF CYP2B GENES BY PHENOBARBITONE.

J. E. Sidaway, L. Scotney, J. M. Loughlin, T. C. Orton and J. D. Tugwood. *AstraZeneca Pharmaceuticals, Macclesfield, United Kingdom.*

The rodent hepatocarcinogen phenobarbitone (PB) induces expression of the mouse cyp2b10 gene and rat CYP2B1/2 genes at the transcriptional level. Within the promoter of each gene, an essentially identical regulatory element has been defined which mediates PB transcriptional induction, termed the PB-Responsive Enhancer Module (PBREM) [Honkakoski, P. & Negishi, M. (1997) J. Biol. Chem. 272, 14943-14949]. The constitutive androstane receptor-beta (CAR-beta) nuclear receptor exhibits intrinsically high transcriptional activity which is abolished by the mammalian pheromone 5-alpha-androst-16-en-ol (androstenol) [Forman, B.M., Tzameli I., Choi H.S., Chen J., Simha D., Seol W., Evans R.M. and Moore D.D. (1998) Nature 395, 612-5], and binds to a direct repeat (DR4) element within the cyp2b10 PBREM [Honkakoski, P., Zelko I., Sueyoshi T. and Negishi M. (1998) Mol. Cell. Biol. 18, 5652-8]. In HepG2 cells, PB activates CAR-beta at a substantially high concentration than that observed for induction of the cyp2b10 in mouse hepatocytes [Sueyoshi, T., Kawamoto, T., Zelko, I., Honkakoski, P., and Negishi, M. (1999). J. Biol. Chem. 274, 6043-6]. We have constructed a luciferase reporter gene containing the cyp2b10 PBREM DR4 element and carried out co-transfection assays in CV-1 cells with mouse CAR-beta. CAR-beta caused a 4-fold induction of reporter gene activity, which was ablated by administration of 10microM androstenol for 20 hours Addition of 500microM PB for the same period did not alter reporter gene activity in the presence of androstenol. However, 300nM of the potent PB-like inducer 1,4-bis[2-(3,5-dichloropyridyloxy)]benzene (TCPOBOP) restored reporter gene activity to control levels when incubated with 10microM androstenol. In contrast, when CAR-beta was co-transfected in rat hepatocytes with the same reporter gene, both 300microM PB and 300nM TCPOBOP induced reporter gene activity (3 and 5 fold respectively) and this was suppressed by 50microM androstenol. Our results imply that CAR-beta mediates the transcriptional effects of PB, although clearly the cellular context is important for this event.

1508 TRANSCRIPTIONAL ACTIVATION OF DNA POLYMERASE α BY ESTROGEN IN MCF-7 CELLS REQUIRES INTERACTION OF ESTROGEN RECEPTOR α/Sp1 WITH A GC-RICH ELEMENT.

I. Samudio, C. Vyhlidal and S. Safe. *Texas A&M University, Department of Veterinary Physiology & Pharmacology, College Station, TX.*

17β-Estradiol (E2) is mitogenic in human breast cancer cells and stimulates DNA synthesis, cell cycle progression, and genes associated with cell proliferation. Treatment of MCF-7 breast cancer cells with 10nM E2 results in increased DNA polymerase α mRNA levels, and in MCF-7 cells cotransfected with estrogen receptor α (ERα) plus a construct containing the -1515 to +45 region of the DNA polymerase α gene promoter linked to a luciferase reporter gene (pDNAP1), E2 induced a 2.8-fold increase of luciferase activity. Deletion analysis of the DNA polymerase α gene promoter identified a region from -116 to -65 required for ERα-mediated transactivation, and this sequence contained a GC-rich site and a c-AMP response element. Subsequent mutational analysis of this region of the promoter showed that only the GC-rich site was required for transcriptional activation by E2. Gel electromobility shift assays and antibody supershifts showed that nuclear extracts from MCF-7 cells bound this region of the promoter and formed retarded bands with both Sp1 and Sp3 proteins. ERα did not directly bind to the promoter but enhanced Sp1-DNA complex formation. *In vitro* footprinting experiment demonstrated that recombinant human Sp1, but not ERα, protein bound the GC-rich sequence (-106 to -100); however, coincubation with both Sp1 plus ERα proteins demonstrated that ERα significantly enhanced the Sp1 footprint. These results demonstrate that transcriptional activation of DNA polymerase α by E2 requires ERα/Sp1 interactions with a proximal GC-rich element in the gene promoter. (CA76636 and ES09106)

1509 ENHANCED DNA-INDEPENDENT TRANSCRIPTIONAL ACTIVITY OF ZINC FINGER DOMAIN - DELETED MOUSE ESTROGEN RECEPTOR THROUGH THE ESTROGEN RECEPTOR/SP1 PROTEIN INTERACTION.

K. H. Kim and S. Safe. *Texas A&M University, Department of Veterinary Physiology & Pharmacology, College Station, TX.*

Several estrogen-inducible genes are transactivated through estrogen receptor α (ER_α)-Sp1 protein interactions that do not require direct binding of ER_α to estrogen response elements (EREs). To further characterize these interactions, we generated a mouse estrogen receptor (MOR) mutant using PCR-based mutagenesis. Twenty-one amino acids from one of the zinc finger domains of wild-type MOR (aa 189 to 209) were deleted. The mutant (MORΔZF1) did not bind [^{32}P]-ERE in a gel mobility shift assay, whereas both wild-type ER_α and ER_β bound as homo or heterodimers to give specifically-bound retarded bands. In MDA-MB-231 cells transiently transfected with a construct containing a triple ERE promoter insert ($pERE_3$) and wild-type MOR expression plasmid, treatment with 10 nM E2 resulted in 3.1-fold induction of reporter gene (luciferase) activity. In contrast, replacement of MOR with MORΔZF1 expression plasmid resulted in loss of E2-induced activity, and this is consistent with the failure of the mutant to bind DNA. In MCF-7 and MDA-MB-231 cells cotransfected with a construct containing a consensus triple GC-rich Sp1 binding motif ($pSp1_3$) and MOR expression plasmid, treatment with E2 resulted in a 2- and 2.3-fold induction of luciferase activity, respectively. However, replacement of MOR with MORΔZF1 expression plasmid resulted in a significantly increased 77- and 10.6-fold induction of reporter gene activity in these cell lines respectively, suggesting that unknown inhibitory protein(s) may be interacting with aa 189 to 209 of the DNA binding domain of wild-type MOR. Current studies are investigating transactivation potential of this mutant compared to MOR mutants of the second zinc finger motif and human analogs and their functional differences in ER/Sp1-mediated transactivation in various cell lines.

1510 IDENTIFICATION OF PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR ALPHA-DEPENDENT GENES RESPONSIVE TO A HEPATOCARCINOGENIC PEROXISOME PROLIFERATOR CHEMICAL.

W. S. Lee and S. S. T. Lee. *The Chinese University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region of China.* Sponsor: K. Chan.

Peroxisome proliferators (PPs) are a diverse group of rodent non-genotoxic carcinogens that include hypolipidemic drugs and industrial chemicals. Short-term treatment of rats and mice with PP results in an increase in liver peroxisome number, hepatomegaly and target genes transcription. Chronic treatment of rodents with PP results in hepatocarcinogenesis. It is important to determine the risks to humans of environmental and therapeutic exposure to these compounds by understanding the mechanisms of non-genotoxic heptocellular carcinoma formation in rodent. Earlier studies suggested that a member of steroid hormone receptor called peroxisome proliferator-activated receptor (PPAR) mediates the action of PP (e.g. Wy-14,643). There are three subtypes of PPAR within vertebrates termed alpha, beta and gamma and PPAR alpha appears to be the one that is most strongly activated by PP. Gene-knockout mice lacking PPAR alpha definitely confirmed that PPAR alpha mediates PP-induced peroxisome proliferation, hepatomegaly and hpatocarcinogenesis. However, the underlying mechanisms by which PPAR alpha mediates these pleiotropic responses are still not clear. It is suggested that activation of PPAR alpha by PPs will lead to altered transcription of some gene(s) involved in hepatocyte growth regulation. Identification of such PP responsive genes that are PPAR alpha dependent might gain an insight into the molecular mechanisms involved in the PPAR alpha-dependent pathway in PP-induced pleiotropic effects. The aim of the present study is to search genes that are differentially expressed in wild-type but not in PPAR alpha knockout mice after treatment with Wy-14,643 for two weeks by using fluorescent differential display RT-PCR technique. Up to now, twenty differentially expressed cDNAs were obtained and two of them were identified as Cyp4a10 and Cyp4a14. Further characterization of other cDNAs is underway.

1511 SPECIES DIFFERENCES IN RESPONSE TO PEROXISOME PROLIFERATORS: INCREASING HUMAN PEROXISOME PROLIFERATOR-ACTIVATED-RECEPTORα (PPARα) EXPRESSION LEVELS IN HUMAN CELLS IS NOT SUFFICIENT FOR FATTY ACYL-COA OXIDASE RESPONSIVENESS.

J. W. Lawrence, G. Zhou, Y. Li, S. Chen, D. Umbernhauer, D. Moller and J. G. DeLuca. *Merck & Co., Inc., West Point, PA.* Sponsor: R. Dixit.

We compared the ability of rat and human hepatocytes to respond to fenofibric acid and a novel phenylacetic acid PPARα agonist (compound 1). Fatty acyl-CoA oxidase (FACO) activity and mRNA were increased after treatment with either fenofibrate or compound 1 in rat hepatocytes. In addition, apoCIII mRNA was decreased by both fenofibric acid and compound 1 in rat hepatocytes. Both agonists decreased apoCIII mRNA in human hepatocytes; however, very little change in FACO activity or mRNA was observed. Moreover, other genes that are regulated in human hepatocytes, such as mitochondrial HMG-CoA synthase and carnitine palmitoyl transferase-1 (CPT-1), were also regulated in HepG2 cells in culture by PPARα agonists. Several stabily transfected HepG2 cell lines were established that overexpressed human PPARα (between 2 and 26-fold over normal human hepatocytes). These PPARα overexpressing cells had higher basal mRNA levels of mitochondrial HMG-CoA synthase and CPT-1; however, basal FACO mRNA levels were not affected. In addition, FACO mRNA levels were not increased by PPARα agonist treatment in the PPARα overexpressing cells, although mitochondrial HMG-CoA synthase and CPT-1 were both induced. These results suggest that other factors besides PPARα levels determine the species specific response of human and rat hepatocytes to the induction of peroxisome proliferation.

1512 EVIDENCE FOR DIVERGENT SIGNALING PATHWAYS IN REGULATION OF RECEPTOR MEDIATED EFFECTS OF PEROXISOME PROLIFERATORS.

B. D. Thrall, B. J. Mounho, R. J. Bull and M. K. Lingohr. *Battelle, Pacific Northwest National Laboratory, Richland, WA.*

Peroxisome proliferators are a diverse group of environmentally, pharmacologically and economically important chemicals associated with widespread human exposure. In rodents, chronic exposure to these agents causes hepatocellular proliferation and hepatic tumors. It is established that many of the hepatic effects of peroxisome proliferators are mediated through the nuclear receptor, PPARα. Using primary mouse hepatocytes, we previously found that peroxisome proliferators also cause a rapid phosphorylation and activation of the extracellular signal-regulated kinase (ERK). Activation of ERK by Wy-14,643 is associated with an increase in replicative DNA synthesis, which could be blocked by inhibitors of both ERK kinase (PD098059) and phosphatidylinositol 3-kinase (LY294002). To further investigate the role of these pathways in mediating response to peroxisome proliferators,we are currently determining whether the ERK and PI3K pathways directly modulate or regulate PPARα transcriptional activity. In transfection experiments with luciferase reporter vectors to measure PPARalpa activation, the transactivation activity of PPARα was inhibited by low concentrations of LY294002, but

unaffected by concentrations of PD098059 which block ERK activation. In addition, although epidermal growth factor strongly activated ERK in a PI3K-independent manner, it did not specifically modulate PPARα transactivation. Therefore, we hypothesize that PI3K is an upstream effector of ERK activation by peroxisome proliferators and participates in the mitogenic response to these chemicals. In contrast, our results suggest PI3K and ERK play separate roles in modulating PPARα transactivation. (Supported in part by US DOE contract DE ACO6 76RLO 1830.)

1513 INHIBITION OF PEROXISOME PROLIFERATOR ACTIVATED RECEPTOR ALPHA BY MK886.

J. P. Kehrer[1], S. Biswal[1], P. Thuillier[2], J. P. Vanden Heuvel[3] and S. Fischer[2]. [1]*The University of Texas at Austin, Austin, TX,* [2]*M.D. Anderson Cancer Center, Smithville, TX and* [3]*Penn State University, University Park, PA.*

MK886 was originally identified as a potent inhibitor of leukotriene biosynthesis. Its mechanism is related to its ability to inhibit 5-lipoxygenase activating protein (FLAP), and this has also been presumed to underlie the apoptosis inducing activity of MK886. It is now evident that MK886-induced apoptosis is unrelated to lipoxygenase (*Biochem. J.* **340**: 371 [1999]). FLAP is a fatty acid binding protein, and MK886 may bind to other such proteins. Peroxisome proliferator activated receptors (PPARs) have been labeled as 'fatty acid receptors' because they are activated by endogenous fatty acids as well as exogenous peroxisome proliferators. The ability of MK886 to inhibit PPAR activity was assessed using both transient and stable transfection reporter assays in CV-1, keratinocyte 308, and CHO cells. In all systems examined, 1-10 μM MK886 inhibited PPARα ~80%. Higher doses appeared to be less effective, perhaps due to a partial agonist effect. Effects on PPARδ were substantial (~50%) using the stable transfection assay in CV-1 cells, but were not evident using the transient transfection reporter assay or in keratinocytes, perhaps because of low basal activity. Inhibition of PPARγ was substantially lower than the other receptor subtypes. Although there are numerous PPAR activators, only one xenobiotic was recently shown to antagonize PPARγ, and MK886 is the first xenobiotic shown to inhibit PPARα and PPARδ. (Supported by HL51005 and Center Grant ES07784.)

1514 THE MAPK SIGNAL TRANSDUCTION PATHWAY REGULATES PPARα THROUGH DIRECT PHOSPHORYLATION OF THE RECEPTOR.

C. A. Nugent[1], J. W. Davis[2], J. P. Vanden Heuvel[1], E. T. McCune[1] and A. J. Mundis[1]. [1]*Penn State University, University Park, PA and* [2]*University of New Mexico, Albuquerque, NM.*

Peroxisome proliferators (PPs) induce the expression of target genes by activating a member of the steroid receptor superfamily, Peroxisome Proliferator-Activated Receptor alpha (PPARα). To further elucidate the PP signaling pathway, the ability of the mitogen-activated protein kinase (MAPK) pathway to regulate PPARα activation was examined. The specific MAPK/Erk kinase (MEK) inhibitor, PD098059 inhibited the transcriptional activity of ectopically expressed PPARα. The effect of PD098059 on PPARα was further demonstrated to be due to MEK inhibition since co-transfection of a dominant negative MEK gave similar results. Further, when a rat hepatoma cells were pretreated with PD098059, the Wy-14,643-mediated induction of the PP-responsive gene fatty acyl-CoA oxidase (ACO) was completely abolished. PD098059 pretreatment inhibited MAPK phosphorylation in these cells without affecting the expression of PPARα. In addition, MAPK was able to phosphorylate PPARα *in vitro*. Taken together, these results suggest that growth factor signal transduction pathways positively regulate PPARα, and this effect is through direct phosphorylation of the receptor by MAPK. (Supported by NIH ES07799 and DK49009.)

1515 ARSENITE ALTERS SIGNAL TRANSDUCTION BY INDUCING THE PRB-E2F PATHWAY AND NOT *VIA* EFFECTS ON P53.

B. L. Vogt and T. G. Rossman. *NYU Medical Center, Tuxedo, NY.*

Human exposure to inorganic arsenic in drinking water is associated with cancers at a number of sites. Yet little is known of the molecular biological changes of such long-term low dose exposure. While not a mutagen itself at low concentrations, arsenite (AsO_2-) enhances the mutagenicity of other genotoxicants. Previous studies have shown that nontoxic levels of arsenite interfere with DNA repair mechanisms although not through direct inhibition of DNA repair enzymes. We investigated whether chronic, low-dose arsenite interferes with DNA damage responses involving the p53 checkpoint. WI38 normal human diploid fibroblasts were grown under standard conditions in media containing 0.1 μM sodium arsenite for at least 5 days. DNA damage was induced by X-rays (XIR, 6 Gy) and after 4 hr, p53 protein was measured in whole cell lysates by immunoprecipitation and Western Blotting. XIR induced p53 protein and its downstream targets p21 and gadd 45. However, arsenite did not prevent WI38 fibroblasts from mounting these responses. Short-term (18 hr) effects of higher concentrations of arsenite were also examined. P53 protein elevation occurred only at a toxic dose of arsenite (50 μM). The response to 6 Gy XIR was not inhibited at any dose. However, proteins in the pRb-E2F pathway did exhibit quantitative changes after long-term (30 days, 0.1μM) and short-term (18 hr, 0.5 μM) exposure to arsenite. Immunohistochemical staining of whole cells revealed increased amounts of E2F1 and cyclin D1, proteins controlling progression of the cell cycle into S phase. These results indicate that environmentally relevant levels of arsenite may alter signal transduction in the G_1 to S phase of the cell cycle, encouraging cell cycling at the expense of DNA repair and providing an explanation for arsenite's observed effects on comutagenesis and gene amplification.

1516 INHIBITION OF GAP JUNCTION COMMUNICATION, ACTIVATION OF MAPK, AND THE RELEASE OF ARACHIDONIC ACID BY SPECIFIC ISOMERS OF METHYLATED ANTHRACENES.

B. L. Upham[1], K. Sai[2], P. K. Tithof[3], G. Chen[1], M. R. Wilson[1] and J. E. Trosko[1]. [1]*Michigan State University, East Lansing, MI,* [2]*National Institute of Health Sciences, Tokyo, Japan and* [3]*University of Tennessee, Knoxville, TN.*

The mitogenic activity of tumor promoters requires the removal of an initiated cell from growth suppression by inhibiting gap junctional intercellular communication (GJIC) and the activation of intracellular mitogenic pathways. We tested the structure activity relationship of two isomers of 1- and 2-methylanthracene (1-MeA and 2-MeA) on the temporal activation of mitogen activated protein kinase (MAPK), the release of arachidonic acid (AA) from the plasma membrane, and the inhibition of GJIC in F344 rat liver epithelial cells. Noncytotoxic doses of 1-MeA, which contains a bay-like region, reversibly inhibited GJIC, induced the release of AA, and strongly activated ERK 1 & 2 and P38 but only weakly activated SAPK/JNK. In contrast, the linear-planar isomer 2-MeA had no effect on GJIC, AA release, and MAPK activation. MAPK was activated 10-20 min after the down-regulation of GJIC and release of AA, which indicates that MAPK is not involved in the initial regulation of GJIC and that AA may play an upstream role in activating all MAPKs. Our results are consistent with the hypothesis that mitogenesis requires the removal of growth suppression by inhibition of GJIC and then the activation of mitogenic pathways. (This research was supported by the NIEHS Superfund grant #P42 ES04911-07.)

1517 MAP KINASE ACTIVATION IN HUMAN AIRWAY EPITHELIAL CELLS EXPOSED TO AMBIENT AIR PARTICULATE MATTER.

W. Wu[1], J. M. Samet[2], A. J. Ghio[2] and R. B. Devlin[2]. [1]*Center for Environmental Medicine and Lung Biology, University of North Carolina, Chapel Hill, NC and* [2]*Human Studies Division, National Health Effects and Environmental Research Laboratory, Chapel Hill, NC.* Sponsor: M. C. Madden.

Exposure to ambient particulate matter (PM) in the Utah Valley (UV) has previously been associated with a variety of adverse health effects. In the present study we investigated intracellular signaling mechanisms that may contribute to pulmonary responses to PM inhalation in human airway epithelial cells exposed to PM collected from the UV. Aqueous extract of PM sampled in the year before (Y1), during (Y2), and after (Y3) the closure of a local steel mill located in the UV were used to expose primary human airway epithelial cell cultures (HAEC). UV PM induced IL-8 expression in a dose- and time-dependent manner in HAEC with a potency rank of Y1>Y3>Y2. Transfection with dominant negative constructs of ERK1 or ERK2 effectively blocked UV PM-induced IL-8 promoter reporter activity in HAEC. In contrast, overexpression of dominant negative P38 or JNKK1 had no effect. Similarly, the P38 inhibitor SB203580 failed to block UV PM-induced IL-8 release. The ERK MAP kinase kinase (MEK1/2) inhibitor PD98059 significantly diminished IL-8 released in response to UV PM, as did the EGF receptor kinase inhibitor tyrphostin AG 1478. Western blotting analyses showed UV PM-induced phosphorylation of EGF receptor tyrosine, MEK1/2 and ERK1/2, which could be ablated with AG1478 or PD98059 in HAEC. For all findings the potency of UV PM collected during Y2 was found to be lower relative to that of Y1 and

Y3. These data demonstrate that UV PM can induce IL-8 expression through the ERK signaling pathway by activating ERK upstream kinases, including the EGF receptor kinase. Moreover, these results show that UV PM collected during the closure of the steel mill is less active in inducing IL-8 expression through ERK signaling activation in HAEC. This study suggests that activation of the ERK MAP kinase pathway is a mechanism that can mediate pulmonary responses to ambient PM inhalation. (This abstract of a proposed presentation does not necessarily reflect EPA policy.)

1518 SARIN AND STRESS MODULATION OF NICOTINIC AND MUSCARINIC ACETYLCHOLINE RECEPTORS IN SARIN EXPOSED RATS.

K. H. Jones, A. M. Dechkovskaia, W. A. Khan and M. B. Abou-Donia. *Duke University Medical Center, Department of Pharmacology, Durham, NC.*

Stress is known to affect central nervous system (CNS) functions. The role of stress in CNS toxicity of organophosphate esters such as sarin (isopropyl methyl phosphonofluoridate) remains to be established. In the present study, we evaluated the role of stress in the manifestation of low dose sarin toxicity in the CNS of rats. Male Sprague-Dawley rats were exposed to stress 5 min./day, by placing the rats individually into a Plexiglas® restraint tube (60 days) followed by a single subclinical dose (0.1 X LD_{50}) of sarin (10ug/kg, i.m.). Twenty-four hours after the sarin treatment, nicotinic acetylcholine receptor (nAChR) and muscarinic receptor was determined in different brain regions using receptor-specific ligands. Sarin exposure caused a significant decrease in nAChR binding in cortex, brainstem and midbrain, while there was no change in the cerebellum. Stress exposure in animals caused further decrease in acetylcholine receptor nAChR binding. In contrast, sarin exposure caused upregulation in m2 muscarinic receptor binding in midbrain, cortex and brainstem, while there was no change in cerebellum. Stress exposure did not exhibit any modulating response on m2 muscarinic receptor binding. Sarin exposure did not cause any change in brain choline acetyl transferase and acetylcholinesterase activity whereas plasma acetylcholinesterase and butrylcholinesterase activities were slightly inhibited. No effect of stress, however, was observed in plasma cholinesterase activities. These data suggest that sarin at low subclinical doses may cause CNS-related abnormalities through differential regulation of nicotinic and muscarinic ACh receptors, with stress playing a critical role in manifestations of CNS toxicity by sarin. (Supported in part by a DOD grant DAMD 17-98-C-8027.)

1519 A NOVEL MECHANISM FOR ELECTRICAL SIGNALING BY INTERLEUKIN-1.

M. T. Romano[1], A. S. Stern[2] and E. J. Flynn[1]. [1]*UMD-Graduate School of Biomedical Sciences, Newark, NJ and* [2]*Hoffmann-LaRoche, Nutley, NJ.*
Sponsor: L. G. Sultatos.

Interleukin-1 (IL-1) is a proinflammatory cytokine implicated in a wide variety of diseases, but little is known about its central actions. It has been associated with Alzheimer's, Down's, and AIDS-related dementia. In the hippocampus, IL-1 has been reported to affect changes in synaptic plasticity by enhancing synaptic inhibition and mitigating long-term potentiation. In the present study, it was postulated that IL-1 receptor (IL-1R) might behave as or be homologous with an ion channel(s)in the brain. GCG programming was employed to search Genebank using IL-1R as a template. This search revealed that IL-1R has a high degree of homology and identity with a specific voltage-gated, chloride channel (CLC-3), localized in the brain. A chloride-flux assay was employed using CHO cells stably transfected with IL-1R and IL-1R accessory protein, whose presence is required for biological activity. These assays were performed in microtiter plates using radiolabeled chloride. Termination was effected by vacuum suctioning assay buffer and quantitation of chloride uptake was performed by scintillation counting. A time course of specific uptake, relative to naïve cells, demonstrated a two-fold increase in chloride uptake in the presence of 0.1uM IL-1.This uptake was significantly blocked (~75%) with a 10-fold excess of IL-1R antagonist. In conclusion, functional genomic searching of Genebank has revealed an association between IL-1R and CLC-3.Ion flux assays demonstrated that IL-1R might have channel activity itself. The inhibitory influence of such channel activity by IL-1R, or the possible interaction of the IL-1 ligand with CLC-3 in the brain, would constitute a mechanism by which IL-1 could affect dementia.

1520 STIMULUS-RESPONSE RELATIONSHIPS DEMONSTRATE THE CONTRIBUTIONS OF AFFINITY AND INTRINSIC EFFICACY TO ARYL HYDROCARBON RECEPTOR LIGAND POTENCY.

E. V. Hestermann, J. J. Stegeman and M. E. Hahn. *Woods Hole Oceanographic Institution, Woods Hole, MA.*

Models of receptor action describe properties of the ligand-receptor interaction and are necessary for risk assessment of receptor-mediated toxic effects. In order to build such a model for the aryl hydrocarbon receptor (AHR), binding affinities and CYP1A induction potencies were measured in PLHC-1 cells for ten AHR ligands: TCDD, TCDF, and PCB congeners 77, 81, 105, 118, 126, 128, 156 and 169. From these data, an operational model of AHR action was used to: 1) determine intrinsic efficacies of these ligands, 2) predict their properties in mixtures, and 3) determine the relationship between receptor occupancy and response. TCDD, TCDF, and non-ortho-substituted PCBs 77, 81, 126 and 169 behaved as full agonists and displayed high intrinsic efficacy. In contrast, the ortho-substituted PCBs bound to the AHR but displayed decreased or no intrinsic efficacy. PCB 156 was a full agonist, but with lower intrinsic efficacy. PCB 118 was a very weak partial agonist. PCBs 105 and 128 were competitive antagonists. When the properties of PCBs 126, 128 and 156 were measured in mixtures with TCDD, PCBs 156 and 128 inhibited the response to TCDD. Thus, the relative insensitivity of fish to ortho-substituted PCBs is a result of both lower receptor affinity and decreased intrinsic efficacy. The stimulus-response model predicts that only 1-2% of the receptors in the cell are occupied for 50% CYP1A induction by one of the high intrinsic efficacy agonists, demonstrating the existence of "spare" receptors in this system. Separation of AHR ligand action into the properties of affinity and intrinsic efficacy allows for comparison across species and toxic endpoints. (This work was supported by the EPA (R823889), NIH (ES06272), and WHOI Sea Grant.)

1521 DIFFERENTIAL EXPRESSION OF ARYL HYDROCARBON RECEPTOR ISOFORMS IN A FISH MODEL OF DIOXIN RESISTANCE.

R. Bright[1], W. H. Powell[2] and M. E. Hahn[2]. [1]*Haverford College, Haverford, PA and* [2]*Woods Hole Oceanographic Institution, Woods Hole, MA.*

Fundulus heteroclitus, an estuarine teleost, is a well-characterized fish model of aryl hydrocarbon toxicity noted for the expression of two distinct genes for the aryl hydrocarbon receptor (AHR), AHR1 and AHR2. The *F. heteroclitus* population in New Bedford Harbor, MA (NBH), a Superfund site, exhibits heritable resistance to the toxic effects of halogenated aromatic hydrocarbons, including 2,3,7,8 tetrachlorodibenzo-p-dioxin (TCDD). To investigate the role of AHR signaling in TCDD resistance, we used quantitative RT-PCR to measure relative levels of mRNA for AHR1 and AHR2 in whole embryos at different developmental stages, comparing expression of these genes in NBH fish with fish from a reference site (Scorton Creek, MA; SC). We also compared the tissue distribution of these mRNAs in adult fish from both populations. AHR1 and AHR2 transcripts were present in eggs, decreasing over the forty-eight hours after fertilization, but subsequently increasing to steady state levels by the hatch (day 10). Embryonic expression of AHR1 mRNA was delayed relative to AHR2. At all stages examined, embryos of TCDD-resistant fish exhibited no measurable differences in expression of either AHR isoform compared to SC fish. In adult fish from the reference site, AHR2 mRNA was detected in all organs examined, while AHR1 transcripts exhibited a restricted distribution, found primarily in the heart, brain, gonad, and spleen. In contrast, AHR1 mRNA was widely expressed in NBH fish, appearing with unusual abundance in gill, gut, kidney, and liver. This striking discrepancy suggests that AHR1 expression may play a role in the TCDD-resistant phenotype of the NBH *Fundulus* population. Ongoing studies are examining the heritability and functional importance of ubiquitous AHR1 expression in this fish model of TCDD resistance. (Support: NIH ES07381 (MEH) and ES05800 (WHP), WHOI Sea Grant, the Donaldson Charitable Trust, and the WHOI Postdoctoral Scholar Program.)

1522 ANALYSIS OF THE NUCLEAR EXPORT SIGNAL OF THE MURINE ARYL HYDROCARBON RECEPTOR.

E. R. Barbour and R. S. Pollenz. *Medical University of South Carolina, Charleston, SC.*

The aryl hydrocarbon receptor (AHR) is a ligand activated basic helix-loop-helix protein that forms a heterodimer with the ARNT protein to mediate the effects of aromatic hydrocarbons. Previous studies from this lab (*J. Biol.*

Chem. 274:28708) have shown that the AHR protein is degraded in the cytoplasm and that the process is inhibited when nuclear export is blocked by treatment of cells with leptomycin B (LMB). Thus, it is likely that nuclear export and degradation are important steps in regulation of gene expression and necessary for termination of the ligand induced signal. The current study was designed to examine the effects of blocking degradation of AHR by mutating the Nuclear Export Signal (NES). The study of AHR mutated for nuclear export will permit analysis of AHR-mediated gene induction without concern for effects that may be caused by blocking global nuclear export with LMB. A first step in this process is the generation and functional analysis of AHR NES mutants. The NES for AHR protein spans residues 64-72 (LDKLSVLRL) in the helix 2 region that is also involved in protein dimerization with ARNT. In vitro mutagenesis was used to generate expression constructs with single residue mutations: L67A and L70A; or double mutations: L70A:L72A and L67A:L70M. The results show that the L70A:L72A does not form a functional AHR-ARNT heterodimer when analyzed by EMSA, and does not induce XRE driven reporter plasmids when transfected into cells even though it is functional in ligand binding and nuclear import. In contrast, L67A and L67A:L70M show DNA binding and gene induction to approximately 50% of wild type levels, while L70A appears to function to near wild type levels in both DNA binding and reporter gene assays. The reduced function of the L70A:L72A mutant shows the importance of these residues in dimerization and the difficulty of analyzing a sequence with dual functionality. The continued analysis of L67A, L70A and L67A:L70M will be important in determining the relationship between degradation of AHR and regulation of gene expression. (Supported by ES08980.)

1523 ANALYSIS OF RAINBOW TROUT AH RECEPTOR PROTEINS *IN VITRO*.

R. S. Pollenz and B. M. Necela. *Medical University of South Carolina, Charleston, SC.*

Two cDNAs for the Ah receptor (AHR) have recently been isolated from rainbow trout (Oncorhychus mykiss). The cDNAs are highly homologous showing >97% sequence identity within the amino acid and nucleotide sequences including regions of the 3' and 5' untranslated regions. Both of the encoded proteins show sequence homology to the AHR 2 isoform initially isolated from fundulus. Studies were initiated to develop techniques to study aquatic receptors *in vitro* and compare the function of these two proteins to mammalian AHR *in vivo*. To facilitate study of the rtAHR proteins, they were expressed with FLAG peptide at the NH-terminus. Both rtAHRa and rtAHRb were expressed in an *in vitro* transcription/translation system and could be detected with anti-FLAG antibodies. To assess these protein further, equal amounts were mixed with either mARNT or $rtARNT_b$ and activated at 20-30°C. The activated complexes were tested for their ability to associate with mammalian xenobiotic response elements (XRE) or aquatic XREs. In this assay, mFLAGAHR/mARNT and mFLAGAHR/$rtARNT_b$ showed strong TCDD-dependent binding to both XRE sequences, however, neither rtAHR isoform showed significant binding activity compared to the mammalian sequence. In vitro activation of cytosol derived from trout gonad cell line, RTG-2, also showed a low level of activity compared to cytosol derived from mouse Hepa-1 cells whether activated at 4, 20 or 30°C for 2-5 hours. These results suggest trout AHR protein is extremely sensitive to *in vitro* analysis likely due to instability of the protein at the temperatures used for the assay. Thus, it appears that the analysis of these protein requires cell culture models that will support the integrity of the rAHR complex. (Supported by ES08980.)

1524 SCREENING FOR GENETIC VARIABILITY OF THE HUMAN *ARNT* GENE AND ANALYSIS OF THE 5'- FLANKING REGION.

J. Scheel, H. J. Schmitz and D. Schrenk. *University of Kaiserslautern, Kaiserslautern, Germany.*

The human ARNT (aryl hydrocarbon receptor nuclear translocator) is widely expressed in human tissues. As a member of the basic-helix-loop-helix (bHLH) superfamily of proteins it acts as a heterodimerizartion partner of various structurally related proteins to form active transcription complexes influencing diverse cellular processes. The most prominent heterodimerization partner is the dioxin receptor/aryl hydrocarbon receptor (AhR). Ligand activation of AhR leads to induction of responsive genes via AhR/ARNT, some of them encoding for enzymes such as CYP1A2 that can metabolize xenobiotics to carcinogenic intermediates. Several studies have reported interindividual differences in the susceptibility towards effects of AhR agonists and in the activities of AhR/ARNT-regulated enzymes. In this study we investigate if there are any genetic variations in the *ARNT* gene that may contribute to these differences or that affect other cellular processes in which ARNT is involved. The *ARNT* gene including part of the 5'-flanking region has been isolated and characterized from a human BAC genomic library. DNA was isolated from peripheral blood samples in a cohort of 94 healthy Caucasian volunteers. Subsequently, PCR-SSCP (single strand conformation polymorphism) analysis was carried out. Fragments that showed a variant pattern were cloned and sequenced. The fragments investigated so far did not show genetic variants of possible functional significance. Completion of the analysis will give further insights. The promoter region of the human *ARNT* gene was found to contain a number of putative regulatory elements such as a TATA-box, a cAMP-responsive element, an E-box and a CAAT-box.

1525 SUBCELLULAR LOCALIZATION OF THE ARNT PROTEIN IN RAINBOW TROUT, MOUSE, AND CHICKEN OVER DEVELOPMENTAL TIME.

K. Marks-Sojka, C. B. Kern, E. L. Krug and R. S. Pollenz. *Medical University of South Carolina, Charleston, SC.*

The aryl hydrocarbon receptor nuclear translocator (ARNT) is a basic-helix-loop-helix/Per, ARNT, Sim (bHLH/PAS) transcription factor that is involved in multiple signaling pathways. The gene targeted deletion of ARNT in a mouse model resulted in a lethal phenotype on embryonic day 10.5, emphasizing ARNT is critical for development. It is important to comprehend the subcellular localization of ARNT in tissues to obtain a complete understanding of its function. However, studies investigating ARNT in tissues over developmental time are limited and concentrate on mammalian models. Previous immunocytochemical studies on a range of cell lines indicate that the ARNT protein is found mainly in the nucleus, which is logical considering vertebrate ARNT has a nuclear localization signal. In contrast, one study on mammalian ARNT localization in tissues found cytoplasmic staining, as well as, nuclear staining. Thus, the precise localization of ARNT protein in tissue remains controversial. This study focuses on the presence and localization of ARNT in a range of tissues over developmental time in the rainbow trout, mouse, and chicken. Three different species were chosen to determine the consistency of the ARNT staining pattern. Immunohistochemical techniques were used to stain sections of embryos over at least three developmental time points for each species. Mice were stained on embryonic day 10.5, 12.5, and 15, and the tissues evaluated showed predominant nuclear staining. Developing chicken were stained on embryonic day 2, 4, and 10, and the tissues evaluated also showed predominant nuclear staining. Studies using developing rainbow trout show predominantly nuclear ARNT staining. Therefore, in all tissues examined, regardless of the species, ARNT was found to be expressed and was predominately nuclear over all the time periods investigated. At no time point has ARNT reactivity been detected in the cytoplasm to a greater level than in the nucleus. These data overwhelmingly support the localization of ARNT in tissues to be nuclear and are consistent with and the location of ARNT in cell culture lines the presence of a nuclear localization signal in the ARNT protein. (Supported by ES08980.)

1526 THYROID DISRUPTING CAPACITY OF SELECTED PESTICIDES IN *XENOPUS*: POTENCIES AND MODES OF ACTION.

D. J. Fort[1], M. F. Miller[1], R. L. Rogers[1], E. L. Stover[1], P. D. Guiney[2] and J. A. Weeks[2]. [1]*The Stover Group, Stillwater, OK and* [2]*S.C. Johnson Wax, Racine, WI.*

The thyroid disrupting capacity of eight pesticides or herbicides, including p,p-DDE, o,p-DDE, dieldrin, methoxychlor, methoprene, pyriproxyfen, sulfometuron methyl, and nicosulfuron, were evaluated using the 14-d *Xenopus* metamorphosis assay. In this assay, tail resorption during metamorphic climax (stage 60 to stage 66) was used as a morphological marker of thyroid disruption. Methoxychlor was most potent in its capacity to inhibit tail resorption, yielding no adverse effect concentrations (NOAEC) of 0.01μg/L and lowest adverse effect concentrations (LOAEC) of 0.1μg/L. o,p-DDE, dieldrin and p,p-DDE were found to be somewhat less inhibitory with NOAEC and LOAEC values of 0.1 and 1.0μg/L, 1.0 and 10.0μg/L, and 10.0 and 100.0μg/L, respectively. Methoprene, pyriproxyfen, nicosulfuron and sulfometuron methyl were the least inhibitory, with NOAEC and LOAEC values of 1,000 and 10,000μg/L, respectively. Results from these studies indicate that methoxychlor, dieldrin and o,p-DDE possessed the greatest capacity to slow the rate of tail resorption. The remaining test materials possessed a lesser capacity to inhibit the rate of tail resorption. The *Xenopus* tail resorption assay appears to be capable of evaluating the effect of selected environmental compounds on amphibian metamorphosis. More work will be required to

fully elucidate whether this assay is specific for determining effects on the thyroid axis or a more generalized ecotoxicology assay for amphibians.

1527 ECDYSTEROIDS ELICIT LATE LIFE-CYCLE TOXICITY WITHOUT REDUCING FECUNDITY IN *DAPHNIA MAGNA*.

R. Coffey[1] and W. S. Baldwin[2]. [1]*Anderson College, Biology Department, Anderson, SC and* [2]*Anderson College, Biology Department: Anderson, SC; Clemson Institute of Environmental Toxicology, Clemson University, Pendleton, SC.*

Daphnia magna were exposed for 21 days to the ecdysteroids, 20-hydroxyecdysone (20-HE), the accepted molting hormone, and Ponasterone A, an exogenous ecdysteroid found in some crustaceans and many plants. Daphnids were monitored for alterations in molting, fecundity, and death. 20-HE elicted no effects on reproduction in healthy animals and had no effects on molting until the death of adult daphnids. Typically, death came to daphnids that were presumably healthy and usually greater than 14 days old. At that time nearly 100% of the daphnids died because of incomplete ecdysis, indicating that the exogenous ecdysone elicited a molting effect without effects on reproduction although these two processes are closely co-regulated in daphnids. Ponasterone A, which has been reported to have approximately 10X higher affinity for the ecdysone receptor than 20-HE and is probably a constituent of pulp and paper mill effluents, was examined next. We hypothesized that Ponasterone A may be comparatively more potent *in vivo* because it may not be as easily metabolized as 20-HE. However, Ponasterone A elicited late-stage molting effects at approximately 10X lower concentrations than 20-HE. Ponasterone A also did not elicit a reproductive effect, suggesting that in Daphnia magna, Ponasterone A is an ecdysteroid that is easily metabolized and eliminated. Thus, both 20-HE and Ponasterone A show similar effects and the overall difference in toxicity is mostly likely due to recepor affinity. Furthermore, the overall chronic toxicity of these steroid hormones was less than anticipated.

1528 REPRODUCTIVE CHANGES IN THE ESTUARINE FISH CUNNER (*TAUTOGOLABRUS ADSPERSUS*) EXPOSED TO 17β-ESTRADIOL AND ETHINYL ESTRADIOL IN THE LABORATORY.

L. J. Mills, R. E. Gutjahr-Gobell, D. Borsay-Horowitz and G. Zaroogian. *USEPA, NHEERL, Atlantic Ecology Division, Narragansett, RI.* Sponsor: W. Boyes.

Both 17β-estradiol and ethinyl estradiol are environmental estrogens that have been shown to cause estrogenic effects in fish collected from rivers receiving sewage treatment effluent. Cunner (*Tautogolabrus adspersus*) are being studied in our laboratory to evaluate how 17β-estradiol and ethinyl estradiol affect aspects of their reproductive endocrinology and reproductive success. Cunner was selected because this species is common in estuarine areas, easily obtainable, amenable to laboratory holding and spawns daily. Fish of both sexes were exposed through subcutaneous implant of the test estrogen in a controlled release matrix (ethylcellulose and ethoxylated castor oil). In two eight-week experiments, male and female laboratory-held cunner were taken from winter conditions, injected with the appropriate treatment, and gradually acclimated to spring spawning conditions. Treatments tested in these experiments were uninjected control, matrix-injected control, and 0.05, 0.5 or 2.5 mg/kg concentrations of either 17β-estradiol or ethinyl estradiol. Plasma was taken from a subsample of treated fish over the course of these experiments and analyzed to determine circulating levels of the steroid hormones 17β-estradiol and testosterone, as well as the estrogen-induced yolk protein vitellogenin. Egg production and egg viability were recorded daily over the eight-week exposure period. Over the course of the entire experiment, fish treated with the lowest concentration of 17β-estradiol produced more eggs per female than any other treatment. Cunner given the highest concentration of 17β-estradiol produced fewer viable eggs. In the fish treated with ethinyl estradiol, the viability of eggs from fish receiving the lowest concentration was half that of the controls. Gonadosomatic index (GSI) was determined at the end of each experiment for all surviving fish. Males treated with 17β-estradiol showed a concentration-related increase in GSI, while those treated with ethinyl estradiol exhibited a concentration-related decrease. Overall, results of these experiments suggest that exposure to estrogens can impact the reproductive success of cunner.

1529 VITELLOGENIN TRANSCRIPTIONAL ACTIVATION IN SHEEPSHEAD MINNOW FOLLOWING ACUTE ESTROGEN EXPOSURE *IN VIVO*.

C. J. Bowman[1], K. Kroll[2], L. C. Folmar[3], M. J. Hemmer[3] and N. D. Denslow[2]. [1]*Department of Pharmacology & Therapeutics, University of Florida, Gainesville, FL,* [2]*Molecular Biomarkers Core-Interdisciplinary Center for Biotechnology Research, University of Florida, Gainesville, FL and* [3]*United States Environmental Protection Agency, Gulf Breeze, FL.*

Many environmentally persistant xenobiotics appear to disrupt the endocrine system by acting as ligands for endogenous steroid receptors, such as the estrogen receptor. Activation of these receptor systems in wildlife using *in vivo* model systems is not well characterized. By characterizing transcriptional and translational activation of genes following exposures to 17β-estradiol (E_2), baseline physiological responses in gene regulation can be established. We have cloned partial cDNA fragments of vitellogenin (VTG) from sheepshead minnow (*Cyprinodon variegatus*). Two fragments (α and β) with 70% nucleotide sequence homology were found, each corresponding to a homolog in fundulus heteroclitus, suggesting that sheepshead minnow have two VTG genes. The fragments isolated can be used as sensitive genetic probes to study early steps in the response of exposed fish to estrogen or to estrogen mimics. We have quantified VTG gene induction in sheepshead minnow *in vivo* using two routes of exposure; IP-injection with E_2 and flow-through water exposures with E_2 and 17α-ethinylestradiol (EE_2). VTG messenger ribonucleic acid (mRNA) induction was characterized by Northern analysis and quantified using slot blots and *in vitro* synthesized RNA standards. Plasma VTG protein was identified by Western and quantified using a previously validated enzyme-linked immunosorbent assay specific for sheepshead minnow. VTG mRNA exhibited a maximum induction of 1300 pg/μg total RNAwith E_2-injection and 120 ng/μg total RNA with E_2 water exposure, under the conditions and doses tested. The data illustrates hormone induction profiles of VTG mRNA and protein to E_2 and EE_2.

1530 NON-MAMMALIAN ESTROGENICITY SCREEN: RAINBOW TROUT ESTROGEN RECEPTOR BINDING.

T. R. Henry[1], J. S. Denny[2] and P. K. Schmieder[2]. [1]*NHEERL, Toxicology Division, Duluth, MN and* [2]*NHEERL, Mid-Continent Ecology Division, Duluth, MN.*

The U.S. EPA has been mandated to screen industrial chemicals and pesticides for potential endocrine activity. Current assays for measuring endocrine activity are primarily mammalian-based. The appropriateness of extrapolating mammalian results to non-mammalian species is uncertain, primarily due to the lack of non-mammalian data from which to make such an assessment. The primary objective of the study was to establish the relative binding affinity of a number of xenobiotics in a widely used non-mammalian toxicity model, the rainbow trout. Binding affinity to the rainbow trout estrogen receptor (rtER) was measured by radioligand competition assay. Trout liver cytosol (300μl) was incubated (20 hr at 4°C) with a saturating concentration (5 nM) of ^{3}H-estradiol (^{3}H-E2) and a range of xenobiotic concentrations. Bound xenobiotic was determined as the amount of ^{3}H-E2 displaced from the rtER. The relative binding affinity (RBA) was calculated as the EC_{50} for displacement of xenobiotic relative to the EC_{50} for displacement of estradiol (E2). E2 bound to rtER with high affinity (K_d = 1.5 nM; B_{max} = 13.3 nM) as did known ER agonists, diethylstilbestrol (RBA ~ 400) and ethinyl estradiol (RBA ~ 400). A variety of other chemicals, including p,p'-methoxychlor (MXC), 4-tert-pentylphenol (PTPP), and 4,4'-diaminostilbene-2,2'-disulfonic acid (DAS) were tested and found to have orders of magnitude lower RBAs or did not bind to the rtER at solubility-limited concentrations (e.g., MXC). The absolute affinity and capacity of xenobiotic binding to the rtER are generally lower than in mammalian systems, however, the relative binding affinities of various chemicals are comparable. These data will be used to help establish the basis for extrapolating estrogenic potential of xenobiotics across species. (This abstract may not represent EPA policy.)

1531 SYNERGISTIC EFFECTS OF THE XENOESTROGEN 4-OCTYLPHENOL (4-OP) AND UV-B RADIATION ON SOMATIC DEVELOPMENT AND GENE EXPRESSION IN THE FOREBRAIN OF THE LEOPARD FROG (*RANA PIPIENS*).

D. Crump, V. L. Trudeau and D. R. S. Lean. *University of Ottawa, Ottawa, Ontario, Canada.* Sponsor: M. E. Hahn.

Newly-hatched *Rana pipiens* tadpoles were exposed to three concentrations of 4-OP (1nM, 1μM, 10μM) and two levels of UV-B radiation (25 μW/cm^2, 6

μW/cm²) in a ten-day static renewal experiment. An RNA-arbitrarily primed PCR (RAP-PCR) strategy was used to identify candidate genes differentially expressed in the forebrain (including pre-hypothalamic tissue) of the exposed tadpoles. Twenty tadpoles from each treatment group were raised to metamorphosis in order to assess any possible effects on later development. A cDNA fragment (774 base pairs) approximately 66% identical to the 3'-end of human and rat plectin at the predicted amino acid level was up-regulated by 1 nM 4-OP as defined by the differential display technique. Plectin is a cytoskeletal intermediate filament binding protein which provides mechanical strength to cells and tissues. Another transcript (762 base pairs) up-regulated by 1 nM 4-OP was 89% identical to human Nck, Ash and phospholipase C gamma-binding protein (NAP4). NAP4 is implicated in coordinating various signaling pathways including growth factor and cell adhesion receptors. One transcript (517 base pairs) was down-regulated by both 1 nM and 1 μM 4-OP and was 59% identical to human brain-specific angiogenesis inhibitor 2 (BAI2). BAI2 is a candidate for involvement in the development of glioblastoma (primary brain tumor development). Finally, a transcript (403 base pairs) was down-regulated by the high UV-B treatment (25 μW/cm²) and was 56% identical to rat arcadlin. Arcadlin is a novel cadherin molecule expressed at the synapses that may play an important role in activity-induced synaptic reorganization underlying long term memory. Prior to hind-limb emergence (stage 30), tadpoles from the combination group of UV-B (6 μW/cm²) and 4-OP (1 μM) were significantly larger ($p<0.05$) while those in the UV-B treatment (6 μW/cm²) displayed a significant reduction in weight ($p<0.05$). These results indicate that levels of 4-OP commonly found in the environment and sub-ambient levels of UV-B radiation alter developmentally important genes and disrupt normal growth patterns. (Research supported by NSERC [DL] and CNTC [VLT].)

1532 INVESTIGATION OF THE POTENTIAL *IN VIVO* INTERACTION OF ESTRADIOL AND TCDD IN *FUNDULUS HETEROCLITUS*.

T. A. Young and K. R. Cooper. *Rutgers, The State University of New Jersey, UMDNJ, Piscataway, NJ.*

The estuarine fish *Fundulus heteroclitus* comes into contact with mixtures of contaminants that have the potential to interact the organism. 17β-estradiol (E2) and 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) have previously been found to be antagonistic in *in vitro* and *in vivo* mammalian and some fresh water fish systems. In the present study plasma vitellogenin (as assessed by plasma alkaline phosphate (PALP)) and hepatic ethoxyresorufin deethylase (EROD) were used as markers of estrogenic and dioxin-like activity, respectively. Animals were treated for 6 days by intraperitoneal injection, on days 0 and 3, with E2 in olive oil. TCDD was given in a krill gelatin food mixture on day 3, or both days 0 and 3. No reduction of EROD activity was observed from 2.2ng TCDD/g in animals pretreated with 0.25-0.5mg E2 / g fish. No TCDD related reduction in PALP was observed in animals co-administered 0.6-4.9ng TCDD/g and 0.25mg E2 / g body weight. A dose responsive relationship was, however, found for each ligand and its respective marker. Based on these results there does not appear to be any interaction between E2 and TCDD using this protocol. These results may be altered by pretreatment for longer periods with either E2 or TCDD. The potential for interactions between toxic chemicals is of great importance when assessing complex mixtures in the field. The results presented here reinforce the importance of investigating different organisms, and multiple pathways of toxicity. (USEPA CR825437, NIEHS ES07148, ES005022)

1533 AN ADVANCED PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL FOR *MYA ARENARIA* USING 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN (TCDD).

M. Wintermyer[1], A. Skaidas[2], P. Georgapoulou[2], J. Burger[2], A. Roy[1] and K. Cooper[1]. [1]*Rutgers, The State University of New Jersey, New Brunswick, NJ and* [2]*Environmental and Occupational Health Sciences Institute, Picataway, NJ.*

A more robust physiologically-based pharmacokinetic model (PBPK) was developed for the soft-shelled clam (*Mya arenaria*). The version 2.0 model was optimized using the ^{14}C-inulin data and validated using 28-day 2,3,7,8-Tetrachlorodibenzo-*p*-dioxin (TCDD) elimination data. The original (version 1.0) model was improved by the addition of the foot and siphon into the model, and the incorporation of binding parameters. At 24 hours post mantle injection (2.13 pg/g), the highest TCDD level was in the siphon (137 pg). The highest TCDD concentration at day 28 was in the gonad followed by the siphon, gill, mantle, digestive gland, kidney, foot, adductor muscle, heart, and hemolymph. TCDD was initially assumed to distribute within the clam according to lipid content based on passive diffusion with no metabolism. The model based solely on lipid content fit the TCDD data poorly by over estimating and underestimating concentrations in the various tissues. Examination of the literature suggested that the gonad might have a binding protein for 2,3,7,8-TCDD. Incorporating a binding parameter in the gonad compartment resulted in a better fit to the data. The PBPK model predicted the uptake and elimination concentrations for 2,3,7,8-TCDD within each of the clam tissue compartments based on the flow rates, tissue compartment sizes, lipid content of each organ, binding parameters, and blood circulation. The version 2.0 model can be further modified to incorporate metabolic processes for compounds that undergo metabolism. This PBPK model can be valuable for estimating tissue burdens following environmental exposures.

1534 MODELING BIOACCUMULATION OF POLYCYCLIC AROMATIC HYDROCARBONS IN AN AQUATIC ECOSYSTEM.

K. H. Watanabe and R. Luna. *Tulane University, New Orleans, LA.* Sponsor: M. B. Anderson.

In 1996 and 1997 the Tulane/Xavier Center for Bioenvironmental Research (CBR) supported ecological studies in the LaBranche Wetlands of Louisiana. The study area was selected because Bayou Trepagnier was the receiving stream for effluents from a petrochemical manufacturing complex for nearly 50 years ending in 1995. As a result of the industrial discharges to the system, the bayou is contaminated with heavy metals and polycyclic aromatic hydrocarbons (PAHs). Samples of sediment, water, and biota were collected from fixed stations along the bayou and analyzed for approximately 50 semi-volatile organic compounds. Spotted gar gut contents were examined to determine feeding preferences and establish the food web for the bioaccumulation model. We developed a spatially referenced food-web bioaccumulation model for spotted gar using established bioaccumulation modeling assumptions for hydrophobic organic chemicals and site specific data. In this study we focused on seven PAHs: naphthalene, anthracene, phenanthrene, benz(a)anthracene, chrysene, benzo(a)pyrene, and dibenz(a,h)anthracene. Model simulations show that bioaccumulation occurs through the benthic invertebrates consumed by the gar. For octanol water partition coefficients between $10^{3.3}$ and $10^{4.6}$ the highest concentrations in the food web are found in the benthic invertebrates. These concentrations range from 61 μg/kg for naphthalene to 150 μg/kg for anthracene. For PAHs with partition coefficients between $10^{5.6}$ and $10^{6.5}$, the predicted gar concentrations are highest among organisms in the food web ranging from 206 μg/kg for benz(a)anthracene to 547 μg/kg for benzo(a)pyrene.

1535 PCB TOXICITY IN FISH, SEAL AND POLAR BEAR.

A. Chiu[1], D. Singh[1], N. Chiu[2], J. Beaubier[3], R. Nalesnik[4], C. S. Hong[5], W. R. Hill[6], C. Lau[7] and J. Riebow[8]. [1]*National Center Environment Assessment, Office Research/Development, USEPA, Washington, DC,* [2]*Office Science Technology, USEPA, Washington, DC,* [3]*Office Policy Pesticide, Toxic Substance, Washington, DC,* [4]*National Center ERQA, ORD, USEPA, Washington, DC,* [5]*Wadsworth Center, New York State Health Department, State University New York, Albany, NY,* [6]*Environment Sciences Division, Oak Ridge National Laboratory, Oak Ridge, TN,* [7]*Endocrinology Branch, Reproductive Toxicology Division, National Health Environement Effect Research Laboratory, USEPA, Research Triangle Park, NC and* [8]*Environmental Epidemiology Division, Bureau of Laboratory, Lansing, MI.*

PCB have 209 congeners. Chlorinating atoms increase fat solubility, reduce metabolic degradation from P450 nonspecific oxidase, or biphenyls dioxygenase and prolonged the biological half-life. Bioaccumulation from fish to seal, or birds and to polar bear are summarized. There is an overall 3 or more order of magnitude increase in concentration of these chemicals from plankton to polar bear via fishes and birds up the food chain. Planktonivorous, herbivorous and carnivorous fishes accumulate different congeners from their diets. Different fishes in different tributaries have different patterns. Migratory salmon have less PCB than the bass, that stay in the contaminated locale. Fishes exposed to PCB have lost the P450 inducibility from xenobiotics. Gulls have a high load of PCBs because of its habitat. Seals consumed contaminated fishes developed endometrosis, fetal abortion and reproductive failures not to mentioned other stigmata from hyperaldosteronism. Disclaimer: The opinions and conclusions expressed in this paper are those of the authors and do not necessarily reflect those of affiliated institutions.

1536 AURAL ABSCESSES IN WILD-CAUGHT TURTLES: POSSIBLE INVOLVEMENT OF ORGANOCHLORINE-INDUCED HYPOVITAMINOSIS A.

S. D. Holladay, J. C. Wolfe, S. A. Smith, D. E. Jones and J. L. Robertson. *Virgina-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA.*

Wild-caught box turtles (Terapene carolina carolina) with aural abscesses were observed over a period of several years. Histopathologic evaluation of the lining of the middle ear and other epithelial tissues (conjunctiva, pharynx, trachea, auditory tube) revealed mucosal hyperplasia and squamous metaplasia, and accumulated keratin-like material in the middle ear cavity. Together these manifestations suggested the possibility of vitamin A deficiency in the wild turtles. Ten additional turtles were therefore collected (5 with an externally visible aural abscess and 5 without an externally visible aural abscess). Mean serum and hepatic vitamin A levels in turtles with abscesses were 71% and 49% of respective levels found in turtles without abscesses. Using gas chromatography, eight different organochlorine (OC) compounds were detected in livers of turtles. Three individual OC compounds (a-benzene-hexachloride, heptachlor epoxide, and oxychlordane) and total mg/g OCs were significantly higher in livers from turtles with abscesses compared to turtles without abscesses. No OC compounds were higher in turtles without abscesses compared to turtles with abscesses. These data suggest a possible effect of environmental chemicals on the metabolism or utilization of vitamin A in wild box turtles, resulting in a state of hypovitaminosis A.

1537 TOXICIT EVALUATION OF 1,3,5-TRINITROBENZENE (TNB) IN SHREWS (*Cryptotis parva*).

T. V. Reddy[1], G. R. Olson[2], B. Weichman[2], F. B. Daniel[1] and G. Reddy[3]. *[1]USEPA, NERL-Cincinnati, OH, [2]PAI, Westchester, OH and [3]US Army CHPPM, Health Effects Research Program, Aberdeen Proving Ground, MD.*

TNB has been detected as an environmental contaminant of soil and water at certain Army installations and production waste disposal sites. At present, there are no toxicity data on TNB in small wild mammals that might be used for ecological risk assessment. Therefore, a 14-day toxicity study was conducted to determine the No Observed Adverse Effect Level (NOAEL) of TNB in the least shrew (*Cryptotis parva*). Male and female shrews (10/group/sex) were fed a mixture of wet-dry Purina Cat Chow containing 0, 5, 10, 20 and 40 ppm for 14 days. The calculated average consumed doses were 0, 10.68, 22.24, 37.79 and 98.27 mg/kg/day for males and 0, 10.75, 21.60, 45.26 and 98.72 mg/kg/day for females. There were no significant differences in food and water consumption among the groups. However, there was a decrease in body weight in males (10 to 40 ppm) and a significant increase in body weight in females in the 20 ppm dose group. The relative spleen weights were increased in females (10 to 40 ppm). There were no significant changes in hematology parameters in females while in males there was a significant decrease in RBC and an increase in WBC in the 40 ppm dose group. Histpathological change noted was erythroid cell hyperplasia in the spleen of males receiving 20 and 40 ppm TNB diet. The NOAEL for male and female shrews was determined as 10.75 mg/kg/day for the 14-day study. (Abstract does not reflect US EPA/ US Army policy.)

1538 STUDIES EVALUATING THE ENVIRONMENTAL TOXICITY OF ARSENIC PENTOXIDE, CUPRIC CHLORIDE, PENTACHLOROPHENOL, AND 1,2,3,6,7,8 HEXACHORODIBENZO-*P*-DIOXIN IN SINGLE AND BINARY MIXTURES.

S. H. Adair, B. Buckley and K. R. Cooper. *Rutgers, The State University of New Jersey, New Brunswick, NJ.*

Arsenic pentoxide, cupric chloride, pentachlorophenol, and 1,2,3,6,7,8-hexachlorodibenzo-p-dioxin are common contaminants found in combination in the environment. The first three compounds listed are currently used for wood treatment, while 1,2,3,6,7,8-hexachlorodibenzo-p-dioxin is one of the most toxic contaminants found in technical grade pentachlorophenol. Dose-response curves were developed for these compounds based on the experimental results obtained from the Japanese Medaka (Orzias latipes) Embryo-Larval Assay (MELA). The LC50 values estimated from the single compound dose-response curves for arsenic pentoxide, cupric chloride, pentachlorophenol, and 1,2,3,6,7,8-hexachlorodibenzo-p-dioxin were 50 mg/l, 5 mg/l, 84 μg/l, and 2.3 μg/l, respectively. Tube heart and pericardial edema were frequently observed lesions at the highest concentrations tested during each of the single compound MELA studies. Additional compound specific lesions included vitelline vein dilation and hemorrhage for cupric chloride, hypopigmented blood and yolk-sac cloudiness for arsenic pentoxide, hypopigmented blood and swollen spleen for pentachlorophenol, and brain swelling, brain and caudal area hemorrhage, and hypopigmented blood for 1,2,3,6,7,8-hexachlorodibenzo-p-dioxin. The LC25 values of 4.1 mg/l for cupric chloride and 48.5 mg/l for arsenic pentoxide were determined from their respective dose-response curves for the cupric chloride/arsenic pentoxide binary study. The binary mixture of cupric chloride and arsenic pentoxide appeared to have a greater than additive effect on lesions in the Japanese Medaka embryos. Complex mixtures at wood treating facilities may pose a greater risk than determined from single compound studies. (USEPACR825437, NIEHSES07148, ES005022)

1539 CHANGES IN ARSENIC SPECIATION DURING MICROBIAL GROWTH.

E. Casarez and D. E. Carter. *Department of Pharmacology and Toxicology, Center for Toxicology, University of Arizona, Tucson, AZ.*

Arsenic (As) is ubiquitous in the environment, both as a natural component of rocks and minerals and as a contaminant from human activities. Arsenic in the soil often leaches into water supplies. Sub-ppm levels of As in drinking water have been shown to lead to skin, bladder, and lung cancer. Different forms of As have different chemical and physical properties and therefore different cellular toxicities and soil binding properties. The As species present in the soil, and therefore the toxicity and risk from the As, is affected by biotic and abiotic influences. This study's aim was to determine the changes in As species when a soil microbial community is grown with the four common forms of As—- arsenite (AsIII), arsenate (AsV), monomethylarsonate (MMA), and dimethylarsenate (DMA). Minimal salts media (glucose as the carbon source and pyrophosphate as the phosphorous form, pH 6.00) containing 0, 30, or 300ppm As as AsIII, AsV, MMA, or DMA was inoculated with microbes from a non-contaminated soil and microbial growth measured as optical density at 660nm over time. During different points of the growth curve, As speciation was determined by HPLC-hydride generation-atomic-fluorescence-spectrometry and compared to non-inoculated controls. Results were similar with either 30ppm or 300ppmAs. While there were no changes in either the level or form of As when the initial As species was MMA or DMA, AsV was consistently reduced to AsIII during the exponential growth phase. When the initial As species was AsIII, oxidation to AsV was found in one of the three replicates, while the other two had similar AsIII levels as controls. This indicates that the ability to reduce AsV to AsIII may be more prevalent than As oxidation in the soil community. Reducing AsV to AsIII may increase the bioavailability and the toxicity of the As in the environment. (Work supported by NIH Grant ES06644, NIEHS Grant ES07091, Center Grant P30ES06694, and the Caldwell Health Sciences Research Fellowship.)

1540 HEAVY METALS, PESTICIDES AND ENVIRONMENTAL CONTAMINANT RESIDUES IN RESIDENT GIANT CANADA GEESE (*BRANTA CANADENSIS*) FROM NORTH EAST AND SOUTH WEST OHIO.

A. M. Kadry[1], M. K. Hoffman[1], W. M. Hockman[2], D. Risely[3] and I. S. Kim[1]. *[1]Emerging Issue Branch, Chemistry and Toxicology Division, Food Safety and Inspection Service, United States Department of Agriculture, Washington, DC, [2]Animal Disease Diagnostic Laboratory and Division of Meat Inspection, Ohio Department of Agriculture, Reynoldsburg, OH and [3]Division of Wildlife, Ohio Department of Natural Resources, Columbus, OH.* Sponsor: D. Acosta, Jr.

In contrast to forty years ago when Canadian geese (*Branata canadensis*) approached extinction due to loss of wetland habitat, unrestricted egg taking, and over-hunting, they are now common residents of American golf courses, ponds and lakes. Because of protection, their numbers have increased from a few thousand to well over a million, and the Canadian goose population is now widely viewed as out of control. Many risks to animal, human and environmental health are associated with the geese, from transmitting diseases to other animals, eutrophication of ponds and lakes and decreasing water quality through extensive droppings, viciously attacking humans, and damaging landscapes. States are now beginning efforts to reduce their Canadian goose population. In the present investigation, FSIS cooperated with the state of Ohio to reduce the geese over-population while simultaneously trying to meet food requirements of needy families. To determine the suitability of these wild birds for human consumption, 18 geese were collected from northeastern (NE) and southwestern (SW) Ohio. Muscle, liver, kidneys and fat samples were analyzed for a number of metals (aluminum, arsenic, barium, boron, cadmium, calcium, chromium, cobalt, copper, iron, lead, manganese, mer-

cury, molybdenum, nickel, sodium, zinc), pesticide residues (dieldrin, DDE, HCB, chlorinated organophosphate, and PCBs). Fat contained traces of dielderin, heptachlor, PCBs and HCB. None of the detected levels exceeded the pesticide tolerances. However, livers from these geese (both locations) contained elevated levels of some of the examined metals. Livers from SW contained 2-fold increase of lead (1.06±0.21 vs. 0.57±0.17 ppm) and iron (1540±172 vs. 766±145 ppm), and a 1.7X increase of molybdenum (1.71±0.41 vs. 1.05±0.06 ppm) compared to those found in NE livers. Kidneys from NE geese lead concentrations that were 4X that found in livers from the same group. Surprisingly, this difference was not repeated in the SW geese. Data suggests that the muscle tissues of these animals are fit for human consumption. The migration path may affect the range and level of contaminants in the examined birds. Risk assessment and through analysis of these animals before using them in any food program is important procedure.

1541 PARASITE SUSCEPTIBILITY AND STRAIN-SPECIFIC RESPONSES TO LONG-TERM CADMIUM EXPOSURE IN THE FRESHWATER GASTROPOD, *BIOMPHALARIA GLABRATA*.

C. J. Salice and G. Roesijadi. *University of MD Chesapeake Biological Laboratory, Solomons, MD.*

Different strains of Biomphalatia glabrata can be resistant or susceptible to trematode parasites that cause schistosomiasis. Our interest is to ascertain whether such differences can be related to differences in resistance to Cd toxicity. Initial experiments showed that a parasite-resistant strain, BS90, is less tolerant of acute Cd exposure than a parasite-susceptible strain, NMRI. Strain-related responses were further examined in continuous exposures over three generations. NMRI was exposed to higher Cd concentrations to account for its greater Cd resistance. Low concentrations of 0.0125 μM for BS90 and 0.025 μM for NMRI had no effects on survival or reproduction. NMRI at the intermediate Cd concentration of 0.05 μM exhibited reduced growth and reproduction in the first generation and failed to produce viable offspring in the second. Strain-specific differences in Cd resistance were apparent at the 0.025 μM Cd exposure common to both strains: NMRI was more tolerant than BS90, reflecting the instrinsic difference in Cd resistance noted originally. At this concentration, the response of NMRI was similar to that of controls, while Cd-exposed BS90 exhibited decreased survival rates in each of the three generations. At 0.10 μM Cd, at which only NMRI was subjected, there was substantial mortality in the first generation, but not in subsequent generations, which were derived from the Cd-resistant survivors of the first. These results were consistent with selection for Cd resistance in NMRI. This rapid increase in Cd resistance (<3 generations) is indicative of only one or a few responsible genes. We determined the number of genes involved in Cd resistance in this species using a quantitative genetic approach and report a preliminary estimate of 1.35 genes. It appears, thus far, that selection for parasite resistance is associated with increased sensitivity to Cd toxicity and decreased ability to adapt to Cd exposure.

1542 GLYCEROL-MEDIATED PHOTOREDUCTION OF HEXAVALENT CHROMIUM.

E. J. Yurkow[1], J. Hong[2], S. Min[2], S. Wang[2], D. R. Cerven[1] and G. L. DeGeorge[1]. [1]*MB Research Laboratories, Spinnerstown, PA and* [2]*Rutgers University, Piscataway, NJ.*

Chromium is an important industrial metal and an environmental pollutant. In the hexavalent [Cr(VI)] form, this metal is known to be a human carcinogen, while trivalent chromium [Cr(III)] is considered much less toxic. We have found that hexavalent chromium in the form of potassium dichromate can be rapidly photoreduced to trivalent chromium [Cr(III)] in aqueous solutions containing glycerol. This photoreduction occurred after irradiation with either UVA (320-400 nm) or a wide spectrum light source, but not a UVB (290-320 nm) light source. Photoreduction of hexavalent chromium was found to be pH-dependent and did not occur in dilute solutions of sodium hydroxide. In acidified solutions, the photoreduction occurred at elevated rates and at lower concentrations of glycerol. This reaction is apparently dependent on the unsubstituted alcohol groups of glycerol since alpha-phosphoglycerol or beta-phosphoglycerol did not support the photoreduction of hexavalent chromium. These findings may have significant applications in the remediation of hexavalent (carcinogenic) chromium at contaminated environmental sites. (Funded in part by the Consortium of Risk Evaluation with Shareholder Participation (CRESP), DOE# DE-FC01-95EW55084.)

1543 REPRODUCTIVE TOXICITY OF ERGOT ALKALOIDS IN MINK.

C. Sharma[1], S. J. Bursian[1], R. J. Aulerich[1], J. A. Render[2], T. Reimers[3] and G. E. Rottinghaus[4]. [1]*Department of Animal Science, Michigan State University, East Lansing, MI,* [2]*Department of Pathology, Michigan State University, East Lansing, MI,* [3]*Diagnostic Laboratory, Cornell University, Ithaca, NY and* [4]*Veterinary Medical Diagnostic Lab., University of Missouri, Columbia, MO.*

Ergot alkaloids are synthesized by fungi of the Claviceps family that infect rye as well as other cereals and grains. Since a portion of the ranch mink diet is cereal, mink are at a risk of being exposed to ergot alkaloids. This study was performed to determine the reproductive toxicity of ergot alkaloids derived from ergot-contaminated wheat in mink. Four groups of 12 female mink each were fed diets containing 0, 3, 6, or 12 ppm ergot alkaloids from 2 weeks prior to the breeding season until the kits were approximately 33 days old (133 days). Females were mated with untreated males. Ergot alkaloids caused a transient decrease in feed consumption, but body weights were unaffected. The gestation period of the mink in the 12 ppm group was longer compared to controls. The number of mink whelping varied significantly with 9 mink whelping each in the control and 3 ppm group compared to 4 mink in the 6 ppm group and 1 in the 12 ppm group. Ergot alkaloids had a significant effect on kit survivability with no kits surviving in the 12 ppm group. Plasma prolactin was significantly depressed in the 3 ergot alkaloid groups compared to the controls. This study indicated that ingestion of ergot alkaloids at 3 ppm or higher resulted in reproductive toxicity in mink.

1544 MERCURY IN FISH FROM THE SHOALS AREA OF THE TENNESSEE RIVER.

A. C. Nichols[1], T. P. Murray[2], T. D. Richardson[2] and W. M. Sprague[3]. [1]*Auburn University, Auburn University, AL,* [2]*University of North Alabama, Florence, AL and* [3]*Southern Environmental Testing, Florence, AL.* Sponsor: S. Ansari.

Kentucky, Pickwick and Wilson are the first three impoundment lakes from the mouth of the Tennessee River. Collectively, they extend from Kentucky Dam, TRM (Tennessee River Mile) 22, to Wheeler Dam in the Shoals area of northwest Alabama, TRM 275. Pickwick, the middle of these three contiguous lakes, goes from Pickwick Dam (TRM 206) to Wilson Dam (TRM 260). Pickwick Lake was the site of an historic discharge of mercury from a chlor-alkali facility. Fish tissue studies conducted by the Tennessee Valley Authority's Office of Water Management showed that average values for mercury in muscle tissue of largemouth bass from Pickwick Lake peaked in 1973 at 1.03 ppm. By 1979, this value had declined to 0.14 ppm. Similar data from Kentucky Lake (the next lake downstream) showed levels of 1.07 and 1.01 ppm for 1973 and 1974 respectively. Data from 1979 demonstrated a decrease of this average to 0.32 ppm. To determine if residual mercury in Pickwick Lake was currently being incorporated into the food chain, tissue samples from fish collected from the lake were analyzed for total mercury. Tissue was freeze-dried, weighed and solubilized with nitric acid and hydrogen peroxide at 45°C. Solvent controls were included with each assay. USEPA Method 245.1, Cold Vapor Atomic Absorption, was used for mercury analysis. NIST standard Reference Material 2976, mussel tissue, was used to validate the analytical procedures. Mercury was detected in all tissue samples from fish collected from Pickwick Lake. Tissue concentrations ranged from 0.02 ppm in muscle tissue from a white bass 25 cm long to 2.13 ppm in liver from a fresh water drum 43 cm in length. Fish collected from Kentucky Lake, down river from Pickwick, also contained mercury. These tissue concentrations ranged from 0.05 ppm for the liver of a 19 cm long drum to 0.18 ppm seen in a muscle sample from a 34.5 cm long drum. Unexpectedly, mercury was found in fish from Wilson Lake, up river from Pickwick. This lake is separated from Pickwick by a 30 m high dam. Mercury in Lake Wilson cannot be attributed to pollution from the chlor-alkali source that contaminated Pickwick. Highest tissue levels from Wilson were found in a liver sample from a blue catfish (3.28 ppm) and from the liver of a channel catfish (1.47 ppm). Possible sources of mercury pollution in this lake include down river wash from the estimated 75-150 tons of mercury released into East Poplar Creek by the Y-12 Plant at Oak Ridge National Laboratory. Another possible source is atmospheric deposition. Mercury contained in coal can be released into the atmosphere by stack gases from coal burning steam plants during the production of electricity. There is one such plant in the Shoals area.

1545 STRESS PROTEINS AND MDA.

J. J. Moreland and B. S. Washburn. *UTEP, El Paso, TX.*

Relationship between oxidative stress and induction of stress proteins in copper exposed fathead minnows, Pimephales promelas.Induction of heat shock or stress proteins (hsp) in fish has been used as a biomarker of exposure to environmental contaminants. Although hsp are well studied with respect to exposure, little is known about the relationship of hsp to adverse biochemical or physiological effects. To investigate the relationship between heat shock proteins and cellular damage, 32 fathead minnows, Pimephales promelas were divided into 4 10-gallon tanks and exposed to 0, 10, 20, and 40 ppb copper. Fish were maintained under static-renewal conditions for 96 hours, at which time they were sacrificed with an overdose of MS222. Liver, gills, and muscle were dissected and frozen for later analysis. Heat shock proteins 60 and 70 were analyzed by Western blotting. Oxidative stress was assessed by HPLC analysis of malonaldehyde (MDA). Hsp60 in liver and muscle, but not gill, increased in a dose-dependent fashion, up to 200% above control. Hsp70 was induced 67% and 194% in the gills and muscle respectively, but not the liver. MDA levels were elevated up to 6-fold at 20 ppb copper in the liver only. No apparent relationship was observed between hsp70 and oxidative stress. The data suggests a relationship between hsp60 and oxidative stress may exist, but further analysis is required.

1546 MICROCYSTIN-LR OZONATION BY-PRODUCTS: CHEMICAL AND TOXICOLOGICAL CHARACTERIZATION.

S. J. Hoeger, D. R. Dietrich and B. C. Hitzfeld. *Environmental Toxicology, University of Konstanz, Konstanz, Germany.*

Cyanobacterial toxins pose a health risk for humans especially since these toxins, such as microcystins (MC), are suspected tumor promoters. It is therefore necessary to develop procedures to effectively destroy these toxins during water treatment. Ozonation of MC in raw water with 1.0 mg O3/l completely destroys the toxin after 9 min (Höger et al. Toxicol. Sci. 48 1-S, 152, 1999). During a bloom episode or when the organic load of the water is high, the oxidation potential might be insufficient to completely destroy the toxin. In such a situation, ozonation by-products are found. These by-products have not been adequately identified and the aim of this study was to characterize them according to their toxic effects and their chemistry. Products from treatment of MC with 0.5mg O3/l were fractionated by HPLC. Using an ELISA with Adda (the amino acid unique for MC/Nodularin) as the antigen, the products were tested for the presence of the Adda side chain. Their phosphatase inhibition and protein binding capacities were tested with an inhibition assay and by immunoblotting, respectively. The results show that one fraction, which had an HPLC retention only slightly shifted from that of MC-LR, still exhibited protein phosphatase inhibitory activity and was also detectable by ELISA and immunoblotting. These findings show that incomplete oxidation of cyanobacterial toxins may lead to products showing toxic effects and protein adducting activity.

1547 IMMUNOCHEMICAL DETECTION OF MICROCYSTIN-LR IN TISSUES OF RAINBOW TROUT AND CARP.

B. C. Hitzfeld[1], W. J. Fischer[1], V. Fleischhauer[1], J. E. Eriksson[2], A. Mikhailov[2] and D. R. Dietrich[1]. [1]*Environmental Toxicology, University of Konstanz, Konstanz, Germany and* [2]*Turku Centre for Biotechnology, Turku, Finland.*

Microcystins (MC) are cyclic heptapeptide toxins produced by cyanobacteria such as Microcystis aeruginosa and are known to possess hepatotoxic and tumor-promoting activity. Intoxication with MC has lead to death of humans and animals such as livestock or fish. In order to determine the localization of microcystin in various fish tissues, an anti-MC-antibody was employed. Microcystin was probed in tissue of carp and rainbow trout after *in vivo* exposure to the toxin. Both immunocytochemistry and immunoblotting were used to detect organ/cellular distribution and protein adducts respectively. In order to identify putative protein adducts, Western blots were also stained with anti-human protein phosphatase 2A (PP2A). Immunocytochemistry showed positive staining in the liver and kidney while immunoblotting detected three microcystin-protein adducts with approximate molecular weights ranging from 23 to 38 kD in the liver, kidney, intestine, skeletal muscle, and brain. One of these adducts had an approximate molecular weight of 36 kD and this band was identified as PP2A by using a specific PP2A antibody. Other microcystin-protein adducts were isolated for further identification.

1548 DETECTION OF CYANOBACTERIAL TOXINS IN WHITEFISH (*COREGONUS LAVARETUS* L.) FROM LAKE AMMERSEE.

B. Ernst, B. C. Hitzfeld and D. R. Dietrich. *Environmental Toxicology, University of Konstanz, Konstanz, Germany.*

Lake Ammersee is one of the biggest lakes in southern Germany. Whitefish (*Coregonus lavaretus*) is the dominating fish species with great importance for the local fishery. In recent years whole age groups of the coregonid population in Lake Ammersee have been lost and reductions in body weight of fish were observed. The causes for this, however, remain unclear. The metalimnic cyanobacterium Planktothrix agardhii, known to produce the cyclic peptide toxin 3-desmethyl microcystin-RR (3dmRR), has become one of the dominating planktonic species causing regular blooms in summer. The aim of this study was to elucidate the effect these cyanobacterial blooms might have on coregonid population dynamics. During bloom episodes, gut contents of whitefish displayed a blue discoloration, possibly representing phycobiliproteins typical for cyanobacteria. Microcystins (MC) were determined in P. agardhii by protein-phosphatase assay and by HPLC. ELISA and immunoblotting techniques were used to detect microcystins in liver tissue samples and gut contents of whitefish. The cytotoxicity of the cyanobacterial bloom sample was tested with trout hepatocytes using the MTT assay. Toxin analysis of a massive P. agardhii bloom in July 1998, revealed an average of $1.6 \pm 0{,}1\mu g$ 3dmRR/mg dry weight (N=8). ELISA analyses of the gut content were positive for microcystin congeners. Similarly, immunoprobing with microcystin-antibodies demonstrated microcystin-protein adducts in liver homogenates of whitefish caught during P. agardhii blooms. In addition, extracts of the P. agardhii were cytotoxic when tested in the trout hepatocyte assay.

1549 AN ELISA WITH BROAD SPECIFICITY TO CYCLIC PEPTIDE CYANOBACTERIAL TOXINS.

W. J. Fischer[1], V. Fleischhauer[1], R. Chamberlin[2], J. B. Aggen[2], I. Garthwaite[3], C. Miles[3], K. Ross[3], N. Towers[3] and D. R. Dietrich[1]. [1]*Department of Environmental Toxicology, University of Konstanz, Konstanz, Germany,* [2]*Department of Chemistry, University of California, Irvine, CA and* [3]*Toxicology & Food Safety, AgResearch, Ruakura, New Zealand.*

Cyanobacteria (blue–green algae) capable of producing hepatotoxins, e.g., *Microcystis spp.* can be present in fresh water worldwide. These toxins, inhibit ser/thr protein-phosphatases, and induce hepatocyte necrosis/apoptosis. They are toxic to man, other mammals, and to fish—including salmonid species. This group includes the microcystin (MC) heptapeptides (over 50 known variants) and nodularin, a pentapeptide. Antibodies raised against a novel cyanobacterial toxin analogue-cBSA conjugate were used, together with ovalbumin-toxin-conjugates as a plate coater to develop a competitive ELISA. The ELISA is designed to detect most cyanobacterial hepatotoxins with equal sensitivity. Although not fully optimised, it has a detection limit below 0.1 ng/ml, and a limit of quantitation lower than the WHO-proposed guideline (1 mg/l) for drinking water. The assay is more sensitive than other available ELISAs, thus water analyses can be performed without sample preconcentration. The assay shows good cross-reactivity with all microcystin analogues tested to date, and has ~100% cross-reactivity with nodularin (relative to MC-YR). The assay is robust and has been used successfully in the analysis of an array of aqueous matrices, including raw river and reservoir water, algal culture, and algal bloom samples. The broad specificity of the ELISA makes suitable for use as a quick screening procedure for the detection of cyanobacterial hepatotoxins in water and the aquatic food chain.

1550 LETHAL AND SUBLETHAL EFFECTS OF IVERMECTIN IN A FRESHWATER OLIGOCHAETE, *LUMBRICULUS VARIEGATUS.*

J. Ding, C. D. Drewes and W. H. Hsu. *Iowa State University, Ames, IA.*
Sponsor: S. Hendrich.

Ivermectin is a potent antiparasitic drug against nematode and arthropod parasites. Although lethal levels have been determined in some non-target species, the effects of sublethal doses have seldom been examined. In this study, we examined the lethal and sublethal effects of ivermectin in a freshwater oligochaete, *Lumbriculus variegatus* (order Lumbriculida). LC_{50} at 72 h after ivermectin treatment was 0.62 μM. The endpoints for sublethal effects of ivermectin focussed on several stimulus-evoked locomotor behaviors: (1) escape reflex controlled by giant interneuron pathways; (2) swimming and reversal in open water; and (3) crawling on wet surface or in confined spaces under water. Swimming, reversal and crawling are controlled by non-giant

interneuron pathways. Ivermectin inhibited swimming, reversal, crawling frequency, and crawling speed in a time- and concentration-dependent manner with an EC_{50} at 3 h of 1.1, 16, 91 and 51nM, respectively. Ivermectin at 0.3 nM, or higher, also significantly decreased the frequency of helical swimming waves after 3h treatment. Picrotoxin (Cl^- channel blocker) antagonized the ivermectin-induced decrease in swimming frequency, crawling frequency and crawling speed. The worms retained escape reflex function 3 h after treatment with 0.3μM ivermectin. Electrophysiological recordings showed that ivermectin had no effects on the conduction velocity of medial or lateral giant fiber systems (MGF or LGF), or on muscle potentials evoked by MGF action potentials. The results indicate that locomotor behaviors controlled by non-giant interneuron pathways are more sensitive to ivermectin than are those controlled by giant interneurons, and suggest that Cl^- channels are involved in mediating ivermectin's inhibitory effects.

1551 EFFECTS OF *CLAVICEPS PURPUREA* VAR *SPARTINAE* (*SPARTINA* ERGOT) FED TO ADULT JAPANESE MEDAKA (*ORYZIAS LATIPES*).

C. Beck[1], R. A. Duncan[2], R. Sullivan[2], J. White[2] and K. R. Cooper[1]. [1]*Joint Graduate Program in Toxicology, Rutgers University, New Brunswick, NJ and* [2]*Depart. of Plant Pathology, Cook College, Rutgers University, New Brunswick, NJ.*

Studies were carried out to examine the potential effects of *Spartina* ergot on fish that might consume the sclerotia. This variant is in the class with *Claviceps purpurea* but floats on the surface of water. The sclerotia might be consumed by fish inhabiting salt marshes contaminated by the *C.p. spartina*. Japanese medaka (*Oryzias latipes*) were fed a diet containing 10% sclerotia at an 8% body weight for 17 days. There was no difference between the treatment group and the control fish for any growth parameters. No visible lesions were observed in the control fish (N=10) while a number of lesions were observed in the exposed fish (N=9). The major lesions that were observed included hemorrhages in the small capillary beds (44-55%), brown appearing blood (55%), and hemorrhages along the trunk muscle (22.2%). Altered pigmentation was observed in treated fish. These studies demonstrate that the *Spartina* ergot if eaten by fish could result in severe lesions. The widespread distribution of *C.p. spartinae* in North America, South America and Europe could pose a potential risk to wildlife. (ES07148, ES005022.)

1552 BIOLOGICAL STUDIES CONDUCTED ON SOUTH MONMOUTH AND CAPE MAY SEWERAGE AUTHORITIES EFFLUENTS AND RECEIVING WATERS TO A MARINE FISH (*FUNDULUS HETEROCLITUS*), A FRESHWATER FISH (*ORYZIAS LATIPES*), AMERICAN OYSTER (*CRASSOSTREA VIRGINICA*), AND A CRUSTACEAN (*MYSIDOPSIS BAHIA*).

A. S. Blankinship[1], K. R. Cooper[1], R. I. Hires[2] and C. C. Obrupta[2]. [1]*Rutgers, The State University of New Jersey, New Brunswick, NJ and* [2]*Stevens Institute of Technology, Hoboken, NJ.*

There are fourteen outfalls that discharge chlorinated, treated municipal wastewater into the coastal waters off New Jersey. Since none of these wastewater treatment plants have dechlorination systems, their effluent may cause toxic chlorine-produced oxidants (CPOs) to be released into the receiving waters as well as be in violation of the New Jersey Water Quality Criteria for these CPOs. Two of these plants were examined for toxicity on marine organisms, South Monmouth and Cape May Sewerage Authorities. Grab samples were taken from each plant periodically from September 1998 through August 1999. Some of the grab samples from each plant was sewage containing Rhodamine WT, a tracer dye, as well as sewage that was dechlorinated later in the lab. Acute and sub-chronic toxicity assay were conducted for a freshwater finfish (*Oryzias latipes*), and a crustacean (*Mysidopsis bahia*). These effluent collection assays showed significant differences ($P \leq 0.05$) for fecundity for *Mysidopsis bahia*, and embryo development (bubbling of chorion) for either one or both the South Monmouth and Cape May sewerage effluents when compared to controls. A transplant study was also conducted near the ocean outfall effluent pipe during July and August of 1999 for both sewage treatment plants. The animals that were used in the transplant were the American oyster (*Crassostrea virginica*), juvenile and embryo mummichog fish (*Fundulus heteroclitus*), and the shrimp *Mysidopsis bahia*. A significant increase in the underdevelopment, disintegration and death of mummichog fish (*Fundulus heteroclitus*)embryos was observed near the outfall pipe when compared to a farfield control site for both South Monmouth and Cape May sites. Also, juvenile oyster growth initially significantly ($P \leq 0.2$) increased for the nearfield outfall site when compared to the farfield for the Cape May site, but over 30 days the farfield oysters increase in growth was significantly ($P \leq 0.2$) larger than the nearfield oysters. This may suggest that the effluent may over time inhibit the growth of the oysters by contaminants bioaccumulating or other physical factors such as temperature or salinity changes from the effluent plume.

1553 *RANUNCULUS* SP: INVESTIGATION OF THE POTENTIAL FOR USE OF A TOXIC PLANT IN AMPHIBIAN HABITAT RESTORATION.

J. E. Murphy[1], J. K. Johnson[2], R. B. Cope[1] and V. R. Beasley[1]. [1]*Dept. of Veterinary Biosciences, University of IL, Urbana, IL and* [2]*Dept. of Veterinary Pathobiology, University of IL, Urbana, IL.*

Management strategies to control aquatic vegetation often conflict with the habitat and life cycle requirements of amphibians. The loss of aquatic plants leads to numerous direct and indirect effects upon amphibian populations. We report the results of a study to examine the persistence of two native aquatic plants, water buttercup (*Ranunculus* sp.) and creeping water primrose (*Jussiaea repens*), to grazing by grass carp (*Ctenopharyngodon idella*). These plants offer the potential for restoration of aquatic systems unbalanced by the introduction of grass carp. Water buttercups (buttercups) are a member of the Ranunculacae which produce ranunculin, a vesicant extremely irritating to mucous membranes. To test both the hypothesis that carp would avoid buttercup and creeping water primrose (primrose), we employed a two-part study. In part I, carp were allowed to graze freely on plants placed in the aquaria. In addition to primrose and buttercup, curly pondweed (*Potamogeton crispus*) and duckweed (*Lemna major*) were provided as control plants. Carp were placed in four treatment groups which consisted of the following: carp + buttercup; carp + all plant species except buttercup; carp + all plant species; and carp isolated from all plant species by nylon mesh and fed trout chow. Pondweed and duckweed were readily consumed, while both primrose and buttercup were avoided, even when buttercup was the sole source of food. In part II we delivered a filtrate of blended primrose, buttercup or pelleted food, by gavage, to the pharynx and esophagus. Carp were allowed to digest the material overnight, killed by immersion in MS222, and tissues were fixed in 10% NBF and routinely processed for histopathology. Eight of nine carp in the buttercup group manifested significant lesions characterized by effects on mucosal epithelial cells including granular clumping of cytoplasm, pyknosis, karyorrhexis and loss. These results are consistent with the proposal that buttercup and primrose can be used to enhance habitat complexity in the presence of grass carp.

1554 DETERMINATION OF CORRELATION COEFFICIENTS FOR AQUATIC TOXICITY DATABASE ENDPOINTS.

E. L. Puglielli Freeman, L. M. Milchak and T. A. Dobson. *ChemADVISOR, Inc., Pittsburgh, PA.*

An Ecotoxicity list in the LOLI(R) for Windows database has been developed to provide a standardized resource of aquatic toxicity data for use in ecological risk assessment, environmental health and safety, and hazardous chemical evaluation. This dynamic list is comprised of data derived from a large amount of acute toxicity testing conducted on freshwater aquatic species for over 600 commonly used industrial chemicals. An investigation was undertaken to determine if a correlation exists between the data obtained from toxicity testing of varying species of freshwater fish [fathead minnow (n=79), rainbow trout (n=54), and bluegill (n=51)], water flea (n=51), freshwater algae (n=15) and Photobacterium phosphoreum Microtox test outcomes. The correlation coefficients included in this abstract are calculated from the data obtained in the Ecotoxicity list comprised of approximately 600 chemicals. The r values for Photobacterium phosphoreum and the comparative species follow: fathead minnow (r=0.722), rainbow trout (r=0.643), bluegill (r=0.645), water flea (r=0.513), and algae (r=0.600). The results of our statistical analyses concluded that positive correlations do exist between Photobacterium phosphoreum and all of the species tested, with the strongest positive correlation between fathead minnow data and Photobacterium phosphoreum. This may be due to the differences in availability of data for the other test parameters (n values), the susceptibility of the other species to the chemicals, and/or the susceptibility of the other species to test conditions (duration of test, method of test, age of organism, pH, water hardness, and temperature).

1555 SYSTEMIC BIOCHEMICAL EFFECTS IN CATTLE EXPOSED TO REPEAT LOW DOSAGES OF A PETROLEUM CRUDE OIL AND DIESEL.

A. A. Khan[1], R. W. Coppock[1], M. M. Schuler[1], M. N. Hiltz[1] and M. S. Mostrom[2]. [1]*Alberta Research Council, Vegreville, Alberta, Canada and* [2]*Mostrom Veterinary Clinic, Manly, IA.*

In Alberta, Canada, the proximity of some oil-field operations to land used for cattle pasture has raised concerns that long-term exposures to operational contaminants are deleterious to cattle health. In this investigation, we have probed in cattle the systemic effects of an Alberta crude oil (ACO) and a commercial diesel fuel (CDF) on biochemical components responsible for xenobiotic metabolism. Cattle were dosed on day 0, 14, 28, and 42 with either water (control) at 10 mL/kg, or CDF at 5 mL/kg, or ACO at 2.5, 5 and 10 mL/kg. Animals were killed on day 56, and liver, kidneys and lungs were analyzed for biochemical activities. Cattle exposed to ACO and CDF showed a significant, dose-dependent increase as compared to the control animals in the activity of aryl hydrocarbon hydroxylase (AHH) in kidneys (2.5- to 8-fold) and lungs (2- to 10-fold). Among the other biochemical components, the activity of ethoxyresorufin-O-deethylase (EROD) was also markedly higher (2.5-fold) in lungs of CDF and ACO treated cattle than the control cattle. Although the frequency of higher activities than average values of the control group was found to be more in livers of CDF and ACO exposed groups for several biochemical components (e.g., cytochrome P-450, AHH, EROD), the treatment effects were masked due to biological variations between animals. Evaluation of hepatic AHH activity with inhibitory probes showed a different response pattern in ACO and CDF treated cattle as compared to control animals, suggesting alterations in the composition of cytochrome P-450 isoforms.

1556 ESTROGEN-INDEPEDENT EFFECTS OF ATRAZINE(ATR) ON MAMMARY GLAND(MG) DEVELOPMENT IN RATS.

S. N. Greiner, G. L. Youngblood and S. E. Fenton. *EB, RTD, USEPA, Research Triangle Park, NC.* Sponsor: R. J. Kavlock.

Because of its widespead use as a herbicide and its ability to induce MG tumors in rats, the effect of ATR on pubertal MG development was examined in Long-Evans hooded rats. On postnatal day (PND) 22, rats were either ovariectomized (OVX) (N=27) OR SHAM OPERATED (N=18). Beginning on PND26, ten OVX and 10 sham rats were gavaged with ATR (100 mg/kg/day). The remaining rats (9 vehicle, 10 ATR) were injected with estradiol (E, 10 µg/day, s.c.) and progesterone (P,10,g/day) for 7 days. All other animals received sesame oil only. During this 121 day treatement period, the animals were examined for vaginal opening (VO). Females were killed on PND 37, trunk blood collected, pituitaries and MG removed for histology. Sham rats dosed with ATR had delayed VO (con=PND33 vs. ATR=PND35). While, VO was absent in OVX rats, there was no difference in the age of VO in control or ATR OVX rats receiving E+P. ATR-treated rats had smaller pituitaries (both sham-ATR and OVX & E+P-ATR), decreased pituitary and serum prolatin, and decreased serum LH. The MGs of the ATR-sham rats had decreased lateral branching, puberty-induced lobul formation, and retained more terminal end structures than untreated controls. In the E+P-ATR OVX rats, decreased branching (less dense lobule formation) and more persistent terminal end structures were still evident. These data suggest that ATR decreases puberty-induced MG development by altering normal pituitary functions. (This abstract does not reflect EPA policy).

1557 ANTIOXIDANT PRETREATMENT PREVENTS SEIZURE-INDUCED LOSS OF CYTOCHROME C OXIDASE AND HIGH-ENERGY PHOSPHATES DEPLETION IN BRAIN REGIONS OF RAT.

W. D. Dettbarn[1], D. Milatovic[1] and R. C. Gupta[2]. [1]*Vanderbilt University, Nashville, TN and* [2]*Murray State University, Hopkinsville, KY.*

Cytochrome c oxidase (CO) of mitochondria is responsible for electron transport and oxidative phosphorylation yielding ATP. A reduced capacity of this enzyme can cause incomplete reduction of oxygen which leads to an increased production of reactive oxygen species (ROS). We have examined changes in CO activity and high-energy phosphates in brain regions of rats following kainic acid (KA, 15 mg/kg, sc)-induced status epilepticus (SE). With the onset of seizures, CO activity in amygdala (0.533 µmole/min/mg protein), hippocampus (0.514 µmole/min/mg protein) and frontal cortex (0.569 µmole/min/ mg protein) increased up to 140% of control during the first hour of SE, while ATP and posphocreatine (PCr) were significantly reduced to 34%-55% of control. Within 3 to 7 days after induced SE, both CO activity and high-energy phosphates values were significantly decreased. Pretreatment with the spin trapping agent N-*tert*-butyl-α-phenylnitrone (PBN, 200 mg/kg, ip) or the antioxidant vitamin-E (100 mg/kg, ip) prevented KA-induced decline in high-energy phosphates and significantly attenuated the reduction of CO activity in amygdala and hippocampus. These findings support the suggestion that SE-induced neuronal injury within these brain regions may be linked to excessive generation of ROS. (Supported by NIH Grant, ES04597.)

1558 PROTECTION BY ANTIOXIDANTS AGAINST DEPLETION OF HIGH-ENERGY PHOSPHATES IN RAT BRAIN REGIONS FOLLOWING CARBOFURAN-INDUCED SEIZURES.

R. C. Gupta[1], D. Milatovic[2] and W. D. Dettbarn[2]. [1]*Murray State University, Hopkinsville, KY and* [2]*Vanderbilt University, Nashville, TN.*

The effects of the carbamate carbofuran (CF, 1.25 mg/kg, sc) induced status epilepticus (SE) were studied on high-energy phosphates in cortex, amygdala and hippocampus of rats sacrificed by head-focused microwave. Control values of ATP, ADP, AMP, PCr and Cr were significantly higher in cortex (25-35%) than in amygdala or hippocampus. Within 1 hr following CF administration, at a time when AChE was maximally inhibited (75%), the induced brain hyperactivity caused a marked decline in these determinants (ATP, 33-49%; and PCr, 25-50%). Total adenine nucleotides (TAN) and total creatine compounds (TCC) were also reduced (TAN, 28-32%; and TCC, 26-29%). Adenylate energy charge, an indicator of high-energy phosphate bond availability, remained unchanged. Three days after the onset of SE, recovery was seen in the amygdala and hippocampus, but not in the cortex. Pretreatment of rats with an antioxidant, such as the spin trapping agent N-*tert*-butyl-α-phenylnitrone (PBN, 200 mg/kg, ip), or vitamin-E (100 mg/kg, ip), provided partial protection against CF-induced neurotoxicity and depletion of high-energy phosphates. These results suggest that CF-induced SE, associated with depletion of high-energy phosphates contributes to the generation of radical oxygen species. (Supported by NIH Grant, ES04597.)

1559 ANTIOXIDANTS PREVENT DEPLETION OF HIGH-ENERGY PHOSPHATES ASSOCIATED WITH *STATUS EPILEPTICUS* IN BRAIN REGIONS OF RAT.

D. Milatovic[1], R. C. Gupta[2] and W. D. Dettbarn[1]. [1]*Vanderbilt University, Nashville, TN and* [2]*Murray State University, Hopkinsville, KY.*

Systemic injection of the excitatory amino acid, kainic acid (KA, 15 mg/kg, sc) or the anticholinesterase diisopropylphosphorofluoridate (DFP, 1.3 mg/kg, sc) induced status epilepticus (SE) causing depletion of high-energy phosphates in brain regions of rats sacrificed by head-focused microwave. Control values of ATP and phosphocreatine (PCr) were significantly higher in cortex (2.50 and 11.02 µmol/g, respectively) than in amygdala (1.72 and 8.48 µmol/g) or hippocampus (1.77 and 7.46 µmol/g). A significant decline in ATP and PCr was seen as early as 1 hour following KA- or DFP-induced SE. Three days after KA- or DFP-induced SE, levels of ATP remained decreased in amygdala (45% or 84%) and cortex (56% or 49%) while hippocampus values returned to normal. Pretreatment with the spin trapping agent N-*tert*-butyl-α-phenylnitrone (PBN, 200 mg/kg, ip) prevented seizures and protected high-energy phosphates levels depleted by DFP but not by KA. Pretreatment with the antioxidant vitamin E (100 mg/kg, ip), afforded protection for ATP and PCr in amygdala and hippocampus of both KA- and DFP-induced seizures groups. These results suggest that SE-induced depletion of high-energy phosphates caused by KA are in part protected by antioxidants such as vitamin E and PBN. PBN prevented DFP-induced SE and associated ATP and PCr changes by protecting AChE from critical inhibition. (Supported by NIH Grant, ES04597.)

1560 THE CORNEAL EFFECTS OF 2-(2-NITRO-4-TRIFLUOROMETHYLBENZOYL)-CYCLOHEXANE 1,3-DIONE (NTBC) IN THE RAT.

M. Robinson and M. Provan. *AstraZeneca, Macclesfield, United Kingdom.* Sponsor: L. L. Smith.

NTBC is a triketone used for the treatment of tyrosinaemia type 1. Rats dosed with NTBC at 2-40mg/kg/day by oral gavage daily develop corneal lesions. By ophthalmoscopy the corneal changes ranged from hazy or complete areas of opacity 1mm diameter or affecting the whole corneal surface. Some eyes showed vascularisation of the cornea. The earliest histopathological lesion

was a focal disorganisation of the corneal epithelium. This was rapidly followed by inflammatory changes until a well developed keratitis was seen. After 14 weeks of dosing some rats were dosed vehicle only until week 21 to represent a recovery phase. At week 21 the eyes of these rats showed a marked reversal of the lesions. The ophthalmoscopic and histopathological features closely resemble those when rats are dosed orally with 5% L-tyrosine in a low protein diet. Previous work has shown that NTBC inhibits 4-hydroxyphenylpyruvate deoxygenase, the second enzyme in the catabolic pathway of tyrosine, and an increase in plasma tyrosine has been demonstrated after dosing rats with NTBC.It is concluded that the corneal lesions of NTBC in the rat are a result of increased plasma levels of tyrosine.

1561 THE EFFECT OF 2-(2-NITRO-4-TRIFLUOROMETHYLBENZOYL)-CYCLOHEXANE-1,3-DIONE (NTBC) ON TYROSINE CATABOLISM IN THE MOUSE.

E. A. Lock[1], P. Gaskin[1], M. K. Ellis[2], W. M. Provan[1], M. Robinson[1] and L. L. Smith[1]. [1]*AstraZeneca Central Toxicology Laboratory, Alderley Park, Macclesfield, United Kingdom and* [2]*Zeneca Agrochemicals, Fernhurst, Haslemere, United Kingdom.*

NTBC is a drug used to treat a rare inborn error of tyrosine metabolism, tyrosinaemia type 1. In the rat, NTBC inhibits hepatic 4-hydroxyphenylpyruvate dioxygenase (HPPD), producing a marked tyrosinaemia which results in injury to the cornea of the eye. We report studies in the mouse where we have examined the effect of NTBC on hepatic HPPD, the extent of tyrosinaemia and whether cornea injury occurs. Administration of a single oral dose of NTBC to mice increased the concentration of tyrosine in the plasma and aqueous humour of the eye. The tyrosinaemia was both time and dose-dependent with a single dose of 10 mg/kg NTBC producing maximal concentrations of tyrosine in plasma of about 1,200 nmol/ml and in aqueous humour of about 2,200nmol/ml 16h after dosing. Analysis of the key hepatic enzymes involved in tyrosine catabolism, following a single dose of 10mg/kg NTBC, showed that HPPD was markedly inhibited soon after dosing and that the activity recovered very slowly. In response to the tyrosinaemia, the activity of hepatic tyrosine aminotransferase was induced about 2-fold, while the activity of hepatic homogentisic acid oxidase was reduced at 4 and 5 days after dosing. Daily oral administration of NTBC at doses up to 160mg/kg/day NTBC/kg to mice produced a maximal tyrosinaemia of about 600-700nmol/ml plasma, showing some adaptation relative to a single dose. Unlike the rat, no treatment-related corneal lesions of the eye were seen at any dose levels up to 6 weeks. Our studies show that NTBC is a potent inhibitor of mouse liver HPPD, which following repeat exposure produces a marked and persistent tyrosinaemia, which does not result in ocular toxicity.

1562 MESOTRIONE: THE RELEVANCE OF TYROSINE IN MAMMALIAN TOXICITY.

M. Provan, J. W. Botham, M. Robinson, R. W. Lewis, J. E. Doe and E. A. Lock. *AstraZeneca, Macclesfield, United Kingdom.*

Mesotrione is a triketone developed for use as a herbicide in corn with 4-hydroxyphenylpyruvate dioxygenase (HPPD) inhibition as the sole mode of action in plants and animals. Administration of mesotrione to rats causes a marked increase in plasma tyrosine. The consequence of this increase is a range of toxicities in subchronic, chronic and reproductive studies in the rat. The purpose of this presentation is to provide evidence that all of these toxicities are produced by elevated plasma tyrosine and are not direct effects of mesotrione administration. The dose response profile of plasma tyrosine closely matches that for HPPD inhibition and also the toxicity dose response for a wide range of endpoints in the rat. Conversely the dose response profile for the chemical in plasma is very different to the above profile and is linear over a wide range of doses. For a large number of HPPD inhibiting triketones of different chemical structures the incidence of one of the toxic endpoints in the rat - corneal opacity - closely correlates with the maximal steady state plasma tyrosine levels measured for each chemical structure. Furthermore, a range of toxicities of mesotrione in the rat were either induced by tyrosine administration alone without the presence of mesotrione or could be markedly exacerbated by co-administration of exogenous tyrosine with mesotrione. This work provides both direct and indirect evidence that the toxicity of mesotrione in the rat is mediated by the amino acid tyrosine.

1563 THE BIOCHEMICAL RESPONSE OF HUMANS TO THE TRIKETONES MESOTRIONE AND NTBC.

M. G. Hall, M. Provan, M. Robinson, J. W. Botham, J. E. Doe, R. W. Lewis and L. L. Smith. *AstraZeneca, Macclesfield, United Kingdom.*

Mesotrione is a triketone developed as a herbicide in corn. NTBC is a structurally related triketone developed as a drug in the treatment of hereditary tyrosinemia type I in humans. The sole biochemical mode of action of these chemicals is identical in both plants and animals and is the specific inhibition of the enzyme 4-hydroxyphenylpyruvate dixygenase (HPPD). The consequence of this inhibition in mammals is an increase in plasma tyrosine concentration. The extent of this tyrosinemia across different mammalian species is determined by the innate activity of the hepatic enzyme tyrosine aminotransferase (TAT). Both HPPD and TAT are enzymes in the catabolic cascade of tyrosine. The purpose of this presentation is to report the biochemical changes in tyrosine catabolism associated with administration of these chemicals to humans and to suggest the relevance of this information in the human risk assessment of mesotrione. TAT activities were measured in rats and mice and compared with the reported levels in humans. The results of the clinical use of NTBC in the treatment of hereditary tyrosinemia type I were reviewed and compared with the results obtained in human healthy male volunteer studies with NTBC and Mesotrione. TAT activities differed across species. The activities in mice and humans are similar and up to 4-fold greater than those levels detected in rats. In patients treated with the drug NTBC the levels of steady state plasma tyrosine does not exceed 800nmol/ml - the level similar to that seen in mice treated with the herbicide mesotrione. In rats similar treatment with mesotrione induces much higher levels of plasma tyrosine at steady state. Human volunteer studies with NTBC and mesotrione have shown NTBC to be 1000-fold more potent in terms of the dose levels required to induce tyrosinemia than the herbicide mesotrione. Even so, the extent of the tyrosinemia following NTBC administration did not exceed 800nmol/ml at steady state. The results indicate that due to the innate levels of TAT, mice and humans respond similarly to HPPD inhibiting triketones and the rat responds differently with much greater levels of plasma tyrosine being achieved at steady state. These biochemical data are important in the extrapolation of toxicology data in experimental animals to man and show that the mouse is the more relevant species for human risk assessment.

1564 THE REGULATORY TOXICOLOGY OF MESOTRIONE: IDENTIFICATION OF THE MOST RELEVANT ANIMAL MODEL FOR HUMAN RISK ASSESSMENT.

J. W. Botham, M. Provan, R. W. Lewis, M. Robinson, J. E. Doe and L. L. Smith. *AstraZeneca, Macclesfield, United Kingdom.*

In order to properly assess the potential risk to humans, it is a regulatory requirement that all new chemicals including pesticides undergo a thorough evaluation in a battery of toxicology tests. In this way the intrinsic hazard associated with a chemical can be identified. In relating intrinsic hazard as identified in animal models to those effects likely to occur in humans, certain assumptions have to be made; a central assumption is that the effect of a compound observed in an animal model is relevant and can be used to predict possible effects in humans. The purpose of this work is to provide a regulatory compliant animal database recognising, for mesotrione, the relevance of species differences in toxicity to predict effects in humans. To this end a complete toxicological database is provided for mesotrione which has been extended to cover the most relevant animal model, the mouse. Across a range of species, mesotrione causes no significant toxicity in short term studies. The compound is not neurotoxic and is not genotoxic in short term studies both *in vitro* and *in vivo*. Mesotrione is not oncogenic in the mouse or in the rat and is not a repro-toxicant. The specific toxicities of mesotrione in rats which are absent in mice include corneal opacity, reduced litter size, pup survival and pup renal pathology, and increased incidence of spontaneous degenerative pathology in lifetime studies. Other toxicities of mesotrione occur in both species but occur at much lower dose levels in rats. These include liver, kidney and body weight changes in subchronic studies. Potential developmental effects have been investigated in the rat, rabbit and mouse with mesotrione producing no teratogenicity or other significant effects in any species tested. In chronic bioassays in the dog and mouse the material is of low potency. These data show that mechanistic understanding coupled with regulatory toxicology studies in the most relevant species can provide the optimum database for human health risk assessment.

1565 SPECIES DIFFERENCES IN MESOTRIONE-INDUCED TYROSINEMIA.

S. Meadowcroft, M. Provan and M. Robinson. *AstraZeneca, Macclesfield, United Kingdom*. Sponsor: E. A. Lock.

Mesotrione is a triketone herbicide for use in corn with 4-hydroxyphenylpyruvate dioxygenase (HPPD) inhibition as the single mode of action in both plants and animals. In mammals, HPPD is the second enzyme in the catabolic cascade of the amino acid tyrosine. Inhibition of HPPD results in an increase in plasma tyrosine. A range of toxicities associated with exposure to mesotrione occurs in rats but not mice, mediated by tyrosine. The purpose of this presentation is to report the mechanistic basis for the species difference in toxicity. The specific toxicities of mesotrione in rats which are absent in mice include corneal opacity, reduced litter size, pup survival and pup renal pathology, and increased incidence of spontaneous degenerative pathology in lifetime studies. Other toxicities of mesotrione occur in both species but occur at much lower dose levels in rats. These include liver, kidney and body weight changes in subchronic studies. For example, the no effect levels for liver weight increase in 90 day studies were: male rats 1ppm, female rats 7.5ppm and male and female mice 350ppm. Rats and mice have marked differences in the innate activity of hepatic tyrosine aminotransferase (TAT) the rate limiting enzyme in the tyrosine catabolic cascade. This results in marked differences in the maximum achievable steady-state levels of plasma tyrosine. Each toxicity which is shown in the respective species requires a steady-state tyrosine elevation above a particular threshold for that toxicity. Because of the species differences in innate TAT levels and hence maximum achievable steady-state tyrosine levels there are marked differences in the nature and extent of the toxicities exhibited in each species. In conclusion, although the primary biochemical target of mesotrione is hepatic HPPD, it is the innate activity of another catabolic enzyme (TAT) which determines the species specificity in mesotrione toxicity.

1566 SPECIES DIFFERENCE IN DEVELOPMENTAL CHANGES AFTER TREATMENT WITH MESOTRIONE.

R. W. Lewis, M. Provan, M. Robinson, M. E. Moxon and L. L. Smith. *AstraZeneca, Macclesfield, United Kingdom.*

In mammals, the single mechanism of action of mesotrione, a selective herbicide, is inhibition of the hepatic enzyme, 4-hydroxyphenylpyruvate dioxygenase (HPPD). This enzyme is important in the catabolism of the amino acid, tyrosine. The consequence of prolonged inhibition of this enzyme is an increase in plasma tyrosine levels i.e. a tyrosinemia. Following inhibition of HPPD, the maximal extent of any tyrosinemia is controlled by a second hepatic catabolic enzyme, tyrosine aminotransferase, TAT. Rats have relatively low innate activity of TAT and consequently, on exposure to mesotrione, develop a severe tyrosinemia. The purpose of this work was to compare developmental changes in the rat (low TAT, high tyrosinemia) with the rabbit and mouse (high TAT, low plasma tyrosine) after treatment with mesotrione. Time mated female AP rats, New Zealand White rabbits and AP mice received up to 1000, 500 or 600mg/kg/day mesotrione respectively by oral gavage; Prior to parturition animals were killed and their *uteri* examined for live foetuses and *intra-uterine* deaths. The foetuses were weighed, examined for external and visceral abnormalities, sexed, eviscerated and stained for skeletal examination. At high doses of mesotrione there were no teratogenic effects in the rat, the rabbit and the mouse. In the rat and the rabbit noteworthy changes were confined to high dose level i.e. reduced foetal bodyweight, at the limit dose in the rat and a low level of whole litter losses in the rabbit at the high dose levels of 250 and 500 mg/kg/day. There were no noteworthy changes in the mouse at any dose level tested. Following treatment with mesotrione at a range of dose levels in the rat and the rabbit, differences from concurrent control were observed in the number of foetuses showing minor skeletal defects. A marginal difference was also observed in the mouse, but only at the highest dose level tested. All of observed skeletal defects were indicative of a small reduction in ossification or a slight shift in the normal and highly variable pattern of ossification in experimental animals. Such changes do not adversely affect post-natal development as shown in multigeneration reproduction studies in the rat and mouse. The changes show a close relationship in their extent to the different innate levels of tyrosine amino transferase across the three species. The weight of evidence strongly suggests that these changes are tyrosine mediated and are not due to a direct effect of mesotrione. Due to the differences in the innate activation of TAT in different species, the mouse is the more relevant species for human risk assessment.

1567 GROSS ANATOMY AND HISTOPATHOLOGICAL CHANGES FROM CHRONIC EXPOSURE TO 2,4-DICHLOROPHENOXYACETIC ACID IN RATS.

M. H. Kadri[1] and M. Tawfik[2]. [1]*Department of Pathology, Faculty of Veterinary Medicine, Zagazig University, Zagazig, Egypt and* [2]*The Research Institute of Animal Health, Zagazig, Egypt*. Sponsor: D. Acosta, Jr.

Many forms of 2,4-dichlorophenoxyacetic acid(collectively known as 2,4-D) are herbicides used to control a wide variety of broadleaf and woody plants. The herbicides have been used extensively in Egypt and many other countries. This study was designed to evaluate the safety of the commercial formulation of 2,4-D in male and female rats. Animals received 2,4-D orally at a daily dose of 20 ppm for 1,2 and 3 months respectively. Animals were observed for clinical symptoms of toxicity. As early as one month, 2,4-D induced weight loss and slow movement in some of the examined animals. Post-mortem examination revealed the presence of congestion with hemorrhagic spots in liver, kidneys, salivary glands and lungs in addition to pneumonic patches in lungs. The stomach and intestine were congested and mucous exudate in their lumina was present. The heart, spleen, brain, thyroid glands, testes, ovaries, fallopian tube and uterus showed congestion with hemorrhagic spots on their surfaces. However, the severity of the symptoms varied with the exposure time. Histopathological examination indicated the presence of telangiectiasis in liver, congestion and hemorrhage in glomeruli; absence of the granuloma in lung with the presence of perivascular round cell infiltration. Sialoadenitis and necrosis of uterine glands with edema and fibroblastic cell proliferation in the subendometrium were also detected.

1568 EFFECT OF 2-METHYL-4-CHLOROPHENOXYACETIC ACID (MCPA) ON THE PLASMA AUC AND URINARY ELIMINATION OF 2,4-DICHLOROPHENOXYACETIC ACID (2,4-D) IN THE DOG.

L. M. Dickow, D. F. Gerken, R. A. Sams and S. Ashcraft. *Ohio State University College of Veterinary Medicine, Columbus, OH.*

The phenoxy herbicide 2,4-dichlorophenoxyacetic acid (2,4-D) is widely used for post emergent broadleaf weed control, often in combination with other phenoxy compounds. 2,4-D and MCPA have been shown to undergo similar metabolism and are primarily renally excreted in the dog at a substantially slower rate than in other species. The purpose of this study was to investigate the toxicokinetics of 2,4-D alone and in the presence of a second phenoxy herbicide, 2-methyl-4-chlorophenoxyacetic acid (MCPA). Six female beagle dogs were used in a crossover design study consisting of two treatment groups (A and B) of three dogs. Treatment group A received intravenously administered 0.5 mg 2,4-D/kg b.w. Treatment group B received orally administered 5 mg MCPA/kg b.w. followed 12 hours later by intravenously administered 0.5 mg 2,4-D/kg b.w. Blood and urine were collected at various times during 96 hours post administration and frozen until analysis. Plasma and urine 2,4-D and MCPA concentrations were determined using HPLC with fluorescence detection. The area under the plasma 2,4-D concentration-time (AUC) to the last quantitatable concentration-time point was greater in 5 of the 6 dogs following MCPA co-administration when compared to 2,4-D only administration. The percent of administered 2,4-D found in the urine ranged from 18-57% when 2,4-D was administered alone and from 24-44 % when 2,4-D was given after MCPA administration. The amount of 2,4-D excreted in the urine from 0-96 hours post 2,4-D administration following MCPA co-administration was not statistically different from the amount excreted when 2,4-D was administered alone. When 5.0 mg MCPA/kg was orally administered to beagle dogs, no statistically significant changes in the plasma AUC or urinary elimination of 2,4-D were observed.

1569 EVALUATION OF NEUROTOXICITY OF DIMETHOATE 4E FOLLOWING SHORT-TERM DERMAL EXPOSURE TO SPRAGUE-DAWLEY RATS.

B. H. Neal[1], R. J. Hilaski[2], D. O'Shaughnessy[3], D. Sondergaard[4], M. B. Sonawame[1] and G. J. Schaefer[2]. [1]*JSC, Inc., Arlington, VA,* [2]*MPI Research, Mattawan, MI,* [3]*Cheminova Inc., Wayne, NJ and* [4]*Cheminova Agro A/S, Harbooere, Denmark.*

This study was designed to estimate the no-observed effect level (NOEL) for cholinesterase inhibition and clinical signs following short-term dermal exposure to Dimethoate 4E formulation. Dimethoate 4E (undiluted) was dermally administered (6 hours per day for 5 days) to male and female Sprague-Dawley rats, at doses of 5, 10, 20, 40, and 100 mg active ingredient (ai)/kg/day. A control group received a Blank formulation vehicle. Clinical signs, dermal irrita-

tion, an abbreviated Functional Observational Battery (FOB), and body weights were evaluated. Gross necropsies were conducted and brain weights recorded. Cholinesterase (ChE) activities were evaluated in plasma, erythrocytes, and 3 brain regions (hippocampus, striatum, and cortex) sampled following exposures on Days 3 and 5. There were no treatment-related effects on body weight, brain weights or gross necropsy findings. Dermal irritation in control and dosed groups included desquamation (males and females) and erythema (females only), with a possible dose-relationship for desquamation in males. Clinical signs of ChE inhibition were observed only in four females from the 100 mg ai/kg dose group whose collars came off during the exposure period. Two of the four also showed abnormal findings in the Day 3 FOB. Oral exposure of the four 100 mg ai/kg/day females that lost their collars cannot be excluded. Other FOB observations were unremarkable. The NOEL for clinical signs of toxicity or FOB observations was 100 mg ai/kg/day for males and 40 mg ai/kg/day for females. Dose-related inhibition of ChE activity was seen in this study. The NOEL for ChE inhibition in this study was 40 mg ai/kg/day for males and 10 mg ai/kg/day for females, based on statistically significant inhibition of erythrocyte and regional brain ChE activities at higher dose levels.

1570 DIETHYLDITHIOCARBAMATE CHELATES CATALYZE THE FORMATION OF CATECHOL THIOETHERS.

V. A. Fitsanakis, V. Amarnath, T. J. Montine and D. G. Graham. *Vanderbilt University, Nashville, TN.*

Parkinson's Disease (PD) is currently second to Alzheimer's Disease as the most common neurodegenerative disorder in the United States. Epidemiological studies have repeatedly demonstrated an increased risk for PD associated with pesticide exposure. Particularly prominent in recent studies are the diethyldithiocarbamate (DEDC) family of pesticides, including Maneb and Mancozeb. DEDC complexes have been hypothesized to react with catechols, resulting in oxidative stress. The oxidation of catechols to quinones is followed by reaction with GSH to form catechol thioethers. In these studies, varying concentrations of *N*-acetyl-dopamine and *N*-acetyl-cysteine were incubated together at 37°C for 30 minutes with 50 μM $Mn(DEDC)_2$, $Fe(DEDC)_3$ or $Cu(DEDC)_2$. At various time points, 100 μL of the reaction mixture was removed for HPLC detection of the catechol thioether. Under these conditions, no significant formation of the catechol thioether was observed when either $MnCl_2$, $FeCl_3$, or $Cu(NO_3)_2$, or NaDEDC were added alone. However, the $Mn(DEDC)_2$ and $Fe(DEDC)_3$, but not $Cu(DEDC)_2$, catalyzed the formation of the catechol thioether in a linear manner out to 15 minutes. On the contrary, when 3,4-dihydroxyphenylacetate (DOPAC) was substituted as the catechol, no corresponding thioether was formed under these conditions. These experiments show that $Mn(DEDC)_2$ and $Fe(DEDC)_3$ can catalyze both the depletion of low molecular weight thiols, and the formation of catechol thioethers. (Supported by grants ES02611, AG00774, AG16835, and ES/NS10196.)

1571 DEVELOPMENTAL EXPOSURE TO TRIADIMEFOM: BEHAVIORAL AND DOPAMINERGIC EFFECTS.

C. R. Filbrandt[1], M. Thiruchelvam[1], D. A. Cory-Slechta[1] and B. J. Brockel[2]. [1]*University of Rochester, Rochester, NY and* [2]*Kansas State University, Manhattan, KS.*

Triadimefon (TDF), an antifungal triazole commonly used on fruits, grains and shrubs, has been shown to exert CNS-stimulant effects similar to other known psychomotor stimulants such as amphetamine and methylphenidate in adult rodents. Specifically, TDF targets the dopamine (DA) transporter, blocking DA reuptake. Furthermore, adult exposures have been shown to alter motor activity, stereotypical behaviors, and performance on fixed interval schedules of reinforcement. Little is known, however, about what consequences these stimulant properties could impose on CNS development. Long-Evans male rats were exposed either prenatally, postnatally, or pre- and postnatally to 0, 25, or 50 mg/kg TDF. Prenatal exposure (maternal gavage) occurred from gestational day 6 to 19, and postnatal exposure (i.p.) occurred from postnatal day 4 to 21. DA and DA metabolite levels in the striatum and tyrosine hydroxylase density in striatum and nucleus accumbens were determined at postnatal day 21. The results of these analyses were consistent among all exposure groups. However, locomotor activity on postnatal days 21-23 and 50-52, and response rate on a repeated learning and performance task were significantly lower in the pre- and postnatal 50 mg/kg exposure group compared to controls. These results indicate that developmental exposure to TDF could produce long-term behavioral deficits. It is hypothesized that these effects may be related to changes in DA transporter function. (Supported by ES01247, ES07026, Strong Children's Research Center.)

1572 EFFECTS OF TOXAPHENE ON THE IMMUNE SYSTEM OF CYNOMOLGUS (*MACACA FASCICULARIS*) MONKEYS.

H. Tryphonas, D. L. Arnold, F. Bryce, J. Huang, M. Hodgen, D. T. Ladouceur, S. Fernie, S. Hayward and V. Liston. *Department of Health, Government of Canada, Ottawa, Ontario, Canada.*

The immunotoxic effects of toxaphene were investigated in female and male Cynomolgus monkeys. Toxaphene, in glycerol/corn oil, was administered in gelatin capsules at 0.1, 0.4 or 0.8 mg/kg b.w./day seven days/week to 10 healthy young adult female cynomolgus/group while a group of 5 male monkeys received 0.8 mg/kg b.w./day. Control male (5 monkeys/group) and female (10 monkeys/group) ingested glycerol/corn oil only. Testing for immune effects was initiated at 34 weeks of treatment. Statistically significant treatment-related effects included: a trend towards reduced primary and secondary anti-sheep red blood cell (SRBC) titres for immunoglobulin (Ig) M across all post-immunization dates and IgG for days 14 ($p=0.243$) and 21 post immunization in treated females ($p<0.05$); reduced (primary) anti-SRBC titers in treated males ($p<0.05$); a trend towards lower anti-tetanus toxoid titres in treated females for days 14, 21 and 28 post immunization ($p<0.05$) and a trend towards reduced T helper/inducer:T suppressor/cytotoxic cell ratio ($CD4^+$:$CD8^+$) due to reduced $\%CD8^-$ and increased $\%CD4^+$ with increasing dose ($p<0.05$). Increased NK cell activity was observed in the treated males ($p<0.05$). The differences between control and treated groups were not statistically significant for the following parameters: Lymphocyte transformation following mitogen stimulation, delayed type hypersensitivity response, antibody titers to pneumococcus antigens and cortisol levels. Based on pairwise comparisons between the treated and control monkeys the no effect level for adverse immunologic effects was 0.1 mg/kg b.w./day for female and below the 0.8 mg/kg b.w./day level for male monkeys.

1573 TOXAPHENE IS ANTIESTROGENIC IN A HUMAN BREAST-CANCER CELL ASSAY.

J. F. Gierthy[1], K. F. Arcaro[2], Y. Yang[1] and D. D. Vakharia[1]. [1]*Wadsworth Center, NYSDOH, Albany, NY and* [2]*School of Public Health, University at Albany, Albany, NY.* Sponsor: L. S. Kaminsky.

Toxaphene, a complex mixture of chlorinated bornanes, bornenes, and bornadienes, was a heavily used insecticide in the US until its use was restricted in 1982. There are conflicting reports regarding the potential for toxaphene to induce estrogenic responses in human and animals. Therefore we examined the estrogenicity of toxaphene in a human breast-cancer cell assay, the MCF-7 focus assay, which is based on *in vitro* postconfluent cell proliferation and tissue restructuring. Toxaphene was also tested for its ability to bind the estrogen receptor (ER) and to alter the catabolism of E_2 in MCF-7 cell cultures. Results from the MCF-7 focus assay showed that toxaphene alone and in binary combinations with other pesticides was not estrogenic between the concentrations of 0.5 nM and 10 μM, but rather that toxaphene was weakly antiestrogenic (it reduced the number of foci induced by 0.01 and 0.1 nM E_2 by 40 - 50%). Results from the mechanistic studies showed that 1) toxaphene alone or in binary combinations with other pesticides did not bind rhER or ER in MCF-7 cells, 2) toxaphene did not alter the growth rate of MCF-7 cell cultures over 13 days, and 3) toxaphene did not alter the catabolism of E_2. In conclusion, results from the MCF-7 focus assay demonstrate that toxaphene is weakly antiestrogenic rather than estrogenic. (Supported by NIH ES04913.)

1574 *IN VIVO* PROMOTING POTENCY OF TECHNICAL TOXAPHENE, UV-IRRADIATED TOXAPHENE, AND WEATHERED TOXAPHENE.

H. T. Besselink[1], E. Nixon[2], B. McHugh[2], J. Klungsoyr[3] and A. Brouwer[1]. [1]*Institute for Environmental Studies - Free University, Amsterdam, Netherlands,* [2]*Fisheries Research Centre, Dublin, Ireland and* [3]*Institute for Marine Research, Bergen, Norway.*

The pesticide toxaphene has been classified as possible carcinogenic to humans. Human exposure mainly occurs through the consumption of toxaphene contaminated fish. Due to weathering and biotransformation, the bornane composition of technical toxaphene (TT) differs from the bornane composition in consumption fish. Therefore information on the carcinogenicity and general toxicology of weathered and biotransformed TT would be of major interest. To mimic the weathered toxaphene found in fish, we developed a so-called 'realistic exposure' procedure for toxaphene. This procedure makes use of cod that were exposed to TT. Toxaphene residues that were extracted from cod liver (CLE), were then used in an *in vivo* exposure study with rats to obtain information on its tumor promoting potency. Besides CLE,

we also studied the tumor promoting properties of UV-irradiated toxaphene (UVT) and TT. The carcinogenic potency of CLE, TT and UVT was studied using a medium-term two stage promotion assay, measuring the development of altered hepatic glutathione S-transferase (GST-p) positive foci. In short, 2/3 hepatectomy was performed on female Sprague Dawley rats, ± 6 weeks of age, followed by a single i.p. NDEA injection. Starting 5 weeks after partial hepatectomy, rats were dosed weekly with CLE, TT, or UVT (0.46-12.5, 0.67-18, and 0.33-9 mg/kg/week respectively) by s.c. injection, using corn oil as a carrier. Control animals received corn oil only whereas TCDD (1 mg/kg/week) was administered as positive control. No effect on body and liver weight gain was observed in rats treated either with CLE, TT, UVT, or TCDD. In addition, no liver damage was observed as measured by plasma ALT and AST levels. Moderate induction of GST-p positive foci were observed in livers of TT and UVT exposed rats as compared to TCDD exposed rats. Development of altered hepatic GST-p positive foci in CLE exposed rats is currently under investigation. This new toxicological information may have its consequences for tolerance levels of toxaphene in fish consumption. (This study was supported by a grant from the European Commission [FAIR CT PL.96.3131].)

1575 *IN VITRO* GENOTOXICITY AND TUMOR PROMOTING POTENCY OF TECHNICAL TOXAPHENE, UV- IRRADIATED TOXAPHENE, AND WEATHERED TOXAPHENE.

A. Brouwer[1], E. Nixon[2], B. McHugh[2], J. Klungsoyr[3] and H. T. Besselink[1]. [1]*Institute for Environmental Studies - Free University, Amsterdam, Netherlands,* [2]*Fisheries Research Centre, Dublin, Ireland and* [3]*Institue for Marine Research, Bergen, Norway.*

Toxaphene, a complex mixture of polychlorinated camphenes, has been used extensively as a pesticide. Due to its lipophilic, persistent, and volatile nature, toxaphene has become widespread globally. Reports on the mutagenic and carcinogenic properties of toxaphene in mammalian test systems, have led to the assumption that toxaphene poses a serious thread to humans. However, data on the risk for humans associated with toxaphene exposure is scanty. Since exposure of humans mainly occurs through consumption of contaminated fish, we studied the *in vitro* genotoxicity and tumor promoting potency of toxaphene residues extracted from contaminated cod (CLE), in addition to technical toxaphene (TT) and uv-irradiated toxaphene (UVT).Weathered toxaphene was obtained by feeding cod toxaphene spiked diets after which livers were collected and extracted for toxaphene residues. Direct as well as indirect genotoxicity was studied employing the umu-assay. The *in vitro* tumor promoting potency was studied by means of inhibition of gap junctional intercellular communication. Hepa 1c1c7 cells were allowed to grow in small disks for 48 hrs after which a small amount of lucifer yellow was injected into single cells and the number of communicating cells counted. 0-24 hrs prior to injection of lucifer yellow, growing medium was replaced by exposure medium spiked with CLE (1-10 mg/ml), UVT or TT (0.5-5, and 1-10 mg/ml respectively). Preliminary results indicate that TT as well as UVT and CLE are only slightly genotoxic in the presence or absence of S9 mix. TT, UVT and CLE already inhibited GJIC after 0.5 hrs up to 50%. After 6 hrs of exposure, GJIC was restored to 80% in the presence of TT and UVT, but not CLE. The highest concentrations of TT, UVT and CLE inhibited GJIC by 60, 20 and 40% respectively after 24 hrs of exposure. These results emphasize the possible risk for humans of consumption of toxaphene contaminated fish.This study was granted by the Europian Community (FAIR CT PL.96.3131).

1576 THE INSECTICIDE DPX-MP062 AND ITS METABOLITE DCJW BLOCK SODIUM CHANNELS IN MAMMALIAN NEURONS.

X. Zhao, K. Nagata, J. Z. Yeh and T. Narahashi. *Northwestern University Medical School, Chicago, IL.*

DCJW, a metabolite of an oxadiazine insecticide DPX-MP062, is known to block compound action potentials in insect nerve preparations at submicromolar concentrations and to cause a concentration-dependent inhibition of Na^+ currents in cultured insect neurons. However, little is known about the effects of these compounds on the Na^+ channels of mammalian neurons. We compared the effects of DPX-MP062 and DCJW on tetrodotoxin-sensitive Na^+ channels in rat dorsal root ganglion neurons by using the whole-cell patch clamp technique. DPX-MP062 and DCJW blocked Na^+ channels in a voltage-dependent manner. At a holding potential of -80 mV, DPX-MP062 at 1 μM suppressed the Na^+ current by 52%, whereas no suppression occurred at -100 mV. Surprisingly, DCJW at 1 μM was more potent than DPX-MP062 suppressing the Na^+ current by 85% and 50% at holding potentials of -80 mV and -100 mV, respectively. The analysis of the Na^+ channel inactivation curve clearly indicated that both agents shifted the fast and slow inactivation curves in the hyperpolarizing direction resulting in an enhanced block at more depolarized holding potentials. DCJW had an additional blocking mechanism, which contributed to the more potent blocking action of the metabolite. Thus, DCJW is more potent than DPX-MP062 in blocking the mammalian Na^+ channel, and is less potent in blocking mammalian Na^+ channels than insect Na^+ channels. (Supported by NIH grant NS14143.)

1577 ACUTE FISH TOXICITY OF PHOSPHOROTHIONATE-ESTERS DUE TO TWO INDEPENDENT TOXIC EFFECTS ON THE NERVOUS SYSTEM.

A. P. Freidig and J. L. M. Hermens. *Research Institute of Toxicology, Utrecht University, Utrecht, Netherlands.* Sponsor: M. vandenBerg.

Toxicity of organophosphorus(OP)-esters in fish is generally attributed to their ability to inhibit acetyl-cholinesterase (AChE). For phosphorothionates, metabolic activation to the oxon-analog is required to form the active inhibitor. However, for a test set of 20 phosphorothionates, the measured in-vitro inhibition rates of AChE by the oxon-analogs did not correlate with the observed acute toxicity of the parent compound in guppy (p. reticulata). To understand the mechanism of acute toxicity we tested whether narcosis (general anesthesia), being a second plausible mode of action, governs the acute toxicity of some of the compounds in the test set. Narcosis potency at observed lethal exposure levels was modeled with a critical body burden approach. Nine out of 20 OP-esters in the test set were thereby identified as possible narcotic compounds. For the 11 remaining, non-narcotic compounds a good correlation between acute toxicity and measured in-vitro AChE inhibition rate was found (r^2=0.68). Thus, the interpretation of acute toxicity data of fish may be improved by effect-based clustering of test set chemicals. This is an alternative to the more often used structure-based clustering.

1578 MALE REPRODUCTIVE FUNCTION AND ENDOCRINE PROFILE IN MEXICAN PEASANTS EXPOSED TO P,P'-DICHLORODIPHENYL DICHLOROETHYLENE (P,P'-DDE).

P. Ayotte[1], S. Giroux[1], M. Hernandez-Avila[2], I. Romieu[3], J. P. Weber[4] and É. Dewailly[1]. [1]*Public Health Research Unit, Laval University Medical Research Center, CHUQ, Beauport, Quebec, Canada,* [2]*Instituto Nacional de Salud Publica, Cuernavaca, Mexico,* [3]*Pan American Health Organization, Washington, DC and* [4]*Quebec Toxicology Center, CHUQ, Ste-Foy, Quebec, Canada.*

DDT has been banned during the 1970's in developed countries but is still being used in the developing world for agriculture and malaria control. The main metabolite of p,p'-DDT, p,p'-DDE, is a potent anti-androgen that was shown to affect male reproductive function in rodents. We conducted a pilot cross-sectional study to evaluate possible relationships between p,p'-DDE body burden, androgen status and male reproductive function in a group of 24 peasants (mean age=21 years; range=16-28) from the Chiapas region (Mexico). After informed consent was obtained, a blood sample was collected from each individual from a cubital vein, centrifuged and the serum analyzed for organochlorines by high-resolution gas chromatography with electron capture detectors. Testosterone (total and bioavailable), sex-hormone binding globulin (SHBG), LH and FSH concentrations were also determined in serum samples using ELISA or RIA assays. Sperm quality was assessed in 21 participants using standard andrological tests. Mean p,p'-DDE concentration in serum lipids was 69.7 mg/kg (range=0.6-177.2). Simple correlation analyses (Spearman correlation coefficient) revealed that p,p'-DDE concentration was positively correlated to serum SHBG concentration (r=0.484; p=0.02) and negatively correlated to the bioavailable/total testosterone ratio (r=-0.572; p=0.003). Mean sperm density averaged 146 millions/ml (range=10-650) and sperm volume 2.1 ml (range=0.7-5.0). p,p'-DDE concentration was inversely correlated to both sperm volume (r=-0.450; p=0.04) and sperm density (r=-0.421; p=0.06). These results suggest that p,p'-DDE body burden in this group of young men may alter male hormone status and decrease sperm quality.

1579 TOXICOKINETICS OF METHYL PARATHION AFTER DIFFERENT ROUTES OF EXPOSURE.

R. C. Baker, D. B. Couch, J. M. Farley, A. S. Hume, R. E. Kramer, R. W. Rockhold, S. E. Wellman and I. K. Ho. *University of Mississippi Medical Center, Jackson, MS.*

Methyl parathion became a public health concern with its illegal use in private homes. Yet, there are limited data with which to predict the long-term health effects resulting from a pattern of exposure such as occurs in a domestic setting. The objective of these studies was to compare the toxicokinetics of methyl parathion in adult female rats following intravenous, oral and dermal exposure. The toxicokinetics of methyl parathion after intravenous exposure (2.5 mg/kg) best fit a model in which it was distributed between multiple compartments and rapidly eliminated ($T^1/_2$ ~1.5 h). The toxicokinetics of methyl parathion after single oral exposure (2.5 mg/kg) contrasted with those after intravenous exposure. First, methyl parathion concentrations in blood were ≤2% of those after intravenous exposure. Second, there was no discernible peak in blood methyl parathion concentrations. These data indicate a significant 'first pass' effect. After single dermal exposure (25 mg/kg), blood methyl parathion levels increased during the first 6 h and then remained constant for the next 42 h. Levels of methyl parathion in blood after dermal exposure were comparable to those after oral exposure. Despite differences in toxicokinetics and maximal blood concentrations, time-dependent changes in blood cholinesterase activity following intravenous or oral exposure to methyl parathion were similar. A maximal inhibition of 70-80% occurred within 15-30 minutes, and activity recovered within 30 to 48 h. In contrast, after a single dermal exposure (25 mg/kg) to methyl parathion, blood cholinesterase activity declined to a minimum by 21-24 h that was sustained. Repeated dermal exposure to a smaller dose (1 mg/kg/day) of methyl parathion also caused a sustained decrease in blood cholinesterase activity. These data indicate that the toxicokinetics and toxicodynamics of methyl parathion are complex, and the complexity of the model varies with route of exposure. These data also suggest that repeated dermal exposure to methyl parathion, as occurred with the illegal spraying of private homes and businesses, exacerbates its toxicity and increases the potential for long-term adverse health effects. (Supported by ATSDR Grant U50/ATU486513-01.)

1580 RECOVERY OF BLOOD CHOLINESTERASE ACTIVITY AFTER ORAL AND DERMAL EXPOSURE TO METHYL PARATHION.

J. K. Smith, R. C. Baker, C. S. Berry, I. K. Ho, R. E. Kramer, A. E. Lister, M. M. Mumtaz, R. W. Rockhold and J. M. Farley. *University of Mississippi Medical Center, Jackson, MS.*

Methyl parathion is an organophosphate insecticide which has been used inappropriately to rid private residences of pests. Methyl parathion is bioactivated to methyl paraoxon, and the covalent attachment of methyl paraoxon to the active site of acetylcholinesterase causes inhibition of the enzyme. In the present study, the time-dependent action of oral (2.5 mg/kg) and dermal (25 or 50 mg/kg) administration of methyl parathion on the activity of blood cholinesterase of female Harlan Sprague Dawley rats was examined. Femorally-cannulated rats were given a single dose of methyl parathion, and blood samples were collected over the next 48 h. All samples were diluted immediately in heparinized saline and kept at 0-4°C prior to measurement of cholinesterase activity. After oral gavage, cholinesterase activity decreased by 70-80% within 15 min, but recovered completely 48 h after dosing the animals. In the presence of the butyrylcholinesterase inhibitor Iso-OMPA total cholinesterase activity was decreased, but there was no change in the onset of inhibition or recovery of enzyme activity. In dermally exposed rats, inhibition of cholinesterase activity in the blood was not dose-dependent at 25 or 50 mg/kg, developed more slowly than the inhibition observed after gavage and showed no recovery 48 h after dermal exposure. In blood collected 30 min after gavage of methyl parathion, cholinesterase activity recovered spontaneously *in vitro* in a time- and temperature-dependent fashion. In blood allowed to stand at 37°C, recovery was complete within 6 h. In contrast, only slight recovery occurred in blood stored at 4°C for up to 24 h. These preliminary findings suggest major differences in the pharmacokinetics of methyl parathion as a function of route of exposure. Recovery of cholinesterase after oral exposure can be partially explained by spontaneous recovery and suggests a rapid clearance of methyl parathion. On the other hand, the prolonged inhibition of cholinesterase caused by dermal administration suggests the presence of a depot from which the release of methyl parathion and/or its active metabolite is sustained. (Supported by ATSDR Grant U5O/ATU486513-01.)

1581 GENE EXPRESSION IN HUMAN NEUROBLASTOMA CELLS AND IN NERVES FROM HENS EXPOSED TO NEUROPATHIC ORGANOPHOSPHORUS ESTERS (OPS).

G. Schroder, M. Ehrich, D. Barber and B. S. Jortner. *Virginia-Maryland Regional College of Veterinary Medicine, Blacksburg, VA.*

To test the hypothesis that neuropathic OP compounds could cause early expression of gene products, *in vitro* and *in vivo* models of OP-induced delayed neuropathy (OPIDN) were exposed to neuropathy-inducing compounds. For studies in cell culture, SH-SY5Y human neuroblastoma cells exposed to mipafox, 10^{-4} M or PSP 10^{-6} M for 1,2,4,6,8 and 12 hr before examination for expression of hsp72 by western blotting. This stress response protein was expressed in untreated as well as treated cells. The expression was greater after OP exposure, especially at 6 and 8 hr, but the increases were not dramatic and definitive. Data were more difficult to obtain with tissues from hens exposed to a neuropathy-induced OP, phenyl saligenin phosphate (PSP, 2.5 mg/kg) when fresh-frozen spinal cord sections were immunostained for c-fos, c-jun and GFAP. These results suggest that dramatically increased expression of early markers of cell injury are not easily detected in SH-SY5Y cells and hens following acute exposure to neuropathic OP compounds, with these methodologies. (Supported by US EPA R825356.)

1582 QUANTITATION OF LOW DOSE ORGANOPHOSPHATE BINDING IN MURINE BLOOD AND BRAIN.

J. S. Vogel, G. A. Keating, B. A. Buchholz and X. S. Lu. *Lawrence Livermore National Laboratory, Livermore, CA.* Sponsor: B. D. Hammock.

Organophosphate (OP) compounds are a class of commonly used insecticides and are similar to offensive nerve agents. Their principal extracellular targets are soluble plasma esterases and membrane-bound acetylcholinesterase (AChE) on erythrocytes (RBC) and throughout the nervous system. We quantitate persistent [14C]-OP binding to AChE as a probe of chemical synergism at low exposures. We measured the bound levels of 14C-paraoxon (PXN) and 14C-diisopropyl-fluoro-phosphate (DFP) in the plasma, RBC, and brains of CD2F1 mice as functions of time to 1 week after single 100 ng/kg doses, given IP (DFP) and orally in peanut butter (PXN). DFP had an initial blood clearance mean life (t) of 6 hours. Peak protein binding occurs in blood at 24 hours, with RBC containing 5% (on per gram basis) of the plasma 14C levels. Peak brain binding arguably occurs 24 hours later at a level 30% of the RBC peak. OP-AChE complexes in both the brain and RBC show a clearance t>200 hour, significantly longer than the plasma clearance at t=35 hour. Esterase activity assays are inadequate to quantify OP binding at these environmentally relevant doses (<1 μg/kg). Work was performed under the auspices of the U.S. Department of Energy at Lawrence Livermore National Laboratory under contract W-7405-ENG-48.

1583 ORGANOPHOSPHORUS COMPOUNDS INDUCE CASPASE-3 ACTIVATION.

K. Carlson, B. S. Jortner and M. Ehrich. *Virginia-Maryland Regional College of Veterinary Medicine, Blacksburg, VA.*

Organophosphorus (OP) compound exposure *in vitro* elicits a predominantly apoptotic response as evaluated by morphological criteria. The activation of caspase-3, a cysteine-aspartate effector protease, was examined in SH-SY5Y human neuroblastoma cells to assess functional attributes of activated cell death programs. For this, SH-SY5Y cells were exposed to the OP compounds paraoxon, parathion, phenyl saligenin phosphate (PSP), tri-ortho-tolyl phosphate (TOTP), and triphenyl phosphite (TPPi) at 10μM to 1mM for 60 to 4320 minutes. The cells were then fixed, permeabilized, incubated with phycoerythrin conjugated anti-active caspase-3 antibodies, and analyzed on an Epics XL-MCL flow cytometer (ex488nm em575nm). All OP compounds induced time and dose-dependent activation of caspase-3 proteases. Nine hour pretreatment with the caspase-3 inhibitor Ac-DEVD-CHO or the caspase-8 inhibitor Ac-IETD-CHO (25μM) decreased protease activation following parathion and TPPi exposure when compared to OP-only controls. Similar pretreatment with the serine/cysteine protease inhibitor phenylmethylsulfonyl fluoride (PMSF, 1mM) had little effect (parathion) or resulted in increased caspase-3 activation (PSP, TOTP). Thirty hour pretreatment with 500nM cyclosporin A decreased caspase-3 activation following incubations with paraoxon, parathion, TOTP, and TPPi. Caspase-3 activation and inhibition indicated these proteases were important in OP-induced apoptosis. Decreased OP-induced caspase-3 activation following caspase-8 inhibition suggested potential apoptotic initiation through TNF or Fas receptors. Caspase-3 activation paralleled apoptotic nuclear condensation and fragmentation induced by

paraoxon, parathion, and TPPi. Caspase-3 was also activated following PSP and TOTP exposure, even though these induced nuclear morphologies not typically considered apoptotic (type-II apoptosis). Discrepancies between morphological estimates of apoptosis illustrate the importance of using additional functional assays (e.g., caspase) for the determination of cell death.

1584 HUMAN PARAOXONASE (PON1) ISOZYMES: QUANTITATIVE ANALYSIS OF ISOZYMES AFFECTING INDIVIDUAL SENSITIVITY TO ORGANOPHOSPHATES.

S. Billecke[1], C. Hsu[1], R. Haley[2], C. Broomfield[3], C. Furlong[4], H. Davies[4], R. Richter[4] and B. La Du[1]. [1]*University of Michigan, Ann Arbor, MI,* [2]*University of Texas Southwestern Medical Center, Dallas, TX,* [3]*U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD and* [4]*University of Washington, Seattle, WA.* Sponsor: Y. Osawa.

Epidemiological evidence and *in vitro* experiments rather than direct testing must be used in human studies to demonstrate a direct relationship between enzymatic deficiencies (or polymorphic variability)and toxicity resulting from exposure to organophosphates (OPs). Ourrecent studies on Gulf War veterans who developed neurological symptoms showed significantly lower levels of the PON1 type Q allozyme than thenon-deployed or deployed healthy controls (Haley, Billecke and La Du,Toxicol & Appl. Pharmacol., 157:227, 1999). Human sensitivity to OP'sdepends upon the particular OP involved, the level and type of PON1 isozyme (Q or R) of the person exposed, and the hydrolytic efficiency ofthat isozyme for that OP compound. The relative order of hydrolytic rates with the Q and R isozymes for representative organophosphates has been determined by both their rates of hydrolysis in serum and by their kinetic characteristics with purified human serum enzymes (Vmax/Km). For the type Q isozyme the order is: sarin, soman, diazoxon, chlorpyrofos oxon and paraoxon. In contrast, the type R isozyme shows the completely reverse preference order. Heterozygous individuals, with various proportions of the two isozymes, can also be evaluated by taking into account the levels of each component isozyme. The latter analysis should be done if one isozyme is considerably more important than the other in protection against OP toxicity. Our finding that the Gulf War veterans developing neurotoxicity were either type R or low in their level of isozyme Q (as heterozygotes or homozygotes) suggests that they were exposed to a toxic compound or some OP that is preferentially inactivated by isozyme Q. The level of the latter isozyme seems to have been critical for protection in that environ-ment. Similar quantitative analyses may be useful inunderstanding "genetic predisposition" and individual variable response to environmental agents, based upon the toxic agent, its metabolicinactivation, and the level of polymorphic allozymes involved in that pathway.

1585 TISSUE PARTITIONING OF PARATHION AND PARAOXON AS ASSESSED BY EQUILIBRATION DIALYSIS.

A. Kousba and L. G. Sultatos. *UMDNJ Graduate School of Biomedical Sciences, Newark, NJ.*

A valid physiologically based pharmacokinetic model requires an accurate estimation of partition coefficients which represent the relative distribution of the chemical of concern between the tissues and the blood at equilibrium. While a variety of approaches for estimating partition coefficients are available, determination of partition coefficients for non-volatile chemicals that can undergo metabolism within certain tissues can be problematic. In the present study the technique of equilibrium dialysis was evaluated for assessing the partitioning of the organophosphorus pesticide parathion (*O,O*-diethyl-*O-p*-nitrophenyl phosphorothioate) and its active metabolite paraoxon (*O,O*-diethyl-*O-p*-nitrophenyl phosphate) into various tissues in the mouse. Dialysis of several dilutions of tissue homogenates (brain, liver, heart/lung, fat, and skin) against buffer containing a variety of parathion and paraoxon concentrations (0.5 μM/ml-25 μM/ml) over time (0-150 min) indicated that equilibrium was achieved in about 60-100 min and 20-25 min for parathion and paraoxon respectively at 37°C. While high performance liquid chromatography analyses revealed limited metabolism of both compounds in certain tissues, this loss of parathion and paraoxon had a minimal effect in the partitioning of these compounds from buffer to homogenate as evidenced by achievement of equilibrium.These data suggest that the equilibrium dialysis is a valid approach for assessing tissue partitioning for parathion and paraoxon.

1586 KINETIC INTERACTIONS OF PARAOXON WITH RAT BRAIN ACETYLCHOLINESTERASE.

L. G. Sultatos. *New Jersey Medical School/UMDNJ, Newark, NJ.*

Previous studies from this laboratory have indicated that the $appk_i$ for *in vitro* inhibition of mouse brain acetylcholinesterase by the organophosphate paraoxon (*O,O,*-diethyl-*O-p*-nitrophenyl phosphate) changed as a function of oxon concentrations below about 10 nM. Furthermore, studies utilizing mouse brain recombinant monomeric acetylcholinesterase showed similar findings, suggesting that attentuation of paraoxon's phosphorylation of acetylcholinesterase might occur through oxon binding to a peripheral binding site known to occur on acetylcholinesterase. In the present study, incubation of rat brain homogenate with various concentrations of paraoxon and 1% Triton X-100 resulted in an increase of acetylcholinesterase activity (as assessed by the Ellman method) by 20-100%, depending on the experimental conditions, compared to incubations without detergent. Application of a continuous systems computer model, which included the bimolecular inhibition rate constant *ki*, the first order rate constant for reactivation of phosphorylated acetylcholinesterase, paraoxon concentration, and acetylcholinesterase active site concentration, indicated that the presence of 1% Triton X-100 increased the concentration of active sites. These data suggest that changes in $appk_i$ as a function of oxon concentration might result, at least in part, from different pools of enzyme, with respect to paraoxon access, within brain homogenate.

1587 *IN VIVO* AND *IN VITRO* RECOVERY OF CHOLINESTERASE ACTIVITY IN THE RAT BRAIN CORTEX AFTER ORAL ADMINISTRATION WITH METHYL PARATHION.

J. M. Farley, H. Zhu, R. W. Rockhold, R. C. Baker, R. E. Kramer and I. K. Ho. *University of Mississipi Medical Center, Jackson, MS.*

The recovery of brain cholinesterase activity *in vivo* and *in vitro*, after acute methyl parathion treatment, was studied in adult Sprague-Dawley female rats. Animals received a single dose of methyl parathion (2.5 mg/kg) by gavage. To examine the *in vivo* inhibition and recovery of cholinesterase activity, animals were sacrificed 30 minutes, 2 hours, 4 hours and 24 hours after methyl parathion administration. There was a 65% decrease in brain cortex cholinesterase activity 30 minutes after methyl parathion treatment compared to activity in brain of untreated rats. Brain cholinesterase activity recovered fully within 24 hours. For the *in vitro* study, animals were sacrificed 30 minutes after methyl parathion administration, and homogenates of the brain cortex were incubated at 4°C, 22°C, or 37°C for 0.25, 2, 4, 6, or 24 hours. At 37°C, cholinesterase activity showed a rapid recovery (from 35% of control values to 60% of control values) during the first 2 hours of incubation and a slower phase of recovery during the next 22 hours. At 22°C, cholinesterase activity recovered more gradually. In homogenates incubated at either 37°C or 22°C, cholinesterase activity was completely recovered by 24 hours. There was no significant recovery in the cholinesterase activity at 4°C. Cholinesterase activity of control animals did not change at any of the tested temperatures. These results indicate a rapid recovery of brain cholinesterase activity *in vivo* and *in vitro* following a single dose of methyl parathion given by gavage. Additional studies are required to identify the mechanisms contributing to enzyme recovery and to determine if they are tissue specific. (Supported by Grant U50/ATU486513-01.)

1588 EFFECTS OF SINGLE DERMAL ADMINISTRATION OF METHYL PARATHION ON BEHAVIOR AND BLOOD CHOLINESTERASE ACTIVITY IN THE RAT.

H. Zhu, R. Rockhold, R. C. Baker, J. M. Farley, R. E. Kramer and I. K. Ho. *University of Mississippi Medical Center, Jackson, MS.*

Methyl parathion (O,O-dimethyl O-p-nitrophenyl phosphorothioate), an organophosphorous insecticide, has gained notoriety as a consequence of its illegal use in private homes across several states. As a result, at least 10,000 children were repeatedly exposed to methyl parathion by direct contact. As an initial step to identify potential effects of such exposure on behavior studies were performed to correlate blood cholinesterase activity with selected behaviors in adult Sprague-Dawley female rats. Animals were treated with a single dermal application of methyl parathion (6.25 mg/kg or 12.5 mg/kg), doses that correspond to about 10% and 20% of the dermal LD_{50}, respectively. Locomotor activity (open field test), neuromuscular coordination (rota-rod test), and blood cholinesterase activity were each examined before and 48 hours, 1 week, 2 weeks, 3 weeks, and 4 weeks following treatment. Exposure to 12.5 mg/kg methyl parathion resulted in about 80%, 30%, and 20% inhibition of blood cholinesterase activity 48 hours, 1 week, and 2 weeks after treat-

ment. Cholinesterase activity had recovered fully after 3 weeks. Spontaneous locomotor activity, neuromuscular coordination and body weight were significantly decreased in rats exposed to 12.5 mg/kg methyl parathion after 48 hours and recovered after 1 week. Exposure to 6.25 mg/kg methyl parathion resulted in a 50% inhibition of cholinesterase activity 48 hours after the treatment that recovered within 1 week. Spontaneous locomotor activity, neuromuscular coordination and body weight were not affected. Thus, single dermal administration of relatively high doses of methyl parathion can cause both cholinesterase inhibition and behavioral changes. Repeated dermal exposure, as occurred in a domestic setting, may have even more profound and persistent effects. (Supported by Grant U50/ATU486513-01.)

1589 SIMULTANEOUS EXPOSURE TO ENDOSULFAN AND METHYL PARATHION CAUSES SPATIAL LEARNING DEFICITS IN ADULT RATS.

C. G. Castillo, M. Montante and M. E. Jimenez-Capdeville. *Universidad Autonoma de San Luis Potosi, Mexico.* Sponsor: E. Diaz-Barriga.

Endosulfan and Methyl Parathion are widely used by mexican agricultors and chronic exposure to several pesticides is a frequent consequence of application. Simultaneous exposure to Endosulfan and Methyl Parathion may have effects at the nervous system because their targets are the GABAergic and Cholinergic systems, respectively. These systems are the main modulators of neuronal excitability in the cortex and hippocampus. We tested whether low-level, subchronic exposure of adult rats to Endosulfan and Methyl-Parathion disrupts learning in absence of symptoms of intoxication. Endosulfan (Agrevo, Mexico), Methyl-Parathion (Anajalsa, Mexico) and mixtures of both products were administered subcutaneosly to male Wistar rats. Dose-response curves were performed in groups of 3 animals to select NOAEL dosages. Afterwards, 5 groups of 8 animals received 10 days the following doses (NOAEL, mg/kg): saline, Endosulfan: 25, Methyl-Parathion: 2, 2 Endosulfan plus 25 Methyl-Parathion and 25 Endosulfan plus 1 Methyl-Parathion. Markers of hepatic or renal toxicity (alanine aminetransferase, creatinine, glomerular filtration) and acetilcholinesterase inhibition were analyzed in blood and urine. After 7 days of exposure the rats were tested in the water maze. Controls, Endosulfan and Methyl Parathion exposed rats decreased the escape latency from 90±31 s on the first day to 35±11 s on the seventh day. Exposure to mixtures caused significant differences from control and from single-exposure values. Mean escape latency on the first day was 166±14 s and remained 124±14 s on the last day. None of the groups presented hepatic or renal damage, nor weight loss. Acetilcholinesterase inhibition (40%) was the same for all three groups exposed to Methyl Parathion. These results demonstrate that combined exposure to Endosulfan and Methyl-Parathion disrupts spatial learning.

1590 IDENTIFICATION OF THE ACETYLCHOLINESTERASE (ACHE) ADDUCT, AFTER INHIBITION WITH (1*S*,3*S*)-ISOMALATHION, USING MATRIX-ASSISTED LASER DESORPTION/IONIZATION-MASS SPECTROMETRY (MALDI-MS).

J. A. Doorn[1], D. A. Gage[2], T. T. Talley[3], C. M. Thompson[4] and R. J. Richardson[1]. [1]*Toxicology Program, Department of Environmental Health Sciences, The University of Michigan, Ann Arbor, MI,* [2]*Department of Biochemistry, Michigan State University, East Lansing, MI,* [3]*Department of Chemistry, University of Montana, Missoula, MT and* [4]*Department of Pharmaceutical Sciences, University of Montana, Missoula, MT.*

Previous work found a difference in postinhibitory kinetics for ACHE inhibited with (1*R*)- versus (1*S*)-stereoisomers of isomalathion. Moreover, a discrepancy in postinhibitory kinetics for ACHE inhibited with (1*S*,3*R*)- versus (1*S*,3*S*)-diastereomers led to the hypothesis of an unusual mechanism of inhibition and three possible modes of "rapid aging" for enzyme inhibited with (1*S*,3*S*)-isomalathion. This study sought to identify the adduct that renders ACHE refractory towards reactivation when inhibited with the (1*S*,3*S*)-isomer using peptide mass mapping with MALDI-MS, thereby elucidating the mechanisms of inhibition and aging. Electric eel ACHE was inhibited to <10% of control activity with (1*S*,3*S*)-isomalathion. An aliquot was removed and treated with pyridine-2-aldoxime methiodide to verify aging. Peptides from tryptic digests of control and treated ACHE were separated with reverse-phase HPLC. Eluted fractions and unseparated peptides were analyzed with MALDI-MS. Active-site peptide with covalently bound *O*-methyl phosphate was discovered in treated, but not control, samples. This adduct was strikingly different from the *O*-methyl-phosphorothiolate group predicted by the conventional inhibition mechanism. Identities of the modified active site peptide and adduct were confirmed using MALDI-MS in reflectron mode, and peaks representing loss of the adduct as phosphoric/phosphorous acid *O*-methyl ester were observed. The results support the hypothesis that inhibition of ACHE with (1*S*,3*S*)-isomalathion proceeds by the novel mechanism predicted by kinetics and specifies the mode of aging. (Supported by Dow AgroSciences, NIH ES07062, NIH RR00480 and NSF MCB9808372.)

1591 INHIBITORY AND POSTINHIBITORY KINETICS OF ELECTRIC EEL ACETYLCHOLINESTERASE (ACHE) WITH THE CHIRAL PROBE ISOMALATHION.

R. J. Richardson[1], J. A. Doorn[1], T. T. Talley[2] and C. M. Thompson[3]. [1]*Toxicology Program, Department of Environmental Health Sciences, The University of Michigan, Ann Arbor, MI,* [2]*Department of Chemistry, University of Montana, Missoula, MT and* [3]*Department of Pharmaceutical Sciences, University of Montana, Missoula, MT.*

Previous work has demonstrated that ACHE is stereoselectively inhibited by isomalathion and a difference exists in the postinhibitory kinetics of enzyme inhibited with (1*R*)- versus (1*S*)-isomers. This study sought to determine if isomalathion reacts with electric eel ACHE in a chiral manner and to assess the viability of the isomalathion stereoisomers as chiral probes of active site topology for ACHE. Electric eel ACHE was inhibited stereoselectively with the order of potency being (1*R*,3*R*) > (1*R*,3*S*) = (1*S*,3*R*) > (1*S*,3*S*). A 61-fold difference was found between the bimolecular rate constant (k_i) for most to least potent isomer. ACHE inhibited with the (1*R*)-isomers rapidly reactivated both spontaneously and in the presence of pyridine-2-aldoxime methiodide (2PAM) with $t_{1/2}$ less than 5 and 2 min, respectively. On the contrary, enzyme inhibited with the (1*S*)-isomers was refractory towards spontaneous and 2PAM-mediated reactivation with $t_{1/2}$ values equal to or greater than 114 and 55 min, respectively. Disparity in rates of reactivation between ACHE inactivated with (1*S*,3*R*)- versus (1*S*,3*S*)-isomalathion was observed, which suggests that a different ACHE inhibitory adduct is formed for each (1*S*)-isomer. Both the inhibitory and postinhibitory kinetic parameters of isomalathion with electric eel ACHE are strikingly different from values previously determined with ACHE from other species. These results demonstrate that electric eel ACHE reacts with isomalathion in a remarkably stereoselective manner and the stereoisomers of isomalathion can function as chiral probes of active site topology. (Supported by Dow AgroSciences, NIH ES07062 and NSF MCB9808372.)

1592 INTRACYTOPLASMIC CISTERNAL HYPERPLASIA IN CHICKEN EMBRYO BRAIN REAGGREGATE CULTURES FOLLOWING EXPOSURE TO THE NEUROTOXIC ORGANOPHOSPHATE PHENYL SALIGENIN PHOSPHATE (PSP).

B. S. Jortner, J. Hinckley, S. K. Perkins, D. S. Barber and M. Ehrich. *Virginia Tech, Blacksburg, VA.*

Ultrastructural studies of neurodegenerative lesions in organophosphorus ester-induced delayed neuropathy (OPIDN) revealed the presence of proliferation of intra-axonal vesicles and cisterns resembling smooth endoplasmic reticulum (SER) early in the degradative process (Bischoff, Acta Neuropath 9:158; Prineas, J Neuropath Exp Neurol 28:571). The significance of this event is unclear. We report replication of this putative OPIDN lesion in an *in vitro* system. Reaggregate cultures of chicken embryo brain were grown and maintained in a serum free medium (Funk et al., Tox Appl Pharm 124:149) for 28 days. These were exposed to the direct acting organophosphorus delayed neurotoxicant phenyl saligenin phosphate (PSP) at 10-5M for 24 hours and prepared for transmission electron microscopic examination. Cell necrosis was enhanced in treated cultures. Viable cells in these preparations often contained arrays of excess intracytoplasmic vesicles and cisternal structures resembling SER and the intra-axonal structures described by Bischoff and Prineas in early OPIDN. These cisterns were frequently associated with enhanced cytoskeletal filaments, and sometimes with lesions of sub-lethal injury (membranous bodies, lipid droplets). The presence of an *in vitro* system for induction of these cytoplasmic cisterns by a neurotoxic organophosphate provides an opportunity to investigate the possible pathogenetic significance of this alteration. (Supported by USEPA R825356.)

1593 ADENOSINE TRIPHOSPHATE (ATP) CONCENTRATION IN HEN SCIATIC NERVES AFFECTED WITH ORGANOPHOSPHORUS ESTER-INDUCED DELAYED NEUROPATHY (OPIDN).

C. Massicotte, D. S. Barber, B. S. Jortner and M. Ehrich. *Virginia Tech, Blacksburg, VA.*

Continuing local supply of ATP is critical for anterograde and retrograde axonal transport and other nerve fiber functions (Goodrum and Morell, Neurotoxicology, 1992). To assess the role of alterations of ATP in OPIDN, we evaluated concentrations of that molecule in hen peripheral nerves following exposure to an organophosphate capable of inducing delayed neuropathy. To provide an appropriate model of OPIDN, a single 2.5 mg/kg dose of phenyl saligenin phosphate (PSP) was administered to adult hens. ATP concentrations were determined at days 2, 4, 7, and 14 post-dosing, from five segments (n=5/group) representing the entire length of the sciatic nerve. Initial effects of PSP dosing was seen in the most distal segment of sciatic nerve at day 2, when a transient ATP concentration increase (388±79 pmol/ml/mg vs. control value of 215±23, $p<0.05$) was noted. Subsequently, ATP concentration in this distal segment returned to normal. In all other nerve segments, ATP concentration decreased with time, and was significantly lower than control values on day 14 post-dosing ($p<0.05$). Changes in ATP concentration corresponded to incidence of decreased nerve conduction velocity, beginning 2 days post-dosing ($p<0.01$), and preceded development of clinical neuropathy and axonopathic lesions. These results suggest that variations in sciatic nerve ATP concentration are early events in the development of OPIDN.

1594 PROMOTION AND PROTECTION FROM AN ORGANOPHOSPHATE- INDUCED DELAYED POLYNEUROPATHY (OPIDP) BY MOLINATE: BIOCHEMICAL, CLINICAL AND MORPHOLOGICAL STUDIES.

A. Moretto[1], G. Gardiman[1], M. A. Colle[2], E. A. Lock[2] and M. Lotti[1]. [1]*Università di Padova, Padova, Italy and* [2]*AstraZeneca Central Toxicology Laboratory, Alderley Park, United Kingdom.*

Certain esterase inhibitors, including thiocarbamates, carbamates, organophosphinates and sulfonyl fluorides, protect from OPIDP by inhibiting its target, neuropathy target esterase (NTE), when given before the neuropathic organophosphate. They promote OPIDP when given afterwards and this effect is associated with inhibition of an esterase called M200. Hens were treated with technical molinate (purity 95% w/w) (180 mg/kg sc) and 24 hours later inhibitions of brain and peripheral nerve NTE was were (mean±SD, n=3): 92±4 and 86±1% and brain and peripheral nerve M 200for brain and peripheral nerve NTE and 91±5 and 70±10%, for brain and peripheral nerve M200, respectively (mean±SD, n=3). No clinical neuropathy developed and morphological findings on day 21-23 after dosing were normal. Hens treated with DBDCVP (0.4 mg/kg sc) developed a mild OPIDP which was promoted by molinate (180 mg/kg sc), given 24 hours later: the clinical score (0-8 point scale, median, range, n) increased from 1 (0-1) (5) to 3 (2-5) (5) and axonal degeneration was more widespread in sciatic, tibial and peroneal nerves. Hens treated with a higher dose of DBDCVP (1 mg/kg sc) developed OPIDP with clinical score 3.5 (3-6) (4) and widespread axonal degeneration in peripheral nerves. This OPIDP was protected by molinate (180 mg/kg sc) pre-treatment 24 hours earlier [clinical score 0 (0-1) (5) and normal morphological findings]. These biochemical and clinical data are comparable with those previously obtained with a commercial formulation of molinate (Gardiman et al., Toxicologist, 1999, 48:466). Newly presented morphological data are consistent with the clinical and biochemical findings.

1595 AGE-RELATED INHIBITION OF FORSKOLIN-STIMULATED CAMP FORMATION BY CHLORPYRIFOS OXON IN RAT CORTICAL SLICES.

K. J. Olivier and C. N. Pope. *University of Louisiana, Monroe, LA.*

Chlorpyrifos (CPF) is a common organophosphorus pesticide (OP). Young animals are generally more sensitive than adults to the acute toxicity of CPF. CPF elicits toxicity, following metabolic transformation to the reactive metabolite chlorpyrifos oxon (CPO), via inhibition of acetylcholinesterase (AChE). Recent studies have reported that CPO may also directly activate muscarinic receptors, specifically m2 and/or m4 subtypes coupled to inhibition of adenylyl cyclase. We studied the direct activation of muscarinic receptors and inhibition of adenylyl cyclase/cAMP formation by CPO in frontal cortex from 7, 21 and 90 day-old rats. Fresh cortical slices from each age group were pre-loaded with [3H]adenine and then incubated in the presence or absence of forskolin (FS, 20 micromolar) with CPO (1 nM-1 mM) or the muscarinic agonist oxotremorine (100 micromolar). Atropine was used to demonstrate muscarinic specificity. FS increased (about 100%) cAMP formation in cortical slices from all age groups. CPO inhibited FS-stimulated cAMP formation in a concentration-dependent manner (about 40% maximal), and this inhibitory action was partially sensitive to atropine. CPO was more potent at inhibiting FS-stimulated cAMP formation in neonatal compared to juvenile or adult tissues (IC50s: neonate=15 nM; juvenile=62 nM; adult=158 nM). Oxotremorine also inhibited FS-stimulated cAMP formation to a lesser degree (about 30%) but in a completely atropine-sensitive manner. We conclude that CPO can directly modulate cortical cAMP formation through muscarinic receptor-dependent and independent mechanisms and that the developing nervous system may be more sensitive to these non-cholinesterase actions. (Supported by U.S. EPA R 825811 and University of Louisiana Board of Regents Fund.)

1596 AGE PROFILE OF CARBOXYLESTERASE AND A-ESTERASE ACTIVITIES AND THEIR RELATIONSHIP TO THE TOXICITY OF CHLORPYRIFOS AND PARATHION IN RATS.

S. Karanth and C. Pope. *The University of Louisiana at Monroe, Monroe, LA.*

Carboxylesterases (CEs) and A-esterases (AEs) are known to play an important role in the detoxification of organophosphorus insecticides (OPs). AEs (such as chlorpyrifos oxonase and paraoxonase) catalytically inactivate OP-toxic metabolites (oxons) while CEs act as molecular scavengers, stoichiometrically binding to OPs. Earlier studies indicate a relationship between OP toxicity and the developmental profile of these esterases, i.e., higher sensitivity and lower AE and CE activities were noted in younger animals. Little information exists, however on the relative OP sensitivity and biotransformation capacities of aged animals. In the present study, we investigated the relationship between toxicity of chlorpyrifos (CPF) and parathion (PS) with levels and OP-sensitivity of esterases in liver, plasma and lung of neonatal (7 day), juvenile (21 day), adult (3 month) and aged (24 month) rats. Acute maximum tolerated dosages for CPF and PS were estimated (CPF = 45, 127, 279, 279 mg/kg; PS = 2.1, 4.8, 18, 8 mg/kg, sc, in neonatal, juvenile, adult and aged rats, respectively). There were no significant age-related differences in *in vitro* sensitivity of CEs. Levels of esterases in neonatal and juvenile rats were significantly lower than in adult tissues, e.g. neonatal tissues showed 3-11, 5-12 and 2-9 fold less CE, CPF-oxonase and paraoxonase activity, respectively, compared to adults. Only plasma CE was significantly lower (about 50%) in aged compared to adult rats. Reduction in plasma CE may be important in the higher sensitivity of aged rats to PS. (Supported by NIEHS R01-09119 and University of Louisiana Board of Regents Fund.)

1597 AGE-RELATED EXPRESSION OF CORTICAL NICOTINIC AUTORECEPTOR FUNCTION: PARTIAL CHARACTERIZATION AND EVALUATION OF SENSITIVITY TO ORGANOPHOSPHORUS PESTICIDES.

Y. J. Wu and C. N. Pope. *The University of Louisiana at Monroe, Monroe, LA.*

Nicotinic autoreceptors enhance acetylcholine (ACh) release in the adult central nervous system. We studied the expression of nicotinic autoreceptor function (NAF) in rat cortex from neonatal, juvenile, adult and aged rats. NAF was defined by the difference in the area under the curve (AUC) for [3H]ACh release in cortical synaptosomes stimulated in the presence of atropine (ATR, 100 nM) with buffer containing potassium (9 mM) with or without exogenous ACh (0.01 mM). NAF increased in an age-related manner to adulthood (AUC: 7-day, 6.9±6.0; 21-day, 44.4±5.5; 90-day, 196.3±37.0; 24-month, 172.9±51.5). The effects of ATR, epibatidine (EPI), nicotine (NIC), and mecamylamine (MEC) on NAF were studied. When ATR was omitted from the superfusion buffer, exogenous ACh did not stimulate further release. EPI and NIC, nicotinic receptor agonists (0-0.1mM), had no effect on release. The nicotinic antagonist MEC (0.1 mM), however, inhibited NAF by 79%. The *in vivo* effect of chlorpyrifos (CPF, 280 mg/kg, sc) on NAF in aged rats was also evaluated. Ninety-six hours after treatment with CPF, cortical cholinesterase activity was inhibited about 85% but minimal signs of acute toxicity were noted. NAF was substantially reduced (91%), however. From these preliminary data, high levels of CPF appear to markedly alter this modulatory neurochemical process in aged animals. Together, these data suggest that NAF is mediated by atypical nicotinic receptors (i.e., ATR, NIC, and EPI-resistant but MEC-sensitive) in an age-dependent manner and that this neuromodulatory

process may be sensitive to anticholinesterase exposures. (Supported by NIEHS R01ES09119 and University of Louisiana Board of Regents Fund.)

1598 EFFECTS OF CHRONIC DIETARY AND REPEATED HIGH-LEVEL SPIKE EXPOSURE TO CHLORPYRIFOS ON LEARNING IN RATS.

T. E. Samsam, P. J. Bushnell, R. S. Marshall and D. L. Hunter. *USEPA, Research Triangle Park, NC.*

The cholinesterase (ChE)-inhibiting compound chlorpyrifos (diethyl 3,5,6-trichloro-2-pyridyl phosphorothionate) is the most widely used organophosphorus (OP) insecticide in the United States. Whereas OPs including chlorpyrifos (CPF) have been associated with impaired cognitive and motor function in both animals and humans, the consequences of chronic dietary exposure to these insecticides has not been evaluated. The present study examined the effects of chronic dietary and repeated high-level spike exposure to CPF on learning a lever-press response and visual discrimination. Adult male Long-Evans rats were fed CPF in their diet at the rate of 0, 1, or 5 mg/kg body weight/day. In addition, half of each feeding group received an oral dose (spike) of CPF (45 mg/kg) every 2 months, resulting in 6 exposure groups: Control-Oil, Control-Spike, Low-Oil, Low-Spike, High-Oil and High-Spike. During initial training (autoshaping) the groups differed in their acquisition of the lever-press response, acquiring the response in the following order: High-Oil, High-Spike, Low-Oil and Control-Oil. The Control-Spike and Low-Spike groups did not learn the response to criterion in 3 sessions of training. There were no effects of CPF on learning a subsequent visual discrimination. These data suggest that repeated spike exposures to CPF may retard learning a motor response, whereas chronic exposure may accelerate it. These effects of CPF are consistent with previous work that linked motor impairment to changes in autoshaping. (This abstract does not necessarily reflect U.S. EPA policy.)

1599 *IN VITRO* AND *IN VIVO* EFFECTS OF CHLORPYRIFOS ON CARDIAC MUSCARINIC RECEPTORS.

M. D. H. Stiles and C. N. Pope. *The University of Louisiana at Monroe, Monroe, LA.*

Organophosphorus (OP) insecticides elicit toxicity through inhibition of acetylcholinesterase (AChE). Typically, young animals are more susceptible than adults to the acute toxicity of OPs. Several studies have shown that there may be additional macromolecular targets for some OPs, including muscarinic receptors. Recent reports have focused on the possibility that CPF (or its active metabolite, chlorpyrifos oxon, CPO) can bind directly to muscarinic M2 receptors. The effects of CPO *in vitro* on cardiac muscarinic ([3H]oxotremorine, OXO) receptor binding were evaluated in neonatal (7 days) and adult (90 days) rats. We also compared age-related effects of CPF on AChE activity and OXO binding following either acute or repeated CPF exposures. CPO affected M2 receptor binding similarly in both age groups across all concentrations tested (about 30% maximal displacement at 100 nM). Following acute dosing with equitoxic (LD10) dosages similar levels of AChE inhibition were noted in both age groups but recovery was more rapid in neonates. OXO binding was reduced in neonates at all timepoints (4, 24 and 96 hrs after exposure) but was reduced only at the 24 hr timepoint in adults. With repeated dosing (0-7.5 mg/kg/day for 14 days), similar levels of AChE inhibition were noted between the age groups 4 hrs after the last treatment but more extensive reductions in OXO binding were noted in adult tissues: kinetic analysis suggested changes in affinity. The results suggest that OXO binding may be differentially modulated by CPF in neonates and adults following relatively similar levels of AChE inhibition depending on the nature of the exposures. (Supported by University of Louisiana Board of Regents Support Fund.)

1600 CIRCADIAN VARIATIONS IN CHLORPYRIFOS (CHP)-INDUCED ALTERATIONS IN CORE TEMPERATURE (T_C) AND MOTOR ACTIVITY (MA) IN THE RAT.

C. M. Mack[1], P. J. Rowsey[2] and C. J. Gordon[1]. [1]*U.S. EPA, NEERL, Research Triangle Park, NC and* [2]*University of North Carolina, Chapel Hill, NC.*
Sponsor: R. C. MacPhail.

CHP is a heavily used organophosphate (OP) pesticide that causes an acute period of hypothermia followed by a delayed fever in the rat. Since T_c and MA display a natural circadian variation, the thermoregulatory and other toxic effects of OP pesticides could be influenced by the time of day of exposure. In this study, T_c and MA were monitored by radio telemetry in 90-day-old, male LE rats. The rats were gavaged with corn oil (n=12) or 30 mg/kg CHP (n=14) in the morning (9am) or in the afternoon (3pm). CHP induced a marked drop in T_c, reaching a nadir by ~4 hr after treatment. However, afternoon CHP exposure resulted in a greater decrease in T_c (-1.57°C) than the morning exposure (-0.4°C). A fever was observed the day after CHP exposure in rats dosed in the afternoon but not in the morning. MA measured the night after CHP exposure was depressed to a similar extent (40%) regardless of the time of administration. We have previously shown that the thermoregulatory response to cholinergic antagonists is greatest during the late afternoon. This may explain why CHP is more efficacious in altering T_c when administered in the afternoon. The nocturnal elevation in T_c of control animals is also thought to play a role in the thermoregulatory effects of CHP. The effects of CHP on MA appear to be independent from effects on T_c. These data suggest that time of day of exposure affects the toxicity of OP pesticides. (This abstract does not necessarily reflect US EPA policy.)

1601 PROLONGED ELEVATION IN BLOOD PRESSURE (BP) IN THE RAT EXPOSED TO CHLORPYRIFOS (CHP).

C. J. Gordon, B. K. Padnos and P. Becker. *USEPA, Research Triangle Park, NC.* Sponsor: R. C. MacPhail.

Organophosphate (OP) pesticides are likely to alter BP because brain stem centers for control of BP utilize cholinergic synapses and the irreversible inhibition of acetylcholinesterase activity by OP's causes cholinergic stimulation in the CNS. This study used radiotelemetric techniques to monitor systolic (S), diastolic (D), and mean (M) BP, pulse pressure (PP=S-D), heart rate (HR), core temperature (T_c), and motor activity (MA) in the male rat treated with the OP pesticide chlorpyrifos (CHP) at doses of 0, 5, 10, and 25 mg/kg (p.o.). 10 and 25 mg/kg CHP led to parallel elevations in S-BP, M-BP, and D-BP within 2 hr after dosing. M-BP increased 15 to 20 mmHg above controls and persisted throughout the night and into the next day. HR decreased slightly in the 25 mg/kg but not in the 10 mg/kg group. T_c was initially reduced by 25 mg/kg and then increased above controls the next day. MA was reduced by 25 but not 10 mg/kg CHP. PP was elevated by 2 to 4 mmHg for 40 hr after exposure to 10 and 25 mg/kg CHP. CHP-induced hypertension developed without changes in T_c, HR, and MA. The elevation in BP without an increase in HR suggests that CHP increases total peripheral resistance and alters the baroreflex control of BP. (This abstract does not necessarily reflect US EPA policy.)

1602 FIPRONIL MODULATION OF GABA(A) RECEPTORS IN RAT DORSAL ROOT GANGLION NEURONS.

T. Ikeda[3], K. Nagata[2,3], Y. Kono[1], J. Z. Yeh[1] and T. Narahashi[3]. [1]*University of Tsukuba, Tsukuba, Japan,* [2]*Brain Sciences Inst., Inst. of Physical & Chemical Research Waco, Japan and* [3]*Northwestern University Medical School, Chicago, IL.*

The insecticide fipronil is known to act on the GABA system. To elucidate the mechanism of fipronil interaction with the GABA system, patch clamp experiments were performed using rat dorsal root ganglion neurons in primary culture. Bath application of fipronil with an infrequent short GABA test puff was used to examine the onset of block of resting GABA receptor. Fipronil blocked the currents in a concentration-dependent manner with an IC_{50} of 1.3 μM. The onset of block was slow. For example, the time constant was ~60 sec in the presence of 10 μM fipronil. Co-application of 10 μM GABA and 10 μM fipronil was used to examine the onset of block of activated GABA receptor. In this experiment, fipronil was found to accelerate the current decay with a time constant of ~10 sec. These results suggest that the affinity of the GABA receptor for fipronil increases by channel opening. However, the steady-state fipronil block was independent of the degree of receptor activation. The suppressive action of fipronil on the GABA(A) receptor is deemed directly responsible for the symptoms of poisoning in animals characterized by hyperactivity and convulsions. (Supported by NIH grant NS14143 and a Grant-in-Aid from the Ministry of Education, Science and Culture of Japan.)

1603 EXAMINATION OF THE INCREASED OCCURRENCE OF DYSTOCIA AND STILLBIRTHS OBSERVED IN A REPRODUCTIVE BIOASSAY WITH AN EXPERIMENTAL CYANAMIDE (YRC 2894).

W. R. Christenson[1], B. S. Wahle[1], B. H. Hamilton[2], P. D. Dass[3], A. B. Astroff[1], C. R. Croutch[1], G. K. Sangha[1] and J. H. Thyssen[1]. [1]*Bayer Corporation, Stilwell, KS,* [2]*Glaxo Wellcome, Research Triangle Park, NC and* [3]*Bayer Corporation, Clayton, NC.*

Both an increase in stillbirths as well as signs of dystocia (difficult labor) were noted during the 1st generation of a 2-generation reproductive bioassay with [3-[(6-chloro-3-pyridinyl)methyl]-2-thiazolidinylidene]-cyanamide (YRC 2894), a chemical agent with insecticidal properties. To develop data that could contribute to a mechanistic understanding of the YRC 2894-induced alterations in the two reproductive endpoints, a modified 1-generation reproductive study was designed, which included a pre-mating phase, a gestation phase, and a post-partum phase. General toxicological endpoints as well as non-routine hormonal and histo-pathological assessments were made at 9 weeks pre-mating, gestation Days 18 and 21, and at 2 days post-partum. Exposure was carried out via the diet at constant concentrations of either 0 or 800 ppm YRC 2894. It was hypothesized, insofar as dystocia has been associated with a hormonal inbalance in the rat, that a link may exist between chemical induction of metabolic activity in the liver and hormonal regulation of reproductive processes. Three specific areas of interest involved circulating levels of estrogen as well as the measurement of uterine and cervical levels of glutathione and prostaglandin. In addition to a moderate decline in body weight gain, YRC 2894 induced a marked increase in both absolute and relative liver weight. Centrilobular hepatocytomegaly, microsomal enzyme induction, and proliferation of the smooth endoplasmic reticulum (SER) were also noted in the liver; microscopic analysis of the pituitary, hypothalamus, ovary, and adrenal showed no change. Though prostaglandin and reduced glutathione measurements were unremarkable, elevations in circulating estradiol, progesterone, corticosterone, and luteinizing hormone were measured at either two or all three of the sampling phases of this study (pre-mating, gestation day 18 or 21, lactation day 2). Estrogen and progesterone receptor populations in the uterine cytosolic and nuclear fractions remained unchanged. All other hormones evaluated (T_4, T_3, TSH, oxytocin, prolactin and FSH) were unaltered. These data suggest that YRC 2894 is promoting, via its action at the liver, some form of interference with the capacity of the animals to regulate steroidal homeostasis.

1604 TOLERANCE AND SENSITIZATION TO WEEKLY NICOTINE EXPOSURES ON THE MOTOR ACTIVITY OF RATS.

R. C. MacPhail, J. D. Farmer and H. A. Tilson. *Neurotoxicology Division, USEPA, Research Triangle Park, NC.*

Motor activity was examined in adult female Long-Evans rats in a photocell device during daily (M-F) 30-min sessions. Following adaptation to the testing routine the rats were divided into six groups of eight that were designated to receive either nothing (non-injected control), saline vehicle, or 0.3, 0.6, 1.2 or 1.8 mg/kg nicotine, s.c. (in 1 ml/kg) five-min prior to a session. Nicotine (or vehicle) was administered at weekly intervals for four weeks. Initially, nicotine produced either no effect on horizontal activity or a decrease (30%) at the highest dose, but a substantial dose-related decrease in vertical activity. Weekly dosing produced tolerance to nicotine's effect on vertical activity, and increases (ca. 100%) in horizontal activity at all doses. Baseline activity levels determined throughout the period of weekly dosing did not differ between dose groups. Alterations in motor activity due to weekly nicotine were still obtained after three weeks without nicotine. Finally, when all rats received 0.3 mg/kg, prior controls (non-injected, vehicle-injected) displayed the same effect of nicotine obtained initially in the 0.3-mg/kg group, which differed from that obtained in all prior nicotine dose groups. Systematic changes in the behavioral effects of insecticidal nicotinic agonists may therefore occur with episodic (weekly) exposures. ()This abstract does not necessarily reflect US EPA policy.)

1605 AN APPROACH TO NEUROLOGICAL/BEHAVIORAL TESTING WITHIN THE LONG-TERM RODENT STUDY.

B. S. Wahle, L. P. Sheets and W. R. Christenson. *Bayer Corporation, Stilwell, KS.*

A new component of recently adopted chronic toxicity test guidelines (OPPTS 870.4100 and 870.4300) is the enhanced neurological / behavioral assessment. We have developed an approach to accommodate the requirements of this assessment, without compromising our ability to achieve the core goals of the basic guideline chronic rat study. First, our approach assumes that both a chronic study (1-year) and a subchronic (3-month) neurotoxicity screen (OPPTS 870.6200) will be conducted as part of the development of a toxicological data package for a given chemical. Secondly, the chronic neurological assessment then takes the form of a modified subchronic assessment, consisting of key elements that can be practically incorporated into the study design of the chronic rat bioassay. Specifically, during months 6 and 12 of the 12-month chronic rat study, a representative sample (10 animals/sex/dose) is subjected to a functional observational battery which includes observations in the home cage, during handling, and in an open field, as well as various reflex/physiologic observations and measurements. Observations in the home cage and open field include assessments of motor activity. In addition, all animals (~25/sex/level) are observed weekly outside the home cage in a standard arena. At termination, 5 rats/sex/dose are selected for perfusion and collection of neural tissues for microscopic evaluation. Representative sections of the tissues from control and high dose animals are evaluated; tissues in which compound-related neuropathology is detected are examined at lower doses, as necessary, to establish a no-observed-effect level. Based on both scientific and practical considerations, landing foot splay, aerial righting, and motor activity evaluated in a maze have been excluded. Overall, this approach provides a sound neurotoxicological assessment that integrates well with the conduct of the chronic rat study.

1606 DETERMINATION OF HEXACHLOROBENZENE IN RODENT BLOOD AND TISSUE.

R. M. Moore[1], A. Y. Shan[1], W. F. Sherman[1], A. P. Clark[1], R. K. Harris[1] and D. Overstreet[2]. [1]*Midwest Research Institue, Kansas City, MO and* [2]*US NIH, NIEHS, Research Triangle Park, NC.* Sponsor: M. L. Cunningham[2].

Hexachlorobenzene (HCB) is an environmental contaminant that was selected for evaluation by NIEHS. To determine internal dose, methods were developed and validated to measure the concentration of HCB in blood, fat, liver and lung taken from rats used in toxicology studies. Tissue was extracted with a mixture of acetonitrile/hexane and the extracts analyzed by gas chromatography with either electron capture (ECD) or mass spectrometric (MSD) detection, depending upon the concentration of HCB. Fat samples required additional clean-up using alumina solid-phase extraction cartridges. Chromatographic conditions were developed to resolve HCB from the internal standard and matrix components. Separation was obtained using a 5% phenyl capillary column and a thermal gradient from 180°C to 275°C. ECD was used for blood samples with HCB concentrations from 5000 to 20 ng/mL and fat samples from 400 to 50 ng/g. MSD was used for blood samples with HCB concentrations from 400 to 1 ng/mL and liver and lung samples from 10,000 to1.25 ng/g. A method validation (MV) showed weighted (1/y) regression equations for data were linear, ($r > 0.99$) with relative errors < than 10%, blood (ECD); 12%, blood (MSD); 10%, lung; 11%, liver; and 9%, fat. Relative standard deviations for triplicate determinations at the lowest concentrations were 2.3%, blood; 1.2%, lung; 1.5%, liver; and 3.5%, fat. Limits of detection were 0.07 ng/mL, blood; 0.05 ng/g, lung and liver; and 5.2 ng/g, fat. These methods are suitable for the analysis of HCB in the range of 1 to 10,000 ppb in the tissues examined as demonstrated by the MV and recoveries >80% obtained upon analysis of spiked tissue samples.

1607 DETERMINATION OF HEPTACHLOR AND METABOLITES IN RODENT TISSUE.

R. K. Harris[1], R. M. Moore[1], W. F. Sherman[1], T. A. Westermeyer[1], A. P. Clark[1] and D. Overstreet[2]. [1]*Midwest Research Institute, Kansas City, MO and* [2]*US NIH, NIEHS, Research Triangle Park, NC.* Sponsor: M. L. Cunningham[2].

Heptachlor (HEP) is a persistent environmental contaminant that was selected for evaluation by NIEHS. To determine internal dose, methods were developed and validated to measure the concentration of HEP and its metabolites (epoxides a & b) in rat blood, milk, fat, liver, and whole pup samples taken from rats used in toxicology studies. Tissue was extracted with an acetonitrile/ethyl acetate mixture and extracts analyzed using gas chromatography with electron capture detection. Fat samples required additional clean-up using alumina solid-phase extraction cartridges. Chromatographic conditions were developed to resolve HEP, epoxide a, epoxide b, and internal standard from each other and matrix components. Separation was obtained using a 5% phenyl capillary column with a thermal gradient from 180°C to 275°C. A method validation (MV) showed weighted (1/y) regression equations for data for all three analytes were linear ($r > 0.99$) over the concentration ranges studied: 10 to 500 ng/mL, blood; 5 to 180 ng/mL, milk; 5 to 180 ng/g, whole pup;

25 to 150 ng/g, liver; and 100 to 1000 ng/g, fat with relative errors were less than 9%, blood; 15%, milk; 14%, pup; 14%, liver; and 16%, fat. Relative standard deviations for triplicate determinations at the lowest concentrations were 4.6%, blood; 7.5%, milk; 8.4%, pup; 14.9%, liver; and 9.9%, fat. Limits of detection were found to be 1 ng/mL, blood and milk; 1 ng/g, pup; 10 ng/g, liver; and 40 ng/g, fat. Confirmation of the identity of analytes found in study samples was provided by gas chromatography with mass spectrometric detection. These methods are suitable for the analysis of HEP in the range of 5 to 1000 ppb in the tissues examined as demonstrated by the MV and recoveries > 80% obtained upon analysis of spiked tissue samples.

1608 STATISTICAL PERFORMANCE OF MATHEMATICAL CORRECTIONS FOR THE INVERSE RELATIONSHIP BETWEEN QT INTERVAL AND HEART RATE.

M. M. Cooper, W. H. Packwood, T. F. Platte, C. Lancaster, F. G. Robinson and A. S. Bass. *Pharmacia & Upjohn, Inc., Kalamazoo, MI.*

Pharmacodynamic prolongation of ventricular repolarization (QT Interval) has the potential liability of inducing polymorphic ventricular tachycardia (Torsades de Pointes), ventricular fibrillation and death. An inverse relationship exists between changes in heart rate and the QT interval, which poses a dilemma for studying drugs that affect heart rate. Of the various mathematical formulae that have been proposed as a correction for this problem, 4 of these ($aoRR^{(1/2)}$, $aoRR^{(1/3)}$, $aoRR^{(1/4)}$ and aolog RR) were evaluated in the present study. In addition, an analysis of covariance (ANCOVA) of QT interval was evaluated using heart rate as the covariate. The statistical power of each of these models was determined for a 10% change from control. This magnitude of difference is similar to that actually observed in a study of PNU-142093, a $5HT_{1D}$-serotonin receptor agonist known to cause QT Prolongation. Electrocardiograms were collected by radiotelemetry using a lead II configuration from unrestrained, cynomolgus monkeys. A statistical power of 80% is considered good. Of the 4 correction formulae, Fridericia's formulae $aoRR^{(1/3)}$ was the best, with a power of 62% and 95% for 4 and 8 animals/group, respectively. Bazett's formulae $aoRR^{(1/2)}$ was close to Fridericia's with a power of 60% and 95% for 4 and 8 animals/group, respectively. The quartic root $aoRR^{(1/4)}$ and log formulae aolog RR had lower power, between 45% and 55% for 4 animals/group and 85% and 92% for 8 animals/group, respectively. Based on these analyses, either Fridericia's or Bazett's formulae could provide a corrected QT interval for analysis of variance. However, the analysis of covariance of QT would provide the best model for detecting QT prolongation with a power of 72% and 99% for 4 and 8 animals/group, respectively.

1609 CARDIAC TOXICITY OF NITROGEN TETROXIDE: QTC PROLONGATION IN EXPOSED PATIENTS.

N. Brautbar[1], T. Callahan[2], W. Shell[2] and L. Joyner[3]. [1]*USC, School of Medicine, Department of Medicine, Los Angeles, CA,* [2]*Beverly Glen Medical Systems, Los Angeles, CA and* [3]*Joyner Pulmonary Clinic, Bogalusa, LA.*

Exposure to dinitrogen tetroxide (N2O4) has been shown to precipitate the onset of reactive airway dysfunction syndrome (RADS), and neurocognitive symptomatology. In addition, exposure to other airborne toxins and pollutants have been implicated in an increased number of ectopic cardiac beats as a result of parasympathetic neurotoxicity. This study examined additional cardiac effects after exposure to dinitrogen tetroxide; specifically, QTc prolongation in the Bogalusa, LA cohort of patients. Thirty-eight (38) patients who were exposed to the N2O4 gas cloud were graded symptomatically as mild, moderate, or severe by one of the investigators. Each subject underwent a 24-Hour Holter recording. The QT interval was measured for each normal ECG complex from the Holter recording. The QT interval data were then removed to an off-line computer for additional analysis. QTc interval measurements were calculated for each beat using Bazett's formula. Mean QTc intervals, the percentage of beats greater than 450 milliseconds (pQTc450), and the percentage of beats greater than 500 milliseconds (pQTc500) were calculated for each Holter recording. These data were compared to a group of 19 normal subjects who also underwent Holter recording. The overall cohort showed a significantly prolonged QTc interval calculation in each of the three measurements compared to normals. Moderately symptomatic patients had a significant increase in all of the calculations compared to mildly symptomatic. Severely symptomatic patients had significantly increased QTc calculations compared to moderately symptomatic. Patients exposed to N2-04 had a significant increase in the QTc interval measurements. Increases in the QTc interval have been linked to an increase in syncopal episodes and sudden cardiac death. In light of this information, patients exposed to toxins of this type should undergo additional studies, among those, 24-Hour Holter recordings to have their QTc interval measured.

1610 A GUINEA PIG ANIMAL MODEL FOR EVALUATION OF QTc INTERVAL PROLONGATION.

V. B. Ciofalo[1], G. Aberg[2], P. A. Gayheart-Walsten[1] and C. B. Spainhour[1]. [1]*Chrysalis Preclinical Services Corp., Olyphant, NC and* [2]*Bridge Pharma, Inc., Sarasota, FL.*

The QT interval represents the entire duration of ventricular systole and is measured from the end of the QRS complex to the end of the T wave. The normal QT interval varies with heart rate and numerous formulae and data are available to obtain the corrected interval time (QTc). There is a brief moment in the middle of repolarization, during the T wave in the ECG, when some myocardial fibers are refractory and others are not. This has been called the vulnerable period. A variety of agents can prolong this vulnerable period and include but are not limited to: β adrenergic antagonists, carbamazepine, cyclic antidepressants, erythromycin, nonsedating antihistamines and antidysrhythmics. This activity can lead to peracute death. We have modified the Hey anesthetized guinea pig model to evaluate the potential of test articles to prolong the QTc interval. Five to nine week old, 481 - 790 gram guinea pigs/Elm(HA) were apportioned into four test groups, each group consisting of 6 animals. Guinea pigs were anesthetized, placed on a ventilator and a catheter inserted into the jugular vein for i.v. administration of test articles(TA). Subdermal pin electrodes were placed in each limb to record a Lead II electrocardiogram. Animals were stabilized for 30min. prior to administration of TA. TA were administered via i.v. infusion over a 30 min. period at a dose level of 5 mg/kg. The vehicle (10%DMSO/90% PEG 200) was administered over 30 min. at 1ml/kg. ECG recordings were made at -30, -20, -10 and 0 minutes prior to the start of the i.v. infusion, at one minute intervals during the infusions and 5, 10, 15, 20, 25 and 30 minutes after the termination of the infusions. Means from three predose recordings were used as baseline data and means from five post-dose recordings were used to determine TA effect. Heart rate was significantly decreased by the vehicle (-13.6%), norastemizole (-13.6%) and sotalol (-8.0%). These changes were not considered biologically relevant. Sotalol, vehicle and norastemizole did not have any effect on the QTc interval. As expected, the reference compound terfenadine significantly ($p<0.01$) prolonged the QTc interval (+27%) and reduced the heart rate (-40%).

1611 A CANINE ANIMAL MODEL FOR THE EVALUATION OF QTc - INTERVAL PROLONGATION.

P. A. Gayheart-Walsten[1], V. B. Ciofalo[1], V. Sallee[2] and C. B. Spainhour[1]. [1]*Chrysalis Preclinical Services Corporation, Olyphant, PA and* [2]*Alcon Research Limited, Fort Worth, TX.*

The QT interval represents the entire duration of ventricular systole and is measured from the end of the QRS complex to the end of the T wave. The normal QT interval varies with heart rate and numerous formulae and data are available to obtain the corrected interval (QTc). There is a brief moment in the middle of repolarization, during the T wave in the ECG, when some myocardial fibers are refractory and others are not. This has been called the vulnerable period. A variety of different agents can prolong this vulnerable period and include but are not limited to: β adrenergic antagonists, carbamazepine, cyclic antidepressants, erythromycin, nonsedating antihistamines and antidysrhythmics. This activity can lead to peracute death. We have developed an anesthetized canine model to evaluate the potential of a test article to prolong the QTc interval. Seven to thirteen month old dogs (Marshall) weighing between 6 - 11 kg were distributed equally between four test groups, with two males and two females in each group. Animals were given Brevital® (10 mg/kg, i.v.) as a preanesthetic and then maintained on a stable anesthetic plane with a mixture of oxygen and isoflurane (2.5-4%). Effects on the cardiovascular system were determined by changes in arterial blood pressure (systolic, diastolic and mean), heart rate and a Lead II electrocardiogram. Following stabilization, baseline values for each parameter were established over a minimum time of ten minutes. Vehicle or reference standard was administered as a continuous infusion over a fifteen minute period. Arterial blood pressure and electrocardiograms were evaluated every 60 sec. during infusion and at five minute intervals for a minimum of 30 minutes following the completion of the dose. Additional ECG recordings of AVR, AVL, AVF, I, II, III, RV_2 and V_{10} were performed prior to the initial treatment, at the conclusion of each dose and at 10, 20 and 30 min following dose administration completion. At doses of 4 mg/kg and 10 mg/kg, dl-Sotalol prolonged the QTc interval by 23% and 43%, respectively. At this high dose, dl-Sotalol slightly reduced systolic (16%), diastolic (27%) and mean (23%) arterial blood pressures and heart rate (37%). The QTc prolongation observed with dl-Sotalol is expected for this Class III antiarrhythmic agent.

1612 QUINOLONE QTC PROLONGATION AND HEMODYNAMICS IN AN ANESTHETIZED DOG MODEL.

V. Murphy[1], S. Mittelstadt[1], B. Kuzmak[1], G. Gromelski[2] and P. Gayheart-Walsten[2]. [1]*P&G Pharmaceuticals, Mason, OH and* [2]*Chrysalis Int., Olyphant, PA.*

Sparfloxacin is a quinolone antibiotic known to prolong the QT interval corrected for heart rate (QTc) whereas ciprofloxacin and trovafloxacin have not been shown to prolong QTc. These compounds were tested in an anesthetized dog model to see if the model could differentiate between quinolones with demonstrated clinical effects on QTc versus those with no known clinical effects. The model consists of beagle dogs (6-15 kg, 6-12 months) which are artificially ventilated with a mixture of oxygen and isoflurane to maintain anesthesia. Dogs were cannulated in the femoral vein for compound administration and in the opposite vein for blood sample collection. The femoral artery on the blood collection side was cannulated for blood pressure measurement. Electrodes were installed for recording Lead II electrocardiogram. Blood pressure, heart rate and Lead II ECG were monitored. QT interval was determined from ECG recordings taken prior to dosing and at the end of each infusion and QTc was calculated as QT - [0.087 x (60/heart rate - 1)]. Ciprofloxacin, trovafloxacin mesylate (as alatrovafloxacin) and sparfloxacin were infused at 0, 5, 25 and 50 mg/kg as sequential infusions (2.5 ml/kg over 30 minutes each for a total of 10 ml/kg over 120 minutes). Four dogs were used per compound. Sparfloxacin prolonged QTc at all doses (16, 88 and 105% from vehicle) whereas ciprofloxacin and trovafloxacin only prolonged QTc at 50 mg/kg (19% from vehicle). Heart rate was decreased at all doses in all dogs with sparfloxacin, at 25 and 50 mg/kg with trovafloxacin in 3 dogs and ciprofloxacin in 2 dogs. Blood pressure was decreased at all doses in all dogs with trovafloxacin and at 25 and 50 mg/kg with ciprofloxacin in 3 dogs and sparfloxacin in 2 dogs. One sparfloxacin dog had an increase in blood pressure at all doses. These results demonstrate that sparfloxacin prolongs QTc in the dog similar to clinical observations. Ciprofloxacin and trovafloxacin that have no known clinical effects on QTc had significantly smaller changes in the dog.

1613 INFLUENCE OF THE RESPIRATORY SINUS ARRHYTHMIA ON THE QT INTERVAL LENGTH AND ON THE QT/RR RELATIONSHIP IN CONSCIOUS BEAGLE DOGS.

J. Legrand[1], C. Delubac[2], C. Fisch[2] and R. Forster[2]. [1]*Institut Henri Beafour, Les Ulis, France and* [2]*Centre International de Toxicologie, Miserey, France.*

The length of the QT interval is generally considered to be directly dependent on the length of the preceding cardiac cycle. In dogs, unlike man, respiratory sinus arrhythmia induces considerable variation in the length of contiguous cardiac cycles. This study was performed to describe the relationships between the instantaneous cardiac cycle length or average heart rates and the length of the QT interval. The relationships between the instantaneous cardiac cycle length (RR) or the average heart rate (Fm) and the length of the QT interval were studied from ECG records obtained in 36 male and 35 female beagle dogs aged six to seven months. These ECGs were performed as pretest routine investigations during toxicology studies. Quantification of the parameters was performed manually on hardcopy traces (50 mm/s; 1 cm/mV; 10 seconds) of lead II ECGs. Fm ranged from 66 to 186 beats per minute. The QT duration remained relatively constant despite great variation in contiguous RR intervals resulting from respiratory sinus arrhythmia. There were no differences between male and female animals. We found that for this data, derived from normal non-treated animals, Van de Water's approximation formula gave the best correction of QT as a function of average heart rate and Bazett's formula was the least suitable.

1614 EFFECTS OF COCAINE ALONE OR COCAINE PLUS GBR-12909 ON CARDIOVASCULAR HEMODYNAMIC AND ELECTROGRAPHIC PARAMETERS IN CONSCIOUS UNRESTRAINED BEAGLES.

M. P. Smith[1], J. H. Ludens[1], L. H. Hulsebos[1], G. J. Schaefer[1], P. E. Newton[1], N. B. Olivier[2] and J. B. Terrill[3]. [1]*MPI Research, Mattawan, MI,* [2]*Michigan State University, East Lansing, MI and* [3]*National Institute on Drug Abuse, Bethesda, MD.*

To eliminate anesthesia, restraint and investigator presence as confounding factors in an assessment of potential cardiovascular interactions of cocaine and other modulators of the sympathetic nervous system, we conducted studies in chronically instrumented, conscious, unrestrained Beagles in dog runs using telemetry (ITS®) and a programmable infusion pump (Cadd-Prizm®). Eight dogs were instrumented with aortic and left ventricular pressure transducers (Konigsberg®), flow probes (Triton®) on the pulmonary artery to monitor cardiac output and ECG leads (base/apex placement) to obtain a lead II electrocardiogram. Animals pretreated with 0, 1 or 10 mg/kg of GBR-12909 given orally in gelatin capsules were dosed 3 hrs later with 0.56, 1.7 or 3.0 mg/kg of cocaine delivered through a vascular access port with the programmable infusion pump. Cocaine alone dose-dependently increased systolic, mean and diastolic blood pressures, heart rate, cardiac output, and left ventricular contractility (dP/dt), peak and end diastolic pressures. In contrast, increases in total peripheral resistance calculated as the quotient of systemic pressure and cardiac output were less with the high dose than with the middle and low doses, due to a disproportionate increase in flow with the high dose. GBR-12909 (1 or 10 mg/kg) did not alter any of these hemodynamic parameters either before or after the low and middle doses of cocaine. The effects of cocaine on electrographic parameters were slight and were generally dose dependent. They included a decrease in the PR interval, an increase in QRS duration, an increase in the corrected QT interval (Bazett's), and were not altered by pretreatment with GBR-12909. In conclusion, this study revealed a divergence in the pressure-flow relationship with the high dose of cocaine that was not previously seen in anesthetized or sling-restrained dogs. Further, 1 and 10 mg/kg of GBR-12909 given orally had no effect on any of the cardiovascular parameters either before of after cocaine. (Supported by NIDA contract N01DA-6-8068.)

1615 A NEW PERSPECTIVE FOR IDENTIFYING POTENTIAL CARDIAC SENSITIZERS.

E. A. Smith[1], T. Nakayama[2], E. Herderick[2], J. Powers[2], G. Briggs[1], K. Still[1] and R. Hamlin[2]. [1]*Geo-Centers, Inc./NHRC/TD, Wright-Patterson AFB, OH,* [2]*The Ohio State Univeristy, Columbus, OH and* [3]*Naval Health Research Center/Toxicology Detachment, Wright-Patterson AFB, OH.*

The purpose of this investigation is to construct a mathematical model for predicting the onset of cardiac sensitization using ouabain, a digitalis glycoside known to provoke ventricular arrhythmia. Both the dog (conscious and anesthetized) and the pig (anesthetized) were used as animal models. Physiologic and electrocardiographic measurements were taken during the baseline period and after each dose of ouabain. The model was based on logistic regression because of the binary nature of the data. Logistic regression allows the observer to predict the probability of developing an arrhythmia for a given value of the observed parameter. Five parameters were significant predictors of arrhythmia in dog, and three were significant in the swine. The study demonstrates that a mathematical model can be constructed to predict the onset of ouabain induced arrhythmia, in both the dog and the swine, and that there are similarities in the two animal models. However, efforts to reduce the number of parameters to a single term showed colinearity among simple pair wise combinations. At the moment the data suggest the QT interval to be the most promising of all the parameters for predicting cardiac sensitization regardless of species.

1616 NORMAL ELECTROCARDIOGRAPHIC VARIANTS IN UNANESTHETIZED MACAQUES.

J. W. Richig. *Anilab, Inc., Englishtown, NJ.* Sponsor: D. M. Schiavo.

Nonhuman primates are commonly used in toxicology and biomedical research. The electrocardiogram is one of the most important evaluations performed on macaques (cynomolgus or rhesus monkeys) prior to and during drug safety evaluation studies. Electrocardiograms are performed in order to ascertain what, if any, effects pharmaceutical agents may have on cardiac conduction. However, prior to such studies electrocardiographic evaluations are performed to ascertain whether a monkey is electrocardiographically suitable for use on a study. It is through these pre-study screens that it has come to light that normal variants exist in these monkeys. These normal variants are listed as follows: sinus arrhythmia, an occasional atrial or ventricular premature complex, low-voltage QRS complexes, right bundle branch block (incomplete or complete) and tall T waves. In addition, these variants can be found in combinations of two or more together. Monkeys exhibiting these variants have been found to be clinically normal and healthy, and thereby suitable for use on study.

1617 HEART RATE VARIABILITY IN HEALTHY- AND MONOCROTALINE-TREATED RATS DURING EXPOSURE TO LOWERED AMBIENT OXYGEN.

M. J. Campen[1], J. P. Nolan[2], T. P. Jenkins[3], S. M. Dowd[2], R. Mebane[2], Q. T. Krantz[2], D. L. Costa[2] and W. P. Watkinson[2]. [1]*UNC School of Public Health, Chapel Hill, NC,* [2]*Pulmonary Toxicology Branch, NHEERL, USEPA., Research Triangle Park, NC and* [3]*ECU Department of Physics, Greenville, NC.*

Heart Rate Variability (HRV) is reported to predict adverse clinical cardiac outcomes. While HRV has been used in a number of recent animal studies, little is known about its toxicological significance. The present study describes initial observations of HRV indices in healthy rats (male, 60-day, Sprague-Dawley) and rats with monocrotaline (MCT; 60 mg/kg)-induced pulmonary hypertension during both normoxic and hypoxic conditions. Frequency domain indices were defined as follows: very low frequency power (VLF) = 0.0033-0.2 Hz; low frequency power (LF) = 0.2-0.6 Hz; high frequency power (HF) = 0.6-3.0 Hz; total power (TP) = 0.0-3.0 Hz. Time domain indices and fractal domain approximations were also determined. Animals were exposed to decreasing ambient oxygen (O_2) levels (16.75% and 12.5%, each for 5 min periods) while anesthetized with urethane. Continuous electrocardiograms (ECG) from each rat were recorded to magnetic tape; RR-interval series were extracted from the recorded ECG signal by computer and analyzed by a modified fast Fourier transform algorithm. Conscious MCT-treated rats displayed significantly lowered HF and TP values compared to saline-treated rats. Decreased O_2 tended to cause an increase in VLF and LF domains in all rats under anesthesia, while TP and HF values decreased. A few MCT-treated rats displayed severe decreases in HF during 16.75% O_2, while the response to 16.75% O_2 in healthy animals was mild or absent. TP consistently decreased during hypoxic exposures in healthy and MCT-treated rats. These initial findings demonstrate HRV alterations caused by experimental stressors, as well as by an existing cardiopulmonary pathology. (This abstract was funded in part by EPA/UNC T901915 research training grant and does not represent EPA policy.)

1618 A CARDIOVASCULAR RADIOTELEMETRY STUDY OF A SUBCUTANEOUS DOSE OF APOMORPHINE HCL IN BEAGLE DOGS.

A. F. Youssef[1], C. Hassler[2], R. Hamlin[3] and F. L. Fort[1]. [1]*TAP Holdings Inc., Deerfiled, IL,* [2]*Battelle, Columbus, OH and* [3]*The Ohio State University, Columbus, OH.*

Apomorphine is a dopamine D1/D2 receptor agonist with a subcutaneous T_{max} ~ 15 to 30 min. In the current study, 5 male beagle dogs were surgically instrumented with implantable telemetry for monitoring ECG, BP, and/or to measure left ventricular end diastolic pressure (LVEP). All dogs were injected with vehicle once daily for 3 days followed by 0.04 mg/kg of apomorphine for 3 days, then a washout period, followed by 0.04 mg/kg of apomorphine preceded by 500 mcg/kg of Domperidone® (a peripheral D2 antagonist), then a washout period followed by 500 mcg/kg Domperidone® alone. Cardiovascular evaluations included: BP, HR and ECG. To evaluate the effect on baroreceptor function and vagal tone, HR was calculated from beat to beat ECGs during head-up and head-down maneuvers. Vomiting and lethargy resulted only with apomorphine. Following apomorphine treatment, the head-up maneuver produced a significant increase in the HR relative to control (i.e., no inhibition of sympathetic tone). The head-down maneuver resulted in decreased HR which was not different from control (i.e. no potentiation of vagal tone). BP values were significantly lower ($p < 0.01$) following apomorphine compared to vehicle. The maximum decline in BP over the first 3 hours was 10 mmHg. The decrease in BP was not associated with a change in HR or LVEP (one animal). Domperidone® reversed all clinical and cardiovascular changes. The decline in BP was due to peripheral D2-mediated increased venous capacitance or arteriolar dilatation.

1619 AN ACUTE INTRAVENOUS STUDY OF A LONG HALF LIFE FORM OF LEPTIN IN THE CONSCIOUS BEAGLE DOG.

K. Moore[1], G. Washer[2], D. Miller[1] and H. Davis[1]. [1]*Department of Toxicology, Amgen Inc., Thousand Oaks, CA and* [2]*ClinTrials BioResearch, Quebec, Canada.*

Leptin is a protein hormone, produced by adipose tissue, involved in the regulation of body fat. Recombinant leptin administered to normal animals results in rapid loss of body weight primarily due to body fat reduction. Additionally, leptin has been reported to effect other physiological parameters, including the cardiovascular system. This study was conducted in conscious beagle dogs to evaluate the acute toxicity and cardiovascular effects of a long half life form of leptin following a single bolus IV injection. All animals dosed at 5, 25 and 100 mg/kg experienced a dose-related loss in body weight for 14 days following treatment. Males dosed at 100 mg/kg sustained this body weight loss for 28 days (28% of baseline). Additionally, hemodynamic parameters were evaluated continuously for 48 hours following treatment. In the majority of animals, including controls, heart rate tended to increase immediately following treatment, returning to baseline ranges within ~ 40 minutes. Blood pressure changes were more variable, with mild increases usually coinciding with the increased heart rate. Clinical signs, indicative of a Type-1 hypersensitivity reaction (i.e. red skin, swollen extremities) were seen in all animals, including controls, within 20 minutes of treatment. The formulation for the long half life form of leptin contains small amounts of Tween 20 (0.01%). To investigate if the clinical signs and hemodynamic changes were related to the Tween concentrations, dogs received either 0.01 or 0.1% Tween 20 in PBS by IV bolus. Both doses of Tween produced clinical signs and hemodynamic changes as expected, with the effects at 0.1% more pronounced. In summary, this long half life form of leptin was well tolerated in the dog at doses up to 100 mg/kg. An expected and reversible loss in body weight was seen, as well as slight hemodynamic changes related to Tween 20.

1620 THE USE OF PROPOFOL AND ALFENTANIL AS A NOVEL ANAESTHETIC REGIME FOR CONDUCTING CARDIOVASCULAR AND RESPIRATORY SAFETY PHARMACOLOGY STUDIES IN THE ANAESTHETISED BEAGLE DOG.

I. Hallett, C. Fuller and A. Esmail. *Covance Laboratories Ltd, Harrogate, United Kingdom.* Sponsor: J. Norris.

An assessment of the pharmacological effects of novel chemical entities (NCEs) on the cardiovascular and respiratory system of a non-rodent species is considered as an essential pre-clinical test prior to Phase 1 clinical trials. Furthermore, this is recognised as an important test in the Japanese Guidelines for nonclinical testing of drugs. This test is most commonly performed in the anaesthetised laboratory beagle dog which can be instrumented under anaesthesia for monitoring arterial blood pressure, left ventricular pressure, systemic blood flow, ECG, and respiratory parameters. However, many of the anaesthetic regimes currently employed for this purpose have profound effects on many of the parameters measured, or may effect the ability of the anaesthetised preparation to respond to any pharmacological challenge. Furthermore, some anaesthetics may depress respiration to such an extent that it becomes neccessary to ventilate the animals artificially, thus preventing the measurement of any respiratory parameters. At Covance, Harrogate, we have devised an intravenous anaesthetic regime using a mixture of the anaesthetic, propofol, and the sedative, alfentanil, which can be administered by continuous infusion. Using this anaesthetic regime gives us a stable preparation, capable of breathing spontaneously, to which drugs can be administered over the course of several hours while haemodynamic and respiratory recordings are taken. Using a continuous intravenous infusion of propofol at a rate of 0.14 to 0.18 mg/kg/min, supplemented by an intravenous infusion of alfentanil of 2 to 3 mg/kg/min, in a group of 4 dogs we were able to maintain the group mean arterial blood pressure between 79 to 86 mmHg, the heart rate between 72 to 79 bpm, mean femoral artery blood flow between 110 to 126 mL/min, respiratory rate between 22 to 31 cycles/min, and tidal volume between 37 to 54 mL over 150 minutes of continuous anaesthesia.

1621 THE USE OF KETAMINE AND PROPOFOL AS A NOVEL ANAESTHETIC REGIME FOR CONDUCTING CARDIOVASCULAR AND REPIRATORY SAFETY PHARMACOLOGY STUDIES IN THE ANAESTHETISED CYNOMOLGUS MONKEY.

A. Esmail, C. Fuller, H. Prior and I. Hallett. *Covance Laboratories, Harrogate, United Kingdom.* Sponsor: J. Norris.

An assessment of the pharmacological effects of new chemical entities (NCEs) on cardiovascular and respiratory system of a non-rodent species is an essential pre-clinical test prior to Phase 1 clinical trials. The test is commonly performed in the laboratory beagle. However, the non-human primate is increasingly used as an alternative species, especially when the metabolism of the test compound in the primate is more comparable to that in man. Some anaesthetic regimes currently used have profound effects on many of the parameters measured, or may depress respiration necessitating artificial ventilation. We have devised an intravenous anaesthetic regime, suitable for cardio-

vascular and respiratory measurements following test compounds in anaesthetised cynomolgus monkey. Cynomolgus monkeys, of either sex, were pretreated with ketamine (21-23 mg/kg). Anaesthesia was induced with propofol (5-8 mg/kg iv) and maintained with a continuous infusion of propofol (0.42-0.48 mg/kg/min). Animals were instrumented to measure cardiovascular and respiratory parameters. Using this model, we were able to obtain stable anaesthesia for several hours. Typical values and ranges for the cardiovascular and respiratory parameters were as follows: Mean Arterial Blood Pressure 75-82 mmHg, heart rate 174-184 beats/min, RR interval of the ECG 330-346 ms, QT interval 205-213 ms, QTc interval 354-361 ms, Respiratory rate 54-60 cycles/min, Tidal volume 5.9-6.2 ml, Minute Volume 320-364 ml, Peak inspiratory flow 26-30 ml/s, peak expiratory flow 26-29 ml/s. This regime gives us a stable preparation, capable of breathing spontaneously, to which drugs can be administered over the course of several hours while haemodynamic and respiratory recordings are taken.

1622 CARDIOVASCULAR EFFECTS OF FUMONISIN B_1 IN MILK-FED CALVES.

S. Mathur[1], P. D. Constable[1], R. M. Eppley[2], M. E. Tumbleson[3], G. W. Smith[1], W. J. Tranquilli[1], D. E. Morin[1] and W. M. Haschek[4]. Fumonisins are a group of mycotoxins produced primarily by *Fusarium verticillioides*, a fungus that commonly contaminates corn. Fumonisin ingestion leads to altered sphingolipid biosynthesis and dose-dependent increases in serum and tissue sphinganine and sphingosine concentrations in all species. Fumonisin B_1 (1 mg/kg, IV, daily) caused lethal pulmonary edema in pigs within 4 days, probably due to sphingosine-mediated left heart failure. Pigs died when plasma sphinganine and sphingosine concentrations were ≥2.2 and 1.0 μM/L, respectively. We therefore examined whether fumonisin B_1 induced similar cardiovascular effects in calves. Ten milk-fed male Holstein calves aged 7 to 14 days were instrumented to obtain blood and cardiovascular measurements. Treated calves (n = 5) were administered fumonisin B_1 at 1 mg/kg, IV, daily for 7 days and controls (n = 5) were administered 10 ml 0.9% NaCl, IV, daily. All calves were euthanized on day 7. In treated calves, serum sphinganine concentration was increased from day 3 onwards (day 7, 0.158±0.129 μM/L; baseline 0.006±0.002 μM/L) and serum sphingosine concentration was mildly increased from day 3 onwards (day 7, 0.029±0.022 μM/L; baseline, 0.014±0.008 μM/L). Heart rate, cardiac output, stroke volume, mean arterial pressure, mean pulmonary artery pressure, pulmonary artery wedge pressure, central venous pressure, plasma volume, base-apex electrocardiogram, arterial P_{O2}, and systemic oxygen delivery were unchanged in treated and control calves. Fumonisin treated calves developed a metabolic acidosis (arterial blood pH, 7.27±0.11; base excess, -9.1±7.6 mEq/L), but all survived for 7 days. We conclude that calves are more resistant to fumonisin B_1 toxicity than pigs. This resistance is probably due to an increased ability of the calf to metabolize or excrete sphinganine and sphingosine. Alternatively, fumonisin may not inhibit sphingolipid biosynthesis to the same extent in calves as it does in pigs.

1623 ABCIXIMAB PHARMACODYNAMICS ARE UNAFFECTED BY ANTECEDENT THERAPY WITH OTHER GPIIB/IIIA ANTAGONISTS IN NON-HUMAN PRIMATES.

M. A. Nedelman[1], M. T. Nakada[2], P. M. Sassoli[2], K. A. Hwalek[1], M. A. Scalaro[1] and R. E. Jordan[2]. [1]*Primedica, Worcester, MA and* [2]*Centocor, Malvern, PA.* Sponsor: G. Treacy.

Tirofiban or eptifibatide, small molecule GPIIb/IIIa antagonists, are used for the medical stabilization of patients with unstable angina. If an unplanned percutaneous coronary intervention is necessary, conversion from tirofiban or eptifibatide to abciximab, a monoclonal antibody Fab fragment that blocks GPIIb/IIIa and alphav/beta3, may be desirable. The purpose of this study was to determine if the pharmacodynamics, pharmacokinetics and safety profile of abciximab were affected by prior treatment with either tirofiban or eptifibatide in non-human primates. Cynomolgus monkeys (either sex) were surgically instrumented with venous vascular access ports for continuous infusions and blood sampling prior to study start. At the time of study, animals were administered an intravenous bolus plus 18 hour infusion of saline (n=4), tirofiban (n=4) or eptifibatide (n=4). At the end of the 18 hour infusion, a bolus plus 12 hour infusion of abciximab was immediately initiated. Inhibition of platelet aggregation was measured using the bedside Rapid Platelet Function Analyzer (RPFA, Accumetrics) at a variety of time points during and after both infusions. In addition, GPIIb/IIIa receptor occupancy and abciximab pharmacokinetics were also measured. Abciximab pharmacodynamics and pharmacokinetics were not affected either during or after abciximab administration by prior treatment with tirofiban or eptifibatide. In addition, there were no unexpected adverse findings associated with the crossover therapy. Thus, abciximab retains a predictable magnitude and duration of effect despite antecedent therapy with small molecule GPIIb/IIIa antagonists.

1624 THE SYSTEMIC EFFECTS OF RHVEGF WHEN ADMINISTERED TO MALE CYNOMOLGUS MONKEYS BY INTRAVENOUS INFUSION (IV) OR INTRAMUSCULAR INJECTION (IM).

S. Ortega[1], T. Reynolds[1], S. Eppler[1], T. Zioncheck[1], T. Gelzleichter[1], D. Thomas[1], J. Nelson[2] and N. A. Turner[3]. [1]*Genentech, Inc., South San Francisco, CA,* [2]*Sierra Biomedical, Inc., Sparks, NV and* [3]*Battelle, Columbus, OH.*

Recombinant human vascular endothelial growth factor (rhVEGF) is a basic, heparin-binding, homodimeric protein paracrine growth factor that is secreted by a number of tissues and acts to promote angiogenesis. rhVEGF has been proposed as a therapeutic for coronary artery disease and peripheral arterial disease. The two studies discussed here were conducted to characterize systemic toxicity in monkeys from high dose IV infusion or IM injection. Both studies employed radiotelemetry, and the maximum tolerated dose (MTD) in each study was defined as a 20%-50% drop in mean arterial pressure (MAP) from baseline MAP. In the IV study, four monkeys were infused for 4 hours at various doses to determine the MTD. Once determined, two monkeys were dosed at the MTD (0.54 mg/kg/min) to characterize PK parameters. In a separate IM study, three monkeys were given escalating doses of rhVEGF into a caudal thigh muscle, with at least 72 hours between doses, to the MTD (1440 mg/kg). To determine PK parameters, an additional IM dose was administered 72 hours later at the MTD. Rapid and significant decreases in MAP and increases in heart rate were observed at the MTDs in both studies. While the PK profiles of both studies showed similarities, the IM study produced additional clinical signs of scrotal swelling and facial edema. It is unclear if these differences were route-specific or due to differences in study design. Tolerance of rhVEGF for both studies at the MTD was limited by the substantial drop in MAP.

1625 A TIME COURSE STUDY OF GENE EXPRESSION PATTERNS AND PATHOLOGY IN THE HEARTS OF RATS TREATED WITH DOXORUBICIN HYDROCHLORIDE.

H. R. Brown[1], G. Benavides[1], K. Hyder[2], L. Yoon[1], G. Gardner[1], B. Gaskill[1], L. Brown[1], L. Watkins[1] and K. T. Morgan[1]. [1]*GlaxoWellcome, Inc., Research Triangle Park, NC and* [2]*Clontech Laboratories, Palo Alto, CA.* Sponsor: C. W. Qualls.

Doxorubicin-induced cardiomyopathy is a limiting factor in the use of this anthracycline anti-neoplastic agent in cancer patients. Doxorubicin dose levels might be increased and its efficacy improved if the mechanisms of doxorubicin toxicity were more fully understood and if protective measures could be established to protect the heart during treatment. The increasing use of gene expression array technology may permit the detection of underlying mechanisms susceptible to manipulation. This study was undertaken to establish the gene expression patterns induced by a weekly toxic dose of doxorubicin hydrochloride (4mg/kg ip) in the rat heart and to follow the sequential changes of gene expression that occur leading to the eventual morphologic endpoint of dilated cardiomyopathy. Clontech Atlas and Stress Arrays (~700 genes) were used to evaluate mRNA expression from whole hearts from animals treated for 2, 7 and 43 days. Gene expression on d2 after initiation of treatment indicated an early stress pattern consistent with activation of hypertrophic and insulin signaling pathways(MAPK/ERK kinase kinase), increased mitochondrial protein trafficking (HSP60), increases in protein degradation (polyubiquitin) and in genes associated with chromosome rearrangements and DNA damage (helicase II and GADD45). By day 43, the pattern of gene expression had changed and reflected a huge down regulation cAMP-response element binding protein 1 and thus of cyclic AMP responsive genes and an increase in p53 responsive genes (waf 1) and DNA repair genes (homologues to RAD genes of yeast). Histologic samples were taken from all organs and clinical and histopathological endpoints were compared to the accompanying patterns of gene expression. Study design and knowledge of the physiologic and pathologic status of the whole animal are essential when interpreting such patterns of gene expression.

1626 IMMUNOGOLD LOCALIZATION OF METALLOTHIONEIN AND SUBCELLULAR PROTECTION AGAINST DOXORUBICIN TOXICITY IN TRANSGENIC MOUSE HEARTS.

Z. X. Zhou and Y. J. Kang. *University of Louisville, Louisville, KY.*

Previous studies using a cardiac-specific metallothionein (MT)-overexpressing transgenic mouse model have demonstrated that MT provides protection against cardiotoxicity of doxorubicin (DOX). The present study was undertaken to examine the relationship between subcellular distribution of MT and its protective action among organelles in the heart of transgenic mice. Transgenic mice containing high levels of cardiac MT (about 40 fold) and non-transgenic littermate controls were treated with DOX in a dose of 15 μg/kg via ip. Four days after the treatment, animals were anesthetized and heart tissues were removed for analyses. Electron microscopy and immunogold staining of the transgenic myocardial tissues after incubation with monoclonal mouse anti-MT antibody identified that MT was localized in nucleus, myofibers and cytoplasm. DOX induced cytoplasmic vacuolization and severe damages in myofilaments and nucleus in non-transgenic myocardium. The most predominant injury, however, ocurred in mitochondria, including striking size and shape changes, focal swelling and loss of cristae. These damages were rarely found in the DOX-treated transgenic myocardium. In particular, the internal morphology of mitochondria maintained essentially normal, although MT was not localized in this compartment. This study thus demonstrates that while subcellularly localized action of MT is important, it also plays a significant role in protection against oxidative injury by DOX in remote organelles. (Supported in part by NIH grants CA68125 and HL59225, American Heart Association EI Award (9640091N), and Jewish Hospital Foundation, Louisville, Kentucky.)

1627 PREVENTION OF VERAPAMIL-INDUCED MYOCARDIAL DEPRESSION *VIA* AN EXPERIMENTAL VERAPAMIL-SPECIFIC IGG.

R. E. Hill[1], K. Heard[1], G. M. Bogdan[2], C. Cairns[1] and R. C. Dart[2]. [1]*University of Colorado Health Sciences Center, Denver, CO and* [2]*Rocky Mountain Poison and Drug Center-Denver Health, Denver, CO.*

Verapamil-related fatalities have steadily increased resulting in approximately 30 deaths reported to the American Asssociation of Poison Control Centers in 1998. Current treatment focuses on reversal of post-binding effects of verapamil. Our laboratory has produced an ovine verapamil-specific IgG (VSIgG) that could be used as a therapeutic aid in preventing verapamil toxicity. Determine the dose response of verapamil toxicity towards left ventricular papillary muscles isolated from rats and the preventative effect of verapamil-specific IgG towards verapamil toxicity in a premixed preparation. The study was approved by the Institutional Animal Care and Use Committee. Following carbon dioxide narcosis, left ventricular papillary muscles were dissected from the hearts of male Sprague-Dawley rats (350-410g) isolated in 30 mM 2,3-butanedione monoxime-Tyrode buffer. Muscles were suspended in a oxygen perfused 30 ml Tyrode buffer bath at 37.5 degrees Celsius, stimulated at 1 Hz, and equilibrated for 90 minutes. Baseline tension was increased until Lmax was reached; isometric forces were monitored using a force displacement transducer; changes in developed tension were expressed as percent reduction from initial developed force at 15 minutes post-treatment. Concentrations of verapamil for the dose response experiment ranged from 31-1020 nM. In the VSIgG trial phase 0.1 g simethicone was added to each bath to prevent protein foaming and the following treatments were used: 510 nM verapamil, 510 nM verapamil + 1x VSIgG, and 510 nM verapamil + 1x non-specific ovine IgG. Results: Based on the calculated dose-response curve a verapamil concentration of 510 nM reduced developed tension by a mean of 53.7% (range 50-56%). VSIgG + verapamil had a mean reduction of 15.8% (+13.3%) compared with the verapamil-only mean of 31.1% (+11.2%). No statistically significant difference was shown between the non-specific ovinve IgG + verapamil and the verapamil-only treatments. The use of rat left ventricular papillary muscles proved a useful model in studying the effect of VSIgG in preventing verapamil toxicity *ex vivo*. With the production of more VSIgG further experiments could be performed to test the ability of VSIgG to reverse the effects of muscles already intoxicated with verapamil in the same model.

1628 ANTI-APOPTOTIC EFFECT OF METALLOTHIONEIN CONTRIBUTES TO ITS INHIBITION OF ISCHEMIA/REPERFUSION-INDUCED INFARCTION IN MOUSE HEARTS.

X. C. Sun, Z. X. Zhou and Y. J. Kang. *University of Louisville, Louisville, KY.*

Using a Langendorff-perfused mouse heart model, we have previously demonstrated that metallothionein (MT), a potent antioxidant, functions in cardiac protection against ischemia/reperfusion-induced infarction. The present study was undertaken to investigate possible mechanisms by which MT functions in this cardioprotection. Because apoptosis is a constant feature of myocardial damage following ischemia/reperfusion and reactive oxygen radicals are inducers of apoptosis, this study focused on effects of MT on myocardial apoptosis induced by ischemia/reperfusion. Transgenic mice with high levels of cardiac MT (40 fold) and non-transgenic controls were subjected to a left anterior descending coronary artery occlusion for 30 min followed by reperfusion. Four hrs after reperfusion, the area at risk and infarct size were assessed by Evens blue dye and triphenyltetrazolium chloride staining with computerized planimetry using an image analysis software program. Heart tissue within the area of risk was also collected and processed for a TUNEL assay to determine myocardial apoptosis. In addition, immunohistochemical method was applied to detect caspase-3 activities within the area of risk. Mitochondrial release of cytochrome c was examined by Western blot after mitochondria were separated from cytosol. Ischemia/reperfusion markedly induced infarction in non-transgenic myocardium. This occurrence was significantly suppressed in the transgenic myocardium. Corresponding to this effect, ischemia/reperfusion caused remarkable apoptosis within the area of risk in non-transgenic myocardium, which was also inhibited in the transgenic myocardium. The anti-apoptotic effect of MT correlated with its inhibition of mitochondrial release of cytochrome c and activation of caspase-3. These results thus demonstrate that MT inhibition of ischemia/reperfusion-induced infarction can at least partially be attributed to its anti-apoptotic effect through inhibition of cytochrome c-mediated pathway. (Supported in part by NIH grants CA68125 and HL59225, American Heart Association EI Award (9640091N), and Jewish Hospital Foundation, Louisville, Kentucky.)

1629 PHOSPHODIESTERASE TYPE III (PDE III) INHIBITOR INDUCES VASCULITIS PRECEDED BY APOPTOSIS IN MESENTERIC VESSELS AND LYMPHOID TISSUES IN RATS.

J. Zhang, E. H. Herman, J. L. Weaver, D. P. Chadwick, D. Broud, B. A. Rosenzweig, A. D. Knapton, V. E. Whitehurst and F. D. Sistare. *Center for Drug Evaluation and Research, FDA, Laurel, MD.*

PDE inhibitors have been shown to cause vasculitis in nonclinical toxicology studies with numerous species. Due to the lack of mechanistic details and predictive monitorable biomarkers the clinical relevance of this toxicity is uncertain. Previously, we have found vasculitis associated with necrosis and apoptosis of endothelial cells (EC) and smooth muscle cells (SMC) and with enhanced expression of ICAM-1 and von Willebrand Factor on EC in mesenteric vessels of rats 24 hrs after treatment with the PDE III inhibitor, SK&F 95654 (±-5-methyl-6-[4-(4-oxo-1,4-dihydropyridin-1-yl)phenyl]-4,5-dihydro-3(2H)-pyridazinone). The present study further defined the course of apoptosis in the mesenteric vessels and lymphoid tissues within this time frame. Sprague-Dawley rats received a single injection of 100 mg/kg of SK&F 95654 (s.c.) and were euthanized at 1, 2, 4, 6, 8, 12, 24 hrs and 2 weeks later. Control rats were given DMSO (s.c.). TUNEL assay was used to identify apoptotic cells. Apoptosis was detected in EC and SMC of mesenteric vessels and mononuclear cells in lymphoid tissues (mesenteric lymph nodes, bronchial-associated lymphoid tissue, spleen, and bone marrow). Apoptosis of circulating lymphocytes and monocytes in the lumina of mesenteric vessels was also detected. Electron microscopy confirmed the occurence of apoptosis. Apoptosis began as early as 1 hr. A time dependent increase in apoptosis reached its highest incidence at 4 hrs, gradually decreased at 6-12 hrs, and disappeared at 2 weeks. Apoptosis of mononuclear cells in peripheral blood was confirmed by flow cytometry using Annexin V-FITC assay. In the SK&F 95654-treated rats, the percentage of Annexin V binding of mononuclear cells rose to 6.4±1.9 at 1 hr, increased to 7.4±2.9 at 4 hrs, and declined to 4.4±0.7 at 24 hrs. These values were significantly different ($p<0.05$) from a value of 2.3±0.6 in control rats. These results suggest that apoptotic cell death of EC and SMC may play an important role in the pathogenesis of SK&F 95654-induced vascular toxicity in rats and that this response was also observed in peripheral blood leukocytes.

1630 EFFECT OF LEAD ACETATE AND CADMIUM CHLORIDE ON ENDOTHELIAL NITRIC OXIDE SYNTHASE EXPRESSION.

S. Ramasamy and M. Delong. *Emory University, Atlanta, GA.*

Both epidemiological and animal studies suggest a positive correlation between chronic exposure to lead and hypertension. Similarly, cadmium exposure is also linked to increase in blood pressure in animals. The mechanisms involved in the heavy metal-induced hypertension is not clear. It is well established that endothelium derived nitric oxide serves as a potent vasodilator and could play an important role in the regulation of vascular tone and blood pressure. To our knowledge, effect of lead as well as cadmium on endothelial nitric oxide synthase (eNOS) expression is unknown. It is hypothesized that lead and cadmium exposure could decrease the expression of endothelial nitric oxide synthase. Using bovine aortic endothelial cells (BAECs) as the model system, we investigated the effect of lead or cadmium on endothelial nitric oxide synthase mRNA, and protein levels as well as enzyme activities. Exposure of endothelial cells to lead acetate (0 to 10 μg/ml) or cadmium chloride (0 to 1.0 μg/ml) caused no morphological changes as observed by phase contrast microscopy. Individual exposure of BAECs to high concentrations of lead (10 μg/ml) and cadmium (1.0 μg/ml) caused 53.5% and 81.8% increase in eNOS mRNA levels, respectively, by Northern analysis. Similar increase in eNOS protein content was found by lead and cadmium treatment, by Western analysis. The eNOS activity, as measured by the conversion of labeled arginine to labeled citrulline, was significantly elevated by lead (8.93±1.16 vs 14.05±2.76 pmoles citrulline/mg protein/min) but not by cadmium (8.93±1.16 vs 10.68±1.04 pmoles citrulline/mg protein/min) treatments. Additionally, measurement of endothelin-1 by ELISA indicated that lead or cadmium treatment had no effect on endothelin-1 secretion. Contrary to our hypothesis, these results suggest that lead- or cadmium-induced hypertension may not be related to decrease in eNOS expression or increase in endothelin-1 levels. Further studies are necessary to completely understand the mechanisms of lead and cadmium-induced hypertension.

1631 PLASMA CARDIAC TROPONIN T LEVELS IN THE SPRAGUE-DAWLEY RAT AS AN INDICATOR OF CARDIOTOXICITY.

C. M. Cinege and A. B. Combs. *Division of Pharmacology and Toxicology, College of Pharmac, Austin, TX.*

Chronic abuse of the alkaloid emetine in ipecac syrup can result in cardiac toxicity. We investigated the effects of emetine cardiac toxicity on plasma cardiac troponin T (cTnT), plasma creatine kinase-MB (CK-MB), EKGs, body weights and histopathology in Sprague-Dawley rat. Male rats weighing 150-174 g were randomized to 3 groups, and were injected ip with 2 mg/kg or 4 mg/kg of emetine diHCl daily or with equivalent volumes of saline. Parameters were measured at 0, 20, 30, and 40 days of emetine treatment. The animals were anesthetized with methoxyflurane, and 400 ml of blood was collected by retro-orbital puncture. Results showed significant increases above control for cTnT activity ($p<0.05$) in the 4 mg/kg animals. CK-MB levels remain unchanged in all groups. The homology of SD rat cTnT was similar enough to the mouse monoclonal cardiac troponin T (used in human kits) for detection. During the study, the control rats continued to grow, while the emetine rats lost weight. At the end of the study the heart rates in the treated animals were less than the controls. The QRS-waveforms generally were less complex in the treated animals. Exposure to emetine left notable ventricular scarring as confirmed by histopathology. In this model, the elevations in cTnT correlated with EKG and histopathology results. These results suggest that the use of cTnT for detecting cardiac toxicity is more sensitive than CK-MB and that it may prove useful for the *in vivo* evaluation of cardiotoxicity in general.

1632 CARDIAC HYPERTROPHY IN MICE LACKING THE ARYL HYDROCARBON RECEPTOR.

E. A. Thackaberry and S. M. Smith. *University of Wisconsin, Madison, WI.*

2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD), a common environmental contaminant, has been shown to cause cardiac malformations such as ventricular-septal defects (VSDs), aortic arch anomalies, and general hypertrophy in the developing chick. These effects are believed to be mediated via the aryl hydrocarbon receptor (AhR), a bHLH/PAS protein, which binds TCDD with high affinity. Upon TCDD binding, AhR dimerizes with the aryl hydrocarbon receptor nuclear translocator protein (ARNT), binds xenobiotic responsive elements, and upregulates a battery of xenobiotic metabolism genes, including P4501A1. In response to hypoxia, ARNT also heterodimerizes with hypoxia-inducible factor 1-alpha (HIF1a), and facilitates transcription of hypoxia-responsive genes such as vascular endothelial growth factor (VEGF). This suggests a possible competition for ARNT between TCDD and hypoxic stress responses within the developing embryo. The purpose of this investigation was to use mice with a genetic deletion of AhR to dissect the roles of AhR/ARNT and HIF1a/ARNT signaling pathways in cardiogenesis. Mice lacking AhR show a marked cardiac hypertrophy, which begins before birth, and typically survived less than one year. At birth neonate heart weights for the knockouts were 0.79% of the total body weight, compared to 0.68% in controls ($p<0.001$). At six months of age, the knockout hearts were 0.82% of the total body weight, compared to0.67 for controls ($p<0.005$). Histological examination of the hearts revealed a thickening of the ventricular wall and septa, as well as an enlarged diameter of the coronary vasculature, consistent with over-stimulation of HIF1a signaling. This data suggests that AhR/ARNT signaling may have a role in normal cardiogenesis, and disruption of this normal function may lead to characteristic heart malformations.

1633 INHIBITION OF FATTY STREAK FORMATION AND LIPID OXIDATION BY LOW DOSES OF ACETAMINOPHEN IN HYPERCHOLESTEROLEMIC RABBITS.

L. K. Rogers, A. A. Taylor, J. L. Raya, A. L. Gest and C. V. Smith. *Baylor College of Medicine, Houston, TX.*

Acetaminophen inhibits LDL oxidation *in vitro*. To investigate the antioxidant and the potential anti-atherosclerotic properties of acetaminophen *in vivo*, rabbits were placed on a 1% cholesterol diet for 12 weeks, with 0 or 1 mg/ml of acetaminophen in the drinking water. The dosed animals received average doses of 28 mg/kg/d, which is lower than doses used therapeutically in humans. At the time of sacrifice, blood was collected for measurements of lipids, renal and hepatic functions, and for isolation of LDL. The aortas were removed, opened longitudinally, stained for lipid, photographed, and the total fatty streak areas determined by planimetry. Aorta fatty streaks are expressed as areas of fatty streaks relative to total aortic areas. Acetaminophen attenuated fatty streak accumulation significantly (0.32+/-0.05 vs. 0.58+/-0.06; $P<0.001$). No effects of acetaminophen were observed in total plasma cholesterol, triglycerides, BUN, or creatinine levels or in ALT/AST activities. LDL isolated from the acetaminophen-treated rabbits showed no differences in rates of Cu-catalyzed oxidation (TBARS) *in vitro*. However, the levels of 7-oxysterols in the LDL isolated from the acetaminophen-treated animals were lower than in the animals not dosed (7a-OH, 0.58+/-0.12 vs. 2.31+/-0.62; 7b-OH, 0.32+/-0.07 vs. 1.01+/-0.26; 7-keto, 0.41+/-0.14 vs. 3.86+/-1.72 nmol/mg LDL protein, $p<0.05$). The data demonstrate that low therapeutic doses of acetaminophen can diminish fatty streak formation and inhibit accumulation of oxysterols in circulating LDL. The attenuation of the levels of the cytotoxic oxysterols in circulating LDL, in conjunction with the inhibition of an important early step in atherogenesis, suggests that oxidation of circulating LDL may contribute to atherosclerosis.

1634 DIFFERENTIAL EFFECTS OF BENZO[A]PYRENE AND 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN ON CELL ADHERENS JUNCTION AND ACTIN CYTOSKELETAL PROTEINS IN HUMAN UTERINE RL95-2 CELLS.

M. A. McGarry, M. R. Bubb, M. Cambell-Thompson, T. Medrano and K. T. Shiverick. *Department of Pharmacology & Therapeutics, & Medicine, University of Florida, Gainesville, FL.*

This study investigated potential mechanisms whereby benzo(a)pyrene (BaP) and 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) may contribute to uterine disease pathology using the human endometrial adenocarcinoma RL95-2 cell line. The effects of BaP and TCDD were evaluated on the level and localization of the adherens junction proteins β-catenin, cadherin and vinculin, as well as the cytoskeletal protein actin. RL95-2 cells were cultured for 48 hours in the presence of 10 nM TCDD, 10 μM BaP or 0.1% DMSO vehicle. Western immunoblot analysis showed the presence of 92 kDa β-catenin, 120 kDa cadherin, and 130 kDa vinculin proteins in cell membrane preparations and whole cell lysates of control cells. In BaP-treated cells, membrane preparations exhibit a significant 80% decrease in β-catenin and 38% decrease in cadherin protein levels, while vinculin levels were unchanged compared to control cells. In contrast, TCDD treatment had no effect on the level of β-catenin, cadherin or vinculin in isolated membranes or whole cell lysates. Further immunocytochemical studies used the fluorescent-labeled peptide phalloidin to visualize filamentous actin. In control cells, actin filaments were localized in a continuous subcortical layer, whereas BaP-treated cells show aggregation of subcortical actin. Thus evidence from Western blot analysis and immuno-

cytochemistry indicate that BaP, but not TCDD, is associated with selective alterations in the membrane localization of key adherens junction and actin cytoskeletal proteins in RL95-2 cells. These data indicate that BaP and TCDD have different effects on uterine cells. (Supported by NIEHS Superfund Grant 07375.)

1635 OXIDATION OF POLYCYCLIC AROMATIC HYDROCARBONS AND THEIR EFFECT ON GAP JUNCTION INTERCELLULAR COMMUNICATION.

S. E. Ottinger, R. Barhoumi, K. S. McKenzie, T. McDonald, R. Autenrieth, R. C. Burghardt and T. D. Phillips. *Texas A&M University, College Station, TX.*

Polycyclic aromatic hydrocarbons (PAHs) and ozone oxidized PAHs have been reported to suppress gap junction-mediated intercellular communication (GJIC). However, toxic effects of ozonated PAHs were attributed only to the least polar of a liquid chromatography (LC) fraction. We tested the hypothesis that aqueous solutions of benzo[a]pyrene (BaP), pyrene, and other PAHs subjected to short temporal ozone exposure, would cause toxicity in the GJIC assay that would correlate with oxidation of the polycyclic rings as observed by liquid chromatography/mass spectrometry (LC/MS). Following ozonation of a 5 mg/l BaP (19.6 μM) aqueous mixture (containing 0.5% acetonitrile) at varying time intervals, the products were isolated using a solid phase extraction technique and reconstituted in DMSO for dosing in a rat liver cell line (Clone 9). Treatment with 5μg/ml of ozonated BaP resulted in a decrease in GJIC which was inversely proportional to the amount of ozonation. After 1 min (7 mmol) ozonation of BaP, there was a 90% reduction in GJIC compared to controls, whereas after 5min (35 mmol) the GJIC was the same as controls. For each ozonation time the decrease in GJIC was the same regardless of exposure duration (i.e. 1 min through 16 hr) in the Clone 9 cells. Products of pyrene ozonation exhibited an opposite pattern of toxicity. At 0.5 μg/ml the products from 1 and 2 min of ozonation showed an 18 and 37% reduction in GJIC (respectively), however 3, 4, 5, and 6 min of ozonation produced products which were still lethal to the cells. LC/MS, using atmospheric pressure chemical ionization (APCI), revealed numerous mass fragments above 252 (MW of BaP) following 1 min of ozonation but almost none after 5 min. The data indicates the reduction in GJIC may result from the oxidation of polycyclic rings and not from the cleaved oxidized chains. (Supported by NIH P42 ES04917, USDA 9703230, and TAES H6215.)

1636 COMPARISON OF *IN VITRO* BINDING AND GENE EXPRESSION OF BENZO[A] PYRENE AND TWO HYDROXYLATED BENZO[A]PYRENE METABOLITES MEDIATED THROUGH THE ESTROGEN RECEPTORS ALPHA AND BETA, AND LACK OF *IN VIVO* EFFECTS ON MOUSE UTERINE WEIGHT OR LACTOFERRIN mRNA EXPRESSION.

K. C. Fertuck, J. B. Matthews and T. R. Zacharewski. *Department of Biochemistry and National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI.*

The ability of benzo[a]pyrene (B[a]P), a polycyclic aromatic hydrocarbon, to bind to the alpha and beta forms of the estrogen receptor (ER) and to produce *in vitro* and *in vivo* estrogenic responses was assessed. While B[a]P did not significantly compete with tritiated 17-beta-estradiol ([3H]E2) for binding to the human ER alpha (bacterially expressed fusion protein consisting of GST and the DEF domains of the receptor) or human ER beta (full-length) *in vitro*, two hydroxylated B[a]P metabolites showed strong differential binding to the alpha and beta receptor isoforms. 3-hydroxy- and 9-hydroxy-B[a]P competed fully with [3H]E2 for binding to hER beta, with IC50 values of 49 nM and 1.0 mM respectively. However with hER alpha, concentrations of up to 10 mM caused only 60% and 30% displacement of [3H]E2 respectively. In transiently transfected MCF-7 human breast cancer cells, B[a]P, 3-hydroxy- and 9-hydroxy-B[a]P were similarly potent in causing human ER alpha- and mouse ER beta-mediated reporter gene expression (EC50 values 0.3 - 2 mM). Furthermore, at a concentration of 10 mM all three compounds in both the hER alpha and mER beta systems induced reporter gene expression to levels equal to that of E2 at 10 nM, with one exception: B[a]P in the hER alpha system induced levels only 25% of those of E2. Three daily doses as high as 10 mg/kg oral B[a]P or 20 mg/kg subcutaneous 3- or 9-hydroxy-B[a]P did not significantly increase uterine wet weight or lactoferrin mRNA expression in C57BL/6 or DBA/2 mice. These results suggest that the alpha and beta isoforms of the ER have a different capacity to bind and interact with B[a]P and its major hydroxylated metabolites *in vitro*. However, these compounds do not cause increased uterine weight or lactoferrin expression in the mouse.

1637 THE K-REGION, 8,9-DIHYDRODIOL OF DIBENZO[A,L]PYRENE IS A POTENT MORPHOLOGICAL CELL TRANSFORMING AGENT IN THE APPARENT ABSENCE OF STABLE COVALENT DNA ADDUCTS.

S. Nesnow, C. Davis, W. T. Padgett, L. Adams, M. Yacopucci and L. C. King. *USEPA NHEERL/ECD, Research Triangle Park, NC.*

K-region dihydrodiols of polycyclic aromatic hydrocarbons (PAHs) have been considered to be detoxification products. We previously reported on the metabolic activation of the K-region dihydrodiol of dibenzo[*a,l*]pyrene (DB[*a,l*]P), *trans*-DB[*a,l*]P-8,9-diol, to intermediates that form polar DNA adducts. This suggested that this K-region dihydrodiol might serve as an intermediate along an alternate route of metabolic activation of DB[*a,l*]P and possibly lead to genotoxic effects. We now report on the comparative genotoxic effects of *trans*-DB[*a,l*]P-8,9-diol and DB[*a,l*]P in transformable mouse embryo C3H10T½C18 (C3H10T½) fibroblasts. The C3H10T½ mouse embryo morphological transforming activities of these PAHs were conducted using concentration-response studies. At concentrations of 31 nM and above, both *trans*-DB[*a,l*]P-8,9-diol and DB[*a,l*]P produced significant (and similar) numbers of Type II and III foci per dish, and numbers of dishes with Type II&III foci. Concomitant cytotoxicity studies revealed a reduction in colony survival of approximately 25% up to 200 nM for both PAHs. DNA adducts of *trans*-DB[*a,l*]P-8,9-diol and DB[*a,l*]P in C3H10T½ cells were analyzed by a ^{32}P-postlabeling-TLC/HPLC method. Adducts were not detected in the DNA of C3H10T½ cells treated with *trans*-DB[*a,l*]P-8,9-diol at a concentration that induced morphological cell transformation. The DNA of DB[*a,l*]P-treated cells did bear adducts of deoxyadenosine and deoxyguanosine derived from the fjord-region diol epoxides of DB[*a,l*]P. These results indicate that *trans*-DB[*a,l*]P-8,9-diol has intrinsic genotoxic activity equal to that of DB[*a,l*]P, based on morphological cell transformation of mouse embryo cells. This activity is apparently not associated with the formation of observable stable covalent DNA adducts. These results suggest that under appropriate conditions *trans*-DB[*a,l*]P-8,9-diol may serve as an intermediate in the genotoxicity of DB[*a,l*]P. (This abstract does not necessarily reflect US EPA policy.)

1638 DIFFERENTIAL PROTECTION BY RAT UDP-GLUCURONOSYL TRANSFERASE UGT1A7 AGAINST BENZO[A]PYRENE-3,6-QUINONE- VERSUS BENZO[A]PYRENE-INDUCED CYTOTOXIC EFFECTS IN HUMAN LYMPHOBLASTOID CELLS.

J. K. Ritter[1], A. D. Grove[1], G. C. Llewellyn[1], K. L. White[1], C. L. Crespi[2] and F. K. Kessler[1]. [1]*Virginia Commonwealth University, Richmond, VA and* [2]*Gentest Corp., Woburn, MA.*

UDP-glucuronosyltransferase 1A7 (UGT1A7) is a polyaromatic hydrocarbon (PAH)-inducible UGT with activity towards various benzo(a)pyrene [B(a)P] metabolites. To investigate the influence of rat UGT1A7 on B(a)P-induced cytotoxicity, human lymphoblastoid L3 cells were transfected with either pMF6 (control expression vector), p167Dtk2 (microsomal epoxide hydrolase expression vector) or p167Dtk2-1A7 (epoxide hydrolase/UGT1A7 co-expression vector), and the cell populations were compared for sensitivity to B(a)P-induced effects. B(a)P inhibited cell proliferation and decreased relative cell survival of p167Dtk2- and p167Dtk2-1A7-cells to a similar extent. Metabolism studies using [^{3}H]-B(a)P revealed increased formation of glucuronide conjugates of B(a)P-4,5-diol, 3-OH- or 9-OH-B(a)P and an unidentified metabolite by p167Dtk2-1A7 cells but the presence of unconjugated metabolites suggested that glucuronidation capacity may be limited. No differences between p167Dtk2 and p167Dtk2-1A7 L3 cells were observed in the growth inhibitory effects of 3-OH-B(a)P or B(a)P-7,8-diol, but p167Dtk2-1A7 expressing cells were found to be less sensitive to B(a)P-3,6-quinone-induced effects on cell proliferation and relative cell survival. The effect was also observed in AHH-1 lymphoblastoid cells expressing UGT1A7 without epoxide hydrolase. The UGT1A7-expressing AHH-1 cells were also less sensitive to growth inhibition by B(a)P-1,6-quinone and B(a)P-6,12- quinone. Flow cytometric analysis of vehicle and B(a)P-3,6-quinone-exposed cell populations showed an association between UGT1A7 expression and resistance to B(a)P-3,6-quinone-induced apoptosis and loss of cell viability. These data suggest that UGT1A7 may be preferentially active towards B(a)P-quinones and that UGT1A7 may represent the PAH-inducible UGT activity previously implicated in protection against toxic redox cycling by B(a)P-3,6-quinone.

1639 EXPRESSION OF CYTOCHROME P-450 1A1 (CYP1A1) AND DNA ADDUCT FORMATION IN RAT LIVER AND LUNG SLICES INCUBATED WITH BENZO[A]PYRENE (BAP) IN DYNAMIC ORGAN CULTURE.

J. A. Hand[1], B. P. McGarrigle[1], A. E. Maccubbin[2] and J. R. Olson[1]. [1]*Dept. Pharm. Toxicol., SUNY at Buffalo, Buffalo, NY and* [2]*Dept. Pharm., Roswell Park Cancer Institute, Buffalo, NY.*

The cytochrome P-450 (CYP450) dependent monooxygenase system is the primary route by which xenobiotics and environmental contaminants are detoxified in mammals. However, polycyclic aromatic hydrocarbons (PAHs) are one class of compounds that are activated by CYP450s to mutagenic, carcinogenic, and toxic metabolites. BaP is a prototypical PAH which is metabolized by the subsequent actions of CYP1A1 and epoxide hydrolase to its ultimate carcinogen BaP-7,8-diol-9,10-epoxide (BPDE). Furthermore, BaP can enhance its own metabolism by binding to the aryl hydrocarbon receptor, inducing expression of genes containing xenobiotic response elements, including CYP1A1. Precision cut rat liver and lung slices maintained in dynamic organ culture were utilized as an *in vitro* model to assess expression of CYP1A1 and DNA adduct formation under various conditions. Rat liver and lung slices were incubated for 4 or 24 hrs in medium containing 0, 1, 10, or 80 μM BaP. The *in vitro* expression of CYP1A1 was measured by competitive reverse transcriptase polymerase chain reaction (RT-PCR). Rat liver slices incubated for 24 hrs with 1, 10, or 80 μM BaP contained 8.09×10^5, 2.49×10^6, and 1.58×10^7 molecules of CYP1A1 mRNA, respectively. CYP1A1 mRNA in rat liver slices incubated for 24 hrs without BaP was below the limit of detection. DNA was isolated from tissue slices and DNA adduct formation was measured by ^{32}P-postlabeling. Rat liver slices incubated for 24 hrs with 0, 1, 10, or 80 μM BaP contained 0.02, 0.05, 0.32, and 2.43 fmoles adduct/μg DNA, respectively. Thus, the induction of CYP1A1 mRNA by BaP correlates with the formation of BaP-DNA adducts. Furthermore, the adduct levels correlate directly with the concentration of BaP. The preliminary results suggest this is a useful model for the detection of CYP450 expression and the quantitation of DNA adduct formation under these conditions and may be suitable for the examination of other tissues and species, including humans.

1640 TRANSIENT ANEMIA INDUCED IN NZB/WF1 MICE TREATED WITH BENZO[A]PYRENE.

E. K. Leffel, C. D. Booker and K. L. White, Jr. *Virginia Commonwealth University, Richmond, VA.*

The NZB/WF1 mouse is an autoimmune model for systemic lupus erythromatosus (SLE) and it is derived from the cross of the New Zealand Black (NZB) and the New Zealand White (NZW). The NZB parent develops an autoimmune hemolytic anemia, which can be fatal. In previous studies, no changes in autoimmune SLE parameters (serum total IgG, or IgG titers to double stranded DNA, DNP-HSA, or laminin) were observed in BaP treated NZB/WF1 mice. However, hematological characteristics of anemia and an increase in spleen weight was observed in mice treated with 20 mg/kg BaP dermally. The objective of this study was to determine if the observed anemia was autoimmune-related. NZB/WF1 female mice, 7 weeks of age, were exposed dermally to BaP (0.02, 0.2, 2, 20 mg/kg) daily for thirty days. Vehicle mice were dermally exposed to acetone/olive oil (9:1). A significant increase (40-90%) was seen in spleen weight in the 20mg/kg BaP treated groups, however, evaluation of spleen cellularity demonstrated that the elevated spleen weight was not due to an increase in spleen leukocytes. At this dose level there was a significant decrease in erythrocytes (17%), hemoglobin (7%), and hematocrit (8%) and an 11% increase in both mean corpuscular volume and mean corpuscular hemoglobin. No significant effects were observed in spleen weights or hematological parameters at doses less than 20 mg/kg. In animals treated with 20 mg/kg for 30 days and then maintained for 50 days, hematological values returned to normal and did not differ from the vehicle controls. Furthermore, serum from anemic animals did not differ from control serum in its ability to lyse NZB/WF1 erythrocytes. These results suggest that BaP administered dermally at a dose of 20mg/kg has the potential to produce transient anemia in NZB/WF1 mice, which is not autoimmune mediated. (Supported in part by NIEHS Contract ES 55387.)

1641 BENZO[A]PYRENE METABOLITES MODULATE SP1 DEVELOPMENTAL EXPRESSION PROFILES IN RATS SUBSEQUENT TO AEROSOL EXPOSURE.

D. B. Hood, A. Ramesh, T. Nayyar, M. M. Greenwood, F. Inyang, A. Nyanda and A. Archibong. *Meharry Medical College, Nashville, TN.*

Control male and female and timed-pregnant rats were dosed via nose-only exposure for four hours to acute doses of B(a)P : carbon black aerosol. A subgroup of the control animals was sacrificed at 30, 60, 120, and 240 minutes post-exposure and blood, lung, liver, testis, and ovaries were removed and analyzed for B(a)P metabolites. Nuclear extracts from various brain regions from pups that resulted from exposure of the timed-pregnant dams on gestation day 15 were analyzed by electrophoretic mobility shift assay on postnatal days (PND) 3, 5, 10, 15, 20 and 30. The results demonstrate a dose-dependent increase in B(a)P metabolite bioavailability in reproductive tissues. Tissue metabolite levels were maximal at 60 minutes post exposure with females exhibiting a 5-fold statistically significant increase ($p < 0.05$) compared to males within the 1.0 mg/m^3 exposure group. At 240 minutes post exposure, 95% clearance from tissues was observed when compared to the 30-minute post exposure group ($p < 0.05$). Sp1 cortex and cerebella developmental expression profiles from pups exposed transplacentally to B(a)P : carbon black aerosol exhibited a dose-dependent ($p < 0.05$) premature peak of Sp1-DNA binding on PND 3. The results suggest a possible neurotoxic molecular mechanism involving the 7β, 8α dihydroxy-9α, 10α-epoxy 7, 8, 10-tetrahydro-benzo(a)pyrene metabolite augmenting gene expression through modulation of the function of transcription factors. (Supported by Cooperative Agreement MHPF/ATSDR U50/ATU398948, NIH G12 RRO 3032, and NIEHS 00287.)

1642 DIETARY 3-METHYLCHOLANTHRENE (3MC) INDUCES CYP1A AND CONVERSION OF BENZO[A]PYRENE-7,8-DIHYDRODIOL TO METABOLITES THAT BIND DNA IN CATFISH INTESTINE.

M. O. James[1], C. J. Li[1], Z. Lou[1], K. M. Kleinow[2] and J. J. Stegeman[3]. [1]*University of Florida, Gainesville, FL,* [2]*Louisiana State University, Baton Rouge, LA and* [3]*Woods Hole Oceanographic Institution, Woods Hole, MA.*

The intestine is both a target organ and site of uptake of environmental carcinogens. Dietary exposure of catfish to 3MC (10 mg/kg diet) prior to use in an *in situ* intestinal perfusion affected the extent of biotransformation, but not systemic uptake of [^{3}H]-benzo(a)pyrene-7,8-dihydrodiol (BaP-7,8D), introduced at 20μM and 40μM. Portions of the mucosa collected from *in situ* isolated intestinal preparations were homogenized and used to prepare subcellular fractions. DNA was isolated from the nuclear fraction and the radioactivity measured. AHH activity of intestinal microsomes was determined with a fluorescence assay and CYP1A content was detected by Western immunoblots, using a scup monoclonal antibody, and quantitated relative to the signal from rat CYP1A. DNA adducts were found in all samples. In controls, 0.8 to 2.6 pmol BaP-7,8-D molar equivalents bound per mg DNA, with no difference between fish exposed to 20 or 40 μM BaP-7,8D. The extent of DNA binding was higher in samples from 3MC-exposed fish. Fish exposed to 40 μM BaP-7,8D bound 42.5 ± 18.2 pmol/mg DNA(mean±S.E., n=5) than the 20 μM group 9.22±2.86 pmol/mg DNA, n=5. CYP1A was undetectable in intestinal microsomes from control fish but was present in all 3MC-exposed fish, 20±4 pmol/mg protein, n=10. AHH activity was low in control fish, 2.7±0.4 pmol 3OHBaP/mg protein, n=12 and induced in 3MC-exposed fish, 26.9±4.1, n=9. These results indicate the importance of CYP1A in activation of BaP-7,8D to DNA-reactive metabolites, and suggest the possibility that other CYP contribute to the formation of reactive metabolites in intestine. (Supported in part by NIEHS/NIH grant ES05781.)

1643 CHEMISTRY OF FINE PARTICLES, PAHs AND ORGANIC FREE RADICALS (OFRS) IN SOOT FROM COMBUSTION OF 1,3 BUTADIENE AT PETROCHEMICAL PLANTS AND REFINERIES.

J. Catallo[1], S. Grace[2] and S. Barker[1]. [1]*LSU School of Vet. Med.; Physiol., Pharm. & Tox., Baton Rouge, LA and* [2]*LSU Biodynamics Institute, Baton Rouge, LA.* Sponsor: A. Penn.

Production, processing, containment, and transport of C2-C8 hydrocarbon streams at refineries and petrochemical plants gives rise to losses of volatile organic chemicals (VOCs). These materials typically are flared, and this generates soot particles over a broad size range (0.002 - >5μm). Work in our laboratories shows that flaring of common VOCs such as acetylene, butane,

toluene, ethyl benzene, and styrene can give rise to substantial amounts of soot and other partially combusted products (up to 1% w/w). Working with 1,3-butadiene (a major component of petrochemical VOC mixtures to be flared) as a model, we found that its soot contains a broad and unique array of polycyclic aromatic hydrocarbons (PAHs). These included several known and suspected human carcinogens and high molecular weight PAHs (mass 300 - >1000 amu) in substantial amounts (e.g., 1000-5000 cigarette equivalents of (benzofluoranthenes+benzopyrenes) + perylene per g substrate burned; 2040 µg benzo(a)pyrene per g soot). When NOx were present during or after combustion, nitro- and polynitro- phenols, toluenes, and PAHs were found in the mixture in similar amounts. Further, the soot particles were found to have strong solid state free radical character in ESR analyses (i.e., g=2.0024; approx. 4% spin/weight). This free radical was stable for more than a year in the solid state, and extractable into solvents (toluene, DMSO) where it was stable for days. Butadiene soot extract also is electrochemically active at electrodes (+1.2 V vs. SCE) and in solution where it oxidized dissolved ascorbate. These and other data are offered in support of ongoing toxicological studies of these mixtures in normal human cell lines (q.v., sister presentation of C. Kennedy, et al.).

1644 EFFECTS OF PCB MIXTURES AND CONGENERS ON THE BILIARY EXCRETION OF THYROXINE.

L. A. Martin[1], M. A. Gallo[1], N. R. Vansell[2] and C. D. Klaassen[1]. [1]*Rutgers, The State University of New Jersey, Piscataway, NJ and* [2]*University of Kansas Medical Center, Kansas City, KS.*

Polychlorinated biphenyl (PCB) mixtures and congeners effectively reduce circulating concentrations of thyroxine (T_4). This is thought to occur because of their ability to induce the UDP-glucuronosyl transferases that conjugate T_4 and the subsequent excretion of the glucuronide into bile. To determine whether there is a good correlation between the ability of PCBs to reduce T_4 and increase the biliary excretion of T_4 glucuronide, PCB congeners 95 (16 mg/kg), 99 (16 mg/kg), 118 (16 mg/kg) and 126 (40 µg/kg); Aroclors 1242 (32 mg/kg) and 1254 (32 mg/kg), and TCDD (3.9 µg/kg) were administered *via* gavage to male Sprague-Dawley rats for seven days. Twenty-four hours after the last dose, the femoral artery and vein and the common bile duct were cannulated. Following administration of $[^{125}I]T_4$, bile was collected at 30-min intervals for two hrs. Blood was collected at the mid-point of each bile collection period. Urine was also collected at two hrs. The total excretion of T_4 and its metabolites was quantified by gamma spectrometry, followed by HPLC analysis. All seven treatments decreased the serum concentration of T_4. Of the congeners, PCB 99 and 118 produced the largest decreases in serum T_4 concentration, whereas PCB 95, PCB 126 and TCDD had the least effect. None of the seven treatments had a marked effect on the urinary excretion of T_4 and its metabolites. In contrast, biliary excretion of T_4 glucuronide after administration of TCDD, PCB 118 or Aroclor 1254 was increased 6 to 8-fold, PCB 126 produced a 3 to 5-fold increase, whereas PCB 95 and PCB 99 produced less than a doubling. TCDD, one of the treatments that had the least effect on decreasing the concentration of T_4 in serum, increased the biliary excretion the most. In contrast, PCB 99, one of the congeners that decreased the serum concentration of T_4 the most, had the least effect on its biliary excretion. Therefore, there does not appear to be a good correlation between the ability of PCBs to decrease plasma T_4 concentration and increase its biliary excretion. (Supported by NIH grant ES-08156 and ES-05022, and EPA grant R826297.)

1645 ANTIESTROGENICITY OF CLARIFIED SLURRY OIL AND TWO CRUDE OILS IN A HUMAN BREAST-CANCER CELL ASSAY.

K. F. Arcaro[1], J. F. Gierthy[2] and C. R. Mackerer[3]. [1]*University at Albany, School of Public Health, Albany, NY,* [2]*New York State Department of Health, Albany, NY and* [3]*Mobil Business Resources Corporation, Paulsboro, NJ.*

Clarified slurry oil (CSO), a refinery stream produced by processing crude oil, and two crude oil samples, Belridge Heavy Crude Oil (BHCO) and Lost Hills Light Crude Oil (LHLCO) were examined for their estrogenic and antiestrogenic properties in a human breast-cancer cell (MCF-7) assay. The MCF-7 focus assay is based on postconfluent cell growth and tissue restructuring measured as the development of multicellular layers or foci. Oil samples were prepared in DMSO resulting in extraction of virtually all of the aromatic hydrocarbons including the 3-7 ring polycyclic aromatic compounds (PACs) comprising 62.2% of the CSO, 9.0% of the BHCO, and 2.0% of the LHLCO by total weight. None of the three samples were estrogenic in the MCF-7 focus assay. In contrast, all of the samples were antiestrogenic, i.e. they inhibited the development of foci induced by 1.0 nM 17β-estradiol (E_2). The potency of the samples was correlated with the percent of PACs they contained. Radiometric analysis of the catabolism of $[^3H]E_2$ in MCF-7 cell cultures demonstrated that all three samples resulted in an increase in the catabolism of E_2. It is suggested that PACs in the samples induced enzymes in MCF-7 cells that catalyzed the catabolism of E_2, accounting for at least part of the observed antiestrogenicity. (Supported by NIH ES04913 and Mobil Business Resources Corporation.)

1646 CHARACTERIZATION OF ASPHALT FUME GENERATION SYSTEM.

J. Wang, D. G. Frazer, S. Tomblyn, S. Stone, A. Afshari, B. Z. Zhong, D. M. Lewis and P. D. Siegel. *NIOSH/HELD, Morgantown, WV.*

A dynamic asphalt fume generation system (Heritage Research Group, Indianapolis, IN) was modified to provide consistent test atmospheres emulating road asphalt paving conditions. Characterization of the asphalt fume test atmospheres included (1) identification and characterization of chemical composition of polycyclic aromatic hydrocarbons (PAHs) by gas chromatography-mass spectrometry (GC-MS) of asphalt fume fractions collected by TPFE filter (0.5µm pore size at a flow rate of 1.0 liters/min), XAD-2, charcoal, and cold trap (-190°C, liquid N_2); (2) determination of the asphalt fume generation system uniformity of the aerosol distribution within the generator and exposure chamber; (3) gravimetric analysis (4) use of a photoionization detector (PID) for the vapor phase and a light scattering aerosol monitor for on-line monitoring of chamber concentration; and (5) detection and minimization of interferences from insulation and gasket materials within the system. The asphalt was initially preheated in an oven to 170°C, pumped to a large bitumen kettle, which maintained the asphalt temperature at between 150-170°C and then transferred to the generator (inlet temperature of 145-150°C). The fume was then conducted from the generator to an exposure chamber through a heated transfer line. Positive chemical ionization GC-MS using methane as the reagent gas and a 30 meter, 5% phenyl fused silica capillary column was used to characterize the fume. A total ion chromatography of PAHs was obtained with an initial temperature 50°C increased at 5°C/min to 310°C. The results indicated that asphalt fume chemical group characterization can be achieved using a combination of sampling methods with GC-MS detection. The generator output was both qualitatively and quantitatively very consistent when run 3 to 3.5 hrs/day for 5 consecutive days (CV < 20%). The results demonstrate that reproducible, consistent road paving type asphalt fumes can be generated for inhalation toxicity studies. (This work was supported, in part, by NIEHS/NTP.)

1647 THE AHR AND CYP1B1 AS TARGETS FOR PEPTIDE/TUMOR-SPECIFIC CANCER IMMUNOTHERAPY.

B. Maecker[1], R. Vonderheide[1], M. von Bergwelt-Baildon[1], M. Bedor[1], C. Shen[2], J. Schultze[1] and D. H. Sherr[2]. [1]*Dana-Farber Cancer Institute, Boston, MA and* [2]*Boston University School of Public Health, Boston, MA.*

Recent advances in the definition of requirements for antigen presentation suggest novel strategies for inducing tumor-specific CTL with peptides derived from tumor-associated antigens. The demonstration here of extremely high *AhR* and *CYP1B1* mRNA levels in human myeloma, ovarian carcinoma, and breast carcinoma cell lines indicates that the AhR and the AhR-regulated CYP1B1 enzyme may be two such proteins. Peptide-MHC class I binding algorithms were used to identify human AhR and CYP1B1 peptides predicted to bind the product of the relatively common HLA-A201 allele. Of 3 AhR and 3 CYP1B1 nanomers predicted by the algorithms, 2 derived from each protein bound HLA-A201 with relatively high affinity. To test their immunogenicity, these peptides were loaded onto HLA-A201 dendritic cells (DC) and CD40 ligand (CD40L)-activated B cells and presented to autologous $CD8^+$ T cells. $CD8^+$ T cell lines were generated following an initial stimulation with peptide-pulsed DC (with IL-7) and repeated stimulations with peptide-pulsed CD40L-activated B cells (with IL-7 and IL-2). These putative CTL lines specifically lysed autologous CD40L-B cells pulsed with cognate but not unrelated peptides. Furthermore, both AhR peptide- and CYP1B1 peptide-specific CTL lines lysed human myeloma and/or carcinoma cell lines expressing both HLA-A201 and high levels of AhR and CYP1B1, respectively, but did not kill tumors expressing little or no AhR/CYP1B1 or tumors expressing a different HLA-A allele. These results encourage the generation of AhR- and CYP1B1-specific CTL for adoptive immunotherapy of AhR^{high} and $CYP1B1^{high}$ cancers.

1648 COMPARATIVE RESPONSIVENESS OF LONG EVANS RATS VERSUS C57BL/6J MICE GIVEN TCDD-LIKE AND PHENOBARBITOL-LIKE PCB (POLYCHLORINATED BIPHENYL) CONGENERS.

E. S. Craft[1], D. G. Ross[2], M. J. DeVito[2] and K. M. Crofton[3]. [1]*North Carolina State University, Raleigh, NC,* [2]*USEPA NHEERL Experimental Toxicology Division, Research Triangle Park, NC and* [3]*USEPA NHEERL Neurotoxicology Division, Research Triangle Park, NC.*

PCBs decrease thyroxine (T4) in the rat by induction of uridine diphosphate glucuronosyl-transferases (UDPGTs) via two different mechanisms; activation of the aryl hydrocarbon receptor (AhR) (PCB126), or a phenobarbitol-like mechanism (PCB153). This study compared the sensitivity of rats and mice to PCB induced hypothyroxemia. Eight-week old male and female C57BL/6J mice, and 25 day-old Long Evans rats were orally dosed with PCB126 (0.03-300.0 μg/kg/day, and 0.03-100.0 μg/kg/day, respectively) or PCB153 (0.3-90.0 mg/kg/day, 0.9-90 mg/kg/day) in 10 ml/kg corn oil vehicle for four consecutive days. Trunk blood and livers were collected one day post-dosing. Total serum T4 was measured via radio-immunoassay. Liver microsomal CYP1A1(EROD) and CYP2B2(PROD) were determined as biomarkers for AhR and Pb-like activities, respectively. T4-glucuronide was determined in both the rat and mouse. PCB153 decreased T4 (up to 80%) in both the rat and the mouse, while PCB126 did not effect T4 in the mouse, but decreased T4 (up to 50%) in the rat. PCB153 produced a 10-fold induction of PROD activity in the rat, and a smaller 3-4 fold induction in the mouse. EROD activity increased by approximately 20 fold in rats and mice given PCB126. These data suggest species differences in induction of glucuronosyltransferase activity between mice and rats. The lack of effect of PCB126 on T4 in mice suggests a lower sensitivity or altered responsiveness compared to rats. (This abstract does not necessarily reflect the policy of NCSU or the US EPA.)

1649 EFFECTS OF CO-EXPOSURE OF BENZENE AND RADIATION (YTTRIUM-90) ON HEMATOPOIESIS IN CBA/CA MICE.

C. Timchalk[1], J. E. Morris[1], R. A. Corley[1] and K. Rithedech[2]. [1]*Battelle, Pacific Northwest National Laboratory, Richland, WA and* [2]*State University New York at Stony Brook, Stony Brook, NY.*

The hematopoietic system may be sensitive to the effects of low-dose chemical mixtures and ionizing radiation. Exposure to benzene or radiation causes acute bone marrow toxicity and increased incidence of acute myelogenous leukemia in humans. Based on common target tissues and similar biological response it is proposed that biological interactions between benzene and radiation are plausible. Male CBA/Ca mice (5/group) were utilized. Mice were orally administered benzene, by gavage, at doses of 0, 30, 100 and 300 mg/kg as single doses for 5 consecutive days (5 doses/animal). Mice were also given a single ip dose of Yttrium-90 (Y-90) a beta emitting bone-seeking radionuclide at doses of 0, 250, 500 or 1250 μCi/kg and the mice were held for 7 days. The results from these initial studies were used to set dose levels for the mixed exposure. For the co-exposure, mice were dosed benzene alone (all doses), Y-90 alone (1250 μCi/kg) or benzene + Y-90 (100 & 300 mg/kg + 1250 μCi/kg). Y-90 was dosed on day 1, and benzene exposure started on day 3 through day 7 as previously described. Hematological evaluations of bone marrow and peripheral blood were conducted. For all treatment groups, a dose-dependent decrease in the volume of packed red cells and total nucleated cells was observed and the response was greater following co-exposure. Co-exposure to benzene + Y-90 increased the erythroid cells relative to benzene alone (149-171%), but the increase was less than seen with Y-90 (85-89%). In contrast, co-exposure elevated the myeloid cells (119-134%) relative to Y-90 alone, but was less than or comparable to benzene (79-106%). Both benzene and Y-90 alone decreased the lymphocyte cells, however, only high dose co-administration enhanced the inhibition to 24% and 27% of the Y-90 and benzene doses, and 17% of control. The individual responses are consistent with previous results with benzene or radiation on hematopoiesis. However, the biological response following co-exposure is more complex since benzene and Y-90 induce different shifts in the myeloid and erythroid cells. Future studies are needed to elucidate the biological implications of these interactions.

1650 A COMPARISON OF THE CELISA ASSAY AND THE CLONOGENIC COLONY ASSAY IN DETERMINATIONS OF MYELOTOXICITY.

D. E. Greenwalt and J. Szabo. *Poietics/BioWhittaker, Gaithersburg, MD.* Sponsor: G. E. Dearlove.

A comparison of the CELISA™ assay and the clonogenic colony assay in determinations of myelotoxicity. Bone marrow is extremely sensitive to the toxic side effects of chemotherapeutic drugs. Bone marrow toxicity is often a limiting factor in the dosing and duration of chemotherapy. Discovery and elimination of toxic compounds early in the drug discovery process is a high priority. Myelotoxicity is currently assayed through use of the clonogenic "colony assay". The extremely low throughput nature of the colony assay precludes its use in high throughput toxicity testing. A high-throughput CELISA assay of hematopoiesis based on the quantification of differentiation-specific cell surface markers now allows high-throughput analysis of the effects of experimental drugs on hematopoiesis. The CELISA assay is a 96-well-based suspension culture system for human hematopoietic progenitor cells which quantifies the commitment and differentiation of CD34+ cells to specific lineages. The expression of maturation and lineage markers on the cells in culture is measured by use of a time-resolved fluorescence immunoassay. The expression of three different lineage markers can be measured: CD11b for myeloid cells, platelet glycoprotein IIb/IIIa (or CD41a) for megakaryocytic cells, and glycophorin A for erythroid cells. The assay is set up specifically to examine more than one lineage as there are numerous examples of lineage-specific effects. Quantification of the CELISA assay requires only 60 minutes as opposed to the lengthy process of manually counting colonys required by the colony assay. Results of direct comparisons of the CELISA and colony assays document a direct correlation between data from these two assays. These results indicate that the CELISA assay system can substitute for the clonogenic colony assay for screening potential myelotoxic agents and affords researchers the opportunity to perform high-throughput screening for myelotoxicity.

1651 TREATMENT OF RATS WITH CLOZAPINE DECREASES THE NUMBER OF CD34+ BONE MARROW CELLS.

J. H. Zhan and J. P. Uetrecht. *University of Toronto, Toronto, Ontario, Canada.*

Clozapine therapy is associated with a relatively high incidence of agranulocytosis (~0.8%). Neutrophil precursors in the bone marrow appear to be the target because these cells are markedly decreased in patients with clozapine-induced agranulocytosis. We have previously demonstrated that a reactive metabolite of clozapine covalently binds to neutrophils in humans and to bone marrow cells in rats *in vivo* even though neither the persons nor the rats that were studied developed agranulocytosis. In this study we examined the bone marrow of rats that had been treated with clozapine (65 mg/kg/day for 6 weeks) using a fluorescent antibody against CD34 and a fluorescence activated cell sorter (FACS). CD34 is a marker for bone marrow precursor cells. We found that this clozapine treatment decreased the fraction of CD34+ cells from 7% to 3% ($P < 0.005$), but such treatment does not cause a significant decrease in the number of peripheral neutrophils. This indicates that clozapine has a significant effect on precursor cells in the bone marrow, and the lack of an effect on peripheral neutrophil numbers suggests that the bone marrow can generally compensate for these changes. We propose that the covalent binding of clozapine to bone marrow cells and the decrease in the number of these cells expressing CD34 in bone marrow are precursors to the development of agranulocytosis; however, additional steps, which do not occur in most patients or animals, must be required. (Supported by a grant from the Medical Research Council of Canada.)

1652 ROLE OF MEK KINASE PATHWAYS IN HEMATOPOIESIS.

S. I. Wert[1], B. A. Jones[2], P. A. Scherle[2] and B. D. Car[1]. [1]*Dupont Pharmaceuticals Company, Newark, DE and* [2]*Dupont Pharmaceuticals Company, Wilmington, DE.*

Mitogen actived protein (MAP) kinase inhibitors are under development as potential antiinflammatory and anticancer agents. A role for MAP kinase signal transduction pathways in hematopoiesis has been proposed, therefore, a study was conducted to assess the potential myelotoxic effects of MAP kinase inhibition. Bone marrow from C57BL/6 mice was cultured for 9 days in the presence of erythropoietin, IL-3 and IL-1. Specific inhibitors of the P42/44 MAP kinase pathway (UO126, SL327 and PD 098059; MEK inhibitors), an inactive analogue of UO126 (SM015), an inhibitor of P38 MAP kinase

(SK&F 86002), and of p70/S6 kinase (rapamycin) were added to primary bone marrow cultures at 1 or 10μM, and the effects on erythroid and myeloid colony growth and differentiation were evaluated. To confirm the presence of an active P42/44 MAP kinase pathway in proliferating hematopoietic cells, ERK phosphorylation was assessed. It was found to be rapidly induced (5 min) in bone marrow cells by a cocktail of IL-1, IL-3 and erythropoietin as shown by phosphoimaging and western immunoblot analysis. UO126, SL327 and PD 098059 inhibited ERK phosphorylation in order of potency from most (>95%) to least (approximately 50%), but had no effect on erythroid or myeloid colony growth. SM015 did not alter signal transduction or *in vitro* hematopoiesis. The p38 MAP kinase inhibitor had a mild potentiating effect on erythropoiesis but no effect on myelopoiesis. Rapamycin resulted in a marked reduction in erythroid and myeloid colony formation, confirming an essential role for signals transduced through P70/S6 kinase in hematopoiesis. Both major MAP kinase pathways (P42/44 and P38) were shown to be largely redundant for *in vitro* hematopoiesis, thus inhibitors of MAP kinase pathways were, therefore, considered unlikely to be myelotoxic.

1653 HEMATOTOXICITY OF DITHIOCARBAMATES ON CD34+ HUMAN BONE MARROW CELLS.

R. D. Irons, Y. Yang, A. Le, W. S. Stillman and D. W. Pyatt. *University of Colorado, Denver, CO.*

Dithiocarbamates (DTC), an important class of therapeutic and industrial chemicals, have been alternatively suggested to be either beneficial or toxic to the hematopoietic system. DTC have also been shown to be potent inhibitors of the transcription factor, nuclear factor kB (NF-kB) in a variety of cell types. Previous studies in our laboratory have demonstrated that NF-kB is required for normal clonogenic response in CD34+ human bone marrow cells (Pyatt et al., 1998). Therefore, we investigated the potential of two DTC, dimethyl- and diethyl- DTC, to directly alter clonogenic response of primary human CD34+ bone marrow cells *in vitro*. Our results demonstrate that DTC suppresses cytokine-dependent colony formation in human CD34+ bone marrow cells at concentrations between 0.1-0.5 μM. Inhibition of colony formation by DTC is not likely to be the result of cytotoxicity, because DTC-induced apoptosis only occurs at doses significantly higher than those required for colony inhibition. Surprising, experiments reveal that DTC does not inhibit cytokine activation of NF-kB in CD34+ bone marrow cells. These results indicate that extremely low concentrations of DTC suppress growth factor-dependent clonogenic response of CD34+ bone marrow cells *in vitro* which may explain the hematotoxicity observed in previous clinical trials with DTC. DTC induced hematotoxicity also appears to occur via a mechanism that is independent of NF-kB inhibition. (This research project was supported in part by the Chemical Manufacturers' Association.)

1654 HEMATOTOXICITY OF THE CHINESE HERBAL MEDICINE, TRIPTERYGIUM WILFORDII HOOK F IN CD34+ HUMAN BONE MARROW CELLS.

D. W. Pyatt, Y. Yang, B. Mehos, A. Le, W. S. Stillman and R. D. Irons. *University of Colorado, Denver, CO.*

T2, a chloroform/methanol extract of the herb Tripterygium wilfordii Hook f, has been used in the treatment of autoimmune and inflammatory diseases by the Chinese for many years. Recent experimental evidence has confirmed that T2 has potent anti-inflammatory and immunosuppressive activity and a FDA approved clinical trial is ongoing in the US to explore the efficacy of T2 in the treatment of rheumatoid arthritis. Despite the potential therapeutic benefits of T2, there is ample documentation that T2 is toxic, targeting among other things the hematopoietic system, and it's use has resulted in cases of leukopenia, thrombocytopenia and aplastic anemia. This investigation was undertaken to characterize the *in vitro* effects of T2 on primary human CD34 positive bone marrow cells. Our results demonstrate that T2 has a potent inhibitory effect on the clonogenic response of human bone marrow cells to exogenously added hematopoietic growth factors. This inhibition occurs at concentrations well below those required for immunosuppression and may represent a serious consequence for patients treated with this drug. The inhibition of colony formation by T2 is not the result of direct cytotoxicity nor increased apoptosis and indicates a functional suppression of hematopoiesis. Additional experiments demonstrate that T2 also alters transcriptional regulation in bone marrow cells by inhibiting Nuclear Factor-kB (NF-kB). This transcription factor is found in CD34+ bone marrow cells and has been recently shown to be a requirement for colony formation. These results demonstrate that therapeutic concentrations of T2 exert a significant hematotoxic effect by inhibiting growth factor response in CD34+ bone marrow cells and suggest that inhibition of NF-kB may play a role in the blood dyscrasias encountered with the use of this drug.

1655 R. K. Baker, D. W. Pyatt, R. D. Irons and D. J. Kroll. *University of Colorado Health Sciences Center, Denver, CO.*

Chronic exposure to benzene has been associated with hematotoxicity including the development of acute myelogeous leukemia (AML). Clonal cytogenetic aberrations are thought to play an important role in the pathogenesis of AML developing secondary to drug or chemical exposure. Recent studies have implicated the inhibition of topoisomerase II alpha, an essential nuclear enzyme that catalyzes the interconversion of various forms of DNA, as a mechanism to explain benzene-induced cytogenetic aberrations. While chemotheraputic modalities that include topoisomerase poisons are also known to be leukemogenic, the factor determining the potential to produce cytogenetic abnormalities is dependent on the mechanism of inhibition (catalytic inhibition versus cleavable-complex stabilization). The purpose of this study was to determine the mechanism by which topoisomerase II alpha is inhibited by the following benzene metabolites: benzoquinone, 1,2,4-benzenetriol, 4,4-biphenol, and hydroquinone. In a DNA cleavage/relaxation assay where topoisomerase II alpha is exposed to different benzene metabolites prior to analysis of enzyme activity, we observe inhibition of topoisomerase II alpha with the above benzene metabolites at 30 mM, 100 mM, 100 mM, and 1.0 mM respectively. However, no stabilization of cleavable complex formation is formed and, in fact, an antagonistic effect on etoposide-stabilized cleavable complex formation is observed. Our data suggests that these benzene metabolites are actually catalytic inhibitors of topoisomerase II alpha and therefore are not likely to contribute to the development of AML through this mechanism. This project was suppored in part by NIH grant ES06258.

1656 FLOW CYTOMETRIC ANALYSES OF MAGNETICALLY-ENRICHED BONE MARROW LINEAGE NEGATIVE CELLS REVEAL TCDD-MODIFIED HEMOPOIETIC STEM CELL DIFFERENTIATION PROFILES.

F. G. Murante and T. A. Gasiewicz. *University of Rochester Medical Center, Rochester, NY.*

Treatment of C57BL/6 mice with the environmental contaminant 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) elicits altered bone marrow hemopoietic cellular potentials and markedly-reduced T-lymphoid reconstituting activity. The latter has been hypothesized to play a role in TCDD-induced thymic atrophy. To investigate hemopoietic cellular targets responsible for reduced prothymocyte capacity, lineage-negative (lin$^-$) bone marrow stem cells from adult male C57BL/6 mice were magnetically enriched, stained and assessed in terms of cell surface Thy-1, Sca-1, Sca-2, HSA, c-Kit, CD34, CD38 and IL7Rα expression by flow cytometry 8 days following a single dose of 30μg/kg TCDD. The data reveal reduced lin$^-$ Sca-1$^{-/lo}$ c-Kit$^-$ -defined cells as well as reduced lin$^-$ Thy-1$^{-/lo}$ Sca-1$^{-/lo}$ -defined cells contained within the bone marrow small lymphoblast stem cell compartment. In contrast, the bone marrow granular cell compartment contained an increased complement of lin$^-$ Sca-1$^{-/lo}$ c-Kit$^+$ -defined cells and lin$^-$ Thy-1$^{-/lo}$ Sca-1$^{-/lo}$ -defined cells. At the day 8 timepoint, CD34$^-$ / CD38$^+$ long-term repopulating stem cell subsets were elevated overall, while multipotent, CD34$^+$/CD38$^-$ short-term repopulating subsets were numerically depressed. Taken together with numerically reduced lin$^-$ c-Kit^{lo} Sca-1^{lo} Thy-1$^{-/lo}$ IL-7Rα^{lo} expressing cells classified as common lymphoid progenitors, these data suggest a stem cell mobilization following TCDD treatment with a myelopoietic precedence over lymphopoiesis. These data further indicate that proliferation and/or differentiation processes of hemopoietic stem cells are affected by TCDD and that these effects contribute to a reduced capacity of bone marrow to generate pro-T lymphocytes.

1656 FLOW CYTOMETRIC ANALYSES OF MAGNETICALLY-ENRICHED BONE MARROW LINEAGE NEGATIVE CELLS REVEAL TCDD-MODIFIED HEMOPOIETIC STEM CELL DIFFERENTIATION PROFILES.

F. G. Murante and T. A. Gasiewicz. University of Rochester Medical Center, Rochester, NY.

Treatment of C57BL/6 mice with the environmental contaminant 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) elicits altered bone marrow hemopoietic cellular potentials and markedly-reduced T-lymphoid reconstituting activity. The latter has been hypothesized to play a role in TCDD-induced thymic

atrophy. To investigate hemopoietic cellular targets responsible for reduced prothymocyte capacity, lineage-negative (lin-) bone marrow stem cells from adult male C57BL/6 mice were magnetically enriched, stained and assessed in terms of cell surface Thy-1, Sca-1, Sca-2, HSA, c-Kit, CD34, CD38 and IL7Ra expression by flow cytometry 8 days following a single dose of 30mg/kg TCDD. The data reveal reduced lin- Sca-1-/lo c-Kit+ -defined cells as well as reduced lin- Thy-1-/lo Sca-1-/lo -defined cells contained within the bone marrow small lymphoblast stem cell compartment. In contrast, the bone marrow granular cell compartment contained an increased complement of lin- Sca-1-/lo c-Kit+ -defined cells and lin- Thy-1-/lo Sca-1-/lo -defined cells. At the day 8 timepoint, CD34- / CD38+ long-term repopulating stem cell subsets were elevated overall, while multipotent, CD34+/CD38- short-term repopulating subsets were numerically depressed. Taken together with numerically reduced lin- c-Kitlo Sca-1lo Thy-1-/lo IL-7Ralo expressing cells classified as common lymphoid progenitors, these data suggest a stem cell mobilization following TCDD treatment with a myelopoietic precedence over lymphopoiesis. These data further indicate that proliferation and/or differentiation processes of hemopoietic stem cells are affected by TCDD and that these effects contribute to a reduced capacity of bone marrow to generate pro-T lymphocytes.

1657 DENDRITIC CELLS: TARGETS FOR, AND MEDIATORS OF IMMUNOTOXICITY AND ALLERGY.

I. Kimber[1] and N. I. Kerkvliet[2]. [1]*AstraZeneca Central Toxicology Laboratory, Cheshire, United Kingdom and* [2]*Oregon State University, Corvallis, OR.*

Dendritic cells (DC) are a family of bone marrow-derived cells that are found in small numbers in lymphoid organs and in those tissues that come into closest contact with the external environment, including the epidermis, gastrointestinal tract and respiratory epithelium. The main functions of DC are the recognition, internalization, processing and presentation of antigen and the stimulation of T lymphocyte responses. Indeed DC are mandatory antigen-presenting cells for the effective induction of primary immune responses. It is clear that DC play pivotal roles in the initiation and regulation of allergic responses, including those provoked by chemical sensitizers. The participation of these cells in allergic responses is orchestrated by chemokines and cytokines that together control the movement, migration and functional activity of DC. The growing appreciation of the contributions of DC to allergic responses has facilitated consideration of their use in the design of alternative methods for sensitization testing. There is increasing evidence also that DC provide targets for immunotoxic agents. These cells play an important part in the development of immunosuppression caused by exposure to ultraviolet B irradiation and, moreover, DC have been implicated in the immunotoxicity associated with certain chemicals, including TCDD.

1658 DENDRITIC CELLS IN IMMUNOBIOLOGY AND PATHOLOGY.

S. Knight. *Imperial College School of Medicine, Middlesex, United Kingdom.* Sponsor: I. Kimber.

Antigens do not activate T lymphocytes directly. Instead they are acquired in peripheral tissues, as either free antigen or associated with damaged or dying cells, by dendritic cells (DC). These DC have the specialized properties of acquiring and processing antigen. To then initiate a primary immune response the cells must mature and migrate to draining lymphoid tissues where DC lose their ability to process antigen, but become effective at clustering with and activating resting T lymphocytes. The maturation, migration and changing functions of DC are therefore defining events in the stimulation of immunological responses. There exists heterogeneity among DC. Different lineages related to lymphoid or myeloid differentiation pathways have been identified and these include cells that are able to interact with T lymphocytes or B lymphocytes. Both the type of antigenic stimulation and the cytokine milieu influence the maturation pathways followed by DC. For example, an immunosuppressive mouse retrovirus switches DC from interleukin 12 to interleukin 4 production, accompanied by the loss of T lymphocyte priming activity and possibly represents the basis for compromised immune function. Autocrine pathways may reinforce the function of DC. These cells are able to transfer antigens to other DC and the distribution of antigenic material between cells may be an important aspect of immune stimulation. The influence of antigens and toxic insults on the functional characteristics of DC may be a critical determinant of immune-mediated pathology.

1659 ALTERATION OF DENDRITIC CELL CYTOKINE SECRETION BY TOTAL BODY UV EXPOSURE.

S. E. Ullrich. *MD Anderson Cancer Center, Houston, TX.* Sponsor: I. Kimber.

The UV radiation present in sunlight is the primary cause of skin cancer, the most common form of human neoplasia. In addition, UV radiation is immune suppressive and the immune suppression induced by UV exposure has been identified as a major risk factor for skin cancer induction. One consequence of whole body UV-exposure is differential activation of T helper subsets. The ability of antigen presenting cells from UV-irradiated mice to present to T helper (Th) 1 cells is severely depressed, whereas presentation to Th2 cells is normal. We tested the hypothesis that altered antigen presentation to Th1 and Th2 cells results from a modulation of IL-12 secretion by dendritic cells. The secretion of biologically active IL-12p70 by dendritic cells isolated from UV-irradiated mice is suppressed. In addition, secretion of IL-12p40 homodimer, a naturally occurring IL-12 receptor antagonist is increased. We suggest that secretion of IL-12p40 homodimer by dendritic cells isolated from UV-irradiated mice, coupled with suppressed IL-12p70 secretion may help to explain suppressed Th1 cell activation following UV-irradiation. Because Th2 cells require IL-4 and not IL-12 as their growth factor, UV-induced suppression of IL-12p70 and increased secretion of IL-12p40 homodimer should not affect the activation of Th2 cells. Moreover, because we know that cytokines such as prostaglandin E2 and IL-10 suppress the production of biologically active IL-12, we suggest that the cytokines induced following UV exposure may be involved in the modification of IL-12 secretion by dendritic cells isolated from UV-irradiated mice. This leads to suppressed cell mediated immune reactions and permits the out growth of UV-induced skin tumors.

1660 DENDRITIC CELLS AS A POTENTIAL TARGET FOR THE IMMUNOTOXICITY OF TCDD.

N. I. Kerkvliet. *Oregon State University, Corvallis, OR.*

Primary T cell-mediated immune responses are highly susceptible to suppression by TCDD exposure, yet direct effects of TCDD on T cell functions have been difficult to demonstrate. Since the activation of naive T cells has been shown to be mediated, perhaps exclusively, by DC, they represent a potential target for TCDD immunotoxicity. Initial studies have examined the influence of TCDD exposure on splenic DC phenotype and function in the absence of antigenic stimulation in C57B1/6 mice. Results showed that DC from TCDD-treated mice expressed higher levels of several constitutively-expressed costimulatory molecules, including B7-2, CD40, ICAM-1 and CD24. In contrast, the expression of LFA-1 was significantly reduced. These effects were dose-dependent, occurred within 48 hr, and persisted for at least 14 days. Interestingly the number of DC recovered from TCDD-treated mice was significantly decreased 7 and 14 days after exposure. When DC from TCDD-treated mice were incubated with allogeneic T cells, the proliferative response of the T cells and cytokine production was increased. IL-12 production was also increased in comparison to cells from vehicle-treated mice. Taken together, these results suggest that TCDD provides an activation stimulus to DC in the absence of antigen. This inappropriate stimulation may inhibit the ability of DC to process and present antigen or may lead to their premature deletion. Similarly, the decrease in LFA-1 expression may interfere with the ability of DC to migrate to the T cell areas of the lymphoid tissue. These possibilities are under investigation. (Supported by NIH grants ES003966 and ES00040.)

1661 DENDRITIC CELLS AND THE INDUCTION AND REGULATION OF ALLERGIC RESPONSES TO CHEMICALS.

I. Kimber. *AstraZeneca Central Toxicology Laboratory, Cheshire, United Kingdom.*

In non-lymphoid tissues dendritic cells (DC) can be regarded as sentinels of the immune system having responsibility for sampling the external antigenic environment. In the skin this function is performed by Langerhans cells (LC) which form a semi-contiguous network within the epidermis. In response to skin sensitization (or other forms of dermal trauma) a proportion of local LC, many of which bear high levels of antigen, are mobilized to leave the epidermis and migrate from the skin, via afferent lymphatics, to draining lymph nodes. During this migration LC are subject to functional differentiation such that by the time of their arrival in peripheral lymph nodes they have acquired the properties of mature DC and are able to present antigen effectively to responsive T lymphocytes. There is increasing evidence that the mobilization, migration and differentiation of LC are initaited and directed by epidermal

cytokines. The maturation of LC from antigen processing to antigen presenting cells is effected by granulocyte/macrophage colony-stimulating factor (GM-CSF) acting in concert with interleukin 1 (IL-1) and tumor necrosis factor α (TNF-α). The initiation of migration is dependent upon the receipt by LC of two independent cytokine signals, one provided by TNF-α, an inducible product of keratinocytes, and the other by IL-1β, a constitutive product of LC themselves which is upregulated further in response to skin sensitization. Collectively, these cytokines provoke changes in LC phenotype, including the altered expression of adhesion molecules necessary for the release of LC from the skin and their movement through the tissue matrix to lymph nodes. The directed migration of LC from the skin to lymph nodes is facilitated further by chemokines expressed locally. Perturbation of cytokine or chemokine signalling results in the modulation and/or inhibition of allergic sensitization.

1662 DENDRITIC CELLS AND THE DEVELOPMENT OF ALTERNATIVE STRATEGIES FOR SKIN SENSITIZATION TESTING.

G. F. Gerberick. *Proctor & Gamble Co., Cincinnati, OH.*

Dendritic cells (DCs) are professional antigen presenting cells which are widely distributed in the body and are key for initiating T cell mediated immune responses, including their role in allergic contact dermatitis (ACD). Methods for culturing human DCs from peripheral blood (PB) have been developed by several laboratories. We evaluated the ability of PB-derived DCs to present chemical haptens to sensitized T cells in an *in vivo* lymphocyte proliferation assay. Immature DCs (iDCs) were generated from PB of patients sensitive to dinitrochlorobenzene (DNCB) using standard GM-CSF/IL-4 protocols iDCs were treated with a water soluble form of the test allergen (dinitrobenzenesulfonic acid [DNBS]), or an unrelated contact allergen (squaric acid [SA]), then cultured with 105 autologous T cells. Mature DCs (mDCs) were generated from iDCs with the addition of TNF-α IL-1β, IL-6 and PGE_2. Compared to hapten treated iDCs, mDCs treated with DNBS stimulated a greater proliferative response in sensitized T cells at responder: stimulator ratios of 50:1 and 100:1. No proliferation was observed in T cells cultured with SA treated DC demonstrating the specificity of the proliferative response. These results indicate that mDCs are more efficient antigen presenting cells than iDCs for the chemical hapten DNBS. Finally, because of the limited number of DCs obtained from PB, we have successfully induced a bone marrow derived $CD34^+$ myeloid leukemia cell line (KG-1) to a DC phenotype and morphology. KG-1 treated 3-days GM-CSF, IL-4, TNF-α, SCF, TPO, and Flt3-ligand remain negative for lineage makers (CD3, CD14,CD16, CD19, CD20, CD56) and express Class I MHC (HLA-A,B,C), Class II MHC (HLA-DR, HLA-DQ), CD54, CD11a, CD11b, CD11c, CD83, CD86 and CD1a. Functionally, KG-1 derived DCs are capable of phagocytosing latex micropheres and inducing a potent allogeneic T-cell response in a mixed lymphocyte reaction. We conclude that the study of DCs offers potential for the development of new skin sensitization test methods.

1663 INTRODUCTION.

R. Tennant. *NIEHS, Research Triangle Park, NC.*

A plethora of technological and conceptual advances in molecular biology and medicine, genetics and genomics, and related research has opened significant opportunities for development of an abundance of new therapies. These opportunities provide a challenge to the assessment of the safety and efficacy of these new candidate therapies. This symposium will provide a review of the current status of toxicology biomarkers in drug development and clinical safety assessments. Particular emphasis is on the demonstration that biomarkers can serve as early predictors of adverse effects and on the development of technological approaches to find out more and better toxicology biomarkers.

1664 CONCORDANCE OF PHARMACEUTICALS TOXICITY IN HUMANS WITH ANIMAL DATA.

H. M. Olson[1], G. Betton[2], A. Monro[1], K. Thomas[3] and D. Robinson[3]. [1]*Pfizer, Inc., Groton, CT,* [2]*AstraZeneca Pharmaceuticals, Macclesfield, United Kingdom and* [3]*ILSI-HESI, Washington, DC.*

This investigation describes the procedure for compiling data and summarizes the results of a multinational pharmaceutical company survey to better understand concordance of the toxicity of pharmaceuticals in humans with that in animals. The main aim of this project is to examine the usefulness of animal studies to identify toxicity biomarkers for pharmaceutical-associated human toxicity (HT), and to identify opportunities to improve anticipation of HT. The database was developed from a survey which tabulated significant HTs for pharmaceuticals identified during clinical development, and determined whether animal toxicity studies did or did not identify target organ biomarkers for the relevant HTs. Data collected included: codified compound therapeutic category, the type (organ system) of HT that was identified, and the duration of animal studies in which the corresponding toxicity was either first identified or not observed. To-date the survey includes input from 10 pharmaceutical companies with data compiled from approximately 171 compounds with more than 230 human toxicity events reported. At a recent HESI project workshop, which included representatives from academia, industry and regulators, the results showed the true positive concordance rate for HT of 73% for rodent plus non rodent species with non rodents being predictive in 65% of HTs and rodent in 45%. The results support the utility for identifying HTs in non-clinical studies of one month's duration. These survey results support the value of *in vivo* studies to predict for many significant HTs associated with pharmaceuticals, while identifying those toxicities requiring improved methods.

1665 RESEARCH NEEDS AND APPLICATIONS OF TOXICITY BIOMARKERS IN THE EVALUATION OF NOVEL THERAPEUTICS.

G. J. Downing. *National Institutes of Health, Bethesda, MD.* Sponsor: J. C. Barrett.

High throughput technologies are enabling production of large numbers of new chemical entities to be evaluated as target-specific candidate therapies. Improved safety evaluation methods are needed to provide preclinical and clinical toxicity testing in an efficient and timely fashion. The use of biological markers, or biomarkers, defined as characteristics that are objectively measured and evaluated as indicators of normal biologic processes, pathogenic processes, or pharmacologic responses to a therapeutic intervention, is one approach to enhance toxicity testing. Mass spectroscopy, cDNA microarray, protein expression, and imaging technologies are examples of basic discovery tools that may serve as platforms to evaluate predictive biomarkers of toxicity. These fundamental research discovery tools now provide opportunities to develop highly efficient assay systems to establish specific and sensitive indicators of cellular and molecular injury. For example, biomarkers may represent components of cell signaling pathways for apoptosis, growth factors, cytokines, and chemokines, and xenobiotic metabolic pathways. Establishment of the linkage of biomarkers to clinical features of toxicity is critical to their application in drug safety testing. Harnessing new technologies for toxicology testing will be expedited by cooperative efforts among government, universities, and private industry partners. These interactions will facilitate the development of a technology and information-based infrastructure that will support the standardization of testing methods, validation of assay systems, establishment of databases, and development of statistical analyses that are needed to better characterize toxicity biomarkers. Collaborations through public-private partnerships are proposed to address growing needs in safety assessment of new therapeutics using toxicity biomarkers.

1666 DETERMINATION OF SERUM CARDIAC TROPONIN-T AS A BIOMARKER OF ANTHRACYCLINE CARDIOTOXICITY.

S. E. Lipshultz. *University of Rochester Medical Center, Rochester, NY.* Sponsor: R. Tennant.

Anthracyclines, important agents for the treatment of childhood cancer, are associated with progressive cardiotoxicity that is differentially expressed in most long-term survivors (LTS). >50% of LTS of childhood cancer have been treated with anthracyclines. Echocardiographic abnormalities are noted in 60% of these patients 6 years after therapy and is progressive in 75% of these patients. The heart is a major source of morbidity and mortality for LTS. The identification of myocardial injury during therapy should allow individualization of anthracycline therapy and evaluation and implementation of cardioprotective and therapeutic strategies. We employed a multidisciplinary, multispecies approach to determine whether serum cTnT is a biomarker of early and late anthracycline cardiotoxicity. In rats, we found cTnT elevations correlated with cumulative anthracycline dose and myocardial histologic scores of anthracycline cardiotoxicity. The specificity of cTnT elevations for myocardial injury was confirmed by cTnT immunohistochemical staining (J Clin Oncol 1999;17:2237-2243). In children, the level and length of cTnT ele-

vations following anthracycline therapy correlated with cumulative dose (Proc ASCO 1999;18:568A). The level of cTnT elevation after therapy correlated with echocardiographic abnormalities 9 months later, suggesting that early cTnT levels are useful biomarkers of cardiotoxicity at intermediate follow-up (Circulation 1997;96:2641-2648). The utility of cTnT levels during anthracycline therapy to predict late cardiotoxicity in LTS is under investigation. In summary, the use of a multidisciplinary multispecies approach has accelerated the investigation of cTnT as a useful biomarker for late anthracycline cardiotoxicity.

1667 TOXICOGENOMICS IN SAFETY ASSESSMENT.

R. D. Tyler. *Glaxo Wellcome, Inc., Research Triangle Park, NC.*

Most toxicities that are not lethal within minutes are likely to have some impact on gene expression, be a result of gene expression, or both. Some of the gene expression changes (GECs) that occur as toxicity develops are expected to be unique to the mechanism of toxicity (e.g., free radical production, inhibition of cellular respiration). Some GECs are expected to be unique to the type of toxicity, e.g., apoptosis, nongenotoxic carcinogenicity, but common amongst mechanisms that cause the same type of toxicity. Other GECs are expected to be adaptive in response to changes in such things as blood pressure, nutrition, etc. Determination of GECs that reliably indicate the above would allow development of gene expression based biomarkers of toxicity. The most valuable GECs will probably be critical "core" genes that have been conserved during evolution. These GECs will be shared amongst species, greatly improving interspecies comparisons and extrapolations. If gene expression analyses in discovery and toxicology studies identify GECs indicative of toxicity and *in vitro* studies with human and animal cell lines establish that the human gene homologues behave as the animal genes do, the GECs can be used as biomarkers of toxicity in clinical trials and patients. These biomarkers will be especially valuable when they occur in easily assessable tissues, e.g., lymphocytes, and for early detection of chronic toxicity. Although functional and/or morphologic evidence of chronic toxicities may take weeks to years to develop, characteristic GECs likely occur in hours or days. Identification of these GECs would enable early detection of the chronic toxicity, markedly shortening necessary animal studies and protecting clinical trial subjects and patients.

1668 ARSENIC: CARCINOGENIC MECHANISMS, RISK ASSESSMENT AND THE MAXIMUM CONTAMINANT LEVEL (MCL).

K. T. Kitchin[1] and B. Beck[2]. [1]*USEPA NHEERL, Research Triangle Park, NC and* [2]*Gradient Corporation, Cambridge, MA.*

This workshop will provide an up-to-date overview on key issues related to cancer risk assessment of arsenic: carcinogenic mechanisms; application of mechanistic information to risk assessment models; and the development of the MCL for arsenic in drinking water. The two presentations on mechanisms will focus on the possible role of methylated arsenic species as mediators of carcinogenesis. Dr. Kitchin will briefly summarize proposed carcinogenic mechanisms for arsenic and will address the possible role of methylated arsenic metabolites, in particular dimethylarsinic acid (DMA), in carcinogenesis. Dr. Fukushima will present current (and controversial) studies of DMA as a rodent multi-organ tumor promoter and a rat urinary bladder complete carcinogen. The next two presentations will describe risk assessment models for use in quantifying exposures and risks of arsenic. Dr. Mann will describe a physiologically based pharmacokinetic (PBPK) model for inhaled and oral exposures to arsenic, evaluating the validity of this model under different exposure conditions. A biologically-based dose-response model for arsenic based on understanding of arsenic's mode-of-action will be described by Dr. Clewell. Finally, Dr. Abernathy will address the important issue of setting an MCL for arsenic, describing not only the toxicologic and risk issues, but also issues of feasibility and implementation. It is expected that this workshop will be of interest to a broad range of scientists, including basic researchers, risk assessors, and regulators. (Disclaimer: This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.)

1669 PROPOSED CARCINOGENIC MECHANISMS FOR ARSENIC.

K. T. Kitchin. *USEPA NHEERL, Research Triangle Park, NC.*

Arsenic is a human carcinogen in skin, lung, liver, urinary bladder and kidney. In contrast, there is no experimental animal model of inorganic arsenic carcinogenesis. Proposed mechanisms/modes of action for arsenic carcinogenesis include but are not limited to clastogenic effects, mutation, oxidative stress, gene amplification, altered DNA methylation, cell proliferation, promotion, effects on the progression stage, inhibition of DNA repair and interaction with important cellular proteins. At this time, there is not a scientific consensus on the mechanisms/modes for arsenic carcinogenesis. In regulating human exposure to arsenic, this uncertainty in arsenic's carcinogenic mechanisms/modes makes the risk assessment and extrapolation model selection process considerably more difficult. Recently, dimethylarsinic acid (DMA) has showed both promotional and complete carcinogenic activity in rats and mice. Therefore, arsenate, arsenite, monomethylarsonic acid (MMA) and dimethylarsinic acid (DMA) were administered to rats to determine their biochemical effects. In our laboratory, DMA at 387 mg/kg caused DNA damage in rat lungs, but not in rat liver. Neither arsenate or arsenite damaged rat DNA. Sodium arsenite at doses of 1.6, 8.2 and 24.6 mg/kg increased rat hepatic ornithine decarboxylase activity by 40 to 140%. DNA damage and ornithine decarboxylase induction are interpreted as indicators of initiation and promotion of cancer, respectively. Based on recent experimental findings, for carcinogenesis, methylation of inorganic arsenic may be a "toxification" pathway. The arsenic metabolite DMA may be or may generate an active promoting/carcinogenic chemical(s). (Disclaimer: This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.)

1670 RODENT CARCINOGENICITY OF DIMETHYLARSINIC ACID, AN ORGANIC ARSENIC METABOLITE.

S. Fukushima, H. Wanibuchi, S. Yamamoto, M. Wei and E. I. Salim. *Osaka City University Medical School, Osaka, Japan.*

Dimethylarsinic acid (DMA) is a major metabolite of inorganic arsenic compounds in most mammals. Promotional effects of DMA were investigated using a rat multi-organ bioassay. The rats were pretreated with 5 initiating carcinogens and then subsequently administered DMA at various concentrations in the drinking water. Significantly increased tumor induction due to promotion of carcinogenesis by DMA was observed in rat urinary bladder, kidney, liver, and thyroid gland. Further experiments with two-stage rat urinary bladder and liver model systems showed that DMA enhanced tumor development in both organs. In a recent complete carcinogen study, male rats received DMA at doses of 0, 12.5, 50 and 200 ppm in the drinking water for 104 weeks. Rat urinary bladder carcinomas were observed in 6 of 31 animals at 50 ppm and in 12 of 31 at 200 ppm. Thus, the results indicate that DMA is a complete carcinogen in rat urinary bladder. In addition, p53 heterozygous knockout and C57BL/6T wild type male mice were given DMA at doses of 0, 50 and 200 ppm in the drinking water for 80 weeks. DMA induced malignant lymphoma in wild type mice. Carcinogenicity of DMA was evident by significantly earlier induction of tumors in both mouse genotypes. Overall, the results indicate that DMA enhanced the development of spontaneous tumors in both types of mice. In conclusion, DMA is a rodent carcinogen and promoter which may be related to the human carcinogenicity of arsenics.

1671 A PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODEL FOR THE FOUR MAJOR ARSENIC METABOLITES IN ANIMALS AND MAN.

S. Mann[1] and P. O. Droz[2]. [1]*Le Borgeau, Carrouge, Switzerland and* [2]*Lausanne University, Lausanne, Switzerland.* Sponsor: K. T. Kitchin.

The absorption, distribution, metabolism and excretion of arsenate (As(V)), arsenite (As(III)), methylarsonate (MMA) and dimethylarsinate (DMA), the four major metabolites of inorganic arsenic were used to develop a physiologically based pharmacokinetic (PBPK) model. Model routes of arsenic intake were respiratory for dust and fumes and oral for drinking water. Tissue distribution is calculated based on physiological and physico-chemical parameters: blood perfusion, tissue volumes, diffusion coefficients, membrane characteristics, and tissue affinities. Oxidation-reduction reactions between As(V) and As(III) are described by first order kinetic reactions in plasma, and methylation reactions are based on Michaelis-Menten kinetics in the liver. Numerical values are obtained from physiological references and by fitting

the model to *in vivo* studies. Validation of the human arsenic model was carried out by comparison of the results obtained with the human PBPK model to urinary excretion data obtained after exposure of workers to As2O3 and a community exposed to arsenic via drinking water. The PBPK model allows prediction of biological indicator concentrations in human urine (AsV, AsIII, MMA, and DMA). Scenarios are presented for estimation of biological arsenic concentrations under various conditions: for example, exposure of smelter workers to aerosols, workers exposed to coal fly ash and a community exposed to arsenic via drinking water. Finally, the uses and the limitations of the PBPK model will be presented.

1672 REQUIREMENTS FOR A BIOLOGICALLY-REALISTIC CANCER RISK ASSESSMENT FOR INORGANIC ARSENIC.

H. Clewell, III[1], M. E. Anderson[2] and J. W. Yager[3]. [1]*ICF Consulting, Ruston, LA,* [2]*Colorado State University, Fort Collins, CO and* [3]*EPRI, Palo Alto, CA.*

Considerable controversy has centered on whether there is epidemiological evidence of a "threshold" for the carcinogenic effects of inorganic arsenic (InAs)i, or at least of a highly nonlinear dose-response. Saturation of metabolism in the dose-range associated with tumors does not appear to be adequate to produce a major impact on the dose-response for carcinogenicity. If there is a strong nonlinearity, it results from the nature of the carcinogenic mechanism(s) of InAsi. A biologically realistic cancer risk assessment for InAsi would require a quantitative description of the dose of active arsenic species in target tissues, the interactions between the active arsenic species and tissue constituents, and the manner in which these interactions result in tumor formation in multiple organs in humans, but not in experimental animals. Although InAsi has only infrequently been associated with tumors in animal studies, it has repeatedly been shown to act as a co-mutagen *in vitro* and as a co-carcinogen *in vivo*. InAsi is clastogenic, producing chromatid aberrations, but does not produce point mutations at single gene loci. Of particular interest, InAsi has been shown to inhibit repair of DNA single-strand breaks, a possible mechanism for its observed co-mutagenicity and co-carcinogenicity. We propose a co-carcinogenic mode of action in which InAsi acts primarily on intermediate cells deficient in cell cycle control at a late stage in a pre-existing carcinogenic process. This interaction enhances genomic fragility and accelerates conversion of pre-malignant lesions to more aggressive, clinically observable tumors. An indirect effect of InAsi on DNA repair is consistent with the expectation of a nonlinear dose-response rather than the linear dose-response traditionally assumed for mutagenic carcinogens. However, defining the exact nature of this tumor dose-response will require further experimental data on the dose-response for the cellular effects of InAsi.

1673 THE ARSENIC (AS) MAXIMUM CONTAMINANT LEVEL (MCL) PROPOSED BY THE USEPA.

C. O. Abernathy, A. Kapadia, J. Bennett, W. Miller, A. Schulman, J. Wu and I. Dooley. *USEPA, Washington, DC.*

The Safe Drinking Water Act, as amended in 1996, directed EPA to propose an arsenic regulation by January 1, 2000. The proposed arsenic regulation includes a maximum contaminant level goal (MCLG), an MCL (which can be measured), a list of feasible treatment techniques for large systems and three size categories of small systems, and a health risk reduction and cost analysis (HRRCA) which identifies costs and benefits likely to occur with each MCL considered. EPA will use the National Research Council report's bladder cancer risk assessment, with an estimated point of departure at the 1% excess cancer risk in humans of approximately 400 :g/L, as the basis for proposing an MCLG. Linear regression analysis of EPA water study data yielded a practical quantitation limit (PQL) of 3 µg/L, which provides a lower bound on the MCL. EPA's national occurrence estimate provided exposure data for the HRRCA. Many treatment factors affected EPA's compliance cost analysis, which was stratified into system size and source types. These include treatment performance, costs, operating complexity, residuals issues, and effects of contaminants on choice of treatment. (Disclaimer: This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.)

1674 GENE EXPRESSION ARRAY TECHNOLOGY REVEALS UNDERLYING MECHANISMS OF MITOTIC ARREST AND APOPTOSIS INDUCED IN RAT MESOTHELIAL CELL CULTURES BY POTASSIUM BROMATE.

L. M. Crosby[1], K. S. Hyder[2], A. B. DeAngelo[3], L. Yoon[4] and K. T. Morgan[4]. [1]*North Carolina State University, Raleigh, NC,* [2]*Clontech Laboratories, Inc., Palo Alto, CA,* [3]*US Environmental Protection Agency, Research Triangle Park, NC and* [4]*Glaxo Wellcome, Inc., Research Triangle Park, NC.*

Use of gene expression array technology to elucidate mechanisms of toxicity is becoming widespread, but meaningful interpretation of results obtained remains a challenge. We report that potassium bromate (KBrO3), a known rat mesothelial, kidney and thyroid carcinogen and oxidative stressor, produces gene expression changes in mesothelial cells *in vitro* concordant with morphological and biochemical changes. An F344 rat mesothelial cell line was exposed to 6 mM KBrO3 (RNA extraction followed by expression analysis using Clontech Rat Atlas and Rat Stress Arrays and TaqMan; GSH analysis) under standard culture conditions. After 30 min and four hr, when GSH was severely depleted, morphologic analyses showed apoptosis to be significantly increased. Notably, mRNA expression of TNF, FasL and iNOS were also significantly elevated at four hours. Quantitative morphologic evidence of mitotic arrest at four and 12 hr agreed with the observed decreased expression of cyclins B1, C, D1, D2, D3 and E and increased PCNA, Waf1, cyclin G, and GADD45. The oxidative stress-inducible genes HMOX1, NMOR1were highly expressed in KBrO3-treated cells, indicating redox imbalance may play a key role in KBrO3-induced disturbances of the cell cycle. Other changes observed in the >700 genes on these platforms, consistent with the above conclusions, demonstrate (a) the challenge associated with the interpretation of such rich data sets, and (b) that such data represent the beginning and not the end of this research approach. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.)

1675 UPREGULATION OF FAS LIGAND IN VARIOUS TISSUES FOLLOWING TCDD ADMINISTRATION.

M. T. Sproull[1], A. Zeytun[1], M. Nagarkatti[2], L. M. Hudson[1], R. Duncan[2] and P. S. Nagarkatti[1]. [1]*Dept. of Biology, Virginia Polytechnic and State University, Blacksburg, VA and* [2]*Dept. of Biomedical Sciences and Pathobiology, VA-MD Regional College of Veterinary Medicine, Blacksburg, VA.*

Previous studies from our laboratory demonstrated that 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) induces apoptosis in thymocytes of C57BL/6 wild-type but not Fas-deficient C57BL/6- lpr/lpr or Fas ligand (L)-defective C57BL/6- gld/gld mice. In the current study, we tested whether TCDD would increase the expression of Fas and/or FasL. When C57BL/6 wild-type mice were injected with 50mg/kg body weight TCDD, there was a significant upregulation of FasL but not Fas in the thymus 1 or 5 days after treatment, as detected by semi-quantitative RT-PCR. On day 5, FasL but not Fas expression also increased in the spleen, lymph nodes, liver, lungs and testes. The upregulation of FasL in the thymus was detected at lower concentrations of TCDD including 0.1,1 and 10 mg/kg body weight. When the organs from wild-type, lpr and gld mice treated with 50mg/kg body weight of TCDD were histopathologically analyzed, on day 5, no significant changes in the lungs, lymph nodes, spleen and testes were observed. The thymus of all three strains exhibited hypocellularity after TCDD exposure. TCDD-treatment also induced hepatocellular vacuolation in wild-type and lpr strains, and to a lesser extent in the gld strain. The TCDD-treated wild-type and gld strains also exhibited multifocal inflammatory cell foci in the liver, which was lacking in the lpr strain. These data indicate that Fas-FasL interactions play an important role in TCDD-induced toxicity. (Supported in part by grants from NIH ES 09098, HL 058641 and AI 01392, Sigma Xi and EPA.)

1676 OKADAIC ACID INDUCED APOPTOSIS AND RESISTANCE IN HT 1080 HUMAN FIBROSARCOMA CELLS.

W. Zhao and B. A. Merrick. *NIEHS, NIH, Research Triangle Park, NC.*

Phosphorylation and dephosphorylation are key cellular events that regulate important signaling pathways such as apoptosis and cell cycle progression. Okadaic acid (OA) is an inhibitor of protein phosphatase (PP)-2A and PP-1 and is mitogenic in normal cells but may induce apoptosis in some tumor cells. This study examined the association between p53 protein expression and OA-induced apoptosis in normal wild type (wt) expressing cells and mutant (mt) tumor cell lines. OA at 10-30 nM and the positive apoptotic control, H2O2 at 100-300 µM, both produced DNA ladder formation in wt p53

expressing HT1080 fibrosarcoma cells but not in a chemically-derived mt p53 HT1080 line (6TG c5) or in the p53 null Saos-2 cell line. However, OA-induced apoptosis in HT1080 cells could be prevented by stimulating mitotic pathways by 24 hr pretreatment with IGF-1. In normal wt p53 fibroblasts (IMR-90), only the positive control, H2O2, produced DNA ladders while OA had no apoptotic effect. Western blots from HT1080 cells show that OA up-regulates expression of p53, p21-Waf1, and pro-apoptotic Bax, but decreases Bcl-2, suggesting a biochemical shift favoring apoptosis. We also created an OA-resistant HT1080 subline (OA-R) after 4 months of OA exposure. OA-R cells were resistant to OA-induced apoptosis and showed increased p53 and bcl-2 expression as well as P-glycoprotein compared to parent HT1080 cells. These results suggest OA-apoptosis requires wt p53 expression but may be selective for certain tumor phenotypes like HT1080 fibrosarcoma cells. Furthermore, OA-induced reversal of apoptosis by acute mitogen treatment or by chronic OA exposure suggest an alteration of the p53 pathway or induction of p-glycoprotein can circumvent the effect.

1677 POTENTIAL REGULATION OF MEKK3 KINASE ACTIVITY BY CASPASE-CLEAVED BCL-XL.

R. R. Vaillancourt and D. G. Adams. *University of Arizona, Tucson, AZ.* Sponsor: D. C. Liebler.

The anti-cancer drug, etoposide, induces apopotosis. However, the signaling proteins involved in this process are unclear. Since the Jun kinase pathway has been implicated in apoptosis signal transduction, our studies have focused on MEKK3, Mitogen-Activated Protein (MAP) Kinase/Extracellular Signal-Regulated Kinase (ERK) Kinase Kinase) which is a protein kinase that activates Jun kinase. The proteins that regulate MEKK3 are not known and the yeast two hybrid system was used to identify such proteins Two known proteins were isolated that interact with MEKK3 in the yeast two hybrid system, 14-3-3epsilon and Bcl-xL. Subsequent experiments have shown that only the caspase-cleaved form of Bcl-xL interacts with MEKK3. One of the functions of the Bcl-xL and 14-3-3epsilon proteins is to maintain cell survival or inhibit apoptosis. An interaction between MEKK3 and these proteins suggests that MEKK3 regulates the apoptotic process. Recently, proteolytic cleavage of Bcl-xL by caspases has been demonstrated in cells treated with apoptotic stimuli such as etoposide or IL-2 deprivation. The hypothesis of our studies is that caspase-dependent cleavage of Bcl-xL produces a protein, Delta 61 Bcl-xL (amino acids 62-233), that functions as an intracellular activator of MEKK3 kinase activity. A consequence of MEKK3 activity is phosphorylation of a downstream kinase, JNKK (Jun Kinase Kinase) and ultimately translocation of c-Jun into the nucleus to activate apoptosis-dependent genes. Future research will characterize the interaction between MEKK3 and caspase-cleaved Bcl-xL in mammalian cells and the possible signaling pathways that may be involved in etoposide-induced apoptosis.

1678 ROLE OF PROTEOLYSIS IN BCL-X_L DEPLETION DURING MK886-INDUCED APOPTOSIS IN FL5.12 CELLS.

K. Datta, S. Biswal and J. P. Kehrer. *University of Texas at Austin, Austin, TX.*

The caspase family of proteases is considered the major regulator of apoptotic death. However, several reports indicate the association of non-caspase serine proteases in apoptosis. Apoptosis induced by the 5-lipoxygenase activating protein (FLAP) inhibitor MK886 is accompanied by the rapid loss of the antiapoptotic bcl-2 and bcl-x_L proteins (Datta *et al., J. Biol. Chem.* **273**: 28163 [1998]). This loss could only partially be prevented by caspase inhibitors. In the current study, the participation of serine, cysteine or aspartic acid proteases in MK886-induced apoptosis and the loss of bcl-x_L protein in the murine pro-B lymphocytic (FL5.12) cell line was investigated. Phenylmethylsulfonyl fluoride (PMSF), pepstatin and leupeptin were capable of significantly inhibiting MK886-induced apoptosis. Disappearance of bcl-x_L from FL5.12 cells upon MK886 treatment was completely prevented by pretreatment with these inhibitors. Pretreatment with leupeptin, pepstatin or PMSF blocked about half the increase in caspase-3 activity spurred by MK886. None of the inhibitors were able to directly inhibit active caspase-3 activity suggesting they were preventing the activation of this caspase. The broad-spectrum caspase inhibitor, Boc-D-FMK, inhibited all markers of MK886-mediated apoptosis including caspase-3 activity in cell lysates *in vitro*. Together, these observations suggest the involvement of either serine cysteine or aspartic acid proteases, upstream of active caspase-3, in the loss of bcl-x_L protein and in the signaling pathway of MK886-induced apoptosis in FL5.12 cells. (Supported by HL51005 and Center Grant ES07784.)

1679 DIFFERENTIAL INVOLVEMENT OF CASPASES IN HYDROQUINONE-INDUCED APOPTOSIS IN HUMAN LEUKEMIC HL-60 AND JURKAT T CELLS.

S. H. Inayat-Hussain, S. L. Winski and D. Ross. *Department of Pharmaceutical Sciences, School of Pharmacy, University of Colorado Health Sciences Center, Denver, CO.*

Hydroquinone (HQ), a major metabolite of benzene is known to induce apoptosis in hematopoietic cells. We examined the role of caspases in HQ induced apoptosis in MPO-rich HL-60 human promyelocytic leukemia and MPO-deficient Jurkat T cells. Treatment of HL-60 and Jurkat cells with HQ (75 μM and 50μM respectively) resulted in apoptosis as assessed by ultrastructural, flow cytometric and biochemical apoptotic changes, including phosphatidylserine (PS) exposure, activation of caspases-3 and -7, cleavage of poly(ADP-ribose)polymerase (PARP) and DNA. In HL-60 cells, pre-treatment with the caspase inhibitor Z-VAD.FMK blocked caspases-3 and -7 processing and cleavage of both PARP and DNA, but PS externalisation, nuclear morphology and cytoplasmic changes were relatively unaffected. Interestingly, pre-treatment with the caspase-3 specific inhibitor, Z-DEVD.FMK, did not block any apoptotic features in these cells. In marked contrast, in HQ-treated Jurkat cells, all ultrastructural, flow cytometric and biochemical changes associated with apoptosis were completely inhibited by pre-treatment with Z-VAD.FMK. Pre-treatment with Z-DEVD.FMK blocked caspases-3 and -7, cleavage of PARP and DNA, but PS exposure and ultrastructural nuclear changes were only partially blocked. We propose that HQ induces apoptosis via a caspase-independent pathway in HL-60 cells but requires caspase activation in Jurkat cells. The different mechanisms of apoptosis in HL-60 and Jurkat cells may reflect the MPO activity of these cells and the amount of reactive 1,4-benzoquinone that is generated. (Supported by HHS ES 09554 and EPA R825281010.)

1680 REGULATION OF HEPATOCYTE SURVIVAL: DIVERSE ROLES FOR MAP KINASE AND AKT (PKB) MEDIATED PATHWAYS.

R. A. Roberts, N. H. James and S. C. Cosulich. *AstraZeneca CTL, Macclesfield, United Kingdom.*

Perturbation of hepatocyte growth regulation is associated with a number of liver diseases such as fibrosis and cancer. These diseases are mediated by a network of growth factors and cytokines that regulate the induction of hepatocyte proliferation and apoptosis. In this study, we have investigated the role of signalling pathways activated by tumor necrosis factor α (TNFα) and epidermal growth factor (EGF) in the regulation of apoptosis induced by transforming growth factor β1 (TGFβ1) since this physiological factor is believed to regulate spontaneous apoptosis in the liver. We show that while both EGF and TNFα can suppress apoptosis in isolated rat hepatocytes, they act by engaging different protein kinase signalling pathways. Suppression of apoptosis by EGF is dependent on activation of PI3 kinase and the ERK MAP kinase pathways but not p38 MAP kinase. In contrast, TNFα does not require PI3 kinase and Akt (PKB) - mediated pathways but is dependent on ERK and p38 MAP kinases to suppress apoptosis. These data contribute to our understanding of the intracellular survival signals which play a role in normal liver homeostasis and in diverse pathological conditions.

1681 SALICYLATE ENHANCES NECROSIS AND TNFα-INDUCED APOPTOSIS MEDIATED BY THE MITOCHONDRIAL PERMEABILITY TRANSITION (MPT) IN RAT HEPATOCYTES.

K. W. Oh, T. Qian, E. Hatano, C. A. Bradham, D. A. Brenner and J. J. Lemasters. *University of North Carolina, Chapel Hill, NC.*

Salicylate, the major metabolite of aspirin, lowers the threshold for onset of the MPT in isolated liver mitochondria (JPET 278:1000). At higher concentrations, salicylate causes MPT-mediated necrotic death of cultured hepatocytes (TAP 147:431). The MPT also mediates hepatocyte apoptosis after tumor necrosis factor-alpha (TNFα) and necrotic cell killing after oxidative stress and Ca^{2+} ionophore (Molec Cell Biol 18:6353; Biochem J 307:99; TAP 154:117). Accordingly, our aim was to determine whether non-toxic salicylate concentrations potentiate MPT-mediated cell killing by other agents. Cultured rat hepatocytes were exposed to Br-A23187 (Ca^{2+} ionophore, 0.5-5 μM) or *tert*-butylhydroperoxide (*t*-BuOOH, 5-50 μM), and cell killing was assessed by propidium iodide fluorometry. *t*-BuOOH and Br-A23187 both caused dose-dependent cell killing. After 1 μM Br-A23187, cell killing after 1 hr increased from 14.6% to 25.0, 41.6 and 55.3% in the presence of 0.1, 0.5, and

1 mM salicylate, respectively. Cell killing was prevented by cyclosporin A (1-10 μM), a specific MPT inhibitor, and salicylate by itself was not cytotoxic. Salicylate also potentiated the toxicity of 20 μM *t*-BuOOH from 30.9% to 46.4, 58.6 and 74.1% after 0.1, 0.5 and 1 mM salicylate. In hepatocytes infected with IκB adenovirus, TNFα apoptotic cell killing of 12.5, 35.2, 54.5 and 77.6% after 12, 16, 20 and 24h. Salicylate (1 mM) increased this cell killing to 38.5, 65.9, 77.2, and 83.2%, respectively. Salicylate also accelerated TNFα-induced caspase 3 activation from 105, 121 and 308% of control after 8, 12 and 16 hr to 169, 264 and 389%. In conclusion, salicylate potentiated both necrotic and apoptotic cytotoxicity mediated by the MPT. Thus, aspirin has the potential to enhance the hepatotoxicity of xenobiotics. Promotion of MPT-mediated apoptosis may also account for salicylate-induced potentiation of anticancer drug cytotoxicity and the protection of aspirin against colon, lung and breast cancer.

1682 POST-TRANSLATIONAL MODIFICATION OF P53 FOLLOWING TREATMENT WITH PSORALEN AND UV-A RADIATION (PUVA).

A. B. Santamaria[1], M. Kapoor[2], G. Lozano[2] and H. N. Ananthaswamy[3]. [1]*UT School of Public Health - M.D. Anderson Cancer Center, Houston, TX,* [2]*M.D. Anderson Cancer Center - Department of Molecular Genetics, Houston, TX and* [3]*M.D. Anderson Cancer Center - Department of Immunology, Houston, TX.*

The p53 protein participates in the regulation of several cellular processes, including cell cycle arrest, DNA repair, and apoptosis. p53 is regulated at the post-translational level and it appears to exist in a latent, inactive form that requires modification to become activated. Phosphorylation of p53 on specific residues can apparently modulate its activity. A number of studies have shown that cells treated with different DNA-damaging agents exhibit different patterns of phosphorylation. The generation of cleavage products may be another mechanism for regulating the activity of p53. Using cell-free systems, investigators have shown that treating p53 protein with single-stranded DNA, damaged DNA, or proteases results in the generation of cleavage products. In this study, we determined whether wild-type or mutant p53 exhibit different patterns of phosphorylation following treatment with PUVA. The aim of these studies was to elucidate the functional relevance of different phosphorylation patterns with respect to cell cycle arrest and/or apoptosis. Immortalized mouse keratinocytes (JB6) that have wild-type p53 and two mouse skin tumor cell lines containing mutant p53 were used for these studies. Following treatment, gel electrophoresis was performed and the blots were probed with several N- and C-terminus phosphoserine-specific antibodies. The results indicated that p53 was phosphorylated following PUVA treatment in JB6 cells while it was constitutively phosphorylated in the tumor cell lines. In addition to phosphorylation of p53, PUVA treatment of JB6 cells resulted in the generation of two cleavage fragments that were each missing the N-terminus. However, only one tumor cell line exhibited both fragments constitutively. Interestingly, treatment of JB6 cells with UV-C did not result in the generation of cleavage products. These results suggest that PUVA treatment causes phosphorylation and cleavage of p53 in JB6 keratinocytes. It is possible that these post-translational modifications in p53 play a role in PUVA-induced apoptosis.

1683 THE ROLE OF DNA MISMATCH REPAIR, P53 AND OTHER SIGNALING PATHWAYS IN DNA DAMAGE-INDUCED APOPTOSIS.

M. J. Hickman and L. D. Samson. *Harvard School of Public Health, Boston, MA.*

All cells are unavoidably exposed to chemicals that can alkylate DNA to form genotoxic damage. Among the various DNA lesions formed, O6-alkylguanine lesions can be highly cytotoxic and we recently demonstrated that O6-methylguanine (O6MeG) and O6-chloroethylguanine (O6CEG) specifically initiate apoptosis. Here we show that the MutS-alpha branch of the DNA mismatch repair (MMR) pathway (but not the MutS-beta branch) is absolutely required for signaling the initiation of apoptosis in response to O6MeGs, and partially required for signaling apoptosis in response to O6CEGs. Further, O6MeG lesions signal the stabilization of the p53 tumor suppressor and such signaling is also MutS-alpha-dependent. Despite this, MutS-alpha-dependent apoptosis can be executed in a p53-independent manner. This experimental system will allow dissection of the signal transduction events that couple a specific type of DNA base lesion with the final outcome of apoptotic cell death. Currently, we are examining the role of p53-independent signaling pathways in this process.

1684 DELINEATION OF THE GLUCOCORTICOID-INDUCED APOPTOTIC PATHWAY IN RAT THYMOCYTES.

C. L. Mann[1] and J. A. Cidlowski[2]. [1]*Curriculum in Toxicology, University of North Carolina-Chapel Hill, Chapel Hill, NC and* [2]*National Institute of Environmental Health Sciences, National Institutes of Health, Research Triangle Park, NC.* Sponsor: D. Holbrook.

In primary rat thymocytes, glucocorticoids induce a rapid apoptotic response, which is dependent upon gene expression and involves the activation of the caspase cascade. However, these conclusions were based largely on studies that analyzed DNA fragmentation, a late event in apoptosis. To determine whether upstream components of the glucocorticoid-induced apoptotic pathway are also dependent upon gene expression, we have now conducted a multiparametric analysis of cell viability, cell shrinkage, the loss of mitochondrial membrane potential, and externalization of phosphatidyl serine in the absence and presence of protein and RNA synthesis. Because caspases are activated during glucocorticoid induced apoptosis, we also analyzed the role of caspase activity in glucocorticoid-induced cell death. We show that the glucocorticoid-induced loss of viability, phosphatidyl serine externalization, and cell shrinkage in rat thymocytes are dependent upon both macromolecular synthesis and caspase activity. Interestingly, the loss of mitochondrial membrane potential was also dependent upon macromolecular synthesis in glucocorticoid-induced death, but was independent of caspase activity. We have also shown that glucocorticoids activate both caspase-9-like and caspase-8-like activity within thymocytes, the latter finding suggesting that glucocorticoid-induced apoptosis of rat thymocytes may also involve components of the Fas cell death pathway. In this regard, we show that glucocorticoids can impede Fas-mediated apoptosis, suggesting that glucocorticoids may act distal to the Fas receptor to induce thymocyte apoptosis.

1685 N-ACETYLSPHINGOSINE (C2-CERAMIDE) DISRUPTION OF LYSOSOMES AND CATHEPSIN B DISTRIBUTION.

J. J. Reiners, Jr.[1], P. A. Mathieu[1] and D. H. Kessel[2]. [1]*Institute Chemical Toxicology, Wayne State University, Detroit, MI and* [2]*Department of Pharmacology, Wayne State University School of Medicine, Detroit, MI.*

Exposure to N-acetylsphinogosine (C2-ceramide) triggers apoptosis in a variety of cell lines. The basis for this response is not known. The murine hepatoma cell line 1c1c7 undergoes apoptosis following exposure to C2-ceramide. Caspase-3 activation occurs within 12 hr of treatment, but does not reach its maximum (~500-fold increase) until 18-20 hr post treatment. DNA laddering is detectable within 16 hr of treatment and readily observed in an additional 8 hr. The fluorescent probe MTODT was used to analyze mitochondria respiration and membrane potential. MTODT staining was weakly diminished in some cells 6 hr post C2-ceramide exposure. Staining progressively, but slowly, diminished thereafter. Analyses with the fluorescent probes acridine orange and LysoTracker™ demonstrated coalescence of acidic organelles/lysosomes within 3 hr of treatment. Coalescence was complete by 6 hr. Thereafter, the fluorescent signals with these probes diminished with increasing treatment time. Analyses with an antibody to human pro- and processed cathepsin B revealed a punctate, peri-nuclear staining pattern in solvent-treated cultures. Within 3-6 hr of C2-ceramide treatment cathepsin B staining became diffuse and throughout the cell. *In situ* enzymatic analyses revealed a time-dependent progressive increase in cytoplasmic cathepsin B activity beginning 3 hr post C2-ceramide treatment. These studies raise the issue of whether C2-ceramide triggered apoptosis in 1c1c7 cells is initiated by released lysosomal enzymes. Such enzymes might facilitate the activation of procaspase 9 by damaging mitochondria and causing the release of cytochrome c. (This work was supported by grant ES09392.)

1686 1,2-DIACETYLBENZENE: A NEUROTOXIC & CHROMOGENIC AROMATIC HYDROCARBON.

M. S. Kim[1], R. Kayton[1], D. Pham[2], I. Tinsley[2], V. Miller[3], M. J. Sabri[1] and P. S. Spencer[1]. [1]*Oregon Health Sciences University, Portland, OR,* [2]*Oregon State University, Corvallis, OR and* [3]*Center for Research Information, Silver Spring, MD.*

Isomers of diethyl benzene have been selected to initiate studies on the neurotoxic potential of aromatic hydrocarbons. Occupational exposure to 1,2-diethylbenzene (1,2-DEB) and 1,3-diethylbenzene (1,3-DEB) occurs in workers handling jet fuels, such as JP4 and JP8. 1,2-Diacetylbenzene (1,2-DAB), the putative metabolite of 1,2-DEB, reacted differentially with amino acids and proteins to form a blue chromogen that was not seen in comparable experiments with 1,3-DAB (Kim et al., this meeting). Male Sprague-Dawley rats

were treated intraperitoneally with 10 or 20 mg/kg/day 1,2-DAB 5 days/week for 30 and 9 days, respectively. Animals developed hindlimb weakness and blue discoloration of tissues, including brain, spinal cord and peripheral nerves. Lumbar spinal motor neurons and corresponding dorsal root ganglia exhibited pathological changes in the form of proximal axonal swellings filled with 10-nm neurofilaments. Sequestration of axonal organelles by adaxonal oligodendrocyte or Schwann cell cytoplasmic processes was observed in the central and peripheral nervous system, respectively. By contrast, rats treated comparably for 30 days with 1,3-DAB lacked tissue discoloration and showed no behavioral or pathological evidence of neurotoxicity. These data demonstrate a close relationship between the neurotoxic and chromogenic properties of diethyl benzene and suggest chromogenicity could serve as a biological marker of human exposure to the neurotoxic isomer. 1,2-DAB, but not 1,3-DAB, shares the molecular arrangement (gamma-diketone) and neuropathological property (induction of proximal neurofilamentous axonopathy) of aliphatic hydrocarbons (e.g., 3,4-dimethyl-2,5-hexanedione) that have high mammalian neurotoxic potency.

1687 DIACETYLBENZENE: AMINO ACID, PROTEIN AND ENZYME REACTIVITY.

M. S. Kim[1], M. I. Sabri[1], D. Pham[2], I. Tinsley[2] and P. S. Spencer[1]. [1]*Oregon Health Sciences University, Portland, OR and* [2]*Oregon State University, Corvallis, OR.*

We have reported a relationship between the neurotoxic and chromogenic properties of the isomers of diacetylbenzene, the first of several chromogenic aromatic hydrocarbon compounds to be examined for neurotoxic properties (Kim et al., this meeting). 1,2-Diacetylbenzene (1,2-DAB), a gamma diketone-like neurotoxic isomer that blocks neurofilament transport in central and peripheral nerve fibers, forms a blue chromogen with certain amino acids *in vitro*. Of 20 amino acids (0.1 M) tested with 1,2-DAB (1 mM, pH 7.0, 37OC, 1 h), glycine and basic amino acids (lysine > histidine > asparagine) formed strong chromogenic reaction products. Proline, valine, tyrosine, and isoleucine were least reactive. 1,3-Diacetylbenzene (1,3-DAB), a non-chromogenic and non-neurotoxic isomer reacted modestly only with asparagine and glutamine. Protein reactivity of 1,2-DAB (but not of 1,3-DAB) was evident from the formation of a blue color with crystalline glyceraldehyde-3-phosphate dehydrogenase (GAPDH) and, to a lesser extent, with lactate dehydrogenase (LDH). Incubation of these glycolytic enzymes with 125, 250, 500 or 1000 micromolar concentrations of 1,2-DAB produced, respectively, ~10%, ~20%, ~40% and ~60% inhibition of the enzyme activity of GAPDH but not of LDH, which was essentially unaffected. Similar concentrations of 1,3-DAB had no significant effect on the activity of GAPDH or LDH. These data demonstrate that 1,2-DAB, one of several aromatic hydrocarbons reported to have chromogenic properties, reacts differentially with amino acids and proteins. 1,2-DAB showed a time-dependent, concentration-dependent and selective inhibition of GAPDH enzyme activity. The failure of 1,2-DAB to react with glutathione suggests that inhibition of GAPDH activity is unrelated to thiol groups in the protein.

1688 ACUTE AND SUBCHRONIC NEUROTOXICOLOGICAL EVALUATION OF TETRAHYDROFURAN BY INHALATION IN RATS.

L. A. Malley[1], G. R. Christoph[1], J. C. Stadler[1], J. F. Hansen[1] and J. A. Biesemeier[2]. [1]*The DuPont Co. Haskell Laboratory for Toxicology and Industrial Medicine, Newark, DE and* [2]*Great Lakes Chemical Corporation, West Lafayette, IN.*

The potential neurotoxicity of THF was evaluated in Crl:CD®BR male and female rats by acute or subchronic exposure followed by a battery of functional tests designed to assess nervous system dysfunction and neuropathology. Acute exposure concentrations were 0, 500, 2500, or 5000 ppm for 6 hours. Behavioral sedation, as indicated by diminished startle response to an unexpected auditory stimulus, occurred during exposure to 2500 and 5000 ppm. Immediately after removal from the inhalation chambers, rats in the 5000 ppm group exhibited lethargy, abnormal gait or mobility, slow or absent righting reflex, and splayed rear feet. A few animals (not statistically significant) exposed to 2500 ppm exhibited lethargy and splayed rear feet. Females exposed to 5000 ppm had reduced number and duration of movements after exposure on test day 1. No compound-related effects were observed during observations conducted on or after day 2 post-exposure. During the 14-week subchronic study, rats were exposed 6 hours per day, 5 days per week to 0, 500, 1500, or 3000 ppm. Neurobehavioral evaluations occurred on non-exposure days at approximately monthly intervals. Transient sedation, which appeared to be a daily reinstatement of acute sedation, was observed during exposure to concentrations of 1500 and 3000 ppm. There were no other compound-related effects on any neurobehavioral parameter or any morphological changes in nervous system tissues. The NOEL for both the acute and subchronic studies was 500 ppm in males and females. This project was sponsored by the THF Task Force.

1689 NEUROBEHAVIORAL ASSESSMENT OF HYDROCARBONS AND ITS APPLICATION TO THE DEVELOPMENT OF OCCUPATIONAL EXPOSURE LIMITS FOR HYDROCARBON SOLVENTS.

C. S. Nessel[1], D. E. Owen[2], J. H. C. Lammers[3], H. Muijser[3] and B. M. Kulig[3]. [1]*Exxon Chemical Europe, Machelen, Belgium,* [2]*Shell Chemicals Europe, London, United Kingdom and* [3]*TNO Nutrition and Food Research Institute, Zeist, Netherlands.*

A neurobehavioral testing program on aliphatic, cycloaliphatic, and aromatic hydrocarbons was conducted to develop a database on acute hydrocarbon solvent neurotoxicity. The data from this research program provide additional information for setting occupational exposure limits (OELs) for hydrocarbon solvents. Twelve hydrocarbons or hydrocarbon mixtures, with carbon chain lengths ranging from C5-C11, were tested for acute neurotoxicity. Male WAG/RijCrlBR rats were exposed by inhalation for 8 hr on 3 consecutive days and evaluated daily for effects on motor activity, functional observation measures, and learned performance of a visual discrimination task. C5 aliphatics (pentane, isopentane, cyclopentane) did not cause significant effects at exposures up to 20 g/m^3, and C7/C8 aliphatics (methylcyclohexane, n-octane, iso-octane) did not cause any significant effects at exposures up to 14 g/m^3. n-Decane caused some limited, but statistically significant neurobehavioral effects at 5 g/m^3, with no effects at 1.5 g/m^3. A commercial solvent containing a mixture of C9 aromatics caused significant neurobehavioral effects at 5 g/m^3 and reversible effects on learned performance at 1 g/m^3, with a NOAEL of 0.2 g/m^3. These data will be used with existing toxicological data on hydrocarbon solvents to recommend occupational exposure limits for the whole range of complex hydrocarbon solvents.

1690 INVESTIGATION OF THE EFFECTS OF REPEATED EXPOSURE TO JP-8 VAPOR ON THE COGNITIVE CAPACITY OF RATS.

J. Rossi[1], D. Wright[2], G. D. Ritchie[1], W. Malcomb[1], R. L. Carpenter[1], M. Y. V. Bekkedal[1] and A. F. Nordholm[1]. [1]*Naval Health Research Center Detachment-Toxicology (NHRC-TD), Wright-Patterson AFB, OH and* [2]*University of Arkansas Medical School, Little Rock, AK.*

Forty-eight male Sprague-Dawley rats were exposed by whole body inhalation to JP-8 jet fuel vapor (1000 mg/m3 + 10%) or room air control conditions for 6 hr/day, 5 days/wk for 6 consecutive weeks (180 hr). No physiological or neurobehavioral deficits were observed, although jet fuel-exposed rats gained body weight at a lower rate (not significantly different) than controls. Following a 60-day recovery period, rats were trained successively on increasingly complex operant schedules of reinforcement from CRF to successive lever press, in which rats were required to learn a new response sequence to a 3-lever array during each operant session. The effects of repeated JP-8 vapor exposure are reported for cognitive performance capacity on tasks ranging from simple acquisition of lever-pressing behavior to development of complex cognitive strategies.

1691 PBPK MODELING OF PEAK EXPOSURES TO WHITE SPIRIT.

B. M. Kulig[1], A. M. Hissink[1], J. Kruse[1], J. Lammers[1], F. Salmon[1], R. H. McKee[2], D. Owen[3] and C. S. Nessel[2]. [1]*TNO Nutrition and Food Institute, Zeist, Netherlands,* [2]*Exxon Chemical Europe, Brussels, Belgium and* [3]*Shell Chemicals Ltd., London, United Kingdom.*

Ocupational exposure limits are often 8-hour time-weighted averages (TWAs), but, in the workplace exposures fluctuate and TWAs may be exceeded for short periods of time. To assist in using animal data to set occupational exposure levels, we conducted toxicokinetic studies in rats and in human volunteers to develop a physiologically based pharmacokinetic (PBPK) model for two constituents of white spirit (WS), namely 1,2,4-trimethylbenzene (TMB) and n-decane (nDEC), representing the aromatic and aliphatic fractions. The model then compared the kinetic behavior of TMB and nDEC in blood and brain following different WS exposure scenarios, all equivalent to the 8-hour TWA value for WS (100 ppm). The modeling studies showed

that concentrations of these hydrocarbons may be higher in brain than in blood regardless of exposure scenario with a brain:blood ratio higher for nDEC than for TMB. External exposure scenarios involving short exposures above the TWA value are expected to produce concentrations in brain and blood that are higher than those from a constant exposure when total doses (i.e., ppm x hours) are equal. However, the expected increase is relatively less than the increase in external exposure levels. Finally, with respect to total dose, external exposures involving short exposures higher than the TWA value are not expected to significantly affect the area under the concentration vs. time curve (AUC) for the parent compound unless metabolism is saturated.

1692 METHYL *TERTIARY*-BUTYL ETHER (MTBE) AND RELATED COMPOUNDS INHIBIT BINDING AT A RECOGNITION SITE OF THE $GABA_A$ RECEPTOR IN MEMBRANES FROM RAT BRAIN.

J. V. Martin[1], N. M. Bilgin[1] and M. M. Iba[2]. [1]*Rutgers University, Camden, NJ and* [2]*Rutgers University, Piscataway, NJ.*

A major concern in the use of methyl *t*-butyl ether (MTBE) as a gasoline additive is the risk of neurological signs and symptoms after exposure. Since a variety of alcohols and ethers are known to modify aspects of the $GABA_A$ receptor function, we tested MTBE and related compounds for effects on binding of tritiated *t*-butyl-bicycloorthocarboxylate (^{3}H-TBOB), a ligand for the convulsant site of the complex. Whole forebrains of male albino rats were homogenized in 500 mM sodium chloride including 50 mM potassium phosphate buffer (pH 7.4), and the membrane fragments were frozen at -70°C and washed repeatedly by centrifugation and resuspension in newly added salt-buffer solution. Varying amounts of the compounds were incubated with ^{3}H-TBOB and resuspended membranes for 60 min at 25°C. Membrane-bound radioactivity was determined after filtering the membrane suspensions in a vacuum manifold and washing the filters twice. Data were corrected for non-specific binding in the presence of 10μM picrotoxin. All the ethers and alcohols tested were inhibitory of ^{3}H-TBOB binding at 30-300 mM concentrations. The most potent of the compounds tested was *t*-amyl alcohol (TAA), followed by ethyl *t*-butyl ether (ETBE), *t*-amyl methyl ether (TAME), *t*-butyl alcohol (TBA), and methyl *t*-butyl ether (MTBE), in descending rank order of potency. Generally, then, the potency of inhibition correlated roughly with the carbon chain length, and, for compounds with equal numbers of carbons, the inhibition of ^{3}H-TBOB was greater for the alcohols than for the ethers. In additional studies, MTBE was found to have primary effects on ^{3}H-TBOB receptor density (B_{max}) rather than affinity (K_d). (Support: NSF IBN-9809943.)

1693 BEHAVIORAL EFFECTS OF TRICHLOROETHYLENE (TCE): EXPOSURE VS. MODEL PREDICTIONS.

P. J. Bushnell[1], M. V. Evans[2], J. E. Simmons[2], J. H. Raymer[3] and W. K. Boyes[1]. [1]*Neurotoxicology Division, USEPA, Research Triangle Park, NC,* [2]*Experimental Toxicology Division, USEPA, Research Triangle Park, NC and* [3]*Research Triangle Institute, Research Triangle Park, NC.*

The hazard from inhaled volatile organic compounds is presently assessed in terms of lifetime exposure to the average vapor concentration (C). This strategy yields rational predictions of risk if the product of C and the exposure duration (t) yields a constant effect. This assumption was tested by assessing the acute behavioral effects of inhaled TCE vapor in rats in terms of C, t and the concentration of TCE in the target organ (brain), $[TCE]_{Br}$. Adult male Long-Evans rats (n=11) were trained to perform a signal detection task in which a press on one lever produced food on trials with a signal (a 300-msec light flash); a press on a second lever produced food on trials lacking a signal. Proportions of correct detections of the signal [P(hit)], proportions of errors on non-signal trials [P(fa)] and response time (RT) were calculated at 20-min intervals during repeated daily 70-min exposures conducted in air containing 0, 400, 800, 1200, 1600, 2000, or 2400 ppm TCE. Each measure remained stable during tests in air. In TCE, P(hit) declined, and P(fa) and RT increased with increasing C and t; these effects depended more on C than t. The effects of TCE were larger during early exposures to TCE than during the later exposures. $[TCE]_{Br}$ at times of behavioral testing was estimated with a PBPK model for TCE using a fat volume and cardiac output appropriate for the tested rats. $[TCE]_{Br}$ accurately predicted the behavioral effects of TCE during both early and late exposures. Thus, behavioral effects of TCE depended more closely on the internal dose of TCE than on either its inhaled concentration (C) or cumulative inhaled dose (C × t product). (This abstract does not necessarily reflect U.S. EPA policy.)

1694 TIME COURSE OF TOLERANCE TO REPEATED INHALATION OF TRICHLOROETHYLENE (TCE) IN RATS.

W. M. Oshiro and P. J. Bushnell. *US Environmental Protection Agency, Research Triangle Park, NC.*

Previous work showed that tolerance to the organic solvent trichloroethylene (TCE) develops in rats performing a visual signal detection task (SDT) while inhaling TCE. The present experiment was designed to assess the persistence of this tolerance. In Phase 1, two groups of adult male Long-Evans rats with equivalent accuracy on the SDT inhaled TCE at 2000 ppm in daily 1-hour sessions for 2 weeks (Monday - Friday). One group performed the SDT during TCE exposure (Paired) while the other group performed the SDT prior to daily TCE exposure (Unpaired). The Paired group showed a decrease in accuracy and an increase in response time (RT) on Day 1; these effects abated during the two weeks of exposure, displaying the development of tolerance. In contrast, the Unpaired group maintained their pre-exposure baseline accuracy and RT. In Phase 2, all rats were challenged with SDT tests in 2000 ppm TCE on Days 1, 7, 14, 28, and 56 after termination of Phase 1. All rats performed the SDT in air only on the days between each challenge. The Unpaired rats showed reduced accuracy and increased RT during each challenge test. The RT of the Paired rats remained unaffected by TCE until Day 56, whereas their accuracy progressively deteriorated after Day 7. Thus the tolerance in the Paired group lasted from 7 to 28 days after induction, depending on the index measured. In contrast, the Unpaired group showed no beneficial effects from the pre-exposure to TCE received in Phase 1 on accuracy or RT during Phase 2. (This abstract does not necessarily reflect EPA policy.)

1695 ACUTE NEUROTOXIC EFFECTS OF INHALED TOLUENE ON PATTERN VISUAL EVOKED POTENTIALS AS A FUNCTION OF EXPOSURE AND ESTIMATED BLOOD AND BRAIN CONCENTRATION.

W. K. Boyes[1], T. Jackson[2], M. Bercegeay[1] and M. Evans[1]. [1]*USEPA, Research Triangle Park, NC and* [2]*Duke Univ., Durham, NC.*

The effects of acute inhalation exposure to the volatile organic compound trichloroethylene (TCE) are related to the target tissue concentration of TCE at the time of testing (Boyes et al., Toxicologist 48:291, 1999). The current studies examined exposure to another VOC, toluene, for comparison to the previous results with TCE. A physiologically-based pharmacokinetic (PBPK) model was developed for ad-lib feed (350-450 g) adult male Long-Evans rats. Rats were exposed by inhalation to 3,000 ppm toluene for 1.3 hr, or 4,000 ppm toluene for 1 hr. Both conditions gave constant C x t products of about 4,000 ppm-hrs. Pattern-elicited visual evoked potentials were recorded before and at the end of the exposure period. The pattern stimulus was a 0.16 cpd vertical sinusoidal grating with a contrast of either 60% or 0% ("noise" evaluation), that was modulated in an appearance/disappearance mode at 5 Hz. Exposure to toluene, like TCE, reduced the amplitude of the frequency-double spectral component (F2) without changing response amplitude at the primary stimulation rate (F1). The mean±SEM F2 amplitude was reduced from 11.2±1.6 to 3.8±0.4 uV at 3000 ppm, and from 13.2±2.3 to 4.7±0.7 uV at 4000 ppm. At the time of VEP testing, blood and brain concentrations of toluene were estimated to be approximately 68 and 152, or 81 and 182 mg/l, following exposure to 3,000 or 4,000 ppm, respectively. Toluene appears to reduce VEP F2 amplitude at roughly similar brain concentrations as did TCE. Further research at lower concentrations is planned to more fully examine this relationship. (This abstract does not necessarily reflect EPA policy.)

1696 ACUTE BEHAVIORAL EFFECTS OF n-DECANE, 1,2,4-TRIMETHYLBENZENE AND WHITE SPIRIT IN RATS IN RELATION TO BRAIN AND BLOOD LEVELS.

J. H. Lammers[1], B. M. Kulig[1], R. H. McKee[3], D. Owen[2] and C. S. Nessel[3]. [1]*TNO Nutrition and Food Research Institute, Zeist, Netherlands,* [2]*Exxon Chemical Europe, Brussels, Belgium and* [3]*Shell Chemicals Ltd., London, United Kingdom.*

Studies are being conducted to assist in setting occupational exposure limits for hydrocarbon solvents. The current series examined the acute behavioral effects of inhalation exposure to white spirit (WS: –100, 400, 800 ppm), a complex substance, and two WS constituents, 1,2,4-trimethylbenzene (TMB: –25, 250, 1000 ppm) and *n*-decane (nDEC: –85, 260, and 860 ppm). Rats were exposed 8 hours/day for 3 consecutive days in two experiments. Exp. I included functional observational battery (FOB) and motor activity (MA) assessments; Exp. II examined effects on two-choice visual discrimination performance (VisDisc). In separate experiments, brain and blood concentra-

tions were determined to validate toxicokinetic models for nDEC and TMB alone and as components of WS. FOB testing indicated changes in gait and body temperature for the high WS group and changes in forelimb grip strength in the high nDEC group. MA was reduced in a dose-responsive manner in WS- and TMB-exposed rats. All three substances produced dose-responsive psychomotor slowing in the visual discrimination test. Clearance rates of nDEC and TMB increased in WS- and TMB-exposed rats over the 3-day exposure period. In contrast, exposure to n-DEC did not affect its kinetics. It is hypothesized that these differences are due to induced metabolism by TMB and other WS consitutents but not n-DEC. The no-effect level (NOELs) for neurobehavioral effects were 0.6 g/m^3 (100 ppm) for WS, 1.25 g/m^3 (250 ppm) for TMB, and 1.5 g/m^3 (260 ppm) for nDEC.

1697 PBPK MODELING OF *n*-DECANE AND 1,2,4-TRIMETHYLBENZENE ALONE OR AS CONSTITUENTS OF WHITE SPIRIT.

A. M. Hissink[1], B. M. Kulig[1], J. H. Lammers[1], J. Kruse[1], F. G. Salmon[1], R. H. McKee[2], D. Owen[3] and C. S. Nessel[2]. [1]*TNO Nutrition and Food Institute, Zeist, Netherlands,* [2]*Exxon Chemical Europe, Brussels, Belgium and* [3]*Shell Chemical Ltd., London, United Kingdom.*

A physiologically-based pharmacokinetic (PBPK) model, was developed for white spirit (WS), n-decane (nDEC) and 1,2,4-trimethylbenzene (TMB) to facilitate the use of animal data in setting occupational exposure levels for hydrocarbon solvents. Blood and brain levels of nDEC and TMB, as representative of the aliphatic and aromatic WS constituents, were measured in rats. Parameters which described the saturable metabolism of nDEC and TMB (K_m and V_{max}) which were obtained by best simultaneous visual fits of the blood kinetics in the rat were 20 mg/kg/hr for V_{max} and 0.1 mg/l for K_m for nDEC and 3.5 mg/kg/hr and 0.25 mg/l for TMB. The simulated brain concentrations of these two compounds were consistent with measurements. The rat model was then allometrically scaled to humans. The predicted concentrations of TMB and nDEC in blood and expired air in humans were compared to those measured during and following a 4-hour exposure to WS at 100 ppm. For TMB, good agreement was found. The model tended to underestimate nDEC blood levels during WS exposure, but simulations agreed well with the data following the termination of exposure. Because the white spirit model, did not accurately simulate the rat blood and brain kinetics for nDEC and TMB, the maximum capacity of biotransformation parameter was increased. This suggests competition for metabolism of TMB and DEC by other WS constituents.

1698 SUPPRESSION SUBTRACTION HYBRIDIZATION IDENTIFIES GENES DIFFERENTIALLY EXPRESSED IN ETHYLENE GLYCOL MONOMETHYL ETHER (EGME)-INDUCED TESTICULAR APOPTOSIS.

W. Wang and R. E. Chapin. *National Institute of Environmental Health Sciences, Research Triangle Park, NC.*

The solvent Ethylene Glycol Monomethyl Ether (EGME) produces the same testicular lesions in rodents and human testis cultures, which is characterized by apoptosis of pachytene spermatocytes. To identify gene changes early in the lesion and determine the possible involvement of cells other than the spermatocytes, we employed a suppression subtractive hybridization technique using whole testes from mice treated 8 hours previously with 500 mg/kg EGME, to generate two subtracted mouse testis cDNA libraries enriched for gene populations either upregulated or downregulated by EGME. A total of seventy clones were screened, and six of them were shown by Northern blotting to be differentially expressed in the EGME lesion. The three clones with increased expression after EGME were one identical to t-complex testis expressed gene 1 (tctex1), a gene encoding ribosomal protein S25 and a heretofore uncharacterized mouse testis EST 774, while three other genes suppressed by EGME were tctex2, alpha-2,6-sialyltransferase (STF) and another uncharacterized mouse testis EST 842. These clones contain multiple motifs for phosphorylation, glycosylation and myristoylation. Anti-sense RNA probes were generated, and in situ hybridization with these probes localized the expression changes of these six clones in multiple germ cell stages as well as other cell types: Sertoli cell (upregulated: S25, EST 774; downregulated: tctex2, EST 842), the interstitial cell (upregulated: tctex1; downregulated: STF). These data at the gene expression level are the first to demonstrate the early involvement in this lesion of cell types other than the dying spermatocytes, and yield new insights into the early responses to this testicular toxicant.

1699 LACK OF EFFECTS OF CYCLOSPORIN A ON SPERM MOTILITY AND TESTICULAR SPERMATID HEAD COUNTS IN WISTAR AND SPRAGUE-DAWLEY RATS.

L. A. Dostal, S. L. Higginbotham, J. A. Murray and M. M. Dannemiller. *Parke-Davis Pharmaceutical Research, Ann Arbor, MI.*

Cyclosporin A is an immunosuppressive drug derived from soil fungi that is often used in organ transplantation. Based on previous reports of adverse effects on male reproduction in Sprague Dawley rats, the present study was designed to use Cyclosporin A as a positive control compound for effects on sperm motility. Groups of 3-4 Wistar or Sprague Dawley rats were given daily s.c. doses of 0, 5, 10, or 20 mg/kg Cyclosporin A for 14 days. At termination, male reproductive organs were weighed, sperm motion parameters were analyzed using CASA, and testicular spermatid head counts were determined. In contrast to previous reports, 20 mg/kg Cyclosporin A produced significant body weight loss, morbidity and mortality in Wistar rats within 9 days of dosing, but had no consistent effect on sperm parameters or testis and epididymis weights in surviving animals. Doses of 5 and 10 mg/kg were tolerated with minimal effects on body weight in Wistar rats, and had no significant effects on testis and epididymis weights, sperm motility and velocity (VCL), or testicular spermatid head counts. Absolute and relative accessory sex organ weights were significantly reduced by 11% - 52% at all doses. In order to determine if the lack of effects on sperm parameters was due to strain differences, Sprague Dawley rats were given doses of 10 or 20 mg/kg Cyclosporin A. All animals survived, and body weights were significantly reduced (11%-24 %). As in Wistar rats, there were no significant effects on testis and epididymis weights, sperm motility and velocity, or testicular spermatid head counts. Accessory sex organs weights were reduced by 28% and 50% at 10 and 20 mg/kg, respectively; relative weights were reduced by 20% and 35%. These results suggest a strain difference between Wistar and Sprague Dawley rats in sensitivity to the general toxicity of Cyclosporin A, but no specific effect on testis or epididymis weights, or sperm parameters. However, the effects on accessory sex organs weight could suggest an adverse effect on androgen status.

1700 DI-(2-ETHYLHEXYL) PHTHALATE (DEHP) CAUSES FORMATION OF GIANT MULTINUCLEATED GONOCYTES AND INHIBITS SERTOLI CELL PROLIFERATION BY SUPPRESSING CYCLIN D2 EXPRESSION IN THE NEONATAL RAT TESTIS.

L. Li, W. F. Jester and J. M. Orth. *Department of Anatomy & Cell Biology, Temple University School of Medicine, Philadelphia, PA.*

In this study, we explored the effects of di-(2-ethylhexyl) phthalate (DEHP) and the underlying mechanism in the neonatal rat testis. Three-day-old rats received a single oral dose of corn oil (control) or 20-500 mg/kg DEHP or 500 mg/kg of di-ethyl phthalate (DEP). The morphology of the testis was evaluated with light microscopy and proliferation of Sertoli cells was quantified by BrdU-labeling. Exposure to 200 or 500 mg/kg DEHP caused formation of giant gonocytes, each containing 2-4 apparently normal nuclei, while Sertoli cells appeared morphologically normal and there were no indications of cell death up to 48 hr after dosing. However, the percentage of BrdU-labeled Sertoli cells in pups 24 hr after treatment with 100, 200, or 500 mg/kg of DEHP was decreased to 20.83, 9.95% or 4.13%, respectively, compared to 27.03% of the control group ($p<0.05$). When serum FSH was measured by RIA, we found no significant difference between controls and pups treated with 200 or 500 mg/kg DEHP. Exposure to 20 mg/kg DEHP or 500 mg/kg of DEP had no effect on either morphology or Sertoli cell proliferation. To determine if DEHP reduces Sertoli cell proliferation by suppressing expression of cell cycle proteins, Western and Northern blotting were used to analyze and compare the relative protein and mRNA levels of cyclin D1, D2, D3 and p27kip1 in testes of control and DEHP-treated pups. Exposure to 200 mg/kg DEHP resulted in decreased cyclin D2 protein at 8 and 12 hr after dosing, while cyclin D1, D3 and p27kip1 in DEHP-treated rat testes remained unchanged. Moreover, the relative level of cyclin D2 mRNA was also decreased 12 hr after exposure to 200- or 500-mg/kg DEHP. Taken together with our previous findings *in vitro*, these data clearly indicate that exposure to relatively low levels of DEHP causes abnormal morphology in gonocytes and significantly decreases Sertoli cell proliferation in the intact testis. Furthermore, our findings also suggest that DEHP inhibits Sertoli cell proliferation by suppressing expression of cyclin D2 in an FSH-independent manner. (Supported by NIH grant ES09102 to JMO.)

1701 A GUANYLATE CYCLASE INHIBITOR ATTENUATES THE RELAXATION RESPONSE OF UTERINE SMOOTH MUSCLE TO HYDROGEN PEROXIDE.

T. Clipson and R. Loch-Caruso. *University of Michigan, Ann Arbor, MI.*

Hydrogen peroxide (H_2O_2) stimulates contractile activity of the pregnant rat uterus through the activation of prostaglandin synthesis. This stimulation of activity is often preceeded by a period of relaxation. Using standard muscle baths and myometrial cells, the present study evaluated the possible roles of nitric oxide and cGMP in H_2O_2-induced relaxation of spontaneous oscillatory uterine contractions and myometrial cells isolated from gestation day 10 rats. Exposure of cultured myometrial cells to 25, 50 or 100 μM H_2O_2 increased the release of nitric oxide (as measured by the spectrophotometric quantitation of nitrite using the Griess reagent) to concentrations 50, 120, and 170%, respectively, above solvent control levels. However, pretreatment of uterine strips with the endothelial and inducible nitric oxide synthase inhibitors 3mM Nω-nitro-$_L$-arginine methyl ester (L-NAME) or 500 μM aminoguanidine did not protect against relaxation elicited by 200 μM H_2O_2. Uterine strips pretreated with 5 μM 1*H*-[1,2,4]oxadiazolo[4,3,-*a*]quinoxalin-1-one (ODQ), a selective inhibitor of soluble guanylate cyclase, were partially protected against the inhibition of uterine contractility induced by 200 μM H_2O_2. It is proposed that hydrogen peroxide can directly activate guanylate cyclase, increasing the level of cGMP and contributing to relaxation of the uterine smooth muscle. Direct activation of guanylate cyclase by hydrogen peroxide may have important implications for the regulation and timing of uterine smooth muscle activity during pregnancy and labor under pathophysiological and normal conditions.

1702 INHIBITION OF TESTOSTERONE BIOSYNTHESIS BY MOLINATE SULFOXIDE IN LEYDIG CELL-ENRICHED CULTURES.

W. L. Phillips and M. G. Miller. *University of California, Davis, Davis, CA.*

Molinate (Ordram) is a thiocarbamate herbicide widely used in rice fields to restrict the growth of grassy weeds. Our laboratory and others have previously shown that administration of molinate to rats produces testicular injury characterized by Sertoli cell vacuolation, phagocytosis of spermatids and failed spermiation. Previous studies have also shown that molinate is metabolized *in vivo* via a sulfoxidation pathway, and that molinate sulfoxidation products are electrophilic, more toxicologically potent than the parent and capable of covalently inhibiting a serine esterase, hydrolase A, that possesses cholesterol ester hydrolysis activity. Because the *in vivo* effects on hydrolase A activity and spermatid retention may represent a respective cause and effect of decreased testosterone levels, we have tested the hypothesis that molinate and molinate sulfoxide are capable of decreasing testosterone biosynthesis *in vitro*. Leydig cell-enriched cultures were stimulated with human chorionic gonadotropin and treated for one hour with a DMSO vehicle and either molinate, molinate sulfoxide or ketoconazole, a known inhibitor of testosterone biosynthesis, respectively. After one hour of treatment the medium was changed and the cells were allowed to recover until the experiment was terminated 12 hours later. Although molinate and molinate sulfoxide both decreased testosterone production, only molinate sulfoxide significantly inhibited testosterone biosynthesis without diminishing cellular ATP. These data indicate that only molinate sulfoxide inhibited testosterone biosynthesis through a mechanism not associated with impairment of cell health. Molinate sulfoxide completely inhibited nonspecific esterase activity at much lower concentrations (< 0.5 μM) than that required to significantly decrease testosterone biosynthesis (50 μM), suggesting that nonspecific esterase inhibition may not be directly involved in the sulfoxidation-dependent decrease in testosterone production.

1703 LEYDING CELLS MEDIATE LEUPROLIDE STIMULATION OF SPERMATOGENESIS IN 2,5-HEXANEDIONE-INDUCED TESTICULAR ATROPHY.

H. A. Schoenfeld, S. J. Hall and K. Boekelheide. *Department of Pathology & Laboratory Medicine, Brown University, Providence, RI.*

2,5-Hexanedione (2,5-HD), a reactive metabolite of the environmental toxicant n-hexane, produces a persistent testicular atrophy in rats when administered for 3.2 weeks (1% v/v) in drinking water. While the initial injury to seminiferous tubules by 2,5-HD has been attributed to a disruption of Sertoli cell microtuble transport, it has been hypothesized that the persistent nature is due to an increase in intratesticular testosterone (ITT) levels. Consistent with this hypothesis, we observed a 2.5 fold increase, relative to controls, in concentration of ITT in atrophic testes of Fisher rats (n=6) 30 weeks after treatment with 2,5-HD. Leuprolide, a GnRH agonist that produces a transient increase followed by a sustained suppression of ITT, reverses testicular atrophy induced by 2,5-HD. When 2,5-HD rats (n=6) were administered leuprolide (1.5 mg/animal, 3 injections, 24 days apart) ITT levels were suppressed below the limits of detection during leuprolide treatment. Twelve weeks after the last leuprolide injection ITT levels (280±53 ng/mL) had returned to control values (214±26 ng/mL), with a concomitant 10-fold increase in the percent of populated seminferous tubules. To further examine the role of ITT in the maintenance of testicular atrophy, an additional group of 2,5-HD treated rats (n=7), received a single dose (85 mg/kg i.p.) of the Leydig cell toxicant ethane dimethanesulphonate (EDS), followed by 3 doses of Leuprolide. EDS caused an ablation of testosterone-producing Leydig cells, which was sustained for the duration of leuprolide treatment. The combination of leuprolide and EDS also significantly depressed ITT levels (33±ng/ml). As with the group of animals which had received leuprolide alone, ITT levels (241±31 ng/mL)had returned to control values (214±26 ng/mL) 12 weeks after the last leuprolide injection, however the combination of EDS and leuprolide failed to stimulate a repopulation of seminiferous tubules. These results indicate that paracrine acting factoring or testosterone precursors by Leydig cells, are necessary for the stimulation of spermatogenesis by leuprolide.

1704 EARLY RESPONSE OF THE TESTIS TO AN ORAL EXPOSURE TO THE FUNGICIDE CARBENDAZIM IN THE RAT.

M. Nakai[1], M. G. Miller[2] and R. A. Hess[1]. [1]*University of Illinois at Urbana-Champaign, Urbana, IL and* [2]*University of California Davis, Davis, CA.*

The fungicide carbendazim, a microtubule poison, is a toxicant that causes serious testicular damage. It is known that in the rat all seminiferous tubules, except in Stages III-V, show sloughing of elongate spermatids, as early as 3 hr after an oral exposure. However, the mechanism that is responsible for sloughing remains unknown. To study the pathophysiology of sloughing, the earliest changes in the seminiferous epithelium after a single exposure of carbendazim were determined in the present study. Adult Sprague Dawley rats were treated orally with the agent (400 mg/kg) and the testes were processed for light microscopy 45, 60, 90, 120 and 150 min later. Little change was noted in the testes up to 90 min post-exposure. The earliest change observed was mainly in Stages VI and XIII at 120 min, which was characterized by narrow gaps between the layers of elongate and round spermatids. These gaps became evident in more stages at 150 min, indicating sloughing of spermatids. Immuno-histochemistry for tubulin and vimentin indicated that, in tubules with the gaps and/or sloughing of spermatids, some Sertoli cells showed a diffused staining pattern for tubulin and collapse of vimentin, respectively, but staining patterns of both cytoskeletal elements in other Sertoli cells appeared to be normal. These results indicate that the earliest change after a carbendazim exposure is sloughing of spermatids in stages VI and XIII that occurs sometime between 90 and 120 min. It is suggested that depolymerization of tubulin and collapse of vimentin are related to sloughing of germ cells, but further studies are needed to explain the biochemical mechanisms.

1705 MICROTUBULE DISRUPTION BY CARBENDAZIM IS REGULATED BY MICROTUBULE-ASSOCIATED PROTEINS.

B. S. Winder, C. S. Strandgaard and M. G. Miller. *University of California, Davis, CA.*

The fungicide carbendazim is known to disrupt microtubular structures in the testis and to cause testicular toxicity in rats. To investigate how carbendazim affects testis cytoskeletal proteins, tubulin and microtubule-associated proteins (MAPs) were isolated from rat testes and brains using three techniques. The effects of carbendazim on microtubule (MT) assembly were compared with the known MT disruptors colchicine and nocodazole. Carbendazim (100 μM) had no effect on the assembly of MTs from tubulin containing MAPs isolated with taxol, while colchicine (40 μM) and nocodazole (12.5 μM) strongly inhibited the assembly reaction. Similarly, formation of MTs from tubulin prepared with glycerol was strongly inhibited by colchicine and nocodazole but only weakly by carbendazim. However, in the presence of carbendazim these MTs were less stable and more prone to depolymerization. The assembly of MTs from MAP-free tubulin isolated with glutamate was inhibited by all three compounds but the inhibition by carbendazim was reversed by the inclusion of high molecular weight MAPs and not by unrelated protein (BSA). Inclusion of colchicine or nocodazole but not carbendazim during isolation of microtubular proteins resulted in the loss of tubulin indicating a different mechanism of action for carbendazim. The data suggest that carben-

dazim enhances the dynamic instability of MTs and that specific MAPs prevent this effect. Further studies are exploring the possibility that carbendazim affects the binding and/or hydrolysis of guanosine triphosphate.

1706 PERINATAL/JUVENILE EXPOSURE TO METHOXYCHLOR REDUCES SERTOLI CELL NUMBERS IN ADULT RATS.

L. Johnson[1], R. E. Chapin[2], M. W. Harris[2], R. L. Silge[1], A. C. Guidry[1] and W. R. Lee[1]. [1]*Center for Environmental and Rural Health, Texas A&M University, College Station, TX and* [2]*Reproductive Toxicology Group, National Institute of Environmental Health Sciences, Research Triangle Park, NC.*

Perinatal and juvenile treatment of rats with methoxychlor (MXC) reduced testicular size and other reproductive indices in those animals as adults (Chapin et al., 1997). The objective was to determine if these males have fewer Sertoli cells which might explain these effects. Rat dams were gavaged with MXC at 0, 5, 50, or 150 mg/kg/day for the week before and after they gave birth. Resulting male pups (14-16/group) then were dosed directly from postnatal day 7 to 42. Testes were fixed in Bouin's and in OsO4, embedded in Epon and sectioned at 0.5 μm, stained with toluidine blue, and evaluated stereologically or cut at 20 μm to measure Sertoli cell nuclei with Nomarski optics. Single Sertoli cell nuclear volume was calculated using a sphere times a correction factor for the nonspherical shape of the Sertoli cell nuclei. Sertoli cell number equaled [volume density of the nucleus times the parenchymal weight (90% of testicular weight)] divided by the volume of a single Sertoli cell nucleus. Across dose groups, there were no changes in the nuclear volume density (control: 1.46±0.04%), the volume of a single nucleus (474±16 fl), and the number of Sertoli cells per g parenchyma (28.2±1.3 million). There were dose-related changes in the volume of nuclei per testis (23.4±1.2, 23.1±0.8, *19.3±0.8, or *16.3±0.6 μl) and the number of Sertoli cells per testis (50.3±3.0, 48.6±2.0, *41.2±1.8, or *32.7±1.3 million). The two highest dose groups were the ones with fewer testicular spermatids. Male rats exposed to MXC prior to puberty had reduced numbers of Sertoli cells and spermatids as adults. (Supported by NIEHS.)

1707 NINETY DAY INHALATION TOXICITY STUDY OF HCC-230FA IN RATS.

J. R. Bamberger[1], R. S. Scott[1], J. F. Hansen[1], G. S. Ladics[1], W. J. Brock[1], G. S. Elliott[2], M. E. Hurtt[3] and M. S. Swanson[4]. [1]*Dupont Company, Newark, DE,* [2]*Sierra Biomedical Inc., Sparks, NV,* [3]*Pfizer Inc., Groton, CT and* [4]*Vulcan Chemicals, Birmingham, AL.*

The inhalation toxicity of 1,1,1,3,3,3-hexachloropropane (HCC-230fa) was evaluated by exposure of male and female rats to 0, 0.50, 2.5, or 25 ppm over a 90-day period. Body weights and food consumption were measured weekly. Clinical pathology was evaluated at 45 and 90 days. A morphological evaluation was conducted at 14 weeks or at the end of the 1-month or 3-month recovery periods (males only). In addition, sperm assessment and primary humoral immune response evaluations were conducted at 14 weeks or at the end of the 1-month recovery period. Body weights and food consumption in rats exposed to 25 ppm were lower than the corresponding controls. Male and female rats exposed to 25 ppm and sacrificed immediately after the exposure period had minimal statistically significant decreases in total leukocyte and lymphocyte counts. These leukocytic changes in the 25 ppm groups were considered to be marginally adverse. Pathologic examination revealed hepatocellular hypertrophy in male rats from the 25 ppm group sacrificed after the exposure period, and an increased incidence and/or severity in chronic progressive nephropathy in 0-day, 1-month recovery, and 3-month recovery males at 25 ppm. The hepatocellular hypertrophy was considered a non-adverse pharmacological adaptive response to HCC-230fa. Evaluation of sperm parameters at the end of the exposure period showed biologically significant decreases in percent motile sperm at 25 ppm (63.1% vs. 78.3% for controls). In addition, decreases in epididymal sperm number per cauda epididymis and percent normal sperm morphology were seen in rats at 25 ppm; however, these changes were not believed to be biologically significant. There were no compound-related effects on humoral immune response. The no-observed-effect level for repeated exposure to HCC-230fa in male and female rats was 2.5 ppm based on effects on body weight, food consumption, percent motile sperm, clinical pathology parameters, and histology.

1708 EFFECT OF 4-VINYLCYCLOHEXENE DIEPOXIDE DOSING ON EXPRESSION OF *bax* IN RAT AND MOUSE SMALL PREANTRAL FOLLICLES.

K. E. Thompson, S. M. Borman, I. G. Sipes and P. B. Hoyer. *University of Arizona, Tucson, AZ.*

The occupational chemical 4-vinylcyclohexene diepoxide (VCD) is known to destroy small ovarian follicles in rats and mice. In rats, this destruction occurs by accelerating the basal rate of atresia in the ovary, however, the exact mechanism is unknown. Concurrent VCD and 17β-estradiol (E_2) treatment protects rat primary follicles from VCD-induced toxicity. The pathway of this follicular rescue is unknown. Previously, repeated daily dosing with VCD was demonstrated by semi quantitative RT-PCR to increase mRNA encoding the cell death enhancer *bax* in rat small preantral follicles. In the present experiment, quantitative ribonuclease protection assay (RPA) was used to compare expression of mRNA encoding *bax* in rat and mouse small preantral follicles. F344 rats (28 days) were treated for 15 days with either vehicle control (sesame oil), VCD (80 mg/kg, i.p.), E_2 (0.1 mg/kg, s.c.), or VCD and E_2. Four hours after the final dose, ovaries were collected and small follicles were isolated. RNA was isolated from follicles less than 100μ (target population for VCD), hybridized to ^{32}P labeled *bax* and *18s* probes overnight, visualized by PAGE, and quantified. Compared with controls, the ratios of mRNA for *bax* were similar across treatments (expressed as treatment/control ratios; 2.27, VCD; 2.20, E_2; 2.08, VCD plus E_2). Although, all treatments increased expression of *bax*, it is yet to be determined whether VCD- and E_2-associated pathways converge. $B6C3F_1$ mice (28 days) were treated daily for 15 days with either vehicle control or VCD (80 mg/kg, i.p.). Unlike rats, in mice, there was no difference in *bax* mRNA levels in mouse small preantral follicles between treated and control animals (VCD/control=0.97). This supports that VCD may destroy small preantral follicles by different mechanisms in rats and mice. (ADCRC 9809, NIEHS Center Grant 06694, ES09246, ES08979.)

1709 MONO-(2-ETHYLHEXYL) PHTHALATE (MEHP)-INDUCED GERM CELL APOPTOSIS PRECEDES ITS DETACHMENT FROM SERTOLI CELLS.

H. Gao and J. H. Richburg. *College of Pharmacy, University of Texas, Austin, TX.*

Germ cell apoptosis occurs as a mechanism to limit the number of germ cells in the seminiferous epithelium. It has been proposed that Sertoli cells regulate germ cell apoptosis. Exposure of mice to the Sertoli cell toxicant MEHP results in a detachment of germ cells from the seminiferous epithelium and increases the numbers of apoptotic germ cells. The Fas receptor (Fas)/Fas ligand (FasL) signaling system has recently been demonstrated to be a key regulator of germ cell apoptosis. To investigate the relationship between germ cell detachment and apoptosis, we used Sertoli cell-germ cell co-cultures prepared from gld mice that express a dysfunctional form of FasL. Addition of MEHP (200 μM) to co-cultures prepared from wild-type (C57/b16) mice led to a progressive increase (at 6 & 12 h) in the numbers of detached germ cells. However, in co-cultures from gld mice, only a marginal increase in detached germ cells was observed at 6h after MEHP treatment, and no further increase was observed after 12h,. Caspase-8 and caspase-3 are Fas downstream signal effectors that participate in the early phases of apoptosis. Processing of the pro-forms of caspases to the active form is revealed by western blot analysis. An early (3 h) increase in the processing of caspase-8 and caspase-3 was observed in testis homogenates from 28-day-old rats exposed to a single oral dose of MEHP (2 g/kg). This corresponds to a time that precedes the morphological observation of germ cell detachment. Taken together, these observations indicate that the initiation of germ cell apoptosis precedes germ cell detachment and that the primary toxic mechanism of MEHP is not likely at the germ cell-Sertoli cell adhesion complex. (Supported by NIEHS grants ES09145 & ES07784.)

1710 DOES CIGARETTE SMOKE AFFECT MYOMETRIAL ACTIVITY DURING ESTRUS AND EARLY PREGNANCY *IN VIVO*?

M. M. Rubio. *University of California, Riverside, CA.* Sponsor: J. T. Arey.

To determine if cigarette smoke interferes with normal myometrial activity, we developed an experimental technique that employs video laparoscopy to monitor the changes in myometrial activity in nonpregnant and pregnant hamster *in vivo*. Using video laparoscopy, we are able to record myometrial activity before, during, and after a single 40-minute smoke exposure. Analysis of the videotape data revealed that during the cigarette smoke exposure period

(for both mainstream and sidestream smoke), the number of unidirectional peristaltic and longitudinal contractions decreased in estrus females and day 4 pregnant females. These inhalation experiments were followed up by additional *in vivo* experiments to determine if nicotine, a major component of cigarette smoke, was responsible for decreasing in the number of contractions seen during smoking. In the first follow-up experiment, nicotine was applied topically to the uterine horns. The nicotine solution concentrations ranged from 10 nM to 10 mM. Even at the highest concentration nicotine had no effect on the myometrial activity, suggesting that nicotine cannot exert an effect directly on the uterine horns. The next experiment delivered nicotine tartrate solution directly into the heart then throughout the body. Within 15-20 minutes after being injected directly into the bloodstream it caused a transient decrease in unidirectional peristaltic contractions in these nonpregnant females. T-tests comparing total number of unidirectional peristaltic contractions/5-minute intervals during the control and after the injection showed that the 40-45 minute and the 45-50 minute intervals were significantly different from the control intervals. A decrease or inhibition of uterine smooth muscle contractions could slow blastocyst movement in the uterus. If the blastocyst transport rate is delayed, then sites may be crowded, as seen previously in hamsters exposed to smoke. When taken together, these data could explain why women who smoke have decreased rates of fecundity.

1711 COMPARATIVE STUDY IN LABORATORY RATS TO VALIDATE SPERM QUALITY METHODS AND ENDPOINTS.

W. A. Price[1], G. B. Briggs[1], W. K. Alexander[2], K. R. Still[2] and K. A. Grasman[3]. [1]*GEO-Centers Inc., NHRC/TD, Wright-Patterson Air Force Base, OH,* [2]*NHRC/TD, Wright Patterson Air Force Base, OH and* [3]*Wright State University, Department of Biological Sciences, Dayton, OH.* Sponsor: R. L. Carpenter.

The Naval Health Research Center, Detachment (Toxicology) performs toxicity studies in laboratory animals to characterize the risk of exposure to chemicals of Navy interest. Research was conducted at the Toxicology Detachment at WPAFB, OH in collaboration with Wright State University, Department of Biological Sciences for the validation of new bioassay methods for evaluating reproductive toxicity. The Hamilton Thorne sperm analyzer was used to evaluate sperm damage produced by exposure to a known testicular toxic agent, methoxyacetic acid and by inhalation exposure to JP-8 and JP-5 in laboratory rats. Sperm quality parameters were evaluated (sperm concentration, motility, and morphology) to provide evidence of sperm damage. The Hamilton Thorne sperm analyzer utilizes a DNA specific fluorescent stain (similar to flow cytometry) and digitized optical computer analysis to detect sperm cell damage. The computer assisted sperm analysis (CASA) is a more rapid, robust, predictive and sensitive method for characterizing reproductive toxicity. The results presented in this poster report validation information showing exposure to methoxyacetic acid causes reproductive toxicity and inhalation exposure to JP-8 and JP-5 had no significant effects. The CASA method detects early changes that result in reproductive deficits and these data will be used in a continuing program to characterize the toxicity of chemicals, and combinations of chemicals, of military interest to formulate permissible exposure limits.

1712 A SINGLE HEAT SHOCK OF JUVENILE MALE MICE CAUSES A LONG-TERM DECREASE IN FERTILITY AND REDUCES EMBRYO QUALITY.

J. C. Rockett, J. B. Garges and D. J. Dix. *USEPA, Research Triangle Park, NC.* Sponsor: G. R. Klinefelter.

Testicular hyperthermia adversely affects spermatogenesis in a wide range of mammalian species. Indeed, mild testicular heating has been reported as a possible safe, effective and reversible contraceptive method for men. In adult mice, a single acute heat shock has been shown to reduce fertility for about 1 spermatogenic cycle. Scrotal heating of adult sires has also been shown to have direct effects on embryo growth in untreated female mice. However, there have been no reported studies examining the effects on fertility of testicular heating in juveniles. We examined the long-term reproductive consequences of a single, acute heat shock on juvenile male C57BL/6 mice. Heat shocks were given at 7, 14, 21, 28, 42 or 56 days after birth. The animals were sedated with ketamine and the posterior half of their body submerged in a 43°C waterbath for 20 min. The males were mated at 14 weeks of age. The dams were sacrificed at gestation day 14.5, and litters assessed for number and weights of embryos, resorptions and terata. Juvenile male mice exposed to a single heat shock at 14 days postnatal (dpn) have a long-term reduction in fertility as indicated by the total number of litters and embryos sired per male. Although the incidence was not significant, we also observed more terata in progeny of the heat-shocked males (3/14 litters contained one embryo with anophthalmia) than the control males (1/11 litters contained one embryo with microphthalmia). There was also a significant reduction in the weights of embryos sired by the heat shocked males compared to the controls. Similar results were not obtained from males exposed at time points other than 14dpn. Overall, these observations suggest that the developing testis has a window of susceptibility to heat shock in terms of long-term adverse effects on fertility, and that male-mediated developmental toxicity may be initiated by the heat-shock event. The 14dpn susceptibility window we have found in this juvenile model may provide a useful starting point for investigating the effects of environmental toxicants on spermatogenesis and the developing testis. (This is an abstract for a proposed presentation and does not necessarily reflect EPA policy.)

1713 ANTIANDROGENIC EFFECTS OF DI(2-ETHYLHEXYL) PHTHALATE (DEHP) ON MALE REPRODUCTIVE AND SEXUALLY DIMORPHIC CNS DEVELOPMENT IN RATS.

R. W. Moore, T. A. Rudy, T. M. Lin, K. Ko and R. E. Peterson. *University of Wisconsin, Madison, WI.*

Research was conducted to determine effects of *in utero* and lactational DEHP exposure on male reproductive and sexually dimorphic CNS development. Sprague-Dawley rats were dosed with corn oil or DEHP (0, 375, 750, or 1500 mg/kg/day, po) from Gestation Day 3 through Postnatal Day (PND) 21. Dose-related effects on male offspring include reduced ano-genital distance, nipple retention, undescended testes, and delayed or incomplete preputial separation. Dose-related reductions in testis, epididymis, seminal vesicle, ventral prostate, anterior prostate, dorsolateral prostate, and glans penis weights were observed at PND 21, 63, and/or 105-112. Additional effects include unilateral or bilateral absence of the anterior prostate and seminal vesicles, partial or complete absence of the ventral prostate, dorsolateral prostate agenesis, testicular and epididymal malformations, and cleft phallus. No abnormalities were found in any of 8 control litters, but DEHP caused reproductive toxicity in 5 of 8 litters at 375 mg/kg/day, 8 of 8 litters at 750 mg/kg/day, and 5 of 5 litters at 1500 mg/kg/day. Masculine sexual behaviors were also examined. Seven of 8 control males displayed typical behaviors and ejaculated within the 45-min observation period (ejaculatory latencies averaged 14 min). In contrast, 3 of 7 low dose males never mounted, intromitted, or ejaculated; all 7 males at the middle dose mounted but 3 never intromitted and 4 didn't ejaculate; and neither rat at the high dose mounted, intromitted, or ejaculated. These results strongly suggest that sexual differentiation of the CNS was incomplete. In summary, *in utero* and lactational DEHP exposure profoundly alters male reproductive system development and appears to alter sexually dimorphic CNS development in rats. The LOAEL was the lowest dose tested (375 mg/kg/day), which prevented testis descent, reduced weights of several sex organs, caused permanent nipple retention, and demasculinized sexual behaviors. The pattern of effects demonstrates that DEHP (and/or its metabolites) is an antiandrogen. (Supported by NIH Grant ES06806.)

1714 *PARA*-NONYLPHENOL (NP) ADMINISTERED TO CD RATS IN A SOY- AND ALFALFA-FREE DIET AFFECTS TESTES AND FEMINIZES LIVER METABOLIC PATTERNS IN 50-DAY-OLD PUPS.

C. C. Weis[1], J. R. Latendresse[1], E. M. Laurenzana[1], R. R. Newbold[2] and K. B. Delclos[1]. [1]*NCTR, Jefferson, AR and* [2]*NIEHS, Research Triangle Park, NC.*

NP is widely used in the manufacture of nonionic surfactants, lubricant additives, polymer stabilizers, and antioxidants. The weak estrogenic activity of NP has led to much recent research on its toxicity, and we have evaluated NP in a dose range-finding study to determine the doses of NP to be further tested in a multigeneration study. NP was fed in the diet at 0, 5, 25, 200, 500, 1000 and 2000 ppm to F_0 dams beginning on gestation day 7. Exposure of the F_1 pups continued via the dams milk until postnatal day (PND) 21 and then by feed until sacrifice on PND 50 (n=5 litters with 4 pups of each sex per litter). We previously reported the severe polycystic kidney disease and weight loss observed in both sexes of the 2000 ppm dose group (Latendresse *et al.*, Toxicologist **48**: 321, 1999). No other significant effects were observed in females of the lower dose groups. In the testes, retention of elongated spermatids was observed in both control and dosed groups, but the degree of retention appeared higher in the 25 ppm dose group and above. Depletion of elongated spermatids was observed only in dosed groups, with an apparent increase in severity at 500 ppm and above. In addition to the lesions noted above, cytoplasmic vacuolization of interstitial cells, an increase in severity of degeneration of pachytene and prepachytene spermatocytes, and minimal to

mild depletion of round spermatids were observed in testes from the 2000 ppm animals. The severe kidney toxicity and body weight loss seen at that dose make it unclear as to whether observed effects are primary or secondary. Hepatic microsomes from the 25, 500, and 2,000 ppm dose groups were also assayed for testosterone metabolism. No significant effects were observed in females. In males, a decreasing dose trend in formation of androstenedione and decreased formation of 2α- and 16α-hydroxytestosterone at 2000 ppm were observed. In addition, significant, dose-dependent increases in the formation of dihydrotestosterone (DHT) and DHT diols were observed, and 7α-hydroxytestosterone production was increased at 25 and 500 ppm. These effects suggest a feminization of hepatic metabolism by NP as well as effects on spermatogenesis at doses that are not overtly toxic.

1715 FUNCTIONAL STUDIES TO INVESTIGATE DYSTOCIA AND STILLBIRTHS OBSERVED DURING A REPRODUCTIVE BIOASSAY WITH AN EXPERIMENTAL CYANAMIDE (YRC 2894).

D. A. Eigenberg[1], A. B. Astroff[1], R. E. Garfield[2], O. D. Sherwood[3], G. K. Sangha[1] and J. H. Thyssen[1]. [1]*Bayer Corporation, Stilwell, KS,* [2]*University of Texas Medical Branch, Galveston, TX and* [3]*University of Illinois, Urbana, IL.*

During the conduct of a two-generation reproductive toxicity study with [3-[(6–chloro-3-pyridinyl]methyl]-2-thiazolidinylidene]-cyanamide (YRC 2894) an increase in stillbirths and evidence of dystocia were observed. In order to investigate the potential mechanisms by which YRC 2894 may have interfered with parturition a modified one-generation study was conducted. In this study male and female SD rats were continuously exposed to dietary levels of 0 or 1000 ppm YRC 2894 during premating, mating, and gestation phases. Specific functional and morphologic changes in the uterus and cervix were examined during the third week of pregnancy and also at parturition. Cervical evaluations included morphology (collagen content and organization), gross weight and water content, and extensibility. Uterine examinations included electrical activity (EMG), mechanical activity (intrauterine pressure), evaluated *in vivo*; uterine contraction, evaluated *in vitro*; and morphologic changes (histology and gross weight). Additionally, the potential effect of YRC 2894 on tissue innervation was investigated via enumeration of uterine alpha-adrenergic receptors. As determined following these studies, YRC 2894 did not affect the functional capabilities of the cervix or uterus, nor did it affect the uterine alpha adrenergic receptor population. Based on these results, the original observation of dystocia is not explained by YRC 2894 affecting the functional aspects of parturition.

1716 DISRUPTION OF OVARIAN CYCLES BY CHLOROTRIAZINES AND THEIR METABOLITES IN THE RAT.

R. L. Cooper, W. K. McElroy and T. E. Stoker. *USEPA, Research Triangle Park, NC.* Sponsor: R. J. Kavlock.

Previously, we reported that the chlorotriazine (CZ) herbicide atrazine (ATZ) disrupts the ovarian cycles in rats [i.e., induces repetitive pseudopregnancies (RPP) or prolonged diestrus (di)]. In the present study we examined the effect of ATZ, simazine (SIM) and cyanazine (Cy), as well as three CZ metabolites [2-amino-4-chloro-6-isopropylamino-S-triazine (IS), 2-amino-4-chloro-6-ethylamino-S-triazine (EA) and diaminochlorotriazine (DACT)]. Regularly cycling, 90-day old female Long-Evans hooded rats were gavaged with 75, 150 and 300 m/kg ATZ, SIM, IS, EA, or DACT or 18.8, 37.5 and 75 mg/kg CY for 21 days. Vaginal smears were monitored during treatment and for the ensuing 21 days. A dose-dependent disruption of ovarian cycles (i.e., RPP or di) was observed for all three parent compounds (ATZ, SIM & CY) and all doses altered cycling. IS, EA, and DACT also disrupted cycling at each dose tested in a dose-dependent manner. Compared to ATR and SIM, ovarian cycles were disrupted in a greater number of animals receiving the same dose of IS, EA and DACT. These data demonstrate that the CZ and their metabolites share a common endocrine disrupting ability. Such information should provide insight into the CZ structure responsible for the disruption of ovarian function. (This abstract does not reflect U.S. EPA policy.)

1717 THE EFFECT OF ATRAZINE (ATR) ON PUBERTY IN MALE WISTAR RATS.

T. E. Stoker, D. L. Guidici, W. K. McElroy, S. C. Laws and R. L. Cooper. *NHEERL USEPA, Research Triangle Park, NC.* Sponsor: R. J. Kavlock.

The chlorotriazine herbicide ATR is known to suppress serum prolactin (PRL) and luteinizing hormone and alter neurotransmitter concentration in female rats. Because puberty in mammalian species is a period of rapid interactive endocrine and morphological changes, we hypothesized that exposure of male rats to ATR may interfere with several of the endpoints described in the Endocrine Disrupters Screening and Testing advisory Committee prepubertal assay including preputial separation (PPS), body weight, testes, seminal vesicle, prostate and epididymal weights, serum testosterone (T), thyroxin (T4) and thyroid stimulating hormone (TSH). ATR (0, 50, 100 or 200 mg/kg) was administered by gavage to male rats from postnatal day (PND) 23 to 53. PPS was significantly delayed by all ATR doses. On PND 53 males were killed by decapitation. ATR (200 mg/kg) decreased ventral and lateral prostate weight but testes weight was not altered. ATR (200 mg/kg) significantly decreased serum T, while serum estradiol was significantly increased at this dose. Serum T3 and T4 were unaltered at any dose. As ATR suppresses serum PRL and LH in the adult rats, these data would indicate that puberty is delayed in the male rat by altering hypothalamic-pituitary maturation, although a direct effect on the testes can not be ruled out at this time. (This abstract does not reflect EPA policy.)

1718 THE EFFECT OF ATRAZINE ON PUBERTY IN FEMALE WISTAR RATS.

S. C. Laws, J. M. Ferrell, T. E. Stoker and R. L. Cooper. *Endocrinology Branch, USEPA, Research Triangle Park, NC.* Sponsor: R. J. Kavlock.

Atrazine (ATR), a chlorotriazine herbicide, has been shown to decrease serum LH and prolactin in adult female rats. In this study, the effect of ATR on the onset of puberty was evaluated using the 20-day Pubertal Female Protocol recommended by Endocrine Disupters Screening and Testing Advisory Committee. Female Wistar rats were dosed from postnatal days (PND) 22-41 with ATR (0, 50, 100, 200 mg/kg). Vaginal opening (VO) was significantly delayed 3 or 4 days in rats dosed with 50 or 100 mg/kg ATR. VO did not occur in 9 of 16 rats at 200 mg/kg ATR during the 20-day dosing period. Body weight gain during the 20-day dosing period was unaltered at 50 and 100 mg/kg ATR, but was reduced by 8.5% in the 200 mg/kg group. Half the animals in each treatment group were killed on PND 41 and tissue weights (e.g., liver, kidney, adrenal, ovaries, uterus, pituitary) and serum were collected. Uterine weights (no fluid) were significantly reduced in the 100 and 200 mg/kg groups. Kidney and pituitary weights were also significantly reduced in the 200 mg/kg group. Estrous cyclicity was evaluated in the remaining rats from VO until 30 days after treatment was terminated. Irregular cycles were observed in ATR (50 and 100mg/kg) rats between VO and PND 41. However, ATR did not alter the number of regular cycles during the ensuing 30 days. Of the 8 rats in the 200 mg/kg group, VO occurred in only 3 rats by PND 41. However, once treatment was terminated, VO occurred in the remaining 5 rats within 3 days (PND 44). The estrous cycles of the rats in the 200 mg/kg group were initially irregular, but were similar to controls by the end of the 30 day post treatment period. In summary, these data demonstrate that atrazine can modify the onset of puberty in the female rat. (This abstract does not reflect U.S. EPA policy.)

1719 METALLOTHIONEIN ISOFORM 1 AND 2 GENE EXPRESSION IN THE HUMAN PROSTATE: DOWN REGULATION OF MT-1X IN ADVANCED PROSTATE CANCER.

S. Somgi, S. H. Garrett, M. A. Sens, D. Shukla, L. Flores, J. H. Todd and D. A. Sens. *Department of Pathology, West Virginia University, Morgantown, WV.*

Metallothionein (MT) over expression has been associated with a wide variety of human tumors. However, a family of genes underlies the expression of these proteins. The goals of this study were to define the expression of MT genes and protein in normal prostate tissue and to provide evidence that expression of the MT isoforms is altered in prostate cancer. Immunohistochemistry was used to localize MT protein, RT-PCR to determine MT isoform-specific mRNAs, and immuno-blot analysis to determine MT protein levels in fresh and archival biopsy specimens. The localization of MT in the prostate was defined using E9 antibody. This antibody determines the co-expression of MT-1 and MT-2 proteins. Immunohistochemical analy-

sis demonstrated that MT protein was expressed in the normal prostate and this was supported by mRNA from the MT-1A, MT-1E, MT-1X and MT-2A genes. In advanced prostate cancer, MT protein was over expressed. MT-2A was expressed in all cases of advanced prostate cancer, whereas MT-1A and MT-1E expression were present in some, but not all cases of prostate cancer. No expression of the MT-1X gene was demonstrated in any of the cases of advanced prostate cancer. The expression of MT-1 and MT-2 isoform-specific mRNA varied among three commonly utilized prostate cancer cell lines providing further evidence that MT gene expression may be altered among individual prostate cancers.

1720 METALLOTHIONEIN ISOFORM 3 EXPRESSION IN THE HUMAN PROSTATE AND CANCER-DERIVED CELL LINES.

S. H. Garrett, M. A. Sens, D. Shukla, S. Nestor, S. Somji, J. H. Todd and D. A. Sens. *Department of Pathology, West Virginia University, Morgantown, WV.*

Expression of metallothionein isoform 3 (MT-3) was initially reported to be confined to neural tissues. However, it was recently demonstrated that MT-3 is expressed in epithelial cells of human kidney. This motivated the current examination of MT-3 expression in human prostate. Selected epithelial and stromal cells of normal human prostate were shown to have low levels of MT-3 expression based on immunohistochemical localization using an MT-3 specific antibody. This protein was increased in prostatic intraepithelial neoplasia (PIN) lesions and further increased in a highly variable fashion in prostatic adenocarcinoma. Expression was also measured in cultures of three commonly utilized human prostate tumor cell lines, DU-145, LNCaP, and PC-3, using RT-PCR with MT-3 specific primers. MT-3 was detected in DU-145 and LNCaP cells at 35 cycles of cDNA amplification; however, for the PC-3 line, the level of expression was below the detection limit (40 cycles). Expression of the house keeping gene, glyceraldehyde 3-phosphate dehydrogenase (G3PDH) was detected in all three cell lines at 30 cycles. MT-3 mRNA was also detected in RNA isolated from normal prostate tissues using this technique. Authenticity of the MT-3 RT-PCR product from normal tissues and tumor cell lines was verified by FokI restriction enzyme analysis. These results show that MT-3 is expressed in the human prostate and indicate a possible dysregulation of its expression in prostate cancer.

1721 DIBROMOACETIC ACID (DBA)-INDUCED EFFECTS ON ESTROUS CYCLICITY AND FOLLICULAR STEROID SECRETION IN THE RAT.

J. M. Goldman[1], S. K. Balchak[2], J. M. Hedge[1], A. E. Shearin[1] and L. Mole[1]. [1]*U.S. Environmental Protection Agency, Research Triangle Park, NC and* [2]*University of North Carolina, Research Triangle Park, NC.* Sponsor: G. R. Klinefelter.

Chlorination of public water supplies generates a large number of treatment-related chemicals. A number of these disinfection by-products (DBPs) are reported to have adverse reproductive effects in rodent test populations. The haloacetic acid DBA has been found to alter testosterone levels in male rats and affect sperm quantity and quality. Since there are limited data in the female rat, the present study investigated the influence of DBA on estrous cyclicity and the effects of *in vitro* exposures on ovarian follicular steroid secretion. In exp. 1, DBA (0,10,30,90 or 270 mg/kg, in distilled H2O adj. to pH 6.5) was administered daily by gavage for 14d to regularly cycling Sprague-Dawley rats. Vaginal cytology was monitored for 6 wks over the pre-dosing, dosing, and post-dosing periods (2 wks each). Cyclicity was significantly affected at the 2 highest doses, with periods of persistent estrus most evident in the 270 mg/kg group during dosing/ post-dosing segments. At this dose, plasma concentrations (measured by capillary GC) averaged 130 μg/ml at a 1hr peak (T1/2=1.05 hr.). Values over a 5 hr period were used to select a concentration for Exp. 2. Immature females were given 10IU PMSG on d26 and killed 2d later. Preovulatory follicles from 8-10 rats were separated out and paired in teflon vials containing oxygenated Medium 199 (M199, pH 7.4) with 0.1% BSA, 10 mM HEPES and 50 μg/ml gentamicin sulfate. Follicles were exposed to 1 of 4 conditions: M199 only, DBA (50 μg/ml), hCG (100 IU), or DBA+hCG. Aliquots taken at 4, 8, 12 & 24 hrs were assayed for estradiol (E) and progesterone (P). Data showed that in non-stimulated follicles, DBA significantly elevated E secretion, while P release was unaffected. In contrast, DBA completely inhibited the hCG-stimulated increase in P, with no effect upon the hCG-induced rise in E. Results indicated that follicular steroid secretion could be altered by DBA exposure, although the effect was differentially influenced by hCG stimulation. Such alterations may also have had an impact on estrous cyclicity.

1722 TWO-GENERATION ORAL (DRINKING WATER) REPRODUCTIVE TOXICITY STUDY OF PHENOL IN RATS.

B. M. Ryan[1], R. Selby[1], R. Gingell[2], J. M. Waechter[3], J. H. Butala[4], S. S. Dimond[5] and B. J. Dunn[6]. [1]*IIT Research Institute, Chicago, IL,* [2]*Shell Chemical Co., Houston, TX,* [3]*The Dow Chemical Co., Midland, MI,* [4]*Consultant to Aristech, Pittsburgh, PA,* [5]*General Electric Company, Pittsfield, MA and* [6]*AlliedSignal, Morristown, NJ.*

This study was designed to assess the potential reproductive toxicity of Phenol in rats. Phenol was administered to 30 Sprague-Dawley rats/sex/group in the drinking water at concentrations of 0, 200, 1000 or 5000 ppm. Parental (P_1) animals were treated for 10 weeks prior to mating, during mating, gestation, lactation, and until sacrifice. The F_1 generation (P_1 offspring) was treated using a similar regimen, while the F_2 generation was not treated. After mating, 10 P_1 males/group were evaluated using standard clinical pathology parameters and an immunotoxicity screening plaque assay. No evidence of immunotoxicity, and only a minimal increase in BUN, were noted in the 5000 ppm group. Significant reductions in water and food consumption were observed in the 5000 ppm group in both generations; corollary reductions in body weights/body weight gain were also observed. Mating performance and fertility in both generations were similar to controls, and no adverse effects on vaginal cytology or male reproductive function were observed. Vaginal opening and preputial separation were delayed in the 5000 ppm group, and were considered to be secondary to the reduction in F_1 body weight. Litter survival of both generations was reduced in the 5000 ppm group. Absolute uterus and prostate weights were decreased in the F_1 generation at all dose levels; however, no underlying pathology was observed and there was no functional deficit in reproductive performance, therefore these findings were not considered to be adverse. Most of the adverse effects noted were presumed to be associated with flavor aversion to Phenol in the drinking water. Based on a comprehensive examination of all of the parameters, the no-observed-adverse-effect level (NOAEL) for reproductive toxicity of phenol administered in drinking water to rats is 1000-ppm. (This study was sponsored by the Chemical Manufacturers Association Phenol Panel.)

1723 DEVELOPMENTAL REPRODUCTIVE EFFECTS OF A MIXTURE OF DIOXINS, FURANS AND CO-PLANAR PCBS ON LONG EVANS RATS.

J. T. Hamm and L. S. Birnbaum. *USEPA/University North Carolina-Chapel Hill, Research Triangle Park, NC.*

TCDD causes a spectrum of adverse biological responses including alterations in reproductive development. However, within the environment and within animal tissues, TCDD is found as part of a complex mixture of dioxins and dioxin-like compounds. Therefore, the effect of a mixture of dioxins, furans and co-planar PCBs on reproductive development was examined. This mixture was based upon the relative mass ratio of the compounds as they are found in foodstuff and doses were calculated using the Toxic Equivalency Factor (TEF) scheme. Single oral doses of 0, 0.05, 0.2, 0.8 and 1.0 μg/kg toxic equivalency were administered on gestation day 15 (GD15). As with TCDD, our mixture delayed the time to puberty, from 39.8±0.3 to 41.9±0.5 in the male and from 31.3±0.2 to 33.7±1.1 in the female at the high dose. In contrast, the weights of the reproductive tract tissues were not affected at PND49 or 63. However, PND32 is a more sensitive time point for effects on the seminal vesicle and at this time tissue weight was decreased in a dose response fashion, from 40.4mg in controls to 26.4mg at the high dose. Comparison of ethoxyresorufin-*O*-deethylase (EROD) induction between the mixture and TCDD alone revealed relatively higher levels of induction during gestation but lower postnatal induction. Since effects on reproductive development may occur pre- or postnatally, results with EROD may help to explain the variable degree of responsiveness to the mixture observed between endpoints. (This abstract does not necessarily represent USEPA policy. JTH, EPA, CT 902908.)

1724 A SIMPLE TECHNIQUE FOR DETERMINING FAILURE OF FERTILISATION IN THE RAT.

L. M. Burns and F. W. Ross. *Quintiles, Ledbury, United Kingdom.* Sponsor: A. K. Palmer.

In the commonly used design of reproduction studies, assessment of whether a reduction in the numbers of implantations results from a failure in fertilisation or early death of the embryos is impossible. We report here on the successful use of a simple technique to identify if fertilisation has taken place. In a recent male fertility study reduced numbers of implantations were observed

in untreated females mated with males dosed for 10 weeks but pregnancy rate was unaffected. In the males the incidence of morphological sperm abnormalities was increased and cauda epididymis weights were reduced. There were no effects on homogenisation resistant spermatid counts nor were there any histopathological findings. From these results it was impossible to establish whether the reductions in implantations were due to failure of fertilisation or early post-fertilisation mortality and an additional study was designed to provide clarification. Males were mated 1:1 with untreated females to provide baseline assessments of fertility. On Day 4.5 after mating the females were killed and the ova were flushed from the uterus and examined for fertilisation and subsequent degree of development. Males shown to be fertile were selected to provide a group of 20 and were dosed at a level known to induce effects before being mated 1:1 with a second group of untreated females. Ova were again flushed from the uterine horns on Day 4.5 after mating and examined for fertilisation and degree of development. Results clearly indicated that the reduced numbers of implantations were a result of failure of fertilisation.

1725 EVALUATION OF A SOY- AND ALFALFA-FREE DIET FOR USE IN STUDIES OF ENDOCRINE-ACTIVE COMPOUNDS.

K. B. Delclos[1], D. R. Doerge[1], C. L. Holder[1], M. I. Churchwell[1], H. C. Chang[1], B. Blaydes[1], A. Dalu[1], C. C. Weis[1], J. R. Latendresse[1] and R. R. Newbold[2]. [1]*NCTR, Jefferson, AR and* [2]*NIEHS, Research Triangle Park, NC.*

Standard laboratory rodent chows contain hormonally active agents, including the isoflavones genistein and daidzein, that could modulate responses to agents under test for endocrine activities. In a series of studies of endocrine active agents, we are utilizing a soy- and alfalfa-free irradiated diet (Purina 5K96) that is formulated to be similar to NIH-31 and contains a low percentage of casein (<3%). Diet analysis indicated that NIH-31 contained approximately 24 ppm genistein and 22 ppm daidzein whereas these compounds were present at approximately 0.5 ppm each in 5K96. 50 CD rats of each sex were removed from NIH-31 pellets at weaning and placed on either NIH-31 or 5K96 meal (25 animals of each sex per diet). Body weight and food consumption data were collected for 6 months; males and females were bred at 10-12 weeks and data on the litters collected. 24 F_1 male pups were maintained on the same diet as their parents until PND 63 for evaluation of kidneys, mammary glands, and thyroid peroxidase (TPO). These endpoints were selected since diet composition could significantly alter kidney function, and stimulation of male mammary gland and inactivation of TPO had been previously observed at doses of genistein similar to those present in NIH-31. For the F_0 animals, food consumption was significantly lower in both sexes in the 5K96 groups throughout the experiment. Only the males in the 5K96 group showed a significantly lower body weight than NIH-31 males, with the difference first evident at about 11 weeks of age. No differences in fertility or litter parameters were observed between the two groups. Serum genistein and daidzein levels at sacrifice were 0.35-0.62 μM and 0.20-0.25 μM, respectively, in NIH-31-fed animals, with females slightly higher than males. In contrast, serum levels in animals fed 5K96 were <0.02 μM for both isoflavones. TPO activities were significantly lower in F_0 and F_1 NIH-31 animals, while thyroid hormones and TSH were unchanged or slightly elevated. Other endpoints remain to be evaluated, but the data above suggest that 1) 5K96 is a suitable diet for reproductive toxicity studies and 2) isoflavones in rodent chows are bioavailable and may affect responses to other endocrine active test agents.

1726 ONE GENERATION INHALATION REPRODUCTIVE TOXICITY STUDY OF HEXAMETHYLDISILOXANE (HMDS) IN RATS.

W. H. Siddiqui[1], D. G. Stump[2], V. L. Reynolds[1], D. T. Kirkpatrick[2], J. F. Holson[2] and R. G. Meeks[1]. [1]*Dow Corning Corporation, Midland, MI and* [2]*WIL Research Laboratories, Ashland, OH.*

This study was conducted to evaluate the potential adverse effects of whole body vapor inhalation exposure of F0 parents and F1 offsprings to HMDS. Groups of male and female Sprague-Dawley rats (24/sex) were exposed to either 0, 100, 1,000 or 5,000 ppm HMDS for 6 hours/day for at least 28 days prior to mating, during mating, and through gestation day (GD) 20. Exposure was suspended from GD 21 through postnatal day (PND) 4 and resumed on PND 5 until weaning. Clinical observations, body weights and food consumption were recorded at appropriate intervals. All F0 dams were allowed to deliver and rear their pups to weaning; were necropsied on PND 21; selected organs weighed and designated tissues from the control and 5,000 ppm groups examined microscopically. Spermatogenic evaluations were performed on all F0 males. F1 offsprings (60/sex/group) were selected for HMDS exposure from PND 22 to PND 27, necropsied on PND 28 and selected organs were weighed. All F0 animals survived to the scheduled necropsy. A slight reduction in body weight gains was observed in the 5,000 ppm group males and females during the first 3 weeks of the study. No other exposure-related findings were noted for any of the F0 endpoints evaluated. F1 pup survival in the 5,000 ppm group was slightly, but not statistically significantly decreased from birth to PND 4 when compared to controls. No exposure-related findings were noted for any of the other F1 endpoints evaluated. (Supported in part by the Silicone Environmental Health and Safety Council.)

1727 FERTILITY, DEVELOPMENTAL AND REPRODUCTIVE EFFECTS OF SUBCUTANEOUS ADMINISTRATION OF LEPTIN IN MICE.

J. Nokleby[1], M. Nemec[2], W. Davis[1], C. LeBel[1] and H. Davis[1]. [1]*Amgen Inc., Thousand Oaks, CA and* [2]*WIL Research Laboratories, Ashland, OH.*

Leptin is a protein hormone, produced by adipose tissue, involved in the regulation of body fat. Recombinant leptin administered to normal animals results in rapid loss of body weight primarily due to body fat reduction. These studies were conducted in mice to evaluate the fertility, developmental and reproductive toxicity of leptin. To assess the fertility and early embryonic development doses of 1, 10, and 30 mg/kg/day were administered to male mice 28 days prior to mating until sacrifice and to female mice 14 days prior to mating until Gestation Day (GD) 6. Equivalent doses were given to female mice GD 6 through 15 to evaluate embryo-fetal development. To assess the pre- and postnatal development, including maternal function 3, 10, and 30 mg/kg/day were administered to female mice on GD 6 through Lactation Day (LD) 21. Reproductive parameters and spermatogenic endpoints were unaffected by r-metHuLeptin administration. Mean body weights were reduced in a dose-related manner. Food consumption was reduced for males. Intrauterine growth and survival were unaffected by the test article and there were no treatment related fetal malformations or variations. Postnatal pup survival was reduced from birth to postnatal day (PND) 0, PND 0-1 and birth to PND 4. Mean body weights were reduced and developmental landmarks were delayed for the F_1 pups. Mean body weight for the F_1 adults were decreased. There were no adverse effects on F_1 reproductive performance or on the F_2 fetuses. The NOEL for reproductive and developmental toxicity was 30 mg/kg/day and the NOAEL for neonatal toxicity was less than 3 mg/kg/day.

1728 REPRODUCTIVE EFFECTS OF JP-8 JET FUEL ON MALE AND FEMALE SPRAGUE-DAWLEY RATS AFTER EXPOSURE BY GAVAGE.

D. Mattie[1], T. Sterner[2], B. Schimmel[1], T. Bausman[1], S. Young[1] and J. Cooper[1]. [1]*AFRL/HEST, Wright-Patterson AFB, OH and* [2]*Operational Technologies Corp, Dayton, OH.*

The jet engine fuel designated JP-8 is the standardized fuel for the U.S. military, which has resulted in exposure to both male and female personnel. Limited information is available on the reproductive effects of JP-8 jet fuel in humans and animals. In this report, data are presented from two reproductive studies. In the first study male rats were given 0, 750, 1500 or 3000 mg/kg neat JP-8 daily by gavage for 70 days prior to mating with naive females to assess fertility and semen parameters. After 70 days of dosing, body weights in the 3000 mg/kg group were over 30% lower than control weights. There were no significant changes for pregnancy rate, gestation length or semen parameters as compared to control values. In the second study female rats were dosed with neat JP-8 (0, 325, 750, 1500 mg/kg) daily by gavage for a total of 21 weeks (90-days plus mating with naïve males, gestation and lactation) in an effort to assess fertility and reproductive endpoints. There were no statistically significant changes from control values for gestation length, pregnancy rate, percent live pups at birth and numbers of pups per litter. Pregnancy rates were decreased among dose groups but not significantly or in a dose-dependent manner. There was a trend for decreased pup weight with increasing dose from postnatal days 4-21 with the 1500 mg/kg pups significantly lower in weight than controls at 21 days. Recovery occurred by 90 days. Based on the results of both studies, the no observable adverse effect level for JP-8 reproductive effects is 750 mg/kg with 1500 mg/kg as a lowest observable adverse effect level.

1729 REPRODUCTIVE EFFECTS OF AZIDOTHYMIDINE IN CD-1 MICE WHEN ASSESSED BY THE CONTINUOUS BREEDING PROTOCOL.

G. W. Wolfe, S. Borst, S. Pepperl, Y. Wang and R. E. Chapin. *TherImmune Research Corporation, Gaithersburg, MD.*

Azidothymidine (AZT) was evaluated for potential reproductive toxicity using the multigenerational Continuous Breeding protocol. With the increasing prophylactic use of AZT come concerns about the function of the offspring of treated parents. AZT was administered twice daily via oral gavage at dose levels of 0, 50, 100, and 200 mg/kg/day to adult male and female mice (N=20) during the F_0 generation only to test for effects of prenatal/lactational exposure on fertility, gestation, and development of the subsequent generation. F_1 animals were not dosed. Mating pairs were allowed to produce three litters (F_{1a}, F_{1b}, and F_{1c}). On PND 74±10, F_{1c} animals were assigned to mating pairs and allowed to produce three litters (F_{2a}, F_{2b}, and F_{2c}). Endpoints evaluated included body weight, food consumption, clinical signs, number and weight of pups, anogenital distance, sperm analysis, vaginal cytology, organ weights, and gross and microscopic pathology. In the F_0 generation, the Pregnancy Index in the high-dose was 65% and 60% for the 2nd and 3rd litters, respectively, compared to 100% in controls. Days to Litter was increased (4-11%) in all treated groups. There was a dose-related decrease (35-72%) in the Number of Pups/Litter in all treated litters from F_0 mice. In addition, there was a trend toward decreased Percent Males in all treated groups. F_0 sperm analysis revealed decreases in sperm motility, velocity, linearity, density and spermatid head counts at all dose levels. There were no differences in estrous cycles for the F_0 generation. In the F_1 matings, there were no effects on Pregnancy Index or Number of Pups/Litter, except for 23% fewer Pups/Litter in the F_{2c} litter at 200 mg/kg. Sperm and vaginal cytology for the F_1 generation were unchanged. Under conditions of this study, AZT had a significant reproductive effect at 50, 100, and 200 mg/kg/day in the F_0 generation when these mice were dosed, but had little reproductive effect in the F_1 generation when the F_1 pups were not dosed.

1730 EVALUATION OF DECAMETHYLCYCLOPENTASILOXANE (D5) IN A 2-GENERATION INHALATION REPRODUCTIVE TOXICITY STUDY IN RATS.

D. G. Stump[1], J. F. Holson[1], C. E. Ulrich[1], R. W. Mast[2] and V. L. Reynolds[3]. [1]*WIL Research Laboratories, Ashland, OH,* [2]*TPSRC, Inc., Midland, MI and* [3]*Dow Corning Corporation, Midland, MI.*

Sprague-Dawley rats (30/sex/group; 45 days old at study start) were exposed to Decamethylcyclopentasiloxane (D5) by whole-body vapor inhalation (30, 70, or 160 ppm) 6 hr/day for 70 consecutive days before mating. A concurrent control group (30/sex) was exposed to filtered air. Exposure continued during mating and gestation through Gestation Day (GD) 20. Maternal exposure was interrupted from GD 21 through Postnatal Day (PND) 4, resumed on PND 5, and continued until weaning on PND 21. Starting on PND 22, F1 weanlings were exposed to D5 for at least 70 consecutive days before mating and continuing through mating, gestation, and lactation as described for the F0 generation. The F2 pups were not directly exposed to D5. Clinical observations, body weights and feed consumption were recorded at appropriate intervals. Parental rats were necropsied after weaning. Unselected F1 and F2 weanlings were necropsied on PND 21 or 28. There were no effects in any generation on appearance, behavior, clinical signs, body weight, body weight gain, or feed consumption. Estrous cyclicity, time between pairing and mating, mating and fertility indices, duration of gestation, and parturition in the F0 and F1 were unaffected by D5 exposure. Litter size, sex ratio, pup weights and pup viability were also not affected. Anogenital distance, vaginal patency, and balanopreputial separation were unchanged. Spermatogenic endpoints and primordial follicle and corpora lutea counts were unchanged. There were no effects on organ weights. Other than minimal alveolar histiocytosis in all exposed groups, there were no noteworthy microscopic findings. The NOAEL (no-observed-adverse-effect level) for reproductive toxicity was equal to or greater than 160 ppm. (Supported in part by the Silicones Environmental, Health and Safety Council.)

1731 EFFECT OF MANGANESE ON REPRODUCTIVE PERFORMANCE OF SD RATS.

M. B. Iszard, K. A. Graves, K. Bailey, T. P. Ponnapakkam and G. A. Henry-Sam. *Xavier University, New Orleans, LA.*

Manganese (Mn) is a ubiquitous constituent in the environment occurring in air, water, and soil. While Mn is beneficial at low intake levels, inhalation or oral exposure to high levels can cause adverse effects. Effects of manganese acetate treatment on the reproductive performance of SD rats were evaluated. Male and female Sprague-Dawley rats were dosed by oral gavage with 76, 153, 306 and 1838 mgMn/kg for 63 days. At the end of the dosing period, one half the animals were sacrificed. Significant decreases in ovarian weights were observed in all treatment groups. This effect was more pronounced in rats treated with 153 mgMn/kg. Insignificant increases in testicular weight were observed. The second half of animals were sacrificed after two weeks following mating, during which time Mn was continuously administered. Control groups (0 mgMn/kg) had an 80% pregnancy rate whereas 25, 0 100 and 24% pregnancy rates for 76,153, 306 and 1838mgMn/kg, respectively were observed. Mean litter size were reduced in the treated groups compared to the controls. These results suggest that manganese administration adversely affected the fertility index of rats while the animals were orally dosed with manganese during the two week mating period.

1732 A SEGMENT I REPRODUCTION STUDY OF LY353381 HYDROCHLORIDE ADMINISTERED ORALLY TO MALE CD RATS.

V. Reddy, D. Seyler, J. Hoyt and D. Swisher. *Eli Lilly and Company, Greenfield, IN.*

LY353381 hydrochloride is a selective estrogen receptor modulator (SERM) which acts as a potent estrogen antagonist in uterine and mammary tissue while acting as an estrogen agonist to maintain bone density and lower serum cholesterol. The Segment I reproduction study was designed to evaluate the reproductive toxicity of LY353381 in adult male CD rats. LY353381 was administered by oral gavage in daily doses of 0, 0.3, 3, or 30 mg/kg to 20 male rats/group for 10 weeks prior to cohabitation, throughout cohabitation, and until termination. Males were cohabited with untreated females (1:1) for up to 2 weeks. Female rats were euthanized on Postmating Day 20 for assessment of reproductive parameters, and fetuses were collected for examination. Necropsies were conducted on the males after a total of 13 weeks of treatment. Epididymal and testicular sperm concentrations and epididymal sperm motion characteristics were evaluated. Testis and epididymis were collected, weighed, and preserved for histological examination. All rats survived until scheduled termination with no compound-related clinical signs of toxicity. Body weight (~20%), body weight gain (42% to 52%), and food consumption (9% to 31%) were decreased in a non-dose-responsive manner in males of all LY353381-treatment groups when compared to controls. The mating index was decreased for males of the 30-mg/kg group (6 of 20 failed to mate); however, there were no decreases in time to mating or the fertility index for males that mated. The decreased mating index at the 30-mg/kg group was likely an effect of LY353381 on libido. Epididymal sperm concentration parameters, epididymal sperm motion parameters, and spermatid numbers per testis were not adversely affected. In addition, there were no significant differences in absolute epididymal and testicular weights and no compound-related gross or microscopic changes in these tissues. Nineteen, 20, 18, and 12 females in the 0-, 0.3-, 3-, and 30-mg/kg groups, respectively, were pregnant. No important effects were seen in maternal reproductive parameters or in fetal viability, weight, gender, or external morphology. Based on upon the decreased mating index at 30-mg/kg, the no-observed-effect level for reproductive toxicity in male CD rats was 3 mg/kg.

1733 A PRELIMINARY STUDY ON THE REPRODUCTIVE CAPABILITY OF RATS TREATED WITH ZINC CHLORIDE.

A. T. Khan, A. Atkinson, T. C. Graham, M. Green, S. Ali, S. Thompson and S. Hussain. *College of Veterinary Medicine, Tuskegee University, Tuskegee, AL.* Sponsor: R. R. Dalvi.

The effects of zinc chloride (Zn) on the reproductive performance of Sprague-Dawley rats was evaluated. Both male and female rats (45-50 days old) were administered 0.0 (control), 7.50 (low), 15.0 (mid) and 30.0 (high) mg/kg/day of Zn via oral gavage for 77 days prior to mating. At the end of premating dosing, males and females were paired as follows: 0.0:0.0, 7.5:7.5, 15.0:15.0 and 30.0:30.0 mg/kg/day. Dosing was continued for both sexes throughout mating (21 days). All males were euthanized at the conclusion of mating. Dosing was continued in females throughout gestation (21 days) and lactation (21 days). Evaluation of reproductive performance included sex ratios, fertility index, viability index, weaning index, litter size, andbody weights of pups on days 0, 4, 7, 14, 21 of lactation. There was no effects on fertility, weaning indices and sex ratios. However, pup viability indices on days 0 and 4 at the high dose were significantly lower than the control. Also, the body weights of pups in high dose group on days 14 and 21 were significantly lower than the control. These results suggest that Zn produced mild effects on reproductive perfor-

mance of rats. (Supported by MHPF/ATSDR Cooperative Agreement # U50/ATU398948-07.)

1734 EVALUATION OF OCTAMETHYLCYCLOTETRASILOXANE (D4) IN A 2-GENERATION REPRODUCTIVE TOXICITY STUDY IN RATS.

D. G. Stump[1], J. F. Holson[1], D. T. Kirkpatrick[1], V. L. Reynolds[2], W. H. Siddiqui[2] and R. G. Meeks[2]. [1]*WIL Research Laboratories, Inc., Ashland, OH and* [2]*Dow Corning Corp., Midland, MI.*

Sprague-Dawley rats (30/sex/group) were exposed to 0, 70, 300, 500 or 700 ppm D4 vapor by whole-body inhalation 6 hr/day for at least 70 consecutive days prior to mating, during mating and gestation through gestation day (GD) 20. Exposure was suspended from GD 21 through postnatal day (PND) 4 and resumed on PND 5 until weaning on PND 21 (F_0 generation) or until euthanasia (F_1 generation). Starting on PND 22, F_1 weanlings were exposed to D4 for at least 70 consecutive days before mating and continuing as described for the F_0 generation. The F_2 pups were not directly exposed to D4. Clinical observations, body weights and feed consumption were recorded at appropriate intervals. F_0 animals were mated once to produce the F_1 generation; F_1 parental animals were mated twice to produce two F_2 litters. Also, the F_1 males were mated with unexposed, nulliparous females. Extended parturition and/or dystocia were observed in 2 and 3 F_0 females in the 500 and 700 ppm groups, respectively, and in 1 F_1 dam in each of the 300, 500 and 700 ppm groups. The cause of death for 2 F_0 700 ppm group dams and 1 F_1 500 ppm group female was considered to be dystocia. Reductions in the mean number of pups born and mean live litter size were observed in the 300, 500 and 700 ppm groups in the F_0 generation and all D4-exposed groups in the F_1 generation; the reductions were statistically significant in the 500 and 700 ppm groups for both the F_0 and F_1 generations. No adverse effects were observed at any exposure level on anogenital distance, vaginal patency and preputial separation. Prolonged estrous cycles, delayed ovulation progressing to an anovulatory state, and decreased mating and fertility indices were observed in all F_1 groups exposed to D4. No adverse effects were seen on reproductive parameters on male spermatogenic endpoints, on microscopic evaluation of male reproductive tissue, or when the D4-exposed F_1 males were mated with the unexposed, nulliparous females, demonstrating that the reproductive toxicity observed was due to D4 exposure to the females. (Supported in part by the Silicones Environmental Health and Safety Council.)

1735 A VALIDATION STUDY OF DOG SPERM MOTILITY ASSESSMENT WITH A COMPUTER-ASSISTED SPERM ANALYZER.

C. I. Gordon, M. Chagnon, A. Fraser, K. Robinson and P. Tellier. *ClinTrials BioResearch Ltd., Senneville, Quebec, Canada.* Sponsor: G. W. Lulham.

Male reproductive assessments in dogs have been subjected to problems associated with substantial variability in the methodology for the assessment of motility of dog spermatozoa between laboratories. The Computer Assisted Sperm Analyzer (CASA) system has provided a rapid, reliable and accurate assessment of rat spermatozoa motility and was considered appropriate to measure consistently the motility of dog spermatozoa.The purpose of this study was to validate the technique for evaluating motility of semen samples from male Beagle dogs with the use of the CASA.Semen samples were collected from 10 untreated Beagle dogs (approximately 15 months of age) by manual stimulation on 7 occasions. Samples collected on the last 4 occasions were used for the validation. Computer assisted motility assessments were performed, following semen dispersion in medium that was adjusted to facilitate optimum motility. Comparison of analyses over time (reanalysis of sample following 30 minutes, 1 hour and 2 hours at room temperature), reanalysis of stored disk images, assessments on non-motile samples and comparison to on screen manual assessments were performed.The differences between the CASA results and the manually assessed values were within the acceptance criteria of ±10% for the relevant samples analysed. Reanalysis of digitally stored images with the same settings were 100% accurate when compared to the results obtained by the original analysis. It was concluded that the use of a computer-assisted sperm analyzer gave consistent, reliable results of parameters such as overall motility, progressive motility and motion parameters (straight-line velocity, curvilinear velocity and path velocity) for spermatozoa collected from Beagle dogs.

1736 IMPAIRED SEMEN QUALITY IN MEXICAN AGRICULTURAL WORKERS EXPOSED TO ORGANOPHOSPHOROUS PESTICIDES.

R. Recio[1], G. Ocampo[2], J. Moran-Mtz[3], W. A. Robbins[4], V. Borja[2], G. Chapa[4], J. Froines[4] and M. E. Cebrian[5]. [1]*Universidad Autonoma de Coahuila and Cinvestav, Torreon and Mexico, Mexico,* [2]*Censa-SSA, Mexico, Mexico,* [3]*Universidad Autonoma de Coahuila, Torreon, Mexico,* [4]*COEH, UCLA, Los Angeles, CA and* [5]*Cinvestav, Mexico, Mexico.*

Organophosphorous pesticides (OP) are used worldwide. Human beings are exposed through environmental contamination and occupational exposure. It has been suggested that these chemicals disrupt human germinal cell homeostasis. Disruption is a common cause of poor reproductive outcomes, therefore, is of major public health significance. The objective of this study was to evaluate semen quality before and during pesticide spraying period between a non-occupationally exposed group (less exposed) and agricultural/sprayer workers (highly exposed). The study was conducted in an agricultural community where OP are the most widely used and sold pesticides. We constructed an exposure index based on OP use. Semen quality was assessed according to WHO methodology in 240 semen samples. In addition, 25 semen slides (13 from the highly exposed group and 12 from the less exposed group) were chosen for aneuploidy scoring by the three color chromosome fluorescence in situ hybridization (FISH) method for chromosomes X, Y and 18. Bivariate and multivariate analyses were performed. The results obtained after adjustment for several confounders disclosed that volume, total sperm count, total motility, motility grade A, viability, dead forms and mobile live forms were affected significantly in pesticide sprayers when compared with a non-occupationally exposed group, in both sampling periods. The parameters most affected were motility and viability. The crude proportion of all aneuploidy combined was 0.68% and 0.67% for sperm from highly exposed and less exposed men, respectively. However, these values were twice as high as those reported in similar studies. The most frequent aneuploidy observed was the lack of one sexual chromosome. Therefore, our results indicate that exposure to OP significantly impair semen quality.

1737 DIISOPROPYLFLUOROPHOSPHATE (DFP) ANTAGONISM BY RECOMBINANT ORGANOPHOSPHORUS ACID ANHYDROLASE (OPAA) ENCAPSULATED WITHIN STEALTH LIPOSOMES (SL).

I. Petrikovics[1], T. C. Cheng[2], D. Papahadjopoulos[3], K. Hong[3], R. Yin[2], J. J. DeFrank[2], J. Jiang[1], W. D. McGuinn[1], L. Pei[1], P. Yuzapavik[1], T. Barcza[1] and J. L. Way[1]. [1]*Texas A&M University, College Station, TX,* [2]*Army Chemical and Biological Defense Agency, Aberdeen Proving Ground, MD and* [3]*University of California-San Francisco, San Francisco, CA.*

Stealth liposomes containing recombinant OP hydrolyzing enzyme (OPAA) were employed as a carrier model to antagonize the lethal effects of DFP. DFP was employed as a model OP, as it serves as a good substrate for OPAA as well as some chemical warfare agents, e.g., soman and sarin. The properties of this carrier system and the antidotal protection was studied alone and in a combination with 2-PAM and/or atropine. The carrier liposomes were made by mechanical dispersion method, and the hydrolysis of DFP was determined by measuring the increase of fluoride ion concentration using fluoride sensitive electrode. Recombinant OPAA enzyme originated from Alteromonas Strain J6D has a broad substrate specificity for OP compounds, especially for DFP, soman and sarin. The OPAA encapsulated within (SL) could rapidly hydrolyze DFP. The rate of DFP hydrolysis was directly proportional to the amount of (SL)* added to the reaction mixture. (SL) with no enzyme did not hydrolyze DFP. Rate of hydrolysis was first order to fluoride and diisopropylfluorophosphate. These studies suggest that the antidotal protection of the classic OP antidotes 2-PAM and/or atropine can be strikingly enhanced when they are used in a combination with the OPAA encapsulated (SL)*.

1738 METABOLITES OF HEXAMETHYLDISILOXANE AND DECAMETHYLCYCLOPENTASILOXANE IN FISCHER 344 RAT URINE.

S. Varaprath, L. Cao, J. M. McMahon and K. P. Plotzke. *Dow Corning Corporation, Midland, MI.*

Hexamethyldisiloxane (MM or HMDS) and decamethylcylclopentasiloxane (D_5) are examples of a linear and a cyclic siloxane respectively. These volatile low molecular weight siloxanes are of significant commercial importance. They find use as ingredients in a wide range of cosmetic and personal care product formulations. These applications stem from a variety of favorable

physical characteristics such as adequate evaporation rate, low surface tension, lack of odor, a high degree of compatibility with other ingredients in formulations, solubility characteristics etc. Typical examples of applications include moisturizing creams, lotions, bath oils, colognes, shaving products and perfumes. They are also used as cleaners, lubricants and penetrating oils. To aid in the pharmacokinetic investigations, major metabolites of MM and D_5 were identified in urine collected from rats following exposure to [^{14}C]-MM and [^{14}C]-D_5. The structural assignments were based on GC-MS analysis of the tetrahydrofuran extract of urine containing the metabolites. The metabolites in the extract were first protected with trimethylsilyl groups prior to GC-MS analysis using bis(trimethylsiloxytriflouro- acetamide. The structures were also confirmed by comparisons with synthetic ^{14}C-labeled metabolite standards. The following are among the major metabolites identified in the case of MM: $Me_2Si(OH)_2$; $HOMe_2SiCH_2OH$; $HOCH_2Me_2SiOSiMe_2CH_2OH$; $HOMe_2SiOSiMe_2CH_2OH$; $HOCH_2Me_2SiOSiMe_3$; Me_3SiOH. The metabolites of D_5 are as follows: $Me_2Si(OH)_2$; $MeSi(OH)_3$; $MeSi(OH)_2OSi(OH)_3$; $MeSi(OH)_2O$- $Si(OH)_2Me$, $MeSi(OH)_2OSi(OH)Me_2$; $Me_2Si(OH)OSi(OH)Me_2$; $Me_2Si(OH)OSiMe_2OSi(OH)Me_2$; nonamethylcyclopentasiloxanol and hydroxymethylnonamethylcyclopentasiloxane. The presence of certain metabolites clearly established some demethylation at the silicon-methyl bonds. Although the initial oxidation step in the metabolic path way may be similar, at the end, the cyclic D_5 yielded, following ring opening, metabolites that are structurally different from that obtained for MM except for the commonly present $Me_2Si(OH)_2$.

1739 [13C8]LABELED STYRENE: TOXICOKINETICS AND URINARY METABOLITES IN MAN.

G. Johanson[1], C. Williams[2], L. Ernstgard[1], E. Gullstrand[1], A. Lof[1] and S. Sumner[2]. [1]*Toxicology and Risk Assessment, National Institute for Working Life, Stockholm, Sweden and* [2]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Styrene is used in the manufacture of plastics and polymers. Styrene is metabolized to styrene oxide (SO) in rodents and humans. SO is hydrolyzed and metabolized to products (e.g. mandelic acid, MA; phenylglyoxylic acid, PGA) that have been used as markers of exposure in humans. Formation of SO-mercapturic acids (rodents and humans) and metabolites derived from phenylacetaldehyde (PAA, rodents) have also been described. The purpose of this study was to obtain quantitative information on the metabolism of styrene in humans for comparison with rodent data. Four healthy male volunteers were exposed to 50 ppm [13C8]styrene for 2 hr. Blood, expired air, and urine were time-course collected and analyzed by GC, HPLC, and NMR. Subjects exhaled 1-2% of the dose as styrene. Peak ~2 hr blood levels of SO were 3-13 nM and peak styrene blood levels were 7-9 μM. Peak urinary concentrations of MA (~22% of uptake) were reached ~2 hr following exposure termination and peak concentrations of PGA (~6% of uptake) were reached between 4 and 6 hr. MA and PGA were detected in urine up to 23 hr and 42 hr, respectively, following exposure. Hippuric acid (0.11 mM) and phenylacetic acid (0.09 mM) were quantitated in urine collected at 4 hr following exposure initiation. Based on evaluation of urinary metabolites, >95% of styrene metabolism in humans occurs via hydrolysis to SO while <5% occurs via conversion to PAA. These observations are similar to a low level of conversion to PAA (3-5%) in rats and in contrast to a significantly greater conversion (~12-20%) in mice (rodents were exposed to 125-500 ppm styrene for 6 hr). (This study was funded by the Styrene Information and Research Center.)

1740 METABOLISM AND DISPOSITION OF BISPHENOL A IN FEMALE RATS.

T. R. Fennell, R. W. Snyder, S. C. Maness, K. W. Gaido, S. C. J. Sumner and F. Welsch. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Bisphenol A (BPA), which is used to manufacture polycarbonates, is weakly estrogenic in *in vitro* and some *in vivo* test systems. The effects of BPA on rodent offspring have been investigated following administration to pregnant animals during late gestation and continuing during lactation. The objectives of this study were to compare the metabolism and excretion of ^{14}C BPA in female Fischer 344 (F-344) and Sprague Dawley (SD) rats, to evaluate the transfer of BPA and metabolites from lactating dams to pups, and to assess the estrogenic activity of BPA metabolites *in vitro*. Adult female SD and F-344 rats were administered ^{14}C BPA (100 mg/kg) by gavage. Over 6 days, F-344 rats excreted more radioactivity in urine and less in feces than SD rats. Both strains had similar urine radioactivity profiles, with F-344 rats excreting more free BPA. The major urinary metabolite was characterized by ^{1}H and ^{13}C NMR spectroscopy as BPA glucuronide. In lactating SD rats administered ^{14}C BPA (100 mg/kg), the majority of the dose was recovered in the intestines at 1, 8, and 26 h after gavage. Only a small fraction of the dose was found in milk, with 0.95±0.66, 0.63±0.13, and 0.26±0.10 μg equivalents/ml (mean±SD) in the milk collected at 1, 8, and 26 h after dosing, respectively. Radioactivity in pup carcasses ranged from 44-78μg equivalents/kg. BPA glucuronide was the major metabolite in milk and plasma. In an *in vitro* test system for activity with the estrogen receptors α and β, BPA glucuronide (in contrast to BPA) did not show any appreciable activity at concentrations of up to 0.03 mM. These results indicate that metabolism of BPA via glucuronidation is a detoxication reaction.

1741 BENZENE METABOLISM BY ISOLATED PERFUSED RABBIT LUNG.

M. Powley and G. P. Carlson. *School of Health Sciences, Purdue University, West Lafayette, IN.*

Benzene is an occupational hazard and environmental pollutant associated with acute myelogenous leukemia in humans. There is limited evidence suggesting that lung cancer may result from benzene exposure. Pharmacokinetic models take into account benzene metabolism by liver but not lung, although recent analysis suggests they underestimate metabolite formation and that extrahepatic tissues may be important. *In vitro* studies have shown that lung is capable of metabolizing benzene. To further evaluate the capacity of lung to metabolize benzene in an *in vitro* preparation simulating *in vivo* metabolism, the isolated perfused rabbit lung was used. Lungs from male New Zealand White rabbits were placed in an artificial thorax and perfused via the vasculature with 55 μM ^{14}C-benzene for 30 min. One ml samples were taken at predetermined time intervals, and metabolites were separated by HPLC and quantified by liquid scintillation counting. Lung samples were also analyzed following the perfusion. They were solubilized, and metabolites were determined by HPLC and liquid scintillation counting. Analysis of the perfusate samples showed the decrease of benzene was 1st-order. Phenol in the perfusate increased in a non-linear manner for the first 20 minutes and then decreased. Phenylsulfate was detected in a few samples but not consistently. Tissue samples contained hydroquinone, phenol, and an unidentified metabolite. The results demonstrate that lung has the capability of metabolizing benzene in an *in vivo* simulation and should be included in pharmacokinetic models. (Supported by EPA Grant R826191.)

1742 BIOCHEMICAL EVIDENCE FOR INVOLVEMENT OF TYR381 AND TYR465 IN THE CATALYTIC MECHANISM OF MOUSE SOLUBLE EPOXIDE HYDROLASE.

T. Yamada[1], C. H. Morisseau[1], J. E. Maxwell[1], M. Derbel[1], M. Argiriadi[2], D. W. Christianson[2] and B. D. Hammock[1]. [1]*University of California Davis, Davis, CA and* [2]*University of Pennsylvania, Philadelphia, PA.*

Mammalian soluble epoxide hydrolase (sEH) plays an important role in the detoxification of xenobiotic epoxides as well as in the biosynthesis of inflammation mediators. In order to improve our understanding of the catalytic mechanism, we produced mutant mouse sEH based on the X-ray diffraction structure of the corresponding enzyme-inhibitor complex, the potent dialkylurea N-cyclohexyl-N'-(3-phenyl)propyl urea (CPU) being the inhibitor (M. Argiriadi et al. Proc. Natl. Acad. Sci. USA, 96, 10637-10642, 1999). The site directed mutagenesis was performed in a baculovirus expression system. The mutant enzymes, Y381F and Y465F reduced 98 and 97% of the activity of hydrolysis of trans-diphenylpropene oxide, respectively, compared to that of the wild-type enzyme. The Y465F-Y381F double mutant lost the activity completely, indicating that both tyrosines are required for the activity. Inhibition by potent urea inhibitors were effected in both Y381F and Y465F mutants. Particularly Y381F increased the IC50 by 8-10 fold. To investigate the roles of Y381 and Y465 in the catalytic mechanism, kinetic experiments were carried out with a series of para-substituted chalcone oxides. These biochemical and kinetic results suggest that the two tyrosine residues in the active site have important functions in the inhibition by urea and in the catalytic mechanism.

1743 CHARACTERIZATION OF COUMARIN 3,4-EPOXIDATION IN B6C3F1 MOUSE, F-344 RAT AND HUMAN LUNG MICROSOMES.

D. Caudill[1], G. B. J. Smith[2], T. E. Massey[2] and S. L. Born[1]. [1]*The Procter & Gamble Company, Cincinnati, OH and* [2]*Dept. Pharmacology/Toxicology, Queen's University, Kingston, Ontario, Canada.*

Coumarin is a mouse lung and rat liver toxicant. Acute coumarin administration (200 mg/kg) causes the selective necrosis of mouse lung Clara cells. However, equimolar dosages of this chemical do not cause rat lung injury, indicating that coumarin-mediated lung injury is species-specific. The goal of the current study was to relate species differences in susceptibility to lung toxicity with levels of pulmonary coumarin bioactivation. Coumarin-mediated toxicity results from the formation of coumarin 3,4-epoxide and its product *o*-hydroxyphenylacetaldehyde (*o*-HPA). Coumarin bioactivation was quantitated via the formation of *o*-HPA in whole lung microsomes. Clear species differences were observed in the rate of pulmonary microsomal *o*-HPA formation, with *o*-HPA production in mice being 20-fold higher than in rats. *o*-HPA formation was biphasic in pooled mouse lung microsomes. The apparent K_m and V_{max} values were 134 μM and 1.21 nmol/min/mg, and 753 μM and 2.58 nmol/min/mg for the high and low affinity enzymes, respectively. Consistent with the lack of Clara cell toxicity observed in rat lung *in vivo*, the single enzyme involved in *o*-HPA formation in F344 rat lung produced low levels of *o*-HPA, exhibiting a K_m and V_{max} of 183 μM and 0.218 nmol/min/mg, respectively. Furthermore, *o*-HPA formation was not detected in 10 individual human lung microsomal samples, indicating that humans are unlikely to be susceptible to coumarin-mediated pneumotoxicity.

1744 INHIBITION OF CYTOCHROME P450 2E1 ACTIVITY BY NICOTINE, COTININE, AND AQUEOUS CIGARETTE TAR EXTRACT *IN VITRO*.

T. R. Van Vleet[1], D. W. Bombick[2] and R. A. Coulombe, Jr.[1]. [1]*Utah State University, Logan, UT and* [2]*R.J. Reynolds Tobacco Co., Winston-Salem, NC.*

Tobacco-specific N-nitrosamines, N-nitrosodimethylamine (NDMA) and 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK), are both activated by cytochrome P450 (CYP) 2E1 in rat *in vivo*. Previous reports indicate that nicotine and its main metabolite, cotinine, reduce the mutagenicity of both NNK and NDMA in *Salmonella typhimurium*. To study the mechanism for this inhibition, we examined the effect of nicotine, cotinine, and aqueous cigarette tar extract (ACTE) on CYP 2E1 activity, as assessed by hydroxylation of *p*-nitrophenol, in CYP 2E1-expressing microsomes. Both nicotine and cotinine inhibited 2E1 hydroxylase over a range of pNP concentrations. At 0.12 mM *p*NP, IC_{50} for inhibition of *p*NP hydroxylase was 3.93 and 64.37 mM for nicotine and cotinine, respectively. At 0.24 mM *p*NP, IC_{50} values were 3.87 and 37.71 mM, respectively. Similarly, ACTE inhibited 2E1 activity over a range of pNP concentrations, and the extent of inhibition was dependant on ACTE concentration. These data show that nicotine, cotinine, and ATCE inhibit CYP 2E1 activity in this system, and that nicotine is a more potent inhibitor than cotinine. Thus, CYP 2E1 inhibition is a possible mechanism for the observed inhibition of NNK and NDMA mutagenicity by these compounds *in vitro*.

1745 TROGLITAZONE TOXICITY IN PRIMARY CULTURES OF HUMAN HEPATOCYTES.

V. E. Kostrubsky[1], S. C. Strom[2], V. Ramachandran[3], R. Venkataramanan[3], M. Wen[1], K. Rose[1] and M. Sinz[1]. [1]*Parke-Davis Pharmaceutical Research, Ann Arbor, MI,* [2]*University of Pittsburgh Medical Center, Pittsburgh, PA and* [3]*School of Pharmacy, University of Pittsburgh, Pittsburgh, PA.* Sponsor: M. R. Bleavins.

Treatment of primary human hepatocytes cultured in serum-free media for 2 hr with 10, 20, 25, 35 and 50 μM of troglitazone resulted in concentration-dependent decreases in total protein synthesis, with 90% inhibition observed at 50 μM. Decreases at 10 and 20 μM were reversible by 24 hr. However, protein synthesis did not recover at concentrations >25 μM. This change was associated with decreased inducible enzymatic and immunochemical levels of CYP3A. Troglitazone at 50 μM was lethal to the cells and associated with 70% decrease in MTT reduction by 24 hr. Addition of 5 mM acetaminophen or 2 mM phenobarbital 30 min. before and concomitant with 10 μM troglitazone, resulted in 70% and 60% decreases in protein synthesis, respectively. The effect on protein synthesis was associated with 3.6- and 1.4-fold decreases in formation of the troglitazone-sulfate metabolite by acetaminophen and phenobarbital, respectively. Troglitazone-quinone formation was increased 2-fold with acetaminophen and unaffected by phenobarbital. Exposure of human hepatocytes to a combination of 10 μM troglitazone and an inhibitor of sulfation (pentachlorophenol) resulted in a 90% inhibition in protein synthesis. Analysis of total cellular glutathione after treatment of hepatocytes with 50 μM troglitazone showed only a 25% decrease by 2 hr. These data suggest that inhibition of troglitazone metabolism by drugs competing for a common metabolic pathway may affect hepatotoxicity from troglitazone.

1746 THE HYPEROXIDATION OF L- DOPA BY CHLORPROMAZINE IN A LIPOXYGENASE CATALYZED REACTION.

A. S. Persad, T. J. Stedeford and A. P. Kulkarni. *Florida Toxicology Research Center, Tampa, FL.*

This study tests the effect of chlorpromazine (CPZ) on the lipoxygenase-catalyzed oxidation of L-Dopa in the presence of hydrogen peroxide. Soybean lipoxygenase (SLO)-catalyzed oxidation of L-Dopa was evaluated in the presence and absence of CPZ. The oxidation of L-Dopa to dopaminochrome was found to be proportional to the concentration of SLO, L-Dopa, CPZ, hydrogen peroxide, and linear with time. In the presence of 1.0 mM CPZ and 20 μg of SLO, the optimal conditions required to observe the maximal stimulation of the rate of L-Dopa oxidation at room temperature, included pH 4.0, 1.0 mM L-Dopa, 0.4 mM hydrogen peroxide. Under these assay conditions; CPZ radical was found to stimulate L-Dopa oxidation by ~25 fold. This stimulatory response was markedly suppressed by the addition of the classical inhibitors of lipoxygenase, nordihyroguaiaretic acid (NDGA) and gossypol. These results explain the ineffectiveness of CPZ-Dopa combination therapy for Parkinson's disease.

1747 REGENERATION OF QUERCETIN AND OTHER FLAVONOIDS BY NAD(P)H:QUINONE OXIDOREDUCTASE 1.

D. Siegel and D. Ross. *University of Colorado Health Sciences Center, Denver, CO.*

Flavonoids are a class of naturally occurring compounds which are found in vegetables and fruits. Epidemiological studies suggest that dietary intake of flavonoids may reduce the incidence of heart disease and certain types of cancer. Quercetin in both aglycone and glycosylated forms is one of the most common flavonoids found in the diet and recent experiments suggest that quercetin has both antioxidant and prooxidant properties. Oxidation of quercetin has been proposed to generate a transient quinone metabolite. The purpose of this study was to examine whether any metabolites generated during quercetin oxidation could serve as substrates for NAD(P)H:quinone oxidoreductase 1 (NQO1, DT-diaphorase) and undergo two-electron reduction to regenerate quercetin. HPLC analysis was used to examine quercetin oxidation reactions in the presence and absence of purified rhNQO1. Enzymatic oxidation (tyrosinase, myeloperoxidase), superoxide-dependent oxidation (xanthine/xanthine oxidase) and copper-stimulated, pH-dependent (pH 8) oxidation of quercetin resulted in generation of a metabolite which could be reduced by purified rhNQO1. In the absence of NQO1, quercetin (50μM) was substantially depleted (60-70%) following oxidation. In the presence of NQO1, however, only 5-10% of quercetin was depleted. In addition, the presence of NQO1 increased oxygen consumption 2-fold during copper-stimulated, pH-dependent oxidation of quercetin. The NQO1-dependent regeneration of quercetin and the increase in oxygen consumption was NAD(P)H-dependent and dicumarol-inhibitable. Similar results were observed with NQO1 and other flavonoids. These data suggest that NQO1 may be able to regenerate quercetin and other flavonoids following oxidation and individuals who are homozygous for the NQO1*2 polymorphism and lack NQO1 activity may have a decreased capacity to regenerate these compounds. 1748 ETHANOL METABOLISM IN HUMAN FETAL BRAIN CATALYZED BY A NOVEL OXIDASE ENZYME.

M. R. Brzezinski, R. E. Person and M. R. Juchau. *University of Washington School of Medicine, Seattle, WA.*

Ethanol is a well-known teratogen that often causes a pattern of morphologi-

cal and neurological abnormalities in the fetus referred to as fetal alcohol syndrome. Mechanisms have been proposed to explain alcohol's deleterious effects, several involving the enzyme-catalyzed oxidation of ethanol to its highly reactive metabolite acetaldehyde. In prenatal human brain (gestational days 90-115), the contribution of several enzymes to acetaldehyde production was evaluated using high performance liquid chromatography with fluorescence detection. The addition of specific inhibitors and cofactors/cosubstrates did not affect the activity substantially suggesting that an enzyme system other than alcohol dehydrogenase, CYP2E1, or catalase may be involved during early development. Heat inactivation and substrate saturation confirmed this was an enzymatic process while additional experiments determined the activity was localized in the cytosolic fraction, dependent on molecular oxygen, and inhibited weakly by sodium azide. Collectively, these results indicate that an alcohol oxidase might be largely responsible for catalyzing the conversion of ethanol to acetaldehyde in human fetal brain. Alcohol oxidases have not been reported in mammals but have been identified in lower species, such as yeast and bacteria. Further characterization of the enzyme revealed a two-component system consisting of a large protein (molecular weight>100,000) and smaller molecule (molecular weight<1,000) essential for activity. The specific activity in human fetal brain was approximately 20% of that measured in adult rat liver. The significant level of ethanol-oxidizing activity observed in prenatal brain suggests that the quantities of reactive metabolite generated may be of extreme importance and this novel enzyme could play a major role in eliciting neurotoxic effects during human development. (Supported by ES-04041 and ES-07032.)

1749 FETAL N-ACETYLTRANSFERASES: A POTENTIAL ROLE IN 4-AMINOBIPHENYL PRENATAL GENOTOXICITY.

C. A. Mcqueen, M. K. Mitchell, L. N. Dang, R. B. Tjalkens[2] and M. A. Philbert[2]. *University of Arizona College of Pharmacy, Tucson, AZ and [2]University of Michigan, Ann Arbor, MI.*

Exposure to aromatic amines such as 4-aminobiphenyl (4ABP) results in hemoglobin or DNA adducts in adults, neonates or fetuses. Biotransformation of 4ABP is required for production of DNA-reactive species. One pathway involves N-hydroxylation followed by O-acetylation, which is catalyzed by N-acetyltransferases (NAT). The contributions of maternal and fetal NAT to the genotoxicity of 4ABP were investigated in C57Bl/6 mice. NAT activity in maternal liver and conceptal tissue at gestational days (GD) 10, 15, and 18 was evaluated by measuring the formation of 4-acetylaminobiphenyl (4AABP) by S9 fractions. NAT activities were 0.2±0.03 nmol 4AABP/min/mg protein at GD 10, 0.26±0 at GD 15 and 0.36±0.04 at GD18 compared to 1.55±0.43 for maternal liver. There was a statistically significant (p=0.05) increase in 4ABP-NAT activity from GD10 to GD15 and from GD 15 to 18. The formation of 4ABP-DNA adducts was assessed in maternal liver and fetal tissue at GD15 and GD18. Pregnant animals were killed 24h after a single oral dose of 120 mg 4ABP/kg or corn oil. Tissue was frozen, histological sections prepared and adducts detected by immunofluorescence. Little or no fluorescence was observed with corn oil. For animals exposed to 4ABP, the relative fluorescent intensities were similar at GD15 and GD18, 23.4±1.4 and 24.5±3.3 respectively. At GD15, the value for maternal liver was 35.6±3.6 and 39.6±4.0 at GD18. The presence of 4ABP-DNA adducts is further evidence that maternal exposure to 4ABP can damage fetal DNA. Although it is not clear whether the DNA-reactive products are formed *in utero*, the present data demonstrate that conceptal tissue has the ability to acetylate 4ABP. Consequently, fetal biotransformation may contribute to the prenatal genotoxicity of 4ABP. (Supported by Arizona Disease Control Research Commission and NIEHS, ESO6694 (CAM) and ESO8846 (MAP).)

1750 NON-LYTIC EXPRESSION OF XENOBIOTIC-METABOLIZING ENZYMES IN INSECT CELLS.

W. Zhu, L. Song, Y. Li, H. Zhang, L. Matoney and B. Yan. *University of Rhode Island, Kingston, RI.* Sponsor: Z. A. Shaikh.

Insect cells are widely used for heterologous expression due to high yield and capability of producing functionally active proteins. However, the currently used insect cell expression systems are cell-lytic, which creates uncertainties when cell injuries are used as experimental end points. We used a non-lytic system and established insect cell lines which expressed several xenobiotic-metabolizing enzymes (e.g., carboxylesterases and cytochrome P450s). cDNAs encoding these enzymes were inserted into the pIZ/V5-His vector, which were then used to transfect Sf9 insect cells. The transfected cells underwent selection against Zeocin-containing media for stable integration in the genome. Western immunoblotting analyses showed that specific antibody to each enzyme detected a single protein only in the Sf9 cells expressing the corresponding enzyme which co-migrated with the native protein in human liver microsomes. Two cell lines expressing human carboxylesterases (HCE-1 and HCE-2) were further characterized for the correlation of the expression levels with plating density and requirement for selective media. Cells at all plating densities (30-80%) exhibited little difference in the expression levels of the recombinant protein. However, over-confluence caused slightly lower expression levels. Cells cultured in Zeocin-containing media expressed higher levels of the recombinant protein but exhibited a lower proliferation rate. The recombinant carboxylesterases were enzymatically active and both HCE-1 and HCE-2 rapidly hydrolyzed *para*-nitrophenylacetate. HCE-1 was more sensitive to the inhibition by phenylmethylsulfonyl fluoride (PMSF), whereas HCE-2 was more sensitive to the inhibition by sodium fluoride SF). Finally, carboxylesterase-expressing cells are more resistant (20-30 times) to either PMSF or SF than the control Sf9 cells. (Supported by a PHS grant ES07965.)

1751 DOSE-DEPENDENT EFFECT OF TRI-*O*-TOLYLPHOSPHATE ON HEPATIC AND PANCREATIC FATTY ACID ETHYL ESTER AND METHYL ESTER SYNTHESIZING ACTIVITIES.

K. A. Mericle, B. S. Kaphalia and G. A. S. Ansari. *University of Texas Medical Branch, Galveston, TX.*

Background: Fatty acid ethyl ester synthase (FAEES) is an enzyme that catalyzes the conjugation of alcohols with fatty acids. The formation and accumulation of these lipophilic conjugates in target organs may result in toxicity. Previous studies from this laboratory have shown that FAEES purified from rat liver is structurally and functionally different from that of pancreas. **Objective:** In this study the functional relationship of hepatic and pancreatic FAEES is further characterized *in vivo*, using tri-o-tolylphosphate (TOTP; a β esterase inhibitor) in a dose-dependent manner. **Methods:** Five groups of rats received i.p. injection of 10, 25, 50, or 100 mg/kg TOTP in corn oil, or vehicle alone. The animals were sacrificed 18 hours later, and the liver and pancreas were excised. FAEES activity was analyzed by measuring the ester formation following incubation of [1-^{14}C] oleic acid with ethanol or methanol in the presence of post-nuclear fraction of liver or pancreas at 37°C for 2 hours, while esterase activity was determined using p-nitrophenyl acetate (PNPA) as a substrate. **Results:** The percent inhibition of FAEES activity was found to be 61, 65, 78 and 87% in the liver (at 10, 25, 50, and 100 mg/kg TOTP respectively). Using methanol as the substrate, the percent inhibition was 74, 72, 88, and 93%, respectively. No inhibition was found in the pancreas of rats treated with TOTP as compared to the controls. The PNPA assay gave similar results with the percent inhibition in the liver being 73, 77, 88 and 93%, respectively. In the liver, maximal inhibition of fatty acid methyl ester or ethyl ester synthesizing activities was at the 100 mg/kg dose. Western Blot analysis demonstrated that the pancreatic FAEES does not cross-react with the FAEES antibody that recognizes both liver and plasma FAEES. **Conclusions:** From these studies we conclude that hepatic ethyl ester and methyl ester synthesizing activities could be expressed by the same enzyme, inhibited by TOTP, and are functionally and structurally different from that found in the pancreas.

1752 PURIFICATION AND CHARACTERIZATION OF RAT PANCREATIC FATTY ACID ETHYL ESTER SYNTHASE AND ITS RELATIONSHIP TO FATTY ACID METHYL ESTERS AND ANILIDE SYNTHESIZING ACTIVITIES.

B. S. Kaphalia, V. Leslie and G. A. S. Ansari. *University of Texas Medical Branch, Galveston, TX.*

Fatty acid ethyl esters (FAEEs), formed by a fatty acid ethyl ester synthase (FAEES)-catalyzed reaction of ethanol with fatty acids, have been implicated in pathogenesis of diseases of extrahepatic organs during alcohol abuse. Among all the organs and tissues, pancreas possesses the highest FAEES activity. In previous studies, we demonstrated that FAEES, purified from rat liver microsomes, is identical to carboxylesterase (pI 6.1) and structurally and functionally different than that of pancreas. In the present studies, synthesizing activities towards FAEEs, fatty acid methyl esters (FAMEs) and fatty acid anilides (FAAs) from rat pancreas were purified and their interrelationship was evaluated with cholesterol esterase (ChE). p-Nitrophenyl acetate (PNPA) hydrolyzing activity (a measure of esterase activity) was also determined. The synthesizing activity for FAEEs, FAMEs and FAAs as well as hydrolyzing activities for PNPA were co-purified at each step of purification by ammonium sulfate saturation, and Q Sepharose XL and heparin-agarose column chromatography. The FAEE, FAME and FAA synthesizing activity of heparin-agarose purified protein was found to be 3380, 5800 and 670 nmol/hr/mg protein, respectively, while PNPA hydrolyzing activity was 35 micromol/min/mg protein. The purified protein showed a molecular weight of ~68kD by SDS-

PAGE under reduced denaturing conditions and cross-reacted with antibodies to rat pancreatic ChE. Based on molecular weight and cross-reactivity with

antibodies to rat pancreatic ChE, the purified protein appears to be ChE, which catalyzes the formation of FAEEs as well as FAMEs and FAAs.

1753 CLONING, MUTAGENESIS AND EXPRESSION OF A MAJOR RAT CARBOXYLESTERASE REST1 IN THE BACULOVIRUS SYSTEM.

M. Derbel[1], Y. Takashi[1], R. Wudayagiri[2] and B. D. Hammock[1]. [1]*University Of California Davis, Davis, CA and* [2]*Sri Venkateswara University, Tirupati, India.*

Liver microsomal carboxylesterases (EC 3.1.1.1) hydrolyze xenobiotics containing ester, thioester or amide groups and thus play an important role in drug metabolism and detoxification of many chemicals in the environment. They also are common activators of prodrugs and are proposed as therapeutics agents. The baculovirus expression of these enzymes allows the study of the metabolism of drugs and the efficient production of antibodies towards these proteins. In this study, a major rat liver carboxylesterase, rEST1, was cloned from a double-stranded library using PCR. The 1.7 kb insert was subcloned to a baculovirus vector, pFASTBac. The rEST1 carboxylesterase was expressed successfully in the High5 derived cells from Trichoplusia ni egg cell. Carboxylesterases are located in the luminal site of the endoplasmic reticulum and attached to a specific receptor through an HXEL motif located at the C-terminal. A mutation in the last amino acid of the rEST1 carboxylesterase, from leucine to arginine, perturbed the trafficking of the enzyme. The mutant form of rEST1 is secreted to the media and thus purification is achieved easily through one step classical or affinity purification. In conclusion, the expression of carboxylesterase in the baculovirus system combined with the single mutation of the last amino acid which makes the carboxylesterase rEST1 secretory results in inexpensive, high yield and homogenate enzyme.

1754 ORAL MUCOSAL METABOLISM OF VINYL ACETATE.

P. T. Symanowicz[1], R. Sarangapani[2] and J. B. Morris[1]. [1]*University of Connecticut, Storrs, CT and* [2]*K.S. Crump ICF Consulting, Research Triangle Park, NC.*

Statistically significant increases in tumor incidences in several sites within the oral cavity of the rat and mouse have been observed following chronic oral exposure to vinyl acetate (VA). Since carboxylesterase-dependent hydrolysis of VA to acetic acid and acetaldehyde has been implicated in the nasal inhalation carcinogenesis of this ester, the potential for oral mucosa of the rat and mice to hydrolyze VA was examined. Homogenates were prepared by scraping the mucosa from four regions of the oral cavity: dorsal interior (all tissues interior to the teeth), dorsal tongue surface, ventral interior (sublingual area and lower interior tissues) and exterior (all tissues exterior to the teeth). The oral cavity was rinsed once with saline prior to dissection to determine if oral secretions possessed metabolic capacity. Aliquots of the homogenates or rinse fluid were incubated for 30 minutes with varying concentrations of vinyl acetate (0.05-10 mM), and the production of acetaldehyde was quantitated by HPLC. All tissue regions possessed VA hydrolysis activity. In both species the hydrolysis activity was greatest in the dorsal interior region (Vmax of 90 and 6 nmol/min in the rat and mouse, respectively, Km values of 0.5 and 0.9 mM). Activity in the other oral regions was 2-15 fold lower. Activity was observed in the rinse fluid, but was 30-50 fold less than the dorsal interior region. Local hydrolysis of VA may play a role in the oral toxicity of ingested VA.

1755 DEVELOPMENTAL EXPRESSION AND CHARACTERIZATION OF HEPATIC MICROSOMAL AND SERUM A-ESTERASES IN THE RAT.

T. A. Couch, H. W. Chambers[2] and J. E. Chambers. *Center for Environmental Health Sciences, College of Veterinary Medicine, Department of Entomology, Mississippi State University, Mississippi State, MS.*

A-esterases (AEST) are primarily involved in the metabolism of oxidized lipids and detoxification of the oxons of organophosphorus (OP) insecticides. AEST have been found in two isozyme forms in several species. Previous studies have shown that differences in the pattern of AEST activity for direct and indirect methodologies (high and low substrate concentrations, respectively) may be due to different isozymes operating in the assays. This study investigated the developmental expression of hepatic (microsomal) and serum AEST isozymes in male and female rats at postnatal days (PND) 1, 3, 12, 21, 33, and 80, using native polyacrylamide gel electrophoresis (PAGE), with B-naphthylacetate (BAC) as the substrate (esterase stain). Equivalent amounts of tissue (for each age) were added to the gels. Hepatic AEST activity was present at all ages in both sexes studied, with two high molecular weight (MW) proteins (250 kDa and 200 kDa; isozymes 1 and 2, respectively) stained for activity. At PND 1 and 3, isozyme 1 was faintly detected. Both isozymes stained with increasing intensity at PND 12, 21, 33, and 80. Serum activity toward BAC was also present at all ages and in both sexes studied. As in the liver, two high MW proteins were identified (200 kDa and 137-200 kDa; isozymes 1 and 2, respectively). At PND1 and 3, isozyme 2 was only faintly detected. At PND12, 21, 33, and 80, both isozymes stained for activity. To further characterize the biochemical aspects of AEST and determine the relative contribution of each AEST isozyme to the hydrolysis of OP oxons, liver AEST were purified through the application of detergent solubilized microsomes to a stirred ultrafiltration cell, followed by excision from a native PAGE gel and application to an anion exchange chromatography column. By observing the rate of development of AEST isozymes and determining their role in the detoxification of OP insecticides, the reasons for age-related differences in OP toxicity may be discerned further. (Supported by NIH RO1 ES04394 and F31 Eso5752.)

1756 INVOLVEMENT OF THE TYROSINE CATABOLIC PATHWAY IN THE INHIBITION OF DCA METABOLISM.

R. Cornett-Mueller[1], M. O. James[1], A. E. Ally[1], G. N. Henderson[2], J. Cheung[2], A. L. Shroads[2], C. Ammini[2] and P. W. Stacpoole[2]. [1]*University of Florida College of Pharmacy, Gainesville, FL and* [2]*University of Florida College of Medicine, Gainesville, FL.*

Dichloroacetate (DCA) has been shown both clinically and in animal models to inhibit its own metabolism. The mechanism of this inhibition remains to be elucidated. The enzyme responsible for the dechlorination of DCA to glyoxylate is GST Zeta (GSTz), also known as maleylacetoacetate isomerase, an enzyme in the tyrosine catabolic pathway responsible for the cis/trans isomerization of maleylacetoacetate (MAA) and its decarboxylation product, maleylacetone (MA), to fumarylacetoacetate (FAA) and fumarylacetone, respectively. MAA is a known alkylating agent, and it is theorized that inhibition of MAA and/or MA metabolism by DCA could lead to alkylation of GSTz, rendering it inactive. In vitro pre-incubation of DCA (0.5 mM) with dialyzed rat cytosol caused a direct inhibition of GSTz activity which was not seen in dialyzed human hepatic cytosol. Incubation of rat and human hepatic cytosol with 0.2 mM DCA in the presence of MA (0.05-0.4 mM) led to a concentration dependent inhibition of DCA metabolism. Administration of DCA to male Sprague Dawley rats, 4 mg/kg x 5 days-1000 mg/kg for one or five days, led to a dose dependent inhibition of *in vitro* GSTz activity in hepatic cytosol and up to a 30 fold increase in urinary excretion of MA in rats dosed with greater than 50 mg/kg. Using a polyclonal antibody to human GSTz, western blots of hepatic cytosol from these animals revealed a dose dependent decrease in GSTz expression. These data taken together suggest more than one mechanism may be operational in DCA's inhibition of its own metabolism. (Supported by U.S. Public Health Service ES 07375.)

1757 *IN VITRO* METABOLISM AND GLUCURONIDATION OF THE HOP FLAVONOID XANTHOHUMOL.

M. Yilmazer and D. R. Buhler. *Oregon State University, Corvallis, OR.*

Xanthohumol (XN) is the major prenylated flavonoid of hops (*Humulus lupulus*) and has been detected in beer. Recent studies have suggested it may have potential cancer chemopreventive activity, but little is known about its metabolism. We investigated the glucuronidation and conversion of XN to various metabolites by rat and human liver microsomes. Three major polar metabolites were found with hepatic microsomes from either untreated rats or phenobarbital pretreated rats as detected by HPLC analysis. Isosafrole- and β-naphthoflavone-pretreated rat liver microsomes formed an additional major nonpolar metabolite. Human liver microsomes produced the same three metabolites formed by untreated rat liver microsomes. *In vitro* glucuronidation of XN using rat liver microsomes and human liver microsomes produced two monoglucuronide conjugates. As determined by LC-MS and ^{1}H-NMR analysis, two of the major polar microsomal metabolites of XN were tentatively identified as 5''-(2-hydroxyisopropyl)-[2'',3'':3',4'] dihydrofurano-2',4-dihydroxy-6'-methoxychalcone and a derivative of XN with a hydroxyl addition on the B ring. Additionally, the nonpolar metabolite appears to be dehydrocycloxanthohumol. By the same analytical methods, the monoglucuronide conjugation was shown to occur at either the 4- or 4'- position of

XN. The biological activity of these metabolites and their involvement in cancer chemoprevention remains to be established. (Supported by the Hop Research Council and NIEHS grant ES00210.)

1758 INDOLE-3-CARBINOL, A GLUCOSINOLATE BREAKDOWN PRODUCT OF CRUCIFEROUS VEGETABLES, INDUCES QUINONE REDUCTASE GENE EXPRESSION THROUGH TWO GENE REGULATORY ELEMENTS, ARE AND XRE.

C. W. Nho and E. H. Jeffery. *University of Illinois at Urbana-Champaign, Urbana, IL.*

Epidemiological studies show that cruciferous vegetables play a role in protection against cancers. These protective effects are thought to be associated with plant secondary metabolites, termed glucosinolates. Indole-3-carbinol (I3C), the breakdown product of the glucosinolate glucobrassicin, is known to increase phase I and phase II detoxification enzymes. We and others previously showed that I3C increased quinone reductase (QR), Glutathione-S-Transferases (GSTs), and CYP 1A activities and mRNA levels *in vivo*. In this study, we confirm the finding of others that both I3C and I3C acid condensates bind to the cytosolic aryl hydrocarbon receptor (AhR) to activate the xenobiotic response element (XRE) for QR gene expression. To measure the QR gene expression, we performed transient transfection of HepG2 human hepatoma cells with a reporter gene construct. 12-fold and 1.7-fold activation of the XRE over control were observed with 50 μM I3C or I3C acid condensates treatments, respectively. Here we show also for the first time that I3C acid condensates and I3C both caused dose-dependent activation of the antioxidant response element (ARE) in a dose range of 10 μM-200 μM. Both I3C and I3C acid condensates showed significant activation of the ARE at 25 μM and greater concentrations. The data suggest that QR is upregulated by I3C via both the ARE and the XRE.

1759 EFFECTS OF CHRONIC DIETARY INDOLE-3-CARBINOL (I3C) EXPOSURE ON BLOOD CHEMISTRY AND DRUG METABOLISM IN FISCHER 344 RATS.

D. A. Leibelt, S. A. Larsen-Su and D. E. Williams. *Oregon State University, Corvallis, OR.*

I3C is a naturally occurring component of the human diet and is found in high concentrations in cruciferous vegetables. I3C is also marketed as a dietary supplement and has been proposed as a chemopreventive agent for women against breast cancer. A sub-chronic exposure of I3C is known to induce several phase I and phase II drug metabolizing enzymes while inhibiting the flavin-containing monooxygenase (FMO). Less is known about the effects of long term dietary I3C exposure to rats. Fischer 344 rats were fed diets containing 0, 1000 or 2500 ppm I3C for 28 weeks. A small animal chemistry panel was performed, and serum testosterone levels determined. The total cytochrome 450 (CYP) content of the liver was also investigated. Alkaline phosphatase, creatine kinase, alanine aminotransferase and testosterone levels were significantly decreased in the rat serum while globulin levels were increased. As seen in sub-chronic studies, the liver total P450 content was significantly induced. The alterations observed in this study following long-term dietary I3C administration raises concerns relative to potential adverse effects on hormone levels and drug/xenobiotic metabolism. (Supported by PHS grant ES07060.)

1760 SELECTIVE INDUCTION OF TRIIODOTHYRONINE (T_3) GLUCURONIDATION BY PREGNENOLONE-16α-CARBONITRILE (PCN) IN RATS.

N. R. Vansell and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

It has been postulated that UDP-glucuronosyltransferase inducers decrease circulating thyroid hormone concentrations by increasing the biliary excretion of thyroid hormones. The inducers 3-methylcholanthrene (3-MC) and Aroclor 1254 (PCB) are extremely effective at reducing serum thyroid hormones, whereas pregnenolone-16α-carbonitrile (PCN) is less effective. However, only PCN treatment results in a marked increase in serum levels of thyroid stimulating hormone (TSH), whereas 3-MC and PCB cause little to no increase in TSH. Sustained TSH elevation is considered the primary stimulus for thyroid tumor development in rats, yet the mechanism by which enzyme induction leads to TSH elevation is not fully understood. Whereas PCN, 3-MC, and PCB all increase microsomal glucuronidation of T_4, only PCN causes an increase in microsomal glucuronidation of T_3. The purpose of this study was to determine whether PCN, which increases serum TSH, causes an increase in the glucuronidation and biliary excretion of T_3 *in vivo*. Male rats were fed control diet or diet containing either PCN (1000 ppm), 3-MC (250 ppm), or PCB (100 ppm) for seven days. Animals were then given [^{125}I]-T_3 *iv*, and bile was collected for two hours. Radiolabeled metabolites in bile were analyzed by reverse-phase HPLC with γ-detection. The biliary excretion of total radioactivity was increased 1.7 fold by PCN, but not by 3-MC or PCB. Of the T_3 excreted into bile, approximately 75% was recovered as T_3 glucuronide, with remaining amounts represented as T_3 sulfate, T_2 sulfate, T_3, and T_2. Biliary excretion of T_3 glucuronide was increased 1.5 fold by PCN, while neither 3-MC nor PCB altered T_3 glucuronide excretion. These findings indicate that PCN induces the glucuronidation and biliary excretion of T_3 *in vivo*, and suggest that increased elimination of T_3 may be the mechanism responsible for the increases in serum TSH caused by PCN. (Supported by NIH grants ES-08156 and ES-07079.)

1761 EFFECT OF PERINATAL EXPOSURES OF RATS TO THE PCB MIXTURE AROCLOR® 1254 ON HEPATIC MICROSOMAL METABOLISM OF ESTRADIOL AND THE PRO-ESTROGEN METHOXYCHLOR.

J. E. Chambers[1], R. L. Carr[1], C. P. McCoy[1], J. L. Wagner[1], D. S. Respess, Jr.[2] and N. M. Cox[2]. [1]*Center Environmental Hlth. Sci., College of Veterinary Medicine and* [2]*Dept. Animal & Dairy Sciences, Mississippi State University, Mississippi State, MS.*

Polychlorinated biphenyls (PCB's) are well known inducers of hepatic cytochrome P450. The influence of gestational and lactational exposures of rats to the PCB mixture Aroclor 1254 was determined for hepatic microsomal metabolism of 17β-estradiol (E2) and the proestrogenic organochlorine insecticide methoxychlor (MXC). Dams were administered 4 mg/kg-day of Aroclor 1254 in safflower oil p.o. from gestational day 6 to post-natal day (PND) 22 (weaning). Pups were sampled on PND 15, 23, or 31. There was little E2 metabolism in microsomes of controls of either sex at PND 15 or 23, but there was greater metabolism in the PCB-treated animals, with 2-hydroxyestradiol (2-OH-E2) the major metabolite. There was more 2-OH-E2 production in the control microsomes at PND 31 than from the younger ages, and several additional metabolites were observed in the microsomes from PCB-treated animals. Enhanced hepatic metabolism of E2 may have been responsible for lower serum E2 levels observed in PCB-treated prepubertal females. There was greater MXC disappearance and a higher level of appearance of the estrogenic metabolite hydroxyphenyl- trichloroethane (HPTE) as well as other MXC metabolites in hepatic microsomes from the PCB-treated animals compared to the controls in both sexes. In high dose *in vivo* treatments with MXC, the enhanced uterine weights and depressed testicular weights induced by MXC were attenuated in the animals also treated with PCBs. It appears that MXC is metabolized to non-estrogenic metabolites more quickly in PCB-treated animals than in controls. Therefore, PCB exposure is capable of altering the hepatic metabolism of both endogenous estrogens and the pro-estrogen MXC which may influence the response of the developing reproductive system to endogenous or exogenous estrogens. (Supported by EPA R825296.)

1762 NOVEL SUBSTRATE AND INHIBITOR PROPERTIES OF CATFISH INTESTINAL PHENOL SULFOTRANSFERASE (SULT) WITH HYDROXYLATED BENZO[A]PYRENES.

P. van den Hurk and M. O. James. *University of Florida, Gainesville, FL.*

Hydroxylated xenobiotics ingested in the diet, including phenolic and dihydrodiol metabolites of benzo(a)pyrene (BaP) may be sulfated in the intestine, and this may influence their absorption and toxicity. Mammalian SULT enzyme activity can be inhibited by environmental compounds, including pentachlorophenol (PCP) and 2,6-dichloro-4-nitrophenol (DCNP), as well as bioflavonoid natural products. Cytosol from intestinal mucosa of the channel catfish was incubated with 3- or 9-hydroxyBaP, BaP-7,8-dihydrodiol (BaP-7,8D) or 2-naphthol as substrates and PAPS as cosubstrate. The phenolic metabolites were readily sulfated, whereas BaP-7,8-D was a very poor substrate. Incubation of intestinal cytosol with 35S-PAPS and increasing concentrations (1 to 50 μM) of BaP-7,8-D revealed dose-dependent sulfation of unknown compounds in the reaction mixture. Preliminary results showed a comparable stimulation of the sulfation of 3-OH-BaP when low concentrations (0.05 to 5 μM) of BaP-7,8-D was added to the reaction mixture, suggesting separate regulatory and catalytic sites of the SULT enzyme. Neither PCP nor DCNP, 0.1 to 10 μM, inhibited sulfation of 3-OHBaP or 2-naphthol as substrates, whereas quercetin inhibited sulfation of both substrates in a

dose-dependent manner. The IC50 of quercetin for 3-OHBaP was 0.5 μM and for 2-naphthol was 5 μM. These results show the potential for intestinal sulfation of phenolic, but not dihydrodiol metabolites of BaP and suggest the catfish SULT differs from mammalian phenol SULT, which is effectively inhibited by PCP, DCNP and BaP-7,8-D. (Supported by ES 05781.)

1763 DIFFERENTIAL BENZO[A]PYRENE METABOLISM AND EXCRETION IN TWO RELATED FISH.

K. L. Willett[1], P. Gardinali[2], J. Rogers[1] and R. T. Di Giulio[1]. [1]*Duke University, Durham, NC and* [2]*Florida International University, Miami, FL.*

Differential susceptibility of polycyclic aromatic hydrocarbon (PAH)-mediated liver cancer exists in two related species of Ictaluridae catfish. The hypotheses to explain this difference are that the relatively insensitive channel catfish 1) do not produce the PAH metabolites associated with DNA binding, 2) they more quickly eliminate PAHs due to greater phase II enzyme activities, and/or 3) they more rapidly repair PAH-DNA adducts than the more sensitive brown bullhead. Livers and bile were collected from each species 6, 24, 72, and 168 hr after a single 10 mg/kg i.p. BaP exposure. Cytosolic 1-chloro-2,4-dinitrobenzene-glutathione-S-transferase (GST) and cis-stilbene oxide-microsomal epoxide hydrolase activities were not significantly different in BaP-treated and control animals. Furthermore, enzyme activities were not significantly different across the time course or between species. HPLC-APCI-MS of bile and bile enzymatically digested to detect glucuronyl transferase (GT), GST, and sulfotransferase (ST) conjugated metabolites indicated that channel catfish more quickly eliminated total biliary metabolites compared to brown bullhead. GT and GST conjugates predominated; ST conjugates were minimal. BaP-diones accounted for the majority of metabolites in both species. Formation of BaP-7,8-dihydrodiol and slower metabolite excretion in brown bullhead samples may be linked to the increased PAH susceptibility in this species.

1764 3-METHYLCHOLANTHRENE (3MC) ALTERS BIOTRANS FORMATION BUT NOT THE BIOAVAILABILITY OF BENZO[A] PYRENE -7,8- DIHYDRODIOL (7,8D) IN AN *IN-SITU* INTESTINAL CATFISH PREPARATION.

K. M. Kleinow[1], M. O. James[2], B. Johnson[1], Z. Lou[2], E. Holmes[1], J. Li[2], C.S. Venugopal[1] and L. Rowland-Faux[2]. [1]*School of Veterinary Medicine, Louisiana State University, Baton Rouge, LA and 2College of Pharmacy, University of Florida, Gainesville, FL.*

Catfish gavage fed semipurified diet with or without 3-MC (10 mg/kg diet) for 10 days were utilized for in situ isolated perfused intestinal preparations. A micelle solution containing either 20 or 40mM [3H]7,8D was administered in the lumen. After a 60 minute perfusion, mucosa, postinfusate and perfusion blood were utilized for assessment of bioavailability and intestinal biotransformation of [3H]7,8D. [3H]7,8D molar equivalents (Meq) were readily available from the intestinal lumen to the intestinal mucosa and the systemic circulation. The mucosa demonstrated dose responsive increases in [3H]7,8D Meq from the 20 to 40mM treatments, however, no significant differences were evident with 3-MC pretreatment from respective controls for both [3H]7,8D concentrations. [3H]7,8D Meq concentrations were consistently greater in the mucosa as compared to the postinfusate and greater for the postinfusate as compared to the blood. The blood demonstrated similar [3H]7,8D Meq concentrations for control and 3-MC treatments at the 40 mM dosage and marginally lower values for the 3-MC treatment at the 20mM [3H]7,8D dose. Postinfusate demonstrated dose related changes in [3H]7,8D Meq concentrations, but no significant changes were evident with 3-MC pretreatment. HPLC analysis demonstrated that [3H] 7,8D, was the primary constituent found in all biological media in all treatments with triols, tetrols and glutathione and glucuronide conjugates also evident. 3MC treated animals exhibited increased amounts of triols, tetrols and glutathione conjugates. These results indicate that dietary 7,8D was readily absorbed and biotransformed by the intestine with variations in metabolite profile evident with 3-MC pretreatment. (NIH ES05781.)

1765 GENDER SPECIFIC ALTERATION OF GLUCURONIDATION IN BROOK TROUT DURING THE ANNUAL REPRODUCTIVE CYCLE.

L. E. Solem[1], R. C. Kolanczyk[2], P. K. Schmieder[2] and J. M. McKim[2]. [1]*NRC, Duluth, MN and* [2]*USEPA, NHEERL, Mid-Continent Ecology Division, Duluth, MN.*

There is limited information on the effect of physiological and biochemical changes associated with the annual reproductive cycle on hepatic phase II biotransformation rates in fish. The purpose of this study was to provide insight regarding metabolic deactivation of xenobiotics and to provide data for the prediction of altered hepatic biotransformation rates and pathways during the reproductive cycle. *In vitro* phase II biotransformation of phenol was assessed using hepatic microsomes isolated from three male and three female brook trout (*Salvelinus fontinalis*) every four weeks from June through December. Glucuronidation of phenol over a range of substrate concentrations (1 to 60 mM) was quantified for the determination of Michaelis-Menten constants (k_m, V_{max}) by HPLC with UV DAD. Initially there were no significant differences in glucuronide rate of formation (pmol/min/mg protein) or total capacity (pmol/min/liver) between immature adult females and males. At the peak of maturation, the maximum rate of glucuronide formation was 4-fold less in females, however, the total capacity was approximately equal between the sexes, due to the increased liver size in the females. The peak alteration in metabolic parameters coincided with increases in the hepatic and gonadal somatic indices and with changes in plasma hormone concentrations. These data provide valuable insight for resolving uncertainties which are central to fish predictive toxicity namely, the role of biotransformation and maturation in chemical disposition.

1766 SEX-LINKED CHANGES IN PHASE I BIOTRANSFORMATION OF PHENOL IN BROOK TROUT OVER AN ANNUAL REPRODUCTIVE CYCLE.

R. C. Kolanczyk[1], L. E. Solem[2], A. D. Hoffman[1], P. K. Schmieder[1] and J. M. McKim[1]. [1]*USEPA, NHEERL, Mid-Continent Ecology Division, Duluth, MN and* [2]*NRC, Duluth, MN.*

The microsomal metabolism of phenol (11°C) over an annual reproductive cycle from June to December has been studied using fall spawning adult brook trout (*Salvelinus fontinalis*). Hepatic microsomes were isolated from three male and three female fish each month. Incubations were optimized for time, cofactor concentration, pH, and microsomal protein concentration. Formation of phase I ring-hydroxylation metabolites, i.e., hydroquinone and catechol, was quantified by HPLC with dual channel electrochemical detection. Sample preparation and chromatographic conditions were optimized to achieve the separation and sensitivity required for the analysis of these labile products. Metabolism of phenol over a range of substrate concentrations (1 to 150 mM) was quantified for calculation of Michaelis-Menten constants (K_m and V_{max}) for each month. Results indicate a nearly equal production of hydroquinone and catechol among males and females in late June. At the peak of maturity (October) there was an approximate ten fold greater production of ring-hydroxylation metabolites noted in females in comparison with males on a total liver basis. The increased production correlated with increased liver size and ovarian development in females. These experiments indicate the importance of quantifying changes in metabolic capacity, in response to large seasonal changes in physiology and biochemistry noted during sexual maturation and spawning.

1767 EVALUATION OF LIVE PRECISION-CUT TISSUE SLICES USING MULTIPLE INDICATORS OF CELLULAR INJURY VIA A CONFOCAL MICROSCOPIC TECHNIQUE.

J. Orozco, R. C. Lantz, D. E. Cromey and A. J. Gandolfi. *University of Arizona, Tucson, AZ.*

Previous studies have shown that cytotoxic effects of toxicants can be monitored in live precision-cut liver slices using confocal microscopic techniques. Initial studies used the live/dead probes Syto-10 and Dead Red to examine cytotoxic effects. These fluorescent probes were again used in conjunction with the intracellular calcium probes Fluo-4 and Oregon Green BAPTA-1, to examine the sequence of toxic effects produced by the toxicant vinylidene chloride (VDC). At multiple timepoints from 2 to 8 hr, toxicant exposed slices from male adult SD rats were removed and stained with various fluorescent probes. Living and dead cells were stained with Syto-10 and Dead Red. Slices were exposed to 2.5μl dye/500 μl media for 15 min in the dark at room temperature, followed by two washes. The Fluo-4 and Oregon Green BAPTA-1 dyes were used to visualize intracellular calcium changes. For each calcium probe, slices were exposed to 5μl dye/500μl media for 20 min. After staining, slices were placed in a 35 mm tissue culture plate (modified to contain a glass coverslip base) and were held in place with aluminum meshing. Slices were viewed using a Leica TCS confocal microscope containing an IRBE inverted microscope and Kr/Ar laser. Simultaneous visualization of the stains was obtained by excitation with the 488/568 laser lines accompanied by FITC and TRITC emission bandpass filters. VDC lead to a selective progressive dam-

age of the slices. Slices displayed little or no dead cells at 2 hr. Dead cells began to appear at 3 hr around blood vessels and progressively spread to encompass the entire slice by 7 hr. Slices stained with calcium probes displayed a similar pattern. Calcium was present in both control and dosed slices; however, dosed slices showed increased levels around the blood vessels. By 7 hr, calcium levels were increased throughout the slices. Control slices showed no cellular damage at timepoints up to even 8 hr. These results indicate that multiple indicators of cell viability can be monitored by evaluation of live tissue slices using confocal microscopy. (Procter & Gamble Exploratory Research Grant).

1768 OPTIMIZATION AND CHARACTERIZATION OF PRECISION-CUT PROSTATE SLICES AS A TOOL FOR TOXICOLOGICAL STUDIES.

J. Orozco[1], A. R. Parrish[2], M. Smelz[1], R. B. Nagle[1] and A. J. Gandolfi[1]. [1]*University of Arizona, Tucson, AZ and* [2]*Texas A & M University, College Station, TX.*

Precision-cut prostate slices offer a valuable new model for studying the prostate. This human slice system has advantages since it maintains stromal-epithelial relationships. In our initial studies, human prostate slices from the peripheral and transitional zones were maintained up to 72 hr. However, due to the androgen dependence for cell-cell interactions in prostate tissue, unsupplemented media was unable to maintain optimal prostate function. Thus, slices from peripheral and transitional zones of the prostate were incubated for 24, 48, and 72 hr in serum free keratinocyte basal medium supplemented with bovine pituitary extract, bovine insulin, hydrocortisone, bovine transferrin, and human epidermal growth factor. Androgen supplemented media contain either 30 nM 5α-androstan-17β-ol-3-one (A) or 30 nM cyclodextrin-encapsulated testosterone (T). Media was collected at 24, 48 and 72 hr and assayed for lactate dehydrogenase (LDH) and prostate specific antigen (PSA). These two viability markers are measures of cellular damage (LDH) and maintenance of secretory function (PSA). Slices were also collected and formalin fixed for histological evaluation. Androgen supplemented media slightly enhanced PSA secretion and reduced LDH leakage in transitional and peripheral slices. Of the two forms of testosterone, A showed the most effect. These results show that the supplementation of testosterone, in particular the 5α-androstan-17β-ol-3-one form, increases the viability and maintains cellular function. (Arizona DCRC Grant I-345.)

1769 PRECISION-CUT TISSUE SLICES FROM TRANSGENIC MICE AS AN *IN VITRO* TOXICOLOGY SYSTEM.

J. M. Catania[1], A. R. Parrish[2], D. S. Kirkpatrick[1], M. Chitkara[1], G. T. Bowden[1], M. Rincon[3], C. J. Henderson[4], K. Brendel[1] and A. J. Gandolfi[1]. [1]*University of Arizona, Tucson, AZ,* [2]*Texas A & M University, College Station, TX,* [3]*University of Vermont, Burlington, VT and* [4]*University of Dundee, Dundee, United Kingdom.*

Using transgenic animals with specific promoter regions encoding for biomarkers coupled to reporter genes as the source of tissue allows for an easily detectable signal for toxic insult, which can readily be measured by *in vitro* methods. This approach combines the power of the transgenic animals with the practicality of *in vitro* systems to investigate the biological impact of xenobiotics. When key regulatory sequences are "tagged," a wide array of mechanistic studies can be performed with specific detection of when and where the gene is expressed in the normal tissue architecture and, more importantly, its role in a sequence of toxic events. Two transgenic mouse lines, one of which couples a 2X tetradecanoyl phorbol acetate (TPA) repeat element (TRE) to luciferase, and another which couples cytochrome P450 1A1 to beta-galactosidase are used to determine the feasibility of this approach. Precision-cut kidney and liver slices from both transgenic lines remain viable as determined by slice ion content and enzyme release. Kidney and liver slices from the 2X TRE transgenic mice demonstrate induction of luciferase (up to 2.5 fold) when treated with TPA. The studies with the P450/beta-galactosidase transgenic mice exhibit an increase in beta galactosidase activity (1.5 fold induction in liver slices) when treated with beta-napthoflavone for 24 hr. These data indicate that precision-cut tissue slices from transgenic mice offer a novel *in vitro* method for reporter detection while maintaining normal cell homogeneity.

1770 A THEORETICAL MODEL FOR SIMULATING THE OUTCOME OF MECHANISM-BASED *IN VITRO* TOXICITY TESTING STRATEGIES.

J. Frazier. *AFRL/HEST, Wright-Patterson AFB, OH.*

In order to investigate the fundamental principles that control the optimum selection of alternative test methods for the evaluation of chemical hazards, it is necessary to have a model system to explore possible alternative testing strategies. In general, our lack of detailed knowledge of the mechanisms of toxicity (including not only the early events in the interaction of chemicals with biological systems, but the sequence of subsequent events that lead to measurable toxicity) limit the development of quantitative dynamic models of the toxicological process for individual chemicals. We report here the development of a theoretical model that includes various potential mechanisms of toxicity. The "mechanisms" incorporated into the model are qualitatively similar to known mechanisms of action. The model is exercised to simulate the responses that would be observed using alternative batteries of *in vitro* endpoint measurements for a collection of test chemicals. The data generated are used to evaluate the relative effectiveness ("validity") of several testing strategies based on *in vitro* toxicity tests. (This research was supported by the Air Force Office of Scientific Research.)

1771 A NOVEL *IN VITRO* SYSTEM FOR EXPOSURES OF CELL CULTURES TO VOLATILE CHEMICALS.

K. Geiss[1] and J. Frazier[2]. [1]*Geo-Centers, Inc., Dayton, OH and* [2]*AFRL/HEST, Wright-Patterson AFB, OH.*

A major concern when conducting *in vitro* testing of volatile chemicals is loss of the chemical during the course of experimental studies. Such losses, due to volatility, affect dosimetry. Different engineering solutions have been developed, previously, to address this issue. However, the limitations of those systems make them impractical for many research applications. We have designed a novel system for exposing microwell plate cultures of primary rat hepatocytes to volatile chemicals. Our system allows for static or flow-through dosing methodologies, with ports for continuous sampling of both the headspace and media. Each chamber can hold multiple microwell plates or petri dishes and fits easily into a standard laboratory incubator. We have evaluated the efficacy of the chamber by comparing the responses of cells in the chamber to those cultured in a standard incubator, without chemical dosing and with dosing of low-volatility chemicals, e.g. hydrogen peroxide. The results show no difference between the treatments, as indicated by the responses of standard viability markers (MTT and LDH). Our current experiments have focused on halogenated chemicals. In one series of experiments, cell cultures were dosed with carbon tetrachloride in the chamber. When compared to cells not exposed to the chemical, cells receiving doses of 0.55, 1.75 and 3.11mM carbon tetrachloride exhibited catalase activity decreased to 66%, 25%, and 8%, lipid peroxidation products were elevated 205%, 294%, and 382%, and cellular viability was 95%, 90%, and 15%, respectively.

1772 THE DEVELOPMENT OF SIMPLE *IN VITRO* CYTOXICITY SCREENING MODELS FOR DRUG DEVELOPMENT.

M. Tsai[1], A. DePeyster[1] and G. Stevens[2]. [1]*San Diego State University, San Diego, CA and* [2]*Agouron Pharmaceutical Inc., San Diego, CA.*

The goal of this study is to design two to three *in vitro* cytotoxicity screening models to support drug development and discovery. Cytotoxicity screening models are useful in assessing the toxicity in early stages of drug discovery, as well as investigating the toxicity of degradants, impurities (byproducts, intermediates), and metabolites in the later stages of drug development. Three cell lines (MDCK, HepG2, and Caco-2) representing kidney, liver, and colon, respectively, were used to evaluate the cytotoxic and apoptotic effects of different toxicants. The assays were performed in a 96-well plate format with each concentration of test article incubated in triplicate for 24 hours. Solvent (DMSO)-treated wells were used as the control at a final concentration of 1%. The three cell lines showed differences in sensitivity to known target organ toxicants as measured by colormetric (MTT) and fluorometric endpoints (apoptosis). The rank order for cytotoxicity in MDCK cells was cisplatin > 5-fluorouracil > acetaminophen. Cisplatin showed dose-dependent cytotoxicity, which induced significant cytotoxic effects at 5 mM. The rank order for cytotoxicity in HepG2 cells was bromobenzene > tamoxifen > alfatoxin B1. Less than 1% of bromobenzene and 50- 100 micro-M of tamoxifen induced substantial cytotoxicity within 24 hours. The rank order for cytotoxicity in Caco-2 cells was cisplatin > 5-fluorouracil > etoposide. Besides cisplatin at 5 mM, 5-fluorouracil and etoposide revealed minimal toxicity in Caco-2 cells. These established cells lines and endpoints provide for a rapid and simple method to screen a large number of compounds with a minimum amount of test material (<25 mg).

1773 *IN VITRO* CYTOTOXICITY TESTING WITH CULTURED HUMAN LUNG AND DERMAL CELLS.

A. Yang, D. L. Cardona and F. A. Barile. *City University of New York, York College, Jamaica, NY.*

An extensive *in vitro* study using human cultured cells was conducted to test the basal cytotoxicity theory. This theory suggests that most chemical injury, at least *in vitro*, is a manifestation of one or more insults to the basic cellular structures and functions common to mammalian cells. This accounts for the similarity of results in multilaboratory studies. Human lung epithelial carcinoma (A549) cells, and human skin fibroblasts (WS1 and Detroit551) were studied in culture to evaluate their potential to screen for cytotoxicity. Confluent monolayers were incubated in the absence or presence of increasing concentrations of test chemicals for 24-hours, and fluorescent-labelled probes were used to assess toxicity. Inhibitory concentrations were extrapolated from concentration-effect curves after linear regression analysis. Ten chemicals, including arsenic, mercury, copper, sodium flouride, nicotine, caffeine, thioridazine, paraquat, amitriptyline, and chloroquin, were tested with each cell line using calcein-AM and Sytox. The data suggest that fluorescent probes are sensitive indicators of toxicity and contribute to understanding the mechanisms for each chemical. In addition, A549 cells revealed some significant differences from skin fibroblasts in their response to toxic insult. In combination with previously published reports, our study suggests that a basal cytotoxic phenomenon may only explain the similarity of results between skin fibroblasts and other finite human cell lines. (Supported by NIH, NIGMS Grant GM08153.)

1774 OXYGEN BIOSENSOR SYSTEMS: A HOMOGENEOUS FLUORESCENCE TECHNOLOGY FOR TOXICITY ASSAYS.

M. Timmins[1], R. Guarino[2], M. Wodnicka[2], D. Asa[1] and D. Stitt[3]. [1]*BD ViaSante, Bedford, MA,* [2]*BD Technologies, Research Triangle Park, NC and* [3]*BD Biosciences, Baltimore, MD.* Sponsor: D. Acosta, Jr.

BD ViaSante's Oxygen BioSensor System* represents a platform technology adaptable to a large number of cellular and subcellular applications in the Drug Discovery and Development arena. This technology allows researchers to fluorescently and unobtrusively monitor the level of dissolved oxygen in an assay medium, and may be adapted to any number of automation-friendly platforms, including 96- and 384-well FALCON® brand microtiter plates. Because they allow for continuous real-time read-out without the need for additional reagents, Oxygen BioSensor Systems are ideally suited for kinetic monitoring of cells in toxicity assays, proliferation assays, or any other assay where researchers would like to know the relative viability of the cells in the assay. Because the Oxygen BioSensor is entrapped within an inert polymeric matrix, the determination of oxygen concentration in no way perturbs the cell culture, this makes these systems an ideal platform for assay multiplexing. To demonstrate the simplicity and effectiveness of this platform technology, a series of standard toxicity screens were performed using a range of toxic agents and cell lines. In all cases, the signal from the Oxygen BioSensor System was easily detected, and correlated directly to the number of cells in the assay. In a side-by-side comparison with standard MTT assays for cellular toxicity, the Oxygen BioSensor System gave the same IC50 values as MTT, but without the need for additional reagents, handling steps, or incubation periods. Moreover, the fact that Oxygen BioSensor Systems could be read repeatedly, facilitated the generation of kinetic toxicology profiles. These profiles also correlated to the known modes of action of the drugs studied. Hence, with minimal additional effort, and no additional reagents, the BD ViaSante Oxygen Sensor System upgraded a standard toxicity screen into a more predictive and informative assay for cellular toxicity.

1774A EVALUATION OF THE EFFECT OF 2,3-DIMERCAPTO-PROPANE-1-SULFONATE (DMPS) AGAINST MERCURY CYTOTOXICITY IN PRIMARY LIVER AND KIDNEY CELL CULTURES.

O. Torres-Alanis and L. Garza-Ocanas. *Fac. De Medicina Universidad Autonoma, Neuvo Leon, Mexico.*

The effect of 2,3-Dimercaptopropane-1-sulphonate (DMPS) against the mercury cytotoxicity was studied in primary rat liver and kidney cells cultures. Hepatocytes and kidney cells were pretreated with DMPS (0.2mM) and 30 minutes later were exposed to $HgCl_2$ (60μM) for 12 and 24 h. Cytotoxicity was evaluated by neutral red (NR) uptake and mitochondrial metabolic activity (methylthiazoltetrazolium (MTT) test). A significant decrease of 96% on MTT reduction and of 75% on NR uptake was observed after 12 h exposure to 60μM $HgCl_2$. On the other hand in the DMPS pretreated cells and then exposed to $HgCl_2$ (12 h) a decrease of 14% on MTT reduction and of 20% on NR uptake was observed in the hepatocytes and 20% (MTT) and 25% (NR) in the kidney cells. DMPS (60 μM) did not produce cytotoxicity. **Conclusion:** DMPS produced a significant protective effect against the *in vitro* cytotoxicity of mercury in primary liver and kidney cell cultures.

1775 RELATIVE TOXICITY OF KETOCONAZOLE (KETO) AND CHLORAMPHENICOL (CAP) IN RAT AND HUMAN HEPATOMA CELL LINES: APPLICATIONS FOR *IN VITRO* TOXICITY SCREENING.

P. C. Wilga, D. K. Petrella, J. F. Pregenzer, G. N. Cosma, M. A. Fisher, G. L. Cockerell and J. M. McKim. *Pharmacia & Upjohn, Kalamazoo, MI.*

Toxicity and mechanistic data, incorporated early in the drug discovery process, should allow compounds to be prioritized in a manner that would maximize efficacy while reducing toxicity. *In vitro* toxicity screening allows compounds within a therapeutic class to be prioritized for subsequent development based on the concentration that produces a half-maximal toxic response (TC50). Immortalized cell lines are routinely used for *in vitro* screening. However, the potential for cell lines from different species to respond differently when exposed to the same drug (e.g.TC50 values) must be defined. Therefore, the primary objective of the present study was to compare the toxicity of KETO and CAP in rat (H4Ile) and human (HepG2) hepatoma cell lines by monitoring cell viability via MTT reduction and ATP levels. Both cell types were seeded into 96-well plates at a density of 50,000 cells/mL in minimum essential medium with 10% serum in a final volume of 200 μl. Following a 48 hr growth period, media was removed and the cells were dosed with either KETO (0 to 300 μM) or CAP (0 to 20 mM) in media (0.5% DMSO). After 24 hrs, media was removed and MTT and ATP assays performed. KETO produced a dose-related decrease in MTT and ATP in H4Ile cells with TC50 values of 50 μM and 70 μM respectively. In HepG2 cells, exposure to KETO produced TC50 values for MTT and ATP of approximately 70 μM. Exposure to CAP produced a dose-related decrease in MTT and ATP with a TC50 of 2 mM in H4Ile cells. In HepG2 cells, CAP yielded TC50 values of 4 mM for MTT and 10 mM for ATP. In conclusion, both cell lines responded in a similar manner to CAP and KETO with H4Ile cells being slightly more sensitive than HepG2 cells. Ongoing studies of mitochondrial dysfunction as a common biological pathway of CAP and KETO toxicities are being performed in isolated hepatic mitochondria to elucidate and compare the subcellular responses of both cell lines to these agents.

1776 THE CELISA ASSAY CAN BE USED IN PLACE OF THE HEMATOPOIETIC COLONY ASSAY TO SCREEN FOR ERYTHROTOXICITY.

D. E. Greenwalt and A. Bossie. *Poietics/BioWhittaker, Walkersville, MD.* Sponsor: G. E. Dearlove.

The CELISA™ assay can be used in place of the hematopoietic colony assay to screen for erythrotoxicity. Erythrotoxicity is currently assayed through use of the clonogenic "colony assay". The extremely low throughput of the colony assay precludes its use in high throughput toxicity testing. A high-throughput CELISA assay of erythropoiesis based on the quantification of differentiation-dependant synthesis of hemoglobin has been developed. Either human hematopoietic progenitors or committed erythroid precursors can be utilized to initiate the assay; the time required for completion of the assay with these two cell types is 10 and 5 days respectively. The erythroid progenitors do not express classical markers of erythroid differentiation but rapidly begin to synthesize hemoglobin and express cell-surface glycophorin A after they are placed in culture. The CELISA assay was used to examine the effect of a known inhibitor of hemoglobin biosynthsis, succinylacetone, on hemoglobin accumulation in erythroid progenitors. Inhibition of hemoglobin biosynthesis by succinylacetone was 86%, a value nearly identical to that reported previously. After the required cell culture period, the CELISA assay requires only 90 minutes for quantification, as opposed to the lengthy process of manually counting colonys required by the colony assay. The CELISA assay is a 96-well-based suspension culture system available for use by researchers seeking a more high-throughput protocol for toxicity screening. These results indicate that the CELISA assay system can substitute for the clonogenic colony assay for screening potential erythrotoxic agents.

1777 PREVALIDATION OF THE EPIDERM PHOTOTOXICITY TEST (ED-PT).

M. Liebsch[1], D. Traue[1], C. Barrabas[1], H. Spielmann[1], F. Gerberick[2], L. Cruse[2], W. Diembeck[3], U. Pfannenbecker[3], J. Spieker[3], H. Holtzhutter[4], P. Brantom[5], P. Aspin[5] and J. Southee[6]. [1]*ZEBET BgVV, Berlin, Germany,* [2]*Procter & Gamble Co., Cincinnati, OH,* [3]*Beiersdor AG, Hamburg, Germany,* [4]*Humbolt University, Berlin, Germany,* [5]*BIBRA International, Carshalton, United Kingdom and* [6]*MA Bioservices, Richmond, United United Kingdom.*

The EpiDerm™ phototoxicity test was chosen for prevalidation within ECVAM's tiered prevalidation procedure. In phase 1, ZEBET drafted an SOP and project plan for conducting the study. ZEBET's task in phase I was to adapt the existing Skin2 methodology to the specific needs of the epidermal model EpiDerm. UVA sensitivity experiments revealed 6J/cm2 as the highest non-cytotoxic UVA dose and exposure to test materials for 3, 6, and 21 hours before UVA irradiation revealed 21 hours to be the optimum exposure time. Established phototoxins were used to evaluate the method and were correctly identified. In phase II, taking into account the patch technique used *in vivo*, the three participating laboratories amended this technique and evaluated its usefulness for the EpiDerm test. Results revealed that the patch technique was useful for chemicals applied in oil but not in water. Since reproducibility of the data within, and between, the laboratories was excellent, it was decided to proceed to phase III. In phase III, ZEBET drafted the final SOP, and BIBRA selected ten chemicals for the blind trial. Each of the chemicals was tested twice independently in each laboratory and the data were submitted for biometrical analysis, which confirmed the expected predictivity and robustness of the test; only one positive chemical (tetracycline) was not detected as a phototoxin and none of the negative chemicals was over predicted as a phototoxin. We conclude that the ED-PT 1) meets the criteria previously determined for the Skin2 PT, 2) allows use of complex matrixes, 3) is an adjunct test to the 3T3 NRU PT, 4) is ready to undergo formal validation.

1778 CORROSITEX®, AN *IN VITRO* DERMAL CORROSIVITY TEST FOR PREDICTING THE *IN VIVO* CORROSIVITY POTENTIAL OF CHEMICALS/COMPOUNDS: ANALYSIS OF PERFORMANCE.

K. E. Haneke[1], T. L. Goldsworthy[1], R. R. Tice[1] and W. S. Stokes[2]. [1]*NTP Interagency Center for the Evaluation of Alternative Toxicological Methods, NIEHS and ILS, Inc., Research Triangle Park, NC and* [2]*NTP Interagency Center for the Evaluation of Alternative Toxicological Methods, NIEHS, Research Triangle Park, NC.*

The performance of Corrositex®, an *in vitro* dermal corrosivity testing method for predicting *in vivo* dermal corrosivity, was analyzed. Corrositex® data from several sources for 163 test materials were compared against data generated using the rabbit skin corrosivity test. The overall accuracy of Corrositex® was 79% (128/163) for all test materials; 75% (27/36) for inorganic and organic acids plus acid mixtures; 93% (13/14) for acid derivatives; 80% (20/25) for amines; 83% (29/35) for inorganic and organic bases plus base mixtures; and 81% (69/85) for organic and inorganic acids and bases. Corrositex® data were also compared to results obtained using pH extremes as an indicator of the corrosivity potential of chemicals. Current US Environmental Protection Agency regulations (40 CFR 158.690) specify that primary dermal irritation testing requirements can be waived for chemicals that have pH values less than 2 or greater than 11.5; such materials are labeled as toxicity category 1 because of the potential corrosive effect. A detailed comparison of data for these pH extremes and Corrositex® showed that both pH and Corrositex® are highly predictive of the corrosivity of chemicals in the pH extreme ranges. However, Corrositex® was more accurate than pH for predicting corrosivity potential. (Supported by NIEHS Contract N01-ES-85424 to ILS, Inc. Sponsored by the SOT Regulatory and Safety Subspecialty Committee.)

1779 RESULTS OF AN ICCVAM-SPONSORED PEER REVIEW PANEL EVALUATION OF CORROSITEX®.

R. R. Tice[1], R. A. Scala[2], R. Hill[3], T. L. Goldsworthy[1], K. E. Haneke[1] and W. S. Stokes[4]. [1]*NTP Interagency Center for the Evaluation of Alternative Toxicological Methods, NIEHS and ILS, Inc., Research Triangle Park, NC,* [2]*NTP Interagency Center for the Evaluation of Alternative Toxicological Methods, NIEHS, Tuscon, AZ,* [3]*USEPA, Washington, DC and* [4]*NTP Interagency Center for the Evaluation of Alternative Toxicological Methods, NIEHS, Research Triangle Park, NC.*

Corrositex®, an *in vitro* dermal corrosivity test method, was recently evaluated by an independent Peer Review Panel (Panel) convened by the Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM). The method was evaluated as to its usefulness as an alternative test method for predicting the *in vivo* corrosivity potential of chemicals and compounds. The Panel assessed inter- and intra-laboratory performance and the testing results for 163 chemicals tested with Corrositex® and for which there was *in vivo* data. In a January 21, 1999 public meeting in Bethesda, MD, the Panel concluded that, in specific testing circumstances such as that required by the US Department of Transportation, Corrositex® is useful as a stand-alone assay for evaluating the corrosivity or noncorrosivity of acids, bases, and acid derivatives. In other testing circumstances and for other chemical/product classes, the Panel concluded that Corrositex® may be used as part of a tiered testing strategy, where positive responses require no further testing and negative responses must be followed by dermal irritation testing. The Panel recommended that in either testing strategy, an investigator may conclude that confirmation testing is necessary based on consideration of supplemental information (e.g., pH, structure-activity relationships). The use of Corrositex® as part of a tiered testing approach reduces and refines animal use by eliminating the need to further test substances that are determined to be corrosive. Substances that are negative in Corrositex® or that do not qualify for testing are also unlikely to be corrosive. Corrositex®, when used as a stand-alone assay for certain chemical classes, replaces animal use for corrosivity testing. (NICEATM supported by NIEHS Contract N01-ES-85424 to ILS, Inc. Sponsored by the SOT Regulatory and Safety Subspecialty Committee.)

1780 AN *IN VITRO* MODEL TO STUDY THE PROTECTIVE EFFECT OF BISMUTH AGAINST CISPLATIN INDUCED NEPHROTOXICITY.

B. T. Leussink[1], E. de Heer[2], G. B. van der Voet[1], A. Slikkerveer[1], J. A. Bruijn[2] and F. A. de Wolff[1]. [1]*Toxicology Laboratory, Leiden University Medical Center, Leiden, Netherlands and* [2]*Department of Pathology, Leiden University Medical Center, Leiden, Netherlands.* Sponsor: G. J. Mulder.

Renal impairment due to tubular damage is an important, dose-limiting side effect of the cytostatic agent cisplatin. Animal and clinical studies provided evidence that bismuth salts are able to reduce cisplatin nephrotoxicity without compromising its anti-tumour activity. We developed an *in vitro* model to elucidate the mechanism of this protective effect using NRK-52E cells, a rat kidney cell line of tubular origin, grown to near-confluence on glass slides. The cells were pre-treated with 100 μM BiCl3 and 400 μM citrate in serum free medium for 12 to 48 hours. Subsequently, the cells were incubated in serum free medium for 6 to 24 hours before being treated with 50 μM cisplatin for 41 hours. Normal, necrotic and apoptotic cells could be discerned after staining with Hoechst 33258, a DNA-specific dye. Cisplatin treatment caused part of the cells to become apoptotic as detected by the fragmentation of the nuclei. Bismuth pre-treatment significantly lowered the percentage of apoptotic cells when compared to controls which had been pre-treated with citrate only. The largest reduction found was from 77% ±15 (SD) to 41% ±9 apoptotic cells. Conclusion: This *in vitro* model can serve to investigate the mechanism of the protective effect of bismuth against cisplatin induced nephrotoxicity in order to prevent or reduce this side effect or enabling the use of higher cisplatin doses.

1781 NEUROPROTECTIVE ROLE OF MELATONIN IN METHAMPHETAMINE-INDUCED DOPAMINERGIC NEUROTOXICITY.

H. M. Duhart[1], S. Z. Imam[1], G. D. Newport[1], W. Slikker, Jr.[1], Y. Itzhak[2] and S. F. Ali[3]. [1]*National Center for Toxicological Res./FDA, Jefferson, AR,* [2]*University of Miami School of Medicine, Miami, FL and* [3]*National Center for Toxicological Res./FDA, Jefferson, AR.*

Methamphetamine (METH)-induced dopaminergic neurotoxicity is thought to be associated with the formation of free radicals. Since evidence suggests that melatonin may act as a free radical scavenger and antioxidant, the present study was undertaken to investigate the effect of melatonin on METH-induced dopaminergic neurotoxicity, both *in vitro* and *in vivo*. PC12 cell cultures were exposed to METH (250-1000 μM) in the presence or absence of melatonin (500 μM). METH caused a dose dependent depletion of dopamine (DA), and its metabolites DOPAC and HVA in PC12 cells. Treatment with melatonin did not protect against the depletion of DA or its metabolites. For *in vivo* studies, adult male Swiss-Webster mice were injected with METH (5 mg/kg x 3) and humanely killed after 72 hr. METH administration caused 45-57% depletion in the content of striatal DA and its metabolites, DOPAC and

HVA. The administration of melatonin (10 mg/kg) before each of the three injections of METH (on day 1), and thereafter for two additional days, afforded full protection against METH-induced depletion of DA and its metabolites DOPAC and HVA. Body temperature was also recorded during METH treatment. Melatonin significantly diminished METH-induced hyperthermia. Since it is postulated that METH-induced hyperthermia is related to its neurotoxic effect, the protective effect of melatonin observed *in vivo* but not *in vitro* may be due primarily to diminishing METH-induced hyperthermia.

1782 USE OF CELL AND ORGANOTYPIC CULTURES TO DEFINE MECHANISMS UNDERLYING THE MARKED TOXICITY OF THE TERATOGENIC RETINOID, TTNPB.

M. A. Pignatello[1], F. C. Kauffman[2] and A. A. Levin[3]. [1]*Lab. of Cell. & Biochem. Tox., Rutgers Univ.: Piscataway, NJ; Department of Non-Clin. Drug Safety, Hoffmann-LaRoche, Inc., Nutley, NJ,* [2]*Lab. of Cell. & Biochem. Tox., Rutgers Univ., Piscataway, NJ and* [3]*Dept. of Tox., ISIS Pharmaceuticals, Carlsbad, CA.*

The aromatic retinoid, (E)-4-[2-(5,6,7,8-tetrahydro-5,5,8,8-tetramethyl-2-naphthylenyl)-1-propenyl] benzoic acid (TTNPB) is 1000-fold more teratogenic than all trans-retinoic acid (tRA) in several species. The remarkable potency of TTNPB is due, in part, to binding to nuclear receptors (RARs) in the nanomolar range, reduced affinities for the cytosolic binding proteins and slow rate of metabolism (Toxicol. Appl. Pharmacol. 142:319-327, 1997). The present work investigates whether differences in transcriptional activity of the ligand receptor complex and/or the long half life of TTNPB could account for the great toxicity of TTNPB. The ability of TTNPB and tRA to activate the RARs was determined using a reporter construct driven by the tRA response element that was transfected into JEG3 cells. After 24 hours, tRA activated the RARs with greater efficacy and with EC50s that range from 30-90% greater potency than those of TTNPB. However, after 72 hours, TTNPB was more efficacious in activating RARs, and EC50s were 7- to 63-fold more potent than those for tRA. Mouse limb bud cell cultures, a well characterized model for retinoid teratogenesis, were used to examine the role of metabolic stability and teratogenesis. We examined whether inhibiting the metabolism of tRA in the limb bud assay markedly increases its potency in relation to that of TTNPB. Liarozole, a 4-hydroxylase inhibitor of tRA was used at concentrations that did not affect chondrogenesis. In the absence of liarozole, tRA was 465-fold less potent than TTNPB. In the presence of liarozole, the potency of tRA was only 12-fold less than tRA despite the fact that inhibition of metabolism was less than 2-fold. Thus, inhibiting metabolism of tRA by a small amount may have marked effects on the toxicity of this compound in the mouse limb bud cell assay. This data strongly suggests that the long half life of TTNPB may be the most significant factor in understanding the toxicity of TTNPB.

1783 REACTIVE OXYGEN SPECIES FORMATION IN EXPERIMENTAL MODELS OF HUNTINGTON'S DISEASE.

L. Osorio-Rico[1], H. Duhart[2], S. Ali[2], C. Rios[1] and A. Santamaria[1]. [1]*Instituto Nacional de Neurologia y Neurocirugia, Mexico D.F., Mexico and* [2]*Division Neurotoxicology NCTR-FDA, Jefferson, AK.*

Experimental models of Huntington's disease (HD) can provide information on biochemical and molecular aspects leading to brain damage. Three models of HD are well-known so far: a) Quinolinic acid (QUIN), a tryptophan metabolite, induces overactivation of NMDA subtype of glutamate receptors and enhances oxidative stress by lipid peroxidation; b) intrastriatal administration of kainic acid (KA) produces neuronal death involving non-NMDA and NMDA receptors, and calcium influx via voltage-gated Ca^{2+} channels, also activating toxic pathways and generating free radicals; and c) 3-nitropropionic acid (3-NP) acts at mitochondrial level producing a depletion of ATP synthesis and membrane depolarization, overactivation of voltage-gated NMDAr and excitoxicity. In this study we compared the effects of QUIN, KA and 3-NP on the formation of reactive oxygen species (ROS) in rat brain synaptosomes. Synaptosomes were incubated with QUIN, KA and 3-NP (25-2000 μM) during 60 min at 37°C. ROS technique used 2'7'-dichlorofluorescein-diacetate (DCFH-DA) to detect cerebral ROS. These toxins produced a concentration-dependent increase of ROS formation in synaptosomes. 3-NP resulted more potent than QUIN and KA to produce ROS at all concentrations tested (3-NP>QUIN>KA). Results indicate involvement of ROS in the pattern of toxicity elicited by these toxins as well as differential potencies to produce oxidative damage. (CONACyT Grant J28612-M.)

1784 EVALUATION OF THE EFFECT OF RODENT CARCINOGENS ON THE EXPRESSION OF BIOTRANSFORMATION ENZYMES IN HUMAN HEPATOCYTES.

M. D. Mitchell, D. L. Morris and J. C. Davila. *Monsanto, St. Louis, MO.*

The objective of this study was to develop a feasible, reproducible and simple human hepatocytes culture system for evaluating xenobiotics as hepatic enzyme inducers, which could be used for routine toxicology. Human hepatocytes cultured with Matrigel in a serum-free medium containing low concentrations of insulin (1 μM) and hydrocortisone (0.1 μM), responded to prototypical liver CYP450 enzyme inducers (phenobarbital, PB; dexamethasone, DEX; rifampicin, RIF; 3-methyl-cholanthrene (3MC); and clofibrate; CLO) and rodent carcinogens (methapyrilene, MET; tamoxifen, TAM; cyproterone, CY; isoniazid, INZ, and 2-acetyl aminofluorene, 2AAF) with enhanced levels of expression of inducible forms of CYP450. The mRNA levels of human CYP450 isoforms (CYP1A, CYP2B, CYP3A, CYP4A) were measured by RT-PCR and fluorogenic DNA probe technology. Hepatocytes were found to respond to chemical CYP450 inducers with marked increases in enzyme expression at the mRNA levels and in a concentration related fashion. CYP3A was found to be induced by RIF, DEX, TAM, CY, MET, and PB; CYP1A was induced by 3MC, MET, TAM, INZ; CYP2B was induced by PB, MET, DEX, RIF and TAM. And CYP4A was found to be induced by CLO and MET. The results from this study indicate that human hepatocytes cultured with diluted Matrigel and coupled with enzyme mRNA expression analysis by RT-PCR have proven to be a valuable and important *in vitro* toxicological approach to assess the chemical-induced changes in expression of liver CYP450 enzymes in humans.

1785 DRUG METABOLIZING ENZYME ACTIVITIES IN THE HUMAN COLORECTAL CARCINOMA CELL LINES CACO2 AND HT29.

S. Weber, S. Birkner and W. Föllmann. *Institute for Occupational Physiology at the University of Dortmund, Dortmund, Germany.* Sponsor: K. Golka.

Drug metabolizing enzyme activities were characterized in $CaCo_2$ and HT29, two frequently used human colorectal carcinoma cell lines, in order to give an overview of the metabolic potency of the cells and to use them as cellular model system in toxicological *in vitro* studies. The influence of the status of confluency of the cell monolayer on enzyme activities was studied by performing measurements after 2, 7, 14 and 21 days of culture. Scanning electron microscopic investigations demonstrated a differentiation during prolonged culture detectable by an increase of microvilli of the apical membrane and development of domes in $CaCo_2$ cultures. Cytochrome P 450 1A1/2-associated EROD activity was detectable only in induced $CaCo_2$ cells but not in HT29. In both cell lines no cytochrome P 450 3A4-associated activity was observed in the BEROD-assay. Expression of mRNA of the two isoforms of prostaglandin H synthase (PHS) was evaluated by RT-PCR. $CaCo_2$ cells exhibit only the PHS 2 isoform whereas HT29 exhibits both isoforms, PHS 1 and 2. PHS-mediated production of prostaglandin E2 was 2-fold higher in $CaCo_2$ cells compared to HT29 cells. N-acetyltransferase-1 could be detected in both cell lines and increased during the observed culture period. Total glutathion S transferase activity was constant in both cell lines. For UDP-glucuronyl-transferase a decline of activity was observed during the culture period. Only low activity of amino- and phenol-sulfotransferase was observed. Our results show that both cell lines maintain several enzyme activities required for the biotransformation of xenobiotics mostly independent from the confluency of the monolayer. In further studies the suitability of the cell lines for detection of genotoxic effects in the single cell gel electrophoresis assay (comet assay) should be investigated.

1786 PROCEDURE TO ESTIMATE THE PHAGOCYTIC ACTIVITY OF NAÏVE AND PARTICLE-EXPOSED MACROPHAGES USING LATEX MICROSPHERES.

H. A. Ragan, D. L. Redetzke and K. M. Lee. *Battelle, Richland, WA.*

Lack of clear guidelines makes the comparison of phagocytic activity of macrophages difficult and inconsistent, as the results are subject to interlaboratory variations. This study was conducted to standardize the procedure to estimate the phagocytic activities of naïve and particle-exposed pulmonary alveolar macrophage (PAM). The procedure was adapted from Cohen et al.

(1997) and generated case-by-case pictures of PAM in various stages of phagocytosis. Young male F344 rats (BW: 200-250g) were used in all experiments (n=3-5/group). Naïve PAM were obtained from non-treated lungs and particle-exposed PAM were from lungs instilled with vanadium pentoxide (V_2O_5: 0, 0.63, or 6.3 mgV/kg). The bronchoalveolar lavage (~7 ml/wash) was done at 3 days following the instillation. Cell pellets from all six washes were combined to make the cell suspension that was diluted to 5.56×10^5 PAM/ml RPMI buffer and incubated at 37° for up to 150 min with serum-opsonized polystyrene latex microspheres ([bead:cell]=[100:1]). Slides were made by a cytospin, fixed in methanol, and stained for light microscopic examination. Xylene washing was effective in removing superficially attached beads on the slides. Incubation for at least 90 min was required to obtain the maximum estimates for the phagocytic index (PI:1-2 beads) and the phagocytic capacity (PC:≥3 beads), which were 40±6% and 21±5% for naïve PAM. Guidelines employed were: 1) the beads and the cells shall be in the same plane, 2) beads attached to cells or in the process of phagocytosis are not counted unless at least 2/3 engulfed by the cytoplasm of the cells, and 3) ingested beads exhibit a characteristic dark ring around, whereas merely attached ones are not. There was no difference in PI or PC among naïve or saline-instilled controls and the low V_2O_5 dose group. With the high dose group, PI increased to 56±9% while PC stayed the same (23±6%). V_2O_5-exposed lungs also contained significant numbers of PMN especially at high dose. Both PI and PC for PMN (PI=23±6%; PC=5±4%) of the high dose group were substantially lower than those of PAM.

1787 ESTABLISHMENT AND CHARACTERIZATION OF THE FOLLICULAR THYROID CARCINOMA CELL LINE ML-1 — A TOOL FOR TOXICOLOGICAL STUDIES.

D. Grimm[1], J. Schönberger[2], M. Paul[1] and I. Chahoud[1]. [1]*Institute of Clinical Pharmacology and Toxicology, Berlin, Germany and* [2]*Department of Nuclear Medicine, Regensburg, Germany.* Sponsor: R. Stahlmann.

Chemicals may interfere with the production of thyroid hormones. Therefore, the aim of this study was to establish a human hormone-producing thyroid carcinoma cell line to obtain a permanent tool for toxicological investigations.The human cell line ML-1 was derived from a dedifferentiated follicular thyroid carcinoma recidive, which progressed despite of one preceding surgery followed by two radioiodine therapies. More than 90% of the cells of this line produce thyroglobulin, chondroitin sulfate and vimentin antigens, but only about 70% of them show cytokeratin filaments and a negative surface charge density like human erythrocytes. The cell line forms tumors with follicular structures, when transplanted to nude mice. More important, cells of this line are able to take up iodine and/or glucose *in vitro* as well as *in vivo* and to secrete thyroglobulin, chondroitin sulfate and fibronectin into the interstitial space. As measured by radioimmunoassay and ELIZA, even triiodothyronine is released constitutively into culture supernatants. Due to these unique features, the ML-1 cell line, so far the first human cell line derived from a follicular thyroid carcinoma, appears to be a very suitable test model for toxicological, pharmacological and cell biological studies.

1788 THE UROTSA CELL LINE AS A MODEL OF HUMAN UROTHELIUM.

M. R. Rossi[1,2], J. H. Todd[1], D. A. Sens[1], S. H. Garrett[1], J. Nath[2], M. A. Sens[1] and S. Somji[1]. [1]*Dept. of Pathology and* [2]*Dev. Biology and Genetics Program, West Virginia University, Morgantown, WV.*

The only available human urothelial cell line for use in toxicology-based research studies is the UROtsa cell line obtained from normal human urothelium by immortalization using an SV40 large T-antigen construct. These cells are immortal, proliferate on a simple growth medium (RPMI with 10% fcs), form monolayers and have an epithelial morphology, but do not possess morphological features expected for bladder urothelium. Rather, they have features characteristic of undifferentiated basal cells. The goal of the present study was to determine if growth of UROtsa cells on serum-free medium could restore urothelial morphology. The serum-free medium consisted of a 1:1 mixture of Dulbecco's modified Eagles' medium (DME) and Ham's F-12 medium supplemented with selenium (5ng/ml), insulin (5μg/ml), triiodothyronine (4pg/ml), hydrocortizone (36.4ng/ml) and epidermal growth factor (10ng/ml). Under these conditions, the cultures became multilayered in selected areas and demonstrated a stratified organization of undifferentiated basal cells and apically located umbrella-like cells. The cultures remained viable and were able to be subcultured. When grown on filter inserts, cell multilayers were obtained that were morphologically similar to human urothelium. Ultrastructural analysis showed that tight junctions were present in the apical-most cell layers and freeze fracture analysis revealed tight junction sealing strands, gap junctions and desmosomes. The similarity of the UROtsa cells to human urothelium suggests they will be a valuable tool for the study of human bladder toxicology.

1789 ALTERNATIVE METHODS FOR ASSESSING CELL PROLIFERATION AND PROTEOGLYCAN PRODUCTION IN MICROMASS CULTURE.

G. L. Anderson, E. S. Hanson, J. L. Hill and M. A. Smith. *University of Georgia, Athens, GA.*

Micromass cultures of chick limb bud mesenchyme differentiate into cartilage provided cells are plated at densities greater than confluence. Cell proliferation and production of proteoglycans, predictable manifestations of chondrogenesis, are commonly measured variables in micromass cultures. Our objective was to evaluate alternative procedures for quantifying each of these variables. Cultures were seeded with 30μl aliquots (20E+06 cells/ml) and incubated for 24, 48, 72, 96 or 120 hr., or seeded with 10μl, 20μl or 30μl (20E+06 cells/ml) and incubated for 0 to 120 hr. Cell proliferation assessed by image analysis or optical density of crystal violet (Cv) stained cultures was compared with DNA, extracted from plated cells. Alcian green (Ag) extracted with 4M guanidine and propanol provided the standard against which optical density or image analysis of Ag stained cultures was compared. Stained and fixed unstained cultures were quantified by image analysis under controlled conditions for illumination and at known magnification. Variables evaluated included measured gray scale value and area as well as their calculated product. The image analysis product for unstained cultures correlates (R^2>0.960) both with the number of cell seeded as well as extracted DNA. Alcian green staining of fixed cultures measured spectrophotometrically with a plate reader correlated highly (R^2=0.989) with the optical density of extractable Ag. *In summary*: 1) Image analysis of unstained cultures provides a means to monitor cultures during the course an experiment. In addition in Ag stained cultures, by selecting the range of gray scale levels included in a given sample, a highly reproducible measurement of the portions of a culture dominated by Ag staining is obtained. 2) Plate read optical density of Ag stained cultures and fluorometric determination of extracted DNA provide quantitatively rigorous assessments of proteoglycan production and cell proliferation, respectively. (Supported in part by Hatch Funds and the US Air Force Office of Scientific Research.)

1790 DONOR VARIATION IN CHEMICAL ALLERGEN INDUCED IL-1β mRNA EXPRESSION BY CULTURED HUMAN BLOOD-DERIVED DENDRITIC CELLS.

J. S. Pichowski , M. Cumberbatch[1], R. J. Dearman[1], D. A. Basketter[2] and I. Kimber[1]. [1]*AstraZeneca Central Toxicology Laboratory, Macclesfield, United Kingdom and* [2]*Unilever Safety and Enviromental Assurance Centre, Sharnbrook, United Kingdom.*

The development of *in vitro* methods for the identification of potential contact allergens based upon analysis of Langerhans cell (LC) function has been constrained by the fact that these cells represent only a minority population in the epidermis. However, methods have been developed recently that allow the expansion in culture of LC-like dendritic cells (DC) from human blood. We have shown previously that treatment with the contact allergen 2,4-dinitrofluorobenzene (DNFB) is associated with increased interleukin (IL-) 1β mRNA expression by DC derived from a proportion (3 of 8) donors. The differential ability of DNFB to influence IL-1β expression was donor dependent, with stable responder and nonresponder phenotypes being identified. We have therefore examined alterations in cytokine mRNA expression by human blood derived DC following exposure to a second contact allergen, paraphenylenediamine (PPD). Peripheral blood derived DC were expanded in culture for five days in the presence of IL-4 and granulocyte/macrophage colony-stimulating factor and then exposed to DNFB or PPD, or to vehicle alone, for 30 minutes at 37°C. Cytokine mRNA expression was analyzed by semi-quantitative reverse transcriptase polymerase chain reaction. All DC expressed IL-1β mRNA constitutively. Exposure to either DNFB or PPD resulted in up-regulation of mRNA for IL-1β in DC derived from two donors. DC derived from a third donor displayed a nonresponder phenotype to both allergens. These data demonstrate that the potent contact allergens DNFB and PPD upregulate IL-1β mRNA expression by human blood-derived DC, but that such responses are donor dependent.

1791 CHARACTERIZATION OF HUMAN DENDRITIC CELL CULTURES AND THEIR ROLE IN THE ANTIGEN PRESENTATION OF PENICILLIN, A PROTOTYPIC DRUG ALLERGEN.

M. Scott, J. McDermott, G. Warnes and C. Meredith. *TNO BIBRA International Ltd., Carshalton, United Kingdom*. Sponsor: B. G. Lake.

To develop a model *in vitro* system with the capacity to identify potential drug allergens, we studied the actions of penicillin on dendritic cell (DC) cultures and their influence on Th1/Th2 lymphocyte development. DCs were cultured from both human cord blood CD34+ haemopoietic progenitor cells (HPC) and peripheral blood monocytes. HPC-derived DC activated by LPS and CD40 ligation showed increased levels of the co-stimulatory surface molecules, CD54, CD80, CD86, CD40, MHC II and the cytokines, IL-12, IL-6 and IL-1β. Activated DC increased stimulation of allogeneic T cells which was inhibited by IL-10 or by neutralising IL-6 antibody. Cytokine treated HPC-derived DC were cultured with allogeneic CD4+CD45RA+ T cells. T cells stimulated with IL-4 treated DC failed to express IFNγ. IL-4 but not IL-6 treatment inhibited IL-12 expression by LPS-stimulated DC. IL-6 treated DC induced IL-4 and inhibited IFNγ expression within an allogeneic MLR. DCs were treated with penicillin (0, 0.5, 1.0 mg/ml) for 24 hours during their *in vitro* generation, then used to stimulate peripheral blood mononuclear cells in an allogeneic MLR. In cultures from atopic volunteers we found a dose-dependent increase in both IL-4 and IFNγ mRNA whereas from non-atopics we found a low stimulation of IL-4 and a dose- dependent decrease in IFNγ mRNA. There were also differences in DCs from atopics and non-atopics in the degree of inhibition of expression of CD40, CD80 and CD86 following treatment with penicillin. (Supported by EU BIOTECHNOLOGY contract CT96-0246.)

1792 EFFECTS OF AIRBORNE PARTICULATES ON THE RELEASE OF IL-1 BETA AND TNF ALPHA AND ON THE EXPRESSION OF HLA-DR BY A HUMAN MONOCYTIC CELL LINE (THP-1).

A. Don Porto Carero[1], P. H. M. Hoet[2], B. Nemery[2] and G. Schoeters[1]. [1]*Environmental Toxicology, Vito, Mol, Belgium and* [2]*Laboratorium voor Pneumologie, Longtoxicologie, K.U., Belgium.*

The mechanisms by which exposure to environmental particulates may contribute to the occurrence of allergic diseases have not been elucidated. The aim of the present study was to investigate *in vitro* whether environmentally relevant particles may influence the immunological processing of allergens. The effects of particles of three different sources, namely carbon black, diesel exhaust particles (SRM1650, NIST) and urban particulate matter (SRM1648, NIST) were studied using the human monocytic THP-1 cell line, maturated to the macrophage phenotype with PMA (phorbol myristate acetate). The studied endpoints were the expression of HLA-DR molecules, assessed by fluorometry, and the release of Il-1b and TNFa, measured by RT-PCR. The cells were exposed for 48 hours with particles (0.16 - 1.6 - 16 - 160 - 1600 ng/ml) with or without IFNg (100U/ml). At least 3 independent incubations were performed. IFNg alone was able to significantly increase the expression of HLA-DR, Il-1b and TNFa by a factor 2 compared to basal values for non-exposed cells, while exposure to the particles alone did not change basal values. Particles in combination with IFNg were able to significantly increase the expression of HLA-DR by a factor 3 to 4 compared to IFNg exposure alone. The expression of Il-1b and TNFa were also raised when compared to IFNg alone. The increase in the release of inflammatory mediators and in HLA-DR expression caused by co-exposure of IFNg and particles in a cell type considered to be involved in antigen presentation is compatible with the hypothesis that particulates exert an "adjuvant" activity for environmental sensitisers.

1793 *IN VITRO* ASSESSMENT OF THE PULMONARY RESPONSE TO LOW SOLUBILITY PARTICLES: A SPECIES COMPARISON.

J. M. Carter and K. E. Driscoll. *Procter & Gamble Co., Cincinnati, OH.*

At present, the mechanisms underlying the development of particle-induced rat lung tumors observed at doses that cause marked, persistant inflammation are not completely understood. This response seems to be unique to the rat and has not been observed in mice or hamsters. *In vitro* assay systems can be utilized to identify and evaluate mediators orchestrating complex signaling mechanisms involved in regulating the inflammatory process. By evaluating individual cell types, mechanistic data can be obtained and compared to *in vivo* findings. Briefly, pulmonary macrophages, neutrophils and epithelial cells were isolated from rats, mice and hamsters and exposed to varying doses of carbon black and silica for various times. Samples were evaluated for oxidant and anti-oxidant production, pro- and anti-inflammatory cytokines, and cytotoxicity. Activation of signal transduction pathways was also evaluated. A dose and time related effect was observed for all parameters measured in rat inflammatory and epithelial cells. Hamsters and mice were less susceptible to the cytotoxic and inflammatory effects of these particles. This data correlates with the *in vivo* data previously generated.

1794 TOXICITY OF ORGANIC CHEMICALS ASSOCIATED WITH URBAN AIRBORNE PATICULATE MATTER IN PUERTO RICO USING BRONCHIAL EPITHELIAL CELLS.

D. R. Reyes, L. Maldonado-Baez and B. D. Jimenez. *University of Puerto Rico-Medical Sciences Campus, San Juan, PR.*

Health issues with respect to airborne particulate matter arise as a consequence of urban development, population growth, and industrialization. Epidemiological studies throughout the world point at airborne particulate matter as one of the principal causes of respiratory illnesses, cardiovascular disease mortality, acute bronchitis, and asthma attacks. Although organic constituents of particulate matter have been suggested to contribute to the overall toxicity in urban areas, few work have been conducted evidencing this fact. We have evaluated the cytotoxicity of four organic compounds (Metylmorpholine, Ethylmorpholine, Diethyl Phthalate and Tributyl phosphate) using Normal Human Bronchiotracheal Epithelial Cells (NHBEC) with the Neutral Red Uptake bioassay (NR50). These compounds or family related compounds were identified in particles less than 10 μm (PM10) from an urban site in Puerto Rico. They were extracted using Soxhlet extraction and analyzed by GC/MS. The NR50's using NHBEC were determined as 1500 μg/mL (metylmorpholine), 1425 μg/mL (ethylmorpholine), 42 μg/mL (diethyl phthalate) and 5 μg/mL (tributyl phosphate). A combination of these chemicals at different proportions showed higher toxicity when combined at concentrations lower than their NR50's. A mixture of the two morpholines at higher ethylmorpholine concentration (but lower than their NR50's), showed higher toxicity levels when compared to the opposite concentration for the same morpholines. Other mixtures with the same two compounds at lower concentrations did not exhibit significant cytotoxicity. The mixture containing the NR50 for both compounds showed the highest toxic response. Four compound mixtures containing diethyl phthalate concentration above its NR50, but less toxic concentrations of the other three compounds exhibited a non-toxic effect suggesting a masking effect on this compound. Tributyl phosphate was found to exert a higher cytotoxic effect than any of the other three compounds evaluated.

1795 COMPARISON OF THE INTERACTIONS OF BISPHENOL A AND ITS METABOLITE BISPHENOL A GLUCURONIDE WITH ESTROGEN RECEPTORS α AND β.

T. R. Zacharewski and J. B. Matthews. *Department of Biochemistry and National Food Safety and Toxicology Center, Michigan State University, E. Lansing, MI.*

Bisphenol A (BPA) and its major metabolite BPA glucuronide (BPA-G) were assessed for their ability to compete with [^{3}H]17β-estradiol (E2) for binding to estrogen receptor (ER) α and β, and for inducing and antagonizing ERα- and β-mediated reporter gene activity *in vitro*. BPA competed with [^{3}H]E2 for binding to mouse uterine cytosol ER, a bacterially expressed glutathione-S-transferase (GST)-ER fusion protein consisting of the human ER α D, E and F domains linked to GST (GST-hERαdef) and a commercially available full length recombinant hERβ. The IC_{50} values for E2 were similar among receptor preparations (mouse uterine cytosol ER, GSThERαdef and hERβ were $3.0\pm0.2 \times 10^{-9}$ M, $2.2\pm1.4 \times 10^{-9}$ M and $5.5\pm1.9 \times 10^{-9}$ M, respectively). In contrast, BPA exhibited greater affinity for hERβ ($3.3\pm1.7 \times 10^{-7}$ M) than for GST-hERαdef ($2.7\pm1.4 \times 10^{-6}$ M) and for mouse uterine cytosol ER ($2.6\pm1.1 \times 10^{-5}$ M). BPA-G did not competitively displace [^{3}H]E2 from any of the ER preparations. In MCF-7 cells transiently transfected with Gal4-hERαdef (human) or Gal4-mERβdef (mouse) chimeric receptors and a Gal4-regulated luciferase reporter gene, 17m5-G-Luc, BPA fully induced luciferase reporter gene activity with comparable EC_{50} values ($7.1\pm2.9 \times 10^{-7}$ M and $3.9\pm1.2 \times 10^{-7}$ M, respectively). No significant response was seen for BPA-G. Cotreatment studies showed that concentrations of (1-30 ∝M) BPA and BPA glucuronide did not result in any significant changes in the level E2 (10 nM) induced luciferase activity in MCF-7 transiently transfected with either Gal4-hERαdef or Gal4-mERβdef. These results demonstrate that BPA can interact with ERα and β, and can induce ERα- and β-mediated gene expression *in vitro*. In contrast, BPA-G did not exhibit any *in vitro* estrogenic activity. (This research was supported by the Bisphenol A Global Industry Group.)

1796 DIFFERENTIAL ESTROGEN RECEPTOR BINDING OF ESTROGENIC SUBSTANCES: A COMPARISON ACROSS SPECIES.

J. B. Matthews, T. Cellius, R. Halgren and T. R. Zacharewski. *Department of Biochemistry and National Food Safety and Toxicology Center, Michigan State University, E. Lansing, MI.*

This study investigated the potential species-specific estrogenic receptor (ER) activity of several natural and synthetic chemicals for bacterially expressed fusion proteins using a semi high throughput competitive binding assay. The fusion proteins consisting of the D, E and F domains of human (α), mouse (α), chicken, green anole and rainbow trout ER linked to the glutathione-S-transferase (GST) protein were prepared and partially purified. Saturation ligand-binding analysis of GST-hERαdef (human), GST-mERαdef (mouse), GST-cERdef (chicken), GST-aERdef (green anole) and GST-rtERdef (rainbow trout) fusion proteins revealed a single high affinity binding component for E2 with dissociation constants (K_d) ranging from of 0.3 to 0.9 nM. Although, the ERs from the different species exhibited similar binding preferences and binding affinities for many of the compounds examined, several differences in absolute and relative binding affinities were observed. Of the 38 chemicals examined, 4-hydroxytamoxifen was found to bind with greatest affinity for the ERs of all 5 species. The ranking of the potency of the xenobiotics and phytoestrogens varied among species with no predictable patterns and many examples of species-specific ligand preference. For example, α-zearalenol ($IC_{50} = 1.5 \pm 0.7 \times 10^{-9}$ M) competed for binding with greater affinity than E2 for GST-rtERdef which was in contrast to all other GST-ERdef fusion proteins examined. However, the phytoestrogen coumestrol ($IC_{50} = 1.6 \pm 0.3 \times 10^{-6}$ M) bound with lowest affinity to GST-rtERdef, while genistein ($IC_{50} = 3.0 \pm 2.0 \times 10^{-8}$ M) bound with greatest affinity to GST-aERdef. These results demonstrate that ERs from different species exhibit differential ligand preferences and relative binding affinities for estrogenic substances and that these differences may be due to the variability in the amino acid sequence within the ER ligand binding among species.

1797 TRANSCRIPTIONAL PROFILING OF PHENOBARBITAL (PB) HEPATOTOXICITY IN THE MOUSE.

M. P. Carver[1] and B. Clancy[2]. [1]*Wyeth-Ayerst Research, Princeton, NJ and* [2]*Wyeth-Ayerst Research, Andover, MA.*

The hepatic effects of 4 daily, 80 mg/kg (ip) doses of PB, an epigenetic rodent carcinogen, were examined by analyzing mRNA isolates at 6-hr post-dose (i.e., at 6-, 30-, 54-, and 78-hr) on Affymetrix Mu11k GeneChips®. This dosage regimen of PB produced the expected 20-40 fold increases in CYP2B (testosterone-16β-hydroxylase) and 5-fold increase CYP3A (testosterone-6β-hydroxylase) activities in the murine liver microsomes. In addition, the Mu11k GeneChip analysis demonstrated that a total of 341 unique gene transcripts were affected by PB in the mouse. Of the 12 genes previously shown to be induced in rodents, which include CYP450's, phase II drug-metabolizing enzymes, $\alpha 2\mu$-globulin, and δ-ALAS, 10 of these were also induced in the mouse. Only epoxide hydrolase and UDP-glucuronosyltransferase were not detected in the mouse experiment. These results compare favorably with similar studies of PB transcriptional effects in rat liver and in rat primary hepatocyte cultures in our laboratory, where a total of 323 unique transcripts were shown, by READS™ differential display analysis (Gene Logic, Inc.; Gaithersburg, MD), to be affected by 80 mg/kg/d ip doses of PB *in vivo*, and by exposure to 2 mM concentrations of PB *in vitro*. Many of these effects on hepatic mRNA levels were similar in the two species, typically slight (<5-fold) increases which were not maintained over the entire 78-hr time course of these studies, and involved previously unknown mechanisms of action of PB on the liver. PB affected rodent genes for apoptosis, DNA repair proteins, cell cycle/signal transduction pathways, fatty acid/lipid intermediary metabolic enzymes, cell surface receptors, cytokine effectors, and steroid hormone metabolic enzymes. Finally, a set of about 50 novel transcripts were identified by the "open" system in the rat (READS™ differential display), which did not match any known gene or EST sequences in the public databases. These studies are among the first to utilize such powerful new technologies to examine the mechanisms of drug and chemical hepatotoxicity on a genome-wide basis.

1798 EFFECTS OF A PEROXISOME PROLIFERATOR (WY-14,643) ON HEPATOCYTE TRANSCRIPTION USING MICROARRAY TECHNOLOGY.

M. A. Carfagna, T. K. Baker, L. A. Wilding, L. A. Neeb, S. Torres, T. P. Ryan and L. M. Gelbert. *Eli Lilly and Company, Lilly Research Laboratories, Greenfield, IN.*

Peroxisome proliferators produce a number of hepatocellular changes that are mediated through transcriptional regulation. The cellular changes in rats and mice include increases in the number of peroxisomes, mitogenic effects, and induction of cytochrome P450, however humans lack these responses. Nonetheless, both species respond to the therapeutic effects of peroxisome proliferators on lipid metabolism. This study was designed to characterize the transcriptional response of isolated rat hepatocytes to the peroxisomal proliferator (WY-14,643). The goal of the study was to validate microarray data by evaluating expected biochemical and molecular changes, and identify novel genes that may be associated with the species-specific effects of peroxisome proliferators. F344 rat hepatocytes were isolated, incubated over night, and exposed to WY-14,643 (0.1-100 μM) for 4 or 48 hours. Peroxisomal beta-oxidation (Pbox), cytochrome P4504A (CYP4A) protein, and lactate dehydrogenase leakage were quantitated in the isolated hepatocytes. In addition, RNA was isolated from hepatocytes for evaluation using microarray technology (Affymetrix). WY-14,643 had no effect on Pbox after 4 hr of exposure but increased Pbox approximately 14 fold after 48 hours of exposure without affecting cell viability. Similarly, WY-14,643 did not affect CYP4A protein at 4 hr but produced a significant increase at 48 hours. These biochemical effects were a result of transcriptional regulation as determined by RT/PCR and microarray. Acyl coA oxidase and CYP4A transcription was increased at 4 hr (prior to biochemical effects) and continued to increase at 48 hr. In addition, a number of genes associated with oxidative damage (glutathione transferase, catalase, SOD dismutase) and apoptosis (BCL-2, topoisomerase) were induced in response to WY-14,643, suggesting a potential relationship between effects on redox potential and apoptosis in hepatocytes. Taken together, these data indicate that microarrays are capable of detecting and validating biochemical responses.

1799 TOXICOGENOMICS: ACETAMINOPHEN-INDUCED HEPATOTOXICITY.

L. Suter, U. A. Boelsterli, M. Winter, F. Crameri, R. Gasser, M. Bedoucha, M. C. de Vera and S. Albertini. *F. Hoffmann-La Roche, Nonclinical Drug Safety, Basle, Switzerland.*

In spite of the large amount of data collected in the past years, the mechanisms underlying the toxicity of acetaminophen (APAP) are not fully understood. So far, the involvement of metabolic activation and the conjugation of acetylbenzoquinoneimine (NAPQI) to GSH and selective protein arylation have been reported. The generation of oxidative stress and DNA fragmentation, the inhibition of apoptosis and the activation of Kupffer cells are other characteristics of APAP-induced hepatotoxicity. However, the molecular mechanisms involved in the initiation and progression of liver injury remain unclear. In this study, we sought to further investigate the mechanisms of APAP-induced hepatotoxicity on the gene expression level using DNA microarrays. Adult male mice (C57BL/6) were administered APAP at doses of 100 or 300 mg/kg. To differentiate toxicity-related gene expression from that unrelated to liver injury, a matched group treated with 300 mg/kg of the non-toxic positional isomer AMAP was also included. Eight hours after treatment, hepatic transcripts were analyzed and liver damage was assessed by increased liver enzyme release and histopathology. Gene expression analysis showed that a subset of genes involved in stress response, cell cycle regulation and apoptosis was regulated by APAP but not by AMAP. These findings were corroborated using RT-PCR. In the high-dose group, the regulation of the gene transcription correlated well with the extent of liver injury. Among the identified genes, the early and dramatic induction of the transcription factor LRG-21 in the animals exhibiting liver injury suggests the possible involvement of this gene in the initiation of APAP-induced hepatotoxicity. In conclusion, APAP-induced liver injury in mice positively correlated with the regulation of genes implicated in hepatotoxicity. Moreover, the gene expression profile of the animals in the low-dose group suggests that the modulation of some genes is detectable prior to the appearance of overt toxicity.

1800 GENOMIC AND PROTEOMIC INVESTIGATIONS OF ACETAMINOPHEN (APAP) TOXICITY IN MOUSE LIVER *IN VIVO*.

S. Ruepp, R. P. Tonge, N. T. Wallis, M. D. Davison, T. C. Orton and F. Pognan. *AstraZeneca, Macclesfield, United Kingdom.*

APAP toxicity has been postulated to involve covalent modification of critical proteins and inhibition of their functions. In order to understand the molecular events associated with toxicity we have assessed mRNA and protein changes in mouse liver after APAP i.p. at 150 (subtoxic) or 500mg/kg (toxic). Mice were sacrificed at 15, 30, 60, 120 and 240 minutes. mRNA expression was conducted using Gene Discovery Array filters (Genome System Inc.) and in-house mouse and human micro-array filters. After 33P cDNA probe hybridization, the filters were scanned by phosphorimager and spot intensities quantified using ArrayVision (Imaging Research). Genes showing reproducible repression or induction of more than 2 fold were noted. Proteins in liver mitochondrial fractions were separated by fluorescent 2D-differential gel electrophoresis and differences identified by mass spectroscopy. Electron microscopy revealed swollen (at 30 min) and mega-mitochondria (at 120 min) after 500mg/kg. Mitochondrial specific or associated genes like protoporphyrinogen oxidase or sterol carrier protein 2 along with the proteins catalase, aldehyde dehydrogenase , HSP10 and HSP60 were up and down regulated in time and dose dependent fashion. In addition, mRNA expression of metallothioneins, beta-actin, cathepsin D, c-fos, glutathione peroxidase and MAP kinase phosphatase were induced with varying time course profiles. We have described the modulation of genes and gene products in APAP-induced mouse liver damage and these changes may be involved in the biochemical basis of this toxicity.

1801 CUSTOM MADE CDNA ARRAYS FOR TRANSCRIPT PROFILING: IMPLICATIONS FOR DRUG DISCOVERY AND EARLY SCREENING FOR THIAZOLIDINEDIONE TOXICITY.

K. M. Beckett, C. Lenaghan, F. Carey, J. E. Sidaway, W. D. Pennie and J. D. Tugwood. *AstraZeneca Pharmaceuticals, Macclesfield, United Kingdom.* Sponsor: T. C. Orton.

Thiazolidinediones (TZD's), recognised for improving insulin sensitivity and intended for the treatment of type II diabetes, have limited efficacy in humans due to the observed dose dependant toxicity. Animal exposure data suggests that one TZD-induced toxic effect is adipocyte accumulation within the bone marrow, perhaps as a consequence of stromal cell changes. TZD's are ligands for the Peroxisome Proliferator-Activated Receptor Gamma (PPARγ) which is involved in lipid and glucose homeostasis. The aim of our ongoing research programme is to identify novel compounds for treating type II diabetes that does not possess the undesirable toxicological profile seen with the TZD's. We have employed transcript profiling technology using a nylon-based cDNA array, with a view to assisting in the toxicological evaluation of insulin sensitizing compounds. Human genes were selected for an array that include adipocyte and osteoblast markers, and PPARγ activators. 170 such 'specific' clones were selected, together with 768 random clones for experimental normalisation. A human bone marrow stromal cell line was used in these experiments. Cells were left untreated or treated with vehicle, test compounds including the TZD's rosiglitazone and troglitazone, or with rabbit serum as a positive control. cDNA was prepared and radiolabelled, and hybridised to the arrays. Phosphorimager scans of array images were analysed using ArrayVision software. Using this system we are able to detect changes in gene expression patterns that correlate with differentiation of the stromal cells towards an adipocyte phenotype. Such changes include upregulation of G3PDH, adipsin and E2F4 transcript levels. Further work is in progress to extend and confirm these observations, and to determine whether specific gene 'fingerprints' are associated with different classes of insulin sensitizers.

1802 COMPARISON OF TOXICANT-INDUCED GENE EXPRESSION PATTERNS IN HEPG2 HUMAN HEPATOMA CELLS.

M. K. McMillian[1], J. Ciervo[1], L. Li[1], R. Dunn[2], E. Fairfield[2], S. B. Farr[2] and M. D. Johnson[1]. [1]*R. W. Johnson Pharmaceutical Research Institute, Raritan, NJ and* [2]*Phase-1 Molecular Toxicology, Inc., Santa Fe, NM.*

Gene arrays may be used to distinguish different types of toxicities (eg., DNA damage, hepatic necrosis, peroxisomal proliferation). We show that gene arrays can identify toxic compounds that cause DNA damage, but only after isolating subsets of genes that respond consistently. HepG2 cells were treated with cisplatin, a DNA crosslinker, and gene array results were compared with those resulting from parallel treatments with equitoxic concentrations of transplatin (an inactive isomer) and two hepatotoxic NSAIDs, flufenamic acid and diflunisal. Cells in log phase growth were treated for 24 hours with compound concentrations eliciting an approximate ED_{30} cytotoxic response, based on inhibition of reductase activity or protein synthesis. Reproducibility was found to be critically important and initial experiments were performed multiple times to ensure statistically meaningful data. A dozen genes (from a total of about 400 on arrays enriched in DNA damage indicator genes) distinguished statistically between cisplatin and transplatin/flufenamic acid/diflunisal treatments. The analysis used a variety of computer algorithms designed to maximize differences between cisplatin-induced and transplatin/flufenamic acid/diflunisal-induced expression patterns. More importantly, the subsets of genes identified in these experiments correctly predicted the genotoxic compounds in Phase-1's proprietary database even though these were not part of the learning set. Moreover, clustering was observed for several other mechanistic classes of database compounds. In contrast, correlational analysis using all the genes on the arrays showed little if any difference between DNA damaging compounds and other drug classes. As we refine the approach, we expect to obtain subsets of genes showing representative responses for each major type of toxicity. Ultimately, by comparing the gene expression profiles to an established database, we should know what types of toxicity to expect with any compound.

1803 IDENTIFICATION OF ESTROGEN-INDUCED GENES DOWNREGULATED BY 2,3,7,8-TETRACHLORODIBENZO-*p*-DIOXIN BY COUPLING SUPPRESSION SUBTRACTIVE HYBRIDIZATION AND cDNA MICROARRAYS.

I. Chen[1], T. Hsieh[2], T. Thomas[2] and S. Safe[1]. [1]*Texas A&M University, Department of Veterinary Physiology & Pharmacology, College Station, TX and* [2]*Texas A&M University, Department of Biology, College Station, TX.*

The antiestrogenic activity of 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) is mediated through crosstalk between the aryl hydrocarbon (AhR) and estrogen receptor (ER) signaling pathways. Identification of 17β-estradiol (E2)-induced genes downregulated by TCDD utilized suppression subtractive hybridization (SSH) using poly(A)-RNA from MCF-7 cells treated with 1 nM E2 and 1 nM E2 + 1 nM TCDD as targets and references, respectively. Results of SSH confirmed that 43 clones isolated using this technique have sequence homology to previously described genes; in addition, three potential novel sequences were identified. The following genes were downregulated (>2-fold) after treatment with E2 + TCDD compared to treatment with E2 alone: nucleotide synthases, cell cycle regulators, X-chromosome related genes, protein synthesis regulators, homeotic FSH homology, calmodulin, and two unmatched clones. Similar expression profiles were observed after probing with cDNA from MCF-7 cells cotreated with E2 + diindolylmethane (DIM), although the magnitude of some of the decreased responses were less than that observed after cotreatment with E2 + TCDD (1 nM). Despite these quantitative differences between the inhibitory effects of TCDD and DIM, the overall pattern of antiestrogenic activity for 25 μM DIM was similar to that observed for TCDD. Some of the changes in levels of gene expression induced by TCDD may also be attributed to other activities (including toxicity) of this compound compared to DIM. In combination with high-throughput gene screening methods, SSH or SSH-array can be a powerful technique for studying crosstalk between two signaling pathways. (ES04176 and ES09106)

1804 THE EFFECT OF SHORT TERM TREATMENT OF VARIOUS HEPATOCARCINOGENS AS ASSESSED BY GENOMIC MICROARRAY TECHNOLOGY.

K. L. Kolaja[1], R. T. Bunch[1], S. Curtiss[2], L. Tam[1], J. Davila[2], L. Hankin[1], C. Jackson[2], E. Blomquist[2], C. Alden[2] and D. L. Morris[2]. [1]*Monsanto/Searle, Skokie, IL and* [2]*Monsanto/Searle, St. Louis, MO.*

Chronic administration of high doses of certain drugs/chemicals may induce hepatocellular tumors in rodents. Although the exact mechanism of tumorogenesis is unknown, technological advancements in examining genetic expression can be utilized to characterize chemical treatment and further the understanding of how hepatocarcinogens produce tumors. The objective of this study was to determine if chemically-induced changes in gene expression are altered during toxicity and/or are there expression patterns that may be predictive of carcinogenicity. Male Sprague Dawley rats were treated daily for 5 days with a variety of mutagenic or non-mutagenic carcinogenic or non-carcinogenic compounds which were bemitradine, clofibrate, phenobarbital, tamoxifen, 2-AAF, 4-AAF, doxylamine, methapyrilene, and isoniazid. In general, all doses were well tolerated. One 200 mg/kg phenobarbital animal died, but no other mortality was observed. Few clinical signs were noted during the

study except reduced activity in phenobarbital treated animals and altered gait in clofibrate treated animals. No gross abnormalities were noted at necropsy. However, the percentage body weight gain from Day 1 to Day 5 was decreased in a dose-responsive manner for bemitradine, clofibrate, phenobarbital, tamoxifen, 2-AAF, and methapyrilene. In addition, increased liver/body weight ratios were observed in a dose-responsive manner for bemitradine, clofibrate, phenobarbital, and 4-AAF treated rats. Expression analysis of nearly 8000 genes indicate a marked expression pattern change that is unique to specific carcinogen classes.

1805 GENE EXPRESSION IN LIVER TISSUES OF FEMALE RATS DURING THE EARLY STAGES OF DMBA-INDUCED MAMMARY TUMORIGENESIS.

L. Wang[1], C. E. Frantz[2], A. Cheng[2], W. Leach[2], D. A. Eastmond[1] and J. L. Bussiere[2]. [1]*University of California, Riverside, CA and* [2]*Genentech, Inc., South San Francisco, CA.*

In addition to inducing tumorigenesis, DMBA (7,12-dimethylbenz[a] anthracene) has previously been reported to alter gene expression in both target and non-target tissues of exposed animals. However the alterations to liver gene expression throughout the early stages of female rat mammary tumorigenesis still remain largely unknown. Gene expression in liver tissue obtained from both control and DMBA-treated female rats at 6, 24, 72 hrs and 2 weeks post-exposure, was assessed using the branched DNA assay (bDNA). Among the 16 genes studied, WAF1/p21 appeared to be the only gene overexpressed in all the DMBA-treated rats at all tested time points (4 to 6 fold). Several genes exhibited peak expression at 72 hours, MDM-2, Cyclin G, Cyclin D1, and MDR-1 (up to 18 fold). The expression of Catechol-O-Methyltransferase and Calreticulin decreased significantly at 6 hours and recovered to control levels at later time points. Comparison of the bDNA assay results with a microarray study showed an 83% agreement between the two assays when comparing genes which showed significant changes in both methods (5/6 comparable genes). This study demonstrates comparable results between the bDNA and cDNA microarray assays in measuring differential gene expression in the livers of female rats in the early stages of DMBA-induced mammary tumorigenesis. Moreover, the identification of changes in gene expression in a non-target organ provides valuable information for evaluating tumor development and tissue-specific response to toxicological stress.

1806 EXAMINATION OF GENE EXPRESSION CHANGES OVER TIME IN MAMMARY AND LIVER TISSUES OF RATS EXPOSED TO A CARCINOGENIC DOSE OF DMBA.

C. E. Frantz[1], R. T. Dunn, II[2], K. Achilles[1], A. Cheng[1], N. Dybdal[1], W. Leach[1], E. Pegg[1], M. Van Hoy[1], L. Wang[1], S. B. Farr[2] and J. L. Bussiere[1]. [1]*Genentech, Inc., South San Francisco, CA and* [2]*Phase-1 Molecular Toxicology, Santa Fe, NM.*

7,12-dimethylbenz[a]anthracene (DMBA) is a carcinogen widely used to induce mammary tumors in female Sprague-Dawley rats. In this study gene expression was examined in mammary tissues over time in order to identify the changes associated with DMBA induced mammary tumorigenesis. Gene expression was also examined in the liver tissues. RNA levels were measured with cDNA microarrays which contained DNA targets for 125 genes selected specifically for toxicological investigations. Fifty-one day old female rats were administered 10 mg/ rat of DMBA by gavage and RNA levels were measured at 6 hrs, 72 hrs, 6 weeks, and 12 weeks post-exposure. By 12 weeks all DMBA exposed animals tested had palpable mammary masses. Changes in liver gene expression were observed 6 hours post-exposure, with RNA levels of COMT, an enzyme involved in metabolism of catechol estrogens exhibiting decreased expression at 6 and 72 hours. In the mammary tissues of exposed animals numerous genes were differentially expressed in all animals 72 hours post-exposure including: C-reactive protein (+), capases 2, 6, and 7 (+), cyclin E (+), HGF receptor (+), hydroxysteroid sulfotransferase A (+), MDM-2 (+), and TGF β-3 (+). At the 6 week time point among the 7 genes differentially expressed were cyclin D3 (+) and EGF (+). Five genes exhibited altered expression at 12 weeks including, cyclin D1 (+), p53 (+), and TGF β-3 (+). In this study differential gene expression and patterns were observed over time for genes in both mammary and liver tissues that are associated with metabolism, cell cycle control, DNA damage, protein damage, and carcinogenesis. The gene expression results observed in mammary tissue appear consistent with tumorigenesis induced by a genotoxic carcinogen such as DMBA.

1807 EXPLORING GENE REGULATION BY IMMUNOSUPPRESSANTS USING AN IN HOUSE TOXICITY BASED CDNA MICROARRAY.

G. J. Beran, S. Broadey, J. E. Sidaway, W. D. Pennie and J. D. Tugwood. *AstraZeneca Pharmaceuticals, Macclesfield, United Kingdom.* Sponsor: T. C. Orton.

We are interested in applying 'transcript profiling' technology to assist safety evaluation of development drugs. Using an in house filter array ('ToxBlot'), we have been able to monitor expression patterns of a large number of genes. This array has been custom designed to include major 'toxicologically relevant' genes including those associated with apoptosis, cancer, signal transduction and immunology. The 620 genes on the array are sequence-verified human cDNAs which have been spotted in duplicate. Initially we are performing transcript profiling experiments using reference immune suppressants including Cyclosporine A (CsA). CsA is widely used in the treatment of solid organ transplant grafting as well as T cell driven autoimmune diseases, but with nephrotoxic side effects including tubular injury. CsA principally inhibits renal phosphate calcineurin by binding to the intracellular immunophilin cyclophilin resulting in the inhibition of T-lymphocyte activation. It is intended to use transcript profiling to assist screening for novel immunosuppressants with reduced toxicity. To obtain transcript profiles, human HepG2 hepatoma cells were dosed at incremental concentrations from 0-125μM of CsA (n=3). In addition, profiling has been performed with populations of primary human peripheral blood mononuclear cells (PBMCs) to determine gene changes associated with proliferative arrest of activated T cells induced by immunosuppressants. Our data show that CsA causes reproducible transcript level changes, both in HepG2 cells and in PBMCs. Genes that are transcriptionally upregulated by CsA in HepG2 cells include transferrin and integrin b4, and downregulated genes include telomerase, ApoCIII and clathrin. Further work is in progress to extend and confirm these observations with CsA and other immune suppressants, and to determine whether specific gene 'fingerprints' can be ascribed to different classes of compounds.

1808 EXPRESSION ANALYSES OF THE EFFECTS OF RESERPINE ON HUMAN HEPATOMA (HEPG2) CELLS USING MICROARRAYS.

P. S. Rao, P. R. Harbach, J. M. McKim, J. M. Fostel and C. S. Aaron. *Pharmacia and Upjohn, Kalamazoo, MI.* Sponsor: W. B. Mattes.

Xenobiotic exposure often results in altered gene expression patterns, which may be predictive of subsequent adverse events. This study was conducted to evaluate reserpine-induced changes in gene expression patterns in human hepatoma (HepG2) cells. Reserpine (RES) is a rodent-carcinogen, but not a human carcinogen that is currently being evaluated in transgenic animal models. In order to understand how changes in gene expression correlate with cytotoxicity, initial studies determined the toxicity of RES in HepG2 cells by measuring changes in MTT activity and ATP levels following a 24-hr exposure. The TC50 for MTT and ATP was estimated at 50 μM respectively. These studies indicated alterations in mitochondrial functions and cell viability. To evaluate RES-induced changes in gene expression, HepG2 cells were seeded at a density of 300,000/ml in a final volume of 6 ml and were cultured for 96 hr prior to dosing. Following the 96-hr growth period, media was removed and the cells were dosed by adding media with 50 μM RES and 0.5% DMSO. After a 24-hr exposure the media was removed, cells were processed to recover mRNA and the target RNA was hybridized to human oligonucleotide microarrays. Preliminary results indicate alterations in expression of approximately 340 genes; based on changes of ±3 S.D as a level of significance for analysis. Upregulation of about 170 genes and down-regulation of approximately the same number of genes was observed. These and additional studies may lend themselves to a better understanding of the role of gene expression in mechanistic and predictive toxicity studies.

1809 DIFFERENTIAL GENE EXPRESSION IN BUTYRATE-TREATED HT 29 COLON CARCINOMA CELLS.

J. Cai[1], R. Y. Odom[2], W. Kirlin[2], P. Sternberg, Jr.[1] and D. P. Jones[1]. [1]*Emory University, Atlanta, GA and* [2]*Morehouse School of Medicine, Atlanta, GA.*

Dietary compound sodium butyrate (NaB) is a potential chemopreventive agent. Treatment of HT 29 cells with NaB resulted in cell differentiation, apoptosis, together with increased activity of phase-II detoxification enzymes. To determine the mechansim of these effects, we performed differential gene expression array assays using Clontech human stress and toxicology arrays (234 genes). After 3 mM NaB treatment for 3 days, the most dramatically

induced mRNAs were members of heat shock protein (HSP) family, which included HSP 70, HSP 47, HSP 27, HSP 40 and HSP 110. The increased expression of hsps was confirmed by RT-PCR. HSF-1, a transcription factor that regulates hsp expression, was found to be activated. Similar effects could be achieved by tricostatin, an inhibitor of histone deacetylase. We conclude that the cellular response to butyrate includes upregulation of hsp expression, possibly by a mechanism that involves altered histone acetylation. This response may function in elimination of proliferative machinary as the cell becomes differentiated, or represent a response to the differentiation-associated cellular redox change. (Supported by NIH grants ES-09047 and GM-08248.)

1810 AN EVALUATION OF THE DNA ARRAY: PREDICTING TOXICOLOGICAL ENDPOINTS USING THE LOCAL LYMPH NODE ASSAY AS A MODEL.

C. M. Glatt[1], L. G. Davis[1], P. J. Ciaccio[2], G. S. Ladics[1], C. Smith[1] and B. Car[2]. [1]*The DuPont Company, Haskell Laboratory for Toxicology and Industrial Medicine, Newark, DE and* [2]*The DuPont Pharmaceuticals Company, Newark, DE.*

The DNA array technology is becoming a widely used method for associating gene expression changes with cellular phenotypic changes. The high-density DNA array is a powerful tool for evaluating changes in global gene expression. Arrays have the potential to address a number of key toxicological issues, including mode of action, dose-response relationships, hazard identification, and human exposure assessment. This study examines the reliability of the DNA array technology by performing intra- and inter-animal tissue reproducibility experiments. These experiments demonstrated that DNA arrays provide reproducible detection of expressed genes. Subsequently, the local lymph node assay (LLNA) was used as a model to evaluate the use of DNA arrays for predicting toxicological endpoints. We exploited the proliferative response and other salient conditions of this model to identify the underlying genetic mechanisms of dermal sensitization. Pooled draining auricular lymph nodes from 4:1 acetone:olive oil (AOO) vehicle-control and 1-chloro-2,4-dinitrobenzene-treated CBA mice were collected. Total RNA was purified and reverse transcribed using ^{32}P-dATP and gene-specific primers for probing a murine cDNA expression array from Clontech Laboratories, Inc. The LLNA proliferative response is known to correlate well with sensitization potential and we now report a concomitant gene expression pattern using this model. Treatment-induced changes in gene expression levels were detected in 4% of the arrayed genes. Of particular interest was an elevation in PD-1, an Ig gene superfamily member, integrin beta, and MHR23B, a Rad23 ultraviolet excision repair protein homolog. Also of interest was a down-regulation of CD2 antigen as well as GLYCAM1, an endothelial ligand for L-selectin. Thus, we demonstrate that the DNA array has the ability to detect genes that respond to treatment.

1811 ANALYSIS OF GENE EXPRESSION IN TRANSGENIC AND KNOCKOUT MICE USING GLASS MICRO-ARRAYS.

J. A. Styles, T. W. Gant, D. Judah, J. Riley, R. Davies and A. G. Smith. *MRC Toxicology Unit, Leicester, United Kingdom.*

Transgenic and knockout mice are used with increasing frequency to elucidate toxicological mechanisms but the influence of the specific gene involved in the transgene or knockout on the expression of other genes is largely unknown. A glass microarray containing over 4000 mouse cDNAs was used to analyze levels of gene expression in selected target tissues from Big Blue lacI transgenic and p53, Ahr and P450 knockout mice compared with normal controls of the same background strain. Among the groups of genes present on the array are representatives of those involved in cell cycle, oxidative stress, DNA replication and repair, xenobiotic-metabolizing enzymes, apoptosis and hormone responses. Cy3 and Cy5 labeled cDNA reverse transcribed from RNA isolated from the liver, kidney, g.i. tract, brain, muscle, lung and heart of young adult mice was hybridized to the microarray. For each cDNA element on the array the ratio of fluorescence intensity for each fluor was detected simultaneously with a twin laser scanner. A 16 bit gray scale image was generated for each fluor. The fluorescence intensity of each feature at each wavelength was normalized by reference to median fluorescence across the whole array. After normalization the array was reproduced using false color and the two images superimposed. Red represents increased and green decreased gene expression while yellow indicates no change. Finally the data was clustered within, and across, experiments to indicate genes with related expression patterns.

1812 MICROARRAY ANALYSIS OF 4500 HUMAN GENE EXPRESSIONS, AMPLIFICATIONS AND DELETIONS IN CELLS WITH LOW CYTOTOXIC DRUG SENSITIVITY.

T. W. Gant, D. Judah, J. Riley, R. Davies, J. A. Styles, N. J. Turton and A. G. Smith. *MRC Toxicology Unit, Leicester, United Kingdom.*

Differential sensitivity to xenobiotics is manifest in many forms including such responses as adverse drug reactions, and resistance to insecticides, antibiotics and cytotoxic drugs. In animals differential sensitivity is often species and strain specific, and in man variation is found between different population groups for some xenobiotics. Such variation can be due to the differential expression of one gene, but in most cases there is a contribution from many genes. It is our aim to elucidate the genes involved in xenobiotic sensitivity in a number of models, and the underlying genotype. To do this we have used glass based micro-array technology. These arrays are manufactured in our own facility using equipment we have built from published designs (DeRisi et al). The micro-arrayer has a 16 split pin print head capable of spotting up to 7000 spots/cm2 with an interspot distance of 125mm, and diameter of 90-100mm. We are using an Axon GenePix scanner with commercial and custom software for analysis. In this study we examined the differential gene expression of 4500 genes in human cell lines that had acquired a decreased sensitivity (i.e., resistance) to cytotoxic drugs. The patterns of differential gene expression have been clustered to reveal groups of genes that are co-regulated. In addition gene amplifications and deletions have been examined by micro-array technology and correlated to the differential gene expression.

1813 THE SELECTION OF AN ENDOGENOUS REFERENCE GENE IN QUANTITATIVE GENE EXPRESSION ANALYSIS CAN GREATLY AFFECT INTERPRETATION OF THE DATA.

Q. Zhang and K. Augustine. *SmithKline Beecham Pharmaceuticals, King of Prussia, PA.* Sponsor: P. J. Wier.

Real time PCR (TaqMan) is an accurate and relatively high-throughput method to analyze relative quantitative gene expression changes using a reference gene for sample normalization. Housekeeping genes, such as glyceraldehyde-3-phosphate dehydrogenase, beta-actin and 18S ribosomal RNA are commonly used reference genes. However, such genes may not be appropriate references because some embryo-toxic compounds cause general growth retardation and therefore may alter metabolic processes and/or cytostructural organization of various embryonic structures. We compared relative gene expression changes in cultured rat embryos treated with vehicle or tool compounds. The test compounds ranged from non-teratogenic, to mild, to severe teratogencity (growth retardation and disorganization of posterior axial structures at varying severity). The gene expression data was ormalized against several housekeeping reference genes as well as against krox20, a zinc finger gene which is expressed exclusively in rhombomeres 3 and 5, and S100-beta, which is expressed primarily in the notochord during early organogenesis. Normalization against the housekeeping and structure-specific genes produced dramatic differences in the data outcome. Normalization with krox-20 reflected graded changes of certain gene expressions, which would be expected in embryos which exhibited graded severities in axial developmental abnormalities, and these expression changes were also reflected by evaluation of the target gene expression by wholemount in situ hybridization. We have concluded that caution in reference gene selection is important in embryonic gene expression evaluations. The reference gene should not exhibit expression in a region or biological process that may be affected by the teratogen. Also, lower copy number reference genes may be advantageous since they are more suitable for multiplex PCR experiments and they may also reduce background expression variations in individual embryos.

1814 GENE EXPRESSION IN THE MOUSE TESTIS: DEVELOPMENT OF A MURINE TESTIS TRANSCRIPTOME BY MINING PUBLIC DATABASES.

R. G. Halgren, M. R. Fielden and T. R. Zacharewski. *Michigan State University, East Lansing, MI.*

The murine testis transcriptome (MTT) represents a database of all genes currently known to be expressed in the murine testis, and will used to construct high density cDNA arrays for toxicogenomic analyses. The NCBI UniGene, Jackson Laboratories Mouse Gene Expression (GXD), and National Library of Medicine (MEDLINE) databases were searched to identify genes expressed in mouse testicular tissue. By combining these publicly available data, it was possible to create a more comprehensive MTT than by using any of these sources exclusively. 1767 known genes were identified. 1164 (66%)

were obtained from the UniGene database as clusters containing ESTs sequenced in libraries derived from murine testis. Analysis of the GXD and MEDLINE for genes expressed in the testis or component cell types identified an additional 335 (19%) and 268 (15%) genes, respectively. In addition to identifying genes experimentally determined to be expressed in the murine testis, the search of the literature also identified genes known to be involved in testis function in humans or rats, resulting in the selection of a significant number of homologous genes in the murine databases that would not have otherwise been included in the MTT. Of these 268 genes, 151 (56%) were derived from mouse, 98 (37%) were derived from rat, and the remaining nine (4%) were derived from human model systems. Gene expression analysis of 588 genes using a commercially available array identified 171 genes expressed at high levels in murine testis. Of these 171, 107 (63%) were already contained in the MTT. The remaining 64 (37%) were added to the MTT, bringing the final total of known genes in the MTT to 1831 (www.bch.msu.edu/~zacharet-/MTT.htm). This approach represents an inexpensive, efficient, and productive method for creating comprehensive cell type, tissue, or organism specific transcriptomes, and takes full advantage of the exhaustive cDNA sequencing efforts of other researchers.

1815 TIME RELATED TUMOR NECROSIS FACTOR-ALPHA (TNFα) EXPRESSION AND SIGNALING DUE TO FUMONISIN B_1 *IN VIVO*.

N. Bhandari[1], E. N. Enongene[2], R. T. Riley[2], F. I. Meredith[2] and R. P. Sharma[1]. [1]*University of Georgia, Athens, GA and* [2]*U S Department of Agriculture, Athens, GA.*

Fumonisin B_1 (FB_1), a toxic metabolite of *Fusarium moniliforme*, is a carcinogen and causative agent of various animal diseases. Our previous studies indicated the involvement of TNFα in FB_1-induced toxic responses. To further investigate the time-course of TNFα production and signaling, mice (4/group) were treated subcutaneously (sc) or orally (po) with 25 mg/kg of FB_1 as a single dose and sacrificed at 0, 2, 4, 8, 12, 24 and 48 h after treatment. Both sc and po treatment increased alanine aminotransferase (ALT) and aspartate aminotransferase in plasma, with erythrocyte counts lowering at 4 h and 24 h after sc and po treatments, respectively. The leukocyte counts decreased at 2-8 h in sc, and at 8-12 h after po treatment. The TNFα mRNA expression in liver after sc treatment, measured by reverse-transcriptase polymerase chain reaction, showed a biphasic increase at 2 h and 12 h compared to control. This biphasic increase in liver was supported by a similar trend observed for inhibitor of apoptosis protein (c-IAP2) at 4 h and 24 h in liver, determined by western blot, and in ALT in plasma at 4 h and 24 h. The biphasic trend of c-IAP2 was related to the decrease in nuclear factor κB level (western blot) at 8 h. Kidneys showed an increase in TNFα expression at 2 h after po but no effect seen in spleen, suggesting that FB_1 acts locally on the tissue to induce TNFα expression without any contribution from peripheral macrophages. (Supported in part by NIEHS grant ES09403.)

1816 FUMONISIN TOXICITY IN TUMOR NECROSIS FACTOR RECEPTOR 2 (TNFR2)-KNOCKOUT MICE.

R. P. Sharma[1], N. Bhandari[1], R. T. Riley[2], K. A. Voss[2] and F. I. Meredith[2]. [1]*University of Georgia, Athens, GA and* [2]*USDA-ARS, Athens, GA.*

Fumonisin B_1 (FB_1), a mycotoxin prevalent in corn, causes a variety of toxic effects in different mammalian species. The biochemical responses of FB_1 involve inhibition of ceramide synthase leading to accumulation of free sphingoid bases and expression of tumor necrosis factor α (TNFα). Cytotoxic effects of TNFα are mediated via two distinct membrane receptors. Toxic response to FB_1 was investigated in wild-type (WT) male C57BL/6J mice and a corresponding TNFR2-knockout strain (TRK). The hepatotoxic effects of 5 daily injections of 2.25 mg/kg/day of FB_1 were observed in WT but were considerably reduced in TRK, evidenced by circulating alanine aminotransferase and aspartate aminotransferase levels and histopathological evaluation of the tissue. FB_1 induced TNFα expression in the livers of both WT and TRK mice to a similar extent (3-4 fold over control); however, a corresponding increase of cellular NFκB, expected after the downstream cellular signaling of TNFα, was noted only in the WT. Accumulation of liver sphingosine after FB_1 treatment was similar in both WT and TRK, but the FB_1-induced increases in liver sphinganine and kidney sphingosine and sphinganine were lower in TRK than in WT. Results emphasized the role of TNFα in FB_1-induced hepatotoxicity in mice and the possible relationship of sphingoid base accumulation and TNFα induction. (Supported in part by NIEHS grant ES09403.)

1817 EXPRESSION ANALYSIS OF RAT MULTIPLE DRUG RESISTANCE (MDR1A, 1B AND 2) BY BRANCHED DNA SIGNAL AMPLIFICATION.

N. J. Cherrington, D. P. Hartley, N. Li and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

Branched DNA (bDNA) signal amplification is a powerful tool for monitoring the expression of a selected gene in a high-throughput manner. We describe the tissue expression patterns of three rat mdr isoforms using bDNA technology. P-glycoprotein (encoded by mdr) is responsible for multidrug resistance to cancer chemotherapy and efflux of xenobiotics. The purpose of this study was to quantify mRNA in tissues that are known to express the mdrs and to assess the capability of the bDNA technique to detect mdr isoforms in low copy tissues. Oligonucleotide probe sets were designed to individual isoforms of the mdr family within this highly homologous family. Previously, mdr1a expression was detected to high levels in intestine and was reported in brain and kidney. The bDNA technique verifies that conclusion, but indicates that mdr1a is expressed 10-fold higher in intestine than brain, and detectable in essentially all tissues with concentrations in brain slightly higher than kidney, bladder, and lung. Most reports indicate that mdr1b is prevalent in lung, is expressed to a lesser extent in liver, and is possibly present in kidney and intestine. Using bDNA, mdr1b expression was 6-fold higher in lung than intestine, kidney, and other tissues but detected at low levels in liver. Expression of mdr2 has been reported to be most prevalent in the liver and spleen followed by heart. Using the bDNA technique, mdr2 expression was 2-fold higher in liver than in spleen, lymph node and heart, whereas mdr2 expression in other tissues was much lower. Therefore, bDNA is sensitive and specific for individual mdr isoforms and is capable of reliably quantifying expression in low copy tissues. (ES-07079; Lied Foundation 559086.)

1818 INDUCIBILITY OF THE RAT AND HUMAN MRP2 ('MULTIDRUG RESISTANCE PROTEIN 2') GENE AND IDENTIFICATION OF SEQUENCE ELEMENTS REGULATING THE EXPRESSION OF THE RAT GENE.

H. M. Kauffmann, P. R. Baus and D. Schrenk. *University of Kaiserslautern, Kaiserslautern, Germany.*

The drug-resistance mediating transporter MRP1 and the biliary efflux transporter MRP2 mediate ATP-dependent efflux of e.g., drug conjugates through cellular membranes. So far four further MRP genes have been identified but little is known about their function. In this study we characterized the 5'-flanking region of the rat mrp2 gene with respect to basal expression and inducibility of the gene. Furthermore we demonstrated the inducibility of the human MRP2 gene. In rat hepatocytes and hepatoma cells mrp2 gene expression is inducible e.g., by the chemical carcinogen 2-acetylaminofluorene (2-AAF), the synthetic glucocorticoid dexamethasone, the barbiturate phenobarbital, and chemotherapeutic drugs like vinblastin and cisplatin. Sequencing of the 5'-flanking region of the rat gene and transfection assays with reporter gene constructs containing unidirectional deletions in the flanking region revealed sequences which might mediate these inducing effects. Site-directed mutagenesis experiments demonstrated that a Y-box and a GC-box play a decisive role for the basal expression of the gene. In conclusion the gene seems to be regulated in a similar way as related ABC transporter genes in which also a Y-Box (human MDR1) and a GC-Box (human MRP1) are involved in basal expression.Furthermore, the inducibility of the MRP2 gene might have clinical relevance i) with respect to pharmacokinetic properties of therapeutic drugs, and ii) with respect to the induction of multidrug resistance in malignant and non-malignant cells.

1819 INDUCTION OF ALANINE AMINOTRANSFERASE GENE EXPRESSION BY TACRINE IN HEPG2 CELLS.

P. L. Heard, M. R. Bleavins, K. J. Johnson, M. M. Shi and F. A. de la Iglesia. *Parke-Davis Pharmaceutical Research/University of Michigan, Ann Arbor, MI.*

Tacrine (1,2,3,4-tetrahydro-9-acridinamine monohyrdochloride monohydrate; Cognex) is a drug for the treatment of Alzheimer's disease. The most common adverse effect of tacrine therapy has been increased serum levels of alanine aminotransferase (ALT) activity in approximately 50% of patients receiving the drug. The mechanism(s) by which tacrine elevates ALT is not known. In vitro isolated hepatocyte data showed mitochondrial damage as an early event, and ALT release near cytotoxic levels. In the present study, we explored whether tacrine induces ALT levels through activation of ALT gene expression. Human hepatoma cells, HepG2, were incubated with 0, 0.1, 0.6

and 1 mM tacrine for 4 and 24 hours. Cytotoxicity, assessed by determination of extracellular lactate dehydrogenase activity, was not observed during the 4hr treatment but at 24hr the LDH activity in the medium increased by 50% at 1 mM tacrine. ALT mRNA expression was quantitated using real-time quantitative reverse- transcriptase polymerase chain reaction (RT-PCR). Tacrine caused dose- and time-dependent increases in ALT gene expression with maximal elevations of 2 fold (4hr) and 10 fold (24hr) after 0.6 mM treatment. Co-treatment with actinomycin D had no effect on ALT mRNA induction at 4hr. Extracellular ALT levels were also increased in response to tacrine in these cells. These results indicate that tacrine induces ALT gene expression during non-toxic and toxic exposures which may play a role in the increased ALT activity seen clinically.

1820 TRANSCRIPTION OF MOUSE CYP1B1 DEPENDS ON AHR ACTIVITY AT A SINGLE RESPONSE ELEMENT THAT IS CRITICALLY MODULATED BY NOVEL PROXIMAL UPSTREAM COMPLEXES.

L. Zhang, W. Zheng and C. R. Jefcoate. *University of Wisconsin, Madison, WI.*

Cyp1B1 is expressed constitutively under control of the Ah receptor (AhR) and is induced by 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD). CYP1B1 enhancer region contains four XRE consensus sequences that typically form complexes with AhR and the dimerization partner Arnt. However a complex of similar size which contains neither AhR or Arnt and is unresponsive to TCDD forms at two elements (XRE1, XRE4). Only one element selectively binds AhR/Arnt (XRE5). Systematic mutation of XRE1 and XRE4 shows that this anomalous complex (anC) binds to a consensus sequence ACG-CACGCGGCG. Only the GG pair is not present in XRE5 which is therefore critical to selection between AhR or anC. This anC binding site overlaps with the XRE core sequence. Four XRE5 tandem repeats when linked to a 210 base pair Cyp1B1 proximal promoter and a luciferase reporter gene responded to TCDD to reach activity levels similar to those seen with the full enhancer. The equivalent XRE4 construct was ten fold less inducible. The full enhancer potentiates basal activity 3-4-fold whereas XRE5 and XRE4 tandem repeats were ineffective. Selective site mutations show that XRE1 and XRE4 function as potentiating elements particularly for basal activity whereas AhR/Arnt binding to XRE5 is essential for both basal and induced activity. The downstream half-region (with XRE4 and XRE5) was six-fold less effective in basal regulation but nevertheless exhibited a full induction by TCDD. An upstream half-region (with XRE1 and XRE3) was inactive when used separately.

1821 TCDD AND SUSPENSION ACTIVATE CYP1B1 EXPRESSION IN HUMAN KERATINOCYTES AND DERMAL FIBROBLASTS.

M. A. Weitzel, L. A. White, C. J. Jefcoate and B. L. Allen-Hoffmann. *University of Wisconsin, Madison, WI.*

Binding of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) to AhR results in dimerization with ARNT and expression a number of AhR-responsive genes, including members of the cytochrome p-450 (CYP) family of monoxygenases. TCDD is a potent inducer of CYP1A1 expression in adherent human epidermal keratinocytes. Loss of adhesion and suspension of keratinocytes in the absence of known exogenous AhR ligands also induces CYP1A1 expression through the AhR pathway. However, neither TCDD treatment nor suspension induces the expression of CYP1A1 in normal dermal fibroblasts. To determine if the AhR/ARNT pathway is functional in this mesenchymally derived cell type; we performed northern and western analysis to show that AhR and ARNT are expressed in dermal fibroblasts. We found that another AhR-responsive member of the CYP superfamily, cytochrome P-450 1B1 (CYP1B1), was responsive in dermal fibroblasts. Northern analysis demonstrated that steady state mRNA levels for CYP1B1 were increased in fibroblasts and keratinocytes by either TCDD treatment or suspension. CYP1B1 mRNA levels were increased at 1.5 h after suspension or TCDD treatment, peaked at 12 h, and returned to basal levels by 24 h. We are using fibroblasts and keratinocytes from AhR null mice to investigate the requirement of the AhR signal transduction pathway in CYP1B1 expression in these two cell types. Our data suggest that AhR responsive gene expression may be cell type specific in the epidermis.

1822 IDENTIFICATION OF AN ENHANCER ELEMENT REQUIRED FOR EXPRESSION OF CLASS PI GLUTATHIONE S-TRANSFERASE GENE BY A CO-PLANAR POLYCHLORINATED BIPHENYL.

M. Matsumoto[1], M. Imagawa[2] and Y. Aoki[1]. [1]*National Institute for Environmental Studies, Tsukuba, Japan and* [2]*Graduate School of Pharmaceutical Sciences, Osaka University, Suita, Japan.*

Coplanar polychlorinated biphenyl (PCB) congeners and related compounds, e.g. 2,3,7,8-tetrachlorodibenzo-*p*-dioxin, are recognized as potent hepatocarcinogens. These compounds are teratogenic and have endocrine disrupting activities. 3,3',4,4',5-pentachlorobiphenyl (PenCB), one of the most toxic coplanar PCB congeners, specifically induces class Pi glutathione *S*-transferase (GSTP1), a marker enzyme for preneoplastic hepatic foci and hepatocarcinomas, as well as cytochrome P450 1A1 in primary cultured rat liver parenchymal cells. However, the 5'-flanking sequence of GSTP1 gene does not contain a xenobiotic responsive element, to which arylhydrocarbon receptor binds. To understand the mechanism for the induction of GSTP1, we have identified a 5'-upstream region required for GSTP1 induction by PenCB using chloramphenicol acetyltransferase (CAT) assay. Plasmids containing a 3.0 kb fragment of the 5'-flanking region of the GSTP1 gene and its deletion mutants fused with the CAT gene were transfected into primary cultured rat liver parenchymal cells, and CAT activity was determined after treatment of the cells with PenCB. We have shown that GSTP1 enhancer I (GPEI) located 2.5 kb upstream is required for PenCB stimulation of GSTP1 gene expression in primary cultured rat liver cells. Epidermal growth factor (EGF), an inducer of GSTP1, also stimulated GPEI-mediated gene expression. The sequence of GPEI is similar to that of antioxidant responsive element. It is suggested that a novel signal transduction pathway activated by PenCB contributes to the stimulation of GSTP1 expression.

1823 ESTROGEN AND ARYL HYDROCARBON RECEPTOR EXPRESSION AND CROSSTALK IN HUMAN ISHIKAWA ENDOMETRIAL CANCER CELLS.

M. Wormke, E. Castro-Rivera, I. Chen and S. Safe. *Texas A&M University, Department of Veterinary Physiology & Pharmacology, College Station, TX.*

Ishikawa endometrial cancer cells express the estrogen and progesterone receptor, and 17β-estradiol (E2) induces proliferation of cells used in this study. Treatment of Ishikawa cells with [^{3}H] 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) gave a radiolabeled nuclear complex that sedimented at 6.0 S in sucrose density gradients, and Western blot analysis confirmed that Ishikawa cells expressed human aryl hydrocarbon receptor (AhR) and AhR nuclear translocator (Arnt) proteins. Treatment of Ishikawa cells with 10 nM TCDD induced a 9.7-fold increase in CYP1A1-dependent ethoxyresorufin *O*-deethylase (EROD) activity and a 10.5-fold increase in chloramphenicol acetyltransferase (CAT) activity in cells transfected with pRNH11c containing an Ah-responsive human CYP1A1 gene promoter insert (-1142 to +2434). TCDD and related AhR agonists exhibit antiestrogenic activity in human breast cancer cells, and inhibitory AhR-estrogen receptor (ER) crosstalk was investigated in Ishikawa cells using E2-induced cell proliferation and transcriptional activation assays. AhR agonists including TCDD, benzo[a]pyrene (BaP) and 6-methyl-1,3,8-trichlorodibenzofuran, inhibited 32-47% of the E2-induced responses. In contrast, neither estrogen nor progesterone inhibited EROD activity induced by TCDD in Ishikawa cells, whereas inhibitory ER-AhR crosstalk was observed in ECC-1 endometrial cells suggesting that the interactions were cell context dependent and probably governed by limiting concentrations of transcription factors. (CA64081 and ES09106.)

1824 THERAPEUTIC, DIETARY PHYTOCHEMICALS GENISTEIN, CATECHIN, RESVERATROL, QUERCETIN AND NARINGENIN ACT VIA THE ESTROGEN CELL-SIGNALING PATHWAY.

W. N. Ratna, S. D. Ray, Y. Y. Naroo, C. Oyeamalu, J. Simonelli and B. Amin. *College of Pharmacy, Long Island University, Brooklyn, NY.*

Hepatic expression of apolipoprotein (apo) II is in part modulated by estrogen-mediated stabilization of its mRNA. This stabilization is due to the estrogen-regulated mRNA stabilizing factor (E-RmRNASF) expressed in the liver in response to estrogen (Ratnasab*apathy, 1995, Cell. Mol. Biol. Res, 41: 583-594*). E-RmRNASF protects the RNA from targeted endonucleolytic degradation. The hepatic expression of E-RmRNASF is modulated by certain estrogenic and antiestrogenic nonsteroidal environmental xenobiotics (*Ratnasabapathy et al. 1997, Biochem. Pharmacol., 53: 1425-1434*). To

determine whether dietary phytochemicals purported to prevent hormone-dependent breast and prostate cancers and atherosclerosis, acted via the estrogen cell-signaling pathway, roosters were administered increasing doses up to 1 mmol./kg of genistein, daidzein, resveratrol, quercetin, catechin or naringenin parenterally and tested for hepatic expression of E-RmRNASF. Besides estrogen, resveratrol, genistein and catechin stimulated the expression of E-RmRNASF in the liver, and hence were estrogenic. A lack of E-RmRNASF expression was seen with the roosters treated with the vehicle, naringenin, quercetin or daidzein. To determine whether the agents exerted partial agonistic or antagonistic effects, roosters were administered combinations of estrogen and increasing doses of the above phytochemicals. Resveratrol showed agonistic activity at all concentrations (10-1000 μmol./kg) tested. Genistein, and catechin showed partial agonistic activity, while quercetin and naringenin appeared to be antagonistic. At the concentrations used daidzein appeared not to affect estrogenic stimulation of E-RmRNASF expression.

1825 IDENTIFICATION AND CHARACTERIZATION OF POLYMORPHISMS IN THE 5'-REGULATORY REGIONS OF HUMAN CYTOCHROME P450 1A1 AND 1B1.

C. M. Vezina[1], J. R. Olson[1], S. T. Koury[2] and A. T. Drahushuk[1]. [1]*Dept. Pharm. and Tox. SUNY at Buffalo, Buffalo, NY and* [2]*Dept. Clin. Lab. Sciences SUNY at Buffalo, Buffalo, NY.*

The cytochrome P450 (CYP) superfamily plays an important role in phase I metabolism and detoxification of xenobiotics. However, these enzymes have also been implicated in the paradoxical activation of pro-carcinogens into carcinogenic species. Furthermore, many CYP substrates are also transcriptional inducers of CYPs. Our laboratory has used polymerase chain reaction single strand conformation polymorphism to scan the promoter regions of human cytochrome P450s 1A1 and 1B1 in order to identify single nucleotide polymorphisms that may affect constitutive expression and/or induction of these genes. Two novel polymorphisms have been identified in CYP1B1 ($T_{-350}C$ and $C_{-238}T$) and three polymorphisms have been identified in CYP1A1 ($A_{-469}G$, $A_{-562}G$, and $G_{-594}T$). Each polymorphism was confirmed by DNA sequencing and polymerase chain reaction restriction fragment length polymorphism. The promoter regions of these CYP polymorphisms have been cloned and the functional properties of allelic variants are being investigated by transient transfection and mobility shift assays. Allele-specific alterations in CYP induction and/or expression may be a contributing risk factor for the development of certain forms of cancer and other human diseases. (Supported in part by US EPA R825808 and Multidisciplinary Research Pilot Program, SUNY at Buffalo.)

1826 BRANCHED DNA (BDNA) SIGNAL AMPLIFICATION FOR ANALYSIS OF CYTOCHROME-P450 GENE EXPRESSION.

D. P. Hartley and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

The importance of the cytochrome-P450 enzyme (CYP) family in xenobiotic metabolism, as well as its differential expression and activity in response to a wide range of chemicals and drugs is well documented. In this report, we evaluate the design and specificity of a branched DNA (bDNA) assay for the detection of multiple isoforms of rat CYPs from hepatocellular RNA. Oligonucleotide probe sets were designed to various chemically inducible rat CYP mRNA transcripts, including CYP1A1, CYP1A2, CYP2B1/2, CYP3A1/23, and CYP4A2/3. The robustness of the bDNA assay was assessed with the CYP2B1/2-specific probe set and total hepatic RNA isolated from control and phenobarbital-treated rats. Analysis of these RNA samples by bDNA signal amplification resulted in a linear quantifiable signal from an RNA concentration range that spanned three orders of magnitude (0.1-100 μg). The fidelity of the bDNA assay was evaluated within a single assay and between assays where repeated measurements of a single sample were reproduced reliably. The specificity of each individual CYP probe set was evaluated by utilizing the well-known effect of specific chemicals on the expression of hepatic CYP isoforms. Male Sprague-Dawley rats were administered 3-methylcholanthrene (3MC), phenobarbital (PB), pregnenolone-16α-carbonitrile (PCN), or clofibric acid (CLO). bDNA analysis of chemical-induced differences in CYP gene expression indicated that 3MC induced CYP1A1 and CYP1A2 mRNA levels 670- and 11-fold, respectively; PB induced CYP2B1/2 expression 71-fold; PCN induced CYP3A1/23 expression 34-fold; and CLO induced CYP 4A2/3 expression 4.7-fold. Overall, these data support the use of bDNA signal amplification technology as a reliable, sensitive, and specific method to monitor the differential expression of multiple isoforms of the CYP gene family. (Support: NIH ES-03192, ES-07079; Kansas Health Foundation KHF-411606.)

1827 USE OF REAL TIME GENE-SPECIFIC POLYMERASE CHAIN REACTION (PCR) TO MEASURE RNA EXPRESSION OF THREE FAMILY MEMBERS OF CYTOCHROME P450 4A IN RATS.

K. B. Bleicher, T. R. Pippert, J. F. Sina and D. R. Umbenhauer. *Merck and Co., West Point, PA.*

Exposure of rats to peroxisome proliferators induces members of the cytochrome P450 4A (CYP4A) family. In rats the CYP4A family consists of 3 related genes, CYP4A1, CYP4A2 and CYP4A3, each of which is expressed and induced in a tissue- and sex-dependent manner. While CYP4A1 is sufficiently different from the other two members to enable relatively easy gene-specific quantitation, the close similarity between CYP4A2 and 4A3 makes quantitative discrimination more difficult. We have combined a fluorescent real-time PCR assay (TaqMan®) with the gene-specific Mismatch Amplification Mutation Assay (MAMA) to allow us to carry out gene-specific quantitation of all three members of this family. We have designed the assay such that a single fluorescent TaqMan® probe binds to all three gene members while the specificity is conferred by gene-specific primers. The specific MAMA technique takes advantage of the ability of the Taq polymerase to discriminate between the two genes based on mismatches at the 3' end of a PCR primer. In the 84-base PCR product used for this assay, there is only a singe base difference between 4A2 and 4A3. Despite this similarity, there is at least a 1000-fold discrimination between the two sequences using authentic standards. Analysis of rat liver and kidney RNA from both sexes demonstrates that this discrimination is also achieved in complex RNA mixtures. The technique should be broadly applicable to other research areas such as allelic discrimination, detecting mutational hotspots in tumors, and discrimination among closely-related family members of other genes.

1828 BASAL AND XENOBIOTIC-INDUCIBLE EXPRESSION OF UGT1A6 IS MEDIATED BY THE XENOBIOTIC RESPONSIVE ELEMENT.

D. J. Auyeung, F. K. Kessler and J. K. Ritter. *Virginia Commonwealth University, Medical College of Virginia Campus, Richmond, VA.*

UDP-Glucuronosyltransferases (UGT) isoform 1A6 facilitates the removal of simple phenolic compounds from the body, thereby preventing further metabolism and subsequent toxicity. In liver, UGT1A6 exhibits low basal levels of expression and high inducibility by various agents including dithiole thiones (oltipraz), phenolic antioxidants (tBHQ), and polycyclic aromatic hydrocarbons (PAH) (3MC). The inducibility of UGTs is thought to represent an adaptive response conferring increased liver detoxication capacity in response to chemical exposures and involves transcriptional activation. Transient transfection studies using a luciferase reporter plasmid under the control of the UGT1A6 gene promoter indicated the induction of UGT1A6 gene expression in response to 24 h treatment with 50μM oltipraz (3-fold), 50μM tBHQ (3-fold), and 2.5μM 3MC (20-fold) in primary rat hepatocytes or HepG2 cells. The mechanism of the 3MC effect on UGT1A6 has been proposed to involve the XRE (at position -134 to -129), however the mechanism of the oltipraz and tBHQ effect is unknown. To determine the mechanism(s), UGT1A6 promoter 5' deletion constructs and constructs with mutated XRE were prepared. Deletion to -161 maintained oltipraz, tBHQ, and 3MC inducibility. A single base pair mutation and deletion of the XRE reduced basal expression by 90% and resulted in loss of inducibility by all three compounds. Therefore, these data suggest that the XRE is involved in basal and inducible expression of UGT1A6 upon treatment by PAH and selective phase 2 enzyme inducers.

1829 CELL-TYPE SPECIFIC DIFFERENCES IN THE REGULATION OF HUMAN γ-GLUTAMYLCYSTEINE SYNTHETASE HEAVY (GCSh) AND LIGHT (GCSl) SUBUNIT GENES.

E. L. Dahl and R. T. Mulcahy. *University of Wisconsin, Madison, WI.*

γ-glutamylcysteine synthetase (GCS), the enzyme catalyzing the rate-limiting step of glutathione synthesis, is composed of a catalytic and a regulatory subunit, designated GCSh and GCSl respectively. Northern blot analysis using mRNA from human tissues has shown that the ratio of GCSl to GCSh mRNA is not uniform, suggesting tissue-dependent regulation. We used human cell lines derived from liver (HepG2), lung (A549), kidney (HEK 293) and skeletal muscle (RD) to examine cell-type specific regulation. We transfected luciferase reporter gene constructs containing the 5' promoter region of each gene into each cell line to study differences in transcriptional regulation. The ratio of GCSl to GCSh promoter-mediated transcription was approximately

4.0 in A549 cells, 1.6 in HepG2 and RD cells, but only 0.25 in HEK 293 cells. To examine cell-type dependent gene-induction, we treated each cell line with the GCS inducing agents pyrrolidine dithiocarbonate (PDTC), phenethyl isothiocyanate (PEITC), and b-naphthoflavone (b-NF) and measured changes in steady state RNA levels of GCSl and GCSh using an RNAse protection assay. Preliminary results suggest that although both GCSl and GCSh are induced in HepG2 cells by all three agents, in the other three cell lines there is little or no induction of either subunit by PEITC or b-NF while only GCSl is induced by PDTC. While some differences may reflect variations in metabolic capabilities (i.e., for b-NF), these studies indicate that GCSl and GCSh are not always coordinately regulated and that there are cell-type specific differences in basal and induced regulation of these genes. (This work was supported by ES09749, CA57549, T32-ES0715-21.)

1830 INDUCTION OF HEPATIC MICROSOMAL EPOXIDE HYDROLASE AND CYTOSOLIC RGSTA3/5 AND ACTIVATION OF ACTIVATOR PROTEIN-1 BY PROTEIN-CALORIE MALNUTRITION IN RATS: REVERSAL BY CYSTEINE SUPPLEMENTATION.

S. G. Kim, M. K. Cho, Y. G. Kim and M. G. Lee. *Seoul National University, Seoul, Republic of Korea.*

Protein-calorie malnutrition (PCM), as one of global problems, arises during protein and/or energy deficit due to disease and nutritional inadequacy. Cellular adaptive responses and gene expression associated with PCM remain poorly understood. The present study was designed to assess the expression of hepatic phase II detoxifying enzymes in PCM rats and to investigate the molecular mechanistic basis. A 4 week-protein restriction of rats resulted in 4-fold induction of hepatic microsomal epoxide hydrolase (mEH) with a 21-fold increase in mRNA. Immunoblot and Northern blot analyses revealed that rGSTA3/5 was induced by protein deprivation. Supplementation of rats fed the low casein diet with cysteine prevented increases in hepatic mEH and rGSTA3/5 protein and mRNA levels. Gel shift analysis revealed that the nuclear hepatic activator protein-1 (AP-1) transcription complex was activated in PCM rats. AP-1 binding activity was reduced by anti-JunB, and anti-c-Jun antibodies, whereas antibodies directed against c-Fos, FosB, Fra-1 and JunD were not inhibitory. Cysteine supplementation prevented the activation of AP-1 and the decrease in hepatic GSH level by PCM. PCM caused marked decreases in cytoplasmic eosinophilic contents and nuclear shrinkage in hepatocytes, whereas PCM rats supplemented with cysteine showed only mild fat degeneration with well-preserved portal structures. The current study provided evidence that PCM induced mEH and rGSTA3/5 and that cysteine was active in preventing the enzyme induction and AP-1 activation as well as in preserving morphological structures of hepatocytes.

1831 SPECIES DIFFERENCES IN THE EXPRESSION OF OCULAR AND STOMACH ALDH3A1.

A. Pappa, J. Kupfner and V. Vasiliou. *University of Colorado Health Science Center, Denver, CO.*

The class 3 aldehyde dehydrogenase (ALDH3A1) is a cytosolic NAD(P)+-dependent enzyme that efficiently catalyzes the oxidation of medium-chain aldehydes, such as those produced during lipid peroxidation. The ALDH3A1 gene exhibits a tissue-specific expression pattern. It has been shown that it is constitutively expressed at high levels in corneal cells and to a lesser extent in stomach in various mammalian species. This study was undertaken to investigate the species distribution of ocular and stomach ALDH3A1 in pig, mouse, rat, rabbit, chicken, turkey, zebrafish, trout and frog, which represent different orders of mammals as well as other non-mammalian classes. High ALDH3A1 activity was detected in both ocular and stomach tissues in pig, mouse and rat. Immunohistochemistry on ocular and stomach sections of these species showed that ALDH3A1 is abundantly present in the corneal and stomach epithelial cells, detected as a 54 kDa protein in immunoblots. The ocular tissues contained higher ALDH3A1 levels as compared to the stomach tissues. Lack of ALDH3A1 protein and enzymatic activity was observed in rabbit, zebrafish, trout, frog, chicken, turkey, and frog ocular and stomach extracts. Interestingly, significant levels of the cytosolic ALDH1A1 and the mitochondrial ALDH2 were detected by immunoblot analysis in the ocular and stomach tissues of the above species. These data suggest that expression of ALDH3A1 occurs in a taxon specific manner. Furthermore, the presence of ALDH3A1 or ALDH1A1/ALDH2 in ocular and stomach tissue supports the proposed catalytic role of those ALDHs in the detoxification of lipid peroxidation aldehydes. (Supported by NEI 1 R29 EY11490.)

1832 DIFFERENTIAL GENE EXPRESSION IN RABBIT RENAL CORTICAL SLICES EXPOSED TO ARSENIC COMPOUNDS.

X. Zheng[1], C. L. Wilson[2], A. R. Parrish[3] and A. J. Gandolfi[1]. [1]*University of Arizona, Tucson, AZ,* [2]*Naval Health Research Center Detachment, Wright-Patterson AFB, OH and* [3]*Texas A & M University, College Station, TX.*

Differentially expressed genes were determined in an *in vitro* system -precision-cut rabbit renal cortical slice- after 3 hr exposure to 0.1 μM inorganic arsenite (As III), arsenate (As V), or 0.1 and 100 μM dimethylarsenate (DMA). The high-density Gene Discovery Array System (Genome Systems, Inc.) representing 18,376 non-redundant human cDNA clones was used to determine gene expression pattern. mRNA from renal slices was reverse transcribed to [α-^{33}P]dCTP-labeled cDNA and hybridized to the membrane. The differentially expressed cDNA clones were identified using the Genome Systems website following phosphoimager analysis. Up-and down-regulated genes (>3-fold from control) were:

AsIII	(0.1	μM):	11	up	and	12	down
AsV	(0.1	μM):	13	up	and	19	down
DMA	(0.1	μM):	14	up	and	18	down
DMA	(100	μM):	22	up	and	18	down

There are 12 common genes, such as ubiquitin, metallothionein-II, thyroxine-binding globulin, and anion exchange protein. Nine genes were unique to AsIII, such as ATP synthase subunit 9, nuclear protein p68, and insulin-like growth factor binding protein 6. Five genes were unique to AsV, such as GDP-dissociation inhibitor, and HLA class II histocompatibility antigen DQ5. Only 2 genes were unique to DMA (0.1 μM): interlekin 1 receptor accessory protein and thy-1 glycoprotein, while the high concentration of DMA had numerous unique genes such as transcriptional activators hSNF2 and STAT5A, and tumor necrosis factor precursor 2 related protein. Although these genes need to be confirmed by Northern analysis, Gene Array technology has been proven to be a powerful tool to provide a global view of molecular alterations induced by specific arsenic species. (NIH ES04940.)

1833 GENE EXPRESSION AND CELL FUNCTION IN CISPLATIN TREATED RAT AND HUMAN KIDNEY AND LIVER SLICES.

S. J. Hasal, K. Rose and A. Vickers. *Novartis Institute for Biomedical Research, East Hanover, NJ.*

Cisplatin is a chemotherapeutic agent that induces cell death through an apoptotic mechanism. The role of apoptosis in cisplatin induced kidney and liver damage was investigated in precision-cut rat and human kidney and liver slices. Slices were incubated with cisplatin (10 - 100 μM) for up to 24 hours. Viability of the slices was monitored in conjunction with the expression of genes regulating cell cycle progression and apoptosis. In rat kidney slices, p53 gene and protein expression, early indicators of apoptosis, were induced by ≤20 μM cisplatin at 24 hours. Additionally, the expression of the early response gene c-fos was elevated at all concentrations. The expression of Gadd45, a gene involved in growth arrest and DNA damage, was induced at all concentrations of cisplatin, with the greatest expression change at 10μM. Genomic DNA laddering, one of the final events in the apoptotic cascade, was evident in slices treated with ≥60 μM cisplatin. This increase in DNA laddering coincided with a decrease in slice viability, as measured by ATP content and organic anion transport. In rat liver slices, at 24 hours, p53 gene and protein expression levels were below control at all concentrations. In work previously reported in this lab, p53 gene and protein expression in rat liver slices was shown to be transient and elevated prior to 24 hours of incubation. In this study, Gadd45 gene expression and DNA laddering was evident in rat liver slices incubated with all concentrations of cisplatin, while viability was decreased at concentrations ≥40 μM as assessed by ATP and GSH content. Human kidney slices were less sensitive to cisplatin (≥100 μM) than were human liver or rat kidney and liver slices out to 24 hours. In both species, cisplatin induced apoptotic events occur in liver and kidney slices, and these apoptotic events precede and may accompany the decrease in slice viability.

1834 QUINOL-THIOETHERS REGULATE A VARIETY OF GENES INCLUDING A NOVEL G PROTEIN BETA SUBUNIT IN HL-60 CELLS PRIOR TO APOPTOSIS.

S. Ramachandiran, S. S. Lau and T. J. Monks. *Division of Pharmacology and Toxicology, College of Pharmacy, University of Texas at Austin, Austin, TX.*

Benzene mediated hematotoxicity and bone marrow suppression may be due to the combined effects of hydroquinone and its glutathione conjugates. 2,3,5-tris-(glutathion–S-yl)hydroquinone (TGHQ) induces oxidative stress and apoptosis in human promyelocytic leukemia (HL-60) cells. Induction of apoptosis occurs 6-8 hrs after treatment of HL-60 cells with 200 μM of TGHQ. In order to understand the role of gene expression in the early phase of induction of apoptosis, a differential screening of cDNA libraries from TGHQ treated and untreated HL-60 cells was performed. Primary screening of 90,000 clones identified 385 differentially regulated cDNAs. Secondary screening by dot blot analyses revealed 111 cDNAs regulated by TGHQ. Sequencing of the cDNA clones identified 41 independent clones differentially regulated by TGHQ in HL-60 cells, and these were categorized into five groups: 1. Global modifiers of gene expression (transcriptional repressor GCF2, RNA polymerase II, elongation factor 1ß); 2. Tumor specific genes (TACC1, laminin binding protein); 3. Ribosomal proteins (RPLp1, L17); 4. Signalling and apoptosis related genes (clathrin associated protein AP-2, bax, thymosin ß-10, chaperonin containing TCP-1) and 5. Novel genes (novel G protein ß subunit, a protein kinase C receptor). The expression pattern and physiological significance of TGHQ regulated genes is being determined. Since many of these genes are not generally associated with apoptosis or oxidative stress, the results imply additional functions for these genes. (Supported by ES07784.)

1835 EFFECT OF THE EXPOSURE TO P-BENZOQUINONE AND HYDROQUINONE ON THE BINDING ACTIVITY OF THE TRANSCRIPTION FACTOR AP-1 IN PROMYELOCYTIC LEUKEMIA CELLS (HL-60).

R. Ruiz, E. S. Calderon-Aranda, M. E. Cebrian and J. E. Garrido. *Cinvestav, Mexico, Mexico.*

Benzene is one of the most heavily used chemicals in the world and has a wide environmental occurrence. The pathways of benzene metabolism are important in the bioactivation and therefore in the toxicity of this compound. Cytochrome P450-mediated oxidation of benzene to phenol and the polyhydroxylated metabolites: hydroquinone (HQ), catechol, and 1,2,4-trihydroxybenzene. The oxidation of these benzene metabolites generate reactive benzoquinone (BQ) and free radicals as well as other reactive oxygen species, which are involved in transcriptional regulation of some genes. Numerous studies have associated exposure to benzene with blood and bone marrow toxicity in occupational exposed workers, including lymphocytopenia, pancytopenia, aplastic anemia, acute myelogenous leukemia, and possibly lymphoma. This work evaluated alterations in the expression levels of c-Jun and c-Fos, and the binding activity of AP-1, using the mobility shift asay, in HL-60 cells exposed to HQ and BQ. Our results showed that BQ and HQ induced an increased gene expression of c-jun and c-fos, as well as an increased AP-1 binding activity when cells were treated with 1μM for 1 or 4h; however, we could not detect c-Jun in the AP-1 complex at 4 h. In contrast, when cells were treated for 1h with BQ or HQ, c-Jun was present in the AP-1 complex. Therefore our results suggest that another member of the Jun family is present in the AP-1 complex at 4 hours.

1836 EFFECT OF ACROLEIN ON AP-1 AND GENE EXPRESSION IN A549 CELLS.

S. Biswal, G. Acquaah-Mensah, J. Pabalan, K. Datta and J. P. Kehrer. *The University of Texas at Austin, Austin, TX.*

Acrolein, a reactive α,β–unsaturated aldehyde is a common environmental pollutant. Recently, it has been shown to be a byproduct of lipid peroxidation, and increases in acrolein production may be a marker for Alzheimer' disease, diabetic glomerular lesions and atherosclerosis. Although the overt toxicity of acrolein has been widely studied, the effects of low dosages are not known. We previously reported that DNA synthesis and NF-κB activation were inhibited by acrolein in the A549 lung adenocarcinoma cell line (*J. Biol. Chem.* **274**: 9200 [1999]). The current data demonstrate that AP-1 activation is decreased by 26 and 50% at 0.5 and 1 h, respectively, after exposure to 45 fmol/cell of acrolein. This was further confirmed by an AP-1 reporter assay. This effect may result from changes in the redox status of cells due to the depletion of glutathione as well as covalent modification of AP-1 protein. Differential gene expression was monitored using a cDNA microarray containing 4000 well characterized genes after treating A549 cells with 45 fmol/cell acrolein for 0.5 h followed by 0.5 h of recovery. Redox related genes including *quinone oxidoreductase, glutathione synthetase, NADH-quinone oxidoreductase* and *c-Jun* were elevated more than 9-fold. There was also an elevation in *cytochrome P450 IIE1* and some death-related genes. Based on the results of the microarray, several genes are being further studied to help understand the mechanism of toxicity of acrolein. (Supported by HL48035, ES09791 and Center Grant ES07784.)

1837 ETHIONINE INCREASES TUMOR NECROSIS FACTOR α EXPRESSION BY LIPOPOLYSACCHARIDE-STIMULATED MURINE MACROPHAGES.

W. H. Watson and R. K. Chawla. *University of Kentucky, Lexington, KY.* Sponsor: D. P. Jones.

Increased serum tumor necrosis factor-α (TNF) and hepatic deficiency of S-adenosylmethionine (AdoMet) are observed in patients with alcoholic liver disease as well as in experimental models of inflammatory liver injury induced by hepatotoxins. AdoMet is a major methylating agent and its deficiency is attributed to impaired hepatic synthesis. However, the biochemical mechanisms for elevated serum TNF are not fully understood. We previously reported that rats with hepatic AdoMet deficiency had ninefold more serum TNF upon lipopolysaccharide (LPS) treatment as compared to LPS- treated normal controls. The present study examined the effect of AdoMet deficiency on LPS-induced TNF production in the murine macrophage/monocyte cell line RAW 264.7. The cells were made AdoMet deficient by pre-incubating them with ethionine, a structural analogue of methionine. Ethionine, when converted to S-adenosylethionine (AdoEth), prevents utilization of AdoMet for methylation reactions and creates a functional deficiency of AdoMet. The effects of ethionine treatment on intracellular AdoMet and AdoEth concentrations, TNF protein and TNF mRNA levels, TNF mRNA stability, and transcription from the TNF promoter were determined. Ethionine treatment increased the intracellular concentration of AdoEth but did not significantly affect AdoMet concentrations. Ethionine treatment increased the amount of TNF protein released and the induction of TNF mRNA in response to LPS, but the stability of the TNF mRNA was unaffected by ethionine. A TNF promoter reporter construct was similarly affected by ethionine; LPS-induced CAT activity (reporter gene) and CAT mRNA levels were higher in ethionine-treated cells than in control cells. Therefore, ethionine acts at the transcriptional level to enhance LPS-induced TNF expression in RAW 264.7 cells.

1838 MODULATION OF THE EXPRESSION OF p53 DURING DIFFERENTIATION AND APOPTOSIS IN MURINE EMBRYONIC STEM CELLS WITH ALL-*TRANS*-RETINOIC ACID.

S. A. Sarkar and R. P. Sharma. *Department of Physiology and Pharmacology, The University of Georgia, Athens, GA.*

The role of all-*trans*-retinoic acid (RA) in embryonic development has been established. RA is a morphogen but its excess can produce teratological effects. P53, a tumor suppressor gene that encodes for phosphoproteins, controls cellular proliferation, differentiation and apoptosis. The temporal modulation of p53 by RA was investigated in murine embryonic stem cells (ES) during normal differentiation. Undifferentiated ES cells express high levels of p53 mRNA and protein followed by a decrease in p53 as differentiation progressed. At 11-21 days of spontaneous differentiation the p53 level increased, presumably contributing to inhibition of proliferation in cells entering terminal differentiation. The addition of RA during 8-10 days increased the levels of p53 mRNA and protein, corroborated by increased apoptosis. RA-induced morphological differentiation provided specific, predominantly neural type of cells. The maximum increase in p53 mRNA in RA-treated ES cells was at day 17, whereas maximum protein expression occurred at 14-17 days. The level of p53 decreased in terminally differentiated ES cells. Marked apoptosis was observed at 10 and 20 hours after RA treatment. Results demonstrated that RA accelerated cellular differentiation and apoptosis in ES cells and increased the expression of p53. However, RA increased apoptosis earlier than it caused changes in p53 expression, suggesting that RA-induced apoptosis is not initiated by the induction of p53.

1839 IDENTIFICATION & CHARACTERIZATION OF A NOVEL TUMOR SUPPRESSOR GENE IN WILMS TUMOR.

K. P. Singh and D. Roy. *Department of Environmental Health Sciences, University of Alabama, Birmingham, AL.*

Wilms tumor or nephroblastoma is an embryonal malignancy of the kidney affecting about 1 in 10,000 children. It comprises about 6 % of all childhood cancers. Mutations mainly in two tumor suppressor genes, WT1 and WT2, do not account for all (hereditary as well as sporadic) cases of Wilms tumors. In an effort to screen mutations in the genome of wilms tumors, we previously reported a common mutations detected through AP-PCR analysis in 5 out of 15 (30 %) human Wilms tumor tissue samples. We also reported the chromosomal localization of this mutation at human chromosome $11q^{23.2}$. Here we report the further characterization of the amplified gene loci. We cloned and sequenced the variant AP-PCR amplified fragment and DNA sequence was compared with the known gene sequence in the Gene Bank database using the BLASTn program. The level of expression of this novel gene in tumor and control tissue from the same patient was done with the RT-PCR, and confirmed by Nothern as well as RNase protection assay. Sequence homology search did not reveal significant homology with any known gene. However it has 99% sequence homology with one of the human EST sequence in the gene bank. Both, RT-PCR and RNase protection assay indicated the down regulation of this gene in tumor as compared to their normal tissues. Findings of this study indicate the presence of the novel gene in Wilms tumors. Presence of normal copy of this gene and it normal expression in the control tissue samples and its downregulation of expression as a result of mutation in the tumor tissues indicates that it may be a novel tumor suppressor gene.

1840 GENOMIC IMPRINTING ANALYSIS OF THE MANNOSE-6-PHOSPHATE/INSULIN-LIKE GROWTH FACTOR 2 RECEPTOR IN CANCER SUSCEPTIBLE MICE.

J. G. Falls, A. A. Wylie and R. L. Jirtle. *Department of Radiation Oncology, Duke University Medical Center, Durham, NC.*

The M6P/IGF2R functions in the activation of the potent growth inhibitor, transforming growth factor β, and the degradation of IGF2, a mitogen often overproduced in tumors. The M6P/IGF2R has also been shown to be inactivated in both human and rodent cancers, and is genomically imprinted in rodents (i.e., only the maternal allele is expressed). The purpose of this study was to examine the imprint status of the M6p/Igf2r in the mouse strains C3H and C57BL/6, which are relatively susceptible and resistant to liver cancer, respectively. To investigate, a sequence polymorphism must first be identified. RT-PCR followed by mismatch detection found no difference in the M6p/Igf2r sequence between C57BL/6 and C3H. Therefore, 12 additional strains of mice were analyzed for sequence polymorphisms. DNA sequencing revealed a C to A base change in the 3' UTR of M6p/Igf2r in the SKH2 strain with respect to C57BL/6 and C3H. Crosses of C57BL/6 x SKH2 and C3H x SKH2 were generated to introduce the polymorphism in the F1 hybrids. Liver, heart, and brain RNA samples from each F1 cross were then analyzed for monoallelic or biallelic expression at the M6p/Igf2r locus. Results indicated a maternally derived, monoallelic expression pattern of the M6p/Igf2r in the liver and heart, but not in the brain. Importantly, no difference was observed in the imprint status of M6p/Igf2r between the F1 crosses in each tissue analyzed.

1841 HUMAN KERATINOCYTE EARLY TRANSCRIPTIONAL GENE ACTIVITY FOLLOWING SULFUR MUSTARD.

J. J. Schlager, H. R. Benjamin, C. F. Levine, D. P. Avery and J. H. Clark. *US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

Sulfur mustard (SM) by intramolecular rearrangement forms a stabilized carbonium ion that alkylates DNA, RNA, protein, and membrane molecules through electrophilic reaction. SM exposure on human skin produces delayed skin vesication at the dermal-epidermal basal contact of the keratinocyte epidermal stem cell. The primary changes occurring within the basal keratinocyte layer producing the loss of its attachment are not known. We were interested in determining the predominant mRNA changes in cultured human epidermal keratinocytes (HEK) shortly following SM exposure. Our hypothesis is that gene transcription following exposure to SM should be indicative of the level and type of specific cellular damage. In this study, we produced subtraction libraries (PCR-Select, Clontech, Palo Alto, CA) containing the up-regulated gene transcripts at 30 min after exposure to SM. Cultured normal HEK (Clonetics, San Diego, CA) at 70% confluence (150cm² flask) were exposed to 25 μM SM, an estimated subvesicating skin exposure, or to 200 μM, a vesicating exposure of SM. The polyA mRNA was purified, and the untreated control HEK cDNA subtracted from the cDNA from SM-treated HEK. The up-regulated gene transcripts were PCR-amplified, and the library was cloned and transformed into bacteria for cDNA sequence determination from colony isolation. Considerable diversity was found at 25 μM SM with 60 different transcripts of the 83 sequenced. In contrast, 57 cDNA sequenced at 200 μM SM produced only 16 different transcripts containing 9 known genes. The predominant known transcripts identified at 200 μM SM included γ-filamin, poly(rC)-binding protein 1, prothymosin and RAB11A. The down-regulated gene transcripts at 30 min after exposure to these SM concentrations are presently under investigation.

1842 LEAD INDUCTION OF TRANSCRIPTION FACTORS AND VEGF EXPRESSION IN HUMAN FETAL ASTROCYTES.

M. A. Hossain and J. Laterra. *The Kennedy Krieger Institute and Johns Hopkins School of Medicine, Baltimore, MD.* Sponsor: J. Bressler.

Lead (Pb) is a widespread environmental neurotoxicant whose developmental neurotoxicity remains a major medical issue. High levels of lead exposure increases the permeability of the blood-brain barrier (BBB) the function of which is regulated by perivascular astrocytes. The exact mechanism(s) of action of lead have not been fully elucidated. We hypothesized that VEGF, an angiogenic growth factor and vascular permeability factor, plays a role in Pb effects on the BBB. Using immortalized human fetal astrocyte (HFA) cultures we examined the effects of lead on VEGF expression and on the activity of the transcription factors HIF-1 and AP-1 that are capable of regulating VEGF expression. Induction of VEGF and transcription factors were determined by Northern blot analysis and electrophoretic mobility shift assay, respectively, and quantified by phosphor imaging. Maximum induction of HIF-1, AP-1 and VEGF resulted from exposing cells to 10 M lead acetate for 4 h and 20 h, respectively, in medium containing 10% serum. Induction of HIF-1 was increased 86% by lead ($p<0.01$) and 96% ($p<0.05$) by the protein kinase C (PKC) agonist PMA (100 nM). Induction of AP-1 was increased ~2 fold ($p<0.01$). VEGF expression was increased ~4 fold by lead ($p<0.001$) and ~2.5 fold by PMA ($p<0.001$). However, overexpression of a dominant negative form of HIF-1 in HFA cells did not block the induction of VEGF by Pb. In contrast, pretreatment with GF109203 (2 M), a specific inhibitor of PKC, inhibited lead and PMA mediated activation of VEGF transcription. These findings suggest that lead induces VEGF via a PKC-dependent and HIF-1 independent pathway in human fetal astrocytes. (Supported by NIH grant PO1 ES08131.)

1843 DIFFERENTIAL EXPRESSION OF NEUROFILAMENT SUBUNITS IN DIISOPROPYL PHOSPHOROFLUORIDATE (DFP)-TREATED HEN SPINAL CORD AND THEIR PRESENCE IN AXONAL AGGREGATES.

R. P. Gupta[1], A. Abdel-Rahman[1], K. F. Jenson[2] and M. B. Abou-Donia[1]. [1]*Duke University, Durham, NC and* [2]*Neurotoxicology Division, US. EPA, Research Triangle Park, NC.*

Diisopropyl phosphorofluoridate (DFP) is an organophosphorus ester,that produces organophosphorus ester-induced neuropathy (OPIDN) in hen and other sensitive species. A single dose of DFP (1.7mg/kg,sc.) produces mild ataxia in 7-14 days in hens, that develops into severe ataxia or paralysis with the progression of the disease. OPIDN is associated with axonal swellings and degeneration of axons. This study was carried out to investigate the expression of neurofilament (NF) subunits in spinal cord of DFP-treated hens. Hens were treated with a single dose of DFP and sacrificed 1,5,10,20 days post-treatment. Western blot analysis showed increased expression of NF-M and decreased expression of NF-H and NF-L in the 2 M urea extracts of spinal cord particulate fraction within 24 hr of DFP administration. Thus, there was increase in the stoichiometry of NF-M:NF-L in the spinal cord of DFP-treated hens. Immunoprecipitation, cross-linking, and two-dimensional polyacrylamide gel electrophoresis showed the presence of heterodimers in hen spinal cord extract. The formation of heterotetramers, however, was not detectable by disuccinimidyl suberate (DSS) mediated cross-linking. Immunohistochemical staining revealed the presence of all three NF subunits in the cytoskeletal aggregates in DFP-treated hen spinal cord cross-sections. The results suggest that each NF subunit probably gets accumulated by a different mechanism in the axonal aggregates of DFP-treated hen. (Supported in part by NIEHS Grant ESO 5154.)

1844 PRECLINICAL SAFETY EVALUATION OF THE LIPID-REGULATING AGENT CI-1027 IN CYNOMOLGUS MONKEYS.

E. J. McGuire[1], D. Manca[1], M. A. Albassam[2], R. M. Walker[1], L. Radulovic[2], D. Gibson[2] and F. A. de la Iglesia[2]. [1]*Parke-Davis Pharmaceutical Research Division, Warner-Lambert Co., Mississauga, Ontario, Canada and* [2]*Parke-Davis Pharmaceutical Research Division, Warner-Lambert Co., Ann Arbor, MI.*

Subacute effects of CI-1027 (6,6'-oxybis[2,2-dimethyl-4-hexanoic acid]-Ca) were investigated in male and female monkeys (3/sex/dose) given 10, 30, 100, or 300 mg/kg daily by gavage for 4 weeks. No significant treatment-related clinical signs, and no changes in body weight and food consumption were observed at 10 to 100 mg/kg (Day 28 $AUC_{(0-24)}$: 954 to 8220 μg·hr/mL). At 300 mg/kg (Day 28 $AUC_{(0-24)}$: 10400 μg·hr/mL), 1 male and 2 females were symptomatic and were euthanatized for humane reasons during Week 3 or 4. Clinical laboratory changes consisted of decreased red blood cell counts, hematocrit, and hemoglobin concentration (10% to 30% from pretest) in females at 100 and 300 mg/kg, and increased activated partial thromboplastin time (41% to 72%) and prothrombin time (14%) in males at 100 and 300 mg/kg. Changes observed in the 300 mg/kg group reflected deteriorating clinical condition. Pathological changes included increased relative liver weight (58% to 93%) at 300 mg/kg, and hepatocellular hypertrophy and/or hepatocellular fatty change, and decreased fine vacuolation of the adrenocortical zona fasciculata at 100 and 300 mg/kg. There was no evidence of microsomal enzyme induction. Pharmacologic effects at 10 to 300 mg/kg consisted of a 44% to 88% decrease in lipoprotein(a) and up to 35% decrease in total cholesterol. No adverse effects were noted at 30 mg/kg.

1845 EVALUATION OF HEPATIC PEROXISOMAL PROLIFERATION AND MICROSOMAL ENZYME INDUCTION BY THE LIPID-REGULATING DICARBOXYLIC ACID CI-1027 IN RATS, DOGS, AND MONKEYS.

R. M. Walker[1], L. M. King[1], E. J. McGuire[1], D. Manca[1], L. Radulovic[2] and F. A. de la Iglesia[2]. [1]*Parke-Davis Pharmaceutical Research Division, Warner Lambert Co., Mississauga, Ontario, Canada and* [2]*Parke-Davis Pharmaceutical Research Division, Warner Lambert Co., Ann Arbor, MI.*

CI-1027 (6,6'-oxybis[2,2-dimethyl-4-hexanoic acid]-Ca) is a lipid-regulating agent in experimental models of dyslipidemia. Hepatic peroxisome proliferation and microsomal enzyme induction were evaluated in beagle dogs receiving oral CI-1027 for 2 weeks, and Wistar rats and cynomolgus monkeys for 2 and 4 weeks. Peroxisomal enzyme activity markers were carnitine acetyltransferase, acyl CoA oxidase, β-oxidation, and catalase, and microsomal enzyme activity markers were ethoxy- and pentoxyresorufin O-dealkylase, aminopyrine (monkey only) and erythromycin N-demethylase, lauric acid hydroxylase, and UDP glucuronyl transferase (GT). No hepatic changes occurred in dogs given doses up to 1000 mg/kg. In monkeys, liver weight increased at 150 to 1000 mg/kg, but was unchanged at 10 to 100 mg/kg. While β-oxidation was higher than controls in some drug-treated monkeys, there was no pattern of enzyme changes indicative of peroxisomal proliferation or microsomal enzyme induction. In rats at all doses, 30 to 750 mg/kg, liver weight increased up to ~100% and peroxisomal enzyme activities up to 6-fold. Lauric acid hydroxylase, a marker for CYP4A1, increased up to 11-fold at all doses in rats and GT activity increased up to 1.5-fold at 100 to 750 mg/kg. Increased CYP4A concentrations were confirmed with an ELISA. Toxicokinetic profiles revealed that CI-1027 exposures were less than dose-proportional and higher in monkeys than in dogs at the same dose. In rats given 300 or 750 mg/kg, exposures were lower at study termination than on Day 1, which may reflect GT induction. It is concluded that CI-1027 is similar to related compounds that cause hepatic peroxisome proliferation and microsomal enzyme induction in rats, but not in nonrodent species.

1846 ACUTE TOXICIOLOGY AND PHARMACOKINETIC ASSESSMENT OF A RIBOZYME (ANGIOZYME™) TARGETING VEGF RECEPTOR mRNA IN THE CYNOMOLGUS MONKEY.

J. Sandberg[1], C. Sproul[1], K. Blanchard[1], L. Bellon[1], J. Powell[1], F. Caputo[2] and D. Kornbrust[2]. [1]*Ribozyme Pharmaceuticals, Inc. (RPI), Boulder, CO and* [2]*Sierra Biomedical, Inc., Sparks, NV.*

The potential acute toxicity of a ribozyme (ANGIOZYME™) targeting the flt-1 VEGF receptor mRNA was evaluated in cynomolgus monkeys following iv infusion or sc injection. ANGIOZYME™ was administered as a 4 h iv infusion at doses of 10, 30 or 100 mg/kg or a sc bolus at 100 mg/kg. Endpoints included blood pressure, ECG, clinical chemistry, hematology, complement factors, coagulation parameters, and ANGIOZYME™ plasma concentrations. ANGIOZYME™ was well tolerated with no drug-associated morbidity or mortality. There was no clear evidence of ANGIOZYME™ related adverse effects in this study. Slight increases in spleen weight and lymphoid hyperplasia were observed in several animals; however, these changes were not dose-dependent. Average steady-state concentrations of ANGIOZYME™ were achieved during the 4 h infusion of 10, 30 or 100 mg/kg. Dose-dependent elimination of ANGIOZYME™ was observed in steady-state concentrations for the 9 h sampling period. Thus, monkeys in this toxicology study received significant plasma ANGIOZYME™ exposure by the sc and iv routes.

1847 SAFETY STUDIES IN DOGS AND CATS OF A FABRIC REFRESHER.

F. W. Oehme[1], T. Covey[1], E. M. Micek[1] and C. E. Manderfield[2]. [1]*Comparative Toxicology Laboratories, Manhattan, KS and* [2]*SC Johnson and Son Inc., Racine, WI.*

The safety of Oust®, a commercially available fabric refresher containing water, isopropanol, propylene glycol, surfactants, fragrances, zinc chloride and preservatives, was studied in cats and dogs under exaggerated exposure. Eight dogs and 8 cats were orally gavaged with 2 g product or water/kg bw. Another 8 dogs and 8 cats were whole-body sprayed with the product or water every other day for 14 d; each had 5cm by 5cm of trunk clipped to assess dermal irritation. A sensitization assessment was performed on 6 cats with clipped 5cm by 5cm trunk areas occlusively patched with gauze saturated with 0.2ml product and another with saline (first 3 d) and 2ml product and saline (2 additional d) for 5 consecutive days. After 14 d 0.2ml product challenge patches were applied to virgin clipped skin for 24 h. All animals were observed for skin, respiratory and general behavior or physiological alterations for 14 d after each last exposure. Blood samples were evaluated for hematology, serum chemistry, and liver and kidney function throughout. None of the dogs or cats exposed by the various routes exhibited ill effects or dermal or respiratory tract irritation. No behavioral or physiological changes occurred in normal functions, and all blood parameters remained within normal species' ranges. Sensitization did not occur. After each phase of the study, each animal was humanely neutered, rabies vaccinated and adopted into an approved household. No ill effects resulted to dogs and cats from exaggerated oral exposure, repeated whole-body topical exposure, or repeated dermal patching with this fabric refresher.

1848 TWENTY-SIX-WEEK DAILY REPEATED DOSE INTRAMUSCULAR TOXICITY STUDY OF THE KAPPA OPIOID AGONIST CI-977 IN BEAGLE DOGS.

N. J. Gragtmans[1], L. M. King[1], G. E. Macallum[1] and M. A. Albassam[2]. [1]*Parke-Davis Pharmaceutical Research, Mississauga, Ontario, Canada and* [2]*Parke-Davis Pharmaceutical Research, Ann Arbor, MI.* Sponsor: R. M. Walker.

The analgesic agent CI-977, a potent and selective kappa opioid receptor agonist, was characterized in beagle dogs as part of the preclinical safety assessment. CI-977 was administered daily by intramuscular injection to groups of 5 beagle dogs per sex per group at 1, 3, and 6 μg/kg. The high dose was lowered from 10 to 6 μg/kg during Week 5 or 6 because of progressive weight loss. Central nervous signs (ataxia, persistent circling to the right, hypoactivity, tremor) and gastrointestinal signs (salivation, emesis, and diarrhea) were observed at 3 to 10 μg/kg. The intensity and frequency of clinical signs increased with dose, but did not diminish or increase throughout the treatment period. One male at 10 μg/kg had a single convulsion during Week 2. Body weight loss in the high dose group was noted up to Week 5 in males (ranging from 11% to 29% of pretest) and up to Week 8 in females (ranging from 18% to 39% of pretest). CI-977 plasma concentrations increased with dose, and were similar in males and females and throughout the treatment period. Testicular changes (atrophy, depletion of spermatids, single cell necrosis of spermatocytes, and multinucleated giant cells in the lumen of seminiferous tubules) were observed at 3 and 6 μg/kg. In summary, intramuscular administration of CI-977 daily at 1 μg/kg did not induce toxicity. Clinical signs observed at 3 and 6 μg/kg have been reported after treatment with opioid analgesics. Contrary to most opioid analgesics, CI-977 showed no indication of tolerance with repeated dosing. CI-977 induced testicular toxicity at 3 and 6 μg/kg.

1849 ARTERIAL AND HEPATIC EFFECTS OF CONTINUOUS INFUSION OF SIX ENDOTHELIN ANTAGONISTS IN DOGS.

L. M. King[1], M. A. Albassam[2], H. Hallak[2], S. Haleen[2], R. W. Walker[1] and G. S. Smith[1]. [1]*Parke-Davis Pharmaceutical Research, Mississauga, Ontario, Canada and* [2]*Parke-Davis Pharmaceutical Research, Ann Arbor, MI.*

Endothelin-1 (ET-1) is a potent vasoconstrictor interacting with at least two distinct receptors, endothelin A (ET_A) and B (ET_B), and its potential role in the circulatory system has elicited interest in endothelin antagonists as therapeutic agents. Butenolide analogs, PD 166673, 166004, 167088, 166309 and 170246 with selective affinity for the ET_A receptor and Bosentan, an ET_A and ET_B receptor antagonist were infused at 2 μmol/kg/hr for 96 hr to groups of 2 catheterized beagle dogs/sex. Controls received saline. Blood for determination of compound and ET-1 concentrations were collected predose and at 6, 24, 47 and 96 hr. All compounds were well tolerated and there were no effects on electrocardiograms or blood pressure. Hepatic microsomal erythromycin N-demethylase activity decreased in PD 166004 and 170246 treated dogs to ~ 20% of controls. ET-1 concentrations increased 6 and 40 times after PD 166309 and Bosentan, respectively. Bosentan steady state concentrations of 7.4 to 22 μM were achieved at 47 hr. Plasma concentrations of PD 166673, 167088, 166309 and 170246 approached steady state of 0.6 to 2.7 μM by 24 hr. PD 166004 concentration increased at each time point consistent with inhibition of hepatic CYP mediated-metabolism. Coronary arteriopathy was observed in all dogs given butenolide analogs and in 1 of 4 dogs given Bosentan. Arterial lesions was also present in other tissues in all drug-treated groups expect PD 166673 treated dogs. Arteriopathy may be a class effect of infusion of endothelin antagonists in dogs. Receptor selectivity, chemical structure and ET-1 concentrations were not predictive of the distribution and severity of arteriopathy.

1850 REPRODUCTIVE TOXICITY OF 1-BROMOPROPANE, A NEWLY INTRODUCED ALTERNATIVE TO OZONE-LAYER DEPLETING SOLVENTS, IN MALE RATS.

G. Ichihara[1], X. Yu[2], J. Kitoh[1], N. Asaeda[3], T. Kumazawa[3], H. Iwai[3], E. Shibata[4], T. Yamada[1], H. Wang[1], Z. Xie[1], K. Maeda[5], H. Tsukamura[5] and Y. Takeuchi[1]. [1]*Nagoya University Graduate School of Medicine, Nagoya, Japan,* [2]*National Institute of Industrial Health, Kawasaki, Japan,* [3]*Sanwa Kagaku Kenkyusho Co. Ltd., Hokusei, Japan,* [4]*Nagoya University School of Health Sciences, Nagoya, Japan and* [5]*Nagoya University Graduate School of Bioagricultural Sciences, Nagoya, Japan.*

1-Bromopropane has been newly introduced as a alternative to ozone-depleting solvents. We aimed to clarify its dose-dependent reproductive toxicity in male rats. Thirty-six Wistar male rats were randomly divided into four groups of nine. The groups were exposed to 200, 400, 800 ppm 1-bromopropane or only fresh air, eight hours per day for 12 weeks. Epididymal sperm indices were evaluated after 12 week's exposure. The testes, epididymides, seminal vesicle, prostate and other organs were weighed and examined histopathologically. Spermatogenic cells in the stage VII seminiferous tubules and degenerating spermatids in the stages IX-XI seminiferous tubules were counted. Plasma testosterone levels were measured by a radioimmunoassay. The testicular weight did not significantly change, but the weight of epididymides, seminal vesicle and prostate dose-dependently decreased. The weight of seminal vesicle decreased significantly at the lowest concentration of 200 ppm or over. 1-Bromopropane induced a dose-dependent decrease in epididymal sperm count and motility, and an increase in tailless sperm and sperm with an immature head shape. The spermatogonia, preleptotene spermatocytes, pachytene spermatocytes and round spermatids at stage VII did not decrease significantly. Degenerating elongated spermatids at the postspermiation stages, stages IX-XI increased dose-dependently. Plasma testosterone level significantly decreased at 800 ppm. We revealed that 1-bromopropane impairs spermatogenesis by disturbing transformation process of spermatids in the testis. Its reproductive toxicity might be different from that of 2-bromopropane which specifically impairs spermatogonia. Thus this solvent may have serious reproductive toxic effects in men and should be used carefully in the workplace.

1851 1-BROMOPROPANE IS DOSE-DEPENDENTLY NEUROTOXIC TO RATS IN LONG-TERM INHALATION EXPOSURE.

Y. Takeuchi[1], G. Ichihara[1], J. Kitoh[1], X. Yu[2], N. Asaeda[3], H. Iwai[3], T. Kumazawa[3], E. Shibata[4], T. Yamada[1], H. Wang[1] and Z. Xie[1]. [1]*Nagoya University Graduate School of Medicine, Nagoya, Japan,* [2]*National Institute of Industrial Health, Kawasaki, Japan,* [3]*Sanwa Kagaku Kenkyusho Co. Ltd., Hokusei, Japan and* [4]*Nagoya University School of Health Sciences, Nagoya, Japan.*

1-Bromopropane has been newly introduced as an alternative to ozone layer-depleting solvents. We aimed to clarify the dose-dependent effects of 1-bromopropane on the nervous system. Fourty-four Wistar male rats were randomly divided into four groups of eleven. The groups were exposed to 200 ppm, 400 ppm, 800 ppm 1-bromopropane or only fresh air eight hours per day for 12 weeks. Grip strength of forelimbs and hindlimbs, maximum motor nerve conduction velocity (MCV) and distal latency (DL) of the tail nerve were measured in nine rats of each group every four weeks. The other two rats of each group were perfused at the end of the experiment for morphological examinations. The rats of the 800-ppm group showed poor kicking and impossible standstill on the slope. Forelimb grip strength decreased significantly at 800 ppm and hindlimb grip strength decreased significantly at 400 ppm or over after 12 week's exposure. MCV and DL of the tail nerve deteriorated significantly at 800 ppm. Ovoid or bubble-like debris of myelin sheaths was prominent in the unraveled muscular branch of the posterior tibial nerve in the 800-ppm group. Swelling of preterminal axons in the gracile nucleus increased dose-dependently. Plasma CPK decreased dose-dependently with significant changes at 400 ppm and 800 ppm. 1-Bromopropane induced paralysis and deteriorated grip strength, MCV and DL dose-dependently with morphological changes in peripheral nerve and preterminal axon in the gracile nucleus. 1-Bromopropane may be so seriously neurotoxic to humans that it should be used carefully in the workplace.

1852 OVARIAN TOXICITY OF 1-BROMOPROPANE, AN ALTERNATIVE TO OZONE LAYER-DEPLETING SOLVENTS, IN RATS.

T. Yamada[1], G. Ichihara[1], H. Wang[1], X. Yu[2], M. Kamijima[1] and Y. Takeuchi[1]. [1]*Nagoya University Graduate School of Medicine, Nagoya, Japan and* [2]*National Institute of Industrial Health, Kawasaki, Japan.*

This study was aimed at clarifying the effect of 1-bromopropane (1-BP), an alternative to ozone layer-depleting solvents, on female reproductive function in rats. Forty female Wistar rats were divided into four groups of ten. Each group was daily exposed to 0, 200, 400, or 800 ppm 1-BP for eight hours a day. After 7 weeks of exposure, all the rats in the 800 ppm group were debilitated, then they were decapitated during the 8th week. Other groups were exposed for 12 weeks. Vaginal smears were examined every day to monitor ovarian cyclicity during the experimental period. After 12 weeks of exposure, the rats were decapitated on the day of diestrus I during the 13th week. In the 800 ppm group, the body weight gain was significantly suppressed compared to the control, but body weight of the other two groups did not significantly differ from the control. Vaginal smear test showed that the number of irregular estrous cycles significantly increased dose-dependently. Both the weights of reproductive organs in the 200 ppm and 400 ppm groups showed no significant difference compared to the control. The present study indicates that relatively low concentration exposure to 1-BP affect reproductive organs in female rats. Ovarian cyclicity is probably a more sensitive index for monitoring the reproductive toxicity than the weight of reproductive organs in 1-BP intoxication.

1853 LACK OF PHOTOTOXICITY OF COSMETIC FORMULATIONS CONTAINING GLYCOLIC ACID IN AN *IN VITRO* HUMAN SKIN MODEL.

B. C. Jones[1], H. A. Raabe[2], A. Sizemore[2], G. C. Mun[2], E. H. Theophilus[1] and M. S. Dickens[1]. [1]*Avon Products, Inc., Suffern, NY and* [2]*Institute for InVitro Sciences, Inc., Gaithersburg, MD.*

Glycolic acid (GA) is a naturally occurring product found in sugar cane and is a member of a class of chemicals known as alpha-hydroxy acids. GA has been widely used in cosmetic and dermatological formulations for over a decade. These formulations are often used in dermal applications where they may be subject to ultraviolet radiation (UV) exposure from sunlight. We have investigated the potential for phototoxicity of typical cosmetic concentrations of GA (4% and 8%) in a generic cosmetic formulation with and without a

chemical sunscreen (octyl methoxycinnamate, SPF2). The assays were conducted following a cytotoxicity protocol using a human keratinocyte model, EpiDerm™ (Epi-200), utilizing a colorimetric thiazolyl blue (MTT) endpoint. Prior to formulation exposure, a maximum non-cytotoxic dose in EpiDerm was established for UVA/B radiation (290-400nm) utilizing a metal-halide lamp solar simulator. The maximal dose of UVA/B radiation that caused negligible cytotoxic effects was 1.35/ 0.135 J/cm² UVA/UVB, respectively. The maximal exposure for UVA treatment alone (320-400nm) was 6 J/cm². For subsequent assays, EpiDerm cultures were treated with the maximal non-cytotoxic dose of UVA/B or UVA. EpiDerm cultures were exposed to test materials or controls (negative control, vehicle; positive control, chlorpromazine) for two hours prior to UV exposure and returned to the incubator (0-45 hours) after exposure, followed by MTT cytotoxicity analysis. GA treated tissues exposed to UV showed relative survival percentages comparable to tissues that received no UV (89-109%); positive phototoxic control showed an expected cytotoxic response (7.5%). These studies indicate that glycolic acid contained in these cosmetic formulations is not phototoxic after UVA/B or UVA exposure and can be used in dermal cosmetic applications where UV radiation exposure may occur.

1854 MULTI-GENERATION REPRODUCTION STUDIES WITH GLYPHOSATE IN RATS.

D. R. Farmer, T. A. Kaempfe, W. F. Heydens and W. R. Kelce. *Monsanto Company, St. Louis, MO.*

Glyphosate is a non-selective herbicide with activity on most annual and perennial plants. Glyphosate inhibits essential aromatic amino acid synthesis by blocking the activity of a plant specific enzyme. Glyphosate based-formulations are used in over 100 countries in virtually every phase of agricultural and residential weed control and are increasingly used in applications involving genetically modified plants tolerant to glyphosate. This expansive use necessitates a proactive product stewardship program ensuring a wide distribution of the health and safety information for glyphosate. To this end, the results from two multi-generation reproductive toxicity studies with glyphosate are presented. Glyphosate (98.7% pure) was fed to groups of CD rats (12 males and 24 females per dose group) for three successive generations at dose levels of 0, 3, 10, and 30 mg/kg/day. There were no treatment-related effects on mating, fertility or reproductive parameters. An equivocal increase in unilateral renal tubule dilation occurred at the top dose in the F3b pups, however, a more extensive evaluation in the subsequent multigeneration reproduction study conducted at much higher dose levels did not show the effect. This second dietary rat study (30 rats/sex/dose group) was conducted over two generations using 0, 2000, 10000 and 30000 ppm glyphosate (97.7% pure). Decreased body weight gains were seen at the highest dose in parental animals and in pups during the later part of lactation and there was an equivocal decrease in average litter size. No treatment related effects were observed at lower dose levels. The NOAELs for systemic and reproductive toxicity were 10000 ppm (740 mg/kg/day) and 30000 ppm (2268 mg/kg/day), respectively.

1855 A 2-MONTH TOXICITY STUDY OF PEN110-TREATED RED BLOOD CELLS FOLLOWING INTRAVENOUS ADMINISTRATION IN ALBINO RABBITS.

J. J. W. Mertens[1], G. R. Kiplinger[1], C. B. Jackson[1] and J. Salvesen[2]. [1]*WIL Research Laboratories, Inc., Ashland, OH and* [2]*Pentose Pharmaceuticals, Inc., Cambridge, MA.*

PEN-110 (trade name INACTINE™) is a low MW electrophilic compound, which inactivates a wide range of viruses in whole blood and red blood cells (RBCs) through selective interaction and irreversible modification of nucleic acids. Following viral inactivation, PEN110 is removed to non-detectable levels (<0.03 μg/ml). The current study was conducted to evaluate the effects of infused PEN110-treated autologous RBCs in support of a Phase 1 clinical study. Blood was collected from New Zealand White Rabbits and 3 mL of a citrate phosphate dextrose solution was added to ~10 mL of isolated RBCs. After overnight-refrigerated storage, the resuspended RBCs were incubated for 6 h at room temperature in the presence of a sodium phosphate solution (pH 7.0) or a freshly prepared solution of PEN110 (12 mM). Subsequently, the RBCs were washed 4x with 0.2% dextrose/0.9% sodium chloride solution to partially remove PEN110. The supernatant was discarded and 3 mL of an RBC storage solution an Additive Solution Formula was added to the RBCs after which they were stored under refrigeration overnight. Treated RBCs containing residual PEN110 were administered via a lateral ear vein to achieve a dose of ~10 μg/kg PEN110 (i.e., >2,500 X the clinical Phase 1 dose). Animals were observed for 2 months. Clinical examinations were performed daily. Physical examinations were conducted weekly. Body weights were recorded weekly. Food consumption was determined daily. Hematology and serum chemistry parameters were analyzed prior to the initiation of dosing, 24 h following administration (day 1) and on days 3, 7, 29, and 59 (prior to necropsy). Ophthalmological examinations were performed prior to the initiation of dosing and during week 7. In addition, hematology parameters were evaluated on samples of treated RBCs collected prior to administration. A complete necropsy and a microscopic examination was conducted on all tissues from all animals. Treatment of isolated RBCs with ~12 mM PEN110 and subsequent administration of the treated RBCs in the presence of remaining PEN110 at a dose level of ~10 μg/kg to rabbits caused no test article-related effects over a 2-month monitoring period after two months.

1856 ASSESSMENT OF THE REPRODUCTIVE TOXICITY POTENTIAL OF GASOLINE VAPOR IN A TWO-GENERATION STUDY IN RATS.

A. J. Riley[1], C. S. Nessel[1], R. H. McKee[2], R. A. J. Priston[1], C. R. Mackerer[1], R. Hagemann[1], G. W. Trimmer[2], F. T. Whitman[2], J. Urbanus[1], G. Cruzan[1] and B. J. Simpson[1]. [1]*CONCAWE, Brussels, Belgium and* [2]*Exxon Biomedical Sciences, Inc., Annandale, NJ.*

A 2-generation study was conducted on gasoline vapor to assess its reproductive toxicity potential. The test material was collected from vapor recovery units of a gasoline distribution terminal and was shown to be similar in composition to vapors to which humans are exposed through occupational or public contact. In the two-generation reprotoxicity study, groups of male and female Sprague-Dawley rats were exposed daily for 6 hours to gasoline vapor at concentrations up to 20000 mg/m³. This dose is approximately 50% of the lower explosive limit and the highest level considered safe to test. There were no treatment-related effects in parental animals, and no microscopic changes other than hyaline droplet nephropathy in the kidneys of male rats. There were no effects on fertility and reproductive parameters, and no fetal effects. Additionally, there was no evidence of endocrine modulating activity as indicated by a lack of effect on estrous cycling, sperm count and quality, quantification of primordial oocytes, and no changes in any specific landmarks related to sexual development in either generation. Thus, no toxicologically important findings were identified in this study, and the NOAEL for reproductive effects for gasoline vapor was 20000 mg/m³.

1857 TOXICITY DATA USE IN TEMPORARY EMERGENCY EXPOSURE LIMIT (TEEL) DERIVATION.

D. K. Craig. *Westinghouse Safety Management Solutions LLC, Aiken, SC.*

Methodology for deriving Teels for chemicals without Emergency Response Planning Guidelines (ERPGs) uses published toxicity parameters (e.g., LC_{50}, LD_{LO}, where L=lethal, LO=low). Data precedence is human, rat, mouse, or other species, using Inhalation, oral (os), skin, intraperitoneal, intravenous, subcutaneous, or other routes. Current route adjustment factors (RAF) are independent of species and properties of chemicals. Non-inhalation data are transformed to concentration equivalent mass per unit volume units (mg/m³) using species-specific mean body weights (BW) and breathing rates (BR). The objective of this study was to test the adequacy of these adjustments. Toxicity data for 90 chemicals with ERPGs were extracted for six parameters for all animal species. Same species, different routes of intake (ssdr), and different species, same route of intake (dssr os) were analyzed for LD_{50} and LD_{LO} data. For LD_{50} and LD_{LO} ssdr data, ratios (R) were taken of the dose by route "i" to the oral dose for each chemical. The mean (MR_i), standard deviation (SD) and standard error (SE) were calculated for all R_is for each route of intake "i". There are some differences between revised RAFs ($RAF_{REV}=(1/MR_i)x0.25$, the oral RAF) from LD_{50} and LD_{LO} data, particularly for intravenous (0.41 and 1.96, RAF=1.00) and for subcutaneous (0.09 and 0.31, RAF=0.10) intake. No attempt was made to eliminate outliers from this data set. For LD_{50} and LD_{LO} dssr os data, ratios were taken of dose for species "j" to rat LD_{50}s or human LD_{LO}s. The mean (MR_j), SD and SE were calculated for all R_js. The BW/BR for rats (1.31) was divided by the LD_{50} MR_j. BW/BR for humans (3.50) was divided by LD_{LO} MR_j. These values are an indication of the adequacy of the species adjustments for this set of data. Although there are considerable scatter in the data, elimination of just 3 (of 37) mouse to rat LD_{50} ratios gives a BW/BR_{REV} of 0.76, close to the current value (0.714). The analyses need to be completed for other routes of intake and animal species before changes are made to the current TEEL methodology.

1858 SAFETY EVALUATION OF INTRAVENOUS GLYCINE.

J. M. Daniels[1], V. M. Tai[2], E. J. Mitchell[1], R. J. Rose[1] and E. R. Nestmann[3]. [1]*Cantox Health Sciences International, Mississauga, Ontario, Canada,* [2]*Cantox Health Sciences International, Vancouver, British Columbia, Canada and* [3]*Cantox Health Sciences International, Bridgewater, NJ.*

Solutions of the amino acid glycine are used for organ irrigation during abdominal and musculoskeletal surgeries, and significant systemic absorption of glycine during these procedures has been reported. In addition, glycine is used as an inactive ingredient in intravenous drug products and as a component of total parenteral nutrition amino acid injections. Post-surgical adverse events have included local and cerebral edema, visual effects (including blurring or loss of acuity) and immune-mediated symptoms. To more fully understand the potential risks, the safety of intravenous glycine has been evaluated. In clinical investigations conducted with healthy male volunteers, reversible visual effects (acuity and visual evoked potentials) were observed in one subject following a bolus intravenous dose of 4.4g glycine in 200ml over 5 minutes. Similar effects were also observed at doses of 15 to 22g, infused over a period of 20 minutes. The absence of a dose- or time-dependent relationship, and the mild, transient nature of the visual effects suggest that bolus intravenous doses of up to 22g of glycine are well-tolerated. Animal data for intravenous glycine administration support the reported effects of systemic glycine exposure in humans. Transient effects on visual parameters (diminished visual evoked potentials) were observed in dogs following single doses of 1g/kg, while single doses of glycine in sheep equivalent to 0.9g/kg produced reversible behavioural blindness and loss of pupillary response. Based on these data, it is concluded that serious adverse events are not likely to occur in response to a bolus intravenous dose of up to 22 g glycine (i.e., 0.44g/kg in a 50kg adult).

1859 NINETY-DAY ORAL GAVAGE TOXICITY STUDY OF C_9-C_{16} AROMATIC FRACTION OF JET-A IN FEMALE SPRAGUE-DAWLEY CD RATS AND MALE C57BL/6 MICE.

P. B. Smith[1], K. E. Veley[1], W. H. Baker[2], A. W. Singer[1], M. J. Ryan[1], W. H. Weisman[2], D. R. Mattie[2], L. D. Harvey[2] and R. W. Slauter[1]. [1]*Battelle Memorial Institute, Columbus, OH and* [2]*Air Force Research Laboratory, Wright-Patterson AFB, OH.*

This study was conducted to characterize the potential toxic effects of C_9-C_{16} aromatic fraction of Jet-A in female Sprague-Dawley CD rats and male C57BL/6 mice following daily oral administration for 90 days. Four groups of 15 female rats/group and 15 male mice/group were administered a daily oral gavage dose of the test substance at 0 (vehicle control), 20, 100, and 500 mg/kg in a corn oil vehicle. Mean hemoglobin, hematocrit, and red blood cell counts (HGB/HCT/RBC) were decreased in the mid- and high-dose female rats. Necropsy examinations revealed enlarged livers in the high-dose group rats. This correlated with the organ weight measurements indicating significant liver weight increases (absolute and relative to brain and body weight) in the high-dose rats compared with their controls. There were no pathological lesions observed or changes in serum chemistry parameters which were related to the test substance. Clinical observations included hunched posture in all groups of mice, with the frequency of the observation increasing with higher doses. Lethargy was recorded from all of the high-dose mice and half of the high-dose rats. Lethargy was also observed in 5/15 low-dose and 12/15 mid-dose mice. Salivation was observed in all of the high-dose rats and from 6/15 from the mid-dose rats. Rats in the mid- and high-dose groups were observed shoveling their contact bedding with their noses within minutes after being dosed. The shoveling and salivation observed in the rats is consistent with an irritation response in the mouth. There were no apparent effects of the test substance on the body weights during the study. Increased food consumption was observed in the rats that received test substance; with significant increases observed during most of the study in the high-dose group. Based on the results of this study a NOEL for the C_9-C_{16} aromatic fraction would be 20 mg/kg/day.

1860 SAFETY ASSESSMENT OF THE HUMAN FACTOR VIII RETROVIRAL VECTOR.

C. F. Runham[1], S. M. Henwood[2], G. H. I. Wolfgang[1] and M. E. I. Leibbrandt[1]. [1]*Chiron Corporation, Emeryville, CA and* [2]*Covance Laboratories Inc., Madison, WI.*

A gene therapy product consisting of a retroviral vector expressing human Factor VIII (hFVIII(V)) has been developed for the treatment of Hemophilia A. To assess the acute toxicity of the retroviral vector particle, studies were conducted in rabbits and mice. Male rabbits (10/group) or mice (14/group) were injected intravenously with hFVIII(V) at doses of 0.67, 3.3 and 16.7 x 10^8 or 1.7, 6.7 and 26.7 x 10^8 TU/kg (transduction units), respectively, once daily on each of three consecutive days. Half of the animals in each group were sacrificed on day 4 and remaining animals on day 15. There was no mortality in mice treated with up to 26.7 x 10^8 TU/kg, or rabbits at doses of up to 3.3 x 10^8 TU/kg. At a dose of 16.7 x 10^8 TU/kg, 2/10 rabbits died of an anaphylactoid reaction following the second or third injection. Histopathologic evaluation indicated acute heart failure secondary to pulmonary artery constriction. In addition, there was a dose-dependent enhancement of pre-existing neutrophil infiltration to the walls of larger pulmonary vessels in rabbits treated with mid and high dose hFVIII(V). Resolution of these vascular changes was in progress by day 15. In contrast, no similar infiltration was reported in mice at doses as high as 26.7 x 10^8 TU/kg or in rabbits sacrificed 3 months to 2 years following treatment with hFVIII(V). The acute vascular effects observed in this study are similar to those reported in rabbits treated with adenoviral vectors. In mice there was a slight (~20%) increase in spleen weights in the high dose animals at both intervals, and a dose-dependent incidence of lymphocytic hyperplasia of generally minimal severity at day 15. There was no effect of hFVIII(V) in either species on body weight, food consumption, clinical pathology or macroscopic observations at necropsy. In summary, the acute reaction to hFVIII(V) gene therapy and the enhancement of pre-existing neutrophil infiltration in lung of rabbits may be a species-specific response to treatment with viral vectors. No similar findings were seen in mice.

1861 EVALUATION OF ANGIOZYME™, A RIBOZYME, IN 28 DAY TOXICITY STUDIES IN MONKEYS AND MICE.

I. A. Ivens[1], M. E. I. Leibbrandt[1], J. A. Sandberg[2], F. A. Caputo[3], C. P. Chengelis[4] and E. L. Padgett[4]. [1]*Chiron Corporation, Emeryville, CA,* [2]*RPI, Boulder, CO.* [3]*SBI, Reno, NV and* [4]*WIL Research Laboratories, Ashland, OH.*

ANGIOZYME™ is an anti-angiogenic ribozyme (inhibiting the Flt-1 receptor mRNA for vascular endothelial growth factor (VEGF)), intended for treatment of cancer. Toxicity studies were conducted in CD-1 mice and cynomolgus monkeys. Monkeys were injected subcutaneously with doses of 2.5, 8.3, or 25 mg/kg/d and mice with 10, 33, or 100 mg/kg/d for 4 weeks followed by a 4-week recovery period. Doses in both species corresponded to 30, 100 or 300 mg/m^2/d, potential doses for clinical studies. Standard toxicity parameters were evaluated in both species and in addition ECG, BP and complement were examined in primates. In monkeys and mice sacrificed after 4 weeks, there was a dose-dependent accumulation of basophilic granules in renal tubular epithelial cells and local irritation/inflammation at the injection site accompanied by minimal to mild muscle fiber degeneration in monkeys only. In addition a minimal to mild hypertrophy of Kupffer cells was observed in monkeys treated with 8.3, or 25 mg/kg/d which correlated with a slight liver weight increase. No changes in serum chemistry parameters or urinalysis indicative of hepatic or renal dysfunction were seen. There were no other effects on any antemortem assessment including complement. In both species hepatic, renal and injection site effects recovered partially or completely. The hepatic and renal changes were consistent with changes reported with other oligonucleotides. With the exception of microscopic changes in kidney and liver and minimal local effects at the injection site, ANGIOZYME™ was well tolerated.

1862 CYTOTOXICITY TESTS FOR BIOCOMPATIBILITY ASSESSMENT OF MEDICAL DEVICES: A COMPARISON OF ISO 10993 AND MHW JAPAN METHODOLOGIES.

V. P. Anand and F. W. Deckert. *Toxikon Corporation, Bedford, MA.*

Cytotoxicity tests are initial screening methods prior to more specific tests for assessing biocompatibility of medical devices. Cytotoxicity testing methodologies differ between the US Pharmacopoeia (USP), the International Standards Organization (ISO), and the Japanese Guidelines for Basic Biological Tests for Medical Devices and Materials-Notification 99 (MHW-Japan). We compared the sensitivities of the USP/ISO test (48 hour exposure) and MHW-Japan procedure (7 day exposure) using cell culture medium extracts (37°C/24 hours) of materials (Silicone, Polypropylene, Latex) used in medical devices and positive controls (Zinc-diethyldithiocarbamate/ZDEC, and Zinc-dibutyldithiocarbamate/ZDBC) utilizing standard evaluation criteria. We also evaluated protein content of the cell cultures as an additional index of cytotoxicity. Good correlation was observed in the toxicity assessments by visual quantitation and protein content in the V79 cell line (MHW-Japan) and in the L929 (USP/ISO) method. However the neat extract of sili-

cone was cytotoxic in the V79 (MHW-Japan) colony formation assay, while it was non-cytotoxic in the L929 (USP/ISO) assay, by both visual grading/colony counting and protein content. In addition, toxicity by Latex, ZDEC and ZDBC extracts was observed at a 2-fold lower concentration in the V79 assay as compared to the L929 test. These results suggest that the V79/MHW-Japan procedure may be more sensitive than the L929 USP/ISO assay, due to differences in test methodologies although the physiological relevance of these differences is uncertain. Current efforts at harmonization of international guidelines for pre-clinical evaluation of medical devices/materials should take into consideration such variations in test methods and their physiological relevance, since the choice of cytotoxicity methods used can influence the outcomes of submissions of test devices for regulatory approval.

1863 A DERMAL SAFETY EVALUATION OF EXTRACTS FROM TAGETES PLANTS USED IN FRAGRANCES.

C. S. Letizia and A. M. Api. *Research Institute for Fragrance Materials, Inc., Hackensack, NJ.*

Extracts can be obtained from various species of Tagetes, particularly Tagetes minuta and Tagetes patula. Tagetes oil is obtained by steam distillation and Tagetes patula absolute and Tagetes minuta absolute are obtained by solvent extraction. Irritation, phototoxicity, sensitization and photosensitization were evaluated. None of the 3 materials produced irritation in hairless mice when applied undiluted. However, irritation was observed with undiluted Tagetes oil when applied via semi-occlusion on the clipped dorsal skin of 4 rabbits. Slight irritation was observed in guinea pigs when tested with a 3% sample of Tagetes patula absolute. Tagetes minuta absolute was slightly irritating in guinea pigs but not irritating in humans when applied under occluded or semi-occluded patches for 24 hours at dose levels ranging from 0.01% to 2%. All 3 materials produced phototoxicity in hairless mice at dose levels of 0.1 to 100%. A NOAEL for the oil was observed at 0.01%. Tagetes minuta absolute was also tested in guinea pigs and humans and produced phototoxic responses in both. In humans, a NOAEL was observed at 0.1% after 24 hour occluded applications followed by irradiation with UVA at doses of 16-20 J/cm. Tagetes minuta absolute produced no sensitization in 22 human volunteers (5 induction applications followed 2 weeks later by challenge) or in 25 human volunteers after six 24 hour occluded induction applications followed 2 weeks later by a 24 hour occluded challenge. No photosensitization was observed when these same 25 volunteers were evaluated for photosensitization using the same protocol as for sensitization but with UVB irradiation after each induction application and UVA irradiation after the challenge application.

1864 90-DAY ORAL TOXICITY STUDY ON *n*-NONANE IN FEMALE FISCHER 344 RATS AND MALE C57BL/6 MICE.

D. Dodd[1], E. Merrill[2], R. Wolfe[1], D. Pollard[1], J. English[3] and W. Weisman[3]. [1]*ManTech Environmental Inc., Dayton, OH.* [2]*Operational Technologies Corp, Dayton, OH and* [3]*AFRL/HEST, Wright-Patterson AFB, OH.*

Long chain petroleum hydrocarbons, ranging from C9 to C15 are pre-dominant constituents in weathered jet-fuel spills. To evaluate potential toxic effects of a C9 hydrocarbon following repeated oral gavage, *n*-nonane (neat) was administered to groups of 10 female Fischer 344 rats and 10 male C57BL/6 mice at daily doses of 5.0, 1.0, 0.1 and 0 (control) g/kg, 7 d/wk for 90 d. Clinical observations included urogenital wetness, perianal alopecia, diarrhea, and hunched posture at 5.0 g/kg in both species. Mean body weights were similar between control and treated groups. Significant differences in hematology and serum chemistry values were observed; however, values were within normal species limits. Rats had increased liver and adrenal weights and decreased spleen and ovary weights at 5.0 g/kg. Increased adrenal and decreased ovary weights were observed also at 1.0 g/kg. In mice, an increase in liver weight and a decrease in kidney weight were observed in the 1.0 and 5.0 g/kg groups. Individual rat blood levels of *n*-nonane, collected 2 hrs post dosing at 90 d, ranged from 0.44 (0.1 g/kg) to 9.53 μg/g (5.0 g/kg). Microscopic lesions consisted of varying degrees of hyperplasia and hyperkeratosis of squamous epithelium in the non-glandular stomach in all nonane-treated groups of both species. Mild inflammation of the proximal small intestinal mucosa was present in 20% of the high dose rats only. Mild perianal squamous hyperplasia was observed in high and mid dose rats and mice. The NOAEL for this study is 0.1g/kg in both species, for all biological endpoints except the lesions in the non-glandular forestomach. The lack of an analogous structure in the human stomach, and the absence of lesions in the glandular stomach of the study animals suggests that the proliferative forestomach lesions represent a species-specific response, of no clinical significance to humans.

1865 PHYSIOLOGICAL AND PHARMACOLOGICAL STUDIES IN CYNOMOLGUS MONKEYS USING A TELEMETRY SYSTEM (IV), AND THE VALUE OF USING CONSCIOUS MONKEYS IN SAFETY PHARMACOLOGY STUDIES.

R. Nagata, T. Kamenosono, A. Akune, T. Hamada, K. Fukuzaki, H. Miyajima and G. Kito. *Shin Nippon Biomedical Laboratories, Ltd., Kagoshima, Japan.*

Safety pharmacology studies, as presently defined in ICHM3, require the evaluation of effects on vital functions such as the central nervous, cardiovascular and respiratory systems. We studied the effects of two well characterized drugs (Amiodarone and Acetazolamid) on the vital functions of conscious monkeys, in order to evaluate the potential of the telemetry system as a safety assessment bridging test between pre-clinical and clinical studies. Furthermore, circadian rhythms of normotensive and hypertensive monkeys were also investigated. Male cynomolgus monkeys (4-5 years old) were used for this study. The animals were anesthetized using ketamine anesthesia prior to the surgical implantation of a telemetry system transmitter. After surgery the animals were placed in a measuring cage mounted on a receiver board and allowed several weeks to recover prior to use in the study. All parameters such as blood pressure, heart rate, ECG, respiratory rate and body temperature were continually recorded utlizing the telemetry system. Amiodarone at 40 mg/kg/day for 4 days produced decreases in blood pressure by 20-25% and nocturnal heart rate by 10%, and also showed a tendency to prolong the QT interval. Amiodarone is known to induce QT interval prolongation, resulting in ventricular arrhythmia. Acetazolamid, administered once at 300 mg/kg, produced increases in the heart rate and respiratory rate with changes in blood gas parameters (HCO_3^-, BE). Acetazolamid is known to induce a metabolic acidosis. In order to examine the effects of hypertension on circadian rhythm in cynomolgus monkeys, renal hypertension was produced using the 2 kidneys 1 clip method. In the acute stage of renal hypertension, the circadian rhythms of blood pressure and heart rate disappeared. In the chronic stage, circadian rhythms were observed, however, hypertension was maintained. The above results clearly demonstrate the potential of telemetry system usage in safety pharmacology studies.

1866 EMBRYOTOXIC AND TERATOGENIC EVALUATION OF TNK-TPA IN RABBITS; A STUDY AROUND ANTIGENICITY ISSUES.

M. C. Gross[1], W. Leach[1], W. Prince[1], A. Hoberman[2], J. Barnett[2] and C. O'Neill[1]. [1]*Genentech, Inc., South San Francisco, CA and* [2]*Argus Research Laboratories, Inc., Horsham, PA.*

The purpose of this study was to assess the effects of TNK-tPA in presumed pregnant rabbits and evaluate the development of the embryo and fetus following exposure of the doe from implantation to closure of the hard palate. To ensure exposure to TNK-tPA without interference of neutralizing anti- TNK-tPA antibodies, daily intravenous (IV) dosing for no more than 5 consecutive days during gestation days (GDs) 6–18 were administered. Cesarean-sectioning (C-sections) were performed on all surviving does on GD 29. The following parameters were evaluated in this study: antemortem observations and mortality, maternal body weights, maternal body weight change, food consumption, abortions, C-sections and litter observations, and fetal alterations (including fetal body weights, fetal anomalies and fetal ossification). Based on the results of this study, it was concluded that bolus IV administration of TNK-tPA at doses up to and including 5 mg/kg/day did not elicit maternal toxicity or developmental toxicity, including teratogenicity, when administered daily on gestation GDs 6 through 10. TNK-tPA Vehicle did not elicit maternal toxicity or developmental toxicity, including teratogenicity, when administered daily on GDs 6 through 10, 11 through 14, or 15 through 18. Daily bolus intravenous administration of TNK-tPA at doses greater than or equal to 0.5 mg/kg/day produced maternal and fetal toxicity when administered on GDs 11 though 14 or 15 through 18 in rabbits.

1867 AN ANIMAL MODEL FOR IDIOSYNCRATIC REACTIONS TO CHLORPROMAZINE.

J. P. Buchweitz[1], S. Bursian[1], P. E. Ganey[2] and R. A. Roth[2]. [1]*Department of Animal Science, Michigan State University, East Lansing, MI and* [2]*Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI.*

Neuroleptic malignant syndrome (NMS) is an idiosyncratic reaction to therapy with neuroleptic drugs such as chlorpromazine (CPZ). Rhabdomyolysis is associated with the development of NMS. Mortality from rhabdomyolysis is

approximately 50%, yet animal models for this drug-induced reaction are lacking. Risk factors for its appearance include conditions associated with inflammation, such as trauma and bacterial sepsis. Accordingly, we tested the hypothesis that an inflammatory stimulus, bacterial lipopolysaccharide (LPS), renders animals susceptible to rhabdomyolysis from CPZ. Male, Sprague-Dawley rats (150-200 grams) were fasted for 24 hours. A small dose of E. coli LPS (7.4 x106 EU/kg) or its vehicle (saline) was administered by tail vein two hours before an intraperitoneal injection of CPZ (70mg/kg) or its vehicle (saline). Serum enzymes indicative of striated muscle necrosis were measured. Neither creatine kinase (CK) nor aspartate aminotransferase (AST) were elevated in serum of rats treated with vehicle, LPS, or CPZ alone, but these were markedly increased in animals treated with LPS and CPZ. All animals receiving CPZ quickly became cataleptic and remained so for the duration of the experiment. The observation that serum enzymes were elevated only in the group given LPS plus CPZ suggests that LPS enhances striated muscle necrosis in the presence of the neuroleptic drug. These results may form the basis for an animal model with which to study drug-induced NMS and raise the possibility that concurrent, modest inflammation may underlie the susceptibility of individuals to this "idiosyncratic" reaction. (Supported by NIH grants ESO4139 and ESO8789.)

1868 TWO-YEAR TOXICITY/ONCOGENICITY STUDY OF α-DIFLUOROMETHYLORNITHINE IN $B_6C_3F_1$ MICE.

W. D. Johnson[1], M. J. Cwik[1], M. E. Kearns[1], M. A. Cahill[1], R. L. Morrissey[2], J. A. Crowell[3] and D. L. McCormick[1]. [1]*IIT Research Institute, Chicago, IL,* [2]*Pathology Associates, International, Chicago, IL and* [3]*National Cancer Institute, Bethesda, MD.*

α-Difluoromethylornithine (DFMO) is a suicide inhibitor of ornithine decarboxylase, the rate-limiting enzyme in polyamine biosynthesis. DFMO demonstrates a broad range of chemopreventive activity in animals, and is being evaluated for chemopreventive efficacy in human trials. This study was designed to evaluate the chronic toxicity and potential oncogenicity of DFMO in mice. Beginning at 6 weeks of age, $B_6C_3F_1$ mice (50 Main Study mice + 35 Satellite mice/sex/group) were received DFMO at 0 (control), 100, 300, or 1000 mg/kg diet for two years. Plasma levels of DFMO were determined during months 3 and 18, and clinical pathology evaluations were performed during months 6, 12, and 24. Gross lesions from all Main Study mice, and all tissues from all Main Study mice in the high dose and control groups were evaluated histopathologically. DFMO had no effect on animal survival, and induced no gross toxicity identifiable by clinical observations. Small but statistically significant reductions in body weight gain were seen between weeks 25 and 85 in males at all DFMO doses; this effect was not seen in females. DFMO had no effect on clinical pathology, and induced no gross pathology or microscopic pathology. Within a sex, patterns of neoplastic lesions were similar in all groups. Aside from the transient reduction in body weight gain seen in male mice, chronic administration of DFMO at levels of up to 1000 mg/kg diet induced no evidence of toxicity. When administered at doses of up to 1000 mg/kg diet, DFMO is not oncogenic in $B_6C_3F_1$ mice. (NCI-N01-CN-25506-01.)

1869 DERMAL ONCOGENICITY STUDY OF BENZOYL PEROXIDE CARBOPOL GEL IN FISCHER 344 RATS.

L. C. Totman[1], R. L. Binder[2], S. J. Freeman[3], E. J. Winkelman[3], D. J. Minnema[4] and J. F. Nash[2]. [1]*Consumer Healthcare Products Association, Washington, DC,* [2]*Procter & Gamble Co., Cincinnati, OH,* [3]*SmithKline Beecham Consumer Healthcare, Parsippany, NJ and* [4]*Covance Laboratories, Inc., Vienna, VA.*

The oncogenic potential of benzoyl peroxide (BPO) was evaluated in male and female F344 rats by topical application in a carbopol gel vehicle. BPO gel was applied at doses of 5, 15 and 45 mg BPO/rat once daily for 104 weeks to a 3.5-x-5-cm treatment area on the dorsal skin. A discontinuous-treatment group received the high dose (45 mg of BPO/day) for 52 weeks and the vehicle for the remainder of the study. Vehicle-only and no-treatment groups served as controls. Rats were sacrificed at 52 (interim-sacrifice) or 104 weeks, and necropsies were performed. Treatment with BPO carbopol gel had no effect on survival, body weights, food consumption or gross pathology. Microscopic evaluation revealed treatment-related findings confined to the site of application. Specific findings were mild-to-moderate degrees of hyperkeratosis, acanthosis, sebaceous gland hyperplasia and chronic subepidermal inflammation in all treatment groups. These effects were observed in the interim-sacrifice groups and in the rats sacrificed at 104 weeks. In the discontinuous-treatment group, hyperkeratosis was present approximately twice as frequently as in the controls, which suggests a partial but incomplete recovery. No findings indicative of oncogenicity resulted from daily topical application of BPO gel at doses up to 45 mg of BPO/day for 104 weeks. The absence of any skin tumors is particularly important considering the presence of chronic hyperplasia and other skin effects indicative of reaching the maximum tolerated dose in this study. These data together with chronic studies in mice support the conclusion that BPO lacks carcinogenic potential.

1870 DERMAL ONCOGENICITY STUDY OF BENZOYL PEROXIDE CARBOPOL GEL IN B6C3F1 MICE.

R. L. Binder[1], L. C. Totman[2], S. J. Freeman[3], E. J. Winkelman[3], D. J. Minnema[4] and J. F. Nash[1]. [1]*Procter & Gamble Co., Cincinnati, OH,* [2]*Consumer Healthcare Products Association, Washington, DC,* [3]*SmithKline Beecham Consumer Healthcare, Parsippany, NJ and* [4]*Covance Laboratories, Inc., Vienna, VA.*

The oncogenic potential of benzoyl peroxide (BPO) was evaluated in male and female B6C3F1 mice by topical application in a carbopol gel vehicle for 104 weeks. BPO gel was applied at doses of 1, 5 and 25 mg of BPO/mouse once daily to a 2-x-3-cm treatment area on the dorsal skin. A discontinuous-treatment group received 25 mg of BPO/day for 52 weeks and the carbopol gel vehicle for the remainder of the study. Vehicle-only and no-treatment groups served as controls. Mice were sacrificed at 52 (interim-sacrifice) or 104 weeks, and necropsies were performed. The high dose (25 mg of BPO/day) exceeded the maximum tolerated dose (MTD), in that it caused treatment-site ulceration, and was lowered to 15 mg of BPO/day at week 57. Because ulceration also occurred in mice receiving 15 mg/day, BPO treatment of the high-dose mice was suspended and vehicle was administered from week 93 until the end of the study. BPO had no effect on survival, body weights, food consumption or gross pathology, except for treatment-site ulceration in the high-dose group. Microscopic evaluation revealed treatment-related findings confined to the site of application. Specific findings were dose-dependent induction of acanthosis, hyperkeratosis, sebaceous gland hyperplasia and subepidermal inflammation was evident at the interim sacrifice as well as at the terminal sacrifice in groups continuously treated with BPO. Ulceration, observed grossly, was confirmed microscopically. No findings indicative of oncogenicity resulted from topical application of BPO gel in any of the treatment groups. Importantly, 5 mg of BPO, administered in carbopol gel daily for 104 weeks, produced skin effects consistent with reaching but not exceeding the MTD. These data further support the conclusion that BPO lacks carcinogenic potential.

1871 TOXICOLOGICAL CHARACTERIZATION OF A NOVEL CIGARETTE PAPER.

G. Patskan[1], F. Hsu[1], T. Meisgen[2], R. Stabbert[2], P. Vanscheeuwijck[3] and D. Veltel[2]. [1]*Philip Morris USA, Richmond, VA,* [2]*INBIFO Institut fuer biologische Forschung, Cologne, Germany and* [3]*CRC Contract Research Center, Zaventem, Belgium.* Sponsor: R. P. Solana.

Through the use of novel papermaking technology a cigarette paper has been developed that possesses evenly spaced bands. These bands are comprised of paper with a higher basis weight than the paper in between the bands. Cigarettes made with this new paper are less likely to ignite certain test fabrics used in several laboratory testing methods. The toxicological evaluation of this change in cigarette paper design was determined under standard smoking conditions (35cc puffs of 2 seconds duration taken every minute). The effect of this paper on the delivery of up to ~50 analytes/parameters in cigarette smoke was investigated. The mutagenic activity of cigarette smoke condensate was evaluated in the Salmonella typhimurium reverse mutation assay using strains TA98, TA100, TA102, TA1535 and TA1537 with and without S9. The neutral red uptake assay with BALB/c 3T3 cells was used to assess the cytotoxicity of the particulate and gas/vapor phases of smoke. Changes in the respiratory tract of male Sprague-Dawley rats were assessed following 90 days exposure to smoke. The novel paper caused only minor changes in chemical smoke composition (the largest changes were a 20% decrease in phenol and a 27% increase in cadmium) and no changes in *in vitro* or *in vivo* biological activity.

1872 TOXICOLOGY OF BENZOFLEX®9-88 PLASTICIZER.

J. P. McBriarty[1], R. E. Masters[2], T. G. Smith[2] and J. R. Reel[3]. [1]*Velsicol Chemical Corporation, Rosemont, IL.* [2]*Huntingdon Life Sciences Limited, Huntingdon, United Kingdom and* [3]*Bioqual, Inc., Rockville, MD.*

Benzoflex®9-88 plasticizer (dipropyleneglycol dibenzoate) was evaluated in numerous safety studies. The acute toxicity ranged between 2 and <6.5 g/kg in rats. Other short term tests including skin sensitization were unremarkable. A battery of *in vitro* genetic toxicity tests including assays for gene mutations in bacteria (Ames *Salmonella* strains & *E. Coli*) and mammalian (mouse lymphoma) cells as well as for chromosomal aberrations in mammalian (Chinese hamster lung) cells showed no evidence of mutagenic or clastogenic activity. In a study to evaluate estrogenic activity, adult ovariectomized rats were dosed at 0, 500, 1000, 1500 and 2000 mg/kg/day for 7 days via oral gavage. No estrogenic activity was noted, using vaginal cornification and uterotrophic response as endpoints, at doses up to and including the maximally tolerated dose. A 13-week subchronic dietary study was conducted in male and female rats at doses of 0, 250, 1000, 1750 and 2500 mg/kg/day. Toxicity was observed only at the two highest doses. This included a decrease in bodyweight, increased plasma enzyme activity associated with slight liver cell hypertrophy, a moderate increase in the normal background hemosiderosis in the spleen, and minimal epithelial hyperplasia in the caecum only at 2500 mg/kg/day. Urinary pH was decreased in a dose-related manner consistent with a previous ADME study. All treatment related effects were reversible or showed a tendency to reverse in the four-week recovery period. The non-toxicologically significant NOEL was judged to be 1000 mg/kg/day. Finally, studies to date suggest a low order of mammalian toxicity for this plasticizer.

1873 TOXICOLOGY OF BENZOFLEX®2-45 PLASTICIZER.

R. E. Masters[1], T. G. Smith[1], J. P. McBriarty[2] and J. R. Reel[3]. [1]*Huntingdon Life Sciences Limited, Huntingdon, United Kingdom,* [2]*Velsicol Chemical Corporation, Rosemont, IL and* [3]*Bioqual, Inc., Rockville, MD.*

Benzoflex®2-45 plasticizer (diethyleneglycol dibenzoate) was evaluated in numerous safety studies. The acute toxicity ranged between 2 and 5 g/kg in rats. Other short-term tests including skin sensitization were unremarkable. A battery of *in vitro* genetic toxicity tests including assays for gene mutations in bacteria (Ames *Salmonella* strains & *E. Coli*) and mammalian (mouse lymphoma) cells as well as for chromosomal aberrations in mammalian (Chinese hamster lung) cells showed no evidence of mutagenic or clastogenic activity. In a study to evaluate estrogenic activity, adult ovariectomized rats were dosed at 0, 500, 1000, 1500 and 2000 mg/kg/day for 7 days via oral gavage. No estrogenic activity was noted, using vaginal cornification and uterotrophic response as endpoints, at doses up to and including the maximally tolerated dose. A 13-week subchronic dietary study was conducted in male and female rats at doses of 0, 250, 1000, 1750 and 2500 mg/kg/day. Toxicity was observed only at the two highest doses. This included decreases in body weight, slight liver cell hypertrophy and a moderate increase in the normal background hemosiderosis in the spleen. In addition, at 2500 mg/kg/day only, minimal epithelial hyperplasia was seen in the caecum and there were a few clinical signs and a single mortality resulting from the stress associated with treatment at this very high dosage. Urinary pH was decreased in a dose-related manner consistent with a subsequent ADME study. All treatment related effects were reversible or showed a tendency to reverse in the four-week recovery period. The non-toxicologically significant NOEL was judged to be 1000 mg/kg/day. Finally, studies to date suggest a low order of mammalian toxicity for this plasticizer.

1874 TOXICOLOGY OF BENZOFLEX®S-358 PLASTICIZER.

S. J. Crome[1], R. A. Paffett[1], J. P. McBriarty[2] and J. R. Reel[3]. [1]*Huntingdon Life Sciences Limited, Huntingdon, United Kingdom,* [2]*Velsicol Chemical Corporation, Rosemont, IL and* [3]*Bioqual, Inc., Rockville, MD.*

Benzoflex®S-358 plasticizer (triethyleneglycol dibenzoate) was evaluated in numerous safety studies. The acute toxicity ranged between 2 and 6.5 g/kg in rats. Other short term acute toxicity tests including skin sensitization were unremarkable. A battery of *in vitro* genetic toxicity tests including assays for gene mutations in bacteria (Ames *Salmonella* strains & *E. coli*) and mammalian (mouse lymphoma) cells as well as for chromosomal aberrations in mammalian (Chinese hamster lung) cells showed no evidence of mutagenic or clastogenic activity. In a study to evaluate estrogenic activity, adult ovariectomized rats were dosed at 0, 250, 700, 1400, 2100 and 2800 mg/kg/day for 7 days via oral gavage. No estrogenic activity was noted, using vaginal cornification and uterotrophic response as endpoints, at doses up to and including the maximally tolerated dose. A 13-week subchronic dietary study was conducted in male and female rats at doses of 0, 400, 1000, 1600 and 2200 mg/kg/day. Toxicity was observed only at the two highest doses. This included a decrease in body weight, slight liver cell hypertrophy, a moderate increase in the normal background hemosiderosis in the spleen. Urinary pH was decreased as with other analogous chemicals. All treatment related effects were dose-related, reversible or showed a tendency to reverse in the four-week recovery period. The NOEL was judged to be 1000 mg/kg/day. Finally, studies to date suggest a low order of mammalian toxicity for this plasticizer.

1875 LY3353381, A SELECTIVE ESTROGEN RECEPTOR MODULATOR (SERM): ^{32}P-POSTLABELING ANALYSIS OF IN VIVO DNA ADDUCTS IN F-344 RAT LIVERS.

V. R. Reddy[1], R. K. Newton[1], L. E. Rinkema[1] and V. Reddy[2]. [1]*Eli Lilly and Company, Greenfield, IN and* [2]*Covance Laboratories, Vienna, VA.*

LY353381 is a SERM, acts as a potent estrogen antagonist in uterine and mammary tissue while acting as an estrogen agonist to maintain bone density and lower serum cholesterol. Groups of female and male Fischer 344 rats were administered 20, 60, and 140 mg/kg LY353381 hydrochloride by oral gavage once a day for 3 days. The positive control group of rats received 45 mg/kg tamoxifen. At 2-3 hours after the last dose, the rats were euthanized and livers collected. Nuclear DNA isolated from livers of female and male rats of vehicle control, high dose, and positive control groups were analyzed by the ^{32}P-postlabeling assay using both butanol extraction and nuclease P1 digestion for enrichment of adducts. The low- and mid-dose groups were analyzed by the nuclease P1-enhanced postlabeling assay alone. Autoradiograms or scanned images of thin layer chromatograms obtained for LY353381-treated groups at the three dose levels were similar to those obtained for the corresponding vehicle control group. There were no extra spots indicative of adducts on the chromatograms of DNA from LY353381-treated animals. Determination of radioactivity associated with the background spots showed no statistically significant increase in background adduct levels in DNA samples of LY353381-treated animals compared with the vehicle control DNA samples. The positive control, tamoxifen, produced detectable levels of DNA adducts in the livers of both male and female rats. The results indicate that LY353381 does not produce detectable levels of DNA adducts at dose levels of 20, 60 and 140 mg/kg after oral administration for 3 days. The high dose is approximately 70% of a maximum tolerated dose (MTD).

1876 SAFETY AND PHARMACOLOGICAL EFFECTS OF LOCALLY ADMINISTERED CCI-1004 AFTER BALLOON ANGIOPLASTY IN RABBITS.

C. Finkle[1], A. Ezrin[1], P. Williams[2], A. Fleser[1], R. Stewart[3], C. Nguyen[2] and S. Lo[2]. [1]*ConjuChem Inc., Montreal, Quebec, Canada,* [2]*SRA Life Sciences, Inc., Falls Church, VA and* [3]*ITR Laboratories Canada Inc., Montreal, Quebec, Canada.*

CCI-1004, an antithrombotic that forms covalent bonds with vascular proteins, can potentially be applied to various situations where thrombotic complications arise, including the prevention of post-surgical thrombosis following angioplastic surgery. The safety profile of CCI-1004 was therefore investigated in a model of local delivery in rabbits to simulate the therapeutic setting for this agent. CCI-1004 (12.5, 50.0, or 312.5 nmole/rabbit) or vehicle was administered once by direct vascular injection to an isolated segment of the carotid artery, which was injured by balloon angioplasty prior to dosing or left intact. After a 3-min incubation, the blood flow through the carotid artery segment was re-established and the test article systemically released. Group mean values of APTT showed no statistically significant differences between control or treated animals, although elevated values (26.3-32.8 sec) were observed in 3 high dose rabbits. This observation was consistent with the mechanism of action of CCI-1004, and measurements in these animals decreased within 24 hours to levels comparable to those in controls. No gross or microscopic findings were attributed to CCI-1004 administration. It was concluded that CCI-1004 is well tolerated in rabbits following single intra-arterial local incubation with systemic release at doses of 12.5, 50.0, and 312.5 nmoles.

1877 CHARACTERIZATION OF ATYPICAL HISTOPATHOLOGY NOTED IN A 4-WEEK INTRAVENOUS INFUSION STUDY IN RATS.

M. D. Walker, R. H. Cardy and M. E. McKeon. *Covance Laboratories, Inc., Vienna, VA*. Sponsor: M. R. Moore.

Identical validation studies were conducted at our Vienna, VA and Madison, WI laboratories, to determine the feasibility of using vendor-supplied precannulated rats, to compare the use and manageability of Fisher-344 and CD® rats, to evaluate the jugular and femoral routes of intravenous infusion, and to assess survival when a known vascular irritant is infused. The rats were precannulated by the supplier (Charles River Laboratories) using their custom-made polyurethane (Microrenathane®) catheter, which included silicone retention beads adhered with a cyanoacrylate adhesive. Eighty animals (10/sex/strain/route, for a total of 4 groups) were assigned to each study. A standard battery of in-life evaluations were performed, to include mortality, clinical signs, body weights, food consumption, and clinical pathology. After completion of the treatment period, all animals were necropsied, select organ weights were recorded, and the heart, kidneys, liver, lungs,lymph nodes, spleen, thymus, catheterization sites, and infusion sites were preserved. Tissues were embedded in paraffin, sectioned at approximate 5μ, stained with hematoxylin and eosin, and examined microscopically. Neutrophil counts were considerably higher in the jugular-Solutol males at Day 30, consistent with the higher incidence of infusion/catheter site abscesses these rats. Mean total cholesterol values were significantly lower in both strains of rats exposed to Solutol, regardless of route of administration. Microscopically, reactions to the presence of the catheter were variable and were within a fairly defined spectrum of changes,typified by the developed of a fibrous capsule and an accompanying chronic inflammatory response. Foreign body reactions to suture material were typically granulomatous, often with foreign body giant cells and mineralization. A clear,spicule-shaped material was seen frequently within or adjacent to the lumen of small arterioles in the lungs of many rats, characteristically eliciting a substantial inflammatory reaction and development of multiple microgranulomas. Thematerial appeared to originate from the silicone retention bead at the catheterization site, where a mass of similar appearance was found. Lesions of this kind may pose serious problems in safety assessment studies, particularly where the lung is a target organ. Based on these findings, it is suggested that one use caution when usingcustom-made implanatable materials for chronic infusion studies in rats.

1878 ASCORBIC ACID-STIMULATED DEPOSITION OF COLLAGEN IV IS ASSOCIATED WITH REPAIR OF RENAL CELL FUNCTIONS FOLLOWING SUBLETHAL INJURY.

P. A. Nony, G. Nowak and R. G. Schnellmann. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Pharmacological concentrations of L-ascorbic acid phosphate (AscP), a stimulator of collagen synthesis, have been shown to promote proliferation and repair of physiological functions in renal proximal tubular cells (RPTC) sublethally injured by S-1,2-dichlorovinyl-L-cysteine (DCVC). We hypothesized that AscP promotes this proliferation and repair by stimulating collagen synthesis and deposition. Primary cultures of rabbit RPTC were grown to confluence in the presence of physiological (50 μM) or pharmacological (500 μM) concentrations of AscP and exposed to 200 μM DCVC to produce ~50% cell death and loss 24 hrs after exposure. Proliferation, mitochondrial function (oxygen consumption, QO_2), and collagen IV synthesis and deposition were determined over the following six days. On day 1 after DCVC exposure, total monolayer protein content and QO_2 were ~50% of controls in cells grown in both 50 and 500 μM AscP. On day 6 after injury, protein content in cells grown in 500 μM AscP was significantly higher (89±9% of control) than the 50 μM AscP group (69±9% of control). On day 6, QO_2 in the 50 μM AscP group was still inhibited (64±7% of control) whereas QO_2 in the 500 μM AscP group was equal to control. Collagen IV synthesis and deposition was determined by immunoprecipitation and autoradiography of ^{35}S-methionine-labeled collagen IV. Autoradiography showed that DCVC exposure inhibited deposition, but not synthesis, of collagen IV in cells grown in 50 μM AscP at days 1, 4, and 6 post-injury. In contrast, synthesis and deposition of collagen IV by DCVC-injured cells grown in 500 μM AscP was equal to that of control on days 1, 4, and 6 post-injury. These results demonstrate the novel findings that 1) DCVC inhibits deposition, but not synthesis, of collagen IV and 2) pharmacological concentrations of AscP protect against the inhibition of collagen IV deposition in DCVC-injured RPTC. This study shows that repair of physiological functions in RPTC injured by DCVC is associated with AscP-stimulated deposition of collagen IV and suggests that collagen IV plays a role in RPTC regeneration and repair following toxicant injury.

1879 LINOLEIC ACID METABOLITES INDUCE RENAL CELL DEATH AT PATHOLOGICALLY RELEVANT CONCENTRATIONS.

J. H. Moran, L. A. Mitchell, R. G. Schnellmann and D. F. Grant. *Department of Pharmacology and Toxicology, University of Arkansas for Med. Science, Little Rock, AR.*

Linoleic acid is metabolized *in vivo* to a variety of important products. The epoxides of linoleic acid can be formed by specific cytochrome P450 isoforms and have been associated with increased mortality of severely burned patients. Recent *in vitro* studies using methyl ester derivatives suggested a soluble epoxide hydrolase (sEH) dependent pathway for linoleic acid epoxide mediated toxicity and have shown the diols of linoleic acid to be the toxic intermediate. In the present study, we tested the hypothesis that the free acid metabolites of linoleic acid would have a similar mechanism of toxicity in rabbit renal proximal tubular cells (RPT). Linoleic acid, cis-9,10-epoxyoctadecenoic acid (9,10-EOA), cis-12,13-epoxyoctadecenoic acid (12,13-EOA), 12,13-dihydroxyoctadecenoic acid, and 9,10-dihydroxyoctadecenoic acid produced concentration- and time-dependent cell death (LDH release) at pathologically relevant concentrations (100-500 μM). 12,13-EOA (500 μM) was the most toxic metabolite of linoleic acid and induced approximately 35% LDH release after a 30 min exposure. All other metabolites showed no difference from diluent controls at 30 min (10% LDH release). However, the diols and epoxides were equally toxic at 3 hr (50% LDH release). Glycine (2 mM), deferoxamine (500 μM), N,N'-diphenyl-1,4-phenylene-diamine (2 μM), and nifedipine (100 μM) did not block linoleic acid, 9,10-EOA and 12,13-EOA mediated LDH release. Metabolism studies demonstrated that less than 1% of ^{14}C-linoleic acid was metabolized to the epoxide, diol, and HODE metabolites after 1 hr. Minimal metabolism of linoleic acid prior to cell death suggests that toxicity is due to the parent compound. These results show that linoleic acid and the free acid epoxides and diols of linoleic acid are equally toxic in RPT. Also, the mechanism of toxicity is different than the methyl ester derivatives and is not mediated through a sEH dependent pathway or oxidative stress.

1880 THE ROLE OF HEME OXYGENASE IN OCHRATOXIN A MEDIATED NEPHROTOXICITY.

G. J. Schaaf[1], R. F. M. Maas[1], E. M. deGroene[2] and J. Fink-Gremmels[1]. [1]*Utrecht Univ., Department of Vet. Pharmacology and Toxicology, Fac. Vet. Medicine, Utrecht, Netherlands and* [2]*TNO Pharma, Department of Pharmacology, Zeist, Netherlands*. Sponsor: M. vandenBerg.

Ochratoxin A (OTA) is a mycotoxin which has been shown to have nephrotoxic and nephrocarcinogenic potential. A proposed mechanism for OTA-toxicity is induction of oxidative stress. Heme oxygenase (HO) is a stress protein and its induction has been proposed to protect against oxidative stress caused by heme and hemoprotein. Increased HO expression has been shown in renal cell carcinoma. In the current study, renal cells in culture (primary rat proximal tubular cells and LLC-PK1 cell line) were used to investigate the role of HO in OTA-mediated toxicity. A specific inhibitor (zinc-protoporphyrin: ZnPP) and an inducer (hemin) of HO activity were used to manipulate HO activity in cell cultures exposed to different concentrations of OTA. In the presence of hemin, no difference in the production of reactive oxygen species (ROS) by OTA was observed, while ZnPP appeared to decrease both basal as well as OTA-induced ROS production. The presence of hemin did not alter the cytotoxic effect of OTA in these cells, while ZnPP appeared to exacerbate OTA-induced cytotoxicity. Western blot analysis showed a clear increase in HO expression in primary PTC after incubation with hemin (almost 2-fold) and a considerable decrease after incubation with ZnPP (about 25 % of control HO expression). Incubation for 2 h with OTA (50 μM) slightly decreased HO expression (79 % of control). These preliminary data suggest that induction of HO expression by hemin did not protect these cells against OTA-induced oxidative stress and cytotoxicity. Furthermore, it may be proposed that OTA decreases HO expression and thereby facilitates development of oxidative damage.

1881 FUMONISIN B_1 IS HEPATOTOXIC AND NEPHROTOXIC IN MILK FED CALVES.

W. M. Haschek[1], S. Mathur[2], R. M. Eppley[3], A. L. Waggoner[1], M. E. Tumbleson[4] and P. D. Constable[2]. [1]*Department of Veterinary Pathobiology, University of Illinois, Urbana, IL,* [2]*Department of Veterinary Clinical Medicine, University of Illinois, Urbana, IL,* [3]*USFDA, Washington, DC and* [4]*Department of Veterinary Biosciences, University of Illinois, Urbana, IL.*

Fumonisins are a group of mycotoxins that alter sphingolipid biosynthesis and

induce leukoencephalomalacia in horses and pulmonary edema in pigs. Experimental administration of fumonisin induces acute hepatotoxicity in all species, including cattle, and nephrotoxicity in rats, rabbits, sheep, and goats. We further investigated the toxicity of fumonisin to calves. Ten milk-fed male Holstein calves aged 7 to 14 days were instrumented to obtain blood and urine. Treated calves (n = 5) were given fumonisin B_1 at 1 mg/kg, IV, daily and controls (n = 5) 10 ml 0.9% NaCl, IV, daily. All calves were euthanized on day 7. Fumonisin treated calves were lethargic and had a decreased appetite from day 4 to 7, and had serum biochemical evidence of severe liver and bile duct injury (increased serum sorbitol dehydrogenase, aspartate aminotransferase, gamma-glutamyl transferase [GGT], and alkaline phosphatase activities), and impaired hepatic function (increased serum bile acid and total bilirubin concentrations). Fumonisin treated calves also had biochemical evidence of renal injury (increased serum creatinine concentration) that functionally involved the proximal convoluted tubules (increased urine protein and GGT concentration, increased fractional clearance of potassium and phosphorus, increased urine GGT to creatinine ratio). Sphinganine and sphingosine concentrations in the liver, kidney, lung, heart, and skeletal muscle were increased in fumonisin treated calves. Sphinganine, but not sphingosine, concentration was increased in the brain of treated calves. In fumonisin treated calves, hepatic lesions were characterized by disorganized hepatic cords, variable severity of hepatocyte apoptosis, increased hepatocyte proliferation, and proliferation of bile ductular cells. Renal lesions in fumonisin treated calves consisted of apoptosis, karyomegaly, and increased cell proliferation of proximal renal tubular cells, as well as dilation of proximal renal tubules which contained cellular debris and protein. This is the first report of fumonisin induced renal injury and organ sphingolipid alterations in cattle.

1882 URINARY ANTIGENS AS MARKERS OF PAPILLARY TOXICITY.

F. W. Falkenberg[1,2], H. Hildebrand[2], M. Rinke[2], G. Schluter[2] and E. Bomhard[2]. [1]*RUHR-Universitat Bochum, Bochum, Germany and* [2]*Bayer AG Institut für Toxikologie, Wuppertal, Germany.*

Renal papillary toxicity of xenobiotics is generally determined by inspection of necropsy specimens obtained from treated laboratory animals. This procedure is invasive and provides information on the state of the tissue at the day the organ is taken for inspection. It does not allow a day-by-day follow-up during the treatment period. To overcome this obstacle we have prepared monoclonal antibodies specific for antigens localized in functional (collecting duct, loop of Henle) and structural (extracellular matrix) components of the rat renal papilla. Applying these monoclonal antibodies in ELISA-type tests antigens with known localization in the tissue were determined in urine samples collected during day-by-day follow-ups. The results obtained with ELISA tests for 3 different antigens have shown that extent and profile of antigen release depend on the kind of drugs applied and on the application route. Whereas a single intraperitoneal application of 2-bromoethanamine or propylenimine resulted in a strongly increased release of one of the antigens (Papillary Antigen 1), single or repeated oral applications of bromoethanamine had minor effects. In contrast, both single intraperitoneal or repeated oral applications of indomethacin resulted in an increased release of all the three antigens. In most cases, histopathology findings correlated with the ELISA results. The observation of papillary alterations that led to enhanced antigen release but not to permanent damage indicate the potential of the new method. After daily application of ipsapirone in the diet or in drinking water release of Papillary Antigen 1 increased incrementally during the application period, but returned to normal pre-treatment levels after discontinuation of the treatment. Release of the other antigens was not affected. These results show that with the tests developed changes in the rat renal papilla caused by xenobiotics can be detected early by urinary analysis and monitored during follow-up studies. Moreover, the different antigen release patterns obtained after application of the different compounds indicate that they differ in their mode of action.

1883 A 28-DAY METHYL *tert*-BUTYL ETHER (MTBE) PALATABILITY STUDY AND THE EVALUATION OF PROTEIN DROPLET ACCUMULATION IN THE KIDNEYS OF RATS.

S. J. Borghoff, H. D. Parkinson, T. M. Williams, D. B. Janszen and J. I. Everitt. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

MTBE is added to fuel to increase its oxygen content thereby reducing certain toxic emissions. MTBE has been found to contaminate groundwater in certain urban areas. Limited information exists to characterize the possible health risks from exposure to MTBE via drinking water (DW). The objective of this study was to assess the palatability of MTBE in DW as a basis for longer-term studies, and its ability to cause protein droplet nephropathy in male rats. Male and female F-344 rats were given DW containing 0, 1.5, 3, 7, or 15 mg MTBE /ml for 28 days, euthanized with CO2 and kidneys collected. Fixed sections of kidney were stained with Mallory's Heidenhain, a nonspecific protein stain, or for α2u-globulin (α2u) immunohistochemically. The concentrations of MTBE and its metabolite tert-butyl alcohol (TBA) were quantitated in the kidney by GC/MS. Body weight gain, and food and water consumption (FC and WC) was evaluated in each rat on a daily basis. Female rats drank ~3-5 ml less water/day throughout the study at all levels of MTBE. Initally WC was less (~3 ml) in male rats given 7 or 15 mg MTBE/ml compared to the control group. After the second week of the study no differences in WC were observed between the control and exposure groups. Throughout this study rats received ~110 to 1234 mg MTBE/kg/day. Body weight gain and FC was not affected in rats given MTBE DW. MTBE (15 mg/kg) caused a mild accumulation of protein droplets that stained positive for α2u in male rat kidneys. MTBE was detectable in male, but not female rat kidneys with male rats having a 7 to 35-fold higher kidney level of TBA compared to the female rat. MTBE was found to be palatable in DW. MTBE given in DW induced a male rat kidney response similar to what has been previously observed following inhalation exposure to MTBE. (Sponsored in part by the American Petroleum Institute.)

1884 CHARACTERIZATION OF *TERT*-BUTYL ALCOHOL BINDING TO α2U-GLOBULIN.

T. M. Williams, E. R. Howell, E. C. Mooney and S. J. Borghoff. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

tert-Butyl alcohol (TBA) is used as a chemical intermediate with a wide range of uses, including solvents for pharmaceutical products, paint removers, and personal care products. In both rodents and humans, TBA is a major metabolite of methyl *tert*-butyl ether, an oxygenated fuel additive. Chronic TBA exposure causes protein droplet nephropathy, α2u-globulin (α2u) accumulation, renal cell proliferation, and tumor formation in male, but not female, rats, suggesting an α2u-mediated mechanism for renal tumors. The objective of the present study was to determine whether TBA or a metabolite of TBA binds to α2u. Male and female F344 rats were administered a single gavage dose of 500 mg/kg TBA, 500 mg/kg [^{14}C]TBA, or corn oil. [^{14}C]TBA-derived radioactivity was detected at a higher percentage, relative to dose administered, in the male kidney, liver, and blood compared with the female tissue 12 h following [^{14}C]TBA administration. Gel filtration and anion-exchange chromatography demonstrated that [^{14}C]TBA-derived radioactivity coeluted with α2u from male, but not female, kidney cytosol. Protein dialysis studies demonstrated that the interaction between the [^{14}C]TBA-derived radioactivity and α2u was reversible. The low-molecular-weight protein fraction (LMWPF) from the kidney of [^{14}C]TBA-treated animals was isolated and incubated with *d*-limonene oxide, a chemical with a high affinity to α2u. *d*-Limonene oxide displaced the [^{14}C]TBA-derived radioactivity from the LMWPF. GC/MS analysis of the LMWPF confirmed that TBA was present in this fraction. These results demonstrate that TBA interacts with α2u, which explains the accumulation of α2u in the male rat kidney following exposure.

1885 BISMUTH BIOKINETICS AND NEPHROTOXICITY AFTER ACUTE COLLOIDAL BISMUTH SUBCITRATE OVERDOSE IN RATS.

B. T. Leussink[1], A. Slikkerveer[1], W. J. J. Krauwinkel[2], G. B. van der Voet[1], E. de Heer[3], J. A. Bruijn[3] and F. A. de Wolff[1]. [1]*Toxicology Laboratory, Leiden University Medical Center, Leiden, Netherlands,* [2]*Yamanouchi Europe BV, Research Laboratories, Leiderdorp, Netherlands and* [3]*Department of Pathology, Leiden University Medical Center, Leiden, Netherlands.* Sponsor: G. J. Mulder.

Bismuth(Bi)-induced nephrotoxicity has been reported to occur after acute overdoses of Bi-containing therapeutic drugs, used to treat peptic ulcers and *Helicobacter pylori* infections. We studied bismuth biokinetics and development of Bi-induced nephropathy in rats. Bi nephropathy was induced at t=0 hr by feeding a single overdose of colloidal bismuth subcitrate containing 3.0 mmol Bi/kg to 33 ten- to twelve-weeks-old female Wistar rats. The control group consisted of seven rats fed the vehicle. Kidney function parameters and Bi concentration in blood and urine were followed until the animal was sacrificed between t=1 and 48 hr to determine kidney histology and Bi content. Plasma creatinine increased during the whole experimental period. Proximal tubular cells of the S3 segment had vacuolated at t=1 hr and had become necrotic at t=3 hr. Cells of the S1/S2 segment started to vacuolate at t=3 hr to

become necrotic at t=12 hr. Biokinetics of bismuth in blood could best be described with a one compartment model characterized by an absorption half-life of 0.32 hour and an elimination half-live of 16 hours. The peak concentration of about 7.0 mg Bi/l was reached at t=2 hr. Conclusion: Of all proximal tubular segments, S3 necrotized first after an oral CBS overdose, followed by the S1/S2 segment. The Bi in blood curve for the first 48 hours was best described by a one compartment model.

1886 EFFECT OF ORAL ADMINISTRATION OF MANGANESE ON URINARY SYSTEM IN RATS.

G. A. Henry-Sam, T. P. Ponnapakkam and M. B. Iszard. *Xavier University, New Orleans, LA.*

Oral toxicity studies were conducted to identify the toxicologic and reproductive performance in Sprague-Dawley rats during manganese administration. Both sexes were dosed in two-phase trials at 0, 360, 612, 1225, and 1838 mgMn/kg for 63 days. At the end of the dosing, 50% of animals were sacrificed, and the remaining cross-mated to evaluate reproductive efficiency with no dosing. After two weeks, the remaining animals were sacrificed. Male animals were noted to have viscous, gritty urine in the urinary bladder, and in the high dose groups had urinary bladder stones (uroliths). Proliferative masses associated with genitourinary structures were found in 66% of male rats from the 1838 mg/kg group. Phase I female liver weights were increased in all treatment groups, while male liver weights decreased in all groups. Phase I female kidney weights were not affected with treatment, while males in all treatment groups had decreased kidney weights. The most striking lesions were observed in the kidneys and prostate gland of male animals. Mild to moderate tubulointerstitial nephritis with tubular proteineous and glomerulosclerosis was observed in animals of all treatment groups. Moderate to severe changes were seen in combination in animals receiving 1225 and 1838 mgMn/kg. Urolithiasis in the urinary bladder was confirmed in 33-66% of treated animals. Prostatic changes included focal to locally extensive suppurative inflammation within tubules and interstitum, primarily in the two high-dose groups without correlation to testicular lesions. Female animals did not show a significant difference above controls in renal tissues. (Supported by ATSDR #U50/ATU398948-08.)

1887 ASSYMETRIC TRANSEPITHELIAL TRANSPORT AND ACCUMULATION OF CISPLATIN-N-ACETYLCYSTEINE IN S_1, S_2, AND S_3 SEGMENTS OF THE RABBIT RENAL PROXIMAL TUBULE.

R. J. Kolb, D. W. Barfuss and A. M. Ghazi. *Georgia State University, Atlanta, GA.*

We measured the lumen-to-bath and bath-to-lumen transport, cellular accumulation and assessed the toxicity of cisplatin-N-acetylcysteine (cDDP-NAC) in isolated perfused segments (S_1, S_2, and S_3) of the rabbit renal proximal tubule. We observed the tubular epithelial cells under the light microscope for signs of cellular injury. Cellular swelling, blebbing, and the uptake of the vital dye FD & C green were indicative of cellular necrosis. Visible cellular damage occurs within 20 minutes after exposure of renal proximal tubular cells to 2mM cDDP and 4 mM N-acetylcysteine (presumably forming a 2 mM cDDP-NAC complex) at the basolateral and luminal membranes. This is in contrast to previous experiments that demonstrated that tubules bathed and perfused in the same concentration of cDDP only, displayed minimal toxicity. Lumen-to-bath transepithelial transport of cDDP-NAC was uniform for all segments at approximately 20 pMol min^{-1} (mm tubule length)$^{-1}$ while the bath-to-lumen transepithelial transport was much less at approximately 1 pMol min^{-1} (mm tubule length)$^{-1}$. Cellular accumulation of cDDP-NAC was greatest for the lumen-bath transepithelial transport as compared to bath-lumen transepithelial transport, 40 and 4 pMol (mm tubule length)$^{-1}$, respectively. When 2 mM p-aminohippurate was added to the bathing solution in the bath-to-lumen experiments, cellular accumulation decreased to non-detectable levels and elevated the apparent visual toxicity. We conclude that a potential "metabolite" of cisplatin, cDDP-NAC, is primarily sequestered by the proximal tubule at the luminal membrane. However, there is substantial uptake at the basolateral membrane which appears to be mediated by the PAH sensitive organic anion transporter.

1888 ENDOTOXIN AUGMENTED MERCURY-INDUCED NEPHROTOXICITY.

W. K. Rumbeiha, S. D. Fitzgerald, R. A. Roth, W. E. Braselton and C. L. O'Connor. *Michigan State University, East Lansing, MI.*

Both endotoxin (LPS) and mercury are nephrotoxic compounds. The effects of either toxicant alone on the kidney have been well investigated but their toxic interaction has not. Endotoxin is a product of gram-negative bacteria cell walls. Humans are exposed to LPS through sepsis, by increased translocation across the gastrointestinal wall, or in the event of compromised liver function. Mercury is a food contaminant and the highest risk of human exposure is by consumption of contaminated fish. We have recently demonstrated that endotoxin potentiates mercury-induced nephrotoxicity in endotoxin-sensitive mice. In this study we tested the hypothesis that endotoxin augments mercury-induced nephrotoxicity in rats. Thirty two 41-43 day old, male Sprague-Dawley rats were randomly allocated to 4 groups of 8 rats each as follows: Group I (control) received 0.9% sodium chloride once IV, Group II received 2.0 mg of *E.coli* 0128:B12/kg once IV, Group III received 0.5 mg of mercury/kg (as mercuric chloride) once IV, Group IV received 2.0 mg endotoxin/kg (as in group II) once IV 4 hours before receiving 0.5 mg mercury/kg (as in group III) once IV. Rats were monitored for 48 hours. Serum and urine were assayed for markers of renal failure. Immunohistochemistry was done on kidneys for neutrophils. Rats given LPS plus mercury had a significant increase in serum creatinine and urea nitrogen concentrations than the rest of the groups. Kidneys from rats given endotoxin alone were normal but the most severe lesions were found in rats given endotoxin plus mercury. These kidneys also had a significant increase in neutrophils. Endotoxin significantly increased renal mercury concentration ($p \leq 0.05$). In conclusion, LPS augmented mercury-induced nephrotoxicity. This was associated with increased neutrophil infiltration and mercury content.

1889 COMPARATIVE EVALUATION OF NEPHROTOXIC RESPONSE OF YOUNG AND OLD RATS TO MERCURIC CHLORIDE.

C. Bai and S. K. Chakrabarti. *Université de Montréal, Montréal, Quebec, Canada.*

Degenerative changes in kidney function over the life span have been well documented. Furthermore, the changes in renal structure and function in aged rats are qualitatively similar to those in humans (Levi, Rowe, 1992; Mayersohn, 1994). However, how the degenerative processes of aging affect toxic vulnerability to metals has not received much experimental attention. This study was therefore carried out to evaluate age-dependent susceptibility of male Fisher-344 rats to nephrotoxicity due to subchronic treatment with mercuric chloride (HgCl2). Groups (5-6 rats/group) of both very young (7 weeks) and old (25-30 months) rats were treated by gavage with 0, 2 and 4 mg HgCl2 per kg b.w. once daily for 4 consecutive weeks. At the end of such treatment, the urines were collected at 0°C for 24 hours after each of 2 and 4 weeks of treatment and the animals were then immediately sacrificed for blood withdrawal and kidney removal. Both dose- and age- dependent increase in nephrotoxicity and accumulation of renal mercury were observed. A significant 5-fold increase in the urinary excretion of proteins, a 3-fold increase in the urinary excretion of N-acetyl-ß-D-glucosaminidase and gamma-glutamyltransferase and a 2-fold increase in BUN (measured by the ratio of treated/control) were observed in old rats compared to young rats when treated with 4 mg HgCl2 per kg for 4 weeks. These data demonstrate that very old rats are more susceptible than very young rats to the nephrotoxicity due HgCl2 caused by, in part, age-dependent difference in mercury accumulation in the rat kidney.

1890 EXPRESSION OF HEAT SHOCK PROTEIN 60 IN HUMAN PROXIMAL TUBULE CELLS EXPOSED TO ACUTE AND CHRONIC DOSES OF CADMIUM CHLORIDE.

J. H. Todd, S. Somji, M. A. Sens, S. H. Garrett and D. A. Sens. *Department of Pathology, WVU, Morgantown, WV.*

The heat shock proteins (hsps) are members of a large superfamily of stress response proteins that provide protection from physical and chemical insults including heavy metals. The goal of this study was to determine if hsp 60 has a protective role against toxicity from the heavy metal pollutant cadmium (Cd^{+2}) in human proximal tubule (HPT) cells. The expression of hsp 60 mRNA and protein were determined in HPT cells exposed to lethal and sub-lethal concentrations of Cd^{+2} under both acute and chronic conditions. Acute exposure to Cd^{+2} involved a 4 hr exposure followed by a recovery period in

Cd^{+2}-free growth medium. Chronic exposure to Cd^{+2} was modeled by continuous treatment with Cd^{+2} at both lethal and sub-lethal levels over a 16 day time course. Expression of hsp 60 gene and protein was determined using RT-PCR and western analysis. Acute exposure of HPT cells to 53.4 μM $CdCl_2$ resulted in an increase in hsp 60 mRNA and protein. Chronic exposure to Cd^{+2} failed to increase either hsp 60 mRNA or protein expression in HPT cells even at concentrations that were lethal to cells during the time course. Lethal exposure to Cd^{+2} resulted in a decrease in expression of hsp 60 protein compared to control levels. These findings suggest that hsp 60 expression may have a protective role when HPT cells are acutely exposed to Cd^{+2} and a deleterious role when hsp 60 protein is down regulated during extended exposure to Cd^{+2}.

1891 ACETAMINOPHEN-CYSTEINE (APAP-CYS) INDUCED RENAL GLUTATHIONE (GSH) DEPLETION.

S. T. Stern[1], M. K. Bruno[1], D. W. Hill[2], J. C. Roberts[3] and S. D. Cohen[1]. [1]*Dept. of Pharmaceutical Sciences, University of Connecticut, Storrs, CT,* [2]*Dept. of Pathobiology, University of Connecticut, Storrs, CT and* [3]*Dept. of Medicinal Chemistry, University of Utah, Salt Lake City, UT.*

Acetaminophen (APAP) nephrotoxicity has been observed both in man and research animals. Inhibitors of either gamma-glutamyl transpeptidase (GGT) or the probenecid sensitive organic anion transporter protected against APAP-induced nephrotoxicity but not hepatotoxicity in mice (Hart et al. *Toxicol. Appl. Pharmacol.* 136:161-169, 1996) and suggested that transport of an APAP - cysteine conjugate (APAP-CYS) may contribute to the toxicity. APAP-CYS, is an ideal candidate for involvement in APAP nephrotoxicity since it is both a product of the GGT pathway and a likely substrate for the organic anion transporter. Administration of APAP-CYS (50 mg/kg, ip) to 18-hr-fasted, 3-month-old male CD-1 mice resulted in rapid depletion of renal GSH to <60% of control at 30 min with recovery to control levels by 2 hr. Hepatic GSH levels were unaffected, and no changes in blood urea nitrogen or plasma sorbitol dehydrogenase activity were observed. Renal-specific GSH depletion has been demonstrated in mice and rats following administration of amino acid glutamyl acceptor substrates for GGT. To determine if APAP-CYS might be acting similarly as a glutamyl acceptor, 10 units of bovine GGT/ml were incubated with 1mM APAP-CYS and 2mM GSH. HPLC analysis documented a time dependent loss of APAP-CYS with a corresponding, stoichiometric increase in glutamyl-cysteinyl APAP. These findings are consistent with the hypothesis that APAP-CYS contributes to APAP nephrotoxicity by depletion of renal GSH stores through interaction with the gamma-glutamyl cycle. (Supported by NIEHS ES07163.)

1892 THE EFFECT OF LOW CONCENTRATIONS OF ACETAMINOPHEN AND P-AMINOPHENOL ON PGE2 PRODUCTION IN THE HUMAN AND RAT KIDNEY.

M. G. Goodin[1], R. Walker[2] and R. J. Rosengren[1]. [1]*University of Otago, Dunedin, New Zealand and* [2]*Dunedin School of Medicine, Dunedin, New Zealand.*

Co-oxidation of acetaminophen (APAP) and p-aminophenol (p-AP) by prostaglandin H synthetase (PHS) was investigated in human and rat kidneys. APAP and p-AP serve as reducing co-substrates by supplying electrons to the peroxidase of PHS, and thereby undergoe an oxidation to reactive intermediates. In this study, microsomes were prepared from the cortex, outer medulla and inner medulla of human kidneys, and from cortex and inner medulla of rat kidneys. Microsomes were incubated with arachidonic acid (AA) and different concentrations of APAP and p-AP (0, 0.1, 0.3, 0.5, 1.0, 3.0 and 5 mM) to assess the formation of prostaglandin E2 (PGE2). The formation of PGE2 during APAP incubations was significantly higher in inner medulla microsomes than in cortex microsomes for both human and rat kidney. An increase in PGE2 formation in the rat inner medulla was observed at low APAP concentrations (0.1, 0.3, 0.5, 1 and 3 mM) compared to 5 mM, where an inhibition of PGE2 was observed. Such inhibition was not observed in human inner medulla microsomes incubated with 5 mM APAP. Microsomes incubated with different concentrations of p-AP, showed a significantly higher level of PGE2 production in inner medulla versus cortex microsomes. An concentration dependent inhibition of PGE2 production in inner medulla microsomes was observed with 5 mM p-AP in both human and rat samples. Levels of total CYP450 were significantly higher in rat renal cortex (0.29 ± 0.01 nmol/mg) compared to inner medulla (0.21 ± 0.01 nmol/mg). No significant difference of total CYP450 between cortex and inner medulla was observed in the human kidney. CYP2E1 polypeptide levels in human inner medulla microsomes were 52% lower than the levels in cortex microsomes. The same trend was observed in rat kidney, where CYP2E1 polypeptide levels were 57% lower versus cortex. No significant difference was observed in the catalytic activity of CYP2E1 between cortex and inner medulla in both human and rat kidney. Furthermore there was no CYP1A2 and CYP3A catalytic activity in human and rat kidneys. These results correlate with the absence of CYP1A2 and CYP3A polypeptide levels in these tissues.

1893 EFFECTS OF ENZYME INHIBITION ON THE TOXICITY OF 4-AMINOPHENOL IN LLC-PK_1 CELLS.

M. Hallman and J. B. Tarloff. *University of the Sciences in Philadelphia, Philadelphia, PA.*

4-aminophenol (PAP) is selectively toxic *in vivo* to the S3 segment of the proximal tubule. However, the mechanisms responsible for PAP cytotoxicity are not entirely clear. PAP may undergo enzymatic as well as nonenzymatic oxidation to form reactive intermediates. To investigate the role of specific enzymes in the mechanism of PAP cytotoxicity, we coincubated LLC-PK_1 cells for four hours with 0.1 mM PAP and various concentrations (0.10-1.0 mM) of inhibitors of cytochrome P450 (CYP450), flavin monooxygenase (FMO), or prostaglandin sythase (PHS). Twenty hours later, viability was measured using Alamar Blue. In previous studies, 0.1 mM PAP reduced cell viability to 50-60% of control using this protocol. Cells coincubated with methimazole, an inhibitor of FMO, and 1-aminobenzotriazole, an inhibitor of CYP450, showed no change in viability as compared to cells incubated with PAP alone. PHS inhibitors included nonselective (phenylbutazone, indomethacin, piroxicam), and COX2-selective (nabumetone) agents. Only 0.10 mM phenylbutazone protected cells from PAP toxicity. Coincubation of cells with other PHS inhibitors had no effect on PAP-induced cytotoxicity. These data suggest that (1) neither CYP450 nor FMO play a role in the bioactivation or detoxification of PAP (2) metabolism of PAP or its metabolites by PHS may be involved the detoxification of PAP. (Supported by PHS GM51361.)

1894 COMPARISON OF CYTOTOXICITY INDUCED BY *PARA*-AMINOPHENOL IN ISOLATED RAT RENAL EPITHELIAL CELLS AND HEPATOCYTES.

Y. Li and J. B. Tarloff. *University of the Sciences in Philadelphia, Philadelphia, PA.*

para-Aminophenol (PAP) produces proximal tubular necrosis in the absence of hepatic damage within 24 h of administration (300 mg/kg) to rats. Studies in our laboratory using LLC-PK_1 cells suggest that PAP-induced cytotoxicity depends on oxidation. We reasoned that since PAP is directly cytotoxic, both renal epithelial cells and hepatocytes should be injured when incubated with PAP. Therefore, we compared oxygen consumption and ATP content in rat renal epithelial cells and hepatocytes induced with various concentrations of PAP. Renal epithelial cells and hepatocytes were isolated from female SD rats by collagenase digestion. Cell suspensions were incubated with PAP (0-2.5 mM) in a shaking water bath at 37°C in Erlenmeyer flasks gassed with 95% O_2/5% CO_2 for up to 4 h. Aliquots of cells were collected hourly for determination of oxygen consumption ATP content. Cells incubated in the absence of PAP showed no time-dependent differences in oxygen consumption or ATP content. Renal epithelial cells or hepatocytes incubated with 0.5 mM PAP showed no differences in oxygen consumption or ATP content over the 4 h incubation period. Renal epithelial cells but not hepatocytes incubated with 1.0 mM PAP had a 50% decrease in oxygen consumption and a 37% decrease in ATP concentration after 4 h. At 2.5 mM PAP, hepatocytes showed a 55% decline in oxygen consumption and 29% decrease in ATP content after 4 h while renal epithelial cells had a 28% decrease in oxygen consumption and 33% decline in ATP content in the same time interval. These data suggest that renal epithelial cells are more susceptible to PAP cytotoxicity than are hepatocytes. However, at high concentrations of PAP, hepatocytes are injured and the biochemical responses are similar to those observed in renal cells. (Supported by PHS GM51361.)

1895 EVIDENCE FOR NEPHROTOXIC SULFATE CONJUGATES OF N-(3,5-DICHLOROPHENYL)SUCCINIMIDE METABOLITES.

S. L. Miles, S. K. Hong, O. Noe, II, D. K. Anestis, M. A. Valentovic, J. G. Ball and G. O. Rankin. *Marshall University School of Medicine, Huntington, WV.*

The agricultural fungicide, N-(3,5-dichlorophenyl)succinimide (NDPS), induces nephrotoxicity *in vivo* characterized by proximal tubular necrosis and

acute polyuric renal failure. However, previous *in vitro* studies have failed to reproduce the *in vivo* nephrotoxicity seen with NDPS or its nephrotoxic metabolites N-(3,5-dichlorophenyl)-2-hydroxysuccinimide (NDHS) and N-(3,5-dichlorophenyl)-2-hydroxysuccinamic acid (2-NDHSA). The purpose of this study was to examine the nephrotoxic potential of NDPS, its known non-conjugated metabolites, the O-sulfate conjugate of NDHS (NSC), and the putative metabolites N-(3,5-dichlorophenyl)maleimide (NDPM) and its hydrolysis product N-(3,5-dichlorophenyl)maleamic acid (NDPMA) using isolated renal cortical cells (IRCC) obtained from untreated male Fischer 344 rats. IRCC cells were obtained following collagenase perfusion of the kidneys. Cells (2-3 x 10^6 per flask) (N = 4) were incubated with up to 1.0 mM NDPS or an NDPS metabolite or vehicle for up to 120 min. Cytotoxicity was determined by measuring lactate dehydrogenase (LDH) release into the media. Only NSC (> 0.5 mM) and NDPM (≥ 0.5 mM) exposure increased LDH release from IRCC. NSC 1.0 mM increased LDH release within 15 min of exposure. NDPS and the remaining NDPS metabolites did not increase LDH release at bath concentrations of 1.0 mM for exposures of 120 min. These results demonstrate that sulfate conjugates of NDPS are fast-acting nephrotoxicants and could contribute to NDPS nephrotoxicity. These results also suggest that the kidney accumulates toxic sulfate conjugates on NDPS metabolites rather than forming the conjugates. (Supported by NIH grant DK31210.)

1896 ATTENUATION OF 4-AMINO-2,6-DICHLOROPHENOL (ADCP) NEPHROTOXICITY IN RENAL CORTICAL SLICES BY ASCORBATE, AMINOOXYACETIC ACID (AOAA), INDOMETHACIN AND GLUTATHIONE.

G. O. Rankin, S. K. Hong, D. K. Anestis, J. G. Ball and M. A. Valentovic. *Marshall University School of Medicine, Huntington, WV.*

ADCP is a potent acute nephrotoxicant *in vivo* inducing prominent renal corticomedullary necrosis. *In vitro*, ADCP exposure increases lactate dehydrogenase (LDH) release from rat renal cortical slices at 0.05 mM or greater. The purpose of this study was to examine the ability of antioxidants, CYP and FMO inhibitors, indomethacin, glutathione, and inhibitors of glutathione conjugate metabolism to attenuate ADCP nephrotoxicity *in vitro*. Renal cortical slices prepared from untreated male Fischer 344 rats (N=4/group) were preincubated at 37°C under a 100% oxygen atmosphere with an inhibitor or vehicle for 5-30 min. ADCP (0.1 or 0.5 mM) or vehicle was added and incubations continued for 120 min. At the end of the incubation period, LDH release was measured as an index of nephrotoxicity. ADCP nephrotoxicity was partially attenuated by ascorbate (1.0 or 2.0 mM), but not by DPPD, α-tocopherol or deferoxamine. Inhibitors of CYP450 (metyrapone, piperonyl butoxide, isoniazid) and FMO inhibitors (methimazole, N-octylamine) had no effect on ADCP nephrotoxicity. Indomethacin or glutathione 1.0 mM completely and partially blocked ADCP 0.1 and 0.5 mM nephrotoxicity, respectively. AOAA 1.0 mM, but not AT-125 1.0 mM, partially attenuated ADCP 0.1 mM nephrotoxicity. These results suggest that reactive metabolites may be produced from ADCP primarily via a cyclooxygenase-mediated mechanism. The difference in the ability of ascorbate and glutathione to attenuate ADCP nephrotoxicity could indicate that the reactive benzoquinoneimine metabolite might be the ultimate toxicant *in vitro* rather than a free radical-mediated mechanism.

1897 GENERATION OF PUTATIVE CYTOTOXIC METABOLITES OF N-(3,5-DICHLOROPHENYL)SUCCINIMIDE (NDPS) IN A HEPATIC/RENAL COINCUBATION SYSTEM.

X. Hu[1], D. Cui[2], R. Tchao[1] and P. J. Harvison[1]. [1]*University of the Sciences in Philadelphia, Philadelphia, PA and* [2]*Merck and Co., Inc., West Point, PA.*

Previous studies implicated a role for glucuronide and sulfate conjugates in NDPS nephrotoxicity. This study was designed to investigate the possibility of generating cytotoxic phase II metabolites from the NDPS metabolite, *N*-(3,5-dichlorophenyl)hydroxysuccinimide (NDHS), using a hepatic/renal coincubation system. LLC-PK_1 cells (5x10^4/well) were plated in 24-well plates on the day prior to the experiment. NDHS (200-800 μM) and cells were then coincubated with rat liver microsomes (0.5-3 mg protein/ml) or cytosol (0.25-2 mg protein/ml). Incubations also contained the appropriate cofactors, either UDPGA (2 mM) or PAPS (1-4 mM). After 4-8 hr, the coincubation medium was removed and analyzed for the presence of glucuronide and sulfate conjugates by HPLC-tandem mass spectrometry. Cell viability was measured cytofluorometrically with alamarBlue. The cells were then reincubated in fresh media and viability was reassessed at 24 and 48 hours. A known cytoxicant, *N*-(3,5-dichlorophenyl)maleimide (NDPM, 2-50 μM), was incubated with LLC-PK_1 cells as a positive control. LC-MS/MS confirmed that glucuronide and sulfate conjugates were generated in the coincubation system. NDPM dramatically decreased cell viability at concentrations above 25 μM. Cell viability declined in coincubations with hepatic microsomes, even in the absence of substrate, suggesting that some component of the microsomes was damaging the cells. In contrast, cell viability was not affected in cytosolic coincubations, even in the presence of PAPS and substrate. These results suggest that glucuronide and sulfate conjugates of NDHS may not be toxic to the LLC-PK_1 cell line. It is also possible that the conjugates were not produced in sufficient quantities to cause cytotoxicity or are not transported into the cells. However, these experiments have shown that it is possible to generate Phase II metabolites in the coincubation system, which may be applicable to other compounds. (Supported by USPHS grant ES05189.)

1898 2-AMINO-4,5-DICHLOROPHENOL (2A45CP) TOXICITY IN RENAL CORTICAL SLICES FROM FISCHER 344 RATS.

M. A. Valentovic, J. G. Ball and G. O. Rankin. *Department of Pharmacology Marshall University School of Medicine, Huntington, WV.*

2A45CP is an aromatic ring hydroxylated metabolite of 3,4-dichloroaniline. 3,4-Dichloroaniline is nephrotoxic with primary damage located in the proximal tubules. The purpose of this study was to first assess the *in vitro* toxicity of 2A45CP in renal cortical slices and second, to determine the effect of antioxidants and sulfhydryl containing agents on the severity of 2A45CP toxicity. Renal cortical slices were prepared from male Fischer 344 rats (200-245 g). Renal slices were rinsed 3 times for 3 min each in 5-ml renal Krebs buffer. Tissues were then incubated for 90-120 min with 0-1 mM 2A45CP. In a separate series of experiments, the slices (50-100 mg tissue) were preincubated for 30 min with 0 or 1 mM dithiothreitol (DTT) or glutathione (1mM) prior to exposure to 0, 0.25, 0.5 or 1 mM 2A45CP. Loss of membrane integrity was monitored by measurement of lactate dehydrogenase (LDH) leakage. 2A45CP produced a concentration and time dependent increase in LDH leakage from renal cortical slices. Total glutathione levels were diminished by 0.5 mM 2A45CP within 60 min. Pretreatment with DTT did not alter 2A45CP toxicity as indicated by comparable changes in pyruvate directed gluconeogenesis and LDH leakage between vehicle and DTT pretreated slices. Preincubation with 1 mM GSH reduced the extent of LDH leakage to levels that were similar to control values. Pretreatment with 1 mM ascorbic acid also reduced 2A45CP toxicity. These findings indicate 2A45CP is directly toxic to renal cortical slices inducing a rise in LDH leakage, diminished pyruvate directed gluconeogenesis and diminished glutathione. Pretreatment with ascorbic acid or glutathione prevented 2A45CP toxicity in renal slices. (Supported by NIH grant ES08834.)

1899 INHIBITION OF A MICROSOMAL CA^{2+}-INDEPENDENT PHOSPHOLIPASE A_2 INCREASES OXIDANT-INDUCED APOPTOSIS IN RENAL PROXIMAL TUBULAR CELLS.

B. S. Cummings[1], J. McHowat[2] and R. G. Schnellmann[1]. [1]*University of Arkansas for Medical Sciences, Little Rock, AR and* [2]*Saint Louis University, St. Louis, MO.*

Phospholipase A_2(s) are esterases that hydrolyze the *sn-2* ester bond in phospholipids releasing a fatty acid and a lysophospholipid. While reports have examined the role of PLA_2s in the genesis of apoptosis in a number of cell types, the exact role of PLA_2 and the isoforms involved are not clear. We have shown previously that approximately 90% of PLA_2 activity in rabbit renal proximal tubular cells (RPTC) was Ca^{2+}-independent and located in the microsomes. We hypothesized that this microsomal Ca^{+2}-independent PLA_2 (m-$iPLA_2$) plays a role in oxidant-induced RPTC apoptosis. Using an antibody against Ca^{2+}-independent PLA_2 ($iPLA_2$) and immunoblot analysis an 85 kDa protein band was identified in rabbit RPTC microsomes but not the cytosol. Immunocytochemistry using the same antibody revealed punctate staining in RPTC cytosol but not in the nucleus, supporting the microsomal localization of m-$iPLA_2$. Oxidant (tert-butylhydroperoxide) exposure caused both time- (0.5 to 24 hr) and concentration- (50 to 500 μM) dependent increases in annexin V binding (an early marker for apoptosis) prior to increases in propidium iodide (PI) DNA staining (a late marker for apoptosis and oncosis). Treatment of RPTC with bromoenol lactone (BEL) (1 to 10 μM), a specific inhibitor of $iPLA_2$, decreased m-$iPLA_2$ activity in RPTC in a concentration-dependent manner. Pretreatment of RPTC with increasing concentrations of BEL prior to TBHP exposure increased both annexin V and PI staining compared to TBHP alone. These results show that oxidants can cause RPTC apoptosis and that inhibition of m-$iPLA_2$ potentiates oxidant-induced apoptosis. Thus, m-$iPLA_2$ may act in a protective manner in RPTC by inhibiting apoptosis.

1900 TRANSLOCATION OF μ-CALPAIN MEDIATES MITOCHONDRIAL INHIBITOR-INDUCED CELL INJURY IN RENAL PROXIMAL TUBULES (RPT).

X. Liu, J. F. Harriman and R. G. Schnellmann. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Calpains, Ca^{2+}-activated cysteine proteases, play a role in physiological and pathological processes. Previous data from our laboratory demonstrated the translocation of calpain activity from the cytosol to the membrane fraction during the late phase of RPT cell injury. The goals of this study were to determine 1) the expression of calpain isoforms in rabbit RPT; 2) the alterations of each calpain isoform during mitochondrial inhibitor-induced RPT cell injury; and 3) the effects of various cytoprotectants on cytosolic calpain levels during RPT cell injury. RNA was isolated from RPT S_2 segments and subjected to RT-PCR with either rabbit μ- or m-calpain large subunit specific primers. Sequencing of the 700 bp PCR product of the m-calpain large subunit and the 500 bp PCR product of the μ-calpain large subunit confirmed their presence. Freshly isolated RPT were exposed to the mitochondrial inhibitor antimycin A (AA 10 μM) for up to 60 min in the absence or presence of glycine (2 mM), strychnine (1 mM), muscimol (100 μM), or pregnenolone sulfate (PS 100 μM). AA induced significant cell death (40±2% LDH release vs 6% control at 60 min). Immunoblot analysis showed that AA treatment resulted in a time-dependent reduction in cytosolic 80 kD μ-calpain (39±7% of control at 60 min). In contrast, immunoblot analysis did not demonstrate a significant decrease in cytosolic 80 kD m-calpain (90±3% of control). Glycine, strychnine, muscimol, and PS improved cytosolic μ-calpain levels to 66±%, 101±8%, 89±9% and 89±% of control, and reduced LDH release to 7±%, 10±%, 9±% and 12±%, respectively. While rabbit RPT express μ- and m-calpains, only the reduction of cytosolic μ-calpain correlates to the previously observed translocation of calpain activity to the membrane during mitochondrial inhibitor-induced RPT cell injury. The cytoprotective mechanism of action of glycine, strychnine, muscimol, and PS involves the blockade of the translocation of μ-calpain.

1901 CALRETICULIN REGULATES BRANCHING MORPHOGENESIS AND CELL PROLIFERATION OF RENAL PROXIMAL TUBULAR EPITHELIAL CELLS.

S. Ashmellash and R. C. Bowes, III. *Campbell University School of Pharmacy, Department of Pharmaceutical Sciences, Buies Creek, NC.*

Renal regenerative repair is a common event that follows nephrotoxic damage to proximal tubular epithelial cells. The exact molecular mechanisms that regulate the regenerative process are unclear. Calreticulin is a 46-kDa protein that binds to a specific consensus sequence (KXGFFKR) present on α-integrin subunits (1,2). Previous studies have shown that calreticulin appears to regulate the activation state of α integrins resulting in modulation of cell attachment and spreading. We wanted to determine if calreticulin regulates the ability of LLC-PK1 cells to undergo growth factor-induce branching morphogenesis and cellular proliferation. Thus, LLC-PK1 cells were transfected with an expression vector, pRC/CMV, containing a full-length (1.9 kb) human calreticulin cDNA. After transfection, G-418 resistant clones for calreticulin (pkCRT) or pkNEO were selected and processed for Western blot analysis. LLC-PK1 cells transfected with calreticulin exhibited increased calreticulin expression relative to pkNEO cells. When grown on monolayer, calreticulin overexpressing cells exhibited no differences in cellular proliferation rates, relative to pkNEO clones. In addition, migration rates of pkCRT were similar to those of the pkNEO clones. Attachment rates between pkCRT clones and pkNEO clones were also comparable. Cells were then seeded into collagen type I matrix and treated with growth factors to stimulate branching morphogenesis. Treatment of the various clones with 10% serum alone did not induce a proliferative response in any of the clones tested. pkNEO clones treated with growth factors exhibited a dramatic increase in cellular proliferation, a response blocked by co-treatment with TGF-β1. In contrast, overexpression of calreticulin resulted in a complete inhibition of growth factor-induced cellular proliferative rates. Furthermore, unlike the pkNEO clones, the pkCRT clones failed to undergo growth factor-induced branching morphogenesis. These findings demonstrate that calreticulin plays a critical role in the ability of renal proximal tubule cells to undergo growth factor-induced branching morphogenesis.

1902 CYTOPROTECTION AGAINST QUINONE-THIOETHER-MEDIATED CYTOTOXICITY BY AN "ENDOTHELIAL-LIKE" THROMBOXANE A2 RECEPTOR (TP) ALTERNATIVE SPLICE VARIANT COUPLED TO NUCLEAR FACTOR KAPPA B (NF-κB).

T. J. Weber[1], T. J. Monks[2] and S. S. Lau[2]. [1]*Battelle, Pacific Northwest Division, Richland, WA and* [2]*The University of Texas-Austin, Austin, TX.*

11-deoxy-16,16-dimethyl prostaglandin E2 (DDM-PGE2) induces cytoprotection against 2,3,5-(trisglutathion-S-yl)hydroquinone [TGHQ]-mediated cytotoxicity via a receptor that is pharmacologically distinct from the known PGE2 receptor subtypes (EP) in renal epithelial cells (LLC-PK1). The present studies were conducted to determine whether the cytoprotective response to DDM-PGE2 is mediated by a TP receptor. DDM-PGE2-mediated cytoprotection against TGHQ-mediated cytotoxicity can be reproduced by TP agonists (U46619; IBOP), and is inhibited by TP antagonists (SQ 29,549; ISAP). DDM-PGE2-mediated 12-O-tetradecanoyl phorbol-13-acetate (TPA) responsive element (TRE)-binding activity is inhibited by a TP antagonist (SQ 29,548), but not by cyclooxygenase (aspirin, indomethacin) or thromboxane synthase (sulfasalazine) inhibitors, indicating that the cytoprotective response is not dependent on de novo TXA2 biosynthesis. DDM-PGE2- and U46619-mediated NF-κB-binding activity is inhibited by SQ 29,548, suggesting that the renal epithelial TP receptor couples to multiple transcription factors. Sulfasalazine inhibits DDM-PGE2-mediated cytoprotection and NF-κB-, but not TRE-binding activity. RT-PCR coupled with Southern blot indicates that porcine (LLC-PK1) and human (HK-2) renal epithelial cells express an "endothelial-type" TP receptor transcript, but not a placenta-type TP receptor. Collectively, these observations suggest that a cytoprotective TP receptor is expressed in renal epithelial cells, and that the cytoprotective response is mediated by NF-κB. (This work was supported in part by an award from the National Institute of Environmental Health Sciences [T32 ES 07247] and [GM56321 to SSL].)

1903 COMPARISON OF THE STRESS RESPONSE BETWEEN CULTURED HUMAN PROXIMAL TUBULE CELLS AND THE DERIVED CELL LINE HK-2.

D. Kim, S. Somji, S. H. Garrett, J. H. Todd and D. A. Sens. *Department of Pathology, West Virginia University, Morgantown, WV.*

Heat shock protein (hsp) 27 is a member of a large superfamily of proteins collectively referred to as the heat shock or stress response proteins. These proteins are believed to provide protection against environmental insult, both physical and chemical. The goal of this study was to define expression of hsp 27 in an immortalized human proximal tubule cell line, HK-2, and compare it to cultured human proximal tubule cells (HPT). Cells were exposed to elevated temperature, sodium arsenite, and cadmium chloride under both acute and chronic conditions. HK-2 cells were more sensitive than HPT cells to cadmium and lower doses were used to achieve lethal and sub-lethal effects. Expression of hsp 27 gene and protein was determined using RT-PCR and western analysis. Upon exposure to elevated temperature of 42.5°C for 1 hour, the expression of hsp 27 mRNA and protein increased in HK-2 and HPT cells, however the level of induction in HK-2 cells was lower than the HPT cells. Acute exposure to sodium arsenite and cadmium chloride resulted in an increase in hsp 27 mRNA in HK-2 and HPT cells without a significant increase in protein levels in HK-2 cells. Chronic exposure to cadmium failed to increase either hsp 27 mRNA or protein expression in HK-2 and HPT cells. These results demonstrate that Hsp 27 expression is reduced in the immortalized cell line as compared to normal proximal tubule cells.

1904 PENTAMIDINE-INDUCED ALTERATION IN MITOCHONDRIAL MEMBRANE POTENTIAL IN LLC-PK1 CELLS.

R. L. Baty[1] and M. A. Smith[2]. [1]*University of Texas-Houston Graduate School of Biomedical Sciences, Houston, TX and* [2]*University of Texas-Houston School of Public Health, Houston, TX.*

Nephrotoxicity is the therapy-limiting toxicity associated with pentamidine, a second line agent used in the treatment of AIDS-associated Pneumocystis Carinii Pneumonia. Inhibition of oxidative phosphorylation has been proposed as a possible pharmacologic mechanism of action in some protozoa. This effect could be related to the mechanism of nephrotoxicity. Previously, we have demonstrated that pentamidine inhibits basal and uncoupled respiration in LLC-PK1 cells (a proximal tubule epithelial cell line) after a 1 hour incubation. The purpose of this study was to examine the effect of pentami-

dine on mitochondrial function. LLC-PK1 cells grown in 35cm2 dishes, were treated with 0.005, 0.05, 0.125 and 0.5mM pentamidine for 1 hour and 20 hours. Then the cells were exposed to Rhodamine 123 (mitochondrial fluorescent dye) for 15 minutes at 37°C. The cells were harvested and washed once with phosphate-buffered saline(PBS) and resuspended in 1ml of PBS. The distribution of rhodamine 123 was determined using a Coulter Flow Cytometer . Pentamidine decreases mitochondrial membrane potential in a concentration and time dependent fashion. After treating the cells with pentamidine for 1 hour there was a significant decrease in membrane potential at 0.5mM. After 20 hours of incubation with pentamidine, there was a significant decrease in potential at 0.05 and 0.125mM and the shift at the 0.5mM concentration increased more than the 1 hour results. Preliminary data suggests that the decrease in membrane potential is not reversed when media containing pentamidine is replaced with fresh media without the agent for 24 hours. These experiments in conjunction with the data showing the inhibitory effect on cellular respiration demonstrate that pentamidine does alter mitochondrial function in LLC-PK1 cells. Further research is required to establish a link between altered mitochondrial function and nephrotoxicity. (Supported by NIEHS Training Grant T32-ES-07290 [RLB].)

1905 MODULATION OF THE BENZODIAZEPINE (BZD) RECEPTOR/GAB COMPLEX AFFECTS CELL DEATH INDUCED BY OXIDANT STRESS IN MADIN DARBY CANINE KIDNEY (MDCK) CELLS.

J. P. Bercu and M. A. Smith. *University of Texas-Houston School of Public Health, Houston, TX.*

The role of the central benzodiazepine receptor has been widely studied in the central nervous system (CNS) and has been linked to the GABA receptor, potentiating Cl-movement into the cell. The peripheral benzodiazepine receptor (PBR) has been studied as well, and it has been found mainly, but not exclusively, on the mitochondria in myriad cell types. BZD receptors found in the kidney are mainly localized in the distal tubule of the nephron. Renal BZD receptors have yet to be fully characterized with respect to the exact nature of their type (CBR vs. PBR) and function. The purpose of this study was to determine if modulation of BZD receptors by agonists or antagonists would alter MDCK cell responses to oxidant stress. Cells were pretreated for one hour with a nonspecific GABA antagonist and possible PBR antagonist (Lindane 1X10-6 M), a PBR specific antagonist (PK11195 1X10-6 M), and a CBR specific agonist (Flurazepam 1X10-4 -1X10-6 M). Following treatment with Lindane and PK11195, the cells were exposed to Menadione (0.125-1.0 mM). Cells pretreated with Flurazepam were conincubated with Menadione and Flurazepam. Necrotic cell injury was determined by lactate dehydrogenase (LDH) leakage and apoptotic cell injury was determined by propidium iodide (PI) exclusion. Pretreatment with Lindane caused a 37% reduction in Menadione (1.0 mM) induced necrotic injury. PK11195 had no effect on Menadione (0.25 mM) induced necrotic injury. Flurazepam (1X10-4 M) caused a 44% increase in Menadione (0.25 mM) induced necrotic injury and a 528% reduction in apoptosis. These results suggest that modulation of the CBR can alter the cell death response to an oxidative injury, possibly through altering Cl-movement into the cell.

1906 INDUCIBLE NITRIC OXIDE SYNTHASE INHIBITION DOES NOT PREVENT PROTEINURIA IN PUROMYCIN AMINONUCLEOSIDE INDUCED NEPHROTIC INJURY.

L. M. Walker, S. V. Shah and P. R. Mayeux. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Puromycin aminonucleoside (PAN) administration in rats causes glomerular epithelial cell injury and proteinuria. The purpose of this study was to examine the role nitric oxide (NO) in this model of minimal change glomerular disease. Aminoguanidine (AG) was used to inhibit inducible nitric oxide synthase (iNOS). Sprague-Dawley rats were divided into Control (N=9), PAN (N=14), and PAN+AG (N=12) treatment groups. Control animals received saline (i.v.), PAN animals received PAN (75 mg/kg, i.v.), and PAN+AG animals received a PAN plus AG (50 mg/kg, i.p., administered twice daily). All animals were kept in metabolic cages, and urinary protein excretion and NO_2- excretion were measured daily. At day 7, plasma was collected and kidneys were harvested. PAN administration increased urinary NO_2- excretion by day 2, and levels remained elevated through day 7. AG prevented this PAN induced increase in urinary NO_2- excretion. Plasma nitrate (NO_3-) and NO_2- (NOx) concentrations were also increased in PAN and PAN+AG. iNOS protein expression was not detected in either the glomeruli or cortex at day 7. Proteinuria developed in PAN animals on day 4 and increased steadily through day 7. PAN+AG animals had a pattern of urinary protein excretion similar to the PAN group. These results indicate that in contrast to models of proliferative glomerulonephritis, NO formation during PAN-induced nephrotic syndrome is increased but does not participate in the development of glomerular injury as measured by proteinuria.

1907 ANTAGONIST NEPHROTOXIC INTERACTIONS IN BINARY AND TERNARY MITURES OF POLYCYCLIC AROMATIC HYDROCARBONS.

M. H. Falahatpisheh, R. Metz, K. C. Donnelly and K. S. Ramos. *Faculty of Toxicology and Center for Environmental and Rural Health, Texas A&M University, College Station, TX.*

Polycyclic aromatic hydrocarbons (PAHs) are widespread contaminants present in multiple sources of environmental pollution. Although the hepatic and pulmonary toxicities of PAHs have been extensively characterized, limited data concerning their nephrotoxic potential are presently available. In previous studies we have shown that rat glomerular mesangial cells (rGMCs) are preferentially injured by benzo(a)pyrene (BaP) and anthracene, while porcine cortico-tubular epithelial cells (LLCPK-1) are affected by chrysene. Recognizing that exposure to environmental chemicals, even at a single contaminated site, is rarely limited to a single compound, the present studies were conducted to evaluate the nephrotoxic potential of binary and ternary mixtures of these chemicals. Mixtures of BaP, chrysene and anthracene yielded unexpected antagonistic nephrotoxic interactions in both rGMCs and LLCPK-1 cells. Northern and reverse transcription polymerase chain reaction analyses revealed that *CYP1A1* inducibility decreased in LLCPK-1 cells, but not rGMCs, treated with binary mixtures of BaP and chrysene (0.3-30μM). Although binary treatment of rGMCs did not alter *CYP 1A1* expression, reduced *CYP 1B1* inducibility was observed. Therefore, the profile of *CYP* inducibility in both cell types was consistent with antagonistic nephrotoxic interactions between these chemicals. However, a direct correlation between nephrotoxicity and *CYP* induction cannot be inferred because anthracene effectively inhibited BaP and chrysene toxicity in rGMCs, but did not inhibit *CYP1A1* inducibility. We conclude that significant cell-specific nephrotoxic interactions occur upon exposure to PAH mixtures, with some of these interactions involving *CYP* expression. (Supported in part by ATSDR Grant TU68450502 and NIEHS Center Grant 09106.)

1908 MODULATION OF GLOMERULAR CELL FUNCTIONS bBENZO(a)PYRENE: IMPLICATIONS FOR MESENCHYMAL/ EPITHELIAL INTERACTIONS *IN VITRO*.

N. F. Alejandro and K. S. Ramos. *Texas A&M University, College Station, TX.*

Epidemiological and experimental studies have implicated aromatic hydrocarbons in the onset and/or progression of kidney diseases. Recent studies in this laboratory have shown that single or repeated *in vitro* exposure of glomerular cells to 3.0μM benzo(a)pyrene (BaP) inhibits mesangial cell proliferation and affords a proliferative advantage to visceral epithelial (i.e. podocyte) cells. On the basis of these findings we hypothesized that BaP differentially modulates glomerular cell function leading to disruption of critical mesenchymal/epithelial interactions *in vitro*. To study these relationships, single cell clones of mesangial cells and podocytes were established in serial culture. RT-PCR analysis revealed that CYP1A1 is expressed constitutively in mesangial cells, but not podocytes. Using TGFβ1 as a mesangial cell-derived candidate inhibitory factor of podocyte proliferation affected by BaP, single cell clones were challenged with TGFβ1 (0.01-0.5nM). TGFβ1 markedly reduced DNA synthesis in mesangial cells at all concentrations examined, but was without effect in podocytes under the same experimental conditions. Therefore, differences in the rate of oxidative metabolism between mesangial cells and podocytes may contribute to differential toxicant susceptibility, but this response is not likely mediated by interference with mesangial cell-derived TGFβ1. The paracrine signals affected by BaP and responsible for altered mesenchymal/epithelial cell interactions in our *in vitro* model system remain to be identified. (Supported in part by NIEHS Grant ES 09106.)

1909 MITOCHONDRIAL FUNCTION IN RAT KIDNEY AFTER COMPENSATORY HYPERTROPHY.

R. K. Zalups[1], D. A. Putt[2], S. J. Horky, III[2] and L. H. Lash[2]. [1]*Mercer University School of Medicine, Macon, GA and* [2]*Wayne State University School of Medicine, Detroit, MI.*

Suspensions of mitochondria were isolated from renal cortical homogenates from control rats and rats that had undergone uninephrectomy and compensatory renal growth (NPX) to test the hypothesis that renal cellular hypertrophy is accompanied by increases in mitochondrial metabolism. This increase in metabolism involves increases in rates of electron transport, which may then lead to release of reactive oxygen species. Consequently, mitochondria from the remnant kidney may exhibit oxidative stress or be more susceptible to injury from oxidants and agents or conditions that deplete ATP and inhibit mitochondrial function. Specific activities of malic and succinic dehydrogenase were significantly increased in mitochondria from NPX rats. While rates of state 3 respiration, normalized to protein, were elevated, rates of state 4 respiration, normalized to protein, and respiratory control values were unaffected by compensatory hypertrophy. Although specific activities of glutathione (GSH) redox cycle enzymes were unchanged relative to protein in mitochondria from NPX rats, rates of uptake of GSH into these mitochondria, which occur by the dicarboxylate and 2-oxoglutarate carriers, were elevated approximately 2.5-fold as compared to those in control mitochondria. Susceptibility to toxicants was assessed by measurements of effects on respiration and lipid peroxidation. *tert*-Butyl hydroperoxide, methyl vinyl ketone, and *S*-(1,2-dichlorovinyl)-L-cysteine (0.1-2 mM) all produced more inhibition of state 3 respiration and larger decreases in malondialdehyde formation in mitochondria from NPX rats than in control mitochondria, indicating that mitochondria from hypertrophied cells are indeed more sensitive to oxidants or mitochondrial toxicants. Baseline levels of malondialdehyde were also significantly elevated in NPX mitochondria, suggesting that a basal oxidant stress is present in mitochondria from hypertrophied cells.

1910 COMPARATIVE ANALYSIS OF SIGNAL TRANSDUCTION PROTEINS IN TUMOR *VERSUS* NON-TUMORIGENIC RENAL EPITHELIAL CELLS.

T. M. Kolb, D. E. Carbott and M. A. Davis. *University of Maryland, School of Medicine, Baltimore, MD.*

Several new cancer chemotherapeutics are designed to induce cell death by targeting signal transduction pathways that mediate the death response. Genetic alterations that lead to tumor cell phenotypes may cause functional alterations in cell signaling pathways that can influence efficacy of therapies. For this reason, we have examined the expression and activities of several key signal transduction kinases in tumor and non-tumorigenic renal epithelial cells. Tumorigenic renal epithelial cell lines that have a homozygous mutation in the tumor suppressor gene TSC-2 (ERC-18) or are expressing oncogenic H-ras (NRK-H/6.1) were compared to non-tumorigenic renal epithelial cells (TRKE, NRK 52E). We examined protein expression and activities of ERK-1, ERK-2, AKT, PKCa, Raf-1, and p38 in ERC-18, NRK H/6.1, TRKE, and NRK 52E renal epithelial cells. We also examined overall serine/threonine kinase activities in cell lysates. We found that the renal epithelial tumor cells appear to have higher basal levels of serine/threonine kinase activities and ERK-1 and ERK-2 protein than non-tumorigenic cells. In addition, ERC-18 tumor cells appear to have higher basal levels of PKCa protein than all cell types examined. Remarkably, ERC-18 and NRK H/6.1 tumor cells are more susceptible to apoptotic cell death induced by detachment (anoikis). These results indicate that kinase profiles of tumor versus non-tumorigenic epithelial cells may be a useful screen in the discovery phase of development to test the efficacy of potential death-inducing chemotherapeutics.

1911 ROLE OF MITOCHONDRIA IN S-(1,2-DICHLOROVINYL)-L-CYSTEINE (DCVC) INDUCED APOPTOSIS.

Y. Chen[1], J. Cai[2], M. W. Anders[3] and D. P. Jones[2]. [1]*Program of Biochemistry, Cell Biology & Developmental Biology, Emory University, Atlanta, GA,* [2]*Dept. of Biochemistry Emory University, Atlanta, GA and* [3]*University of Rochester Medical Center, Rochester, NY.*

DCVC, the cysteine conjugate of trichloroethylene, is a potent nephrotoxicant. In this study, we investigated the mechanism of DCVC-induced apoptosis in the cultured porcine proximal tubular cell line, LLC-PK1. DCVC exposure induced caspase activation after 10 hr followed by DNA fragmentation at 12 hr. Apoptosis was completely inhibited by aminooxyacetic acid, suggesting the toxicity of DCVC was caused by β-lyase-dependent bioactivation. When labeled with JC-1 and analyzed by flow cytometry, a decrease of mitochondrial membrane potential ($mt\Delta\psi$) was detected at 4 hr. The loss of $mt\Delta\psi$ was accompanied by release of mitochondrial cytochrome *c*, as measured by Western analysis. Immunostaining of mitochondrial HSP 60 showed its localization was not changed after DCVC treatment, indicating the general structure of mitochondria was preserved. Both DCVC-induced cytochrome c release and caspase activation were observed in cells lacking mitochondria DNA (ρ^0 cells). Because mitochondria in ρ^0 cells do not produce ATP, these experiments indicate that DCVC-induced toxicity is not due to disrupted mitochondrial ATP production. We conclude that DCVC induces cell death in proximal tubular cells by selectively disrupting the mitochondrial outer membrane, releasing cytochrome c, and activating caspase-mediated apoptosis. (Supported by NIH grant ES 0904.7.)

1912 ACETYL-L-CARNITINE REDUCES TAXOL EFFECTS ON MYELOID CELL LINEAGE IN THE DOG.

I. Andreini. *Research Toxicology Centre, Rome, Italy.* Sponsor: A. I. Nikiforov.

One of the most significant side-effects of Taxol, a major anticancer drug, is severe neutropenia. Acetyl-L-Carnitine (ALCAR) is an agent investigated to counteract the cytostatic effect of Taxol on myeloid proliferative cells. This hypothesis was studied in 16 female Beagle dogs treated with a single dose of Taxol (100 mg/m^2) administered via slow intravenous infusion. Dogs were divided into two groups of 8 animals each. One group was treated intramuscularly twice a day with 10 mg/kg of ALCAR for at least 7 consecutive days before Taxol treatment and for 15 days after. The second group received physiological saline in place of the ALCAR solution. Standard haematological parameters were monitored for 15 days after Taxol administration. Bone marrow samples were obtained by aspiration from the iliac bone before and 24 hours after Taxol treatment. Complete myelogram counts and cell ratios, with a detailed morphological examination, were carried out on bone marrow smears. This study showed that: (i) all animals treated with Taxol were affected by severe neutropenia; (ii) the nadir for circulating neutrophils was about 5 days after Taxol administration; (iii) a high intra-group variability was found in the haematological analysis compared to a lower standard deviation observed in the bone marrow counts; (iv) in myelogram counts, proliferative cell pool values of the animals treated with ALCAR were higher than the control group. This study suggests a positive action of ALCAR on the myeloid side-effects of Taxol.

1913 BIOLOGICAL ACTIVITY, PHARMACOKINETICS, AND SAFETY ASSESSMENT OF HUMAN GROWTH HORMONE (HGH) DELIVERED *VIA* A SUBCUTANEOUS DEPOT.

R. Bannister, K. Baudouin, E. Maze, N. Modi and K. Brodbeck. *ALZA Corporation, Mountain View, CA.*

The objectives of these studies were 1) to determine the biological activity of hGH delivered in an injectable depot formulation in hypophysectomized (hypox) male rats; 2) to determine the pharmacokinetic profile for hGH release; and 3) to assess the potential toxicity of the depot formulation in rats after 28 days. The ALZA depot is a non-aqueous, biodegradable poly(lactide-glycolide) copolymer (PLGA)/benzyl benzoate solution. The biological activity of hGH delivered from the subcutaneous depot was confirmed in hypox rats injected on Day 0 with 400 mg depot containing hGH (20 mg), as determined by body weight gain, and elevated IGF-1 levels for 28 days. The pharmacokinetics of hGH over 28 days from a subcutaneous depot was assessed in immunosuppressed, non-hypox rats (cyclosporin, 10 mg/kg, IP). Analysis of serum hGH profiles over 28 days revealed that hGH was released with a low acute drug burst and with sustained delivery (with serum hGH levels above 10 ng/mL) through 28 days. To assess potential toxicity, rats were injected SC with 100, 350 or 700 mg depots (containing 4.9% hGH). No significant adverse effects were noted in rats after injection of up to 700 mg depot as assessed by body weight gain, clinical pathology, tissue weights, and histopathological evaluation of injection sites and representative tissues. In conclusion, a biodegradable depot platform has been developed which releases biologically active hGH, with a low acute drug burst and sustained drug delivery through 28 days.

1914 A SAFETY ASSESSMENT OF ORAL GLYCOLIC ACID IN RODENTS.

A. V. Wilke, G. D. Williams, M. A. P. Strnat, R. A. Heim, C. B. Jensen, T. W. Jones and M. J. Kallman. *Eli Lilly and Co., Greenfield, IN.*

Glycolic acid (GA; CAS 79-14-1) is a potential counter ion for pharmaceutical agents, but is also a toxic intermediate in the biotransformation of ethylene glycol to oxalic acid. The safety of orally administered GA at doses relevant for pharmaceutical use was assessed in a 2-week rat study and in acute safety pharmacology studies in rats or mice. In the 2-week Fischer 344 rat study (n=10/sex), daily oral doses of 240 mg GA/kg had no important effects on clinical signs, body weight, food consumption, ophthalmic effects, liver cytochrome P450, hematology, clinical chemistry, urinalysis, organ weights, gross pathology or histopathology. In safety pharmacology studies in rats or mice, single oral doses of 48 mg GA/kg had no effect on renal function, central nervous system (CNS) function, and gastrointestinal motility. Renal function was assessed in male Fischer 344 rats (n=8) based on urine volume, pH, sodium, potassium, chloride, creatinine, and osmolality, creatinine clearance and fractional excretion of sodium. CNS and behavioral effects assessed in male CD-1 mice (n=10) were spontaneous activity, clinical signs, temperature, grip strength, hexobarbital-induced sleep times, acetic acid-induced writhing, auditory startle responding, and convulsive thresholds. Gastrointestinal motility was evaluated in fasted male CD-1 mice (n=10) by assessing the transit rate of charcoal meal. Although no effects were observed, this result should be interpreted with caution because rodents may be less sensitive than humans to GA toxicity as is well established for ethylene glycol toxicity.

1915 SAFETY ASSESSMENT OF RECOMBINANT BASIC FIBROBLAST GROWTH FACTOR (RFGF-2) FOR THE TREATMENT OF CORONARY ARTERY DISEASE.

D. L. Novicki[1], M. A. Bush[1] and M. Nedelman[2]. [1]*Chiron Corp., Emeryville, CA and* [2]*Primedica, Worcester, MA.*

The safety assessment program for rFGF-2 included efficacy, safety pharmacology, pharmacokinetics (PK), pharmacodynamics (PD), and toxicological evaluations. Single intravenous (IV) and intracoronary (IC) doses were studied in healthy pigs and IV, IC, and intrapericardial routes were used in pigs with experimental coronary disease (ameroid constriction model). Multiple doses (IV once per week for 3 or 6 weeks) were studied in healthy rats and pigs. The effect of heparin on toxicity, PK and PD was also examined, since heparin is used during cardiac catheterization procedures and it is known that heparin and heparin-like molecules (heparan sulfates) can play a significant role in the biological activity of basic FGF in some systems. Doses of 30-300 and 0.65-20 μg/kg of rFGF-2 were studied in rats and pigs, respectively. Heparin doses of 40-70 U/kg were used in interaction studies. The only toxicity identified for rFGF-2 was a slight, reversible tachycardia in conscious telemetered rats (1 dose/week for 3 weeks), dose-related hypotension in unconscious pigs (single dose), and slight increases in selected organ weights in rats (1 dose/week for 6 weeks). Heparin given ~10 minutes prior to rFGF-2 did not have a significant effect on PD parameters (blood pressure, heart rate, ECG) in pigs. However, heparin decreased plasma clearance and steady-state volume of distribution in both species. The effect of heparin on rFGF-2 PK was more pronounced in pigs. No predictable effect on terminal elimination half-life was seen. **Conclusion:** With the exception of transient hypotension, which is a known pharmacological effect of the molecule, single and multiple doses of rFGF-2 were well tolerated in rats and pigs.

1916 DETERMINATION OF TISSUE SPECIFIC DRUG TOXICITY USING EPITHELIAL CELLS FROM EIGHT DIFFERENT NORMAL HUMAN TISSUES.

E. Elmore[1], T. T. Luc[1], V. E. Steele[2], G. J. Kelloff[2] and J. L. Redpath[1]. [1]*University of California, Irvine, Irvine, CA and* [2]*National Cancer Institute, Bethesda, MD.* Sponsor: A. de Peyster.

An important concern in drug development is unexpected toxicity in one or more tissues during clinical trials. This concern is amplified for cancer prevention agents where repeated dosing will occur over the course of the patient's lifetime. To address this issue, we have developed the Human Epithelial Cell Cytotoxicity Assay that uses epithelial cells from normal human skin, kidney, breast, prostate, oral mucosa, cervix, bronchus, and liver to determine changes in growth, mitochondrial function, and PCNA expression or albumin synthesis (hepatocytes). We will present data on twenty potential chemopreventive agents for each of the endpoints for all cell types. Our data indicate that epithelial cells from each tissue source are unique in their response to agent exposure. The data can be used to compare tissue specific differences in agent toxicity and as well as differences between structurally related agents.

1917 HYDROXYAPATITE-CEMENT AS A CARRIER FOR ANTIBIOTICS IN A 6-WEEK TOXICITY STUDY IN THE RABBIT.

U. Joosten[1], C. von Eiff[1], S. Mohr[2], W. Mueller[2], B. Brandt[1], A. Joist[1] and E. Brug[1]. [1]*Westf. Wilhelms University, Muenster, Germany and* [2]*Covance Laboratories GmbH, Muenster, Germany.* Sponsor: J. C. Norris.

A study was performed to investigate the effectiveness of a new carrier - active substance system [Hydroxyapatite-Cement (HAC) as carrier for antibiotics] in treatment of chronic, posttraumatic osteomyelitis research. In the *in vivo* study, bone infection was induced in the tibia of 29 *New Zealand White Rabbits* by injection of 1mL Na-morrhuat and $3x10^6$ CFU *Staphylococcus aureus*. After 3 weeks, when chronic stage of infection was obtained, 17 animals were treated by debridement and filling the marrow either with HAC alone or HAC mixed with gentamicine (32 mg/g). Animals of the control groups were left untreated. After 6 weeks, all animals were sacrificed. 28 of 29 rabbits developed a chronic osteomyelitis, which could be confirmed by radiological and histopathological investigations. Best evidence of the efficiency of treatment was observed in histopathological and microbiological findings. In all swabs of the control groups taken 6 weeks following infection *S. aureus* were detected which was clonal to the strain used for induction of osteomyelitis. In HAC/gentamicine treated animals no colonies were detectable. In the HAC/gentamicine treated group, there was no histopathological evidence of infection. In all other groups different stages of chronic osteomyelitis were found. No side effect was observed, neither locally nor systemically by HAC or gentamicine. Therefore HAC is considered to be a very effective carrier for antibiotics in treatment of chronic, posttraumatic osteomyelitis.

1918 THE TWENTY-EIGHT DAY ORAL TOXICITY OF NITAZOXANIDE IN THE CANINE.

T. P. O'Neill[1], M. S. Ayers[2], J. F. Rossignol[2], E. P. Zimmer[1], V. B. Ciofalo[1] and C. B. Spainhour[1]. [1]*Chrysalis Preclinical Services, Olyphant, PA and* [2]*Romark Laboratories, L.C., Tampa, FL.*

Nitazoxanide (N) is a broad spectrum antimicrobial. It also possesses a degree of antiinflammatory activity associated with its potential to inhibit PGE2 and preferential inhibition of COX-2 over COX-1. The purpose of this study was to evaluate the toxicity of N administered orally by gavage for 28 consecutive days to Beagle Dogs and focus on the potential for adverse gastrointestinal effects associated with its NSAID activity. The study was comprised of five total groups. Three groups were composed of three dogs/sex/group and received N at dosages of either 7.5, 15 or 30 mg/kg/day. Two groups were composed of five dogs/sex/group and received either a dosage of N at 60 mg/kg/day or the vehicle, 0.25% carboxymethylcellulose at 5ml/kg/day. Two dogs each from the vehicle control and high dose groups were retained for an additional 14 days following the last dose to be observed as recovery animals. In all cases, the total daily dose of N was divided into two equal portions (3.75, 7.5, 15 and 30 mg/kg) 12 hours apart. No mortality or overt clinical signs of toxicity were observed in any animals during the course of the study. There were no test article associated effects noted on body weights, body weight changes, food consumption values, hematological parameters, clinical chemistry values or coagulation times. Similarly, both quantitative and qualitative urinalyses data were not remarkable in their comparison to controls. Necropsy revealed no treatment-related effects on absolute organ weights, relative organ-to-body weight ratios or relative organ-to-brain weight ratios. Histomorphological evaluation of tissues demonstrated occasional focal congestion of the gastrointestinal tract. This lesion was interpreted as not being associated with the administration of N, since no dose-response relationship was established. Several other incidental lesions were also infrequently noted and are typical of those found in dogs. The findings from recovery animals did not differ from those generated from the main study. Based upon the results of this study, N administered via oral gavage, daily at dose levels of 7.5, 15, 30 and 60 mg/kg/day, divided into two equal portions given at 12 hr intervals for 28 consecutive days produced no abnormal findings at any dose level tested.

1919 SPECIES DIFFERENCES IN TARGET ORGAN EFFECTS OF BENZOYLPHENYLUREA (BPU) IN RATS AND DOGS.

J. C. Mirsalis[1], J. E. Schindler-Horvat[1], D. G. Fairchild[1], K. M. Schweikart[2], S. J. Donohue[2], J. E. Tomaszewski[2] and C. E. Tyson[1]. [1]*SRI International, Menlo Park, CA and* [2]*National Cancer Institute, Bethesda, MD.*

Toxicity studies were conducted on BPU, a promising antineoplastic therapeutic, in Fischer-344 rats and Beagle dogs. BPU was administered orally to rats at 0, 3, 6, or 12 mg/kg/dose for 5 consecutive days. At the highest dose level, there were significant decreases in WBC (↓79%), RBC (27%)↓, and neutrophils (↓96%). These parameters remained depressed 14 days after the final dose. Myeloid, erythroid, and megakaryocyte depletion of bone marrow and lymphoid depletion of lymph nodes, spleen and thymus were observed at the 12 mg/kg/dose level, but these effects generally resolved after two weeks. In addition, significant testicular toxicity was observed which was not resolved 14 days after treatment ended. A regimen of 0, 5, 10 and 20 mg/kg every 4 days x 3 (q4dx3) did not alter toxicity significantly and testicular lesions were present 4 weeks after the last dose; therefore, effects are dependent on total cumulative dose, irrespective of dosing schedule. Oral administration of BPU to dogs at 0, 0.4, or 4.0 mg/kg/dose given q4dx3 resulted in deaths in 2 of 4 dogs within 7 days of the last 4 mg/kg/dose. Substantial depressions in RBC, WBC, neutrophils and lymphocytes, accompanied by bone marrow depletion of erythroid, myeloid, and megakaryocyte elements; thymic lymphoid depletion; and lymphoid depletion of the tonsils, but no testicular lesions were observed in dogs. No effects were observed at the 0.4 mg/kg/dose. In summary, the total maximum tolerated dose of BPU is ~60 mg/kg (360 mg/m^2) in rats and <12 mg/kg (<240 mg/m^2) in dogs. Myelotoxicity was dose-limiting in both rats and dogs and irreversible testicular lesions were observed in rats only. (Supported by NCI Contract N01-CM-87101.)

1920 DOSE-DEPENDENT HYPERLIPIDEMIA IN RABBITS FOLLOWING ADMINISTRATION OF POLOXAMER 407 GEL.

J. M. Blonder[1], L. Baird[1], J. C. Fulfs[2] and G. J. Rosenthal[1]. [1]*RxKinetix, Inc., Louisville, CO and* [2]*Inhausen Research Institute, Inc., Fort Collins, CO.*

Poloxamer 407 (P-407) is a tri-block polymer that exhibits concentration-dependent reverse thermal gelation, a characteristic potentially useful for developing sustained release injectable drugs. While some reports suggest that P-407 is 'non-toxic', rodent studies demonstrate that P-407 induces hyperlipidemia, an action that makes this polymer a questionable drug delivery vehicle. Unfortunately, the majority of earlier studies employed supraphysiologic doses of P-407. The present study examined if lower, clinically useful, doses of gel-forming concentrations of P-407 induced hyperlipidemia in rabbits. Male and female rabbits were injected with 5.5 mg/kg (0.025 mL/kg), 27.5 mg/kg (0.125 mL/kg), or 137.5 mg/kg (0.625 mL/kg) of 22% P-407 and the actions of this polymer on blood chemistry were assessed at 6h, 1d, 2d, 7d, and 14d following injection. Control rabbits received no injection. The highest dose of P-407 (137.5 mg/kg) significantly increased serum triglycerides and cholesterol in both male and female rabbits with the maximum increase observed at 2 d after injection. Male rabbits were more sensitive to P-407 than females following injection of 137.5 mg/kg P-407. The lower doses of P-407 did not alter serum triglycerides or cholesterol. In all groups, serum triglycerides and cholesterol were at baseline levels by 14 d. P-407 did not affect other blood chemistry parameters. Although P-407 induces a dose-dependent hyperlipidemia in rabbits, low doses of this polymer may be used in controlled release drug delivery applications without the untoward hyperlipidemic effect.

1921 CLINICAL STUDY OF HEPATIC EFFECTS OF PHENOBARBITAL IN EPILEPTIC DOGS.

C. L. Gaskill, L. M. Miller, J. S. Mattoon, S. A. Burton, H. C. J. Gelens, S. L. Ihle, J. B. Miller, D. H. Shaw and A. E. Cribb. *Atlantic Veterinary College, University of Prince Edward Island, Charlottetown, Prince Edward Island, Canada.* Sponsor: J. P. Uetrecht.

Hepatotoxicity is a potentially fatal complication of phenobarbital (PB) therapy in dogs. PB may also induce liver enzyme activities. Our study goal was to determine if healthy PB-treated dogs with liver-related serum biochemical (LRSB) abnormalities >2X upper limit of normal (>2XULN) had histopathological evidence of liver injury. Serum PB concentrations (sPB) and LRSB profiles were obtained for 100 epileptic dogs receiving PB. Elevations >2XULN of alkaline phosphatase (AP) and alanine aminotransferase (ALT) occurred in 26% and 11% of PB-treated dogs, respectively. Liver biopsies were obtained from 15 dogs (cases) with at least one LRSB >2XULN (AP and ALT ranged from normal to 40X and 3.3X ULN, respectively); from 8 healthy dogs (controls) not receiving PB; and from 2 PB-treated epileptic dogs (PB-controls) with no LRSB >2XULN. All cases demonstrated induction-associated changes (hepatocyte swelling, ground-glass cytoplasmic appearance), and 14/15 had evidence of hepatic injury (inflammation, necrosis, fibrosis, and/or vascular changes). There was no correlation between severity of histopathological injury and magnitude of AP, ALT, or sPB (range: 37-192 μmol/L), but a significant correlation with duration of therapy (range: 2 months to 6.5 years). Histopathological evidence of liver injury was present in 7/8 control dogs; however, median scores for fibrosis and inflammation were significantly higher ($P<0.05$) for cases. The 2 PB-control dogs also had histopathological evidence of liver injury. No diagnostic or histopathological markers specific for PB-induced liver injury were identified.

1922 TWENTY-ONE-WEEK INTRAVENOUS TOXICITY STUDY OF MGI 114 IN DOGS.

R. F. Marshall[1], A. L. Kiorpes[2], G. Leatherberry[2], S. J. Waters[1] and J. R. MacDonald[1]. [1]*MGI Pharma, Inc., Bloomington, MN and* [2]*Covance Laboratories, Inc., Madison, WI.*

MGI 114 (6-hydroxymethylacyfulvene, irofulven), a semi-synthetic derivative of the mushroom toxin illudin S, has potent preclinical antitumor activity and is currently in Phase II clinical trials for several solid tumors. The toxicity and reversibility of toxicity in dogs resulting from intravenous administration of MGI 114 for four treatment cycles (daily X 5 days followed by 23 non-treatment days) was assessed. Groups of dogs (4M/4F) were given doses of 0, 0.06, 0.15 and 0.3 mg/kg (1.2, 3, and 6 mg/m^2). Death of 2 high-dose males during the first treatment cycle due to hematologic toxicity resulted in a 20% dose reduction to 0.24 mg/kg (4.8 mg/m^2) for the remaining 3 courses of the study and 2 replacement males were added. Food consumption and body weights were recorded throughout the study. Blood samples were collected for hematology and clinical chemistry on Days 4, 8, 15, 22, and 28 of each course and approximately day 14 and 30 of the reversal period. Electrocardiograms, blood pressure measurements, and samples for urinalysis were collected prior to the initial dosing and the scheduled sacrifices (2/sex on Day 8 and Day 65 of the fourth dosing cycle). Selected organ weights were determined and tissues examined microscopically. Dose-related, but reversible toxicity, observed at doses ≥ 0.15 mg/kg consisted of emesis, decreased body weight and food consumption and hematopoietic toxicity (primarily thrombocytopenia and neutropenia). These effects did not increase in severity from one cycle to the next. No clinically significant hematopoietic toxicity was observed at 0.06 mg/kg. Testicular atrophy and degeneration was the only toxic effect that was not reversible within 60 days of the last dose. Bone marrow toxicity is the only dose-limiting effect of MGI 114 when administered over multiple cycles of a clinically relevant dose schedule to dogs.

1923 DOSE RESPONSE OF A NASAL DOSING SYSTEM FOR MICE.

J. C. Norris, N. M. Shepherd and B. Whitby. *Covance Laboratories, Harrogate, United Kingdom.*

A nasal dosing technique was developed to facilitate the local and systemic delivery of conventional and biotech pharmaceuticals in rats, using the large surface area and the rich vascular system within the nasal cavity for drug delivery. This procedure now has been studied for its applicability in mice by conducting a dose response study. Different volumes of radiolabelled 14C-glucose were administered to mice. The volumes were 1, 3, or 5 microL, and the animals were sacrificed at 2.5 or 5 minutes after dosing. These animals were then processed for whole-body autoradiographic imaging in order to assess the distribution of the radiolabelled 14C-glucose within a variety of tissues. The brain, liver, blood, myocardium and lungs were selected and evaluated for their radioactivity concentration. After 2.5 minutes, the radioactivity levels between 1, 3, and 5 microL groups were increased for the blood (38 and 217% respectively) and myocardium (158 and 161%, respectively). A dose response increase was not observed after 2.5 minutes for the remaining tissues. However, 5 minutes after dosing the radioactive concentrations for all tissues had a dose response increase, except for the lung. The mean percentage increase of the tissues between 1 and 3 microL-treated animals ranged from 26 to 114% and between 3 and 5 microL-treated animals the range was 95 to 186%. Thus, a relationship exists between the volume of a test substance and the tissue distributions using mice and small dosing volumes.

1924 MASS BALANCE AND TISSUE DISTRIBUTION OF LEFLUNOMIDE (SU101) IN THE RAT.

T. Kim[1], J. Chemidlin[2], Z. M. Gu[2], L. Antonian[1], D. Wu[2], Q. Zhang[1], J. Sukbunthern[1], S. Chanda[1], L. Shawver[1] and G. Wagner[1]. [1]*SUGEN, Inc., South San Francisco, CA and* [2]*XenoBiotic Laboratories, Inc., Plainsboro, NJ.*

SU101 (Leflunomide), N-(4-[Trifluoromethyl]phenyl)-5-methylisoxazole-4-carboxamide, is an inhibitor of PDGF receptor signaling and is being developed as an anti-cancer drug for the treatment of glioblastoma. The absorption, distribution, metabolism, and excretion (ADME) of [14C]SU101, labeled with 14C in either phenyl or isoxazole ring, was investigated in male and female rats. Recovery of total radioactivity from urine, cage rinse, feces, expired air and tissues up to 168 hours post-dose were determined after bolus intravenous injection at 25 mg/kg. The parent drug, SU101, was readily converted *in vivo* to SU0020 primarily, followed by further conversion to other metabolites including trifluoromethylanaline (TFMA) and TFMA-related derivatives. Total recovery ranged from 92-98% in males and 93-100% in females, with ~7% as 14CO2 (derived from isoxazole ring labeled compound). Tissue distribution was studied at 0, 6, 12, 24, and 48 hours post-dose following a thirty minute intravenous infusion (via jugular vein cannula) at a nominal dose of 25 mg/kg body weight. At 48 hours after dosing, very low concentrations of radioactivity remained in all tissues, representing about 3% of the total dose. Radiochromatographic data indicated that SU101 was rapidly transported into the brain and existed as the parent molecule (SU101), even though some amounts of the drug had been converted to SU0020 in plasma. These data support the use of SU101 in the treatment of glioblastoma.

1925 A CHRONIC REPEAT DOSE TOXICITY STUDY OF A NOVEL ANTHRACYCLINE IN DOGS.

J. Brightwell. *Research Toxicology Centre, Rome, Italy.* Sponsor: A. I. Nikiforov.

MEN 10755 is a new disaccharide anthracycline in early clinical development. It possesses a notable antitumor activity in a wide panel of human tumors xenografted in nude mice, including tumors naturally resistant to other anthracyclines. As part of the non-clinical development program, a repeat dose intravenous (iv) study has been conducted in dogs. Groups of 4 male and 4 female beagle dogs were given iv injections of MEN 10755 at dosages of 0, 1.0, 2.5 and 3.0 mg/kg. Injections were given once every 2 weeks for a total of 8 injections. Treatment was followed by a 13 week treatment-free period. The 2 week interval between treatments was determined on the basis of complete recovery from drug-induced leukocytopenia. The high dose level was selected to be close to the single dose MTD (maximum tolerated dose), which was determined to be in the region of 3.75 mg/kg. Principal *in vivo* signs were diarrhea and/or emesis in the first days after each treatment cycle; severe hair-loss, from which there was complete recovery during the 13 week treatment-free period; reduced body weight gain in the mid and high dose groups; leukocytopenia after each treatment cycle. Major clinical chemistry changes were only seen towards the end of the study and were probably related to late occurring cardiotoxicity. Testes and spleen weights were reduced. The study demonstrates that the pattern of toxicity of MEN 10755 in dogs is similar to that seen with existing drugs of the same class. However, these toxic effects occurred at markedly higher dosages of MEN 10755 compared with other anthracyclines.

1926 CLINICAL MANIFESTATIONS IN DIAZEPAM AND ETHANOL INTOXICATED WHITE RATS: TOLERANCE TO ANAESTHETICS.

M. R. Basha and G. R. Reddy. *Sri Venkateswara University, Department of Zoology, Tirupati, India.* Sponsor: P. S. Kodavanti.

It is well known that in the medical practices the chronic alcoholic patients are resistant to usual doses of anaesthetics. However, age-related changes in the development of tolerance are still unclear. The present study was designed to elucidate the age-related changes in tolerance development to various doses of anaesthetics such as Diazepam and Thiopental in rats following chronic intake of Diazepam or Ethanol or both. Anaesthetic responses were measured using righting reflex test (RRT) for induction of anaesthesia, hot plate test (HPT) for analgesia, and sleep monitoring test (SMT) for duration of anaesthesia. The experiments were performed following the administration of Diazepam and Thiopental. The data suggests that the both young and old control rats were sensitive to both Diazepam and Thiopental as compared to Ethanol and Diazepam treated rats. The combined intake of both Ethanol and Diazepam enhanced the tolerance level as compared to the rats treated with Ethanol or Diazepam alone. In general, the old rats were more affected by the anaesthetic drugs which could be attributed to reduction in the drug metabolizing mechanism(s) during senescence.

1927 EFFECT OF CRF RECEPTOR-1 INHIBITION ON IMMUNE SYSTEM FUNCTION.

D. L. Burcham, B. Gemzik and B. D. Car. *Dupont Pharmaceuticals Company, Newark, DE.*

A role for the Corticotrophin Releasing Factor receptor-1 (CRF R1) in host defense, based on leukocyte expression and a central role in the HPA axis, has been postulated. The effects of CRF-R1 antagonism on host defense were examined in a series of rat studies with the potent CRF R1 antagonist, DMP 904 (Ki=1 nM human, 0.6 nM rat). DMP 904 was dosed (80 mg/kg/day) to provide continual high level receptor inhibition. The effect of CRF-R1 inhibition on lipolysaccharide (LPS)-induced toxemia was examined in rats sensitized with D-galactosamine. LPS-induced toxemia, as assessed by serum transaminase activities, was not altered by DMP 904. The sheep red blood cell antibody-forming assay was used to assess potential effects on T- and B-lymphocyte function. Rats dosed with DMP 904 or vehicle demonstrated comparable responses. Finally, we investigated the effect of CRF-R1 inhibition on the clearance of a facultative intracellular bacterium, Listeria monocytogenes. Bacterial clearance was not impaired in the presence of DMP 904. Collectively, results of these experiments have not demonstrated a clear role for CRF-R1 in host defense. Pharmacologic inhibition of this receptor is, therefore, unlikely to compromise immune system function.

1928 SHORT PHOSPHOROTHIOATE OLIGOMERS FOR CHELATION AND ENHANCED IRON EXCRETION.

J. E. Mata and P. L. Iversen. *AVI BioPharma, Corvallis, OR.*

Iron overload is a significant human health problem that will benefit from effective, nontoxic chelation therapy. We previously observed an increase in urinary iron excretion following systemic therapy with a phosphorothioate oligodeoxynucleotide (PS-ODN) in myelodysplastic patients. In vitro binding studies with a 27 base PS-ODN confirm metal binding properties with a higher affinity for mercury, iron, tin, lead and cadmium. These observations lead to the hypothesis that a short PS-ODN may be designed to evade toxicities associated with PS-ODNs but would also possess properties which would enhance the excretion of iron. A 10 base poly-cytidine PS-ODN with a 3'-ribose modification was synthesized and purified by HPLC. Four groups of eight rats each were injected with 10 mg of iron dextran bi-weekly for 4 weeks to produce iron overloaded animals. Animals were then treated with saline, desferoxamine, one injection of 100 µg of poly-C PS-ODN, or three consecutive days of 30 µg of poly-C PS-ODN. Urinary excretion, histology and modulation of metal responsive genes in the liver were evaluated. Analysis of liver tissues reveals diminished iron per milligram of liver tissue compared to saline and desferoxamine treated animals. These studies warrent the further development of short PS-ODNs for nontoxic chelation therapy.

1929 HPLC METHOD FOR THE DETERMINATION OF SELAMECTIN (REVOLUTION®), A NOVEL PET ENDECTOCIDE.

L. P. Harran[1], D. Perry[1], S. Cambers[2], D. Walker[2] and U. A. Pillai[1]. [1]*Pfizer Inc., Groton, CT and* [2]*Pfizer Ltd., Sandwich, United Kingdom.*

Selamectin is a semi-synthetic avermectin indicated for prophylactic use against heartworm and for the control or treatment of endo- and ectoparasites in dogs and cats. To enable detection of very low levels of selamectin in biological fluids, an analytical method similar to that used for other avermectins (Demontigny et. al. 1990) in general was developed. The analyte was extracted from plasma matrix using methanol/acetonitrile mixture. The extracted analyte was then subjected to a series of derivatization steps which involved use of triethylamine, trifluoroacetic anhydride, and ammonia. The fluorescent derivative was identified as containing an N-trifluoroacetamide group. The fluorescent derivative in the extracted sample was separated by HPLC and detected using a fluorescence detector. Two dynamic ranges, 10 to 200 ng/ml and 25 to 800 ng/ml, were established for this assay. The recovery of the analyte from the plasma matrix ranged from 91-105%. The intra and inter-assay accuracy was determined by analyzing quality control standards at the low (20% above), mid, and high (20% below) concentrations of the standard curve

and was between 91-109% and 88-101%, respectively. The precision of the assay was between ±1 to ±10% over a plasma concentration range of 10 - 800 ng/mL. In summary, the validated assay proved to be sensitive and reproducible in quantitating plasma levels of the drug ranging from 10 to 800 ng/ml. Demontigny P, Shim JSK, Pivnivhny JV (1990). Liquid-chromatographic determination of ivermectin in animal plasma with trifluoroacetic-anhydride and N-methylimidazole as the derivatization reagent. Journal of Pharmaceutical and Biomedical Analysis, 8(6):507-511

1930 THE VALUE AND ETHICS OF USING HUMAN DATA FOR THE REGISTRATION OF PESTICIDES.

E. E. McConnell. *ToxPath, Inc., Raleigh, NC.*

A joint meeting of the EPA Science Advisory Board and FIFRA Science Advisory Panel was convened on December 10-11, 1998 to provide advice and comment to the EPA on issues related to data derived from testing on human subjects, particularly the use of human data for making pesticide registration decisions. Both scientific and ethical questions were raised about such data, the manner in which they are obtained, and how these data should be used in risk assessments. Proponents of using human data felt such data were of prime value for developing a risk assessment of a given pesticide, if the data were obtained in a scientifically credible and ethical manner, similar to what is expected in the field of pharmaceutical testing. In fact, it was felt that testing in human volunteers was particularly important in the case of pesticides because of their potential for contamination of food and water. Opponents felt it was unethical to test pesticides in human volunteers under most circumstances. They posed two basic arguments for supporting their case: 1) Pesticides are unique chemicals because they are designed to be "poisons," and 2) Many pesticides are neurotoxic and it is unethical to test neurotoxins in people. This is a particularly important issue because it impacts on some fundamental concepts in toxicology and is a basic policy decision for the EPA.

1931 METALLOTHIONEIN SUBCELLULAR LOCALIZATION AND REGULATION OF CELL CYCLE AND APOPTOSIS.

Y. J. Kang[1] and M. P. Waalkes[2]. [1]*University of Louisville, Louisville, KY and* [2]*NCI at NIEHS, Research Triangle Park, NC.*

Metallothionein (MT), a transition metal binding protein, has been implicated in a diversity of biologic functions. Recent work has provided new insights into the subcellular localization of MT and its role in regulation of cell cycle and apoptosis. A better understanding of cellular and molecular mechanisms for MT protection from oxidative tissue injury has also been achieved. These areas of high impact progress in MT research are the focus of this symposium. MT is well below the size exclusion limit for diffusion through the nuclear envelope. However, its nuclear localization involves the action of glycoproteins and is energy dependent. Translocation of MT into and out of nucleus is regulated by cell cycle progression and linked to cell differentiation. Cellular redox status also regulates the subcellular localization of MT. Cytoplasmic MT interferes with signaling pathways evoked by oxidative stress. For example, p38 mitogen-activated protein kinases (MAPKs) are activated in cardiac myocytes treated with doxorubicin (DOX), an antitumor agent causing cardiac apoptosis by producing reactive oxygen species. MT inhibits DOX-induced p38 MAPK activation and apoptosis. DOX also induces mitochondrial cytochrome c release, thereby causing activation of proteases, such as caspases 9 and 3, that are involved in apoptosis. MT inhibits this process as well. Nuclear MT protects against oxidative DNA damage and regulates activities of transcription factors. For example, MT prevents DNA damage induced by antitumor agents and regulates nuclear factor κB activity. Continued efforts on these fundamental investigations will help to further define these important roles of MT in regulation of cell cycle and apoptosis.

1932 REGULATION OF NUCLEAR AND CYTOPLASMIC LOCALIZATION OF METALLOTHIONEIN.

J. S. Lazo. *University of Pittsburgh, School of Medicine, Pittsburgh, PA.*
Sponsor: Y. J. Kang.

Spatial compartmentalization of intracellular macromolecules represents a potentially powerful yet poorly understood post-translational regulatory mechanism. Metallothionein (MT) represents a prototype low molecular weight, stress-activated protein with protective functions against exogenous toxins that is found partitioned in the nucleus or cytoplasm of cells even though it has a size well below the exclusion limit for diffusion through the nuclear envelope. Work from several laboratories indicate that the subcellular distribution of MT is cell type specific and inherited. Three general approaches have been used to detect MT subcellular localization: immunocytochemistry, fusion protein tagging and exogenous fluorescent labeling techniques. Nuclear sequestration appears to require cellular ATP, is saturable and involves one and more nuclear glycoproteins. Recent data also suggest nuclear entry is diffusion-based and nuclear retention is an active process that involves at least two biochemically distinct binding locales. These nuclear binding sites may have an important role in regulating the protective function of MT or other low molecular weight proteins against heavy metals and other toxins.

1933 INHIBITION OF METALLOTHIONEIN OF OXIDATIVE STRESS-INDUCED APOPTOSIS.

Y. J. Kang, G. W. Wang, Z. X. Zhou and J. B. Klein. *University of Louisville, Louisville, KY.*

Cardiac-specific metallothionein (MT) overexpressing transgenic mice are highly resistant to oxidative myocardial injury induced by doxorubicin (DOX), an anticancer agent. This resistance is associated with MT inhibition of lipid peroxidation. Most of the elevated MT is localized in cytosol. DOX induces myocardial apoptosis, which is highly responsible for the cardiomyopathy. MT significantly reduces the number of myocytes undergoing apoptosis. At least two distinct signaling pathways are involved in the DOX-induced myocyte apoptosis, as demonstrated by using primary cultures of neonatal mouse cardiomyocytes. First, DOX activates p38 mitogen-activated protein kinases (MAPK), which plays an important role in DOX-induced apoptosis, as revealed by a specific p38 MAPK inhibitor, SB203580, which partially inhibits DOX-induced apoptosis. Second, DOX causes mitochondria to release cytochrome c, which leads to activation of caspases 9 and 3, and subsequent apoptosis. MT inhibits DOX-induced p38 MAPK activation, which correlates with its inhibition of apoptosis in the myocyte cultures. MT also blocks DOX-induced cytochrome c release. This event is accompanied by inhibition of activation of caspases 9 and 3 and suppression of apoptosis. Two possible mechanisms are implicated for MT protection from oxidative stress-induced apoptosis *in vivo*: (1) zinc released from MT is an anti-apoptotic agent, and (2) MT reacts with oxidants to preserve cellular reductant potential.

1934 NUCLEAR TRANSLOCATION OF METALLOTHIONEIN DURING CELL CYCLE PROGRESSION AND DIFFERENTIATION.

M. G. Cherian and M. D. Apostolova. *University of Western Ontario, London, Ontario, Canada.*

Although metallothionein (MT) is localized mainly in the cytoplasm of hepatocytes in adult liver, its translocation to the nuclei has been observed during development in fetal liver, and after partial hepatectomy. The high levels of MT in the cell nucleus may be related to the increased requirement for Zn and Cu for several metallo-enzymes and transcription factors for gene expression. High levels of MT expression including its nuclear localization have been observed in proliferative epithelial cell tumors which are not well differentiated. The cellular signals responsible for nuclear localization of MT during proliferation and differentiation are not well defined. Studies in myoblast cell lines (L_6 and H9C2) showed that during early stage of differentiation with either insulin-like growth factor-1 or low serum concentration MT is translocated to the nucleus along with Zn. This was demonstrated by FITC labeling of MT antibody and TSQ binding to Zn using fluorescent confocal microscopy. When differentiation is completed as shown by morphology or creatinline kinase activity, both MT and Zn are found only in the cytoplasm or myotubes. The results demonstrate that nuclear localization of MT in early differentiation coincides with the increased requirement for Zn. In 3T3-L1 fibroblasts, when the growth is synchronized with low serum, the cells enter intoG_0/G_1 phase of cell cycle, and MT is detected in the nucleus. When cell cycle is blocked at S-phase with aphidicoline, an inhibitor of DNA polymerase-alpha, the nuclear localization MT persists. However, after removal of aphidicoline, the cells re-enter the cell cycle, and at G_2/M phase, MT is localized mainly in the cytoplasm. These results demonstrated that localization of MT in the nuclear occurs during G1/S phase transition of cell cycle when the requirement for Zn is highest.

1935 REGULATION OF NUCLEAR FACTOR-κB ACTIVITY BY METALLOTHIONEIN.

S. Hara, A. Sakurai and N. Imura. *Kitasato University School of Pharmaceutical Sciences, Tokyo, Japan.*

Metallothionein (MT), a low molecular weight, cysteine-rich metal binding protein, has multiple functions such as detoxification of heavy metals and protection of cells against reactive oxygen species. As MT has an ability to scavenge hydroxyl radicals, MT may control intracellular redox status. Recently, several evidences suggest that some transcription factors such as nuclear factor κ-B (NF-κB) are regulated by intracellular redox status. One of the functions of MT may be regulation of the activity of such factors. We here examined whether or not MT regulates the activity of NF-κB using the MT null embryonic cell lines (MT-/- cells) established from MT null mice. We first found that tumor necrosis factor (TNF)-induced activation of the binding of NF-κB protein to DNA in wild type MT+/+ cells was lower than that in MT-/- cells by an electrophoretic mobility shift assay. The NF-κB activation in MT-expressing cells obtained from MT-/- cells by the transfection of mouse MT-I (mMTI) gene was also significantly lower than that in MT-/- cells. In addition, the transfection of MT gene suppressed NF-κB-dependent gene expression induced by TNF. These results demonstrate that MT may function as a negative regulator of NF-κB activity. To clarify the mechanism by which MT regulates NF-κB activity, we next examined the effects of transfection of mMT-I gene on TNF-induced degradation of inhibitory protein IκB. IκB was degraded after the treatment of TNF in mock-transfected MT-/- cells. In mMT-I-transfected cells, however, a lesser extent of IκB degradation was observed in response to TNF. These results suggest that MT may suppress TNF-induced NF-κB activation by inhibiting IκB degradation in the cytoplasm of cells, although the possibility still remains that MT may also regulate NF-κB activity in the nucleus.

1936 NEW HORIZONS IN METALLOTHIONEIN RESEARCH.

M. P. Waalkes and J. Liu. *NIEHS, Research Triangle Park, NC.*

Metallothionein (MT) is a remarkable, low-molecular weight protein with a variety of potential functions. However, none has been conclusively defined and, unfortunately, even the advent of MT over-expressing transgenic and MT knock out animals and cells has still not allowed for a conclusive assignment of functionality. MT, which normally binds zinc, is likely important in metal toxicity, essential metal metabolism, and resistance to oxidative injury, but beyond this precise roles are not well characterized. The intentional nuclear localization of MT presents several intriguing possibilities for control of cell cycle and gene regulation and probably impacts development and carcinogenesis. A model whereby nuclear MT provides zinc for enzymes during their synthesis or for transcription factors that could modify gene expression at critical times would likely include specific MT-binding proteins and a means for controlled zinc release form MT. However, very little is known about exactly what signals the nuclear accumulation of MT and how the zinc bound to MT is released and these should be fertile avenues for future studies. The release of zinc from MT may be important blocking apoptosis, as zinc can inhibit caspases, but MT also sequesters reactive intermediates and thereby inhibits oxidative stress-induced apoptosis. So defining the conditions under which MT acts as an proapoptotic or antiapoptotic agent is also another important future direction. It appears that MT may also effect transcription factor activity outside the nucleus through post-translational events, such as inhibition of degradation inhibitory factors. So the roles of MT in the control or modification of gene expression, cell cycle, or apoptosis need to be defined at many different levels and this creates a large number of fascinating research opportunities.

1937 TOXICOLOGICAL DATABASE MINING IN THE TWENTY-FIRST CENTURY.

M. J. Cunningham. *Incyte Pharmaceuticals, Palo Alto, CA.*

Genomic technologies are currently being used as an investigative tool in risk and safety assessment. Data obtained from gene expression assays using microarrays (10^5 to 10^6 data points/assay) can be overwhelming. Recent research into data mining and visualization may provide answers to this key issue. Initially, the raw data may need to be filtered for noise and threshholding parameters set for the differential expression values. Then, several methods such as subsetting and agglomerative clustering, multidimensional scaling, motif discovery, and prinicipal components analysis may be applied to numerically analyze the trends due to various compound treatments. Finally, the trends can be visualized using pattern recognition methods. Data analysis by these methods may help predict unknown or alternative modes of action, classification of unknown NCEs by their expression profiles and comparison to known compound profiles and allowing further analysis of dose-response relationships and chemical interactions. This symposium will start with an overview of the current database mining practices and then delve into each method available and its application to a gene expression data set (containing several time points) resulting from the treatment of rat livers with three different hepatotoxins.

1938 IDENTIFYING THERAPEUTIC PROTEINS AND TARGETS IN DNA DATABASES.

J. R. Greene. *Schering-Plough Research Institute, Kenilworth, NJ.* Sponsor: M. J. Cunningham.

The rapid and voluminous accumulation of genomic and cDNA sequence data as well as the rapid advance in genome-scale analysis technologies have presented opportunities and challenges in the area of new drug development. This onslaught of information has affected drug development efforts in virtually all therapeutic areas. Not only must the sequences be analyzed and evaluated for their potential as therapeutic proteins or targets, but the results of multiple analyses must be communicated to the appropriate laboratory scientists. In the environment of a large pharmaceutical company, several practical approaches must be applied to this problem given the diverse needs of the company's research community. This presentation will discuss some of the ways that genomic and post-genomic information can be integrated into the drug discovery process. Examples will be provided from pre-clinical drug development efforts in the areas of oncology and infectious diseases, two areas in which genomic sequence information and microarray gene expression analysis have driven drug development programs out of the databases and into the laboratories.

1939 FUNDAMENTAL GENE EXPRESSION ANALYSIS TO TOXICOLOGICAL PROFILING.

R. Somogyi. *Incyte Phamaceuticals, Palo Alto, CA.* Sponsor: M. J. Cunningham.

Through large-scale gene expression analysis we aim to increase the depth of toxicological and therapeutic drug-effect profiling, and accelerate the discovery of key molecular indicators and processses. Success hinges on the integration of computational tools for data analysis with measurements that reflect the breadth of the biological complexity, e.g. large numbers of genes surveyed on microarrays. Basic data analysis can be broken down into three consecutive stages: 1) filtering of noisy data, 2) thresholding for differential expression and subsetting, and 3) clustering of expression response profiles. These techniques allow us to classify drugs according to their gene expression profiles and identify typical pathways of drug action. We have applied this analysis to set of temporal expression profiles (6 time points; >7000 genes) of rat liver to three different drugs from different classes. Comparison of these results to existing knowledge allows for a critical evaluation of these new technologies in how much they reproduce previous conclusions and provide new insight.

1940 APPLYING VISUAL AND NUMERICAL PATTERN RECOGNITION TOOLS TO GENE EXPRESSION DATA.

T. J. Downey, D. J. Meyer and M. K. Greene. *Partek Incorporated, St. Peters, MO.* Sponsor: M. J. Cunningham.

Microarray technologies have created challenges for biologists and data analysts alike. Designing an experiment to achieve clearly defined research goals is difficult during the uncertainty surrounding the infancy of new and powerful technologies. We will look at visual and numerical techniques used in pattern recognition and statistical analysis to identify patterns in the genes. Two examples are a.) genes which exhibit significantly similar expression patterns within treatment groups but different patterns in different treatment groups and b.) genes whose expression patterns can be identified as statistically linked to a particular treatment. The analyzed data comes from a microarray experiment where rat liver genes are measured under toxic doses from three different compounds. The analysis methods will include Pincipal Components Analysis (PCA) and Multi-Dimensional Scaling (MDS) for visualization of expression patterns, and cluster analysis, analysis of variance (ANOVA) and t-tests to identify patterns of genes which display significant similarity and/or

dissimilarity in expression within and between the treatment groups. In short, we will identify which genes fall into particular groups, which genes are unlike all others, and which genes appear to be uninvolved in the treatment(s).

1941 COMBINING CHEMICAL STRUCTURE AND GENE EXPRESSION ANALYSES FOR TOXICOLOGICAL PROFILING AND PREDICTION.

E. W. Steeg. *Molecular Mining Corporation, Kingston, Ontario, Canada.* Sponsor: M. J. Cunningham.

As ever-larger databases arise and are linked over networks, knowledge discovery and data mining (KDD) methodologies are making an impact in toxicological analysis and prediction. In recent years two distinct streams of KDD application have emerged. One stream, the focus of this session, is characterized by clustering and pattern recognition in high-throughput gene expression data. The second, stream features motif discovery in 2D and 3D chemical structure databases: for example, the discovery of recurring substructures in compounds of different known toxicity classes, using inductive logic programming (ILP). By uniting the gene-based and structure-based approaches within one discovery methodology, it is possible to get more value from the available data. I will discuss how our combined approach contributes to the creation of systems for the classification and prediction of mode of action, dose-response relationships and chemical interactions with respect to toxicity data.

1942 TRICHLOROETHYLENE HEALTH ASSESSMENT: INTRODUCTION.

W. Farland. *USEPA, Washington, DC.*

USEPA's trichloroethylene health assessment is being shaped by several new developments in risk assessment. Foremost among these developments is revision of EPA's cancer guidelines which emphasize detailed characterization discussions; replace classification groups with a brief narrative description; and promote the use of mode-of-action information in evaluating relevance of experimental results, suggesting approaches for dose-response assessment, and identifying susceptible populations. Also evident is a trend toward harmonizing cancer and non-cancer assessment methods. Other influences come from recommendations for improving risk assessment by the National Research Council, Executive Order 13045 which focuses on risks that may disproportionately affect children, and on EPA guidance on cumulative risk assessment. The updated trichloroethylene assessment illustrates these concepts. The assessment takes steps toward integrating assessment of cancer and non-cancer effects, using common methods as it considers mode of action for both; uses pharmacokinetic models and uncertainty analysis of these models; and applies benchmark-dose models for some cancer and non-cancer effects utilizing similar dose-scaling procedures. Further, the assessment discusses intrinsic and acquired factors that affect susceptibility to TCE, and discusses joint effects of other chlorinated solvents and agents that have metabolic pathways, potential modes of action, and toxicity effects similar to TCE. This presentation provides a background as support for the new integrative approach to the trichloroethylene risk assessment and introduces the more detailed presentations that follow.

1943 WHAT DO THE HUMAN DATA TELL US?

C. Siegel Scott[1] and D. Wartenberg[2]. [1]*USEPA/NCEA, Washington, DC and* [2]*UMDNJ-RW Johnson Medical School, Piscataway, NJ.* Sponsor: W. H. Farland.

The updated trichloroethylene (TCE) health assessment utilizes mode of action data to understand the development of carcinogenic effects. Findings from a review of the epidemiologic body of literature are discussed from this perspective. The cancers that are most well studied and show the strongest evidence include kidney cancer, liver cancer, cervical cancer, and non-Hodgkin's lymphoma. Several of these findings are biologically plausible. Trichloroethylene exposure has demonstrated target organ toxicity to the kidney, liver, and immune system. The kidney cancer finding is strengthened by the observation of larger risks among those with genetic polymorphisms of the glutathione-S-transferase metabolic pathway and by recent molecular epidemiologic observations. The liver cancer observation suggests that humans may not be very different from rodents regarding susceptibility to TCE. TCE and metabolites affect carbohydrate handling. In support of the linkage between carbohydrate metabolic control and cancer is the association of glycogen storage disease in humans with early development of hepatic adenomas and the increased risk diabetics show for liver cancer. The remaining site-specific cancers have more limited direct mechanistic support. The review of the TCE epidemiologic studies reinforces the essentiality of information from humans when evaluating mode-of-action hypotheses.

1944 IS THE INDUCTION OF MUTATION A KEY EVENT IN THE ETIOLOGY OF TRICHLOROETHYLENE-INDUCED TUMORS?

M. Moore. *USEPA NHEERL, Research Triangle Park, NC.*

This presentation addresses the evidence that trichloroethylene (TCE) or its metabolites might mediate tumor formation via a mutagenic mode of action. We review and draw conclusions from the published mutagenicity and genotoxicity information for TCE and several of its metabolites. Consistent with the thinking outlined in the proposed Cancer Risk Assessment Guidelines, which provide for an assessment of the key events involved in the development of specific tumors, we provide a new and general strategy for interpreting genotoxicity data that goes beyond a simple determination that the chemical is or is not genotoxic. For TCE, we conclude that the weight of the evidence argues that chemically induced mutation is unlikely to be a key event in the induction of human tumors that might be caused by TCE. This conclusion derives primarily from the fact that TCE and those metabolites for which information is available require very high doses to be genotoxic. However, conclusions as to whether TCE will induce tumors in humans via a mutagenic mode of action cannot be drawn from the available information. More research, including the development and use of new techniques, is required before it is possible to make an assessment as to whether chemically induced mutation is a key event in any human tumors resulting from exposure to TCE.

1945 INTEGRATION OF MODE-OF-ACTION INFORMATION TO GUIDE DOSE-RESPONSE ANALYSES.

V. J. Cogliano. *USEPA NCEA, Washington, DC.* Sponsor: W. H. Farland.

New approaches are being used in the updated health risk assessment for trichloroethylene (TCE). Past TCE assessments emphasized linear extrapolation from bioassays in which TCE induced liver tumors and lung tumors in mice and kidney tumors in rats. The updated TCE assessment is an example of how EPA's new cancer guidelines encourage the use of mechanistic information in risk assessment. Pharmacokinetic and mechanistic studies on TCE are able to suggest better ways to use the high-dose animal results to make inferences about human environmental exposure and to guide approaches to dose-response modeling. Further, the revised cancer guidelines encourage the utilization of biologically based modeling and, as a default, establishes a two-step dose-response process that separates analysis of observed data from extrapolation to lower doses. Pharmacokinetic models describe how TCE's cancer response is mediated though several metabolites. Mechanistic information is evaluated to identify the key events involved in tumor formation and indicate whether linear or nonlinear extrapolation to lower doses is more appropriate.

1946 FUTURE DIRECTIONS IN THE USE OF MODE OF ACTION INFORMATION IN ASSESSING CANCER RISKS FROM TRICHLOROETHYLENE (TCE).

R. J. Bull. *Battell-Pacific Northwest National Laboratory, Richland, WA.*

TCE is an environmental chemical that has diverse data implicating it as a carcinogen. Its activity between species and strains is diverse with tumors appearing at different sites in experimental animals. In all cases very large doses have been required to induce tumors. Epidemiological studies provide limited support for TCE as a human carcinogen for a variety of reasons. Different metabolites and modes of action induce tumors in the different organs and species. Moreover, the type of tumor produced in each species relates largely to organs in which there is a high spontaneous rate. Assessing liver cancer induction was relatively straight forward because there was experimental evidence that certain metabolites (principally trichloroacetate and perhaps dichloroacetate) are both liver carcinogens and produced at concentrations in the metabolism of TCE to account for liver tumor induction.

The modes of action of both metabolites affect cell cycle kinetics and do not require direct interaction with cellular DNA, allowing a consideration of liver cancer risk being non-linear with dose. What remains to be pursued is a better understanding of the mechanisms that actually underlie the induction of these tumors. Kidney tumor induction remains unresolved. Pharmacokinetic modeling of the kidney needs to be better defined and key events in tumor induction identified. One metabolite, dichlorovinylcysteine (DCVC) is both mutagenic and cytotoxic. However, it is important to also recognize that the involvement of DCVC as the renal carcinogen remains a hypothesis, not a fact.

1947 TOXICOLOGICAL CONSIDERATIONS OF PHARMACEUTICALS FOR PEDIATRIC PATIENTS.

H. V. Sheevers[1] and M. S. Tassinari[2]. [1]*Milestone Biomedical Assoc., A Division of PAI-SAIC, Rockville, MD and* [2]*Pfizer Central Research, Groton, CT.*

The number of pharmaceuticals designed and tested clinically for use by pediatric patients is rapidly increasing. Additionally, it has long been recognized that important stages of development continues postnatally in both humans and animals. These two factors—more drugs developed for pediatric populations and the importance of needed evaluations of postnatal development—have led toxicologists to recognize and manage a rapidly increasing demand for juvenile animal studies. At the same time, however, it is increasingly recognized that the necessary scientific basis to design reasonable studies may not exist. This workshop will introduce some of the issues associated with testing in juvenile animals. The workshop will first focus on the development of several important organ systems that undergo postnatal development, including skeletal growth, the immune system, and the central nervous system. It is clear that some drugs, such as the corticosteroids, may affect development. It is not clear, however, whether all drugs will affect pediatric populations differently from adults during this postnatal developmental period. Available animal models will be described and evaluated, and regulatory expectations will be discussed. It is expected that this workshop will help define the questions that studies should answer, review current animal models, and identify research gaps that should be considered prior to additional regulation. While this workshop will be focussed primarily on recent testing requests by the US FDA, recent changes in EPA policy will be noted as well. The workshop will conclude with a presentation of several case studies of pharmaceuticals intended for pediatric patients.

1948 SKELETAL GROWTH AND GROWTH DYNAMICS: ASPECTS TO CONSIDER FOR THE DESIGN OF JUVENILE ANIMAL STUDIES.

M. S. Tassinari. *Pfizer Central Research, Groton, CT.*

How well a child or young animal grows is typically viewed as a measure of the health and nutritional status of that individual. Recent changes in the labeling for the use of corticosteroids in children have highlighted the need to carefully assess overall growth in drug safety testing in addition to the evaluation of specific organ systems. Growth is easily measured by following the incremental changes in height and weight. Growth velocity yields a useful measure of growth over time and is easily determined by frequent measures of weight and height (length) in most model systems. Catch-up growth provides periods of recovery after periods of growth inhibition. Recovery from growth failure is influenced by the age and stage of maturation of the young animal at the time of the growth impairment, as well as the duration and the severity of the insult. Postnatal skeletal growth is affected not only by nutrition but also by genetics, gender and hormonal status. Most maturational changes in the skeleton are closely linked to the maturation of the reproductive system. Sexual dimorphism evident at puberty is inherent in most species and affects both skeletal mass and size. In addition to discussion of the above elements influencing growth, approaches to the evaluation of skeletal growth and overall growth in available animal models will be discussed in the context of regulatory testing strategies.

1949 ANIMAL MODELS AND CONSIDERATION OF IMMUNE SYSTEM DEVELOPMENT.

K. L. Hastings. *FDA/CDER, Rockville, MD.*

The developing immune system is an important potential target of drug toxicity. Assessing immunotoxicologic effects in animals can provide clues that such effects could be of concern in pediatric patients, but as yet there appears to be a very small data base upon which to draw definitive conclusions. In some cases, *in utero* exposure (in reproductive toxicology studies) is used to model potential adverse effects of pediatric exposure. For example, *in utero* exposure to diazepam has been shown to impair host defense to challenge infections in rats and hamsters. Similarly, in Fisher 344 rats maternal exposure to lead has been shown to impair immune function in the offspring. In both cases it is not clear that these effects would also be seen in animals first exposed after birth. The timing of immune system development in animals relative to humans presents a further complication. The immune systems of rodents are immature relative to humans at birth: it is thus likely that rodents would be more sensitive to xenobiotic-induced immunotoxicity when exposed *in utero*. Cocaine and ethanol have been shown to be immunotoxic in Lewis rat pups: the implications for human immunotoxicity are unclear given the species differences in immune system development. Developmental immunotoxicology is an area where much research is needed and ideas concerning particular problems and approaches will be presented.

1950 CNS DEVELOPMENT: DEVELOPMENT OF THE AXIS AND CONSEQUENCES OF EARLY DRUG EXPOSURE.

M. T. Williams and C. V. Vorhees. *Children's Hospital Research Foundation, Cincinnati, OH.*

The development of the central nervous system (CNS) is dependent upon many different factors. The influence of steroid hormones on CNS development has been investigated extensively in recent years. The adrenal steroids, namely the glucocorticoids and mineralocorticoids, have been implicated in both cell death and cell survival, especially in the hippocampus, an area important in spatial learning and memory. Early environmental influences, such as drugs that cause release of glucocorticoids, may have deleterious effects on the ability of an animal to learn and recall memories or may result in physiological changes that cause an animal to behave abnormally when faced with a challenging situation. Behavioral testing, such as learning and memory paradigms, following drug exposure during development is a useful measure to detect functional changes in the CNS that may not be related to gross physical alterations. Animal models used to detect changes in learning and memory are invaluable, since controlled studies in humans presents many ethical concerns. This presentation will focus on the development of the central nervous system, age-related correlations between human and rat brain development, and the development of the HPA axis. Furthermore, animal models of learning and memory following exposure to substituted amphetamines during different periods of neonatal development will be discussed. We will show data demonstrating that exposure of neonatal animals to substituted amphetamines produces no alterations to neurotransmitter systems, pronounced elevations in pituitary and adrenal hormones during drug exposure, and deficits in learning and memory when tested as adults. The effects on learning and memory may be related to elevated levels of HPA axis hormones produced by drug exposure during development. Such effects may have implications for understanding potential risks associated with pediatric exposure to new drugs that cause HPA axis activation.

1951 INTERNATIONAL REGULATORY CONSIDERATIONS OF PHARMACEUTICALS FOR PEDIATRIC PATIENTS.

H. V. Sheevers. *Milestone Biomedical Assoc., A Division of PAI-SAIC, Rockville, MD.*

Developmental toxicologists have long recognized that postnatal development continues for years in humans, and that potent drugs may have deleterious effects on that development. Widely recognized examples include decreased skeletal growth caused by glucocorticosteroids and the effects on bone by fluoroquinolones. Pharmaceutical development has often included testing in juvenile animal models for drugs intended for very young patients. This testing has been requested by the Food and Drug Administration (FDA) on a case-by-case basis. Drug divisions within the FDA have had relative freedom to request whatever studies they thought appropriate, and there was an

expectation that the pharmaceutical industry would perform the tests requested. With the recent enactment of the Pediatric Rule (in the Food and Drug Administration Modernization Act), which focused primarily on clinical testing, the FDA as well as industry recognized that there was a need for a more standardized approach to juvenile animal testing to support the more standardized expectation of human clinical testing of children for pharmaceuticals. This presentation will focus on juvenile animal testing currently being performed to meet FDA requirements, as well as testing that has been found acceptable to meet international expectations. Examples of juvenile animal tests that have been requested by various FDA divisions will be discussed. For example, the FDA Pulmonary Division requests inhalation testing in animals "as young as possible" for drugs intended for children less than 2 years old. Other divisions, however, specify that rats be 4 days old or younger and specify additional needed brain histopathology. This presentation will focus on various suggested FDA approaches, and will focus on an update of FDA and worldwide guidance of juvenile animal testing.

1952 CASE STUDIES: JUVENILE ANIMAL TESTING FOR PHARMACEUTICAL PRODUCTS.

S. Morseth. *Quintiles Consulting, Rockville, MD.*

Case studies of ten serve as excellent examples of the challenges associated with real life experiences based on either theoretical considerations or the lack of appropriate testing. This presentation will cover several case studies that are intended to demonstrate and emphasize major points made in the target organ presentations, to suggest an appropriate approach for designing juvenile animal studies, as well as to identify and clarify areas of basic research needed to better design future studies. Case studies will include examples from drugs commonly used by children, such as antibiotics used for numerous childhood infections; and glucocorticosteroids currently used as first line therapy for asthmatics. Several studies in children have shown that even nasal glucocorticosteroids can decrease total height. The case studies will also include illustrative examples of drugs that effect the central nervous system, such as methamphetamine, and cardiovascular drugs, such as verapamil. The case study presentations will end with an overview of the lessons learned from the case studies in order to identify future research, testing, and regulatory decisions.

1953 CADMIUM UPTAKE KINETICS IN RAT HEPATOCYTES: CORRECTION FOR ALBUMIN BINDING.

N. DelRaso[1], B. Foy[2] and J. Frazier[1]. [1]*AFRL/HEST, Wright-Patterson AFB, OH and* [2]*Wright State University, Dayton, OH.*

Primary rat hepatocytes isolated from male Fischer 344 rats were exposed to cadmium concentrations ranging from 0.42 to 1000μM in protein-free buffer or 32 to 8000 μM in buffer containing physiological albumin (~ 600μM). Cadmium toxicity following a 1 h exposure was observed to occur at free cadmium concentrations exceeding 80μM (equivalent to 1,000μM Cd in buffer containing albumin). A Scatchard plot of cadmium binding to albumin indicated a single high affinity binding site. This was supported by the finding of a rapid rise in free-cadmium concentrations at total cadmium concentrations greater than 1000μM (in the presence of albumin). Comparison of cadmium uptake rates (15 to 60 min) between hepatocytes exposed in buffer containing albumin and buffer lacking albumin indicated that uptake rates, when related to free-cadmium concentrations, were faster when hepatocytes were exposed in buffer containing albumin. In the presence of albumin in the exposure buffer a complex, dose-dependent uptake process was observed. The observed anomalous behavior of cadmium uptake in the presence of albumin is hypothesized to result from diffusion limited non-equilibrium conditions occurring at the cell surface.

1954 DIURETICS ENHANCE CADMIUM ENTRY IN DISTAL NEPHRON CELLS.

F. A. Gesek and K. J. DiPetrillo. *Dartmouth Medical School, Hanover, NH.*
Sponsor: J. W. Hamilton.

Cadmium (Cd) is an environmental pollutant of increasing concern due to its widespread use in batteries and anticorrosive agents. The kidney is the main target organ of Cd toxicity. Significant toxic effects of Cd are postulated to occur in the distal tubule (DT). The DT is the site that critically regulates Na excretion and dissociates Na and Ca reabsorption. The mechanism for the enhanced retention of Na that occurs in Cd-induced hypertension is unknown but likely to occur in DT. To test this we treated DT cells with 10 μM Cd for 6 hours then measured uptake of 22Na. Cd-increased Na entry by 30% from a basal rate of 289±25 to 377±32 nmols/min/mg protein in Cd-treated DT cells. Thiazide diuretics inhibit NaCl cotransport and amiloride inhibits epithelial Na channels (ENaC) in DT. Diuretics are commonly used first line agents to treat hypertension. Both diuretics increase Ca entry through dihydropyridine-sensitive Ca channels. To test if diuretics increase Cd uptake we measured 109Cd entry in DT cells. The basal rate of Cd entry in DT cells is 0.47±.02 nmols/min/mg protein. Cells treated with 100 μM chlorothiazide or 1 μM amiloride increased Cd uptake by 40 and 46%, respectively. Diuretic-induced uptake was abolished with the Ca channel blocker nifedipine. These findings provide evidence that diuretics increase Cd entry in DT through a dihydropyridine-inhibitable Ca channel. We conclude that Cd enhances Na entry in DT cells and that the clinical use of the diuretics amiloride and thiazides as antihypertensive agents may not be an appropriate choice for increasing Na excretion since these agents increase Cd absorption in DT cells. As a result, the concomitant use of these diuretics in workers exposed to Cd may enhance Cd nephrotoxicity.

1955 TUMOR NECROSIS FACTOR INCREASES CADMIUM UPTAKE IN THE DISTAL NEPHRON.

K. J. DiPetrillo and F. A. Gesek. *Dartmouth Medical School, Hanover, NH.*
Sponsor: J. W. Hamilton.

Cd is reported to induce release of inflammatory cytokines in the kidney. One cytokine released is tumor necrosis factor alpha (TNF-α). Receptors for TNF-α are located in the distal tubule (DT). We previously showed that TNF-α increases Na absorption and decreases parathyroid hormone (PTH)-stimulated Ca absorption in DT cells. To understand the role of TNF-a in DT toxicity, we tested the hypothesis that TNF-α regulates Cd absorption in DT cells. As an index of Cd entry, we measured 109Cd uptake in immortalized distal convoluted tubule cells. The basal rate of Cd entry in these cells is 0.45±.02 nmols/min/mg protein. DT cells treated with TNF-α (1 ng/ml) for 5 min exhibited a rate of 0.74±.02 nmols/min/mg protein, an increase of 64%. PTH stimulates Cd entry by activating dihydropyridine-sensitive Ca channels. PTH-stimulated Cd entry is blocked by nifedipine. To test if this is the mechanism for TNF-α stimulated Cd entry in DT cells, uptake was performed in cells pretreated with 10 μM nifedipine. There was no discernible difference in the basal rate of entry in DT cells treated with nifedipine (0.43 nmols/min/mg protein). TNF-α stimulated Cd entry was not blocked by nifedipine (0.71 nmols/min/mg protein). We conclude that TNF-α increases Cd entry in DT cells. The mechanism of entry is unknown but does not occur through nifedipine-inhibitable Ca channels. In summary, Cd induces TNF-α release and in turn stimulates Cd uptake in DT cells. Agents that prevent TNF-α synthesis or binding may alleviate TNF-α stimulated Cd uptake and nephrotoxicity.

1956 CADMIUM-INDUCED UP-REGULATION IN EXPRESSION OF THE REGULATORY γ-GLUTAMYLCYSTEINE SYNTHETASE SUBUNIT IN RAT LUNG AND ALVEOLAR EPITHELIAL CELLS.

G. Shukla, J. F. Chiu and B. Hart. *University of Vermont College of Medicine, Burlington, VT.*

Inhalation of cadmium (Cd) has been implicated as a causative factor in the development of several pulmonary diseases, including emphysema, pulmonary fibrosis, and cancer. Glutathione (GSH) is thought to play a pivotal role in modulating Cd toxicity. The controlled step in *de novo* GSH synthesis is catalyzed by γ-glutamylcysteine synthetase (γ-GCS), a dimeric enzyme consisting of a heavy (~ 72 kDa) catalytic subunit (γ-GCS-HS) and a light (~ 28 kDa) regulatory subunit (γ-GCS-LS). We previously reported that Cd exposure induces pulmonary γ-GCS-HS mRNA and protein and that these alterations in the catalytic subunit are accompanied by increases in GSH. The current study was designed to test the hypothesis that Cd exposure also up-regulates the gene expression of the regulatory γ-GCS subunit. Using a Northern blotting procedure, we demonstrate that a single 3 hr (nose-only) Cd aerosol exposure of Lewis rats results in time- and dose-dependent increases in the pulmonary levels of γ-GCS-LS mRNA. Transcripts of γ-GCS-LS in rat lung are maximally elevated (8-fold) 2 hrs following Cd inhalation exposure and remain significantly higher than air controls at 24 hrs. This response is highly correlated with Cd dose, that ranged from 0.9 mg Cd/m^3 to 5 mg Cd/m^3, and with lung Cd burden. We also examined Cd-induced regulation of γ-GCS-LS expression *in vitro* using an alveolar epithelial cell (AEC) line. Treatment of AECs by the addition of 10 μM $CdCl_2$ to the culture medium also caused increases in γ-GCS-LS mRNA that achieved levels approximate-

ly 13-fold higher than in unexposed cells. Epithelial cells that were made resistant to Cd by repeated culturing in Cd-containing medium also had γ-GCS-LS mRNA levels about 4-fold higher than cells that were not adapted to Cd. The studies presented support the conclusion that coordinate up-regulation in the gene expression of the regulatory and the catalytic subunits of γ-GCS occurs in the lungs of rats following inhalation of Cd aerosols and in AECs exposed to Cd *in vitro*. These responses may contribute to pulmonary Cd resistance.

1957 INHIBITION OF DNA-(CYTOSINE-5) METHYLTRANSFERASE ACTIVITY BY CARCINOGENIC METALS.

M. Takiguchi and M. P. Waalkes. *Laboratory of Comparative Carcinogenesis, NCI at NIEHS, Research Triangle Park, NC.*

Several different metal compounds have been identified as human carcinogens. The methylation of cytosine by the DNA-(cytosine-5) methyltransferase (DNA-MeTase) is the predominant post-replication base modification and defects resulting in hypo- or hyper-methylation of particular DNA sequences have also been shown to be either the cause or consequence of malignant transformation. Therefore, we have carried out a study on the effects of a series of metals (As^{3+}, As^{5+}, Cd^{2+}, Cr^{6+}, Ni^{2+}, Pb^{2+}, Zn^{2+}) on the DNA-MeTase activity. Both lysed rat liver epithelial cells (TRL 1215) or purified bacterial *M. SssI* were used as the source of DNA-MeTase. Regardless of source, the activity of DNA-MeTase was found to be strongly inhibited by a number of metal ions. Cd^{2+} (IC_{50} = 25 μM) was the most effective followed by Zn^{2+}, Pb^{2+}, and Ni^{2+}. Only in the case of mammalian cell lysis did As^{3+} inhibit the activity of DNA-MeTase. Kinetic analysis revealed Cd^{2+} to be a noncompetitive inhibitor with respect to DNA, and an uncompetitive inhibitor with respect to the methyl donating co-factor for DNA-MeTase, S-adenosylmethionine. These results indicate that Cd^{2+} interacts with DNA binding domain on DNA-MeTase. DNA-MeTase activity in intact TRL 1215 cells, when treated with 10 μM Cd for 24 hours, was depressed by up to 84%. During longer exposure experiments 0.5-2.5 μM Cd was used. After 1 week of Cd exposure, DNA-MeTase activity in cells was decreased in a concentration dependent fashion. Although Cd decreased DNA-MeTase activity, global DNA hypermethylation occurred after Cd exposure for 10 weeks. These results raise the possibility that one of the mechanisms of Cd^{2+} carcinogenicity could be an induction of abnormal DNA methylation. For other carcinogenic metals such as As^{3+}, Pb^{2+} or Ni^{2+} altering DNA methylation status may also contribute to their carcinogenic effects.

1958 ARSENIC-SELENIUM INTERACTIONS IN HUMAN AND RAT HEPATOCYTES.

M. Styblo[1], E. L. LeCluyse[2], G. A. Hamilton[2] and D. J. Thomas[3]. [1]*Department of Pediatrics, School of Medicine, University of North Carolina, Chapel Hill, NC,* [2]*Division of Drug Delivery and Disposition, School of Pharmacy, University of North Carolina, Chapel Hill, NC and* [3]*Experimental Toxicology Division, NHEERL, USEPA, Research Triangle Park, NC.*

Arsenic (As) and selenium (Se) are metalloids that share chemical properties and metabolic fates. The metabolism of either metalloid involves glutathione (GSH)-dependent reduction and enzymatic methylation to mono-, di- and trimethylated metabolites. Each metalloid modifies the metabolism and toxicity of the other in laboratory animals. It has been suggested that Se might be used as an antidote to mollify the adverse effects associated with exposure to As in humans. The present work examines the effects of Se on the metabolism and toxicity of As in primary cultures of human and rat hepatocytes. The simultaneous addition of 2 μM sodium selenite (Se^{IV}) to cultures significantly increased cellular retention and inhibited methylation of 0.1 μM sodium arsenite (iAs^{III}) in both cell types. The ratio of the methylated metabolites, dimethylarsenic (DMAs): monomethylarsenic (MAs), decreased markedly in the presence of Se^{IV}, suggesting that synthesis of DMAs from MAs may be more susceptible to inhibition by Se^{IV} than is the production of MAs from iAs^{III}. The inhibitory effect of Se^{IV} was concentration-dependent and enhanced by concurrent addition of 2.5 mM GSH. The addition of 2 μM Se^{IV} into the culture 24 hours before addition of 0.1 or 1 μM iAs^{III} increased cellular retention of iAs^{III} but did not alter the rate and yield of the methylation reactions. 24-hour exposure to 2 μM Se^{IV} had no effect on the viability of cultured hepatocytes. Concurrent addition of 2 μM Se^{IV} increased the cytotoxicity of iAs^{III} and its trivalent metabolites, MAs^{III} and $DMAs^{III}$. GSH effectively protected cells against toxicity of arsenicals. However, the protective effect of GSH was significantly less in the presence of Se^{IV}. These data suggest that treatment with Se may in fact enhance the toxic effects of As, increasing its retention in tissues and reducing its methylation which may be pathway for the detoxification of As. (This abstract does not necessarily reflect EPA policy.)

1959 DMPS MODULATION OF ARSENIC SPECIES, INCLUDING MONOMETHYLARSONOUS ACID (MMAIII), IN HUMAN URINE.

S. M. Healy[1], H. V. Aposhian[1], B. Zheng[2], M. M. Aposhian[1], X. C. Le[3], M. E. Cebrian[4], W. R. Cullen[5], R. A. Zakharyan[1] and R. C. Dart[6]. [1]*University of Arizona, Tucson, AZ,* [2]*Institute of Geochemistry, Guiyang, China,* [3]*University of Alberta, Edmonton, Alberta, Canada,* [4]*CINVESTAV-IPN, Mexico D.F., Mexico,* [5]*University of British Columbia, Vancouver, British Columbia, Canada and* [6]*Rocky Mountain Poison and Drug Center, Denver, CO.*

The administration of sodium 2,3-dimercapto-1-propane sulfonate (DMPS) to humans chronically exposed to inorganic arsenic in their drinking water resulted in the increased urinary excretion of arsenic, the appearance and identification of monomethylrsonous acid (MMAIII) in their urine and a large decrease in the urinary excretion of dimethylarsinic acid (DMA). Experiments were designed to understand the appearance of MMAIII and decrease of DMA in the urine. DMPS, *in vitro*, inhibited rabbit liver MMAIII methyltransferase. This and other evidence supports the hypothesis that DMPS competes with endogenous ligands for MMAIII, forming a complex that is readily excreted in the urine and points out the need for studying the toxicology of MMAIII. The results of these studies raise many questions about the potential central role of MMAIII in the toxicity of inorganic arsenic and to the potential involvement of MMAIII in the little understood etiology of hyperkeratosis, hyperpigmentation and cancer that can result from chronic inorganic arsenic exposure. (Supported in part by Superfund Basic Research Program NIEHS Grant ES-04940 and Southwest Environmental Health Sciences Center Grant P30-ES-06694.)

1960 MEDICAL MONITORING SURVEY RESULTS AND BERYLLIUM EXPOSURE AT A BERYLLIUM MINE AND EXTRACTION FACILITY.

M. Kelsh[1], D. Deubner[2], L. Maier[3], M. Kent[2], B. Smith[1], P. Chapman[1], K. Zhao[1], D. J. Paustenbach[1] and M. Kolanz[4]. [1]*Exponent, Menlo Park, CA,* [2]*Brush Wellman Inc., Elmore, OH,* [3]*National Jewish Center, Denver, CO and* [4]*Brush Wellman Inc., Cleveland, OH.*

A survey to evaluate employees for beryllium sensitization and chronic beryllium disease (CBD) was conducted at the Brush Wellman Inc. mine and beryllium extraction mill in Delta, Utah, using a medical history and the beryllium blood lymphocyte proliferation test (BLPT). Historical industrial hygiene data, including general area, breathing zone, and limited personal lapel measurements were used to assess the levels of ambient beryllium exposures at this worksite. Beryllium exposures at this facility occur as a result of the presence of dust from bertranite (hydrated beryllium silicate) and beryl (beryllium aluminum silicate) ores, mists containing soluble beryllium salts (beryllium sulfate, beryllium ammonium carbonate and beryllium carbonate), and the precipitation and packaging of the plant's end product, hydrated beryllium hydroxide. 76 of 85 current employees agreed to participate. The rates of beryllium sensitization (4%) and CBD (1.4%) at Delta were intermediate compared to rates expected in the general population (1% and 0% respectively) and those found in other company beryllium surveillance programs (6% and 4% respectively), but were not significantly different from either reference point (P values > 5%). Furthermore, the one case of CBD detected was in the only individual who had spent significant time working elsewhere with beryllium (10 years) where clinical and subclinical CBE is more prevalent. Excluding this individual, the plant has never detected a case of CBD in current or former workers, which yields a rate of CBD significantly lower than that observed in persons ever employed at either the Elmore and Tucson facilities. Former and current levels of occupational exposure to airborne beryllium at the three plants are comparable. We hypothesize that differences in rates of sensitization and CBD result from the a) low bioavailability of beryllium in ore dusts, b) low potency of soluble beryllium salts, and c) localized presence of beryllium hydroxide and/or d) differences in work practices and personal protection controls.

1961 LUMINAL TRANSPORT OF DI-N ACETYLCYSTEINYLMERCURY ($(NAC)_2$ -HG) IN THE RABBIT PROXIMAL TUBULE.

D. W. Barfuss[1] and R. K. Zalups[2]. [1]*Georgia State University, Atlanta, GA and* [2]*Mercer University, Macon, GA.*

Previous animal experiments indicate that inorganic mercury is not taken up or accumulated significantly when it is in the proximal tubular lumen in the form of a di-*N*-acetylcysteinylmercury ($(NAC)_2$-Hg) complex. These studies do, however, indicate that $(NAC)_2$-Hg is taken up by cortical epithelial cells via transport mechanism(s) in the basolateral membrane. To extend these findings further we studied the luminal disappearance rate and cellular uptake of $(NAC)_2$-Hg in isolated perfused S_2 segments of the rabbit proximal tubule. The perfusion fluid was a balanced saline solution that contained 20μM Hg^{++} and 80μM *N*-acetylcysteine. Under these conditions the disappearance rate of $(NAC)_2$-Hg from the luminal fluid was 9.6 fmol min^{-1} (mm tubule length)$^{-1}$ while cellular accumulation was 103.6 fmol (mm tubular length)$^{-1}$. In pervious studies with dicysteinylmercury these values were 102 and 169 respectively. This is in contrast to the luminal disappearance rate of125.5 fmol min^{-1} (mm tubular length)$^{-1}$ and cellular accumulation of 1147.4 fmol (mm tubular length)$^{-1}$ when tubules were perfused with the balance saline solution containing 20μM Hg^{2+} only. The presence of NAC in the lumen eliminated the acute toxicity that is present in tubules perfused with Hg^{2+} alone. No evidence of cellular blebbing, tubular swelling or cellular uptake of the vital dye were detected. When NAC (200μM) was present in the bathing solution and 20μM Hg^{2+} in the perfusate only, the disappearance rate of Hg^{2+} from the lumen was reduced to 77.4 fmol min^{-1}(mm tubular length)$^{-1}$, while cellular accumulation was reduced to 368 fmol (mm tubular length)$^{-1}$. The acute toxicity in these tubules was reduced but not eliminated. We conclude that $(NAC)_2$-Hg is not transported well at the luminal membrane of the S_2 segment of the proximal tubule. This confirms our findings from intact animals. Also, when NAC is present in the bathing solution, it provides protection to perfused proximal tubular segments from toxic effects of luminal Hg^{2+}.

1962 WATER LEAD EXPOSURE IN BRUSSELS CHILDREN.

A. Y. Steenhout. *Free University of Brussels, Brussels, Belgium.* Sponsor: G. J. Pounds.

Water lead exposure has been studied in houses inhabited by young children in Brussels, with 3 types of sampling: (1) overnight stagnation, (2) running water at the end of a volume used for preparing meal (3) stagnation daytime til return from work. Values higher than WHO 10μg/l are encountered even in flushed water. 37% of the houses display water Pb content higher than 10μg/l at least in one sample. Whereas Pb pipes or mixed (i.e., Pb and Cu) material account for more than 3/4 of the cases >10μg/l, 1/4 of the excessive amounts occur within pipes in other material than Pb (Cu, galva, PVC). Concern about drinking water quality is increased in lower socio-economic status (SES) families: poorer calcium intake, a factor of enhanced Pb ingestion, is more frequent in children in ancient housing with lead piping. WHO guideline has just been included in the new drinking water European directive, but for up to 15 yrs, the intermediate 25μgPb/l upper value will be accepted. More than 17% of the houses show water lead higher than this upper value. By reference to our risk assessment model ECOTOX (presented in 1998 SOT meeting), the increment in blood lead resulting from various sources can be evaluated, as well as the prevalence of blood lead higher than 10μg/dl. Even in houses without lead paints in Brussels, a level of 25μg/l is not be considered as safe, or the acceptable uptake from other sources should be reduced as well.

1963 DISTINCT EFFECTS OF LEAD ON INDIVIDUAL PROTEIN KINASE C ISOFORMS.

A. A. Coppi, D. Zieba and F. A. X. Schanne. *St. John's University, Jamaica, NY.*

Lead is an important toxicant that can affect the function of several different organ systems over a range of exposures and blood levels. Protein kinase C (PKC) has been identified as an extremely high affinity target of lead in several cells and tissues, with lead inducing activation of this kinase at concentrations less than 10^{-9} M. PKC is a family of ser/thr kinases with some isoforms that normally require calcium for activation and others that do not. In this study, the ability of lead to activate individual calcium-dependent and calcium-independent isoforms of PKC was examined. PKC isoforms were made from human cDNAs expressed in a baculovirus sf9 system. Free divalent lead and calcium concentrations were set using 5F-BAPTA as a buffer and free metal concentrations were confirmed using ^{19}F NMR. Of the calcium-dependent isoforms, PKC alpha was most sensitive to activation. Lead activated PKC alpha to the same extent as calcium but at lead concentrations from 10^{-11} to 10^{-7} M compared to calcium concentrations from 10^{-7} to 10^{-4} M. PKCs beta and gamma were not as potently activated by lead. PKC gamma was most sensitive to inhibition, with inhibition by lead occurring at concentrations greater than 10^{-9} M. Neither PKC delta nor epsilon, calcium-independent isoforms, was activated by lead or by calcium. PKC epsilon was the most sensitive to inhibition, with complete inhibition at 10^{-9} M lead. These data demonstrate that only calcium dependent isoforms of PKC are activated by lead suggesting that lead simply replaces calcium in the activation of the enzyme. However, lead does not replace calcium with the same effectiveness in all calcium dependent isoforms. Furthermore, the sensitively to inhibition by lead differs greatly across this family of kinases. Altogether, these findings indicate that while low levels of lead may activate the overall PKC activity in cells and tissues, the specific effects of lead on the PKC signal transduction may depend on both the specific isoform composition of the cells and the specific free lead concentration achieved upon exposure.

1964 FERRITIN IS A NUCLEAR PROTEIN THAT RESPONDS TO CELL STRESS AND PROTECTS DNA.

K. Thompson, Z. Ye and J. R. Connor. *Pennsylvania State University, Hershey, PA.* Sponsor: E. Malecki.

The cytoplasmic iron storage protein ferritin has been recently described as a transiently expressed protein in select cell nuclei. Within nuclei, ferritin's function may involve both DNA protection and DNA damage. We found ferritin is present in neuronal nuclei in both humans and rodents at early postnatal periods but is predominantly cytoplasmic in the adult. In adult mice, ferritin can be induced to return to neuronal nuclei by hypoxic ischemic insult indicating selective cell expression and suggesting a protective role. We established a cell culture model to determine the mechanism and consequence of ferritin nuclear translocation using human astrocytoma cells. Ferritin's presence in the nucleus increases by increasing cellular iron levels and through exposure to hydrogen peroxide and cytokines indicating cell stress as a factor in inducing ferritin movement into the nucleus. In vitro extracellular uptake studies reveal that H-ferritin is selectively taken up into the nucleus, whereas extracellular L-ferritin remains cytoplasmic. Nuclear translocation of ferritin is blocked by wheat germ agglutinin, ATP depletion, and incubation at 4°C indicating entry through an active nuclear pore. Cycloheximide treatment decreased ferritin nuclear levels indicating that the presence of ferritin in the nucleus is post-transcriptionally regulated and requires de novo synthesis. Cells in which ferritin is removed from the nucleus and translocation blocked with WGA are susceptible to hydrogen peroxide induced DNA damage. Supercoil relaxation assays found H-ferritin protects DNA better than other weak iron binding proteins. In conclusion, this study presents evidence for the novel findings that localization of ferritin to cell nuclei is ferritin subunit specific, post-transcriptionally regulated, actively transported into the nucleus through nuclear pore complexes *in vitro*, and protects DNA. These data expand the function of ferritin and suggest ferritin nuclear localization is a well-regulated cellular event that responds to cell stresses and protects DNA from oxidative damage.

1965 PEROXISOME PROLIFERATOR ACTIVATED RECEPTOR ALPHA: SPECIES DIFFERENCES IN QUALITY AND QUANTITY.

N. Macdonald, K. Lambe, N. J. Woodyatt and R. A. Roberts. *AstraZeneca CTL, Macclesfield, United Kingdom.*

Peroxisome proliferators (PPs) are nongenotoxic rodent hepatocarcinogens that cause liver enlargement and hepatocarcinogenesis associated with peroxisome proliferation, induction of hepatocyte DNA synthesis and suppression of apoptosis. Acyl CoA oxidase (ACO) is a key enzyme of peroxisomal β-oxidation and its transcriptional activation by PPs is often used as marker for the rodent response. PPs activate the peroxisome proliferator activated receptor-alpha, PPARα. There are marked species differences in response to nongenotoxic carcinogens and the data available support the position that human and guinea pigs are resistant to the adverse effects of PPs seen in rodents. Species differences could be attributed both to quantity of PPARα and the quality of the PPARα-mediated response. Human and guinea pig liver has a reduced quantity of full length functional PPARα; we and others have found hPPARα8/14, a truncated receptor that results from aberrant splicing of the PPARα mRNA, in all samples at levels of between 10-40% relative to the full length hPPARα. To determine if species differences in response to PPs are due to the low levels of PPARα in nonresponsive species, we over-expressed PPARα in guinea pig hepatocytes and monitored PCO as a measure of perox-

isome proliferation. As expected, control guinea pig hepatocytes failed to respond to PPs but the overexpression of mouse, human or guinea pig PPARα conferred responsiveness. This induction of PCO in guinea pig hepatocytes over-expressing PPARα demonstrates that species differences in quantity of PPARα is at least in part responsible for species differences in response. In addition, species differences could be attributed to qualitative differences in the PPARα-mediated response since we have shown recently that the promoter for human ACO differs in sequence and activity from the rat equivalent. Additionally, back mutagenesis of the rat ACO PPRE to the human sequence resulted in a loss of activity at the rat promoter. These data contribute to our understanding of how chemicals may cause tumours in rodents and how this response may differ in humans.

1966 USE OF MICROARRAY EXPRESSION PROFILING IN PPARα NULL AND WILD-TYPE MICE TO INVESTIGATE THE MECHANISM OF HEPATOCARCINOGENESIS INDUCED BY THE PEROXISOME PROLIFERATOR DIETHYLHEXYLPHTHALATE (DEHP).

G. Orphanides[1], N. H. James[1], S. Chevalier[1], W. D. Pennie[1], I. Kimber[1], F. J. Gonzalez[2], J. Peters[2] and R. A. Roberts[1]. [1]*AstraZeneca Central Toxicology Laboratory, Macclesfield, United Kingdom and* [2]*NCI, Bethesda, MD.*

Peroxisome proliferators (PPs) are a diverse group of chemicals that cause non-genotoxic hepatocarcinogenesis in rodents. Administration of PPs to rodents results in peroxisome proliferation, suppression of apoptosis, hepatocellular proliferation and, ultimately, hepatocarcinogenesis. The adverse effects of these compounds are mediated by the PPARα receptor (Peroxisome Proliferator Activated receptor α). Mice lacking functional PPARα do not exhibit the characteristic response to PPs and do not develop liver tumours. In addition, hepatocytes isolated from PPARα null mice are refractory to the effects of PPs, including induction of fatty acid oxidising enzymes and suppression of apoptosis. We have used microarray gene expression profiling to examine in greater detail alterations in mouse hepatocyte gene expression associated with activation of PPARα. PPARα null and wild-type mice received diethylhexylpthalate (DEHP; 1150 mg/Kg in corn oil) daily for two days by gavage and their livers isolated at 48 hrs after the first administration for extraction of mRNA. Probes generated from these mRNAs were hybridised to custom-made cDNA microarrays containing approximately 1200 cDNA sequences representing 600 genes relevant to mechanisms of toxicity. Using this approach, we have identified genes regulated by PPARα in response to DEHP which may be implicated in cellular proliferation and hepatocarcinogenesis. These include genes involved in lipid metabolism in the liver and several genes not previously known to be regulated by PPs.

1967 ROLE OF PPAR ALPHA IN HEPATIC RESPONSES TO DIISONONYL PHTHALATE (DINP).

E. G. Valles[1], A. Laughter[1], C. Dunn[1], R. C. Cattley[2] and J. C. Corton[1]. [1]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC and* [2]*Amgen, Thousand Oaks, CA.*

Diisononyl phthalate (DINP) is a compound widely used as a plasticizer in the production of polyvinyl chloride (PVC) products. Many phthalates are considered to be relatively weak peroxisome proliferators (PP), a group of rodent hepatocarcinogens that cause a variety of adaptive responses in liver through the PP-activated receptor alpha (PPAR). The objective of this study was to determine if DINP-induced effects in the liver are mediated by PPAR. Male and female SV129 PPAR-null (-/-), SV129 PPAR (+/+) and B6C3F1 mice were fed a control diet or a diet containing 8000 ppm of DINP for 1 or 3 weeks. There was an increase in relative liver weight in male and female PPAR (+/+) and B6C3F1 mice exposed for 1 week. The increase in liver weights was abolished in the 1 week treated male and female PPAR (-/-) mice. Western blot analysis of liver protein extracts demonstrated a strong induction of acyl-CoA oxidase and Cyp4a proteins in PPAR (+/+) but not PPAR (-/-) female mice after a 3 week exposure. Preliminary experiments using arrays containing 144 genes showed that 6 genes were altered in livers after a 3 week exposure in female PPAR (+/+) but not in PPAR (-/-) mice. These genes include those involved in drug metabolism and protein trafficking. These data support the hypothesis that DINP, like other PP induces liver effects through a PPAR alpha-dependent mechanism.

1968 SUPPRESSION OF APOPTOSIS AND INDUCTION OF DNA SYNTHESIS BY THE PEROXISOME PROLIFERATORS MONOETHYLHEXYLPHTHALATE (MEHP) AND DIISONONYLPHTHALATE (DINP): A COMPARISON OF RAT AND HUMAN HEPATOCYTES *IN VITRO.*

S. C. Hasmall, N. H. James, N. Macdonald, D. West, S. C. Chevalier, S. C. Cosulich and R. A. Roberts. *AstraZeneca CTL, Macclesfield, United Kingdom.*

Diethylhexylphthalate (DEHP) and diisononylphthalate (DINP) are plasticizers with many important commercial, industrial and medical applications. However, both DEHP and DINP are rodent peroxisome proliferators, a class of compounds that cause rodent liver tumours associated with peroxisome proliferation, induction of hepatic DNA synthesis and the suppression of apoptosis. Despite these effects in the rodent, humans appear to be nonresponsive to the adverse effects of PPs. Previously, we have shown that the fibrate hypolipidaemic peroxisome proliferator, nafenopin, induced DNA synthesis and suppressed apoptosis in rat but not in human hepatocytes. Here, we have examined species differences in the response of rat and human hepatocytes to DEHP and DINP *in vitro*. In rat hepatocytes *in vitro*, both DINP and MEHP (a principle metabolite of DEHP and the proximal peroxisome proliferator) caused a concentration-dependent induction of DNA synthesis and suppression of both spontaneous and TGFβ1-induced apoptosis. Similarly, both MEHP and DINP caused a concentration-dependent induction of peroxisomal β-oxidation although the response to DINP was less robust. In contrast to the pleiotropic response noted in rat hepatocytes, neither DINP nor MEHP caused an induction of β-oxidation, stimulation of DNA synthesis or suppression of apoptosis in human hepatocytes cultured from three separate donors. These data provide evidence for species differences in the hepatic response to the phthalates DEHP and DINP, suggesting that human hepatocytes are refractory to the hepatocarcinogenic effects of PPs noted in rodents.

1969 THE USE OF PROTEOMIC TECHNOLOGY AND AN EPIDERMAL GROWTH FACTOR RECEPTOR TYROSINE KINASE INHIBITOR TO COMPARE PEROXISOME PROLIFERATOR AND GROWTH FACTOR - INDUCED S PHASE.

S. Chevalier[1], N. Macdonald[1], R. Tonge[2], J. Sykes[2], M. Davison[2] and R. A. Roberts[1]. [1]*AstraZeneca CTL, Macclesfield, United Kingdom and* [2]*AstraZeneca Pharmaceuticals, Macclesfield, United Kingdom.*

Rodent hepatocytes undergo rapid proliferation in response to peroxisome proliferators, a diverse group of chemicals of therapeutic, industrial and environmental significance. It has been suggested that peroxisome proliferators may cause tumors by altering the epidermal growth factor (EGF) signalling pathway and therefore inducing DNA synthesis and cell proliferation in rodents. In rat primary hepatocyte cultures, EGF (1 ng/ml) induced a 3.27-fold increase, HGF (0.5 ng/ml) a 2.84-fold increase, and the peroxisome proliferator nafenopin a 1.92 fold increase in S phase. A specific EGF-Receptor tyrosine kinase inhibitor (4-anilinoquinazoline; EGFR-TKI) efficiently inhibited EGF -induced S phase but did not prevent HGF-induced S phase. Nafenopin-induced S phase remained at 1.91 fold in the presence of the EGFR-TKI, indicating that signalling through EGF-R is not required for nafenopin to induce DNA replication. Cyclin-dependent kinases (CDKs) and cyclins allow cells to progress from G1 to S phase in response to growth factors. Cyclin E, cyclin D1, CDK4 and CDK2 accumulated upon stimulation with nafenopin although their expression was delayed by 24 hours compared to EGF stimulation. Overall, there was no gross dysregulation of the CDK and cyclin protein expression profile upon stimulation with nafenopin. Using proteomic technology, we compared the molecular mechanisms that induce hepatocyte proliferation in response to peroxisome proliferators or EGF. BioImage analysis of highly reproducible 2 dimensional-gels have indicated that the stimulation of S phase with nafenopin produces a protein profile different to its vehicle control (DMF) and to EGF. Stimulus dependent differences in protein expression have been analysed, and individual proteins with altered expression have been identified by mass spectrometry.

1970 HEPATIC EXPRESSION OF DNA POL BETA, REF-1, BCL-2 AND BAX PROTEINS IN PEROXISOME PROLIFERATOR(PP)-TREATED RATS AND HAMSTERS.

E. W. Holmes[1], C. M. Bingham[1], A. Keshavarzian[2] and M. L. Cunningham[3]. [1]*Loyola University Stritch School of Medicine, Maywood, IL,* [2]*Rush Presbyterian St. Luke's Medical Center, Chicago, IL and* [3]*NIEHS, Research Triangle Park, NC.*

The mechanism of PP-induced hepatocarcinogenesis and the basis for species differences in the tumorigenic potential of the PP's in mammals have yet to be fully elucidated. We investigated the hepatic expression of oxidant-sensitive gene products in male SD rats(R) (which are relatively susceptible to PP-induced tumors) and male Syrian hamsters(H) (which are relatively resistant) after 6 days of ad lib administration of feed containing one of the following PP's at the level indicated: WY-14,643 (WY): 500 ppm; gemfibrozil (G):16,000ppm(R) or 24,000ppm(H); 2,4-dichloro phenoxyacetic acid (24D): 2,500ppm(R) or 5,000ppm(H); dibutyl phthalate(DBP): 20,000 ppm. Proteins in liver supernatants from treated animals and matched controls were separated by one-dimensional SDS-PAGE and transferred to PVDF membranes. Relative levels of protein expression were estimated by immunoblotting, scanning densitometry and image analysis. Evaluation of constitutive protein expression in untreated R and H showed: a 6-fold increase in 38 kD Pol Beta in R as compared to H; a 20-fold increase in 35 kD Ref-1 and a 1.5-fold increase in 19 kD Bax in H as compared to R; expression of 26kD Bcl-2 in H but not in R. PP treatment was associated with the induction of a novel 47 kD isoform of Pol Beta in R but not in H. This isoform was only slightly induced by 24D but markedly induced by the other 3 PP's. The expression of 35 kD Ref-1 was increased 6-fold in WY treated R but decreased to 30% of control levels in treated H. PP treatment did not significantly affect the expression of 19 kD Bax or 26 kD Bcl-2. These results suggest that increased basal and PP-induced expression of Pol Beta, which has poor fidelity compared to other DNA polymerases, may lead to cancer predisposition and tumor progression in R. The WY-related increase in Ref-1 expression in R is consistent with an increase in oxidative stress to the liver. A decreased constitutive Ref-1 expression in R as compared to H suggests a significant species difference in the capacity for DNA repair. (Supported by 1 R03 ES09783-01 to EWH.)

1971 GLUTATHIONE RELATED ENZYME ACTIVITIES IN RATS AND HAMSTERS ADMINISTERED THREE PEROXISOME PROLIFERATORS: DIBUTYL PHTHALATE, GEMFIBROZIL, AND WY-14,643.

M. L. O'Brien, B. T. Spear and H. P. Glauert. *University of Kentucky, Lexington, KY.*

Peroxisome proliferators (PPs) are a diverse group of compounds that cause hepatomegaly and peroxisome proliferation, ultimately resulting in hepatocarcinogenesis, in rats and mice. Conversely, species such as humans and hamsters are non-responsive to these compounds. PPs are non-genotoxic carcinogens that activate the peroxisome proliferator activated receptor (PPAR), resulting in increased transcription of genes involved in peroxisomal beta-oxidation. This increased peroxisomal beta-oxidation has been hypothesized to result in oxidative stress. We hypothesized that differential modulation of antioxidant enzymes and/or cofactors could account for the resulting difference in species susceptibility following PP administration. Accordingly, we have measured glutathione transferase (GST), Se and non-Se dependent glutathione peroxidase (GPx), and glutathione reductase (GR) activities as well as total glutathione (GSH) in male Sprague Dawley rats and Syrian hamsters fed two doses of three known peroxisome proliferators [dibutyl phthalate (DB), gemfibrozil and Wy-14,643] for 6, 34, or 90 days. In rats, a decrease in GR, GST, and Se-GPx was observed following the administration of Wy-14,643 and DB; the effect following DB treatment was less than that seen with the more potent PP Wy-14,643. A decrease in total GSH was also observed with both compounds. Rats treated with gemfibrozil had elevated GR and total GSH; however, Se-GPx was decreased in the 90-day treatment group. In hamsters, we observed a higher basal level of activities for GR, GST, and Se-GST as compared to rats. In addition, hamsters also showed a decrease in GR and GST activities but had increased total GSH following Wy-14, 643 administration. Gemfibrozil treatment in hamsters increased GR but decreased GST activity. Interestingly, Se-GPx activity was increased in hamsters at various time points in DB and gemfibrozil treatment groups and in all three-time points of the Wy-14, 643 group. Furthermore, the decrease in GPx1 in rats was not at the mRNA level, while the increase in hamsters correlated with an increase in mRNA. This divergence in the hydrogen peroxide detoxification ability between rats and hamsters could be a contributing factor in the proposed oxidative stress mechanism of PP's observed in responsive and non-responsive species. (Supported by ES 09771.)

1972 EFFECTS OF 9-CIS, 11-TRANS CONJUGATED LINOLEIC ACID (CLA) ON HUMAN HT-29 COLON CARCINOMA CELLS.

S. A. Khan, E. Zajko and J. P. Vanden Heuvel. *Penn State University, University Park, PA.*

Epidemiological studies have demonstrated a strong correlation between dietary fat intake and the development of colon cancer. Interestingly, conjugated linoleic acid (CLA), an animal-derived dietary fat consisting of a group of linoleic acid isomers, inhibits several animal models of chemical carcinogenesis including colon cancer. The anti-cancer mechanism of CLA remains unclear. Our data for the first time indicate that 9-cis, 11-trans CLA significantly inhibits cellular proliferation of the colon epithelial cell line HT-29 following a twenty four hour treatment; the effect was similar to 15-deoxy-Δ12, 14- PGJ2, a natural PPAR gamma ligand. Equimolar concentration of linoleic acid however, failed to produce any effect on cell growth. Lactate dehydrogenase activity measured in the growth media was found not to be different from the untreated cells suggesting absence of toxic effects produced by the compound per se. Induction of apoptosis may not be an anti-cancer mechanism of 9-cis, 11-trans CLA as it did not increase caspase-3, a marker of apoptotic cell death. Since PPAR gamma has been previously reported to be associated with cellular differentiation and CLA has been shown to activate this steroid hormone receptor, we propose that CLA's anti-cancer effect may be via enhanced cellular differentiation. We are testing this hypothesis by examining CEA (carcinoembryonic antigen) gene in 9-cis, 11-trans CLA-treated colon cancer cells utilizing RT-PCR techniques. (Supported by PDA grant ME 448435.)

1973 NADPH OXIDASE IS THE SOURCE OF OXIDANTS FOR ACTIVATION OF NF-κB BY THE PEROXISOME PROLIFERATOR WY-14,643.

I. Rusyn[1], R. Schoonhoven[3], B. Segal[4], S. M. Holland[4], R. C. Cattley[5], J. A. Swenberg[1,3] and R. G. Thurman[1]. [1]*Curriculum in Toxicology, UNC-CH, Chapel Hill, NC, Department of* [2]*Pharmacology and* [3]*Environmental Sciences & Eng., UNC-CH, Chapel Hill, NC,* [4]*Lab. of Host Defences., NIAID, Bethesda, MD and* [5]*CIIT, Research Triangle Park, NC.*

The role of oxidants in the mechanism of tumor promotion by peroxisome proliferators (PPs) remains controversial. The idea that induction of acyl-CoA oxidase leads to increased production of H_2O_2 which damages DNA appears unlikely; still, radicals might be important in signaling in specialized cell types such as Kupffer cells, which produce mitogens (*e.g.*, TNFα) and increase proliferation of hepatocytes. In fact, it was shown that superoxide production by isolated Kupffer cells is stimulated by PPs (*e.g.*, WY-14,643) and that activation of transcription factor NF-κB by PPs occurs in Kupffer cells and is oxidant dependent. Since NADPH oxidase is the major source of radicals in Kupffer cells, it was hypothesized that this enzyme is involved in production of oxidants *in vivo* after treatment with PPs. Indeed, both the activation of NF-κB and an increase in cell proliferation due to a single dose of WY-14,643 (WY, 100 mg/kg, *i.g.*) were prevented completely when rats were pretreated with the NADPH oxidase inhibitor diphenyleneiodonium (1 mg/kg, *s.c.*) for 4 days. Further, NADPH oxidase deficient ($p47^{phox}$-/-) mice were used to specifically address the hypothesis of NADPH oxidase involvement. When mice were fed WY-containing (0.1% w/w) or control (NIH-07) diets for 7 days, the increase in liver weight and cell proliferation caused by WY in +/+ mice was blocked in $p47^{phox}$ -/- mice. Moreover, in +/+ mice, WY (100 mg/kg, *i.g.*) caused a 2.5-fold activation of NF-κB in liver 5-8 hrs after treatment. This effect was followed by an increase in mRNA levels for mitogenic cytokines (*i.e.*, TNFα, IL-6). Importantly, neither activation of NF-κB nor increase in cytokine transcription occurred in $p47^{phox}$-/- mice. It is concluded that PPs activate NADPH oxidase to produce superoxide which increases NF-κB. This triggers production of mitogens and causes hepatocellular proliferation characteristic of this class of carcinogens (ES 04325).

1974 EFFECT OF WY-14,643 ON THE METHYLATION AND EXPRESSION OF C-*MYC* AND CONNEXINS-26 AND -32 IN THE LIVER OF B6C3F1 MICE AND SPRAGUE-DAWLEY RATS.

R. Ge[1], M. Fernstrom[1], L. Tao[1], M. Cunningham[2], R. J. Ruch and M. A. Pereira. [1]*Medical College of Ohio, Toledo, OH and* [2]*NIEHS, Research Triangle Park, NC.*

Peroxisome proliferators including Wy-14,643 are carcino-genic in rodent liver. Increased expression of protooncogenes and decreased expression of

connexin have been associated with non-genotoxic carcinogens. One mechanism controlling expression of these genes is the presence of 5-methylcytosine in their promoter regions resulting in decreased expression. Male $B6C3F_1$ mice and male Sprague-Dawley rats were administered Wy-14,643 (0,10, 50, 100 and 500 mg/kg diet) for 6, 34, or 90 days. Exposure of mice to Wy-14,643 resulted in the liver in decreased methylation in the promoter region of the C-*myc* gene as determined by *Hpa* II restriction endonucle-ase digestion and Southern blot analysis. However, expression of the mRNA for C-*myc* was not altered. In rat liver, Western blot analysis revealed that connexins-26 and -32 levels were decreased at 6, 34, and 90 days. Using *Hpa* II and Southern analysis, no evidence was found for methylation of the promoter region of the gene for connexin-32. Thus, Wy-14,643 decreased both the methylation of the C-*myc* gene in mouse liver and the expression of connexins-26 and -32 proteins in rat liver, two activities associated with hepatocarcinogenesis. (Supported in part by a NIEHS grant #1R03 ES09772-01.)

1975 TUMOR NECROSIS FACTOR α (TNFα) IS NOT REQUIRED FOR WY-14,643 INDUCED CELL PROLIFERATION IN MICE.

B. L. Givler, D. W. Alberts, G. Wollenberg, M. H. Pitzenberger, J. G. Deluca and J. W. Lawrence. *Merck & Co Inc., West Point, PA*. Sponsor: R. Dixit.

It has been proposed that peroxisome proliferators induce hepatic cell proliferation through the induction of the cytokine TNFα. To test this hypothesis, peroxisome proliferation and cell proliferation induction was compared in wild-type C57Bl/6 and TNFα knockout mice. Animals were dosed for with either vehicle or 100 mg/kg/day WY14,643 by oral gavage for 4 days. Liver to body weight ratios increased in both wild-type and TNFα knockout animals after WY14,643 administration. In addition, WY14,643 treated wild-type C57Bl/6 and TNFα knockout mice displayed marked induction of fatty acyl-CoA oxidase activity (approximately 8-fold) and mRNA content (approximately 5-fold). Electron microscopic examination confirmed hepatocellular proliferation of peroxisomes in both mouse models. Moreover, WY14,643 markedly induced hepatic cell proliferation (approximately 20-fold) in both wild-type and C57BL/6 TNFα knockout mice as measured by BrdU incorporation into hepatocyte nuclei. In addition, a 50% decrease in TNFα mRNA was observed in wild-type mice after treatment with WY14,643. These results suggest that the hepatocellular proliferation induced after peroxisome proliferator treatment can occur independently of TNFα signaling.

1976 HEPATIC MITOGENESIS AND CARCINOGENESIS INDUCED BY PEROXISOME PROLIFERATORS IS ASSOCIATED WITH ALTERATIONS IN IL-1β SIGNALING PATHWAYS.

S. P. Anderson[1], C. S. Dunn[1], R. C. Cattley[2] and J. C. Corton[1]. [1]*CIIT, Research Triangle Park, NC and* [2]*Amgen, Thousand Oaks, CA.*

Peroxisome proliferator exposure is associated with hepatocellular mitogenesis, carcinogenesis, and altered synthesis of acute-phase proteins in the livers of rats and mice. Several of the cytokine signaling pathways that regulate acute-phase gene expression have also been implicated as mediators of hepatic regeneration following partial hepatectomy or exposure to certain hepatotoxins. We investigated the mRNA expression of select cytokine signaling pathways during hepatic mitogenesis and carcinogenesis in mice treated with the potent peroxisome proliferator and experimental hypolipidemic drug, Wy-14,643 (WY). Hepatic mitogenesis was associated with increased expression of IL-1β, IL-1 receptor 1, and the Stat-3, and Hnf-4 transcription factors. Normal and adenomatous liver from mice chronically treated with Wy-14,643 had increased expression of IL-1β, IL-1 receptor 1, and PPARΓ, as well as increases in the cell-cycle regulatory genes p21, c-Myc, and Cyclin D1. p21, c-Myc, Cyclin D1, and Bcl-xL, which we previously found altered in the majority of WY-induced hepatic adenomas, are all downstream targets of Stat-3. Recently, Stat-3 was identified as an oncogene and a downstream target of IL-1β. These results suggest that the hepatic mitogenesis and carcinogenesis induced by treating rodents with peroxisome proliferators may be mediated in part via a pathway involving IL-1β and Stat-3. Preliminary expression data from cDNA arrays suggest that additional, related genes involved in cytokine signaling may be altered as well. (Supported in part by NIEHS grant ES09775-01.)

1977 DOSE-RELATED CHANGES IN THE PHARMACOKINETICS OF TRICHLOROETHYLENE IN RAT.

M. G. Soni[1], M. M. Mumtaz[2], H. Clewell[3], V. V. Vaida[4] and M. M. Mehendale[4]. [1]*Burdock and Associates, Inc., Vero Beach, FL,* [2]*ATSDR, CDC, Atlanta, GA,* [3]*ICF Kaiser International, Ruston, LA and* [4]*The University of Louisiana at Monroe, Monroe, LA.*

Trichloroethylene (TCE), a widely used organic solvent, and degreasing agent, is regarded as a hepatotoxicant. The overall objective of these studies were to investigate the role of parent compound as well as its metabolites in eliciting injury as well as tissue repair and to evaluate the potential for predictive metabolite dosimetry using a physiologically based pharmacokinetic (PB PK) model. Male S-D rats were injected with a ten-fold dose range of TCE (250, 500, 1250 and 2500 mg/kg) and hepatotoxicity, tissue repair and bioactivation of TCE were studied during a time course of 0 to 96 hr. Results on hepatotoxicity and tissue repair were presented earlier. In the present study the plasma levels of TCE, trichloroacetic acid (TCA) and trichloroethanol (TCOH) were measured at different time points. Peak levels of TCE were reached between 1 and 3 h after TCE administration and by 24 to 36 h TCE levels in plasma declined to very low levels. By 1 h TCOH levels were significantly increased and peak levels were noted between 3 to 12 hr. After 12 h TCOH levels started declining and by 36 to 72 h almost all TCOH was eliminated from plasma. TCA, an important metabolite of TCE, appeared by 1 h and peaked between 12 to 24 h. Plasma TCA levels were dose-dependent. TCA declined to very low levels by 48 to 72 h suggesting rapid metabolic and excretory elimination. A PBPK model was utilized to compare the model prediction from this study with predictions from previously published studies. Model predictions of TCE, TCA and TCOH concentrations in rats by intraperitoneal route are in good agreement with previously published experimental data by oral route. (Supported by ATSDR U61/ATD 681482.)

1978 PHYSIOLOGICALLY BASED ESTIMATES OF THE HETEROGENEITY IN CANCER RISK VALUES FOR TETRACHLOROETHYLENE.

J. Z. Byczkowski[1], H. Choudhury[2] and J. C. Lipscomb[2]. [1]*Consultant, Fairborn, OH and* [2]*USA EPA, NCEA, Cincinnati, OH.*

In 1996, the US Environmental Protection Agency (EPA) released for public comment a revised draft guidelines for carcinogen risk assessment. This prompted us to test how the ranges of cancer risk values, estimated by following these new guidelines, compare to the values obtained by the classical EPA-prescribed 1986 method. Tetrachloroethylene (PERC) was selected as a test compound for this comparison (q1*=2.373E-2 ppm-1). The purpose of this study was to provide estimates of the cancer risk values for PERC, based on heterogeneity of cytochrome P450 (CYP) activity in humans. This was accomplished by the use of a physiologically based pharmacokinetic (PBPK) model coupled with a Monte Carlo (MC) analysis and mouse bioassay data. Based on these simulations the lower 95% confidence limit on a dose associated with a 10% extra tumor probability in mice was determined. The distribution of CYP activities in humans was estimated from trichloroethylene experimental data and converted to the equivalent PERC metabolism rates. Because liver is the site of tumors in mice, it was assumed that the same amounts metabolized per kg of liver tissue over the lifetime of mice and humans give the same probabilities of causing tumors. Based on these PBPK/MC simulations a carcinogenicity slope factor for PERC in humans was derived (geomean q1*=2.073E-2 ppm-1; mean q1*=2.99E-2 ppm-1), along with its probability distribution (5th and 95th percentile: 7.3E-3 and 8.0E-2 ppm-1) and confidence interval for a simulated human population (95% CLs on arithmetic mean=2.59E-2 to 3.39E-2 ppm-1).

1979 DERIVATION OF A HUMAN HEALTH-BASED GROUNDWATER CRITERION FOR *TERTIARY*-BUTYL ALCOHOL.

T. Ledoux and G. Post. *New Jersey Department of Environmental Protection, Trenton, NJ.*

A human health-based groundwater criterion for tertiary- butyl alcohol (TBA) was derived, based on lifetime exposure to TBA in drinking water. TBA contamination of groundwater may arise from its uses in chemical processes and as a gasoline additive, and because TBA is an environmental degradation product of methyl tertiary-butyl ether. TBA was classified as a possible human carcinogen based on renal tumors in male rats and thyroid tumors in male and female mice in a bioassay conducted by the National Toxicology Program. A Reference Dose of 0.0175 mg/kg/day was developed based on

increased severity of nephropathy in female rats at a dose of 175 mg/kg/day, with an additional uncertainty factor of 10 for possible carcinogenicity. The application of exposure assumptions appropriate for drinking water resulted in a criterion of 122.5 μg/L, which was rounded to 100 μg/L. The TBA criterion is currently applied on an interim basis, and proposal as part of an upcoming regulation is anticipated.

1980 UNIFIED PROBABILISTIC APPROACH TO CHARACTERIZE CANCER AND NONCANCER RISKS: THE CASE OF TRICHLOROETHYLENE IN RESIDENTIAL WATER.

K. T. Bogen. *Lawrence Livermore National Laboratory, University California, Livermore, CA.* Sponsor: H. Witschi.

Traditional risk estimates may be inflated, particularly if cancer is the dominant endpoint and there is fundamental uncertainty as to mechanism(s) of action. Risk is more realistically characterized if it accounts for joint uncertainty and interindividual variability (JUV) after applying a unified probabilistic approach to the distributed parameters of all (linear as well as nonlinear) risk-extrapolation models involved. Such an approach was applied to characterize lifetime risk of incurring either cancer or a noncancer endpoint due to hypothetical residential exposure to trichloroethylene (TCE) from ground water at an inactive landfill site on a U.S. Air Force Base in California. Variability and uncertainty were addressed in exposure-route-specific estimates of applied dose, in pharmacokinetically based estimates of route-specific metabolized fractions of absorbed TCE, and in corresponding biologically effective doses estimated under a genotoxic/linear (MAG) vs. a cytotoxic/nonlinear (MAC) mechanistic assumption for TCE-induced cancer. Increased risk conditional on effective dose was estimated under MAG based on seven rodent-bioassay data sets, and under MAC from data on acute hepatocellular lipoperoxidation in mice exposed to the reactive TCE metabolite, trichloroacetic acid. Mean and upper-bound risk estimates of were estimated to be <2 and <50 per million, respectively; estimates based on traditional deterministic methods were >100 per million. Based on JUV analysis, the potential for any site-induced harm was estimated to be very unlikely. The approach used is well suited to characterize risks involving uncertain and/or diverse mechanisms of action. [This work was performed under the auspices of the U.S. Department of Energy at Lawrence Livermore National Laboratory under contract W-7405-Eng-48.]

1981 DERIVATION OF A DRINKING WATER ACTION LEVEL FOR 1-HYDROXYETHYLENE DIPHOSPHONIC ACID (HEDP).

M. H. Whittaker[1], G. Ball[2], L. Bestervelt[2] and A. Phelka[2]. [1]*The Weinberg Group, Washington, DC and* [2]*NSF International, Ann Arbor, MI.* Sponsor: M. Dourson.

1-Hydroxyethylene diphosphonic acid (HEDP) is a chelating agent that has secondary direct and indirect food additive approvals from U.S. FDA. It has been granted an exemption from a pesticide tolerance by U.S. EPA. HEDP is also used in potable water as a scale control chemical. Its disodium salt, ethane-1-hydroxy-1,1-diphosphonate (EHDP) is used pharmacologically to treat bone mineralization disorders such as Paget's disease. In order to derive a maximum drinking water level (MDWL) for HEDP, clinical, toxicological, and pharmacokinetic data on HEDP and EHDP were examined. Both compounds are biphosphonates, which inhibit bone and cartilage mineralization. Sufficient chronic animal data, as well as clinical data, exist to characterize the potential for HEDP and EHDP to adversely affect the bone matrix. This critical effect was used to evaluate HEDP toxicity because effects on the bone matrix were observed at much lower concentrations than other effects, such as kidney damage. The MDWL was calculated using a NOAEL of 1 mg/kg/day EHDP reported from a six-month oral study in humans. This study was selected over other HEDP and EHDP studies because of its use of multiple dose groups, a clear NOAEL, and an evaluation of EHDP's effect on the bone matrix. Because humans have safely ingested EHDP at concentrations up to 5 mg/kg/day for a six-month time period, followed by a six-month recovery period, the 1 mg/kg/day NOAEL was multiplied by 0.5 (180 days/365 days). This adjustment results in a NOAEL of 0.5 mg/kg/day. As part of the MDWL derivation, safety factors totaling 100 were used (10 to account for sensitive human subpopulations (particularly individuals with increased bone turnover, such as growing children) and 10 to account for less-than-chronic exposures).

1982 RISK ASSESSMENT OF ALUMINUM, BENZENE, CARBOFURAN, CARBON TETRACHLORIDE, DICHLOROMETHANE, DIQUAT, NICKEL, SIMAZINE, TETRACHLOROETHYLENE, THIOBENCARB, URANIUM AND VINYL CHLORIDE IN DRINKING WATER.

A. Fan, J. Brown, T. McDonald, T. Parker, Y. Wang, D. Ting, A. Salmon, D. Morry, M. DiBartolomeis, G. Alexeeff, H. Russell and E. Hernandez. *California Environmental Protection Agency, Oakland, CA.*

Risk assessments were performed to develop health protective concentrations of chemicals in drinking water, along with an analysis of the toxicological basis for differences between these concentrations and the corresponding federal maximum contaminant levels, or MCLs. The concentrations (mg/L) are provided below for non-cancer endpoint and cancer endpoint, and federal MCL (NA means not applicable), respectively, for each chemical: Aluminum, 0.06 - increased blood level, NA, NA; benzene, 0.026 - hematological effects, 0.00014, NA; carbofuran, 0.0017 - testes changes, NA, 0.04 - cholinesterase inhibition, testicular toxicity, clinical signs; carbon tetrachloride, 0.007 - liver lesion, 0.00012, 0.005 - cancer; dichloromethane, 0.133 - liver toxicity, 0.00013, 0.005 - cancer; diquat, 0.015 - lens opacity, NA, 0.02 - lens opacity and cataracts; nickel, 0.001 - reproductive toxicity, NA, NA; simazine, 0.004 - reduced body weight, 0.0004, 0.004 - cancer; tetrachloroethylene, 0.011 - neurobehavioral effect, 0.000056, NA; thiobencarb, 0.07 - decreased body weight gain, NA, NA; uranium, 0.0002/0.2 pCi/L - kidney function, NA, NA; and vinyl chloride, 0.004 - liver toxicity, 0.00005, 0.002 - cancer. The concentrations derived (the more protective one when two values exist for a single chemical) are proposed as the public health goals (PHGs) which are to be used for derivation of California MCLs.

1983 RISK ASSESSMENT OF TETRACHLOROETHYLENE (PCE) FOR CALIFORNIA DRINKING WATER.

A. G. Salmon[1], E. W. Fanning[2], J. P. Brown[1] and A. M. Fan[1]. [1]*Office of Environmental Health Hazard Assessment, California Environmental Protection Agency, Oakland, CA and* [2]*University of California, Berkeley, CA.*

As part of California's update of drinking water standards, a Public Health Goal (PHG) of 0.056 μg/L for PCE in drinking water is proposed. The PHG is based on carcinogenic effects observed in animals, and a *de minimis* theoretical excess individual cancer risk of 10^{-6}. Exposure to PCE induced hepatocellular adenoma or carcinoma in mice by inhalation (NTP, 1986) or ingestion (NCI, 1977), and mononuclear cell leukemia in rats by inhalation (NTP, 1986). Increases in tumor incidence at several sites have been observed in studies of workers in the dry-cleaning industry (Blair et al., 1990; Ruder et al., 1994). For the proposed PHG, cancer potency was estimated by fitting a time-dependent polynomial model to the experimental data in animals to establish the lower 95% confidence bound on the dose associated with a 10% tumor incidence (LED_{10}). Oral and inhalation human potency estimates, estimated from data in mice and (for inhalation) rats were 0.42 $(mg/kg\text{-}day)^{-1}$ (oral) and 0.26 $(mg/kg\text{-}day)^{-1}$ (inhalation). Dosimetry for oral and inhalation exposures in animals was based on a steady-state pharmacokinetic calculation. For human potency estimates, the fractions of PCE metabolized during low dose inhalation and oral exposures predicted by Bois et al. (1996) were used. The epidemiological studies of PCE-exposed humans are subject to many uncertainties, and are not useful as the primary basis of a cancer risk assessment. However, the observed outcomes appear to be consistent with the potency estimates based on animal studies. The concentration of PCE in drinking water protective against non-cancer chronic toxicity is estimated to be 11 ppb, based on neurobehavioral effects observed in three epidemiological studies of humans inhaling PCE.

1984 REASSESSMENT OF THE CANCER RISKS OF BENZENE FOR CALIFORNIA'S DRINKING WATER PROGRAM.

T. A. McDonald, E. W. Fanning and L. Zeise. *State of California, EPA, Oakland, CA.*

A Public Health Goal (PHG) of 0.00014 mg/L (0.14 ppb) is proposed for benzene in drinking water, and assumes a de minimis cancer risk level of 10^{-6} from lifetime exposure to benzene. The PHG is based on observations of increased rates of leukemia among two cohorts of workers exposed to benzene: rubber hydrochloride workers in the U.S. (Paxton et al., 1994) and benzene-exposed workers from various industries in China (Hayes et al., 1997). After evaluating the evidence regarding the expected shape of the dose-response curve at low doses, cancer potency estimates were calculated from

the cohort data using Poisson regression and linear relative risk models. Estimates of lifetime risk to the general population from constant exposure to benzene were calculated using life table analyses. The pattern of leukemia risk following exposure to benzene was investigated and observed to be similar to the pattern of risk observed for radiation and chemotherapeutic agents. Accordingly, lifetime risk estimates were calculated such that exposures greater than 30 years in the past would not contributed significantly to leukemia risk. The best upper-bound estimates of lifetime leukemia risk resulting from air exposures of the general population to benzene were similar for the U.S. rubber workers (0.044 ppm^{-1}) and the Chinese workers (0.056 ppm^{-1}). The two risk estimates were combined and converted to a population-based cancer potency of 0.055 $(mg/kg\text{-}d)^{-1}$ for inhalation exposures, which was scaled to 0.11 $(mg/kg\text{-}d)^{-1}$ for oral exposures. Due to the shape of the dose-response curves and other considerations, the best estimates were calculated from workers in the lowest exposure groups only. Additional estimates, based on the use of linear extrapolation of all dose groups, the absolute risk model, and U.S. EPA proposed methodology, were also calculated and ranged from 0.19 to0.0014 $(mg/kg\text{-}d)^{-1}$.

1985 RISK ASSESSMENT OF DRINKING WATER DISINFECTION BY- PRODUCTS (DBPs): USE OF STRUCTURE-ACTIVITY RELATIONSHIPS (SAR) ANALYSIS IN RANKING OF CARCINOGENIC POTENTIAL AND PRIORITIZATION FOR TESTING.

Y. Woo[1], D. Y. Lai[1], M. K. Manibusan[2], J. L. McLain[2] and V. L. Dellarco[3]. [1]*USEPA, OPPT, Washington, DC,* [2]*USEPA, OW, Washington, DC and* [3]*USEPA, OPP, Washington, DC.*

Disinfection by-products (DBPs) are formed when disinfectants such as chlorine, chloramine and ozone react with inorganic and organic matters in the water. The observations that some DBPs such as trihalomethanes (THMs), haloacetic acids, and halo-furanones (e.g., MX) are carcinogenic in animal studies have raised public concern over the possible adverse health effects of DBPs. Several hundreds DBPs have been identified. An in-depth mechanism-based SAR analysis, supplemented by extensive literature search for genotoxicity and other data, was used for ranking of the carcinogenic potential of DBPs that met the following criteria: 1) detected in actual drinking water samples; 2) have insufficient cancer bioassay data for risk assessment; and 3) genotoxicity and physicochemical properties indicate possible concern. Of the 215 DBPs analyzed, only 14 were found to be of a moderate or moderate-high concern level for carcinogenic potential. Of these, four were structurally related to MX. Five other are halogenated alkanes which presumably will be controlled by existing and future THM regulations. The halogenated nitriles, propanones, and nitrobromomethane in the moderate or moderate-high concern categories may be suitable candidates for testing. (The scientific views expressed are solely those of the authors and do not necessarily reflect those of the USEPA.)

1986 DAILY WATER INGESTION IN THE U.S. - AN UPDATE.

J. T. Du. *USEPA, Washington, DC.*

Water ingestion rate is used in risk assessments. To obtain up-dated estimates of water ingestion, we analyzed data from USDA's 1994 - 1996 Continuing Survey of Food Intake by Individuals. Mean and percentile distributions of water ingestion for community, bottled, and other water were estimated by age, gender, race/ethnicity, socioeconomic status and geographic region. Water ingestion refers both to the drinking water (direct) and water added in final preparation of beverages and foods at home or in a restaurant (indirect). Intrinsic water (water contained in foods and beverages at times of market purchase) is not included in our estimate. Since we presented our preliminary results in SOT last year, we have checked thousands of food recipes to refine the estimates of indirect water. Current results show that the estimated mean, 90th and 95th percentile of community water ingestion are 0.9, 2 and 2.5 L/day, respectively for the general population; and 0.3, 0.9 and 1 L/day, respectively for a child less than one-year old. These values are equivalent to 0.02, 0.03 and 0.04 L/kg body weight/day, respectively for the general population; and 0.05, 0.13 and 0.16 L/kg bw/day, respectively for a child less than one-year old. (The opinions expressed are those of the authors and do not necessarily reflect U.S. EPA policy.)

1987 ACCEPTABLE CONCENTRATIONS FOR CHLOROFORM (TCM) IN DRINKING WATER ON THE INTERNATIONAL SPACE STATION.

H. D. Garcia. *Wyle Laboratories Life Sciences Systems and Services, Houston, TX.* Sponsor: C. Lam.

Drinking water on the International Space Station (ISS), and possibly on Mars missions, will be generated from recycled hygiene water, urine, and humidity condensate. On ISS, this will be supplemented by water from the U.S. Shuttle or Russian Progress resupply vehicles. Since trace levels of volatile chlorinated organic compounds are often found in spacecraft air, traces of TCM are expected occasionally in spacecraft drinking water under normal conditions. Astronauts will ingest this water for 6 months (ISS), 2 years (Mars) or longer. In collaboration with the National Research Council's Committee on Toxicology, NASA's Toxicology Group has calculated acceptable concentrations (ACs) of TCM in spacecraft water, based on a critical review of the scientific literature on the toxicity of ingested TCM. All major toxic effects were evaluated; hepatotoxicity and taste aversion (reduced water consumption) were the most sensitive indicators of TCM ingestion. Central nervous system depression, a major effect of inhaled TCM vapors, has not been reported for TCM ingested in drinking water, even at high concentrations, probably due to a "first pass" effect of metabolism by the liver before reaching the blood and brain. The weight of evidence from many studies indicates that TCM exposures that do not produce cytotoxicity and cell regeneration will not result in tumorigenesis. In humans, the liver is the organ most sensitive to TCM toxicity. Thus, ACs that protect against hepatotoxicity will also protect against nephro-toxicity, thyroid toxicity, carcinogenicity, reproductive and developmental toxicity. AC calculations assumed a 70 kg healthy adult astronaut consuming 2.8 liters of water per day (including 0.8 L for food preparation). Safety factors of 1 to 10 were applied for inter-species extrapolation, inter-individual variations, and exposure duration. ACs were calculated for both hepatotoxicity and taste aversion for exposure durations of 1 day to 1000 days. The lower of the ACs for each duration was selected as the Spacecraft Water Exposure Guideline (SWEG): 1-d: 60 mg/L, 10-d: 60 mg/L, 100-d: 18 mg/L, and 1000-d: 6.4 mg/L. Due to differences in the safety factors applied and toxic effects considered, these SWEGs are substantially higher than limits set by government agencies for public drinking water.

Key Word Index

(alpha)2u-globulin, 1883
(anti-) estrogenicity, 1114

1, 1275
1,1,2,2-Tetrachloroethylene, 973
1,1-dichloroethylene, 480
1,2-dichlorobenzene, 1190
1,2-dichloroethane, 480
1,3,5-Trinitrobenzene, 1537
1,3-butadiene, 1072
11-deoxy-16,16-dimethyl prostaglandin E2, 994
17beta-estradiol, 1108
1-bromopropane, 1850, 1851, 1852
1-nitronaphthalene, 1471
1-nitropyrene, 1448

2, 1275
2-(2-iodoethyl)-1,3-propanediol diacetate, 1366
2,3,5-Tris-(glutathion-S-yl)hydroquinone, 116, 137
2,3,7,8-TCDD, 1533
2,4-D, 1567, 1568
2,4-dichlorophenoxyacetic acid, 261
2,4-toluenediamine, 506
2,5 hexanedione, 832
2,5-Hexanedione, 831, 1460, 1703
20-hydroxyecdysone, 1527
28 day, 1918
2-Butoxyethanol, 744, 942, 943
2-Chloroacrylonitrile, 133

3, 1275
3,4-dichloroaniline, 1898
3',4'-dimethoxyflavone, 1293
32P-postlabeling, 1065
3-methylindole, 489, 537

4-aminobiphenyl, 1749
4-hydroxynonenal, 142, 213
4-hydroxyphenylpyruvate dioxygenase, 1561
4-vinylcyclohexene, 493
4-vinylcyclohexene diepoxide, 1708

5-aza-2'-deoxycytidine, 332, 1376
5-FU, 438

6-Hydroxydopamine, 795
6-MCDF, 1019
6-nitrochrysene, 469

7,12-dimethylbenz[a]anthracene, 663
7H-Dibenzo[c,g]carbazole, 528

8-oxoguanosine, 441A

abnormalities, 933
absorption, 146, 700, 1923
accelerator ms, 1435
accumulation, 177
acetaminophen, 196, 197, 199, 200, 203, 228, 229, 230, 294, 447, 479, 525, 661, 783, 1119, 1228, 1458, 1633, 1799, 1800, 1891, 1892
acetylaminofluorene, 1097
acetylation, 173
acetylcholine receptor, 901, 904
acetylcholine release, 1597
acetylcholinesterase, 1246, 1586, 1590, 1591
acetylcholinesterase inhibition, 1239, 1240, 1241
acetyl-l-carnitine, 1912
acetylocholine receptor, 905
AChE inhibition, 1577
acid anhydrides, 578
acivicin, 105
aconitase, 354, 394
acrolein, 534, 1487, 1836
acrylamide, 833, 979, 1276, 1385
acrylonitrile, 940, 941, 980, 1098
actin, 1371
activator protein, 25
acute, 81, 347
acute exposure level, 520
acute exposures, 856
acute toxicity, 1055
acute toxicity data, 1857
adduct, 1030
adduction, 979
adenocarcinoma, 1033
adenosine deaminase, 1110
adenovirus, 201, 1017
adenylyl cyclase, 314
adherens junction, 1634
adipocyte, 452
adjuvanticity, 1157
adjuvants, 1118
ADME, 1924
adolescence, 820, 821
adrenal, 1123
adsorption, 673
adverse effects, 1153
adverse event reports, 1151
aerosol, 970, 1641
aerosol deposition, 91
aerosol sampling, 75
aerosols, 71
a-esterases, 1755
aflatoxin, 674, 675, 1445
aflatoxin B1, 658, 677, 934, 936, 1021, 1214, 1260
age, 80, 187, 1595
age-dependent susceptibility, 1889
agent orange, 328
age-related, 1472, 1596, 1599
age-specific parameters, 429
aggregation, 1319
aging, 185
agranulocytosis, 1651
Ah Receptor, 319, 326, 482, 497, 642, 746, 750, 919, 1128, 1132, 1303, 1520, 1521, 1522, 1523, 1632, 1656
AH Receptor knockout mice, 272
AhR, 56, 320, 325, 367, 452, 467, 755, 982, 983, 984, 985, 1298, 1308, 1647, 1820, 1821
AhR antagonist, 1293
air pollutants, 1394
air pollution, 72, 73, 73A, 1148
airborne Particles, 300
airborne particulate matter, 1794
airway reactivity, 931
AKT, 1680
alachlor, 312, 623
alamarBlue, 796
albendazole, 488
alcohol, 191, 819, 1135, 1138
alcohol dehydrogenase, 232, 1010
alcohols, 479
ALDH3A1, 1831
aldo-keto reductase, 36
alkaline phosphatase, 225
alkylating agents, 135
alkylating drugs, 117

allegenicity, 585
allergen, 100
allergens, 1162
allergic contact dermatitis, 722
allergic responses, 653
allergy, 583, 584, 589, 666, 1156, 1157, 1158, 1160, 1164, 1480, 1657, 1661
all-trans-retinoic acid, 1838
allylamine toxicity, 1191
alpha 2u, 1266
alpha-2u-globulin, 1884
alpha-Hederin, 804
ALT, 1819
alternative bioassay, 1039
alternative to chlorofluorocarbons, 1850, 1851
altitude, 864
aluminum, 164, 165, 166, 878
alveolar macrophages, 89
alzheimer, 834
ames, 1092
ames assay, 1095
amino acid, 380, 1858
aminolevulinic acid dehydratase, 151
aminophenols, 1896
aminopterin, 1378
amiodarone, 86, 1496, 1497
ammonium perchlorate, 1386, 1387
amnesic shellfish poisoning, 21
ampakine, 844
amphetamine, 1379
amphetamines, 104
amphibians, 1531
amprenavir, 270
anaesthesia, 1620, 1621
anaesthetics, 1926
analgesic agent, 1848
analysis, 557, 674, 803, 1606, 1607, 1608
analytical methods, 75
androgen, 643
androgen receptor, 1505
androgens, 1449
anemia, 1297
anesthetized swine, 253
aneuploidy, 1736
angelan, 1419
angiogenesis, 1861
angioplasty, 1876
aniline, 1197
animal model, 1161
animal models, 583, 584, 722
animal studies, 1664, 1948, 1949, 1952
anntiandrogen, 273
anoikis, 1910
anoxia, 545
anthelmintic, 488
anthracycline, 1666, 1925
anthracyclines, 1092
anthraquinone, 439
antiandrogen, 1215, 1351, 1357, 1713
antiandrogens, 1364
antiangiogenesis, 891
anti-apoptosis, 183
antibiotics, 1465, 1917
antibodies, 11
antibody, 758, 1136, 1164
antibody response, 764
anticancer, 1925
anti-carcinogens, 1261
antiestrogen, 1292
antiestrogenicity, 1823
antiestrogens, 1102, 1645
antifertility, 809
antigen presentation, 763
antineoplastic, 1919
antioxidant, 33, 783
antioxidant enzymes, 780
antioxidant loading, 789
antioxidant system, 138
antioxidant/electrophile, 988
antioxidant/electrophile response element, 925
antioxidants, 946, 1262, 1434, 1473, 1558, 1559
antioxidative enzymes, 24, 788
antisense, 296, 241, 269, 728, 730, 1372
antisense oligonucleotide, 729
antithrombotic, 1876
antitumor agent, 1922
antitumorigenicity, 1019, 1020
antivenom, 803
antoantibodies, 1237
AP-1, 1195, 1271, 1835, 1836
apligraf, 687
apomorphine, 1618
apoptosis, 23, 26, 163, 194, 293, 295, 296, 337, 407, 523, 524, 526, 529, 531, 532, 533, 534, 535, 536, 537, 538, 542, 545, 548, 549, 550, 553, 554, 558, 614, 617, 618, 619, 620, 621, 622, 623, 624, 634, 754, 847, 995, 1141, 1313, 1327, 1402, 1403, 1489, 1583, 1628, 1629, 1675, 1676, 1677, 1678, 1679, 1683, 1684, 1685, 1698, 1709, 1833, 1834, 1899, 1911, 1936
apurinic/apyrimidinic sites, 1088
ARDS, 654
ARE/EpRE, 54
ARNT, 55, 984, 1131, 1525
aromatase, 451, 1122, 1124
aromatic amines, 260
aromatic hydrocarbon receptor, 1350
aromatic hydrocarbons, 1907
array, 1000
array hybridization, 919
arsenic, 257, 258, 259, 339, 346, 349, 405, 625, 627, 629, 630, 631, 633, 634, 635, 636, 725, 1070, 1313, 1314, 1315, 1316, 1318, 1319, 1322, 1324, 1441, 1539, 1668, 1669, 1670, 1671, 1672, 1673, 1832, 1958, 1959
arsenic exposure, 1168
arsenite, 540, 628, 632, 1317, 1320, 1321, 1515
arteriopathy, 1849
arteriosclerosis, 1487
