Abstracts of the
38th Annual Meeting
Volume 48, Number 1-S
March 1999

Preface

This issue of *The Toxicologist* is devoted to the abstracts of the presentations for the symposium, platform, poster / discussion, workshop, roundtable, and poster sessions of the 38th Annual Meeting of the Society of Toxicology, held at the Ernest N. Morial Convention Center, New Orleans, Louisiana, March 14-18, 1999.

An alphabetical Author Index, cross referencing the corresponding abstract number(s), begins on page 419.

The issue also contains a Keyword Index (by subject or chemical) of all the presentations, beginning on page 444.

The abstracts are reproduced as accepted by the Program Committee of the Society of Toxicology and appear in numerical sequence.

Copies of *The Toxicologist* are available at $45 each plus $5 postage and handling (U.S. funds) from:

Society of Toxicology
1767 Business Center Drive, Suite 302
Reston, VA 20190-5332

This abstract book has been produced electronically by Coe-Truman Technologies, Inc. Every effort has been made to faithfully reproduce the abstracts as submitted. However, no responsibility is assumed by the organizers for any injury and/or damage to persons or property as a matter of products, instructions or ideas contained in the material herein. Because of the rapid advances in the medical sciences, we recommend that independent verification of diagnoses and drug dosage be made.

1 GENOMIC TECHNOLOGIES AND NEW SCREENING STRATEGIES FOR TOXICOLOGY.

M J Cunningham. *Incyte Pharmaceuticals, Inc., Palo Alto, CA, USA.*

New genomic technologies aimed at assessing molecular toxicity may now play a major role in pharmaceutical drug development. These technologies include: a.) cDNA and oligonucleotide microarrays, b.) the branched DNA (bDNA) assay, c.) the scintillation-based mRNA assay and d.) proteomics (protein gel electrophoresis/mass spectrometry). These assays may be used to screen combinatorial chemistry libraries, select drug candidates for further development or study mechanisms of toxicity. Several applications will be presented in the areas of hepatocarcinogenesis, disruption of hormonal signaling by environmental estrogens and comparing gene expression profiles of chemotherapeutic agents and peroxisome proliferators.

2 INTEGRATION OF MOLECULAR TOXICOLOGY INTO THE DRUG DISCOVERY PROCESS.

M D Todd. *Department of Toxicology, Chiron Corporation, Emeryville, CA, USA.* Sponsor: G H I Wolfgang.

Toxicity assessment of novel drug candidates is rapidly expanding into the arena of higher throughput, in vitro assays. This trend requires validated molecular endpoints, as well as sensitive and robust assays. Monitoring changes in gene expression, especially at the level of mRNA, is one area of current focus. The Quantigene Assay (bDNA) has been used to: 1) screen compounds from a combinatorial library, 2) search for novel molecular endpoints of hepatotoxicity, and 3) investigate the mechanism of cisplatin toxicity. A validation subset of combinatorial chemistry compounds was screened for changes in HSP70 and GADD45 mRNA levels. There was a significant correlation between compound structure and up-regulation of these genes and cytotoxicity. To identify new endpoints, the liver specific genes cytochrome P450 3A1 and quinone reductase as well as the oxidative stress gene, hemeoxygenase were monitored in rat hepatoma cells in response to hepatotoxins such as acetaminophen and valproic acid. Induction of CYP3A4 or QR did not correlate with hepatotoxic damage while HMO-1 was induced by most of the hepatotoxins tested. To delineate the mechanism of toxicity of cisplatin, several genes, including HSP70, c-fos, and GADD45, were monitored in target and non-target cell populations. Differences in c-fos expression and cell cycle transit were detected between target and non-target cells. These differences may help explain the greater sensitivity of the target cells to cisplatin. Overall, the studies presented here exemplify innovative ways in which molecular toxicology can be integrated into the drug discovery process.

3 MODERATE AND HIGH THROUGHPUT STRATEGIES FOR DETERMINING HEPATIC EFFECTS OF PHARMACEUTICAL LEADS.

R G Ulrich. *Strategic and Exploratory Sciences, Abbott Laboratories, Abbott Park, IL, USA.* Sponsor: M J Cunningham.

The early refinement of pharmaceutical leads can reduce drug developmental costs and enhance the potential for success. Adverse hepatic effects (toxicity and effects on drug metabolism) are commonly encountered developmental issues. While information-intensive platforms such as chip technologies and traditional investigative approaches can provide a mechanistic basis for hepatic effects for selected compounds, the evaluation of large numbers of leads for reduced adverse effects or structure-activity relationships requires the selection of precise, mechanism-linked endpoints and an assay platform that uses milligram quantities of chemical leads. Using primary cultured hepatocytes, moderate throughput, fluorescence-based assays for the detection of organelle functional changes such as phospholipidosis or mitochondrial dysfunction can be used to guide chemical synthesis and select leads with reduced toxicity. Often, changes in cell function are accompanied by changes in gene expression that can be measured quantitatively using hybridization strategies. High throughput gene expression-based assays using radiolabeled antisense riboprobes and scintillation detection or oligonucleotide, enzyme labeled branched DNA and chemiluminescence detection can be used to identify and screen for cellular responses including cell growth and death, cytochrome p450 induction and peroxisomal proliferation. By comparing results obtained from rat hepatocytes with those obtained from human hepatocytes, some prediction of potential human responses or susceptibility is also possible.

4 EVALUATING DRUG MECHANISMS AND TOXICITIES BY MICROARRAY EXPRESSION ANALYSIS.

D A Jones and A R Karpf. *Molecular Pharmacology Division, Huntsman Cancer Institute, Salt Lake City, UT, USA.* Sponsor: M J Cunningham.

Recent advances in cancer biology offer exciting new prospects for developing novel classes of chemotherapeutics that may reduce cancer mortality. These advances are coupled to rapid elucidation of the expressed human genome by means of high-throughput genomics and bioinformatics technologies. One such technology promises to advance our understanding of the pharmacology and toxicology of cancer chemotherapeutics. Microarray expression analysis allows quantitative measurement of thousands of transcripts simultaneously. This creates a comprehensive transcript profile that permits study of cellular responses in comparison to the majority of a cell's expressed genome. We have produced cDNA microarrays that encompass genes putatively involved in tumor cell chemotherapeutic responsiveness and toxicities. We are using these arrays to generate comprehensive expression profiles of cultured cells responding to current and candidate anti-tumor agents. This profiling has identified signature gene expression patterns that parallel chemotherapeutic induction of apoptosis. The presence or absence of these specific signature gene sets in cells may provide a diagnostic clue that predicts chemotherapeutic mechanisms and toxicities. This predictive ability may reveal drug toxicities early in development and could, therefore, accelerate the assessment and selection of clinical candidates.

5 THE POTENTIAL OF TRANSCRIPT AND PROTEIN PROFILING FOR THE ASSESSMENT OF CHEMICALLY-INDUCED TOXICITY.

J D Tugwood[1], I Kimber[2], G J A Oliver[1], T C Orton[1], and W D Pennie[2]. [1]*Safety of Medicines Group, Zeneca Pharmaceuticals and* [2]*Zeneca Central Toxicology Laboratory, Macclesfield, U.K.*

Many laboratories are currently exploring genomics and proteomics technologies as a means of obtaining biological information from a variety of in vitro and in vivo systems. A range of analytical methods is being developed to facilitate this, including cDNA and oligonucleotide-based microarrays, and high resolution electrophoresis coupled with mass spectrometry. While the potential for generating useful data with these technologies is great, a number of fundamental issues need to be addressed, particularly if they are to be used with the aim of evaluating chemical safety. These include whether small changes in low-abundance transcripts and proteins can be measured accurately and reproducibly, which experimental approaches are most appropriate for microarray analyses, and how best transcript and protein profiles can be deployed for assessment of adverse health effects. At Zeneca, we are tackling these and other issues through a combination of internal programmes and strategic collaborations with other companies developing the necessary technologies. Some of our initial applications of this technology are aimed at improving prediction of genotoxicity, understanding disruption of normal hormonal signalling by environmental estrogens, and exploring mechanisms of hepatocarcinogenesis. Data from both transcript and protein profiling experiments will be presented and discussed.

6 CELL CYCLE CHECK-POINTS AND CHEMICAL-INDUCED STRESS RESPONSE: SURVIVAL VERSUS DEATH.

A-N T Kong. *College of Pharmacy, University of Illinois at Chicago, Chicago, IL, USA.*

Cellular responses to toxicants, radiation, and other environmental insults can result in cell cycle arrest, proliferation, differentiation, homeostasis, apoptosis, or necrosis. Checkpoints arrest cell cycle progression before DNA replication (G1 checkpoint) or mitosis (G2 checkpoint) when the integrity of the genome is compromised either as a consequence of DNA damage, perturbed metabolism/signaling, or programmed cellular events such as senescence. Many of these checkpoints are deregulated in cancer. Recent advances in gene-targeted mice that lack these cell cycle regulators, p21(WAF1/CIP1) and p27Kip1 cyclin-dependent kinases (CDK) inhibitors showed the important functions of p21 in G1 checkpoint and p27 in replicative capacity of differentiation-associated cell divisions. Furthermore, after the hepatic toxicant carbon tetrachloride-induced liver cell death and regeneration, p21 CDK inhibitor showed two waves of expression. The first occurred in the damaged pericentral region, in conjunction with early proto-oncogene expression, the second occurred later, consistent with post-mitotic expression after regeneration was completed. The persistent effects of radi-

ation- or xenobiotic-induced DNA damage on genetic stability and fitness in yeast appeared in the progeny of survivors as many as 50 generations after exposure, implying mechanisms other than carry-over DNA damage or mutations at specific loci. Integration of signaling transduction pathways in response to cellular stress is critical for cell survival or death. Various chemicals can induce differential activation of the mitogen-activated protein kinases (MAPK) and ICE/Ced-3 proteases (caspases). Studies with phenolic compounds showed that low concentrations activated MAPK leading to gene expression and cell survival, whereas higher concentrations activated caspases leading to apoptosis. In summary, this symposium will focus on the cell cycle checkpoints, genetic stability, cell death and cell survival. The information from this symposium may be of importance in assessing the potential risks of environmental toxicants leading to cellular injury.

7 ROLES OF CYCLIN-DEPENDENT KINASE INHIBITORS IN CELL CYCLE CHECKPOINTS: LESSONS FROM KNOCKOUT MICE.

H Kiyokawa. *Cancer Center, University of Illinois, Chicago, IL, USA.* Sponsor: A-N T Kong.

Cyclin-dependent kinases (CDKs) form the central machinery of the cell cycle. The serine/threonine protein kinase activity of each CDK depends on the association of the regulatory cyclin subunit, and is subject to negative regulation by inhibitory subunits, known as CDK inhibitors. In mammalian cells, cyclin D/CDK4 (or CDK6) and cyclin E/CDK2 regulate the G1 to S transition, cyclin A/CDK2 controls S phase progression, and cyclin B/CDK1 is essential for the G2 to M transition. When genomic stability is compromised by DNA damage, perturbation of the nucleic acid metabolism, or shortened telomere, checkpoint mechanisms suppress the CDK activity to cause cell cycle arrest in either G1 or G2. The CDK inhibitors, including $p21^{WAF/Cip1}$ and $p27^{Kip1}$, are involved especially in the G1 checkpoint. DNA damage or perturbation of nucleotide pool induces the transcription of p21 in a p53-dependent manner. It has been shown that p21-knockout mice develop normally, but p21-deficient cells in culture are impaired in their ability to undergo G1 arrest following γ-irradiation or treatment with PALA, an inhibitor of uridine synthesis. These data are consistent with the G1 checkpoint function of p21. p27 has a unique function programmed in a cell-intrinsic fashion. p27-knockout mice, we previously created, exhibit a gigantism-like phenotype. Our studies suggest that p27 determines the replicative capacity of differentiation-associated cell divisions. p27-deficient cells undergo additional cell divisions during differentiation before they finally arrest in G0, ending up with increased numbers of differentiated cells. In contrast to p21-deficient cells, p27-deficient cells have normal sensitivity to γ-irradiation. However, p27-deficient cells are partially resistant to rapamycin- or TGF-β-induced growth arrest, suggesting that p21 and p27 regulate distinct types of G1 checkpoints. Our comparative studies on proliferation and apoptosis of p21- and p27-deficient cells will be further discussed.

8 $p21^{(WAF1/CIP1)}$ EXPRESSION IN THE LIVER FOLLOWING CARBON TETRACHLORIDE ADMINISTRATION.

A L Tyner, A L Gartel, E Goufman, M Feuerman, and M S Serfas. *Dept. of Molecular Genetics, University of Illinois College of Medicine, Chicago, IL, USA.* Sponsor: A-N T Kong.

The cyclin dependent kinase inhibitor (CKI) $P21^{(WAF1/CIP1)}$ can induce G1 arrest, and its expression coincides with the cessation of replication in many systems. To address the role of p21 during liver regeneration, we examined p21 expression using in-situ hybridization and RT-PCR, following administration of carbon tetrachloride, which induces liver cell necrosis. We found that carbon tetrachloride-induced liver damage leads to two waves of p21 expression. The first occurs in the damaged pericentral region, in conjunction with early proto-oncogene expression. The second wave of p21 expression occurs later, and is consistent with post-mitotic expression after regeneration is complete. In the healthy adult liver we also detected p21 expression in a few cells in a pattern that was suggestive of rare post-mitotic expression. Since the tumor suppresser protein p53 has been shown to activate p21 gene expression following DNA damage, we examined p21 expression in p53 deficient mice following administration of carbon tetrachloride. In these animals the early wave of pericentral specific p21 induction was still detected, indicating that activation of p21 transcription is not p53 dependent. These data suggest a role for p21 expression subsequent to normal cell division in normal and regenerating liver. As an inhibitor of cell replication and a component of a cell cycle checkpoint, p21 expression may generally precede necrosis in cells subjected to damage.

9 THE EFFECT OF RADIATION AND XENOBIOTIC-INDUCED DNA DAMAGE ON GENETIC STABILITY IN YEAST.

R J Brennan and R H Schiestl. *Dept. Cancer Cell Biology, Harvard School of Public Health, Boston, MA, USA.*

The development of a "hypermutable" phenotype is thought to be a critical component of the multistage development of an invasive tumor from a normal somatic cell. Cultured mammalian cells which survive exposure to ionizing radiation and other DNA damaging agents often subsequently develop a genomic instability reminiscent of that observed in tumor cells. Such delayed effects can include a reduced plating efficiency, an increased frequency of chromosome abnormalities, increased levels of genetic recombination and an increased mutation frequency. We have studied the development of similar phenotypes in the yeast Saccharomyces cerevisiae. Following exposure to gamma radiation, a high proportion of colonies derived from surviving cells displayed significantly elevated frequencies of genetic deletions up to 50 generations post-irradiation. Other phenotypes observed included elevated frequencies of forward mutation and low plating efficiency. The appearance of High Frequency of Deletion (HFD) clones was dose-dependent and the elevated deletion frequency was dominant when HFD cells were mated with unexposed cells. Deletion frequencies and forward mutation frequencies appeared to be correlated. These delayed effects cannot be explained by the carry-over of DNA damage, due to the large number of generations between exposure and observation; nor can they be due to mutations at specific loci, as they appear in a significant proportion of survivors. Similar phenotypes were also observed following exposure to other DNA damaging agents (UV, alkylating agents, oxidants). Elucidating the mechanism by which these effects arise may shed light on the development of genomic instability in human cancers.

10 CHEMICAL-INDUCED DIFFERENTIAL ACTIVATION OF MAPK AND CASPASES IN CELL SURVIVAL AND DEATH.

A-N T Kong, R Yu, S Mandlekar and L Wei. *College of Pharmacy, University of Illinois at Chicago, Chicago, IL, USA.*

Cellular responses to chemical-induced stress can signal proliferation, differentiation, hemeostasis, apoptosis or necrosis. To better understand the underlying molecular mechanisms after exposure to chemicals, we investigated the signal transduction pathways, the mitogen-activated protein kinase (MAPK), and the ICE/Ced-3 protease (caspase) pathways, activated by different agents. Butylated hydroxyanisole (BHA) and its metabolite, t-butylhydroquinone (tBHQ), both are well known phenolic antioxidants (PAs) used as food preservatives, strongly activated c-Jun N-terminal kinase 1 (JNK1) and/or extracellular signal-regulated protein kinase 2 (ERK2) in a time- and dose-dependent fashion. Free radical scavengers N-acetyl-L-cysteine, or glutathione, inhibited ERK2 activation and, to a much lesser extent, JNK1 activation by PAs, implicating the role of oxidative stress. Under conditions where MAPKs were activated, PAs also activated transcription factors NF-(B, AP-1, or ARE (antioxidant response element), with the induction of early genes c-jun, c-fos, and Phase 2 genes GST, NQO. Increasing the concentrations of PAs, the activities of caspases were stimulated and resulted in apoptotic cell death. Further increase in concentrations led to rapid cell necrosis. Other phytochemicals including phenylethyl isothiocyanate (PEITC), sulforaphane, and green tea polyphenols, also differentially regulated the activities of MAPKs or caspases. A model is proposed, that at low concentrations, these chemicals (BHA, PEITC) activate MAPK pathway leading to induction of gene expression which may protect the cells against toxic insults and enhance cell survival. At relatively high concentrations, these agents activate both MAPK, and the caspase pathways, leading to apoptosis. The balance between these signaling pathways may dictate the fate of cells upon exposure to chemicals. (Supported by NIH grants ES06887 and GM49172.)

11 COGNITIVE TESTS: INTERPRETATION FOR NEUROTOXICITY?

W Slikker, Jr. and B D Beck. *Division of Neurotoxicity, National Center for Toxicological Research, Jefferson, AK, USA and Gradient Corporation, Cambridge, MA, USA.*

The aim of this workshop is to help provide a scientific basis for the appropriate interpretation of cognitive tests with respect to neurotoxicity and human health risk. Cognitive tests should measure the total functional output of the nervous system, yet cognitive function cannot be directly

observed. The lack of direct measures makes interpretation of cognitive tests problematic. The Intelligence Quotient (IQ), for example, reflects factors in addition to intelligence, such as socioeconomic status; the difficulty in interpreting cognitive function tests in humans exposed to neurotoxicants is thus complicated by a range of factors, such as the adequacy of control of confounders. Difficulty in test interpretation is an issue with species other than humans. To overcome these problems, sophisticated assessment tools have been developed to assess selected aspects of complex brain function (cognition) and their alteration by toxicant exposure. Improvement of the interpretation of animal cognitive function tests has resulted from data generated from carefully designed operant and non-operant problem solving tasks, especially those that can be modeled in both animals and humans. These include delayed matching to sample (short-term memory); repeated acquisition (learning); temporal discrimination (timing ability); and progressive ratio (motivation). Interpretation of cognitive test results in exposed humans with respect to causation is enhanced by consistency with results from animal species. Challenges still remain regarding interpretation of results with respect to adverseness of effect. This workshop will discuss: the range of cognitive tests available; their use and reliability in different species for predicting neurotoxicity; and the appropriate interpretation of such tests with respect to overall function, including whether an effect is adverse or not.

12 ASSESSMENT OF COMPLEX COGNITIVE FUNCTION IN RODENTS AND EXTRAPOLATION ACROSS SPECIES.

D A Cory-Slechta. *Department of Environmental Medicine, University of Rochester Medical School, Rochester, NY, USA.*

Cognitive function subsumes three overlapping and interactive behavioral processes: learning, memory and attention. The elaboration of a learning impairment in the rodent and its differentiation from other interpretations is most easily achieved using repeated learning paradigms in conjunction with a performance-only assessment. Potential behavioral and neurobiological mechanisms of a learning impairment can be further determined using carefully designed probe procedures in such paradigms. Delayed match-to-sample procedures offer generally the same precision and interpretative facility within a memory context. Both approaches exhibit substantial cross-species generality of the associated performance. Attention deficit remains a global behavioral construct with no unifying theoretical basis. However, reaction time and vigilance paradigms are useful for evaluating sustained attention across species. Aversion to delays has recently been suggested as the basis for attention deficits and can be evaluated across species using delay of gratification and self-control approaches. Interpretation of such data can be difficult if important experimental variables are not controlled. The use of these approaches to cognitive function across species offers not only the soundest basis for precise risk characterization and for elaboration of both behavioral and biological mechanisms of neurotoxicant effects: precise characterization of behavioral deficits in experimental animals can then to be compared to effects observed in human populations with known exposures, and experimental animal experiments can attempt to mimic the precise behavioral deficits identified in populations with defined neuropsychiatric or neurodegenerative conditions.

13 ASSESSMENT OF COMPLEX BRAIN FUNCTION IN BOTH NON-HUMAN PRIMATES AND HUMANS USING IDENTICAL BEHAVIORAL TASKS.

M G Paule. *National Center for Toxicological Research, Jefferson, AR, USA.*

The use of animal models for predicting the potential effects of neuroactive agents on complex brain functions in humans is critical. This need has led to the development of automated systems for administering identical behavioral tasks to both animals and humans. Maintaining task continuity across species allows for direct observations of interspecies similarities and differences in a variety of functional domains and should assist in the extrapolation of data from lab animals to humans. Data from identical operant behavioral tasks, designed to require responses thought to depend upon specific functions including motivation, color and position discrimination, time estimation, and short-term memory, and learning, have been obtained from both rhesus monkeys and children. Remarkable interspecies comparabilities portend the utility of such an approach in neurotoxic risk assessment procedures.

14 ASSESSING THE EFFECTS OF NEUROTOXICANTS ON CHILDREN'S COGNITION.

D Bellinger. *Children's Hospital, Boston, MA, USA.* Sponsor: W Slikker, Jr.

Most studies evaluating the cognitive effects of environmental exposures on children employ test batteries consisting of tests of global (or apical) function (e.g., IQ, general development), supplemented by tests of specific domains (e.g., language, attention, visual-motor integration). This presentation will address several issues that need to be considered in the analysis and interpretation of such data: (1) apical test scores represent final common pathways, so they may be sensitive to neurotoxicant exposure but lack specificity; (2) apical test scores generally reflect the product of a child's past learning rather than the process of learning, providing relatively little insight into behavior mechanisms; (3) apical test scores are influenced by many biological, sociological, and psychological factors, creating the potential for misattribution of effect (e.g., confounding bias) and/or effect modification; (4) the supplementary tests used are often not well matched in terms of psychometric characteristics, complicating the effort to draw interferences about the relative magnitude of a neurotoxicant's impact on different aspects of cognitive function; (5) traditional neuropsychological tests are administered in the context of an interaction between examiner and child, requiring close attention to issues of quality control in test administration.

15 HUMAN NEUROBEHAVIORAL TEST METHODS FOR STUDYING NEUROTOXICITY IN WORKING POPULATIONS.

W K Anger, D S Rohlman, and D Storzbach. *Oregon Health Science University, Portland, OR , USA.*

Tests of cognitive performance have been widely applied in human behavioral neurotoxicology research since clinicians initiated workplace or field studies in the 1960s. Reports of statistically significant differences between workers and controls reveal consistent but unique patterns of cognitive deficits associated with chronic exposures to metals (e.g., lead, mercury), organophosphate pesticides, and solvent mixtures, the agents/categories for which there is a sufficient body of evidence to establish replication. Those deficits are consistent with reports of human poisonings and animal research on the same chemicals. Evidence of the impact of human subject variables (e.g., age, education, gender, motivation) on standard neurobehavioral tests used in this field establishes the importance of these variables in selecting appropriate comparisons (controls or eferencts) just as do parallel factors in animal research. The impact of parameters of human tests (e.g., match-to-sample, selective attention task, progressive ratio) that are comparable to tests employed in animals when studying neurotoxic chemicals will be described. The sensitivity of human cognitive tests to low-concentration chemical exposures will be discussed, citing evidence from recent research on occupational groups (e.g., orchard workers) and veterans returning from the Persian Gulf.

16 RELATIONSHIPS BETWEEN BIOPERSISTENCE, IN VITRO DISSOLUTION RATE, AND FIBER TOXICITY.

D M Bernstein[1] and T W Hesterberg[2]. [1]*Consultant in Toxicology, Geneva, Switzerland;* [2]*Johns Manville Corporation, Littleton, CO, USA.*

For many years, inorganic fibers have been viewed with suspicion as potential pulmonary toxins. However, extensive new research reveals that inorganic fibers encompass a broad range of biological reactivity, from innocuous to pathogenic. The fibrous shape is problematic in that it permits penetration into the lower lung of very long particles that cannot be fully phagocytized and cleared by macrophages. If the fiber contains a high proportion of soluble components, it quickly dissolves in the lung environment and thus has little time to induce toxicity. Research suggests that only those fibers that persist in the lung can lead to disease. In contrast to asbestos, synthetic vitreous fibers chemically and physically degrade in the lung relatively quickly, with the new generation of vitreous fibers clearing from the lung within weeks or days. This workshop focuses on fiber biopersistence as a determinant and predictor of fiber toxicity and examines the possible mechanisms of biopersistence, including dissolution rate. Fiber biopersistence research is also discussed as the scientific basis for fiber classification schemes adopted by the Europe Union and Germany and those that are currently being developed in the US.

17 SCIENTIFIC BASIS OF BIOPERSISTENCE METHODS TO CHARACTERIZE THE CARCINOGENIC POTENTIAL OF FIBERS.

G Oberdörster. *University of Rochester, Department of Environmental Medicine, Rochester, NY, USA.*

The assumption that biopersistence of a fiber in the lung correlates with its long-term toxicity and carcinogenicity is well supported by experimental data. Methods to determine pulmonary biopersistence include fiber administration in rats by intratracheal instillation or by inhalation over a five-day period. The subsequent disappearance of fibers in the lung is due to physical (cellular removal; breakage) and chemical (dissolution; leaching) processes. Since there are significant species differences (rat vs. human) of these different processes, the extrapolation of results from rat biopersistence studies to humans may not be as straightforward. The focus is on fibers > 20 μm in length. The problem for inhalation of these fibers is that respirability in rats is very poor compared to humans. Intratracheal instillation results in other problems, such as clumping of the fibers, especially if long ones are present, and induction of significant inflammatory reactions when high doses (>1 mg) are delivered. Although the inhalation method is not without problems when it comes to administering long human respirable fibers, it is still superior to intratracheal instillation which is prone to influences by artifacts. However, a promising method combining the advantages of inhalation and instillation and avoiding their disadvantages is the use of intratracheal inhalation in rats. This method has successfully been used to deliver particles to the alveolar region for determining long retention halftimes, it circumvents the rat's nasal filter and can deposit human respirable fibrous and non-fibrous particles into the pulmonary region of the rat. The method is easy to establish and should be tested for its suitability for biopersistence testing.

18 THE BIOPERSISTENCE OF SYNTHETIC VITREOUS FIBERS: A CRITICAL DETERMINANT OF THE BIOLOGICAL ACITIVITY OF FIBERS.

J G Hadley and W Eastes. *Owens Corning Science and Technology Center, Granville, OH, USA.*

The lung has highly efficient defense systems to protect the gas exchange surfaces from inhaled particles. Airway geometry precludes large particles from entering the deep lung and those that do penetrate can be readily phagocytized by alveolar macrophages. The fibrous shape is unique in being able to penetrate the deep lung with a dimension (length) which precludes effective macrophage ingestion. Absent a removal mechanism, long fibers, if durable and in adequate concentrations will accumulate and lead to disease. Identifying the relationships between fiber composition, in vitro and in vivo durability, and chronic effects has led to the development of a simple predictive model of the biological effects of inhaled fibers based on their composition. This understanding of the critical nature of fiber durability provides guidance for fiber manufacturers to assure the safety of their products and has important implications for the regulation of synthetic vitreous fibers.

19 IMPORTANCE OF THE BIOPERSISTENCE OF MINERAL FIBERS TO FIBER TOXICITY.

H Muhle and B Bellmann, and O Creutzenberg. *Fraunhofer Institute of Toxicology and Aerosol Research, Hannover, Germany.*

The biopersistence of various synthetic mineral fibers (glass, stone, ceramic) was investigated after 5day inhalation exposure or intratracheal instillation of rats. The test protocols proposed for regulation in the European Community were used (ECB/TM/26 and ECB/TM/27). Only a limited database is available to correlate the biopersistence to chronic toxicity data. Some information exists for chronic inhalation studies and after intraperitoneal instillation. Studies after inhalation exposure for up to 90 days and a post-treatment observation period are useful to investigate the inflammatory potential, the proliferation rate of the bronchial and alveolar epithelia, and the impact on the macrophage mediated clearance. Such studies were performed with MMVF 21 and RCF 1. Further studies are currently performed. For soluble fibers only transient effects are seen whereas for persistent fibers the effects are more pronounced.

20 COMPARISONS OF LUNG CLEARANCE MECHANISMS OF TWO ORGANIC FIBER-TYPES: IN VITRO AND IN VIVO MECHANISTIC STUDIES.

D B Warheit. *DuPont Haskell Lab, Newark, DE, USA.*

Studies were undertaken to investigate the mechanisms through which inhaled p-aramid fibrils (RFP) are biodegraded in the lungs of exposed rats and hamsters; in contrast cellulose fibers are biopersistent. In earlier 2-week inhalation studies, rats were exposed to RFP (419 or 772 f/ml) or to Thermocell mechanical wood pulp cellulose fibers (300 and 575 fibers/ml). Hamsters were exposed to RFP concs. of 358 and 659 f/ml. The lungs of fiber-exposed animals were assessed over time for clearance and biopersistence. p-Aramid was biodegradable, as evidenced by progressive shortening of inhaled RFP (mean RFP lengths decreased from 12.5 um to 7 um with increased residence time in the lung). In contrast, lung clearance of cellulose was slow with mean lengths and no shortening of retained fibers. To investigate the mechanisms of RFP biodegradation, we have postulated that lung fluids activate RFP following deposition and are then vulnerable to enzymatic attack in the lungs. To test the hypothesis, RFP or cellulose were instilled into the lungs of rats and the lungs digested 24 hrs postexposure using two different digestion techniques, 1) a conventional ethanolic KOH method, and 2) an enzyme method (which simulates lung enzymes). The enzyme but not KOH method artificially cleaved the RFP recovered from rat lungs. Next, RFP or cellulose fibers were incubated with saline or lung fluids and then processed by the 2 digestion techniques. Mean lengths of RFP processed with KOH and evaluated by SEM were 13.4 um; in contrast, mean lengths of RFP samples, incubated in lung fluids and treated with the enzyme method were 8.8 um. The enzyme digestion method had no discernible effect on shortening of cellulose fibers, indicating that the results with p-aramid were specific. Our results suggest that components of lung fluids coat and catalyze the p-aramid, rendering the fibrils vulnerable to enzymatic attack, and this could result in the mechanism of transverse cleavage of inhaled p-aramid fibrils in the lungs of exposed rats and hamsters.

21 EFFECTS OF LEAD ON CELLULAR AND HUMORAL IMMUNE RESPONSE OF ENVIRONMENTALLY EXPOSED CHILDREN.

A P Pineda-Zavaleta, G García-Vargas, A Gómez-Muñoz, V H Borja-Aburto, E Vera, M E Cebrián and E S Calderón-Aranda. *Sección de Toxicología Ambiental, CINVESTAV IPN, México DF.*

Lead has different toxic effects on immune system as suppressed cell mediated immunity or/and enhanced humoral response has been reported in humans occupationally exposed and animals. Thus, we investigated the immune response in 65 children having blood lead concentrations (PbB) ranging from 3 to 50 μ g/dl. Children were divided in three groups according to their PbB: low (PbB ≤ 10 μ g/dl), medium (10 < PbB < 25 μ g/dl) and high exposure (PbB ≥ 25μ g/dl). The cell mediated response was evaluated as lymphoproliferation to tetanic toxoid (Txt) or to phytohaemagglutinine (PHA). Humoral response was evaluated by quantitating Txt specific immunoglobulines G (IgG) after programmed immunization. Finally, we evaluated unspecific responses, such as nitric oxide (NO) and superoxide (O_2) production by macrophages, activated either directly with interferon-γ and lipopolysaccharide or indirectly with lymphocytes and PHA. Production of $O_2^-$was directly related to PbB. The IgG titer was also directly related to PbB up to 22 μ g/dl, suggesting an enhanced Th_2 activity, and then decreased without reaching control group values. This course of action suggests that at high PbB, cells are downregulated or too damaged to activate or produce antibodies. The NO production, by indirect activation, was inversely related to PbB, suggesting a decreased Th_1 activation, whereas no significant impairment was observed upon direct activation. There were no significant associations among PbB and the other parameters evaluated. Thus, lead exposure could result in two different immunotoxic effects on children: 1) The altered cell mediated NO production could prevent an efficient response to intracellular parasites and 2) The increase in specific IgG titers, suggest that lead may induce autoimmune responses by enhancing autoantibodies production by a mercury-like mechanism.

22 EMBRYONIC EXPOSURE TO LEAD MODULATES TH1/TH2 ASSOCIATED IMMUNE FUNCTIONS AND IS INFLUENCED BY DEVELOPMENTAL STATUS.

S Chen, K A Golemboski and R R Dietert. *Institute of Comparative and Environmental Toxicology, Department of Microbiology and Immunology, College of Veterinary Medicine, Cornell University, Ithaca, NY, USA.*

Following a prior developmental immunotoxicology study in rats, the current study utilized a second species, the chicken, to examine potential direct effects of lead on the developing immune system. Lead acetate at sublethal doses or control solution (sodium acetate) was administered to fertilized Cornell K strain White Leghorn eggs via the air sac at day 5 or day 12 of embryonic development. Immunological assessment was performed in female chickens at 5-6 weeks of age. The day 5 lead exposed group (10 ug Pb/egg dose) showed significantly elevated anti-BSA antibody production with no change in the delayed-type hypersensitivity (DTH) response to BSA when compared with the control. In contrast, day 12 lead exposed groups (100, 200, 400 ug pb/egg doses) demonstrated both increased anti-BSA antibody production and depressed DTH response to BSA compared with that of the control. Nitric oxide production from macrophages was significantly decreased in day 5 (10 ug pb/egg dose) and day 12 (50 ug pb/egg dose) lead treated groups. This present study suggests that lead has direct persistent immunotoxic effects on the developing immune system in the absence of the maternal system; the range of effects is influenced by the developmental stage of exposure. The results support the hypothesis that embryonic exposure to lead disrupts the Th1/Th2 balance by inducing a strong Th2 response (antibody production) and/or a suppressed Th1 response (DTH response). (Supported by NIEHS grant #ES05950.)

23 MERCURY: EFFECTS ON IMMUNE RESPONSE IN MICE MAY INVOLVE GLUTATHIONE DEPENDENT MECHANISMS.

E K Silbergeld[1,2], W Huang[1], J L Powell[3], A Azad[4], J Sacci[4,5]. [1]*Program in Human Health and the Environment,* [2]*Program in Toxicology,* [3]*Hospital Epidemiology,* [4]*Department of Microbiology and Immunology, University of Maryland Medical School, Baltimore, MD, USA; and* [5]*NNMRI, US Navy, Bethesda, MD, USA.*

Immunotoxic effects of mercury (Hg) are well described, although most research has dealt with Hg-induced autoimmunity. As reported at SOT 98, we have found that Hg impairs murine resistance to *Plasmodium yoelii*, a murine malaria. In these studies, we examined the effects of Hg exposure on acquisition of immunity to malaria. Male and female BalbC and CD1 mice were exposed to $HgCl_2$ (100 µg/kg, s.c.) every other day for 11 days. For immunization, they were administered (i.v.) irradiated sporozoites of *P. yoelii* on days 12 and 26 On day 40, they were challenged with live sporozoites. Exposure to Hg, over 5 weeks earlier, blocked acquisition of immunity to *P. yoelii*. Mechanisms of these effects are unknown. In general Hg inhibits Th1 and upregulates Th2 responses; consistent with this, we found that exposure of mouse splenocytes or human monocytes to 10^{-9} to $^{-6}$ M $HgCl_2$ in vitro inhibits production of interferon γ and increases production of IL-4. Hg also blocks LPS-induced nitric oxide synthase. These are important elements of host response to malaria and may explain at least in part decreased resistance. Depletion of cellular glutathione by DEM in vitro also inhibits interferon and nitric oxide production. This suggests that immunotoxic effects of Hg may involve interactions with thiol proteins. The mechanisms by which Hg interferes with the acquisition of immunity are not known. (Supported by grants from the W Alton Jones and Heinz Family Foundations.)

24 EFFECTS OF *IN VIVO* EXPOSURE TO HEXACHLOROBENZENE AND *TRICHINELLA SPIRALIS* INFECTION ON CYTOKINE EXPRESSION AND PRODUCTION BY CULTURED SPLENOCYTES FROM LEWIS AND BROWN NORWAY RATS.

H Van Loveren[1], C Meredith[2], M P Scott[2], M E A Van Dijk[1] and R J Vandebriel[1]. [1]*Laboratory for Pathology and Immunobiology, RIVM, Bilthoven, NL;* [2]*Immunotoxicology, BIBRA, Carshalton, UK.*

In a previous study, exposure of Wistar rats to the immunotoxic compounds bis(tri-*n*-butyltin)oxide, hexachlorobenzene (HCB), and benzo(a)pyrene was found to affect IL-2, IFN-γ, and IL-2R α -chain (IL-2Rα) mRNA expression. No exposure effects on IL-4 expression were found. To study whether this lack of effect was due to the nature of the compound, the rat strain used, or the parameter tested, Lewis (TH1-prone) and Brown Norway (BN; TH2-prone) rats were exposed to various doses of HCB for 6 weeks. HCB exposure was previously found to increase serum IgE levels, an IL-4 dependent response, in BN but not Lewis rats. As a positive control for expression and production of TH1 and TH2 cytokines, BN rats were infected with *Trichinella spiralis*. Spleen cells were cultured with Con A and analyzed for IL-2, IFN-γ, IL-2Rα , IL-4, and IL-10 expression, and IFN-γ, IL-4, and IL-10 production. HCB exposure resulted in Lewis rats in reduced IFN-γ and IL-10 expression and reduced IFN-γ , IL-4, and IL-10 production, with no or small effects in BN rats. *T. spiralis* infection resulted in increased IFN-γ , IL-4, and IL-10 expression and increased production of IL-10 and IFN-γ . Remarkably, IL-4 production was strongly reduced. In both studies, however, IL-4 production was below or around the detection limit. In sum: (1) A good correlation exists between cytokine expression and production for IFN-γ and IL-10. (2) IL-10 seems more useful than IL-4 as a parameter for TH2 cytokines. (3) A poor correlation exists between effects on IL-4 and effects on IgE. (4) Lewis, BN, and Wistar rats (data for Wistar are obtained from earlier observations) show different response profiles after HCB exposure, with Lewis and BN being more sensitive than Wistar. (5) *T. spiralis* infection induces both the TH1 cytokine IFN-γ and the TH2 cytokine IL-10.

25 AFLATOXIN B_1 EXPOSURE IMPAIRS HOST RESISTANCE THROUGH DEFECTS IN MACROPHAGE DERIVED CYTOKINE PRODUCTION.

K E Jordan, M Wills-Karp and G J Jakab. *Division of Toxicological Sciences, Johns Hopkins University, School of Hygiene and Public Health, Baltimore, MD.*

Aflatoxin B_1 (AFB_1), is a well characterized environmental carcinogen. In addition to its known carcinogenic endpoint, AFB_1 has been demonstrated to be immunosuppressive. We have previously shown that male Fisher 344 rats intratracheally exposed to AFB_1 (750 µg/kg) and subsequently challenged with *Listeria monocytogenes*, are unable to clear the systemic infection as compared to controls. These data demonstrate that there is a functional impairment in cell populations intrinsic to infectious immunity resulting from an acute dose of AFB_1. Resolution of infection with *L. monocytogenes* is dependent upon activation of the macrophage system through cytokine interactions, namely TNFα and IFNγ. To investigate the mechanism whereby AFB_1 affects cellular immunity, splenic macrophages were harvested from AFB_1-treated rats, cultured *in vitro* with LPS 2 days following treatment, and TNFα production was subsequently quantitated by ELISA. There was a striking suppression (54% of controls) of macrophage TNFα production from AFB_1-treated animals, whereas splenic lymphocytes from AFB_1-treated animals showed no difference in Con A-stimulated IFNγ production. These data demonstrate that there is a defect in the macrophage mediated immune response rather than an impairment in T cell function. Similarly, there was an equal degree of TNFα suppression (50%) when splenic macrophages were isolated from untreated rats and exposed *in vitro* to 30µM AFB_1 for 24 hr, as compared to cells treated with media alone. These data suggest that AFB_1 is metabolized by the macrophage itself to a reactive intermediate which then results in functional impairment. We conclude that the mechanism of AFB_1-induced immunosuppression involves a defect in macrophage secretion of the proinflammatory cytokine TNFα.

26 IMMUNOTOXICITY TESTING: A COMBINED LISTERIA IMMUNIZATION/INFECTION MODEL IN WISTAR RATS.

S Spanhaak, A Laarman and A H Penninks. *TNO Nutrition and Food Research Institute, Zeist, The Netherlands.* Sponsor: B Kulig.

The Plaque Forming Cell (PFC) assay with sheep red blood cells or an alternative T cell dependent B cell response is generally recommended for testing immunotoxicity. Investigation of other aspects/functions of the immune system require additional studies. A more comprehensive and possibly more sensitive model, reducing the number of studies required, is under development. In this model an immunization procedure using dead, irradiated *Listeria monocytogenes* bacteria with a subsequent infection with live virulent *L monocytogenes* is combined. Female Wistar rats were immunized with dead *L. monocytogenes* bacteria at days 0, 9 and 18. The immunization doses ranged from 10^5 to 10^9 bacteria per animal. All applied doses resulted in clear T cell responses as measured by proliferation assays with spleen cells at day 28. Moreover, administration of especially the higher doses (>10^6 bacteria per animal) resulted also in a marked IgM and IgG (specifically IgG2a) production on days 18 and 28. There was no clear distinction between immunization protocols wich used either two (days 0 and 18) or three (days 0, 9 and 18) applications of the antigen. These findings indicate that the immunization procedure at least may be used as an alternative to the PFC assay.

However, infecting the animals subsequently with live *L. monocytogenes* and determining the survival of the bacteria two days thereafter in liver and spleen not only enables to investigate effects on the innate immunity but also on the adaptive immunity. Currently a validation study is underway in which effects of an immunosuppressive drug (cyclophosphamide) and an immune enhancing compound (the adjuvant alumiumhydroxide) are investigated with this new model. It is expected that the model being developed will be a good and more comprehensive alternative to the PFC in which, besides effects on the T cell dependent B cell response, also effects on the innate immunity and the interaction between the adaptive and the innate immunity can be tested.

27 A MOUSE MODEL OF INFLUENZA EXHIBITS INCREASED MORBIDITY, MORTALITYAND THYMIC ATROPHY ASSOCIATED WITH ALTERED LUNG CYTOKINE PATTERNS FOLLOWING EXPOSURE TO MILD ULTRAVIOLET RADIATION (UVR).

L K Ryan, L Bishop, M Daniels, M I Gilmour, Y S Huang, M Ward, W Dong and M J K Selgrade. *US EPA, NHEERL, Immunotoxicology Branch, Research Triangle Park, NC, USA.*

Low level exposure to dioxin, UVR and ozone increases mortality in mice subsequently infected with influenza virus without increasing virus titers in the lung; little toxicity is induced in uninfected animals. Protective immunity to influenza is not compromised by UVR, even though UVR is known to suppress contact and delayed-type hypersensitivity. In this study, the nature of the increased mortality was investigated using a BALB/c female mouse model exposed to 8.2 kJ/m^2 UVR 3 days prior to infection with mouse-adapted Hong Kong influenza A/68 virus. We hypothesized that UVR exposure, which induces interleukin-10 (IL-10), tumor necrosis factor (TNF) and other mediators, alters cytokine responses to influenza virus. After UVR or control light pre-exposure and subsequent viral or sham infection, groups were sacrificed daily from 0-6 days. The UVR-virus group exhibited increased body weight loss, thymic atrophy and pulmonary erythrocyte congestion compared with the light-virus group. The virus-induced lymphocytic lung infiltrate on day 5 was also dampened by UVR. Lung virus titers and numbers of opportunistic bacteria and elevated serum cortisol levels were similar in both infected groups. No elevation in serum IL-10 or TNF was found. In both lung lavage (BAL) fluid and homogenates (LH), influenza virus caused an increase in TNF, IL-1α , IL-6, IL-10, total IL-12 (p40), and interferon (IFN)-γ , but not IL-12 p70, GM-CSF, IL-4, IL-5, or IL-1β . In LH samples, virus-induced total IL-12 (mostly p40) and IFN-γ were dampened by UVR, whereas IL-10 induction was not altered. In BAL, virus-induced IL-10 and IFN-γ release in the lung on day 5 was decreased by UVR. TNF or IL-1α levels were similar in both BAL and LH from the UVR-virus group and the light-virus groups. IL-6 levels were elevated in the UVR-virus group. The data suggest that alteration of protective cytokines by environmental agents may be a mechanism for increasing the morbidity and mortality to influenza virus in the nonimmune host following primary infection. (This abstract does not reflect EPA policy.)

28 SUPPRESSION OF ALLERGIC IMMUNE RESPONSES TO HOUSE DUST MITE (HDM) IN RATS EXPOSED TO 2,3,7,8-TCDD.

R W Luebke[1], C B Copeland[1], M Daniels[1], A L Lambert[2] and M I Gilmour[1]. [1]*Experimental Toxicology Division, US EPA, Research Triangle Park, NC, USA;* [2]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC, USA.*

Exposure to various xenobiotics, including NO_2, diesel exhaust and certain pesticides, has been reported to exacerbate pulmonary allergic hypersensitivity responses. To determine whether TCDD exposure affects allergic immune responses and subsequent clinical disease, Brown Norway rats were injected i.p. with 0, 1, 10 or 30 μ g TCDD/kg 7 d before intratracheal (i.t.) sensitization to semipurified house dust mite allergen (DMA). After 14 d, rats were challenged with DMA and immediate bronchospasm was measured. At this time point and 2 and 7 d later, inflammatory cells in bronchoalveolar lavage fluid (BALF), DMA-specific IgE levels in serum and BALF, and DMA-driven cell proliferation in bronchial lymph nodes and spleen were evaluated. TCDD exposure decreased immediate bronchoconstriction and IgE levels after DMA challenge; 7 d later, DMA-specific IgE responses remained suppressed, while total IgE levels increased in rats exposed to the highest dose of TCDD. DMA challenge significantly increased cellular and biochemical indicators of lung injury, all of which were suppressed by TCDD exposure. The proliferative response of lymph node cells, but not spleen cells, to DMA was suppressed at the highest TCDD dose and the splenic response to Con A was elevated. At present, we have no explanation for elevated total IgE levels. Nevertheless, these data show that TCDD exposure suppresses, rather than increases, local allergic sensitization to HDM and subsequent expression of clinical disease on re-exposure to antigen. (This abstract does not reflect EPA policy.)

29 EXPOSURE TO TCDD SUPPRESSES THE RECRUITMENT OF T CELLS TO THE LUNGS OF C57Bl/6 MICE IINFECTED WITH INFLUENZA VIRUS.

B P Lawrence and T K Warren. *Dept. of Pharmaceutical Sciences, College of Pharmacy, Washington State University, Pullman, WA.*

The immune response to infection with influenza virus is exquisitely sensitive to suppression by halogenated aromatic hydrocarbons such as 2,3,7,8–tetrachlorodibenzo–Dioxin r (TCDD). Exposure of C57Bl/6 mice to TCDD (1–10 μg/kg bodyweight) caused a dose–responsive increase in mortality following infection with a nonlethal strain of influenza virus (A/HKx31). The association between enhanced susceptibility to the pathological effects of influenza virus and TCDD exposure has been reported by other laboratories; however, the mechanism is unknown. It is generally accepted that a positive outcome from a primary infection with influenza virus is dependent upon the generation of an effective cell–mediated response, which includes the activation and differentiation of naive CD8 T cells in the regional lymphoid organs and the subsequent migration of effector cytotoxic T lymphocytes 9 (eCTL) to the lung. We have tested the hypothesis that exposure to TCDD suppresses the activation and differentiation of CD8 T cells, leading to decrease CTL in the lungs. Initial experiments have revealed that exposure to TCDD dose–dependently decreased the recruitment of cells to the lungs in response to influenza virus. Moreover, flow cytometric analyses of bronchoalveolar lavage (BAL) cells showed that, when compared with BAL cells from infected controls, exposure to TCDD decreased the number of CD8 lymphocytes and there was a decrease in the percent of CD8 BAL cells bearing an eCTL phenotype (CD44). However, when compared on a per cell basis, the CTL activity 9 of BAL cells against HKx31–infected targets was equal to that of virus–infected controls, which suggests that exposure to TCDD affects the development of eCTL rather than the eCTL lytic machinery. In conclusion, reduced CTL in the lung are one mechanism which may underlie the enhanced mortality observed following influenza infection and exposure to TCDD.

30 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN (TCDD) DIFFERENTIALLY ALTERS THE COURSE OF LEISHMANIASIS IN RESISTANT AND SUSCEPTIBLE MICE.

G K Dekrey and R G Titus. *Colorado State University, Fort Collins, CO, USA.*

T helper type (Th)-1-like cellular immune responses can be suppressed by TCDD in mice, although the exact mechanism(s) involved are unclear. In contrast, little is known of the effects of TCDD on Th-2 driven cellular immunity. We used a model of experimental cutaneous leishmaniasis to compare the effects of TCDD on both Th-1 and Th-2 responses. Most mouse strains successfully resist infection with *Leishmania major* via a Th-1 response [interferon (IFN)-γ^{high}, interleukin (IL)-4^{low}], whereas BALB/c mice are lethally susceptible to infection due to an ineffective Th-2 response (IFN-γ^{low}, IL-4^{high}). TCDD was given orally (0, 0.6, 2.5, 10 or 40 μg/Kg) one day prior to infection of each mouse in one rear foot pad with 10^6 *Leishmania major*. Foot lesion size was followed as an index of disease status. Lesions of vehicle-treated C57Bl/6 (B6) mice reached a maximum of ~1.5 mm on day 26 and had completely resolved by day 75. TCDD did not alter maximum lesion size; however, a dose-dependent delay in lesion resolution was observed (a 59 day delay in the 10 μg/Kg dose group). Although the number of *L. major* per lesion varied significantly between dose groups, the variation was not dose-dependent suggesting a lack of a direct TCDD effect on *L. major*. Ex vivo cytokine production by lesion-draining lymph node cells indicated no dose-dependent change in IFN-γ production, whereas IL-4 production decreased in a dose-dependent manner — from 8 pg/mL of supernatant for vehicle-treated mice to undetectable for mice given TCDD at 10 μg/Kg. Other standard dose-dependent effects of TCDD in B6 mice (decreased thymus weights and specific antibody levels) were observed. In contrast to B6 mice, TCDD significantly slowed the progression of lesion development in BALB/c mice. Whereas euthanization of vehicle-treated BALB/c mice was necessary 49 days after infection because of the severity of foot lesions, euthanization of BALB/c mice treated with TCDD at 10 μg/Kg was not necessary until 96 days after infection. We spec-

ulate that TCDD-induced suppression of IL-4 production plays a role in immune modulation in BALB/c mice infected with *L. major*.

31 ABILITY OF SPLENIC DENDRITIC CELLS (DC) FROM 2,3,7,8-TETRACHLORODIBENZO-P-DIOXIN (TCDD)-TREATED MICE TO INDUCE T CELL ACTIVATION EX VIVO.

B A Vorderstrasse and N I Kerkvliet. *Department of Environmental and Molecular Toxicology, and Environmental Health Science Center, Oregon State University, Corvallis, OR, USA.*

Dendritic cells are a population of antigen presenting cells whose primary function is to activate T cells. Previously we reported that *in vivo* exposure of mice to TCDD altered the expression of costimulatory/adhesion molecules on the DC. Specifically, the expression of B7-2, CD40, ICAM-1 and CD24 molecules was enhanced and LFA-1 was suppressed on the DC taken from TCDD-treated mice. In order to evaluate the impact of these phenotypic alterations on DC function, we tested the ability of DC to activate T cells *in vitro*. DC were enriched from spleens of C57BL/6 mice which had been treated with vehicle or TCDD (15μg/kg) 3 days prior to sacrifice. DC were then incubated with either allogeneic T cells or KLH-specific cloned T cells. Proliferation was measured as ^{3}H-TdR uptake. Cytokine production, including IL-2, IFN-γ, and IL-12 in the allogeneic cultures, or IL-4 in the T clone cultures, was measured by ELISA. *In vivo* exposure to TCDD did not suppress the ability of the DC to activate T cells. On the contrary, all responses that were statistically different indicated enhanced activation. T cell proliferation tended to be enhanced and, in one experiment, IL-4, IFN-γ, and IL-12 production was increased. Thus, under the conditions of these experiments, TCDD exposure *in vivo* does not suppress, but may change, the way DC stimulate basic T cell activation. The impact, if any, on immune function remains unknown. (Supported by NIEHS grant #s ES07060 and ES003966.)

32 LIVER PROTEIN ADDUCTS OF QUINONES AND SEMIQUINONES FROM METABOLIC ACTIVATION OF PENTACHLOROPHENOL.

C H Tsai, P H Lin, S Waidyanatha, and S M Rappaport. *Dept. of Environmental Sciences & Engineering, School of Public Health, UNC, Chapel Hill, NC, USA.* Sponsor: J Swenberg.

Metabolic activation of pentachlorophenol (PCP) to chlorinated quinones and semiquinones was investigated *in vitro* in a microsomal or peroxidase mediated activation system and *in vivo* in rodents. Mono-S- and multi-S-substituted cysteinyl adducts derived from tetrachloro-1,2-benzoquinone (Cl_4-1,2-BQ) were identified in liver cytosol treated with PCP *in vitro* and in B6C3F1 mice administered with PCP *in vivo*. Adduct levels increased with increasing dosage of PCP in B6C3F1 mice (0-40 mg/kg body weight). No Cl_4-1,2-BQ-derived liver protein adducts were detected in PCP-treated Sprague-Dawley (0-40 mg/kg body weight) and Fischer 344 rats (60 mg/kg body weight/day in the diet for 6 months). These results confirmed our previous observation that Cl_4-1,2-BQ is a mouse-specific quinone derived from bioactivation of PCP *in vivo*. In parallel, we confirmed that tetrachloro-1,4-benzoquinone (Cl_4-1,4-BQ)-derived adducts in 3-methylcholanthrene and phenobarbital-induced rat and mouse microsomes were 3-7 fold higher than in non-induced microsomes *in vitro* where levels of Cl_4-1,2-BQ, tetrachloro-1,4-semiquinone, and tetrachloro-1,2-semiquinone derived adducts remained unchanged. The K_m for the formation of all PCP-derived adducts in 3-methylcholanthrene-induced microsomes was to 52 μ M for both rats and mice. When cumene hydroperoxide was used as a cofactor, with or without microsomes, the levels of quinone and semiquinone adducts increased by 8-130 fold in rats and 1.5-40 fold in mice compared to using NADPH as a cofactor. Taken together, these results suggest that species differences exist in the metabolism of PCP to quinones and semiquinones, and that cumene hydroperoxide supported bioactivation is the dominant pathway for the conversion of PCP to quinoid derivatives *in vitro* in both rats and mice. (This work was supported by the National Institute of Environmental Health Sciences through grant P42ES05948.)

33 PROTEIN ARYLATION IS NOT BY ITSELF SUFFICIENT FOR HEPATIC NUCLEAR TRANSLOCATION OF THE 58-KDa ACETAMINOPHEN BINDING PROTEIN (58-ABP).

A M Luças, M K Bruno, and S D Cohen. *Department of Pharmaceutical Sciences, University of Connecticut, Storrs, CT, USA.*

APAP overdose can result in covalent binding (CVB) of APAP to cellular proteins with subsequent hepatotoxicity. In particular, APAP targets the 58-ABP in the cytosol with subsequent translocation from the cytosol to the nucleus before there are detectable perturbations of the nuclear membrane. Earlier studies demonstrated translocation after a toxic dose but not after a nontoxic dose of APAP. However, the non-toxic dose was also associated with less covalent binding. To determine this translocation occurs with binding in the absence of toxicity male CD-1 mice were administered either multiple non-toxic doses of APAP (400 mg/kg, ip, 2 times/day) for either 2, 4, or 10 days and then killed the following day, or they were administered a single toxic dose of APAP (600 mg/kg, ip) and killed 1, 2, or, 4 hours after challenge. APAP CVB and 58-ABP in cytosolic and nuclear fractions were detected by western blot analysis using anti-APAP antibody or anti-58-ABP antisera, respectively. Bound APAP was detected in cytosolic and nuclear membrane fractions from treated mice, but not controls. By contrast, in mice dosed repeatedly with the nontoxic dose of APAP, by 10 days the level of APAP adduct was similar to that seen after toxic doses yet there was no toxicity and no detectable 58-ABP in the nucleus. Thus when approximately equivalent APAP CVB to cytosolic and nuclear membrane proteins was present in each treatment group, 58-ABP translocation was only observed after a toxic APAP dose. These data suggest that APAP CVB alone is not sufficient for translocation and that translocation may reflect a cellular response to toxic insult. (Boehringer Ingelheim Pharmaceuticals Predoctoral Fellowship in Toxicology, NIEHS E507163.)

34 IDENTIFICATION OF A NOVEL 210 KDA PLASMA MEMBRANE PROTEIN ARYLATED BY ACETAMINOPHEN IN MOUSE LIVER.

J E Manautou[1], C Chen[1], and D J McCann[2]. [1]*Dept. Pharmaceutical Sciences, Univ. Connecticut, Storrs, CT;* [2]*Drug Disposition and Metabolism Dept., Zeneca Pharmaceuticals, Wilmington, DE.*

Selective covalent binding of acetaminophen (APAP) to cytosolic, microsomal, mitochondrial and nucleic, but not to plasma membrane proteins has been reported *in vivo*. In these studies, male CD-1 mice were injected *i.p.* with 600 mg APAP/kg. Controls received vehicle only. A mixed canalicular (cLPM) and basolateral (bLPM) plasma membrane fraction was generated by percoll density gradient, and probed for APAP covalent binding by western blotting using anti-APAP antibodies. Alkaline phosphatase activity and western blot analysis of P-glycoprotein served as markers of cLPM enrichment, while western blot analysis of Na+/K+ ATPase was used as a marker of bLPM enrichment. A single protein adduct of approximately 210 kDa was detected on this mixed membrane fraction, with maximal binding detected at 2-4 hrs after APAP challenge. In an attempt to better understand the identity and/or function of this APAP binding protein, mice were injected *i.v.* with 12 μmol/kg indocyanine green (ICG), a non-biotransformable anionic dye mostly excreted into bile, immediately followed by APAP challenge. Interestingly, ICG pretreatment of mice increased APAP binding to this protein. Further studies are needed to determine the function and role of this protein in the development of APAP toxicity. (Supported by Zeneca Pharmaceuticals and UCONN Research Foundation.)

35 A COMPARISON OF THE COVALENT BINDING OF VESNARINONE AND CLOZAPINE TO HUMAN NEUTROPHIL POLYPEPTIDES *IN VITRO*.

I Gardner, N Zahid and J Uetrecht. *Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada.*

The use of vesnarinone, a novel positive inotropic agent, has been associated with an incidence of agranulocytosis of 0.3 %. We have previously shown that activated neutrophils metabolize vesnarinone to a reactive iminium ion. In this abstract we describe the use of an anti-vesnarinone antiserum to characterize the covalent binding of the vesnarinone iminium ion to human neutrophils *in vitro*. Immunochemical studies demonstrated that vesnarinone reactive metabolite (0-100 μM) (generated directly by addition of HOCl to drug) covalently modified neutrophil polypeptides with apparent molecular masses of 126, 98, 90, 57 and 41 KDa. Further studies revealed that the 57 KDa vesnarinone adduct was formed by temperature-dependent degradation of the 98 KDa adduct. When vesnarinone was incubated with neutrophils in the presence of the cell activator phorbolmyristate acetate (PMA), a large number of vesnarinone modified-polypeptides (including major 126, 98 and 90 KDa adducts) were observed. When the covalent binding of clozapine, another drug that causes agranulocytosis, and vesnarinone were compared in PMA-activated neutrophils, the pattern of polypeptides modified was different (major drug-polypeptide adducts were 58 and 49 KDa with clozapine and 126, 98 and 90 KDa with vesnarinone). However, with both drugs polypep-

tide adducts of 126, 45, 41 and 31 KDa were formed suggesting that a subset of neutrophil proteins are covalently modified by both drugs. In addition, incubation of either drug with myeloperoxidase in the presence of H_2O_2 led to covalent modification of the enzyme. It may be that covalent modification of these common cellular targets plays a role in the agranulocytosis caused by the two drugs. (This research was supported by PMAC and the Medical Research Council of Canada (Grant number MT-13478).)

36 METABOLISM OF TRIMETHOPRIM BY ACTIVATED HUMAN NEUTROPHILS AND RAT LIVER MICROSOMES: IMPLICATIONS FOR TRIMETHOPRIM-INDUCED AGRANULOCYTOSIS AND LIVER TOXICITY.

W G Lai, N Zahid, and J P Uetrecht. *Faculty of Pharmacy, University of Toronto, ON, Canada.*

An antibacterial agent, trimethoprim (TMP), is normally used synergistically with sulfonamides. Its use is associated with agranulocytosis and liver toxicity. In this study, we demonstrated that trimethoprim was oxidized by activated human neutrophils, as well as a combination of myeloperoxidase/hydrogen peroxide/chloride, or hypochlorous acid to a reactive pyrimidine iminoquinone methide intermediate with a MH^+ ion of m/z 289 as detected by electrospray mass spectrometry (ESMS). In the presence of N-acetyl-L-cysteine (NAC), the pyrimidine iminoquinone methide could be trapped as three NAC adducts. The three NAC adducts were separable on HPLC but showed the same protonated molecular ion of m/z 452. The proton nuclear magnetic resonance spectrum of the major NAC adduct showed that the NAC group was at the 6 position of the pyrimidine ring. Incubation of trimethoprim with isolated rat-liver microsomes in presence of NAC gave the same set of TMP-NAC adducts. LC/MS/MS of the two minor metabolites of TMP generated by neutrophils and rat-liver microsomes indicated that they were the two diastereomers in which NAC was attached to the *exo*-cyclic prechiral carbon of the pyrimidine iminoquinone methide. We propose that the formation of this pyrimidine iminoquinone methide by both neutrophils and hepatic microsomes may be responsible for trimethoprim-induced idiosyncratic agranulocytosis and hepatotoxicity. (This work was supported by the PMAC and MRC of Canada.)

37 COVALENT BINDING SITES OF CLOZAPINE IN HUMAN NEUTROPHILS *IN VITRO* DETECTED BY CONFOCAL AND ELECTRON MICROSCOPY.

J H Zhan[1], I Gardner[1] and J P Uetrecht[1,2]. *Faculties of [1]Pharmacy and [2]Medicine, University of Toronto, Toronto, ON, Canada.*

Clozapine is often effective in the treatment of refractory schizophrenia but its use is limited by a high incidence of agranulocytosis. We recently demonstrated by immunoblotting that a reactive metabolite of clozapine covalently binds to several neutrophil proteins, both *in vitro* and *in vivo* in patients taking the drug. In this study, we used antibodies against clozapine and myeloperoxidase combined with confocal microscopy and electron microscopy to determine the localization of the covalent binding in neutrophils that occurs *in vitro*. When the reactive metabolite was generated externally with HOCl, confocal microscopy demonstrated that the reactive metabolite penetrated the cell and the pattern of binding appeared homogeneous except that no binding was detected in the nucleous. In contrast, when only clozapine and H2O2 were added to neutrophils, the pattern of covalent binding (visualized with a second layer fluoresceine antibody) appeared to match the pattern observed with an antibody against myeloperoxidase labeled with rhodamine. This suggests that the reactive metabolite was formed by myeloperoxidase/ H2O2. The results with electron microscopy using a second layer antibody tagged with gold, supported this hypothesis because most of the staining occured in the granules which is the location of myeloperoxidase. It was also observed in earlier *in vivo* studies that covalent binding occured to granulocytes but not to lymphocytes. These results suggest that most of the *in vivo* covalent binding of clozapine is due to a myeloperoxidase-dependent reactive metabolite. (This work was supported by a grant from the Medical Research Council of Canada (13478).)

38 INHIBITION OF GLUTATHIONE S-TRANSFERASES BY REACTIVE METABOLITES OF BUTYLATED HYDROXYTOLUENE.

J-N Lemercier, J P Desjardins, and J A Thompson. *University of Colorado Health Sciences Center, Denver, CO, USA.*

Butylated hydroxytoluene (BHT) is a phenolic antioxidant that causes a number of adverse biological effects in animals due to the formation of reactive metabolites including a quinone methide (BHT-QM) and a hydroperoxide (BHTOOH). Both of these metabolites are highly cytotoxic in vitro but little is known about their specific cellular targets responsible for toxicity. The electrophile BHT-QM is active in stress gene assays employing recombinant HepG2 cell lines by stimulating the xenobiotic response element and glutathione S-transferase (GST) and P450 1A1 promoters. The catalytic activity of P450 1A1 was enhanced in HepG2 cells treated with BHT-QM while GST activity was substantially decreased in these cells. Studies with purified GST demonstrated that the quinone methide is an irreversible inhibitor of dinitrochlorobenzene conjugation, presumably through alkylation of a critical nucleophile. With BHTOOH, GST exhibited peroxidase activity but the ability to conjugate dinitrochlorobenzene was greatly compromised. Further studies demonstrated that BHTOOH oxidizes methionine residues of GST to methionine sulfoxide (MetSO) and that this process occurs much more readily than with H_2O_2. Although it is possible that cysteine oxidation also occurs with BHTOOH, methionine residues appear to be more susceptible to this hydroperoxide. Investigation of BHTOOH-treated proteins by electrospray mass spectrometry confirmed the formation of MetSO and facilitated identification of the residues affected. These data indicate that both alkylating and oxidizing metabolites of BHT inhibit an important detoxification pathway. (Supported by NIH grant CA41248.)

39 GLUTATHIONE CONJUGATION OF ELECTROPHILIC METABOLITES OF 1-NITRONAPHTHALENE IN RAT TRACHEOBRONCHIAL AIRWAYS AND LIVER, IDENTIFICATION BY MASS SPECTROMETRY AND PROTON NUCLEAR MAGNETIC RESONANCE SPECTROSCOPY.

K C Watt[1], D M Morin[1], M J Kurth[2], R S Mercer[3], C G Plopper[4], and A R Buckpitt[1]. [1]*Dept. of Molecular Biosciences, School of Veterinary Medicine;* [2]*Dept. of Chemistry;* [3]*Facility for Advanced Instrumentation;* [4]*Dept. of Anatomy, Physiology and Cell Biology, University of California, Davis, CA, USA.*

1-Nitronaphthalene (1-NN) is a mutagenic nitroaromatic which has been detected in emissions from both heavy- and light-duty diesel engines, as well as in urban airborne particles. 1-NN is a cytochrome P450 (P450)-bioactivated, non-ciliated bronchiolar epithelial (Clara) cell cytotoxicant. The current studies examined the metabolism of 1-NN to electrophilic metabolites which were trapped as glutathione conjugates in highly susceptible (lung) and less susceptible (liver) tissues in rat. Significant depletion of reduced glutathione was observed in all levels of tracheobronchial airways of rats treated with 200 mg/kg 1-NN, ip. This was consistent with the HPLC radioactivity profiles demonstrating five putative glutathione conjugates isolated from liver microsomal incubations with 1-NN, glutathione S-transferase and tritiated [^{3}H] glutathione. Mass spectrometry in positive ion mode yielded a *m/z* of 497 (M+H), and daughter ions of *m/z* 479 (loss of water) and *m/z* 306 (glutathione), which were consistent with the formation of hydroxy-dihydro-glutathionyl derivative of 1-NN. Proton nuclear magnetic resonance (NMR) spectroscopy analysis suggested the formation of two major conjugates from liver microsomal incubations, namely 1-nitro-5-glutathionyl-6-hydroxy-5,6-dihydronaphthalene and 1-nitro-5-hydroxy-6-glutathionyl-5,6-dihydronaphthalene. These data show that P450 metabolizes 1-NN in the liver to an intermediate 5,6-epoxide, which is further metabolized by glutathione S-transferase to form 1-NN glutathione conjugates. HPLC radioactivity profiles demonstrate that major conjugate(s) generated in the lung differ from those generated in the liver, thus suggesting that either the intermediate epoxide is formed at different carbon positions, or the stereoisomer of the liver conjugate is formed in the lung.

40 FORMATION OF 1,1-DICHLOROETHYLENE EPOXIDE IN CENTRILOBULAR HEPATOCYTES OF MURINE LIVER.

P G Forkert and K Collins. *Department of Anatomy and Cell Biology, Queen's University, Kingston, ON, Canada.*

Hepatocellular injury ensues after treatment of mice with 1,1-dichloroethylene (DCE), a chemical used in the plastics industry. Necrosis of centrilobular hepatocytes is ascribed to P450-catalyzed formation of a reactive metabolite believed to be the DCE epoxide. *In vivo* studies were undertaken to test the hypothesis that *in situ* formation of the epoxide mediates the DCE-induced centrilobular damage. Epoxide levels were estimated by trapping the metabolite with glutathione (GSH), and identifying the conjugated products as *S*-(2,2-dichloro-1-hydroxy)ethyl glutathione [B] and 2-(*S*-glutathionyl) acetyl glutathione [C]. HPLC analyses showed that [C] was the major product found in liver cytosol isolated from mice treated *in vivo* with [^{14}C]DCE; the amounts of [B] formed were negligible. Epoxide levels were

dose-dependent at DCE doses ranging from 25 to 225 mg/kg (1.9 to 15.4 nmol/mg protein). Pretreatment of mice with buthionine sulfoximine (BSO) significantly decreased GSH content and inhibited formation of the epoxide (83%) from DCE (125 mg/kg). Pretreatment of mice with diallyl sulfone, an inhibitor of CYP2E1, also significantly decreased epoxide formation (82%). Immunohistochemical studies with a polyclonal antibody specific for conjugate [C] demonstrated staining in the centrilobular region of the liver lobule. The level of staining was dose-dependent and was highest at 225 mg/kg DCE. Staining of adjacent liver sections with a CYP2E1 antibody revealed labeling that was also located in the centrilobular region, and coincided with the areas in which [C] was found. These data demonstrated that the DCE epoxide is formed *in vivo*, and is localized in the target centrilobular hepatocyes. (Supported by MRC of Canada (Grant MT-11706) and NCI/NIH (CA 73220-01).)

41 CYP2F1 KINETIC STUDIES WITH DEUTERATED ANALOGS OF 3-METHYLINDOLE REVEAL MECHANISMS OF DEHYDROGENATION TO 3-METHYLENEINDOLENINE.

C R Borges and G S Yost. *Department of Pharmacology and Toxicology, University of Utah, Salt Lake City, UT.*

The reactive intermediate 3-methyleneindolenine (3MEI) is a major contributor to the systemic pulmonary toxicity of 3-methylindole (3MI). Dehydrogenation of 3MI by specific cytochrome P450s leads to the formation of 3MEI. To study this dehydrogenation mechanism, inter- and intramolecular isotope effect studies were conducted using CYP2F1—a human P450 enzyme that is selectively expressed in lung tissue and known for its ability to catalyze dehydrogenation reactions. For the intermolecular studies, four deuterated analogs at the 3-methyl position of 3MI were used (3MI-d0 through 3MI-d3). As suspected, increased deuterium substitution at the 3-methyl position caused sequential decreases in V_{max}. However, enzyme inhibition was observed at high substrate concentrations for all four isotopologs. Interestingly, the inhibition increased with increases in deuterium substitution. A possible mechanism for the inhibition may be isotopically sensitive formation of a mechanism-based inhibitor of 2F1. Intramolecular isotope effect studies with 3MI-d1 and 3MI-d2 isotopologs revealed an isotope effect (^{D}k) of 3.9 ± 0.53. A low isotope effect such as this may be explained by metabolic switching to form oxygenated rather than dehydrogenated products of 3MI. However, oxygenated products were not observed, and an alternate mechanism involving an aminium cation radical that inactivates the enzyme is proposed as an explanation for the relatively low intramolecular isotope effect and isotopically sensitive inhibition. Thus, deuterium-substituted isotopologs of 3MI were useful tools in elucidating the catalytic mechanisms of the human lung P450 enzyme CYP2F1. (Supported by USPHS grant HL13645.)

42 DOSE-DEPENDENT PROTEIN ADDUCT FORMATION IN RATS AND HUMANS AFTER PERCHLOROETHENE INHALATION.

A Pähler[1], J Parker[2], and W Dekant[1]. [1]*Institut für Toxikologie, Universität Würzburg, Germany;* [2]*US EPA, NCEA, Washington, DC, USA.*

Perchloroethene (PER) is an environmental contaminant. In bioassays for carcinogenicity PER was found to increase renal tumors in male rats. Toxic effects of PER after repeated administration are likely caused by bioactivation. PER bioactivation occurs by two pathways. Oxidation by cytochrome P450 results in trichloroacetyl chloride, which binds to lipids and proteins. Glutathione *S*-conjugate formation from PER and further processing of the formed *S*-(trichlorovinyl)glutathione to *S*-(trichlorovinyl)-*L*-cysteine followed by cysteine conjugate ß-lyase catalyzed cleavage results in the reactive dichlorothioketene which also binds to proteins. The objectives of this study were to quantify the dose-dependent formation of protein adducts from PER in rats and humans using antibodies specific for N^{ε}-(trichloroacetyl)-*L*-lysine (TCL) or N^{ε}-(dichloroacetyl)-*L*-lysine (DCL) in proteins. Male and female rats were exposed to 400, 40 and 10 ppm PER for 6 h and sacrificed at various time points. Formation of DCL and TCL in proteins was quantified in subcellular fractions from liver and kidney and in blood. In addition, male and female human volunteers were exposed to 10 and 40 ppm PER and formation of protein adducts in blood was analyzed using antibodies and GC/MS after immunoaffinity enrichment of modified proteins. In liver and kidney subcellular fractions and blood of PER-exposed rats, dose-dependent formation of DCL and TCL in proteins was observed. Highest concentrations of DCL were present in kidney. Blood concentrations of DCL were 5 to 10 fold lower than in kidney. Highest concentrations of TCL were found in the liver. In human blood samples taken 0 and 24 h after PER inhalation, TCL containing proteins were present in low concentrations. DCL containing proteins were not detected either by Western blotting or by GC/MS after immunoaffinity chromatography. The obtained results indicate a dose-dependent covalent binding of PER metabolites to proteins in rat liver, kidney and blood and suggest that covalent binding is much lower in blood of humans exposed under identical conditions.

43 A MECHANISM FOR THE ADDUCTION AND CLEAVAGE OF PEPTIDES BY NITROGEN DIOXIDE.

K C Hodge and D B Hood. *Dept. of Pharmacology, Meharry Medical College, Nashville, TN.* Sponsor: N H Zawia.

Nitrogen dioxide (NO_2), is an environmental pollutant and a nitroxide species is hypothesized to mediate reactions which result in the adduction and/or cleavage of peptides by NO_2. A mechanism for the adduction and cleavage reaction of peptides by NO_2 is presented. Phosphate buffered solutions of the model peptides (G4KG5), (K10) and alpha-1-proteinase inhibitor were exposed to varying molar ratios of NO_2 to target peptide. Analysis of the post exposure peptide solutions by HPLC and Matrix Assisted Laser Desorption Ionization (MALDI) Mass Spectroscopy demonstrated significant preferential fragmentation of the K10 polypeptide as compared to the G4KG5 control peptide. Exposure of alpha-1-proteinase inhibitor to NO_2 also revealed significant fragmentation. The fragmentation pattern of alpha-1-proteinase inhibitor is consistent with cleavage at sequences which are rich in positively charged amino acids. With proteins, the reaction may be conformational-dependent, in that the polypeptide backbone of positively charged amino acids tends to be acessible to solvent which may allow for the reactive uptake of NO_2. We conclude that NO_2 reactive uptake occurs at aqueous-surface interfaces, and as such, amino acid residues which are accessible to solvent appear to serve as excellent substrates for derivatization by NO_2. (Supported by NIH ES00287.)

44 N-ACETYLBENZIDINE PEROXYGENASE METABOLISM BY PROSTAGLANDIN H SYNTHASE.

T V Zenser[1], V Lakshmi[1], F Hsu[2], and B Davis[1]. [1]*VA Medical Center, St. Louis, MO;* [2]*Washington Univ., St. Louis, MO, USA.*

Synthesis of prostaglandin H_2 by prostaglandin H synthase (PHS) results in a two-electron oxidation of the enzyme. An active reduced enzyme is regenerated by reducing cofactors, which become oxidized. This report examines the mechanism by which PHS, from ram seminal vesicle microsomes, catalyzes the oxidation of the reducing cofactor N-acetylbenzidine (ABZ). During the conversion of 0.06 mM ABZ to its final end product 4'-nitro-4-acetylamino-biphenyl, a new metabolite was observed when 1 mM ascorbic acid was present with either 0.2 mM arachidonic acid or 0.5 mM H_2O_2 as substrate. This metabolite co-eluted with synthetic N'-hydroxy-N-acetylbenzidine (N'HA) and not N-hydroxy-N-acetylbenzidine. The new metabolite was identified as N'HA by ESI/MS/MS. N'HA represented as much as 10% of the total radioactivity recovered by HPLC. When N'HA was substituted for ABZ, PHS metabolized N'HA to 4'-nitro-4-acetylaminobiphenyl. Inhibitor studies demonstrated that metabolism was due to PHS not cytochrome P-450. DMPO, mannitol, and superoxide dismutase did not alter metabolism. Oxygen uptake studies did not demonstrate a requirement for molecular oxygen. When $[^{18}O]H_2O_2$ was used as substrate, ^{18}O enrichment was observed for 4'-nitro-4-acetylamino-biphenyl, but not N'HA. A 97% enrichment was observed for one atom of ^{18}O and 17 ± 7% for two ^{18}O atoms. The rapid exchange of ^{18}O-N'HA with water was suggested to explain the lack of enrichment of N'HA and the low enrichment of two ^{18}O atoms into 4'-nitro-4-acetylaminobiphenyl. Results demonstrate a peroxygenase oxidation of ABZ and N'HA by PHS and suggest stepwise oxidation of ABZ to N'-hydroxy, 4'-nitroso, and 4'-nitro products.

45 AN NMR ANALYSIS OF THE REACTION OF UBIQUITIN WITH [ACETYL-1-13C] ASPIRIN.

J M MacDonald[1], D A LeBlanc[1], A L Haas[2], R E London[1]. [1]*NIEHS, Research Triangle Park, NC;* [2]*Medical College of Wisconsin, Dept. of Biochemistry, Madison, WI.*

The acetylation of ubiquitin by [acetyl-1-^{13}C]aspirin has been studied using 2D NMR methods. Studies performed in a 50:50 H_2O:D_2O medium show doubling of the acetyl carbonyl resonances, indicating all of the stable adducts formed involved amide linkages. Assignment of the HMQC reso-

nances was accomplished based on comparison of resonance intensities with the results of an Edman degradation analysis, pH titration studies of acetylated ubiquitin, and analysis of two ubiquitin mutants, K33R and K63R. The presence of a single tyrosine residue in close proximity to lysine-48 suggested another assignment strategy. Nitration of tyrosine-59 resulted in a small, pH-dependent shift of the resonance assigned to lysine-48, with a pK of 7.0, close to that expected for the nitrotyrosyl hydroxyl group. An additional adduct resonance with very low intensity is also observed, and tentatively assigned to the acetylated N-terminal methionine residue. The relative rates of acetylation of the various lysine residues were obtained from time-dependent HMQC studies. Since no sample preparation artifacts are introduced, the levels of modification of the various residues can be determined with relatively high accuracy as compared to other methods; the relative degree of acetylation of ubiquitin by aspirin under the conditions of the study was: K6 > K48 > K63 > K11 ~ K33. These results are in much better agreement with predictions based on the crystal structure of the ubiquitin monomer, than with predictions based on the ubiquitin structure in the cystallized dimeric and tetrameric forms. This approach provides a useful basis for understanding how local environmental factors can influence protein adduct formation, as well as for comparing the extent and specificity of various acetylation reagents.

46 HEMOGLOBIN ADDUCT DOSIMETRY OF ACRYLONITRILE FOLLOWING CHRONIC ADMINISTRATION IN THE MOUSE.

T R Fennell[1], J P MacNeela[1], M J Turner, Jr.[1], D G Serota[2], and B Ghanayem[3]. [1]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA;* [2]*Southern Research Institute, Birmingham, AL, USA;* [3]*NIEHS, Research Triangle Park, NC, USA.*

Acrylonitrile (AN) is widely used in the manufacture of plastics and fibers. Hemoglobin adducts can provide a marker of exposure and internal dose, and can verify the extent of exposure in long-term animal studies. The objective of this study was to measure adducts formed by reaction of AN with the N-terminal valine residue in hemoglobin from B6C3F1 mice administered AN by gavage for up to 89 days. Blood samples were obtained from a study conducted by the Acrylonitrile Group, Inc. at Southern Research Institute, in which mice were administered 1.2, 4.8 or 9.6 mg AN/kg/day, 5 days/week for up to 89 days. Blood was collected on days 1, 5, 12, 26, 40, 68, and 89. Globin was isolated from erythrocytes, and the cyanoethylvaline (CEVal) hemoglobin adduct was derivatized by a modified Edman procedure for analysis by gas chromatography/mass spectrometry. Dose response evaluations at days 68 and 89 indicated a sublinear relationship between administered dose and CEVal. This behavior is consistent with saturable metabolism of AN to cyanoethylene oxide. With repeated administration of 9.6 mg AN/kg/day, CEVal reached a plateau between 40 and 68 days. Comparison of these data with simulations of CEVal accumulation conducted with a model for erythrocyte turnover suggests that CEVal is stable. These studies indicate that the animals on this long-term study were exposed to AN. This data set provides an important validation of CEVal as a biomarker for AN exposure.

47 ENVIRONMENTAL EXPOSURE OF CHILDREN LIVING IN MONTREAL TO PAH.

A Vyskocil[1], C Viau[1], V Chénier[1], Z Fiala[2], L Krajak[3], and S Emminger[3]. [1]*University of Montreal, Montreal, Canada;* [2]*Charles University, Hradec Kralove, Czech Republic;* [3]*EMPLA, Hradec Kralove, Czech Republic.*

The aim of study was to assess the intake of polycyclic aromatic hydrocarbons (PAH) by children living in a city. Two groups of children (n=11 and 13; 3-6 years old) were chosen: (1) a group from a kindergarten situated near a road with a high traffic density ("polluted" area); (2) a group from a kindergarten situated in a green zone ("non-polluted" area). Food consumption was recorded in all children and PAH intake from foodstuffs was estimated. Ambient air samples were collected on the playground and indoor of kindergartens during 3 days in summer 1997. Urine samples were collected in the morning and in the evening. Mean outdoor total PAH concentration (sum of 12 individual PAH) in "polluted" area was 10 times higher than that in "non-polluted" area (20.7 vs 1.9 ng/m^3). However, indoor concentrations were similar (2.2 vs 1.7 ng/m^3). The same trend was observed for pyrene concentrations. The contribution to the total pyrene intake from the food consumption (daily intake of 2.8 and 3.4 µg, respectively, in "polluted" and "non-polluted" area) was much more important than that from inhalation (0.008 and 0.002 µg, respectively) in both areas. No statistical difference between the two groups was found in urinary concentrations of 1-OHP, used as a biomarker of the total internal dose of pyrene or the PAH. In conclusion, the food seems to be a main source of the total pyrene and total PAH intake in Canadian children, even under a relative high PAH air exposure in the city.

48 COAL TAR WASTES (CTWs) IN SOIL: A QUALITATIVE EVALUATION OF HAZARDS POSED BY DERMAL CONTACT.

A S Susten[1], R E Grissom[1], M Mumtaz[1], and K Markiewicz[2]. [1]*Agency for Toxic Substances and Disease Registry (ATSDR), Atlanta, GA, USA;* [2]*Iowa Department of Public Health (IDPH), Des Moines, IA, USA.*

A literature review was performed to assist in determining hazards to individuals whose activities resulted in dermal contact with coal tar wastes (CTW) in soil. The primary focus areas were the potential for (1) systemic effects related to percutaneous absorption of polycyclic aromatic hydrocarbon (PAH) constituents present in CTWs and (2) direct dermal toxicity. In vivo and in vitro percutaneous absorption studies in animals and humans were evaluated. Factors considered in the evaluation were: experimental design, role of vehicles, and relevance to potential human exposures to contaminated soils. Also, the extent of human effects associated with exposures to CTWs and PAHs under a variety of exposure situations was assessed. The latter was considered in the context of plausible exposures to the public, both children and adults, to CTW-contaminated soils. The data indicate that the percutaneous absorption of soil-bound PAHs is likely to be less than indicated by experimental protocols in which PAHs are applied to the skin in vehicles solvents such as acetone. Thus, risk assessments using default assumptions for dermal absorption of PAH components of CTWs in soils, without consideration of factors that influence absorption and plausible exposure conditions, are likely to overestimate risk. ([1]The opinions expressed are those of the authors and do not necessarily reflect the opinions or policies of the ATSDR or IDPH.)

49 NEUROTOXIC IMPLICATIONS FOR THE TRANSPLACENTAL DISPOSITION OF BENZO(A)PYRENE: CARBON BLACK AEROSOLS.

D B Hood, M M Greenwood, T Nayyar, A Ramesh, F Inyang, and M E Knuckles. *Department of Pharmacology, Meharry Medical College, Nashville, TN.*

A novel model for the illumination of potential neurotoxic mechanisms as a result of the transplacental disposition of desorbed benzo(a)pyrene [B(a)P] from a particulate aerosol is presented. Sprague Dawley timed-pregnant rats were exposed for four hours on gestation day 15 to an acute dose of 100 ug/m3 B(a)P : Carbon black aerosol. Controls received carbon black only. Nominal and chamber concentrations of the particulate aerosol were determined gravimetrically with a seven stage cascade impactor and analyzed for the: mean mass aerosol diameter (MMAD), cumulative frequency, cumulative percent, and differential particle-size distribution using a Windows Cascade Impactor Data Reduction System. The MMAD for the B(a)P : carbon black aerosol was 0.4 ± 0.02 µm. Mobility gel shift analysis of nuclear extract incubations from various brain regions of the resulting pups on postnatal days 3, 5, 7, 10, and 15 with an Sp1 consensus sequence oligonucleotide revealed perturbations in the developmental profile of Sp1 as a result of nose-only particulate aerosol exposure to the timed-pregnant dam. The data suggest that Sp1 DNA-binding is developmentally regulated and expressed very highly in actively developing brain regions. We conclude that "in utero" exposure to B(a)P may alter the DNA-binding and possible levels of critical transcription factors involved in growth and differentiation in the brain. The results from these studies contribute to an understanding of the biological mechanisms by which particulate matter hazardous constituents mediate adverse acute health effects associated with particulate matter exposure. (Supported by Cooperative Agreement MHPF/ATSDR U50/ATU398948, NIH G12 RRO 3032, and NIEHS ES00287.)

50 COMPARATIVE BIOAVAILABILITY OF BENZO(a)PYRENE IN RATS DOSED ORALLY VS. INHALATION.

A Ramesh, F Inyang, M Greenwood, A Archibong, M E Knuckles, and D B Hood. *Department of Pharmacology, Meharry Medical College, Nashville, TN.*

The focus of the present study was to evaluate the bioavailability of blood Benzo(a)pyrene [B(a)P], subsequent to oral and inhalation exposure. Eight week old F-344 rats were dosed either orally with 0.5 and 1.0 mg/kg body weight B(a)P or via nose-only inhalation with 0.1, and 1.0 mg/m^3 of B(a)P

and sacrificed at 0, 0.5, 1.0, 2.0, 3.0, 4.0, 8.0, 10.0 and 12.0 hours post exposure. Blood, lung, liver, testes, and ovaries were removed at necropsy and was analyzed for parent B(a)P by HPLC with fluorescence detection. The results demonstrate that subsequent to inhalation exposure at 0.1 mg/m^3, (0.857 m g/kg body weight equivalence) mean blood B(a)P concentrations were maximal 30 minutes post exposure with females exhibiting approximately a 1.65 fold increase in blood B(a)P levels compared to males within the exposure group. At 4.0 hours post exposure, greater than 95% of the parent B(a)P compound was cleared from the blood in these animals when compared to the 30 minute post exposure group. In contrast, subsequent to oral dosing at 1 mg/kg body weight, mean blood B(a)P concentrations were maximal at 8.0 hours post exposure. (Supported by MHPF/ATSDR U50/ATU398948 and NIH G12 RRO 3032, and NIEHS ES00287.)

51 ESTIMATES OF THE *IN VITRO* PERCUTANEOUSABSORPTION OF TWO PAH CONTAMINATED SOILS AND THEIR ORGANIC EXTRACTS.

E C Lonardo[1], D A Edwards[1], T Aruta[2], and L Racioppi[2]. [1]*Exxon Biomedical Sciences, Inc., East Millstone, NJ, USA;* [2]*Exxon USA, Linden, NJ, USA.*

Sorption of polynuclear aromatic hydrocarbons (PAHs) on soil can impede their penetration through skin. Previous *in vitro* dermal penetration experiments of PAHs in crude oil and coal tar sorbed onto soil (Roy et al.,1998) showed dramatic reduction of PAH absorption through skin relative to unbound materials. The present study evaluated the dermal penetration properties (flux rates) of two PAH contaminated soils (149 and 228 ppm project-specific PAHs) and compared them with those of the solvent extracts of the respective soils (16,000 and 14,900 ppm project-specific PAHs). *In vitro* percutaneous absorption experiments (96 hr) were performed with the two soil samples (sieved to < 150 μ m) and two soil extracts. Infinite doses (25 mg/cm^2) were applied to the donor side of human abdominal skin sections mounted in Franz *in vitro* diffusion cells to provide flux rates for risk assessment. In order to facilitate the measurement of skin penetration, all doses were spiked with ^{3}H-benzo(a)pyrene (^{3}H-BaP) prior to the study. Based on ^{3}H-BaP, the dermal flux rates for the infinite dose soil extracts were 501 (Soil 102) and 504 (Soil 80) ng/cm^2/hr. The dermal flux rates for the contaminated soils were 0.072 and 0.088 ng/cm^2/hr, respectively. The large reduction in target PAH dermal absorption rate from the two soils in comparison to soil extracts was a consequence of PAH concentration and soil binding. Concentration differences account for a 107 and 65 fold reduction in PAH dermal flux rate from Soil 102 and Soil 80, respectively. Soil binding phenomena accounted for a 65-fold (equivalent to a 98.5%) reduction for Soil 102 and 88-fold (equivalent to 98.9%) reduction for Soil 80 compared to their extract. The combined effects resulted in an overall 5700-7000 fold reduction in PAH dermal penetration from soils as compared to unbound PAHs. These data are in accord with the results of previous experiments (Yang et al., 1989) which indicate significantly reduced risk from dermal exposure to soil-bound PAHs.

52 COMPARATIVE ANALYSIS OF CHEMICAL:DNA ADDUCT FORMATION IN MOUSE LUNG FOLLOWING THE INGESTION OF NEAT MGP TAR AND SOILS CONTAMINATED WITH MGP TAR.

A Koganti, D A Spina, B-L Ma, K Rozett and E H Weyand. *College of Pharmacy, Rutgers-The State University of New Jersey, Piscataway, NJ.*

The types of chemical:DNA adducts formed in mouse lung following the ingestion of neat manufactured gas plant (MGP) tar and soils contaminated with MGP tar were evaluated. B_6C_3F1 mice were fed diets containing neat MGP tar or contaminated soil for 14 days and the types of chemical:DNA adducts formed in lung tissue were determined using ^{32}P-postlabeling and HPLC analysis. DNA adduct profiles were qualitatively similar between the four neat MGP tar samples evaluated. However, the extent of adduct formation varied with the PAH content of each tar sample. Three major adducts were observed with each tar sample. Two of these adducts were determined to be derived from B[b]F and B[a]P. The third adduct corresponded to the unidentified chemical:DNA adduct detected in previous studies. The ingestion of soil contaminated with MGP tar also resulted in detectable levels of chemical:DNA adducts in lung tissue. The extent and types of adducts formed varied considerably between soil samples. DNA adducts derived from B[b]F and the unidentified component of MGP tar were formed with each of the three soil samples evaluated. The most abundant adduct was derived from the unidentified component of MGP tar. In contrast, B[a]P:DNA adducts were detected with only one soil sample. These results demonstrate that the adsorption of MGP tar to soil significantly influences the type of adducts formed *in vivo*. In addition, the presence and abundance of the unidentified chemical:DNA adduct suggests that it may play a critical role in the carcinogenic potential of neat MGP tar and soil contaminated with MGP tar. (EPRI Grant WO2963-06)

53 EVALUATION OF 3-HYDROXYBENZO[A]PYRENE AS A POTENTIAL BIOMARKER OF PAH BIOAVAILIBILITY FROM MGP TAR.

N Modi, T Stakhiv, B-L Ma, R Singh, A Koganti, K Rozett, and E H Weyand. *College of Pharmacy, Rutgers-The State University of New Jersey, Piscataway, NJ.*

Recent studies have used 1-hydroxypyrene (1-OH pyrene) levels in urine and chemical DNA adduct formation in lung as biomarkers to estimate the bioavilability of PAH from complex mixtures following ingestion. However, there is considerable concern that pyrene may not adequately represent the absorption, distribution, metabolism, and excretion of carcinogenic PAH (cPAH) present within these mixtures. In the present study, the urinary excretion of 3-hydroxybenzo[a]pyrene (3-OHB[a]P) was evaluated as a biomarker for estimating PAH bioavailability. Urine previously collected from mice fed diets containing MGP tar contaminated soil and extracts of soils were evaluated for 3-OHB[a]P content. Urine samples were treated with β - glucuronidase/aryl sulfatase and 3-OHB[a]P was extracted using C_{18} sep-pak cartridges. 3-OHB[a]P levels were determined using reverse-phase HPLC with fluorescence detection. 3-OHB[a]P was detectable in urine of animals ingesting diets containing B[a]P concentration ranging from 5-50 ppm. Detection and quantitation limits were determined to be 10 pg and 50 pg respectively under the conditions used in this study. Detectable levels of 3-OHB[a]P were observed with soils at all levels evaluated. 1-5% of ingested B[a]P was excreted as 3-OHB[a]P in urine. The detection of 3-OHB[a]P in urine of animals ingesting soils and the corresponding extracts provides the ability to calculate a bioavailability estimate of PAH. These estimates appear to be similar to those calculated based on chemical:DNA adduct formation. The results of this study suggest that 3-OHB[a]P urinary excretion may provide a better biomarker relative to 1-OH pyrene, to assess the bioavailibility of cPAH within a mixture. (EPRI Grant WO2963-06)

54 BENZO[A]PYRENE BIOAVAILABILITY FROM RESIDENTIAL SOILS.

B H Magee[1], D G Dolan[2], D A Paley[2], and E H Weyand[3]. [1]*Ogden Environmental & Energy Services, Westford, MA, USA;* [2]*AlliedSignal Inc., Morristown, NJ, USA;* [3]*Rutgers, The State University of New Jersey, Piscataway, NJ, USA.*

Eight soil samples were collected from four residential yards in the vicinity of a waste site. A chemical concentration screen was used to guide selection of the samples to use in the animal experiments. This involved using micro-solvent extraction and GC/FID analysis to obtain initial PAH concentrations in unsieved soil. The three samples chosen for the animal study were sieved to <250 μm and Soxhlet extracted with dichloromethane. Soil samples, soil extract samples, and extract-ed soil samples were chemically analyzed for PAHs and then fed to female B6C3F1 mice (7 weeks of age) for two weeks in dietary vehicles. Total PAH concentrations for the three soils ranged from 66 mg/kg to 388 mg/kg, and benzo[a]pyrene-toxic equivalent con- centrations ranged from 9 mg/kg to 70 mg/kg. Two measures were employed to determine the relative oral bioavailability of benzo[a]- pyrene (B[a]P). First, B[a]P urinary metabolite excretion was studied. Relative oral B[a]P bioavailability as estimated by dividing the fractional urinary excretion (FUE) of 3-hydroxy-benzo[a]pyrene in animals treated with contaminated soil by the FUE in animals treated with the soil extract ranged from 0.07 to 0.27. The average relative bioavailability of 0.15 is equivalent to the Oral-Soil Absorption Adjustment Factor (AAF) required for use in risk assessment, because the cancer slope factor for B[a]P is based on a rodent dietary study. Second, levels of chemical:DNA adducts in lung tissue were measured. The level of chemical:DNA adducts was higher in the animals fed the soil extracts compared with animals fed unextracted, sieved soil. Relative oral PAH bioavailability on the basis of chemical:DNA adducts ranged from 0.08 to 0.36. The average Oral-Soil AAF based on DNA adduct results was 0.21. This experimental approach is a useful way to obtain site-specific data to support realistic risk assessment of potentially carcinogenic PAHs.

55 TRANSFER OF SPERMATOZOA BENZO(A)PYRENE-DNA ADDUCTS TO FERTILIZED EGGS ASSOCIATED WITH EMBRYOTOXICITY.

S B Hooser[1], W M Baird[2], L J Schild[2], and G U Lee[1]. [1]*Purdue Univ., Dept. of Vet Pathobiology, W Lafayette, IN;* [2]*Oregon State Univ., Environmental Health Sciences Center, Corvallis, OR.*

In epidemiological studies, men who smoke have children with lower birth weight and increased incidence of childhood cancer even if the mothers do not smoke. Smoking may result in formation of spermatozoa benzo(a)pyrene-DNA adducts and DNA damage, which are then transferred to fertilized embryos. Previously, we identified a sperm B(a)P-DNA adduct [(+)-anti-BPDE-deoxyguanosine] in B(a)P-treated mice in vivo and trout sperm treated with BPDE in vitro, using 33P-postlabeling and an anti-B(a)P-DNA antibody. In the present studies, trout sperm were incubated with 10 (g/ml benzo(a)pyrene diol epoxide (BPDE) or saline for 1h, washed, and used to fertilize untreated trout eggs. The eggs from each group were placed in separate hatching trays covered with running water. After 24h , several hundred eggs from each group were removed for DNA isolation while the rest (several thousand/ group) were left in the trays for daily observation, removal/counting of dead eggs, and weighing of the trout fry at hatching and 14d of age. DNA from the saline or BPDE-treated sperm and from the two groups of fertilized eggs was isolated and postlabeled with 33P-ATP. HPLC of postlabeled DNA from sperm incubated with BPDE and eggs fertilized with those sperm revealed a major DNA adduct with the same retention time as purified (+)-anti-BPDE-deoxyguanosine. No adducts were detected in control sperm or eggs. Eggs from BPDE-treated sperm had significantly increased mortality (% dead eggs: Control = 25.8%, BPDE-treated sperm = 55.9%) while trout fry from BPDE sperm had significantly decreased wts (24h wt: Control=0.12832g, BPDE=0.11365g 14d wt: Control= 0.198821g(0.000024, BPDE=0.192843g(0.000024, p(0.005). Conclusion: B(a)P-DNA adducts are present in BPDE-treated sperm and can be detected in eggs fertilized with those sperm. Those sperm B(a)P adducts are associated with increased embryomortality and decreased hatching weights. (Support by March of Dimes grant No. 96-0555 & American Cancer Society grant IRG 17-35 and CA40228(WB).)

56 QUALITATIVE AND QUANTITATIVE CHARACTERIZTION OF 7,12-DIMETHYLBENZ(A)ANTHRACENE (DMBA) HEMOGLOBIN (HB) ADDUCTS.

S R Myers[1], C J Grubbs[2] and R A Lubet[3]. [1]*Dept. Pharmacology and Toxicology, University of Louisville School of Medicine, Louisville, KY;* [2]*Dept. Nutritional Sciences, Univ. Alabama Birmingham, Birmingham, AL; and* [3]*DCPC, NCI, NIH, Bethesda, MD.*

Previous studies have demonstrated that the carcinogens benzo(a)pyrene, 4-aminobiphenyl, and the tobacco specific nitrosamines bind covalently to hemoglobin and the adducts can be quantitatively determined by numerous methods, including gas chromatographic and mass spectrometric tools (GC/MS). In this study, we demonstrate the use of Hb adducts as a biomarker of the potent mammary carcinogen, 7,12-dimethylbenz(a)anthracene (DMBA). DMBA is one of the most potent chemical carcinogens and displays extreme potency at inducing mammary tumors in animal models. In this study, female Sprague Dawley rats were administered DMBA at doses ranging from 0.6 mg to 12 mg. 48 hours to 7 days later, animals were sacrificed and the red cells removed by cardiac puncture for determination of Hb adducts. Adducts were determined by enzymatic digestion of the protein, followed by analysis by GC/MS and LC/MS. Additionally, we examined the effect of various antioxidants, including 5,6-benzoflavone, butylated hydroxyanisole, and 1,2-dithiolthione on the formation of Hb DMBA adducts. Rats treated with DMBA alone (12 mg, 7 days) yielded a hemoglobin adduct level of 41.5 ± 7.25 pmol DMBA / mg globin. Rats treated with DMBA and with either 5,6-benzoflavone (1650 mg/kg diet), butylated hydroxyanisole (5000 mg/kg diet) or 1,2-dithiolthione (600 mg/kg diet) resulted in a decrease of DMBA detected hemoglobin adducts from 5.89 ± 2.52, 28.6 ± 9.23, and 12.4 ± 6.43 pmol/mg globin respectively. These results demonstrate that hemoglobin adducts of DMBA are potential biological markers of carcinogen exposure and that the modulation of adduct seen by treatment with antioxidant may be a potential marker for changes in levels of DNA damage caused by this potent mammary carcinogen.

57 THE EFFECT OF A COMPLEX MIXTURE OF POLYCYCLIC AROMATIC HYDROCARBONS (PAH) ON PAH ACTIVATION.

C P Marston and W. M Baird. *Oregon State University, Corvallis, OR, USA.*

Human exposure to PAH occurs through complex mixtures such as coal tar. To determine how a complex mixture of PAH affects the metabolic activation, PAH-DNA binding and carcinogenicity of individual PAH, mice were treated topically with Standard Reference Material 1597 (SRM), a complex mixture of PAH extracted from coal tar, and either benzo[*a*]pyrene (B[*a*]P) or dibenzo[*a,l*]pyrene (DB[*a,l*]P). At various times after treatment, the epidermal DNA was analyzed for PAH-DNA adducts by ^{33}P-postlabeling and HPLC. At early times after exposure, SRM decreased the total level of PAH-DNA adducts and B[*a*]P-DNA adducts compared with mice treated with B[*a*]P alone. However, after 24 hours, there was no significant difference in the levels of PAH-DNA adducts between these groups. After 16 weeks of promotion in a mouse skinn tumor initiation-promotion study, the SRM plus B[*a*]P-treated mice have only slightly more papillomas per mouse than the B[*a*]P-treated group. In contrast, mice treated with SRM and the potent carcinogen DB[*a,l*]P had a significantly lower level of PAH-DNA adducts after 24 hour exposure compared to mice treated with DB[*a,l*]P alone. The co-treated group has less than half the number of papillomas per mouse than mice treated with DB[*a,l*]P alone after 13 weeks microsomes indicate that the major effect of a complex mixture on the carcinogenic activity of a PAH within it may be related to the ability of the mixure to inhibit the activation of that PAH by the cytochrome P450s that are induced. (Supported by grant CA 28825, DHHS.)

58 PURIFICATION SCHEME FOR A POLYCYCLIC HYDROCARBON-BINDING PROTEIN FROM RAINBOW TROUT LIVER CYTOSOL.

K A Clossey and L R Curtis. *Department of Environmental Health, East Tennessee State University, Johnson City, TN.*

Feeding rainbow trout a diet containing 5-15 parts per million of dieldrin, increases the biliary excretion of a challenge dose of the tritiated polycyclic hydrocarbon 7,12-dimethylbenz[a]anthracene (DMBA). This increase in biliary excretion appears without evidence of induction of cytochrome P450, UDP-glucuronyl transferase or glutathione -S-transferases. (Fund. Appl. Toxicol.30:187). Induction of hepatic cytosolic binding protein may play a role in xenobiotc trafficking to smooth endoplasmic reticulum for oxidative and conjugative metabolism.Size exclusion chromatography indicated dieldrin increases the activity of [3H] DMBA and [3H] benzo[a]pyrene (BP)binding protein(s) in rainbow trout hepatic cytosol over untreated cytosol by 2-3 fold. A purification scheme was designed to purify this BP-binding protein. Ammonium sulfate fractionation was performed on the control and dieldrin-treated cytosol: 0-20%, 20-40%, 40-60% and 60-80% saturation. These fractions were then assayed for BP binding. The 20-40% fraction retained approximately 80-100% of the total BP binding and retained approximately 15-30% of the original cytosolic protein. This 20-40 % ammonium sulfate fraction was then loaded onto a hydrophobic interaction chromatography (HIC)column. The gradient was run with decreasing concentrations of ammonium sulfate supplemented with 0 .1% Triton X-100. The fractions containing the highest protein concentrations were then assayed for binding. Protein recovery off the HIC column was between 60-80 % and total activity retained was between 80-110%. Purification was between 5-12 fold over the ammonium sulfate fraction. The HIC fractions retaining binding activity were loaded onto an anion exchange column after removal of the Triton X-100 method. The gradient run on this column was increasing NaCl concentration. The fractions with the highest protein concentration were then assayed for binding. Enrichment in specific binding for the final purification was up to 300 fold higher than the original cytosol. 4-20 % SDS-PAGE gels yielded approximately 4-6 bands ranging from 100 Kd to 22 Kd in the most purified and enriched fraction. (Supported by NIEHS R15ESO8817.)

59 EFFECTS OF ACENAPHTHENE, ACENAPHTHYLENE AND 1,2:5,6-DIBENZANTHRACENE ON IMMUNE FUNCTIONS AND CYP450 IN ADULT MALE DEER MICE (*PEROMYSCUS MANICULATUS*).

A B Bodine[1], M M Peden-Adams[2], S Kunteson[2], J Dancik[2], R L Dickerson[3] and J Liu[2]. [1]*Department of Animal and Veterinary Science, Clemson University, Pendleton, SC, USA;* [2]*Department of Environmental Toxicology, Clemson University, Pendleton, SC, USA;* [3]*The Institute of Environmental and Human Health, Texas Tech U/TTU Health Sciences Center, Lubbock, TX, USA.*

Polynuclear aromatic hydrocarbons (PAHs) are among the most common chemicals found in uncontrolled waste site. These chemicals produce diverse of toxic and biochemical responses in most species. Immune function alterations caused by PAHs are often overlooked, however, the objectives of this study were to determine the effects of three PAHs, acenaphthene, acenaphthylene and 1,2:5,6-dibenzanthracene, on immune function and CYP450 activity in a non-traditional mammalian species. In this study, adult male deer mice (*Peromyscus maniculatus*) were dosed with acenaphthene, acenaphthylene or 1,2:5,6-dibenzanthracene every other day for 12 days. Five concentrations of these chemicals (0.3, 1, 3, 10, and 30 mg/kg) and a corn oil vehicle (control) were used. Immune function was assessed using both T- and B- cell proliferation, antibody plaque forming cell response (PFC) and macrophage phagocytosis to determine potential effects on cell-mediate immunity, humoral immunity, and non-specific immunity. Treatment with acenaphthylene or 1,2:5,6-dibenzanthracene resulted in stimulation that appeared to be dose-responsive for both T- and B- cell proliferation. CYP450 activity was measured using ethoxyresorufin-O-deethylase (EROD) and pentoxyresorufin-O-deethylase (PROD). Differences were observed within chemical treatments and among treatments. The PFC assay exhibited a dose-dependent reduction for all three chemicals tested. There was no obvious effect noted on macrophage phagocytosis in this study

60 ALTERATIONS IN IMMUNE FUNCTION AND CYP450 ACTIVITY OF ADULT MALE DEER MICE FOLLOWING EXPOSURE TO EITHER CHRYSENE, PYRENE, OR BENZO-A-PYRENE.

M M Peden-Adams [1], J Liu[1], J Dancik[1], S Knuteson[1], A B Bodine[1,2], and R L Dickerson[3]. [1]*Department of Environmental Toxicology, Clemson University, Pendleton, SC, USA;* [2]*Department of Animal and Veterinary Sciences, Clemson University, Clemson, SC, USA;* [3]*The Institute of Environmental and Human Health, Texas Tech. University, Lubbock, TX, USA.*

The realization that wildlife immunity can be affected by environmental contaminants has stimulated the use of immunotoxicity measurements in the field of environmental toxicology for determining the deleterious effects of contaminants on wildlife health as a basis for environmental risk assessment. The use of immunotoxicity parameters as biomarkers of environmental exposure has great potential once they are validated in non-traditional sentinel species. The objective of this study was to determine the effects of two PAHs on immune function and cytochrome P450 (CYP450) activity in a nontraditional murine species. Adult male deer mice were exposed every other day for a period of twelve days to the chemicals (0.3,1,3,10, and 30 mg/kg) or the corn oil control. Immune endpoints assessed were lymphoproliferation, macrophage phagocytosis, and the antibody plaque-forming cell response (PFC). Significant differences from control were observed in the PFC response for all chemicals tested. Other immune endpoints also exhibited differences from control for all of the chemicals tested. CYP450 activity was measured using EROD and PROD assays. Differences were observed within chemical treatments and among treatments. The plaque forming cell response was observed to be the most sensitive of the immune endpoints which were assessed and was also more sensitive than those observed from CYP450.

61 POTENTIATION OF DNA ADDUCT FORMATION IN RAT LIVER AND LUNG SLICES INCUBATED WITH BENZO(A)PYRENE (BAP) IN DYNAMIC ORGAN CULTURE FOLLOWING PRETREATMENT WITH 2,3,7,8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) *IN VIVO*.

J A Hand[1], B P McGarrigle[1], A E Maccubbin[2] and J R Olson[1]. [1]*Dept. Pharm. Toxicol., SUNY at Buffalo, Buffalo, NY, USA;* [2]*Dept. Pharm., Roswell Park Cancer Institute, Buffalo, NY, USA.*

Chemical-DNA adducts are a useful biomarker of exposure/effect that integrate absorption, metabolic activation/detoxification, and DNA repair following exposure to a genotoxic chemical. The covalent binding of chemicals to DNA (adduct formation) is generally accepted as an initial necessary step in the carcinogenic process. Precision cut rat liver and lung slices maintained in dynamic organ culture were utilized as an *in vitro* model to assess DNA adduct formation under various conditions. Rats were pretreated *in vivo* with TCDD (5 μ g/kg, po), to induce phase I and phase II metabolizing enzymes, or vehicle alone. Two days following pretreatment, rat liver and lung slices were incubated for 4 or 24 hrs in medium containing 0, 10, or 80 μ M BaP. At 4 hrs, 2.38 % of the BaP was associated with liver slices (~ 52 mg/3slices/vial), while 5.98 % of the compound was retained in lung slices (~ 26 mg/3 slices/vial). At 24 hrs, 4.29 and 11.16 % of the BaP was associated with liver and lung slices, respectively. DNA was isolated from tissue slices and DNA adduct formation was measured by ^{32}P-postlabeling. Liver slices contained at least 2 adducts while lung slices contained 2 or 3 adducts. One of the prominent adducts in both tissues was the BPDE-I-DNA adduct (BaP-7,8-diol-9,10-epoxide bound to guanine). Rat liver slices incubated with 0 and 80 μ M BaP for 24 hrs contained 0.49 and 1.60 fmol adduct/μ g DNA, respectively. Following pretreatment with TCDD *in vivo*, rat liver slices incubated with 80 μ M BaP for 24 hrs contained 5.23 fmol adduct/μ g DNA. Rat lung slices pretreated with TCDD *in vivo* and incubated for 24 hrs with 10 or 80 μ M BaP contained 8.23 and 12.28 fmol adduct/μ g DNA, respectively. Thus, *in vivo* exposure to TCDD potentiated DNA adduct formation. The preliminary data suggest this model is useful for the quantitation of DNA adduct formation under these conditions and may be a suitable model for other target tissues and species, including humans.

62 LIGHT-INDUCED FORMATION OF BENZO[A]PYRENE QUINONES: ROLE IN ALTERED CALCIUM HOMEOSTASIS IN HUMAN MCF10A MAMMARY EPITHELIAL CELLS.

M D Reed[1], J S Seagrave[2], S P Meserole[1], J L Born[1], and S W Burchiel[1]. [1]*The University of New Mexico, College of Pharmacy, Toxicology Program and the* [2]*Lovelace Respiratory Research Institute, Albuquerque, NM, USA.*

Previous studies in this laboratory have shown that benzo[a]pyrene (B[a]P) and B[a]P-7,8-diol increase basal levels of intracellular Ca^{2+} in human lymphocytes and human mammary epithelial cells. Recently, we have observed that simultaneous exposure of the human mammary epithelial cell line, MCF10A, to near ultraviolet (nuv) light (350-400nm) and B[a]P results in alterations intracellular Ca^{2+} homeostasis and cell morphology. In the present studies we show that short exposures (5-30 min) to light activates B[a]P to form BaP-quinones, as determined by measuring ^{3}H-B[a]P conversion to 1,6- 3,6- and 6,12-quinones separated by reverse phase HPLC. The amounts of quinone produced were dependent on the time exposed to light . Exogenously added 1mM glutathione (GSH) attenuated the light-induced conversion of B[a]P without the appearance of an HPLC peak corresponding to a B[a]P-GSH conjugate. B[a]P(3μ M) + light (5min) produced a near total inhibition of thapsigargan induced Ca^{2+} release and capacitative Ca^{2+} entry, as compared to MCF10A cells kept in the dark and treated with B[a]P. These results indicate that formation of B[a]P quinones may induce changes in cellular redox status leading to the oxidation of critical protein sulfhydryls involved in maintaining intracellular Ca^{2+} homeostasis. (Supported by NIH ES07259.)

63 2,3,7,8-TETRACHLORODIBENZO-P-DIOXIN AND BENZO(a)PYRENE DIFFERENTIALLY REGULATE CELL ATTACHMENT AND EXPRESSION OF EPIDERMAL GROWTH FACTOR RECEPTOR, E-CADHERIN, AND PROSTAGLANDIN H-SYNTHASE IN HUMAN UTERINE ENDOMETRIAL CELLS.

M A McGarry, G D Charles, T Medrano, M Campbell-Thompson, and K T Shiverick. *Departments of Pharmacology and Therapeutics and Medicine, University of Florida, Gainesville, FL, USA.*

This study investigated mechanisms whereby 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and benzo(a)pyrene (BaP) may contribute to uterine disease through alteration in cell adhesion molecules and cell surface receptors. Exposure of human uterine endometrial adenocarcinoma RL95-2 cells to 10 μM BaP for 48 hours completely inhibited their ability to attach to matrigel-coated membranes, whereas 10 nM TCDD treatment had no effect. Immunohistochemistry and western blot analysis showed that BaP caused a marked loss of plasma membrane epidermal growth factor receptor (EGF-R) along intercellular boundaries, while TCDD produces no change in the localization of EGF-R immunostaining. Western blot analysis of E-cadherin, a key cell adhesion molecule, showed a significant decrease with BaP treat-

ment with no change for TCDD. In comparison, prostaglandin H-synthase (PGSH-1), a pathway for the biotransformation of BaP, is constitutively expressed in RL95-2 cells and is significantly increased 150% by BaP exposure, but not by TCDD. These results indicate that the BaP-mediated loss of cell attachment involves decreased localization of molecules important for cell-cell and cell-extracellular matrix interactions. Data further suggest that constitutive and induced PGHS may be a pathway for BaP bioactivation and toxicity. (Supported by NIEHS Superfund Grant 07375.)

64 ESTRADIOL ENHANCES THE EFFECT OF 2,3,7,8-TETRA CHLORODIBENZO-*P*-DIOXIN ON 7-ETHOXYRESORUFIN-*O*-DEETHYLASE (EROD) ACTIVITY IN A MOUSE OVARIAN EPITHELIAL CANCER CELL LINE.

D-S SON[1,2], K F Roby[3], K K Rozman[4,6], and P F Terranova[1,2,5]. [1]*Center for Reproductive Sciences;* [2]*Departments of Molecular & Integrative Physiology;* [3]*Anatomy & Cell Biology;* [4]*Pharmacology, Toxicology & Therapeutics;* [5]*Obstetrics & Gynecology, University of Kansas Medical Center, Kansas City, KS;* [6]*Section of Environmental Toxicology; GSF-Institut für Toxikologie, Neuherberg, Germany.*

2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD), a ubiquitous environmental pollutant, is a well known toxin and promoter of carcinogenesis. TCDD induced the activity of EROD (representing mainly CYP1A1) dose-dependently in a mouse ovarian epithelial cancer cell line (ID8). The K_m and V_{max} of induced EROD activity were 180 *p*M and 1085 *p*M/min/mg, respectively. TCDD did not induce the activity of methoxyresorufin-*O*-demethylase (MROD) in the same cell line, which is in accordance with a lack of expression of CYP1A2 in extrahepatic tissues. Induction of EROD by TCDD was inhibited by alpha-naphthoflavone, an aryl hydrocarbon receptor (AhR) antagonist. Interestingly, estradiol increased the induction of EROD by TCDD dose-dependently. The K_m and V_{max} of EROD activity in the presence of estradiol (1μM) were 200 *p*M and 2304 *p*M/min/mg, respectively. The effect of estradiol on EROD induction by TCDD was at maximum in the concentration range of 1-5 μM. Estradiol did not increase the number of ID8 cells during 48 hr in culture. Progesterone and gonadotropins (FSH and LH), which are important hormones for ovarian function, had no effect on the induction of EROD by TCDD. In conclusion, estradiol enhanced the induction of EROD by TCDD in ovarian epithelial cancer cells suggesting that TCDD might affect the manifestation of ovarian cancer.

65 ESTROGEN RECEPTOR-MEDIATED ACTIVITIES OF BENZO[A]PYRENE: RECEPTOR BINDING, INDUCTION OF GENE EXPRESSION, AND UTEROTROPHIC EFFECTS.

K C Fertuck, J B Matthews, J H Clemons, M R Fielden and T R Zacharewski. *Department of Biochemistry and National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI, USA.*

Polycyclic aromatic hydrocarbons (PAHs) are a class of contaminants that are widely dispersed in the environment, and that are suspected of having the ability to mimic endogenous estrogen. The ability of the PAH benzo[a]pyrene (B[a]P) to: 1) competitively displace [^{3}H]17β-estradiol (E2) from a bacterially expressed GSThERαdef fusion protein, 2) induce gene expression in MCF-7 breast cancer cells transiently transfected with a Gal4-hER chimeric receptor and a Gal4-regulated luciferase reporter gene, and 3) cause a uterotrophic response in ovariectomized (OVX) DBA\2 mice was assessed. Binding assay results indicate that B[a]P was unable to significantly displace E2 from the recombinant hER protein at concentrations as high as 10 μM. However, B[a]P was able to induce gene expression in the *in vitro* gene expression assay; though a full dose response was not observed due to insolubility at high concentrations, 10 μM B[a]P, the highest dose studied, was able to cause a 35-50% increase in hER-mediated gene expression relative to 10 nM E2. Potency appeared to be approximately 10^5-fold lower than that of E2. *In vivo*, increases in uterine wet weight in OVX DBA\2 mice caused by doses of 6-25 mg /kg B[a]P were statistically significant ($p < 0.001$; n=10), but not dose-dependent. Since competitive binding data indicates that B[a]P does not significantly bind to the hER, metabolites may be responsible for the observed *in vitro* induction of hER-mediated gene expression and *in vivo* uterotrophic activity of B[a]P.

66 METABOLISM AND RECEPTOR BINDING OF ANTIESTROGENIC POLYCYCLIC AROMATIC HYDROCARBONS.

K F Arcaro[1], Y Yang[2] and J F Gierthy[1,2]. [1]*School of Public Health, State University of New York at Albany, Albany, NY;* [2]*Wadsworth Center, New York State Department of Health, Albany, NY.* Sponsor: L S Kaminsky.

In an earlier study we demonstrated that eight PAHs (benz[a]anthracene, chrysene, benzo[b]fluoranthene, benzo[k]fluoranthene, benzo[e]pyrene, benzo[a]pyrene, indeno[1,2,3-cd]pyrene and dibenz[a,h]anthracene) detected in sediment samples from two rivers in upstate New York were antiestrogenic in human breast cancer cells (MCF-7 cells). In the present study we demonstrate that the antiestrogenicity was due to both increased metabolism of 17β-estradiol (E_2) by enzymes induced by the PAHs and by displacement of E_2 from the estrogen receptor (ER). Radiometric analysis showed that benz[a]anthracene, benzo[k]fluoranthene, benzo[a]pyrene and dibenz[a,h]anthracene significantly increased the metabolism of E_2 in MCF-7 cell cultures. Competitive binding assays showed that none of the PAHS directly bound human recombinant ERα or β. However, seven of the PAHs (all except dibenz[a,h]an-thracene) significantly displaced ^{3}H[E_2] in a whole-cell binding assay in MCF-7 cells only under conditions in which the PAHs could be metabolized by endogenous or induced enzymes. In conclusion, PAHs can be antiestrogenic in metabolically intact human breast cancer cells through at least two mechanisms, one involving competition by PAH metabolites for the ER and the other involving depletion of E_2 through induction of metabolism. (NIH ES04913-07.)

67 HUMAN PROSTATE CANCER LNCaP CELLS DERIVED FROM LOW AND HIGH PASSAGE NUMBERS DISPLAY DIVERGENT EXPRESSION OF CYP1A1 IN RESPONSE TO ENZO[A]PYRENE.

V G Samedi[1], T I Medrano[1], S Devereaux[1], L Rice[2], P Narayan[2], and K T Shiverick[1]. *Departments of* [1]*Pharmacology and Therapeutics and* [2]*Surgery, Division of Urology, College of Medicine, University of Florida, Gainesville, FL.*

This study examined the expression of cytochrome P450 (CYP1A1) in two strains of the androgen responsive LNCaP human prostate cell line. Cells at a low passage number (LP), 20 to 30, or a high passage number (HP), 50 to 60 were grown in the presence of 20μM benzo(a)pyrene BaP with 0.1% DMSO as control. Western immunoblot analyses showed induction of CYP1A1 protein by BaP in LP, but not in HP LNCaP cells. In the absence of CYP1A1 induction in HP cells, however, BaP inhibited cell proliferation by 75%, as well as significantly decreased levels of EGF-R by 85% and c-myc immunoreactive proteins by 50%. We further evaluated whether prostaglandin H synthase (PGHS) is expresses in LNCaP cells which could serve as an alternative pathway for the biotransformation of BaP. PGHS-1 immunoreactive proteins were found to be constitutively expressed at a high level in both HP and LP cells. In addition, PGHS-1 expression over 48 hours appears to be regulated by 10μM BaP and 10nM TCDD. In summary, the inhibitory effects of BaP on proliferation and growth factor expression in the HP cells in the absence of CYP1A1 may be mediated by PGHS-1 through the peroxidase pathway for bioactivation. Furthermore, effects of BaP on LP cells may involve dual metabolism by the constitutive pathway through PGHS and induced CYP1A1.

68 REPAIR OF DNA LESIONS: RELATIVE EFFICIENCIES OF REPAIRING POLYCYCLIC AROMATIC HYDROCARBON ADDUCTS IN HUMAN CELL-FREE EXTRACTS.

E K Braithwaite, X Wu and Z Wang. *University of Kentucky, Lexington, KY.*

Polycyclic aromatic hydrocarbons (PAHs) are ubiquitous, genotoxic compounds. DNA lesions induced by these compounds are normally removed by excision repair mechanisms. In contrast to the extensively studied repair mechanisms, much less is known about the relative repair efficiencies of various DNA lesions. Since DNA repair is a crucial defense against carcinogenesis, it may constitute an important factor affecting the carcinogenicity of DNA damaging agents. We have adopted a human cell-free system for measuring relative DNA repair efficiencies based on the concept of repair competition between acetylaminofluorene adducts and other DNA lesions of interest. Using this *in vitro* system, we determined the relative repair efficiencies of PAH adducts induced by: anti-(±)-benzo[*a*]pyrene-*trans*-7,8-dihydrodiol-9,10-epoxide (BPDE), anti-(±)-benz[*a*]anthracene-*trans*-3,4-dihydrodiol-1,2-epoxide (BADE-I), anti-(±)-benz[*a*]anthracene-*trans*-8,9-dihydrodiol-10,11-epoxide (BADE-II), anti-(±)-benzo[*b*]fluoranthene-*trans*-

9,10-dihydrodiol-11,12-epoxide (BFDE), anti-(±)-chrysene-*trans*-1,2-dihydrodiol-3,4-epoxide (CDE), and anti-(±)-dibenzo[*a,l*]pyrene-*trans*-11,12-dihydrodiol-13,14-epoxide (DBPDE). While damage by BPDE, DBPDE, CDE, and BFDE were repaired by nucleotide excision repair as efficiently as AAF adducts, the repair of BADE-I and BADE-II adducts were significantly slower in human cell extracts. Damage by DBPDE at 3 μM *in vitro* yielded ~5-fold higher DNA adducts than BPDE as determined by quantitative PCR. This potent DNA reactivity may account in part for the potent carcinogenicity of dibenzo[*a,l*]pyrene. The correlation of these results to the carcinogenic properties of the PAH compounds is discussed. Furthermore, we show that NER plays a role in AP site repair *in vivo* in the eukaryotic model organism yeast.

69 ANALYSIS OF THE SUBCELLULAR DISTRIBUTION AND CYTOTOXICITY OF BENZO(a)PYRENE IN RAT LIVER CELLS.

R Barhoumi, K Ramos, S H Safe, T D Phillips, and R C Burghardt. *Faculty of Toxicology, Texas A&M University, College Station, TX, USA.*

The subcellular distribution and effects of benzo(a)pyrene (B(a)P) exposure on cellular homeostasis in a rat liver cell line (Clone 9) was monitored in cells exposed for 30 min or overnight (12 - 16 hr) to graded doses (0, 0.1, 1.0, 2.5, 5.0 and 10 μg/ml) of B(a)P. The uptake and distribution of B(a)P into cells combined with analysis of a number of vital fluorescence bioassays for intracellular glutathione (GSH) content, gap junction-mediated intercellular communication (GJIC), intracellular Ca^{2+} levels, intracellular pH, reactive oxygen species (ROS) generation, and mitochondrial and plasma membrane potentials (MMP and PMP) were performed with a laser cytometer. A rapid partitioning of B(a)P into cytoplasmic membranes within 30 min was verified using organelle-specific fluorescence probes, however, there were no significant alterations in the above referenced functional endpoints by 30 min. In cells treated overnight with B(a)P, there was a significant reduction in both PMP and GJIC at the lowest dose tested (0.1 μg/ml). Elevation of basal intracellular Ca^{2+} and suppression of signaling induced by 0.5 nM vasopressin, in the form of Ca^{2+} oscillations, were also significant beginning at the 1.0 μg/ml doses. Significant effects on intracellular GSH levels, pH, ROS production, and MMP were not detected at the time points examined. There appears to be a direct relationship between the partitioning of B(a)P into cellular membranes and effects on PMP and GJIC. These effects were similar in Clone 9 cells synchronized by serum deprivation (0.5%) for 24 hr, however, the effects were pronounced at lower B(a)P concentrations. These studies indicate that the partitioning of B(a)P into cytoplasmic membrane systems contributes to the alterations in plasma membrane and intracellular membrane functions. The time course needed to detect these effects is consistent with the involvement of cytochrome P450-mediated metabolism in these responses. (Supported by NIH P42-ES04917 and P30-ES09106.)

70 USE OF MUTATION SPECTRA TO COMPARE ONE-ELECTRON AND TWO-ELECTRON PATHWAYS OF BENZO[A]PYRENE (BAP) ACTIVATION.

D E Watson and K R Tindall. *NIEHS, Research Triangle Park, NC, USA.* Sponsor: G Erexson.

Two metabolic pathways have been proposed for the generation of mutagenic metabolites from polycyclic aromatic hydrocarbons (PAHs): one-electron oxidation and two-electron oxidation. One-electron oxidation generates PAH-radical cations that can form unstable DNA adducts that yield abasic sites in DNA. Two-electron oxidation produces PAH metabolites such as diolepoxides that can form stable DNA adducts. To better understand the role of these two pathways in benzo[a]pyrene (BP)-induced mutagenesis we compare the *lacI* mutation spectrum from Big Blue animals exposed to BP with mutation spectra from mammalian cells exposed to BP or BP-diolepoxides (BPDE). Additional comparisons are made with mammalian cells transfected with shuttle vectors modified at specific sites to contain BPDE/DNA adducts or abasic sites. The data indicate that the *lacI* mutations in the liver of Big Blue mice exposed *in vivo* to BP reflect mutagenesis by BPDE/DNA adducts, not by abasic sites. Therefore, we conclude that two-electron oxidation of BP has greater significance for BP mutagenesis than one-electron oxidation. Nevertheless, further research is warranted because appropriate mutation spectra for PAHs other than BP are not yet available. Similarly, mutation spectra are not available for the skin or mammary gland of PAH-exposed animals, two organs where one-electron oxidation may be important.

71 THE DOUBLE-STAINING OF RAT FETAL SKELETONSUSING ALIZARIN RED S AND ALCIAN BLUE IN AN INDUSTRIAL LABORATORY.

A D Young, D E Phipps, and A B Astroff. *Bayer Corporation, Agriculture Division, Toxicology Department, Stilwell, KS.*

The present regulatory guidelines on the conduct of rodent developmental toxicity studies recommend that fetal skeletal evaluations include an assessment of both bone and cartilage. Current methods to double-stain the fetal skeleton using Alizarin Red S and Alcian Blue are typically described for small sample sizes. In an industrial setting there is a need for an effective means to double stain fetal skeletons on a large scale (i.e., hundreds of fetuses simultaneously). This paper describes a method utilized in our laboratory to stain both fetal bone and cartilage using solutions and procedures on an industrial scale. Specifically, following cesarean section, fetuses retained for skeletal evaluation are eviscerated, skinned, and placed in 250 ml jars containing 150 mls ethanol (70% or greater) for at least three days but no longer than four weeks. Fetuses are double stained in 70% ethanol containing: 0.0015% Alizarin Red S, 0.0005% Alcian Blue, and 2% Potassium Hydrogen Phthalate, for 72 hours and should be agitated at least once during this step. Following staining, the fetuses are rinsed with deionized water and then macerated with 0.75% potassium hydroxide [w/v] in deionized water for 72 hours with agitation at least once during this step. Following maceration, the fetuses are rinsed with deionized water and then cleared with a 2:2:1 solution of 70% ethanol:glycerin:100% benzyl alcohol for 24 hours. Following clearing, the fetuses are kept in holding solution (glycerin 50% [v/v] in 70% ethanol) for a minimum of 6 days prior to examination. Fetuses may be stored in 100% glycerin (with thymol) indefinitely. Using the aforementioned procedure up to 20 litres of each solution may be prepared for each step, enabling one to process approximately 1000 fetuses simultaneously.

72 DEVELOPMENTAL TOXICITY STUDY OF PENTANENITRILE,3-AMINO (3-APN) IN RATS.

S M Munley, M E Hurtt, G L Kennedy. *DuPont Haskell Laboratory, Newark, DE, USA.*

The developmental toxicity of pentanenitrile, 3-amino (3-APN) was assessed in rats by orally administering solutions of the test material in water over days 6-20 of gestation. Groups of 25 time-mated female Crl:CD® BR rats were gavaged at daily dose levels of 0, 5, 30, 100 or 300 mg/kg. The dams were euthanized on day 21 and examined grossly. The fetuses were weighed, sexed, and examined for external, visceral, and skeletal alterations. Evidence of maternal and developmental toxicity was seen at 100 and 300 mg/kg. Regarding maternal toxicity, there were compound-related, statistically significant reductions in maternal body weight, weight change, and food consumption. The incidence of alopecia was significantly increased at these levels as well. Regarding developmental toxicity, mean fetal weight was significantly reduced at 100 and 300 mg/kg. In addition, at 300 mg/kg, there were significant increases in several skeletal variations consistent with developmental delay. There was no evidence of either maternal or developmental toxicity at 5 or 30 mg/kg. Thus, the maternal and developmental no-observed-effect level (NOEL) was 30 mg/kg.

73 DEVELOPMENTAL NEUROTOXICITY SCREEN - A COMBINED DEVELOPMENTAL TOXICITY ASSESSMENT WITH RATS FROM A MULTI-GENERATION REPRODUCTION STUDY.

R G Gilmore, K J Freshwater, A B Astroff and L P Sheets. *Bayer Corporation, Agriculture Division, Toxicology, Stilwell, KS, USA.*

The U.S. EPA guideline for a developmental neurotoxicity (DNT) study (OPPTS 870.6300, 1998) allows the option to perform the study "as a separate study, as a follow-up to a standard developmental toxicity and/or adult neurotoxicity study, or as part of a two-generation reproduction study, with assessment of the offspring conducted on the second (F2) generation." This paper outlines an experimental design for DNT study that uses rats from a multi-generation reproduction study and discusses the resulting advantages (e.g., fewer animals, less labor, a more comprehensive assessment, and potential cost savings) for conducting both as a combined study at the first tier of assessment. With this approach, the registrant assumes responsibility for the conduct of the DNT study, which is currently only required on a conditional basis. On the other hand, the registrant may benefit by avoiding an additional "FQPA" uncertainty factor for infants and children in lieu of the

results from a DNT study. The DNT study can utilize certain offspring from either the F1 or the F2 generation. These animals will have been exposed continuously to the test substance from conception, during gestation (via the placental circulation), continuing after birth (via the milk) and lactation (via the milk and feed), through postnatal day 21. Exposure may then be discontinued at weaning. This time period exceeds the duration of exposure that is outlined in the existing EPA guideline but this extended period of exposure provides for the possibility of a change in the EPA requirement or a new requirement (e.g., OECD). This paper outlines the advantages of this approach for both the registrant and the responsible regulatory agencies.

74 DEVELOPMENTAL TOXICITY OF SELEXOL® SOLVENT BY CUTANEOUS DOSING OF CD® RATS.

H W Leung and T R Tyler. *Union Carbide Corporation, Danbury, CT.*

Selexol® solvent is a mixture of polyethylene glycol dimethyl ethers (CAS No. 24991-55-7) used extensively in the natural gas treatment industry. Timed-pregnant CD rats, 25/group, were dosed with Selexol® solvent by occluded skin contact for 6 h/d on gestation days (gd) 6-15. Doses employed were 0, 1, 2 and 4 ml/kg/d and were selected on the basis of maternal and fetal effects observed in a range-finding study with similarly dosed pregnant rats. Monitors for maternal toxicity included body weight and food consumption measurements and clinical observation including skin irritation scores. At necropsy on gd 21, the liver, kidney, and uterus were weighed. Fetuses were evaluated for body weight and for external, visceral and skeletal anomalies. The pregnancy rate was 96-100%. No treatment-related mortality occurred during the study. Clinical signs observed in the 4 ml/kg group included exfoliation, excoriation, and crusting of the skin. Microscopic evaluation revealed acanthosis and epidermitis. There were no effects on maternal body weight, body weight gain, food consumption, or organ weights. There were also no effects on gestational parameters including the number of ovarian corpora lutea, pre- and post-implantation losses, or sex ratio. However, the fetal body weight of the high dose group was significantly decreased. There were no significant increases in the incidences of any malformations, thus Selexol® solvent was not teratogenic to rats. However, statistically significant increases in the incidences of variations in several skeletal districts (cervical centra, thoracic centra and sternebrae) were observed in the high dose group. In conclusion, occluded cutaneous application of Selexol® solvent to pregnant rats during organogenesis resulted in maternal effects and developmental delay at 4 ml/kg/day. The NOEL for developmental toxicity was 2 ml/kg/day.

75 DEVELOPMENTAL TOXICITY OF STRUCTURALLY RELATED DISUBSTITUTED HALOACETIC ACIDS IN EMBRYO CULTURE.

J E Andrews[1], J Schmidt[2], H Nichols[1], E S Hunter[1], and G Klinefelter[1]. [1]*Reproductive Toxicology Division,*[2]*Research Support Division, NHEERL, USEPA, RTP, NC.*

Disinfection of water for drinking results in numerous byproducts. One important class of disinfection byproducts is the haloacetic acids. Recent studies have shown several of the haloacetic acids to be developmentally toxic in mouse embryos. We chose representative haloacetic acids (dichloro-(DCA) and dibromo-(DBA) acetic acid) for comparative toxicity testing on rat embryos in whole embryo culture (WEC) and included bromochloro acetic acid (BCA) as a mixed haloacetic acid. Gestational day (GD) 9 embryos were exposed to 50-300 μM BCA, 10-400 μM DBA or 500-5000 μM DCA for 48 hours and then evaluated for dysmorphology, developmental score (DEVSC), head length (HL), somite number (SN), crown rump length (CRL) and embryo lethality. All three acids were dysmorphogenic in rat WEC, and DBA and DCA were effective at concentrations less than or comparable to those reported previously in mice. DCA was dysmorphogenic at concentrations ≥ 2500 μM which is only half the concentration necessary to cause dysmorphology in the mouse. DEVSC, HL, SN and CRL were significantly reduced at concentrations ≥ 1000 μM. DBA was dysmorphogenic in rat WEC at concentrations ≥ 200 μM which is similar to the 250 μM reported in mice. DEVSC, HL, SN and CRL were significantly affected at concentrations ≥ 300 μM. In general, these LOEL's are similar to those reported in the mouse, however, a striking difference between the rat WEC data and those from mice was the absence of significant effects on neural tube closure as reported in mice. The mixed haloacetic acid, BCA, was dysmorphogenic at 300 μM and HL, SN and DEVSC were significantly reduced at concentrations ≥ 200 μM. Following the 300 μM exposure, there was a significant incidence of delayed embryonic caudal development with apparent normal development anterior to the 2nd visceral arch. This is a rare observation in our lab and suggests selective inhibition of segmentation or gastrulation. (This abstract does not reflect EPA Policy.)

76 SHORT TERM REPRODUCTIVE AND DEVELOPMENTAL EFFECTS OF TRIBROMOACETIC ACID, BROMOCHLOROACETIC ACID, AND BROMODICHLOROMETHANE IN THE S-D RAT WHEN ADMINISTERED IN THE DRINKING WATER.

G W Wolfe[1], L B Kaiser[1], R N Mowry[2], G Klinefelter[3], E S Hunter[3], and R E Chapin[4]. [1]*R.O.W. Sciences Inc., Gaithersburg, MD;* [2]*PAI, Frederick, MD;* [3]*NHEERL, EPA, RTP, NC;* [4]*NTP, NIEHS, RTP, NC.*

Three drinking water disinfection byproducts (DBP), Tribromoacetic Acid (TBA), bromochloroacetic acid (BCA), and bromodichloromethane (BDCM), were evaluated using a modified short-term reproductive/ developmental toxicity protocol (Harris *et al.*, 1992). TBA (10, 70, and 400 ppm), BCA (60, 200, and 600 ppm), and BDCM (100, 700, and 1300 pm) were administered in drinking water over a 35-day period to one group of male rats (10/group) and two groups of female rats, Group A (10/group for effects of exposure during conception and early gestation) and Group B (13/group for effects of exposure during gestation and birth). Group A female endpoints included no. of corpora lutea, live and dead fetuses, and implantation sites. Group B female endpoints included maternal body wt.; feed and water consumption; no., wt., and anogenital distance of pups; visceral evaluation of hearts and brains, and no. of uterine implantations. Male endpoints included clinical pathology, organ weights, sperm analysis, and histopathology. Compound consumption (mg/kg/d) was: TBA-1, 7, and 39; BCA-7, 20, and 50; and BDCM-11, 53, and 88. TBA marginally reduced water consumption at 400 ppm with no general toxicity. In contrast, BCA and BDCM produced decreases in water consumption by 17-86% and general toxicity in both sexes at doses at and above 600 and 700 ppm, respectively. BDCM also decreased body wt. by 5-13%, and feed consumption by 14-47% at doses at and above 700 ppm. TBA and BDCM produced no reproductive toxicity in either sex while BCA reduced litter size and implant no. at 600 ppm. Of the 3 DBPs administered to S-D rats in the drinking water, TBA produced no toxicity, BDCM produced only general toxicity, and BCA produced general and potential reproductive and developmental toxicity.

77 THE EFFECTS OF PERINATAL TEBUCONAZOLE EXPOSURE ON ADULT NEUROLOGICAL, IMMUNOLOGICAL, AND REPRODUCTIVE FUNCTION IN RATS.

V C Moser[1], R C MacPhail[1], R J Smialowicz[1], M W Harris[2], and R E Chapin[2]. [1]*NHEERL/US EPA;* [2]*NTP/NIEHS, Research Triangle Park, NC, USA.*

Studies are underway to address concerns of potential persistent immunotoxic, reproductive, and neurotoxic effects of perinatal exposure to several pesticides. Tebuconazole, a triazole fungicide, was evaluated as part of this project. Sprague-Dawley dams were administered tebuconazole (0, 6, 20, or 60 mg/kg) by oral gavage daily from gestational day 14 to postnatal day (PND) 7; the pups were then dosed at the same levels from PND 7 to 42. Separate groups of rats were used for testing of immuno-logical parameters, and neurobehavioral testing using a screening battery of functional tests, including cognitive evaluations. Other groups of rats were evaluated for repro-ductive development and function, while others were sacrificed at designated times for histological analyses. Pup viability and body weight were decreased (13-17%) at the high dose. Histological analyses were generally unremarkable. There were no differences in the fertility indices. Although spleen weights were increased in high-dose rats immunized with sheep RBCs, there were no biologically significant changes in the rats evaluated for immunotoxicity. Acquisition of learning the platform location in a water tank (*i.e.*, Morris water maze) was impaired in high-dose rats, but there were no differences in neuromuscular ability, motor activity, or swim speed to account for this finding. Furthermore, there was no effect on recall of the position during a free-swim trial. In rats trained on a multiple fixed-ratio (FR) fixed-interval (FI) schedule of operant responding for food reinforcement, the high-dose rats showed faster FR responding but FI responding was not altered. Thus perinatal exposure to tebuconazole produced specific neurobehavioral deficits in rats, but did not alter immunological or reproductive function.

78 THE EFFECT OF ELIPRODIL ON EMBRYONIC DEVELOPMENT USING THE RAT POST-IMPLANTATION WHOLE EMBRYO CULTURE SYSTEM.

C L Taylor[1], J Stewart[2], A Burns[1], and M C Brady[1]. *Zeneca [1]CTL/[2]Pharmaceuticals, Macclesfield, Cheshire, UK.* Sponsor: E A Lock.

Eliprodil is an experimental neuroprotectant which mediates its effects by antagonism of NMDA and possibly sigma receptors in the brain. Recent studies suggest that sigma receptors are enzymes in the post-squalene cholesterol biosynthetic pathway. Eliprodil and other sigma receptor binding compounds are, therefore, likely to be inhibitors of cholesterol biosynthesis. The developing embryo/fetus is dependent upon *de novo* cholesterol biosynthesis, only a small proportion is derived from the maternal supply. The purpose of this study was to determine the effects of eliprodil on developing embryos and investigate the mechanism of any observed toxicity using rat post-implantation whole embryo culture. Rat embryos were explanted and cultured for 48 hours during early/mid organogenesis (9.5-11.5 days). After this time embryos were evaluated microscopically and scored for lethality, growth, development and incidence of malformation. Eliprodil at 0.5μM induced growth and developmental retardation in addition to forebrain and eye abnormalities. Total embryolethality was observed at 5μM. In order to determine whether the observed effects were attributable to cholesterol biosynthesis inhibition, further studies were conducted in the presence of cholesterol, which was added to the culture media at 12.5μg/ml (in an appropriate vehicle). The presence of cholesterol had no effect upon eliprodil-induced growth and developmental retardation, however, the incidence of malformations was inhibited at concentrations of 1.5μM eliprodil and below. Furthermore, embryolethality was reduced to 44% at 5μM eliprodil. These findings suggest that inhibition of cholesterol biosynthesis is at least partially responsible for the observed developmental toxicity of eliprodil.

79 FREE RADICAL-MEDIATED OXIDATIVE DNA DAMAGE IN THE MECHANISM OF THALIDOMIDE TERATOGENICITY.

T Parman[1], M J Wiley[2] and P G Wells[1,3]. [1]*Faculty of Pharmacy and Depts. of [2]Anatomy and [3]Pharmacology, Univ. of Toronto, ON, Canada.*

Our preliminary rabbit studies suggested that thalidomide oxidises embryonic DNA, which along with its teratogenicity was inhibited by the free radical trapping agent alpha-phenyl-N-t-butylnitrone (PBN). In this completed study, New Zealand white rabbits (thalidomide sensitive) and mice (resistant) were treated on gestational day (GD) 12 with PBN (40 mg/kg) or its vehicle iv 15 min prior to thalidomide (400 mg/kg, rabbits; 1200 mg/kg, mice) or its vehicle po. Six hr later, in rabbits, thalidomide enhanced DNA oxidation 3.8-fold in embryos, and 5.5- to 63-fold in various maternal tissues ($p<0.05$), while mice were unaffected. In rabbits treated as above, but from GDs 8-12, controls had no birth defects, while thalidomide caused a 35 % incidence of phocomelia ($p<0.005$), 10% omphalocele and 10% adactyly, and enhanced fetal resorptions, postpartum lethality ($p<0.005$) and fetal weight loss ($p<0.05$). PBN pretreatment inhibited thalidomide-initiated DNA oxidation by 73% in embryos and 61-86% in maternal tissues, virtually abolished phocomelia ($p<0.001$) and other anomalies, and substantially reduced all other embryopathies ($p<0.05$). These results suggest a free radical-mediated mechanism of thalidomide teratogenesis, and provide the first direct insight into a potential embryonic determinant of species-dependent susceptibility. (Support: Medical Research Council of Canada.)

80 DEVELOPMENTAL CARDIOTOXICITY OF BETA-ADRENERGIC AGONISTS: UNIQUE RECEPTOR SIGNALING MECHANISMS.

J L Zeiders, F J Seidler, and T A Slotkin. *Duke University Medical Center, Durham, NC, USA.*

Beta-adrenergic agonists are potentially cardiotoxic but the adult heart is protected from excessive adrenergic stimulation by receptor desensitization. In contrast, fetal and neonatal hearts sensitize in response to repeated stimulation. We have examined the mechanisms underlying the developmental regulation of cardiac beta-adrenoceptor responsiveness by assessing adenylyl cyclase activity, receptor/G-protein coupling and BARK1 activity. Two hours after a single s.c. injection of isoproterenol to adult rats, homologous receptor desensitization was demonstrable as a loss of the ability of isoproterenol, but not glucagon, to stimulate adenylyl cyclase in isolated cell membranes. At later time points, adults showed heterologous desensitization, a loss of the response to glucagon, which shares the same transduction protein (Gs) but not the same receptor. There was also a decrement in the ability of receptors to couple to Gs after isoproterenol treatment in adults, demonstrated as the loss of the ligand binding response to GTP. When isoproterenol was given to neonates, neither homologous nor heterologous desensitization was seen. Instead, the treatment enhanced the coupling of beta-receptors to Gs and increased the adenylyl cyclase response to either isoproterenol or glucagon. The absence of desensitization in neonates did not reflect a deficiency in the activity or subcellular distribution of BARK1, the enzyme that initiates receptor phosphorylation and consequent desensitization. The absence of desensitization in the fetus and neonate, and the presence instead of desensitization, is likely to play a role in cardiotoxicity of adrenergic agents such as those used to arrest premature labor. Furthermore, as fetal/neonatal adrenergic signals establish the proper set-point for future receptor responsiveness, exposure to adrenergic agonists or antagonists during this period may result in long-lasting changes in cardiac responses to physiological or environmental challenge. (Supported by USPHS HD-09713 and a fellowship from the American Heart Association.)

81 EFFECTS OF ACETAMINOPHEN ON PREIMPLANTATION EMBRYO GLUTATHIONE CONCENTRATION AND DEVELOPMENT IN VIVO.

D N Laub, N M Elmagbari, N O Elmagbari, and C S Gardiner. *Department of Biological Sciences, University of Northern Colorado, Greeley, CO.*

This study investigated whether high doses of acetaminophen (APAP) adversely affect preimplantation embryos in vivo. Previous studies indicate that cleavage stage embryos cannot synthesize reduced glutathione (GSH) de novo and may as a result be sensitive to GSH depleting toxicants. Alternatively, there may be maternal mechanisms that protect the embryos from the adverse effects of these toxicants. To address these possibilities, we measured GSH in embryos, livers, and ovaries of female mice after treatment with either vehicle (C) or APAP. Treatment with 800mg/kg/day APAP (A800) from day -8 to day 3 (d3) of gestation (day 0 being the day of detection of vaginal plugs) did not affect embryo (E) or liver (L) GSH concentration on d1 or d3 of gestation (d1E C 0.58 pmol/embryo, A800 0.51; d3E C 0.10, A800 0.24; d1L C 8.2mM, A800 8.9; d3L C 5.0, A800 5.0). Embryos also did not exhibit developmental effects in vitro (% blastocyst C 70, A800 80) or in vivo (% blastocyst C 76, A800 75). Two hours (h) after 1 dose of 800 or 1430mg/kg/day (A1430) on d2 of gestation, GSH concentration in the liver had decreased (C 7.7mM, A800 1.8, A1430 1.2; $p<.01$) but it recovered by 16h (C 7.2, A800 6.6, A1430 8.1). There was no effect on embryo development (% morula C 81, A800 93, A1430 99) or embryo GSH concentration at 2h (C 0.39 pmol/embryo, A800 0.37, A1430 0.33) or at 16h (% morula C 88, A800 73; C 0.51 pmol/embryo, A1430 0.39). Ovary GSH concentration did not decrease at 2h or 16h (2h C 2.5mM, A800 3.3, A1430 2.2; 16h C 1.2, A800 1.1, A1430 0.71). Preliminary data indicate no significant difference in the number of fetuses (C 9.3, A800 7.5), the number of resorptions (C 5.3, A800 1.5) or the number of gross malformations (C 0, A800 0) on d17 of gestation after treatment with 800mg/kg/day from d -8 to d3 of gestation. In summary, large doses of APAP depleted liver GSH temporarily but did not affect the development of preimplantation embryos or their GSH concentration. In conclusion, preimplantation embryos appear to be protected from GSH depleting toxicants in vivo.

82 GLUCOSE-6-PHOSPHATE DEHYDROGENASE (G6PD): EMBRYONIC GENOTYPE AND PHENOTYPE CONTROL TERATOLOGIC SUSCEPTIBILITY TO ENDOGENOUS OXIDATIVE STRESS AND PHENYTOIN.

C J Nicol[1], J Zielenski[2], L-C Tsui[2] and P G Wells[3]. [1]*Depts. of Pharmacology, Univ. of Toronto and [2]Genetics, Hospital for Sick Children, and [3]Faculty of Pharmacy, Univ. of Toronto, Toronto, ON, Canada.*

While the major risk from hereditary G6PD deficiencies is thought to be red blood cell hemolysis, we have shown in mutant pregnant mice that both heterozygous (+/–) and homozygous (–/–) G6PD–deficient dams are more susceptible to embryopathies and teratogenicity caused by oxidative stress arising endogenously, or enhanced by phenytoin (Fund. Appl. Toxicol. 30[S1,P2]: 197, 1996; 36[S1,P2]: 98, 1997 In this study, compared to G6PD–normal littermates on gestational day 19, G6PD activity was 48% in +/– G6PD deficient fetuses and 18% in combined –/– and –/y G6PD deficient fetuses ($p<0.05$). There was an 11–fold difference between the highest (spleen) and the lowest (heart) activities in various maternal organs. G6PD–deficient fetuses with a mutation in all G6PD alleles (–/–, –/y) had more embryopathies, including teratologic anomalies, with +/– G6PD–deficient fetuses showing intermediate risk ($p<0.05$). This gene dose–dependent pattern was observed in both vehicle– and phenytoin–exposed fetuses, with

greater, drug dose–dependent teratogenicity in the latter ($p<0.05$). Genotyped fetal resorptions were primarily G6PD–deficient. This is the first direct evidence that embryonic G6PD is a critical determinant of susceptibility to the embryopathic and teratogenic effects of developmental oxidative stress and phenytoin. (Support: Medical Research Council of Canada.)

83 THE STRESS GENE HSP90 FUNCTIONS IN NORMAL VERTEBRATE MYOGENESIS, IN ADDITION TO ITS FUNCTION AS AN INDICATOR OF BIOLOGICAL STRESS.

J B Sass[1], P H Krone[2]. [1]*University of Maryland, Program in Human Health and the Environment, Baltimore, MD, USA;* [2]*University of Saskatchewan, Dept. of Anatomy and Cell Biology, Saskatoon, Canada.* Sponsor: E K Silbergeld.

The accumulation of Hsps (heat shock proteins) is a universal cellular response to chemical and environmental insults, elevated temperatures, and disease states. The presence of Hsps in every living organism examined, and in every tissue type, make them an extremely sensitive indicator of cellular stress. In addition to an examination of *hsp90* gene regulation following stress, this work examined the in vivo regulation of the *hsp90a* gene during zebrafish embryogenesis. Whole mount in situ hybridization analysis using gene specific DIG-riboprobes was used in order to examine the in vivo spatial expression pattern of *hsp90a* and *hsp90b*. Constitutive accumulation of *hsp90b* mRNA was visible in a wide range of embryonic tissues, whereas *hsp90a* mRNA was localized specifically to the skeletal myogenic tissue of the trunk and pectoral fin. This suggests that *hsp90a* and *hsp90b* expression is uncoupled during embryogenesis. Similar experiments performed on mid-somitogenic chicken embryos gave similar results, suggesting that the stage- and tissue-specific expression of *hsp90a* is indicative of an evolutionarily conserved function in vertebrate myogenesis. In order to examine the cell-specific localization of *hsp90a*, whole zebrafish embryos were sectioned following hybridization with antisense riboprobe. Results confirmed high level expression of *hsp90a* within the myogenic cells, prior to segmentation and somite formation. Zebrafish mutant embryos which exhibit aberrant myogenesis were analysed, and results confirmed the localization of *hsp90a* within the cells fated to form striated trunk muscle. This work demonstrates, for the first time, the independent regulation of *hsp90a* and *hsp90b*, and the uncoupling of stress-induced and constitutive expression of *hsp90a*.

84 CONSTRUCTION OF A BIOLOGICALLY BASED DOSE-RESPONSE MODEL FOR DEVELOPMENTAL TOXICITY OF 5-FLUOROURACIL IN THE RAT.

C Lau, *R W Setzer, M L Mole, J M Rogers, R J Kavlock and R M Zucker. *Reprod. Tox. Div., *Off. Assoc. Dir., NHEERL, US EPA, RTP, NC.*

Biologically based dose-response modeling is an emerging approach to improve human health risk assessment. For a developmental toxicant, these models provide an integrated picture of the sequence of events from exposure of the pregnant dams, to molecular interactions within the embryonal cells, interference with organogenesis, and ultimately defective anatomical structures and/or deficient organ functions. Our laboratory has attempted to construct such a model using the chemotherapeutic agent 5-fluorouracil (5-FU) as a prototype developmental toxicant. A single sc injection of 5-FU (doses ranging from 1 mg/kg to 40 mg/kg) was given to pregnant Sprague-Dawley rats on gestational day 14, and various biochemical parameters were measured. 5-FU had a short half-life in maternal serum and direct incorporation of 5-FU into embryonic nucleic acids was low. However, activity of thymidylate synthetase and deoxyribonucleotide (dNTP) pools in the whole embryos, cell cycle profiles of embryonic tissues, total embryonic DNA content and fetal weights were profoundly altered by 5-FU in a dose-dependent manner. Frank terata were noted at doses above 25 mg/kg. The relationship between dNTP pool imbalance and incidence of anatomical defects as well as fetal weight deficits were evaluated by mathematical simulation. These models indicated different associative patterns between dNTP alterations and the two endpoints of toxicity, perhaps reflecting different underlying mechanims. (This abstract does not reflect US EPA policy.)

85 ENDOTHELIN-A RECEPTOR ANTAGONISM PRODUCES DEFECTS OF NEURAL CREST-DERIVED TISSUES IN WHOLE EMBRYO CULTURE.

K C Brannen[1], E S Hunter III[2], and J M Rogers[2]. [1]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC;* [2]*Reproductive Toxicology Division, NHEERL, U.S. EPA, Research Triangle Park, NC, USA.*

Endothelin-1 (ET-1) is a potent vasoconstrictor and has recently been shown to be important in development of the cranial neural crest (CNC) derivatives. Furthermore, recent evidence suggests that the role of ET-1 in CNC development is mediated by the ET_A receptor. Whole embryo culture was used to determine whether ET_A receptor antagonism in gestation day (GD) 8-10 embryos produced defects in CNC-derived tissues. CD-1 mouse embryos at GD8 (4-5 somite) were cultured for approximately 52 hours in the presence of 0 or 100 μM BQ-123 (an ET_A selective antagonist). Embryos exposed to the antagonist had abnormalities of the pharyngeal arches, especially the first and second arches. Also, preliminary data suggest that treatment with 200 μM BQ-123 does not cause malformations that are obviously more severe than those resulting from exposure to 100 μM. To determine the period of greater sensitivity, embryos exposed for the full culture period were compared with those exposed for either the first or second half of that period only (i.e., day 8 or 9). The effect on arch development appeared greater in day 8- than day 9-exposed embryos. Therefore, blockade of the ET-1/ET_A pathway interferes with development of the pharyngeal arches with the greater effect apparently occurring on GD8. This further implicates ET-1 and the ET_A receptor in the early events of CNC cell development, such as emigration, migration, proliferation, and/or differentiation. (This abstract does not necessarily reflect US EPA Policy and was partly funded by EPA/UNC Toxicology Research Agreement CT902908.)

86 REPRODUCTIVE AND DEVELOPMENTAL TOXICITY IN RATS TREATED ORALLY WITH 2-AMINO-6-CHLOROPURINE.

F J Guerriero[1], C W Seaman[1], G L Sprague[1], T J Sutton[1] and E Wood[2]. [1]*SmithKline Beecham Corporation, King of Prussia, PA, USA;* [2]*SafePharm Laboratories Limited, Derby, UK.*

Reproductive studies were undertaken with 2-amino-6-chloropurine (ACP), a pharmaceutical intermediate (CAS RN 10310-21-1), because it was found to be an *in vitro* and *in vivo* mutagen. Male fertility was assessed at 10, 50 and 100 mg/kg/day after 32 and 67 days of dosing by mating with untreated females. Effects on female fertility were examined at 10, 50 and 75 mg/kg/day by dosing prior to mating, throughout mating (with untreated males), and during pregnancy, delivery and lactation. Developmental toxicity was assessed at 10, 50 and 100 mg/kg/day by dosing females from days 6 to 17 of pregnancy and sacrificing day 20 for examination of their uterine contents. In the male fertility study severe toxicity and lethality occurred at 100 mg/kg/day. All animals died or were terminated prior to mating, but no morphological changes were detected in the testes and there was no reduction in sperm counts. Male fertility was unaffected at lower doses and there were no changes in the testes or sperm counts. In the female fertility study even with adult toxicity at 75 mg/kg/day there was no effect on estrous cycles and mating performance but embryo and fetal lethality occurred. At 50 mg/kg/day adult toxicity was minimal with a reduction in litter size, birth weight, growth and viability during lactation. No treatment related effects were observed at 10 mg/kg/day. In the developmental toxicity study at 100 mg/kg/day there was maternal toxicity, embryolethality and reduced fetal and placental weights. The surviving fetuses showing visceral and skeletal anomalies. At 50 mg/kg/day there was no maternal toxicity, but placental weights were decreased and there was an increase in fetuses with supernumerary ribs. No adverse fetal effects were seen at 10 mg/kg/day. The reproductive NOEL of ACP for both sexes was 10 mg/kg/day in this study.

87 TERATOLOGICAL RELEVANCE OF EMBRYONIC GENOTYPE IN BENZO[A]PYRENE (B[a]P)–TREATED KNOCKOUT MICE.

P G Wells, C J Nicol and M J Wiley. *Faculty of Pharmacy and Depts. of Pharmacology, Anatomy and Cell Biology, University of Toronto, Toronto, ON, Canada.*

B[a]P teratogenicity is enhanced in knockout mice, suggesting serves a teratological suppressor role with DNA–damaging teratogens (Nature Genet. 10: 181–185,1995). We report here by embryonic genotype that pooled –/– fetuses exposed in vivo to B[a]P had about a 60% higher incidence of col-

lective anomalies than either +/+ or +/– fetuses (p>0.05), while +/– fetuses from +/– dams had a 2.8–fold higher incidence than those from +/+ dams p<0.003).Conversely, +/+ fetuses were more susceptible to 2 anomalies (omphalocele, red nevÍ 7ÛI ´Ís) (p=0.09), and +/+ fetuses from +/+dams had a 4–fold higher incidence of postpartum lethality (p<0.002) than +/– littermates, with a similar but lesser gene pattern in +/– dams (p<0.02). Also, +/+ and +/– fetuses from +/– dams had 3.2– and 8.8–fold higher postpartum lethality than their respective genotypes in +/+ dams (p<0.0001). In staged embryos analyzed by Nile blue sulfate staining during organogenesis, a pattern of cell death was evident 3 hr after B[a]P exposure, independent of genotype. Our results suggest that the protective role of p53 for most B[a]P anomalies and in utero death may involve DNA repair, while postpartum lethality and 2 anomalies involve dependent apoptosis, and some embryopathies are independent. Maternal genotype remains an important risk determinant, but the embryonic genotype is teratologically relevant, and determines whether B[a]P–exposed fetuses will die in utero or postpartum. (Support: Medical Research Council of Canada.)

88 PROTEIN KINASE C ONTOGENY IN THE DEVELOPING PALATE AND THE EFFECT OF SECALONIC ACID-D ON ITS EXPRESSION IN MICE.

G Balasubramanian and C S Reddy. *Department of Veterinary Biomedical Sciences, University of Missouri, Columbia, MO.*

Protein Kinase C (PKC) is a central player in signaling pathways mediating cell proliferation. Since cell proliferation is critical in palatal shelf growth and since PKC-inhibition may play a role in secalonic acid-D (SAD)-induced cleft palate, this study was undertaken to establish the normal ontogeny of Ca^{2+}-dependent (-α , -β I, -β II and -γ) and independent isozymes (-δ , -ε , -ζ) in developing murine palate during gestation days (GD) 12 through 15 and to evaluate the effects of SAD on PKC ontogeny. Palatal tissue extracts from control and SAD-exposed offspring were subjected to western blot analysis using isozyme specific antibodies and quantitative densitometry. The Ca^{2+}-dependent isozymes ε and ζ were expressed in controls at high levels on GD 12 and increased further throughout palatogenesis. The isozyme δ was expressed at constant but lower levels with a ~60 Kd band of equal intensity being also present. The expression of Ca^{2+}-dependent isozymes β I and γ was negligible. The expression of β II progressively decreased between GD 12 and 14.5 and was noticeably reduced by SAD on GD 14. PKC-α was expressed moderately between GD 12 and 14.5 but was drastically reduced on GD 15. The observed ontogeny of PKC isozymes may suggest isozyme-specific roles for PKC in palate development. Lack of effects of SAD on isozyme expression suggests a greater role for inhibition of PKC activity by SAD in its teratogenic effect. (Supported by NIH grant # DE/OD 11822.)

89 DEVELOPMENTAL, PHYSIOLOGICAL, AND CHEMICAL REGULATION OF RAT HEPATIC STEROID SULFATASE.

D P Hartley, D Max, and C D Klaassen. *Univ. of Kansas Med. Ctr., Kansas City, KS.*

Steroid sulfatase is a microsomal enzyme that mediates the hydrolysis of sulfate esters formed in part through sulfotransferase-mediated sulfation. The expression and activity of steroid sulfatase in proximity to sulfotransferase enzymes may effectively negate cellular sulfation of drug and chemical moieties. To understand the role of steroid sulfatase in sulfation we characterized the effect of gender, age, physiological hormones, and chemicals on the expression and activity of steroid sulfatase. Western-blot analyses and enzymatic activity with estrone-3-sulfate as substrate indicated that there were no significant differences in steroid sulfatase expression and activity between male and female Spraque-Dawley rats. Steroid sulfatase was present at day-1 post-partum and remained relatively constant during development (1-90 days of age). Manipulation of endogenous endocrine hormones by surgical hypophysectomy (25-day-old rats) did not significantly alter expression of steroid sulfatase in male and female rats. In addition, male and female rats were treated with phenobarbital, 3-methylcholanthrene, Aroclor 1254, and pregnenolone-16α-carbonitrile for 7 days to determine whether steroid sulfatase is responsive to chemical induction. In contrast to many microsomal drug-metabolizing enzymes, steroid sulfatase is refractory to induction by these classical enzyme-inducing chemicals. Our results suggest that steroid sulfatase is fully developed at birth, is not sexually divergent, and is not modulated by either hormonal status or chemical treatment. Therefore, the activity of steroid sulfatase must be accounted for when assessing sulfation-mediated detoxication or bioactivation of sulfotransferase substrates. (Supported by USPHS grants ES-07079 and ES-03192, and Kansas Health Foundation grant KHF-411606.)

90 DEVELOPMENTAL ANALYSIS OF GENE EXPRESSION IN THE MALE REPRODUCTIVE TRACT DURING *IN UTERO* EXPOSURE TO DI-*N*-BUTYL PHTHALATE.

V D Shultz, E Mylchreest, P M D Foster, and K W Gaido. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA.*

Di-*n*-butyl phthalate (DBP), a plasticizer and solvent with widespread commercial use, produces severe developmental abnormalities of the male reproductive tract via a nonreceptor-mediated mechanism following *in utero* high-dose exposure. The testis is postulated to be the primary target of DBP toxicity. Therefore, the objective of this study was to examine the steady-state levels of critical genes expressed in the testis that are involved in the development of the male reproductive tract. Pregnant Sprague-Dawley rats were administered 500 mg/kg/day DBP in corn oil by gavage from gestation days 12 to 21, the period of reproductive organ development in the fetus and, consequently, the critical window of exposure for induction of DBP-mediated reproductive tract malformations. Steady-state message levels of steroidogenic factor-1 (SF-1) and androgen receptor (AR) were analyzed from combined testes and epididymides total RNA of individual DBP- and corn oil-treated offspring using semi-quantitative PCR. Flutamide-treated animals (50mg/kg/day) served as positive controls. Preliminary studies showed a slight (10-20%) decrease in SF-1 mRNA expression in combined DBP-treated testes and epididymides and a similar increase in flutamide-treated animals at GD 21. However, AR message levels were unaltered by DBP or flutamide treatment during the same period of development. More recently, immunohistochemical analysis of AR protein levels has shown an apparent increase in AR protein staining in DBP-treated testes and decreased AR protein staining in DBP-treated epididymides. These findings suggest that changes in gene expression may be tissue-specific in the reproductive tract of DBP-treated males, and therefore, additional analysis of individual tissues will be necessary to observe significant changes in gene expression that may lead to the observed reproductive tract malformations.

91 DI(*n*-BUTYL) PHTHALATE INDUCES CHANGES IN MORPHOLOGY AND ANDROGEN RECEPTOR LEVELS IN THE FETAL TESTIS.

M Sar, E Mylchreest, D G Wallace, R C Cattley, and P M D Foster. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA.*

Fetal exposure to di(*n*-butyl) phthalate (DBP) causes epididymal agenesis, decreased sperm production, and interstitial cell hyperplasia and adenoma in adult male rats. Similar effects are produced by the potent androgen receptor (AR) antagonist flutamide (FLU). Although these effects are indicative of disruption of male sexual differentiation via an antiandrogenic mechanism, DBP is not an AR antagonist. Because AR-mediated signaling pathways are essential for male sexual differentiation, changes in fetal AR levels may occur in response to DBP. Pregnant CD rats were dosed from gestation day (GD) 12 to 21 with DBP at 500 mg/kg/day (n = 5) or FLU at 100 mg/kg/day (n = 2). On GD 21, AR levels in the fetal testis and epididymis were evaluated by immunohistochemistry. In the testicular interstitial cell compartment, DBP caused an increase in the number of cells and an apparent increase in AR immunostaining. Seminiferous tubules were also enlarged and contained multinucleated, undifferentiated germ cells. AR staining in interstitial cells was decreased by FLU with no change in testis morphology. In the epididymis, fewer ducts were apparent in DBP- and FLU-exposed fetuses. An overall decrease in AR staining was seen with FLU whereas DBP caused decreased staining in some epididymal ducts. Unlike FLU, the antiandrogenic activity of DBP is not mediated through an overall decrease in AR levels and suggests that DBP disrupts sexual differentiation through a different mechanism. The early morphological changes induced by DBP in the fetal testis are likely to be associated with the testicular lesions seen in adults.

92 TOXIC RESPONSES OF MEDAKA (d-Rr STRAIN) TO POLYCHLORINATED NAPHTHALENE (PCN) MIXTURES AFTER EMBRYONIC EXPOSURE BY IN OVO NANOINJECTION: A PARTIAL LIFE CYCLE ASSESSMENT.

S A Villalobos[1], D M Papoulias[2], J Meadows[2], A L Blankenship[1], S D Pastva[1], K Kannan[1], D E Tillitt[2], J P Giesy[1]. [1]*Zoology Department, National Food Safety and Toxicology Center, Institute of Environmental Toxicology, Michigan State University, East Lansing, MI, USA;* [2]*Environmental and Contaminants Research Center, USGS, Columbia, MO, USA.*

PCNs are compounds with some chemical properties/uses similar to polychlorinated biphenyls (PCBs), and have been detected in biota from some aquatic environments. The toxicities of several PCN technical mixtures (Halowax) to medaka (*Oryzias latipes*), were determined using an embryo nanoinjection method. Medaka eggs (early gastrula) were injected 0.5 nl of triolein (vehicle control) or 0.5 nl of 4-5 graded doses (0.3-30 ng/egg) of Halowax 1014, Halowax 1013, or Halowax 1051 in triolein. Following exposure, embryos developed and fry were reared for approximately 4 mo (sexual maturity), at which time they were euthanized. Responses were evaluated as early life stage (ELS), and early adult life stage (EALS) assessments. For ELS, lethality and sublethal alterations in embryos and larvae (< 16-d old) such as craniofacial, cardiovascular, and myoskeletal deformities, and abnormal or delayed hatch were monitored for the first 9 d, and a severity index computed. EALS assessment examined survival of 16 d-old larvae until early adulthood (122 ± 2 d-old), including gonadosomatic index (GSI) and morphometry. Halowax 1014 was found to be the most toxic mixture (LD_{50} 4.2 μg/g egg), while Halowax 1013 and 1051 were significantly less toxic. GSI of females was significantly less in fish dosed with Halowaxes 1014 (dose response manner) or 1051. The LD_{50} for embryos nanoinjected with 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) is approximately 0.8 ng/g. Thus, Halowax 1014 was 5250-fold less potent than TCDD. ELS assessments accurately predicted the results of EALS assessments.

93 EFFECTS OF DEVELOPMENTAL EXPOSURE TO AROCLOR 1254 ON LEARNING AND SUSTAINED ATTENTION IN RATS.

W M Oshiro, P J Bushnell and P R S Kodavanti. *Neurotoxicology Division, National Health and Environmental Effects Research Laboratory, USEPA, Research Triangle Park, NC, USA.*

Perinatal exposure to polychlorinated biphenyls (PCB) in humans is suspected of causing behavioral and developmental deficits in infancy and childhood. In addition, *ortho*-substituted PCBs accumulated selectively in brain during *in vivo* exposure and these PCB congeners altered Ca^{++} homeostasis *in vitro* in neuronal cultures. The present studies were designed to determine whether perinatal exposure to Aroclor 1254 (Lot #124-191, AccuStandard), a commercial PCB mixture containing a high proportion of *ortho*-substituted congeners, would affect cognitive function. We assessed the ability of perinatally-exposed rats to learn a lever press response and a two-choice, discrete-trial visual signal-detection task (SDT). The SDT was then used to assess sustained attention. Thirty-five dams received daily oral doses of 0, 1, or 6 mg/kg Aroclor 1254 in corn oil from gestational day 6 through postnatal day 21. One male and one female pup were selected from each litter for behavioral assessment. Assessments began at 110 days of age and included 1) autoshaping a lever press for food reinforcement; 2) learning the SDT; and 3) manipulation of the inter-trial interval (ITI), from constant to variable, in the SDT. Control male rats learned the lever press response faster during autoshaping than did the PCB treated males, while the high-dose females learned more quickly than the control and low dose females. No significant differences were seen in learning or performing the SDT on measures of probability of a hit [P(hit)], or probability of a false alarm [P(fa)]. However, when the ITI was made variable, P(hit) of the high dose PCB animals fell less than that of the control or low-dose animals. These results provide little support for reports that perinatal exposure to PCB causes deficits in cognitive function in children. Here, Aroclor 1254 appeared to exert a gender-specific, transient effect on learning, but no persistent effects on sustained attention.

94 PERINATAL EXPOSURE TO AROCLOR 1254 SUPPRESSES THE ONTOGENETIC PEAK OF MOTOR ACTIVITY IN LONG-EVANS RATS.

A S Driver[1,2], H A Tilson[2], and R C MacPhail[2]. [1]*University of North Carolina at Chapel Hill, Chapel Hill, NC;* [2]*Neurotoxicology Division, NHEERL, US Environmental Protection Agency, Research Triangle Park, NC.*

Previously, this laboratory has shown that Long-Evans rats have a reproducible pattern of motor activity during development which peaks between postnatal days (PND) 14 and 16 followed by a decline in activity until stasis is reached at approximately PND 21. In this study we examined the effect of perinatal Aroclor 1254 exposure on the established ontogeny of motor activity in developing rats. Maternal dosing via oral gavage was carried out daily from gestational day six through weaning (PND 21). The doses of Aroclor 1254 chosen were 0, 1, and 6 mg Aroclor 1254/kg body weight/day; thus pups were exposed only via the dams. One male and one female each from eight litters were tested for each dose level. Each animal was placed in a Motron chamber and horizontal activity was measured for 30 minutes. There was no effect of Aroclor 1254 on motor activity in the males. However, there was a significant depression of the peak in motor activity in females (-34.4%, p=0.02) at the 6 mg/kg/day dose level. This experiment was repeated twice, once using the same male and female from each litter and in the second cohort choosing one male and one female at random each day. This suppressive gender-specific effect was robust to be observed in both protocols. Thus it appears ontogeny of motor activity, a recognized developmental milestone, is suppressed in a gender-specific manner by perinatal Aroclor 1254 administration. (Supported in part by USEPA/UNC Training Agreement, CT 901915.)

95 PERINATAL EXPOSURE TO AROCLOR 1254 ALTERS MOTOR ACTIVITY IN ADULT LONG-EVANS RATS CHALLENGED WITH NICOTINE.

H A Tilson[1], R C MacPhail[1], A S Driver[1,2]. [1]*Neurotoxicology Division, NHEERL, US Environmental Protection Agency, Research Triangle Park, NC;* [2]*University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Previously, this laboratory has shown that Long Evans rats have a reproducible pattern of motor activity during development which peaks between postnatal days (PND) 14 and 16 followed by a decline in activity until stasis is reached at approximately PND 21 and that perinatal Aroclor 1254 exposure suppresses the peak of this ontogenetic pattern of motor activity in females. In this study, we examined the alteration of responses to drug challenges using motor activity as an easily measured endpoint of drug exposure. Maternal dosing via oral gavage was carried out daily from gestational day six through weaning (PND 21). The doses of Aroclor 1254 chosen were 0, 1, and 6 mg Aroclor 1254/kg body weight/day; thus pups were exposed only via the dams. At PND 90, pharmacological challenges were administered to probe alterations of GABAergic, cholinergic, or dopaminergic neurotransmitter systems. Specific agonist and antagonists were used on a Tuesday/Friday dose schedule to allow at least 2 days wash-out time between drugs. Each animal was treated with each drug in a pseudorandom order, placed in a Motron chamber, and horizontal and vertical activity was measured for 30 minute sessions. Notably, all drugs chosen affected motor activity. The only drug which showed any significant interaction of drug treatment and Aroclor 1254 exposure was nicotine. Changes in motor activity induced by nicotinic agonists were altered by prior perinatal exposure to Aroclor 1254. (Supported in part by USEPA/UNC Training Agreement, CT 901915.)

96 CULTURED RAT NEURAL CREST CELLS RELEASE A MACROPHAGE REGULATORY FACTOR IN RESPONSE TO POLYCHLORINATED BIPHENYL (PCB) EXPOSURE.

D A Hill and C Harris. *Toxicology Program, Department of Environmental and Industrial Health, University of Michigan, Ann Arbor, MI.*

Neural crest cells (NCCs) are essential progenitors for many developmental structures. They are a highly migratory population of differentiating cells that are sensitive to toxic insults. The mechanisms that mediate NCC toxicity are not fully understood. Inflammatory cells (e.g. neutrophils, macrophages, mast cells) play a role in the mechanisms of various toxicities. Our recent data has suggested that conditioned medium collected from NCCs exposed to a single dose of PCBs is chemotactic for macrophages. Accordingly, the present study was designed to determine if PCBs, in a dose/time dependent manner, cause NCCs to release a factor(s) that regulates macrophage activity. To conduct this study, NCC cultures were treated with

various doses of Aroclor 1248 (a standard PCB mixture) and incubated for 8, 16, or 24 hours. The resulting NCC-derived conditioned media (NCC-CM) was collected. The ability of NCC-CM to induce macrophage chemotaxis (expressed as % positive control) and cytokine release was determined using a two-chambered chemotaxis system and spectrophotometric detection assays, respectively. NCC-CM derived from treatment with 25 and 50 uM Aroclor 1248 demonstrated chemotactic activity for macrophages and caused them to release both tumor necrosis factor-alpha (TNF-alpha) and interleukin-1 (IL-1). The production of NCC-CM that caused macrophage chemotaxis and cytokine release was dose and time dependent. NCCs required atleast 16 hours incubation with 25 or 50 uM Aroclor 1248 to produce stimulatory NCC-CM. These data suggest that the PCB mixture, Aroclor 1248, causes NCCs to release a factor(s) that is chemotactic for macrophages and induces their release of cytokines. (Supported by the Paul Cornely Fellowship and NIH grant ES05235.)

97 LONG-TERM EFFECTS OF POLYCHLORINATED BIPHENYLS (PCBS) IN THE NEONATAL BALB/C MOUSE MODEL.

J M Martinez and L A Jones. *The University of Texas, M.D. Anderson Cancer Center, Houston, TX, USA.* Sponsor: M A Smith.

The neonatal mouse model has been a valuable tool in determining the long-term effects of early exposure to estrogenic agents in mammals. Using this model our specific aim was compare the effects of two hydroxylated polychlorinated biphenyls (HO-PCBs): 2Ô4Ô6Ô-trichloro-4-biphenylol (TRI) and 2Ô3Ô4Ô5-tetrachloro-4-biphenylol (TETRA) alone, and in combination (BI) to the effects of 17b-estradiol (E2). Treatment was administered via 5 subcutaneous injections beginning within 16 hrs after birth, days 1 - 5. The treatment groups were as follows: a) Control = vehicle, sesame oil b) E2 = [5 mg/g]; c) E2/Tri = [2.5 mg/g & 105 mg/g,]; d) Tri-Hi = [210 mg/g], e) Tri-Lo = [21 mg/g]; f) Tetra-Hi = [400 mg/g]; g) Tetra-Lo = [40 mg/g]; h) Bi-Hi = [100 mg/g Tri and 100 mg/g Tetra]; i) Bi-Lo = [10 mg/g Tri and 10 mg/g Tetra]. Vaginal openning results indicate that both HO-PCB congeners are estrogenic in the neonatal mouse model. The average day of vaginal opening in mice treated with these compounds were as followings: a) 25.4, b) 12.2, c)11, d) 12.6, e) 23.6, f) 12.6, g) 19.3, h) 11.1, and i) 25.1. These results also indicate that lower doses of HO-PCB3, HO-PCB4 or a mixture of these congeners exhibit no effect. At 20 month of age percent of mice which developed solid tumors from these neonatal treatments are as follows: a) 0, b) 5, c)5, d) 0, e) 30, f) 20, g) 26, h) 18, and i) 24. Additional results indicate that at the high dose TRI can induce an increase in uterine wet weight similar to E2 (141% and 140% of control, respectively). However, E2 was more effective in inducing persistent vaginal cornification (71% versus 53%). Based on these results in the neonatal mouse model, the PCBs tested are strongly estrogenic when exposure occurs during development. Such results may have very important implications for risk assessment in determining the effects of xenoestrogens exposure early versus later in life.

98 ARNT KNOCKOUT MICE EXPRESS VEGF INTROPHOBLASTIC GIANT CELLS AND PLACENTA.

B D Abbott. *RTD, NHEERL, US EPA, Research Triangle Park, NC, USA.*

The aryl hydrocarbon nuclear translocator protein (ARNT) is a transcriptional regulator that heterodimerizes with other members of the basic helix-loop-helix/ Per-ARNT-Sim family, the Ah receptor, and hypoxia inducible factor 1α (HIF-1α). Under hypoxic conditions HIF-1α and ARNT upregulate vascular endothelial cell growth factor (VEGF). VEGF regulates vasculogenesis and plays a critical role in embryonic development. Transgenic mouse embryos null for ARNT expression die in utero and lethality is attributed to placental abnormality. This study compares VEGF expression of the wild type, heterozygous and homozygous ARNT conceptus. ARNT heterozygotes were mated; pregnant females sacrificed on gestation day 9.5; conceptuses removed from the uterus and a sample of embryonic tissue collected for genotypic analysis by PCR. The conceptuses were fixed in 3% paraformaldehyde, embedded in paraffin, and sectioned for immunohistochemical localization of VEGF. The polyclonal antibodies were prepared with either amino acids 1-20 of the amino terminus of mouse VEGF (P-20, sc-1836; peptide sc-1836P, Santa Cruz Biotechnology, Inc, Santa Cruz, CA) or with recombinant mouse VEGF, expressed in Sf-21 insect cells using a baculovirus expression system (AF-493-NA, peptide 493-M, R&D Systems, Inc, Minneapolis, MN). Antibody specificity was confirmed by competition for binding with excess purified VEGF peptide. VEGF was expressed strongly in trophoblastic giant cells and in decidual cells in contact with maternal blood lacunae at the periphery of the placenta. The localization did not differ across genotypes and was completely eliminated by competition with excess peptide. It has been hyopothesized that hypoxia is a factor in developmental regulation of VEGF, particularly during placentation. If ARNT were obligatory for this process, then a difference would be expected between ARNT null and wild type embryos and this was not the case. (Disclaimer: This abstract does not necessarily reflect EPA policy.)

99 DETERMINATION OF THE DEVELOPMENTAL EXPRESSION AND ACTIVATION OF THE ARYL HYDROCARBON RECEPTOR IN TCDD- RESPONSIVE *LacZ* MICE.

D A Nazarenko, J J Willey, R B Baggs, B R Stripp and T A Gasiewicz. *University of Rochester, Department of Environmental Medicine, Rochester, NY, USA.*

The Aryl-hydrocarbon Receptor (AhR) is a ligand-dependent transcription factor that mediates the toxicity of halogenated aromatic hydrocarbons including 2,3,7,8-tetra-chlorodibenzo-p-dioxin (TCDD). These compounds are potent immunologic, reproductive and developmental toxicants due to their ability to alter gene expression and affect cell differentiation and proliferation. We do not yet know which tissues are most sensitive to these compounds nor do we know what genes are modulated to produce toxicity. The determination of the tissue-specific transcriptional activity of the AhR complex *in vivo* will allow the identification of tissues where the AhR may have some functional role and where exposure to TCDD may be disruptive. A transgenic mouse model has been developed in our lab that can delineate the temporal and spatial context of active AhR in a cell- and region-specific manner. This reporter gene based model has recently provided evidence for the presence of transcriptionally active AhR by *in situ* staining for β-galactosidase activity in the genital tubercle, facial regions, paws and other tissues after 24 hour exposure *in utero* to 30μg/kg TCDD. Specifically, in the genital tubercle, a pattern of staining was observed with intense staining at GD 14, a bifocal pattern on GD 15 and a single line of staining on GD 16. Staining is also observed in the genital tubercle without TCDD treatment and preliminary gel shift data points to the potential for ligands to exist in this tissue. On the paw, a circular pattern of staining was observed in the palm on GD 15. This mouse model will prove useful in the examination of the developmental targets of the dioxin-like compounds and for the identification of potential endogenous roles for the AhR in development. (Supported in part by NIEHS Grant ES04862 and Training Grant ES07026.)

100 ALTERED CELLULAR PROLIFERATION IN THE SEMINAL VESICLES OF RATS GESTATIONALLY EXPOSED TO TCDD.

J T Hamm[1,2] and L S Birnbaum[2]. [1]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC;* [2]*U.S. EPA, NHEERL/ETD, RTP, NC.*

2,3,7,8-Tetrachlorodibenzo-*p*-dioxin (TCDD) has been shown to alter male reproductive development in gestationally exposed laboratory animals. The accessory glands of the male reproductive tract, including the seminal vesicle, are decreased in size as determined by total weight of the tissue. Analysis of seminal vesicles over time suggests that the changes in weight may be transient (Mably *et al.*, 1992a and Gray *et al.*, 1997). However, Gray *et al.* (1995) reported that gestational exposure to 1.0 mg/kg of TCDD caused a significant decrease in seminal vesicle weights of 8-11 month old offspring. Therefore, we examined the proliferation of TCDD exposed rat seminal vesicle in the early postnatal period until the time of puberty. Pregnant Long-Evans rats were exposed to 1.0 mg/kg TCDD on GD 15 in corn oil. Male pups were sacrificed on postnatal days (PND) 14, 25, 32, and 49 and whole body, liver, and paired seminal vesicle, epididymal, and testis weights were recorded. In addition, seminal vesicles were fixed in 10% neutral buffered formalin for histological examination. No significant differences were seen in body weights throughout the study. Seminal vesicle weights were not significantly different between control and exposed animals at PNDs 14 (10.3± 1.5 versus 9.8± 2.2 mg) or 25 (16.9± 1.7 versus 16.1± 1.8 mg), by PND 32 exposed animals had lower seminal vesicle weights (59.6± 11.1 versus 36.7± 9.4 mg). By PND 49 total seminal vesicle weight was determined along with fluid content. While there appeared to be less of a difference in total seminal vesicle weight, seminal vesicle fluid content of exposed males was approximately 2/3 that of control animals. Differences in proliferation were examined histologically with identification of cell types using immunohistochemical markers. Data suggest that prenatal TCDD exposure alters seminal vesicle epithelial development. (This abstract does not necessarily represent USEPA policy. JTH, EPA, CT 902908).

101 TREATMENT OF RATS DURING PUBERTAL DEVELOPMENT WITH 2,3,7,8-TETRACHLORODIBENZO-P-DIOXIN ALTERS BOTH SIGNALING KINASE ACTIVITIES AND EPIDERMAL GROWTH FACTOR RECEPTOR BINDING IN THE TESTIS AND THE MOTILITY AND ACROSOMAL REACTION OF SPERM.

F El-Sabeawy[1], S Wang[2], J Overstreet[1], M Miller[1], B Lasley[1] and E Enan[1]. [1]*Dept. of Environmental Toxicology, and ITEH, University of California, Davis, CA;* [2]*Nanjing Medical University, School of Medicine, Nanjing, China.*

Different doses of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) (0.1, 1, 5 and 10 mg/kg body weight) were administered ip to 21day old male Sprague-Dawley rats. Control animals received the same volume of the vehicle (acetone: corn oil, 1:19). Body weight and daily food intake were recorded during the 90 day time course of the study. Random samples of five rats were sacrificed at 34, 49, 62 and 90 days of age. Epidermal growth factor receptor (EGFR) in whole testis was measured, as were the activities of c-Src kinase, protein tyrosine kinase (PTK), mitogen activated protein 2 kinase (MAP2K also termed as Erk2), protein kinase A (PKA) and protein kinase C (PKC). Testicular tissue from 90 day old rats was evaluated for histopathology, and sperm numbers in whole testis were counted to estimate daily sperm production. The motility of sperm in the vas deferens and caudal segments of the epididymis of 90 day old rats was measured by computer assisted sperm analysis (CASA) and the function of the sperm was tested by assessment of acrosome reactions. A dose of 10 mg/kg resulted in testicular atrophy and histopathologic examination revealed a decrease in the diameter of the seminiferous tubules. Sertoli cell nuclei were clearly seen, but the spermatogonial population was totally absent. Lower doses of TCDD did not affect testicular histology, but doses as low as 1 mg /kg significantly decreased testicular sperm numbers and effected some sperm functions (motility parameters and acrosome reactions) in 90 day old rats. Significant decreases in EGFR were found in 34 day old rats and this effect on EGFR was sustained until the end of the experiment (90 days). Although TCDD significantly increased c-Src kinase activity in immature and mature rats, opposite effects of TCDD on activities of PTK, PKA and PKC were found in 34 day old rats vs 49, 62 and 90 day old rats. These findings provide evidence for involvement of signaling kinases and EGFR in the mechanism by which TCDD disrupts testicular development and subsequently affects testis function.

102 ACUTE AND SUBCHRONIC ADMINISTRATION OF TCDD IN LONG EVANS RATS: COMPARISON OF FETAL TISSUE LEVELS AND ADVERSE DEVELOPMENTAL EFFECTS.

C H Hurst[1], M J DeVito[2], B D Abbott[2], J S Ostby[2], L E Gray, Jr.[2], and L S Birnbaum[2]. [1]*UNC-CH, Curr. in Toxicol., Chapel Hill, NC;* [2]*US EPA, NHEERL, RTP, NC.*

Prenatal exposure to TCDD interferes with fetal development at doses lower than those causing maternal toxicity. Studies have demonstrated that exposure to TCDD during development produced alterations in the reproductive system of developing pups, such as reduced sperm counts in males and malformations in the external genitalia of females. The objective of this study was to determine whether tissue concentration is the appropriate dose metric by relating fetal concentrations of TCDD after acute and subchronic exposure to the development of adverse effects in LE pups. In the acute studies, pregnant LE rats were dosed orally with 1.0 μ g [^{3}H]TCDD/kg on gestation day (GD) 8 or 0.05, 0.20, 0.80 and 1.0 μ g [^{3}H]TCDD/kg on GD15. In the subchronic study, LE rats received 1, 10 or 30 ng [^{3}H]TCDD/kg, 5 days/wk for 13 weeks. After 13 weeks, females were mated and dosing continued. Dams were sacrificed on GD16 and GD21 and analyzed for [^{3}H]TCDD in maternal and fetal tissues. A dose of 1.0 μ g TCDD/kg on GD8 produced fetal concentrations of TCDD on GD16 of approximately 18-22 pg/g. Exposure on GD15 to 0.05, 0.20, 0.80 or 1.0 μ g TCDD/kg produced fetal concentrations ranging from 7-58 pg/g on GD16. Repeated administration of 1, 10, or 30 ng TCDD/kg/d resulted in fetal tissue concentrations of 1.3, 7.2 and 14.8 pg/g, respectively. For the end-points examined (ejaculated sperm counts and puberty delay in males and urethra-phallus distance and vaginal thread incidence in females), GD16 fetal concentrations after acute exposure on either GD8 or GD15 result in comparable adverse responses. Furthermore, subchronic administration of 10 ng/kg/d produced similar fetal concentrations on GD16 as well as a similar incidence of vaginal thread formation as a single dose of 0.20 μ g TCDD/kg on GD15. These dispositional studies after different exposures demonstrate that tissue concentration, during a critical window of sensitivity, is the appropriate dose metric to predict adverse reproductive and development effects. (This abstract does not necessarily represent US EPA policy. CHH supported by EPA, CT 902908.)

103 DOSE-DEPENDENT INTERACTION OF SIMPLE CHEMICAL MIXTURES.

J G Pounds[1], P L Pokorski[1], D G Chen[2], and M Mumtaz[3]. [1]*Institute of Chemical Toxicology, Wayne State University, Detroit, MI;* [2]*Pacific Biological Station, Nanaimo, BC, Canada; and* [3]*Division of Toxicology, ATSDR, P.H.S., Atlanta, GA, USA.*

The risk assessment for chemical mixtures requires several assumptions including that the nature of the aggregate toxicity at low total doses is similar to that at high doses. High to low dose extrapolation is a fundamental issue of toxicology and the experimental assessment of interactive toxicity is typically performed at dose levels which produce significant toxicity. In ongoing studies through a cooperative agreement with the ATSDR, issues related to refinement and development of methods for the toxicity assessment of mixtures are being explored. A series of experiments were performed to investigate the dose-dependent interactive toxicity of simple mixtures of toxic metals. Cultured Rhesus renal cortical cells, LLC-MK2, target cells for Cd and Hg toxicity, were treated with 12 concentrations of $CdCl_2$ (0 to 40 μM), $HgCl_2$ (0 to 80 μM), or binary mixtures of Cd and Hg (1:2 molar ratio) as to bracket ED_{50}s estimated for each toxicant. The cytotoxicity was determined at 24 hr by lactate dehydrogenase release. The data were analyzed four times; first as a complete data set, then using only the lowest, the middle, or the highest six metal concentrations. The data were analyzed statistically and graphically by the linear model of null interaction of Kodell and Pounds. Analysis of the full data set and the highest six concentrations revealed Response Additivity ($p \leq 0.0003$ and 0.02), while the middle dose set was neither Dose nor Response Additive but was within the envelope of additivity ($p \leq 0.27$), while the low dose data set was Dose Additive ($p \leq 0.0004$). These results suggest that (a) an elaborate data set is needed to identify and define interactive toxicity at low doses, and (b) illustrate the complexity of integrating toxicity from exposures to multiple chemicals in the environment. (Supported by ATSDR U61/ATU581481.)

104 DEVELOPMENT OF ISOBOLOGRAMS FOR THE ACUTE LETHAL INTERACTION OF PYRIDOSTIGMINE BROMIDE, PERMETHRIN, AND DEET IN THE LABORATORY RAT.

W C McCain[1], M Michie[1], J Ferguson[1], R Lee[2] and L Metker[1]. [1]*Toxicology Directorate, U.S. Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD;* [2]*Robyn B. Lee and Associates, Fawn Grove, PA.*

In order to better understand the interactive effects caused by concurrent exposure to certain chemicals associated with Gulf War Illness, a study was conducted which examined the lethal effects in the male laboratory rat when given various two-compound combinations of pyridostigmine bromide (PB), permethrin, or DEET orally. The study was conducted in two phases. The first phase determined the lethal response to varying doses of individual compounds and a dose-response curve with 95% confidence intervals was generated to allow prediction of responses for a given dose. The second phase, using the isobologram approach, determined the interactive effect of two-compound combinations. Each compound was given at a minimum of three fixed doses, less than its median lethal dose (LD_{50}), with four varying doses of one of the other two-compounds. The LD_{50} for the second compound in the presence of the first fixed dose compound was determined. All LD_{50}s for the combination of two-compounds were plotted on the isobologram and compared to the hypothesized LD_{50}s. The combination of PB and DEET as well as permethrin and DEET produced 100% lethality at the lowest dosage levels (LD_{10} X LD_{10}, additive LD_{20}) and isoboles could not be developed for these combinations. An isobole was developed for the combination of PB and permethrin. The results of this study indicate that two-compound combinations of PB, permethrin or DEET, given orally to male rats, produce a significant increase in lethality when compared to expected results. Preliminary follow-up experiments suggest that the increased lethality may result from changes in the absorption of these materials from the gut following concurrent oral administration.

105 AN EMPIRICAL APPROACH TO PREDICTING BIOLOGICAL RESPONSES FOLLOWING EXPOSURES TO MIXTURES.

M G Ménache[1], R C Graham[2], M DeVito[3] and L S Birnbaum[3]. [1]*Lovelace Respiratory Research Institute, Albuquerque, NM, USA;* [2]*PPD Pharmaco Inc, Morrisville, NC, USA;* [3]*US EPA, RTP, NC, USA.*

In prior years, we developed an empirical method to calculate relative potencies (REP) for dioxin-like compounds (SOT, 1997) and validated the model by comparison to a mixture experiment (SOT, 1998). The REP is commonly calculated using a ratio of reference to test compound ED50s. That approach assumes that the test compound behaves as a dilution of the reference compound. The empirical method was developed because experimental data do not always result in an estimable ED50. This might be because the response is not saturable or because the maximum dose in the experiment did not result in a saturated response. A characteristic of the empirical method, therefore, is that it makes no assumptions about the biological relationship of test compounds to the reference compound. For this reason, the empirical method can be applied to any mixture of compounds. The empirical model is developed from dose-response experiments for a reference compound and as many test compounds as would be in the mixture. First, a calibration curve is fit for the reference compound. Second, inverse prediction is used to express the test compound data in the dose-metric of the reference compound. Third, a regression is fit using the dose-metric as the dependent variable and the test compound dose as the independent variable. This regression provides information about the biological relationship between the responses generated by the test and reference compounds. For example, if the regression is a straight line through the origin, then the slope will be identically equal to the REP calculated using ratios of ED50s. Because the method is based on statistical curve fitting, the variability estimates may be used in conjunction with Monte Carlo techniques to perform uncertainty analyses. The focus of this presentation will be to describe 1) appropriate experimental design to fit a 'good' calibration curve and 2) the information concerning biological relationships that can be determined from the regression relationships. (This abstract does not reflect US EPA policy.)

106 MULTIPLE CHEMICAL EXPOSURES SHOULD ALWAYS BE CONSIDERED BUT MIGHT NOT BE A CONCERN.

M M Mumtaz, J Risher, H Pohl, A Susten, D Mellard, T Forrester, R Canady, and D Abouelnasr. *Agency for Toxic Substances and Disease Registry (ATSDR), Atlanta, GA, USA.*

National attention has been focused recently on health risks from air pollutants produced in urban areas where concentrated industrial activity coexists with high population density. In this study, ATSDR collected air monitoring data from the interior of houses of one such community and evaluated the potential for health effects from exposure to various chemicals. Detectable levels of 25 volatile organic compounds, 7 semi-volatiles, and three metals were found including benzene, chloroform, methylene chloride, polycyclic aromatic hydrocarbons, and lead. Benzene, methylene chloride and tetrachloroethylene were the most noteworthy chemicals, being found at levels ranging from 1.3 to 33.9 ug/m^3 (mean 4ug/m^3), 2 to 1194 ug/m^3 (mean 161ug/m^3), and 0.5 to 13 ug/m^3 (mean 2.6ug/m^3), respectively. Comparison of the indoor air levels of the chemicals found in these houses with levels reported in other studies, evaluations of exposure to individual chemicals using health-based comparison values developed by ATSDR/EPA, and assessment of multi-chemical exposures for noncarcinogenic effects were conducted. For the multi-chemical assessment, a 3-tier paradigm was designed using the hazard index (HI) approach. If the HI was<1, no threat was perceived. When the HI was >1, in the second tier, target-organ-specific toxicities were determined. If for the target-organ-specific toxicities the HI was >1, in the third tier, issues related to pharmacokinetics, bioavailability and mechanism of action of the chemicals were considered. The results indicate that residents in these houses were being exposed to concentrations of indoor air pollutants comparable to concentrations found in houses elsewhere in the United States. Also, the levels of contaminants detected, either singly or in combination, would not be expected to cause adverse health effects.

107 SUBCHRONIC TOXICITY OF AIDS COMBINATION THERAPIES 3'-AZIDO-3'-DEOXYTHYMIDINE (AZT) AND NITAZOXANIDE (NTZ) IN B6C3F1 MICE.

G N Rao[1], C D Hebert[2], R Fulton[2] and H D Giles[2]. [1]*National Institute of Environmental Health Sciences, Research Triangle Park, NC, USA;* [2]*Southern Research Institute, Birmingham, AL, USA.*

Combination therapy with anti-HIV drugs and opportunistic infection therapies is a common practice in treatment of AIDS patients. Toxic effects of most individual therapies are available, but toxic consequences of most combination therapies are not known. To understand the toxicity of AIDS combination therapies, the commonly used anti-HIV drug AZT and an anti-cryptosporidial drug NTZ, either alone or in combination, were evaluated by 13 week gavage studies in B6C3F1 mice. The doses were AZT 200 and 400; and NTZ 250, 500, and 1000 mg/kg/day. AZT alone did not cause any mortality but caused dose-related hematological toxicity that was manifested as decreases in erythrocyte and hemoglobin values. NTZ alone did not cause mortality or significant changes in hematological parameters. Co-administration of NTZ with AZT caused a dose-related reduction in body weight gain in both sexes and markedly increased the hematological toxicity of AZT. All mice in the highest dose combinations and all female mice in the middle dose combinations died during the course of the study due to treatment-related hematological toxicity. Female mice were more sensitive to hematological toxicity with mortality at lower dose combinations. NTZ alone caused dilatation of the cecum. AZT did not appear to influence the dilatation of cecum caused by NTZ. However, NTZ potentiated the hematological toxicity of AZT even at the doses closer to the therapeutic dose. Results of our studies indicate that the toxic effects of combination therapies could be severe and different than the toxicity of individual therapies.

108 ALTERATIONS IN EXPRESSION OF TGFα, TGFβ, AND *C-MYC* IN HUMAN KERATINOCYTES EXPOSED TO ARSENIC OR A CHEMICAL MIXTURE OF FOUR METALS.

D Bae, J A Campain, and R S H Yang. *Center for Environmental Toxicology and Technology, Department of Environmental Health, Colorado State University, Fort Collins, CO, USA.*

A number of cellular and molecular biomarkers along the carcinogenic pathway in human keratinocytes were studied following exposures to arsenic (As) and an arsenic-containing metal mixture. To this end, two immortalized human keratinocyte cell lines, RHEK-1 and HaCaT, were exposed to arsenic alone and arsenic in a mixture of the environmentally relevant heavy metals, cadmium, lead, and chromium. Alterations in expression of the important keratinocyte growth regulatory factors, TGFα, TGFβ, and *c-myc* in treated versus control cells were analyzed by RT-PCR. In both HaCaT and RHEK-1 cells, exposure to increasing concentrations of As for 4 hr induced expression of both TGFα and TGFβ in a linear manner. Maximum induction of TGFα (12-fold over control) and TGFβ (5-fold) occurred at 0.05 μM As. At higher As concentrations (up to 2 μM), expression levels for both genes dropped substantially to control values. In HaCaT, *c-myc* mRNA was induced at all As concentrations tested (maximum induction 5-fold). In contrast, there was no detectable effect on *c-myc* expression in RHEK-1 cells under any conditions examined. We are currently comparing these results with alterations in RHEK-1 exposed to an arsenic-containing metal mixture. Although the exact significance of our findings is unclear at this time, these or other changes in gene expression may mediate, in part, the observed carcinogenic effect of As. This study was supported by ATSDR (Cooperative Agreement U61/ATU881475), and NIEHS Superfund Basic Research Program (P42 ES05949).)

109 DIFFERENTIAL TOXICITY OF ARSENIC, CADMIUM, CHROMIUM, AND LEAD SINGLY AND IN COMBINATION IN HUMAN KERATINOCYTES.

J A Campain, D Bae, J C Rastatter, and R S H Yang. *Center for Environmental Toxicology and Technology, Department of Environmental Health, Colorado State University, Fort Collins, CO, USA.*

As an initial phase of a project exploring the carcinogenic potential of As, Cd, Cr, and Pb alone or in combination in human keratinocytes, cytotoxicity studies were conducted. Three immortalized keratinocyte cell lines (RHEK-1, HaCaT, and NM-1) and primary human keratinocytes were exposed to increasing concentrations of the individual metals or to a mixture containing equimolar concentrations of all four metals. Cell viability was determined by MTT and clonogenicity assays after 24 hr treatment. The overall range of concentrations studied was from 0.001 μM to 100 μM and

at least 8 concentrations were used for each dose-response cytotoxicity curve. These studies demonstrated that the four types of keratinocyte cells exhibited different sensitivities to the four metals. Estimated LD_{50}s for As, Cd, or Cr in RHEK-1 were 4.5μM, 20μM, 6.4μM, respectively. Those for HaCaT were determined to be 4.6μM, 58μM, 5.6μM, respectively. The lead toxicity in RHEK-1 was low (only 12% cytotoxicity with the highest concentration). We are comparing these metal sensitivities in NM-1 cells and primary keratinocytes. Toxicity of the four metal mixture was studied in RHEK-1 and HaCaT cells; preliminary results suggest additive or antagonistic effects as compared to the individual metals. Cellular mechanisms conferring this differential sensitivity to heavy metals could potentially involve alterations in intracellular glutathione and/or expression of metallothionein. (This study was supported by ATSDR (Cooperative Agreement U61/ATU881475), and NIEHS Superfund Basic Research Program (P42 ES05949).)

110 THE EFFECT OF MIXING RATIO ON THE HEPATOTOXICITY OF MIXTURES OF TRIHALOMETHANE (THM) DISINFECTION BYPRODUCTS.

A McDonald[1], C Gennings[2], W Hartley[3], L K Teuschler[4], A Thiyagarajah[3], Y M Sey[1], S W Krasner[5], and J E Simmons[1]. [1]*NHEERL, U.S. EPA, RTP, NC, USA;* [2]*MCV, VCU, Richmond, VA, USA;* [3]*Tulane U. Med. Center, New Orleans, LA, USA;* [4]*NCEA, U.S. EPA, Cincinnati, OH, USA;* [5]*MWDSC, La Verne, CA, USA.*

Chlorination of water containing organic matter results in the production of a variety of halogenated byproducts, including the THMs, chloroform (CHCl3), bromodichloromethane (BDCM), chlorodibromomethane (CDBM) and bromoform (CHBr3). Water treatment processes that involve ozonation/chloramination decrease the total amount of THMs formed but alter their relative distribution. Thus, the objective of this investigation was to determine the effect of mixing ratio on mixtures of the 4 THMs. Female CD–1 mice (~65–70 days old) were gavaged daily for 14 days with the THM mixtures in 10% Alkamus El–620. Hepatotoxicity was assessed on day 15 by serum sorbitol dehydrogenase (SDH) and by histopathology. Relevant mixing ratios were selected from a study in which a high bromide water was treated either by pre-chlorination/post–chlorination (CL) or by pre–ozonation/post chloramination (OZCM). The proportions of the CL mixture were: CHCl3, 0.319; CHBr3, 0.049; BDCM, 0.342; and, CDBM, 0.290. The proportions of the OZCM mixture were: CHCl3, 0.655; CHBr3, 0.029; BDCM, 0.187; and, CDBM, 0.129. Three experiments were conducted, each testing a different total dosage of these two mixtures: 0.05, 1.50 and 3.0 mmol/kg/day. At each total mixture dosage, the SDH values for the CL and OZCM mixtures did not differ significantly. Similarly, the proportion of mice with centrilobular hepatocellular necrosis did not differ significantly between the two mixing ratios. In conclusion, at the same dosage, mixing ratio, or at least the two mixing ratios tested here, had little/no apparent effect on the hepatotoxicity of THM mixtures. Data such as these may help in selection of optimal water treatment strategies. As the total mixture dose was held constant in each experiment, differences due to the amount of THMs produced by each treatment are not reflected in these experiments, but are worthy of future investigation. (Abstract may not reflect EPA policy.)

111 CO-EXPOSURE TO EPICHLOROHYDRIN ON THE ELIMINATION OF URINARY METABOLITES OF DIMETHYLFORMAMIDE.

M J W Chang and C Y Ko. *Chang Gung University, Tao-Yuan, Taiwan.*

Co-exposure of dimethylformamide (DMF), an organic solvent and epichlorohydrin (ECH), an ingredient of epoxy-resins not only occurs in industries but, to a lesser degree, also in the use of household products. Chronic effects of exposure to DMF include changes in liver function and reproduction. The detoxification of both DMF and ECH involves a metabolite conjugation with glutathione. This study was designed to determine the effect of a co-exposure to ECH on the elimination of urinary metabolites of DMF. Male Wistar rats, 4 per dose group, were gavaged consecutively with a dose of ECH (0, 4.5, 9.0, & 18.0 mg/kg) and a dose of DMF, 72 mg/kg. Urinary DMF and demethylated DMF (NMF) were analyzed by GC/FID. DMF-OH was analyzed by the method of Chang and Lin (1991) and creatinine, by Jaffe reaction. The results showed that at the dose levels studied, no effect of ECH co-exposure on elimination of urinary DMF, DMF-OH, NMF, creatinine, and urine volume was observed. It was concluded that in the presence of ECH, the biological exposure threshold limits of DMF required no change. (Supported by a grant NSC 86-2621-B-182-001Z, ROC.)

112 COMPENSATORY HYPERTROPHY AND CELLULAR FUNCTION AND TOXICITY IN PRIMARY CULTURES OF RAT RENAL CELLS.

D A Putt[1], L H Lash[1] and R K Zalups[2]. [1]*Dept. Pharmacology, Wayne State Univ. Sch. Med., Detroit, MI;* [2]*Div. Basic Med. Sciences, Mercer Univ. Sch. Med., Macon, GA.*

Primary cultures of rat renal proximal tubular (PT) and distal tubular (DT) cells from control and uninephrectomized (NPX) Sprague-Dawley rats were established to study whether the biochemical properties and toxicological responses identified in freshly isolated cells are maintained in culture. Cells were grown in serum-free, hormonally-defined DMEM: Ham's F12 (1:1) media and measurements of cellular protein and DNA contents, markers of cellular differentiation, activities of GSH-dependent enzymes, and transport activities were performed on days 1, 3 and 5 of primary culture. Epithelial cell differentiation was maintained in all cell types as evidenced by cytokeratin staining. PT and DT cell differentiation were maintained, as judged by γ-glutamyltransferase and hexokinase activities. PT cells from NPX rats retained their hypertrophic properties, as evidenced by increased cellular size and protein content. Previously, we demonstrated that freshly isolated PT cells from NPX rats were more susceptible to injury from environmental toxicants such as $HgCl_2$ than cells from control rats, even though they exhibited no difference in the cellular accumulation of $^{203}HgCl_2$. In this study, no significant differences in cellular accumulation of $^{203}HgCl_2$ were observed. However, PT cells from NPX rats were more susceptible than PT cells from control rats to cellular injury induced by either $HgCl_2$, KCN, or t-butyl hydroperoxide. Active transport of GSH was 3-fold higher in acivicin-pretreated PT cells from NPX rats than in those in control rats, suggesting that this could be an important defensive response to the increased susceptibility to toxicants. These results are in agreement with earlier *in vitro* and *in vivo* studies, demonstrating that primary cell culture provides a useful model to study the biochemistry and toxicology of uninephrectomy and compensatory renal growth.

113 NEPHROTOXIC AGENTS AND EXTRACELLULAR MATRIX PROTEINS INHIBIT CELL PROLIFERATION OF RENAL PROXIMAL EPITHELIAL CELLS UNDERGOING GROWTH FACTOR-INDUCED BRANCHING TUBULOGENESIS.

R C Bowes III. *Department of Pharmaceutical Sciences, Campbell University, School of Pharmacy, Buies Creek, NC.*

Previous studies have shown that LLC-PK1 cells seeded into collagen type I matrix and treated with specific growth factor combinations undergo *in vitro* tubulogenesis. The present studies were conducted to determine if nephrotoxic agents or extracellular matrix proteins modulate cell proliferation of RPTEs undergoing branching tubulogenesis. In initial studies, cells were grown to post-confluence, treated with cisplatin or S-1,1',2,2'-tetrafluoroethyl-L-cysteine (TFEC) and seeded into collagen matrix. Both cisplatin and TFEC inhibited cell proliferation of LLC-PK1 cells undergoing branching tubulogenesis in a concentration-dependent fashion. In parallel experiments, cells were seeded into collagen gels, stimulated to undergo branching morphogenesis and then treated with cisplatin or TFEC. Under these conditions, only cisplatin inhibited cell proliferation of LLC-PK1 cells undergoing branching tubulogenesis. The effects of extracellular matrix on LLC-PK1 cell proliferation was then evaluated. Prior to seeding cells in collagen matrix, various concentrations of laminin, fibronectin, collagen type IV and poly-L-lysine were added to the matrix. LLC-PK1 cells were then seeded in the matrix and stimulated to undergo branching tubulogenesis. Laminin enhanced growth factor-induced proliferation of LLC-PK1 cells, while fibronectin, collagen IV and poly-L lysine caused a concentration-dependent inhibition in cell proliferation. In conclusion, growth conditions can profoundly effect the way specific nephrotoxicants modulate the proliferation of LLC-PK1 undergoing branching tubulogenesis *in vitro*. Furthermore, extracellular matrix components differentially regulate the ability of LLC-PK1 cells to undergo cell proliferation during growth factor-induced branching tubulogenesis. (These studies were supported by a grant from NIDDK (F32 DK09253-03).)

114 GLYCINE, STRYCHNINE, MUSCIMOL AND THAPSIGARGIN BLOCK INCREASES IN CYTOSOLIC FREE Ca^{2+} LEVELS IN RENAL CELL INJURY.

J F Harriman, X Liu, J H Moran, and R G Schnellmann. *Department of Pharmacology and Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR.*

We have shown previously that the cytoprotectants glycine, strychnine, muscimol and thapsigargin block $^{45}Ca^{2+}$ influx in the late stage of cell injury in renal proximal tubules (RPT) exposed to the mitochondrial inhibitor antimycin A. The goal of the current study was to determine the effects of glycine, strychnine, muscimol and thapsigargin on cytosolic free Ca^{2+} concentrations in rabbit RPT suspensions during antimycin A exposure. RPT were loaded (30 min) with the fluorescent Ca^{2+} indicator Fura-PE3-2AM (2 μM) in the presence of 0.1% pluronic acid. Thapsigargin (5 μM) was added 5 min prior to antimycin A (10 μ M) while glycine (2mM), strychnine (1 mM), or muscimol (100 μ M) was added simultaneously with antimycin A. Cytosolic free Ca^{2+} concentrations were 266 ± 14 nM in controls and increased to 515 ± 36 nM 30 min after antimycin A addition. Addition of glycine, strychnine, muscimol or thapsigargin prevented the antimycin A-induced increase in cytosolic free Ca^{2+} (273 ± 10 nM, 250 ± 5 nM, 277 ± 3 nM and 289 ± 28 nM, respectively). LDH release, a marker of cell death, was 8% in controls and 21% in antimycin A exposed RPT after 30 min. Glycine, strychnine, muscimol and thapsigargin prevented antimycin A-induced LDH release (8%, 7%, 8% and 11%, respectively). These experiments provide evidence that glycine, strychnine, and muscimol are cytoprotective through their ability to prevent a rise in cytosolic free Ca^{2+} and subsequent cell death. The inhibition of the rise in cytosolic free Ca^{2+} and cytoprotection produced by prior depletion of endoplasmic reticulum Ca^{2+} stores with thapsigargin provides further evidence that endoplasmic reticulum Ca^{2+} release may mediate extracellular Ca^{2+} influx and cell death.

115 CYTOTOXICITY OF 4-AMINOPHENOL IN LLC-PK_1 CELLS.

M Hallman, R Tchao, and J B Tarloff. *Department of Pharmaceutical Sciences, University of the Sciences in Philadelphia, Philadelphia, PA.*

4-Aminophenol (PAP) is nephrotoxic *in vivo*, causing morphological damage to the proximal tubule. However, we were unable to reproduce cytotoxicity *in vitro* using renal tubule suspensions unless hepatic post-mitochondrial supernatant was included in the incubation medium. These results were at variance with previous reports that PAP was directly cytotoxic in suspensions of renal tubular cells. Therefore, the present experiments were designed to determine if PAP produced cytotoxicity in an established cell line. LLC-PK_1 cells were seeded in 24 well plates and incubated in DMEM F12 medium until log phase growth was attained. Cells were incubated with medium containing various concentrations of PAP for 4 hr at 37 °C under 5% CO_2. PAP-containing medium was removed and cells were incubated for an additional 24 h. Viability was determined using MTT, Alamar Blue, and lactate dehydrogenase release. Below 0.1 mM PAP, cell viability was unchanged. At 0.1 mM, viability in PAP-treated cells was 50% of viability in untreated control cells. At 0.2 mM PAP, viability was less than 15%. Thus, PAP induces cytotoxicity in LLC-PK_1 cells. One mechanism by which PAP may induce cytotoxicity involves autoxidation (nonenzymatic oxidation). To determine if autoxidation of PAP contributed to cytotoxicity, we incubated cells with 0.1 mM PAP in the presence or absence of various antioxidants, including glutathione (GSH), ascorbate (Vit C), butylated hydroxytoluene (BHT), α-tocopherol (Vit E), NADPH, and NADH. GSH, Vit C and NADPH significantly attenuated the cytotoxicity of PAP. BHT, Vit E and NADH were ineffective. To determine if intracellular antioxidants exerted cytoprotection, cells were preincubated with GSH, Vit C, or NADPH for 1 h. Cells were washed, incubated with 0.1 mM PAP for 4 h, then incubated in DMEM F12 medium for 24 h as previously described. GSH and Vit C significantly prevented PAP-induced cytotoxicity, whereas NADPH was ineffective. These data suggest that PAP cytotoxicity involves nonenzymatic oxidation in both the medium and intracellular compartments. (Supported by NIH GM51361.)

116 EXAGGERATED PHARMACOLOGY OF THE ORALLY ACTIVE IRON CHELATOR ICL 670 IN THE KIDNEY.

C Lorez, U Schramm, H Thomas, W E Trommer[1], and A Wolf. *Novartis Pharma AG, Experimental Toxicology, Basel, Switzerland; [1]University of Kaiserslautern, Germany.* Sponsor: A De Brugerolle de Fraissinette.

ICL 670 is an orally active iron chelator entering Phase I clinical trials. Its potent and specific ability to mobilize tissue iron and promote its excretion has been demonstrated in several animal models. In subchronic studies in rats and marmosets treatment with ICL 670 at high dosages was associated with changes in the renal tubular epithelium. In the present study the mechanism of this effect, which most likely is caused by iron deprivation, was investigated. LLC-PK1 and RPTEC human proximal tubular epithelial cells were incubated with ICL 670 for 48 h in the presence or absence of equimolar amounts of Fe^{3+} (iron citrate). ICL 670 induced a concentration-dependent increase of lactate dehydrogenase (LDH)-leakage, which was not detected when an equimolar amount of Fe^{3+} was added. Treatment with the stable iron complex CGP 82813 (ICL 670 : Fe^{3+} = 2 : 1) did not increase LDH-leakage significantly. Rat kidney slices were treated with 1 mM ICL 670 for 4.5 h in the presence or absence of 0.1, 0.5 and 1 mM Fe^{3+}. ICL 670 increased LDH-leakage and decreased the ATP-dependent para-aminohippuric acid (PAH)-uptake. In parallel ATP-content and energycharge were also reduced significantly. All effects were prevented in the presence of an equimolar amount of Fe^{3+}. In the present in vitro systems ICL 670 induced renal effects only in the absence of Fe^{3+}. These results support the hypothesis that the compound exerts the changes in the renal tubular epithelium by sequestering the vitally important iron which will be less likely to occur in iron overloaded patients.

117 INVESTIGATION OF VANCOMYCIN (VAN)–INDUCED RENAL REGENERATION: ROLE OF GROWTH FACTORS.

D W King and M A Smith. *Toxicology Program, University of Texas School of Public Health, Houston, TX, USA.*

Vancomycin (VAN) is a nephrotoxic glycopeptide antibiotic used in the treatment of gram-positive infections. Previous studies in our laboratory have suggested that a regenerative response occurs following VAN exposure. Epidermal growth factor (EGF) has been demonstrated to enhance regenerative hyperplasia, and studies on tubular injury and regeneration have shown an elevation in soluble EGF. The purpose of this study was to demonstrate the induction of a VAN-induced regenerative response in vitro and to investigate the role that growth factors might play. To examine the role of growth factor release in nephrogenic repair, conditioned media postulated to contain elevated levels of released growth factors was utilized. $LLCPK1_1$ cells were exposed for 6 hours to medium containing 5mM VAN. The VAN medium was then removed and replaced with fresh medium which was harvested and stored for use as conditioned medium. Serum-deprived quiescent $LLCPK1_1$ cells were then treated with the conditioned medium for 24 hours. Cell number, total protein, and ^{3}H-thymidine incorporation were analyzed to investigate a possible regenerative or hyperplastic response. SDS gel electrophoresis was also performed for the detection of protein expression levels of the 6kd entity of epidermal growth factor (EGF) after conditioned media exposure. A 15% increase in cell number and 10% in total protein were both observed when comparing VAN and control conditioned media. A 19% statistically significant increase in ^{3}H-thymidine uptake was also observed. Exposure to VAN-conditioned media was suggestive of increased expression of the 6kd protein when comparing samples from control conditioned medium to VAN treated conditioned medium. This data demonstrates that the induction of a regenerative/hyperplastic response is occurring and suggests the involvement of EGF in this process. (Supported by NIEHS Training Grant T32–ES–07290[DWK] andGM47549[MAS].)

118 INHIBITION OF CELLULAR RESPIRATION IN NONPERMEABILIZED LLC-PK1 CELLS: A POSSIBLE MECHANISM FOR PENTAMIDINE NEPHROTOXICITY.

R L Baty and M A Smith. *Toxicology Program, University of Texas Graduate School of Biomedical Sciences and University of Texas School of Public Health, Houston, TX, USA.*

Pentamidine is a nephrotoxic antiprotozoal drug used in the treatment of Trypanosomiasis and AIDS-associated Pneumocystis Carinii Pneumonia.

Previously, we have demonstrated a nephrotoxic effect induced by pentamidine in vivo and in vitro in renal cortical slices and cell culture. The mechanism of antiprotozoal action is unknown, but has been proposed to involve changes in oxidative phosphorylation in some organisms. Inhibition of mitochondrial ATP production could be related to pentamidine–induced toxicity. The purpose of this study was to examine the effects of pentamidine on basal cellular respiration, as well as nystatin-induced and uncoupled respiration in LLC-PK1 cells. LLC-PK1 cells were grown to confluence in T75 flasks. Oxygen consumption was measured polarographically in a magnetically stirred chamber at 37° C. A pentamidine dose–response curve was constructed by adding the drug at 0.05, 0.1, 0.2, and 0.5mM to the cell suspension in the oxygen consumption chamber and recording oxygen consumption immediately. Pentamidine significantly reduced basal respiration at a concentration of 0.5mM. Cells were incubated for 5 minutes with pentamidine 0.5mM before oxygen consumption was recorded, to determine if the effect was time dependent. To examine the effect on maximal (nystatin-induced) and uncoupled respiration (2,4 Dinitrophenol-induced), pentamidine was added before and after each of the respiratory stimulants. Nystatin-induced respiration initially increased as expected, but pentamidine inhibited oxygen consumption by almost 33% compared to control. This suggests that pentamidine may inhibit ATP production rather than utilization. Pentamidine inhibited uncoupled respiration within 5 minutes compared to control, which suggests an effect occurs within the respiratory chain or prior to it. (Supported by NIEHS Training Grant T32–ES–07290 [RLB].)

119 MODULATION OF THE PERIPHERAL BENZODIAZEPINE (BZD) RECEPTOR AS A POSSIBLE MECHANISM FOR LINDANE (LIN) TOXICITY IN MADIN DARBY CANINE KIDNEY (MDCK) CELLS.

A L Stock and M A Smith. *Toxicology Program, University of Texas School of Public Health, Houston, TX, USA.*

Previous research in our laboratory has shown that LIN can produce distal tubular toxicity in renal cortical slices, and this toxicity may be attenuated by the addition of BZD/GABA receptor agonists and the peripheral BZD antagonist PK11195. We have also demonstrated LIN induction of apoptosis in MDCK and not in LLC–PK1 cells, which are models for distal and proximal tubular cells. In addition, LIN induce increased apoptosis in cells subjected to volume challenge. The purpose of these experiments is to further investigate the mechanism by which LIN induces toxicity in volume challenged and non–volume challenged MDCK cells. We are also interested in the role the peripheral BZD receptor plays in LIN's mechanism of toxicity. MDCK cells were pretreated with LIN ($1x10^{-5}$ M) in DMSO or DMSO alone (vehicle control) for 1hr. The media was removed and 500 mOsm media was added. The cells were harvested at 4, 8, 12, 24, and 36 hrs. after volume challenge. Western blot analysis for stress protein HSP70 showed no induction of the stress protein in either control, vehicle control, or treated cells at 4 and 8 hrs. Control and vehicle control showed modest induction of the stress protein at 12 hrs and increased induction at both 24 and 36 hrs. Modest induction of HSP70 was seen in LIN treated cells at 24 hrs followed by increased induction at 36 hrs. No effect was seen in LLC–PK1 cells. In order to investigate the involvement of the peripheral BZD receptor MDCK cells were treated with LIN ($1x10^{-5}$ M), Flunitrazepam (FLU, $1x10^{-5}$ M), a BZD receptor agonist, LIN+ FLU, or DMSO alone for 1 hr and then subjected to volume challenge (500 mOsm). DNA ladders showed an apparent amelioration of apoptosis in the LIN + FLU treated cells. These results suggest an involvement of the peripheral BZD receptor in LIN induced apoptosis in MDCK cells.

120 DIFFERENTIAL EXPRESSION OF HSP 70A, B AND C GENES IN HUMAN PROXIMAL TUBULE CELLS IN RESPONSE TO STRESS.

S Somji, J H Todd, S H Garrett and D A Sens. *Department of Pathology, West Virginia University, Morgantown, WV, USA.*

Heat shock protein (hsp) genes are induced by a variety of agents such as heat shock, heavy metals and chemical agents. This study investigates the expression of hsp 70 genes in cultured human proximal tubule cells exposed to elevated temperature, sodium arsenite and cadmium chloride. Reverse transcriptase - polymerase chain reaction was used to determine the expression of inducible hsp 70 genes (hsp 70A, B and C) and the cognate hsc 70 gene. In unstressed cells, there was no expression of hsp70B mRNA, whereas hsp 70A and C were expressed at low levels. Upon exposure to elevated temperature of 42.5° C for 1 hour or sodium arsenite for 4 hours followed by a recovery period, the expression of hsp 70 mRNA and protein increased. There was transient expression of hsp 70B mRNA while 70A and C mRNA remained elevated during most of the recovery period. There was a slight increase in hsc 70 mRNA without any induction of protein. Acute exposure to cadmium for 4 hours followed by a recovery period resulted in increased expression of hsp 70A, B and C mRNA and hsp 70 protein. Chronic exposure to Cd^{+2} over a 16 day time course resulted in an increase in mRNA and protein during the first 24 hours only. Exposure to Cd^{+2} did not increase hsc 70 mRNA or protein levels. This study demonstrates variation in the expression pattern of hsp 70 genes under normal and stress conditions.

121 HEAT SHOCK PROTEIN 27 IS INCREASED IN HUMAN PROXIMAL TUBULES CELLS BY ACUTE, BUT NOT CHRONIC, LETHAL EXPOSURE TO $CdCl_2$.

J H Todd, S Somji, S H Garrett and D A Sens. *Department of Pathology, West Virginia University, Morgantown, WV, USA.*

Cadmium is a potent poison responsible for acute and chronic toxicity in man. This heavy metal causes nephrotoxicity due to a slow accumulation of Cd^{+2} in the proximal tubules of the kidney. Heavy metals can induce a response know as the heat shock response which results in the expression of heat shock proteins (hsp). These proteins are believed to protect cells during periods of stress. In this study, the expression of hsp 27 mRNSA and protein was determined in cultured human proximal tubule cells following exposure to lethal concentrations of Cd^{+2} under both acute and chronic conditions. Acute exposure to Cd^{+2} involved a 4 hour exposure followed by a 48 hour recovery period in Cd^{+2}-free growth media. Chronic exposure to Cd^{+2} was modeled by continuous treatment with Cd^{+2} at lethal and sub-lethal concentrations over a 16 day time course. Acute exposure to 53 μ M $CdCl_2$ resulted in an increase in hsp 27 mRNA and protein and a shift to the more phosphorylated protein isoform. This increase in hsp 27 mRNA and protein occurred in the presence of Cd^{+2}. Chronic exposure to Cd^{+2} failed to increase either hsp 27 mRNA or protein expression in human proximal tubule cells, even at lethal Cd^{+2} concentrations. Overall, these results demonstrate that human proximal tubules have different patterns of hsp 27 expression when exposed to Cd^{+2} under acute versus chronic conditions.

122 THE IN VITRO CYTOTOXICITY OF HYDROQUINONE AND SELECTED HYDROQUINONE METABOLITES TO ISOLATED RAT RENAL PROXIMAL TUBULAR CELLS.

R J Boatman, T S Hill, L M Taylor and J C English. *Eastman Kodak Company, Health and Environment Laboratories, Rochester, NY, USA.*

The cytotoxicity of hydroquinone (HQ) and several metabolites was studied using rat proximal tubular (PT) kidney cells. Incubations were conducted for up to 4 h at 37° C with cytotoxicity measured either as increased leakage of lactate dehydrogenase (LDH) or as a decreased energy status, as determined by adenine nucleotide (ATP and ADP) concentrations. Incubation atmospheres consisted of either 95% O_2/5% CO_2, to promote cell viability *in vitro*, or 5% O_2/5% CO_2/90% N_2, to more closely simulate physiological (*in vivo*) conditions. Incubations were performed with either the addition or exclusion of 2% bovine serum albumin (BSA). In the presence of BSA, PT cells were unaffected by high (1 mM) concentrations of HQ, 2-(glutathion-S-yl)hydroquinone, 2,3,5-(triglutathion-S-yl)hydroquinone, or 2-(N-acetylcystein-S-yl)hydroquinone. 2-(Cystein-S-yl)hydroquinone (Cys-HQ) at 1 mM displayed some minimal toxicity affecting primarily ATP levels late (4 h) in the incubation period. Similar results were obtained regardless of the oxygen atmosphere used. In the absence of BSA, Cys-HQ and HQ had pronounced effects on both cell viability and ATP. Under 95% O_2, PT cells from male F344 rats were significantly more sensitive to HQ than those from male SD rats with decreases in ATP concentrations seen as early as 1 h at a concentration of 0.5 mM. Increased LDH leakage occurred later in the incubation and was less sensitive as an indicator of toxicity. Under 5% O_2, toxicity was observed later (4 h) in the incubation period and was more similar in magnitude for the two strains. These results show that variations in the *in vitro* incubation conditions of atmosphere and media can dramatically influence the toxicity of hydroquinone and its metabolites. Current study results are discussed in relation to the known toxicity of HQ and its glutathione-derived metabolites. (Supported by the Chemical Manufacturers Association Hydroquinone Panel.)

123 NEPHROTOXICITY ASSESSMENT OF SELECTED POLYCLIC AROMATIC HYDROCARBONS.

M H Falahatpisheh and K S Ramos. *Department of Veterinary Physiology and Pharmacology and Center for Environmental and Rural Health, Texas A&M University, College Station, TX, USA.*

Polycyclic aromatic hydrocarbons (PAHs) are widespread contaminants present in multiple forms of environmental pollution. Although hydrocarbon-induced nephropathies have been recognized for some time, the nephrotoxic potential of individual members of this class of chemicals remains undefined. The present study was conducted to define the kidney cell-specific responses to anthracene (ANTH) and chrysene (CHRY) relative to those elicited by benzo(a)pyrene (BaP). Measurements of mitochondrial membrane permeability, protein synthesis, cytoplasmic enzyme leakage, and trypan blue exclusion were conducted in established cultures of rat glomerular mesangial cells (rGMCs) and porcine tubular epithelial kidney cells (LLCPK-1) challenged with hydrocarbons at concentrations ranging from 0.03 - 30 mM for 24 hr. Dose-related injury to mitochondrial membranes and reduced rates of protein synthesis were observed in rGMCs treated with BaP. Modest rates of cell death were measured in rGMC cultures challenged with BaP at the highest concentration. BaP was not overtly toxic to LLCPK-1 cells at any of the concentrations examined, but increased mitochondrial permeability in a concentration-dependent manner. ANTH challenge with concentrations > 3 mM induced mitochondrial membrane injury and reduced rates of protein synthesis in rGMCs, while LLCPK-1 cells remained unaffected. In contrast to BaP, CHRY was devoid of toxicity in rGMCs, but increased mitochondrial injury and inhibited protein synthesis in LLCPK-1 cells challenged with concentrations ≥ 3 mM. On the basis of these data we conclude that ANTH and CHRY exhibit nephrotoxic potentials different from BaP, with rGMCs being preferentially injured by BaP and ANTH and LLCPK-1 cells by CHRY. (Supported in part by ATSDR Grant TU68450502 and NIEHS Center Grant 09106.)

124 EFFECTS OF TAURINE ANALOGS ON QUINONE FORMATION AND CYTOTOXICITY

R Dawson, Jr., S A Messina, and D J Salzano. *Department of Pharmacodynamics, College of Pharmacy, University of Florida, Gainesville, FL, USA.*

Taurine is an abundant amino acid present in mammalian tissues. Recent evidence has supported a role for taurine as an antioxidant and cytoprotective agent. Endogenous catecholamines such as dopamine can spontaneously oxidize or be metabolized to cytotoxic quinones. Studies were conducted to determine how various structural analogs of taurine affect the metal-stimulated oxidation of 3,4-dihydroxyphenylalanine (DOPA) in the presence and absence of DNA. Studies were also conducted in renal epithelial cells (LLC-PK_1) to test the ability of taurine analogs to prevent or cause cellular injury in the presence or absence of DOPA and $FeCl_3$. DOPA (100 μ M), $FeCl_3$ (60 μ M) and H_2O_2 (2.8 mM) were incubated for 15 minutes in the presence or absence of calf thymus DNA with taurine or taurine analogs (homotaurine or hypotaurine) present. Quinone formation was monitored spectrophotometrically at 480 nM. Taurine or taurine analogs (homotaurine, aminomethane sulfonic acid, hypotaurine, or isethionic acid) were incubated with LLC-PK_1 cells for 60 minutes in the presence of DOPA (250 μ M) and $FeCl_3$ (75 μ M) and cell death was monitored 24 hours later using a tetrazolium-based assay. Quinone formation in the presence of DNA was enhanced about 3 fold above the levels seen when DNA was not present. Taurine, homotaurine and hypotaurine significantly ($p<0.05$) inhibited quinone formation in the presence of DNA. Homotaurine alone was not cytotoxic to LLC-PK_1 cells, but in the presence of DOPA/$FeCl_3$ it significantly potentiated cytotoxicity. Aminomethanesulfonic acid alone (10 mM) was extremely cytotoxic to LLC-PK_1 cells. Taurine, hypotaurine, and isethionic acid reduced the cytotoxic response to DOPA/$FeCl_3$ in LLC-PK_1 cells. These studies suggest that taurine and certain taurine analogs can prevent cell death and DNA damage associated with quinones generated from catecholamine oxidation. (Supported by a grant from the American Heart Association-Florida Affiliate.)

125 TRANSPORT OF CHLOROTRIFLUOROETHYLGLUTATHIONE (CTFG) BY PRIMARY CULTURES OF RABBIT PROXIMAL TUBULE CELLS (RPTC) AND SUSPENSIONS OF RABBIT PROXIMAL TUBULES.

C E Groves and M N Morales. *University of Florida, College of Veterinary Medicine, Dept of Physiological Sciences, Gainesville, FL, USA.*

Organic anion transport has been proposed as the excretory pathway for many toxic xenobiotics. We have demonstrated that CTFG inhibits fluorescein secretion and accumulation in primary cultures of RPTC, but its direct transport has yet to be measured. Thus, the goal was to characterize the direct transport of CTFG by proximal tubule cells. The uptake of [^{35}S]-CTFG into tubule suspensions was reduced ~50% by 2 mM CTFG, 5 mM PAH, 1 mM α-ketoglutarate and 25 μM ochratoxin A. In cells pre-incubated for 15 min with 250 μM acivicin to inhibit γ-glutamyl transpeptidase, 5 mM PAH reduced the basal-to-apical flux and basolateral uptake of [^{35}S]-CTFG ~ 65% and 60%, respectively, after 2 hr. The organic cation TEA at a concentration of 10 mM also had no effect on the basolateral uptake of [^{35}S]-CTFG by primary cultures. In contrast, 5 mM PAH had no effect on the apical-to-basal flux and apical uptake of [^{35}S]-CTFG, but was reduced ~ 70% by 2 mM CTFG, which is consistent with carrier-mediated [^{35}S]-CTFG uptake in the apical membrane. Thus, although the reabsorptive flux and accumulation of CTFG appear to involve a pathway other than organic anion transport, basolateral [^{35}S]-CTFG flux and accumulation appears to involve the organic anion pathway. (Supported by NIEHS 08860 and AHA Faculty development award.)

126 EFFECTS OF ANTIVIRAL DRUGS CIDOFOVIR AND FOSCARNET ON THE SODIUM-GLUCOSE COTRANSPORTER IN CULTURED RABBIT KIDNEY PROXIMAL CONVOLUTED (PCT) AND STRAIGHT (PST) TUBULAR CELLS.

P L Del Valle, A Trifillis and A S Kane. *Department of Pathology, University of Maryland School of Medicine, Baltimore, MD, USA.*

Rabbit kidney proximal convoluted (PCT) and proximal straight tubular (PST) cells were independently isolated and cultured on plastic support. The kinetics of the Na^+ / glucose transporter (SGLT) present in these epithelial cells were characterized by determining the uptake of the glucose analog alpha-methylglucoside (AMG). Results indicated the presence of two distinct transporters; a high capacity-low affinity (Vmax ≅ 3 μ M, Km ≅ 6 mM) transporter in PCTs and a low capacity-higher affinity (Vmax ≅ 0.5 μ M, Km ≅ 2 mM) transporter in PSTs. Both transporters discriminated between fructose (a pentose) and glucose and galactose (hexoses). Further, galactose transport was similar in PSTs and in PCTs. Phlorizin inhibited the uptake of AMG in PCTs to a much greater extend than in PSTs. Effects of antiviral drugs cidofovir (30 μ M to 3 mM) and foscarnet (500 μ M to 3 mM) on the SGLT were evaluated after exposures up to 96 hours under the same culture conditions. Results from these experiments indicate that both antiviral drugs reduce AMG uptake in PCTs and PSTs. However, PCT transporters appear more sensitive to exposure than PSTs transporters. This is the first report of a kinetic characterization of the sodium-glucose cotransporter in cultured PST cells compared to PCT cells. Results suggest that intrinsic cellular attributes between proximal tubular cell types, independent of blood flow or passive concentrating mechanisms, are important in determining vulnerability to drug effects.

127 ENDOTOXIN POTENTIATES MERCURY-INDUCED NEPHROTOXICITY.

W K Rumbeiha[1], S D Fitzgerald[1], R A Roth[2], W E Braselton[2] , and J J Pestka[3]. [1]*Department of Pathology and the AHDL,* [2]*Department of Pharmacology and Toxicology, and* [3]*Department of Food Safety and Human Nutrition, Michigan State University, East Lansing, MI, USA.*

Both endotoxin (LPS) and mercury are nephrotoxic compounds of food safety concern. The effects of either toxicant alone on the kidney have been well investigated but their toxic interaction has not. Endotoxin is a product of gram negative bacterial cell walls. Humans are constantly exposed to LPS through contaminated food and air. Mercury is a food contaminant and the highest risk of human exposure is by consumption of contaminated fish. Endotoxin has recently been shown to potentiate the toxicity of a number of xenobiotics *in vivo*. In this study we tested the hypothesis that endotoxin enhances mercuric chloride-induced nephrotoxicity. Forty 6 weeks old C3H/HeN male mice were randomly allocated to 4 groups of 10 mice each

as follows: Group I received 0.9% normal saline IV (Control), Group II received 2.0 mg of E.Coli 0128:B12 LPS/kg once IV, Group III received 1.75 mg mercury/kg once IV, and Group IV received E.Coli 0128:B12 LPS/kg once IV 4 hours prior to receiving 1.75 mg mercury/kg once IV. Mice were monitored for 48 hours. Twelve hours prior to termination, they were placed in metabolic cages individually for urine collection. Monitored end-points included body and renal weights, renal histology and ultrastructural pathology, blood urea nitrogen and creatinine, serum and urine IL-1β, IL-6, and TNF-α, and renal mercury concentrations. Results showed that serum creatinine, urea, IL-1β, IL-6, proteinuria, and urine IL-6 in Group IV mice were all significantly greater than the rest of the groups ($p \leq 0.05$). Histologically, kidneys from mice given endotoxin alone were normal but the most severe lesions were found in mice given both endotoxin and mercury. Endotoxin significantly increased renal mercury concentration ($p \leq 0.05$). In conclusion, LPS potentiates mercury induced nephrotoxicity in mice.

128 EFFECT OF INDUCIBLE NITRIC OXIDE SYNTHASE INHIBITOR L-IMINOETHYL-LYSINE ON RENAL TOXICITY AFTER LIPOPOLYSACCHARIDE.

C Zhang and P R Mayeux. *University of Arkansas for Medical Sciences, Little Rock, AR, USA.*

The effects of lipopolysaccharide (LPS) on the kidney during sepsis are poorly understood. The role of nitric oxide (NO) generated from inducible nitric oxide synthase (iNOS) in LPS-induced renal injury was evaluated using the iNOS inhibitor L-iminoethyl-lysine (L-NIL). Male rats (250 g) were divided into three groups. One group received LPS (S. minnesota) 2 mg/kg iv. A second group received LPS plus an ip injection of L-NIL (3 mg/kg) at the time of LPS administration followed by a second dose 3 hr later. A third group received saline iv. At 6 hr blood, liver and kidneys were collected. iNOS was induced in both liver and kidney. Serum nitrate/nitrite levels (n=4) were increased from 4 ± 2 nmole/ml in the saline group to 431 ± 23 nmol/ml in the LPS group. Values for the LPS + L-NIL group was significantly reduced to 42 ± 9 nmol/ml. Tissue maldondialdehyde levels, a marker of oxidant stress, were increased in the kidney from 0.16±0.01 nmol/mg (n=4) in the saline group to 0.30±0.03 (n=7) in the LPS group. L-NIL significantly reduced values to 0.22±0.02 nmol/mg (n=7). Similar results were observed in the liver. LPS increased blood urea nitrogen levels from 13±2 mg/dl to 43±5 mg/dl (n=8). L-NIL reduced these levels to 36±4 mg/dl (n=8) but this reduction was not significant. Hematocrit was unchanged in all groups. These data indicate that LPS-induced NO generation can result in oxidant stress in the kidney and inhibiting iNOS may have therapeutic benefit.

129 TOXICITY OF A SEVOFLURANE DEGRADATION PRODUCT TO RAT LIVER AND RENAL CORTICAL SLICES.

J M Catania[1], A R Parrish[2], and A J Gandolfi[2]. [1]*Department of Pharmacology and Toxicology, and* [2]*Department of Anesthesiology, University of Arizona, Tucson, AZ.*

Compound A (2-fluoromethoxy-1,1,3,3,3-pentafluoro-1-propene) produced by reaction of the inhalation anesthetic, sevoflurane, with CO_2 absorbents. Past *in vivo* and *in vitro* studies have demonstrated that Compound A is nephrotoxic, possibly via bioactivation through the β-lyase pathway. Although glutathione (GSH) conjugates of Compound A have been reported, it is not clear if they are formed enzymatically or via direct reaction with GSH. To determine if these metabolites are produced and toxic, a tissue slice system that first exposes male Fischer 344 rat liver slices to volatilized Compound A, followed by exposure of rat kidney slices to the liver incubate was employed. Liver slices exposed to volatilized Compound A (6-12 uM medium conc ; ~50 ppm air space) exhibited a loss of K+ by 6 hr, which was not seen in kidney slices exposed to Compound A. Aminobenzotriazole, a P-450 suicide inhibitor, initially inhibits the cytotoxicity of Compound A to liver slices at these times and concentrations. As yet, the sequential liver/kidney slice experiments using Compound A have not demonstrated nephrotoxic results. However, both of the saturated synthetic Compound A-GSH conjugates have proven to be nephrotoxic at concentrations above 91 uM (24 hr), with higher concentrations showing toxicity at earlier times. Non-enzymatic reactions of Compound A with GSH or sulfhydryl-containing medium produce nephrotoxic products. These studies show that Compound A is directly toxic to the liver, possibly via P-450 activation, and Compound A can react with sulfhydryls directly to produce a nephrotoxic product. (Supported by Baxter Pharmaceutical Products Inc.)

130 2-AMINO-5-CHLOROPHENOL (2A5CP) TOXICITY IN RAT RENAL CORTICAL SLICES: EFFECT OF ANTIOXIDANTS.

M A Valentovic, J G Ball and G O Rankin. *Dept. of Pharmacology, Marshall Univ. Sch. of Med., Huntington, WV, USA.*

2A5CP is nephrotoxic to the proximal tubules. This study assessed whether the presence of a sulfhydryl group or an antioxidant could reduce 2A5CP toxicity in renal cortical slices. Renal cortical slices were prepared from male Fischer 344 rats (200-245 g). Renal slices were rinsed 3 times for 3 min each in 5-ml renal Krebs buffer. The slices (50-100 mg tissue) were preincubated for 10-30 min with 0.25 or 1 mM dithiothreitol (DTT), 50-100 μ M N, N'-diphenyl-1, 4-phenylenediamine (DPPD) or 1 mM glutathione (GSH) at 37°C under oxygen in 3 ml. An aliquot of 2A5CP was added at a final concentration of 0.25, 0.5 or 1 mM. Loss of membrane integrity was monitored by measurement of lactate dehydrogenase (LDH) leakage. 2A5CP at a concentration of 0.5 and 1 mM induced LDH leakage and lipid peroxidation above control values. Addition of the antioxidant DPPD did not reduce 2A5CP mediated LDH leakage or lipid peroxide formation. A 30-min pretreatment with 1 mM DTT reduced 2A5CP toxicity. DTT pretreatment also reduced lipid peroxidation induced by 2A5CP when compared to tissue not pretreated with DTT. A 30-min pretreatment with 1 mM GSH also reduced the extent of LDH leakage induced by 2A5CP. Lipid peroxidation induced by 2A5CP was also reduced by GSH pretreatment. These results indicate that a sulfhydryl containing antioxidant was more effective in reducing 2A5CP toxicity. The protection associated with GSH and DTT may be related to reduction of lipid peroxidation. (Supported by NIH Grant ES08834.)

131 S-(1,2,2-TRICHLOROVINYL)-L-CYSTEINE SULFOXIDE (TCVCS), A POTENTIAL METABOLITE OF TETRA-CHLOROETHYLENE (TCE), IS A POTENT NEPHROTOXIN.

A A Elfarra, J I Laboy, and A J Cooley. *School of Veterinary Medicine, Univ. of Wisconsin, Madison, WI, USA.*

Previously we have shown that rabbit liver microsomes and cDNA-expressed rabbit FMO3 catalyzed the sulfoxidation of *S*-(1,2,2-trichlorovinyl)-L-cysteine (TCVC), a known metabolite of TCE, to yield the reactive metabolite TCVCS. In the present study, incubations of male rat liver or kidney microsomes with TCVC (10 mM) and NADPH (2 mM) led to TCVCS detection, with liver microsomes exhibiting much higher activity than kidney microsomes. TCVCS formation in liver microsomes was not inhibited by the addition of superoxide dismutase, KCN, or deferoxamine, but was inhibited by the inclusion of methimazole or 1-benzylimidazole, suggesting the involvement of both FMOs and cytochrome P450s. Rats given TCVC or TCVCS (230 μmol/kg, ip) exhibited acute nephrotoxicity, as indicated by histopathological examinations at 2 and 24 h after treatment and kidney function tests at 24 h. However, TCVCS was a much more potent nephrotoxin than TCVC. No significant liver lesions were observed with either TCVC or TCVCS. The TCVCS treatment decreased the reduced non-protein thiol (NPT) concentrations in the kidneys at 2 h after treatment by nearly 50% compared to saline treated rats without affecting the liver NPT status. An equimolar dose of TCVC did not affect the NPT status of either kidney or liver. Pretreatment of rats with the β -lyase inhibitor, aminooxyacetic acid, enhanced TCVC toxicity. Collectively, the results suggest that both TCVC and TCVCS play roles in TCE-induced nephrotoxicity. (Supported by NIH grant DK 44295.)

132 PHENOBARBITAL POTENTIATES N-(3,5-DICHLORO-PHENYL)-2-HYDROXYSUCCINIMIDE (NDHS) AND N-(3,5-DICHLOROPHENYL)-2-HYDROXYSUCCINAMIC ACID (2-NDHSA) NEPHROTOXICITY IN MALE BUT NOT FEMALE FISCHER 344 RATS.

G O Rankin, S K Hong, D K Anestis, J G Ball and M A Valentovic. *Department of Pharmacology, Marshall University School of Medicine, Huntington, WV, USA.*

The agricultural fungicide, N-(3,5-dichlorophenyl)succinimide (NDPS) induces nephrotoxicity as its primary toxicity. Two metabolites of NDPS [N-(3,5-dichlorophenyl)-2-hydroxysuccinimide (NDHS) and N-(3,5-dichlorophenyl)-2-hydroxysuccinamic acid (2-NDHSA)] are four times more potent than NDPS as nephrotoxicants in both male and female Fischer 344 rats. Recent work has shown that pretreatment with phenobarbital , an inducer of CYP2B1, CYP2B2, and UDP-glucuronosyltransferase, potentiates NDHS nephrotoxicity in male Fischer 344 rats via a non-oxidative bio-

transformation pathway. The purpose of this study was to determine if phenobarbital pretreatment also potentiated 2-NDHSA nephrotoxicity in male rats and NDHS and/or 2-NDHSA nephrotoxicity in female rats. Fischer 344 rats (4/group) were pretreated intraperitoneally (ip) with phenobarbital (75 mg/kg/d, 3 d). At 24 hr following the last phenobarbital injection, male rats were administered 2-NDHSA (0.05 mmol/kg, ip) or vehicle, while female rats were treated with NDHS (0.025 mmol/kg, ip), 2-NDHSA (0.025 mmol/kg, ip) or vehicle. Renal function was then monitored for 48 hr. Phenobarbital markedly potentiated 2-NDHSA nephrotoxicity in male rats but did not potentiate NDHS or 2-NDHSA nephrotoxicity in female rats. These results suggest that different metabolites may mediate NDPS metabolite nephrotoxicity in male and female rats. (Supported by NIH grant DK31210.)

133 SODIUM SULFATE POTENTIATES N-(3,5-DICHLORO-PHENYL)-2-HYDROXYSUCCINIMIDE (NDHS) AND N-(3,5-DICHLOROPHENYL)-2-HYDROXYSUCCINAMIC ACID (2-NDHSA) NEPHROTOXICITY IN FISCHER 344 RATS.

S K Hong, D K Anestis, J G Ball, M A Valentovic and G O Rankin. *Department of Pharmacology, Marshall University School of Medicine, Huntington, WV, USA.*

N-(3,5-Dichlorophenyl)succinimide (NDPS) is an agricultural fungicide which induces nephrotoxicity as its major toxicity. Previous studies have shown that NDPS induces nephrotoxicity following oxidation of the succinimide ring to form N-(3,5-dichlorophenyl)-2-hydroxysuccinimide (NDHS) and the hydrolysis product of NDHS, N-(3,5-dichlorophenyl)-2-hydroxysuccinamic acid (2-NDHSA). Both NDHS and 2-NDHSA induce nephrotoxicity in male rats at intraperitoneal (ip) doses of 0.1 mmol/kg or greater. Recent work found that sodium sulfate (10 mg/kg, ip) pretreatement potentiated NDPS nephrotoxicity. The purpose of this study was to determine if sodium sulfate also potentiated the nephrotoxicity of the two nephrotoxicant metabolites of NDPS. Male Fischer 344 rats (4-16 rats/group) received an ip injection of sodium sulfate (10 mg/kg) 20 min before a non-nephrotoxicant dose (0.05 mmol/kg, ip) of NDHS, 2-NDHSA or metabolite vehicle (12.5% dimethylsulfoxide in sesame oil). Renal function was then monitored over 48 hr. Sodium sulfate pretreatment potentiated the non-nephrotoxicant dose of NDHS and 2-NDHSA to a nephrotoxicant dose. Nephrotoxicity was characterized by diuresis, increased proteinuria, elevated blood urea nitrogen (BUN) concentration, increased kidney weight and proximal tubular necrosis. These results support the likelihood that sulfate conjugates of NDPS metabolites contribute to NDPS nephrotoxicity. (Supported by NIH grant DK31210.)

134 EVIDENCE FOR THE FORMATION OF PHASE II METABOLITES OF *N*-(3,5-DICHLOROPHENYL) SUCCINIMIDE (NDPS) IN RATS.

D Cui[1,2] and P J Harvison[1]. [1]*Dept. of Pharmaceutical Sciences, Univ. of the Sciences in Phila., Philadelphia, PA;* [2]*Merck and Co., Inc. West Point, PA.*

The agricultural fungicide NDPS is nephrotoxic in rats. Previous studies have shown that NDPS undergoes extrarenal biotransformation prior to induction of kidney damage. Although Phase II metabolites of NDPS have been implicated in nephrotoxicity, no direct evidence for their formation has been found yet. The studies described here were therefore conducted to determine if NDPS undergoes Phase II metabolism. Male Fischer 344 rats received NDPS or its nephrotoxic Phase I metabolite, *N*-(3,5-dichlorophenyl)-2-hydroxysuccinimide (NDHS). Urine, plasma, and tissue samples (liver and kidneys) were collected. NDPS and NDHS were also incubated with rat liver S9 fractions, microsomes and cytosol. Samples were analyzed using HPLC coupled with an electrospray tandem mass spectrometer (LC-ESI-MS/MS). Metabolites were identified in negative ionization mode using a combination of Q1, neutral loss, and collision induced dissociation of the pseudomolecular ion $(M-H)^-$ scans. In addition to the known metabolites of NDPS, isomers of several mercapturic acid derivatives (m/z 421) were found in urine. Glucuronide (m/z 452) and sulfate conjugates (m/z 356) of *N*-(3,5-dichlorophenyl)-2- and -3-hydroxysuccinamic acids (2-NDHSA and 3-NDHSA, respectively), were detected in all the *in vivo* samples from rats dosed with NDPS or NDHS. The same conjugates were formed *in vitro* from NDHS, but not from NDPS. In conclusion, we have demonstrated for the first time the formation of Phase II metabolites of NDPS in rats. However, prior Phase I metabolism is required. The role of the Phase II metabolites in NDPS nephrotoxicity requires further investigation.

135 8-,CHLORO-CYCLIC AMP, BUT NOT 2-,FLUORO-8-, CHLORO-CYCLIC AMP IS NEPHROTOXIC IN MICE.

A P Brown[1], R L Morrissey[2], S J Donohue[3], B R Vishnuvajjala[3], J E Tomaszewski[3], and B S Levine[1]. [1]*University of Illinois at Chicago, Chicago, IL, USA;* [2]*Pathology Assoc. Intl., Chicago, IL, USA;* [3]*National Cancer Inst., Bethesda, MD, USA.*

8-,Chloro-cyclic adenosine monophosphate (8Cl-cAMP) has been shown to inhibit tumor growth, possibly due to modulation of cAMP-dependent protein kinases. However, 8Cl-cAMP is nephrotoxic to animals and man. A fluorinated analog, 2,-fluoro-8,-chloro-cyclic AMP (2Fl-8Cl-cAMP), was synthesized by the National Cancer Institute in an attempt to modulate the toxicity of the parent compound by blocking metabolism at the 2-position. The toxicities of 2Fl-8Cl-cAMP and 8Cl-cAMP were compared in male CD_2F_1 mice following constant subcutaneous infusion using an osmotic pump at a dose rate of 10 mg/kg/hr for up to 7 days. Infusion of 8Cl-cAMP produced lethality by day 5, most likely due to nephrotoxicity (renal tubule necrosis and mineralization). Both serum creatinine and blood urea nitrogen levels were significantly increased 2- and 4-fold, respectively, in the 8Cl-cAMP group. Neither lethality nor nephrotoxicity were produced by 2Fl-8Cl-cAMP. Both 2Fl-8Cl-cAMP and 8Cl-cAMP produced lymphoid depletion in thymus and spleen, with incidence and severity greater in the latter group. Salivary gland and stomach lesions were produced by both compounds, and 8Cl-cAMP produced single cell necrosis in the intestines, and periportal degeneration in liver in a few animals. In conclusion, fluorine substitution at the 2-position of 8Cl-cAMP inhibits a metabolic pathway that results in nephrotoxicity and results in a molecule that is significantly less toxic than the parent. (Supported by NCI Contract No. N01-CM-37838.)

136 SPECIES DIFFERENCES IN *ORTHO*-DIPHENOL MEDIATED NEPHROTOXICITY.

H H Lo[1], T J Monks[1], C Whitman[1], T W Jones[2], and S S Lau[1]. [1]*College of Pharmacy, Univ. of Texas at Austin, TX and* [2]*Lilly Corporate Center, Indianapolis, IN, USA.*

Para-diphenols such as bromohydroquinone and hydroquinone produce selective nephrotoxicity in rats via a mechanism that involves oxidation, conjugation with glutathione, and delivery of the conjugates to renal proximal tubules. Necrosis is evident in the S3 segment of the outer strip of the outer medulla (OSOM). In contrast, *ortho*-diphenols are nephrotoxic in mice, but not rats. We have evaluated the nephrotoxicity of catechol (CA) and its mono-methyl (Me)-, chloro (Cl)-, and bromo (Br)- substituted derivatives in male ICR mice and Sprague-Dawley rats. Only halogenated CAs induced substantial nephrotoxicity in mice, at doses between 0.56 to 1.0 mmol/kg, i.v. Blood urea nitrogen (BUN) levels were elevated in mice following treatment with 3-ClCA, (1.0 mmol/kg), 4-ClCA or 4-BrCA (0.56 and 0.75 mmol/kg). No significant increases in BUN were seen after treatment of mice with CA, 3- or 4-MeCA in mice at a dose as high as 1.0 mmol/kg. Morphological evaluation of renal tissue from 3-ClCA, 4-ClCA and 4-BrCA treated mice revealed renal tubular necrosis in the cortex, beginning at the lower doses, in the S1 and S2 segments, and extending to the OSOM region at higher doses. The severity of necrosis correlated with increases in BUN. At a dose of 0.75 mmol/kg, none of the *ortho*-diphenols were capable of elevating BUN levels in male Sprague-Dawley rats. In conclusion, rats are sensitive to *para*-diphenol- but not to *ortho*-diphenol-induced nephrotoxicity. In contrast, mice are sensitive to *ortho*-diphenol- induced nephrotoxicity but not to *para*-diphenol. Moreover, the addition of an electronegative substituent (halogen) to *ortho*-diphenols increases nephrotoxic potency, probably by making the corresponding *ortho*-quinone a stronger oxidant. (GM 39338)

137 FUNCTIONAL, MORPHOLOGICAL AND MOLECULAR ALTERATIONS INDUCED BY BENZO[A]PYRENE IN THE ADULT RAT KIDNEY.

N F Alejandro and K S Ramos. *Department of Veterinary Physiology and Pharmacology & Center for Environmental and Rural Health, Texas A&M University, College Station, TX, USA.*

Epidemiological and occupational studies have suggested a link between aromatic hydrocarbon exposures and glomerulo-nephropathies. With this in mind, previous studies in this laboratory have shown that glomerular mesangial cells are preferential targets of benzo[a]pyrene (BaP) relative to the cortico-tubular epithelial cell population. Based on these data we hypothesized

that BaP induces glomerular injury in vivo and compromises renal function leading to the onset of kidney disease. To test this hypothesis, Sprague Dawley rats (175-225 g) were injected with BaP (10 mg/kg, i.p.) once a week for up to 16 weeks and renal function was monitored by measurements of 24 hr urinary albumin levels. Computer-assisted morphometric analysis was conducted to evaluate glomerular cellularity, urinary space, area of Bowman's capsule and glomerular tuft density. Expression of α-smooth muscle (SM) actin was used as an index of mesangial cell injury. Urinary albumin levels were elevated at 16 weeks of BaP treatment relative to 11 week counterparts. Glomerular cellularity increased in BaP-treated rats relative to vehicle controls. No changes in the urinary space, Bowman's capsule and glomerular tuft densities were observed in treated kidneys. Immunohistochemical analysis detected α-SM actin in the glomerulus of BaP-treated rats. These data suggest that the glomerulus is a target of BaP within the kidney and reinforces the need to conduct further research in this area. (Supported by NIEHS 04847, ES 09106 and CVM Enhancement Funds.)

138 SENSITIVITY OF MICE TO PHENACETIN TOXICITY IS STRAIN-SPECIFIC.

M M Halleck[1], F M Poulet[1], L E Beebe[2], L Reyderman[1], P Statkevich[1], L Y Rosenblum[1], M E Cartwright[1], and J S MacDonald[1]. [1]*Schering-Plough Research Institute Lafayette, NJ, USA;* [2]*Covance Laboratories, Vienna, VA, USA.*

As part of the ILSI effort to evaluate alternatives to the two year rodent carcinogenicity assay, we are testing phenacetin, a group 2A carcinogen, in the p53 hemizygous knockout model and Tg.AC transgenic model. Four-week dose range finding studies were conducted in C57BL/6 and FVB/N mice, the respective background strains of the alternative models. Phenacetin was admixed in the diet at concentrations of 0.3, 0.7, 1.4 and 2.0%. Although phenacetin-associated mortality was not observed in C57BL/6 mice at any dose tested, all FVB/N mice dosed with 1.4% or 2.0% phenacetin were either sacrificed or found dead within the first eight days of dosing. Subsequently, a 0.14% dose group was added to the FVB/N dose range finding study. This differential strain sensitivity can be explained, in part, by the higher systemic phenacetin exposure in FVB/N mice compared to that in C57BL/6 mice at similar doses. However, histopathologic findings indicate that differential susceptibility of C57BL/6 and FVB/N mice cannot be explained solely by differences in systemic exposure. Differences in target organ susceptibilities were found in the kidney and liver. For example, even at the highest concentration of phenacetin (2.0%), histopathologic findings in the kidneys of C57BL/6 mice were limited to minimal to mild pigment accumulation in the tubular epithelium. In contrast, renal papillary necrosis was noted in FVB/N mice following dietary administration of 0.7%, a dose that resulted in AUC values that were approximately 33-75% lower than AUC values determined in C57BL/6 mice administered 2.0% phenacetin. Biotransformation of phenacetin is complex. Metabolic pathways include de-ethylation, *N*-deacetylation and ring hydroxylation. Although the contribution of metabolites in each of these pathways to phenacetin toxicity remains to be fully explored, it is likely that strain-specific differences in phenacetin metabolism could account for strain-specific sensitivity to phenacetin toxicity.

139 PROTEIN DROPLET NEPHROPATHY AND DOSIMETRY OF *t*-BUTYL ALCOHOL IN MALE AND FEMALE F-344 RATS.

S J Borghoff, J S Prescott-Mathews, T P Poet, B Wong, and T M Williams. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA.*

t-Butyl alcohol (TBA) is used as a chemical intermediate with a wide range of applications including solvents for pharmaceutical products, paint removers, and personal care products. A major use of TBA is in the synthesis of methyl *t*-butyl ether (MTBE). In both rodents and humans, TBA is a major metabolite of MTBE. Chronic TBA exposure caused an increase in renal tumors in male, but not female, F-344 rats. The objective of the present study was to determine if TBA induces α2u-globulin (α2u) nephropathy and renal cell proliferation in male, but not female, rats. The dosimetry of TBA in male and female rats and the interaction of TBA with the male rat-specific protein α2u were also investigated. Male and female F-344 rats were exposed to TBA vapors at 0, 250, 450, or 1750 ppm for 6 hr/day for 10 consecutive days. Significant proximal tubule degeneration (450 and 1750 ppm), protein droplet accumulation (450 and 1750 ppm), α2u immunoreactivity (1750 ppm), and an increase in renal cell proliferation (250, 450, and 1750 ppm) were observed in TBA-exposed male, but not female, rats. The renal concentration of α2u increased in male rats exposed only to 1750 ppm TBA. TBA kidney-to-blood ratio was greater in male rats compared with female rats at all time points following TBA exposure. When α2u was purified from male rats treated with 500 mg/kg TBA, TBA coeluted with the protein fraction containing α2u. TBA causes a mild α2u-mediated nephropathy in male rats and it appears to interact with α2u which causes the protein as well as the chemical to accumulate in the male rat kidney. These results suggest that male rat-specific nephropathy from TBA exposure is mediated through its interaction with α2u. (Sponsored in part by the Oxygenated Fuels Association.)

140 RE-EVALUATION OF THE CHLOROFORM 2-YEAR DRINKING WATER BIOASSY IN OSBORNE-MENDEL RATS INDICATES THAT SUSTAINED RENAL TUBULE INJURY IS ASSOCIATED WITH RENAL TUMOR DEVELOPMENT.

G C Hard[1] and D C Wolf[2]. [1]*American Health Foundation, Valhalla, NY, USA;* [2]*U.S. EPA, Research Triangle Park, NC, USA.*

Chloroform is a non-genotoxic compound and a rodent carcinogen. Chloroform produced renal tubule tumors in Osborne-Mendel rats when administered by corn oil gavage or in the drinking water. There is a lack of data on intermediate endpoints that are linked to renal cancer development in this strain of rat. Specifically, the evidence linking chloroform induced renal and hepatic tumors in mice with cytotoxicity and regenerative cell proliferation is very strong, but weak for chloroform-induced rat renal tumors. In the present study, kidneys from the 2-year drinking water cancer bioassy in Osborne-Mendel rats were re-evaluated for microscopic evidence of chloroform-induced cytotoxicity and regeneration. HE stained sections of kidney from rats exposed to at water concentrations of 0, 200, 400, 900, and 1800 ppm for 6, 12, 18 or 24 months were examined. The toxicity associated alterations were characterized by slightly increased cytoplasmic basophilia, cytoplasmic vacuolation, karyomegaly, anisokaryosis, nuclear crowding, and mild tubule hyperplasia. Characteristic changes associated with toxicity were present inproximal tubule epithelial cells from rats treated with 1800 ppm chloroform at all time points and from rats treated with 900 ppm for 18 or 24 months. None of the other treatment groups or controls had these characteristic changes. These data are consistent with other studies indicating that chloroform-induced cancer is secondary to sustained cytotoxicity and regenerative hyperplasia. (This abstract does not reflect EPA policy.)

141 SEQUENTIAL ANALYSIS OF THE HEPATO-RENAL TOXICITY AND CADMIUM ACCUMULATION IN RATS GIVEN MINIMUM TO LARGE AMOUNTS OF CADMIUM CHLORIDE FOR 2 YEARS.

M Shibutani[1], K Mitsumori[1], S Sato[2], H Onodera[1], J Nakagawa[3], Y Hayashi[4], M Hirose[1], and M Ando[1]. [1]*National Institute of Health Sciences, Tokyo;* [2]*Ina Research Inc., Nagano;* [3]*Tokyo Metropolitan Research Laboratory of Public Health, Tokyo;* [4]*KitasatoUniversity, Tokyo, Japan.*
Sponsor: T Shirai.

To clarify the threshold dose of cadmium (Cd) to induce hepato-renal toxicity, groups of female SD rats were fed diet containing cadmium chloride ($CdCl_2$) at 0, 8, 40, 200 or 600 ppm for 2, 4 or 8 months. All surviving rats given 600 ppm Cd were killed at 4 month because of deterioration of their general condition. Hepatotoxicity was observed after 2 months in the groups treated with 200 ppm or more. By 4 months, the rats in the 600 ppm group had developed periportal liver cell necrosis. Renal toxicity characterized by degeneration of proximal tubular epithelia was apparent in the rats given 200 ppm or more from the 2 month. Liver showed high capacity to accumulate Cd even at the highest dose. In contrast, the renal Cd in the 600 ppm group reached a plateau level within the first 2 months. The renal Cd-concentration in the 200 ppm group when renal toxicity was first detected at 2 months ranged from 104 to 244 μ g/g. Similar level of renal Cd (91-183 μ g/g) was found in the 40 ppm group after 8 months, whereas no renal lesions were detected. The results suggest that renal toxicity would not be induced by exposure with minimum amounts of $CdCl_2$ for periods longer than 8 months, although accumulation of Cd might gradually progress. A further 2-year feeding study of very low amount of Cd, up to 40 ppm in diet, is now in progress. At 1-year interim sacrified, blood chemistry, urinalyses and pathological analyses revealed no indication of Cd-related hepato-renal toxicity.

142 EFFECT OF SODIUM FLUORIDE & VERAPAMIL ON CULTURED HUMAN CELLS USING SYTOX & CALCEIN FLUORESCENT PROBES.

A Yang, D Cardona, and F A Barile. *City University of New York, Dept. of Health Sciences, New York, NY.*

Male Wistar rats (6 weeks old) were given Cd (as CdCl2) at a dose of 0, 2, 5, 10, 20, 30 and 60 mgCd/kg/day by gastric tube daily for 6 consecutive days a week for 60 weeks. Animals were sacrificed at 0, 1, 3, 5, 10, 30, and 60 week after oral Cd administration. Cd concentration in the kidney, urinary excretion of enzymes (NAG,AAP,GST,ALP), the urinary excretion of Pyridinoline (Pyr) and Deoxypyridinolin (Dpyr) were determined. Bone mineral density of the femur was determined by microdensitometry (MD) method, and the osteoid volume (%) was also determined by the Quantitative Image Analysis method. At low Cd administration groups of 2 and 5 mgCd/kg/day, the prominent renal dysfunction was not observed. On the other hand, in the high Cd dose groups of 20, 30 and 60 mgCd/kg/day, the renal proximal tubular dysfunction was observed, and the decreased bone mineral density was found at before and after the manifestation of renal dysfunction. Osteoid volume (%) in the femur was shown the lower level compared to that of control animal. The increased osteoid volume was not found in all animals except the case of 2 mgCd/kg group at the 5th week. The increased urinary excretion of Pyr, Dpyr and Ca was observed in the high Cd dose groups from the 3rd week after the Cd administration. It was suggested that the bone resorption is activated. These results suggest that the renal dysfunction, the decreased bone mineral density, and the decreased osteoid volume in the femur are resulted at different time corresponding to the Cd accumulation resulted by the different condition of Cd exposure.

Dpyr and Ca was observed in the high Cd dose groups from the 3rd week after the Cd administration. It was suggested that the bone resorption is activated. These results suggest that the renal dysfunction, the decreased bone mineral density, and the decreased osteoid volume in the femur are resulted at different time corresponding to the Cd accumulation resulted by the different condition of Cd exposure. (This study is supported by the research grants from the Kitasato PRG B-10 and the Japanese EA.)

143 SUBACUTE INHALATION TOXICITY OF PERFLUOROETHYL VINYL ETHER (PEVE) IN RATS.

J R Bamberger, D A Lavoie, G S Elliott, T Chiu, and W J Brock. *The DuPont Company, Haskell Laboratory for Toxicology and Industrial Medicine, Newark, DE.*

The toxicity of PEVE was evaluated by exposing Crl:CD® (SD) BR male and female rats to 0, 500, 3000, or 18,000 ppm for 4-weeks. Body weights and food consumption were measured weekly. Clinical pathology and morphological evaluations were conducted at the end of the exposure period and after 2 weeks of recovery. Rats exposed to 18,000 ppm had significantly lower mean body weights, body weight gains, food consumption, and food efficiency during the exposure period. Rats had a diminished response to an auditory alerting stimulus during exposure to 18,000 ppm, which was reversible. Female rats exposed to 18,000 ppm had significantly increased absolute and relative kidney weights at the end of the exposure period. Microscopic changes were observed in the kidneys in the 18,000 ppm males and females at the end of the exposure period, and in the 18,000 ppm females at the end of the recovery period. The renal lesions occurred in the outer stripe of the outer medulla, and were characterized by tubular epithelial cell degeneration, necrosis, sloughing, and basophilia and megalocytosis of regenerative cells. Urine analytical changes which indicated diuresis were seen in rats in the 3000 and 18,000 ppm groups at the end of the exposure period and at the end of the 2-week recovery period. The changes in the 18,000 ppm groups were considered biologically adverse because they were accompanied by histopathologic lesions in the renal tubules. The no-observed-adverse-effect level (NOAEL) for repeated exposure to PEVE in male and female rats was 3000 ppm.

144 CHARACTERIZATION AND EFFECTS OF CRYSTAL DEPOSITS IN RENAL CORTEX AFTER ORAL ADMINISTRATION OF CI-1007 IN MONKEYS.

L M King[1], M R Feng[2], M A Albassam[2], J Wright[2], K W Baker[1], M Sinz[2], L Meltzer[2], G E Macallum[1], and R M Walker[1]. *Parke-Davis Pharmaceutical Research Division, Warner-Lambert Co., [1]Mississauga, ON, Canada and [2]Ann Arbor, MI, USA.*

CI-1007 (pyridine, (R) 1,2,3,6-tetrahydro-4-phenyl-1-[(3-phenyl-3-cyclohexen-1-yl)methyl]) was administered orally for 13 weeks at 10, 35 and 75 mg/kg to 4 cynomolgus monkeys/sex/group; 3/sex/group were euthanatized after 13 weeks and 1/sex/group after a 4 week non-dosing period (Week 17). Renal lesions were observed at 35 and 75 mg/kg (Weeks 13 and 17), and in one male at 75 mg/kg euthanatized moribund (Week 5). Birefringent, crystalline deposits in the renal cortex were observed in the interstitium, and tubular cells and lumina. Crystals were associated with mononuclear cell infiltrates and tubular epithelial regeneration was observed in moderately affected animals. Ultrastructurally, crystals were electron dense spicular composites ranging in diameter from 2 to 25 m m with individual spicule length of 0.5 to 2.0 μ m. They appeared plate- or flake-like by scanning electron microscopy. Energy dispersive X-ray analyses revealed high sulfur concentrations in the crystals. Concentrations of CI-1007, 3 hydroxylated metabolites, and 5 sulfated conjugates were determined in formalin-fixed renal cortices. At 10 mg/kg, all analytes were below limit of quantification, while at 35 and 75 mg/kg there was a disproportional increase in PD 163639 (sulfated conjugate of a dihydroxylated metabolite) concentrations. In animals with renal crystals, PD 163639 concentrations ranged from 0.32 to 10.4 mg/g compared to <0.0002 to 0.07 mg/g in unaffected animals. Plasma concentrations of PD 163639 increased with dose and were 21 to 66 times higher than those of CI-1007 at all doses. It is concluded that PD 163639 is responsible for the crystal formation with three-dimensional structure that elicit minor tissue response and no effects on kidney function. No crystals in the kidney and high plasma concentrations of PD 163639 at 10 mg/kg indicated elimination of conjugate.

145 EFFECT OF RENAL INJURY ON PHOSPHOROTHIOATE OLIGONUCLEOTIDE (P=S ODN) PLASMA AND TISSUE DISTRIBUTION AND EXCRETION IN RATS.

L Masarjian[1], A de Peyster[1], and D K Monteith[2]. [1]*San Diego State University, San Diego, CA;* [2]*Isis Pharmaceuticals, Carlsbad, CA.*

The kidney is a major organ for the accumulation of P=S ODN, antisense therapeutic agents; therefore, injury to the kidney may alter the distribution and elimination of these compounds. In this experiment renal injury was induced by a single intravenous administration of 5 mg/kg cisplatin along with a concurrent group of saline treated animals to serve as controls. Three days following cisplatin or saline administration, all animals received P=S ODN by a single intravenous dose of 2 or 10 mg/kg. Blood samples were collected at 1, 2, 4, 6, 24, 48 and 72hr after P=S ODN dosing. Urine was collected at 0-6, 6-24, 24-48 and 48-72 hours. Renal injury was assessed by water consumption, urine output volume, pH, BUN values and histopathology. P=S ODN concentrations in urine, plasma and tissue were determined using capillary gel electrophoresis. There was a significant increase in kidney weights, urine output, and BUN levels in cisplatin treated animals. Histopathologic examination of the kidneys indicated moderate proximal tubule injury consistent with cisplatin nephrotoxicity. In tissue and plasma, distribution and concentrations of P=S ODN were similar between control and cisplatin-treated animals. An exception was the kidney, where concentration of P=S ODN was 30-70% lower in the cisplatin-treated animals than controls. There was approximately a two fold increase in urinary excretion of P=S ODN. However, urinary excretion of P=S ODN was only 0.1-0.4% of dose. This study indicates that injury to kidney proximal tubules does not effect distribution of P=S ODN to tissues other than the kidney or effect excretion significantly.

146 EXPRESSION OF METALLOTHIONEIN-3 IN THE HUMAN KIDNEY.

D A Sens, S H Garrett, M A Sens, X M Zhang, J H Todd, and S Somji. *Department of Pathology, West Virginia University, Morgantown, WV.*

The original description of metallothionein-3 (MT-3) indicated that this protein was limited to brain and neural tissues; however, recent reports show a much wider tissue distribution. This study determines the tissue distribution of MT-3 in the human kidney and its expression in cultures of human proximal tubule cells. An antibody was generated against the unique eight amino acid sequence that is not shared by any other MT family member and was used for immunohistochemical staining. Staining with this antibody showed: moderate staining in the parietal epithelial cells of Bowman's capsule and in visceral epithelial cells of the glomerular tuft, as well as the proximal convoluted tubule cells; strong cytoplasmic staining in the distal tubules, particularly in the medullary rays; weak to moderate staining in the medullary collecting ducts; and a general absence of staining in the thin loops of Henle and in the transitional epithelium of the renal pelvis. Expression was also deter-

mined in cultures of human proximal tubule cells exposed to various metals. It was shown that there was an increase in the production of MT-3 in response to metals (Cd and Zn); however, the response was only transient and MT-3 levels decreased after an initial induction, despite continued exposure to metals. The finding that MT-3 is constitutively expressed in several glomerular and tubule epithelial elements of the human kidney warrants consideration of an expanded role for this protein family in maintaining renal homeostasis.

147 NAPROXEN TOXICOSIS IN DOGS: A REVIEW OF FIFTY-SEVEN CASES.

S A Khan[1], M A Khan[2], J C Albretsen[1], and S M Gwaltney[1]. [1]*ASPCA-National Animal Poison Control Center;* [2]*Department of Veterinary Biosciences, University of Illinois, Urbana, IL, USA.*

Naproxen, a propionic acid derivative, is a nonsteroidal anti-inflammatory drug (NSAID) available over the counter as acid and as the sodium salt. Structurally and pharmacologically, naproxen is similar to carprofen and ibuprofen. In humans and the dog, it has been used for its anti-inflammatory, analgesic, and antipyretic properties. The objective of this study was to summarize characteristic clinical signs, alteration of clinical chemistries, duration of illness, and success of treatment, following ingestion of excessive doses of naproxen in dogs. For this purpose, the National Animal Poison Control Center (NAPCC) database was searched for records of dogs ingesting naproxen or naproxen sodium from January 1992 to December 1994. Data were retrieved based upon clinical signs, laboratory test results, exposure history, response to treatment, and final outcome. Fifty-seven cases were found where dogs had ingested naproxen ranging between 10 mg/kg to more than 500 mg/kg. Out of 57 cases, thirty-four dogs (60.00%) developed clinical signs. The commonly observed clinical signs included anorexia, drooling, vomiting and diarrhea (with or without blood), polydipsia, hematuria, ataxia, shock, depression, renal failure, and death. Increase in blood serum nitrogen, serum creatinine, some liver specific enzymes, and decreased hematocrit were some commonly reported alterations in clinical chemistry profiles. Four dogs died or were euthanized. The majority of the dogs recovered with treatment which included, induction of emesis, administration of activated charcoal, fluids, gastrointestinal protectants, and other supportive measures.

148 EFFECTS OF α -HEDERIN ON TCDD-MEDIATED *Cyp1a1* EXPRESSION IN THE MOUSE HEPATOMA HEPA 1c1c7 CELLS.

H G Jeong[1], S S Lee[2], H K Kim[1], and C Y Choi[1]. [1]*Department of Biological Science, Chosun University, Kwangju, Korea;* [2]*Immune Regulation Research Unit, KRIBB, Taejon, Korea.*

Cultured mouse hepatoma cell line Hepa-1c1c7 cells were treated with α -Hederin to assess the role of α -Hederin in the process of Cyp1a-1 induction. Treatment of Hepa-1c1c7 cultures with 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) induced Cyp1a-1, as indicated by analysis of 7-ethoxyresorufin *O*-deethylation (EROD) activity and Cyp1a-1 protein. When α -Hederin and TCDD were both added to cultures, TCDD-inducible EROD activity was greatly suppressed by α -Hederin in a dose-dependent manner. TCDD-induced Cyp1a-1 protein and mRNA levels were markedly reduced in the concomitant treatment of TCDD and α -Hederin consistent with EROD activity. Electrophoretic mobility shift assay using nuclear extract of cells revealed that α -Hederin reduced transformation of the Ah receptor to a form capable of specifically binding to a oligonucleotide containing a dioxin-response element (DRE) sequence of the *Cyp1a-1* gene. These results suggest that the suppressive effect of α -Hederin on TCDD-induced *Cyp1a-1* gene expression in Hepa-1c1c7 cells might be antagonism of the DNA binding potential of nuclear Ah receptor. (Supported by KOSEF Grant 98-0503-008-1.)

149 MODIFICATION OF FUMONISIN B1 RESPONSE IN MICE CARRYING HUMAN TUMOR NECROSIS FACTOR ALPHA TRANSGENE.

R P Sharma[1], M Tsunoda[1], N Bhandari[1], R T Riley[2] and K A Voss[2]. [1]*University of Georgia and* [2]*USDA-ARS, Athens, GA, USA.*

Our previous studies indicated the possible involvement of tumor necrosis factor alpha (TNF) in fumonisin B1 (FB)-induced toxic responses (J. Pharmacol. Exp. Ther. 285:317-324, 1998). To further investigate the role of TNF we employed transgenic mice expressing human TNF gene (TG) and their wild-type equivalent C57BL/6 (WT). It was hypothesized that TG animals would have enhanced response to FB. Repeated subcutaneous treatment of animals with 2.25 mg/kg/day of FB for 5 days caused minimal changes in body weight, organ weights, blood cell counts, and TNF levels (measured by immunoassay) in serum, liver or kidney, one day after the last injection. The mRNA for TNF in liver increased in TG but not WT after FB treatment. Liver and kidney lesions were found in TG after FB treatment. More extensive liver lesions were seen in FB-treated WT. In both FB-treated groups the liver pathology was directly correlated with sphinganine increase but inversely with TNF mRNA levels. Alterations of regional brain neurotransmitters and their metabolites by FB in both TG and WT were similar to those observed earlier; the increase in dopamine metabolite, homovanillic acid, was widespread in all regions of FB-treated TG. While the data do not support the original hypothesis, they provide evidence that hepatotoxic response to FB was modified in TG mice.

150 ALGAL PRODUCTS AS NATURALLY OCCURRING MODULATORS FOR THE MULTIDRUG RESISTANCE (MDR) TRANSPORTER, P-GLYCOPROTEIN.

N Eufemia[1], S Girshick[1], G Duran[2], B Sikic[2] and D Epel[1]. [1]*Hopkins Marine Station, Pacific Grove, CA;* [2]*Stanford Medical Center, Stanford University, Palo Alto, CA.* Sponsor: R T Di Giulio.

Extracts of various marine algae modulate activity of the multidrug resistance (MDR) transporter in the filter-feeding mussel, Mytilus californianus, and also in an MDR1/P-glycoprotein (P-gp) expressing human tumor cell line, MES-SA/Dx5. M. californianus has high titer of the MDR-transporter possibly to provide protection from products contained in its diet of seaweed particulates and phytoplankton. To test this hypothesis, extracts of various seaweeds and phytoplankton were examined for the presence of substrates by competition assays in mussel gills with a fluorescent P-gp substrate, rhodamine B. Methanol extracts of the seaweeds Macrocystis pyrifera, Egregia menziesii and Phyllospadix scouleri exhibited modulating activity in mussel gills as shown by increased accumulation of rhodamine and slowing of dye efflux. These data suggest that the mussel diet contains compounds that may be P-gp substrates, thus providing evidence that mdr genes may have evolved in response to dietary pressures. Recently, we have tested some of these algal extracts on the MDR overexpressing MES-SA/Dx5 human uterine sarcoma cell line for possible MDR modulating activity in tumor cells. Preliminary results suggest that methanol extracts of the seaweed Macrocystis pyrifera contain compounds that modulate P-gp-mediated drug transport in these human tumor cells when tested in competition assays using a radiolabelled MDR substrate, vinblastine. These findings indicate that marine algae contain compounds that are substrates for the MDR transporter in both marine organisms and in human tumor cells.

151 TOXIC PROPERTIES OF EXTRACTS OF CYANO-BACTERIAL MATS COLLECTED FROM ANTARCTIC MELTWATER PONDS.

C S Lampert[1], H Kaspar[2], P A Broady[3], D R Dietrich[1], and B C Hitzfeld[1]. [1]*Environmental Toxicology, University of Konstanz, Konstanz, Germany;* [2]*Cawthron Institute, Nelson, New Zealand;* [3]*Department of Plant and Microbial Sciences, University of Canterbury, Christchurch, New Zealand.*

Cyanobacteria occur worldwide in temperate as well as extreme environmental conditions and are capable of producing toxic secondary metabolites. Even in Antarctica benthic and floating cyanobacterial mats colonize ponds originating from meltwater during the Antarctic summer. In samples taken in 1997 the toxic properties of Antarctic cyanobacteria were demonstrated (Hitzfeld et al. Toxicol. Sci. 42 (1-S), 288, 1998). In order to further characterize the toxins involved and to identify the toxin-producing species, 56 samples were collected on Bratina Island on the McMurdo Ice Shelf, Antarctica in January 1998. Taxonomy of the fresh samples was determined using light microscopy. Samples were freeze-dried and organic contents determined by furnace incineration. For toxicity assessment 32 samples were extracted with 70% methanol, rotary-evaporated and finally taken up in a defined volume of water. The protein-phosphatase-inhibition assay was used to demonstrate toxicity. Microcystin-LR was employed as a standard. HPLC was used for further characterization of the extracts. Cytotoxic properties of the extracts were investigated on isolated rainbow trout hepatocytes using the MTT assay. The results show that Oscillatoriales (*Phormidium* sp.) and the genera *Nodularia* sp. and *Nostoc* sp. constitute the most common strains in the cyanobacterial mats. Samples collected in 1997 and in 1998 show comparable species composition. Protein-phosphatase-inhibiting activity is shown by all samples although to a different degree. Sixteen of the 32

extracts had more than 50% and twelve extracts more than 70% inhibiting activity. A correlation between toxin content (protein-phosphatase inhibition) and species composition was detected. *Phormidium* sp. and *Nodularia* sp. were present in nearly all of the toxic samples. In contrast, cytotoxic properties could not consistently be detected in all samples.

152 EFFECT OF OZONATION IN DRINKING WATER TREATMENT ON THE REMOVAL OF CYANOBACTERIAL TOXINS.

S J Höger, D R Dietrich, and B C Hitzfeld. *Environmental Toxicology, University of Konstanz, Konstanz, Germany.*

The presence of cyanobacterial toxins, such as microcystin, in drinking water supplies poses a serious health risk. Human exposure to drinking water containing toxins may result in chronic liver injury and possibly in the promotion of liver tumors. It is thus important to monitor cyanobacterial densities and toxin levels in water reservoirs and, in the event of a bloom, to remove these toxins by adequate water treatment procedures. Conventional water treatment (chlorination, flocculation, sand filtration) is ineffective in reducing cyanobacterial toxin levels to below acutely toxic concentrations; only activated charcoal can effectively remove the toxins. Public waterworks often take their raw water from lakes or rivers containing cyanobacteria. Previous studies have suggested that the best method to remove cyanobacterial toxins from drinking water is oxidation with ozone. In order to investigate the efficacy of ozone in the removal of cyanobacterial toxins *Microcystis aeruginosa* PCC 7806 and *Oscillatoria rubescens* (sample from Lake Zurich) were ozonated in a batch reactor with different O_3 concentrations ranging from 0,3-2 mg/l for 9 mins contact time and 60 mins reaction time (ozone off). The presence of toxins was detected by the protein phosphatase inhibition assay, HPLC and a primary hepatocyte assay. Ozone treated water still containing Microcystins was filtered with a system modeled on the Zurich Water Supply (fast filter, activated charcoal filter, slow filter). Ozonation by-products of cyanobacterial toxins were analyzed by HPLC to determine the presence of toxins. The results show that the residual toxicity of the cyanobacterial material depends on the cell number, the ozone concentration, the duration of ozonation and the temperature of the ozonated water. The level for a total detoxification of cyanobacteria (10^5 cells/ml) lies at 1mg ozone/ l water (7°C, 9 mins). Ozonation of higher cell numbers results in increased toxicity due to lysis of cyanobacterial cells and release of toxins. An ozone residual (0,05 mg/l) should therefore remain in order to completely destroy the toxins.

153 IMMUNOCHEMICAL DETECTION OF MICRO-CYSTIN-LR IN TISSUES AND CELLS OF RAINBOW TROUT.

B C Hitzfeld[1], W J Fischer[1], J E Eriksson[2], A Mikhailov[2], and D R Dietrich[1]. [1]*Environmental Toxicology, University of Konstanz, Konstanz, Germany;* [2]*Turku Centre for Biotechnology, Turku, Finland.*

Microcystins (MC) are cyclic heptapeptide toxins produced by cyanobacteria such as *Microcystis aeruginosa*. MC have hepatotoxic and tumor-promoting activity. Intoxication with MC has lead to death of humans and animals such as livestock or fish. In order to determine the localization of microcystin in trout, an antibody was developed against MC-LR and tested for suitability of toxin detection in liver and other tissues and in isolated primary trout hepatocytes. Antibodies against MC-LR were produced in rabbits via conjugation of the toxin to keyhole limpet hemocyanin, antiserum was obtained and used directly for microcystin detection. Microcystin was probed in tissue, cell and subcellular homogenates after *in vivo* and *in vitro* exposure to the toxin by immunoblotting and immunocytochemistry. In order to identify putative protein adducts, Western blots were also stained with anti-human protein phosphatase 1 (PP1) as well as anti-human protein phosphatase 2A (PP2A). In Western blots of trout liver and hepatocyte homogenates the antibodies detected several microcystin-protein adducts with approximate molecular weights ranging from 34 to 38 kD. One of these adducts had an approximate molecular weight of 36 kD and this band was identified as PP2A by using a specific PP2A antibody. Immunoblotting of hepatocyte proteins showed that the activity was largely localized in the cytosol, while immunocytochemistry demonstrated cytosolic as well as nuclear staining.

154 MICROCYSTIN-LR TOXICODYNAMICS, INDUCED PATHOLOGY AND IMMUNOHISTOCHEMICAL LOCALIZATION IN LIVERS OF RAINBOW TROUT.

W J Fischer[1], B C Hitzfeld[1], F Tencalla[2], J E Eriksson[3], A Mikhailov[3] and D R Dietrich[1]. [1]*Environmental Toxicology, University of Konstanz, Konstanz, Germany;* [2]*Institute of Toxicology, Schwerzenbach, Switzerland;* [3]*Turku Centre for Biotechnology, Turku, Finland.*

The temporal pattern of toxin exposure and pathology, as well as the topical relationship between hepatotoxic injury and localization of microcystin-LR (MC), a potent hepatotoxin, tumor promoter and inhibitor of protein phosphatases 1 and -2A (PP), was investigated in livers of MC-gavaged rainbow trout (*Oncorhynchus mykiss*) yearlings via an immunohistochemical detection method using antibodies specific to MC (see Hitzfeld et al., SOT 1999). H&E-stains of liver sections were used to determine pathological changes (e.g. necrosis). Nuclear morphology of hepatocytes and TUNEL analysis were employed as endpoints to detect the advent of apoptotic cell death in hepatocytes. Trout were gavaged with lyophilized cyanobacteria (*Microcystis aeruginosa*, strain PCC 7806) at acutely toxic doses of 5700µg MC per kg bw, as described by Tencalla and Dietrich (Toxicon **35**, 583-595, 1997). Three of each, control and test animals were sacrificed after 1, 3, 12, 24, 48 and 72h and the livers frozen for determination of remaining PP-activity or fixed for immunostaining and histological analyses. Immunohistochemistry revealed a time dependent discernible increase in staining intensity throughout the liver, concurring with the kinetics of hepatic PP-inhibition. After 3h marked immunopositivity was observed in the cytoplasm, as well as the nuclei of hepatocytes which reached a constant level of staining intensity after 12h. Apoptotic cell death could be detected after 48h at the very earliest. These data suggest that accumulation of MC and subsequently changes in cellular morphology, PP-inhibition and hepatocyte necrosis represent the primary events in microcystin induced hepatotoxicity, while apoptotic cell death, as demonstrated here, is only secondary.

155 PROTECTION BY RED GINSENG TOTAL SAPONIN AGAINST ADRIAMYCIN-INDUCED CARDIOTOXICITY AND CISPLATIN-INDUCED NEPHROTOXICITY.

C W Park, S H Lee, J S Lee, D H Cho, J T Hong and J I Kim. *Department of Toxicology, National Institute of Toxicological Research, Korea Food and Drug Administration, Seoul, Korea.*

The usefulness of adriamycin(ADR) and cisplatin(CP), potent anticancer agents, is limited by the those cardiotoxicity and nephrotoxicity, respectively. Subcellular changes leading to target organ(heart, kidney) toxicities are suggested to be mediated by a drug-induced increase in free radicals and lipid peroxidation. The present study was undertaken to examine whether this protection by red ginseng total saponin(RGTS) against adriamycin-induced cardiotoxicity and cisplatin-induced nephrotoxicity can be improved by co-administration with anticancer agents through *in vivo* experiments. Male SD rats were injected with (1) vehicle control, (2) ADR or CP, (3) RGTS, and (4) ADR or CP plus RGTS. ADR(cumulative dose, 10mg/kg, I.V.) was injected in four equal injection(I.V.) over a period of 10 days. CP(5mg/kg, I.V.) was injected as an I.V. single injection. These groups were sacrificed three days after the end of injection. ADR or CP-induced toxicities were characterized by antioxidant enzymes activities(GPx, SOD), glutathione(GSH) contents, lipid peroxidation in isolated organs, chemistry examination in blood and urine. The results of the study were as fellows. Co-administration of RGTS can provide partial protection against ADR-induced cardiotoxicity and CP-induced nephrotoxicity. This study suggests that the protection offered by RGTS against anticancer-induced target organ toxicity is partly related to antioxidant systems. This study suggests partial usefulness of RGTS therapy in ADR- and CP-induced target organ toxicity.

156 SAFETY AND EFFICACY OF DEGLYCOSYLATED A-CHAIN OF RICIN (DGCA-RICIN) VACCINE FOR THE PROTECT AGAINST AEROSOLIZED RICIN.

R W Wannemacher, R E Dinterman, G M Zaucha and, J W Boles. *Toxicology and Pathology Divisions, U.S. Army Medical Research Institute of Infectious Disease, Fort Detrick, MD, USA.*

Ricin, a highly toxic plant lectin, consists of two distinct ~ 30,000 MW polypeptides (A- & B-chain) held together by a single disulfide bond. Aerosolized ricin, at an inhaled dose of 10 to 20 µg/kg, causes severe lung injury and death in experimental animals. The A-chain separated from the B-chain has little or no toxicity. Partially deglycosylated A-chain has an increased biological half-life but retains an epitope that is highly antigenic.

A pilot lot of cGMP-produced DGCA-ricin was vialed, lyophilized, and stored at –20°C. This product was reconstituted with saline and used to determine its safety and efficacy when experimental animals were inoculated by intramuscular (im) injection of DGCA-ricin. Mice and rats inoculated with two or three im injections of 10-μg of DGCA-ricin developed neutralizing antibodies and at 90 days after the last inoculation all survived an aerosol challenge with 5 LD_{50} of ricin. In an acute dose preclinical study, 20 male and female BALB/c mice per group were injected with a single im dose of 100, 50, 10, or 0-μg of reconstituted DGCA-ricin. On day one and 15 after dosing, 10 male and female mice from each group were bled for blood samples and necropsied for tissue pathology. None of the mice died before necropsy and all gained weight. Except for a dose- related transient neutrophilia on day one after injection of DGCA-ricin, all of the other blood analyses were normal. The primary pathological lesion was a dose-related local inflammatory response at the sight of injection that had not yet completely resolved by day 15. To evaluate possible low level toxicity, a repeat dose preclinical safety study was initiated in which 570 female mice were dosed im with 10-μg of DGCA-ricin vaccine at 0, 4, and 8 weeks. On day one, 15 and 90 after the third dose, 20 mice were bled for blood samples and necropsied for tissue pathology. None of the DGCA-ricin treated mice died before necropsy and all gained weight. Thus, from the above data, DGCA-ricin appears to be a safe and efficacious vaccine.

157 HEALTH HAZARD ASSESSMENT FOR THE CONSUMPTION OF FRUIT BRANDIES CONTAINING CYANIDE-BASED COMPOUNDS.

S A Assimon[1], M A Adams[1], E Jagerdeo[2], S M Dugar[2], P M Bolger[1]. [1]*Food and Drug Administration, Washington, DC, USA;* [2]*Bureau of Alcohol, Tobacco, and Firearms, Rockville, MD, USA.*

Fruit brandies contain prussic acid (PA) and lactonitriles (LN), both cyanide (CN)-based compounds that are highly toxic. This assessment addresses the potential health hazard of short-term and of chronic consumption of fruit brandy products that contain PA and LN. Fifteen fruit brandies were analyzed for the content of PA and LN by gas chromatography. The estimate of exposure to CN from fruit brandy consumption was based on total CN levels derived from brandy PA and LN content and point estimates of brandy intake (USDA, CSFII, 1989-1992). Mean and 90-99th percentile CN exposures were estimated for acute, single-day and chronic exposures. Consumption of three of the brandy products sampled, 2 cherry and an apricot, is associated with CN exposure levels of toxicological concern. Consumption of one of the cherry brandies over a day at the 99th percentile level could involve CN exposure in the acute lethal dose range. Some mean and higher percentiles of acute and one-day estimates of brandy-derived CN exposure exceed the oral minimum risk level (MRL) of 3 mg CN/day for an intermediate duration of exposure (ATSDR, 1995). The estimated chronic exposure to the three brandies noted exceeds the chronic reference dose (RfD) of 1.2 mg CN/person/day (IRIS, EPA, 1985) at several intake percentiles (mean, 90-99th). Thus, the possibility exists that some brandy products with particularly high levels of PA and LN may represent a hazard to human health.

158 NOVEL TOXINS AND NEW STRUCTURAL VARIANTS OF ENZYMES FROM COLUBRID SNAKE VENOMS.

S P Mackessy, R E Hill and P Huang. *Department of Biological Sciences, University of Northern Colorado, Greeley, CO, USA.* Sponsor: C S Gardiner.

Snake venom toxins have provided instrumental tools for developing a molecular understanding of ligand binding at ion channels, and metalloproteases common in venoms have served as models for inducing endothelial damage and hemorrhage. Whereas many venoms from front-fanged snakes are well-characterized, venoms from rear-fanged snakes of the family Colubridae (comprising nearly 700 species worldwide) represent a promising and largely unknown source of novel compounds. Recently we published a method which greatly facilitated extraction of these venoms, and we have screened numerous venoms from this diverse family for novel toxins and structural variants of described toxic proteins (using SDS-PAGE, HPLC, enzyme analyses, protein sequencing and bioassays). Partial N-terminal sequence has been obtained for several purified components and subjected to homology analysis on the BLAST and FASTA protein sequence databases. Based on *in vitro* and *in vivo* assays, one toxin is a phospholipase A_2 (14 kD) which appears to contain novel structural motifs, and a second toxin is a potent metalloprotease (~44 kD) with fibrinogenolytic, myonecrotic and hemorrhagic activities. The phospholipase shows considerable homology with other venom phospholipases, but the protease shows no homology to venom proteins. Two additional proteins (26 kD and 3.5 kD) show no homology to protein sequences in databases and appear to be novel venom components. Further work with venoms from this family likely will yield additional novel compounds.

159 COMPARATIVE TOXICITY OF FUMONISIN DERIVATIVES IN 28-DAY FEEDING STUDY USING FEMALE B6C3F$_1$ MICE.

P C Howard[1], L H Couch[1], M Muskhelishvili[2], R M Eppley[3], D R Doerge[1], and C Okerberg[2]. [1]*National Center for Toxicological Research, Jefferson, AR, USA;* [2]*Pathology Associates International, Jefferson, AR, USA; Center for Food Safety and Applied Nutrition, Washington, DC, USA.*

Fumonisin mycotoxins are produced by *Fusaria* fungi which grow on corn. Our goal was to determine the relative toxicity of several fumonisins and derivatives. Female B6C3F$_1$ mice were fed diets for 28-days containing 0, 14, 70, and 140 μmol/kg fumonisin B_1 (FB_1), fumonisin B_2, fumonisin B_3, fumonisin P_1, hydrolyzed-FB_1, N-acetyl-FB_1, or N-carboxymethyl-FB_1. Serum analytes and tissue sphinganine:sphingosine ratios were elevated only with 70 and 140 μmol/kg FB_1. Cellular changes included increased hepatocellular apoptosis, hypertrophy, Kupffer cell hyperplasia, and macrophage pigmentation at 70 and 140 μmol/kg FB_1. The other fumonisin derivatives did not alter serum analytes, organ weights, or hepatic structure. These results suggest that, among the compounds evaluated, FB1 causes the most severe acute toxicity.

160 INHIBITION AND STABILIZATION OF TOXIC PROTEINS: A MODEL SYSTEM IN SNAKE VENOMS.

S M Munekiyo and S P Mackessy. *Department of Biological Sciences, University of Northern Colorado, Greeley, CO, USA.* Sponsor: C S Gardiner.

Rattlesnake venoms are complex biological products containing potentially autolytic components, and they provide a useful tool for the study of long-term maintenance of enzymes in a competent state, both *in vivo* and *in vitro*. In the venom gland of the snake, venom is secreted into a lumen and stored in an inactive and competent state for months. We examined the effects of temperature and storage conditions on *Crotalus molossus molossus* venom using SDS-PAGE, metalloprotease zymogram gels, a cricket LD_{50} toxicity assay and enzyme assays. The results demonstrated that the venom contained at least 24 distinct protein components, and electrophoretic, toxic and enzymatic activities were largely unaffected by dilution effects and storage conditions, which varied by as much as 117° C. Therefore, endogenous mechanisms must be present within the gland and venom stored in the lumen that inhibit autolysis and promote protein stability during long-term storage. Further investigation focuses on the elucidation of these mechanisms. A tripeptide component (present in the venom at millimolar concentrations) inhibited the main metalloprotease (Cvo V) isolated from *C. viridis oreganus* venom. We hypothesize that endogenous polypeptide components both inactivate and stabilize metalloproteases (and perhaps other enzyme components) present in the stored venom. Upon injection, this low affinity inhibitor will spontaneously dissociate, releasing an active toxic enzyme in tissues which induces hemorrhage and tissue necrosis.

161 ISOLATION OF CERAMIDE SYNTHASE: ENRICHMENT OF PROTEIN FRACTIONS FROM RAT LIVERS CONTAINING CERAMIDE SYNTHASE ACTIVITY.

G R Jenkins, W B Melchior, Jr., D R Roberts, W H Tolleson, R L Sams, and P C Howard. *National Center for Toxicological Research, Jefferson, AR, USA.*

Ceramide synthase (CeSyn) catalyzes the synthesis of ceramides from sphinoid bases (sphinganine or sphingosine) and acyl-coenzyme A. CeSyn is the key enzyme inhibited by fumonisin B_1. CeSyn activity was determined through the incubation of ^{14}C-palmitoyl coenzyme A and sphinganine, product separation using TLC, and detection of the N-[^{14}C]palmitoyl-sphingosine using phosphoimagery. The soluble proteins from sonicated rat liver microsomes were separated using strong anion exchange chromatography. Fractions enriched for CeSyn activity eluted under low salt conditions. CeSyn was further isolated using size exclusion, hydroxyapatite, and weak anion exchange chromatography; and electroelution from non-denaturing polyacrylaminde gels. Purification of CeSyn from the electroeluted fractions is in progress.

162 METABOLIC ACTIVATION OF GENOTOXINS IN *FUSARIUM* EXTRACTS AND EVIDENCE THAT FUSARIN C IS NOT RESPONSIBLE FOR DNA ADDUCT FORMATION.

R J Bever, Jr., L H Couch, J B Sutherland, A J Williams, D R Doerge, and P C Howard. *National Center for Toxicological Research, Jefferson, AR, USA.*

Fusarin C (FC) is a metabolite produced by some *Fusarium* fungi that contaminate crops worldwide. The consumption of feed containing *Fusarium moniliforme* is tumorigenic in rats. The incubation of *Fusarium* extracts with DNA in the presence of liver subfractions (S9) results in the formation of a unique DNA adduct detected by the ^{32}P-postlabeling assay. FC was purified from *Fusarium* cultures and characterized by NMR and HPLC/MS methods. FC did not produce the DNA adducts when incubated with S9 and DNA. Likewise, the formation of DNA adducts with extracts of different *Fusarium* cultures did not correlate with FC content. These and other data suggest neither FC, nor its metabolites, are responsible for the genotoxicity observed from *Fusarium* fungi.

163 INHIBITION OF TCDD-INDUCIBLE TRANSCRIPTION OF HUMAN CYP1A1 AND CYP1A2 GENES BY POLYPHENOLIC COMPOUNDS OF GREEN TEA.

S N Williams[1], H Shih[2], and L C Quattrochi[2]. [1]*Department of Pharmaceutical Sciences, University of Colorado Health Sciences Center, Denver, CO, USA;* [2]*Department of Medicine, University of Colorado Health Sciences Center, Denver, CO, USA.*

Green tea contains several polyphenolic flavonoids known as catechins which possess chemoprotective properties. Members of the plant-derived flavonoid family, including tea catechins, have been shown to alter the activities of some carcinogen-metabolizing enzymes. We examined the effects of commercially available polyphenolic extracts of green tea, Polyphenon 60 and Polyphenon 100 (from Sigma), on the expression of human CYP1A mRNA. We demonstrated that pretreament of the human hepatoma cell line, HepG2, and also primary cultures of human hepatocytes with P60 and P100 inhibits: i) TCDD-inducible CYP1A1 and CYP1A2 gene transcription, ii) mRNA expression, and iii) nuclear uptake of the Arylhydrocarbon Receptor (AhR). These data indicate that green tea polyphenolics (GTPs) can alter CYP1A expression by inhibiting gene transcription, most likely through changes in AhR function. We have shown P60 or P100 alone do not induce CYP1A1 mRNA, and it seems most likely that GTPs are not AhR ligands. To investigate the possibility that the individual catechins found in P60 and P100 could transform the cytosolic AhR into a DNA binding species, cytosol from the mouse hepatoma cell line, Hepa-1c1c7, was isolated. Incubation of cytosol for two hours with 20nM TCDD induced the transformation of the AhR in vitro to an XRE binding species, while treatment with the individual catechin components (from Sigma, product numbers E4143, E3768, E3893) at 50 mM or 200 mM did not transform the AhR as judged by electrophoretic mobility shift assays. We are currently investigating the mechanism by which GTPs inhibit the TCDD induced expression of human CYP1A genes. (Supported by NIH Grants GM54477.)

164 EFFECT OF DIVICINE ON SULFHYDRYL STATUS, MEMBRANE SKELETAL PROTEINS AND MORPHOLOGY OF RAT ERYTHROCYTES.

L C Bolchoz and D C McMillan. *Dept. of Pharmacology, Medical University of South Carolina, Charleston, SC.*

Divicine (2,6-diamino-5-hydroxy-4-pyrimidinone) has been implicated as a mediator of an acute hemolytic anemia, known as favism, in susceptible individuals who ingest fava beans. We have shown recently that divicine is a direct-acting hemolytic agent in the rat. In this study, the effect of hemolytic concentrations of divicine on rat erythrocyte sulfhydryl status, membrane skeletal proteins and morphology was examined. *In vitro* exposure of red cells to divicine (0.8-2.0 mM) induced a concentration-dependent depletion of GSH with a concomitant increase in the formation of GSH-protein mixed disulfides. SDS-PAGE analysis of skeletal protein indicated that divicine induced the formation of high molecular weight protein aggregates (>250 kDa), an apparent loss of protein bands 2.1 and 4.2, and a broadening of bands 1, 2 and 3. Scanning electron microscopy revealed the presence of non-spherocytic echinocytes. Treatment of red cells with dithiothreitol following divicine exposure reversed both the skeletal protein and morphological changes with concomitant release of hemoglobin, indicating that these changes were due to disulfide-linked adducts between hemoglobin and the skeletal proteins. The data indicate that divicine alters sulfhydryl status, skeletal proteins and morphology under conditions that result in premature sequestration of injured cells by the spleen. (Supported by NIH grant DK47423.)

165 CYTOTOXICITY AND GENOTOXICITY OF CAPSAICIN IN THE HUMAN NEUROBLASTOMA CELLS SHSY-5Y.

F Richeux[1,2], R Ennamany[1,2], M Cascante[3], D Saboureau[2], E E Creppy[1]. [1]*Laboratory of Toxicology and Applied Hygiene, Faculty of Pharmaceutical Sciences, University of Bordeaux, Bordeaux, France;* [2]*Palmer Research, Arbanats, France;* [3]*Departament de Bioquimica, Universitat de Barcelona, Barcelona, Spain.*

Capsaicin, a natural product of *Capsaicum* species, induces excitation of nociceptive terminals involved in pain perception. Our previous studies have shown that capsaicin inhibits protein synthesis on cultured monkey kidney cells (Vero cells) and in primary culture of rat astrocytes. The effect of capsaicin on human neuroblastoma cells SHSY-5Y are now investigated. The cytotoxicity was assessed by incorporation of [^{3}H]L-leucine into cellular protein in the presence of capsaicin, the genotoxicity using the comet assay and the fragmentation assay by electrophoresis in agarose gel after incubation of neuroblastoma cells with capsaicin 25 to 100µM. The concentration required to inhibit 50% of the protein synthesis (IC_{50}) was found to be 60µM after incubation with the toxin during one cellular cycle (5 days) of SHSY-5Y. The results of the comet test and DNA fragmentation assay clearly suggest that capsaicin is able to induce DNA strand breaks already with concentrations in the range of 50µM. Several daily topic applications of preparations containing 0.075% of capsaicin could lead to blood capsaicin concentration of this order following transdermal passage (5% of the total quantity applied). Because DNA strand breaks may affect cellular functions, lead to cell death, and/or carcinogenesis, our data may have important implications for the possible health threats of capsaicin, specially in case of unreasonable use of capsaicin preparations in pathological situations.

166 EVALUATION OF CASTOR BEAN TOXICITY IN ANIMALS.

J C Albretsen, S M Gwaltney-Brandt, and S A Khan. *ASPCA-National Animal Poison Control Center, Urbana, IL, USA.*

Castor bean (*Ricinus communis*) contains the toxic lectin, ricin. Ricin is a highly toxic glycoprotein reported to cause hypotension, gastroenteritis, hemolysis, hemorrhage, depression, and death. All parts of the castor bean plant contain the ricin, however, the protein is most abundant in the seeds, and the pericarps are four times as toxic as the fresh leaves. Ingestion of even one castor bean can be lethal in a child. Human deaths are often attributable to hypovolemic shock. Ricin has been used as both a homocidal and suicidal agent in humans, and is considered one of the most toxic agents known. In spite of this, very few deaths are reported following castor bean ingestion in animals. From January 1987 to September 1998, the National Animal Poison Control Center received 103 incidents of castor bean ingestion in animals. Although most calls (89%) concerned canines that ingested castor beans, feline, caprine, bovine, and equine cases of castor bean ingestion were also reported. The most commonly reported clinical signs were vomiting (with or without blood) 61%, diarrhea (with or without blood) 43%, and depression 35%. Death or euthanasia occurred in only 8% of the cases. Other signs reported include abdominal pain/colic, tachycardia, liver enzyme elevation, tremors and seizures. Most cases recovered uneventfully with appropriate veterinary care. Treatment of castor bean toxicosis includes induction of emesis followed by oral activated charcoal if given soon after ingestion, gastro-intestinal protectants, fluid therapy, anticonvulsants when necessary, and monitoring of cardiac, renal and hepatic function.

167 INHIBITION OF NADP(H) QUINONE OXIDOREDUCTASE BY COUMARIN (1,2-BENZOPYRONE) IN HUMAN, RAT AND CHICK EMBRYO LIVER.

D E Goeger, A W Hsie and K E Anderson. *Department of Preventive Medicine and Community Health, University of Texas Medical Branch, Galveston, TX, USA.*

Coumarin, a naturally occurring dietary compound and drug currently under investigation for the treatment of some cancers and lymphedema, inhibits certain cytochrome P450 enzymes. In studies comparing effects on ethoxyresorufin *O*-deethylase activity in liver S9 from Aroclor 1254-treated

rats and chick embryos, coumarin increased accumulation of the resorufin product with chick embryo liver S9. The increase was two-fold with 25 μM coumarin and three-fold at concentrations greater than 50 μM. The increase was associated with coumarin inhibition of cytosolic NAD(P)H quinone oxidoreductase (QR) for which resorufin is a substrate. Coumarin had no effect on resorufin accumulation with Aroclor 1254-treated rat liver S9. Using 40 μM 2,6-dichloroindophenol as the electron acceptor, dicoumarol-sensitive QR activity was inhibited 50% by coumarin at approximately 5 μM in liver cytosol from untreated chick embryos with total inhibition at concentrations above 50 μM coumarin. Coumarin inhibition of chick embryo QR activity also occurred with menadione as substrate. Rat and human liver QR were much less sensitive with 50% inhibition at approximately 150 μM. These findings demonstrate a species difference in coumarin inhibition of liver cytosolic QR with the chick embryo enzyme being more sensitive than human or rat QR. Since QR is involved in the metabolism of many xenobiotics and therapeutic drugs, coumarin may alter the disposition of these chemicals. (Supported by UTMB Preventive Medicine & Community Health Research Initiative Program.)

168 FLOW CYTOMETRIC ANALYSIS OF BONE MARROW COMPARTMENTS CHIMERIC FOR EITHER THE ARYL HYDROCARBON OR ESTROGEN RECEPTORα REVEAL CELLULAR TARGETS OF TCDD AND ESTROGEN.

F G Murante[1], J E Staples[2], T A Gasiewicz[1], A E Silverstone[2].
[1]*Department of Environmental Medicine, University of Rochester School of Medicine and Dentistry, Rochester, NY, USA;* [2]*Department of Microbiology and Immunology, SUNY Health Science Center, Syracuse, NY, USA.*

The hemopoietic and stromal compartments of bone marrow may each contain cellular targets that mediate receptor-dependent and/or receptor-independent responses associated with either the environmental contaminant 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) or the endogenous hormone estrogen. The identity of marrow target cell(s) that respond to TCDD and estrogen through activation of the aryl hydrocarbon receptor (AhR) or the estrogen receptor isoform Erα, respectively, to effect marrow immunotoxicities remains uncertain. We have determined that single dose administration of either 30 μg/kg TCDD or 5 mg/kg estrogen result in altered flow cytometric enumerations of lineage-negative, c-Kit$^+$ Sca-1$^+$ murine pluripotent hemopoietic stem cells (HSC). While increases in HSC were detected in response to TCDD treatment, similar effects were absent in TCDD-treated AhR knock-out mice. Estrogen, however, caused reductions in the number of HSC both in wild-type mice and in estrogen-treated, estrogen receptor knock-out (ERKO) mice. These data provide evidence of differential hemopoietic immunotoxicities in response to *in vivo* TCDD or estrogen treatment. To determine whether these compounds differentially targeted bone marrow hemopoietic and/or stromal cellular elements, HSC responses to TCDD or estrogen were studied, respectively, in marrow-chimeric mice bearing TCDD- or estrogen-responsive (AhR+/+ or ERα+/+) stromal elements and TCDD- or estrogen-unresponsive (AhR−/− or ERα−/−) hemopoietic elements. Our results showed that the TCDD-induced HSC alterations were dependent upon the presence of the AhR within hemopoietic cells and occurred in the absence of AhR-bearing bone marrow stromal cells. Furthermore, while estrogen treatment caused reductions in the number of HSC through mechanisms independent of ERα gene-mediated signaling, proportionately more significant and global reductions to hemopoietic cell numbers were mediated through ERα genetically-dependent mechanisms associated with hemopoietic cells.

169 THE ROLE OF THE ARYL HYDROCARBON RECEPTOR IN THE MATURATION OF CONVENTIONAL B LYMPHO-CYTES AND IN 2,3,7,8–TETRACHLORO–P–DIOXIN (TCDD)–INDUCED B LYMPHOCYTE ALTERATIONS.

T S Thurmond[1], J E Staples[2], A E Silverstone[2], and T A Gasiewicz[1].
[1]*University of Rochester, Dept. of Environmental Medicine, Rochester, NY, USA;* [2]*SUNY–Health Science Center, Dept. of Microbiology and Immunology, Syracuse, NY, USA.*

The ligand–activated aryl hydrocarbon receptor (AhR) is a cytosolic protein belonging to the basic–helix–loop–helix superfamily of DNA binding proteins. Although a biologic role for AhR has not been fully elucidated, it has been shown to mediate the immunotoxicity of exogenous compounds such as TCDD. Several investigators have shown its involvement in altering the functional response of activated B lymphocytes following TCDD administration; however, little research has been done on its possible function in the early development of these cells, and whether exogenous ligands have an impact on this process. The purpose of this study was to determine, 1), the role, if any, of this receptor in the maturation of conventional B lymphocytes, 2), if a role exists, the relative importance of its presence in hematopoietic and/or stromal components and, 3), whether TCDD alters this process. Bone marrow chimeras were produced which were positive (AhR+/+) or negative (AhR −/−) for AhR in either their stromal or hematopoietic elements, or both. Bone marrow cells were analyzed for alteration of B lymphocyte maturation stages in both naive and TCDD–treated (30 μg/kg body weight) animals. Our results showed that, 1), naive AhR+/+ animals had higher percentages of mature B cells versus the naive AhR−/− animals, 2), TCDD treatment of AhR+/+ animals produced a shift toward a more mature B cell, as opposed to having a minimal effect on AhR−/− animals, and 3), 5 < AhR is required in both hematopoietic and stromal elements for maintenance of normal B cell maturation and mediation of the TCDD induced maturation alteration. (Supported by NIEHS grants ESO5774, ESO7216, ESO1247 and ESO4862.)

170 POTENTIAL FACTORS FOR DECREASED PLATELET COUNTS IN MICE ADMINISTERED PHOSPHOROTHIOATE OLIGODEOXYNUCLEOTIDES.

M V Templin and K M Lemonidis. *Isis Pharmaceuticals, Carlsbad, CA.*

Sustained and significant decreases in platelet count have been noted in mice following dosing with phosphorothioate oligodeoxynucleotides (ODN). Interestingly, ODNs that induce the greatest decrease in platelet count also show the most significant immune stimulation, of which splenomegaly is a prominent aspect. To investigate the correlation between splenomegaly and decreased platelet count, mice were dosed with either a highly stimulatory (ISIS 12449) or non-stimulatory (ISIS 12450) ODN. In addition to spleen weight, number of megakaryocytes (production), % reticulated platelets (release), and platelet life-span (destruction) were examined. In ISIS 12449-treated mice, megakaryocyte numbers were unchanged in sternum marrow, and increased in spleen. The percentage of reticulated platelets (12%) and platelet life-span (5 days) were similar to controls. Spleen weight, however, increased with a maximum (> 2-fold) at 96 to 120 hrs after dosing. Platelet counts progressively decreased, with the nadir (40% of control) at 120 hrs. As spleen weight returned to baseline values, circulating platelet counts returned to normal levels. There was no decrease in platelet count or increase in spleen weight in ISIS 12450-treated mice. Overall, these data support sequestration within an enlarged spleen as a primary factor in the severity and prolongation of decreased platelet counts in rodents. Immune stimulation, i.e. splenomegaly, is not a principal effect in monkeys, however mild and transient decreases in platelet counts have been observed. Thus, species specific factors need to be considered in determining the mechanism(s) most relevant for assessing and managing potential effects in humans.

171 PHARMACOKINETICS AND PHARMACODYNAMICS OF ERYTHROPOIETIN IN ETHANOL TREATED MICE.

F N Agbo and E J Flynn. *UMD-New Jersey Medical School, Newark, NJ.*
Sponsor: L G Sultatos.

A number of clinical findings in patients implicate ethanol as a causal factor in the development of hematological abnormalities. However, it has been difficult to separate the direct effect of ethanol from the multiple factors existing in the alcoholic patient. Erythropoietin (EPO), normally produced in the kidney, is the major growth hormone that stimulates the proliferation, differentiation and maturation of red blood cells. The hematological observations following chronic ethanol may result from modification of EPO production, changes in EPO disposition and/or alterations in response of its target cells. The current study was undertaken to determine the effect of chronic ethanol administration on the response to recombinant human EPO and on the disposition of EPO. Male adult mice were allowed to drink only ethanol (30% v/v) for 80 days. On day 42 the mice were administered EPO (1.2 μg/30g bw) and the % hematocrit determined over the next 40 days. The area under of percent hematocrit vs time curve was 61.2 in control mice (water treated) compared to only 45.6 in ethanol treated mice. In two other groups of mice, similarly allowed to drink either ethanol or water, EPO was administered iv and its disposition assessed from blood samples withdrawn at various times. There was no difference found in the EPO serum levels in these mice. Since ethanol decreased the response to exogenously administered recombinant human EPO, it is not due to an effect on EPO production or release. Furthermore, since EPO's disposition was unaffected, it appears the decreased effect is a consequence of a qualitative or quantitative change in EPO-responsive cells.

172 HYDROQUINONE ALTERS THE PHOSPHORYLATION STATE OF THE TRANSCRIPTION FACTOR PU.1 IN HUMAN CD34+ HEMATOPOIETIC PROGENITOR CELLS (HPC).

S A Gross, D W Pyatt, Y Yang, J Zheng, and R D Irons. *Molecular Toxicology and Environmental Health Sciences, School of Pharmacy, University of Colorado Health Sciences Center, Denver, CO.*

As part of ongoing studies to elucidate the mechanism of HQ-induced alterations in the regulation of myeloid differentiation, we examined the effects of HQ on PU.1-DNA binding activity in human CD34+/CD19- HPC. PU.1 plays a critical role in myeloid differentiation by regulating genes such as the M-CSF receptor, GM-CSF receptor α, G-CSF receptor, FcγR1, IL-1β, CD18, CD11b and PU.1 itself. Control and HQ-treated CD34+/CD19- HPC (>95%) were cultured in liquid media supplemented with growth factors and the pattern of PU.1-DNA binding was compared in Electrophoretic Mobility Shift Assays (EMSA) over a three day period. Following single exposure to HQ, EMSAs performed with whole cell lysates from treated CD34+/CD19- HPC exhibit a decrease in a faster migrating PU.1-DNA binding species and a subsequent increase in a slower migrating PU.1-DNA binding species. Additional experiments using whole cell lysates reveal that the HQ-induced alterations in PU.1-DNA binding activity are the result of alterations in the phosphorylation state of PU.1 and theses alterations appear to be independent of protein kinase C (PKC) activation. These results demonstrate that HQ-induces an alteration in the phosphorylation state of PU.1 in human CD34+/CD19- HPC and suggests that PU.1 may be an important molecular mediator in benzene-induced alterations in myeloid development.

173 ROLE OF NITROSOBENZENE IN THE SPLENIC TOXICITY OF ANILINE.

M F Khan and X Wu. *Department of Pathology, University of Texas Medical Branch, Galveston, TX, USA.*

To elucidate the mechanism(s) of selective toxicity of aniline to the spleen, studies were conducted with nitrosobenzene (NB), an N-oxidized metabolite of aniline. Male SD rats were given 0.025, 0.05, 0.1 or 0.2 mmol/kg/day of NB in 0.5 ml of 0.25% agar by gavage for four days; control rats received the vehicle only. Animals were euthanized at 24 hr following the last dose. NB exposure resulted in decreased erythrocyte counts, whereas methemoglobin content increased at 0.1 and 0.2 mmol/kg doses. Splenic weight-to-body weight ratios were greater by 55 and 81% at 0.1 and 0.2 mmol/kg NB doses, respectively. Total iron content in the spleen showed dose-dependent increases of 27, 90, 192 and 213% at 0.025, 0.05, 0.1 and 0.2 mmol/kg doses, respectively. Splenic lipid peroxidation also showed a dose-dependent response and was greater by 19, 56, 74 and 85% at the four doses, respectively. Furthermore, NB exposure resulted in greater protein oxidation (carbonyl content) in the spleen at 0.1 and 0.2 mmol/kg doses. These results suggest that NB is a splenotoxin and therefore, can contribute to the splenic toxicity of aniline. Results of this study along with our earlier findings with aniline further support that oxidative stress is a potential mechanism in the splenotoxicity of aniline.

174 COMPARISON OF IN VITRO MYELOTOXICITY OF A NOVEL ONCOLYTIC AGENT, LY355703, TOWARD RAT AND DOG BONE MARROW PROGENITORS.

J L Blackbourne, A G Borel, P J Sausen, and C M Zwickl. *Eli Lilly and Company, Greenfield, IN, USA.*

For several oncolytics in which bone marrow suppression is the dose-limiting toxicity, in vitro inhibition of colony forming unit granulocyte-macrophage progenitors (CFU-GM) has been shown to be predictive of concentrations which cause neutropenia. By comparing the CFU-GM dose response in several species, including humans, the rational selection of a starting dose and escalation intervals may be possible. This could benefit clinical trial patients by arriving at safe, but efficacious doses earlier in the trial. To evaluate this approach in animals, species sensitivities to a novel oncolytic agent, LY355703, were compared in CFU-GM assays following in vitro exposure to the compound. Bone marrow cells from six dogs and six rats (3 per sex) were exposed for 14 hours to target concentrations of LY355703 ranging from 1 to 80 ng/ml, then assayed in the CFU-GM assay using GM-CSF as the sole cytokine. LY355703 concentrations interpolated at 90% colony inhibition (IC_{90}) were used to evaluate the ability of the CFU-GM assay to predict in vivo plasma concentrations at the MTD. The IC_{90} value in the rat and dog was 25.0±6.6(sd) and 14.5±1.0(sd) ng/ml, respectively. Comparison of IC_{90} values to the C_{MAX} at MTDs in toxicity studies in the rat (59.0 ng/ml) and dog (7.2 ng/ml) indicated there was relatively good agreement between the in vitro IC_{90} values and plasma LY355703 concentrations which resulted in significant myelotoxicity in vivo. This suggests that similar determinations of IC_{90} values using human bone marrow cells may be useful for predicting myelotoxic plasma levels of LY355703 in humans.

175 DIFFERENTIAL EXPRESSION OF GLUTATHIONE S-TRANSFERASE ISOZYMES IN K562, HL60 AND U937 HUMAN LEUKEMIA CELL LINES.

J T Piper, S S Singhal, M K Saini, J Cheng, T Zhao, Y C Awasthi and S Awasthi. *The University of Texas Medical Branch, Galveston, TX.*

The K562, HL60 and U937 cell lines have been used extensively to examine the effects of a variety of differentiating agents which may function through increased formation of membrane lipid peroxidation (LPO) products. Because electrophilic products of LPO are substrates for glutathione S-transferases (GSTs), we have studied isozyme compositions and kinetic properties of GSTs in these cell lines which are characterized by distinct morphology and lineage specificity of differentiation. These studies showed GST isozyme compositions were nearly identical for both myeloid origin cell lines, HL60 and K562, with the -class isozyme predominating (64% and 63% of total GST protein, respectively), followed by the µ-class isozymes (32% and 33%, respectively). The -class GSTs (GST A1-1 and A2-2) were absent in the K562 or HL60 cells, but both cell lines contained a GST isozyme, pI 6.0 (4 % and 3%, respectively) which was recognized by antibodies against mGSTA4-4, a GST isozyme belonging to a subclass of -class GSTs with high activity towards the LPO product 4-hydroxynonenal (4-HNE). The -class GST was also predominant in U 937 cells (93%). Unlike the erythroleukemic (K562) and promyelocytic leukemia (HL60) cell lines, GST-µ was not present in monocyte/macrophage origin U937 cells, but these cells contained significant amounts of GSTA 1-1 and GSTA 2-2. The pI 6.0 isozyme was present in U937 cells at levels comparable to K562 and HL60 cells. The catalytic efficiency (kcat/Km) towards 4-HNE was higher for the pI 6.0 isozyme (622 mM-1 s-1) than the -class (17.9 mM -1 s -1) or the µ-class (42.6 mM-1 s-1) GST isozymes, suggesting an important role of this enzyme in detoxification of LPO products. Because individual GST isozymes differ remarkably in their affinity for electrophilic products of LPO, their levels of expression may regulate intracellular levels of LPO products and perhaps the lineage specificity of differentiation. (USPHS grant CA-27967 to YCA and CA63660 to SA.)

176 THE PRESENCE OF A MUSCARINIC RECEPTOR ON CANINE ERYTHROCYTE MEMBRANES.

F W Oehme and R R Dalefield. *Comparative Toxicology Laboratories, Kansas State University, Manhattan, KS, USA.*

A uniform population of M1 muscarinic receptors exhibiting similar pharmacological responses to those in mouse brain homogenates is present on human erythrocyte (RBC) membranes, and there is negligible nonspecific binding (Gen.Pharmac.17,281-285). We undertook this study to determine whether canine RBC membranes contain a similar population of muscarinic receptors. RBC membranes were prepared from canine blood by washing, lysis and serial centrifugation. Protein concentration was determined by the Lowry method. Suspensions of RBC membranes were incubated for various times at 25° C with various amounts of *l*-quinuclidinyl [*phenyl*-4-^{3}H] benzilate (^{3}H-QNB), with and without pre-incubation for 20 min with oxotremorine. RBC membranes were isolated on glass fiber filters by vacuum filtration. Radioactivity of filters and washings was measured and specific binding was calculated by subtracting binding in the presence of oxotremorine (nonspecific binding) from total binding. Using various concentrations of ^{3}H-QNB/membrane protein, association/dissociation curves over time and a Scatchard plot at 40 min were constructed. Muscarinic receptors were present on canine RBC ghosts at a concentration of 0.61 nmol/mg protein and had a K_D of 62.5 nmol. Saturation at 0.45 nmol ^{3}H-QNB/μg protein was reached in a plateau between 20 and 40 min, at which ligand depletion was 2.6%. Practical problems with this model were encountered; adherence of additional molecules of radioligand to receptor-ligand complexes occurred at only twice the radioligand concentration required to ensure saturation. This and other properties, including a mean nonspecific binding of 80% and the need for extensive dilution of RBC membrane suspensions to obtain practical quantities of muscarinic receptors, lead us to conclude that the canine RBC membrane is not a practical model to study

muscarinic receptors and their interactions with cholinergic agonists or antagonists.

177 COMPARITIVE EFFECTS OF PHENYLHYDRAZINE (PHZ) AND PHLEBOTOMY ON PERIPHERAL BLOOD, BONE MAR ROW AND ERYTHROPOIETIN LEVELS IN WISTAR RATS.

K A Criswell, A P Sulkanen, A F Hochbaum, and M R Bleavins. *Pathology and Experimental Toxicology, Parke-Davis Pharmaceutical Research, Warner-Lambert Co., Ann Arbor, MI, USA.*

This study was conducted to better characterize the response of rats to blood loss and hemolysis and to incorporate automated methods into the routine evaluations of those responses. Serial phlebotomies of 1.5 -2.0 mL blood per day for 5 days, or intraperitoneal injections of 50 mg/kg PHZ for 3 days, were used to cause anemia associated with blood loss or hemolysis, respectively. Comparable decreases in red blood counts and hematocrits (30-47%) were achieved in both groups. In the routine complete blood count (CBC), hemoglobin, hematocrit:hemoglobin ratio, and erythrocyte indices, could be used to discriminate between the two treatments. Free plasma hemoglogin in PHZ-treated animals resulted in marked elevations of mean corpuscular hemoglobin (MCH) and mean corpuscular hemoglobin concentration (MCHC) with a 2:1 hematocrit:hemoglobin ratio rather than the anticipated 3:1 ratio. Although both groups of animals had elevated white blood cell counts, PHZ-treated animals also had monocytosis and basophilia. Reticulocyte counts were more sensitive than erythropoietin (EPO) concentrations in predicting erythroid changes. Mean reticulocyte values were approximately 20% in serially phlebotomized animals and greater than 97% in PHZ-treated rats. Plasma EPO levels were 4-10 fold higher than EPO levels in urine, kidney, or liver. Flow cytometric differentials of rat bone marrow using 2'7'-dichlorofluorescin successfully predicted erythroid hyperplasia in both experimental groups. This method also provided information on absolute differential counts and non-nucleated erythrocyte number shifts not detectable either by manual examination of bone marrow smears or by histologic examinations of femur sections.

178 EFFECT OF GENDER ON THE HEMATOTOXICITY OF 2-BUTOXYETHANOL (BE) IN F344 RATS.

B Chanas, S Ward, R Healy, A Nyska, and B I Ghanayem. *NIH/NIEHS, RTP, NC.*

BE is an extensively produced chemical with a wide range of uses. Administration of BE to rodents causes acute hemolytic anemia, and metabolic activation of BE to butoxyacetic acid (BAA) is required for the development of this effect. Recent studies showed that female rats treated with BE exhibited a variety of histopathologic lesions that were absent in males and many of these lesions were attributed to the hemolytic effects of BE. Current studies were designed to compare the hematotoxicity of BE in 3 month old male and female F344 rats. Rats were treated with 250 mg BE/kg (po). At 4, 8, or 24 hr after dosing, rats were anesthetized and EDTA-anticoagulated blood was collected via cardiac puncture. Using the Technicon H1 hematology analyzer, blood parameters were measured and included: red blood cell (RBC) counts, hemoglobin (Hgb), hematocrits (Hct), mean cell volumes (MCV). As expected, BE resulted in a time-dependent swelling of erythrocytes as evident by an early increase in Hct and MCV in both males and females. Subsequently, RBC, Hgb, and Hct declined as hemolysis progressed. However, the onset of BE-induced hemolysis was faster and the severity was significantly greater in females vs. males. In vitro incubation of BAA with blood showed no difference in the sensitivity of RBCs obtained from male and female rats. These data suggest that female rats are more sensitive to BE-induced hemolysis than males and it is likely that gender-related differences in the kinetics of BE and BAA may account for this observation.

179 MOLECULAR AND CELLULAR MECHANISMS OF ANTIOXIDANT ACTION.

D C Liebler. *University of Arizona, Tucson, AZ, USA.*

Antioxidant enzymes and small molecule antioxidants play key roles in cellular defense against reactive oxidants associated with environmental chemicals. Recent work provides new insights into the complex interplay of oxidants and antioxidants and places antioxidant chemistry into a cellular perspective. This symposium will address the chemistry of small molecule antioxidants and the enzymatic linkage of cellular redox metabolism to antioxidant function. The small molecule antioxidants vitamin E and ubiquinol provide mutually supportive antioxidant protection through redox cycles that can be coupled to electron transport pathways. The mitochondrial electron transport protein cytochrome c acts as a redox switch in the control of cellular redox status and may provide a link between mitochondrial redox status and apoptosis. Polymorphisims of NAD(P)H-quinone oxidoreductase (DT-diaphorase) may dictate susceptibility to oxidant stress-related toxicity and new work suggests links the enzyme to regulation of vitamin E antioxidant actions. Other molecular species may be key players in cellular antioxidant function. Emerging evidence suggests that nitric oxide acts both as an important cellular antioxidant and as a prooxidant. Rapidly growing interest in chemoprotective effects of plant derived polyphenols focuses new interest in antioxidant mechanisms and chemistry of green tea catechins, which exert notable chemoprotective actions against chemical carcinogenesis.

180 ANTIOXIDANT LABYRINTHS: VITAMIN E/COENZYME Q TRAILS.

V E Kagan. *University of Pittsburgh, Pittsburgh, PA, USA.*

Free radical challenge results in either physiological adaptive changes (including elevated antioxidant protection) or progresses into execution of cell death mechanisms. Recently, antioxidant recycling has been established as one of the important pathways of antioxidant enhancement. In particular, recycling of vitamin E through ascorbate/thiol-cascades has been shown to operate as an important source of antioxidant equivalents in membranes. Reduced coenzyme Q (CoQ) represents another potentially essential vitamin E recycling mechanism as it links regeneration of vitamin E to major intracellular electron transport pathways. Reduced CoQ, ubiquinol, functions as an important lipid-soluble antioxidant. Our previous work demonstrated that in addition to its direct antioxidant activity, ubiquinol is capable of reducing vitamin E phenoxyl radical i.e., recycle vitamin E. Semireduced CoQ, ubisemiquinone are not realized in the presence of vitamin E. This is due to the ability of ubisemiquinone to reduce vitamin E phenoxyl radicals. As a result, when both CoQ and vitamin E, are present superoxide is consumed in CoQ-mediated vitamin E recycling. We have demonstrated that superoxide-driven recycling of vitamin E is mediated by ubisemiquinone in simple chemical models (an aprotic solvent, DMSO), as well as in enzymatic model systems (human recombinant NADPH-cytochrome P450 reductase and plasma membrane NADH-CoQ reductase). We conclude that vitamin E and CoQ are mutually beneficial as antioxidants because their combination provides for effective scavenging of radicals through redox coupling with the major electron transport pathways.

181 OXIDANTS AND ANTIOXIDANTS IN CELL GROWTH AND APOPTOSIS SIGNALING.

D P Jones, J Cai and S Jiang. *Department of Biochemistry and Program in Molecular Therapeutics and Toxicology, Emory University, Atlanta, GA, USA.*

Improved understanding of the mechanisms of redox signaling and the factors controlling cellular redox is providing new insight into oxidant induced toxicity. Of particular importance, effects on normal redox signaling provide a mechanism whereby oxidants can cause toxicity and antioxidants can protect against toxicity through subtle changes that can occur without irreversible oxidative damage to macromolecules. Under normal conditions, mitochondria are a major source of reactive oxygen species (ROS) that determines the redox poise of the cell. Apoptosis occurs in association with a substantial oxidation of cytosolic redox state. In staurosporine-induced apoptosis, oxidation occurs due to enhanced superoxide generation triggered by the release of cytochrome c (cyt c). Mitochondrial loss of cyt c results in a switch in electron flow from the normal 4-electron reduction of O(to water, to a pathway in which only 1 electron is transferred to O2. This switch is blocked by Bcl-2, indicating that regulation of distribution of redox active components provides an underlying control of redox signaling and phenotype control. (° cells, which lack a mitochondrial genome and do not consume oxygen, maintain cyt c-dependent activation of apoptosis and redox signaling. Antioxidants inhibit or delay apoptosis in several systems but do not interfere with cyt c-dependent activation of caspase 3. Thus, the data indicates that oxidants can exert toxicity and antioxidants can modulate this toxicity by altering redox signaling pathways that function to control cell phenotype, proliferation and apoptosis.

182 DT-DIAPHORASE (NQO1) AS AN ANTIOXIDANT ENZYME. RELEVANCE OF POLYMORPHISMS IN NQO1 FOR CHEMOPROTECTION.

D Ross. *Department of Pharmaceutical Sciences, School of Pharmacy, University of Colorado Health Sciences Center, Denver, CO, USA.*

NQO1 is an obligate two electron reductase that catalyzes the reduction of a wide variety of substrates including quinones. Since reduction of quinones to hydroquinones generally results in the production of less reactive species, NQO1 is considered to be a detoxification enzyme. Many xenobiotic quinones are substrates for NQO1 but endogenous substrates have been more difficult to identify. Recently, NQO1 has been shown to catalyze reduction of ubiquinone and (-tocopherolquinone (TQ) to their antioxidant hydroquinone forms. TQ is formed via free radical attack on (-tocopherol and has no intrinsic antioxidant activity while its hydroquinone derivative is a potent antioxidant. This data suggests that one of the physiological functions of NQO1 may be to regenerate antioxidant forms of (-tocopherol after free radical attack. We have characterized a polymorphism in NQO1, a single point mutation coding for a proline to serine change in the protein. Cells carrying the homozygous mutation have no detectable NQO1 activity and genotype-phenotype relationships have been confirmed in human tissues. The prevalence of the NQO1 polymorphism varies from 4-22% as a function of ethnic group. A lack of NQO1 activity due to the polymorphism may result in a decreased capacity to protect against oxidative damage and has potential implications for chemoprotection. Individuals carrying the NQO1 polymorphism are more susceptible to hematotoxicity after occupational exposure to benzene and the role of the NQO1 polymorphism in susceptibility to various cancers is also under investigation. (Supported by CA 51210 and EPA R825281.)

183 THE ANTIOXIDANT ACTIVITIES OF NITRIC OXIDE.

N Hogg, R J Singh, S P A Goss, and B Kalyanaraman. *Biophysics Research Institute, Medical College of Wisconsin, Milwaukee, WI, USA.* Sponsor: D C Liebler.

Nitric oxide (NO) is a hydrophobic free radical whose synthesis is catalyzed in vivo by the action of nitric oxide synthase. NO is multifunctional, and in some cases its actions are paradoxical. This is exemplified in studies of oxidative stress where NO has been demonstrated to have both pro- and antioxidant activities. In general, the pro-oxidant activities are associated with high flux NO formation or with co-generation of a secondary species (e.g. superoxide, hydrogen peroxide). The antioxidant activity tends to be associated with low flux NO. In addition, the terms 'pro-oxidant' and 'antioxidant' are relative to the biomolecule under examination. If lipid peroxidation is used as an index of oxidative stress then the following picture emerges. i) NO does not oxidize unsaturated lipid when generated slowly. ii) Rapid generation of NO or bolus additions of NO can oxidize lipid due to the formation of higher oxides of nitrogen. iii) Co-generation of NO and superoxide oxidizes lipid due to peroxynitrite formation. iv) Nitric oxide inhibits lipid oxidation when initiated by additional oxidants (e.g. copper ions/hydroperoxide, azo-initiators, iron/hydrogen peroxide, SOD/hydrogen peroxide, ferryl heme complexes, peroxynitrite). The mechanism of inhibition appears to be either the scavenging of the initiating agent or the scavenging of the propagatory lipid peroxyl radical. NO, on a mole-per-mole basis, is about a 105-times more potent peroxyl radical scavenger than (-tocopherol. The elevation of endothelial superoxide formation observed in hypercholesterolemia and hypertension is likely to remove the protective and regulatory effects of vascular NO and replace them with the pro-oxidant effects of peroxynitrite. Peroxynitrite has been implicated in several vascular pathologies.

184 ANTIOXIDANT CHEMISTRY OF GREEN TEA CATECHINS.

D C Liebler. *Department of Pharmacology and Toxicology, University of Arizona, Tucson, AZ, USA.*

Extracts of green tea are effective inhibitors of chemical and physical carcinogenesis. These activities are thought to be due in large part to antioxidant actions of catechins (flavan-3-ols) including (-)-epigallocatechin gallate (EGCG) and (-)-epigallocatechin (EGC). We have found that EGCG reacts with peroxyl radicals in aqueous acetonitrile to yield a novel seven-membered B-ring anhydride and a symmetrical B-ring oxidized dimmer as major antioxidant reaction products. The B-ring of EGCG appeared to be the exclusive site of antioxidant reactions. Analogous products were formed in antioxidant reactions of EGC, which lacks a 3'-galloyl moiety. Surprisingly, the model compound methyl gallate, which is similar to the 3'-galloyl moiety in EGCG was largely unreactive under the same conditions. The identification of product structures provides potential markers for EGCG antioxidant reactions. Although reaction with peroxyl radicals certainly is among the most probable antioxidant reactions of polyphenolic compounds in biological systems, reactions with the other oxidants singlet oxygen, peroxynitrite and hydroxyl radicals also may occur. The identification of oxidant-specific products together with the application of sensitive and specific analytical methods will provide analytical approaches to evaluating the antioxidant actions of catechins in biological systems. (Supported by NIH grants CA 75599 and ES06694.)

185 BIOTECHNOLOGY PRODUCTS: NOVEL COMPOUNDS AND CHALLENGING TOXICOLOGY.

D K Monteith. *Isis Pharmaceuticals, Carlsbad, CA, USA.*

Biotechnology is a significant industry with over 300 compounds for the treatment of human disease in development by over 100 companies. Inherent in the design of these products is species specificity, and thus, testing in animals may indicate adverse effects unique to the animal model. Also, animal models will not typically identify potential exaggerated pharmacologic effects. Thus, selection of animal models is critical to the appropriate evaluation of effects relevant to humans. Typically, these compounds are evaluated in non-human primates because of the potential homology with humans. In addition, other novel animal models or testing strategies are adopted so that safety may be characterized to allow the ethical administration of these agents to patients. Toxicology testing strategies and regulatory issues for the evaluation of recombinant proteins, cytokines, gene therapy, and oligonucleotides will be presented for a few selected compounds. The information in this session should be of interest to individuals in the pharmaceutical and regulatory sectors. In addition, the methodology associated with the use of these agents will be useful to basic researchers.

186 ANTISENSE OLIGONUCLEOTIDES: TOXICOLOGY FROM MICE TO HUMANS.

D K Monteith, R Geary, S P Henry, M Templin, and A A Levin. *Isis Pharmaceuticals, Carlsbad, CA, USA.*

Antisense therapeutics are modified oligodeoxynucleotides (ODN) that have species and target specificity derived from the genetic code and Watson-Crick base-pairing. These antisense therapeutics demonstrate broad tissue distribution in animal models and cellular uptake. Toxicities and pharmacokinetics are independent of sequence (i.e. effects observed regardless of molecular target). Currently, most antisense ODNs in development contain a sulfur substitution for an oxygen in the nucleotide linkage resulting in a phosphorothioate (P=S) backbone. In general, toxicities of these compounds correlate well with pharmacokinetic or tissue distribution parameters. The preclinical testing strategy typically involves mice and primates. In mice, both the human and murine specific homologues are evaluated to assess general toxicities, as well as target specific effects of suppression of protein translation (i.e., exaggerated pharmacology). In many instances, the pharmacology models evaluate the efficacy of an animal specific antisense ODN. However, human tissue xenograft models with immune deficient mice can be used to evaluate the efficacy and toxicity of a human antisense ODN in an animal model. In clinical studies, P=S ODNs induce only minimal side effects as is predicted by the animal studies and the large margin of safety established in preclinical evaluations. Specific examples of preclinical testing strategies for antisense oligonucleotides targeting cancer and inflammation will be presented.

187 GENE THERAPY: CHALLENGES IN THE DESIGN AND INTERPRETATION OF TOXICOLOGY STUDIES.

M E I Leibbrandt. *Department of Toxicology, Chiron, Emeryville, CA, USA.*

The ability to deliver genes through retroviral, DNA and other vectors provides exciting opportunities for the management of disease while demanding creative approaches to safety evaluation of these novel agents. For example, gene therapies require assays which assess biodistribution of the gene or vector, activity of the final product, and its efficacy in animal models. Because

gene therapy can require targeting to and uptake by appropriate cell types, transport to the nucleus, integration into native DNA, mRNA expression and translation, protein processing and functional activity, there are numerous steps at which successful therapy may fail or inadvertent toxicity develop. Toxicity may be associated with the inappropriate expression of the gene product or with the vector particle itself. Laboratory methods such as PCR and in situ hybridization assays are standard tools for the safety evaluation of gene therapies. A retroviral vector gene therapy for hemophilia A will be used to illustrate unique issues in the design and interpretation of nucleic acid-based toxicology studies.

188 CONSIDERATION OF BIOLOGY IN THE DESIGN OF TOXICOLOGY STUDIES TO SUPPORT CLINICAL DEVELOPMENT OF NEUROTROPHIC FACTORS.

H Davis, D Miller, A Standeven, C LeBel. *Amgen, Thousand Oaks, CA, USA.*

Amgen is developing neurotrophic factors (GDNF, NT-3 and BDNF) for Parkinson's Disease, peripheral neuropathies (PN) and amyotrophic lateral sclerosis (ALS), respectively. Intracerebroventricular (ICV) GDNF improved behavioral performance in 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine-lesioned (MPTP) monkeys. The ICV route was chosen to target dopaminergic neurons in the brain, to avoid the blood brain barrier and to avoid potential systemic side effects from GDNF receptors outside of the CNS. Monkeys treated monthly with ICV injections of GDNF had transient vomiting and weight loss at 75, 500 and 3,000 10 g/month. GDNF caused inflammation in the CNS and Schwann cell proliferation secondary to axonal sprouting in the pia mater and dorsal nerve roots, but no systemic histopathology. NT-3 was efficacious in pyridoxine-, cisplatin-, and streptozotocin-induced PN in rats. Chronic studies were performed in the rat and monkey with neuropathological findings limited to the rat. Rats received NT-3 at doses of 2, 10, or 30 mg/kg/day subcutaneously for 3/6 months. Reductions in body weight and food consumption occurred in all NT-3 groups. Myelinated fiber degeneration in sciatic nerves and neurofilament swellings in dorsal root ganglion neurons occurred at 10 and 30 mg/kg/day. BDNF promotes survival of developing and adult motoneurons. BDNF was administered intrathecally (IT) for 28 days in dogs and monkeys. Dogs were more sensitive to IT BDNF and were chosen for chronic IT studies. Dogs were treated by continuous IT infusion of 100, 300 or 1,000 10 g/day for 3/6 months. Prolonged IT catherization caused gross and histological changes. BDNF was well tolerated but caused hyperactivity and hindlimb effects including twitching and tremors at 1000 10 g/kg. Understanding the molecular biology and pharmacology of GDNF, BDNF, and NT-3 was fundamental to the design and interpretation of data from these toxicology studies.

189 ISSUES AND STRATEGIES IN THE DEVELOPMENT OF RECOMBINANT HUMAN INTERLEUKIN-4 (rhuIL-4).

M W Leach. *Schering-Plough Research Institute, Lafayette, NJ, USA.*

Interleukin-4 (IL-4) is a potent immunoregulatory cytokine. Initial preclinical biology studies showed activity against tumors, and thus the initial clinical indication was cancer. As rhuIL-4 was biologically active only in primates, safety studies were conducted primarily in the cynomolgus monkey. Single and repeated dose toxicology studies, with daily administration for up to six months, were conducted. Genotoxicity and developmental toxicity studies were also performed. Mortality, cardiotoxicity (inflammatory cell infiltrates and necrosis), and hepatotoxicity (inflammatory cell infiltrates and necrosis) were the most significant findings observed during the preclinical toxicology studies. Although these preclinical toxicology findings were significant, initial clinical trials were conducted in patients with terminal cancer where the benefit/risk ratio was high. Based on the preclinical toxicology findings, these patients were required to undergo extensive monitoring, including endomyocardial biopsies. Administration of rhuIL-4 was generally safe and well tolerated in human patients. The significant toxicity observed in monkeys was not generally seen, allowing initiation of clinical trials in non-life threatening conditions. To further determine whether the mortality, cardiac, and hepatic changes in the monkey were related to a response to the heterologous rhuIL-4 cytokine, recombinant murine IL-4 was administered to three strains of mice (BALB/c, C57BL/6, CD-1) selected for their differing immune responses. Doses were selected to provide 1X and 10X multiples of the systemic exposure in monkeys that resulted in significant toxicologic changes in the monkeys. Administration of the homologous IL-4 cytokine to mice, even at extremely high systemic exposures, did not reproduce the most significant toxicologic changes observed in monkeys receiving the heterologous IL-4 cytokine. As humans receiving homologous (rhu) IL-4 also lack the significant findings seen in the monkey, the toxicologic changes in monkeys may be related to atypical immunologic responses to the heterologous IL-4 cytokine, and may not represent relevant risks to humans receiving homologous IL-4.

190 DEFINING RELEVANT ANIMAL SPECIES FOR TOXICITY EVALUATION OF BIOLOGIC THERAPEUTICS; CRITICAL GROUNDWORK FOR BASING PRECLINICAL TOXICITY PROGRAM STRATEGIES.

L E Black and M D Green. *Food and Drug Administration, CBER/OTRR, Rockville, MD, USA.*

Unlike the development programs for small molecule drugs which typically employ two or more species, one relevant animal species may be sufficient to characterize the toxicity of biologic therapeutics (BTs). However, the value of the data derived from a single species is dependent on establishing a scientific basis for extrapolating between the laboratory species and human patients. This talk will focus on BT toxicity programs where the availability or absence of this scientific basis aided or impeded clinical development. Numerous factors contribute to establishing the correlation between animal and human responses; among these are the species differences which may affect the presence of functional receptors, physiologic role of cytokines, endogenous inhibitory/regulatory pathways, and dispositional or pharmacokinetic factors. Interferons are a well known example of species-specific receptor binding. However, some cytokines, like IL-2, produce similar toxicity profiles across a number of species. In cases where cross-reactivity is broad, toxicity model selection may be guided by avoiding species in which the human drug product is highly immunogenic. Selection of a relevant animal model may involve in vitro binding and activity studies, in vivo response profiles, or transgenic models. When no useful animal species can be identified, toxicity studies with analogous products may be useful in evaluation of toxicity.

191 VALIDATION OF TOXICOLOGY TEST METHODS: IMMUNOTOXICOLOGY CASE STUDIES.

G F Gerberick and A E Munson[1]. *Procter & Gamble, Miami Valley Laboratories, Cincinnati, OH, USA; [1]NIOSH/HELD, Morgantown, WV, USA.*

In the US and Europe guidelines exist for evaluation and validation of new alternative test methods. These guidelines have been used as a framework for the assessment of novel methods which offer benefits in the context of the requirement for experimental animals with respect to Replacement, Reduction and/or Refinement. The objective of this Workshop is to use examples, primarily form the discipline of Immunotoxicology, to consider the strategies necessary to gain acceptance of novel test methods by regulatory authorities and to bring to the attention of the toxicology community the issues that need to be addressed in assay evaluation and validation. The current guidelines used for consideration of alternative methods will be reviewed with particular emphasis on those developed by the Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM). As a classic illustration of a validation exercise, the evaluation of a novel phototoxicity method, the 3T3 Neutral Red Uptake Phototoxicity Assay, will be discussed. In addition, a rather different approach used for the assessment of the local lymph node assay, a method for the identification of contact allergens, will be described and the current validation status of this method discussed. Finally, the validation needs of the methods currently available for the identification of potential immunotoxicants will be considered in the context of new and emerging regulatory requirements. The main goal of this workshop is to stimulate discussion between those who are applying modern science to the development of novel approaches to toxicity testing and those charged with evaluating those new methods to ensure the level and consistency of performance necessary for regulatory acceptance.

192 GUIDELINES FOR VALIDATION AND ACCEPTANCE OF TOXICOLOGY TESTING METHODS.

W S Stokes. *Environmental Toxicology Program, National Institute of Environmental Health Sciences, Research Triangle Park, NC, USA.* Sponsor: G F Gerberick.

Innovative new alternative test methods offer the potential benefits of improved safety assessments, greater efficiency (less expense and time), and refinement, reduction, and replacement of animal use. Before new test methods are used to generate information to support regulatory decisions, validation studies must be conducted to determine their performance characteristics, limitations, and usefulness for specific proposed uses. These results are used to determine the acceptability of the method for regulatory risk assessment purposes. Criteria and guidelines for test methods to be considered adequately validated and acceptable for regulatory risk assessment purposes have been published in a recent report prepared by an ad hoc Federal interagency committee. An Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM) and an Interagency Center for the Evaluation of Alternative Toxicological Methods (Center) have been established by the U.S. government to work with federal agencies and test developers to coordinate the evaluation and adoption of new test methods. The Center and ICCVAM collaborate to provide guidance to agencies and developers on criteria and processes for test method validation and acceptance; coordinate technical peer reviews of proposed new test methods of interagency interest; facilitate information sharing among agencies; and serve as an interagency resource and communications link with test method developers. These guidelines and initiatives seek to encourage the development, validation, and acceptance of new methods that will provide enhanced protection of public health and the environment, and that will benefit animal welfare where scientifically feasible.

193 IN VITRO 3T3 NEUTRAL RED UPTAKE PHOTO-TOXICITY TEST (3T3 NRU PT): A COORDINATED VALIDATION PROCESS.

H Spielmann. *ZEBET (National Center for Validation and Evaluation of Alternative Methods to Animal Experiments) at the BgVV (Fed. Inst. for Health Protection of Consumers and Veterinary Medicine), Berlin, Germany.* Sponsor: G F Gerberick.

UV-absorbing chemicals are employed as ingredients in various cosmetic products. Until now an accepted protocol to test for photoirritation potential does not exist. In 1991 the EU Validation Centre ECVAM (Ispra, Italy) and COLIPA (Brussels), the European Cosmetic, Toiletry and Perfumery Association, agreed to establish a joint EU/COLIPA program on developing and validating in vitro phototoxicity tests. The first phase (1992-93) was designed as a prevalidation study to identify in vitro test procedures for a validation trial under blind conditions. In the second phase (1994-95) the most promising in vitro phototoxicity tests were validated with 30 carefully selected test chemicals in 11 laboratories in a blind trial, in which the 3T3 NRU PT test was carried in all laboratories. The purpose of the second phase was to confirm reliability and relevance of the in vitro tests to predict phototoxic effects and to identify photoirritant chemicals. Results obtained with the 3T3 NRU PT test in the second phase were reproducible and the correlation between in vitro and in vivo data was very high even for chemicals insoluble in water. Therefore, in 1997 ECVAM and in 1998 the EU Direction Generals III (industry) and IX (environment) (both Brussels, Belgium,) concluded from the formal validation study under blind conditions "that the 3T3 NRU PT test is well validated test that is ready to be used for regulatory purposes".

194 LOCAL LYMPH NODE ASSAY: AN APPROACH TO VALIDATION AND CURRENT REGULATORY STATUS.

I Kimber. *Zeneca Central Toxicology Laboratory, Macclesfield, England.*

The murine local lymph node assay (LLNA) is a method for the identification of chemicals which have the potential to cause skin sensitization and allergic contact dermatitis. Contact sensitizing activity is measured as a function of proliferative responses induced in draining lymph nodes by topical exposure of mice to the test chemical. The performance of the LLNA has been compared with that of guinea pig predictive tests (the guinea pig maximization test and the occluded patch test of Buehler) and with the human maximization test. In addition, the assay has been evaluated extensively in the context of both national and international inter-laboratory trials. These investigations have demonstrated that the LLNA provides a reliable means of assessing the skin sensitization potential of chemicals and yields equivalent results when performed in independent laboratories. Moreover, it is clear that the assay is sufficiently robust to embrace minor procedural modifications without performance being compromised. On this basis it is proposed that the LLNA is suitable for use as a 'stand alone' method for the evaluation of sensitizing activity and as such provides a realistic alternative to guinea pig methods, not only for the accurate identification of contact allergens, but also for confirmation of the absence of skin sensitizing potential. It is in this context that the regulatory status of the LLNA is currently being considered.

195 VALIDATION STATUS AND REGULATORY ACCEPTANCE OF LABORATORY ANIMAL-BASED TESTING METHODS TO ASSESS DRUG AND CHEMICALLY-INDUCED IMMUNOSUPPRESSION.

P T Thomas. *Covance Laboratories Inc., Madison, WI, USA.*

The impact of environmental chemical immune dysregulation is of particular importance to children and the unborn fetus. Furthermore, unintentional immunosuppression in non clinical safety studies can have a significant impact on the drug development process and on the design of human clinical trials. It is for these reasons that considerable attention has been paid in recent years to the predictability of laboratory animal-based immune function assays. In an early effort to determine the utility of incorporating functional assays of immunity and host challenge into standardized subchronic toxicology studies, the National Toxicology Program sponsored a multilaboratory validation exercise in which performance of over 15 functional tests and challenge assays was evaluated. Furthermore, to improve risk assessment, the degree to which immune function correlated with experimental infectivity or tumor challenge assays was determined. The results of evaluation of more than 50 compounds in carefully designed study protocols demonstrated that: (1) the degree of correlation between host challenge models and immune function assays was good; and (2) certain combinations of assays were reliable predictors of immunotoxicity in rodents when employed in screening protocols. The functional tests that comprise the screening batteries represent immunologically relevant endpoints that are common to both rodents and humans. Many of the compounds evaluated in this exercise, however, were known or potential carcinogens. Nevertheless, pharmacokinetic and toxicokinetic differences must be taken into account during interspecies extrapolation. The results of this and other studies will be discussed in the context of risk assessment and future validation needs will be identified.

196 ANIMAL MODELS OF CARDIOPULMONARY DISEASE: IMPACT OF AIR POLLUTION ON AT RISK POPULATIONS.

J T Zelikoff[1] and D L Morgan[2]. [1]*New York University School of Medicine, Tuxedo, NY, USA;* [2]*NIEHS, Research Triangle Park, NC, USA.*

The adverse effects of exposure to ambient air pollution are often manifested primarily in individuals within certain segments of the general population. One such group may be those with preexisting cardiopulmonary disease. For example, evidence from various disciplines strongly suggests that individuals with preexisting heart and respiratory conditions are more susceptible to ambient particulate matter. This may be due to differences in dosimetry, exposure patterns or the influence of various lesions upon biological response to inhaled pollutants. Studies using animal models which mimic human disease conditions are essential to obtain data for exposure and dose modeling in such susceptible subgroups, to examine the mechanisms by which such individuals may succumb to environmental insults and to understand host characteristics which place individuals at increased risk. Use of these models allows for studies which cannot be carried out in humans. However, an understanding of the similarities and differences between the animal model and the actual human disease state is essential in order to correctly interpret data obtained in such studies.

197 ANIMAL MODELS OF CARDIOPULMONARY DISEASE: ROLE IN AIR POLLUTION TOXICOLOGY.

R B Schlesinger. *Department of Environmental Medicine, NYU School of Medicine, Tuxedo, NY, USA.*

The adverse effects of exposure to ambient air pollution are often manifested primarily in individuals within certain segments of the general population. One such group may be those with preexisting cardiopulmonary dis-

ease. For example, evidence from various disciplines strongly suggests that individuals with preexisting heart and respiratory conditions are more susceptible to ambient particulate matter. This may be due to differences in dosimetry, exposure patterns or the influence of various lesions upon biological response to inhaled pollutants. Studies using animal models which mimic human disease conditions are essential to obtain data for exposure and dose modeling in such susceptible subgroups, to examine the mechanisms by which such individuals may succumb to environmental insults and to understand host characteristics which place individuals at increased risk. Use of these models allows for studies which cannot be carried out in humans. However, an understanding of the similarities and differences between the animal model and the actual human disease state is essential in order to correctly interpret data obtained in such studies.

198 MODELS OF ASTHMA/ALLERGY.

T Gordon. *NYU School of Medicine, Tuxedo, NY, USA.*

Considerable evidence has demonstrated that gaseous and particulate pollutants can alter the incidence or severity of asthma. Among the body's portals to the external environment, the mammalian respiratory system has the largest surface area. Correspondingly, a specialized and partially compartmentalized immune system has evolved for protection against inhaled microbes and particulate and gaseous agents. Several endogenous and exogenous factors could play a role in the acute exacerbation of asthma, which is characterized by reversible (typically) airway obstruction, inflammation, and airway hyperresponsiveness. Hence, an important issue to be considered in examining the effect of air pollution on allergic asthma is its effect on the localized immune system's response to inhaled antigen. This talk will discuss animal models that are appropriate for: 1) examining the potential of inhaled agents to produce or exacerbate asthma and 2) studying the mechanisms involved in pollutant induced allergic asthma. A number of investigators have studied air pollution induced alterations in immune effector cells in the lungs of mice, rats, and guinea pigs. Studies have also directly examined the effect of pollutants on specific allergic responses in these test animals. This talk will focus on the utility of each animal model and its relevancy to the human disease process.

199 MODELS OF CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD).

D L Costa. *Pulmonary Toxicology Branch, ETD/ NHEERL, USEPA, Research Triangle Park, NC, USA.*

Clinically, COPD encompasses an array of lung diseases that exhibit a pattern of chronic impairment of airflow, especially upon forced expiration. However, while asthma and fibrotic disease affect airway structure and function, the term COPD most often is reserved for chronic bronchitis and emphysema. These diseases alter airway function via distinct mechanisms, mucus obstruction and loss of structurally tethering, respectively. In the human, these conditions typically develop over decades and frequently coexist - often associated with smoking. In contrast, the animal models of these conditions are usually the result of an imposed injury or insult which relatively rapidly progresses to disease, and it is this pathophysiology which is often studied along with various investigations of therapeutic mitigation. Bronchitis models can be induced by protracted high level exposure to SO2 or subacute inhalation to LPS, both of which stimulate mucus secretion and goblet cell proliferation. This disease in animal models, however, is largely reversible. Emphysema, on the other hand, is typically irreversible (as in the human) induced by exposure of the lung to elastolytic enzymes which damage and promote abnormal remodeling of the alveoli with overinflation and loss of compliance. The elastolytic process is thought to be part of the human pathophysiology as well. Recently, genetic models that spontaneously develop emphysema have also gained interest. Collectively, these models have had limited applications in air pollution studies representing potential susceptible groups, but have yielded only marginal evidence of unusual sensitivity. However, recent attempts to combine these models to sustain an inflammatory component of disease appear to be both more representative of the human disease and more promising. (Does not reflect EPA policy.)

200 MODELS OF RESPIRATORY INFECTION.

J T Zelikoff. *New York University School of Medicine, Nelson Institute of Environmental Medicine, New York, NY, USA.*

The imposition of respiratory infections in otherwise healthy animals is often used in an attempt to reflect those disease processes in humans. A variety of infectious agents have been used to develop models of respiratory infections in rodents. Viral infectivity in rodents, achieved by a variety of methods including intranasal inoculation and/or intratracheal instillation with influenza, respiratory syncytial virus, and parainfluenza type 1, focus primarily upon pollutant induced changes in viral proliferation, clearance, and associated pulmonary injury, or pathology. Alternatively, bacterial infectivity models have long been used to demonstrate air pollution induced increases in bacterial infection and related mortality. Although not as common as viral infections in healthy individuals, respiratory bacterial infections can be quite pathogenic in humans. In general, infected rodent models develop symptoms similar to those in humans; however, the pathologic outcome in rodents usually tends to be relatively mild in comparison, possibly because of the absence of human predisposing factors. While bacteria such as Hemophilus influenzae, Pseudomonas aeruginosa, and Staphylococcus aureus have been used with the aim of assessing pollution induced changes in susceptibility to a subsequent infection, the majority of studies have employed Streptococcus species. Although most previously performed studies have involved pre-exposure to the pollutant followed by bacterial challenge, in light of more recent studies demonstrating the ability of particulate air pollutants to exacerbate ongoing infections, interest is increasing in examining the effects of pollutant exposure on previously infected hosts. (Supported by contracts from CIAR# 94 03 and HEI # 95.)

201 MODELS OF CARDIAC AND CARDIOPULMONARY VASCULAR DISEASE.

U P Kodavanti. *NHEERL, U. S. Environmental Protection Agency, Research Triangle Park, NC, USA.* Sponsor: D L Costa.

There is an intimate hemodynamic relationship between the heart and the lung, such that disease of either organ is likely to impair the function of the other. The pathogenesis of hypertension and cardiac disease leading to congestive heart failure typically involves an initial cardiac burden, adaptive remodeling of the vasculature, cardiac tissue damage, and ultimately heart failure. Just as systemic hypertension and congestive heart failure are associated with impaired pulmonary function, chronic obstructive pulmonary disease is a common cause of right cardiomegaly. A number of genetic, surgical and chemical-induced animal models are available to represent human cardiac and cardiopulmonary diseases, each with advantages and disadvantages in regards to their ability to mimic human pathobiology, their ready availability, or ease of induction. The extent of cardiac involvement is critical in defining susceptibility to air pollution-related mortality and morbidity in cardiopulmonary compromised humans: thus, animal models representing these diseases offer an opportunity to investigate plausible biologic mechanisms underlying their susceptibility. Recently, a monocrotaline-induced pulmonary vasculitis/injury model has shown particulate matter (PM)-induced alterations in cardiac function leading to mortality. On the contrary, a hamster model of congestive heart failure was shown not to be more susceptible to PM. We have used a genetically based systemic hypertension model to assess susceptibility to inhaled PM and noted that hypertensive rats exhibited increased vascular leakage and pulmonary hemorrhage, but not inflammation/inflammatory cytokine expression in the lung. Thus, the availability of cardiac and cardiopulmonary disease models opens an avenue to pursue not only the susceptibility issue but also to understand the overall systemic host responsiveness in disease pathogenesis. (This abstract does not necessarily reflect EPA policy.)

202 THE UTILITY OF DATA FROM ANIMAL MODELS OF CARDIOPULMONARY DISEASE FOR AIR POLLUTION RISK ASSESSMENT.

J L Mauderly. *Lovelace Respiratory Research Institute, Albuquerque, NM, USA.*

The Clean Air Act mandates that the National Ambient Air Quality Standards be set to protect health "with an adequate margin of safety". Congress noted that the standards should protect "particularly sensitive citizens". Examples of air quality standards strongly influenced by estimated

risks to individuals having cardiopulmonary disease include carbon monoxide (coronary vascular disease and angina), ozone (exercising asthmatics), and particulate matter (the elderly with cardiopulmonary disease). The precision with which we can judge risks to sensitive subpopulations from epidemiological data is limited, and human exposure studies of seriously compromised individuals are limited by ethical concerns. Validated animal models of human cardiopulmonary disorders are needed to bolster the mechanistic foundations for pollution health relationships, and may, with sufficient ancillary knowledge, aid in the development of quantitative estimates of risk. Toxicological data are reviewed in the setting of all standards, but few standards are based primarily on results from animals. Reliance on animal models requires validation that the model accurately mimics the human condition, or some important feature of the condition, knowledge of the comparative sensitivities of both normal and abnormal animals and humans, and a high level of confidence in dosimetric extrapolations.

203 POTENTIATION OF ENVIRONMENTAL TOXICANTS CONTRIBUTES TO FROG DEFORMITIES.

J G Burkhart[2], D J Fort[1], T L Propst[1], E L Stover[1], K Gallagher[2] and J C Helgen[3]. [1]*The Stover Group, Stillwater, OK;* [2]*NIEHS Research Triangle Park, NC;* [3]*MPCA, St. Paul, MN.*

Evaluation of water samples from reference sites and sites associated with the increased incidences of malformations in frogs has revealed that separate environmental factors isolated from sites with low rates of malformation were capable of potentiating the toxicity of water from affected sites when tested in *Xenopus*. C-18 concentration followed by methanol gradient elution of pond water from affected sites has produced fractions that induce abnormal embryo-larval development (organogenesis) and limb mal-development in *Xenopus*. Various organic compounds have been identified within those fractions. Similar treatment of water from reference sites produced fractions which did not induce toxicity. However, addition of these nontoxic methanol fractions isolated from the reference sites to unaltered pond water from the affected sites markedly increased the incidence rate and severity of deformities produced. Compounds have been identified in the potentiating fractions and little similarity exists with the chemicals identified in the affected sites. The primary composition of the potentiating fractions appears to be a series of sterols and phytoestrogen-like compounds. Because the potentiating fractions are also capable of interfering with advanced stages of metamorphosis, the potentiating factors appear to be interfering with normal endocrine activity, particularly in the thyroid axis. Overall, these results indicate that complex mixtures such as those found in the environment must be thoroughly evaluated for potential toxicant interactions.

204 SULFONYL UREA HERBICIDES DISRUPT NORMAL LIMB DEVELOPMENT AND TAIL RESORPTION IN *XENOPUS LAEVIS*.

D J Fort[1], T L Propst[1], R Rogers[1], E L Stover[1], D Rappaport[2]. [1]*The Stover Group, Stillwater, OK;* [2]*The Vermont Public Interest Research Group, Montpelier, VT.*

Two sulfonyl urea herbicides, sulfometuron methyl (CAS #074222-97-2) and nicosulfuron (CAS #111991-09-4), were evaluated for effects on limb development (day 0-30) and impact on metamorphosis in *Xenopus*. In these studies, the rate of tail resorption was monitored as a morphological biomarker of thyroid disruption. A 14-d test starting at stage 60 (ca. day 50) and continuing through stage 66 (ca. day 64) was performed. During the 14-day assay, the rate of tail resorption was monitored by video image capture and tail length digitization at stages 63-66. The NOAEC and LOAEC values for limb development following exposure either to sulfometuron methyl or nicosulfuron were 0.01 and 0.05 mg/L, respectively. Malformations induced by sulfometuron methyl included selective reduction deficiencies distal to the femur. Malformations induced by nicosulfuron were similar to those observed with sulfometuron methyl, but also included a general necrosis of the soft tissue (connective tissue) throughout the hind limb. For sulfometuron methyl, the NOAEC and LOAEC values for tail resorption inhibition were 0.001 and 0.01 mg/L, respectively. For nicosulfuron, the NOAEC and LOAEC values for tail resorption inhibition were 0.0001 and 0.001 mg/L, respectively. Addition of 100 μ g/L thyroxin partially reversed the inhibitory effects of both sulfonyl urea herbicides. Results from the studies clearly document the importance of evaluating longer-term developmental processes in amphibians to assess ecological hazard.

205 BIOMONITORING OF ACRYLAMIDE EXPOSURE BY IMMUNOASSAY.

J L Wong[1,2], Y T Zheng[1], G Gang[1], C H Tamburro[2], and F S He[3]. *Departments of* [1]*Chemistry and* [2]*Pharmacology & Toxicology, University of Louisville, Louisville, KY, and* [3]*Chinese Academy of Preventive Medicine, Louisville, KY.*

Acrylamide (AM) is a ubiquitous chemical used in the manufacture of suntan lotion, soaps, shampoo, cosmetics, in water treatment systems, etc. Concerns are raised by FDA, EPA, TSCA about its potential neuro, reproductive, and carcinogenic toxicity at presently detectable levels. A simple, sensitive and accurate immunoassay for biomonitoring acrylamide exposure via hemoglobin (Hb) adduct has been developed. This study's goal was to determine the relationship between the Hb-AM biomarker levels and health effects of AM by surveillance of acrylamide workers and suburban residents. A monoclonal antibody reagent is added to a microplate as the first layer of a sandwich immunoassay. Hemoglobin of subjects is added to the plate as a second layer of the sandwich with any Hb-AM present binding with the monoclonal antibody. An anti-human hemoglobin antibody coupled with multiple enzyme molecules is added as the third layer of the sandwich. This immunoassay was applied in the medical surveillance of exposed workers in Xinxiang, China factories specializing in polyacrylamides for oil field applications. In our preliminary double-blind study of 2 controls and 9 AM workers (3 with AM poisoning, 6 exposed but no immediate effect), the AM immunoassay identified the 3 workers with disease as having the highest AM level, and 2/6 exposed group who later went on to develop disease as having higher AM levels. Control had lowest levels of AM. Biomonitoring of diseased and exposed workers showed anticipated changes in AM levels over time. Screening survey of Louisville residents (USA volunteer controls) revealed lowest detectable AM levels without chemical disease. Biomonitoring of AM exposure by immunoassay provides safe, simple, and accurate means to document risk of exposure to a ubiquitous chemical used in daily activities both in the home and workplace.

206 AVIAN BIOMONITORING OF HEAVY METALS IN LITHUANIA USING IMMUNODETECTION FOR METALLOTHIONEIN.

B L Bukaveckas[1] and J M Steffen[1]. [1]*University of Louisville, Louisville, KY.* Sponsor: H E Hurst.

The newly independent state of Lithuania has a legacy of heavy metal contamination. The cause was primarily the widespread application of heavy metal rich mineral fertilizers. Secondarily, electroplating industry and military bases were coupled with no wastewater treatment facilities. Finally leaded gasoline is still in use in this country. We decided to use immunodetection of metallothionenin (Mt) for a pilot study of urban metal contamination using pigeons as the sentinel species. In the fall of 1996 we collected 20 pigeons (*Columba passerina*) from two cities in Lithuania, Klaipeda and Smyltina. Bird livers were homogenized in 1:4 weight to volume in ice cold Tris-HCl buffer pH 8.0, then centrifuged at 10,000g for 10 minutes. We measured hepatic Mt content of the supernatant using dotblots. Immunodetection was carried out using polyclonal Mt antibodies (Alpha Gamma Laboratories, Inc.). A standard Mt curve was generated on each membrane using mixed Mt I and Mt II. Mt ranged from 3.78e-4 to 3.10e-3 μ g/g per wet weight of liver tissue. This range is below what would have been able to be detected with standard Mt assays, and do not indicate acute metal intoxication of pigeons from these two study areas in Lithuania. However the study successfully demonstrated the usefulness of immunodetection of Mt in avian species for biomonitoring.

207 COMPARISON OF SOIL METALS ALONG BUSY THOROUGHFARES VS. RESIDENTIAL STREETS OF INNER AND OUTER NEW ORLEANS.

H W Mielke, M K Smith and C R Gonzales. *Xavier University of Louisiana, New Orleans, LA, USA.*

A soil survey (SS-I) conducted in New Orleans in 1989-91 elucidated the environmental health impact of Pb accumulations in the city. This report describes a preliminary evaluation of soil survey (SS-II) begun in 1998. SS-II includes soil samples from busy thoroughfares along with soil samples collected along residential streets. This preliminary report (55 or 19.2% of 286 census tracts) compares soil metal results of busy thoroughfares versus residential street samples for communities in the inner city and outer city of New Orleans. All soil samples were air-dried, sieved (2 mm screen), shaker

extracted 5:1 (volume to weight) with 1 mol L^{-1} nitric acid for 2 hours at room temperature, centrifuged (1000 x g for 15 min.), and filtered (Qualitative P4 Filter Paper). Extracts were analyzed for Pb, Zn, Cd, Mn, and Ni using Inductively Coupled Plasma Atomic Emission Spectroscopy (ICP-AES). Using categories established in Survey I, the data from busy thoroughfares and residential street samples were stratified into inner city and outer city groups. The non-parametric data are described as percentiles. The Wilcoxon Signed Rank Test is used to evaluate differences and similarities of each element in different parts of the city. In the inner city, significant differences do not appear between busy thoroughfares and residential streets. In outer city areas, significant differences do appear for Pb, Zn, Cd, and Ni between busy thoroughfares and residential streets. Except for Mn, significant differences appear between inner city and outer city busy thoroughfares and residential streets. In the inner city of New Orleans, Pb, Zn, Cd and Ni are more uniformly distributed and exhibit a significantly higher concentration than in the outer city census tracts. (Supported by ATSDR cooperative agreement # U50/ATU398948 to Xavier University.)

208 MODIFICATION OF TOLERANCE OF SENSITIVE FISH SPECIES TO BATH TREATMENT WITH HYDROGEN PEROXIDE.

M J Tort and P R Bowser. *Microbiology and Immunology, College of Veterinary Medicine, Cornell University, Ithaca, NY, USA.*

Hydrogen peroxide and its primary decomposition products, oxygen and water, are considered environmentally compatible. The apparent lack of adverse environmental impacts of hydrogen peroxide combined with its effectiveness as an antimicrobial agent makes this compound an excellent candidate for further evaluation in aquaculture. Hydrogen peroxide is currently being tested for its potential as a chemotherapeutant for a variety of external disease organisms of fish. Research in our laboratory has focused on delineating effective hydrogen peroxide dosing regimes for treating bacterial gill disease in rainbow trout and walleye. Results from target animal safety studies indicate that toxicity of H2O2 is dependent on species, age, dose and water temperature. Acute toxicity is evident from histopathologic inspection of gills (e.g. extensive epithelial lifting, necrosis) of fish treated with high doses of H2O2. The value of hydrogen peroxide as a therapeutic compound for use in walleye culture has been questioned due to the high sensitivity of walleyes to this compound at suggested treatment levels. Studies indicate that exposure of walleye to low levels of hydrogen peroxide would result in increased tolerance to subsequent exposure. Mechanisms involved in the modification of tolerance of fish to treatment with hydrogen peroxide (e.g. induction of antioxidant enzymes) are currently being investigated. This phenomenon of increased tolerance may be of value in the development of management strategies that will permit the use of hydrogen peroxide with walleyes and other sensitive species.

209 CALCIUM DEPENDENT ZN ACCUMULATION ON RAINBOW TROUT GILLS.

M G Barron[1], R P Playle[2], P Welsh[1], J Lipton[1]. [1]*Stratus Consulting, Boulder, CO, USA;* [2]*Wilfrid Laurier University, Waterloo, ON, Canada.*

This study measured and modeled the accumulation of zinc on the gills of rainbow trout because the gill is the site of toxic action. Zinc accumulation was lowest when fish were acclimated in hard water (Ca = 120 mg/L) and tested in hard water and highest when fish were acclimated in soft water (Ca = 8 mg/L) and tested in soft water. Intermediate Zn accumulation was observed when fish were either acclimated in soft and tested in hard water or acclimated in soft and tested in hard water. Total Zn concentrations in gills ranged from 20 to 55 µg/kg fish in the different treatments after 24 hours exposure to 100 µg ^{65}Zn/L. Using gill ligand constants for Ca and Zn, we modeled the gill-Zn concentration on the gill surface over time in the various exposure waters tested using the geochemical speciation program MINEQL+. The results of this study show that the concentration of calcium in water determines the toxicity and accumulation of zinc in fish through both changes in gill permeability and competition for binding sites.

210 USE OF H4IIE BIOASSAYS TO ESTIMATE THE CONTRIBUTION OF HALOGENATED ENVIRONMENTAL CHEMICALS TO TOXIC POTENCIES IN FISH EXTRACTS FROM THE LOWER FOX RIVER, WISCONSIN.

K T Connor[1], T J Iannuzzi[1], D F Ludwig[1], M M Moore[2], J P Giesy[3], and S H Safe[4]. [1]*Exponent, Inc., Washington, DC, USA;* [2]*Exponent, Inc., Bellevue, WA, USA;* [3]*Michigan State University, East Lansing, MI, USA;* [4]*Texas A&M University, College Station, TX, USA.*

The toxic equivalency (TEQ) approach to ecological risk assessment of environmental mixtures of halogenated aromatic hydrocarbons (HAHs) has been judiciously applied where aryl hydrocarbon (Ah) receptor-mediated toxicological responses have the potential for affecting reproduction in birds or mammals. The H4IIE rat hepatoma cell line has been used as a bioassay for estimating TEQs of environmental samples based on the responsiveness of this cell line to Ah receptor "active" compounds. Bioassay determination of TEQs has the advantage of accounting for the Ah activity of compounds that have not yet been identified analytically. H4IIE bioassays were used in the present study to estimate TEQs in fish caught from the lower Fox River, and together with analytically-derived TEQs, bioassay-derived TEQs were used to find the incremental contribution of certain classes of HAHs (e.g., polychlorinated biphenyls) to overall toxic potencies of fish extracts. TEQs were determined in H4IIE cell bioassays on the basis of the dose-dependent induction of CYP1A1-dependent ethoxyresorufin-*O*-deethylase (EROD) activity, and the responses observed with whole fish extracts were compared with the response produced by 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD). Fish extracts were prepared using methods that preserved to the greatest extent possible the range of Ah receptor active compounds which could reasonably be expected to be present in whole fish extracts from the study area. Analytically-derived TEQs were calculated on the basis of measured concentrations of individual HAHs and toxicity equivalency factors (TEFs) established previously in H4IIE cells. Comparisons were made for several fish species caught in various areas of the lower Fox River. Bioassay-determined TEQs were consistently higher than TEQs calculated with measured concentrations of coplanar and mono-*ortho*-coplanar PCBs, suggesting that the total TEQ in fish from the lower Fox River are the result of a mixture of compounds. Further studies will test reconstituted mixtures of coplanar PCBs to validate the comparisons among bioassay and analytically-derived TEQs.

211 MOLECULAR CHARACTERIZATION OF AN ARYL HYDROCARBON RECEPTOR IN A WHALE, THE BELUGA DELPHINAPTERUS LEUCAS).

B A Jensen, S I Karchner, and M E Hahn. *Woods Hole Oceanographic Institution, Woods Hole, MA, USA.*

The aryl hydrocarbon receptor (AHR) is a cytosolic, ligand-activated transcription factor that mediates some, if not all, of the toxic effects of 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) and related polycyclic halogenated aromatic hydrocarbons (PHAH). Studies in mouse strains show that slight variations in the AHR sequence can drastically change their sensitivity to dioxin effects. Similarly, differences in AHR expression or function may contribute to species-specific differences in susceptibility to PHAH toxicity. Because of their high trophic level and physiological dependence on large lipid stores, odontocetes (toothed cetaceans) bioaccumulate some of the highest PHAH tissue concentrations reported. Despite this, very little is known about the effect of such burdens on cetacean health. To ascertain the potential for PHAH effect at the biochemical level, we cloned, sequenced, and expressed an AHR from beluga. The 3.2 kb cDNA encoded an 845 amino acid protein with a predicted size of 95.5 kDa. The amino acid sequence is 83, 78, and 71% identical to the human, rabbit, and mouse AHRs, respectively. Protein synthesized in a rabbit reticulocyte lysate system demonstrates specific, high affinity ^{3}H-TCDD binding in the velocity sedimentation assay. Western blotting with an anti-mouse AHR polyclonal antibody detected a band of expected size in cytosols prepared from beluga liver, lung, thymus, and spleen cytosols. No band was detected in heart, kidney, or testis. The lysate-expression system is an abundant source of functional beluga AHR protein that reduces the need for tissue samples that can be difficult to obtain. Using *in vitro* expressed proteins is a promising approach for addressing molecular and biochemical questions in endangered and protected species where logistical and ethical concerns preclude the testing of PHAH effects in live animals. (Supported by NIH E506272 and NOAA Sea Grant.)

212 CHRONIC DOSING STUDY TO ASSESS HEALTH AND REPRODUCTIVE EFFECTS OF TUNGSTEN-IRON AND TUNGSTEN-POLYMER SHOT ON GAME-FARM MALLARDS.

R R Mitchell[1], D M Powell[1], R J Aulerich[1,3], R J Balander[1], S D Fitzgerald[2], and S J Bursian[1,3]. [1]*Department of Animal Science,* [2]*Animal Health Diagnostic Lab,* [3]*Institute for Environmental Toxicology, Michigan State University, East Lansing, MI, USA.*

In 1991, the United States banned the use of lead shot for waterfowl hunting because of its toxic effects on waterfowl and other wildlife species upon ingestion. Steel shot is used as a nontoxic alternative to lead, but there has been a continual effort to develop shot compositions that emulate the ballistic characteristics of lead. Shot composed of tungsten-iron and tungsten-polymer were given conditional approval for hunting by the U. S. Fish and Wildlife Service based on the results of a 30-day acute toxicity trial. The present study examined the health and reproductive effects of the 2 shot types on mallards over a 150-day period. Sixteen male and sixteen female adult mallards were dosed with 8#4 steel shot, 8#4 tungsten-iron shot, or 8#4 tungsten-polymer shot every 30 days over the 150-day period. An additional 6 males and 6 females received 8#4 lead shot. During the first 60 days of the trial, birds were fed a nutritionally-deficient diet (shelled-corn) and maintained in a cold environment. Birds were then switched to a commercial layer mash for the subsequent 90 days during which reproductive performance was examined. Tungsten-iron and tungsten-polymer shot had no deleterious effect on adult body weights, blood parameters, egg production, fertility, hatchability, and duckling survivability. Lead-dosed mallards had significantly decreased hematocrit, hemoglobin concentration and delta aminolevulinic dehydratase activity on day 7. The only pathological changes were observed in the liver and kidneys of lead-dosed birds. All lead-dosed birds died by day 25. The erosion rates of lead, steel, tungsten-iron and tungsten-polymer shot were 20, 55, 75 and 97% respectively. The results of this study indicated that game-farm mallards dosed with tungsten-iron and tungsten-polymer shot were not adversely affected during the 150-day trial.

213 IN VITRO TOXICITY EVALUATION OF SUMITHION USING CILIATED PROTOZOAN *PARAMECIUM CAUDATUM*.

M M Hussain. *Environmental Biology Lab, Dept. of Zoology, University College of Science, Osmania University, Hyderabad, India.* Sponsor: S Hussain.

Experiments were designed to investigate the intrinsic toxicity of sumithion (Fenitrothion) o-o dimethyl o-4-nitro-3-methyl phenyl thiophosphate pesticide on ciliated protozoan Paramecium caudatum (Pc). The free living protozoa are valuable organisms for toxicological investigations as they possess at the same time the specific features of single cells and whole organism. Bioassay experiments were conducted to evaluate acute and chronic toxicity. Concentration of 10 ppm and above killed the Pc instantly . The calculated Lc 50 value of sumithion for three hours duration time was found to be 4.2 ppm for Pc. The cytotoxicity was evident from the progressive inhibition of growth in treated cultures of Pc and the growth inhibition was dose dependent. The role of contractile vacuole of Pc. As a visible marker of physiological responses to pesticide was investigated which provide additional information for assessing ecosystem viability and stress recovery. Variations in phagocytic activity was significant. The cytotoxicity of Pc was evident by macro nuclear aberrations when exposed to 4.2 and 1.0 ppm of pesticide. Treatment of organisms resulted in fragmentation, vacuolation, stretching of macronucleus and its degenaration. An intresting development concerning research in this field could be to investigate in detail the indicator value of ciliate species in toxicity evaluations.

214 MERCURY EXPOSURE, TOXICITY, AND MALARIA PREVALENCE AMONG BRAZILIAN GOLD MINERS.

D Nash[1], G T Strickland[1], C Trevant[1], J M de Souza[2], R S U da Silva[2], and E K Silbergeld[1]. [1]*University of Maryland School of Medicine, Baltimore, MD;* [2]*Instituto Evandro Chagas, Belem, Brazil.*

Introduction. The use of mercury to extract alluvial gold is widespread in Amazonia and other regions of Brazil, resulting in significant dermal and inhalation exposures to inorganic mercury. Malaria prevalence is also high in this region. Limited animal data suggest that mercury exposure may compromise the immune system, increasing host susceptibility to malaria. **Methods.** Cross-sectional information was collected for 135 persons at a gold mine in Para, Brazil. A clinical exam and medical histories were carried out, blood and urine specimens were obtained for mercury determinations, and current malaria infection status was assessed by thin smears. **Results.** Mean mercury levels in the blood (25.6 μ g/dl) and urine (21.5 μ g/dl) were elevated in this population, well above the World Health Organization reference value of 10 μ g/dl. Almost 20% of the study subjects were currently infected with malaria and over 50% reported a history of 5 or more lifetime malaria episodes. However, individuals with mercury levels of 15 μ g/dl or more in the blood and urine did not have a higher prevalence of current malaria infection or symptoms associated with mercury toxicity compared to those below 15 μ g/dl. Mean mercury levels were lower among those with current malaria infection compared to those who were not infected (blood: 22.1 versus 26.4 μ g/dl; urine: 20.9 versus 24.0 μ g/dl) but the differences were not statistically significant. Those who had been working less than one year at the gold mine had a significantly (p=0.03) higher prevalence of current malaria infection (24.6%) compared to those who worked for 1 or more years (9.6%). **Conclusions.** The results of this field investigation indicate that gold miners are at risk for elevated mercury exposures. In addition, in the lower Tapajos, gold miners are also at high risk for exposure to malaria. The higher prevalence of current malaria infection among those more recently employed at the gold mine may be due to malaria exposure in an immunologically naïve population. (Supported by Pan American Health Organization, W. Alton Jones Foundation, and the Heinz Family Foundation.)

215 EVALUATION OF REPRODUCTIVE ORGAN DEVELOPMENT IN CF-1 MICE AFTER PRENATAL EXPOSURE TO BISPHENOLA.

J M Waechter, Jr.[1], S S Dimond[2], W J Breslin[3], J H Butala[4], S Z Cagen[5], F W Jekat[6], R L Joiner[2], R N Shiotsuka[7], and G E Veenstra[8]. [1]*The Dow Chemical Co., Midland, MI, USA;* [2]*General Electric Co., Pittsfield, MA, USA;* [3]*MPI Research, Mattawan, MI, USA;* [4]*Consultant to Aristech, Pittsburgh, PA, USA;* [5]*Shell Chemical Co., Houston, TX, USA;* [6]*Bayer AG, Wuppertal, Germany;* [7]*Bayer Corp., Stilwell, KS, USA;* [8]*Shell Chemicals Ltd., London, England.*

The objective of this study was to investigate potential effects on male reproductive organs of low-dose exposure to bisphenol A (BPA) during prenatal development as previously reported by Nagel *et al.* [*EHP* 1997;105:70-76] and vom Saal *et al.* [*Tox. Ind. Health* 1998;14:239-260]. Groups of 28 females were given 0.2, 2.0, 20, or 200 μ g/kg/day of BPA in tocopherol-stripped corn oil, once daily by deposition in the mouth on Days 11 to 17 of gestation. An additional group of 28 females administered 0.2 μ g/kg/day of diethylstilbestrol (DES) and a group of 56 females administered corn oil vehicle were treated for the same time period. Following the exposure period, the dams were allowed to deliver and raise their pups. On Day 22 of lactation, the litters were weaned, and a maximum of 4 males/litter was retained until 90 days of age. No treatment-related effects were observed in adult females or on growth or survival of offspring from dams treated with any dose of BPA. There were no treatment-related effects of BPA on prostate weights, sperm count or daily sperm production, testis histopathology, or preputial gland, seminal vesicle, or epididymis weights in offspring at any dose of BPA. There were no effects on any parameter measured in dams or on the growth or sexual development of male offspring of dams exposed to DES during gestation. In conclusion, those findings previously reported by Nagel et al. (1997) and vom Saal et al. (1998) were not confirmed at doses equivalent to theirs and at an order of magnitude higher and lower. (The study was sponsored by The Society of the Plastics Industry, Inc. and the European Chemical Industry Council.)

216 EVALUATION OF REPRODUCTIVE ORGAN DEVELOPMENT IN THE MALE OFFSPRING OF FEMALE WISTAR RATS EXPOSED TO BISPHENOL A IN THE DRINKING WATER.

S S Dimond[1], J M Waechter, Jr.[2], W J Breslin[3], J H Butala[4], S Z Cagen[5], F W Jekat[6], R L Joiner[1], R N Shiotsuka[7], and G E Veenstra[8]. [1]*General Electric Co., Pittsfield, MA, USA;* [2]*The Dow Chemical Co., Midland, MI, USA;* [3]*MPI Research, Mattawan, MI, USA;* [4]*Consultant to Aristech, Pittsburgh, PA, USA;* [5]*Shell Chemical Co., Houston, TX, USA;* [6]*Bayer AG, Wuppertal, Germany;* [7]*Bayer Corp., Stilwell, KS, USA;* [8]*Shell Chemicals Ltd., London, England.*

The objective of this study was to evaluate potential effects of bisphenol A (BPA) on sexual development as previously reported by Sharpe *et al.* [*10th Int. Congress of Endocrinology*:1996; S23-4]. Groups of 28 female Han Wistar Albino rats were given drinking water that contained 0, 0.01, 0.1, 1.0 or 10 ppm BPA or 0.1 ppm DES, 7 days per week for 10 weeks. Treatment

of the females began at 10 weeks of age and continued throughout a 2-week premating period, 2 weeks of mating, 21-22 days of gestation and 22 days of lactation. After 2 weeks of exposure the females were mated to untreated males. Weanling males were given untreated drinking water and maintained until 90 days of age. No treatment-related effects on growth or reproductive endpoints were observed in adult females exposed to any concentration of BPA. Similarly, no treatment-related effects on the growth, survival, or reproductive parameters (including testes, prostate and preputial gland weight, sperm count, daily sperm production, or testes histopathology) of offspring from dams exposed to BPA during gestation and lactation were observed. DES administered in the drinking water at 0.1 ppm resulted in decreased body weight, body weight change and food consumption in adult females. An increase in the duration of gestation and a decrease in the number of pups delivered and number of live pups were also observed in animals exposed to DES. In conclusion, these results do not confirm the previous findings of Sharpe *et al.* and show that low doses of BPA had no effects on male sexual development in the rat. (The study was sponsored by The Society of the Plastics Industry, Inc. and the European Chemical Industry Council.)

217 THE INFLUENCE OF LIFETIME EXPOSURE TO DIETARY BISPHENOL A ON THE MALE RAT REPRODUCTIVE TRACT.

W A Fritz and C A Lamartiniere. *University of Alabama at Birmingham, Birmingham, AL, USA.*

Exposure to estrogenic compounds during critical periods of development have been implicated in the induction of abnormalities in the male reproductive tract and on fertility. Bisphenol A, the monomer used in the formation of several common resins and plastics, is one of the major environmental compounds shown to possess estrogenic activity. In this study, male Sprague Dawley CD rats were exposed to 20 and 200 ng bisphenol A per gram diet from conception until day 70 postpartum. Adult animals were found to consume 2.2 and 23.1 ug bisphenol A /kg body weight per day, respectively. Lifetime exposure to bisphenol A resulted in significantly reduced body weights from days 1–70 postpartum for all ages investigated. The number of male and female offspring, anogenital distances for both sexes, and age of testes descent were not significantly altered. The seminal vesicles and epididymis were increased in weight in a dose–dependent manner, and kidney and spleen weights were decreased for both concentrations. Dorsolateral and ventral prostates, and testes weights were not significantly altered compared to control animals. Sperm density and motility were decreased in a dose–dependent manner, although the decrease was not significant. Androgen receptor protein levels were increased significantly in the 200 ng/g concentrations of bisphenol A in the diet are subtle but significant.

218 LACK OF DEVELOPMENTAL/ REPRODUCTION EFFECTS WITH LOW CONCENTRATIONS OF BUTYL BENZYL PHTHALATE IN DRINKING WATER IN RATS*.

R S Nair[1], F W Jekat[2], D H Waalkens-Berendsen[3], R Eiben[2], R A Barter[1] and M A Martens[4]. [1]*Solutia Inc., St. Louis, MO;* [2]*Bayer AG, Wuppertal, Germany;* [3]*TNO Nutrition and Food Research Institute, Zeist, The Netherlands;* [4]*Monsanto Technical Center, Louvain-la-Neuve, Belgium.*

There are conflicting reports on sexual development of male offspring from rats administered ultra low doses (1 ppm) of butyl benzyl phthalate (BBP) in drinking water during mating, gestation and lactating (Sharpe et al., Environ. Health Perspect. 103, 1136-1143, 1995; Ashby et al., Regul. Toxicol. Pharmacol. 26, 102-118, 1997). We investigated the effects of BBP using a dosing regimen identical to that used by Sharpe et al. (1995) with the following enhancements: higher number of dose levels and test animals per group, use of glass bottles for dosing solutions, complete analytical characterization of dosing solutions and evaluation of female pups through maturity. Groups of 28 female Wistar rats were given nominal concentrations of 0.1, 1.0 and 3.0 ppm BBP in the drinking water 2 weeks prior to mating, during mating, gestation, and lactation. At weaning, groups of approximately 80 male and female pups were placed on regular drinking water and food for a period of 90 days. During maturation, sexual development endpoints, preputial separation and vaginal opening, were followed. At necropsy, gonadal organ weights, and caudal and testicular sperm counts were obtained. Unlike the results of Sharpe et al. (1995), no treatment related changes in organ weights or epidydmidal or testicular sperm production counts were observed among male rats receiving BBP in utero and during lactation. No treatment-related changes were observed in the sexual development of females following administration of low doses of BBP. Our results on lack of low dose BBP testicular effects confirm the results reported by Ashby et al. (1997). *Sponsored by the European Coucil of Plasitcizers and Intermediates and the Phthalate Ester Panel of CMA.

219 LACK OF EFFECTS ON MALE REPRODUCTIVE PARAMETERS IN RATS BY PERINATAL DIETHYLSTILBESTROL (DES) EXPOSURE AT MATERNALLY TOXIC LEVELS IN DRINKING WATER*.

F W Jekat[1], J M Waechter Jr.[2], R S Nair[3], W J Breslin[4], D H Waalkens-Berendsen[5], R A Barter[3], S S Dimond[6], J H Butala[7], S Z Cagen[8], R L Joiner[6], M A Martens[9], R N Shiotsuka[10], and G E Veenstra[11]. [1]*Bayer AG, Wuppertal, Germany;* [2]*Dow Chemical Co., Midland, MI, USA;* [3]*Solutia Inc., St. Louis, MO, USA;* [4]*MPI Research, Mattawan, MI, USA;* [5]*TNO Food and Nutrition Research Institute, Zeist, The Netherlands;* [6]*General Electric Co, Pittsfield, MA, USA;* [7]*Consultant to Aristech, Pittsburgh, PA, USA;* [8]*Shell Chemical Co., Houston, TX, USA;* [9]*Monsanto, Louvain-la-Neuve, Belgium;* [10]*Bayer Corp, Stilwell, KS, USA;* [11]*Shell Chemical Ltd., London, England.*

A study by Sharpe et al. (EHP 1995;103:1136-1143) reported decreased daily sperm production and testes weights in male offspring of dams exposed to low doses of DES (0.1 ppm in drinking water), a well-characterized synthetic estrogen. In two independent studies groups of 28 female rats were given nominal concentrations of 0.1 ppm (study 1) and 0.05/0.01 ppm DES (study 2), respectively, in the drinking water 2 weeks prior to mating, and during mating, gestation and lactation. At weaning, groups of approx. 80 male pups were placed on tap water and food until an age of 3 months. The DES-dosed dams showed significant toxicity in terms of reduced food and water consumption, an increase in duration of gestation and a decreased number of live pups. In 3 month-old offspring of DES-dosed dams, however, no effects were seen on the relative weights of the reproductive organs, and no significant changes in epididymal or testicular sperm counts were observed. These results corroborate the latest findings reported by Sharpe et al. (EHP 1998;106:A220-221), and challenge the allegation of a special susceptibility of mammals to in utero exposure of low-dose exogenous estrogens. (*Studies sponsored by the European Council of Plasticizers and Intermediates, the Phthalate Ester Panel of CMA, and The Society of Plastics Industry, Inc.)

220 PRENATAL EXPOSURE TO ESTROGENIC ENDOCRINE DISRUPTING CHEMICALS (EDCs) AFFECTS SEXUAL DIFFERENTIATION OF THE RAT BRAIN.

S A Laessig, M M McCarthy and E K Silbergeld. *University of Maryland, Baltimore, MD, USA.*

Sexual differentiation of the rat brain occurs in response to perinatal production of gonadal steroids and results in permanent changes to brain architecture and neuroendocrine function. The sexually dimorphic nucleus of the preoptic area (SDN-POA) in the hypothalamus is the most apparent morphological sex difference in the rat brain. The nucleus is 2.2-8 times larger in adult males than in adult females and this volumetric difference is entirely dependent on estrogen during a restricted perinatal period. Estrogen masculinizes the SDN-POA by preventing apoptotic cell death. We utilized this developmental event to examine the effects of EDCs. Pregnant female Sprague-Dawley rats were given (ip) chlordecone (5 mg/kg), bisphenol A (BPA; 5 mg/kg), or diethylstilbestrol (DES; 5μg/kg) on day 16 of gestation. Offspring were weighed and the anogenital distance (AGD) was measured on the day of birth (PN0) and on postnatal day (PN) 6. The volume of the SDN-POA was measured on PN6. Chlordecone and BPA treatment increased body weight in males and females on PN0 and PN6. DES increased body weight in males and females only on PN0. AGD was increased on PN0 and PN6 in males given DES or BPA and on PN 6 in males given chlordecone. As in earlier experiments, female offspring exposed prenatally to chlordecone were shown to have increased SDN-POA volume compared to controls. The present experiments indicate that these three EDCs have varying effects. Only chlordecone and DES have estrogen-like effects on the SDN-POA in females, while all three have estrogen-like effects on weight gain in pups and on AGD in males. (Supported by grants from the Heinz Family Foundation and a VA Merit Award to MMM and EKS.)

221 APOPTOSIS IN THE SEXUALLY DIMORPHIC NUCLEUS OF THE PREOPTIC AREA AND PUBERTAL DEVELOPMENT IN RATS EXPOSED TO BISPHENOL A DURING PRENATAL AND POSTNATAL DEVELOPMENT.

S Kwon, R C Cattley and F Welsch. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA.*

Bisphenol A (BPA) is used to manufacture epoxy resins and polycarbonates. BPA can leach from these materials into food stuffs and be ingested in small quantities. BPA has weak estrogenic properties. CIIT researchers previously observed that maternal exposure to BPA at 320 mg/kg/day from gestation day (GD) 2 through postnatal day (PND) 10 increased the volume of the sexually dimorphic nucleus of the preoptic area (SDN-POA) in the hypothalamus of female rat offspring. Apoptosis has been implicated in sexual dimorphism in this specific region of rat brains. In the present study, we examined whether BPA would decrease the incidence of apoptosis in the preoptic area of female offspring and affect pubertal development. The chemical was administered to pregnant Sprague-Dawley rats by daily gavage at 0, 3.2, 32, or 320 mg/kg/day from GD 11 through PND 21. F1 females were examined for the effects of BPA on the incidence of apoptosis in the SDN-POA and on puberty. Fresh-frozen brains collected from 10-day-old females exposed to 320 mg/kg/day perinatally were analyzed for apoptosis with an ApopTag® in situ apoptosis detection kit. Under the present experimental conditions, there was no significant difference in the percentage of apoptotic cells in the SDN-POA (n = 4; 4 female offspring from 4 different litters) between BPA exposed (0.51 ± 0.09%) and control animals (0.64 ± 0.18%). BPA treatment of the dams with 320 mg/kg/day did not alter the age or body weight at which vaginal opening or first ovulation in the F1 offspring occurred. These preliminary data indicate that other factors in addition to apoptosis may be involved in the previously observed nucleus-enlarging effects of BPA on the SDN-POA during the critical period of sexual differentiation of the rat brain. Studies are in progress to determine whether BPA affects normal reproductive functions following pubertal development.

222 TESTICULR DAMAGE IN MALE RATS FOLLOWING NEONATAL EXPOSURE TO NONYLPHENOLS (NPs).

P C Lee and K C Nickels. *Department of Pediatrics, Medical College of Wisconsin, Milwaukee, WI.*

We have reported previously that exposure of neonatal male pups to NPs led to cryptorchidism, testicular atrophy and infertility. We further examined the effects of NPs on the histology and biochemistry of the affected testes. Newborn male pups were given NPs at 8.0 mg/Kg or vehicle only (controls) for 15 days. They were sacrificed at 31 days of age and also at maturity after several matings to establish if they were fertile. At 31 days of age, NP treatment resulted in lesser cellular differentiation of the seminiferous tubules (ST) and increase in intertubular space compared to controls. At maturity, NP-treated males showed varying degrees of changes in the affected testes. In the moderately affected ones, about 20-30% of their STs showed poorly differentiated germinal elements. Cell lineage was less organized. In most severe cases, all the STs from the affected testis showed complete lack of differentiation. The center of the STs was occupied by large vacuoles. These impairments in germinal element differentiation might be the primary cause for a number of the NP-treated males to have a lower epididymal sperm count and a lower % of sperms that are motile compared to control age-matched males. Examination of testes homogenates by zymogram analysis using SDS gelatin gels revealed 2 major forms (64-66kD and 50-52kD) of gelatinases. The 50-52kD form was greatly reduced or absent in the affected testis. Thus exposure of neonatal male pups to NPs might affect their testicular proteinases that might be associated with abnormal development (cryptorchidism) and differentiation of their germinal elements (lowering of sperm counts and reduction in the % of sperms that are motile).

223 TWO-GENERATION REPRODUCTION STUDY WITH *P*-TERT- OCTYLPHENOL (OP) IN RATS.

R W Tyl[1], C B Myers[1], M C Marr[1], D R Brine[1], P A Fail[1], J C Seely[2], and J P Van Miller[3]. [1]*Research Triangle Institute, Research Triangle Park, NC;* [2]*PATHCO, Inc., Research Triangle Park, NC, USA;* [3]*Union Carbide Corporation, Danbury, CT, USA.*

OP is an important commercial intermediate used primarily for the production of OP ethoxylate surfactants. Recently, OP has been implicated as an "environmental estrogen" due to its weak binding to the estrogen receptor and related responses. To determine if OP presents a risk to reproductive health, a 2-generation reproduction study in CD rats was conducted, following U.S. EPA OPPTS Draft Guidelines (870.3800) with the addition of dorsal prostate weights in adults, and monitoring F2 females through vaginal opening and F2 males until age 111± 5 days to evaluate possible reproductive organ effects and measurement of sperm parameters. Dietary concentrations of 0, 0.2, 20, 200, and 2000 ppm were used. The high dose resulted in OP intake near or exceeding known liver metabolic capacity, and the 0.2 ppm dose was used to evaluate potential low dose effects. Treatment-related effects in adult F0, F1, and F2 animals were limited to reduced body weights and feed consumption at 2000 ppm. No effects on any reproductive parameters were observed in either generation. No effects on sperm measurements, estrous cyclicity, or reproductive organs were observed in adult animals. Pup body weights during lactation were reduced at 2000 ppm. Minimal organ weight changes in weanling animals were attributed to the high daily intake of OP at this age and related body weight effects. Minimal (≤ 1.5 days) delays in vaginal opening and preputial separation, attributed to body weight decreases, were observed in the F1 and F2 generations at 2000 ppm. Slight increases in anogenital distance (<0.1 mm) were observed in newborn F2 females at all OP doses without clear dose response and were not attributed to OP toxicity. The NOAEL for systemic and postnatal toxicity was 200 ppm and for reproductive toxicity was >2000 ppm. In conclusion, although OP has weak estrogenic activity in some screening assays, no estrogenic or reproductive effects occurred from dietary exposure to rats for two generations over a 10,000 fold dose range.

224 EFFECTS OF DIETARY GENISTEIN EXPOSURE DURING DEVELOPMENT ON SPRAGUE-DAWLEY RATS.

K B Delclos[1], L G Lomax[2], C C Weis[1], C L Holder[1], D R Doerge[1], and R R Newbold[3]. [1]*NCTR, Jefferson, AR, USA;* [2]*PAI, Jefferson, AR, USA;* [3]*NIEHS, Research Triangle Park, NC, USA.*

Genistein (CAS #446-72-0) is a naturally occurring isoflavone which interacts with the estrogen receptor and with multiple other targets. Human exposure to genistein is predominantly through consumption of soy products, and genistein has been implicated as being of potential benefit in preventing cancers at multiple sites and many adverse effects associated with menopause. A dose range-finding study was conducted as a prelude to a multigeneration bioassay. Genistein was administered in a soy-free diet at 0, 5, 25, 100, 250, 625, and 1250 ppm to dams (5 per dose group) from gestation day 7. Litters were standardized to 4 pups per sex at birth. Exposure of pups continued through lactation and after weaning until postnatal day 50. Plasma levels in animals at sacrifice ranged from approximately 10 nM to near 10 μM. Body weight and food consumption showed a decreasing trend with a signifcant reduction at the highest dose. Relative liver, pituitary and preputial gland weights showed increasing trends, with significant effects at the highest dose. Relative ventral prostate weight showed a decreasing trend, with a signifcant effect at 1250 ppm. Femur length and length:body weight ratio, as well as eye opening and ear unfolding were also affected at 1250 ppm. In female pups, mammary gland ductal/alveolar hypertrophy and hyperplasia were observed at 625 and 1250 ppm, and similar effects were observed in males at 5 ppm. Estrous cycle morphologic abnormalities were observed at 625 and 1250 ppm, and abnormal ovarian antral follicles at 1250 ppm. Males showed decreased spermatogenesis at 1250 ppm. Genistein thus affected multiple estrogen-sensitive tissues under these conditions, with males showing effects at lower doses than females.

225 MODULATION OF STEROID RECEPTOR EXPRESSION IN THE PROSTATE AND TESTES OF RATS BY DIETARY GENISTEIN.

A Dalu[1], B S Blaydes[1], C C Weis[1], J R Latendresse[2], R R Newbold[3], and K B Delclos[1]. [1]*National Center for Toxicological Research and* [2]*Pathology Associates International, Jefferson, AR, USA;* [3]*NIEHS, RTP, NC, USA.*

Steroid receptors play critical roles in growth, development, and maintenance of the male reproductive tract, including prostate and testes. Genistein is a naturally occurring isoflavanoid that is primarily found in soybeans. It is known that genistein exerts its estrogenic/antiestrogenic effects primarily through binding to estrogen receptors α and β (ERα and β), and thereby may affect the growth and development of prostate and testes. The current study was undertaken to examine if exposure to dietary genistein through an extended period that included development modulates the expression of selected steroid receptors such as ERα & β, and androgen receptor (AR). Genistein was fed to pregnant rats from gestation day 7 (GD7) at 0, 25, 250,

or 1250 ppm. Exposure of pups continued through lactation and after weaning until postnatal day 63 (PND63). At sacrifice (PND63), ventral prostate (VP), dorsal prostate (DP), and testes were removed from male pups (n=5) for histopathological evaluation and measurement of selected hormone steroid receptors levels by Western blot. Serum testosterone (T) levels were measured by radioimmunoassay. No treatment related histopathological lesions were observed in prostate or testis at this age. Serum T levels were elevated in dose-dependent manner (except at 25 ppm). Western blot analysis indicated that protein levels of AR increased in DP at 25 and 1250 ppm. In testes, AR protein levels increased at 250 ppm and decreased at 1250 ppm. Protein expression of ERα exhibited a significant increase in the DP at 25 ppm and in the VP at 250 and 1250 ppm. In contrast, ERα levels in the testes were reduced at all doses in comparison to the controls. ERβ protein levels were significantly decreased in DP at all doses, increased in VP at 250 and 1250 ppm, and were unchanged in the testes compared to the controls. The overall findings of this study suggest that genistein acts in a dose- and tissue-dependent manner in modulating the expression of AR, ERα, and ERβ which may have important implications in male reproductive tract function and susceptibility to or prevention of prostatic or testicular carcinogenesis.

226 EFFECTS OF DIETARY GENISTEIN ON STEROID AND GROWTH FACTOR RECEPTORS INVOLVED IN MAMMARY GLAND GROWTH AND DEVELOPMENT.

B S Blaydes[1], A Dalu[1], J R Latendresse[2], and K B Delclos[1]. [1]*National Center for Toxicological Research and* [2]*Pathology Associates International, Jefferson, AR, USA.*

Growth and development of the mammary gland, including neoplastic growth, are dependent on complex interaction among steroids and peptide growth factors. Previous studies have shown that the soy isoflavone genistein binds to estrogen receptors α and β (ERα and β) and affects mammary gland growth and development. Genistein was fed to pregnant rats from gestation day 7 (GD7) at 0, 25, 250, or 1250 ppm. Exposure of pups continued through lactation and after weaning until postnatal day 77 (PND77). At sacrifice (PND77), mammary gland from female pups (n=8) were removed for histopathological evaluation and measurement of selected steroid and growth factor receptors protein levels by Western blot. Serum sex hormones (17β-estradiol (E_2), progesterone (P), and prolactin (PLN)) were also measured. In the 1250 ppm dose group, hyperplasia and hypertrophy of primitive lobules was observed. In comparison to controls, serum levels of E_2 were significantly reduced at 25 and 250 ppm. P levels were elevated at 25 ppm, but reduced at 250 and 1250 ppm. PLN was significantly increased at 1250 ppm. ERα, epidermal growth factor, and erbB-2 were significantly increased over control level at all doses. ERβ and progesterone levels were unchanged. These data indicate that dietary genistein exposure during organogenesis (GD7-PND77) influences levels of hormones, and hormone and growth factor receptor that are critical to mammary gland growth and differentiation in a manner that suggests possible enhanced susceptibility to mammary carcinogenesis.

227 ANALYSIS OF PUBLIC HEALTH IMPACTS ASSOCIATED WITH REMOVAL OF LEAD PAINT FROM NYC BRIDGES.

T M Slayton, J T Cohen, P Sinha and T S Bowers. *Gradient Corporation, Cambridge, MA, USA.*

The New York City Department of Transportation (NYCDOT) is responsible for 770 bridges in NYC. To maintain structural integrity, NYCDOT must remove weathered paint that no longer protects against corrosion; much of the existing paint contains lead. To assist NYCDOT in developing health-protective paint removal procedures, potential public health impacts associated with exposure to lead particles generated during abrasive blasting and other paint removal techniques were analyzed. Six "surrogate" bridges, representing the range of environments and bridge structures in NYC, were evaluated. Emissions were modeled reflecting normal daily releases and catastrophic containment failures. Street dust and exterior soil lead levels were calculated using modeled deposition of bridge repair emissions and background dust fall, taking into account dust removal *via* precipitation washout. Based on air, dust, and soil concentrations, the IEUBK Model and the Bowers *et al.* Model were used to evaluate steady state blood lead levels (PbB) in children and adults, respectively, and the O'Flaherty Model was used to evaluate transient exposures. Predicted maximum incremental increases to geometric mean PbB, assuming maximum worst case release scenarios without mitigation, were approximately 1 ug/dL for children and substantially less for adults. Assuming a maximum worst case release scenario, a child may experience a one-day maximum PbB above typical levels of concern, but this level would decline quickly. PbB increments would be far less for residents living more than a few hundred feet from a bridge. With implementation of inspection and oversight procedures, precautionary work practices, and immediate clean-up of any release, the predicted impact on steady state PbB would be negligible. Overall, this analysis indicated that the proposed containment and mitigation measures are adequately protective of human health.

228 ISSUES RELATED TO MODELING OF AGE-DEPENDENT ABSORPTION AND BIOKINETICS OF LEAD.

M Maddaloni[1], P E Goodrum[2] and G L Diamond[2]. [1]*U.S. Environmental Protection Agency, New York, NY, USA;* [2]*Syracuse Research Corporation, Syracuse, NY, USA.*

The U.S. EPA utilizes two models to assess lead risks at Superfund sites: the IEUBK Model for Lead in Children, applicable at residential sites to children <7 yrs of age, and the Interim Adult Lead Methodology (IALM), applicable at non-residential sites, where adults, rather than children, are the primary receptors. The IALM uses a simplified biokinetic slope factor (BKSF) to relate the blood lead concentration (PbB) to absorbed Pb. Default values used in the model include: BKSF=0.4 μg/dL per μg/day, and absorption fraction for soil-borne Pb (AFsoil) = 0.12. An issue commonly encountered in site risk assessments is: How representative are the model defaults (BKSF, AF) for increasingly younger age groups (e.g., adolescents, teenagers)? Although an empirically-based answer to this question is currently beyond us, it is useful to consider how these two variables are being represented in models of lead biokinetics. Current models, including the forementioned, and models developed by O'Flaherty and by Leggett, predict (or assume) similar BKSFs in children and adults; thus, the models predict that higher Pb uptakes per kg bw in children compared to adults can result in similar PbBs in children and adults. This implies that other biokinetic variables are represented differently in child and adult models. Current models also assume a 2 to 5-fold higher AF in children compared to adults. Although this is supported by data in young children and adults, it is uncertain at what age the child converts to the less efficient absorption status of the adult. Relevant new data on age-dependency of AF may shed some light on this issue, however, from a risk assessment perspective, it remains unclear how far can we *press the envelope* in applying the EPA adult methodology and IEUBK models to the ages between childhood and adulthood. (Conclusions do not necessarily reflect the opinions or policies of U.S. EPA.)

229 USING BLOOD LEAD STUDIES TO ESTIMATE SOIL INGESTION RATES IN CHILDREN.

J C Willson[1] and W J Adams[2]. [1]*Kleinfelder Inc.,Englewood, CO;* [2]*Kennecott Utah Copper Corporation, Magna, UT.*

Tracer studies have long been the only approach available to estimate soil ingestion rates. These studies suffer from serious, well known drawbacks, including brief duration, detection limit problems, and exogenous sources of the tracers. When a problem seems intractable, it can be helpful to address the problem from a completely different angle, sometimes called "triangulation." Using blood lead data has been attempted before in the US and elsewhere; new drawbacks arose, including bioavailability issues, presence of lead-based paint and other non-soil lead sources, statistical uncertainty, and measurement error. We have taken three data sets from Rocky Mountain mining communities in which careful environmental measurements have been made and paired with blood lead levels in resident children. Using regression analysis, the IEUBK model assumptions, in vivo and in vitro bioavailability tests (performed by EPA), elimination of children exposed to lead-based paint where possible, and a Monte-Carlo based approach to account for measurement error, we have produced estimates of mean soil ingestion ranging from 10 to about 80 mg/day depending on the base study and level of uncertainty. The estimates depend on the IEUBK model, however, and errors in that model will produce errors in the soil ingestion estimates. This approach is useful in broadening our understanding of soil ingestion rates to use in risk assessments for all chemicals in soils, not just lead.

230 CALCULATION OF SOIL PRGS FOR LEAD FOR INTERMITTENT ADULT EXPOSURE.

J M LaVelle[1], A K Fisher[2], G M Henningsen[3], E Hoffman[3], M Maddaloni[4], and B L Beatty[2]. [1]*Camp Dresser & McKee (CDM) Inc., Denver, CO;* [2]*CDM Federal Programs Corp, Golden, CO,* [3]*US Environmental Protection Agency, Denver, CO;* [4]*US Environmental Protection Agency, New York, NY.*

Historical mining operations in the eastern end of the Oquirrh Mountains in Salt Lake County, Utah, have produced large amounts of mine wastes and tailings, and migration of these materials has contaminated significant areas of soils. Certain individuals, mainly adults (e.g., industrial workers, agricultural workers, or recreational visitors), may be exposed intermittently to lead and other metals in these wastes and soils. To assesses potential lead exposure, a physiologically-based kinetic model for lead (O' Flaherty 1997) was evaluated to determine whether it could be used to develop PRGs for intermittent exposure. However, attempts to use an electronic version of the model to assess exposures that vary on a daily basis did not yield useful output because of run-time computer errors. Further investigation, however, supports the use of US EPA's adult lead methodology for assessing intermittent adult exposure. The US EPA provided information that suggests a linear response in pseudo-steady state blood lead levels in adults subchronically exposed to lead intermittently from one to three times per week. Monte Carlo simulation indicates that exposure frequency is the most sensitive input, and soil ingestion rate is the next most sensitive input to the US EPA's algorithms. Using site-specific inputs for the gastrointestinal absorption fraction (about 0.06 based on measurements in young swine) and exposure frequency, the US EPA Region VIII developed a range of possible risk-based PRGs for lead in soil using the adult blood lead algorithms. Depending on exposure assumptions, these PRGs range from less than 2,000 mg/kg to over 10,000 mg/kg. The PRGs are intended to protect the fetus in an exposed pregnant female from elevated blood lead levels.

231 AN INTEGRATED MODEL OF BLOOD LEAD AND BONE LEAD DURING AND AFTER PREGNANCY IN LATINA IMMIGRANTS.

R Cuellar[1], S J Rothenberg[1,2], F Khan[1], M Manalo[1], J Jiang[1], B Reynoso[1], S Reyes[1], A Aguilar[1], A C Todd[3], and C Johnson[1]. [1]*Drew University of Medicine and Science, Los Angeles, CA, USA;* [2]*Instituto Nacional de Perinatología, Mexico City, Mexico;* [3]*Mt. Sinai School of Medicine, New York, NY, USA.* Sponsor: M R I Soliman.

Single equation models, such as the multiple regression analyses previously used to examine the relationship between maternal bone lead and post-pregnancy maternal blood lead, cannot adequately describe relationships among the various lead variables when the same factors simultaneously affect both blood lead and bone lead. We used a system of simultaneous equations known as structural equation modeling to construct a single model of the effects of bone lead on maternal blood lead in the third trimester of pregnancy and in the first months after delivery. Blood lead was measured by atomic absorption spectrometry with graphite furnace. Bone lead was measured at mid-tibia (cortical bone) and calcaneus (heel: trabecular bone) by K shell x-ray fluorescence at the time of postnatal blood lead measurement. We restricted our analysis to immigrant Latina women in South Central Los Angeles (N>300). Geometric mean (range) prenatal blood lead was 2.8 μg/dL (0.4-81), calcaneus and tibia mean (range) lead concentration were 8.5 μg/g (-30.1 - 66.4) and 6.6 μg/g (-33.7 - 62.2). Blood lead during pregnancy was the strongest predictor of blood lead after pregnancy, as expected. Calcaneus lead had significant and independent positive effects on both prenatal and postnatal blood lead, although the effect on prenatal blood lead was about 25% larger than its effect on postnatal blood lead. Although tibia and calcaneus lead were significantly correlated, tibia lead was positively associated only with prenatal, not postnatal blood lead. Increasing length of time resident in the US was associated with simultaneous decrease in both prenatal blood lead and calcaneus lead in a logarithmic fashion. After accounting for the effects of bone lead on prenatal blood lead, inadequate dietary calcium during pregnancy was related only to increased prenatal blood lead. These results suggest increased risk of higher blood lead during and after pregnancy in immigrant Latinas may be due to lead stored in bones before immigration.

232 A LEAD MODEL (ECOTOX) FOR FULL-AGE RANGE HUMAN EXPOSURE BUILT FROM HUMAN DATA.

A Y Steenhout. *Free University of Brussels, Brussels, Belgium.* Sponsor: J G Pounds.

A biokinetic risk assessment full-age range model has been built from data on bio-indicators (including tooth lead and blood lead up to 60-80æg/dl) collected in Belgian children and adults with known exposure to Pb. Input in the exposure model of time-related factors (exposure and nutritional)and of contamination (food, water, air, dust,paint..) results in lead uptake estimates.The human body is represented by blood - and fluids in rapid exchange with it, soft tissues and several compartments for hard tissues (various types of bone and teeth). Adjustment to observed data points out that lead transfers rates between compartments are age-related. First order kinetics fit data up to the highest blood lead. An "impact" law relates blood Pb and lead contamination or uptake. This relation is applied to data in the literature for validation exercises. Calculated PbBlood deduced from chronic environmental exposure differ from observed blood lead by less than 5% . Curvilinear relations (for example PbBlood vs PbAir) are explained by reference to exposure factors rather than by the order of lead kinetics. The model also explains the occurrence of peaks and plateaus in blood lead. Among other capabilities, the model also assesses the release of Pb from hard tissues vs storage, or others lead fluxes in- and out the body compartments, for any exposure history and at any time before reaching the steady state (SS). Response time (R), defined for each compartment, is the time required to reach a given % of the value that would be reached at SS. The time to reach critical values is estimated, and is shorter in children than in adults. It introduces new variables of interest for dose-effects studies,such as the dose to target tissue or compartment. This, and the higher transfer rates in early childhood have important implications for assessing risks in groups more vulnerable to Pb such as children.

233 SPATIAL DISTRIBUTION OF EEG THETA ACTIVITY AS A FUNCTION OF LIFE-TIME LEAD EXPOSURE IN NINE-YEAR OLD CHILDREN.

A Poblano[1,2], S J Rothenberg[3,4], and L Schnaas[2]. [1]*Instituto de Comunicación Humana, Mexico City, Mexico;* [2]*Instituto Nacional de Perinatología, Mexico City, Mexico;* [3]*Instituto Nacional de Salud Pública, Cuernavaca, Mexico;* [4]*Drew University of Medicine and Science, Los Angeles, CA, USA.* Sponsor: M R I Soliman.

Relative power of EEG theta activity (4-8 Hz) reaches a maximum in the first years of life, and generally declines at most scalp locations with increasing age. Children with attention deficit disorder show higher relative power of theta than age-matched controls. To determine how lead exposure might alter the relative power of theta in children participating in the Mexico City Prospective Lead Study, we measured eyes-closed, resting EEG for 60 seconds at 18 scalp electrode locations placed according to the 10-20 system. Informed consents were obtained. Spectral analysis of digitized data with a fast Fourier transform yielded power of theta relative to total EEG power. Lead exposure histories were calculated as mean blood lead levels for 12-36 week maternal concentrations (every 8 weeks during pregnancy) for prenatal exposure, and mean 18 month blood lead levels (every 6 months) from 6 to 96 months for postnatal exposure. Mapping of relative theta power across the scalp as a function of developmental stage of lead exposure was evaluated by spatially weighted multiple regression using Monte Carlo sampling, adjusting for chronological age at EEG testing and presence or absence of fetal suffering at delivery. Although most blood lead indices showed a significant positive effect of lead on theta at many electrode derivations, the most significant ($p<.001$) spatial gradient of lead effect on theta was with averaged blood lead between 54 and 72 months of age (blood lead range 5.0-26.2 μg/dL). The regression coefficient of theta on blood lead increased significantly in a frontal to occipital gradient, while there was no significant spatial gradient of theta on chronological age or on fetal suffering. EEGs of children with low to moderate blood lead levels resemble those of children with attention deficit disorder and the effect of lead is strongest in posterior (visual) cerebral areas.

234 REDUCTION OF ELECTRORETINOGRAM AMPLITUDE IN THE DARK-ADAPTED EYE OF CHILDREN ASSOCIATED WITH PRENATAL AND POSTNATAL BLOOD LEAD LEVEL.

S J Rothenberg[1,2], L Schnaas[3], M Salgado[3], H K Hudnell[4], and A Geller[4]. [1]*Instituto Nacional de Salud Pública, Cuernavaca, Mexico;* [2]*Drew University of Medicine and Science, Los Angeles, CA, USA;* [3]*Instituto Nacional de Perinatología, Mexico City, Mexico;* [4]*Environmental Protection Agency, Research Triangle Park, NC, USA.* Sponsor: M R I Soliman.

Early, low-level lead exposure has been associated with alterations in rod-mediated retinal function in animal preparations from rat to monkey. The electroretinogram (ERG) provides information regarding retinal function across species including humans. We recorded ERGs from children in the Mexico City Prospective Lead Study aged 7-10 years to determine the effect of prenatal lead exposure on retinal function. Informed consents were obtained. Subjects were dark-adapted for 40 minutes, Jet contact lenses were placed, and ERGs evoked by 5 consecutive white light flashes in a ganzfeld were averaged at each of 9 ascending flash intensities varying over a four common log luminance range. Interflash interval and intertrial interval increased over the series to reduce adaptation effects. Peak amplitudes of averaged a-wave and b-wave were measured by cursor placement for each stimulus intensity and a-wave - b-wave difference was calculated. Maternal blood lead level at 36 weeks gestation (range 1.0-32.5 μg/dL) was the only blood lead measure significantly associated with a reduction in ERG amplitude in multiple regressions adjusted for chronological age, and serum vitamin A and zinc levels. The association was apparent for each luminance level at which an a-wave and b-wave amplitude could be measured (3.6 - 1.0 log unit flash filtration). Across the range of blood lead levels the reduction in ERG a-wave - b-wave amplitude was 25%. The significant lead effect is temporally coincident with the rapid retinal development that takes place in the third trimester of pregnancy. Detection of the effect as late as middle or late childhood suggests that the effect of prenatal lead exposure on retinal response may be permanent.

235 BIPHASIC EFFECT OF PRENATAL BLOOD LEAD LEVEL ON BRAINSTEM AUDITORY EVOKED RESPONSE IN CHILDREN AT FIVE YEARS.

L Schnaas[1], A Poblano[1,2], and S J Rothenberg[3,4]. [1]*Instituto Nacional de Perinatología, Mexico City, Mexico;* [2]*Instituto de Comunicación Humana, Mexico City, Mexico;* [3]*Instituto Nacional de Salud Pública, Cuernavaca, Mexico;* [4]*Drew University of Medicine and Science, Los Angeles, CA, USA.* Sponsor: M R I Soliman.

Most, but not all, studies examining the effect of lead exposure on brainstem auditory evoked response (BAER) in children find significant associations between prior blood lead level and intervals measured between various peaks of the response. An earlier publication from the Mexico City Prospective Lead Study reported that increasing maternal blood lead level at 20 weeks gestation was most strongly related to increasing Peak III - Peak V interval in infants of about one month of age. We measured BAERs in children between 57 and 78 months from the same study. Biphasic clicks at 80 dB HL were monaurally delivered to each ear (contralateral ear masked with noise at 30 dB HL). We averaged 2048 responses from vertex electrodes referenced to linked mastoid to two separate click sequences presented at 11/sec. Latencies to Peaks I, III, and V were measured by cursor placement, and interpeak intervals were calculated. Maternal blood lead level at 20 weeks gestation was related to Peak III - Peak V interval, and Peak I - Peak V interval in a quadratic orthogonal polynomial regression, adjusting for chronological age and head circumference at recording. Peak intervals decreased significantly ($p=.004$) with blood lead levels between 1 and 8 μg/dL, then increased significantly ($p=.004$) with blood lead levels from 8 to 33 μg/dL. The quadratic regression was a significantly better fit to the data ($p=.009$) than was a linear regression. Brainstem auditory structures in humans undergo rapid development at mid-pregnancy. Though the biphasic nature of the lead effect on BAER may have several interpretations, the persistence of the effect of mid-pregnancy lead level on BAER beyond five years of age suggests a long-lasting effect of prenatal lead exposure on auditory brain response.

236 EFFECTS OF IN VIVO VERSUS IN VITRO Pb ON BRAIN PROTEIN KINASE C (PKC) ACTIVITY.

K Ellacott, J D Cremin, Jr., and D R Smith. *Environmental Toxicology, University of California, Santa Cruz, CA, USA.*

Previously, we reported that Pb increased PKC activity in the brain of Pb-exposed rats (Toxic. Sci. 1998. 42:198.). Addition of an equivalent amount of Pb acetate in vitro to brain homogenates from those rats resulted in a greater than expected increase in PKC activity in both membrane and cytosol fractions. This lead to the hypothesis that in vivo (endogenous) Pb was less biologically available compared to Pb added in vitro, possibly as a result of differences in Pb complexation. Here we investigated differences in the subcellular partitioning in rodent brain of Pb delivered in vivo (i.e., oral exposure to the animal) versus in vitro (Pb added to brain homogenate), using a sensitive stable Pb isotope tracer method that allowed us to distinguish between in vivo Pb versus in vitro Pb. Animals were administered Pb-acetate from birth to 34 days age, sacrificed, and brain immediately removed for PKC analyses, as previously reported. Here, tracer ^{204}Pb (exogenous Pb) was added to brain homogenates from those animals in amounts comparable to the Pb present in the tissue. Homogenates were separated into pellet and cytosolic fractions by centrifugation at 40,000x g, and the cytosol further partitioned into <3,000 MW and >3,000 MW fractions using Amicon centrifugation. All fractions were analyzed for in vivo Pb and in vitro ^{204}Pb tracer using trace metal clean techniques and ICP-MS. The ratio of in vitro/in vivo Pb in the starting homogenate (0.82) compared to the cytosol (1.04) and pellet (0.18) indicate that a substantially greater proportion of in vitro Pb partitioned in the cytosol veers pellet, as compared to in vivo Pb. No differences in partitioning between in vitro versus in vivo Pb were seen within the cytosolic fraction (i.e., < or > 3000MW). These results are consistent with our previous observations that Pb added in vitro had a greater effect on increasing brain PKC activity than the Pb present in vivo. They also may in part explain existing discrepancies in the effects of Pb on PKC reported from studies using in vivo versus in vitro models. (Supported by NIEHS Grant #ES07535.)

237 EFFECT OF PRENATAL LEAD EXPOSURE ON COCAINE CONDITIONED PLACE PREFERENCE IN RATS.

J A B Alfaro[3], B A Sorg[1], E K Silbergeld[2], and J O Schenk[3]. [1]*Department of VCAPP, Washington State University, Pullman, WA;* [2]*Program in Human Health and the Environment, University of Maryland Medical School, Baltimore, MD, and* [3]*Department of Chemistry, Washington State University, Pullman, WA.*

Prenatal lead exposure in children and animal models is associated with neurodevelopmental delays, learning deficits, and behavioral problems. In rodents, pre- and postnatal lead exposure is known to affect several neurotransmitter pathways in the CNS, specifically the release of dopamine, dopamine transporter proteins, and certain dopamine receptors (D2). These mechanisms have been associated with changes in arousal, activity, and learning. In addition, rodents exposed to lead perinatally show altered responses to several drugs that act on dopaminergic pathways (d-amphetamine, apomorphine, methylphenidate, haloperidol). We tested the interactions between prenatal lead exposure and later response to cocaine. Rats were exposed through pregnancy to lead via drinking water (25 ppm). This dose did not affect gestation, litter size, sex ratio, postnatal survival, or body weight in offspring. Pups were cross fostered to avoid postnatal exposure via lactation. As adults the F_1 offspring were trained on a conditioned place preference task, using 3, 6, or 12 mg/kg cocaine (i.p.). Prenatal lead exposure altered performance on this task. Male pups were less able to detect cocaine at the lowest dose, while females had an enhanced ability to detect cocaine. The results are consistent with the involvement of dopamine transporters and receptors in lead neurotoxicity. (Supported by a grant from the Heinz Family Foundation (EKS).)

238 EXPRESSION OF HEAT SHOCK PROTEIN 27, 60, AND 70 IN BLADDER FROM CONTROLS AND PATIENTS WITH INTERSTITIAL CYSTITIS.

M A Sens, S Somji, J H Todd, S H Garrett and D A Sens. *Department of Pathology, West Virginia University, Morgantown, WV, USA.*

Interstitial cystitis (IC) is a chronic inflammatory bladder disease of unknown etiology. Several causes of IC have been proposed including toxic chemicals, autoimmune reactivity, hypersensitive response, defects in

urothelial cell permeability barrier and infection. A major intrinsic cellular mechanism for protection against stress is provided by the heat shock proteins (hsp) which are induced by a wide range of stimuli. This study examines the expression of hsp 27, 60 and 70 in normal human bladder and in bladder specimens obtained from patients with IC. Immunohistochemical methods were utilized to determine the localization of hsps in paraffin-embedded bladder specimens. Western blotting and reverse transcriptase polymerase chain reaction were used to confirm gene expression in normal bladder tissue samples. In normal bladder, the expression of hsp 27 was high in the transitional epithelium whereas the expression of hsp 60 was moderate. Heat shock protein 70 was present only in basally located transitional epithelial cells. The expression of hsp 27 was not altered significantly in the transitional epithelium of IC patients, though its intensity increased in smooth muscle cells and vessel walls of IC bladder specimens. In patients with IC, there was reduced expression of hsp 70 in basal transitional epithelial cells. The expression of hsp 60 was absent in the urothelial cells or smooth muscle cells from patients with IC. These results suggest that hsp 70 and 60 are down regulated in the bladder or patients with IC.

239 THE SUPPRESSIVE EFFECTS OF CORTEX MORI ON NO, TNF-α AND IL-1 PRODUCTION BY MACROPHAGE.

C Yoon, J T Hong, D Shin and C Hong. *Korea Food and Drug Administration, KFDA, Seoul, Korea.*

Cortex Mori (*Morus loba L.*), the root bark of mulberry tree has been used as an autiphlogistic, diuretic and expectorant in herbal medicine. Recently, a few papers reported that phenolic extract of Cortex Mori had the hypotensive, hypolglycemic, antiviral and anticancer effects, and hot water extract of Cortex Mori had inhibitory effect on the degranulation and histamine release from activated mast cells. These previous studies suggest a possibility that CM has an antidotal activity against inflammation which was mediated mainly by macrophage-secreting inflammatory factors. This study was performed to evaluate the influences of Cortex Mori on carrageenan-induced edema *in vivo* and release of inflammatory mediators such as NO, TNF and IL-1 by macrophages stimulated with LPS or IFN-γ *in vitro*. Subcutaneous njections of carrageenan into the mouse paw rapidly induced local edema by increasing vascular permeability, but single intraperitoneal injection of CM extract at 30 minutes before carrageenan suppressed the development of edema. NO- and TNF production from macrophage stimulated by LPS or INF-γ were significantly suppressed, especially TNF secretion by up to 3-4 folds. LPS stimulated IL-1 production was also inhibited, but not significantly. Cell viability assay verified that the inhibition was not due to general cell toxicity. These results suggest that reduction of NO, TNF and IL-1 production may be one of the means by which Cortex Mori prevent inflammation associated diseases.

240 DECREASED RESPONSE TO ENDOTOXIN CHALLENGE BY PRE-TREATMENT WITH ERGOTAMINE.

N M Filipov[1], F N Thompson[1], J A Studemann[2], D L Dawe[1], T H Elsasser[3], S Kahl[3], C R Young[4]. [1]*University of Georgia, Athens, GA;* [2]*USDA/ARS, J. Phil Campbell, Sr., NRCC, Watkinsville, GA;* [3]*USDA/ARS, Growth Biology Laboratory, Beltsville, MD;* [4]*USDA/ARS, FAPRL, College Station, TX.*

The objective of this experiment was to investigate whether the ergot alkaloid, ergotamine (ET), an alkaloid used to model fescue toxicosis in cattle, increases the response of cattle to endotoxin (LPS) challenge. Steers (n=16) were divided into the following treatment groups: control (C), ergotamine (ET), endotoxin (LPS), and ET+LPS. ET and ET+LPS groups received a single bolus i.v. injection of ET (40 μ g/kg/BW), whereas C and LPS steers received a single bolus injection of sterile vehicle. Thirty minutes after ET/vehicle administration, a single bolus i.v. injection of LPS (0.2 μ g/kg/BW) was given. Blood was collected at various time points for 48 h post LPS. Endotoxin alone increased the circulating levels of tumor necrosis factor alpha (TNF-α), cortisol, the acute-phase protein haptoglobin (Hp), thromboxane B_2 (TXB_2), and rectal temperature (RT), and decreased plasma glucose and insulin-like growth factor-1 (IGF-1). Importantly, haptoglobin, TNF-α , and TXB_2 increases were blunted by pretreatment with ET compared to LPS. The combination ET+LPS resulted in hyperglycemia followed by profound hypoglycemia. Ergotamine alone, increased RT, plasma urea nitrogen, packed cell volume and glucose and decreased serum prolactin (PRL). Therefore, administration of LPS to steers resulted in a typical metabolic and endocrine response. The combination of ET+LPS attenuated major effects of LPS alone. Thus, acute administration of ET appeared to be anti-inflammatory as it decreased the inflammatory response to LPS.

241 PLASMA INTERLEUKIN-10 AND NITRATE/NITRITE CONCENTRATIONS IN THE HUMAN ENDOTOXIN MODEL.

C R Cunningham, R T Tosheva, S I Shedlofsky. *Department of Medicine (III), VA Medical Center, Univ. of Kentucky, Lexington, KY, USA.*

I.v. administration of *E.coli* lipopolysaccharide (LPS, U.S. Standard Reference Endotoxin, CC-RE-Lot 2) to healthy volunteers has been used as a safe reproducible model of sepsis. To further characterize this model, studies were performed to evaluate patterns of plasma interleukin-10 (IL-10) and products of nitric oxide metabolism. **Methods**: To elicit the inflammatory response, two doses of LPS (20 EU/kg) were administered on two consecutive days to 15 men, and clinical responses (temperature/pulse) were monitored and compared to responses after a saline injection. At 4 time points after saline and 10 time points after the LPS injections, plasma IL-10 and NO_2/NO_3 concentrations were assayed. TNF-α and IL-6 were also assessed. **Results:** Expected clinical signs after each LPS injection were observed with mean temperature rise of 3.1 ±1.0 °F and pulse rise of 30 ± 9 bpm. Peaks of IL-10 concentration were found at 3.5 hr after each dose of LPS (176 ± 36 and 198 ± 30 pg/ml respectively). Baseline IL-10 after saline ranged from 32 to 60 pg/ ml. Unlike TNF-α and IL-6, the IL-10 peak after the second LPS dose was higher than after the first dose. Plasma NO_2/NO_3 profiles showed approximately 2-fold elevations after LPS with a delayed peak of 74 ± 12 μM at 12 hr after the first dose and an earlier 3 hr peak of 75 ± 13 μM after the second dose. NO_2/NO_3 concentrations after the saline injection ranged from 24 to 40μM. **Conclusions:** These data are the first to characterize the increases in plasma IL-10 and NO_2/NO_3 in the human endotoxin model of sepsis.

242 PERSISTENT PULMONARY INFLAMMATION AFTER INTRATRACHEAL INSTILLATION OF ABRASIVE BLASTING AGENTS.

N S Minhas, L A Battelli, D W Porter, W T Goldsmith, A Dotson, W Jones, M Greskevitch, J Y C Ma, and A F Hubbs. *HELD and DRDS, NIOSH, CDC, Morgantown, WV.*

Use of silica sand in abrasive blasting is associated with pulmonary disability due to silicosis. However, the pulmonary toxicity of substitutes for silica sand in abrasive blasting remains incompletely investigated. Therefore, Sprague Dawley rats received a single intratracheal instillation (IT) dosage of 2.5 or 10 mg of the respirable fractions of abrasive blasting agents collected from the air during blasting of a steel bar. Four weeks post-IT, the right lung lobe was lavaged to isolate bronchoalveolar lavage cells and acellular bronchoalveolar lavage fluid (BALF); the left lung was processed for histopathology. Polymorphonuclear leukocyte (PMN) cell yield and alveolar macrophage (AM) chemiluminescence (CL) were significantly increased above control levels in rats instilled with coal slag (2.5 and 10 mg), silica sand (10 mg), staurolite (10 mg), and treated sand (10 mg). Rats which received garnet (10 mg) also had increased PMN numbers versus control but AM CL was not increased. Lactate dehydrogenase (LDH) was significantly elevated in the BALF of rats instilled with coal slag (2.5 and 10 mg), garnet (2.5 and 10 mg), silica sand (2.5 and 10 mg), staurolite (10.0 mg), and treated sand (10 mg), whereas BALF albumin was not increased in any of the exposed rats versus control. Hydroxyproline was significantly elevated over saline controls only in the rats receiving coal slag (10 mg). However, trichrome stained lung sections showed focal to multifocal, minimal fibrosis in 6 of 6 silica exposed rats (10 mg) and 3 of 6 coal slag exposed rats (2.5 and 10 mg). Only specular hematite (iron oxide) failed to increase some measure of pulmonary toxicity.

243 EFFECTS OF OZONE EXPOSURE ON CYTOKINE EXPRESSION IN HUMAN NASAL EPITHELIAL CELLS.

B G Nichols, J Q Koenig, J S Woods, and D L Luchtel. *Department of Environmental Health, University of Washington, Seattle, WA, USA.*

Ozone is an oxidant pollutant gas that has been shown to induce adverse respiratory effects in humans, including airway inflammation. Although the mechanisms are poorly understood, airway epithelium is thought to play an active role in ozone-induced inflammation, since it is one of the first cellular targets to come into contact with inhaled ozone and/or its free radical

products. The present study investigated the mechanism of this inflammatory response. Cultures of human nasal epithelial (HNE) cells were initiated from excised nasal turbinates and exposed to 120, 240, or 500 ppb ozone for 3 hours. Basal media was then collected for tumor necrosis factor alpha (TNF-α) quantification by enzyme-linked immunosorbent assay. Mean TNF-α concentration in cultures exposed to 120 ppb ozone (10.34 ± 1.32 pg/ml) was not significantly different than in those exposed to air (11.01 ± 1.10 pg/ml). Exposure to 240 and 500 ppb ozone significantly increased mean TNF-α expression relative to controls by 75% (from 34.25 ± 4.39 pg/ml to 59.77 ± 8.72 pg/ml) and 28% (from 30.54 ± 4.61 pg/ml to 39.25 ± 7.42 pg/ml), respectively. These findings support the active role of HNE in ozone-induced airway inflammation and warrant further studies that delineate the interaction between ozone and inflammatory signal transduction molecules. Examples include possible ozone-induced activation of NF-κB, a transcription factor known to upregulate TNF-α expression. (Supported by NIH grant ES07033.)

244 AP-1 BINDING ACTIVITY IS ALTERED IN LPS-TREATED TNF ALPHA (p55/p75) DOUBLE RECEPTOR KNOCK-OUT MICE.

A L Roe[1], G W Warren[2], M P Mattson[3,4], and R A Blouin[2,5]. [1]*Department of Environmental Health, University of Cincinnati, Cincinnati, OH;* [2]*Graduate Center for Toxicology,* [3]*Sanders-Brown Research Center,* [4]*Department of Anatomy and Neurobiology, and* [5]*College of Pharmacy, University of Kentucky, Lexington, KY, USA.*

It is well established that pro-inflammatory mediators of LPS induction of the acute phase response (APR) include interleukins (IL), interferons, and tumor necrosis factor alpha (TNF). Using TNF p55/p75 double receptor knockout mice (DKO), the role of TNF on transcription factor activation during the APR was examined. DKO and C57BL6 mice were administered LPS (2 mg/kg, i.p.) or saline and euthanatized 2 or 24 hours following LPS administration. Sera and liver tissue were then collected and analyzed for cytokine levels (sera) and transcription factor activation (liver). Serum cytokine levels were determined using direct ELISA. Serum levels of IL-1, IL-6, and TNF supported induction of the APR. Hepatic nuclear extracts were isolated and DNA binding to STAT3, $NF_{\kappa}B$, and AP-1 elements was analyzed using EMSA. The binding activity for STAT3 and $NF_{\kappa}B$, was increased with LPS treatment, but did not differ between DKO and C57BL6 mice at either time point. However, AP-1 binding activity was decreased in the DKO mice at 2 and 24 hours. The dampened AP-1 binding activity in the DKO mice may be explained by disruption of the TNF/SAPK/MAPK signalling pathway. The ultimate step in this pathway is the phosporylation of c-Jun; part of the dimeric complex of AP-1. These results support the role of TNF in the signalling pathways necessary for AP-1 activation following LPS administration.

245 JP-8 JET FUEL INDUCED RELEASE OF PRO-INFLAMMATORY CYTOKINES IL-1β AND IL-6 FROM RAT ALVEOLAR TYPE II CELLS IN CO-CULUTRE WITH RAT ALVEOLAR MACROPHAGES.

R S Young and M L Witten. *Department of Pediatrics and Department of Pharmacology/Toxicology, University of Arizona, Tucson, AZ, USA.*

Jet propulsion-8 (JP-8) jet fuel has been shown to induce lung injury after inhalation, however the mechanism of injury still remains unknown. Previous work conducted in our laboratory shows that aerosolized JP-8 jet fuel causes increased lung permeability and changes in lung compliance and resistance in an animal model. The purpose of this study focused on the interaction of the alveolar type II cell and the resident immune cell in the lung, the pulmonary alveolar macrophage (PAM). RLE-6TN cells (RLE cells), a rat alveolar type II epithelial cell line, were grown to confluence, dosed with JP-8 jet fuel at concentrations of 0.25, 0.3, 0.4, 0.5, 0.6, and 0.8 ug/ml, alone or in co-cultures with PAM isolated from F344 rats. At time points of 1, 2, 6, 12, and 24 hours cell culture supernatant was removed and assayed, by ELISA, for the presence of IL-β and IL-6. Results from these experiments show that JP-8 induces the release of IL-β and IL-6 in a time dependent manner, however the levels of cytokines released were not dose dependent in the cultures of RLE-6TN cells alone. In co-cultures of RLE cells and PAM the levels of cytokines released were increased significantly ($p<0.05$) versus the RLE cultures alone. The pattern of release of cytokines was similar to that seen in the cultured RLE cells. From this study it appears that injury to the alveolar epithelium may be caused by immune activation of the alveolar type II cells and this injury may be exacerbated by the presence and activation of PAM in the alveolar space. The release of these pro-inflammatory and chemotactic cytokines may lead to increased airway inflammation and recruitment of various immune cells to the lung which could exacerbate injury. (This work supported by AFOSR 49260-97-0217 and DoD AASERT program.)

246 INSTILLED SOLUBLE VANADIUM EVOKES PULMONARY INFLAMMATION BUT DOES NOT ELICIT PRO-INFLAMMATORY CHEMOKINE mRNA IN THE HEART.

J D Paulauskis[1], H Danaee[1], J M Antonini[2], E Al-Mutairi[1], T Rice[1], J J Godleski[1], and R W Clarke[1]. [1]*Harvard School of Public Health, Boston, MA, USA;* [2]*HELD/NIOSH, Morgantown, WV, USA.*

Inhalation of vanadium-rich fly-ash (~ 500 μ g/m³) results in increases in pulmonary inflammation and increased expression of pro-inflammatory chemokine levels in cardiac macrophages (Killingsworth et al, *Inhal Tox* **9**:541). Intratracheal instillation of vanadium compounds causes significant pulmonary inflammation and enhanced pulmonary chemokine mRNA levels (Pierce et al, *Tox Appl Pharm* **138**:1). HYPOTHESIS: Cardiac chemokine induction is due to soluble metal ions transported from the pulmonary region. METHODS: Rats were lightly anesthetized and intratracheally instilled with 210 μ g/kg sodium metavanadate or PBS. Following sacrifice at 24, 48, and 168 hr post-instillation (PI), bronchoalveolar lavage (BAL) was performed and cardiac tissue prepared for RNA extraction and Northern analysis. RESULTS: As previously observed, significant metavanadate-induced pulmonary inflammation was observed in BAL samples at 24 and 48 hr PI marked by significantly increased neutrophil and eosinophil levels ($p < 0.05$) and significant changes in inflammatory biochemical parameters in acellular BAL fluid; inflammation was resolved by 168 hr. Northern analysis for the pro-inflammatory chemokines macrophage inflammatory protein (MIP)-1α and MIP-2 showed only trace amounts of mRNA in heart tissue from vanadium-exposed animals at 24 and 48 hr PI. CONCLUSION: These results indicate that soluble vanadium induces pulmonary, but not cardiac, inflammation following instillation. This suggests that inflammation-related cardiac dysfunction is not caused by soluble vanadium transported following pulmonary exposure. (Supported by ES00002, ES08129, HL05947, and HL54958.)

247 DEVELOPMENT OF A TAQMAN® BASED QUANTITATIVE RT-PCR ASSAY FOR CANINE CYTOKINE INDUCTION.

T R Pippert, K B Bleicher, J F Sina, T R Skopek, and D R Umbenhauer. *Merck Research Labs, West Point, PA, USA.*

The inflammatory response consists of multiple components, including induction of several cytokine mRNA's. Accurate quantitation of cytokine levels in specific tissues can aid in understanding the extent and source of inflammatory mediators. Using a fluorescence-based ABI Prism® 7700 Sequence Detection System (TaqMan®), a quantitative RT-PCR assay has been developed to measure specific cytokine gene induction in canine tissues and cultured cells. Using the Primer Express software developed by Perkin-Elmer, primer/probe sets were designed for canine IL6, IL8, IL10, TNFα, and GMCSF. Each primer/probe set was specifically designed to span intron-exon junctions to eliminate detection of genomic DNA. GAPDH and 18s primer/probes were used as internal standards in co-amplification reactions. RNA expression vectors containing cloned RT-PCR product from canine RNA were used to generate RNA and DNA standards for absolute quantitation. LPS treatment was used to validate the assays. In canine liver, all the cytokines tested showed a dramatic induction relative to control 1 hour after oral gavage with LPS with the exception of GMCSF and IL 10. LPS also induced cytokines in canine large vessel endothelial cells. The TaqMan RT-PCR method of detecting and quantifying RNA has multiple advantages over endpoint RT-PCR, Northern blot and Rnase protection analysis. The use of specific primers and fluorescent probe results in an assay that is extremely sensitive and specific, does not require gel-based analysis, is very reproducible, and gives a linear response over 6 orders of magnitude without the need for dilutions.

248 A MODEL OF SUBCUTANEOUS ABSCESS FORMATION IN NON-HUMAN PRIMATES.

M A Gallo and C J Horvath. *Primedica Corporation, Dept. Experimental Medicine, Worcester, MA, USA.* Sponsor: F J Mecler.

Many anti-inflammatory agents affect the trafficking, adhesion and activation of cells of the immune system. Treatment with anti-inflammatory drugs

or biologics can impair the body's ability to respond to or prevent bacterial infections as demonstrated in a rabbit model of subcutaneous abscess formation (J. of Immunol, 151:4982-88, 1993). A non-human primate model of subcutaneous abscess formation was characterized and employed as a means of assessing the potential side effects of primate specific anti-inflammatory agents. Cynomolgus monkeys (*Macaca fascicularis*, n=4) were shaved to expose the dorsal intrascapular skin. Duplicate challenge (1.0 mL/site) of gram-positive bacteria, *Staphylococcus aureus* (*S. aureus*), were injected subcutaneously. Challenge doses ranged from 10^5 to 10^{10} colony forming units (cfu). Animals were then treated with an antibiotic (Cefazolin 25 mg/kg, IM) to prevent bacteremia. The effect of bacterial challenge was assessed by abscess incidence, body weight, body temperature, clinical observations, hematological and serum chemistry parameters. Morphometric analysis of the abscess surface area was also determined by photographic projection/planimetry. In the absence of anti-inflammatory drugs, subcutaneous inoculation with *S. aureus* resulted in an abscess incidence of approximately 25% at 10^8 cfu/mL, and 100% at 10^9 and 10^{10} cfu/mL. Bacterial challenge induced transient fever, leukopenia, neutropenia, lymphopenia and mild monocytosis but had no effect on body weight. Abscesses of variable size formed in those animals inoculated with *S. aureus*. The surface area (mm^2) was 433.89 at 10^8, 393.07 ± 52.91 at 10^9 and 534.26 ± 194.88 at 10^{10}. The demonstrated consistency of abscess formation formed by carefully titrated doses of bacteria provides a reliable and reproducible endpoint for evaluation of the safety of anti-inflammatory compounds.

249 REAPPLICATION OF A NOVEL NONINVASIVE TAPE S AMPLING METHOD FOR ASSESSING THE RELATIONSHIP OF GINGIVAL INFLAMMATION AND BLEEDING TO GINGIVAL EPITHELIUM CYTOKINE CONCENTRATIONS.

M A Perkins, A R Biesbrock, M K Robinson and M A Osterhues. *The Procter & Gamble Company, Cincinnati, OH.* Sponsor: L D Lehman-McKeeman.

We previously reported development of a simple noninvasive method to assess inflammatory changes in human skin using a dermal tape (Sebutape™) to adsorb molecular mediators (Fund. & Applied Tox. 42:1:388, 1998). In the present human clinical study, we reapplied this tape adsorption method to collect cytokines from gingival epithelium, as opposed to the more commonly sampled gingival crevicular fluid. The primary objective of this study was to examine the relationship between changes in cytokine levels and clinical inflammation. In this clinical study, 10 subjects participated in a 14 day Experimental Gingivitis (EG) model, where 5 days following a dental prophylaxis, subjects refrained from all oral hygiene measures for 14 days. Clinical measures including both Loe-Silness Gingival Index (GI) and a bleeding index derived from the GI were made at baseline and following 14 days of EG. Sebutape samples of each subject's gingival surface were collected from the right posterior buccal quadrant at baseline (prior to EG) and day 14 (post EG). The tapes were extracted in buffered saline and the extracts analyzed for both IL-1α and IL-1β using commercial immunoassay kits. Over a 14 day EG period, statistically significant ($p < 0.05$) increases in GI, gingival bleeding, and IL-1α were observed (tested by matched pair t-test and Wilcoxan signed ranks test). A directional increase in IL-1β was also observed. These data confirm the utility of using dermal tape for sampling of epithelium cytokine levels from the gingiva and demonstrate a positive relationship between changes in IL-1α and IL-1β concentrations and changes in gingival inflammation.

250 CHARACTERIZATION OF SULFUR MUSTARD-INDUCED DERMAL PROINFLAMMATORY MEDIATOR RESPONSE.

M M Danne[1], R P Casillas[2], M C Babin[2], and J A Blank[1]. [1]*Battelle Memorial Institute, Columbus, OH, USA;* [2]*U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD, USA.*

Sulfur mustard, [bis(2-chloroethyl) sulfide; HD] is an alkylating agent that produces incapacitating dermal injuries to exposed individuals. Although the mechanism(s) of dermal toxicity are not fully understood, the pathologic changes occurring within 24 hr of exposure include erythema, edema, epidermal necrosis, and vesication. Recent studies suggest that cytokines/chemokines may be useful biomarkers of cutaneous injury. Studies were undertaken to characterize proinflammatory mediator expression in the skin of animals exposed to HD vapor. Male euthymic hairless mice, housed under AAALAC guidelines, were used in this study. The dorsal surface of anesthetized animals was exposed to HD vapor for 6 min. At approximately 2 hr, 6 hr, and 24 hr following exposure, skin biopsies from euthanatized animals were taken, snap frozen in liquid nitrogen, and stored < -70 C. Samples were processed and analyzed for proinflammatory mediator messenger ribonucleic acid (mRNA) with a ribonuclease protection assay. Results demonstrated an elevation of mRNA coding for interleukin-1 beta, monocyte chemoattractant protein (MCP-1), and macrophage inflammatory proteins (MIP-1 alpha and MIP-2) in exposed sites relative to sham control tissue. In general, mediator message was elevated by 2 hr and increased through 24 hr. These data contribute to the understanding of the early events associated with HD-induced skin injury. (Supported by USAMRDC Contract 17-89-C-9050.)

251 THE EFFECT OF TCDD EXPOSURE ON SERUM AMYLOID A (SAA) INDUCTION IN RESPONSE TO ENDOTOXIN OR SHEEP RED BLOOD CELL STIMULATION IN C57BL/6 MICE.

J Y Choi and N I Kerkvliet. *Department of Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR, USA.*

2,3,7,8 Tetrachlorodibenzo-p-dioxin (TCDD), a highly toxic environmental contaminant, is suppressive to both humoral and cell-mediated immune responses in mice. In addition, TCDD enhances inflammatory responses to endotoxin and sheep red blood cells (SRBC). Inflammatory responses are accompanied by increased production of various acute phase proteins (APPs) including serum amyloid A (SAA) by hepatocytes. SAA, a major APP in mice, is an apolipoprotein and is known to be induced by proinflammatory cytokines such as interleukin-1 and TNF. Chronic production of SAA has been shown to suppress immune responses. This series of experiments was conducted to address the hypothesis that TCDD exposure in C57Bl/6 mice modulates the APP response to inflammatory stimuli that may contribute to immune suppression. In order to determine the effect of TCDD on APP, mice were gavaged with vehicle or 15 μg/kg TCDD and injected ip one day later with endotoxin (*E. coli* 055:B5) or SRBC. SAA levels were measured by ELISA while plasma TNF levels were measured using a L929 bioassay. Plasma SAA levels were greatly increased as early as 5 hours after endotoxin treatment with peak levels occurring at 24 hours and declining by 48 hours. When TCDD was given prior to endotoxin injection, an increased level of SAA was observed at 24 hours while the kinetics of the overall response was similar to vehicle treated mice. Plasma TNF levels were maximally elevated 1.5 hours after stimulation with endotoxin and TCDD did not influence these TNF levels. In response to SRBC sensitization, vehicle-treated animals exhibited basal levels of SAA and TCDD exposure did not affect SAA levels in plasma or in the peritoneal cavity. TNF was not detected in plasma of SRBC-sensitized mice. We conclude that TCDD exposure up-regulates SAA production in endotoxin-challenged mice but not in SRBC-sensitized mice. However, this TCDD-induced SAA modulation in endotoxin-treated mice does not appear to be mediated by altered TNF production. (Supported by NIEHS Grant ES03966.)

252 ROLE OF PROLIFERATION IN THE *IN VIVO* RESPONSE OF RAT LIVER TO FUMONISIN B.

W Li, R T Riley, K A Voss and W P Norred. *Toxicology and Mycotoxin Research Unit, Russell Research Center, ARS/USDA, Athens, GA, USA.*

Fumonisin mycotoxins are produced by several species of *Fusaria* fungi which are common contaminants of maize, and are the responsible agents for several fatal animal diseases. Fumonisin B_1 (FB_1) is the predominant analog found, and has been shown to be a tumor promoter and possible carcinogen. The mechanism by which fumonisins cause toxicity is believed to be through their ability to disrupt sphingolipid metabolism by inhibition of ceramide synthase. It has previously been noted in our lab and others that although liver is a target organ of fumonisins in intact animals, hepatocytes and liver slices *in vitro* are resistant to cytotoxicity when exposed to fumonisins, even for periods up to 72-96 hr. Several hepatoma cell lines, on the other hand, were sensitive to the effects of fumonisins. We hypothesized that a requisite for fumonisin cytotoxicity is cell proliferation, and used partial hepatectomy (PH) as a model to determine whether fumonisins produced greater toxic response in PH-treated rats than in sham-operated controls. Rats were dosed (ip) with FB_1 24 hr after sham operation or PH, and killed 24 hr later. The dose related increase in free sphingoid bases (a biomarker of ceramide synthase inhibition) caused by FB_1 was enhanced in the PH-treated rats. Serum cholesterol and enzymes (ALP and ALT) were higher in PH-treated rats dosed with FB_1 than those given PH without FB_1 or sham operated, FB_1-dosed rats. Multiple doses of FB_1 after surgery elevated the number of apoptotic hepatocytes observed in both sham and PH-treated rats to about the same degree, suggesting that apoptosis is not associated with the enhanced

cytotoxicity of FB_1 in regenerating liver. The results suggest that proliferating cells are more sensitive to the toxic effects of fumonisins. Whether this enhanced cytotoxicity is related to the ability of fumonisins to disrupt sphingolipid metabolism is yet to be determined.

253 FUSARIC ACID DID NOT MODIFY THE HEPATIC OR RENAL TOXICITY OF FUMONISIN-PRODUCING *FUSARIUM MONILIFORME.*

K A Voss, J K Porter, C W Bacon, F I Meredith, and W P Norred. *Russell Research Center, ARS/USDA, Athens, GA, USA.*

Fumonisins B (FB) and fusaric acid (FA) are mycotoxins produced by *Fusarium moniliforme* and other *Fusarium* spp. They are commonly found in corn and may naturally co-occurr. FB cause the animal diseases associated with *F. moniliforme*, promote liver cancer in rats, and are suspected human carcinogens. FA inhibits beta-hydroxylases and is a hypotensive agent. When given together, fumonisin B_1 (FB_1) and FA were synergistically embryotoxic to chicks *in ovo* and it has been hypothesized that FA may exacerbate the effects of co-occurring mycotoxins *in vivo*. To investigate this possibility using a 3 x 4 exposure scheme, male rats (n=5/group) were fed 3.4 (four groups), 18.4 (four groups), or 437 ppm (four groups) FB (FB_1 + FB_2 + FB_3) provided by *F. moniliforme* culture material to which, at each FB concentration, 0, 20, 100, or 400 ppm FA were added. An FA control group was fed 400 ppm FA only and untreated controls were given neither FB nor FA. Toxicity was evaluated over four weeks by observation, body weight, food consumption and selected clinical chemistry, organ weight, kidney sphingolipid profile, and histopathology endpoints. All FB diets were nephrotoxic and the four high dose FB diets were hepatotoxic: microscopic lesions and other findings were consistent with the known, organ-specific effects of FB. In addition, relative heart weights of the four groups fed the high dose FB diets were decreased. FA was without effect. No differences between the untreated and FA controls were found and no significant differences were found in the type or severity of effects among the four groups fed 3.4, the four groups fed 18.4, or the four groups fed 437 ppm FB. Thus, simultaneous dietary exposure to high levels of FA, up to 400 ppm, did not modify the subchronic toxicity to rats of FB provided by *F. moniliforme* culture material.

254 THE MYCOTOXIN FUMONISIN B_1 ALTERS SPHINGO-LIPID BIOSYNTHESIS AND INHIBITS BACTERIAL PHAGOCYTOSIS.

Fumonisins, fungal metabolites produced by *Fusarium moniliforme*, contaminate corn world-wide and interfere with sphingolipid biosynthesis by inhibiting ceramide synthase. Based on our previous finding that pulmonary clearance of intravenous *Pseudomonas aeruginosa* was decreased in fumonisin-treated pigs, we hypothesized that macrophage phagocytosis would be inhibited by fumonisins. A murine monocyte/macrophage (RAW 264) cell line was incubated with 0, 2.5, 25, 100, 500, or 1000 μM of purified fumonisin B_1 (FB_1) for 24 or 41 hr, respectively. After FB_1 exposure, RAW cells were incubated with FITC-labeled Salmonella for 0, 3, 7, 15, and 60 min and analyzed by flow cytometry. There was a significant dose-dependent decrease in phagocytosis for cells treated with 25, 100, 500, and 1000 μM FB_1 for $\geq$3 min as compared to controls. Similar results were obtained *in vivo* in pigs fed FB_1-containing culture material at 15 mg FB_1/kg BW for 3 days. Phagocytosis by pulmonary alveolar macrophages (PAMs) from treated pigs was significantly decreased when incubated with FITC-labeled Salmonella for 10 and 30 min. Sphinganine (Sa) and sphingosine (So) concentrations were increased in RAW cells exposed to FB_1 (Sa:So maximum of 38.67) as compared to control (0.06), and in PAMs from treated pigs (Sa:So 2.74) as compared to controls (0.34). Thus, FB_1 inhibited macrophage phagocytosis. Interference with sphingolipid biosynthesis by FB_1 may be causally related to this inhibition. Therefore, FB_1 can cause immune suppression which may increase susceptibility to infectious diseases.

255 THE EFFECTS OF FUSARIUM TOXINS IN LOW DOSE ON HOST DEFENSE AGAINST INFECTIOUS DISEASE.

Y Sugia-Konishi and S Kumagai. *National Institute of Infectious Diseases, Shinjuku, Tokyo, Japan.* Sponsor: R T Riley.

Fusarium toxins are potent immunosuppressive mycotoxins which frequently contaminate common agricultural producs, such as corn and wheat. The immunosuppressive effects of these mycotoxins include decreased host resistance to infectous diseases. However in previous studies, animals have been exposed toa high doses and the effect of low doses of these mycotoxins on host resistance against bacterial infectious diseases is still unknown. We studied the effect of relatively low doses of six fusarium toxins (fumonisin B1(FB1), deoxynivalenol (DON), diacetoxyscirpenol (DAS), T-2 toxin (T-2), fusarenon-X (FX) and nivalenol (NIV)),on the host resistance against Salmonella infection using mice. Mice given daily each fusarium toxin in drinking water were infected orally with Salmonella enteritidis 14 days after the commencement of exposure to these toxins. It was found that DON was the most effective among these fusarium toxins in decreasing the resistance against salmonellosis. At 24 microgram/Kg/day dietary exposure, DON reduced serum anti-Salmonella IgM titer and delated type hypersensitivity reaction , both of which are regarded as defense mechanisms against Salmonella infection. These results suggest that dietary exposure to low doses of DON enhance the susceptibility to oral infection to Salmonella through toxic effects on cellular and humoral immunity.

256 SUBCUTANEOUS FUMONISIN ADMINISTRATION DISRUPTS SPHINGOLIPID METABOLISM IN THE DIGESTIVE EPITHELIA IN MICE.

E N Enongene[1], R P Sharma[2], K A Voss[1], and R T Riley[1]. [1]*Toxicology and Mycotoxin Research Unit, USDA-ARS, Athens, GA,USA;* [2]*College of Veterinary Medicine, University of Georgia, Athens, GA, USA.*

Fumonisins are mycotoxins produced by *Fusarium moniliforme*. Fumonisins are commonly found in corn and corn products. They are known to be potent inhibitors of ceramide synthase (sphinganine [sphingosine] N-acyltransferase). Fumonisin inhibition of ceramide synthase causes a rapid increase in free sphinganine, the immediate sphingoid base precursor in the *de novo* biosynthesis of dihydroceramide and ceramide. High levels of free sphinganine in tissues and biological fluids are used as a biomarker for fumonisin exposure. The liver and kidney are target organs in all species tested thus far. Because fumonisins are poorly absorbed and rapidly excreted, the digestive epithelia of farm animals consuming low quality corn-base feeds can be exposed to high concentrations of fumonisins. Thus, the gastrointestinal tract may also be a target of fumonisins. The purpose of this study was to determine if a single subcutaneous (s.c.) injection of fumonisin B1 (25 mg/kg body wt) could cause an increase in free sphinganine in epithelial cells harvested from the small intestines of eight week old BALB/c mice (n=3/time point) over a 24 h period. It was hypothesized that because fumonisins are excreted in the bile following i.p. or i.v. administration, fumonisin administered s.c. should be excreted in the gut via biliary excretion and this should be detectable by an elevation of free sphinganine in the digestive epithelial cells of the small intestines. The results of this preliminary study indicate that there is a significant ($p \leq 0.05$) time-dependent increase in free sphinganine that peaks at 4 to 8 h and declines to near the control level by 24 h post dosing. The increase in free sphinganine suggests that s.c. administered fumonisin B1 is rapidly excreted into the small intestines. However, the rapid return to control levels is unexpected since ceramide synthase inhibition in cultured epithelial cells is quite persistent. Nonetheless, s.c. administration may prove to be a useful tool for studying the effects of fumonisin on the digestive epithelia *in vivo*.

257 PATULIN EXHIBITS MULTIPLE ELECTROPHILIC PROPERTIES AND COVALENTLY CROSSLINKS PROTEINS *IN VITRO.*

R Fliege and M Metzler. *Institute of Food Chemistry, University of Karlsruhe, Karlsruhe, Germany.*

The mycotoxin patulin is thought to exert its cytotoxic and chromosome damaging effects by covalent modification of cellular nucleophilic sites such as thiol groups of proteins and glutathione. In the course of elucidating chemical structures of patulin adducts with simple thiol and amine model compounds *in vitro*, we observed a high preference for adduct types containing two and three molecules of nucleophile per molecule of patulin. As similar reactions at the protein level could lead to covalent intra- or inter-

molecular crosslink formation which might severely disturb the biological functions of proteins, we have investigated the ability of patulin to induce protein-protein crosslinks. By means of sodium dodecylsulfate - polyacrylamide gel electrophoresis, the formation of patulin-induced protein-protein crosslinks was clearly demonstrated *in vitro* for bovine serum albumin containing one thiol group per molecule, but also for the thiol-free hen egg lysozyme. Characterization of the crosslink sites was carried out by modulation of the thiol status (N-ethylmaleimide, 2-iminothiolane), comparison with various positive controls (phenylenedimaleimide, glutaraldehyde, dimethylsuberimidate), and protein fluorescence incorporation studies using dansyl-labelled amino acid derivatives and glu-N-dansyl-glutathione. The amino acids responsible for patulin-induced crosslink formation were shown to be preferably cysteine, but also lysine, histidine, and α-amino-groups. Patulin can act both as a homobifunctional as well as a heterobifunctional crosslinking reagent: the formation of an initial thiol adduct appears to activate patulin for a subsequent reaction with either thiol groups or amino groups. These results raise the question whether patulin can also react with DNA, possibly leading to protein-DNA or DNA-DNA crosslink. (Supported by Fonds der Chemischen Industrie and Deutsche Forschungsgemeinschaft (Me 574/14-1).)

258 APPLICATION OF IMMOBILIZED ACTIVATED CARBON FOR THE SORPTION OF PATULIN FROM AQUEOUS SOLUTION.

H J Huebner, K Mayura, C L Ake, S L Lemke, and T D Phillips. *Faculty of Toxicology, Department of Veterinary Anatomy and Public Health, Texas A&M University, College Station, Texas, USA.*

Patulin, a heterocyclic lactone produced by various species of *Penicillium* and *Aspergillus* fungi, is often detected in apple juices and ciders. The cytotoxic and mutagenic properties of patulin warrant its removal from juices consumed largely by infants and children. Previous research has shown the effectiveness of activated carbon (AC) for reducing patulin in aqueous solutions, apple juices and ciders. In this study, ultra-fine activated carbon (< 45 μm particle size) was tightly bonded onto granular quartz (212-300 μm particle size) to achieve a sorbent with high surface area, enhanced flow characteristics, and increased bulk density. The immobilized carbon (IMAC) was packed in glass columns and tested for its ability to sorb patulin from aqueous solution. Columns containing 1.0 g, 0.5 g and 0.25 g of IMAC were continuously loaded with a patulin solution (10 μg/ml; pH 3.5) and eluted at a flow rate of 1 ml/min. Eluate from the columns was collected in 2 ml aliquots with an automated fraction collector, then analyzed with UV spectrophotometry for patulin content. Results indicated that 50% breakthrough capacities for patulin on 1.0 g, 0.5 g and 0.25 g IMAC columns were 137.5, 38.5, and 19.9 μg, respectively. The effectiveness of IMAC columns to sorb patulin and prevent toxicity was further confirmed *in vitro* using adult hydra in culture. Hydra were sensitive to the effects of patulin, with a minimum affective concentration equal to 0.7 μg/ml; following filtration with IMAC, toxicity was prevented until breakthrough capacities were achieved. The results clearly demonstrate a correlation between patulin levels and toxicity, and indicate that IMAC may provide an effective and practical strategy for the clarification of apple juices and ciders. (Supported by USDA 9703230.)

259 BIOCHEMICAL FACTORS INVOLVED IN AGE-RELATED SENSITIVITY TO AFLATOXIN B_1 IN POULTRY.

P J Klein, R E Buckner, and R A Coulombe, Jr. *Programs in Toxicology and Molecular Biology, Utah State University, Logan, UT.*

Poultry are the most susceptible food animal species to the toxic effects of the mycotoxin aflatoxin B_1 (AFB_1). The extreme sensitivity of turkeys to AFB_1 is due to a combination of efficient AFB_1 activation by cytochrome P450s (CYPs) 1A2 and 3A4 and deficient detoxification by glutathione *S*-transferases (GSTs). In addition, younger poultry are more sensitive to AFB_1 than older ones. To determine the underlying factors involved in age-related sensitivity, AFB_1 activation and AFB_1-relevant phase II enzyme activities were assessed in liver microsomes and cytosol prepared from 9, 21, 31, 41, and 65 day old turkeys. Younger turkeys were more efficient activators of AFB_1, as measured by a lower apparent Km and higher Vmax toward the microsomal formation of the AFB_1-8,9-epoxide, compared to older birds. General cytosolic GST activity was approximately two-fold greater among the 41 and 65 day old birds, as compared to the younger poults. However, immunoblots against a rat Yc2 antibody indicated that with increasing age, the amount of GST Yc2 immunoreactive protein decreased. There was an age-related increase in cytosolic aflatoxin aldehyde reductase (AFAR), an important AFB_1-detoxifying enzyme. Thus, the greater sensitivity of younger poultry to the toxic effects of AFB_1 may be explained by the combination of more efficient hepatic AFB_1 activation and less efficient AFB_1 detoxification compared to older birds. (Supported by USDA-NRI grants 970-3081 and 980-3754.)

260 ALTERATIONS IN CYTOCHROME P-450 EXPRESSING HUMAN LUNG CELLS AFTER AFB_1 EXPOSURE.

T R Van Vleet[1], K Mace[2], and R A Coulombe, Jr.[1]. [1]*Programs in Toxicology and Molecular Biology, Utah State University, Logan, UT, USA;* [2]*Nestle Research Centre, Lusanne, Switzerland.*

Aflatoxin B_1 is a potent dietary hepatocarcinogen in animals and probably in humans. Inhalation of AFB_1-laden grain dusts has been associated with an increased incidence of lung cancer. Mutations in the tumor suppresser gene p53 have been seen in liver tumor tissue from people exposed to high dietary AFB_1 levels. To study the effects of AFB_1 on p53 levels in immortalized human lung cells, we exposed SV40 immortalized human bronchial epithelial cell types (BEAS-2B), transfected with the genes for either cytochrome P450 (CYP) 1A2 or 3A4, to AFB_1. These isozymes are thought to be responsible for AFB_1 activation in the liver and possibly lung. Immunoblotting revealed that untreated, non-transfected normal human bronchial epithelial cells (NHBE) did not express detectable amounts of p53. Untreated, SV40 immortalized (1A2 and 3A4 expressing) cells constitutively expressed p53. Exposure to 0.015μM-15μM AFB_1 for 30 min caused a dose-related decline in p53 expression in 1A2 cells, and to a lesser extent, 3A4 cells. The AFB_1-elicited decrease in p53 continued for at least 6 hrs after exposure to 1.5 μM AFB_1. At these doses 1A2 expressing cells were affected to a greater extent than 3A4 expressing cells. These data indicate that AFB_1 exposure significantly alters p53 protein levels in SV40 immortalized human lung cells. The fact that p53 was altered to a greater extent in 1A2-expressing cells agrees with our previous studies showing that this isozyme is more catalytically active toward AFB_1 activation than 3A4 at these concentrations.

261 DEVELOPMENT OF LIVER INJURY IN RATS TREATED WITH AFLATOXIN B_1 AND ENDOTOXIN, AND PROTECTION BY NEUTROPHIL DEPLETION.

C C Barton, P E Ganey, and R A Roth. *Dept. of Pharmacology and Toxicology, Institute for Environmental Toxicology, and National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI, USA.*

Exposure to small, nontoxic doses of bacterial endotoxin augments the toxicity of a variety of hepatotoxicants. This study was conducted to delineate the development of injury in a rat model of augmentation of aflatoxin B_1 (AB1) hepatotoxicity by endotoxin and to explore the role of neutrophils in the pathogenesis. Male, Sprague-Dawley rats (200-300 g) were treated with either 1 mg AB1/kg, ip, or its vehicle (2% DMSO/water) and 4 hours later with either endotoxin (E. coli LPS; 7.4 X 10^6 EU/kg, iv) or its saline vehicle. Liver injury was assessed 6, 12, 24 or 48 hr after AB1 administration from alterations in the concentration of bile acids and the activities of alanine aminotransferase (ALT), aspartate aminotransferase (AST) and 5'-nucleotidase (5'-ND) in serum and from histologic examination of liver. At all times and for all markers, injury in rats treated with either AB1 or LPS was absent or modest. In the AB1/LPS group, injury was significant by 12 hr and maximal by 24 hr. Increased numbers of neutrophils were apparent in liver lesions from this group. To examine the role of neutrophils in the pathogenesis, an antibody to rat neutrophils was given prior to AB1/endotoxin treatment to reduce blood concentration of these cells. Neutrophil depletion protected against hepatocellular injury as evidenced by prevention of the increase in ALT and AST and attenuation of morphologic injury. By contrast, neutrophil depletion did not affect the increase in 5'-ND or bile acids. These results suggest that endotoxin potentiates AB1 hepatocellular injury by a mechanism which is dependent on neutrophils; however, cholestatic changes appear to be neutrophil-independent. (Supported by NIH grant ES04139.)

262 EFFECTS OF PHYTOCHEMICALS ON AFLATOXIN-INDUCED CYTOTOXICITY.

J W Ho and H T Chan. *Department of Biochemistry, C.U.H.K., Shatin, Kowloon, Hong Kong.*

Aflatoxin is a potent mycotoxin produced by strains of Asperigillus flavus

and parasitius. The cytotoxicity induced by aflatoxin B1 to fibroblasts and the toxic effects on human cancer cells have been examined. The cellular responses were measured by MTT assays. The results show that different cellular responses among cell lines were observed. The cancer cell displayed greater viability in an equivalent solution of the toxicant. Also, the chemoprotective effects of some common dietary vitamins such as vitamins C, A and E on the aflatoxin-induced cytotoxicity were studied. By comparing the cellular responses, all three vitamins show chemoprotective effects on the cytotoxicity. Vitamin C appeared to be more effective in protecting the cell from the toxicity. The cells show better viability (>30%) than the control in the presence of vitamin C. The study provides useful information on the toxic action of aflatoxin and allows us to get an understanding of the defense mechanism of cancer cells against the aflatoxin-induced toxicity.

263 QUALITATIVE STRUCTURE ACTIVITY RELATIONSHIP ANALYSIS OF TRICHOTHECENE MYCOTOXINS.

J R Clarke[1], R L Uzarski[1,2], D G Uzarski[3], and J J Pestka[1,2]. [1]*Department of Food Science and Human Nutrition;* [2]*Institute of Environmental Toxicology;* [3]*Department of Fisheries and Wildlife, Michigan State University, E. Lansing, MI, USA.*

Trichothecenes are a group of secondary fungal metabolites which are common contaminants of grain based food and feeds. The effect of trichothecene physical and chemical characteristics on toxicity was assessed using previously reported values generated from *in vivo* and cellular toxicity model systems. Three dimensional structures were generated using Allinger's molecular mechanisms force field analysis (Chem 3-D Software, CambridgeSoft, Cambridge, MA). Physico-chemical properties were calculated using Molecular Modeling Pro (WindowChem Software, Fairfield, CA). The software generated thirty four variables, although many were highly correlated. To reduce problems associated with colinearity, Pearson correlation, Gittin's condition number, and consideration of variable calculation were used to reduce the variables to Hansch Log P, Crippen's Log P, CNDO Log P, molecular connectivity index, solubility parameter (Sol), and hydrophilicity - lipophilicity balance (HLB). Seven data sets were analyzed using principal components analysis and canonical correlation analysis. Sol and HLB always weighted heavily as predictors of toxicity in canonical correlation. The same variables served as surrogates for toxicity, structuring the data set in principal component analysis. These results suggest that solubility is an important influence on trichothecene toxicity.

264 EFFECT OF PIROXICAM ON OCHRATOXIN A–INDUCED INHIBITION OF PROTEIN SYNTHESIS IN VERO CELLS.

I Baudrimont and E E Creppy. *Laboratoire de Toxicologie et d'Hygiène Appliquée, UFR des Sciences Pharmaceutiques, Université Victor Segalen Bordeaux, Bordeaux, France.*

Ochratoxin A (OTA) is a mycotoxin produced by *Aspergillus ochraceus* as well as other moulds. It is a natural contaminant of mouldy food and feed. OTA is increasingly regarded as the main causal agent of Balkan Endemic Nephropathy (BEN). In addition to its nephrotoxic effects OTA is immunosuppressive, teratogenic, genotoxic and carcinogenic. It also interferes with blood coagulation and carbohydrates metabolism. OTA induces oxidative damage by enhancing lipid peroxidation and inhibits protein synthesis by competition with phenylalanine in the phenylalanine - tRNA aminoacylation reaction. An attempt to prevent its toxic effects, mainly the inhibition of protein synthesis, has been made using piroxicam, a non-steroidal anti-inflammatory drug (NSAID). Protein synthesis was assayed in monkey kidney cells (Vero cells) treated with increasing concentrations of OTA (10 - 100 μM). Vero cells lines were cultured in 24-well culture discs, in RPMI 1640 medium, supplemented with L-glutamine (2 mM) and penicillin (100 U) - streptomycin (100 mg / ml). Cells (10^5 cells/ml) were routinely incubated, for 24 h, in an humidified 5% CO_2 / 95 % air mixture, at 37°C. Protein synthesis was assessed by [^{3}H] - leucine (5.0 Ci / mmol) incorporation during a 2h - pulse. After 24h incubation with the toxin, protein synthesis was inhibited by OTA in a concentration dependant manner. The 50% inhibitory concentration (IC_{50}) was about 9μM. When cells were pretreated with piroxicam (10 - 100 μM) 4h before OTA intoxication (10 - 100 μM) the inhibition of protein synthesis induced by OTA was partially prevented (IC_{50} = 27 μM). This result could explain the protective effect of piroxicam on OTA - induced nephrotoxicity in rats (I. Baudrimont et al., 1995, Toxicology, 95, 147).

265 OCHRATOXIN A(OTA) REVERSIBLY INHIBITS PROLIFERATION IN THE LLCPK-1 CELL LINE.

F Schwöbel, E O'Brien and D R Dietrich. *Environmental Toxicology, University of Konstanz, Konstanz, Germany.*

Ochratoxin A is a mycotoxin produced as a secondary metabolite by certain *Aspergillus* and *Penicillium* species. It is commonly found as a contaminant of both human and animal feedstuffs. All human blood samples tested to date have proved positive for OTA. Average daily intake in humans is estimated to be approximately 5 – 10ng/kg. OTA has been demonstrated to be immunotoxic in pigs (antiproliferative effect in T-cells) and teratogenic in several species including rat, mouse, hamster and chick, primarily giving rise to craniofacial abnormalities such as exencephaly, micropthalmia and facial clefts. Although little is known about its potential for human teratogenesis, OTA displays similarities in animal models to other well-characterized human teratogens such as valproate and thalidomide, especially with respect to dose-dependency and gestational sensitivity periods. A disruption in the normal cellular proliferation control could contribute to both the observed immunotoxicity and teratogenicity of OTA. Therefore, we investigated the effect of the toxin on proliferation rates in LLCPK-1 cells following acute exposure. Cells were exposed to increasing concentrations of OTA over 24 and 48hrs. Antiproliferative effects were determined by direct counting of crystal violet stained nuclei and confirmed using a Coulter counter. The concentrations producing 50% proliferative arrest were 5 and 1μM following 24 and 48h exposure respectively, with an IC_{80} of 10μM following 48 hour exposure to the agent. The antiproliferative effect was observed to be time dependent and reversible as cells which had been exposed to 10μM OTA for 24h resumed proliferation within 24h of drug removal and replacement of full fresh medium whereas cells exposed to the same concentration for 48h required 48h to re-enter the cell cycle. The nature of the proliferative arrest was examined using standard flow cytometric /ICP analysis of propidium iodide/Hoechst stained DNA and was found to be specifically located to the G2- + M-phase of the cell cycle suggesting e.g. a reversible inhibition of cell cycle specific protein synthesis.

266 TOXIC EFFECTS OF OCHRATOXIN A ON CATECHOLAMINE - RICH HUMAN NEUROBLASTOMA CELL LINE.

A Belmadani and E E Creppy. *Laboratory of Toxicology, University Bordeaux, Bordeaux, France.*

Ochratoxin A (OTA) is a mycotoxin produced by mould spores such as *Aspergillus* and *Penicillium*. It is a natural contaminant of a wide variety of both human and animal foodstuffs. Via dietary intake, it passes into the blood of both human and animal and accumulates in several organs such as the kidney, being nephrotoxic to all animal species studied so far and the brain with selective toxicity in the ventral mesencephalon (VM) and the cerebellum. Structural analogue to phenylalanine (phe), OTA inhibits protein synthesis in cells but with higher sensitivity of neurones of the ventral mesencephalon (NVM). In order to confirm the regional selectivity and the sensitivity of NVM primary cultures, investigations were designed to study the mechanism of the cytotoxicity of OTA in cultures of NB69 cell line whose biochemical and pharmacological profiles previously described resemble VM neurone profiles. The NB69 cells, a human catecholamine neuroblastoma were then studied in the presence of OTA for MTT conversion, lactate dihydrogenase release (LDH), protein synthesis and lipid peroxidation evaluated by production of malondialdehyde (MDA). The protective effects of some substances (structural analogues of OTA and antioxidants such as SOD+catalse, vitamin E, epicatechin, trans-resveratrol) were also assayed. After a 24h incubation period, OTA (10-150 μM) decreased MTT conversion and increased of LDH release in a dose-dependent manner. In parallel levels of MDA produced were increased significantly and protein synthesis was inhibited (inhibitory concentration 50% (CI50% = 14μM). Interestingly the levels of dopamine were decreased from 3.56 ± 0.84 to 1.02 ± 0.34 ng/mg of protein with 28 μM of OTA. Analogues of OTA and antioxidants partially reversed the inhibition of protein synthesis and MDA production. Altogether these results indicate that OTA is also a neurotoxic in addition to its well-documented nephrotoxicity and that its effects are partially related to phe-dependent enzymes in addition to its oxidative pathway and protein synthesis inhibition.

267 ERYTHRITOL: AN INTERPRETIVE SUMMARY OF BIOCHEMICAL, METABOLIC, TOXICOLOGICAL AND CLINICAL DATA.

I C Munro[1], W O Berndt[2], J F Borzelleca[3], G Flamm[4], B S Lynch[1], E Kennepohl[1], A Bär[5], and J Modderman[6]. [1]*CanTox Inc., Consultants in Toxicology, Health and Environmental Sciences, Mississauga, ON, Canada;* [2]*University of Nebraska Medical Center, Nebraska's Health Science Center, Omaha, NE;* [3]*Department of Pharmacology and Toxicology, Medical College of Virginia, Richmond, VA;* [4]*Flamm Associates, Vero Beach, FL;* [5]*Bioresco AG, Binningen, Switzerland; and* [6]*Keller and Heckman, LLP, Washington, DC.*

A critical and comprehensive review of the safety information on erythritol was undertaken. Numerous toxicity and metabolic studies have been conducted on erythritol in rats, mice, and dogs. The toxicity studies consist of long-term feeding studies conducted to determine carcinogenic potential, intravenous and oral teratogenicity studies to determine the potential for effects on the fetus, oral studies in which erythritol was administered over 1 or 2 generations to determine the potential for reproductive effects, and studies in bacterial and mammalian systems to determine mutagenic potential. The majority of the safety studies conducted were feeding studies in which erythritol was mixed into the diet at concentrations as high as 20%. The metabolic studies in animals have shown that erythritol is almost completely absorbed, not metabolized systemically and is excreted unchanged in the urine. The safety studies have demonstrated that erythritol is well-tolerated and elicits no toxicological effects. The clinical program for erythritol involved a series of single-dose and repeat-dose, short-duration studies which have been used to investigate the human correlates to the physiological responses seen in the pre-clinical studies. The clinical studies showed erythritol to be well-tolerated and not to cause any toxicologically relevant effects, even following high-dose exposure. Erythritol administered orally to humans was rapidly absorbed from the gastrointestinal tract and quantitatively excreted in the urine without undergoing metabolic change. At high oral doses, urinary excretion accounted for approximately 90% of the administered dose with minimal amounts appearing in the feces. A comparison of the human and animal data indicated a high degree of similarity in the metabolism of erythritol and this finding supports the use of the animal species used to evaluate the safety of erythritol for human consumption. It can be concluded, based on the available studies that erythritol did not produce evidence of toxicity.

268 ORAL TWO-GENERATION REPRODUCTION STUDY IN RATS ON PHYTOSTEROL-ESTERS (PE)) - A NOVEL FUNCTIONAL FOOD.

D H Waalkens-Berendsen[1], A P M Wolterbeek[1], M Richold[2], P A Hepburn[2]. [1]*TNO Nutrition and Food Research Institute, Toxicology Division, Zeist, The Netherlands and* [2]*Safety & Environmental Assurance Centre, Unilever Research, Colworth House, Sharnbrook, UK.*

A new margarine has been developed by Unilever which contains the novel ingredient, phytosterol esters. PE are a natural component of vegetable oils which lowers blood cholesterol by blocking the absorption of cholesterol from the gut. As part of an extensive programme of safety evaluation studies we have conducted a two-generation reproduction study in rats, in which the possible effect of PE on male and female reproductive performance and on the growth and development of the offspring, was carried out. Wistar rats were fed diets containing various levels of PE (0, 1.6, 3.2 and 8.1% w/w) over two successive generations and a wide range of reproductive- and developmental parameters were determined. Histopathological examinations were performed on various organs of F1- and F2-weanlings and of F0- and F1-parental animals.

Daily clinical observations did not reveal any remarkable findings. In the highest-dose group, food intake and body weights were statistically significantly decreased. In both generations no effects of PE were observed on pup mortality calculated on litter basis, precoital time, mating index, male and female fertility, female fecundity, gestation index, duration of gestation and number of females with stillborn pups and post-implantation loss, pup development, sexual maturation and estrus cycle length. Apart from an increased relative liver weight of the F0-males of the 1.6 and 3.2% PE groups no differences were observed in organ weights of adrenals, brain, epidymides, pituitary, prostate, seminal vesicles, ovaries and uterus. Furthermore, no histopathological changes were observed in these organs.

In conclusion, dietary administration of up to 8.1% PE during two generations had no effects on reproduction of parental F0- and F1-generation Wistar rats and the development of the F1- and F2-pups.

269 GENETIC TOXICITY *IN VITRO* OF BISPHENOL A-DIGLYCIDYL ETHER (BADGE) AND ITS HYDROLYSIS PRODUCT.

E Pfeiffer and M Metzler. *Institute of Food Chemistry, University of Karlsruhe, Karlsruhe, Germany.*

BADGE is released from epoxy resins and organosoles, which are used for the interior lacquer-coating of food cans. Hydrolysis may occur at the epoxide rings leading to a diglycol, and, after metabolic hydroxylation, at the ether bonds leading to bisphenol A (BPA). The health implications of BADGE and its putative hydrolysis products are yet unclear. We have recently reported that BPA induces metaphase arrest and micronuclei with whole chromosomes in cultured Chinese hamster V79 cells, indicative of an aneuploidogenic potential (Mutat. Res. 390, 21, 1997). In the present study, the induction of micronuclei and gene mutations in V79 cells by BADGE and its epoxide hydrolysis product was investigated. BADGE was very stable in cell culture medium at pH 7.5 and 37°C: after 24 h, only unchanged BADGE was extracted and identified by HPLC. However, in the presence of rat liver microsomes or S-9 supernatant with or without NADPH-regenerating system at 37°C, BADGE disappeared completely within a few min, and the only product formed was the diglycol. At concentrations ranging from 10 - 50 μ M, BADGE in the absence of S-9 mix clearly induced micronuclei with acentric chromosomal fragments and gene mutations at the HPRT locus. Higher concentrations were cytotoxic. In contrast, the diglycol of BADGE was devoid of clastogenicity and mutagenicity even at concentrations up to 200 μ M. Contrary to BPA, neither BADGE nor its diglycol exhibited aneuploidogenic potential. The present study provides evidence that BADGE is a gene mutagen and very resistant against chemical hydrolysis, but is rapidly inactivated by enzymatic epoxide hydrolysis to a non-mutagenic metabolite. (Supported by Deutsche Forschungsgemeinschaft (Me 574/9-2).)

270 SUBCHRONIC ORAL TOXICITY OF EPIGALLOCATECHIN GALLATE (EGCG) IN RATS AND DOGS.

D L McCormick[1], W D Johnson[1], R L Morrissey[2], and J A Crowell[3]. [1]*IIT Research Institute, Chicago, IL;* [2]*Pathology Associates International, Chicago, IL; and* [3]*National Cancer Institute, Bethesda, MD.*

Human consumption of green tea is inversely associated with cancer risk in several organ sites. EGCG is the most abundant polyphenol in green tea, and has significant chemopreventive activity in animal carcinogenesis models. Ninety-day oral toxicity studies were conducted to characterize the toxicity of EGCG, and to establish its No Adverse Effect Level (NOEL). Sprague-Dawley rats (20/sex/group) received oral doses of 0, 45, 150, or 500 mg EGCG/kg/day via gavage; beagle dogs (4/sex/group) received oral doses of 0, 30, 100, or 300 mg EGCG/kg/day via capsule. Toxicologic endpoints included survival, body weight, food consumption, clinical signs, clinical pathology, ophthalmology, electrocardiography (dogs only), organ weights, gross pathology, and microscopic pathology. In dogs, EGCG induced no gross toxicity, body weight effects, alterations in functional parameters, or gross or microscopic pathology. By contrast, early deaths in the high dose group and a dose-related suppression of body weight gain were seen in both sexes of rats. Intestinal dilatation was a common finding both in rats dying or euthanized *in extremis* during the dosing period, and in rats surviving until the terminal necropsy; this change may be secondary to alterations in digestive processes and/or gut microflora. Microscopic findings suggesting possible alterations in gastrointestinal function included pancreatic necrosis and hepatic (periacinar) degeneration and necrosis; modest elevations in ALP, AST, and ALT were seen in female rats in the high dose group. High dose rats of both sexes also demonstrated necrosis/atrophy of the thymus. In dogs, the NOEL of EGCG is ≥ 300 mg/kg/day. Histopathologic data suggests that the NOEL of EGCG is 150 mg/kg/day in both male and female rats. However, body and organ weights appear to be more sensitive indicators of EGCG toxicity in male rats. On the basis of reduced body weight gain and decreased absolute and relative thymus weights, the NOEL of EGCG in male rats is 45 mg/kg/day. (Supported by NCI-N01-CN-55146.)

271 SUBCHRONIC ORAL TOXICITY OF GREEN TEA POLYPHENOLS IN RATS AND DOGS.

W D Johnson[1], R L Morrissey[2], J A Crowell[3], and D L McCormick[1]. [1]*IIT Research Institute, Chicago, IL;* [2]*Pathology Associates International, Chicago, IL; and* [3]*National Cancer Institute, Bethesda, MD.*

Consumption of green tea is inversely associated with human cancer risk in

several tissues; green tea contains a number of polyphenols whose biological activity is consistent with anticarcinogenic efficacy. These studies were designed to evaluate the subchronic oral toxicity of a green tea polyphenol (GTP) fraction [Polyphenon E; Mitsui Norin] whose major components are: epigallocatechin gallate (EGCG; 53.4%); epigallo-catechin (11.4%); epicatechin (9.1%); gallocatechin gallate (5.1%); and epicatechin gallate (4.9%). Sprague-Dawley rats (20/sex/group) received daily oral doses of 0, 90, 300, or 1000 mg GTP/kg via gavage; beagle dogs (4/sex/group) received daily doses of 0, 60, 200, or 600 mg GTP/kg via capsule. Toxicologic endpoints included survival, body weight, food consumption, clinical signs, clinical pathology, ophthalmology, electro-cardiography (dogs only), organ weights, and gross and microscopic pathology. When administered to dogs, GTP induced no gross toxicity, suppression of body weight gain, alterations in functional parameters, or gross or microscopic pathology. By contrast, early deaths were seen in both male and female rats receiving the high dose of GTP. Dose-related suppression of body weight gain, food consumption, and relative and absolute spleen and thymus weights were also seen in both sexes. As seen with purified EGCG, intestinal dilatation was a common finding in early deaths, moribund kills, and in rats surviving until the terminal necropsy; gross intestinal pathology may be secondary to alterations in digestive processes and/or gut microflora. Microscopic findings included pancreatic necrosis, hepatic degeneration/necrosis, and thymic necrosis/atrophy. The NOEL of GTP in dogs (both sexes) is ≥ 600 mg/kg/day; the NOEL of GTP in rats (both sexes) is 90 mg/kg/day. Mortality patterns in rats indicate that GTP is more toxic than would be predicted based on its EGCG content alone, suggesting that polyphenols other than EGCG play a role in its toxicity. (Supported by NCI-N01-CN-55146.)

272 ADRENERGIC AGONISTIC EFFECTS AND CYTO-TOXICITY OF *CHINESE EPHEDRA* (MA-HUANG) USED FOR WEIGHT REDUCTION.

M K Lee, Y H Wong, C T Che[1] and D P H Hsieh. *Department of Biology and [1]Department of Chemistry, Hong Kong University of Science & Technology, Clear Water Bay, Kowloon, Hong Kong, PRC.*

Ma-huang is a traditional Chinese medicinal herb derived from stems and branches of *Ephedra sinica* Stapf and other species of *Ephedra* plants. It contains 1 - 2% by weight of ephedrine alkaloids, of which ephedrine accounts for 40 - 90%. Through their β -adrenergic agonistic action, these alkaloids can induce thermogenesis and energy expenditure and hence sustain weight loss when ma-huang is taken on a long-term basis. However, these alkaloids produce myocardial stimulation through their β_1-agonistic effect. They also constrict peripheral blood vessels via their α -agonistic effect, causing an increase in blood pressure and heart rate. Recently, great volumes of ma-huang have been used as an active ingredient in some dietary supplements used for weight reduction, causing serious side effects and numerous cases of poisoning, some of which were fatal. In the present study, ma-huang extracts were prepared under various conditions for possible different potencies. For each extract, ephedrine content was analyzed by HPLC, biological activities were determined with mammalian cell lines stably expressing adrenergic receptors, and cytotoxicity to a hepatocarcinoma cell line (HepG2) was measured using MTT colorimetry. The results indicate that the potencies of adrenergic agonistic activity and cytotoxicity of ma-huang extracts are in correlation with their ephedrine contents. Grinding of herb was found to be a crucial condition for increased potency. (Supported by Hong Kong UGC PGS and Hong Kong ISF.)

273 HEAT RESISTANCE CHARACTERISTICS OF *ESCHERICHIA COLI* O157:H7 ISOLATED IN JAPAN.

F U Kasuga, Y Itoh, and S Kumagai. *National Institute of Infectious Diseases, Tokyo, Japan.* Sponsor: W Norred.

Thermal resistance of enterohemorrhagic *E. coli* O157:H7 was compared between the strains isolated from large outbreaks occurred in Japan in 1996. Difference in the shape of heat resistance curves upon pH at the heating was also studied. Four strains isolated in outbreaks and one from meat specimen in Japan and one obtained from ATCC were cultured individually in Tryptic Soy Broth (TSB) for 16 hr at 37°C. The cultures were diluted in TSB (pH 7.3) to give 1 x 106 cells per ml of cell suspension, and pH was adjusted to 4.0 or 5.0 with HCl when needed. Syringe vials (15 x 40 mm) were used instead of TDT ampules or plastic bags to heat the samples, in order to improve the handling efficiency and to enable to measure inner temperature during the heating process. Temperature of the contents was monitored using a type K thermocouple. Duplicate vials were removed at each prescribed time interval, transferred to an ice bath, and the content of the vials was spiral plated on Tryptic Soy Agar. When the bacterial suspension was heated at 55°C in the medium with pH 7.3, D-value varied from 2.46 to 5.34 within the strains isolated in Japan. Heat resistance curve has been understood as logarithmically declining against heating time. However, the pattern of the curve was dramatically altered and accordingly different D-value was given when the samples were heated in the medium with different pH. Our observations suggest that there exist various types of *E. coli* O157:H7 strains from the viewpoint of thermal resistance, and arrest attention to the effect of pH on the thermal resistance of pathogenic bacteria when heating duration is estimated for food processing.

274 STRATEGIES FOR ESTIMATING PROVISIONAL ACCEPTABLE RESIDUES (PAR) FOR EXTRALABEL DRUG USE IN FOOD ANIMALS.

R E Baynes[1], T Martín-Jiménez[1], A L Craigmill[2], and J E Riviere[1]. [1]*Center for Cutaneous Toxicology and Residue Pharmacology, College of Veterinary Medicine, North Carolina State University, Raleigh, NC, USA;* [2]*Environmental Toxicology Extension, University of California, Davis, CA, USA.*

In 1996, the US Congress passed AMDUCA, which allows some veterinary drugs to be used off label. In order to implement this and protect the US consumer, tolerances, or safe concentrations are required before a withdrawal time can be adequately estimated for extralabel drug use. This paper presents several strategies that can be used to derive an equivalent safe concentration, referred to as a Provisional Acceptable Residue (PAR) for specific tissues, that may be used to estimate drug withdrawal times after extralabel use of several antibiotics and other drugs. Derivation of the proposed PAR ensures that daily intakes of drug residues in milk and/or edible tissues do not exceed Acceptable Daily Intakes (ADIs) specific for the US and also takes into account safety factors and food consumption values. Method A requires partitioning of 50% of the ADI to the target tissue and reserving the remainder for milk. Method B equally partitions the ADI into all edible tissues, including milk. Method C assigns 50% ADI to milk and equally partitions the remaining 50% ADI into edible tissues. These simulations showed that provided the safe concentration or its equivalent PAR is based on rigorous toxicology data (e.g., ADIs), the health of the most sensitive population may not be compromised. It is proposed that these PARs can be used for estimating withdrawal times after extralabel drug use and for purposes of trade harmonization.

275 BELL-SHAPED RELATIONSHIP BETWEEN MOLECULAR WEIGHT AND DOSE-RESPONSE TO WHITE MINERAL OILS IN FISCHER 344 (F344) RATS.

J G Drummond, J J Freeman, D J Letinski and M J Miller. *Exxon Biomedical Sciences, Inc., E Millstone, NJ, USA.*

Dietary exposure to certain white mineral oils (WO) causes inflammatory effects in the liver and lymph nodes of F344 rats, but not in other strains or species. The average molecular weight (MW) of previously tested oils ranged from ~300-500. The inflammatory effects were inversely related to MW and were not seen with heavier paraffinic WO (MW 485). This study extends the relationship between MW and dose-response to lighter (MW<300) WO. Four groups of female F344 rats (n=15/group) were fed a diet with 0, 0.02, 0.2, or 2.0% of a light white mineral oil (MW=270) for 90 days. No effects were seen in the 0.02% group. Treatment related changes included increased relative liver and mesenteric lymph node (MLN) weights at 0.2%, MLN inflammation (macrophage accumulations) at 0.2%, and liver histopathologic changes (microgranuloma formation) at 2% dose level. These effects had a lower incidence and were less severe than those seen previously with heavier oils (MW=320-420), suggesting a bell-shaped structure activity relationship may exist for WO-induced inflammatory effects in F344 rats. Analysis of WO residues in livers from these study animals showed that lower hydrocarbons (C_{15}-C_{21}) were underrepresented compared to the original test material. The relative absence of lower MW hydrocarbons in liver tissue is most probably due to increased metabolism rather than decreased absorption of the WO.

276 LOW MELT POINT PARAFFIN WAX (LMPW) CAUSES FORIEGN BODY RESPONSE IN FISCHER 344 (F344) AND SPRAGUE-DAWLEY (SD) RATS.

L E Twerdok[1], S J Waterman[1], J Nold[2], S Francke[2], J Rojko[2], and W Hall[2]. [1]*American Petroleum Institute White Oils and Waxes Research Group, Washington, DC, USA;* [2]*Pathology Associates International, Frederick, MD, USA.*

Previous 90-day feeding studies of LMPW have shown differences in tissue response between F344 and SD rats. F344 histopathology included liver and mesenteric lymph node (MLN) microgranulomas, and cardiac mitral valve inflammation; whereas, effects in SD were limited to a low incidence of MLN effects. This study further assesses strain differences by phenotypically characterizing the inflammatory cell infiltrates in affected tissues. Samples of liver, MLN and cardiac mitral valves were taken from female F344 and SD rats fed 0, 0.2 or 2.0% LMPW for up to 90 days. Sections were stained for the presence of cells expressing CD3+ (T-cells), CD4+ (helper T-cells) CD8+ (suppressor/cytotoxic T-cells), CD45R+ (B-cells), ED2+ (resident macrophages), and lysozyme (activated macrophages). The microgranulomas observed in both the F344 (liver and MLN) and SD (MLN only), were consistent with a foreign body reaction as characterized by the presence of large epithelioid lysozyme+ macrophages and multinucleated giant cells (predominantly Langhan's type). Lymphocytes (mostly CD3+) surrounded the macrophages; CD4+ and CD8+ cells were present in about equal numbers. CD45R+ were a minor component of the lymphoid infiltrates. The minimal lymphoid infiltrates observed in the F344 mitral valve consisted predominantly of CD3+ cells with few CD45R+ cells and macrophages. Electron microscopic analysis of the liver indicated activated KCs in the F344 only, as well as intralysosomal crystalloids with angular shapes in KCs and hepatocytes from the F344 but not the SD. In conclusion, dietary LMPW induced a classic foreign body response in F344 (MLN and liver) and SD (MLN only) rats.

277 POTENTIAL PROBLEMATICAL GLYCOALKALOIDS IN PORK CHOPS.

J M Betz[1] and T Garland[2]. [1]*US FDA, Center for Food Safety and Applied Nutrition, Washington, DC, USA;* [2]*Texas A&M University, Department of Veterinary Physiology & Pharmacology, College Station, TX, USA.*
Sponsor: J Spoo.

Sensitivities or allergic responses to certain foods is documented in veterinary and human medicine. A woman with known sensitivity to members of the Solanaceae family (tomatoes, potatoes, nightshades) became ill after consuming part of a cooked pork chop purchased from a local butcher. She experienced severe gastric upset, trembling, weakness and near prostration. She recognized her symptoms as being identical to those she commonly experienced following consumption of potatoes or tomatoes. The next day when she tried the remains of the pork chop the clinical signs recurred, and she was taken to the hospital. The clinical signs are consistent with those produced by glycoalkaloid intoxication. When questioned, the butcher indicated the pigs had been raised locally. Local producers fed their pigs the potato remains and leavings from a nearby potato chip manufacturing company. Analysis of the pork chops by gradient reverse-phase HPLC confirmed the presence of the potato glycoalkaloids, solanine and chaconine, albeit at levels not normally associated with human intoxications. Implications of this finding are far reaching for sensitive individuals, who may inadvertently consume natural toxicants which they are normally able to avoid.

278 CHOLESTYRAMINE PROTECTION AGAINST OCHRATOXIN A (OTA) TOXICITY: ROLE OF OTA ADSORPTION BY THE RESIN AND BILE ACID ENTEROHEPATIC CIRCULATION.

A Kerkadi[1], C Barriault[1], R R Marquardt[3], A A Frohlich[3], I M Yousef[2] and B Tuchweber[1]. [1]*Dept of Nutrition and* [2]*Pharmacology, Université de Montréal, Québec, Canada;* [3]*Dept of Animal Science, University of Manitoba, Winnipeg, Canada.*

Ochratoxin A (OTA)may contaminate animal feed and food, leading to major health problems. The addition of cholestyramine (CHA), a bile acid binding resin, to OTA contaminated diets, reduced plasma levels of the toxin which was associated with enhanced fecal excretion. To elucidate the mechanism of action of CHA, we carried out *in vitro* experiments to determine whether the resin may adsorbe the toxin. Results showed that CHA adsorbes OTA and has greater affinity for OTA than for bile salts. However, the saturation of the resin was reached at higher levels with bile acids than with OTA. The binding of OTA to CHA was electrostatic in nature and reinforced by hydrophobic links. The results of the *in vivo* study showed that the toxin's plasma levels were significantly decreased in bile salt depleted rats compared to the control. The decreased OTA plasma levels in CHA treated animals may be explained by direct adsorption of the toxin and also by the alteration of bile salt biliary pool. (Supported by NSERC.)

279 EFFECT OF MENTHA PIPERITA AND MENTHOL ON CCL_4-INDUCED HEPATIC LIPID PEROXIDATION IN FEMALE RATS.

Z A Fadhel and S J Abdul-Rahman. *College of Pharmacy, Jordan University for Women, Amman, Jordan.*

Leaves of Mentha piperita (peppermint) are considered carminative and stomachic, and are used against pains and headache. Menthol, an active constituent of peppermint has been used as a counter irritant, an antiseptic and a stimulant. The effects of an aqueous extract of peppermint on CCl_4-induced lipid peroxidation, phosphorylase a activity and protein content in female rats were investigated. In vitro addition of menthol on hepatic lipid peroxidation was also studied. A 0.5 % peppermint extract was administered as an oral dose of 1 ml/kg twice/day for 21 days before and during CCl_4 treatment. This peppermint extract contained 1.24 mg/ml of peppermint solid per ml. The results demonstrate that peppermint administration markedly inhibited hepatic lipid peroxidation and produced a 32 % decrease in thiobarbituric acid reactive substances (TBARS) in livers of CCl_4- treated animals, but had no effect on phosphorylase a activity or protein content. In contrast, In vitro addition of menthol produced a dose-dependent increase in TBARS. Thus, administration of Mentha piperita provided significant protection against CCl_4-induced lipid peroxidation. However, decreased CCl_4-induced lipid peroxidation cannot be attributed directly to its active constituent menthol since addition of menthol to liver homogenates significantly increased TBARS. Therefore, other active ingredients in Mentha piperita may have provided protection against CCl_4- induced lipid peroxidation.

280 OXYGEN REACTIVE RADICALS PRODUCTION IN CELL CULTURE BY OKADAIC ACID AND THEIR IMPLICATION IN PROTEIN SYNTHESIS INHIBITION.

W G Matias, A Traoré, M Bonini, and E E Creppy. *Laboratory of Toxicology, University of Bordeaux, Bordeaux, France.*

Okadaic acid (OA), a diarrhetic shellfish toxin is a potent promoter of tumours in mouse skin and a specific inhibitor of protein phosphatases 1 and 2A. Recently it has been shown that OA inhibited protein synthesis in a cell-free system, with 50% inhibitory concentration of 6.3 x $10^{12}M^{-1}$ but the mechanism whereby this inhibition is mediated was still unclear. In this study, the effect of OA on protein synthesis in Vero cell was investigated. Protein synthesis was inhibited by OA alone in Vero cells in a concentration-dependent manner. Since OA also induced lipid peroxidation and likely oxygen reactive radicals, it was interesting to know whether these radicals impair the protein synthesis process. Therefore, SOD + catalase were added in the culture medium in the presence of OA and labelled leucine. These enzymes partially prevented the inhibition of protein synthesis induced by OA, indicating that the formation of high reactive free radicals could be one of the pathways this marine toxin induces its toxicity. Since this prevention was only partial, it was speculated that the production of oxygen reactive radical scavenged by SOD + catalase is not the main mechanism whereby OA induces its cytotoxicity. Vitamins E and C also prevent the lipid peroxidation induced by OA in cells, but failed to reduce the inhibition of protein synthesis to the same level, indicating that a more specific mechanism might be responsible for protein synthesis inhibition. However our results pointed to lipid peroxidation being a precocious phenomenon following the OA exposure, since a concentration wich enhanced MDA production was lower than that inducing significant cellular protein synthesis inhibition.

281 MECHANISM OF ASCIDIDEMIN TOXICITY TO CHO CELLS.

S S Matsumoto[1], D M Schmehl[1], B R Copp[2], J A Holden[3] and L R Barrows[1]. [1]*Department of Pharmacology and Toxicology and* [3]*Department of Pathology, University of Utah, Salt Lake City, UT, USA;* [2]*Department of Chemistry, The University of Auckland, Auckland, New Zealand.*

Ascididemin, a marine pyrido[2,3,4-kl] acridine-based alkaloid, is cytotoxic

to tumor cell lines *in vitro* and *in vivo*. In this study ascididemin and two analogs are shown to produce DNA cleavage through the production of reactive oxygen species (ROS). A whole plasmid assay quantitated concentration dependent DNA cleavage for BC-109-1, BCMH-1-48 and BC-1-51 (ascididemin). This assay highlighted the enzyme independence of ascididemin DNA cleavage, the sole requirement for maximal cleavage being dithiothreitol (DTT). Reacting the compounds with NiCl or $FeSO_4^+$ failed to increase DNA cleavage. This argues against a Fenton-mediated mechanism of DNA cleavage. Likewise, chelating agents failed to provide protection. However, catalase and reduced glutathione, antioxidants, protected against DNA cleavage *in vitro* and protected Chinese hamster ovary (CHO) cells in culture from toxicity. This result is consistent with a mechanism based on production of ROS. Also consistent with this mechanism was the non-specific fragmentation of plasmid by ascididemin or its analogs visualized by PAGE. Cyclic voltammetry revealed less energy is necessary to reduce the three DNA cleaving analogs than the two inactive analogs. Treatment of mutant CHO cells highlighted a predilection of these drugs to induce single strand breaks in cells. Preclinical screening at NCI revealed the cytotoxic and antineoplastic features of ascididemin and BCMH-1-48. BC-109-1 is set to enter screening. It is therefore important to characterize the mechanism of DNA cleavage by these marine natural products, a mechanism likely responsible for their anticancer activity.

282 FUNCTIONAL CHARACTERIZATION OF ARYL HYDROCARBON RECEPTOR PHOSPHORYLATION MUTANTS IN THE MAJOR PHOSPHORYLATION REGION.

S K Park and T A Gasiewicz. *Department of Environmental Medicine, School of Medicine and Dentistry, University of Rochester, NY, USA.*

The Aryl Hydrocarbon Receptor (AhR) is a ligand-dependent transcription factor that increases the transcription rate of many dioxin-responsive genes, including some drug-metabolizing enzymes and cytokines. Binding of a ligand, such as 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) to AhR initiates the multi-step transformation process, including release of HSP90s, nuclear localization, dimerization with Ah Receptor Nuclear Translocator (ARNT), binding to the dioxin-responsive element (DRE), and recruitment of the basal transcription machinery proteins into the promoter region of the target genes. Indirect biochemical studies have shown that phosphorylation signal transduction pathway is extensively involved in this process. In addition, a 32P-radiolabeling study with mouse hepatoma cell line suggested that both AhR and ARNT are phosphoproteins and the major phosphorylation site in AhR is located within amino acids 368 - 398. This fragment has six hydroxylated amino acid residues that are potentially phosphorylated. In this study, all the six amino acid residues in the major phosphorylation fragment of AhR were changed to non-phosphorylatable amino acids by site-directed mutagenesis to determine the physiological role of the phosphorylation in this region. All testing mutants have similar DNA binding activity compared to that of wild-type (WT) AhR. However, the mutants which have alanines instead of threonine and serine showed lower TCDD-dependent transcription activity than WT AhR when they were expressed in the AhR-deficient cells along with DRE-reporter gene. These data suggest that phosphorylation on those residues might be important for the interaction of AhR with the crucial components of the cellular machinery that regulate the dioxin-responsive genes. (Funded in part by NIEHS Grant ES02515 and Center Grant ES01247.)

283 MODULATION OF BENZO[a]PYRENE TOXICITY BY 3'-METHOXY-4'-NITROFLAVONE.

S D Dertinger and T A Gasiewicz. *Department of Environmental Medicine, University of Rochester, Rochester, NY, USA.*

This laboratory has previously evaluated a number of flavone derivatives for aryl hydrocarbon receptor (AhR) agonist and antagonist potential using cell free and cell culture systems. The experiments presented here extend this line of investigation by testing the most potent AhR antagonist, 3'-methoxy-4'-nitroflavone (3'M4'NF), for in vivo activity. Male C57Bl/6J mice were treated with solvent, 60mg 3'M4'NF/kg, 150mg benzo[a]pyrene/kg, or concurrently with 60mg 3'M4'NF/kg and 150mg benzo[a]pyrene/kg. Fifty-four hours after benzo[a]pyrene (B[a]P) exposure, peripheral blood samples were collected. An index of genotoxicity was obtained by scoring the incidence of micronucleated reticulocytes. Results from this experiment demonstrate that 3'M4'NF is not genotoxic in this assay, but does significantly reduce the frequency of B[a]P-induced micronuclei. To isolate the effects that 3'M4'NF has on AhR-mediated gene transcription from possible modulations to constitutive P450 activities, a follow up study was conducted with wildtype C57Bl/6J mice and AhR knockout mice (C57Bl/6 background). These animals were treated with solvent, 3'M4'NF, B[a]P, or 3'M4'NF and B[a]P. In this experiment, peripheral blood samples were collected over a 72hr time frame, and animals were closely monitored for an extended period of time (120 hours post-B[a]P exposure) for overt signs of toxicity. Additionally, spleens were collected at time of sacrifice and histology was performed on these tissue samples. The peripheral blood micronucleus data again demonstrate that 3'M4'NF can antagonize the genotoxicity of B[a]P. Since attenuation of B[a]P genotoxicity occurred in both knockout and C57Bl wildtype animals, it is likely that AhR-dependent and independent mechanisms contribute to the protecting effect of 3'M4'NF. Even though this chemical was able to reduce bone marrow clastogenicity associated with B[a]P exposure, overt toxicity (death) and histological observations indicate that other toxicities are in fact enhanced. Further experiments will be needed to determine whether a 3'M4'NF dose level and/or treatment schedule can be developed which provides protection from B[a]P-induced DNA damage, while eliminating or minimizing the toxicity evident in splenic architecture. (This work was supported in part by NIEHS Training Grant ES07026 and Center Grant ES01247.)

284 ANALYSIS OF AH-RECEPTOR-MEDIATED SIGNAL TRANSDUCTION IN CELL CULTURE MODELS EXPOSED TO HYPOXIC CONDITIONS REVEALS LACK OF COMPETITION FOR THE ARNT PROTEIN.

T Shearer, N Davarinos and R S Pollenz. *Dept. Biochemistry and Molecular Biology, Medical University of South Carolina, Charleston, SC.*

The aryl hydrocarbon nuclear translocator (ARNT) protein is a dimerization partner the AH receptor (AHR) and for hypoxia factor 1a (HIF-1a). Central questions with respect to ARNT are whether utilization of this protein by one pathway can affect another and whether sequestration of ARNT can account for some of the toxicity associated with 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). The current study focused exclusively on AHR-mediated changes in endogenous expression of CYP1A1 and the utilization of ARNT in cell culture models, placed under various hypoxic stimulation. AHR mediated signaling was evaluated by measuring the TCDD-mediated induction of the endogenous CYP1A1 mRNA and P4501A1 protein and the presence of AHR•ARNT heterodimers. The results show that (i) the concentration of ARNT protein tightly associated with nuclear structures following treatment of cells with hypoxia depends on the time course of exposure and the cell type being evaluated, (ii) hypoxia does not influence the concentration of ARNT but may affect the concentration of AHR, and (iii) hypoxia affects the induction of P4501A1 protein and CYP1A1 mRNA in most cells, but the effects ARE NOT related to reductions in AHR•ARNT complexes. The implications of these findings are that inhibition of AHR-mediated gene regulation under hypoxia may be cell specific and is the result of secondary effects related to the hypoxic condition of the cell and not functional interference of hypoxia and AHR-mediated signaling through competition for ARNT protein. (Supported by NIH grant #ES-08980.)

285 IDENTIFICATION OF A DOMAIN RESPONSIBLE FOR THE NEGATIVE FUNCTION OF rtARNTa IN AH RECEPTOR DEPENDENT SIGNALLING.

B Necela and R S Pollenz. *Dept. Biochemistry and Molecular Biology, MUSC, Charleston, SC.*

Rainbow trout express two isoforms of ARNT, termed a and b, which have divergent functions in AHR-mediated signalling due to the presence of distinct COOH-terminal domains. rtARNTb functions positively in AHR-dependent signalling while rtARNTa has a negative impact on this pathway due to the failure of the rtARNTa• AHR heterodimer to bind DNA. Previous analyses revealed that the PST-rich COOH terminal domain of rtARNTa was responsible for repression of DNA binding. Studies were performed to determine whether domains existed within the PST-rich region that contributed to the negative function of this sequence. Computer analysis of the PST-rich COOH domain revealed that the last 20 amino acids are strongly hydrophobic. Truncation of the hydrophobic domain of rtARNTa restored the ability to complement P4501A1 induction in ARNT defective cells. Gel shift assays revealed that the gain in function was related to the recovery of DNA binding. Addition of the hydrophobic domain to mARNT or Gal4 resulted in proteins that were unable to bind DNA. These findings suggest that the hydrophobic domain and not the PST-rich region of rtARNTa is primarily responsible for repression of DNA binding. In addition, Gal4 analysis revealed that the truncated COOH terminal domains are capable of binding

DNA but lack strong transactivation function. Our previous studies revealed that transactivation of rtARNT is not needed for function in AHR-dependent signalling. Collectively, these results narrow the negative function of rtARNTa to the presence of a C-terminal hydrophobic domain and illustrates how changes in the C-terminal domain can affect protein function. (Supported by ES08980.)

286 ANALYSIS OF AH-RECEPTOR DOWN REGULATION IN CELL CULTURE LINES DERIVED FROM HUMAN TISSUES.

R S Pollenz. *Dept. Biochemistry and Molecular Biology, MUSC, Charleston, SC.*

Previous studies have documented that the AH-receptor (AHR) protein is rapidly degraded following ligand binding and that the concentration of AHR protein is a sensitive indicator of exposure to AHR agonists (typified by 2,3,7,8 tetrachlorodibenzo-p-dioxin; TCDD). To date, studies on AHR down regulation have utilized hepatic and non-hepatic cell culture lines as the *in vitro* model and rats and mice as the *in vivo* model of this process. Therefore, studies were initiated to investigate whether AHR protein was depleted form human cell culture lines that had been treated with TCDD. The cell culture lines used in this study included the HepG2 hepatoma line and the MCF-7 breast cancer line. Cells were treated with graded concentrations of TCDD for 16 hours and the level of AHR, AH-receptor nuclear translocator (ARNT), P4501A1 and ß-actin protein determined by quantitative Western blotting. The results showed that the AHR but not ARNT protein levels were depleted in both cell lines in a dose-dependent manner. A concentration of 500pM TCDD was sufficient to deplete 95% of the AHR in both cell lines. Of interest was the finding that the induction of P4501A1 and reduction in AHR protein showed distinct EC_{50} values in the HepG2 cell line. The EC_{50} for induction of P4501A1 was 8pM while the EC_{50} for AHR down regulation was approximately 80pM. Collectively, the results of these studies suggest that AHR down regulation occurs in humans and offers a model for evaluating the percentage of the AHR pool required for induction of P4501A1. (Supported by ES08980.)

287 OXIDATIVE STRESS IN FEMALE B6C3F1 MOUSE LIVER AND BRAIN FOLLOWING ACUTE AND SUBCHRONIC EXPOSURE TO 2,3,7,8-TETRACHLORODIBENZO-P-DIOXIN (TCDD).

B P Slezak[1], G E Hatch[2], M Devito[3], J J Diliberto[3], R Slade[2], K Crissman[2], L S Birnbaum[3]. [1]*Curriculum in Toxicology, UNC, Chapel Hill, NC;* [2]*US EPA, NHEERL/ETD/PTB, RTP, NC;* [3]*US EPA, NHEERL/ETD/PKB, RTP, NC.*

TCDD is a highly persistent trace environmental contaminant and is one of the most potent toxicants known to man. Our laboratory has reported an increase in the production of reactive oxygen species (ROS) in the brain of female B6C3F1 mice following subchronic exposure to TCDD at doses as low as 0.45 ng/kg/day. In this study, oxidative stress was characterized in the brain and liver following subchronic (0.15 to 150 ng/kg; 5 days/ wk for 13 weeks, *p.o.*) and acute exposure (0.001 to 100 µg/kg, *p.o.)* to TCDD in order to investigate the interaction between tissue concentration and time on the production of ROS. Seven days following acute administration of TCDD, mice were sacrificed and demonstrated an increase in liver superoxide anion production (SOAP), and thiobarbituric acid reactive substances (TBARS) at doses of 10 and 100 µg/kg. In addition, increases in glutathione, alpha tocopherol (AT), and a reduction of incorporation of O^{18} into macromolecule and lipid fractions in the liver suggests a "rebound" effect 7 days following TCDD treatment. The brain did not exhibit an increase in SOAP, TBARS, or O^{18} incorporation, but AT levels in the brain were increased following 10 and 100 µg/kg TCDD dosing. The preliminary data suggests that much higher tissue TCDD concentrations are required to elicit oxidative stress following acute dosing when compared to responses observed following subchronic TCDD dosing. Therefore, the mechanism of ROS production following TCDD exposure does not appear to be solely dependent upon the concentration of TCDD within the tissue. (This abstract does not necessarily represent EPA policy.) (BPS supported by EPA, CT 902908.)

288 INTERFERON γ ABROGATES CYPIA1 mRNA EXPRESSION IN MURINE SPLENOCYTES FOLLOWING TCDD EXPOSURE.

R S Marcus[1], M P Holsapple[2], and N E Kaminski[1]. [1]*Michigan State University, East Lansing, MI, USA;* [2]*Dow Chemical Company, Midland, MI, USA.*

These studies sought to begin to characterize the mechanism by which IFNγ attenuates the biochemical actions of TCDD in murine leukocytes. Cotreatment with TCDD and increasing doses of IFNγ in primary splenocytes and purified primary splenic B cells, produced a dose dependent decrease in the magnitude of TCDD-mediated CypIa1 mRNA induction. Interestingly, a gamma activated sequence (GAS) overlaps the DRE3, but not the DRE4 site, in the murine CypIA1 promoter which can be bound by STAT1α homodimers following activation of the IFNγ receptor by IFNγ. DNA binding studies employing either a DRE3 or DRE4 oligomer were undertaken in order to investigate the potential of competition for DNA binding between protein complexes activated following TCDD and IFNγ cotreatment. These studies demonstrated a loss of DNA binding to both DRE3 and DRE4 in the cotreated group (i.e. TCDD+ IFNγ) relative to the DNA binding demonstrated by nuclear proteins in the TCDD treated group when using either of the radiolabeled oligomers as a probe. These results suggest an interaction between the TCDD and IFNγ signal transduction pathways upstream of DNA binding. Our findings also negated the possibility that STAT1α homodimers were competing for DRE binding and therefore precluding the ability of TCDD to induce CypIA1 mRNA expression. Western analysis of AhR protein in the nuclear versus cytosolic fractions of mouse splenocytes demonstrated that the relative magnitude of nuclear and cytosolic AhR protein expression was comparable in the TCDD and cotreated groups, suggesting that there was no interference with AhR nuclear translocation. In summary, these findings suggest that the ability of IFNγ to attenuate TCDD-mediated CypIA1 induction in lymphoid cells is due to a disruption of AhR/ARNT DRE binding. The mechanism responsible for this phenomenon is presently unclear, but may be due to crosstalk between the signal transduction pathways activated by both of these agents. Moreover, the nature of this interaction does not appear to interfere with the ability of the AhR to translocate from the cytosol into the nucleus. (This work was supported in part by NIEHS Grants ES 07255 & ES 02520.)

289 CHARACTERIZATION OF THE AH RECEPTOR ASSOCIATED PROTEIN, ARA9.

J J LaPres[1], L A Carver[1], C A Bradfield[2]. [1]*University of Wisconsin Medical School,* [2]*McArdle Laboratory for Cancer Research, Madison, WI.*

The unliganded aryl hydrocarbon receptor (AHR) is found in a complex with other proteins including the 90 kDa heat shock protein (Hsp90) and a 37 kDa protein we refer to as ARA9. We found that the three tetratricopeptide repeats found in the C-terminus of ARA9 are necessary and sufficient for interaction with the AHR complex. Conversely, the AHR's "repressor"/Hsp90 binding domain is required for interaction with ARA9. Because ARA9 closely resembles the 52-kDa FK506 binding protein (FKBP52), found in the unliganded glucocorticoid receptor (GR) complex, we compared the binding specificities of ARA9 and FKBP52 for AHR and GR. In coimmunoprecipitation experiments, ARA9 specifically associated with AHR-Hsp90 complex but not with GR-Hsp90 complexes. In addition, ARA9 showed a greater capacity than FKBP52 to associate with AHR-Hsp90 complexes. The biological importance of this interaction was demonstrated by the observation that in a yeast expression system ARA9 expression enhanced the response of AHR to the agonist β -napthoflavone, decreasing the EC_{50} by greater than 5-fold and increasing the maximal response 2.5 fold. In contrast, co-expression of FKBP52 had no effect on AHR signaling. In addition, although ARA9 contains a domain similar to that found in other FK506 binding proteins, ARA9 binding to ^{3}H-FK506 could not be detected. Finally, we have characterized the developmental and expression pattern of ARA9 in the developing mouse embryo and mapped the ARA9 locus to human chromosome 11q13.3.

290 TCDD AND OTHER AH-RECEPTOR AGONISTS ARE POTENT ANTI-ESTROGENS IN CULTURED CARP HEPATOCYTES.

M van den Berg[1], J M W Smeets[1], C W M van Holstein[1], J Komen[2], K M Nichols[3], N E Kaminsky[4], J P Giesy[3] and W Seinen[1]. [1]*Research Institute of Toxicology, Utrecht University, Utrecht, the Netherlands;* [2]*Agricultural University Wageningen, Animal Sciences, Wageningen, The Netherlands;* [3]*Michigan State University, Fisheries & Wildlife, East Lansing, MI;* [4]*Michigan State University, Pharmacology & Toxicology, East Lansing, MI.*

The yolk-protein vitellogenin (Vtg) is excreted by the liver of female, as well as male fish, in response to estrogenic compounds. An in vitro system was developed, using cultured hepatocytes from a genetically defined strain of carp (Cyprinus carpio), in which Vtg-production could be determined after exposure to 17β -estradiol or other estrogenic compounds. Vtg was measured by means of a competitive ELISA, using an anti-goldfish-Vtg antibody that also reacts specifically with carp-Vtg. Cyt. P4501A induction, measured as EROD, was used to assess Ah-receptor activation. The hepatocytes were co-exposed to 17β -estradiol and a concentration-range of anti-estrogens. 2,3,7,8-TCDD was shown to be approximately 10,000 times more potent than the model anti-estrogen tamoxifen. Anti-estrogenicity, measured asVtg-reduction, did not concur with EROD induction, but started at concentrations at which EROD was already maximally induced. Also other (weaker) Ah-receptor agonists were tested (PCB 126, β -naphtoflavone, benzo(a)pyrene, benzo(a)anthracene, PCB 118, hexachlorobenzene, MCDF and DIM. If these compounds caused Vtg-reduction, it was also at higher concentrations than the EROD induction. However, their relative anti-estrogenic potencies were approximately equal to their relative EROD inducing potencies; suggesting that the anti-estrogenicity is linked to the Ah-receptor. These results raise mechanistical questions, but also stress the potential importance of anti-estrogenicity in environmental endocrine disruption.

291 TWO AH RECEPTORS IN THE MARINE FISH, *FUNDULUS HETEROCLITUS*: TCDD BINDING AND TISSUE-SPECIFIC EXPRESSION.

S I Karchner, W H Powell, and M E Hahn. *Woods Hole Oceanographic Institution, Woods Hole, MA, USA.*

The aryl hydrocarbon receptor (AHR) is a bHLH-PAS family transcription factor through which halogenated aromatic hydrocarbons such as 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) cause altered gene expression and toxicity. We are examining the AHR signaling pathway in the estuarine fish *Fundulus heteroclitus*. *Fundulus* is abundant in both pristine and polluted estuaries and is capable of developing heritable xenobiotic resistance, and thus it represents a unique aquatic model for the study of AHR signaling. Unlike mammals, in which a single functional AHR has been reported to date, *Fundulus* has two distinct AHR genes, FhAHR1 and FhAHR2 (PNAS 94:13743). FhAHR1 and FhAHR2 cDNAs encode proteins of approximately 100 kDa. Both contain bHLH and PAS domains that share extensive sequence identity with mammalian AHRs; FhAHR1 is more closely related to mammalian AHRs than is FhAHR2. FhAHR1 and FhAHR2 cDNAs were expressed by *in vitro* transcription/translation and analyzed for ligand and DNA binding. Velocity sedimentation on sucrose gradients showed that both proteins specifically bind TCDD. FhAHR2 exhibits specific, TCDD-, and ARNT-dependent interactions with a mouse DRE sequence; the DNA-binding activity of FhAHR1 is as yet unresolved. The two *Fundulus* AHR genes display different tissue-specific patterns of expression; the FhAHR1 transcript is primarily expressed in brain, heart, and ovary, while the FhAHR2 transcript is equally abundant in many tissues. Sequence and phylogenetic analysis of AHRs in other fish demonstrates that AHR2 orthologs exist in several other species of bony and cartilaginous fish. The widespread distribution of AHR2 forms in fish suggests important functional roles for this protein. (Supported by NIEHS ES06272, ES07381, and ES05800.)

292 FUNCTIONAL DIVERSITY OF VERTEBRATE ARNT PROTEINS: ARNT2 IS THE PREDOMINANT FORM OF ARNT IN THE MARINE FISH, *FUNDULUS HETEROCLITUS*.

W H Powell, S I Karchner, R Bright, and M E Hahn. *Woods Hole Oceanographic Institution, Woods Hole, MA, USA.*

The aryl hydrocarbon receptor nuclear translocator (ARNT) is a member of the bHLH/PAS protein superfamily. ARNT dimerizes with several PAS superfamily members, including the ligand-activated aryl hydrocarbon receptor (AHR), forming a complex that alters transcription by binding specific elements within the promoters of target genes. Two genes encode different forms of the protein in rodents: ARNT1, which is widely expressed, and ARNT2, which is limited to the brain and kidneys of adults and specific neural and branchial tissues of embryos. In an effort to characterize aryl hydrocarbon signaling mechanisms in *Fundulus heteroclitus*, a marine teleost that can develop heritable xenobiotic resistance, we have isolated a liver cDNA encoding an ARNT homolog. The protein exhibits AHR-dependent DNA binding capability typical of other vertebrate ARNTs. Unexpectedly, phylogenetic analysis reveals that the cDNA encodes an ARNT2. This is the only detectable ARNT sequence in *Fundulus* liver, gill, ovary, and brain, suggesting that ARNT2 is the predominant form of ARNT in this species. Also surprising is the relative lack of sequence identity with another fish ARNT protein, rainbow trout ARNTb, which we show forms a distinct branch outside the ARNT1 and ARNT2 clades in phylogenetic analyses. Functional diversity of ARNT proteins in fish may have significant implications for the assessment of aryl hydrocarbon effects on natural populations. The increasing use of fish models in toxicological studies underscores the importance of identifying taxon-specific roles of ARNT proteins and their potential dimeric partners in the PAS superfamily. (Supported by NIH: ES05800 ES07381, ES06272.)

293 ISOLATION AND EXPRESSION OF TWO RAINBOW TROUT ARYL HYDROCARBON RECEPTOR cDNAs WITH DISTINCT FUNCTIONS.

C C Abnet[1,2], R L Tanguay[1,2], M E Hahn[3] and R E Peterson[1,2]. [1]*Environmental Toxicology Center and* [2]*School of Pharmacy, University of Wisconsin, Madison, WI;* [3]*Woods Hole Oceanographic Institution, Woods Hole, MA.*

Two rainbow trout (rt) aryl hydrocarbon receptors (AhRs) were cloned from a gonad cell line (RTG-2). Screening of two cDNA libraries produced two full length cDNAs, rtAhRα and rtAhRβ, which encode distinct AhR proteins of 1058 and 1059 amino acids. The two forms of rtAhR appear to be derived from separate genes. rtAhRα and rtAhRβ mRNAs are expressed in a tissue specific manner with highest expression of rtAhRβ in the heart. Exposure of RTG-2 cells to graded concentrations of 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) caused a significant increase in rtAhRβ mRNA abundance whose time course and EC_{50} were essentially identical to that for CYP1A mRNA induction. Exposure of juvenile rainbow trout to an overtly toxic dose of TCDD caused a significant, 2-fold increase in rtAhRβ mRNA in liver. Both clones were expressed by *in vitro* transcription/translation producing 125 kDa proteins. Gel shift analysis demonstrated rtAhRα and rtAhRβ proteins dimerize with the aryl hydrocarbon nuclear translocator (rtARNTb) and recognize rainbow trout dioxin response elements (DREs). In COS-7 cells expressing rtAhRα or rtAhRβ in conjunction with rtARNTb, TCDD induced transcription of a reporter gene driven by the mouse CYP1A1 enhancer containing 4 DREs (pGudluc1.1). In COS-7 cells expressing rtAhRα and rtARNTb, TCDD induced transcription of a reporter gene driven by the rainbow trout CYP1A promoter and enhancer containing 2 DREs (prt1Aluc) approximately 9-fold. Unexpectedly, TCDD induced transcription of prt1Aluc only approximately 2-fold in COS-7 cells expressing rtAhRβ and rtARNTb. Determining the basis for the differential transcriptional activity of rtAhRα and rtAhRβ is currently underway. This study, in conjunction with the previous cloning of two rainbow trout ARNT transcripts, will now allow a detailed examination of the AhR pathway in the TCDD-sensitive species rainbow trout. (Supported by UW Sea Grant and NIEHS.)

294 TEMPORAL AND SPATIAL EXPRESSION OF zfAhR2, zfARNT2, AND zfP4501A mRNA IN DEVELOPING CONTROL AND TCDD-TREATED ZEBRAFISH.

E A Andreasen[1], R L Tanguay[2], W Heideman[1,2] and R E Peterson[1,2]. [1]*Environmental Toxicology Center and* [2]*School of Pharmacy, University of Wisconsin, Madison, WI.*

To understand the etiology of the tissue-specific signs of 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) toxicity in developing zebrafish, the temporal and spatial expression of zebrafish aryl hydrocarbon receptor (zfAhR2) and aryl hydrocarbon nuclear traslocator (zfARNT2) mRNA was determined by *in situ* hybridization. To localize tissues with a functional AhR/ARNT pathway, expression of zebrafish cytochrome P4501A (zfP4501A) mRNA was also determined. Embryos within 4 hours of fertilization were exposed to vehicle or a LC_{100}egg concentration of TCDD for 1 hour. Control and TCDD-exposed embryos were sacrificed for *in situ* analysis at 12, 18, 24, 36, 48, 72, 96, 120, 144, and 168 hours post fertilization (hpf). Whole mount *in situ* hybridization was conducted on embryos up to

48 hpf using RNA probes specific for zfAhR2, zfARNT2, and zfP4501A. *In situ* hybridization of embryos older than 48 hpf was conducted on mounted tissue sections. zfAhR2 mRNA expression was first detected 12 hpf in both control and TCDD-treated embryos. zfAhR2 mRNA expression in the branchial arches, vasculature, and otic capsule was evident beginning 36 hpf. zfARNT2 mRNA was first detected at 12 hpf in control and treated embryos. zfARNT2 expression was localized in the fore-, mid-, and hindbrain at 18 hpf. Expression of zfARNT2 was also evident in the vasculature by 36 hpf. zfP4501A mRNA was not detected in control embryos. zfP4501A mRNA was observed in TCDD-treated embryos as early as 24 hpf and localized in the developing vasculature. zfP4501A was expressed in the vasculature of the head, trunk and tail beginning at 36 hpf in TCDD-treated embryos. Co-expression of zfAhR2, zfARNT2 and zfP4501A was most evident in the vasculature prior to the appearance of signs of TCDD toxicity. These results are consistent with previous studies suggesting that the vasculature is a primary target of TCDD toxicity during zebrafish development. (Supported by UW Sea Grant and NIEHS.)

295 ISOLATION AND EXPRESSION OF TWO ZEBRAFISH ARYL HYDROCARBON RECEPTOR NUCLEAR TRANSLOCATOR (ARNT2) cDNAs WITH DISTINCT FUNCTIONS.

R L Tanguay[1,2], W Heideman[1,2], D Nesbit[2] and R E Peterson[1,2].
[1]*Environmental Toxicology Center and* [2]*School of Pharmacy, University of Wisconsin, Madison, WI.*

In order to further establish zebrafish as a vertebrate model for studying the mechanism of TCDD toxicity it is necessary to characterize the aryl hydrocarbon receptor/aryl hydrocarbon receptor nuclear translocator (AhR/ARNT) signaling pathways in zebrafish. Previously we have cloned and characterized zebrafish AhR2 (zfAhR2). In this study two zfARNT cDNAs were isolated, expressed, and characterized. Degenerate PCR primers were used to amplify a partial zfARNT cDNA. The 974 bp amplicon was used to screen cDNA libraries derived from adult zebrafish and zebrafish liver cells. This probe failed to identify ARNT clones in either library. Rapid amplification of cDNA ends (RACE) was used to obtain the 5' and 3' ends of the cDNA. A single 0.8 kb 5' RACE product was isolated and found to be most similar to mouse ARNT2. Two 3' RACE products of 1.0 kb and 1.7 kb were amplified and found to terminate in polyA tails. Primers were designed to amplify 1.6 kb and 2.3 kb full length cDNAs named zfARNT2a and zfARNT2b, respectively. The deduced proteins zfARNT2a and zfARNT2b are identical over the first 424 amino acids but differ in their C-terminal domains as a result of alternative mRNA splicing. zfARNT2a and zfARNT2b encode proteins with apparent molecular weights of 49 kDa and 91 kDa, respectively. Both zfARNT2 splice variant mRNAs are expressed in zebrafish embryos, adult zebrafish, and liver cells. In COS-7 cells expressing zfARNT2b and zfAhR2, TCDD causes an approximately 20-fold induction of a dioxin responsive reporter gene. In cells expressing zfARNT2a, TCDD fails to induce reporter gene expression. DNA gel shift analysis suggests that the decreased function of zfARNT2a is due to inefficient binding of zfARNT2a/zfAHR2 complexes to dioxin responsive elements. The physiological significance of the two zebrafish ARNT2 proteins with different functional properties is currently under investigation. (Supported by UW Sea Grant and NIEHS.)

296 INTERSPECIES COMPARISON OF ARYL HYDROCARBON RECEPTOR (AhR) ACTIVITY IN A TRANSACTIVATION ASSAY.

W Heideman[1,2], C C Abnet[1,2], R L Tanguay[1,2] and R E Peterson[1,2].
[1]*Environmental Toxicology Center and* [2]*School of Pharmacy, University of Wisconsin, Madison, WI.*

The potency of individual polychlorinated dibenzo-*p*-dioxins (PCDDs), dibenzofurans (PCDFs) and biphenyl (PCBs) in causing toxicity correlates with their binding affinity to the AhR. While this structure-activity relationship appears to be consistent within a vertebrate class, there are differences in the relative potencies of some congeners between mammals and fish. In mammals, mono-*ortho* PCBs are the weakest group of AhR agonists among all PCDDs, PCDFs and PCBs tested and cause signs of toxicity at high levels of exposure. In fish, mono-*ortho* PCBs are nearly inactive as AhR agonists and are incapable of eliciting signs of TCDD toxicity in early life stages of rainbow trout. One possible explanation for the insensitivity to the mono-*ortho* PCBs is differences in fish and mammalian AhR structure and function. To investigate this possibility, transient transactivation assays in COS-7 cells were used to compare the potency and efficacy of PCDD, PCDF and PCB AhR agonists in inducing luciferase activity with two rainbow trout AhRs (rtAhRα and rtAhRβ), a zebrafish AhR (zfAhR2) and the human AhR with their species-specific ARNTs. For all four AhRs, differences in TCDD EC_{50} and maximal induction of luciferase activity were seen between a rainbow trout *cyp1A* DRE reporter (prt1Aluc) and a mouse *cyp1A1* DRE reporter (pGudluc1.1). Thus, responsiveness to TCDD of different AhRs is altered by changes in the context of the DREs. EC_{50s} and maximal induction levels were determined for seven PCDD, PCDF and PCB AhR agonists with each of the four AhR/ARNT pairs using prt1Aluc. The differences in potencies of the mono-*ortho* PCBs in producing toxicity in fish and mammals *in vivo*, is reflected at the molecular level. The human AhR responded to each mono-*ortho* PCBs while amongst fish AhRs, rtAhRα alone responded weakly to a single mono-*ortho* PCB. (Supported by UW Sea Grant and NIEHS.)

297 ACTIVATION OF REDOX-CONTROLLED TRANSCRIPTION FACTORS BY TCDD.

S J Barnes[1], C Y Chang[1], H Zhu[1], K P Nephew[2], S A Khan[2], H G Shertzer[1] and A Puga[1]. *Department of Environmental Health*[1] *and Department of Cell Biology, Neurobiology and Anatomy*[2]*, University of Cincinnati Medical Center, Cincinnati, OH.*

2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD), the prototype agonist of the aromatic hydrocarbon (Ah) receptor, is a potent tumor promoter as well as a complete liver carcinogen. Since TCDD is not directly mutagenic, it has been proposed that it promotes neoplastic transformation through cellular signal transduction pathways resulting in the activation of proto-oncogene expression. Even though a clear oxidative stress response occurs in TCDD-treated female rats, in other animal models and in established cell lines, the oxidative stress induced by TCDD is difficult to evaluate and to quantitate by biochemical assays. To examine whether other biomarkers of oxidative stress could be more readily used to assess TCDD-mediated oxidative stress and to determine the extent of Ah receptor participation in such a response, we evaluated the effect of TCDD treatment on the activation of several transcription factors, including those in the NF-κB and AP-1 families, that are activated by changes in the redox state of cells. In an extension of prior results, we found that TCDD produced a sustained overexpression of AP-1 for at least 72 h in wild-type mouse hepatoma Hepa-1 cells, but not in Ah receptor-deficient Hepa-1-derived *c*35 cells or in CYP1A1-negative *c*37 cells. In addition, TCDD-treatment cause a significant increase in the DNA-binding activity of NF-κB, but not of the other transcription factors tested. Electrophoretic mobility supershift analyses with specific antibodies showed that increases in p50/p50 dimers accounted for most, but not all, the increases in NF-κB binding activity. TCDD-induced NF-κB increases did not take place in *c*35, *c*37, and ARNT-deficient *c*4 cells. These data suggest that TCDD causes the sustained activation of NF-κB and AP-1 possibly by an oxidative stress signal that is CYP1A1- and Ah receptor complex-dependent. (Supported by NIH Grants R01 ES06273 and P30 ES06096.)

298 CROSS-TALK BETWEEN THE ARYL HYDROCARBON RECEPTOR (AHR) AND HYPOXIA SIGNALING PATHWAYS.

M Nie, A L Blankenship and J P Giesy. *Michigan State University, East Lansing, MI, USA.* Sponsor: P E Ganey.

Aryl hydrocarbon receptor (AHR), aryl hydrocarbon receptor nuclear translocator (ARNT), and hypoxia inducible factor 1α (HIF-1α) are involved in two important signaling pathways in the cell. The AHR and ARNT are dimeric partners that transcriptionally up-regulate genes involved in the metabolism of xenobiotic compounds. ARNT forms a heterodimer with HIF-1α under hypoxic conditions, and together they activate a number of genes whose products regulate hematopoiesis in response to oxygen deprivation. The fact that ARNT is essential for both pathways may result in interference between these two pathways. In this report, the cross-talk between the two pathways is examined. B-1 cells, a Hep3B-derived cell line, express luciferase activity in response to hypoxia stimuli. The administration of 1.25 nM TCDD reduced the response of B-1 to hypoxia inducers by approximately 30%. H4IIE-luc cells and Hepa1 cells express luciferase and CYP1A1, respectively, in response to AHR-active compounds. The administration of a hypoxia inducer, desferrioxamine, resulted in a dose-dependent reduction of AHR-mediated luciferase activity in H4IIE-luc cells and CYP1A1 activity in Hepa1 cells. A complete inhibition of luciferase activity by 10 μ M desferrioxamine and a 67% of inhibition of CYP1A1 activity by 250 μ M desferrioxamine were observed in H4IIE-luc and Hepa1 cells, respectively. Together, these results suggest that an interference exists between the hypoxia and Ah receptor signaling pathways.

299 GENOTOXICITY STUDIES WITH BINARY, TERTIARY AND ISOLATED FRACTIONS OF COMPLEX ENVIRONMENTAL MIXTURES.

K C Donnelly[1], M Mumtaz[2], W R Reeves[1] and S Safe[1]. [1]*Texas A&M University, College Station, TX;* [2]*Agency for Toxic Substances & Disease Registry, Atlanta, GA.*

This project addresses the development of in vitro methods for assessing the toxicity of complex environmental mixtures. Contaminated media at Superfund sites typically consist of complex mixtures of organic and inorganic chemicals. While a site may host a limited number of inorganic chemicals, literally hundreds of organic chemicals may be present at a particular site. These mixtures are difficult to characterize, both analytically and toxicologically. This project has employed a microbial genotoxicity assay to analyze binary and tertiary mixtures of polycyclic aromatic hydrocarbons (PAHs), as well as complex mixtures of PAHs and isolated PAH fractions. The model PAH carcinogen benzo(a)pyrene (BAP) induced 227 40 net revertants at a dose of 0.3 mM, while a mixture of BAP at 0.3 mM and chrysene at 1.0 mM induced 105 12 net revertants. While these responses were within the anticipated biological variability of the assay, a dose-response gradient was observed with the BAP-chrysene mixture suggesting an interaction that influenced genotoxicity. Studies with complex mixtures and isolated fractions indicate that the BAP content of the PAH mixture cannot be used to predict genotoxicity. An extract of a Manufactured Gas Plant Residue (MGPR) was separated into four fractions using Thin Layer Chromatography (TLC). The extract of Fraction 3 from site 4 contained 26.61 ppm BAP and induced 1,339 77 net revertants at a dose of 1 mg of residue per plate, whereas the extract of Fraction 4 contained only 0.88 ppm BAP and induced 1,350 86 net revertants. It is unknown whether the response observed in Fraction 4 was a result of high molecular weight PAHs or possibly alkyl substituted PAHs. (Supported by NIEHS SBRP Grant No. P42 ES004917 and ATSDR Grant No. TU68450502.)

300 NUCLEAR RECEPTOR COREPRESSOR INTERACTIONS WITH Ah RECEPTOR SIGNALING.

J-G Lee, T A Nguyen and S Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA.*

Corepressors, such as silencing mediator for retinoic acid and thyroid hormone receptor (SMRT), interact with thyroid hormone receptor (TR) and retinoic acid receptor (RAR) to repress transcriptional activation. The aryl hydrocarbon receptor (AhR) mediates induction of CYP1A1 gene expression by 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) in human breast cancer cells. This study investigates the effects of SMRT on AhR-mediated induction of CYP1A1 in MCF-7 human breast cancer cells. TCDD induced CAT activity in MCF-7 cells transfected with Ah-responsive pRNH11c containing a human CYP1A1 gene promoter insert (-1142 to +2434) and cotransfection with pCMX (an SMRT expression plasmid) inhibited the induction response. Coincubation of AhR/Arnt with SMRT decreased formation of the AhR-Arnt-[^{32}P]-dioxin response element (DRE) retarded band in a gel mobility shift assay. A time course study showed that TCDD-induced maximal AhR-Arnt binding to [^{32}P]DRE with 2 min in the absence of *in vitro* expressed SMRT; however, after coincubation with SMRT, maximal binding was not observed until 10 min. Coimmunoprecipitation experiments showed that SMRT physically interacted with both AhR and Arnt *in vitro*. SMRT also decreased the luciferase activity of GAL4-dependent luciferase reporter with a GAL4-Arnt fusion protein in MCF-7 cells transfected with expression vectors containing GAL4DBD-Arnt, GAL4-luciferase reporter, and SMRT. These data suggest that SMRT functions as a transcriptional corepressor for AhR-mediated gene expression in MCF-7 cells.

301 PRO-OXIDANT METALS UNCOUPLE THE COORDINATE EXPRESSION OF PHASE I AND PHASE II GENES BY AH RECEPTOR LIGANDS.

A Maier and A Puga. *University of Cincinnati Medical Center, Department of Environmental Health, Cincinnati, OH, USA.*

Recent reports describing the redox sensitivity of aromatic hydrocarbon receptor (AHR) activation led us to test the hypothesis that pro-oxidant metals alter AHR ligand-inducible expression of Phase I and Phase II genes responsible for xenobiotic metabolism. Our results in Hepa-1 cells demonstrate that pro-oxidant metals differentially alter 2,3,7,8-tetrachlorodibenzo-*p*-dioxin-inducible (TCDD) *Cyp1a1* and *Nqo1* mRNA accumulation, two markers of Phase I and Phase II detoxification, respectively. $CdCl_2$ and $NaAsO_2$ did not alter *Cyp1a1* mRNA levels but enhanced TCDD-inducible levels of *Nqo1* mRNA, probably as a result of electrophile response element-dependent (EpRE) gene activation. $K_2Cr_2O_7$, on the other hand, inhibited mRNA accumulation for both *Cyp1a1* and *Nqo1*, with the greater effect on *Nqo1*. $NiSO_4$ did not alter mRNA levels for either gene. CYP1A1 and NQO1 activities were also measured to determine whether changes in mRNA accumulation resulted in altered biological activity. All enzyme activity changes mirrored the changes in mRNA levels. To test the relative contribution of AhRE-dependent and EpRE-dependent inducible gene expression, we used Hepa-1 cell lines with stably integrated AhRE-luciferase or EpRE-β -galactosidase reporters. For the AhRE-driven reporter, $CdCl_2$ increased and $K_2Cr_2O_7$ decreased the TCDD-inducible luciferase activity, while $NaAsO_2$ and $NiSo_4$ had no effect at noncytotoxic doses. For the EpRE-driven reporter, both $CdCl_2$ and $NaAsO_2$ increased β -galactosidase activity, while $K_2Cr_2O_7$ and $NiSO_4$ had no effect. These data indicate that co-exposure to pro-oxidant metals and ligands for the AHR uncouples the coordinate regulation of Phase I and Phase II genes. This imbalance between metabolic activation by Phase I genes and conjugation by Phase II genes may have important ramifications for the toxicity of complex mixtures. (Supported by NIEHS ES06273 and U.S. EPA STAR Fellowship Grant.)

302 MOLYBDATE INHIBITION OF ARYL HYDROCARBON RECEPTOR ACTIVATION.

S E Heid[1], R S Pollenz[2], and H I Swanson[1]. [1]*Department of Pharmacology, College of Medicine, University of Kentucky, Lexington, KY; and* [2]*Department of Biochemistry, Medical University of South Carolina, Charleston, SC.*

The aryl hydrocarbon receptor (AHR) is a cytosolic basic helix-loop-helix protein that associates with a chaperone complex including two molecules of heat shock protein 90 (HSP90). After ligand binding the AHR dissociates from its chaperone complex and translocates into the nucleus where it heterodimerizes with its DNA binding partner, the AH receptor nuclear translocator (ARNT), and activates specific genes. The gene activation of other HSP90-bound molecules such as the glucocorticoid receptor (GR) has been shown to be inhibited by molybdate, blocking the receptor's nuclear import by stabilizing the GR-chaperone complex interaction. Therefore the objective of this study was to ascertain whether molybdate inhibits AHR gene activation in a similar manner. Using HepG2 cells (human liver carcinoma) stably transfected with a luciferase reporter gene that is regulated by the cytochrome p450 1A1 promoter we demonstrated that sodium molybdate inhibits AHR gene activation in a dose-dependent manner. We confirmed this result through western blot analysis of p450 1A1 protein levels in whole cell lysates in HepG2 as well as Hepa-1 cells (murine hepatoma). Western blots of whole cell lysates also revealed that sodium molybdate could stabilize the AHR from agonist-induced down-regulation. Western blots of nuclear lysates in HepG2 cells demonstrated that sodium molybdate causes a dramatic reduction in agonist-induced nuclear AHR protein levels. Furthermore, gel mobility shift assays using a [^{32}P] dioxin responsive element and nuclear extracts from both Hepa-1 and HepG2 cells indicate that molybdate greatly diminishes the amount of active nuclear AHR/ARNT complex that can be isolated. These results suggest that dissociation of AHR from its chaperone complex is an essential aspect of AHR-mediated signaling and provide a model for further study.

303 ALTERATION OF OXYTOCIN- AND VASOPRESSIN-INDUCED CALCIUM OSCILLATIONS IN A RAT LIVER CELL LINE BY TCDD.

Y Mouneimne, R Barhoumi, T D Phillips, S H Safe, and R C Burghardt. *Faculty of Toxicology, Texas A&M University, College Station, TX, USA.*

A communication-competent rat liver cell line (Clone 9) was examined as a model system to investigate the effects of graded concentrations of 2,3,7,8-TCDD on the frequency of stable intracellular Ca^{2+} oscillations induced by oxytocin and vasopressin. Control Clone 9 cells treated with oxytocin (0 - 10 μM) or vasopressin (0 - 1 μM) exhibit stable, long term oscillations beginning at 10 nM or 0.1 nM for oxytocin and vasopressin, respectively. These oscillations reached maximal frequencies at 75 mHz and 100 mHz, respectively. Fast Fourier Transform analysis indicated that the inositol trisphosphate-sensitive pool contributes approximately 2/3 of the total frequency of Ca^{2+} oscillations while the contribution of a ryanodine-sensitive pool is approximately 1/3. To study the effect of TCDD on hormone-induced Ca^{2+} oscillations, cells were treated overnight with 0.1 to 10 nM TCDD and the frequency of Ca^{2+} oscillations was monitored following stimulation with dif-

ferent oxytocin or vasopressin concentrations. Results indicated that TCDD has no effect on basal intracellular Ca^{2+} levels, however, TCDD treated cells have a distinct frequency-hormone dose relationship that is significantly different from untreated Clone 9 cells. These studies indicate that, in addition to genomic effects mediated through the Ah receptor, TCDD can alter signal transduction mediated by frequency encoded Ca^{2+} signals. (Supported by NIH P42-ES04917 and P30-ES09106.)

304 ISOLATION AND CHARACTERIZATION OF NOVEL ARNT-INTERACTING PROTEINS.

C M Sadek[1], S Jalaguier[1], E P Feeney[1], M Aitola[2], M Pelto-Huikko[2], and J-Å Gustafsson[3]. [1]*Center for Biotechnology and* [3]*Department of Medical Nutrition, NOVUM, Karolinska Institute, Huddinge, Sweden;* [2]*Department of Anatomy, Tampere University Medical School, Tampere, Finland.*

The aryl hydrocarbon receptor nuclear translocator protein (ARNT) was first identified as a heterodimerization partner of the ligand-activated aryl hydrocarbon receptor (AhR). This complex mediates the transcription of genes via the xenobiotic response element. ARNT and AhR are members of the basic helix-loop-helix Per-Arnt-Sim (bHLH-PAS) family of transcription factors. ARNT has more recently been shown to heterodimerize with the bHLH-PAS protein hypoxia inducible factor-1α, leading to activation of genes regulated by the hypoxia response element. In addition, Tango, the Drosophila ARNT homolog, forms heterodimers with the bHLH-PAS proteins Single-minded and Trachealess to regulate neurogenesis and treachea development via the central nervous system midline enhancer element. As ARNT appears to play a central role in this family, we have employed the yeast two-hybrid system to isolate novel ARNT-interacting proteins. One clone, termed ARNT interacting protein-1 (AINT-1), interacts with ARNT in vitro, as determined by GST pull-down assays and has strong transactivational ability in yeast. The full length cDNA encoding this protein reveals little homology to published sequences. Finally, Northern analyses and in situ hybridizations provide evidence that AINT-1 is important in embryonic development and tissue differentiation. These results suggest that AINT-1 may play an important role in bHLH-PAS protein function.

305 THE LACK OF ALDH3A1 INDUCTION BY TCDD IN CORNEAL EPITHELIAL CELLS MAY INVOLVE TISSUE-SPECIFIC REGULATORY PROTEINS THAT COMPETE WITH THE AHR-ARNT COMPLEX.

V Vasiliou and T Shiao. *Molecular Toxicology and Environmental Health Sciences, Department of Pharmaceutical Sciences, University of Colorado Health Sciences Center, Denver, CO.*

The cytosolic aldehyde dehydrogenase (ALDH3A1) is inducible in liver cells by 2,3,7,8,-tetrachlorodibenzo-*p*-dioxin (TCDD), and constitutively elevated in extrahepatic tissues such as cornea, stomach, skin, urinary bladder and lungs. Induction by TCDD requires the aromatic hydrocarbon receptor (AHR) and its counterpart aromatic nuclear translocator protein (ARNT), and operates via the aromatic responsive elements (AhRE). Three corneal epithelial cell lines from human, rat and rabbit were used to study the regulation of *Aldh3a1* gene by TCDD using various deletions of the 3.2 kb 5'flanking region linked to luciferase reporter gene. Our results showed that this 5' flanking region did not respond to TCDD inducibility, although both AHR and ARNT were present and functional in all three cell lines. In addition, we found that AhRE motifs can drive high luciferase expression in corneal cells, indicating that AHR might be involved in the constitutive tissue-specific *Aldh3a1* expression. The latter can be ruled out since ALDH3A1 mRNA levels were found in high levels in the eye and stomach of AHR-knockout mice. Pax-6, a transcription factor that regulates lens determination and crystallin gene expression, is known to be present in corneal epithelium. Alignment of the Pax-6 consensus binding site with the AhRE sequences of the *Aldh3a1* gene revealed a 55-75% overlap between these two responsive elements. It is possible that Pax-6, as a corneal regulatory protein, binds to AhRE motifs and prevents the up-regulation of *Aldh3a1* via the TCDD-activated AHR-ARNT transcriptional complex. *(Supported by NIH EY11490.)*

306 THE CONTRIBUTION OF SEVERAL HYDROXY- AND DIHYDROXYBENZENES FOUND IN CIGARETTE SMOKE TO THE OVERALL CYTOTOXICITY OF THE CIGARETTE SMOKE MIXTURE.

D W Bombick, K P Putnam, and D J Doolittle. *Environmental and Molecular Toxicology Division, R. J. Reynolds Tobacco Company, Winston-Salem, NC, USA.*

The complex mixture of cigarette smoke is reported to contain over 3000 chemicals representative of several chemical classes, including hydroxy- and dihydroxybenzenes. Examples of hydroxy and dihydroxybenzenes detected in cigarette smoke include phenol, catechol, resorcinol, hydroquinone, and the three isomers of cresol. Previous studies have examined the toxicity of these compounds as pure chemicals; however, there is no information on the contribution of these compounds to the overall toxicity of cigarette smoke. The specific objective of this study was to determine if the hydroxy- and dihydroxybenzenes phenol, catechol, resorcinol, hydroquinone, and cresols are major contributors to the cytotoxic potential of cigarette smoke. In a preliminary study, the cytotoxicity of each pure chemical to Chinese hamster ovary cells was assessed using the neutral red uptake assay. The order of toxicity from most to least cytotoxic was hydroquinone > catechol > cresols > phenol > resorcinol. The cytotoxicity of cigarette smoke condensate was then assessed after each single chemical was added back to the cigarette smoke condensate at concentrations up to 100 times the concentration normally reported for the chemical in cigarette smoke. The cytotoxicity of cigarette smoke was not increased when cresols, phenol, or resorcinol was added back to the condensate even at concentrations 100 times what is normally reported in cigarette smoke. The most cytotoxic dihydroxybenzenes, hydroquinone and catechol, did not increase the cytotoxicity of cigarette smoke until concentrations approximately five times normally present in cigarette smoke were added back to the condensate. These results support the hypothesis that these hydroxy- and dihydroxybenzenes are not biologically important cytotoxic chemicals in cigarette smoke.

307 SMOKELESS TOBACCO INDUCED MODULATION OF p53 GENE AND PROTECTIVE EFFECT OF ANTIOXIDANTS.

M Bagchi[1], S S Joshi[2], D Bagchi[1], X Ye[1] and S J Stohs[1]. [1]*Creighton University School of Pharmacy and Allied Health Prof., Omaha, NE;* [2]*University of Nebraska Medical Center, Omaha, NE, USA.*

Oral cancers account for 3% of all the cancers in the U.S.A. and is the seventh most common cancer. The p53 gene is defined as a tumor suppressor gene, and mutations in p53 occur in high frequency in most of the common types of human cancer. Previously, we have reported the oxidative stress and DNA damage in human oral cells following treatment with different concentrations of smokeless tobacco extract (STE). Apoptopic cell death of human oral keratinocytes was also increased with increasing concentration of STE. In the present study, human oral keratinocytes were treated with (0-300 μg/ml) of STE for 24 hours and changes in the expression of p53 gene was measured by reverse transcriptase polymerase chain reaction (RT-PCR). Thirty-five cycles were performed for 5 min at 94°C and β–tubulin was used as the housekeeping gene. Approximately a 2.0-fold increase in p53 gene expression was observed following incubation of the cells with 100 μg/ml of STE, beyond which the expression of p53 dramatically decreased with higher concentrations, confirming increased apoptopic cell death with a higher concentrations of STE as reported by us earlier. Furthermore, the comparative abilities of vitamin C (75 μM), vitamin E (75 μM), a combination of vitamins C plus E (75 μM each) and a novel grape seed proanthocyanidin extract (GSPE; IH636) (100 μg/ml) were determined. The results demonstrate that STE significantly modulates p53 gene expression, and approximately 22-46% decreases in STE altered parameters were observed with antioxidants. GSPE demonstrated significantly better protection as compared to vitamins C and E, singly and in combination.

308 IN VITRO RESPONSE OF MOUSE OVARIAN SMALL FOLLICLES TO EPOXIDES OF 1,3-BUTADIENE.

E A Cannady, I G Sipes, and P B Hoyer. *The Departments of Physiology and Pharmacology/Toxicology, The University of Arizona, Tucson, AZ.*

1,3-Butadiene (BD), a widely used occupational chemical, is a known carcinogen in laboratory animals. The epoxide metabolites butadiene monoepoxide (BMO) and butadiene diepoxide (BDE) are thought to play a critical

role in its toxicity. Previous *in vivo* studies in our laboratory found these epoxides to be ovotoxic. Also, the rate of nicotinamide alkylation was 5 times greater for BDE than BMO. BDE also exhibited 3.8 times greater alkylating activity than that of the related ovotoxicant, 4-vinylcyclohexene diepoxide (VCD). Our laboratory has developed a method to isolate mouse small ovarian follicles for *in vitro* studies. Increased Trypan blue dye uptake ($p<0.05$) was observed in granulosa cells, but not oocytes, of small follicles incubated with VCD (76 μ M). The purpose of this study was to investigate *in vitro* effects of BMO and BDE on isolated follicles. Trypan blue dye uptake in mouse small follicles incubated with 600 μ M BMO was not significant ($p>0.05$) at any time point. Conversely, when compared with control media, follicles incubated with 76 μ M BDE exhibited increased ($p<0.05$) dye uptake into granulosa cells at 4 h (12.5± 0% follicles incorporating dye), 6 h (21± 3.5% follicles), and 24 h (45.7± 9.7% follicles). Following 24 h incubation with BDE, not all follicles were intact (oocyte surrounded by granulosa cells), however, the initial number of follicles incubated could be accounted for by counting intact follicles and isolated oocytes. There was no LDH release into the media. Thus, we propose that integrity of follicles but not cellular membranes is compromised. Our results suggest that BDE has a similar effect to VCD and is more potent than BMO. This further supports *in vivo* structure activity studies indicating that the diepoxide metabolite is the more ovotoxic form. Based on these findings, measurement of Trypan blue dye uptake in isolated small follicles incubated with a variety of environmental chemicals may provide an *in vitro* method to assist in the evaluation of ovotoxic chemicals. (Center Grant ES06694, ADCRC #9808, and CMA.)

309 THE RELATIVE TOXICITY OF PARTICLES IN RAT LUNG TISSUE SLICE CULTURES.

R A Westhouse[1,2], F F Hahn[1,2], A H Rebar[2], and N F Johnson[1,2]. [1]*Lovelace Respiratory Research Institute, Albuquerque, NM, USA;* [2]*Purdue University, West Lafayette, IN, USA.*

The purpose of the present study was to assess the relative toxicity of instilled diesel soot (DS), residual oil fly ash (ROFA), or carbon black (CB) particles (1 mg/ml) in rat lung tissue slices. Tissue viability parameters [morphology, adenosine triphosphate (ATP), protein synthesis], and secreted cytokines [macrophage inflammatory protein-2 (MIP-2), tumor necrosis factor-alpha (TNF-α), and interleukin-1 beta (IL-1β)] were assessed on days 1, 4, 7, and 11 post-slicing. Transmission electron microscopy revealed particles free within alveoli, airways, and interstitium, and intracellularly within alveolar and interstitial macrophages, and alveolar type I cells. ATP content and protein synthesis in ROFA- or DS-treated slices were generally less than observed in vehicle-treated slices at early harvest time points. At harvest days 0, 1, and 4, ROFA-treated slices contained 58%, 15%, and 46% of the ATP content of control slices, respectively. DS-treated slices had a reduced amount of ATP (59% of control) only at day 4. Protein synthesis at harvest days 1 and 4 for ROFA-treated slices was 53% and 56% of controls, respectively, while that of DS-treated slices was 66% and 61%, respectively. For cytokine analysis of culture medium, MIP-2 was significantly induced at days 7 and 11 in ROFA-treated slices (213% and 218% of controls, respectively) and in DS-treated slices (157% and 202%, respectively). TNF-α did not demonstrate a significant particle effect. IL-1β was undetectable for all slice cultures throughout the culture time period. CB-treated lung slices did not produce any aberrations from values of control slices in any of these assays. Treatment of lung slices with ROFA produced greater deviations from control slices than DS, and CB-treated slices were indistinguishable from control slices, suggesting that ROFA is more toxic than DS, and toxicity of CB could not be detected in lung slice systems. (Support from DOE/OBER and NIH grant ES 07665-01.)

310 THE RELATIVE TOXICITY OF PARTICLES IN A549 CELL CULTURES.

N F Johnson[1,2], R A Westhouse[1,2], F F Hahn[1,2], A H Rebar[2], and K J Nikula[1]. [1]*Lovelace Respiratory Research Institute, Albuquerque, NM, USA;* [2]*Purdue University, West Lafayette, IN, USA.*

A549 cells were individually treated with 40 μ g/cm^2 of seven different particulate materials [nickel subsulfide (Ni_3S_2), crystalline silica (S), residual oil fly ash (ROFA), diesel soot (DS), carbon black (CB), titanium dioxide (TiO_2), and an ambient air particulate sample from Ottawa, Canada (OAA, dust EHC-93)] for 20 hr. Cultures were assessed 18 hrs post-treatment for viability [lactate dehydrogenase (LDH) concentration in the culture media, cellular adenosine triphosphate (ATP) content, and protein synthesis] and cytokines [interleukin-8 (IL-8) and growth-regulated oncogene-alpha (gro-α) proteins] in the culture media by the ELISA technique and intracellularly by immunocytochemistry and flow cytometry. Treatment with Ni_3S_2 induced the greatest decrease in viability parameters, which were significantly different from all other particle treatments and controls. Because of this high toxicity, the IL-8 and gro-α protein levels were low (similar to or lower than controls). ROFA treatment was second to Ni_3S_2 in toxicity, but induced the highest levels of IL-8 and gro-α protein. Viability parameters and cytokine analyses for treatment with DS, CB, or TiO_2, as well as vehicle-treated controls were not statistically different. Treatment with S produced LDH release similar to ROFA treatment; however, the ATP content, protein synthesis, and cytokine analyses reflected levels similar to vehicle-treated controls, DS, CB, and TiO_2. The toxicity of OAA was generally less than ROFA, but greater than vehicle-treated controls or TiO_2. In the LDH and secreted IL-8 assays, OAA particles induced a significantly higher response than DS. The toxicity of S was difficult to interpret, possibly because our bioassay system lacked macrophages, which appear to play a significant role in the pathogenesis of S-induced lung disease in vivo. This system determined the relative toxicity as follows: Ni_3S_2 > ROFA ≥ OAA ≥ DS, CB, TiO_2. (Support from DOE/OBER and NIH grant ES 07665-01.)

311 ANALYSIS OF DIFFERENCES IN THE MECHANISM OF TOXICITY OF *ORTHO-* AND *PARA*-ISOPROPYLPHENOL ISOMERS IN CULTURED RAT LIVER CELLS USING KINETIC FLUORESCENCE BIOASSAYS.

D C Thompson, R Barhoumi, and R C Burghardt. *Texas A&M University, College Station, TX, USA.*

In order to examine possible differences in the mechanism of toxicity of alkylphenol isomers, we compared the effects of *ortho* and *para* isopropylphenol (2-IP, 4-IP) on several cellular functions in cultured rat liver cells (Clone 9, ATCC) using kinetic fluorescence bioassays and a Meridian Ultima laser cytometer. Parameters monitored included intracellular glutathione (GSH), gap junction-mediated intercellular communication (GJIC), calcium levels, intracellular pH, reactive oxygen species (ROS) generation, mitochondrial and plasma membrane potentials (MMP and PMP), and cell death. Cells were exposed to concentrations of test compounds ranging from 1 to 1000 μM, and all parameters were monitored directly after addition at 15 sec intervals for at least 10 min. No differences in effect on MMP or GJIC were observed between the two isomers. Both compounds elicited a minor drop in GJIC at 1 and 10 μM, followed by almost complete inhibition of GJIC at 100 μM. Similarly, both isomers elicited a concentration-dependent decrease in MMP, with significant effects being seen at concentrations as low as 1-10 μM. However, isomer-dependent differences were seen in all other parameters monitored. 2-IP was more potent in depleting GSH, inhibiting PMP, and decreasing intracellular pH than was 4-IP. No changes in calcium levels were seen with 2-IP until the highest concentration (1000 μM), whereas 4-IP caused a significant spike in calcium at a concentration of 100 μM. In 48 h cell proliferation assays 2-IP was more cytotoxic than 4-IP (IC50s were 103 μM and 222 μM, respectively). In summary, the most significant effects observed in the present study which may contribute to differences in cytotoxic potency among alkylphenol isomers in cultured rat liver cells include the rate of depletion of intracellular glutathione and effects on PMP. (Supported in part by NIH grants ES06016 and P42-ES04917.)

312 BIDRIN-INDUCED RENAL TUBULAR CYTOTOXICITY: ROLE OF OXIDATIVE STRESS AND ANTIOXIDANT PROTECTION.

V S Poovala[1,2] and A K Salahudeen[3]. [1]*Jackson State University, Jackson, MS, USA;* [2]*Toxikon Corp., Bedford, MA, USA;* [3]*University of Mississippi Medical Center, Jackson, MS, USA.* Sponsor: F W Deckert.

Bidrin (BD) is an organophosphate (OP) insecticide formulation containing dicrotophos. OPs are efficient pesticides and are often misused, resulting in detrimental exposure to humans and other non-target species from environmental and occupational sources. BD's main mechanism of toxicity is inhibition of acetylcholinesterase (AChE), hindering nerve conduction. Studies have shown that OPs induce renal tubular necrosis that does not correlate with the degree of AChE suppression. This suggests additional mechanisms of toxicity. Since reactive oxygen species (ROS) are known as mediators of many toxin-induced renal injuries, we investigated whether ROS play a role in BD-induced renal tubular epithelial cell ($LLC-PK_1$) toxicity. $LLC-PK_1$ cell death, determined by lactate dehydrogenase (LDH) release, increased concentration- and time-dependently following exposure of cells to 1000-

2000ppm BD for 6-48hrs. Cell damage following incubation with 1250ppm BD for 24hrs was found to decrease in a concentration-related manner by antioxidants 2-methylaminochroman (2-MAC: 0.3-2.5μM) and desferrioxamine (DFO: 0.25-2mM). The greatest reductions in LDH (n=3, ANOVA, $p<0.05$, mean±SE) were produced by DFO 2mM and 2-MAC 2.5μM, both significantly lower than BD alone (DFO: 29.67±3.29 vs. BD: 47.67±1.46; 2-MAC: 26.67±2.61 vs. BD: 47.67±1.46, $p<0.05$). H_2O_2 levels were significantly elevated following exposure to 1250ppm BD. Significantly increased malondialdehyde (MDA) formation compared to the control was also found in BD-exposed cells indicating enhanced lipid peroxidation. MDA generation was significantly suppressed by 2-MAC and DFO. These results implicate ROS and accompanying lipid peroxidation, at least in part, in the toxic effects of BD on kidney cells and suggest that oxidative stress may play a role in the pathogenesis of BD-induced acute tubular necrosis and renal dysfunction observed in OP poisonings.

313 CADMIUM TOXICITY IN RAT HEPATIC STELLATE CELLS.

M C Escobar, V Souza, L Bucio, E Hernández, and M C Gutiérrez-Ruiz. *Dpto. Cs. De la Salud, DCBS, UAM-I, México City, Mexico.*

Hepatotoxicity caused by exposure to toxic agents is often associated with the pro-oxidant activity of the agent. Cadmium (Cd) is a very toxic transition metal with pro-oxidant activity. This study examined the effects of Cd on lipid peroxidation damage, glutathione content, glutathione peroxidase and superoxide dismutase activity on rat hepatic stellate cells (CFSG-2G). Cells were exposed during 24 and 48 hs to 0.3 μ M $CdCl_2$ or 24hs to 3 μ M $CdCl_2$. Under these experimental conditions cells did not present lysosomal (neutral red probe) or mitochondrial (MTT probe) damage. Lipid peroxidation was measured as malondialdehyde production in the presence of thiobarbituric acid. Reduced glutathione was quantitated by means of the Ellman reaction, glutathione peroxidase and superoxide dismutase were determined spectrophotometrically. Intracellular Ca was determined by arsenazo III. Lipid peroxidation damage increased slightly in all experimental conditions, while GSH content diminished 22% in 0.3 μ M Cd treated cells and 47% with higher Cd concentration. Intracellular Ca increased approximately 50% in 0.3 μ M $CdCl_2$ treated cells and 135% in the 3 μ M treatment. SOD activity diminished principally in 24 hs treated cells, 51% in 0.3 and 56 % in 3 μ M $CdCl_2$ treated cells. GSH peroxidase activity decreased only in cells treated with 3 μ M $CdCl_2$ during 24 hs. No significative changes of glutathione reductase activity were found in any treatment.

Cd produced damage on rat hepatic stellate cells through an oxidative stress mechanism and altered Ca homeostasis.

314 DIFFERENTIAL EFFECTS OF SERA ON BASAL AND CHEMICAL-INDUCED CELL PROLIFERATION AND DIFFERENTIATION IN RAT EMBRYONIC MIDBRAIN AND LIMB BUD CELL MICRO-MASS CULTURE.

K S Park, S Y Han, K L Park, J T Hong, H S Kim, H J Park, S S Kook, R D Lee, Y J Choi, and S J Jang. *National Institute of Toxicological Research/Korea Food and Drug Administration, Seoul, Korea.*

Fetal bovine serum (FBS) and NuSerum have been widely used for cell culture including embryonic cell micromass culture. The type and components of sera in cell culture media have been implicated in the cell proliferation and differentiation since they contain many different growth modulating factors. FBS contains very high proteins, while NuSerum contains many hormones. In this study, we compared the effects of FBS and NuSerum on the cell proliferation and differentiation of rat embryonic midbrain (MB) and limb bud (LB) cells and their effects on chemical-induced teratogenicity. Cells derived from MB and LB of 12.5 day-old rat embryo were cultured in the medium containing 10% of FBS or NuSerum in the absence or in the presence of teratogenic compounds, ethylenethiourea (ETU) or ochratoxin A (OTA) for 4 days. Cell proliferation was assessed by neutral red staining and differentiation was determined by measuring of foci area after hematoxylin staining (MB cells) or alcian blue staining (LB cells). Cell differentiation was significantly higher in FBS medium than that in NuSerum medium while cell proliferation was not different. The concentration of ETU inhibiting 50% of cell proliferation and differentiation (IP_{50} and ID_{50}) were 11.4, 27.7 μ g/ml (NuSerum medium) and 23.0, 9.2 μ g/ml (FBS medium) in MB cells. In MB and LB cells, IP_{50} and ID_{50} of OTA were 10 fold higher in Nuserum medium than in FBS medium. IP_{50} and ID_{50} of OTA in NuSerum medium containing bovine serum albumin were corresponding with those in FBS medium. These results show that the type and components of sera in culture media may be important in the teratogenic potential of chemicals by alteration of chemical-induced cell proliferation and differentiation.

315 EXPRESSION OF HUMAN MICROSOMAL EPOXIDE HYDROLASE PROTECTS AGAINST AFLATOXIN B1-INDUCED GENOTOXICITY IN YEAST CO-EXPRESSING HUMAN CYP1A ENZYMES.

E J Kelly[1], C Sengstag[2] and D L Eaton[1]. [1]*Center for Ecogenetics and Environmental Health, Department of Environmental Health, University of Washington, Seattle, WA, USA;* [2]*Institute of Toxicology, Swiss Federal Institute of Toxicology, Schwerzenbach, Switzerland.*

A recent epidemiological study has suggested that a polymorphism in human microsomal epoxide hydrolase (mEH) increases susceptibility to aflatoxin B1 (AFB)-induced hepatocarcinogenesis (McGlynn et al, PNAS 92:2384-7, 1995), although studies in vitro and in laboratory animals have generally not found mEH to play an important protective role in AFB genotoxicity. However, in contrast to rodents, human liver does not express a glutathione S-transferase enzyme with high activity toward AFB-8,9-*exo*-epoxide. Thus, in the absence of significant GST activity, it is possible that human mEH could play an important protective role against AFB genotoxicity. The goal of this study was to determine if human mEH is capable of attenuating the genotoxic effects of AFB in an intact cell system. mEH was co-expressed with various human CYP 450s capable of activating AFB to the genotoxic AFB-8,9-*exo*-epoxide, in a heterologous yeast expression system. Yeast that expressed human CYP1A2, and to a lesser extent CYP1A1, exhibited a large, dose-related increase in mitotic recombination at the *trp* locus following AFB exposure, relative to non-CYP expressing yeast. Co-expression of mEH reduced the number of *trp* revertants by more than 50%. Expression of CYP1A2, but not CYP1A1, significantly increased the extent of AFB-DNA adduct formation at 0.5 and 1.25 μM AFB, and co-expression of mEH with CYP1A2 reduced AFB-DNA adduct formation by 50% or more. These results provide direct evidence that human microsomal epoxide hydrolase is capable of protecting eukaryotic DNA from human CYP mediated AFB-epoxide adduction in an intact cell system in spite of the fact that AFB-*exo*-epoxide is rapidly and spontaneously hydrolyzed in vitro. (Supported by NIH grants R01-ES05780, P30-ES07033 and T32-ES07032.)

316 SPECIES DIFFERENCES IN KUPFFER CELL-MEDIATED CYTOTOXICITY.

T Hamano[1], V Tong[2], T Murase[1], E Tanaka[1], J Dabbs[3] and C A Tyson[3]. [1]*Toxicology Laboratory, Yokohama Research Center, Mitsubishi Chemical Co., Tokyo, Japan;* [2]*University of British Columbia, Vancouver, BC, Canada;* [3]*SRI International, Menlo Park, CA, USA.*

Kupffer cells (KC) are the resident macrophages of the liver and represent the largest population of macrophages in the mammalian body. Recently, many reports have described KC-mediated cytotoxicity. We developed an assay to measure KC-mediated cytotoxicity and used this assay to compare the toxicity of lipopolysaccharide (LPS; *E. coli*-derived)–stimulated KC from different species. KC were isolated from rats, dogs, monkeys and human donor livers by percoll gradient centrifugation. KC and target cells (WRL68, Human Liver Embryo) previously prelabelled with BrdU were incubated with LPS in 96 well plates for 24 hours. Cell-mediated cytotoxicity was assessed by measuring BrdU-labelled DNA release to the conditioned medium using DNA fragmentation ELISA. Cytokine release (TNF-alpha, IL-1 beta and IL-6) from LPS-stimulated KC was also assessed. In another experiment, $GdCl_3$ (0, 5 and 10 mg/kg), an inhibitor of KC activity, was administrated to rats (i.v.). After 24 hours, KC were isolated for the cytotoxicity assay. The KC-mediated cytotoxicity induced by LPS was restrained by $GdCl_3$ administration in a dose-dependent manner. Target cell toxicity was greater with dog than rat, monkey or human KC. Species differences in cytokine release which correspond with toxicity were also observed. The differences between dog and rat correlated with the known difference in sensitivity of these species to LPS in vivo.

317 TOXICITY OF 1,3,5-TRINITROBENZENE (TNB) ON ASTROCYTES AND ENDOTHELIAL CELLS.

E L Stair[1], S Kuruvilla[1], S Kim[1], G Reddy[2], and C W Qualls, Jr.[1]. [1]*Dept. of Anatomy, Pathology, and Pharmacology, Oklahoma State University College of Veterinary Medicine, Stillwater, OK;* [2]*US Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD.*

In vitro studies with nitrobenzenes by others have focused on *m*-dinitrobenzene and its effects on cultured astrocytes and brain capillary endothelial cells. These studies have attempted to elucidate some of the mechanisms of toxicity focusing on oxidative stress and free radical production. We have used similar *in vitro* techniques with TNB to determine if cellular toxicity develops in tissue culture as observed with DNB. Primary cultures of Fischer-344 rat astrocytes were exposed to 0.0, 20, 30, 40, 50, 60, 70, 80, 90, 100, 125 μ M TNB and 0.0, 0.5, 1, 2 mM DNB (carrier 0.5% dimethyl sulfoxide [DMSO]) for 24 hours. Commercially obtained cultures of human (umbilical vein origin) and bovine (corneal origin) endothelial cells were exposed to 0.0, 20, 30, 40, 50, 60, 70, 80, 90, 100 μ M TNB (carrier 0.5% DMSO) for 24 hours. Decreases in metabolic activity were used to assess cellular toxicity. Cellular metabolic activity was measured in astrocytes and endothelial cells via reduction of the tetrazolium compound [3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium; MTS] to a MTS formazan product and was recorded at 490 nm with a 96 well plate reader. Astrocytes and endothelial cells exhibited increases in metabolic activity in several of the lower dose TNB and DNB treatment groups. This stimulation with increased metabolic output occurred in response to low dose TNB (20 μ M) or DNB (1.0 mM) exposure. Astrocytes displayed a 50% decrease in metabolic activity when exposed to concentrations of TNB in the 25 to 30 μ M range. A 50% decrease in metabolic activity of endothelial cells was observed in the 50 to 55 μ M range. Cultured astrocytes displayed an increased sensitivity to the toxic effects of TNB (micromolar range) in comparison to astrocytes treated with DNB (millimolar range). Astrocytes also displayed increased sensitivity to the toxic effects of TNB when compared with endothelial cells. Abstract does not reflect U. S. Army policy.

318 EVALUATION OF TWO IN VITRO CILIATED EPITHELIAL SYSTEMS, DOG TRACHEA AND FROG PALATE, FOR POTENTIAL AS SCREENS FOR ACUTE INHALATION TOXICITY.

J M Swann[1], J R Kennedy[2] and T W Schultz[3]. [1]*Itawamba Community College, Fulton, MS, USA;* [2]*The University of Tennessee, Knoxville, TN, USA;* [3]*The University of Tennessee College of Veterinary Medicine, Knoxville, TN, USA.* Sponsor: W Farkas.

Two aquatic-based *in vitro* ciliated epithelial systems, dog trachea and frog palate, have been evaluated for potential as screens for acute toxicity of inhaled chemicals. Initially, the effects of a series of nonpolar narcotic agents (ethanol, 2-butanone, 2-pentanone, 1-pentanol, 1-heptanol, 1-octanol, 2-decanone, 2-undecanone) were assessed by monitoring ciliary beat frequency under standard (static, 5 min exposure) conditions with the molar concentration eliciting a 50% reduction in ciliary beat frequency (i.e., EC_{50}) being determined. These data along with 1-octanol/water partition coefficient (log K_{ow}) were used to formulate baseline predictive models. The minimal toxicity model for the canine trachea (ct) system is log $1/ctEC_{50} = 0.79$ (log K_{ow}) – 0.002; n = 7, $r^2 = 0.987$, s = 0.15, F = 373, Pr > F = 0.0001. The frog palate (fp) baseline toxicity equation is log $1/fpEC_{50} = 0.80$ (log K_{ow}) - 0.12; n = 7, $r^2 = 0.995$, s = 0.09, F = 1112, Pr > F = 0.0001. Pre-validation of both *in vitro* systems were undertaken by regression analyses with *in vivo* mouse inhalation toxicity data. The slopes of both analyses are not statistically different than 1.0. The intercepts reveal the *in vivo* endpoint to be 10 times more sensitive. Also, a set of bioreactive chemicals (*trans*-2-octenal, heptaldehyde, benzyl chloride, 4,6-dinitro-*o*-cresol, carbaryl, malathion) was tested. Mechanisms of toxicity represented by this set of chemicals included three specific electro(nucleo)philic mechanisms, weak acid respiratory uncoupling, and reversible and irreversible acetylcholinesterase inhibition. While the relative ranking varied between the two *in vitro* systems, all bioreactive chemicals were found to have observed toxicity greater than twice that predicted by the baseline models. Based on these preliminary data, the authors feel that such a ciliary beat frequency *in vitro* system would provide valuable hazard information about potential acute effects of inhaled chemicals.

319 DETERMINATION OF IN VITRO DOSIMETRY FOR EXPOSURES OF PRIMARY RAT HEPATOCYTE CULTURES TO GLYCOL ETHER BASED COMPOUNDS.

K T Geiss, D L Pollard, J M Frazier. *Human Effectiveness Directorate, Air Force Research Laboratory, Wright-Patterson AFB, OH, USA.*

The US Air Force has sought the replacement of current operational chemicals with alternatives that pose less potential toxic risk. Alternatives to glycol ethers, such as diethylene glycol monomethyl ether (M-DE), a jet fuel system ice-inhibiting agent (FSII), are being investigated by our laboratory. The group of chemicals currently being evaluated include three derivatives of 1,3-dioxolane-4-methanol (M-1, M-2, and M-3) and two 1,3-dioxanes (M-26 and M-27). In addition, ethylene glycol monomethyl ether, MPDIOL glycol, and M-DE, are being evaluated as reference compounds. Our initial approach to evaluating the potential toxicities of these chemicals includes the assessment of acute toxicity in primary rat hepatocyte cultures. This set of experiments was performed to develop analyt-ical methods for the analysis of these chemicals and to assess the potential variations in aqueous concentrations of the test chemicals, due to volatilization during cell culture experiments. The vapor pressures of these compounds range over four orders of magnitude (0.001-70 mmHg at 37° C). The test chemicals were prepared at 1mM and 10mM concentrations and incubated in 6-well culture plates at 37° C for 0, 1, 2, 4, or 6 hr. One ml aliquots were taken at each time point and analyzed by gas chromatography to determine variations in test chemical concentrations over time. These data allowed us to determine the aqueous concentrations of the chem-icals, thus indicating the potential in vitro dosimetry for the primary hepatocytes in culture. The results of this study indicate that for these chemicals, for a six-hour exposure scenario, the aqueous concentrations do not vary significantly ($p>0.05$, less than 10% change) from their initial concentration. We conclude that in vitro assessment of these chemicals is reasonable, given their low potential for significant changes in aqueous concentration, due to volatilization.

320 TESTING OF GENETICALLY MODIFIED BACULO VIRUSES AND ESTABLISHED HUMAN CELL LINE.

K Wun-Kim, and M L Taylor. *Haskell Laboratory for Toxicology and Industrial Medicine, DuPont Company, Newark, DE, USA.* Sponsor: M W Himmelstein.

Baculoviruses have extensive literature documentation of their safety to mammals and have been developed and safely used as biopesticides. To enhance the insecticidal activity of the baculoviruses, *Autographa californica* multiple nuclear polyhedrosis virus (AcMNPV) and *Helicoverpa zea* nuclear polyhedrosis virus (HzNPV), a gene encoding an insect selective toxin (LqhIT2) was inserted into these viruses' genome to create genetically modified organisms (GMO). These GMOs were compared to the wild-type AcMNPV and HzNPV for differences in cytotoxicity and infectivity in a human cell line. In order to test the effect on cells by a mixture of baculoviruses, cells were exposed to individual viruses as well as mixture of two viruses and compared. The test groups with a single GMO virus exposure were compared to the untreated group and the groups treated with individual parental wild type viruses. The test group that was treated with a mixture of GMO AcMNPV and GMO HzNPV was compared to the untreated group and the group treated with a mixture of wild type parental viruses. A human liver cell line was used for the infectivity evaluation. Human liver was chosen to represent systemic exposure to virus. Cells were exposed to a single dose of virus or mixture of viruses. Cells were observed for the signs of cytopathic effect (CPE) and the presence of occlusion bodies (OBs). Budded virus titers in the cell culture media at different time point after the exposure were determined by TCID50 (tissue culture infectivity dose). There was no virus associated CPE or OBs observed in any test group. Budded virus titers in media decreased with time indicating that the human cell line in this test was not able to support virus replication in any test group. The result of this study indicated that there were no deleterious effects or evidence of viral infection to human cell line from exposure to either recombinant baculoviruses or the parental wild-type viruses when treated separately or in a mixture form.

321 IN VITRO MODEL FOR INVESTIGATION OF COMPLEMENT ACTIVATION BY A PHOSPHOROTHIOATE OLIGODEOXY-NUCLEOTIDE.

S P Henry[1], M Jagels[2], T Hugli[2], R S Geary[1], A A Levin[1]. [1]*Isis Pharmaceuticals, Inc. Carlsbad, CA;* [2]*Scripps Research Institute, La Jolla, CA.*

Activation of the alternative pathway of complement following rapid intravenous infusion of phosphorothioate oligodeoxynucleotides (P=S oligo) has been observed in monkeys. Investigation of the mechanism of complement activation has been hampered by the absence of activation in other laboratory animal models (rodents and dogs), and heretofore, the absence of *in vitro* models of complement activation. Monkey serum and whole blood has been used to establish a model for studying the mechanism of complement activation. P=S oligos produced concentration-dependent increase in comple-

ment split products Bb, C3a, and C5a *in vitro*, consistent with that observed in monkeys. The level of activation appeared to be greater in whole blood as compared to serum. Concentrations of oligonucleotide required to activate the alternative pathway *in vitro* were consistent with the threshold concentrations established in treated monkeys (~50 μ g/ml). Activation of complement by P=S oligo was also time-dependent, with full activation occurring within the first 30 min. Interpretation of results from these models is complicated by the inhibition of complement activation, both classical (aggregated IgG) and alternative pathways (zymosan stimulated), at higher P=S oligo concentrations (>250 μ g/ml). Slight increases in split product formation were observed at low concentrations in human serum, however, it appears to be less sensitive to complement activation than monkey serum. This model will be utilized to further study the mechanism of complement activation by P=S oligonucleotides.

322 DEVELOPMENT OF A HIGH-THROUGHPUT SCREENING ASSAY FOR HUMAN HEPATOTOXICITY.

A P Li, J A Brent, P M Silber and C E Ruegg. *In Vitro Technologies, Inc., Baltimore, MD, USA.*

Besides pharmacological properties, pharmacokinetic and toxicological (ADME-Tox) properties are important determinants of a successful drug candidate. The key ADME-Tox properties include bioavailability, metabolic stability, and toxicity. Screening for desirable ADME-Tox properties, in addition to efficacy screening, should allow one to select new chemical entities with improved chances of clinical success. Research emphasis of our laboratory is the development of high-throughput screening (HTS) assays for ADME-Tox evaluation using human-based in vitro systems. Of the various in vitro experimental systems of the liver, hepatocytes represent the most relevant model for studies for metabolic stability and hepatotoxicity studies. To overcome the universal concern of limited availability of fresh human livers for experimentation, procedures were developed in our laboratory for cryopreservation of freshly isolated human hepatocytes. The cryopreserved hepatocytes had high post-thaw viability and xenobiotic metabolizing capacity (both phase I oxidation and phase II conjugation) similar to freshly isolated cells. A 96-well-based HTS assays for hepatocytotoxicity have been developed using cryopreserved human hepatocytes and using MTT as the endpoint for viability. Automated procedures were used to increase the throughput and to eliminate well-to-well differences in the 96-well plates. The assay was found to yield quantitative and highly reproducible results. Dose-dependent decreases in viability were observed for known hepatotoxic agents including tamoxifen, tranycypromine, clozapine, diclofenac and cadmium chloride. Data obtained with this human hepatocyte-based HTS for hepatotoxicity should be useful in the selection of lead drug candidates for further development.

323 NOVEL HIGH THROUGHPUT FLUORESCENT CYTOCHROME P450 ASSAYS.

C L Crespi, V P Miller, J M Ackermann, D M Stresser, and W F Busby, Jr. *GENTEST Corporation, Woburn, MA, USA.*

Cytochromes P450 (CYP) are the principal, hepatic xenobiotic metabolizing enzymes. We have developed microtiter plate-based, direct, fluorometric assays for the activities of the five principal human drug metabolizing enzymes, CYP1A2, CYP2C9, CYP2C19, CYP2D6 and CYP3A4. For CYP1A2, CYP2C9, CYP2C19, and CYP2D6, the potency of enzyme inhibition (IC_{50}) is consistent regardless of probe substrate or assay method employed. In contrast, CYP3A4 inhibition for a specific inhibitor shows significant differences in potency (>30 fold) depending on the probe substrate being used. We have investigated these differences through the use of several structurally distinct fluorescent substrates for CYP3A4 and several classical substrate probes with a panel of known, clinically significant, CYP3A4 inhibitors. The use of multiple probe substrates appears to be needed to characterize the inhibition potential of xenobiotics for CYP3A4. This fluorometric substrate-based methodology provides a rapid means (using methodology compatible with existing high throughput screening instrumentation) to assess the potential for xenobiotics to inhibit cytochrome P450 - a mechanism for clinical drug-drug interactions and associated toxicities.

324 QUANTITATION OF HUMAN FLAVIN-CONTAINING MONOOXYGENASES ON IMMUNOBLOTS.

E L Code, J McNamara, and C L Crespi. *GENTEST Corporation, Woburn, MA, USA.*

The flavin-containing monooxygenases (FMOs) catalyze the NADPH-dependent oxidation of drugs, pesticides and other foreign compounds containing a soft nucleophile (*e.g.* nitrogen, phosphorous, or sulfur). The mammalian FMOs are separated into 5 families each containing about 50% sequence similarity. One or more of these enzymes are expressed in every organ examined to date. Since tissue distribution of family members can overlap, there is a need for reagents for specific quantitation of the different enzymes. We have developed antipeptide antibodies specific for human FMO1, FMO3, and FMO5. These antibodies were found to be form-specific using a panel of cDNA-expressed enzymes and western blotting. These reagents were used to quantitate levels of FMO expression in human tissue fractions. Substantial interindividual variation in expression was observed. For example, in 12 individuals, hepatic FMO3 and FMO5 levels varied 11- and 6-fold respectively. FMO1 was not detected in human liver. The ability to quantitate the levels of specific FMO enzymes should lead to a better understanding of the roles of these enzymes in human xenobiotic metabolism and toxicity.

325 DEVELOPMENT OF A RAINBOW TROUT RECOMBINANT CHIMERIC RECEPTOR REPORTER BIOASSAY TO SCREEN FOR THE POTENTIAL ESTROGENICITY OF ENVIRONMENTAL CONTAMINANTS IN FISH.

J H Clemons, J B Matthews and T R Zacharewski. *Department of Biochemistry, Michigan State University, East Lansing, MI, USA.*

Recently, the U.S. EPA has supported the use of estrogenic screening assays for both mammalian and wildlife species in order to elucidate the contribution of environmental contaminants in the endocrine disrupter issue. Our lab has established an in vitro rainbow trout (Oncorhynchus mykiss) bioassay to screen for compounds that act through the rainbow trout estrogen receptor. The assay utilizes a recombinant chimeric receptor consisting of the Gal4-yeast DNA-binding domain linked upstream to the ligand-binding domain (amino acids 214-576) of the rainbow trout estrogen receptor (RtGal4DEF). This cDNA is co-transfected with a Gal4-regulated luciferase reporter gene that is expressed in the presence of ligand-bound Gal4RtDEF. The transfection efficiency and performance of the Gal4RtDEF and Gal4 reporter gene was evaluated in 3 fish cell lines, PLHC-1, RTG-2 and RTH-149 and the human breast cancer cell line, MCF-7. A comparison of the ability of Gal4RtDEF and the human chimeric Gal4-estrogen receptor (Gal4HEG0) to mediate 17b-estradiol (E2)-induced reporter gene expression in the MCF-7 cells indicated that Gal4HEG0 had approximately two orders of magnitude greater sensitivity for E2 than Gal4RtDEF. This was also reflected when two different fish cell lines, PLHC-1 and RTG-2, were transfected with either construct. The PLHC-1 appeared to be the best cell line for transfection efficiency and inducibility; however, E2 was equally potent in all three cell lines. The potency of nonylphenol and benzo[a]pyrene as compared to E2 in the MCF-7 cells was similar in both the human or Gal4RtDEF; however, the overall response was consistently less with the Gal4RtDEF than seen with the Gal4HEG0. Therefore, it appears that it may be inappropriate to use a single surrogate species to monitor for estrogenicity in wildlife. In addition, this in vitro fish recombinant receptor bioassay is an excellent tool for fast, accurate, cost-effective screening of environmental contaminants or mixtures for estrogenic activities in fish.

326 HISTOLOGICAL INTEGRITY, CELL VIABILITY AND DRUG-METABOLIZING ENZYMES IN RAT LIVER SLICES AFTER CRYOPRESERVATION.

H Martin, B Bournique, I Jager, J P Sarsat, H J Toutain and C Lerche-Langrand. *Rhône-Poulenc Rorer SA, Nonclinical Safety Assessment and Drug Metabolism, Vitry sur Seine, France.*

Cryopreservation is a method for organ long-term storage used to overcome the scarcity of human tissues. We investigated the effect of cryopreservation on the morphological, biochemical and functional integrity of rat liver slices. Slices were incubated in modified University of Wisconsin solution containing 50% fetal calf serum and 10% dimethyl sulfoxide for 20 min on ice prior to a rapid freezing in liquid nitrogen. After 10-40 days, slices were thawed rapidly at 42°C. We found no changes in the lobular architecture and no microscopic findings in hepatocytes of cryopreserved liver slice sections

immediately after thawing. ATP content and MTT reduction in cryopreserved slices, measured respectively immediately and 1 h after thawing, were 40-50% that of freshly prepared slices (FPS). Total protein content decreased respectively by 40% and 60%, immediately and 24 h after thawing, relative to FPS values. To evaluate the catalytic activities of Phase I and II drug-metabolizing enzymes, antipyrine metabolism (10 mM for 24 h) was determined in cryopreserved slices. The antipyrine metabolites in FPS and cryopreserved slices were qualitatively similar but quantitatively different. The formation of Phase I and II metabolites in cryopreserved slices was 30% and 10-30% that in FPS. In conclusion, in rat liver slices cryopreserved for 10 to 40 days, i) histology was well preserved immediately after thawing, ii) viability was altered 1 h after thawing and iii) catalytic activities of drug-metabolizing enzymes were partly maintained after 24 h.

327 DETERMINING RELATIVE ESTROGENICITY BY QUANTIFYING VITELLOGENIN INDUCTION IN RAINBOW TROUT LIVER SLICES.

A D Shilling and D E Williams. *Dept. of Environmental and Molecular Toxicology and Marine/Freshwater Biomedical Sciences Center, Oregon State University, Corvallis, OR, USA.*

Precision cut tissue slices are a valuable tool for studying protein induction or inhibition by test chemicals by modeling the entire organ. We developed parameters to quantify relative estrogenicity of chemicals by measuring vitellogenin induction, a well characterized biomarker of estrogen receptor binding, in rainbow trout liver slices. Hank's medium (phenol-red free) supplemented with HEPES, sodium bicarbonate and 1% bovine serum albumin was utilized. We optimized parameters using 1 - 1000 nM 17 -estradiol, a potent estrogen in rainbow trout that induces vitellogenin production *in vivo*. Adding trout serum and not changing the media was essential, probably to allow for the accumulation of vitellogenin in the slices and media. Histological examination and ATP analyses indicated no toxicity in control or 17 -estradiol treated liver slices after 120 hours. Induction was 4-fold greater with 25% serum containing media compared to media with 10% serum. We observed an over 100 fold induction of vitellogenin at 96 hours in liver slices and media containing 25% serum and 1000 nM 17 -estradiol. Controls without 17 -estradiol, incubated in media with 10% or 25% serum, exhibited no detectable vitellogenin production, indicating that the induction seen was not from the media or serum. We observed that 48 hours was required for significant vitellogenin induction or at least accumulation to detectable levels in the media and liver slices. Maximum induction in slices occurred at 96 hours whereas media vitellogenin levels continued to increase to 120 hours. This suggests a time delay between vitellogenin production and excretion by the liver. Our results indicate the importance of media, serum, and time selection for optimal vitellogenin induction. This study will allow for the determination of relative estrogenicity of chemicals in a controlled *in vitro* system while utilizing the advantages of precision cut slice technology. (Supported by NIH grants ES-07060, ES-03850, and ES 04766.)

328 DEVELOPMENT OF OPTIMAL CONDITIONS FOR THE CULTURE OF PRECISION-CUT RAT LIVER AND LUNG SLICES.

A B Renwick, P T Barton, R J Price and B G Lake. *BIBRA International, Carshalton, Surrey, England.*

The aim of this study was to compare some experimental conditions for the culture of precision-cut rat liver and lung slices. Liver and lung (prepared using an agarose instilling technique) slices were prepared from untreated male Sprague-Dawley rats using a Krumdieck tissue slicer. Tissue slices were cultured in a dynamic organ culture system for periods of 1, 24 and 48 hr in an atmosphere of either 95% O_2/5% CO_2 or 95% air/5% CO_2. Media were supplemented with 0.1 m M insulin, 0.1 m M dexamethasone, 50 m g/ml gentamicin and 2.5 m g/ml fungizone. Liver slices (diameter 10 mm, thickness around 250 m m) were cultured in Williams' medium E (WE), RPMI 1640 (RPMI), Waymouth's (WAY) and Hepatozyme (HEP) media. While levels of protein synthesis and potassium content were similar in WE, RPMI and WAY media, they were lower in HEP media. Rates of protein synthesis were similar in rat liver slices cultured in WE containing either 0.1 or 1 m M insulin, but markedly reduced in WE containing 0.01 m M insulin. Rat lung slices (diameter 8 mm, thickness around 500 m m) were cultured in WE, RPMI, CMRL 1066, Medium 199 and Minimal Essential Medium Alpha (MEMα) media containing the above additions. No marked differences were observed in potassium content and in the metabolism of 200 m M 7-ethoxycoumarin to free and conjugated 7-hydroxycoumarin. As an additional marker of functional viability, rat lung slices were cultured in MEMα with 0-20 m g/ml Aroclor 1254 (ARO) for 24 and 48 hr. ARO treatment produced a concentration dependent induction of 7-ethoxyresorufin O-deethylase activity. These studies demonstrate that it is important to use an appropriate medium and insulin concentration for the culture of rat liver slices. Like liver slices, cultured lung slices may also be employed for xenobiotic metabolism studies and to investigate the induction of xenobiotic metabolising enzymes. (Supported by EU BIOTECH Contract No. B104-CT97-2145.)

329 MAINTENANCE AND INDUCTION OF CYTOCHROME P-450 (CYP) ISOFORMS IN CULTURED PRECISION-CUT HUMAN LIVER SLICES.

B G Lake[1], P S Watts[2], R J Edwards[2], A R Boobis[2], J M Tredger[3], A B Renwick[1] and R J Price[1]. [1]*BIBRA International, Carshalton, Surrey, England;* [2]*Imperial College School of Medicine, Hammersmith Hospital, London, England and* [3]*Institute of Liver Studies, King's College School of Medicine and Dentistry, London, England.*

In this study we have employed a panel of monospecific antibodies to examine the stability of CYP isoforms in cultured human liver slices and the induction of CYP isoforms by xenobiotics. Liver slices were prepared from samples of human liver (surplus to transplant requirements) with a Krumdieck tissue slicer. Precision-cut liver slices were cultured in RPMI 1640 medium for 0 (i.e. a 1 hr preincubation period), 24, 48 and 72 hr in a dynamic organ culture system in an atmosphere of 95% O_2/5% CO_2. After culture, liver slice microsomal fractions were prepared for Western immunoblotting studies. Levels of CYP1A2 and CYP2C19 apoproteins declined in culture, being around 20% of 0 hr levels after 72 hr. In contrast, levels of CYP2C9, CYP2D6 and CYP3A4 apoproteins were around 50% of 0 hr levels after 72 hr culture. CYP isoform dependent enzyme activities also declined in cultured liver slices. After 72 hr, activities of 7-ethoxyresorufin 0-deethylase (CYP1A2), tolbutamide methylhydroxylase (CYP2C9) and testosterone 6β -hydroxylase (CYP3A4) were around 20, 50 and 40%, respectively, of levels in 0 hr cultured slices. Human liver slices were also cultured in control medium or medium containing 0.5 mM sodium phenobarbitone (NaPB) or 50 m M rifampicin (RIF) for 72 hr. Compared to 72 hr control liver slice microsomes, both NaPB and RIF induced levels of CYP3A4 and CYP3A5. RIF treatment also induced levels of CYP2C19, but neither NaPB nor RIF had any marked effect on CYP2D6. These results demonstrate that while levels of CYP-dependent enzyme activities fall in cultured human liver slices, there is a differential loss of specific CYP isoforms. However, this does not preclude their use for *in vitro* CYP isoform induction studies. (Supported by EU BIOMED Contract No. BMH4-CT96-0254.)

330 SODIUM ARSENITE TOXICITY IN PRECISION-CUT RAT LUNG SLICES.

J B Wijeweera and R C Lantz. *Department of Cell Biology and Anatomy, University of Arizona, Tucson, AZ.*

While precision-cut liver slices have been extensively used for toxicity and metabolism studies, studies using precision-cut lung slices are limited in the literature. This is probably due to the limited availability of lung tissue for such studies when using agar-instilled lung slices. Another draw back is that enzyme leakage or potassium leakage from lung tissue may not be appropriate markers of toxicity due to entrapment in agar matrix. In the present study ATP content was used to assess toxicity of sodium arsenite in agar-instilled precision-cut lung slices. Lung slices (10 mm diameter, 550-600 μ thickness) were prepared from male Sprague Dawley rats (250-300 g) and cultured for up to 24 hr in Waymouths MB752/1 medium. Lung slices were exposed to 100 nM-1 mM sodium arsenite. Control slices retained viability up to 24 hr as observed by slice ATP content and histology. Exposure to 100 nM arsenite did not result in any toxicity while 1 mM arsenite caused toxicity as early as 2 hr. Ten μ M arsenite decreased cellular ATP by 6 hr. Studies on arsenic smelter workers have shown that cigarette smoking increased the number of arsenic-induced lung cancer. Our preliminary studies show that coexposure to arsenic and cigarette smoke results in enhanced pulmonary toxicity *in vivo*. Therefore our goal is to extend these studies in the lung slice model in order to determine interactive toxicity and early sensitive molecular markers of cytotoxicity of these agents. (Supported in part by ADCRC grant 9703.)

331 LIVE TIME EVALUATION OF CELL TOXICITY IN PRECISION-CUT TISSUE SLICES USING CONFOCAL MICROSCOPY.

D Cromey, R C Lantz, C Rocha, A R Parrish, and A J Gandolfi. *Southwest Environmental Health Sciences Center, University of Arizona, Tucson, AZ.*

Based upon the retention of organ architecture and cellular heterogeneity, precision-cut tissue slices offer a unique in vitro model to investigate site-specific effects of toxicants. The production of specific fluorescent dyes for various indices has allowed investigators to assess the live-time effect of xenobiotics using confocal microscopy in cell culture systems. However, the current studies were designed to determine if precision-cut liver slices would provide a suitable in vitro toxicity model for confocal microscopy. Male adult SD rat liver slices were exposed to 1,1-dichloroethylene (DCE). At 2, 3.5, 5 and 7 hr, DCE exposed slices were removed and stained with a combination of nucleic acid dyes. Live cells were stained with Syto-10, which is permeable to plasma membranes of living cells, while dead cells were identified with Dead Red. Dyes (1µl/500 µl medium) were made immediately prior to staining at each timepoint. Staining was for 15 min at room temperature in the dark, followed by two washes. After staining, slices were placed in a 35 mm tissue culture plate (modified to contain a glass coverslip base) and were held in place with aluminum meshing. Slices were viewed using a Leica TCS confocal microscope containing an IRBE inverted microscope and Kr/Ar laser. Simultaneous visualization of the stains was obtained by excitation with the 488/568 laser lines accompanied by FITC and TRITC emission bandpass filters. DCE lead to a selective progressive damage of the slices. Little or no dead cells were apparent at 2 hr of exposure. At 3.5 hr, the appearance of dead cells around blood vessels became apparent. The damage was progressively worse at 5 hr. However, by 7 hr, the distribution of dead cells was uniformly distributed across the surface of the slice. No damage was noted even in controls that had been incubated for up to 8 hr. These results indicate that toxicity can be observed live-time in tissue slices and offers a dynamic system for examining mechanisms of intoxication. (Supported by a Procter & Gamble Exploratory Research Grant.)

332 ESTABLISHMENT OF PRECISION-CUT HUMAN PROSTATE SLICES AS AN IN VITRO TOXICOLOGY MODEL.

R B Nagle[1], A Cress[2], B Dalkin[3] A R Parrish[1] and A J Gandolfi[1]. *Southwest Environmental Health Sciences[1] Center, Departments of Radiation Oncology[2] and Surgery[3], University of Arizona, Tucson, AZ.*

Benign prostate hyperplasia (BPH) and prostate cancer (PC) are a significant cause of morbidity and mortality. However, understanding of molecular mechanisms underlying prostate pathobiology is limited by i) the lack of a widely accepted animal model; ii) the zonal specificity of the two diseases [BPH-transitional zone; PC-peripheral zone] and iii) the complex network of stromal-epithelial interactions which limit the use of cell cultures. Recently, we have developed a novel *in vitro* approach to the prostate – the use of precision-cut human prostate slices. This system has several advantages, including the use of human tissue, maintenance of stromal-epithelial relationships, and the ability to investigate differences between the transitional and peripheral zones. Viability of stromal and epithelial (both basal and secretory) cells is maintained for up to 72 hr as assessed by histological evaluation. LDH leakage peaks at 3 hr, indicating damage due to the slicing process, however, by 48 hr media LDH activity is not detectable. Conversely, secretion of prostate specific antigen is detected throughout the 72 hr culture period. Preliminary results have shown that 1 µM cadmium, a putative prostate carcinogen, increases LDH leakage 181% in peripheral zone slices at 48 hr, but not transitional zone slices. These results suggest that human prostate slices represent a powerful tool to investigate prostate pathobiology. (Supported by Arizona Disease Control Research Commission (1-345) and an SOT Colgate-Palmolive Fellowship.)

333 IN VITRO DERMAL ABSORPTION OF JET FUEL (JP-8) AND ITS COMPONENTS.

C M Garrett[1], D L Pollard[2], T E Miller[3] and J N McDougal[1]. [1]*Geo-Centers, Inc.,* [2]*ManTech Environmental Technology,* [3]*Human Effectiveness Directorate, Air Force Research Laboratory, Wright-Patterson AFB, OH, USA.*

Military personnel are exposed to jet fuels during many activities. These kerosene-based fuels cause irritation to the skin with repeated or continuous dermal contact and high levels have been associated with renal, hepatic, neurologic, immunologic and pulmonary toxicity in animal inhalation studies. Although the local dermal toxicity of these fuels is recognized, the potential for systemic toxicity from dermal absorption due to skin exposures has not been completely assessed. The purpose of our study was to determine the absorption of JP-8 (the Air Force's primary jet fuel since 1996) and its components so that the potential for systemic toxicity can be addressed. The dermal penetration of this complex mixture was measured over a 24-hour period using static diffusion cells with Fischer-344 rat skin. Receptor solution (6% volpo/saline) was collected at two-hour intervals and assayed by gas chromatography. The sum of the peak areas at each time point was taken as the total mass of JP-8 absorbed. Flux was determined from the slope of the cumulative absorbed curve plotted over time. The steady-state flux of JP-8 was 41.4 µ g/cm^2/hr. Among the major peaks in the receptor solution, several were identified as methyl benzene, ethyl benzene, dimethyl benzene, naphthalene, methyl naphthalene, dimethyl naphthalene, tridecane and dodecane. The flux of these chemicals ranged from 0.4 to 1.4 µ g/cm^2/hr. These results show that it will be possible to estimate systemic toxicity of the individual components of this complex hydrocarbon mixture from dermal exposures. (Supported by Office of AF Surgeon General - AFMOA/SGOE.)

334 DERMAL ABSORPTION AND TOXICITY OF JET FUELS.

J E Riviere[1], N A Monteiro-Riviere[1], J D Brooks[1], K Budsaba[2] and C Smith[2]. [1]*Cutaneous Pharmacology and Toxicology Center,* [2]*Department of Statistics, North Carolina State University, Raleigh, NC, USA.*

Dermal exposure to jet fuels has received increased attention with the recent release of newer fuels with novel performance additives. The purpose of these studies was to assess the percutaneous absorption and cutaneous disposition of topically applied (25µ l / 5cm^2) neat JetA, JP-8, and JP-8 (100) jet fuels by monitoring the absorptive flux of the marker components ^{14}C naphthalene (N) and ^{3}H dodecane (D) simultaneously applied non-occluded to isolated perfused porcine skin flaps (IPPSF) (n=4). Absorption of these markers were also assessed using JP-8 applied to cotton fabric and from a non-volatile JP-8 fraction reflecting exposure to residual fuel that might occur 24 hrs after a jet fuel spill. Perfusate, stratum corneum and skin concentrations were assessed over 5 hrs. Cutaneous toxicity to all jet fuels was separately evaluated *in vivo* in pigs at 5 and 24 hrs. N absorption demonstrated a clear peak absorptive flux within 30 min while D had a prolonged, albeit ten fold lower, absorption flux profile. N absorption into perfusate was two-fold greater from JP-8 and JP-8 (100) compared to Jet-A, however Jet-A produced double the skin concentrations of either JP-8 fuel. D absorption was mildly suppressed in JP-8 (100) compared to Jet-A and JP-8, with Jet-A again showing the highest skin concentrations. Topical exposure to JP-8 from fabric resulted in a six-fold (N) and 20 fold (D) decrease in perfusate absorption compared to liquid JP-8 exposure, however it also produced the highest N skin levels of any exposure scenario. These studies clearly demonstrate differential jet fuel additive effects on N and D absorption as well as uncoupling of perfusate absorption from skin disposition. (Funded by the U.S. Air Force Office of Scientific Research (FQ8671-98-000462).)

335 PREDICTION OF SKIN PERMEABILITY COEFFICIENTS OF VOLATILE ORGANIC CHEMICALS FROM INFORMATION ON THEIR MOLECULAR STRUCTURE.

K Krishnan[1] and P Poulin[2]. [1]*TOXHUM, Université de Montréal, Montréal, Canada;* [2]*Hoffmann-La Roche, Ltd., Basel, Switzerland.*

Skin permeability coefficients (K_p) are required for estimating the dermal absorption of volatile organic chemicals (VOCs) using a pharmacokinetic model. At the present time, K_p of VOCs are empirically predicted by fitting molecular structure information of VOCs to experimental data on K_p. Considering the number of VOCs presents in our environment and that the resources are limited, these empirical equations have a limited use in risk assessment because *in vivo* and/or *in vitro* data on skin absorption are required to derive such empirical equations. Alternatively, mechanistic/molecular structure-based equations need to be developed for predicting K_p of VOCs. The objective of the present study was to develop a mechanistic approach for predicting the human abdominal K_p of 35 VOCs only from information on their molecular structure. The approach consisted of estimating the stratum corneum:water ($P_{s:w}$) partition coefficients (PCs), the diffusion coefficients (D), and the path length of diffusion (l) for eventually calculating K_p (= $P_{s:w}$ x D/l). $P_{s:w}$ of VOCs were predicted only from molecular structure information based on a recently validated equation used for predicting the tissue:water PCs of organic chemicals from data on oil:water PCs

and lipid and water contents in tissue. Whereas, D were predicted according to the conventional Einstein-Stoke equation using molecular structure information (i.e., molecular radius) of VOCs and data on skin viscosity as the only input parameters. Finally, l was estimated in accordance with the characteristics of the diffusion pathway in the stratum corneum (i.e., transcellular and intercellular pathways). The predicted human abdominal K_p value of several VOCs (alcohols, haloalkanes, aromatics) differed to the experimentally-determined ones with an average ratio of 1.04 (S.D. = 0.88, r = 0.85, n = 35). Incorporating the mechanistic/ structure-based equation validated in this study in a pharmacokinetic model should facilitate the risk assessment for a skin exposure to the several VOCs present in our environment.

336 PENETRATION GRADIENTS OF NICKEL SALTS ABSORBED IN HUMAN *STRATUM CORNEUM IN VIVO.*

J J Hostynek, T Nakada, F Dreher, D A Schwindt, and H I Maibach.
School of Medicine, Department of Dermatology, University of California, San Francisco, CA, USA.

The standard protocol of sequential adhesive tape stripping was implemented to examine the absorption of several nickel salts through human *stratum corneum in vivo* following their application on the volar forearm and back skin of healthy adult volunteers. Exposure areas of the salts applied in low volume, open, as methanol solutions at nickel concentrations from 2 to 300 μg/cm2 were stripped at intervals from 30 min. to 24 hrs. post dosing. The strips were analyzed for metal content by inductively coupled plasma-atomic emission spectroscopy. For the nickel (II) salts chloride, sulfate, nitrate and acetate, the concentration-versus-depth profiles obtained allow the following conclusions, several in support of earlier observations: a) Accumulation of nickel in the SC was observed in function of exposure time, as the concentration gradient between the superficial and deeper layers of the SC increases commensurate with duration of exposure. b) The counter ion in nickel salts plays a major role in their passive diffusion through the SC, suggestive of ion pairing. c) While the concentration gradients of nickel retained in the stratum corneum (SC) vary with counter ion, anatomical site, dose and exposure time, for all variables tested the profiles converge towards non-detectable levels (<20 ppb) beyond the fifteenth strip, independent of these parameters. d) For most applications, mass balance based on cumulative SC analysis for nickel to the *stratum compactum* level (to include material deposited in furrows) shows a deficit. Depending on the variables of application, varying amounts of the metal applied as salt thus appear to penetrate beyond the SC, presumably via the skin shunts.

337 IN VIVO DECONTAMINATION OF METHYLENE BISPHENYL ISOCYANATE (MDI): SOAP AND WATER INEFFECTIVE COMPARED TO POLYPROPYLENE GLYCOL, POLYGLYCOL-BASED CLEANER AND CORN OIL.

X Hui[1], T Landry[2], H I Maibach[1] and R C Wester[1]. [1]*Dept. of Dermatology, University of California, San Francisco, CA; and* [2]*Health and Environmental Research Laboratory, The Dow Chemical Co., Midland, TX.*

Decontamination of a chemical from skin is traditionally done with soap-and-water wash, some workplaces may have an emergency water shower. It has been assumed that these procedures are effective, yet workplace illness and even death occure from chemical contamination. This study determined whether there are more effective means of removing methylene bisphenyl isocyanate (MDI), a potent contact sensitizer, from the skin. MDI is an industrial chemical for which skin decontamination using traditional soap-and-water and nontraditional polypropylene glycol, a polyglycol-based cleaner (PG-C) and corn oil was done *in vivo* in the Rhesus monkey over 8 hours. Water and soap and water (5% and 50% soap) were partially effective in the first hour removing 51-69 percent applied dose. However, decontaminatin fell to 40-52 percent at 4 hours and 29-46 percent at 8 hours. Thus, the majority of MDI was not removed by traditional soap and water wash; skin tape stripping after wash confirmed that MDI was still on the skin. In contrast polypropylene glycol, PG-C and corn oil removed 68-86 percent MDI in the first hour, 74-79 percent at 4 hours, and 72-86 percent at 8 hours. Statistically polypropylene glycol, PG-C and corn oil were all better ($P<0.05$) than soap and water at 4 and 8 hours after dose application. These results indicate that traditional soap-and-water wash and the emergency water shower are relatively ineffective at removing MDI from the skin. More effective decontamination procudures, as shown here, are available.

338 AN INNOVATIVE METHOD TO DETERMINE DERMAL UPTAKE OF SOLVENTS FROM SOIL AND WATER IN VIVO IN HUMANS.

R C Wester[1], X Hui[1], H I Maibach[1], T S Poet[2], K K Weitz[2], J A Edwards[2], R A Corley[2], and K D Thrall[2]. [1]*Dept.of Dermatology, University of California, San Francisco, CA, and* [2]*Pacific Northwest National Lab, Richland, WA.*

Realistic estimates of dermal bioavailability following exposures to contaminated soil or water are critical to understanding human health risk. A method was developed to determine dermal uptake of volatile organics using real-time breath analysis. This data was subsequently analyzed using physiologically based pharmacokinetic (PBPK) models to estimate dermal bioavailability. For exposures lasting from 2-6 hr, soil was contained against the skin by a patch with a non-occlusive membrane, and volatilized material was trapped using activated charcoal. The water counterpart was an occlusive glass culture dish, sealed to the skin with silicone adhesive. Short-term exposures (2-4 hr) were by one hand immersion in a bucket containing circulating water or soil. In all cases, subjects were provided breathing air via a facemask to eliminate inhalation exposure. The subject's exhaled breath was analyzed using an ion trap mass spectrometer, which can quantitate individual chemicals in the breath stream in the 1-5 ppb range. This methodology was evaluated using 1,1,1-trichloroethane (methyl chloroform: MC) as a test compound. The results showed that the length of time between exposure and appearance of MC in exhaled breath varies between subject and exposure scenario, but there appeared to be a 30-60 min post application delay. The method also clearly discerned the uptake phase, peak concentrations and clearance phases. Furthermore, quantitation of MC in exhaled breath at several orders of magnitude above the detection limit of the instrument show the methodology is well suited for human dermal studies utilizing low exposures, for a short period of time, to a small percentage of the body. (Supported by a grant from US DOE, No. DE-FG07-97ER62509.)

339 ASSESSING THE DERMAL BIOAVAILABILITY OF VOLATILE ORGANICS IN RATS.

T S Poet[1], R A Corley[1], K D Thrall[1], and R C Wester[2]. [1]*Pacific Northwest National Lab, Richland, WA; and* [2]*Dept. of Dermatology, University of California, San Francisco, CA.*

Assessing the bioavailability of soil contaminants is critical to understanding human health risk. In this study, 1,1,1-trichloroethane (methyl chloroform: MC) was used to develop methods to assess the bioavailability of volatile organics in soil following dermal exposures in F-344 rats. Physiologically based pharmacokinetic (PBPK) modeling has been used to fully describe the dermal dosimetry. For exposures in a soil matrix, a non-occlusive patch system was developed to hold the soil against a clipper-shaved area on the flank of the rats. Volatilized MC was trapped with activated charcoal. The amount of MC in exhaled breath was determined by placing rats in sealed off-gassing chambers and sampling chamber air every 4 sec using an ion trap mass spectrometer. Regardless of dose, peak chamber MC concentrations were reached within 30 min of exposure, and concentrations dropped to <25% of peak by 2 hr of exposure. This is consistent with the volatilization of test material as determined by the analysis of MC in the activated charcoal. A chamber concentration dose-response was observed with peak MC concentrations ranging from ~800 to ~3000 ppb following application of soil containing from 0.3% to 1% MC. The permeability coefficient (k_p) for the dermal uptake of MC applied in a soil matrix, estimated using the PBPK model was between 0.34 and 0.44 cm/hr. These rat studies will be used to compare the impact of concentration, exposure duration, and soil characteristics on bioavailability of volatile organics. Human studies are being run concurrently to validate the extrapolation from rat to human using PBPK models. The end product of this research will be methodology to rapidly evaluate dermal exposures to organics in contaminated soil. (Supported by US DOE grant No. DE-FG07-97ER62509.)

340 DERMAL ABSORPTION OF N-METHYLPYRROLIDONE (NMP) IN THE RAT.

S V J Bounds[1], J Griffiths[2], T McCarthy[2], A Lorman[2], and R Parod[2].
[1]*Huntingdon Life Sciences, Eye Research Centre, Suffolk, UK;* [2]*NMP Producers Group, Inc., Washington, DC, USA.*

The dermal absorption of radiolabelled material in male Sprague Dawley CD rats following a single topical application of undiluted [^{14}C]-N-

methylpyrrolidone (NMP) and also diluted at 4 concentrations in 2 dose vehicles, water and (R)-(+)-limonene, was determined. For each dose solution (constant application rate of 10 µl/cm²), 1 group of 4 male rats was sacrificed at 1, 3, 6 and 24 hours after dosing to assess the distribution of the radioactivity. The animals were individually housed in glass metabowls equipped to separately collect urine, faeces, expired air and volatile material from the dose site (carbon filters). Following a single topical application of 100% NMP, the majority of radiochemical dose (>67%) was recovered as volatile material from the dose site. Only a small proportion of dose remained in the treated skin and was washed from the skin, falling from approximately 6% to <1% of dose from 1 to 24 hours. At 24 hours after dosing, 32% of the dose had been absorbed, and largely eliminated in the urine (94%), faeces (1.6%) and expired air (0.6%). As the NMP dose solutions contained increasing proportions of water, from 35% to 97% (by vol), so the percentage of the dose absorbed decreased from 15% to <1% respectively at 24 hours after dosing. At this time point, <3% of dose remained at the dose site and <0.5% in the untreated skin and carcass for all the aqueous dose solutions, the majority of dose had evaporated from the dose site and was recovered in the carbon filters. Dilution of NMP with limonene over the range 35% to 90% limonene increased the proportion of dose absorbed compared to 100% NMP. The absolute quantity of [^{14}C]-NMP absorbed (approximately 2-3 mg/cm²) was similar for the 3 dose solutions containing 0, 35 and 70% limonene. The maximum dose absorbed (72%) was found after dosing with a mixture of 30:70, NMP:limonene. At 24 hours after dosing with this solution, >67% of the dose had been excreted in the urine with <2% remaining in the untreated skin and carcass and <0.5% at the dose site.

341 HUMAN SYSTEMIC EXPOSURE AFTER DERMAL ABSORPTION OF AHTN AND HHCB AS USED IN FRAGRANCES–EVIDENCE FOR LACK OF ABSORPTION FROM A SKIN RESERVOIR.

R A Ford[1], D R Hawkins[2] and R Schwarzenbach[3]. [1]*Research Institute for Fragrance Materials, London, England;* [2]*Huntingdon Life Sciences, Huntingdon, England;* [3]*Givaudan Roure Research, Duebendorf, Switzerland.*

7-Acetyl-1,1,3,4,4,6-hexamethyl-1,2,3,4-tetrahydronaphthalene (AHTN) and 1,3,4,6,7,8-Hexahydro-4,6,6,7,8,8-hexamethylcyclopenta-gamma-2-benzopyran are the two largest volume materials of a group of substances known collectively as polycyclic musks. AHTN and HHCB are widely used in a variety of fragrances that are in consumer products. As part of the risk evaluation, the systemic exposures to these materials was determined under simulated conditions of exposure. Ring ^{14}C labeled AHTN and HHCB were each applied without occlusion to human volunteers in a hydroalcoholic solution at concentrations approximating that which might be encountered in a cologne type product. After a 6-hour period, all material was removed from the surface of the skin. Blood, feces and urine were collected over a 5-day period following application. For both materials, levels in blood and plasma were below limits of detection at all times. Based on measurements in urine and feces, the total systemic availability was 0.9% and <0.1% for AHTN and HHCB respectively although both were initially significantly absorbed into the skin. Over the period of 5 days, 14.5% of AHTN and 19.5% of HHCB was recovered from the skin in dressings over the site of application indicating that a reservoir had formed but the material in the skin was excreted either by sloughing of the skin or by reverse absorption. A mean of 24.2% (AHTN) and 21.8% (HHCB) was shown to evaporate under the conditions of exposure. Thus, while absorption into the skin occurred, most absorbed material was not available for systemic exposure.

342 EFFECTS OF AN ALCOHOL DEHYDROGENASE INHIBITOR ON CINNAMALDEHYDE ABSORPTION AND BIOTRANSFORMATION IN HUMAN SKIN.

C K Smith, A T S Smart, and S A M Hotchkiss. *Imperial College School of Medicine, London, UK.* Sponsor: R A Ford.

Cinnamaldehyde (CAld), a component of cinnamon, is an aromatic aldehyde that is commonly used as a fragrance and flavouring agent. Following skin exposure, CAld has been reported to act as a strong contact sensitizer. In this study, the biotransformation of the protein-reactive CAld to the non-protein-reactive cinnamic alcohol (CAlc) and cinnamic acid (CAcid) was investigated. A series of 24 hour percutaneous absorption and metabolism experiments were performed for CAld, in the absence and presence of the alcohol dehydrogenase (ADH) inhibitor, pyrazole. Fresh full-thickness human breast or abdomen skin (n = 3) was used in an established skin absorption model, which maintained the viability of the skin at 37°C, in a receptor fluid at pH 7.3. CAld (78 mmoles/10 µl neat) was applied to a 0.32 cm² epidermal area of skin occluded over 24h. In vehicle control and inhibition studies, 20 ml water, 80 or 320 µmoles pyrazole were applied 30min prior to CAld application. Receptor fluid samples, collected at 2h intervals, and methanol washes of occlusion cells and skin surface swabs were analyzed for metabolites by high performance liquid chromatography. In experiments with CAld, a total of ~55% of the initial dose was accounted for by a) evaporation (~0.95%), b) skin surface residue (~43.7%) and c) penetration (2.70± 0.60% CAlc, 4.66± 1.32% CAcid and 2.72± 0.68% CAld). Preincubation of an approximate 1:1 molar ratio of aqueous pyrazole resulted in a reduction in penetration of both CAlc (0.79± 0.02%) and CAcid (1.41± 0.06%) and similar penetration of CAld (3.89± 1.33%). CAld is detoxified to CAlc and CAcid in human skin, although CAld may be regenerated by ADH mediated reoxidation of CAlc. The altered profile for the penetration of CAld metabolites in the presence of pyrazole may be due to inhibition of alcohol dehydrogenase function or as a result of altered absorption kinetics for CAld in the presence of aqueous solutions.

343 PERCUTANEOUS ABSORPTION AND METABOLISM OF BUTOXYETHANOL IN RAT.

D J Lockley[1], D J Sanders[2], H J Minter[2] D Howes[2] and F M Williams[1]. [1]*Department of Environmental and Occupational Medicine, Medical School, Newcastle University, Newcastle, UK;* [2]*SEAC Toxicology Unit, Unilever Research, Colworth House, Sharnbrook, Bedford, UK.* Sponsor: E Lock.

Low molecular weight glycol ethers (ethoxylates) are used as solvents in industrial and household products. Dermal exposure and absorption of butoxyethanol (BE) can produce toxicity following metabolism to the corresponding aldehyde and acid. The aim of this study was to investigate the disposition of BE after dermal and parenteral exposures. The distribution and metabolism of BE in male, Wistar rats (n=3) was studied. BE was applied topically (88.5 mg / 9.6cm², 10µ Ci) or in saline by intraperitoneal injection (5.14 mg/g, 50µ Ci) to rats and excreta analysed for total radioactivity. At 24 hours, following topical application 28.4 % of the dose was absorbed. The major route of ^{14}C excretion was in the urine (18.6 %) with expiration in air, as $^{14}CO_2$ (5.7 %) and the faeces (0.4 %) being more minor routes. Approximately 1.34 % of the dose remained in the carcass. Overall recoveries of ^{14}C were reproducible and the total non-absorbed dose was 34.3 %. A similar profile of distribution was observed following ip administation. Whole Body Autoradiography (WBA) at 4 hours revealed widespread tissue distribution particularly in gut contents, kidney, liver, harderian gland, and intraorbital lacrimal gland following either dose route. Thin layer chromatography with phosphoimage analysis of rat urine samples indicated almost complete metabolism of BE to ethylene glycol or butoxyacetic acid, 81.7 % and 14.1 % (topical study) and 63.8 %, and 35.2 % (ip study). Several minor but distinct bands were also observed after phosphoimage analysis and could constitute a series of unidentified conjugates. By comparing profiles of BE metabolism following topical and ip administation there is little evidence of local dermal metabolism of this compound.

344 DERMAL ABSORPTION AND CUTANEOUS DISPOSITION OF 3,3',4,4'-TETRACHLOROBIPHENYL (TCB) IN A SWINE MODEL.

G L Qiao[1], J D Brooks[2], and J E Riviere[2]. [1]*EAB/HELD, National Institute for Occupational Safety and Health (NIOSH), Morgantown, WV, USA;* [2]*Cutaneous Pharmacology and Toxicology Center, North Carolina State University, Raleigh, NC, USA.*

The impacts of exposure variables on dermal absorption and tissue disposition of TCB were explored following topical dose of [^{14}C]TCB in pigs (40µ g/cm², n=3/dose). Application vehicles included acetone, methylene chloride (MC), water- and soil-based mixtures. An occlusion study was performed using a soil vehicle with/without antibiotics. In one group, skin P_{450} was pre-induced by benzo[a]pyrene prior to TCB exposure. Additionally, an IV study was also carried out. During the 11-day experiments, blood, urine, and feces were collected. At the experimental end, full mass balance procedures were performed. On average, 64-96% of the dose was recovered. The IV data revealed a half-life of 4-5 days in blood. Following topical exposure, the 11-day absorption (vehicle) was determined as 22% (acetone), 32% (MC), 22% (water-acetone mixture), and 33% (soil mixture) under non-occlusive exposure. The corresponding values for occluded soil were 52% (no antibiotics) and 17% (with antibiotics). A greater absorption of 29% (vs 22%) was observed if cutaneous P_{450} was pre-induced. The urine/feces

excretion (U/F) ratios ranged 0.4-1.5 and about 2/3 of the absorbed dose was found in tissues 11 days after TCB dermal exposure. Interestingly, topical doses yielded much higher ^{14}C concentrations in most tissues although the topical absorption and excretion were lower than IV as expected. TCB was absorbed much more efficiently from soil-based mixtures than from pure organic vehicles and water-organic mixture. Occlusion enhanced absorption and modified the U/F ratio (0.4 to 0.7). Skin microbial inhibition could largely offset the absorption-enhancement effect of occlusion. Addition of water to acetone changed the U/F ratio (1.3 to 0.7). In conclusion, absorption data from pure organic solvents or organic-water mixture might underestimate the risk of TCB from soil exposure. Concentration-dependent tissue uptake and/or unique skin metabolism might exist for TCB. Exposure variables may change dermal absorption via skin metabolism modification. Therefore, careful dermal exposure assessment is critical for occupational and environmental safety analysis and management. (Supported by USEPA-CR 824007.)

345 COMPARISON OF PERCUTANEOUS ABSORPTION CHARACTERISTICS FOR TWO STRUCTURALLY RELATED DIRECT HAIR DYES, HC BLUE NO. 1AND HC BLUE NO. 2, *IN VITRO* AND *IN VIVO*.

W E Dressler, R S Grabarz, and R K Sharma. *Bristol-Myers Squibb Worldwide Beauty Care Research and Development, Stamford, CT.*

Two structurally related direct (semi-permanent) hair dyes, HC Blue No. 1 and HC Blue No. 2, were compared for their percutaneous absorption potential using human cadaver skin mounted in Franz-type static diffusion cells in vitro. Under simulated use conditions, ^{14}C-radiolabeled dyes in hair dye formulations for which human in vivo penetration data had been obtained previously (Wolfram LJ, Maibach HI. 1985. Arch Dermatol Res 277:235-241) were applied to heat-separated epidermal membranes. The appearance of ^{14}C in 30 minute skin rinsates, in periodic receptor fluid samples, and in both a final wash and the epidermis after termination of the experiment at 48 hours was determined via liquid scintillation. For HC Blue No. 2, the absorption of dye into the receptor fluid was maximal within 4 hours after application, with a total cumulative mass absorbed of about 0.20 ug/cm^2. For HC Blue No. 1 the cumulative mass absorbed was 0.42 ug/cm^2 after 48 hours with a slope suggestive of continuing incremental absorption. The amounts remaining on or in the epidermis were similar for both dyes (approximately 1.3 ug/cm^2). Comparison of the human in vitro data with historical human in vivo data obtained under application and wear conditions indicated that for HC Blue No. 2 the in vitro receptor fluid concentration alone approximated the Day 1 in vivo value (0.23 ug/cm^2) whereas it underestimated the Day 1 in vivo value for HC Blue No. 1 (2.81 ug/cm^2). Consideration of the in vitro time course data suggested that incremental absorption of HC Blue No. 2 over time (Days 2-30) in vivo resulted primarily from re-exposure to dye leached from the hair reservoir whereas incremental absorption of HC Blue No. 1 may have resulted, at least in part, from continued mobility of dye in the epidermis.

346 IN VITRO PERCUTANEOUS ABSORPTION AND METABOLISM OF 2-NITRO-P-PHENYLENEDIAMINE IN HUMAN AND FUZZY RAT SKIN.

J J Yourick and R L Bronaugh. *Office of Cosmetics and Colors, Food and Drug Administration, Laurel, MD.*

2-Nitro-p-phenylenediamine (2NPPD) is a "coal-tar" dye used in semipermanent and permanent (tinting color) hair dye formulations. In previous work, we reported on the percutaneous absorption and metabolism of 2NPPD in fuzzy rat skin and intestinal tissue (Toxicologist, 36:188, 1997). These studies were expanded to include *in vitro* absorption and metabolism of 2NPPD in human skin from ethanol and from a spiked semipermanent formulation, and in fuzzy rat skin from ethanol and from a spiked permanent formulation. Dosing vehicles were applied to skin in the diffusion cells for 30 min. Absorption was measured over 24 hr by using flow-through diffusion cells (0.64 cm2) with a receptor fluid consisting of HHBSS (pH 7.4). 2NPPD metabolites were determined by HPLC. In human skin, the percentages of total applied dose absorbed (receptor fluid + skin) over 24 hr were 9.2 ± 5.7 (mean ± SD) and 9.5 ± 3.2 for the ethanol and semipermanent vehicles, respectively, with approxi-mately 3% remaining in skin. In rat skin, the percentages of total applied dose absorbed over 24 hr were 9.3 ± 1.2 (mean ± SEM) and 4.2 ± 0.1 for the ethanol and permanent form-ulation vehicles, respectively, with approximately 3% remaining in skin. 2NPPD rapidly penetrated both human and fuzzy rat skin from the product formulations with 47 and 64%, respectively, of the total absorbed dose found in the receptor fluid within 3 hr. In human and rat skin, 2NPPD was metabolized to triaminobenzene and N4-acetyl-2NPPD. 2NPPD was also metabolized to a sulfated 2NPPD metabolite in rat skin, but not in human skin. These results suggest that 2NPPD is rapidly absorbed and extensively metabolized in both human and rat skin. 2NPPD metabolism upon absorption appears to be species-dependent.

347 NATURAL RUBBER LATEX PROTEIN PENETRATION AND LOCALIZATION IN ANIMAL AND HUMAN SKIN.

B B Hayes[1,2], A E Munson[1], and B J Meade[1]. [1]*National Institute for Occupational Safety and Health (NIOSH), Health Effects Laboratory Division, Morgantown, WV;* [2]*Virginia Commonwealth University, Richmond, VA.*

In the past few years, recognition of natural rubber latex allergies has increased dramatically throughout the world. In fact, many hospitals have taken steps to reduce exposure to natural latex products (e.g. low powder, low protein gloves) in part because of the NIOSH 1997 alert, "Preventing Allergic Reactions to Natural Rubber Latex in the Workplace." However, there remains a need to understand better the factors affecting sensitization to latex proteins. These studies begin to appraise the skin's role in latex protein allergies. Initial studies evaluated *in vitro* penetration of latex proteins through hairless guinea pig skin. Non-ammoniated latex proteins were radiolabeled with ^{125}I using Iodo-Beads™ and dialyzed against K_2PO_4 for 48 hours to remove any unincorporated label. SDS-Page and phospho-imaging were used to separate individual proteins and to identify which proteins had been radiolabeled. The protein mixture was applied to dermatomed skin sections (250 μm) that were intact or abraded via tape stripping to remove the stratum corneum. To further mimic human exposure conditions, diffusion cells were occluded for the 24-hour dosing period. The data demonstrated latex proteins penetrated significantly more through the abraded skin (3.37% ± 0.87) than the intact skin (1.36% ± 0.04). Immunohistochemistry on skin samples using a rabbit anti-latex serum localized latex proteins mainly to the stratum corneum and the viable epidermis. These results suggest that certain latex proteins can penetrate deep enough into the epidermis to sensitize and subsequently to evoke an immune response via the skin. Furthermore, the appearance of radioactivity in the receptor fluid indicates latex proteins or peptides can penetrate into the dermis, which gives rise to the possibility of systemic sensitization via the skin. Future studies will evaluate ammoniated protein mixtures and purified latex proteins in animal and human skin. (These studies were supported in part by NIOSH/NIEHS interagency agreement # Y02ES10189.)

348 IMMUNOCHEMICAL DETECTION AND LOCALIZATION OF ALDEHYDE DEHYDROGENASE ISOZYMES IN HUMAN AND RODENT SKIN.

C Cheung and S A M Hotchkiss. *Imperial College School of Medicine, London, UK.* Sponsor: R A Ford.

Human skin is exposed to potentially reactive aldehydes in the form of environmental chemicals, occupational chemicals and consumer products. These aldehydes may be absorbed across the skin and result in local and systemic toxicity. Aldehyde dehydrogenase (ALDH, E.C. 1.2.1.3.) enzymes play a toxicologically important role in the detoxification of such aldehydes. The highest activities of ALDHs are found in the liver, but these enzymes are also detected extrahepatically. In this study, the presence of ALDH isozymes in human and rodent skin has been investigated. Fresh human, mouse (BALB/c and CBA/CA strains), Fischer 344 rat and Dunkin-Hartley guinea-pig skin was homogenized in ice cold sucrose buffer, pH 6.8. Cytosol and mitochondrial fractions were prepared by differential centrifugation and subjected to SDS-PAGE and immunoblotting. For immunohistochemical analyses, 5 μm sections were cut, of formalin fixed, paraffin-wax embedded skin. Immunoblotting of human, mouse (both strains), rat and guinea-pig skin cytosol, using an ALDH class 1 antiserum, revealed a single band at ~55kDa, equivalent to the molecular weight of the ALDH protein. Immunoblotting of human skin mitochondrial fraction, with ALDH class 2 antiserum, revealed a double band at ~55kDa, while in mouse (both strains), rat and guinea-pig skin, a single ~55kDa band was observed. Immunoblotting of human, mouse (both strains), rat (but not guinea-pig), skin cytosol, using an ALDH class 3 antiserum, revealed a single ~50kDa band. Immunohistochemistry of human skin sections revealed the presence of all three classes of ALDH in the epidermis and, to a lesser degree, in the dermis. In mouse, rat and guinea-pig skin, in addition to epidermal expression, these isozymes were detected in the hair follicles/sebaceous glands,

with the exception of class 3 ALDH which was not detected in guinea-pig skin. In summary, ALDH class 1, 2 and 3 have been detected in human and rodent skin. These enzymes may serve to detoxify reactive aldehydes during percutaneous absorption.

349 FLUOROQUINOLONE ANTIBIOTIC (FQA) TOXICO-KINETICS IN MURINE SKIN AND BLOOD: ANALYTICAL METHODS, SKIN CONCENTRATION AND PHOTO-TOXICITY RELATIONSHIPS.

D B Learn[1], M Netsch[2], J Jersey[2], J Amin[2], R Hills[2], M Coache[2], C P Sambuco[1], and P D Forbes[1]. [1]*Primedica/Argus Research Laboratories, Horsham, PA, USA*; [2]*Primedica/Mason Laboratories, Worcester, MA, USA.*

Certain FQA are acutely phototoxic in experimental animals and man. The degree of phototoxicity induced by these drugs is strongly influenced by the number and location of halogen constituents. However, some variation in phototoxicity could be a function of the kinetics and deposition of these drugs in the skin. We developed successful methods to quantify FQA in murine skin and plasma. Several concentrations of ciprofloxacin, grepafloxacin, levofloxacin, lomefloxacin or ofloxacin dissolved in saline were administered to Crl:SKH1-*hr*BR hairless mice by gavage. Blood and skin samples were taken at various times after administration. Skin samples were homogenized in 0.2 M phosphate buffer, pH 6.2. Skin homogenate and plasma from anti-coagulated blood were extracted with acetonitrile and the extract analyzed by high pressure liquid chromatography using a C18 column and a water:acetonitrile:methanol:triethanolamine pH 3.0 mobile phase. All FQA were found in the plasma and skin at dose and time of dose-appropriate concentrations. The acute phototoxic potential of some of these FQA was determined by exposing mice to solar-simulated radiation, including ultraviolet radiation, 30-60 minutes after gavage dose. Skin changes (erythema, edema, flaking) were assessed for up to 3 days after exposure. "First generation" FQA such as lomefloxacin showed high skin and blood levels and elicited robust skin changes indicative of photo-toxicity. Many of the subsequently developed FQA, e.g., levofloxacin, while showing comparably high levels in the skin and blood, elicited lower or no skin changes indicative of phototoxicity. These results indicate that the phototoxic potential of these FQA appears dependent on the chemical structure of the FQA and not the deposition of the drug in the skin.

350 OCULAR AND DERMAL PHOTOTOXICITY INDUCED BY A SINGLE 8-METHOXYPSORALEN (8-MOP) AND SIMULATED SUNLIGHT EXPOSURE IN ALBINO AND PIGMENTED RATS.

C P Sambuco[2], T E McCullough[1], D B Learn[2], and P D Forbes[2]. [1]*Cerus Corporation, Concord, CA, USA*; [2]*Primedica/Argus Research Laboratories, Horsham, PA, USA.*

The cutaneous phototoxic response to 8-MOP and ultraviolet (UV) radiation in experimental animals is a well-described model for photo-sensitizing drugs. How well such cutaneous phototoxic responses predict adverse effects in ocular tissue has not been established. In this test system we investigated whether the threshold dose for phototoxic damage to the skin and eye was similar and whether constitutive melanin pigmentation influenced the phototoxicity response. Sprague-Dawley (Crl:CD BR VAF/Plus) and Long-Evans (Crl:(LE)BR) rats were anesthetized and the hair clipped from their backs. A 1.3cm^2 skin site was isolated with an exposure mask covering the clipped area. On the Long-Evans rats, both lightly and heavily pigmented skin sites were isolated. One hour after the rats were injected with a single intravenous 10 mg/kg dose of 8-MOP in polyethylene glycol 400, the skin and eyes were exposed to 0.5 to 2.0 MED of solar-simulated radiation (SSR), containing UV, visible, and infrared radiation. Skin responses were assessed 1, 2, and 3 days after exposure, and ocular damage assessed 3 days after exposure. Incidence and severity of skin responses (erythema, edema, flaking) were SSR dose-dependent in both rat strains, with the albino rats showing more severe responses than the pigmented rats. Skin responses were more severe in the lightly pigmented skin than the heavily pigmented skin. Incidence and severity of ocular damage (keratitis, blepharitis, iritis) were also SSR dose-dependent. As compared to the albino rats, the pigmented rats showed fewer kinds and less severe ocular damage. Retinal damage was not found in any rats. The threshold dose for cutaneous responses was lower than the dose for ocular tissue responses. The results, generated by a light source mimicking full spectrum sunlight, demonstrate the capability for generating information on eye safety related to a wide range of potentially phototoxic drugs under various light exposure conditions.

351 PHOTODYNAMIC ACTIVATION OF TOPICAL ATMPn BY UVA OR RED LIGHT IN RABBITS AND MINISWINE.

W Dairman[1], C Sambuco[2], J Wedig[3] and D DeMagistris[4]. [1]*Wallace Dairman Associates, Manahawkin, NJ, USA*; [2]*Primedica/Argus, Horsham, PA,USA*; [3]*Primedica-Redfield, Redfield, AR*; [4]*Glaxo Wellcome Inc., Research Triangle Park, NC, USA.*

ATMPn, a 9-ACETOXY-2,7,12,17- TETRAKIS(METHOXYETHYL) PORPHYCENE, is a photodynamic compound activated by either UVA or red light. It has been preliminarily evaluated in humans as an anti-psoriatic. The effects of a 0.1% ATMPn gel given topically for 5 days followed on day 6 by either fluorescent UVA or red light exposure has been studied for 16 days post-irradiation in the rabbit and Hanford miniswine. In the rabbit robust dermal photodynamic effects occurred with topical administration of 40 ul/cm^2/day followed by irradiation with either light sources (UVA 3-50 J/cm^2, red 6-70 J/cm^2). Post irradiation effects were erythema, edema, flaking, occasional scabbing and ulceration, acanthosis, hyperkeratosis, dermal inflammation and dermal fibrosis. Dermal responses were irradiation dependent with either source but were dose dependent only for UVA. No or minimal responses occurred at skin sites exposed to irradiation alone, ATMPn gel alone, or irradiated vehicle gel sites. Other rabbits were given topically 0.1% ATMPn (1.0 to 60 ul/cm^2 /day) followed by irradiation with 13 J/cm^2 of either UVA or red light. Dose responses to ATMPn were demonstrated. In life post-irradiation dermal responses consisted of erythema, edema, flaking and fissuring. Responses to irradiated sites alone, vehicle treated irradiated sites, or ATMPn treated sites alone were either minimal or non-detectable. In Hanford miniswine 0.1% ATMPn was topically applied for 16 weeks (60 ul/cm^2, 3 x /week, 700 cm^2) 24 hrs preceding 3 X weekly irradiation by either UVA (3, 10, and 50 J/cm^2) or red fluorescent (3, 10, and 70 J/cm^2) light. A very minimal cumulative photodynamic effect occurred consisting of slight increases in erythema and darkening in the irradiated ATMPn sites compared to vehicle treated irradiated sites, vehicle treated non-irradiated sites or ATMPn non-irradiated sites. The difference in degree of dermal photodynamic response between rabbits and miniswine can be explained by a difference in epidermal and dermal penetration of ATMPn following topical administration.

352 NINETY DAY DERMAL TOXICITY STUDY OF 1-(3-CYCLOHEXEN-1-YLCARBONYL)-2-METHYL PIPERIDINE IN RATS.

J T Houpt and H L Snodgrass. *US Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD, USA.* Sponsor: G J Leach.

This study was conducted to determine the dermal toxicity of the candidate insect repellent 1-(3-cyclohexen-1-ylcarbonyl)-2-methyl piperidine, designated by the United States Department of Agriculture as AI3-37220. AI3-37220 (CAS# 77251-47-9) has been proposed for use as a topical insect repellent. Entomological studies showed that AI3-37220 was as effective as N, N-diethyl-m-toluamide (DEET) against most mosquito species and better than DEET for repelling biting flies. The entomological data supports continued development of AI3-37220 as a topical insect repellent. Ninety-five male and 95 female Sprague-Dawley rats 7 to 9 weeks old were used for this study. Dosage levels were set at 0, 63, 125, 250, and 500 mg/kg/day (2 satellite recovery groups at 0 and 500 mk/kg/day were also utilized). Neat AI3-37220 was applied on a five day per week schedule (excluding weekends and holidays) for 92 calendar days and a total of 65 test compound application days. The liquid test substance was applied to the animals clipped backs covering the area with a thin, uniform film. Dermal application of neat AI3-37220 causes dose-dependent skin irritation in rats. The compound was more irritating to the skin of female rats than male rats. The effects were mild and reversible upon cessation of treatment. Subchronic dermal exposure of AI3-37220 for 90 days to male rats was associated with accumulations of hyaline (protein) droplets in the renal tubules and an increase in the regeneration of renal tubular epithelium. This effect is unique to male rats and is not seen in humans. No compound related renal effects were seen in the satellite recovery groups at 140 days indicating the reversibility of these effects. This information, along with results from other laboratory animal toxicity studies, will be utilized to predict the potential risk to human health upon exposure to this compound.

353 ADVERSE RESPONSES TO SEMISYNTHETIC METAL WORKING FLUIDS IN B6C3F1 MICE.

N H Al-Humadi, C Kommineni, A A Shvedova, L Battelli, and V Castranova. *Health Effects Laboratory Division, NIOSH, CDC, Morgantown, WV, USA.*

About 10 million industrial workers of both sexes are exposed to Metal Working Fluids (MWFs) via inhalation or skin or both. Our preliminary results, following dermal application of 200ul of 50 % unused (neat) semi-synthetic MWF (pH 7 or pH 9.7) to the unshaved backs of 6 week old B6C3F1 mice, twice a week for 6 weeks , show significant increase in weights of the liver of both sexes. The present study is to determine if this weight change is related to oxidative stress consequent to MWF exposure. Therefore we exposed 6 month old mice of both sexes to MWFs following the above protocol except that the topical application was with 5% MWFs, 5 days a week for 13 weeks. Chemical analyses of tissues from these mice indicate significant reduction in ascorbic acid and glutathione levels in the liver of both sexes and in the gonads of the male. Malonaldehyde levels in the male liver and gonads show significant increase. The skin histamine levels are significantly increased in the female. These results suggest that MWFs are absorbed through the skin, exhibit liver toxicity, and may represent an important health risk to industrial workers exposed to these fluids.

354 RESTRAINT STRESS DIFFERENTIALLY AFFECTS CYTOKINE PRODUCTION AND EAR SWELLING IN ALLERGIC CONTACT DERMATITIS (ACD) AND IRRITANT CONTACT DERMATITIS (ICD).

M S Flint, D B Miller and S S Tinkle. *National Institute for Occupational Safety and Health, Centers for Disease Control and Prevention, Morgantown, WV, USA.*

Previous studies have demonstrated that glucocorticoids suppress the immune response to antigen and that restraint stress increases serum corticosterone levels. Additional research using rats has shown that mild, acute restraint stress increases ear swelling and lymphocytic infiltration in allergic contact dermatitis (ACD), but not in irritant contact dermatitis (ICD). We hypothesized that mild restraint stress alters the murine cutaneous response to chemicals and that these changes would be reflected in the cytokine profile and be gender-specific. For ACD studies, male and female B6,129 mice were sensitized on the flank with 0.5% DNFB (Days 1 & 2) and challenged with 0.25% DNFB on the ear immediately following mild restraint stress (Day 6). For irritant studies, 5% croton oil was applied to the ear immediately after restraint. We measured ear swelling, cytokines TNF-a, IL-1b, IFN-g and IL-4 and serum corticosterone levels as an indicator of activation of the hypothalamic-pituitary axis. Restraint increased serum corticosterone levels in all mice. In the ICD studies, we measured irritant-induced increases in ear thickness and TNF-a and IL-1b production. Ear thickness and TNF-a levels were not altered by restraint stress, however, the concentration of IL-1b was suppressed at 8 and 24 hours. IFN g and IL-4 were minimally detectable in all treatment conditions. There were no gender differences in the irritant response. For ACD, in both males and females, DNFB induced ear swelling and increased TNF-a, IL-1b and IFN-g. Restraint stress coupled with DNFB treatment resulted in an additional, but transient, increase in ear thickness and, at 24 hours, increased IFN-g but decreased IL-1b. TNF-a was more elevated at 8 and 24 hours in females only, and IL-4 was not detected for any ACD treatment conditions. These data suggest a complex interaction between restraint stress-induced changes in the dermal response to chemicals that may be mediated by elevations in serum glucocorticoids in B6,129 mice.

355 USE OF GREEN FLUORESCENT PROTEIN IN A HUMAN ORGANOTYPIC STRATIFYING SQUAMOUS EPITHELIUM FOR MOLECULAR AND PHARMACOLOGICAL STUDIES OF NORMAL AND MALIGNANT EPITHELIAL GROWTH.

M A Pickart, S J Liliensiek, A Aumock, K N Reagans, P M Harari, and B L Allen-Hoffmann. *University of Wisconsin Medical School, Madison, WI, USA.*

We have developed a novel organotypic *in vitro* model for the study of normal and malignant human squamous epithelial cell proliferation and pharmacological response. This model utilizes expression of green fluorescent protein (GFP) in transfected epithelial cells to identify and isolate cells within an organotypic stratifying squamous epithelium. Prototypic non-malignant and malignant cell lines, BC-1-Ep/SL and SCC13y, respectively, have been developed which stably express GFP. GFP-labeled SCC13y cells (GFP13y) grown in mixed cultures with unlabeled BC-1-Ep/SL cells, do not appear to effect the normal stratification of BC-1-Ep/SL cells in organotypic cultures. Individual and groups of GFP13y cells are visualized in frozen sections using fluorescent microscopy. This report characterizes a number of standard skin differentiation and proliferation markers such as involucrin and PCNA. Data observed in studies using confocal microscopy and flow cytometry are also presented which demonstrate the growth of GFP13y cells over a period of 5-15 days in organotypic culture. This model has potential broad use with all types of stratified epithelia and associated tumors (oral cavity, cervix, trachea, cornea) and melanoma. We believe it is particularly valuable to screen for efficacy of pharmacological agents on normal and malignant epithelia cultured in a context which maintains the cell interactions present in functioning human epithelial tissue. By entirely reconstructing human epithelial cell growth within a tissue-like environment, epithelial cell growth characteristics can be monitored in a physiologically relevant context. Preliminary data characterizing the radiation response and antiproliferative response of a set of standard chemotherapeutic agents are described herein. We believe this approach may provide a more accurate assessment of epithelial cell proliferation kinetics and prove to be a valuable tool for the pharmacologic studies.

356 2,3,7,8-TETRACHLORODIBENZO-P-DIOXIN (TCCD) CAUSES ALTERATIONS IN DIFFERENTIATION OF KERATINOCYTES IN ORGANOTYPIC CULTURE.

J A Loertscher, C A R Ivarie, M A Weitzel, and B L Allen-Hoffmann. *Environmental Toxicology Center and Department of Pathology, University of Wisconsin-Madison, Madison, WI.*

Human exposure to the environmental toxin TCDD produces a severe skin pathology known as chloracne. Although several laboratories have previously reported on the aryl hydrocarbon receptor (AhR)-mediated cellular responses of normal human or rodent keratinocytes to TCDD *in vitro*, little evidence has been available to link these observations to the specific pathology observed in skin. To approximate the three dimensional microenvironment of human skin, we have established organotypic cultures utilizing BC-1-Ep/SL cells, a novel human keratinocyte cell line. The BC-1-Ep/SL cell line was isolated in our laboratory and is identical to normal keratinocytes in its growth and differentiation characteristics. These cells differentiate normally *in vitro* and are morphologically indistinguishable from normal human keratinocytes at both the light and electron microscope level. The BC-1-Ep/SL keratinocytes are immortal and have been shown to be non-tumorogenic in nu/nu mice. Upon treatment of the organotypic model system with TCDD, we have observed an altered morphology as compared to controls. In treated samples we observed a thickening of the granular and cornified superbasal layers of keratinocytes in organotypic cultures. This phenomenon was observed in organotypic culture seeded with normal human keratinocytes and subsequently with BC-1-Ep/SL keratinocytes. We present new data on the differentiation characteristics of TCDD-treated keratinocytes in organotypic culture and examine the effect of TCDD on epithelial-mesenchymal interactions *in vitro*.

357 EFFECT OF CACL2 CONCENTRATION ON THE RATE OF PROLIFERATION OF CULTURED HUMAN KERATINOCYTES.

J Medina, A de Brugerolle de Fraissinette, D Roman, P Ulrich, M Bobadilla and R Ettlin. *Novartis Pharma AG, Basel, Switzerland.*

Topical formulations of drugs may contain $CaCl_2$ and citrate as excipients. In order to analyze the influence of calcium on the epidermal cells' behavior, the effects of $CaCl_2$ on the proliferation and cell cycle distribution of cultured normal human epidermal keratinocytes (NHEK) and HaCaT keratinocytes were investigated. The cells were continuously (24 h) or transiently (1, 2, 4 h) exposed to $CaCl_2$ (0.09, 0.2, 1, 2 and 5 mM), or to combinations of $CaCl_2$ and citrate (5 / 5 mM, and 40 / 40 mM). BrdU incorporation determined by ELISA was used as a marker for cell proliferation. Flow cytometric evaluation of the propidium iodide staining of fixed cells served for cell cycle distribution analysis. $CaCl_2$ induced a concentration-dependent decrease in keratinocyte cell growth with respect to non-treated cells. This effect was more pronounced for NHEK than for HaCaT cells. The combination of $CaCl_2$ and citrate (40 / 40 mM) strongly decreased this parameter in both cell types, and induced cytotoxicity as measured by LDH release. After 24 h treatment, NHEK and HaCaT cells incubated with 40 mM $CaCl_2$ + 40 mM citrate showed changes in the cell cycle distribution (increase in the percentage of cells in G1 phase and decrease in S phase) which were indicative

of a decrease of the proliferation rate. Although changes of the medium osmolarity played a role in these effects, their contribution was only minor. In conclusion, $CaCl_2$ modulates the proliferation rate and the cell cycle distribution of cultured human keratinocytes.

358 BIOTRANSFORMATION AND CYTOTOXICITY OF SULFAMETHOXAZOLE (SMX) AND DAPSONE (DDS) IN NORMAL HUMAN-NEONATAL EPIDERMAL KERATINOCYTES (NHEK).

T P Reilly, P M Woster and C K Svensson. *Department of Pharmaceutical Sciences, Wayne State University, Detroit, MI, USA.*

SMX and DDS are both associated with a high incidence of cutaneous drug reactions (CDR), though SMX causes a significantly greater frequency of adverse effects. Proposed mechanisms for the pathogenesis of these CDR suggest that bioactivation to a hydroxylamine metabolite is a critical initiating step. However, conventional metabolism studies demonstrating the bioactivation of SMX or DDS to systemically available hydroxylamine species have failed to adequately explain how these toxic metabolites may elicit the site-specific reactions observed clinically. Because the skin possesses substantial metabolic capacity, we hypothesized that local bioactivation of SMX and/or DDS by keratinocytes may be a contributing factor in the development of CDR. NHEK suspensions ($7x10^5$/mL) derived from cultures grown in high Ca^{+2} (2mM) media for 48 hr were able to metabolize 1mM SMX and DDS to N-acetyl and hydroxylamine derivatives, albeit at low levels. Greater amounts of N-acetyl-SMX were formed than monoacetyl-DDS (3.6 vs. 2.0 nmoles, respectively, at 12 hr), though hydroxylamine formation was more comparable (0.9 vs. 1.2 nmoles). Metabolite formation occurred in a time- dependent manner from 0.5 to 24 hr. A similar metabolic profile was also observed for SMX using NHEK cultured in low Ca^{+2} (0.15mM) media. Despite this bioactivating capability, however, evaluation of the effect of SMX and DDS (31.3μM-4mM) on NHEK viability failed to demonstrate a significant increase in cell death above controls, even after 24 hr exposure. Comparison of the cytotoxic effects of synthetic hydroxylamines toward NHEK showed that 3 hr exposure to DDS-hydroxylamine caused a concentration-dependent increase in cell death (LC_{50}=281±80μM). In contrast, NHEK demonstrated no increase in cell death when incubated with SMX-hydroxylamine (31.3μM-4mM). Considering the predominance of keratinocytes in normal human skin, local formation and release of hydroxylamine metabolites into the micro-environment of the skin may play a role in the development of CDR. (Supported by NIH Grant AI41395.)

359 COMPARISON OF DERMAL CORROSION VALUES FOR SELECTED INDUSTRIAL CHEMICALS USING CORROSITEX.

[1] L Stobbe[1], K D Drake[1], K J Maier[2]. [1]*Buckman Laboratories International, Memphis, TN, USA;* [2]*University of Memphis, Memphis, TN, USA.*

Skin irritation is the most frequently reported occupational hazard for those employees engaged in the use and transport of industrial chemicals. The rabbit test is most common *in vivo* method used to evaluate dermal irritation and/or corrosion. Several *in vitro* test methods have been developed, with Corrositex® being the first to gain approval by a regulatory agency (DOT). Several classes of industrial chemicals, 24 formulations, were tested using the Corrositex® method and the results were compared to standard animal data for each of the formulations. Based on the results, Corrositex® accurately predicted a corrosive endpoint in 8 of the 24 formulations, when compared to the animal data, and accurately predicted a non-corrosive endpoint for 1 of the 24 formulations. The Corrositex® assay overpredicted a corrosive endpoint for 9 of the 24 formulations, and underpredicted a corrosive endpoint for 6 of the 24 formulations. In addition, corrosive classifications (DOT Packing Groups) were also evaluated. The Corrositex® assay overpredicted the Packing Group classification for 12 of the 24 formulations tested and underpredicted 7 of the 24 formulations tested.

The Corrositex® assay did not adequately predict a corrosive endpoint or Packing Group for the 24 formulations used in this study. This study was a practical application of the Corrositex® method, and the method appears to have failed for predicting the corrosive hazards of the chemical classes included in this study.

360 FURTHER EVALUATION OF THE EPIDERM™ AND EPIOCULAR™ *IN VITRO* IRRITATION MODELS.

S C Nicastro and G S Ladics. *The DuPont Co., Haskell Laboratory for Toxicology and Industrial Medicine, Newark, DE.*

Both EpiDerm™ and EpiOcular™ are commercially available *in vitro* models for assessing the skin and eye irritation potential, respectively, of chemicals. The EpiDerm™ and EpiOcular™ tissue models are organotypic three-dimensional human skin and corneal analogues derived from human epidermal keratinocytes. Both are colorimetric cytotoxicity models based on the ability of chemically exposed tissues to reduce MTT. An MTT effective time-50 (ET-50; time required to decrease cell viability by 50%) is established for each chemical. The objective of this study was to evaluate both EpiDerm™ and EpiOcular™ for their ability to assess the skin and eye irritation potential, respectively, of several water soluble and insoluble compounds previously evaluated *in vivo*. All animal data was obtained from previously published animal studies. No new *in vivo* testing was performed. The following compounds were examined with both EpiDerm™ and EpiOcular™ : benzyl alcohol; dibasic ester; heptyl acetate, propylene carbonate; N-methylpyrrolidone; sodium lignosulfate; sodium alkylnaphthalene sulfonate; polyethoxylated polyarylphenol; polysorbate 85; and sodium dodecylbenzene sulfonate. The following were examined only with EpiDerm™ : 2 and 100% 1-octyl-2-pyrrolidinone and an aromatic hydrocarbon. One or 0.3% Triton X-100 were used as positive controls for EpiDerm™ and EpiOcular™ , respectively. Of the 13 compounds evaluated, EpiDerm™ correctly identified 10 (77% concordance with *in vivo* data). EpiDerm™ overpredicted the remaining 3 compounds. EpiOcular™ correctly identified 7 of the 10 examined compounds (70% concordance with *in vivo* data). The eye irritancy of 2 compounds was underpredicted, while that of the remaining compound was overpredicted. Although these systems have proved useful for evaluating the irritancy potential of water soluble compounds, further evaluation of their ability to predict the skin and eye irritation potential of various classes of water insoluble compounds needs to be conducted.

361 A STRUCTURE-ACTIVITY RELATIONSHIP (SAR) MODEL FOR ESTERS THAT CAUSE HUMAN SKIN IRRITATION.

J S Smith, O T Macina, N B Sussman, and M H Karol. *Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA, USA.*

A structure-activity relationship (SAR) model has been developed to discriminate active from inactive esters on the basis of their ability to cause skin irritation in humans. The model is based on patch test data gathered from a critical review of the literature. Esters were selected from a broader database of human irritants and represented a large subset of homologous chemicals. Nineteen physicochemical parameters that represented transport, steric and electronic properties, were calculated for each chemical. Best subset regression analysis identified models for further analysis. Regression analyses were performed to identify all significant models ($p < 0.05$) that had variables that were also significant ($p < 0.05$). These models were evaluated using linear discriminant analysis to determine if the irritant esters could be discriminated from non-irritant esters. Cross validation was employed to estimate the sensitivity and specificity of the model. The model with the greatest discriminating ability contained the parameters density, Hansen dispersion, Hansen hydrogen bonding, and hydrogen bond donor. The overall sensitivity of the model was 0.85, while the specificity was 0.76. Active irritant esters had lower densities, lower hydrogen bond donor and lower Hansen hydrogen bonding param ters, and higher Hansen dispersion parameter. These characteristics indicate that irritant esters would tend to be less water soluble and less likely to be involved in hydrogen bonding to protein components of the skin. Thus, they are more likely to penetrate the epidermis. Absent from the model are the electronic parameters to indicate a relationship between activity and reactivity. The stability of the model was tested using random subsets of the database. The above parameters were observed with consistency over the random subsets indicating stability with regard to parameters in subsets of the data. The results imply that the model should be predictive for the irritant activity of esters toward human skin. (Supported by NIOSH-CDC #0009653058.)

362 A TWO CENTER STUDY OF THE DEVELOPMENT OF ACUTE IRRITATION RESPONSES TO FATTY ACIDS.

M K Robinson[1], E Whittle[2], and D A Basketter[2]. [1]*Procter & Gamble Co., Cincinnati, OH;* [2]*Unilever, Sharnbrook, Bedford, England.* Sponsor: G F Gerberick.

A human 4 hour patch test has been developed for testing the irritation hazard potential of chemicals. This method was developed for comparative irritation assessments. Although skin irritation responses in human subjects can be quite variable, this acute irritation test method has proven robust in both intra- and inter-laboratory tests. The previous inter-laboratory studies were not optimal in that slightly differing protocols were used and the studies were not controlled for time of year or source of test chemicals. As a result, some variation in acute irritation responses were seen, that might have been reduced somewhat had these variables been controlled to a greater extent. In the present study, two laboratories conducted a direct comparison study of the acute irritation potential of 3 structurally related, concentrated fatty acids (octanoic acid, decanoic acid, and dodecanoic acid) in comparison to a benchmark positive control chemical (20% sodium dodecyl sulfate [SDS]). The studies were run within a 4 month period using the same commercial source of test chemicals. Test subjects were treated with each chemical under occluded patch conditions for gradually increasing exposure time intervals up to 4 hours. The results were then evaluated in terms of total cumulative incidence of positive responses and time response patterns. Using statistical comparisons of cumulative irritation, the rank order of irritation potential was decanoic acid ≥ octanoic acid > SDS >> dodecanoic acid. The statistical comparisons and the time response patterns for each chemical were nearly identical at the two laboratories. There were also very similar, and intriguing, variations in the inter-chemical response patterns seen in the two studies. Hence, when conducted under as controlled a set of test conditions as possible, this acute irritation protocol shows remarkably high consistency across independent test laboratories; further supporting its continued development and acceptance as an alternative skin irritation test method.

363 SKIN IRRITATION POTENTIAL OF N,N'-DI(2-HYDROXY-BENZYL)ETHYLENE-DIAMINE-N,N'-DIACETIC ACID (HBED) IN RATS.

D G Fairchild, K S Cook, J M Brune, and C A Tyson. *SRI International, Menlo Park, CA, USA.*

N,N'-di(2-hydroxybenzyl)ethylenediamine-N,N'-diacetic acid (HBED) is a promising alternative to desferrioxamine for treating Fe overload. HBED releases more Fe from Fe-loaded rats and *Cebus* monkeys at bioequivalent doses via the s.c. route. The irritation potential of the commercially available compound was assessed before proceeding with preclinical toxicity studies. Initially, young adult Sprague Dawley rats (6/sex/group) were administered HBED·HCl at 50 mg/mL in propylene glycol (PG), glycerol, or 40:60 PG:aqueous (pH 7.4) solution as a single injection to the upper back. The same volume of vehicle was applied to each rat at an adjacent site. The sites were scored on Days 3 and 8 after the injections. HBED in either glycerol or aqueous PG was slightly irritating; in pure PG, irritation by the vehicle masked any effects of the test compound. Subsequently, Na salts of HBED were prepared with (+Cl) and without (-Cl) chlorine present and tested in aqueous solution in rats using the same protocol. (+Cl) was slightly irritating whereas (-Cl) was nonirritating. The results indicate that irritation produced by commercially available HBED was due to the HCl component or to NaCl after neutralization and suggest that the chlorine-free Na salt would be better tolerated in patients receiving repeated s.c. doses. (Sponsor: NIDDK Contract No. N01-DK-3-2201.)

364 INHIBITION OF NEUROGENIC INFLAMMATION BY PEPTIDES FROM MONOSTROMA GRAVILLEI.

R Ennamany[1,2], F Richeux[1,2], N Mekidech[3], D Saboureau[1], and E E Creppy[2]. [1]*Palmer Research, Arbanats, France;* [2]*Laboratory of Toxicology and Applied Hygiene, University Victor Segalen Bordeaux, Bordeaux, France;* [3]*SECMA, Marine Biotechnology, Pontrieux, France.*

Monostroma, anti-inflammatory peptides from the algae *Monostroma gravillei*, licenced by Secma Biotechnology shows strong anti-inflammatory properties. According to the characteristic structure of anti-inflammatory peptide agonists : double basic residues Arg-Lys, Lys-Arg, Arg-Arg or Lys-Lys accompanied by hydrophobic residues such as leucine, isoleucine, methionine or valine and since the peptides purified from *Monostroma gravillei* algae showed the NH2 end-sequence as given below – peptide 1 : NH_2-Glu-Ala-Ile-Leu-Asp-Pro-His-Phe-Lys-Lys-Leu-Leu-Ile-Lys- peptide 2 : NH_2-Asp-Ala-Ile-Leu-Asn-Pro-His-Phe-Lys-Lys-Leu-Leu-Ile-Lys, investigations were designed to know whether they compete with SP for binding on NK1 from human primary culture of keratinocytes and/or inhibit the leakage of SP by the dorsal root ganglion neurone (which convoy nociceptive stimuli). These peptides display a mitogenic activity as shown by the increased incorporation of tritiated thymidine in the DNA of human keratinocytes in culture by 24, 48 and 32% for respectively 2, 4 and 10μg/ml as compared to the control. The Monostroma inhibits the binding of substance P on NK1 receptors by 55, 67 and 58% for respectively 2, 4 and 10 μg/ml and reduces the substance P release by 15 and 31% for respectively 2 and 4 μg/ml as compared to the control in dorsal root ganglia.

365 LOCALIZATION OF EPIDERMAL-DERMAL JUNCTION EPITOPES IN THE MOUSE EAR VESICANT MODEL EXPOSED TO BIS (2-CHLOROETHYL) SULFIDE.

N A Monteiro-Riviere[1], A O Inman[1], M C Babin[2], and R P Casillas[2]. [1]*Cutaneous Pharmacology and Toxicology Center, North Carolina State University, Raleigh, NC, USA;* [2]*US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD, USA.*

Bis (2-chloroethyl) sulfide (sulfur mustard, HD), a potent cutaneous vesicant and bifunctional alkylating agent, produces significant time-dependent histopathologic changes in the mouse ear vesicant model (MEVM). The right ear of male CD1 mice were exposed topically to 5.0μ l of 195mM (0.16mg) HD in dichloromethane while the left ear control was dosed with 5.0μ l of dichloromethane. The ears of all mice were harvested after 6, 12, 18, and 24 hrs. Indirect immunofluorescence (IF) revealed the frequency of microvesicles in the HD-exposed ear at 6 hrs (2/8), 12 hrs (6/8), 18 hrs (7/8), and 24 hrs (6/6). In all controls and HD-treated mouse skin, IF of the epidermal-dermal junction (EDJ) stained moderately with bullous pemphigoid (BP), epidermolysis bullosa acquisita (EBA), and laminin (Lam) antibodies, and stained lightly with bullous pemphigoid 180 (BP180), fibronectin (Fn), and type IV collagen (Coll IV). Mouse anti-human monoclonal antibodies for GB3, L3d, and 19-DEJ-1 (Uncein) did not cross-react in mouse skin. Within the microvesicles, BP, BP180, and Fn exhibited focal areas of light epidermal staining and homogeneous dermal staining, while EBA, Lam, and Coll IV showed moderate dermal staining. BP and Fn staining was weaker but more inconsistent with time. Immunoelectron microscopy studies revealed similar results, with an increase in tissue damage from 6 to 24 hrs which corresponded to a decrease in antibody staining intensity. These results indicate that in the MEVM, HD causes separation in a *'zone'* between the uppermost lamina lucida and the basal cell plasma membrane/ hemidesmosome complex. While the MEVM differs significantly from other models in which the split occurs within the lamina lucida, it is still a valuable tool in the development of specific prophylactic and therapeutic strategies. (Supported by USAMRMC DAA H04-96-0086.)

366 DETECTION OF PROLIFERATING CELL NUCLEAR ANTIGEN IN THE MOUSE EAR VESICANT MODEL FOLLOWING EXPOSURE TO BIS (2-CHLOROETHYL) SULFIDE.

A O Inman[1], N A Monteiro-Riviere[1], M C Babin[2], and R P Casillas[2]. [1]*Cutaneous Pharmacology and Toxicology Center, North Carolina State University, Raleigh, NC, USA;* [2]*US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD, USA.*

Microvesicles were induced in the mouse ear vesicant model (MEVM) in response to bis (2-chloroethyl) sulfide (sulfur mustard, HD), which produces significant time-dependent histopathologic changes. The right ear of male CD1 mice were topically exposed to 5.0μ l of 195mM (0.16mg) HD in dichloromethane while the left ear was dosed with 5.0μ l of the vehicle dichloromethane (control). Tissue was harvested at 6, 12, 18, and 24 hrs post-dose. Immunohistochemical staining of the tissue fixed in 10% neutral buffered formalin and embedded in paraffin allowed quantification of the proliferating cell nuclear antigen (PCNA), a nuclear marker for cell proliferation. While the growth fraction (GF = PCNA stained cells per unit length / total number of cells per unit length) showed no significant differences ($P<0.05$) between exposure times, several interesting trends were apparent. The GF of the vehicle control ears (inner and outer surfaces, respectively) were marginally lower than the corresponding HD-treated ears (inner and outer surfaces, respectively) at 6 and 12 hrs and marginally higher at 18 and

24 hrs. Also, the inner ear (applied vehicle and HD) GF was slightly lower than the GF of the corresponding outer ear. Overall, the GF in the HD-treated ears was the greatest at 6 hrs, with a slight downward trend from 12 to 24 hrs.

367 SYSTEMIC ADMINISTRATION OF CANDIDATE ANTIVESICANTS TO PROTECT AGAINST TOPICALLY APPLIED SULFUR MUSTARD IN THE MOUSE EAR VESICANT MODEL (MEVM).

M C Babin[1], K Ricketts[1], J P Skvorak[1], M Gazaway[1], L W Mitcheltree[2], and R P Casillas[1]. [1]*Drug Assessment and* [2]*Comparative Medicine Divisions, United States Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.* Sponsor: J A Romano.

The MEVM provides a quantitative edema response as well as histopathological and biochemical endpoints as measurements of inflammation and tissue damage following exposure to the chemical warfare agent sulfur mustard (HD). In the MEVM, several topically applied anti-inflammatory agents provided a significant degree of protection against HD-induced edema and dermal-epidermal separation. This study evaluated the protective effects of these same pharmacologic compounds when administered systemically in the MEVM. Alzet osmotic pumps were used to deliver a subcutaneous dose of the appropriate anti-inflammatory agent starting 24 h before exposure to sulfur mustard and continuing until 24 h post-exposure to HD. Twenty-four hours after pump implantation, 5 µl of a 195 mM (0.16 mg) solution of sulfur mustard (d=1.27 g/ml; MW 159; purity 97.5%) in methylene chloride was applied to the inner surface of the right ear of each mouse. HD injury in the mouse ear was measured by both edema response (fluid accumulation) and histopathological damage (necrosis, epidermal-dermal separation). The systemic administration of hydrocortisone, indomethacin and olvanil provided a significant reduction in edema (24%, 26% and 22%, respectively) from positive control. Hydrocortisone, indomethacin and olvanil also caused a reduction in subepidermal blisters compared with the HD positive control (71%, 52% and 57%, respectively). We show here that these anti-inflammatory drugs are effective when administered systemically in the MEVM.

368 COMPARISON OF SPECTROPHOTOMETRIC AND FLUOROMETRIC ASSAYS OF PROTEOLYSIS IN CULTURED HUMAN CELLS EXPOSED TO SULFUR MUSTARD.

W J Smith, S A Kelly, C Corun, M Nelson, and C L Gross. *Drug Assessment and Pharmacology Divisions, United States Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.* Sponsor: T M Shih.

Histopathologic evaluation of sulfur mustard (HD) vesication suggests an involvement of proteolysis in the pathogenesis of the epidermal-dermal separation. Drug screening of candidate therapeutic compounds as medical countermeasures to vesicant agents requires the use of sensitive, reproducible assays of known biomarkers of the HD injury. Commercial protease substrates with either chromogenic or fluorogenic properties have been used to assess proteolytic activity in human PBL and HEK exposed *in vitro* to HD. In the spectrophotometric assays, PBL demonstrated significant increases in proteolysis as measured with the Chromozym TH and TRY serine protease substrates. This activity is donor specific in that 5 out of 11 donors showed marked reproducible activity. HEK presented a very different pattern of response with negligible TH or TRY activities but marked urokinase increases. Using fluorescent substrates that identify different proteases than the chromogenic substrates, PBL demonstrated a general decline in all aminopeptidase activities tested. However, in HEK, considerable variabilities were detected that might be related to culture and handling conditions. When HEK were trypsinized into cell suspensions and analyzed by flow cytometry, no changes in aminopeptidase activities were detected following HD. When the HEK were grown in 24-well plates and assayed *in situ*, certain aminopeptidase activities (K aminopeptidase B and G aminopeptidase) were increased while others (L aminopeptidase) were decreased. Assays of HD increased proteolysis in PBL with serine protease substrates are reproducible within a given donor population and can be used for screening candidate compounds. Proteolytic assessment in HEK is variable and subject to culturing and handling procedures and will require a considerable amount of research before it can be used in screening compounds.

369 PROTEIN PHOSPHATASE 2A IDENTIFIED AS THE CYTOSOLIC ENZYME INHIBITED BY THIODIGLYCOL, THE HYDROLYSIS PRODUCT OF SULFUR MUSTARD.

A A Brimfield. *U S Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD, USA.*

Sulfur mustard (2,2'-dichlorodiethyl sulfide) is a potent vesicant used in chemical warfare. Injury to exposed epithelial tissue is delayed and ranges from erythema to massive fluid-filled blisters and necrosis in a dose dependent manner. The mechanism is unknown. However, the chemical warfare agent Lewisite and the natural vesicant cantharidin have been shown to inhibit protein (serine/threonine) phosphatase 2A (PP2A) *in vitro*. We reported several years ago that sulfur mustard inhibited enzymatic non-alkaline phosphatase related *p*-nitrophenyl phosphate hydrolysis in mouse liver cytosol, activity usually attributed to protein (serine/ threonine) phosphatases (Brimfield (1995) Toxicol. Lett. 78, 43-48). At that time we showed that the actual inhibitor was thiodiglycol (TDG), the hydrolysis product of sulfur mustard, rather than sulfur mustard itself. The IC_{50} in cytosol was 100 µM. We report here that thiodiglycol inhibits the activity of purified PP2A from human red blood cells. The methodology employed was the real time spectrophotometric measurement of *p*-nitrophenol formation by following the increase in optical density at 405 nm and 30° C. Samples contained 1.3 mg/mL *p*-nitrophenyl phosphate in 40 mM Tris buffer, pH 8.1 containing 1 mM $MgCl_2$, 1% bovine serum albumin, enzyme and various quantities of TDG. Reactions were started by the addition of PP2A in 20 mM MOPS buffer, pH 7.5 in a quantity to bring the final activity to 1.0 unit per assay. Final volume was 3.0 mL. The IC_{50}, in this initial work, was approximately 1.0 mM. This is a higher value than we observed in the cytosol and suggests that additional metabolism occurred in the cytosol to produce the ultimate inhibitor. PP2A is a target for cantharidin and Lewisite, and is the probable source for the enzymatic *p*-nitrophenyl phosphate phosphatase activity we found in mouse liver cytosol in our earlier work. PP2A inhibition by TDG provides an indication that Lewisite, cantharidin and sulfur mustard work by a common mechanism.

370 CHARACTERIZATION OF NERVE AGENT PENETRATION THROUGH PORCINE AND HUMAN SKIN AND THE EFFICACY OF A FIELDED DECONTAMINANT.

T H Snider[1], J D Waugh[1], and J P Skvorak[2]. [1]*Battelle Memorial Institute, Columbus, OH;* [2]*US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.* Sponsor: C T Olson.

The chemical warfare nerve agents, pinacolyl methylphosphonofluoridate (GD) and O-ethyl S-2-diisopropylaminoethylmethylphosphonothiolate (VX), are potent cholinesterase inhibitors that are rapidly absorbed through skin. Studies were performed using dermatomed skin in an *in vitro* skin penetration model, the RCR Low-Flow Cell, to determine (1) the effect of -70 C cryopreservation on the penetration rates of GD and VX through porcine skin, (2) the relative penetration rates of GD and VX through cryopreserved human skin, and (3) the decontamination efficacy of the powder fielded in the U.S. Army M291 decontamination pack against GD and VX applied onto cryopreserved human skin. The two endpoints used to assess agent skin penetration were (1) the time period between agent application and significant inhibition of acetylcholinesterase (AChE) added to the receptor fluid, and (2) gas chromatographic assay for agent extracted from the receptor fluid. Cryopreservation of porcine skin slightly but significantly slowed GD but not VX penetration. There was no significant difference between the mean times of human skin penetration, as measured by AChE inhibition, of GD (9.3 min) and VX (13.9 min). The M291 powder significantly reduced the amount of both agents that penetrated cryopreserved human skin. (Supported by USAMRDC Contract DAMD17-89-C-9050.)

371 COMPARING OCCUPATIONAL AND ENVIRONMENTAL RISK ASSESSMENT METHODOLOGIES USING PHARMACOKINETIC MODELING.

L M Sweeney. *Concurrent Technologies Corporation, Johnstown, PA, USA.*

Human health risks from occupational exposures are managed by limiting exposures to acceptable levels established by the American Conference of Governmental Industrial Hygienists or another similar body. Acceptable environmental exposures are benchmarked by values such as U.S. Environmental Protection Agency Reference Doses and Reference Concentrations. The approaches to establishing these values are different, as are the groups they are intended to protect, complicating direct comparisons.

In this evaluation, physiologically based pharmacokinetic modeling was used to predict tissue doses from acceptable/safe exposures as established by different organizations and agencies. Internal doses calculated for an agency's acceptable/safe exposures via oral and inhalation routes may differ substantially, but are sometimes in excellent agreement. Based on the 14 compounds modeled in this effort, acceptable occupational exposures almost always produce greater internal doses than acceptable environmental exposures. This finding suggests different mindsets among these groups regarding how safe is "safe." (This work was supported by Contract No. DAAA21-93-C-0046 (Task No. N.113, Subtask R1-4) to the National Defense Center for Environmental Excellence, operated by Concurrent Technologies Corporation.)

372 COMPARISON OF ACUTE INHALATION EXPOSURE LEVELS FOR CHEMICAL IRRITANTS AMONG FIVE AGENCIES IN THE UNITED STATES.

A K Madl, R M Kalmes, and D J Paustenbach. *ChemRisk, McLaren-Hart Inc., Alameda, CA, USA.*

Acute inhalation exposure limits have recently been developed by various agencies to protect the community. Many of the chemicals for which limits have been set are sensory irritants. In general, these limits have been established to give guidance regarding the need to evacuate following accidental releases. The purpose of this paper was to compare the various scientific approaches used to set these limits. Proposed one-hour exposure limits intended to prevent sensory irritation for the chemicals formaldehyde, xylene, toluene, methyl ethyl ketone and hydrogen sulfide were evaluated. Comparisons between the AIHA Emergency Response Planning Guideline (ERPG), EPA Acute Reference Exposure (ARE), Minnesota Health Risk Value (HRV), New York Air Guide-1 (AG-1), and California Acute Reference Exposure Level (REL) were made. A set of recommended criteria for calculating alternative one-hour exposure limits for these chemicals was developed. These criteria included the use of specific toxic endpoint selection, correction for short-term experimental exposure duration, and a recommendation to build a dose-response curve based on the a collection of the best published sources. Our analysis indicated that there was significant variability between short-term ambient air exposure limits developed by the five different agencies and that these were often different from our recommended values. The selection of the most sensitive adverse effect, the application of default uncertainty factors and the identification of a NOEL from a single study rather than a "blended" NOEL based on the weight of evidence accounted for the differences among the agencies. Disparities in the methodologies used to establish exposure limits will likely be resolved as more experience is accumulated.

373 VALIDATION STUDY OF AN OCCUPATIONAL EXPOSURE BAND (OEB) CLASSIFICATION SYSTEM.

C S Schwartz[1] and K A Traul[2]. [1]*Pfizer Inc, New York, NY, USA;* [2]*Ingle & Traul Pharmaceutical Consulting, Inc., Princeton, NJ, USA.*

The purpose of an OEB Classification / Handling Guideline System is to provide an exposure control and containment strategy for handling substances when the available data are insufficient to establish a numerical Occupational Exposure Limit (OEL). In such a system, substances are assigned to one of several bands (OEBs) based upon the substance's presumed hazard and/or whatever limited toxicological and hazard data may be available at the time the classification is made. For each OEB there is then a general containment philosophy, a Handling Guideline (HG), specific for differing scales of operations. The HG identifies engineering controls, personal protective equipment, administrative controls, waste disposal methods, and decontamination practices generically appropriate for limiting exposure to materials with the designated level of hazard. In order to validate the OEB Classification Scheme used by Pfizer, we examined certain information contained in 29 drug substance OEL monographs approved by the corporation's Technical Review Committee (TRC) and, independent of the TRC's OEL, cast each compound into one of the 5 OEBs described by the Classification Scheme. The data considered for the banding exercise were limited to those generally available early in product development, and consisted of: clinical potency, acute toxicity, irritation / corrosion, sensitization, mutagenicity, and ≤ 30-day repeat-dose toxicity. In 27 of 29 instances, the OEB Criteria caused the compound to be classified at the same or a more conservative Band than that called for by the OEL. Indeed, in 12 of the 27 "correct" cases, the OEB and the OEL were in concurrence. In the 2 cases of non-concurrence, the cause of the failure was judged to be rounding error inherent in the OEL setting process. Based upon the high level of concordance and low failure rate in this study, the Pfizer OEB Classification Criteria have been successfully validated and adopted for corporate application worldwide.

374 DETERMINATION OF ACCEPTABLE EXPOSURE LIMITS FOR THE ANTI-VIRAL AGENT RIBAVIRIN.

J Gandy[1,2], S W Williams[2], R Hill[3], and P T Goad[2]. [1]*Univ. Ark. Med. Sciences, Little Rock, AR, USA;* [2]*Center for Toxicology and Environmental Health, Little Rock, AR, USA;* [3]*Hill Research Associates, Inc., Los Gatos, CA, USA.*

Ribavirin is a potent and broad spectrum antiviral agent commonly given in aerosol form to treat respiratory syncytial virus infections in children. Oral administration of ribavirin has been tested for teratogenicity in rats, mice, rabbits and baboons. The most susceptible test species for reproductive effects was the rabbit, with a no observable adverse effect level (NOAEL) of 1 mg/kg/day (Huntington Laboratories). Even though no adverse health effects have been reported in patients treated with ribavirin, potential fetal toxicity is a major concern among occupationally exposed health care professionals, since many of these workers are women of child-bearing age. Previous approaches to calculating a permissible exposure limit (EL) in humans were based on pharmacokinetic studies reporting an oral bioavailability of about 45%. However, a recent human study provides more relevant bioavailability data for inhalation exposures received by medical personnel. In this study, we used this recent human data that demonstrates that ribavirin bioavailability following inhalation exposure is only 0.5% of the total inhaled dose (Linn et al., 1995). We then used this human bioavailability data together with plasma and red blood cell (RBC) concentrations of ribavirin in pregnant rabbits administered a NOAEL dose of ribavirin during organogenesis. The rabbit teratology study showed that plasma and RBC ribavirin levels at the NOAEL are 2.4 and 23.6 μmol/l, respectively. An upper limit of an inhaled dose for occupational exposure was then derived using a 100-fold uncertainty factor applied to blood ribavirin levels at the rabbit NOAEL. Assuming an average female worker of 60 kg, a ventilation rate of 25 l/min, and continuous exposure during an 8-hr shift, the calculated 8-hr EL for inhalation of ribavirin was 7.4 mg/m^3.

375 THE CONCENTRATION-EXPOSURE DURATION RELATIONSHIP FOR INHALED TOXICANTS.

K A Davidson, S S Talmage, C B Bast, C S Forsyth, S Milanez, C M Troxel, and R A Young. *Toxicology and Risk Analysis Section, Life Science Division, Oak Ridge National Laboratory, Oak Ridge, TN, USA.*

When desired exposure-duration data are lacking for an assessment of acute inhalation toxicants, scaling across time may be based on the relationship between exposure concentration and exposure duration for a specific response such as lethality (LC_{50}). A log-log regression analysis similar to the probit analysis described by ten Berge et al. (1986, J. Hazard. Mat. 13:301-309) was used to extrapolate concentration-response data across different exposure times. The regression analysis by ten Berge et al. resulted in the following equation: $C^n \times t = k$, where C= concentration, t = exposure time, k = a constant, and the exponent n is = b_1/b_2 (probit regression coefficients) or the negative reciprocal of the slope of the log-log regression analysis. Data sets were evaluated for 40 different inhalation toxicants including respiratory tract irritants such as ammonia and hydrogen fluoride, systemic toxicants such as hydrogen cyanide, and combined respiratory tract irritant and systemic toxicants such as ethylene oxide. All data sets were not sufficient to conduct a regression analysis. The results showed that n fell between 0.8 and 2.5 for almost all data sets. This evaluation suggests that a default n between 1.5 and 1.7 (mid point) may be a good estimate for chemicals with insufficient data. Evaluation of these data sets also suggests that n may be based on data for a breakdown product (HCl for chloromethylsilanes) or a structurally/mechanistically similar chemical (ethylenimine for propylenimine) for chemicals with insufficient data.

376 RE-EVALUATING CANCER RISK ESTIMATES FOR SHORT-TERM EXPOSURE SCENARIOS.

N C Halmes[1], J K Tolson[1], C J Portier[2], and S M Roberts[1]. [1]*Center for Environmental and Human Toxicology, University of Florida, Gainesville, FL;* [2]*National Institute for Environmental Health Sciences, Research Triangle Park, NC.*

Cancer risk estimates have traditionally been calculated with the assumption that excess cancer risk is directly proportional to the cumulative carcinogen dose. For exposure to a carcinogen at a given rate, this means that the excess cancer risk is a linear function of exposure duration (e.g., exposure for 7 years is assumed to carry one-tenth the cancer risk of exposure for 70 years). The validity of this assumption was tested empirically using data from chronic lifetime and stop-exposure studies of carcinogens conducted by the National Toxicology Program. Seven compounds were identified as having data sufficient for comparison of relative cancer potencies from short-term versus lifetime exposure. In every case, the tumor incidence was higher in the stop-exposure group than the corresponding cumulatively dosed, lifetime exposure group. For both the chronic and stop-exposure studies, the data were modeled and the maximum likelihood estimates of the dose corresponding to a 10% added cancer risk (ED_{10}), as well as 95% lower confidence limits (LED_{10}), were calculated. These comparisons suggest that linear reductions in cancer risk for less-than-lifetime exposures in risk assessments may underestimate risks of short-term exposures to carcinogens.

377 USE OF LETHALITY DATA DURING CATEGORICAL REGRESSION MODELING OF ACUTE REFERENCE EXPOSURES.

J A Strickland. *National Center for Environmental Assessment, U.S. Environmental Protection Agency, Research Triangle Park, NC, USA.* Sponsor: M W Stevens.

Categorical regression is being considered by the U.S. EPA as an additional tool for derivation of acute reference exposures (AREs) to be used for human health risk assessment for exposure to inhaled chemicals. Categorical regression is used to calculate probability-response functions for health effect data which has been classified into ordered severity categories such as no-observed-adverse-effect level (NOAEL), adverse effect level (AEL) and lethal effect level (FEL). The categorical regression model calculates the exposure concentrations and durations at which there is a 10% probability of adverse effects, the EC-T10, which can be used to derive AREs. Concerned that the use of lethality data would not be conservative, peer reviewers of the categorical regression approach recommended excluding lethality data from EC-T10 calculations. To determine the effect of removing lethality data, data sets for the acute toxicity of perchloroethylene, methyl isocyanate, phosgene, trichloroethylene, hydrogen sulfide and ethylene oxide were analyzed with and without lethality data. The effect of excluding lethality data seemed to be related to the amount of lethality data in the database. EC-T10s for databases with the largest amounts of lethality data were increased when lethality data was excluded, while EC-T10s for databases with the smallest amounts of lethality data were decreased. To confirm this observation, analyses were performed on hypothetical data sets with various amounts of lethality data. Calculations with hypothetical data sets did not confirm the observation on actual data sets; addition or removal of lethality data did not change the EC-T10. This study showed that the percentage of lethality data in a data set does not determine how the inclusion or exclusion of lethality data affects the ECT-10. Further investigations may examine the location of lethality points at low vs high concentrations and durations; and the intermingling of NOAEL, AEL and FEL data.

378 TOXIC EQUIVALENCY (TEQ) OF POLYCHLORINATED DIBENZO-*P*-DIOXINS (PCDDS) IN AN OVULATION MODEL: VALIDATION OF THE TEQ CONCEPT FOR ENDOCRINE DISRUPTION.

X Gao[1], D-S Son[2,3], P F Terranova[2,3,4], and K K Rozman[1,5]. [1]*Department of Pharmacology, Toxicology & Therapeutics;* [2]*Center for Reproductive Sciences;* [3]*Department of Molecular & Integrative Physiology;* [4]*Department of Obstetrics & Gynecology, University of Kansas Medical Center, Kansas City, KS;* [5]*Section of Environmental Toxicology; GSF-Institut für Toxikologie, Neuherberg, Germany.*

Polychlorinated dibenzo-*p*-dioxins (PCDDs) are structural analogues, which produce a similar spectrum of biological and toxicological responses in animals, albeit with differential potencies. The gonadotropin-primed immature female rat model was used to study the effect of PCDDs on ovulation. Single doses of different PCDDs and their mixtures were given orally to 23-day-old rats. Gonadotropin from Pregnant Mare's Serum (PMSG) was injected (5 IU) 24 hr later to induce follicular maturation. Rats were decapitated at various times after PMSG, blood collected and ovarian weight measured. Serum concentrations of 17ß-estradiol (E_2), progesterone (P_4), luteinizing hormone (LH) and follicle stimulating hormone (FSH) were determined by radioimmunoassay. Ovulation was measured 72 hr after injection of PMSG by counting ova flushed from oviducts. PCDDs dose-dependently decreased the number of ova shed and reduced ovarian weight gain induced by PMSG. The slopes of the dose responses generated by individual PCDDs and/or their mixture were similar. PMSG-induced increase in serum E_2 was dose-dependently enhanced by PCDDs on the day of expected ovulation; in contrast, serum P_4 and FSH were dose-dependently decreased at that same time point. PCDDs also altered the temporal pattern of serum FSH and LH. The results indicate that all PCDDs have the same mode of action on ovulation and related reproductive hormone systems. Furthermore, parallel dose responses for the individual congeners as well as for their equipotent mixture represent a validation of the TEF concept for endocrine disruption by PCDDs.

379 ESTIMATING RISK FROM EXPOSURE-RESPONSE RELATIONSHIPS BASED ON CONTINUOUS VARIABLES.

P R McClure, M Odin and W M Stiteler. *Syracuse Research Corp., North Syracuse, NY, USA.* Sponsor: G Diamond.

Health risk from a chemical hazard is typically expressed as the probability that an individual at a specified exposure level will have an adverse response. This formulation readily accommodates quantal exposure-response data (e.g., tumor incidence), where an individual is either a responder (has tumor) or not a responder (does not have tumor), and where the exposure-response relationship attained from the data provides a direct measure of risk. With continuous data (e.g., blood pressure), however, the exposure-response relationship is not directly translatable to risk. In this case, estimation of risk requires designation of what constitutes a responder by defining a response criterion. A response criterion can relate to clinically or empirically established critical levels (e.g., diastolic blood pressure greater than 90 mm Hg or a 20% decrease in nerve conduction velocity), or a statistical difference from the mean response in an unexposed population (e.g., 3 standard deviations from the control mean). Alternatively, the proportion of responders in an exposed population can be predicted without specifying a critical level (either in terms of the response variable or the proportion of controls considered to be responders) by estimating the probability density function for the control and exposed groups, ascertaining the point(s) of intersection, and taking the difference of the area under the curves. Case studies on carbon disulfide illustrate these techniques for estimating risk from continuous data and comparing the resulting risk estimates. It is concluded that each of these methods can successfully be used to estimate risk from continuous data and that characteristics of the specific data set determine which method provides the most meaningful risk estimate in a given situation.

380 ALUMINUM: AN ASSESSMENT OF ITS POSSIBLE ASSOCIATION WITH THE DEVELOPMENT OF ALZHEIMER'S DISEASE.

A B Kerr, R J Rose, J M Daniels and E R Nestmann. *CanTox Inc., Mississauga, ON, Canada.*

Alzheimer's Disease (AD) affects the central nervous system and is the most common cause of age-related intellectual decline. The current lack of effective treatments for AD is partly due to a poor understanding of its etiology, although this appears to be multi-factorial. Endogenous factors that may be associated with the development of AD include genetic predisposition, abnormalities in neurological proteins, biochemical changes associated with oxidative stress, poor circulation, anaemia, and autoimmune disorders. External factors may also cause or promote AD, including viral infection, metal exposure or head trauma. Considerable effort has been directed towards elucidating a possible role for aluminum in AD. The totality of data do not refute a link between aluminum and AD, but it is more likely that aluminum accumulates in the brain as a result of more fundamental causes and may facilitate the neurological changes which characterize the manifestation of AD. The possible relationship between aluminum and AD has been studied using animal models and post-mortem examination of humans. Recent investigations have included the histological evaluation of aluminum-

induced neurotoxicity, mapping of aluminum accumulation in different regions of the brain and in AD-associated brain lesions, epidemiological studies of aluminum ingestion through drinking water, the effect of chelating metal ions on the progression of AD, and *in vitro* studies of lesion development. Our investigations found that, although aluminum may cause neuropathic changes, the changes were not consistent with the changes found in AD patients. Even the possibility that aluminum may have a secondary role in AD development is debatable, since aluminum is not always found in brain lesions of some AD patients. Strong reservations about inferring causality from correlative data are warranted, and other causes or mechanisms for this disease must be investigated.

381 PROPOSED NEW RISK ASSESSMENT FOR BORON.

C Smallwood[1] and M Odin[2]. [1]*National Center for Environmental Assessment, US EPA, Cincinnati, OH;* [2]*Syracuse Research Corp., North Syracuse, NY.* Sponsor: H Choudhury.

EPA is in the process of developing a new risk assessment for boron. Animal studies conducted using boric acid by oral exposure identified developmental toxicity as the critical effect. Studies in dogs and rodents reporting testicular effects were at higher doses or had limitations. Developmental effects occurred in rats, mice and rabbits and included high prenatal mortality (highest doses), reduced fetal body weight (lowest doses), and malformations and variations of the eyes, central nervous system, cardiovascular system and axial skeleton (intermediate doses). The RfD (Oral Reference Dose) is based on a published benchmark dose of 10.3 mg B/kg-day for reduced fetal body weight in rats. An uncertainty factor (UF) of 30 (3 for interspecies extrapolation and 10 to protect sensitive individuals) was applied to derive an RfD of 3E-1 mg B/kg-day. The UF of 3 for interspecies extrapolation was considered adequate because boric acid is not metabolized (differences in metabolism being a major contributor to interspecies differences in toxicity) and absorption, distribution and excretion are similar in rats and humans. Based on the RfD, an exposure dose of 21 mg B/day for a 70 kg person can be calculated. Most exposure to boron comes from diet and drinking water. The value of 21 mg B/day is greater than typical dietary exposure (0.5-3.1 mg B/day) and the estimated basal requirement (0.25 mg B/day) for this suspected essential element. Data were not adequate to derive an RfC (Inhalation Reference Concentration) for boron. Under EPA's 1986 guidelines for carcinogen risk assessment, boron is classified as Group D. Under the proposed 1996 guidelines, the data are considered to be inadequate. (This abstract does not necessarily reflect U.S. EPA policy.)

382 THE DEVELOPMENT OF THE CADMIUM DIETARY EXPOSURE MODEL (CDEM).

T F Lockwood[1,2], G L Diamond[1], H C Choudhury[3], J M Hassett[2], P E Goodrum[1] and W M Stiteler[1]. [1]*Syracuse Research Corporation, North Syracuse, NY, USA;* [2]*State University of New York College of Environmental Science and Forestry, Syracuse, NY, USA;* [3]*National Center for Environmental Assessment, U.S. EPA, Cincinnati, OH, USA.*

In most human populations, diet is a major source of cadmium exposure. Since dietary intake of cadmium plays a major role in total exposure, risk associated with cadmium due to other environmental pathways can not be evaluated without quantification of the diet pathway. This presentation describes a newly developed Cadmium Dietary Exposure Model (CDEM) for estimating dietary cadmium exposure in humans. The methodology utilizes national survey data on food cadmium concentrations contained in the U.S. Food and Drug Administration Total Diet Studies (FDA TDS, 1982-1994), and food consumption patterns, derived from the Third National Health and Nutrition Examination Survey (NHANES III, 1988-1994), to estimate demographically stratified dietary intakes in the U.S. population. The CDEM predicts a central tendency estimate (CTE) of daily cadmium intake for the U.S. population of 21 μ g/day, which is consistent with estimates derived from other approaches. The CDEM has been used to construct frequency distributions for cadmium intakes, from which probability density functions can be derived for use in risk assessment. (Supported in part by U.S. EPA Cooperative Agreement CR822761-01. Methodology and conclusions do not necessarily reflect the opinions or policies of U.S. EPA.)

383 DEVELOPMENT OF COPPER TOXICITY VALUES FOR HUMAN HEALTH RISK ASSESSMENT.

B D Beck, H E Daly and T M Slayton. *Gradient Corporation, Cambridge, MA, USA.*

Currently USEPA does not provide reference values for copper toxicity *via* oral or inhalation routes of exposure on their Integrated Risk Information System (IRIS). While toxicity values for occupational exposure have been established, their applicability to residential populations is uncertain. USEPA does recommend an oral reference dose (RfD) of 1.3 mg/L in their Health Effects Assessment Summary Tables, based on the national drinking water standard (MCLG). Therefore, we performed a comprehensive review of the available toxicity literature and derived toxicity values (TVs) for both ingestion and inhalation exposure to copper. For copper ingestion, the most sensitive health endpoint is acute irritation of the gastrointestinal lining. Copper is unusual in this regard; for most compounds, chronic health endpoints are more sensitive than acute health endpoints. Although many of the available studies poorly quantified actual exposure levels, concentrations of 4 mg/L seem to consistently represent the lowest effect level for gastrointestinal effects. Application of default drinking water consumption rate and body weight conversion factors, as well as an uncertainty factor (UF) of 3 yields a TV of 0.04 mg/kg-day, consistent with the daily dose at the MCLG. Application of additional UFs would lower this value below the recommended "safe and adequate" nutritional level, and thus not be appropriate. For inhalation of copper, the most sensitive health endpoint is metal fume fever, which has been observed in workers exposed to 1.4 mg/m^3 copper dust. We converted this Lowest Observed Adverse Effect Level (LOAEL) to a mg/kg-day dose by applying body weight, inhalation rate, and exposure time conversion factors. We then divided this dose by appropriate uncertainty factors (UFs) to derive a TV of 0.0044 mg/kg-day for copper inhalation.

384 USE OF MERCURY VAPOR FLUX MEASUREMENTS FOR REDUCING UNCERTIANTY IN THE ASSESSMENT OF INHALATION EXPOSURES

D B Mathur[1], T C Bernhardt[1], R J Wenning[1], and P S Scott[2]. *ChemRisk Service, McLaren/Hart, Inc.,* [1]*Alameda, CA, USA;* [2]*Pittsburgh, PA, USA.* Sponsor: D J Paustenbach.

In this study, a risk assessment was conducted to evaluate occupational exposures to mercury vapors emitted from soil and groundwater in the mercury cell area at a large chlor-alkali plant. Evaluation of potential exposures from unregulated releases of mercury to ambient air from historical sources was complicated by permitted releases to air from facility operations. Soil and mercury vapor flux chamber samples were collected from several locations across the plant. Both long and short term, as well as day and night flux chamber samples were collected to account for anticipated diurnal variability in mercury fluxes. Mercury vapor fluxes ranged from below 1 to >894 :g/m^2/hr, and soil concentrations ranged from below 0.51 to 6,300 ppm. Mercury fluxes were 2-3 times higher in daylight than at night, but correlated well with mercury concentrations in soil. The measured emission rates were used to calculate breathing zone concentrations and potential risks for different worker groups using the point estimate approach and Monte Carlo Analysis (MCA). Mercury concentrations calculated for the breathing zone ranged between $1x10^{-4}$ and $3.3x10^{-5}$ mg/m^3, and were significantly below the OSHA PEL (0.01 mg/m^3) or ACGIH TLV (0.05 mg/m^3). Mercury concentrations at the breathing zone were associated with hazard indices ranging between 0.01 (50th percentile, MCA) to 3.8 (RME, point estimate). The results of this study suggest, that for chemicals like mercury where volatilization into ambient air is of concern and for which modeling may be unrealistic, flux chamber sampling provides more meaningful information regarding exposures by reducing the uncertainty inherent in the use of models.

385 EFFECTS OF POLYMORPHISM OF GLUTATHIONE TRANSFERASE THETA ON THE RISK ESTIMATE OF DICHLOROMETHANE IN HUMANS.

H A El-Masri, D A Bell, and C J Portier. *Laboratory of Computational Biology and Risk Analysis, NIEHS, NC, USA.* Sponsor: B J Ghanayem.

The carcinogenic potential of dichloromethane (DCM) was linked to its metabolism by the theta (θ) family of the glutathione-S-tranferase (GSTT) system (Casanova et al., 1995). Humans, based on their ethnic background, are polymorphic with respect to this family of isoenzymes (Hallier et al., 1994). We investigated the effect of population polymorphism on the risk estimate of DCM by the application of Monte-Carlo simulation methods in

combination with physiologically based pharmacokinetic/pharmacodynamic (PBPK/PD) models. The PBPK/PD model was used to estimate the DNA-Protein cross-links (DPX) caused by metabolism of DCM (Casanova et al., 1995). Human risks were estimated based on the carcinogenic potency of DCM to mice and PBPK/PD-predicted DPX in humans. The Monte-Carlo simulations were used to provide distributions of risk estimates for a sample of 1000 PBPK/PD runs. Our results show that average and median risk estimates were about 23 to 30% significantly higher when polymorphism was not included at different inhalation doses of DCM. This increase in risk was reduced when it was based on the 95% percentile estimates for all the doses. The specific effect of polymorphism on risk estimates was further investigated by varying the probability at which a Caucasian may have a non-functional form of the enzyme at a constant dose level of 1000 ppm of DCM. As this probability increased the risk decreased correspondingly. Again, this drop in risk estimate was not as significant when the 95% percentile measure was used.

386 USING PHYSIOLOGICALLY BASED PHARMACOKINETIC MODELING TO ASSESS NON LINEARITY IN THE DOSE-RESPONSE RELATIONSHIP FOR METHYLENE CHLORIDE CARCINOGENESIS.

C R Kirman[1], S M Hays[1], M L Gargas[1], M E Andersen[2], R H Reitz[3], F P Guengerich[4], T Green[5], E E McConnell[6], A Buckpit[7], P Voytek[8], and P H Dugard[9]. [1]*McLaren-Hart/ChemRisk, Cleveland, OH, USA;* [2]*ICF Kaiser, Research Triangle Park, NC, USA;* [3]*RHR Toxicology Consulting, Midland, MI, USA;* [4]*Vanderbilt University, Nashville, TN, USA;* [5]*Zeneca, Cheshire, England;* [6]*Tox Path, Inc., Raleigh, NC, USA;* [7]*University of California, Davis, CA, USA;* [8]*Regulatory Sciences International, Alexandria, VA, USA;* [9]*Halogenated Solvents Industry Alliance, Washington, DC, USA.*

Historically, chemical cancer risk assessment has been based on applying the linearized multistage (LMS) model to the results of a single, animal study at relatively high doses. In the process, a great deal of useful dose-response information generated in other studies is not used. To illustrate the utility of an alternative approach, an analysis was conducted for methylene chloride (dichloromethane, DCM). The carcinogenicity of methylene chloride has been well studied in laboratory animals. A total of twelve cancer bioassays, across three species (rats, mice, hamsters) and two routes of exposure (inhalation, oral) were used to support the analysis. The combined data set contains more than 4,800 animals and 50 treatment groups. A physiologically based pharmacokinetic (PBPK) model was used to determine several internal dose estimates for methylene chloride in the lung (peak tissue concentration, average concentration, area-under-the-curve, amount metabolized). Each dose measure was then assessed for its ability to describe a consistent dose-response relationship for DCM-induced carcinogenesis in the lung. Consistent with our current understanding of the mechanism of action for DCM, the dose-response relationship was best characterized by total amount metabolized. Several statistical models were fit to the dose-response data and evaluated with respect to goodness of fit. Graphical analysis of the results indicates that the dose-response relationship for DCM is non-linear in the low-dose region. Furthermore, several alternative dose-response models provided better fits than the LMS model to the combined dose-response data. This type of approach provides a more complete picture than do current practices of the dose-response relationship for DCM, and should be included when assessing the potential health risks associated with human exposures.

387 TRICHLOROETHYLENE HEALTH RISK ASSESSMENT: USING MECHANISTIC INFORMATION TO IMPROVE DOSE-RESPONSE ASSESSMENT.

J Cogliano. *United States Environmental Protection Agency, Washington, DC, USA.* Sponsor: J C Caldwell.

New approaches are being used in an updated health risk assessment for trichloroethylene (TCE), a major environmental contaminant of air, water, and waste sites. Past TCE assessments emphasized linear extrapolation from bioassays in which TCE induced liver tumors and lung tumors in mice and kidney tumors in rats. More recently, however, pharmacokinetic and mechanistic studies on TCE are able to suggest better ways to use the high-dose animal results to make inferences about human environmental exposure. In a new TCE assessment, pharmacokinetic models describe how TCE's cancer response is mediated though several metabolites. Mechanistic information may lead to identifying the key events involved in tumor formation and indicate whether linear or nonlinear extrapolation to lower doses is more appropriate. The new TCE assessment is an example of how EPA's new cancer guidelines encourage use of mechanistic information in risk assessment. These new guidelines, together with assessments like TCE, should stimulate more mechanistic research and promote better collaborations between toxicologists and risk assessors. (The information contained in this abstract does not represent EPA policy.)

388 DEVELOPMENT OF INHALATION AND ORAL BENCHMARK DOSES FOR TRICHLOROETHYLENE BASED ON CARCINOGENICITY IN MICE.

C J Saranko[1], R L Sielken[2], P S Guzelian[3], R C James[4], and S M Roberts[1]. [1]*Center for Environmental & Human Toxicology, University of Florida, Gainesville, FL;* [2]*Sielken Inc., Bryan, TX;* [3]*Department of Medical Toxicology, University of Colorado, Denver, CO;* [4]*TERRA Inc., Tallahassee, FL.*

Trichloroethylene (TCE) is an important industrial chemical and environmental contaminant commonly found at hazardous waste sites. Assessing cancer risks associated with exposure to TCE has been hampered by the absence of a cancer slope factor endorsed by the USEPA. Emerging carcinogen risk assessment methodology makes use of the benchmark dose approach. To date, the only benchmark dose reported for TCE based on carcinogenicity (Haag-Gronlund et al., Reg. Toxicol. Pharmacol., 21:261-269, 1995) was developed using the extra risk definition of increase in tumor incidence rather than the more straightforward added risk definition. In addition the benchmark dose developed by Haag-Gronlund et al. is limited to the inhalation route. In the present study, we used several data sets from chronic mouse bioassays to develop oral and inhalation benchmark doses for TCE based on liver and lung tumor incidences, respectively. Our benchmark doses were derived using the added risk definition. Our analysis resulted in oral ED_{10} values for TCE that range from 124 to 717 mg/kg/day and oral LED10 values that range from 82 to 403 mg/kg/day. The inhalation ED_{10} values for TCE ranged from 362 to 1336 mg/kg/day and the inhalation LED10 values range from 127 to 854 mg/kg/day. These benchmark doses can be used as points of departure for linear extrapolation as a cancer slope factor for TCE. Alternatively, the same benchmark doses could be used in a margin of exposure analysis to assess the risk associated with particular exposure scenarios.

389 AN AMBIENT AIR GUIDELINE FOR TETRACHLOROETHENE BASED ON NON-ONCOGENIC EFFECTS IN HUMANS.

K G Bogdan, A J Grey and D Luttinger. *Center for Environmental Health, New York State Department of Health, Albany, NY, USA.* Sponsor: R Seegal.

Air levels of tetrachloroethene in residences above dry-cleaning shops are frequently elevated compared to residences not near such shops. We reviewed the scientific literature on tetrachloroethene and derived criteria for evaluating the potential for non-oncogenic health risks from low-level chronic exposures. Animal and human data show the primary targets are the central nervous system (CNS), kidney, liver, and possibly the reproductive system. Results from cross-sectional occupational studies of central nervous system (CNS), kidney, and liver effects in dry-cleaning workers were deemed the most appropriate for use in criteria derivations. A no-observed-effect level for impaired vision and lowest-observed-effect levels for evidence of CNS dysfunction (motor and cognitive effects) and kidney and liver dysfunction were used. These workplace exposures were adjusted to continuous exposures based on inhalation rates. Uncertainty factors were applied to derive criteria for the general adult population. However, children may not be adequately protected by criteria derived for adults because they have higher inhalation rates per unit body weight than adults and their developing organs/systems may be more sensitive to the same dose than those of adults. Thus, scaling and uncertainty factors were applied to adult continuous exposure levels to derive criteria for children of 0.12 mg/m^3 (CNS effects), 0.14 mg/m^3 (kidney effects), and 0.11 mg/m^3 (liver effects). A criterion of 0.1 mg/m^3 was recommended. This criterion is estimated to provide the general population, including sensitive subpopulations, a sufficient margin-of-exposure over the air levels of tetrachloroethene associated with non-oncogenic effects in humans and animals.

390 REASSESSMENT OF THE POTENTIAL CANCER RISK OF PERCHLOROETHYLENE.

P E Voytek. *Regulatory Sciences International, Alexandria, VA, USA.*
Sponsor: B R Stern.

A physiologically based pharmacokinetics model (PBPK) was used to determine trichloroacetic acid (TCA) levels in mouse liver to generate dose-response relationships for hepatocellular carcinomas from two inhalation bioassays at low perchloroethylene inhalation exposure levels. The model was fit to existing mouse data that measured TCA and perchloroethylene blood levels. The dose-response relationships were analyzed based on the biological evidence that perchloroethylene is metabolized to TCA in the liver which in turn is responsible for stimulation of peroxisome proliferation and an increase in S-phase cells. Peroxisome proliferation leads to increases in organelle fatty acid β-oxidation resulting in the formation of hydrogen peroxide and free radicals that may reach nuclear DNA causing mutations and chromosomal aberrations. Increase cell division may enhance the number of target cells providing greater opportunity of occurrence of spontaneous and chemically induced mutations leading to cell transformations. Furthermore, the growth of transformed cells may also be stimulated by TCA, thus promoting the opportunity for further spontaneous or chemically induced transformation leading to hepatocellular carcinoma. Several biological mechanisms were examined involving interactions of TCA with a cytosolic receptor as well as the effects of TCA on enhancing levels of a natural receptor ligand. These various biological relationships were used to estimate incidences of hepatocellular carcinoma below the observable exposure range and showed different risk values when compared to estimates based on none-biological extrapolations.

391 DEVELOPMENT OF AN RFD FOR DICAPRYLPHTHALATE USING DATA FROM STRUCTURE-ACTIVITY RELATIONSHIPS AND IN VITRO STUDIES.

I S Chaudhuri. *ENSR, Corp., Acton, MA, USA.*

Dicaprylphthalate (DCP) is a phthalate compound that does not have a dose-response value derived by the U.S. Environmental Protection Agency (U.S. EPA), and no appropriate animal studies on which to base a dose-response value. Therefore, a structurally-similar chemical was selected to represent DCP toxicity. Amongst the various phthalate compounds, dicaprylphthalate is the closest in chemical structure to di(2-ethylhexyl)phthalate (DEHP) and di(n)octylphthalate (DNOP). DEHP is considered potentially carcinogenic by U.S. EPA, whereas DNOP is evaluated as a noncarcinogen. Therefore, there are important risk implications in selecting DEHP or DNOP as the surrogate chemical. DEHP, DCP and DNOP were entered in the Quantitative Structure Activity Relationship (QSAR) program, Case Tox II, to evaluate the carcinogenicity endpoint. DEHP was found to be positive for carcinogenicity in all of the databases, whereas DCP and DNOP were negative. Studies evaluating the mechanism of phthalate ester rodent carcinogenicity indicate that DCP behaves similarly to DNOP, rather than to DEHP. DEHP is thought to cause cancer in rodents through the mechanism of peroxisome proliferation. Lake et al. (1987) showed that the 2-ethylhexyl phthalate monomer was more potent than the 1-ethylhexyl phthalate and n-octyl monomers in inducing peroxisome proliferation. This study is directly relevant to DCP, since DCP has a methyl group at the 1-carbon position, and suggests that DCP behaves similarly to DNOP. In addition, there are serious questions as to the relevance of DEHP's rodent carcinogenicity data to humans. The combined evidence indicated that the noncancer RfD for DNOP (0.02 mg/kg-day) should be used to conduct a risk assessment on DCP.

392 FORMALDEHYDE RISK ASSESSMENT BY BENCHMARK DOSE ANALYSIS USING DNA-PROTEIN CROSS-LINKS AS AN INTERNAL DOSE METRIC.

P M Schlosser[1], D B Janszen[1], J S Kimbell[1], and P D Lilly[1,2]. [1]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA;* [2]*Boehringer Ingelheim Pharmaceuticals, Ridgefield, CT, USA.*

Formaldehyde induced tumors in specific regions of the rat nose in two cancer bioassays. Analysis of inspiratory air flow and gas transport indicated that these processes play a key role in tumor site specificity. Formaldehyde also induced DNA-protein cross-links (DPX) in a dose- and a site-dependent manner in rats and monkeys. A distributed model of formaldehyde transport and formation of DPX in the rat nasal lining was developed, using computational fluid dynamics (CFD) to model airflow and regional gas uptake, and fit to DPX data. This model was used to estimate time-averaged DPX levels for each exposure concentration in the rat cancer bioassays. Benchmark dose (BMD) analysis is a statistical curve-fitting approach that can be used to determine from dose-response data the maximum likelihood estimate (MLE), or central estimate, and the lower 95% confidence limit on dose associated with a specific level of risk. This BMD is the dose or concentration predicted to result in a specified increase in risk. BMDs were calculated for the cancer response in rats using DPX values as doses. A monkey CFD model and monkey DPX data were used to estimate how DPX model metabolic parameters scale across species and this scaling was used to obtain values for a human DPX model. The human DPX model was used to estimate formaldehyde flux values that yield DPX in humans equal to the rat-based BMDs, and a human CFD model was used to estimate the corresponding exposure levels. These exposure concentrations were identified with human BMDs based on the assumption that DPX is a good metric of tissue formaldehyde levels, and that cancer risk is identical for rats and humans when tissue formaldehyde levels are the same. These results indicate that humans are somewhat less sensitive than rats to formaldehyde-induced cancer.

393 CLONAL GROWTH MODELS AND CANCER RISK ASSESSMENT: SIGNIFICANCE OF THE TUMOR GROWTH RATE FOR INTERSPECIES SCALE-UP.

R Conolly. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA.*

Multistage clonal growth models are being used for cancer risk assessment because they are biologically more realistic than the linearized multistage model or model-free approaches such as linear extrapolation through the dose-response origin. The time interval (or time lag) required for clonal expansion of a single malignant cell into a clinically observable tumor is one aspect of the carcinogenic process that can be described explicitly using clonal growth models. This capability allows the role of the time lag in interspecies scale-up to be evaluated. We have developed a new cancer risk assessment for inhaled formaldehyde in which a clonal growth model of nasal squamous cell carcinoma incidence data in F344 rats is scaled for the prediction of cancer risk in humans. Maximum likelihood estimation of the parameters of the rat model indicated a lag time for clinical appearance of squamous cell carcinoma of about 6 – 9 months. This represents 20 - 30% of the typical 2.5-yr lifetime of the F344 rat. A similar clonal growth model was fit to data on age-specific incidence of human respiratory tract cancer by maximizing the Poisson likelihood. A time lag of 10 - 12 yr was estimated. This lag was subsequently used in cancer risk assessment for formaldehyde-exposed people assuming that humans live for 80 yr. The human lag is 12 to 15% of human lifetime. Thus, these clonal growth models predict that, for the tumor types studied, the fraction of life span for which humans are at risk of developing clinically detectable cancer is greater than that of rats. These model predictions need to be validated by measurement of actual tumor growth rates in rodents and humans. Assuming that the predictions are found to be consistent with such data, these results indicate that rat carcinogenesis bioassays may underestimate human cancer risk to the extent that time lags in rats are significantly greater proportions of rat life span than are human lags of human life span. However, other factors, particularly the typical differences between rodent bioassay exposure levels and human environmental exposure levels, are quantitatively more important determinants of interspecies differences in risk.

394 EPOXY RESINS AND POLYAMINE DERMAL AND SYSTEMIC TOXICITY

T T Martinez. *St. Louis College of Pharmacy, St. Louis, MO.*

Dermal exposure to epoxy compounds may result in severe skin irritation, contact dermatitis and burns. This is a report of a case which also produced axillary lymph adenopathy and chronic neuralgia. An adult male was working with Metalink 5000 epoxy compound. Unfortunately the gloves he used were porous, and the effects were not immediately noticeable. Shortly thereafter his hands turned yellow. Two weeks later he developed an erythematous rash with small papules. Avoidance of the chemical and Diprolene AF cream were prescribed. The pain increased and spread to his arms. At 7 weeks he had burn-like areas over the dorsum and palms of his hands. He was treated with Medrol Dosepack and Cortisone cream and the local inflammatory reaction resolved over the next 2 weeks. Two years later he was still having pain in the forearms and proximal arm into the axilla. There was some loss of strength in his arms and grip. Prednisone temporarily

improved but did not resolve the condition. Given the history of exposure and the pain which had never existed before, it is reasonable to believe a relationship exists between the injury and his symptoms. Both direct chemical damage and immune system hypersensitivity are likely. The diagnosis of hypersensitivity reaction is supported by 1) the propensity of these chemicals to produce this effect, 2) the site of pain which corresponds with expected lymph flow, 3) delayed onset and prolonged duration of the effect, and 4) temporary response to imunosuppression with corticosteroids.

395 THE EFFECT OF AGING IN SOIL ON THE DERMAL BIOAVAILABILITY OF MERCURY.

R M Turkall, G A Skowronski and M S Abdel-Rahman. *University of Medicine and Dentistry of New Jersey/New Jersey Medical School, Newark, NJ, USA.*

Soil cleanup standards based on exhaustive extraction of chemicals from contaminated soil may overestimate the risk from exposure and the extent of needed soil remediation. Instead, this study assessed the effect of chemical "aging" on dermal bioavailability from soil using mercury as an example. Experiments were performed with 203-mercury chloride on dermatomed male pig skin by flow-through diffusion cell methodology. After aging for 3 months in either a sandy or a clay soil, the bioavailability of mercury was decreased by 91-96% compared to chemical without soil. In contrast, a 40% reduction in bioavailability was observed for the compound added immediately to soil. Both soils bind mercury more strongly with time as supported by larger quantities of radioactivity in soil after aging than in soil for 16 h. Decreased mercury bioavail-ability with aging indicates lower health risk and reduced soil cleanup. (Supported in part through funding from the Hazardous Substance Management Research Center and the New Jersey Commission on Science and Technology.)

396 AN ALTERNATE VIEW OF DERMAL ABSORPTION OF HEXACHLOROBENZENE FROM SOIL.

M A Katona[1], T F Long[1], C R Kirman[1], E S Golpashin[2], M A Bono[1], and M L Gargas[1]. [1]*ChemRisk, A Service of McLaren/Hart, Inc., Cleveland, OH, USA;* [2]*McLaren/Hart, Inc., Irvine, CA, USA.*

Estimates of the amount of contaminant absorbed systemically as the result of dermal contact with soil remain an area of significant uncertainty in risk assessment. It has been common to use default values such as 25% for volatile compounds, 10% for semi-volatile compounds, and 1% for metals to account for dermal uptake of these compounds from soil even though there is little or no experimental evidence to support these values for most compounds. Using hexachlorobenzene (HCB) as a model semi-volatile compound, a better estimate of the amount absorbed through the skin from soil was developed. Using published literature on the dermal absorption of HCB in an *in vivo* rat study (Koizumi, 1991) and information on the relative permeability of rat and human skin, an estimate of the amount of free HCB likely to be absorbed by humans was determined. In addition, extraction studies of soil contaminated with HCB were used to confirm the matrix effects as well as account for the effects of aging on the availability of this compound from soil. These results indicate that far less than 0.1% of HCB in soil is likely to be absorbed from soil under normal conditions. These findings are similar to the results of a dermal absorption fugacity model developed for soil-bound compounds by McKone and Howd (1992), and applied to HCB. Based on these results, it is likely that dermal absorption of compounds with similar physical and chemical characteristics to HCB are significantly overestimated by the default assumptions currently in use. Similar evaluation of related and unrelated compounds is needed in order to extend and generalize these findings and improve risk estimates from the dermal pathway.

397 EFFECT OF TEMPORAL ASSUMPTIONS ON RISK ASSESSMENTS FOR DERMAL TOXICITY.

J N McDougal[1], J L Jurgens[1] and W H Weisman[2]. [1]*Geo-Centers, Inc.,* [2]*Human Effectiveness Directorate, Air Force Research Laboratory, Wright-Patterson AFB, OH, USA.*

The skin can be an important route of entry for chemicals that may subsequently cause toxicity. After dermal exposures, irritation of the skin may result or if the chemical is absorbed through the skin, systemic toxicity may result. Dermal exposures can occur from contact with contaminated surfaces, spills on the skin or during showering and bathing in contaminated water. Most of these exposures are short duration and the rate of absorption does not approach steady-state. The time before chemical penetrates through the skin and becomes available for systemic absorption can be minutes to hours and is known as the "lag time". This lag time may impact duration extrapolations used for risk assessments, which assume that flux is constant over time. Using static diffusion cells and rodent skin, we measured time profiles for diffusion of dibromomethane (pure chemical and aqueous solution) into and through rat skin. Chemical concentration in the skin slowly increases and then becomes constant, without any lag time. After a fifteen-minute lag time, the concentration of chemical that comes through the skin slowly increases and then becomes constant. When he total amount of dibromomethane (in both the skin and the receptor solution) is plotted over time, the plot is linear without a lag time. These results suggest that duration extrapolations for chemical in the skin and diffusing through the skin can be inaccurate depending on the length of the lag time compared to the exposure time. (Supported by the Air Force Office of Scientific Research.)

398 POPULATION ATTRIBUTABLE RISKS FOR BLADDER CANCER ASSOCIATED WITH EXPOSURE TO CHLORINATED SURFACE WATER.

M K Manibusan, M W Cox, J M Donohue, S G Selevan, and R Calderon. *Office of Water, US EPA, Washington, DC, USA.* Sponsor: C O Abernathy.

In the US, approximately 240 million people are served by public water systems. Most of these systems rely on chlorination for disinfection. Benefits of chlorination are decreased morbidity and mortality from waterborne diseases. Some DBPs produce tumors in animals, and studies have been conducted to investigate potential carcinogenicity of exposure to disinfected water. A population attributable risk (PAR) analysis was completed to support the benefits analysis for the Stage 1 Disinfection Byproducts Rule. To date, there are fifteen bladder cancer epidemiological studies on chlorinated water. Of these, five studies were selected for analysis based on specific selection criteria. Study-specific relative risks (RR ~ 1.01-1.5) and case fractions were used to generate PARs that ranged from 2 to 17 percent. This is equivalent to 1,100 - 9,300 new bladder cancer cases per year potentially attributable to disinfection byproducts in chlorinated surface water assuming a causal relationship. This range is based on 54,500 incident bladder cancer cases expected in the US for 1998.

399 CANCER CHARACTERIZATION OF THE DISINFECTION BYPRODUCT BROMATE.

J S Dollarhide[1], J Jinot[2], Y Patel[3], and V Dellarco[3]. [1]*Toxicology Excellence for Risk Assessment, Cincinnati, OH, USA;* [2]*National Center for Environmental Assessment, U.S. EPA, Washington, DC;* [3]*Office of Water, U.S. EPA, Washington, DC.*

Bromate ion may be formed in drinking water following ozonation of water containing bromide. The potential of this disinfection byproduct to cause cancer in humans was evaluated following U.S. EPA's 1996 Proposed Guidelines for Carcinogen Risk Assessment. No human studies are available which assess the potential carcinogenicity of bromate. However, three key studies demonstrate that exposure to bromate in drinking water results in kidney tumors, thyroid tumors, and mesotheliomas in rats. Evidence in rats demonstrating that bromate has the potential to be a human carcinogen includes tumors at multiple sites, a clear dose-response relationship both in tumor incidence and in severity or progression of tumors in rats, and the consistent observation of an uncommon tumor mesotheliomas. Bromate has been found to be positive in a variety of *in vitro* genotoxicity assays, although there is no evidence that bromate is directly DNA reactive. Oxidative stress may play a role in the formation of kidney tumors; treatment with bromate causes an increase of 8-hydroxydeoxyguanosine in the kidney only. Recent studies suggest that in the intact kidney, there is not a direct mechanism of DNA damage; rather, at toxic doses, bromate induces DNA damage through lipid peroxidation. However, the overall evidence is insufficient to establish lipid peroxidation and free radical production as the key events responsible for the induction of kidney tumors. In addition, no data are currently available to suggest any single mechanism, including oxidative stress, is responsible for the production of thyroid and peritoneal tumors by bromate. Therefore, bromate was evaluated as a likely human carcinogen and the default linear low-dose extrapolation was done. Using a time- to-tumor analysis and a Monte Carlo analysis to sum the cancer potency estimates for kidney renal tubule tumors, mesotheliomas, and thyroid follicular cell tumors, an upper bound cancer potency estimate for bromate ion is 0.70 per mg/kg-day. (This abstract does not necessarily reflect EPA policy).

400 CATEGORICAL REGRESSION ANALYSIS OF BROMODICHLOROMETHANE (BDCM) LIVER TOXICITY AND PATHOLOGY DATA.

L K Teuschler[1], J E Simmons[2], W R Hartley[3], A Thiyagarajah[3], and J C Lipscomb[1]. [1]*NCEA, U.S. EPA, Cincinnati, OH;* [2]*NHEERL, U.S. EPA, RTP, NC;* [3]*Tulane University Medical Center, New Orleans, LA.*

A categorical regression (CR) procedure is being investigated as an way of comparing new toxicity data with existing benchmarks, such as a Reference Dose (RfD), and as a method for predicting pathology scores from other hepatotoxic endpoints. CR was used to model data on liver toxicity and histopathology scores from female CD-1 mice exposed for 14 days by gavage to BDCM (0, 0.152, 0.305, 0.76, 1.52, 3.05 mmol/kg/day), a common by-product of drinking water disinfection processes. The toxic effects, which included both continuous endpoints (liver enzyme elevations, liver weight changes) and categorical data (centrilobular necrosis designations) were classified into ordered categories of total toxic severity (e.g., none, mild, adverse, severe) at the individual animal level. CR was then used to regress these severity categories on dose to estimate the probability of observing an adverse or severe effect (P=A,S). At the animal chronic LOAEL of 17.9 mg/kg/day based on renal cytomegaly in male mice (an effect considered minimal in the absence of renal function impairment), which was used to calculate the RfD, the (P=A,S) liver effect was 0.01 (95% CI of 6E-4, 0.14), consistent with the fact that the kidney effect should be a more sensitive endpoint. Because some additional enzyme and organ weight data were available from the same laboratory, but without corresponding pathology results, another CR model was used to predict liver necrosis designations from the enzyme and organ weight data for the additional data, which were then used to rerun the first CR model. The predictive CR model was significant, indicating that the severity category for centrilobular necrosis can be estimated from the percent liver weight and the log of ALT. (Abstract may not reflect U.S. EPA policy.)

401 DAILY WATER INTAKE IN THE U.S.

J T Du, H Jacobs, and H Kahn. *U.S. EPA, Washington, DC.*

Water intake is used in the drinking water risk assessment. In general, a default water intake for an adult has been assumed to be 2 liters. This value agrees with Ershow and Cantor's report (1989) which is based on a US Department of Agriculture survey from 1976 to 1977. To obtain current estimates of water intake, we analyzed data from USDA's 1994 - 1996 Continuing Survey of Food Intake by Individuals. This project estimates municipal tap, bottled water, and other water intake with percentile distribution by age, gender, race, socioeconomic status and geographic region. Water refers to both drinking water and water added in final preparation of beverages and foods at home or in a restaurant. Intrinsic water (water contained in foods and beverages at times of market purchase) is not included in our estimate. Preliminary results show that there has been a substantial increase in the intake of bottled water, and that the estimated 95 percentile distribution of tap water intake for people of all ages supports the assumed value of 2 liters per day. Details of our analysis will be presented. The opinions expressed are those of the authors and do not necessarily reflect U.S. EPA policy.

402 RISK ASSESSMENT FOR CHLORITE AND CHLORINE DIOXIDE BASED ON NEW NONCANCER DATA.

Y Patel[1], P M McGinnis[2], L Ingerman[3] and V Dellarco[1]. [1]*Office of Water (OW), U.S. EPA, Washington, DC and Syracuse Research Corporation,* [2]*Philadelphia, PA and* [3]*Portland, OR.*

Chlorine dioxide (ClO_2) and chlorite (ClO_2^-) are disinfection byproducts of chlorination treatment of drinking water. In support of Stage 1 Disinfectant/Disinfection Byproducts Rule (D/DBP), EPA has reassessed the noncancer health risk for these chemicals considering new data submitted since the 1994 proposed D/DBP rule. The 1994 proposal included a maximum residual disinfectant level goal (MRDLG) of 0.3 mg/L and a maximum residual disinfectant level (MRDL) of 0.8 mg/L for ClO_2 and a maximum contaminant level goal (MCLG) of 0.08 mg/L and a maximum contaminant level (MCL) of 1.0 mg/L for ClO_2^-. It has consistently been shown that neurotoxic/ behavioral effects are the critical effect for ClO_2 and ClO_2^-. A recent 2-generation rat study with ClO_2^- (CMA, 1997), which filled a database gap, showed alterations in auditory startle response and brain weight, supporting the studies of Orme et al. (1985) and Mobley et al. (1990) showing alterations in exploratory and locomotor activity. The weight of the evidence from these and supporting studies indicate 3 mg/kg/d ClO_2^- is the NOAEL and the LOAEL occurs at a dose of 6 mg/kg/d. The RfD of 0.03 mg/kg/d is derived from the NOAEL by application of a 100-fold uncertainty factor (UF) for interspecies extrapolation and intra-human variability. This RfD is applied to both ClO_2 and ClO_2^- because ClO_2 in drinking water rapidly degrades to ClO_2^- , and both chemicals have similar pharmacokinetics, targets of toxicity, and potency. (This abstract does not necessarily reflect EPA policy.)

403 COMPARATIVE RISKS OF DRINKING WATER TREATMENT SYSTEMS.

G Rice, L K Teuschler and J C Lipscomb. *U.S. EPA, National Center for Environmental Assessment, Cincinnati, OH, USA.*

Disinfection of drinking water (DW) reduces the risks associated with microbial infections, but produces several compounds whose toxicity warrants concern. To develop a method to compare these disparate risks and include costs associated with different DW intervention strategies, a cost-effectiveness analysis (CEA) approach to a public health intervention was employed. CEA is a comparative-risk approach capable of concurrently evaluating the benefits of intervention (i.e., disinfection of public drinking water), the risks of unintended side effects of the intervention [i.e., potential health risks posed by disinfectants and disinfectant byproducts (D/DBP)], and the relative costs of implementing one or more intervention strategies. CEA was applied to compare the potential health impacts from exposure to 13 D/DBP and to a representative microorganism, *Cryptosporidium*, resulting from conventional chlorination with and without a pre-ozonation step. Response-addition was assumed to estimate cancer and non-cancer human health risks from exposure to mixtures of D/DBP. Risks of cryptosporidiosis were estimated through a simple linear infectivity/sequella model. Results indicate that the implementation of a pre-ozonation step was not as cost effective as conventional chlorination; however, an uncertainty analysis showed that the results depended heavily on several key assumptions. A second iteration of the comparison will be performed to reduce uncertainties by including various source water quality indicators, a larger number of D/DBP, an assessment of D/DBP genotoxicity data, and further work on the application of various additivity assumptions as the basis for estimating mixtures risk. (Abstract may not reflect U.S. EPA policy).

404 RISK ASSESSMENT OF FURFURAL FOR THE DEVELOPMENT OF A MAXIMUM ALLOWABLE LEVEL (MAL).

C I Cailipan, A D Phelka, M C Sanders and L L Bestervelt. *NSF International, Ann Arbor, MI, USA.* Sponsor: M L Dourson.

A human health risk assessment was conducted by NSF International to determine a safe concentration limit for furfural in drinking water according to ANSI/NSF Standard 60/61, Appendix A. Furfural has been detected in laboratory extractions as a leachate of coatings (Standard 61, Section 5) and adsorption process media (Standard 61, Section 7). NSF International reviewed scientific literature, including recommendations from international bodies, genetic data, subchronic toxicity testing, reproductive and developmental data, chronic and long term cancer bioassay studies, metabolism data, structure activity, and other supplemental studies. The newly proposed EPA guidelines on risk assessment methods were analyzed and incorporated as applicable. This review led to the development of a Maximum Allowable Level (MAL) in drinking water for furfural of 75 ppb. The MAL value was derived based on the LOAEL of 30 mg/kg/day from a NTP chronic rat oral gavage two-year study. A safety factor was considered to account for intraspecies extrapolation, interspecies variation, and the use of a LOAEL instead of a NOAEL. In accordance with the Standard, lack of reproductive toxicity and teratology studies were limiting factors in this analysis. Furfural is not likely to be carcinogenic to humans at or below the MAL level. MAL development was subject to peer review and discussion joint committees. Study summaries and the MAL value derivation are discussed.

405 USE OF HUMAN DATA IN THE HEALTH ASSESSMENT OF DIMETHYLAMINE (DMA).

E C Bisinger. *Calgon Corporation, Pittsburgh, PA, USA.*

DMA has been identified as a contaminant in certain polymer products used

in the production of drinking water. An initial review of the existing DMA toxicology database indicated that additional toxicology studies might be required to assess the potential health effects of DMA when present as a contaminant in drinking water at part per billion (ppb) levels. However, prior to intitiating costly, toxicology studies in whole animals by the oral route, an exhaustive examination of the literature on human data was performed. It was determined that DMA is naturally present in the human diet at parts per million (ppm) levels that exceed the estimates of DMA when present as a contaminant in drinking water. DMA is endogenously produced during normal metabolic processes in the human body, and in addition, is manufactured in vivo by the gut microflora. Levels of DMA naturally present in human blood and urine exceed the estimated DMA contaminant levels in drinking water. Ingested or inhaled DMA does not undergo metabolic transformation in humans but rather is excreted unchanged in the urine. These data can be used with existing toxicology study results to complete the health assessment of DMA without the need for additional, whole animal testing. (*Now with Underwriters Laboratories Inc., Northbrook, IL, USA)

406 SPECIFIC ANTIAPOPTOTIC ACTIVITY OF THE NEURORESCUING COMPOUND TCH346.

A Wolf, B Greiner, D Roman, S Grub, J Medina, M Bobadilla, and U Schramm. *Novartis Pharma AG, Experimental Toxicology, Basel, Switzerland.* Sponsor: A De Brugerolle de Fraissinette.

TCH346 (dibenzo[b,f]oxepin-10-ylmethyl-prop-2ynyl-amine) is a novel compound that is believed to possess neurorescuing properties potentially beneficial in the treatment of chronic degenerative diseases such as amyotrophic lateral sclerosis and Parkinson's disease. Although TCH346 has been proven to be non-genotoxic, its antiapoptotic activity rose the concerns that the compound might have some tumor promoting activity in various tissues outside the brain. The purpose of the present study was to evaluate TCH346 concerning its anti-apoptotic activity in different cellular model systems from different target organs/tissues. Annexin V assay, TUNEL assay, chromatin condensation and fragmentation were evaluated as parameters of apoptosis. The potential antiapoptotic activity was determined in presence of a positive reference compound. TCH346 concentrations were in the range of 10^{-11} to 10^{-6} M. The following cellular models and apoptosis inducers were used: Rat thymocyte suspensions (dexamethasone), human HaCaT keratinocytes (anti-Fas + IFNλ , or UV), rat cardiac myocytes primary cultures (atrial natriuretic peptide, ANP), rat hepatocyte primary culture (TGFβ), renal LLCPK1 cell line (rotenone), human astrocytes (rotenone) and human neuronal cell line PAJU (rotenone).TCH346 neither had an inhibitory effect on apoptosis in rapidly proliferating cells from thymus and skin, nor did it inhibit apoptosis in cells of the frequently affected cancer targets liver and kidney. In a non-neuronal astrocyte cell culture, TCH346 did not have any effect, however, in neuronal cells it effectively inhibited apoptosis. The inhibition of the ANP-stimulated apoptosis found in cardiomyocytes does not suggest a risk of heart tumor formation, since inhibition was not below the basic apoptotic rate and these cells are known not to be a target of tumorigenic responses. The results suggest that TCH346 possesses a great brain specific antiapoptotic activity and that the risk of a tumor promoting activity by inhibition of apoptosis in target organs different from the brain is very low.

407 INVOLVEMENT OF CASPASE-3-LIKE ACTIVITY IN CYANIDE-INDUCED NEURONAL APOPTOSIS.

P G Gunasekar, S Yan, J L Borowitz and G E Isom. *Department of Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN, USA.*

The caspase family has been proposed to play a role in neuronal apoptotic death. We have shown that neurons from the brain that are vulnerable to cyanide undergo apoptosis. To identify the mechanism of neuronal apoptosis after cyanide exposure, studies were conducted to determine the involvement of the caspase-3 proteases in cerebellar granule cells (CGS). Exposure to 100-300 μ M KCN, that produces apoptosis in CGS, were used to measure caspase-3-like activity by spectroflurometry. KCN-induced a concentration dependent increase of caspase-3-like activity with a maximum at 300 μ M KCN exposure. Maximum activity of the caspase-3 proteases was seen at the 24 hrs time period. The level of caspase-3 activity with various concentration of KCN treatment reciprocally paralleled neuronal apoptosis. Involvement of caspase-3 activity was confirmed by the observation that the inhibitor z-VAD abrogated KCN-induced increase of caspase-3 activity. Moreover, treatment of neurons with MK-801 (NMDA antagonist) and an inhibitor of redox transcription factor $NF\text{-}_{k}B$ (SN50 NF-kB) also blocked caspase-3 activity induced by cyanide. To determine the link between caspase-3 activity and apoptosis, cells were pretreated with agents that block the caspase-3-like proteases and MK-801 and SN50 $NF\text{-}_{k}B$. Inhibition of caspase 3-like activity (z-VAD) and blockade of NMDA receptor activation and $NF\text{-}_{k}B$ translocation all reduced apoptosis showing that caspase 3-like activity is increased in cyanide-induced apoptosis. Gel electrophoresis showed that DNA fragmentation induced by KCN was blocked by the caspase-3-like protease inhibitor, MK-801 and SN50 $NF\text{-}_{k}B$. These data suggest that cyanide induces apoptosis by NMDA receptor mediated process leading to activation of caspase cascades. (Supported by NIH grant ESO4140.)

408 PYRIDOSTIGMINE-INDUCED ACUTE AND DELAYED NEURONAL APOPTOSIS.

L Li, P G Gunasekar, J L Borowitz and G E Isom. *Department of Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN, USA.*

Pyridostigmine Bromide (PB) is a reversible inhibitor of acetylcholinesterase (AChE) which may be a contributing factor in the Gulf War Syndrome. To determine whether PB produces neurotoxicity, TUNEL staining for apoptotic cell death was conducted in rat brain sections after treatment with PB twice daily for 4 days over the dose range of 0.25-1.85 mg/kg. PB induced a dose-related neuronal apoptosis in select brain areas. At 1.85 mg/kg, 3 of 4 rats showed marked TUNEL staining in the cortex, striatum and hippocampus. Electron microscopy was used to confirm PB-induced apoptosis. Ultrastructural changes characteristic of apoptosis were observed (chromatin margination to the nuclear membrane, chromatin clumping and cytoplasmic condensation) in the brain sections. To detect any possible delayed neurotoxicity, rats were sacrificed at 5, 10, 20 or 30 days after cessation of PB treatment (1.85 mg/kg twice daily for 4 days). At all time periods apoptotic cell death was observed in the cortex; the apoptotic process continued up to 30 days after expsoure to PB. In mechanistic studies, pretreatment with atropine (25 mg/kg, ip) blocked the apoptotic death in all brain areas. Pretreatment with PBN (antioxidant) or l-NAME (NOS inhibitor) did not alter the neurotoxic response to PB. Serum AChE was also measured as a marker of PB exposure. All doses significantly inhibited serum AchE activity, however at 5, 10, 20 or 30 days after the last PB dose, serum AChE activity was not different from control. These results suggest that apoptosis induced by PB may be mediated by excessive activity of cholinergic receptors and the apoptotic process continues up to 30 days after PB exposure. (Supported by U.S. Army grant DAM 17-97-71354.)

409 MODULATION OF NEURONAL APOPTOSIS BY AN INTERACTION BETWEEN TNFα AND NGF SIGNAL CASCADES.

N J Macdonald[1], F Decorti[2], T C Pappas[3] and G Taglialatela[2]. *Departments of [1]Neuroscience, [2]Human Biological Chemistry and Genetics and [3]Internal Medicine, The University of Texas Medical Branch at Galveston, TX, USA.* Sponsor: M T Moslen.

Background: High levels of inflammatory cytokines such as tumor necrosis factor-alpha (TNFα) are often associated with aging and age-related diseases such as Alzheimer's disease and Parkinson's disease. Target-derived neurotrophins (NT) such as nerve growth factor (NGF) are essential for neuronal survival. Thus, impairments in NT signal transduction may be responsible for neuronal degeneration observed during aging or chronic inflammation in the central nervous system (CNS). NGF binds to tyrosine kinase receptor A (TrkA) and to a common NT receptor $p75^{NTR}$, a member of the TNFα receptor (TNFR) superfamily. While TrkA mediates most of the NGF actions, the role of $p75^{NTR}$ is less clear; one possible role is that NGF modulates neuronal apoptosis via $p75^{NTR}$. **Objective:** Determine if TNFα-induced neurotoxicity affects NGF-mediated cell survival by interfering with the $p75^{NTR}$ signal cascade and whether high concentrations of NGF can rescue cells from TNFα-induced cell death by interfering with the TNFα signal cascade, in a Trk-independent fashion. **Experimental Design:** Rat pheochromocytoma (PC12) cells, a neuronal-like model, were treated with TNFα, NGF or both in the presence or absence of the Trk inhibitor, K252a. Cell death and apoptosis were assessed as well as levels of key signal transduction elements [nuclear factor kappa B (NFκB), protein kinase C zeta (PKCζ), caspases, n-terminal c-jun terminal kinase 1 (JNK-1) and phospholipase $A2(PLA_2)$] associated with TNFα or NGF receptors. **Results:** We found that TNFα

induces apoptosis in PC12 cells but high concentrations of NGF rescued the cells from TNFα-induced apoptosis. The Trk inhibitor K252a did not block this NGF-mediated rescue which indicates independence from TrkA signaling. TNFα-induced apoptosis was linked to inhibition of the active forms of PKCζ and NFκB, signaling elements associated with cell survival. Rescue by high concentrations of NGF abolished TNFα-induced increases of JNK-1, caspases and PLA_2, key signaling elements in the induction of neuronal cell death. **Conclusions:** We conclude that TNFα and NGF may modulate neuronal apoptosis by affecting key signal elements in each other's signal transduction pathways. These results are important for understanding the mechanisms leading to neuronal death during aging and age-related diseases. (Supported by the National Institute of Aging Grant AG13945 to GT.)

410 APOPTOSIS INDUCED BY ETHANOL AND SERUM DEPRIVATION ARE MECHANISTICALLY DISTINCT.

J Oberdoerster and R A Rabin. *Dept. of Pharmacol. & Toxicol., Sch. of Med. & Biomed. Sci., Univ. at Buffalo, Buffalo, NY.*

Ethanol exposure results in a loss of neurons that appears to be, at least in part, due to an ethanol-mediated increase in apoptosis. PC 12 cells were used as neuronal models to compare the pro-apoptotic effects of ethanol and trophic factor deprivation. Apoptosis induced by serum deprivation occurred within 4 hr. After 24 hr the activity of Caspase-3, a principle effector of apoptosis, was increased 2.6-fold and immunoblot analysis revealed a 2.1-fold increase in the amount of the active (17 kDa) subunit of Caspase-3. In contrast, ethanol treated cells did not undergo apoptosis until 21 hr after ethanol treatment. Caspase-3 activity was increased 1.6-fold by ethanol, however, no ethanol-mediated processing of Caspase-3 to its active form was detected. The Bcl-2 family of proteins act as a rheostat for apoptosis. Immunoblot analysis of five Bcl-2 homologues revealed that serum deprivation increased the pro-apoptotic homologues Bax and Bcl-X_S and decreased the anti-apoptotic homologue Bcl-2. No ethanol-mediated change in the amount of Bcl-2, Bcl-X_L, Bcl-X_S, Bad, or Bax was detected. The second messenger ceramide can induce apoptosis that can be blocked by sphingosine-1-phosphate (SPP). SPP completely protected PC 12 cells from cell death due to trophic factor deprivation. Ethanol-induced cell death, however, was not affected by treatment with sphingosine-1- phosphate. These findings suggest that ethanol-mediated apoptosis is mechanistically distinct from apoptosis initiated by serum withdrawal. (Supported by AA06207.)

411 THE POLY (ADP-RIBOSE) POLYMERASE INHIBITOR (PARPI), BENZAMIDE IS NEURO-PRETECTIVE AGAINST SOMAN-INDUCED SEIZURE-RELATED BRAIN DAMAGE.

H L Meier, G P H Ballough[2], J S Forster, and M G Filbert. *US Army Medical Research Institute of Chemical Defense, APG, MD, USA; [2]La Salle University, Philadelphia, PA, USA.* Sponsor: T Shih.

Soman produces limbic seizures and seizure-related brain damage (SRBD). Soman irreversibly inhibits acetylcholinesterase, causing an elevation in acetylcholine concentration in the brain. However, there is considerable evidence that soman-induced SRBD stems from glutamate excitotoxicity. Studies have shown that metabolic impairment greatly exacerbates the excitotoxic effects of glutamate. Prevention of ATP depletion by PARPI provides considerable neuroprotection in various models. To examine the neuroprotective effects of the PARPI, benz-amide, on brain damage from soman-induced seizures, rats were challenged with 180m g/kg soman (i.e., 1.6 LD_{50}). HI-6 and atropine methylnitrate given to protect against the peripheral effects of soman. Rats received two intraperitoneal injections of 320mg/kg benzamide: 5 and 40min post-seizure onset, or 40 and 120min post-seizure onset, and euthanatized 29h after soman administration. Alternate brain hemispheres were processed for microtubule-associated protein 2 (MAP2) immunohistochemical staining or hematoxylin and eosin (H&E) histochemical staining. Macroscopic temporal lobe necrosis was assessed using morphometric image analysis of MAP2-negative immunostaining. H&E-stained sections were examined for classical histo-pathology. In all rats that received benzamide, severity of convulsions was greatly diminished within 3min following the first injection, i.e., for both the 5/40min and 40/120min groups. Despite its marked effect on convulsions, benzamide did not overtly alter ECoG evidence of status epilepticus, compared to soman-positive controls. However, a marked decrease in macroscopic temporal lobe necrosis was seen in both benzamide treatment groups, and was most pronounced in the 40/120 min treatment group. These preliminary findings suggest that inhibition of PARP by benzamide can provide neuroprotection against soman-induced SRBD.

412 CHARACTERIZATION OF DOPAMINE-INDUCED EXPRESSION OF *GADD45* AND *GADD153* IN HUMAN NEUROBLASTOMA CELLS.

K E Vrana, W M Freeman, M Aschner, W G Jerome III, K W Grant and A H Stokes. *Wake Forest University School of Medicine, Winston-Salem, NC, USA*

Dopamine (DA), while an essential neurotransmitter, is also a known neurotoxin and has been implicated in several neurodegenerative diseases. DA metabolism and oxidation have been demonstrated to produce reactive oxygen species (ROS). Moreover, DA can be oxidized to a reactive quinone through spontaneous and catalyzed (*via* enzymes or metals) reactions. In the present studies, human neuroblastoma (SK-N-SH) cells were killed by high concentrations of DA (100-300 mM). The sensitivity of the cells was dramatically enhanced by treatments that reduced endogenous glutathione (2 mM L-BSO). Cells undergoing DA-induced cell death exhibit molecular markers (internucleosomal DNA fragmentation, chromatin condensation, membrane blebbing) consistent with programmed cell death (apoptosis). These results indicate that apoptotic pathways are induced in response to DA toxicity. Multiplex hybridization array technology demonstrated that cells, treated with DA (300 mM for 18 hours), induced *GADD45* and *GADD153* (Growth arrest and DNA-damage inducible) gene expression by three-fold. Subsequent northern blot analysis confirmed these DA-induced changes in *GADD* gene expression. Currently, the precise function of the *GADD* gene products is unclear. It is known that these genes are upregulated in response to stress to allow the cells to repair the damage. It appears that DA, through the formation of ROS and quinones, can damage cellular macromolecules to a point of inducing *GADD* gene expression.

413 OVEREXPRESSION OF CYCLIN D1 AND METALLOTHIONEIN AND CELL KINETICS IN THE EARLY PROCESS OF URINARY BLADDER CARCINOGENESIS INDUCED BY TREATMENT WITH *N*-BUTYL-*N*-(4-HYDROXY BUTYL)NITRO-SAMINE OR SODIUM L-ASCORBATE.

K Takaba[1,2], K Saeki[1], K Suzuki[1], H Wanibuchi[2] and S Fukushima[2]. [1]*Toxicol Res Lab, Kyowa Hakko, Yamaguchi, Japan;* [2]*Dept Pathol, Osaka City Univ Med Sch, Osaka, Japan.*

This experiment is to clarify effects of genotoxic *N*-butyl-*N*-(4-hydroxybutyl)nitrosamine (BBN) and non-genotoxic sodium L-ascorbate (Na-AsA) on significant protein expression, cell proliferation and apoptosis of the bladder epithelium during and after treatment with these chemicals. The influence of testicular castration was also investigated. A total of 320 six-week-old male F344 rats were divided into six groups. Testicular castration was conducted to groups 4-6 at 2 weeks before chemical treatment. BBN (0.05% in drinking water) was given to groups 1 and 4 for 8 weeks. Na-AsA (5% in diet) was given to groups 2 and 5 for 8 weeks. Groups 3 and 6 were used non-treatment controls. The urinary bladder was removed at the end of weeks 6, 10, 11, 12, 14 and 18, and examined by H&E, TUNEL, immunohistochemistry (incorporated BrdU, cyclin D1 and metallothionein: MT) and FCM. Overexpression of cyclin D1 and MT was induced with BBN but not with Na-AsA. Cyclin D1 positive cells were scarcely found in metallothionein-positive region. MT overexpression was seldom observed in papillomas and never found in a carcinoma, suggesting MT would protect genes from insult by genotoxic carcinogens. Cell proliferation and apoptotic parameters showed no qualitative distinctions between treatment and cessation of BBN or Na-AsA. The testicular castration only inhibited the BBN induced bladder tumor development as comparison with total number of neoplasm in non-castrated animals.

414 ROLE OF OXIDATIVE STRESS IN CHROMIUM(VI)-INDUCED APOPTOSIS IN NORMAL HUMAN LUNG CELLS.

J Singh[1], D E Pritchard[1], D L Carlisle[1], J A McLean[2], A Montaser[2], V Hu[3] and S R Patierno[1]. *Departments of* [1]*Pharmacology,* [2]*Chemistry and* [3]*Biochemistry, George Washington University Medical Center, Washington, DC.*

Particulate forms of chromium(VI) [Cr(VI)] cause lung cancer and respiratory tract toxicity in occupationally-exposed workers. Both soluble sodium chromate and particulate lead chromate induced apoptosis in cultured normal human lung fibroblasts (HLF) and small airway epithelial (HSAE) cells. To determine whether oxidative damage contributes to Cr(VI)-induced apoptosis, oxidative stress was measured in Cr(VI)-treated HLF by fluorescent imaging using dichlorodihydro fluorescein diacetate. Elevated oxida-

tive stress was observed in HLF within minutes of exposure to apoptogenic doses of sodium chromate and also at the end of a 24 hour exposure. Individual Cr(VI)-treated cells differed in the magnitude of increase in oxidative stress, suggesting heterogeneity of cellular responses. DNA from Cr(VI)-treated HLF and HSAE cells was analysed by inductively coupled plasma mass spectrometry to quantitate Cr-DNA adducts as a biomarker for exposure. A dose-dependent formation of Cr-DNA adducts was seen. Melatonin, a potent physiological free radical scavenger, abrogated Cr(VI)-induced apoptosis in both cell types. Further studies will test the following hypotheses: (i) melatonin increases clonogenic survival of Cr(VI)-treated HLF; (ii) melatonin diminishes Cr(VI)-induced oxidative stress; and (iii) melatonin modulates the formation of Cr-DNA adducts. Our results suggest that oxidative stress may play a role in Cr(VI)-induced apoptosis, and thus, may also be involved in chromium-induced toxicity and carcinogenesis. (Supported by NIEHS grant ES05304.)

415 APOPTOSIS A POTENTIAL MECHANISM OF GERM CELL DEATH IN MERCURIC CHLORIDE INDUCED REPRODUCTIVE TOXICITY.

A Atkinson, A Khan, T Graham, S Thompson, K Ali, S Hussain, and S Ali. *CVMNAH, Tuskegee University, Tuskegee, AL.*

The potential for reproductive toxicity of mercuric chloride (HgCl2) was evaluated in Sprague Dawley rats . For twelve weeks Fo male and female rats were exposed to mercuric chloride by daily gavage. Treatment groups consisted of 0.0 :00, 0.5:0.75 and 1.0:1.50 mg/kg/day in males and females, respectively. Fo males were dosed continuously throughout mating and the females were dosed continuously throughout mating, gestation and lactation. The Fo generation showed that oral exposure to HgCl2 impairs fertility, litter size, viability and weaning indices. In the F1 generation, the absolute weights of the left and right testes in the middle dose group were significantly lower than the control. Serum testosterone levels in the 1.5 mg/kg/day for males was reduced by 60%, suggesting that steroidogenesis in these animals may have been impaired. In the present study, the role of apoptosis in the germ cell loss was evaluated. Apoptosis was assessed in control and treated animals by terminal deoxynucleotidel transferase binding to exposed 3'-OH ends of DNA Fragment End Labeling (FragELTM). Observation of oligonuclesomal DNA fragments detectable as a DNA ladder in agrose gels was barely detectable after HgCl2 exposure. However, FragEL staining of testis cross section indicated that germ cell apoptosis increased significantly after toxicant exposure, thus providing a molecular-biology based, end-labeling histochemical (or cytochemical) technique for toxicant-induced testicular injury.

416 EPOXYBUTENE AND DIEPOXYBUTANE INDUCE APOPTOSIS IN MOUSE THYMOCYTES THROUGH DIFFERENT PATHWAYS.

C M Zwickl[1], J E Klaunig[2], and D Wierda[1]. [1]*Eli Lilly and Company, Greenfield, IN, USA;* [2]*Indiana University School of Medicine, Indianapolis, IN, USA.*

1,2-epoxybutene-3 (EB) and 1,2,3,4-diepoxybutane (DB) are reactive metabolites of 1,3-butadiene, a chemical commodity and air pollutant. Chronic exposure of mice to butadiene is associated with an increased incidence of T-cell leukemia/lymphoma, bone marrow and reproductive organ toxicity, and reduced thymus cellularity. In $B6C3F_1$ mice injected ip daily with 60, 90, or 120 mg/kg of EB for up to 14 days, the number of thymocytes decreases rapidly, reaching a nadir between the 3rd and 7th doses. To investigate potential mechanisms which could lead to a loss of thymocytes, the ability of EB and DB to initiate apoptosis was determined in vitro. One million freshly isolated thymocytes from young adult C57Bl/6 mice were exposed to increasing concentrations of EB or DB and the percentage of viable, apoptotic, and necrotic cells was determined at various times using HO33342 and 7-AAD dye uptake. Dexamethasone (0.1 μM) and γ-irradiation (500 cGy) were used as positive controls. EB (1 mM) and DB (0.1 mM), both induced thymocyte apoptosis which reached a maximum level at 12 hours. Using thymocytes from homozygous p53 knockout mice (C57Bl/6 background), it was determined that apoptosis induced by EB or dexamethasone operated independently of p53, whereas apoptosis induced by DB or γ-irradiation depended on p53 function. Further, EB-induced apoptosis was blocked by actinomycin but not by cycloheximide, whereas apoptosis induced by DB was blocked by either inhibitor. It is concluded that EB and DB both induce apoptosis in thymocytes, but through different induction pathways.

417 CELL DEATH OF HUMAN HT29 COLON CARCINOMA CELLS IS ACTIVATED BY CANCER PREVENTIVE DETOXIFICATION ENZYME INDUCERS.

W G Kirlin[1], J Cai[2], M J DeLong[3], E J Patten[3], Y G Wirsiy[1], and D P Jones[2]. [1]*Morehouse School of Medicine, Atlanta, GA; Emory University* [2]*School of Medicine and* [3]*School of Public Health, Atlanta, GA.*

Chemicals that induce the detoxification enzymes glutathione S-transferase (GST) and NAD(P)H:quinone reductase (N:QR) are under intense investigation as potential cancer chemopreventive agents with the capacity to enhance elimination of carcinogens. Representative chemicals, including allyl sulfide, benzyl isothiocyanate (BIT), butylated hydroxyanisole, dimethyl fumarate (DMF) and Sudan I, were found to activate a delayed cell death in HT29 colon carcinoma cells over the same concentration range that induces GST and N:QR enzyme activity. This cell death has some features of apoptosis, including morphological changes, an increased proportion of sub-G1 phase cells, caspase activation and a weakly expressed TUNEL-positive assay. Of the enzyme inducers tested, BIT and DMF were the most effective in promoting cell lifting by 20- and 4-fold, respectively, and a two-fold increase in caspase activation, as compared to controls. The effects of these chemicals on both enzyme activity and cell death were potentiated by pretreatment with sodium butyrate, which induces HT29 cell differentiation. Activation of cell death in cancerous or precancerous cells may provide an additional mechanism whereby these dietary constituents may protect against cancer. (Support: GM-028248, ES-09047.)

418 SIGNAL TRANSDUCTION IN PAH-INDUCED PREB CELL APOPTOSIS.

S A Quadri, A N Qadri and D H Sherr. *Department of Environmental Health, School of Public Health, Boston University Medical Center, Boston MA.*

Protein kinase C (PKC) activation has been implicated in the rescue of B cell apoptosis as well as aryl hydrocarbon receptor (AhR)-mediated signal transduction under *in vitro* conditions. We have previously reported that a prototypic polycyclic aromatic hydrocarbon, 7,12-dimethylbenz[a]anthracene (DMBA), induces apoptosis in AhR^- mouse preB (BU-11) cells grown on AhR^+ bone marrow stromal cells and that apoptosis is dependent on the AhR or AhR-regulated genes. These studies have been extended to evaluate potential signaling pathways within bone marrow stromal cells or apoptotic preB cells. Herein, it is shown that DMBA-induced BU-11 cell apoptosis was inhibited by PKC activators (PMA and mezerein) in a dose dependent manner. In contrast, the PKC inhibitors staurosporin, fisetin, quercetin and apigenin increased the percentage of apoptotic BU-11 cells when stromal/BU-11 cell cultures were co-treated with DMBA. A mitogen activated protein kinase (MAPK) inhibitor PD98059 blocked DMBA-induced apoptosis at the dose of 10 μ M. The possibility that this documented AhR antagonist inhibited apoptosis by blocking AhR activity as well as MAPK activity is under investigation. Collectively, these data implicate AhR, PKC and/or MAPK activation in either inducing a death signal from bone marrow stromal cells and/or transducing the apoptosis signal within target preB cells. 419 THE ROLE FOR APOPTOSIS IN THE CYTOTOXIC RESPONSE TO KEY MILITARY COMPOUNDS.

D S Rosenthal[1], C M Simbulan-Rosenthal[1], H Boulares[1], S Iyer[1], W J Smith[2], R Ray[2] and M E Smulson[1]. [1]*Department of Biochemistry and Molecular Biology, Georgetown University School of Medicine, Washington, DC;* [2]*USAMRICD, Aberdeen Proving Ground, MD.* Sponsor: A R Scialli.

We are testing the mechanisms by which two substances of military significance, sulfur mustard (SM) and jet fuel (JP-8), cause pathology. SM may cause basal cell death and detachment via induction of terminal differentiation and apoptosis. Following treatment of normal human epidermal keratinocytes with 10 μM or 100 μM SM, epidermal differentiation-specific markers are induced. Examination of biochemical markers of apoptosis following treatment of either primary or immortalized keratinocytes revealed a burst of poly(ADP-ribose) synthesis, proteolysis of poly(ADP-ribose)polymerase (PARP) *in vivo* and *in vitro* into characteristic 89 kDa and 24 kDa fragments, processing of caspase-3 into its active form, and appearance of DNA ladders. The intracellular calcium chelator BAPTA suppressed differentiation markers, while antisense oligonucleotides and chemical inhibitors

specific for calmodulin blocked both markers of differentiation and apoptosis. Modulation of p53 levels utilizing retroviral constructs expressing the E6, E7, or E6 +E7 genes of human papillomavirus (HPV) 16 revealed that SM-induced apoptosis was partially p53-dependent. Finally, immortalized fibroblasts derived from PARP -/- "knockout mice" were exquisitely sensitive to SM-induced apoptosis. These cells became SM-resistant when PARP was stably reintroduced in these cells. These results indicate that SM exerts its effects via calmodulin, p53, and PARP-sensitive pathways. We are performing similar experiments with JP-8 to determine if this compound exerts similar effects on keratinocytes and hepatocytes. (This work was supported by contract DAMD17-96-C-6065 (to DSR) and contract DAMD17-90-C-0053 (MES) from the US Army Medical Research and Development Command, and US Air Force Office of Scientific Research Grant AFOSR-89-0053.)

420 ACETAMINOPHEN (APAP) INDUCES CLEAVAGE OF POLY(AD-RIBOSE) POLYMERASE (PARP) AND DNA-DEPENDENT PROTEIN KINASE (DNA-PK) BY ACTIVATING CASPASES IN JURKAT T CELLS.

A H Boulares, B A Stoica, S K Hasan, S Iyer and M E Smulson. *Georgetown University, Department of Biochemistry and Molecular Biology, Washington, DC, USA.* Sponsor: A R Scialli.

APAP is a widely used analgesic and antipyretic drug which can be toxic at non-therapeutic doses. We have examined the effect of 10 mM APAP on cell viability of the human Jurkat T cells. Cell death was observed as early as 6 h after treatment which increased with time to reach 50% by 12 h. Hoechst staining of treated cells revealed nuclear condensation indicating that APAP was causing apoptosis in these cells. However, little DNA fragmentation was observed when analyzed by electrophoresis. APAP treatment lead to cleavage of the DNA repair enzymes PARP and DNA-PK through the activation of caspase-3. Activation of caspase-3 could be due, in part, to an activation of caspase-8 without an apparent upregulation of the Fas receptor. An early activation of PARP manifested by poly(ADP-ribosyl)ation of nuclear proteins was also observed indicating a generation of DNA breaks. Pulse field electrophoresis analysis of DNA from treated cells revealed a generation of 50 kb fragments which accumulated overtime without further processing explaining the lack of DNA ladders. This could be in part, to an inhibition of the DNA fragmentation factor (DFF-40) responsible for DNA fragmentation since its inhibitor DFF-45 was cleaved. Our results indicate that APAP activates early and intermediate events of apoptosis, however, it interferes with DNA fragmentation. (This work was supported by contracts DAMD17-90-C-0053 from the US Army Medical Research and Development Command and AFOSR-89-0053 from US Air Force office of Scientific Research.)

421 GENERATION AND DETECTION OF APOPTOSIS IN RAT LIVER SLICES.

M K Chitkara, J S Petrick, A R Parrish, and A J Gandolfi. *Department of Anesthesiology, University of Arizona, Tucson, AZ.*

Apoptosis has been previously produced and detected in cell cultures. Since organ cultures reflect the whole animal more closely than cell cultures, this study was designed to determine whether apoptosis will occur in precision-cut rat liver slices exposed to specific toxic insults, and to find a compound that will induce apoptosis in liver slices in a consistent manner. Staurosporine, a protein kinase C inhibitor, is known to consistently cause apoptosis in hepatocyte cell cultures. Liver slices were prepared from 250 g male Sprague-Dawley rats and incubated with 0.5 or 10 μM staurosporine for 2-8 hr. Apoptosis was detected by DNA fragmentation, amplification of the Bax gene, and histologically. A concentration-dependent loss of LDH and K^+ was observed in liver slices. Agarose gel electrophoresis of DNA harvested from the slices contained a 'smear' with only minimal laddering. Bax gene expression was enhanced following a 2 hr exposure to 0.5 μM staurosporine, but not 10 μM. Nuclear margination of chromatin was observed in cells, however, a considerable amount of necrosis was also seen. Combined, these results indicate that although several apoptotic features were observed, staurosporine also elicited necrosis at the concentrations used in precision-cut rat liver slices. More importantly, however, the data suggests that precision-cut tissue slices present a useful in vitro system for the detection of apoptosis.

422 SPECIES-SPECIFIC INDUCTION OF APOPTOSIS IN RAT AND DOG LIVER SLICES BY SDZ 249 665.

U Schramm, C Lorez and A Wolf. *Novartis Pharma AG, Experimental Toxicology, Basel, Switzerland.* Sponsor: A De Brugerolle de Fraissinette.

SDZ 249 665 is a capsaicin analogue with promising data on its pharmacological profile in the clinical indication pain. SDZ 249 665 was well tolerated in preclinical safety studies in rats but not in dogs. In dogs the compound caused severe liver toxicity in a 2 week study already at a dose levels of 2 mg/kg/day with periportal apoptosis like hepatocellular necrosis/lysis. It was the purpose of the present study to mimic the in vivo situation by an in vitro model, which can be also used for the risk assessment in man. Liver slices of rat and dog were selected in order to evaluate the SDZ 249 665 species specific effects on apoptosis. Rat and dog liver slices were incubated for 24 hours with SDZ 249 665 at concentrations of 0.1, 1, 10 and 100 μ M. TGFβ $_1$ at concentrations of 5 and 10 ng/ml was used as positive control. Apoptosis was determined by chromatin condensation (Feulgen) and DNA fragmentation (TUNEL). Lactate dehydrogenase (LDH) leakage was determined as a parameter of cytotoxicity. In both rat and dog liver slices TGFβ $_1$ caused a dose-dependent increase of apoptosis, reaching maximum values of about 2-3 fold above the basic apoptotic level of controls (1-3 %). In dog liver slices treatment at non cytotoxic concentrations of 0.1, 1 and 10 μ M SDZ 249 665 resulted in apototic rates which were about 2-3 times greater than that of controls. In rat liver slices SDZ 249 665 had no effect. Since the present results reflect the in vivo species-specific findings very accurate, risk extrapolation to man seems possible by means of human liver slices.

423 URIDINE ADMINISTRATION DOES NOT PROTECT FROM GALACTOSAMINE-INDUCED HEPATOCTYE APOPTOSIS IN RATS.

J M McMillan. *Department of Cell and Molecular Pharmacology and Experimental Therapeutics, Medical University of South Carolina, Charleston, SC.*

Galactosamine is a well-known model hepatotoxin. The hepatic lesion described by Keppler *et al.* in 1968 is a scattered focal hepatic necrosis. Recent reports have demonstrated that galactosamine also induces hepatocyte apoptosis when given to rats or mice. In the present studies we wanted to examine the time-dependency for the development of apoptosis and compare it to that for development of hepatic necrosis. Further, we wished to determine whether galactosamine-induced apoptosis could be prevented by administration of a hepatoprotective dose of uridine. For the time course studies, male rats were given a hepatotoxic dose of galactosamine (800 mg/kg) by ip injection. At various times later their livers were removed and processed for microscopic examination by H&E staining (apoptosis and necrosis) and by staining for apoptosis using the ApopTag® protocol. We observed a time-dependent increase in apoptosis, with peak induction (15%) occurring at 12 hrs after galactosamine treatment, followed by a subsequent decline over the next 24 hrs. In contrast, hepatic necrosis (11%) was not evident until 36 hrs after galactosamine treatment. In additional studies, animals were treated with uridine (800 mg/kg) at the same time as galactosamine and the livers were examined for apoptosis and necrosis 12 hrs and 36 hrs later. Uridine administration effectively prevented galactosamine-induced necrosis as observed at 36 hrs, however, development of apoptosis at either 12 or 36 hrs was not prevented. These data demonstrate that development of galactosamine-induced apoptosis precedes development of hepatic necrosis. Of importance, development of apoptosis appears to be independent of uridine nucleotide depletion. (Supported by NIH DK47185.)

424 DYSREGULATION OF APOPTOSIS BY c-*myc* IN TRANS-GENIC HEPATOCYTES AND EFFECTS OF GROWTH FACTORS AND NONGENOTOXIC CARCINOGENS.

J G Christensen[1,2], T L Goldsworthy[2], and R C Cattley[2]. [1]*Department of Toxicology, North Carolina State University, Raleigh, NC;* [2]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

Regulation of apoptosis is an important factor in multistage hepatocarcinogenesis. The objectives of the present study were to determine (1) whether apoptosis regulation is altered in transgenic hepatocytes that overexpress c-*myc* and (2) if growth factors or nongenotoxic carcinogens alter apoptosis regulation in c-*myc* vs. wild-type (wt) hepatocytes. Hepatocytes isolated from c-*myc* transgenic mice had 3 to 4-fold increased c-*myc* RNA and protein levels in addition to increased apoptosis compared to wt hepatocytes. The increased apoptosis in c-*myc* hepatocytes was accompanied by

increased p53, bax, and bak and decreased bcl-2 protein levels. Hepatocytes overexpressing c-*myc* were more sensitive to bleomycin-induced apoptosis but less sensitive to TGF-b-induced apoptosis. TGF-a inhibited apoptosis, increased bcl-xL, and decreased bak protein levels in c-*myc* hepatocytes but not wt hepatocytes. IGF-II did not affect apoptosis in c-*myc* or wt hepatocytes. Phenobarbital inhibited apoptosis in c-*myc* hepatocytes but not wt hepatocytes and decreased p53 and bax and increased bcl-2 protein levels. Nafenopin inhibited apoptosis in both c-*myc* and wt hepatocytes, while TCDD did not inhibit apoptosis in either wt or c-*myc* hepatocytes. This study demonstrated that overexpression of c-*myc* altered the response to apoptotic stimuli in transgenic hepatocytes. Furthermore, phenobarbital and TGF-a inhibited c-*myc*-induced apoptosis, potentially resulting in a selective growth advantage for an initiated cell population and representing a mechanism for tumor promotion.

425 POLY (ADP-RIBOSE) POLYMERASE MODULATORS 4-AMINOBENZAMIDE (AB) AND NOCOTINAMIDE (NICO) PROTECT AGAINST ACETAMINOPHEN (AAP)-INDUCED HEPATOTOXICITY IN MICE BY INFLUENCING EXPRESSION OF BCL-XL AND p53.

S D Ray, G Balasubramanian[1], A Khander, C S Reddy[1] and D Bagchi[2]. *Dept. of Pharmacol., Toxicol. & Med. Chem., Coll. of Pharm. and Hlth. Scs., Long Island Univ., Brooklyn, NY; [1]Dept. of Vet. BioMed Scs., Univ. of Missouri, Columbia, MO; [2]Creighton Univ., Coll. of Pharm. and Allied Hlth. Prof., Omaha, NE.*

It is well known that the oncogene bci-X_L and anti-oncogene p_{53} play a role in apoptotic death *in vitro* and *in vivo*. This study was designed to investigate whether agents that modulate DNA repair through poly (ADP-ribose) polymerase (PARP) activity (AB & NICO) can protect against AAP-induced DNA fragmentation and hepatotoxicity, and do so by altering expression of the apoptosis-regulating genes, bci-X_L and p_{53}. Male ICR mice (3 months old, 30-40 gms) were administered AAP (500mg/kg, ip) or AAP plus one of the protective agents one hr later (AB, 400mg/kg, ip; NICO, 250mg/kg, ip). Chlorpromazine (CPZ, 25mg/kg, ip), a Ca^{2+}-antagonist acting through another mechanism was also used. Animals were sacrificed 24 hrs following the drug administration. Serum chemistry (ALT) and hepatic histopathology, DNA and western blot analysis for bci-X_L was downregulated and p_{53} was upregulated by AAP. The effect of AAP on bci-X_L was antagonized and that on p_{53} was synergized by both PARP-modulating agents, whereas CPZ was without effect on both bci-X_L and P_{53}. These results suggest that antagonism of AAP-induced hepatocellular apoptosis and/or necrosis by modulators of PARP may be mediated by their influence on bci-X_L and/or p_{53}.

426 ARYL HYDROCARBON RECEPTOR REGULATION OF CERAMIDE-INDUCED APOPTOSIS IN MURINE HEPATOMA CELLS.

J J Reiners, Jr., and R E Clift. *Institute of Chemical Toxicology, Wayne State University, Detroit, MI, USA.*

The relationship between aryl hydrocarbon receptor (AHR) content and susceptibility to apoptosis was examined in the murine hepatoma 1c1c7 cell line and a series of variant cell lines having different levels of AHR expression. Exposure of 1c1c7 cultures to N-acetyl-sphingosine (C2-ceramide), a cell permeable analog of ceramide, caused a concentration-dependent inhibition of cell proliferation and induction of apoptosis, as monitored by analyses of caspase activation and DNA fragmentation. A variant line (Tao) having ~10% of the AHR content of 1c1c7 cells also arrested following exposure to C2-ceramide. However, Tao cells were resistant to C2-ceramide-induced apoptosis. Modulation of Tao and 1c1c7 AHR contents by transfection of *Ahr* sense and antisense constructs, respectively, confirmed the relationship between AHR content and susceptibility to C2-ceramide-induced apoptosis. The AHR ligands 2,3,7,8-tetrachlorodibenzo-*p*-dioxin and alpha-naphthoflavone neither induced apoptosis nor modulated the development of apoptosis in C2-ceramide treated 1c1c7 cultures. Ceramide also induced the apoptosis of BP^{r}c1 cells, a variant line having normal AHR contents, but lacking a functional aryl hydrocarbon receptor nuclear translocator (ARNT) protein. These results suggest that the AHR modulates aspects of ceramide signaling associated with the induction of apoptosis but not cell cycle arrest, and does so by a mechanism that is independent of its interaction with ARNT. (This work was supported in part by NIH grant CA34469.)

427 PARTICIPATION OF SERTOLI CELL-EXPRESSED FASL IN THE INITIATION OF GERM CELL APOPTOSIS IN YOUNG RAT TESTIS AFTER EXPOSURE TO MONO-(2-ETHYLHEXYL) PHTHALATE (MEHP).

J H Richburg, K D Wurm, H Gao and A Nañez. *College of Pharmacy, Division of Pharmacology & Toxicology, The University of Texas, Austin, TX.*

The Fas/Apo-1/CD95 signaling system is an important regulator of germ cell apoptosis in mammalian testis. Germ cell apoptosis occurs to limit their numbers in order to match the Sertoli cell's supportive capacity. Sertoli cells, via expression of FasL, initiate apoptosis of Fas-bearing germ cells (*Endocrinol.*, 1997, 138:2081). In this study, alterations in the expression of FasL were measured in 28-day-old Fisher rats after exposure to the widely studied Sertoli cell toxicant, mono-(2-ethylhexyl) phthalate (MEHP, 2 g/kg, p.o). After 3 h of MEHP exposure, immunohistochemical staining of FasL was changed from a Sertoli cell basal membrane to an adluminal membrane localization. The intensity of theFasL staining increased over the exposure time course (3, 6 & 12 h). It is along the adluminal membrane of the Sertoli cell where apoptotic germ cells are observed after MEHP treatment. Western blot analysis demonstrated a time-dependent increase in the production of the soluble form of FasL after MEHP exposure (129, 144 & 161% at 3, 6 &12h, respectively). The ability of FasL to bind to Fas is abolished in *gld* mice which have a point mutation near the C-terminus of the coding region for FasL. Exposure of *gld* mice to MEHP did not result in a significant increase in germ cell apoptosis up to 24 h after exposure. However, in control mice there was a 2.5 fold increase in apoptosis. These data support the direct involvement of Sertoli cell-expressed FasL in the initiation of MEHP-induced germ cell apoptosis. (Supported by NIH/NIEHS ES09145 & ES07784.)

428 ALTERATIONS IN TESTICULAR CYTOSKELETAL AND SIGNALING PROTEIN DISTRIBUTION DURING GERM CELL DEATH.

T Jindo, R Wine, and R E Chapin. *NTP/NIEHS, RTP, NC, USA.*

Previous work on the testis lesion induced by ethylene glycol monomethyl ether (EGME) has found that several stages of spermatocytes are vulnerable, although pachytene spermatocytes are the most sensitive . Trans-cellular calcium movement has been implicated as an early event. Still unknown are other early responses to toxicity, and changes associated with cell death. In these studies, we used adult F344 rats killed 4, 8, 16 and 24 hrs after a single dose of 200 mg/kg EGME. Apoptotic death was histologically detectable 16 hrs after administration of EGME, so the 16 and 24 hr timepoints were used for subsequent studies. Reasoning that cytoskeleton and cell-cell signalling proteins would likely be involved in this cell death, we used immunohistochemistry to determine changes in the distribution of cytoskeletal (actin, tubulin) and signaling proteins (β -catenin, pp120, src, paxillin, E-cadherin, talin, α -catenin, vinculin, tensin). In addition, since one blocker of PKC had been previously shown to inhibit this lesion, we explored the distribution of a panel of antibodies to various PKC isoforms (μ , ζ , γ , α , β , ε , θ , λ , δ) in both control and EGME-treated rats. These studies found an increase in the staining intensity of PKC-μ , ζ and γ , pp120, actin, src, and paxillin around and/or in the dying germ cells at 16 and 24 hrs after treatment. With the exception of reduced src staining in Sertoli cells seen at 4 hrs after treatment, none of the changes preceeded visible apoptosis. These results identify at least some of the proteins involved in the development of this lesion.

429 BREATH VOLATILE ORGANIC CHEMICALS (VOCs) AS BIOMARKERS FOR HEPATIC CYTOCHROME P450 (CYP) ISOZYME ACTIVITIES.

J M Mathews[1], J H Raymer[1], A S Etheridge[1], G R Velez[1], and J R Bucher[2]. [1]*Research Triangle Institute, Research Triangle Park, NC and* [2]*NIEHS, Research Triangle Park, NC, USA.*

These studies were designed to determine if certain breath components are reflective of the activity of hepatic CYP enzymes. We have reported methodology for collection of VOCs in rat breath and analysis for over 100 consitiuent components (Raymer et al., Toxicol Methods 4:243-258, 1994). Changes in the profiles of VOCs present were determined after treatment with a general inhibitor of hepatic CYP isozymes (1-aminobenzotriazole, ABT), as well as isozyme-selective inhibitors. The major rat hepatic CYP isozymes monitored included CYP1A2 (<5% of P450), 2B1 (1%), 2C6

(20%), 2C11 (40%), 2E1 (10%), and 3A1 (20%). ABT is an inhibitor of CYP 2C6, 2C11, 2B1, 3A, 1A2 and 2E1 in rat. ABT treatment led to marked increases in a broad spectrum of VOCs (Mathews et al., Biomarkers 1:196-201, 1996). Isozyme-selective inhibitors were next used to link individual isozymes with specific components in breath. Inhibition of CYP1A2 with furafylline gave rise to only minor changes in the VOC profile and similarly, only minimal changes were linked to inhibition of CYP2C6 and 2C11. There was no effect on breath volatiles following inhibition of CYP3A. Inhibition of CYP2E1 with trans-1,2-dichloroethylene led to several-fold increases in n-hexane (26-fold) and methylketones (Mathews et al., Toxicol Appl Pharmacol 146: 255-260, 1997). Percent increases of methylketones in response to inhibition were inversely related to chain length, with acetone and 2-butanone > 2-pentanone >>2-hexanone > 2-heptanone. The remainder of the VOCs associated with general P450 inhibition with ABT, but not CYP2E1, were associated with a group of gas chromatography peaks eluting with eight-carbon volatile chemicals, including 1-octene, n-octane, 3-octene, 2-octene, 1,3-octadiene, and 3-methyl-1-heptene. These breath VOCs also increased following inhibition of CYP 2B1, but these inhibitors were not completely selective for 2B1. It is likely that these C8 breath components reflect the hepatic activity of this phenobarbital-inducible CYP. Thus, selected VOCs in breath can serve as biomarkers for the activity of CYP2E1 and possibly CYP2B1, but no breath markers for isozymes of the 1A, 2C, or 3A families were found.

430 EXPRESSION, CHARACTERIZATION, AND INHIBITION BY TELLURITE (TeO_3) OF RECOMBINANT HUMAN SQUALENE MONOOXYGENASE (SQUALENE EPOXIDASE).

B P Laden and T D Porter. *Graduate Center for Toxicology, University of Kentucky, Lexington, KY.* Sponsor: M Vore.

Tellurium is an element with a growing number of industrial applications, including the manufacture of semiconductors, doping of metal alloys, and vulcanization of rubber; however, little is known about its toxicology. In weanling rats tellurium produces a transient peripheral demyelination due to the inhibition of squalene monooxygenase, an enzyme in the pathway for cholesterol biosynthesis. Squalene monooxygenase is a membrane-bound flavoprotein that uses NADPH-cytochrome P450 reductase as a source of reducing equivalents. To study the potential mechanisms of tellurium toxicity in humans, the cDNA for human squalene monooxygenase was cloned and expressed in *Escherichia coli*. Expression was enhanced by deleting the first 110 amino acids from the N-terminus, based on studies by others with the rat enzyme. The enzyme was expressed as a chitin binding domain-intein fusion protein and purified by affinity chromatography. Squalene monooxygenase activity was determined by measuring the formation of 2,3-oxidosqualene from ^{14}C-radiolabeled squalene; the products were separated by thin layer chromatography and visualized by electronic autoradiography. Preliminary results indicate a Km of 10 μ M for squalene, similar to published values for the rat and pig enzymes. An estimated IC_{50} of 17 μ M was obtained with sodium tellurite (TeO_3); tellurate (TeO_4) was not inhibitory. Thus, squalene monooxygenase is a potential target of tellurium toxicity in man. (Supported by the American Heart Association, Kentucky Affiliate; KY EPSCoR NSF Cooperative Agreement; and NIEHS Training Grant ES-07266.)

431 EFFECTS OF XENOBIOTICS ON STEROIDOGENIC CYTOCHROME P-450 (CYP450) ENZYME EXPRESSION IN HUMAN H295R ADRENOCORTICAL CARCINOMA CELLS.

J T Sanderson and M van den Berg. *Research Institute for Toxicology, Utrecht University, Utrecht, The Netherlands.*

The H295R cell line was deployed to investigate potential effects of xenobiotics on the expression and catalytic activity of several steroidogenic CYP450s. H295R cells, cultured in medium containing steroid-free serum, produce many steroid hormones and express numerous steroidogenic CYP450s, including CYP11A, CYP11B1, CYP11B2, CYP17, CYP19 and CYP21. We examined the effects of several environmental contaminants on the levels of messenger RNA and the catalytic activity of CYP11A (cholesterol side-chain cleavage) and CYP19 (aromatase) in untreated or 8-bromocyclic AMP-(8BrcAMP)-treated H295R cells. mRNA levels were determined semi-quantitatively using RT-PCR and catalytic activities were determined using specific substrates and inhibitors. 8BrcAMP induced CYP11A and CYP19 in H295R cells (mRNA levels 3- and 10-fold relative to β-actin; catalytic activities 2- and 10-fold, respectively). Established pharmacological inhibitors were able to inhibit the activity of both enzymes by >90%. Exposure of H295R cells to 100 μM tetrachlorodibenzo-*p*-dioxin (TCDD) 24 h prior to treatment with 8BrcAMP led to a significantly reduced ability of 8BrcAMP to induce CYP11A mRNA (about 40% reduction; $p<0.05$). The same was true for benzo[a]pyrene. TCDD and benzo[a]pyrene exposure resulted in a moderate reduction in the ability of 8BrcAMP to induce the catalytic activity of CYP11A (about 30% reduction). No effects of exposure to the two compounds were observed on basal activities of CYP11A. Significant effects on CYP19 mRNA levels or activities (with or without induction) were not observed. At present, potential effects of a number of environmentally important pesticides including atrazine and several of its metabolites are being investigated in the H295R cell line. In summary, our results indicate that the H295R cell line is suitable for the detection of potential effects of xenobiotics on the expression and activity of steroidogenic CYP450 enzymes.

432 INFLUENCE OF TAMOXIFEN ON HORMONALLY REGULATED CYTOCHROME P450 ENZYME EXPRESSION IN RATS.

L M Ickenstein and S M Bandiera. *Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada.*

Tamoxifen, a partial estrogen antagonist in humans used widely in the treatment of breast cancer, has been reported to suppress growth hormone (GH) secretion in both rats and humans and therefore may alter expression of hormonally regulated cytochrome P450 (CYP) enzymes. The purpose of this study is to investigate the long-term hormone-mediated effects of tamoxifen on CYP enzymes in rat liver. Adult female rats were injected s.c. with tamoxifen at 0.5, 5, 20, 100, or 200 mg/kg b.w. for two consecutive days and hepatic microsomes were prepared 35 days later. Administration of tamoxifen at all doses tested decreased somatic growth in male and female rats. The testosterone 7α-hydroxylase activity and CYP2A1 protein content in hepatic microsomes from female rats that received doses greater than 5 mg/kg was decreased by approximately 40% and 35%, respectively, as compared to the control group. The same treatment had no effect on the testosterone 6α-, 6β-, 16α-, 16β-, 2α-, and 2β-hydroxylase activities and on the hepatic microsomal content of CYP 2B1, CYP2B2, and CYP3A. In adult male rats, the testosterone 7α-hydroxylase activity was increased by approximately 40%, but the hepatic microsomal CYP2A1 protein level was not affected significantly in the treatment group receiving doses of 200 mg/kg. The testosterone 16α- and 2α- hydroxylase activities were decreased by approximately 44% and the hepatic microsomal CYP2C11 content was decreased by approximately 30%. The same treatment had no effect on the testosterone 6β-, 16β-, and 2β-hydroxylase activities and on the hepatic microsomal content of CYP 2B1, CYP2B2, and CYP3A. Thus far, analysis of plasma GH concentrations suggests that the effect of tamoxifen on specific hepatic CYP enzymes was not mediated by changes in plasma GH levels. In conclusion, tamoxifen treatment resulted in a long-term alteration of specific hepatic CYP enzymes in male and female rats, which has not been reported previously and is different from the direct, inductive effects of tamoxifen on hepatic CYP enzymes.

433 DETECTION OF CATECHOL ESTROGENS BY GAS CHROMATOGRAPHY / ELECTRON CAPTURE (GC-ECD).

K Pinnella, J Tessari, B Cranmer, and G Cosma. *Department of Environmental Health, Colorado State University, Fort Collins, CO, USA.*

Catechol estrogens, the oxidative metabolites of estrogen, have been shown to play important roles in both physiologic and pathologic processes. Catechol estrogens may be further metabolized via cytochrome P450 (P450)-catalyzed reactions to quinones that can undergo redox cycling reactions, producing oxygen radical species that can cause oxidative DNA damage. Thus, P450-catalyzed estrogen metabolism may play an important role in carcinogenesis, and environmental chemicals that alter P450 activities may contribute to oncogenesis through this mechanism. We have modified a GC-ECD method to detect 2-hydroxyestradiol (2-OHE2) and 4-hydroxyestradiol (4-OHE2) metabolites in rat liver microsomes. The modified method employs a simple, multiphase extraction procedure which first extracts the analytes from microsomal preparations (quenched with 2% sodium sulfate solution (2% Na_2SO_4)) into dichloromethane (DCM), followed by solvent exchange into acetonitrile-saturated with hexane (ACN/HEX) . Metabolites are then derivatized by acylation to heptafluorobutyrl esters in the ACN/HEX extract, the derivatization reaction quenched by addition of 2% Na_2SO_4, and the analytes extracted into n-hexane. Derivatized catechol estrogens are then separated by capillary column gas chromatography and quantified by electron capture detection. 4-bromoestradiol (4-BrE2) was chosen as a surrogate. This protocol optimizes sample clean up, improves

chromatography, and increases column life while maintaining extraction efficiency. A method quantitation limit normalized for microsomal protein content was 1.2 ng/μ g. All compounds achieved an acceptable level of reproducibility, with an average coefficient of variation of 8.6%. Ongoing studies are measuring 2- and 4-OHE2 in liver microsomes from animals exposed to chlorinated hydrocarbon inducers of P450 enzymes. (Support from NIEHS ES 09455-01.)

434 RAPID PURIFICATION OF BACULOVIRUS EXPRESSED HUMAN CYTOCHROME P-450 AROMATASE BY PERFUSION CHROMATOGRAPHY.

C A Gartner[1], S J Thompson[1], A E Rettie[1], N Harada[2], and S D Nelson[1]. [1]*Department of Medicinal Chemistry, University of Washington, Seattle, WA;* [2]*Division of Molecular Genetics, Institute for Comprehensive Medical Science, Fujita Health University, Toyoake, Aichi, Japan.*

Cytochrome P-450 aromatase catalyzes the conversion of androgens to estrogens. Because of the importance of estrogens in hormone dependent diseases such as breast cancer, and the enigmatic mechanism involved in estrogen formation, aromatase has been the subject of much clinical and academic interest in the recent past. We have developed a method to purify human aromatase using classical chemistries of adsorptive chromatography, but applied via high flow perfusion chromatography. *Tricoplusia ni* TN5 cells expressing aromatase were solubilized in buffer containing 1.1% sodium cholate and centrifuged. After removal of detergent by dialysis, lipids and suspended fines could be rapidly removed from the supernatant with complete recovery of the target protein by passage of the solution through a pad of Cell Debris Remover. At least 13 nmol P-450 per run could then be applied to a high-density phenyl perfusion hydrophobic interaction chromatography column at 6 mls per minute, washed, and eluted in under 15 minutes with 80-85% yield. The column eluate could then be directly applied to a high-density sulfopropyl perfusion cation exchange column at 7 mls per minute, washed, and eluted in about 5 minutes with 80-85% recovery. This preparation was applied to a hydroxyapatite column at high flow rates, washed, and eluted in about 20 minutes. All chromatographic purification steps, including equilibrations, could be performed in approximately two hours, with total yields of 50% being typical. This method yielded preparations which were homogenous when deglycosylated with peptide-N-glycosidase F and were suitable for kinetic analysis. (This project was supported in part by NIH Grant No. GM32165 (SDN), and NIH Training Grant No. GM07750 (CAG).)

435 FINGERPRINTING CYTOCHROME P450 AND mEH GENE EXPRESSION IN HUMAN LEUKEMIA CELL LINES.

B C Krovat, J H Tracy, and C J Omiecinski. *University of Washington, Department of Environmental Health, Seattle, WA, USA.*

The present study was conducted to validate human peripheral blood cells as a model to assess chemical induction of cytochrome P450 gene expression and to investigate the association between cell lineage and inducibility. We compared three different human blood cell lines, the erythroleukemia cell line HEL 92.1.7., the promyelocytic leukemia cell line HL-60 and the monocytic leukemia cell line THP, each representing a different lineage of human hemopoiesis. Using a highly sensitive quantitative-competitive RT-PCR assay, we established gene expression patterns for seven different CYP enzymes and microsomal EH. All cell lines exhibited relatively high constitutive mRNA levels of CYP2D6 and CYP2E1 (1.6-5.8x104 molecules/μg total RNA) and mEH (0.9-4.7x105 molecules/μg total RNA). CYP1A1 and CYP3A4/5 were expressed at very low levels, 2x102 and 103 molecules per μg total RNA respectively. CYP1A2, CYP2A6/7 and CYP2F1 were only marginally detectable. Overall, we observed low variation (1.5-4.4 fold) in basal expression profiles between the three cell lines. Treatment (24 and 48 hours) with different concentrations of β-naphthoflavone (βNF) and AROCLOR 1254 (ARO) revealed no significant increase of CYP1A1 or 1A2 message or detectable response in CYP3A mRNA expression. In contrast, corresponding treatment of the human hepatoma cell line, HepG2, induced CYP1A1 mRNA 200 fold (107 molecules/μg total RNA). These results indicate that human leukemia cell lines are not substantially responsive to the prototypic inducers, βNF and ARO, and that CYP expression patterns essentially are conserved across cell types. (Supported by NIH grant ES04696.)

436 OXIDATIVE INJURY IN HUMAN BREAST TUMOR CELLS VIA CATECHOL ESTROGEN METABOLISM.

C Dowell[1], G Cosma[1], A Scott[1], R Wells[1] and H Gardner[2]. [1]*Dept. Environmental Health, Colorado State Univ., Ft. Collins, CO, USA;* [2]*US Army Ctr. Environ Health Research, Ft. Detrick, MD, USA.*

Recent literature has suggested a role for catechol estrogens in oxidative cellular injury, and their possible role in carcinogenesis. We have investigated the ability of catechol estrogens to produce oxidative DNA damage, via cytochrome P450 (CYP) mediated metabolism, in an estrogen receptor positive human breast tumor cell line, MCF-7. We measured the following endpoints after exposure to a CYP1 inducer, dioxin (TCDD), with and without 2-hydroxy (2OHE2) and 4-hydroxyestradiol (4OHE2) treatments: 1) CYP1 enzyme activity; 2) DNA fragmentation. TCDD induced a 25-fold increase in CYP 1 enzymatic activity in MCF-7 cells, as measured by the aryl hydrocarbon hydroxylase (AHH) and ethoxyresorufin -o-dealkylase (EROD) assays. Co-treatment with alpha-napthoflavone (A-NF), an aryl hydrocarbon receptor (AhR) antagonist, abolished induction of CYP1 by TCDD. While 4OHE2 did not alter CYP1 induction by TCDD, 10μM 2-OHE2 decreased CYP1 activity approximately 2-fold. Inhibition of CYP1 activity by 2-OHE2 does not appear to be related to feedback inhibition by 2-OHE2 methylation, as the catechol-o-methyl transferase (COMT) inhibitor, RO 41-0960, failed to reverse this inhibitory effect. 10μM 4-OHE2, but not 10μM 2-OHE2, resulted in a 3-fold increase in DNA strand breaks in MCF-7 cells after 12 hours treatment, as measured by immunoassay/ELISA. Surprisingly, 10nM TCDD produced a 2-3 fold increase in DNA strand breaks, even in the presence of A-NF. Following CYP1 induction by TCDD, treatment with 10μM 4OHE2 alone, or 10μM 4-OHE2 and the peroxide cofactors necessary for quinone cycling, did not increase DNA fragmentation over TCDD alone. To conclude, dioxin appears to produce DNA fragmentation in MCF-7 cells through a non-AhR pathway, while quinone cycling does not appear to play a significant role in the production of oxidative DNA damage by catechol estrogens. Ongoing studies include measuring the production of oxidized DNA base adducts following these cell treatments. (Support from College of Vet Med/CSU and USACEHR.)

437 EFFECTS OF DDT ON THE HEPATIC METABOLISM OF TESTOSTERONE.

A Sierra-Santoyo, A Albores and M E Cebrian. *Seccion de Toxicologia Ambiental, CINVESTAV-IPN, Mexico City, Mexico.*

DDT is considered to be an endocrine disruptor, therefore, we studied the effect of single doses of technical DDT (0, 0.1, 1, 5, 10 and 100 mg/kg body weight) on the hepatic microsomal metabolism of testosterone *in vitro*. DDT was administered by gavage to male or female adult Wistar rats. Animals were sacrificed 24 h later. Microsomal hydroxylation of [4-^{14}C]-testosterone was assayed *in vitro*. Testosterone and its metabolites were extracted with ethyl acetate, analyzed by TLC and quantitated by radioscanning. DDT increased the rate of testosterone metabolism without following a clear dose-related response. The maximum effect (2.2-fold) was obtained at 1 mg/kgbw. Female rats metabolized [4-^{14}C]-testosterone faster (20%) than males at doses of 0.1 and 1 mg/kgbw. DDT also altered the hydroxylation pattern of testosterone in a sex-related manner. In males, the synthesis of 6β - and 6α - hydroxylated metabolites (CYP3A2- and 2A1-mediated, respectively) was increased ~4-fold over control values and 2-fold in 16α - (CYP2C11- and 2B- mediated). In females, the synthesis of 16α -, 16β - (CYP2B1-mediated) and 6β - was increased ~4-fold over control values. 15α -OHT (CYP2A2-mediated) synthesis increased 2-fold and the oxidation of testosterone to 6-dehydrotestosterone increased ~4-fold in both sexes. No significant effects were observed on 7α -OHT and androstenedione formation. Western blot densitometric analysis showed a preferential induction of CYP2B1 (17- fold in males and 42-fold in females). CYP3A1 was induced 32-fold and CYP3A2 18-fold in females. CYP2C11 increased 2.2-fold in males. Testosterone hydroxylation in positions 6α - and 15α - suggest an induction of CYP2A1 and 2A2, respectively. These results suggest that one of the mechanisms by which DDT may disrupt endocrine functions is its ability to modulate the expression of CYPs involved in the metabolism of sexual hormones and the induction of sex-specific CYPs normally non-expressed in a particular sex. Supported by the John D. and Catherine MacArthur Foundation.

438 THE EFFECTS OF DIET RESTRICTION ON EXPRESSION OF HEPATIC CYTOCHROME P450 ENZYME mRNA LEVELS IN THE RAT.

R Gilles, M Mitchell, C Alden, D Morris and J Davila. *Monsanto Life Sciences Co., St. Louis, MO.*

Utilization of moderate diet restriction (DR) in life time rodent cancer bioassays results in a more appropriate model to assess the human safety of xenobiotics. Moderate diet restriction improves survival and reduces the variability of spontaneous tumor incidences thereby potentially increasing the sensitivity of the assay to detect weaker carcinogens. However, DR has been reported to affect the maximum tolerated dose (MTD) for carcinogenicity testing. This suggests a possible influence of DR on hepatic biotransformation enzyme activity. The purpose of the present study was to define the influence of moderate diet restriction, specifically 75% of ad libitum control, on basal and induced levels of mRNA for the major liver cytochrome P450 (CYP450) isoforms and UDPGT in 5-7 week old male and female rats. After four weeks, mean body weights with DR were 19% (male) or 15% (female) less than respective ad libitum controls, whereas mean relative liver weights between the two groups were similar. The mean basal relative mRNA expression levels of the CYP1A1 and UDPGT enzymes were elevated in the DR group as compared to controls. In male, but not in female, DR rats, 3MC was found to induce a lower mean level of CYP1A1 mRNA expression as compared to controls. Differences in induced mRNA expression levels of the CYP3A1 isoform were also observed between DR and control rats of both sexes. Evaluations of other liver CYP450 isoforms did not reveal meaningful differences between ad libitum and DR rats. This data suggests that differences may exist in the basal and xenobiotic-induced levels of hepatic biotransformation enzymes between ad libitum and DR rats.

439 CYTOTOXICITY OF HCFC-123 IN ISOLATED RAT HEPATOCYTES.

M Manno, R Ferrara, A Zanovello, S Bortolato and R Tolando. *Inst. of Occupational Med, University of Padua, Padua, Italy.* Sponsor: M Lotti.

The hydrochlorofluorocarbon 1,1-dichloro-2,2,2-trifluoroethane (HCFC-123), a close structural analogue of the hepatotoxic anaesthetic halothane, is bioactivated by microsomal cytochrome P450 (P450) to reactive metabolites both oxidatively1 and reductively2. Since more recent work in our laboratory has shown that HCFC-123 is also cytotoxic to isolated rat hepatocytes, we investigated the mechanism of HCFC-123 cytotoxicity and the role played in it by P450. Hepatocytes from Wistar male rats were incubated, both under aerobic and hypoxic (4% O2) conditions, with HCFC-123 (1-10 mM). A time- and dose-dependent increase in LDH leakage was observed, which reached its maximal level after 60 min with 10 mM HCFC-123. At the same time, a dose-dependent depletion of total cellular glutathione was observed. The intensity of these effects is apparently not related to O2 levels. LDH leakage was prevented by the free radical scavenger PBN (30 mM) under both aerobic and hypoxic conditions, whereas glutathione depletion was partially reduced by PBN under hypoxic but not aerobic conditions. A complete protection against cytotoxicity was provided also by the aspecific P450 inhibitor metyrapone (100 M), and a partial protection was observed in presence of the P450 2E1 inhibitor 4-metylpyrazole (500 M) or the P450 3A2 inhibitor troleandomycin (100 M), under aerobic condititons. No effect of these inhibitors was observed on glutathione depletion. These results indicate that HCFC-123 hepatocytotoxicity is dependent on its activation to reactive metabolites by P450 2E1 and 3A2, and that, as observed for the microsomal system, free radical intermediates may be also involved in cell damage.

440 USE OF RAT ANTI-CYTOCHROME P450 ANTIBODIES TO DETECT THE PRESENCE OF DOG LIVER CYTOCHROME P450 ISOZYMES.

A L Bayer, K Halloran, D J Quinn and D A Hartman. *Ricerca, Inc., Painesville, OH, USA.* Sponsor: M C Savides.

Cytochromes P450 are important enzyme systems for Phase I metabolism of xenobiotics and the biotransformation of endogenous substrates. Many forms of cytochrome P450 have been isolated from various species. The most well-studied species include rats and rabbits. However, much less is known about the cytochromes P450 of the dog despite its use in preclinical toxicology studies. Recently in the literature the isolation and purification of various dog cytochrome isoforms have been described. In addition, the production of polyclonal antisera against dog cytochrome P450 isozymes has been described but as yet these antibodies are not commercially available. In our laboratories, we use a Western blot assay to quantitate the levels of various cytochrome P450 proteins in microsomal preparations after treatment of an animal with a given drug. This paper describes the use of commercially available rat cytochrome P450 antibodies to detect the presence of various cytochrome P450 isoforms in dog liver microsomal preparations. The dog microsomal proteins were first separated using SDS-PAGE, followed by blot transfer and subsequent immunoblotting. Antibodies against rat cytochromes 1A1, 2B1, 2C6, 2E1, 3A2 and 4A1 were used to assess the ability of rat antibodies to recognize the corresponding dog cytochrome P450 isozymes. Rat microsomes with induced levels of the target cytochrome P450 isozymes were used as positive controls. All of the rat antibodies tested recognized dog proteins of the same molecular weight as the rat positive controls. We conclude that commercially available rat antibodies can be used to detect the presence of a particular cytochrome P450 isozyme in dog liver microsomes.

441 CYTOCHROME P-450 INDUCTION IN PRECISION-CUT RAT LIVER SLICES EXPOSED TO 5-LIPOXYGENASE (5-LO) INHIBITORS IN DYNAMIC ORGAN CUTURE.

L-H Chi[1], B P McGarrigle[1], W P Beierschmitt[2], M D Aleo[2], and J R Olson[1]. [1]*Dept. of Pharmacology and Toxicology, SUNY, Buffalo, NY;* [2]*Drug Safety Evaluation, Pfizer, Inc., Groton, CT.*

Hepatomegaly and induction of cytochrome P-450 (CYP) enzymes have been reported in rats exposed to the N-hydroxyurea-containing 5-LO inhibitors CJ-11,802 and zileuton (Beierschmitt *et al.*, 1998). The present study investigated the potential of these and tetrahydropyran-containing 5-LO inhibitors have to modulate CYP activities in precision-cut rat liver slices maintained for 96 hr in dynamic organ culture. Liver slices were exposed to medium containing zileuton (0, 5, 50, 100, or 300 μM), CJ-11,802 (0, 5, 50, or 100 μM), CJ-12,918 (0, 5, 20, 50, or 100 μM), or CJ-13,454 (0, 5, 20, 50, or 100 μM). Liver slice viability, as assessed by maintenance of intracellular K^+, was maintained under these conditions except for 50 and 100 μM exposures to CJ-12,918 and CJ-13,454. The O-deethylation of ethoxyresorufin (EROD), methoxyresorufin (MROD), and pentoxyresorufin (PROD) were assessed at 96 hr in liver slice microsomes as markers of CYP1A1, CYP1A2, and CYP2B activities, respectively. CJ-11,802 (50 μM) was the most potent inducer *in vitro* producing a significant ($p<0.05$) concentration-related increase in EROD (80-fold), MROD (12-fold), and PROD (5-fold). Zileuton (300 μM) increased EROD (10-fold), MROD (5-fold), and PROD (1-fold), while CJ-13,454 (20 μM) and CJ-12,918 (20 μM) produced little or no change in CYP. The modulation of CYP1A1 *in vitro* by these 5-LO inhibitors followed their rank order of potency *in vivo*. CJ-11,802 (200 mg/kg/d) and zileuton (300 mg/kg/d) induced EROD 26- and 4-fold, respectively while CJ-12,918 and CJ-13,454 (250 mg/kg/d) had little activity (<2-fold). Although CJ-11,802 and zileuton both induced PROD *in vivo* they did not show the same correlation *in vitro*. These studies show that the rank order potency of 5-LO inhibitors to induce CYP1A1 *in vivo* is preserved *in vitro* and further illustrate the use of precision-cut liver slices to assess the potential of pharmaceutical drug candidates to modulate liver CYP expression.

442 EFFECT OF ORGANIC SOLVENTS ON *IN VITRO* cDNA-EXPRESSED HUMAN CYTOCHROME P450 ACTIVITIES.

W F Busby, Jr., J M Ackermann and C L Crespi. *GENTEST Corporation, Woburn, MA, USA.*

Organic solvents are typically utilized to add lipophillic chemicals to *in vitro* incubations. The effects of methanol, ethanol, DMSO and acetonitrile were studied *in vitro* on the catalytic activities of nine individual, cDNA-expressed cytochromes P450: CYP1A1, CYP1A2, CYP2A6, CYP2B6, CYP2C8, CYP2C9, CYP2C19, CYP2D6 and CYP3A4, in commercially available microsomes. These data show that specific solvents have enzyme-selective effects on P450 activities. Methanol did not substantially inhibit (≤10%) any of the activities at 0.3%, but did inhibit CYP1A1, CYP2B6, CYP2C9, and CYP2D6 by 12-26% at 1%. In contrast, 0.1% ethanol inhibited CYP1A1, CYP2B6, and CYP2C19 by 20-30%. Ethanol at 1% did not inhibit CYP1A2, CYP3A4, CYP2C8, and CYP2C9. DMSO inhibited CYP3A4, CYP2C19, and CYP2D6 by 15-25% at 0.1%. However, DMSO

had little effect on CYP1A2, CYP2A6, and CYP2C8. Acetonitrile, like methanol, did not inhibit any P450 activity at 0.3% solvent except for CYP1A1 (26%) and CYP2B6 (13%). At 1%, acetonitrile decreased activities of these enzymes by 40-60%, and inhibited CYP2A6, CYP3A4, CYP2C19, and CYP2D6 activity by 10-20%. Acetonitrile also increased CYP2C9 activity by 10-15% above control values at 1-3% solvent. Excluding solubility considerations, methanol and acetonitrile appear to be the most suitable solvents for the introduction of substances to cytochrome P450 incubations for *in vitro* toxicology or metabolism studies.

443 THE EFFECT OF LEPTIN ON CYTOCHROME P450, CONJUGATION, AND ANTIOXIDANT ENZYMES IN THE OB/OB MOUSE.

A M Watson, S M Poloyac, G Howard, and R A Blouin. *University of Kentucky, Graduate Center for Toxicology and College of Pharmacy, Lexington, KY, USA.*

Leptin is a hormone that is secreted by adipocytes and regulates body weight through it's effect on satiety and energy metabolism. The ob/ob mouse is deficient in this protein and is characterized by obesity and other metabolic disorders. This study investigated the alterations of several hepatic cytochrome P450-related, conjugation and antioxidant enzymes in lean and ob/ob mice and the role leptin may play in the modulation of these enzymes. Lean and ob/ob male mice were injected with leptin (100μg) or PBS (100μl) for 15 days. Mice were euthanized and livers removed and processed to assess the various enzyme activities. Liver microsomes from ob/ob mice, when compared to lean controls, displayed significantly lower total hepatic cytochrome P450 levels (22%) and chlorzoxazone 6-hydroxylation activity (27%); however, 2β- 7α- and 16α- testosterone hydroxylation and pentoxyresorufin *O*-dealkylation activities were significantly higher (34%, 47%, 22% and 39%, respectively). Leptin administration corrected alterations seen with all activities except 2β-testosterone hydroxylation and total hepatic P450 levels. Dealkylation of ethoxyresorufin (EROD) and ω-hydroxylation of lauric acid activities from ob/ob and lean mice were not statistically different; however, leptin exposure significantly increased EROD activity in lean mice (14%) and decreased the activity in ob/ob mice (36%). UDP-glucuronosyltransferase and glutathione S-transferase activities were not altered with obesity or leptin exposure. The antioxidant enzymes, catalase (11%) and glutathione peroxidase (26%), as well as glutathione reductase (17%) were lower in the ob/ob mice and leptin treatment corrected these alterations. Total glutathione levels were not affected by obesity or leptin treatment. The results of this study demonstrate alterations in constitutive expression of numerous xenobiotic metabolizing enzymes in ob/ob mice which were restored to lean control values following leptin treatment.

444 MOLECULAR CLONING, HETEROLOGOUS EXPRESSION, ENZYMATIC CHARACTERIZATION AND TISSUE DISTRIBUTION OF A NOVEL MOUSE CYTOCHROME P450.

W Qu, J Ma, and C Zeldin. *National Institute of Environmental Health Sciences, Research Triangle Park, NC, USA.*

A cDNA encoding a new cytochrome P450 designated CYP2J9 was isolated from a mouse brain library. Sequence analysis reveals that this 1,958-base pair cDNA has an open reading frame and encodes a 502-amino acid protein that contains the highly conserved heme binding peptide. Based on the deduced amino acid sequence, this protein shares less than 31% identity with members of the CYP1, CYP3 and CYP4 families, 40-49% identity with other members of the CYP2 family, and 70-91% identity with other CYP2J subfamily P450s. Reverse-transcriptase polymerase chain reaction analysis of total RNA prepared from various mouse tissues using CYP2J9 sequence-specific primer pairs shows that CYP2J9 transcripts are present in brain, kidney, liver, intestine, heart, lung, and ovary. Northern analysis using the full length CYP2J9 cDNA probe shows that CYP2J9 mRNAs are most abundant in brain and kidney. Western blots using a polyclonal antibody prepared against a CYP2J9-specific peptide demonstrates abundant CYP2J9 protein in microsomal fractions prepared from brain and kidney. Recombinant CYP2J9 protein was co-expressed with NADPH-cytochrome P450 oxidoreductase (CYPOR) in *Sf9* insect cells using a baculovirus expression system. Microsomal fractions prepared from CYP2J9-CYPOR transfected insect cells metabolize arachidonic acid primarily to 19-HETE as the principal reaction product. We conclude, based on this data, that CYP2J9 is an enzymologically distinct mouse P450 that is expressed primarily in extrahepatic tissues. We speculate that CYP2J9 products play important functional roles in the brain and kidney. (Supported by the Division of Intramural Research, NIH/NIEHS.)

445 INDUCTION OF CYP2K1 EXPRESSION IN STARVED MUMMICHOG: A PROBLEM FOR USE AS A BIOMARKER OF PEROXISOME PROLIFERATION?

M L Haasch and M F Johnston. *Chesapeake Biological Laboratory, University of Maryland Center for Environmental Science, Solomons, MD, USA.*

In addition to peroxisome proliferation, peroxisome proliferating agents (PPAs) are known to induce the expression of lauric acid hydroxylase (LA-OHase) cytochromes P450. In mammals, LA-OHase expression can also be regulated by endogenous fatty acids and ketotic states such as starvation and diabetes. In fish, induction of LA-OHase by starvation could be problematic for using induction as a biomarker of PPA exposure and effect. The purpose of this study was to assess the effect of starvation on fish LA-OHase (CYP2K1) expression. The effect of dimethylsulfoxide (DMSO), a vehicle for waterborne PPA exposure, was also investigated. Wild-caught, female mummichog (*Fundulus heteroclitus*) were acclimated in the laboratory for at least two weeks prior to the start of the experiment. Treatments (9 fish each; n=3) consisted of non-treated/fed, non-treated/not fed, DMSO/fed and DMSO/not fed. After 4 days, microsomes were prepared and frozen at –80°C until used for SDS-PAGE and immunodetection using trout anti-LMC2 (CYP2K1; gift of D. R. Buhler, Oregon State University). Starvation for 4 days resulted in significant ($P<0.001$) induction of CYP2K1 that was approximately 4-fold higher than induction ($P<0.01$) in the presence of DMSO. There was no difference between the non-treated/fed and DMSO/fed groups suggesting that DMSO has no effect on basal CYP2K1 expression. The results indicate that DMSO may decrease induction and that CYP2K1 is induced by starvation. Caution is suggested when using CYP2K1 expression as a biomarker of PPA exposure and effect.

446 METABOLISM OF PHENANTHRENE BY HOUSE FLY CYP6D1 AND DOG MICROSOMES.

P J Korytko[1], F W Quimby[2] and J G Scott[3]. [1]*Field of Environmental Toxicology, Center for the Environment;* [2]*Department of Veterinary Pathology, Field of Environmental Toxicology; and* [3]*Department of Entomology, Cornell University, Ithaca, NY.*

Polycyclic aromatic hydrocarbons (PAHs) consist of a ubiquitous class of environmental contaminants and phenanthrene is a model PAH. A novel fluorometric method for measuring phenanthrene metabolism *in vitro* was developed and verified with direct measurement of [^{14}C]phenanthrene using mammalian microsomes. The fluorometric assay and direct measurement of [^{14}C]phenanthrene metabolism were used to show that CYP6D1, a house fly cytochrome P450, is the major house fly P450 involved in phenanthrene metabolism. Phenanthrene was metabolized by microsomes from the LPR house fly strain that over-expresses CYP6D1, but metabolism was not observed in the CS strain that has a lower level of CYP6D1. Furthermore, phenanthrene metabolism was inhibited completely by a CYP6D1 specific antibody. This study increases the number of known substrates of CYP6D1, identifies PAHs as potential substrates of CYP6D1, and enhances the utility of CYP6D1 as an agent in bioremediation.

447 ACETAMINOPHEN HEPATOTOXICITY CAUSED BY SHORT-TERM TREATMENT WITH ETHANOL PLUS ISOPENTANOL: PROTECTION BY TRIACETYL-OLEANDOMYCIN.

J Sinclair[1,2,3], J Szakacs[4], S Wood[1], V Kostrubsky[5], E Jeffery[6], S Wrighton[7], D Wright[1], and P Sinclair[1,2,3]. [1]*VA Med. Ctr., White River Junction, VT; Depts.* [2]*Pharmacol/Toxicol and* [3]*Biochem, Dartmouth Med. Sch., Hanover, NH;* [4]*VA Med. Ctr, Salt Lake City, UT;* [5]*Dept. Pathol., U. Pittsburgh Med.Ctr. Pittsburgh, PA;* [6]*Inst. Environ. Studies, U. Illinois, Urbana, IL;* [7]*Depart. Drug Disposition, Eli Lilly Res. Labs, Indianapolis, IN.*

We have previously reported that pretreatment of rats with ethanol plus isopentanol for 7 days resulted in a synergistic increase in acetaminophen (APAP) hepatotoxicity compared to pretreatment with ethanol alone. We have now found that combined treatment with ethanol and isopentanol triggered APAP hepatotoxicity at a very low dose (0.25 g APAP/kg) even when rats were pretreated for only 3 days with this alcohol combination. When rats were pre-exposed to a mixture of isopentanol with 6.3 % ethanol for 3 days, a dose of isopentanol as low as 0.1 % was sufficient to cause an increase in APAP hepatotoxicity. Treatment of rats with triacetyloleandomycin (TAO, 500 mg/kg), which forms a metabolic intermediate complex with CYP3A, 2 h before administration of APAP protected against the development of liver

damage, as seen histologically and by decreases in serum levels of ALT. CYP3A, measured immunohistochemically, appeared to be destroyed by APAP and, as expected, protected by TAO. Our findings suggest that CYP3A has a major role in alcohol-mediated increases in APAP hepatotoxicity and that alcoholic beverages rich in isopentanol may be a risk for developing liver damage from APAP. (Supported by the Dept. of Veterans Affairs.)

448 MULTIPLE FACTORS REGULATE PROMOTER ACTIVITY OF THE NADPH CYTOCHROME P-450 OXIDOREDUCTASE GENE.

K A O'Leary and C B Kasper. *McArdle Laboratory for Cancer Research, University of Wisconsin, Madison, WI.* Sponsor: C A Bradfield.

The mixed function oxidase system is composed of NADPH-cytochrome P-450 oxidoreductase (P450R) and the cytochromes P-450 (CYPs). Unlike the CYP gene superfamily, P450R is encoded by a single gene with a TATA-less, GC-rich promoter containing multiple Sp1 consensus sites, similar to many housekeeping genes. Transient transfection analyses demonstrated that basal expression of the P450R gene was dependent on multiple cis-acting elements. Transcription factor binding sites located within the minimal promoter include two upstream Sp1 motifs, a CACCC element containing overlapping Sp1/Egr-1/CACCC box motifs, and a site designated the Oxidoreductase Upstream element (ORU). More than one Sp1 site was necessary for maximal promoter function, although in longer constructs containing upstream motifs, distal sites were able to compensate for loss of proximal sites. Analysis of the CACCC region revealed that mutation of the Sp1 motif produced little change in promoter function, whereas mutation of the Egr-1 site resulted in ~90% drop in activity, indicating a factor other than Sp1 stimulated transcription under basal conditions. Finally, mutation of the bases within ORU demonstrated that this element played an essential role in promoter function. The P450R promoter thus differs from a number of TATA-less promoters; Sp1 was not the primary regulator, rather, the CACCC and ORU elements were critical for basal activity. Furthermore, although multiple sites were necessary, Sp1 enhancer activity was independent of position. (Supported by Grants CA22484 and CA0920.)

449 INFLAMMATORY CYTOKINE-MEDIATED DOWN REGULATION OF CYTOCHROME P450 BY POKEWEED MITOGEN IN MICE.

H K Kim, C Y Choi, and H G Jeong. *Department of Biological Science, Chosun University, Kwangju, Korea.*

Inhibition of cytochrome P450 (P450)-mediated metabolism by immunostimulation may involve one or more mediators. Inflammatory cytokines and nitric oxide were suggested as mediators of down-regulation of P450 during immune stimuli. These cytokines are synthesized and released by activated mononuclear phagocytes from various sources. Therefore liver macrophages (Kupffer cells), via their cytokines, may affect P450. We demonstrated previously that suppressive effects of B and T lymphocyte mitogens on the activities of several isozymes of mouse hepatic P450s might be different and B cell mitogens such as lipopolysaccharides and pokeweed mitogen (PWM) selectively depress the expression of P450. In the present study, we investigate the role of Kupffer cells and inflammatory cytokines in PWM-induced down-regulation of the microsomal activities of P450 in mice. Treatment of PWM significantly reduced hepatic microsomal total P450 contents and activities of dealkylation of ethoxyresorufin, methoxyresorufin, benzyloxyresorufin, and aniline hydroxylation, a representative activity of P4501A1, P4501A2, P4502B1/2, and P4502E1, respectively. However, when the mice treated with gadolineum chloride, the inhibitor of Kupffer cells function, P450 activities were less suppressed by PWM alone. In this investigation, we also examine the expression profiles of inflammatory cytokines in the liver, after following the treatment of PWM. The reduced these microsomal monooxygenase activities in PWM-treated mice were accompanied by increase of transcripts for IL-1α , IL-1β , IL-6 and TNF-α in RT-PCR analysis. These results show that the inflammatory cytokines that are induced by PWM-activated Kupffer cells do play an important role in the PWM-induced down-regulation of P450. (Supported by KOSEF Grant 961-0505-044-2.)

450 EXPRESSION OF DRUG METABOLISM ENZYMES IN HUMAN RENAL PROXIMAL TUBULAR CELLS.

B S Cummings[1], J M Lasker[2], and L H Lash[1]. [1]*Dept. of Pharmacology, Wayne State Univ. Sch. Med., Detroit, MI;* [2]*Dept. of Biochemistry, Mount Sinai Sch. Med., New York, NY.*

Expression and activity of several GSH-dependent enzymes and cytochrome P450 (CYP) monooxygenases in freshly isolated and primary cultures of human proximal tubular (hPT) cells were determined to assess the drug metabolism capabilities of these cells and to validate their use as *in vitro* models. hPT cells were isolated from human renal cortical slices by enzymatic dissociation from minced cortical tissue, filtration to remove tissue fragments, and then low-speed centrifugation to pellet hPT cells. In freshly isolated hPT cells, γ-glutamyltransferase activity, a marker enzyme for PT cells, was 18.8 – 3.3 mU/mg. Enzymatic activities were also assessed for γ-glutamylcysteine synthetase, glutathione reductase, glutathione peroxidase, and glutathione S-transferase (GST). Previous studies showed that CYP4A11, CYP4F2, and CYP3A5, but not CYP2E1, CYP2A6, CYP2C8, CYP2C9, CYP2C19, or CYP3A4, are expressed in human kidney microsomes. Western blot analysis of hPT cell lysates demonstrated the presence of CYP4A11, GSTA, and GSTP, but not CYP2E1 or GSTM. CYP4A11 activity in freshly isolated hPT cells, as determined by rates of lauric acid hydroxylation, was 0.474 – 0.053 nmol/min per mg protein. Primary cultures of hPT cells maintained expression of GSH-dependent enzyme activities and cytokeratin for 7 days. After several passages, however, some GSH-dependent enzyme activities were lost. Primary cultures of hPT cells maintained expression of CYP4A11 for up to 4 days in primary culture and preliminary studies suggested that exposure of cultures to ethanol (50 mM) for 48 hr induced CYP4A11 expression. These results provide the first accounting of drug-metabolizing capability of both freshly isolated and cultured hPT cells. Furthermore, this is the first demonstration of CYP4A11 expression in freshly isolated or cultured hPT cells.

451 CYTOCHROME P450 INDUCTION BY p,p'-DDE IN THE DEER MOUSE, VOLE AND LABORATORY RAT.

R L Dickerson and L T Frame. *The Institute of Environmental and Human Health, Texas Tech University / Texas Tech University Health Sciences Center, Lubbock, TX, USA.*

It has been previously reported that 2,2-bis(4-chlorophenyl)-1,1-dichloroethylene (*p,p'*-DDE) induces cyp2B activity but not cyp1A1 activity in the laboratory rat (*Rattus rattus*) (Nims et al, 1998). We have observed significant increases in benzyl-resorufin-O-dealkylase (BROD), ethoxyresorufin-O-dealkylase (EROD), and methoxyresorufin-O-dealkylase (MROD) but not pentoxyresorufin-O-dealkylase (PROD) activity in deer mouse dosed *per os* with p,p'-DDE. In this study, we dosed both prairies voles (Microtus) and deer mice (*Peromyscus maniculatus*) with five environmentally relevant doses of p,p'-DDE. Hepatic microsomes were prepared from each animal, solubilized, and run on SDS-PAGE. These gels were transferred to nitrocellulose, blocked and sequentially probed with goat anti-rat P450 1A1 and goat anti-rat 2B. Anti-goat antibodies labeled with alkaline phosphatase were used as secondary antibodies in conjunction with a photoluminescence substrate to visualize the blots. These blots showed that p,p'-DDE induced only cyp1A1 protein in the deer mouse but both cyp1A1 and cyp2B (predominantly) in the vole. Immuno-inhibition studies showed that EROD, MROD and BROD activities were inhibited by anti-cyp1A1in the deer mouse but anti-cyp2B was ineffective at neutralizing these activities. In the vole, anti-cyp1A1 inhibited EROD activity but not PROD or BROD activities. Anti-cyp2B inhibited PROD and BROD but not EROD activity in the vole. These studies indicate that conclusions about isozyme induction cannot be based solely upon substrate activity.

452 DIFFERENTIAL EXPRESSION OF CYTOCHROMES P450 1A1 AND 1B1 IN HUMAN LUNG FROM SMOKERS, NON-SMOKERS AND EX-SMOKERS.

J H Kim[1], M E Sherman[2], P T Strickland[1], F P Guengerich[3], and T R Sutter[1]. [1]*Johns Hopkins School of Hygiene and Public Health, Baltimore, MD, USA;* [2]*Johns Hopkins School of Medicine, Baltimore, MD, USA;* [3]*Vanderbilt University School of Medicine, Nashville, TN, USA.*

Cytochromes P450 1A1 and 1B1 are known to bioactivate procarcinogens such as polycyclic aromatic hydrocarbons (PAH) found in cigarette smoke, and are known to be inducible via an Ah-receptor mediated mechanism. The

aim of this study was to examine levels of P4501A1 and P4501B1 expression in human lung samples from smokers, non-smokers and ex-smokers. Using highly specific polyclonal IgG and immunoblot analysis of microsomes from lung tissues, we determined the specific content for P4501A1 and 1B1. P4501A1 was determined to have mean levels of 53.3 pmols/mg microsomal protein (n=12) in smokers, 7.5 pmols/mg microsomal protein (n=4) in non-smokers, and 32.9 pmols/mg microsomal protein (n=6) in ex-smokers. P4501B1 was determined to have mean levels of 4.2 pmols/mg microsomal protein (n=12) in smokers, 1.4 pmols/mg microsomal protein (n=4) in non-smokers, and 4.3 pmols/mg microsomal protein (n=6) in ex-smokers. These results indicate that both P4501A1 and P4501B1 are at higher levels of expression in lung tissues from smokers and ex-smokers when compared with non-smokers. In conclusion, induced expression levels for P4501A1 and P4501B1 may be due to smoking and exposure to PAHs present in cigarette smoke, such that smokers may be more susceptible to chemical carcinogenesis. Additional studies are underway to determine the variance, activity and cellular localization of these proteins.

453 CYTOCHROME P450 1A1 AND 2B1 IN THE RAT LUNG: EXPOSURE TO SILICA AND INDUCERS OF XENOBIOTIC METABOLISM.

L A Battelli, A F Hubbs, R D Simoskevitz, V Vallyathan, L Bowman, and P R Miles. *HELD, NIOSH, Morgantown, WV.* Sponsor: V Castranova.

Pulmonary exposure to respirable silica causes alveolar type 2 cell proliferation. Cytochrome P450 (CYP) is present in type 2 cells and increased levels of CYP1A1 are reported in silicotic rats. Because carcinogen activation by CYP1A1 may contribute to human lung cancer and because silica is often present in occupational mixed dust exposures, we hypothesized that new type 2 cells in silicosis are potential sites of CYP1A1 induction and carcinogen activation. Male, Sprague-Dawley rats received intratracheal silica (20mg) or vehicle (saline). The silicotic and control rats were then exposed to inducers of xenobiotic metabolism by the intraperitoneal injection of phenobarbital (PB), β-naphthoflavone (NF), NF and PB, or vehicle (corn oil). 7-ethoxyresorufin (ER)-O-deethylase (EROD) and 7-ethoxycoumarin (EC)-O-deethylase (ECOD) activities were increased by NF but unaffected by PB. Morphometrically, the number of cells expressing immunoreactive CYP2B1 was not significantly affected by silica, NF, and/or PB. CYP 1A1 positive airway and alveolar epithelial cells were absent in controls, present after NF exposure but not significantly increased by PB or silica. Although we had hypothesized that induction of type 2 cells would lead to more xenobiotically active cells in silicotic rats, NF-exposed silicotic rats had significantly less EROD activity than NF-exposed control rats. We conclude that the new type 2 cells of silicosis were not a major site of 1A1 induction in combined exposures in this rat model.

454 REGULATION OF CYP1A EXPRESSION BY NICOTINE IN THE RAT: DOSE- AND ROUTE OF EXPOSURE-DEPENDENCE.

J Fung[1], H Scholl[1], Y Park[1], P Thomas[2], G Wagner[3], A Halladay[3], H Fisher[4], J Alam[5], and M M Iba[1]. *Depts. Of [1]Pharmacology, [2]Chem. Biology, [3]Psychology and [4]Nutrition, Rutgers Univ., Piscataway, NJ; [5]Ochsner Fdn. Hospital, New Orleans, LA.*

The induction of pulmonary, renal and hepatic CYP1A expression by the major tobacco constituent nicotine was examined in rats administered either a single subcutaneous (SC, 2.5 mg/kg) dose, a vapor (VP, 200 μ g/m^3) dose or a 30-day, low (20 mg/kg), medium (60 mg/kg) or high (200 mg/kg) dietary dose of the alkaloid. SC nicotine caused a lung-specific but transient upregulation of CYP1A1 mRNA, protein and catalytic activity, as did VP nicotine, with the induction peaking (15-fold) 12 h post exposure. Dietary nicotine caused a dose-dependent induction of pulmonary, renal and hepatic CYP1A1 and of hepatic and renal CYP1A2. The hepatic CYP1A1 induction was not accompanied by elevated mRNA abundance and occurred only at the high nicotine dose, at which the pulmonary and renal induction was 21-fold and 55-fold, respectively. Nicotine bound weakly to the Ah receptor in a gel shift assay, suggesting some involvement of transcriptional mechanisms in the induction. Nicotine-fed rats had plasma levels of nicotine and cotinine comparable to those reported in heavy smokers. However, administered cotinine did not induce CYP1A1. The findings suggest that CYP1A induction by cigarette smoke may be contributed by nicotine. (Supported by ES06414 and DK43135.)

455 COMPARISON OF LOW-OXYGEN MEDIATED CYP1A1 INDUCTION IN 3 HEPATOMA CELL LINES.

L T Frame, D Settachan, and R L Dickerson. *The Institute of Environmental and Human Health, Texas Tech University, Lubbock, TX, USA.*

Hepatoma cell lines are useful *in vitro* models for understanding liver metabolism of xenobiotics. However, when standard cell-culture incubation conditions (5%CO2/95% air) are used, oxygen concentrations are generally higher than the physio-logical range. This may have an impact on the responsiveness of cells and general applicability for toxicological testing. When oxygen was lowered to 10%, we found that 3-methyl-cholanthrene (3-MC)-mediated induction of ethoxyresorufin O-dealkylase (EROD) activity in human HepG2 cells was significantly enhanced (14-fold). Immunoprecipitation studies using specific antibodies showed that the low-oxygen effect was mediated primarily by the CYP1A1 isoform. Interestingly, the specific CYP1A1-specific inducer, 2,3,7,8 tetrachlorodibenzo-p-dioxin (TCDD) did not show a similar enhancement in EROD activity, but may have been more acutely toxic to the cells. The low-oxygen effect was also tested in hepatoma cell lines derived from mouse (1c1c7) and rat (H4IIE). The mouse cell line showed a similar response but it was much less pronounced than in the human HepG2 cell line. The rat-derived cell line was totally unresponsive. These results indicate that physiological oxygen tension may be an important regulator of inducer-mediated drug metabolism in cultured hepatoma cell lines; however, the response is inducer- and species-specific.

456 INDUCTION OF CYP1A1, CYP1A2, AND CYP1B1 IN PRECISION-CUT HUMAN LIVER SLICES BY 2,3,7,8-TETRACHLORODIBENZO-*p*-DIOXIN AND OMEPRAZOLE.

A T Drahushuk[1], M D Aleo[2], B P McGarrigle[1], and J R Olson[1]. *[1]Dept. Pharmacology and Toxicology, SUNY, Buffalo, NY; [2]Drug Safety Evaluation, Pfizer, Inc., Groton, CT.*

Precision-cut human liver slices incubated in dynamic organ culture were utilized as an *in vitro* model to investigate the ability of the environmental pollutant TCDD and the clinically relevant proton pump inhibitor omeprazole to modulate the cytochrome P450s 1A1 (CYP1A1, 1A2 (CYP1A2), and 1B1 (CYP1B1). These cytochrome P450s have been specifically implicated in the metabolic activation of compounds, such as the polycyclic aromatic hydrocarbons and heterocyclic aromatic amimes, into carcinogenic species. Liver slices were incubated in dynamic organ culture for up to 96 hours in Waymouth's medium (supplemented with 25 mM HEPES, 25 mM glucose, 5% horse serum, 5% fetal calf serum, and penicillin and streptomycin) containing either 10 nM TCDD (initial 24 hr), 50 μM omeprazole, or vehicle alone (0.1% DMSO). The slices remained viable throughout the incubation period maintaining an intracellular potassium content of 40 μmoles/g liver or greater. The levels of CYP1A1, CYP1A2, and CYP1B1 proteins and corresponding activities were measured in microsomal preparations from the human liver slices and the levels of CYP1A1 and CYP1B1 mRNA were quantitated by reverse transcriptase-polymerase chain reaction. Induction of CYP1A1, CYP1A2, and CYP1B1 was observed following exposure to either TCDD or omeprazole. Interestingly, variability in responsiveness was observed between different individual liver specimens. For example, the fold induction of CYP1B1 mRNA following exposure to 50 μM omeprazole for 48 hours ranged from ≈5 to 18, compared to control. Likewise, the same liver specimens displayed a ≈7 to 41 fold induction of CYP1A1 mRNA following omeprazole (50 μM) treatment for 48 hours, compared to control. The present study demonstrates the utility of precision-cut human liver slices as *in vitro* model for studying the modulation of cytochrome P450s by xenobiotics. Furthermore, the ability of omeprazole to induce the recently identified CYP1B1 is a novel observation which warrants further investigation.

457 SEA OTTER (*ENHYDRA LUTRIS*) CYTOCHROME P450 1A GENE EXPRESSION IN PERIPHERAL BLOOD MONO-NUCLEAR CELLS AS A BIOMARKER OF EXPOSURE TO CRUDE OIL.

P W Snyder[1], T P Kondratyuk[1] and J P Vanden Heuvel[2]. *[1]School of Veterinary Medicine, Purdue University, West Lafayette, IN, USA; [2]Department of Veterinary Science, Pennsylvania State University, University Park, PA, USA.*

The nearshore ecosystem of the Prince William Sound (PWS) serves as a

repository for the spilled oil from the *Exxon Valdez* tanker. Responses associated with exposure to residual oil may include transcriptional activation of mRNA for cytochrome P450 1A. Here, we report on the isolation, cloning, and sequencing of a PCR product for sea otter (*Enhydra lutris*) cytochrome P450 1A. Additionally, we developed a quantitative RT-PCR technique to quantify the level of P450 1A expression in sea otter peripheral blood mononuclear cells (PBMC). Using this quantitaive RT-PCR method with PBMC isolated from sea otters captured in oiled (n=20) and non-oiled (n=21) areas of the PWS, we detected a significant difference ($p < .001$) in the level of P450 1A expression between the two study areas. The mean level of expression in PBMC from sea otters (molecules/100 ng total RNA) was 1.96×10^6 for the oiled area and 0.12×10^6 for the non-oiled area. Analysis of the expression of P450s in circulating mononuclear cells by RT-PCR represents a sensitive and non-lethal method for evaluating potential exposure to environmental contaminants.

458 INHIBITION OF CYP1A1 ENZYME ACTIVITY IN MOUSE HEPATOMA CELL CULTURE BY SOYBEAN ISOFLAVONES.

H G Shertzer[1], A Puga[1], C-y Chang[1], P Smith[1], D W Nebert[1], K D R Setchell[2] and T P Dalton[1]. [1]*Department of Environmental Health/Center for Environmental Genetics and* [2]*Department of Pediatrics, Children's Hospital Research Foundation, University of Cincinnati Medical Center, Cincinnati, OH, USA.*

These studies investigated the mechanisms by which soybean- and soybean isoflavone-enriched diets inhibit carcinogenesis. We found that genistin and daidzin, and their respective aglucone forms daidzein and genistein, block the TCDD-inducible activity of CYP1A1 and prevent CYP1A1-mediated covalent binding of benzo[*a*]pyrene (BaP) metabolites to DNA. Although daidzein and genistein appear structurally similar to known aromatic hydrocarbon receptor (AHR) agonists and antagonists, gel mobility shift assays indicated that the isoflavones do not inhibit dioxin-induced activation of the AHR or the accumulation of CYP1A1 mRNA, suggesting that the isoflavones do not act at the transcriptional level. We therefore evaluated the isoflavones for direct effects on the CYP1A1 enzyme. Daidzein and genistein are noncompetitive with the CYP1A1 substrate BaP for microsomal BaP hydroxylation, with apparent K_i values of 325 μM and 140 μM, respectively. The extent of CYP1A1 inhibition increases with time of preincubation at 37°C, but not at 4°C, in the presence of isoflavone plus NADPH; after 60 min preincubation the inhibition remains noncompetitive, with apparent K_i values of 55 μM and 50 μM, respectively. Inhibition is neither prevented nor reversed by the thiol antioxidant dithiothreitol, nor by the iron chelator deferoxamine. Repeated washing of the microsomes does not reverse the inhibition. These results suggest that the isoflavones undergo NADPH-dependent formation of metabolites that inhibit CYP1A1 activity, contributing to the mechanism by which these soybean isoflavones protect against carcinogenesis. (Supported by NIH Grants P30-ES06096, RO1-AG09235, RO1-ES06811 and RO1-ES06273.)

459 ETHANOL-MEDIATED INDUCTION OF CYP1A1/2 IN RAT SKELETAL MUSCLE.

M R Miller, C Smith, S C Stamm, J E Riggs, W Stauber, V Harsh, and P M Gannett. *West Virginia University Health Sciences Center, Morgantown, WV, USA.*

This study tested the hypothesis that feeding rats an ethanol-containing diet would induce CYP2E1 and/or CYP1A1/2 in skeletal muscle tissue; these cytochrome P450 enzymes were also analyzed in liver, as a positive control tissue. Enzymatic assays, *p*-nitrophenol (PNP, for CYP2E1) and ethoxyresorufin O-deethylase (EROD, for CYP1A1/2), as well as Western blot analysis, demonstrated that a liquid diet containing 6% ethanol and delivered via a feeding system using glass bottles and rubber stoppers with a stainless steel tube (Feeding System 1) induced CYP2E1 and CYP1A1/2 in liver tissue. Immunocytochemistry studies confirmed induction of these liver enzymes by the ethanol-containing diet. Immunohistochemical analysis of skeletal muscle (soleus, plantaris and diaphragm) indicated ethanol-containing diets administered by Feeding System 1 induced CYP1A1/2, and immunohistochemical staining was predominantly localized to capillaries surrounding myofibers. However, antibodies to CYP2E1 did not detectably react with skeletal muscle tissue from animals receiving a control or ethanol-containing diet. Identical results were obtained when highly purified ethanol was prepared and administered in the diets. However, when liquid diets were administered via Feeding System 2 (all-glass feeding system), CYP1A1/2 was not induced by ethanol-containing diets in liver or in skeletal muscle tissue; CYP2E1 was induced in liver by Feeding System 2. The results indicate that feeding ethanol can mediate induction of CYP1A1/2 in liver and in capillaries of skeletal muscle; however, this induction was not attributed to ethanol *per se*, but rather to an unidentified compound(s) apparently solubilized by 6% ethanol from rubber stoppers or stainless steel tubing.

460 IN VITRO INHIBITION BY PRENYLATED FLAVONOIDS OF HUMAN CYP1A2-MEDIATED METABOLISM OF ACETANILIDE AND AFLATOXIN B_1.

M C Henderson[1], C L Miranda[1], J F Stevens[2], M L Deinzer[2] and D R Buhler[2]. [1]*Departments of Environmental and Molecular Toxicology and* [2]*Chemistry, Oregon State University, Corvallis, OR, USA.*

Three prenylated flavonoids, xanthohumol (XN), isoxanthohumol (IX), and 8-prenylnaringenin (8PN), have recently been isolated from hops (*Humulus lupus*) and their presence detected in beer. Studies with human breast cancer cell lines indicate possible cancer chemopreventive activity of these compounds. We examined these flavonoids for their ability to inhibit cDNA-expressed human CYP1A2 activity toward the diagnostic substrate acetanilide and the carcinogen, aflatoxin B_1 (AFB_1). At 10 μM concentration, IX and 8PN eliminated more than 90% of the acetanilide 4-hydroxylase activity of CYP1A2 compared to ETOH-treated controls. XN inhibited this P450 activity by 68%. When the inhibitory activity of the flavanone, IX, and the chalcone, XN, were compared in a dose-response study, they gave IC50 values of 4.5 and 31.4, respectively. Since the metabolism of AFB_1 is also catalyzed, at least partially, by CYP1A2, IX and 8PN were further examined for their effect on this activity. When added to incubation mixtures at 25 μM for 8PN and 100 μM for IX, both flavonoids were potent inhibitors of the conversion of AFB_1 to tris dihydrodiols and AFM_1, with virtually none of the diols and only 4-5% of the AFM_1 remaining as compared to ETOH-treated controls. Even at 5 μM, 8PN and IX inhibited production of AFM_1 by 65.3 and 38.3%. These results suggest possible use of these flavonoids as chemopreventive agents and additionally, as diagnostic inhibitors of CYP1A2. (Supported by the Hop Research Council and NIEHS grant ES00210.)

461 CYP1A1 AND CYP1B1 IN BREAST CELL LINES.

W G R Angus, M C Larsen, L Zhang, S E Eltom, P R Hanlon, and C R Jefcoate. *Dept. of Pharmacology and Environmental Toxicology Center, University of Wisconsin, Madison, USA.*

Eight human breast tumor cell lines differing with respect to estrogen receptor (ER) status and indicators of progression (invasiveness, chemotaxis), were assessed for expression levels of CYP1A1 and CYP1B1 and for AhR, AhR nuclear translocator protein (ARNT),. The response to TCDD was measured with respect to each of these genes. In selected lines, we measured the response to TCDD with respect to AhR nuclear translocation and activation from AhR/ARNT complexes with the transcription response element (gel mobility shift assay). Four of the lines utilized were characterized as more progressive, and differed collectively from three lines typically categorized as in the earlier stages of tumorigenesis, with respect to AhR mRNA levels and maximal induction of CYP1A1. AhR mRNA was low in early, ER-positive lines, and basally undetectable CYP1A1 induced to very high levels. In the later, ER-negative lines, AhR mRNA was at modest to high levels, while CYP1A1 was poorly induced. Basal and induced levels of CYP1B1 were also lower in the late lines. The MCF 10A line, like primary human breast epithelial cells, expressed high AhR, but CYP1A1 and CYP1B1 levels that were typical in the early lines. Expression of ARNT mRNA was inversely related with AhR mRNA. TCDD effected downregulation of AhR protein in all cells to about the same extent but did not affect AhR or ARNT mRNA levels. Although early T47D and later Hs 578T cells differ extensively in AhR activity and expression, amounts of TCDD-induced AhR/ARNT/XRE complex formed from nuclear extracts was similar. This study indicated that expression levels of these four genes provides a marker of breast tumor progression. The correlations between their expression levels suggests a coordination of AhR/ARNT expression and activity that changes from early to late stage tumor cells. (Supported by grants DOD DAMD17-94-J-4054 (CRJ), NIH 144-FR43 (CRJ), NIEHS 144EN46 (CRJ), and NRSA 1-F32-ES05733-03 (WA).)

461A MOLECULAR INDENTIFICATION OF CYTOCHROME P450 1B IN LIVER OF SCUP (*Stenotomus chrysops*) AND STRIPED DOLPHIN (*Stenella coeruleoalba*) AND CYTOCHROME P450 1A1 IN STRIPED DOLPHIN TESTIS.

C A J Godard[1,2], M R Said[1], M J Moore[1], R L D Dickerson[2], and J J Stegeman[1]. [1]*Department of Biology, Woods Hole Oceanographic Institution, Woods Hole, MA;* [2]*Department of Environmental and Human Health, Texas Tech University, Lubbock, TX.*

Cytochrome P450 (CYP) enzymes transform a variety of endogenous substrates and environmental contaminants. The CYP1 family (CYP1A1, CYP1A2 and CYP1B1) is the most active in oxidation of polychlorinated biphenyls and polycyclic aromatic hydrocarbons. CYP1As have been cloned from numerous species (fish, birds and mammals) while CYP1B1, prominent also in estradiol hydroxylation, has been identified only in human, rat, and mouse. We investigated the presence of CYP1B-like sequences in fish and cetaceans. RT-PCR using degenerate primers amplified a 461 base pair (bp) fragment from scup liver and a 388 bp fragment from dolphin liver. The scup sequence shares 62% amino acid (aa) identity and 65% nucleotide (nt) identity with human CYP1B1 and 58% aa and 63% nt identities with both rodent CYP1B1s. The dolphin fragment has 89% aa and 85% nt sequence identities with human CYP1B1 and 86% aa and 82% nt sequence identities with rodent CYP1B1s. Scup and dolphin CYP1Bs share 49% aa and 64% nt sequence identities. A 392 bp fragment also was amplified from dolphin testis and has 77% aa and 83% nt sequence identities with human CYP1A1. The significance of CYP1A1 expression in dolphin testis is unknown. Analysis of function and regulation of fish and cetacean CYP1Bs may indicate further the endogenous and toxicological significance of the CYP1B subfamily. (Supported by Sea Grant NA46RG0470-R/P61,EPA R829890-01, and NIH ES04696.)

462 COMBINATION ANTICONVULSANT TREATMENT OF SOMAN-INDUCED SEIZURES.

I Koplovitz[1], S M Schulz[1], R F Railer[1], R Macalalag[1], M Schons[1], M B Shutz[1], and J H McDonough[1]. [1]*U.S. Army Med. Res. Inst. Chem. Def., Aberdeen Proving Ground, MD.* Sponsor: J A Romano.

Diazepam is the currently fielded anticonvulsant drug for treatment of nerve agent seizures in the U.S. military, but several drawbacks limit its usefulness. This has fueled the search for alternative therapeutic approaches. One approach being considered is to supplement diazepam with a second anticonvulsant drug. These studies investigated the effectiveness of combination treatment of soman-induced seizures with a benzodiazepine and an anticholinergic drug. The anticholinergic drugs considered were biperiden, scopolamine, trihexyphenidyl, and procyclidine; the benzodiazepines were diazepam and midazolam. Male guinea pigs were surgically implanted with cortical screw electrodes to monitor and record electrocorticograms. Pyridostigmine (PB; 0.026 mg/kg, i.m.) was injected as a pretreatment to inhibit erythrocyte AChE by 30 - 40%. Thirty min after PB, 2LD50s (56 μg/kg) of soman was injected s.c. followed 1 min later by i.m. treatment with atropine (2 mg/kg) + 2PAM (25 mg/kg). Electrographic seizures occurred in all animals. Anticonvulsant treatment combinations were administered i.m. at 5 or 40 min after seizure onset. Combination treatment consisted of diazepam or midazolam plus one of the above mentioned anticholinergic drugs. Doses of the treatment com- pounds were utilized that exhibited little or no antiseizure efficacy when given individually. The combination of a benzodiazepine and any of the anticholinergic drugs was effective in terminating soman-induced seizure, whether given 5 or 40 min after seizure onset. The results suggest a strong synergistic antiseizure effect of combining benzodiazepines with centrally active anticholinergic drugs and support the concept of using this approach for treatment of nerve agent-induced seizures.

463 CHOLINESTERASE ACTIVITY: MUSCARINIC RECEPTOR RATIOS IN CANINE AND FELINE BRAINS.

R R Dalefield and F W Oehme. *Comparative Toxicology Laboratories, Kansas State University, Manhattan, KS, USA.*

In response to the findings that brain cholinesterase (ChE): muscarinic receptor density (mChR) ratio is highly conserved between bird species and is useful to diagnose acute organophosphate (OP) toxicosis in birds for which normal brain ChE is unknown (J.Wildlife Dis. 32(2),1996,216-224), our current study investigated the conservation of brain ChE:mChR between mammalian species and assessed the ratio's usefulness for diagnosis of OP toxicosis in dogs. Whole brains of 7 normal greyhounds, 13 normal non-greyhound dogs, 9 normal cats, 2 beagles with subacute (~72 h) OP toxicosis, and 1 greyhound with acute (<4 h) OP toxicosis, were assayed for ChE, mChR and protein. The same assays were made on cerebrum, cerebellum and brainstem from the greyhounds and 6 of the non-greyhound dogs. The Ellman assay was used to measure ChE, mChR were labelled with tritiated quinuclidinyl benzilate, and protein was measured by Lowry assay. The mean brain ChE :mChR (umol/min/mg protein:nmol/mg protein) for non-greyhounds was 1:16.8 (sd 5.5, n=14, range 1:9.9-1:24.8), for greyhounds 1:21.9 (sd 6.4, n=7, range 1:11.9-1:32.5), for cats 1:11.6 (sd 5.36, n=8, 1:6.2-1:20.5), for the greyhound with acute OP toxicosis 1:30.31, and for the 2 beagles with subacute toxicosis 1:68.8 and 1:76.8. Trends for cerebrum, cerebellum and brainstem were similar. Only in cerebrum was ChE:mChR in acute OP toxicosis distinctly different to that of normal greyhounds. Brain ChE:mChR was not highly conserved within or between the species. There was as great a difference in mean ChE:mChR between non-greyhounds and greyhounds as between non-greyhounds and cats. The ChE:mChR was profoundly altered in 2 cases of subacute OP toxicosis, but only slight to moderate change occurred in the acute OP toxicosis. Measurement of ChE:mChR is not a significant improvement to ChE assay alone and is unlikely to be useful in endangered felids or canids for which normal ChE levels are unknown, because it cannot be assumed that endangered species would have the same ChE:mChR as their domestic relatives.

464 EVALUATION OF THE NEUROTOXICITY OF LINDANE USING A FUNCTIONAL OBSERVATIONAL BATTERY.

S Goubin, C Fabreguettes, S de Jouffrey, and R Forster. *CIT (Centre International de Toxicologie), Evreux, France.* Sponsor: R Glomot.

Lindane (γ -hexachlorocyclohexane) is a chlorinated hydrocarbon pesticide that produces an inhibition of the GABA-ergic neurotransmitter system. The neurotoxicity of Lindane in the rat was assessed using a Functional Observational Battery (FOB). In a 2-week preliminary study, mortality and convulsions were noted in females at the beginning of the study, whereas at the same dose-levels, no signs of neurotoxicity were observed in males. In the neurotoxicity study, male animals only were studied. Male Sprague-Dawley rats were given Lindane daily by the oral route for four weeks at 0, 30, 40 and 55 mg/kg/day in corn oil. The FOB was performed in the pre-treatment period, and in weeks 1, 2, 3 and 4 of the treatment period. During weeks 1 and 2, there were marked, dose-related signs of neurotoxicity. After this, the animals appeared to become habituated to Lindane treatment: in weeks 3 and 4 the dose-relationship was less clear and fewer animals showed signs of neurotoxicity. The principal functions altered by Lindane were autonomic functions (soiled fur, ptyalism), muscle tone and equilibrium (gait on tiptoe, round back), central nervous system activity and excitability (hyperactivity, hyperreactivity to the touch escape and to handling, convulsions), sensorimotor functions (hyperreactivity to the touch and tail pinch), and physiologic functions (lower body weight gain in treated groups compared to control group). No variation of spontaneous motor activity was recorded in treated groups using the open field apparatus. The majority of these neurotoxic effects (excepting convulsions and ptyalism, both of which were observed just after administration) could be detected and quantified using the FOB approach.

465 ASSESSMENT OF NEUROTOXICITY IN PESTICIDE-EXPOSED WORKERS USING AUTOANTIBODY (AAb) PROFILES.

H A N El-Fawal[1,2] and M Y Shamy[3]. [1]*Mercy College, Dobbs Ferry, NY;* [2]*NYU Medical Center, NY, NY, USA ;* [3]*Institute of Public Health, University of Alexandria, Alexandria, Egypt.* Sponsor: J P O'Callaghan.

Previously, in human and animal studies, serum AAb to nervous system (NS) proteins were shown to be indicative of metal neurotoxicity. In the present study agricultural workers exposed to pesticides (n=100; 17±6 y exposure) and a reference population from a food processing plant (n=50, no direct exposure) were assessed for possible neurotoxicity using serum AAb detection against neurofilaments (NF), myelin basic protein (MBP), desmin (D), and acetylcholinesterase (AChE). Pesticide exposures included organophosphates (OPs; e.g., metamidophos), carbamates (e.g., ethiophencarb) and pyrethroids (deltamethrin). Blood AChE activity and blood lead levels (PbB) levels were also determined. AAb IgG to NF, neuronal intermediate filaments, and MBP predominated in pesticide workers. IgG to D, a muscle intermediate filament, and to AChE were detected in 70% of the pesticide-exposed group. AChE activity was 40-60% of normal (26 IU/g Hb).

PbB, determined to rule out other neurotoxicants, was 12 ± 5 μg/dl. In contrast, few of the reference population had detectable IgG levels, 40% had IgM to NF. None had either IgG or IgM to MBP, D, or AChE. IgG levels to NF correlated with exposure duration. In addition, IgG levels to NF and D correlated with peripheral sensorimotor deficits (muscle tremor and reflexes). There was some correlation with PbB in a subset of the population. The detection of AAb to NF and AChE suggests neuronal involvement, while detection of AAb to D suggests some myopathy. This is consistent with the sensorimotor deficits detected. AChE inhibition, particularly by OPs, has been shown to induce muscle damage. Some of these OPs are also known to produce a delayed neuropathy which results in AAb. This study suggests that AAb detection may be used in monitoring pesticide neurotoxicity.

466 INFLUENCE OF DITHIOCARBAMATES ON THE DEVELOPMENT OF ORGANOPHOSPHATE INDUCED DELAYED POLYNEUROPATHY (OPIDP).

G Gardiman, A Moretto and M Lotti. *Università di Padova, Padova, Italy.*

Some esterase inhibitors interfere with OPIDP development. By inhibiting neuropathy target esterase (NTE), the target of OPIDP, they protect from OPIDP when given before the neuropathic organophosphate; they promote OPIDP when given afterwards. If they do not inhibit NTE they may promote OPIDP regardless of the dosing sequence. Protection and promotion are associated with inhibition of NTE and M200 (the target of promotion), respectively. Hens were treated with dithiocarbamate herbicides molinate, thiobencarb, thiocarbazyl, or cycloate because they are metabolized to sulfones and sulfoxides. Inhibitions (mean%±SD, n=3) of NTE and M200 in the nervous system measured 24 h after dosing were: molinate (180 mg/kg sc) 84±11 and 99±1, thiobencarb (1350 mg/kg sc) 29±13 and 50±13, thiocarbazyl (1150 mg/kg sc) 17±15 and 3±7, and cycloate (1090 mg/kg sc) 42±1 and 25±10, respectively. No neuropathy developed in paired treated hens. Hens (n=5-9 per group) were treated with either diisopropyl fluorophosphate (DFP, 0.5 mg/kg sc) or dibutyldichlorovinylphosphate (DBDCVP, 0.4 mg/kg sc) followed by the above doses of a dithiocarbamate 24 h later. Molinate or thiobencarb promoted neuropathies by DFP (clinical score from 1 to 3, 0-8 point scale) and DBDCVP (clinical score from 1 to 3, molinate only tested). When given before a neuropathic dose (1 mg/kg sc) of either DFP or DBDCVP, molinate protected from OPIDP (clinical score from 4 and 2, respectively, to 0) whereas thiobencarb promoted both DFP and DBDCVP neuropathies (both scores 8). A new class of compounds has been found to interfere with OPIDP. Data are consistent with the concept that NTE is the target for initiation and protection whereas M200 is the target of promotion.

467 PROTECTION OF CEREBELLAR PURKINJE CELLS IN ORGANOPHOSPHORUS COMPOUND-INDUCED DELAYED NEUROTOXICITY (OPIDN) BY PHENYLMETHANESUL-FONYLFLUORIDE (PMSF).

B R Marable, R L-F Lightle, R J Richardson, and M A Philbert. *Toxicology Program, The University of Michigan, Ann Arbor, MI, USA.*

Previous work has shown that the effects of OPIDN on the adult rat cerebellum can be potentiated by posttreatment with PMSF. We sought to determine if pretreatment with a sub-potentiating dose of PMSF would protect against these effects. Groups of male Wistar rats (8-10 mo old) were pretreated with PMSF (90 mg/kg sc) followed by di-*n*-butyl-2,2-dichlorovinyl phosphate (DBCVP; 6 mg/kg sc) and 2 doses of PMSF (125 mg/kg/day sc). All treatments were separated by 24 hr intervals. Additional groups were treated with PMSF or vehicle (glycerol formal) alone in the indicated doses and intervals. 48 days following the first doses of PMSF an additional group of rats received harmaline (40 mg/kg/day ip in saline for 2 days) to serve as positive controls for vermal Purkinje cell degeneration. On day 50, all rats were perfused with 10% neutral buffered formalin and brains were processed for light microscopy. Sagittal sections of cerebellum were immunostained with a monoclonal antibody directed against calbindin to visualize Purkinje cells. Cerebellar Purkinje cell degeneration was seen only in animals treated with harmaline and was characterized by extensive loss of vermal Purkinje cell bodies and their dendritic processes. These results confirm and extend earlier work showing that pretreatment with OPIDN potentiators such as PMSF protects against the effects of this disease. Future work will include the use of more potent potentiators than PMSF to examine the mechanism of neuroprotection. (Supported by Dow AgroSciences, PHS-NIH grants ES07062, and ES60103.)

468 ACETYLCHOLINESTERASE ACTIVITY IN SPECIFIC REGIONS OF THE CANINE BRAIN.

B A Litzenberger, H Jonassen, D R Compton, and C M Kelly. *Princeton Research Center, Huntingdon Life Sciences, East Millstone, NJ, USA.*

Suggested revisions to the federal guidelines on the evaluation of cholinesterase inhibitors indicate the need to use a more accurate enzyme assay and to determine better biological indicators of human risk. The principal biological target of cholinesterase inhibiting pesticides, of concern in risk assessment, is the enzyme present in the brain, which is primarily acetylcholinesterase (AChE). Several AChE isozymes exist in the brain, but little is known about the specificity of action of pesticides on brain regions. Enzymatic activity in brain tissue was assessed utilizing a modified Ellman procedure [US EPA, Federal Register April 26, 1996; Vol. 61:(82), 18593], which is devoid of the inaccuracies of traditional assays. To investigate the regional activity of AChE, male and female canine brains were dissected using recognized visual landmarks to obtain the cerebellum, cortex, hippocampus and caudate-putamen. AChE activity was similar between males and females, though whole brain activity was not established. AChE activity [mean (± S.E.)] in the canine cerebellum was 17.5 (± 0.9) IU/mL of homogenate, which is approximately equal to that of the whole brain of the rat. Enzymatic activity in the canine cortex and hippocampus was approximately 15% and 40%, respectively, of the cerebellum value. AChE activity in the canine caudate-putamen was approximately 480% of the cerebellum value. This work provides data characterizing regional AChE activity in canine brain, and is a necessary precursor to assessing the regional specificity of action of pesticides, which could further lead to the identification of more appropriate indicators of the potential risk of pesticides to humans.

469 ACETYLCHOLINESTERASE INHIBITION AND [^{3}H]OXO-TREMORINE BINDING IN NEONATAL AND ADULT RAT HEART FOLLOWING REPEATED ORAL CHLORPYRIFOS EXPOSURES.

M Stiles and C Pope. *Div. Toxicol., Northeast LA Univ., Monroe, LA.*

Chlorpyrifos (CPF) is a commonly-used organophosphorus pesticide (OP) whose primary mode of action is inhibition of the enzyme acetylcholinesterase (AChE, EC 3.1.1.7). It has also been reported that some muscarinic receptor subtypes (e.g., m2) may be additional direct sites of action for OPs. Several laboratories have reported marked age-related differences in sensitivity to OPs including CPF. As the heart contains primarily m2 muscarinic receptors, these putative direct interactions may be important in the age-related toxicity of OPs. We studied the comparative AChE inhibition and downregulation of muscarinic m2 receptor ([^{3}H]oxotremorine) binding in neonatal (7 days of age) and adult (90 days of age) rat heart after repeated oral CPF exposures. Neonatal (n=3-6/group) and adult (n=3/group) rats were given CPF (0, 0.15, 0.45, 0.75, 1.5, 4.5 or 7.5 mg/kg/d for 14 d) by gavage in peanut oil and sacrificed 4 hrs after the last exposure for biochemical assays. Relatively similar levels of AChE inhibition were noted in both age groups after repeated CPF exposures ($ED_{50\%}$ 1 mg/kg/d). In contrast, [^{3}H]oxotremorine binding was only reduced in adults (22-35% reduction at 1.5-7.5 mg/kg/d). While the muscarinic agonist carbachol was a potent blocker of specific [^{3}H]oxotremorine binding sites in adult cardiac membranes *in vitro*, the active anticholinesterase metabolite of CPF (CPF-oxon) only marginally affected [^{3}H]oxotremorine binding (≈ 10% reduction at 5 uM). These results suggest that cardiac muscarinic receptors in neonatal and adult rats are differentially modulated by AChE inhibition and that direct binding by the oxon to cardiac receptors is of lesser importance. Differential modulation of cardiac muscarinic receptors in neonates and adults could contribute to age-related differences in response to OPs. (Supported by U.S. EPA R 825811-01-0.)

470 COMPARATIVE EFFECTS OF PARAOXON, CHLORPYRIFOS OXON AND MUSCARINIC AGONISTS ON HIGH AFFINITY CHOLINE UPTAKE IN RAT CORTICAL AND STRIATAL SYNAPTOSOMES.

K Olivier, J Liu and C Pope. *Div. Toxicol., Northeast LA Univ., Monroe, LA.*

High affinity choline uptake (HACU) is the rate limiting step in acetylcholine synthesis and has been reported to be regulated by cyclic adenosine monophosphate (cAMP) levels in the cholinergic presynaptic terminal. The muscarinic m2 and/or m4 receptor subtype is coupled to inhibition of adenylyl cyclase and some organophosphorus (OP) anticholinesterases appear capable of direct activation of these receptors in vitro. We studied the possi-

ble direct activation of synaptosomal muscarinic receptors and consequent modulation of HACU in cortex and striatum by the active anticholinesterase metabolites of the common OP pesticides parathion and chlorpyrifos (paraoxon and chlorpyrifos oxon) in comparison to the well-known muscarinic agonists carbachol, oxotremorine and *cis*-dioxolane. Neither paraoxon nor chlorpyrifos oxon (1-1,000 uM) had any effect on choline uptake in this system. In contrast, all three agonists inhibited HACU in a concentration-dependent manner, with potencies cis-dioxolane ($IC_{50\infty}$ 100 uM) > oxotremorine ($IC_{50\infty}$ 400 uM) > carbachol ($IC_{50\infty}$ 1 mM). While muscarinic agonists all inhibited HACU (presumably through inhibition of cAMP formation), addition of exogenous cAMP (8-bromo-cAMP, up to 3 mM) had no effect on choline uptake. We conclude that muscarinic receptor activation can modulate HACU in cortical and striatal synaptosomes but neither paraoxon nor chlorpyrifos oxon appear capable of directly activating this muscarinic receptor subtype. (Supported by U.S. EPA R 825811-01-0.)

471 EFFECTS OF ORAL CHLORPYRIFOS ON CORTICAL AND STRIATAL MUSCARINIC AUTORECEPTOR FUNCTION IN NEONATAL, JUVENILE AND ADULT RATS.

Y Won, Q Zheng, J Liu and C Pope. *Div. Toxicol., Northeast LA Univ., Monroe, LA.*

Several laboratories have reported marked age-related differences in sensitivity to organophophorus pesticides including chlorpyrifos (CPF). We previously reported that muscarinic receptor-mediated inhibition of acetylcholine release (i.e., muscarinic autoreceptor function, MAF) is disrupted in a time- and OP-selective manner in adult rat striatal slices. The modulation of MAF was studied in cortical and striatal slices of neonatal (7 days of age, n=3-4), juvenile (21 days of age, n=3) and adult (90 days of age, n=3-5) rats at 1 and 4 days following oral CPF exposure. Preliminary studies determined LD_{10} values for each age group (neonate=15 mg/kg; juvenile=47 mg/kg; adult=136 mg/kg) and these respective dosages were used throughout. MAF was studied in brain slices prelabeled with [^{3}H]choline, superfused in the presence of physostigmine (10 μ M), and stimulated twice (S1 and S2) with buffer containing high potassium (15 mM), with atropine (1 μ M) added 10 min prior to the second stimulation (S2). Either an increase in S1 or a decrease in S2/S1 is an indicator of impaired MAF. There were no significant differences in release (either S1 or S2/S1 ratio) in neonates at either timepoint in either brain region. In juveniles, CPF exposure increased (185-224% of control) striatal acetylcholine release (S1) at both timepoints indicating possible impairment of MAF, but no change in the S2/S1 ratio was noted. Cortical release (S1) was only increased (172% of control) at 1d after exposure. Again, no change in S2/S1 was noted in cortex. Adults treated with CPF exhibited no change in striatal or cortical release (S1) at 1 d after exposure but release in both regions was increased (127-149% of control) at 4 d. Reductions in the S2/S1 ratio were also noted in both regions at 4 d after treatment. The results suggest that MAF may be affected in an age- and time-dependent manner by CPF and that alterations in acetylcholine release could contribute to age-related differences in response to CPF. (Supported by U.S. EPA R 825811-01-0.)

472 DIFFERENTIAL ALTERATIONS IN CORTICAL NICOTINIC RECEPTOR-MEDIATED ACETYLCHOLINE (ACh) RELEASE FOLLOWING *IN VIVO* AND *IN VITRO* ORGANOPHOSPHATE (OP) EXPOSURE.

P R Harp and C N Pope. *Div. of Toxicology, Northeast Louisiana Univ., Monroe, LA, USA.*

Parathion (PS) and chlorpyrifos (CPF), two structurally-similar OP insecticides, have been previously reported to produce differing degrees of toxicity in the presence of similar degrees of acetylcholinesterase (AChE) inhibition, suggesting one or both OPs has an additional biochemical target with which interaction can influence anticholinesterase toxicity. The ability of nicotinic autoreceptors, a potential alternative OP target, to positively modulate acetylcholine (ACh) release after OP exposure was evaluated in cortical synaptosomes preloaded with [^{3}H]choline. Nicotinic autoreceptor function (NAF) was measured 4, 24 and 48 hrs after *in vivo* PS (18 mg/kg, sc) or CPF (280 mg/kg, sc) exposure. Synaptosomes were superfused with physiological buffer (in the presence of atropine, 1μM) to determine basal (6mM KCl) and stimulated (KCl + 10μM ACh) [^{3}H]ACh release. Under these conditions, ACh caused 100-125% increase in [^{3}H]ACh release which was completely blocked by mecamylamine (100μM). Neither OP altered [^{3}H]ACh release 4 hrs after OP exposure. CPF, however, reduced (~20%) ACh-stimulated [^{3}H]ACh release 24 hrs after exposure, compared to either control or PS, and both OPs reduced (~25%) ACh-stimulated transmitter release 48 hrs after exposure. *In vitro*, PO (100nM) enhanced ACh-stimulated release but inhibited release at higher concentrations (10-100μM) while CPFO had no effect at any concentration (10nM-100μM). The results suggest both OPs may alter NAF, depending on the specific conditions of exposure. Further, the earlier reduction (24 hrs vs. 48 hrs) of stimulated neurotransmitter release by CPF *in vivo* and the increase in transmitter release by PO *in vitro* (100nM) are both consistent with the higher incidence of toxicity noted following PS exposure. The differential effects of PS and CPF, or their oxon metabolites, on NAF could contribute to the differential toxicity of these agents with similar levels of AChE inhibition. (Supported by U.S. EPA R 825811-01-0.)

473 COMPARISON OF NEUROCHEMICAL EFFECTS OF CHLORPYRIFOS AND METHYL PARATHION ON THE CHOLINERGIC SYSTEM IN EARLY POSTNATAL RATS.

J Tang, R L Carr, and J E Chambers. *Ctr for Environ Health Sci, College of Veterinary Medicine, Mississippi State Univ, Miss. State, MS, USA.*

The effect of repeated chlorpyrifos (CP) and methyl parathion (MPS) exposures on brain acetylcholinesterase (AChE) activity and muscarinic acetylcholine receptor (mAChR) density were studied and compared in early postnatal rats gavaged with CP or MPS in corn oil from postnatal day (PND) 1 through PND 21. In CP treatment groups, young rats were divided into 3 groups and received CP every other day starting at 3 mg/kg and increasing gradually to 6 mg/kg (for medium dosage group) to 12 mg/kg (for high dosage group). In MPS treatment groups, young rats were divided into 3 groups and received MPS every day starting at 0.3 mg/kg and increasing gradually to 0.6 mg/kg (for medium dosage group) to 0.9 mg/kg (for high dosage group). Brain AChE activity was assayed in brain homogenates. Brain mAChR density was assayed in brain synaptosomes with ^{3}H-*N*-methylscopolamine (NMS) and ^{3}H-quinuclidinyl benzilate (QNB) as ligands. Control groups for both treatments showed almost the same brain AChE activities and mAChR densities, indicating that the vehicle or dosing regime did not affect these parameters. In CP treatment, about 29%, 57%, and 63% of AChE activities were inhibited in the low, medium, and high dosage groups, respectively, 1 day after the last dose; reductions of ^{3}H-NMS were observed on PND 6, PND 14, PND 22, and PND 25. In MPS treatment, about 25, 42 and 55% of AChE activities were inhibited in the low, medium and high dosage groups, respectively, 1 day after the last dose; reductions of ^{3}H-NMS were only observed on PND 22. The results indicate that repeated exposures to CP or MPS will result in prolonged inhibition of brain AChE activities and reductions in mAChR densities. The reduction of mAChR density may be differentially regulated by CP and MPS exposures. (Supported by NIH RO1 ES04394.)

474 EFFECTIVENESS OF DETERGENT SOLUBILIZATION OF CHOLINESTERASE FROM PERIPHERAL TISSUES IN THE RAT.

J E Chambers[1], J S Boone[1], R L Carr[1], P D Dass[2] and L P Sheets[2]. [1]*Center for Environmental Health Sciences, College of Veterinary Medicine, Mississippi State University, Mississippi State, MS, USA;* [2]*Toxicology Department, Bayer Corporation, Stilwell, KS, USA.*

The assay of cholinesterase (ChE) activity in peripheral target tissues following exposures to anticholinesterase insecticides may yield more useful information regarding toxic impacts than the traditional analyses of ChE in plasma or red blood cells. However, because of the low ChE activity and the presence of higher levels of connective tissues, a colorimetric assay is problematical. Colorimetric assays were conducted by two independent laboratories using acetylthiocholine as a substrate in homogenates of brain, skeletal muscle, lung, heart, diaphragm and salivary glands prepared with or without detergent (1% TritonX-100) and which had been centrifuged to yield a membrane pellet and supernate. The following percentages of activity of the whole homogenate were present in the supernate for each tissue in the non-detergent-containing and detergent-containing preparations, respectively: brain, 13, 88; skeletal muscle, 30, 66; lung, 37, 65; heart, 40, 79; diaphragm, 26, 49; and salivary gland, 36, 77. Therefore, in contrast to brain, appreciable activity is retained in the membrane fraction of these peripheral target tissues even in the presence of detergent. Homogenization at higher motor speeds or for longer periods of time did not solubilize appreciably greater amounts of enzyme activity. Since these insoluble fractions will not be sampled by the small bore pipet tip of clinical autosamplers, a significant amount of ChE activity in some peripheral tissues will not be analyzed using these machines. It is not known whether these solubilized and insoluble preparations of ChE would contain the same percentage of inhibited ChE from anticholinesterase-treated animals.

475 EFFECTS OF DPX-MP062 and DCJW ON THE NEURONAL NICOTINIC ACETYLCHOLINE AND GABA RECEPTORS IN MAMMALIAN NEURONS.

X Zhao, K Nagata, W Marszalec, J X Zhao, K Nagata, W Marszalec, J Z Yeh and T Narahashi. *Dept. of Mol. Pharmacology and Biol. Chemistry, Northwestern University Medical School, Chicago, IL, USA.*

Little is known about the mechanism of action of a novel insecticide DPX-MP062, indeno(1,2-*e*)(1,3,4)oxadiazine-4α (3*H*)-carboxylic acid, 7-chloro-2,5-dihydro-2-(((methoxycarbonyl)-((4-trifluoromethoxy)phenyl) amino)carbonyl)-methyl ester, except for the blocking action on insect neuronal sodium channels. We studied the effects of DPX-MP062 and its decarbomethoxyllated metabolite, DCJW, on the mammalian neuronal nicotinic acetylcholine receptors (nAChRs) and $GABA_A$ receptors which are known to be the targets of some other insecticides. Currents induced by ACh and GABA were recorded using the whole-cell patch clamp technique from rat cortical and dorsal root ganglion (DRG) neurons in primary culture, respectively. DPX-MP062 applied in bath at 1 or 10 μ M caused irreversible reductions of ACh-induced, rapidly desensitizing, α -bungarotoxin(α -BuTX)-sensitive currents in a dose-dependent manner. By contrast, ACh-induced, slowly desensitizing α -BuTX-insensitive currents were augmented by 1 or 10 μ M DPX-MP062 in dose-dependent, use-independent, and reversible manners. In addition, current decay was accelerated. DCJW at 1 or 10 μ M had similar but less potent actions than DPX-MP062 on both α -BuTX-sensitive and α -BuTX-insensitive currents. In contrast, the peak amplitude of GABA-activated currents was not affected by either 1 or 10 μ M DPX-MP062. However, the decay phase of GABA current was accelerated in a dose-dependent and reversible manner. DCJW at 1 and 10 μ M increased the peak current only slightly without any effect on current decay. These observations suggested that neuronal nAChRs are one of the target sites of DPX-MP062. This insecticide appears to be different from any other insecticides in terms of its mechanism of action.

476 EFFECTS OF THE TRIAZINE HERBICIDE CYANAZINE ON $GABA_A$ RECEPTOR LIGAND BINDING TO RAT BRAIN MEMBRANES AND GABA-STIMULATED $^{36}Cl^-$ FLUX IN SYNAPTONEUROSOMES.

C A Meacham[1], T R Ward[1], R L Cooper[2] and T J Shafer[1]. *Neurotoxicology[1] and Reproductive Toxicology[2] Divisions, NHEERL, US EPA, Research Triangle Park, NC, USA.*

Triazine herbicides disrupt luteinizing hormone (LH) release in female rats following *in vivo* exposure. Although the mechanism of action is unknown, inhibition of LH release by triazines may be mediated by effects in the central nervous system. $GABA_A$ receptors are important for neuronal regulation of gonadotropin releasing hormone and LH release. The ability of the triazine herbicide cyanazine to interact with $GABA_A$ receptors was examined by measuring effects of cyanazine on [^{3}H]muscimol, [^{3}H]Ro15-4513 and [^{35}S]*tert*-butylbicyclophosphorothionate (TBPS) binding to rat cortical membranes and on GABA-stimulated $^{36}Cl^-$ flux into rat cortical synaptoneurosomes. Cyanazine (1-200 μM) was without effect on [^{3}H]muscimol or [^{35}S]TBPS binding. However, cyanazine inhibited [^{3}H]Ro15-4513 binding with an IC_{50} of approximately 50 μM (n = 4). At concentrations of 1 and 5 μM, cyanazine shifted the EC_{50} for GABA-stimulated $^{36}Cl^-$ flux into synaptoneurosomes from 28.8 μM to 22.9 and 19.4 μM, respectively (n = 5). Diazepam (10 μM) and phenobarbital (100 μM) potentiated GABA-stimulated $^{36}Cl^-$ flux to 138% and 184 % of control, respectively. At concentrations of 50 and 100 μM, cyanazine decreased potentiation by diazepam to 119 and 107% of control, respectively, and decreased potentiation by phenobarbital to 167% of control (n = 5). These results suggest that cyanazine interacts with the $GABA_A$ receptor at the benzodiazepine, but not the muscimol (GABA receptor site) or TBPS (Cl^- channel) binding sites. Furthermore, at low concentrations, cyanazine may be a weak agonist at the benzodiazepine site, but at higher concentrations, cyanazine antagonizes the effects of diazepam and phenobarbital.

477 LESSONS LEARNED FROM STUDYING TOXICANT-INDUCED IRREVERSIBLE TESTICULAR INJURY.

K Boekelheide. *Brown University, Providence, RI, USA.*

In the last quarter century, our understanding of male reproductive biology and toxicology has advanced to the point that potential mechanisms of toxicant action can be proposed and tested (without too much laughter in the back of the room). This talk will highlight lessons learned from the mechanistic examination of 2,5-hexanedione-induced testicular injury, an intensely studied model system. LESSON #1: Hypotheses are both gross oversimplifications and useful tools. Since 2,5-hexanedione exposure results in relatively specific injury of the nervous system and testis while reacting globally with primary amines throughout the body, this requires an hypothesis by which a global modification can produce a specific injury. LESSON #2: The most exciting observations are those at odds with basic assumptions. The assumption that 2,5-hexanedione-induced irreversible testicular injury is a consequence of killing all the germ cells is just plain wrong. Primitive germ cells are present and happily proliferating after toxicant exposure—they just die instead of mature. Furthermore, "irreversible" injury is reversible with appropriate hormonal manipulation, opening up new avenues for exploring the basic biology of spermatogenesis, and for treating idiopathic azoospermia. LESSON #3: Life is a balance. Sertoli cells not only make growth factors (i.e., stem cell factor) that support germ cells, these "nurse" cells also make death factors (i.e., Fas ligand) to kill germ cells. The goal of the presentation will be to make these specific realizations broadly generalizable.

478 MECHANISM OF ACTION OF NICOTINE ON NEURONAL ACETYLCHOLINE RECEPTORS: FROM MOLECULE TO BEHAVIOR.

T Narahashi. *Department of Molecular Pharmacology and Biological Chemistry, Northwestern University Medical School, Chicago, IL, USA.*

Nicotine has long been known to interact with nicotine acetylcholine (ACh) receptors since Langley used it extensively to chart sympathetic ganglia a century ago. It has been used as an effective insecticide. However, it was not until 1990's that the significance of nicotine was increasingly recognized from the toxicological, pharmacological and environmental points of view. This is partly because studies of neuronal nicotinic ACh receptors are rapidly coming out of orphanage as fueled by several lines of developments. Since Alzheimer's disease is known to be associated with down-regulation of the cholinergic activity in the brain, a variety of nicotine derivatives are being tested and developed for the treatment of the disease. Public awareness of the adverse effects of nicotine has reached the highest level recently. Since incest resistance to insecticides is one of the most serious issues in the pest control arena, it is urgently needed to develop newer insecticides that act on target sites not shared by the existing insecticides. The neuronal nicotinic ACh receptor is one of them, and new nicotinoids are being developed. Thus time is ripe to discuss the mechanism of action of nicotine from a variety of angles including the molecular, physiological, and behavioral points of view. This is the major focus of the present Symposium.

479 REGULATION OF ACETYLCHOLINE RECEPTOR DESENSITIZATION AT LOW CONCENTRATIONS OF NICOTINE.

R A J Lester, C P Fenster, T Whitworth, M L Beckman, and M W Quick. *Department of Neurobiology, University of Alabama, Birmingham, AL, USA.* Sponsor: T Narahashi.

Tobacco-related concentrations of nicotine produce two major effects through neuronal nicotinic receptors (nAChRs): augmentation of neurotransmitter release and receptor desensitization. Following chronic exposure to low doses of nicotine, the number of CNS (4(2 nAChR binding sites increases while their functional responsiveness decreases. It has been argued that desensitization underlies these changes. We show here that desensitization of (4(2 nAChRs in Xenopus oocytes is strongly regulated by the cellular level of phosphorylation. For example, activation of PKC by PMA markedly enhances the rate of recovery from desensitization, following a 30 min exposure to 300 nM nicotine. Moreover, a mutant receptor, with a PKC consensus sequence on the (4 subunit removed exhibited little recovery from desensitization. These data are consistent with the idea that dephosphorylation may lead to a "permanently" inactive form of the receptor. In addition we have found that the relative increase in [3H]-nicotine binding to (4(2 receptors (and other subtypes) during a 24-48 hr exposure to nicotine is strongly correlated with the level of functional desensitization. Because, in addition, the mutant nAChR is more readily upregulated than the wild-type receptor, we suggest that a desensitized and dephosphorylated receptor conformation may act as a trigger for upregulation and explain the long-lasting decrease in receptor function after chronic treatment with low concentrations of nicotine. (Supported by PHS Grant NS31669.)

480 INTERACTIONS OF NICOTINE AND ALCOHOL AT NEURONAL NICOTINIC ACETYLCHOLINE RECEPTORS.

T Narahashi, W Marszalec and G L Aistrup. *Department of Molecular Pharmacology and Biological Chemistry, Northwestern University Medical School, Chicago, IL, USA.*

A positive correlation between alcohol drinking and tobacco smoking is well established, heavy drinkers tending to be heavy smokers. However, the mechanism underlying this correlation remains largely to be seen. Through patch clamp experiments using rat cortical neurons in primary culture, we obtained a clue to the mechanism. At least two types of currents were generated in response to the application of acetylcholine (ACh), a rapidly desensitizing ((7-like), (-bungarotoxin ((-BuTX)-sensitive current, and a non-desensitizing ((4-like), (-BuTX-insensitive current. The latter current was potentiated by the application of 3-300 mM ethanol, and desensitized without stimulation by nicotine at 200 nM, a concentration found in smoker's blood. This nicotine-induced desensitization may be related to antianxiety effects of smoking. Nicotine markedly desensitized the ACh-induced current potentiated by ethanol. Thus, ethanol-induced potentiation of current may lead to a craving for smoke. In conclusion, ethanol potentiation and nicotinic desensitization of ACh-induced currents may form the basis for the heavy drinking-heavy smoking correlation.

481 NICOTINIC RECEPTOR GENE FAMILY MEMBERS TARGETED BY ANTHELMINTICS AND INSECT CONTROL AGENTS.

D B Sattelle, E Culetto, N Mongan, J C Freeman and K Matsuda. *The Babraham Institute Laboratory of Molecular Signalling, Department of Zoology, Cambridge, UK.* Sponsor: T Narahashi.

Nicotine acetylcholine receptors (nAChRs) of the nematode C. elegans are the largest gene family of nAChRs currently known Molecular diversity is evident in regions of nAChR (subunits that contribute to the ACh binding site and the channel lining second transmembrane (M2) region. Functional expression studies on homomeric and heteromeric nAChRs provide evidence for multiple nAChR subtypes with differing sensitivities to anthelmintic drugs such as levamisole (1, 2). A complex family of nAChR genes is also present in the insect D. melanogaster. Recombinant expressed nAChRs containing a D. melanogaster (subunit SAD have enabled us to show that at certain nAChRs, Imidacloprid, a potent insecticide, is a partial agonist (3). Thus the study of nAChRs in model organisms which permit advanced genetic, genomic and functional analysis not only enhances our understanding of the full physiological spectrum of actions of ACh mediated by nAChRs, but also adds to out knowledge of the actions of anthelmintics and insect control agents.

482 PHARMACOLOGICAL PROPERTIES OF CENTRAL NICOTINIC RECEPTORS.

B R Martin and M I Damaj. *Virginia Commonwealth University, Richmond, VA, USA.*

There are multiple nicotine cholinergic receptors in the central nervous system that are either heterologous or homologous pentameric ion channels. Evidence is emerging that pain perception as well as seizure activity may be mediated through (4(2 and (7 receptors, respectively. Nicotine is effective in a wide range of antinociceptive assays in mice and rate when administered peripherally and centrally. These effects are blocked by mecamylamine but only weakly by methyllycaconitine (MLA, and (7 antagonist). Structure-activity relationship studies reveal that 3H-nicotine binding in rat brain (predominately (4(2) correlated well with both antinociceptive and motor depressant potencies. However, some nicotine derivatives, such as metanicotine, exhibit potent antinociception while being devoid of depressant properties. Nicotine also dose-dependently induced seizures in mice that are effectively antagonized by the centrally active antagonist mecamylamine (AD50 = 0.1 mg/kg), but not by hexamethonium. In addition, methyllycaconitine (MLA), an (7 antagonist, blocks the convulsive effect of nicotine (AD50 = 1.9 mg/kg). MLA fails to block other pharmacological effects of nicotine such as hypothermia, hypomotility and antinociception. While antinociception and seizure activity appear to be mediated via different receptor subtypes, increase in intracellular calcium levels appears to be involved in both effects. Calcium channel blockers as well as a calcium channel activator modulate nicotine-induced antinociception and seizure activity. These findings demonstrate that the multiplicity of nicotine's effects on the central nervous system can now be explored in a systematic manner. (Supported by NIDA Grant #DA-05274.)

483 CHRONIC NICOTINE INFUSION EFFECTS ON MEMORY: A VENTRAL HIPPOCAMPAL MECHANISM.

E D Levin. *Duke University Medical Center, Durham, NC, USA.*

Chronic nicotine infusion has been found to improve cognitive performance in humans and experimental animals. In humans, nicotine administration via skin patch has been found in our studies to significantly improve attentional performance in patients with Alzheimer's disease, schizophrenics, adults with attention deficit/hyperactivity disorder and normal nonsmoking adults. In an experimental rat model, we have found that chronic 4-week nicotine infusion with osmotic minipumps significantly improves working memory performance in the radial-arm maze. Since we found local infusions of nicotinic antagonists into the ventral hippocampus to cause significant working memory impairments, we hypothesized that this area is a critical locus for chronic nicotine infusion induced memory improvements. To test this hypothesis, female Sprague-Dawley rats were pretrained on an 8-arm radial maze and then given small ibotenic acid lesions in the ventral hippocampus or sham lesions. Half of the rats with each lesion treatment were given subcutaneous infusions of nicotine with osmotic minipumps (5 mg/kg/day) or saline ($N = 8 - 10$ in each of the four groups). As seen previously, chronic nicotine infusion significantly ($p < 0.05$) improved working memory performance in the sham lesioned group. The ventral hippocampal lesion blocked this effect even though by itself this small lesion did not impair working memory performance. These data show that the ventral hippocampus is critical for chronic nicotine-induced memory improvements. This mechanism further demonstrates the importance of hippocampal nicotinic systems for cognitive function.

484 DRUG HYPERSENSITIVITY: MECHANISMS OF IMMUNE-MEDIATED REACTIONS.

E E Sikorski[1] and H G Haggerty[2]. [1]*Procter & Gamble, Cincinnati, OH, USA and* [2]*Bristol-Myers Squibb, Syracuse, NY, USA.*

Drug hypersensitivity (DH) is a common side effect of several classes of drugs. Though these reactions are considered to be immune mediated, there is a lack of basic mechanistic information regarding the immunology of DH reactions. Current information regarding the role of the immune system in DH will be presented. In many cases of DH, the antigen or hapten responsible for inducing an immune response is not known. In several cases, reactive drugs or drug metabolites have been shown to be the hapten. However, studies are presented demonstrating that chemically non-reactive drugs can be antigens in a manner independent of drug metabolism. Other studies suggest that the antigens are self proteins that have been altered by the drug resulting in the formation of neoantigens that are recognized by the immune system. These self peptides may either be altered by covalently bound haptens or simpy be made available to the immune system (cryptic self peptides). In studies with mouse globin, both types of neoantigens appear to exist. Once the immune system recognizes these drug antigens as foreign, it is not clear how a particular response (Th1 versus Th2) is generated. The role of cytokines in the development and manifestation of Th1 and Th2 responses will be discussed. Interestingly, a hypothesis is presented stating that the normal immune response against haptens is the development of immunological tolerance. The pathway suggested for this to occur is by oral tolerance. Recent studies have shown that drugs which are very diverse in structure form protein adducts in the gut-associated lymphoid tissue, where tolerance against protein antigens is initiated. DH is an important issue as it can present major hurdles in the development of drugs; DH is generally observed in clinical trials and is not detected in preclinical testing. New revelations in the understanding of DH may lead to new approaches for predicting DH potential.

485 METABOLIC BIOACTIVATION IN DRUG HYPERSENSITIVITY.

L R Pohl. *Molecular and Cellular Toxicology Section, NHLBI, NIH, Bethesda, MD, USA.*

It has been estimated that hypersensitivity (allergic) idiosyncratic reactions

account for between 3-25% of all drug toxicities. In order for a drug to lead to an immune-mediated response, most evidence indicates that the first step involves the covalent attachment of the drug to one or more endogenous carrier proteins. Since most drugs are unreactive, it is usually a reactive metabolite that forms these covalent adducts. With the use of specifically designed antibodies, numerous carrier proteins of reactive metabolites of drugs associated with allergic reactions, such as halothane, tienilic acid, dihydralazine, ethanol, and sulfonamides have been identified. It has been found that patients may develop antibodies against the covalently bound reactive metabolite, covalently altered carrier proteins, and/or native carrier proteins. Moreover, the antibodies may be directed against linear or conformational epitopes. It is not clear, however, why more people do not develop immune reactions against protein adducts of drugs. Perhaps, the normal response against covalently altered carrier proteins is the development of immunological tolerance. One pathway this may occur is by oral tolerance, a hyporesponsive immunological state resulting from the oral administration of antigens. Indeed, recent studies have shown that drugs as diverse in structure as diclofenac, acetaminophen, halothane, and penicillin form protein adducts in the gut-associated lymphoid tissue, where tolerance against protein antigens is initiated.

486 INVOLVEMENT OF T CELLS IN DRUG ALLERGY.

W J Pichler, S V Greyerz, and B Schnyder. *Institute of Immunology and Allergology, Inselspital, Bern, Switzerland.* Sponsor: E E Sikorski.

To understand the role of T cells in drug allergy, we generated T cell clones (TCC), which specificallly interact with drugs like sulfamethoxazole (SMX), lidocaine or various β -lactams. We used these TCC to analyze the recognition of drugs by T cells and to evaluate their functional potential. Recognition: While chemically reactive drugs or drug metabolites were shown to bind in a stable way to the MHC-peptide complexes (covalent binding to proteins, followed by processing), certain chemically non-reactive drugs like SMX or lidocaine were shown to interact directly, in a non-covalent way with MHC/peptide complexes and TCRs. This concept is based on the findings that (a) gluaraldehyde-fixed APC were able to present drugs to specific CD4+ and CD8+ T cell clones; (b) pulsing of APC abrogated the stimulatory capacity, indicating a labile, non-covalent binding; and (c) kinetics of TCR expression after incubation of TCC with APC in the presence or absence of drugs revealed a rapid, drug dependent TCR-down-regulation and an immediate increment of intracytoplasmatic Ca++ in T cells, an early sign of T cell activation. Our data let us develop a new concept of drug recognition by activated T cells, namely a direct, metabolism and processing independent way of drug recognition. Functional analysis of drug specific CD4+ and CD8+ TCCs obtained from peripheral blood and skin revealed IL5 production, which might explain eosinophilia frequently observed in drug allergy. Moreover, some TCC showed a drug specific cytotoxicity against B-LCL and autologous keratinocytes incubated with the drug, which was mediated by perforin as revealed by blocking experiments and immunohistochemistry. Analysis of morbilliforme-like drug eruptions by immunohistochemistry revealed CD4 and CD8 cell infiltrations, some of them perforin containing. We conclude that the frequent morbilliforme drug eruption is a T cell mediated process with active involvement of cytotoxic CD4+ T cells. Dependent on the drug presentation on MHC class I or II, perforin mediated cytotoxicity may lead to more bullous (CD8) or maculopapular exanthema (CD4).

487 TH1/TH2 CYTOKINES AND REGULATION OF SPECIFIC IMMUNE RESPONSE TO DRUGS.

H Lebrec[1], I Gaspard[1], S Kerdine[1], N Bachot[1], M-T Guinnepain[2], J Laurent[2], and M Pallardy[1]. [1]*Immunotoxicology Group, INSERM U461, Faculté de Pharmacie Paris Sud, Chatenay-Malabry, France and* [2]*Institut Pasteur, Paris, France.*

Elicitation of CD4+ and CD8+ T cell responses play a central role in allergic reactions to drugs that behave as haptenic compounds (β-lactamins, lidocaine, sulfamethoxazole). Thus, drug-specific T lymphocytes can be isolated from cutaneous lesions and/or peripheral blood in allergic patients. Recent studies allowed us to demonstrate that immediate-type hypersensitivity to β-lactams (urticaria, shock, Quincke oedema) is not associated with a clear Th2-like response as assessed by quantitative RT-PCR. Indeed, lymphocytes from patients with a clear history of β-lactam-induced immediate allergic reaction can be specifically triggered to express high levels of interferon- (IFN-γ mRNA, combined or not with an interleukin-4 (IL-4) response. However, only patients with immediate reactions can elicit an IL-4 response since subjects with delayed hypersensitivity to penicillins (maculopapular rash, exanthema, contact dermatitis) only show an IFN-γ response. Other investigators have shown that drug-specific (especially lidocaine-specific) CD4+ lymphocytes producing Th2 cytokines (IL-4 and IL-5) can be isolated from patients with delayed cutaneous reactions. These cytokines play critical roles in controlling drug-specific cellular and humoral immune responses. We and others have shown that IL-4 production strongly modulates penicillin-specific IgG and IgE production in the mouse during primary or secondary immune responses to the drug. Another Th2 cytokine, IL-10, also strongly modulates penicillin-specific IgG responses in the mouse. In addition, IL-4 regulates penicillin-specific cellular responses by modulating CD4+ and CD8+ drug-specific cell growth and apoptosis, as assessed by using human penicillin cell lines and clones in vitro.

488 WHAT DO T CELLS RECOGNIZE IN ADVERSE IMMUNE REACTIONS TO CHEMICALS?

E Gleichmann, T Pape, M Wulferink and P Griem. *Med. Inst. Environmental Hygiene, Heinrich Heine University, Düsseldorf, Germany.* Sponsor: E Sikorski.

Adverse immune reactions to chemicals are initiated by T lymphocytes. To be activated, T cells need to receive signal 1 together with signal 2. Signal 1 consists of T cell recognition of MHC-embeded peptides. While the self-peptides normally presented induce T cell tolerance, chemical alteration of self-proteins may lead to a spectrum of altered self-peptides, i.e., neoantigens, presented by APC. The altered self-peptides presented either may carry covalently bound haptens, i.e., reactive metabolites, or consist of cryptic self-peptides. Signal 2 consists of costimulatory signals which can be provided by professional APC. Our studies addressed the potential role of macrophages in the formation of neoantigens induced by xenobiotics and recognized by T cells. Several parent compounds were studied including among others aniline, benzene, gold(I), and procainamide (PA). Whereas the parent compounds mentioned failed to elicit T cell reactions when tested in the murine popliteal lymph node (PLN) assay, their protein-reactive metabolites were able to do so. Hence, for these compounds there is insufficient enzymatic capacity for bioconversion of prohapten into hapten in the PLN assay. In the case of aniline, gold(I), and the SLE-inducing drug PA, it was formally shown that macrophages can generate the immunogenic metates, gold(III) and hydroxylamino-PA, respectively. Whereas myeloperoxidase plus H_2O_2 seems to be the drug-oxidizing enzyme system in the case of gold(I), in the case of PA the macrophage enzyme involved in the oxidations step appears to be prostaglandin-H synthase-2 (PGHS-2 or COX-2).

In studies assessing T cell recognition, T cell clones, obtained from mice that were immunized with mouse globin haptenated with benzoquinone, specifically recognized peptides with benzoquinone coupled to cysteine in position 96. Preliminary data indicate that other CD4+ T cell clones, obtained from the same immunization, recognized cryptic peptides of globin.

489 MECHANISMS OF ACTION OF NATURALLY OCCURRING ANTICARCINOGENS - INTRODUCTION.

S Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA.*

The human diet contains a host of natural products that have been associated with both carcinogenic and anticarcinogenic activities. Cooking proteinaceous food results in formation of highly mutagenic aromatic amines that also exhibit carcinogenic effects in multiple animal models and target organs. The potential role of these compounds in the etiology of human cancers is being extensively investigated. Fruits, vegetables and high fiber diets are known to protect from development of several cancers, and some specific classes of chemicals in these foods have been strongly associated with their anticarcinogenic activities. In this symposium, the mechanisms of action of several different classes of naturally-occurring anticarcinogens and their derivatives will be discussed and these include isoflavones such as genistein, indole-3-carbinol and diinolylmethane, components of green tea and various vegetable-derived organosulfur compounds. These presentations will not only identify sources and mechanisms of action of natural anticarcinogens but also discuss some analogs that may have potential for clinic applications.

490 ANTIESTROGENIC AND ANTITUMORIGENIC ACTIVITIES OF DIINDOLYLMETHANE.

S Safe, A McDougal, I Chen, K Ramamoorthy and M Sethi-Gupta. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Diindolylmethane (DIM) is formed from acid-catalyzed dimerization of indole-3-carbinol, a major anticarcinogenic compound found in cruciferous vegetables. DIM competitively binds to the aryl hydrocarbon receptor (AhR) but is a weak inducer of CYP1A1 gene expression in MCF-7 human breast cancer cells. In contrast, DIM inhibits 17(-estradiol (E2)-induced proliferation of MCF-7 cells, reporter gene activity in cells transiently transfected with an E2-responsive plasmid (containing a frog vitellogenin A2 gene promoter insert), and downregulates the nuclear estrogen receptor (ER). Moreover, DIM (5 mg/kg every other day) also inhibits DMBA-induced mammary tumor growth in Sprague-Dawley rats and this is not accompanied by induction of hepatic CYP1A1-dependent activity. Several new substituted DIMs also bind the AhR and exhibit antiestrogenic and antitumorigenic activities, and mammary tumor growth inhibition is observed at doses as low as 1 mg/kg (administered every 48 h). Thus, DIM represents a new class of relatively non-toxic AhR-based antiestrogens that inhibit E2-dependent tumor growth in rodents, and current studies are focused on development of specific analogs for clinical treatment of breast cancer.

491 ORGANOSULFUR COMPOUNDS IN ALLIUMS: MECHANISM OF CHEMOPREVENTIVE ACTION.

M J Wargovich. *Department of Pathology, University of South Carolina School of Medicine and South Carolina Cancer Center, Columbia, SC, USA.* Sponsor: S H Safe.

Our laboratory has shown that volatile organosulfur compounds from garlic and onion are strikingly inhibitory toward chemical carcinogens activated by CYP 2E1. Diallyl sulfide potently inhibits dimethylhydrazine and azoxymethane-induced colon cancer in mice, as well as nitrososmethylbenzylamine-induced esophageal cancer in rats. Administration of garlic or onion volatiles during initiation results in strong suppression of tumorigenesis but these compounds are inactive when given after initiation despite the fact that we have found them to active inducers of glutathione-s-transferase activity. Limited structure/function studies suggest that the degree of unsaturation in the organosulfur molecule correlates with chemopreventive activity in the animal models. Current studies are focusing on the impact of these agents on CYP 2E1 activity at the protein and gene level.

492 GENISTEIN: IN VIVO MECHANISMS OF ACTION AND CHEMOPREVENTION.

C A Lamartiniere. *Department of Pharmacology and Toxicology, University of Alabama at Birmingham, Birmingham, AL, USA.*

Genistein (5,7,4'-trihydroxyisoflavone) is a phytoestrogen component of soy that has been associated with reduced incidences of breast and prostate cancers. In vitro, genistein has been described as an inhibitor of protein tyrosine kinases, topoisomerase II, angiogenesis, and cell proliferation. It has been reported to have weak estrogenic and antiestrogenic properties, to be an antioxidant, and to induce cell differentiation. However, very little of this has been confirmed in vivo. In the rat uterus, genistein down-regulates estrogen receptor alpha mRNA and EGF-receptor protein, and does not alter progesterone receptor protein levels. In the mammary gland, genistein up-regulates the expression of the EGF-receptor and beta casein proteins, enhances mammary gland differentiation, decreases cell proliferation, and protects against chemically-induced mammary cancer. In the rat prostate genistein up-regulates the androgen receptor protein, and results in less estrogen receptor-alpha and -beta, and EGF-receptor mRNAs. The latter may explain the protective actions of soy against prostate cancer.

493 GREEN TEA IN CHEMOPREVENTION OF CANCER: MECHANISM OF ACTION.

H Mukhtar. *Department of Dermatology, Case Western Reserve University, Cleveland, OH, USA.*

Green tea, obtained from evergreen shrub Camellia sinesis, is a popularly consumed beverage in some parts of the world. Green tea contains several polyphenolic antioxidants known as catechins. The major polyphenolic antioxidants present in green tea are (-)-epicatechin, (-)-epicatechin-3-gallate, (-)-epigallocatechin, and (-)-epigallocatechin-3-gallate (EGCG). Large volumes of data, from several laboratories worldwide, accumulated in last several years has provided convincing evidence that green tea and/or the polyphenolic antioxidant present therein afford protection against cancer risk in a variety of animal tumor bioassay systems. In this presentation, the available information on experimental studies showing an association of reduced cancer development with the consumption of green tea or its constituents will be provided. Most of these studies have been conducted in the skin tumor model systems where oral consumption or topical application of green tea or its major polyphenolic constituent EGCG has shown significant protection against chemically- and ultraviolet B radiation-induced tumorigenesis. Green tea has also been shown to afford protection against carcinogen-induced lung, esophagus, forestomach, duodenum, pancreas, liver, breast and colon carcinogenesis in organ-specific tumor bioassay systems. Epidemiological studies in the human population, though inconclusive, suggest that green tea may prevent against the risk of cancer of some body sites. Understanding the molecular mechanism by which green tea imparts protective effects may provide opportunities to interfere with cancer development. Much of the chemopreventive effects of green tea are attributed to EGCG. A discussion regarding the molecular mechanism(s) responsible for the broad chemopreventive effects of EGCG will be presented.

494 CARCINOGENICITY OF CIGARETTE SMOKE : BRIDGING THE GAP BETWEEN COMPLEX MIXTURES AND INDIVIDUAL COMPONENTS.

S W Burchiel[1] and H R Witschi[2]. [1]*University of New Mexico, College of Pharmacy, Albuquerque, NM;* [2]*University of California, Davis, CA.*

While it is generally accepted that cigarette smoking increases the risk of lung and other cancers in humans, there is not widespread agreement on what specific chemicals in the volatile and particulate fractions might be responsible for these effects. Since the components of cigarette smoke have continued to change over the years, especially with regard to those derived from tar, it is important to utilize state-of-the-art molecular and cellular techniques to analyze potential mechanisms of carcinogenicity of cigarette smoke. It is also important to understand how to extrapolate data obtained from isolated components to complex mixtures. The overall purpose of this workshop will be to bring together scientists with established track records performing cigarette smoke inhalation studies with those focusing on isolated components and mechanisms of carcinogenicity. Early cellular and molecular markers and dosimeters of tissue injury need to be established and validated. The effects of various mainstream and sidestream smoke components, as well as specific chemicals and oxidants present in smoke, on DNA and cell signaling pathways will be the focus of this workshop.

495 FREE RADICALS AND OXIDANTS IN AQUEOUS EXTRACTS OF CIGARETTE SMOKE: DAMAGE TO LIPIDS, PROTEINS, AND DNA.

W A Pryor. *Biodynamics Institute, Louisiana State University, Baton Rouge, LA , USA.*

Cigarette smoke consists of gas and particulate ("tar") phases. Gas-phase smoke contains more than 1017 free radicals per puff, but these radicals are short-lived and disappear rapidly when the smoke dissolves in a liquid. The principal radical in tar consists of low molecular weight semiquinones (QH.) in equilibrium with the related quinones (Q) and hydroquinones (QH2), and this tar radical is virtually infinitely stable either adsorbed on a cigarette filter or as an extract in aqueous or organic solvents. Aqueous cigarette tar (ACT) extracts are potent oxidizing solutions; we believe these ACT solutions represent an excellent model of the oxidants present in a smoker's lungs. ACT solutions initiate lipid peroxidation and oxidize the antiproteinase, alpha-1-proteinase inhibitor (a1PI). The oxidation of a1PI occurs specifically at a methionine residue at the active site (converting it to methionine sulfoxide) as well as to other, possibly random sites causing generalized radical damage. ACT solutions can penetrate viable cells and cause nicks in nuclear DNA. Fractionation of ACT solutions demonstrates that almost all of the DNA nicking activity is present in those fractions that contain the QH./Q/QH2 radical system. (Supported by grants from NIH.)

496 CIGARETTE SMOKE AS A LUNG CARCINOGEN IN MAN AND ANIMALS.

H P Witschi. *Institute of Toxicology and Environmental Health, University of California, Davis, CA, USA.*

At the turn of the century, lung cancer was a rare disease. Nowadays it is in the USA the leading cause of death from cancer in men and women. Although it does occur occasionally in non-smokers, the overwhelming majority of lung cancers can be attributed to the smoking of tobacco products, mostly cigarettes. Other known human lung carcinogens include asbestos, radon, arsenic, silica and some metals and it is suspected that common air pollutants, most notably environmental tobacco smoke, are risk factors, too. At one time it was hoped that reduction of tar and nicotine content of cigarettes would mitigate the adverse effects of smoking, an expectation that remains unfilled. While the epidemiological evidence is overwhelming, attempts to study tobacco smoke carcinogenesis in animal models have been not very successful. For example out of more than 1700 mice exposed for life to tobacco smoke, only 6% developed lung tumors (4% in controls). In rat studies, lung tumor incidence is practically never higher than 10%. A recently developed tobacco smoke lung tumor model in strain A/J mice promises to overcome some of these difficulties and has made it possible to evaluate the effects of tobacco smoke gas phase in comparison with the effects. A recently developed tobacco smoke lung tumor model in strain A/J mice promises to overcome some of these difficulties and has made it possible to evaluate the effects of tobacco smoke gas phase in comparison with the effects of full tobacco smoke as well as to evaluate the effectiveness of putative chemopreventive agents.

497 CIGARETTE SMOKE CARCINOGENS: MECHANISMS OF DNA DAMAGE.

S A Belinsky. *Lovelace Respiratory Research Institute, Albuquerque, NM, USA.* Sponsor: S W Burchiel.

Lung cancer (LC) is the leading cause of cancer-related deaths in adults. Identifying the specific carcinogens within tobacco that are responsible for cell damage and the molecular mechanisms that underlie tumor development is critical for developing approaches to prevent and treat LC. Recent studies within our Institute demonstrated that lifetime exposure of female Fischer 344 rats to mainstream smoke results in a tumor incidence of about 8%. A synergistic interaction between cigarette smoke and 239Plutonium was also observed. Thus, the rat represents a model to study cigarette smoke-induced LC and interactions with other DNA damaging agents. Lung tumors induced by defined exposures indicative of the types of DNA damage from cigarette smoke (e.g., oxidative damage) were used to determine the prevalence for inactivation of the p16 tumor suppressor gene and the estrogen receptor (ER) by aberrant CpG island methylation. Inactivation of the p16 gene was frequent (> 65%) in tumors induced by the tobacco-specific carcinogen NNK, the particulate carcinogen beryllium metal, and by ionizing radiation. Moreover, methylation of p16 was an early event in the development of NNK-induced tumors. Both the timing and frequency for inactivation were recapitulated in human squamous cell carcinoma of the lung. In contrast, inactivation of the ER varied as a function of environmental exposure, occurring at the highest frequency (87%) in tumors induced by ionizing radiation. These studies indicate that the rat may be an excellent model for identifying the critical pathways in cigarette smoke-induced LC and implicate inactivation of the p16 gene as an important event in the development of non-small cell LC. (DE-FC04-96AL76406)

498 DO CIGARETTE SMOKE OXIDANTS ALTER SIGNALING PATHWAYS ASSOCIATED WITH TUMOR PROMOTION AND PROGRESSION?

S W Burchiel[1], J C Seagrave[2], and J L Born[1]. [1]*The University of New Mexico College of Pharmacy, Toxicology Program, and the* [2]*Lovelace Respiratory Research Institute, Albuquerque, NM, USA.*

Polycyclic aromatic hydrocarbons (PAHs) are a well known class of chemical carcinogens that are present in cigarette smoke. PAHs are complete carcinogens capable of both tumor initiation and tumor promotion. Previous studies in this lab have shown that certain PAHs, such as benzo(a)pyrene (BaP) and 7,12-dimethylbenz(a)anthracene (DMBA) alter antigen receptor signaling pathways in lymphocytes as well as growth factor signaling pathways in human mammary epithelial cells (HMEC) and the MCF-10A cell line. In the present studies, BaP (3μ M) was found to elevate intracellular Ca^{2+} in MCF-10A cells by two mechanisms: a P450-dependent process which could be inhibited by α -napthoflavone, and a P450-independent photochemical process. The photochemical process appeared to cause oxidative stress, was cytotoxic to MCF-10A when cells were exposed to BaP + hv for brief periods (5-30 min). Cells surviving BaP + hv were found to have dramatically altered morphology and increased cell adhesion. These results show that chemical oxidants alter Ca^{2+} signaling in MCF-10A cells, which may lead to tumor promotion, and may be relevant to oxidants in cigarette smoke. (Supported in part by NIH ES07259.)

499 CIGARETTE SMOKE CARCINOGENS AND LUNG CANCER.

S S Hecht. *University of Minnesota Cancer Center, Minneapolis, MN, USA.* Sponsor: S W Burchiel.

Lung cancer is the leading cause of cancer death in the United States, with over 160,000 deaths expected in 1998. At least 85% of lung cancer death is caused by cigarette smoking. Cigarette smoke is a complex mixture of approximately 4,000 compounds, of which at least 55 are recognized carcinogens. One can evaluate the role of specific carcinogens in lung cancer induction based on the levels of these compounds in cigarette smoke, their carcinogenicity in laboratory animals and comparative biochemical and molecular biological data in animals and humans. Based on these parameters, polycyclic aromatic hydrocarbons (PAH), typified by benzo[a]pyrene, and the tobacco-specific carcinogen 4-(methylnitrosamino) -1-(3-pyridyl)-1-butanone (NNK) are the most important compounds in cigarette smoke with respect to lung cancer induction in humans. Our goal is to understand uptake, metabolism and macromolecular adduct formation of PAH and NNK in humans. In recent studies, we have quantified urinary metabolites of NNK in smokers, non-smokers exposed to environmental tobacco smoke, newborns exposed transplacentally to cigarette smoke, and smokers who have quit. Other recent results of research in this area will be discussed. It is our view that insights on mechanisms of cancer etiology and strategies for prevention can be developed more readily by focusing on particular relevant carcinogens in a complex mixture, rather than on the whole mixture. (Our research is supported by Grants CA-44377 and CA-46535 from the National Cancer Institute.)

500 TELEMETRY, TOXICOLOGY, AND SAFETY ASSESSMENT.

L B Kinter[1] and D J Murphy[2]. [1]*Astra Pharmaceuticals LP, Wayne, PA and* [2]*SmithKline Beecham Pharmaceuticals, King of Prussia, PA, USA.*

Advances in radio-telemetry technology are providing new approaches for assessing the effects of toxicants in animals for purposes of risk assessment. Telemetry systems consist of miniaturized fully-implantable sensors and transmitters which detect and transmit physiological parameters (pressures, flows, temperatures, pH, electrical potentials, activity) to remote receivers. Currently, the technology can be applied in all commonly used laboratory species, from mice to monkeys. Using telemetry, physiological parameters may be continuously monitored in conscious unrestrained animals maintained in their natural or home environments. For toxicologists, telemetry permits parallel, sensitive, and dynamic assessments of critical organ system functions (blood pressure, respiratory parameters, ECG, etc.) using toxicological study designs, or simultaneous assessments with traditional toxicological endpoints in a single study. In addition to reducing the numbers of animals needed for risk assessment through combining physiological and toxicological endpoints, telemetry is a substitute for traditional anesthetized pharmacological preparations, and is consistent with the use of advanced statistical procedures (blocking and factorial analyses), supporting further reductions and refinements in animal use in safety assessment. Identification of effects of toxicants on critical organ system functions, including cardiac/cardiovascular, respiratory, and central nervous systems, provides useful markers for critical care physicians conducting subsequent studies in humans. Integration of effects of toxicants on physiological and toxicological endpoints contributes to elucidation of target organs and mechanisms of toxicity.

501 TELEMETRY: REAL REDUCTION AND REFINEMENT ALTERNATIVES IN RISK ASSESSMENT.

L B Kinter[1], D K Johnson[2], and J Ventre[2]. [2]*Nycomed Amersham and* [1]*Astra Pharmaceuticals LP, Wayne, PA, USA.*

Using radio-telemetry technology for assessing the effects of toxicants in animals offers significant opportunities to reduce and to refine animal use (Reduction and Refinement alternatives) in risk assessment. Telemetry systems consist of miniaturized fully-implantable sensors and transmitters which detect and transmit physiological parameters (pressures, flows, temperatures, pH, electrical potentials, activity) to remote receivers. Telemeterized animals can be studied in their 'home' environments. Using telemetry to monitor physiological parameters in near-natural conditions minimizes stress factors affecting both absolute values and/or inherent variability (both intra- and inter-subject types) of measured parameters, reducing the numbers of animal s needed to achieve any level of statistical power. Telemeterized animals can be reused indefinitely; using telemeterized animals to study additional doses and control treatments permits the use of blocked (vs. Randomized) study designs, which can reduce animal use by 75% without loss of statistical power. Using animals for 2 or more studies further reduces total animal use 50% per study. Carry-over effects inherent with resue of animals can be minimized by careful consideration of doses, dosing schedules, and pharmacokinetics, and through application of prospective requalification criteria and procedures. Finally, experimental groups of telemeterized animals can be further subdivided to include different ages, sexes, strains, or other variables and the effects of the additional variables evaluated using factorial statistical analyses, with little decrement in overall statistical power. In summary, incorporation of telemetry technology for monitoring effects of toxicants on physiological functions and increase both data quality while decreasing animal use (90%, compared to traditional techniques.

502 CARDIOVASCULAR TELEMETRY: FROM MICE TO MONKEYS.

C Hassler. *Battelle Memorial Inst., Columbus, OH, USA.* Sponsor: L B Kinter.

Modern assessments of effects of toxicants on cardiovascular functions include measurements of blood pressure, ECG, and vascular resistance (blood flow/blood pressure). Modern telemetry technology now permits remote monitoring of blood pressure, ECG, and, most recently, blood flow (and vascular resistance). Pressure catheters and transmitters have been miniaturized to permit chronic blood pressure measurements in all species including mice, while blood flow technology is limited to larger species (dogs and primates). Remote monitoring of cardiovascular parameters in laboratory species maintained in their home cages is redefining many facets of cardiovascular toxicology. Baseline systemic pressure values are significantly lower than in traditional preparations due to removal of experimental stress factors. Conversely, heart rates may be lower (dogs, primates) or higher (mice) in telemeterized preparations, underscoring the differential effects of acute procedures in different species. Reduction of stress factors permits detection of normal cardiovascular rhythms (e.g. circadian rhythms) and acute responses to dosing or husbandry procedures, which can complicate data analysis if not planned for in advance. Telemetry can be particularly useful to detect transient pseudo-allergic phenomena associated with some classes of toxicants, which are otherwise missed in animal preparations, but may be problematic in humans. Technology for measurements of two pressure sources are available, permitting simultaneous remote monitoring of systemic and pulmonary artery or left ventricular pressures. For toxicologists, cardiovascular telemetry permits dynamic assessments of critical cardiovascular functions using toxicological or clinical study designs, facilitating integration of physiological, toxicological, and pharmacokinetic endpoints, and contributing to identification of target organs and elucidation of mechanisms of cardiovascular toxicity.

503 TELEMETRY AS A METHOD FOR MONITORING RESPIRATORY FUNCTION CHRONICALLY IN CONSCIOUS ANIMALS.

D J Murphy, J P Renninger and K A Gossett. *Department of Toxicology, SmithKline Beecham Pharmaceuticals, King of Prussia, PA, USA.*

A novel procedure for chronically monitoring pleural pressure in conscious rats has been developed by surgically implanting the catheter of a pressure sensitive telemetry transmitter beneath the serosal layer of the esophagus within the thoracic cavity. This procedure can be used to monitor breathing rates or to assess (indirectly) airflow obstruction in conscious, non-restrained rats. When combined with lung airflow measurements, obtained using a plethysmograph chamber or a face mask and pneumotachometer, these pleural pressure measurements can be used to chronically measure changes in lung compliance and airflow resistance - two critical parameters for assessing lung function. The accuracy of these measurements was verified by comparison with direct pleural pressure measurements over the range of -3 to -34 cm H20. The pleural pressures remained constant for at least 14 weeks following surgery and there was no evidence of tissue damage or growth around the catheter. This novel method for measuring pleural pressure chronically in conscious rats will facilitate evaluation of the effects of drugs, environmental agents or disease on respiratory function by allowing repeated and simultaneous measurements of both ventilatory (breathing) patterns and lung function in conscious animals.

504 TELEMETRY AND ELECTROCARDIOGRAPHY: CARDIOTOXICITY AND ARRHYTHMOGENICITY.

J-C P Vincent, K M Robinson and G H Bode. *Lead Optimization, Hoechst Marion Roussel, Romainville, France.* Sponsor: L B Kinter.

For the registration of pharmaceuticals, animal toxicological and pharmacological studies need to be performed before the first administration in humans. In safety pharmacology, efforts are underway to harmonize the technical requests among Japanese, American and European regulatory agencies. Safety pharmacology focuses on all functions but vital functions such as cardiovascular, central nervous, and respiratory systems must be investigated before human administration. For the cardiovascular evaluation of novel compounds, the use of telemetry in freely moving dogs and monkeys demonstrates several advantages and provides reliable information on blood pressure, ECG, and heart rate. The QRS complex and the intervals of PR, QT and ST can be determined both by manual and automated measurements of the ECG obtained by telemetry. The accuracy and precision of different software systems are compared and the limitations of the use of this software are described, particularly in the case of arrhythmia. Based upon our experience, ECG measured by telemetry represents considerable progress for evaluating cardiotoxicity of compounds. To increase predictability and sensitivity, further improvements in signal quality (several leads) and data analysis (more sophisticated software) are needed.

505 FREE RADICAL/ANTIOXIDANT APPROACH TO CHEMO-PREVENTION OF ETOPOSIDE-INDUCED ACUTE MYELOID LEUKEMIA (AML).

G G Borisenko, Y Y Tyurina, V A Tyurin, J C Yalowich, J P Fabisiak, V E Kagan. *Depts. Environ. & Occup. Health and Pharmacol. and Cancer Inst., Univ. Pittsburgh, Pittsburgh, PA.*

Etoposide (VP-16) is extensively used to treat cancer, yet its efficacy is calamitously associated with an increased risk of secondary AML. The mechanisms for the extremely high susceptibility of myeloid stem cells to the VP-16 leukemogenic effects have not been elucidated. We propose a mechanism to account for the VP-16-induced secondary AML and nutritional strategies to prevent this complication of VP-16 therapy. We hypothesize that VP-16•-phenoxyl radicals formed from VP-16 by myeloperoxidase (MPO) are responsible for its genotoxic effects in bone marrow, which contains constitutively high MPO activity. Here, we used purified human MPO, as well as, human leukemia HL60 cells with high MPO activity and provide evidence that: (i) VP-16 undergoes one-electron oxidation to VP-16•-phenoxyl radical catalyzed by both purified MPO and MPO activity in HL60 cells; formation of VP-16•-radicals is completely blocked by MPO inhibitors, cyanide and azide. (ii) Intracellular reductants - GSH and protein sulfhydryls (but not phospholipids) – are involved in MPO-catalyzed VP-16 redox-cycling that oxidizes endogenous thiols; pretreatment of HL60 cells with a thiol reagent ThioGlo™ prevents redox-cycling of VP-16•-radicals and permits their direct EPR detection in cell homogenates. VP-16 redox-cycling by purified MPO (in the presence of GSH) or by MPO-activity in HL60 cells is accompanied by generation of GS•-radicals (determined by HPLC-assay of DMPO-SG nitrone adducts). (iii) Ascorbate competitively inhibits VP-16•-radical-induced thiol oxidation. Ascorbate prevents VP-16-induced inhibition of topoisomerase II in MPO-rich HL60 (but not in HL60 cells with MPO activity depleted by pretreatment with succinyl-acetone). (iv) A vitamin E homologue 2,2,5,7,8-pentamethyl-6-hydroxychromane, whose phenoxyl radicals do not oxidize endogenous thiols, competes with

VP-16 as a substrate for MPO. We conclude that nutritional antioxidants can be used for chemoprevention of VP-16-induced AML. (Supported by AICR 97B128, Johns Hopkins CAAT 9829R3, NIH/NINDS/WHO F05 NS 10669 and NCI Oncol.ogy Res. Faculty Devel. Program.)

506 FREE FATTY ACID (FFA)-INDUCED MISHANDLING OF COPPER (Cu) BY SERUM ALBUMIN IN PREECLAMPSIA: CONTRIBUTION TO OXIDATIVE STRESS.

V A Tyurin, G G Borisenko, J P Fabisiak, C A Hubel, M K McLaughlin, J M Roberts, V E Kagan. *Dept. Environ. & Occup. Health, University of Pittsburgh, and Dept. OB/GYN and Reprod. Sci. Magee-Womens Res. Inst., Pittsburgh, PA, USA.*

Redox activity of Cu in plasma may be associated with oxidative stress in the pregnancy disorder, preeclampsia. Mechanisms by which free Cu or Cu-binding proteins are involved in this redox dysregulation are unknown. We hypothesize that preeclampsia is accompanied by alterations in the ability of specific Cu-binding proteins to handle Cu and render it redox inactive. We first assessed the ability of preeclamptic and control plasma to bind exogenous Cu by competition with the specific Cu (I) chelator, bathocuproine. We found that preeclamptic plasma samples had a 2-fold lower capacity to bind Cu than plasma from normal pregnant women. Similarly, we observed by EPR a 2-fold greater rate of ascorbate radical (ASC•) production in preeclamptic samples compared to controls using exogenously supplied Cu/ASC. A candidate protein to account for these effects is human serum albumin (hSA) due to its ability to bind various plasma constituents, including Cu. Since preeclampsia is associated with elevations in plasma FFAs, we hypothesized that enhanced interactions of hSA with FFAs could impair its ability to bind Cu. In a model system, we observed that the ability of hSA to bind Cu (and quench ASC• formation) was decreased by oleic acid. We next compared the effect of a Cu(II) chelator, cuprizone I on Cu-dependent t-BuOOH-induced ASC• production in plasma samples. Cuprizone I had no effect on the rate of ASC• production in any control plasma samples (n = 10). In contrast, preincubation with cuprizone I produced a remarkable decrease in ASC oxidation in half of preeclamptic samples, while the remainder were unchanged. Human ceruloplasmin or apo-transferrin added to control or preeclamptic plasma had no effect on ASC• formation. We conclude that FFA can induce improper handling of Cu by hSA and elevations in chelatable, redox-active Cu can be a significant component to oxidative stress in many preeclamptic women. 507 OXIDATIVE STRESS AND PROTECTIVE SYSTEM AGAINST REACTIVE OXYGEN SPECIES (ROS) IN BLOOD OF WORKERS EXPOSED TO ORGANIC SOLVENTS AND OTHER CHEMICALS.

W Wasowicz, J Gromadzinska, and K Rydzynski. *The Nofer Institute of Occupational Medicine, Lodz, Poland.* Sponsor: E Dybing.

It is now believed that generation of ROS by many occupational and environmental agents might lead to some pathological conditions, mainly of the respiratory tract. Few studies on humans have demonstrated that exposure to organic solvents, heavy metals, and other organic substances may affect the oxidant/antioxidant potential in the body. In this study we examined selenium (Se), glutathione peroxidase (GSH-Px) activity and thiobarbituric acid reactive substances (TBARS) as a marker of lipid peroxidation in the blood of workers in a refining and petrochemical plant (n=131), rubber factory (n=50), in tannery workers (n=34) and in workers exposed to high concentrations of lead (Pb) and cadmium (Cd) (battery plant; n=65). These parameters were used to determine the "oxidative stress status" of individuals, which reflects the state of balance between the numerous exogenous or endogenous prooxidants and antioxidants. It was found that Se levels in blood and excreted in urine were significantly lower in all selected groups of workers as compared to appropriate reference groups. The GSH-Px activity in red blood cells and in plasma of industrial workers was evidently lower than in the reference group, except for tannery workers. TBARS concentrations in blood plasma were significantly increased in petrochemical workers and tannery workers. The concentration of TBARS in plasma of rubber factory workers was higher by 16%, but without statistical significance. In a pilot study some workers exposed to lead and Cd with low blood Se levels were supplemented by 100 μ g Se/day for 3 months. Statistically significant changes in GSH-Px activity in erythrocytes and plasma were observed. We hypothesize that occupational exposure to organic substances and heavy metals may influence the protective antioxidant potential in the blood of exposed workers.

508 MARKERS OF ANTIOXIDANT STATUS IN BRONCHO-ALVEOLAR LAVAGE FLUID AND BLOOD OF RATS FED DIET WITH DIFFERENT AMOUNT OF SELENIUM AND EXPOSED TO NO_x.

J Gromadzinska[1], K Rydzynski[1], W Wasowicz[1], and J Neve[2]. [1]*The Nofer Institute of Occupational Medicine, Lodz, Poland;* [2]*Free University of Brussels, Belgium.* Sponsor: E Dybing.

The aim of the study was to examine whether appropriate concentration of antioxidants in the diet may modify toxic effects of environmental oxidants on the lungs. Three groups of rats were fed a diet with different Se content: low-Se (1.3 μ g Se/day), adequate (3.0 μ g Se/day) and high-Se (6.0 μ g Se/day). Erythrocyte glutathione peroxidase (GSH-Px) activity was monitored weekly during the study. After 12 weeks of feeding, 25% of the animals from each of the groups were whole body exposed in inhalation chambers to 0.5, 1.5 or 5.0 ppm NO_x for 4 week (6 hours/day, 5 days/week). The control group consisted of animals which were not exposed to NO_x and consumed appropriate amounts of Se. Plasma Se levels in rats exposed to 5.0 ppm NO_x were lower than in controls: 473± 73 μ g/l vs. 548± 24 μ g/l ($p<0.01$) for high Se rats, 364± 29 μ g/l vs. 507± 86 μ g/l, ($p<0.001$) for animals on adequate Se diet, and 216± 38 μ g/l vs. 250± 60 μ g/l for low Se rats. Erythrocyte GSH-Px activity was significantly lower in all groups of animals exposed to 0.5 and 1.5 ppm NO_x. In the group exposed to 5.0 ppm NO_x, GSH-Px activity was significantly lower only in low-Se rats. Erythrocyte GSH-Px activity in low-Se rats was inversly proportional to the extent of exposure: 15.4± 3.7 u/g Hb, after exposure to 0.5 ppm NO_x, 24.5± 6.6 u/g Hb after exposure to 1.5 ppm NO_x and 26.6± 6.4 u/g Hb after exposure to 5.0 ppm NO_x vs. 39.2± 10.0 u/g Hb in controls. Brochoalveolar lavage fluid (BAL) GSH-Px activity in rats exposed to 0.5 and 1.5 ppm NO_x was higher than in the corresponding control group, irrespective of the amount of supplied Se. Only in low-Se rats exposed to 5.0 ppm NO_x, GSH-Px BAL was by 40% lower than in the corresponding control group. Low Se-diet causes an exposure-dependent decrease of GSH concentration and total reactive antioxidant potential. A two-fold increase of BAL thiobarbituric acid reactive substances concentration was observed in animals exposed to 0.5 ppm NO_x and fed a low Se diet. Results of our study indicated that different Se levels in the diet may influence the antioxidant potential of animals exposed to NO_x.

509 ENDOGENOUS N^2,3-ETHENOGUANINE IS FORMED BY LIPID PEROXIDATION.

A-J L Ham[1], A Ranasinghe[2], and J A Swenberg[1,2]. *Departments of* [1]*Pathology and* [2]*Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC.*

Recently a number of endogenous DNA adducts have been attributed to the reaction of DNA with products of lipid peroxidation. Here we demonstrate that N^2,3-ethenodeoxyguanosine (εG) is formed from the reaction of either deoxyguanosine (dGuo) or calf thymus DNA (CT-DNA) with either ethyl linoleate (LA) or 4-hydroxynonenal (HNE) under peroxidizing conditions. HNE (100 μg) or LA (10 mg) were reacted with 0.2 μmol of deoxyguanosine in the presence of t-butylhydroperoxide (t-BuOOH) for 72 hr at 50°C. εG was analyzed by immunoaffinity chromatography-gas chromatography-high resolution mass spectrometry (IA/GC/HRMS) of the pentafluorobenzyl derivative of its base. This reaction resulted in a 38- and 82-fold increase in εG for LA and HNE, respectively, as compared to control reactions containing only t-BuOOH and solvent. Similarly, HNE and LA, in the presence of t-BuOOH, were reacted with 300 μg DNA at 37°C for 89 hr. Samples were filtered to separate intact DNA from depurinated bases. The amount of εG in intact DNA was analyzed by IA/GC/HRMS. Under these conditions, 114 ± 32 and 52.9 ± 16.7 pmol εG/μmol dGuo were formed for LA and HNE, respectively. This compared to 0.26 ± 0.05 pmol εG/μmol dGuo in control DNA which was not subjected to incubation or t-BuOOH exposure. Control DNA incubated with t-BuOOH and solvent resulted in 2.02 ± 0.17 and 2.05 ± 0.47 pmol εG/μmol dGuo and controls subjected to incubation with solvents for LA and HNE, but no t-BuOOH resulted in 0.62 ± 0.13 and 1.00 ± 0.86 pmol εG/μmol dGuo for LA and HNE, respectively. These data demonstrate εG is formed from lipid peroxidation and HNE under peroxidizing conditions. These data also suggest εG is formed from an alternative mechanism since a 10-fold increase in εG was seen in control incubations containing t-BuOOH versus control DNA which was not incubated. (Supported by NIH grants ES05779 and ES05948.)

510 SITE SELECTIVE OXIDATION AND REGULATION OF MICROSOMAL RYANODINE-SENSITIVE CALCIUM RELEASE CHANNELS BY QUINONES.

W Feng, G Liu and I N Pessah. *Department of Molecular Biosciences, University of California, Davis, CA, USA.*

Quinones undergo redox cycling and/or arylation reactions with key biomolecules involved with cellular Ca^{2+} regulation. We utilized 10nM of the fluorogenic maleimide CPM to assess changes in the oxidation state of hyperreactive sulfhydryl moieties localized within ryanodine-sensitive Ca^{2+} channel complexes (RyR) found in skeletal and cardiac microsomes (Liu and Pessah, 1994), in the presence or absence of 1,4-naphthoquinone (NQ) or 1,4-benzoquinone (BQ). Kinetic and SDS-PAGE analyses revealed that NQ and BQ rapidly and selectively reduced the rate of forming fluorescent CPM-thioether adducts with hyperreactive thiols residing on the RyR complex (IC_{50}=0.3 and 1.8μM). The reduced forms of quinone, *e.g. tert*-butylhydroquinone, failed to alter the pattern or kinetics of CPM labeling of RyR thiols, suggesting that NQ and BQ site-selectively oxidize hyperreactive channel thiols. The functional consequence of this mechanism was directly assessed by measuring (1) macroscopic microsomal Ca^{2+} fluxes using a metallochromic indicator and (2) open probability of single channels reconstituted in bilayer lipid membranes under voltage clamp. Results obtained from both measurements showed that 200nM NQ or BQ activate microsomal Ca^{2+} efflux by directly interacting with RyR in a reversible manner. NQ $\geq$2μM sequentially activated then irreversibly inactivated RyR. These results suggest that hyperreactive thiols associated with RyR constitute an exquisitely sensitive microsomal "sensor" of redox active quinones. The Ca^{2+}-dependent cytotoxicities observed with quinone metabolites formed at the microsomal surface may be related to their ability to selectively modify hyperreactive thiols regulating normal functioning of microsomal Ca^{2+} release channels. (Supported by NIH ES05002.)

511 MITOCHONDRIA AND THE ENDOPLASMIC RETICULUM ARE SOURCES OF REACTIVE OXYGEN SPECIES IN 2-Br-*bis*-(GLUTATHION-S-YL)HYDOQUINONE TREATED LLC-PK1 CELLS.

C Guo[1], R Barhoumi[2], R C Burghardt[2], S S Lau[1] and T J Monks[1]. [1]*Div. of Pharm./Toxicol., College of Pharmacy, Univ. of Texas at Austin, Austin, TX;* [2]*Dept. of Veterinary Anatomy and Public Health and Image Analysis Lab, College of Veterinary Medicine, Texas A&M University, College Station, TX, USA.*

2-Br-*bis*-(glutathion-*S*-yl)hydroquinone (BBGHQ) causes DNA single strand breaks, growth arrest and cell death in renal proximal tubular epithelial cells (LLC-PK1), all of which are inhibitable by catalase, suggesting a role for reactive oxygen species (ROS) in these processes. We therefore investigated the potential source of ROS in LLC-PK1 cells, upon treatment with BBGHQ (50 - 400 μM). Fluorescence imaging with 2,7-dichlorofluorescein (DCF) was used to assess ROS generation using confocal fluorescence microscopy. A rapid concentration- and time-dependent increase of ROS was observed. The antioxidants 1,10-phenanthroline, deferoxamine and 2-mercaptopropionyl glycine, and catalase, all blocked BBGHQ-induced increases in ROS. Rotenone and thenoyltrifluoro-acetone, inhibitors of the mitochondrial electron transport chain, and cimetidine, a nonisoform-specific inhibitor of cytochrome P-450, also inhibited BBGHQ-mediated increases in ROS. These data suggest that both the mitochondrial electron transport chain, and cytochrome P-450 participate in BBGHQ-mediated generation of ROS. Changes in mitochondrial morphology were followed utilizing MitoTrackerfi green staining. Incubation of LLC-PK1 cells with 200 μM BBGHQ caused mitochondrial swelling subsequent to the initial production of ROS, and 400 μM BBGHQ caused a substantial reduction in the mitochondrial membrane potential (Ψ). Our data indicate that mitochondria and the endoplasmic reticulum are potential sites of ROS production in BBGHQ treated LLC-PK1 cells, and that ROS generation precedes BBGHQ-induced changes in mitochondrial morphology, Ψ, and cytotoxicity. (ES07359)

512 SEX DIFFERENCES IN DIQUAT-MEDIATED HEPATIC NECROSIS IN VIVO.

S Gupta, R C Husser, R S Geske, S E Welty, and C V Smith. *Department of Pediatrics, Baylor College of Medicine, Houston, TX.*

Redox cycling metabolism of diquat catalyzes generation of reactive oxygen species and the acute hepatic necrosis caused in male Fischer-344 rats by diquat has been studied as a model of oxidant mechanisms of cell killing in vivo. At equal doses of diquat, female F344 rats sustained lower levels of hepatic damage than did male rats, as estimated by plasma ALT activities after 6 h. The differences in hepatic injury are observed at equal rates of diquat-stimulated biliary excretion of GSSG, which although requiring higher doses of diquat in female rats than in males, nevertheless indicates that the greater resistance of the female rats is not explained by drug distribution and rates of redox cycling metabolism. Hepatic activities of glutathione peroxidase and superoxide dismutase were similar and glutathione reductase and glutathione S-transferase activities were higher in the more susceptible male rats. Previous studies in male rats have implicated formation of DNPH-reactive "protein carbonyls" and related iron chelate-catalyzed redox reactions as mechanisms critical to the expression of acute cell death in vivo. However, diquat-treated female rats showed higher levels of DNPH-reactive proteins in hepatic homogenates and in bile than did males, both at identical doses and at similar plasma ALT activities. Differences in the specific proteins affected in male and female rats were observed. Fragmentation of hepatic DNA was increased within 2 h, before elevation of plasma ALT activities, and by doses of diquat that did not increase plasma ALT activities in female rats. However, TUNEL analyses showed greater reactivities in diquat-treated female rats than in similarly treated males. In the present studies, hepatic necrosis is most closely associated with DNA fragmentation, although additional studies are needed to determine the mechanisms and pathophysiological consequences of the DNA fragmentation. (Supported by GM44263 from the NIH.)

513 BCL-2 ENHANCES REDOX IMPACT OF NEOCARZINO-STATIN (NCS) IN PC12 RAT PHEOCHROMOCYTOMA CELLS.

Y Y Tyurina, V A Tyurin, J P Fabisiak, N F Schor, and V E Kagan. Depts. Environ. & Occup. Health, Pharmacol., Pediatrics, and Neurol., and Cancer Inst., Univ. Pittsburgh, Pittsburgh, PA.

The product of *bcl-2* gene blocks apoptosis and protects cells from oxidative stress. In our experiments, Bcl-2 overexpression in PC12 cells prevented apoptosis and protected phospholipids against peroxidation by an azo-initiator, AMVN. Paradoxically, Bcl-2 potentiated apoptosis following a reduction-dependent enediyne prodrug, NCS. Our previous studies have identified oxidation of phosphatidylserine (PS) as a signaling pathway preceding PS externalization in apoptotic cells. Therefore, we compared the effects of NCS on phospholipid peroxidation and PS externalization in mock-transfected PC12 cells with those transfected with *bcl-2* gene. We found that 1 h exposure of cells to NCS (1.0-6.0 μg/10^6 cells) resulted in oxidation of all major membrane phospholipids: phosphatidylinositol, phosphatidylethanolamine (PE), phosphatidylcholine and PS in mock-transfected PC12 cells. Overproduction of Bcl-2 rendered a significant protection of all classes of phospholipids except PS against NCS-induced oxidation. PS oxidation preceded externalization of PS and PE as determined by direct fluorescamine staining of external membrane aminophospholipids and staining with Annexin V. PS externalization following NCS was approximately 2-fold greater in *bcl-2*-transfected than in mock-transfected cells. Thus Bcl-2 does not abrogate, but rather potentiates NCS-induced PS oxidation and externalization in PC12 cells. The increased sensitivity of *bcl-2* transfected PC12 cells to NCS may result from increased activation of NCS by GSH. Therefore, enhanced formation of GS• might be expected in *bcl-2*-transfected cells. Indeed, by using our novel HPLC assay of GS•-adducts with DMPO we found a 2-fold greater accumulation of DMPO-GS nitrone in *bcl-2*- than in mock-transfected cells. Thus, enhanced redox activation of NCS by GSH is accompanied by site-specific oxidation of PS and its externalization in *bcl-2* transfected PC12 cells experiencing apoptosis. (Supported by CA74289, ES-09387, DAMD17-97-1-7247, Johns Hopkins CAAT 9829 R3, NIH/ NINDS/WHO F05 NS 10669 and NCI Oncology Res. Faculty Devel. Program.)

514 GLUCOSE DEPRIVATION-INDUCED OXIDATIVE STRESS.

D R Spitz[1], R V Blackburn[2], X Liu[2], S S Galoforo[2], J E Sim[1], L A Ridnour[1], J C Chen[2], B H Davis[2], P M Corry[2], and Y J Lee[2]. [1]*Section of Cancer Biology, Washington University, St. Louis, MO and* [2]*Radiation Oncology Center, William Beaumont Hospital, Royal Oak, MI.*

The mechanism responsible for glucose deprivation-induced cytotoxicity, activation of signal transduction and gene expression was examined in MCF-7/ADR human breast carcinoma cells. Glucose deprivation (0-4 hrs) caused clonogenic cell death and oxidative stress as evidenced by increased

oxidized glutathione content (GSSG) and intracellular prooxidant production (presumably hydroperoxides). In addition glucose deprivation increased the activities of mitogen activated protein kinases (ERK1/ERK2), c-Jun N-terminal kinase and Lyn kinase as well as led to the accumulation of basic fibroblast growth factor (bFGF) and c-Myc mRNA. Treatment with the thiol antioxidant N-acetylcysteine (1-10 mM) during glucose deprivation suppressed cytotoxicity, prooxidant production and GSSG accumulation as well as inhibited kinase activation and bFGF/c-Myc gene expression. These results show that glucose deprivation-induced cytotoxicity, activation of signal transduction, and expression of two genes thought to govern the malignant phenotype appear to be mediated by oxidative stress in MCF-7/ADR cells. This work supports the hypothesis that a common mechanism of glucose deprivation-induced cytotoxicity in tumor cells may involve metabolic oxidative stress as well as the hypothesis that alterations in intracellular oxidation/reduction reactions link changes in glucose metabolism to signal transduction and gene expression. (Supported by NIH HL51469, CA48000, CA44550, CA75556.)

515 A SYSTEM FOR THE DETECTION AND MEASUREMENT OF THE EFFECTS OF OXIDANTS (INCLUDING EXPOSURE TO METHYLENE BLUE PLUS LIGHT), AND ANTIOXIDANTS ON PRODUCTIVE INFECTIONS OF HeLa CD4LTRßGal CELLS WITH HUMAN IMMUNODEFICIENCY VIRUS (HIV).

J E Schneider, Jr.[1], Q Pye[1], X-L Lin[2], P Marble[2], J Tang[2] and R A Floyd[1]. *Free Radical Biology & Aging Research Program[1] and Protein Studies Research Program[2], Oklahoma Medical Research Fnd, Oklahoma City, OK.*

The relationship between oxidative stress and virus-infected cells is an area of medical importance that is incompletely understood. A form of oxidative stress in present use is the purging of viruses, especially the human immunodeficiency virus (HIV), from blood and blood products by photodynamic action based upon the sensitizer methylene blue (MB). Photoinactivation of the RNA bacteriophage Qβ with MB is associated with formation of 8-oxoGuanine, protein carbonyls, RNA strand breaks and RNA-protein crosslinks. HeLaCD4LTRβ Gal cells yield blue nuclei upon infection with HIV-1 (due to tat activation of an LTR region joined to the full length β - galactosidase gene) and histochemical staining, and the cells produce new virions. We show that exposure of suspensions of HIV-1 to MB plus light, rose bengal plus light or UV light inactivates the ability of the virus both to infect HeLaCD4LTRβ Gal cells and to produce new infectious virions. In contrast, and as a control, selected protease inhibitors do not prevent infection by mature virions but do inhibit production of new infectious virions, demonstrating that this system mimics a portion of the normal HIV-1 life cycle. Toxicity of agents toward infected cells can be monitored by staining for the accumulation of ß-galactosidase in situ. It is also demonstrated that selected antioxidants added to the host cells immediately following exposure to virus, do not significantly effect the proportion of cells that are infected. (This research is supported by grant number HL 53585.)

516 THE ROLE OF CYTOCHROME P450 IN THE METABOLISM OF ACRYLAMIDE.

S J Sumner[1], T Fennell[1], T Moore[1], B Chanas[2], F Gonzalez[3], and B Ghanayem[2]. [1]*CIIT and* [2]*NIEHS, Research Triangle Park, NC;* [3]*NCI, Bethesda, MD, USA.*

Acrylamide (AM) is used as a grouting agent, in the production of polyacrylamide, and as an intermediate in the synthesis of plastics and polymers. Previous studies showed that AM is metabolized in rodents to produce the epoxide glycidamide (GA). GA is subsequently metabolized via hydrolysis or glutathione (GSH) conjugation. AM is also metabolized via direct conjugation with GSH. The goal of this study was to determine the role of cytochrome P450 in the in vivo metabolism of AM. Wild-type mice (CYP2E1+/+), aminobenzotriazole (ABT) pretreated (50 mg/kg ip, 2 hr pre-exposure) wild-type mice, and cytochrome P450 2E1 knockout mice (CYP2E1-/-) were administered 50 mg/kg 13C-AM by gavage. Urine was collected for 24 hr. Urinary metabolites were characterized using 13C-NMR, enabling the detection of AM-derived metabolites, as well as detection of possible new urinary metabolites produced by changes in cytochrome P450 activities. Metabolites derived from GA and from direct GSH conjugation with AM were observed after administration of 13C-AM to wild-type mice. Only metabolites derived from direct GSH conjugation with AM were observed in the ABT pretreated wild-type mice and the CYP2E1-/- mice. Based on evaluation of urinary metabolites, this study suggests that CYP2E1 is the major and possibly only cytochrome P450 involved in the metabolism of AM in mice, that inhibiting (via ABT) total P450 activity does not result in new pathways of non-P450 metabolism of AM, and that mice devoid of CYP2E1 do not excrete metabolites of AM that would be produced by other specific cytochromes P450.

517 THE ROLE OF CYTOCHROME P4502E1 (CYP2E1) IN ACRYLONITRILE METABOLISM.

B I Ghanayem[1], T R Fennell[2], T Moore[2], B Chanas[1], F J Gonzalez[3], and S C J Sumner[2]. [1]*NIH/NIEHS and* [2]*CIIT, RTP, NC, and* [3]*NCI, Bethesda, MD.*

Acrylonitrile (AN) is widely used in the manufacturing of many products including acrylic fibers and plastics. AN is a multisite carcinogen after oral or inhalation exposure of rats and is a suspected human carcinogen. AN is metabolized by direct conjugation with glutathione (GSH) and oxidation to 2-cyanoethylene oxide (CEO). CEO conjugates with GSH or hydrolyzes to yield cyanide and glycoaldehyde. Subsequent metabolism of the GSH conjugates of AN and CEO results in the excretion of a variety of urinary metabolites. Current studies were undertaken to characterize the role of CYP2E1 in the metabolism of 1,2,3-13C-AN in CYP2E1-null (KO) or wild-type (WT) mice. 13C-AN was administered at 2.5 or 10 mg/kg by gavage, mice were placed in plastic metabolism cages, and urine was collected over a 24 hr period. AN urinary metabolites were quantitated using 13C NMR spectroscopy. Metabolites originating from the oxidative metabolism of AN and excreted in the urine of WT mice accounted for approximately 24-37% of dose. In contrast, no AN metabolites formed via this pathway were detectable in the urine of KO mice. Further, metabolites formed via the non-oxidative metabolism of AN accounted for approximately 6 and 35% of dose in WT and KO mice, respectively. These data clearly indicate that CYP2E1 is the principal enzyme responsible for the oxidative metabolism of AN in mice. CYP2E1-null mice may be an appropriate model for the investigation of the role of oxidative metabolism in AN toxicity and carcinogenicity.

518 ASSESSING THE ROLE OF CYP2E1 IN THE METABOLISM AND GENOTOXICITY OF 1,3-BUTADIENE.

T E Jackson[1,2], P M Schlosser[2], M A Medinksy[2], F J Gonzalez[3] and L Recio[2]. [1]*Curriculum In Toxicology, University of North Carolina, Chapel Hill, Chapel Hill, NC;* [2]*Chemical Industry Institute of Toxicology, Research Trangle Park, NC;* [3]*Laboratory of Metabolism, National Cancer Institute, Bethesda, MD, USA.*

1,3-Butadiene (BD), a multiple site carcinogen in mice, is metabolized to several DNA-reactive epoxides *in vivo* and *in vitro*. These epoxides are the putative genotoxic compounds. We hypothesized from previous studies that cytochrome P450 2E1 (CYP2E1) is responsible for BD metabolism. To test this hypothesis, we utilized CYP2E1 homozygous null mice (cyp2e1-/-) and the parental strain (SV/129) in closed-chamber gas uptake studies. Mice (5/exposure) were exposed to 0, 1100, or 5000 ppm initial BD concentration for a maximum of 6 hr. The decline in BD concentration in the inhalation chamber with time due to uptake and metabolism was monitored using gas chromatography. The gas-uptake data were analyzed using a previously published physiologically based pharmacokinetic (PBPK) model to evaluate rates of BD oxidation. Preliminary simulations using the PBPK model indicate that BD metabolism is decreased but not eliminated in the cyp2e1-/- mice. To assess genotoxicity, the mouse bone marrow micronucleus assay was utilized. The frequency of micronucleated polychromatic erythrocytes (MN-PCE) per 1000 PCE for the 0, 1100, and 5000 ppm BD exposure groups were 21.4 ± 3.8, 39.4 ± 4.8, 61.5 ± 5.8 for the cyp2e1-/- mice and 19.2 ± 3.7, 51.2 ± 4.9 and 83.1 ± 6.7 for the SV/129 mice, respectively. Preliminary analysis indicates that a correlation exists between the amount of BD metabolized and the micronuclei frequencies. Further, since the cyp2e1-/- mice did not demonstrate the complete elimination of BD metabolism or BD-mediated genotoxicity, enyzmes other than CYP2E1 may be important in the metabolism of BD.

519 THE RATE OF CHLOROFORM METABOLISM CORRELATES WITH THE DEGREE OF TARGET TISSUE TOXICITY.

B E Butterworth, C S Sprankle, A A Constan, and G L Kedderis. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA.*

Chloroform is a nongenotoxic-cytotoxic carcinogen that has been shown to

induce liver and kidney tumors in various rodent strains. Tumor formation appears to be secondary to events associated with cytotoxicity and regenerative cell proliferation in the target organ. The toxicity of chloroform, which varies among rodent strains and often between sexes of the same strain, appears to depend on the rate of conversion of chloroform to toxic metabolites. The purpose of these experiments was to determine if precision-cut kidney slices could be used to measure the rate of chloroform metabolism in target tissues and if the resulting rates of chloroform metabolism correlated with toxicity previously measured by induced pathological lesions and regenerative cell proliferation. A Krumdieck Tissue Slicer was used to generate precision-cut kidney slices from male and female B6C3F1 and BDF1 mice and F344 rats. Chloroform uptake by the slices from the headspace of sealed flasks was measured by gas chromatography. Substantial variations in the rates of chloroform metabolism were observed between the kidney slices that correlated well with species, strain, and sex differences in chloroform-induced renal toxicity in vivo. These results are in agreement with data from CYP2E1 knockout (cyp2e1-/-) mice indicating that chloroform-induced cytotoxicity is obligatory to the production of toxic metabolites. Thus, this approach may be extended to examine the relative metabolic rates in rodent and human tissues as one part of a toxicodynamic model to better define quantitative, target organ-specific, chloroform toxicity and cancer risk assessments.

520 ROLE OF CYP1A2 IN UROPORPHYRIA CAUSED BY POLYHALOGENATED AROMATIC HYDROCARBONS USING CYP1A2 KNOCKOUT MICE.

P R Sinclair[1], N Gorman[1], T P Dalton[2], H S Walton[1], J F Sinclair[1], A G Smith[3], and D W Nebert[2]. [1]*VA Medical Center, White River Junction & Dartmouth Med School, Hanover, NH, USA;* [2]*Dept of Environmental Health, Univ Cincinnati Med Center, Cincinnati, OH, USA;* [3]*MRC Toxicology Unit, Univ of Leicester, Leicester, UK.*

Uroporphyria, characterized by hepatic accumulation of uroporphyrin (URO), is produced in experimental animals by a number of Ah receptor ligands such as TCDD and hexachlorobenzene (HCB). CYP1A2 catalyzes the oxidation of uroporphyrinogen (UROX). Here we have investigated the requirement for CYP1A2 in mouse uroporphyria, by comparing ***Cyp1a2(-/-)*** knockout mice with ***Cyp1a2(+/+)*** wild-type mice. Uroporphyria was produced by injecting animals with iron dextran and giving the porphyrin precursor, 5-aminolevulinic acid, in the drinking water. Some animals also received 3-methylcholanthrene (MC) or HCB to induce hepatic CYP1A2. Uroporphyria was produced by these treatments in the wild-type mice, but not in the null mice. Uroporphyrinogen oxidation activity in hepatic microsomes from untreated wild type mice was 3-fold higher than in the null mice. Hepatic CYP1A2 in the wild type mice was increased by MC, and to a lesser extent, by HCB. Following MC-treatment, microsomal MROD to EROD ratios in wild type mice were twice those of null mice, reflecting the presence of CYP1A2. In wild type mice, treatment with MC increased hepatic microsomal UROX by 9 and 2-fold, and HCB by 2-fold, respectively, whereas there were no increases in the null mice. These results indicate the absolute requirement for hepatic CYP1A2 in causing experimental uroporphyria in mice treated with MC or HCB. (Supported by NIH grants ES 06321 and 06263, and by the Department of Veterans Affairs.)

521 INCREASED SUSCEPTIBILITY TO HYPEROXIC LUNG INJURY OF MICE LACKING THE CYP1A2 GENE.

B Moorthy, R S Geske, and S E Welty. *Department of Pediatrics, Baylor College of Medicine, Houston, TX.*

We reported earlier that 48 h of hyperoxia induces activities and contents of hepatic cytochromes P450 (CYP)1A1 and 1A2 in male Sprague-Dawley rats. In the current study, we tested the hypothesis that liver CYP1A enzymes play a role in lung injury induced by hyperoxia. Twelve week-old wild type (WT) (+/+) (C57BL/6J) male mice or mice lacking the gene for CYP1A2 (-/-), which is normally expressed only in the liver, were exposed to hyperoxia or room air for 48 or 72 h. Activities of ethoxyresorufin O-deethylase (EROD) and methoxyresorufin O-demethylase (MROD), which reflect primarily CYP1A1 and CYP1A2 enzymes, respectively, were determined in livers of these animals. Lung injury was evaluated by histological analysis of formalin-fixed lung tissues. While 11/12 of the (+/+) animals survived 72 h of hyperoxia, 4only 7/12 of the CYP1A2 (-/-) animals survived. The lungs of the surviving CYP1A2 (-/-) mice exposed to 48 or 72 h of > 95% O_2 displayed greater lung damage than similarly exposed wild type mice, suggesting that hepatic CYP1A2 serves protective functions in defenses against hyperoxic lung injury. Hepatic EROD activities, but not MROD activities, were lower (56 %) in WT mice exposed to hyperoxia for 48 h than in air-breathing controls, as determined by two-way ANOVA. The EROD activities returned to control levels after 72 h of hyperoxia. EROD activities in the CYP1A2 (-/-) animals were drastically lowered, by 96% and 85%, after 48 and 72 h of hyperoxia, respectively, than in air-breathing animals. The increased sensitivities of CYP1A2 (-/-) mice to lung injury and the decrease of hepatic EROD activities by hyperoxic exposure suggest an important role for liver CYP1A enzymes in the manifestation of lung injury induced by oxygen. (Supported in part by NIH grant ES09132 and by ALA of Texas.)

522 HEPATIC CYTOCHROME P450 EXPRESSION IN IL-6 GENE KNOCKOUT MICE FOLLOWING ENDOTOXIN ADMINISTRATION.

G W Warren[1], M P Mattson[2,3], and R A Blouin[1,4]. [1]*Graduate Center for Toxicology,* [2]*Sanders Brown Research Center,* [3]*Department of Anatomy and Neurobiology,* [4]*College of Pharmacy, University of Kentucky, Lexington, KY, USA.* Sponsor: L W Robertson.

Hepatic cytochrome P450 (CYP) expression has been shown to decrease following endotoxin (LPS) or pro-inflammatory cytokine (interleukin-1 [IL-1], IL-6, tumor necrosis factor α) administration. Using mice defecient in IL-6, the role of IL-6 in the regulation of various CYP isoforms following LPS administration was evaluated. Mice were given LPS (2 mg/kg i.p.) or saline (control) and euthanatized 24 hours following treatment. Constitutive EROD activity significantly increased in IL-6 knockouts (to 155.0 % of B6x129 mice). Administration of LPS (2 mg/kg i.p.) decreased ethoxyresorufin-O-dealkylase (EROD) activity and 6β hydroxytestosterone (OHT) formation in both normal B6x129 mice (to 67.6 % of control for EROD and 46.6 % of control for 6β OHT) and IL-6 knockout mice (to 48.0 % of control for EROD and 50.1 % of control for 6β OHT). However, no decrease was observed for pentoxyresorufin-O-dealkylase activity, 7α OHT formation, 16α OHT formation, or 6-hydroxychlorzoxazone formation following LPS administration in either B6x129 or IL-6 knockout mice. Hepatic lauric acid hydroxylase (LAH) activity significantly increased following LPS administration in B6x129 mice (to 223.0 % of control) with no effect in IL-6 knockout mice (108.4 % of control). These results support differences in species specific responses of CYP expression following LPS administration. In addition, LAH activity following LPS administration as well as constitutive EROD activity appears dependent upon IL-6.

523 A NEUROBEHAVIORAL DEVELOPMENTAL STUDY OF AMMONIUM PERCHLORATE ADMINISTERED ORALLY IN RINKING WATER TO RATS.

R G York[1], R M Parker[1], D R Mattie[2] and D E Dodd[3]. [1]*Primedica Argus, Inc., Horsham, PA;* [2]*Wright-Patterson AFB, Wright-Patterson AFB, OH;* [3]*ManTech Environmental Technology, Inc., Dayton, OH.*

Ammonium Perchlorate [AP], an oxidizer for solid rocket fuel, has recently been recognized as a persistent and pervasive contami-nant of water supplies. This GLP compliant study followed the 1996 US EPA Developmental Neurotoxicity guideline. Female Sprague-Dawley rats [25/group] were given continual access to 0 (Carrier), 0.1, 1.0, 3.0 and 10.0 mg/kg/day [MKD] AP in drinking water begin-ning on gestation day 0 and continuing through lactation day (DL) 10. On DL 12, 1_/1_ pup/litter/group were assigned to four subsets: 1) brain weights & juvenile neurohistopathology; 2) passive avoid-ance & watermaze testing; 3) motor activity & auditory startle habit-uation; and 4) regional brain weight & adult neurohistopathology. TSH, T_3 and T_4 serum levels were increased on DL 10 at all exposure levels in the Fo generation dams; thyroid weights and morphology were not affected. AP did not cause any neurobehav-ioral effects in the offspring when administered to dams during gestation and lactation at target exposures as high as 10.0 MKD. However, there was a significant increase in follicular epithelium hypertrophy and a significant decrease in the thyroid follicle size from the F1 generation male pups in the 10.0 MKD exposure group culled on DL 5. The 10.0 MKG F1 serum levels for TSH, T_3 and T_4 (pooled by litter) were significantly different than controls. No other effects in the F1 generation rats were observed. Cognitive functions (learning, memory, habituation) were not impaired in the pups at any time at any exposure level. These data demonstrate that AP is not a selective developmental neurotoxicant in the rat. Due to uncertainty in any toxicity associated to thyroid hormone alterations, the NOAEL for maternal toxicity in this study was 10.0 MKD (based on organ weight and histopathology). The NOAEL for pup toxicity was 3.0 MKD (based on the histopathology findings in the thyroid).

524 KINETICS OF RADIOLABELED IODIDE IN THE MALE SPRAGUE DAWLEY RAT.

K O Yu, D R Mattie and J W Fisher. *AFRL/HE, Human Effectiveness Directorate, Air Force Research Laboratory, Wright-Patterson Air Force Base, OH, USA.*

Iodide is actively transported by the sodium/iodide (Na^+/I^-) symporter, a carrier protein located in the basolateral membrane of the thyroid follicles. The objective of this project was to investigate the kinetics of iodide uptake, organification in the rat thyroid, tissue distribution and elimination in urine. A physiologically based kinetic model (PBPK) for iodide will be developed for examining the competitive inhibition of iodide uptake in the thyroid by perchlorate. Male Sprague Dawley rats were given two doses (2.6 pg and 33μ g/300 g rat) of ^{125}I via tail vein (6 rats per group). The latter dosing solution was prepared with cold and hot iodide. These doses do not inhibit iodide uptake in the rat thyroid (autoregulation). Thyroid gland and blood were collected at 5, 15, and 30 min, 1, 2, 6, 9 and 24 hours post dosing. Rats exposed for 24 h were placed in the metabolism cages to collect urine, and water and powdered food were freely available. Free and bound iodide was determined by precipitating bound iodide by trichloroacetic acid, and free and bound iodide was determined by a γ -counter. In the thyroid gland more than 90% of the radioactivity was bound within 2h and remained same till 24 h. In serum 70% of the radioactivity was free upto 6h and decreased to less than 10% at 24h. About 80% of the dose was excreted as free iodide in the urine in 24h. All the results were same in both doses.

525 TWO-GENERATION REPRODUCTION STUDY OF AMMONIUM PERCHLORATE IN RATS.

M F Girard[1], M L Dourson[2], R G York[3], J S Dollarhide[2], and K A Poirier[2]. [1]*Aerojet, Sacramento, CA, USA;* [2]*Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH, USA;* [3]*Primedica Argus Research Laboratories, Inc., Horsham, PA, USA.*

Sprague-Dawley rats (30/sex/dose) were randomly assigned to either 0.0, 0.3, 3.0 or 30.0 mg ammonium perchlorate (AP)/kg/day in drinking water in a two-generation reproduction study. Concentrations were adjusted based on consumption data to approach the targeted dose. No deaths, abortions or premature deliveries in the P1 generation were attributed to the test substance, nor were clinical observations observed in the P1 generation. Mating and fertility parameters were unaffected by dosages as high as 30.0 mg AP/kg/day. No necropsy observations were related to the test substance in the P1 generation. Absolute thyroid weights for P1 male rats were increased in all three treated groups in a dosage-dependent manner and were significant at 3.0 and 30.0 mg/kg/day and in female rats at 30.0 mg/kg/day. Relative thyroid weight was increased at 30.0 mg/kg/day in both males and females. No significant results were found on sperm parameters or male reproductive function, nor were delivery observations or clinical and necropsy observations seen in the F1 generation pups. The weight of the thyroid and parathyroid glands was significantly increased for both male and female F1 generation pups at 30.0 mg/kg/day. Thus, the paternal rat NOAEL for AP is 0.3 mg/kg/day and the maternal rat NOAEL for AP is 3.0 mg/kg/day based on the significant increase in absolute thyroid weights. The reproductive NOAEL is greater than 30.0 mg/kg/day; no effects on mating or fertility occurred. The NOAEL for viability and growth in F1generation pups is 3.0 mg/kg/day based on the significant increase of thyroid and parathyroid weights in both male and female F1 generation pups. Based on these data, AP should not be identified as a reproductive toxicant.

526 DEVELOPMENTAL TOXICITY OF AMMONIUM PER CHLORATE IN RABBITS.

K A Poirier[1], M L Dourson[1], J S Dollarhide[1], M F Girard[2], and R G York[3]. [1]*TERA, Cincinnati, OH, USA;* [2]*Aerojet, Sacramento, CA, USA;* [3]*Primedica Argus Research Laboratories, Inc., Horsham, PA, USA.*

Naturally-bred female New Zealand White rabbits were randomly assigned (25/dose) to six dosage groups of ammonium perchlorate (AP). Targeted doses of 0.0, 0.1, 1.0, 10.0, 30.0 and 100.0 mg AP/kg/day were continuously administered in the drinking water on gestational days 6 through 28. Concentrations were adjusted based on consumption data to approach the targeted dose. On day 29, blood was collected and analyzed for TSH, T3 and T4 levels. Gross necropsy was performed and the thyroids and parathyroids evaluated histologically. Pregnancy parameters were evaluated and fetuses were examined. There were no deaths attributed to the test substance. All clinical observations were considered unrelated to the test substance. Microscopic examination of the thyroid glands revealed hypertrophy of the follicular epithelium at 10.0, 30.0 and 100 mg/kg/day which was considered treatment-related. In the affected thyroids, the hypertrophy of the follicular epithelium was occasionally accompanied by a decrease in the lumen of the follicles. Serum T4 levels appeared to decrease in an exposure-related pattern with statistically significant decreases at the 30.0 and 100.0 mg/kg/day target doses. Dosages as high as 100.0 mg/kg/day did not affect day 29 Caesarean-sectioning or litter parameters. No fetal alterations were attributable to exposures of AP as high as 100.0 mg/kg/day. The maternal NOAEL for AP is 1.0 mg/kg/day based on a critical effect of hypertrophy of the follicular epithelium of the thyroid gland of the rabbit. The developmental NOAEL is greater than 100.0 mg/kg/day. Based on these data, AP should not be identified as a developmental toxicant.

527 ACUTE AND CHRONIC EFFECTS OF LOW DOSE PERCHLORATE ON HUMAN THYROID FUNCTION.

J P Gibbs[1] and K S Crump[2]. [1]*Kerr-McGee Corp., Oklahoma City, OK, USA and* [2]*ICF Kaiser, the KS Crump Group, Ruston, LA, USA.* Sponsor: S H Lamm.

Pre-shift and post-shift thyroid function profiles of subjects with occupational exposure to soluble perchlorate dust were obtained and compared with a larger number of control workers without occupational perchlorate exposure. Workplace perchlorate exposure measurements were made and analyzed using highly sensitive ion chromatography methodology. Equivalency of oral and respiratory doses could be assumed because of the high solubility of perchlorate salts at body temperature and because the target organ effects related to systemic absorption. Doses were estimated based on airborne concentrations and standard breathing rates. Calculated single shift doses ranging from 0.2 to 436 μ g/kg (average 36 μ g/kg) had no effect on thyroid stimulating hormone levels or the free thyroxine index at the end of the shift. Working lifetime cumulative doses ranging from 8,000 to 88,000 μ g/kg (average 38,000 μ g/kg) did not show any effect relative to control subjects on these same hormone levels. Average daily doses among exposed subjects were 1,000 times higher than doses attainable from drinking two liters of water from Lake Mead.

528 FETAX ASSAY OF AMMONIUM PERCHLORATE.

J A Bantle[1], J N Dumont[1], G J Harvey[2] and D R Mattie. [1]*Oklahoma State University, Stillwater, OK, USA;* [2]*Aeronautical System Center, Wright-Patterson AFB, OH, USA.*

Amphibian metamorphosis is thyroid driven. Addition of thyroid hormone accelerates development. Methods for inhibiting metamorphosis include hypophysectomy, thyroidectomy, and exposure to chemicals such as dinitophenol, thiocynate, thiouracil, and perchlorate salts. Perchloric acid and its salts have been used in a number of commercial applications ranging from wet digestions, organic synthesis, pyrotechnics, and missile propellants. Perchlorate has recently been found in the ground and surface water in several western states. The largest surface water concentrations of up to 1700 ppb have been found in a Lake Mead inlet. To investigate possible ecotoxicity ammonium perchlorate was tested using FETAX (Frog Embryo Teratogenesis Assay Xenopus) in accordance with ASTM guidelines. 100% embryo mortality is attained by 600 mg/L. The LC-50 for all tests is 496.1 mg/L. Malformations appear over a broader concentration range and the average EC-50 is 396.1 mg/L. The Tertatogenic Index or (TI) is 1.25 which suggest that ammonium perchlorate is a significant threat . Instead embryotoxicity is apparently the most significant threat. The NOEC (No Observed Effect Concentration) and LOEC (Lowest Observed Effect Concentration) concentrations for mortality are 271.8 and 356 mg/L respectively. Those for malformations are 203.3 and 247.2mg/L. The most dramatic malformation observed is the dorsal curvature of the tail which suggest abnormalities of in the notochord. Additionally malformations of the head and face were commonly observed. The head is reduced in size and appears flattened in anterior-posterior axis. These malformations are dose dependent in that more severe developmental consequences are found in embryos exposed to higher concentrations. In summary, the FETAX tests indicate that although severe malformations are caused, the TI and growth criteria suggest that perchlorate is embryotoxic and not teratogenic.

529 THYROID STATUS OF PERCHLORATE WORKERS.

S H Lamm[1], L E Braverman[2], F X Li[1], S Pino[2], and G Howearth[3]. [1]*Consultants in Epidemiology and Occupational Health, Inc., Washington, DC, USA;* [2]*Brigham & Women's Hospital, Boston, MA, USA; and* [3]*American Pacific Corp., Cedar City, UT, USA.*

Thyroid examinations and thyroid function tests were conducted on workers at an ammonium perchlorate manufacturing plant to determine whether perchlorate exposure has adversely affected the thyroid status. Perchlorate is known to affect the thyroid as an inhibitor of iodine uptake. Thirty-seven perchlorate workers and twenty-one comparison workers were examined. Both respirable and total particle perchlorate inhalation during a 12-hour work shift were measured, as was urinary perchlorate excretion. Perchlorate concentrations were measured in urine samples obtained both before and after a 12-hour work shift. Total particle perchlorate was a better measure of perchlorate exposure than was respirable perchlorate. The exposure groups (high, medium, and low) averaged 30 mg/day, 4 mg/day and 0.3 mg/day, respectively. The workers in the comparison group averaged an exposure of 0.01 mg/day. Blood was drawn at the end of the shift for a blood chemistry panel, a complete blood count, and thyroid function studies. No differences in the distribution of thyroid function test results (including thyroid stimulating hormone and free thyroxine index) existed across the exposure groups or with respect to the comparison group. Further, no evidence of hematotoxicity, nephrotoxicity, or hepatotoxicity was found. A three-day post-exposure study of two highly exposed workers indicated an excretion half-time of about eight hours. Long-term occupational exposure to perchlorate at levels at or exceeding 30 mg/day did not demonstrate an adverse effect on the thyroid.

530 PERCHLORATE IN DRINKING WATER AND RISK OF CONGENITAL HYPOTHYROIDISM.

M L Doemland and S H Lamm. *Consultants in Epidemiology and Occupational Health, Inc., Washington, DC, USA.*

Perchlorate has been detected in the public water supply for much of Southern California and Southern Nevada at levels of 4-16 μ g/l (ppb). Since perchlorate is a known inhibitor of iodine uptake by the thyroid, an investigation has been carried out to examine whether maternal exposure to perchlorate through the drinking water supply has increased the risk of congenital hypothyroidism. The US Environmental Protection Agency (EPA) has identified one county in Nevada and six counties in California with perchlorate in the water supply. The water source for 96% of the supply for Clark County, Nevada (Las Vegas) has been found to contain perchlorate, as does the Colorado River which is an intermittent source of water for much of Southern California. This investigation has sought to determine whether the congenital hypothyroidism rate is increased in the counties with perchlorate-containing water. The state health departments maintain a neonatal screening program for congenital hypothyroidism using heel-stick blood samples. The county-specific 1996 and 1997 congenital hypothyroidism screening data for California and Nevada have been obtained from the respective health departments. The congenital hypothyroidism birth prevalence rate for Clark County did not differ from that for the rest of the state. The California data also showed that the rates did not differ. The California data have been adjusted for ethnicity. The observed to expected ratios for the six counties together was 1.0 (95% confidence limits, 0.9-1.2). The ratios for the individual counties ranged between 0.6 and 1.1. These data do not support the hypothesis that these levels of perchlorate in the drinking water have increased the rate of congenital hypothyroidism. (Funding was provided by American Pacific Corp.)

531 PERCHLORATE ENVIRONMENTAL CONTAMINATION: TESTING STRATEGY BASED ON MODE OF ACTION.

D R Mattie[1] and A M Jarabek[2]. [1]*Operational Toxicology Branch, AFRL, Wright-Patterson Air Force Base, OH, USA;* [2]*National Center for Environmental Assessment, US EPA, Research Triangle Park, NC, USA.*

Perchlorate (ClO_4^-) is an anion that originates as a contaminant in ground and surface waters from its readily dissolved salts of ammonium, potassium or sodium. The anion is exceedingly mobile and stable under environmental conditions. A recent increase in detection capabilities led to discovery of ClO_4^- at various sites in CA, NV, UT, AZ, TX, AK, NY and MD. The existing clinical and toxicity database on ClO_4^- in March 1997 was determined by an expert peer review panel to be inadequate as the basis for an oral reference dose (RfD). No data on its carcinogenicity were available. Consideration of the known mode-of-action (MOA) for ClO_4^- at the time, competitive inhibition of iodide uptake into the thyroid gland, was used to construct a testing strategy that targeted potential endpoints indicated by disruption of the thyroid-pituitary-hypothalamic axis as well as provided data critical for health assessment approaches. Specific concerns included the potential for developmental toxicity, notably neurological development. Tests were also included to determine the genotoxic effects of ClO_4^-, with a recovery satellite to evaluate the reversibility of thyroid hyperplasia after cessation of exposure, in order to characterize its potential for thyroid neoplasia. Interspecies aspects were also a design factor. The MOA strategy allowed an expedited evaluation of a widespread contaminant without a 2-year assay.

532 HARMONIZED HEALTH RISK ASSESSMENT FOR PERCHLORATE BASED ON MAPPING ITS MODE OF ACTION(MOA).

A M Jarabek[1], A M Geller[2], and K M Crofton[2]. [1]*National Center for Environmental Assessment and* [2]*National Human and Ecological Effects Laboratory, US EPA, Research Triangle Park, NC, USA.*

Perchlorate anion (ClO_4^-) competitively inhibits iodide uptake into the thyroid. A testing strategy that utilized this information confirmed that the primary target tissue for ClO_4^- is the thyroid gland in rats, rabbits, and mice. Perturbations of thyroid hormone economy were measured by monitoring T3, T4 and TSH levels at various time points. The challenge to the health risk assessment was to integrate this information to map toxicity, in adult versus developing organisms, against T3, T4 and TSH levels as internal biological markers of response. Thyroid hyperplasia in the adult rats can be mapped along a pathogenesis continuum that could include neoplasia. The lack of evidence for direct action on DNA from a genotoxicity testing battery, together with demonstration of recovery of hyperplasia after cessation of exposure, supported proposal of an indirect mechanism for potential carcinogenicity. The lack of any other target toxicity in adult animals allowed harmonization of the noncancer and cancer effects based on the adverse T3, T4 and TSH levels correlated with hyperplasia. Consideration of developmental toxicity, however, required that hormone levels be mapped against lesions observed in the neonatal thyroid and neurobehavioral effects. Pharmacokinetic data will be used to refine the MOA approach as well as influence the magnitude of the uncertainty factors for intra- and interspecies extrapolation.

533 DOSE-RESPONSE AND PHYSIOLOGY PERTINENT TO DEVELOPMENT OF A REFERENCE DOSE FOR PERCHLORATE.

G Goodman[1] and R C Pleus[2]. [2]*Intertox, Inc., Seattle, WA, USA;* [1]*Human Health Risk Resources, Inc., Seattle, WA, USA.*

Recent application of a sensitive analytical method led to detection of perchlorate in major drinking-water supplies in Nevada, California, and Arizona. Using standard assumptions for drinking-water consumption and body weight for an adult male, the highest level of perchlorate measured, 16 ppb, leads to an estimated perchlorate intake of 0.00046 mg/kg-d. The current provisional RfD for perchlorate is based on an acute exposure study in Graves'-disease patients pretreated with an inhibitor of iodide organification (Stanbury and Wyngaarden, 1952). The dose-response for the effect observed in that study (acute discharge of iodide from the organification-blocked thyroid) is unlikely to be predictive of the dose-response for the critical health effect defined by US EPA (functional disturbance of the thyroid-pituitary axis) under conditions of chronic exposure. US EPA is in the process of reevaluating the RfD, taking into account new toxicity data from four drinking-water-exposure studies of ammonium perchlorate in experimental animals: subchronic, developmental, neurobehavioral developmental, and reproductive. The lowest ammonium perchlorate dose tested in each of these four studies was 0.01, 0.1, 0.1, and 0.3 mg/kg-d, respectively. The dose spacing was such that a factor of 5 or 10 between doses was common. Such large gaps between dose levels can lead to several-fold underestimation of the no-observed-adverse-effect level (NOAEL). Analysis and comparison of uncertainties associated with NOAEL-based and benchmark-dose (BMD) approaches to derivation of possible RfD values, given the dose levels employed, demonstrates the superiority of the BMD approach. Another consideration in the derivation of a perchlorate RfD is thyroid homeostasis, *i.e.*, the maintenance of normal thyroid function over a broad range of thyroid-hormone and thyrotropin levels in serum. Treatment-related changes in these

hormone levels should not be considered adverse as long as the levels remain within normal physiological bounds. Consideration of the underlying physiology, and not just the statistical significance of changes, should be incorporated consistently into risk assessment methodology.

534 A 90-DAY DRINKING WATER TOXICITY STUDY IN RATS WITH AMMONIUM PERCHLORATE.

J C Siglin[1], D E Dodd[2], D R Mattie[3]. [1]*Springborn Laboratories, Inc., Spencerville, OH;* [2]*ManTech Environmental Technology, Dayton, OH;* [3]*AFRL/HEST, Wright-Patterson AFB, OH.*

Ammonium Perchlorate (AP) is an oxidizer that has been used as a component of solid rocket fuel. Perchlorate, the dissociated ion of AP, has been recently recognized as a persistent and pervasive contaminant of drinking water supplies in a number of major metropolitan areas. Current efforts at assessing the health risks of perchlorate have been hampered by a lack of relevant toxicity data and by a lack of understanding of the potential toxic mechanism(s) of action. The purpose of this study was to evaluate the potential toxic effects of AP when administered to rats in the drinking water for 14 or 90 days at dosage levels of 0.01, 0.05, 0.2, 1.0 and 10.0 mg/kg/day (10 rats/sex/group/exposure period). Additional animals in the control, 0.05, 1.0 and 10.0 mg/kg/day groups (10/sex/group) were scheduled for euthanasia following a 30 day nontreated recovery period to assess the reversibility or persistence of effects. No toxicologically meaningful differences were observed among the groups with respect to clinical observations, body weights, food and water consumption, hematology and clinical chemistry parameters, ophthalmology, male sperm parameters, female estrous cyclicity, or bone marrow micronuclei formation. Increased thyroid weights and corresponding follicular cell hyperplasia were observed after 14 and 90 days at the 10.0 mg/kg/day level. These changes were reversible after the 30 day recovery period. Significant changes in thyroid hormones (primarily increased TSH and decreased T_3 and T_4) were observed at levels of 0.01 mg/kg/day and above; however, no thyroid organ weight or histopathological effects were noted at levels of 1.0 mg/kg/day and lower. Based on the absence of organ weight and histopathological effects, 1.0 mg/kg/day was considered the no-observed-adverse-effect level (NOAEL) for the study. In the absence of other effects, the toxicological significance of thyroid hormone alterations remains to be determined.

535 EFFECTS OF AMMONIUM PERCHLORATE ON THYROID, HEMATOLOGICAL, AND IMMUNOTOXICOLOGICAL PARAMETERS.

M Jenny[1], D Keil[1], A Warren[2], J Eudaly[1], R Bullard-Dillard[3]. [1]*Medical University of SC, Charleston, SC, USA;* [2]*TERRA, Inc., Tallahassee, FL, USA;* [3]*Claffin University, Orangeburg, SC, USA.*

The use of AP as an oxidant in solid propellants has resulted in soil and ground water contamination and the potential for human exposure via ingestion. As part of an effort to create a toxicological database that could serve as the basis for regulatory decision making, this study was undertaken to assess thyroid, hematological, and immunological effects of AP. Adult, female $B6C3F_1$ mice were administered AP in their drinking water (0, 0.1, 1.0, 3.0, or 30 mg/kg/day) for 14 or 90 days, after which several toxicological endpoints were examined. These same endpoints were also examined 30 days after a 90-day drinking water exposure to assess the reversibility of any observed effects. Preliminary results indicate that the AP concentrations examined had no significant effect on body and organ weights, red blood counts and indices, hemoglobin levels, hematocrit, white blood counts and differentials, cytotoxic T cell activity, and splenocyte CD4/CD8 subpopulations. In addition, there was no change in nitrite production by peritoneal macrophages after 14-day exposure to AP. This is in contrast to increased nitrite production observed after 90-day exposure to 3 and 30 mg/kg/day AP. Phagocytosis of *Listeria monocytogenes* by peritoneal macrophages was decreased by as much a 50% after 14 and 90-day exposure to AP. This effect was reversible when measured 30 days post-exposure. No changes were detected in serum T_4 levels after 14 days at any dosage level. Exposure for 90-days to 30 mg/kg/day AP significantly affected T_4 levels by 30%, however, these levels returned to normal when measured 30-days post-exposure. Thyroid stimulating hormone levels (TSH) were not significantly affected in any of the treatment groups after exposure to AP for 90-days. To identify histological changes after AP exposure, thyroid from mice exposed to AP have also been submitted for pathology. While preliminary, results suggest that in mice, AP might have immunotoxic effects at dosage levels at or below those inducing changes in thyroid hormone levels. (Funded by DSWA01-97-0008.)

536 COMPARISON OF END-POINTS TO DETECT PULMONARY PHOSPHOLIPIDOSIS FOLLOWING INHALATION EXPOSURE OF RATS AND DOGS.

J Pauluhn. *BAYER AG, Institute of Toxicology, Wuppertal, Germany.*

The pulmonary response of Wistar rats and beagle dogs to single and repeated nose-/head-only inhalation exposures to an aerosolized dicationic amphiphilic drug (DCAD) was examined using either a high (hydrochloride) or low (sulfate) water soluble salt of the drug. The objective of this study was to test the hypothesis whether DCAD-aerosols interact directly with surfactant by formation of surfactant-DCAD precipitates and whether high-/low soluble particles differ in response. Bronchoalveolar lavage (BAL) was used to evaluate the following end-points: neutrophil and macrophage numbers, protein, phosphatidylcholine in BAL-fluid and -cells, lactate dehydrogenase (LDH), alkaline and acid phosphatase, and β -N-acetylglucosaminidase (β -NAG). At higher exposure doses the results indicate that the most salient finding in both species was a pulmonary lipoproteinosis elicited by increased loading of phospholipids in alveolar macrophages. This response was associated with increased activities of β -NAG, alkaline and acid phosphatase, and LDH. In regard to the relative magnitude of response, pulmonary lipoproteinosis appears to precede the other effects. Appreciable differences in response to low or high water soluble particles were not observed. It appears, however, that higher exposure doses of low-soluble dust particles might stimulate more effectively their phagocytosis by alveolar macrophages and, subsequently, the test agent is leached from this cell in a more protracted manner. Toxicokinetic evidence demonstrated a concentration x time - dependent accumulation of DCAD in lung tissue and BAL-cells. Nevertheless, concomitant adverse effects occurring in lung parenchyma were not observed. In summary, after dosimetric adjustment, the data obtained in rats and dogs demonstrate similar response.

537 A NEW RESPIRATORY MONITORING SYSTEM FOR CONSCIOUS PRIMATES DURING INHALATION EXPOSURES POSSIBLY DEMONSTRATING A CORRELATION BETWEEN RESPIRATORY RATES AND HISTOPATHOLOGICAL CHANGES IN THE LUNG.

J A L Saywell and J C Norris. *Inhalation Toxicology, Covance Laboratories, Harrogate, UK*

A technique for respiratory monitoring of conscious primates has been developed for use during inhalation exposures to a gas/vapour, liquid aerosol, or solid aerosol of chemicals or drugs. This respiratory monitoring can include measurements of the respiratory rate, duration of inspiration, duration of expiration, duration of end inspiratory pause, and the number of discontinuous flow events. A review of data from two studies was conducted to determine if respiratory rates could be indicative of other toxicological findings. During a 7-day primate study, the respiratory rate was monitored at pre-exposure and on days 1 and 7. The percentage of the pre-exposure respiratory rates on day 1 (mean ± s.d.) were 101 ± 11%, 153 ± 24%, and 199 ± 28%; and on day 7, these values were 102 ± 11%, 134 ± 18%, and 173 ± 20% for the low, mid, and high groups, respectively. The histological examination demonstrated the presence of bronchiolitis involving terminal and alveolar bronchioles in 1 low group male, 1 intermediate group female, and all high group animals. For a 26-week primate study of a protein, respiratory rate was monitored. No statistically significant exposure-related respiratory changes were observed, however, a slight increase in the respiration rate at the high group was noted at the end of the study. Histopathological evaluation of the lungs revealed no statistically significant changes. Consequently, a new procedure has been established for measuring respiratory parameters during inhalation exposures, permitting an immediate assessment of the pulmonary responses to exposures of drugs/chemicals. Additionally, data produced during two studies suggested that changes in respiratory rates might indicate some histopathological changes in the lung.

538 SUBCHRONIC EXPOSURES OF RATS TO AN AEROSOL OF GENERIC COMMERCIAL ENGINE OIL.

W E Dalbey and C A Schreiner. *Mobil, Paulsboro, NJ, USA.*

A 13-week inhalation study was performed with aerosolized Generic Commercial Engine Oil (GCEO). Rats (15/sex) were exposed 6 hr/d, 5 d/wk to 0 (both untreated and sham-exposed controls), 50, 150, or 400 mg/m³. An additional 10 males were in each group for pulmonary function tests at the end of exposures. No treatment-related effects were noted during the course

of exposures and no changes were found in body weights, clinical observations, serum chemistry, or the number and morphology of sperm at the terminal sacrifice. In the blood, the percentage of segmented neutrophils increased and the percentage of lymphocytes decreased in a concentration-related manner at 13 weeks of exposure. Otherwise, the lung was the primary organ affected by exposure. Increased lung weight and grossly visible plaques occurred in a concentration-related manner. Histologically, foamy alveolar macrophages accumulated in the alveoli. Lung volumes, pressure-volume curves, and maximal forced exhalations were not significantly different from the control groups. The lack of a significant tissue reaction in the lung, other than increased macrophages, after exposure to aerosol concentrations as high as 400 mg/m³ indicates a relatively low order of toxicity for GCEO.

539 INHALATION TOXICITY STUDIES OF METHYLVINYL KETONE IN RATS AND MICE.

D L Morgan[1], H C Price[2], R W O'Connor[2], J F Mahler[1], S M Ward[1], R E Wilson[1] and M E Cunningham[1]. [1]*NIEHS, Research Triangle Park, NC;* [2]*METI, Research Triangle Park, NC.*

Methylvinyl ketone (MVK) is a prototype of the straight-chain aliphatic α,β-unsaturated ketones and is used in the production of pesticides, perfumes, plastics and resins and as a pharmaceutical intermediate. Exposure to MVK is widespread due to its presence in cigarette smoke and its production by γ-irradiation of sugars in fruit. Although occupational and consumer exposure to MVK has been documented, health effects testing has been inadequate. Prechronic inhalation studies were conducted to provide data required to design chronic toxicity and carcinogenicity studies of MVK. In initial studies, rats and mice were exposed to 0, 0.25, 0.5, 1, 2, 4, or 8 ppm MVK 6 hr/day, 5 days/week for 12 days. No toxicity was observed in animals exposed to up to 1 ppm. Morbidity and early deaths occurred in male and female rats (day 1) and male mice (day 10) exposed to 8 ppm. Rats exhibited nasal cavity toxicity and lung necrosis at 4 ppm. Decreased body and liver weights were observed in male rats exposed to 2 ppm. Mice appeared to be less sensitive than rats to the toxic effects of MVK. Based on these results a 13-week study in mice and rats was conducted at 0, 0.5, 1, and 2 ppm MVK. As in the first study, the respiratory tract was the main target organ and mice were less sensitive than rats to inhaled MVK.

540 TWO-WEEK (TEN-DAY) INHALATION TOXICITY AND TWO-WEEK RECOVERY STUDY OF PHENOL VAPOR IN THE RAT.

G M Hoffman[1], B J Dunn[2], C R Morris (deceased)[3], J H Butala[4], S S Dimond[5], R Gingell[6] and J M Waechter, Jr.[7]. [1]*Huntingdon Life Sciences, East Millstone, NJ, USA;* [2]*AlliedSignal, Morristown, NJ, USA;* [3]*ICC USA, Morrisville, NC, USA;* [4]*Consultant to Aristech, Pittsburgh, PA, USA;* [5]*GE Plastics, Pittsfield, MA, USA;* [6]*Shell Chemical Co., Houston, TX, USA;* [7]*The Dow Chemical Co., Midland, MI, USA.*

The toxicity of phenol vapor was evaluated in male and female Fischer 344 rats (20/sex/group) via flow-past nose-only inhalation exposure. The test animals were exposed to target concentrations of 0 (air control), 0.5, 5 or 25 parts per million (ppm) of phenol in air for 6 hours/day, 5 days/week for two weeks. HPLC (high pressure liquid chromatography) measurement of phenol test atmospheres determined mean (±standard deviation) analytical concentrations of 0.0±0.0, 0.52±0.078, 4.9±0.57 and 25±2.2 ppm, respectively. Test animals were examined daily for signs of toxicity. Body weights and food consumption were measured weekly. After two weeks of exposure, ten test animals/sex/group were sampled for clinical chemistry and hematology parameters. The test animals were then sacrificed, organs weighed and tissues collected. Histopathological examination included the nasopharyngeal tissues, larynx, trachea, lungs with mainstem bronchi, kidney, liver and spleen. The remaining ten animals/sex/group were retained for a two-week recovery period. Recovery groups of animals were then sampled and sacrificed as described previously. No signs of toxicity in clinical observations, body weights, food consumption, clinical pathology, organ weights, macroscopic pathology or microscopic pathology were seen during the exposures or at either sacrifice interval. In conclusion, two-week inhalation exposures to phenol vapor at concentrations up to and including 25 ppm did not produce any adverse effects. (The Phenol Panel of the Chemical Manufacturers Association sponsored this study.)

541 TISSUE AND SERUM MARKERS OF JP-8 EXPOSURE: TWO-DIMENSIONAL PROTEIN MAPPING.

F A Witzmann[1], C D Fultz[1], R Young[2], M L Witten[2], L S Wright[3], S E Kornguth[3], and F L Siegel[3]. [1]*Molecular Anatomy Laboratory, Dept. of Biology, Indiana Univ. Purdue Univ., Columbus, IN, USA;* [2]*University of Arizona Health Sciences Center, Tucson, AZ, USA;* [3]*The Waisman Center, University of Wisconsin, Madison, WI, USA.*

We analyzed protein expression in the cytosolic fractions of cerebellum, cerebrum, kidney, liver and lung tissues and serum samples from male Swiss-Webster mice exposed 1 h/day for 7 days to aerosolized JP-8 jet fuel at 1000 and 2500 mg/m³, simulating occupational exposure. Cytosol/serum samples were solubilized and separated via large scale, high resolution two-dimensional electrophoresis (2-DE) and gel patterns scanned, digitized and processed for statistical analysis. Quantitative changes in tissue cytosol proteins resulting from 2500 mg/m³ exposure were significant (P<.001) for 12 cerebellar, 10 cerebral, 65 kidney, 12 liver, 42 lung and 4 serum proteins. In comparison, the 1000 mg/m³ exposure altered 5 cerebellar, 5 cerebral, 7 kidney, 2 lung, 3 kidney and 0 serum proteins. At the 2500 mg/m³ exposure, of all the proteins altered, only 19 kidney, 2 liver, 14 lung and 3 serum proteins changed quantitatively by 2-fold or more. None of the proteins underwent >3-fold alterations in abundance. These results demonstrate a significant but comparatively moderate JP-8 effect on protein expression, particularly in kidney and lung, and corroborate previous morphological and biochemical evidence. Further molecular biomarker development and mechanistic inferences from these observations await proteomic analysis of whole tissue homogenates and cell compartments, *i.e.* mitochondria, microsomes, and nuclei of these and other targets. (Supported by AFOSR Grants F49620-96-1-0156 and F49620-96-1-0074.)

542 AN INHALATION ONCOGENICITY AND CHRONIC TOXICITY STUDY OF PHOSPHINE IN RATS.

P E Newton[1], D A Banas[2], N H Wilson[2], W M Busey[2], and D G Shaheen[3]. [1]*MPI Research, Mattawan, MI;* [2]*Experimental Pathology Laboratories, Herndon, VA;* [3]*DEGESCH America, Inc. Weyers Cave, VA.*

Phosphine is a highly toxic gas used as a fumigant, a dopant in semiconductor manufacturing, and in the production of organophosphines. In a chronic toxicity and oncogenicity study of phosphine, 60 male and female F344 rats per group were exposed via whole-body inhalation for 6 hours per day, 5 days per week for up to 104 weeks to mean concentrations of 0, 0.3, 1, or 3 ppm of phosphine. Ten per sex per group were sacrificed after 52 weeks of exposure. Survivors were sacrificed after 104 weeks of exposure. There were no test article-related effects seen on clinical observations, body weight, food consumption, hematology, clinical chemistry, urinalysis, or ophthalmology. There were no test article-related macroscopic findings or effect on absolute or relative organ weights. No histomorphologic alterations attributable to test article exposure were seen. In conclusion, under the conditions of this study, there were no treatment related changes suggestive of a toxic or carcinogenic effect seen in rats following 52 weeks and 2 years of whole-body inhalation exposure to 0.3, 1, or 3 ppm of phosphine. (This research was supported by the 1996 Phosphine Task Force.)

543 FOURTEEN-DAY INHALATION TOXICITY STUDY OF N-ETHYL-M-TOLUIDINE IN RATS.

E Stephens[1], N Rajendran[2], D Sullivan[2], and J Gerhart[2]. [1]*ChemFirst Inc, Pascagoula, MS;* [2]*Life Sciences Research, IIT Research Institute, Chicago, IL.*

N-Ethyl-m-toluidine (NEM) is a chemical intermediate used in the manufacture of photographic developers. To study the effects of repeated inhalation exposure, 5 male and 5 female albino rats were given whole-body exposures to either air, 5.6, 32.8, or 67.6 ppm NEM for 6 hours per day, 5 days per week over a 14-day period. A satellite group of 5 males at each exposure concentration was exposed similarly and used for methemoglobin determinations. Additional groups of 5 rats/sex were added to the air exposure and high exposure groups and observed for 14 days post-exposure to assess recovery. Core toxicology and recovery animals were bled for clinical pathology, euthanized and necropsied the day after final exposure and recovery period observation, respectively. There were no deaths during the study and no significant changes in mean body weight by comparison to controls. The 5.6 ppm group had decreased methemoglobin and hemoglobin, erythro-

poiesis in the bone marrow, liver, and spleen, and congestion of the spleen. In addition to these effects, the 32.6 and 67.6 ppm core groups had increased spleen weight; increased leukocytes, lymphocytes, mean corpuscular volume and mean corpuscular hemoglobin; decreased erythrocytes and hematocrit, macrophage pigmentation in the spleen; and hyaline droplet formation and tubule cell pigmentation in the kidney. Males in the high exposure core group had increased incidence and severity of nephropathy. While the incidence and severity of findings were generally reduced, the 67.6 ppm recovery group still had decreased methemoglobin, increased mean corpuscular volume, enlarged spleens, erythropoiesis in the bone marrow, and macrophage pigmentation in the spleen; and, in addition, platelets were decreased in males. Findings were consistent with hemolytic anemia.

544 TOXICITY OF BREVETOXIN-2 IN RATS FOLLOWING ACUTE AND REPEATED ADMINISTRATION VIA THE RESPIRATORY TRACT.

D Tischler[1], J Benson[1], F Hahn[1] and D Baden[2]. [1]*Lovelace Respiratory Research Institute, Albuquerque, NM, USA;* [2] *Marine and Freshwater Biomedical Sciences Center, Rosenstiel School of Marine and Atmospheric Science, University of Miami, Miami, FL, USA.*

Brevetoxins are cyclic polyether neurotoxins produced by the marine dinoflagellate, *Ptychodiscus brevis*. Blooms of *P. Brevis* (red tides) can be lethal to fish and marine mammals and toxic to humans. Although a common route of human exposure is through inhalation of seaspray aerosols, the health effects associated with repeated inhalation of low levels of brevetoxin remain unknown. The purpose of these studies was to evaluate the toxicity of brevetoxin administered to rats via the respiratory tract. Acute toxicity was estimated by administering 100 - 200 μ g/kg brevetoxin 2 (PbTx-2) to male F344/Crl Br rats by intranasal (IN) and intratracheal instillation (IT; one rat per dose). Clinical signs of toxicity included gasping and dyspnea; no rats died. The median lethal concentration (LC50) for PbTx-2 administered IT is 100 - 150 μ g/kg. This is approximately twice the estimated LC50 for PbTx-2 administered iv to rats (Templeton *et al*, 1989). For repeated exposures, groups of 5 male F344/Crl Br rats were administered saline (controls) or 100 μ g/kg PbTx-2 IN for 5 consecutive days. PbTx-2-exposed rats lost weight. Clinical signs included ataxia, gasping, and dyspnea. Total cells recovered in bronchoalveolar lavage fluid were not different from control values. Numbers of neutrophils and lymphocytes were increased. No DNA damage to the lavage cells was detected using the COMET single cell gel electrophoresis assay. Histopathological evaluation of the respiratory tract is being conducted. Results of these studies indicate that PbTx-2 is less acutely toxic when administered IT or IN than when administered iv and that repeated inhalation may cause pulmonary inflammatory and immune responses.

545 DEVELOPMENT OF A RECIRCULATING, NOSE-ONLY EXPOSURE SYSTEM TO STUDY UPTAKE OF [14C]-STYRENE.

B A Wong[1], J E Murphy[1], P J Boogaard[2], and S C J Sumner[1]. [1]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA;* [2]*Shell International Chemicals, Amsterdam, The Netherlands.*

An exposure of rats and mice to [14C]-styrene was conducted to study the disposition of styrene. An exposure system for conducting nose-only exposures was adapted to recirculate a portion of the flow. The purpose of the recirculating portion was to reduce the total amount of [14C]-styrene required from a single-pass dynamic system operating at an equivalent air flow. A condenser was used to remove moisture from the system, and soda lime was used to remove carbon dioxide. Oxygen was also added to the system to maintain levels above 19%. The labeled styrene was allowed to evaporate in a stainless steel pressure vessel and then pressurized with nitrogen to a predetermined level. The styrene mixture was added to the recirculated atmosphere to maintain 160 ppm. A group of 12 rats and two groups of 30 mice were exposed separately to 160 ppm styrene over a 6-hr period. The amount of styrene used for the rat exposure was approximately 60% of what would be required for a single-pass nose-only exposure. The amount was approximately 90% for the mouse exposures. Styrene uptake was calculated from the rate of styrene addition to the recirculating system. Uptake was calculated to be 79 μmol/kg/hr for the rats and 135 μmol/kg/hr (average of two experiments) for the mice. The rate of styrene uptake was relatively stable over the 6-hr exposure for the rats, while the rate decreased steadily over the 6-hr period for the mice. (This study was supported by the Styrene Information and Research Center.)

546 ASSESSMENT OF OCCUPATIONAL EXPOSURE OF WELDERS TO MANGANESE.

J Zayed[1], S Savard[1], and G Kennedy[2] and TOXHUM (Research Group on Human Toxicology of the University of Montreal). [1]*Département de médecine du travail et d'hygiène du milieu, Faculté de médecine, Université de Montréal;* [2]*École Polytechnique, Montréal, Canada.* Sponsor: R Tardif.

Exposure to high levels of Mn can lead to toxic effects, notably on the respiratory and central nervous systems. In the workplace, welding operations represent a potential source of exposure to Mn. Recently, ACGIH adopted a new Threshold Limit Value (TLV) of 200 μg/m³ (TWA) for Mn. This study aims to assessing the occupational exposure of welders to Mn. We measured the exposure of 10 welders during a 5-day work period using personal sampling pumps. Total Mn (Mn_T) and respirable Mn (Mn_R, 5 μm) were quantified on filters by neutron activation. Values obtained ranged from 27.4 to 496.5 μg/m³ with a mean of 191.1μg/m³ for Mn_T and from 19.4 to 257.5 μg/m³ with a mean of 114.6 μg/m³ for Mn_R. The mean Mn_R/Mn_T ratio was 60%. These concentrations are lower than the Quebec permissible exposure level of 5000 μg/m³ (Ceiling). However some are higher than, 1) the ACGIH level of 200 μg/m³ and, 2) recent reported Mn concentrations which are associated with observable health effects. This on going research project will provide additional information that will be used eventually in the review of Quebec permissible level.

547 A SMALL ANIMAL PLETHYSMOGRAPH/EXPOSURE TUBE FOR DETERMINATION OF RESPIRATORY MECHANICS DURING EXPOSURE, USING NON-INVASIVE METHODS TO MEASURE INTRAPLEURAL PRESSURE.

E C Kimmel. *Geo-Centers, Inc. at the Naval Health Research Center Detachment/ Toxicology, WPAFB, OH, USA.* Sponsor: R L Carpenter.

The real-time measurement of changes in respiratory mechanics, primarily dynamic compliance (C_{dyn}) and airway resistance (R_L), is often used to assess the acute pulmonary toxicity of inhaled irritants; particularly those thought to cause an airways hyperreactivity response. Simple volume displacement plethysmography for determining ventilation in spontaneously breathing animals can be adapted for the determination of C_{dyn} and R_L by including the simultaneous measurement of intrapleural pressure (Ip). Accurate estimates of Ip can be obtained by measurement of esophageal pressure (Pes) using transoral insertion of a water filled cannula . Measurement of Pes does not require surgical insertion of a cannula through the chest wall as is required for measurement of Ip. However, the use of conventional head-out plethysmography to measure ventilation and respiratory mechanics during exposure, often precludes the use of transoral insertion of an esophageal cannula to measure Pes. Thus invasive methods must be used to measure Ip. We have developed a combination head-out plethysmograph/nose-only exposure tube (PET) suitable for measurement of R_L and C_{dyn} using transoral cannulation for determination of Pes. The cannula neither obstructs the nose of the animals nor prevents insertion of the PET into a nose-only exposure chamber port. Experiments conducted in 25 rats demonstrated that the insertion of the esophageal cannula did not significantly alter ventilation (with exception of an increase in peak inspiratory pause time). R_L and C_{dyn} in measured in normal rats using the PET did not differ from RL and Cdyn determined using more conventional plethysmographic methods.

548 A SIMPLE, INEXPENSIVE SOLID FUEL FURNACE FOR SMALL SCALE COMBUSTION TOXICITY STUDIES.

J E Reboulet and E C Kimmel. *Geo-Centers Inc. at the Naval Health Research Center Detachment (Toxicology). WPAFB, OH, USA.* Sponsor: R L Carpenter.

Red oak combustion atmospheres produced by in an inexpensive furnace designed for use in combustion toxicity studies were compared to similar atmospheres produced by more conventional combustion furnaces. The furnace is based on a simple 1.5 ohm resistance wire heater which achieves temperatures ranging from ambient to 640 °C. The heater temperature produced was linear with input voltage over this working range. Combustion occurred in three phases (initial non-flaming, flaming, and post flaming). In the non-flaming phase, the sample charred and smoked, produced carbon monoxide (CO) concentrations ranging from 2600-4600 ppm, and carbon dioxide (CO_2) ranging from 3300 to 3700 ppm. Carbon monoxide to CO_2 ratios were from 0.8 to 1.3 for the non-flaming phase. In the flaming phase

CO_2 concentrations ranged between 6-11% and CO concentrations ranged from 200-300 ppm. In the final smoldering phase CO levels rose to 2000 ppm and CO_2 levels dropped to 1%. Aerosol size distribution was examined using a time of flight, laser optical, aerodynamic particle sizer. Typical aerosol concentration during the non-flaming phase was 1.70×10^7 particles/cm^3 (1.5 g/m3). Aerosol mass median aerodynamic diameter was 0.84 μ m.

549 THE GENERATION OF RESPIRABLE PARTICULATE AND FIBERS FROM THE PARTIAL PYROLIZATION OF ADVANCED COMPOSITE MATERIALS.

D L Courson[1], E C Kimmel[2], J C Lipscomb[3] and R L Carpenter[2]. [1]*ManTech/Geo-Centers Joint Venture;* [2]*Naval Health Research Center Detachment (Toxicology), Wright-Patterson AFB, OH;* [3]*U.S. Environmental Protection Agency, Cincinnati, OH.*

The increasing use of advanced composite materials (ACM) in weapons platforms and commercial applications has stimulated interest in their potential combustion toxicity. A system based on a modified UPITT II mini-cone calorimeter was used to characterize ACM combustion atmospheres. Partial pyrolysis of ACM (26 g at 625 C°) generated aerosols composed of small, nearly spherical particles, agglomerates of these particles and respirable fibers. Vapor and gas phase chemistry from this ACM generated pyrolysate atmosphere has been reported previously (Kuhlmann et. al. 1997). Aerosol particles were collected using inertial impaction and electrostatic precipitation methods. SEM samples revealed 3 populations of particles: agglomerates, small spherical particles and fibers. Agglomerate chains ranged in size from (approximately 500 nm in length up to non-respirable sizes). Individual particles were (approximately 100 nm diameter up to 450 nm diameter). Fibers were found to be relatively homogenous (approximately 200 nm x 500 nm up to approximately 500 nm x 10 μ m). Energy dispersive x-ray (EDX) of fibers showed them to be predominantly silica, carbon, titanium, copper and aluminum. The combination of these collection techniques coupled with scanning electron microscopic examination and spectral processing and analysis of particle morphometry have provided conclusive evidence for the presence of respirable fibers, though their formation/liberation from pyrolysate ACM generated atmospheres.

550 A 13-WEEK INHALATION TOXICITY STUDY (WITH RECOVERY) OF AMMONIUM PERSULFATE IN ALBINO RATS.

C E Ulrich[1], J Signorin[2], J G Henson[1], and M T Butt[3]. [1]*WIL Research Laboratories, Ashland, OH, USA;* [2]*FMC Corporation, Princeton, NJ, USA;* [3]*PAI, Fredrick, MD, USA.*

The subchronic inhalation toxicity of ammonium persulfate was characterized using Sprague-Dawley rats (20/sex/group) at respirable dust concentrations of 0, 5.0, 10.3 and 25 mg/m3. Whole-body exposures were conducted 6 hours/day, 5 days/week for 13 weeks. Gravimetric airborne test material samples were taken daily from each exposure chamber. Particle size samples were taken weekly from each exposure chamber. Ten animals/sex/group were necropsied after 13 weeks of exposure and 5 animals/sex/group were held for either a 6- or 13-week non-exposure recovery period. Animals were observed for clinical signs of toxicity, effects on body weight, food consumption, clinical pathology, ophthalmologic parameters, organ weights and macroscopic and microscopic pathology. There were no exposure-related deaths during the study. Rales and increased respiration rate were noted in both males and females in the 25 mg/m3 group, and in a few animals in the 10.3 mg/m3 group. The incidence of these clinical signs decreased to zero during the first few weeks of the recovery period. Body weights for both males and females in the 25 mg/m3 group were significantly depressed during most of the exposure period when compared to the control group. Body weights completely recovered during the recovery period. Lung weights were elevated in the 25 mg/m3 group after 13 weeks of exposure, but were similar to controls at 6 weeks post-exposure. Irritation of the trachea and bronchi/bronchiole was noted microscopically after 13 weeks of exposure to 25 mg/m3. These lesions had recovered by 6 weeks post-exposure. Based on the results of this study, the NOEL for exposure of rats to a dust aerosol of ammonium persulfate was 5.0 mg/m3, while the NOAEL was 10.3 mg/m3.

551 ACUTE INHALATION TOXICITY OF ETHYLAMINE, DIETHYLAMINE AND TRIETHYLAMINE - EFFECTS ON RODENT NASAL PASSAGES.

D W Lynch[1], R L Schueler[2] and E J Gorgacz[3]. [1]*NIOSH, Cincinnati, OH;* [2]*Research Pathol. Assoc., Sykesville, MD;* [3]*Expt. Pathol. Labs, Ross, OH.* Sponsor: K L Cheever.

To address occupational toxicology needs, the acute inhalation toxicity of ethylamine (EA), diethylamine (DEA) and triethylamine (TEA) was investigated using F344 rats, and B6C3F1 mice (DEA only). Groups of 4-5 animals were exposed via whole body inhalation to each amine at 250 or 1000 ppm for 6 hrs/day for a total of 10 exposure days. Body weights and histopathological evaluations of major organs including the nasal passages were conducted. In general, mean body weights were unchanged or decreased slightly in the groups exposed at 250 ppm. In contrast, mean body weights were significantly decreased in both sexes from all groups exposed at 1000 ppm, regardless of amine. No deaths occurred in rats exposed to EA or to the other amines at 250 ppm. Two of five male and 1/5 female rats exposed to 1000 ppm TEA died. Four of five male and female rats and 1/5 male and female mice exposed at 1000 ppm DEA also died. Histopathology of the major organs was unremarkable except for the upper respiratory tract and nares. Treatment-related effects seen in the nasal passages of animals exposed at 1000 ppm ranged from moderate necrotizing inflammation (EA, TEA) to squamous metaplasia and turbinate atrophy (DEA, both species). Effects seen in the nasal passages of animals exposed at 250 ppm ranged from slight necrotizing inflammation (EA) to squamous metaplasia and localized turbinate atrophy (DEA, both species). No effects were seen in the nasal passages of rats exposed at 250 ppm TEA. Squamous metaplasia of the tracheal mucosa was found in rats exposed to 1000 ppm TEA and 1000 ppm DEA. Ulcerative tracheitis was also found in rats exposed to 1000 ppm DEA. Squamous metaplasia of the trachea and the mainstem bronchi was found in mice exposed to 1000 ppm DEA. Based on acute toxicity to the nasal passages, the ethylamine series is ranked as follows: DEA > EA > TEA.

552 EFFECTS OF DIFFERENT CELLULOSE-CONTAINING RESPIRABLE SAMPLES IN THE LUNG OF FISCHER 344 RATS.

G M Adamson[1], H Muhle[2], O Creutzenberg[2], B Bellmann[2] and C Dasenbrock[2]. [1]*Procter & Gamble Company, Cincinnati, OH, USA;* [2]*Fraunhofer Institute of Toxicology & Aerosol Research, Hannover, Germany.*

Persistent inflammatory effects of cellulose containing materials, such as cellulose insulation and microcrystalline cotton cellulose, in the lung have been reported previously. Also, prior studies have used high doses likely to overwhelm lung clearance mechanisms. The objectives of the present study were to compare effects of respirable fractions of bleached cellulose (BC), cellulose insulation (CI), and microcrystalline cotton cellulose (MC), following intratracheal instillation. Also, to examine lung effects at low dose to avoid confounding effects of potential lung overload. Male Fischer 344 rats were given four consecutive daily instillations of pre-sized particulate for total doses of 0, 0.25, 1.0 and 4.0 mg/animal. Interim sacrifices were conducted at days 3, 7, 14, 28 and 90 for bronchoalveolar lavage fluid analysis for biochemical markers and differential cell counts, and for histopathology at days 28 and 90. Sample characterization indicated significant differences in size and shape of the three materials influenced by the type of bulk material. Also CI exhibited significant enrichment for borax content with 13% in bulk material and 48% in the respirable fraction. BC caused no significant effects at any dose in the lung. Significant cytotoxicity was observed in the high dose of CI and MC, with greater severity and persistence seen with CI. Evidence of inflammation was also observed with the high dose of MC and CI, exhibited as neutrophyl and leukocyte infiltration. Therefore, there are differences in severity and duration of response to instilled respirable particulate, depending on the type of cellulose-containing material. Differences in response may be due to differences in particulate characteristics and/or different locations of instilled materials in the respiratory tract. Also the high borax content may influence the effects seen for CI. Finally, responses were only observed at the highest dose where lung overload may be an influencing factor.

553 13 WEEK INHALATION TOXICITY STUDIES OF 2-CYCLOHEXENE-1-ONE.

M L Cunningham[1], H C Price[2], J B Nold[3], R W O'Connor[2], M P Moorman[1], and D L Morgan[1]. [1]*NIEHS/NTP;* [2]*METI, and* [3]*PAI, Research Triangle Park, NC.*

2-Cyclohexene-1-one (CHX) is a cyclic α,β-unsaturated ketone with broad human exposure. CHX is an environmental pollutant and is present in tobacco smoke and soft drinks sweetened with cyclamate. Prechronic toxicity studies were conducted to provide data required to design chronic toxicity and carcinogenicity studies of CHX. Groups of 10 male and female F344 rats and B6C3F1 mice were exposed to 0, 2.5, 5, or 10 ppm CHX for 6 hr/day for 13 weeks. All animals survived until sacrifice. Microscopic lesions included hyperplasia, and squamous metaplasia in the nasal cavity in rats and mice of both sexes at all doses. Erosion and suppurative inflammation also occurred in high dose mice. Larynx and lung were not affected in either sex-species. Dose related centrilobular cytoplasmic vacuolation was seen in male rats only. Body weights were not significantly different from controls after 13 weeks of exposure. Liver/body weights were increased in male and female mice exposed to 5 and 10 ppm, and in male and female rats exposed to 10 ppm CHX. No adverse effects on sperm motility or vaginal cytology were observed. These data will be used in the design of a 2-year inhalation bioassay of CHX.

554 CYTOTOXICITY OF ABRASIVE BLASTING SUBSTITUTES.

V Vallyathan[1], M Greskevitch[2], W Jones[2], and V Castranova[1]. [1]*Health Effects Laboratory Division and* [2]*Division of Respiratory Disease Studies, National Institute for Occupational Safety and Health, Morgantown, WV.*

Increased morbidity and mortality from sandblasting with crystalline silica continues to occur even when respiratory protection is used. Because of the high risk of acute silicosis and increased mortality associated with the use of silica in sand blasting, it is banned in many industrialized countries and many substitutes are now being commercially used. We studied few of the most frequently used substitutes for *in vitro* cytotoxicity and tested aerosolized dusts within two hours of blasting and after aging for four weeks. Treated sand, sand, garnet, coal slag, specular hematite, and staurolite were collected by drawing air from a blasting area through a cyclone precipitator and then onto a 47 mm, 0.8 μm FWS-B filter within one meter of the operator's breathing zone. Samples of the pre-blasted and post-blasted materials were used for chemical and electron microprobe analyzes and compared. Samples prepared on polycarbonate filters were analyzed by scanning electron microscopy, x-ray spectrometry, and plasma emission spectrometry. Cytotoxicity studies using rat alveolar macrophage monitored cell viability, and leakage of lactate dehydrogenase (LDH) and N-acetyl-β-D glucosaminidase (NAG). Measurements of hydroxyl radical (•OH) generation and lipid peroxidation potential were also made on blasted dusts. The blasting process changed the trace metal content of all the blasted particles. Blasting generally increased the relative proportion of iron in blasted materials. This iron was apparently derived from the steel plates that were blasted. Blasting also resulted in the generation of particles with an average diameter of 1 μm. Both fresh and aged blasted particles decreased rat alveolar macrophage viability and increased enzyme release to varying degrees. Toxicity was generally more distinct for staurolite, coal slag, and garnet compared to sand. The •OH generation from all freshly blasted particles was generally higher than from aged particles. Lipid peroxidation potential was greatest for garnet and staurolite. This study demonstrates that silica sand blasting substitutes are not without biological effects and in some instances the cytotoxicity exceeds that of sand and may provoke lung injury.

555 GAMMA SCINTIGRAPHY OF RADIOLABELED VIRUS FOR IN VIVO DETERMINATION OF THE DOSE DELIVERED TO TARGET ORGANS IN GENE THERAPY: APPLICATION TO ADENOVIRUS-CFTR ADMINISTERED AS AEROSOL IN BABOONS.

S Lerondel[1], L Routledge[2], S Bernard[3], F Verdier[2], C Sene[4], A Pavirani[4], J Descotes[5], and A Le Pape[1]. [1]*CNRS-INSERM U316, Tours, FRANCE;* [2]*Chrysalis International, L'Arbresle, FRANCE;* [3]*INRA, Tours, FRANCE;* [4]*Transgene, Strasbourg, FRANCE;* [5]*INSERM U98X, Lyon, FRANCE.*

Scintigraphy enables visualization and quantification of pharmaceutical products in the body, both accelerating exploratory research and validating toxicology protocols. For cystic fibrosis therapy via inhalation of CFTR gene vectorized by adenovirus, optimization of aerosol is a prerequisite to obtain a functionnal CFTR in central lung. In preclinical efficacy and safety evaluations, imaging of virus is the only non invasive technique to quantify the lung deposition and baboon is the most relevant species for predictive studies on lung aerosol deposition in humans. Therefore adenovirus was administered to baboons as an aerosol, technetium 99m being used to label adenovirus in such conditions that bioactivity was preserved. Particle size (MMAD) and dispersion (σ g) of the aerosol generated with a breath-activated jet nebulizer were determined using a cascade impactor connected to a pump modelizing baboon respiratory conditions. DTPA-99mTc scintigraphy was used as a reference prior to validation with 99mTc-adenovirus. Three baboons were submitted to scintigraphy, receiving 100 puffes of 99mTc-DTPA. A week later, 99mTc-adenovirus (7.7 10^9 pfu, 814-925 MBq, 2 ml) was administered. Lung regional deposition was assessed from Regions Of Interest corresponding to central and peripheral regions. Granulometry corresponded to a 1.6μ m MMAD with a 1.8 geometric dispersion.Nebulized fraction was 15-17% of the initial dose and total lung deposition 2.7 to 7.5% of the nebulized fraction. Regional deposition to the central lung was 1.0 to 3.5%. These results confirm that this technique allows to determine the actual dose delivered to the target organ. Furthermore, similarities observed between DTPA and virus deposition validates the use of DTPA scintigraphy as a pretherapeutic test for each patient.

556 AMIODARONE-INDUCED PULMONARY TOXICITY (AIPT) IN F344 RATS.

M D Taylor[1], K Van Dyke[1], A F Hubbs[2], L Bowman[2], P R Miles[2], and M J Reasor[1]. [1]*Dept. of Pharmacology and Toxicology, West Virginia University;* [2]*NIOSH/HELD, Morgantown, WV, USA.*

Amiodarone (AD) is a very effective antiarrhythmic drug, but its side effects limit its clinical application. AIPT involves both pulmonary inflammation and fibrosis in humans. The goal of this study was to develop an animal model of AIPT and examine the possible mechanisms leading to its development. F344 rats were intratracheally instilled with AD (6.25 mg/kg with a 3.125 mg/ml solution) in sterile water or the sterile water vehicle on the first day and then again 48 hours later. Animals were killed 5 days after the initial treatment and bronchoalveolar lavage (BAL) was performed. AD-treated rats had increased neutrophils and eosinophils recovered in the BAL fluid. BAL cells from AD-treated rats produced more integrated phorbol-myristate-acetate-stimulated luminol-dependent chemiluminescent (LDCL) counts over 20 minutes than BAL cells from control rats. Experiments using specific inhibitors implicate peroxynitrite in at least part of the LDCL response. When rats were examined 28 days after the initial AD or vehicle treatments, lung fibrosis was present both biochemically and histopathologically in only the AD-treated animals. Hydroxyproline, an amino acid found in collagen and used as a biochemical indicator of fibrosis, was elevated in AD-treated rats compared to controls. Examination of sections of lung tissue revealed minimal to mild, multifocal, interstitial fibrosis in the AD-treated animals. These findings indicate this model exhibits the pulmonary inflammation and fibrosis similar to that occurring in human patients and that elevated immune and oxidative processes may be involved in the development of AIPT in this model. (Supported by NIH 5 T32 GM07039.)

557 POTENTIAL HEALTH EFFECTS OF DBPs USING QUANTITATIVE STRUCTURE TOXICITY RELATIONSHIP.

C J Moudgal[1], R M Bruce[2] and J C Lipscomb[2]. [1]*University of Cincinnati, Dept. Of Env. Health Sci., Cincinnati, OH;* [2]*U. S. EPA, National Center for Environmental Assessment, Cincinnati, OH, USA.*

Disinfection by-products (DBPs) are produced as a result of disinfecting water using various treatment methods. Over the years, chlorine has remained the most popular disinfecting agent due to it's ability to kill pathogens. However, in 1974, it was discovered that the superchlorination of drinking water resulted in the production of chloroform and other trihalomethanes. Since then hundreds of additional DBPs have been identified, including haloacetic acids and haloacetonitriles. Quantitative Structure Toxicity Relationship (QSTR) utilizes a computer based technology to assess the toxicity of a chemical solely from it's molecular structure. The current research was conducted utilizing the TOPKAT® / QSTR software package which is comprised of robust, cross-validated QSTR models, for assessing specific toxic endpoints. A total of 253 DBPs were analyzed using the carcinogenicity and developmental toxicity submodels of TOPKAT®.

The model predictions were evaluated for any correlation between the functional groups (e.g. alcohols, acids, etc) and specific toxic endpoints. Developmental toxicity was identified as an endpoint common to the majority of aliphatic mono- and dicarboxylic acids. Developmental toxicity was also associated with aliphatic halogenated and non-halogenated ketones, and aliphatic haloacetonitriles. In the case of the NTP carcinogenicity submodels, most aliphatic aldehydes were identified as carcinogens only in the female mice submodel. The majority of the aliphatic and aromatic dicarboxylic acids were identified as carcinogens in the female rats submodel. All other functional groups were largely predicted as non-carcinogens in all the NTP cancer submodels, i.e., male/female rats and mice. The QSTR results should aid in the prioritization for evaluation of toxic endpoints in the absence of *in vivo* bioassays. (This abstract does not necessarily reflect U.S. EPA policy.)

558 RATS AND HAMSTERS BOTH EXHIBIT A 9% LUNG DEPOSITION EFFICIENCY FOR INHALATION OF A DISTRIBUTION OF FIBERS GREATER THAN 5 MICRON IN LENGTH.

O R Moss and D B Janszen. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA.*

Previous work on the comparison of pulmonary and pleural responses of rats and hamsters to inhaled refractory ceramic fibers has indicated that rats and hamsters may have similar lung deposition efficiencies for selected size intervals of fiber length with diameters near 1 µm. A quantitative comparison has not been done of the deposition efficiency between species for that portion of a fiber aerosol having lengths greater than 5 µm. In previously reported research on the comparison of pulmonary and pleural responses of 250- to 275 g male rats and 140- to 150 g male hamsters to inhaled refractory ceramic fibers, detailed size analysis was given for both the exposure atmosphere and lung deposition. A count of 296 fibers per cc (Å 45%) of the exposure atmosphere fiber distribution consisted of fibers having length > 5 µm and diameters < 1 µm. Rats and hamsters were exposed nose-only, 4 h a day, 5 days a week for 4 or 12 weeks. The average count in 6 each rat and hamster lungs following exposures of 4, 12, and 12 weeks plus 12-week recovery were respectively, in millions of fibers, 19.0, 49.2, and 60.9 for rats and 8.9, 17.1, and 18.6 for hamsters. An estimate of the deposition fraction was calculated by combining these parameters with the best available information on the minute ventilation of rats and hamsters (158 and 51 ml/min respectively for the size of animals). There was no difference between species, and the deposition efficiency for inhalation of a distribution of fibers > 5 µm length was 9 ± 2 %.

559 NINETY-DAY INHALATION TOXICITY OF TRANS-1,2-DICHLOROETHYLENE IN RATS.

D P Kelly[1], P W Ross[1], W J Brock[1], J A Barter[2], H Burleigh-Flayer[2], and P H Lieder[3]. [1]*DuPont Co., Haskell Laboratory for Toxicology and Industrial Medicine, Newark DE;* [2]*PPG Industries, Newark, DE; and* [3]*3M, Newark, DE.*

trans-1,2-Dichloroethylene (t-DCE) is used as an intermediate in the production of chlorinated chemicals and as a solvent. The toxicity of t-DCE (>99.4% pure) was evaluated in Crl:CD®BR male and female rats exposed to analytically determined mean concentrations of 0, 200, 1000, or 4000 ppm for 6 hrs/day, 5 days/wk over a 90-day period. Body weights and food consumption were measured weekly, liver cell proliferation was evaluated in 5 M and 5 F/group after 7, 45, and 90 days; clinical pathology in 10 M and 10 F/group at 45 and 90 days and anatomical pathology in 10 M and 10 F/group at 90 days and in 5 M and 5 F/group after a one-month post-exposure period. There were no adverse clinical signs noted during or following the exposures. There were no adverse, exposure-related effects on body weight, food consumption, clinical or anatomic pathology parameters, or liver cell proliferation. This contrasts with previous reports of liver and lung changes at 200 and 1000 ppm and cardiac changes at 3000 ppm in single 8 hr rat exposures conducted in the 1970s. The NOEL for this study was 4000 ppm in both males and female rats, the highest concentration tested, suggesting that t-DCE may be appreciably less toxic in rats than previously reported.

560 EFFECTS OF EXPOSURE TO ASPHALT FUME CONDENSATE (AFC) ON ACUTE INFLAMMATORY RESPONSES.

J Y C Ma[1], M W Barger[1], A J Kreich[2] and V Castranova[1]. [1]*HELD, NIOSH, Morgantown, WV;* [2]*Heritage Research Group, Indianapolis, IN.*

Asphalt fumes are complex mixtures of particulate and organic compounds. Field studies report an increased incidence of mucus membrane irritation and workshift decline of peak flow for road pavers. The objective of the present study was to characterize the acute pulmonary responses in rats after AFC exposure. AFC was collected from a paving asphalt storage tank. Rats received a single intratracheal instillation (IT) of saline, 0.1 or 0.5 mg AFC, and were sacrificed 1- or 3-day later. Another set of rats were exposed by IT to saline, 0.1, 0.5, or 2 mg AFC for 3 consecutive days and were sacrificed the following day. Differential cell counts, acellular protein and lactate dehydrogenase (LDH) were measured in bronchoalveolar lavage fluid (BALF) to monitor inflammation and damage. Chemiluminescence (CL) generated from alveolar macrophages (AM) was measured and tumor necrosis factor-α (TNF-α) and interleukin-1 (IL-1) in AM-conditioned media were assayed to monitor AM function. The results show that AFC exposure did not induce significant neutrophil infiltration or alter LDH and protein content in BALF. CL and nitric oxide-dependent CL generated from AFC-exposed AM were not different from control at rest or in response to zymosan stimulation. Likewise, AFC exposure did not induce increased TNF-α or IL-1 secretion from AM at rest or in response to LPS. These results suggest that exposure of rats to AFC did not cause acute pulmonary inflammation or injury. Furthermore, AFC exposure did not alter AM functions such as the release of oxidants or inflammatory cytokines by AM at rest or in response to stimulants.

561 TARGETED DELIVERY OF INHALED PHARMACOLOGIC DRUGS FOR THE TREATMENT OF LUNG DISEASES CAUSED OR EXACERBATED BY AIR POLLUTANTS.

T B Martonen[1], C J Musante[2], and J S Fleming[3]. [1]*US EPA, ETD, NHEERL, Research Triangle Park, NC, USA;* [2]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC, USA;* [3]*Department of Nuclear Medicine, Southampton General Hospital, Southampton, UK.* Sponsor: D L Costa.

We have developed a supercomputer code which describes the position of individual airways in the complex branching structure of the human lung. The code is designed to be used in a complementary manner with SPECT (Single Photon Emission Computed Tomography) protocols. Specifically, the code will aid clinicians and research scientists working with gamma camera images that are divided into discrete volumes (voxels). The code permits a comprehensive mapping of airways, assigning each to an unambiguous location. It itemizes the composition of a three-dimensional (3-D) voxel matrix superimposed over the human lung in terms of the number and type of airways present (e.g., Weibel generation I). The 3-D simulations are integral components of: (1) morphological models for improved gamma camera imaging analyses used to measure particle deposition patterns within human lungs; and, (2) particle dosimetry models used to predict and target the delivery of inhaled pharmacologic drugs used in the treatment of respiratory diseases caused (e.g., cigarette smoke and lung cancer) or exacerbated (e.g., sulfuric acid aerosols and asthma) by air pollutants of health effects concern to the EPA. DISCLAIMER: This is an abstract of a proposed presentation and does not necessarily represent EPA policy. (C J Musante was funded by the EPA/UNC Toxicology Research Program, Training Agreement CT902908.)

562 HUMAN SMOKING BEHAVIOR STUDY: ECLIPSE CIGARETTE COMPARED TO USUAL BRAND.

M F Stiles, T D Guy, W T Morgan, D W Edwards, R A Davis, and J H Robinson. *R J Reynolds Tobacco Company, Winston-Salem, NC, USA.* Sponsor: K-M Chang.

Human smoking behavior measures from several studies conducted in our laboratory have shown significant differences when smokers smoked Eclipse (a cigarette that primarily heats tobacco) compared to their usual brand (UB) of tobacco burning cigarette. Two studies (conducted about 6 months apart) are presented comparing puffing profiles, cigarette sensory attribute ratings, blood carboxyhemoglobin (%COHb), and serum nicotine concentrations in smokers smoking their UB of tobacco burning cigarette to these same measures after smoking Eclipse cigarettes for two weeks. Two groups of smokers (n = 26 for each group) participated in two laboratory smoking tests, each between the hours of 1:30 and 4:30 p.m. Subjects

smoked one of their UB cigarettes in the first test session after reporting the number of cigarettes they had already smoked that day. Smoking profiles were recorded and blood samples were collected for measurement of %COHb and serum nicotine concentrations. Smokers were then sent home with a supply of Eclipse cigarettes which had a hollow filter design (EHF). Subjects smoked these cigarettes exclusively and as desired for two weeks, then returned to the laboratory for their next test session. Identical procedures were used for both laboratory visits. Puffing and absorbed CO measures varied widely as seen in our previous work, indicating a range of smoking behavior. On average, in both groups, smokers took significantly more puffs, closer together in time, resulting in significantly greater total puff volume when smoking Eclipse cigarettes than when smoking their UB. Average %COHb concentrations were: in the first test, UB = 9.6 and EHF = 10.2, and in the second test, UB = 8.3 and EHF = 9.0. Average absorbed CO measures showed no statistically significant difference from UB in either test of the Eclipse cigarette.

563 INHALATION TOLERANCE STUDY FOR P-ARAMID RESPIRABLE FIBER-SHAPED PARTICULATES (RFP) IN RATS.

B Bellmann, H Muhle, O Creutzenberg, H Ernst, and G Pohlmann. *Fraunhofer Institute of Toxicology & Aerosol Research, Hannover, Germany.*

The aim of the study was to assess the maximum functionally tolerated dose (MFTD) for p-aramid respirable fiber-shaped particulates (RFP), and to study inflammatory and proliferative effects of this synthetic organic material. Male Wistar rats were exposed 6 hrs/day, 5 days/week for 3 months to RFPs at concentrations of 25, 100, and 400 RFP/ml. Upon cessation of exposure, recovery effects were followed up during a 9 month postexposure observation period. After 3 months of exposure the retention of RFP (WHO fraction) was 25 x 10^6 RFPs per lung in the low dose group. The corresponding values in the medium and high dose group were 122 x 10^6 and 576 x 10^6 RFPs per lung, respectively. A decrease of the length of the RFPs over the 9 months recovery period was observed. The kinetics are indicative of fragmentation of longer fibers into shorter ones and subsequent removal of the latter. The results of the alveolar clearance (measured by using short-term exposure to γ -labeled particles) indicate a "dust overloading of lungs" for the high dose group (400 RFP/ml). For the medium dose group (100 RFP/ml) the 3-month exposure induced only slight lung overloading. For the low dose no change in tracer clearance was detected compared to controls. BAL parameters (differential cell count and biochemical parameters) revealed that p-aramid RFPs induced pronounced effects in the medium dose group, which were reversible within 3 months postexposure. Effects were stronger in the high dose group; they recovered after 9 months postexposure for biochemical parameters. Also for PMNs and lymphocytes a recovery was observed, but to a lesser extent. No effects were seen in the low dose group. Histopathological examination showed very slight to slight fibrotic and hyperplastic lesions in the medium and high dose groups up to 9 months postexposure. This study demonstrated transient effects of a p-aramid exposure in rats. The MFTD was reached at 400 RFP/ml. Earlier reports demonstrating biodegradation by fragmentation of longer fibers into shorter ones were confirmed. A NOAEL of 25 RFP/ml was found.

564 PULMONARY FUNCTION IN UNTREATED RATS.

G L Whitehead, J E Reboulet, and E C Kimmel. *Geo-Centers, Inc., at the Naval Health Research Center Detachment (Toxicology), WPAFB, OH, USA.* Sponsor: R L Carpenter.

Pulmonary function tests (pfts) often are used in both humans and small animal species as physiologic biomarkers of pulmonary disease caused by the inhalation of toxic atmospheres. Physiologic biomarkers, used in conjunction with histopathological and biochemical biomarkers can be used to diagnose disease, characterize dose/response relationships, assess disease pathogenesis, and indicate the degree of debilitation following pulmonary insult. We have developed methods to perform a battery of pfts which will be used to assess acute and chronic pulmonary toxicity in small animals exposed to inhaled toxins. The pfts developed can be used to assess physiologic responses in real-time during exposure, post exposure progress of induced pulmonary lesions, or both. Included are measures of ventilation (frequency, tidal volume and minute ventilation), breath waveform analysis, dynamic pulmonary mechanics (compliance and resistance), sub-divisions of lung volume, lung pressure-volume relationships and quasistatic compliance, pulmonary dynamics (forced maneuvers), distribution of ventilation (single breath Nitrogen washout), gas exchange (carbon monoxide - single breath diffusing capacity, microcapnometry), and measurement of metabolic activity (microcapnometry). Over 200 untreated Long Evans rats were used to develop the assays and to form a historical data base for normal animals. Values for a variety of indices of pulmonary function measured using the methods developed in our laboratory were comparable to those reported by several other investigators.

565 BIOPERSISTENCE ASSAYS FOR SAFETY EVALUATION OF MAN-MADE VITREOUS FIBRES.

N F Johnson, A Dotti, and P Thévenaz. *RCC Ltd, Toxicology Division, Füllinsdorf, Switzerland.*

There is clear evidence from chronic inhalation studies that fibres longer than 20μm and are persistent in the lung have the potential to cause lung cancer, mesothelioma, and pulmonary fibrosis. This concept is the basis for the recent European Communities Council Directive (67/548/EEC) related to the classification, packaging and labelling of dangerous substances. Exoneration from the carcinogen labelling is based on the results of chronic inhalation (CI), short-term inhalation biopersistence (SI), intratracheal instillation (IT), or intraperitoneal injection (IP) assays conducted with a defined fibre aerosol or suspension. These approaches have limitations in terms of cost, time, or route of administration. RCC has conducted many of the bioassays on which the European Directive (ED) is based and continues to conduct such studies that afford a comparison between the various approaches. CI studies are costly, however they provide evidence of long term effects and fibres that produce no relevant pathology can exceed the weighted half-life (WT½) in SI assays stipulated by the ED. However, fibres with a lower than 10 day WT½ have to date not been shown to be fibrogenic or carcinogenic. The fibre length requirements for the ED (20% greater than 20μm) can cause fibre agglomerations in the conducting airways that adversely affect clearance and biopersistence in IT assays. IP assays are not recommended because of the high number of fibres (1 x 10^9) make this abnormal route of administration inappropriately sensitive compared to inhalation and intratracheal assays. The SI appears to be a valid screen to identify potentially safe MMVFs. In Germany a Federal scheme for classifying fibres is in force that does not include CI and SI tests, but relies on chemical composition, IP, or IT assays with unspecified fibre solutions apart from the WHO size classification. This allows the preparation of fine and short fibre preparations that avoid the agglomeration problem but may not include sufficient fibres longer than 20μm that are thought to be important in the induction of pulmonary disease. The chemical composition index excludes most forms of MMVFs other than glass wools. The German and European regulations are currently incompatible and require separate testing strategies except when an IT assay passes the ED criteria.

566 HEAD-ONLY AND MASK INHALATION EXPOSURE IN THE CYNOMOLGUS MONKEY.

R Salame, A Viau and C Banks. *ClinTrials BioResearch Ltd.(CTBR), Senneville, PQ, Canada.* Sponsor: G Lulham.

The cynomolgus monkey is a standard species used in inhalation toxicity studies. Two methods of exposure can be used in these studies: via inhalation mask or head-only. The first exposure system consists of a pediatric anesthetic-type oronasal face mask fitted with inlet and outlet tubes and a breathing loop. During treatment, animals are placed in a restraint sling. This method limits the exposure to the oronasal route and reduces the amount of material needed for dosing. The procedure is well tolerated by the animals for daily exposures of up to 60 minutes (2 sessions of 30 minutes each). The head-only system consists of an inhalation chamber equipped with individual animal restraint boxes which are fitted onto the sides of the chamber, so that each monkey can sit comfortably in the box with its head projecting into the chamber through a neck-yoke. The head-only method of dosing is ideal for prolonged exposure durations (up to 3 hours) as it minimizes stress on the animals. Method development has provided a goggle and head cover system to minimize ocular and dermal exposures associated with head-only inhalation dosing for primates. This system confines the exposure to the oronasal region. Both methods of exposure are viable routes of administration and have been routinely used on preclinical acute and chronic safety studies for submission to FDA, EC and MHW.

567 COMPARISON OF COMPUTER SIMULATIONS AND HUMAN DATA FOR PARTICLE DEPOSITION IN HEALTHY SUBJECTS AND COPD PATIENTS.

R A Segal[1], T B Martonen[2], and C S Kim[3]. [1]*North Carolina State University, Raleigh, NC, USA;* [2]*US EPA, ETD, NHEERL, Research Triangle Park, NC, USA;* [3]*US EPA, HSD, NHEERL, Chapel Hill, NC, USA.* Sponsor: D L Costa.

A mathematical model was used to predict the deposition fractions of particulate matter (PM) within human lungs. The US EPA has identified COPD (chronic obstructive pulmonary disease) patients as a critical subpopulation to be addressed in regulatory standards. Therefore, we have compared the deposition of monodisperse aerosols in COPD patients and healthy subjects. Simulations using the Weibel lung morphology were previously validated with human subject data, so this geometry was used as a control case. Human subject variation was subsequently accounted for by scaling Weibel lung dimensions based on measured FRC (functional residual capacity) values. COPD was modeled via reductions of airway diameters based on airway resistance measurements. Simulations were performed for VT (tidal volumes) of 360, 500, and 1000ml, respiratory times (T) from 2 to 8s and particle sizes of 1, 2, 3 and 5µm. Deposition patterns depended on particular ventilatory parameters, particle sizes and COPD conditions; for example, when V_T =500ml and T=2s, the deposition of 1µm particles was 100% greater for COPD patients. This may be attributed to increased efficiencies of specific deposition processes in different regions of the lung. The model is used in risk assessment efforts to estimate the inhalation hazards of airborne pollutants. (This is an abstract of a proposed presentation and does not necessarily represent EPA policy. Acknowledgements: RAS is funded by the NCSU/EPA Cooperative Training Program in Environmental Sciences Research, Training Agreement CT826512010, NCSU.)

568 A 28-DAY INTRANASAL STUDY IN RATS WITH AVICEL® RC-591.

J Signorin[1], E R Aguinaldo[1] and M T Butt[2]. [1]*FMC Corporation, Princeton, NJ, USA;* [2]*Pathology Associates International, Frederick, MD, USA.*

A repeated-dose intranasal administration study was conducted to evaluate the toxicity of Avicel® RC-591, a pharmaceutical excipient consisting of coprocessed microcrystalline cellulose (MCC) and carboxymethyl cellulose. Two groups of Sprague Dawley rats (10/sex/group) were dosed for 28 consecutive days with either 1 dose/day (100 uL/day) or 3 doses/day (300 uL/day) of a 1.5% solution of Avicel RC-591 in distilled water. A similar group of animals received 3 doses/day (300 uL/day) of distilled water for 28 days and served as the control. Material was administered to the nasal passages of each animal via a microliter pipettor. Each dose was split into two equal 50-uL doses (50 uL per nostril) and administered once per day for the low dose group and 3 times per day for the control and high dose groups. Clinical observations, body weights and food consumption were recorded weekly. After 28 days, blood was collected for hematological and clinical chemistry evaluations and brain, liver, lungs, kidneys and testes were weighed. Histopathological evaluation was conducted on all organs and tissues. Respiratory tract sections were also examined using polarized light for the presence of birefrigent MCC particles. No deaths or treatment-related effects were noted for clinical signs, body weight, food consumption, hematology, clinical chemistry, organ weights or macroscopic findings. During microscopic examination of the nasal cavity, MCC particles were found embedded in neutrophilic exudate. These particles were associated with neutrophilic inflammation and indicate that Avicel may cause mild irritation to the nasal cavity. Because these findings were attributed directly to the introduction of Avicel particles into the nasal cavity and were found in locations indicating proper biological filtration, these effects were not considered adverse effects of treatment. The no observed adverse effect level (NOAEL) for 1.5% Avicel RC-591 in distilled water is in excess of 300 uL/day (17.7 and 25.2 mg/kg/day Avicel RC-591 for males and females, respectively).

569 DNA-PROTEIN CROSSLINKS (DNAPC) AND DNA STRAND BREAKS (DNASB) IN HL-60 CELLS TREATED WITH THETOXIC BENZENE METABOLITES TRANS,TRANS-MUCONALDEHYE AND HYDROQUINONE.

R P Amin and G Witz. *Joint Graduate Program In Toxicology, Rutgers University/UMDNJ-RWJ Medical School, Piscataway, NJ.*

Benzene hematotoxicity is mediated, in part, by ring-hydroxylated metabolites including hydroquinone (HQ), and ring-opened metabolites including trans,trans-muconaldehyde(MUC). Previous studies from our laboratory indicate that MUC induces DNAPC in HL-60 cells and mouse bone marrow cells as determined by a K^+/SDS precipitation assay. DNAPC are toxic lesions which have been reported by other laboratories to correlate with increased DNASB. Hydroquinone has been reported by other investigators to induce DNASB. The aim of the present studies was to determine DNAPC levels and DNASB in HL-60 cells in response to HQ and MUC, respectively, and to determine effects of co-exposure to MUC and HQ on both endpoints. The present studies indicate that treatment of HL-60 cells with 25-100 uM HQ followed by incubation for 4 hr results in 1.3-2.8 fold increases in DNAPC levels compared with controls. At 25 and 100uM, MUC is 1.8 and 4.9 fold more effective in inducing DNAPC than HQ. Treatment of HL-60 cells with 1-50 uM MUC followed by incubation for 1 or 2 hr resulted in concentration and time-dependent increases in DNASB as measured by a fluorescence-based DNA unwinding (FADU) assay. Exposure to 10 and 25 uM MUC gave Qd values (quantity of strand breaks) of 8 and 34, respectively, at the 1 hr time point and 33 and 67, respectively, at the 2 hr time point. Exposure of HL-60 cells to binary mixtures of 25 and 50uM MUC and HQ was found to lead to additive increases in DNAPC and DNASB levels. (Supported by NIH grants ESO2558 and ESO9676 from the National Institute of Environmental Health Sciences, and NIEHS Center grant ESO5022.)

570 USE OF A CELL-BASED ASSAY FOR THE DETECTION OF NON-COVALENT DNA/DRUG INTERACTIONS.

R D Snyder. *Abbott Laboratories, Abbott Park, IL, USA.* Sponsor: W M Bracken.

Covalent chemical/DNA interactions may be detected and quantified by many methods including direct detection of DNA strand breaks, induction of repair, and adduct formation. Specific chemical moieties conferring DNA reactivity have been identified and the mutagenicity or clastogenicity of a compound can often be predicted based on the presence of these structural alerts alone. However, it is proposed that a largely overlooked component to genotoxicity arises via intercalative and other non-covalent chemical interactions with DNA; interactions which are difficult to study in cellular systems. We present findings showing that DNA intercalation may be detected and quantified in Chinese hamster V79 cells by a bleomycin amplification assay. The antibiotic bleomycin binds DNA in the minor groove and makes DNA double strand breaks which manifest as micronuclei. Intercalation of chemicals into cellular DNA enhances the binding of bleomycin and amplifies the formation of micronuclei. We show that the ability of a chemical to amplify bleomycin clastogenicity is governed by its structural class and that many classes of aromatic compounds beyond the classical intercalative fused planar tricyclics have this capacity. Intercalative activity is ranked: fused tricyclic≥ unfused tricyclic> unfused bicyclic> fused bicyclic, aliphatic and single ring structures. As a specific example of the utility of this approach, it is demonstrated that intercalation may account for the reported genotoxicity of marketed antihistamines. It is proposed that a cell-based bleomycin amplification assay may provide an important new model for the assessment of non-covalent DNA interaction of novel chemical entities.

571 COMPARISON OF HISTOPATHOLOGY AND DNA ADDUCTS IN RATS SUBCHRONICALLY EXPOSED TO SMOKE FROM CIGARETTES THAT BURN OR PRIMARILY HEAT TOBACCO.

P H Ayres, M A Higuchi, B G Brown, D J Doolittle, and A T Mosberg. *R J Reynolds Tobacco Co., Winston-Salem, NC, USA.*

A subchronic nose-only inhalation study comparing the effects of smoke from a cigarette that primarily heats tobacco (Eclipse™ prototype 7-026A), to that of smoke from a Kentucky 1R4F reference cigarette was conducted using Sprague-Dawley rats. Rats of each sex were exposed 1 hour a day, 5 days per week, for 13 weeks to mainstream smoke at 0, 0.16, 0.32, or 0.64 mg/liter of air. Endpoints were carboxyhemoglobin (HbCO), serum nicotine, clinical signs, body and organ weights, serum chemistry, hematology, histopathology, and DNA adducts in heart and lungs using the P^{32} post-labeling procedure. Neither cigarette produced adverse changes in clinical signs, body and organ weights, serum chemistry, or hematology. HbCO and serum nicotine increased with both cigarettes in an exposure-dependent manner. Smoke related histologic changes were nasal chronic/active inflammation and epithelial hyperplasia, chronic/active inflammation of the larynx, squamous metaplasia and acute inflammation of the ventral larynx, tracheal epithelial hyperplasia and increased goblet cells, and increased non-pig-

mented and brown/gold pigmented lung macrophages. Inflammatory changes of the larynx and ventral larynx, and non-pigmented lung macrophages were similar in rats exposed to the 1R4F or Eclipse cigarette. Increased tracheal goblet cells and brown/gold pigmented macrophages were absent in the Eclipse exposed rats. All other smoke related histologic changes were reduced in Eclipse exposed rats when compared to the 1R4F exposed rats. DNA adducts of heart and lungs of Eclipse exposed rats were not different from sham control animals but were reduced compared to 1R4F responses. The reduction or absence of histologic changes and DNA adducts in lungs and heart of rats exposed to smoke of Eclipse cigarettes indicates a reduction of biological activity compared to the smoke of the tobacco burning 1R4F cigarette.

572 CROSSLINKING INTERFERES WITH ASSESSING SULFUR MUSTARD-INDUCED DNA DAMAGE IN HUMAN LYMPHOCYTES USING THE COMET ASSAY.

J Moser, C F Levine, D R Thomas-Dunmeyer, and W J Smith. *Pharmacology Division, U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD, USA.* Sponsor: J J Schlager.

Sulfur mustard (SM) is a vesicating agent that alkylates cellular DNA and produces DNA strand breaks. To detect SM-induced DNA single strand breaks in human peripheral blood lymphocytes (PBL), cells were exposed to various concentrations of SM (1 to 1000 μ M), and the comet assay (single-cell gel electrophoresis) was performed at selected times after exposure. At 4 hours, strand breaks were detected at SM concentrations ≥ 100 μ M. At 8 hours, strand breaks were detected at ≥ 6 μ M SM. Previous data suggest SM produces DNA crosslinks that are removed within 8 hours after exposure. To test the hypothesis that crosslinking inhibits DNA migration in the comet assay at < 8 hours after SM exposure, PBL were exposed to a) H_2O_2 (0.001%), which produces DNA single strand breaks with no crosslinks, b) SM alone (1 to 1000 μ M), or c) SM followed at 2 hours by H_2O_2. With H_2O_2 alone, a large amount of strand breakage was detected. With H_2O_2 and SM, detection of H_2O_2-induced strand breaks decreased as SM concentration increased up to 60 μ M; above 60 μ M, the response with H_2O_2 and SM was similar to that with SM alone. Detection of H_2O_2-induced DNA strand breaks appears to be inhibited by SM in a SM concentration-dependent manner, presumably due to SM-induced crosslinking. It follows that crosslinking in DNA of SM-exposed PBL also interferes with DNA migration and detection of DNA strand breaks when cells are exposed to SM alone.

573 IN VITRO PHOTOGENOTOXIC ACTIVITY OF CLINAFLOXACIN: A PARADIGM PREDICTING PHOTOCARCINOGENICITY.

S J Bulera, J C Theiss, T A Festerling, and F A de la Iglesia. *Parke-Davis Pharmaceutical Research/Warner-Lambert Company, Ann Arbor, MI, USA.* Sponser: S K Duddy.

Fluoroquinolone antiinfective drugs exhibit phototoxic, photogenotoxic, and photocarcinogenic activities in experimental systems which may be interrelated. Clinafloxacin (CLX), a new fluoroquinolone, is a potent antiinfective agent being developed for use in life-threatening infections. While this drug has previously been demonstrated to be phototoxic, this report evaluated the photogenotoxic and photocarcinogenic potential of CLX. When Skh-1 mice were administered CLX in the presence of ultraviolet light (UVA) at the maximum tolerated dose expected for a photocarcinogenicity bioassay, induction of DNA strand breakage was noted in keratinocytes isolated from these animals. When compared with other well studied fluoroquinolones *in vitro*, CLX and Lomefloxacin (LMX) were equally effective in producing chromosome damage and DNA strand breakage in CHO cells exposed to UVA. Treatment of CHO cells with CLX in the presence of UVA also resulted in hydroxyl radical formation. However, coincubation of CHO cells with CLX and various antioxidants markedly reduced hydroxyl radical formation, but inhibited photogenotoxicity only to a limited extent. Thus, while reactive oxygen species contribute to the photogenotoxic activity of CLX, other factors may be involved. Since CLX exhibits both phototoxic and photogenotoxic activity, we predict that CLX would be photocarcinogenic *in vivo*. The present study establishes that under conditions of human exposure, the potential risk for CLX-induced photocarcinogenicity is small.

574 GENOTOXICITY ASSESSMENT OF SURAMIN – A POTENTIAL DRUG FOR PROSTATE CANCER.

G Krishna, G Urda, J Garvin, and D Pegg. *Parke-Davis Pharm Res, Div of Warner-Lambert Co, Ann Arbor, MI, USA.*

Suramin is an aminonapthalene-sulfonic azo dye under development for treatment of prostate cancer and attendant pain. The genotoxic potential of suramin was investigated in this study using a a battery of tests including bacterial mutagenicity, in vitro aberration and in vivo micronucleus. Bacterial mutagenicity was evaluated in *S. typhimurium* strains TA-98, TA-100, TA-1535, or TA-1537 and in *E. coli* strain WP2*uvr*A at 0.5 to 5000 μ g/mL. Results were negative in all strains with the greatest increase in revertant frequency being ≤ 1.7-times solvent control. In vitro aberrations were evaluated in CHO cells using 3 and/or 20 h exposure at 125 to 13000 μ g/mL. Suramin did not significantly increase aberration frequency in either the absence or the presence of S9 at concentrations up to 4000 μ g/mL. However, in the 3-h exposure, higher concentrations (≥ 6000 μ g/mL in S9+ and ≥ 10000 μ g/mL in S9-) caused aberrations 1 to 3-times the upper historical control value (6.3%). This response was not considered biologically significant based on International Conference on Harmonization guidelines because it was not concentration-related, not reproducible in the 20-h exposure, was seen at > 5000 μ g/mL, and these concentrations affected cell survival, osmolality, and pH. In vivo micronuclei were assessed using rats given single doses of 137.5, 275, and 550 (males) or 440 (females) mg/kg. The top dose represented a maximum tolerated dose. Bone marrow micronucleated polychromatic erythrocyte (MNPCE) frequency in suramin-treated groups at 24 or 48-h sampling times was within historical control range of 0.8 to 4.9 MNPCE/1000 cells and thus, was considered negative in this assay. Cmax plasma drug concentration in this assay was ~ 8 to 10 times higher than the human therapeutic range of 150 to 250 μ g/mL. Based on these data, it was concluded that suramin does not have any significant genotoxic potential.

575 ANALYSIS OF TAMOXIFEN-DNA ADDUCTS IN HUMANS AND RATS BY ACCELERATOR MASS SPECTROMETRY.

E A Martin[1], M Gaskell[1], T L Carver[2], K Turteltaub[2], F Al-Azzawi[3], I N H White[1] and L L Smith[1]. [1] *MRC Toxicology Unit, University of Leicester, Leicester, UK;* [2]*Lawrence Livermore National Laboratory, University of California, Livermore, CA, USA;* [3]*Obstetrics and Gynaecology Department, University of Leicester, Leicester, UK.*

Tamoxifen is widely used in the treatment of breast cancer and is currently being evaluated for its use as a chemopreventative agent for the same disease. However, tamoxifen causes liver tumours in rats and an increased incidence of endometrial tumours in women. In rats, liver tumour development is associated with the formation of large numbers of DNA adducts. In women it is not yet clear whether endometrial tumour development is associated with a genotoxic or hormonal mechanism. In breast cancer patients, tamoxifen-DNA adducts are absent or at low levels in the uterus making detection a problem. We have used [^{14}C] labelled tamoxifen and the sensitive technique of accelerator mass spectrometry (AMS) to detect adducts in human uterus DNA and compared this with the formation of adducts in rats. Six female volunteers were given a [^{14}C]tamoxifen capsule containing the therapeutic dose (20mg, 1.85MBq) approximately 18 hours prior to surgery (hysterectomy). Similar studies performed in 6 week old female rats used a single dose of tamoxifen equivalent to the human therapeutic dose (0.3mg/kg). Uterine tissue was removed and DNA, protein and tissue samples were measured for their [^{14}C] content by AMS. Radiolabelled carbon was detected in uterine tissues from the treated patients and rats, indicating that tamoxifen and its metabolites reached the uterus. DNA adducts and protein binding were detected in the uterus. These data show that tamoxifen administration (at comparable dose levels) results in low levels of DNA adducts in the uterus of humans and the reproductive tracts of rats (10-400 adducts per 10^{12} nucleotides). This is at least an order of magnitude lower than adducts levels in rat liver. It is still unclear what the relevance of these low levels of DNA damage is in the development of endometrial tumours in women treated with tamoxifen.

576 REGULABLE REPAIR OF OXIDISED DNA IN STABLE CELL LINES USING TETRACYCLINE-REGULATED EXPRESSION OF *FPG*.

R R Laposa[1], J T Henderson[2], and P G Wells[3]. *Depts. of [1]Pharmaceutical Sciences and [3]Pharmacology, Univ. of Toronto, and [2]Mount Sinai Hospital Research Institute, Toronto, Canada.*

Cell lines with extra repair of oxidised DNA, specifically oxidised purines, were generated by stably transfecting chinese hamster ovary (CHO) AA8 cells with the bacterial DNA repair gene formamidopyrimidine DNA-glycosylase (*fpg*). Expression of *fpg* was controlled by a tetracycline-regulated system. Cells were co-transfected with: (a) a plasmid containing the tetracycline-controlled transactivator (tTA) protein driven by the CMV promoter and,(b) a plasmid containing the tetracycline operator sequence (tetO) placed upstream of the *fpg* gene. The presence of an intact fpg gene was confirmed by sequencing. In this system, regulation of expression was achieved by addition of tetracycline, which binds to tTA protein to prevent tetO-mediated expression. Cells were either transiently transfected, or stably transfected using puromycin resistance selection. Presence of *fpg* in stable lines was confirmed by Southern blotting. In cell lysates, repair of 8-oxoguanine was measured by cleavage of a 32P-labelled oligonucleotide containing an internal oxidised guanine. Radioactivity was visualized after acrylamide gel electrophoresis. Repair activities in transiently transfected cells were 100-fold higher than controls. Activities in individual stable lines were up to 10-fold higher than controls, and were returned to near-baseline levels by 72 h culture in 1 ug/mL tetracycline. This is the first report of cell lines with regulable activities of DNA repair. Since DNA repair activities can vary 100-fold between individuals, these cell lines will be useful in the study of cancer and other diseases thought to involve reactive oxygen species. (Support: Medical Research Council of Canada.)

577 FORMATION AND REPAIR KINETICS OF FURAN-MEDIATED DNA DOUBLE-STRAND BREAKS IN ISOLATED RAT HEPATOCTYES.

S A Ploch, J Shearin, and G L Kedderis. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA.*

Furan is a nonmutagenic, hepatotoxic compound that induces hepatocellular carcinomas in rats and mice through poorly understood mechanisms involving cell death and proliferation. Previous studies in our laboratory have shown that exposure of isolated F-344 rat hepatocytes to toxic concentrations of furan produced concentration- and time-dependent increases in DNA double-strand breaks (dsb), as analyzed by pulsed field gel electrophoresis, prior to cell death. DNA dsb have been linked with cell death and mutation induction. In this study, the repair kinetics of DNA dsb were determined after treatment of F-344 rat hepatocytes with 10 μ M furan for 4 hr in suspension followed by 24 hr in monolayer culture without furan. Hepatocyte viability (lactate dehydrogenase leakage) and DNA dsb (assayed using the fluorescent double-stranded DNA binding reagent PicoGreen®) were measured after 4 hr incubation in suspension (prior to placing in culture), after 90 min in the presence of 5% fetal calf serum (attachment period), and at 1, 2, and 24 hr postattachment in monolayer culture. DNA dsb in hepatocytes exposed to 10 μ M furan for 4 hr were significantly elevated after 4 hr suspension incubation, remained elevated for at least 2 hr in culture, and returned to near control levels at 24 hr without a significant decrease in cell viability. These results indicate that the surviving cells repair a significant portion of the DNA dsb within 24 hr. Erroneous repair of DNA dsb may be involved in the induction of mutations leading to furan-induced liver cancer.

578 THE GENOTOXICITY OF METHYLEUGENOL: A POSSIBLE MECHANISM OF ACTIVATION.

I G Sipes[1], J L Burkey[1], J-M Sauer[2] and C A McQueen[1]. *[1]Department of Pharmacology and Toxicology, The University of Arizona, Tucson, AZ, USA; [2]A Division of Eli Lilly & Company, Lilly Research Laboratories, Indianapolis, IN, USA.*

Methyleugenol is a component of essential oils and is found in many teas, cosmetics, fragrances, soaps, shampoos, and foods. Like safrole, a structurally similar compound, methyleugenol has been found to be a rodent carcinogen in a recent NTP bioassay. We have, therefore, undertaken studies to determine the genotoxicity of methyleugenol over a non-cytotoxic range of doses in hepatocytes isolated from male Fischer 344 rats and female $B6C3F_1$ mice, and to investigate possible mechanisms by which the compound may exert its toxic effects. Cytotoxicity to hepatocytes was measured after 18 hr exposure to the compounds by measuring % lactate dehydrogenase (LDH) release from the cells. Genotoxicity was measured using the unscheduled DNA synthesis (UDS) assay that measures DNA repair by incorporation of [^{3}H]thymidine. Results for rats and mice showed similar patterns for all endpoints examined. Cytotoxicity results indicate that methyleugenol is relatively nontoxic to hepatocytes, showing control levels of LDH leakage up to 1000 μM. Cytotoxicity was increased by both pentachlorophenol (PCP), an inhibitor of sulfation, and cyclohexene oxide (CHO), an inhibitor of epoxide hydrolase. Methyleugenol induced UDS was observed at concentrations between 10 and 1000 μM. UDS levels were reduced to control levels by the presence of PCP but were unchanged by the presence of CHO. These results suggest that the genotoxicity of methyleugenol may be dependent upon the hydroxylation and subsequent sulfation pathway of activation. An epoxide dependent pathway of activation for genotoxicity is not suggested by these data. (This research was supported by NIEHS (NO1-ES-35367, P30-ES-06694 and T32-ES-07091-17).)

579 USE OF COMET ASSAY TO IDENTIFY DNA DAMAGE INDUCED BY *IN VIVO* ADMINISTRATION OF CYCLOPHOSPHAMIDE IN MICE.

T-H Kim, B M Francis and M J Plewa. *University of Illinois, Urbana, IL.*

The COMET assay is a relatively new molecular biological assay that detects, in the nuclei of individual cells, DNA damage leading to strand breaks. As part of a project to identify antimutagenic soybean fractions, we are evaluating the effects of *in vivo* exposure of CD-1 mice to known mutagens on the tail moment (the integrated value of DNA density multiplied by the migration distance) of DNA in bone marrow and liver. Following single intraperitoneal doses of cyclophosphamide (CP) ranging from 75 to 300 mg/kg, tail moments in CP-exposed nuclei were as much as 2.3 times higher than tail moments in control liver nuclei. Tail moments in CP-exposed bone marrow cells were up to 5.0 times those in control bone marrow cells. Five daily doses of 150 mg/kg resulted in sharply decreased survival of bone marrow cells, and tail moments for CP-exposed nuclei were approximately twice those of control nuclei. Both the dose and the interval between exposure and death affected tail moments in CP-exposed cells. We are now evaluating the effects of *in vivo* exposure to 4-aminobiphenyl and benzidine in different dosing regimens.

580 PHARMACODYNAMICS OF FORMALDEHYDE: ARREST OF DNA REPLICATION BY DNA PROTEIN CROSS LINKS IS THE PROXIMAL CAUSE OF MUTATIONS.

H Heck and M Casanova. *CIIT, Research Triangle Park, NC.*

A variety of evidence suggests that DNA protein cross-links (DPX) are potentially mutagenic, but the mechanism of mutagenesis is unknown. A possible mechanism is suggested by the following results: (1) DNA replication in the nasal mucosa of rats exposed to formaldehyde (FA) was inhibited in portions of the DNA that contained DPX; (2) aldehydes including FA that form DPX arrested DNA replication *in vitro*, whereas aldehydes that lack the ability to form DPX did not inhibit DNA synthesis. Together these data suggest that DPX can block DNA replication. Failure to remove the blockage prior to cell division or excision followed by incomplete repair could result in a muta-tion. To determine the dose and time dependence of this mechanism, a model was developed based on the assumptions that DPX are formed randomly in the DNA, and that a replication fork can advance up to but not past a DPX. Incorporation of [14C]thymidine ([14C]TdR) derived from [14C]FA into DNA was used as a measure of DNA synthesis. [14C]TdR incorporation is expected to increase linearly with concentration and time at low values of these parameters, but the rate of increase is predicted to decline at higher values. Using the model, the average length of a replication bubble was estimated to be about 6 x 104 bp, which agrees with published data. The results suggest that DPX should not be regarded merely as dosimeters (pharmacokinetic factors useful for interspecies extrapolation), but they are also important pharmacodynamic factors, as they can block DNA replication and thereby induce a genotoxic response. Appreciation of both roles for DPX is necessary to understand the mechanism of FA carcinogenesis and to develop a sound basis for a biologically-based risk assessment at low concentrations of FA.

581 HUMAN CYTOCHROME P450 SPECIFCITY AND GENOTOXICITY INDUCED BY STYRENE.

D Ribas[3], L Recio[2], E A Anderson[4] and T E Jackson[1,2]. [1]*Curriculum In Toxicology, UNC Chapel Hill, Chapel Hill, NC;* [2]*Chemical Industry Institute of Toxicology, Research Trangle Park, NC;* [3]*Intexter, Universitate Politecnica de Catalonya, Barcelona, Spain;* [4]*Department of Microbiology, University of Madison, WI.*

1,3-Butadiene (BD) and styrene (ST) are metabolized by cytochrome P450 (CYP450) enzymes to epoxide metabolites. Certain styrene metabolites such as styrene 7,8-oxide (SO) are DNA-reactive and have previously been shown to induce micronuclei *in vitro* and *in vivo*. To investigate the role CYP450 enzymes in the genotoxicity of ST, we quantified the induction of micronuclei in cell lines which contain differing amounts and types of CYP450 activity: AHH-1 (CYP1A1 activity), AHH-1/h2E1 (CYP1A1 and CYP2E1), and TK6 (no CYP450 activity). The cell lines were exposed for 24 hours to ST (1 or 5 mM) or its metabolite, SO, (0.125 or 0.250 mM). Two metabolites of BD, epoxybutene (EB, 200 or 400 mM) and diepoxybutane (DEB, 2 or 4 mM),were used as positive controls. Cytochalasin B (2 μg/ml) was added after 24 hr to inhibit cytokinesis, and slides were prepared at 72 hr after initial exposure. The frequency of micronucleated binucleated cells (MN-BNC) per 1000 binucleated cells (BNC) was then determined for each sample. Data were analyzed using either a one-way analysis of variance followed by a Tukey-Kramer post hoc test or a Student's *t*-test where appropriate. Differences were considered statistically significant at $P < 0.05$. TK6 cells exposed to ST did not show any increase in MN-BNC induction. AHH-1 and AHH-1/h2E1 cells exhibited similar background levels of micronucleus induction. ST induced micronuclei in both AHH-1 and AHH-1/h2E1 cells, but the response in AHH-1/h2E1 cells was greater. All cell lines responded with increasing micronuclei frequency to increasing levels of SO. Metabolism of ST is essential for genotoxicity. This is further evident from the increased frequency of MN in all cell lines following exposure to SO. Our data also demonstrate that CYP1A1 and/or CYP2E1 are capable of oxidizing ST to genotoxic metabolites.

582 ERYTHROCYTES (RBCs) AND GLUTATHIONE PEROXIDASE (GSH-Px): EFFECTS ON SPONTANEOUS AND DIEPOXYBUTANE (DEB)-INDUCED SISTER CHROMATID EXCHANGES (SCEs) IN TRANSGENIC BIG BLUE® MOUSE AND RAT PRIMARY FIBROBLASTS.

G L Erexson[1,2] and K R Tindall[1]. [1]*NIEHS, RTP, NC and* [2]*College of Veterinary Medicine, NCSU, Raleigh, NC.*

The lack of the glutathione S-transferase theta gene is an enzymatic component associated with hypersensitivity to SCE induction by DEB in cultured lymphocytes of individuals diagnosed with Fanconi's anemia. Since GSH-Px is a major detoxification enzyme in RBCs, the present study examined the effects of either GSH-Px or species-specific RBCs on spontaneous and DEB-induced SCE frequencies in primary transgenic Big Blue® rat and mouse fibroblasts. Adherent monolayer cultures of 10^6 cells per culture flask per species were treated with either 0, 2 or 4 μ M DEB ± 0, 2 or 20 units of GSH-Px ± 2 x 10^8 species-specific RBCs for the final 70 h of a total 96 h culture period. Separately and together, GSH-Px and RBCs were effective in significantly reducing both the spontaneous and DEB-induced SCEs in mouse and rat cells. A species comparison of the SCE frequencies yielded no significant differences in regards to DEB-induced genotoxicity with GSH-Px alone or in combination with RBCs. Therefore, the present study demonstrates that GSH-Px is an important enzyme that is involved in the detoxification of DNA-damaging lesions that lead to SCEs in mammalian somatic cells.

583 GENETIC TOXICITY TESTING OF HFPO TRIMER AND HFPO TRIMER AMMONIUM SALT.

W J Brock, K Wun-Kim, L R Cox, K M Gerber, and K S Bentley. *Haskell Laboratory for Toxicology and Industrial Medicine, DuPont Company, Newark, DE, USA.*

Hexafluoroprppylene oxide trimer (HFPO trimer) is one of the intermediates that are generated during the fluoproduct synthesis. HFPO trimer and HFPO trimer ammonium salt were evaluated for clastogenic potential in human lymphocytes *in vitro*. Under the test condition, HFPO trimer is partially hydrolyzed to HFPO trimer carboxylate and fluoride anion. In order to evaluate the clastogenic potential of HFPO trimer without the effect of the fluoride ion, approximately equimolar concentrations of HFPO trimer ammonium salt were tested. Approximately equimolar concentrations of fluoride ion, comparable to the amount that would be generated upon complete hydrolysis of HFPO trimer, in the forms of NH_4F and NaF were also tested for comparison. Study was conducted in two independent trials at concentration range of 0 to 1mM. With HFPO trimer or HFPO trimer ammonium salt, extreme toxicity occurred at concentrations at or higher than 0.7 mM with or without metabolic activation. Statistically significant increases in the percent of aberrant cells were also observed with both compounds, HFPO trimer and HFPO trimer ammonium salt. Significant dose related increases in the percent abnormal cells were observed with and without activation with HFPO trimer and HFPO trimer ammonium salt. The statistically significant increases in the percent aberrant cells were only observed at the dose level that caused severe toxicity. Both HFPO trimer and HFPO trimer ammonium salt were negative for induction of micronuclei. No cytotoxicity was observed in cells tested with NH_4F or NaF. No statistically significant increases in the percent aberrant cells or dose related increases in the percent abnormal cells were observed at the concentrations tested. HFPO trimer carboxlyate was clastogenic with or without the presence of fluoride ion.

584 GENETIC VARIATION AND SUSCEPTIBILITY TO THE GENOTOXICITY OF 4-AMINOBIPHENYL (4-ABP).

L N Dang and C A McQueen. *Department of Pharmacology and Toxicology, The University of Arizona, Tucson, Arizona, USA.*

Biotransformation of 4-ABP to reactive products can occur via multiple pathways including N-hydroxylation by P450 1A2 and N- or O- acetylation catalyzed by N-acetyltransferases (*Nat*). In order to assess the contribution of *Nat*, inbred and congenic mice were used. C57Bl/6 (B6) and A/J (A) mice differ at many loci including *Nat* and are considered rapid and slow acetylators, respectively. B6.A.D have the *Nat* allele from the A strain and the Ah genotype of the DBA strain on the B6 background. Animals received 120 mg 4-ABP/kg or corn oil and livers were isolated after 24h. Hepatic 4-ABP-DNA adducts were assessed by an indirect immunofluorescent method. Negligible fluorescence was detected in control animals while there were specific nuclear signals in all animals receiving 4-ABP. No differences were seen in B6 compared to A, the strains with the greatest genetic heterogeneity, while B6.A.D was significantly lower. The mean relative nuclear fluorescent intensities in B6, A and B6.A.D were 22.1 ± 3.8, 21.4 ± 4.8 and 13.6 ± 2.3, respectively. When there was a large degree of genetic variation (A versus B6), there was no apparent association between genotoxicity and *Nat* genotype. However, comparison of the two most closely related strains, B6 and B6.A.D, suggest that the slow acetylator and Ah nonresponsive phenotypes decrease the genotoxicity of 4-ABP.

585 STRUTURE-ACTIVITY RELATIONSHIP STUDIES ON THE INDUCTION OF DNA-PROTEIN CROSSLINKS BY HEMATOTOXIC RING-OPENED BENZENE METABOLITES AND RELATED COMPOUNDS IN HL60 CELLS.

H A Schoenfeld[1] and G Witz[2]. [1]*Brown University, Providence, RI;* [2]*UMDNJ-RWJ Medical School, Piscataway, NJ, USA.*

Benzene, a bone marrow toxin and human leukemogen, induces increases in DNA-protein crosslink (DNAPC) levels in bone marrow cells of CD-1 mice. The DNAPC lesion is a potentially toxic lesion and it is likely that reactive benzene metabolites contribute to DNAPC formation.

Trans,trans-muconaldehyde (MUC) is an α,β-unsaturated six carbon diene dialdehyde well suited for the crosslinking of cellular macromolecules including protein and DNA. The present studies examined structure-activity relationships of ring-opened compounds including MUC, MUC metabolites, and related compounds with respect to induction of DNAPC in HL60 cells using a K+/SDS precipitation assay for DNAPC determination. When HL60 cells were treated with 100 μM MUC followed by incubation for 4 hr, DNAPC levels were 20 fold higher compared with control cells. No increases in DNAPC levels were measured in HL60 cells 4 hr after treatment with the MUC metabolites 6-hydroxy-trans,trans-2,4-hexadienal (CHO-M-OH), 6-oxo-trans,trans-2,4-hexadienoic acid (CHO-M-COOH),or muconic acid (COOH-M-COOH), each at 100 μM. At 500 and 1000 μM and the 4 hr timepoint, significant increases in DNAPC levels were observed for CHO-M-OH, but not CHO-M-COOH. At 100 μM and the 4hr timepoint, no effect on DNAPC lev-

els was observed for trans,trans-2,4-hexadienal, trans-2-hexenal,hexanal, trans,trans-2,4-hexadiene, glutaraldehyde, or acrolein. DNAPC induced by MUC and CHO-M-OH may be cytotoxic lesions, as increases in DNAPC levels by these compounds correlated with decreases in cell viability. Compounds not inducing DNAPC at 100 μM did also not affect cell viability. These studies indicate that both aldehydic carbons of MUC contribute to DNAPC induction, and that the presence of α,β-unsaturated double bonds increases the ability of MUC to induce DNAPC relative to the saturated dialdehyde glutaraldehyde. (Supported by NIH grant ES02558 from the National Institute of Environmental Health Sciences and NIEHS Center grant ES05022.)

586 HUMAN SULFOTRANSFERASE FORMS POTENT MUTAGENS FROM METABOLITES OF 2,4-DIAMINO-TOLUENE (2,4-DAT) AND 2,4-DINITROTOLUENE (2,4-DNT).

H R Glatt[1], U Pabel[1], W Meinl[1], M W H Coughtrie[2], G Sabbioni[3] and C N Falany[4]. [1]*German Institute of Human Nutrition, Potsdam-Rehbruecke, Germany;* [2]*University of Dundee, Dundee, Scotland;* [3]*Walther Straub-Institut, Munich, Germany; University of Alabama at Birmingham, AL, USA.*

2,4-DAT and 2,4-DNT, intermediates in the production of polyurethane foam, are carcinogenic in rodents and mutagenic in various test systems. Possible metabolic activation pathways include the formation of hydroxylamines or benzylic alcohols, followed by introduction of a good leaving group, such as acetate or sulfate. We have investigated the role of various human sulfotransferases in their activation using Chinese hamster V79 cell lines and *Salmonella typhimurium* TA1538 bacterial strains engineered for the expression of human xenobiotic-metabolizing enzymes. 2,4-DAT induced gene mutations in a V79-derived cell line expressing cytochrome P450 1A2 and human phenol-sulfating phenolsulfotransferase (P-PST, SULT1A1). Expression of P-PST (Arg-213 allel) in TA1538 strongly enhanced the mutagenic activity of several potential metabolites of 2,4-DAT and/or 2,4-DNT, that of 2-acetylamino-4-hydroxylaminotoluene from 0.1 to 1.5 revertants/nmol, that of 2,4-dinitrobenzylalcohol from 0.8 to 250 revertants/nmol, and that of 4-amino-2-nitrobenzylalcohol from 0.8 to 600 revertants/nmol. Only minmal activation was observed when the His-213 allel of P-PST was expressed. Expression of other human sulfotransferases (1A2, 1B2, 1C1) also enhanced the mutagenicity of some of these compounds, but the effects were much weaker than when P-PST (Arg-213 allel) was used. The results indicate that a specific form of human sulfotransferase, the predominating allel of P-PST, is particularly active in the final toxification of intermediates in the metabolism of 2,4-DAT and 2,4-DNT. (Supported by DFG (Innovationskolleg 26) BMBF (0311243) and NATO Collaborative Research grant (CRG.971600).)

587 CIGARETTE PARAMETERS THAT INFLUENCE THE MUTA-GENICITY OF MAINSTREAM SMOKE CONDENSATE.

F J Tewes[1], T J Meisgen[1], W A Gomm[1], E Roemer[1], and R A Carchman[2]. [1]*INBIFO Institut für biologische Forschung, Cologne, Germany;* [2]*Philip Morris USA, Richmond, VA, USA.*

The Salmonella reverse mutation assay has been used to determine the influence of various cigarette design parameters on the mutagenicity of mainstream smoke condensate. Cigarette prototypes that differ in blend composition, paper porosity, paper additive (citrate or phosphate), filtration efficiency, and filter ventilation were constructed. In a fractional, factorial study design, 30 cigarette types were selected from 486 possible combinations. Three levels of each parameter were represented by 10 different cigarette types. Cigarettes were smoked according to ISO standards, and 4 condensate batches per type were collected by impaction and dissolved in dimethyl sulfoxide. Mutagenicity determination was carried out in the plate incorporation version of the Ames assay with *S. typhimurium* strain TA98 in the presence of S9. Four equidistant doses from 0.04 to 0.16 mg dry condensate per plate were applied. The specific mutagenicity, i.e., revertants/mg dry condensate, of each batch was calculated using linear regression analysis with Poisson-weighted data. To determine the influence of the cigarette design parameters, a multiple linear regression analysis on the specific mutagenicity values was performed. All regression coefficients except those for the paper additives were statistically significant ($p < 0.001$). Increasing the amount of Burley for bright tobacco from 0 to 65 % resulted in a 2.4-fold increase; filter ventilation from 0 to 60 %, in a 1.2-fold increase; filtration efficiency from 35 to 55 %, in a 1.1-fold increase; and paper porosity from 10 to 45 cm/min, in a 0.89-fold decrease in specific mutagenicity.

588 THE CONFOUNDING ROLE OF IMPURITIES IN THE GENOTOXIC EVALUATION OF A NEW PHARMACEUTICAL.

V Gervais[1], S Horvath[2], and G Descotes[1]. [1]*Drug Safety Assessment and* [2]*Analytical Chemistry Departments, Groupe de Recherche Servier, Orleans, France.*

The mutagenic potential of S 15261-3, a new antidiabetic agent, was assessed on Ames test as part of its safety evaluation. Laboratory scale material was found devoid of mutagenic potential in a preliminary Ames test and the compound selected as a drug candidate. The first batch issued from scale up synthesis elicited a concentration-dependent response of TA1535 at high concentrations, with or without metabolic activation. The mutagenic response still increased at precipitating concentrations leading to the hypothesis that a soluble impurity/degradation product may have been responsible for the discrepancy in the mutagenic response. Several fractions of impurities were collected by semi preparative HPLC from the Ames positive batch and tested on TA1535. One fraction was found mutagenic. The impurity, subsequently identified as a residual intermediate, was then tested in a conventional Ames test where it elicited a concentration-dependent response of TA1535 from minute concentrations which roughly corresponded to those provided in the positive batch of S 15261-3. The two E. coli were also found sensitive but at higher concentrations. The manufacturing process was adjusted to avoid the presence of this highly mutagenic intermediate and S 15261-3 currently used in preclinical and clinical trials is devoid of genotoxic potential in all the core battery of in vitro and in vivo genotoxicity assays. These results confirm the usefulness of the Ames test for monitoring the presence of mutagenic or potentially carcinogenic impurities in otherwise nonmutagenic compounds. They also underscore the importance of careful evaluation of any positive result prior to discard compounds of potential interest.

589 DETECTION OF SPONTANEOUS AND INDUCED MUTATIONS IN TRANSGENIC FISH CARRYING A BACTERIOPHAGE LAMBDA CII TARGET.

R N Winn[1], M B Norris[1], and K J Brayer[1]. [1]*University of Georgia, Athens, GA.* Sponsor: C Dallas.

Transgenic animal models that are capable of measuring mutations are providing powerful new tools for rapidly assessing *in vivo* mutations following mutagen exposure. We describe the development and initial validation trials of transgenic fish (medaka, *Oryzias latipes*) that carry multiple copies per cell of a bacteriophage lambda vector. The lambda vector carries both the lac I and cII genes as mutation target genes which can be analyzed using different assay procedures. The general approach entails the introduction of the vector which carries the target genes into the fish genome, and following exposure to a mutagenic agent, recovering the target gene via indicator bacteria to quantify the frequency of mutations. Transgenic fish from several lineages were examined with regards to efficiency of vector recovery, spontaneous mutation frequency and induced mutation frequency (MF) of the target genes following exposure to the model mutagen ENU. The high number of copies of the vector carried by one fish lineage (>75 copies/haploid genome) facilitated superior packaging and highly efficient recovery of the bacteriophage from fish genomic DNA (8-1.5 X 10^5 phage recovered/packaging reaction). The spontaneous mutation frequencies of the target genes in the fish, although slightly lower, were comparable to the ranges observed in transgenic mice which carry the identical mutation targets (~2-8 X 10^{-5}). Dose response increases in MF were observed following short-term (1 h) ENU treatment and two-fold MF increases were observed five days after exposure to 0.5 mM ENU. The sequencing of selected mutations recovered from the fish indicated a predominance of point mutations detected in the target gene, and demonstrated similar overall mutation spectra compared to lambda transgenic mice. These results indicate that the fundamental requirements for the transgenic fish models for mutation detection have been met, and that fish have a significant promise for a wide number of applications in genotoxicity, with particular environmental relevance to aquatic systems.

590 MUTAGENIC AND CLASTOGENIC ACTIVITY WAS NOT FOUND WITH TRIBUTYLPHENYL CYCLICPHOSPHITE OF BUTYLETHYL PROPRANE DIOL IN A STANDARD GENETIC TOXICOLOGY BATTERY.

V O Wagner, III[1], R Gudi[1], R H C San[1], D Jacobson-Kram[1], S S Dimond[2] and R L Joiner[2]. [1]*MA BioServices, Inc., Rockville, MD, USA and* [2]*General Electric Company, Pittsfield, MA, USA.*

2,4,6-Tri-t-butylphenyl cyclicphosphite of butylethyl propane diol (Ultranox® XR-2677, CAS No. 161717-32-4), an antioxidant/stabilizer used in the manufacture of polymers, was evaluated for mutagenic and clastogenic activity in a standard *in vitro* and *in vivo* genetic toxicology battery. The bacterial mutation assay was conducted with tester strains TA98, TA100, TA1535, TA1537, WP2 uvrA (pKM101) and WP2 (pKM101) in the presence and absence of S9 activation. Each strain was tested using the preincubation method over a dose range of 33 to 5000 μ g/plate. No toxicity and no mutagenic activity were observed in two independent trials. In the mutagenesis assay using L5178/TK$^{+/-}$ mouse lymphoma cells, no mutagenic activity was observed over a dose range of 300 to 500 μ g/mL, with and without metabolic activation. In the *in vitro* chromosome aberration assay using CHO cells, doses up to 877 μ g/mL were used. No significant increases in numerical or structural chromosome aberrations were observed with and without metabolic activation. In the *in vivo* mouse micronucleus assay, male and female mice were dosed with 1250, 2500 or 5000 mg/kg body weight and bone marrow cells were collected 24, 48 and 72 hours after treatment. There was no significant increase in the number of micronucleated polychromatic erythrocytes. Based on the results of these assays, Ultranox® XR-2677 was concluded to be non-genotoxic *in vitro* and *in vivo*.

591 MOLECULAR ANALYSIS OF *HPRT* MUTANTS FROM 1,3-BUTADIENE EXPOSED WORKERS.

H Ma[1], T G Wood[2], and J B Ward, Jr.[1]. [1]*Department of Preventive Medicine and Community Health,* [2]*Sealy Center for Molecular Sciences, University of Texas Medical Branch, Galveston, TX, USA.*

Butadiene, an industrial chemical, is carcinogenic in rodents and, probably, man. Previously, we reported a 3–fold increase in *hprt* mutant lymphocyte frequency in workers. We have analyzed 143 *hprt* mutant clones from butadiene-exposed workers and 197 clones from non-exposed controls to determine whether butadiene exposure is associated with specific changes in the spectrum of mutations. Process workers in a styrene-butadiene rubber plant were exposed to about 1 ppm butadiene. A multiplex PCR-based method was used for detection of exon deletions of the *hprt* gene. Of the mutant clones from BD exposed workers, 25/143 (18%) were identified as large deletion mutations, while 19/197 (10%) mutants in control subjects were deletion mutations, a significant difference ($p<0.05$). Direct sequencing of a PCR amplified target cDNA representing the entire *hprt* coding region was also used to analyze 76 mutants from butadiene-exposed workers and 85 mutants from control subjects. There was no significant difference in the frequency of small deletion mutations between BD exposed workers and the control subjects. There was a non-significant increase in mutations at AT sites among mutants from BD exposed workers (52%) compared to control subjects (42%). The frequency of frameshift mutations in butadiene exposed workers (13%) was significantly higher than control subjects (4%). Our preliminary results indicate that butadiene may induce large structural changes in the *hprt* gene in lymphocytes of exposed workers. The diepoxide metabolite of butadiene, a bifunctional alkylating agent, may play a role in butadiene-induced mutagenesis. Butadiene diepoxide was previously shown to cause an increase in deletion mutations in cultured lymphoblasts (Steen AM, et al, Mutagenesis 12, 61-67). (Supported by ES 06015 and ES06676.)

592 OLIGONUCLEOTIDE-INDUCED MUTATION IN CULTURED CELLS: CHARACTERIZATION, MECHANISM, AND IMPLICATION.

C Ghosh and P L Iversen. *AVI BioPharma Inc., Corvallis, OR, USA.*

Antisense oligonucleotides are a powerful new class of drugs which inhibit gene expression by interfering with transcription, RNA processing and transport, and translation. Little is known about the potential genotoxic effects of the oligonucleotides. This study demonstrates a link between the interaction of a variety of oligonucleotide analogs with cells and mutations in the cellular genome. Further, reactive oxygen is involved in coupling the oligonucleotide interaction with the cell surface and the mutation frequency. We examined a collection of synthetic oligonucleotides and their structural analogs for binding to cells in culture, production of hydroxyl radicals, and induction of mutations at the HPRT locus of cultured V79 cells. Oligonucleotides composed of phosphodiester, phosphorothioate, and methylphosphonate backbones were found to induce mutations in cell culture. The mutagenic response was not sequence-specific but was dose-dependent. The presence of hydroxyl radical was detected shortly after exposure of cells to these oligonucleotides. Phosphorodiamidate morpholine oligonucleotides, a new structural type containing six-membered morpholine replacing the ribose sugar joined by non-ionic phosphorodiamidate backbone, showed no significant increase in mutation frequency. These observations indicate a novel interaction between oligonucleotides and cultured cells leading to oxidative DNA damage and subsequent mutagenicity.

593 MUTAGENIC POTENTIAL OF ADENINE N^6 AND GUANINE N^2 ADDUCTS OF BUTADIENE MONO- AND DIEPOXIDE.

J R Carmical[1] and R S Lloyd[2]. *Departments of* [1]*Preventive Medicine and Community Health and* [2]*Human Biological Chemistry and Genetics, The University of Texas Medical Branch at Galveston, TX, USA.* Sponsor: J B Ward, Jr.

In order to determine the biological effects of specific DNA adducts resulting from the interaction of 1,3-butadiene metabolites with DNA, deoxyoligonucleotides have been synthesized with four different adducts both at the N6 position of adenine and the N2 position of guanine. The deoxyoligonucleotides were designed such that the adduct was centrally located within codon 61 and codon12 of the human N-ras gene, respectively. These adducts are those arising from adduction by either the R or S stereoisomer of the monoepoxide (BDO) or the (R, R) or (S, S) isomer of the diepoxide (BDO2) in which the second ring has been hydrolyzed. These adducted oligonucleotides were utilized in *in vivo* and *in vitro* assays designed both to determine their mutagenic potency and to examine specific interactions with *Escherichia coli* polymerases. Each adducted oligonucleotide was ligated into a single-stranded vector M13mp7L2 that was subsequently used to transfect *E. coli*. The resulting mutagenic spectrum for these modified DNAs was stereoisomer specific. In addition, each of three purified *E. coli* polymerases was used to replicate DNAs containing these adducted deoxyoligonucleotides. These assays demonstrate the ability of each individual polymerase to bypass the adduct and divulge any stereoisomer-specific blockage. This is the first report of stereoselectivity related to butadiene-induced mutagenesis. (Supported by NIH P30-ES06676, ES05355, ES07781, P30-ES00267, and T32-ES07253.)

594 RECONSTRUCTED, DIFFERENTIATED AIRWAY EPITHELIAL CULTURES TO DETECT OCCUPATIONAL ASTHMA CAUSING AGENTS.

J Sheasgreen, M Klausner, J Kubilus, and P Ogle. *MatTek Corporation, Ashland, MA, USA.*

Normal human tracheal-bronchial epithelial cells (NHBE) have been cultured using serum free medium to form a three dimensional tissue-like structure that closely resembles the epithelial tissue of the respiratory tract. Histological cross-sections of both the *in vitro* tissue and a normal human bronchiole reveal a four layer, bipartite structure. Transmission electron microscopy revealed numerous cilia on the apical surface of the cultures and dot blot analysis was used to quantify mucin secretion. These cultures were exposed to a saturated atmosphere of some common respiratory asthma inducing agents including toluene diisocyanate (TDI), phthalic anhydride, and formaldehyde. The culture medium beneath the cultures was analyzed for cytokine release using enzyme linked immunosorbent assay (ELISA) kits. Compared with air-exposed controls, the level of prostaglandin E-2 and 15-hydroxy eicosatetraenoic acid (15-HETE) increased by 2-fold or greater after a 45 minute exposure; interleukin (IL)-8 increased by 2-fold following a 4 hour exposure to TDI. No increases above basal levels of IL-6 or tumor necrosis factor (TNF-a) were observed following exposure to any of the materials tested. These data indicate that the newly developed NHBE culture model may be a useful *in vitro* means to detect chemicals that are likely to cause non-immunological occupational asthma.

595 CLARA CELL SECRETED PROTEIN (CCSP) OXIDATION IN THE FIRST WEEK OF LIFE IS INCREASED IN THE TRACHEAL FLUIDS OF INFANTS THAT DEVELOP BRONCHOPULMONARY DYSPLASIA.

P L Ramsay, S E Hegemier, N Dzidic, L K Rogers, M E Wearden, and S E Welty. *Pediatrics, Baylor College of Medicine, Houston, TX.* Sponsor: C V Smith.

Bronchopulmonary dysplasia (BPD) remains a major cause of morbidity and mortality in prematurely born infants exposed to supplemental oxygen and mechanical ventilation. In the first week of life, infants born prematurely who have evidence of lung inflammation are more predisposed to the development of BPD. This led us to hypothesize that early inflammatory events occurring in the first week of life are secondary to an alteration of the lungs' endogenous anti-inflammatory mediators within the alveolar space. Therefore, this study was designed to test the hypothesis that specific protein oxidation, mediated by, or leading to inflammatory responses would be higher in infants that go on to develop BPD than in infants that do not. Forty-five infants admitted at $\leq$ 29 weeks gestation were studied. Tracheal aspirate samples were collected on days of life 1, 3, and 6 on all intubated infants. The tracheal aspirate fluids were assayed for oxidized proteins by derivatization with 2,4-dinitrophenylhyrazine (DNPH). Oxidized proteins were then identified with N-terminal amino acid sequencing. The infants were evaluated to determine whether they met the criteria for the diagnosis of BPD as defined by a persistent oxygen requirement at 28 days of life, at 36 weeks corrected gestational age and at the time of discharge. A 10 kDa oxidized protein was observed in 31% of the infants that did not develop BPD (n=16), 68% of the infants that did develop BPD (n=19), and 80% of the infants that expired (n=10). This protein was identified as the Clara cell secreted protein (CCSP), which functions as an endogenous anti-inflammatory molecule within the lung. These results suggest that oxidation of CCSP may reduce its function as an anti-inflammatory agent thereby contributing to lung inflammation and injury. Further efforts to determine the precise chemical nature of the oxidation of CCSP are underway.

596 STUDIES OF RESPIRATORY TRACT TOXICITY IN RATS EXPOSED TO MEXICO CITY URBAN AIR.

E A Gross[1], R A James[1], P W Ross[1], K C Roberts[1], A M Howard[1], J R Harkema[2], L Calderón-Garcidueñas[3], K T Morgan[4] and O R Moss[1]. [1]*Chemical Industry Institute of Toxicology (CIIT), Research Triangle Park, NC, USA;* [2]*Michigan State University, East Lansing, MI, USA;* [3]*Instituto Nacional de Pediatria, Mexico City, Mexico;* [4]*GlaxoWellcome Company, Research Triangle Park, NC, USA.*

The rat has been used as a health sentinel, indicator, or monitor of environmental health hazards; yet this model has not been directly validated against human exposures. Humans in Mexico City show upper respiratory tract lesions and evidence of pulmonary damage related to their environmental exposure. Male and female F344 rats were exposed (24hr/d) to Mexico City urban air (MCA) for up to 7 weeks, while controls were maintained at the same location under filtered air. Prior to these exposures, the nasal passages of normal male rats shipped from the U. S. and housed in Mexico City were examined for mycoplasma infection (none were found); a mobile exposure and monitoring system was assembled and tested, along with supporting histopathology techniques and analysis of rat nasal and lung tissues, using ozone as the exposure atmosphere; and the exposure model (equipment and animals) was transported to Mexico City and validated for a 3-wk period. During the 7-wk study there were 15 1-hr intervals where the average ozone concentration of Mexico City urban air in the exposure chamber exceeded the U.S. EPA standard of 0.125 ppm O3. Prolonged exposure of healthy F344 rats to MCA containing episodically low to moderate concentrations of ozone (and other urban air pollutants) did not induce inflammatory or epithelial lesions in the nasal airways (or in the lung), as measured by qualitative histologic and/or quantitative morphometric techniques. These findings are in agreement with those of previously controlled ozone inhalation studies but are in contrast to previous reports indicating that ozone-polluted MCA causes significant nasal mucosal injury in adults and children living in southwestern Mexico City. Taken together, these findings may suggest that human airways are markedly more susceptible to the toxic effects of MCA than the airways of the F344 rat.

597 MONOCROTALINE PYRROLE (MCTP) ALTERS THE TYPE II PNEUMOCYTE RESPONSE TO INTRANASAL ENDOTOXIN (LPS) ADMINISTRATION IN RATS.

P B Lappin[1] and R A Roth[2]. [1]*Sierra Biomedical, Inc., Sparks, NV, USA;* [2]*Michigan State University, East Lansing, MI, USA.*

Monocrotaline pyrrole (MCTP) is a pyrrolizidine alkaloid that causes pulmonary vascular injury with limited type II pneumocyte hypertrophy/megalocytosis *in vivo*. *In vitro*, megalocytosis is seen in cells exposed to MCTP, secondary to the inhibition of normal cell cycle progression and mitosis (Toxicol. Appl. Pharmacol. 1998. 150:37-48). MCTP-induced alterations in cell cycle progression occur in confluent populations, but a stimulus for cell proliferation (ie, subconfluency) enhances the antimitotic and megalocytic effect *in vitro*. We hypothesized that a mitotic stimulus *in vivo* would augment the development of pulmonary cell megalocytosis due to MCTP administration to the rat. Endotoxin (LPS - 100μg per rat), an inducer of transient type II pneumocyte hyperplasia was given intranasally 4 days after MCTP administration (3.5mg/kg, iv). Alterations in lung histomorphology as well as markers of lung injury in bronchoalveolar fluid (BALF) were evaluated at days 6, 7 or 11. Generally, MCTP caused increases in lung weight, BALF protein concentration and BALF lactate dehydrogenase (LDH) activity which (except for increased lung weight on day 6) were unaffected by cotreatment with LPS. LPS given alone induced multifocal type II cell hyperplasia and inflammation, whereas MCTP alone resulted in minimal type II cell hypertrophy and/or megalocytosis. Compared to either agent alone, LPS given after MCTP caused more extensive multifocal inflammation without type II cell hyperplasia, but with more pronounced multifocal hypertrophy/megalocytosis of type II cells. In summary, the addition of a mitotic stimulus (LPS) to the MCTP pulmonary injury model exacerbates type II pneumocyte enlargement in the absence of pneumocyte hyperplasia. (Supported by NIH Grant ES02581.)

598 INTRATRACHEAL INSTILLATION OF ZINC CADMIUM SULFIDE (ZNCDS) IN FISCHER 344 RATS.

J D Bergmann[1], L W Metker[1], W C McCain[1], P A Beall[1], M W Michie[1] and R B Lee[2]. [1]*U.S. Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD, USA;* [2]*Robyn B. Lee & Associates, LLC, Fawn Grove, PA, USA.*

The purpose of this study was to assess the bioavailability and pulmonary toxicity of ZnCdS in rats. Groups of 30 male Fischer 344 rats each were anesthetized and dosed via intratracheal instillation with 5 mg of either ZnCdS, quartz (positive control), or titanium dioxide (TiO_2-negative control) suspended in 0.5 ml saline. A vehicle control group received 0.5 ml saline. Ten animals from each test group were sacrificed at 1 day, 1 week, and 14 weeks after dosing for bronchoalveolar lavage fluid (BALF) analysis and histopathology. The BALF was analyzed for alkaline phosphatase, acid phosphatase, lactate dehydrogenase (LDH), β-glucuronidase (β-glu), total protein, and cell counts. Two separate groups of 24 rats each were dosed as above with either ZnCdS or saline. Eight rats from each group were sacrificed at 1 day, 1 week, and 14 weeks after dosing for determination of cadmium (Cd) and zinc (Zn) concentrations in the lung, liver, kidney and blood. Results indicate that at 1 day after dosing all enzyme activities (except acid phosphatase) and cell counts in BALF from the quartz and ZnCdS groups were significantly higher than TiO_2 and saline groups. At 7 days after dosing, high enzyme activity persisted in the quartz group, while the ZnCdS group showed only LDH and total protein levels significantly higher than the saline group. At 14 weeks after dosing, LDH, total protein, β-glu, and cell counts in the quartz group were significantly higher than all other groups. Histologic examination revealed interstitial inflammation and accumulation of foreign material in the lungs and mediastinal lymph nodes of quartz, TiO2, and ZnCdS treated rats. Metals analyses showed profuse Cd and Zn concentrations in the lung at 1 day, and to a lesser extent, 1week after dosing. In conclusion, ZnCdS appears to cause temporary lung inflammation and is not bioavailable.

599 LUNG MORPHOLOGY AND COLLAGEN DEPOSITION IN AMIODARONE- AND VEHICLE-TREATED HAMSTERS FOLLOWING DIETARY VITAMIN E SUPPLEMENTATION.

J W Card[1], R G Leeder[2], W J Racz[1], J F Brien[1], T M Bray[3], and T E Massey[1,4]. *Departments of [1]Pharmacology and Toxicology and [4]Medicine, Queen's University, Kingston, ON, Canada; [2]Leo Laboratories Canada Ltd., Ajax, ON, Canada; [3]Department of Human Nutrition and Food Management, Ohio State University, Columbus, OH, USA.*

Amiodarone (AM) is a potent antidysrhythmic agent that is limited in clinical use due to the development of numerous adverse effects, including potentially life-threatening AM-induced pulmonary toxicity. Treatment of male golden Syrian hamsters intratracheally with AM (1.83 μmol) or vehicle (0.1 ml distilled H_2O) was performed following 6 weeks of dietary vitamin E supplementation (500 IU d,l-α-tocopherol acetate / kg chow), at which time pulmonary vitamin E content was increased 234% relative to animals on the control diet. At 21 days post-dosing, histological disease index values for the diet and treatment groups were: control diet + vehicle, 5.08 ± 1.34%; vitamin E diet + vehicle, 3.58 ± 0.31%; control diet + AM, 7.25 ± 1.98%; vitamin E diet + AM, 5.58 ± 1.45%. Similarly, pulmonary hydroxyproline contents were: control diet + vehicle, 412 ± 33 μg / right lung; vitamin E diet + vehicle, 339 ± 28; control diet + AM, 521 ± 24; vitamin E diet + AM, 453 ± 73. The increases (p <0.05) in histological disease index and hydroxyproline content data for the control diet + AM group compared to all other groups were indicative of pulmonary fibrosis, while the decreases (p <0.05) of these values in the vitamin E + vehicle group suggest that dietary vitamin E supplementation provides non-specific protection against AM-induced pulmonary toxicity in the hamster. (Supported by Medical Research Council of Canada, grant No. MT-13257.)

600 PULMONARY EFFECTS OF ENDOTOXIN CONTAMINATED METAL REMOVAL FLUID AEROSOLS.

M P DeLorme, X Gao, and D J P Bassett. *Wayne State University, Detroit, MI, USA.*

Endotoxin contamination of metal removal fluid (MRF) aerosols has been implicated in the induction of pulmonary neutrophilia and decrements in airway conductance. In both guinea pigs and rats, acute ozone exposure results in the infiltration of neutrophils into the pulmonary tissues that correlates with increased permeability damage and hyperreactive airways. The present study was performed to determine if the accumulation of neutrophils, caused by endotoxin contaminated MRF aerosols, results in similar permeability damage and airway hyperreactivity. This study exposed male Wistar rats to 10 mg/m^3 MRF aerosols with and without 0.8 μg/m^3 endotoxin. Exposure to MRF aerosols without endotoxin resulted in no significant alterations in bronchial alveolar lavage (BAL)-recovered or lung tissue collagenase digestion-recovered neutrophils. Exposure to MRF aerosols with endotoxin resulted in significant increases in neutrophils, with BAL recoveries increasing from 0.01 (control) to 1.44 million/lung and collagenase digestion recoveries increasing from 6.1 (control) to 32.3 million/lung. These increases returned to control values by 16 hours post exposure. Lung permeability damage, as assessed by BAL recovered albumin, remained unaltered from a control value of 138 μg/ml in all exposure groups. There was also no evidence of hyperreactive airways, since animals exposed to MRF aerosols with and without endotoxin required the same intravenous methacholine dose (32 μg/kg) as control rats to provoke a 200% increase in airway resistance ($PD_{200}R$). These results demonstrate that MRF aerosol exposure, in the absence of endotoxin, did not result in an inflammatory response. In contrast to ozone exposure, the neutrophil accumulation in the BAL and pulmonary tissue brought about by exposure to endotoxin contaminated MRF aerosols did not correlate with permeability damage or hyperreactive airways.

601 EFFECTS OF VITAMIN E ON AMIODARONE-INDUCED CYTOTOXICITY IN ISOLATED HAMSTER LUNG CELLS.

M W Bolt[1], W J Racz[1], J F Brien[1], T M Bray[2], and T E Massey[1,3]. *Departments of [1]Pharmacology and Toxicology and [3]Medicine, Queen's University, Kingston, ON, Canada; [2]Department of Human Nutrition and Food Management, Ohio State University, Columbus, OH, USA.*

Life-threatening pulmonary fibrosis limits the clinical use of amiodarone as an antidysrhythmic agent. The ability of vitamin E to protect isolated hamster lung cell types from amiodarone-induced cytotoxicity was investigated *in vitro*. Preparations enriched with alveolar macrophages (95-98%), alveolar type II cells (75-85%) and non-ciliated bronchiolar epithelial (Clara) cells (35-55%) as well as a fraction consisting of unseparated cells were obtained from male golden Syrian hamsters by protease digestion followed by centrifugal elutriation and Percoll® density gradient centrifugation. Vitamin E (300 μM) did not alter viability (measured by trypan blue exclusion) of the cells not treated with 100 μM amiodarone. However, addition of vitamin E to the incubation medium significantly increased cell viability of the amiodarone-treated alveolar macrophage fraction from 67.8 ± 8.5% (mean ± SD) to 79.6 ± 7.9 % at 24 h and from 45.5 ± 13.4 % to 70.6 ± 4.9 % at 36 h (p < 0.01; n=5). Furthermore, vitamin E did not significantly protect any other cell fraction from amiodarone cytotoxicity. Amiodarone content (measured by reverse-phase HPLC) was not altered by vitamin E in any cell fraction, demonstrating that vitamin E does not decrease drug accumulation. These results suggest that vitamin E may counteract initiating events of amiodarone-induced pulmonary toxicity. (Supported by Medical Research Council of Canada Grant No MT-13257.)

602 EFFECTS OF CYTOCHROME P450 (P450) INHIBITORS ON BIO-TRANSFORMATION OF THE TOBACCO SPECIFIC NITROSAMINE 4-(METHYLNITROSAMINO)-1-(3-PYRIDYL)-1-BUTANONE (NNK) IN FRESHLY ISOLATED HUMAN LUNG CELLS.

G B J Smith[1], A Castonguay[4], K Reid[2], D Petsikas[2], and T E Massey[1,3]. *Departments of [1]Pharmacology and Toxicology, [2]Surgery and [3]Medicine, Queen's University, Kingston, ON, Canada; [4]Laboratory of Cancer Etiology and Chemo-prevention, Faculty of Pharmacy, Laval University, Quebec City, PQ, Canada.*

P450s and lipoxygenases (LOXs) have both been implicated in human pulmonary NNK metabolism. SKF-525A and 1-aminobenzotriazole (ABT) were used to examine P450 monooxygenase contributions to the biotransformation of NNK in isolated human lung cell fractions from 4 peripheral lung specimens obtained during clinically indicated lobectomy. Cells were incubated with [5-^{3}H]NNK and either SKF-525A (1.0 mM) or ABT (1.0 mM) for 24 hr. SKF-525A significantly inhibited keto reduction of NNK to 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanol (NNAL) by 72.4 ± 22.9%, 85.1 ± 10.4%, and 67.3 ± 27.1% (_ ± SD, n=4, paired t test) in preparations of isolated unseparated cells, fractions enriched in alveolar type II cells, and fractions enriched in alveolar macrophages respectively. ABT had no significant effect on the formation of NNAL. SKF-525A and ABT had variable effects on formation of other NNK metabolites. Total bio-activation (reflected by the sum of 4 α-hydroxylation endpoint metabolites) was decreased in some patient's cells treated with either SKF-525A or ABT. However, in some cases SKF-525A decreased total α-hydroxylation, whereas ABT either had no effect, or increased metabolite formation. In addition, both SKF-525A and ABT tended to increase detoxification (reflected by pyridine N-oxidation metabolites), particularly in cells producing detectable N-oxide metabolites in the absence of inhibitors. These results suggest a possible role for P450s in human lung cell NNK metabolism. However, NNK metabolism was subject to large variations among cell types and between individuals, and the results do not rule out LOX-mediated NNK biotransformation. In addition, carbonyl reduction of NNK to NNAL, which is reported to be catalyzed by 11β-hydroxysteroid dehydrogenase, is SKF-525A sensitive. (Supported by Medical Research Council of Canada Grant # MT-10382.)

603 CHANGES IN EPITHELIAL INTEGRITY, ALKALINE PHOSPHATASE ACTIVITY AND FIBRONECTIN EXPRESSION IN LUNGS OF RATS EXPOSED TO OZONE.

P G Reinhart, S K Gupta and D K Bhalla. *Department of Occupational and Environmental Health Sciences, Wayne State University, Detroit, MI, USA.*

The detrimental effects of the air pollutant ozone (O_3) in the lung are dependent on dose, exposure duration, and generally evolve with time post-exposure. This study characterized the time sequence of epithelial injury and fibronectin expression in the lungs of rats exposed to O_3. Bronchoalveolar lavage (BAL) fluid was analyzed for alkaline phosphatase and total protein as markers of epithelial injury and increased permeability, and fibronectin for its role in inflammation and lung injury. The results revealed a time-related increase in total protein in the BAL fluid following a 3 hr exposure of rats to 1 ppm O_3. The protein concentrations peaked at 12 hrs and then declined, but remained higher than the control levels at 24 hrs post-exposure. A similar time-related increase also occurred for BAL fibronectin and alkaline phosphatase activity. However, the return of alkaline phosphatase levels to

baseline prior to a comparable reduction in protein levels suggests repair of injured cells, but a delay in the formation of epithelial junctions that limit the transfer of serum proteins to air spaces. By cytochemistry, alkaline phosphatase activity was detected in association with lung type II epithelial cells and in BAL polymorphonuclear leukocytes (PMNs), but not in macrophages. While a significant increase in cytochemically detectable alkaline phosphatase resulted from the increase in PMN number following O_3 exposure, macrophages constituted the primary cell type responsible for fibronectin mRNA upregulation. The comparability of temporal changes in fibronectin, protein and alkaline phosphatase levels suggest a mechanistic role of fibronectin in lung injury. (Supported by NIEHS grant #ES03521.)

604 ACETAMINOPHEN CYTOTOXICITY IN RAT TYPE II PNEUMOCYTES AND ALVEOLAR MACROPHAGES IN VITRO.

S Dimova[1], P Hoet[2], M Demedts[2], and B Nemery[2]. [1]*Institute of Physiology, Bulgarian Academy of Sciences, Sofia, Bulgaria;* [2]*Laboratory of Pneumology, Unit of Toxicology, KULeuven, Leuven, Belgium.*

Acetaminophen (APAP) liver and kidney cytotoxicity is associated with bioactivation by cytochrome P-450 and/or prostaglandin synthetase to a reactive metabolite, which depletes reduced glutathione (GSH), covalently binds to proteins and leads to oxidative stress. Although APAP may also damage the lung, little is known about the mechanism by which this occurs. We, therefore, studied the *in vitro* toxicity of APAP and its effect on intracellular GSH level in rat type II pneumocytes (TII) - either immediately after isolation, or 24h after plating-and alveolar macrophages (AM). Cytotoxicity was evaluated by changes in membrane integrity (LDH assay) as well as by mitochondrial metabolic activity (reduction of MTT), following a 20h incubation with APAP (0.5-20 mM). The reduction of MTT was significantly decreased at ≥ 5 mM APAP in freshly isolated TII and AM, and at ≥ 10 mM in 24h-old TII. APAP caused a significant decrease in LDH retention in the fraction of attached cells in freshly isolated TII, AM and 24h-old TII at ≥ 10 mM, ≥ 15 mM and 20 mM, respectively. This was associated with increase in LDH activity in the fraction of nonattached cells and in the medium. A concentration-dependent decrease of intracellular GSH occurred in freshly isolated TII and AM during a 2h exposure to subtoxic APAP concentrations (0.01-1 mM). In 24h-old TII the GSH concentration was significantly higher than in freshly isolated TII and there were no changes after 2h APAP exposure. Potassium ethyl xanthate (inhibitor of cytochrome P450) and indomethacin (inhibitor of prostaglandin synthetase) decreased significantly APAP-induced GSH depletion in freshly isolated TII and AM. These observations have demonstrated that i) freshly isolated TII and AM are sensitive to APAP-induced toxicity, ii) APAP affects GSH level in these cells, and iii) cytochrome P450 and/or prostaglandin synthetase are possibly involved in APAP-induced cytotoxicity in freshly isolated TII and AM.

605 QUANTIFICATION OF AGGLOMERATION IN THE RAT LUNG FOLLOWING INTRATRACHEAL INSTILLATION EXPOSURE TO SYNTHETIC MINERAL FIBERS.

D M Bernstein[1], H Furtak[2], R Rogers[3] and P Thevenaz[4]. [1]*Geneva, Switzerland;* [2]*St. Gobain, Paris, France;* [3]*RIC, Boston, MA, USA;* [4]*RCC, Füllinsdorf, Switrzerland.*

Short term biopersistence studies for evaluating the clearance of fibers from the lung have been found to provide an excellent indication of the potential pathogenicity of these fibers. Recently, the European Commission has incorporated both inhalation and intratracheal instillation biopersistence results as one possible criteria for exoneration of fibers from Category 3. However, there has been concern that fiber deposition following intratracheal instillation may not accurately represent fiber distribution in lungs exposed to a fiber-containing aerosols. If fibers do agglomerate, the agglomerates can block the distribution of fibers through the airways and granulomas can form around the fibers which may isolate the fibers inside from the dissolution fluids of the lung. This would produce an artefact which could artificially increase the Intratracheal Instillation biopersistence clearance half-time. In order to quantify agglomeration of fibers in the lung, a novel technique was designed to transform lungs into optically clear specimens allowing the entire airways within intact lung lobes to be directly observed using confocal microscopy and permitting the identification of the fibers therein. Confocal microscopic analysis was performed using laser scanning microscope fitted with a 25 mW argon-ion laser and an upright microscope modified for reflected light imaging. Quantitative measurements of the number (using digital planimetry) and size of fiber agglomerates were made from randomly sampled regions of lung. Aggregate size was determined by measuring the distance (in micrometers) through a fiber agglomeration. The results show strong dependence of fiber agglomeration on fiber diameter and length. When agglomeration is avoided by proper fiber size selection then as shown by our recent studies, both inhalation and intratracheal instillation biopersistence give coherent results.

606 ROLE FOR ICAM-1 AS A SIGNAL TRANSDUCTION MOLECULE IN SILICA EXPOSED MOUSE MACROPHAGES.

A K Hubbard[1] and C Giardina[2]. *Depts. Of* [1]*Pharmaceutical Sciences and* [2]*Molecular and Cell Biology, University of Connecticut, Storrs, CT.*

In a mouse model of silica (SI) induced lung injury, SI exposure increases expression of intercellular adhesion molecule-1 (ICAM-1) on lung (alveolar/interstitial) macrophages.To investigate the regulation and role of SI induced ICAM-1 expression on lung macrophages, the mouse macrophage cell line, MH-S (ATCC CRL 2019) was incubated with SI particles (20 ug/ml), PMA (10 ng/ml), TNFα (10 ng/ml) or media for 48 hrs and levels of cell associated ICAM-1 were measured by ELISA. Both TNFα and SI induced a 20% increase in cellular ICAM-1. Immunoperoxidase staining for ICAM-1 revealed that high levels ICAM-1 were detected in approximately 20% of the cells rather than an overall 20% increase in all cells. To study the role of ICAM-1 as a signal transduction molecule, MH-S cells were stimulated with SI, PMA or TNFα (as above) and incubated first with anti-ICAM antibody and then with a goat anti-rat crosslinking antibody. Crosslinking of ICAM-1 resulted in a significant increase in the respiratory burst as detected by the H2DCF oxidation assay. These data suggest that macrophage associated ICAM-1 may play a role in potentiating the phlogistic effects of particle and cytokine stimulation. (Funded by UCRF.)

607 THE ROLE OF CYP2B1 AND CYP2E1 ON M-XYLENE METABOLISM IN RAT PULMONARY AND HEPATIC MICROSOMES, INVITRO.

E E Reverdy and R A Schatz. *Northeastern University, Boston, MA, USA.*

Xylenes are volatile organic solvents known to be metabolized by the mixed-function oxidase (MFO) system and have previously been shown to selectively inhibit pulmonary cytochrome P450 (CYP450) activities after i.p. or inhalation exposure. The *m*-tolualdehyde (*m*-ALD) metabolite of *m*-xylene (*m*-XYL) was hypothesized to inhibit pulmonary CYP2B1 activity, at least in part, by CYP2E1-mediated formation and removal of *m*-ALD. CYP2B1 and CYP2E1 substrates, benzyloxyresorufin (BZR) and pyrazole (PYR), respectively, were used to modulate the effects of *m*-ALD formation on CYP2B1 activity, *in vitro*. Formation of *m*-ALD was measured using a 2,4-dinitrophenylhydrazine HPLC method. CYP2B1 was the primary isozyme involved in *m*-ALD formation from *m*-XYL in the lung, while CYP2E1 had a greater role in the liver. Participation of these two isozymes in the formation of *m*-ALD from *m*-XYL was dose dependent in both tissues. Inhibition of CYP2E1 activity, *in vitro*, by 1-heptanol confirmed the relationship between *m*-ALD levels and inhibition of CYP2B1 activity in both lung and liver microsomes. In liver, CYP2E1 played a greater role as supported by decreased CYP2B1 inhibition by 1-heptanol-mediated CYP2E1 inhibition and the subsequent increase in *m*-ALD formation. In lung, 1-heptanol significantly increased the *m*-XYL-induced CYP2B1 inhibition with an associated increase in *m*-ALD formation. In addition, lung and liver microsomes had a time-dependent removal of CYP2B1 inhibition correlated (r=0.97) with removal of exogenous *m*-ALD levels. It can be concluded from these studies that the tissue-selective inhibition of pulmonary CYP2B1 activity is a function of rapid *m*-XYL metabolism by high CYP2B1 activity resulting in *m*-ALD formation which is ineffectively removed by low pulmonary CYP2E1 activity as compared with liver.

608 MONOTERPENES AS SENSORY IRRITANTS.

J-P Kasanen[1], A-L Pasanen[1], P Pasanen[1], J Liesivuori[2], and Y Alarie[3]. [1]*University of Kuopio, Kuopio, Finland;* [2]*Kuopio Regional Institute of Occupational Health, Kuopio, Finland;* [3]*University of Pittsburgh, PA, USA.*

The sensory irritancy of the enantiomers of α- and β-pinene (Kasanen et al., Arch. Toxicol. 72; 514, 1998), D-Δ^3-carene and the monoterpene mixture, turpentine, have now been studied using the computerized version of the ASTM E981-84 bioassay. Experimental results revealed that pinenes and carene possess sensory irritation properties; D-pinenes and D-Δ^3-carene being the most potent and L-α-pinene the weakest sensory irritant. RD_{50}

(i.e., the airborne concentration which causes a 50% decrease in respiratory rate) for D-α- and D-β-pinene, and D-Δ^3-carene were almost equal: 1053 ppm, 1279 ppm and 1345 ppm in outbreed OF1 mice, respectively. L-β-pinene was about 4 to 5 times weaker as sensory irritant with RD_{50} of 4663 ppm. For L-α-pinene, the RD_{50} could not be determined because its very weak sensory irritating properties. The RD_{50} of turpentine was 1173 pmm. The turpentine used consisted mainly of D-Δ^3-carene (53.1%), L-β-pinene (14.7%) D-α-pinene (10.6%), L-α-pinene (3.8%) and limonenes (5.6%) indicating that D-monoterpenes might be responsible for the sensory irritation caused by turpentine. For nonreactive chemicals, vapor pressure (P^o) and olive oil-gas partition (L_{Oil}) can be used to estimate their potency as sensory irritant. Thus, for enantiomers with close physicochemical properties, the estimated RD_{50}s will be similar. This can be used to estimate the RD_{50} of a mixture. However, because of the inactivity of L-α-pinene, the 3-dimensional structure must be taken into account. Thus, the target site for nonreactive sensory irritants is most likely a receptor protein capable of chiral recognition and physicochemical descriptors alone may overestimate the potency of some enantiomers in a mixture.

609 GENOTOXICITY AND IMMUNOLOGICAL CHANGES IN ISOCYANATE EXPOSED BROWN NORWAY RATS.

P D Siegel, B-Z Zhong, T E Lawrence, and D M Lewis. *NIOSH, Morgwntown, WV.*

Methylene di-phenyl diisocyanate (MDI) is an important chemical used to make many polyurethane products such as foams and wood binders. The predominant occupational disease attributed to isocyanates including MDI is asthma, however, the potential for genotoxicity has also been of concern. Diisocyanates are very reactive. MDI can be hydrolyzed to methylene dianiline (MDA), and/or react with primary amines and thiols under physiological conditions. MDA is a carcinogen in animals and is a suspected carcinogen in humans. Brown Norway rats (BNR) were exposed to either 7 (LOW) or 113 mg/m^3 (HIGH) MDI aerosol for 1 hr, 1x/week for 3 weeks with sacrifice 1 week later. A third, acute 135 mg/m^3 (ACUTE) MDI aerosol, 1 hr exposure group was sacrificed within 1 hr of exposure to assess acute eosinophilic inflammation. Bone marrow was recovered from HIGH and LOW groups to assess micronuclei formation in polychromatic erythrocytes (PCE) and peripheral blood for measurement of specific antibodies. Trachea and bronchial alveolar lavage were assessed for inflammatory changes. Dose dependent formation of PCE micronuclei formation was noted in MDI exposed BNR. Preliminary *in vitro* evidence suggest that the genotoxicity may have been mediated through the formation of MDA and/or thioester MDI conjugates. Eosinophilic inflammation measured by histochemical diaaminobenzidine staining of tracheal sections was present only in the acute inflammatory response. T-cells were slightly elevated in the BAL of half of the HIGH MDI exposed BNR, and the cd4/cd8 ratio was normal. MDI-specific IgE was detected in 5/6 and 4/6 of the rats from the LOW and HIGH groups, respectively. MDI-specific IgG was detected in all rats from both groups. These data demonstrates the genotoxic potential along with the allergenic effects of MDI aerosol exposure in the BNR model.

610 RESPONSE OF SHEEP HEMOGLOBIN TO NOSE-ONLY, INHALED NITROGEN DIOXIDE AND CARBON MONOXIDE MIXTURE.

N M Elsayed, M T Williams, K L Armstrong, C D McKinley, and A J Januszkiewicz. *Department of Respiratory Research, Division of Medicine, Walter Reed Army Institute of Research, Washington, DC.*

Nitrogen dioxide (NO_2) and carbon monoxide (CO) are gases produced during fires threatening life and health, because they cause lung injury and impair hemoglobin (Hb) O_2 carrying capacity. If the brain's O_2 supply is reduced, the ability for timely and rational response may be impaired. To study the changes in Hb oxygenation after exposure to NO_2+CO mixture, we used 5 healthy crossbred ewes weighing 70-80 kg, each prepared with a chronic carotid artery loop a month earlier. The sheep inhaled a mixture of (150±10 ppm NO_2+3500±400 ppm CO) for 30 min via the nose using a plastic canine anesthesia mask. Gas concentrations were measured. Arterial (A) and venous (V) blood samples were collected before (Pre), and at 0h, 1h, 4h, and 24h post exposure. Blood was immediately analyzed using a Hemoximeter, and packed cell volume was measured. All sheep survived the exposure, and packed cell volume was not altered. Maximum effect in blood was at 0h post exposure where carboxyHb (COHb) increased 40-fold from <1% to 39.5%, and metHb doubled from 0.8 % to 1.6%. Both returned to control levels by 24h. To follow the kinetics of COHb and metHb formation, we collected blood from two sheep every 5 min during exposure. We found that COHb increased 1% / min, whereas metHb increased at 0.025% / min only. Exposures of rats to similar levels of NO_2 + CO were lethal. This raises a question about extrapolating single species data to humans, and whether small animals alone are suitable for predicting human response or setting environmental and occupational standards.

611 TRICHOTHECENE TOXINS ARE PRESENT IN NON-VIABLE *STACHYBOTRYS CHARTARUM* SPORES.

J J McGrath, N Markham, J D Cooley, W C Wong, and D C Straus. *Department of Physiology and Department of Microbiology and Immunology, Texas Tech University Health Sciences Center, Lubbock, TX.*

Fungi are a significant etiological factor in Sick Building Syndrome. Buildings whose occupants register complaints concerning indoor air quality (IAQ) frequently have high concentrations of Penicillium sp. present in the air and/or Stachybotrys on building surfaces. Stachybotrys sp. are thought to be involved in IAQ problems by virtue of their production of trichothecene toxins. This study determined if spore viability was a prerequisite for the toxigenic properties of S. chartarum, or if the trichothecene toxins were contained in the spores. Toxigenic S. chartarum spores were washed with phosphate buffered saline and incubated with rat alveolar macrophages (RAM) attached to microtiter plates. This treatment caused a dose- and time-dependent loss of RAM viability. Rendering the spores non-viable (NV) with ultraviolet-irradiation did not reduce spore toxicity. Washing S. chartarum spores with absolute methanol extracted the trichothecene toxins and rendered the spores NV. Methanol extraction reduced the toxigenic effect, but, overtime, the RAM were still killed by the S. chartarum spores. These data suggest that at least some of the trichothecene toxins are embedded in the S. chartarum spores and emphasizes the importance of removing S. chartarum spores from the indoor environment regardless of their viability. (These studies were supported in part by QIC Systems.)

612 BIOMARKERS OF CELL PROLIFERATION AND FIBROSIS IN MICE AFTER INHALATION OF ASBESTOS: APPLICATION TO TRANSGENIC MODELS USING LUNG EPITHELIAL CELL-SPECIFIC PROMOTERS FOR MODIFICATION OF MITOGEN-ACTIVATED PROTEINKINASE SIGNALING CASCADES.

R F Robledo, A B Cummins, E S Walsh, S A Buder-Hoffmann, M W Jung, C R Timblin, P M Vacek, D J Taatjes and B T Mossman. *Environmental Pathology Program, Department of Pathology, University of Vermont College of Medicine, Burlington VT, USA.*

Work in our laboratory has linked activation of certain Mitogen-Activated Protein Kinases (MAPK) to the advent of asbestos-associated apoptosis and proliferation in rodent mesothelial and alveolar type II epithelial cells *in vitro*. These phenotypic endpoints may be linked to the development of pulmonary or pleural fibrosis and/or repair. To address this question, we are developing transgenic mouse models using dominant negative mutant constructs of the Extracellular Signal-Regulated (ERK) and c-Jun-N-terminal (JNK) kinases using lung epithelial cell-specific promoters. The goal of work here was to characterize the development of inflammation, epithelial cell proliferation, and fibrosis in the parental mouse strain, C57Bl/6, after inhalation of NIEHS chrysotile asbestos (~7mg/m^3 air, 6hr/day, 5d/wk). Mice (2 month old, N=5/group/time period) were exposed for periods of time up to 30 days and evaluated for 1) total protein and cell counts in bronchoalveolar lavage fluid (BAL); 2) hydroxyproline content in lung; 3) increases in incorporation of 5-bromo-2'-deoxyuridine (BrdU) in bronchiolar and alveolar type II epithelial cells; 4) histopathology; and 5) procollagen type I message levels in lung. Data show that inflammation occurs in chrysotile-exposed mice as evidenced by increases ($p<.05$) in total protein and increased neutrophils in BALF after 10 and 20 days of exposure. These changes preceded increases in cell proliferation ($p<.05$) at 30 days in bronchiolar and alveolar epithelial cell compartments. Histopathology revealed the development of focal pulmonary fibrosis at 30 days in the absence of increases in lung hydroxyproline or elevations in procollagen type I mRNA levels. Comparative studies using NIEHS crocidolite asbestos are in progress to determine if patterns of inflammation, proliferation and fibrosis are more striking with use of this asbestos type. (Supported by a NIEHS Environmental Pathology Training grant (T32ES07122) and grants from NHLBI and NIEHS.)

613 MODULATION OF OZONE ABSORPTION BY INTERFACIAL PHOSPHOLIPIDS.

M Jacobson[1], J A Clements[2], J Goerke[2], A Bidani[1], and E M Postlethwait[1]. [1]*Pulmonary Research Laboratories, University of Texas Medical Branch, Galveston, TX and* [2]*Cardiovascular Research Institute, University of California, San Francisco, CA.*

Reactions of ozone (O_3) and nitrogen dioxide (NO_2) with constituents of the lung surface lining layer mediate the net flux of inhaled oxidant into the aqueous phase (reactive absorption). Recent studies have shown that monolayers of dipalmitoyl phosphatidylcholine (DPPC), the major component of alveolar surfactant, modulate NO_2 uptake. When DPPC, deposited on an aqueous surface, was subjected to increased molecular packing (surface compression), NO_2 reactive absorption was significantly reduced. To investigate potential phospholipid (PL) induced effects on O_3 uptake, the rates of O_3 gas phase disappearance (25° C) were evaluated using a specialized exposure-compression apparatus. Determinations of O_3 mass balance across a defined surface area were conducted during graded PL surface compressions. DPPC, dilinoleoyl-PC (DLPC) or palmitoyloleoyl PG (POPG) monolayers were compressed from 121 → 49 Å²/molecule, γ = 72 → 25 dyn/cm respectively. Apparatus constraints prevented further compression. **Results:** 1) At the initial area/molecule level, PL did not alter O_3 (0.6 ± 0.1 ppm) absorption rates. 2) Upon DPPC compression, uptake declined proportional to surface compression (3.5 → 1.2 μg $O_3 \bullet min^{-1} \bullet cm^{-2}$). 3) DPPC-induced reductions occurred regardless of aqueous substrate concentration, composition, or [O_3] (0.3 to 1.0 ppm). 4) Compression of POPG or DLPC monolayers did not significantly decrease uptake. 5) DLPC, extracted from O_3-exposed liposomes, when compressed displayed similar surface tensions and O_3 absorption as previously unexposed. **Conclusions:** Compression of DPPC monolayers to surface tensions which are still greater than those occurring *in vivo* significantly limits O_3 flux into the aqueous phase. Under the exposure conditions employed in these studies, it is unlikely that O_3 reactions with interfacial phospholipids contribute significantly to absorption, nor do such reactions appear to alter PL surface active properties. (HL54696, ESO5749, and HL24075)

614 ADHESION MOLECULES ON BLOOD NEUTROPHILS AND ALVEOLAR MACROPHAGES FROM RATS: MODULATION BY EXPOSURE TO OZONE.

E Hoffer[1], Y Baum[1], A Tabak[1], and C Frevert[2]. [1]*Israel Poison Information Center, Rambam Medical Center, Haifa, Israel;* [2]*Seattle VA Medical Center, Seattle, WA.*

It is known that exposure of rats to the pulmonary irritant ozone results in an infiltration of polymorphonuclear leukocytes (PMNs) into the lungs. The purpose of this study was to investigate whether the ozone-induced inflammatory process is preceded by a change in the expression of integrins and selectins in peripheral blood PMNs and alveolar macrophages. Female Sprague Dawley rats were exposed to air or ozone (1 ppm, 2 or 4 hrs). Bronchoalveolar lavage (BAL) was carried out and blood was collected via intracardiac puncture at 0 or 18 hrs after the exposure. The percent of neutrophils in the BAL fluid was increased only in animals exposed to ozone for 4 hrs and not for 2 hrs, while the expression of CD18 on alveolar macrophages was lowered at all exposure times. The expression of CD62L on blood PMN was not affected by exposure to ozone, while the expression of CD11b was lowered after 2 hrs, and not after 4 hrs of exposure to ozone. This trend was also observed in experiments in which plasma of ozone-exposed animals was incubated with whole blood obtained from non-exposed animals. In these experiments, the expression of CD11b on PMNs of non-exposed animals was lower after incubation with plasma from 2 hours-ozone-exposed animals, but not after incubation with plasma from 4 hours-ozone-exposed animals. (This work was supported by a grant from the Committee on Prevention and Research in Occupational Health at the Ministry of Labour and Social Welfare.)

615 ACUTE INFLAMMATORY REACTION IN RATS AFTER INTRATRACHEAL INSTILLATION OF MATERIAL COLLECTED FROM A NYLON FLOCKING PLANT.

V Castranova, D W Porter, A F Hubbs, V A Robinson, T Goldsmith, L Battelli, J Burkhart, C Piacitelli and W Jones. *NIOSH, Morgantown, WV.*

The etiologic agent responsible for several cases of interstitial lung disease among workers at a nylon flock plant was unknown. Airborne dust collected at the plant was examined for its inflammatory potential in rat lungs. The endpoints measured were: (1) breathing rates, (2) differential cell counts of bronchoalveolar lavage cells, (3) alveolar macrophage (AM) chemiluminescence, (4) albumin in the acellular bronchoalveolar lavage, and (5) pulmonary histopathology. In the first study, rats received a single dose of the airborne dust sample (10 mg/kg body weight) by intratracheal (IT) instillation. At 1 day post-IT, all inflammatory endpoints were significantly increased ($p<0.05$) versus controls but by 29 days post-IT they did not differ significantly ($p>0.05$) from controls. Histopathology demonstrated mild to moderate, multifocal, suppurative pneumonia usually centered around bronchioles at 1 day post-IT. At 29 days post-IT, pulmonary inflammation was minimal to mild and characterized by alveolar histocytosis usually restricted to the immediate area of retained birefringent fibers. In subsequent experiments, airborne dust was extracted with water and the dust (washed airborne dust) and water extract (soluble fraction) were separated by centrifugation. Nylon dust was prepared in the laboratory by milling uncut nylon strands that had not been treated with finish or dyes which are commonly used in nylon flock plants. Rats were administered a single dose of a dust sample (10 mg/kg body weight) or the soluble fraction (1.3 ml/kg body weight) by IT administration and the same endpoints were measured at 1 day post-IT. The dust samples caused significant increases in all of the inflammatory end points; however the soluble fraction was by far the least active. Histological analysis of the lungs 1 day post-IT confirmed lung inflammation was occurring only after dust instillation and tended to center around bronchioles. The results suggest: (1) nylon flocking generates particles of respirable size which can interact with AM and can be detected in the lung 29 days after exposure, (2) the dusts examined cause an inflammatory response, (3) water extractable agent(s) from airborne dust contribute minimally to the inflammatory response, and (4) the acute inflammatory response to these dusts is substantial when compared to other pathologic occupational dusts previously examined.

616 INTRATRACHEAL INSTILLATION OF WELDING FUMES ALTERS THE PULMONARY CLEARANCE OF *LISTERIA MONOCYTOGENES* IN THE RAT.

J M Antonini and T G Charron. *HELD, National Institute for Occupational Safety and Health, Morgantown, WV, USA.*

Epidemiological studies have shown an increased incidence of respiratory illness in welders. Stainless steel (SS) welding fumes have been shown to have a greater effect on alveolar macrophage (AM) function than mild steel (MS) fumes. The objective of this study was to evaluate the effects of different welding fumes on the clearance of a bacterial pathogen from the lungs. Fumes were collected during flux-cored manual metal arc (MMA) and gas metal arc (GMA) welding using either SS or MS consumable electrodes. The fume composition was: **1) GMA-SS**: 52.3% Fe, 22.2% Cr, 18.3% Mn, 4.9% Ni, 2.3% Si; **2) GMA-MS**: 89.2% Fe, 8.2% Mn, 2.6% Si; **3) MMA-SS**: 22.3% K, 19.4% Fe, 13.1% Cr, 12.6% Si, 8.2% Ca, 8.0% Mn, 17.4% other. CD/VAF rats were dosed intratracheally with saline (control) or the welding samples at a dose of 1.0 mg/100 g b wt. At 1 and 35 days post-instillation, 5000 *Listeria monocytogenes* were intratracheally instilled into the treated animals. Five days after intratracheal exposure to *L. monocytogenes*, the lungs and spleen were removed, homogenized, and cultured quantitatively on Brain Heart Infusion agar at 37° C. Colony forming units (CFUs) were counted after an overnight incubation. After a 1 day fume treatment, all three welding samples caused a significant decrease ($p<0.05$) in the 5-day clearance of *L. monocytogenes* from the lungs as compared to control. At 35 days post-instillation, the MMA-SS and GMA-SS samples significantly increased ($p<0.05$) *L. monocytogenes* clearance from the lungs as compared to the GMA-MS and control groups. No significant differences were seen among the treatment groups in the number of bacteria cultured from the spleen. We have demonstrated that subchronic exposure to SS fumes may have a greater effect on the pulmonary clearance of *L. monocytogenes* as compared to MS fumes. This is most likely due to differences in fume composition and the greater effect of SS fumes on AM function.

617 APOPTOSIS INDUCTION AFTER SILICA INHALATION IN RATS.

F Suarez[1], D W Porter[1], R Mercer[1], L Millecchia[1], V Castranova[1], D Ramsey[2], A Khan[2], J L McLaurin[2] and A Teass[2]. [1]*HELD, NIOSH, Morgantown, WV;* [2]*DBBS, NIOSH, Cincinnati, OH.*

Occupational exposure to crystalline silica (quartz) has been associated with lung damage and fibrosis. In vitro studies have shown that silica induces apoptosis in human alveolar macrophages and in vivo after intratracheal

instillation in rats. These studies suggested that silica inhalation may stimulate apoptosis and that apoptosis may play a role in the silicotic process. A first step in investigating these questions would be to establish the temporal relationship between silica exposure, apoptosis and lung inflammation and damage. Thus, rats were exposed to filtered air (control) or silica aerosol of 15 mg/m^3 (6 hr/day, 5 days/week) and apoptosis in bronchoalveolar lavage cells (BALC) or lung tissue were determined during a 116 day exposure. The lung inflammatory response to inhaled silica was monitored by determining polymorphonuclear leukocyte and alveolar macrophages (AM) in BALC while lung damage was assessed by measuring acellular bronchoalveolar lavage fluid albumin. In silica-exposed rats, all three parameters were elevated versus controls from 5-41 days of exposure, then dramatically increased thereafter versus controls. Apoptosis in BALC was measured with a commercial ELISA assay kit, and values from silica-exposed rats were normalized to controls. The BALC data indicate that apoptosis was evident after only 5 days of exposure, increased steadily until 20 days of exposure, remained relatively constant through 79 days of exposure and then decreased. Lungs, removed from both control and silica-exposed rats, were fixed with 10% neutral buffered formalin and embedded in paraffin for further examination. Apoptosis was assessed in lung tissue slices using the TdT-mediated dUTP biotin nick end-labeling (TUNEL) assay. The TUNEL assay results were consistent with the observed trends in apoptosis measured in BALC and also indicated that the apoptotic cells were AM. These data indicate that the inhalation of silica stimulates apoptosis as predicted, and the magnitude of the apoptotic response changed during the silica exposure. Finally, the observed acceleration of lung inflammation and damage was associated with a decline in apoptosis, suggesting that apoptosis may play a role in the silicotic process.

618 TEMPORAL RELATIONSHIPS BETWEEN BIOCHEMICAL MEDIATORS OF LUNG DAMAGE AND FIBROSIS AFTER SILICA INHALATION IN RATS.

D W Porter[1], V Castranova[1], V A Robinson[1], J Y C Ma[1], M Barger[1], A F Hubbs[1], D Ramsey[2], A Khan[2] and J L McLaurin[2]. [1]*HELD, NIOSH, Morgantown, WV;* [2]*DBBS, NIOSH, Cincinnati, OH.*

Crystalline silica (quartz) is a well established inflammatory and fibrogenic occupational dust. Past studies have established numerous biochemical mediators of these processes, but the temporal relationships between them have not been determined. To investigate these temporal relationships, rats were exposed to filtered air (control) or silica aerosol of 15 mg/m^3 (6 hr/day, 5 days/week) and assays were conducted after 5, 10, 16, 20, 30, 41, 79 and 116 days of exposure. Rat lungs were lavaged to isolate bronchoalveolar lavage cells (BALC) and acellular bronchoalveolar lavage fluid (BALF). Pulmonary inflammation was monitored by measuring BALC polymorphonuclear leukocytes (PMN) and alveolar macrophages (AM) differential cell counts. Compared to control, PMN in BALC isolated from silica-exposed rats were significantly increased after 5 days exposure, remained elevated until 41 days, then increased further. BALC AM also were increased in silica-exposed rats, but only after 41 days exposure. Silica cytotoxicity was monitored by analysis of BALF for lactate dehydrogenase (LDH) and albumin. In silica-exposed rats, both LDH and albumin levels were increased versus control after 5 days exposure, remained relatively constant until day 41, then increased further. AM chemiluminesence, a measure of AM activation and reactive oxygen species production, was higher in silica-exposed rats when compared to control. After 41 days of exposure, lung lipid peroxidation was also higher in silica-exposed rats. BALC secretion of TNF-α and IL-1, when considered on a per cell basis, was higher in silica-exposed versus control rats by 116 days exposure. Lung fibrosis was confirmed by increased hydroxyproline levels in the lungs of silica-exposed but not control rats after 116 days exposure. These data indicate that a progressively severe inflammatory reaction occurs in response to inhaled silica and begins to establish the temporal relationships between the various components of the inflammatory response and the development of pulmonary fibrosis.

619 PULMONARY RESPONSES TO SINGLE VERSUS MULTIPLE INTRATRACHEAL INSTILLATIONS OF SILICA IN RATS.

M J Reasor[1] and J M Antonini[2]. [1]*Department of Pharmacology & Toxicology, West Virginia University;* [2]*NIOSH/HELD, Morgantown, WV.*

The pulmonary toxicity of particles is often studied using a single intratracheal (I.T.) instillation of the material. Criticism has been levied that this procedure is not representative of inhalation exposure. In this study, we compared the pulmonary responses in male F344 rats to a single I.T. instillation of crystalline silica (5 mg/100 gm BWt) given on day 0 with those resulting from 5 consecutive daily I.T. instillations of the dust (1 mg/100 gm BWt per day) with the initial dose given on day 0. Controls received the sterile saline vehicle I.T.. The multiple instillation protocol was used as an experimental surrogate for inhalation exposure. The total amount of silica instilled was the same in the two protocols. Responses were assessed on day 14. The indices of response were cellular differentials recovered by bronchoalveolar lavage (BAL) and the level of albumin in BAL fluid (BALF). With both instillation protocols, the total cells, PMNs, and lymphocytes recovered and albumin levels in BALF were increased significantly in the silica-treated rats versus the respective controls. There were no significant differences between the single and multiple instillation protocols for any of these values for either controls or silica-treated rats. Therefore, at this high dose of silica, where particle overload may be occurring, the single and multiple instillation protocols gave similar pulmonary responses using these endpoints. Responses at other doses of silica and the use of additional endpoints are being investigated.

620 HUMAN BRONCHOEPITHELIAL CELLS CAN DIRECTLY INDUCE LUNG FIBROBLAST GENE EXPRESSION OF EXTRACELLULAR MATRIX PROTEINS AND FIBROGENIC CYTOKINES FOLLOWING ASBESTOS EXPOSURE IN VITRO.

D S Lang, H Schocker and S Hockertz. *Fraunhofer Gesellschaft, Dept. of Toxicology and Environmental Medicine, Hamburg, Germany.* Sponsor: H Marquard.

Direct interactions between human pulmonary epithelial cells and lung fibroblasts, representing two cell types of central regulatory potential in (chronic) lung disease, were studied in a coculture system in vitro as a model for chemical-induced pulmonary lesions such as fibrosis. Membrane cultures of human bronchoepithelial cells (BEAS-2B) were exposed to crocidolite asbestos (2-100μg/cm^2) for 24 h or 96 h and subsequently cocultivated with human lung fibroblast (WISTAR-38) cultures in collagen gels for 48 h or 70 h, respectively. Gene expression of procollagens type I and III, fibronectin (FN) and of the fibrogenic cytokines IL-6 and GM-CSF was determined by RT-PCR. Gene expression of procollagens and FN showed slight but consistent increases less than twofold above control levels after 48 h or 70 h of cocultivation with bronchoepithelial cells pretreated with 50 and 100 μg/cm^2 crocidolite, which was most evident for procollagen type III and FN. Cytokine mRNA levels were already enhanced at the lowest fibre concentration and dose-dependently increased more than twofold above control values after 48 h cocultivation. Constitutive expression of steady-state mRNA levels of both cytokines appeared almost maximally induced in fibroblasts when cocultivated with epithelial cells for 70 h and therefore further enhancement by increasing asbestos concentrations remained less than twofold above controls. 24 h pretreatment of bronchoepithelial cells with nonfibrogenic titanium dioxide could only induce mRNA expression of the cytokines in fibroblasts which occured to a considerably lower extent and only at concentrations above 50 μg/cm^2 TiO_2. Our preliminary results suggest that bronchoepithelial cells can mediate enhanced fibroblast activity in vitro by interacting with fibrogenic agents and thus directly contribute to the development of long-term lung lesions such as fibrosis.

621 CELLULAR INJURY AND REPAIR: REVERSIBILITY OF PULMONARY FIBROTIC LESIONS IN RATS INHALING p-ARAMID RFP.

K E Pinkerton[1], A A Elliot[1], M A Hartsky[2], S R Frame[2] and D B Warheit[2]. [1]*Univ. California Davis, Davis, CA;* [2]*DuPont Haskell Lab, Newark, DE.*

Inhalation of asbestos and other fiber-types can induce lung fibrosis. This is considered to be a permanent cellular effect characterized by a progressive tissue thickening response. This study was conducted to assess injury and repair at sites of fiber deposition following high dose inhalation exposures to p-aramid RFP in rats. Rats were exposed to 419 and 772 p-aramid respirable-sized fiber-shaped particulates (RFP) per cubic centimeter (f/cc) for two weeks. Animals were sacrificed and tissue effects analyzed immediately after a 2-week exposure as well as 1, 4, 12, 26, and 52 weeks postexposure. Bronchiole alveolar duct junctions (BADJ) were identified, magnified, and morphometrically analyzed. The volume to surface area ratio (i.e., tissue density or thickness) of BADJs from both exposure groups were compared with sham control rats exposed to filtered air. The results showed that exposures to 419 and 772 p-aramid RFP/cc induced initial increases in tissue density at BADJs for the early postexposure time points. These increases in alveolar tissue volume were most prominent at the 1-4 week postexposure

periods but were not significantly different from controls at 3, 6, and 12 months postexposure. Similarly, morphometric studies measuring alveolar macrophage volume/surface area at BADJs demonstrated a peak at 1 month postexposure but no significant difference thereafter. These results demonstrate that the early fibrotic lesions related to high dose p-aramid exposures are repaired in the absence of continuing exposure, thus indicating reversibility of cellular injury.

622 THE INFLUENCE OF (1→ 3)β -D GLUCAN ON ENDOTOXIN-INDUCED ACUTE PULMONARY INFLAMMATION.

C J Roy, M E O'Neill, and P S Thorne. *Institute for Rural and Environmental Health, University of Iowa School of Public Health, Iowa City, IA, USA.*

Organic dust aerosols, known to cause respiratory disease among farmers, are composed of biogenic agents including bacteria, fungi, aeroallergans, excreta, dander, bacterial endotoxins (Etx) and glucans. *Sclerotinia sclerotiorum* (Ss) is an emerging phytopathogenic soybean fungus rich in highly branched, water soluble (1→ 3)β -D glucans to which farmers are exposed. After a first study revealed reduced Etx-induced pulmonary inflammation in mice instilled with Ss extract and Etx, experiments were performed to assess the influence of Ss glucan content in the blunting of Etx-induced inflammation. BALB/cJ mice were intratracheally instilled with 50 μ g of purified scleroglucan (GL) alone, 50 μ g of Ss alone; or 50 μ g of GL or Ss in combination with 0.25 μ g of Etx, or saline (control). Bronchoalveolar lavage (BAL) collected 4 hr postexposure from the Etx group showed an increase in total BAL cells (96% neutrophils) with an increase of MIP-2, TNF-α and IL-6 over controls. GL or Ss exposure alone did not induce changes in BAL cellularity or MIP-2 concentration when compared to controls. However, a reduction of % BAL neutrophils ($p<0.01$) was observed in the GL+Etx group when compared with the Etx group, although total BAL cells remained elevated. The neutrophil response of the Ss+Etx group was similar to the GL+Etx group ($p<0.01$), and total BAL cells were significantly reduced when compared to the Etx group ($p<0.01$). These results suggest that an antagonistic dose-response relationship exists for concomitant GL+Etx exposures and the soluble glucans in *S. sclerotiorum* may be responsible for the reduction of pulmonary inflammation. (Supported by CDC/NIOSH U07/CCU706145 and the Iowa Center for Health Effects of Environmental Contamination.)

623 PULMONARY INFLAMMATORY RESPONSES AFTER EXPOSURE TO OZONE ARE ENHANCED IN ENDOTOXEMIC RATS.

J G Wagner[1], J R Harkema[2] and R A Roth[1]. *Dept. of [1]Pharmacology and Toxicology and Dept. of [2]Pathology, Michigan State University, E. Lansing, MI, USA.*

Inhalation exposure to environmental ozone and systemic exposure to LPS through infection or translocation from the gastrointestinal tract into the circulation are commonplace in people. Acute exposure to ozone causes pulmonary inflammation in rats that is characterized by an early influx of neutrophils (PMNs) into airways. Systemic exposure of rats to small, nontoxic doses of bacterial endotoxin (lipopolysaccharide, LPS) can potentiate deleterious effects of environmental toxicants. To explore effects of a nontoxic dose of systemic LPS on ozone-induced pulmonary inflammation, we evaluated PMN recruitment and inflammatory cytokines in airspaces of Sprague-Dawley rats exposed first to either ozone (1 ppm for six hr) or air and then to either E. Coli LPS (2 mg/kg, i.v. ; $50x10^6$ EU/kg) or its saline vehicle. Three hr after LPS administration, PMNs and cytokines were quantified in bronchoalveolar lavage fluid (BALF). Exposure to ozone alone caused an increase in PMNs and protein recovered in BALF, whereas exposure to LPS alone did not. In rats made endotoxemic after ozone exposure, BALF PMNs were increased compared to rats exposed to ozone alone. Morphometric evaluation of lung tissues showed increased numbers of PMNs in alveolar septa of rats given LPS irrespective of ozone exposure. Examination of inflammatory mediators revealed no or small amounts of tumor necrosis factor-alpha and macrophage chemotactic protein-1 in BALF of rats exposed to LPS or ozone alone, but markedly elevated levels when ozone-exposed rats were made endotoxemic. These results demonstrate that endotoxemia can enhance PMN recruitment into airways of rats exposed to ozone and that this enhancement is associated with markedly elevated release of inflammatory cytokines. (Supported by NIH grant R37ES02581.)

624 ACUTE SMOKE-INDUCED LUNG INJURY IS RELATED TO TUMOR NECROISIS FACTOR-α mRNA GENE AND PROTEIN EXPRESSION IN ALVEOLAR MACROPHAGES.

S Wang[1], R C Lantz[2], M W Vermeulen[3], and M L Witten[1]. *[1]Department of Pediatrics, [2]Departments of Cell Biology & Anatomy, Center for Toxicology, University of Arizona, Tucson, AZ, USA; [3]Pulmonary and Critical Care Unit, Massachusetts General Hospital, and Harvard Medical School, Boston, MA, USA.*

Acute inhalation of diesel fuel-polycarbonate plastic (DFPP) smoke causes severe lung injury, leading to acute respiratory distress syndrome (ARDS) and death. It has been reported that the initiation of acute lung injury is associated with activation of pulmonary alveolar macrophages (PAM). To further explore the pathogenesis, PAM of New Zealand rabbits ventilated and exposed to a 60 tidal volume of DFPP smoke *in vivo* were recovered at 1 hour post-smoke. Smoke exposure induced a significant increases in both mRNA and protein levels for PAM tumor necrosis factor-α (TNF-α), when compared to smoke control. Smoke also induced a biphasic response (inhibited at 2 hours, enhanced at 24 hours after cell isolation) in the production of superoxide (O_{2-}) by PAM. However, aerosolized lazaroid U75412E (1.6mg/kg body weight) significantly attenuated smoke-induced expression in PAM TNF-α at the protein level, but not at the mRNA level, and smoke-induced changes in PAM O_{2-}. These changes were paralleled with lung cellular morphological alterations and gas exchange function. This study suggests that highly expressing PAM TNF-α following smoke may be a key contributor to the cascade that establishes an acute injury process and exacerbates oxidant-derived cell injury. Whereas, the lazaroid may ameliorate smoke-induced lung injury by attenuating PAM TNF-α release, in addition to its primary antioxidative mechanism. (Supported by DAMD 17-94-J4001 and NIH ES06694.)

625 PHYSICAL AND CHEMICAL DEGRADATION OF SYNTHETIC VITREOUS FIBERS IN THE LUNG AND IN VITRO.

G A Hart, T W Hesterberg, and J F Bauer. *Johns Manville, Denver, CO, USA.*

Recent rodent inhalation studies of synthetic vitreous fibers (SVFs) and asbestos show a correlation between fiber biopersistence in the lung and fiber toxicity. Inhaled fibers longer than 20 μ m cannot be efficiently cleared by macrophages and therefore can be eliminated only by dissolution or by fragmentation into short segments. In rodent inhalation studies, the fast-clearing, non-toxic fibers demonstrated the following over time in the lung: long fibers cleared more rapidly than short fibers; surfaces became pitted; chemical composition changed; and mean length but not necessarily mean diameter decreased. The slower-clearing, toxic fibers did not show these changes to the same extent or at all. This suggests that incongruent dissolution (leaching) and transverse fragmentation were more pronounced in the non-toxic fibers and enhanced their clearance from the lung. The degradation of 18 fiber glasses was studied in vitro; a correlation between rate of leaching and transverse breakage was found. Additionally, two models of dissolution were demonstrated: (a) constant velocity (CV), the most popular model, which assumes a constant dissolution rate and simple dissolution (all components dissolve at the same rate); (b) diffusion controlled (DC), in which dissolution is incongruent and a hydrated, diffusion-limiting silica gel forms on the fiber surface. 901 fiber glass (MMVF10), which was non-toxic to rodents, fit the DC model. Fibers that fit the DC model underwent rapid transverse fragmentation long before they dissolved completely. Fiberization process (flame vs. air attenuation) strongly influenced in vitro leaching and dissolution rates. Taken together, these studies suggest that biopersistence is an important determinant of fiber toxicity and that, in addition to fiber length and dissolution, leaching and transverse breakage may be important mechanisms of fiber biopersistence.

626 STYRENE METABOLISM BY MOUSE AND RAT ISOLATED LUNG CELLS.

D E Hynes[1], D B DeNicola[2] and G P Carlson[3]. *[1]School of Pharmacy, [2]School of Veterinary Medicine and [3]School of Health Sciences, Purdue University, West Lafayette, IN, USA.*

Styrene has been shown to be pneumotoxic in mice. Rat and mouse pulmonary microsomes are capable of metabolizing styrene to styrene oxide (SO). To determine which cell types in lung are responsible for this metabolism, enriched cell fractions were obtained from mouse and rat lung and comparisons made. The rates of formation of both enantiomers of SO were

determined. The roles of specific cytochrome P450 isozymes were also evaluated using chemical inhibitors. Mouse Clara cells readily metabolized styrene to SO. Diethyldithiocarbamate, a CYP2E1 inhibitor, caused less inhibition of SO formation in Clara cells isolated from mice than in pulmonary microsomes. As in microsomes, 5-phenyl-1-pentyne, a CYP2F2 inhibitor, inhibited the formation of both enantiomers in isolated mouse Clara cells. α -Naphthoflavone, a CYP1A inhibitor, did not inhibit SO formation in isolated lung cells. α -Methyl-benzylaminobenzotriazole, a CYP2B inhibitor, exhibited some inhibition of SO production at 10 μ M and less at 1 μ M in isolated mouse Clara cells. The microsomal and isolated cell studies indicate that CYP2E1 and CYP2F2 are the primary cytochromes P450 involved in styrene metabolism. Styrene metabolizing activity was greater in Clara cells than in type II pneumocytes. It was higher in the mouse Clara cells than in rat Clara cells. R-SO was preferentially formed in mice, and S-SO was preferentially formed in rats. These findings suggest that differences in metabolism may be a reason for the greater susceptibility of the mouse to styrene-induced toxicity. (Supported by NIH grant ES04362 and a gift from the Styrene Information and Research Center.)

627 BIOKINETICS OF AN INHALED ULTRAFINE SILVER AEROSOL IN RATS.

G L Finch, K J Nikula, E B Barr, J C Seagrave, M B Snipes, and J L Mauderly. *Lovelace Respiratory Research Institute, Albuquerque, NM, USA.*

The possible role of ultrafine particles in the health effects of ambient air pollution makes it important to better understand the disposition of inhaled ultrafine particles deposited in the respiratory tract. Male F344/Crl rats, 12 wk of age, were exposed by inhalation to a radiolabeled ^{110m}Ag with a count median diameter of 25 nm. Rats received an initial body burden (IBB) of approximately 130 Bq at a particle mass of < 1 ng from the 35-min exposure. Immediately thereafter, then at 2, 6, 24, and 72 hr after exposure, groups of four rats were sacrificed to quantify the ^{110m}Ag in selected tissues. The ^{110m}Ag was cleared rapidly, with 53% and 25% of the IBB present at 24 and 72 hr, respectively. Over 98% of the ^{110m}Ag was excreted through the feces. As a percentage of the sacrifice body burden, the activity in lungs was 27%, 7%, and 2% at 6, 24, and 72 hr after exposure, respectively; the activity in the GI tract was 38% and 45% at 24 and 72 hr, respectively; and the activity in liver was 10% and 5% at 24 and 72 hr, respectively. A tissue digestion and ultracentrifugation technique was used to determine whether the ^{110m}Ag activity was present in selected tissues in a particulate or soluble form. Preliminary data suggest that the activity was predominantly particles in the lung and liver, and soluble in the blood. These data describe the biokinetics of an inhaled ultrafine aerosol in the rat and quantify the extent to which ^{110m}Ag is translocated from lung in particulate versus soluble forms. (Research supported by the US DOE Office of Energy Efficiency and Renewable Energy under Cooperative Agreement number DE-FC04-96AL76406.)

628 PHYSICAL CHARACTERISTICS IMPORTANT FOR THE IgE ADJUVANT ACTIVITY OF PARTICLES.

B Granum[1], P I Gaarder[2], M Løvik[1]. [1]*Department of Environmental Medicine, National Institute of Public Health, Oslo, Norway;* [2]*Department of Immunology and Transfusion Medicine, Ullevål University Hospital, Oslo, Norway.* Sponsor: E Dybing.

Diesel exhaust particles (DEP) are reported to increase the allergic immune response to the model allergen ovalbumin. DEP consist of a non-extractable carbon core with a variety of adsorbed chemical substances. DEP have an irregular shape, and form complex aggregates. Because of DEP's chemical composition and tendency to aggregate, it is difficult to determine which physical characteristics are the most important for the adjuvant effect: size, surface area, weight, shape, chemical composition or the number of particles. We performed, therefore, experiments with well characterised, spherical polystyrene particles. These particles are free from adsorbed chemical substances, and they do not so easily aggregate. We used particles with a diameter ranging from 0.06 to 10 μm. We performed four different types of experiments, in which particle size, total weight, total surface area or number of particles, respectively, was kept constant. NIH/Ola mice were given two intraperitoneal injections with polystyrene particles and ovalbumin or ovalbumin alone, over a sixteen days period. The mice were exsanguinated at the end of each experiment, and the serum concentration of IgE anti-ovalbumin was measured. For analysis of the data, graphs were used, one for each experiment. The IgE concentrations and the various physical factors were plotted in each diagram, with one physical factor kept constant. The concentration of IgE anti-ovalbumin increased with decreasing particle size, and also increased with an increasing number of particles. Neither surface area nor weight appeared to correlate with the concentration of IgE anti-ovalbumin. Our findings indicate that particle size and the number of particles are important factors for the IgE adjuvant activity of polystyrene particles, and possibly particles in general.

629 FURTHER CHARACTERIZATION OF EpRE BINDING PROTEINS AND THEIR FUNCTION IN VASCULAR SMOOTH MUSCLE CELLS.

K P Miller, M T Holderman and K S Ramos. *Department of Veterinary Physiology and Pharmacology & Center for Environmental and Rural Health, Texas A&M University, College Station, TX, USA.*

Ongoing efforts in this laboratory focus on the identification and characterization of proteins that bind and regulate Electrophile Response Elements (EpRE) within *c-Ha-ras* regulatory sequences. The present studies were conducted to further characterize EpRE binding proteins (EBPs) and their regulatory functions in vascular smooth muscle cells (vSMCs). Crosslinking experiments using the consensus *ras* EpRE identified multiple protein complexes that interact specifically with this sequence. A comparison of *c-Ha-ras* protein binding profiles to those in NQO_1 and GSTYa promoters revealed comparable patterns, although the relative abundance of individual complexes appeared to be promoter-specific. To assess the functional relevance of the protein complexes binding to the *c-Ha-ras* EpRE, subsequent experiments were conducted to further evaluate patterns of xenobiotic-inducibility. In agreement with earlier studies showing that activation of EpRE by benzo[a]pyrene (BaP) involves an oxidative mechanism, 3-hydroxy BaP (3-OH BaP) (0.03-3 μM) and BaP 7,8-diol (0.03-3 μM) activated EBP binding in vSMCs. Pretreatment of BaP and H_2O_2-challenged cells with the antioxidant N-acetyl cysteine (NAC) (0.5 mM) reduced oxidant-induced activation of EpRE binding. NAC also reduced constitutive protein binding to this element. Thus, a pathway involving binding of a redox-regulated transcription factor(s) to EpRE may contribute to transcriptional deregulation of *c-Ha-ras* by BaP and related oxidants. (Supported by NIH Grants ES 04849 and ES 09106.)

630 ESTROGEN SIGNALING IN TROUT LIVER: ESTROGEN RECEPTOR AND NON-ESTROGEN RECEPTOR MEDIATED CELLULAR RESPONSE?

S W Kullman[1], Leza Erecius[1], F Matsumura[2], E Enan[2], and D E Hinton[1]. [1]*School of Veterinary Medicine, Department of Anatomy, Physiology and Cell Biology and the* [2]*Institute of Toxicology and Environmental Health, University California, Davis, CA, USA.*

Studies were conducted to determine intracellular hepatic signaling pathways associated with estrogen exposure in rainbow trout. These studies were initiated as a first step in elucidating potential signal transduction pathways associated with exposure to environmental estrogens in fish. Studies include analysis of intracellular pathways that are dependent upon estrogen receptor signaling including vitellogenin and choriogenin biosynthesis, and key pathways thought to act through specific kinase cascades. Exposure of 5mg/kg estradiol to juvenile rainbow trout resulted in a strong and specific "estrogenic" response as measured by the de novo synthesis of vitillogenin and choriogenin in plasma of both male and female trout. Estrogen receptor levels were quantified by both E2 binding and mobility shift assays and demonstrated a significant increase in treated fish. Protein kinaseA (PKA) activity was consistently decreased in estrogen treated males and females, whereas juvenile female trout demonstrated a consistent increase in MAP kinase activity with a concatenate rise in the DNA binding activity of AP-1. Further studies are underway in our laboratories to address whether these cellular responses are estrogen receptor dependent and/or independent signaling events.

631 ANTIESTROGENIC EFFECTS OF 2,3,7,8-TETRACHLORO-DIBENZO-*p*-DIOXIN AND 3,4,4',5-TETRACHLOROBI-PHENYL IN ZR-75-1 HUMAN BREAST CANCER CELLS.

G Oenga[1,2], B C Spink[1] and D C Spink[1,2]. [1]*Wadsworth Center, New York State Department of Health, Albany, NY;* [2]*School of Public Health, State University of New York at Albany, Albany, NY.*

ZR-75-1 human breast cancer cells respond to treatment with 17β-estradiol (E_2) with an increased rate of pre-confluent cell growth and increased levels of mRNA encoding cathepsin D and estrogen receptor α (ER-α). In this

study, antiestrogenic effects of 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) and 3,4,4',5-tetrachlorobiphenyl (PCB 81) were investigated in ZR-75-1 cells. Effects of TCDD and PCB 81 on E_2-induced cell proliferation, estrogen metabolism, and the levels of RNAs encoding cathepsin D, ER-α, and the E_2-metabolizing cytochromes P450, CYP1A1 and CYP1B1, were evaluated. RNA levels were determined by using the competitive reverse-transcription polymerase chain reaction. The increase rate of pre-confluent cell proliferation elicited by 1 nM E_2 (a 1.4-fold increase over control) was completely blocked by co-treatment with 10 nM TCDD or 200 nM PCB 81. Similarly, elevations in the levels of cathepsin D and ER-α RNAs elicited by 1 nM E_2, 3- and 3.9-fold increases over control, respectively, were completely blocked by co-treatment with 10 nM TCDD or 200 nM PCB 81. Both TCDD (10 nM) and PCB 81 (200 nM) caused marked elevations in the levels of CYP1A1 RNA, eliciting 70- and 50-fold elevations over control, respectively. Levels of CYP1B1 mRNA were elevated 7-fold by exposure to 10 nM TCDD and 6-fold by exposure to 200 nM PCB 81. Rates of CYP1A1 and CYP1B1-catalyzed E_2 metabolism at the C-2, C-4, C-6α and C-15α were highly elevated by exposure to 10 nM TCDD or 200 nM PCB 81; E_2 2-hydroxylation was elevated 48-fold by exposure to 10 nM TCDD and 44-fold by exposure to 200 nM PCB 81. These results indicate that both TCDD and PCB 81 are potent antiestrogens in ZR-75-1 cells *in vitro*, and implicate a marked stimulation in the rate of estrogen metabolism in the antiestrogenic mechanisms of the two xenobiotics. 632 SENSITIVE MOLECULAR ASSESSMENT OF XENO-ESTROGEN ACTION IN THE UTERUS AND IN ENDOMETRIAL CELL LINES.

G Vollmer[1,2], E Strunck[1], A-C Hopert[1], W Wünsche[1], P Diel[3] and H Michna[3]. [1]*Med. Universität zu Lübeck, Lübeck, Germany;* [2]*Fraunhofer IUCT, Schmallenberg, Germany;* [3]*Institut für Morphologie und Tumorforschung, DSHS, Köln, Germany.* Sponsor: C-P Siegers.

Receptor dependent function of steroid hormones is known to be tissue specific. Therefore, potential advers effects of xenoestrogens have to be assessed in a tissue specific manner. The aim of the presented study was to assess xenoestrogen action in RUCA-I rat endometrial adenocarcinoma cells in vitro and in the uterus of DA/Han rats in vivo by analyzing the expression of estrogen-responsive marker genes. In vivo ovariectomized, syngeneic DA/Han rats were were treated for 3 days p.o. with bisphenol A (BPA; 200 mg/kg/d), p-tert.-octylphenol (OP; 200 mg/kg/d), o,p-DDT (500 mg/kg/d), daidzein (Dai; 500 mg/kg/d) and ethinylestradiol (100 μg/kg/d). In vitro RUCA-I cells were cultured on matrigel in a serum free defined medium and treated with the above substances in a concentration dependent manner. Estradiol and the antiestrogen ICI 182780 were used as controls. Gene expression was analyzed by either in vivo labelling and consecutive SDS-PAGE, Northern blotting or semiquantitative PCR. Regulation of expression of complement C3 in RUCA-I cells showed that Dai, OP and BPA were weakly estrogenic, whereas o,p-DDT had almost no effect. In vivo, ethinylestradiol and o,p-DDT down regulated clusterin expression dramatically and up regulated complement C3 expression. Treatment with Dai and OP down regulated clusterin expression significantly, indicative of a weak estrogenicity. BPA was ineffective in vivo. In conclusion, all compounds tested showed estrogenic effects in RUCA-I cells or rat uteri or both. Comparing the relative potencies of xenoestrogens in vivo and in vitro three different pictures arise: the relative potencies of Dai and OP were comparable in vitro and in vivo, BPA proofed to be weakly estrogenic in vitro and almost ineffective in vivo, conversely o,p-DDT exhibited a strong estrogenicity in vivo with an almost undetectable activity in vitro.

633 STRESS PROTEINS IN MOUSE UTERUS INCREASE UPON TREATMENT WITH ESTRADIOL, METHYL-TESTOSTERONE, MEDROXYPROGESTERONE AND FLUTAMIDE.

T H Umbreit[1], B R Fisher[1], A D Papaconstantinou[2], and K M Brown[2]. [1]*Health Sciences Branch, Center for Devices and Radiological Health, USFDA, Rockville, MD, USA;* [2]*Department of Biological Sciences, The George Washington University, Washington, DC, USA.*

We have previously shown that treatment of mice with estrogens changes uterine morphology and increases the levels of chaperon proteins in the uterus. These effects were seen with β -estradiol, tamoxifen (a mixed estrogen agonist/antagonist), diethylstilbestrol (a non-steroidal estrogen), and bisphenol A (a weak estrogen). Neither of these responses were observed following treatment with the glucocorticoid, dexamethasone. The changes in chaperon proteins correlated with uterine swelling and histological changes consistent with a typical estrogenic response. Here we examined the effect of three other compounds: methyltestosterone (MET at 10 ug/mouse/day), a weak androgen and anti-glucocorticoid; medroxyprogesterone (MED at 2 ug/mouse/day), a progestin; and flutamide (FLUT at 150 ug/mouse/day), a non-steroidal anti-androgen. B6C3F1 ovariectomized mice were treated with test compound, corn oil or estradiol for 4 days. Uteri were then removed and weighed. Uterine histology was examined, and stress protein levels were determined by Western blot analysis. Blots were probed with commercially available antibodies to the stress proteins hsp72, hsp73, hsp90α and grp94, among others. MED, MET, and FLUT produced increases in stress proteins similar to those seen with estradiol treatment, although they did not elicit uterotrophic effects. Thus, the stress protein response is not induced by uterine tissue alteration.

634 THE ANTIESTROGEN ICI 182,780 REVERSES THE EFFECTS OF β-ESTRADIOL ON UTERINE MORPHOLOGY AND STRESS PROTEIN LEVELS.

A D Papaconstantinou[1], K M Brown[1], B R Fisher[2] and T H Umbreit[2]. [1]*Department of Biological Sciences, The George Washington University, Washington, DC;* [2]*Health Sciences Branch, Center for Devices and Radiological Health, USFDA, Rockville, MD.*

We previously reported that β-estradiol (E2) tamoxifen, diethylstilbestrol, and bisphenol-A (a weak estrogen) increased uterine weights, altered histological morphology, and increased the levels of several stress proteins (hsps) in the uteri of mice. The present study evaluated the ability of the "pure" anti-estrogen ICI 182, 780 (ICI) to reverse the effects of E2 on uterine hypertrophy and hsp induction. Ovariectomized B6C3F1 mice were injected subcutaneously daily for 4 days with either corn oil (CO), 40 ng of E2, or a low (2 μg) or high (20 μg) dose of ICI alone or in combination with E2. Administration of ICI alone did not result in changes in uterine weights compared to control levels (CO). Co-administration of the high, but not the low, dose of ICI and E2 reversed the uterotrophic and body weight gain effects of E2 to near CO levels ($P<0.001$). The increases in the uterus of the levels of hsp90α, hsp72, hsp73 and of the glucose regulated protein, grp94 caused by E2 were decreased by either ICI treatment, whereas ICI alone had no effect on stress protein levels. Thus, stress protein induction by E2 could be prevented by co-administration of the anti-estrogen ICI.

635 IDENTIFICATION OF ELEMENT IN THE *bcl*-2 GENE PROMOTER REQUIRED FOR ESTROGEN RESPONSIVENESS.

L Dong, W Wang and S Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA.*

The *bcl*-2 protooncogene is expressed in diverse tissues and cells, and plays an important role as an inhibitor of apoptosis. Treatment of estrogen receptor (ER)-positive MCF-7 human breast cancer cells with 1 nM 17β -estradiol (E2) resulted in a 2.8-fold increase in *bcl*-2 mRNA levels. Results of initial studies demonstrated that E2-responsiveness of *bcl*-2 was associated with a 360 bp region (-1647 to -1289) of the *bcl*-2 gene promoter. Further deletion analysis showed that a construct containing the -1602 to -1532 region of the promoter (pBcl-2a) was also E2-responsive in transient transfection assays, and a series of constructs, pBcl-2b (-1602/-1577), pBcl-2c (-1577/-1532), and pBcl-2d (-1552/-1532), were prepared to identify functional enhancer elements. In transient transfection studies with pBcl-2a, pBcl-2b, pBcl-2c and pBcl-2d in MCF-7 cells, treatment with E2 resulted in a 2.2- to 3.2-fold induction of reporter gene activity suggesting that functional elements were present in both upstream and downstream regions of the 70 bp sequence. The upstream 25 bp sequence (-1602 to -1577) contained two GC-rich elements that bound Sp1 protein in gel mobility shift assays, and cotreatment with ER enhanced retarded band formation. Mutational analysis confirmed that both Sp1 binding sites are required for hormone-inducibility. Current studies are focused on analysis of the E2-responsive downstream 21 bp sequence (-1552 to -1532), and these results will be discussed. (Welch Foundation and NIH CA76636)

636 A GC-RICH SITE IN THE THYMIDYLATE SYNTHASE GENE PROMOTER IS REQUIRED FOR ESTROGEN-RESPONSIVENESS IN MCF-7 HUMAN BREAST CANCER CELLS.

W Xie, R Duan and S Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA.*

It has previously been reported that 17β -estradiol (E2) induces DNA synthesis and thymidylate synthase (TS) activity in MCF-7 cells. This study investigated the molecular mechanism of this response using a series of constructs containing the following TS gene promoter sequencess: -441 to +28 (pTS1), -229 to +28 (pTS2),-140 to +28 (pTS3) and -229 to -140 (pTS4). Ten nM E2 induced a 2.2-fold increase in chloramphenicol acetyl transferase (CAT) activity in MCF-7 cells transiently transfected with pTS2, whereas minimal induction was observed for pTS1 or pTS3. In cells transfected with pTS4, E2 induced a 2.8-fold increase in CAT activity, thus indicating that the -229 to -140 region of the TS gene promoter contained elements required for E2-mediated transactivation. This region of the promoter contains two GC-rich sites at -299 to -220 and -150 to -140, and pTS4m1 and pTS4m2 are mutated at each of these two sites, respectively. Results of transient transfection studies demonstrated that only pTS4m1 was E2-responsive indicating that the downstream GC-rich site was required for hormone inducibility. In gel mobility shift assays, recombinant Sp1 protein formed a retarded band with the -150 to -140 region of the TS promoter, and co-incubation with estrogen receptor protein enhanced Sp1-DNA binding. The results indicate that TS is another E2-inducible gene in MCF-7 cells that is regulated via ER/Sp1 interactions at a specific GC-rich site. (Welch Foundation and NIH CA76636)

637 ANTIESTROGENIC ACTIVITY OF DIINDOLYLMETHANE ANALOGS IN HUMAN BREAST CANCER CELLS: STRUCTURE ACTIVITY RELATIONSHIPS.

M S Gupta, K Yoon, K Ramamoorthy, A McDougal and S H Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA.*

The anticarcinogenic effects of cruciferous vegetables are due, in part, to indole-3-carbinol and its acid-catalyzed metabolites including diindolylmethane (DIM). This study characterizes the *in vitro* activity of DIM and 18 structurally-related analogs in T47D and MCF-7 human breast cancer cells. Data from cell proliferation assays in T47D cells treated with DIM and 18 halo- and alkyl-substituted analogs show that none of these compounds alone (0.1-10 μ M) induced cell proliferation, whereas 1 nM 17β -estradiol (E2) induced up to an 18-fold increase in cell number. In cotreatment studies (E2 + 0.1-10 μ M DIMs), 5 μ M concentration of all analogs inhibited 50-90% of E2-induced cell proliferation, whereas 5,5N -dichloro- and 5,5N -dimethyl-DIM inhibited 51% and 53% of E2-induced cell growth, respectively, at 1 μ M concentration. Similar results were obtained in MCF-7 cells. IC_{50} values for competitive binding to the rat hepatic aryl hydrocarbon receptor (AhR) varied from 6.9×10^{-10} to 2.4×10^{-6} M, and the most active congeners were DIM, 5,5N -dibromo- and 5,5N -dichloro-DIM. DIM and the substituted analogs (10-100 μ M) exhibited minimal induction (<2-fold) of ethoxyresorufin *O*-deethylase (EROD) activity, whereas TCDD (10 nM) exhibited a maximal 45-fold induction response in T47D cells. The response profile for DIM and its structural analogs, namely low AhR-mediated induction of EROD activity and high antiestrogenic activity, indicates that substituted DIMs represent a new class of AhR-based antiestrogens for treatment of breast cancer. (Supported by the State of Texas Advanced Technology Program.)

638 ESTROGEN RECEPTOR (ER) Sp1 PROTEIN INTERACTIONS WITH ER COACTIVATORS.

T A Nguyen and S Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA.*

Research in this laboratory has demonstrated that the estrogen receptor (ER) and Sp1 proteins physically interact and mediate 17β -estradiol (E2)-dependent transcriptional activation through binding GC-rich elements. Coactivator proteins, such as ERAP-140, SRC-1 and A1B1, bind ER and enhance hormone-dependent transactivation via interaction with promoter sequences containing estrogen-responsive elements (EREs). Interactions of coactivators with ER/Sp1 and Sp1 proteins were investigated by coimmunoprecipitation and gel mobility shift assays. Incubation of [^{35}S]-labeled ERAP 140 and SRC-1 with ER, Sp1 or ER/Sp1 (combined) proteins, followed by addition of Sp1 or ER antibodies, showed that both coactivators coimmunoprecipitated with Sp1/ER and ER proteins. Gel mobility shift assays showed that the intensity of the ER/Sp1-DNA retarded band was decreased by both coactivators in a concentration-dependent manner suggesting that coactivators compete with Sp1 protein for the ER resulting in decreased Sp1-DNA binding. Using [^{32}P]-labeled GC-rich oligonucleotides and combinations of Sp1 (alone), Sp1+ER and Sp1+ER+coactivators, supershifted binary or ternary protein-DNA complexes were not observed in gel mobility shift assays. Current studies are focused on effects of coactivators on ER/Sp1-mediated transcriptional activation using GC-rich promoters.

639 MOLECULAR MECHANISM OF ESTROGEN-INDUCED IGFBP-4 GENE EXPRESSION.

C Qin and S Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA.*

IGFBP-4 is an inhibitory insulin-like growth factor (IGF) binding protein expressed in a variety of tumor cell lines. Treatment of MCF-7, T47D and ZR-75 breast cancer cells and ECC-1 endometrial cancer cells for 6 hr with 10 nM 17β -estradiol (E2) resulted in induction of IGFBP-4 mRNA levels, and this response was decreased in cells cotreated with the antiestrogens 4N -hydroxytamoxifen (OHT) and ICI 182,780. Western blot analysis with IGFBP-4 antibodies showed that E2 caused a 6-fold increase in immunoreactive glycosylated protein in MCF-7 cells. The 5N -promoter region (-1214 to +18) of IGFBP-4 gene was cloned into a vector upstream from the firefly luciferase reporter gene and E2 induced a 10-fold increase in luciferase activity in MCF-7 cells transiently transfected with this construct. Deletion analysis of this region of the IGFBP-4 gene promoter identified two GC-rich sequences at -559 to -553 and -72 to -64 that were important for E2-induced transactivation. Gel mobility shift assays using ^{32}P-labeled IGFBP-4 promoter sequences -569 to -540 and -83 to -54 showed that Sp1 protein bound these oligonucleotides to form a retarded band, and intensity of the band was competitively decreased after co-incubation with unlabeled IGFBP-4 derived and "consensus" Sp1 oligonucleotides. Mutation of the GC-rich sites within these sequences resulted in loss of retarded band formation. Wild-type human estrogen receptor (hER) did not bind directly to the IGFBP-4 oligonucleotides; however, hER enhanced Sp1-DNA binding in a concentration-dependent manner. Results of this study demonstrate that at least two GC-rich sequences at -559/-553 and -72/-64 are required for induction of IGFBP-4 gene expression by E2. (Welch Foundation and NIH CA76636)

640 HALODIINDOLYLMETHANES: NATURAL PRODUCT DERIVATIVES WITH ANTIESTROGENIC AND ANTITUMORIGENIC ACTIVITIES.

A J McDougal, M Gupta, K Ramamoorthy and S H Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA.*

Indole-3-carbinol (I3C) conjugates in cruciferous vegetables dimerize under acidic conditions to form diindolylmethane (DIM). Both I3C and DIM bind with the aryl hydrocarbon receptor (AhR) and exhibit antitumorigenic and antiestrogenic responses. Halogenated DIM analogs were synthesized and examined as antiestrogens in *in vitro* and *in vivo* assays. All compounds used in this study competitively bound to the AhR (IC_{50} values ranged from 2.6×10^{-9} to 2.0×10^{-7} M). In the female B6C3F1 mouse uterine model, 100 mg/kg of 5,5N -dichlorodiindolylmethane (5,5N -Cl_2DIM) and 6,6N -dichlorodiindolylmethane (6,6N -Cl_2DIM) significantly inhibited 17β -estradiol (E2)-induced uterine peroxidase activity (41 - 67%) and progesterone receptor levels (62 - 25%), and only minimally affected uterine wet weight. DihaloDIMs also inhibited growth of 7,12-dimethylbenzanthracene-induced mammary tumors in female Sprague-Dawley rats, and their order of potency was 5,5N -dibromo . 6,6N -dichloro > 5,5N -difluoro > 5,5N -dichloroDIM at doses of 5 or 1 mg/kg every other day. DihaloDIMs also significantly inhibited E2-induced proliferation of MCF-7 and T47D breast cancer cells at concentrations < 5 μ M, thus exhibiting a broad spectrum of antiestrogenic responses. (Supported by the State of Texas Advanced Technology Program.)

641 CROSSTALK BETWEEN THE Ah RECEPTOR AND ESTROGEN RECEPTOR SIGNALING PATHWAYS IN REGULATION OF TRANSFORMING GROWTH FACTOR α.

C Vyhlidal and S Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA.*

17β -Estradiol (E2) induces transforming growth factor-α (TGFα) gene expression in human breast cancer cell lines, and TGFα acts as an autocrine

growth factor. Previous studies in this laboratory have demonstrated that 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) inhibits E2 and TGFα-induced cell proliferation, and the molecular biology of this interaction has been further investigated using the pTGFα-1145/5 construct which contains the -1145 to -5 sequence from the TGFα gene promoter linked to a luciferase reporter gene. Ten nM E2 induced luciferase activity 4- to 5-fold in MCF-7 human breast cancer cells transiently cotransfected with TGFα-1145/5 (5 μ g) and a human estrogen receptor (hER) expression plasmid (0.5 μ g). Cotreatment of transfected cells with TCDD inhibited E2 induced levels. Two downstream (-200 to -252) imperfect palindromic estrogen responsive elements (EREs) have been characterized, and the possible role of other upstream promoter sequences was investigated using the TGFα-1145/377 construct containing a -1145 to -377 TGFα gene promoter insert. In MCF-7 cells cotransfected with 5 μ g of TGFα-1145/377 and 0.5 μ g hER, 10 nM E2 induced luciferase activity 4.5-fold. A perfect ERE half-site in proximity to three Sp1 sites within the -1145 to -377 region of the TGFα gene promoter are required for E2-responsiveness, and the induction response can be inhibited by TCDD. Two potential inhibitory core pentanucleotide dioxin response elements (iDREs) within the -1145 to -377 region of the promoter have been identified at -485 and -465, and current studies are focused on the function of the iDREs in mediating the antiestrogenic response in breast cancer cells. (NIH ES04176)

642 VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF) GENE EXPRESSION IS DOWNREGULATED BY 17β -ESTRADIOL (E2) IN HEC1-A HUMAN ENDOMETRIAL CARCINOMA CELL LINE.

M Stoner and S Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA.*

Vascular endothelial growth factor (VEGF) is a potent angiogenic factor expressed by many cancer cell lines and is implicated in the neovascularization necessary for tumor growth and metastasis. The molecular mechanisms of 17β -estradiol (E2)-induced VEGF gene expression have been investigated in HEC1-A human endometrial cancer cells. After treatment with 10 nM 17β -estradiol (E2), total RNA was extracted, and semiquantitative RT-PCR showed that E2 decreased VEGF mRNA levels by approximately 50% compared to controls. Transient cotransfection of a human VEGF gene promoter luciferase reporter construct [VEGF*ApaI*-Luc (-131/+379)] and human estrogen receptor α (hERα) expression plasmid into HEC1-A cells produced a dose-dependent 40% decrease in luciferase activity in cells treated with E2 (0.1 nM to 1 μ M) compared to controls. Furthermore, 3N and 5N deletion analysis of VEGF*ApaI*-Luc produced VEGF*NheI*-Luc (-131/+57) and VEGF *SmaI*-Luc (-85/+379); and in transient transfection assays in HEC1-A cells, E2 caused a 40% decrease in luciferase activity. Decreased luciferase activity in HEC1-A cells transiently transfected with VEGF*ApaI*-Luc and treated with 10 nM E2 was specifically reversed after cotreatment with 1 μ M ICI 182,780, a pure antiestrogen, but was not affected by tamoxifen, another antiestrogen. Since the VEGF gene promoter contains no consensus estrogen response elements (ERE), we are currently investigating ERα action through one or more transcription factors that bind Sp1, AP1 or AP2 sequences found between positions -85 to -27. (Welch Foundation and NIH CA76636)

643 AhR-MEDIATED ANTIESTROGENICITY AND ANTITUMORIGENICITY OF DIINDOLYLMETHANE AND ANALOGS.

K Ramamoorthy, A McDougal, M Gupta and S Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA.*

Diindolylmethane (DIM) is the dimerization product of indole-3-carbinol (I3C), an antitumorigenic compound commonly found in cruciferous vegetables. DIM has previously been shown to inhibit 7,12-dimethylbenzanthracene (DMBA)-induced mammary tumor growth and 17β -estradiol (E2)-induced cell proliferation of breast cancer cells. Research in this laboratory has shown that the antitumorigenic and antiestrogenic responses are mediated via the aryl hydrocarbon receptor (AhR). DIM and several alkyl-substituted analogs were synthesized and examined for their antiestrogenic activity *in vivo* and *in vitro*. In the DMBA rat mammary tumor studies, 2,2N -dimethylDIM (2,2N -Me_2DIM) and 1,1N,2,2N -tetramethylDIM (1,1N ,2,2N -Me_4DIM) were significantly antitumorigenic at a dose of 1 mg/kg every other day for 3 weeks, and 1,1N -dimethylDIM (1,1N -Me_2DIM) was significantly antitumorigenic at a dose of 5 mg/kg. At these same doses, no induction of hepatic CYP1A1-dependent activities were observed. The female B6C3F1 mouse uterine model was also used for *in vivo* studies, and effects of E2 (0.02 μ g/day) and E2 + substituted DIMs (100 mg/kg) on progesterone receptor levels, uterine peroxidase activity and uterine wet weight were determined. 1,1N -Me_2DIM and 2,2N -Me_2DIM were both significantly antiestrogenic, and methyl-substituted DIMs also inhibited E2-induced proliferation of T47D breast cancer cells at concentrations # 5 μ M. DIM and several substituted analogs exhibit antiestrogenic and antitumorigenic activity in both *in vivo* and *in vitro* models and represent a group of relatively nontoxic AhR-based antiestrogens. (Supported by the State of Texas Advanced Technology Program.)

644 ANTI-INFLAMMATORY EFFECTS OF TRITERPENOIDS ARE MEDIATED THROUGH PEROXISOME PROLIFERATOR ACTIVATED RECEPTORS (PPARS).

W W Porter [1], N Suh [2], C Michnoff [3], M B Sporn [2] and D J Mangelsdorf [1]. [1]*Howard Hughes Medical Institute and the Departments of Pharmacology and* [3]*Biochemistry, University of Texas Medical Center, Dallas, TX;* [2]*Department of Pharmacology, Dartmouth Medical School, Dartmouth College, Hanover, NH.*

Triterpenoids are dietary factors that have been demonstrated to have a protective role in regulating cancer formation and progression. Studies have shown that the naturally occurring triterpenoids, oleanolic acid (OA), and the synthetic derivatives TP82 and TP151, mediate these chemopreventive effects by functioning as anti-inflammatory agents. However, the molecular mechanism by which these compounds regulate these anti-inflammatory responses have not been delineated. In this study, we show that these oleananes differentially bind and activate the nuclear receptors peroxisome proliferator receptor α and γ (PPARα and PPARγ), both of which have been shown to modulate inflammatory responses. Transactivation experiments demonstrate that OA and TP151 activate PPARα and PPARγ, respectively, while TP82 activates both PPAR isoforms. Moreover, these compounds directly bind PPARγ and promote adipocyte differentiation. Evaluation of the anti-inflammatory response shows that these terpenes inhibit inducible nitric oxide synthase (iNOS) promoter reporter activity via disruption of NFκB signaling and this response is dependent upon PPARγ. The dose-dependent effects observed for the most potent triterpenoid (TP151) are identical to those reported for the natural PPARγ ligand, 15-deoxy-$\Delta^{12,14}$-PGJ2 (15d-PGJ2). These data identify a novel class of PPARα and PPARγ ligands and provide one of the molecular components for the anti-inflammatory and chemopreventive action of these compounds.

645 HEPATOCYTE PLASMA MEMBRANE ATP-DEPENDENT TRANSPORT PROTEIN EXPRESSION FOLLOWING INDUCTION OF HEPATO CELLULAR PROLIFERATION IN VIVO.

B J Mounho and B D Thrall. *Molecular Biosciences Dept., Battelle, Pacific Northwest National Laboratory, Richland, WA.*

Peroxisome proliferators are a class of rodent hepatocarcinogens that act as nongenotoxic tumor promoters. While the mitogenic and carcinogenic activity of peroxisome proliferators require the nuclear peroxisome proliferator-activated receptor (PPARα), the mechanisms of PPARα regulation are poorly understood. Previous studies suggest mitogenic growth factors that act through the extracellular signal-regulated kinase (ERK) pathway, including insulin and EGF, modulate PPARα activation and the mitogenic activity of peroxisome proliferators. Furthermore, PPAR proteins have been shown to be phosphorylated after treatment with insulin or EGF. We are investigating whether there is crosstalk between the pathways activated by peroxisome proliferators and these mitogenic growth factors. Our results demonstrate that exposure of primary mouse hepatocytes to peroxisome proliferators, including trichloroacetate, Wy-14,643, and clofibrate, results in a dose-dependent phosphorylation and activation of ERK. Peroxisome proliferator-induced ERK phosphorylation was blocked when cells were pretreated with the MEK (ERK kinase) inhibitor, PD098059, or the phosphatidylinositol 3-kinase (PI3K) inhibitors, LY294002 and apigenin, suggesting that both MEK and a PI3K protein are involved in this response. Under serum-free conditions, Wy-14,643 induced a modest (2-fold) increase in the incorporation of bromodeoxyuridine (BrdU) into primary hepatocytes. However, concentrations of PD98059 which block Wy-14,643-induced ERK phosphorylation also block the stimulation of BrdU incorporation. Our results, therefore, indicate that activation of the ERK pathway through a PI3K-dependent mechanism may play a significant role in promoting the mitogenic activity of peroxisome proliferators.

646 STEREOSPECIFIC ACTION OF NICOTINE ON NASAL NICOTINIC ACETYLCHOLINE RECEPTORS.

M Kaegler[1], N Thuerauf[2], B Renner[2], and G Kobal[2]. [1]*INBIFO - Institut fuer biologische Forschung, Koeln, Germany;* [2]*Institut fuer Pharmakologie, University of Erlangen-Nuernberg, Germany.* Sponsor: R A Carchman.

The responses of the olfactory and the trigeminal system in the nose of humans and rats to nicotine vapor were investigated. An olfactometer was used to stimulate the nasal mucosa with R- and S-nicotine vapor applied randomly at different concentrations. a) In anaesthetized Wistar rats extracellular trigeminal single cell units were recorded from the cranial ipsilateral Gasserian ganglion. An aqueous solution of hexamethonium (41.4 mmol/l) applied to the nasal mucosa inhibited responses to both R- and S-nicotine, indica-ting the involvement of nicotinic acetylcholine receptors. Neuronal activity induced by S-nicotine was significantly greater than that induced by R-nicotine (Anova, $\alpha = 0.05$), indicating stereospecificity of the nicotinic receptor. b) For humans, individual thresholds for odorous, burning and stinging sensations were determined. Enantiomeric differences were seen only for the burning threshold (factor 3) and the stinging threshold (factor 2). Trigeminal activation in the nose was quantified by recording negative mucosa potentials (NMPs) and by estimating the intensity of burning and stinging sensations. NMP amplitudes were two times higher and intensity estimates 2 to 6 times higher for S-nicotine ($p < 0.001$). These observations indicate that in humans and rats the nasal olfactory and the nasal trigeminal system are both involved in the sensory detection of nicotine: receptors in the olfactory epithelium respond equally to R- and S-nicotine. Their threshold concentration is 2 µg/l. Trigeminal receptors are able to discriminate between R- and S-nicotine at concentrations above 35 µg/l and involve a stereospecific nicotinic acetylcholine receptor. (Sponsored by Philip Morris USA.)

647 UV LIGHT INDUCED MODULATION OF RPA PHOSPHORYLATION BY EXPRESSION OF ATM PROTEIN.

G G Oakley[1], M Zernik-Kobak[1], M P Carty[1], K K Khanna[2], M F Lavin[2] and K Dixon[1]. [1]*Department of Environmental Health, University of Cincinnati College of Medicine, Cincinnati, OH, USA;* [2]*Queensland Institute of Medical Research, The Bancroft Centre, PO Royal Brisbane Hospital, Herston, Brisbane, Australia.*

Ataxia telangiectasia (AT) is a rare human autosomal recessive disease that is characterized by sensitivity to radiation and genomic instability. The gene mutated in AT, *ATM* encodes a 350-kDa protein that has a C-terminal region homologous to the catalytic subunit of phosphatidylinositol 3-kinases (PI 3-kinases) which have either lipid or protein kinase activity. An important response in a number of cell types exposed to ultraviolet radiation (UV) includes hyperphosphorylation of RPA, a single-stranded DNA-binding protein involved in DNA replication and repair. To examine the relationship between ATM and RPA phosphorylation following UV treatment two experimental approaches were used. First, while normal cells (CH3ABR) hyperphosphorylated RPA following UVC exposure, a normal cell line expressing an antisense ATM mRNA showed reduced ATM protein levels and failed to hyperphosphorylate RPA. Second, an AT cell line (AT1ABR) that lacks the ATM protein showed decreased hyperphosphorylation of RPA after UVC exposure. However, when recombinant ATM protein was expressed in AT1ABR cells, hyperphosphorylation of RPA p34 was stimulated after UVC exposure. These results suggest that RPA phosphorylation can be either directly or indirectly regulated by the expression of ATM protein and may provide a role for regulation of DNA replication and contribute to genomic stability after toxicant exposure.

648 DOSE ESTIMATING EXPOSURE MODEL (DEEM) ARCHITECTURE TO ESTIMATE RELEVANT TOXICOLOGICAL DOSE.

J N Blancato[1], F W Power[2], M L Rigas[1], and R N Brown[1]. [1]*US EPA, Human Exposure and Atmospheric Sciences Division, Las Vegas, NV;* [2]*Anteon Corporation, Las Vegas, NV.*

Physiologically based pharmacokinetic (PBPK) models are often used to estimate toxicologically relevant dose. Such mechanistic models, based on actual physiologic, biochemical, and thermodynamic parameters, are very useful for high- to-low dose, route-to-route, and species-to-species extrapolations. Typically, models have been developed to address health impacts of a specific chemical or a focused. In addition to the extensive physiologic, biochemical, and thermodynamic data necessary, meticulous and exhausting computer coding is required. Even after all this, considerable testing and code verification is necessary before the system can be applied to a risk assessment. The research presented attempts to develop an architecture that simplifies the formulation of case specific models. While totally generic PBPK models are not feasible, nor even desirable, this type of standardized flexible framework can greatly enhance the ease of use by risk assessors and toxicologists. The DEEM is structured so that any number of metabolic and binding schemes can be simulated. The user merely specifies which metabolites circulate and which remain in the organ where they are first formed. Alternatively, the model framework can be used to simulate exposure to several compounds simultaneously. With DEEM the user may also specify metabolic inhibition, induction, and enzyme resynthesis. Thus, by simply inputting the proper physiologic, biochemical, thermodynamic, and exposure parameters the user can quickly formulate his or her own case specific model without the need to write and compile any new code. We have used this framework to model possible toxicologically relevant doses for chloroform, trichloroethylene, methy tertiary butyl ether (MTBE), and hexachlorobenzene. Model simulation results are presented in this paper. NOTICE: The U.S. Environmental Protection Agency (EPA), through its Office of Research and Development, funded this research and approved this abstract as a basis for an oral presentation. The actual presentation has not been peer reviewed by the EPA.

649 DEVELOPMENT OF A DYNAMIC SYSTEMS MODEL OF PESTICIDE EXPOSURE, DOSE, AND BIOMARKERS.

E J Furtaw[1], C C Dary[1], J J Quackenboss[1], J J Ventresca[1], and C G Saint[2]. [1]*National Exposure Research Laboratory, U.S. EPA, Las Vegas, NV, USA;* [2]*National Center for Environmental Research and Quality Assurance, U.S. EPA, Washington, DC, USA.*

Multi-media and multi-pathway exposure modeling techniques are needed to properly assess aggregate exposure to infants and children as required under the Food Quality Protection Act (FQPA). To help address this need, a modeling system is being developed by linking a multi-pathway residential pesticide exposure model to a physiologically based pharmacokinetic (PBPK) human dose model using the MATLAB® Simulink® icon-based dynamic system modeling software. The exposure model is based partially on selected scenarios from the *Standard Operating Procedures (SOPs) for Residential Exposure Assessment* as used by EPA's Office of Pesticide Programs for aggregate exposure assessments under FQPA. The linked exposure-dose model system was used to reconstruct exposure and dose estimates for selected exposure scenarios from urinary metabolite data. The dose reconstructions were compared with estimations of dose based on assumptions and chemical specific dislodgeable residue and passive dosimetry measurements for the SOP scenarios. The comparisons suggest that the SOPs tend to overestimate actual "typical" exposures. Notice The U.S. EPA Office of Research and Development funded this research. The abstract was reviewed and approved. The oral presentation has not been reviewed. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

650 QUANTITATIVE STRUCTURE-ACTIVITY RELATIONSHIP (QSAR) FOR PREDICTING THE POTENTIAL DERMAL DOSE AND DISPOSITION OF ORGANOPHOSPHORUS INSECTICIDES.

C C Dary[1], E J Furtaw[1], J N Blancato[1], J B Knaak[2] and C G Saint[3]. [1]*National Exposure Research Laboratory, U.S. EPA, Las Vegas, NV, USA;* [2]*Institute of Toxicology and Environmental Health, University of California, Davis, CA, USA;* [3]*National Center for Environmental Research and Quality Assurance, U.S. EPA, Las Vegas, NV, USA.*

Reconstruction of dermal dose and estimation of the disposition of dermal doses through the use of Physiologically Based Pharmacokinetic (PBPK) modeling have been restricted to single organophosphorus insecticide chemicals. With the enactment of the Food Quality Protection Act (FQPA), exposure modeling techniques are needed to assess the aggregate exposure of infants and children to a broad range of organophosphorus insecticides with differing chemical structures. To this end, a database was compiled containing a number of physicochemical parameter values (Log P, Hammett σ, F, R, Taft E_s, molecular weight, Van der Waals volume, and molar refractivity) and percutaneous absorption, pharmacokinetic, and metabolic parameter estimates, for a series of 15 aromatic organophosphate pesticides. The molecular parameters were obtained from published literature or estimated

using molecular modeling software (HyperChem® ChemPlus™). Pharmacokinetic, metabolic, and percutaneous absorption parameter estimates were obtained from the published literature. Results indicate that these quantitative structure-activity relationship (QSAR) techniques can provide reasonable estimates of pharmacokinetic, metabolic, and skin absorption parameter values for individual OP insecticides and mixtures for use in PBPK modeling. (The U.S. EPA Office of Research and Development funded this research. The abstract was reviewed and approved. The oral presentation has not been reviewed. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.)

651 A PRIORI DETERMINATION OF THE LUMPING OF TISSUE COMPARTMENTS.

M Pelekis[1], J M Frazier[2] and J N McDougal[1]. [1]*Geo-Centers Inc.*, [2]*Human Effectiveness Directorate, Air Force Research Laboratory, Wright-Patterson AFB, OH, USA.*

Biologically-based kinetic (BBK) models that simulate the kinetic behavior of volatile organic chemicals divide the body into four compartments, one which corresponds to an actual tissue (liver) and three that represent lumped tissues: the richly perfused tissues, comprised of those tissues most profusely supplied with blood vessels (heart, brain, spinal chord, hepatoportal system, kidney, GI tract and endocrine glands); the slowly perfused tissues comprised of those tissues that are supplied by relatively fewer blood vessels (muscle and skin), and the fat compartment that includes fat depots in the body and the bone marrow. This approach has become standard in BBK modeling but the conditions under which this assumption is valid has not been investigated. The objective of this paper is to develop mechanistically-based guidelines that will allow lumping of several tissues into a single tissue compartment to be based on sound kinetic principles. Of all the parameters necessary to simulate the kinetics of chemicals in a BBK model, only those of tissue volumes, tissue perfusion rates, tissue:blood partition coefficients and metabolic clearance influence the equilibration time for tissues referred to as tissue time constants (TCs, (hr)). The TC is the time required for 63% of the steady-state tissue compartment concentration to be reached and tissues with similar TCs can be lumped together to form a single compartment with no loss in the predictive power of the model. To test this hypothesis, a BBK model consisting of eight tissue compartments (liver, brain, kidney, richly perfused tissues, fat, bone marrow, skin, and muscle) was constructed. Subsequently, the brain and kidney compartments were sequentially lumped into the richly perfused compartment, the bone marrow compartment was incorporated into the fat compartment and lastly the skin and muscle compartments were lumped together to form the slowly perfused tissues compartment. This lumping resulted in a seven, six, five and four compartment models, respectively, which were used to simulate the kinetic behavior of several generic chemicals in rats and humans. The results of the present study indicate that appropriate lumping of tissues depends both on the chemical and the species being modeled.

652 PREDICTION OF THE PHARMACOKINETICS OF DRUGS WHICH ARE HIGHLY METABOLIZED IN LIVER.

F-P Theil and P Poulin. *Hoffmann-La Roche, Ltd., Basel, Switzerland.*

Physiologically-based pharmacokinetic (PBPK) modeling is an effective tool for predicting the plasma concentration-time profile of drugs in mammals. At the present time, simulation of the pharmacokinetics (PK) of drugs can be attempted by providing data on tissue:blood partition coefficients ($P_{t:b}$) and constants for the metabolism (hepatic extraction ratio (E)) and the oral absorption (K_a) as the input in PBPK models. The numerical value of $P_{t:b}$ can be predicted using a mechanistic equation which takes into account the retention of drugs by the lipids, proteins and water. However, data on constants need to be determined experimentally for each new drug. It is known that for highly metabolized drugs (HMDs) in liver, the E value approaches the unity. Whereas, the value of K_a can be estimated by fitting one set of data on plasma concentration-time profile measured following an oral absorption with the simulations obtained using a classical PK model. Then, for HMDs for which an extensive metabolism is suspected principally in liver, their PK after oral or i.v. administration can potentially be predicted using a PBPK model. The objective of the present study was to develop an approach for predicting the PK in rats of HMDs extensively metabolized in liver. The approach consisted of using a conventional PBPK model framework (11 compartments) in which (i) the $P_{t:b}$ values were calculated using a validated mechanistic equation from data on drug solubility in lipids and water and assuming based on literature observations that the magnitude of the protein binding in tissues and blood is identical, (ii) E was set equal to an average value of 0.975 considering that the exact numerical value of E for HMDs ranged probably between 0.95 and 1 (where 1 is hypothetical), and (iii) the K_a value was estimated by fitting using a classical PK approach. The plasma concentration-time profiles in rats of tetrabenazine (after an oral absorption of 1 mg/kg) and of biperiden (after an i.v. injection of 3.2 mg/kg) simulated using the above PBPK model, were comparable to those obtained under *in-vivo* conditions. The PBPK model validated in this study could be a useful mechanistic tool for predicting the PK of HMDs with a minimum of experimental studies.

653 ESTIMATION OF TISSUE:BLOOD PARTITION COEFFICIENTS OF DRUGS BY TAKING INTO ACCOUNT THEIR SOLUBILITY AND PROTEIN BINDING.

P Poulin and F-P Theil. *Hoffmann-La Roche, Ltd., Basel, Switzerland.*

The tissue:blood partition coefficients ($P_{t:b}$) is a composite constant that represents two properties of a drug in tissues and blood, namely, solubility and protein binding. If these two properties can be quantified, estimations of $P_{t:b}$ of drugs could be accomplished. The objective of the present study was to develop a mechanistic approach for estimating the $P_{t:b}$ of drugs in mammals by taking into account their solubility and binding in tissues and blood. The approach consisted of developing an equation that integrates data on drug solubility in neutral lipids, phospholipids, and water with data on protein binding. Based on this equation, $P_{t:b}$ of drugs were calculated from the ratio of the sum of the unbound and bound forms between the tissue and blood. The unbound form in tissues (and blood) was assumed to correspond to the drug solubilities in lipids and water, which were calculated using a recently published methodology. Whereas the magnitude of the protein binding (i.e., relative to the bound form) compared to the drug solubilities in lipids and water was quantified from data on the unbound fraction observed in each tissue and blood. The data on the unbound fraction were obtained from experimental studies published in the literature. The estimated rabbit, rat and human $P_{t:b}$ (brain, fat, kidney, heart, intestine, liver, lung, muscle, skin, spleen, milk) were compared with experimentally-determined data reported in literature for eight drugs (ethoxybenzamide, acetaminophen, prednisolone, barbital, phenobarbital, pentobarbital, thiopental, paracetamol). The estimated $P_{t:b}$ values were close to the experimental ones with an average ratio of 1.01 (S.D. = 0.32, r = 0.89, n = 48). Additionally, experimental data on the unbound fraction in tissues were compared with the ones in blood for the above drugs. The unbound fraction data for tissue differed by an average factor of 1.25 (S.D. = 0.50, n = 48) to the ones observed in blood. The use of the mechanistic equation validated in this study for estimating $P_{t:b}$ should allow to improve the prediction compared to the current standard approach, where the solubility in tissues and blood is assumed to be the same for all the drugs.

654 CRITICAL DETERMINANTS AND IMPACT ON PHARMA-COKINETICS (PK) OF BLOOD PROTEIN BINDING OF VOLATILE ORGANIC CHEMICALS (VOCs).

M Béliveau, G Charest-Tardif and K Krishnan. *TOXUM, Université de Montréal, Montréal, Quebec, Canada.*

The blood:air partition coefficient ($P_{b:a}$) is an important input parameter for predicting the PK of VOCs. The rat $P_{b:a}$ of some VOCs predicted on the basis of lipid and water solubility alone are lower than the experimental $P_{b:a}$ values. This discrepancy is hypothesized to be caused by binding to blood proteins. The objectives of the present study were to: (i) develop and validate an algorithm based on the identification of critical determinants of the blood protein binding of VOCs, and (ii) develop an approach to evaluate the impact of protein binding on the $P_{b:a}$ and PK of VOCs using physiologically-based PK (PBPK) models. Analysis of the various critical determinants of protein binding suggested that only chemicals without an oxygen atom in their structure, having a log oil:water partition coefficient>1, and a geometric volume <300 Å^3 would display binding. An algorithm based on the above observations was developed and applied to identify VOCs for which blood protein binding should be negligible [ether (ETH), methyl ethyl ketone (MEK), and isooctane (ISO)] and those for which protein binding is likely to be important [ethylbenzene (EBZ), bromoform (BRM), chloroform (CHM), and chlorobenzene (CBZ)]. Vial equilibration studies showed that PCs were similar for rat blood and oil/water samples (mean±SE, n=7-8) for ETH (9.24±0.75, 9.53 ±1.16), MEK (139±6, 159.3±8), and ISO (1.92±0.4, 2.88±0.5), whereas the PCs displayed a marked difference for EBZ (50.8±1.3, 7.13±1.6), BRM (161±5, 28.9±3.4), CHM (16.9±1.1, 3.4±0.75),

and CBZ (61.8±2.8, 8.3±2.35). These results confirm that the additional consideration of binding to blood proteins is essential to adequately predict rat $P_{b:a}$ and PK of EBZ, BRM, CHM, and CBZ. Following the estimation and inclusion of the association constant for protein binding into PBPK models of VOCs, the apparent $P_{b:a}$ (=[free+bound blood concentration]/ambient concentration) as a function of exposure concentration was generated. The apparent $P_{b:a}$ of VOCs was dose-dependent. The blood protein binding of VOCs and its dose-dependency elucidated in this study are fundamental to the conduct of scientifically sound extrapolations of the high dose to low dose behavior of VOCs using PBPK models.

655 A QUANTITATIVE STRUCTURE-TOXICOKINETIC RELATIONSHIP (QST_KR) MODEL FOR ALIPHATIC HYDROCARBONS.

M-O Fouchécourt and K Krishnan. *TOXHUM, Université de Montréal, Montréal, Québec, Canada.*

The blood and tissue concentrations of chemicals resulting from an inhalation exposure may be predicted using information on their molecular structure. For example, if the contributions of each molecular fragment of a chemical to its blood concentration (Cb) can be quantified, then Cb for any related chemical can be predicted by summing the contributions of all molecular fragments in its structure. Such a Free-Wilson additive QST_KR model has not been developed previously. The objective of this work was to develop a QST_KR model for inhaled aliphatic hydrocarbons in rat. The literature data on steady-state venous blood concentrations (Cb_{ss}) of n-hexane, n-heptane, n-octane, n-nonane, n-decane, 2-methyl heptane, 2-methyl octane, 2-methyl nonane, 1-octene, 1-nonene and 1-decene in rats exposed to 100 ppm of these chemicals were analyzed using a commercially available software (QSAR-PC®). The resulting QST_KR model was of the form: $Cb_{ss} = A + \Sigma f_S * C_S$, = contribution of $-CH_2-CH_2-CH_2-CH_2-CH_2-$ to Cb_{ss} (+6.8009), f_S = frequency of occurrence of each substituent S on either end of the above basic aliphatic chain (positions 1 and 5), and C_S = contribution of each S to Cb_{ss}. The numerical values of S at position 1 were -3.253, +7.4410, and -2.0190 for H, CH_2=, and $(CH_3)_2$, respectively. For carbon position 5, the values were -1.195, -1.6905, +0.7095, +1.2552 and +2.8223 for CH_3, C_2H_5, C_3H_7, C_4H_9 and C_5H_{11}, respectively. This Free Wilson-type QST_KR model explained 98.8% of the variability in Cb_{ss} among the aliphatic hydrocarbons investigated in the present study. This approach permits to assess the contribution of each S to the toxicokinetics of related compounds. As such, these results can be used to design or choose chemicals with desired toxicokinetic properties, on the basis of specific number, nature and location of S in their molecular structure. This work represents the first attempt to characterize and delineate the quantitative contributions of specific molecular fragments to the toxicocokinetic behavior of volatile organic chemicals.

656 AN INTEGRATED PHYSIOLOGICAL PHARMACOKINETIC MODEL FOR HIGHLY LIPOPHILIC ORGANOHALOGEN SUBSTANCES.

C Emond and K Krishnan. *TOXHUM, Université de Montréal, Montréal, Québec, Canada.*

Physiologically-based pharmacokinetic (PBPK) models have been developed and validated for several organohalogen substances in rodents and humans. These models typically consist of four to six tissue compartments interconnected by systemic circulation. Further these models contain chemical-specific descriptions of certain processes (i.e., receptor binding, biliary excretion, blood protein binding, tissue diffusion coefficients, intestinal reabsorption). A PBPK framework to integrate the models for highly lipophilic organohalogens has not been previously developed. The objective of this work was to construct an integrated PBPK model for simulating the kinetics of highly lipophilic organohalogens. This PBPK model included blood, liver, skin, richly perfused tissues, slowly perfuse tissues, and adipose tissue compartments. This model consisted of input parameters that were kept constant (i.e., tissue:blood partition coefficients, tissue volumes, and blood flow rates) and parameters for which numerical values changed from chemical to chemical (i.e., binding association constants, metabolic rates, biliary clearance, tissue diffusion coefficients and gut reabsorption rate). The tissue:blood partition coefficients were calculated by dividing the fraction of neutral lipids in tissues with the fraction of neutral lipids in whole blood. Blood flow rates and volumes of tissues were obtained from the literature. The numerical values of other chemical-specific parameters were obtained from previously published PBPK modeling work. The resulting integrated model has been used to simulate the pharmacokinetics of several organohalogen substances including 2,2',4,4',5,5'-hexabromobiphenyl, 2,2',4,4',5,5'-hexachlorobiphenyl, and 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). This integrated model provides simulations that are comparable to the individual chemical models that have previously been published. The simulations of this model are being used to derive the toxicokinetic equivalency factors for organohalogen substances, using TCDD as the reference chemical.

657 PHYSIOLOGICAL MODELING TO CHARACTERIZE ADULT-CHILDREN DIFFERENCES IN PHARMACOKINETICS (PK).

S Haddad, C Restieri and K Krishnan. *TOXHUM, Université de Montréal, Montréal, Quebec, Canada.*

Adult-children differences in PK of chemicals may result from age-related changes in physiological, physicochemical and biochemical parameters. A review of the literature suggests that there is no systematic, significant age-related change in tissue lipid and water composition (i.e., the determinants of tissue:blood and blood:air partition coefficients (Pba)). Whereas the hepatic extraction ratio (E) may vary between children and adults for some chemicals, the E value is likely to be 1 for highly metabolized chemicals (HMCs) in all cases. Several physiological parameters, on the other hand, change as a function of age. The objectives of the present study were to develop a physiologically-based PK (PBPK) model that accounts for age-related changes in physiological parameters and to simulate toxicokinetics of HMCs in children and adults. Literature data on physiological parameters (i.e., body weight, cardiac output, ventilation rate and organ volumes) were collected for children of several age groups (newborn – 18 years). Using these data, algorithms relating each physiological parameter to age (or body weight) have been developed. These newly developed algorithms were then introduced in a validated adult human PBPK model for HMCs to create a framework that considers child development. Simulations of inhalation exposure to a given ambient concentration of HMCs (e.g., chloroform) indicated that the initial and steady-state venous blood and liver concentrations of parent chemical are comparable between children of different age groups (except newborns) and adults. This observation can be explained by the fact that the steady-state concentrations are solely determined by factors that do not change with age (i.e., E, which in the case of HMCs is likely to be equal to 1 for all age groups, the fraction of cardiac output flowing through liver, Pba, and the ratio of ventilation rate to the cardiac output). Overall, this study suggests that no adult-children differences in the parent chemical concentrations of HMCs are likely to be observed during inhalation exposures. The PBPK modeling framework developed in the present study can be used to compare PK of chemicals (with varying E values) in adults and children for other exposure routes and dose surrogates.

658 EXPERIMENTAL EVALUATION AND PHYSIOLOGICAL MODELING OF THE PHARMACOKINETICS OF 3, 5-XYLIDINE IN RATS.

C Blanchette, S Shardonofsky and K Krishnan. *TOXHUM, Université de Montréal, Montréal, Québec, Canada.*

Human exposure to xylidines results from their formation as degradation products of certain pesticides and pharmaceutical products, and from their use in the production of azo dyes. Of the six isomers of xylidine, the 3,5-isomer is the most potent inducer of methemoglobinemia. There is no information available in the literature regarding the pharmacokinetics (PK) of 3,5-xyldine (XYL) in rats or humans. The objectives of this study were: (i) to characterize the PK of XYL in the rat and (ii) to construct a physiologically-based PK (PBPK) model for XYL using animal-replacement methods. The PK of XYL was characterized by analyzing the tissue and blood concentrations at 0.12 – 24 hr following a single iv dose of 0.24 to 0.60 mmol/kg or an oral dose of 1.2 to 4.8 mmol/kg. The concentrations of XYL in the various tissues followed the general order: adipose tissue > kidney > brain > liver and muscle. The PBPK model for XYL consisted of five compartments namely stomach, liver, fat, richly-perfused tissues (RPT) and slowly-perfused tissues (SPT), interconnected by blood. All physiological parameters were obtained from the literature. The tissue: blood partition coefficients (PC) were estimated from the log n-octanol:water PC (2.17) of XYL, its pKa (4.79), pH of tissues, and the proportion of lipids and water in the blood and each tissue. For the biochemical parameters, hepatic extraction ratio was set at 0.1 or 0.9. The PBPK model then generated a range of possible XYL concentrations in the blood and tissues of the rat for each iv dose provided as input. Subsequently, an oral absorption constant of 0.1 hr^{-1} was used to simulate the range of plausible concentration profiles of XYL following oral

dosing. The experimental PK data collected following oral and iv administrations, in general, fell within the range of predictions obtained with the PBPK model. The predictions of the PBPK model can be linked with a pharmacodynamic model for methemoglobinemia, for assessing the risks of human exposure to XYL.

659 PHYSIOLOGICALLY-BASED MODELING OF THE PHARMACOKINETICS OF C8 – C10 1-ALKENES AND ISO-ALKANES IN THE RAT.

G Charest-Tardif, P St Jean, R Tardif and K Krishnan. *Groupe de recherche en toxicologie humaine (TOXHUM), Université de Montréal, Montréal, Quebec, Canada.*

Several C8 – C10 1-alkanes and iso-alkanes occur as environmental contaminants. The kinetics of these substances have previously been studied in rats. Physiologically-based pharmacokinetic (PBPK) models for these chemicals have not been developed. The objective of this study was to develop and validate PBPK models for several 1-alkenes (1-octene, 1-nonene, and 1-decene) and iso-alkanes (2-methyl heptane, 2-methyl octane, and 2-methyl nonane) in the rat. The model structure consisted of four compartments (liver, adipose tissues, slowly perfused tissues and richly perfused tissues) interconnected by systemic circulation. The rat physiological parameters were obtained from the literature. The tissue:blood and blood:air partition coefficients (PCs) were predicted from n-octanol:water and water:air PCs estimated from molecular structure information and tissue/blood composition data. The hepatic extraction ratio was initially set at 0 and then at 1. The PBPK model was used to simulate upper and lower limits of venous blood and tissue concentrations of 1-alkenes and iso-alkanes (corresponding to situations of E = 0 and E = 1, respectively) for any given exposure scenario. The simulated envelopes were compared with previously published experimental data obtained in rats exposed to 100 ppm of these chemicals for 12 hr. The simulated range of values contained most of the experimental data available for all three 1-alkenes and iso-alkanes. The PBPK model developed and validated in the present study should be useful for predicting the kinetics of 1-alkenes and iso-alkanes for other exposure concentrations, scenarios and species.

660 COMPARISON OF SOFTWARE ENVIRONMENTS FOR PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODEL SIMULATION.

R L Carpenter. *Naval Health Research Center (Toxicology), Wright-Patterson AFB, OH.*

Physiologically Based Pharmacokinetic (PBPK) simulation modeling involves solving a series of linear differential equations, which are usually of first order. This task is most often carried out by numerical solution of the differential equations using a digital computer. Continued development of computer software automating algebraic calculations and the operations of calculus has resulted in several alternative software environments capable of simulation modeling. For many individuals, the Advanced Continuous Simulation Language (ACSL), produced by MGA Software (Concord, MA), is the simulation environment with which they are familiar. Alternatives to ACSL include Mathematica by Wolfram Software (Cambridge, MA), which is an example of a generalized mathematical solution engine, and MathCad by MathSoft, INC (Cambridge, MA), an example of the "notebook" user interface to an underlying mathematical computation engine. Each of these software environments has its own operating characteristics and it is of interest to compare their use in the development and solution of a PBPK simulation model. This presentation will give examples of equation development, equation solution and graphing of results using each of these three programs.

661 USING PHYSIOLOGICALLY BASED PHARMACOKINETIC MODELING TO MINIMIZE ANIMAL TESTING AND ASSOCIATED COSTS UNDER USEPA'S HAZARDOUS AIR POLLUTANTS TEST RULE.

M L Gargas[1], C R Kirman[1], S M Hays[1], and P Voytek[2]. [1]*McLaren-Hart/ChemRisk, Cleveland, OH, USA;* [2]*Regulatory Sciences International, Alexandria, VA, USA.*

In June of 1996, the USEPA proposed a test rule under the Toxic Substances Control Act (TSCA) which would require manufacturers and processors of 21 hazardous air pollutants (HAPs) to test these compounds for specific health effects identified as data gaps. As an alternative to conducting these tests, the USEPA solicited proposals regarding the use of pharmacokinetic studies that would permit the extrapolation of toxicity information from other routes of exposure (i.e., oral) to fill gaps in the database of existing inhalation studies. Case studies are presented for two HAPs, 1,2-dichloroethane and 1,1,2-trichloroethane. Physiologically based pharmacokinetic (PBPK) modeling was used to reduce toxicity testing costs and animal usage in three ways. First, where toxicity studies are available for the oral route, route-to-route extrapolation of the results was performed to fill data gaps identified by USEPA. Second, where data gaps could not be filled by existing studies, toxicity testing will be conducted by the oral route (at considerable savings over testing by the inhalation route), after which PBPK modeling will be used to extrapolate the results to the inhalation route. Lastly, the PBPK model will be used to identify appropriate test doses for the toxicity studies, thereby eliminating the need to conduct dose range-finding studies. Additional metabolic studies were designed to refine the existing PBPK model so that it may be applied to the toxic endpoints of interest under the test rule. By taking advantage of existing oral toxicity studies and using the best available science, the need to further animal testing was greatly reduced. Additionally, by reducing toxicity testing costs by nearly one million dollars for each chemical, limited research funds may be better focussed on filling true data gaps.

662 EFFECT OF BROMODICHLOROMETHANE (BDCM) ON VENTILATION IN THE MALE F-344 RAT DURING GAS UPTAKE INHALATION EXPOSURE.

D Terrell[1], J L Mansfield[2], R A Pegram[1], and M V Evans[1]. [1]*US EPA/NHEERL, RTP, NC, USA;* [2]*SEE, RTP,NC, USA.*

BDCM is a volatile disinfection by-product of water chlorination within the trihalomethane group which has been found to be carcinogenic in rodents. Gas uptake is a closed inhalation exposure system used to measure rodent metabolism of volatiles non-invasively. The actual estimation of metabolism requires knowledge about the rodent's physiological state during the exposure. The question as to whether BDCM affects ventilation during gas uptake exposure has arisen due to previous inhalation experiments. In this study, 90-day old male F-344 rats were exposed to BDCM at initial concentrations of 200, 800, 1200 and 3200 ppm. The closed inhalation system functioned as a whole body plethysmograph via use of a differential pressure transducer to provide signals from which ventilation frequency, tidal volume, and ventilation rate were derived. Our data shows a marked decrease in ventilation (as minute volume) in the exposed animals compared to controls for each exposure concentration. The percent differences between the time before exposure and the time subsequent to the start of the exposure were also used to determine potential differences. When taking the average of the percent differences for all the data after start of exposure, the difference between controls and exposed was at least two-fold. The impact of the observed decrease in ventilation on the ability to estimate metabolic parameters is currently being evaluated via pharmacokinetic modeling. In summary, preliminary results indicate that BDCM markedly decreases ventilation during closed inhalation exposures used for the measurement of its metabolism. (This abstract does not necessarily reflect EPA policy.)

663 IN VITRO TO *IN VIVO* EXTRAPOLATION FOR TRICHLOROETHYLENE METABOLISM IN HUMANS.

J C Lipscomb[1], J W Fisher[1], P D Confer[2], and J Z Byczkowski[2]. [1]*U.S Air Force Research Laboratory;* [2]*ManTech-GEO Centers Joint Venture, Wright-Patterson AFB, OH, USA.*

The use of *in vitro* systems for metabolic studies has distinct advantages and disadvantages. While human hepatocytes and microsomes generate data for comparisons among species and *in vitro* systems, these are generally performed on milligram recovered microsomal protein or million isolated hepatocytes. Recently, *in vitro* data have been used in quantitative predictions of *in vivo* metabolic capacity. Because many data on the distribution and metabolism of trichloroethylene (TRI) in humans exist, we have examined the metabolism of TRI as a case study in the development of a method to extrapolate metabolic rates from *in vitro* to *in vivo*. Kinetic studies undertaken with isolated human hepatocytes have demonstrated that TRI is well-metabolized in culture with a Km of 266 $\pm$ 202 ppm (mean $\pm$ S.D.) in headspace and a Vmax of 16.1 $\pm$ 12.9 nmol/hr/million viable hepatocytes. To provide a basis on which to extrapolate these hepatocyte-mediated and previously published microsome-mediated metabolic rates to the intact liver, we determined that human liver contains approximately 116 x 10^6 hepatocytes and 20.8 mg microsomal protein per gram, based on DNA recovery and glucose-6-phosphatase activity, respectively. Thus, comparison of apparent Vmax values between these *in vitro* systems can be based on 179 ug microsomal protein/10^6 isolated hepatocytes. The microsomal apparent Vmax value of 1589 pmol/min/mg microsomal protein extrapolates to 17.07 nmol/hr/10^6 hepato-

cytes and to 6.8 mg/hr/kg body mass, while the hepatocyte apparent Vmax extrapolates to 6.9 mg/hr/kg body mass. Our extrapolated Vmax value agrees well with other recently published model-predicted Vmax values for TRI in humans, but slightly underpredicted metabolism when incorporated into an existing TRI physiologically-based pharmacokinetic (PBPK) model. The quantitation, extrapolation and inclusion of extrahepatic and CYP-independent TRI metabolism may increase the predictive value of this approach.

664 APPLICATION OF A PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODEL FOR ETHANOL TO QUANTIFY THE BIOAVAILABILITY IN MALE RATS.

G M Pastino[1] and R B Conolly[2]. [1]*Ciba Specialty Chemicals, Tarrytown, NY;* [2]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

A portion of ingested ethanol does not reach the systemic circulation. Metabolism by gastric and hepatic alcohol dehydrogenase (ADH) has been implicated as a possible mechanism for this decrease in bioavailability. However, the extent to which each pathway contributes is not known with certainty. Variations in gastric metabolism are also thought to contribute to interindividual differences in sensitivity to the adverse effects of ethanol. The purpose of this study was to use a PBPK model for ethanol in the male rat to estimate the relative contribution of gastric and hepatic metabolism to the bioavailability of ingested ethanol and to evaluate factors that affect this process. The PBPK model was also used to re-evaluate conclusions drawn from previous studies. The current model accounted for competition between incoming ethanol from the gastrointestinal tract and recirculating ethanol, whereas previous methods only quantified the effect of ethanol entering the liver from the GI tract on the overall rate of metabolism by the liver. The model predicted that the decrease in bioavailability of ethanol was due to metabolism by both gastric and hepatic ADH. Metabolism by hepatic ADH was responsible for a greater loss in bioavailability than gastric ADH, particularly at doses below 1.5 g/kg. As the dose increased above 2 g/kg gastric and hepatic metabolism contributed almost equally to the decrease in bioavailability. The contribution of hepatic ADH was most sensitive to variations in the hepatic ADH V_{max}. Similarly, the contribution of the gastric mucosa was most sensitive to its relative capacity for metabolism. Bioavailability was also sensitive to the absorption rate and was dose-dependent. Dose dependence of bioavailability is due to the saturable nature of the gastrointestinal and hepatic metabolism of ethanol. In summary, this study shows that, when ethanol bioavailability is examined using a PBPK model, both gastric and hepatic metabolism affect systemic exposure to ethanol.

665 INVESTIGATION OF THE ENHANCED SUSCEPTIBILITY OF THE AGED RAT TO CARBON TETRACHLORIDE (CCl4) BY DEVELOPMENT OF A PHYSIOLOGICALLY–BASED PHARMACOKINETIC (PBPK) MODEL WITH AGE–SPECIFIC INPUT PARAMETERS.

J E Simmons[1], D J Schoeffner[2], J V Bruckner [2], and M V Evans[1]. [1]*NHEERL, U.S. EPA, RTP, NC, USA;* [2]*Dept. Pharm. & Biomed. Sci., Univ. of GA, Athens, GA, USA.*

Previous studies in our laboratory have shown that aged male F-344 rats are much more susceptible to CCl4–induced acute hepatotoxicity than their younger counterparts. The objectives of the present investigation were to develop a PBPK model for CCl4 in the F–344 rat with age–specific input parameters, and to use the resulting model to investigate the mechanism(s) underlying the increased susceptibility of the aged animals. Closed chamber experiments were conducted with individual aged (22 – 23 months old) male F–344 rats (n=2–4/concentration CCl4). Closed chamber data previously collected in our laboratory from young (65 – 72 days old) male F–344 rats (Evans et al., 1994) were reanalyzed with recently available age– and strain–specific physiological parameters. Age–specific values for cardiac output and blood flow were taken from Delp et al. (1998); fat volume, liver volume and partition coefficients for the old rats were determined in our laboratory. Values for the young rats were taken from the literature. Using averaged data for each inhaled CCl4 concentration, the numeric estimates of Vmaxc and Km, optimized with Simusolv©, were 0.32 mg/hr/kg and 1.16 mg/l, respectively, in the young rats and 0.85 mg/hr/kg and 1.47 mg/l, respectively, in the old rats. Assessment of hepatotoxicity in the young and aged rats that were used for estimation of metabolic rate constants revealed substantially greater toxicity in the aged rats. In conclusion, the increased metabolism in the aged F–344 rats is consistent with their increased susceptibility to CCl4. (Abstract may not reflect EPA policy. DJS was supported by a U.S. EPA STAR fellowship.)

666 COMPARATIVE TOXICOKINETICS OF CARBON TETRACHLORIDE IN RATS, MICE, AND HAMSTERS.

K D Thrall[1], M E Vucelick[1] and J M Benson[2]. [1]*Pacific Northwest National Lab, Richland, WA; and* [2]*Lovelace Respiratory Research Institute, Albuquerque, NM.*

The toxicity and toxicokinetics of CCl_4 have been studied under a variety of exposure scenarios. However, no study has comprehensively assessed the uptake, metabolism and tissue distribution of CCl_4 in species other than the rat. Therefore, species differences in the *in vivo* metabolism of CCl_4 were evaluated using groups of 3 F344 rats, 14 B6C3F1 mice or 5 Syrian hamsters exposed for 6 hr to 40-1200 ppm CCl_4 in a closed, recirculating gas-uptake system. For each species, an optimal fit of the family of uptake curves was obtained by adjusting the affinity (K_m in mg/l) and capacity (V_{max} in mg/hr/kg BW) parameters for metabolism using a physiologically based pharmacokinetic (PBPK) model. The results show that across species, the mouse appeared to have a higher capacity (V_{max} 1.15) and lower affinity (K_m 0.34) than the rat, while the hamster had both a higher capacity (V_{max} 1.44) and higher affinity (K_m 0.15) than the rat. This suggests that the hamster metabolizes more CCl_4, and at a faster rate, than either rats or mice. To further evaluate species differences, toxicokinetic studies were conducted using groups of 24 animals exposed by nose-only inhalation to ^{14}C-labeled CCl_4 for 4 hours. Groups of 4 animals/species were sacrificed, and tissues collected for analysis, immediately post exposure, and at 2, 6, 24, and 48 hrs post exposure. Exhaled breath, urine, and feces were collected from animals held for the 48-hr sacrifice time point. These studies show that tissue distribution and clearance rates for CCl_4 differ among species. For example, the relative extent of exhalation of $^{14}CO_2$ was hamster >/= mouse > rat, which is consistent with the gas uptake studies. This information is being used to improve the current PBPK model for CCl_4. (Supported by U.S. Department of Energy under Cooperative Agreement No. DE-FC04-96AL76406.)

667 PHYSIOLOGICALLY BASED PHARMACOKINETIC MODELING OF HUMAN DERMAL ABSORPTION OF CHLOROFORM FROM BATHWATER.

R A Corley[1], S M Gordon[2], and L A Wallace[3]. [1]*Battelle, Pacific Northwest Laboratories, Richland, WA, USA;* [2]*Battelle Memorial Institute, Columbus, OH, USA;* [3]*USEPA, Reston, VA, USA.*

The kinetics of chloroform in the exhaled breath of human volunteers exposed dermally via bathwater were analyzed using a physiologically based pharmacokinetic (PBPK) model. A significant decrease in the amount of chloroform exhaled (and thus bioavailability) was observed as exposure temperatures were decreased from 40 to 35 to 30° C. The blood flow to the skin and skin permeability coefficient were both varied to reflect the temperature-dependent changes in physiology and exhalation kinetics. At 40° C, there were no differences in exhalation kinetics of chloroform between males and females. Therefore, similar skin permeability coefficients were determined (~0.06 cm/hr) at a skin blood flow rate of 18% of the cardiac output. At 30 and 35° C, however, male volunteers absorbed and exhaled more chloroform than comparably exposed females resulting in lower skin permeability coefficients calculated for females. At these lower temperatures, the blood flow to the skin was also reduced reflecting the vasoconstriction and shunting of capillary blood from the skin surface to conserve body heat. Simulations of the dermal uptake of chloroform from bathwater were compared to other potential routes of exposure. Assuming an average human will take a 30 min bath at 40° C and consume 2 L of drinking water/70kg body weight/day at the MCL for total trihalomethanes, the relative contribution of dermal uptake of chloroform to the total body burden is predicted to be approximately 18%. At the lower temperatures, the predicted relative contribution of the skin to total body burdens decreases to 1-6%. (Sponsored by the USEPA 68-D4-0023; this research has not been subjected to Agency review and does not necessarily reflect the views of the Agency, and no official endorsement should be inferred.)

668 PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODELING OF ETHYLENE GLYCOL ETHERS AND ACETATES IN PREGNANT RATS.

S M Hays[1], T R Tyler[2], W M Snellings[2], K K Weitz[3], R A Corley[3], C R Kirman[1], and M L Gargas[1]. [1]*ChemRisk, Cleveland, OH, USA;* [2]*Union Carbide Corporation, Danbury, CT, USA;* [3]*Pacific Northwest Laboratories, Richland, WA, USA.*

Ethylene glycol monomethyl ether (EGME), ethylene glycol monoethyl

ether (EGEE) and ethylene glycol monoethyl ether acetate (EGEEA) have been found to cause teratogenic effects in rodents and non-human primates. For each of these chemicals, the acetic acid metabolites (methoxy acetic acid and ethoxy acetic acid, respectively) are the likely putative teratogens. PBPK models of EGME/MAA and EGEEA/EGEE/EAA disposition in pregnant rats and humans were developed based on the framework from an existing PBPK model for EGME in mice. The model was parameterized for rats using data from studies in which EGME was administered intravenously and orally. Pharmacokinetic studies were conducted in which the exposure conditions of critical toxicity studies in rats were reproduced. Specifically, pregnant rats were exposed to either 10 or 50 ppm EGME or 50 or 100 ppm EGEEA for 6 hours/day for 5 days beginning on gestation day 11. Maternal blood was collected at hours 1,3 and 5 during the exposure on day 5 and for up to 48 or 96 hours post-exposure for EGEEA and EGME exposed animals, respectively. Fetuses were collected at 6 and 14 hours post-exposure and urine was collected for 18 hours post-exposure by placing the animals in individual metabolism cages. The PBPK model accurately predicted observations from the inhalation studies. Internal dose measures (area under the MAA/EAA maternal plasma curve) for the NOELs and LOELs for both EGME and EGEEA were calculated using the PBPK model. The rat PBPK model was then scaled to humans using published information on the metabolism of these glycol ethers in human tissues and the known physiology of pregnancy in humans. The PBPK model was used to determine the workplace exposure concentration at which pregnant women would achieve the same internal dose measure as those in rats exposed at the NOELs in critical toxicology studies.

669 AN APPLICATION OF SENSITIVITY ANALYSIS WHEN USING A PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODEL FOR CHLOROFORM IN RATS.

C R Eklund and MV Evans. *US EPA/NHEERL, RTP, NC, USA.*

A non-invasive technique used for the determination of metabolism for volatile organic chemicals is gas uptake exposure. The question arises as to whether this technique is best for the determination of metabolic parameters. Sensitivity analysis, a numerical tool, was used to obtain an improved experimental design to estimate metabolism (Vmax and Km) for gas uptake inhalation exposures. We used a previously published five compartment model for chloroform, a disinfection by-product of water chlorination. The resulting simulations of liver concentration over time for four different (100, 500, 1000 and 3000 ppm) initial concentrations were used. The calculated sensitivity coefficients (SC) were related to changes in liver concentration (CL) when metabolic rate (Vmax) was changed by ± 10%. The SCs reflected the change in liver concentration given a change in Vmax over exposure time. The largest changes in absolute value for CL correspond to where the largest absolute value in SCs occur. At 100 ppm, the largest change in CL and SCs were observed within the first hour. For 500 ppm, the largest change in CL and SCs were observed within 4 hours. The largest departure from zero indicated the largest potential change in Vmax that is measurable, and these departures suggest the best sampling times. In contrast, 1000 and 3000 ppm had no peaks or valleys, but kept increasing with exposure length, implying no optimal sampling time. Sensitivity analysis suggested an optimal concentration or exposure length useful in the determination of metabolic parameters. In summary, the technique of sensitivity analysis can be helpful in planning improved measurements for future experiments. (This abstract does not necessarily reflect EPA policy.)

670 EFFECT OF AGE ON THE DISPOSITION OF TRICHLORO-ETHYLENE (TCE) USING PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODELING: COMPARISON BETWEEN ALLOMETRIC EXTRAPOLATION AND PHYSIOLOGICAL DATA.

M V Evans[1], E M Westmeyer [1,2], W K Boyes[1], P J Bushnell[1], M D Delp[3] and J E Simmons[1]. [1]*USEPA/NHEERL, RTP, NC;* [2]*MIT Biology, Cambridge, MA;* [3]*Texas A&M, College Station, TX.*

TCE is an environmental contaminant in both air and water which was chosen as a model volatile organic compound. PBPK modeling has traditionally used allometric scaling when comparing across different species. The question arises as to whether this same type of scaling can be used to account for the effect of aging within a given species. In this study, we compared the predicted tissue concentrations obtained using a PBPK model for TCE using allometric scaling. The comparison used aged rats scaled from adult physiological values with those obtained using measured flows in aged (24 month) F344 rats. The PBPK model consisted of the following compartments: blood, fat, liver, brain, muscle, kidney, and rest of the body. A one hour constant level exposure was simulated for concentrations ranging from 0.1 to 4000 ppm TCE. In general, the results of this modeling effort indicate that the most obvious differences between the measured and scaled cases were seen at the lower concentrations. The simulated concentrations using experimental data for fat blood flow were consistently larger than those using extrapolated values. For the liver, the simulations using measured flows had concentrations that were lower than those predicted when using the extrapolation. On the other hand, blood predictions using measured values were higher than the extrapolated for the lower concentrations and then the reverse was observed at the higher concentrations. In summary, preliminary PBPK modeling for TCE indicates that allometric scaling may not accurately account for changes due to aging. (This abstract does not necessarily reflect EPA policy.)

671 DEVELOPING A PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL TO DESCRIBE METHYLENE CHLORIDE KINETICS AT THE SUBCELLULAR LEVEL.

W Rish[1], C R Kirman[1], S M Hays[1], M L Gargas[1], M E Andersen[2], R H Reitz[3], F P Guengerich[4], T Green[5], E E McConnell[6], A Buckpit[7], P Voytek[8], P H Dugard[9]. [1]*McLaren-Hart/ChemRisk, Cleveland, OH, USA;* [2]*ICF Kaiser, Research Triangle Park, NC, USA;* [3]*RHR Toxicology Consulting, Midland, MI, USA;* [4]*Vanderbilt University, Nashville, TN, USA;* [5]*Zeneca, Cheshire, England;* [6]*Tox Path, Inc., Raleigh, NC, USA;* [7]*University of California, Davis, CA, USA;* [8]*Regulatory Sciences International, Alexandria, VA, USA;* [9]*Halogenated Solvents Industry Alliance, Washington, DC, USA.*

Physiologically based pharmacokinetic (PBPK) models are becoming increasingly popular in their application to human health risk assessment. By and large, these models have been used to predict internal doses at the organ level (i.e., peak concentration in the liver). To date, a PBPK model that describes chemical kinetics at the subcellular level has not been developed. A PBPK model was originally developed for methylene chloride in 1987. This model serves as the primary basis for human health risk assessments prepared by USEPA and OSHA. Over the past ten years, a great deal of information has been collected regarding the toxicity, kinetics, and mechanism of action for methylene chloride. For example, recent evidence indicates that differences in subcellular localization of glutathione S-transferase theta [1-1], the key enzyme involved in metabolic activation of methylene chloride, may explain differences across species in their relative susceptibility to methylene chloride-induced carcinogenesis. A panel of six experts on the kinetics, toxicology, and risk assessment concluded that the existing model for methylene chloride no longer reflects the current state of knowledge, and needs to be updated. For this reason, the existing PBPK model was refined to describe the subcellular localization of metabolic activity for glutathione transferases. In addition to extensive cross-species information on cytochrome P-450 2E1 activity, the refined PBPK model will rely on all of the published and unpublished data available for the subcellular localization of glutathione-S-transferase theta activity in the lung and liver of rodents and humans.

672 PHARMACOKINETIC MODELING OF OCTAMETHYLYCYCLOTETRASILOXANE (D_4) IN RATS: SINGLE AND REPEAT INHALATION EXPOSURE.

M E Andersen[1], R Sarangapani[1], R H Reitz[2], R H Gallavan[3], and K P Plotzke[3]. [1]*ICF Kaiser, RTP, NC, USA;* [2]*RHR Toxicology Consulting, and* [3]*Dow Corning Corporation, Midland, MI, USA.*

Male and female Fischer 344 rats were exposed to 7, 70 or 700 ppm octamethylcyclotetrasiloxane (D_4) for a single 6-hr exposure or for 15 consecutive 6-hr exposures. Blood, liver, lung, fat and exhaled breath D_4 concentrations, and urinary metabolite excretion data from these rats formed the basis for physiologically based pharmacokinetic (PBPK) modeling. The initial model had blood, fat, liver, richly perfused and slowly perfused tissues that were all well-mixed aggregates. Partition coefficients and metabolic rate constants were estimated from the time course data. This model provided reasonable simulation of uptake, metabolism of D_4, and blood/tissue D_4 concentrations during exposure but underestimated by orders of magnitude blood/tissue D_4 in the post-exposure period and failed to account for the gradual decline in the rate of exhalation after exposure. Addition of deep-lipid compartments within tissues, multiple fat compartments and a transported-lipid compartment to blood provided a better simulation of post exposure blood/tissue concentrations as well as the rate of exhalation. The combination of high lipophilicity and low blood:air partitioning makes D_4 a unique material requiring special consideration for dealing with transport

between these stores and more hydrophobic regions in the body. (Supported in part by the Silicones Environmental Health and Safety Council.)

673 DEVELOPMENT OF A PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PB-PK) MODEL FOR ISOPROPANOL AND ACETONE.

R Gentry[1], H Clewell[1], J Gearhart[2], T Covington[1], M Andersen[1]. [1]*The K.S. Crump Group, Inc., ICF Kaiser, Ruston, LA;* [2]*Procter and Gamble, Cincinnati, OH.*

Due to the widespread use of isopropanol, the EPA promulgated a Final Test Rule in 1989 requiring that isopropanol be tested for pharmacokinetics, subchronic toxicity, and acute and subchronic neurotoxicity. The goal of the testing was to provide the experimental basis for a more quantitative human health risk assessment for isopropanol exposure. A PBPK model was developed for isopropanol and its major metabolite, acetone. Isopropanol kinetics is described as flow-limited, with metabolism occurring in the liver, lung, and skin compartments. Acetone formed in the different metabolizing organs becomes available for clearance into the venous blood supply or can be further metabolized to carbon dioxide, which is then exhaled. The PBPK model was able to simulate isopropanol and acetone kinetics in the rat after dosing by five different routes of exposure (intravenous bolus, intraperitoneal injection, oral, inhalation, and dermal). With this validated PBPK model describing the kinetics in the rat, it would then be possible to extend this pharmacokinetic description to predict and evaluate kinetics of both isopropanol and acetone in humans. (This work was supported by both the Isopropanol and Acetone Panels of the Chemical Manufacturers Association.)

674 DEVELOPMENT OF A PBPK MODEL FOR THE ANALYSIS OF H_2S KINETICS FOR DIFFERENT ROUTES OF EXPOSURE.

J M Gearhart,[1] H J Clewell,[2] and M E Andersen[2]. [1]*Procter and Gamble, Cincinnati, OH;* [2]*ICF Kaiser, The K.S. Crump Group, Inc., Ruston, LA.*

Hydrogen sulfide (H_2S) inhalation is the chief chemical exposure hazard associated with the production of natural gas in gas fields containing high sulfur contamination. Potential exposure to H_2S also occurs at sites of decaying organic matter or inorganic sulfide under reducing conditions. The great hazard from H_2S exposure results from the combined effects of deadening the olfactory system, preventing warning of exposure, and inhibiting cytochrome oxidase in the respiratory centers of the central nervous system, producing apnea. The dose-response curve for H_2S lethality is very sharp, with concentration and not duration as the primary determinant of toxicity. Because of the occupational hazard of H_2S lethality, most animal studies addressing H_2S effects and pharmacokinetics have been conducted at lethal exposure levels or doses, lasting less than five minutes in duration. In order to make it possible to better understand the dose-response relationship for H_2S, a simple preliminary physiologically based pharmacokinetic (PBPK) model of H_2S pharmacokinetics was developed. The model assumes that upon inhalation H_2S is taken up in the blood stream according to the blood/air partition coefficient. Blood/air and tissue/blood partition coefficients were based on data from short-term inhalation studies reported in the literature. Metabolism of H_2S/HS- to sulfate was modeled as occurring exclusively in the liver. The kinetics of sulfate and its excretion was described with a simple one compartment pharmacokinetic model. Metabolism of H_2S to sulfate species was determined by fitting the model to H_2S kinetic data, and the appearance of sulfate in the urine. Overall metabolism of H_2S was adequately described with a capacity (Vmaxc) of 1.0 mg/hr (scaled by body weight to the three-quarters power), and an affinity (Km) of 1.0 mg/L. The completion and utilization of an interspecies PBPK model should reduce current uncertainties in the evaluation of the potential human health effects of H_2S.

675 PHYSIOLOGICALLY BASED TOXICOKINETIC MODELING OF INHALED ETHYL *t*-BUTYL ETHER IN HUMANS.

A Nihlén and G Johanson. *National Institute for Working Life, Solna, SWEDEN.*

Physiologically-based toxicokinetic (PBTK) models are useful tools to relate external exposure to internal doses and biological exposure markers. A PBTK model was developed for the gasoline additive ethyl *t*-butyl ether (ETBE). The compartments used to describe the kinetics of ETBE correspond to lungs (including arterial blood), liver (first order metabolism-based on experimental results), fat, rapidly perfused tissues, resting muscles, and working muscles (to account for work load). The same set of compartments and, in addition, a urinary excretion compartment were used for the metabolite *t*-butyl alcohol (TBA). Organ volumes and blood flows were calculated from individual body build. Estimates of individual metabolic parameters were obtained by fitting human experimental data, i.e. individual blood, urine and exhaled air data (ETBE and TBA) from 8 volunteers exposed to 5, 25, and 50 ppm ETBE (2 hr, 50 W, Nihlén *et al. Toxicol. Sci., in press*) with WinNonlin. Biomarker levels at end of shift (reflect the exposure during the same day) and next morning prior to shift (indicate several days of exposure) were predicted with Simnon. Workload (0 to 100 W) increases all biomarker levels by 2-fold at end of shift, and by 3-fold next morning. Only slightly increased biomarker levels are seen at end of shift during 5 consecutive work days. Predicted interindividual variability in biomarker levels in 8 subjects illustrate that variability is higher next morning than at end of shift, and higher for TBA than for ETBE. Monte Carlo simulations suggest that ETBE in blood and exhaled air at end of shift is highly sensitive to exposure fluctuations, whereas ETBE next morning and TBA in urine and blood are less sensitive to fluctuations. These simulations suggest TBA as a suitable biomarker for ETBE.

676 PHYSIOLOGICALLY BASED MODELING OF HUMAN EXPOSURE TO DICHLOROMETHANE VAPOR USING MARKOV CHAIN MONTE CARLO SIMULATIONS.

F Jonsson[1], G Johanson[1,2] and F Bois[3]. [1]*National Institute for Working Life, Solna, Sweden;* [2]*Department of Occupational and Environmental Medicine, Uppsala University Hospital, Sweden;* [3]*Lawrence Berkeley Laboratory, Berkeley, CA.*

The kinetics of volatile substances can be assessed with the aid of physiologically based toxicokinetic (PBTK) models. However, such modeling is often performed without assessing the reliability of the parameters or their variability in the population. This can be addressed with Markov chain Monte Carlo (MCMC) simulations. By using existing data on the physiological parameters, including their distributions, improved estimates of the parameters are produced, again as distributions rather than point estimates. Åstrand *et al.* (1975) exposed 14 male volunteers to dichloromethane (DCM) vapor at 250 and 500 ppm during moderate to heavy exercise. Engström and Bjurström (1977) exposed 12 male volunteers to 750 ppm during moderate exercise. Extensive physiological (including pulmonary and alevolar ventilations as well as oxygen consumption) and kinetic (DCM in venous and arterial blood, adipose tissue and exhaled air, carboxyhemoglobin (HbCO) in venous blood) data were collected in both studies. Thus, the DCM data sets were deemed suitable for testing this approach. The kinetic data were fit to a PBTK model for DCM, including HbCO, based on Andersen *et al.* (1991). The results show that already by using prior information on the parameters, these experimental studies are described reasonably well by our model. Furthermore, by using the information supplied by the experimental data it is possible to improve the reliability of the distributions of the physiological parameters. (The study was financially supported by the Swedish Council for Work Life Research.)

677 DEVELOPMENT OF A PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL FOR METHYLEUGENOL IN RATS AND MICE AFTER SINGLE INTRAVENOUS AND ORAL DOSES.

G M Blumenthal and F M Parham. *Laboratory of Computational Biology and Risk Analysis, National Institute of Environmental Health Sciences, Research Triangle Park, NC, USA.* Sponsor: R S Chhabra.

Methyleugenol is a naturally occurring flavoring agent found in nutmeg, mace, and clove oil. It is used also extensively in perfumes. Methyleugenol possesses structural similarity to the carcinogens safrole, isosafrole, estragole and has been shown to form DNA and protein adducts when administered orally to rats. Methyleugenol is rapidly absorbed and metabolized in the liver, with P450-dependent hydroxylation followed by formation of sulfates and glucuronides.We have developed a PBPK model to describe the kinetics of methyleugenol administered to rats and mice by single intravenous injection or by single oral gavage. Absorption from the GI tract is assumed to be rapid but not instantaneous, distribution is described as flow-limited, and metabolism of methyleugenol in the liver is described as saturable. Comparison of the optimized model to data from animals administered methyleugenol multiple times by oral gavage suggests auto-induction of hepatic metabolism.

678 IN VITRO AND IN VIVO KINETIC ANALYSIS OF LIPOPHILIC COMPOUNDS:TETRACHLOROBENZYL-TOLUENES (UGILEC 141).

H J Kramer, M VandenBerg, and J DeJongh. *Research Institute of Toxicology, Utrecht University, Utrecht, The Netherlands.*

Tetrachlorobenzyltoluenes (TCBTs) are present in the technical mixture of Ugilec 141, which was used in Europe as a replacement for polychlorinated biphenyls (PCBs) in the 1980s. The kinetics of some TCBT isomers in the rat were studied using in vitro and in vivo techniques. A preliminary PB-PK model, consisting of 5 compartments (blood, liver, fat, slowly perfused and richly perfused tissue) was established. Partition coefficients were estimated on forehand based on lipophilicity of the compounds and composition of the tissues. In vitro-derived metabolic rate constants for the liver were scaled to the in vivo situation. Metabolic rate constants were also determined from model optimization to in vivo-derived data. Thus, it is demonstrated that the in vitro-derived rate constants differ 3- to 4-fold from the optimized values. The estimated partition coefficients were mostly in accordance with the actual values observed in vivo. In addition, it was observed that diffusion of these compounds from adipose and muscle tissue to the blood compartment influences the elimination from the body. The present study demonstrates that in vitro-derived metabolic parameters can be used for independent parameterisation of PBPK models for lipophilic compounds.

679 SIMULATION OF GLYCYRRHIZIC AND GLYCYRRHETIC ACID KINETICS AFTER INTRAVENOUS AND ORAL ADMINISTRATION TO RATS AND HUMANS WITH A PBPK MODEL.

B A Ploeger[1], T T Mensinga[2] and J De Jongh[1]. [1]*Research Institute of Toxicology, Utrecht University, Utrecht, The Netherlands;* [2]*National Institute of Public Health and the Environment, Bilthoven, The Netherlands.* Sponsor: M vandenBerg.

Glycyrrhizic acid (GD), isolated from the dried root of *Glycyrrhiza glabra*, is used in a variety of products (e.g. as a sweetener in liquorice and chewing tobacco and for its anti-inflammatory properties in clinical therapeutics). Due to 11-β-hydroxydehydrogenase inhibition, GD and its aglycon glycyrrhetic acid (GA) can cause symptoms such as hypertension and edema. The kinetic behavior of GD and GA was studied with a rat PBPK model, for both intravenous and oral administration. Body distribution and elimination were modeled physiologically using literature data from *in vitro, in situ* and *in vivo* studies. This model explains 65% and 88% of the variation in the experimental plasma concentrations of GD and GA after iv doses of 5-50 mg/kg. Variation in the GD bile appearance was explained for 99%. To simulate kinetics of GD and GA after oral dosage, the model was extended with a gastrointestinal tract submodel. This physiologically describes GD and GA transfer to and absorption from stomach, and intestines. Intestinal conversion of GD in GA by commensal bacteria was incorporated in this model. Simulations show that this extended PBPK model is able to simulate the oral absorption of GD and GA in rats. Extrapolation of the PBPK model to humans was also successful. The a priori predicted maximum GA plasma concentration (Cmax) after 130 mg GA in oral suspension to human volunteers (equivalent to 150 g liquorice sweets) was 1.29 mg/l, whereas an average Cmax value of 1.50 mg/l was reported in 16 volunteers.

680 ESTIMATION OF SMOKE UPTAKE FROM CIGARETTE PRODUCTS USING A VALIDATED PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) NICOTINE MODEL.

K-M Chang, M F Stiles, R A Davis, D W Edwards, T Guy, J H Robinson and J D deBethizy. *R J Reynolds Tobacco Company, Winston-Salem, NC.*

A validated physiologically-based pharmacokinetic (PBPK) model has been applied to estimate nicotine absorption as a surrogate for smoke uptake from smoking a single cigarette (Chang et al., 1995 and Chang et al., 1998). In this study, 20 smokers smoked two types of cigarette products in separate sessions. During each session, subjects smoked two cigarettes of usual brands or a test product that primarily heats tobacco, every 30 minutes for one hour. Blood samples were taken before smoking and 5, 7.5, 10, and 30 minutes after smoking each individual cigarette. Serum nicotine was quantified by radioimmunoassay (RIA). Nicotine uptake was estimated by model simulation to best fit data with input of subjects' parameters. There were no statistical differences in nicotine uptake between smoking test product compared to usual brands, nor between the 1st (1.11 mg ± 0.64 mg) and the 2nd (0.85 mg ± 0.31 mg) test cigarette smoked. However, the mean nicotine uptake from usual brands was statistically different between smoking the 1st (1.35 mg ± 0.55 mg) and the 2nd (1.04 mg ± 0.38 mg) cigarettes. Our results indicate that the large interindividual variability in smoke uptake causes great difficulty in empirically defining smoke uptake for any given cigarette product.

681 A PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODEL FOR PENTACHLOROBENZENE: APPLICATION TO A MEDIUM-TERM LIVER FOCI BIOASSAY.

R S Thomas[1], D L Gustafson[1], M E Long[1], S J Borghoff[2] and R S H Yang[1]. [1]*Center for Environmental Toxicology & Technology, Department of Environmental Health, Colorado State University, Fort Collins, CO, USA;* [2]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA.*

A physiologically-based pharmacokinetic (PBPK) model for pentachlorobenzene (PeCB) was modified to incorporate the temporal changes following a partial hepatectomy and describe the disposition within the dosing schedule of a medium-term liver focus bioassay. The study consisted of a 6-week course of daily gavage administration of PeCB in a corn oil vehicle (100 μmoles/kg/day, 7 days/week). One week after the start of gavage dosing, a two-thirds partial hepatectomy was performed followed by time course measurements of PeCB in blood, liver, kidney and fat. Concentrations of PeCB in the fat have a peak concentration at approximately 300 hours after the first gavage treatment (i.e., 132 hours post-surgery). The increase is due to a mobilization of fat and is consistent with previous reports of post-surgery lipogenic enzyme induction. Blood and liver concentrations also rise dramatically following surgery as parent chemical is released from the fat during mobilization. In the kidney, the time-course tissue concentration of PeCB displays a complex behavior that is dependent on both a temporary decrease in hepatic alpha2u protein synthesis and the mobilization of fat. The construction of the PBPK model allows for the physiological changes following surgery by adjusting model parameters representing fat stores, alpha2u synthesis, and metabolism. When compared with the experimental data, the PBPK model was able to accurately describe the changes in tissue concentrations after surgery and provide a means for evaluating the dose-response relationship between the growth of preneoplastic lesions and target tissue concentrations with the medium-term bioassay. This work was supported by AFOSR (f49620-94-1-0304) and NIEHS Superfund Basic Research Program (P42 ES05949).

682 ELEVATED PROLACTIN (PRL) PRIOR TO PUBERTY AND THE DEVELOPMENT OF PROSTATITIS IN ADULT WISTAR RATS.

T E Stoker[1], R L Cooper[1], S C Laws[1], and C L Robinette[2]. [1]*Repro Tox Div, NHEERL, US EPA, RTP, NC, USA;* [2]*APR Dept, Coll Vet Med, NCSU, Raleigh, NC, USA.* Sponsor: R J Kavlock.

Previously, we reported that alterations in rat maternal serum PRL (sPRL) lead to an increased incidence of lateral prostate inflammation (LPI) in the offspring. Based on these results, we hypothesize that if the prepubertal male is made hyperprolactinemic from exposure to estrogen (E) or dopamine (DA) receptor blockers, there would be lasting effects on the prostate in adulthood. To test this hypothesis, pups were exposed daily to a DA receptor blocker, pimozide (PIM, 20 mg/kg, sc), estradiol benzoate (EB, 8 mm silastic capsule) or EB + the DA receptor agonist, bromocriptine (BR, .417 mg/kg, sc, 2 X day) or the environmental estrogen, bisphenol A (BPA) (50mg/kg, sc) from postnatal day (PND) 22 to 32. On PND28, half the males were killed by decapitation 1 h after dosing. sPRL levels were increased in the PIM, EB, and BPA groups, but sPRL was comparable in the vehicle and EB + BR males. At 120 days of age, the incidence of LPI (as determined by a myeloperoxidase assay for neutrophil conentration) in the PIM, EB and BPA groups was greater than the comparable controls. In contrast, EB + BR did not induce LPI. Thus, prepubertal hyperprolactinemia, whether it is induced by estrogen receptor agonists or DA receptor blockers, is associated with an increase in LPI in the adult. (This abstract does not reflect EPA policy.)

683 IN UTERO ANTI-ANDROGEN TREATMENT REDUCES POST-NATAL ENERGY METABOLISM IN RAT SERTOLI CELLS.

I Goddard, F Chuzel[1], R Bars[1], and M Benahmed. *Inserm U407, Faculté de Médecine, Lyon Sud, France;* [1]*Rhône-Poulenc Agro, Sophia-Antipolis, France.* Sponsor: A Blacker.

Human epidemiological studies have suggested a general decrease of quantity and/or quality of spermatozoa in developed countries, and studies on wildlife have shown abnormalities in anatomy and sexual behavior of some

male animals (alligators, bird...). These alterations have thought to be related to the lesions produced by endocrine modulators during the intra-uterine life. In order to test this hypothesis, pregnant Sprague Dawley rats were treated with an anti-androgen, flutamide (0, 2, 10, 50 mg/kg/day; from day 6 up to delivery). At post-natal day 15, male offspring were sacrificed, testes were collected and the primary cultures of Sertoli cells were prepared following enzymatic digestion. Culture media were collected for lactate assay by an enzymatic method and total RNA were extracted. Messenger RNA expression was analyzed using semi-quantitative RT-PCR. Treatment of animals by flutamide during the fetal period resulted in a decrease of lactate production by Sertoli cells (approximately 60% at all doses). In an attempt to explain this decrease and to determine the level of flutamide action, we studied the expression of genes implicated in the production and transport of lactate. The expression of lactate dehydrogenase A (LDHA) messenger (isoform involved in the conversion of pyruvate into lactate) was decreased (about 48% of inhibition) at 10 mg/kg/day. In addition, the level of lactate transporter, MonoCarboxylate Transporter (MCT) 1 and 2, mRNA was decreased in Sertoli (45% and 70%, respectively) at 10 mg/kg/day. In conclusion, the energy metabolism (production of lactate) in Sertoli cells appears to be altered in animals exposed *in utero* to flutamide. As lactate represents the preferential energy substrate for germ cells, it is possible that flutamide, by a decrease of lactate production in Sertoli cells could affect the maturation of germ cells.

684 IN UTERO EXPOSURE TO FLUTAMIDE: EFFECTS ON DEVELOPMENT OF THE MALE REPRODUCTIVE SYSTEM OF THE RAT.

F Chuzel, M Repetto, P Guittin[1], M Benahmed[2], and R Bars. *Rhône-Poulenc Agro, Sophia-Antipolis, France;[1]Rhône-Poulenc Rorer, Vitry-sur-Seine, France; [2]INSERM U407, Faculté de Médecine, Lyon Sud, France.* Sponsor: A Blacker.

The present study examined the development and function of the reproductive system of the male rat after in utero flutamide exposure during the routine dosing period recommended by EPA for developmental toxicity studies. Pregnant Sprague Dawley rats were administered flutamide in methylcellulose daily from gestation day 6 up to delivery at 0, 2, 10 and 50 mg/kg/day. In order to examine effects on the development of the reproductive system, male offspring were examined and sacrificed at specific periods between weanling and adult age (day 3, 15, 28-35 and 90). In addition, sperm analyses were performed on postnatal day 90. Maternal weight gain, parturition, pup weights and survival were unaffected by flutamide exposure at 2 and 10 mg/kg/day. In utero exposure of male offspring at 10 and 50 mg/kg/day resulted in feminization of the external genitalia and strongly reduced development of the reproductive tract. On postnatal day 3 prostate and epididymis were macroscopically affected. However, hypospadia, vaginal pouches, persistence of nipples, absence of testicular descent, reduced testis, epididymis, vas deferent, seminal vesicle and prostate weights were observed at 10 and 50 mg/kg/day from postnatal day 15. In addition, a dose-related reduction of sperm count, motility, velocity parameters of caudal epididymis sperm was noted at these doses. No treatment-related changes in sperm parameters were noted at 2 mg/kg/day. At this dose, the only significant effects were hypospadia and persistence of nipples on postnatal day 15 and 90. These findings demonstrated that flutamide administered from gestation day 6 up to delivery irreversibly altered the male reproductive system and function. In the context of hormonal disruption, the present study has identified some potentially sensitive endpoints and critical periods which could be used in discussion for risk assessment.

685 GESTATIONAL/LACTATIONAL EXPOSURES TO AROCLOR 1254 INDUCE SEVERAL P450-DEPENDENT ACTIVITIES, INCLUDING METHOXYCHLOR DEMETHYLATION, IN RAT HEPATIC MICROSOMES.

R L Carr, L A Cook, T A Couch, C G Durunna, J A Guarisco, A Kachroo, J R Richardson, J Tang, and J E Chambers. *Center for Environmental Health Sciences, College of Veterinary Medicine, Mississippi State University, Mississippi State, MS, USA.*

Polychlorinated biphenyls (PCB's), such as Aroclor 1254, are potent inducers of cytochrome P450 (CYP) in adults. Experiments were conducted to determine whether exposure of rats to Aroclor 1254 during gestation and lactation induces hepatic microsomal P450's, with special interest in the proestrogenic insecticide methoxychlor (MXC) whose didemethylated metabolite dihydroxyphenyl trichloroethane (DHPTE) binds to estrogen receptors. Pregnant female rats were administered 4 mg/kg-day of Aroclor 1254 in safflower oil p.o. from gestation day 6 through weaning, and offspring were sampled on postnatal days (PND) 15, 23, 31, and 70. PCB treatment substantially induced CYP 1A1, 2B1 and 3A2, as determined by Western blots, on PND 15 and 23 (while PCB exposure was still occurring), with moderate induction still present on PND 31 (after PCB exposure had ceased for 9 days), and no induction apparent at PND 70. No induction was observed in CYP 2C11 or 4A1, but sex-dependent development of CYP 2C11 was observed in males. Ethoxyresorufin and pentoxyresorufin *O*-dealkylases were induced 100- and 25-fold, respectively, on PND 15, 15-fold on PND 23 and 31, and not induced on PND 70. Desulfuration activities with parathion and chlorpyrifos were induced 10- and 27-fold, respectively, on PND 15, and the induction declined with age, but a 2-3-fold induction was still present at PND 70. A-Esterases were slightly induced. An age-related increase in the ability of microsomes to produce the monodemethylated MXC metabolite and DHPTE was observed, and the production of DHPTE was induced in the PCB-treated animals at PND 15, 23 and 31. Exposure to PCB's during development may have the potential to alter the organism's response to MXC-induced reproductive toxicity by modifying the amount of estrogenic metabolite produced. (Supported by EPA R825296.)

686 ANTIANDROGENIC EFFECTS OF 2,2-BIS(4-CHLOROPHENYL)-1,1-DICHLOROETHYLENE IN NEONATAL AND FETAL RATS.

B R Sparrow[1] and M J DeVito[2]. [1]*National Research Council-USEPA, USEPA, NHEERL, RTP, NC;* [2]*USEPA, NHEERL, RTP, NC.*

The insecticide dichlorodiphenyltrichloroethane (DDT) was used extensively in the US during the middle part of this century. Although banned in 1970, DDT and its major metabolite 2,2-bis(4-chlorophenyl)-1,1-dichloroethylene (p,p'-DDE) continue to be persistent environmental contaminants. p,p'-DDE acts as an antiandrogen in both *in vitro* and *in vivo* systems. Male rats exposed to high doses of p,p'-DDE *in utero* display feminized external morphology in the form of reduced anogenitial distance and retained thoracic nipples. *In vitro* studies indicate p,p'-DDE antagonizes androgen binding to the androgen receptor and alters transcription of androgen-regulated expression vectors in cell culture. The purpose of this study is to further characterized the antiandrogenic impact of p,p'-DDE upon the developing male. Time-pregnant Long Evans rats were gavaged with either 50,100, or 200 mg/kg p,p'-DDE during gestation days 14-18. Endpoints investigated include the evaluation of post-natal day 21 neonatal organ weight as an indicator of antiandrogenic activity and the quantitation of androgen receptor mRNA expression in gestation day 19 fetal tissues using RT-PCR. Neonatal livers in experimental progeny exposed to 50 or 100 mg/kg p,p'-DDE were increased in size, indicative of microsomal enzyme activation due to continual exposure to p,p'-DDE via lactation. Prostate tissue from exposed male pups displayed a dose-dependent reduction in weight, indicative of potential antiandrogenic action by p,p'-DDE. Conversely, ovaries from exposed females tended to be larger in the exposed groups, suggesting the ovaries may be a potential target for p,p'-DDE. Preliminary results from fetal tissues exposed *in utero* to 200 mg/kg/day imply an alteration of androgen receptor mRNA expression. These results further demonstrate the ability of p,p'-DDE to antagonize androgen action in fetal and neonatal rat tissues. (Funded by a National Research Council-USEPA/NHEERL Research Associateship. This abstract does not reflect USEPA policy.)

687 PRENATAL EXPOSURE TO ANTIANDROGENS ALTERS THE RESPONSIVENESS OF PROSTATE TO *p,p'*-DDE IN MALE ADULT RATS AND INDUCES PROSTATIC INFLAMMATORY RESPONSES.

L You, K A Brenneman, and H d'A Heck. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC.*

1,1-dichloro-2,2-bis(*p*-chlorophenyl)ethylene (*p,p'*-DDE) is a persistent environmental contaminant and a demonstrated antiandrogen in the rat. This study was conducted to investigate the response of adult male rats to a DDE exposure following their prenatal treatment with DDE or the nonsteroidal antiandrogen flutamide. Pregnant Long-Evans rats were dosed by gavage with 0, 10, or 100 mg *p,p'*-DDE/kg/day or 40 mg/kg/day flutamide from gestation day 14 to 18. At the age of 80 days, the male offspring in each treatment group were divided into two subgroups (n = 4 to 9). One group received DDE by gavage at 70 mg/kg/day for 4 days, while the other received the vehicle (corn oil). Prenatal antiandrogen treatment was found to cause a reduction (18, 31, and 53%, for 10 and 100 mg DDE and flutamide groups, respectively) in the ventral prostate (VP) weight on postnatal day 84. The postnatal DDE treatment reduced the VP weight in only the 0 and 10 mg

DDE groups (31 and 19%, respectively) compared to their corresponding second vehicle controls, while the 100 mg DDE and flutamide groups were not affected. Adult serum testosterone and prostate tissue mRNA level of androgen receptor in either the postnatal DDE or control group correlated poorly with the VP weights. In contrary, high correlations were found in the postnatal DDE treatment group between VP weights and the mRNA levels of prostatein C3 or testosterone-repressed prostatic message 2 (r2 = 0.82 and 0.99, respectively). In addition, histological evaluation of prostates from three prenatally exposed rats with grossly abnormal prostate appearance revealed a chronic suppurative inflammatory response. These results indicate that prenatal antiandrogen treatment alters ventral prostate responsiveness to subsequent DDE exposure. (Supported in part by the Chlorine Chemistry Council.)

688 AH RECEPTOR AND ARNT PROTEIN CONCENTRATIONS IN RAT PROSTATE: EFFECTS OF AGE AND 2,3,7,8-TETRACHLORODIBENZO-P-DIOXIN.

K M Sojka[1], R J Sommer[2], P S Cooke[4], R E Peterson[2,3], and R S Pollenz[1]. [1]*Department of Biochemistry and Molecular Biology, Medical University of South Carolina, Charleston, SC;* [2]*School of Pharmacy and* [3]*Environmental Toxicology Center, University of Wisconsin, Madison, WI;* [4]*Department of Veterinary Biosciences, University of Illinois, Urbana, IL.*

The developing male rat reproductive tract is a target of 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) toxicity, thought to be mediated through the aryl hydrocarbon receptor (AHR) and its dimerization partner, the AHR nuclear translocator (ARNT) protein. Thus, studies focused on the effects of age and TCDD exposure on AHR and ARNT protein concentrations in Total Tissue Lysates derived from reproductive organs of male rats using quantitative Western blotting techniques. AHR protein levels in the ventral prostate (VP) and dorsolateral prostate (DLP) of developing rats decreased with age, declining approximately 70% between postnatal day (PND) 1 and 21. ARNT protein levels decreased with age in the DLP, but not VP. High levels of AHR and ARNT protein were also detected on GD 16, 18, and 20 in fetal urogenital sinus (UGS). *In utero* and lactational TCDD exposure (1.0 ug/kg dam, GD15) did not alter ARNT protein levels, but reduced prostatic AHR protein levels on PND 7 and delayed the developmental decrease in AHR protein in VP and DLP. Acute exposure of rat pups to TCDD (5 ug/kg, 24 hr), down regulated prostatic AHR protein on PND 7, but not PND 1. Thus, AHR down regulation and TCDD-mediated toxicity in male rat reproductive tract do not correlate, but the expression of AHR protein appears to correlate with normal prostate differentiation. (Supported by ES08980 and ES01332.)

689 PROFILES OF EFFECTS OF ANTIANDROGENIC PESTICIDES AND TOXIC SUBSTANCES ON SEX DIFFERENTIATION.

L E Gray Jr. and J Ostby. *USEPA, NHEERL, Research Triangle Park, NC, USA.*

Antiandrogenic chemicals alter sex differentiation by a variety of mechanisms and, as a consequence, they induce different profiles of effects. Here, we describe the effects of 10 known or suspected antiandrogens from high dose studies which used over 1500 male pups from 250 litters with more than 40 different treatments conditions. Chemicals included vinclozolin (V, 3-200 mg/kg/d), procymidone (P, 25-200), iprodione (I, 100), chlozolinate (C, 100), linuron (L, 100), p,p' DDE (100), ketaconazole (K, 12-100), dibutyl (DBP, 500) and diethylhexyl (DEHP, 750) phthalate, and the Leydig cell toxicant ethane dimethane sulfonate (EDS, 50). Anogenital distance (AGD), nipple/aerola development and reproductive organ weights were measured. Six of the 10 chemicals altered male sexual differentiation (V, P, DBP, DEHP, L, and DDE). C and I will be retested at a higher dosage level. To date, dose response (DR) studies have been conducted with V, P, K, L (no AGD) and DBP (no AGD). The AR-ligands, V, P, and DDE all produced a "flutamide"-like profile. DBP and DEHP, which do not appear to be AR ligands, produced a different profile which included a surprising incidence of epididymal and testicular lesions. L, an AR ligand, induced a low incidence of hypospadias along with an unanticipated degree of malformed epididymides, suggesting that L may display additional mechanisms of endocrine toxicity. A model based in these AGD and body weight data will be presented that separates specific from nonspecific effects on AGD. We also found that an increase in aerolas/nipples at d 13 was always accompanied by permanent alterations or malformations. Examination of DR curves revealed that 1) threshold and 2) nonthreshold responses were common, but only one endpoint displayed a U-shaped DR. In summary, AGD and aerola/nipple incidence are sensitive to antiandrogens regardless of the mechanism of action, but we currently are unable to predict epididymal or testicular malformations from these early effects. (Disclaimer: These abstracts do not reflect USEPA policy.)

690 DOSE-RESPONSE FOR ALTERED MALE REPRODUCTIVE DEVELOPMENT AND FUNCTION INDUCED BY DI(*n*-BUTYL) PHTHALATE.

E Mylchreest, D G Wallace, R C Cattley, and P M D Foster. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA.*

Di(*n*-butyl) phthalate (DBP) is a commercially important plasticizer and ubiquitous environmental contaminant. Previous limited dose-response studies with DBP that reported alterations in male reproductive development and function failed to establish a NOAEL. An extensive dose-response study was conducted in which pregnant CD rats were given DBP by gavage at 0, 0.5, 5, 50, 100 mg/kg/day (n = 19—22) or 500 mg/kg/day (n = 11) from gestation day 12 to 21. In male offspring, anogenital distance was decreased at 500 mg DBP/kg/day. Retained areolas or nipples were present in 31 and 90% of male pups at 100 and 500 mg/kg/day, respectively. Preputial separation was not delayed by DBP treatment in males with normal external genitalia, but cleft penis (hypospadias) was observed in 5/58 rats (4/11 litters) at 500 mg/kg/day. Agenesis of the epididymis (21/58 rats in 9/11 litters), vas deferens (15/58 animals in 9/11 litters), and ventral prostate (1/58 animals) occurred at 500 mg/kg/day. In mature F1 males, the weights of the testis, epididymis, dorsolateral and ventral prostates, seminal vesicles, and levator ani/bulbocavernosus muscle were decreased at 500 mg/kg/day. Widespread seminiferous tubule degeneration was seen in 2/67 rats (in 2/10 litters) and 13/23 rats (in 3/5 litters) at 100 and 500 mg/kg/day, respectively. Focal interstitial cell hyperplasia (8/23 rats in 3/5 litters) and adenoma (1/23 rats in 1/5 litters) was observed at 500 mg/kg/day. For this 10-day fetal exposure to DBP, the NOAEL and LOAEL were 50 and 100 mg/kg/day, respectively. This is currently the lowest NOAEL for the toxicity of DBP.

691 DEVELOPMENTAL AND REPRODUCTIVE EFFECTS OF LOW-DOSE, STEADY-STATE MATERNAL 2,3,7,8 TETRACHLORODIBENZO-P-DIOXIN (TCDD) ADMINISTRATION.

J Ostby, M Price, O Huey, C Hurst, L Birnbaum and L E Gray Jr. *USEPA, NHEERL, Research Triangle Park, NC, USA.*

When a single dose of TCDD is administered during pregnancy, developmental alterations are seen if the fetal concentration is at 13 ppt or higher. In the current study, 0 or 10 ng TCDD/kg/d was administered to 90 d old (16/group) LE Hooded female rats for 90 d prior to mating, and during mating and gestation. This dosing regime has been reported to result in about 10 ppt TCDD in the fetus. Estrous cycles were monitored for 28 d prior to mating from 150-180 days of age. TCDD-treatment attenuated the normal age-related disruptions of estrous cyclicity and fertility (fertility = 50 % for control versus 87.5 % in the TCDD group, $p < 0.03$). The number of pups, pup weight and sex ratio were not affected by TCDD-treatment. However, infantile viability was reduced ($p < 0.0005$) from 71 % in controls to 32 % in the TCDD group. We did not anticipate an effect of this magnitude or this level of mortality in controls. As hypothesized for the F1, the age of eye opening was accelerated from 34% in controls to 70 % in the TCDD group at 15 d (p 0.005), body weight at weaning and the ages at puberty in males and females were unaffected. In addition, 23.2 % of F1 TCDD females displayed a persistent vaginal thread versus 0 % in the control group ($p < 0.04$ one tailed-t-test). However, in TCDD F1 males (only ten survived), anticipated reductions in ejaculated and epididymal numbers, and cauda epididymal weight, but these measures were not affected by TCDD. In summary, while some TCDD-like effects were seen in exposed offspring (accelerated eye opening and vaginal threads), reproductive effects were not seen in the treated male offspring. The increased incidences of normal estrous cyclicity and fertility in TCDD-treated females may result from the antiestrogencity of TCDD as endogenous estrogen in continuously cycling rats has adverse effects on hypothalamic-pituitary neuroendocrine function. (These abstracts do not reflect USEPA policy.)

692 REPRODUCTION TOXICITY OF DI-2-ETHYLHEXYL PHTHALATE (DEHP).

K Schilling, C Gembardt and J Hellwig. *Department of Toxicology, BASF Aktiengesellschaft, Ludwigshafen, Germany.* Sponsor: J F Regnier.

DEHP was investigated in a reproduction toxicity range-finding study using Wistar rats. The study was sponsored by an industry group and was con-

ducted under GLP. Dietary dose levels of 0; 1,000; 3,000 and 9,000 ppm (about 100; 300 and 900 mg/kg body weight/day) were administered to 10 males and 10 females (F0 generation) and F1 pups. Selected F1 pups were raised and mated (F1 generation) to generate F2 pups, which were sacrificed at day two after birth. DEHP had no effect on fertility up to 9,000 ppm (F0 and F1 generation). Increased liver weights were seen in F0 parental animals at 3,000 and 9,000 ppm and in F1 male parental animals at 9,000 ppm. At 9,000 ppm reduced food consumption, impaired body weight gain (both generations) and reduced weights of testes and epididymies (F1 generation only) were also noted. There was a reduced number of pups (F1 and F2 pups) and increased pup mortality (F1 pups) at 9,000 ppm. At the age of 15-18 days post partum nipple anlagen were noted in 29 out of 35 high dosed male F1 pups. This phenomenon was transient since only one out of six surviving F1 males showed nipple persistence at necropsy. Detailed external examination of F1 rats after weaning revealed no structural abnormalities, including the external genital organs. However, the examined male F2 pups had a reduced anogenital distance and anogenital index at 9,000 ppm, while females were not affected. Thus, although the high dose of DEHP induced some signs of postnatal developmental toxicity in male progeny, no effect on fertility and no abnormalities of external genital organs were found.

693 CHANGES IN THE REPRODUCTIVE ORGANS OF THE MALE RATS EXPOSED MATERNALLY TO 2,3,7,8-TETRA-CHLORODIBENZO-P-DIOXIN (TCDD).

S Ohsako[1], N Nishimura[1], Y Miyabara[2], M Ishizuka[2], Y Aoki[1], C Tohyama[1], H Sone[2] and J Yonemoto[2]. [1]*Environmental Health Sciences Division, and* [2]*Regional Environment Division, NIES, Tsukuba, Ibaraki, Japan.*

Effects of 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) on endocrine functions during developmental stage has gained much attention in terms of health risk assessment of this highly toxic compound. Some researchers reported that the transplacental exposure to TCDD during developmental stage of fetuses caused reproductive disorders, including decrease of sperm numbers, reduced size of genital organs, and also feminized behavior. We here examined relatively low dose TCDD effects on male reproductive system. Pregnant Holtzman rats (JCR) were given a single oral dose of 0, 12.5, 50, 200 or 800 ng TCDD/kg body weight on gestation Day 15, and male offspring were sacrificed on Day 2, 49 or 63 after birth. There was no TCDD effects in litter size, birth weight and sex ratios of pups for all groups. Anogenital distance of Day 2, 49 and 63 male rats showed a significant decrease in the highest dose of TCDD. Prostate was slightly reduced in size. However, there were no changes on testis and epididymal weights by TCDD administration even at the 800 ng/kg dose on Day 49 and 63. In addition, daily sperm production and sperm reserve on Day 63 were not changed by TCDD. GC/MS analysis with the abdominal fat tissue clearly showed the increased amounts of TCDD were still retained in these offspring. These results suggested that relatively low dose of TCDD could affect the external genital organs, but the internal genital organs including testis seems to be less sensitive.

694 INHIBITION OF EMBRYONIC CATALASE BY ARSENICALS AS A POTENTIAL MECHANISM OF DYSMORPHOGENESIS.

E S Hunter[1,2], F Copeland[1], L Gefrides[2]. [1]*Reproductive Toxicology Division, NHEERL, US EPA, RTP, NC, USA and* [2]*UNC–CH, Curriculum in Toxicology, Chapel Hill, NC, USA.* Sponsor: J Rogers.

The adverse developmental effects of arsenicals are well established. Exogenous antioxidants (e.g. glutathione peroxidase) ameliorate the dysmorphogenic effects of arsenite and to a lesser degree arsenate in whole embryo culture. To determine the origin of reactive oxygen species (ROS) we measured embryonic catalase activity at varying times after exposure to arsenicals in CD–1 mouse conceptuses in culture. M arsenite (that induces 100% malformations) produced a progressive decrease in embryonic catalase activity. After 6H of exposure there is a trend towards a reduction in activity (13% reduction) and a 33% reduction after 12H of exposure. By 24H catalase activity was reduced 75% by 5μ M arsenite. Catalase activity was reduced 45% by 4 μ M and 21% by 3 μ M arsenite after 24H. 20μ M arsenate produced a 25% reduction and 10 μ arsenate produced no effect on catalase activity after 24H. Therefore, one mechanism for ROS accumulation produced by arsenicals appears to be an inhibition in endogenous antioxidant defenses. In order to determine if inhibition of catalase would produce malformations, 3–6 somite stage conceptuses were exposed to 3–amino–1,2,4–triazole (3–AT), an irreversible catalase inhibitor. 3–AT produced dysmorphogenesis in embryos after a 26H culture period. The heart and pharyngeal arches were most sensitive to 3–AT and neural tube closure defects are not a major effect of 3–AT exposure. Therefore, inhibition of catalase does not reproduce the full spectrum of arsenical–induced dysmorphogenesis, but does induce the facial and heart effects. These studies suggest that the dysmorphogenic effects of arsenicals are not produced by a single biochemical effect. (This abstract does not necessarily represent US EPA Policy and was partly funded by EPA/UNC Toxicology Research Agreement CT902908 T901915.)

695 GENETIC CONTROL OF THE DIFFERENTIAL SENSITIVITIES OF THE SWV AND C57BL/6 MOUSE STRAINS TO CADMIUM-INDUCED TERATOGENICITY.

D N Hovland Jr., S G Lee, A F Machado, and M D Collins. *Department of Environmental Health Sciences, University of California, Los Angeles, Los Angeles, CA, USA.* Sponsor: O Hankinson.

As with other toxicological endpoints, sensitivity to teratogen-induced birth defects varies greatly among inbred strains of mice, demonstrating the importance of genetic background in determining susceptibility. However, the identity of the genetic factors underlying these strain differences is unknown. In a comprehensive strain comparison, C57BL/6N mice were found to be very sensitive to the induction of forelimb ectrodactyly by treatment with 4 mg/kg cadmium chloride on day 9.0 of gestation, with 73% of fetuses displaying the defect, while SWV mice were entirely resistant. A whole-genome linkage analysis has been initiated to identify the genetic factors controlling this strain-difference. This procedure involves the genotyping of backcross animals at densely spaced genomic markers to compare segregation of the limb defect with the segregation of genomic regions. 54.0 % of the 1009 microsatellite markers that have been tested were found to be polymorphic between SWV and C57BL/6, and of these, 177 were selected to assemble a genome-spanning array at an average spacing of 8.2 centimorgans. A panel of 206 fetuses has been generated from a backcross utilizing male F1 hybrids and female C57BL/6N mice treated on day 9.0 of gestation with 4 mg/kg cadmium chloride. The fetuses have been phenotyped for the presence of forelimb ectrodactyly and are currently being genotyped at each of the markers in the genome spanning array. To date, 116 markers have been genotyped in the complete panel of backcross fetuses. While preliminary analysis has not revealed any loci with significant LOD scores, several loci with scores suggesting linkage have been identified, possibly indicating that sensitivity to cadmium-induced forelimb ectrodactyly is polygenic in nature.

696 EARLY EMBRYONIC LOSS INDUCED BY DIPHENYLTIN DICHLORIDE (DPTCl) IN RATS.

M Ema, E Miyawaki and K Kawashima. *National Institute of Health Sciences, Osaka Branch, Osaka, Japan.*

The present study was conducted to evaluate the adverse effects of DPTCl on initiation and maintenance of pregnancy after administration during early pregnancy in rats. Following successful mating, female rats were given DPTCl by gastric intubation at 0, 4.3, 8.6, 17.2, 25.8 or 34.3 mg/kg on days 0-3 of pregnancy or days 4-7 of pregnancy (sperm day = day 0 of pregnancy). Female rats were sacrificed on day 20 of pregnancy and pregnancy outcome was determined. In females successfully mated, DPTCl caused complete failure in implantation, which was evidenced by total absence of any implantation site, and the pregnancy rate was significantly decreased after administration of DPTCl on days 0-3 at 25.8 mg/kg and on days 4-7 at 34.4 mg/kg. The incidence of preimplantation embryonic loss per litter was significantly increased after administration of DPTCl on days 0-3 at 17.2 (45.4%) and 25.8 mg/kg (62.1%) and on days 4-7 at 25.8 (28.4%) and 34.3 mg/kg (67.4%). In females having implantations, the numbers of implantations and live fetuses per litter and the incidence of pre- and postimplantation embryonic loss per litter in the groups given DPTCl on days 0-3 were comparable to those in the control group. The incidence of postimplantation embryonic loss per litter was significantly increased after administration of DPTCl on days 4-7 at 34.4 mg/kg. It can be concluded that DPTCl during early pregnancy caused embryonic loss and that DPTCl has greater effects on reproduction when administered earlier than later stages of blastogenesis.

697 ACQUISITION OF A MULTIPLE DRH EXTINCTION SCHEDULE OF REINFORCEMENT IN RATS EXPOSED DURING DEVELOPMENT TO METHYLMERCURY.

E B Rasmussen and M C Newland. *Auburn University, Auburn, AL, USA.*

Female rats were exposed to 0, 0.5 or 6.4 ppm Hg as methyl mercury in drinking water beginning at least 4 weeks before mating and ending on postnatal day 16. Female offspring (12 control, 10 low, and 12 high) represented six litters in each group. Concentrations of mercury in the brain for the low and higher-dosed groups were 0.5, and 9.5 ppm respectively at birth and 0.04 and 0.53 ppm at weaning. At 4 mos., female offspring were trained to lever press under Multiple Differential-Reinforcement of-High-Rate Extinction (MULT DRH-N:T EXT) schedules of reinforcement. Under the extinction schedule, lever-pressing had no scheduled consequences. Under the DRH-N:T schedule, a food pellet was delivered whenever N responses occur within T seconds. Two acquisition protocols were examined. First, the DRH parameter imposed in three successive sessions was 3:1, 5:2, and 9:4, values selected so that the same average inter-response time (i.e., rate) was required by the schedules. When the rats did not acquire the schedules in single sessions, as Bornhausen, Musch, & Greim (1980) reported, we implemented each of the three schedules individually until the rats acquired stable performance under each. Acquisition of the schedule was analyzed and marginal effects were apparent. This failed to replicate a similar experiment by Bornhausen et al. (1980) showing effects of mercury on acquisition of a Multiple DRH EXT schedule of reinforcement. (Supported by ES06466 from NIH.)

698 IN VIVO DETERMINATION OF CELL CYCLING RATES IN EMBRYONIC RAT NEURAL CELLS: DEVELOPMENT OF A BIOLOGICALLY-BASED TOXICODYNAMIC MODEL FOR METHYL MERCURY RISK ASSESSMENT.

T A Lewandowski, J L Schroeder, R A Ponce, S M Bartell and E M Faustman. *Institute for Risk Analysis and Risk Communication, Department of Environmental Health, University of Washington, Seattle WA, USA.*

We are developing a linked toxicokinetic-toxicodynamic model of the effects of methyl mercury (MeHg) in the fetal rat. Key components of the toxicodynamic model are the cell cycling rates for fetal neuroepithelial cells. While these rates have previously been determined *in vitro*, *in vivo* data are preferred for use in quantitative modeling. We are using osmotic pumps to deliver 5-bromo-2'-deoxyuridine (BrdU) to the dam at a constant rate of 0.55 mg/hr. BrdU, a thymidine analog, is incorporated into fetal DNA during the S phase of the cell cycle. Fetal midbrain tissues are harvested and evaluated with a FITC-conjugated anti-BrdU Ab and flow cytometry. Preliminary results indicate that the fraction of cells incorporating BrdU (and therefore engaged in replication) is 60±15% (mean ± SE) between gestational days 12 and 13. Cell cycle information for untreated cells has been incorporated into our toxicodynamic model and the model demonstrates good correlation ($r = 0.9$) with midbrain cell number data we have collected between gestational days 12 and 16. Our future plans are to use this system to investigate the effect of MeHg on cell cycle rates. Comparison of cell cycle data obtained *in vivo* with that we have previously obtained *in vitro* will provide a valuable indicator of the utility of *in vitro* data for quantitative risk assessment.

699 DEVELOPMENTAL METHYLMERCURY ADMINISTRATION DECREASES SYNAPTOSOMAL SIALYLTRANSFERASE ACTIVITY AND ALTERS SYNAPTIC EXPRESSION OF SIALOGLYCOCONJUGATES.

P M Dey, M A Polunas, and K R Reuhl. *Neurotoxicology Laboratories, Rutgers College of Pharmacy and the Joint Graduate Program in Toxicology, Rutgers University/UMDNJ, Piscataway, NJ.*

Defective neural structuring and neurological disturbances are recognized consequences of developmental methylmercury (MeHg) exposure, but the underlying molecular mechanisms are poorly understood. MeHg-induced perturbation of neural structure and function may involve alterations in the expression and/or regulation of molecules integral to synaptic structure, such as sialoglycosylated carbohydrates. Sialic acid residues attached to these molecules influence many biological functions, including synaptic adhesion, receptor function, and neurotransmission. To investigate the effects of MeHg on synaptic sialoglycoconjugates, rat pups were dosed with 7.0 mg/kg MeHgCl (s.c.) on alternate days from postnatal days 3-13 and killed on days 15, 30, or 60. Sialyltransferase activity was assayed in purified synaptosomes from rat hippocampus and cerebellum. Expression of sialoglycoproteins was determined by western blotting of synaptosomes and probing with the lectins *Maackia amurensis II*, *Sambucus nigra*, and Wheat Germ Agglutinin. Experiments revealed a significant decrease in synaptosomal sialyltransferase activity in synaptosomes of MeHg-treated rats at PND15 and PND30. In PND15 hippocampus, a 15% reduction was observed while a 30% reduction in sialyltransferase activity was seen on PND30. Lectin immunoblotting indicated decreased expression of various sialoglycoprotein species in the cerebellum and hippocampus of MeHg-treated animals. Altered expression of synaptic glycoconjugates in development may contribute to the behavioral and morphological disturbances observed following MeHg poisoning. (Supported by ES-04976, ES-05022 and a US EPA Graduate Fellowship [PMD].)

700 ACTIVATION OF HUMAN PLACENTAL PHOSPHOLIPASE A_2 BY NICOTINE AND COTININE: A RISK FACTOR FOR SMOKING WOMEN DURING PREGNANCY.

B V R Sastry, M E Hemontolor and M Olenick. *Department of Anesthesiology, Vanderbilt Medical Center, Nashville, TN, USA.*

Tobacco smoking by pregnant women increases frequency of spontaneous abortions and preterm births. Human labor is associated with enhanced intrauterine phospholipid metabolism and production of prostaglandin E_2 (PGE_2), which induces labor and initiates uterine contractions and maintains homeostasis of placental blood flow. Therefore, we studied (a) activation of placental phospholipase A_2 (PLA_2) by nicotine and cotinine using 1-palmitoyl-2-[1-^{14}C]arachidonylphosphatidylethanolamine (PE, 2.2 nmol) as substrate, precursor for formation of PGE_2, and (b) the influence of nicotine and cotinine on the effects of PGE_2 on placental vasculature in perfused human placental cotyledon. These studies gave the following results: (1) Both cotinine (EC_{50} 470-400 fM) and nicotine (EC_{50} 18-32 pM) activated PLA_2 in human placental tissues in low concentrations. (2) Increasing concentrations of PGE_2 (10-150 ng/ml) increased umbilical perfusion pressure by 170 ± 10% (N = 6) of control (100%). Cotinine (2 m g/ml) enhanced this effect at all concentrations of PGE_2. Nicotine (2 m g/ml) prevented the effect of PGE_2. These observations indicated that cotinine was more potent to activate PLA_2 and formation of PGE_2, and potentiate the vasoconstrictive effects of PGE_2 on the fetal placental circulation. Nicotine releases placental acetylcholine, a vasodilator of placental arteries. Acetylcholine stimulates muscarinic receptors of endothelial cells resulting in the release of endothelium-derived relaxing factor (EDRF), and possibly nitric oxide. Therefore, nicotine prevents the vasoconstrictive effects of PGE_2 through the release of EDRF. Cotinine is inactive at nicotinic and muscarinic receptors. Therefore, accumulation of cotinine, the major metabolite of nicotine, in fetal circulation may contribute to production of PGE_2 and induction of preterm labor and spontaneous abortions. (Supported by the Smokeless Tobacco Research Council, Inc.)

701 ACTIVITY OF CHOLINESTERASE ENZYMES FOLLOWING A SINGLE DERMAL DOSE OF CHLORPYRIFOS ALONE, OR IN COMBINATION WITH METHYL PARATHION IN SPRAGUE-DAWLEY RATS.

M B Abou-Donia and A W Abu-Qare. *Department of Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.*

A single subclinical dermal dose of 30 mg/kg (15% of LD_{50}) of chlorpyrifos (*O,O*-diethyl*O*-3,5,6-trichloro-2-pyridyl phosphorothioate) caused maximum inhibition of maternal and fetal brain acetylcholinesterase (AChE) after 24 hr of dosing, corresponding to activity of 48% and 67% of control, respectively. When combined with a single dermal dose of 10 mg/kg (15% of LD_{50}) of methyl parathion (*O,O*-dimethyl*O*-4-nitrophenyl phosphorothioate), peak inhibition of maternal and fetal brain AChE occurred at 24 hr, corresponding to 35% and 73% of control, respectively. Recovery of maternal brain AChE activity was slower following combined exposure compared to chlorpyrifos alone, corresponding to activity of 60% and 76% of control, respectively. Similarly, while fetal brain AChE activity returned to normal96 hrs after chlorpyrifos treatment, it was 69% of control following combined exposure. Activity of maternal plasma butyrylcholinesterase (BChE) was inhibited to 41% and 40% 24 hr after application of chlorpyrifos, or mixture of chlorpyrifos and methyl parathion, respectively. No significant inhibition has been detected in fetal plasma BChE following application of chlorpyrifos alone, or in mixture with methyl parathion. Peak inhibition of maternal liver BChE took place 24 hr after application of chlorpyrifos alone, or in combination with methyl parathion, corresponding to activity of 80% and 61% of control, respectively. Activity of BChE recovered to normal at 96 hr,

following application of chlorpyrifos, or combination of chlorpyrifos and methyl parathion. Mixture of chlorpyrifos and methyl parathion caused more inhibition in placental AChE and BChE enzymes compared to chlorpyrifos alone. Maximum inhibition of placental AChE occurred 12 hr, and 24 hr after application of chlorpyrifos, or mixture of chlorpyrifos and methyl parathion, corresponding to activity of 75% and 56% of control, respectively. No significant inhibition of placental BChE was detected following application of chlorpyrifos, or mixture of chlorpyrifos and methyl parathion. Combined dermal exposure of chlorpyrifos and methyl parathion resulted in persistent inhibition and slower recovery in maternal and fetal ChE enzyme activity.

702 INHIBITION AND RECOVERY OF MATERNAL AND FETAL CHOLINESTERASE ENZYMES FOLLOWING A SINGLE DERMAL DOSE OF DIAZINON ALONE, OR IN COMBINATION WITH METHYL PARATHION IN SPRAGUE-DAWLEY RATS.

A W Abu-Qare, C F Brownie, and M B Abou-Donia. *Department of Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.*

Pregnant Sprague-Dawley rats (14-18 days of gestation) were treated with a single subclinical dermal dose of 65 mg/kg (15% of LD_{50}) of diazinon (*O,O*-diethyl*O*-2-isopropyl-6-methylpyrimidinyl phosphorothioate), or combination of diazinon with a single subclinical dose of 10 mg/kg (15% of LD_{50}) of methyl parathion (*O,O*-dimethyl*O*-4-nitrophenyl phosphorothiate). Following an application of diazinon, maximum inhibition of maternal and fetal brain acetylcholinesterase (AChE) occurred after 24 hr of dosing, corresponding to activity of 50% and 80% of control, respectively. When diazinon was combined with methyl parathion, peak inhibition of maternal and fetal brain AChE took place at 24 hr, corresponding to activity of 46% and 37% of control, respectively. Recovery of maternal and fetal brain AChE activity following application of diazinon alone was to 80% and 90% of control in the mother and in the fetus, respectively. Recovery of maternal and fetal brain AChE activity was slower following combined exposure compared to diazinon alone, corresponding to activity of 75% and 72% of control in the mother and in the fetus, respectively. Peak inhibition of maternal and fetal plasma butyrylcholinesterase (BChE) following diazinon application occurred at 24 hr, corresponding to activity of 75% of control. Exposure to combination of diazinon and methyl parathion caused maximum inhibition of maternal and fetal plasma BChE after 12 hr and 72 hr of treatment, corresponding to activity of 12% and 70%, respectively. Fetal plasma BChE activity recovered to 100% of control following application of diazinon, and combination of diazinon and methyl parathion. Activity of maternal plasma BChE remained inhibited after 96 hr, corresponding to 32% of control. Diazinon alone, or combination of diazinon and methyl parathion did not cause significant inhibition of maternal liver BChE or placental AChE and BChE enzymes. The faster recovery of fetal ChE enzymes is attributed to the rapid *de novo* synthesis of these enzymes in the fetus compared to the mother. Combination of diazinon and methyl parathion resulted persistent inhibition and slower recovery of maternal and fetal acetlcholinesterase enzymes activity.

703 AN EVALUATION OF THE EFFECTS OF MGI 114 ON ORGANOGENESIS IN RATS AND RABBITS.

R F Marshall[1], D G Stump[2], J L Schardein[2], and J R MacDonald[1]. [1]*MGI PHARMA, INC., Minnetonka, MN, USA;* [2]*WIL Research Laboratories, Inc., Ashland, OH, USA.*

MGI 114 (6-hydroxymethylacylfulvene) is a semi-synthetic derivative of the mushroom toxin Illudin S with potent antitumor activity and is currently in Phase I-II human clinical trials. The drug was administered by daily intravenous injections to pregnant rats and rabbits to evaluate its teratologic potential. Based on the results of dose range-finding studies, doses of 0, 0.04, 0.1 and 0.4 mg/kg/d (gestation days 6-17) were used in rats and 0, 0.05, 0.15, and 0.3 mg/kg/d (gestation days 7-20) in rabbits. Body weights, food consumption and clinical observations were recorded. Laparohysterectomy's were performed (d20 in rats and d29 in rabbits). Uteri were weighed, implantation sites evaluated, the number of corpora lutea counted, and fetus viability examined. Each fetus was examined morphologically (external, visceral, and skeletal). In rats, maternal toxicity consisting of reduced mean body weights, food consumption, and gravid uterine weights, was observed at 0.4 mg/kg/d. Developmental toxicity (reduced fetal body weights, increased postimplantation losses, microphthalmia, and skeletal variations) was also observed at 0.4 mg/kg/d. In rabbits, maternal toxicity consisting of two abortions at 0.3 mg/kg/d and reduced mean body weights and food consumption was observed at doses ≥ 0.15 mg/kg/d. Developmental toxicity in rabbits, at doses ≥ 0.05 mg/kg/d, included malformations (lobular agenesis of the lung, paragonadal vascular proliferation, costal cartilage anomalies, fused sternabrae, and 14th full ribs) and skeletal variations. The NOAEL for developmental toxicity was considered to be 0.1 mg/kg/d in the rat study and <0.05 mg/kg/d in the rabbit study.

704 EFFECTS OF DIETHYLENE GLYCOL MONOMETHYL ETHER AND ETHYLENE GLYCOL MONOMETHYL ETHER ON *IN VITRO* CHONDROGENESIS.

E S Hanson and M A Smith. *Department of Environmental Health Science, University of Georgia, Athens, GA, USA.*

Chick embryo limb bud mesenchymal cells, when grown in tissue culture under conditions conducive for chondrogenesis, differentiate into chondrocytes. Ethylene glycol monomethyl ether (EG) and diethylene glycol monomethyl ether (DEG) were added directly to cell cultures in log concentrations (EG=0.00097 - 97mg/ml; DEG=0.00101 - 101mg/ml) to determine their effects on chondrogenesis and cell proliferation. After five days, cultures were fixed and chondrogenesis analyzed by staining with alcian green for proteoglycans and measuring absorbance at 600 nm wavelength. Subsequently, cell proliferation was analyzed by staining with crystal violet and measuring absorbance at 570 nm wavelength. Significant difference from control cultures was determined using a Dunnett's T-test ($p<0.05$). At the highest concentration tested, proteoglycan content was significantly different from controls for both chemicals (1.4% of control for DEG and 1.6% of control for EG), but the decrease did not appear to be concentration-dependent. For cell proliferation, all treatments were significantly different from control and showed a concentration-dependent pattern. Cell proliferation ranged (from the lowest to the highest concentration) from 73.7% to 1.8% of control for DEG and from 83.6% to 2.4% of control for EG. In conclusion, as chemical concentration increased for DEG and EG, a concentration dependent decrease in cell proliferation occurred. For proteoglycans, the decrease is likely a result of general cell toxicity because it does not appear to be concentration dependent. (Supported in part by US Air Force Office of Scientific Research and Hatch Funds to MAS.)

705 CHARACTERIZATION OF OCHRATOXIN A (OTA) UPTAKE AND DEVELOPMENTAL TOXICITY USING THE FETAX SYSTEM.

E O'Brien, A Prietz and D R Dietrich. *Environmental Toxicology, University of Konstanz, Konstanz, Germany.*

The mycotoxin ochratoxin A has been observed to be teratogenic in rat, mouse, hamster and chick models with craniofacial abnormalities being the most commonly noted malformations. Possibly due to its almost ubiquitous nature in foodstuffs, all human blood samples tested to date have proved positive for the toxin. Its half-life in humans has been demonstrated to be well in excess of that in rodents and OTA has been associated with the occurrence of Balkan Endemic Nephropathy (BEN) as well as the formation of urothelial tract tumors in humans. However, the role of OTA in the current incidence of human teratogenic events remains to be elucidated. The aim of this study was to characterize the teratogenic effects of OTA in the FETAX assay, a system, which has previously been shown to be sensitive to human teratogens. Embryos incubated with 2?Ci tritiated OTA showed a time-dependent increase in uptake of radioactivity over 24, 48 and 72 hours, with a two-fold increase in uptake subsequent to the opening of the oral cavity ie feeding reflex (96h). Following standard range-finding experiments, stage 8-11 *X. laevis* embryos were selected and exposed to nM concentrations of the toxin for 96h essentially in accordance with ASTM standard protocol with medium and toxin renewal at 48h only. Embryos were fixed and mortality, malformation and growth inhibition, were assessed. An LC_{50} of 200nM was noted and OTA-exposed embryos displayed a specific and reproducible craniofacial narrowing (EC_{50} 60nM) which was inconsistent with generalized growth retardation known for other teratogens or embryotoxicants. No increased incidence of other common malformations, such as incomplete gut coiling or axial defects were observed in the presence of the toxin. At higher concentrations (200-400nM), a decrease in average embryo length by up to 20% was noted. The type of malformations and growth retardation observed suggests a specifically localised incipient cytotoxicity or inhibited cell proliferation mediated by OTA.

706 RETINOIC ACID-INDUCED HINDLIMB MALFORMATIONS IN WOOD FROGS (*RANA SYLVATICA*).

S J Degitz, P A Kosian, E A Makynen and G T Ankley. *U.S. EPA, MED, Duluth, MN.*

Recently, high frequencies of hindlimb malformations have been reported in amphibians across North America. The phenotype of the malformations is similar to those produced by retinoids in mammalian, avian and amphibian species. The objective of this study was to determine if retinoids induced hindlimb malformations in the wood frog (*Rana sylvatica*). Stage 28 tadpoles were exposed to 0, 250, 500, 750, 1000 and 1250 ng/ml of all-trans retinoic acid (RA) for 24 h. Water and tissue samples were collected at 0, 4, 12 and 24 h and analyzed via HPLC to characterize aqueous degradation and tissue residues in exposed tadpoles. Tadpoles were held until forelimbs emerged, and prepared for skeletal analysis. RA concentrations in water dropped rapidly to 14% of target concentrations within 4 h, and were near detection limits within 12 h. Tissue RA concentrations were greatest at 4 h (10-50 μg/g) and declined rapidly by 24 h (0.1-7 μg/g). A number of unidentified metabolites were observed and are being further investigated. We found a 48% incidence of hindlimb defects at the lowest concentration, and this increased to 68% at the 1250 ng/ml exposure. The malformations ranged from minor effects on the digits to severe disruption of the femur, tibia/fibula, tibiale/fibulare and digits. This is in contrast to experiments conducted with the northern leopard frog (*R. pipiens)* in which the same concentration did not induce hindlimb malformations. Differences in the developmental rate between these two species may explain their seemingly differential sensitivity to pulse doses of RA.

707 LIFE-STAGE SPECIFIC EFFECTS OF ALL-TRANS RETINOIC ACID ON GREEN FROG (*RANA CLAMITANS)* EMBRYOS AND TADPOLES.

P A Kosian, E A Makynen, G T Ankley and S J Degitz. *U S EPA, MED, Duluth, MN, USA.*

It has been suggested that the large number of malformed frogs recently observed in North America may be occurring as a result of disruptions in developmental pathways regulated by retinoic acid. Therefore, a series of experiments were undertaken to examine life-stage specific effects of all-trans retinoic acid (RA) on the North American anuran, green frog (*Rana clamitans)* embryos and tadpoles. Stage 8 embryos were exposed to 0, 3, 6.25, 12.5, 25 and 50 ng/ml RA for 24 h. Embryos were then moved to clean water and at stage 22, tadpoles from all treatments were sub-sampled and scored for dysmorphogenesis. In addition, stage 28 tadpoles were exposed to RA concentrations of 0, 250, 500, 750, 1000 and 1250 ng/ml. These tadpoles were held until forelimbs emerged and prepared for skeletal analysis. In the embryo exposures, RA concentrations of 12.5 ng/ml and above induced lethality, with all animals dying at the 50 ng/ml treatment. Surviving animals from the 12.5 ng/ml and higher treatments exhibited an increase in dysmorphogenesis of the tail, notochord, eye, forebrain and cement gland. Moreover, dose-related delays and growth reductions were observed in treated embryos when compared to the controls. These results were in contrast to the stage 28 tadpole exposure where RA concentrations of 1250 ng/ml did not produce lethality. Overall, our experiments show that RA is teratogenic to *R. clamitans* embryos, with animals approximately 100 times more sensitive to RA-induced lethality than stage 28 tadpoles.

708 DYSMORPHOGENESIS AND LETHALITY OF MINK FROGS (RANA SEPTENTRIONALIS) EXPOSED TO ALL-TRANS RETINOIC ACID AT DIFFERENT LIFE STAGES.

E A Makynen, P A Kosian, G T Ankley and S J Degitz. *U.S. EPA, MED, Duluth, MN.*

An extremely large number of malformed frogs have been found in Minnesota, as well as in other states, and Canadian Provinces. The documented malformations have striking similarities to those produced by retinoids in developing mammalian, avian and amphibians species. The spectrum of malformation is quite broad indicating insult over a broad developmental period. The objective of this study was to examine the stage specific sensitivity of mink frogs, (*Rana septentrionalis*), to retinoid-induced dysmorphogenesis and lethality. Embryos were exposed to all-trans retinoic acid (RA) at stage 8, 26, or 28. Stage 8 embryos were exposed to 0, 6.25, 12.5, 25 and 50 ng/ml RA for 24 h. Stage 26 and 28 tadpoles were exposed to 0, 250, 500, 750, 1000 and 1250 ng/ml RA for 24 h, held until forelimbs emerged and preserved for skeletal examination. Concentrations of 6.25 ng/ml and above produced increased lethality, and dose-related increase in dysmorphogenesis of the eye and forebrain in the stage 8 exposed embryos. In addition to these effects, concentrations of 12.5, 25 and 50 ng/ml produced an increase in tail, notochord, and cement gland dysmorphogenesis as well as developmental delay. This was in sharp contrast to later stage exposures in which RA concentrations as high as 1250 ng/ml did not produce lethality. Not only do these experiments show that RA is teratogenic, but that the embryo is at least 200 times more sensitive to RA-induced lethality than stage 26 and 28 tadpoles.

709 EFFECTS OF CONTINUOUS OR INTERMITTENT INHALATION AND ORAL EXPOSURE OF 4-BROMO-2-NITROPHENOL ON THE WISTAR RAT'S DEVELOPMENT.

A V Lyubimov, K K Kabirov and V V Babin. *Center of Ecology and Biotesting, Perm, Russia.* Sponsor: R D Hood.

4-Bromo-2-Nitrophenol (BNP) is a structure analog (isomer) of the 3-Bromo-4-Nitrophenol which is used as lampricide. Wistar rats were exposed to BNP by whole body inhalation at concentrations of 0, 0.01, 0.14 or 1.0 mg/m^3 for 24 hr/day (24-hr group); and for 4 hr/day at concentrations of 0.14, 1.0, 2.8 mg/m^3 (4-hr group); or by gavage at doses 0, 0.3, 1.0, 6 mg/kg/day (oral group). All animals were treated 7 days/week throughout gestation. General toxic effects on the dam's liver and kidneys were found only at the maximum concentrations/doses in all three experimental groups. Significant depression effects on the maternal CNS was registered in the oral and 24-hr groups but not in the 4-hr group. This depression of the CNS was also registered at the highest of the tested concentrations/doses. BNP treatment by all types of exposure increased embryolethality, retarded weight, length and skeletal ossification of the fetuses, and affected postnatal development of the offspring. Significant suppression in the open field was shown for horizontal movement and orientation reactions of the offspring in the 24-hr group; horizontal movement, orientation reactions and emotionality for the 4-hr group and for the orientation reaction and emotionality in the oral group. These changes were dose/concentration-dependent and statistically significant at the higher levels of exposure. Therefore, depression influence of BNP on the CNS of mothers and their offspring was shown. Analyzing the LOAELS (Lowest Observed Adverse Effect Levels) for the reproductive effects of BNP suggests that developmental toxicity is enhanced approximately 10 fold by both inhalation routes in comparison to an oral route.

710 FISH EMBRYOTOXICITY AND TERATOGENICITY OF PHARMACEUTICALS, DETERGENTS AND PESTICIDES REGULARLY DETECTED IN SEWAGE TREATMENT PLANT EFFLUENTS AND SURFACE WATERS.

D R Dietrich[1,2] and A Prietz[1]. [1]*EUREGIO Ecotoxicology Service Laboratory, Konstanz, Germany;* [2]*Environmental Toxicology, University of Konstanz, Germany.*

Recent chemical analysis of sewage treatment plant effluents (STPE) and surface waters in southern Germany revealed surprisingly high concentrations of pharmaceuticals, especially NSAID's, pesticides and detergents. In view of this laboratory experiments were conducted using the previously established zebrafish embryo assay DRETA (*Danio Rerio* Embryotoxicity and Teratogenicity Assay, Dietrich et al., Toxicol. Sci., 42(1-S), 1279, 1998) to determine the potential detrimental effects of a limited but representative selection of environmentally present compounds to zebrafish embryos. The compounds tested were: Diclofenac, Phenylbutazone, Acetyl salicylic acid, Ibuprofen, Indomethacin, Naproxen, *bis*-Phenol A, Nonylphenol, and Carbendazim. Caffeine, Ethanol and Valproic acid served for further validation of the DRETA and as positive controls. All compounds tested demonstrated embryotoxicity and induced malformations in the zebrafish embryos within the 96 hours of exposure. However, with the exception of Diclofenac, the concentrations necessary to induce lethality or malformation were several orders of magnitude higher than those observed in the STPE or the surface waters. The LC50 and EC50 of Diclofenac was 480±50μg/l and 90±20 μg/l, respectively. Diclofenac concentrations detected in STPE and surface waters range between 0.05-1.6 μg/l and 0.015-0.5 μg/l, respectively. In view of the 9-12 fold longer hatching period of embryos of feral fish species when compared to the zebrafish embryos, detrimental effects (malformation) in feral fish embryos resulting from exposure to environmental concentrations of Diclofenac appears a distinct possibility.

711 ONTOGENY OF HEAT SHOCK PROTEIN RESPONSE IN THE TELEOST, MEDAKA (ORYSIAS LATIPES).

I Werner[1], C Koger[1], J T Hamm[2], D E Hinton[1]. [1]*University of California Davis, Davis, CA;* [2]*USEPA, Apex, NC.*

Different developmental stages of fish and other organisms vary in their susceptibility to toxic compounds and other physiological stressors. In part, this has been linked to the individual's ability to express certain proteins , i.e., stress proteins or cytochrome P450 monooxygenases, after exposure. It is important to understand whether there are developmental landmarks which must be reached before expression may occur. This study used the transparent chorion of a well-characterized fish model to time initiation of heat stress to coincide with particular landmarks of development. Responses, induction of hsp70, hsp60 and hsp90 and developmental defects, were and are being characterized in eight stages of the teleost, medaka, including embryo (11, 19, 23, 28 and 35), larvae (24-36 hours after hatch), sexually immature juveniles (1 month old) and sexually mature adults. Fish were heat-shocked at 40° C for 30 minutes, and subsamples were preserved after 1, 2 3, 6, 12 and 24 hours. Western blotting techniques were used to analyze stress proteins, and developing embryos were examined daily. Hsp70 was not inducible in stage 11 embryos, and these embryos subsequently showed developmental defects. In all other stages, hsp70 levels increased after heat-shock, and embryos developed normally. Although larvae, juveniles and adults were able to mount a stress protein response, they proved more susceptible to heat-shock than embryonal stages (with the sole exception being stage 11). Additional hsp70 isoforms were present in Medaka larvae, juveniles and adults. Constitutive levels of hsp70 were elevated just before (stage 35) and after hatching (larvae). Results suggest that the ability to express hsp70 confers a degree of protection on the individual. Further work will involve exposure to xenobiotics, where timing of exposure may affect toxicity results.

712 APOPTOSIS AS A POTENTIAL MECHANISM OF IMMUNE SUPPRESSION CAUSED BY EXPOSURE TO 2,3,7,8-TETRACHLORODIBENZO-P-DIOXIN (TCDD).

E A Dearstyne and N I Kerkvliet. *Department of Environmental and Molecular Toxicology and the Environmental Health Sciences Center, Oregon State University, Corvallis, OR, USA.*

The immune system is very sensitive to the toxic effects of TCDD. The mechanism by which TCDD suppresses immune function is currently unknown. Apoptosis plays a critical role in the normal immune response during lymphocyte maturation, activation, effector function and down regulation. We hypothesized that one potential mechanism by which TCDD suppresses immune function is by the induction or augmentation of apoptosis in responding immune cells. We have previously reported that in response to anti-CD3, TCDD increased the percentage of $CD4^+$ and $CD8^+$ T cells undergoing late apoptosis/necrosis but not early apoptosis. Apoptosis was measured by phosphatidylserine (PS) exposure on the cell surface, an early marker of apoptotic cells. From these results, we were interested in testing our hypothesis in a model previously shown to be suppressed by exposure to TCDD, the P815 tumor allograft model. Male C57Bl/6J mice were gavaged with vehicle or TCDD (15μg/kg) one day prior to intraperitoneal injection of P815 allogeneic tumor cells ($1x10^7$/ mouse). The spleens were harvested on days 1-7 after P815 injection and analyzed for the apoptotic phenotype by flow cytometry using FITC-Annexin V, 7-AAD, PE-CD4, and Red613-CD8. When compared to vehicle-treated mice, TCDD exposure significantly decreased the percentage of $CD4^+$ and $CD8^+$ T cells that expressed the early apoptotic phenotype. This effect was significant on days 5-7 in $CD4^+$ cells and in $CD8^+$ cells on all days tested. TCDD treatment had no consistent effect on T cell Fas expression or relative intensity of the stain on any of the days tested. These results suggest that apoptosis is not a mechanism by which TCDD causes suppression of the P815 response. However, this conclusion should be tempered by the fact that the data from this study represent a measure of cells with the apoptotic phenotype in the entire population of T cells and not exclusively the antigen-specific cells. (This work is supported by NIEHS grants ES07060 and ES00040.)

713 MECHANISTIC DIFFERENCES IN APOPTOSIS OF PULMONARY NEUTROPHILS FOLLOWING IN VIVO EXPOSURES TO CRYSTALLINE SILICA OR TITANIUM DIOXIDE PARTICLES.

D D Zhou, M A Hartsky, and D B Warheit. *DuPont Haskell Lab., Newark, DE.*

Apoptosis, or programmed cell death has been reported to occur in macrophages in vitro following exposures to fibrogenic dusts such as silica or asbestos. This study was undertaken to test the hypothesis that the inability to resolve the silica-induced inflammatory response via apoptosis is associated with its fibrogenic potential. Groups of rats were exposed by intratracheal instillation to varying doses of crystalline silica (Si) or pigment-grade titanium dioxide (TiO_2) particles and evaluated over several postexposure time periods. Following exposure, the BAL cells of control and exposed rats were assessed for apoptosis using four different techniques 1) cell death ELISA assay, 2) DNA ladder; 3) apoptotic morphology; and 4) TUNEL assay. Silica induced a significant dose-related increase in inflammation and apoptosis of pulmonary inflammatory cells. The inflammation was sustained but the apoptotic effects declined over time. TUNEL assay studies confirmed that the vast majority of apoptotic cells were neutrophils and not alveolar macrophages. In contrast, at high doses, TiO_2 produced lung inflammation but only a weak apoptotic response. The results from this in vivo study show that the PMN is the primary inflammatory cell-type which undergoes apoptosis. In addition, the magnitude of apoptosis induced by Si was significantly larger than that induced by TiO_2 at doses causing similar degrees of inflammation, indicating mechanistic differences between the cellular responses to the 2 dusts. Finally, it seems likely that the apoptotic clearance mechanisms to resolve pulmonary inflammation were overwhelmed in silica-exposed rats.

714 CHARACTERIZATION OF CI-994 INDUCED APOPTOSIS IN HUMAN LEUKEMIA (HL60) CELLS.

T A Padalino, E A Cockrell, A J Gonzales, and M J Graziano. *Department of Pathology and Experimental Toxicology, Parke-Davis Pharmaceutical Research, Ann Arbor, MI.*

CI-994 (acetyldinaline) is an investigative oral anticancer drug with an unknown mechanism of action. In previous in vitro toxicity studies, CI-994 was shown to induce apoptosis in rat blood lymphocytes and HL60 cells based on changes in cell morphology and DNA fragmentation. To identify the molecular pathways involved in this response, HL60 cells were incubated with CI-994 at concentrations of 0, 3, 10, or 30 μ M for up to 24 hours, and immunoblotting techniques were used to evaluate changes in various proteins involved in apoptosis. Apoptosis was confirmed by flow cytometry analysis using Hoechst 33342 and Annexin V stains. CI-994 did not effect protein levels of bax, bcl-2, cyclin D1, CDK-2, or p21/WAF1. However, p27KIP1 levels were increased following CI-994 treatment. The inactive form of caspase-3 was decreased at 30 μ M CI-994, and the caspase-3 substrate poly(ADP-ribose) polymerase (PARP) was cleaved into the signature 89kd fragment at 10 and 30 μ M CI-994, suggesting that caspase-3 was activated during CI-994-induced apoptosis. Interestingly, induction of PARP, which can recognize and bind to DNA strand-breaks, occurred at 3 μ M CI-994, indicating the presence of DNA damage. These results suggest that CI-994-induced apoptosis involves a caspase-3 mechanism which may be precipitated by DNA damage.

715 2,3,5-*TRIS*-(GLUTATHION-*S*-YL)HYDROQUINONE DEPLETES CELLULAR GLUTATHIONE, STIMULATES SPHINGOMYELIN TURNOVER, AND INDUCES APOPTOSIS IN HL-60 CELLS: ROLE OF REACTIVE OXYGEN SPECIES AND NUCLEAR FACTOR-κB.

S B Bratton, S S Lau, and T J Monks. *Division of Pharmacology and Toxicol., College of Pharmacy, Univ. of Texas @ Austin, TX, USA.*

Quinol-thioether metabolites are present in the bone marrow of rats and mice cotreated with hydroquinone and phenol. Several of these metabolites, including 2,3,5-*tris*-(glutathion-*S*-yl)-hydroquinone [TGHQ], are hematotoxic in rats and induce apoptosis in human promyelocytic leukemia (HL-60) cells. The mechanism governing this process is unknown. We now report that TGHQ (200 μM) inhibits γ-glutamyl transpeptidase *in vitro* and depletes cellular glutathione (GSH) in HL-60 cells in a reactive oxygen species-(ROS) independent manner. GSH is a physiological inhibitor of neutral, magnesium-dependent sphingomyelinases *in vitro*. Consequently, TGHQ

also induced sphingomyelin turnover in HL-60 cells, leading to a >300% increase in intracellular ceramide. Ceramide, a lipid second-messenger, mediates a variety of biological effects, including activation of caspase-3, and generation of ROS *via* inhibition of the mitochondrial respiratory chain. Similarly, TGHQ- induced activation of caspase-3 and TGHQ-mediated apoptosis were partially inhibited by the caspase-3 inhibitor, DEVD-CHO, and completely blocked by catalase. Consistent with an increase in ROS, increased NF-κB binding activity was also observed. Cotreatment of TGHQ-treated cells with a cell-permeable peptide (SN50), corresponding to the nuclear localization sequence (VQR**KRQK**LM) of NF-κB, completely blocked TGHQ-induced DNA fragmentation. Surprisingly, catalase did not appear to block the induction of NF-κB. We are therefore currently investigating the precise role of NF-κB in TGHQ-mediated apoptosis. (ES 07247).

716 CATECHOL AND HYDROQUINONE METABOLITES OF BENZENE AND REMOXIPRIDE, TWO COMPOUNDS ASSOCIATED WITH APLASTIC ANEMIA, INDUCE APOPTOSIS IN HUMAN BONE MARROW PROGENITOR CELLS.

S M McGuinness[1], R Johansson[2], J Lundstrom[2] and D Ross[1]. [1]*School of Pharmacy, University of Colorado Health Sciences Center, Denver, CO, USA and* [2]*Astra AB, Sodertalje, Sweden.*

The antipsychotic agent remoxipride ((S-(-)-3-bromo-N-[(1-ethyl-2-pyrrolidinyl) methyl]2,6-dimethoxybenzamide) was introduced to the market in 1992 and withdrawn due to induction of aplastic anemia in a small number of patients. Metabolism of remoxipride generates both pyrrolidine and benzene ring oxidation products. In humans pyrrolidine ring oxidation predominates although phenol, catechol and hydroquinone derivatives are also generated. Benzene has also been associated with aplastic anemia in humans. Induction of apoptosis in human CD34+ bone marrow progenitor cells represents a potential mechanism underlying aplastic anemia and the benzene metabolites, catechol and hydroquinone, but not phenol, induce marked apoptosis in CD34+ cells. Remoxipride metabolites were examined for their ability to induce apoptosis in both HL-60 cells and in CD34+ human bone marrow progenitor cells. Remoxipride and its pyrrolidine ring oxidation products were inactive while catechol and hydroquinone derivatives of remoxipride induced marked apoptosis in both HL-60 cells and in human CD34+ cells. Interestingly, phenol metabolites of remoxipride were inactive at inducing apoptosis in either HL-60 or CD34+ cells. These data demonstrate marked structural similarities between metabolites of benzene and remoxipride that are capable of inducing apoptosis in human hematopoietic progenitor cells and provide insight into cell-specific toxic effects that may be associated with aplastic anemia. (Supported by Astra AB.)

717 THE ROLE OF DMBA METABOLITES IN PREB CELL APOPTOSIS.

K K Mann[1], M E Hahn[2], AF Trombino[1], B P Lawrence[3], N I Kerkvliet[4], and D H Sherr[1]. [1]*Boston Medical Center, Boston, MA, USA;* [2]*Woods Hole Oceanographic Institute, Woods Hole, MA, USA;* [3]*Washington State Univ., Pullman, WA, USA;* [4]*Oregon State Univ., Corvallis, OR, USA.*

PAH, including 7,12-dimethylbenz[a]anthracene (DMBA), are immunosuppressive. Comparable or superior immunosuppression with PAH metabolites has been taken as evidence of a role for metabolism in PAH immunotoxicity. DMBA immunotoxicity may be manifest as apoptosis induction in a preB cell line (BU-11) maintained on cloned bone marrow stromal cells (BMS2). Apoptosis was dependent on the aryl hydrocarbon receptor/transcription factor (AhR) or AhR-regulated genes. Since PAH metabolism is dependent on AhR-regulated cytochrome P-450 (CYP) enzymes, the present study evaluated the role of metabolism in preB cell apoptosis. The AhR antagonist and CYP1A inhibitor α-naphthoflavone (α-NF) blocked DMBA-induced apoptosis. While a general CYP inhibitor completely ablated CYP1A activity in control Hepa-1 cells, it had no affect on DMBA-induced apoptosis in BMS2/BU-11 cultures. Indeed, BMS2 cells expressed little or no constitutive or inducible CYP1A1 mRNA or protein. They did express CYP1B1 mRNA and protein. Since CYP1B1 metabolizes DMBA to DMBA 3,4-dihydrodiol in BMS2 cells, the potential for this metabolite to induce apoptosis and/or circumvent a requirement for the AhR was evaluated. Indeed, DMBA 3,4-dihydrodiol was as potent as the parent compound in inducing BU-11 cell apoptosis. Surprisingly, apoptosis induced with DMBA 3,4-dihydrodiol was blocked with either α-NF or another AhR antagonist, galangin. Furthermore, DMBA 3,4-dihydrodiol induced relatively little apoptosis when added to co-cultures of BU-11 cells and bone marrow stromal cells from $AhR^{-/-}$ mice, suggesting a role for the AhR even after initial oxidation of the PAH substrate. Finally, DMBA-3,4 dihydrodiol was shown to bind to and activate the AhR. Collectively, these data suggest a feedback loop in which DMBA metabolism, possibly mediated by CYP1B1, may augment AhR signaling leading to preB cell apoptosis. (Supported by PHS grants RO1-ES06086 and 1P42ES 07381.)

718 VISUALIZATION OF INTRACELLULAR SIGNALS BEFORE AND DURING DEXAMETHASONE-INDUCED APOPTOSIS OF NB2 RAT LYMPHOMA CELLS.

A P Guanzon and R J Witorsch. *Virginia Commonwealth University, Richmond, VA.*

Synchronized (G_0/G_1) Nb2 rat lymphoma cells were fixed in 3.7% formalin-0.9% NaCl and spotted on to slides after incubation with 100 nM dexamethasone (Dex) or vehicle for 0, 1, 2, 4, 6, and 8 hr. Apoptosis was monitored by the TUNEL assay. Glucocorticoid receptor (GR), IkB-α , and NFkB were visualized with ABC immunoperoxidase assay. The percentage of cells stained by TUNEL or ABC was determined by counting 400 to 1600 cells from photomicrographs. A significant ($p<0.05$) increase in apoptotic cells was first observed 8 hr after Dex (20±2%)* vs control (10±2%)*, which is later than the 4 hr previously reported with DNA laddering or diphenylamine (LaVoie and Witorsch, PSEBM 209: 257, 1995). Synchronized cells revealed similar percentages of immunostaining for GR (42±1%)*, IkB-α (39±0%)*, and NFkB (43±1%)*. Up to 8 hr Dex exposure produced no significant change in the percent GR, IkB-α , or NFkB cell staining. The percent GR+ cells is consistent with the magnitude of Dex-induced cell death at 24 hr (44±4%)* vs control (16±3%)*. The similar percentage of cell staining for GR, IkB-α , and NFkB is consistent with their functional associations. (Supported by the Jeffress Trust of NationsBank and CAAT of Johns Hopkins Univ.) * Mean±SEM from 3 experiments.

719 GROUP II CASPASES (CASPASES-3, -7, -2) ARE NOT INVOLVED IN APOPTOSIS INDUCED BY GLUCOCORTICOIDS AND CYTOKINE DEPRIVATION ON LYMPHOID CELLS.

G Hache, A Biola, and M Pallardy. *Immunotoxicology group, INSERM U461, Faculté de Pharmacie Paris-Sud, Châtenay-Malabry, France.*

Group II caspases (casp-3, -2, -7) cleave key proteins possessing a DExD (asp-glu-x-asp) amino acids consensus sequence during the apoptotic process. Among these caspases, casp-3 has been shown in numerous models to be a key executionner of apoptosis, and is partially or totally responsible for the proteolytic cleavage of key proteins. We investigated the role of different caspases in dexamethasone (dex) and cytokine withdrawal-induced apoptosis on murine interleukin-2 (IL-2)-dependent lymphocytes, CTLL-2 and HT-2 cells. The implication of caspases in the apoptotic process in these cells was evaluated using caspase inhibitors (z-VAD-fmk, ubiquitous inhibitor of caspases; z-DEVD.fmk, selective inhibitor of group II caspases; Ac-VEID-CHO, inhibitor of casp-6) and cell cycle analysis (subG1 peak), cell morphology, annexin V staining and DNA fragmentation. Caspase activities were also measured using specific fluorometric or colorimetric substrates for casp-3, casp-6 and casp-2. All the caspases tested were activated in our cells whatever was the stimulus used. Our results showed that VAD (since 20 μM) but not DEVD (up to 200 μM) or VEID (up to 100 μM) reduced the subG1 peak. VAD was also able to stop the apoptotic process were chromatin margination was observed but not cellular or nuclear fragmentation. This was not the case for DEVD. Neither inhibitors were capable of inhibiting oligonucleosomal DNA fragmentation. Therefore it appears that the inhibition of group II caspases or casp-6 in IL-2-dependent cell lines doesn't prevent apoptosis induced by dex or cytokine withdrawal in our model.

720 OXIDATIVE STRESS AND THE FAS PATHWAY IN APOPTOSIS OF CULTURED HUMAN RETINAL PIGMENT EPITHELIAL CELLS.

S Jiang[1], J Cai[1], M Wu[2], P Sternberg, Jr.[2] and D P Jones[1,2]. [1]*Department of Biochemistry, and* [2]*Department of Ophthalmology, Emory University School of Medicine, Atlanta, GA.*

Age-related macular degeneration (AMD) is the leading cause of blindness in elderly Americans. During the early phase of this disease, loss of retinal pigment epithelial (RPE) cells occurs. The mechanism for the death of RPE cells is not understood clearly. Previous studies from our laboratory have shown that the oxidant t-butylhydroperoxide (tBH) induces apoptosis in cultured human RPE cells. In the present study, the molecular mechanism

involved in tBH-induced apoptosis was investigated. As the Fas/FasL system is a key cellular apoptosis pathway and oxidants can up-regulate Fas and FasL expression, we examined whether the Fas pathway mediates apoptosis in RPE cells and whether this is the initial signaling in tBH-induced apoptosis. By using RT-PCR, flow cytometry, and Western blot analyses, we found that RPE cells constitutively expressed Fas. Treatment of RPE cells with soluble FasL or the agonistic anti-Fas antibody CH-11 triggered apoptosis. In the presence of the antioxidants glutathione and *N*-acetyl-$_L$-cysteine, apoptosis induced by soluble FasL was inhibited. When the expression of Fas was measured in RPE cells undergoing apoptosis after tBH treatment, no change in Fas expression was observed. Moreover, pretreatment of RPE cells with the antagonistic anti-Fas antibody ZB4 (that blocks the interaction between Fas and FasL) had little effect on tBH-induced DNA cleavage, phosphatidylserine exposure and subsequent cell death. Our data suggests that the Fas pathway can mediate apoptosis in RPE cells with reactive oxygen intermediates acting as mediators. However, in tBH-induced apoptosis, the Fas pathway is not directly involved.

721 MERCURY SUPPRESSES CD95/FAS-MEDIATED APOPTOSIS: A SEARCH FOR THE MECHANISM.

M J Whitekus, I Heimler, and M J McCabe, Jr. *Institute of Chemical Toxicology, Wayne State University, Detroit, MI.*

Exposure to inorganic mercury (Hg^{2+}) is associated with autoimmune disease but the molecular mechanisms underlying Hg^{2+}-mediated immunopathology are poorly understood. Since disregulation of CD95/Fas-mediated apoptosis has been implicated in autoimmune disorders, one hypothesis explaining how Hg^{2+} contributes to autoimmune disease could be by blocking the CD95 death pathway in autoreactive lymphocytes. Using the Jurkat T-cell line we have established that 5-10 μM $HgCl_2$ prevents anti-CD95-mediated inhibition of DNA synthesis, induction of cell death, and activation of caspase-3. Here we are pursuing the molecular component(s) that Hg^{2+} interacts with to attenuate apoptosis. Mercury attenuates anti-CD95-mediated DNA damage, a late event in apoptosis, and phosphatidylserine externalization, a relatively early event in apoptosis. Mercury does not down regulate cell surface expression of CD95, nor does it prevent the anti-CD95 agonist from binding to the CD95 receptor. When the human antioxidant enzyme glutaredoxin, which prevents H_2O_2-mediated apoptosis, was overexpressed in Jurkat cells, Hg^{2+} still suppressed anti-CD95-mediated apoptosis, suggesting that Hg^{2+} does not interfere with caspase activation via the production of H_2O_2 as has been suggested previously. Our studies indicate that a functional molecular component of the CD95 death pathway is targeted by Hg^{2+} and that this component is upstream of caspase-3, not shared by other death receptor pathways (e.g., TNF-R), and downstream of the CD95 receptor. This study is the first to correlate Hg^{2+}exposure with disregulation of the CD95 death pathway and represents a model to elucidate the mechanism whereby Hg^{2+} modulates peripheral tolerance leading to autoimmune dysfunction. (Supported by P30-ES06639.)

722 ROLE OF TCDD-INDUCED APOPTOSIS AS A MECHANISM OF IMMUNOTOXICITY IN PERIPHERAL T CELLS ACTIVATED THROUGH THE T CELL RECEPTOR.

I Camacho[1], M Nagarkatti[1], and P S Nagarkatti[2]. [1]*Dept. of Biomedical Sciences and Pathobiology, VA-MD Regional College of Veterinary Medicine, Blacksburg, VA, USA;* [2]*Dept. of Biology, Virginia Tech, Blacksburg, VA, USA.*

Previous studies from our laboratory have shown that treatment with TCDD inhibits the responsiveness of antigen-activated but not naive T cells from C57BL/6 +/+ mice. In the current study, we investigated whether this decreased responsiveness of such T cells resulted from increased apoptosis following restimulation. To this end, C57BL/6 +/+ or C57BL/6 *gld/gld* (Fas ligand defective) mice were injected with TCDD (50 mg/kg body weight, i.p.) and with anti-CD3 mAbs into the footpads. Five days later, axillary lymph nodes cells (source of naive T cells) and popliteal lymph nodes cells (source of activated T cells) were cultured *in vitro* with anti-CD3 mAbs and cell proliferation was measured. Also, such cells were studied for their ability to undergo apoptosis upon *in vitro* culture. The data demonstrated that activated but not naive T cells from TCDD-treated wild-type (+/+) mice showed a significant decrease in their responsiveness to anti-CD3 mAbs. Also such cells exhibited increased levels of apoptosis. In contrast, both naive and activated T cells from C57BL/6 *gld/gld* mice showed normal responsiveness to anti-CD3 stimulation. Also, the activated T cells from TCDD-treated gld mice failed to exhibit increased apoptosis. The current study demonstrates that the immunotoxic effects of TCDD on activated T cells may be mediated through Fas ligand-based apoptosis. (Supported in part by grants from EPA and NIH).

723 ROLE OF CASPASES AND FAS LIGAND IN THE INDUCTION OF APOPTOSIS IN THYMOCYTES BY TCDD.

M Nagarkatti[1], A B Kamath[1], I Camacho[1] and P S Nagarkatti[2]. [1]*Dept. of Biomedical Sciences and Pathobiology, VA-MD Regional College of Veterinary Medicine, Blacksburg, VA, USA;* [2]*Dept. of Biology, Virginia Tech, Blacksburg, VA, USA.*

Recent studies from our laboratory demonstrated that TCDD induces apoptosis and thymic atrophy in C57BL/6 +/+ but not in Fas-deficient (*lpr/lpr*) or Fas-ligand defective (*gld/gld*) mice. In the current study, we further investigated the role of Fas ligand (FasL) in TCDD-induced apoptosis. TCDD-administration at a dose of 50 mg/kg body weight in C57BL/6 +/+ mice caused significant upregulation of FasL in thymocytes. Furthermore, sera from TCDD-treated mice contained increased levels of soluble FasL. This was shown by their ability to induce apoptosis in Fas^+ targets such as thymocytes from +/+ mice or L1210 Fas^+ transfectants and inability to induce apoptosis in Fas^- targets including thymocytes from *lpr/lpr* mice or L1210 Fas^- transfectants. The TCDD-induced apoptosis in thymocytes *in vitro* was inhibited by caspase inhibitors such as YVAD-CMK and DEVD-CHO. Also, injection of YVAD-CMK significantly inhibited the TCDD-induced apoptosis in thymocytes of C57BL/6 +/+ mice. Together, the current study demonstrates that TCDD-induced upregulation of FasL and activation of caspases may constitute an important mechanism by which TCDD mediates immunotoxicity. (Supported in part by grants from EPA and NIH.)

724 DIETHYLSTILBESTROL DOES NOT DIRECTLY, INDUCE APOPTOSIS OF THYMOCYTES UNLIKE DEXAMETHASONE: COMPARISON OF MULTIPLE ASSAYS FOR HORMONE-INDUCED APOPTOSIS.

S A Ahmed, K J Donner, K M Becker, and B D Hissong. *Dept. of Biomedical Sciences and Pathobiology, VMRCVM, Blacksburg, VA, USA.* Sponsor: S D Holladay.

Endocrine disrupting agents, dexamethasone (DEX) and diethylstilbestrol (DES) have been shown to induce atrophy of thymus, a major T cell developmental organ. DEX has been shown to directly induce apoptosis of thymocytes. To definitively ascertain whether DES also directly induces apoptosis of thymocytes, many common assays of apoptosis were performed on thymocytes exposed to various doses of DES or DEX. An additional aim was to critically evaluate common apoptosis techniques, by examining kinetics of induction of apoptosis in dexamethasone (DEX)-exposed thymocytes at 2, 4, 8, 12, 26-28 and 48-50 hours of culture. Apoptotic thymocytes were identified by six methods, including flow cytometric examination of 7-aminoactinomycin D (7-AAD), propidium iodide (PI), or annexin V-FITC stained cells, changes in cell diameter/size by cell-size analyzer and forward/side scatter, and microscopic cytopathologic examination. After 4 hours of DEX exposure, apoptosis was evident by 7-AAD, annexin and cytopathological assays, but no cells with sub-diploid DNA content were evident by PI analysis. Maximal apoptosis was evident by all the above flow cytometric techniques at 12 hours after DEX exposure. The 7-AAD and annexin assays, which allow discrimination between early apoptosis and late apoptosis/necrosis, were comparable and identified similar apoptotic populations. Appearance of a $FS^{lo}/SS^{increased}$ population was evident only after 12 hours of DEX exposure. DEX induced a decrease in cells of the 4.9-6.2 μm diameter range after 12 hours. Importantly, apoptosis could not be detected by any of the above assays in thymocytes exposed to various doses of DES, suggesting that these two synthetic hormones have different mechanisms of thymic atrophy *in vivo*. (Supported by NIEHS/NIH - RO1 ES0843.)

725 MK886, A 5-LIPOXYGENASE ACTIVATING PROTEIN (FLAP) INHIBITOR, INDUCES FLAP-INDEPENDENT APOPTOSIS IN FL5.12 CELLS.

K Datta and J P Kehrer. *Div. of Pharmacology and Toxicology, College of Pharmacy, The University of Texas at Austin, Austin, TX.*

The ability of various inhibitors of lipoxygenase (LOX) enzymes and FLAP to induce apoptosis has implicated these pathways as being important in the mechanisms of this form of cell death. However, although FLAP plays an important role in 5- LOX activity, this protein is found at high levels in cells lacking LOX suggesting it may mediate other effects. Furthermore, the con-

centration of MK886, a FLAP inhibitor, required to induce apoptosis is 100x more than that required to stimulate LOX. We recently reported that MK886 induces apoptosis in an IL3-dependent pro-B lymphocytic cell line expressing FLAP but lacking LOX [*J. Biol. Chem.* **273**: 1998 (in press)]. The mechanism of this effect may be related to the release of free arachidonic acid after MK886 treatment. In support of this concept, arachidonic acid treatment (50 μM) induced ~25% apoptosis after 24 h. The role of FLAP in MK886-induced apoptosis was directly examined by decreasing its expression by incubation with 10 μM of an antisense oligonucleotide. After 48 h, FLAP expression was decreased by more than 50%. This change was not accompanied by any increase in apoptosis. FLAP antisense oligo-treated cells exhibited about 30% apoptosis 8 h after treatment with 10 μM MK886. This level of apoptosis was similar to that seen in control cells. These data suggest that MK886-induced apoptosis may not be directly associated with FLAP. This conclusion is further supported by the fact that a more specific FLAP inhibitor, MK591 (supplied by Merck Frosst, Canada), was unable to induce significant apoptosis in this cell line. (Supported by HL51005 and Center Grant ES07784.)

726 POLY(ADP-RIBOSE) POLYMERASE INHIBITION PREVENTS OXIDANT-INDUCED ONCOSIS AND PERMITS APOPTOSIS IN ENDOTHELIAL CELLS.

J A Walisser and R L Thies. *Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada.*

Reactive oxygen species (ROS) are mediators of cell death, especially in toxic processes involving inflammation where the endothelium is a significant tissue of injury. In endothelial cells (EC), DNA appears to be a critical target of ROS, which cause DNA strand scissions. In response to DNA breaks, the nuclear enzyme, poly(ADP-ribose) polymerase (PARP), is activated resulting in NAD^+ depletion, a decline in cellular energy and cell death. Based on the premise that apoptosis is an active process, we hypothesize that following lethal oxidant injury, oncosis predominates as a result of the consequences of PARP activation. However, if PARP is inhibited and cellular energy sustained, oncosis is prevented and apoptosis is allowed to proceed. Biochemical and morphological indicators of apoptosis were used to investigate the mode of EC death after an oxidant stress (H_2O_2). Following H_2O_2 exposure, EC began to lose membrane integrity between 2-3 hr, which was preceded (~1 hour) by a significant rise in intracellular free calcium ($[Ca^{2+}]_i$). Inhibition of PARP during the oxidant stress delayed both the rise in $[Ca^{2+}]_i$ and cell lysis. Caspase-3-like activity, a hallmark of apoptosis, was negligible in oxidant-treated EC. However, when PARP was inhibited, caspase-3-like activity was dramatically increased at all H_2O_2 concentrations tested. The increased caspase-3-like activity after inhibiting PARP was confirmed by Western analysis showing extensive apoptotic PARP cleavage by caspase. Furthermore, PARP inhibition just prior to the onset of oxidant-induced EC lysis (at 2 hours), reversed the elevated $[Ca^{2+}]_i$ to normal, delayed the loss of membrane integrity and increased caspase-3-like activity. Fluorescence microscopy with acridine orange showed hallmark nuclear features of apoptosis in oxidant-stressed EC when PARP was inhibited, and oncosis when EC were treated with H_2O_2 alone. In addition, maintenance of energy-dependent processes in oxidant-stressed EC following PARP inhibition was demonstrated by the energy-dependent lysosomal concentration of acridine orange and maintenance of low $[Ca^{2+}]_i$. These results show that the mode of oxidant-induced EC death is switched from oncosis to apoptosis when PARP is inhibited and suggest that PARP activity must be suppressed for apoptosis to occur. Therefore, modulation of PARP activity following oxidant-induced DNA damage would appear to provide a mechanism to manipulate this injury into a mode of apoptotic cell death that may ultimately be controlled.

727 N-ACETYL CYSTEINE (NAC) PARTIALLY BLOCKS FLUDARABINE-INDUCED APOPTOSIS IN CLL CELL LINES BY ACTING DOWNSTREAM OF CASPASE-3 ACTIVATION.

S Biswal, K Datta and J P Kehrer. *Div. of Pharmacology and Toxicology, College of Pharmacy, The University of Texas at Austin, Austin, TX.*

B-cell chronic lymphocytic leukemia (B-CLL) is the most common and prevalent form of leukemia. Fludarabine, an adenine nucleoside analog, is being used extensively to treat this disease. Fludarabine inhibits DNA synthesis and induces apoptosis. However, its pro-apoptotic mechanism is unclear. Two human B-CLL cell lines (I-83 & WSU) and another human B cell leukemia cell line (JVM-2) were used to study the mechanism of action of fludarabine. Apoptosis, detected by ELISA for cytosolic histone-associated DNA fragments, was increased 3- and 5-fold relative to controls 18 h after treatment with 50 μM fludarabine in I-83 and JVM-2 lines, respectively. Fludarabine (10 μM) also produced a 10-fold increase in apoptosis in WSU cells after 18 h. All fludarabine-treated cell lines showed significant activation of caspase-3 at the times apoptosis was assessed. Since the analogous nucleoside cytosine arabinoside is known to induce apoptosis via oxidative stress, these three cell lines were co-treated with 15 mM NAC to assess any protective effect. There was 40 and 47% less apoptosis in NAC-treated WSU cells 12 and 18 h after fludarabine, respectively. NAC also partially protected (~50%) JVM-2 and I83 cells treated with fludarabine for 18 and 24 h. Surprisingly, NAC was unable to prevent caspase-3 activation under these conditions. It seems possible that NAC blocks apoptosis at a step downstream of caspase-3 activation. (Supported by HL51005 and HL48035.)

728 DICHLOROACETONITRILE INDUCES OXIDATIVE STRESS AS A MEDIATOR OF APOPTOSIS OR NECROSIS IN MOUSE PERITONEAL MACROPHAGES (MPM).

A E Ahmed and S Jacob. *Department of Pathology, University of Texas Medical Branch, Galveston, TX.*

The water disinfectant byproduct Dichloroacetonitrile (DCAN) is a direct acting mutagen and known to induce DNA strand breaks in cultured human lymphoblastic cells. The effect of DCAN in cultured mouse peritoneal macrophages (MPM, RAW 264.7) was explored. MPMs were exposed to various concentrations (100μ M- 400μ M) of DCAN for 4h. The phagocytic activation of MPMs was characterized by the production of reactive oxygen intermediates (ROI) and secretion of TNF- α . The ratios of intracellular GSH/GSSG were assessed and used as an indicator of oxidative stress. Electrophoretic detection of DNA degradation and light microscopy were utilized for the characterization of DCAN-induced apoptosis. LDH leakage and trypan blue exclusion were used as markers of the necrotic effects of DCAN. Following treatment with DCAN, GSSG was increased (135% of control, $P< 0.05$). DCAN activation of MPMs was observed by elevated levels of ROI (190-250% of control, $P<0.05$) and increased secretion of TNF-α (450% of control, $P<0.05$). Elecrophosresis of DNA of treated MPMs indicated a dose dependent increase in the degradation of genomic DNA. This information combined with morphological studies indicated that exposure of MPMs to lower levels of DCAN (100μ M and 200μ M) incites apoptic cell death. At 400μ M DCAN cellular necrosis was observed as indicated by increased LDH leakage and decreased viability (45% of control, $P< 0.05$). These studies suggest that the dose dependent DCAN-induced apoptosis or necrosis in MPMs is due to the disturbance in GSH/GSSG ratio and initiation of ROI mediated oxidative damage mechanisms. (Supported by USEPA.)

729 ALLOPURINOL INHIBITS POLY(ADP-RIBOSE) POLYMERASE AND CONVERTS OXIDANT-INDUCED ENDOTHELIAL CELL DEATH FROM ONCOSIS TO APOPTOSIS.

H C Wilson, J A Walisser and R L Thies. *Division of Pharmacology and Toxicology, Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada.*

Allopurinol (AP) has been shown to limit tissue damage associated with reperfusion following ischemia, putatively by inhibiting xanthine oxidase (XO), a source of reactive oxygen species (ROS). This study was undertaken to investigate the ability of AP, as an inhibitor of poly(ADP)-ribose polymerase (PARP), to modulate the mode of endothelial cell (EC) death following exposure to ROS. In response to oxidative induced DNA strand scissions, the nuclear enzyme PARP is activated, resulting in NAD^+ depletion, a decline in cellular energy and cell death. We hypothesize that part of the mechanism by which AP protects against oxidant damage is its ability to inhibit PARP, thus preserving cellular energy status and switching the mode of EC death from oncotic necrosis to apoptosis. Since, in vivo, inflammation is associated with necrosis and not with apoptosis, conversion of oncotic necrosis to apoptosis may be of benefit. Bovine pulmonary artery EC were used as a model target cell for oxidant stress, which was produced by exposing cells to H_2O_2. The potential contribution of secondary oxidative stress by endogenous XO was eliminated by growing EC in the presence of 50 μ M tungsten, which replaces the molybdenum in XO thus blocking XO activity. When EC, grown with or without the presence of tungsten, were exposed to H_2O_2 and AP the time-course of oxidant-induced loss of plasma membrane integrity was delayed. Caspase-3-like activity, a hallmark of apoptosis, was negligible in H_2O_2-treated EC, but was significantly increased in oxidant-stressed EC treated with AP. In addition, apoptotic PARP cleavage by caspase was evident only in oxidant-stressed EC treated with AP. Nuclear morphology in EC treated with H_2O_2 plus AP was consistent with apoptosis.

Fluorescence micrographs demonstrated globular, condensed and fragmented DNA, whereas, micrographs of EC treated with H_2O_2 alone illustrated an oncotic necrosis. The biochemical and morphological results obtained from EC treated with H_2O_2 in combination with AP mirror those obtained with EC treated with H_2O_2 and a known PARP inhibitor, 1,5-dihydroxyisoquinoline. These results suggest that, in addition to its action as a XO inhibitor, the effects that are observed with AP in models of oxidative stress may be a result of AP's ability to inhibit PARP and convert oxidant-induced oncotic necrosis to apoptosis.

730 HYDROGEN PEROXIDE INDUCES TWO TYPES OF PROGRAMMED CELL DEATH IN NORMAL HUMAN DIPLOID FIBROBLASTS.

J B Merrett[1], C H Pham[2], J Liu[1], and Q M Chen[1]. [1]*University of Arizona, Tucson, AZ;* [2]*University of California, Berkeley, CA.*

Cell death occurs in normal human cells as a result of aging, diseases and chemical or radiation therapy. The mechanism of normal human cell death is largely unknown. Since oxidants have been suggested as a cause of aging and many diseases, we test whether H_2O_2 can induce apoptosis or programmed cell death in normal human diploid fibroblasts. Apoptosis was observed with low concentrations of H_2O_2 (≤ 150 μM) after exponentially growing cells were treated for 2 hr. The apoptotic cells showed detachment, cell shrinkage, nuclear condensation and S-phase distribution (type I cell death). These cells elevate p53 protein and express a soluble bax protein. Introducing human papillomavirus (HPV) protein E6 results in reduction in p53 protein and apoptosis within 24 hr after H_2O_2 treatment. However, E6 cells appeared to show fragmented nuclei and cell death at 2-3 days after the treatment (type II cell death). Introducing HPV E7 protein did not result in this phenotypic change. Both types of cell death involved activation of caspase-3 and were dose or time dependent. To identify the difference in the molecular programs of the two types of cell death, we measured the level of cyclin B1 and cdc-2 kinase. Western blot showed an elevation of cyclin B1 and phosphorylation of cdc-2 at 48 hr after H_2O_2 treatment in E6 but not wild type or E7 cells. This suggests the possibility that E6 cells exit at G2/M phase to undergo cell death. Our results indicate that H_2O_2 can cause two morphologically different types of cell death in normal human cells. The difference is attributed to the presence p53, cyclin B elevation, cdc-2 phosphorylation and cell cycle position.

731 ANTIOXIDANT GRAPE SEED PROANTHOCYANIDIN EXTRACT (GSPE) AND A DNA REPAIR MODULATOR 3-AMINOBENZAMIDE (3-AB) PROTECT DOORUBICIN (DOX)-INDUCED CARDIOTOXICITY *IN VIVO.*

V Wong, K Fu, B Kohanchi, D Bagchi[1] and S D Ray. *Coll. Of Pharm., Long Island Univ., Brooklyn, NY and* [1]*Creighton Univ. Sch. Of Pharm. And Alld. Hlth. Prof., Omaha, NE.*

Cardiotoxicity of DOX is a major limiting factor for clinical application of this important anticancer drug. Since, DNA is the primary target of DOX *in vivo*, this study was designed to investigate whether GSPE via its antioxidant properties, and 3-AB through its DNA repair capabilities [by influencing PARP: poly (ADP-ribose) polymerase activity], can negate DOX-induced DNA damage and prevent cardiotoxicity. To assess these events, male ICR mice (Fec, 30-40g) were either pre-exposed to GSPE (100 mg/kg for 7 days, po) followed by DOX (20mg/kg,ip), or DOX followed by a post-exposure, all the animals were sacrificed and their serum CPK activities were determined. Hearts were also collected for histopathology and DNA analysis. Results indicate that DOX alone caused significant heart injury, whereas, preexposure to GSPE or post-exposure of 3-AB significantly reduced DOX-induced cardiotoxicity, and prevented DNA damage. Histoathological evaluation of PAS and H&E stained heart sections indicated that GSPE and 3-AB successfully intervened DOX-induced cardiotoxic events and protected cells from both apoptotic and necrotic deaths. In addition to 3-AB, GSPE's ability to abrogate DOX-induced DNA damage in the cardiac tissue may suggest that it can modulate PARP activity and protect cells from toxic assaults. Similarly, 3-AB possibly mimics GSPE's antioxidant property and plays a role in detoxifying toxic intermediates formed during redox-cycling of DOX. (Supported by Inter-Health Nutraceuticals, Concord, CA.)

732 MECHANISM OF MENADIONE TOXICITY IN A LYMPHOBLAST LINE.

P B Calderon[1,3] and J L Holtzman[2,3]. [1]*Catholic University of Louvain, Brussels, Belgium and* [2]*VA Medical Center and* [3]*University of Minnesota, Minneapolis, MN, USA.*

The cell death seen with menadione (MEM) toxicity is presumably due to oxidant stress. Yet it is not clear how this stress causes death. In the current study we have examined various indices of apoptosis in a control lymphoblast line to determine whether the toxicity seen in these cells could be due to enhanced programmed cell death. We find that incubations of the cells with MEM (5-50 μ M) for 24hrs leads to a concentration dependent inhibition of cell proliferation. At 20 μ M the inhibition was 30%. There was an associated 100% increase in DNA fragmentation as determined by the fluorescent assisted cell sorter (FACS)-TUNEL assay and an 800% increase in caspase 3 activity as determined by proteolysis of the synthetic peptide DVED. Paradoxically, at 50 μ M MEM the caspase 3 activity was lower than that observed at 20 μ M. The increase in caspase 3 activity seen at 20 μ M was not associated with changes in the cellular contents of BCL-2, BCL-X, BAX or P53, but there was proteolysis of PAPR as determined by western blot. At 20 μ M leucine incorporation was completely inhibited within 4 hrs of incubation. The complete inhibition of caspase 3 activity by Ac-DEVD-CHO had no effect on any of these indices except PAPR cleavage. These data suggest that while various indices of apoptosis increase in lymphoblasts incubated with MEM, the decrease in proliferation is due to some other mechanism. It is unclear what role the profound decrease in protein synthesis may have in this toxicity.

733 INHIBITION OF DOXORUBICIN-INDUCED APOPTOSIS IN METALLOTHIONEIN OVEREXPRESSING TRANSGENIC MOUSE HEART.

Y J Kang and G-W Wang. *Departments of Medicine, and Pharmacology and Toxicology, University of Louisville, Louisville, KY, USA.*

Previous studies using transgenic mice have demonstrated that metallothionein (MT), a low molecular weight and cysteine-rich protein, protects the heart from oxidative injury by doxorubicin (DOX). To investigate possible mechanisms of this protection, the effect of MT on DOX-induced apoptosis in the heart was examined. Seven-weeks-old transgenic mice overexpressing MT specifically in the heart about 10-fold higher than normal, along with their non-transgenic littermates, were treated with DOX by i.v. injection at 20 mg/kg. Twelve hours after the treatment, the hearts were isolated for analysis of apoptosis by a TUNEL assay, which was further evaluated by an electron microscopic examination. Results showed that DOX induced apoptosis in the mouse heart and MT overexpression markedly suppressed the effect of this drug. Furthermore, neonatal mouse cardiomyocyte cultures were established. The transgenic cardio-myocytes contained higher concentrations of MT than the non-transgenic cells. Other antioxidant activities were comparable between the two cell types. Studies using this cell culture system further confirmed the *in vivo* findings. In addition, it was revealed that preceding the programmed cell death, a delta isoform protein kinase C (PKC_δ) was activated by DOX. MT inhibited this activation, an event that was likely involved in the MT inhibition of the drug-induced apoptosis. (Supported in part by NIH grant CA68125, and an Established Investigator Award from the American Heart Association (9640091N).)

734 THE 'APOSOME' A LARGE (~700 KDA) CASPASE ACTIVATING COMPLEX.

K Cain, D G Brown, X-M Sun and G M Cohen. *MRC Toxicology Unit, University of Leicester, Leicester, UK.* Sponsor: A G Smith.

It is now widely recognised that apoptotic cell death requires the activation of aspartate specific cysteine proteases or caspases, which are related to interleukin converting enzyme (ICE). This enzyme was identified as the first mammalian homologue of CED-3, a protease that is essential for programmed cell death in Caenorhabditis elegans and is activated by CED-4, and regulated by CED-9. The caspases, Apaf-1 and Bcl-2 family members are the mammalian homologues of CED-3, CED-4 and CED-9 respectively. Recent evidence has shown that Apaf-1.dATP and cytochrome c activate caspase-9 which then processes downstream caspases to initiate the caspase cascade. Caspase activation requires proteolytic cleavage at specific tetrapeptide sites to yield small (~10 kDa) and large (~20 kDa) subunits to form the active ~ 60 kDa heterotetramer. However, we now show that in THP.1

cells, activated caspases are associated with a very large ~700 kDa multimeric protein complex, the 'aposome'. This complex has a constitutive protease (IETDase) activity, capable of cleaving the IETD↓ S motif necessary for effector caspase activation. The aposome normally has a very low effector caspase (DEVDase) activity, however during apoptosis or in vitro, dATP dependent caspase activation there is a marked increase in the DEVDase activity of the aposome. This is accompanied by the recruitment of Apaf-1, procaspase-8 and Bcl-X_L to the complex. In addition, procaspases-2, -3 and -7 are also recruited and processed to their active forms. Thus, the aposome is a large multimeric protein complex, which plays a very important role in the processing and activating of the caspases.

735 PROTEASOME INHIBITION INDUCES HSP70 AND PROMOTES APOPTOSIS WHICH IS DECREASED BY *BCL-X_L* OVEREXPRESSION IN MURINE PRO-B LYMPHOCYTIC (FL5.12) CELLS.

J D Robertson, K Datta and J P Kehrer. *Div. of Pharmacology and Toxicology, Coll. of Pharmacy, The University of Texas at Austin, Austin, TX.*

Proteasome is a multi-subunit 700 kDa complex that recognizes and degrades various proteins including polyubiquitinated, misfolded and short-lived regulatory proteins. Previous studies report that inhibitors of proteasome activity, which are currently being used in drug development, promote apoptosis. *bcl-xL* and hsp70 proteins can protect against apoptosis induced by a variety of stimuli. In this study, control and *bcl-xL*-overexpressing IL-3-dependent FL5.12 cell lines were treated with 500 nM MG132, a peptide aldehyde inhibitor of proteasome activity. 24 h after MG132 treatment, apoptosis in control and *bcl-xL* cells, measured by acridine orange/ethidium bromide, was ~35% and ~22% of total cells, respectively. Concomitantly, there were ~7- and ~3.5-fold increases in caspase-3 activity in control and *bcl-xL* cells, respectively. Necrotic cells were a maximum of 7%. Inhibiting caspase-3 activity with 50 M Ac-DEVD-CHO prior to MG132 treatment resulted in a marginal reduction in apoptosis in both cell lines by 24 h. Immunoblot data revealed similar levels of hsp70 in untreated control and *bcl-xL* cells. hsp70 protein levels increased ~3-fold by 8 h following MG132 treatment in both control and *bcl-xL* cells. This increase was maintained up to 24 h. The current data indicate: (1) an inhibitor of proteasome stimulates apoptosis and induces hsp70, perhaps by preventing the degradation of misfolded or key pro-apoptotic regulator proteins; (2) *bcl-xL* overexpression lessens the pro-apoptotic but not the hsp70-inducing effect(s) of proteasome inhibition; and (3) proteasome inhibitor-induced apoptosis involves a caspase-3-independent mechanism. (Supported by HL51005 and Center Grant ES07784.)

736 DEATH OR SURVIVAL IN NORMAL HUMAN FIBROBLASTS IS DETERMINED BY BAX β OR P21 GENE EXPRESSION.

Q M Chen. *Department of Pharmacology, University of Arizona, Tucson, AZ, USA.*

Normal human cells in culture provide a relevant model for elucidating toxin produced molecular changes inside our body. Oxidants have been found to mediate toxicity of many physical or chemical insults. When normal human fibroblasts were treated with sub-necrotic doses of oxidants for 2 hr, a small proportion of cells underwent apoptosis while the rest of cells survived but developed premature senescence after the treatment. Apoptotic cells detached before plasma membrane leakage occurred and showed caspase-3 activation, nuclear condensation, cell shrinkage but not DNA ladder. The ratio of apoptotic versus surviving cells increased with high doses of H_2O_2 and reached 1:1.5 with 200 μM H_2O_2. Since apoptotic cells detach while surviving cells remain attached to the culture matrix, we can easily separate the two populations and identify the difference in the molecular programs leading to the two different cell fates. The p53 tumor suppressor protein showed super elevation in apoptotic cells but some elevation in surviving cells. Inhibiting p53 elevation by human papillomavirus E6 protein reduced apoptosis. The p21 cyclin dependent kinase inhibitor protein was absent in apoptotic cells but was strongly induced in surviving cells. Apoptotic cells expressed a soluble bax protein while surviving cells did not. RT-PCR experiments indicated a reduction of bax α mRNA, which encodes a nuclear membrane protein, but an increase of bax β mRNA, which encodes a cytosolic protein, in apoptotic cells but no change of bax α or β mRNA in surviving cells. Both apoptotic and surviving cells elevated bcl-2 protein with time. Therefore our data support that while expression of bax β is a driven force of apoptosis, expression of p21 is a surviving factor.

737 PRECURSORS DECREASE CONSTITUTIVE LEVELS OF ACTIVATED NFkB AND GRP78 AND PROTECT CELLS AGAINST APOPTOSIS.

C L Crowley[1], C M Payne[1], H Bernstein[1], C Bernstein[1], and D J Roe[2]. [1]*Department of Microbiology and Immunology, College of Medicine, University of Arizona, Tucson, AZ, USA;* [2]*Arizona Cancer Center, Division of Biometry, Tucson, AZ, USA.* Sponsor: C Lantz.

The natural detergent, sodium deoxycholate (NaDOC), induces apoptosis through oxidative stress and DNA damage. NaDOC (0.5mM) treated Jurkat cells show classic features of apoptosis under light and transmission electron microscopy. To determine the effects of NAD^+ precursors on NaDOC induced apoptosis, cells were incubated in 10 mM nicotinic acid (NA) or 10 mM nicotinamide (NAM) for 24 hours before treatment with 0.5 mM NaDOC. Levels of apoptosis were reduced by 60% in cells treated with NA and by 40% in cells treated with NAM. Jurkat cells grown in NA or NAM for four days showed no significant difference between the growth rate of the untreated versus treated cells. Jurkat, HT-29, and HCT-116 cells incubated in the presence of NA or NAM for 24 hours, then fixed and stained for *activated* NFκ B, show significantly (p=0.0001) reduced levels of *activated* NF-κ B in the nuclei of these cells. Effects of NA and NAM on GRP78 levels in Jurkat cells were determined using a polyclonal antibody to GRP78. Digital image analysis showed that NA significantly (p=0.0001) reduced nuclear levels by 40% and cytoplasmic levels by 20%, while NAM significantly (p=0.0007) reduced cytoplasmic levels. Jurkat cells treated with NAM for 24 hours, then fixed and reacted with and antibody to GAPDH, show increased intracellular levels of the protein. HepG2 cells, transfected with 13 different promoter/response element CAT reporter constructs, were treated with 10mM NAM or 10 mM NA. NAM did not activate any of the 13 promoters or response elements of the genes associated with cellular stresses. NA produced only marginal induction of grp78 (1.1 fold induction) and hsp70 (1.1 fold induction). The NAD^+ precursors, NA and NAM, may, therefore, protect against apoptosis by multiple mechanisms that help reduce oxidative stress.

738 p53 SUPPRESSES APOPTOSIS IN ALVEOLAR MACROPHAGES EXPOSED TO BLEOMYCIN *in vivo*.

D W Davis[1], D A Weidner[2], T B Felder[3], A Holian[3], and D J McConkey[1]. *Program in Toxicology, University of Texas-Houston Graduate School of Biomedical Sciences, and* [1]*Department of Cell Biology and* [2]*Department of Molecular Hematology and Therapy, University of Texas-MD Anderson Cancer Center and* [3]*Department of Pulmonary and Critical Care Medicine, University of Texas Medical School, Houston, TX.*

Chronic inflammation in the lung leading to the development of pulmonary fibrosis is a common response to environmental pollutants and cancer chemotherapeutics such as bleomycin. We speculate that pulmonary fibrosis may be initiated by bleomycin-induced apoptosis of alveolar macrophages resulting in impaired clearance of apoptotic cells and/or release of inflammatory cytokines. Here we report that bleomycin stimulated apoptosis in alveolar macrophages from C57/Bl6 mice exposed to bleomycin *in vivo* or *in vitro*. Cell death was associated with oligonucleosomal DNA fragmentation and was inhibited by the caspase inhibitor ZVAD-fmk. Analysis of p53 localization demonstrated translocation of wild-type p53 into the nucleus following exposure to bleomycin *in vivo* but not *in vitro*. Strikingly, alveolar macrophages from homozygous p53-deficient mice were 2 fold more sensitive to bleomycin than those obtained from wild-type mice following exposure *in vivo*. Similarly, TUNEL analysis demonstrated that lung epithelial cells were 4-5 fold more sensitive to bleomycin-induced apoptosis than were wild-type cells. However, there was no difference in levels of apoptosis in wild-type and $p53^{-/-}$ macrophages exposed to bleomycin *in vitro*. Together, our results demonstrate that wild-type p53 and factors within the lung microenvironment play critical roles in modulating the effects of bleomycin within the lung.

739 MECHANISTIC STUDIES OF PUVA INDUCED APOPTOSIS.

A B Santamaria[1] and H N Ananthaswamy[2]. [1]*University of Texas School of Public Health and* [2]*University of Texas, MD Anderson Cancer Center, Houston, TX, USA.* Sponsor: M A Smith.

A combination of psoralens and ultraviolet-A (320-400 nm) radiation (UVA), commonly referred to as "PUVA", is being widely used in the treatment of psoriasis, a skin disorder that affects between 2 and 8 million per-

sons in the U.S. Although it is a highly efficacious treatment for psoriasis, studies have shown that PUVA is a potent mutagen and a carcinogen. PUVA is highly effective in killing hyperproliferative psoriatic keratinocytes but its mechanism of action has not been fully elucidated. Psoralen binds to DNA and forms monofunctional adducts and interstrand DNA crosslinks once it is photoactivated by UVA. It is likely that such damage initiates cell death by apoptosis. *In vitro* studies were undertaken to investigate the molecular mechanisms by which PUVA induces cell death. Immortalized mouse keratinocyte cells (JB-6) were treated with 10 μ g/ml of 8-Methoxypsoralen (8-MOP) for 15 min at 37° C and then irradiated with 10 kJ/m² of UVA radiation, using filtered Sylvania F15T8/BLB lamps. As controls, cells were either untreated or treated with 8-MOP or UVA alone. At various time points after treatment (3, 6, 12, 24, 48, and 72 hr), the cells were quantitatively analyzed for apoptosis by propidium iodide staining. Apoptosis in treated cells was also evaluated by morphological and biochemical assays such as TEM, TUNEL, and DNA ladder formation. In addition, the induction of a variety of apoptosis-related proteins such as p53, p21$^{Waf/Cip1}$, mdm2, Bcl-2, Bax, caspase-3, and PARP were analyzed by western blot analysis. Our results indicate that PUVA inhibits proliferation and causes cell cycle arrest at G1 in JB6 keratinocytes. Results from the morphological and biochemical assays reveal that the cells also undergo apoptosis following treatment with PUVA. p53 is induced in a time-dependent manner beginning at 6 hrs, with peak levels occurring at 24-48 hrs post-treatment. p21 levels were elevated at 6-24 hrs post-treatment. In contrast, there was no evidence of apoptosis or induction of p53 or p21 in cells treated with 8-MOP or UVA alone. These preliminary studies lend credence to our hypothesis that PUVA induces apoptosis involving the p53 pathway.

740 IDENTIFICATION OF THE PREDOMINANT SITE OF COVALENT BINDING OF ACRYLONITRILE TO RAT HEMOGLOBIN.

J Li, F W Benz, W M Pierce, R C Feldhoff[1] and D E Nerland. *Departments of Pharmacology & Toxicology and [1]Biochemistry, University of Louisville School of Medicine, Louisville, KY.*

Acrylonitrile (AN) is a vinyl monomer used in the production of synthetic fibers and plastics. Previous work [Benz et al. (1997) *Fundam. Appl. Toxicol.* **36**: 149-156] has shown that, following sc administration to rats, the extent of AN covalent binding to protein in different tissues varied by nearly 10 fold. Blood was found the most reactive tissue and hemoglobin (Hb) the most highly labeled protein. The current experiments established the primary site of covalent binding of AN to rat Hb. Globin was prepared from a male Sprague-Dawley rat treated sc with [2,3-^{14}C]-AN at a dose of 115 mg/kg. The alpha and beta chains were separated by reverse phase HPLC. More than 98% of the recovered radioactivity was on the beta chains. Electrospray ionization mass spectrometry (ESI-MS) yielded theoretical masses for the alpha chains whereas the masses of the beta chains were 53 Da greater than expected theoretically. This mass increase is consistent with the binding of one molecule of AN to the beta chains. A Staphylococcus V8 protease digest of the beta chains was prepared and the resulting peptides were separated by reverse phase HPLC. A single radioactive peptide was detected that contained 90% of the radioactivity injected on the column. Amino acid sequence analysis of this peptide was consistent with beta 122-146. The theoretical mass for this fragment is 2616.04 Da, however the mass determined by ESI-MS was 2669.96 Da, also a 53 Da increase. Further analysis of this peptide by MS-MS revealed that AN was bound to Cys-125. The data indicate that beta Cys-125 is the dominant site of AN covalent binding to rat Hb *in vivo*. (Supported by NIEHS 06141 and NIH S10 RR11368.)

741 CHARACTERIZATION OF HUMAN SERUM ALBUMIN REACTED WITH TRANS,TRANS-MUCONALDEHYDE, A HEMATOTOXIC BENZENE METABOLITE.

B Winnik and G Witz. *UMDNJ-Robert Wood Johnson Medical School and EOHSI, Piscataway, NJ.*

Trans,trans-muconaldehyde (muconaldehyde, MUC), a six carbon diene dialdehyde, is a ring-opened hematotoxic metabolite of benzene. Reaction of MUC with proteins is of interest since characterization of protein modification by MUC is important in understanding the cellular toxicity of MUC and could potentially lead to the development of cumulative biomarkers of benzene exposure based on protein adducts of ring-opened metabolites. Human serum albumin (HSA) was incubated with 10-1000 μM MUC in PBS, pH 7.4, at 37°C for 16 hr. Control and MUC-reacted HSA was analyzed for the following: (i) available primary amino groups using the fluorescamine assay; (ii) carbonyl group content using reaction with 2,4-dinitrophenylhydrazine; (iii) the presence of pyrrole moieties using Ehrlich's reagent; (iv) number of MUC molecules bound using mass spectrometry, and (v) amino acid modification using amino acid analysis. Incubation of HSA with 10, 50 and 100 μM MUC lead to a 4, 17 and 27% decrease of available primary amino groups, respectively. Reaction of HSA with 10 and 100 μM MUC resulted in a 2.6 and 22.7 fold increase in carbonyl content, respectively. Reaction of MUC-reacted HSA with Ehrlich's reagent indicated the presence of pyrroles detected by UV absorption spectra. MALDI-TOF mass spectrometry suggests that HSA reacted with 1, 10, 100 and 1000 μM MUC contains on average 1, 2, 11 and 30 molecules MUC per molecule HSA, respectively. Amino acid analysis of HSA reacted with 10, 100 and 1000 μM MUC and reduced with $NaCNBH_3$ indicates that 3, 6 and 21 lysine residues are modified, respectively. These studies suggest that amino group modification of proteins by MUC could result in pyrroles, a structural moiety previously identified to be formed in the reaction of MUC with N-acetyl-l-lysine methyl ester, a model nucleophile for lysine in proteins. (Supported by NIH grant ES02558 from the National Institute of Environmental Health Sciences and NIEHS Center grant ES05022.)

742 NITRIC OXIDE (NO) INHIBITS HEME OXYGENASE-2 (HO-2) THROUGH BINDING TO HEME REGULATORY MOTIFS: HO-2 IS A SUICIDE SINK FOR NO.

Y Ding, W K McCoubrey, Jr., T J Huang, and M D Maines. *Departments of Biochemistry and Biophysics and of Environmental Medicine, University of Rochester School of Medicine, Rochester, NY, USA.*

Heme oxygenase-2 (HO-2) is the constitutive cognate of HSP32 family. These proteins catalyze oxidative cleavage of heme to CO and biliverdin and release Fe. HO-2 is a hemoprotein that binds heme at "heme regulatory motifs" (HRMs) with a conserved Cys-Pro pair. Two copies of HRMs are present in HO-2. HRMs are neither present in HO-1 nor are they involved in HO-2 catalytic activity (McCoubrey et al., J Biol Chem 272, 12568, 1997). Presently we have examined spectrophotometrically, using NO donors, reactivity of the hemoprotein with NO and the effect of NO donors on activity of purified *E. coli* expressed HO-2. A red shift of Soret band (405 nm→ 415 nm) was observed when wild-type HO-2 was treated with sodium nitroprusside (SNP), S-nitroglutathione (GSNO), S-nitroso-N-acetylpenicillamine (SNAP), or 3-morpholinosydnonimine (SIN-1). Purified *E. coli* expressed mutant form of HO-2 (HO-2 mut), in which Cys264 and Cys281 of HRMs were substituted with Ala, did not exhibit a Soret band. Treatment of hematin with NO donors also caused similar red shift. SIN-1, in addition, decreased HO-2 Soret absorption, which correlated with a decrease in the pyridine hemochromogen absorption spectrum of the hemoprotein; the decrease was abolished in the presence of superoxide dismutase. The NO donors inhibited HO-2 activity and ranked: GSNO<SNAP≤ SIN<<SNP in potency to inhibit the enzyme. HO-1 or HO-2 mut were not inactivated by NO donors. Trapping of NO with hydroxocobalamin protected HO-2 against inactivation by NO donors. Also the inhibition was reversed partially by dithiothreitol. The decreased HO-2 activity appeared not related to disruption of HO-2 protein integrity, as suggested by Western blot analysis. Data suggest that inactivation of HO-2 requires HRMs and likely involves interation of NO with heme bound the motifs. We propose HO-2 is "suicide sink" for NO, and as such that this hemoprotein can control the level of both signaling molecules, CO and NO. (Supported by NIEHS ES03968, ES04391, ES001247 and ES07026.)

743 LIPIDS AND SERUM-DERIVED PROTEINS SEQUESTER NITRIC OXIDE.

D E Heck[1], B Billack[1], D M Porterfield[2], P J Smith[2], R P Malchow[3] and J D Laskin[4]. *[1]Rutgers University and [4]UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, USA; [2]Marine Biological Laboratory, Woods Hole, MA, USA; and [3]University of Illinois, Chicago, IL, USA.*

Nitric oxide is an important biological mediator, acting to regulate such diverse processes as neuronal transmission and programmed cell death. This reactive free radical is relatively short-lived in biological systems and its physiological effects are believed to be dependent on the immediate presence of specific target molecules. In macrophages nitric oxide is produced by the high-output cytokine-inducible isoform of the enzyme nitric oxide synthase (NOS2). Nitric oxide release from macrophages contributes to tumor cell cytostasis and non-specific host defense. Using a self-referencing nitric oxide sensor we found that RAW 264.7 macrophages release nitric oxide following prolonged treatment (12-24 hr) with gamma-interferon. Nitric oxide activity could be detected for 3-4 cell diameters. Following the

addition of cationic liposomes, or bovine serum albumin, activity of nitric oxide decreased 3-4 fold. These effects were rapidly reversed (<2 min) following removal of the trapping agents indicating that neither the liposomes nor the albumin altered NOS2 activity. Increased solubility of nitric oxide in the liposomes and albumin appears to account for the decrease in activity of nitric oxide. We speculate that the microenvironment surrounding activated macrophages is an important factor mediating the physiological effects of nitric oxide. (Supported by NIH grants ES 03647, ES 06897 and RR 01395.)

744 THE NOVEL TUMOR PROMOTER PALYTOXIN ACTIVATES P38 THROUGH DIFFERENT PROTEIN KINASE CASCADES IN COS7 AND HELA CELLS.

S Li and E V Wattenberg. *Division of Environmental and Occupational Health, School of Public Health, University of Minnesota, Minneapolis, MN.*

We previously showed that the potent skin tumor promoter palytoxin activates c-Jun NH2-terminal kinase/stress-activated protein kinase (JNK) through an SEK1 (MKK4/JNKK)-dependent protein kinase cascade. SEK1 has also been implicated in the regulation of the stress-activated protein kinase p38. Therefore, we investigated whether palytoxin activates p38 through an SEK1-dependent pathway. Expression of a dominant negative mutant of SEK1 inhibited the activation of p38 by palytoxin in COS7 cells, but not in HeLa cells. The kinases MKK3 and MKK6 specifically phosphorylate and activate p38 but not JNK. Our results indicate that in COS7 cells, palytoxin activates SEK1 and MKK6 with kinetics that correspond to the activation of p38, whereas in HeLa cells palytoxin activates MKK3, in addition to SEK1 and MKK6. Finally, expression of a dominant negative mutant of Ras blocked activation of p38 by EGF in both COS7 and HeLa cells, but did not affect activation of p38 by palytoxin. Altogether, these results indicate that palytoxin activates p38 by both SEK1-dependent and SEK1-independent pathways. Furthermore, these studies indicate that the palytoxin-stimulated protein kinase cascades which couple to p38 differ depending on the cell type.

745 THE TEMPORAL EFFECTS OF THE DETOXIFICATION ENZYME INDUCER, BENZYL ISOTHIOCYANATE: ACTIVATION OF C-JUN N-TERMINAL KINASE PRIOR TO THE TRANSCRIPTION FACTORS AP-1 AND NFKB.

E J Patten[1] and M J DeLong[2]. [1]*Nutrition and Health Sciences Program, School of Medicine and* [2]*Department of Environmental and Occupational Health, School of Public Health, Emory University, Atlanta, GA, USA.*

Benzyl isothiocyanate (BIT), a microconstituent found in cruciferous vegetables, is known to be a potent inducer of the detoxification enzyme, NAD(P)H: quinone reductase (QR). QR catalyzes a two-electron transfer to a wide variety of quinones and other redox-cycling species, thereby preventing the mutation of DNA and reducing cancer risk. The 5' promoter region of the human QR gene contains the *cis*-acting AP-1 and NFkB transcription factor binding sites. The upstream signaling mechanisms that lead to the induction of QR through this promoter region remain unclear. When HT29 human colon cells were exposed to 25μM BIT, a physiologically relevant dose, AP-1 binding increased, first at 3 hours and again at 16 hours indicating the possibility of increased *de novo* c-Jun synthesis at the later time point as a result of the initial activation of JNK. NFkB binding also increased with a narrow peak around 6 hours. BIT also activated c-Jun N-terminal kinase (JNK), which phosphorylates and transactivates c-Jun, a component of AP-1. JNK was activated 6-fold over controls, beginning at 60 minutes and continuing through 8 hours. The temporal sequence of these events, JNK activation, followed by increased AP-1 and NFkB binding, resulting in increased QR activity, supports the premise that JNK is involved in the induction of QR. (Supported by the Cancer Research Foundation.)

746 AH RECEPTOR AND NF-κB INTERACTION: FUNCTIONAL DOMAINS INVOLVED IN THE CROSS-MODULATION.

Y Tian[1], S Ke[1], M S Denison[2], A B Rabson[1], and M A Gallo[1]. [1]*Department of Environmental and Community Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ;* [2]*Department of Environmental Toxicology, University of California, Davis, CA.*

The Ah receptor (AhR) mediates many of the toxic responses induced by polyhalogenated and polycyclic aromatic hydrocarbons (PAHs) which are ubiquitous environmental contaminants causing toxic responses in human and wildlife. NF-κB is a pleiotropic transcription factor controlling many physiological functions adversely affected by PAHs, including immune suppression, thymus involution, hyperkeratosis and carcinogenesis. We have recently shown physical interaction and mutual functional repression between AhR and NF-κB. These interactions connect the two important signal transduction pathways and may provide an underlying mechanism for many hitherto poorly understood dioxin-induced toxic responses. In this study, by using transient transfection and deletion mutagenesis, we demonstrated that the transactivation domains of AhR is responsible for the observed suppression of the activity of NF-κB RelA, while the bHLH-PAS domain alone is ineffective in the suppression. Reciprocally, the activation domain of the NF-κB RelA is essential in suppression of activity of DRE-driven reporter gene (pGudLuk 6.1). Interestingly, while the full length of the NF-κB RelA markedly suppresses the activity of dioxin-induced pGudLuk 6.1 in Hepa1c1c7 cells, expressing the Rel homology domain (RHD) of the NF-κB RelA superinduces the activity of pGudLuk 6.1. The results of this study defined the functional domains that are involved in the AhR/ NF-κB interaction. Supported in part by NIEHS Center Grant #ES05002.

747 REGULATION OF CONSTITUTIVE GENE EXPRESSION THROUGH AhR COMPLEX - Sp1 PROTEIN INTERACTIONS.

F Wang and S Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA.*

The -145 to -119 region (CD/L) of the cathepsin D gene promoter contains a GC-rich motif that binds Sp1 protein and an adjacent pentanucleotide (CACGC) corresponding to the core sequence of a dioxin responsive element (DRE) that binds the aryl hydrocarbon receptor (AhR)/AhR nuclear translocator (Arnt) complex. This Sp1$(N)_4$DRE (core) motif has been identified in promoters of several genes in which Sp1 plays an important role in basal gene expression. In transient transfection assays in MCF-7 human breast cancer cells using wild-type pCD/L and constructs mutated in the core DRE (pCD/L_{m1}) and Sp1 (pCD/L_{m2}) sites, it was shown that both motifs were required for maximal basal activity. The requirements for AhR/Arnt interactions with Sp1 protein for maximal activity of pCD/L was confirmed in wild-type MCF-7 and Hepa 1c1c7 cells and Arnt-deficient Hepa 1c1c7 cells using antisense Arnt and Arnt expression plasmids. The functional interactions of Sp1-AhR/Arnt were paralleled by physical interactions showing that AhR/Arnt and Sp1 proteins were coimmunoprecipitated and AhR/Arnt enhanced Sp1-[^{32}P]CD/L binding in electrophoretic mobility shift assays. The physical and functional interactions of Sp1 with AhR/Arnt proteins bound to the Sp1$(N)_4$DRE(core) motif were also dependent on proximity of these sites and both activity and Sp1-DNA binding decreased as the number of intervening nucleotides increased from 4 to 20. These studies show that regulation of basal expression of some genes by Sp1 may also require interactions with AhR/Arnt. (NIH ES04176)

748 SELECTIVE INDUCTION OF SP1 DNA ACTIVITY IN THE MOUSE BRAIN BY METHAMPHETAMINE.

K M McClendon[1], S F Ali[2] and N H Zawia[1]. [1]*Meharry Medical College, Nashville, TN, USA;* [2]*National Center for Toxicological Research, Jefferson, AR, USA.*

Methamphetamine, a derivative of amphetamine is a CNS stimulatory drug, that is widely abused. Repeated administration of methamphetamine causes long lasting depletion of dopamine, a decrease in the number of dopamine transport pumps, a decrease in the activity of tyrosine hydroxylase and degeneration of dopaminergic nerve terminals. These long lasting changes by methamphetamine may be mediated through alterations in gene expression. In an effort to elucidate the mechanisms of methamphetamine toxicity, we examined the effect of methamphetamine on a series of transcription factors: SP1, AP1 and NFkappaB. Mice were administered (i.p.) four repeated doses of methamphetamine (2.5, 5.0, and 10.0 mg/kg) at 2 hour intervals and sacrificed 48 hrs. later. The frontal cortex, caudate nucleus and hippocampus were dissected and analyzed for SP1, AP1 and NfkappaB using the electrophoretic mobility shift assay (EMSA). SP1 DNA-binding was induced in all the brain regions examined and at all doses tested. The greatest induction was observed at the 2.5 mg/kg dose. The pattern of AP1 and NFkB DNA-binding was not significantly altered. SP1 is a member of the zinc finger family of transcription factors that is involved in eukaryotic gene regulation and is induced by various stimuli including differentiation and growth signals. This data suggest SP1 may play a role in the long term cellular response to metamphetamine-induced insults. (Funded by Grant from NIEHS #521140.)

749 ROLE OF HISTONE TAIL MOBILITY IN DNA REPAIR.

V L Burnett[1], M K Bowman[1], J G Marx[1], W Kim[2], J J Hayes[2], and D L Springer[1]. [1]*Molecular Biosciences Dept, Pacific Northwest National Laboratory, Richland, WA;* [2]*Dept. Biochemistry and Biophysics, University of Rochester, Rochester, NY.*

In eukaryotes, DNA is complexed with histone proteins to form nucleosomes and the DNA repair machinery must deal with DNA in this context. Since the N-terminal tails of core histones are positively charged and interact with the negatively charged backbone of the DNA, it is important to determine the energy of these DNA/histone interactions in order to understand how repair enzymes overcome these forces. To study this we used H2A mutated to cysteine at position 2. After covalently attaching a spin label through the sulfhydryl of the Cys, H2A tail mobility was observed at several temperature and at 250, 150, 50 and 0.05 mM NaCl. Under low salt and low temperatures the spin label was relatively immobile indicating that the tail spent most of its time complexed with the DNA. As the salt concentration and temperature increased, the level of mobility increased so that at physiological conditions the tails were poised for dissociation. These results suggest that access of repair enzymes to DNA damage sites may depend strongly on whether the alterations in DNA structure strenghthens or weaken the interactions with core histones. (Supported by US DOE contract DE-ACO6-76RLO 1830.)

750 EFFECT OF A SINGLE UV-INDUCED LESION ON DNA REPLICATION IN EXTRACTS OF NORMAL AND CANCER-PRONE HUMAN MUTANT CELLS.

J Yao, J Elliott and M P Carty. *Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH, USA.*

The conversion of unrepaired chemical and environmental DNA damage to mutations provides the initiating step in many cancers. To understand the biochemical and genetic basis of this process, we have investigated the human skin cancer-prone disease Xeroderma Pigmentosum (XP) Variant. Unlike XP groups A-G, removal of UV-induced DNA damage by the nucleotide excision repair system is normal in XPV cells. XPV is characterized by altered DNA replication and hypermutability after UV irradiation. To investigate the molecular basis of this phenotype, we use cell-free extracts to carry out replication of a set of double-stranded plasmids containing a single pyrimidine dimer or (6-4) photoproduct, on either the leading or lagging strand. Compared to normal extracts, XPV extracts have a reduced capacity to carry out complete replication of DNA containing either lesion, particularly if the lesion is on the leading strand. Both extracts retain some lesion-bypass capacity *in vitro*, but compared to normal extracts, bypass of a pyrimidine dimer is reduced in XPV extracts. The proportion of newly synthesized DNA molecules arrested at the lesion site is increased in XPV extracts, directly demonstrating that XPV extracts have a defect in replication past both major UV-induced lesions, in particular when the lesion is on the leading strand. The present approach should allow further characterization of the proteins involved in the conversion of DNA damage to mutations in human cells. (Supported by ACS-IRG-189 and NIH R29 ES08073-01 to MPC.)

751 THE INVOLVEMENT OF THE ESTROGEN RECEPTOR IN THE DIFFERENTIAL EXPRESSION OF METALLOTHIONEIN-1E IN ESTROGEN RECEPTOR-POSITIVE AND -NEGATIVE HUMAN BREAST CANCER CELL LINES.

R Dutta, S H Garrett, M A Sens, S Somji, J H Todd, D A Sens. *Department of Pathology, West Virginia University, Morgantown, WV.*

Several studies have shown a correlation between immunohistochemically determined metallothionein (MT) expression and disease prognosis in breast cancer. Because these methods do not discriminate between the large number of MT isoforms found in humans, the prognostic value of metallothionein detection could be increased if expression could be correlated to specific metallothionein gene products. As an initial step in determining the possible significance of MT isoform gene expression in human breast cancer, MT-1E was found to be expressed preferentially in estrogen receptor-negative breast cancer cell lines and not expressed in estrogen receptor-positive cell lines as determined by RT-PCR. In order to assess the possible involvement of the estrogen receptor in the expression pattern of MT-1E, the total MT isoform expression pattern was determined in an estrogen receptor negative cell line (MDA-MB-468) that was transfected with the estrogen receptor gene. MT expression was not altered by the presence of the estrogen receptor in this cell line, indicating that the estrogen receptor does not directly influence the expression of MT-1E in breast cancer cell lines.

752 MECHANISM OF ESTROGEN-MEDIATED INDUCTION OF DNA POLYMERASE GENE EXPRESSION IN MCF-7 HUMAN BREAST CANCER CELLS.

I Samudio and S Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA.*

17β -Estradiol (E2) induces DNA synthesis and proliferation of MCF-7 human breast cancer cells and the molecular mechanism of DNA polymerase α induction by E2 has been investigated by promoter analysis. pDNAP1, pDNAP2 and pDNAP3 are constructs containing -258/+1, -120/+1, and -66/+1 bp inserts from the DNA polyerase α gene promoter linked to a luciferase reporter gene; 10 nM E2 induced luciferase activity in MCF-7 cells transiently transfected with pDNAP1 and pDNAP2 (>4-fold), whereas no induction was observed with pDNAP3. These results suggested that enhancer elements required for E2-responsiveness were upstream from -66 and further analysis demonstrated that the -147 to -100 region of the promoter (pDNAP4) were E2-responsive. This region of the promoter contains an upstream estrogen responsive element half-site (ERE½, -147) and downstream E2F (-135) and GC-rich (-106) sites. Mutational analysis of each site showed that the GC-rich site was required for E2-induced transactivation and gel electrophoretic mobility shift assays confirmed that Sp1 protein bound to this region of the promoter. DNA polymerase α represents another E2-responsive gene induced via ER/Sp1 interaction, and current studies are focused on aryl hydrocarbon receptor-mediated inhibition of the hormone-induced transactivation. (Welch Foundation and NIH CA76636)

753 MOLECULAR ANALYSIS OF ESTROGEN RECEPTOR α (ERα) AND ERβ-Sp1-MEDIATED TRANSACTIVATION: ROLE OF ACTIVATION FUNCTION 1.

B Saville, M Wormke and S Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA.*

Estrogen receptor α (ERα) and ERβ physically interact with the nuclear Sp1 protein and bind GC-rich enhancer sequences; however, only ERα/Sp1 results in transactivation after treatment with 17β -estradiol (E2). Human ERα and ERβ proteins differ primarily in the activation function (AF-1) domain where there is only 27% amino acid identity. Differences in ERα/Sp1 and ERβ/Sp1 action were investigated using chimeric proteins that interchange the AF-1 domains; hERα/β contains the AF-1 domain of hERα and the DNA binding and ligand binding domains of hERβ and hERβ/α contains the AF-1 domain of hERβ and the DNA binding and ligand binding domains of hERα. In GST-pulldown assays, both chimeric proteins interact with the transcription factor Sp1 and in gel shift assays, both chimeric proteins bind estrogen responsive element (ERE) and enhance Sp1 binding to a GC-rich motif. In MDA-MB-231 human breast cancer cells, the chimeric proteins induced chloramphenicol acetyltransferase (CAT) activity from an ERE-CAT reporter construct after treatment with E2. E2 also induced CAT activity (3-fold) in cells transiently transfected with hERα/β or ERα and an Sp1-CAT reporter construct; however, hERα/β or hERβ were inactive. Similar results were observed in other cell lines (LnCaP, MCF-7 and Ishikawa) suggesting that the AF-1 domain of ERα is required for E2-induced transactivation via ER/Sp1 interactions at GC-rich elements. (Welch Foundation and NIH CA76636)

754 MOLECULAR CLONING OF THE REPTILIAN, *ANOLIS CAROLINENSIS*, ESTROGEN RECEPTOR LIGAND BINDING DOMAIN: COMPARATIVE AMINO ACID SEQUENCE ANALYSIS TO KNOWN ESTROGEN RECEPTORS.

T R Zacharewski and J B Matthews. *Department of Biochemistry and National Food Safety & Toxicology Center, Michigan State University, E. Lansing, MI, USA.*

The estrogen receptor (ER) ligand binding domain (LBD; D, E and F domains) of the anole, *Anolis carolinensis*, was cloned using degenerate PCR primers coupled with the 3' RACE (rapid amplification of cDNA ends) strategy. Two forward degenerate PCR primers complementary to the DNA binding domain (C domain) and a reverse degenerate PCR primer complementary to a highly conserved region of the E domain were derived from a consensus sequence generated from a multiple species sequence alignment of 10 known ER sequences. Using successive rounds of PCR, an 800 bp fragment representing approximately 75% of the region of interest was

amplified and sequenced. Based on this sequence, anole ER specific primers were generated and used in conjunction with the oligo dT primer to clone the remaining 3' end of the cDNA. The ER LBD amino acid sequence of the anole exhibits a high degree of sequence identity (79%) and similarity (83%) when compared to the human ERα, as determined from sequence comparisons using the GCG suite of programs. The boundaries of the individual D, E and F domains for the anole ER were determined from a primary sequence alignment to the human ERα LBD. The E domain displayed the highest degree of sequence identity (89%) when compared to the human ERα, followed by the D (57%) and F (32%) domains. Relative to other species, the anole ER LBD was intermediate in terms of its sequence identity when compared to the human α (100%), mouse α (90%), chicken (82%), Xenopus (70%) and rainbow trout (40%) ER LBDs. This is the first complete reptilian ER LBD sequence reported and will be used to prepare recombinant chimeric anole ER LBD proteins to identify and assess chemicals and complex mixtures for estrogenic activity that may be specific to reptilian species

755 MUTATIONAL ANALYSIS OF ALU SEQUENCES IN DES-INDUCED HAMSTER KIDNEY TUMORS.

K P Singh and D Roy. *Department of Environmental Health Sciences, University of Alabama at Birmingham, Birmingham, AL, USA.*

Diethylstilbestrol (DES) is a renal carcinogen. The mechanism by which DES causes cancer is not known . In this study we have examined the mutations in cancer cells genome by RAPD compared to control cells . Alu repeat is one of the most common repeat element in the human as well as in hamsters genome . In an effort to examine the status of Alu sequence in DES - induced hamster kidney tumor, genomic DNA isolated from 15 kidney tumors and age- matched control kidney were digested with Alu I restriction enzyme . Kidney tumors were induced by subcutaneous implant of DES . After 7 months of treatment animals were killed to excise the kidney . Amplifications were performed using random primer with the digested as well as undigested DNA . Amplification from undigested DNA did not reveal any difference between control and tumors. Amplifications of Alu digest using random primer revealed that there was a loss of 0.7 kb and gain of 0.4 kb fragments in tumor DNA compared to genome from control .Finding of this study suggest that DES induced mutation in the Alu sequences may be involved in the induction of tumor.

756 11-DEOXY-16,16-DIMETHYL PROSTAGLANDIN E2 PROTECTS AGAINST RENAL TOXICITY IN RATS AND INDUCES SPECIFIC PROTEINS VIA A PUTATIVE THROMBOXANE RECEPTOR IN LLC-PK1 CELLS.

K M Towndrow, S B Bratton, T J Monks, and S S Lau. *Division of Pharmacology and Toxicology, College of Pharmacy, The University of Texas at Austin, Austin, TX, USA.*

Prostaglandin E2 and 11-deoxy-16,16-dimethyl prostaglandin E2 (DDM-PGE2) protect LLC-PK1 cells against 2,3,5-*tris*-(glutathion-*S*-yl)hydroquinone (TGHQ)-induced cytotoxicity via a PKC-coupled receptor that exhibits properties different from those of currently classified PGE receptor (EP) subtypes. The ability of the thromboxane agonist, U-46619, to protect LLC-PK1 cells against chemical insult and the antagonism of this response by the thromboxane antagonist, SQ29,548, suggests that DDM-PGE2 may act via a putative thromboxane receptor. DDM-PGE2 cytoprotection is associated with the increased synthesis of a number of proteins, the most prominent being a ~230 KD protein. U-46619 also induces synthesis of the same ~230 KD protein. Using 35S-methionine labeling, SQ29,548 (1 M) cotreatment completely blocks induction of the ~230 KD protein following DDM-PGE2 (1 M; 24 hr) exposure, consistent with a thromboxane-like receptor-mediated response. To validate the *in vitro* model, the effects of DDM-PGE2 on TGHQ-mediated nephrotoxicity in Fischer 344 rats was investigated. Administration of DDM-PGE2 (75 g/kg, s.c.) 24 and 0.5 hr prior to, and 6 hr after, TGHQ (5 mol/kg, i.p.) decreased TGHQ-mediated elevations in the urinary excretion of glutathione *S*-transferase and glucose by 51% and 56%, respectively, 18 hr after TGHQ treatment. These results suggest that DDM-PGE2 possesses cytoprotective properties *in vivo* and that cytoprotection *in vitro* involves the participation of a thromboxane-like receptor. (GM56321, ES07247).

757 EXTENSIVE DEGRADATION OF DNA IN NUCLEAR EXTRACTS PREPARED FROM ATAXIA TELANGIECTASIA CELLS MAY BE REPONSIBLE FOR THE DECREASE OF THE FIDELITY OF DOUBLE-STRAND BREAK REPAIR IN THIS CELL LINE.

Y Li and K Dixon. *Dept. of Environmental Health, University of Cincinnati, OH, USA.*

Ataxia telangiectasia (A-T) is a human genetic disorder characterized by neurodegeneration, hypersensitivity to ionizing radiation (IR) and increased cancer risk. Cultured fibroblasts and lymphoblasts from A-T patients exhibit a normal rate of repair of IR-induced DNA double-strand breaks (DSB), despite their sensitivity to killing by IR. However, several papers have reported that in A-T cells the fidelity of DSB repair was decreased leading to an increase in the frequency of IR-induced deletion mutations. The underlying mechanism is unclear. We have established an in vitro DSB repair system in order to characterize the defect in DSB repair in A-T cells. We have used the PUC18 vector cut by EcoRI within the lacZ gene to evaluate the DSB-repair efficiency and fidelity of nuclear extracts. The repair efficiency was evaluated by the restoration of the transformation capacity of the vector and the fidelity of break rejoining was measured by the frequency of lacZa mutants. We found that the frequency of lacZa mutants was more than two-fold higher when the vector which is cut by EcoRI and then treated with phosphatase to remove 5' phosphate was incubated in extracts from A-T compared to extracts from normal cells. Southern blotting of DNA products generated during incubation of the cut DNA in cells extracts revealed more extensive degradation of the vector DNA in A-T extracts. These data suggest that A-T cells are defective in protecting DSB ends from nuclease digestion.

758 TELOMERES AND RECOMBINATION: END GAMES.

S M Bailey[1], M N Cornforth[2], J Meyne[1], T Ruscetti[1] and E H Goodwin[1]. [1]*Life Sciences Division, Los Alamos National Laboratory, Los Alamos, NM, USA;* [2]*University of Texas Medical Branch, Galveston, TX, USA.*
Sponsor: B Lehnert.

Telomeres are specialized structures at the ends of linear eukaryotic chromosomes composed of tandom arrays of repetitive DNA sequence plus associated proteins. They protect chromosomal ends against exonucleolytic attack and preserve genomic stability by preventing undesired end-joining reactions. Paradoxically, the vertebrate $(TTAGGG)_n$ sequence is reportedly a hotspot for certain types of genetic recombination. Furthermore, DNA double-strand break repair proteins bind to telomeres where they are thought to limit illicit acts of recombination - a proposed role directly opposed to their known function in non-homologous end joining. We are employing a strand-specific fluorescence *in situ* hybridization technique (CO-FISH) to visualize recombination within telomeric repeats as a means of quantifying this activity. Preliminary evidence indicates that telomeres are indeed dynamic structures showing recombination rates 2 - 3 orders of magnitude above the genomic average. Through the use of DNA repair mutants, we plan to examine the impact of repair genes on telomeric recombination. Other studies will determine whether interstitial repeats are also recombination hotspots, and whether this behavior is confined to telomeric sequences or is a general property of repetitive sequences. It is hoped that these studies will help define the rules governing the paradoxical behavior of chromosome ends.

759 AN INVESTIGATION OF THE STRUCTURAL REQUIREMENTS FOR EFFICACY AND MECHANISM OF ACTION OF A SHORT TELOMERE MIMETIC PHOSPHOROTHIOATE OLIGODEOXYNUCLEOTIDE (S-ODN).

T J Page[1], J E Mata[2], and P L Iversen[1,2]. [1]*University of Nebraska Medical Center, Omaha, NE, USA;* [2]*AVI Biopharma, Corvalis, OR, USA.*

A structure activity study was performed on a series of short telomere mimetic S-ODNs. These compounds were able to inhibit the telomerase enzyme and were lethal to OMA-BL1 (Burkitt's Lymphoma) cells. A cytotoxicity assay was used to screen for active compounds based on length and reading frame. It was found that shorter compounds (6-9 bases) were almost as efficacious, but exhibited a more dose dependent relationship than longer compounds (10-24 bases). Studies to evaluate the influence of reading frame on cytotoxicity concluded 5'-d(GGGTTAGGG)-3' (TAG 9-2) was the most effective reading frame. This compound was then used to test the contribution of hydrogen bonding and the 3' end to cytotoxicity and telomerase inhi-

bition. Blocking hydrogen bonding decreased the efficacy of the compound in both the cytotoxicity assay and the Telomerase Repeat Amplification Protocol (TRAP) assay, a measure of telomerase activity. The 3' end of this compound was blocked by the addition of a glycerol molecule during synthesis, as before this compound was less efficacious in both the cytotoxicity assay and the TRAP assay. The putative mechanism of cytotoxicity was investigated for the TAG 9-2 compound. The telomeric regions of chromosomes contain 50% guanine nucleotides on the leading strand, making them an ideal target for reactive oxygen species (ROS). The interaction of ROS with the telomere could generate a short single stranded fragment having similar properties to the TAG 9-2 compound. The endogenous telomeric fragments may be signals to the cell of oxidative stress. We hypothesize that the TAG 9-2 compound is mimicking these fragments and inducing apoptotic pathways. To test this hypothesis we have treated OMA-BL1 cells with radical generating compounds and then performed a fragment capture assay to detect the endogenous fragments. We were also able to abrogate the generation of fragments by concurent treatment with radical scavengers. In these studies we have investigated the stuctural requirements for activity and also a putative mechanism of action for short, telomere mimetic, S-ODNS.

760 A NOVEL ASSAY FOR MITOCHONDRIAL DNA SYNTHESIS.

W B Mattes, C T Cramer, and C S Aaron. *Investigative Toxicology, Pharmacia & Upjohn, Kalamazoo, MI.*

Mitochondria are a target organelle for a large number of toxic chemicals, and as such parameters of mitochondrial number, respiration, and membrane integrity are often examined to investigate mechanism of toxicity. Mitochondria also possess their own genome and unique RNA transcription, protein translation, and DNA replication activities. We have developed a simple assay that allows quantitative measurement of mitochondrial DNA synthesis, especially in response to toxic events. The assay takes advantage of the large discrepancy in size between the circular mitochondrial genome (16,000 base pairs) and mammalian chromosomes (several million base pairs) and makes use of methodology developed for analysis of chromosomal structure. Control and treated cells are allowed to incorporate radiolabeled thymidine, then are harvested and embedded in agarose plugs. The plugs serve to protect genomic DNA from mechanical shear in subsequent steps. After a detergent and proteinase digestion step, the plugs are embedded in a low percentage agarose gel and the mitochondrial DNA separated from genomic DNA by electrophoresis. Using this technique chloramphenicol was found to specifically inhibit mitochondrial DNA synthesis in H4IIe rat liver hepatoma cells in a dose-dependent fashion, while ethidium bromide at low concentrations appeared to increase mitochondrial DNA synthesis.

761 MULTIPLEX PCR COUPLED WITH RANDOM AMPLIFIED POLYMORPHIC DNA (RAPD) AS A NOVEL METHOD TO DETECT MITOCHONDRIAL DNA POLYMORPHISMS IN HUMAN.

Q Cai and D Roy. *Department of Environmental Health Sciences, University of Alabama, Birmingham, AL, USA.*

Recently, the search for mitochondrial DNA (mtDNA) defects in tumor tissues has drawn attention. Most studies have used PCR or multiplex PCR to detect the mutation of mtDNA. The sensitivity of these methods is limited. In the present study, we have developed an effective multiplex PCR/RAPD method to detect the polymorphims of mtDNA in human tissues. Total DNA were isolated from tumor tissues and normal tissues. Using specific primers to the mitochondrial genome, multiple fragments were amplified. Multiplex PCR did not reveal any mutation in the mitochondrial genome of tumor tissues compared to controls. The fragments of multiplex PCR products were then eluted from agarose gel and used as template for RAPD analysis. The profile of amplification using random primers in tumor tissues was significant different from normal tissues. In summary, the multiplex PCR/RAPD revealed mutation in mitochondrial genome, but not multiplex PCR alone. This method may be useful in detecting mutation in both mitochondrial and nuclear genomes from cancer and age-related disorders.

762 DISRUPTION OF THE E-CADHERIN/CATENIN COMPLEX BY OXIDATIVE STRESS CORRELATES WITH PHOSPHORYLATION OF TYROSINE BUT NOT SERINE.

A R Parrish, J M Catania and A J Gandolfi. *Southwest Environmental Health Sciences Center, University of Arizona, Tucson, AZ.*

E-cadherin, the predominate mediator of cell-cell adhesion in epithelium, regulates adhesion via a Ca^{++}-dependent, homophilic mechanism. β-catenin binds the cytoplasmic domain of E-cadherin and is in turn bound by α-catenin, which links the complex to the actin cytoskeleton. E-cadherin function is regulated by post-translational modification. Therefore, we hypothesized that chemically-induced oxidative stress would disrupt the E-cadherin/catenin complex in precision-cut mouse liver slices via phosphorylation. Diamide (DA), a sulfhydryl depleting agent, and tert-butylhydroperoxide (tBHP) disrupted the protein interactions β-catenin with its adhesion partners. Although a significant decrease in β-catenin:α-catenin interactions was observed, the binding of β-catenin to E-cadherin was also affected. This disruption was associated with a significant increase in the tyrosine phosphorylation of β-catenin. However, no effect on the serine phosphorylation of this protein was observed. Taken together, these results suggest that chemically-induced oxidative activates tyrosine kinases, or inhibits tyrosine phosphatases, that regulate the post-translational modification of β-catenin. Importantly this is associated with a loss of biochemical function of the E-cadherin complex. (Supported by NIEHS Center Grant (T30 ES06694), American Cancer Society Institutional Grant (IRG110T) and an SOT-Colgate Palmolive Fellowship.)

763 TAU PHOSPHORYLATION BY DIISOPROPYL PHOSPHOROFLUORIDATE (DFP)-TREATED HEN BRAIN SUPERNATANT INHIBITS ITS BINDING WITH MICROTUBULES: ROLE OF Ca^{2+}/CALMODULIN-DEPENDENT PROTEIN KINASE II IN TAU PHOSPHORYLATION.

R P Gupta and M B Abou-Donia. *Department of Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.*

Diisopropyl phosphorofluoridate (DFP) produces organophosphorus ester-induced delayed neurotoxicity (OPIDN) in hen, human, and other sensitive species. This is characterized by mild ataxia which progresses to severe ataxia or paralysis in a few days. Ultrastructurally, OPIDN is associated with the degeneration of axons in central and peripheral nervous system. Bacterially expressed longest human tau protein (htau40) was phosphorylated by DFP-treated hen brain supernatant in a shorter time than control brain supernatant to show significant decrease in microtubule binding. The decrease in htau40-microtubule binding observed on phosphorylation of htau40 by recombinant. Ca^{2+}/calmodulin (CaM)-dependent protein kinase II (CaM kinase II) α-subunit showed that CaM kinase II present in brain supernatant could participate in tau phosphorylation even in the absence of Ca^{2+}/CaM and decrease tau-microtubule binding. In addition, use of htau40 mutants, htau40ml (Ala^{416}) and htau40m6 (Asp^{416}), showed that replacement of Ser^{416} by neutral or acidic amino acid produced change in htau40 conformation and exhibited lesser binding with microtubules on phosphorylation by brain supernatant in the presence of EGTA. The change in conformation produced by Ser^{416} phosphorylation, however, was different from that produced by mutants in that only htau40 isoform showed significant decrease in binding with microtubule on phosphorylation by recombinant CaM kinase II in the presence of Ca^{2+}/CaM compared to that obtained by phosphorylation in the presence of EGTA. This study showed that enhanced Ca^{2+}/CaM-dependent protein kinase activity in DFP-treated hen brain supernatant may cause decreased tau-microtubule binding and destabilization of microtubules, leading to axonal degeneration in OPIDN. (Supported in part by NIEHS Grant ESO 5154.)

764 THE ROLE OF cAMP SIGNALING ON INHIBITION OF IL-2, CREB, AND NF-κB BY CANNABINOL.

A C Herring and N E Kaminski. *Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI.*

Ligand binding to CB1 or CB2 cannabinoid receptors inhibits the cAMP signaling pathway in splenocytes and thymocytes. Cannabinol (CBN), a CB2 receptor selective ligand, has been shown to inhibit IL-2 expression and the activation of CREB and NF-κB following stimulation of thymocytes with phorbol ester plus calcium ionophore (PMA/Io). Cross-talk between PKA and PKC has been previously demonstrated by the potentiation of the cAMP pathway following PKC activation. Therefore, the objective of the present

studies was to determine the role of cAMP and PKA in the regulation of IL-2, CREB and NF-κB in PMA/Io activated thymocytes. Dibutyryl cAMP (DBcAMP), a cAMP analog, was used to examine the involvement of cAMP. Stimulation of thymocytes with DBcAMP (10 or 100 M) for 60 min induced CREB phosphorylation. However, the inhibition of CREB phosphorylation produced by CBN in PMA/Io stimulated thymocytes could not be reversed by co-stimulation with DBcAMP (100 M). DBcAMP was also not able to reverse the CBN-mediated inhibition of CRE or κB DNA binding activity. Furthermore, DBcAMP (1 or 5 M) failed to reverse the dose-dependent inhibition of IL-2 protein secretion by CBN. To investigate the role of PKA in the inhibition produced by CBN, the PKA inhibitor H89 was used. Induction of CREB phosphorylation and CRE binding by DBcAMP was inhibited by H89 (50 or 500 nM). Pretreatment of thymocytes with H89 (10-500 nM) produced minimal inhibition of PMA/Io-induced CREB phosphorylation and CRE binding activity. H89 had no effect on protein binding to a κB motif and did not prevent the degradation of IκB-α. Additionally, a modest inhibition of IL-2 protein secretion was detected with H89 at 50 and 100 nM. These results support a modest involvement of the cAMP/PKA pathway in CREB activation and IL-2 regulation following PMA/Io stimulation of thymocytes and further suggest that ligand binding to the CB2 receptor modulates additional signaling pathways in activated T-cells. (This work was supported by NIDA Grants DA07908 and DA09171.)

765 PIVOTAL ROLE OF MITOCHONDRIA IN ARSENIC ACID INDUCED INTERLEUKIN-1α PRODUCTION IN MURINE KERATINOCYTES.

E Corsini[1], L Asti[2], B Viviani[1], M Marinovich[1] and C L Galli[1]
[1]*Laboratory of Toxicology, Institute of Pharmacological Sciences, University of Milan, Milan, Italy;* [2]*Centro Grandi Strumenti, Laboratory of Electron Microscopy, University of Pavia, Pavia, Italy.*

In humans, inorganic arsenicals are skin carcinogens and induce hyperproliferation and hyperkeratosis of the palms and soles and hyperpigmentation/hypopigmentation of the trunk. It has been recently demonstrated that arsenic induces overexpression of keratinocyte-derived growth factors, which are likely to play a significant role in arsenic-induced skin hyperkeratoses and cancer. The mechanism(s) involved in this induction are, however, still elusive. The purpose of this study was to investigate the early intracellular events that follow in vitro treatment with arsenic acid in a murine keratinocyte cell line (HEL30) and that leads to interleukin-1α (IL-1α) overproduction. First, we observed that sodium arsenate (As) induced a dose dependent IL-1α production both intracellular and released, at concentrations as low as 2 μM. Increased intracellular IL-1α could be detected as early as 1 h following treatment. Electron microscopy analysis revealed that As-induced a drammatic alteration in mitochondria, which could be prevented by rotenone pretreatment, suggesting a possible role of mitochondria-derived reactive oxygen species. Arsenic indeed induced a dose and time dependent increase in cellular oxidative activity, which is followed by activation of redox sensitive transcription factors, such as NF-κB and AP-1, essential for IL-1α neosynthesis. Pretreatment with rotenone or prolonged treatment with ethidium bromide, an inhibitor of mitochondrial DNA and RNA synthesis, to deplete cells from functional mitochondria, completely abrogated As-induced IL-1α production, indicating the pivotal role of these organelles in As-induced keratinocyte growth factors. A role of calcium could be ruled out since BAPTA, a calcium chelator, did not affect As-induced reactive oxygen species or IL-1α production, indicating that the first intracellular event following As treatment is the binding at the mitochondria followed by ROS generation, transcription factors activation and finally IL-1α neosynthesis. (Partially funded by UNIPRO.)

766 INDUCTION OF THE MITOCHONDRIAL PERMEABILITY TRANSITION ALTERS THE DISTRIBUTION OF F-ACTIN AND MITOCHONDRIA IN L929 FIBROBLASTS.

C L Neary and J L Farber. *Department of Anatomy, Pathology, and Cell Biology, Thomas Jefferson University, Philadelphia, PA.*

Treatment of L929 fibroblasts with tumor necrosis factor (TNF) and cycloheximide (CHX) induces the mitochondrial permeability transition (MPT), thereby causing the death of the cells. The MPT and the cell killing are prevented by pretreatment with cyclosporin A (CyA) and aristolochic acid (ArA). The current study was designed to study changes in cellular organization that could link the MPT to cell death. L929 cells exhibit a fine meshwork of short F-actin fibers. With TNF and CHX after six hours, there was less fibrillar actin in the cytoplasm and more at the cell periphery. CyA and ArA prevented these alterations. With the mitochondrion-specific dye MitoTracker Green, untreated cells displayed diffuse staining that extended throughout the cytoplasm, although not always to the cell periphery. After four hours with TNF and CHX, there was obvious translocation of the mitochondria to the perinuclear region. The staining also became more punctate, suggesting that the mitochondria are clumping. CyA plus ArA did not prevent this redistribution of mitochondria. We hypothesize that the MPT interferes with a crucial interaction between the mitochondria and the cytoskeleton, leading to a disruption of cytoskeletal architecture. Loss of viability due to induction of the MPT, as evidenced by loss of the permeability barrier function of the plasma membrane, could result from alterations in the structure of the membrane due to loss of the interaction with the cytoskeleton.

767 EFFECT OF VOMITOXIN (DEOXYNIVALENOL) ON THE BINDING ACTIVITY OF A NEGATIVE TRANSCRIPTION FACTOR FOR IL-2 BY IN MURINE EL-4 THYMOMA CELLS.

J J Pestka and G -H Yang. *National Food Safety and Toxicology Center, Department of Food Science and Human Nutrition, Michigan State University, East Lansing, MI, USA.*

The gene expression of IL-2 is superinduced by the trichothecene mycotoxin vomitoxin (VT, deoxynivalenol) in murine T-cells. It has been recently reported that negative regulatory regulatory element (NRE) plays a important role in the silencing of IL-2 expression. Here, the *in vitro* effect of VT on NRE binding activity was studied using EL-4 thymoma cell by electrophoretic mobility shift assay. When cells were treated with phorbol 12-mystate 13-acetate plus ionomycin, NRE binding activity was reduced. Co-treatment of VT caused synergistic reduction of the NRE binding activity in a dose dependent manner. The inhibition of NRE binding activity by VT was shown from 2 hr to 48 hr. The inhibition of the NRE binding activity by VT alone was also found in unstimulated cells. Interestingly, the inhibition of NRE binding activity was shown only at the slower migrating band which has been known to be more sensitive to acid phosphatase than the faster migrating band. These data suggest that IL-2 superinduction by VT and other trichothecenes might be caused in part, through inhibition of the binding activity of a negative transcription factor for IL-2.

768 AKT PHOSPHORYLATION OF p47^{PHOX} PRODUCES ACTIVIATION OF THE NADPH OXIDASE IN A CELL-FREE SYSTEM COMPARABLE TO AMPIPHILE ACTIVATION.

C R Hoyal[1], P N Tsichlis[2], and B M Babior[1]. [1]*The Scripps Research Institute, La Jolla, CA, USA;* [2]*Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA, USA.*

The leukocyte NADPH oxidase catalyzes the 1-electron reduction of oxygen to superoxide at the expense of NADPH. Extensive phosphorylation of p47^{PHOX} has been demonstrated to occur during the assembly and activation of the oxidase. While expression of various serine mutants of p47^{PHOX} no longer support oxidase activity in the whole cell, they are still functional in the amphiphile-activated system. This suggests that activation of the NADPH oxidase is a phosphorylation dependent event. Through the use of kinase inhibitors, the PKC and PI-3 kinase pathways have been implicated in the activation of the oxidase. While p47^{PHOX} phosphorylated with PKC is capable activating the oxidase in a cell free system, the rate is not of the same amplitude as the amphiphile-activated system. Although phosphorylation of p47^{PHOX} has been observed during activation of PI-3 kinase, we have found p47^{PHOX} not to be a direct target. We investigated the activation of p47^{PHOX} by Akt, a direct target of PI-3 kinase. Akt phosphorylated p47^{PHOX} supports NADPH oxidase activity of equal amplitude to amphiphile activation. Fewer serines are phosphorylated by Akt further suggesting that several serines act to restrict activity of p47^{PHOX}. Akt activation of p47^{PHOX} demonstrates the first kinase dependent activation of NADPH oxidase comparable to amphiphile-activation of the oxidase.

769 CONSTRUCTION AND CHARACTERIZATION OF A COLITOSE NEGATIVE MUTANT IN *V. CHOLERAE* 0139.

C R Fiore[1], R J Johnson [1,2], J A Johnson[1,2]. [1]*University of Maryland, Baltimore, MD;* [2]*Veterans Administration Medical Center, Baltimore, MD.*
Sponsor: K S Squibb.

Vibrio cholerae secretes several major toxins, the most important is cholera toxin that elicits fulminant diarrhea in its hosts. In 1992 a new strain appeared which had only two major differences from any other epidemic-causing strain. It was not an 01 strain, and had a capsular polysaccharide (CPS) encoded by 36 kb of novel DNA. It was designated serotype 0139

Bengal. In bacteria, polysaccharides are considered essential virulence determinants and antigens that play important roles in the pathogenicity of the organism. Our lab has determined the chemical and 3 dimensional structure of the CPS, and has sequenced the entire 36 kb. capsular cassette. The capsule region has 35 open reading frames (orfs), many of which have homology to biosynthesis and processing genes in other bacteria. The capsule structure is composed of six sugars, four of which look very similar to Lewis B blood group tetrasaccharide. In particular colitose, an unusual sugar, appears to be encoded by orfs *wbfJ, H, I*, is known to play an immunodominant role in polysaccharides and is found in other gram-negative bacteria such as *E. coli* 011, 055 and several *Salmonella ssp*. The colitose residues in 0139 are found on the sides of the polysaccharide structure and deletion of them is not believed to affect the integrity of the polymer. In order to elucidate if colitose is an immunologically important epitope of the CPS, the *wbfJ, H, I* genes were genetically deleted by allelic exchange. A 4509bp fragment was amplified by PCR and cloned into pUC18. By restriction digests and re-ligation, the above orfs were replaced with an in-frame 840bp kanamycin cassette that lacked a promoter. This construct in pCVD442 was mated into *V. cholerae* 0139. Kanamycin selection allowed for screening of positive clones and PCR and sequencing were used for confirmation. The colitose negative mutant can now be used to determine immunological and pathogenic effects.

770 MOLECULAR PLAYERS IN INCREASED THIOACETAMIDE-HEPATIC INJURY AND DECREASED MORTALITY FOLLOWING DIET RESTRICTION.

S K Ramaiah[1], M G Soni[1], J Seng[2], J E A Leakey[2], and H M Mehendale[1]. [1]*Division of Toxicology & Louisiana Institute of Toxicology, NLU Health Sciences Center, Monroe, LA;* [2]*Div. Microbiol & Chem, National Center for Toxicological Research, Jefferson, AR.*

Earlier studies (TAP, **150,** 12-21, 1998 and Tox. Sci, 45: 233-241, 1998) revealed highly increased liver injury (>6-fold at low dose and >2.5-fold at lethal dose) of thioacetamide is accompanied by up regulation of compensatory liver regeneration response that rescues the diet restricted (DR) rats from a lethal dose of thioacetamide (TA). The objective of this study was to investigate molecular mechanisms for the increased liver injury and liver tissue repair responses. We tested two hypotheses: increased liver injury is due to induction of CYP2E1 and increased liver regeneration due to upregulation of RAS-MAPK pathway involving epidermal growth factor (EGF) and its receptor (EGFr). Male SD rats (225-275 g) maintained on *ad lib* diet regimen were pretreated with isoniazid (INZ) or pyridine (PYR), known inducers of liver microsomal CYP2E1, and liver injury (assessed by ALT and histopathology) of TA (50 mg/kg, ip) was compared. Total CYP450 content was measured and CYP2E1 activity by radioactive HPLC method for chlorzoxazone hydroxylation specific for CYP2E1. Liver EGFr mRNA levels were measured by RT-PCR. EGFr tyrosine phosphorylation and total EGFr density were measured by immunoblotting and bands quantified by imaging densitometer. DR (65% of AL, three weeks) resulted in increased total CYP450 content as well as 150% increase in CYP2E1 activity suggesting CYP2E1 induction by DR. RT-PCR studies indicated that although DR alone did not affect EGFr mRNA levels, TA challenge to DR rats significantly increased the levels at 12 hr compared to AL rats. Investigation into EGFr tyrosine phosphorylation and total EGFr density revealed no change by DR or DR+TA treatment. Results of liver injury indicate the possible mediation of TA bioactivation by CYP2E1. Further, liver tissue repair studies indicate that although EGFr transcriptional activation occurs, this is not accompanied by translation in DR rats treated with TA. We conclude that while increased liver injury is likely due to induction of CYP2E1 as hypothesized, additional studies are needed to test the hypothesis on liver tissue repair. (Supported by ES-08604.)

771 COMPETITIVE BINDING OF POSITIVE- AND NEGATIVE-ACTING TRANSCRIPTION FACTORS TO THE HUMAN *CYP1A1* NEGATIVE REGULATORY ELEMENT.

S M Smolinski, C M Garrett, M P Piechocki, and R N Hines. *Wayne State University, Detroit, MI, USA.*

CYP1A1 is a phase I detoxifying enzyme which is involved in the bioactivation of several polycyclic aromatic hydrocarbons. *CYP1A1* aberrant expression has been correlated with greater risk for developing bronchogenic carcinoma and poor prognosis in breast cancer. We have identified a 275 bp region (position -833 to -558) in the *CYP1A1* promoter that is involved in modulating inducible expression and is likely involved in the aberrant expression of this gene. Further characterization of this negative regulatory element (NRE) revealed two binding regions for an approximately 100 kDa protein, which we termed the negative regulatory factor (NRF). The upstream higher-affinity binding site has been characterized by *in vitro* DNA binding assays and is composed of a CCAAT box separating an 8 bp inverted repeat centered at position -784. EMSA supershift assays reveal that the ubiquitous, positive-acting CCAAT box transcription factor, NF-Y, also binds competitively to this site. The downstream lower-affinity NRF binding site is not as well characterized, but has been localized to a 68 bp region (position -656 to -588). We have shown by EMSA supershift assay that a binding site for the ubiquitous positive- or negative-acting transcription factor, YY-1, is also present within this fragment. Although the binding sites for NRF and YY-1 do not appear to overlap, they also appear to bind competitively. We propose a competitive binding model in which positive- and negative-acting factors contribute to the observed activity of this region. (Supported in part by PHS grant no. ES03832.)

772 USE OF DIFFERENTIAL DISPLAY FOR IDENTIFICATION OF PCN INDUCIBLE GENES IN RAT LIVER.

L Maldonado-Baez[1], H Shih[2], L Quattrochi[2], P Guzelian[2] and B D Jiménez[1]. [1]*U. Colorado, Health Science Center, Denver, CO; and* [2]*U. of Puerto Rico, Department of Biochemistry, San Juan, PR.*

The cytochromes P450 of the CYP3A gene superfamily is a group of microsomal hemoproteins prominent in human liver involved in the metabolism of clinically important drugs such as cyclosporin, nifedipine and in the bioactivation of such carcinogens as aflatoxins and benzo(a)pyrene. Cytochrome P450 3A23 in rat liver is induced by such glucocorticoids as dexamethasone (DEX) and by Pregnenolone-16-alpha-carbonitrile (PCN) an anti-steroid compound, through a non-classical mechanism mediated by PXR, a nuclear receptor which binds both with DEX and PCN and acts through a DNA sequence distinct from the Glucocorticoid Response Element (GRE). To learn the identity of other genes that may be under the control of the PXR receptor, we used the method of Differential Display of liver RNA from Female Sprague-Dawley rats treated for 24hrs with 80mg/kg of DEX or PCN or vehicle alone. The total liver RNA was isolated, transcribed to cDNA, amplified by PCR, submitted to parallel lanes of electrophoresis on DNA sequencing gels. We extracted those amplified cDNA fragments indicating PCN induction and reamplified them for hybridization with total RNA for induced and untreated animals. Cloning and DNA sequence analysis revealed that of several selected bands induced by PCN, one could be identified as MHC class II RT1.BBI. That this gene was inducible in rat liver by PCN within 24 hrs. of treatment was confirmed by Northern blot analysis. We conclude that this reverse gentic approach is invaluable for defining the domain of genes under the control of the PXR/PCN system.

773 EFFECTS OF MICROSOMAL ENZYME INDUCERS ON RAT MULTIDRUG RESISTANCE PROTEIN 2 (Mrp2).

D R Johnson and C D Klaassen. *Univ Kansas Med Ctr, Kansas City, KS.*

Previous studies have shown that certain microsomal enzyme inducers (phenobarbital [PB] and pregnenolone-16α-carbonitrile [PCN]) cause an increase in bile flow and biliary excretion of xenobiotics in rats, while other inducers (3-methylcholanthrene [3MC] and 3,4-benzpyrene [3,4-BP]) do not cause the same effects. Within the past four years, a protein that localizes on the canalicular membrane of hepatocytes and that transports organic anion conjugates from liver to bile, has been cloned, and termed the multidrug resistance protein 2 (Mrp2). The purpose of this study was to determine whether microsomal enzyme inducers increase Mrp2 expression in rat liver, and whether the increase might correlate with previously demonstrated effects on bile flow and biliary excretion. Male Sprague-Dawley rats (250-350 g) were injected *ip* for 4 days with PB (75 mg/kg), PCN (75 mg/kg), 3MC (20 mg/kg), 3,4-BP (20 mg/kg), or control vehicle (saline or corn oil). On the fifth day, rat livers were removed. Mrp2 protein expression was detected using the polyclonal antibody EAG15 by western-blot analysis. Liver samples from EHBR rats lacking Mrp2 were used as negative controls for protein analysis. PB treatment increased Mrp2 protein expression by 183%, while PCN treatment increased Mrp2 protein expression by 288%. Neither 3MC nor 3,4-BP treatments altered Mrp2 protein expression. In conclusion, PB and PCN increase Mrp2 protein expression while 3MC and 3,4-BP do not. There is a good correlation between the ability of the microsomal enzyme inducers to increase Mrp2, and increase bile flow and biliary excretion of xenobiotics. This suggests that induction of Mrp2 may be important in the chemical regulation of bile flow and biliary excretion of xenobiotics.

(Supported by American Heart Association grant KS-98-GS-11 and NIH grant ES-07079.)

774 FLAVIN-CONTAINING MONOOXGENASE 2: POLYMORPHISM CHARACTERIZATION AND DETERMINATION OF ALLELIC FREQUENCY IN AFRICAN AMERICANS, CAUCASIANS, AND ASIANS.

J R Whetstine[1], N A Mercer[1], D G McCarver[1], D E Williams[2], C-S Park[3], Y-N Cha[3], and R N Hines[1]. [1]*Wayne State University, Detroit, MI, USA;* [2]*Oregon State University, Corvallis, OR, USA;* [3]*Inha University, Inchon, Korea.*

The flavin-containing monooxygenases (FMO) are a family of drug metabolizing enzymes that are expressed in a species- and tissue-specific manner. *FMO2* is expressed in the nasal mucosa and type II and Clara cells of the lung. Two point mutations have been reported in the C-terminal end of the human FMO2 cDNA, a C to T transition at position 1475 and a thymidine insertion at position 1650. The transition mutation results in a premature stop codon, eliminating the activity of the enzyme due to truncation. The insertion mutation results in a frameshift, altering the last 6 amino acids of the protein, as well as extending the reading frame. Whether or not these mutations represent true polymorphisms or rare alleles was not known. To address this question, DNA samples from 180 unrelated African Americans, 52 Caucasians, and 100 Asians were genotyped. A region containing both mutations was amplified using gene specific primers and PCR amplification. The amplicons were slot blotted, and allele specific oligonucleotide probes used to identify the presence or absence of the specific sequences. In the African American population tested, the 1475C allele occurred at an overall allelic frequency of 13%; however, all of the Caucasians and Asians tested were homozygous for the 1475T allele. The frameshift mutation occurred at a frequency of 6.9% and 17.4% in the tested African Americans and Caucasians, respectively. The Asian DNA samples are presently being analyzed for the frameshift mutation. A preliminary analysis of those individuals heterozygous for both mutations suggests the 1650T insertion occurs secondarily to the C1475T transition. These data demonstrate that a functional FMO2 enzyme occurs in a small percentage of the population. Given the role of this enzyme in xenobiotic biotransformation, these individuals may be protected from or more susceptible to certain environmental toxicants. (Supported in part by PHS grant CA53106.)

775 MOLECULAR MECHANISMS FOR THE TISSUE-SPECIFIC EXPRESSION OF THE RABBIT FLAVIN-CONTAINING MONOOXYGENASE 1 (*FMO1*) GENE.

Z Luo and R N Hines. *Wayne State University School of Medicine, Detroit, MI, USA.*

The flavin-containing monooxygenases (FMO) are a family of microsomal xenobiotic-metabolizing enzymes differentially expressed in several tissues. Because of their roles in detoxification and bioactivation of exogenous compounds, it is important to understand their tissue-specific expression at the molecular level to fully understand the tissue-targeting toxicities of their substrates. In rabbit, *FMO1* has been identified as the major isoform in liver and is not expressed in lung. We previously identified a dual promoter system that directs the transcription of rabbit *FMO1*. Several sequences corresponding to the consensus binding site for HNF3 were located upstream of both promoters. There are also several other sequences corresponding to the consensus binding sites for HNF1, HNF4 and C/EBP. Electrophoretic mobility shift assays (EMSA) have been used to study these potential hepatic regulatory elements. One region spanning from position -737 to -664 was of particular interest. It can form two specific protein-DNA complexes when incubated with nuclear extract from HepG2 cells, a human hepatoblastoma cell line. However, one of the protein-DNA complexes was absent when incubated with nuclear extract from H441 cells, a human lung papillary adenocarcinoma cell line. DNA methylation interference identified the binding sites for both complexes at position -694, corresponding to the consensus binding site for HNF3β. Besides this region, sequences from position -157 to -37 and from position -412 to -333 also formed specific DNA-protein complexes present in HepG2 cells but not in H441 cells. Our data support the hypothesis that combinatorial regulation involving these factors and associated co-regulatory factors are responsible for the tissue-specific expression of rabbit *FMO1*. (Supported in part by PHS CA53106.)

776 ISOLATION OF A FLAVIN-CONTAINING MONOOXYGENASE CDNA SEQUENCE FROM THE TELEOST RAINBOWTROUT (ONCORHYNCHUS MYKISS).

A El-Alfy and D Schlenk. *Pharmacology Department, Environmental Toxicology Research Program / ECHR, School of Pharmacy, University of Mississippi, University, MS, USA.*

Flavin-containing monooxygenases (FMOs) are microsomal enzymes that play an important role in xenobiotic metabolism and bioactivation. In mammals, FMO(s) catalyze the oxidation of endogenous sulfur-containing compounds as methionine and cysteine. Several lines of evidence suggest an osmoregulatory role for FMOs in euryhaline fish. Since very few non-mammalian FMO sequences are available, the primary goal of this study was to isolate gene(s) encoding FMO(s) from the euryhaline teleost rainbow trout. Total RNA isolated from rainbow trout liver was subjected to reverse transcription-polymerase chain reaction (RT-PCR) using degenerate primers derived from conserved regions of FMO1 proteins (between amino acid residues 27-32 and 304-309). PCR amplification resulted in a 842 bp electrophoretic band. The amino acid sequence deduced from this fragment demonstrated closest identity to rabbit hepatic FMO1 (96%) and pig FMO1 (85%). Using another pair of primers derived from the conserved FAD- and NADP- binding domains, a 400 bp band was obtained. The deduced amino acid sequence was 100% identical to the overlapping region of the 842 bp fragment and 95% homologous to rabbit FMO1. Attempts to amplify the full length cDNA using 5' and 3' rapid amplification of cDNA ends are currently underway. (EPA grant # R-823450-01-0.)

777 TRANSCRIPTIONAL REGULATION OF THE RAT HYDROXYSTEROID SULFOTRANSFERASE (SULT2-40/41) GENE BY GLUCOCORTICOIDS.

M Runge-Morris and T A Kocarek. *Institute of Chemical Toxicology, Wayne State University, Detroit, MI, USA.*

We previously reported that glucocorticoid treatment induces hydroxysteroid sulfotransferase expression in rat liver and primary cultured rat hepatocytes, and that this induction shares features with glucocorticoid-inducible CYP3A gene expression. Current evidence suggests that glucocorticoid-inducible CYP3A transcription is mediated through a *cis*-acting element containing an ATGAACT direct repeat. Sequence analysis of the SULT2-40/41 5'-flanking region revealed an ATGAACT half-site at bp -184 to -178. To begin examining whether this half-site has a functional role in mediating glucocorticoid-inducible SULT2-40/41 expression, we performed transient transfection studies in primary cultured rat hepatocytes using SULT2-40/41-luciferase reporter constructs containing ~1.9 Kb of the 5'-flanking region, either intact or lacking a 70 bp fragment delimited by *Pst*I sites at -227 and -158 (Δ-227 to -158). In hepatocytes transfected with the SULT2-40/41 construct containing the intact 5'-flanking region, 24 h treatment with 10^{-7} M or 10^{-5} M dexamethasone produced an ~6- or ~10-fold increase in luciferase activity, while treatment with 10^{-5} M betamethasone, triamcinolone acetonide, or hydrocortisone produced an increase of ~9-, ~6-, or ~3-fold, respectively. In contrast, steroid treatment failed to induce luciferase activity in hepatocytes transfected with the Δ-227 to -158 construct. These data support a role for the ATGAACT half-site in mediating glucocorticoid-inducible SULT2-40/41 gene transcription. (Supported by NIH Grant ES05823 and NIEHS Center Grant ES06639.)

778 INHIBITION OF RECOMBINANT HYDROXYSTEROID SULFOTRANSFERASES AND MICROSOMAL ARYLSUFATASE-C BY PENTACHLOROPHENOL.

Y Liu[1], R I Sanchez [1], M W H Coughtrie[2] and F C Kauffman[1]. [1]*Joint Graduate Program in Toxicology, Rutgers University, Piscataway, NJ; and* [2]*Dept. Molecular and Cellular Pathology, University of Dundee, Dundee, Scotland.*

Pentachlorophenol (PCP) is a ubiquitous environmental pollutant known to inhibit phenol sulfotransferases. A recent report indicates that PCP treatment elevated plasma levels of dihydroxyepiandrosterone (DHEA) in rats infused with the steroid (Toxicol. and Appl. Pharmacol. 151:105-109,1998). This unexpected action was attributed to elevation of hepatic PAPS but could also be explained by other actions such as inhibition of enzymes hydrolyzing DHEA-SO_4. Consequently, we evaluated the action of PCP on arylsulfatase-C (STS) and recombinant forms of the three hydroxysteroid sulfotransferases in rat, HST_{20}, HST_{40} and HST_{60}. In addition, the action of PCP on human hydroxysteroid sulfotransferase hDHEA-ST (SULT-2A1) was examined. Recombinant enzymes in vectors pET17b or PKK233 were expressed in E.

coli. Arylsulfatase-C was measured using microsomes isolated from rat liver and brain. STS was measured using either methylumbelliferyl sulfate (MUS) or estrone sulfate (ES) as substrate (10-80 μM) in the presence of increasing concentrations of PCP. Half-inhibition of hydrolysis was observed with approximately 5 μM PCP. Activities of the recombinant HSTs were measured using either DHEA (0.5 μM) or pregnenolone (5 μM) as substrates. Half-inhibition (IC_{50}) of HSTs was observed at much higher concentrations of PCP (50-200 μM) than required to inhibit STS. Thus, PCP may elevate circulating steroid sulfates by inhibiting STS in liver and target tissues at concentrations significantly below those required to inhibit HSTs. Collectively, these results suggest a novel mechanism of endocrine disruption by PCP. (Supported in part, by USPHS grants TWO2194 and ES707148.)

779 DIFFERENTIAL SUBCELLULAR LOCALIZATION OF ENDOGENOUS AND TRANSFECTED SOLUBLE EPOXIDE HYDROLASE IN MAMMALIAN CELLS: EVIDENCE FOR ISOZYME VARIANTS.

R T Mullen[1], R N Trelease[1], H Duerk[2], M Arand[2], B D Hammock[3], F Oesch[2] and D F Grant[4]. [1]*Department of Plant Biology, Arizona State University, Tempe, AZ, USA;* [2]*Institute of Toxicology, University of Mainz, Mainz, Germany;* [3]*Departments of Entomology and Environmental Toxicology, University of California, Davis, CA, USA; and* [4]*Department of Pharmacology and Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR , USA.*

Soluble epoxide hydrolase (sEH; EC3.3.2.3) is thought to catalyze the hydrolysis of a variety of toxic and carcinogenic epoxides to their corresponding diols. Previous studies suggest that sEH exists in the cytosol as well as within peroxisomes of mammalian cells. The dual localization of this enzyme has been attributed to the slow uptake of sEH into peroxisomes from its site of synthesis in cytosol due to an impaired peroxisomal targeting signal, Ser-Lys-Ile (SKI), located at the C terminus of the nascent sEH. In this study, immuno-fluorescence microscopy was used to evaluate the subcellular compartmentation of mouse and rat sEH in cultured mammalian and plant cells. Application of mouse sEH antibodies to mouse NIH3T3 cells revealed an exclusive peroxisomal localization of endogenous sEH. However, when wild-type mouse sEH was transiently expressed in NIH3T3 or HeLa cells, it accumulated in the cytosol. In contrast, when Ile at the C terminus of sEH was replaced with Leu to generate sEH-SKL-COOH, the protein was imported into peroxisomes of NIH3T3 and HeLa cells. Similar results were obtained in Chinese hamster cells stably expressing rat sEH appended to the green fluorescent protein (GFP), i.e., GFP-sEH-SKI-COOH was not imported into peroxisomes, whereas GFP-sEH-SKL-COOH was imported. That wild-type mouse sEH-SKI could indeed be sorted to peroxisomes was demonstrated in plant cells. Biolistic transformation of tobacco BY-2 cells with either the wild-type sEH (SKI-COOH), or the modified sEH (SKL-COOH), resulted in the import of both proteins into peroxisomes. We suggest the Ser-Lys-Ile on sEH is a non-functional rather than an inefficient peroxisomal targeting signal, and that two isoforms of sEH exist; a peroxisomal form and a cytosolic form.

780 PROFILE OF GLUTAMINE SYNTHETASE (GS) ACTIVITY IN METHYLMERCURY (MeHg)-EXPOSED ASTROCYTES.

K H Tan[1], M Aschner[2] and J W Allen[2]. [1]*Department of Life Sciences, Winston-Salem State University;* [2]*Department of Physiology and Pharmacology, Wake Forest University School of Medicine, Winston-Salem, NC.*

The glial-specific enzyme GS plays a key role in the maintenance of glutamate homeostasis in the CNS. This report presents data on the dosage effect of methylmercury (MeHg) on the enzymatic activity of GS and its expression in cultured astrocytes. Duplicate sets of astrocyte cultures (3-4 weeks) were exposed to MeHg (50 nM to 8 μM) for 72 or 96 hours. Astrocytes exposed to 50 nM MeHg for 72 hours exhibited a 30% increase in GS activity, but the activity was diminished by 40% at 200 nM MeHg. After 96 hour exposure to MeHg (400 nM), GS activity was reduced by ~50%. However, the GS activity was recovered in astrocytes treated with higher concentrations of MeHg (0.8-6 μM). In parallel to GS activity assays, RNA (RT-PCR and A_{260}) and GS protein level profiles (Western blots) were also obtained. In general, these results corroborated the data of GS enzyme activity. The GS protein profile from this study is consistent to the results of Western blotting analysis from our laboratory (abstract by Allen et al, 1999). The decrease in GS activity at 200-400 nM MeHg may be due to initial inhibition of GS, and the overall restoration of GS activity at later time points is likely due to enhanced expression of the GS gene. (Partially supported by NCRR NIH 2P20RR 22 583.)

781 THE DEVELOPMENTAL TOXICITY OF TOBACCO SMOKE.

J M Rogers. *Reproductive Toxicology Division, NHEERL, U.S. EPA, Research Triangle Park, NC, USA*

Today, tobacco use continues in about 25% of pregnancies, with additional gestational and childhood exposures to environmental tobacco smoke. Maternal smoking has been linked to low birth weight, increased perinatal morbidity and mortality, SIDS, and persistent deficits in learning and behavior. This symposium presents recent studies on effects of prenatal or early postnatal tobacco smoke (TS) exposure. Risks associated with maternal smoking as well as maternal and/or paternal exposure to second-hand smoke will be discussed. Recent studies which reveal lasting effects of prenatal and/or postnatal TS exposure on cognitive development in children, including reading and language, will be presented. Associations between maternal smoking and incidences of specific congenital malformations have been analyzed, including gene-environment interactions which may lead to increased risk of TS-induced birth defects. These studies will be reviewed and summarized. Animal models of developmental TS exposure will be reviewed, and new studies on the effects of perinatal environmental TS on lung development and airway reactivity in rats will be discussed. Nicotine in a known neuroteratogen. The effects of nicotine on the development of neurotransmitter systems and brain development in rats will be discussed in the context of TS-induced morbidity and SIDS in humans. Finally, these talks will be summarized in a risk assessment framework.

782 ANALYSIS OF RISK TO BIRTH DEFECTS ASSOCIATED WITH SMOKING: CONSIDERING THE ROLE OF GENE-ENVIRONMENT INTERACTIONS.

T H Beaty. *Dept. Of Epidemiology, School of Hygiene & Public Health, Johns Hopkins University, Baltimore, MD, USA.* Sponsor: J M Rogers.

Exposure to cigarette smoke during pregnancy is widely recognized as a risk factor for adverse reproductive outcomes, primarily low birth weight, perinatal mortality, and certain birth defects. There are inherent limitations in measuring the strength of associations between an environmental risk factor such as smoking and rare outcomes, such as birth defects. Furthermore, it is very likely that the response to such exposure depends on the genotype of the developing fetus and possibly that of the mother, i.e., there may be gene-environment interaction influencing risk associated with smoking. A number of common epidemiologic study designs are available to test for gene-environment interaction, including case-only, case-control, and case-parent trios. Each has its strengths and limitations. The application of these different study designs will be discussed with particular focus on the effects of maternal cigarette smoking and risk to non-syndromic oral clefts, a common birth defect influenced by both genetic and environmental factors. A number of candidate genes have shown sometimes conflicting evidence of being associated with non-syndromic oral clefts (including transforming growth factor alpha and transforming growth factor beta 3, among others), and frequently the association appears to be dependent on exposure to maternal smoking. (Supported by NIDR grant R01-DE-10293.)

783 ENVIRONMENTAL TOBACCO SMOKE AND PERINATAL AIRWAY REMODELING.

K E Pinkerton, K P Avadhanam, J Bric, K Kott, J P Joad. *University of California, Davis, CA, USA.*

Epidemiologic and experimental studies suggest that passive exposure to cigarette smoke during the perinatal period may have an adverse effect on airway function which can persist into adulthood. However, the mechanisms leading to this process are unknown. We hypothesized that neuroendocrine mediated events due to smoke exposure in the lungs lead to a persistent increase in airway reactivity. Timed pregnant dams were exposed to aged and diluted sidestream cigarette smoke (ADSS) at a particulate concentration of 1 mg/m3 for 6 h/day, 7 days/wk. Following birth, mothers and neonates continued ADSS exposure to 21 days of age. Animals were subsequently maintained in filtered air until 60 days of age. Animals were examined at gestational days (GA) 19 and 21, and postnatal days (PN) 1, 7, 21,

and 60. Airway whole mounts and paraffin sections were prepared to examine the distribution of neuroendocrine cells (NECs) in the airways. A significant increase in the number of NECs were noted at GA 19 and 21 as well as at PN 1 and 7. Isolated perfused lungs and lung slice videomicrometry were used to measure airway response to methacholine challenge at PN 60. Significant increases were noted in airway narrowing by lung slice videomicrometry as well as a significant increase in airway resistance in the isolated perfused lung 5 weeks following the cessation of exposure to ADSS. We conclude that exposure to ADSS during the perinatal period (1) significantly increases NEC number in the airways and (2) is associated with a persistent and significant alteration in airway hyperreactivity to methacholine challenge. These changes in airway function may be due to early developmental changes in NEC differentiation.

784 MATERNAL SMOKING DURING PREGNANCY: ARE THERE CIGNIFICANT LONG TERM COGNITIVE EFFECTS IN OFFSPRING?

P A Fried. *Dept. of Psychology, Carleton Univ., Ottawa, Canada.* Sponsor: J M Rogers.

The Ottawa Prenatal Prospective Study (OPPS), an ongoing, longitudinal investigation underway since 1978, has been studying the effects of cigarettes and other drugs used during pregnancy. The subjects are offspring of primarily middle class, low risk women who entered the study early in their pregnancy. Extensive demographic and lifestyle information was gathered several times during pregnancy and after the birth. The offspring have been assessed repeatedly during the neonatal period, at least annually until the age of 6 and less frequently thereafter. Data will be presented describing these children from birth until early adolescence. The outcome measures to be presented in this symposium include a variety of age appropriate standardized global measures as well as a large series of neuropsychological tests attempting to assess discrete functioning within particular domains including language development, memory, visual/perceptual functioning, components of reading and sustained attention. Data have been collected on the same children for their entire lives allowing for the examination of continuity of observations and making the ascribing of cause and effect somewhat less problematic. Across all ages of assessment, a dose dependent association, that remains after controlling for potential confounds (including second hand smoke), was noted between prenatal cigarette exposure and lower global IQ with tests of auditory/verbal functioning showing the maximum vulnerability. (Supported by NIDA.)

785 DEVELOPMENTAL TOXICITY OF NICOTINE.

T A Slotkin. *Dept. of Pharmacology & Cancer Biology, Duke University Medical Center, Durham, NC, USA.*

Despite extensive publicity, tobacco use continues in one-fourth of all pregnancies. The societal cost of maternal smoking is seen in underweight newborns, higher rates of perinatal morbidity, mortality and SIDS, and persistent deficits in learning and behavior. Animal models and in particular, nicotine infusion paradigms that, like the nicotine transdermal patch, produce nicotine exposure without the confounds of other components of tobacco or episodic hypoxic - ischemic insult, have demonstrated conclusively that nicotine is a neurobehavioral teratogen. Nicotine targets specific neurotransmitter receptors in the fetal brain, eliciting abnormalities of cell proliferation and differentiation and attendant shortfalls in the number of cells and eventually in synaptic activity. Because of the close regulatory association of cholinergic and catecholaminergic systems, adverse effects of nicotine involve multiple transmitter pathways and influence not only the immediate developmental events in fetal brain, but also the eventual programming of synaptic competence and plasticity. Accordingly, behavioral defects may appear after a prolonged period of apparent normality. Comparable alterations in the competence of peripheral autonomic systems can be demonstrated in animal models of nicotine exposure and probably contribute to perinatal morbidity and SIDS in babies born to smokers. In light of the role of nicotine in the physiological and behavioral deficits associated with maternal smoking, factors such as dose, route of administration, and critical periods of development need to be considered before using nicotine substitution during pregnancy. (Supported by the Smokeless Tobacco Research Council.)

786 REGULATION OF GENE-EXPRESSION VIA THE ELECTROPHILE RESPONSE ELEMENT.

K S Ramos. *Center for Environmental and Rural Health and Department of Physiology and Pharmacology, Texas A&M University, College of Veterinary Medicine, College Station, TX, USA.*

Transcriptional activation and repression events are responsible for coordinate regulation of gene expression at all levels of biological organization. Because transcriptional events are susceptible to toxicant interference, and chemical injury often involves disruption of signal transduction to the nucleus, toxicologists have become interested in defining cis-acting elements and DNA-protein/protein-protein interactions which govern these processes. The multiplicity of transrciptional and signaling events triggered by oxidants and electrophiles are not yet fully understood. Of relevance within this context, are studies focusing on redox regulation of xenobiotic-responsive genes mediated by the Antioxidant/Electrophile Response Element (ARE/EpRE). The first two presentations in this symposium will discuss advances in the euclidation of molecular mechanisms by which reactive oxygen species activate the rat glutathione transferase and quinone reductase genes, and the putatinve transcriptional factors that mediate these responses. The third speaker will discuss the role of Nrf1 and Nrf2, and the other leucine zipper proteins, in the activation of ARE-regulated genes. This will be followed by two presentations focusing on the pathophysiological consequences of ARE/EpRE activation as it relates to the identification of a neural-specific ARE/EpRE sequence involved in neuroprotection, and the study of promoter-specific patterns of gene regulation via the ARE/EpRE following oxidant/electrophile injury to vascular cells.

787 TRANSCRIPTIONAL REGULATION OF THE GLUTATHIONE S-TRANSFERASE A2 GENE.

C B Pickett, T Nguyen, L Fareau, and S Liu. *Schering-Plough Research Institute, Kenilworth, NJ, USA.* Sponsor: K S Ramos.

Transcripional activation of the rat liver glutathione S-transferase A2 gene by xenobiotics is mediated by two cis-acting regulatory elements, The ZRE and ARE, found in the 5' flanking region of this gene. The XRE contains a core sequence 5'TNGCGTG 3' that mediates an inducible response to planar aromatic compounds (PAC). The ARE is a unique cis-acting element responsive to metabolize PAC, phenolic antioxidants and oxidants. Using point mutations and transfection inducibility in HepG2 cells, was identified as 5'-GTGACAAAGC-3'. The core sequence is recognized with high affinity by a nuclear protein in vitro. Using a ligation-mediated polymerase chain reaction technique we have found that the core sequence interacts with a nuclear protein in vivo. More recently we have been trying to identify the nuclear protein which interacts with the ARE core consequence. Based on the similarity in sequence between the ARE and the Jun-Fos binding site, we investigated whether members of the AP-1 family of transcriptional factors bind to the ARE. Using in vitro transcription and translation of Jun and Fos coupled with gel shift assays we found that these transrciptional factors did not bind to the ARE. Similar experiments with the maf family of transrciptional factors involve in high affinity binding to the ARE. However, recent gel shift data suggest that nrf-maf heterodimers can bid with high affinity to the core ARE sequence. Current studies are aimed at elucidating how these transcriptional factors are modified by oxidative stress to activate the transcription of genes that contain an ARE.

788 ANTIOXIDANT REGUALTION OF GENES ENCODING ENZYMES THAT DETOXIFY XENOBIOTICS AND CARCINOGENS.

A K Jaiswal and V Radjendirane. *Dept. of Pharmacology, Baylor College of Medicine, Houston, TX, USA.* Sponsor: K S Ramos.

Detoxifying enzymes including quinone oxidoreductases (NQO1 and NQO2) and glutathione S-transferases (GSTs) catalyze metabolic detoxification of xenobiotics, drugs and carcinogens and, thus, protects the cells against redox cycling and oxidative stress. Genes encoding the various detoxifying enzymes are ubiquitiosly expressed and coordinately induced in response to antioxidants and xenobiotics. Deletion mutagenesis and transfection assays have identified antioxidant response element (ARE) in the promoters of the various detoxifying enzyme genes, which regulate the expression and coordinated induction of detoxifying enzyme genes. ARE is a unique cis-element that contains two AP1/AP1 like elements followed by a 'GC' box. Band and supershift assays were used to demonstrate that

nuclear transcription factors Nrf1, Nrf2, Jun, Fos, and Fra bind to the NQO1 and GST Ya genes ARE. Overexpression of Nrf1 and Nrf2 individually in human hepablastoma (Hep-ge2) cells significantly increased the ARE-mediated genes expression and induction by ß-napthoflavone (ß-NF) and tert-butyl hydroquinone (t-BHQ). Nrf2 containing one mutated leucine in its leucine zipper region was more efficient in upregulation of ARE-mediated gene expression, as compared to nrf1 with two mutated leucines. Immunoprecipitation assays demonstrated that Nrf1 and Nrf2 heterodimerize with Jun (c-Jun, Jun-B and Jun-D) proteins that bind to the ARE. Overexpression of Nrf and Jun combinations led to superactivation of ARE-mediated gene expression in transfected Hep-G2 cells. These results suggested that ARE-regulated expression of the NQO1 and other detoxifying enzyme genes and their coordinated induction by antioxidants and xenobiotics are mediated by nuclear factors Nrf (Nrf1 and Nrf2) and Jun (c-Jun, Jun-B, and Jun-D) proteins.

789 FUNCTIONAL INTERACTION OF PROTEINS WITH THE ELECTROPHILE RESPONSIVE ELEMENT.

W E Fahl, W G Chapman, M J Oberley and M Zhu. *McArdle Laboratory for Cancer Research, University of Wisconsin, Madison, WI, USA.*
Sponsor: K S Ramos.

The Electrophile Responsive Element (EpRE) mediates induction of phase II detoxifying enzymes by tert-butyl hydroquinone and other redox-cycling compounds. Most of the trans-acting factors involved in transcriptional activation through the EpRE are unknown. Although candidate factors like Nrf-2 have been identified, functional mechanistic studies need to be done to identify the contributory roles of Nrf-2 and its functional homologues as well as the other factors which interact with the EpRE. Our current efforts involve: i) efforts to purify ARE-BP-1, a 160 kDa transcription factor that has been functionally implicated in mediating the oxidant stress response, ii) studies of reconstituted, in vitro transcription using a synthetic promoter containing an EpRE which confers EpRE-enhanced transcription with nuclear extracts from HeLa cells, and iii) studies of EpRE-mediated transcription in intact HepG2 cells using direct nuclear injection of antibodies, and competitive oligonucleotides and peptides, and iv) collaborative studies to determine the degree of naturally-occurring sequence polymorphism in EpRE elements which regulate transcription of environmentally relevant human genes. Results from these studies illustrating the functional interactions of regulatory molecules at the EpRE will be presented.

790 NAD(P)H:QUINONE OXIDOREDUCTASE 1 (QR1) AND THE ANTIOXIDANT/ELECTROPHILE RESPONSIVE ELEMENT (ARE/EpRE) IN CELLS OF NEURONAL ORIGIN.

J A Johnson, J D Moehlenkamp, J K Padgitt, J M Lenius, and N J Cherrington. *Dept of Pharamacol, Toxicol and Thera, Univ of Kansas Med Ctr, Kansas City, KS, USA.*

The ARE/EpRE is an enhancer element found in the 5'-flanking region of QR1. Others have shown that pretreatment with tert-butylhydroquinone (tBHQ) and increased QR activity protects rodent neuroblastoma cells from glutamate-mediated cytotoxicity. Since induction of the QR1 gene by tBHQ is mediated through the ARE/EpRE, hQR1-ARE/EpRE-luciferase construct was transiently transfected into IMR-32 human nueroblastoma cells and treated with tBHQ. hQR1-ARE/EpRE-luciferase expression was increased 23-fold and subsequent studies defined an expanded core sequence containing a complete 5' palindrome necessary for maximal activation in IMR-32 cells. In addition, the recent finding that women on hormone replacement therapy have a reduced incidence of Alzheimer's disease has lead us to investigate whether estradiol or estradiol metabolites activate the ARE/EpRE in neuroblastoma cells. Estradiol did not activate the ARE/EpRE, but catechols of both estradiol and estrone increased hQR1-ARE/EpRE-luciferase expression and QR1 protein (5- to 10-fold). ARE/EpRE induction by tBHQ and the catechol estrogens is estrogen receptor-independent. Pretreatment with tamoxifen or estradiol had no effect on tHBQ- or catechol-mediated ARE/EpRE-activation suggesting an estrogen receptor-independent mechanism. Furthermore, activation of the ARE/EpRE by catechol estrogens and tBHQ was not blocked by pretreatment with N-acetylcysteine, glutathione, or glutathione ethyl ester. Finally, the hydroquinone-based tyrosine kinase inhibitors lavendustin A, erbstatin and tyrophostin AG957 also activate the ARE/EpRE and increase QR1. These data imply that the mechanism of activation of the ARE/EpRE in IMR-32 cells is not dependent on generation of reactive electrophiles or reactive oxygen species, but results from an effect on tyrosine kinase activity. Finally, ARE/EpRE activation correlates with neuroprotection, but a direct link remains to be determined. (Funded by NIEHS 08089 and Burroughs Wellcome New Investigator in Toxicology Award.)

791 CELL AND PROMOTER SPECIFIC PATTERNS OF GENE REGULATION VIA THE ELECTROPHILE RESPONSE ELEMENT.

K S Ramos, Y-H Chen, M T Holderman, and K P Miller. *Center for Environmental and Rural Health and Department of Physiology and Pharmacology, Texas A&M University, College of Veterinary Medicine, College Station, TX, USA.*

Recent efforts in this laboratory have focused on the study of c-Ha-ras and GST-Ya gene regulation via Electrophile Response Element (EpRE). Four plasmids containing GST-Ya regulatory sequences linked to a chloramphenicol acetyltransferase reporter gene were transfected into murine vascular smooth muscle cells (vSMCs) or HepG2 cells to evaluate transactivation profiles following challenge with benzo(a)pyrene (BaP) (0.3-30 (M), TCDD(0.1-10 nM), or H2O2 (12.5-50 (M0 for 24 hr. The indication patterns by BaP in vSMCs were AhRECAT>1.6CAT=EpRECAT=-164CAT. In contrast, induction profiles in HepG2 cells were AhRECAT = EpRECAT>1.6CAT=-164CAT. In vSMCs, the induction profiles by TCDD differed from those in HepG2 where AhRECAT>1.6CAT=EpRECAT=-164CAT. BaP and TCDD transactivated c-Ha-ras via the EpRE, but not the AhRE, showing that response profiles via EpRE are promoter specific. Interestingly, H2O2 did not transactivate the GST-Ya promoter, but increased EpRE induction of the c-Ha-ras gene in vSMCs. Cross-linking experiments with a BrdU-substituted oligonucleotide EpRE probe identified several specific complexes of Mr 80, 60, 55, 23, 21 kDa in vSMCs. We conclude that gene regulation via EpRE exhibits cell and promoter specific patterns that may be relevant to the spectrum of toxic responses elicited by BaP and related chemicals. (Supported in part by NIH Grants ES 04849 and ES 09106.)

792 TRICHLOROETHYLENE ACCELERATES AN AUTOIMMUNE RESPONSE IN MRL+/+ MICE AT DOSES SIMILAR TO HUMAN EXPOSURE LEVELS.

J M Griffin, K M Gilbert, and N R Pumford. *University of Arkansas for Medical Sciences, Little Rock, AR, USA.*

Trichloroethylene is a volatile organic solvent that is primarily used as a metal degreaser. With its widespread use, trichloroethylene has become a major environmental contaminant. Recently, trichloroethylene has been shown to accelerate an autoimmune response in MRL+/+ mice at relatively high doses. We have previously shown that trichloroethylene exposure in the drinking water is capable of accelerating an autoimmune response at an average dose of 450 mg/kg/day. However, the relationship between trichloroethylene exposure at levels similar to occupational exposure and the exacerbation of autoimmunity has not been established. Consequently, we conducted experiments designed to examine the effects of trichloroethylene at more relevant doses. Autoimmune prone MRL+/+ mice were treated with 0, 0.1, 0.5 or 2.5 mg/ml trichloroethylene in the drinking water for 4 weeks. The average dose received per mouse during the 4 weeks was 0, 22, 99 and 400 mg/kg/day, respectively. At these doses, trichloroethylene was metabolized to a reactive intermediate that covalently bound to protein. Serum levels of the autoimmune markers antinuclear antibodies and total IgG and IgM were significantly increased following treatment. It has previously been shown that $CD4^+$ T cells play a role in the development of an autoimmune response and in this experiment there was a dose-dependant and significant increase in the secretion of IFN-γ by activated $CD4^+$ T cells from treated mice, while the level of IL-4 was unchanged. Taken collectively, the results show that MRL+/+ mice treated with trichloroethylene at doses relevant to human exposure levels develop an accelerated autoimmune response in association with the activation of $CD4^+$ T cells that secrete Th_1 cytokines.

793 INITIATION OF DRUG-INDUCED LUPUS BY DISRUPTION OF POSITIVE SELECTION OF T CELLS IN THE THYMUS.

A Kretz-Rommel and R L Rubin. *The Scripps Research Institute, La Jolla, CA.*

Drug-induced lupus is a systemic autoimmune disease that can be acquired as a side effect of therapy with more than 40 medications. Procainamide poses the greatest risk for development of this syndrome with an annual inci-

dence of 20 % among treated patients. Much of our work to elucidate the underlying mechanisms of this disease has been driven by the hypothesis that systemic autoimmunity results from a failure of self-tolerance during the generation of T cells in the thymus. The mouse model we developed was designed to test this notion and to determine its cellular and molecular basis. We previously demonstrated that two intrathymic injections of procainamide-hydroxylamine (PAHA, a reactive metabolite of procainamide) into B6D2 mice caused the appearance of chromatin-reactive T cells and anti-chromatin antibodies. We now determined how thymic PAHA exposure results in the release of autoreactive T cells. In reaggregate cultures of thymic epithelial cells with $CD4^+CD8^+$ double positive cells derived from TCR-AND mice, the emerging transgenic $CD4^+$ cells expressing a T cell receptor specific for pigeon cytochrome c (PCC) are normally unresponsive to PCC. However, if 20 μM PAHA was present during selection, the T cells subsequently exhibited a 40-fold increase in proliferation in response to PCC. In contrast, when single positive thymocytes were used in the reaggregate, PAHA presence did not result in PCC-responsive T cells. These observations suggest that PAHA affects double positive thymocytes undergoing selection. To determine whether PAHA interferes with negative selection, we measured deletion of $V_\beta3$-expressing PCC-specific transgenic T cells as a result of exposure to PCC during selection. Presence of PAHA did not prevent the deletion of the transgenic T cell population. An effect on positive selection was tested using DPK cells, a double positive thymocyte cell line from a TCR-AND mouse, which mature to $CD4^+$ cells when exposed to fibroblasts presenting PCC. When selected on [PCC] < 2 μM, the emerging cells were unresponsive to PCC. Addition of 20 μM PAHA to this system resulted in a 4-fold increase in IL-2 production upon challenge with PCC. These studies suggest that PAHA induces autoimmunity by preventing acquisition of unresponsiveness to self peptides during positive selection of T cells in the thymus.

794 IMMUNOSTIMULATORY EFFECTS OF ANTI-DEPRESSANTS ON REPORTER ANTIGEN RESPONSE IN THE MODIFIED PLNA: ROLE OF SEROTONERGIC ACTIVITY.

R H H Pieters, M Tiesjema, A Van der Pijl, W Seinen and R Albers. *RITOX/Immunotoxicology, Utrecht University, The Netherlands.* Sponsor: M van den Berg.

The list of pharmaceuticals with autoimmunogenic potential is extensive, and includes drugs of the category of anti-depressants, in particular the serotonin-reuptake blockers. The immunomodulatory effect of these reuptake inhibitors may partly be caused by their capacity to act as hapten or induce neo-antigen formation generating non-cognate T cell help with subsequent determinant spreading to a (true) auto-antigen specific immune response. In addition, these compounds may cause inflammation and thus generate costimulatory signals that stimulate an immune response against an auto-antigen. The aim of this study was to discern whether anti-depressants were able to (non-)cognate help and to assess whether the serotinergic activity of these drugs might be involved in their immunostimulatory potential. To this end, we utilized the PLNA modified to read-out the characteristics of the response by using well defined reporter antigens. A number serotonin-reuptake blockers (clomipramine, imipramine, maprotiline, nortryptyline, zimeldine, paroxetine, fluvoxamine) and also serotonin itself were injected together with the T cell-independent TNP-Ficoll (requiring non-cognate T cell help) into the hind paw of a BALB/c mouse. In a next series of experiments, zimeldine, imipramine or serotonin were co-injected with the T cell-dependent antigen TNP-OVA (requiring cognate T cell help for IgG1). The immune reponse was monitored in the draining popliteal lymph node by using an TNP- and IgG1-specific ELISPOT assay. Results demonstrated that all drugs tested stimulated the IgG1-response against TNP-OVA and TNP-Ficoll whereas serotonin stimulated the response to TNP-OVA only. In addition, it was found that the 5HT2R-antagonist ketanserin caused partial decrease of the stimulatory effect of serotonin and zimeldine to TNP-OVA. Results indicate that the anti-depressive drugs can stimulate both cognate and non-cognate T cell help and that part of the cognate help may arise from their serotonergic activity.

795 POPLITEAL LYMPH NODE RESPONSE TO STREPTOZOTOCIN IS UNDER TYPE-1 CD8+ T-CELL CONTROL.

G Choquet-Kastylevsky[1,2], R Tedone[1,2], J Kehren[1], M-T Ducluzeau[1], J-F Nicolas[1] and J Descotes[1,2]. [1]*Inserm U98-X;* [2]*Dept. Pharmacology, Medical Toxicology and Environmental Medecine, Faculté de Médecine, Lyon-RTH Laennec, Lyon, France.*

The mechanism of chemical-induced autoimmune reactions is not known. The popliteal lymph node (PLN) assay has been proposed to predict the sensitizing potential of xenobiotics, but a better understanding of the mechanisms involved is absolutly needed to establish its value for preclinical safety evaluation. In this respect, the cytokine profile of PLNs was analyzed after the injection of streptozotocin (STZ). We used different groups of mice to assess the role of the CD4+ and CD8+ T-cells subtypes in the occurrence of positive responses: C57 BL/6 mice, CD4+ T-cells and CD8+ T-cells depleted mice, MHC-class I deficient mice and MHC-class II deficient mice. PLNs of 6-8 week-old mice were removed at day 7 after the injection of 0.25mg STZ (right footpad), or saline (left footpad) and the weight indices were calculated. After treatment for RNA extraction, the expression of mRNAs of interleukin (IL)-4, IL-6, IL-10, and gamma interferon (IFN-γ), was assessed in the PLNs by a quantitative RT-PCR method, using the coamplification of an internal plasmid. Naive or saline treated mice expressed few or no gamma-IFN, IL-4, IL-6, and IL-10. The prominent feature of PLNs from STZ treated C57 BL/6 mice was a high increase in IFN-γ mRNA (2900 copies), and in IL-6 mRNA (200 copies). No significant increases in IL-4, nor IL-10 mRNA were noted. CD8+ T-cells depleted mice and MHC-class I deficient mice, deficient in CD8+ T-cells, exhibited no positive PLN response, nor increase in the secretion of IL-6 or IFN-γ . On the contrary CD4+ T-cells depleted mice and MHC-class II deficient mice, deficient in CD4+ T-cells, exhibited a normal PLN response, with a cytokine profile equivalent to non-depleted mice.

These results suggest that positive responses to STZ are mediated by CD8+ T-cells restricted to MHC class-I, with a high production of IFN-γ .

796 TDI-SPECIFIC ANTIBODY GENERATION IS ALTERED IN TUMOR NECROSIS FACTOR R1/R2 DOUBLE KNOCKOUT MICE FOLLOWING EXPOSURE TO THE CHEMICAL.

R W Lange[1], J M Matheson[2], R Lemus[1], M I Luster[2], and M H Karol[1]. [1]*Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA, USA;* [2]*Toxicology and Molecular Biology Branch, NIOSH, Morgantown, WV, USA.*

Toluene diisocyanate (TDI) is a widely used industrial chemical causing respiratory sensitization in some exposed individuals. In spite of intensive research, understanding of the mechanism of chemical allergy is unclear. B and T lymphocyte activation, T helper differentiation and tissue pathology, largely controlled by the release of cytokines, are required for an organism to mount an effective immune response. The pleitropic, potent proinflammatory cytokine TNF may contribute to the induction +/or illicitation phase of TDI sensitization. To address this hypothesis TNF R1/R2 -knockout mice (C57 black) were sensitized (sc, 20 μ l, day 1) boosted (sc, 5 μ l, days 4, 11) and repeatedly challenged (inhal., 100 ppb, days 21, 23 and 25) with TDI (80:20, 2,4:2,6 TDI). TDI sensitized and challenged wild type mice were included in the study as positive controls. Twenty-four hours following the last inhalation challenge the mice were sacrificed and their blood was collected for analysis of total IgE and TDI-specific IgG and IgE. Lungs were collected for RT-PCR measurement of IL-4, IL-5 and INF-γ mRNA expression and histopathologic evaluation of the airways. Total IgE was significantly increased in the knock-out mice compared with the wild type controls. In contrast, the titers of TDI-specific IgG and IgE were reduced in the TNF R1/R2 mice. Histopathology indicated differences in the trachea, nasal area and formation of germinal centers of regional lymph nodes. Similar results were obtained in normal mice receiving TNF neutralizing antibody prior to TDI exposure. The results of this study suggest that the proinflammatory cytokine TNF participates in the murine, immune response to TDI including TDI-specific antibody production and class switching. (Supported by NIEHS # 05651.)

797 QUANTITATION OF IGE ON THE SURFACE OF BASOPHILS USING ANTI-IGE AND QUANTITATIVE FLUORSCENCE.

K K Stank, H W Smith, and D Wierda. *Lilly Research Labs, Eli Lilly and Company, Greenfield, IN, USA.*

The binding of IgE to high affinity receptors on the surface of basophils plays an important role in allergic reactions in man. The number of IgE molecules expressed on the surface of a basophil has been shown to correlate with the serum concentration of IgE, based on measurements made by eluting the IgE from a known number of basophils, measuring the amount of IgE, and then back calculating for the number of IgE molecules/basophil. The purpose of this study was to verify that a 2-color staining method analyzed by flow cytometry could be used to determine number of IgE molecules. Both whole blood and separated lymphocyte preparations were compared. The cells were stained with CD45 FITC and anti-IgE Biotin with a strepavidin PE second step. Basophils exhibit a $CD45^{DIM}/IgE^{BRIGHT}$ phenotype that allows secondary gating on the IgE^{+} population to determine mean fluorescence intensity (MFI). The number of IgE molecules bound to the surface of the basophils was determined using Becton Dickinson's QuantiBRITE system. This system consists of a set of four pre-calibrated bead levels in the form of a lyophilized pellet to calibrate the FL2 axis in terms of PE molecules. Preliminary results of 7 donors (4 with allergies and 3 with no known allergies) are as follows. In whole blood, the range of %total IgE was 0 to 1.15%, the MFI range was 0 to 936.7 and the range of the # of IgE molecules/basophil was 0 to 11490.5. The ranges for the separated lymphocytes were: %total IgE 0 to 1.5%, MFI of 0 to 1418.9 and the # of IgE molecules/basophil was 0 to 17458.8. There appeared to be a correlation between the number of IgE molecules/basophil and allergic status of the donor. Based on the preliminary data, there is no notable difference between the analysis of whole blood preparation verses the separated lymphocyte preparation regarding # of IgE molecules/basophil. The whole blood staining procedure is a rapid and reproducible means for determining the number of IgE molecules/basophil without enriching for basophils.

798 EXPERIENCE WITH A MOUSE INTRANASAL TEST FOR THE PREDICTIVE IDENTIFICATION OF RESPIRATORY SENSITISATION POTENTIAL OF PROTEINS.

L Blaikie and D A Basketter. *Unilever Safety and Environmental Assurance Centre, Colworth House, Sharnbrook, Bedford, England.* Sponsor: I Kimber.

The predictive identification of respiratory allergenic potential is an important primary step in the safety evaluation of (novel) proteins, such as the enzymes used in a range of consumer laundry products. In the past this has been achieved by assessing the relative ability of proteins to give rise to the formation of anaphylactic antibody in the guinea pig. Recently, it has been suggested that the same endpoint can be obtained by measuring the formation of specific IgG1 antibody in a mouse intranasal test (MINT). This procedure has undergone successful initial intralaboratory and interlaboratory assessment. In the present work, the MINT has been evaluated in a more thorough intralaboratory program. The data generated with a reference enzyme protein, Alcalase™, showed great reproducibility, results from 15 separate studies expressed as mean (μ g protein/dose/animal) ± standard deviation were 0.208 ± 0.079 using a statistically based curve comparison method. However, analysis of a range of 8 other proteins demonstrated that while there was reasonable correlation with historical guinea pig data for some, for others there was considerable divergence. When compared to the reference Alcalase, two proprietary enzymes were ~3x more antigenic and a third was of similar antigenicity as assessed in both MINT and guinea pig. Three other proprietary enzymes of similar antigenicity to Alcalase in the guinea pig were all substantially less antigenic in the BDF1 mouse. Another enzyme together with ovalbumin which were both significantly more antigenic in the guinea pig were also less antigenic in the MINT. The variance with data derived from guinea pig/human experience may in part be due to use of a surrogate marker for IgE in the MINT protocol (IgG1 is also regulated by IL-4) and the use of an inbred mouse strain (BDF1), where some antigens may not be recognised (due to differences in immunological repertoire). In consequence, it is concluded that the MINT is at present not suitable as a replacement for the guinea pig models currently used.

799 THE ADJUVANT ACTIVITY OF PARTICULATE POLLUTANTS IN THE PLN-ASSAY WITH REPORTER-ANTIGEN TNP-OVA.

M van Zijverden[1,2,3], M Bol[1], A van der Pijl[1], A H Penninks[2], H van Loveren[3], and R H H Pieters[1]. [1]*RITOX Immunotoxicology, Utrecht University, Utrecht, The Netherlands;* [2]*TNO Nutrition and Food Research Institute, Zeist, The Netherlands;* [3]*RIVM National Institute of Public Health and the Environment, Bilthoven, The Netherlands.* Sponsor: M van den Berg.

The prevalence of respiratory allergy is increasing in industrialized countries. Environmental pollutants may play a role by acting as adjuvants, stimulating Thelper 2 (Th2) immune responses to common allergens. In vivo studies already showed that diesel exhaust particles (DEP) enhance immunoglobulin E (IgE) production in mice and man, but neither the adjuvant activity of other particulate pollutants nor their mode of action has been determined. In these studies, the modulating effects of DEP, silica and carbon black (CB) on the immune response to TNP-OVA (2,4,6 trinitrophenylphosphate-ovalbumin) as a defined reporter antigen were determined in a modified popliteal lymph node (PLN) assay. DEP, CB and silica were coinjected with TNP-OVA into the hind footpad of female BALB/c mice (6-8 weeks), four weeks later an intranasal challenge with TNP-OVA alone was given. Five days later the number of TNP-specific antibody forming cells (AFC) (IgG1, IgE, IgG2a) was determined in the PLN, spleen, bone marrow and parabronchial lymph nodes (PBLN) by ELISPOT assay. ELISA was performed on the sera. In DEP and CB treated animals the number of IgG1 and IgE producing AFC was significantly higher than in silica treated animals, while the latter possessed more IgG2a producing AFC. Serum titers were in accordance with the AFC numbers. TNP-specific antibodies could not be detected when the reporter antigen was injected alone. From these studies it can be concluded that the three particles possess intrinsic adjuvant activity. However, they modulate the immune response to the reporter antigen differently, resulting in Th2-like isotypes being produced in presence of DEP and CB, while the response to silica tends more to a Th1 response. At the moment, T cell cytokines and costimulatory molecules are assessed in the PLN assay.

800 ORAL SENSITIZATION TO FOOD PROTEINS; A BROWN NORWAY RAT FOOD ALLERGY MODEL.

L M J Knippels, A H Penninks and G F Houben. *TNO Nutrition and Food Research Institute, Zeist, The Netherlands.* Sponsor: B Kulig.

We developed an oral sensitization protocol for food proteins for the rat. In addition, we investigated several immune mediated effects after an oral challenge and specific protein recognition was studied to determine whether a comparable spectrum of proteins is recognized by the rat and human immune system. Young Brown Norway (BN) rats were exposed to 1 mg ovalbumin (OVA) by daily gavage dosing during 42 days without the use of an adjuvant. OVA-specific IgE and IgG responses were determined by ELISA. Upon an oral challenge with OVA effects on the respiratory system, blood pressure, and permeability of the gastro-intestinal barrier were studied. In addition, BN rats were orally exposed to a total hen's egg white-protein (HEW) extract and cow's milk (CM) and the specificities of induced antibody responses were compared with the specificities of antibodies in sera from egg and milk allergic patients using immunoblotting. Animals orally exposed to the allergens developed specific IgE and IgG antibodies which recognized the same proteins compared to antibodies from egg or CM allergic patients. After an oral challenge, gut permeability was increased. Some animals demonstrated a temporary decrease in breathing frequency or systolic blood pressure. We show that the Brown Norway rat provides a suitable animal model for inducing specific IgG and IgE responses upon daily intra gastric dosing of OVA without the use of an adjuvant. Moreover, local immune mediated effects upon oral challenge are observed. In addition we showed that enterally exposed BN rats and food allergic patients demonstrate antibody responses to a comparable selection of proteins upon exposure to different protein mixtures and further support that the BN rat may provide a suitable animal model for food allergy research and to study the allergenicity of (novel) food proteins.

801 LOCAL LYMPH NODE ASSAY : HAZARD IDENTIFICATION AND POTENCY ASSESSMENT.

I Kimber[1], D A Basketter[2], P Harvey[3] and R J Dearman[1]. [1]*Zeneca Central Toxicology Laboratory, Macclesfield, England;* [2]*Unilever Safety and Environmental Assurance Centre, Sharnbrook, England;* [3]*Health and Safety Executive, Bootle, England.*

The murine local lymph node assay (LLNA) has been used extensively for the prospective identification of skin sensitization hazard. The method assesses contact sensitization potential as a function of proliferative activity induced in lymph nodes draining the site of topical exposure to test chemical. In the current investigations we have examined the use of the LLNA for the evaluation of relative potency of skin sensitizing chemicals. A range of materials of differing sensitizing potency has been examined using extended dose responses to allow the mathematical derivation of the estimated concentration of chemical required to induce a threefold increase in lymphocyte proliferation (EC3 value). Materials were ranked as strong (2,4-dinitrochlorobenzene, DNCB; Kathon CG; *p*-phenylenediamine, PPD), moderate (formaldehyde, isoeugenol) or weak sensitizers (eugenol) and non-sensitizers (*p*-aminobenzoic acid, PABA) on the basis of sensitization in humans. Each of the sensitizers stimulated a threefold increase in ^{3}H-thymidine incorporation, compared with concurrent vehicle controls, at one or more test concentrations; all materials would be classified therefore as contact allergens according to current LLNA criteria. The non-sensitizer PABA failed to induce signifciant proliferation at any concentration tested (maximum dose, 10%). Derivation of EC3 values revealed a ranking order of potency as follows : DNCB > PPD > Kathon CG > formaldehyde > isoeugenol > eugenol. These data suggest that in addition to hazard identification, the LLNA may be useful for the evaluation of relative skin sensitizing potency as a first step in risk assessment.

802 EVALUATION OF TRANSDERMALLY-DELIVERED DRUGS USING THE LOCAL LYMPH NODE ASSAY.

G C Llewellyn, J F Lockwood, and D Wierda. *Lilly Research Labs, Eli Lilly and Company, Greenfield, IN, USA.*

Continuous exposure of skin to exogenous chemicals can lead to a condition of chemical hypersensitivity, or allergic contact dermatitis. As a predictive measure, guinea pig tests have been considered the model of choice. More recently, the Local Lymph Node (LLN) assay has been shown to be a reliable indicator of moderate to strong sensitizing activity. The purpose of this study was to establish, validate, and test the LLN assay for use in assessing the contact sensitizing potential of transdermally-delivered drugs. CBA/J mice were exposed daily for 3 consecutive days to chemical applied to the dorsal portion of both ears. Five days after the initial dose, radiolabeled thymidine was administered via the tail vein and nodes harvested 5 hours later. In the validation phase, the chemicals tested included 2,4-dinitrochlorobenzene (DNCB) and oxazolone (potent sensitizers), para-aminobenzoic acid (pABA, non-sensitizer), and the irritant, sodium lauryl sulphate (SLS). Oxazolone induced an average stimulation index (SI) of greater than 3-fold at every concentration tested and was dose responsive (0.05%,19.7; 0.1%, 33.5; 1.0%,77.2). DNCB produced a similar response (0.1%,5.7; 0.5%,41.5; 1.0%,45.9), but was less potent even at higher concentrations. SLS induced an SI above 3 that was consistent only at the highest concentration tested (20%), whereas pABA (10%) induced no response as expected. Vehicles tested included acetone:olive oil (4:1), dimethylsulfoxide, and dimethylformamide, with moderate increases observed in DNA radiolabel incorporation as compared to naïve control animals. Based on reports of potential human sensitization, commercially available estradiol and scopolamine were evaluated in the test phase. Concentrations tested included levels above and below human pharmacologic doses for both chemicals. Neither estradiol (0.025-0.4%) nor scopolamine (0.5-8.0%) induced a SI of 3-fold or greater. These results support the utility of the LLN assay in characterizing the sensitizing potential of transdermally-delivered drugs.

803 A MODIFIED MURINE LOCAL LYMPH NODE ASSAY: A TWO-TIERED APPROACH TO IDENTIFY CONTACT (PHOTO)ALLERGENIC POTENTIAL.

P Ulrich[1], S Chibout[1], A de Brugerole de Fraissinette[2], A Cordier[2], and H W Vohr[3]. [1]*Experimental Toxicology and* [2]*Preclinical Safety, Novartis Pharma AG, Basel, Switzerland;* [3]*Institute of Toxicology, Bayer AG, Wuppertal, FRG.*

To improve the predictive differentiation of contact allergy (CA) and photoallergy (CPA) from irritancy (IR) and phototoxicity (PT), induced by low molecular weight compounds, we developed a modified, two-tiered protocol of the murine local lymph node assay (LLNA). During tier I testing groups of female BALB/c mice received compound solution or vehicle (40% Dimethylacetamid, 30% Acetone, 30% Ethanol) alone on the dorsum of both ears on three consecutive days. Immediately after compound application indicated groups of mice were exposed to a UVA light-dose of 10J/cm^2. Auricular lymph nodes draining the ear tissue were excised 24 hr following the last exposure. Both the contact allergens oxazolone (OXA) and 2,4-dinitrochlorobenzene (DNCB) and the contact photoallergens 3,3',4',5-tetrachlorosalicylanilide (TCSA) and chlorpromazine (CLPZ) caused a concentration dependent increase in ear tissue-draining lymph node weights and cell counts pointing to an inflammatory process in the lymph nodes. However, the same effect was found following application of the irritant croton oil and the phototoxic compounds 8-methoxypsoralene (8-MOP) and acridine. To differentiate between allergic and non-allergic reactions, mice were sensitised with a selected tier I concentration of chemicals or treated with vehicle on the shaved back on 3 consecutive days with and without UVA exposure and challenged 12 days later on the ears as described above in order to investigate the expression of relevant cytokines at two stages of the evolution of an allergic response, the induction and the challenge phase (tier II analysis). Cytokine analysis on the gene expression level in freshly prepared total lymph node cells (LNC) by quantitative reverse transcription-polymerase chain reaction (RT-PCR) and on the protein level in vitro following restimulation of magnetically purified LN CD4 T cells via T cell receptor crosslinking revealed an increased expression of IL(Interleukin)-4 and IL-10 during the challenge phase of CA and CPA induced by OXA, DNCB, TSCA and CLPZ in comparison to the corresponding induction controls. This marked increase did not occur, when mice were challenged with the phototoxic or irritant chemicals 8-MOP, acridine and croton oil. In contrast, IL-2 and IFN(Interferon)-γ were detectable during CA, CPA, IR and PT, whereas IL-4 and IL-10 were not found during PT and IR. In conclusion, comparison of IL-4 and IL-10 expression during induction and challenge phase treatment with test chemicals represent a reliable possibility to identify CA and CPA in a two-tiered protocol of the murine LLNA.

804 THE USE OF COMPUTER MODELLING TO DEMONSTRATE THE 3D DISTRIBUTION OF ENZYMES WITHIN THE RAT NASAL CAVITY.

D A Robinson[1], J A Nash[2], J R Foster[2] and C J Reed[1]. [1]*School of Biomolecular Sciences, John Moores University, Liverpool, UK;* [2]*Zeneca Central Toxicology Laboratory, Macclesfield, Cheshire, UK.* Sponsor: E A Lock.

The rat nasal cavity develops site-specific lesions when exposed to toxic compounds. In some cases (eg. formaldehyde) the site-selectivity is dependent upon airflow driven dosimetry, but other factors such as regional metabolism may also be critical. The distribution of biotransformation enzymes within the nasal epithelia is generally studied using immunohistochemistry (IHC) with a small number of standard transverse histological sections, which makes relating regional metabolism to lesion distribution difficult. The aim of this study was to model the distribution of glutathione S-transferase (GST) 3-3 in 3D. A model of the nasal cavity from a six week old male Wistar rat was generated using step wax sections (1 in 100μm) and a 3D image analysis system. Imaging densitometry was then used to semi-quantify GST 3-3 within step wax sections (1 in 600μm) stained by IHC. The distribution of GST 3-3 was then displayed upon the 3D model. The anterior of the cavity expressed relatively low levels of GST 3-3, while the posterior of the cavity stained highest. Staining was most intense at the tips of the ethmoturbinates and within the nasopharyngeal duct, areas which are within the major routes of inspiratory airflow. Other enzymes will now be modelled using this approach and their distribution correlated to lesion development.

805 AN INVESTIGATION INTO THE ANTIOXIDANT STATUS OF THE RAT NASAL CAVITY.

C J Reed[1], D A Robinson[1], J R Foster[2], J A Nash[2], and E A Lock[2]. [1]*School of Biomolecular Sciences, John Moores University, Liverpool, UK;* [2]*Zeneca Central Toxicology Laboratory, Macclesfield, Cheshire, UK.*

Oxidative stress and free radical formation occurs as a result of normal cellular metabolism, or as a by-product of xenobiotic detoxification. This work aimed to characterize the antioxidant status of the metabolically active rat nasal mucosa, and to localize the distribution of several important antioxidant enzymes. The activities of glutathione peroxidase (GP), glutathione reductase (GR), superoxide dismutase (SOD) and catalase were determined using whole homogenates of male Wistar rat (180-200g) lung, olfactory epithelium (OE) and respiratory epithelium (RE). Immunohistochemistry was then used to localize GP, catalase, SOD (Zn/Cu) and SOD (Mn) in paraffin wax nasal sections. In general the RE showed a higher level of anti-oxidant activity compared to that of the OE and lung, however, SOD activity was approximately three fold higher in the OE than the RE. GP and catalase were localized within the apical cytoplasm and cilia of the RE columnar cells, the compound tubular glands and myelinated axon bundles in the lamina propria. Within the OE the apical cytoplasm of the sustentacular cells stained positive along with the neural bundles. SOD (Mn) and SOD (Zn/Cu) both had a similar distribution to catalase and GP within the OE and RE, except the intensity of RE staining was reduced for both isoforms. Thus the nasal epithelia express different antioxidant enzyme profiles, which may reflect different protective needs for each tissue type.

806 CORRELATION OF INHALED FORMALDEHYDE FLUX PREDICTIONS WITH REGIONAL DNA-PROTEIN CROSSLINK MEASUREMENTS IN RAT NASAL PASSAGES.

A V Georgieva, R B Conolly, P M Schlosser and J S Kimbell. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA.*

DNA-protein crosslinks (DPX) are used as a dosimeter for inhaled formaldehyde and are associated with the presence of tumors induced in rat nasal passages in chronic studies. Previous studies (E. Cohen Hubal et al., *Toxicol. Appl. Pharmacol.* **143,** 47-55, 1997) linked airflow-driven uptake with DPX formation in the anterior rat nose. A 3-D computational fluid dynamics (CFD) model of a F344 rat nasal passage developed by J. Kimbell and coworkers, was used to quantify local wall mass flux of formaldehyde. Links between regional uptake estimates throughout the rat nose are needed to provide confidence in the model predictions of formaldehyde flux. Casanova and colleagues studied regional formaldehyde dosimetry in F344 rats (M. Casanova et al., *Fundam. Appl. Toxicol.* **23,** 525-36, 1994) by experimentally measuring DPX in two sites; one corresponding to high tumor incidence and the second corresponding to low tumor incidence in chronic studies. Flux and exposure concentration (ppm) were correlated with DPX separately in the high and low-tumor sites and then the regional results were compared with each other. Correlation of ppm and DPX showed a clear difference between the two regions. When flux, rather than ppm, was correlated with DPX, regional differences decreased, although flux alone was not sufficient to completely explain these differences. Additional information such as regional tissue thickness is needed. This study showed that regional flux is an important factor in estimating DPX formation. Flux predictions using human CFD models can be used to help predict cancer risk from inhaled formaldehyde.

807 LOCATION AND EXTENT OF MAJOR EPITHELIAL TYPES IN THE NASAL PASSAGES OF THE F344 RAT.

J S Kimbell[1], R B Richardson[1], E A Gross[1], and K T Morgan[2]. [1]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC;* [2]*Glaxo-Wellcome Inc., Research Triangle Park, NC, USA.*

Many chemicals induce site-specific responses in the nasal passages of the F344 rat. Major factors affecting such responses are local tissue dose and tissue susceptibility. To help account for tissue susceptibility in nasal lesion formation, the location and extent of the major epithelial types were obtained. Serial step, histological sections through the entire nasal passages of a 315g, male F344 rat were used for digitization of airway perimeters. The locations of squamous, transitional, respiratory, and olfactory epithelial types were determined by light microscopy and mapped onto each cross section. A three-dimensional computer reconstruction was created, color-coded by epithelial type, and used for the calculation of epithelial surface areas. In general, squamous epithelium lined the nasal vestibule, extending about 6 mm into the nose from the external nares and ventrally to the incisive duct. Transitional epithelium lined extravestibular lateral walls and turbinates, interdigitated with squamous epithelium on the lateral wall, and separated respiratory from squamous epithelium on the septal walls. Olfactory epithelium lined the dorsal aspect of the dorsal medial meatus, the ethmoid recesses, and the septum adjacent to the septal olfactory organ. Surface areas of squamous, transitional, respiratory, and olfactory epithelial types were 188, 209, 707, and 764 mm2, representing 10, 11, 38, and 41% of total nasal surface area, respectively. This study provides information for incorporating airway lining characteristics into dosimetry-response models for interspecies comparisons and prediction of risks to the human respiratory tract from inhaled chemicals and air pollutants.

808 MODELING FORMALDEHYDE DOSIMETRY IN THE RESPIRATORY TRACT OF HUMANS.

J H Overton[1], J S Kimbell[2], R P Subramaniam[2] and F J Miller[2]. [1]*US EPA, NHEERL, Research Triangle Park, NC, USA;* [2]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA.*

To provide estimates of lower respiratory tract doses of inhaled formaldehyde (HCHO) for use in a risk assessment, a respiratory tract (RT) dosimetry model was used to simulate the uptake of HCHO in humans. The RT dosimetry model accounted for human RT anatomy, inhalation and exhalation, convection and dispersion of HCHO in the air phase, and it's absorption at the air-liquid lining surface. An activity pattern was used to define ventilatory parameters and oronasal breathing is taken into account. Lower RT anatomy was based on the idealized symmetric model of Wiebel (1963); dimensions for human nasal passages were based on magnetic resonance image scans. The nasal passage compartment of the RT dosimetry model was calibrated by varying parameters to reproduce the same HCHO uptake that a computational fluid dynamic (CFD) model predicted for these passages during unidirectional inspiratory airflow. The calibration also ensured that the appropriate amount of HCHO was delivered to the proximal end of the lower RT during the inhalation phase of the RT dosimetry model. Model results indicate that most of the absorbed HCHO is retained during inhalation and that the CFD unidirectional simulations results are essentially equivalent to those of a complete RT simulation with explicit inhalation and exhalation. HCHO flux to airway and air space surfaces is predicted to be the highest in the nasal passages; then flux decreases distally to the trachea, increases to a local maximum (less than in the nasal passages) at the third or fourth generation, and finally decreases rapidly, resulting in very small pulmonary region surface fluxes. This information allows prediction of human RT response to inhaled HCHO as an extrapolation of rodent cancer data. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.)

809 COMPARISON OF MAGNETIC RESONANCE IMAGING (MRI) AND HISTOLOGY OF THE NASAL PASSAGES OF MICE.

A J Wiethoff[1], J R Harkema[2] and W E Brown[1]. [1]*Department of Biological Sciences, Carnegie Mellon University, Pittsburgh, PA;* [2]*Department of Pathology, Michigan State University, East Lansing, MI.*

Alterations in the nasal passages are important indicators of the effect of irritants on the respiratory system. Classically, histology in animals has been the technique employed to visualize these changes. However, it is known that fixation of tissue causes some shrinkage and/or swelling which can alter the surface area and volume of the airspace. Recently, we have shown cell loss, mucous secretion and other structural changes in mice due to exposure to respiratory irritants by an *in vivo* magnetic resonance imaging (MRI) technique. In the present study, direct comparisons between imaging live and fixed tissue have been made. A surface coil was built to achieve a resolution below 50 μm. Mice were imaged, immediately sacrificed and the heads were fixed. The sections were then paraffin embedded and stained by traditional methods or whole heads were dehydrated with alcohol and immediately imaged to detect tissue shrinkage caused by this process. Preliminary results show dramatic differences between live and fixed heads in control mice. The greatest change, a 2.5 fold increase in area in the fixed tissue, occurs in the dorsal meatus of the turbinates. Significant changes were seen in all parts of the upper respiratory tract. The prominent differences between the images and the histology sections demonstrate the advantage of MRI in assessing respiratory morphology.

810 EFFECTS OF PRE-EXISTING RHINITIS ON OZONE-INDUCED MUCOUS CELL METAPLASIA IN RATS.

H Y Cho[1], J A Hotchkiss[2], C B Bennett[2], and J R Harkema[2]. *Departments of [1]Pharmacology & Toxicology, [2]Pathology, Michigan State University, East Lansing, MI.*

People with inflammatory airway disease may be more susceptible to the adverse health effects of air pollutants compared to the general population. Ozone, the major oxidant pollutant in smog causes rhinitis and nasal epithelial alterations in normal healthy rats. The toxic effects of ozone on rats with pre-existing rhinitis have not been investigated. The present study was designed to determine the effect of endotoxin-induced rhinitis on ozone-induced epithelial alterations, especially mucous cell metaplasia (MCM), in the nasal transitional epithelium (NTE) of rats. Male F344/N rats were exposed to either filtered air (0 ppm) or ozone (0.5 ppm) for 3 days (8 h/day), and killed 2 h or 4 days after the end of the last exposure. Six h prior to daily inhalation exposure, rats were intranasally instilled with either saline or endotoxin (100 μ g/day). After death, the maxilloturbinate from one nasal passage was processed for light microscopy to morphometrically determine the number of epithelial cells and neutrophils, and the amount of stored mucosubstances in the NTE. The maxilloturbinate from the other nasal passage was processed for analysis of mucin-specific (rMuc-5AC) mRNA expression. At 2 h postexposure, endotoxin/ozone-exposed rats had 48 and 3 times more neutrophils in the NTE than did saline/air- and saline/ozone-exposed rats, respectively. At 4 days postexposure, the amounts of intraepithelial mucosubstances and percent mucous cells in endotoxin/ozone-exposed rats were significantly greater than those in saline/air-exposed and saline/ozone-exposed rats (5 and 2 times greater, respectively). No MCM was present in rats exposed to endotoxin and air. Ozone-exposed rats had 35 % more NTE cells than air-exposed rats. At 2 h postexposure, both saline/ozone- and endotoxin/ozone-exposed rats had 2-fold increases in mucin mRNA expression, compared to saline/air-exposed controls. The results of the present study indicated that endotoxin-induced neutrophilic inflammation augments ozone-induced MCM (Research funded by NIHHL59391.)

811 ACROLEIN-INDUCED NASAL VASODILATION IS CGRP- AND NO- MEDIATED.

J B Morris, J Stanek, and G Gianutsos. *Toxicology Program, University of Connecticut, Storrs, CT, USA.*

Previous studies in this laboratory have shown that inspired acrolein produces an immediate, prolonged nasal vasodilatory response without alteration in nasal air flow resistance. The current study was aimed at examining potential mechanisms of this response. Male F344 rats were anesthetized and the nasal cavity isolated by insertion of an endotracheal tube to allow for isolated upper respiratory tract exposure to acrolein vapor. Nasal acetone uptake efficiency was monitored continuously during the 50 min exposure to monitor nasal perfusion rates. As evidenced by a large increase in nasal acetone scrubbing capacity, acrolein (1-10 ppm) produced a vasodilatory response that was fully developed within minutes of the onset of exposure. This response was maintained throughout the exposure. Pretreatment of animals with capsaicin (50 mg/kg, ip) 7 days prior to exposure to defunctionalize sensory c fibers, inhibited the response (p=0.003), providing strong evidence that this response was sensory nerve mediated. The response was not altered by NK-1 receptor antagonism suggesting substance P was not involved. The CGRP antagonist hCGRP 8-37 (200 mg/kg, iv during exposure) significantly attenuated (p=0.02) the response. Similarly, the response was attenuated (p=0.0002) by the nNOS selective inhibitor 7-nitroindazole (64 mg/kg, 30 min prior to exposure). In toto these results suggest that acrolein vapor stimulates nasal sensory neurons to release NO and CGRP which mediate, at least in part, the immediate vasodilatory response associated with exposure to this irritant. (Supported by NIEHS RO1-08765.)

812 ACUTE NASAL RESPONSE TO INSPIRED ACETALDEHYDE: ROLE OF SENSORY NERVES AND METABOLISM.

J Stanek and J B Morris. *Toxicology Program, University of Connecticut, Storrs, CT, USA.*

Acetaldehyde is a sensory irritant present in environmental tobacco smoke. Previous studies have shown that inspired acetaldehyde produces an immediate nasal vasodilatory response. The aims of the current study were to: 1) investigate the role of nasal sensory nerves in this response, and 2) examine the relative importance of the acetaldehyde vis-a-vis its aldehyde dehydrogenase metabolite acetic acid. Towards these ends, the upper respiratory tract of the anesthetized male F344 rat was surgically isolated by insertion of an endotracheal tube, and vapor laden air was drawn through that site for 50 min. Acetone uptake was measured continuously during the exposure period to monitor nasal perfusion rates. To examine the role of nasal sensory nerves in the response to acetaldehyde, rats were pretreated with capsaicin (50 mg/kg sc), a dose known to defunctionalize sensory nerves. This pretreatment was without effect (p>0.05) suggesting that the vasodilatory response is not mediated by sensory nerve stimulation. Exposure to acetic acid vapor (240 ug/L) produced a response identical to that of acetaldehyde, suggesting that this metabolite may play a role in the acetaldehyde-induced nasal vasodilatory response. Pretreatment with the aldehyde dehydrogenase inhibitor cyanamide (10 mg/kg sc), however, did not alter the vasodilatory response to 10, 80, or 350 ug/L acetaldehyde (p>0.05). That cyanamide neither potentiated nor protected against the vasodilatory response suggests this response may be dependent upon both the parent, acetaldehyde, and its metabolite, acetic acid. 813 USING STEADY-STATE CLEARANCE MODELS TO ASSESS TARGET TISSUE METABOLIZED DOSE FOR INHALED VAPORS IN NASAL TISSUES AND IN SYTEMIC ORGANS.

R Sarangapani and M E Andersen. *K S Crump Group, ICF Kaiser, RTP, NC, USA.*

Clearance concepts have been applied to the nasal airflow to determine extraction of metabolized vapors under conditions of negligible systemic (arterial) concentration. This assumption may be appropriate for vapors with metabolism in the systemic tissues and in blood. However most metabolized vapors have significant accumulation in the arterial blood. These compounds can be metabolized both in nose and in systemic tissues with the potential to produce toxicity at these sites. Risk assessments for these metabolized vapors have to be based on rates of metabolism within relevant cell types. Here we link a nasal vapor clearance model with a whole body clearance model and compute nasal and liver dose for compounds that accumulate in arterial blood. These models were used to calculate tissue dose as a function of inhaled vapor concentration for chemicals with varied partition coefficients, metabolic rates and systemic clearance in both rats and humans. Nasal tissue dose estimates differ by several fold depending on the extent of accumulation of chemical in arterial blood. In addition, for metabolic processes with similar affinity constants in nose and liver, the half maximal rate of nasal metabolism occurs at lower inhaled concentrations than does half maximal saturation in the liver. Nasal effects of metabolites are likely to be limiting for risk assessments with inhaled compounds that affect both the liver and nose.

814 EFFECTS OF METHIMAZOLE ON THE OLFACTORY NEUROEPITHELIUM IN MICE.

U Bergman[1] and E B Brittebo[2]. [1]*Dept Pharmacol Toxicol, SLU, Uppsala;* [2]*Dept Pharmaceut Biosci, Div Toxicol, Uppsala Univ, Uppsala, Sweden.* Sponsor: T Malmfors.

Methimazole, a drug used in antithyroid therapy, has been reported to induce olfactory disturbances in humans. NMRI mice were given injections of methimazole (2x50 mg/kg; ip) or saline. Histopathology showed marked morphological changes in the olfactory mucosa; necrosis and detachment of the olfactory neuroepithelium and necrosis in the Bowman's glands were observed. Pretreatment with the cytochrome P450 inhibitor metyrapone, prevented the methimazole-induced toxicity at this site. Using an antibody towards a marker of immature neurons, growth-associated protein 43 (GAP43), the regeneration of the olfactory neuroepithelium following methimazole administration was studied. A markedly increased number of GAP43 stained cells was seen two weeks after administration. Three months after administration the number of GAP43 stained cells were similar to controls suggesting an efficient neurogenesis and repair of the neuroepithelium. Additional mice were given 3H-methimazole (5 mg/kg; iv), killed 4 or 24 hours later and subjected to autoradiography. A distinct labelling of the lamina propria, preferentially in the Bowman's glands in the olfactory mucosa occurred. Also, in solvent-extracted tissue sections, there was a labelling of the lamina propria indicating presence of tissue-bound metabolites at this site. Metyrapone pretreatment reduced the level of binding in the olfactory mucosa. These results suggest a cytochrome P450-dependent metabolic activation and toxicity of methimazole in the mouse olfactory mucosa.

Regenerating olfactory neurons were observed two weeks after administration and after three months the olfactory neuroepithelium was repaired suggesting that the basal stem cells for olfactory neurons in the neuroepithelium were not permanently damaged by methimazole.

815 EFFICACY AND SAFETY OF RECOMBINANT HUMAN INSULIN-LIKE GROWTH FACTOR (rhIGF-I) IN A CANINE MODEL OF OSTEOARTHRITIS.

G H I Wolfgang[1], L Seely[1], M Pike[1] P Hsyu[1], D Novicki[1], C Horvath[2], S L Myers[3], and K Pritzker[4]. [1]*Chiron Corporation, Emeryville, CA;* [2]*Primedica, Worchester, MA;* [3]*Indiana University School of Medicine, Indianapolis, IN;* [4]*Mt Sinai Hospital, Toronto, Canada.*

rhIGF-I is a known growth and maintenance factor for chondrocytes. To test whether this agent may have potential use in the treatment of osteoarthritis (OA), the efficacy and safety were evaluated in a canine model where the anterior cruciate ligament is transected to produce OA of the femorotibial joint. Adult mongrel dogs underwent surgery 4 weeks prior to the initiation of treatment. Animals then received intra-articular injections of 0, 1 or 5 mg rhIGF-I once a week for 13 weeks. In addition to standard toxicological evaluations, monitoring of blood glucose, pharmacokinetics, and specialized pathology of the joint tissues were conducted. Hypoglycemia occurred between 0.5 and 3 hours after the 5 mg dose, while no hypoglycemia occurred in the 1 mg group. Glucose levels corresponded with mean serum rhIGF-I levels which were 1.7 and 2.7 fold baseline values in the 1 and 5 mg groups, respectively. Transient hypoglycemia was the only adverse effect noted in the study. Histological parameters of efficacy, including assessment of cartilage by Mankin scoring of Safranin O stained sections, cartilage structural morphometry, and assessment of collagen content, all demonstrated that osteoarthritic lesions were attenuated in treated groups. The primary effect was preservation of proteoglycan staining. Chondrocytes were also maintained in rhIGF-I treated groups and some indications of chondroregeneration were observed. This study indicated that rhIGF-I treatment was well-tolerated in this disease model and may be a chondroprotective agent in osteoarthritis by acting as an anabolic agent for matrix components.

816 TELEMETRIC EVALUATION OF THE CARDIOVASCULAR EFFECTS OF TNK-tPA IN CYNOMOLGUS MONKEYS.

C A O'Neill[1], N D Kerwin[2], E M Davies[2], and M C Gross[1]. [1]*Genentech Inc., South San Francisco, CA and* [2]*Huntingdon Life Sciences, Huntingdon, UK.*

TNK-tPA, a fibrinolytic being developed for myocardial infarction, is a tPA variant with site-specific amino acid substitutions that have resulted in increased fibrin specificity, PAI-1 resistance and plasma half-life. Due to its extended half-life, TNK-tPA is given bolus IV while tPA is given as a continuous infusion. A primate safety pharmacology study to assess cardiovascular changes attributed to TNK-tPA was performed. Mean arterial blood pressure (MAP), heart rate (HR) and ECG (lead II) after bolus administration of TNK-tPA were assessed in conscious cynomolgus monkeys using telemetry. TNK-tPA at doses of 0.003, 0.03, 0.3, 3.0 and 30 mg/kg were administered IV to 3 female monkeys in a dose-escalation manner. Since TNK-tPA is antigenic in most laboratory species, all animals were treated within a 10-day period. The dosing schedule is shown:

Dose (mg/kg)	0.003	0.03	0.3	3.0	30.0
Study Day	1	3	6	8	10

TNK-tPA (0.003-0.3 mg/kg) did not effect MAP, HR or ECGs. TNK-tPA at 3.0 mg/kg, approximately 6x the expected clinical dose, increased MAP (10-22%) and HR (7-13%). These effects returned to baseline levels within 30 min. No ECG changes were observed. TNK-tPA (30 mg/kg) induced an immediate reduction in MAP (60%) with an increase in HR (17-32%). Epinephrine was administered to improve the status of one animal. The ECG waveform of one animal exhibited an inverted T-wave while the amplitude of the T-waves from the remaining two animals was attenuated. These effects were evident first hour with levels returning to near normal by 6 hours post-dose. All animals were ataxic at 6 hours post-dose with complete recovery in two animals by 24 hours. Bolus IV administration of TNK-tPA up to 3.0 mg/kg was well tolerated and produced pharmacologically expected minor alterations of MAP and HR in conscious monkeys.

817 COMPARISON OF THE PHARMACOKINETIC PROFILE OF A [3H]-CHOLESTEROL-CONJUGATED AND [3H]-UNCONJUGATED P=O MOE.

R E Morgan, R S Geary, J Fitchett, M Winniman, M Manoharan, and A Guzaev. *Isis Pharmaceuticals, Carlsbad, CA.*

First generation phosphorothioate antisense oligodeoxynucleotides (P=S-ODN) have been shown effective as therapeutics in preclinical and clinical trials. Oligonucleotides are being developed to optimize the antisense mechanism of action while minimizing non-sequence dependent effects. The phosphodiester, 2'-methoxyethyl (P=O MOE) oligodeoxyucleotides have been designed in response to the above. However, these compounds are poorly bound to blood-proteins, resulting in rapid excretion. It is hypothesized that conjugation of a P=O MOE with a lipophilic molecule would alter its pharmacokinetic profile. Male rats were administered 3 mg/kg (1.79 uCi/mg) intravenous injections of a tritiated P=O MOE (either conjugated with cholesterol or unconjugated) via the lateral tail vein. Plasma, excreta, and tissues were collected and analyzed for radioactivity by LSC spectroscopy. The plasma elimination half-life of the cholesterol P=O MOE was significantly longer than that of the unconjugated species. In conjunction, urinary excretion of the cholesterol P=O MOE was less (<5% dose from 0-6 hours) than that of the unconjugated P= O MOE (>35% dose from 0-6 hours). Further, the tissue distribution of the cholesterol P=O MOE was significantly broader than that of the unconjugated species. Although the concentration (ug eq/g) of the unconjugated P=O MOE was greater in the kidney cortex 3 and 24 hours post dose, the concentration of the cholesterol P=O MOE was at least 2-fold greater in other tissues; including the plasma, liver, spleen and small and large intestines at 3 and 24 hours post dose. In summary, the addition of a lipophilic molecule to a P=O MOE antisense oligodeoxynucleotide was shown to improve its pharmacokinetic profile.

818 THE EFFECTS OF MODIFIED PHOSPHOROTHIOATE OLIGODEOXYNUCLEOTIDES (P=S ODN) TARGETING C-*RAF* IN THE MOUSE.

J Cornish[1], A de Peyster[1], A A Levin[2], D K Monteith[2]. [1]*San Diego State University, San Diego, CA;* [2]*Isis Pharmaceuticals, Carlsbad, CA.*

Chemical modifications to oligonucleotides are being explored as ways to reduce toxicity and increase potency of antisense therapeutics. This study investigated the toxicity and the reduction in C-*raf* mRNA in CD-1 mice produced by 10 days of IV administration at 10, 50 or 100 mg/kg of a murine-specific 2' methoxyethyl (MOE) modified P=S ODN or a human-specific MOE modified P=S ODN. Clinical pathology indices were normal with both MOE P=S ODNs. Liver weights of mice treated with the murine MOE P=S ODN were ≈ 10% heavier than control, although no histopathology was evident. Levels of C-*raf* mRNA were unchanged from control in the heart; however, levels were decreased at all doses in the liver with the murine MOE P=S ODN. No reduction in C-*raf* mRNA levels was detected with the human-specific MOE P=S ODN. In previous studies with an unmodified P=S ODN active toward murine C-*raf*, doses <25 mg/kg were ineffective in reducing C-*raf* mRNA in mouse liver. Analysis of tissue distribution of the MOE P=S ODNs indicates concentrations are higher in spleen and lower in kidney and liver than with P=S ODNs. To further investigate the liver effect, a 28-day study at a dose of 100 mg/kg was conducted and revealed moderate hepatocellular effects that included cytoplasmic eosinophilia and correlated with an increase in serum transminase levels. These effects were less severe than observed with P=S ODNs. In addition, the MOE P=S ODN did not induce immune stimulation characteristic of the P=S ODNs. In summary, the MOE modified P=S ODNs decreased toxicity and increased potency, and thus, this modification appears promising as a new antisense oligonucleotide.

819 4-WEEK TOXICITY AND TOXICOKINETIC STUDY OF SUBCUTANEOUSLY ADMINISTERED ANAKINRA (IL-1ra) AND ORALLY ADMINISTERED METHOTREXATE IN RATS.

P S Cranmer[1], D M Miller[1], S M Henwood[2], B B Yang[1], and H Davis[1]. [1]*Amgen, Thousand Oaks, CA;* [2]*Covance Laboratories, Madison, WI.*

Recombinant methionyl interleukin-1 receptor antagonist (IL-1ra) is a cytokine proposed to treat rheumatoid arthritis. Since IL-1ra may be used clinically in combination with Methotrexate (MTX), the objective of this study was to assess the interactive effects of IL-1ra (administered subcutaneously) and MTX (administered orally) to rats on target organ toxicity and to determine the toxicokinetic profile of each drug. One hundred fifty-three female rats (17 per group assigned to 9 groups) were treated daily with 0, 10,

or 100 mg/kg/day IL-1ra in various combinations with 0, 0.04, or 0.20 mg/kg/day MTX for 28 days. There were no test article-related effects on body weight, food intake, and ophthalmologic data throughout the study. Pale skin was observed in 15 animals treated with 0.20 mg MTX/kg alone or in combination with IL-1ra. Approximately 50% of the animals receiving 0.20 mg MTX/kg had slightly decreased (~5-10%) red blood cell counts, hemoglobin, hematocrit, and more severely decreased absolute reticulocyte counts (~42-58%). Rats treated with 0.20 MTX/kg had increased (~10-20%) platelet counts, albumin-to-globulin ratio, and potassium. Coadministration of IL-1ra with MTX had no effect on these findings. Neither IL-1ra nor MTX had any apparent effect on the systemic exposure (assessed by AUC over 24 hours) of the other when administered concomitantly. In groups treated with 0.20 mg/kg MTX (with or without IL-1ra), bone marrow hypocellularity and/or an increased incidence of light-colored femoral bone marrow was noted. An increased incidence and severity of histiocytic infiltration was present in the spleens of 5 of 5 animals given 0.20 mg MTX/kg alone. This change was not present in animals treated in combination with IL-1ra. Increased chronic-active inflammation at the injection site was seen in some animals treated with IL-1ra at 100mg/kg. There was no apparent correlation between the dose of IL-1ra and/or MTX on the antibody response to IL-1ra. In conclusion, the no-observable-effect level for MTX was 0.04 mg/kg/day. The no-observable-adverse-effect level for systemic toxicity for IL-1ra was 100 mg/kg/day. Since no evidence of any adverse drug-drug interactions were observed, clinical coadministration of IL-1ra and MTX is not expected to produce any additional or interactive toxicity.

820 CHRONIC TOXICITY ASSESSMENT OF SUBCUTANEOUSLY INJECTED PEG-rHuMGDF IN RHESUS MONKEYS.

K Allan[1], D M Miller[1], D Kornbrust[2], N Gillett[2], E Cheung[1], and H Davis[1]. [1]*Amgen Inc., Thousand Oaks, CA, USA and* [2]*Sierra Biomedical, Sparks, NV, USA.*

PEG-rHuMGDF is a modified recombinant human protein which has pronounced thrombopoietic effects through stimulation of the c-mpl receptor. The objective of this study was to assess the chronic toxicity of PEG-rHuMGDF in rhesus monkeys (3-5/sex/group) after daily subcutaneous doses of 0, 5, 25, 100 or 250 μ g/kg/day. Platelet counts were markedly increased (~5-fold baseline) in all PEG-rHuMGDF treated groups by Day 14. Mean platelet counts generally remained above baseline values for doses ≥ 25 μ g/kg/day throughout the study, although individual animals in all PEG-rHuMGDF treated groups had below normal platelet counts. Mean white blood cell counts were increased in most PEG-rHuMGDF treated animals on Day 14 and declined thereafter. Mean red blood cell counts, hemoglobin, hematocrit, mean corpuscular volume and mean cell hemoglobin were decreased in all PEG-rHuMGDF treated groups, beginning on Day 14. Reticulocytes showed only a modest increase, suggesting inhibition of RBC production as the cause of the anemia. Histologic changes to the bone marrow were characterized as megakaryocyte hyperplasia or hypoplasia, with erythroid hypoplasia and myeloid hyperplasia also observed. Increased numbers of reticulin fibers were present in the marrow of all PEG-rHuMGDF treated animals. Extramedullary hematopoiesis (EMH), predominantly erythroid, occasionally also megakaryocytic, was noted in the spleen, liver and lymph nodes. Other tissues, such as the heart, kidney, testes, and thymus also had evidence of EMH in individual animals. Antibodies to PEG-rHuMGDF developed in all animals and appeared to diminish the biological effects of (i.e., decreased platelet counts and megakaryocyte hypoplasia) and influenced the exposure to PEG-rHuMGDF in some animals, particularly in the lower dose groups. In summary, PEG-rHuMGDF was well tolerated in rhesus monkeys for up to 6 months of daily dosing, producing changes that are consistent with its pharmacologic effects.

821 SUBACUTE TOXICITY STUDY OF A RIBOZYME TARGETING VEGF RECEPTOR mRNA (ANGIOZYME™) IN FEMALE CD-1 MICE.

J A Sandberg, K S Speirer, C D Sproul, L M Blatt, and T J Parry. *Ribozyme Pharmaceuticals, Inc., Boulder, CO, USA.*

Vascular endothelial growth factor (VEGF) has been implicated as a contributing growth factor to the angiogenesis of developing tumors. A ribozyme (ANGIOZYME™) has been developed against VEGF receptor subtype *Flt*-1 mRNA as a potential antiangiogenic therapeutic. In previous rodent studies, daily administration of phosphorothioate oligodeoxynucleotides has been associated with immune stimulation as well as changes in hematology and serum chemistry parameters. ANGIOZYME™ includes some phosphorothioate linkags and it is possible that repeat high-dose administration of ANGIOZYME™ could result in similar effects. To determine the toxicology and toxicokinetic profile of this ribozyme, female CD-1 mice were administered a daily sc bolus of 30, 100, or 300 mg/kg ANGIOZYME™ for 14 days. Body weight and food and water consumption were monitored throughout the 14-day study. Blood was collected for serum chemistry and hematology endpoints on days 1, 7 and 14 after initiation of dosing. In addition, the weights of major organs (kidney, liver, pancreas and spleen) were measured. On days 1 and 14, blood was collected from an additional group of animals at 30, 90 and 180 min following ANGIOZYME™ administration. ANGIOZYME™ concentrations in plasma were quantitated by high-performance liquid-chromatography. Daily sc bolus administration of 30-300 mg/kg ANGIOZYME™ for 14 days was very well tolerated in female CD-1 mice. No animals died or were euthanized prematurely during the study. There were no treatment-related changes in serum chemistry, hematology, food and water consumption, body or organ weight. Peak plasma concentrations 30 min after a 300 mg/kg sc bolus on day 1 were 154 ± 39 μg/mL. No adverse effects were observed in this study despite the appreciable systemic exposure achieved in the mice as indicated by plasma concentrations of ANGIOZYME™.

822 A 13 WEEK TOXICITY STUDY OF OSTEOPROTEGERIN (OPG) IN THE CYNOMOLGUS MONKEY.

M E Cosenza[1], S Y Smith,[2] B Birkestrand[1], A Amicone[1], C Dunstan[1], A Leyshon[2], H Davis[1]. [1]Amgen Inc., Thousand Oaks, CA, USA; [2]ClinTrials BioResearch Ltd, Montreal, Que, Canada.

Osteoprotegerin (OPG) acts as an antiresorptive agent that negatively regulates osteoclast maturation which can lead to the excess accumulation of newly synthesized bone and cartilage *in vivo*. The purpose of this study was to investigate the potential toxicity of a human recombinant form of OPG in the young cynomolgus monkey during intravenous (iv) or subcutaneous (sc) injection three times per week for up to 13 weeks. Six animals/sex/group were randomized to four groups; controls received placebo iv and treated groups received OPG at 1, 5 or 15 mg/kg/occasion iv. An additional group of three animals/sex received OPG at 15 mg/kg/occasion sc. There were no deaths during the study, no clinical signs related to treatment, no effect on body weight, appetence or ophthalmology, and no toxicologically meaningful changes in routine laboratory investigations, organ weights, gross or histopathological findings. Serum ionized calcium and phosphorus were decreased at all dose levels. Evaluations were performed to monitor biochemical markers of bone resorption (N-telopeptide [NTx], deoxypyridinoline [DPD]), bone formation (skeletal alkaline phosphatase [sALP], osteocalcin [OC]), PTH and bone density of the proximal tibia and distal radius *in vivo*. Dose-related decreases in NTx and/or DPD were observed at each dose level with up to 90% decreases in NTx noted for animals treated iv or sc at 15 mg/kg/occasion. Similar decreases were observed for sALP and OC. PTH was increased for animals treated at 5 or 15 mg/kg/occasion (iv/sc). Trabecular bone density was increased for the majority of animals treated iv or sc at 15 mg/kg/occasion and males treated iv at 5 mg/kg/occasion. Microscopic examination of the sternebrae revealed corresponding increases in bone. Decreases in markers of bone turnover, and corresponding increases in bone density, were consistent with the pharmacological action of OPG as an osteoclast inhibitor. The no observable adverse effect level of OPG was 15 mg/kg/occasion.

823 A SAFETY EVALUATION OF HEMOLINK™, AN O-RAFFINOSE, CROSS-LINKED HUMAN HEMOGLOBIN-BASED OXYGEN CARRIER.

E P Zimmer[1], G P Biro[2], P M Watts[1], N J Galiher[3] and C B Spainhour[1]. [1]*Chrysalis Preclinical Services-North America, Olyphant, PA;* [2]*Hemosol, Inc., Etobicoke, Toronto, Ontario, Canada;* [3]*Consultant In Toxicology, Mountain View, CA.*

Hemolink™ is a hemoglobin-based oxygen carrier prepared in a Ringer's Lactate solution vehicle. This material is expected to be used in such clinical indications as acute normovolemic hemodilution to enhance autologous blood donation and substitution for red cell transfusion in cases of acute blood loss. The purpose of this study was to determine the degree of tolerability by dogs of a repeated daily dosing regimen of i.v. administered Hemolink™ over a 14-day period in a daily dose at least equal to that contemplated for a single therapeutic administration. Evaluations were made of mortality, clinical observations, body weights, food consumption values, electrocardiograms, clinical pathology and hematology parameters, urinaly-

sis data, organ weight changes and gross and microscopic pathology. There were no effects of Hemolink™ at 20 and 30 ml/kg per day that resulted in any functionally significant findings, and effects were reversible (except for yellow sclera, increased liver and kidney weights, the presence of iron positive staining material was found in macrophages in some tissues and within the lumina of the proximal tubules of the kidneys). Findings at necropsy, such as organ weight or intestinal changes (thickening), were not accompanied by histopathological findings other than iron accumulation. The absence of demonstrable adverse effects in tissues with iron positive deposits suggests that there should be no long-term adverse effects as a result of Hemolink™ administration. Furthermore, as the clinical administration of this material to humans at doses comparable to 20 and 30 ml/kg would occur as a single dose, which would be cleared from the circulation relatively rapidly, the accumulation of a very large extracellular hemoglobin load as occurred in this 14-day repeat dose study would not be expected to occur under actual conditions of clinical use.

824 INHIBITION OF NF-κB IN PRIMARY HUMAN CD19+ B LYMPHOCYTES BY HYDROQUINONE.

D W Pyatt, J Yang, W S Stillman, R D Irons. *Molecular Toxicology and Environmental Health Sciences Program, University of Colorado HSC, Denver, CO.*

Hydroquinone (HQ), a reactive metabolite of benzene, is known to inhibit mitogen stimulated activation of both T and B lymphocytes. Despite extensive study, the underlying mechanism for HQ's immunotoxicity is not clear. We have previously demonstrated that 1 uM HQ inhibits TNF induced activation of NF-κB in CD4+ T cells, resulting in decreased IL-2 production. NF-κB, known to be important in T lymphocytes, also plays a critical role in normal B cell development and activation. We therefore hypothesized that alterations in NF-κB might be involved in HQ induced B cell immuno-suppression as well. In this study, we demonstrate that 1-5 uM HQ inhibits PMA/ionomycin induced activation of NF-κB in primary human CD19+ B cells. Inhibition of NF-κB is accompanied by a dose dependent decrease in PMA stimulated production of TNF with no corresponding loss in viability. HQ does not appear to alter NF-κB directly as pre-incubation of B cell nuclear extracts with HQ does not diminish activity of this protein. In contrast to our finding in T cells, inhibition of NF-κB by HQ in B cells is not reversible after 72 hours in culture suggesting a long-term functional suppression. These data support our original findings in T cells and suggests that NF-κB is particularly susceptible to inhibition by HQ. We further hypothesize that inhibition of NF-κB in lymphocytes and perhaps other cell types as well may play a significant role in HQ's toxicity.

825 INHIBITION OF MAPK (ERK) ACTIVATION BY CANNABINOL IN PMA/IO-STIMULATED MOUSE SPLENOCYTES.

B L Faubert and N E Kaminski. *Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI.*

Cannabinol (CBN) is a plant derived cannabinoid compound which exhibits immunosuppressive actions with minimal CNS activity. We have previously demonstrated that the immunosuppression by CBN involves decreased AP-1 binding activity to both the proximal AP-1 site and the distal NF-AT site in the IL-2 promoter following cellular activation for 240 min. The decreased AP-1 activity was mediated, in part, by decreased nuclear expression of both c-fos and c-jun. This decrease in protein expression; however, was not due to perturbations in nuclear import, nor to inhibition of steady state mRNA expression. Thus, we investigated the effects of CBN on ERK MAP kinase activation as this is one kinase important in the post translational modification of both c-fos and c-jun. Using the MEK inhibitor D098059, we demonstrated that ERK does indeed play a role in IL-2 production and c-fos nuclear protein expression in activated mouse splenocytes. Activated (i.e., phosphorylated) ERK protein was detected with phorbol ester (PMA, 40 nM) plus calcium ionophore (Io, 0.5 mM) within 5 min, with peak activation at 20 min using Western analysis. This early ERK activation by PMA/Io was inhibited slightly in the presence of CBN. We further demonstrated that ERK activation was inhibited more robustly by CBN following a 240 minute activation with PMA/Io. Interestingly, in the absence of PMA/Io, 20 mM CBN slightly induced ERK activation, confirming earlier reports of the ability of cannabinoid agonists to activate MAP kinases. These studies provide evidence that cannabinoid compounds affect the activation of ERK MAP kinases and this may contribute to the modulation of nuclear protein expression of c-fos and c-jun, and subsequently, AP-1 activity in the IL-2 promoter. (This work was supported by NIH Grant DA070908 and E.I. Dupont DeNemours & Co.)

826 CANNABINOL INHIBITION OF INTERLEUKIN-4 EXPRESSION IN EL4.IL2 CELLS IS MEDIATED THROUGH DOWN-REGULATION OF NF-AT.

T-R Jan and N E Kaminski. *Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI.*

Cannabinoid compounds are widely established as being psychoactive and immunosuppressive. One of the most sensitive immune responses inhibited by cannabinoids is the T-cell dependent IgM antibody forming cell (AFC) response which is a measure of humoral immunity and requires the function of T-cell. To elucidate the mechanisms underlying cannabinoid-mediated immunosuppression, previous experiments in our laboratory have demonstrated that cannabinol and D9-tetrahydrocannabinol inhibit the expression of interleukin-2 (IL-2) in EL4.IL2 cells, a murine T-cell lymphoma line. In addition to IL-2, IL-4 is another T-cell secreted cytokine critical for the development of humoral immunity. IL-4 is also essential in type I hypersensitivity disorders, such as asthma, by mediating immunoglobulin class switching to promote IgE production. The objective of the present study was to examine the effects of cannabinol on the IL-4 expression in EL4.IL2 cells. IL-4 expression in EL4.IL2 cells was induced by ionomycin (1 μM) alone or in combination with PMA (80 nM). It is notable that ionomycin alone induced IL-4 but not IL-2 expression, whereas ionomycin plus PMA induced both IL-4 and IL-2 expression in EL4.IL2 cells. Treatment with cannabinol (1-20 μM) 30 minutes prior to either ionomycin alone or in combination with PMA attenuated both IL-4 mRNA and protein levels in a concentration dependent manner. Decreased binding activity to the IL-4 promoter P0 site, a NF-AT motif, by cannabinol treated cells was also observed in EMSA experiments, indicating that cannabinol down-regulates IL-4 expression at transcription level by disrupting the NF-AT signaling pathway. These results suggest that the inhibition of IL-4 expression by cannabinol may contribute to its immunosuppressive effects and the marked sensitivity of the T-cell dependent AFC response to cannabinoids. (This work was supported by NIDA Grant DA09789 and DA07908.)

827 THE ROLE OF CALCIUM AND CYCLOOXYGENASE ACTIVITY ON THE INHIBITION OF IL-2 BY THE ENDOGENOUS CANNABINOID, 2-ARACHIDONYL-GLYCEROL.

Y L Ouyang, S S Yea and N E Kaminski. *Dept. of Pharmacology and Toxicology, Michigan State University, East Lansing, MI, USA.*

2-arachidonyl-glycerol (2-Ara-Gl), a fatty acid ethanolamide, was recently identified as a putative endogenous ligand for cannabinoid receptor types, CB1 and CB2. Follow-up evaluations demonstrated that 2-Ara-Gl possessed immunomodulatory activity including inhibition of IL-2 expression. The objective of the present studies was to investigate signaling pathways involved in 2-Ara-Gl-mediated IL-2 inhibition. Pretreatment of splenocytes from female B6C3F1 mice with 20 μM 2-Ara-Gl strongly suppressed phorbol 12-myristate 13-acetate plus ionomycin-stimulated IL-2 secretion and steady-state mRNA expression. This inhibition was partially reversed by agents which increased [Ca2+]i including the calcium ionophore ionomycin and Ca+2-ATPases inhibitors, thapsigargin or cyclopiazonic acid. Furthermore, pretreatment of splenocytes with cyclooxygenase inhibitors indomethacin or flurbiprofen completely blocked the 2-Ara-Gl-mediated IL-2 inhibition. This recovery of 2-Ara-Gl-elicited IL-2 inhibition by ionomycin and indomethacin appeared to be mediated at the transcriptional level as evidenced by a similar reversal of the inhibition of a CAT reporter gene under the control of the IL-2 promotor/enhancer region. Phenylmethylsul-fonyl fluoride, an amidase inhibitor, had marginal effects on the 2-Ara-Gl-mediated inhibition of IL-2 expression. In contrast, lipoxygenase inhibitor nordihydroguaiaretic acid failed to block this inhibition. Taken together, these data suggest that a significant component of the IL-2 inhibition by 2-Ara-Gl involves the perturbation of Ca2+ signaling and cyclooxygenase pathway.

828 DEOXYNIVALENOL (VOMITOXIN) AND TNFα ACT SYNERGISTICALLY TO INDUCE THYMOCYTE APOPTOSIS THROUGH MECHANISMS INVOLVING INTRACELLULAR Ca^{2+}, REACTIVE OXYGEN SPECIES, MAPKs, AND CASPASE-3.

R L Uzarski and J J Pestka. *Department of Food and Science and Human Nutrition, Michigan State University, E. Lansing, MI, USA.*

The trichothecene mycotoxins are a group of sesquiterpenoid fungal metabolites produced by several commonly occurring molds. Preliminary studies in our lab indicate that co-exposure of mice to small doses of bacterial lipopolysaccharide (LPS) and the common foodborne trichothecene deoxynivalenol (DON or vomitoxin) results in massive apoptosis of lymphoid organs and that thymocytes are a primary target. The effect of co-exposure to DON and LPS or known apoptotic mediators induced by LPS was assessed in murine thymocytes. Apoptosis was determined morphologically using DNA binding dyes. Co-exposure to DON and LPS, prostaglandin E_2 (PGE_2), dexamethasone (DEX), or anti-Fas did not significantly influence thymocyte apoptosis. Co-exposure to 250 or 500 ng/ml DON and 4 or 20 ng/ml TNFα significantly increased thymocyte apoptosis approximately 3-fold over control values ($p<0.05$). DON or TNFα alone did not significantly increase apoptosis at these concentrations. Signal transduction mechanisms were studied using several pharmacological inhibitors and chelators. Intracellular Ca^{2+} chelator BAPTA-AM, free radical scavengers N-acetyl-cysteine (NAC) and glutathione (GSH), MAPK inhibitor PD98059, SAPK inhibitor SB203580, and caspase-3 inhibitor Ac-DEVD-CHO significat\ntly reduced DON/TNFα induced apoptosis by 87.8%, 88.1%, 74.1%, 78.7%, 87.0%, and 59.9% respectively. Extracellular Ca^{2+} chelator EDTA, and caspase-1 inhibitor Ac-YAD-AOM did not significantly decrease DON-TNFα induced apoptosis. The results demonstrate that thymocyte apoptosis resulting from DON and LPS co-exposure may be mediated by TNFα and involve upregulation of secondary messengers, including intracellular Ca^{2+} and ROS, which trigger the MAP kinases and result in caspase-3 activation. (This work was supported by PHS Grants ES-03358 and T32 ESO7255.)

829 POTENTIATION AND ATTENUATION OF TRANSCRIPTION FACTOR ACTIVITY IN MURINE SPLEEN FOLLOWING ORAL EXPOSURE TO THE TRICHOTHECENE VOMITOXIN (DEOXYNIVALENOL).

H R Zhou and J J Pestka. *Department of Food Science and Human Nutrition, Michigan State University, East Lansing, MI, USA.*

The capacity of the trichothecene mycotoxin vomitoxin (VT or deoxynivalenol) to superinduce expression of mRNAs for TNF-α, IL-6 and other cytokines is likely to involve transcriptional and /or posttranscriptional mechanisms. Using electrophoretic mobility shift assay, we assessed the *in vivo* effects of VT on several transcription factors which bind transcriptional control motifs identified in the TNF-α and IL-6 promoters. The binding of NF-IL6, AP-1, CREB, AP-2, SP-1 and NF-κB was measured at 0, 0.5, 1.5, 4 and 8 hr after oral exposure to 25 mg/kg BW of VT. NF-IL6 binding activity was elevated at 30 min and declined within 90 min with 8 hr values still bellowing control. CREB and AP-1 binding activities decreased slightly at 30 min but gradually increased, reaching a maximum at 4 hr. AP-2 and SP-1 binding activity decreased and reached a minimum at 4 hr. NF-kB was increased slightly only at 4 hr. The specificity of NF-IL6, AP-1, CREB, AP-2, SP-1 and NFκB to the relevant DNA motifs were verified by competition assays using an excess of unlabeled consensus and mutant oligonucleotides. Supershift analyses were used to identify the VT- inducible DNA binding proteins for NF-IL6 (CEBPβ), AP-1 (JunD, cJun/AP-1,cFos), CREB (ATF-2 and ATF-3) and NF-κB (p50 and cRel). Taken together, the results indicate that VT exposure can potentiate or attenuate binding activities of transcription factors specific for potential regulatory motifs in TNF-α and IL-6 promoter region. These altered activities may contribute, in part, to VT-induced gene expression of the cytokines. (Supported by PHS Grant ES 03358.)

830 DOWN-REGULATION OF A ENDOPLASMIC RETICULUM CHAPERONE, GRP78/BiP, BY VOMITOXIN (DEOXYNIVALENOL) IN MURINE EL-4 THYMOMA CELLS.

G -H Yang[1,2], S Li[2] and J J Pestka[1,2]. [1]*National Food Safety and Toxicology Center,* [2]*Department of Food Science and Human Nutrition, Michigan State University, East Lansing, MI, USA.*

The mechanisms by which vomitoxin (VT or deoxynivalenol) causes cytokine superinduction and apoptotic cell death are not fully understood. In the present study, we have applied mRNA differential display analysis to evaluate changes in gene expression induced by VT in murine EL-4 thymoma cells stimulated with phorbol 12-myristate 13-acetate (PMA) and ionomycin (ION). These conditions have been previously shown to promote cytokine superinduction. We found that VT decreased the expression of GRP78/BiP, a stress-response gene induced by agents or conditions that adversely affect endoplasmic reticulum function. Competitive RT-PCR analysis revealed that 250 ng/ml VT decreased GRP78/BiP mRNA expression in both unstimulated and PMA/ION-stimulated EL-4 cells at 6 hr and 24 hr after VT treatment. In accordance with the RT-PCR analysis, Western blot analysis confirmed that GRP/BiP protein level was significantly diminished in a dose response fashion by VT (50 to 1000 ng/ml) in PMA/ION-stimulated cells. GRP78/BiP has been shown to play a role in regulation of protein folding and secretion, and to protect a cell from apoptosis. In PMA/ION-stimulated cells, 200 bp DNA laddering, a hallmark of apoptosis, was shown in a dose-dependent fashion from 50 to 1000 ng/ml VT at 24 hr. In contrast, when the cells were treated with 50 to 1000 ng/ml VT only for up to 48 hr, the 200 bp DNA laddering was not found. These results suggest that the capacity of VT to induce cytokine superinduction or apoptotic cell death may be due, in part, to a reduction of the GRP78/BiP stress response.

831 INHIBITION OF HUMAN CYTOKINE PRODUCTION BY PHENOLIC COMPONENTS OF CIGARETTE TAR.

B M Freed, L T Rael, S Perlman, and M T Aubrey. *Division of Allergy and Clinical Immunology, Department of Medicine, University of Colorado Health Sciences Center, Denver, CO.*

Cigarette smoking has been shown to induce profound, but localized, suppression of T cell responses in the lungs and lung-associated lymph nodes. We previously demonstrated that both HQ and catechol, but not phenol, cause an immediate cessation in DNA synthesis in human lymphocytes. In the current project, we studied the effects of HQ, catechol and phenol on human cytokine production *in vitro*. Human peripheral blood mononuclear cells were treated with 50μ M HQ, catechol or phenol for three hours, then stimulated with 1μ g/ml ConA and 3nM PMA. Supernatants were collected at 16 hrs (IL-1β and TNFα) and 24 hours (IL-2 and IFNγ) and assayed for cytokines levels by ELISA. HQ, catechol and phenol inhibited production of IL-1β , IL-2 and IFN-γ by >75-95% without loss of cell viability, but TNFα production was relatively resistant to these phenolic compounds. Unlike the effects on DNA synthesis, which were immediate and reversible, the inhibitory effects of HQ and catechol on IL-2 and IFNγ production required a three-hour incubation with the cells and could not be reversed by washing. These experiments suggest that HQ and catechol have distinct effects on early and late events in T cell activation, and that phenol also has immunosuppressive properties. (Supported by NIH grant HL60538.)

832 DOSE RELATED SUPERINDUCTION AND SUPPRESSION OF CYTOKINES BY MACROCYCLIC TRICHOTHECENES IN MURINE CLONAL T-CELL AND MACROPHAGE MODELS.

Y Chung[1,2], M Lee[1,2], S Li[1,2], B B Jarvis[3], and J J Pestka[1,2]. [1]*Department of Food Science and Human Nutrition,* [2]*National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI, USA;* [3]*Department of Chemistry and Biochemistry, University of Maryland, College Park, MD, USA.*

Foodborne type A and B trichothecenes including vomitoxin (deoxynivalenol, DON) have been previously assessed for their cytotoxic and immunotoxic effects. Several macrocyclic (group D) trichothecenes, notably the satratoxins, have been associated with cases of sick building syndrome. The effect of macrocyclic trichothecenes on cytokine secretion were assessed in murine EL-4 cells as well as RAW 264.7 cells. The EL-4 cells were stimulated with phorbol 2-myristate 13-acetate (5 ng/ml) and ionomycin (100 ng/ml) for 72 hrs to a various concentrations of satratoxin G (ST-G), satratoxin H (ST-H), isosatratoxin F (iST-F), roridin A (ROR-A), and verrucarin A (VER-A). After 72 hrs incubation, IL-2 secretion was increased by the concentrations of 0.5, 1.0, 1.0, 0.1, and 0.25 ng/ml for ST-G, ST-H, iST-F, ROR-A, and VER-A, respectively. At higher mycotoxin concentrations, cytokine production and proliferation were markedly impaired. RAW 264.7 murine macrophage cells were unstimulated or stimulated with lipopolysaccharide (LPS) and exposed to various concentrations of the macrocyclic trichothecenes mentioned above for 72 hrs. With LPS stimulation (50 ng/ml), the secretion of TNF-α was increased 2-3 fold compared to controls after 48 or 72 hrs incubation in the presence of 1.0, 2.5, 2.5, 1.0, and 1.0 ng/ml of ST-G, ST-H, iST-F, ROR-A, and VER-A, respectively. TNF-α

production was suppressed at higher mycotoxin concentrations. IL-6 secretion was not superinduced even with LPS stimulation. Without LPS stimulation, neither TNF-α nor IL-6 was induced. These results suggest that the macrocyclic trichothecenes can superinduce secretion of IL-2 in EL-4 cells and secretion of TNF-α in RAW 264.7 cells.

833 POTENTIATION OF THE INHIBITORY EFFECT OF HYDROQUINONE ON HUMAN TNFα PRODUCTION BY OXIDATIVE STRESS.

L T Rael, S Perlman, M T Aubrey and B M Freed. *Division of Allergy and Clinical Immunology, Department of Medicine, University of Colorado Health Sciences Center, Denver, CO.*

Hydroquinone is a major constituent of cigarette tar that may play an important role in the suppression of T cell immunity in the lungs of smokers. We have found that hydroquinone (HQ), at concentrations found in smokers lungs, is a potent inhibitor of human IL-1β , IL-2, and IFNγ production, but is less inhibitory against TNFα production. TNFα is an inflammatory cytokine that is induced by oxidative stress. However, since oxidants can also oxidize HQ into the more reactive quinone, we decided to investigate the combined effects of HQ and H_2O_2 on human TNFα production *in vitro*. Human peripheral blood lymphocytes were treated with HQ and H_2O_2 in RPMI1640 + 10% FBS for three hours, then stimulated with 1μ g/ml ConA and 3nM PMA. Supernatants were collected 16 hrs later and assayed for IL-1β and TNFα levels by ELISA. 20μ M HQ, in the absence of H_2O_2, inhibited IL-1β by >70%, but had no effect on TNFα production. Concentrations of H_2O_2 up to 50μ M, in the absence of HQ, enhanced TNFα production. However, the simultaneous addition of 5μ M H_2O_2 and 20μ M HQ resulted in >80% suppression of TNFα and >99% suppression of IL-1β production. HPLC analysis of the culture supernatants demonstrated that H_2O_2 enhanced the disappearance of HQ from the media. (Supported by NIH grant HL60538.)

834 SUPPRESSION OF IL-2 GENE EXPRESSION IN MURINE SPLENOCYTES AND THYMOCYTES BY MICROCYSTINS AND NODULARIN.

S S Yea[1], H-M Oh[2] and K-H Yang[1]. [1]*Dept. of Biological Sciences, Korea Advanced Institute of Science and Technology, Taejon, Korea;* [2]*Environmental Microbiology, Korea Research Institute of Bioscience and Biotechnology, Taejon, Korea.*

Microcystins and nodularin are cyclic peptide toxins produced by cyanobacteria. Both toxins are known to affect hepatocytes and macrophages. In the present study, we investigated effects of microcystins and nodularin on T-cell function. Treatment of microcystins and nodularin significantly inhibited ConA-induced T-cell proliferation in B6C3F1 mouse splenocytes. Microcystins and nodularin also inhibited phorbol 12-myristate 13-acetate (PMA) and ionomycin (Io)-induced IL-2 mRNA expression in murine splenocytes and thymocytes as determined by quantitative RT-PCR. Electrophoretic mobility shift assays indicated that treatment of nodularin showed an inhibition of NF-AT binding in PMA/Io-stumulated murine splenocytes. AP-1 DNA binding was also slightly inhibited, but no effect was observed in NF-kB and Oct DNA binding. These results suggested that microcystins and nodularin inhibit IL-2 gene expression through the down regulation of NF-AT activation. (Supported by the grant from the Ministry of Science and Technology, Korea, #97-N1-05-03-A-01.)

835 FETAL THYMIC ATROPHY FOLLOWING LOW-LEVEL MATERNAL TCDD EXPOSURE IS CHARACTERIZED BY THYMOCYTE HYPOCELLULARITY WITHOUT ALTERED CD4 AND CD8 MARKER EXPRESSION.

J E Whaley and S D Holladay. *Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA, USA.*

We previously reported altered fetal thymocyte surface marker expression and fetal thymic hypocellularity in gestational day (gd) 18 B6C3F1 mice following subacute maternal exposure to 1.5 μg/kg/day TCDD from gd 6-14. In continued experiments, both marker expression and thymic hypocellularity remained significantly changed at doses of TCDD down to 0.3 μg/kg/day. However, at these lower doses it was noted that the magnitude of the hypocellularity effect was greater than that of the inhibited differentiation (i.e., marker) effect. These data suggested that these two effects of TCDD (i.e., induction of thymic hypocellularity and inhibited thymocyte differentiation) may be mechanistically independent and thus may be separable by a further reduction in the subacute dosing with TCDD. Continued experiments in outbred ICR mice verified this hypothesis. Specifically, fetuses of timed-pregnant ICR mice dosed with 0.3-3.0 μg/kg/day TCDD displayed significant thymic hypocellularity without altered marker expression. Given that no TCDD-related reduction of $CD4^+8^+$ (DP) thymocytes was observed in the presence of significant reduction in thymocyte number, these results suggest that TCDD-induced apoptosis of DP cells did not contribute to the fetal thymic atrophy caused by low-level subacute chemical exposure. Taken together with reports by other authors, these data also indicate that the T-lymphocyte progenitor cell (prothymocyte) may represent a more sensitive target of TCDD exposure than does the thymocyte. (Supported by NIH ES 07612-01 SRC.)

836 ACUTE ADMINISTRATION OF ETHANOL IN VIVO DECREASES THE ACTIVATION OF NK CELLS BY POLY I:C IN VIVO OR IN VITRO: AN IN VITRO SYSTEM FOR MECHANISTIC STUDIES.

S D Collier and S B Pruett. *Department of Cellular Biology and Anatomy, Louisiana State University Medical Center, Shreveport, LA, USA.*

Acute administration of ethanol (EtOH) in a mouse model for binge drinking suppresses both basal and polyinosinic-polycytidylic acid (poly I:C)-enhanced natural killer (NK) cell activity. An in vitro system was developed to allow investigation of mechanistic aspects of EtOH-induced inhibition of NK cell activation by poly I:C. Initial experiments indicated that mouse splenocytes cultured at high density (108/ml) can be effectively activated by poly I:C with regard to NK cell lytic function (as measured by a standard 51Cr-release assay using YAC-1 target cells). As previously shown in vivo, addition of corticosterone in vitro suppresses NK cell activation by poly I:C in a concentration-dependent manner. Splenocytes from mice treated in vivo with EtOH respond significantly less effectively to poly I:C in vitro than do splenocytes from control mice treated only with the vehicle for EtOH (water). This suggests that the effects of EtOH in vivo are relatively long-lasting and are evident during similar time frames during subsequent exposure to poly I:C in vivo or in vitro. In addition, administration of RU 486 (a glucocorticoid antagonist) in vivo significantly decreased the EtOH-induced suppression of NK cell activation in response to poly I:C in vitro. The addition of anti-interferon-alpha antibodies to spleen cell cultures significantly decreased poly I:C-induced activation, and addition of exogenous Interferon-alpha partially overcame the suppressed NK cell activation noted when splenocytes were obtained from EtOH-treated mice. Finally, Western blot analysis indicated that upregulation of perforin and granzyme B were induced by poly I:C, and EtOH inhibited this upregulation. These results indicate that EtOH may function by preventing interferon-alpha production or responsiveness and subsequently upregulation of perforin and granzyme B. Glucocorticoids are partially responsible for effects of EtOH in vivo, which persist during NK cell activation in vitro. (This work was supported by NIH grants AA09505 and ES09158, and S.B.P. is supported by an NIAAA Research Scientist Development Award.)

837 TRIBUTYLTIN OXIDE (TBTO) EXPOSURE *IN VIVO* BLOCKS THYMOCYTE MATURATION AT THE $CD25^-CD44^+$ STAGE.

R J Vandebriel, J H G Hoekman, J E Robinson, H Van Loveren, J G Vos and P J M Roholl. *Laboratory for Pathology and Immunobiology, RIVM, Bilthoven, The Netherlands.*

In a previous study we have shown that *in vivo* bis(tri-*n*-butyltin)oxide (TBTO) exposure of rats resulted in reduced CD25 expression on thymocytes. $CD3^-CD4^-CD8^-$ (triple negative, TN) thymocytes maturate in mice through several stages: $CD25^-CD44^+ \rightarrow CD25^+CD44^+ \rightarrow CD25^+CD44^- \rightarrow CD25^-CD44^-$. This prompted us to establish whether TBTO exposure blocks maturation of TN thymocytes at a particular stage. Thymi from rats exposed for 2 and 6 weeks to TBTO at a dose that did not cause thymus atrophy, and from unexposed controls, were double immunostained for CD25/CD44 and analyzed using two-color Confocal Laser Scan Microscopy. Cells staining for CD25 showed a reticular appearance in the medulla, and a thymocyte-like appearance in the cortex and cortico-medullary region. Both a reticular appearance and a thymocyte-like appearance was found for cells staining for CD44. $CD25^-CD44^+$ thymocyte-like cells were confined to the cortex. TBTO exposure resulted in a decreased intensity and number of $CD25^+$ cells, with at the same time an increased intensity of CD44 staining. These effects were more profound after 6 weeks than after 2 weeks. These results indicate a block in thymocyte maturation at the $CD25^-CD44^+$ stage. Most likely these thymocytes are TN. As these thymocytes have the potential to develop a.o.

into T-cells and NK cells, a reduced development of these cell types may result from this block, in line with previous *in vivo* function studies. Exposure of mice to 2,3,7,8-tetrachlorodibenzo-*p*-dioxin has been shown to block TN thymocyte maturation at this stage. Possible mechanisms that result in this block include reduced interaction with thymic and bone marrow stromal cells, and reduced transcription factor expression.

838 A STRUCTURE ACTIVITY RELATIONSHIP OF VARIOUS POLYCHLORINATED DIBENZO-p-DIOXIN CONGENERS: INHIBITION OF IMMUNOGLOBULIN EXPRESSION VERSUS AhR-MEDIATED ENZYME INDUCTION.

C E W Sulentic, M P Holsapple[1] and N E Kaminski. *Dept. of Pharmacology & Toxicology, Michigan State University, East Lansing, MI; [1]Dow Chemical Company, Midland, MI.*

The immune system has been identified as a sensitive target for the toxic effects produced by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). Furthermore, the B-cell has been identified as a sensitive cellular target of TCDD by previous cell-type fractionation studies from this laboratory. The actual molecular mechanism responsible for the immunotoxic effects produced by TCDD is unclear; however, many of the biological effects produced by TCDD are thought to be mediated by the aryl hydrocarbon receptor (AhR). Our previous results describing the CH12.LX and BCL-1 B-cell lines, which differ markedly in their expression of the AhR and in their sensitivity to TCDD, have implicated a role for the AhR in TCDD-induced inhibition of B-cell function. The purpose of the present studies was to further investigate this role of the AhR through a characterization of the structure activity relationship between inhibition of immunoglobulin (Ig) secretion and of Ig heavy chain transcription and AhR-mediated enzyme induction in CH12.LX cells. Results demonstrated an inhibition of IgM secretion with the following rank order potency, TCDD > 1,2,3,4,7,8-hexachlorodibenzo-p-dioxin (HxCDD) > 2,3,7-trichlorodibenzo-p-dioxin (TriCDD) > > 1-monochlorodibenzo-p-dioxin (MCDD). The rank order potency for induction of *Cyp1a1* expression in the CH12.LX cells for these congeners is TCDD > HxCDD > TriCDD >> MCDD. This correlates well with the previously reported induction of aryl hydrocarbon hydroxylase (AHH) activity and with the sensitivity to inhibition of IgM secretion from CH12.LX cells. In addition, TCDD, HxCDD, TriCDD and MCDD also had no effect on IgM secretion from the AhR-deficient BCL-1 cells. Furthermore, preliminary results demonstrate a concentration-dependent inhibition of Ig heavy chain gene transcription by TCDD and HxCDD that closely resembles the concentration-dependent induction of Cyp1a1 gene expression suggesting a potential DRE-mediated regulation of the Ig heavy chain gene. The results from these studies further support an AhR-dependent mechanism for the inhibition of IgM secretion by dibenzo-p-dioxin congeners. (These studies were supported by the NIH grant ES02520.)

839 IMMUNOMODULATION OF MACROPHAGE RESPONSE BY 2,4-DICHLOROPHENOXYACETIC ACID: TIME- AND TISSUE-SPECIFIC DIFFERENCES IN MUMMICHOG (FUNDULUS HETEROCLITUS).

C Baier-Anderson, R S Anderson and M L Haasch. *University of Maryland, Chesapeake Biological Laboratory, Solomons, MD, USA.*

The herbicide 2,4-dichlorophenoxyacetic acid (2,4-D) is a known peroxisome proliferating agent (PPA) with potential immunomodulating abilities. PPA exposure induces hepatic fatty acid metabolizing cytochromes P450 (CYP2K1 and CYP2M1 in fish) and may modulate liver and extrahepatic tissue macrophage activities. Hallmarks of macrophage activation are induction of nitric oxide synthase (iNOS) and generation of reactive oxygen species (ROS). The aim of this study was to evaluate the immunomodulatory effects of 2,4-D through measurement of hepatic iNOS expression and ROS production by anterior kidney macrophages. 2,4-D exposure was evaluated by immunodetection of induced CYP2K1-like proteins. Female fish were exposed to 2,4-D (0.1 or 1.0 ppm) or vehicle control for 1, 7, 14 or 21 days. At each time point, livers and anterior kidneys were collected. Pooled livers (n=3 pools/ treatment) were processed to retrieve microsomal and cytosolic fractions. Proteins were separated by SDS-PAGE and transferred to PVDF membrane. Immunodetection of induced microsomal CYP2K1 and cytosolic iNOS was performed using rabbit anti-trout CYP2K1 (D.R. Buhler) and rabbit anti-mouse iNOS (Transduction Labs). Macrophages from the anterior kidneys of individual fish (n=4 individuals/treatment) were tested for ROS production as measured by luminol-augmented chemiluminescence, using zymosan as an immunostimulant. Preliminary results indicate that 2,4-D increased hepatic CYP2K1 by day 7, but decreased levels to near control by day 21, whereas iNOS expression was increased at day 1, suppressed at day 7, and near control levels at other time points. Immunostimulated ROS production is slightly increased at day 14, while baseline (non-stimulated) ROS production is suppressed at day 21. These results suggest that 2,4-D is capable of modulating macrophage function, however the response varies over time, and differs by macrophage tissue source.

840 INHIBITION OF THE LYSOSOMAL PROTEASE CATHEPSIN L BY TRIVALENT ARSENIC.

M T Harrison and K L McCoy. *Department of Microbiology and Immunology, Virginia Commonwealth University, Richmond, VA, USA.* Sponsor: K L White.

Gallium arsenide (GaAs), a semiconductor with useful electronics applications, is classified as an immunotoxicant. Previous work by our laboratory has shown that intraperitoneal injection of GaAs into mice suppresses antigen processing by splenic macrophages. Additionally, GaAs exposure diminishes cathepsin L (cathL) activity in splenic macrophages. CathL is a widely expressed lysosomal cysteine protease that plays an important role in antigen processing through the major histocompatibility class II pathway. Previous studies have demonstrated that GaAs dissociates *in vivo* into its respective components and the arsenic component is primarily responsible for immunosuppression. To identify the mechanism by which GaAs inhibits cathL, we characterized arsenic inhibition of cathL *in vitro*. We utilized the trivalent form, arsenite, because it is a well-characterized inhibitor of enzymes containing active site sulfhydryl groups, such as cathL. Lysates from the murine B cell line, TA3, as well as cathL purified from human liver were sources of cathL for this study. Enzymatic activity was measured by fluorometric assay using a synthetic peptide substrate and specific inhibitor. Arsenite caused a dose-dependent inhibition of cathL in TA3 lysates and completely ablated cathL activity at higher doses. Arsenite also decreased activity of purified cathL in a dose-dependent manner, although not completely. Reversal experiments, using an equimolar concentration of dithiothreitol, demonstrated that arsenite inhibition is reversible. Dixon and Lineweaver-Burk analyses suggest that arsenite is a mixed inhibitor of TA3-derived cathL; however, arsenite inhibits the purified enzyme differently. These findings offer insight into one mechanism by which GaAs causes immunosuppression. (This work was supported by National Institutes of Health grant ES07199. M.T.H. was supported by training grant T32ES07087.)

841 IMMUNE ALTERATIONS IN SPRAGUE DAWLEY RATS EXPOSED TO GENISTEIN FOR 77 DAYS.

J A McCay[1], R D Brown[1], D L Musgrove[1], S S Griffey[1], D R Germolec[2] and K L White, Jr.[1]. *[1]Virginia Commonwealth University, Richmond, VA; [2]NIEHS, Research Triangle Park, NC, USA.*

Genistein, an endocrine disruptor, is found occurring naturally as a phytoestrogen in several plants including the soya plant which is used increasingly in food products. These studies were conducted in Sprague Dawley rats utilizing the F0 females and F1 generation males and females to assess the potential of immunogical alterations. Rats were exposed to genistein both *in utero* and in feed for up to 77 days. NIH-31C diet was the control with genistein doses of 25, 250 and 1250 PPM. The exposures took place at the National Center for Toxicology Research. On the day of sacrifice the spleen and bone marrow samples were shipped to Richmond for assay assessment the following day. A significant decrease in body weight was observed at 1250 PPM (9 to 12%). A decrease in relative spleen weight was seen in the F1 male and female rats. In the bone marrow evaluation, data from the F1 males showed a significant decrease in colony forming units (CFU) for granulocytes-monocyte (GM) cells and CFU-M cells up to 32% as compared to the control. In the immune parameters, no alteration was observed in the T-dependent antibody forming cells response to sheep red blood cells with exception of the F1 female rats with a significant increase at 1250 PPM. A significant dose-dependent increase (75%) was observed with the F0 female rats at all effector-to- target ratios in the natural killer cell response at 250 and 1250 PPM. Using the anti-CD3 antibody to assess T cell receptor-mediated proliferation, splenocytes from both F1 male and females demonstrated significant dose-dependent increased proliferation up to 41% and 59% respectively. No effect was seen with the absolute number of splenic surface markers in the F0 rats, however, a significant increase in splenic surface markers was seen with T cell and T cell subsets for both the F1 male and female rats. In the F1 generation rats exposed to genistein for 77 days, alterations were observed in both T cell number and T cell function. (These studies were conducted under NIEHS Contract ES 55387.)

842 GENDER-BASED DIFFERENTIAL HUMORAL RESPONSES TO A FOREIGN VERSUS SELF ANTIGEN AFTER IN OVO EXPOSURE TO LEAD.

T L Bunn, J A Marsh, K A Golemboski and R R Dietert. *Department of Microbiology and Immunology, Cornell University, Ithaca, NY, USA.*

To examine the potential role of gender in the nature of immunotoxic responses to lead, five-day old avian embryos were injected once with lead acetate (5 or 10 ug) or sodium acetate as control. At four weeks post-hatch, animals were immunized with a foreign antigen (BSA) and serum collected two weeks after. At six weeks and eight weeks of age, a self-antigen, thyroglobulin (Tg) injected as thyroid extract was used as a sensitizing antigen. At 10 weeks of age, various immune parameters were examined. In females, absolute thyroid weights and anti-thyroglobulin antibody levels were significantly decreased following lead treatment. In comparison, males showed no differences in response to thyroglobulin between treatment groups but immunomodulatory effects were observed after exposure to a foreign antigen, BSA. Males differed in anti-BSA antibody levels and total leukocyte counts between treatment groups, whereas females did not. A significant difference in ex vivo interferon-gamma production was also observed in males. No differences were observed in males or females in the delayed-type hypersensitivity response or in spleen, thymus or bursa weights. These results suggest that there is a persistent differential immunotoxic effect after in ovo exposure to lead based on gender. While both genders exhibited certain changes in antibody production following lead exposure, females were more sensitive to dose-response permutations in response to thyroglobulin, a self-antigen, whereas male humoral response changes were detected only with BSA, a foreign antigen. (Supported by NIEHS grant #ES05950.)

843 ENDOGENOUS METALLOTHIONEIN ALTERS IMMUNE RESPONSES TO EXTERNAL STIMULATION.

K C Crowthers and M A Lynes. *Department of Molecular and Cell Biology, University of Connecticut, Storrs, CT.*

Metallothionein (MT) has been characterized as a stress-induced protein capable of modulating a cell's exposure to heavy metals and reactive intermediates. Toxicants, such as metals cations, organic compounds and acute phase proteins, can induce the expression of MT; therefore, it has been proposed that one of MT's function is to reduce the toxic effects of these compounds. However, MT also plays an important role in normal cellular functions. MT can act as a reservoir for essental trace metals, regulate the activity of Zn-dependent transcription factors, and maintain a reduced cytoplasmic environment. These various roles are clearly essential to normal cellular homeostasis. One of the critical systems effected by toxicant exposure is the immune system. The central premise of this work is that MT can function as an intermediate in toxicant-induced immunomodulation. Previous work has shown that exogenous MT can influence a developing immune response, reducing the levels of humoral antibodies produced after immunization. The negative regulatory functions of endogenous pools of MT during a humoral immune response is demonstrated in the experiments described here. MT-1 mRNA expression decreases in immune tissues during a normal immune response, as shown by RT-PCR. These observations suggest that MT expression during a normal immune response is tightly regulated, decreasing during the height of an immune response. The absence of MT-1 and MT-2 in 129/Sv-*Mt1tm1BriMt2tm1Bri* (MT-null) mice correlates with a two-fold increase in antibody titer to a T-dependent antigen challenge when compared to wild-type control animals (129/SvJ). Assays of lymphocyte function show that MT-null mice are hyper-responsive to external mitogen and antigen stimulation, as demonstrated in proliferation and ELISPOT assays. Naive MT-null mice have increased total numbers of plasma cells and splenic weights, although markers of autoimmune disease are not upregulated. Our experiments suggest that MT can be a potent modifier of humoral immune responses, and that manipulation of MT levels may serve as a novel therapeutic treatment to autoimmune disease or inflammation.

844 TOPICAL PERMETHRIN EXPOSURE ALTERS SKIN IMMUNE RESPONSES AND PRODUCES SYSTEMIC IMMUNE EFFECTS.

K Punareewattana[1], S D Holladay[1], B J Smith[1], and B L Blaylock[2]. [1]*Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA, USA;* [2]*College of Pharmancy, Northeast Louisiana University, Monroe, LA, USA.*

Inhibited immune responses have been observed following occupational, inadvertent, or therapeutic exposure to chemically-diverse xenobiotics. In the present studies, preliminary data were generated showing limited but significant systemic and regional immunotoxicity following low-level topical exposure to the pyrethroid insecticide, permethrin (formerly not considered an immunotoxicant). Permethrin was applied to the shaved dorsal interscapular region of C57Bl/6N mice at doses of 0.5, 1.5, or 5.0 μl/day. The highest of these doses is approximately equal to 215 μg/kg/day, which is about seven times the estimated daily human exposure in individuals wearing permethrin treated clothing for insect protection. Mice were exposed to permethrin daily for 10 or 30 consecutive days, or every other day for 7 or 14 exposures. Body weight was not affected by the treatment. However, thymic weight was decreased and splenic weight increased 2 days after termination of the topical exposure. Splenic macrophages showed significantly depressed chemilumeniscent responses up to 10 days following termination of exposure. The contact hypersensitivity response, measured by quantitating the ear swelling response to chemical exposure, was also significantly depressed. Taken together, these data indicate that low-level topical permethrin exposure may produce both local and systemic immunotoxicity.

845 EFFECTS OF THE NON-STEROIDAL ANTI-INFLAMMATORY DRUGS NAPROXEN AND INDOMETHACIN ON CANINE LEUKOCYTE CHEMOTAXIS *IN VITRO*.

S W Curtiss, E M Blomquist, and D L Morris. *Monsanto Safety Evaluation, G.D.Searle/ Monsanto Co., St. Louis, MO.*

Experiments were conducted to determine whether dog leukocyte chemotaxis *in vitro* is affected by treatment with the non-steroidal anti-inflammatory drugs (NSAIDs) naproxen and indomethacin. Peripheral blood leukocytes from male beagle dogs were isolated using a Ficoll gradient procedure. Isolated leukocytes were pre-incubated for 40 minutes with 0, 1, or 10 μ M naproxen or indomethacin. Chemotaxis of 100,000 cells was assessed in 96-well chemotaxis chambers in the presence or absence of 0.5% zymosan-activated dog serum. Treatment of leukocytes with 1 or 10 μ M naproxen or indomethacin resulted in similar, concentration-dependent increases in chemokinetic activity in the absence of chemoattractant. In the presence of chemoattractant, naproxen and indomethacin treatment resulted in concentration-dependent decreases in the mean number of cells migrating through the filter. Similar results were obtained in replicate experiments done with peripheral blood from seven different dogs. These results show that *in vitro* NSAID treatment at therapeutically relevant concentrations can inhibit canine leukocyte chemotaxis.

846 MODULATION OF THE IMMUNE RESPONSE BY THE DRINKING WATER DISINFECTION BY-PRODUCT DIBROMOACETIC ACID.

K L White, Jr.[1], J A McCay[1], D L Musgrove[1], R D Brown[1], and D R Germolec[2]. [1]*Virginia Commonwealth University, Richmond, VA;* [2]*NIEHS, Research Triangle Park, NC, USA.*

Dibromoacetic acid (DBA) is a disinfection by-product contaminant found in drinking water. DBA is formed as a result of the bromination process used to purify water to acceptable drinking water standards. The purpose of this study was to determine the potential effects of DBA on the immune system when administered in the drinking water. Female B6C3F1 mice were exposed daily, *ad libitum*, to DBA in the drinking water at dose levels of 125, 250, 500, 1000, and 2000 mg/l for 28 days. While body weight was not affected, a decrease (40%) in body weight gain was observed in the high dose (2000 mg/l) animals. While the high dose produced a decrease in absolute thymus weight (36%), increases were observed in spleen (25%), liver (46%) and kidney (17%) weights. All dose levels produced significant increases in absolute liver weight and the four highest dose levels produced elevated kidney weights. Hematological parameters were not affected with the exception of reticulocytes which were elevated (30%) at the three highest dose levels. Increases in splenic B cell and T cells appeared to be related to an increase in spleen cell number following exposure to DBA. A dose related increase in splenic macrophages ($Mac1^+$ cells) was observed. DBA produced a dose dependent decrease (50%) in the antibody forming cell response to sRBC conversely an increase in natural killer cell activity was observed. No effect was observed on the mixed leukocyte response (MLR). These studies demonstrate that the immune system can be a target for disinfection by-products and that both immune suppression and enhancement can result following exposure to dibromoacetic acid in the drinking water. (Supported by NIEHS Contract ES 55387.)

847 EFFECT OF *N, N*-DIETHYLANILINE ON SISTER CHROMATID EXCHANGE OF LYMPHOCYTE, NATURAL KILLER ACTIVITY, CYTOTOXIC T LYMPHOCYTE ACTIVITY AND MITOGENS-STIMULATED LYMPHOCYTE PROLIFERATION.

Q Li, Y Hirata, S Piao and M Minami. *Nippon Medical School, Tokyo, Japan.* Sponsor: T Yoshida.

N,N-Diethylaniline (DEA) is a reagent used in organic synthesis and is an important intermediate in the manufacturing of dyes. We found that DEA induced high frequency sister chromatid exchange (SCE) of lymphocytes *in vitro* that was about 5 times greater than the control, and was as great as positive controls of SCE such as cyclophosphamide. To determine whether or not DEA affects other functions of lymphocytes, we evaluated the immunotoxicity of DEA using CBA/N mice. Mice were divided into 4 groups and received 0, 100, 200, or 400mg/kg body weight of DEA by a single subcutaneous injection. The following items were investigated on days 3 and 7 after the injection: weight of spleen, number of splenocytes, natural killer (NK) activity, cytotoxic T lymphocyte (CTL) activity, and concanavalin-A (Con-A) and lipopolysaccharide (LPS)-stimulated lymphocyte proliferation using splenocytes. NK and CTL activity in exposed groups significantly decreased compared to controls in a dose-dependent manner. Spontaneous proliferation of lymphocytes, the relative weight of the spleen and number of splenocytes in exposed groups were significantly higher than in the control. On the other hand, DEA did not affect the Con-A or LPS-stimulated lymphocyte proliferation. The results from day 3 were similar to those from day 7. These findings indicate that DEA induces SCE and selectively affects NK and CTL activity, but not mitogens-stimulated lymphocyte proliferation. This study was supported by a grant from the Ministry of Education, Science and Culture of Japan.

848 ALTERATION OF T-2 TOXIN INDUCED IMMUNOTOXICITY BY A SELENIUM ENRICHED DIET IN BALB/C MICE.

S Zhao, P Singh, and B L Blaylock. *Division of Toxicology, College of Pharmacy and Health Sciences, Northeast Louisiana University, Monroe, LA, USA.*

The objective of this project is to determine whether a selenium (Se) enriched diet will reduce immunotoxicity induced by T-2 toxin. Preliminary results from our laboratory, using mice orally exposed to T-2 toxin for five days at 1.5 mg/kg, revealed that: (1) Se supplementation has significant protection on reduction of spleen weight, thymus cellularity and weight, contact hypersensitivity response, and cytotoxic T-lymphocyte activity. (2) Se supplementation did not alter suppression of humoral immunity. The present work investigates Se protection on immunotoxicity induced by T-2 toxin *via* topical exposure, a main route for occupational exposure. Female BALB/c mice were fed a defined diet containing either 0.75, 1.5 or 2.5 ppm Se for 4 weeks. After topical exposure to T-2 toxin at 1.0 mg/kg for four days, several immunotoxic endpoints were determined. In mice topically treated with T-2 toxin, total thymus cellularity reduced to 25% of the control, and thymus weight was reduced to 58% of the control. However, dietary Se supplementation did not alter these suppressive effects induced by T-2 toxin. As compared to control group, no significant changes were observed in spleen weight and cellularity, cytotoxic T-lymphocyte activity in T-2 treated control. On the other hand, IgM plaque forming responses were significantly decreased in T-2 treated control and 0.75 ppm Se groups. This suppressive effect was not observed in T-2 treated and Se-supplemented (1.5 and 2.5 ppm) groups. Expression of major histocompatiblity class II (MHC II), a surface marker on epidermal Langerhans cell, was also investigated. Oral exposure to T-2 toxin at 1.5 mg/kg did not alter MHC II expression. However *in vitro* T-2 toxin treatment at a concentration of 10-7M significantly inhibited MHC II expression, this inhibition was not protected by Se supplementation. These results suggested that protective effects of Se against to T-2 toxin depend on the route of exposure to T-2 toxin.

849 QUANTITATIVE MODELING OF STRESS-INDUCED IMMUNOSUPPRESSION.

S B Pruett, R Fan, S D Collier, and W-J Wu. *Dept. of Cellular Biology & Anatomy, Louisiana State University Medical Center, Shreveport, LA, USA.*

A number of chemicals induce neuroendocrine stress responses, some of which can be immunosuppressive. Although the impact of stress-related immunosuppression in humans and animal models has been well documented, it is not yet possible to estimate the degree of immunosuppression by simple measurements of the concentrations of neuroendocrine mediators. The present study was conducted to obtain such data and to ascertain the relative importance of glucocorticoids as opposed to other stress-induced mediators in suppression of selected immune parameters. The area under the corticosterone concentration vs. time curve (AUC) was measured following subcutaneous administration of various dosages of corticosterone and during the course of restraint stress (1-8 hr) in female B6C3F1 mice. The percentage of bound vs. free corticosterone was not substantially affected by exogenous corticosterone or restraint, indicating that measurement of total corticosterone is appropriate. Twelve hours after the initiation of stress (or corticosterone administration) spleens were obtained. Natural killer (NK) cell activity was measured using a standard 4-hr 51Cr release assay, and expression of major histocompatibility class (MHC) II proteins on splenocytes was evaluated by flow cytometry. Th1 and Th2-dependent antibody responses (IgG2a and IgG1, respectively) to keyhole limpet hemocyanin as well as host resistance to B16F10 cells were also evaluated. The results demonstrate that corticosterone AUC correlates well with the suppression of each of these immunological parameters, but there were marked variations in sensitivity to corticosterone (MHC II > B16F10 > NK > antibody response). The linear regression models for MHC II expression were not significantly different for exogenous corticosterone and restraint. This was also true for NK cell activity. The results indicate that corticosterone AUC can be used to predict at least the minimal immunosuppression expected following exposure to an acute stressor. Because glucocorticoid measurements can easily be done for human subjects, these models could provide valuable information for cross-species extrapolation. (This work was supported by NIEHS grant ES09158.)

850 FLOW CYTOMETRY IMMUNOPHENOTYPING FOR THE MEASUREMENT OF LEUKOCYTE SUB-POPULATIONS IN THE RAT.

H Diep and Y Deschamps. *ClinTrials BioResearch Ltd., Clinical Laboratories, Montreal, Canada.*

Immunophenotyping by flow cytometry is the method proposed by the Center for Drug Evaluation and Research (Rockville, MD) to evaluate potential immunosuppression by drugs (SOT '98, Seattle, WA). In toxicology, the rat is a standard rodent species for use in preclinical studies. The objective of this study was to validate a flow cytometry immunophenotyping method to quantitate five leukocyte sub-populations in the Fisher rat. EDTA blood samples were collected from non-treated animals and were analyzed with anti-rat antibodies to determine the percentage of five leukocyte sub-populations using a flow cytometry method according to ClinTrials BioResearch's Standard Operating Procedures. The following parameters were assessed: intra- and inter-assay precision, physiological range and 24-hour stability at 2 - 8°C of samples fixed with Formalin (0.5% v/v). Intra- and inter-assay precision were considered acceptable at 1.06% and 1.28% for thymocytes and T lymphocytes (CD5-positive cells), 5.92% and 4.47% for B lymphocytes (CD45RA-positive cells), 1.46% and 1.78% for T helper lymphocytes (CD4-positive cells), 2.74% and 2.91% for T suppressor/cytotoxic lymphocytes (CD8-positive cells) and 15.96% and 19.4% for monocytes/macrophages (ED1-positive cells). Physiological distribution was determined with 5 males and 5 females for each of the five respective markers. Samples fixed with Formalin 0.5% v/v kept for 24 hours at 2 - 8°C were shown to be stable for all markers, except for thymocytes and T lymphocytes in the females. A higher percent difference for monocytes/macrophages was obtained due to the small absolute values for this cell type. The experimental procedures used during the course of this validation were considered appropriate since acceptable precision was obtained and physiological range of the five sub-populations was as expected.

851 IMMUNOTOXICOLOGY GUIDELINE STUDIES: SOME PRACTICAL CONSIDERATIONS.

M P Holsapple, P K Anderson, C M Wiescinski and M R Shankar. *HERL, Dow Chemical Co., Midland, MI.*

The new EPA immunotox guidelines emphasize the antibody (Ab) response to SRBC, which can be measured as either a plaque assay or an ELISA. While the ELISA may afford greater technical flexibility, the database which was used to support the selection of the Ab response is based on the plaque assay, and there is much more limited experience with the ELISA. One of our goals was to determine if the technical flexibility of the plaque assay

could be increased. We observed good agreement when various parts of the spleen were recorded as percent of wet weight when compared to the same parts recorded as percent of total cell number. We also observed good agreement between the Ab response of the whole spleen when compared to the response by various parts of the spleen. These results indicate that it should be feasible to use half of the spleen for the Ab response (i.e., plaque assay) and the other half of the spleen for other purposes (i.e., histopathology or phenotypic analysis). The EPA guidelines also indicate that an NK assay may be required when the Ab response is negative. A second goal was to determine the feasibility of measuring these endpoints in the same animals (female B6C3F1 mice). Dexamethasome (DEX) was administered (daily for 14 days) as a known immunosuppressant. NK cytotoxicity was reduced due to immunization in both control and immunosuppressed mice - the reduction due to DEX was comparable to that associated with SRBC, and the two were additive. These results indicate that a one-mouse model is not suitable for guideline studies in immunotoxicology.

852 INTEGRATION OF PUPS AND WEANLINGS INTO STUDIES TO ADDRESS THE POTENTIAL FOR DEVELOPMENTAL IMMUNOTOXICOLOGY.

P K Anderson, C M Wiescinski and M P Holsapple. *HERL, Dow Chemical Co., Midland, MI.*

There is increased interest in determining whether the developing immune system demonstrates a unique sensitivity to chemical perturbation. The overall goal of these studies is to integrate both pups (i.e., 10 days old) and weanlings (i.e., 21 days old) into immunotox studies. The antibody (Ab) response to SRBC is the focus of current guideline studies in young adults, and will be the primary endpoint in these studies. Our initial results have indicated that the conditions to elicit an Ab response in weanlings were comparable to the optimal conditions used in young adults. To further address the feasibility of using weanlings, we determined the effects of maternal food restriction (FR) during *in utero* and neonatal life. Groups of time-mated Sprague-Dawley rats were fed standard diets at 100%, 90%, 70% or 50% of the historical feed consumption quantities, which resulted in treatment-related body weight gain decreases in the dams and their pups. Necropsies conducted on pups 24 hours after they were weaned showed that relative thymus and spleen weights were significantly decreased. Parallel studies indicated that the Ab response was not significantly affected. Therefore, changes in organ weights caused by FR were not associated with marked functional impairment. Our results to-date with 10-day old pups have been disappointing. We have had no success with i.v. injections in pups until about 16 days of age. Immunization by the i.p. route in pups has not elicited an acceptable Ab response (i.e., either "plaque" or ELISA). Taken together, these results indicate that weanlings; but not pups can be integrated into developmental immunotox studies, which include a functional parameter.

853 EVALUATION OF CYCLOPHOSPHAMIDE IMMUNOTOXICITY IN RATS: THE USE OF FUNCTIONAL ASSAYS AND FLOW CYTOMETRY.

D F Lanham, S M McHugh, S R Wilkins and P F Uphill. *Huntingdon Life Sciences Limited, Huntingdon, Cambs, England.* Sponsor: R J Harling.

In order to comply with recent EPA and OPPTS guidelines we have evaluated three specific tests to assess immunomodulation in rats, with the aim of incorporating them into standard sub-chronic toxicity studies. These tests were: the plaque forming cell (PFC) assay for the detection and enumeration of antigen specific B cells, induced by sheep red blood cells (SRBC) a T cell dependent antigen. A ^{51}Cr release natural killer (NK) assay, to assess changes in innate immunity, and thirdly flow cytometric analysis of T, B and NK cell populations in both blood and spleen. Using Cyclophosphamide (CY) a known immunosuppressive agent we treated five groups of female CD rats (10/group) i.p.; three groups received CY for a total of 8 days at 1, 3 or 10 mg/kg/day, one group received a single dose of 50 mg/kg 2 days before sacrifice and one group received saline. In addition half the animals in each group were challenged i.v. with SRBC four days before sacrifice, to allow measurement of the primary humoral response in the PFC assay. We demonstrated 1) dose-dependent reductions in the lymphocyte populations of both spleen and blood, 2) a dose dependent reduction in the PFC response from over 28,000 plaques/spleen in untreated animals to less than 50 in the 10 mg/kg/day group, also reflected by an almost complete loss of the CD45R+ (B cell) population in spleen and blood, 3) an enhancement of NK activity, associated with a relative enrichment in NKR+ cells amongst the declining lymphocyte populations, this was most notable in the spleen, also 4) a reduction in the CD4:CD8 T cell ratios of both spleen and blood, indicating the preferential depletion of CD4+ cells from the T cell population and survival of CD8+ cells. These observations show that it is viable to use the above parameters for assessment of immunomodulation in rats, but emphasise the importance of combining flow cytometry, functional assays and pathology data when attempting to assess immunotoxicity.

854 COMBINED EFFECTS OF CHEMICAL AND NATURAL STRESSORS ON NONSPECIFIC IMMUNITY IN RED VERSUS BLACK ABALONE.

L M Martello[1] and R S Tjeerdema[2]. [1]*Department of Biology,* [2]*Department of Chemistry and Biochemistry, University of California, Santa Cruz, Santa Cruz, CA, USA.*

The chemotactic and phagocytic efficiency as well as gross morphological characteristics of hemocytes withdrawn from red (Haliotis rufescens) and black abalone (H. cracherodii) after in vivo exposure to 25, 35, or 45 0/00 seawater salinity plus 1.2 mg/l pentachlorophenol (PCP) was determined. Red and black abalone exposure durations of 3.5 and 6.5 h, respectively, were based on species specific metabolic endpoints (MEPs) derived from previous NMR data. Extracted hemocytes were incubated with FITC conjugated Saccharomyces cerevisiae and the percent phagocytosis (%P: number of cells that had phagocytosed yeast) and phagocytic index (PI: number of yeast within each phagocytic cell) were quantified using epifluorescence microscopy. Chemotactic activity was quantified in Boyden chambers using a live marine bacterium as the chemotactic stimulus. Hemocyte chemotaxis was found to be augmented by low salinity in red but not black abalone while high salinity seemed to reduce chemotactic ability in both species. PCP did not potentiate the effects demonstrated by salinity variations alone in red abalone although chemotaxis was further compromised in black abalone exposed to both high salinity stress combined with PCP. Although chemotactic ability was similar among both species both %P and PI were greater among black abalone. Generally, low salinity seems to offset the effects of PCP in red but not black abalone. Whereas red abalone demonstrate a reduction in phagocytic ability upon exposure to high salinity alone, black abalone appear more resilient to high salinity stress alone. Furthermore, whereas the effect of high salinity plus PCP is subadditive among red abalone, high salinity seems to potentiate the effect of PCP on black abalone. Finally hemocytes exposed to acute salinity variations plus PCP show varying morphological characteristics when compared to controls. When allowed to settle on glass, over 30% of the hemocytes of exposed abalone remain rounded and generally unattached with only a few pseudopod extensions. Furthermore, they do not clump. Hemocyte preparations incubated in rhodamine-conjugated phalloidin were observed with fluorescence microscopy and reveal an altered actin filament pattern. While PCP is a potent inhibitor of ATP synthesis, use of varying water salinities simulated an additional stress imposed on intertidal animals by transient or seasonal environmental changes.

855 EFFECTS OF SUB-ACUTE *IN VIVO* EXPOSURE OF FORMALDEHYDE (HCHO) ON FISH.

R M Gogal Jr., B J Smith, J L Robertson, K A Douglas, S A Smith, and S D Holladay. *Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA, USA.*

Formaldehyde (HCHO), an inhalational toxicant, dermal contact irritant, mutagen and carcinogen has been shown to exert its effect in both laboratory animals and humans based on concentration, exposure route and duration of exposure. A 1998 report from the U.S. EPA indicates that HCHO was detected at levels greater than the cancer benchmark concentration in approximately 90% of the 60,000 census tracts measured in the United States. Since HCHO mixes with water extremely well and is a common aquatic contaminant, it is reasonable to believe that aquatic life is also exposed. Further, HCHO is used therapeutically in aquaculture facilities to remove bacterial pathogens from gills of fish. A study was undertaken to evaluate the effects of sub-acute exposure to HCHO on a variety of immune endpoints in tilapia (*Oreochromis niloticus).* The fish were exposed to 0, 50,100, 150 and 250 ppm of HCHO. Immune parameters examined included blood hematology, spleen and pronephros body weight ratios, spleen and pronephros total cellularity, leukocyte blastogenesis, mixed lymphocyte reaction and natural killer cell activity. Organ/body weight ratios and total cellularity were not significantly different from controls. Similarly, mitogen response and mixed lymphocyte reactions were not significantly altered. However, natural killer cell activity was enhanced. These findings agree with a previous study in mice in which no significant immunosuppression

was observed with similar endpoints, suggesting fish may respond immunologically in a manner similar to mammals following exposure to HCHO. (Supported by NIH ES 07612-01 SRC.)

856 CHEMICAL EXPOSED TILAPIA SHOW SIMILAR IMMUNE EFFECTS AS RODENTS.

S D Holladay, D A Smith, S A Smith, and G G Schurig. *Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA, USA.*

The ability to produce specific antibody following challenge with antigen has been found to be a powerful predictor of immunosuppression in chemical-exposed rodents. Similarly, ability of cytotoxic immune cells to target and lyse foreign cells has been widely used as a predictor of immunosuppression in rodents. The efficacy of these assays for predicting immunosuppression in non-rodent species remains unknown, however. In the present report, tilapia (*Oreochromis niloticus*) were exposed to 9 chemical agents known to inhibit humoral and/or cytolytic immune responses in mice (benzo[a]pyrene (B[a]P), 7,12-dimethylbenzanthracene (DMBA), 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD), dimethylnitrosamine (DMN), cadmium chloride ($CdCl_2$), azathioprine (AZA), hexachlorocyclohexane (lindane, HCH-g), T2 mycotoxin (T2 toxin), and toluene) and 5 chemical agents not classified as rodent immunotoxicants (oxymethalone, acetonitrile, diethylstilbesterol (DES), *t*-butylhydroquinone (TBHQ), and formaldehyde). Eight of nine humoral immunotoxicants caused decreased antibody production in fish. All five of the compounds with negative humoral effects in rodents were also negative in fish. In like manner, eight of nine agents which inhibit rodent cytolytic responses also caused decreased cytolytic activity in fish. Thus, in each case (i.e., when a humoral and when a cytolytic endpoint was evaluated) 13 of the 14 chemical agents tested gave similar results in tilapia as reported in rodents, indicating a comparable pattern of immunosuppression in chemical-exposed tilapia. (Supported by NIH ES 07612-01 SRC).

857 ROLE OF METABOLISM IN THIOACETAMIDE-INDUCED SUPPRESSION OF ANTIBODY RESPONSE IN MALE BALB/c MICE.

T C Jeong, H K Gu, H C Kim and J K Roh. *Toxicology Research Center, Korea Research Institute of Chemical Technology, Taejon, Korea.*

Effects of thioacetamide, a potent hepatotoxicant, on T-dependent antibody response to sheep red blood cells(SRBCs) were investigated in male BALB/c mice. When mice were treated intraperitoneally with thioacetamide once 30 min prior to the immunization with SRBCs, the number of antibody-forming cells (AFCs) enumerated 4 days after was significantly reduced at the dose of 200 mg/kg in accompanying with the elevation of SGPT and SGOT activities. When mice were treated with 10, 20, or 50 mg/kg of thioacetamide for 7 consecutive days, the number of AFCs was reduced at the dose of 50 mg/kg. To determine the possible role of metabolic activation by cytochrome P450 (P450) in thioacetamide-induced suppression of the antibody response, mice were pre-treated with 80 mg/kg of phenobarbital intraperitoneally for 3 days, followed by the intraperitoneal administration of 100 mg/kg of thioacetamide for 3 days. Four days after the immunization with SRBCs, the AFCs were enumerated. The spleen and thymus weights were significantly reduced when mice were pre-treated with phenobarbital prior to thioacetamide administration. The elevated SGOT and SGPT activities by thioacetamide were significantly potentiated by the pre-treatment with phenobarbital. In liver microsomes, the activities of P450 2B-specific enzymes induced by phenobarbital recovered to normal level a week after the pre-treatment. Meanwhile, the suppression of antibody response by thioacetamide was significantly potentiated by the pre-treatment with phenobarbial. Our present results indicate that thioacetamide may require metabolic activation by P450 2B to its immunosuppressive form(s). (Supported by a grant from the MOST, Korea.)

858 ETHANOL DECREASES HOST RESISTANCE TO PULMONARY METASTASES IN A MOUSE MODEL: ROLE OF NATURAL KILLER CELLS AND THE ETHANOL-INDUCED STRESS RESPONSE.

W-J Wu and S B Pruett. *Dept. of Cellular Biology & Anatomy, Louisiana State University Medical Center, Shreveport, LA, USA.*

Ethanol (EtOH) consumption activates the hypothalamic-pituitary-adrenal (HPA) axis. EtOH consumption, even at moderate levels, is also associated with an increased incidence of cancer at several anatomical locations in humans, and these cancers are often associated with subnormal natural killer (NK) cell function. Mediators induced by activation of the HPA axis such as glucocorticoids and catecholamines can suppress the activity of NK cells, which are important in resistance to some cancers. The work described here was done to evaluate cause-effect relationships between the EtOH-induced stress response, NK cell activity, and resistance to experimental metastases of B16F10 melanoma cells in female B6C3F1 mice. Increased numbers of metastatic nodules in the lungs were noted 2 weeks after challenge in mice treated with dosages of EtOH at 5 or 6 g/kg (dosages that produce peak blood levels of ~0.25-0.4%). Increased numbers of nodules were observed when EtOH (6 g/kg) was administered from 1 h before to 10 h after intravenous administration of tumor cells. Depletion of NK cells using a monoclonal antibody substantially increased the number of B16F10 nodules in the lungs, confirming a key role for NK cells. Treatment of NK cell-depleted mice with EtOH did not further decrease resistance to B16F10 cells, indicating that suppression of NK cell activity is the major mechanism by which EtOH suppresses resistance to B16F10 metastases. Adrenalectomy or a glucocorticoid antagonist was used to prevent the production or effects of glucocorticoids and this partially prevented EtOH-induced increases in the number of B16F10 nodules in the lungs. Administration of exogenous corticosterone increased the number of B16F10 nodules to a similar extent as EtOH. These results indicate an important role for the EtOH-induced stress response in decreasing resistance to B16F10 metastases. Along with similar findings in rats in another laboratory, these results suggest that this is a generalized phenomenon, which could occur in humans. (This work was supported by NIH grants AA09505 and ES09158. S.B.P. is supported by a Research Career Development Award from NIAAA.)

859 MORPHOLOGICAL EVALUATION OF PROMOTION AND PROTECTION IN ORGANOPHOSPHORUS ESTER-INDUCED DELAYED NEUROPATHY (OPIDN) IN HENS USING PERIPHERAL NERVE TEASED MYELINATED FIBERS.

C Massicotte, K D Inzana, M Ehrich, and B S Jortner. *Virginia-Maryland Regional College of Veterinary Medicine, Blacksburg, VA, USA.*

The serine/cysteine protease inhibitor phenylmethylsulfonyl fluoride (PMSF) has been used to promote or to protect against neuropathic events of OPIDN in hens (Lotti et al., Toxicol. Appl. Pharmacol. 108:234). This is the first study evaluating peripheral nerve teased myelinated fibers to demonstrate lesion intensity in protection and promotion of OPIDN. Single phenylsaligenin phosphate (PSP) dosages of 0.5 and 2.5 mg/kg were administered to adult hens. PMSF (90 mg/kg) was given 4 hours after 0.5 mg/kg PSP (promoted group) or 12 hours prior to 2.5 mg/kg PSP (protected group). PMSF and negative (vehicle) controls were also used. Scores of clinical signs (weakness, ataxia, 0-8 scale) and teased fiber lesions (axonal/fiber degeneration, 0-4 scale) were determined. At 15 days post-dosing, the following teased fiber lesion scores were observed: PSP 2.5 mg/kg alone 2.3 ± 0.6; promoted group (PSP 0.5 mg/kg) 2.0 ± 0.3 (n=2-4). No lesions were noted in the following groups of hens: 0.5 mg/kg PSP, the protected group, PMSF alone, and negative controls (n=4-8). At the time of sacrifice, there was a significant correlation (r=0.91) between the terminal clinical and the neuropathology scores ($p<0.0001$). This study demonstrates that PMSF-induced protection against OPIDN of 2.5 mg/kg PSP and promotion of 0.5 mg/kg PSP are associated with significant changes in the degree of peripheral nerve lesions ($p<0.0001$). In addition, the nerve teased fiber technique provides a powerful method to quantitate peripheral nerve lesions observed in toxic neuropathies.

860 COMPARATIVE EFFECTIVENESS OF ORGANOPHOSPHORUS (OP) PROTOXICANT ACTIVATING SYSTEMS IN NEUROBLASTOMA CELLS AND BRAIN HOMOGENATES.

M Ehrich, L Correll, and D Barber. Virginia-Maryland Regional College of Veterinary Medicine, Blacksburg, VA.

Oxidation in the presence of bromine and incubation with rat liver microsomes (RLM) can convert the OP protoxicants chlorpyrifos and parathion to inhibitors of human neuroblastoma cell acetylcholinesterase (AChE) [Barber et al., *Toxicological Sciences*, in press]. Products formed and effectiveness of AChE inhibition differed between the activating systems. To determine if this was compound and/or species specific, additional OP protoxicants (TOTP, EPN, leptophos, fenitrothion, malathion) were examined for their capability to inhibit AChE and neuropathy target esterase (NTE) in human neuroblastoma cells and brain homogenates from the hen, which is the animal model for OP neurotoxicity. Only preincubation with RLM activated

TOTP; inhibition of AChE was less in hen brain (31% ± 14) than in neuroblastoma cells (73% ± 1) at 10^{-6} M (mean ± SE, n>3); inhibition of NTE was more in hen brain (89% ± 1) than in the cells (72% ± 4). For EPN and leptophos, bromine activation resulted in greater esterase inhibition than RLM and human cell esterases were more sensitive to inhibition than hen brain esterases. Bromine activation also resulted in greater AChE inhibition than RLM with fentitrothion (>65% compared to <50%) and malathion (>90% compared to <60%) at 10^{-6} M. These results suggest that bromine activation, although effective for many OP protoxicants, is not effective for all, and that differences exist in the esterase inhibition determined in human neuroblastoma cells and hen brain homogenates following OP activation. (Supported by EPA grant R825356.)

861 INTERACTIONS OF ACETYLCHOLINESTERASE (ACHE) WITH ORGANOPHOSPHATES (OPS).

S A Kardos and L Sultatos. *UMDNJ, Newark NJ.*

The interactions of acetylcholinesterase (AChE) with organophosphates such as paraoxon (*O,O,* diethyl-*O-p*-nitrophenyl phosphate)(PO) and methyl paraoxon (*O,O*-dimethyl *O-p*-nitrophenyl phosphate)(MPO) have been characterized previously. However studies from this lab designed to model mouse brain AChE inhibition by PO MPO in vitro suggest that the current view of how these organophosphates interact with AChE must be modified. The computer model developed included the bimolecular rate constant K_i to quantify the inhibitory power of PO and MPO toward AChE, as well as a first order rate constant describing reactivation of phosphorylated AChE. These studies revealed that the $appK_i$ for inhibition of mouse brain AChE by PO and MPO decreased as the organophosphate concentration increased. For example 0.5nM MPO yielded an $appK_i$ of 0.54 $nM^{-1}h^{-1}$, while 5 nM MPO gave an $appK_i$ of 0.10$nM^{-1}h^{-1}$. Furthermore, studies utilizing mouse brain recombinant AChE showed similar findings. For example a PO concentration of 0.25nM yielded an $appK_i$ of 0.023$nM^{-1}h^{-1}$, while 10nM yielded an $appK_i$ of 0.0048$nM^{-1}h^{-1}$. These results together with the current understanding of the structure of AChE, suggest that attenuation of AChE phosphorylation by MPO and PO might occur through their binding to a peripheral anionic site known to exist on AChE.

862 MORPHOLOGIC STUDY OF NON-LETHAL CYTOPATHIC EFFECTS OF PARATHION AND PAROXON IN SH-SY5Y HUMAN NEUROBLASTOMA CELLS.

B S Jortner, D Barber, S K Perkins, J Hinckley and M Ehrich. *Laboratory for Neurotoxicity Studies, Virginia Tech, Blacksburg, VA.*

The organophosphate pesticide parathion and its oxygen analog, paraoxon, produce toxicity associated with inhibition of acetylcholinesterase (AChE) in exposed animals, but other actions could contribute to their toxicities *in vitro*. Retinoic acid-differentiated SH-SY5Y human neuroblastoma cells were treated with 10^{-5} M parathion or paraoxon for 24 hours. Acute cytopathic effects of parathion and paraoxon on these cultures were evaluated in morphologically viable cells using light and electron microscopy. A striking feature in treated cells was the presence of regions of cytoplasmic clearing, primarily related to lysis and granular degeneration of cytosol and cytoskeleton. While similar small lytic areas were occasionally observed in controls, the effect was markedly enhanced in toxicant-treated cells. The lesions suggest that the activity of intracellular proteolytic enzymes may increase after treatment with parathion or paraoxon. Parathion does not exert anticholinesterase effects without being converted to paraoxon and little conversion occurs in SH-SY5Y cultures (Barber et al., Toxicological Sciences, in press). As similar effects were caused by treatment with parathion or paraoxon, the results suggest that anticholinesterase mechanisms were not a primary cytotoxic factor. (Supported by USEPA grant R825356.)

863 CHANGES IN ACTIVATION AND DETOXIFICATION ENZYMES RESPONSIBLE FOR ORGANOPHOSPHATE (OP) METABOLISM DURING PREGNANCY.

D M Grant[1], R C Zangar[2], A L Barnes[2], D L Springer[1], and C Timchalk[1]. [1]*Battelle, Pacific Northwest Division, Richland, WA, USA;* [2]*Associated Western Universities, Richland, WA, USA.*

Fetal susceptibility to the toxic effects of OP insecticides may be determined, in part, by a balance among pathways of maternal and fetal metabolic activation and detoxification. It is hypothesized that OP activation/detoxification by cytochrome P450 (CYP450) and detoxification by carboxyl- (CaE) and A-esterase (A-est) enzymes is modified during pregnancy in response to normal hormonal modulation of these enzymes. Changes in enzyme expression can quantitatively and qualitatively impact OP metabolism and thus the dose of OP and its toxic metabolite, OP-oxon delivered to the fetus. The present study examines the expression and marker substrate activities of these critical enzymes at 4 gestational stages. Plasma and liver subcellular fractions were prepared from age-matched nulliparous control female or pregnant Sprague-Dawley rats at gestation days 8, 13 and 20 (GD8, GD13 & GD20, respectively). Western blots of CYP450 isoforms implicated in activation/ detoxification of OPs, indicated that isoform activities did fluctuate during gestation. Specifically, CYP2B3 was increased (~2.5 – 2.7 fold) from GD8 to GD13, while CYP1A1 steadily increased to a peak (3 fold) at GD20. CYP3A exhibited considerable fluctuation, peaking at GD13 (~1.5 fold), but decreasing markedly to below control activity by GD20. In contrast, CYP2B2 was suppressed (50%) throughout pregnancy, while CYP1A2 and female-specific CYP2C12 were unchanged. Plasma A-est activity was suppressed at GD8 and GD20, whereas hepatic CaE and A-est were unchanged from control levels. In conclusion, these data suggest that alterations in the expression and activity of enzymes involved in OP metabolism could result in changes in maternal activation and detoxification of OPs.

864 ORGANOPHOSPHORUS COMPOUND-INDUCED MODIFICATION OF SH-SY5Y HUMAN NEUROBLASTOMA CELL MITOCHONDRIAL TRANSMEMBRANE POTENTIAL.

K Carlson and M Ehrich. *Virginia-Maryland Regional College of Veterinary Medicine, Blacksburg, VA, USA.*

Decreases in mitochondrial respiration and ATP generation, inhibition of mitochondrial enzymes, and structural changes such as swelling occur following organophosphorus (OP) compound exposure and implicate mitochondria as primary subcellular targets for *in vitro* cytotoxicity. The health and function of cellular mitochondria following OP compound exposure was further assessed by evaluating the mitochondrial transmembrane potential ($\Delta\Psi$), a loss of which can be induced through the opening of a permeability transition pore (PTP). To assess $\Delta\Psi$, SH-SY5Y cells were incubated with rhodamine 123 (5μ g/ml), a mitochondrial-specific cationic fluorochrome, and OP test compounds (tri-ortho-tolyl phosphate - TOTP, phenyl saligenin phosphate - PSP, parathion, and paraoxon) for 7.5 to 960 minutes. Following incubation, the plates were read on a Cytofluor II multiwell fluorescence spectrometer (ex530nm em590nm). Cytotoxic doses of OP compounds (10^{-5} to 10^{-3}M) induced significant dose-dependent mitochondrial hyperpolarization with monomodal or bimodal peaks at 60 and 120 minutes. Following this, the mitochondrial membranes gradually depolarized. Thirty hour pretreatment with the PTP inhibitor cyclosporin A (5μ M) and the phospholipase A_2 inhibitor aristolochic acid (500nM) decreased the hyperpolarization induced by 10^{-3}M paraoxon (20%), parathion (50%), TOTP (70%), and PSP (120%), indicating potential modulation through a PTP. In contrast, 30 hour pretreatment with the muscarinic agonist carbachol (1mM) increased the amount of mitochondrial hyperpolarization induced by TOTP by approximately 90% (10^{-4}M) and 73% (10^{-3} M) and also delayed subsequent depolarization. This indicated that second messenger systems were also involved in the generation of mitochondrial hyperpolarization. Hyperpolarization of the mitochondrial membrane 1 to 24 hours prior to depolarization, a loss of substrate adhesion, and an increase in DNA fragmentation indicated that mitochondria were a primary target in OP compound-intiated cytotoxicity. (Supported in part by a Novartis predoctoral fellowship from the Society of Toxicology.)

865 EVIDENCE OF AZINPHOS-METHYL HEMOGLOBIN ADDUCT.

B B Eiser and J J Jenkins. *Oregon State University, Corvallis, OR, USA.*

Azinphos-methyl (AZM) is an organophosphate insecticide commonly used by U.S. growers on a variety of crops. Agricultural laborers who apply AZM or work in AZM treated fields are exposed to AZM. Acute, high-level AZM exposure causes cholinesterase inhibition leading to short-term neurological dysfunction. The effects of chronic, low-level AZM exposure, typical of most worker scenarios, are unknown. Methods for monitoring occupational AZM exposure have limitations. Urinary metabolites can only be detected within 48 hours of exposure. Cholinesterase monitoring requires pre-exposure testing because of high individual variation in cholinesterase activity. Our work has focused on using hemoglobin adducts as a biomarker of internal dose for AZM. Hemoglobin adducts are useful biomarkers of exposure to xenobiotics because of sampling ease (a 5-10 mL blood sample contains about 1 g of hemoglobin) and the long biological lifespan of hemoglobin (120 days in humans), which allows for retrospective exposure monitoring.

We hypothesize that an AZM metabolite forms an adduct to hemoglobin present in red blood cells. Previously, we reported a dose dependent association of radioactivity with hemoglobin collected from [^{14}C]AZM treated rats. Recent experiments provide more evidence to support our hypothesis. We exhaustively washed hemoglobin from [^{14}C]AZM treated rats with organic solvents. After washing, 30% of the radioactivity remained. HPLC analysis of washed hemoglobin resulted in a single radioactive peak with an elution time consistent with the hemoglobin alpha chain. Washed hemoglobin was hydrolyzed under mild acid conditions. We found ~50% of the radioactivity in the organic phase extract of the hydrolysate. These results indicate that the radioactive moiety is covalently bound to hemoglobin, supporting our hypothesis of an AZM hemoglobin adduct.

866 THE USE OF OPH ENZYME FOR THE DETOXIFICATION OF METHYL PARATHION.

T Cho[1], J R Wild[2], E Tiffany-Castiglioni[1], and K C Donnelly[1]. [1]*Depts of VAPH and* [2]*Biochemistry and Biophysics, Texas A&M University, College Station, TX, USA.*

Methyl parathion (MP) is a pesticide widely distributed in the environment and chemically similar to nerve agents used in biological warfare. Bioremediation of this class of compounds is a critical environmental concern. MP toxicity is primarily associated with the inhibition of cholinesterase activity and resulting effects on the nervous system. MP can induce a genotoxic effect in bacterial and mammalian cells. However, the major metabolite of MP degradation, p-nitrophenol, is generally considered less toxic. This study reports on the evaluation of the genotoxic effect of MP, p-nitrophenol (PNP), and a 1:1 MP:PNP mixture. While MP induced a positive genotoxic response in *S. typhimurium* TA100 at a dose of 1000 μ g per plate, PNP and a 1:1 mixture of PNP and MP did not induce a positive response. The cytotoxic effect of MP was also evaluated in a human neuroblastoma cell, SH-SY5Y. At the highest dose of MP tested (50 μ M), significant decreases of both cell proliferation and viability were observed. Studies were also conducted to evaluate the utility of an organophosphate hydrolase (OPH) enzyme for degradation of MP. MP dissolved in LB broth containing 5 % methanol was treated with intact *E. coli* cells containing the OPH enzyme. Significant rates of MP biodegradation were observed in the liquid culture. Within 50 hours, approximately 85 % of the MP was converted to PNP as measured spectrophotometrically. After the samples were extracted by liquid/liquid extraction with methylene chloride, PNP and MP were analyzed by capillary gas chromatography with NP detector. With this extraction procedure, the average recovery of PNP and MP was 66% and 89%, respectively. The genotoxic potential of extracts of OPH treated and untreated MP amended media was measured with *S. typhimurium* strain TA100. The untreated media induced about 2.3 times the number of spontaneous revertants at a dose equivalent to 54 ml of medium (MP 0.025 mg/ml) per plate, while the OPH treated media failed to induce a positive genotoxic response. Chemical analysis indicated that about 90% of MP was removed from the media by treatment with OPH enzyme. These studies indicate that the OPH enzyme is capable of degrading MP and eliminating its genotoxic potential in liquid culture.

867 INHIBITION OF BRAIN SYNAPTOSOMAL Ca-ATPase BY ORGANOPHOSPHOROUS (OP) COMPOUNDS.

D Barber, J Hunt and M Ehrich. *Virginia-Maryland Regional College of Veterinary Medicine, Blacksburg, VA.*

Exposure to neuropathy-inducing OP compounds can result in elevated intracellular calcium (Ca_i). We hypothesize that OP exposure could contribute to changes in Ca_i by inhibition of Ca-ATPases in susceptible animals. To examine this, synaptosomes were prepared from the brains of adult hens, which are susceptible to OP-induced delayed neuropathy (OPIDN) and adult rats, which are not. Synaptosomes were incubated with OP compounds which can produce neuropathy [chlorpyrifos (CPF), chlorpyrifos-oxon (CPO), tri-*o*-tolyl phosphate (TOTP), phenyl saligenin phosphate (PSP), diisopropyl phosphate (DFP)] and with parathion (PTN) and its active metabolite paraoxon (PXN), which do not induce OPIDN. In hen brain synaptosomes, incubation with CPF and PTN for 30 minutes produced significant inhibition of Mg/Ca-ATPase activity (35% and 25%, respectively). In rat brain synaptosomes, no compound produced significant inhibition of Mg/Ca-ATPase activity. Ca-ATPase activity in brain synaptosomes prepared from hens treated with DFP (0.5 x LD50, 1 mg/kg) was decreased by 50% 24 hours after dosing. Ca-ATPase was not inhibited in hens treated with CPF (0.5 x LD50, 25 mg/kg). The results suggest that inhibition of Ca-ATPase occurs rapidly after exposure to OP insecticides and this may contribute to their neurotoxicity. (Supported by EPA grant R825356.)

868 INCREASED IN VITRO ANTICHOLINESTERASE ACTION OF THE INSECTICIDE CHLORPYRIFOS WHEN TESTED IN MIXTURES CONTAINING SEVERAL POLYCYCLIC AROMATIC HYDROCARBONS.

R V Navoa and D A Jett. *Department of Environmental Health Sciences, The Johns Hopkins University, Baltimore, MD.*

Research on complex mixtures is of high of priority to EPA, NIH, and other agencies because most environmental agents that affect human health are found in mixtures. The study reported here tested the hypothesis that several polycyclic aromatic hydrocarbons (PAHs) found in house dust modify the ability of the insecticide chlorpyrifos (CPF) to inhibit acetylcholinesterase (AChE) in vitro. AChE (EC 3.1.1.7; 0.125 Units) purified from electric eel was incubated at 25°C for 4 min in buffer containing increasing concentrations of CPF-oxon dissolved in ethanol (0.01-800 nM). AChE activity was then determined by standard colorimetric analysis using acetylthiocholine iodide as substrate. CPF-oxon inhibition curves were generated in the presence or absence of different concentrations of the PAHs pyrene, benzo[a]pyrene, anthracene, and fluoranthene (0.1-10 ppm dissolved in ethanol). AChE inhibition curves were also established for these four PAHs alone, relative to ethanol-only controls. Results indicate that all four PAHs inhibited AChE activity potently with IC50 values in the range of 3-7 ppm, in close agreement with another recent study demonstrating this effect [Kang and Fang, *Biochem Biophysic Res Comm* 238, 367-369 (1997)]. When AChE was incubated with CPF-oxon together with the PAHs, the efficacy of CPF-oxon was dramatically increased. This was exemplified by large (~70%) and significant ($p<0.001$) decreases in AChE activity at nanomolar concentrations of CPF-oxon, and similar decreases in the Vmax estimates from kinetic studies. The effects of the PAHs followed a dose-response relationship in all cases, and kinetic studies indicated that the PAHs inhibited AChE in a non-competitive manner. These findings may have implications on the hazard assessment of indoor exposure to CPF, especially since these PAHs increased markedly the anticholinesterase activity of low nanomolar concentrations of this insecticide. (Supported by JHU Professional Development Award to DAJ.)

869 cAMP-DEPENDENT PROTEIN KINASE (PKA) ACTIVITY IN THE BRAINS OF RATS AFTER ACUTE EXPOSURE TO CHLORPYRIFOS.

D A Jett, and R V Navoa. *Department of Environmental Health Sciences, The Johns Hopkins University, SHPH, Baltimore, MD.*

We have previously shown that anticholinesterases such as paraoxon cause a decrease in intra-neuronal levels of the second messenger cAMP, either by direct interaction with G-protein linked neurotransmitter receptors, or by some indirect mechanism [e.g. Jett et al., *Pest Biochem Physiol* 39:149-157 (1991)]. Others have found similar results with other organophosphate insecticides [e.g. Ward and Mundy, *Brain Res Bull* 39:49-55 (1996)], and it is generally believed that these compounds preferentially affect cAMP signaling when compared to other signal transduction pathways. Also it was recently demonstrated that adenylyl cyclase is a primary target for the developmental toxicity of chlorpyrifos [Song et al., *Toxicol Appl Pharmacol* 145:158-174 (1997)]. These findings are significant because cAMP signaling is known to be extremely important in learning and memory in both vertebrates and invertebrates. Surprisingly, nothing is known about the significance of OP-induced changes in cAMP signaling downstream of adenylyl cyclase activity. We report here on the first of several experiments on the effects of chlorpyrifos on cytoplasmic and nuclear cAMP signaling. Subadult Long-Evans rats (~150 g) were injected subcutaneously with 125 mg/kg chlorpyrifos dissolved in peanut oil; control rats were given oil alone. Rats were euthanized 48 hr after dosing, and the cerebral cortex was dissected on ice and immediately frozen and stored at −70°C. In this study, cAMP-dependent protein kinase (PKA) levels were determined by a colorimetric assay using the fluorescent dye-labeled Kemptide substrate (LRRASLG) and SpinZyme affinity columns, both from Pierce Chem. Co. Results indicated that rats exposed acutely to chlorpyrifos had ~30% decrease in PKA activity as judged by the amount of phosphorylated substrate in the assay. These data suggest that the documented decrease in cAMP levels by OPs may result in changes in PKA activity in vivo. Research is underway to examine the effects of chlorpyrifos on transcriptional events and gene expression associated with this pathway. (Supported by JHU NIEHS Center in Urban Health Pilot Project to DAJ.)

870 ALTERATIONS OF RAT BRAIN DNA AND NEUROTROPHIN LEVELS BY PRENATAL EXPOSURE TO CHLORPYRIFOS.

K P Das[1], T L Lassiter[1,2], C Lau[3] and S Barone Jr.[1]. [1]*Neurotoxicology and* [3]*Reproductive Toxicology Division, NHEERL, US EPA, Research Triangle Park, NC;* [2]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC, USA.*

From embryogenesis to senescence, neurotrophic factors are intimately involved in proliferation, differentiation, plasticity, and survival of neurons and glia in the central nervous system. In the present study, the effects of organophosphate pesticide chlorpyrifos (CPF) on the regional and temporal distribution of neurotrophic factors (NGF, BDNF and NT-3), and DNA and protein levels were examined in the developing brain. Pregnant Long-Evans rats were dosed daily (*p.o.*) with CPF in corn oil (0, 3, 5, 7, and 10 mg/kg) on gestational days 14-18. Results show that CPF (5 h after last dose) decreased the level of BDNF in a dose-dependent manner (5-40%), increased the level of NGF (20-40%), and increased the content of DNA (3%-15%) but had no effect on NT-3 in fetal whole brain. The rest of the rats (0, 5, 7, and 10, CPF mg/kg) were allowed to give birth and the pups were sacrificed on postnatal day (PND) 1, 4, 7, 21, or 114. CPF did not alter pregnancy outcomes appreciably at any dose. The content of DNA, protein, NGF, BDNF and NT-3 were quantitated in the cerebral cortex (CTX), hippocampus (HPC), cerebellum (CB) and brainstem (BS). These regions were chosen based on differences in cholinergic innervation and differential maturational profiles. In the CTX and HPC, CPF decreased the level of BDNF (5-60%) and NT-3 (10-55%) in a dose-dependent manner across all the ages except at PND-1, but had no effect on regional NGF levels. CPF decreased the level of NGF, BDNF and NT-3 in CB only at PND-1 and in the BS at PND-114 as compared to controls, suggesting that CPF had differential effects on neurotrophins during development in different regions of the brain. No alterations were noted on regional DNA and protein content.The postnatal effects on regional neurotrophin levels were much more robust in regions (CTX and HPC) developing primarily during the perinatal period. The effects of gestational CPF exposure were long-term and persistent on regional levels of BDNF and NT-3, suggesting that subtle alterations might be manifested in plasticity and maintenance of neural function within the adult nervous system.

871 AN EVALUATION OF THE SIGNIFICANCE OF DICHLORVOS (DDVP) INDUCED ALTERATIONS OF CHOLINERSTERASE (ChE) LEVELS IN BIOLOGICAL SYSTEMS: FINAL REPORT OF THE EXPERT PANEL.

B K Bernard[1], R J Richardson[2], E X Albuquerque[3], M Lotti[4], and R Snyder[5]. [1]*SRA International, Washington, DC, USA,* [2]*Univ Mich., Ann Arbor, MI, USA;* [3]*Univ Maryland, Baltimore, MD, USA;* [4]*Univ Degli Studi di Padova, Padova, Italy;* [5]*Rutgers Univ, Piscataway, NJ.*

A group of 11 internationally-known scientists were members of an Expert Panel (the Panel) which evaluated the biological significance of DDVP induced ChE inhibition. The Panel's major conclusions included: - The primary source of information for estimating human health risks is the presence or absence of clinically observable signs of toxicity. - Brain ChE activity (not plasma or RBC) is predictive of toxicity only after a significant threshold has been surpassed. - Significant RBC AChE inhibition (< 50%) occurs in the absence of clinical signs or symptoms of toxicity. - DDVP has extensive human safety data available. - The human acute dietary NOEL of DDVP is 1.0 mg/kg based upon human data. - The human chronic dietary NOAEL and NOEL are 0.3 and 0.1 mg/kg/day, respectively. - The chronic dietary NOAEL and NOEL in dogs are 1.0 and 0.05 mg/kg/day, respectively. - Extensive human data demonstrate the safety of maintaining humans at continuously reduced RBC cholinesterase levels (50 - 75%) for periods in excess of six years.

872 FUR RESIDUE AND CHOLINESTERASE INHIBITION OF DOGS DIPPED WITH CHLORPYRIFOS OR PHOSMET.

S Boone, J Tyler, and J E Chambers. *Center for Environmental Health Sciences, College of Veterinary Medicine, Mississippi State University, Miss State, MS, USA.*

Dogs were dipped with a commercial chlorpyrifos (Dursban[R]) or phosmet (Imidan[R]) flea dip using the recommended guidelines for four consecutive treatments in order to determine the residues available for transfer to humans from the fur of the dogs. The inhibition of plasma cholinesterase in the dogs was also determined over the study as a biomarker. Twelve dogs were used for each of the chlorpyrifos experiments and the fur was sampled by rubbing with cotton gloves for 5 min. in a 10 x 4 in. area along the upper back before dipping and at times 4 hrs, 7, 14, and 21 days after dipping. Over the 4 dippings the 4 hr samples averaged 1229 ± 158 μg, the 7, 14, and 21 day samples averaged 332 ± 68 μg, 215 ± 61 μg, and 139 ± 43 μg, respectively. The highest sample was 7000 μg at 4 hrs. Chlorpyrifos (CP) was quantified using gas chromatography with electron capture detection. For phosmet 24 dogs were used and were sampled at 4 hours and at days 1, 3, 7, and 14. Over the 4 dippings the 4 hr samples averaged 3723 ± 426 μg, the 1, 3, 7, and 14 day samples averaged 1431 ± 205 μg, 728 ± 131 μg, 231 ± 59 μg, and 62 ± 18 μg, respectively. The highest sample was 13817 μg at 4 hrs. The gloves were extracted using an accelerated solvent extractor. Plasma cholinesterase levels were measured as butyryl cholinesterase (BChE) using butyrylthiocholine (BTCh) and as acetylcholinesterase (AChE) using acetylthiocholine (ATCh). The average specific activities (nmole min^{-1} mg $protein^{-1}$) at zero time were: 54 ± 3 for BChE, and 10 ± 1 for AChE. The average percent inhibition ± standard error of BChE for the four dippings of CP were: 4 hours - 60 ± 4; 7 days - 76 ± 2; 14 days - 66 ± 3; and 21 days - 54 ± 3. The average percent inhibition ± standard error of AChE for the four dippings of CP were: 4 hours - 13 ± 2; 7 days - 18 ± 3; 14 days - 15 ± 3; and 21 days - 11 ± 2. Phosmet did not significantly decrease the levels of plasma BChE or AChE during the study, with inhibition ranging from 0 to 15%. (Supported by EPA R 825170)

873 POSSIBLE INFLUENCE OF VITELLOGENIN SYNTHESIS ON THE TOXICITY OF CHLORPYRIFOS IN CHANNEL CATFISH.

J R Richardson and J E Chambers. *Center for Environmental Health Sciences, College of Veterinary Medicine, Mississippi State University, Mississippi State, MS, USA.*

Vitellogenin, the egg yolk precursor, is secreted by the liver of oviparous animals in response to estrogen during vitellogenesis. Vitellogenin is rich in serine hydroxyl residues, the same residues present in the esteratic site of acetylcholinesterase (AChE), which is the target enzyme for organophosphorus insecticides. The oxon-metabolite of the phosphorothionate insecticide chlorpyrifos (C=S) inhibits AChE by phosphorylating these serine residues. The effect of vitellogenin synthesis on AChE inhibition by C=S was investigated in channel catfish (*Ictalarus punctatus*) fingerlings. Fish were injected i.p. with 2 mg/100g 17β-estradiol to induce vitellogenesis, and exposed to 0.125 mg/L C=S at 24, 36, and 48 hours post-injection in a static environment. Fish were sacrificed 24 hours after termination of the C=S exposure, and brain and liver AChE activities were determined. The presence or absence of vitellogenin in the serum was confirmed by native gel-electrophoresis. Brain AChE inhibition for estrogen treated fish at 24, 36, and 48 hours was about 76%, 75%, and 71% respectively, as compared to 86%, 87%, and 88% for non-induced fish . Liver AChE inhibition for all groups was about 90%. These results suggest that vitellogenin may provide a means of partial protection against brain AChE inhibition following organophosphorus insecticide exposure, possibly by providing alternate phosphorylation sites for the oxon-metabolite of chlorpyrifos.

874 COMPARATIVE CHOLINERGIC NEUROTOXICITY OF ORAL CHLORPYRIFOS EXPOSURES IN NEONATAL AND ADULT RATS.

Q Zheng, K Olivier, Y Won and C Pope. *Div. Toxicol., Northeast LA Univ., Monroe, LA.*

Chlorpyrifos (CPF) is an organophosphorus acetylcholinesterase (AChE) inhibitor and commonly-used insecticide. Previous studies have demonstrated that neonatal (7 days of age) rats are more sensitive than adults to the acute lethality of high subcutaneous dosages of CPF. The present study examined age-related differences in neurochemical and functional signs of

neurotoxicity following oral CPF exposures. Lethality studies determined substantial differences in acute sensitivity following high dosages (LD_{10}: adult = 136 mg/kg; neonate = 15 mg/kg). Neonatal and adult rats (n=3-6/group) were given CPF (0, 0.15, 0.45, 0.75, 1.5, 4.5 or 7.5 mg/kg/d) for fourteen days and sacrificed 4 hrs after either the 1st or 14th dose for neurochemical measurements (AChE in plasma, RBC, frontal cortex and diaphragm, and muscarinic receptor ([^{3}H]QNB) binding and nicotinic receptor ([^{3}H]epibatidine) binding in frontal cortex). No overt signs of cholinergic toxicity were noted in either age group 4 hrs after the 1st dose. After acute exposure, AChE in neonates was inhibited similarly in all tissues ($ED_{50\approx}$ 0.5-2.5 mg/kg). In contrast, only RBC and plasma AChE were inhibited 4 hrs after the 1st exposure in adults ($ED_{50\approx}$ 3 mg/kg). Four hrs after the 14th dose, levels of AChE inhibition in neonates were again relatively similar in all tissues ($ED_{50\approx}$ 1-2 mg/kg). In contrast, there was a wide range of sensitivity to inhibition in adult tissues (ED_{50}: RBC = 0.5 mg/kg; plasma = 1 mg/kg; cortex = 2.3 mg/kg; diaphragm = 6.6 mg/kg). Interestingly, dose-related inhibition of cortical AChE was essentially the same (ED_{50} = 1.9-2.4 mg/kg) and similar reductions in both cortical QNB and epibatidine binding were noted between the age groups after repeated dosing. We conclude that while neonates are more sensitive to acute effects of oral CPF, very similar cholinergic neurochemical changes are noted in frontal cortex in both age groups following repeated exposures. (Supported by U.S. EPA R 825811-01-0.)

875 RESULTS OF A 2-MONTH CHLORPYRIFOS FEEDING STUDY IN ADULT, MALE RATS.

D L Hunter[1], R S Marshall[1], T L Lassiter[1,2], S B McMaster[1], and S Padilla[1]. [1]*NHEERL, USEPA, RTP, NC;* [2]*Curriculum in Toxicology, UNC-CH, Chapel Hill, NC.*

Chlorpyrifos [CPF; (*O,O'*-diethyl *O*-3,5,6-trichloro-2-pyridyl) phosphorothionate] is a commonly used organophosphorus pesticide. The widely accepted mechanism of toxicity for CPF is cholinesterase (ChE) inhibition. The present study was devised to assess the toxicodynamic and toxicokinetic responses of animals exposed to a relatively long-term, low-dose level of CPF in the feed. Long-Evans, male rats were given CPF in their feed at a level designed to deliver a dosage of 0, 0.8 or 4.0 mg/kg/day. After 2 months of feeding, half the animals in each feeding group were challenged with a single, oral dose of CPF (60 mg/kg in corn oil). This experimental design results in six groups of animals (n=5/group): the unchallenged group at the three feeding levels and the challenged group at the three feeding levels. Twenty-four hours after the challenge dose, the animals were killed, and blood, brain, and liver were collected and frozen. In the unchallenged animals, the 0.8 mg/kg dose produced only ChE inhibition in the blood with no inhibition in the brain, whereas the 4.0 mg/kg dose produce inhibition in both blood and brain (~ 50%). The animals challenged with CPF showed maximal blood and marked (~ 70%) brain ChE inhibition which did not differ according to the amount of CPF in the feed. There were no changes in the muscarinic receptor density in any of the dosage groups. Levels of CPF, CPF-oxon, and trichloropyridinol (TCP) were measured by HPLC in both brain and liver. No CPF or metabolites were detected in brain in any of the dosage groups, whereas both CPF and TCP were detected in liver of the challenged animals. In the unchallenged animals, only the 4.0 mg/kg/day group showed measurable liver TCP levels. It appears, therefore, that previous, low-level exposure to CPF does not alter the biochemical responses to a challenge dose of higher level of CPF.

876 TIME OF ADMINISTRATION AFFECTS ORGANOPHOSPHATE PESTICIDE-INDUCED ALTERATIONS IN BODY TEMPERATURE.

J M Kuperberg[1], K Henderson[1], K F A Soliman[1], C M Teaf[2] and M G Kolta[1]. [1]*Environmental Toxicology Graduate Program, Florida A&M University, Tallahassee, FL, USA;* [2]*Center for Biomedical & Toxicological Research, Florida State University, Tallahassee, FL, USA.*

Chlorpyrifos (Cpf) is an organophosphate pesticide (OP) and is among the most common and widely used commercial insecticides. Cpf, as well as other OPs, exerts its toxic effects through inhibition of acetylcholinesterase, resulting in increased cholinergic activity. Human intoxication results in a typical set of responses, which include an immediate and long lasting hyperthermic response. Rodent exposure, however, results in a biphasic thermal response: short-term hypothermia followed by subtle hyperthermia several days after administration. The current study was designed to determine whether exposure to Cpf at different times of the day would influence this biphasic response. Male Sprague-Dawley rats (200-250 gm) were exposed to Cpf via oral gavage at one of four time points (0600, 1200, 1800, 2400). Core body temperature was recorded every six hours from two days prior to administration to three days after administration. The results of this study show that the timing and magnitude of the initial (hypothermic) response (6 hours post-dosing) was independent of time of exposure, while the delayed (hyperthermic) response (48-72 hours post-dosing) was related to light/dark phase. Regardless of time of administration, at six hours after treatment, animals exposed to Cpf demonstrated a significant decrease in body temperature as compared to controls. However, the delayed hyperthermic effect differed with time of administration. Light phase administration resulted in increased temperature only during the light phase, while dark phase administration resulted in sustained temperature elevation. Identifying these mechanisms and the underlying neurochemistry is necessary in order to evaluate protective limits for exposure to compounds such as Cpf.

877 ERYTHROCYTE ACETYLCHOLINESTERASE ACTIVITY IN A KOREAN POPULATION.

K H Lee[1], W G Chung[1], C S Park[1], J H Kang[1], H M Baek[1], H K Roh[2] and Y N Cha[1]. [1]*Department of Pharmacology and Toxicology;* [2]*Department of Internal Medicine, College of Medicine, Inha University, Inchon, KOREA.*

To assess the degree of organophosphate poisoning, acetylcholinesterase (AChE) activity is measured. While the plasma AChE activity is easy to determine, it is labile and is not specifically correlated with the enzyme activity in neuronal tissues. AChE activity in red blood cells (RBC) is not labile and is more closely related to the enzyme activity in neuronal tissues. However, there were no reference range of AChE activities in RBC for Korean population. Thus, RBC AChE activities were measured using modified Ellman's method in 109 healthy Korean adults (age: 19 - 58 yr). Blood sample (3 ml) was collected in heparinized tube and RBC was separated from plasma within 1 - 2 hr. Interference by butyrylcholinesterase was eliminated by quinidine sulfate, a specific inhibitor. RBC AChE activities in Korean subjects were unimodally distributed with inter-individual variation of 15% (coefficient of variation) similar to the values obtained in other ethinic groups. The RBC AChE activity ranged from 8,132 to 23,562 U/L packed RBC. Comparing the RBC AChE activity of 76 male and 33 female subjects, they were not significantly different (Mann-Whitney U test, $p = 0.675$). Median activities for male were 13,526 (range: 10,402 - 21,027) and for female were 13,408 (range: 8,132 - 23,562). However, there was a positive correlation for smoking intensity (Spearman's correlation coefficient = 0.253, $p = 0.048$, smoking index = daily cigarette packs × smoking years) but a negative correlation for age (Spearman's correlation coefficient = -0.184, $p = 0.055$). (Supported by an intramural research grant from Inha University in 1998.)

878 REVERSIBLE INHIBITION OF CHOLINESTERASE BY SPIN TRAPPING AGENTS.

D Milatovic and W-D Dettbarn. *Vanderbilt Univ., Dept. of Pharmacology and Neurology, Nashville, TN.* Sponsor: R C Gupta.

The spin trapping agent phenyl-N *tert*-butylnitrone (PBN) prevented anticholinesterase induced fasciculations and seizures, withouth affecting kainic acid or pilocarpine produced seizures. Consequently this study was performed to quantitate and identify the probable mechanism of action. The inhibitory potency of PBN and α-(4-pyridyl 1-oxide)-N-*tert*-butylnitrone (POBN) on rat brain and diaphragm, purified mouse brain and electric eel acetylcholinesterase (AChE; EC 3.1.1.7) were studied in vitro using spectrophotometric kinetic assay with acetylthiocholine (ASCh) as substrate. The inhibition was in a reversible and concentration-dependent manner. Double reciprocal plots of the reaction velocity against varying ASCh concentration were linear and generally indicated mixed competitive/non-competitive inhibition. PBN was the most potent inhibitor of mouse brain AChE with Ki and Ki' of 0,58 mM and 2.99 mM respectively. PBN was less effective for rat brain (Ki=0.69 mM, Ki'=3.87 mM) and diaphragm (Ki=1.33 mM, Ki'=2.40 mM) and was the weakest inhibitor of electric eel AChE in contrast to POBN which showed the highest affinity for this enzyme, with Ki and Ki' values of 1.065 mM and 3.15 mM respectively. These data support the suggestion that preinhibition with these agents prevents critical irreversible inhibition of AChE in brain and muscle and consequently seizures and fasciculations. (Supported by NIH Grant, ES04597.)

879 PIPERONYL BUTOXIDE POTENTIATES THE SYNAPTOSOME ATPase INHIBITING EFFECT OF PYRETHRIN.

I Kakko, T Toimela, and H Tähti. *University of Tampere, Medical School, Tampere, Finland.* Sponsor: K Savolainen.

Pyrethrins are widely used insecticides both in agriculture and households. In many commercial formulations piperonyl butoxide (POB) is used with pyrethrins. POB is a known synergist of pyrethrins, used to intensify their effect. The cellular target of pyrethrins is the sodium channel in the membrane. In the present study the activity of membrane-bound integral protein ATPase was studied as a biomarker for the membrane effect of pyrethrin and POB. Male Sprague-Dawley rats were used for cerebral synaptosome preparation. The isolation of synaptosomes was performed with the Percoll gradient method. Both total ATPase and Mg^{2+} activated ATPase were studied by determining inorganic phosphate. Exposure to 0.1, 1, 10, 100 and 1000 μ M of pyrethrin and to 0,4, 4, 40 and 400 μ M of POB decreased ATPase activity dose-dependently. Most efficient was the mixture of pyrethrin and POB (1:4). The activity of total ATPase decreased 10 % in concentrations of 1-10 μ M pyrethrin alone and the 50 % decrease was found at 100 μ M pyrethrin. The mixture of pyrethrin and POB caused 30-60 % decrease in the total ATPase activity at 1-10 μ M pyrethrin and 4-40 μM POB. 85 % decrease was found after exposure to the mixture of 100 μM pyrethrin and 400 μM POB. POB alone had no effect at 1-10 μM concentrations, but a marked effect was seen at over 40 μ M concentrations. The results illustrate that POB is an effective synergist of pyrethrin and that it is very toxic in high concentrations. The results also confirm that sodium homeostasis is a target of the neurotoxic effect of pyrethroid compounds.

880 BIOCHEMICAL AND MICROSCOPIC CHANGES IN DIAPHRAGM MUSCLE BY ACUTE CARBAMATE TOXICITY.

R C Gupta[1], W-D Dettbarn[2], R K Sanecki[1], and J T Goad[1]. [1]*Murray State University, Hopkinsville, KY, USA;* [2]*Vanderbilt University, Nashville, TN, USA.*

The objective of this study was to investigate the biochemical and microscopic changes in diaphragm muscle of rats acutely intoxicated with aldicarb (0.4 mg/Kg, ip) or carbofuran (1.5 mg/Kg, sc). With either carbamate, rats developed signs of muscle fasciculations within 30-60 min. During this time, diaphragm AChE was maximally reduced (75-80%). Biomarker enzymes, such as CK (isoenzyme CK-MM3) and LDH (isoenzymes LDH-1→ LDH-5) showed characteristic changesin muscle. These enzymes/isoenzymes leaked into circulation due to significant depletion of high-energy phosphates (ATP, 20% and PCr, 30%) in muscle. Declines in the corresponding ratios of ATP/ADP (26%), ATP/AMP (39%) and PCr/Cr (20%) were suggestive of a greater utilization of ATP and PCr in response to their increased demand for carbamate-induced sustained high-frequency muscle fasciculations. Lesions in muscle were greater with aldicarb than with carbofuran, causing cell swelling characterized by loss of myofibrillar structure, cytoplasmic clearing and necrosis. Electron microscopic changes included mid focal loss of myofibrillar structure, inter-myofibrillar clearing (fluid accumulation)m and swelling of mitochondria. It can be concluded from these findings that carbamate-induced muscle hyperactivity caused muscle lesions due to a depletion of high-energy phosphates, which are required to maintain mitochondrial/cellular membrane permeability and integrity. (Partially supported by NIEHS Grant 5RO1ES05193-03).

881 RELATIVE CONTRIBUTION OF TRANSMITTER RELEASE AND GABA ANTAGONISM IN THE ACTIONS OF CYCLODIENES ON THE MURINE NIGROSTRIATUM.

E R Freeborn, R Barlow, M L Kirby, and J R Bloomquist. *Department of Entomology, Virginia Polytechnic Institute and State University, Blacksburg, VA.*

Neurochemical changes were investigated in C57BL6 mice given 3 intraperitoneal doses of the cyclodiene insecticide, heptachlor, over a 2 week period. Heptachlor increased [^{3}H]dopamine uptake in *ex vivo* striatal synaptosomes, which we attribute to dopamine transporter up-regulation in response to increased synaptic levels of dopamine. Neurotransmitter release studies with striatal synaptosome preparations revealed that heptachlor and heptachlor epoxide stimulated release of pre-loaded dopamine, serotonin, glutamate and GABA. The potency for release of dopamine was at least 7-fold greater than that of the other transmitters. Picrotoxinin and bicuculline were inactive in this assay, which precludes an interaction with the GABAa receptor as a mechanism for release of transmitter. Accordingly, mice treated with sublethal doses of picrotoxinin failed to show any upregulation of dopamine transport in *ex vivo* synaptosomes. In electrophysiological studies of murine striatal brain slices, the cyclodiene dieldrin mimicked the inhibitory action of applied dopamine, an effect consistent with induced release of dopamine, but not GABA antagonism. These studies suggest that cyclodiene-dependent release of transmitter from nerve terminals, and not GABA antagonism, induces upregulation of dopamine transport and may serve as a predisposing factor in environmental Parkinsonism.

882 DEET BLOOD LEVEL STUDIES IN RATS FOLLOWING A SINGLE ORAL ADMINISTRATION, AND SINGLE AND REPEATED DERMAL APPLICATIONS.

T G Osimitz[1], M W Gill[2], K L Gabriel[3], S J Hermansky[4], and G P Schoenig[2]. [1]*S.C. Johnson and Son, Inc., Racine, WI;* [2]*Toxicology/Regulatory Services, Inc., Charlottesville, VA;* [3]*McLaughlin Gormley King Company, Minneapolis, MN;* [4]*Schering-Plough Health Care Products, Memphis, TN.*

Studies were conducted in rats to determine diethyl-*m*-toluamide (DEET) blood levels following oral and dermal administration of DEET using the same dosing procedures and dose levels used previously in an acute oral neurotoxicity study in rats and a 90-day dermal toxicity study in rats. The purpose of the present studies was to develop information regarding the blood profile and maximum DEET blood levels likely to have occurred at the highest no observable effect levels in the previous studies. In the acute oral study, DEET plasma levels were determined following bolus administration of 200 mg/kg undiluted DEET to rats. Three rats/sex were anesthetized and exsanguinated 15, 30, 45, 60, 90, 120, 180 and 240 min. after dosing. DEET was detected in plasma within 15 min. and reached an apparent mean plateau of 9.6 and 13.6 μg/ml for males and females, respectively, between 45 to 240 min. In the dermal study, DEET plasma levels were determined following application of 1000 mg/kg undiluted DEET to rats on a single occasion or once per day for five consecutive days. Four rats/sex were anesthetized and exsanguinated 2, 4, 8, 12, and 24 hours after the first or final applications. DEET plasma levels in males reached a mean plateau of 4.5 μg/ml between 2 and 12 hours and decreased thereafter. In females, mean plasma levels peaked during the 4 to 8 hour period at 17 to 24 μg/ml and decreased thereafter. There was no evidence of DEET accumulation with repeated application. These data were compared to analogous blood level data generated recently for humans following dermal application of DEET under a worst-case exposure scenario. These comparisons, along with the toxicity data from previous studies, indicate margins of exposure of at least 10-fold between the no-effect blood levels in animals and peak blood levels in humans. (Sponsored by the DEET Joint Venture/CSMA, Washington, DC.)

883 PARADOXICAL ALTERATION OF DIBROMOETHANE (EDB)-INDUCED NEPHROTOXICITY BY ADRENERGIC AGENTS.

S Babu, R Francois, J McCluskey, C Muro-Cacho and R D Harbison. *Dept. of Environmental and Occupational Health, College of Public Health and Dept. of Pathology, College of Medicine, University of South Florida, Tampa, FL.*

Stress, adrenergic agonists, and antagonists can influence chemical and drug-induced hepatotoxicity. Previous studies have shown that adrenergic agonists such as phenylephrine (PE) can enhance the cytotoxicity produced by selected hepatotoxicants and by bromohydroquinone, a known nephrotoxicant. The purpose of this study was to extend these observations to evaluate the effect of adrenergic agents on the pesticide dibromoethane (EDB), a nephrotoxicant. Male ICR mice, 23-26gms were treated with EDB and subsequently with either an adrenergic agonist, antagonist, or a combination of both. Each treatment group contained 8-10 mice. All animals were maintained in a controlled environment and provided food and water ad libitum. EDB treatment resulted in kidney cytotoxicity as measured by increases in urinary gamma glutamyl transpeptidase (GGTP). Severe to moderate cell damage was detected with this first treatment regimen. Concomitant with the increase in urinary GGTP, a significant decrease in kidney tissue glutathione was detected. Phenylephrine (PE) (50mg/Kg ip) potentiated the cytotoxic effects of EDB resulting in a significant increase in urinary GGTP. Several pathological changes were also observed in kidney tissue, consistent with the observation of hematuria. The enhancement of the pesticide-induced nephrotoxicity was antagonized by an adrenergic antagonist, phentolamine. The results of this study indicate that adrenergic agonists and antagonists can significantly alter the toxicity of the pesticide EDB. The mechanism by which

adrenergic modulation alters the nephrotoxicity of this pesticide remains to be elucidated. However, the adrenergic modulation of cytotoxicity may be a useful tool for evaluating drug and chemical-induced organ changes. (Supported in part by NIOSH Grant T42/CCT 412874.)

884 COMPARISON OF KINETIC PARAMETERS FOR *IN VITRO* METABOLISM OF ALACHLOR AND 2-CHLORO-*N*-(2,6-DIETHYLPHENYL)ACETAMIDE (CDEPA) IN MOUSE, RAT, AND HUMAN.

S C Coleman, S L Liu, R L Rose and E Hodgson. *Department of Toxicology, North Carolina State University, Raleigh, NC.*

Alachlor (2-chloro-*N*-methoxymethyl-*N*-(2,6-diethylphenyl)acetamide) is a widely used pre-emergent herbicide which has been shown to be carcinogenic in rats. The mechanism for carcinogenesis has not been elucidated, however it has been proposed that alachlor forms a DNA reactive metabolite, 2,6-diethylbenzoquinone imine (DEBQI). A key step in the formation of DEBQI is the metabolism of 2-chloro-*N*-(2,6-diethylphenyl)acetamide (CDEPA) to 2,6-diethylaniline (DEA) through an aryl amidase reaction. It has been suggested that humans lack the aryl amidase necessary to metabolize CDEPA to DEA. We have shown that humans are able to metabolize alachlor to CDEPA and that this is catalyzed by CYP 3A4. We have also shown, for the first time, that CDEPA is metabolized to DEA in humans at a rate which is greater then that of rats and mice. We have determined the K_m and V_{max} of the formation of DEA from CDEPA using liver microsomes from male rats (231.9 μM, 1.218 μM/min/mg), male mice (257.0 μM, 1.541 μM/min/mg), and male humans (9.0 μM, 7.246 μM/min/mg). Further investigation of the kinetic parameters of CDEPA formation from alachlor and DEA metabolism are being pursued using microsomes from rats, mice and humans.

885 A COMPARATIVE ANALYSIS OF DNA ADDUCT FORMATION BY ALACHLOR METABOLITES *IN VITRO* AND *IN VIVO* IN RAT LIVER AND OLFACTORY TISSUES BY ^{32}P-POSTLABELING.

D A McLaughlin, S A Meyer, and R L Rose. *North Carolina State University, Raleigh, NC, USA.*

Alachlor (2-chloro-2'6'-diethyl-N-(methoxymethyl) acetanilide) is a restricted use herbicide associated with nasal carcinogenicity and hepatotoxicity in rats; however, the mechanism responsible for its biological effects remains unclear. The complex metabolism of alachlor to reactive metabolites capable of binding DNA has been implicated in its carcinogenicity. This study was undertaken to investigate the formation of DNA adducts upon bioactivation of alachlor and 2,6-diethylaniline (DEA), a major metabolite of alachlor, *in vitro* with calf thymus DNA in the presence of liver and olfactory microsomal activation systems from male Long-Evans rats. Results were compared with adducts formed by alachlor *in vivo* in DNA from liver tissues of rats exposed ip to 126 mg/kg/day of alachlor for 1, 4, or 28 days. DNA adduct analysis was performed using ^{32}P-postlabeling with adduct enrichment by either nuclease P1 or butanol extraction and adduct resolution by thin layer chromatography. Comparison of adduct migration patterns resulting from alachlor bioactivation in olfactory and hepatic *in vitro* activation systems identified a metabolism dependent adduct specific for each tissue. Metabolism of DEA using the same activation systems revealed comigration of three adducts in addition to one adduct unique to liver metabolism. *In vivo* adduct formation in DNA from liver tissues revealed several adducts for all time points. One adduct common to all *in vivo* treatments comigrated with the adduct formed following *in vitro* liver metabolism. These data indicate that bioactivation of both alachlor and DEA result in formation of reactive metabolites capable of covalent binding to DNA as evidenced by the formation of multiple DNA adducts in both *in vitro* systems and *in vivo* treatments. Finally, evidence is provided indicating bioactivation of alachlor to tissue specific adduct-forming metabolites consistent with different target tissue effects.

886 THE RATIONAL SELECTION OF HPPD INHIBITORS FOR AGROCHEMICAL AND PHARMACEUTICAL USE.

W M Provan[1], E A Lock[1], M K Ellis[1], M Robinson[1] and S Lindstedt[2]. [1]*Zeneca, Central Toxicology Laboratory, Macclesfield, Cheshire, UK;* [2]*Department of Clinical Chemistry, Gothenburg University, Sahlgren's Hospital, Gothenburg, Sweden.*

Zeneca discovered a series of selective herbicides with a novel mode of action - the inhibition of the enzyme 4-hydroxyphenylpyruvate dioxygenase (HPPD) in plants. Investigative toxicology studies at CTL showed that these chemicals also inhibited hepatic HPPD in rats and mice. Collaborative studies with Dr Sven Lindstedt revealed that the purified human liver enzyme was also inhibited. This finding led to the concept of using of one of these chemicals for the treatment of tyrosinaemia type 1, a hereditary disorder of tyrosine catabolism, by blocking the formation of the toxic metabolites of tyrosine which are produced in this disease. The detailed understanding of the biochemical toxicology associated with inhibition of HPPD in mammals led to the rational selection of one of this series of chemicals, namely NTBC, for the treatment of tyrosinaemia type I in children and another, namely ZA1296, as a selective herbicide. For the treatment of tyrosinaemia type I, where prevention of toxic metabolites of tyrosine catabolism is required, a chemical which produces a rapid and prolonged inhibition of HPPD is most desirable. Therefore chemicals, such as NTBC, which exhibit low enzyme-inhibitor dissociation rates are favoured for the therapeutic use of HPPD inhibitors. In contrast, in the selection of an agrochemical, although exposure to the human population will be negligible, if the inhibition of HPPD and hence interference with tyrosine catabolism is slight, the toxicological consequences of exposure are minimised. Therefore, chemicals such as ZA1296, which exhibit a fast enzyme-inhibitor dissociation rate, complimented by rapid urinary clearance are preferred agrochemical products.

887 BLOOD PROTEINS AND DNA ADDUCTS OF ATRAZINE IN *PEROMYSCUS LEUCOPUS* AS BIOLOGICAL INDICATORS OF TRIAZINE HERBICIDE EXPOSURES IN THE ENVIRONMENT.

T V Reddy[1], H Wang[2], B Wiechman[2], F B Daniel[1] and G Toth[1]. [1]*US EPA, NERL, Cincinnati, OH;* [2] *PAI, West Chester, OH.*

Atrazine is being used extensively in agriculture around the globe as an herbicide for the control of broadleaf and grass weed growth. Atrazine has been detected in ground water, streams, rivers, and lakes in several areas where agricultural crops are predominant. We have investigated the potential of atrazine to form adducts with blood proteins and DNA, and use of these adducts as biological indicators for exposure assessment. *Peromyscus leucopus* were given varied concentrations of [^{14}C]-atrazine (1-280 mg/kg, sp. act. 109-5.7 mCi/m mol) as a single oral gavage and sacrificed at different intervals (0.33-70 days). Our results indicate that atrazine forms stable adducts with the major blood proteins globin and albumin in a dose dependent manner. The adduct levels were maximum at 24 (albumin), and 48 hours (globin) after treatment. Albumin adduct levels were six times higher than globin adducts; however, albumin adduct levels decreased faster than did those of globin. Seven days after treatment, the radioactivity retained in globin and albumin were 80% and 20%, respectively. Atrazine also formed stable adducts with DNA in liver and testis. The binding levels in testis DNA (45 pico mol/mg DNA) were 8 fold higher than in the liver DNA. The peak adduct levels were detected at 24 h. These results demonstrate that both blood proteins and DNA adducts may be used as indicators for assessing atrazine and other triazine herbicide exposures in the environment.

888 QUANTITATION OF ATRAZINE IN HAIR.

D L Hubbard, D G Wilkins and D E Rollins. *Center for Human Toxicology, Department of Pharmacology and Toxicology, University of Utah, Salt Lake City, UT, USA.*

Atrazine, a s-triazine herbicide used extensively in commercial agriculture, has been implicated in endocrine disruption and certain cancers. Exposure to atrazine is highest among applicators and agricultural workers; residues are also found in foodstuffs and in groundwater. The use of hair as a biomatrix to measure pesticide exposure offers the ability to monitor passive exposure (acute or chronic) with minimally invasive sampling and possible temporal correlation to the time of exposure. The rodent model used to test the incorporation of atrazine into hair was the Long Evans (LE) rat, an animal that has both pigmented and nonpigmented hair. Atrazine was administered to male LE rats for five consecutive days at 90, 120 or 150 mg/kg (n=6/dose) via intraperitoneal injection. An area of the dorsal region was shaved prior to dosing and again 14 days after the initiation of dosing. Using a previously developed assay, atrazine was measured in the pigmented and nonpigmented hair. The concentrations (mean±SEM) at the low, mid and high doses were 0.16±0.02, 0.97±0.4 and 0.93±0.09 ng/mg in pigmented hair, and 0.48±0.07, 1.72±0.3 and 1.49±0.24 in nonpigmented hair. Since the potential for surface contamination of hair is of concern with respect to the interpretation of atrazine hair concentrations, decontamination (wash) studies

were performed. First, pesticide-free pigmented and nonpigmented LE rat hair was fortified with atrazine at concentrations similar to those observed in the hair of dosed animals. Fortified hair was then washed with one of five conditions: water, 0.1 % SDS, 1% SDS, Tris buffer (pH 6) or Tris buffer (pH 10). The experiment was then repeated using hair from animals that had been dosed with atrazine. After washing with solutions of either 0.1 or 1% SDS, all atrazine was removed from the fortified hair. The atrazine remaining in the dosed hair samples ranged from 47.03 to 73.18% (0.1% SDS) and from 37.89 to 70.38% (1% SDS). Results of the other wash treatments were more variable; generally, more atrazine was removed from fortified hair than from the dosed hair.

889 AGGREGATE EXPOSURE MODEL FOR PESTICIDE DRIFT.

H E Daly, C Schmidt and B D Beck. *Gradient Corporation, Cambridge, MA, USA.*

The Food Quality Protection Act (FQPA) directs the United States Environmental Protection Agency (USEPA) to perform an aggregate exposure assessment (which considers exposure from all sources and all routes) when setting tolerances for pesticide residues in food. We have used this approach to determine risks associated with exposure to methidathion in a community exposed to pesticide drift from a nearby farm. A field study was performed to determine air concentrations and surface deposition of pesticide residues in the community. Data from the field study were supplemented with air modeling to provide estimates of pesticide concentrations throughout the community. Based on a comparison of age-specific inhalation rate to body weight (BW) and skin surface area to BW ratios, the most exposed population was determined to be the 2-3 year old child. Relevant sources/routes of exposure were direct dermal contact, ingestion from hand to mouth activity and homegrown vegetables, and inhalation of airborne pesticide. Hazard indices were determined by comparing route-specific toxicity factors to pesticide levels for inhalation, dermal, and ingestion routes of exposure. The total hazard for the 2-3 year old from all of these sources combined exceeded a Hazard Index of 1.0 (a typical risk management target). Of this total risk, dermal exposure accounted for 76%, ingestion of homegrown vegetables accounted for 13%, ingestion from hand to mouth activity accounted for 10%, and inhalation accounted for 0.1%. Thus, a more traditional "non-aggregate" approach would have missed about 23% of the total exposure. Other sources of pesticide exposure such as well water consumption, soil ingestion, and laundry hanging outdoors were qualitatively evaluated and determined to be relatively insignificant.

890 DEVELOPMENT OF AN IMMUNOASSAY FOR THE DETERMINATION OF HERBICIDE IN SEMEN.

J C Hall[1], L Ritter[2], T Arbuckle[3] and S Deshpande[1]. [1]*University of Guelph, Guelph, Ontario, Canada;* [2]*Canadian Network of Toxicology Centres, University of Guelph, Guelph, Ontario, Canada;* [3]*Health Canada, Ottawa, Ontario, Canada.*

Exposure studies on the uptake and distribution of chemical contaminants that involve human subjects require non-invasive methods of analysis to profile the distribution of chemicals throughout the body. In those studies involving males where the chemical agent may be a reproductive toxicant, analysis of semen is often the most expedient way to determine the extent of exposure. However, small sample volumes combined with a non-homogeneous matrix present complex problems for chemical analysis using traditional chromatographic methods. We have recently developed a method for the analysis of herbicides in semen using ELISA. The primary advantage of this method is the minimum sample preparation in comparison with that required using chromatographic methods. The analytical resolution of the method, LOD and LOQ of 5 and 25 ppb, respectively, was sufficiently sensitive to determine the presence of a herbicide. The detection limits were verified using samples spiked with radiolabeled herbicide. Moreover, the small quantities required for the ELISA left enough sample to conduct more traditional determinations for sperm count and sperm morphology. Method development for the detection of a toxicant is important from a regulatory perspective. The ease of development of this method indicates that other chemical agents, with an existing ELISA, can be detected with relative ease in semen as well as other complex matrices.

891 ROLE OF CALCIUM CHANNELS IN THE SEXUAL DIMORPHISM OF CADMIUM-INDUCED HEPATOTOXICITY.

T K Baker and M A Carfagna. *Investigative Toxicology, Lilly Research Laboratories, A Division of Eli Lilly & Co., Greenfield, IN, USA.*

Acute cadmium (Cd) toxicity has been evaluated in many *in vivo* and *in vitro* toxicological studies. *In vivo* rat studies assessing the effect of Cd have demonstrated sexual dimorphism, with the female species being more susceptible to Cd uptake, accumulation, and toxicity. The mechanism of female sensitivity to acute cadmium exposure has not been determined. However, it has been reported that as much as 51% of Cd entering the cytoplasm of hepatocytes does so via the receptor mediated Ca^{2+} channels. The effects of progesterone on Ca^{2+} channels has been implicated in the mechanism of acute toxicity. Given these findings, the hypothesis that progesterone is acting as a Ca^{2+} agonist, thus facilitating increased uptake, accumulation, and cytotoxicity of Cd through receptor mediated Ca^{2+} channels was examined. Male rat hepatocytes were used to evaluate the role of Ca^{2+} channels in the sexual dimorphism of acute cadmium toxicity. Twenty four hour cultures of primary rat hepatocytes were exposed to Cd, progesterone, and/or verapamil for 4 hours and cytolethality was measured. Using isolated hepatocytes it was shown that pretreatment with the Ca^{2+} channel blocker verapamil increased the Cd concentration producing 50% cytolethality (LC_{50}) from 8.1 μ M to 19.8 μ M. In contrast, pretreatment with progesterone enhanced the Cd LC_{50} from 8.1 μ M to 4.0 μ M. The pretreatment combination of progesterone followed by verapamil inhibited the progesterone enhanced Cd cytolethality yielding an LC_{50} of 7.3 μ M (Cd alone LC_{50} = 8.1 μ M). Verapamil and/or progesterone in the absence of Cd did not affect hepatocyte viability. Overall, the results of this study demonstrate that inhibition of progesterone-induced Ca^{2+} influx with the Ca^{2+} channel blocker verapamil, decreases Cd cytolethality in primary isolated rat hepatocytes. These findings suggest that progesterone activation of receptor-mediated Ca^{2+} channels is involved in the sexual dimorphism seen following acute Cd exposure.

892 INVOLVEMENT OF PHASE II ENZYMES IN HEPATOTOXICITY BY E2011.

G Sato[1], Y Tsutsui[1], T Aoki[2], S Hosokawa[2], and K Tsukidate[1]. [1]*Eisai Co., Ltd., Tsukuba, Ibaraki, Japan;* [2]*Eisai Co., Ltd., Kawashima, Gifu, Japan.*

(R)-3-[2-(S)-3-Cyano-1-hydroxypropyl)banzothiazol-6-yl]-5-methoxymethyl-2-oxazolidinone (E2011), a benzothiazole derivative, is a selective inhibitor of monoamine oxidase type A. A subchronic toxicity study of E2011 in rats after 13 weeks of p.o. administration revealed hepatotoxicity including GST-P positive liver foci and karyomegaly in hepatocytes (female > male). The present study was intended to clarify the role of phase II enzymes in the hepatotoxicity by repeated administration of E2011. Female SD rats were orally treated with E2011 daily for 2 weeks at a dose of 150 mg/kg. Forty-five minutes before the E2011 administration, the animals were pretreated with drug metabolizing enzyme inhibitors, i.e., 2,6-dichloro-4-nitrophenol (DCNP) (10 mg/kg, i.p.; inhibitor of sulfotransferase (ST)), pentachlorophenol (PCP) (5 mg/kg, i.p.; inhibitor of both ST and acetyltransferase (AT)) or ranitidine (RA) (100 mg/kg, p.o.; inhibitor of UDP-glucuronosyltransferase (UDP-GT)). Treatments with E2011 in combination with DCNP caused more dramatic karyomegaly in hepatocytes than treatments with E2011 alone. On the other hand, the karyomegaly was clearly diminished by pretreatment with PCP. No additional effect was found in animals pretreated with RA. The differences were attributed to inhibitory effects of AT in addition to ST by PCP. Ames tests of E2011 and its related compounds using Salmonella typhimurium strains TA98 and YG1024 suggested that E2011 exhibits mutagenicity after decarbonation and sequential metabolic activation by cytochrome P450 and AT. In conclusion, AT rather than ST or UDP-GT plays an important role in E2011-induced karyomegaly in hepatocytes. A further studies to clarify the mechanisms of E2011-induced GST-P positive foci are now in progress in our laboratory.

893 HEPATOPROTECTION BY DIMETHYL SULFOXIDE AND AMINOBENZOTRIAZOLE: COMPARISON OF EFFECTS ON HEPATIC MICROCIRCULATION WHEN ADMINISTERED 24 HOURS AFTER CHLOROFORM.

Y Ito[1], R C Lind[2], C K Begay[2], A J Gandolfi[2], and R S McCuskey[1]. [1]*Department of Cell Biology and Anatomy and* [2]*Department of Anesthesiology, College of Medicine, University of Arizona, Tucson, AZ, USA.*

Both dimethyl sulfoxide (DMSO) and aminobenzotriazole (ABT) protect against developing $CHCl_3$-induced centrilobular necrosis when given 24 hr after the toxicant. Although both DMSO and ABT are CYP2E1 inhibitors, recent studies have shown that ABT, but not DMSO, decreases the bioactivation and covalent binding of $CHCl_3$ at this late time. Since DMSO is also known to enhance organ blood flow following ischemia and to have anti-inflammatory effects, these potential mechanisms of protection were compared between the two antidotes. Groups (N=6-9) of male Sprague Dawley rats (250-300 g) received 0.75 ml/kg $CHCl_3$, 20% in corn oil, po, followed 24 hr later by either 2.0 ml/kg DMSO, 30 mg/kg ABT, or saline vehicle, ip. In vivo microscopy was then utilized to examine events occurring within the hepatic sinusoids 4 hr after antidotal treatment. At 28 hr after $CHCl_3$ dosing, the number of sinusoids containing blood flow was decreased by 40%. DMSO, but not ABT, caused a restoration of blood flow to 85% of normal. Only DMSO moderated the 3-fold increase in centrilobular Kupffer cell phagocytic activity caused by $CHCl_3$. $CHCl_3$ intoxication also increased the numbers of leukocytes adhering to sinusoidal walls in the centrilobular region by 10-fold and increased numbers of swollen (i.e., activated) periportal endothelial cells by 4-fold. Both antidotes equally reduced these parameters by 57% and 78%, respectively. The shared effects by DMSO and ABT on these indicators imply that attenuation of developing liver injury was responsible for the observed decreases in the inflammatory response. That DMSO helped maintain sinusoidal blood flow, while ABT did not, indicates this as a potential mechanism of DMSO's protective action. (ES 08414)

894 HEPATOPROTECTION BY DIMETHYL SULFOXIDE AND AMINOBENZOTRIAZOLE WHEN ADMINISTERED 24 HR AFTER CHLOROFORM: ROLE OF INHIBITION OF ONGOING BIOACTIVATION.

R C Lind, C K Begay, and A J Gandolfi. *Department of Anesthesiology, University of Arizona, Tucson, AZ, USA.*

Dimethyl sulfoxide (DMSO) rapidly attenuates developing $CHCl_3$-induced liver injury when given as late as 24 hr after the toxicant. This protection has been duplicated with aminobenzotriazole (ABT). Since both DMSO and ABT inhibit CYP2E1 which is responsible for bioactivating $CHCl_3$ to a reactive intermediate, they were evaluated for their effect on the degree of $CHCl_3$ binding to hepatic protein following their late administration. Male Sprague Dawley rats (300-350 g) received 0.75 ml/kg $CHCl_3$ (30 μCi/kg $^{14}CHCl_3$), 20% in corn oil, po, followed 24 hr later by either 2.0 ml/kg DMSO, 30 mg/kg ABT, or saline vehicle, ip. Groups (N=4) were then killed at 24, 30 and 34 hr after $CHCl_3$ dosing. ^{14}C concentrations in liver, blood, and fat, as well as ^{14}C covalently bound to hepatic protein, were measured. There were no differences in total ^{14}C content of the liver between DMSO and ABT treated animals. Covalent binding to hepatic protein (6.5 nmol/mg protein) remained unchanged from 24 to 34 hr after $CHCl_3$ dosing in the animals that received saline. While DMSO had no effect on this binding, ABT caused a 35% reduction by 34 hr. The normal loss of ^{14}C from fat (1520 to 270 nmol/g fat) that occurred during this time was not significantly affected by DMSO but was inhibited 60% by ABT. Blood ^{14}C concentrations (160 nmol/ml) did not change from 24 to 34 hr and were not significantly affected by DMSO. However, ABT caused a 50% decrease by 34 hr. These studies indicate that at 24 hr after its administration, there was ongoing biotransformation of $CHCl_3$ and covalent binding of reactive intermediates in the liver that may well contribute to lesion development. However, the lack of effect by DMSO on the disposition of $CHCl_3$ and covalent binding in the liver indicates that other beneficial effects may be responsible for its protective action. (ES08414)

895 ROLE OF MDR2 P-GLYCOPROTEIN IN THE CHOLESTASIS MEDIATED BY ESTRADIOL-17β(β-D-GLUCURONIDE) ($E_2$17G) IN ISOLATED PERFUSED MOUSE LIVER.

L Huang and M Vore. *Graduate Center for Toxicology, University of Kentucky, Lexington, KY, USA.*

MDR1 substrates/modulators protect against $E_2$17G-induced cholestasis and $E_2$17G is transported by MDR1. mdr2/MDR3, localized in the canalicular membrane of hepatocytes, translocates phospholipids into bile. Recent studies show that MDR3 contributes to the transport of several MDR1 substrates. The present studies were designed to determine the role of mdr2 in cholestasis mediated by $E_2$17G and its biliary excretion. **Methods**: The single-pass isolated perfused liver from FVB/NJ and mdr2(-/-) mice (5-7 weeks old) was used as a model to monitor bile flow (BF, μl/min/g liver) and biliary concentration of $E_2$17G equivalents following administration of a bolus dose of ^3H $E_2$17G. Bile duct was cannulated and gallbladder was ligated. Values are mean±SE, n=3. **Results**: Liver weights of female control (FC), male control (MC), female mdr2(-/-) (FO) and male mdr2(-/-) (MO) mice were ~ 0.8, 1.1, 1.8, and 1.8 g, respectively. In FC, $E_2$17G (0.6 μmol) decreased BF maximally by 51.6%±5.4% with the peak biliary concentration of $E_2$17G of 5.1±0.3 mM. In FO, $E_2$17G (2 μmol) inhibited BF maximally by only 21.4 %±2.8% ($p<0.05$, vs FC) with the peak $E_2$17G concentration in bile of 1.5±0.02 mM; BF recovered to initial level in 20 min. In MO, $E_2$17G (2 μmol) inhibited BF by 49.7%±7.0% and BF did not recover to initial level. Maximal biliary $E_2$17G concentration (1.7±0.06 mM) in MO was similar to that in FO. BF in MC was inhibited 68.0% ±2.5% by 0.6 μmol $E_2$17G with the peak concentration of 5.5±1.1 mM. Following a noncholestatic dose of $E_2$17G, cummulative excretion over 80 min was 94.7%±1.7%, 68.5%±5.9%, 55.3%±0.9% in MC (0.1 μmol), MO (0.1 μmol), MO (0.2 μmol) with peak $E_2$17G concentrations of 3.1±0.4, 1.1±0.1, 1.7±0.1 mM, respectively. **Conclusions**: FO are resistant to $E_2$17G cholestasis. Maximal concentrations of $E_2$17G achieved in bile are significantly lower ($p<0.05$) in FO and MO than control. These data indicate that mdr2 contributes to $E_2$17G cholestasis and in concentrating $E_2$17G into bile.

896 HEPATOBILIARY DISPOSITION OF ACETAMINOPHEN AND ITS METABOLITES IN MALE CD-1 MICE PRETREATED WITH CLOFIBRATE.

C Chen[1], G Hennig[2], D J McCann[3], and J E Manautou[1]. *Depts.* [1]*Pharmaceutical Sciences and* [2]*Pathobiology, Univ. Connecticut, Storrs, CT, and* [3]*Drug Disposition & Metabolism Dept., Zeneca Pharmaceuticals, Wilmington, DE.*

Mice pretreated with the peroxisome proliferator clofibrate (CFB) are protected against acetaminophen (APAP) toxicity. CFB is also known to induce P-glycoprotein in canalicular membrane of hepatocytes. In this study, we investigated the effect of CFB pretreatment on the biliary excretion of APAP and its metabolites. Male CD-1 mice received 500 mg CFB/kg, daily for 10 days. Controls were given corn oil. After overnight fasting, the common bile duct was cannulated and 1mmol APAP/kg was administered *i.v.* Bile was collected for 180 min, and then analyzed by HPLC. CFB had no effect on bile flow rate, nor did it alter the excretion of APAP or its metabolites. To better understand the mechanism underlying the biliary excretion of APAP and its metabolites, indocyanine green (ICG), a non-metabolizable organic anion that is exclusively excreted into the bile via an ATP-dependent process, was administered *i.v.* to bile duct cannulated mice immediately prior to APAP. ICG (30 μmol/kg) significantly reduced the biliary excretion of APAP-GSH. In conclusion, our studies indicate that CFB dosing does not alter the biliary excretion of APAP or its metabolites, and that biliary excretion of APAP-GSH might be mediated through a canalicular transport protein for organic anions. Further studies are needed to fully elucidate the role of ATP-dependant transport proteins in the biliary disposition of APAP (Supported by a grant from Zeneca Pharmaceuticals.)

897 HEPATOCYTE PLASMA MEMBRANE ATP-DEPENDENT TRANSPORT PROTEIN EXPRESSION FOLLOWING INDUCTION OF HEPATOCELLULAR PROLIFERATION *IN VIVO.*

G Hennig[2], C Chen[1], H Whiteley[2], D J McCann[3] and J E Manautou[1]. *Depts.* [1]*Pharmaceutical Sciences and* [2]*Pathobiology, Univ. Connecticut, Storrs, CT;* [3]*Drug Disposition and Metabolism Dept., Zeneca Pharmaceuticals, Wilmington, DE.*

Chemically-induced mitogenic and compensatory hepatocellular proliferation can result in increased protection to hepatotoxicants. Enhanced expression of liver plasma membrane transport proteins may contribute to this protection. To investigate this, mitogenic proliferation was induced in male CD-1 mice receiving 500 mg clofibrate (CFB)/kg, *i.p.*, for five or ten days; while compensatory proliferation was induced with 350 mg acetaminophen (APAP)/kg, *i.p.* Control mice received vehicle only. Portions of livers were formalin-fixed for immunohistochemical analysis of proliferating cell nuclear antigen (PCNA). Liver plasma membrane fractions were generated by sucrose and percoll density gradients for western blot analysis of the fol-

lowing ATP-dependent transporters: p-glycoprotein (P-gp), multidrug resistant protein-1 (Mrp1) and multidrug resistant protein-2 (Mrp2). Enhanced PCNA staining was evident in both CFB and APAP treatment groups. P-gp expression was increased in CFB treated mice, but not in the APAP group; while Mrp1 expression did not change following either treatment. Interestingly, Mrp2 expression was elevated in both treatment groups. In conclusion, hepatocellular proliferation increases the expression of one or more plasma membrane transporters, which could potentially increase resistance to hepatotoxicants (Supported by grants from Zeneca Pharmaceuticals and PhRMA Foundation.)

898 INVERSE ROLES OF TUMOR NECROSIS FACTOR-α AND NITRIC OXIDE IN ACUTE LIVER INJURY INDUCED BY CARBON TETRACHLORIDE.

L A Morio[1], H Chiu[1], M Marino[2], and D L Laskin[1]. [1]*Joint Graduate Program in Toxicology, Rutgers University and UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ;* [2]*Memorial Sloan-Kettering Cancer Center, New York, NY.*

Our laboratory has been investigating the role of macrophages in chemically-induced hepatotoxicity. In a number of different experimental models, hepatotoxicity is prevented or reduced by pretreatment of animals with the macrophage inhibitor, gadolinium chloride. These findings demonstrate that macrophages play a critical role in the pathogenesis of liver injury. Macrophages are known to release a number of different inflammatory mediators with cytotoxic potential. In the present studies we analyzed the role of two macrophage-derived mediators, tumor necrosis factor-α (TNF-α) and nitric oxide (NO), in liver injury induced by carbon tetrachloride (CCl_4). Treatment of mice with CCl_4 (0.3 ml/kg, i.p.) resulted in a time-dependent induction of centrilobular hepatic necrosis. This was correlated with a dramatic increase in serum transaminase levels. CCl_4 induced hepatotoxicity was associated with increased serum and hepatic TNF-α as well as inducible nitric oxide synthase (NOS II) in the liver. To study the role of TNF-α and NO in hepatotoxicity, we used knockout mice lacking the gene for the 55 kDa TNF-α receptor, TNF-α cytokine, or NOS II. We found that CCl_4 was significantly less effective in inducing hepatotoxicity in mice lacking the p55 TNF-α receptor or the TNF-α cytokine. These mice also expressed less hepatic NOS II. In contrast, CCl_4-induced liver injury was markedly increased in knockout mice lacking the gene for NOS II. This was associated with a dramatic increase in serum TNF-α levels. These data suggest that NO is hepatoprotective in this model system. Moreover, the hepatotoxic effects of TNF-α in CCl_4 induced injury may be mediated in part by the inhibition of NO. (Supported by NIH GM34310, ES06897, and the Burroughs Wellcome Fund.)

899 TOXICITY OF CONCANAVALIN-A AND CADMIUM IN IL-6 GENE KNOCK-OUT MICE.

O Molotkov, M Satoh and C Tohyama. *National Institute for Environmental Studies, Tsukuba, Japan.*

IL-6 is a well-known inducer of hepatic acute phase protein synthesis. Recently we found that the induction of hepatic metallothionein (MT) after partial hepatectomy was considerably decreased in IL-6 gene knock-out (GKO) mice. MT plays important role in protection of liver and kidneys against various chemicals. In the present study toxicity of concanavalin (Con) A and cadmium (Cd) were compared in IL-6 GKO and B6J129Sv (wild-type control) female mice. Con A was injected ip at a dose of 25 mg/kg; Cd was injected sc at a dose of 2 mg/kg, 2 times with a 24 h interval. At 24 h after injection liver, kidneys and blood were collected. MT level in the tissues was measured by MT RIA. Liver and kidney damage was estimated by activities of GPT, GOT, LDH, ALP, and levels of creatinine, BUN in the serum. We found that Con A induced liver injury in both kinds of mice. Nevertheless, GPT, GOT and LDH activities were increased more in the IL-6 GKO mice than in the wild-type mice. The induced hepatic MT level in IL-6 GKO mice was one-half of that in wild-type mice. On the other hand, Cd induced a similar level of MT in the liver and kidney in the both kinds of mice. The present study shows that IL-6 GKO mice are more susceptible to Con A due to decreased MT synthesis.

900 HIGHER EFFICIENCY OF THE PHOSPHORYLATIVE SYSTEM OF DIABETIC GOTO-KAKIZAKI (GK) RATS.

C M Palmeira[1], F M L Ferreira[1], R Seiça[2], K Suzuki[3] and M S Santos[1]. [1]*Department of Zoology, Center for Neurosciences of Coimbra, University of Coimbra, Portugal;* [2]*Faculty of Medicine, Center for Neurosciences of Coimbra, University of Coimbra, Portugal ;* [3]*Department of Medicine, Tohoku Kosei-Nenkin Hospital, Sendai, Japan.* Sponsor: K B Wallace.

Liver mitochondrial bioenergetics of Goto-Kakizaki (GK) rats (a model of non-insulin dependent diabetes mellitus - NIDDM), reveals a mitochondrial membrane potential upon energization with succinate that is significantly increased relative to control animals. The repolarization rate following ADP phosphorylation is also significantly increased in GK mitochondria in parallel with increased ATPase activity. The increase in the repolarization rate and ATPase activity is presumably related to an improved efficiency of F0F1-ATPase, either from a better phosphorylative energy coupling or as consequence of a greater number of catalytic units. Titrations with oligomycin indicate that diabetic GK mitochondria require excess oligomycin pulses to completely abolish phosphorylation relative to control mitochondria. This uggests that mitochondria of diabetic GK rats are provided with extra catalytic units relative to mitochondria of non-diabetic rats.

901 MECHANISM OF INHIBITION OF RAT LIVER CLASS 2 ALDH BY 4-HYDROXYNONENAL.

S W Luckey, R B Tjalkens and D R Petersen. *Molecular Toxicology and Environmental Health Program, Univ. of Colorado Health Sciences Center, Denver, CO, USA.*

4-hydroxy-2-trans-nonenal (4-HNE) is an aldehydic product of lipid peroxidation which produces a diversity of adverse cellular effects. Previous studies from our laboratory have established that 4-HNE is a potent competitive inhibitor (K_i = 0.48 ?M) and, to a lesser extent, a mixed-type inhibitor of acetaldehyde oxidation of the high-affinity form of Class 2 rat liver aldehyde dehydrogenase (ALDH). Because of this complex pattern of enzyme inhibition, experiments were designed to further elucidate the mechanism of 4-HNE inhibition using purified Class 2 rat liver ALDH incubated with or without NAD^+ in the presence of 0 to 250 μM 4-HNE. At all concentrations of 4-HNE evaluated, the activity of ALDH declined most rapidly in the absence of NAD^+, suggesting that the inhibition was not mechanism-based. To assess the reversibility of ALDH inhibition by 4-HNE, experiments were performed with varying concentrations of ALDH and 4-HNE, in the presence or absence of NAD^+. Plots of the data revealed that after 5 minutes of incubation, the inhibition was reversible, however, irreversible inhibition was observed after 120 minutes as evidenced by an increasing *x*-intercept with increasing 4-HNE concentrations. The irreversible nature of ALDH inactivation by 4-HNE adduction was verified to be concentration-dependent through ELISA procedures using antisera produced against 4-HNE adducted proteins. Samples were also processed for quantitation of thiol groups obtained after 2 hours of incubation with 250 μM 4-HNE demonstrating adduction by the loss of over 50% of the sulfhydryl groups. Additionally, increased ALDH-bound carbonyl groups were detected following derivitization with 2,4-dinitrophenylhydrazine (DNPH) and subsequent detection by Western blot analysis using anti-DNPH antisera. The immunoblots demonstrated a concentration-dependent increase in carbonyl formation with 125 μM HNE exhibiting the strongest signal. These data imply that, during the time course studied, a number of nucleophilic amino acid residues in ALDH2 can be alkylated leading to irreversible inactivation. (Supported by AA09300 and AA05536.)

902 TUMOR NECROSIS FACTOR RECEPTOR (TNFR) SIGNALING ON CELLS OF HEMOPOIETIC ORIGIN CONTRIBUTES TO DIMETHYLNITROSAMINE (DMN)-INDUCED HEPATOTOXICITY.

D G Fraser, V R Lappi, M S Rutherford, and L B Schook. *Dept. of Veterinary PathoBiology, U. of Minnesota, St Paul, MN, USA.*

Repeated exposures to low doses of DMN in humans and mice causes a centrilobular necrosis with inflammatory cell infiltration. Studies in this laboratory involving TNFR knockout mice have demonstrated a role for TNF in this pathology. The purpose of this study was to test whether TNFR on cells of hemopoietic origin were contributing to this event. Irradiated wild type mice (TNFR intact) were rescued with 10^7 white blood cells (WBC) from bone marrow from wild type or from TNFR knockout mice lacking type 1

and type 2 receptors (DKO). After 10 weeks the mice receiving DKO bone marrow cells had greater than 90% of the circulating blood cells of DKO genotype. At this time mice were injected i.p. with 5 mg/kg DMN daily for 7 days. Mice were sacrificed on days 1, 3, 4, 5, and 7 six hours after the DMN injection. Counts of WBC were determined and serum ALT, AST, and SDH activities were measured. No significant differences in circulating WBC were observed between these two treatment groups. Serum enzyme activities were greatest on day 4, with decreasing amounts on days 5 and 7. Significant decreases in the maximum serum enzyme activity were measured on day 4 from irradiated mice having DKO donors when compared to TNFR intact mice (in units/L., 195±44 vs. 533±62 for ALT; 214±22 vs. 330±47 for AST; 214±30 vs. 315±37 for SDH). These data suggest that signaling through TNFR on hemopoietic cells contributes to DMN-induced hepatotoxicity. (Supported by NIH grants 5F32 ES05745-02 and ES04348.)

903 EFFECT OF DICLOFENAC ON CELL FUNCTION AND PROTEIN BINDING IN PRECISION-CUT WISTAR RAT, CYNOMOLGOUS MONKEY AND HUMAN LIVER SLICES.

S J Hasal, M A Mehesy, E E Cruz, A B Pollack, J Mangold and A Vickers. *Novartis Institute for Biomedical Research, E. Hanover, NJ.*

Diclofenac, a non-steroidal anti-inflammatory agent, can alter liver cell function which is associated with the binding of diclofenac metabolites to cellular proteins. This study examines the biochemical changes and metabolism of diclofenac in precision-cut liver slices (8 mm diameter, ~250 μm thick) derived from rat, monkey and man. Liver slice viability, as assessed by slice ATP, GSH and potassium content, and LDH leakage, was decreased significantly compared to control slices only after a 48 hr exposure to 350 μM diclofenac. The metabolism and binding of [^{14}C]-diclofenac (30-60 μM) products to cellular proteins was investigated at 2, 24 and 48 hr of culture. Both the rat and monkey liver slices showed a time and dose dependent increase in protein binding of radiolabeled diclofenac products, as measured by non-extractable radioactivity. [^{14}C]-Diclofenac metabolite formation correspondingly increased with culture time, indicating that metabolite formation was necessary for binding. Additionally, dead slices lacked metabolite formation and non-extractable binding of diclofenac products. Separation of both liver slice homogenate and microsomal proteins by 10% polyacrylamide gel electrophoresis followed by imaging on a phosphor screen revealed several distinct radiolabeled protein bands, which increased in intensity with slice culture time. A majority of the proteins binding radiolabeled diclofenac products were in the microsomal fraction. This study has confirmed the association of diclofenac metabolism and cellular protein binding in conjunction with altered cell viability as shown previously with rat hepatocyte cultures. The species similarities and differences of rat, monkey and man will be presented.

904 ROLE OF P4502E1 IN RETINOL'S ATTENUATION OF CARBON TETRACHLORIDE HEPATOTOXICITY IN THE MOUSE.

R E Inder, B J Bray, and R J Rosengren. *University of Otago Medical School, Dunedin, New Zealand.*

Retinol has been shown to attenuate carbon tetrachloride (CCl4)-induced hepatotoxicity in the mouse. To determine the mechanism of this attenuation, we have investigated cytochrome P4502E1 activity. Swiss Webster mice were administered retinol (75 mg/kg/d) or vehicle for 3 days prior to a dose of CCl4 (30 μl/kg i.p.) or corn oil. Hepatotoxicity produced by CCl4 was assessed 24 hours after the CCl4 dose by plasma alanine aminotransferase (ALT) activity (1391 ± 430 vs. 274 ± 92 IU/L for vehicle + CCl4 and retinol + CCl4 treatments respectively, $p < 0.05$). Hepatic microsomes were prepared to assess P4502E1 activity. Aniline hydroxylase activity was significantly reduced in vehicle + CCl4 (5.70 ± 0.75) vs retinol + CCl4 (9.02 ± 1.02, $p < 0.05$) treatments. Results from western blotting demonstrated that P4502E1 immunoreactive protein was 67% lower in vehicle + CCl4 vs retinol + CCl4 treatment groups. Retinol's ability to attenuate CCl4 hepatotoxicity potentiated by acetone (4.8 mg/kg) was also determined. Protection against potentiated hepatotoxicity was also observed in the acetone-nduced group (ALT activity of 2741 ± 1066 vs 247 ± 77 IU/L for vehicle and retinol treatments respectively, $p < 0.05$). In acetone-induced mice, a significant decrease in vehicle + CCl4 vs retinol + CCl4 for aniline hydroxylation was also observed. These results demonstrate that retinol itself does not alter cytochrome P4502E1 activity or polypeptide levels. However, in combination with CCl4, retinol does reduce the amount of CCl4 bioactivated to its toxic metabolite. We conclude that retinol's attenuation of CCl4-induced hepatotoxicity is associated with a decrease in CCl4 bioactivation but not a decrease in P4502E1 activity or polypeptide levels. (Supported by grants from the University of Otago Medical School.)

905 INDOCYANINE GREEN PRETREATMENT DOES NOT ALTER SUSCEPTIBILITY TO ACETAMINOPHEN HEPATOTOXICITY IN MALE CD-1 MICE.

V M Silva[1], G Hennig[2], H Whiteley[2], and J E Manautou[1]. *Depts. [1]Pharmaceutical Sciences and [2]Pathobiology, Univ. Connecticut, Storrs, CT.*

Recent studies showed that the administration of the non-metabolizable organic anion indocyanine green (ICG) significantly reduced the biliary disposition of APAP-GSH in mice, suggesting that this APAP metabolite may compete with other organic anions for excretion into the bile via a canalicular organic anion transporter. This study was conducted to determine if changes in biliary disposition of APAP induced by ICG could lead to alterations in susceptibility to APAP toxicity. To investigate this, groups of overnight fasted male CD-1 mice received 30 μmol ICG/kg, *i.v.*, immediately prior to APAP dosing (600 mg/kg, *i.p.*). Controls were given vehicle. Mice were killed at 4 or 24 hr after APAP dosing for immunochemical detection of APAP protein binding and assessment of liver toxicity, respectively. Hepatocellular necrosis was evident at 24 hr in control mice receiving APAP as determined by sorbitol dehydrogenase activity and histopathology. Pretreatment with ICG did not alter the incidence or severity of hepatocellular necrosis induced by APAP. Furthermore, ICG did not alter APAP-induced glutathione depletion nor selective covalent binding to cytosolic target proteins at 4 hr after dosing. These data indicate that ICG does not change the susceptibility to liver injury produced by high doses of APAP (Supported by a grant from PhRMA Foundation.)

906 EFFECTS OF WEEKLY DAPM EXPOSURES ON LIVER AND LUNG IN FEMALE RATS.

R R Williams, V Santa Cruz, H Liu, T Dugas, and M F Kanz. *Pathology Department, University of Texas Medical Branch, Galveston, TX, USA.*

Background: Humans acutely exposed to methylene dianiline (4,4'-diaminodiphenylmethane, DAPM), a chemical used in the production of polyurethanes and epoxy resins, develop jaundice, toxic hepatitis and cholangitis. But DAPM exposures in the workplace are likely chronic, intermittant and very low. Recent acute studies suggest females are more susceptible to DAPM than males. ***Objective:*** Evaluate once-a-week exposures to a low dose of DAPM in female rats. ***Methods:*** Female Sprague Dawley rats (~250 g) were gavaged with 25 mg/kg of DAPM in 35% ethanol or vehicle once a week for 17 weeks. Animals were sacrificed at 8, 12, and 17 weeks. Tissues and sera were collected for histology and assessment of hepatotoxicity and liver function. Morphometric analysis of blood vessel architecture in lung and liver was performed using Optimas® software. ***Results:*** *8 WEEKS:* DAPM caused prominent eosinophilia in liver and lung with mild fibrosis around bile ducts and proliferation of biliary epithelial cells (BEC). *12 WEEKS:* Liver weights and serum bilirubin were elevated. Bile duct fibrosis and BEC proliferation were more marked, and inflammation increased in lung. *17 WEEKS:* Serum bilirubin and liver weights remained elevated. Increased fibrosis occurred around smaller bile ducts with concentric fibrosis around larger bile ducts. Nests of proliferated BEC extended from larger portal tracts. Minor lung fibrosis was observed. The thickness of arterial walls in both liver and lung were increased. ***Conclusions:*** Female rats exposed to a "non-hepatotoxic" dose of DAPM on a weekly basis show chronic BEC injury and proliferation with mild to moderate lung injury, and a proliferative effect on arterial vasculature. The pathological effects of intermittant, low-dose exposure to DAPM are more severe and involve more tissues in female than male rats. (Supported by ES 06348 and T32 ES07254.)

907 INCREASES IN ENTEROCYTE GLUTATHIONE AND ALKALINE PHOSPHATASE AS POTENITAL ADAPTIVE RESPONSES TO DICLOFENAC-INDUCED ENTEROPATHY.

B K Shipp[1], C R Atchison[2], L Kaphalia[2], S Abdel-Rahman[1], and M T Moslen[2]. *Departments of [1]Preventive Medicine and Community Health and [2]Experimental Pathology, The University of Texas Medical Branch at Galveston, TX, USA.*

Background: Our laboratory is currently investigating the mechanism of small intestinal (SI) ulcerogenesis following administration of the non-steroidal anti-inflammatory drug diclofenac (Voltaren®). In a rat model of diclofenac-induced enteropathy, we have found that the treatment interval affects the enteropathy of 10 mg/kg, the recommended dose for rodents.

Specifically, two-thirds fewer SI ulcers are observed when the drug is given at 24 hr versus 12 hr intervals. **Objective:** Determine if potentially adaptive biochemical changes can be detected in enterocytes at 24 hr versus 12 hr following diclofenac treatment. **Experimental Design:** Fed adult male Sprague-Dawley rats were treated with either 0 or 50 mg/kg diclofenac via oral gavage. At 12 and 24 hours after diclofenac treatment, enterocytes were isolated from each quintile of the SI and assayed for glutathione (GSH) content and alkaline phosphatase (ALP) activity. **Results:** Consistent with the known heterogeneity of the SI, both GSH content and ALP activity decreased progressively from the 1st to 5th quintiles of the SI with levels in the 5th quintile being 15% and 1% of the 1st quintile, respectively. Diclofenac treatment produced time-dependent increases in both GSH content and ALP activity. Most notably at 24 hr, ALP activity rose by 67% in the 1st quintile, while GSH levels were markedly elevated by 600% in the 3rd and 4th quintiles, which are most vulnerable to ulceration. **Conclusions:** Our observations of GSH and ALP increases in the SI by 24 hr after diclofenac treatment are consistent with an adaptive response in this target tissue. This response may explain why diclofenac is better tolerated at 24 hr versus 12 hr intervals in our rat model. Increased brush border ALP activity could exert a beneficial effect through its ability to detoxify bacterial endotoxin to a biologically inactive form. Higher enterocyte levels of the nucleophile GSH could facilitate the detoxification of electrophilic metabolites of diclofenac or enhance protection against oxidative insults mediated by an inflammatory response to either diclofenac or permeating endotoxin. (Supported by NIH DK 34806, NIH T32E507254, and Brown Family Foundation.)

908 CLONING AND EXPRESSION OF THREE HUMAN INTESTINAL UDP-GLUCURONOSYLTRANSFERASES (UGTs):1A5, 1A8 AND 1A10.

Z Cheng[1], A Radominska-Pandya[2], and T R Tephly[1]. [1]*Dept. of Pharmacology, Univ. Iowa, Iowa City, IA;* [2]*Dept. Biochemistry and Molecular Biology, Univ. Arkansas for Medical Sciences, Little Rock, AR.*

Although the liver has been considered as the most important organ involved in glucuronidation, recent studies have shown that the gastrointestinal tract plays a much greater role than previously thought in the metabolism of xenobiotics. We have identified three UGT isoforms of human intestinal mucosa which are absent in liver using reverse transcriptase-polymerase chain reaction (RT-PCR) technique. mRNAs of UGT1A8 and 1A10 were found in both small intestine and colon, whereas the transcript of UGT1A5 was identified only in jejunum and ileum but not in 25 other human tissues screened, including colon. Full-length cDNAs for UGT1A5, 1A8 and 1A10 were amplified from ileal RNA by RT-PCR and inserted into the mammalian expression vector pcDNA3. Membrane preparations of HK293 cells stably expressing UGT1A5, UGT1A8 or UGT1A10 were obtained and the expression of each isoform was observed by western blot analysis. Stably expressed UGT1A8 and 1A10 catalyzed glucuronidation of catechol estrogens, coumarins, flavonoids, anthraquinones and phenolic compounds. Unlike UGT1A10, UGT1A8 also catalyzed the glucuronidation of certain opioids, bile acids, fatty acids and drugs, such as ciprofibrate, clofibrate, valproic acid, furosemide and diflunisal. However, glucuronidation activity has not been detected for stably expressed UGT1A5. These studies show that human intestinal UGTs may play an important first step in the detoxification of xenobiotic compounds and, in some cases, limit the bioavailability of therapeutic agents. (This research was supported by NIH Grant GM26221 (TRT) and DK49715 (AP-R).)

909 DO DICLOFENAC PROTEIN ADDUCTS PLAY A CAUSAL ROLE IN SMALL INTESTINAL ULCEROGENESIS?

C R Atchison[2], A B West[1], A Balakumaran[1], D H Daiker[1], J F Aronson[1], L R Pohl[2] and M T Moslen[1]. [1]*Department of Pathology, The University of Texas Medical Branch at Galveston, TX;* [2]*Laboratory of Molecular Immunology, NIH, Bethesda, MD.*

Background: Diclofenac, a NSAID used worldwide for the treatment of arthritis, produces liver injury occasionally and more frequently GI tract damage. Mechanisms responsible for the toxicity of this drug are not well understood and could involve the bioactivation of diclofenac to a reactive acyl glucuronide which forms potentially injurious diclofenac protein adducts (Dcf-pA). **Objective**: Explore the hypothesis that Dcf-pA have a causal relationship to intestinal ulceration by determining if Dcf-pA precede morphological and biochemical characteristics of small intestinal ulceration. **Experimental Design**: Male fed Sprague-Dawley rats were administered diclofenac by a physiological oral gavage route at doses of 0 or 50 mg/kg. Blood, liver and other tissues were collected at 0.5, 1, 3, 6, 12, 24 or 48 hr. GI tracts were grossly inspected for number of ulcers; area of ulceration was measured by image analysis; intestinal leakage was estimated by serum protein levels. Immunohistochemistry was performed using polyclonal antisera against diclofenac adducted proteins. **Results**: Ulcers were evident in the small intestine at 6 hr and were chiefly located in the quintiles 2 to 4. No ulcers were evident in the stomach or colon. Area of intestinal ulceration increased in a time dependent manner from 6 to 24 hr concurrent with progressive declines in serum protein levels. Dcf-pA were first observed in the cytoplasm of small intestinal enterocytes at 1 hour; by 6 hr adduct localization shifted to enterocyte brush borders. Sites of intestinal ulceration were associated with intense Dcf-pA staining. Semiquantitative immunohistochemistry for Dcf-pA in intestinal rings at 3 hr showed greatest intensity in quintiles with ulcers. **Conclusions**: Key observations consistent with a causal role for Dcf-pA in ulceration were: first, that Dcf-pA formation within enterocytes preceded the formation of intestinal ulcers and second, that Dcf-pA were most intense I the ulcer-prone intestinal quintiles. 910 EFFECT OF INTERMITTENT EXPOSURES OF AFLATOXIN B_1 ON HEPATIC AND TESTICULAR GLUTATHIONE S-TRANSFERASE IN RATS.

S C Sahu[1], M W Chou[2], R E Sotomayor[1] and D M Hinton[1]. [1]*CFSAN and* [2]*NCTR, Food and Drug Administration, Washington, DC.*

Glutathione S-transferase (GST) plays a major role in the detoxification of the potent hepatocarcinogen aflatoxin B_1 (AFB_1). Since AFB_1 is an inducer of hepatic GST, the quantitation of this enzyme is an important biomarker in AFB_1 activation. The induction of GST activity has been studied in animals treated with a single exposure or continuous exposure of AFB_1; however, the induction of hepatic GST activity by intermittent exposure of AFB_1 has not yet been investigated. Also little is known about the effects of AFB_1 on testicular GST activity. Male Fischer 344 rats were fed diets containing AFB_1 (0, 0.01, 0.04, 0.4 and 1.6 ppm) inter- mittently at 4-week intervals up to 20 weeks. The control animals were fed an AFB_1-free NIH-31 diet. Rats consuming diets with low AFB_1 concentrations did not show the induction of hepatic or testicular GST activity. Intermittent exposures at high concentrations of AFB_1 significantly increased the GST activi- ties. The increase of the enzyme activity was proportional to the dose and length of AFB_1 exposure.

911 SODIUM ARSENITE INDUCES CYTOKERATIN EXPRESSION IN WRL-68 CELL LINE.

M E Gonsebatt and P Ramírez. *Instituto de Investigaciones Biomedicas, UNAM, D.F., Mexico.* Sponsor: C Rios.

Intermediate filaments (IF) constitute an important superfamily of genes that form part of the cytoskeleton. Among the type I and type II IF proteins are the keratins, which are broadly expressed in epithelial cells. It is now clear that a major function of skin keratins is to impart mechanical integrity to cells, but there are still many questions to be answered with regards to the role cytokeratins play in other epithelial tissues. Altered expression of these proteins have been observed in liver after exposures to carcinogens like aflatoxin B1 and in some disorders like hepatic cirrhosis. Liver cancer and cirrhosis have been associated to chronic exposure to arsenic by drinking water. We investigated the effects of sodium arsenite on cytokeratins expression in WRL-68 cells, a human hepatic cell line of epithelial origin, that maintains enzymatic activities of liver cells. Non-proliferating cells were treated during 16 hs with different concentrations of sodium arsenite (10^{-5} to 10^{-9} M). Fluorescent immunostaining using Pancytokeratin polyclonal and cytokeratin 18 monoclonal antibodies showed heavier staining in cytoplasm and in the nuclear envelope of treated cells that obscured the delicate net-like pattern observed in controls. Also, increased amounts of protein were detected in total protein westernblotts. This increased expression could represent a mechanism to compensate impairments in the polymeric association of cytokeratins because of the presence of the metalloid and could help to explain the keratin changes observed in skin epithelial cells by arsenic poisoning. (This work was partially supported by PAPIIT IN207196.)

912 CADMIUM PRETREATMENT PROTECTS METALLOTHIONEIN-NULL MICE AGAINST TESTICULAR TOXICITY BUT NOT HEPATOTOXICITY.

S S M Habeebu, J Liu, Y P Liu, and C D Klaassen. *Univ Kansas Med Ctr, Kansas City, KS.*

Low dose cadmium (Cd) pretreatment has been shown to protect animals against subsequent toxic and lethal doses of Cd. This protection is thought to be due to induction of intracellular metallothionein (MT), but Cd pretreatment alters a host of other defense mechanisms in animals. To define conclusively the role of MT in Cd-induced self-tolerance, control and MT-I/II null mice were pretreated with 2 or 5 μmol Cd/kg sc daily for two days, followed by 10, 20, or 30 μmol Cd/kg ip 24 hrs later. Cd toxicity was determined 24 hrs later. Cd-induced lethality was 0%, 11% and 44% after 10, 20 and 30 μmol Cd/kg, respectively, in control mice. In MT-null mice lethality was 0%, 40% and 100% after 10, 20 and 30 μmol Cd/kg, respectively. Cd pretreatment eliminated lethality after these doses of Cd in both control and MT-null mice. Pretreatment with Cd protected against hepatotoxicity in control mice. In contrast, Cd pretreatment enhanced hepatotoxicity in MT-null mice. For example, Cd pretreatment increased ALT from 600 to 1650 U/L after 15 μmol Cd/kg. Pretreatment provided protection in control mice against Cd-induced testicular injury, and surprisingly, it also provided similar protection in MT-null mice. This study demonstrates that (i) MT plays a major role in Cd-induced tolerance to Cd-induced hepatotoxicity, and (ii) MT is not responsible for Cd-induced protection against Cd-induced testicular injury. (Supported by NIH grants ES-01142 and ES-07079.)

913 INHIBITION OF CONJUGATION AS A TARGET FOR ACETAMINOPHEN (APAP) TOXICITY IN CULTURED HUMAN HEPATOCYTES.

V E Kostrubsky[1], J F Sinclair[3], K Dorko[1], J E Esplen[1], D Beer-Stolz[2], S G Wood[3], P R Sinclair[3], S A Wrighton[4] and S C Strom[1]. [1]*Depts. Path. &* [2]*Cell Biol., Univ. Pittsburgh Med. Ctr., Pittsburgh, PA, USA;* [3]*VA Med.Ctr., WRJ, VT & Depts. of Biochem. & Pharmacol/Toxicol, DMS, Hanover, NH, USA;* [4]*Lilly Res. Laboratories, Indianapolis, IN, USA.*

Simultaneous exposure to phenobarbital (PB) and acetaminophen (APAP) caused toxicity in cultured human hepatocytes prepared from different donors, as measured by inhibition of protein synthesis and reduction of MTT. A 6 hr exposure to the combination of APAP and PB was associated with complete disappearance of glycogen, enlargement of endoplasmic reticulum and blebbing of mitochondria membranes, as demonstrated by electron microscopy. Pretreatment with 2 mM PB (48 h) did not increase APAP toxicity unless PB was readded with APAP. PB decreased APAP-glucuronide and APAP-sulfate formation by 85% and 50%, respectively. Salicylamide and 7-hydroxycoumarin, substrates of sulfation and glucuronidation, also increased APAP toxicity when added with APAP. There was no correlation between toxicity and binding of radiolabeled APAP to cellular proteins. The amount of APAP bound to protein was similar following treatment with APAP alone or in combinations with PB or salicilamide. PB and salicylamide each delayed the metabolism of 7-hydroxycoumarin, suggesting an interference with conjugation. These data suggest that compromising conjugation of APAP, particularly glucuronidation, by simultaneous administration of APAP and other drugs may result in hepatotoxicity. This work was supported in part by the Dept. of Veterans Affairs and the Anatomical Gift Foundation.

914 SUSPENSIONS OF FRESHLY ISOLATED RAT HEPATOCYTES GENERATE HIGH LEVELS OF NITRIC OXIDE.

F A Nicholls-Grzemski, M A Tirmenstein, and M W Fariss. *College of Pharmacy, Washington State University, Pullman, WA, USA.*

Nitric oxide (NO) is a reactive radical and intracellular/intercellular messenger. NO can induce numerous biochemical alterations in hepatocytes including inhibition of protein synthesis, mitochondrial respiration and CYP450 activities. In addition, NO can act as an antioxidant by scavenging reactive oxygen species and inhibiting lipid peroxidation. We investigated NO production in freshly isolated rat hepatocyte suspensions. Hepatocytes were isolated by standard collagenase perfusion techniques and incubated in modified Waymouths media at 37ûC for 6 hours. Extracellular nitrite levels (a breakdown product of NO) were measured by a fluorimetric assay. The level of extracellular nitrite remained at basal levels (<0.2 nmole/10^6 cells) for approx. 3 hours post-isolation, which was followed by a rapid increase in nitrite formation reaching 5 to 10 nmole/10^6 cells by 6 hours, constituting an up to 100-fold increase in nitrite level. The formation of nitrite was blocked by the nitric oxide synthase (NOS) inhibitors, N-methyl arginine or aminoguanidine. The nitrite burst was also inhibited by a nontoxic concentration of the protein synthesis inhibitor, cycloheximide. Collectively, these findings suggest that hepatocytes in suspension produce high levels of NO and that the inducible form of NOS may be involved. The NO production by hepatocyte suspensions was also inhibited by thiol depleting agents including diethylmaleate, ethylmethane sulphonate and N-ethylmaleimide, and the absence of extracellular calcium. In addition, antioxidants such as trolox and deferoxamine, were shown to both delay and attenuate nitrite production suggesting a relationship between the formation of reactive oxygen species and nitrite. These results provide the first evidence of marked NO production by rat hepatocyte suspensions that may have important implications for both mechanistic and metabolic studies conducted with this model system. (This work was supported by NIEHS/NIH grant # R01ES 05452.)

915 VALPROIC ACID HEPATOTOXICITY AND PROTECTION BY GLYCINE.

C-P Siegers, M Deters[1], L Hildebrandt and R Pentz. *Institute of Toxicology, Medical University of Lübeck, Germany;* [1]*Institute of Pharmacology and Toxicology, University of Rostock, Germany.*

The anticonvulsant drug valproic acid (VPA) is metabolized via the cytochrome P450-dependent pathway to a hepatotoxic compound 4-ene-VPA. Glycine, on the other hand, potentiates the action of anticonvulsant drugs in rats (Neuropharmacology 29, 399, 1990). Our group showed that glycine protected the isolated perfused rat liver against the damage induced by several hepatotoxic agents (Toxicology 128, 63-72, 1998). Therefore we questioned whether glycine was able to antagonize the VPA-induced hepatotoxic response in a human cell line (HepG2) and in the isolated perfused rat liver. As a measure of cytotoxicity the neutralred uptake and the release of LDH into the medium were tested. Glycine (12 mmol/l) completely protected HepG2 cells against the hepatotoxic response to VPA (4 mmol/l). The same concentration of VPA (4 mmol/l) was toxic to the isolated perfused liver of fasted rats (enzyme release of GPT, LDH and GLDH into the perfusate). Addition of glycine (12 mmol/l) to the perfusate counteracted the VPA induced enzyme release and increase of liver weight. Moreover, we studied the effect of glycine on the metabolism of VPA to the hepatotoxic intermediate, which is under current investigation.

916 TOXICITY OF ACRYLATES IN COMBINATION - INVESTIGATIONS IN HUMAN CELL CULTURES AND THE ISOLATED PERFUSED RAT LIVER.

C-P Siegers, J Freudenstein[1], M Tegtmeier[1] and O Strubelt. *Institute of Toxicology, Medical University of Lübeck, Germany;* [1]*Schaper & Brümmer, Salzgitter-Ringelheim, Germany.*

A review of the toxicological and ecotoxicological profile of 16 different acrylate and methacrylate compounds was published recently (Greim et al., Chemosphere 31, 2637-2659, 1995). Some of these compounds are common excipients in pharmaceutical preparations serving at least two different functions. In accordance with actual Pharmacopoeia polyacrylates may contain small amounts of the highly reactive monomeric acrylates. The question arose whether these monomeric acrylates in the matrix of coated tablets might be responsible for or at least contribute to hepatotoxic effects of these drug preparations. 5 different commercially available substances (acrylic acid esters, methacrylic acid esters) were tested for their toxicity as monomers or as a mixture in 3 different cell lines (liver: HepG2, kidney: LLC-MK_2, intestine: I-407) as well as in the isolated perfused rat liver. As a measure of cytotoxicity the neutral-red uptake and the LDH-release into the medium were tested. The acrylate-mixture was more toxic in the kidney cells (IC_{50} 210 mg/l) than in hepatoma (IC_{50} 310 mg/l) and intestinal cells (IC_{50} 700 mg/l). In the isolated perfused rat liver the mixture was hepatotoxic at a concentration of 320 mg/l (enzyme release of GPT, LDH and GLDH into the perfusate). Moreover, a strong depletion of hepatic reduced glutathione and an increase of lipid peroxidation (MDA in liver tissue and perfusate) was observed. Conjugation with glutathione (GSH) seems to be the major pathway of metabolic detoxification of acrylates and methacrylates.

917 COCAINE-PROTEIN ADDUCTS IN MOUSE LIVER: COMPARISON OF DETECTION BY RADIOCHEMICAL AND IMMUNOCHEMICAL METHODS.

F M Ndikum-Moffor and S M Roberts. *Center for Environmental & Human Toxicology, University of Florida, Gainesville, FL, USA.*

Covalent binding of reactive metabolites to proteins has been proposed as mechanism of cocaine-induced hepatotoxicity. In this study, detection of cocaine-protein adducts by immunochemical and radiochemical methods was compared. ICR male mice were dosed with ^{14}C-labeled or unlabeled cocaine (60 mg/kg, i.p.). Livers were removed and fractionated, and the proteins in homogenate and fractions were separated by SDS-PAGE. For detection of radiolabeled cocaine-protein adducts by fluorography, gels were dried and exposed to x-ray film. Immunochemical detection of cocaine-protein adducts utilized an anti-cocaine antibody and Western blots. Results showed adducts present only in the microsomes and mitochondria, with the former accounting for most of the binding. Fluorography revealed binding to proteins with pls between 4-6 and approximate molecular masses of 25-33, 40, 44-60, and 100 kDa. Western blotting found cocaine binding to proteins with similar masses. Sequence analysis identified two of the target proteins (64 and 70-80 kDa) detected by Western blotting as hsp60 and transferrin. As has been observed previously, pretreatment of mice with the hepatic enzyme inducing agents phenobarbital or beta-naphthoflavone resulted in a shift in the intralobular site of the lesion – toward the portal triad in the case of phenobarbital pretreatment, and toward the central vein in the case of beta-naphthoflavone pretreatment. Western blots using 1-D SDS-PAGE gels suggest that the same proteins are adducted in induced and uninduced mice. Insight into the role of each adducted protein in cocaine hepatotoxicity may come from determining the effect of adduction on protein function. Supported by DA-06601.

918 CYTOPROTECTION FROM THIOACETAMIDE-INDUCED LIVER INJURY ASSOCIATED WITH HEAT SHOCK PROTEIN INDUCTION.

J K Tolson and S M Roberts. *Center for Environmental and Human Toxicology, University of Florida, Gainesville, FL.*

Increased expression of the heat shock proteins (hsps) is a highly conserved response to cellular stress in both eukaryotic and prokaryotic cells. Elevated levels of hsps provide cytoprotection from many of the stressors that induce hsps. Thioacetamide is a model hepatotoxicant that causes both necrotic and apoptotic liver injury. In order to study the effects of hsp induction on thioacetamide-induced liver injury, male ICR mice were made hyperthermic with either thermal (42.5°C for 30 min) or amphetamine (15 mg/kg i.p.) treatment with a resulting transient elevation of hepatic hsps. Mice were subsequently challenged with thioacetamide (70 mg/kg i.p.). Serum aminotransferase (ALT) activities were measured and compared to controls without hsp induction 3, 6, 12, 24, and 48 hours after thioacetamide treatment. The thermal or amphetamine pretreated animals were protected from thioacetamide-induced hepatotoxicity as evidenced by significantly lower serum ALT levels. Histological examination revealed marked necrotic and apoptotic injury surrounding the central veins of thioacetamide-treated animals, which was attenuated by pretreatment with either hsp induction regimen. Western blot analysis of livers from mice treated with thioacetamide alone showed strong induction of hsp70i and hsp25, weak induction of hsp32 and hsp90, and no induction of hsp60. Immunohistochemical staining of liver slices using anti-hsp70i or anti-hsp25 antibody showed strong immunostaining in areas corresponding to regions of hepatocellular injury. Thioacetamide appears to cause strong induction of at least two hsps, and these hsps may afford protection against thioacetamide cytotoxicity. (Supported by ES-07213.)

919 ENHANCED BIOACTIVATION AND IMPAIRED TISSUE REPAIR IN THIOACETAMIDE HEPATOTOXICITY IN DIABETIC RATS.

T Wang[1], M J J Ronis[2] and H M Mehendale[1]. [1]*Division of Toxicology and Louisiana Institute of Toxicology, College of Pharmacy, Northeast Louisiana University Health Sciences Center, Monroe, LA, USA;* [2]*Department of Pediatrics, University of Arkansas for Medical Sciences and Arkansas Children's Hospital Research Institute, Little Rock, AR, USA.*

Previously we reported that a sublethal dose of TA (300 mg/kg, ip) caused 90% lethality in streptozotocin-induced diabetic rats. Further studies suggested that the increased lethality of TA in diabetic rats was due to dual effects of enhanced TA liver injury and impaired liver cell proliferation and tissue repair. Diabetes and Diet restriction are known to induce CYP 2E1 and Phase I bioactivation may play a role in the enhanced TA liver injury. Work in our laboratory also showed increased TA liver injury in diet restricted rats. Therefore, the objective of present study was to test our hypothesis that increased TA hepatotoxicity in diabetic rats might be due to enhanced TA bioactivation. Specific aims were: **(a)** test the effect of isoniazid, a CYP 2E1 inducer, on TA liver injury; **(b)** study change of CYP 2E1 expression in the diabetic rats; **(c)** investigate if and how this change affects TA bioactivation; **(d)** quantitate TA sulfoxide, a proximate reactive metabolite, formed from diabetic and control microsomes by HPLC. Male Sprague-Dawley rats were pretreated with STZ (60 mg/kg, ip), isoniazid (200 mg/kg, ip) or saline (1 ml/kg, ip). TA (300 mg/kg, ip) was injected 10 days after STZ and saline treatment or 18 hr after isoniazid pretreatment. Liver injury was measured by plasma alanine aminotransferase (ALT) at 0-36 hr after TA injection. ALT activities increased and reached peak at 24 hr in all three groups (STZ > isoniazid > saline). Western blot analysis revealed that CYP 2E1 was increased 8- and 2.5-fold in STZ and isoniazid pretreated rats compared to the control, respectively. CYP 2E1 activity as assessed by *p*-nitrophenol hydroxylase assay was increased 5- and 2-fold in diabetic and isoniazid groups compared to the control. Collectively, these studies suggest that CYP 2E1 may be responsible for the increased TA liver injury in diabetes. Ongoing studies are aimed to investigate whether flavin monooxygenase (FMO) system is involved in the mechanism-driven increase in liver injury of TA in diabetes. (Supported by Louisiana Board of Regents Support Fund.)

920 CHRONIC ENTERAL ETHANOL CAUSES TRANDUCTION OF ADENO-ASSOCIATED VIRUS IN THE LIVER.

M D Wheeler[1], H Kono[1], D McCarty[2], R J Samulski[2], and R G Thurman[1]. [1]*Laboratory of Hepatobiology and Toxicology and* [2]*Gene Therapy Center, University of North Carolina, Chapel Hill, NC, USA.*

The transduction of adeno-associated virus (AAV) in the liver has been extensively studied using DNA damaging agents such as etopiside, hydroxyurea, or UV-irradiation. Also, helper adenovirus has been useful in AAV transduction in the liver. The precise mechanism by which these agents cause *in vivo* transduction is unknown but most likely involves an increase in DNA synthesis and repair. Ethanol is known to induce mild liver damage, leading to an increase in DNA repair and synthesis *in vivo*. Therefore, it was hypothesized that chronic delivery of ethanol would increase AAV transduction *in vivo*. To test this idea, recombinant AAV ($1x10^{10}$ particles) encoding the β -galactosidase reporter gene under a cytomegalovirus promoter (rAAV-CMV*lacZ*) was given to ~250 g male Wistar rats by tail vein injection. Rats then received either ethanol diet (12.5 g/kg/day) via the Tsukamoto- French enteral-feeding protocol or high-fat control diet for three weeks. This enteral ethanol feeding model induces steatosis, inflammation, and mild necrosis within the liver after three weeks. Pathology scores (0.4 ± 0.2 vs. 3.75 ± 0.2) and serum aspartate trans-aminase levels (36.2 ± 3.5 vs. 132.3 ± 11.0) were measured in control and ethanol-treated animals. The expression and activity of *lacZ* in the liver was measured by Western blotting and enzymatic cleavage of the substrate 2-nitrophenyl-β -D-galactopyranoside, respectively. Both expression and activity of *lacZ* was increased nearly 4-fold over values in high-fat controls by chronic exposure to ethanol. Interestingly, *lacZ* activity correlated (r^2=0.91) with liver injury measured both by pathology score and serum transamimase levels. These results support the hypothesis that chronic ethanol treatment increases AAV transduction *in vivo*. Thus, ethanol may be a useful tool in AAV gene therapy rather than more harmful and damaging transducing agents. Additionally, alcoholic liver disease is an attractive target for adeno-associated viral gene therapy, since excessive consuption of ethanol could be used to increase expression of therapeutic genes (e.g., superoxide dismutase).

921 INHIBITION OF FAS-RECEPTOR (CD95)-INDUCED CASPASE ACTIVATION AND APOPTOSIS BY ACETAMINOPHEN IN MOUSE LIVER.

H Jaeschke and J A Lawson. *Pharmacia & Upjohn, Inc., Kalamazoo, MI, USA.*

The mechanism of liver cell injury induced by an overdose of the analgesic acetaminophen (AAP) remains controversial. Recently, it was hypothesized that a significant number of hepatocytes die by apoptosis. Since caspases have been implicated as critical signal and effector proteases in apoptosis, we investigated their potential role in the pathophysiology of AAP-induced liver injury. Male C3Heb/FeJ mice were fasted overnight and then treated with 500 mg/kg AAP. Liver injury became apparent at 4 hr and was more severe at 6 hr (plasma ALT: 4110 ± 320 U/L; centrilobular necrosis). DNA

fragmentation increased parallel to the increase of plasma ALT values. At 6 hr there was a 420% increase of DNA fragmentation and a 74-fold increase of TUNEL-positive cells located predominantly around central veins. However, the activity of the proapoptotic caspase-3 was not increased at any time after AAP. In contrast, injection of the anti-Fas antibody Jo-2 (positive control) caused a 28-fold increase of caspase-3 activity and severe DNA fragmentation before significant ALT release. Treatment with the caspase inhibitor ZVAD-CHF_2 had no effect on AAP toxicity but completely prevented Jo-mediated apoptosis. In contrast, Jo-induced caspase activation and apoptosis could be inhibited by AAP treatment in a time- and dose-dependent manner. We conclude that AAP-induced DNA fragmentation does not involve caspases suggesting a direct Ca^{2+}-dependent activation of endonucleases. In addition, electrophilic metabolites of AAP may inactivate caspases or their activation pathway. Thus, AAP metabolism has the potential to inhibit signal transduction mechanisms of receptor-mediated apoptosis.

922 EFFECTS OF ACUTE ALCOHOL EXPOSURE ON HEPATIC PARTITIONING OF CARBON TETRACHLORIDE: AN ADDITIONAL MECHANISM FOR ALCOHOL-MEDIATED POTENTIATION.

J K Stanton[1], Y M Sey[2], and J E Simmons[2]. [1]*UNC-CH School of Public Health, Chapel Hill, NC, USA; Benchmark Environmental Corporation, White Rock, NM, USA;* [2]*US EPA, NHEERL, Research Triangle Park, NC, USA.*

Possible mechanisms underlying isopropanol and ethanol potentiation of carbon tetrachloride (CCl_4) hepatotoxicity were investigated in male Fischer-344 rats (67-77 days old). In separate experiments, animals were dosed with isopropanol (0, 2.5, 5, 10 or 20 mmol/kg, p.o.) or ethanol (0, 5, 10, 20 or 40 mmol/kg, p.o.) in aqueous solutions. Eighteen hours later, animals were either terminated to determine the effects of alcohol alone or dosed with CCl_4 (0.0 or 0.5 mmol/kg in 10 percent Alkamuls solution, p.o.). Termination of alcohol plus CCl_4 animals occurred 24 hours post CCl_4 exposure. No increases in aspartate aminotransferase (AST), alanine aminotransferase (ALT), lactate dehydrogenase (LDH) and sorbitol dehydrogenase (SDH) activities were seen for either alcohol alone. Relative to CCl_4 alone, significant increases in AST, ALT, LDH and SDH were observed at all isopropanol dosages examined and only the two highest ethanol dosages. Isopropanol alone increased CYP2E1 activity beginning at 5 mmol/kg. The isopropanol dosage eliciting peak AST, ALT, LDH and SDH levels following isopropanol and CCl_4 exposure did not correspond with the dosage eliciting peak CYP2E1 induction. Two dosages of isopropanol resulted in similar CYP2E1 increases, but differed greatly in their potentiation of CCl_4 hepatotoxicity. Ethanol alone did not induce CYP2E1 activity. A dose-related increase in liver:blood CCl_4 partitioning was observed following exposure to isopropanol alone, but not to ethanol alone. In conclusion, it appears that CYP2E1 induction is not the sole mechanism responsible for acute alcohol potentiation of CCl_4 hepatotoxicity. The data from this study suggest both CYP2E1 induction and alteration of hepatic CCl_4 partitioning as mechanisms of acute isopropanol potentiation of CCl_4 hepatotoxicity. In contrast, neither appears to be involved in acute ethanol potentiation of CCl_4 hepatotoxicity, implying that another, as yet unidentified, mechanism is involved. (This research was funded by the US DOE, Industrial Hygiene Graduate Fellowship Program, administered by Oak Ridge Institute for Science and Education. This abstract may not reflect US DOE or US EPA policy.)

923 ANTIOXIDANT AND ANTIHEPATOTOXIC ACTIVITIES OF PRENYLATED FLAVONOIDS FROM HOPS.

R J Rodriguez[1], C L Miranda[2], S Kingkeohoi[1], J F Stevens[3], M L Deinzer[3] and D R Buhler[2]. [1]*College of Pharmacy;* [2]*Department of Environmental and Molecular Toxicology; and* [3]*Department of Chemistry, Oregon State University, Corvallis, OR.*

Eleven flavonoids (chalcones and flavanones) from hops were examined for their antioxidant and antihepatotoxic effects in vitro. The prenylated chalcones [xanthohumol (XN), 2',4',6'4'-OH-3'-prenylchalone(TP), dehydrocycloxanthohumol hydrate (DH), prenylxanthohumol (PX) and xanthogalenol (XG)] were more effective than the flavanones [isoxanthohumol (IX), 6-prenylnaringenin (6PN) and 8-prenylnaringenin (8PN)] in inhibiting lipid peroxidation induced by iron-ascorbate in rat liver microsomes. The non-prenylated chalcone, chalconaringenin (CN), had the same inhibitory activity as XN. XN, but not IX, inhibited tert-butylhydroperoxide(TBH)-induced lipid peroxidation in rat liver microsomes. XN, XG and CN, at 5, 10 and 25 (M, were effective in inhibiting lipid peroxidation induced by iron-ascorbate in rat liver mitochondria. At 5 and 10 (M, XN and PX protected cultured rat hepatocytes from the toxicity of TBH. Other chalcones (TP, DH and XG), with similar antioxidant activities as XN, were not hepatoprotective. These results indicate that prenylated chalcones are more effective antioxidants than the prenylated flavanones; however, the antioxidant activity of the chalcones (with or without prenyl groups) may not be predictive of their ability to protect the liver from injury caused by toxicants that induce lipid peroxidation. (Supported by the Hop Research Council and NIEHS grants ES00210 and ES03850.)

924 PROTECTION BY ZINC AGAINST ACUTE ETHANOL HEPATOTOXICITY AND ITS RELATION TO METALLOTHIONEIN PRODUCTION.

C J Chen, H-Y Wu, and Y J Kang. *Division of Gastroenterology/Hepatology, Department of Medicine, University of Louisville, KY, USA.*

Recent studies have shown that oxidative stress is critically involved in alcoholic liver injury. Metallothionein (MT), a low molecular weight and cysteine-rich protein, plays an important role in protection against oxidative injury in multiple organs including the liver. This study was undertaken to determine whether induction of MT in the liver by zinc, a potent MT inducer, can protect the liver from acute ethanol toxicity. Mice (24-30g) were randomly assigned into the control and Zn-treated groups (n=20 in each group). Animals in Zn-treatment group were given $ZnCl_2$ in a dose of 10 mg/kg via ip 24 hr prior to ethanol administration, and saline was given to the controls. A half of the animals in each group were then treated with ethanol by ip in a dose of 5g/kg. The animals were sacrificed 20 hrs after ethanol treatment. Serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) activities were examined as indicators of liver injury. Liver pathological changes, lipid peroxidation and MT concentrations were also measured. The results showed that Zn significantly increased liver MT concentrations. Serum ALT and AST activities were markedly elevated by ethanol, but were significantly lower in the Zn-pretreated than in the saline-pretreated mice. Ethanol-induced pathological changes and lipid peroxidation in the liver were also significantly depressed in the Zn-pretreated mice. It is therefore possible that MT functions in hepatic protection against ethanol-induced oxidative injury.

925 DOSE RESPONSE OF ETHANOL IN RELATION TO THE ANTIOXIDANT DEFENSE SYSTEM OF THE LIVER, LUNG, AND KIDNEY IN RATS.

R B Scott, K Husain, K S Reddy, L P Rybak, and S M Somani. *Southern Illinois University School of Medicine/Departments of Pharmacology and Surgery, Springfield, IL, USA.*

This study investigated the alterations in levels of glutathione, lipid peroxidation, and antioxidant enzyme activity in the liver, lung, and kidney of rats treated with acute doses of alcohol. Male Fisher-344 rats were randomly divided into groups, and were treated as follows: 1) vehicle (saline) control; 2) ethanol 2 g/kg, p.o.; 3) ethanol 4g/kg, p.o.; and 4) ethanol 6 g/kg, p.o. The most significant changes in the antioxidant system were observed following 6 g/kg treatment. Ethanol administration resulted in a depletion of GSH levels (70% of control) and SOD activity (70% of control) in the liver, a increase of GSH levels (158% of control) in the kidney, an elevation of GSH-Px activity and lipid peroxidation levels in the lung (151% and 124% of control respectively) and kidney (141% and 134% respectively), and a decrease of GR activity in the lung (89% of control) and kidney (83% of control). These results showed that the antioxidant system was influenced by ethanol administration in a tissue specific manner. The degree of oxidative stress on these antioxidant systems was proportional to the amount of alcohol administered. (Supported by the American Heart Association, IL Affiliate Grant #9708751A.)

926 TIME COURSE RESPONSE OF ETHANOL ON ANTIOXIDANT DEFENSE SYSTEM OF BRAIN, HEART AND LIVER OF RAT.

K S Reddy, R B Scott and S M Somani. *Department of Pharmacology, Southern Illinois University School of Medicine, Springfield, IL,USA.*

This study was undertaken to determine the effect of acute ethanol dose on time response of antioxidant defense system in brain, heart and liver of rat. Male Fisher 344 rats were administered ethanol 4g/kg p.o. and sacrificed at 1.5; 2.0; 4.0 and 6.0 hr. The SOD activity was significantly decreased in brain at 1.5; 2.0 and 4.0 hr(84%,80% and 82% of control), in heart at 2.0 and

6.0 hr (83% and 82% of control) and in liver at 4.0 and 6.0 hr(78% and 66% of control) respectively. CAT activity was significantly low in brain and heart , where as it was elevated in liver. GSH-Px activity decreased significantly at 1.5 and 4.0 hr, but increased at 6.0 hr in brain and a significant increase at 6.0 hr in heart. The liver GSH-Px activity showed a consistent increase from 1.5 to 4.0 hrs(145%,153%, and 154% of control). GR activity exhibited a significant decrease in heart at all time points. In liver GSH and GSSG values are decreased significantly at 4.0 and 6.0 hr. MDA, the marker of lipid peroxidation increased significantly at 1.5; 4.0 and 6.0 hr (123%,123% and 131% of control) in heart and at 6.0 hr(124% of control) in liver. The AOE ratios are significantly altered during the time course study in all tissues. This study suggests that the altered activity of AOE reflects the oxidative stress of ethanol in a time dependent manner for a specific tissue (Supported by American Heart Association, IL Affiliate Grant #9708751A.)

927 PERIPHERALLY ADMINISTERED SODIUM AZIDE STRONGLY BUT VARIABLY INHIBITS BRAIN CYTOCHROME OXIDASE ACTIVITY IN RATS.

A Cada and F Gonzalez-Lima. *Department of Psychology, University of Texas at Austin, Austin, TX, USA.* Sponsor: W Slikker.

Sodium azide is a specific inhibitor of cytochrome oxidase (C.O.) activity, which is the terminal enzyme in the respiratory chain that allows cells to use oxygen. In the present study we investigated the metabolic effects in brain of systemically administered sodium azide on the brain of male Sprague-Dawley rats. Osmotic minipumps subcutaneously delivered sodium azide at 400 μ g/hr for 14 days. Fresh-frozen sections (40 μ m) were stained for C.O. activity. Sodium azide was found to significantly decrease gray matter activity in all imaged areas (73 regions with a range of decreases between control and azide-treated of 14-53%). The average brain C.O. activity for the control group was 212 μ mol/min/g tissue wet weight and 144 for the azide-treated group resulting in a treatment-induced decrease of 32.32% across all analyzed regions. Thalamo-striatal projection areas exhibited the largest overall decreases in C.O. activity. The parafasicular thalamic nucleus, subthalamic nucleus, and rostral and caudal caudate-putamen all showed relative decreases of 45-53%. The caudate-putamen and thalamus, along with the cerebellum and visual structures, have been implicated in visuospatial motor integration (Lalonde, 1997), which has been shown to be consistently dysfunctional with chronic sodium azide administration (Bennett and Rose, 1998). The pattern of behaviors seen in this model parallel Balint's syndrome, a disorder affecting orchestration of oculomotor and frontostriate circuits often diagnosed in humans before the onset of Alzheimer's disease.

928 A COMPARATIVE STUDY OF A TYPICAL ANTIPSHYCHOTIC DRUG HALOPERIDOL AND AN ATYPICAL ANTIPSYCHOTIC OLANZAPINE IN AMELIORATING OXIDATIVE STRESS.

V Mahapatra and H P Misra. *Virginia-Maryland Regional College of Veterinary Medicine. Virginia Tech, Blacksburg, VA, USA.*

Haloperidol, a typical anti-psychotic drug, is used for the treatment of schizophrenia and other psychotic diseases. Its use is however limited because of the severe extrapyramidal side effects. The atypical antipsychotics, such as olanzapine, have not been associated with extrapyramidal symptoms. Because oxidative stress has been suggested as a causative factor of schizophrenia, we investigated the different oxidative profiles of these drugs. Interestingly, we found that both haloperidol and olanzapine are effective hydroxyl radical scavengers. In hydroxyl radical-dependent deoxyribose degradation assay, olanzapine was found to be more efficient in scavenging hydroxyl radicals than haloperidol. Thus, as little as 0.5mM olanzapine inhibited deoxyribose degradation by 50 percent whereas 1mM of haloperidol was required to inhibit deoxyribose degradation by just 30 percent. Because iron was used to generate hydroxyl radicals in a Fenton's type reaction, we studied the chelating ability of these drugs. In fluorescence studies, using calcein as a fluorescent probe, neither haloperidol nor olanzapine were found to chelate iron. In lipid peroxidation assay, 10μM of haloperidol was found to cause a 100 percent increase in lipid peroxidation relative to the controls, whereas olanzapine up to 0.5mM had trivial effects. These data indicate that the antipsychotic effects of both drugs may, at least in part, be due to their ability to scavenge hydroxyl radicals; and oxidative stress, as evidenced by the lipid peroxidation caused by haloperidol may, in part, be responsible for the extrapyramidal side-effects.

929 DOSE DEPENDENT PROTECTION BY LIPOATE AGAINST CISPLATIN-INDUCED OTOTOXICITY IN RATS: ANTIOXIDANT DEFENSE SYSTEM.

S M Somani[1], K Husain[1], C Whitworth[2] and L P Rybak[2]. *Departments of [1]Pharmacology and [2]Surgery, Southern Illinois University, School of Medicine, Springfield, IL, USA.*

This study investigated the alterations in auditory brainstem evoked responses (ABRs) with the changes in the cochlear antioxidant defense system in cisplatin-induced ototoxicity and dose dependent otoprotection by lipoic acid. Male Wistar rats were divided into different groups and were treated as follows: 1) vehicle (saline) control; 2) cisplatin (16 mg/kg, i.p.); 3) lipoate (100 mg/kg, i.p.) plus saline; 4) cisplatin plus lipoate (25 mg/kg); 5) cisplatin plus lipoate (50 mg/kg), and 6) cisplatin plus -lipoate(100 mg/kg). Post-treatment ABRs were performed after three days and the rats were sacrificed, cochleae harvested, and analyzed. The cisplatin injected rats showed ABR threshold elevations above the pretreatment thresholds. Rats treated with lipoate plus cisplatin did not show significant elevation of hearing threshold. Cisplatin administration resulted in a depletion of cochlear GSH concentration, superoxide dismutase (SOD), catalase (CAT), GSH-peroxidase (GSH-Px), and GSH-reductase (GR) activities (69%, 57%, 78%, 59% and 58% of control), respectively, and an increase in malondialdehyde (MDA) concentration (196% of control). Cochlear SOD, CAT, GSH-Px and GR activities, GSH and MDA concentrations were restored in the rats injected with cisplatin plus graded doses of lipoate, compared to cisplatin alone. The data suggest that cisplatin-induced ototoxicity is related to impairment of cochlear antioxidant defence system. The dose dependent otoprotection conferred by an antioxidant lipoate against cisplatin ototoxicity is associated with sparing of the cochlear antioxidant defense system. (Supported by NIH,R01DC0239602.)

930 EXAMINATION OF HYDROGEN PEROXIDE FORMATION IN COCHLEAR OUTER HAIR CELLS AND SUPPORT CELLS USING 2',7'- DICHLOROFLUORESCIN DIACETATE.

W J Clerici[1], L Yang[1] , and R R Hicks[2]. *Departments of [1]Surgery and [2]Clinical Sciences, University of Kentucky College of Medicine, Lexington, KY, USA.*

The cochlea has been shown to participate in reactive oxygen species (ROS) generation following various ototoxicant administrations. Exposure of isolated cochlear outer hair cells (OHCs) to direct ROS generating systems leads to cytoplasmic blebbing, shortening and calcium disequilibrium; instillation of these generating systems into the cochlea alters auditory function. To see whether OHCs might participate in ROS generation, this study examined the abilities of OHCs and Deiters' support cells to convert the superoxide anion (O_2^-) to hydrogen peroxide (H_2O_2). Cells were isolated in a 600 μ l chamber of artificial perilymph mounted on an inverted fluorescent microscope with videomicrography/ image analysis capabilities. 2',7'-dichlorofluorescin diacetate (DCF-DA, 100 μ M), a fluorescent marker for H_2O_2, was superfused, followed by a direct O_2^- generating system which included xanthine (100 μ M) and xanthine oxidase (8.0 mM). O_2^- production was spectrophotometrically confirmed by following cytochrome *c* reduction at 550 nm. Cell images were captured at 1 min intervals using excitation and emission wavelengths of 488 and 530 nm, respectively. OHCs fluoresced robustly on O_2^- generating system administration, prior to observable morphological changes. Fluorescence intensity exceeded that of control OHCs in which the O_2^- generating system or DCF-DA was omitted, or, superoxide dismutase (50,000 U/l) was included. Deiters' cells fluoresced more intensely during O_2^- generating system exposure than did control cells or similarly treated OHCs. These results suggest that OHCs can participate in cochlear ROS generation under conditions which lead to morphological and functional changes, but that the more numerous support cells may contribute more to total cochlear ROS generation.

931 EXAMINATION OF THE ANTIOXIDANT PROPERTIES OF TEA IN SMOKERS AND NONSMOKERS.

Y Xu, L M Kamendulis, C Han, J Chen, C M Heiser, M Gordon, E R Mohler and J E Klaunig. *Division of Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

Tea has been shown to exhibit chemopreventive activity against chemically induced carcinogenesis in rodent species. This chemopreventive activity appears to be based, in part, on the antioxidant properties of tea. In contrast to animal and in vitro investigations, no evidence of the antioxidant proper-

ties of tea in humans has been described. Oxidative stress has been implicated as a causative or participating factor in several human diseases including cancer, neurodegenerative diseases, and heart disease. Increased oxidative stress and oxidative damage have been associated with certain lifestyle behaviors, including smoking. The present investigation was performed to determine if tea consumption reduced oxidative stress in humans. Smokers and non-smokers were given tea or placebo for up to a week in duration. Blood and urine samples were taken before and after tea drinking. Biomarkers of oxidative stress including urine and WBC oh8dG and MDA, plasma antioxidants and reactive oxygen radicals (ROS) were analyzed. Basal levels of oh8dG and MDA (WBC and urine) and ROS were higher in smokers than in non-smokers. In most individuals, tea consumption resulted in a decrease in oxidative damage with this effect being more pronounced in smokers. While tea consumption increased the plasma total antioxidant capability, no changes in individual antioxidants were observed. Tea also reduced ROS. These results confirm that smoking increases oxidative stress and that tea functions as an antioxidant in humans.

932 LIPID PEROXIDATION AND ANTIOXIDANT STATUS IN LUNGS AFTER GRADED SMOKE INHALATION IN SHEEP.

M A Dubick, M Park, B S Jordan, R L Villarreal, L C Cancio and C W Goodwin. *U S Army Institute of Surgical Research, San Antonio, TX.* Sponsor: V Castranova.

In our efforts to elucidate the mechanisms associated with smoke inhalation injury, the present study investigated evidence for lipid peroxidation and the antioxidant status in sheep lungs after graded exposure to smoke. Adult, male sheep (n=4-5/gp) were anesthetized and received 0, 5, 10 or 16 units of a 1:1 mixture of cooled Western bark (fir and pine) smoke and 100% O_2 through an orotracheal tube. Sheep were euthanitized 48 hr after smoke exposure and lung samples from left and right apical, middle and diaphramatic lobes were analyzed for thiobarbituric acid reactive substances (TBARS), antioxidant capacity, glutathione (GSH) concentrations and myeloperoxidase (MPO) activity. Smoke inhalation induced a dose-dependent 3-fold increase in TBARS (16±2 to 48±3 nmol/g; $p<0.05$) and a 30% decrease in antioxidant capacity (8.5±0.5 to 5.8±0.6 μmol/g; $p<0.05$) in the severe smoke group than in controls. Lung GSH concentrations were not significantly different from controls in the mild or moderate smoke groups, but were about 30% lower in the severe smoke group than in controls. MPO activity tended to be higher in all smoked groups than controls, but statistical significance ($p<0.05$) was achieved only in the sheep that received 16 units of smoke. These data support the hypothesis that oxygen radical mechanisms are associated with smoke inhalation injury and that leukocyte sequestration into lung may be an important component.

933 THE STRESS RESPONSE OF CULTURED CELLS INDUCED BY AQUEOUS EXTRACTS OF CIGARETTE SMOKE (CS) CAN BE MIMICKED BY THE COMBINED ACTION OF CS-RELATED ALDEHYDES AND PEROXYNITRITE.

T Mueller and S Gebel. *INBIFO – Institut fuer biologische Forschung, Koeln, Germany.* Sponsor: R A Carchman.

Previous studies[1] have identified peroxynitrite ($ONOO^-$) as a possible stress gene- (*e.g.*, c-*fos*) inducing compound formed by O_2^-• and NO• in phosphate-buffered saline solutions (PBS) bubbled with CS ('smoke-bubbled PBS'). However, these studies can not explain the discrepancy between the calculated maximum concentration of ~ 15 μ M $ONOO^-$ that forms in 0.045 puffs/ml smoke-bubbled PBS and the concentration of ~ 500 μ M that is required to elicit a detectable c-*fos* response in cultured 3T3 fibroblasts when synthetic peroxynitrite is used. Here we demonstrate that CS-related aldehydes - a mixture of formaldehyde, acetaldehyde, and acrolein at the concentrations calculated to appear in smoke-bubbled PBS - in combination with as little as 20 m M $ONOO^-$ are sufficient to mimic the stress-specific c-*fos* response seen with smoke-bubbled PBS, although these aldehydes are incapable of inducing c-*fos* by themselves. Mechanistic investigations revealed that: (i) CS-related aldehydes lower the intracellular glutathion (GSH) content in much the same way as smoke-bubbled PBS, and (ii) 3T3 cells artificially depleted of GSH by pretreatment with BSO require significantly lower amounts of smoke-bubbled PBS to produce a detectable c-*fos* expression, whereas (iii) *N*-acetyl-cysteine is an efficient inhibitor of CS-induced c-*fos* response. Therefore, we conclude, that lowering the intracellular GSH content with these aldehydes may allow $ONOO^-$ to interfere with critical components that feed into stress signal transduction resulting in the expression of c-*fos*. (Sponsored by Philip Morris USA). [1] Müller et al. (1997) Carcinogenesis, **18**, 295-301.

934 DOSE DEPENDENT PROTECTION BY LIPOIC ACID AGAINST CISPLATIN-INDUCED NEPHROTOXICITY IN RATS: ANTIOXIDANT DEFENSE SYSTEM.

K Husain[1], C Whitworth[2], L P Rybak[2], and S M Somani[1]. *Departments of [1]Pharmacology and [2]Surgery, Southern Illinois University, School of Medicine, Springfield, IL, USA.*

This study elucidated the role of antioxidant defense system in cisplatin-induced nephrotoxicity and dose dependent nephroprotection by an antioxidant lipoate. Male Wistar rats were divided into different groups and were treated as follows: 1) vehicle (saline) control; 2) cisplatin (16 mg/kg, i.p.); 3) lipoate (100 mg/kg, i.p.) plus saline; 4) cisplatin plus lipoate (25 mg/kg); 5) cisplatin plus lipoate (50 mg/kg), and 6) cisplatin plus lipoate(100 mg/kg). The rats were sacrificed three days post-treatment, blood and kidneys were isolated and analyzed. The cisplatin injected rats showed elevation of plasma creatinine (677% of control) which significantly decreased by lipoate in a dose dependent manner. Cisplatin administration resulted in a depletion of renal GSH, increased GSSG concentrations and decreased GSH/GSSG ratio (62%, 166% and 62% of control) which were restored by lipoate pretreatment. Cisplatin significantly decreased superoxide dismutase (SOD), catalase (CAT), GSH-peroxidase (GSH-Px), and GSH-reductase (GR) activities (62%, 75%, 62% and 80% of control), respectively, and an increase in malondialdehyde (MDA) concentration (204% of control). Renal SOD, CAT, GSH-Px and GR activities, and MDA concentrations were restored in the rats injected with cisplatin plus graded doses of lipoate, compared to cisplatin alone. The data suggest that cisplatin-induced nephrotoxicity is related to depletion of renal antioxidant defense system, enhanced lipid peroxidation and plasma creatinine concentrations . The dose dependent nephroprotection conferred by an antioxidant lipoate against cisplatin-induced nephrotoxicity is associated with sparing of the renal antioxidant defense system, reduction of plasma creatinine, renal platinum concentration and lipid peroxidation. (Supported by NIH,R01DC0239602.)

935 THE ROLE OF PIRFENIDONE IN SCAVENGING HYDROXYL RADICALS.

H P Misra and C L Rabideau. *Virginia-Maryland Regional College of Veterinary Medicine, Blacksburg, VA, USA.*

Pirfenidone (Deskar; PF), a broad-spectrum anti-fibrotic agent, is known to offer protection against bleomycin-induced lung fibrosis in hamsters. Because reactive oxygen species (ROS) are thought to be involved in these events, we investigated the mechanism(s) by which PF reduces oxidative stress. PF was found to be ineffective as a superoxide radical scavenger in cytochrome c reduction and epinephrine oxidation assays. In deoxyribose degradation assay, PF was found to be a potent scavenger of hydroxyl radicals with a rate constant of 5.39 e6/M/s . EPR spectroscopy, in combination with spin trapping techniques, was performed to verify the ability of PF to scavenge hydroxyl radicals. In a Fenton reaction, utilizing DMPO as a spin trapping agent, PF was found to scavenge hydroxyl radicals in a dose-dependent manner. The concentration of PF required to inhibit 49% signal height was found to be approximately 10 mM. PF was also found to inhibit NADPH-dependent lipid peroxidation in sheep liver microsomes in a dose-dependent manner. The concentration of PF required to cause 57% inhibition of lipid peroxidation was approximately 6mM. In an assay utilizing the fluorescent probe, calcein, it was concluded that PF does not chelate free iron in solution. This is of importance since the above assays used iron dependent systems to generate ROS. Based upon the above findings, we conclude that PF ameliorates oxidative tissue injury by scavenging hydroxyl radicals.

936 TOTAL OXIDANT SCAVENGING CAPACITY OF ANTIOXIDANTS TOWARD PEROXYNITRITE AND HYDROXYL AND PEROXYL RADICALS.

F Regoli[1] and G W Winston[2]. *[1]Istituto di Biologia e Genetica, Universiti di Ancona, Ancona, Italy; [2]Department of Toxicology, North Carolina State University, Raleigh, NC, USA.*

Cellular balance between oxidant challenge and antioxidant response is complex because antioxidants exhibit marked differences in their capacities to scavenge different oxidants. We used the Total Oxidant Scavenging Capacity (TOSC) assay, developed in our laboratory (Free Rad. Biol. Med., 24: 480, 1998), to quantify the ability of benchmark antioxidants to scavenge 3 potent oxidants. 3-Morpholinosydnonimine (SIN-1), the iron/ascorbate-driven Fenton reaction, and thermal homolysis of 2,2'-azo-*bis*- amidinopropane (ABAP) were used to generate, respectively peroxynitrite (PXN),

hydroxyl radicals (· OH), and peroxyl radicals (ROO·). After normalizing controls to yield equivalent time courses of ethylene production from α -keto-γ -methiolbutyric acid (KMBA), the endpoint of the TOSC assay, with the 3 oxidant-generating systems, antioxidants were compared for their abilities to compete for oxidants with KMBA. Glutathione (GSH) was ca. an order of magnitude more effective as a scavenger of ROO· than of PXN or · OH, which were similarly absorbed by GSH. Uric acid was a potent scavenger of PXN and ROO· ; the efficiency toward these oxidants was >10-times that toward · OH. The water-soluble vitamin E analog, Trolox®, most potently absorbed ROO· , followed by PXN and · OH. The TOSC of 3 benchmark · OH scavenging agents, showed mannitol, benzoic acid and dimethylsulfoxide (DMSO) to be at least 10 times more potent as scavengers of · OH. Mannitol and benzoic acid, but not DMSO scavenged ROO· . The results indicate the need to characterize chemicals and biological samples toward different oxidants when evaluating their antioxidant potential.

937 EFFECT OF ENCAPSULATED SUPEROXIDE DISMUTASE (SOD) AND NITRIC OXIDE SYNTHASE (NOS) INHIBITORS ON ACETAMINOPHEN HEPATOTOXICITY IN MICE.

J A Hinson, S L Pike, N R Pumford, M R Niesman, and P R Mayeux. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Acetaminophen (APAP) induced liver toxicity is believed to be mediated by CYP450 metabolism to N-acetyl-*p*-benzoquinone imine which covalently binds to proteins. We recently reported that a toxic dose APAP produced protein adducts and nitrated tyrosine residues in centrilobular cells. Tyrosine nitration occurs by reaction of tyrosine with peroxynitrite (PN), generated from nitric oxide (NO·) and superoxide (O_2^-). Kupffer cells are important in their formation. We have investigated the effect of SOD and NOS inhibitors on APAP hepatotoxicity in mice as determined by increases in serum alanine aminotransferase (ALT) levels (IU/L). APAP (300 mg/kg) plus liposomes increased serum ALT from 21 ± 3 (control; mean±SE) to 3418 ± 1200 at 4 hrs in mice (n=5 /group). APAP plus liposome encapsulated SOD had ALT levels of 102 ± 10. Serum levels (μM) of NO_2 + NO_3 (from NO·) increased from 30 ± 2 in control to 59 ± 8 in APAP plus liposomes and further to 88 ± 13 in APAP plus SOD. The effects of the nontoxic iNOS inhibitors L-NIL (3 mg/kg, 2 doses) at -0.5hr and +1.0hr and AG (aminoguanidine; 15 mg/kg, 2 doses) at 0.5hr and 2.0hr, and the nontoxic nonselective NOS inhibitor L-NMMA (30 mg/kg, 2 doses) at -0.5hr and +1.0hr on APAP hepatotoxicity were examined. APAP (300 mg/kg) increased ALT to 3225 ± 891 at 4 hrs. L-NIL plus APAP increased ALT to 6040 ± 1185. AG plus APAP increased ALT to 6470 ± 2005. L-NMMA plus APAP increased ALT to 6709 ± 1185. Thus, relative formation of O_2· and NO· are important determinants of toxicity.

938 PEROXYNITRITE SCAVENGING ACTIVITY OF NITRIC OXIDE SYNTHASE (NOS) INHIBITORS.

L M Walker and P R Mayeux. *University of Arkansas for Medical Sciences, Little Rock, AR, USA.*

NO and superoxide can combine to generate peroxynitrite, a potent and versatile oxidant that can attack a wide range of biological targets. To examine the relative roles of NO and peroxynitrite in biology, specificity of inhibitors must be determined. Peroxynitrite-mediated protein tyrosine nitration was used as a measure of peroxynitrite activity to examine the ability of NOS inhibitors to also scavenge peroxynitrite. We tested the inducible NOS inhibitors 2-amino-5,6-hydro-6-methyl-4H-1,3-thiazine (AMT), aminoguanidine (AG), and L-N-1-iminoethyl -lysine (LNIL), the non-selective NOS inhibitor L-N-monomethyl -arginine (LMMA), the NO scavenger [2(4-carboxyphenyl-4,4,5,5-tetramethylimidazoline oxyl-3-oxide) (CPTIO) and the iron chelator/peroxynitrite scavenger deferoxamine (DFO) for their abilities to inhibit nitration of bovine serum albumin (BSA) by peroxynitrite. Peroxynitrite (1mM) was added to a solution of BSA (2mg/ml) in 500mM phosphate buffer (pH 7.4) at 37°C. After 5 min absorbance was measured at 430nm, (E=4500$M^{-1}cm^{-1}$) for nitrotyrosine). Untreated BSA contained 0.7±0.6 nmol/mg. Peroxynitrite treatment produced 19±1 nmol/mg. Inhibitors were preincubated with BSA at 0.1mM, 1mM and 10mM. Of the iNOS inhibitors tested, only AG inhibited nitration (39±5% at 10mM; n=3). LMMA and CPTIO were not inhibitory at any concentration. DFO was a potent inhibitor even at 0.1mM (68±8%; n=3). These data indicate that the protective effects of AG, and the iron chelator DFO in NO-mediated biology may be due in part to their ability to scavenge peroxynitrite.

939 INACTIVATION AND HEME ALTERATION OF RECOMBINANT NEURONAL NITRIC OXIDE SYNTHASE BY GUANABENZ.

S Jianmongkol, D Demady, and Y Osawa. *Department of Pharmacology, The University of Michigan, Ann Arbor, MI, USA.*

Guanabenz, an antihypertensive drug, is an active site-directed metabolism-based inactivator of rat brain and penile nitric oxide synthase (NOS). The inactivation of NOS is concomitant to a decrease in immunodetectable NOS protein *in vivo*. To better understand these *in vivo* effects, we examined the mechanism of inactivation, with the use of recombinant neuronal NOS protein obtained by baculovirus-mediated expression in Sf9 cells. The kinetics of inactivation were followed by measuring rates of nitric oxide-mediated conversion of oxyhemoglobin to methemoglobin. *In vitro* studies with the use of a cytosolic fraction from Sf9 cells overexpressing neuronal NOS, the inactivation was found to depend on NADPH, time and concentration of guanabenz, similarly to that found for the native enzyme. The inactivation could be described by a pseudo-first order rate constant (k_{inact}) and an apparent dissociation constant (K_i) of 0.027 min^{-1} and 1.2 μ *M*, respectively. The inactivation of NOS activity in the presence of cytosol involved the alteration of the prosthetic heme group of NOS. The presence of L-arginine protected NOS from the loss of activity and alteration of heme. Interestingly, purified preparations of neuronal NOS were less sensitive to guanabenz inactivation and heme loss. The characterization of the mechanism of inactivation *in vitro* will likely lead to a better understanding of the regulation of NOS *in vivo*. This may be of importance as NO has a variety of biological roles and the inactivation of NOS may explain the toxicological effects of some chemicals. (Supported by NIH grant ES08365. YO is a recipient of the Burroughs Wellcome New Investigator Award in Toxicology.)

940 INDUCIBLE NITRIC OXIDE SYNTHASE KNOCKOUT MICE ARE LESS SUSCEPTIBLE TO THE TOXIC EFFECTS OF ACETAMINOPHEN THAN WILD TYPE MICE.

S L Pike, N R Pumford, P R Mayeux, and J A Hinson. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Metabolism of acetaminophen (APAP) by CYP450 to N-acetyl-*p*-benzoquinone imine and covalent binding to proteins is the accepted mechanism of hepatotoxicity. We recently reported that a toxic dose APAP produced APAP-protein adducts and nitrotyrosine protein adducts in the hepatic centrilobular cells of mice. This product is formed by nitration of tyrosine by peroxynitrite (PN). PN is formed by reaction of nitric oxide (NO·) with superoxide. Also, we recently showed that the Kupffer cells inhibitors gadolinium chloride and dextran sulfate decrease APAP hepatotoxicity and hepatic nitrotyrosine protein adducts. In this work we show that APAP is less toxic in mice lacking inducible nitric oxide synthase (iNOS) (C57BL/6-$Nos2^{tm1Lau}$). APAP (300 mg/kg) administration to wild type male mice (n=4) resulted in significant hepatotoxicity by 4hrs, increase in serum alanine aminotransferase (ALT). ALT levels (IU/L) were 3389 ± 766 at 4 hrs, 8954 ± 654 at 6 hrs, and 7354 ± 963 at 8 hrs. In the iNOS knockout mice ALT levels were 1838 ± 432 at 4 hrs, 4021 ± 960 at 6 hrs, and 2824 ± 1011 at 8 hrs (saline =8 ± 2). ALT levels were significantly less in the APAP treated iNOS knockout mice at each time point than the wild type. APAP treatment did not cause serum levels of NO_2 + NO_3 (from NO·) to increase in the iNOS knockout mice. In the wild type serum levels of NO_2 + NO_3 (μM) were 53 ± 2 in saline treated controls. APAP treatment of mice produced significant increases to 70 ± 2 at 2 hrs, to 96 ± 5 at 4 hrs, and to 168 ± 27 at 6 hrs. At 8 hrs the levels were 49 ± 8. Thus toxic doses of APAP lead to increased synthesis of NO· from iNOS and NO· is important in APAP hepatotoxicity.

941 MICE LACKING INDUCIBLE NITRIC OXIDE SYNTHASE ARE PROTECTED FROM OZONE-INDUCED LUNG INJURY.

L Fakhrzadeh, J D Laskin, and D L Laskin. *Joint Graduate Program in Toxicology, Rutgers University, Piscataway, NJ.*

Ozone is a highly reactive oxidant present in photochemical smog. Inhalation of ozone causes epithelial cell necrosis and Type II cell hyperplasia and proliferation. This is associated with an accumulation of macrophages in the lower lungs. We have previously shown that these cells contribute to ozone induced tissue injury. Macrophages are known to release a number of mediators with cytotoxic potential. One mediator of particular interest is nitric oxide which is produced in macrophages in response to inflammatory stimuli via an inducible form of nitric oxide synthase (NOSII). To study the role of nitric oxide in ozone induced tissue injury we used

knockout mice lacking the gene for NOSII. Treatment of wild type control mice with ozone (0.8-1 ppm) for 3 hr resulted in a time dependent increase in protein in bronchoalveolar lavage fluid (BAL) reaching a maximum 24-48 hr after exposure. Alveolar macrophages isolated from animals treated with ozone were found to produce increased amounts of nitric oxide. This was correlated with induction of NOSII protein and mRNA which was identified in macrophages *in situ* in histologic sections and in isolated cells. Alveolar macrophages from ozone exposed animals also produced increased amounts of peroxynitrite which was associated with nitrotyrosine staining in the lungs, a marker of peroxynitrite induced tissue injury. In contrast to cells from wild type control mice, alveolar macrophages from NOSII knockout mice did not produce nitric oxide or peroxynitrite even after ozone treatment of the animals. Moreover, these mice were protected from ozone induced tissue injury, as evidenced by the finding that BAL protein levels were at control levels. In addition, there was no evidence of peroxynitrite mediated injury in these animals. Taken together these data demonstrate that nitric oxide produced via NOSII plays a critical role in ozone induced tissue injury. (Supported by NIH grants ES04738, ES06897 and the Burroughs Wellcome Fund.)

942 KINETICS OF NITRIC OXIDE INHIBITION IN SINGLE CELLS MEASURED USING A SELF-REFERENCING NITRIC OXIDE SENSOR.

B Billack[1], J D Laskin [2], D M Porterfield[3], P J Smith[3], R P Malchow[4] and D E Heck[1]. [1]*Rutgers University and* [2]*UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, USA;* [3]*Marine Biological Laboratory, Woods Hole, MA, USA and* [4]*University of Illinois, Chicago, IL, USA.*

Nitric oxide produced by macrophages is known to be critical in mediating toxicity induced by a variety of chemicals including acetaminophen, carbon tetrachloride, inhaled ozone and asbestos. In macrophages this reactive nitrogen intermediate is produced via the high output cytokine-inducible form of nitric oxide synthase (NOS2). Although the production of nitric oxide has been quantified using measurements of the stable oxidation products nitrite and nitrate, direct real time measurements of nitric oxide flux from single cells have not been reported. Using a novel self-referencing nitric oxide sensor we found that single cells or clumps of RAW 264.7 macrophages readily release nitric oxide following stimulation with gamma-interferon. Release of nitric oxide could be detected at distances up to 10-20 microns from single cells and remained constant for up to 3 hours, even when cells were examined in serum-free medium. Nitric oxide flux was dependent on the presence of L-arginine in the cell culture medium and was completely removed by oxy-hemoglobin. The nitric oxide synthase inhibitor L-arginine methyl ester (L-NAME, 1 mM) suppressed nitric oxide production within 7 min, an effect that was rapidly reversed. Taken together our data indicate that measurement of nitric oxide release can be obtained using single isolated cells. In addition, the inhibitory action of L-NAME is reversible and the cells do not sequester the drug. (Supported by NIH grants ES 03647, ES 06897 and RR 01395.)

943 ELUCIDATION OF SUPEROXIDE DISMUTASE (SOD1) COPPER LOADING WITH LYS7 FROM *S. CEREVISIAE*.

P J Schmidt, J Strain, T Hamma, and V C Culotta. *Johns Hopkins University School of Public Health, Baltimore, MD, USA.*

Superoxide dismutase 1 (SOD1) is a cytosolic protein that functions in cellular antioxidant defense. This enzyme catalyzes the dismutation of superoxide radical (O_2^-) to hydrogen peroxide (H_2O_2) and oxygen (O_2). For proper activity and function, SOD1 requires a copper chaperone, either yeast LYS7 or its human homologue CCS, to deliver copper to the enzyme. LYS7 is a small, soluble protein containing a single consensus metal binding sequence MT/HCXXC. Studies are currently underway to characterize the LYS7 gene product, and to ascertain the manner in which LYS7 controls copper incorporation into SOD1. It has been shown that LYS7 can be proteolytically clipped into three distinct domains (I, II, III). Domain I is homologous to ATX1, another small copper chaperone, and domain II is highly homologous to SOD1. Recent data suggests that a protein containing only domains II and III of LYS7 (but missing domain I) can very poorly complement *lys7* null mutants under normal copper conditions; however, this protein does not complement at all under copper starvation conditions. Conversely, a protein containing only domains I and II does not complement the *lys7* null phenotype. Furthermore, site directed mutagenesis of possible metal binding histidines to alanines at positions 130/134, 151, and 198 in domain II of LYS7 do not diminish the ability of the protein to rescue the *lys7* null phenotype. Work is under way to mutagenize two possible metal binding cysteines in domain III. These studies suggest a possible model for copper delivery to SOD1. Domain I captures the copper, perhaps from the copper transporter, while domain II acts in a "docking" fashion to properly align LYS7 and SOD1 for copper transfer; furthermore, actual insertion of the copper ions is accomplished through the flexible domain III.

944 HYPEROXIC LUNG INJURY IS POTENTIATED BY SPC-PROMOTOR DRIVEN EXPRESSION OF AN HO-1 TRANSGENE IN MICE.

L K Rogers, D J Tom, K J McNaughton, R S Geske, F J DeMayo, S E Welty, and C V Smith. *Departments of Pediatrics and Cell Biology and CCM, Baylor College of Medicine, Houston, TX.*

Heme oxygenase (HO) catalyzes the first step in metabolism of heme to biliverdin and bilirubin, with concomitant production of CO and liberation of heme-bound iron. Some investigators have proposed that the inducible isoform, HO-1, may contribute to adaptive responses to oxidant stresses, in part through the production of bilirubin, which can exhibit antioxidant activities. To test this hypothesis in vivo, we generated a line of transgenic mice that express the rat spleen HO-1 cDNA driven by a human surfactant protein C promoter. HO activities (660+/-71 vs. 181+/-15 pmol/min/g tissue) and HO-1 protein and mRNA levels were greater in the lungs of the transgenic animals than in lungs from control animals The transgenic animals were more susceptible to lung injury in response to exposure to >95% O_2, as assessed by lung weights (12.17+/-2.80 vs 7.76+/-0.78 mg lung/ g animal by 96 h). Hyperoxia increased lung HO activities and HO-1 mRNA levels in the control animals, as has been reported previously, but message levels and HO activities were diminished by hyperoxia in the lungs of transgenic animals (242+/-82 pmol/min/g after 48 h). HO-1 expression in air-breathing transgenic animals appeared by immunohistochemistry to be predominantly in lung type II cells, but expression in type II cells was largely lost by 48 h or more of hyperoxia. Increased HO-1 protein in both transgenic and wild-type animals exposed to hyperoxia appeared to be associated almost exclusively with macrophages. (Supported by HD01124 and HD27823.)

945 QUINOL-THIOETHER-MEDIATED CYTOTOXICITY IN A RENAL PROXIMAL TUBULAR EPITHELIAL CELL LINE: EVIDENCE FOR MULTIPLE REACTIVE OXYGEN SPECIES.

R E Maldve, T J Monks and S S Lau. *Div of Pharm/Tox., College of Pharmacy, Univ. of Texas at Austin, TX, USA.*

Treatment of LLC-PK1 cells with 2,3,5-*tris*-(glutathion-*S*-yl)-hydroquinone (TGHQ) causes the generation of reactive oxygen species (ROS) and subsequent induction of prostaglandin E2 (PGE2) synthesis. PGE2, and its analog 11-deoxy-16,16-dimethyl prostaglandin E2 (DDM-PGE2), protects LLC-PK1 cells against TGHQ-induced cytotoxicity. In this study we investigated the mechanisms by which by TGHQ elicits cytoxicity in order to delineate the pathways by which DDM-PGE2 evokes cytoprotection. Rutin hydrate (1 μM), a scavenger of nitric oxide (NO), increased cell viability by 20% in LLC-PK1 cells that were pretreated for 30 min prior to TGHQ. In addition, 10 μM ebselen, a peroxynitrite scavenger blocked the cytotoxic effects of TGHQ. Pre-treatment of LLC-PK1 cells for 30 min with 20 μM U-83836E ([2-methyl]aminochroman; a scavenger predominately of lipid radicals), significantly blocked TGHQ-mediated cytotoxicity. These data suggest that multiple ROS may mediate the cytotoxic effects of TGHQ in LLC-PK1 cells. The synthesis of PGE2 is catalyzed from arachidonic acid by one or both of the two isoforms of cyclooxygenase (COX). COX-1 is constitutively expressed in a number of tissue types and cell lines, while COX-2 is induced by a variety of stimuli, including ROS. Resveratrol (10 μM), a specific inhibitor of COX-1, or NS-398 (10 μM), a COX-2 inhibitor, blocked DDM-PGE2-mediated cytoprotection by 51% and 57%, respectively. Taken together, NO and peroxynitrite appear to contribute to TGHQ-induced cytotoxicity, and the cyclooxygenase pathway may, in part, mediate the cytoprotective effects of DDM-PGE2. (GM56321, ES07247).

946 IMMUNODETECTION OF NAD(P)H:QUINONE OXIDOREDUCTASE 1 (NQO1) IN HUMAN TISSUES.

D Siegel and D Ross. *Department of Pharmaceutical Sciences, School of Pharmacy, University of Colorado Health Sciences Center, Denver, CO, USA.*

Human tissues were examined by immunoblot analysis and/or immunohisto-

chemistry for NQO1 expression. High levels of NQO1 expression were detected in many tissues including lung, breast, stomach, and eye, while low levels of NQO1 were detected in bone marrow and liver. In lung and breast tissues, intense staining for NQO1 was observed in columnar epithelium, vascular endothelium and adipocytes. In the stomach, intense staining for NQO1 was observed in chief cells localized in the gastric pits. In the small intestine and colon, moderate staining for NQO1 was observed in areas of columnar epithelium. Throughout the GI tract intense staining for NQO1 was observed in vascular endothelium and adipocytes. In the eye intense staining for NQO1 was observed in corneal, lens and retinal epithelium and vascular endothelium. Moderate staining for NQO1 was observed in optic nerve fibers. In the myocardium only trace levels of NQO1 were detected by immunoblot analysis, however, NQO1 was detected in the aorta. In immunohistochemical studies with monkey aorta, NQO1 was localized to vascular endothelium. No NQO1 could be detected by immunoblot in human bone marrow aspirates or isolated haematopoetic cells. In addition, only trace levels of NQO1 could be detected in liver by immunoblot analysis or immunohistochemistry. In tissues from individuals genotyped as homozygous for the NQO1 *2 (609C-T) allele, NQO1 protein was either non-detectable or present at only trace levels. The high levels of NQO1 observed in epithelium and vascular endothelium of many tissues and the low levels of NQO1 detected in liver suggests that NQO1 may function primarily as an antioxidant enzyme, and in contrast to rodents, NQO1 may not play a major role in hepatic xenobiotic metabolism in humans (Supported by EPA grant R82-5281-010 and CA 51210.)

947 PHARMACOLOGICAL RESCUE OF THE *14CoS/14CoS* MOUSE AS A MODEL FOR ENDOGENOUS OXIDATIVE STRESS.

M Z Dieter[1], S Freshwater[1], T P Dalton[1], N L Childs[1], M Grompe[2], E A Lock[3], and D W Nebert[1]. [1]*University of Cincinnati Medical Center, Cincinnati, OH, USA;* [2]*Oregon Health Sciences University, Portland, OR, USA;* [3]*Zeneca Central Toxicology Laboratory, Alderly Park, Macclesfield, Cheshire, UK*

Mice homozygous for the radiation-induced *14CoS/14CoS* albino deletion die within 24 h post partum, due in large part to the disruption of the *Fah* gene encoding fumarylacetoacetate hydrolase, which catalyzes the last step in tyrosine catabolism. It has been hypothesized that death in *14CoS/14CoS* animals is the result of accumulation of electrophilic precursors of fumarylacetic acid and acetoacetate. Our lab has previously demonstrated that *14CoS/14CoS* mice exhibit a robust oxidative stress response both *in utero* and after birth. We show here the rescue of *14CoS/14CoS* mice by treatment with 2-(2-nitro-4-trifluoromethyl-benzoyl)-1,3-cyclohexanedione (NTBC), a potent inhibitor of *p*-hydroxyphenylpyruvate dioxygenase, the second enzyme in the tyrosine catabolic pathway. On a dose of 10 μg NTBC / mL in the drinking water, ~70% of *14CoS/14CoS* mice survive past day 20, whereas removal of NTBC results in death within 48 h. Growth, as measured by weight gain through day 28, is impaired in rescued mice compared with that in *ch/14CoS*, *Fah(+/-)* or *Fah(-/-)* mice. Cataracts occur in at least one eye of ~80% of the rescued *14CoS/14CoS* mice, but are not observed in *ch/14CoS*, *Fah(+/-)* or *Fah(-/-)* mice on NTBC, indicating that cataractogenesis involves at least one gene in addition to the *Fah* deletion. Finally, *14CoS/14CoS* mice on NTBC continue to exhibit a significant oxidative stress response over a 60-day time course: Northern blots of liver and kidney RNA demonstrate striking elevations in mRNA levels of the oxidative stress-responsive genes glutamate cysteine ligase (structural and regulatory subunits, *Gcls* and *Gclr*), and NAD(P)H:quinone reductase (*Nqo1*). These results suggest that *14CoS/14CoS* mice on NTBC might serve as a useful model for aging associated with the generation of endogenous oxidative stress. (Supported in part by NIH Grants RO1 AG09235, RO1 ES06321 and P30 ES06096.)

948 OXIDATIVE STRESS, ANTIOXIDANT ACTIVITY AND MECHANISM OF HEPATOTUMORIGENESIS IN PCB-DOSED RATS.

K M Fish, J B Silkworth, B A Mayes, J F Brown Jr. and J F Smith. *General Electric Corporate Research and Development, Schenectady, NY, USA.*

We have recently described our toxicological findings in male and female Sprague Dawley rats undergoing chronic, parallel, multi-dose bioassays of Aroclors 1016, 1242, 1254, and 1260. Our correlations among those data are suggestive of two routes to hepatotumorigenesis: a liver TEQ-dependent one that was predominant in the females and a TEQ-independent route predominant in the males. Our detailed biochemical post mortem examinations of cryopreserved livers after the intermediate and terminal sacrifices, indicate a strong empirical correlation between hepatotumorigenesis and production of the reactive oxygen species (ROS) superoxide and peroxide, via redox cycling of cytosolic low molecular weight species. By liquid chromatographic methods we have tentatively identified some of these redox cyclers in the female rats as glutathionylated estrogen catechols. Antioxidant and phase II enzyme activities were measured to evaluate effects of elevated peroxide and superoxide production. In contrast to unaltered catechol-o-methyltransfease activity, superoxide dismutase activity showed limited increases while glutathione S-tranferase (GST) and quinone reductase (QR) showed increases with tumor yields. Regression analyses indicated that the GST/QR ratio was positively correlated with tumor yield. Finally, glutathione peroxidase activities showed a strong negative correlation with tumor yields. These results are consistent with stabilization of a catechol/semiquinone redox couple resulting in increased oxidant production by redox cycling. In addition, the limited antioxidant activity could not adequately scavenge the resulting elevated ROS. Mechanisms linking a series of events from chronic MTD exposure to oxidative stress via quinone-glutathione coupling, redox cycling and mutant cell promotion would appear capable of explaining the observed carcinogenic activities.

949 HEPATOTUMORIGENESIS IN PCB-DOSED AND CONTROL SPRAGUE-DAWLEY RATS PARALLELS CYSTOSOLIC REDOX CYCLING ACTIVITY.

J F Brown, Jr., K M Fish, J B Silkworth and B A Mayes. *General Electric Corporate Research and Development, Schenectady, NY, USA.*

In order to identify the events leading from chronic, MTD administration of a non-genotoxic promoter to rodent liver tumors, we first characterized the dependencies of hepatotumorigenesis on sex, PCB internal dose, and composition via parallel, multidose, chronic, near-MTD bioassays of Aroclors 1016, 1242, 1254, and 1260 in male and female Sprague-Dawley (SD) rats (Mayes *et al.*, *Toxicol. Sci.* 41, 62-76, 1998), and then examined the progression of changes in liver biochemistry that occurred during the process of hepatotumorigenesis. These studies turned up one biochemical parameter (out of >20) that showed the same distinctive pattern of responses to the experimental variables as did the tumor count: namely, the production of superoxide by low MW redox-cycling agents in the liver cytosols. Such superoxide, or the derived peroxide, is believed to promote clonal expansion of spontaneously initiated cells, possibly via activation of NF-κ B. At least two routes for the formation of the redox cycling activity were identified. The first, predominant in the SD females, correlated with the hepatic levels of coplanar PCB congeners, which, presumably via the Ah-receptor, induced CYP1A, CYP1B, and associated oxidase activities. The second, predominant in the males, correlated with total adipose PCB (mostly non-coplanar congeners), which, presumably via an immunophilin-like receptor, induced CYP2B, CYP3A, and other oxidases. The oxidation products thus far identified as responsible for the tumorigenesis-correlated redox-cycling activity include a family of glutathionylated estrogen 2, 3- and 3, 4- quinones.

950 CHARACTERIZATION OF NORMAL AND CIRRHOTIC FAT-STORING CELL ALCOHOL AND ALDEHYDE METABOLISM.

J F Reichard and D R Petersen. *School of Pharmacy, University of Colorado Health Sciences Center, Denver, CO, USA.*

Chronic liver injury initiated by alcohol, iron or chlorinated hydrocarbons produces enhanced lipid peroxidation and activation of fat-storing cells (FSC). *Trans*-4-hydroxy-2-nonenal (4-HNE), an α-β unsaturated aldehyde produced by ω-6-polyunsaturated fatty acid peroxidation, reportedly stimulates FSC collagen gene expression and type 1 collagen production. An important question concerning the ability of α–β unsaturated aldehydes to modulate FSC collagen production is the potential for these cells to detoxify 4-HNE. In this study, we have characterized the ability of FSC lines derived from a normal (NFSC) and cirrhotic (CFSC) rat liver to metabolize 4-HNE by reductive (alcohol dehydrogenase; ADH) oxidative (aldehyde dehydrogenase; ALDH) and conjugative pathways (glutathione S-transferase; GST). Spectrophotometric analysis indicated that both cell lines had negligible ADH activity. ALDH specific activity was 0.90 ± 0.2 and 2.31 ± 0.55 nmoles min^{-1} mg^{-1} protein for NFSC and CFSC, respectively. The capacity of ADH and ALDH was also evaluated in cell suspensions by headspace gas chromatography using either ethanol or acetaldehyde as substrates. Both cell types lacked significant ADH activity but displayed ALDH activity of 44.57 and 53.51 μmoles hr^{-1} 10^6 cells for the NFSC and CFSC lines, respectively. Glutathione-S-transferase (GST) activity measured in NFSC and CFSC for CDNB conjugation were of 26.18 ± 10.97 (NFSC) and 53.72

± 10.59 (CFSC) nmoles min^{-1} mg^{-1} protein, and 4-HNE conjugation 9.53 ± 2.16 (NFSC) and 3.63 ± 2.53 (CFSC) nmoles min^{-1} mg^{-1} protein. Immunoblots for GST classes Ya, Yb and P1-1 demonstrate CFSC possess greater quantities of Yb and P1-1 GST; Ya was not detected. HPLC measurement of glutathione (GSH) reveled that CFSC lines displayed 3-fold higher concentrations of GSH (4.72 nmols/10^6 cells) as compared to NFSC (1.6 nmols/10^6 cells). Taken together this data suggests that CFSC have a greater capacity than NFSC to deactivate aldehydes through glutathione conjugation and oxidation to acid metabolites. (Supported by AA09300.)

951 PURIFICATION AND CHARACTERIZATION OF A MITOCHONDRIAL THYMINE GLYCOL ENDONUCLEASE FROM RAT LIVER.

R H Stierum[1], D L Croteau[2] and V A Bohr[1]. [1]*Laboratory of Molecular Genetics, National Institute on Aging, National Institutes of Health, Baltimore, MD, USA;* [2]*Department of Molecular and Cellular Biology, University of California at Berkeley, Berkeley, CA, USA.* Sponsor: J Yager.

Mitochondrial (mt) DNA is exposed to damage caused by oxygen radicals produced during oxidative phosphorylation or during exposure to chemical or physical agents. Structural alterations in mtDNA and associated mt dysfunction have been correlated with aging and diseases. Accumulation of oxidative mtDNA damage may be responsible for these mtDNA alterations. mtDNA repair may therefore be important in preventing mt dysfunction. Here, we report the purification of a novel rat liver mt thymine glycol (TG) endonuclease (mtTGendo). Initially, we observed that crude protein extracts from purified rat liver mitochondria incised a radiolabeled oligonucleotide duplex containing one TG. Utilizing subsequent DEAE, cation exchange, hydrophobic interaction and size exclusion (SE) chromatography, a ~450-fold purification of the mtTGendo activity was achieved. Active SE fractions displayed a single band of ~37 kDa on a silverstained gel. mtTGendo is EDTA resistant and active within a broad KCl concentration range. Further, mtTGendo has an associated AP-lyase activity, making a similar incision into the TG-containing DNA as *E. coli* endonuclease III, the bacterial enzyme that repairs TG. Duplexed oligonucleotides containing 8-oxodeoxyguanosine or uracil and single-stranded oligonucleotide containing one TG are no substrates for mtTGendo. Given the fact that TG blocks DNA replication, this novel DNA repair enzyme may help to prevent accumulation of structural mtDNA changes, mt dysfunction and associated (patho)-physiological alterations *in vivo* that are associated with oxidative stress.

952 EFFECTS OF N-*TERT*-BUTYL-α-PHENYL NITRONE (PBN) ON DIISOPROPYLPHOSPHOROFLUORIDATE (DFP) OR KAINIC ACID (KA) INDUCED SEIZURES, FASCICULATIONS AND MUSCLE NECROSIS.

W-D Dettbarn[1], D Milatovic[1], and M Zivin[2]. [1]*Vanderbilt Univ., Dept. of Pharmacology and Neurology, Nashville, TN;* [2]*University of Ljubljana, Ljubljana, Slovenia.* Sponsor: R C Gupta.

Indirect evidence suggests that reactive oxygen species (ROS) may mediate DFP and KA induced neuronal and muscle fiber necrosis following seizures and fasciculations. Therefore the spin trapping agent PBN was used *in vivo* to assess formation of ROS during DFP and KA treatment. Pretreatment with PBN (150–300 mg/kg, i.p.) completely prevented seizures, fasciculations and necrosis induced with DFP (1.3 mg/kg, s.c.), but did not prevent seizures and fasciculations when given following DFP, nor did pretreatment with PBN prevent seizures induced by KA or pilocarpine, a muscarinic receptor agonist. DFP alone reduced AChE activity in brain to 3% and in diaphragm to 25% of control. Pretreatment with PBN attenuated this inhibition in brain to 37% and diaphragm to 80% of control. PBN given after DFP neither protected AChE from DFP inhibition nor prevented seizures and fasciculations. It is suggested that PBN has a direct, dose dependent reversible inhibitory effect on AChE of brain and muscle and thus protects the enzyme from critical irreversible inhibition by DFP. While the role of PBN as an effective antioxidant is well established its protection against DFP induced seizures, fasciculation and necrosis are not due to its antioxidant action. (Supported by NIH Grant, ES04597.)

953 ISOTOPIC DILUTION METHOD FOR THE IDENTIFICATION AND QUANTIFICATION OF 2-AMINO 6,8-HYDROXYPURINE (8ohG).

A Scott[1], G Cosma[1], C Jackson[1], J Tessari[1], B Cranmer[1], and H Gardner[2]. [1]*Dept.of Env. Health, Colorado State University, Fort Collins, CO, USA;* [2]*US Army Ctr Environ Health Research, Ft. Detrick, MD, USA.*

Oxidative injury to DNA is a common cellular insult following exposures to many xenobiotic agents. The hydroxyl adduct of guanine at the C8 position (8ohG) of DNA has been associated with mutagenic base transitions and has been identified as a potential biomarker for human cancer risk. Analytic methods for identification of 8ohG include high pressure liquid chromatography (HPLC), gas chromatography mass spectroscopy (GC-MS), P^{32} postlabeling, and alkaline unwinding assays, each with inherent strengths and weaknesses. Our laboratory has evaluated the performance of an isotopic dilution method for GC-MS identification of 8ohG using a C^{13} N^{15} ring labeled internal surrogate ($8ohG_L$) with emphasis on quantifying artifactual oxidation of guanine. Data from repeat injections of the compound and replicate calibration curves over a four week period indicates that $8ohG_L$ is stable in 10mM sodium hydroxide. Precision of the method to reproducibly hydrolyze 8-hydroxyguanosine and then derivatize and quantify 8ohG was indicated by a 6.8% coefficient of variation (CV) in multiple replicate analyses of the base-sugar compound. Recovery of the 8OH-guanosine was 99%, and sensitivity was 20 pg (120 femptomoles). The detection limit (with 50 ug of DNA in a final extract volume of 100ul) was 20pg of 8ohG per ug of DNA. Replicate samples containing 50 ng of HPLC purified guanine were derivitized with bis(trimethylsilyl)-trifluoroacetatamide (BSTFA) and analyzed using this method to quantify artifactually produced 8ohG. Levels of 8ohG ranged from 500pg (1/2 detection limit) to 1200 pg, suggesting that artifactual oxidation during derivitization accounts for less than 2% of total guanine. Replicate analyses of MCF-7 carcinoma cell DNA and calf thymus DNA samples prepared by a high salt extraction procedure resulted in CVs of 22% and 23%, respectively. Ongoing work is comparing the method to HPLC using DNA samples extracted from cells and animal tissues treated with pro-oxidant agents. (Support from NIEHS #ES09455-01 and USACEHR.)

954 CORRELATION BETWEEN THE FORMATION OF 8-HYDROXY-2'-DEOXYGUANOSINE (OH8dG) AND MORPHOLOGICAL TRANSFORMATION IN SYRIAN HAMSTER EMBRYO (SHE) CELLS.

H Zhang, Y Xu, L M Kamendulis, and J E Klaunig. *Division of Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

The formation of OH8dG is one of the most prevalent oxidative DNA modifications. Previously reported studies have suggested an association between OH8dG formation and carcinogenesis. However, it is not clear whether OH8dG formation results in the necessary genotoxic events for cancer development. In the present study, the formation of OH8dG and its ability to transform SHE cells was examined. Methylene blue, a photosensitizer which in the presence of light can generate singlet oxygen by a type II mechanism, was used to generate oxidative DNA damage. This model has been shown to predominantly produce OH8dG. Methylene blue plus light produced a dose-dependent increase of OH8dG as well as morphological transformation in SHE cells. SHE cells transfected with DNA that contained increasing concentrations of OH8dG, produced a dose-dependent increase in morphological transformation. Co-treatment of SHE cells with both β-carotene, a singlet oxygen quencher, and methylene blue and light inhibited the morphological transformation (in a dose dependent manner). These results suggest that formation of OH8dG through methylene blue and light can induce morphological transformation. In addition, these data provide further support for a role of OH8dG formation in the carcinogenesis process.

955 OXIDATIVE STRESS AND 8-HYDRODEOXYGUANOSINE IN RATS FOLLOWING ACUTE EXPOSURE TO TRICHLOROETHYLENE OR PERCHLOROETHYLENE.

M Toraason, J Clark, D Dankovic, P Mathias, S Skaggs, C Walker, D Werren. *CDC, NIOSH, Cincinnati, OH, USA.*

8-Hydroxydeoxyguanosine (8OHdG) is a product of DNA oxidation and has been employed in occupational studies as a marker of biologically effective dose. Trichloroethylene (TCE) and perchloroethylene (PERC) are used in the dry cleaning industry and their metabolism can produce reactive oxygen compounds with the potential to oxidize DNA. The objective of the present study was to determine if acute exposure to TCE or PERC caused oxidative DNA damage in rats that could be detected as an increase in lymphocyte

8OHdG/dG or urinary excretion of 8OHdG. Thiobarbaturic acid reactive substances (TBARS) and 8-epi -prostaglandin 2 alpha (8epiPGF2) were also measured as biomarkers of increased oxidative stress. Male Fisher rats were administered a single i.p. injection of 0, 100, 500, or 1000 mg/kg of PERC or TCE. Control rats received only vehicle (1:4 v/v of Alkamuls/water) and a positive control group received 100 mg/kg 2-nitropropane (2NP). Rats were sacrificed 24 hrs after dosing. In rats receiving 2NP or TCE, TBARS and the 8OHdG/dG ratio were significantly elevated in liver. Lymphocyte 8OHdG/dG was also elevated, but not significantly. In rats receiving 2NP, urinary excretion of 8OHdG and 8epiPGF2 were significantly increased at 12 and 24 hrs. In rats receiving TCE, no change in urinary excretion of 8epiPGF2 was evident, but an increase in 8OHdG was noted at 24 hr. Results indicate that a single high dose of TCE, can result in detectable elevation in 8OHdG. Despite an absence of statistically significant effects in rats receiving PERC, dose-dependent trends in several endpoints suggest a slight increase in oxidative stress.

956 EFFECT OF SOY ISOFLAVONE DIETARY SUPPLEMENTATION ON LEVELS OF OXIDATIVE DNA DAMAGE IN BLOOD OF WOMEN.

Z Djuric, F Sarkar, J N Redd and O Kucuk. *Karmanos Cancer Institute, Wayne State University, Detroit, MI, USA.*

Dietary intake of soy has been linked with decreased cancer risk. Some of the active compounds in soy have been identified and include the isoflavones genistein and daidzein. As part of a pilot study to assess the potential benefits of a soy extract, NovaSoy® (Archer Daniels Midland Co.), we examined levels of oxidative DNA damage in blood of six women before and after soy supplementation daily. The NovaSoy® supplement is a soy extract tablet that contains 50 mg of soy isoflavones, chiefly genistein and daidzein in a 1:1 ratio. Blood samples were obtained at weekly intervals for three weeks from the women taking this tablet once daily. DNA was isolated from the blood nuclei and analyzed for levels of 5-hydroxymethyl-2'-deoxyuridine (5-OHmdU). Levels of 5-OHmdU decreased in four of the six women. The subjects who displayed decreased levels tended to have higher baseline levels of 5-OHmdU. Average levels of 5-OHmdU were 93 $\pm$ 36 at baseline and 48 $\pm$ 15 after 3 weeks of intervention (given as mean $\pm$ SD in pg 5-OHmdU/ng thymidine, n=6 in each case). This decrease was noted as soon as 2 weeks after starting on the soy supplement, indicating a fairly rapid decrease in levels of oxidative stress. Since increased levels of 5-OHmdU have been associated with increased breast cancer risk, these results indicate that soy supplementation could potentially be useful to decrease breast cancer risk in women.

957 OXIDATION OF LOW DENSITY LIPOPROTEIN BY HYDROGEN PEROXIDE-ALTERED MYOGLOBIN.

J L Vuletich[1], M Aviram[2], and Y Osawa[1]. [1]*Department of Pharmacology, University of Michigan, Ann Arbor, MI, USA;* [2]*Lipid Research Laboratory, Rambam Medical Center, Israel Institute of Technology, Haifa, Israel.*

Oxidized low density lipoprotein (Ox-LDL) is believed to play a significant role in the pathogenesis of atherosclerosis; however, the exact mechanism by which Ox-LDL is formed *in vivo* is not yet known. A variety of biological molecules, including the hemoproteins myoglobin and hemoglobin, have been shown to induce the formation of Ox-LDL *in vitro*. We have discovered, in *in vitro* studies with purified LDL, that hydrogen peroxide-altered myoglobin was approximately 2.5-fold more efficient than native myoglobin (Mb) at oxidation of LDL, as demonstrated by the formation of lipid peroxides, TBARS, and conjugated dienes. The oxidation of LDL appeared to be catalyzed by a peroxide-altered heme group covalently-bound to apomyoglobin (Mb-H). We have also discovered that Mb-H was formed during the reaction of Mb with purified LDL. Therefore, the previously observed capacity of Mb to oxidize LDL may be due, in part, to the generation of Mb-H. These results are consistent with the known redox activity of Mb-H. The formation of covalently-bound heme adducts has been shown to occur *in vivo* with a variety of hemoproteins. Thus, these observations suggest a potential role for oxidatively-modified hemoproteins in the initiation and progression of atherosclerosis. (Supported by BWF New Investigator Award in Toxicology (YO), Training Grant GM07767 (JLV), and ES08365.)

958 H_2O_2 INDUCES HYPERTROPHY AND APOPTOSIS IN RAT CARDIOMYOCYTES.

C V Tu, J J Bahl, J P Liu, Y W Wu, and Q M Chen. *Department of Pharmacology, School of Medicine, University of Arizona, Tucson, AZ, USA.*

Cardiovascular disease is the leading cause of nature death in U.S. Many heart diseases involve cardiomyocyte hypertrophy and cell death. The trigger and mechanism of these two cellular changes are unknown under most pathological conditions. Oxidants are by-products of aerobic metabolism and increase in the heart in many heart diseases associated with ischemia-reperfusion. Using H9C2 and primary cultured rat cardiomyocytes, we test whether H_2O_2 can induce hypertrophy and apoptosis. The majority of cells survived a 2-hr treatment with H_2O_2 up to 250 μM. These cells developed hypertrophy over 6 days judging by increases in cell surface area, protein content per cell and protein to DNA ratio. The enlarged cells showed enhanced actin filaments. Myosin was presented in a filament structure instead of myofibrils. Protein degradation rate showed a transient reduction but increased at 24 hr after H_2O_2 treatment, suggesting that increased protein content was not a result of reduced protein degradation. Cycloheximide prevented cell enlarging, indicating that new protein synthesis was critical for hypertrophy. In contrast, the same treatment, i.e. H_2O_2 =250 μM, 2 hr, caused a maximum of 45% cells to undergo apoptosis over 24 hr. These cells detached, showed nuclear condensation, and activated caspase-3. Thus, our data indicate that H_2O_2 can cause apoptosis in one fraction of the cardiomyocytes and hypertrophy in the other fraction.

959 CARDIOSELECTIVE OXIDATION OF MITOCHONDRIAL DNA FOLLOWING SUBCHRONIC ADMINISTRATION OF DOXORUBICIN.

J Serrano[1], C M Palmeira[2], D W Kuehl[1], and K B Wallace[3]. [1]*Midcontinent Ecology Division, U.S. EPA, Duluth, MN;* [2]*Centro de Neurociencias, Department of Zoology, Universidade de Coimbra, Coimbra, PORTUGAL;* [3]*Department of Biochemistry & Molecular Biology, University of Minnesota, Duluth, MN, USA.*

Acute intoxication of rats with doxorubicin causes the preferential formation of 8-hydroxydeoxyguanosine (8OHdG) in mitochondrial DNA (mtDNA) compared to nuclear DNA (nDNA) of cardiac tissue (Palmeira et al., 1997). The present investigation was designed to assess the persistence of these adducts and to determine whether they accumulate with repetitive injections of clinically relevant doses of doxorubicin. Adult male Sprague-Dawley rats received weekly intraperitoneal injections of either 2 mg/kg doxorubicin or isotonic NaCl. Selected animals were killed at weekly intervals, the nDNA and mtDNA isolated from both heart and liver, and the concentration of 8OHdG measured by LC/ESI-MS/MS. The concentration of 8OHdG in nDNA and mtDNA from heart or liver of saline-treated rats was less than 5 per 100,000 unmodified deoxyguanosine (dG) bases at all time points examined. However, the abundance increased to $65/10^5$ dG in cardiac mtDNA after 8 weekly injections. The rank-order abundance of 8OHdG adducts was cardiac mtDNA > hepatic mtDNA > cardiac nDNA > hepatic nDNA. Interestingly, the concentration of 8OHdG did not decline in any of the DNA fractions after allowing as much as 3 weeks of drug-free recovery. This preferential oxidation of cardiac mtDNA is consistent with the bioenergetic failure and the cumulative and irreversible cardiomyopathy that limits the clinical utility of this important antineoplastic drug. (Supported in part by HL 58016.)

960 PYRIDOSTIGMINE AND EXERCISE INTERACTION ON CARDIAC ANTIOXIDANT DEFENSE SYSTEM IN MICE.

R Jagannathan, K Husain, K S Reddy and S M Somani. *Department of Pharmacology, Southern Illinois University School of Medicine, Springfield, IL, USA.*

This study investigated the interactive effects of pyridostigmine and exercise on cardiac antioxidant defense system in mice. Male NIH Swiss mice were divided into four groups and treated as follows: 1) sedentary control (4 weeks sitting on treadmill belt followed by two weeks saline treatment and 4 weeks sitting on treadmill belt); 2) pyridostigmine [4 weeks sitting on treadmill belt followed by pyridostigmine (1.2 mg/kg, p.o) daily for two weeks and 4 weeks sitting on treadmill belt]; 3) exercise daily for ten weeks (saline treatment only at 5th and 6th week) and 4) pyridostigmine plus exercise for ten weeks. The animals were sacrificed 24 hours after the last treatments, hearts were isolated and analyzed. Pyridostigmine significantly increased cardiac SOD activity (125% of control) while GSH-Px activity

significantly decreased (78% of control). Pyridostigmine depleted cardiac GSH and GSSG concentrations (40% and 45% of control), respectively while lipid peroxidation was increased (116% of control). Exercise significantly decreased cardiac GSH-Px activity (78% of control) and depleted GSH concentration (75% of control). The combination of pyridostigmine and exercise decreased cardiac CAT and GSH-Px activities (56% and 72% of control), GSH concentration and GSH/GSSG ratio (73% and 47% of control), respectively and increased GSSG concentration (133% of control). The data suggest that pyridostigmine and exercise interaction perturb the cardiac antioxidant defense system leading to oxidative stress in mice (Supported by US Army contract # DAMD17-97-C-7066.)

961 COMBINATION OF PHENOLIC COMPOUNDS WITH ARACHIDONIC ACID INDUCES "FUTILE THIOL PUMPING" AND OXIDATIVE STRESS IN EPIDERMAL HUMAN KERATINOCYTES.

A A Shvedova[1], Y Y Tyurina[2], V A Tyurin[2], B Jeffries[1], C Kommineni[1], V Castranova[1], and V E Kagan[2,3]. [1]*Health Effects Laboratory Division, National Institute for Occupational Safety and Health, Morgantown, WV;* [2]*Departments of Environmental and Occupational Health, and* [3]*Pharmacology, University of Pittsburgh, Pittsburgh, PA.*

In human epidermis, active metabolism of arachidonic acid to prostaglandins is regulated by prostaglandin H synthase (PHS) which is also known to catalyze xenobiotic biotransformation. In particular, peroxidase activity of PHS may catalyze one-electron oxidation of phenolic compounds to their phenoxyl radicals. The phenoxyl radical may attack intracellular thiols to regenerate the phenolic compound that may repeatedly undergo peroxidase-catalyzed oxidation. This thiol-supported redox-cycling of phenolic compounds (i.e,. "futile thiol pumping") has been demonstrated in keratinocytes exposed to acetaminophen (Mason et al., 1989). n the present work, we tested whether redox-cycling of phenolic compounds can induce peroxidation of membrane phospholipids and deplete antioxidants in keratinocytes. We used a fluorescence-HPLC assay for quantitation of membrane phospholipids metabolically prelabelled with oxidation-sensitive natural fluorescent fatty acid, cis-parinaric acid (PnA). We found that a combination of phenol/arachidonic acid or cresol/arachidonic acid caused a pronounced oxidation of major phospholipids: phosphatidylcholine, phosphatidylethanolamine, and phosphatidylserine in keratinocytes. Exposure to phenol (cresol) + arachidonic acid decreased total antioxidant reserves in keratinocytes as measured by luminol-enhanced chemiluminescence in the presence of a water-soluble azo-initiator, AAPH. Measurements with a thiol-reagent, ThioGlo-1™ showed that phenol (cresol) + arachidonic acid depleted GSH and oxidized protein sulfhydryls in keratinocytes. Electron microscopy revealed characteristic apoptotic nuclear fragmentation in keratinocytes exposed to a combination of phenolic compounds with arachidonic acid. These results suggest that peroxidase activity of PHS may be involved in phenol (cresol)-induced "futile thiol pumping" in human epidermal keratinocytes.

962 ROLE OF p53 TUMOR SUPPRESSOR GENE IN THE TOXICITY OF TCDD, ENDRIN, NAPHTHALENE AND CHROMIUM (VI) IN THE LIVER AND BRAIN TISSUES OF MICE.

D Bagchi, J Balmoori, M Bagchi, X Ye, C B Williams, and S J Stohs. *Creighton University Health Sciences Center, Omaha, NE, USA.*

It has been postulated that tumor suppressor genes are involved in the cascade of events leading to the toxicity of diverse xenobiotics. Therefore, we have assessed the comparative effects of 0.01 LD_{50}, 0.10 LD_{50} and 0.50 LD_{50} doses of TCDD, endrin (EN), naphthalene (NAP) and chromium (VI) (CrVI) on lipid peroxidation (LP), DNA fragmentation and enhanced production of superoxide anion (cytochrome c reduction) in the liver and brain tissues of TSG-P53 deficient mice in order to determine the role of p53 in the toxic manifestations produced by these diverse xenobiotics and compare these data with C57BL/6J mice. In general, p53 deficient mice are more susceptible to all four xenobiotics. Dose-dependent effects were produced by the four xenobiotics which were studied in both the p53 deficient mice and the C57BL/6J mice. At a 0.50 LD_{50} dose, TCDD, EN, NAP and CrVI induced 2.5-, 2.3-, 3.7- and 3.3-fold greater increases in hepatic LP in p53 deficient mice as compared to the C57BL/6J mice. At this dose in brain tissues 1.8-, 2.4-, 3.0- and 2.1-fold greater increases in LP occurred in p53 deficient mice as compared to the C57BL/6J mice. Similar results were observed with respect to DNA fragmentation and production of superoxide anion. The results support the hypothesis that p53 tumor suppressor gene plays a role in the toxicity of structurally diverse xenobiotics.

963 AUTOFLUORESCENCE IN PRIMARY RAINBOW TROUT HEPATOCYTES INTERFERES WITH MEASUREMENT OF OXIDATIVE ACTIVITY VIA THE EXOGENOUS PROBE, DCF, BUT PROVIDES INTRINSIC MEASURE OF CELLULAR OXIDATIVE STATE.

T R Henry, R D Johnson, D B Lothenbach and P K Schmieder. *USEPA, NHEERL, Mid-Continent Ecology Division, Duluth, MN, USA.*

The compound 2',7'-dichlorodihydrofluoroscein diacetate (DCF-DA; Molecular Probes) is a probe commonly used to detect oxidative activity in live cells. Studies were undertaken to measure reactive oxygen species generated in freshly isolated rainbow trout hepatocytes exposed to a variety of redox cycling compounds, including 1,4-napthoquinone (NQ) and diquat (DQ). During our studies we found unusually high background levels of fluorescence (Ex: 490nm; Em: 520nm) in control, NQ- and DQ-treated cells loaded with DCF-DA. Similar levels of fluorescence were observed in freshly isolated cells which were not loaded with DCF-DA, indicating that the fluorescence in not due to the oxidized metabolite, DCF. It was determined that the background fluorescence apparent immediately upon isolation correlates with cell density, indicating that it is endogenous autofluorescence. The fluorescence was observed to increase with time in culture up to 24 hours post-isolation, reaching a maximum fluorescence up to an equivalent of 50 pmol DCF. This temporal change in autofluorescence confounds interpretation of measurements of DCF fluorescence as an indicator of oxidative activity. However, the autofluorescence itself may be a useful endogenous indicator of the oxidative state of the cells. Examination of the rainbow trout hepatocyte autofluorescence using multi-photon excitation microscopy indicates that it is consistent with previous reports of autofluorescence of flavoproteins and pyridine nucleotides in mammalian cells. Exploitation of these intrinsic fluorescent molecules will provide a means of monitoring cellular oxidative activity in future mechanistic studies of cellular responses to oxidants in rainbow trout heptocytes.

964 MAITOTOXIN-1 INDUCES LIVER AND PLASMA LIPID PEROXIDATION IN CF-1 MICE TREATED WITH SUBLETHAL ORAL DOSES.

J Matta and M Milad. *Dept. of Pharmacology & Toxicology, Ponce School of Medicine, Ponce, PR.*

Human consumption of tropical fish containing polyether marine toxins (e.g. maitotoxins) can cause acute and chronic ciguatera fish poisoning. We tested the hypothesis that oral ingestion of maitotoxin-1 (MTX-1) causes significant increases in liver and plasma lipid peroxidation. Mice (CF-1 strain, n=5/dose/time interval) were gavaged with 0% (control), 0.1%, 1%, 10%, 25%, 50%, 75% of the MTX-1 LD_{50} (130 ng/kg, Calbiochem) and groups were sacrificed after either 3, 6, 24 or 72 h. Analysis was done of liver and plasma lipid peroxidation (HPLC), plasma protein, ALT and AST activities. MTX-1 caused a significant increase ($p<0.01$, 2-way ANOVA) in liver and plasma lipid peroxidation in many animals. This effect was more pronounced in liver than in plasma and varied substantially depending on dose utilized and time interval sampled. In the 3 h group a maximum effect was found; liver lipid peroxidation increased nearly 1800% relative to controls in animals treated with 75% of the LD_{50}. MTX-1 caused an increase of at least 300% in plasma lipid peroxidation in the 3 h group treated with 50% of the LD_{50}. These effects were abolished in animals treated with alpha tocopherol (100 μ M) after MTX-1 exposure. Collectively, these studies suggest that lipid peroxidation is a mechanistic component of acute ciguatera fish poisoning.

964A SHIFT IN FTIR (FOURIER TRANSFORM INFRARED) ABSORPTION SPECTRA OF AMIDE BOND-VIBRATION IN METHYL-CARBAMATE (METHOMYL) EXPOSED RAT SPLEEN CELLS IS RELATED TO DISRUPTION OF CYTOSKELETON.

T Suramana[1], R Sindhupak[2], N Dusitsin[2], T Posayanonda[3], and P Sinhaseni[3]. [1]*Department of Forensic Medicine, Faculty of Medicine;* [2]*Institute of Health Research;* [3]*Pesticide Safe Use Unit and Department of Pharmacology, Faculty of Pharmaceutical Sciences, Chulalongkorn University, Bangkok, Thailand.*

Oxidative stress caused by many toxicants to red blood cells can lead to apoptosis and release of lactate delydrogenase enzymes in plasma of exposed rats. We earlier reported that rats exposed to 8 mg/kg methomyl (s-methyl N -[(methylcarbamoyl) oxy] thioacetimidate) showed transient increase of lactate dehydrogerase isozyne (type 4) in plasma and the elevated level which subsided on day 2 after exposure. N-acetyl-cysteine, a free

radical scavenger which promotes glutathione anti-oxidant capacity can block this effect (Lohitnavy et al. 1997). We report a small significant shift in infrared absorption spectra detected by fourier transformed infra-red spectroscopy (Wong, 1995), in spleen cells of rats exposed to 8 mg/kg methomyl. It is known that cysteine groups of ~ tubulin can be cross-linked by a bivalent sulfhydryl reagent and that the cross-link can be inhibited by colchicine (Little and Lu Dena 1985). This result is discussed in terms of mechanism which -SH cysteine agents may alter cell growth and development. Methomyl binding to specific protein in mutant maize which alters cellular oxidative status is also discussed.

965 ORAL INGESTION OF TRICHLOROACETATE IN DRINKING WATER OF RATS AND MICE.

J W Fisher, D A Mahle[1], T A Bausman, S M Young, G W Buttler[1] and J C Parker[2]. *Air Force Research Laboratory, Human Effectiveness Directorate, WPAFB, OH, USA; [1]ManTech Environmental Air Force Research Lab, Wright Patterson AFB, OH, USA; [2]US EPA, Washington, DC, USA.*

A physiologically based pharmacokinetic (PBPK) model is under development for oral ingestion of neutralized trichloroacetic acid in drinking water of rats and mice. To develop a drinking water TCA rodent model, previously existing solvent PBPK models that described TCA as a metabolite were used in addition to kinetic data collected from conducting drinking water studies with TCA. Male Fischer 344 rats were placed on drinking water for up to 14 days containing either 2.0, 0.5 or 0.1 g/L TCA, and male B6C3F1 mice were administered drinking water containing either 0.8 or 0.08 g/L TCA. Water consumption rates for rats were 15.1, 19.2 and 19.0 ml/day/rat for the 2.0, and 0.5 and 0.1 g/L dose groups and in mice, 3.8 and 4.2 ml/day/mouse for the 0.8 and 0.08 g/L dose groups. Rats and mice were taken off treatment on Days 3 and 14. In rats, tail vein blood samples were collected immediately after removal from treatment water and then at selected times for up to 6 hours to monitor systemic clearance of TCA. Mice were killed by CO_2 on Days 3 and 14 of treatment, immediately after removal from water containing TCA and then selected times up to 16 hrs after removal from treatment. Blood and liver were removed at each time point for analysis of TCA. Peak blood concentrations of TCA were 4.3, 30.6 and 93.6 ug/ml in rats drinking 0.1, 0.5 and 2.0 g/L of TCA, respectively, and 10.3 and 72.9 ug/ml in mice drinking 0.08 and 0.8 g/L of TCA, respectively. A PBPK model for TCA in rats and mice will be used to calculate dosimetry of TCA after oral ingestion in drinking water.

966 SIMULATION OF TRICHLOROACETIC ACID KINETICS IN THE ISOLATED PERFUSED RAT LIVER USING A BIOLOGICALLY BASED KINETIC MODEL.

C Toxopeus[1] and J M Frazier[2]. *[1]Wright State University, Dayton, OH, USA; [2]Human Effectiveness Directorate, Air Force Research Laboratory, Wright-Patterson AFB, OH, USA.*

Trichloroacetic acid (TCA) is a contaminant of groundwater. It induces peroxisome proliferation in livers of rats and mice and is hepatocarcinogenic in the latter species. To gain more insight into the mechanistic processes controlling TCA kinetics in the liver: 1) the isolated perfused rat liver (IPRL) was used to experimentally investigate TCA kinetics at two doses, and 2) a biologically based kinetic (BBK) model for the IPRL was used to analyze the experimental data. This BBK model integrates mechanism of protein binding, membrane transport, metabolism and biliary excretion in order to simulate the kinetic behavior of water-soluble chemicals. The IPRL was exposed to 25 and 250 μ M TCA for 2h in a recirculating system. These doses were not cytotoxic as determined by LDH leakage and bile formation. The BBK model simulated the TCA concentration in perfusion medium, the liver concentration at the end of the experiment, and the biliary excretion of TCA. Separate protein binding studies showed that over 90% of TCA was bound to albumin in the perfusion medium whereas binding in liver homogenate was negligible. Integrating the information on protein binding into the BBK model, the hepatic uptake of TCA and its biliary excretion could be fitted assuming active transport and passive diffusion, respectively. Additional experiments using a higher dose of TCA (1000 μ M) were conducted to validate the BBK model. This approach illustrates the usefulness of BBK modeling for analyzing experimental data and gaining insight in mechanisms involved in chemical kinetics.

967 PHARMACOKINETICS AND METABOLISM OF DICHLOROACETATE (DCA) ADMINISTERED IN DRINKING WATER IN RATS AND MICE.

D A Mahle[1,2], J W Fisher[1], A G Taylor[1], R J Godfrey[1,2], G W Buttler[1,2], L Narayanan[1,3] and J C Parker[4]. *[1]Air Force Research Laboratory, Human Effectiveness Directorate, [2]ManTech Environmental Technology, Inc.; and [3]Geo-Centers, Inc., Wright Patterson AFB, OH; [4]USEPA, NCEA/ORD, Washington, DC.*

As a by-product of water chlorination dichloroacetic acid (DCA) is a ubiquitous contaminant of drinking water supplies. DCA is a complete hepatocarcinogen and a tumor promoter in B6C3F1 mice. To describe the pharmacokinetics of orally ingested DCA, male Fischer 344 rats and B6C3F1 mice were given DCA in drinking water at 3 different dose levels (rat – 0.1, 0.5 and 2.0 g/l; mice - 0.08, 0.8 and 2.0 g/l) for 3 or 14 days. Blood and liver samples were collected at selected time points up to 8 hr after being taken off treated drinking water. Cytosol was prepared from the remaining rat and mouse livers for investigation of metabolic competency. At the end of 14 days of treatment the blood DCA concentrations for mice and rats were 18.5 and 73.3 ug/ml, respectively, at the 2.0 g/l dose level. Liver concentrations at the same time point and dose level for mice and rats were 8.3 and 11.6 ug/ml, respectively. At the 0.08 and 0.8 g/l DCA dose level DCA was not measured in mouse blood or liver. Cytosol from control rat liver had a Km of 206 nmol and a Vmax of 3.8 nmol/min/mg protein, with Km and Vmax from the 0.1 g/l dose level being similar. Alteration of metabolic degradation of DCA was substantial at the 0.8 and 2.0 g/L drinking water dose levels in both rats and mice. These results may play an important role in interpreting DCA and drinking water dose-response studies that have been conducted with rodents.

968 INHIBITION OF METABOLISM BY CHLORINATED AND BROMINATED DI-HALOACETATES AND DIFFERENTIAL RECOVERY IN B6C3F1 MICE AND F344 RATS.

A Gonzalez-Leon[1], J L Merdink[1], R J Bull[2] and I R Schultz[2]. *[1]Pharm/Tox Program, Washington State University, Pullman, WA; [2]Battelle PNNL, Richland, WA.*

Chloro, bromo and mixed bromo- chloro haloacetates (HAs) are by-products of drinking water disinfection and exhibit both carcinogenic and reproductive/developmental toxic properties in rodents. Previously, dichloro-acetate (DCA) was demonstrated to auto-inhibit its metabolism in mice and rats, with rats being noticeably more sensitive to this effect than mice. Presently, we were interested if other di-haloacetates, bromochloro (BCA) and dibromo (DBA) also caused metabolic inhibition. We pretreated male F344 rats with DCA, BCA or DBA at 2 g/L in their drinking water for 2 weeks. After a 16 hr recovery period, rats were euthanized and hepatic S9 fractions prepared. The rate of metabolism of each HA (measured from the loss of added substrate) was determined at several initial concentrations using S9 prepared from the various di-HA treated rats. The observed data was fitted to the Michaelis-Menten equation using non-linear regression methods to obtain estimates of the apparent K_m and V_{max}. The results indicated that pretreatment with a di-HA caused a substantial decrease in the metabolism all di-HAs. In general, the K_m tended to remain unchanged or increased, while the V_{max} was reduced 50-75 %. In additional experiments, we investigated the recovery time necessary to restore normal metabolic activity in mice and rats following a 2 week pretreatment with DCA at 0.2 or 2 g/L. These experiments used both in-vivo (mice- blood elimination after i.v. injection; rats- CO_2 formation after gavage dosing) and in-vitro methods to quantify metabolic activity. Results showed that mice completely recover from DCA treatments within 48 hours while rats require a considerably longer period of time. These results indicate that rats more closely resemble humans in regards to the persistence of di-HA induced metabolic inhibition. (Supported by EPA grant R825954.)

969 DOSE-DEPENDENT PHARMACOKINETICS OF MONOCHLOROACETIC ACID (MCA) IN ADULT MALE SPRAGUE-DAWLEY RATS.

K Fried[1], S A Saghir[1] and K K Rozman[1,2]. *[1]Department of Pharmacology, Toxicology, and Therapeutics, University of Kansas Medical Center, Kansas City, KS; [2]Section of Environmental Toxicology, GSF-Institut für Toxikologie, Neuherberg, Germany.*

This study was conducted to determine the distribution, metabolism and excretion of MCA in male rats at a moderately toxic dose of 10 mg/kg and a highly toxic dose of 75 mg/kg (approximate LD_{50}). Rats were injected with ^{14}C-MCA (2.5-3.0 μCi/animal) into the tail vein and housed individually in

metabolism cages. Urine and feces were collected separately. Animals were euthanized at different time intervals (5, 15, 45 min, 2, 4, 8, and 16 hrs) and a whole array of tissues were collected by gross dissection. Radioactivity in weighed aliquots of tissues was determined by scintillation counting following digestion. The injected radioactivity was very rapidly distributed to tissues leaving 0.1 and 0.6 percent/ml of the dose in blood at 45 minutes after injection of the low and high doses, respectively. Concentrations of MCA in plasma, liver, heart, lungs, and brown fat were parallel to each other, whereas that in brain remained almost constant from 15 min until the end of the experiment (16 hrs). At later time points (2–16 hrs), concentration in thymus was noticeably higher than in other tissues including liver. Very large amounts of radioactivity (47 and 23% of the low and high dose, respectively, at 45 min) were found in the GI tract, almost all of which were reabsorbed. Only a negligible fraction was excreted in the feces (<0.6% of the low and ≈ 2% of the high dose) or recovered in the GI tract (only 0.4 and 1.4 percent of the low and high dose, respectively, at 16 hrs). A very large fraction of both doses was found in urine (73% of the low and 59% of the high dose at 16 hrs). There was no dose proportionality in tissue concentrations of radioactivity.

970 INFLUENCE OF ORAL ADMINISTRATION OF A QUATERNARY MIXTURE OF TRIHALOMETHANES ON THEIR BLOOD KINETICS IN THE RAT.

M L da Silva, G Charest-Tardif, K Krishnan, R Tardif. *TOXHUM (Groupe de recherche en toxicologie humaine), Université de Montréal, Montréal, Québec, Canada.*

Trihalomethanes (THMs) are disinfection by-products in drinking water which are formed by the reaction between chlorine and organic materials (e.g. humic and fulvic acids). THMs are metabolized by cytochrome P-450 that may lead to metabolic interactions. The purpose of this study was to verify the potential metabolic interactions, following oral administration of THMs in quaternary mixture on their blood kinetics in rat. A single dose of 0.25 mmol/kg or 0.5 mmol/kg b.w. of each THM alone, and of a quaternary mixture containing 0.25 mmol/kg of each THM/kg b.w (total dose of 1.0 mmol/kg) were administered by gavage. The venous blood concentrations of the THMs were measured by headspace gas chromatography at several time points (40, 60, 120, 180, 270 and 360 minutes) following administration. Results showed a non-linear relationship between area under the venous blood concentration time curves (AUCs) and doses for individual THMs, which suggests that the metabolism is saturated in this dose range. Administration of THMs in quaternary mixture resulted in higher AUC values by comparison with single administration. The ratios of increase for chloroform, dibromochloromethane, dichlorobromomethane and bromoform were 6.5, 8.1, 4.1 and 2.6, respectively. Additional experiments using binary mixtures of various THMs showed that mutual metabolic interaction occur between THMs. The likelihood of the occurrence of this interaction, at low doses in humans, will be evaluated using mechanism-based kinetic models. (Supported by CNTC.)

971 IN VITRO METABOLISM OF DIAZEPAM BY HORSE LIVER SLICES.

D F Gerken, R A Sams, and M Sadler. *College of Veterinary Medicine, The Ohio State University, Columbus, OH, USA.*

The information resulting from the use of horse liver slices to determine the metabolism of an unknown drug has potential to be very helpful for laboratories regulating illegal drug use in performance animals. Use of in vitro horse liver slice systems for metabolism studies has not been validated. The drug, diazepam, was selected for in vitro validation because the multiple metabolic pathways - hydroxylation, demethylation and glucuronidation - could be evaluated. Freshly prepared horse liver slices from six horses were incubated with 68 mg of diazepam for 6 hours in a rotating 37°C incubator in Waymouths medium under 95% O2/5 % CO2. Slices and medium were homogenized and analyzed for diazepam and its metabolites by HPLC. Identities and mean (±SD) quantities of the four metabolites produced were 9.4 (± 3.5) nmoles of oxazepam, 14.7 (± 2.5) nmoles of temazepam, 26.2 (± 11.3) nmoles of nordiazepam and 27.7 (± 9.1) nmoles of temazepam glucuronide. Diazepam and the four metabolites accounted for 96.7% of the drug added to the incubation mixture. The in vitro metabolites identified from horse liver slices in this study are consistent with those reported from in vivo studies in the horse.

972 KINETICS OF BROMOSULFOPHTHALEIN CONJUGATION AND BILIARY EXCRETION AT VARYING ALBUMIN CONCENTRATIONS IN THE ISOLATED PERFUSED RAT LIVER.

B D Foy[1], C Toxopeus[1] and J M Frazier[2]. [1]*Wright State University, Dayton, OH, USA;* [2]*Human Effectiveness Directorate, Air Force Research Laboratory, Wright-Patterson AFB, OH, USA.*

A better understanding of the kinetics involved in bromosulfophthalein (BSP) metabolism will enhance its utility as a test compound, and also provide a framework for the kinetic analysis of other chemicals. The biliary excretion of BSP was studied using a recirculating isolated perfused rat liver system. The initial BSP concentration was 20 μ M and BSP clearance was studied for 150 min at 0, 1, or 4% bovine serum albumin (albumin, w/v) in perfusion medium. With this design, different clearance kinetics of BSP were observed without changing the initial total BSP concentration. Bile was collected at 30 min intervals and BSP and its glutathione conjugate were determined by HPLC. The appearance of total BSP in bile reflected its disappearance from perfusion medium. With no albumin present, the concentration of total BSP in bile was >10 mM until BSP was depleted from the perfusion medium, whereas in the presence of albumin the total biliary BSP concentration was lower and more constant throughout the experiment. Regarding the conjugation of BSP, for 0% albumin, the fraction of BSP conjugate in bile was between 70 and 85% at all times. For the 1% albumin case, the percentage of conjugate was initially 62% and rose to 83% by the end of the experiment. For 4% albumin, the conjugation fraction was initially 47% and rose to 61%. The data indicate that BSP conjugation is not saturated even at high BSP uptake rates and provide insight into the relative kinetics of metabolism and excretion of BSP and its conjugates.

973 PRECLINICAL PHARMACOKINETICS AND INTERSPECIES SCALING OF A NOVEL VITRONECTIN RECEPTOR ANTAGONIST.

K W Ward, K L Salyers, L M Azzarano, D Lundberg, J L Pirhalla, W H Miller, T J Roethke, G J Stelman, and B R Smith. *SmithKline Beecham Pharmaceuticals, King of Prussia, PA, USA.*

Allometric scaling may be used in risk assessment or drug development to predict from animal data the pharmacokinetics of xenobiotics in man. Although allometry may be successful for compounds that are excreted unchanged or are oxidatively metabolized (with corrections for metabolic capacity), it is more challenging for compounds excreted primarily as conjugates in bile. SB-265123 (S-10,11,dihydro-3-[3-(pyridin-2-ylamino)-1-propyloxy]-5H-dibenzo[a,d]cycloheptene-10-acetic acid) is a novel α vβ 3 (vitronectin receptor) antagonist. In this study, the *in vivo* pharmacokinetics and *in vitro* plasma protein binding of SB-265123 were examined in mice, rats, dogs, and monkeys. In monkeys and dogs, SB-265123 exhibited moderate clearance, while low clearance (< 20% hepatic blood flow, Qh) was observed in the rat, and high clearance (> 70% Qh) was seen in the mouse. Visual inspection of the concentration-time profiles indicated the possibility of enterohepatic recirculation; subsequent studies in bile duct-cannulated rats demonstrated extensive biliary excretion of an acyl-glucuronide of SB-265123. Allometric scaling was used to attempt to predict the disposition of SB-265123 in man. Various standard correction factors for protein binding, maximum lifespan potential, or neoteny were employed; each failed to produce adequate scaling of clearance across the animal data set (r2 < 0.88). Thus, a novel correction factor incorporating bile flow and microsomal UDPGT activity in each species was used; this correction substantially improved the interspecies scaling (r2 = 0.96). This study demonstrates the use of allometry in interspecies scaling of compounds that undergo Phase II and Phase III metabolism and excretion, and describes a new correction technique that may improve interspecies scaling of such xenobiotics.

974 ABSENCE OF DIFFERENTIAL SENSITIVITY TO CHOLINESTERASE INHIBITION IN DEVELOPING RATS COMPARED TO DAMS TREATED PERINATALLY WITH CHLORPYRIFOS.

J L Mattsson[1], J P Maurissen[2], R J Nolan[1], and K A Brzak[2]. [1]*Dow AgroSciences, Indianapolis, IN;* [2]*Dow Chemical Company, Midland, MI, USA.*

Pregnant Sprague-Dawley rats were exposed to chlorpyrifos (*O,O*-diethyl-*O*-[3,5,6-trichloro-2-pyridinyl] phosphorothioate; CPF) by gavage (in corn oil) from gestation day (GD) 6 to postnatal day (PND) 10. Dosages to the dams were 0 (control), 0.3 (low), 1.0 (middle) or 5.0 mg/kg/day (high). On GD 20, the blood CPF content in fetuses was about one half to one third the

level found in their dams, indicating about a 2 to 3-fold level of maternal protection. Consistent with maternal:fetus differences in blood CPF, cholinesterase (ChE) inhibition occurred in dams at 0.3 mg/kg/day, but not in fetuses from dams given 1 mg/kg/day. Interestingly, no blood CPF could be measured (limit of detection 0.7 ng/g) in dams given 0.3 mg/kg/day, while fetuses of dams given 1 mg/kg/day had a blood CPF level of about 1.1 ng/g. Thus, based on these data, pups were more tolerant to ChE inhibition than were dams at these dosage levels. Inhibition of ChE occurred at all dosage levels in dams, but only at the high-dosage level in pups. At the high dosage, ChE inhibition was greater in dams than in pups, and the relative degree of inhibition was RBC≈plasma>heart>brain (least inhibited). Pup exposure via milk from dams given 5 mg/kg/day was estimated to be roughly 120 μg/kg/day, which would be sufficient to inhibit blood ChE if pups were extra sensitive. Instead, ChE levels of all tissues of high-dosage pups rapidly returned to near control levels by PND 5, further indicating a lack of differential sensitivity at this dosage level.

975 IN VIVO METABOLISM, ACETYLCHOLINESTERASE INHIBITION, AND TOXICOKINETICS OF ALDICARB IN CHANNEL CATFISH (*ICTALURUS PUNCTATUS*).

E J Perkins and D Schlenk. *Environmental Toxicology Research Program, Department of Pharmacology, University of Mississippi, University, MS.*

The carbamate pesticide, aldicarb, demonstrates significant acute toxicity in mammals, birds, and fish through the inhibition of acetylcholinesterase (AChE) and may present high potential for exposure of aquatic organisms during periods of runoff. Toxicity studies have shown that channel catfish are approximately 10 times less sensitive to the acute toxic effects of aldicarb than are rainbow trout or bluegill. It is suggested by an earlier *in vitro* study, that the aldicarb resistance may be related to a low level of bioactivation to the potent aldicarb sulfoxide in catfish. The current study examines the plasma kinetics and *in vivo* metabolism of aldicarb in mature catfish in order to further understand this resistance. The dorsal aorta of 4 channel catfish (1 kg) were cannulated, and animals were given a 0.32mg (2 μCi) intravascular dose of ^{14}C-aldicarb. Blood samples were taken at time points ranging from 0.04 h to 48 h. Plasma was removed and analyzed for total plasma radioactivity, AChE activity, and parent:metabolite ratio. HPLC analysis showed the occurrence of a single polar metabolite (not aldicarb sulfoxide) which accounted for 100% of the total radioactivity by 12 h. The 2-compartment kinetics of total aldicarb equivalents displayed a rapid distribution phase ($t_{1/2}$ = 0.14 h) followed by a prolonged elimination phase ($t_{1/2}$ = 27.82 h) of similar duration to trout; whereas the 2-compartment model of parent compound gave α and β half-lives of 0.044 h and 1.67 h respectively. Inhibition of plasma AChE mirrored the profile of total ^{14}C, with maximal inhibition at 2.5 min, and return to control activity by 48 hours. These data support the hypothesis that a low rate of aldicarb bioactivation is a significant contributor to aldicarb resistance in catfish.

976 PHARMACOKINETICS OF DANTROLENE IN THE HEN: FOR TREATMENT OF ORGANOPHOSPHORUS CHEMICAL EXPOSURE.

K F Dockery, A W Dreisbach, J J Lertora, and W J George. *Tulane University School of Medicine, New Orleans, LA, USA.*

The hen is the model of choice for the investigation of organophosphorus-induced neuropathy. A proposed therapeutic intervention is the blocking of neuronal intracellular calcium release with dantrolene. Repeated drug administration can be achieved more efficiently and with less trauma to the animals using the oral route as opposed to intravenous administration. This report describes data after giving dantrolene orally at 25 mg/kg. Oral doses were administered via gavage as dantrolene sodium dissolved in propylene glycol. Blood samples were taken at selected time intervals (0.5, 1, 2, 4, 6, 8, 12, 24 hrs), extracted, and analyzed via high performance liquid chromatography (HPLC) for dantrolene. The data were then applied to model pharmacokinetic parameters (WinNonlin). Blood levels of dantrolene sodium exhibited considerable variability after oral administration (data given as mean ± standard deviation [SD]). Peak blood concentration (Cmax) was 29.34 ug/mL (SD = ±7.14) at 4.7 hrs (Tmax) and declined to 18.1 ug/mL (SD = ±9.83) at 23.4 hrs. The area under the curve (AUC 0-24 hrs) was 517 mg-hr/L. The estimated apparent oral clearance (CL/F) was 67.37 mL/hr. Though the average time course for absorption is similar to that expected from other animal studies, the results suggest a best fit for a two-compartment model with a long terminal elimination phase not previously reported.

977 DISPOSITION OF 3-CHLORO-4-(DICHLOROMETHYL)-5-HYDROXY-2(5H)-FURANONE (MX) IN B6C3F1 MICE.

E H Lebetkin, L T Burka, L-J Chen. *NIEHS, RTP, NC.* Sponsor: H B Matthews.

MX is a potent mutagen formed as a by-product of chlorination of drinking water, particularly where the water contains humic matter. MX has been estimated to account for 50% of the mutagenic activity in some drinking water. A recent bioassay in rats demonstrated an increased tumor incidence, primarily in liver and thyroid. An NTP study in mice is underway to complement the rat study. A distribution/metabolism study of MX in mice is being conducted in support of this study. MX is rapidly absorbed in mice when administered orally and is excreted in urine and feces as several polar metabolites. At doses from 0.2 to 20 mg/kg about 50 and 42% are excreted in urine and feces, respectively, in 72 hours. Most excretion occurs in the first 24 hours. Tissue/blood ratios are highest in forestomach (> 100), glandular stomach, intestine, and kidney, in that order. After iv administration of 0.2 mg/kg 72 h excretion in urine and feces accounts for 73 and 18 % of the dose. Intravenous administration results in high, prolonged levels of radioactivity in blood compared to oral dosing. MX disposition appears to be dominated by its chemical reactivity with highest concentrations of radioactivity being found at the site of administration.

978 THE USE OF A VALIDATED METHOD FOR THE ANALYSIS OF 3,3',4,4',5-PENTACHLOROBIPHENYL (PCB-126) IN PRELIMINARY TOXICOKINETIC RAT SAMPLES.

B Burback[1], J D Johnson[1], C S Smith[2], D Reichelderfer[1], B Harritos[1], E Psurny[1], K Carrico[1] and S W Graves[1]. [1]*Battelle Memorial Institute, Columbus, OH, USA;* [2] *National Institute of Environmental Health Sciences, National Institutes of Health, Research Triangle Park, NC, USA.* Sponsor: M R Hejtmancik.

A gas chromatography mass spectrometry method was developed to analyze tissue samples for a preliminary toxicokinetic study, which provided information to set doses, time points and limits of quantification (LOQ) for the definitive toxicokinetic study. This method will also be used in the National Toxicology Program's (NTP) chronic toxicity studies that comprise the Dioxin Toxicity Equivalency Factor Initiative. Female Harlan Sprague-Dawley rats were given a single gavage administration of PCB-126 at a dose of 3 or 3000 ng/kg and a dose volume of 2.5 or 5 mL/kg. The vehicle was corn oil that contained 1% acetone. Tissue samples were taken from a single animal per time point at 0.5, 2, 3, 5, 7, 11, 16, 21, 31, 41, 56, 71, 91 and 119 days after administration. Serum concentrations (ranged from 12 to 129 pg/mL; 3000 ng/kg dose) were 2 to 3 times higher than blood for a given time point and dose. Half-life values for blood and serum ranged from 95 to 112 days. Liver concentrations ranged from 34 to 94 pg/g (3 ng/kg) and 4.2 to 27.3 μ g/g (3000 ng/kg); lung concentrations ranged from 2.4 to 4.4 pg/g (3 ng/kg) and 152 to 476 pg/g (3000 ng/kg); and fat concentrations ranged from 56.7 to 190 pg/g (3 ng/kg) and 3.3 to 14.0 μ g/g (3000 ng/kg). The lower LOQ values were 5 pg/mL (or pg/g) in blood, serum or lung and 10 pg/g in liver or fat. The lower LOQ is limited by environmental factors such as the presence of small amounts of PCB-126 in the feed, vehicle, bedding and process carry over. (This work was supported by the NTP Chemistry Support Services Contract N01-ES-55395.)

979 THE USE OF A VALIDATED METHOD FOR THE ANALYSIS OF 2,3,4,7,8-PENTACHLOROCIBENZOFURAN (PeCDF) IN PRELIMINARY TOXICOKINETIC RAT SAMPLES.

E Psurny[1], D Reichelderfer[1], B Burback[1], J D Johnson[1], C S Smith[2], B Harritos[1], K Carrico[1] and S W Graves[1]. [1]*Battelle Memorial Institute, Columbus, OH, USA;* [2]*National Institute of Environmental Health Sciences, National Institutes of Health, Research Triangle Park, NC, USA.* Sponsor: M R Hejtmancik.

A gas chromatography mass spectrometry method was developed to analyze tissue samples for a preliminary toxicokinetic study, which provided information to set doses, time points and limits of quantitation (LOQ) for the definitive toxicokinetic study. This method will also be used in the National Toxicology Program's (NTP) chronic toxicity studies that comprise the Dioxin Toxicity Equivalency Factor Initiative. Female Harlan Sprague-Dawley rats were given a single gavage administration at a dose of 10 or 1000 ng/kg and a dose volume of 2.5 or 5 mL/kg. The vehicle was corn oil that contained 1% acetone. 980 COMPARATIVE PHARMACOKINETICS OF SARAFLOXACIN IN RAINBOW TROUT AND CHANNEL CATFISH.

G R Stehly, J R Meinertz, and W H Gingerich. *U.S. Geological Survey, Upper Mississippi Science Center, La Crosse, WI, USA.*

Sarafloxacin HCl ([6-fluoro-1-(4-fluorophenyl)-1,4-dihydro-4-oxo-7-(1-piperazinyl)-3-quinolinecarboxylic acid hydrochloride) is a broad spectrum fluoroquinolone potentially effective in controlling a number of bacterial infections in fish. Of the aquaculture therapeutants that are under consideration for approvals by the U.S. Food and Drug Administration, sarafloxacin, a flouroquinolone antibacterial is an example of an orally administered drug that would be readily metabolized, and therefore a model compound to study the concept of crop grouping in fish. The concept hypothesizes that species of fish can be grouped based on defining characteristics such as activity level, phylogeny, and temperature preference. As an initial test of the crop grouping concept, the similarities and differences in the pharmacokinetics of sarafloxacin after a single intraarterial dose of 5 mg/kg were tested in two surrogate fish species (rainbow trout and channel catfish) that differ greatly in group defining characteristics. The mean apparent volume of distribution of individual trout was approximately 10 L/kg and 4 L/kg for catfish while total body clearance was 0.05 L/kg/h for trout and 0.17 L/kg/h for catfish. Rainbow trout had an extended terminal elimination with a half-life of approximately 158 h, compared to 18 h for channel catfish. The results indicate that the two surrogate fish species differ dramatically in their ability to distribute, store, and eliminate sarafloxacin.

981 EFFECT OF OCTANOL:WATER PARTITION COEFFICIENTS OF ORGANOPHOSPHORUS COMPOUNDS ON BIODISTRIBUTION AND PERCUTANEOUS TOXICITY.

S E Czerwinski, J P Skvorak, D M Maxwell, and D E Lenz. *US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD, USA.* Sponsor: J A Romano, Jr.

In amplifying our understanding of the pharmacokinetic and pharmacodistribution properties of chemical warfare agents (CWA), knowledge of partition coefficient (log P) data can play a critical role. Using a recently published gas chromatographic method, the octanol:water log P for the CWA tabun, sarin, soman, GF, and VX were determined to be 0.384 ± 0.033, 0.299 ± 0.016, 1.824 ± 0.109, 1.038 ± 0.055, and 0.675 ± 0.070 respectively. Based on these data, the theoretical fluorophosphonate fragment value was determined to be -2.256 ± 0.273. There is a well established inverse relationship between log P and the rate of percutaneous penetration. In this study, using the time to onset of local fasciculations as an indicator of the percutaneous penetration rate, guinea pigs exposed to equitoxic doses of either soman or VX showed signs of intoxication at times (6.3 and 29.0 minutes respectively) inversely proportional to the derived log P values (1.824 and 0.675 respectively). Equilibrium tissue:blood log P may be estimated from octanol:water log P by assuming a direct correspondence between octanol:water partitioning and the partitioning between the lipid and aqueous phases of biological samples. Comparison of the estimated and directly measured tissue:blood log P revealed a correlation of 0.98 for soman in liver, muscle, and adipose tissue. Our results demonstrate that log P data can be used to both predict rates of absorption or determine the biodistribution of CWA in selected tissues. This will help us to identify possible therapeutic compounds and treatments for CWA exposure and investigate potential interactions between multiple therapeutic regimens in various mammalian species.

982 CROSS-SPECIES PHARMACOKINETIC COMPARISON OF AN ICAM-1 ANTISENSE OLIGONUCLEOTIDE, ISIS 2302, FROM MOUSE TO MAN.

R S Geary, R Yu, S P Henry, and A A Levin. *Isis Pharmaceuticals, Carlsbad, CA.*

ISIS 2302 is a 20-mer phosphorothioate antisense oligodeoxynucleotide (P=S ODN) targeted to the 3' UTR of human ICAM-1 mRNA. This compound has been studied in mouse, rat, rabbit, dog, and monkeys. ISIS 2302 is currently being developed as an anti-inflammatory therapeutic. The pharmacokinetics and metabolism of ISIS 2302 are remarkably similar across this broad range of species. Following IV dosing, the pharmacokinetics of ISIS 2302 are characterized by rapid distribution ($t_{1/2}$ = 30-60 minutes) to a wide variety of tissues followed by slow metabolism and elimination from these tissues. Plasma clearance (Cl) and steady-state volume of distribution (V_{ss}) are both related across species by body weight, not surface area. This relationship suggests that the plasma disposition is driven primarily by distribution to tissues. In fact, metabolism and urine excretion in plasma are minor contributors to plasma clearance of ISIS 2302. The plasma disposition half-lives and metabolism rate constants are similar between species and allow for direct prediction of plasma exposure in human patients. Finally, the pattern of distribution to tissues is similar across species. The similarity between the animal and human plasma pharmacokinetics give confidence in the predictions of exposure to human tissues derived from preclinical models.

983 4-METHYLIMIDAZOLE TOXICOKINETIC STUDY USING F344 RATS AND B6C3F$_1$ MICE.

D L Reichelderfer[1], J D Johnson[1], D L Walters[1], B L Burback[1], A Zutshi[1], S W Graves[1], and C Smith[2]. [1]*Battelle Memorial Institute, Columbus, OH, USA;* [2]*NIEHS, Research Triangle Park, NC, USA.* Sponsor: M R Hejtmancik.

Male and female F344 rats and B6C3F$_1$ mice were given a single intravenous (10 mg/kg BW) or gavage (10, 50 or 100 mg/kg BW) administration of 4-methylimidazole (4-MI), using 0.05 M phosphate buffered saline as the vehicle. Dosing volumes were 2 (rats) and 4 (mice) mL/kg for IV administration; 5 (rats) and 10 (mice) mL/kg for gavage administration. Animals were 14± 2 weeks of age when dosed. Serial blood samples were collected at specified time points after dosing (range 2 min to 24 hours). The plasma was analyzed for 4-MI using a validated gas chromatography method, which utilized a nitrogen phosphorus detector. The limit of quantitation was 1 μ g/mL. The IV plasma concentration time profiles were monophasic for the rats and mice. The $Conc_{(2\ min)}$, V_d and Cl values were ~ 11 μ g/mL, 750 mL/kg and 700 mL/hr, respectively, for the rats and 7.5 μ g/mL,1575 mL/kg and 2600 mL/hr, respectively, for the mice. After gavage administration, the C_{max} values for the 10, 50 or 100 mg/kg groups were 4.2, 11.9 and 20.5 μ g/mL (male rats); 6.6, 15.3 and 20.2 μ g/mL (female rats); 3.9, 18.6 and 30.2 μ g/mL (male mice) and 3.6, 18.7 and 30.2 μ g/mL (female mice), respectively. Oral doses of 50 and 100 mg/kg resulted in non-linear kinetics. (Chemistry Support Services Contract No. N01-ES-55395.)

984 PLASMA PROTEIN BINDING OF 2,4-DICHLOROPHENOXYACETIC ACID (2,4-D) AND 2-METHYL-4-CHLOROPHENOXYACETIC ACID (MCPA) IN THE DOG.

L M Dickow[1], D K Gerken[1], R A Sams[2], and S A Ashcraft[2]. [1]*The Ohio State University, Department of Veterinary Biosciences, Columbus, OH, USA;* [2]*The Ohio State University, Analytical Toxicology Laboratory, Columbus, OH, USA.*

The purpose of this study was to determine plasma protein binding of 2,4-D and MCPA in dogs. Determinations of protein binding of 2,4-D and MCPA were performed by ultracentrifugation of freshly obtained pooled beagle plasma supplemented with 42.5 - 574 μg/mL 2,4-D or 45.0 - 515 μg/mL MCPA. Total 2,4-D and MCPA plasma concentrations and unbound 2,4-D and MCPA ultrafiltrate concentrations were determined by HPLC with fluorescence detection. The percent of unbound 2,4-D was 4 % and 27 % at total 2,4-D concentrations of 48.2 μg/mL and 574 μg/mL, respectively. Determinations of the percent unbound of MCPA resulted in similar findings with the percent unbound of MCPA being 3 % and 29 % at total MCPA concentrations of 45.0 μg/mL and 515 μg/mL respectively. Non-linear regression of the hyperbolic curve of bound 2,4-D versus free 2,4-D, and bound MCPA versus free MCPA were best fit as 2 classes of binding sites. From the fit of these data, the sites were determined to be a low capacity, high

affinity binding site, and a high capacity, low affinity binding site. Protein binding of 2,4-D was also determined in plasma supplemented with 2,4-D + MCPA. At a plasma concentration of 50 µg 2,4-D/mL, fraction of unbound 2,4-D was 4% after no supplementation of MCPA and increased to 16% after supplementation of 200 µg MCPA/mL. When the plasma concentration of 2,4-D was 400 mg/mL, the fraction of unbound 2,4-D increased from 21% to 31% after co-supplementation of zero or 200 µg MCPA/mL.

985 MEASURING BIOAVAILABILITY OF DIESEL SOOT-ADSORBED BENZO(A)PYRENE IN DOGS FOLLOWING A SINGLE-BREATH INHALATION EXPOSURE.

P Gerde[1,2], B A Muggenburg[1], and A R Dahl[3]. [1]*Lovelace Respiratory Research Institute, Albuquerque, NM, USA;* [2]*Institute of Environmental Medicine, Karolinska Institutet, Stockholm Sweden;* [3]*Battelle, Columbus, OH, USA.*

Exposure to inhaled diesel soot is suspected to increase the risk of lung cancer in humans. Whether it is the carbonaceous core of the diesel particle or its coat of adsorbed organics that poses the greater lung cancer risk is a matter of controversy. The extent to which carcinogenic hydrocarbons on diesel soot are bioavailable in the lungs is also disputed. Here we report the alveolar absorption in the Beagle dog of tritiated benzo(a)pyrene (BaP) adsorbed on the carbonaceous core of diesel soot particles. The concentration of BaP on the soot was 0.015 g/g, which corresponds to 25% of a monomolecular coating of BaP on the soot surface. A novel method was used to expose the dogs to a bolus of resuspended diesel soot in a single breath. Following inhalation into the deep lung, the appearance of BaP in the systemic circulation was monitored by repeatedly sampling blood from the ascending aorta and the posterior vena cava. The particle-adsorbed BaP falls into two categories in terms of bioavailability: an instantaneously available fraction desorbed quickly from the soot particles upon deposition in the lungs; a second—either slowly desorbing or permanently adsorbed— fraction gave a low dose rate to surrounding lung tissues. The findings suggest that the rapidly desorbed fraction in the lungs poses the greater lung cancer risk. (Research sponsored by HEI Grant EPI 1351901, and the Swedish Council for Working Life Research, Grant 95-0192 in facilities provided by the U.S. DOE/OHER under Cooperative Agreement DE-FC04-96AL76406.)

986 BUTADIENE RESOLVED CHIRAL EPOXIDES: REACTIONS WITH DNA.

K K Divine[1] and A R Dahl[2]. [1]*Lovelace Respiratory Research Institute, Albuquerque, NM;* [2]*Battelle, Columbus, OH.*

Butadiene (BD), a major environmental/occupational toxicant, is both mutagenic and carcinogenic in rodents and is classified by IARC as a Group 2A carcinogen. BD is metabolized to the reactive epoxides butadiene monoepoxide (BO) and butadiene diepoxide (BDO_2). Each epoxidation of BD introduces an asymmetric carbon, thus producing five possible stereoisomers: (S)-BO, (R)-BO, (2S,2S')-BDO_2, (2R,2R')-BDO_2, and diastereomeric *meso* BDO_2. Stereoisomers of chiral monofunctional alkylating agents like BO react with DNA to form diastereomeric adducts. Each diastereomeric adduct is a distinct chemical species that will be both formed and repaired at a unique rate. In addition, if the diastereomeric adduct contains a second chiral electrophilic group, as with BDO_2, each second group also will have a unique reaction rate with chiral nucleophiles. To examine the role of stereochemistry in BD-DNA adduct formation, we have synthesized, purified and characterized (S)-BO, meso-BDO_2 and (2R,2R')-BDO_2. Purity was determined by boiling points, GC/MS, and/or NMR analysis. Enantiomeric purity was determined by polarography and/or circular dichroism. The rate of reaction between butadiene-epoxide stereoisomers and DNA was determined using an isotope-dilution, multi-dimensional GC/GC/MS method. Initial results suggest that the half-life of the racemic BDO_2-DNA reaction is approximately 17 hr and follows first-order reaction kinetics. Further studies will determine the effect BD-epoxide stereochemistry has upon DNA interactions. (Supported by NIH Grant 1 F32 ES05836-01 from NIEHS and U.S. DOE cooperative agreement No. DE-FC04-96AL-76406.)

987 COMPARATIVE DI-(2-ETHYLHEXYL)PHTHALATE (DEHP) TOXICOKINETIC PROFILE IN FEMALE WISTAR RATS AND CD1 MICE.

C Nativelle[1], K Picard[1], J-C Lhuguenot[1], N-C Chagnon[1] and J-F Régnier[2]. [1]*ENSBANA, Laboratoire de Toxicologie Alimentaire, Dijon, France;* [2]*Elf-Atochem S.A., Département de Toxicologie Industrielle, Paris-la-Défense, France.*

Di-(2-ethylhexyl) phthalate is extensively used as plasticiser for PVC. Developmental toxicity studies have shown that mice are more sensitive than rats. Mono-(2-ethylhexyl)phthalate (MEHP), the major DEHP-metabolite is excreted in the urine of mice but not in rats. Furthermore, glucuronidation phase-2 pathway is not involved in rats for the metabolism of MEHP. In this study, female mice and rats have received DEHP by oral gavage at the dose levels of 200 or 1000 mg/kg bw, either as a single dose of [^{14}C]-DEHP, or as a 5-day pre-treatment with unlabelled-DEHP followed by a single dose of [^{14}C]-DEHP on the 6th day. Blood was collected at defined time interval, and analysed quantitatively for ^{14}C-radioactivity. The major difference observed is a much higher level of ^{14}C-radioactivity in mice than in rats during the blood peak time (1-4 hours after administration) after a single administration at 200 and 1000 mg/kg, and after a repeated administration at 200 mg/kg. ^{14}C-radioactivity levels are quite similar after repeated administration at 1000 mg/kg. Repeated treatment have no effect in rats at both dose levels on the ^{14}C-blood levels compared to a single administration, and in mice at 200 mg/kg. In contrast, ^{14}C blood level is significantly decreased in mice after repeated administration of 1000 mg/kg. However, DEHP was toxic at that dose level. In conclusion, higher blood ^{14}C-radioactivity levels were observed in mice than in rats, after single or repeated oral administration of non-toxic DEHP dose levels.

988 COMPARATIVE DI-(2-ETHYLHEXYL)PHTHALATE (DEHP) TOXICOKINETIC PROFILE IN PREGNANT WISTAR RATS AND CD1 MICE.

J-C Lhuguenot[1], C Nativelle[1], K Picard[1], M-C Chagnon[1] and J-F Régnier[2]. [1]*ENSBANA, Laboratoire de Toxicologie Alimentaire, Dijon, France;* [2]*Elf-Atochem S.A., Département de Toxicologie Industrielle, Paris-la-Défense, France.*

A "sister" study have highlighted some significant toxicokinetic differences between female rats and mice after single or repeated oral administration of DEHP. In the present study, pregnant rats or mice received DEHP by oral gavage at the dose levels of 200 or 1000 mg/kg bw, either as a single dose of [^{14}C]-DEHP on gestation day (GD) 7, or as a 5-day pre-treatment with unlabelled-DEHP followed by a single dose of [^{14}C]-DEHP on GD11. Blood was collected at defined time interval, and analysed qualitatively and quantitatively for ^{14}C-radioactivity and DEHP-metabolites. The concentration in ^{14}C-radioactivity during the peak time (1-4 hours after administration) was significantly higher in mice than in rats only after a single dose of 200 mg/kg. In the other cases, ^{14}C-radioactivity blood levels were comparable between the species. At 1000 mg/kg, repeated administration increased the ^{14}C-radioactivity blood level at 1000 mg/kg in both species compared to a single treatment. GC analysis have demonstrated that in all cases the majority of ^{14}C-radioactivity was associated with MEHP. After a single dose, MEHP peak blood levels were higher in mice than in rats. After a repeated administration, MEHP peak blood levels were comparable in both species at 200 mg/kg, but lower in mice than in rats at 1000 mg/kg. In both species, after a single administration of 1000 mg/kg and to a less extend at 200 mg/kg, a significant part of the blood ^{14}C-radioactivity comes from non-hydrolysed DEHP. After repeated administration the contribution of non-hydrolysed DEHP to ^{14}C-radioactivity level is minimal. In conclusion, the administration of high dose levels of DEHP affects significantly its toxicokinetic in pregnant mice and rats.

989 ELIMINATION AND DISTRIBUTION OF TETRYL FOLLOWING SUBCUTANEOUS ADMINISTRATION IN THE MALE SPRAGUE DAWLEY RAT.

J A Spinnato and S R Myers. *Department of Pharmacology and Toxicology, University of Louisville, Louisville, KY.*

Tetryl is a booster explosive used in the production of detonators and blasting caps, and exposure to tetryl has been associated with numerous toxicities in humans such as dermatitis, respiratory irritation, gastric disorders, neuro-

logical disorders, anemia, and possibly, bone marrow suppression. While tetryl is no longer produced in the United States, large stores of tetryl are present in areas, which were once sites of tetryl production and use, such as, army depots, ammunition plants, and proving grounds. Currently, there are twelve sites on the National Priorities List, which are contaminated, with tetryl. Environmental exposure to these sites and potential threat to human health has yet to be determined. At present, there is very little information concerning the distribution and elimination of tetryl. To study the distribution and elimination, of tetryl, Sprague Dawley rats were administered tetryl subcutaneously at doses of 25, 100, and 300 mg/kg, which contained 14C-tetryl as a marker. The animals were placed in metabolism cages, and at twenty-four hours, urine, feces, blood, and various organs were collected and radioactivity was determined. The percent dose eliminated in the urine at 25, 100, and 300 mg/kg was 10.02 ± 2.48, 10.3 ± 1.66, and 13.24 ± 5.79 respectively

990 PHARMACOKINETICS OF RECOMBINANT HUMAN RELAXIN IN RATS: EFFECTS OF INDUCED ANTIBODIES.

A L Salles, L D T Guzman, J Browning, L J Frey, B H Grove, M E Erikson, and L B Pickford. *Connetics Corporation, Palo Alto, CA, USA.*
Sponsor: R Hill.

Relaxin (Rlx), a hormone of pregnancy in most mammalian species, is a 6 kD protein member of the insulin family. The pharmacokinetics (PK) of recombinant human Rlx (rhRlx), an investigational therapeutic, have been described previously in intravenously dosed naïve animals. However, the effects of anti-rhRlx antibodies (Ab) on serum rhRlx levels and PK parameters were not known. To study this, high titers of serum anti-rhRlx Ab were pre-generated in young adult female Sprague-Dawley rats (Ab-positive). Rlx naïve and Ab-positive rats received either 1 or 5 daily bolus subcutaneous doses of rhRlx, at 0.1, 0.5 or 1.0 mg/kg/day (N=4 per dose level). Blood was sampled at –0.5, 0.25, 0.5, 1, 2, 4, 6, 8, 10 and 24 hours. Serum rhRlx levels and anti-rhRlx Ab titers were measured by ELISA. Data underwent non-compartmental analysis. Following a single bolus dose (1.0 mg/kg) to naïve rats, the maximal concentration (C_{max}) and area under the curve (AUC) were 1288 ng/mL and 3507 ng*h/mL, respectively. The time at which the highest concentration was observed (T_{max}) and the β-phase elimination half-life ($T_{1/2\beta:4-10\ h}$) were 60 and 52.5 minutes, respectively. The residual serum rhRlx level at 24 hours (C_{24}) was 0.33 ng/mL. A dose-proportional relationship was found in both C_{max} and AUC. In naive rats, there were minimal differences between single and repeat-dose groups. By comparison, in Ab-positive rats, a single bolus resulted in a reduced C_{max} (40%), increased AUC (10%), doubled T_{max} (120 min), while the C_{24} was 43 ng/mL, or about 100 times higher. However, repeat dosing in Ab-positive rats increased C_{max} (107%), AUC (270%), but not T_{max} values, over the repeat-dose, naïve group. $T_{1/2\beta}$ was extended by about 2.5 times, consistent with increased binding capacity for rhRlx. In conclusion, prolonged treatment of rats with rhRlx, like other recombinant human proteins, generates Ab that affect clearance and thus potentially, exposure. Rat anti-rhRlx Ab caused an increase in serum rhRlx levels and delayed clearance, especially following repeat dosing.

991 TOXICOKINETICS OF FORMAMIDE IN RODENTS.

E J Little[1], R Moore[1], R Harris[1], T Morton[1], and D Overstreet[2]. [1]*Midwest Research Institute, Kansas City, MO, USA;* [2]*National Institute of Environmental Health Sciences, Research Triangle Park, NC, USA.*
Sponsor: M L Cunningham.

The pharmacokinetics of formamide (FM) were assessed after a single i.v. or single oral administration to rats (Fischer 344) and mice ($B_6C_3F_1$) at 3 dose levels/route/species. Pharmacokinetic (PK) parameters, including dose normalized area under the concentration time curve (DNAUCs), peak plasma levels (C_{max}), and clearance (Cl), determined for rats after an i.v. dose suggest linear kinetics over the dose range. FM was rapidly absorbed into the systemic circulation after oral dosing to rats, with C_{max} determined at 1 to 2 hr. DNAUCs and Cl were comparable between sex and dose level. These data suggest linear kinetics after oral administration of FM over the dose range. The estimate of absolute bioavailability (F) for rats was greater than 1 at all dose levels. This observation, unexpected due to the apparent linear kinetics, may result from route-dependent first pass lung clearance, or route-dependent enterohepatic cycling, or from intergroup variability in the elimination half-life ($t_{1/2}$) which may have resulted in an overestimation of the AUC and ultimately F. F-values of greater than 1 were also observed in mice. However, the PK behavior of FM in mice appeared different than in rats. Trends in route dependent changes in parameters were not clear for mice. There was rapid absorption into the systemic circulation following oral administration with C_{max} occurring within 1 hour. Although Cl in mice appeared to remain constant at the different oral doses, DNAUCs, $t_{1/2}$ and mean residence time increased with increasing dose. Comparison of i.v. and oral data suggested a dose dependent decrease in Cl. The PK data obtained for mice are indicative of the saturation of metabolism (Michaelis-Menten type). If observed decreases in the elimination rate constant and Cl are real, the system is not linear. This is consistent with the observed increase in DNAUCs for the oral route, since a decrease in elimination capacity will result in a higher AUC for a given dose. In conclusion, FM is rapidly and completely absorbed after oral administration to rats and mice. Estimated parameters suggest a linear kinetic system for this compound in rats. PK data obtained for mice are suggestive of the saturation of metabolism, with evidence of a nonlinear kinetic system for this species.

992 BRANCHIAL ELIMINATION OF SUPERHYDROPHOBIC ORGANIC CHEMICALS BY FISH: DEPENDENCE ON CHEMICAL LOG K_{ow}.

J W Nichols, P N Fitzsimmons, J D Fernandez, A D Hoffman, and B C Butterworth. *U.S. EPA, Mid-Continent Ecology Division, Duluth, MN.*

The development of PBTK models for fish has been slowed by a lack of understanding of factors that control branchial elimination of superhydrophobic compounds. Branchial efflux of high log K_{ow} compounds is difficult to measure directly because chemical concentrations in expired water are extremely low. A method was therefore developed based on the extraction of large volumes of expired water by Ambersorb® resin followed by high-resolution GC/MS analysis of toluene extracts using an isotope dilution technique. Data for a model PCB (2,2',5,5'-tetrachlorobiphenyl; tetraCB, log K_{ow} = 5.84) were reported previously (The Toxicologist, 42:1-S, no. 1039). In this poster we present branchial efflux data for two additional PCBs, 2,2',3,3',5,5',6,6'-octachlorobiphenyl (octaCB, log K_{ow} = 7.24) and decachlorobiphenyl (decaCB, log K_{ow} = 8.18). OctaCB and decaCB were present in water at low (< 1 ppt) but measurable concentrations. These data were converted to apparent blood/water partition coefficients (K_{bw}) based on measured residues in blood. Estimated K_{bw} values for octaCB and decaCB were 228,000 and 630,000, respectively. A regression of partitioning data for the three PCBs against chemical log K_{ow} yielded a log-linear equation: log K_{bw} = 0.72 log K_{ow} + 0.02 (r^2 = 0.98). The slope and intercept terms in this equation do not differ significantly from those of an equation developed previously using less hydrophobic compounds (log K_{bw} = 0.63 log K_{ow} - .58; calculated using blood data for rainbow trout). It is suggested, therefore, that branchial elimination of high log K_{ow} compounds proceeds to an equilibrium between afferent blood and expired respiratory water, as assumed in current models for branchial flux at fish gills.

993 DERMAL PHARMACOKINETICS OF METHYL TERTIARY BUTYL ETHER (MTBE) AND TERTIARY BUTYL ALCOHOL (TBA) IN HUMAN VOLUNTEERS.

J D Prah[1], D L Ashley[2], and M W Case[1]. [1]*U S Environmental Protection Agency, NHEERL, Research Triangle Park, NC, USA;* [2]*Centers for Disease Control and Prevention, NCEH/EHLS, Atlanta, GA, USA.*

The extensive use MTBE as a fuel additive has resulted in its contamination of water sources from run off, spills, and leaks from below ground sources. As a result of such contamination drinking water wells have been closed or remediated. MTBE contamination of domestic has raised the probability that it will result in dermal exposure. Dermal pharmacokinetics of MTBE is important to assess this risk. To that end, one arm of five males subjects was exposed to MTBE in an aqueous exposure system for one hr at a water temperature of 40°C. Each subject received one concentration of MTBE (30, 45, 60, 75, or 90 mg/L). Fourteen blood samples were obtained from each subject at intervals during exposure and up to 24 hrs post-exposure. The objective was to determine the uptake and elimination of MTBE and the elimination of a metabolite, TBA. The basic results indicated that, after a lag of about 15 min, MTBE appeared in the blood, rose rapidly, and was rapidly eliminated. The MTBE blood elimination data were well-described by a double exponential fit. The half life ranged from about 40 min to 2 hr for a first compartment and about 5 to 6 hrs for a second compartment. TBA slowly increased during and after the exposure and was slowly eliminated approaching baseline after 24 hrs. This is an abstract of a proposed presentation and does not reflect EPA policy.

994 TOXICOKINETICS OF METHYL-TERTIARY BUTYL ETHER INHALED ALONE AND IN COMBINATION WITH GASOLINE.

J Benson, B Tibbetts, and J Krone. *Lovelace Respiratory Research Institute, Albuquerque, NM, USA.*

Methyl-tertiary butyl ether (MTBE) is the most commonly used fuel oxygenate added to gasoline to decrease carbon monoxide and hydrocarbon emissions. Little is known of the toxicokinetics of MTBE inhaled over a range of concentrations relevant to human exposure or the effects of co-exposure to gasoline vapors on its toxicokinetics. The objectives of this study were to compare the toxicokinetics and metabolism of MTBE in rats inhaling 4, 40, or 400 ppm MTBE and to evaluate the effects of acute and repeatedly inhaled gasoline on the toxicokinetics and metabolism of 40 ppm MTBE. Groups of 51 male F344/Crl rats, 8-10 wk old, were acutely exposed nose-only for 4 hr to 4, 40, or 400 ppm ^{14}C-MTBE or to 200 ppm gasoline containing 40 ppm MTBE. A group of 51 male rats was similarly exposed for 7 consecutive days to 200 ppm gasoline containing 40 ppm MTBE, followed by an 8th day of exposure to 200 ppm gasoline containing ^{14}C-MTBE. Separate groups of five rats each were designated for determination of: 1) respiratory minute volumes; 2) initial MTBE body burden; and 3) rates of excretion and identification of metabolites in breath, urine, and feces up to 72 hr post exposure. The remaining rats were sacrificed after 0.5, 1, 2, and 4 hr of exposure and at selected time points after exposure for determination of tissue uptake, metabolism, and clearance. Concentrations of MTBE equivalents in liver, lung, kidney, testes, and brain were highest at the end of the 4-hr exposure. Uptake and retention of MTBE equivalents in these tissues were greatest for rats inhaling 4 ppm MTBE and least for rats inhaling 400 ppm. MTBE and/or its metabolites were chiefly excreted in breath and urine. The single co-exposure to gasoline vapor had little effect on the uptake, tissue clearance, and excretion of 40 ppm MTBE. Repeated exposure to gasoline in combination with 40 ppm MTBE altered the tissue uptake and clearance of MTBE and enhanced excretion of MTBE metabolites in urine. These results suggest that the tissue uptake and retention are dependent on MTBE concentration and that repeated inhalation of MTBE in gasoline may alter its toxicokinetics. (Research funded under DOE Cooperative Agreement No. DE-FC04-96AL76406.)

995 STUDIES OF THE INTESTINAL PERMEABILITIES OF HYDROCARBONS IN THE RAT.

K Rozett[1], E C Lonardo[2], P J Sinko[3], and E H Weyand[1]. [1]*Joint Graduate Program in Toxicology, Rutgers University/UMDNJ, Piscataway, NJ, USA;* [2]*Exxon Biomedical Sciences, Inc., East Millstone, NJ, USA;* [3]*Graduate Program in Pharmaceutical Sciences, Rutgers University, Piscataway, NJ, USA.*

Petroleum products are complex mixtures of hydrocarbons. Understanding the absorption and distribution of individual hydrocarbons constituting these mixtures will aid in assessing the potential exposure to petroleum products. n-Nonane, an aliphatic hydrocarbon found as a component of some petroleum products, has demonstrated significant distribution to the rat brain after inhalation. However, little is known of the absorption and distribution associated with the ingestion of n-nonane. The purpose of the present study is to determine the intestinal permeabilities of n-nonane and isomers of n-nonane using the single pass intestinal perfusion (SPIP) procedure. Age matched male and female Sprague Dawley rats and Fisher 344 rats were perfused with either [^{14}C]-n-nonane or [^{14}C]-1,2,4-trimethylcyclohexane in an isoosmotic MES buffer. [^{3}H]-Polyethylene glycol 3350 was used as a nonabsorbable marker for the purpose of assessing net intestinal water transport. Outlet samples were collected and analyzed by liquid scintillation counting. Effective intestinal permeabilities were calculated using ratios of inlet and outlet concentrations of n-nonane and 1,2,4-trimethylcyclohexane corrected for water flux. 1,2,4-Trimethylcyclohexane demonstrated greater permeability than n-nonane in male Sprague Dawley (1.37 and 1.11, respectively), male Fisher 344 (1.68 and 1.18, respectively), and female Fisher 344 (1.37 and 0.93, respectively) rats. Female Sprague Dawley rats exhibited similar permeabilities for 1,2,4-trimethylcyclohexane (1.46) and n-nonane (1.45). These results suggest that both compounds would be systemically available following ingestion.

996 KINETICS AND ORAL BIOAVAILABILITY OF FUMONISIN B_1.

M R Martínez-Larrañaga, M L Fernández-Cruz, M A Martínez, M T Frejo, M Tafur, M Martínez, M J Díaz, and A Anadón. *Dept. of Toxicology, Institute of Pharmacology and Toxicology, CSIC, Faculty of Veterinary Medicine, Complutense University, Madrid, Spain.*

Fumonisin B_1 (FB_1), mycotoxin from fungus *Fusarium moniliforme*, a common contaminant of corn worldwide, possesses hepatocarcinogenic and hepatotoxic properties in rats and has been statistically associated with an increased risk of oesophageal cancer in man. The risk assessment of FB_1 requires detailed information on kinetic properties. We investigated plasma disposition of FB_1 after iv (2.0 mg/kg) and oral (10 mg/kg) administration in Wistar male rats. After FB_1 dosing, serial blood samples were obtained and plasma samples separated. FB_1 levels in the plasma samples were analyzed by a HPLC method which involves solid-phase anion-exchange clean-up, precolumn derivatisation with *o*-phthaldialdehyde and reversed-phase HPLC (LiChrosorb RP-8 column) with fluorescence detection (excitation 335 nm, emission 440 nm). Plasma samples were deproteinised with methanol and then centrifuged. The sample supernatant applied to a SAX cartridge. FB_1 eluted with 5% acetic acid in methanol. The eluate was taken to dryness under N_2 at < 60° C and the residue was finally taken up in 0.1M sodium borate prior to derivatisation and HPLC analysis. The mobile phase was methanol- 0.1M sodium di-hydrogenphosphate (63:34) adjusted to pH 3.4. FB_1 kinetic behaviour was best described by a 2-compartment open model. FB_1 was rapidly, but incompletely absorbed ($t_{1/2}a$, 0.13h). T_{max} and C_{max} in plasma were 0.58 h and 0.23 μ g/ml. Oral bioavailability was 3.6 %. FB_1 distributed more quickly after iv than after oral dosing ($t_{1/2}\alpha$, 0.23 and 0.33h. The apparent volume of distribution [$V_{d(area)}$] and at steady state [$V_{d(ss)}$] were 0.11 and 0.10L, after iv dosing, suggesting a considerable diffusion of FB_1into tissue. The elimination half-lives ($t_{1/2}\beta$) for iv and oral dosing were 1.07 and 3.46 h, indicating rapid disappearance of the FB_1 from blood. The fate of FB_1 is still unclear, but our results might to support the hypothesis that a FB_1 portion undergoes metabolic activation. Further studies will be necessary to provide this information. This work has been supported by the *European Union*, Brussels, Project AIR3-CT94-1325.

997 TOXICOKINETICS OF CYHALOTHRIN IN THE RAT.

A Anadón, M Martínez, M L Fernández-Cruz, M A Martínez, M T Frejo, M Tafur, M J Díaz, and M R Martínez-Larrañaga. *Department of Toxicology, Institute of Pharmacology and Toxicology, CSIC, Faculty of Veterinary Medicine, Complutense University, Madrid, Spain.*

Cyhalothrin is a synthetic pyrethroid insecticide which is used topically for the control of ectoparasites. It is also widely used in agriculture and in-home desinsection. Pyrethroids are neurotoxic compounds. In humans, intoxications are usually very light, and neurological symptoms, such as tremor and seizures, are found only in animals. Sensory facial irritation is a very common syndrome (paraesthesia and dysaesthesia). Dermal irritative and allergic effects are very often reported following occupational exposure. The data on toxicokinetics of insecticide pyrethroids are very sparce. Due to toxicokinetic data generated from experimental animal studies are an important component in the overall assessment of human health risk, the objective of this work was to determine the toxicokinetic profile of cyhalothrin. Wistar rats were treated with single iv dose of 3 mg cyhalothrin/kg. Serial blood samples were obtained, plasma was separated and concentrations of cyhalothrin were determined by HPLC assay. Plasma samples were extracted in three 5-ml portions of acetonitrile. After shaking and centrifugation, the combined acetonitrile extracts were rinsed with hexane. The acetonitrile phase was taken to dryness under N_2 at < 30° C, and the residue was finally taken up in 0.5 ml of mobile phase (acetonitrile and distilled-deionized water 80:20) for HPLC analysis using a Nucleosil 120-5 C_{18} column. Detection was effected using ultraviolet absorption at 266 nm. Cyhalothrin plasma kinetics were adequately described by a two-compartment open model with a relatively rapid distribution ($t_{1/2}\alpha$ = 0.11h) and a slow elimination phase ($t_{1/2}\beta$ = 8.15h). The kinetic variables obtained after iv administration confirm the belief that cyhalothrin is well distributed to the tissues ($V_{d(area)}$ and $V_{d(ss)}$ are 0.14 and 0.11 liters). The value of the K_{12} / K_{21} (found to be 11.7) is also indicative of good tissue penetration. (This work has been supported by the *Dirección General de Enseñanza Superior e Investigación Científica, Ministerio de Educación y Cultura*, Spain, Project No. PB97-1236.)

998 TOXICOKINETIC AND INDUCTION OF HEPATIC P 450 1A1/1A2 ENZYME ACTIVITIES IN MALE RATS AFTER SINGLE S.C. DOSES OF 3,3',4,4'-TETRACHLOROBIPHENYL (PCB 77).

A S Faqi[1], B Heinrich-Hirsch[2], W Mathar[2] and I Chahoud[1]. [1]*Institut für Klinische Pharmakologie und Toxikologie, Freie Universität, Berlin and* [2]*Bundesinstitut für gesundheitlichen Verbraucherschutz und Veterinärmedizin, Berlin, Germany.* Sponsor: R Stahlmann.

The polychlorinated biphenyls (PCBs) found in blood and other tissues of humans, wildlife, and fish exposed via the food chain are mainly non-coplanar congeners, thus toxicokinetic data of such PCBs are much needed. We have conducted a toxicokinetic study of a non-coplanar PCB (PCB 77) and determined whether it induces 7-ethoxyresorufin O-deethylase (EROD) and 7-methoxyresorufin O-deethylase (MROD) activities. The animals were treated subcutaneously with single doses of 18 mg (PC18) or 60 mg/kg PCB 77/kg bw (PC60). The concentration of PCB 77 was determined in the blood, liver, fat, testis 1, 4, and 8 weeks following treatment, whereas EROD and MROD activities in the liver were only determined 1 and 4 weeks after treatment. The concentration of PCB 77 in the whole blood 1 week after treatment was 1590 and 3800 in PC18 and PC60 groups, respectively. Four weeks following treatment, the blood concentration declined to 8.8 % in PC18 and 20 % in PC60. The concentration ratio: liver/adipose tissue 1, 4 and 8 weeks following treatment in PC60 group was 1.8, 2.6 and 1.9. Significant amount of PCB 77 corresponding up to 60 % of liver concentration was detected in the testis 1 week following treatment. PCB 77 elicits dose-dependent induction of EROD and MROD activities in the liver with a time-course of induction directly correlated to the concentration of the substance in this organ.

999 STRAIN-DEPENDENT DISPOSITION OF ARSENIC IN THE MOUSE.

M F Hughes, E M Kenyon, B C Edwards, C T Mitchell and D J Thomas. *Experimental Toxicology Division, National Health and Environmental Effects Research Laboratory, U.S. Environmental Protection Agency, Research Triangle Park, NC.*

Inorganic arsenic (iAs) is methylated and excreted by most mammalian species. The role methylation has in As toxicity is not clear. Acutely, it appears to be a detoxication mechanism, but a methylated metabolite of iAs, dimethylarsinic acid (DMA), promotes tumors. There may be genetic polymorphisms in iAs metabolism. Potential differences between inbred mouse strains in iAs disposition was examined. Female mice (90 days old, inbred strains C3H/HeNCrlBR, C57BL/6NCrlBR and hybrid B6C3F1/ CrlBR) were administered [^{73}As]-arsenate (AsV) or -arsenite (AsIII) po (0.5 or 5.0 mg As/kg). The 24 hr clearance of ^{73}As in one group was monitored by whole-body radioassay. In a second group, excreta and tissues were collected at 24 hr. The clearance of 0.5 mg As/kg AsV and AsIII was similar in the three strains. By 4 hr, > 50% of the dose was eliminated and < 10% remained at 24 hr. ^{73}As retention was slightly higher in C57BL/6 mice up to 6 hr in mice dosed with 0.5 mg/kg AsV. In the 5 mg As/kg AsV group, the clearance was slower than in the low dose group. Elimination of 50% of the dose required 6-8 hr. ^{73}As retention at 4 and 6 hr was greatest in the C57BL/6 mice, followed by B6C3F1 and C3H mice. However, 10% of the dose remained in all strains at 24 hr. The three strains had similar clearance of 5.0 mg As/kg AsIII. It took more than 8 hr for 50% of the dose to be cleared and < 10% remained at 24 hr. Except in liver of AsIII-exposed mice, there was a trend of higher tissue ^{73}As concentration (%dose/gm) in the high AsIII and AsV dose groups. DMA was the major urinary metabolite. There was a trend of lower DMA and higher AsIII, AsV and monomethylarsonic acid excretion with increased dose of iAs. The results suggest a strain-dependent clearance of arsenate at time points less than 8 hr after an acute dose. Thus genotype may affect arsenate disposition in the mouse. Uncertainty in the arsenic risk assessment will be reduced with a better understanding of the factors that affect its disposition. (This abstract does not necessarily reflect U.S. EPA policy.)

1000 INTRATRACHEAL INSTILLATION OF GANCICLOVER AS AN ALTERNATIVE DRUG DELIVERY ROUTE.

H J Kim[1], T C Donaghey, and J D Brain. *Dept. Environmental Health, Harvard School of Public Health, Boston, MA, USA;* [1]*Dept. Toxicology, Korea Food and Drug Administration, Seoul, Korea.*

Ganciclovir, an antiviral drug, is usually given by the intravenous route. In this study we explored the possibility of administering ganciclovir directly to the lungs by characterizing the pharmacokinetics and tissue disposition of ganciclovir after pulmonary delivery. We first determined whether intratracheal (*it*) instillation of ganciclovir could elicit toxic or inflammatory responses in the lungs. Bronchoalveolar lavage analyses showed that ganciclovir at up to 20 mg/kg dose had neither toxic nor inflammatory effects in the lungs of male CD rats 24 hr post-instillation. To determine the fate of ganciclovir, rats with indwelling arterial cannulas were given 5 or 20 mg/kg by *iv* and *it* administration and followed for up to 7 hr. Serial blood samples as well as lung tissue and lung macrophages were taken and analyzed by HPLC to measure ganciclovir content. Ganciclovir was eliminated from the blood at approximately the same rate in *iv* and *it* groups at both doses, as reflected by similar elimination rate constants and half-life values. Ganciclovir was absorbed rapidly from the lungs; peak concentrations in blood of 1.93 and 11.13 μ g/ml were reached within 15-20 min after *it* dosing at 5 and 20 mg/kg, respectively. *It* instillation enhanced the drug levels in the arterial blood during the elimination phase. The absolute bioavailability of instilled ganciclovir was 0.99 ± 0.08 or 1.28 ± 0.14 (mean ± SE) for the respective doses. One hr after *iv* and *it* administration of 5 mg/kg, respective ganciclovir levels in the lungs after multiple lavages were 0.46 and 56.0 μ g/g tissue. From 30 min to 7 hr, the area under the lung tissue concentration-vs.-time curve was 107-fold higher for *it* than *iv* routes. Interestingly, ganciclovir levels in the lung macrophages were more than 150-fold higher in *it* instilled animals than in *iv* animals at both doses at all times examined. These findings imply that *it* administration of ganciclovir not only results in efficient delivery of the drug to lung tissue, but also offers the prospect of systemic drug delivery as well. (Supported by NIH grant HL43510.)

1001 KINETICS OF ZICONOTIDE GIVEN INTRATHECALLY IN DOG.

T L Yaksh[1], J Provencher[1], A W de Kater[2], R R Dean[2], S Bowersox[2]. [1]*Anesthesiology, University of California, San Diego, CA, USA;* [2]*Elan Pharmaceuticals, Menlo Park, CA, USA.*

Ziconotide is a peptide that blocks N-type calcium channels and exerts analgesic effects after intrathecal delivery. We characterized the pharmacokinetics of Ziconotide given intrathecally by bolus injection and infusion in dog. Male Beagles (N = 5) were prepared with chronic lumbar intrathecal injection and a cerebrospinal fluid (LCSF) sampling catheters, passed from the cisterna to the L_{2-3} and L_{1-2} level. Externalized portions of the catheters were connected to vest mounted pumps (100μL/hr). Each dog received: i) intrathecal bolus injection of Ziconotide-10μg + ^{3}H-Inulin-1μCi; ii) continuous intrathecal infusion for 48 hrs of Ziconotide-1μg/hr; iii) continuous intrathecal infusion for 48 hrs of Ziconotide at 5μg/hr; and iv) intravenous injection of Ziconotide-100μg/kg. After intrathecal bolus injection, both LCSF Ziconotide and inulin showed an initial peak and biphasic clearance (Ziconotide: $T_{1/2}\alpha$ = 0.4 and $T_{1/2}\beta$ = 1.8 hours; MRT=0.28 hrs). The Ziconotide/Inulin ratio for each animal fell over time from 0.007 to 0.0006, consistent with the more rapid disappearance of Ziconotide. After initiation of intrathecal infusion of 1 and then 5 g/hr, LCSF concentrations peaked at 8-24 hrs and were stable through 48 hrs at 343 and 1527 ng/mL, respectively. Corresponding plasma levels were 0.05 and 1.12 ng/mL. Upon termination of infusion, the terminal half-life of ziconotide in LCSF was $T_{1/2}$ β = 1.34 hrs. Intrathecal Ziconotide displays dose proportional kinetics after bolus injection or infusion, which are consistent with a molecule that is cleared similar to inulin from the spinal space.

1002 HEPATIC γ-GLUTAMYL TRANSPEPTIDASE-POSITIVE FOCI DEVELOPMENT IN RATS CO-TREATED WITH 17β-ESTRADIOL AND 2,3,7,8-TETRACHLORODIBENZO-*p*-DIOXIN.

M E Wyde[1,2], G W Lucier[2], J Seely[3] and N J Walker[2]. [1]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC;* [2]*NIEHS, Research Triangle Park, NC;* [3]*Pathco, Research Triangle Park, NC.*

2,3,7,8-Tetrachlorodibenzo-*p*-dioxin (TCDD, dioxin) is a potent hepatocarcinogen in female, but not male rats. Several lines of evidence suggest a key

role of ovarian hormones, presumably estrogen, in the mechanism of TCDD-induced hepatocarcinogenesis. The aim of this current study was to test the hypothesis that estrogen is required for TCDD-induced formation of enzyme altered hepatocellular foci. Diethylnitrosamine-initiated female Sprague-Dawley intact and ovariectomized rats were co-treated with 17ß-estradiol and TCDD for 20 weeks and preneoplastic altered hepatocellular foci expressing γ-glutamyl transpeptidase (GGT) were measured. Increased formation of GGT positive foci was observed in TCDD-treated intact but not ovariectomized rats as compared to controls. These data confirm previous observations demonstrating the effect of ovariectomy on TCDD-induced events in hepatocarcinogenesis. No foci were observed in ovariectomized rats receiving 17β-estradiol alone. In ovariectomized rats, the number of foci/cm^3, percentage of liver occupied, and mean focus volume in rats co-treated with TCDD and 17β-estradiol were significantly greater than in rats that received 17β-estradiol alone, but significantly lower than rats receiving only TCDD. These data suggest that 17β-estradiol inhibits foci formation possibly through effects on initiation and/or growth of initiated foci in the liver. This may lead to the creation of an environment that is more permissive for growth of TCDD-responsive altered hepatocellular foci at later timepoints.

1003 MECHANISM OF INHIBITION OF ESTROGEN-INDUCED GENE EXPRESSION BY TCDD.

M Wormke and S Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA.*

17β -Estradiol (E2) induces progesterone receptor (PR) gene expression in MCF-7 human breast cancer cells, and 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) inhibits the hormone-induced response. PR gene promoter sequences required for aryl hydrocarbon (Ah)-responsiveness were investigated using the following constructs containing PR gene promoter inserts linked to the bacterial chloramphenicol acetyltransferase (CAT) reporter gene: pPR1 (-2762 to +788); pPR2 (-325 to +788); pPR3 (-165 to +788); pPR4 (-30 to +788); and pPR6 (+340 to +788). In transient transfection studies using pPR1 - pPR6, E2 induced a 3.5-, 10-, 5.8-, 4.2-, 8.0- and 26.2-fold increase, respectively, in CAT activity. The PR^{ERE} construct (+698 to +729) which contains a functional estrogen responsive element (ERE) (+707 to +719) is also induced by E2 (4.1-fold). The PR gene promoter contains two putative inhibitory dioxin responsive elements (iDREs) at +43 to +47 and +300 to +304; however, in MCF-7 cells treated with 10 nM E2 + 10 nM TCDD and transiently transfected with pPR1 - pPR6 or pPR^{ERE}, there was a 47 to 72% decrease in hormone-induced CAT activity. These results suggest that the iDREs are not functional genomic sequences required for the antiestrogenic activity of TCDD using PR gene promoter-derived constructs. TCDD significantly decreased basal and E2-inducible nuclear and cytosolic immunoreactive ER protein in MCF-7 cells, and the role of decreased ER and other nuclear proteins in mediating the antiestrogenic activity of TCDD will be discussed. (NIH ES04176)

1004 INHIBITION OF ESTROGEN-INDUCED RETINOIC ACID RECEPTOR α1 GENE EXPRESSION IN MCF-7 CELLS BY Ah RECEPTOR AGONISTS: MECHANISM OF Ah RECEPTOR-ESTROGEN RECEPTOR CROSSTALK.

G Sun[1], Y Lu[2] and S Safe[1]. [1]*Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA;* [2]*Department of Biological Chemistry, Chicago Medical School, North Chicago, IL, USA.*

Retinoic acid receptor α (RARα) is a member of the nuclear steroid/thyroid/retinoic acid receptor superfamily and mediates effects of retinoids on gene expression in target cells. 17β -Estradiol (E2) induced RARα gene expression (2-fold) in MCF-7 human breast cancer cells lines and 10^{-8} M 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) inhibited basal and E2-induced RARα gene expression in these cells. Similar effects were also observed for retinoids and antiestrogens. pRARA12 is an estrogen-responsive construct containing an insert from the -509 to +105 region of the RARα1 gene promoter linked to a bacterial chloramphenicol acetyl transferase (CAT) reporter gene. In MCF-7 cells transiently transfected with pRARA12 (10 μ g) plus human estrogen receptor (hER) expression plasmid (1 μ g), 10^{-9} M E2 induced a 2.5-fold increase in CAT activity, and in cells cotreated with 10^{-9} M E2 + 10^{-8} M TCDD, induced CAT activity was decreased by 90%. In parallel experiments, 10^{-6} M α-naphthoflavone, an aryl hydrocarbon receptor(AhR) antagonist, reversed the antiestrogenic effects of TCDD, and TCDD did not exhibit antiestrogenic activity in Ah-nonresponsive benzo[a]pyrene-resistant MCF-7 cells. TCDD also inhibited E2-induced CAT activity in MCF-7 cells transiently transfected with pRAR5(-111 to -49) and pRAR5-m1 (mutated in a potential AhR binding motif at -110 to -106). These results demonstrate that the antiestrogenic activity of TCDD is AhR-mediated but is not dependent on the core binding motif that is functional in other E2-responsive gene promoters. Therefore, other possible mechanisms of AhR-mediated antiestrogenic responses are currently being investigated. (NIH ES04176)

1005 ESTROGEN AND ARYL HYDROCARBON RESPONSIVENESS OF ECC-1 ENDOMETRIAL CANCER CELLS IN CULTURE.

E Castro-Rivera and S Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA.*

ECC-1 human endometrial cancer cells were evaluated for aryl hydrocarbon (AhR) and estrogen receptor (ER) functionality. Nuclear AhR and ER were detected in the ECC-1 cells line by Western immunoblot analysis of nuclear extracts. 17β -Estradiol (E2) induced proliferation of ECC-1 cells (~7-fold); in cells cotreated with several AhR agonists including 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD), benzo[a]pyrene (BaP), 6-methyl-1,3,8-trichlorodibenzofuran (MCDF), and diindolylmethane (DIM), there was a significant inhibition (45 to 75%) of this hormone-induced response. TCDD significantly induced CYP1A1-dependent ethoxyresorufin *O*-deethylase (EROD) activity in ECC-1 cells. E2 and TCDD also induced reporter gene activity in ECC-1 cells transiently transfected with estrogen and Ah-responsive constructs. E2 induced cathepsin D and pS2 gene expression in ECC-1 cells, and in cells cotreated with E2 plus TCDD, there was a significant decrease in E2-induced gene expression. These results indicate that ECC-1 endometrial cancer cells are both Ah- and E2-responsive and current studies are focused on mechanisms of AhR-ER crosstalk. (NIH CA64081)

1006 INHIBITION OF E2-INDUCED c-*fos* PROTOONCOGENE EXPRESSION BY 2,3,7,8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD) IN MCF-7 HUMAN BREAST CANCER CELLS.

R Duan, W Porter, I-C Chen and S Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA.*

17β -Estradiol (E2) induced c-*fos* protooncogene mRNA levels in MCF-7 human breast cancer cells and maximal induction was observed within 1 hr after treatment. 2,3,7,8-Tetrachlorodibenzo-*p*-dioxin (TCDD) inhibited the E2-induced response within 2 hr. The molecular mechanism of this response was further investigated using the pFC2-BLCAT plasmid which contains the -1400 to +41 5N-flanking sequence from the human c-*fos* protooncogene linked to a bacterial chloramphenicol acetyltransferase (CAT) reporter gene. In MCF-7 cells, transiently transfected with the pFC2-BLCAT plasmid and treated with 10 nM E2, there was an 8.5-fold induction of CAT activity. Cotreatment with 10 nM E2 + 10 nM TCDD resulted in a 46% decrease in E2-induced CAT activity; moreover the antiestrogenic effects of TCDD were blocked by the Ah receptor antagonist, α-naphthoflavone. Similar results were obtained with a construct (pF1) containing the E2-responsive (-1220 to -1155) sequence. This region of the *fos* promoter also contains two core dioxin-responsive elements (DREs); and transient transfection studies using constructs containing wild-type or mutant core DREs showed that the downstream core DRE (-1161 to -1157) was required for Ah-responsiveness. The nuclear Ah receptor complex from MCF-7 cells also crosslinked to the core DRE, confirming that the iDRE motif is required for Ah receptor-mediated antiestrogenicity. (NIH ES04176)

1007 IDENTIFICATION OF ESTROGEN-INDUCED GENES DOWNREGULATED BY 2,3,7,8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD) BY SUPPRESSION SUBTRACTIVE HYBRIDIZATION.

I Chen and S Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA.*

The antiestrogenic activity of 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) is mediated through crosstalk between the aryl hydrocarbon receptor (AhR) and estrogen receptor (ER) signaling pathways. Identification of 17β -estradiol (E2)-induced genes downregulated by TCDD utilized suppression subtractive hybridization (SSH) using poly(A)$^+$RNA from MCF-7 cells treated with 1 nM E2 and 1 nM E2 + 1 nM TCDD as targets and references, respectively. The subtraction efficiency was determined using DNA blot analysis and a subtractive cDNA library containing 396 clones was constructed.

Forty-eight clones were further characterized using E2 and E2 + TCDD treated cDNA probes by dot blot analysis. Twenty-one putative candidate clones were further subjected to sequence analysis and GenBank database search. Preliminary results indicate that some of these clones have sequence homology to previously described genes including heat shock protein 27, thymidylate synthase, Wilm's tumor-related protein, cytokeratin 18 (3 clones), early growth response gene, prothymosin-α, heparin-binding growth factor receptor, mitochondrial ATP synthase, Cdc28/Cdc2-associated protein and ribosomal protein L7 α (2 clones). In addition, two potential novel sequences were also identified. Northern blot analysis confirmed that levels of heat shock protein 27, early growth response gene, and Wilm's tumor-related protein mRNAs were down-regulated by treatment with TCDD. Expression patterns of the remaining genes and 2 novel sequences are currently under investigation and will provide further information on E2-regulated genes that are targeted by AhR agonists. (NIH ES04176)

1008 IN UTERO AND LACTATIONAL TCDD EXPOSURE ALTERS ESTROGEN INDUCED MAMMARY GLAND GROWTH IN THE RAT.

P A Furth[1], B Lewis[1], A Lewis[1], R Sommer, R E Peterson[2], J Flaws[3]. [1]*Institute of Human Virology, Medicine & Physiology, Univ MD Med School, Baltimore, MD;* [2]*School of Pharmacy, Environmental Toxicology Center, Univ WI, Madison, WI;* [3]*Epidemiology & Prev Med, Univ MD Med School, Baltimore, MD.*

In the mammary gland, estrogen triggers ductal cell proliferation. Intact estrogen signaling pathways are required for normal duct development. This study was initiated to determine whether in utero and lactational (IUL) 2,3,7,8–tetrachlorodibenzo- p–dioxin (TCDD) exposure alters estrogen signaling in the rat mammary gland. To test this hypothesis, pregnant Holtzman rats were administered a single oral dose of 1μ % g/kg, or vehicle, on gestation day 15 and offspring were weaned on postnatal day 21. TCDD exposed and control non-exposed female offspring were oophorectomized at 9 weeks of age. Two weeks later both the TCDD and control rats were divided into three groups: Group 1: 0.1 mg 17 Symbol estradiol implant, Group 2: 0.025 mg 17 Symbol estradiol implant, Group 3: placebo implant. After 48 hours all rats were euthanized and the mammary tissue removed for analysis. Whole mount studies revealed that IUL TCDD exposure resulted in baseline morphological abnormalities in the lobular alveolar structures. In addition, acute 17 Symbol estradiol exposure initiated enhanced ductal growth and accelerated lobular-alveolar development in IUL TCDD exposed as compared to control rats. Ki67 immunohistochemistry demonstrated that ductal cells from IUL TCDD exposed mammary glands have a higher rate of cell proliferation at the 0.025 mg 17 Symbol estradiol dose than the non-exposed control rats. Gene expression studies are focused on identifying effector genes which mediate the abnormal growth response. In conclusion, this study demonstrates that in utero and lactational TCDD exposure can alter the growth response to estrogen in the mammary gland.

1009 APPARENT MODULATION OF PRENEOPLASTIC FOCI BY OVARIAN HORMONES IN RESPONSE TO TCDD.

C Bishop-Robinson, T Nayyar and D B Hood. *Dept. of Pharmacology. Meharry Medical College, Nashville, TN.* Sponsor: N H Zawia.

Dioxin (2,3,7,8-tetrachloro-p-dibenzodioxin; TCDD) is a polychlorinated biphenyl. TCDD is a potent environmental toxin that is carcinogenic in two stage models of hepatocellular carcinogenesis in female rats. Ten week old female rats either intact sham-operated, or ovariectomized (OVX) were intraperitoneally initiated by diethylnitrosamine (DEN) [200mg/kg] in saline (S) followed by promotion with TCDD in corn oil (C) [1.5mg/kg every 15 days for 43 weeks] by gavage. Both intact and OVX rats were divided into four groups, S/C (controls receiving saline and corn oil), DEN/C (initiated only), S/TCDD (promoted only), and DEN/TCDD (initiated and promoted). Intact sham-operated and OVX animals from the DEN/TCDD group developed hepatic focal lesions indicative of preneoplastic foci. All TCDD treated animals showed significant ($P<0.05$) induction of hepatic microsomal cytochrome P450d (1A2/1A1) with the exception of the OVX-DEN/TCDD group. Immunohistochemical analysis of liver sections with placental glutathione-S-transferase revealed a significant reduction in preneoplastic foci in the OVX-DEN/TCDD group relative to it's control group. These data suggest that ovariectomy exerts a protective effect with regard to the promotion of liver tumors by TCDD. (Supported by NIH G12 RRO 3032 and NIEHS ES00287.)

1010 EFFECT OF ESTROGEN AND DIOXIN ON IL-1B ACTIVITY.

M F Ruh, Y Bi, and C Bellone. *Saint Louis University School of Medicine, St. Louis, MO.*

We recently reported that endogenous and some environmental estrogens markedly enhanced lipopolysaccarhide (LPS)-induced IL-1β activity in a macrophage cell line stably transfected with the human estrogen receptor (ERα) and an IL-1β promoter-chloramphenicol acetyltransferase (CAT) reporter construct. In the present study we examined the effect of estrogens and the environmental contaminant 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) on the ability of LPS to induce two different IL-1β promoter-CAT constructs transiently transfected into the RAW macrophage cell containing endogenous ER. Estradiol markedly enhanced LPS stimulated CAT activity 2-3 fold in RAW264.7 cells transfected with either a CAT reporter construct driven by 4000 bp of upstream IL-1β promoter sequence or the isolated NFIL-6 element found in the IL-1β promoter. The RAW264.7 cells contain the Ah receptor and TCDD alone also enhanced LPS stimulated CAT activity 2-fold in cells transfected with the 4000 bp upstream promoter. However, this was not the case with cells transfected with the NFIL-6 driven reporter. Most dramatic was the synergy observed when the cells transfected with either reporter construct were treated with both TCDD and estradiol prior to LPS stimulation. In these cases a two-fold additional increase was observed over LPS plus either estradiol or TCDD alone. These results demonstrate that TCDD potentiates the synergism between estrogen and LPS to markedly enhance IL-1β promoter activity, although the exact mechanism is not understood. (Support: NIH ES05968.)

1011 BIOLOGICALLY BASED MODELING OF ALTERED HEPATIC FOCI AFTER TREATMENT WITH 2,4,5,3',4'-PENTACHLOROBIPHENYL.

M Haag-Grönlund[1,3], R Conolly[2], G Scheu[1,3], L Wärngård[1,3] and R Fransson-Steen[3]. [1]*Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden;* [2]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA;* [3]*Astra AB, Södertälje, Sweden.*

A biologically based quantitative foci growth model was used to analyze the effect of 2,4,5,3',4'-pentachlorobiphenyl (PCB118) on foci development in rat liver initiated with partial hepatectomy and diethylnitrosamine (DEN). Six DEN-initiated PCB dosed groups + DEN-initiated control animals were treated weekly for 20 weeks. Three DEN-initiated PCB dosed groups + DEN-initiated controls were treated for 52 weeks. All groups were included in the computer simulation. Hepatocyte proliferation in foci and normal tissue was experimentally examined using bromodeoxyuridine as a marker of proliferating cells. The proliferation data were used in the selection of division rates for the computer simulations of foci growth. The labeling index in foci was generally larger than in non-focal tissue for PCB-treated as well as untreated initiated animals. A strong correlation was found between foci occurrence and proliferation in both foci and non-focal tissue. The foci data were adequately simulated by the foci growth model when certain assumptions were introduced. Given that PCB118 is a non-mutagenic compound, the foci data could not be modeled assuming one homogeneous cell population, but was adequately fitted assuming two separate cell populations that respond differently to the promotion stimulus. Another assumption was a selective growth advantage for initiated cells during and shortly after the initiation treatment. Furthermore, a transient increase of proliferation in focal hepatocytes at the first PCB administration was assumed in the higher dose groups to account for the large occurrence of foci in these groups at the end of the experiment. At high doses (640, 2500 and 10,000 μg/kg/week), an increased rate of focal cell death was also predicted by the simulation model. These assumptions are well supported by literature data for other carcinogens, indicating the importance of studying cell kinetics and balance between cell division and cell death in PCB induced hepatocarcinogenesis.

1012 2,3,7,8-TETRACHLORODIBENZO-P-DIOXIN ALTERS CHICK EMBRYO CARDIAC ELECTRICAL CONDUCTION.

M K Walker. *College of Pharmacy, University of New Mexico, Albuquerque, NM, USA.*

We have previously shown that in the chick embryo TCDD induces a phenotype consistent with congestive heart failure: ventricular cavity dilatation, cardiac hypertrophy, and increased myosin synthesis, culminating in peripheral edema. To further characterize TCDD-induced cardiotoxicity, we

assessed the electrical conduction properties of the chick embryo heart in ovo following TCDD exposure. Fertile chicken eggs were injected with control (triolein) or 0.4 pmol TCDD/g egg in triolein prior to incubation. On day 11 or 12 of development, embryos were anesthetized with a chloralose/urethane mixture injected into the air cell. Silver wire electrodes were inserted through small holes made in the shell and EKGs were measured at ca. 1 min intervals. Following EKG measurements, embryos were collected and body and heart wet weights taken. EKG tracings were analyzed for heart rate (beats per minute), RR interval (one contraction/relaxation cycle), QT interval (ventricular repolarization time) and QT interval corrected for heart rate ($QT_c = QT/(RR)^{1/2}$). On incubation day 11, TCDD did not significantly alter heart weight or the heart/body weight ratio. In addition, TCDD did not alter heart rate or the RR interval. However, TCDD did significantly shorten the QT_c interval (TCDD: 0.283 ± 0.02; Control: 0.351 ± 0.14). On incubation day 12, TCDD significantly increased heart weight (TCDD: 69 ± 3.5; Control 48 ± 1 mg) as well as shorten the QT_c interval (TCDD: 0.277 ± 0.04; Control 0.369 ± 0.01). The shortened QT_c interval induced by TCDD was a more sensitive endpoint than changes in heart weight or heart/body weight ratio. In TCDD-exposed chick embryos a shortened QT_c interval reflects that the ventricles repolarize faster after contracting than in the hearts from control embryos. A shortened QT_c could reflect hyperkalemia, reduced Ca release from the sarcoplasmic reticulum, or a decreased proliferation of the myocardial wall. Future studies will test the relative contributions of these possible mechanisms to the altered cardiac conduction induced by TCDD.

1013 COMPUTER–ASSISTED ANALYSIS OF EPIDIDYMAL SPERM MOTILITY OF RATS EXPOSED MATERNALLY TO 2,3,7,8–TETRACHLORODIBENZO–DIOXIN (TCDD).

J Yonemoto, S Ohsako, N Nishimura, C Tohyama and H Sone. *Regional Environment Division, Environmental Health Sciences Division, National Institute for Environmental Studies, Tsukuba, Japan.*
