Spermatogenesis is one of the most sensitive endpoints of toxicity of rat offspring maternally exposed to TCDD. TCDD reduced epididymal but not testicular sperm numbers in rats and caused epididymal lesion in rat and hamster (Gray et al, 1995, 1997). Epididymis is specifically altered by TCDD during sex differentiation. Within the epididymis, sperm acquires progressive motility and fertility capacity. Epididymal sperm motility might be susceptible to TCDD exposure in utero. However, no report has been published on evaluating sperm motility by CASA (computer assisted semen analysis) system. In the present study, epididymal sperm o²9DdÍ of rat offspring exposed maternally to TCDD was analyzed by the CASA system. Pregnant Holtzman rats (JCR) were given a single oral dose of 0, 12.5, 50, 200 t²9Dd 800 ng TCDD/kg body*²9De weight on gestational Day 15, and male offspring were sacrificed on Day 63 and 120 after birth. On Day 63, percentages of motile sperm and progressive sperm were decreased by 200 and 800 ng TCDD/kg body weight, but these tendencies were not statistically significant (ANOVA). Other parameters of sperm motility, path velocity (VAP), progressive velocity (VSL), track speed (VCL), lateral amplitude (ALH), beat frequency (BCF), straightness (STR) and linearity (LIN) were not affected. In conclusion, maternal dosage up to 800ng TCDD/kg body weight had no effects on epididymal sperm motility o u²9Dd Day 63 v²9Dd rat offspring.

1014 DOES VOLUME OF INJECTION MATTER WHEN CONCENTRATIONS ARE IDENTICAL.

J C DeWitt, E B Meyer, and D S Henshel. *School of Public and Environmental Affairs, Indiana University-Bloomington, Bloomington, IN.*

Studies with TCDD (2,3,7,8-tetrachlorodibenzo-*p*-dioxin) in our laboratory have indicated that TCDD is induces an interhemispheric brain asymmetry with associated behavioral changes, when injected *in ovo* into fertilized chicken eggs in volumes of 0.1 μ m per egg. Other research facilities often use injection volumes of 1.0 μ m per egg. The purpose of this study was to determine whether differences in the volume of injection, when concentrations are identical, would differentially affect behavior. Fertile domestic chicken eggs were air sac injected prior to incubation with either 2, 20 or 200 picagrams of TCDD per gram of egg, diluted in a sunflower oil or corn oil vehicle. Stock solutions of TCDD were diluted so that either 0.1 μ m or 1.0 μ m per egg resulted in the appropriate concentration. Control eggs received the oil alone or no injection at all. One group of eggs received 0.1μ m of TCDD per gram prior to incubation, at embryonic day zero, whereas the other group received 1.0 μ m per gram of egg, also prior to incubation. Eggs were incubated until hatch and chicks were run through several reflexive, locomotor and perceptual tests within 24 hours of hatching. Analysis indicated that the volume of injection detestably alters the behavioral status of chicks. Activity was increased tenfold, timed movement in a fixed direction was nearly doubled, pecks made at food were reduced by almost half and a righting reflex was mildly suppressed in the high volume groups when compared to the behavioral responses in low volume groups.

1015 PRENATAL TCDD EXPOSURE AND PREDISPOSITION 9® MAMMARY CANCER IN RATS.

J Wang, M C Brewer, W A Fritz and C A Lamartiniere. *Department of Pharmacology and Toxicology, University of Alabama at Birmingham, Birmingham, AL, USA.*

We have previously reported that prenatal TCDD exposure enhances dimethylbenz(a)anthracene (DMBA) induced mammary cancer (Carcinogenesis 19:1623,1998). To gain insight into the mechanism of short–term TCDD exposure predisposing for mammary cancer, we have investigated specific mRNA and protein expressions. Pregnant Sprague Dawley CD rats were gavaged with 1 ug TCDD/kg body weight. At parturition, the offspring were transferred to surrogate dams. At 50 days post–partum, the female offspring were gavaged with DMBA or sesame oil (S.O.). At 100 days postpartum, mammary glands were dissected. Early increased lobular hyperplasia correlated with increased mammary tumorigenesis in rats exposed prenatally to TCDD and in adulthood to DMBA (TCDD/DMBA) as compared to S.O./DMBA treated rats. CYP1A1 as measured by western blot analysis was higher in mammary glands of S.O./DMBA and TCDD/DMBA treated rats as compared to non–DMBA treated rats. Estrogen receptor–alpha and beta mRNAs as measured by RT–PCR were similar in all groups. We conclude that prenatal TCDD exposure confers early permanent alterations to predispose the resulting adult for susceptibility to mammary cancer.

1016 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN (TCDD)-DEPENDENT ALTERATIONS IN B CELL LYMPHOPOIESIS ARE MEDIATED AT THE LYMPHOCYTE LEVEL DIRECTLY.

A L Lavin and T A Gasiewicz. *University of Rochester, Department of Environmental Medicine, Rochester, NY, USA.*

TCDD, acting through the aromatic hydrocarbon receptor (AhR) and its dimerization partner, arnt, elicits numerous toxicological effects including immunosuppression. Previous work from our laboratory has suggested that TCDD exposure in mice is associated with altered lymphopoietic development in the bone marrow compartment. Furthermore, it has been demonstrated that bone marrow stromal cells express functional AhR and arnt proteins. Because these cells play an important role in the support and direction of lymphopoiesis, it is possible that TCDD treatment could be altering lymphopoietic development through effects mediated at the stromal cell level. In order to determine what role, if any, bone marrow stromal cells play in such TCDD-dependent lymphopoietic alterations, a bone marrow stromal cell/B cell co-culturing system was established using the M2-10B4 cell line. When B220+ bone marrow lymphocytes derived from AhR-expressing mice were co-cultured with M2-10B4 cells, TCDD exposure was associated with dose-dependent decreases in the total number of hematopoietic cells, lymphocytes, and B220+CD43- pre-B cells. Similar alterations were not observed using B220+ cells derived from AhR-deficient mice. These results indicate that TCDD exposure alters B cell development *in vitro* and suggests that this effect is mediated at the lymphocyte level directly rather than through the bone marrow stromal cells. Furthermore, these results suggest that the B220+CD43- pre-B cell population may be particularly sensitive to the immunotoxic effects associated with TCDD exposure. (This work supported by NIH Grant ES04862, Center Grant ES01247, and Training Grant ES07026.)

1017 THE EFFECTS OF 2,3,7,8 - TETRACHLORODIBENZO-p-DIOXIN (TCDD) ON INSULIN IN A MURINE MODEL OF TYPE II DIABETES.

[1]L T Blackwell, [2]L S Birnbaum, M J Devito. [1]*North Carolina Central University, Durham NC;* [2]*NHEERL, USEPA, RTP, NC, USA.*

Recent studies suggest an association between exposure to TCDD and increases in type II diabetes. When fed a high -fat high simple carbohydrate diet (HFHSC) C57/BL6J mice develop signs of type II diabetes. The goal of this project is to determine if TCDD alters the severity or decreases the time to onset of type II diabetes in this murine model. The effects of TCDD on serum glucose, cholesterol, and insulin concentrations in mice following

subchronic exposure to TCDD were determined. The subchronic studies include a four, eight, and twelve week exposure to TCDD (0,1.5 and 150 ng/kg/day) with mice either on the HFHSC diet or a normal diet . All animals were terminated three days after the last exposure. Blood was collected for cholesterol, glucose, and insulin analysis. The liver was removed for histological and lipid analysis. The HFHSC diet increased insulin concentration. TCDD exposure produced a dose dependent decrease in serum insulin in mice fed either the normal or HFHSC diet. The HFHSC diet increased resting serum glucose and cholesterol concentrations after 8 weeks. TCDD administration did not alter serum glucose concentrations in animals on either the normal or the HFHSC diet. TCDD decreased resting serum cholesterol concentrations only in animals on the HFHSC diet. Hepatic total lipid concentrations and cholesterol were increased by TCDD in both normal and HFHSC diet fed mice. However, the HFHSC diets led to a greater concentration of hepatic lipid. In conclusion, TCDD does appear to have a moderate effect on signs of type II diabetes. (This abstract does not reflect USEPA policy.)

1018 ENDOCRINE FUNCTION OF MALE RATS EXPOSED MATERNALLY TO 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN (TCDD).

N Nishimura[1], S Ohsako[1], M Ishizuka[2], C Tohyama[1], H Sone[2] and J Yonemoto[2]. [1]*Environmental Health Sciences Division,* [2]*Regional Environment Division, NIES, Tsukuba, Ibaraki, Japan.*

The environmental pollutant 2,3,7,8-tetrachlorodibenzo-dioxin (TCDD) is known to disrupt vertebrate endocrine system. It is generally believed that the embryonic stage of development is highly susceptible to toxicity of TCDD. To evaluate of influence of maternal exposure to TCDD on neonatal development especially on endocrine function, pregnant Holtsman rats (JCR) were given a single oral dose of 0, 12.5, 50, 200 or 800 ng TCDD/kg body weight on gestation Day 15, and male offspring were sacrificed on Day 2, 49 or 63 after birth. There was no TCDD effect in litter size, birth weight and sex ratios of pups for all groups. The highest maternal dose of TCDD caused an increase in liver weight (15.3%) as well as significant thymic atrophy (20.1%) on Day 63. No changes in weight of body, brain, thyroid, pituitary gland and adrenal gland were observed in the offspring exposed to TCDD. Of hormones examined in this experiment, the highest dose of TCDD induced a decrease in serum T4 levels (14.7%) on Day 63 (postpubertal), but not on Day 2 and Day 49 (pubertal), whereas serum T3 levels were not affected in these offspring. TCDD did not affect serum levels of thyroid-stimulating hormone (TSH), luteinizing hormone (LH) and follicle-stimulating hormone (FSH) in the offspring in all the dose groups. The present study showed that the earliest sign detectable in the offspring following maternal exposure to relatively low level of TCDD was a decreased serum T4, not in pubertal, but postpubertal stage.

1019 HEPATIC EFFECTS OF PRENATAL AND POSTNATAL EXPOSURE TO AROCLOR 1254 OR PCB 126.

D G Ross[1], K M Crofton[2], P R S Kodavanti[2], D Rice[3], and M J DeVito[1]. [1]*ETD and* [2]*NTD, NHEERL, USEPA, RTP, NC, USA;* [3]*Health Canada, Ottawa, ON, Canada.*

The present study examines the hepatic effects of developmental exposure to a PCB mixture, Aroclor 1254 (Lot 124–191) or to PCB 126. Hepatic EROD activity, retinyl palmitate, and porphyrin concentrations were determined. In the first study, female Long Evans(LE) rats were treated with PCB 126(0, 0.25 and 1 ug/kg/day) starting 35 days before mating and ending on PND 21. Pups were examined on PND 28 thru 30 and 115. There was a significant increase (10 fold) in EROD activity and a significant decrease(58%) in retinyl palmitate levels at the highest dose at PND 28–30. At PND 115, these responses were no longer present. In the second study, LE– rats were treated with Aroclor 1254 (0,1, and 6 mg/kg/day) starting on GD6¿ and ending on PND 21. Pups were examined on PND 4, 7, 14, 21, and 60. There were significant increases in EROD activity, up to 218 fold, at the highest dose on PND 4,7,14 and 21. At the highest dose, retinyl palmitate levels were decreased at PND14(80%) and PND 21(54%). On PND 60, no effects were observed for EROD activity or retinyl palmitate concentrations. There were moderate increases in porphyrin levels(50%) at all time points at the high dose. Finally, LE–rats were dosed to approximate steady state concentrations prior to mating by treating with Aroclor 1254(0, 0.3,1 and 3 mg/kg/day) starting 90 days before mating and ending on PND 21. Pups were examined on PND 14 and 21. EROD activity was significantly increased, up to 108 fold, at doses of 1 and 3 mg/kg/day at both timepoints. Retinyl palmitate levels were decreased by approximately 40% (1 mg/kg/day) and 70%(3 mg/kg/day) on both days. Porphyrin levels were moderately increased at both time points at 1 and 3 mg/kg/day. Previous studies in our laboratories using the same dosing regimens produce pronounced decreases in thyroid hormone concentrations and neuro behavioral effects. The present study indicates that moderate dioxin–like biochemical changes in hepatic tissue are occuring in these animals and that dioxin like effects may be useful markers for alterations in thyroid hormones or neurodevelopment. (This abstract does not necessarily reflect EPA policy.)

1020 QUANTITATIVE ANALYSIS OF LYMPHOCYTE CYP1B1 EXPRESSION IN INDIVIDUALS OCCUPATIONALLY EXPOSED TO 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN (TCDD).

D L Spencer[1], V R Walker[1], J A Grassman[1], C R Miller[1], L Edler[2], D Jung[3], L L Needham[4], G W Lucier[1] and S A Masten[1]. [1]*NIEHS, RTP, NC, USA;* [2]*Univ of Mainz, FRG;* [3]*German Cancer Research Center, Heidelberg, FRG;* [4]*CDC, Atlanta, GA, USA.*

Cytochrome P450 1B1 mRNA is constitutively expressed and TCDD-inducible in human peripheral blood lymphocytes, as previously demonstrated in our laboratory using a competitive RT-PCR assay. The present study evaluated lymphocyte CYP1B1 expression as a potential biomarker of dioxin exposure and individual responsiveness in 95 individuals occupationally exposed to dioxin-like compounds. These individuals were employed at a German chemical plant and were highly exposed to dioxins during the production of chlorinated herbicides and pesticides; blood plasma dioxin toxic equivalents (TEQ) values ranged from 15-916 ppt lipid. Constitutive levels of CYP1B1, as measured in uncultured lymphocytes, ranged from 3×10^4 to 3×10^6 copies/μg RNA. For the subpopulation of individuals with elevated plasma TEQ (>40 ppt lipid), there was an increased frequency of individuals with high constitutive CYP1B1 mRNA levels. CYP1B1 mRNA levels were also measured in mitogen-stimulated cultured lymphocytes (MSL) from 82 of these individuals. Addition of TCDD to the MSL induced CYP1B1 mRNA levels in the individuals with varying magnitude. The induction (treatment/control) ranged from 1 to 18-fold, with an average induction of 6-fold. CYP1B1 induction *in vitro* did not appear to be related to plasma dioxin TEQ. These data indicate that CYP1B1 may be useful as a marker of *in vivo* human exposure to dioxin, and for characterizing interindividual variation in biological response.

1021 ORAL TOXICITY OF 1,2,3,4,6,7,8-HEPTACHLORODIBENZO-*p*-DIOXIN (HpCDD) OBEYS HABER'S RULE OF INHALATION TOXICOLOGY.

M Lebofsky[1] and K K Rozman[1,2]. [1]*Department of Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS, USA;* [2]*Section of Environmental Toxicology, GSF-Institut für Toxikologie, Neuherberg, Germany.*

Eight different doses (2.5 to 10.0 mg/kg) of 1,2,3,4,6,7,8-heptachlorodibenzo-*p*-dioxin (HpCDD) were administered acutely to a total of 271 female Sprague-Dawley rats. The doses ranged from a NOAEL for wasting/hemorrhage to supralethal doses. Dose-and time-responses of wasting/hemorrhage, anemia and cancer were and are being studied as end points of toxicity. The experiments will be continued until the last rat dies. There was a very steep dose- and time-response between the LOAEL for wasting/hemorrhage (2.8 mg/kg) and the third highest dose (4.1 mg/kg) of HpCDD. The dose-and time-responses were symmetrical obeying Haber's Rule of inhalation toxicology ($c \times t$ = constant) even beyond 100% mortality. Introduction of a minimum of 25% body weight loss as a discriminatory criterion to separate wasting from hemorrhage as the primary cause of death reduced variability from 5.8 to 3.1%. An arithmetic plot of the dose and time data resulted in a nearly perfect hyperbola. A logarithmic plot of these data yielded a straight line of similar perfection. Surviving rats in all groups started developing anemia 120 days after dosing but no rat died of wasting/hemorrhage after day 74. Thus, although the experiment is completed as far as dose-and time-responses of wasting/hemorrhage are concerned, it will be about another 2 years before complete dose-and time-responses are available for anemia and cancer.

1022 CONSTITUTIVE AND 2,3,7,8-TETRACHLORODIBENZO-*p*-DIOXIN- INDUCED EXPRESSION OF CYP1A1 AND CYP1B1 IN HUMAN LYMPHOCYTES.

V R Walker, D L Spencer, S A Masten, C R Miller, N J Walker, G W Lucier, and J A Grassman. *NIEHS, RTP, NC, USA.*

2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is a ubiquitous environmental contaminant which produces a spectrum of biological responses. We are using the dioxin inducible genes CYP1A1 and CYP1B1 to identify individuals who are highly responsive and possibly highly susceptible to the adverse health effects of dioxins. The study cohort consists of local volunteers (n=40) who provided blood samples and questionnaire information. Individual responsiveness was assessed by measuring CYP1A1 enzyme activity in peripheral blood lymphocytes after 3 days of *in vitro* incubation with 10nM TCDD. The effect of exposure to dioxins from environmental sources was evaluated by measuring CYP1B1 expression in uncultured peripheral blood lymphocytes by quantitative RT-PCR. *In vitro* TCDD treatment induced detectable levels of CYP1A1 enzyme activity in the lymphocytes of 38 (95%) of the individuals. Comparison of the 5th and 95th percentiles shows that the range of expression for constitutive CYP1B1 mRNA varied 26-fold compared to 9-fold for *in vitro* CYP1A1 enzyme inducibility. CYP1A1 enzyme activity showed a small, but significant negative correlation with age. Neither constitutive CYP1B1 mRNA nor *in vitro* TCDD-induced CYP1A1 enzyme activity correlated with plasma levels of TCDD, total dioxin toxic equivalents (TEQs) (range 3-33 ppt lipid), gender, or smoking. However, the 3 individuals with the highest levels of constitutive CYP1B1 expression had dioxin exposures within the lowest quartile for the cohort. These results combined with continuing studies of the *in vitro* inducibility of CYP1B1 demonstrate variation in human response to dioxins that may be associated with adverse health effects.

1023 EFFECTS OF TCDD ON MICE CHRONICALLY INFECTED WITH THE PROTOZOAN PARASITE, *TOXOPLASMA GONDII.*

M D King, M F Ehrich and D S Lindsay. *Department of Biomedical Sciences and Pathobiology, Virginia-Maryland Regional College of Veterinary Medicine, Blacksburg, VA.*

Toxoplasmic encephalitis is a life threatening condition observed in patients with AIDS. It is caused by reactivation of a latent infection with the protozoan parasite, *Toxoplasma gondii*. Cysts that contain latent bradyzoites become reactivated and progress into rapidly dividing stages, tachyzoites, which then begin to destroy tissue. This reactivation is possible because of the immunocompromised condition of the AIDS patient. TCDD exposure is known to cause immunosuppression. The present study was conducted to determine if treatment with TCDD would influence the course of infection in chronically infected C57/BL6 mice. Twelve female mice were fed 25 cysts of *T. gondii* and chronic infections established for 10 weeks. Control mice (n=11) were not infected. After the 10 week period, 6 *T. gondii* infected mice and 6 control mice were fed 20 μ g/kg TCDD and 6 *T. gondii* infected mice and 5 control mice were fed corn oil. One mouse with chronic toxoplasmosis fed TCDD died 12 days postinoculation (PI) while none of the other mice died. One-half the remaining mice in each group were killed and examined 3 weeks PI. Cyst counts in TCDD treated *T. gondii* infected mice were 200 ± 144 (mean ± SD) and the numbers of cysts in *T. gondii* infected nontreated mice were 173 ± 46. Brain lesions were similar in both groups of *T. gondii* infected mice. Results of this study suggest that TCDD may cause reactivation of latent toxoplasmosis in some mice but does not influence cyst numbers or lesions in the brains of mice.

1024 ROLE OF OXIDATIVE STRESS IN THE SUBCHRONIC TOXICITY OF TCDD IN C57BL/6J FEMALE MICE.

L Tang[1], N Z Alsharif[1], E Hassoun[2], C Pederson[1] and M Shara[1]. [1]*Creighton University, School of Pharmacy and Allied Health Professions, Omaha, NE;* [2]*Toledo University, School of Pharmacy, Toledo, OH.*

Oxidative stress (OS) resulting from increase production of reactive oxygen species (ROS) have been established as one of the mechanisms of the acute toxicity of TCDD. However, no extensive studies have investigated the role of OS in the subchronic toxicity of this compound. To assess the involvement of OS in the subchronic toxicity of TCDD, effects of 13 weeks oral treatment with daily doses of 0.05 (high), 0.025 (medium) and 0.005 (low) LD_{50} TCDD/kg on animal weights, target organs weights and on measures of oxidative stress in C57BL/6J female mice was determined. The high dose of TCDD produced a significant body weight wasting that was not observed with the low and medium dose. The high dose produced approximately 60% mortality at three months and all the remaining animals in that group were sacrificed at that point. The low and medium dose had 100% survival at three months following TCDD treatment. TCDD produced a dose response increase in liver and kidney weight and a dose-response decrease in thymus and spleen weight. TCDD produced a dose dependent increase in hepatic and spleen lipid peroxidation following subchronic exposure. Furthermore, DNA-SSB was observed in the liver nuclei and production of ROS was enhanced by the liver mitochondria and microsomes. The results implicate a role for OS in the subchronic toxicity of TCDD.

1025 ROLE OF OXIDATIVE STRESS IN THE CHRONIC TOXICITY OF TCDD IN C57BL/6J FEMALE MICE.

N Z Alsharif[1], L Tang[1], E Hassoun[2], T El-Metwally[1], C Pederson[1], M Shara[1] and S J Stohs[1]. [1]*Creighton University, School of Pharmacy and Allied Health Professions, Omaha, NE;* [2]*Toledo University, School of Pharmacy, Toledo, OH.*

Oxidative stress (OS) plays a role in the acute toxicity of TCDD and may contribute to the toxic effects following chronic exposure to this compound. Therefore, to assess the involvement of OS in the chronic toxicity of TCDD, effects of 26 weeks oral treatment with daily doses of 0.05 (high), 0.025 (medium) and 0.005 (low) LD_{50} TCDD/kg on animal weights, target organs weights and on measures of OS in C57BL/6J female mice was determined. The low and medium dose produced no body weight wasting following chronic treatment. The high dose produced approximately 60% mortality at three months and all the remaining animals in that group were sacrificed at that point. The medium dose produced 20% mortality at four and a half month following TCDD treatment. TCDD produced a dose response increase in liver, kidney and spleen weight and a dose-response decrease in thymus weight. The low and medium dose of TCDD produced a significant increase in lipid peroxidation in the liver and spleen. The medium dose produced a significant increase in brain lipid peroxidation. The low dose produced 6.6 fold increase in liver nuclei DNA-single strand breaks. Furthermore, the low dose enhanced the production of ROS by peritoneal lavage cells; by liver mitochondria and liver microsomes. The results implicate a role for OS in the chronic toxicity of TCDD.

1026 VITAMIN SUPPLEMENTATION TO PREVENT DEVELOPMENTAL TOXICITY OF 2,3,7,8-TETRA-CHLORODIBENZO-*p*-DIOXIN (TCDD) IN TCDD-SENSITIVE RATS.

H Huuskonen, R Purkunen, T Vartiainen, and J Tuomisto. *National Public Health Institute, Division of Environmental Health, Kuopio, Finland.*

Supplemetation with folic acid and other vitamins has been reported to have a protective effect against malformations and fetotoxicity. This developmental study was performed in TCDD-sensitive Long-Evans rats (L-E; LE/AB/KTL (SPF); LD_{50} about 10 μg/kg) to investigate whether the gestational multivitamin administration reduces the incidence of cleft palate and fetotoxic effects induced by TCDD. Pregnant rats were administered orally with different composition of group B vitamins (thiamin, riboflavin, pantothenic acid, pyridoxine, and cobalamin), folic acid and ascorbic acid on gestation days 1-19 and once with TCDD (2 μg/kg or 4 μg/kg) on gestation day 8. The dams were necropsied on gestation day 20. All fetuses were fixed in Bodian's solution and assessed for visceral anomalies. The high TCDD dose, with or without vitamin supplementation, was slightly maternotoxic (decreased corrected body weight gain but no clinical signs). The maternal thymus weight decreased in all TCDD-dosed groups. The mean fetal weight decreased at the high TCDD dose level. The anogenital distance in TCDD-dosed male fetuses with or without vitamin supplementation was less than in control animals. The number of resorptions increased at high TCDD dose level; this effect was slightly protected with vitamin supplementation. To the incidence of fetuses with cleft palate the vitamin supplementation had no effect. This preliminary study did not reveal any clear preventive effect of these vitamins to TCDD-induced teratogenicity in these TCDD-sensitive L-E rats. However, vitamin supplementation slightly modulated TCDD-induced fetotoxicity.

1027 TCDD INCREASES THE PRODUCTION OF VASOACTIVE EICOSANOIDS AND COFRACTIONATES WITH LIPOPROTEIN PARTICLES IN HYPERLIPIDEMIC MICE.

T P Dalton, M Z Dieter, M Miller, R Yunker, M Carty, H Shertzer, D W Nebert and A Puga. *University of Cincinnati Medical Center, Cincinnati, OH, USA.*

Studies over the years document numerous adverse health affects to humans and experimental animals that result from exposure to aryl hydrocarbon receptor agonists such as TCDD or other environmental pollutants. Much of what we understand about the effect of this class of compounds on human health results from epidemiological studies of populations subjected to accidental high-level exposures. For example, exposure to halogenated aromatic hydrocarbons from a chemical plant explosion in Hamburg (Germany) resulted in a greatly increased incidence of death from ischemic heart disease (IHD). IHD is a progressive disease and all humans are affected to varying degrees as a function of age. TCDD may accelerate the onset of IHD either by affecting the levels of the molecular mediators of IHD (i.e. lipoprotein particles, lipid second messengers etc.) or by directly influencing the progression of the atherosclerotic lesion. We have tested aspects of these two alternatives using C57BL/6J and apolipoprotein E-null (ApoE) mice, respectively. Because ApoE mediates the clearance of lipoproteins, ApoE-null mice have elevated cholesterol levels. In C57BL/6J mice, we find that TCDD treatment results in a rapid increase in urinary levels of the vasoactive eicosanoids. Such lipid second messengers have been implicated in the manifestation of IHD. On the other hand, hyperlipidemic ApoE-null mice given a single IP injection (12.5 nmol/kg) of TCDD show a partition of TCDD to lipoprotein particles of all densities. This contrasts their wild-type counterparts. These data suggest that lipoprotein particles are likely a vehicle for TCDD delivery to atherosclerotic plaques. This process may exacerbate the severity of IHD. (Supported by NIH P30ES06096, ES08147, ES06273.)

1028 HISTOPATHOLOGICAL CHANGES FOLLOWING SUBCHRONIC AND CHRONIC EXPOSURE TO TCCD IN C57BL/6J FEMALE MICE.

W J Hunter[1], N Z Alsharif[2] and L Tang[2]. *Creighton University, [1]School of Medicine and [2]School of Pharmacy and Allied Health Professions, Omaha, NE, USA.*

The aim of this studty is to evaluate the histopathological changes following the subchronic and chronic toxicity of TCDD. Groups of twenty C57BL/6J (bb) female mice were treated orally with daily doses of 0.05 (high), 0.0025 (medium) and 0.005 (low) LD_{50} TCDD/kg for thirteen and twenty six weeks. Control animals only received the corn oil vehicle. Animals were sacrificed on day 92 or 182 following TCDD treatment. Selected tissue samples from the different organs were fixed in 10% buffered neutral formalin and paraffin-embedded. Sections were stained with hematoxylin and eosin and trichrome stains and then evaluated. Selected samples were also analyzed by electron microscopy. Following subchronic and chronic treatment with TCDD, a dose response effect was observed with the low dose and the medium dose of TCDD. TCDD produced major histopathological changes in the liver with less dramatic changes in thymus, kidney, spleen, adrenals, and brain. A striking cholangiopathic and lobular hepatitis was seen in the medium dose following subchronic and chronic exposure with more severe changes present in the chronic treatment group. The thymus showed progressive loss of small lymphocytes in the cortex with a loss of demarcation between the cortex and medulla. The spleen showed foci of extramedullary hematopoiesis and loss of white pulp (small lymphocytes). Histopathology from the kidneys, adrenals and brain, will be presented. Thus, subchronic and chronic TCDD exposure resulted in similar histopathological changes in target organs of TCDD to what is observed following acute exposure.

1029 COMPARISON OF BIOMARKER SENSITIVITY IN PREPUBESCENT FEMALE DEER MICE FOLLOWING EXPOSURE TO 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN.

J Liu[1], M M Peden-Adams[1], A B Bodine[1,2] and R L Dickerson[3]. [1]*Department of Environmental Toxicology, Clemson University, Pendleton, SC, USA;* [2]*Department of Animal and Veterinary Science, Clemson University, Pendleton, SC, USA;* [3]*The Institute of Environmental and Human Health, Texas Tech U/TTU Health Sciences Center, Lubbock, TX, USA.*

TCDD (2,3,7,8-tetrachlorodibenzo-*p*-dioxin) causes a broad range of immunotoxic effects including immunosuppression of nonspecific as well as specific cell-mediated and humoral immunity. TCDD administration to experimental animals also results in induction of cytochromes P450 (CYP450). The objectives of this study were to determine the effects of TCDD on immune function and CYP450 activity and to determine which one is the more sensitive biomarker in a non-traditional mammalian species. In this study, 21-day old female deer mice (*Peromyscus maniculatus*) were dosed with 2,3,7,8-TCDD via oral gavage. Five concentrations of TCDD (0.1, 0.3, 1, 3,and 10 μ g/kg) and a corn oil vehicle (control) were used for the dose response study. Immune function was assessed using T- and B-lymphoblastogenesis, and macrophage phagocytosis to determine potential effects on cell-mediate immunity, humoral immunity, and non-specific immunity. Ethoxyresorufin-O-deethylase activity (a CYP450 enzyme), as expected, was increased in activity compared to control. Humoral immune function was suppressed compared to control. However, there was no obvious effect on T-cell proliferation nor macrophage phagocytosis. These results indicate that at levels as low as 0.1 μ g TCDD/kg EROD is significantly induced in this non-traditional mammalian species and that humoral immune function may be an adjunct descriptor of mammalian species exposure to xenobiotics.

1030 TOXICITY OF 2,3,7,8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD) UNDER CONDITIONS OF TOXICOKINETIC STEADY-STATE IN ADULT FEMALE SPRAGUE-DAWLEY RATS.

S A Saghir[1] and K K Rozman[1,2]. [1]*Department of Pharmacology, Toxicology, and Therapeutics, University of Kansas Medical Center, Kansas City, KS;* [2]*Section of Environmental Toxicology, GSF-Institut für Toxikologie, Neuherberg, Germany.*

Groups of ten adult female Sprague-Dawley rats (240-270 g) were administered by gavage 3 different oral doses of TCDD (35, 52.5, and 70 μg/kg of body weight) in corn oil (4 ml/kg). In order to maintain steady-state concentration, rats were injected into the tail vein every 4th day with a maintenance dose of TCDD contained in a stable emulsion (4.5, 6.8, and 9.1 μg/kg for the low, middle and high dose, respectively). The doses were selected to be equipotent to a total dose of 10,000, 7,500 and 5,000 μg/kg of 1,2,3,4,6,7,8-heptachlorodibenzo-*p*-dioxin (HpCDD). The total number of rats per dosage group (at least 30) and the number of doses administered (at least 8) were chosen in analogy to the HpCDD study (*ibid*). Currently, ten rats of each of the 3 dosage groups are available for evaluation. Rats were weighed and examined daily for signs of wasting/hemorrhage. Mortality was recorded every day between 8 am and 6 pm. As expected all 10 rats died in each of the 3 dosage groups. Time to first mortality and mean time to death, both were proportional to the dose. The product of dose *x* time appears to be reasonably constant although variability (~20%) is higher than in the HpCDD study. This is not surprising considering the smaller number of animals per dosage group and the smaller number of different doses administered as yet in this experiment. These preliminary data in conjunction with our other posters presented here and also in agreement with previous reports support the notion that Haber's Rule of inhalation toxicology probably is a fundamental Law of Toxicology which can be seen only under ideal conditions of experimentation (e.g., toxicokinetic/ toxicodynamic steady state).

1031 AN ALTERNATIVE MECHANISM FOR TCDD INDUCED NEUROTOXICITY.

T Nayyar, N H Zawia, and D B Hood. *Dept. of Pharmacology, Meharry Medical College, Nashville, TN.*

We have conducted studies to evaluate the effect of TCDD on perturbing normal developmental gene expression in the brain. The rationale is that differential gene expression is in part, regulated by transcription factors which may be targets for perturbations by TCDD. As reviewed by Zawia et al., (1998) an essential sequence of genes are required to coordinate the differentiation of cells and to promote migration, dendritic arborization, synapse formation, and myelination in the developing nervous system. As such, we hypothesized that intrauterine exposure to TCDD would have deleterious consequences on the developing nervous system. Timed pregnant Sprague-Dawley rats were given single oral doses on gestation day 15 of 0.25, 0.5, and 1.0 μg TCDD/kg body weight. Mobility gel shift analysis of nuclear extract incubations from various brain regions of the resulting pups on postnatal days 3, 5, 10, 15, 20 and 30 with an Sp1 consensus sequence oligonucleotide revealed perturbations in the developmental profile of Sp1 as a result of intrauterine exposure to TCDD. A secondary goal of this work was to relate TCDD induced changes in the Sp1 DNA-binding properties with that of protein product levels. Nuclear extracts from cortex and cerebelli

were analyzed by western blot analysis with anti-Sp1, Sp2, Sp3, and Sp4 antibodies. The results suggest that the observed alterations in the DNA-binding properties of target proteins may not always be the result of perturbations in the biosynthetic processes of that transcription factor. (Supported by NIH G12 RRO 3032 and NIEHS ES00287.)

1032 DOSE-RESPONSE RELATIONSHIP OF SUBCHRONIC DOSING WITH [3H]TCDD ON DOSIMETRY AND CYP1A ACTIVITIES.

J J Diliberto, M J DeVito, D G Ross, and L S Birnbaum. *US EPA, NHEERL, ETD, Research Triangle Park, NC, USA.*

Subchronic dosing of low-level exposures of TCDD (2,3,7,8-tetrachlorodibenzo-*p*-dioxin) mimics the most probable mode for human exposure, including dietary consumption. Steady-state kinetics resulting from repeated dosing permits more accurate assessment of the relative potency for TCDD. Ideally, TCDD dosimetry should be evaluated in an animal model under steady-state conditions. The present study was conducted to examine the disposition of TCDD following subchronic oral dosing in female B6C3F1 mice. Doses were 0.15, 0.45, 1.5, 4.5, 15, 45, 150, or 450 ng [3H]TCDD/kg/day (Mon-Fri) for 90 days. Endpoints examined were dosimetry in various tissues and hepatic CYP1A1 and CYP1A2 enzymatic activities. The present study demonstrated dose-dependency of [3H]TCDD in hepatic and non-hepatic tissues. Liver/fat (L/F) concentration ratios range from 0.2 to 3.4 (low to high dose). At higher doses (i.e., induced animals), greater TCDD concentrations were found in liver than in fat—indicating hepatic sequestration due to the inducible binding protein, CYP1A2. At 15 ng/kg/day, L/F conc ratio was 1; CYP1A2 enzymatic activity was ~5 fold ($p<0.0001$) greater than controls. Hepatic CYP1A1 activity was significantly increased ($p<0.02$) starting at the lowest dose (0.15 ng/kg/day) with L/F conc ratio of 0.2 and body burden of 2.7 ng [3H]TCDD/kg. This study provides direct evidence of low dose effects at steady-state conditions on a measured response and body burdens that are within background levels of the general human population. Futhermore, this study emphasizes that body burden or tissue dose for a persistent chemical such as TCDD is more important to consider than daily dose. (This abstract does not necessarily reflect EPA policy.)

1033 EXAMINATION OF GENE EXPRESSION IN CENTRILOBULAR AND PERIPORTAL CELLS AFTER TCDD EXPOSURE BY QUANTITATIVE RT-PCR.

V M Richardson[1], M J Santostefano[2], N J Walker[3], G W Lucier[3], and L S Birnbaum[1]. [1]*USEPA, NHEERL/ETD, Research Triangle Park, NC;* [2]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC;* [3]*NIEHS, RTP, NC.*

Previous immunolocalization studies revealed that the hepatic distribution of CYP1A1/1A2, and CYP1B1 was mainly localized to the centrilobular region after subchronic/chronic exposure to 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD). Therefore, in order to examine the differential inducibility of populations of hepatocytes, this study examined the dose-dependent effects of TCDD in unfractionated, centrilobular and periportal cells on gene expression after acute exposure (3 days) of female Sprague-Dawley rats to a single oral dose of 0.01, 0.3 or 10.0 μg TCDD/kg by quantitative RT-PCR. Whole hepatocytes were isolated by a collagenase perfusion technique; whereas centrilobular and periportal enriched-hepatocytes were isolated by a dual pulse digitonin-collagenase perfusion method. Actin mRNA expression in unfractionated, centrilobular and periportal hepatocytes was relatively constant over the dose-range tested. A dose-dependent increase in TCDD-induced CYP1A1, CYP1A2 and CYP1B1 mRNA expression was observed in all liver cell populations. The centrilobular hepatocytes exhibited a 7.0-fold higher concentration of TCDD-induced CYP1A1 mRNA as compared to the periportal hepatocytes within the 0.01 μg TCDD/kg treatment-group with an equal distribution of CYP1A1 mRNA in both cell types at higher doses. Furthermore, CYP1A2 and CYP1B1 mRNA concentrations were higher in centrilobular cells as compared to periportal cells isolated from animals dosed with either 0.01 or 0.3 μg TCDD/kg. This study demonstrates that acute exposure to TCDD results in a differential expression of multiple cytochrome P450 genes in isolated centrilobular and periportal hepatocytes. (Abstract does not necessarily represent USEPA policy.)

1034 COMPARISONS OF RELATIVE POTENCIES (REPs) FOR EROD INDUCTION AND DECREASES IN SERUM THYROXINE FOR TCDD AND PCBS 77, 126 AND 118.

M J DeVito[1], D G Ross[1], E S Craft[2], and K M Crofton[2]. [1]*ETD &* [2] *NTD, NHEERL, USEPA, RTP, NC, USA.*

The TEF methodology has been used to assess the potential health effects of mixtures of dioxin-like chemicals and assumes that the REPs are the same for all endpoints. The present study examines this hypothesis by comparing the REP values for enzyme induction and decreases in serum T4 by TCDD, and two coplanar dioxin-like PCBs 77, 126 and one mono-ortho dioxin-like PCB, 118. Female Long-Evans rats (28 days old) were administered test chemicals by oral gavage on 4 consecutive days and killed on the fifth. Serum T4 and hepatic EROD activity were determined and REPs were estimated based on ED50 ratios. All chemicals induced EROD activity with a similar maximum of approximately 30-40 fold induction and the REPs are 0.07, 0.00005, 0.00003 for 126, 77 and 118 respectively. TCDD and 126 produced a maximal 40-45% decrease in T4 while 77 and 118 produced 80-90% decreases. The REP values for decreases in T4 are similar to those for EROD induction: 0.08, 0.00007 and 0.00005 for 126, 77, and 118. Because 77 and 118 are more efficacious for T4 decreases compared to TCDD, these REP values may not be valid for predicting T4 decreases using the dioxin TEF methodology. REP values based on ED50's do not take into consideration differences in efficacy between chemicals. These data suggest that PCBs 77 and 118 are decreasing T4 concentrations through both Ah receptor and non-Ah receptor mediated mechanisms and that the dioxin TEF methodology may not predict decreases in T4 in mixtures containing PCBs due to the different mechanisms of action of these chemicals. Future work will examine mixtures of these chemicals to examine their interactions (This abstract does not represent EPA policy).

1035 EFFECT OF IN VIVO TCDD EXPOSURE ON SECRETION OF ACTH AND CORTICOSTERONE BY PERIFUSED PITUITARY AND ADRENAL GLANDS.

J A Pitt[1], A Buckalew[2], and B D Abbott[2]. [1]*Curriculum in Toxicology, UNC, Chapel Hill, NC;* [2]*DBB, RTD, NHEERL, US EPA, Research Triangle Park, NC.*

Although *in utero* maternal stress can have lasting effects on male rat offspring, chemical-induced alterations of the maternal/fetal hypothalamic-pituitary-adrenal axis (HPA) have not been well studied. This study examined the effects of *in vivo* TCDD exposure on pituitary-adrenal function in perifusion culture. Male and pregnant female (gestation day 8) Sprague-Dawley rats were gavaged with 10 μg/kg TCDD and euthanized 10 days later. Hemi-pituitary and right adrenal glands from the same animal were quartered, placed in separate chambers, perifused at 200 μl/min with Medium 199 (4.4 μM NaHCO3, 10 mM HEPES, 50 μM Bacitracin, 0.3% BSA, pH 7.4, 37° C) and samples collected every 10 min. After two hours of perifusion, glands were stimulated twice, 30 min each, with either 10-9 M CRH (pituitary) or 10-9 M ACTH (adrenal). In males, TCDD caused about a 1.7-fold increase in CRH-stimulated ACTH secretion (4.2 ± 0.69 μg/ml vs 6.8 ± 1.01; 3.9 ± 0.75 μg/ml vs 6.6 ± 1.91 μg/ml, control vs TCDD). No difference was observed in total pituitary or plasma ACTH (3.2 ± 0.69 μg/mg vs 3.5 ± 1.13 μg/mg tissue; 13.5 ± 4.10 ng/ml vs 8.6 ± 1.51 ng/ml, control vs TCDD). In females, there was no difference in CRH-stimulated ACTH secretion (9.5 ± 2.55 ng/ml vs 17 ± 4.05; 10.6 ± 3.84 vs 14 ± 5.07 ng/ml control vs TCDD) or total tissue ACTH (1.4 ± 0.15 μg/mg vs 1.2 ± 0.31 μg/mg tissue, control vs TCDD). ACTH-stimulated CORT secretion was not affected by TCDD in either sex. Adrenal tissue CORT levels were unchanged in males and pregnant females (23.6 ± 4.59 vs 26.9 ± 8.55 ng/mg tissue; 4.4 ± 1.49 vs 2.3 ± 0.31 ng/mg tissue, control vs TCDD). Plasma CORT levels were increased in TCDD treated males but unchanged in pregnant females (553 ± 24.7 vs 691 ± 35.4 ng/ml; 62.8 ± 15.70 vs 48.1 ± 13.43 ng/ml, control vs TCDD). Thus, it appears that in male, but not female rats, TCDD alters pituitary response to CRH which suggests that *in utero* exposure may have a direct affect on male fetus and its adult pituitary response in adulthood. (This abstract does not necessarily represent EPA policy.)

1036 METABOLISM AND DISPOSITION OF LUMINOL IN RATS.

J M Sanders, L Chen, T M Lewter, L T Burka, and H B Matthews. *National Institute of Environmental Health Sciences, Research Triangle Park, NC.*

Luminol (LMN, 3-aminophthalhydrazide) chemiluminesses upon oxidation

and therefore is useful in assays for the detection of a variety of organic and inorganic substances. A major use of LMN is as a forensic tool for detecting biological fluids at crime scenes. Since there is considerable potential for human exposure, the present work has investigated the metabolism and disposition of [ring-^{14}C] LMN in male F344 rats. Results indicated that LMN was well absorbed from the gut following po administration of either 0.5, 5, or 50 mg/kg. The rate of elimination was proportional to dose with greater than 80% total dose excreted in urine within 12 hr post-dosing. Urine contained two radiolabeled metabolites, a glucuronide and a sulfate conjugate of parent LMN. No 3-aminophthalic acid was detected in urine. Little or no ^{14}C was present in tissues at 24 hr post-dosing. Similar results were obtained following iv administration of 0.5 mg/kg. Approximately 8% of an iv administered dose was excreted in bile within 6 hr post-dosing. LMN-derived radioactivity in bile consisted of the same glucuronide and sulfate conjugates isolated from urine. Transdermal absorption of LMN was negligible following application to the skin of 0.1 mg/kg in ethanol. Results of this study indicate that LMN has little apparent potential for bioaccumulation or toxicity at anticipated levels of human exposure.

1037 THE METABOLISM AND DISPOSITION OF 1-NITRONAPHTHALENE IN THE MALE SPRAGUE-DAWLEY RAT.

J S Halladay, J-M Sauer, and I G Sipes. *Department of Pharmacology and Toxicology, The University of Arizona, Tucson, AZ.*

1-Nitronaphthalene (1-NN) is a nitroaromatic mutagenic compound and environmental contaminant. 1-NN is mainly found in airborne particulates (0.7 mg 1-NN/kg of particulate) resulting from both light- and heavy-duty diesel engine emissions. 1-NN has been shown to produce both lung and liver toxicity. Even though these toxicities have been reported, the metabolism and disposition of 1-NN have not been elucidated. Studies were performed to characterize the disposition, metabolism, and excretion of 1-NN following i.p. and i.v. administration to male Sprague-Dawley rats. Ninety-six hr following i.p. (100 mg/kg) or i.v. (10 mg/kg) administration of [^{14}C]-1-NN, 55-60% of the dose was recovered in the urine, 32-36% in the feces, O% as expired [^{14}C]-CO_2 and [^{14}C]-organics, and 1% collectively in selected tissues, blood, and GI contents. Interestingly, 88% of the administered dose was excreted into the bile within 8 hr, suggesting extensive enterohepatic recirculation. The elimination rate constants of 1-NN were 1.26 (i.p.) and 0.84 hr^{-1} (i.v.) and elimination half-lives were 0.57 (i.p.) and 0.80 hr (i.v.). The systemic bioavailability of 1-NN following i.p. administration was 3%. Urinary metabolites were seperated by reverse-phase HPLC and identified by LC-MS/MS. The major metabolite following both routes of administration was identified as *N*-acetyl-*S*-(hydroxy-1-nitronaphthalene)-L-cysteine, which accounted for 26% (i.p.) and 18% (i.v.) of the dose. Hydroxylated (5-8%), dihydroxylated (1%), glucuronidated (1-2%), and sulfated (3-5%) metabolites were also identified in the urine. The presence of glucuronide and sulfate metabolites was confirmed by enzymatic hydrolysis. From these data, it appears that 1-NN undergoes extensive metabolism, enterohepatic circulation, and is rapidly eliminated. (Southwest Environmental Health Sciences Center P30-ES-06694.)

1038 INDUCTION OF RAT HEPATIC DRUG METABOLIZING ENZYMES BY DIMETHYLCYCLOSILOXANES.

J Zhang, X Xie and C N Falany. *Department of Pharmacology and Toxicology, University of Alabama at Birmingham, Birmingham, AL.*

Low molecular weight dimethylcyclosiloxanes (DMCS) are important precursors in the synthesis of polydimethylsiloxane polymers widely used in industry and in personal care products. The objective of this study as to characterize the ability of the small DMCS, octamethylcyclosiloxane (D4) and decamethylcyclopentasiloxane (D5) to induce drug metabolizing enzymes in rats. Male Sprague Dawley rats were administered D4 or D5 in corn oil daily by gavage at different doses and for different times. Changes in the levels of activity and/or immunoreactivity of CYP6R2B1/2, CYP1A1/2, CYP3A2 and NADPH cytochrome P450 reductase in liver microsomes were determined. A dose response in CYP2B1/2 induction was observed with increasing concentrations of both D4 and D5. Significant increases in 7 pentoxyresorufin–O–depentylase (PROD) activity and CYP2B1 immunoreactive protein were detected after 4 days treatment with D4 and D5 doses 5 mg/kg. At higher doses, D4 induced PROD activity and CYP2B1 protein levels more efficiently than D5. Small but significant increases were also observed in 7–ethoxyresorufin–O–deethylase (EROD) activity at the same concentrations. Significant induction of reductase immunoreactive protein was observed D5 but not D4. To determine the time course of induction, rats were treated daily with 5 mg/kg D4 and sacrificed after 4, 8, 14 and 21 days. PROD activity was significantly increased after 4 days (2.4–fold) and 8 days (4.4–fold) and was slightly higher after 21 days (5.2–fold). Immunoreactive CYP2B1 levels increased to 8 days then remained relatively constant. In summary, D4 and D5 induced drug metabolizing enzymes in rat liver, especially YP2B, in manner similar to phenobarbital.

1039 REDUCTIVE BIOACTIVATION OF HCFC-141b TO FREE RADICAL INTERMEDIATES BY RAT LIVER MICROSOMAL CYTOCHROME P-450.

R Ferrara[1], R Tolando[1], A Zanovello[1], A Tomasi[2] and M Manno[1]. [1]*Inst of Occupational Med, University of Padua, Padua, Italy;* [2]*Dept of Biomedical Sciences, University of Modena, Modena, Italy.* Sponsor: M Lotti.

The hydrochlorofluorocabon 1,1-dichloro-1-fluoroethane (HCFC-141b) is reductively metabolized to reactive species by rat liver microsomal cytochrome P-450 (P-450) resulting in the loss of the enzyme's activity and content, due to inactivation of its prosthetic heme group1. Since the addition of the spin trapping agent *N*-t-butyl—phenylnitrone (PBN) prevented P-450 loss, suggesting that free radical intermediates of HCFC-141b may be involved, we investigated whether free radical species a) are actually formed, by an electron spin resonance (ESR) technique, and b) are involved in the mechanism of the inactivation reaction, by measuring the level of conjugated dienes. Anaerobic incubations of liver microsomes from pyridine induced rats, at 37°C for 30 min, in presence of the substrate and of the spin trapping agent PBN resulted in the formation of an ESR spectrum compatible with that of a carbon centered radical intermediate. Similar incubations, but for the absence of PBN and in presence of increasing concentrations of substrate (0.1-10 mM), showed a dose-dependent formation of conjugated dienes as measured by the peak formed at λ=233 nm in the second derivative spectrum2. Conjugate dienes formation was inhibited by the addition of saturating concentrations of CO but not by 10 mM GSH or vit C. Our results indicate that HCFC-141b is reductively metabolized by P-450 2E1 to free radical intermediates leading to the modification of microsomal membrane lipids, a process which may contribute to the previously reported HCFC-141b-dependent inactivation of microsomal P-450.

1040 DETECTION OF THE DICHLOROACETATE RADICAL FROM THE REDUCTIVE DEHALOGENATION OF TRIHALOACETATES.

J L Merdink[1], R J Bull[2], and I R Schultz[2]. [1]*Graduate Program in Pharmacology and Toxicology, Washington State University, Pullman, WA;* [2]*Battelle, Pacific Northwest National Laboratory, Richland, WA.*

The risk assessment of trichloroethylene (TRI) is currently being driven by the carcinogenic properties of its reported metabolite, dichloroacetate (DCA). The formation of DCA is hypothesized to proceed through the reductive dehalogenation of trichloroacetate (TCA), via a free radical intermediate. Although proof of this radical has been elusive, the detection of fully dechlorinated metabolites in the urine and the formation of lipid peroxidation by-products in microsomal incubations with TCA argue for its existence. We report here the trapping of the dichloroacetate radical with the spin trapping agent PBN, and its identification by GC/MS. By employing bromodichloroacetate (BDCA), a mono-brominated analog of TCA, to generate a high yield of the dichloroacetate radical, initial studies on its formation and on the subsequent characterization of the PBN adduct could be performed. The PBN/dichloroacetate radical adduct was found to undergo an unexpected intramolecular rearrangement during its extraction into organic solvent. A condensation reaction is hypothesized to eliminate an OH radical, thus rendering the PBN/adduct undetectable by ESR, the standard analytical tool for free radical detection. The dichloroacetate radical has been identified by GC/MS in both a chemical Fenton system and in murine microsomal incubations. (Supported by EPA grant R825954.)

1041 INDUCTION OF QUINONE REDUCTASE BY CRAMBENE, A NITRILE FROM CRUCIFEROUS VEGETABLE, IN HEPA 1c1c7 CELLS.

A S Keck and E H Jeffery. *Division of Nutritional Sciences. University of Illinois, Urbana, IL, USA.*

Previously, we have shown that oral crambene (1-Cyano-2-hydroxy-3-butene) induces quinone reductase in the rat liver. Here we show that crambene is also active in a cell culture system. Mouse hepatoma cells, Hepa 1c1c7 cells, were cultured in 12 well plates with crambene in DMSO (0.1%), and β-naphthoflavone (2-5 μM) was used as positive control. Cells were analyzed for induction of quinone reductase and reported as specific activity per 10^6 cells. When cells were treated with β-naphthoflavone for 24 h at different times after plating (1 x 10^5 cells/well), they showed maximal induction if treated at approximately 3 x 10^5 cells per well, or 30% confluence. In all subsequent experiments, cells were treated when there were approximately 3 x 10^5 cells per well and then grown for 24 hours. Crambene (1 μM-1 mM) was incubated with Hepa 1c1c7 cells for 24 hours. This resulted in a typical dose-respond curve for quinone reductase induction. A higher concentration of crambene (10 mM) showed cytotoxicity, but only when DMSO was included. This indicates that DMSO (0.1%) increases the uptake of crambene into the cell. DMSO (0.1%) alone or with β-naphthoflavone caused no cytotoxicity (>95% viability). Crambene is present naturally in cruciferous vegetables and its ability to induce quinone reductase may be partly responsible for the effect of cruciferous vegetables in protecting against cancer. That induction occurs in cell culture as well as in the whole animal permits cell culture to be used in future mechanistic studies. (Supported by The Illinois Council on Food & Agricultural Research.)

1042 METABOLISM AND TOXICITY STUDIES ON NOVEL QUINOLINE QUINONES: QUINONE ACTIVATION BY NAD(P)H:QUINONE OXIDOREDUCTASE.

H D Beall[1], T Fryatt[2], D T Goroski[1], Z D Nilson[1] and C J Moody[2]. [1]*The University of Montana, Missoula, MT, USA;* [2]*University of Exeter, Exeter, UK.* Sponsor: D L Gustafson.

We report on the effects of functional group changes on the metabolism of novel quinoline quinones by human recombinant NAD(P)H:quinone oxidoreductase (NQO1) and on the toxicity of these agents to non-small cell lung cancer (NSCLC) cells with either high NQO1 activity (H460) or with no detectable NQO1 activity (H596). Various substituents were added to the 2- and/or 6-positions of quinoline-5,8-dione. Overall, the quinoline quinones were much better substrates for NQO1 than analogous indolequinones. For example, the reduction rate for 5-methoxy-1,2-dimethylindole-4,7-dione, was 5.31 ± 0.93 μmol/min/mg whereas 6-methoxyquinoline-5,8-dione was reduced at a rate of 58.7 ± 18.5 μmol/min/mg. Substitution at the 2-position with phenyl, naphthyl or biphenyl yielded the lowest reduction rates for quinoline quinones, while heterocycles such as pyridyl were among the best substrates. The prototype quinoline quinone bioreductive agent, streptonigrin (SN), has a pyridyl group at the 2-position and is reduced by NQO1 at a rate of 47.4 ± 11.5 μmol/min/mg. The quinoline quinones were relativley non-toxic to both cell lines with IC_{50} values generally > 10 μM. The most selective compound, 6-(pyrrolidin-1-yl)quinoline-5,8-dione, was thirteen times more toxic to the high NQO1 H460 cells (IC_{50} = 3.72 μM) than to the NQO1-deficient H596 cells (IC_{50} > 50 μM). On the other hand, SN is over 90 times more toxic to the H460 cells (IC_{50} = 0.0143 μM) than to the H596 cells (IC_{50} = 1.36 μM). This is likely due to differences in the capacity of the quinoline quinones to form complexes with metals and DNA.

1043 POTENTIATION OF ACETAMINOPHEN-INDUCED HEPATOTOXICITY BY RETINOL IN THE BALB/C MOUSE.

B J Bray, R E Inder, and R J Rosengren. *University of Otago Medical School, Dunedin, New Zealand.*

Previous results have shown that retinol pretreatment potentiates and attenuates various classical hepatotoxicants in male Swiss Webster mice. This study was designed to determine if retinol treatment would potentiate acetaminophen (APAP) hepatotoxicity in another mouse strain. Once this was established, we targeted the various metabolic pathways for acetaminophen metabolism to determine the mechanism of retinol's potentiation. 4 days of retinol (75 mg/kg/d) was required to potentiate APAP hepatotoxicity (ALT activity of 1954.1 ± 280 vs 4656 ± 951 for vehicle and retinol treatments, respectively, $p<0.05$). Hepatic microsomes prepared from all treatment groups in the 4 day retinol potentiation model were used to determine activity and polypeptide levels for cytochrome P450 enzymes. Results showed that Total hepatic P450 was not altered by 4 days of retinol treatment (1.04 ± 0.19 vs. 1.12 ± 0.08 nmol/mg for retinol and untreated respectively). Aniline hydroxylation and p-nitrophenol hydroxylation (p-NP) demonstrated that 4 days of retinol treatment did not alter P4502E1 catalytic activity compared to untreated or vehicle treated mice (aniline, 4.10 ± 0.74 vs 4.22 ± 0.41 nmol/mg/min and p-NP, 2.1 ± 0.19 vs 2.6 ± 0.49 nmol/mg/min for retinol and untreated respectively). Since glutathione (GSH) is the major detoxification route for APAP, the effect of retinol on GSH was also measured. The results showed that retinol treatment itself did not alter hepatic GSH. These results demonstrate that retinol treatment is not altering 2 of the metabolic pathways for APAP. However, we must determine if retinol alters APAP associated reductions in GSH via oxidative stress and we must determine if P450 catalytic activity is altered in APAP vs APAP + retinol treated groups. (Supported by a Laurenson Award from the Otago Medical Research Foundation.)

1044 CHEMICAL INDUCTION OF RAT UDP-GLUCURONOSYL TRANSFERASE (UGT) mRNAs RESPONSIBLE FOR THYROID HORMONE METABOLISM.

N R Vansell and C D Klaassen. *Univ Kansas Med Ctr, Kansas City, KS.*

Treatment of rats with the hepatic enzyme inducers phenobarbital (PB), pregnenolone-16α-carbonitrile (PCN), 3-methylcholanthrene (3-MC), and Aroclor 1254 (PCB) has been shown to decrease circulating levels of thyroid hormones as well as increase microsomal glucuronidation of thyroxine. Members of both the UGT1 and UGT2 families have been suggested to contribute to thyroid hormone glucuronidation. The purpose of this study, then, was to determine whether the aforementioned chemical inducers cause specific increases in the messenger RNAs that encode two UGT isoforms in rats, UGT1A1 and UGT2B2. Male Sprague-Dawley rats were placed on control diet or diet containing PB (800 ppm), PCN (1000 ppm), 3-MC (250 ppm), or PCB (100 ppm) for seven days, at which time livers were collected for RNA isolation. Analysis of thyroid hormones in serum samples revealed significant decreases in T_4 concentrations, with PCB treatment having the largest effect. No changes in T_3 were caused by any treatment. Increases in mRNA were examined by northern-blot analysis using a 100 bp synthetic probe for UGT1A1, and a specific full-length cDNA probe for UGT2B2. An increase in UGT1A1 mRNA of just over 3 fold was found in PCN-treated animals, as well as an increase in UGT2B2 mRNA of nearly 3 fold. Little or no increase in mRNA for UGT1A1 or UGT2B2 was found for animals treated with other inducers. These findings suggest that decreases in circulating T_4 following PCN treatment in rats may be due to increases in thyroid hormone glucuronidation by UGT1A1 and UGT2B2, but that induction of other UGT isoforms may be important for increases in glucuronidation caused by PB, 3-MC, and PCB. (Supported by NIH Grants ES-07079 and ES-008156, and EPA Grant R826297.)

1045 METABOLISM AND PHARMACOKINETICS OF IBUPROFEN IN THE CHIMPANZEE.

R C Couch, J C Savage, T B Griffin, and F Coulston. *Coulston Foundation, White Sands Research Center, Alamogordo, NM, USA.*

Ibuprofen, a commonly used nonsteroidal antiinflammatory nonprescription drug is also an effective analgesic and antipyretic. Ibuprofen was included in a series of studies evaluating the chimpanzee as a surrogate human model for examining the metabolism and pharmacokinetics of xenobiotics. Three male and 3 female chimpanzees (10 to 14 years; 35 to 56 kg) were administered a single oral dose, 10 mg/kg, of ibuprofen. Whole blood was collected predose, 20, 40, 60 and 90 min, 2, 3, 4, 6, 8, and 24 h postdose. Plasma was harvested and analyzed by gas chromatography with mass spectrometric detection after the addition of a suitable internal standard. Plasma half-life ($t_{1/2}$; h) averaged 2.03 ± 0.16, quite similar to 2.0 ± 0.5 in humans. Clearance (Cl; L/kg•h) was 0.0307 ± 0.0073 in chimpanzees as compared to 0.0426 ± 0.0010 in humans. These data indicate that the chimpanzee may prove to be an excellent model for human pharmacokinetic studies.

1046 METABOLISM AND DISPOSITION OF ARSENITE (AsIII) AND ITS RELATIONSHIP TO HEME OXYGENASE (HO) INDUCTION IN MICE.

E M Kenyon, L M Del Razo, J L Brown, W A Anderson, M F Hughes and K T Kitchin. *NHEERL, US EPA, RTP, NC.*

HO is the rate limiting enzyme in heme degradation and it has a significant impact on intracellular heme pools. Rat studies indicate that HO induction is a sensitive, dose-dependent response to AsIII exposure in both liver and kidney. The objective of this study was to evaluate the relationship of HO induction and tissue levels of inorganic arsenic (iAs) and its metabolites in mice because human AsIII disposition and kinetics are more similar to mice compared to rats. Female B6C3F1 mice were given a single oral dose of 0, 1, 10, 30 or 100 μmol/kg AsIII. Levels of inorganic, mono- (MMA) and dimethylated arsenic (DMA) as well as HO activity were determined in liver and kidney 6 hr post dosing since HO induction peaks at 4 to 8 hrs after a single oral dose of 100 μmol/kg AsIII in mice. There was a significant dose-dependent trend of increasing HO induction in both liver and kidney with HO induction being ~two-fold higher in liver. Inorganic As was the predominant form of arsenic (As) in liver at all doses, whereas DMA was the predominant form of As in kidney at all doses. Three- to 4-fold higher levels of iAs were achieved in liver compared to kidney. MMA was the least abundant form of As in both liver and kidney, never exceeding more than 20% of the total As present. The concentration of iAs, rather than mono- or dimethyl As, demonstrated the strongest linear correlation with HO activity in both liver (r=0.9988) and kidney (r=0.9705). Results of this study suggest that HO induction is a biomarker of effect that is specific for tissue iAs since a maximally tolerated dose of DMA (5220 μmol/kg) was ineffective in inducing HO in mice. HO induction thus has potential for use as a biomarker of inorganic arsenic internal dose to target tissue and can be used as a tool to further the development of a biologically-based dose response model for As. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.)

1047 DIVERSITY OF HEPATIC ARSENITE METHYLTRANSFERASE AND ARSENATE REDUCTASE ACTIVITIES AMONG NEW AND OLD WORLD PRIMATES: AN IN VITRO STUDY.

E Wildfang, T R Radabaugh, R A Zakharyan, and H V Aposhian. *The University of Arizona, Tucson, AZ, USA.*

Common laboratory animals respond with a great degree of metabolic variation when challenged with inorganic arsenic exposure. Patterns of arsenic metabolic diversity are also beginning to emerge among human populations. This study investigated an evolutionary-related group of animals to determine whether distinctions could be made to explain the diversity in the metabolism of inorganic arsenic among mammals. A total of 30 animals representing 17 different species within the phylogenic order Primates were examined for hepatic cytosol arsenite methyltransferase and arsenate reductase activities. Three *Macaca sp.* (Rhesus, pig-tailed and long-tailed) and one of three *Saimiri sciureus* (squirrel monkey) animals demonstrated arsenite methyltransferase activity. The remaining 13 primate species were deficient of arsenite methyltransferase activity. The diversity of arsenite methyltransferase activity could not be related to dietary differences, geographical habitat or evolutionary relatedness among the primate species surveyed. All primate species examined showed arsenate reductase activity, with wide variation within and between species. There was no correlation between cytosolic sulfhydryl concentration and the amount of arsenate reductase activity in these cytosols. (Supported in part by the Superfund Basic Research Program NIEHS Grant ES-04940.)

1048 TERT-BUTYL HYDROPEROXIDE SUPPORTS LIPOXYGENASE-MEDIATED XENOBIOTIC OXIDATION.

T Stedeford , C G Hover, and A P Kulkarni. *Florida Toxicology Research Center, College of Public Health, University of South Florida, Tampa, FL.*

This study tests the hypothesis that organic hydroperoxides support xenobiotic oxidation mediated via the lipoxygenase pathway. Soybean lipoxygenase (SLO)-catalyzed oxidation of 3,3',5,5'-tetramethylphenylenediamine (TMPD), 3,3'5,5'-tetramethylbenzidine (TMBz), benzidine, guaiacol, and pyrogallol was evaluated in the presence of tert-Butyl hydroperoxide. Oxidation of TMPD to Wurster's Blue Free Radical was found to be proportional to the concentration of SLO, TMPD, and tert-Butyl hydroperoxide, and was linear with time. These results suggest the enzymatic nature of the reaction. TMPD exhibited the highest specific activity, while the lowest rate of oxidation was noted with guaiacol. The optimal conditions required to observe the maximal rate of oxidation of TMPD included: pH 8.5, 1.0 mM tert-butyl hydroperoxide, 1.25 mM TMPD, and 20 μg of SLO. Similar to tert-Butyl hydroperoxide, cumene hydroperoxide also supported oxidation of these xenobiotics. In contrast to the previously reported acidic pH optimum (pH 6.5) for hydrogen peroxide supported xenobiotic oxidation by SLO, both organic hydroperoxides displayed maximal xenobiotic oxidation rates under alkaline conditions (pH 8.5). The classical inhibitors of lipoxygenase viz. nordihydroguaiaretic acid (NDGA), butylated hydroxyanisole (BHA), butylated hydroxytoluene (BHT), and gossypol, significantly inhibited the oxidation of TMPD, TMBz, benzidine, guaiacol, and pyrogallol. These results support the contention that SLO can metabolize xenobiotics in the presence of organic hydroperoxides.

1049 LIPOXYGENASE-MEDIATED HYDROGEN PEROXIDE-DEPENDENT N-DEMETHYLATION OF XENOBIOTICS.

C G Hover, J Hu, X Yang, A V Rajadhyaksha, V Reddy and A P Kulkarni. *Florida Toxicology Research Center, College of Public Health, University of South Florida, Tampa, FL.*

The hydrogen peroxide dependent N-demethylation capability of soybean lipoxygenase (SLO), a model enzyme, and human term placental lipoxygenase (HTPLO) was evaluated. Formaldehyde (HCHO), the product of N-demethylation, accumulated in the reaction media was estimated using Nash reagent. Model compounds, drugs, and pesticides, were tested as substrates. The reaction was dependent on the incubation time, pH of the medium, amount of enzyme, concentrations of the substrate and hydrogen peroxide. Under optimal assay conditions, the specific activity (nmoles HCHO/min/mg protein) of the SLO catalyzed N-demethylation of N, N-dimethylaniline was 200. Specific activities for phenothiazines tested ranged from 10 to 828, with promethazine displaying the highest activity. N-demethylation of a variety of pesticides yielded rates between 7 and 144, with aminocarb posting the highest value. Imipramine and related tricyclic antidepressants reacted at rates between 9 (Doxepin) and 210 (Triipramine). The SLO mediated reaction of aminopyrine showed a specific activity of 823, while the HTPLO supported aminopyrine oxidation showed a specific activity of 16. The aminopyrine cation radical, the presumed intermediate absorbing at 565 nm was detected in both systems. Under similar conditions, HTPLO catalyzed N, N-dimethylaniline N-demethylation at a rate of 33, while chlorpromazine exhibited a rate of 6. The results suggest that xenobiotics undergo N-demethylation via the lipoxygenase pathway, with significant substrate specificity.

1050 IN VITRO BIOTRANSFORMATION OF XANTHOHUMOL BY RAT LIVER MICROSOMES.

M Yilmazer[1], J F Stevens[2], M L Deinzer[2] and D R Buhler[1]. [1]*Department of Environmental and Molecular Toxicology,* [2]*Department of Chemistry, Oregon State University, Corvallis, OR, USA.*

Xanthohumol, a flavonoid from hops (*Humulus lupulus*) has been shown in various *in vitro* tests to have cancer chemoprevention properties. The flavonoid inhibits the growth of human breast, ovarian, and prostate cancer cells and also inhibits a number of carcinogen-activating human cytochrome P450s. We investigated the conversion of xanthohumol to various metabolites by rat liver microsomes. Two major metabolites were found with hepatic microsomes from untreated rats as detected by HPLC analysis. The reduced metabolite levels produced in incubations containing P450 inhibitors or cytochrome P450 reductase antibody suggest that cytochrome P450s were primarily responsible for the observed metabolites. Microsomes from phenobarbital-pretreated rats produced the same metabolites but changed their relative proportions. However, microsomes from β -naphthoflavone- and isosafrole-pretreated rats produced a new nonpolar metabolite in addition to the other two. As determined by LC-MS and ^{1}H-NMR analysis, two of the xanthohumol microsomal metabolites were tentatively identified as 5''-(2-hydroxyisopropyl)-[2'',3'':3',4']dihydrofurano-2',4dihydroxy-6'-methoxychalcone and a dehydrocycloxanthohumol derivative. The biological activity of these metabolites and their involvement in cancer chemoprevention remain to be established. (Supported by the Hop Research Council and NIEHS grants ES00210.)

1051 THE *IN VIVO* DISPOSITION AND METABOLISM OF METHYLEUGENOL IN THE FISCHER 344 RAT AND THE B6C3F$_1$ MOUSE.

J L Burkey, N C Hoglen, M J Kattnig, M E Rice and I G Sipes. *Department of Pharmacology and Toxicology, The University of Arizona, Tucson, AZ, USA.*

Methyleugenol is an alkenylbenzene compound found in many essential oils. It is added to cosmetics, soaps, fragrances, and herbal products as well as being found naturally in some foods. While human exposure to this compound is limited to low levels, its use in many products makes it likely that exposure is relatively constant. Therefore, the metabolic fate and possible activation of this compound *in vivo* is of interest. Studies were undertaken to examine the absorption, distribution, metabolism, and excretion of the compound following oral and intravenous (I.V.) administration to male Fischer 344 rats and oral administration to female B6C3F$_1$ mice. Following oral administration of [^{14}C]-methyleugenol (118 mg/kg, 50 uCi/kg) to rats, approximately 72% of the administered radioactivity was recovered in the urine and 13% in the feces within 72 hr. After I.V. administration (11.8 mg/kg, 120 uCi/kg) to rats, approximately 85% was recovered in urine and 8% in feces by 72 hr. In rats, following oral administration, no significant amount of [^{14}C]-equivalents could be detected in the blood. Following I.V. administration, methyleugenol and two possible metabolites were seen in the blood by HPLC; both metabolites were below the limit of detection within 50 min and were no more than 2.5% of the total dose at their peak in the blood at 8 min. Methyleugenol itself disappeared from the blood by 6 hr and was almost totally cleared from the blood by 1 hr. Similar to the rat, when methyleugenol (118 mg/kg, 50 uCi/kg) was administered orally to mice, 85% was recovered in urine and 6% in feces at 72 hr. Major urinary metabolites for both species were quantified by HPLC radioassay. Preliminary identification of metabolites by LC-MS/MS suggest the presence of sulfate and glucuronide conjugates of hydroxylated derivatives and a mercapturic acid. These results indicate that methyleugenol is almost totally metabolized following an oral dose in both species, and is quickly eliminated from the body. (This research was supported by NIEHS (NO1-ES-35367, P30-ES-06694 and T32-ES-07091-17).)

1052 THE DISPOSITION OF ISOEUGENOL IN THE MALE FISCHER-344 RAT.

D A Badger, M J Kattnig, R L Smith, J Bao, and I G Sipes. *Department of Pharmacology and Toxicology, College of Pharmacy, The University of Arizona, Tucson, AZ, USA.*

Isoeugenol is an oily liquid found in a number of plant oils including clove, bay leaves and pimento. Because of its clove-like fragrance, it is used in a number of consumable products including beverages, baked goods and chewing gums, as well as home and personal products such as soaps, detergents and perfumes. Although exposure to humans appears to be low but continual, no information is available on the disposition and metabolism of isoeugenol. Therefore the primary objective of these studies was to determine the absorption, distribution, metabolism and excretion of isoeugenol following oral and intravenous administration to male Fischer-344 rats. Following a single oral dose of [^{14}C]-isoeugenol (156 mg/kg, 50 μCi/kg), greater than 85% of the administered dose was excreted in the urine as sulfate or glucuronide metabolites by 72 hr. Approximately 10% was recovered in the feces, and less than 0.1% was recovered as CO_2 or expired organics. No parent isoeugenol was detected in the blood at any of the time-points analyzed. Following intravenous administration of a single dose of [^{14}C]-isoeugenol (15.6 mg/kg, 100 μCi/kg), isoeugenol was cleared from blood within one hr. Within 72 hr following intravenous administration, 82% of the total administered radioactivity was excreted as sulfate or glucuronide conjugates into the urine, 10% was recovered in the feces, and less than 0.1% was recovered as CO_2 and expired organics. The total amount of radioactivity remaining in selected tissues was less than 0.25% following either oral or intravenous administration. The results of these studies show that isoeugenol is rapidly metabolized and is excreted predominantly in the urine as phase II conjugates of the parent compound. (This research was supported by NIEHS (N01-ES-35367, and P30-ES-06694).)

1053 METABOLISM OF STRUCTUAL ANALOGS OF EUGENOL BY PULMONARY CYTOCHROME P450 ENZYMES.

K W Skordos and G S Yost. *Department of Pharmacology and Toxicology, University of Utah, Salt Lake City, UT.*

Eugenol, a food additive and dental anesthetic, has been shown to be a potent pulmonary toxicant. The toxicity of eugenol is dependent on cytochrome P450-mediated desaturation to a quinone methide reactive intermediate that can alkylate cellular macromolecules by a Michael-like addition reaction. The metabolism of structural analogs of eugenol, such as 4-ethyl-methoxyphenol (EMP), by rat liver microsomes, has been previously studied (Bolton, J.L., *et. al.*). A cytochrome P450-dependent quinone methide of EMP can be conjugated with glutathione at the exocyclic position resulting in chromatographically separable diastereomers. The present investigation utilizes goat lung microsomes as a metabolic model system, for the study of the reactive intermediates of the EMP. In addition to the previously characterized benzylic isomers of the glutathione conjugate of EMP, additional conjugates were formed. Incubations performed in the absence of glutathione produced a single metabolite that was depleted in the presence of gluathione. This metabolite has UV spectral characteristics that might be expected of a 3,4-substituted styrene. This metabolite may represent the product of a unique cytochrome P450-dependent terminal dehydrogenation of the alkyl substituent of EMP. Thus, pulmonary cytochrome P450 enzymes appear to uniquely catalyze the terminal dehydrogenation of EMP, a reaction that does not usually occur with hepatic cytochrome P450 enzymes. (Supported by USPHS Grant #HL13645.)

1054 AFLATOXIN B1 OXIDATION BY HUMAN CYTOCHROMES P450 CYP1A1, 2A6, 2C8, 2C9, 2C18 and 2C19.

T K Bammler[1], S J Thompson[2], E P Gallagher[3], C Sengstag[4], D H Slone[1], R L Haining[3], A E Rettie[2] and D L Eaton[1]. [1]*Dept. of Environmental Health, and* [2]*Dept. of Medicinal Chemistry, University of Washington, Seattle, WA, USA;* [3]*Department of Physiological Sciences, University of Florida, Gainesville, FL, USA;* [4]*Institute of Toxicology, Swiss Federal Institute of Technology, Schwerzenbach, Switzerland.*

Several human cytochrome P450 (CYP) isoenzymes are known to metabolize the potent hepatocarcinogen aflatoxin B1 (AFB). However, the physiological relevance of individual CYPs is somewhat controversial. To clarify the situation, we examined the capacity of recombinant human CYPs 1A1, 2A6, 2C8, 2C9, 2C18 and 2C19 to metabolize AFB. All CYPs examined metabolized AFB to the genotoxic *exo*-aflatoxin-8,9-epoxide (AFBO) to varying degrees (2C18>1A1>2A6>2C19 ~2C8>2C9). In addition, CYP1A1 was very efficient in forming AFM1. The activities of CYPs 1A1 and 2C18 were sufficiently high to carry out kinetic analysis. The Kms for CYPs 1A1 and 2C18 with respect to AFBO formation were 55 ±33 (A.S.E.) and 298 ±33 μM and the corresponding Vmax values were 180 ±32 and 1144 ±66 pmol/min/nmol respectively. In addition, CYP1A1 possessed a Km and Vmax for AFM1 formation of 62 ±6 μM and 12,151 ±375 pmol/min/nmol respectively. Our data suggest that of the CYPs examined, only CYP1A1 is likely to metabolize AFB at low physiologically encountered concentrations. In contrast to liver, CYP1A1 is expressed at significant levels in lung, which maybe a target organ following AFB inhalation of contaminated grain dust. As CYP1A1 forms approximately 70-fold more of the detoxification product AFM1 relative to the genotoxic metabolite AFBO, it can be considered mainly a detoxification enzyme. (Supported by NIH ES 05780, ES 07033, GM32165 and 49054.)

1055 MICROSOMAL EPOXIDE HYDROLASE IS ASSOCIATED WITH, BUT NOT NECESSARY FOR, VITAMIN K$_1$ EPOXIDE REDUCTASE ACTIVITY.

D Cai[1], R Wallin[2] and T M Guenthner[1]. [1]*Department of Pharmacology, University of Illinois at Chicago, College of Medicine, Chicago, IL, USA;* [2]*Department of Medicine, Section on Rheumatology, The Bowman Gray School of Medicine, Winston-Salem, NC, USA.* Sponsor: B S Levine.

Microsomal epoxide hydrolase (mEH) has been identified as a major component of the partially purified Vitamin K$_1$ epoxide reductase (VKOR) multi-protein complex by criteria of co-elution of hydrolase and reductase activity, Western blotting, and N-terminal micro-sequencing of a predominant 50 kD protein isolated from the VKOR preparation. Km values of the partially purified VKOR complex for hydrolysis of styrene 7,8-oxide were similar to those for homogeneous mEH itself. A functional role for mEH in

VKOR activity was suggested by experiments showing that anti-mEH antiserum inhibited up to 80% of the VKOR activity of the partially purified reductase preparation. However, over-expression of mEH in V79 fibroblast cells did not produce a concomitant increase in VKOR activity. To directly assess the possible functional role of mEH in VKO reduction, we compared VKOR activity in hepatic microsomes isolated from wild-type and mEH-null ("mEH knockout") mice. Results of these experiments show that VKOR activity in mEH knockout microsomes is comparable to that present in wild type microsomes. Furthermore, anti-mEH antibody inhibits VKOR activities in both wild type and mEH knockout microsomes. We observe a protein in the knockout microsomes that is immunoreactive with anti-mEH antibody, and postulate that this protein may be required for VKOR activity.

1056 SELECTIVE HYDROLYSIS OF FATTY ACID MONOEPOXIDES INTO TOXIC *VICINAL* DIOLS BY SOLUBLE EPOXIDE HYDROLASE.

K C Williamson, J F Greene and B D Hammock. *University of California at Davis, Davis, CA, USA.*

The goal of this research was to test the hypothesis that soluble epoxide hydrolase (sEH) selectively hydrolyzes isomers of linoleate monoepoxides into toxic *vicinal* diols. By studying sEH metabolites of oxidized lipids, insight can be gained into the selective chemistry and the mechanism of action of this enzyme. The regioselectiviy of sEH for leukotoxin (LTX, 9,10-epoxy-12Z-octadecenoate) and isoleukotoxin (iLTX, 12,13-epoxy-9Z-octadecenoate) was determined. This was accomplished by developing and comparing analytical methods to separate epoxide and diols isomers, synthesizing standards for analysis, and optimizing the incubation assay and extraction method. It was found that both the mouse and human recombinant sEH have the same selectivity and that there is no preference by these enzymes for one regioisomer over the other. These data indicate that the mouse is a good animal model for humans in these studies. Also, the cytotoxicity of the linoleate diol regioisomers formed by sEH were measured *in situ*. In this assay, LTX and iLTX were added to cells expressing human sEH and cell death was measured after 24h. The LC_{50} for both regioisomers is similar, 156 uM (range of 155-157 uM) and 153 uM (range of 152-155 uM) for LTX and iLTX, respectively. LTX and iLTX were found to be non-toxic to cells expressing a control enzyme. Since the metabolism of LTX and iLTX by sEH appears to be non-preferential, and these metabolites have equivalent toxicity in this system, then a general sEH inhibitor could protect the system from diol toxicity.

1057 STRUCTURE-ACTIVITY RELATIONSHIPS OF EPOXY FATTY ACIDS.

J F Greene, K C Williamson, J W Newman, and B D Hammock. *University of California at Davis, Davis, CA, USA.*

We have previously noted that leukotoxin (9,10-epoxy-12Z-enoic acid, methyl ester; ltx), an epoxy fatty acid correlated with adult respiratory distress syndrome, is toxic in various cell and mammalian systems (Moghaddam *et al. Nat. Med.* 3, 562-566 (1997)) when soluble epoxide hydrolase is expressed. The purpose of this research was to characterize structural elements necessary for toxicity. We hypothesized that: (1) altered alkyl chain length; (2) increased ester length; or, (3) a change in position of the epoxide would decrease toxicity. Conversely, we hypothesized that: (4) substitution of the carbonyl; or, (5) epoxide hydrolysis would increase toxicity. Eighty compounds were used to test these hypotheses. Compounds were either purchased or synthesized using standard oxidation and hydrolysis reactions, purified by flash chromatography and verified by TLC, GC-FID, GC-MS and NMR. Toxicity was assessed using a model system of eukaryotic cells expressing either transgenic human soluble epoxide hydrolase (hsEH) or β-galacatosidase (lacZ) as a control enzyme. We found that chain length, ester size, change in epoxide position, carbonyl substitution and epoxide hydrolysis all altered toxicity. Notably, we found: (1) significant differential toxicity, due to expressed enzyme, was only observed with 17-19 carbon compounds with internal epoxides; (2) increased ester length was strongly correlated with decreased toxicity; (3) hsEH protected cells exposed to compounds with terminal epoxides; (4) mixed results were observed with carbonyl substitution. In cases where the epoxide was toxic only to hsEH expressing cells, (5) the corresponding diol was toxic to cells expressing both enzymes, suggesting that these alkyl epoxides are pro-toxins. Overall these results strongly suggest that minor structural changes have major effects on the potency and mode of action of these compounds. This knowledge could lead to a means of reducing leukotoxin toxicity in humans.

1058 METABOLISM OF BUTADIENE MONOEPOXIDE BY FRESHLY ISOLATED HEPATOCYTES FROM MICE AND RATS.

R A Kemper and A A Elfarra. *Dept. of Comparative Biosciences and Center for Environmental Toxicology, University of Wisconsin, Madison, WI, USA.*

Butadiene monoepoxide (BMO) is the primary oxidative metabolites of the commonly-used petrochemical 1,3-butadiene (BD), and is thought to play a major role in BD-induced carcinogenicity. Studies of BMO metabolism in subcellular fractions have demonstrated formation of both bioactivation products, such as diepoxybutane (DEB), and detoxification products, such as 3-butene-1,2-diol (BDD) and GSH conjugates. The current study investigates metabolism of BMO in freshly isolated hepatocytes from B6C3F1 mice and Sprague-Dawley rats. Formation and elimination of BMO metabolites were examined over time (45 min) at low (5 μM), intermediate (25 μM), and high (250 μM) BMO concentrations. Hepatocytes from both species retained > 80% viability at these BMO concentrations throughout the experiments. To facilitate comparison, time course data were expressed as area-under-the-curve (AUC). In mouse hepatocytes, *meso*-DEB, *(±)*-DEB, and BDD were detected by GC/MS at all BMO concentrations. At the low BMO concentration, oxidation to DEB predominated over BDD formation, whereas at the high BMO concentration, hydrolysis to BDD became the major pathway. In rat hepatocytes, AUCs for DEB formation were 10 to 20-fold lower than in mice, and *meso*-DEB was detectable only at the high BMO concentration. The opposite was observed for BDD, with AUCs being much greater than seen in mouse hepatocytes. Elimination of *(±)*-DEB (10 μM) and BDD (30 μM) in both species could described empirically as pseudo-first order processes. Although methods to assess the contribution of GSH conjugation to BMO metabolism in hepatocytes are still under development, the results of our experiments demonstrate the ability of the isolated hepatocyte model to provide detailed information on coordinated metabolism of BMO. (Supported by NIEHS Grant R01 ES06841.)

1059 INTERRELATIONSHIPS AMONG FATTY ACID ETHYL AND METHYL ESTER SYNTHASES AND FATTY ACID ANILIDE SYNTHASE IN HEPG2 AND AR42J CELLS.

B S Kaphalia[1], S M Green[2], and G A S Ansari[1]. *Departments of Pathology[1] and Pharmacology & Toxicology[2], University of Texas Medical Branch, Galveston, TX, USA.*

We have previously demonstrated that fatty acid ethyl ester synthase (FAEES), purified from rat liver microsomes, is structurally and functionally similar to rat liver microsomal carboxylesterase (CE, pI 6.1) and suggested its role in conjugation of fatty acids with a variety of xenobiotic alcohols [Kaphalia et al., (1997) Chem. Res. Toxicol. 11, 211-218]. In the present studies, we further determined interrelatioship among various hepatic and pancreatic enzyme(s) involved in the biosynthesis of fatty acid ethyl esters (FAEEs), fatty acid methyl esters (FAMEs) and fatty acid anilides (FAAs) using HepG2 and AR42J cells. Incubation of HepG2 cells with tri-O-tolyl phosphate (TOTP), a specific inhibitor for hepatic S-esterase, resulted in a dose (0.1 - 5.0 FM)- and time (0.25-24 hr)- dependent inhibition of FAEE, FAME and FAA synthesizing activities in an identical manner. The optimum inhibition for FAEE, FAME and FAA synthesizing activities was found to be 86, 92 and 87%, respectively, in HepG2 cells following exposure to 2.5 FM TOTP for 24 hr. However, similar inhibition by TOTP was not observed in AR42J cells. A ~60 kD protein (subunit molecular weight) was detected in the postnuclear fractions of only HepG2 cells by Western blot analysis using antibodies raised against FAEES, purified from rat liver microsomes. Therefore, the conjugation of fatty acids with ethanol, methanol or aniline in the HepG2 cells appears to be catalyzed by the same enzyme(s). These studies also suggest that FAEE, FAME and FAA synthases present in HepG2 cells may be structurally and functionally similar to rat liver microsomal CE, however, different from that present in AR42J cells.

1060 IN VITRO RATES OF COUMARIN 3,4-EPOXIDATION ARE NOT PREDICTIVE OF SPECIES DIFFERENCES IN HEPATOTOXICITY.

S L Born and L D Lehman-McKeeman. *The Procter and Gamble Co., Cincinnati, OH.*

Coumarin, a perfume ingredient, is a rat liver and mouse Clara cell toxicant. Coumarin-mediated injury results from the formation of coumarin 3,4-epoxide (CE) and the subsequent quantitative rearrangement of CE to form a hepatotoxic aldehyde, *o*-hydroxyphenylacetaldehyde (*o*-HPA). Clear species

differences exist in the hepatotoxicity of coumarin, with injury being greatest in the rat> > mouse> human. To better understand the relationship between hepatic injury and CE formation, *o*-HPA production in F344 rat and B6C3F1 mouse hepatic microsomes was quantitated using a sensitive gas chromatographic method coupled with flame-ionization detection. At coumarin concentrations ranging from 10-2000 μM, *o*-HPA formation exhibited biphasic kinetics in rat and mouse liver microsomes. In both rat and mouse, a high-affinity CYP450 exhibited a K_m of 20 μM, with V_{max} values of 0.580 and 2.3 nmol/min/mg, respectively. At concentrations > 100 μM, the rat high capacity enzyme(s) exhibited a K_m of 1300 μM and V_{max} of 6 nmol *o*-HPA/min/mg. In contrast, mice are resistant to coumarin-mediated liver injury, yet the low affinity enzyme catalyzes *o*-HPA formation with a K_m of 462 μM and a V_{max} of 10 nmol/min/mg. Furthermore, the intrinsic clearance (V_{max}/K_m) of coumarin via epoxidation was 4-fold greater in mice than rats. These data indicate that, in liver, toxicity does not directly correlate with the rate of CE/*o*-HPA formation *in vitro*. Rather, the balance between bioactivation and detoxification likely dictates the susceptibility of a species to coumarin-mediated liver toxicity.

1061 EFFECTS OF XENOBIOTICS ON EXPRESSION OF HUMAN MICROSOMAL EPOXIDE HYDROLASE.

S M Marcic and T M Guenthner. *Dept. of Pharmacology, University of Illinois at Chicago Coll. Med., Chicago, IL, USA*. Sponsor: B S Levine.

Although microsomal epoxide hydrolase (mEH) is known to be readily inducible following exposure of laboratory animals to a variety of xenobiotics, little is known about the inducibility and regulation of human microsomal epoxide hydrolase. In the present study, we investigated the effects of several prototypic inducers of xenobiotic-metabolizing genes on human mEH mRNA, protein and enzyme activity levels in cultured HepG2 cells. Continuous treatment of cells for 12 to 72 hours resulted in a rapid and sustained 2- to 3-fold increase in mEH mRNA levels, as measured by Northern blotting. Induction of CYP1A1 mRNA was simultaneously determined as an internal control of cellular response to Ah receptor-mediated induction. Induction of mEH protein, determined by Western blot analysis, and enzyme activity, determined as [^{3}H] styrene oxide hydrolase activity, were preceded by mEH mRNA elevation. We conclude that modulation of human mEH is regulated, at least in part, at the transcriptional level. mEH mRNA expression was stimulated after 12 hours exposure to ?-naphthoflavone (BNF), a compound known to upregulate several xenobiotic metabolizing enzymes via both ARE (antioxidant responsive) and XRE (xenobiotic responsive) elements. mRNA expression was also stimulated by exposure to 2,3,7,8-tetrachlorodibenzodioxin (selective for XRE) and *tert*-butylhydroquinone (selective for ARE) alone, suggesting that both elements may play a role in regulation of mEH expression in human liver. Finally, we showed that concomitant exposure of cells to BNF and tumor necrosis factor α (TNFα) results in a decrease in mEH activity, suggesting a negative regulatory role for TNFα and, possibly, other cytokine substances.

1062 INHIBITION OF MICROSOMAL AND SOLUBLE EPOXIDE HYDROLASE BY METALS.

A J Draper and B D Hammock. *University of California, Davis, CA, USA.*

Inhibition of xenobiotic-metabolizing enzymes by metals may represent an important mechanism in regulating enzyme activity. Fourteen cations were evaluated for inhibition of microsomal epoxide hydrolase (mEH) in mouse, rat and human liver microsomes and soluble epoxide hydrolase (sEH) in mouse, rat and human liver cytosol. The IC_{50} values determined for inhibition of mEH and sEH in all three species were remarkably similar. Of the metals tested, Hg^{2+} was the most potent inhibitor (IC_{50} = 1 μM); Zn^{2+}, Cd^{2+} and Cu^{2+} were also strong inhibitors (IC_{50} = 10 μM, 10 μM, 20 μM respectively). Nickel (divalent) and Pb^{2+} were moderate inhibitors (IC_{50} = 500 μM), but Al^{2+}, Ba^{2+}, Ca^{2+}, Co^{2+}, Fe^{2+}, Fe^{3+}, Mg^{2+} and Mn^{2+} inhibited epoxide hydrolase activity less than 50 % at 1 mM metal concentration (IC_{50} < 1 mM). Inhibition by all metals except Hg^{2+} could be reversed with the chelators EDTA, EGTA, 1,10-phenanthroline and dipicolinic acid. Additionally, mouse liver microsomes and cytosol were incubated with these chelators. Following incubation at 4° C, samples were dialyzed to remove chelator. Both mEH and sEH activity recovered was greater in samples treated with chelator than in control incubations. Similar treatment with the protease inhibitor Nα-*p*-tosyl-L-lysine chloromethyl ketone (TLCK) did not affect enzyme activity recovered. During systemic inflammation, hepatic metallothionien is induced, and liver metal concentrations increase while serum metal concentrations are decreased. The inhibition of microsomal and soluble epoxide hydrolase by metals may represent a mechanism of downregulation of enzyme activity during inflammation.

1063 BIOTRANSFORMATION AND KINETICS OF EXCRETION OF METHYL TERT.-BUTYL ETHER IN RATS AND HUMANS.

A Amberg, E Rosner, and W Dekant. *Institut für Toxikologie, Universität Würzburg, Würzburg, Germany.*

Methyl tert.-butyl ether (MTBE) is widely used as an additive to gasoline to increase oxygen content and reduce tail pipe emmission of pollutants. Therefore, widespread human exposure may occur. To contribute to the characterisation of potential adverse effects of MTBE, its biotransformation was compared in humans and rats after inhalation exposure. Human volunteers (3 males and 3 females) and rats (5 males and 5 females) were exposed to 4 (4.5 ± 0.4) and 40 (38.7 ± 3.2) ppm MTBE for 4 hours in a dynamic exposure system. Urine samples were collected for 72 h in 6 h intervals and blood samples were taken in regular intervals for 48 h in humans. In urine, the MTBE-metabolites *tert*.-butanol, 2-methyl-1,2-propane diol and 2-hydroxyisobutyric acid were quantified, MTBE and tert.-butanol were determined in blood samples. After the end of the exposure period, blood concentrations of MTBE were similar after 40 (6.7 ± 1.6 μM in humans and 5.9 ± 1.8 μM in rats) and 4 ppm MTBE (1.9 ± 0.4 μM in humans and 2.3 ± 1.0 in rats). MTBE was rapidly cleared from blood with a half life of 2.6 ± 0.94 h in humans and 0.5 ± 0.2 h in rats. The blood concentrations of tert.-butanol were 21.8 ± 3.7 in humans and 36.7 ± 10.8 in rats after 40 ppm MTBE and 2.7 ± 0.3 in humans and 1.9 ± 0.5 in rats after 4 ppm MTBE. Tert.-butanol was also rapidly cleared from blood with half lifes of 5.3 ± 2.1 h in humans and 0.4 ± 0.1 h in rats. In urine of both species, 2-hydroxyisobutyrate was recovered as major excretory product in urine. Both tert.-butanol and 2-methyl-1,2-propane diol were minor metabolites. All metabolites of MTBE excreted with urine were also rapidly eliminated in both species. Elimination half lives for the different urinary metabolites of MTBE were between 10 and 17 h in humans and 3.5 and 4.5 h in rats. The obtained data indicate that MTBE-biotransformation and excretion is similar in rats and humans and MTBE and its metabolites are rapidly excreted in both species. Approximately 50 % of the calculated amount of MTBE retained after the end of the exposure was recovered as metabolites in urine of both humans and rats. (Supported by the Health Effects Institute, agreement No. 96-3.)

1064 TOXICOKINETICS AND URINARY METABOLITES IN HUMANS AFTER EXPOSURE TO ^{13}C-LABELED METHYL *t*-BUTYL ETHER.

A Löf[1], S Sumner[2], A Nihlén[1] and G Johanson[1,3]. [1]*National Institute for Working Life, Solna, Sweden;* [2]*CIIT, Research Triangle Park, NC, USA;* [3]*University Hospital, Uppsala, Sweden.*

Methyl *t*-butyl ether (MTBE) is widely used as an oxygenate in gasoline for a complete combustion. Following inhalation exposure to MTBE, *t*-butyl alcohol (TBA) has been identified in human urine with a low recovery (<1%) (*Nihlén et al. TAP 1998;148:274*). The present study was conducted to characterize additional metabolites in urine of MTBE exposed humans and to evaluate the toxicokinetics of MTBE and TBA. Four healthy male volunteers were exposed to 50 ppm [1,2-$^{13}C_2$]-MTBE vapor (mouth only) for 2 hr during light physical work load (50 W). Blood, urine, and expired air were collected up to 22 hr post exposure. MTBE, TBA and acetone were analyzed by gas chromatography. In addition, characterization of urinary metabolites were accomplished by ^{1}H-decoupled ^{13}C nuclear magnetic resonance (NMR) spectroscopy. Low net uptake (39%), postexposure exhalation (17%), and recovery of TBA in urine (<1%) were observed. Toxicokinetics of MTBE and TBA in this mouth only exposure did not differ from a previous whole-body chamber exposure. Chemical shifts for the ^{13}C-labeled portion of the urinary metabolites were consistent with the shifts obtained for spiked standards of α-hydroxybutyric acid (HBA) and 2-methyl-1,2-propanediol (MPD). NMR signals were not present for labeled MTBE, TBA, or possible MTBE-derived glucuronide conjugates. HBA and MPD occur at significantly higher levels in the urine (detected by NMR) than MTBE and TBA (detected by GC). To our knowledge this is the first characterization of MTBE metabolites, other than TBA, in humans. These data are important for assessing human health risks associated with MTBE exposure. (Funded, in part, by PREEM Environment Foundation, Sweden and dues payments of CIIT member companies.)

1065 ACTIVATION OF RAT LIVER MICROSOMAL FLAVIN-CONTAINING MONOOXYGENASE BY DEPRENYL, AN INHIBITOR OF MONOAMINE OXIDASE B.

W G Chung, S D Ryu, C S Park, K H Lee and Y N Cha. *Department of Pharmacology and Medicinal Toxicology Research Center, College of Medicine, Inha University, Inchon, Korea.*

Deprenyl, a well known inhibitor of monoamine oxidase (MAO) B, inhibits the conversion of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) to 1-methyl-4-phenyl pyridinium (MPP) which causes parkinsonism in experimental animals. Deprenyl inhibits MAO B by binding to the flavin moiety contained in MAO. Flavin-containing monooxygenase (FMO) also possesses the flavin moiety but is known to metabolize MPTP to a non-toxic MPTP N-oxide. As the FMO contains flavin moiety, we thought that deprenyl may also inhibit FMO activity in liver microsomes and limit the production of MPTP N-oxide. In an effort to determine whether deprenyl inhibits liver microsomal FMO activity, thiobenzamide S-oxidation (a standard FMO assay method) was conducted in the presence of varying concentrations of deprenyl . With liver microsomes obtained from mouse, rat, rabbit and human, deprenyl (0.1 to 1.0 mM) was found to activate, instead of the expected inhibition, the FMO activity up to 2.9 fold. When compared with the ability of n-octylamine to activate the liver microsomal FMO activity, deprenyl was found to be more potent. Clogyline, a well known inhibitor of MAO A activity, also activated the liver microsomal FMO activity, but was not as potent as deprenyl. Thus, by activating the liver microsomal FMO activity, deprenyl may enhance the metabolism of MPTP toward its non-toxic N-oxide producing pathway. This together with inhibition of MAO B, deprenyl may serve as an effective antidote against MPTP inducible parkinsonism.

1066 N-DEMETHYLATION OF CAFFEINE BY RECOMBINANT HUMAN FLAVIN-CONTAINING MONOOXYGENASES.

Y N Cha, C S Park, K H Lee and W G Chung. *Department of Pharmacology and Medicinal Toxicology Research Center, College of Medicine, Inha Univeristy, Inchon, Korea.*

Caffeine (CA), a trimethylxanthine contained in coffee, is known to be N-demethylated to theobromine (TB), paraxanthine (PX) and theophylline (TP) and also to trimethethylurate by various cytochrome P-450 (CYP) isoforms. Recently, using human liver microsomes and specific inhibitors of CYP and flavin-containing monooxygenase (FMO), we reported that majority of TB and TP, but minor portion of PX produced from CA are catalyzed by FMO [BBRC 235: 685-688 (1997); Chem-Biol. Interact. 113: 1-14 (1998)]. The aim of this study is to confirm and compare the role of recombinant human FMOs and CYP1A2 expressed in E. coli and purified in N-demethylating CA. CA was oxidized with various recombinant FMO isozymes or CYP1A2 and the produced metabolites were analyzed using an HPLC system. With recombinant human FMO1, FMO2 and FMO5, TB and TP, but no PX were produced. TB was produced at 0.023, 0.021 and 0.018 pmol/min/pmol FMO and TP at 0.011, 0.020, and 0.017 pmol/min/pmol FMO, respectively by FMO1, FMO2 and FMO5. With FMO3, the major form in human liver, 2.12 pmol TB/min/pmol FMO (nearly 100 fold faster than other FMO isozymes) and 23.69 pmol PX/min/pmol FMO were produced. With recombinant human CYP1A2 expressed together with P-450 reductase in E. coli, 11.22 pmol TB, 65.64 pmol PX and 1.3 pmol TP were produced per min per pmol of CYP. In the FMO catalyzed CA oxidation, formaldehyde was generated along with the formation of N-demethylated metabolites of CA. This suggested that FMOs could produce N-demethylated CA metabolites instead of the expected N-oxide metabolites. In conclusion, both TB and PX are produced from CA by FMO3 and CYP1A2 and supported the observation made in our previous studies. (Supported by an intramural grant from Inha University for 1998).

1067 IDENTIFICATION OF A HUMAN LUNG FMO2 VARIANT.

M-F Yueh, R N Hines[1], S K Krueger and D E Williams. *Dept. of Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR and [1]Dept. of Pharmacology, Wayne State University School of Medicine, Detroit, MI.*

Flavin-containing monooxygenase (FMO) is a phase I biotransformation enzyme which catalyzes oxygenation of N, S and P soft nucleophiles. FMO2 is a lung-specific isoform in rabbit and monkey, in which FMO2 levels are high compared with other monooxygenases and might play a significant role in xenobiotic metabolism. FMO2 has not been well characterized in humans. Human FMO2 cDNA has a premature stop codon and produces a truncated protein. In this study, we examined FMO2 DNA and protein from human lung specimens. Among samples we examined, results of genotyping by PCR showed that some individuals were heterozygous for full-length FMO and expressed a full size protein observed by western blotting; other samples were homozygous for the truncated gene and no measurable protein was detected by western blotting. Genotyping results to date indicate that the expression of the full-length FMO2 variant is seen only in African Americans. Enzyme activity measured by N,N-dimethylaniline (DMA) assay revealed that none of the samples had detectable activity. mRNA levels were quantitated by both RT-PCR and Northern blotting. Compared with monkey, various amounts of FMO2 transcript are expressed in human lungs (0% to 100% of monkey) which indicates that protein levels might be determined by postranscriptional stability. The results from heterologous expression of monkey FMO2 indicated that full-length FMO2 N-oxygenates both DMA and nicotine, whereas, no activity was detectable with the truncated protein. In summary, human FMO2 might not play the same role in drug metabolism as it does in monkey or rabbit. (Supported by NIH grant HL38650.)

1068 DIETARY INDOLE-3-CARBINOL (I3C) AND 3',3-DIINDOLYLMETHANE (DIM) INHIBIT FMO-MEDIATED TAMOXIFEN (TAM) N-OXIDATION IN THE RAT.

S Katchamart, D M Stresser[1], S S Dehal[1], D Kupfer[1] and D E Williams. *Dept. of Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR and [1]Dept. of Pharmacology and Molecular Toxicology, University of Massachusetts Medical Center, Worcester, MA.*

Our laboratory has previously shown that indole-3-carbinol administered in the diet to male Fischer 344 rats has the very unusual property of inducing a number of cytochromes P450 (CYPs), especially CYP1A1, while markedly inhibiting the levels of FMO1 protein and its catalytic activity [Larsen-Su, S. and Williams, D.E., *Drug Metabol. Disp.* 24:927-931, 1996]. We hypothesized that liver microsomes from rats fed I3C or one of its major acid condensation products formed *in vivo*, DIM, should exhibit a marked shift in the metabolic profile of drugs which are substrates for both monooxygenase systems. Male rats were fed AIN76A powdered diets containing 0, 1000 or 2500 ppm I3C or DIM for 4 weeks. Liver microsomal FMO1 levels were determined by western blotting and CYP (N-demethylation and 4-hydroxylation)- and FMO (N-oxide)-mediated TAM metabolism by TLC. Both I3C and DIM reduced FMO1 protein levels (8% (I3C) and 84% (DIM) at 1000 ppm, and 90% (I3C) and 97% (DIM) at 2500 ppm. In liver microsomes from rats fed I3C, the ratio of CYP to FMO metabolites of TAM increased from 1.3 in controls to 1.9 and 4.1 in the 1000 and 2500 ppm groups, respectively, mostly due to a reduction in N-oxidation. Likewise, DIM diets increased the ratio to 3.0 and 3.1 at levels of 1000 ppm and 2500 ppm, respectively. These results agree with a previous preliminary study which also found that covalent binding of ^{14}C-TAM to liver microsomal protein was increased about 2-fold in rats fed I3C. The observation that we could not completely inhibit TAM N-oxidation (maximum of 55-65% at doses with decreased FMO by >95%) suggests a role for CYP in this reaction. (Supported by PHS grants HL38650 (DEW) and ES00834 (DK) from NIH.)

1069 DEVELOPMENTAL AND BIOCHEMICAL CHARACTERIZATION OF HEPATIC AND SERUM A-ESTERASES IN THE RAT.

T A Couch[1], H W Chambers[2], and J E Chambers[1]. [1]*Ctr for Env Hlth Sci, Coll of Vet Med, and* [2]*Dept of Entomology, Miss State Univ, Miss State, MS, USA.*

Juveniles are more susceptible than are adults to the acute toxicity of organophosphorus (OP) insecticides. Juvenile detoxication capabilities are significantly lower than those of adults. The development of liver and serum A-esterase (AEST) isozymes was studied in male and female rats at postnatal days (PND) 3, 12, 21, 33, and 80 by direct (production of 3,5,6-trichloro-2-pyridinol) and indirect (inhibition of exogenous cholinesterase by low concentrations of non-hydrolyzed substrate) quantitation. All activities increased substantially with age in both tissues. Male hepatic microsomal activity measured directly had comparable activities at PND33 and 80, while activity measured indirectly was different at each age. Female hepatic activity (direct) declined at PND80, whereas activity measured indirectly was similar at PND33 and 80. Sex differences were found at all ages except PND21 (male>female at PND12, 33, and 80) (direct), and at PND21, 33, and 80 (female>male at PND21 and 33) (indirect). Male serum activity measured

directly had similar activities at PND33 and 80, while activity measured indirectly was similar at PND21 and 33. Female serum activity had its highest activity at PND80 (direct), and was different at each age (indirect). Sex differences were apparent only at PND12 and 80 (male>female at PND12, reversed at PND80) (direct), and at PND33 and 80 (female>male activity) (indirect). These pattern differences may reflect differences in the rates of development of AEST isozymes. To further characterize the biochemical role of AEST in age-related differences in OP toxicity, liver AEST were purified through the application of detergent solubilized microsomes to anion exchange and gel filtration chromatography columns. Native and SDS gel electrophoresis were used to analyze AEST activity in the native and denatured states, respectively. By observing the development of AEST isozymes and determining their role in the detoxication of OP insecticides, the reasons for age differences in OP toxicity may be further understood. (Supported by NIH RO1 ES04394 and F31 ES05752.)

1070 PON1-KNOCKOUT MICE ARE HIGHLY SENSITIVE TO CHLORPYRIFOS-OXON AND DIAZOXON TOXICITY.

W F Li[1], L G Costa[1], D M Shih[2], A J Lusis[2], and C E Furlong[3]. *Departments of [1]Environmental Health, [3]Medicine and Genetics, University of Washington, Seattle, WA; [2]Departments of Medicine, Microbiology and Molecular Genetics, University of California at Los Angeles, Los Angeles, CA.*

Paraoxonase (PON1) is an esterase that can hydrolyze the toxic metabolites of several organophosphate (OP) insecticides, such as parathion, chlorpyrifos and diazinon. Increasing PON1 levels by injection of purified enzyme protects animals from OP poisoning. In the present study, we used PON1-knockout (*PON1*$^{-/-}$) mice to further examine the *in vivo* function of PON1 in detoxifying OP insecticides. *PON1*$^{-/-}$ mice were generated by gene targeting and had no detectable paraoxonase activity in serum and liver. Mice were challenged with chlorpyrifos (CPS), chlorpyrifos-oxon (CPO), diazinon (DZS) and diazoxon (DZO) by dermal exposure. Compared to wild-type mice (*PON1*$^{+/+}$), *PON1*$^{-/-}$ mice were extremely sensitive to CPO. At the lowest dose (1.5 mg/kg), CPO did not affect AChE activity in *PON1*$^{+/+}$ mice but reduced it by 80% and 74% in brain and diaphragm, respectively, in *PON1*$^{-/-}$ mice. *PON1*$^{-/-}$ mice that received 6 mg/kg of CPO died within 2 hours, while *PON1*$^{+/+}$ mice that received the same dose of CPO survived without any symptoms of OP poisoning. *PON1*$^{-/-}$ mice also showed a much higher sensitivity to another PON1 substrate, DZO. The lowest dose of DZO (1 mg/kg) resulted in 80% inhibition of brain AChE in *PON1*$^{-/-}$ mice but had no effect on *PON1*$^{+/+}$ mice. The higher doses (2 and 4 mg/kg) were lethal to *PON1*$^{-/-}$ mice but caused no inhibition of brain AChE in *PON1*$^{+/+}$ mice. Hemizygous (*PON1*$^{+/-}$) mice showed an intermediate sensitivity to DZO. Furthermore, when animals were exposed to the parent compounds, CPS and DZS, *PON1*$^{-/-}$ mice also showed a higher sensitivity to both chemicals compared with *PON1*$^{+/+}$ mice. However, there was no observable difference in DZS toxicity between *PON1*$^{+/-}$ and *PON1*$^{-/+}$ mice. These results clearly demonstrate the significant role of PON1 in OP detoxication. (Supp. in part by NIEHS Grant ES-07033, ES-09601, and NIH Grant PO1HL30568.)

1071 EFFECTS OF TISSUE HOMOGENATE CONCENTRATION ON ORGANOPHOSPHATE OXON INHIBITION AND IC50 VALUES OF HEPATIC ALIESTERASES AND BRAIN ACETYLCHOLINESTERASE IN ADULT RATS.

C G Durunna and J E Chambers. *Center for Environmental Health Sciences, College of Veterinary Medicine, Mississippi State University, Mississippi State, MS, USA.*

The organophosphate (OP) compounds [chlorpyrifos-oxon (C=O), paraoxon (P=O) and methyl paraoxon (MP=O)] are the active oxygen analogs of the parent insecticides, chlorpyrifos, parathion and methyl parathion, respectively. Aliesterases (Aliest) [carboxylesterase (EC. 3.1.1.1)] and acetylcholinesterase (AChE) (EC. 3.1.1.7) are B-esterases which are inhibited by OPs. Each enzyme can be persistently and stoichiometrically phosphorylated by these oxons. Inhibition of Aliest (non-target enzyme) will reduce the amount of oxon that reaches the target, AChE. Dilute tissue homogenates are usually used to conduct enzyme studies to investigate Aliest detoxication pathways and the potencies of inhibitors for AChE, and the results are used to predict activities in intact tissues. It is not known if these predictions could be affected by tissue homogenate concentration. This study was designed to determine if OP oxon inhibition and IC50 values of liver Aliest could be affected by tissue homogenate concentration. Also studied were the *in vitro* sensitivities of AChE to inhibition by these oxons. Aliest and AChE activities increased as the tissue homogenate concentration increased for each sex. The IC50 values remained constant over a range of lower tissue concentrations, but increased at higher concentrations. There were no significant differences in percent inhibition and in the IC50 values between male and female rats. There were no significant differences in IC50 values obtained at various dilutions of purified Aliest (porcine liver) or AChE (electric eel), suggesting that tissue components, other than the enzymes, may be responsible for interacting with the oxons, effectively lowering their concentrations and therefore reducing the IC50 values *in vitro* at higher tissue concentrations. These results indicate that tissue homogenate concentration is a very important factor to be considered when conducting *in vitro* Aliest or AChE activity, inhibition and IC50 assays.

1072 KINETICS AND INDIVIDUAL VARIATION IN GSH CONJUGATION OF TRICHLOROETHYLENE (TRI) IN HUMAN LIVER AND KIDNEY.

L H Lash[1], D A Putt[1], J C Parker[2], and J C Lipscomb[3]. *[1]Dept. Pharmacology, Wayne State Univ. Sch. Med., Detroit, MI, USA; [2]NCEA, U.S. EPA, Washington, DC, USA; [3]U.S. Air Force, Air Force Research Laboratory, Toxicology Branch, Wright-Patterson Air Force Base, OH, USA.*

Isolated human hepatocytes exhibited time-, Tri concentration-, and cell concentration-dependent formation of S-(1,2-dichlorovinyl)glutathione (DCVG) in incubations in sealed flasks with 25 to 10,000 ppm Tri in the headspace (= 0.011 to 4.4 mM in hepatocytes). Maximal formation of DCVG (22.5 ± 8.3 nmol/ 20 min per 106 cells) occurred with 500 ppm Tri. Time-, protein concentration- and both Tri and GSH concentration-dependent formation of DCVG were observed in human liver and kidney subcellular fractions. Two kinetically distinct systems were observed in both cytosol and microsomes from pooled liver samples whereas only one system was observed in subcellular fractions from pooled kidney samples: Liver cytosol exhibited K_m values (μM Tri) of 333 and 22.7 and V_{max} values (nmol DCVG formed/min per mg protein) of 8.77 and 4.27; liver microsomes exhibited K_m values of 250 and 29.4 and V_{max} values of 3. 10 and 1.42; kidney cytosol and microsomes exhibited K_m values of 26.3 and 167, respectively, and V_{max} values of 0.81 and 6.29, respectively. DCVG formation in liver samples from 20 individual donors exhibited 8.5-fold variation in microsomes but only 3.4-fold variation in cytosol. In co-incubations of pooled liver cytosol and microsomes, addition of an NADPH-regenerating system produced marked inhibition of DCVG formation but addition of GSH had no effect on cytochrome P-450-catalyzed formation of chloral hydrate. These results indicate that both human kidney and liver have significant capacity to catalyze DCVG formation, indicating that the initial step of the GSH-dependent pathway is not limiting in the formation of nephrotoxic and nephrocarcinogenic metabolites.

1073 GLUTATHIONE-DEPENDENT METABOLISM OF 3-(7*H*-PURIN-6-YLTHIO) ACRYLIC ACID (PTA) TO THE CHEMOTHERAPEUTIC AGENT 6-MERCAPTOPURINE (6-MP).

S Gunnarsdottir and A A Elfarra. *Department of Comparative Biosciences and Environmental Toxicology Center, University of Wisconsin, Madison, WI, USA.*

The elevated levels of glutathione (GSH) and glutathione-S-transferases (GST) observed in many multi-drug resistant tumor cells, suggest that anticancer agents might be selectively targeted to these cells upon metabolism of carefully designed GST substrates (prodrugs). The reported antimicrobial activity of PTA, a 6-MP derivative, led us to hypothesize that the biological activity of PTA was due to its GST mediated metabolism to 6-MP, making it a potential prodrug targeting drug-resistant cells. Thus, we examined the *in vivo* and *in vitro* metabolism of PTA in rats. HPLC analyses of urine of rats treated i.p. with PTA (100 mg/kg) showed that 6-MP was formed *in vivo* and excreted in urine (mostly within 6 h) without toxicity as indicated by liver and kidney function tests. *In vitro* assays revealed that two metabolites of PTA, 6-MP and the major metabolite, *S*-(6-purinyl) glutathione (PG), were formed in a time- and GSH-dependent manner. Formation of 6-MP occurred non-enzymatically in the presence of GSH, but was enhanced 2- and 7- fold by the addition of liver and kidney homogenates, respectively. Purified rat liver GSTs also mediated the formation of 6-MP from PTA. However, PG formation was not enhanced by the addition of liver homogenate or purified GSTs compared to buffer incubations, suggesting two different pathways by which PG and 6-MP were formed in liver. No time-dependent accumulation of PG was observed in kidney homogenate incubations. This result was due to further metabolism of PG by γ-glutamyltranspeptidase, dipeptidase and β-

lyase, as indicated by the use of the inhibitors acivicin and aminooxyacetic acid. Collectively, the results of this study show that PTA is metabolized to 6-MP both *in vivo* and *in vitro*. Therefore, PTA may have antitumor properties against tumor cells having high levels of GSH and GST.

1074 THE COUPLED REDUCTION OF *p*-NITROSOPHENOL WITH ETHANOL OXIDATION CATALYZED BY HORSE LIVER ALCOHOL DEHYDROGENASE: TOXICOLOGICAL IMPLICATIONS OF THE RECYCLING OF NAD+/NADH.

Z Maskos and G W Winston. *Department of Toxicology, North Carolina State University, Raleigh, NC, USA.*

The kinetics of the coupled reaction of C-nitrosoarene reduction and ethanol oxidation catalyzed by horse liver alcohol dehydrogenase (ADH), in which the ADH-bound coenzyme undergoes oxidation/reduction cycling, has been studied and compared with the kinetics of the corresponding single reactions. The experiments were performed using steady-state kinetic techniques and p-nitrosophenol (pNSP) as an aldehyde-substrate analogue. Analysis of the kinetic data obtained with either unlabeled or deuterium-labeled ethyl alcohol suggests that the coupled reaction can be described by an apparent ping-pong bi bi mechanism with competitive substrate (pNSP) inhibition. This is evidenced by the double-reciprocal plots of the bisubstrate reaction, which generate a series of hyperbolic concave up-lines and a primary deuterium isotope effect, which is observed for only one of the two half-reactions. The pH-dependence of the kinetic constants, the primary deuterium isotope effect and the products distribution indicate that the mechanism of pNSP reduction in the coupled reaction system differs from that observed for the individual single reaction. The reduction of pNSP in the direct single reaction, which appears to proceed in two consecutive steps via two alternative mechanism results predominantly in formation, of pAP. When pNSP is coupled to ethanol oxidation the primary product of reduction is benzoquinoneimine (BQI), which is not reduced to pAP, but subsequently is converted to an arylnitrenium ion. The arylnitrenium ion can undergo nonenzymatic hydrolysis to yield 1,4-benzoquinone, also a strong electrophile. (Supported by NIAAA grant AA06758 to GWW.)

1075 IN VIVO MICRODIALYSIS IN A COMPARATIVE STUDY OF HEPATIC METABOLISM OF PHENOL IN THREE FISH SPECIES.

L E Solem[1], R C Kolanczyk, P K Schmieder and J M McKim. *US EPA (NRC), NHEERL, Mid-Continent Ecology Division, Duluth, MN, USA.*

Physiological-based toxicokinetic (PB-TK) models are valuable tools used to describe the relationship between xenobiotic toxicity at the cellular and organ level to that observed in the whole animal. The ability to obtain metabolic rate constants in several species for chemicals that undergo biotransformation is important to the development of accurate PB-TK models. Numerous *in vitro* techniques have been employed to mimic the *in vivo* system however, data from direct comparisons is limited. In this study, we continue our investigation of *in vivo* phase I hepatic metabolism of phenol using microdialysis as a tool for assessing Michaels-Menton kinetics in various fish species to provide 1) validation of rate and capacity inputs for PB-TK models, and 2) a comparison of rate constants for different species. A microdiaylsis probe was surgically implanted into the liver of adult rainbow, lake and brook trout which were subsequently confined to respirometer-metabolism chambers. Phenol (1-300mM) was delivered directly to the liver in Cortland's saline at a flow rate of 1 µl/min which consistently resulted in 80-85% delivery of phenol. Hydroquinone (HQ) and catechol (CA) production in all three species increased with increasing phenol dose. Maximum production was observed between 200 and 260mM delivered phenol. Relative K_m and V_{max} were comparable between the three species for both HQ and CA. The data obtained through microdialysis may be useful in resolving uncertainties which are central to fish PB-TK modeling namely, the role of metabolism in chemical disposition predicted by the models.

1076 COMPARISON OF THE METABOLISM OF [^{14}C]BENZENE AND [^{14}C]PHENOL IN THE ISOLATED PERFUSED MOUSE LIVER.

M J Hoffmann[1], S Ji[1], C C Hedli[2] and R Snyder[1]. [1]*Joint Graduate Program in Toxicology, EOHSI, Rutgers University and UMDNJ/RWJMS, Piscataway, NJ, USA;* [2]*Schering-Plough Research Institute, Kenilworth, NJ, USA.*

Hepatic metabolism of benzene (BZ) is a necessary first step before BZ can exert its hematotoxic effects (Sammett et al., J. Toxicol. Env. Hlth. 5:785,1979). The major metabolites of BZ both *in vivo* and *in vitro* are phenol (P) and its conjugates (Snyder and Hedli, Env. Hlth. Perspect. 104(Suppl. 6), 1165,1996). Administration of BZ, but not P, to mice results in bone marrow depression (Snyder et al., Env. Hlth. Perspect. 100:293,1993). It was, therefore, of interest to determine whether hepatic BZ metabolism produced potentially hematotoxic metabolites which were not produced during P metabolism. Mouse livers were perfused with a solution of either [^{14}C]BZ or [^{14}C]P in the orthograde (portal vein to central vein) direction or retrograde (central vein to hepatic vein) direction to compare the metabolites formed from each substrate and to investigate the role of hepatic zonation of metabolic enzymes involved in BZ and P hydroxylation and subsequent conjugation. Perfusate samples were collected, metabolites were separated and identified by HPLC, and quantified by the levels of radioactivity found in each peak. Regardless of the substrate or the direction of perfusion the major compounds released from the liver were P, phenylgucuronide, phenylsulfate, hydroquinone (HQ), and HQ glucuronide. Comparison of the orthograde perfusion studies of BZ and P revealed that a larger percentage of the radioactivity released from the liver was identified as the unconjugated, hematotoxic metabolite HQ after BZ perfusion than after P perfusion. A comparison of the results of perfusing BZ or P in orthograde versus retrograde direction showed that the enzymes involved in hydroxylation of BZ or P are generally closer to the central vein than those involved in conjugation of the hydroxylated metabolites. In addition, the amount of radioactivity covalently bound to liver macromolecules was measured after each perfusion and determined to be proportional to the amount of HQ and HQG detected in the perfusate samples.

1077 IN VITRO SPECIES COMPARISON OF THE METABOLISM OF THE ANTITUMOR AGENT NSC 652287.

M I Rivera[1], S F Stinson[1], K Dillah[1], E A Sausville[1], M D Mitchell[2], and J C Davila[2]. [1]*National Cancer Institute-Frederick Cancer Research and Development Center, Frederick, MD;* [2]*Monsanto Life Sciences, St. Louis, MO.*

NSC 652287 is one of a family of thiophene containing compounds that have shown a highly selective pattern of differential growth inhibition and cytotoxic activity in the National Cancer Institute Anticancer Drug Screen. The compound has notable activity against renal carcinoma cell lines with GI50's of 10 - 30 nM. This is of particular interest since there are few therapeutic options with reliable activity against metastatic renal cell carcinomas. However, the compound has shown pulmonary toxicity in dogs and monkeys, renal damage in rats, whereas mice are a relatively resistant species. The target organ toxicity may be a consequence of differential metabolism among species. We have compared the metabolism of NSC 652287 in liver S9 fractions from dogs, monkeys, rats, and mice. The rate of metabolism was found to be faster in the monkey than in the other species tested. HPLC analysis showed that all species produced two metabolites with elution times of 5 and 9.5 min. Dog S9 fractions generated two additional metabolites with elution times of 3 and 7 min. In addition, NSC 652287 was found to be cytotoxic to primary human hepatocytes at concentrations of 10 mM (as indicated by MTT reduction and LDH assay), and a metabolite eluting at 5 min was generated. Metabolism by recombinant microsomes from human lymphoblastoid cells expresssing a specific CYP450, identified the cytochrome P450 1A2 as the major isozyme metabolizing NSC 652287. Current studies are in progress to further determine the potential role of CYP450 in the toxicity of NSC 652287 and to compare the metabolism of NSC 652287 in pulmonary and renal tissues from different species.

1078 THE MUTAGENIC DNA REPLICATION MACHINERY CONTRIBUTES TO THE GENOMIC INSTABILITY OF CANCER CELLS.

J W Sekowski, S Han, L H Malkas, A-L Lu, and R J Hickey. *University of Maryland School of Medicine, Baltimore, MD, USA.* Sponsor: K Squibb.

The development of the malignant cellular phenotype is accompanied by an accumulation of multiple genetic alterations. These alterations are due in part to a reduction in the fidelity of the DNA synthetic process, and potentially a specific reduction in the efficiency and fidelity with which replication-associated DNA mismatch repair proteins function. Using a novel forward mutagenesis assay we have determined that the DNA replication process carried out by the intact cellular DNA replication apparatus, (i.e., the DNA synthesome), derived from malignant breast cells is significantly error-prone when compared to that carried out by the non-malignant breast cell synthesome. In order to evaluate whether mismatch repair proteins contribute significantly to the observed mutation frequency of the DNA synthe-

some of cancer cells, we performed co-localization and co-immunoprecipitation experiments followed by Western blotting analyses to determine whether the mismatch repair proteins are physically associated with the DNA synthesome. We present here, the for the first time, evidence indicating that most of the known DNA mismatch repair proteins are components of the DNA synthesome. Furthermore, our results demonstrate that the *in vitro* DNA synthesome model system can be used to examine the contributions made by both the DNA replication and the mismatch repair proteins to the processes which give rise to the observed genomic instability exhibited by many types of malignancies. (This work was supported in part by an individual U.S. Army D.O.D. Breast Cancer Research Program pre-doctoral fellowship and an NIEHS post-doctoral award to JWS, NIH awards (#CA57350 and CA73060) to LHM, and an NIH award (#CA74904) to RJH.)

1079 DELAYED GENOMIC INSTABILITY INDUCED BY GAMMA IRRADIATION IN YEAST, MAMMALIAN CELLS AND IN VIVO IN THE MOUSE.

R J Brennan, R Rugo, B Secretan and R H Schiestl. *Dept. Cancer Cell Biology, Harvard School of Public Health, Boston, MA.*

Multiple genetic changes are required for the development of a malignant tumor cell and many environmentally-induced cancers show a delayed onset of more than 20 years following exposure. In fact, the frequency of genetic changes in cancer cells is higher than can be explained by random mutation. It was thus proposed that a sub-population of cells develop a mutator phenotype. A common characteristic of cancer cells, widely thought to be a major contributor to the progressive, multistage development of malignant disease, is an unstable, "hypermutable" genome. Cultured mammalian cells which survive exposure to ionizing radiation and other DNA damaging agents often develop a persistent genomic instability reminiscent of that observed in tumor cells. These delayed effects cannot be explained by the carry-over of DNA damage, nor can they be due to mutations at specific loci. We have studied the development of similar phenotypes in the yeast Saccharomyces cerevisiae, in human cells and in vivo in mice. Following exposure to gamma radiation, alkylating agents and oxidative mutagens a high proportion of yeast colonies derived from surviving cells displayed elevated frequencies of genetic deletions up to 50 generations post-irradiation. Other phenotypes observed include elevated frequencies of forward mutation and a lowered plating efficiency. Irradiation of male mice also caused persistent effects on genetic deletions in the offspring after mating with unirradiated females. Irradiated mammalian cell cultures have shown persistent oxidative stress, changes in ploidy, and elevated p53 and p21 levels. Elucidating the mechanism by which these effects arise may shed light on the development of persistent genomic instability in human cancers.

1080 POLYCYCLIC AROMATIC HYDROCARBONS WITH BAY-LIKE REGIONS INHIBITED GAP JUNCTIONAL INTERCELLULAR COMMUNICATION AND INDUCED THE ACTIVATION OF MAPK.

B L Upham, A M Rummel, M R Wilson, and J E Trosko. *Michigan State University, Dept. of Pediatrics and Human Development, East Lansing, MI, USA.*

Many polycyclic aromatic hydrocarbons (PAHs) are known carcinogens. Considerable research has been devoted to predicting the genotoxic-tumor initiating potential of PAHs based on chemical structure. However, structure/function relationships to the nongenotoxic-epigenetic events of tumor promotion are sparse. PAHs containing a bay or bay-like region were shown to be potent inhibitors of gap junctional intercellular communication (GJIC), an epigenetic event involved in the release of an initiated cell from growth suppression. We tested the epigenetic toxicity of PAHs containing bay-like regions by comparing the effects of methylated vs. chlorinated isomers of anthracene on the temporal activation of mitogen activated protein kinase (MAPK) and the down-regulation of GJIC. Specifically, we used anthracene, 1-methylanthracene, 2-methylanthracene, 9-methylanthracene, 1-chloroanthracene, 2-chloroanthracene, 9-chloroanthracene and determined the effects of these compounds on GJIC and the activation of extracellular receptor kinase (ERK 1 and 2), a MAPK, in F344 rat liver epithelial cells. Results showed that bay or bay-like regions formed by either a chlorine or methyl group reversibly inhibited GJIC and activated MAPK, whereas the linear-planar isomers had no effect on GJIC or MAPK. MAPK activation occurred 10-20 min after the down-regulation of GJIC which indicates that MAPK is not involved in the initial regulation of GJIC. Conversely, inhibition of GJIC may somehow trigger activation of MAPK. This study revealed that structural determinants of PAHs affect epigenetic events involved in tumor promotion, namely, the reduction of GJIC followed by the activation of intracellular mitogenic events. 1081 CHARACTERIZATION OF SIGNAL CROSS-TALK BETWEEN THE PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR ALPHA AND SPHINGOMYELINASE PATHWAYS.

P J Lapinskas, C Swanson, M Smith, and J C Corton. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA.*

Kupffer cell activation and release of cytokines have been linked to cell proliferation and suppression of apoptosis induced by peroxisome proliferators (PP) in hepatocytes. Sphingolipids are second messengers for several cytokine receptors. We hypothesized that one or more sphingolipids could activate the peroxisome proliferator-activated receptor alpha (PPARα) and be responsible in part for PP-induced cell proliferation and inhibition of apoptosis. Sphingomyelinase (SMase) is the enzyme responsible for sphingolipid release from membranes. In transactivation assays, we tested the ability of SMase and several cell-permeable sphingolipid analogs to activate a PPAR-responsive luciferase reporter gene in HepG2 Cells. We also examined the ability of these sphingolipid analogs to activate β-oxidation and pro- and antiapoptotic protein expression and induce cell proliferation in mouse primary hepatocytes. SMase treatment resulted in a concentration-dependent activation of the PPAR-responsive luciferase reporter gene in the transactivation assay. Treatment of mouse primary hepatocytes with sphingosine resulted in induction of PP-responsive proteins involved in β-oxidation of fatty acids. The effects of both SMase and sphingosine treatments were additive to the effects of the potent PP Wy-14,643 in the transactivation assay and the induction of β-oxidation enzymes. This additivity suggests that both SMase and sphingosine treatments activate PPARα. However, none of the sphingolipid analogues activated PPARα in a transactivation assay, suggesting that sphingolipid effects on PPARα activation is indirect. Ceramide induced cell proliferation in primary mouse hepatocytes and suppressed proapoptotic proteins, whereas sphingosine induced proapoptotic proteins. Our results suggest sphingolipids may be key lipid mediators involved in PP-induced cell proliferation and suppression of apoptosis via activation of PPARα. Thus there appears to be cross-talk between cytokine and nuclear receptor signal transduction pathways that regulate hepatocyte growth.

1082 IMPACT OF PEROXISOME PROLIFERATORS ON LIVER PHOSPHOLIPID BIOSYNTHESIS.

M Adinehzadeh[1] and N V Reo[1,2]. [1]*Department of Biochem. & Mol. Biol.*, [2]*Department of Physics, Wright State University, Dayton, OH, USA.*
Sponsor: J M Frazier.

Peroxisome proliferators (PPs) are a structurally diverse class of commercial/industrial chemicals and therapeutic drugs that cause hepatocarcinogenesis in rodents. We are studying the effects of these compounds on liver metabolism using nuclear magnetic resonance (NMR) spectroscopy in an effort to understand the biochemical mechanism of action. Previous data have suggested that PPs influence the pathways for biosynthesis of liver phosphatidylcholine (PtdC). These metabolic pathways are important in processes of tumorigenesis. PtdC can be derived from choline (*de novo* pathway) or through methylation of phosphatidylethanolamine (PtdE methyltransferase pathway, PEMT). We examined the effects of various PPs on these pathways utilizing ^{13}C–NMR. Rats were treated with either perfluorooctanoic acid (PFOA), perfluorodecanoic acid (PFDA), di(2-ethylhexyl) phthalate (DEHP), Wy–14,643 (Wy), or vehicle solution. Wy and PFOA are strong tumor promoters, whereas DEHP is much weaker and PFDA is non-tumorigenic. At various times postreatment (specific for each PP) rats were infused (iv) with [1–^{13}C]choline + [2–^{13}C]ethanolamine for 1 h. Livers extracts were prepared and analyzed by NMR. Fluxes were derived for the *de novo* synthesis of PtdC (F1), *de novo* synthesis of PtdE (F2), and the synthesis of PtdC via PEMT (F3). For all groups, F3 was positively correlated with F2 ($n=50$, $r^2=0.83$). The percentage of PtdC derived via the *de novo* vs. PEMT pathways was greatest for Wy (95% vs. 5%) and DEHP (87% vs. 13%), and least for PFDA (39% vs. 61%) ($p<0.02$). These data indicate that Wy and DEHP activate *de novo* synthesis of PtdC and inhibit the PEMT pathway. The increase in PEMT–derived PtdC with PFDA treatment is due to a significant increase in the *de novo* synthesis of PtdE ($p<0.01$). Our data corroborate other studies suggesting that tumorigenesis requires *de novo* synthesis of PtdC, and that the activity of PEMT may regulate these processes.

1083 TISSUE SPECIFIC EFFECTS OF ACRYLAMIDE (AMD) ON DNA SYNTHESIS IN MALE RATS.

J K Kaster, M A Friedman, J Jiang, L M Kamendulis, and J E Klaunig. *Division of Toxicology, Department of Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

Chronic exposure of rats to AMD leads to the formation of tumors in the thyroid, adrenal medulla, and mesothelium of the testes in male rats through apparently nongenotoxic mechanisms. A number of potential mechanisms for nongenotoxic activity have been proposed including increased cell proliferation, induction of oxidative stress, blockage of gap junctional communication (GJIC). In addition, based on the tissue pattern of the tumor response, AMD may cause a disturbance in the hypothalamus-pituitary-endocrine organ axis, which may result in uncontrolled regulation of hormones that affect these organs. The present studies examined DNA synthesis, plasma hormone levels, GJIC, and oxidative stress in the target organs in male rats treated for 7 to 28 days with AMD (2 or 15 mg/kg/day; gavage). DNA synthesis was determined by immunochemical staining for both PCNA and BrdU. Increases in labeling index were observed in adrenal medulla and thyroid consistent with the observed occurrence of AMD-induced tumors. No changes in GJIC or oxidative damage (MDA and OH8dG) were seen in target tissues at the AMD doses examined. Analysis of plasma hormones showed no significant change in prolactin, testosterone, or TSH. A small decrease in LH and FSH was seen in the animals treated at the highest dose of AMD studied (15 mg/kg/day). Overall these results demonstrated that of the nongenotoxic mechanisms examined, AMD only produced a significant increase in cell proliferation in two of the target organs in which tumors were observed.

1084 A POTENTIAL MECHANISM FOR 2-BUTOXYETHANOL (2-BE) INDUCED MOUSE LIVER NEOPLASIA.

H Xue, L M Kamendulis and J E Klaunig. *Division of Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

Results from a recently reported NTP bioassay showed that 2-BE induced liver tumors in B6C3F1 mice but not in F344 rats. 2-BE exposure also resulted in an increase in hemolysis with an apparent iron loading in the liver. Iron accumulation has been linked to the induction of oxidative stress and liver neoplasia. Our hypothesis is that 2-BE induces cancer in the mouse liver through iron loading and subsequent oxidative stress selectively in the mouse liver. Previous studies showed that the mouse liver has a lower antioxidant capacity compared to the rat, potentially making the mouse liver more susceptible to oxidative damage. The present study was undertaken to determine if 2-BE, its major metabolite (BAA), or iron (Fe^{2+}) produced oxidative stress in mouse and rat hepatocytes. Oxidative stress endpoints examined were 8-hydroxydeoxyguonosine (OH8dG), malondialdehyde (MDA) and Vitamin E. Hydrogen peroxide (1 mM) treatment served as a positive control. 2-BE and BAA at sublethal concentrations, failed to induce oxidative stress in either rat or mouse hepatocytes. Treatment with Fe^{2+} resulted in a dose-dependent increase in OH8dG and MDA in hepatocytes from both species. Similarly, vitamin E levels decreased in a dose-dependent manner in hepatocytes from both species following Fe^{2+} treatment. The effects of Fe^{2+} in mouse hepatocytes were significantly greater than those seen in the rat. These results showed that treatment with Fe^{2+} and not 2-BE or BAA, induced oxidative stress in rodent hepatocytes and suggest that in vivo, the liver effects of 2-BE may be related to oxidative stress induced by iron overload.

1085 STRONG, TOXICITY ASSOCIATED, PROMOTION OF RAT URINARY BLADDER CARCINOGENESIS BY PHENETHYL AND BENZYL ISOTHIOCYANATES.

M Hirose[1], M Sano[2], K Ogawa[2], S Sugiura[2], K Toyoda[1], M Shibutani[1], and T Shirai[2]. [1]*Division of Pathology, National Institute of Health Sciences, Tokyo, Japan;* [2]*First Department of Pathology, Nagoya City University, Medical School, Nagoya, Japan.*

Modification effects of phenethyl isothiocyanate (PEITC) and benzyl isothiocyanate (BITC), which are components of cruciferous vegetables generally regarded as potent chemopreventive agents, were examined with regard to rat urinary bladder and liver carcinogenesis. Male F344 rats were given a single i.p. injection of diethylnitrosamine (DEN) and then treated with N-butyl-N-(4-hydroxybuthyl)nitrosamine (BBN) for 4 weeks. Starting 3 days after completion of this initiation, groups of 21 rats each were placed on diets containing PEITC or BITC at a dose of 0.1% each, or basal diet alone for 32 weeks. Further groups of 6 animals each received PEITC, BITC or basal diet alone without initiation. Histopathological examination revealed the incidences of transitional cell carcinoma to be significantly increased in the PEITC (100%) and BITC (100%) groups as compared with the basal diet group value (24%). In addition, bladder tumors were induced in PEITC and BITC groups without initiation. Although the incidences of liver tumors were not significantly altered, multiplicity of foci was increased in the PEITC group. Sequential observation of the bladder epithelium for up to 7 days in male and female rats fed 0.1% PEITC or BITC showed that the initial effect was toxicity as evidenced by degeneration, inflammation and erosion followed by marked papillomatosis. These changes were stronger in the BITC than the PEITC case and in males than in females. These results indicate that PEITC and BITC are strong bladder promoters and further suggest that they can act as bladder carcinogens. Toxicity and cell proliferation appear responsible for the induction of the lesions. Influence on the liver appears weak, if promotion present.

1086 EFFECTS OF DIMETHYLARSENIC ACID (DMA) ON URINARY PARAMETERS AND BLADDER EPITHELIUM IN FEMALE F344 RATS.

S M Cohen[1], L L Arnold[1], M K St. John[1], M Cano[1], M van Gemert[2], and M Eldan[3]. [1]*Dept. of Pathology/Microbiology, Univ. of Nebraska Medical Ctr., Omaha, NE, USA;* [2]*Charles, Conn & van Gemert, L.L.C., Charlotte Hall, MD, USA;* [3]*Luxembourg Industries (PAMOL) Ltd., Tel Aviv, Israel.*

DMA caused urothelial tumors in F344 rats when fed in a chronic long-term study; the female rat was more sensitive than the male rat. Dietary treatment with DMA was not tumorigenic in the mouse. Current evidence indicates that DMA is not genotoxic. We examined the effects of feeding DMA to female F344 rats for 10 weeks at levels of 0, 2, 10, 40, and 100 ppm on urinary parameters and on the urothelium. Reversibility of the effects was evaluated in a high dose recovery group (100 ppm DMA for 10 weeks followed by 0 ppm DMA for 10 weeks). Urine chemistries were similar in the control and treated groups except for a dose responsive increase in calcium levels despite an increase in urine dilution. Examination of the urine by scanning electron microscopy showed no abnormal urinary solids. Urothelial toxicity and regenerative hyperplasia of the bladder were present at the two highest doses by light and scanning electron microscopy with an increased bromodeoxyuridine labeling index. The urothelial effects were reversible when treatment was withdrawn.

1087 COMPARISON OF THE URINARY AND UROTHELIAL EFFECTS OF o-PHENYLPHENOL (OPP) AND SODIUM OPP (Na-OPP) FED TO MALE F344 RATS.

M K St. John, M Cano, T Anderson, L L Arnold, and S M Cohen. *Dept. of Pathology/Microbiology, Univ. of Nebraska Medical Ctr., Omaha, NE, USA.*

OPP and Na-OPP induce bladder tumors in rats, with Na-OPP significantly more potent than OPP. To evaluate the short term effects of OPP and Na-OPP in groups of 10 male F344 rats, the chemicals were fed in Purina diet at the equimolar doses of 1.25 and 2.0%, respectively, for 10 wks. Urinary pH was 6.6 and 7.4, respectively, compared to 6.8 for controls. No urinary precipitate or microcrystalluria was detected following OPP feeding, but calcium phosphate-containing precipitate was present after Na-OPP feeding. Urothelial hyperplasia was detected by light and scanning electron microscopy along with superficial urothelial necrosis; the changes were greatest following Na-OPP. The labeling index following an one hour pulse of bromodeoxyuridine was 2.31, 1.98 and 0.09 for OPP, Na-OPP and controls. These data show that OPP and Na-OPP produce toxicity and regenerative hyperplasia when fed to male rats. The effect with Na-OPP was generally greater compared to OPP and was associated with the appearance of urinary calcium phosphate-containing precipitate, similar to that seen with other sodium salts fed to male rats. (Supported in part by NCI grant CA32513.)

1088 NONADDITIVE DNA-DAMAGING EFFECTS OF GENOTOXINS IN MIXTURE: 1. MUTAGENICITY IN SALMONELLA.

B Said, M K Ross, A Hamade, R C Shank. *University of California at Irvine, Irvine, CA, USA.*

Most animal studies on genotoxins focus on exposures to single chemicals, however, humans are usually exposed to mixtures of genotoxins. Cancer and developmental toxicity risks of gentoxins in mixture are generally estimated by assuming additivity of the components. Two or more genotoxins acting

sequentially or simultaneously may present a greater or lesser risk than could be predicited assuming additivity. We studied the effect of one genotoxin on the binding of a second genotoxin to DNA in an in vitro system; binding of the two toxins was not additive (Said and Shank,1991,1995). In the study reported here the effect on one genotoxin on the mutagenicity of a second genotoxin was evaluated in the Salmonella assay for several pairs of compounds. Pretreatment of frameshift strain TA98 with UV-activated aflatoxin B1 (AFB1) (0.4 ug/plate) or synthetic AFB1-8,9-epoxide (0.17 ug/plate) enhanced the mutagenicity of N-acetoxy-acetylaminofluorene (N-Aco-AAF) 2-3 times above theoretical additive effects. Pretreatment of base-substitution strain TA100 with N-Aco-AAF (0.1 ug/plate) inhibited the mutagenicity of AFB1, N-methyl-N-nitrosourea (MNU) and benzo(a)pyrene by 3,10,and 1.5 times below theoretical additive effect; resp. When strain TA102 containing an excision repair system, was pretreated with N-Aco-AAF for 2 hr, inhibition of MNU mutagenicity was partially released. Dose-response relationships for these enhancing or inhibitory effects were demonstrated. These results show nonadditive effects for mixtures of genotoxins in a bacterial mutagenicity assay.

1089 THE EFFECTS OF IRON ON NUCLEAR CALCIUM AND DNA FRAGMENTATION IN ISOLATED RAT HEPATOCYTES.

L M Milchak and J D Bricker. *Duquesne University, Pittsburgh, PA, USA.*

Although it is well known that iron overdose can produce hepatotoxicity, the exact mechanism of cell death has yet to be determined. Free radical generation, lipid peroxidation and changes in cytosolic calcium concentrations, have been demonstrated in iron toxicity, but not definitively established as the underlying cause of cytotoxicity. This study examined the possibility that the mechanism of iron toxicity may involve disruptions in nuclear calcium regulation, which could result in DNA fragmentation. The study was performed using hepatocytes isolated from male Sprague-Dawley rats. Incubation of hepatocyte cultures with ferrous sulfate (0.5 – 10 μ M) for 18 hours produced dose-dependent decreases in cell viability, as measured by Lactate Dehydrogenase (LDH) release. These same concentrations of ferrous sulfate also produced dose-dependent increases in nuclear calcium concentrations, as measured by o-cresolphthalein complexation. Decreases in cell viability were found to correlate well with increases in nuclear calcium concentration, suggesting that a disruption in nuclear calcium regulation may be involved in, or at least an indicator of cytotoxicity. Ferrous sulfate concentrations (3-10 μ M) which were shown to significantly decrease cell viability and increase nuclear calcium, were also shown to cause DNA fragmentation in the hepatocytes as measured by agarose gel electrophoresis. These results suggest that iron-induced hepatotoxicity may be mediated by increases in nuclear calcium, perhaps through the activation of calcium-dependent endonucleases resulting in DNA fragmentation and ultimately cell death. Further research will examine the time course of cell damage, as well as possible protective mechanisms against iron toxicity.

1090 NONADDITIVE DNA-DAMAGING EFFECTS OF GENOTOXINS IN MIXTURE: 2. COVALENT BINDING TO DNA.

M K Ross, B Said and R C Shank. *University of California at Irvine, Irvine, CA, USA.*

Mutual interactions of pre-existing DNA adducts with a second genotoxin were examined at the level of genomic DNA (calf thymus DNA, ctDNA) and on a sequence-specific level (oligonucleotides). Pretreatment of ctDNA with N-acetoxy-acetylaminofluorene (N-Aco-AAF) (0-1.8% nucleotides modified) reduced levels of Gua-N7-aflatoxin B1 (AFB1) adducts formed after subsequent treatment with AFB1-8,9-epoxide (~2x reduction). No binding modulations following N-Aco-AAF treatment of ctDNA previously modified with AFB1-8,9-epoxide were observed. Oligodeoxynucleotides containing either Gua-C8-AAF or Gua-C8-aminofluorene adducts and a neighboring unadducted guanine (G) (target G), located 1,2 or 4 nucleotides from the adduct, were reacted, as single or double-stranded substrates, with dimethylsulfate (DMS) or AFB1-8,9-epoxide. A modified Maxam-Gilbert technique showed that the presence of the AAF adduct lowerved the extent to which AFB1-8,9-epoxide, but not DMS, reacted with the target G. Binding of AFB1-8,9-epoxide to the target G was attenuated(5-fold) when located immediately adjacent to the AAF, but not an aminofluorene adduct, in ds-DNA. Reaction with AFB1-8,9-epoxide increased when the target G was located 2 or 4 nucleotides from the AAF adduct. An optical titration technique was used to measure non-covalent binding of AFB1 and ethidium to DNA. An enhanced binding affinity of both compounds to DNA was observed in spite of the reduced covalent adduct yields suggesting that the ease by which AFB1-8,9-epoxide forms an intercalative intermediate within DNA does not dictate its overall reaction kinetics. The steady-state presence of specific adducts (e.g. Gua-AAF) in certain sequence contexts may mask favorable binding sites of selected genotoxins (e.g. AFB1-8,9-epoxide) thereby reducing productive adduct yields. Such a mechanism may account for non-additive mutagenic responses observed in Salmonella typhimurium.

1091 MOLECULAR DOSIMETRY OF N2,3-ETHENOGUANINE IN CONTROL AND VINYL CHLORIDE-EXPOSED RATS.

E J Morinello, A-J L Ham and J A Swenberg. *University of North Carolina, Chapel Hill, NC, USA.*

Vinyl chloride (VC) monomer is an important industrial chemical and a widespread environmental contaminant that is a known human and animal carcinogen. VC is metabolically converted to chloroethylene oxide, which alkylates DNA to form exocyclic base adducts, including the promutagenic N^2,3-ethenoguanine (N^2,3-εGua). Here we present the first report of a VC dose-response based on DNA adduct formation. 12 week-old male Sprague-Dawley rats were exposed to 0, 10, 100, or 1100 ppm VC for 1 or 4 wk (6 hr/d, 5 d/wk). Mixed liver cell DNA was digested to deoxynucleosides, and N^2,3-εdGuo was purified with immunoaffinity chromatography, hydrolyzed to N^2,3-εGua, and quantitated with gas chromatography-high resolution mass spectrometry. Endogenous N^2,3-εGua was measured at 0.08± 0.04 and 0.11± 0.05 per 10^6 unmodified dGuo in 1 and 4 wk controls, respectively. Exposure to 10, 100, and 1100 ppm VC for 1 wk increased N^2,3-εGua to 0.20± 0.05, 0.68± 0.09, and 1.25± 0.20 per 10^6 dGuo, respectively. After 4 wk exposure, the corresponding amounts were 0.53± 0.11, 2.28± 0.18, and 3.78± 0.55 N^2,3-εGua per 10^6 dGuo. A statistically significant, 3-fold accumulation of N^2,3-εGua between 1 and 4 wk was observed at all exposures. The dose-response relationship between VC exposure and N^2,3-εGua in the liver was supralinear, with a steep slope between 0 and 100 ppm and relatively little increase at 1100 ppm. This dose-response is consistent with tumor incidences observed in long term cancer bioassays. Relatively small (2.6- and 4.8-fold) increases in N^2,3-εGua over endogenous levels were observed at 10 ppm VC, an exposure only one order of magnitude greater than the occupational TLV. VC appears to be a good model chemical for reevaluation under the EPA Proposed Guidelines for Carcinogen Risk Assessment (1996), which encourages the incorporation of non-tumor data when sufficient evidence exists to support such an alternate approach. (This work was supported by NIH grants ES07126 and ES05948.)

1092 QUANTITATIVE ANALYSIS OF DNA ADDUCTS AND ABASIC SITES INDUCED BY PENTACHLOROPHENOL-DERIVED QUINONE AND HYDROQUINONE IN CALF-THYMUS DNA.

P H Lin, J Nakamura, and J A Swenberg. *Curriculum in Toxicology, Department of Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC, USA.*

Pentachlorophenol (PCP) has been shown to be carcinogenic in mice. The mechanism of PCP carcinogenesis is unknown, but may involve PCP-derived quinoid metabolites, i.e., tetrachlorohydroquinone (Cl_4HQ) and tetrachloro-1,4-benzoquinone (Cl_4-1,4-BQ), and their associated oxidative stress and/or direct DNA adducts. We hypothesized that PCP-derived quinone/hydroquinone are capable of inducing DNA adducts which rapidly form abasic (AP) sites. In this study, we investigated the differential induction of direct DNA adducts and AP sites in calf-thymus DNA treated with Cl_4-1,4-BQ and Cl_4HQ. DNA adducts derived from PCP quinone/hydroquinone were analyzed by ^{32}P-postlabeling after nuclease P1 enrichment and were quantified by relative adduct level. The number of AP sites was measured by a slot-blot technique. Three major and several minor adducts were detected in CT-DNA treated with a high dose of Cl_4-1,4-BQ (5 mM), with total adduct numbers of ~13 adducts per 10^6 total nucleotides. Parallel, treatment-related increases in the number of AP sites were detected with ~ 6 AP sites per 10^6 total nucleotides in the presence of metal ion. In contrast, we detected 250 AP sites per 10^6 nucleotides in CT-DNA treated with Cl_4HQ (0.3 mM). At a low dose of Cl_4HQ (1 μ M) we were able to detect a 3-fold increase in the number of AP sites over control. Formation of stable DNA adducts was also detected in Cl_4HQ (0.3 mM)-treated DNA at 1 adduct per 10^6 total nucleotides. Overall, these results suggest that PCP-derived quinone/hydroquinone were capable of inducing specific types of DNA damage and AP sites. The AP sites induced by PCP quinoids are likely to be the result of oxidative stress and represent a possible mechanism for clasto-

genicity and carcinogenicity of PCP. (This work was supported by the National Institute of Environmental Health Sciences through grant P42ES05948 and T32ES07126.)

1093 EKER RAT MODEL CHARACTERIZATION: THE RESPONSE TO GENOTOXIC CARCINOGENS FOLLOWING FOUR MONTHS OF DOSING.

A F Youssef[1], L Dill Morton[1], F L Fort[1], T Goldsworthy[2], and C W Walker[3]. [1]*TAP Holdings Inc.,Deerfield, IL;* [2]*ILS Research Laboratory Systems, Research Triangle Park, NC; and* [3]*UTMDACC, Science Park, Smithville, TX.*

The Eker rat carries a germline mutation in the Tsc-2 tumor suppressor gene which predisposes these rats to the development of renal cell carcinoma (RCC). This study was an initial effort to characterize the responses of the Eker rat to non-renal carcinogens. Two genotoxic rat liver carcinogens, 2,4-diaminotoluene (2,4-DAT) and 2-nitropropane (2-NP), were administered by oral gavage to male Long Evans rats (wild type or bearing the Eker mutation) for 4 months. Dosages were: 2,4-DAT, 6.5 mg/kg, 7 times per week; 2-NP, 89 mg/kg, 3 times per week. Vehicles were 0.01 M Hcl and 10% Emulphor, respectively. Renal proliferative lesions were counted in two microscopic sections of kidney (one longitudinal and one cross section) from each Eker rat. The incidence of tumors was determined histopathologically in all tissues in all animals. The incidence of renal hyperplastic tubules was increased in 2,4-DAT treated Eker rats compared to vehicle controls. There were increases in renal cell carcinomas in 2,4-DAT treated Eker rats and in the incidence of overall neoplasia in 2-NP treated Eker rats relative to vehicle controls. No increase in renal proliferative lesions or tumors were seen in wild-type rats which lacked the susceptibility mutation. CONCLUSIONS: 1) Eker rats have increased sensitivity to genotoxic carcinogens, and 2) carcinogen exposure increases tumor number and/or decreases tumor latency in this model. (Sponsored by TAP Holdings Inc.)

1094 BINUCLEATED OCTOPLOID HEPATOCYTES DISPLAY INCREASED SUSCEPTIBILITY TO DNA SYNTHESIS INDUCED BY NONGENOTOXIC CARCINOGENS.

S C Hasmall and R A Roberts. *Zeneca Central Toxicology Laboratory, Macclesfield, UK.* Sponsor I Kimber.

Induction of increased hepatic DNA synthesis by nongenotoxic chemicals such as the peroxisome proliferator, diethylhexylphthalate (DEHP) is frequently associated with subsequent hepatocarcinogenesis. However, 1,4-dichlorobenzene (DCB), a noncarcinogen in male rat liver, is a potent hepatomitogen that induces a similar profile of S-phase labelling index (LI) to that of DEHP. Since hepatic polyploidisation is a normal process, we examined the hypothesis that variations in the ploidy class in which DNA synthesis is induced may be indicative of hepatocarcinogenic potential. In a previous study, male Fischer 344 rats were dosed for 7 days with DCB or DEHP and the hepatocytes isolated for flow cytometry and immunocytochemical detection of bromodeoxyuridine (BrdU). DCB, unlike DEHP, reduced the proportion of tetraploid cells (4N plus 2× 2N) and increased the proportion of mononucleated octoploid cells (8N). Also, DEHP induced a higher LI in binucleated octoploid (2× 4N) hepatocytes than did DCB. These 7 day exposure data raised two questions: since the BrdU label could disseminate into other populations, what constituted the target populations for induction of DNA synthesis and, secondly, is the LI profile induced by DEHP common to other nongenotoxic hepatocarcinogens? To identify the target population for S-phase induction, in the present study we used a 1hr BrdU pulse label during the peak of S-phase (29-30hr). Again, DCB and DEHP increased LI in all hepatocyte sub-populations except the 2× 2N population. LI in the 2× 4N population was increased significantly by DEHP, (2.9±0.2% DEHP; 0.2±0.1% control) but not by DCB (1.0±0.2%). In addition, a second nongenotoxic hepatocarcinogen and peroxisome proliferator, methylclofenapate (MCP), induced a similar profile of S-phase to DEHP since the LI in the 2× 4N population was 3-fold the average hepatic LI. Thus, 2× 2N hepatocytes cells may represent a population where induction of S-phase poses a more substantial carcinogenic risk.

1095 THE PEROXISOME PROLIFERATOR RESPONSE ELEMENT (PPRE) UPSTREAM OF THE HUMAN ACYL COA GENE IS INACTIVE IN MOST INDIVIDUALS: SIGNIFICANCE FOR SPECIES DIFFERENCES IN RESPONSE TO PEROXISOME PROLIFERATORS.

N J Woodyatt, K Lambe, K Myers and R A Roberts. *Zeneca Central Toxicology Laboratory, Macclesfield, UK.* Sponsor: I Kimber.

Peroxisome proliferators (PP) cause rodent hepatocarcinogenesis but humans appear to be nonresponsive to the adverse effects of this class of nongenotoxic carcinogens such as hepatocyte growth perturbation, peroxisome proliferation and tumours. The peroxisome proliferator activated receptor alpha (PPARα) mediates the effects of PPs in rodents via a peroxisome proliferator response element (PPRE) upstream of PP responsive such as acyl coenzyme A oxidase (ACO) and CYP4A1. Surprisingly, when the human ACO promoter was cloned, it was found to be active and contained a consensus PPRE (3' TGACCA T TGACCT 3') at 1918 to 1906 base pairs (bp) upstream of the transcription start site. To confirm and extend these findings, we isolated a 2 Kb genomic clone of the 5' region of the human ACO gene. However, in transient transfection reporter gene assays using either Hepa1c1c7 or NIH3T3 cells, this promoter fragment was inactive unlike the rat ACO promoter reporter plasmid. The PPRE within our cloned fragment of the human ACO promoter differed at two positions (3' TGACAG T TGACCT 5') from the previously published active human ACO promoter. Having demonstrated that the PPRE we had cloned from one individual was inactive, we studied the frequency of occurrence of the inactive human PPRE in the human gene pool. Using a polymerase chain reaction (PCR) strategy, we isolated genomic DNA from 22 unrelated human individuals of mixed racial origin. In addition, we isolated genomic DNA from the human hepatoma cell line HepG2, since these cells are used to model the lack of human response to PPs *in vitro*. In each case, the PPRE contained the inactive sequence (3' TGACAG T TGACCT 5'). These data suggest that the human ACO gene promoter found in a representative human population is inactive, providing a molecular basis for lack of human response to the adverse effects of the PP class of nongenotoxic hepatocarcinogens.

1096 A STRATEGY FOR ASSOCIATING PEROXISOME PROLIFERATOR-INDUCED HEPATOCELLULAR CHANGES WITH PATTERNS OF GENE EXPRESSION.

A J Stauber, S P Anderson, L Q Fan, R Conolly, J Preston, and J C Corton. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA.*

Peroxisome proliferators are a class of structurally diverse hepatocarcinogens that are thought to induce liver tumors in rodents by promoting the growth of pre-existing initiated cells, however the mechanism of action is still largely unknown. High-density cDNA arrays can be used as a powerful tool to determine how xenobiotics perturb homeostasis. To further understand mechanism(s) of peroxisome proliferator action, we are developing a strategy for identifying characteristic patterns of gene expression and their association with specific tissue responses resulting from peroxisome proliferator treatment using high-density arrays. Preliminary experiments using the Atlas Mouse cDNA expression array (Clontech) show changes in gene expression of several cell cycle and apoptosis genes in mice treated with the peroxisome proliferator Wy14, 643. An array with peroxisome proliferator-responsive genes will also be used to help identify genes that are characteristic of treatment. Use of these different arrays will allow an association of specific gene expression patterns across dose and treatment with changes in specific endpoints related to both peroxisome proliferation and carcinogenesis (i.e. cell proliferation/apoptosis). Characterization of such changes will become a useful screening tool for not only identifying specific modes of action of chemicals or chemical classes but also providing insights into mechanism(s) of action of different classes of toxicologically and pharmacologically relevant compounds.

1097 SEXUAL DIMORPHISM IN HEXACHLOROBENZENE (HCB)-INDUCED MODULATION OF INTERCELLULAR COMMUNICATION IN THE LIVER.

M Charbonneau, R Abdalian, and D Cyr. *Human Health Research Center, INRS-Institut Armand-Frappier, Université du Québec, Pointe-Claire, Québec, Canada.*

HCB causes liver tumors in female rats whereas only a small percentage of males are responsive. We showed that the administration of 5 consecutive daily doses of HCB promoted, with greater efficiency in female than male rats, liver tumor formation induced by diethylnitrosamine (DEN) injected 95

days later. Reduction of intercellular communication has been postulated to play a role in the mode of action of epigenetic carcinogens such as HCB. Gap junctions are formed by integral proteins, termed connexins. This study aimed to assess the effects of HCB on liver connexins. Male and female rats (N= 6 per group) were given HCB (100 mg/kg, po in corn oil) for 5 consecutive days and sampled on day 50. Hepatic RNA was isolated and subjected to Northern blot analysis for three connexins (Cx26, Cx32 and Cx43). cDNA probes for each connexin were used and gel loading corrected with an 18S rRNA probe. Autoradiograms were quantified by densitometry. mRNA levels for Cx26 and Cx32 were significantly ($p<0.05$) lower in livers from HCB-treated female rats compared to controls, whereas Cx43 mRNA level was 1.5 times lower ($p>0.05$) in treated rats as compared to controls. For male rats no significant differences ($p>0.05$) were observed for any of the three connexins. Together these data suggest that HCB reduces gap junction formation in female rat liver. This female-specific response correlates with the sexual dimorphism for tumor formation, thereby suggesting that the mechanism for the HCB effect involves reduced intercellular communication.

1098 REVERSIBILITY OF PHENOBARBITAL AND DEHP-INDUCED INHIBITION OF GAP JUNCTION INTERCELLULAR COMMUNICATION (GJIC) AND INDUCTION OF DNA SYNTHESIS IN THE RAT.

D C Ackley[1], L M Kamendulis[1], J S Isenberg[1] A W Lington[2], G Pugh Jr[2], J H Smith[2], and J E Klaunig[1]. [1]*Division of Toxicology, Indiana University School of Medicine, Indianapolis, IN, USA;* [2]*Exxon Biomedical Sciences, Inc., East Millstone, NJ, USA.*

While the exact mechanism(s) by which nongenotoxic hepatocarcinogens function has not been completely defined, down regulation of GJIC and increased DNA synthesis appear to be important in the carcinogenesis process. In addition, many nongenotoxic carcinogens appear to function at the tumor promotion stage. A hallmark of tumor promotion is the reversibility of the tumor promoting effect following removal of the promoter. In this study, the reversibility of the effects of phenobarbital (PB) and di-2-ethylhexyl phthalate (DEHP), two rodent hepatic nongenotoxic carcinogens, on GJIC and DNA synthesis was examined. DEHP (20,000 ppm) and PB (500 ppm) were fed to groups of male F344 rats. DEHP produced an increase in DNA synthesis and decrease in GJIC after 2 weeks of treatment. Similar changes were observed with PB. Following removal of PB or DEHP and replacement with control NIH-07 diet, GJIC and DNA synthesis returned to control levels after 2 and 4 weeks. In DEHP treated rats, peroxisomal beta oxidation (PBOx) was significantly elevated (13-fold over control) after 2 weeks of treatment and PBOx returned to control levels after removal of DEHP. Liver analysis of DEHP and metabolites revealed measurable levels of monoester (MEHP) after treatment which were not detectable in liver after removal of DEHP from the diet. This study showed that the modulation of GJIC and DNA synthesis observed after exposure to nongenotoxic hepatic carcinogens is reversible and dependent upon continuous tumor promoter treatment.

1099 DOSE-RESPONSE AND TIME COURSE STUDIES OF DEHP ON HEPATIC PEROXISOMAL β -OXIDATION (PBOx), GAP JUNCTION INTERCELLULAR COMMUNICATION (GJIC) AND DNA SYNTHESIS IN THE RAT.

L M Kamendulis[1], J S Isenberg[1], A W Lington[2], G Pugh Jr[2], J H Smith[2], and J E Klaunig[1]. [1]*Division of Toxicology, Indiana University School of Medicine, Indianapolis, IN, USA;* [2]*Exxon Biomedical Sciences, Inc., East Millstone, NJ, USA.*

In nongenotoxic hepatic carcinogenesis induced by peroxisomal proliferating compounds, several important hepatic processes have been reported to be disrupted and may contribute to the mechanism of carcinogenesis. In the present study, the hepatic effects of DEHP (di-2-ethylhexyl phthalate) on PBOx, GJIC and DNA synthesis were examined in F344 rats following exposure to nontumorigenic (1000 ppm) and tumorigenic (6000, 12000, 20000 ppm) doses of DEHP. Also, DEHP and major metabolites were measured. In the dose-response study, DEHP was administered for 2 weeks at doses of 1000, 6000, 12000 and 20000 ppm. At tumorigenic doses (> 1000 ppm), a dose-dependent increase in the induction of PBOx and DNA synthesis was observed. In addition, inhibition of GJIC at doses above 1000 ppm was seen. Coupled with these cellular changes, analysis of DEHP and metabolites revealed that MEHP was increased in the rat liver in a dose-dependent manner. In the time-course study, effects of DEHP (6000 and 20000 ppm) were examined following 1, 2, 4, and 6 weeks of treatment and compared to the effects of 6000 ppm DEHP for 18 and 24 months. DEHP produced an increase in PBOx (4 to 6 fold) at 6000 ppm at all times and (9 to 20 fold) at 20000 ppm over the 6 weeks of exposure. Similarly, inhibition of GJIC ranged from 25-40% with all DEHP exposures. An increase in DNA synthesis was seen after 2 or 4 weeks (60000 and 20000 ppm DEHP respectively) which returned to control values by 6 weeks. Liver MEHP levels exhibited a dose and time dependent increase. Collectively, these data demonstrate that modulation of the endpoints noted above appear to correlate with the observed tumorigenicity of DEHP and may be predictive indicators for nongenotoxic carcinogenicity.

1100 SPECIES SPECIFICITY FOR HEPATIC EFFECTS OF DEHP ON GAP JUNCTION INTERCELLULAR COMMUNICATION (GJIC), DNA SYNTHESIS AND PEROXISOMAL BETA OXIDATION (PBOx).

R H McKee[1], A W Lington[1], L M Kamendulis[2], G Pugh Jr[1], J H Smith[1], and J E Klaunig[2]. [1]*Exxon Biomedical Sciences, Inc., East Millstone, NJ, USA;* [2]*Division of Toxicology, Indiana University School of Medicine, Indianapolis, IN, USA.*

DEHP (di-2-ethylhexyl phthalate) was examined for its effect on PBOx, DNA synthesis and GJIC in male F344 rats, B6C3F1 mice and SG hamsters to determine if modulation of these parameters correlated with the observed hepatic tumorigenicity of DEHP. DEHP was administered in the diet for 2 and 4 weeks, at tumorigenic and nontumorigenic doses. Tumorigenic doses were 6000, 12000, and 20000 ppm in rats and 6000 ppm in mice. Nontumorigenic doses were 1000 ppm in rats and 500 ppm in mice. Doses of 1000 and 6000 ppm were used in hamsters, which are refractory to DEHP-induced tumorigenicity. In the rat, treatment with 6000-20000 ppm DEHP produced an increase in hepatic DNA synthesis at 2 weeks whereas the 1000 ppm had no effect. In the mouse, increased DNA synthesis was observed at 6000 ppm. No change in DNA synthesis was observed in the hamster. DEHP effects on PBOx were similar, producing a dose dependent increase after both 2 and 4 weeks. In the mouse PBOx was increased whereas in the hamster, a slight increase (2-fold) was observed at the highest dose studied. GJIC was decreased after 2 and 4 weeks of treatment (25-50%) at the tumorigenic doses in the rat and mouse. GJIC was not inhibited in hamster liver at either dose or time studied. Analysis of DEHP and major metabolites in liver showed that the monoester metabolite (MEHP) was greater in mice than in rats or hamsters following DEHP exposure. Comparable levels of MEHP were observed in rats and hamsters. These data show that inhibition of GJIC and increased DNA synthesis in the liver correlated with the observed dose and species specific tumorigenicity of DEHP seen after chronic treatment. This lends additional support to a mechanistic role for blockage of GJIC and increased DNA synthesis in the hepatic carcinogenicity of peroxisome proliferators.

1101 THE HEPATIC EFFECTS OF DI-ISONONYL PHTHALATE (DINP) AND RELATED ANALOGS IN RATS AND MICE.

J H Smith[1], J S Isenberg[2], L M Kamendulis[2], G Pugh Jr[1], D C Ackley[2], A W Lington[1], J E Klaunig[2]. [1]*Exxon Biomedical Sciences, Inc., East Millstone, NJ, USA;* [2]*Division of Toxicology, Indiana University School of Medicine, Indianapolis, IN, USA.*

The short-term hepatic effects of DINP in rats and mice at tumorigenic and non-tumorigenic doses were evaluated for comparison with chronic studies and with data for other structurally similar dialkyl phthalate esters ranging from C7 to C11. Groups of male F344 rats were fed diets with DINP at concentrations of 0, 1000, or 12000 ppm and male B6C3F1 mice at 0, 500, or 6000 ppm DINP. After 2 or 4 weeks of treatment, changes in liver weight, replicative DNA synthesis, peroxisomal β -oxidation (PBOx) and inhibition of gap junction intercellular communication (GJIC) were examined. In addition, hepatic concentrations of the parent compound and major metabolites were determined. Relative to controls in both species, increased liver weight and PBOx at the high dose were consistent with peroxisomal proliferation. Hepatic GJIC was inhibited and DNA synthesis was increased at the high dose, which is also consistent with the tumorigenic response in rats and mice at these doses. These hepatic effects were not observed at the low doses. Similarly, no liver tumors were observed in rats and mice treated with low doses in chronic studies. The monoester metabolite (MINP) was detected in the liver at greater levels in mice than rats. This result is also consistent with the dose-response observations in rat and mouse chronic studies. Similar responses were observed for DEHP and other C7-C11 dialkyl phthalate esters. Collectively, these data indicate that in rats and mice, DINP and other C7-C11 phthalates exhibit a threshold for inducing cellular events which correlated with the tumorigenic response of these compounds in chronic feeding studies.

1102 ABSENCE OF LIVER EFFECTS IN CYNOMOLGUS MONKEYS TREATED WITH PEROXISOMAL PROLIFERATORS.

G Pugh Jr[1], J S Isenberg[2], L M Kamendulis[2], L J Clare[3], W R Brown[4], A W Lington[1], D C Ackley[2], J H Smith[1], and J E Klaunig[2]. [1]*Exxon Biomedical Sciences, Inc., East Millstone, NJ, USA;* [2]*Division of Toxicology, Indiana University School of Medicine, Indianapolis, IN, USA;* [3]*TPS, Mount Vernon, IN, USA;* [4]*Research Pathology Services, New Britain, PA, USA.*

To evaluate the human relevance of liver effects observed in rats and mice, high doses of peroxisome proliferators were given by gavage in 0.5% methyl cellulose (10 ml/kg) to groups of adult male monkeys (n=4) for 14 days. In comparison to vehicle control, di-isononyl phthalate (DINP, 500 mg/kg/d), di-2-ethylhexyl P (DEHP, 500 mg/kg/d), and clofibrate (C, 250 mg/kg/d) produced no statistically significant changes in body weight, organ weights, urinalysis, hematology, clinical chemistry, nor other signs of toxicity. In contrast, related studies show that lower daily doses of these chemicals produce changes in the livers of rats and mice within this time frame. C produced some emesis, small increases in serum triglyceride, decreased calcium, and decreased weights of testes/epididymides and thyroid/parathyroid. In the monkeys that were evaluated by H&E staining, no signs of inflammation or necrosis were observed in the liver, kidney or testes. Treatment with DINP, DEHP, and C produced no change in hepatic peroxisomal β -oxidation or replicative DNA synthesis. DINP, DEHP and C did not inhibit hepatic gap junction intercellular communication (GJIC) in fresh liver slices from treated monkeys using incision loading dye transfer and direct measurement of dye flow (Lucifer yellow). In monkeys, liver analyses indicate that phthalate parent and monoester metabolites were present at much lower levels than in rodents. This study indicates that the hepatic effects produced by high doses of phthalates in rats and mice do not occur in monkeys. These data, along with results from *in vitro* hepatocyte studies, indicate that rodents are not good animal models for predicting the hepatic effects of phthalates in primates, including humans.

1103 INTERACTION OF CO-PLANAR AND NON-PLANAR PCBS IN PROMOTION OF ALTERED HEPATIC FOCI.

C E Dean, Jr., S A Benjamin, L S Chubb, J D Tessari, and R S H Yang. *Center for Environmental Toxicology and Technology, Colorado State University, Fort Collins, CO, USA.*

Synergistic tumor promoting ability has been reported in mixtures of co-planar and non-planar PCBs. This study was designed to evaluate interactive liver cancer promoting effects of two environmentally relevant PCBs, the co-planar PCB 126 (3,4,5,3',5'-pentachlorobiphenyl); and non-planar PCB 153 (2,4,5,2',3',5'-hexachlorobiphenyl). Promotion of altered hepatic foci was evaluated with an 8 week medium term bioassay using rats treated with diethylnitrosamine as an initiator, followed by gavage treatment with PCBs in corn oil and partial hepatectomy. PCBs were administered individually and in combination three times per week by oral gavage; PCB 126 at 0.1-10μ g/kg body weight and PCB 153 at 10-10,000μ g/kg body weight. Treatment with PCB 126 or 153 alone resulted in a dose dependent increase in glutathione-S-transferase placental form (GST-P) positive preneoplastic foci compared with controls. Treatment with the binary PCB mixture resulted in less than additive GST-P positive focus formation. These findings differ from reported studies that demonstrated synergism for preneoplastic liver foci formation between these congeners under a different protocol. Transforming growth factor beta may play a role in altering hepatocellular proliferation and apoptosis rates after PCB exposures. Studies to evaluate this hypothesis are underway. (This work is supported by grants NIEHS 1KO8ES00314 and NIEHS Superfund Basic Research Program P42ES05949.)

1104 METOLACHLOR, A NONGENOTOXIC RAT HEPATOCARCINOGEN, INDUCES CYTOCHROME P450 2B1/2B2 AND ALTERS THYROID HOMEOSTASIS.

S R Dalton, R T Miller and S A Meyer. *Department of Toxicology and College of Veterinary Medicine, North Carolina State University, Raleigh, NC.*

Metolachlor [2-chloro-N-(2-ethyl-6-methylphenyl)-N-(2-methoxy-1-methylethyl) acetamide], the 2nd most popular corn herbicide in the U.S., is a significant contaminant of surface waters. Metolachlor is a weak rat hepatocarcinogen; however, it is nongenotoxic, which suggests a tumor promoter mode of action. Many liver tumor promoters have been shown to induce a panel of xenobiotic metabolizing enzymes, which include cytochrome P450s and Phase II conjugating enzymes. Increased UDP-glucuronyl transferase, a Phase II enzyme, can have an adverse effect on thyroid homeostasis. Phenobarbital, the prototypical rat liver tumor promoter, induces several cytochrome P450s in the rat, particularly CYP2B1/2B2, and decreases serum thyroid hormone levels through an extrathyroidal mechanism. These two parameters were investigated in rats treated with metolachlor. Liver microsomal proteins from male Sprague-Dawley rats treated with a nonhepatotoxic dose of metolachlor (150 mg/kg/day, ip; 1, 4, 9 & 28 days) were probed by immunoblotting with anti-CYP2B1/2B2. We observed a strong induction of CYP2B1/2B2 with metolachlor treatment at all time points. A modest decrease in serum thyroxine was observed at 9 days, with a return to control levels at 28 days. Further, histological examination of H&E and PCNA stained thyroid gland revealed mild hyperplasia and hypertrophy in 9-day metolachlor-treated rats. These data support a phenobarbital-like mode of action for metolachlor hepatocarcinogenicity and further suggest common alterations in thyroid homeostasis. (NIH ES00044, ES07046, and North Carolina ARS)

1105 MECHANISTIC STUDIES OF KOJIC ACID ON THYROID TUMOR PROMOTION ON ENHANCEMENT OF THYROID CARCINOGENESIS.

T Tamura[1], K Mitsumori[1], H Onodera[1], N Fujimoto[2], K Yasuhara[1], K Takegawa[1], and M Mirose[1]. [1]*Div. Of Pathology, National Institute of Health Sciences, Tokyo, Japan;* [2]*Hiroshima University, Hiroshima-shi, Japan.* Sponsor: T Shirai.

In order to elucidate the mechanisms for reduction of serum thyroid hormones caused by continuous administration of kojic acid (KA) and its thyroid tumor promotion effect, male F344 rats were given pulverized basal diet containing 0.008%, 0.03%, 0.125%, 0.5% and 2% KA for 4 weeks. The thyroid ^{125}I uptake was significantly decreased in the groups received 0.03% KA or more. Significant reduction of organic formation ratio of iodine was only observed in the 2% KA group. The serum T3 and T4 levels in the 2% KA group were significantly decreased as compared to those of the control. Pronounced elevation of the serum TSH levels were observed in the 2% KA group. Both absolute and relative thyroid weights were significantly increased in the groups receiving 0.5% of KA or more. Histopathologically, both decreased colloid in the thyroid follicles and follicular cell hypertrophy in the thyroid were apparent at high incidences in the groups given 0.03% of KA or more. In addition, thyroid capsular fibrosis was evident in all rats in the 2% KA group. The results suggest that KA-alteration of thyroid-related hormone levels are due to inhibition of iodide uptake and iodine organification in the thyroid, with promoting effects on development of thyroid proliferative lesions probably secondary to prolonged serum TSH stimulation resulting from negative feedback through the pituitary-thyroid axis.

1106 PROMOTION ACTIVITY OF KOJIC ACID ON RAT THYROID CARCINOGENESIS AND ITS EFFECT ON THYROID HORMONS.

H Onodera[1], K Mitsumori[1], M Takahashi[2], T Funakoshi[3], T Tamura[1], K Yasuhara[1], K Takegawa[3] and M Hirose[1]. [1]*Division of Pathology, National Institute of Health Sciences, Tokyo, Japan;* [2]*Department of Pathology, Sasaki Institute, Tokyo, Japan;* [3]*Pharmacokinetics & Analysis Research, Yoshitomi Pharmaceutical Industries, Ltd., Fukuoka, Japan.* Sponsor: T Shirai.

Kojic acid(KA) is produced by many species of *Aspergillus* , *Acetobactor* and *Penicillium*.. The *Aspergillus flavus* group has traditionally been used in Japan for the production of fermented foodstuffs such as "miso", soy sauce and "sake". Thyroid tumors were observed in mouse caricinogenecity study given diet containing 1.5 and 3% KA. To examine whether KA exerts promoting effect on thyroid carcinogenesis, male F344 rats were initiated with N-bis(2-hydroxypropyl)nitrosamine (BHP: 2800 mg/kg body weight, single s.c. injection), and starting one week later, received pulverized basal diet containing 2% or 0% KA for 12 weeks. Untreated control rats were given basal diet for 13 weeks. Animals were killed at weeks 4 and 12. The serum T3 and T4 levels were significantly decreased (1/2 to 1/3 of values of the BHP alone group) and serum TSH was markedly increased (13 to 19 times higher than the values of the BHP alone group) in the BHP+KA group at weeks 4 and 12. Thyroid weights were significantly increased in the BHP+KA and KA alone groups. Focal thyroid follicular hyperplasias and adenomas were observed in 4/5 rats and 3/5 rats in the BHP+KA group at week 4, respectively. At weeks 12, these lesions were observed in all rats in the BHP+KA group. No changes in thyroid-related hormone levels or thyroid histopathological lesions were observed in either the BHP alone or the

untreated control groups. Measurement of liver T4-uridine diphosphate glucuronosyltransferase (UDP-GT) activity at week 4 revealed no significant intergroup differences. These results suggest that thyroid proliferative lesions were induced by KA administration due to continuous serum TSH stimulation through the negative feedback mechanism of the pituitary-thyroid axis, with decreases of T3 and T4 caused by a mechanism independent of T4-UDP-GT activity.

1107 COMPARATIVE 30-WEEK DERMAL TUMOR PROMOTION EVALUATION OF CIGARETTE SMOKE CONDENSATE FROM A REFERENCE CIGARETTE AND AN ECLIPSE PROTOTYPE (7026A) TEST CIGARETTE IN FEMALE SENCAR MICE.

D R Meckley[1], A T Mosberg[1], J D deBethizy[1], K R Van Kampen[2]. [1]*R J Reynolds Tobacco Co., Winston-Salem, NC;* [2]*The Van Kampen Group, Ogden, UT.*

A 30-week dermal tumor promotion assay was conducted to compare the potential dermal tumor promotion activity of mainstream cigarette smoke condensate (CSC) collected from an ECLIPSE prototype cigarette (7026A), which primarily heats tobacco, and a 1R4F (University of Kentucky) reference cigarette. Mainstream CSC's were collected by cold trap from smoke generators using the Federal Trade Commission puffing regimen. Female SENCAR mice were "initiated" with a single 75 ug application of DMBA to the shaved dorsal skin. The CSC's were then applied to the skin three times per week for 29 weeks. Each CSC was administered at 10, 20, or 40 mg tar/application to groups of 40 animals. End-points included body weights, clinical observations, organ weights, dermal tumor development data and histopathology. The numbers of dermal tumors and the numbers of dermal tumor-bearing animals for the 1R4F reference CSC were statistically different from the "DMBA-initiated" and "acetone-promoted" control groups, and increased with increasing exposure. The number of dermal tumor-bearing animals for the high-dose 7026A prototype CSC was statistically significantly different from the control groups. The numbers of dermal tumors for the mid- and high- dose 7026A prototype CSC were statistically different from the control groups and increased with increasing exposure. When corresponding dose levels of reference and 7026A CSC were compared to each other, the mid- and high-dose 7026A CSC groups had statistically fewer dermal tumors and tumor-bearing animals. In this assay, the dermal tumor-promotion potential of the 7026A CSC was, therefore, substantially reduced when compared to the 1R4F reference CSC.

1108 THE EFFECT OF CIGARETTE SMOKE ON THE METABOLISM OF THE TOBACCO-SPECIFIC NITROSAMINE 4-(METHYLNITROSAMINO)-1-(3-PYRIDYL)-1-BUTANONE (NNK) IN THE A/J MOUSE.

D J Doolittle[1], E Richter[2], A R Tricker[3], and B G Brown[1]. [1]*RJ Reynolds Tobacco Company, Winston-Salem, NC, USA;* [2]*University of Munich, Munich, Germany;* [3]*FTR, Neuchatel, Switzerland.*

The effect of short-term exposure to whole cigarette smoke on the metabolism of the tobacco-specific nitrosamine, 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK) was studied in the A/J mouse. Mice (n=12) were exposed to either HEPA-filtered room air (control group) or 1R4F cigarette smoke for 2 hrs at a concentration of 0.6 mg particulate matter per liter of air. Immediately following nose-only inhalation, all animals received an intraperitoneal (i.p.) administration of 7.5 µmole/mouse of NNK containing 10 µCi of [^{3}H]NNK and then placed in metabolic cages for 24 hr urine collections. Collected urine was used to quantify the stable end products of the α -hydroxylation metabolic pathway, which activates NNK, and stable end products of NNK detoxification. The metabolites resulting from NNK activation by α -hydroxylation (hydroxy acid and keto acid) were significantly ($p<0.05$) reduced to 85% and 58% of control, respectively. Moreover, detoxification to the NNAL and NNAL-glucuronide metabolites increased significantly ($p<0.05$) to 108% and 116% of control, respectively. These results indicate that co-administration of cigarette smoke shifts the metabolism of NNK towards detoxification pathways compared to when NNK is administered alone. These results are consistent with previous studies demonstrating that cigarette smoke co-administration markedly reduces the formation of O^6MeG DNA adducts following NNK administration.

1109 TUMOR PROMOTING ACTIVITIES OF XYLAZINE (XZ) AND ITS METABOLITE, 2,6-DIMETHYLANILINE (DMA), IN A TWO-STAGE NASAL CARCINOGENICITY MODEL IN RATS INITIATED WITH N-BIS(2-HYDROXYPROPYL)NITROSAMINE (DHPN).

T Koujitani[1], K Mitsumori[1], K Yasuhara[1], H Kobayashi[2], H Onodera[1], H Takagi[1], and M Hirose[1]. [1]*Division of Pathology, National Institute of Health Sciences, Tokyo, Japan;* [2]*Chemistry Division, Institute of Environmental Toxicology, Ibaraki, Japan.* Sponsor: T Shirai.

XZ is an a_2-adrenergic agonist that is used in food-producing animals as a sedative agent. It has been reported that DMA, a metabolite of XZ, induced nasal cavity tumors in rat 2-year carcinogenicity study, but a carcinogenicity study of XZ has not been performed. To examine the tumor promoting effects of these chemicals, five-week old F344 male rats were given a single subcutaneous injection of DHPN (2400 mg/kg). Starting one week after the injection, the animals were given diet containing DMA (3000 ppm), XZ (1000 ppm, a maximum tolerated dose), or basal diet for 52 weeks. Histopathologically, the total incidences of the nasal tumors including papillomas, adenomas or carcinomas in the DMA, XZ and basal diet groups were 16/30 ($p<0.01$), 6/20 and 4/20, respectively. Dysplastic cell foci in the DMA, XZ and basal diet groups were observed at the incidences of 10/30 ($p<0.01$), 2/20 and 1/20, respectively. In the second experiment, rats were given diet containing DMA (3000 ppm) or XZ (1000 ppm) for 28 days, and plasma levels of DMA and/or XZ were measured. Plasma levels of DMA in the DMA group at days 7 and 28 were 0.36 and 0.20 µg/ml, respectively, but those of DMA and XZ in the XZ group were below the detection limit (0.02 µg/ml). These results strongly indicate that DMA has a tumor promoting effect in the rat nasal cavity, and suggest that XZ is not carcinogenic to the rat nasal cavity, because the amounts of XZ and DMA in plasma were too small to exert promotion activity in the XZ group.

1110 MIREX SKIN TUMOR PROMOTION IN MALE MICE IS REGULATED BY ESTRADIOL.

K L Porter, C L Robinette and R C Smart. *Dept. of Toxicology, North Carolina State University, Raleigh, NC, USA.*

Mirex, an organochlorine pesticide, is a potent tumor promoter in female mouse skin. Previous studies in our laboratory have shown that intact female mice are 3 to 4 times more sensitive to mirex promotion than ovariectomized (OVX) female mice, and that 17β -estradiol (E2) implants in OVX female mice can partially restore the intact female response. In addition, female mice are 3 to 4 times more sensitive to mirex promotion than male mice, further supporting a role for E2 in mirex promotion. Since male mice are relatively resistant to mirex promotion, we wanted to determine if chronic systemic E2 elevation could increase the mirex tumor response of male mice to that of females. Intact male mice were initiated with 7,12-dimethylbenz[*a*]anthracene and two weeks later were divided into groups and subjected to the following treatments; castration and blank implants, castration and E2 implants or sham castration and blank implants. Castrated male mice developed 3 fold fewer tumors than intact mice, and E2 implants were able to completely reverse the effects of castration on mirex promotion, but could not increase the male tumor response to that of intact female mice. We found that serum E2 in castrated male mice with E2 implants was 15.5 ± 5.7 pg/ml, which is at the low end of the intact cycling female range of 5.8 to 79.6 pg/ml. This difference could account for the inability of male mice to acquire the female mirex tumor response. Surprisingly, the serum E2 levels in intact and castrated male mice with blank implants were 10.1 ± 3.6 pg/ml and 9.1 ± 3.1 pg/ml, respectively. To address the disparity between serum E2 levels and mirex promotion sensitivity in intact and castrate mice, we assayed E2 in skin and found that skin E2 levels are at least ten times greater than serum E2 levels in intact male mice, and we are currently examining skin E2 levels in castrate mice. These data suggest that E2 is important in regulating mirex promotion in male mice and that cutaneous E2 levels and factors regulating E2 levels and/or responsiveness are as important as systemic serum E2. (NEIHS Grant ES08127)

1111 SIMULATION MODELING OF A MULTIDOSE, MULTITIME POINT STUDY TO TEST CLONAL GROWTH MODELS OF 2,3,7,8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) PROMOTION OF ALTERED HEPATIC FOCI IN THE RAT.

J G Teeguarden[1], R B Conolly[2], and H C Pitot[1]. [1]*Environmental Toxicology Center and McArdle Laboratory, University of Wisconsin, Madison, WI, USA;* [2]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA.*

Stochastic clonal growth models utilizing mutation, apoptosis, and cell division rates to describe the growth of single cell clones into altered hepatic foci (AHF) have been used successfully to simulate the growth of AHF under the influence of carcinogens such as TCDD and polychlorinated biphenyls. Three hypotheses involving the mechanism of TCDD mediated promotion were used to guide parameterization of the two-stage clonal growth model: (1) a short-term burst of cell division in clonal cells; induction of a mitoinhibitory environment, from which clonal cells escape through either (2) increased cell division or (3) reduced apoptosis. Seven models of TCDD action predicated on these hypotheses were tested against data on the number and volume fraction of GST-P positive AHF from the study. Models based on a single responsive clone type were not capable of describing the data. A model consisting of two types of clones provided the best fit to the data. One type is unresponsive to TCDD, and one responds to TCDD with a burst of cell division that declines with time. These and other observations highlight the usefulness of clonal growth models for exploring the behavior of preneoplastic clones under the influence of promoting agents.

1112 CORN OIL RAPIDLY ACTIVATES NUCLEAR FACTOR kB (NF-kB) IN KUPFFER CELLS IN VIVO.

I Rusyn[1,2], L Cohn[2], R Schoonhoven[3], J A Swenberg[2,3], and R G Thurman[1,2]. *Laboratory of Hepatobiology and Toxicology, Dept. of Pharmacology*[1], *Curriculum in Toxicology*[2], *and Dept. of Environmental Sciences and Engineering*[3], *University of North Carolina, Chapel Hill, NC.*

N-6 polyunsaturated fatty acids (*N*-6 PUFA), major constituents of corn oil, are tumor promoters and increase the rate of growth of established tumors. Both *N*-6 PUFAs and peroxisome proliferators (PPs; *e.g.*, WY-14,643) activate the peroxisome proliferator activated receptor α. Furthermore, it has been proposed that PPs cause an increase in hepatocyte proliferation by mechanisms involving activation of NF-κ B and production of mitogenic levels of TNFα by Kupffer cells; however, whether *N*-6 PUFAs are involved in increased cell proliferation in liver is not well understood. Here, it was hypothesized that *N*-6 PUFAs would produce mitogens leading to increased cell proliferation in liver. It was found that a single dose of corn oil (2 ml/kg, *i.g.*), but not olive oil or medium-chain triglycerides (saturated fat), caused ~3-fold increase in hepatocyte proliferation. Similarly, when activity of NF-κ B in whole rat liver and isolated hepatocytes or Kupffer cells was measured at various time intervals for up to 36 hours, only corn oil activated NF-κ B. Corn oil increased NF-κ B activity about 3-fold 1 to 2 hours after treatment exclusively in the Kupffer cell fraction. In contrast, increases were small and only occurred after about 8 hours in hepatocytes. The activation of NF-κ B and increase in cell proliferation due to corn oil were prevented completely when rats were pretreated for 4 days with either dietary glycine (5% w/w), an agent that inactivates Kupffer cells, or the NADPH oxidase inhibitor diphenyleneiodonium (1 mg/kg). Furthermore, arachidonic acid (100 μ M), the major metabolite of linoleic acid, activated superoxide production ~4-fold when added to isolated Kupffer cells *in vitro*. It is concluded that corn oil rapidly activates NF-κ B in Kupffer cells via oxidant-dependent mechanisms. This can trigger production of low levels of mitogens in liver and promote proliferation of hepatocytes. (ES04325)

1113 DEFICIENCY OF METALLOTHIONEIN PROMOTES SKIN CARCINOGENESIS CAUSED BY 7, 12 - DIMETHYLBENZ[A]ANTHRACENE.

B Zhang, M Satoh, J S Suzuki, N Nishimura and C Tohyama. *Environmental Health Sciences Division, National Institute for Environmental Studies, Tsukuba, Japan.*

Metallothionein (MT) has been proposed to play an antioxidative role. We studied possible involvement of MT in the process of chemical carcinogenesis using MT-null transgenic mice since chemical carcinogenesis can be suppressed by free radical scavengers and antioxidant supplementation. As a cancer initiator, 7,12-dimethylbenz[a]anthracene (DMBA), a well-studied skin complete carcinogen, was topically applied to the MT-null mice as well as their wild-type control mice. In the first experiment without using promoters, DMBA was applied as an initiator at a single dose of 100, 250, 500 or 1000 g DMBA on the dorsal skin. After 14 weeks of DMBA treatment the skin tumor occurred in a dose-dependent manner in MT-null mice only, while no change was observed in wild-type control mice. In another experiment based upon two-stage carcinogenesis, DMBA was applied at a dose of 50 g, followed by TPA, a phorbol ester, twice a week for 20 weeks, which shows that MT-null mice is considerably prone to skin cancer. Histological examination revealed that skin tumors were squamous cell papillomas. The promotion by TPA gave rise to larger numbers of papilloma than the first DMBA experiment. The tumor cells showed proliferative activity as shown by PCNA staining. The present results demonstrate that deficiency of MT enhances the promotion of DMBA-induced skin carcinogenesis.

1114 THE REGULATORY ROLE OF C-MYC ON TELOMERASE ACTIVITY.

J B Colerangle. *St. John's University, Jamaica, NY.*

The c-myc proto-oncogen is commonly overexpressed and amplified in human breast tumors. The c-myc gene encodes a sequence-specific DNA binding protein involved in cell proliferation and oncogenesis. However, the precise mechanisms by which c-myc promotes oncogenesis are not clear. In the present study, the regulatory role of the proto-oncogen, c-myc, was investigated. The results revealed that overexpression of c-myc following exposure of human breast cancer cells (MCF-7) to 17ß-estradiol mediated a profound increase in cell proliferation without any effect on telomerase activity in cells treated with c-myc sense oligomers. On the contrary, all cells treated with antisense c-myc oligonucleotides showed a profound decrease in cell proliferation as well as telomerase activity.

1115 PHENOLPHTHALEIN METABOLITE INHIBITS CATECHOL-O-METHYLTRANSFERASE (COMT) MEDIATED METABOLISM OF CATECHOL ESTROGENS.

L T Burka, C E Garner, and H B Matthews. *NIEHS, RTP, NC.*

Phenolphthalein (PT), formerly used in over-the-counter laxatives, was recently identified as a multisite carcinogen in rodents, but the molecular species responsible for the carcinogenicity is not known. A novel catechol metabolite of PT, hydroxyphenolphthalein (PT-CAT), was identified and may be the molecular species responsible for at least part of the toxicity/carcinogenicity of PT. We hypothesize that PT-CAT inhibits the enzyme catechol-O-methyltransferase (COMT) and potentiates genotoxicity by either PT-CAT itself or the endogenous catechol estrogens (CEs) in susceptible tissues. The present studies were conducted to determine the effects of PT treatment and PT-CAT itself on the COMT-mediated catabolism of 4- and 2-hydroxyestradiol both in vitro and in vivo. Female mice were treated with PT (50 mg/kg/d) for 21 days and then sacrificed. PT-CAT concentration in urine plateaus by 7 days of exposure. In vitro experiments demonstrated that PT treatment resulted in an increase in free CEs, which are normally cleared by COMT and a concurrent decrease in the capacity of hepatic catechol clearance by COMT. In vitro, PT-CAT was a substrate of COMT, with kinetic properties within the range measured with endogenous substrates. PT-CAT was a potent mixed-type inhibitor of the O-methylation of catechol estrogens, with 90-300 nM IC50s. The above data, when taken together, suggest that chronic administration of PT may enhance metabolic redox cycling of both PT-CAT and the catechol estrogens and this, in turn, may contribute to PT-induced tumorigenesis.

1116 UPREGULATION OF THE AH RECEPTOR IN HUMAN BREAST CARCINOMA CELL LINES IN DIRECT PROPORTION TO THEIR MALIGNANCY.

S E Eltom, W G R Angus and C R Jefcoate. *University of Wisconsin Medical School, Madison, WI, USA.*

The Ah receptor (AhR), a ligand-activated helix loop helix transcription factor, binds environmental polyaromatic hydrocarbons, e.g., dioxin, and mediates their toxic effects. This study was designed to investigate the expression of AhR and its possible role in breast carcinogenesis, using MDA-MB231 and T47D series of breast carcinoma cell lines and Sager's 21T series which are closely matched pairs of mammary carcinoma cell lines characterized by exhibiting gradient order of malignancy (21MT> 21NT> 21PT). The MT lines showed the highest expression of AhR (~10 fold higher than PT), and NT was medium between MT and PT which expressed >20 fold higher than

normal mammary tissues. MDA-MB231 cell lines expressed higher AhR levels than the less malignant T47D cell series, irrespective of their estrogen receptor (ER) status. Although TCDD treatment in MDA-MB231 and T47D series have resulted in substantially lowering the AhR levels, the 21T series were less responsive to that effect of TCDD. TCDD treatment resulted in ~5-fold induction of urokinase plasminogen activator (u-PA) in MB231 while dramatically lowering its level in ER-transfected S30 variant of MB231. The plasminogen activator inhibitor-2 (PAI-2) was induced by TCDD in MB231 and ER-negative T47D with the opposite effect in the ER-positive cell lines. While PAI-2 levels in 21T series were inherently high in all three lines and less sensitive to TCDD treatment, the levels of uPA receptor expressed in these cells were proportional to their malignancy in direct correlation to the AhR levels. In conclusion, these data identify the AhR as a key regulator in breast cancer progression, and establish a positive correlation between the AhR expression and components of uPA system. While the AhR activation by TCDD is associated with induction of some components of u-PA system, the lack of this response in the 21T series suggests that the receptor over-expression and its PAH-dependent activation are probably different pathways. The mechanisms underlying these pathways are currently under investigation. (This work was supported by US Army grant DMAD 17-94-J14054.)

1117 EFFECTS OF BROMOETHANE (BE) ON THE ESTROGEN RECEPTOR (ER) AND PROLIFERATING CELL NUCLEAR ANTIGEN (PCNA) LABELING IN HUMAN MCF7 CELLS.

H He, A Yoshida and D Dixon. *National Institute of Environmental Health Sciences, Research Triangle Park, NC, USA.*

BE is a haloethane used primarily as an intermediate in organic synthesis, and in gasoline ethylation. In a 2-year NTP bioassay, BE induced endometrial neoplasms in the uterus of B6C3F1 mice, but decreased the incidence of mammary neoplasms in female F344/N rats. The mechanisms of these effects are unclear; however, we have shown that BE does not have a direct estrogenic effect on the uterus of ovariectomized B6C3F1 mice, but may regulate ER expression. In the present study, we treated estrogen-responsive MCF7 human breast cancer cells with BE at 100, 250, 500, or 1000 mg/L every 24 hours for 3 consecutive days. Cells were harvested on days 2 and 4, and the expression of ER was evaluated using Western blotting and immunohistochemistry. Immunoexpression of PCNA was done to determine the effects of BE treatment on cell proliferation. On day 2, control and treated cells expressed a 66 kDa protein consistent with the ER. This protein was faintly expressed on day 4 by cells treated with 500 or 1000 mg/L of BE. Immunoexpression of ER was observed in control and BE-treated groups on day 2; however, by day 4 cells exposed to 500 or 1000 mg/L did not express ER. The percentage of ER-positive nuclei in cells exposed to 500 or 1000 mg/L of BE was significantly ($p<0.001$) lower than that of the controls on day 2. On day 4, the PCNA labeling index of cells incubated with 1000 mg/L was significantly ($p<0.01$) lower than that of controls. These data suggest that continuous exposure of MCF7 cells to BE at high concentrations reduces ER expression and PCNA labeling. These observations may be important in understanding the mechanism of decreased mammary gland neoplasia observed *in vivo*.

1118 NEU ACTIVATION BY ORGANOCHLORINES (OCS) IS CORRELATED TO THEIR ESTROGENIC ACTIONS IN MCF-7 CELLS.

M Hatakeyama, and F Matsumura. *Department of Environmental Toxicology, University of California, Davis, CA, USA.*

The question why some OCs which show very low potency as direct agonists to the estrogen receptor act in an estrogenic manner both *in vitro* and *in vivo* has not been adequately answered yet. In the current study, we examined the effects of selected OCs on activation of Neu, a receptor tyrosine kinase known to play an important role in breast cancer. Following the initial finding made in this laboratory, we studied Neu in a cell free system, in intact cells and 14 day foci formation using human breast cancer MCF-7 cells. The OCs most active in all these tests were alpha-, beta-, and gamma-HCH, o,p'-DDT, o,p'-DDT, 2,2'-dichlorobiphenyl and 2,4,5-T. In all cases the order of potencies during these and less active OCs was essentially identical, indicating the closeness in responses. To ascertain that the long term foci formation is also triggered by the initial activation of Neu kinase, we have tested the inhibitory action of a specific antibody against the ligand binding domain of Neu. The result clearly indicated that the OCs induced foci formation which is known to be promoted by estrogen, could be specifically suppressed by Neu antibody, but significantly by antibody against EGF receptor. Neu is known to act in a synergistic manner with estrogen in general, and therefore, our current hypothesis is that the activation of these OCs to activate this tyrosine kinase is causally related to their estrogenic actions on cell proliferation activities in estrogen target tissues. (Supported by NIH R01-ES/CA 07284, ES05233 and ES05707.)

1119 ESTRADIOL METABOLISM IN RAT STRAINS DIFFERING IN SUSCEPTIBILITY TO MAMMARY CARCINOGENESIS.

A M Wilson, J K Padgitt, and G A Reed. *Department of Pharmacology, Toxicology, and Therapeutics and Kansas Cancer Institute, University of Kansas Medical Center, Kansas City, KS, USA.*

Rat strains are known to differ markedly in their susceptibility to estrogen-induced mammary tumors. Specifically, the ACI strain is extremely sensitive to estrogens, whereas the Sprague-Dawley (SD) strain is quite resistant. We are investigating the basis of this strain difference by comparing the metabolism of estradiol (E2) by liver microsomes from the two strains. Both strains exhibit hydroxysteroid dehydrogenase activity, with estrone (E1) being the major product at E2 concentrations above 1 μ M. 2-Hydroxyestradiol (2-OH-E2) also is formed. As the E2 concentration is decreased, however, cytochrome P450-dependent hydroxylation becomes a more dominant pathway for both strains. At the lower concentrations the SD preparations still yield E1 as the major product. ACI liver, however, produces primarily hydroxylated-E2 at these concentrations. Of particular interest is the production of 4-Hydroxyestradiol (4-OH-E2) as a major product by ACI microsomes. This difference is most apparent at E2 concentrations below 100nM. This profound difference in the disposition of E2, and that this difference is most pronounced at E2 concentrations nearing the physiological range, suggests that this difference may contribute to the relative sensitivity of these strains to E2 carcinogenicity. (Supported by DAMD 17-97-1-7155 and ES-07079.)

1120 INDUCTION OF QUINONE REDUCTASE (QR) AND GLUTATHIONE *S*-TRANSFERASE (GST) BY GREEN TEA EPIGALLOCATECHIN GALLATE AND QUERCETIN IN MCF-7 HUMAN BREAST CANCER CELLS.

L G Valerio, Jr. and L C Quattrochi. *Department of Medicine, University of Colorado Health Sciences Center, Denver, CO, USA.*

The polyphenolic compounds quercetin and green tea epigallocatechin gallate (EGCG) are flavonoids which have potent chemopreventive activity in a variety of animal models of cancer. One proposed mechanism for the inhibition of chemical carcinogenesis by these agents is induction of phase-II detoxification enzymes. In this investigation, the effects of quercetin, commercial green tea extract, and EGCG on GST and QR activities were evaluated in MCF-7 human breast cancer cells. Following 24 hr treatment with flavonoids, a maximum 2-fold increase in GST and QR enzyme activities were demonstrated in this cell model. Quercetin caused a significant increase in QR protein expression, as measured by western blot analysis. These results demonstrate that major dietary polyphenols, such as quercetin, green tea EGCG and whole green tea extract are capable of inducing phase-II enzymes in MCF-7 cells. The induction of these enzymes *in vivo* would result in the elimination of reactive metabolites of chemical carcinogens. This suggests a mechanism for chemoprevention of mammary cancer by flavonoids.

1121 PSP94 EXPRESSION IN PROSTATE CANCER PERSISTS AFTER ANDROGEN DEPRIVATION THERAPY.

M Moussa[1], Y Imasato[3], J Xuan[2], H Sakai[3], J Chin[2]. *U.W.O., Departments of [1]Pathology & [2]Surgery, London, Ontario, Canada and [3]Nagasaki University, Department of Urology, Japan.* Sponsor: M G Cherian.

PSP94 is one of the three major proteins secreted by prostate gland. In contrast to PSA and PAP, PSP94 was found to be androgen-independent in vitro. This prompted us to study the effect of hormonal therapy on PSP94 expression in prostate cancer. 87 radical prostatectomies from untreated patients (Group 1) and 74 from patients with neoadjuvant hormonal therapy (Group 2) were studied. Formalin-fixed, paraffin-embedded tissues were stained by ABC technique using a primary rabbit antibody against human PSP94 purified from semen. Tumor foci on each section were identified and were graded according to the scheme of Gleason. The intensity of the staining was graded on a scale of 0 to 2+, and the extent of the staining was classified as

0, 1-25, 25-50, 50-75, 75-100% on each focus. The tumor grade, pathological stage and pretreatment serum PSA levels were correlated with PSP94 expression in both groups. In Group 1, PSP94 positive staining was seen in 100% of low grade tumors and 12.5% in high grade tumors. In Group 2, a decreased PSP94 expression was observed in low grade tumors while a significant higher PSP94 expression was noted in high grade tumors (36%). No significant correlation between PSP94 expression levels and the other variables was noted in both groups.PSP94 expression in untreated prostate cancer has an inverse correlation with the tumor grade ($p<0.001$),while in neoadjuvant hormonal therapy group, an increased PSP94 expression was observed in high grade tumors . This discrepant expression pattern suggests that the regulation of PSP94 may be altered under androgen deprivation conditions.

1122 PROSTATE CANCER RISK FACTORS IN AN AREA OF COAL, IRON, AND STEEL INDUSTRIES.

T H Reckwitz[1], K Golka[2], S Dickhut[2], R Thier[2], H Schulze[1] and H M Bolt[2]. [1]*Urological Department of the Municipal Hospital, Dortmund, Germany;* [2]*Institute of Occupational Physiology at the University of Dortmund, Dortmund, Germany.*

Epidemiological and toxicological data point to an impact of cadmium and polycyclic aromatic hydrocarbons on prostate cancer. Aim of the study was to identify possible risk occupations in an industrial center of the German coal, iron and steel industries. Occupations performed for more than 6 months and life time smoking habits of 238 cases with histologically proven prostate cancer and of 414 controls with benign prostatic hyperplasia were examined with a questionnaire. Confounder-adjusted odds ratios were estimated by Fisher's exact test and logistic regression analysis. No differences in the smoking habits described by pack years could be found between cases and controls. Confounder-adjusted odds ratios for both age (OR 2.56) and duration of employment (OR 2.22) were elevated in a subgroup of underground hard coal miners. An elevated prostate cancer risk was also observed for painters/varnishers (OR 2.84 adjusted for age, OR 2.91 adjusted for duration of employment). Steelworkers showed no increased risk (OR 0.93 adjusted for age, OR 0.94 adjusted for duration of employment). Businessmen showed a remarkably low prostate cancer risk (OR 0.38 adjusted for age, OR 0.37 adjusted for duration of employment). Coal dust components and dietary factors due to high energy expenditure must be discussed as possible risk factors for prostate cancer in hard coal miners.

1123 OCCUPATIONAL AND NON-OCCUPATIONAL RISK FACTORS IN BLADDER CANCER PATIENTS IN AN INDUSTRIALIZED AREA IN EASTERN GERMANY.

K Golka[1], T Seidel[1], C Roetzel[1], F Geller[1], H M Bolt[1], G Staude[2] and R Thier[1]. [1]*Institute of Occupational Physiology at the University of Dortmund, Dortmund, Germany;* [2]*Department of Urology, Paul-Gerhardt-Stiftung, Lutherstadt Wittenberg, Germany.*

Several occupational bladder carcinogens are metabolized by polymorphic enzymes. Therefore, the distribution of the polymorphic enzymes N-acetyltransferase 2 (NAT2; substrates: e.g., aromatic amines), glutathione transferase M1 (GSTM1; substrates: e.g., reactive metabolites of polycyclic aromatic hydrocarbons), and glutathione transferase T1 (GSTT1; substrates: small molecules with 1-2 carbon atoms) were investigated in bladder cancer patients in the former center of the chemical industry in Halle-Wittenberg in the former German Democratic Republic. Occupations performed for more than 6 months by 136 patients of the urological clinic in Wittenberg were examined with a questionnaire. All patients had a histologically approved transitional cell cancer of the urinary bladder. In addition, several occupational and non-occupational risk factors were considered. The genotypes of NAT2, GSTM1, and GSTT1 were determined from leucocyte DNA by PCR. Compared to the normal population in Central Europe, in the entire group the percentage of GSTT1 negative persons (22.1 %) was ordinary, the percentages of slow acetylators (59.8 %) and of GSTM1 negative persons (58.8 %) were slightly elevated. Shifts in the distribution of the genotypes were observed in subgroups who had been exposed to asbestos (6/6 GSTM1 negative, 5/6 slow acetylators), chlorinated solvents (9/15 GSTM1 negative) or who did work in rubber manufacturing (8/10 GSTM1 negative). The overrepresentation of GSTM1 negative bladder cancer patients in the industrialized area, which was more pronounced in several occupationally exposed subgroups, points to chemoprotection by the enzyme GSTM1 in bladder carcinogenesis.

1124 DECREASE OF GLIAL FIBRILLARY ACIDIC PROTEIN IN RAT FRONTAL CORTEX FOLLOWING ALUMINUM TREATMENT.

S X Guo-Ross[1], E Y Yang[1], T J Walsh[2] and S C Bondy[1]. [1]*University of California, Irvine, CA, USA;* [2]*Rutgers University, New Brunswick, NJ, USA.*

Aluminum lactate was either intraperitoneally administered or stereotactically injected bilaterally into rat cerebral ventricles. Rats were sacrificed at various times after aluminum treatment and frontal cortex, hippocampus and striatum were dissected out. A microtiter plate based sandwich ELISA was used to measure glial fibrillary acidic protein (GFAP) concentration. GFAP levels were significantly decreased in frontal cortex seven days after lateral ventricular injection or fourteen days post systemic treatment. In contrast, neither hippocampus nor striatum had any significant changes in astrocytic intermediate filament protein. These results suggest a selective and progressive diminution of astrocytic responsivity in frontal cortex following either systemic or intraventricular aluminum dosing. An increased level of GFAP is considered a marker of reactive astrogliosis and has been reported in aluminum exposed rabbits. The depression of GFAP levels reported here in a species not forming neurofibrillary tangles (NFT) may reflect extended impairment of astrocytic function and suggests that these cells may be the primary targets of aluminum neurotoxicity.

1125 TRIMETHYLTIN ACTIVATES GLIA TO RELEASE TNF-α THROUGH REACTIVE OXYGEN SPECIES PRODUCTION.

B Viviani, C L Galli, and M Marinovich. *Laboratory of Toxicology, Institute of Pharmacological Sciences, University of Milan, Milan, Italy.*

The trisubstituted organotin compound trimethyltin (TMT) is highly neurotoxic after *in vivo* exposure eliciting both neuronal and glial responses in the central nervous system. Recently we demonstrated that *in vitro* TMT-induced neural cell death in the presence of glial cells is reduced by a TNF-α antibody, suggesting that glial cells support neural cell death through TNF-α release. Thus, in this study we evaluated the ability of TMT to activate glia to release TNF-α and other cytokines, and the molecular mechanisms involved. Exposure of a mixed population of glial cells (astrocytes + microglia) to TMT is followed by a dramatic change in morphology and a dose dependent TNF-α release, significative from 1 μM TMT. Differently, no release of IL-6 is detectable. TMT induces TNF-α release from both highly enriched culture of astrocytes and highly enriched culture of microglia, suggesting that both cell populations are sensitive to the compound and collaborate to TNF-α production. It has been demonstrated that TNF-α release often occurs after reactive oxygen species (ROS) production in dependence of NF-κB activation. TMT 0.5 - 2.5 μM induces a dose dependent ROS production in glial cells that precedes TNF-α release. Both ROS production and the release of this cytokine are completely prevented by the use of ETYA 50 μM (a non-metabolizing analogue of arachidonic acid) and indometacine 10 μM. These results suggest that TMT-induced release of TNF-α from glial cells is dependent by the production of ROS as a consequence of the metabolism of arachidonic acid through the activation of ciclooxygenase. (Acknowledgments: this work was supported by CNR grant n° 97.04658.CT13.)

1126 CYTOKINE AND GROWTH FACTOR GENE EXPRESSION IN RESPONSE TO TRIMETHYL TIN (TMT)-INDUCED NEUROTOXICITY IN THE ADULT RAT HIPPOCAMPUS.

A R Little and J P O'Callaghan. *CDC-NIOSH, Morgantown, WV.*

Cytokines and growth factors are proposed to play a role in the homeostasis of the central nervous system (CNS) and its response to injury and disease. A role for these pleiotropic mediators in the early activation of microgial and astrocytic reactions to neural injury constitutes a dominant theme in contemporary neuroscience literature, despite the fact that most data are derived from *in vitro* preparations. Understanding the earliest events associated with toxicant-induced brain injury is necessary to detect and modify CNS damage following injury or disease. Here we examined the *in vivo* expression of interleukin-1alpha (IL-1alpha), interleukin-6 (IL-6), transforming growth factor-beta (TGF-beta), brain-derived neurotrophic factor (BDNF), and nerve growth factor (NGF) using the TMT model of neuronal injury (8mg/kg i.p.) using semi-quantitative Reverse Transcription-Polymerase Chain Reaction (RT-PCR) at 24 hours post TMT. This timepoint was chosen based on reports in the literature that mRNA for TGF-beta and IL-6 are up-regulated at this time with other types of nerve injury. No significant changes for

BDNF, NGF, or IL-1alpha were seen. mRNA for TGF-beta and IL-6 were increased slightly less than 2 fold, which is a very small increase, but is consistent with published reports. These results suggest that these neuroimmune/neurotrophic mediators do not play a crucial role in the activation of microglia and astrocytes following toxicant-induced injury to the CNS. Additional toxicants need to be examined in order to determine the generality of these observations to the neurotoxic condition.

1127 ORGAN DISTRIBUTION OF TIN AND TRACE ELEMENTS IN MICE GIVEN TRIMETHYLTIN (TMT) – RELATION TO THE TMT TOXICITY.

V Eybl[1], D Kotyzova[1], J Koutensky[1], V Mickova[1], J L Borowitz[2], and G E Isom. [1]*Department of Pharmacology and Toxicology, Charles University, Pilsen, Czech Republic;* [2]*Department of Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN, USA.*

Trimethyltin has been recognized as a potent neurotoxic substance. There is no information available concerning its possible interaction with trace elements in the body. In the experiments performed in male mice (CD-1, Charles River) TMT was injected ip in the form of chloride at the dose of 2.5 $mg.kg^{-1}$. The concentration of Sn and various trace elements was determined in the liver, kidneys and in the brain of intoxicated mice divided into 4 subgroups sacrificed at various time intervals (24th –168th h) of the experiment using AAS. The results were compared with the values received in corresponding control group. The concentration of Sn in the liver decreased during the experiment to 10.8%, in the kidneys to 10.6% and in the brain to 12.5% of the value at 24th h. The significant increase of the level of zinc, copper and manganese in the liver at 24th h and 48th h was noticed. Only negligible changes of the trace element levels in the brain – the main target organ of TMT toxicity - were demonstrated. A potent metal binding chelator sodium *N*-benzyl-4-*O*-(β -D-galactopyranosyl)-D-glucamine-*N*-carbodithioate (BLDTC) injected simultaneously sc with TMT decreased the concentration of tin in brain (by 5.1%). The changes of trace element levels in the liver were also corrected. The results suggest the liver might play a role in the acute toxicity of TMT. This hypothesis is supported by the fact that TMT increases the level of lipid peroxidation (measured as malondialdehyde production) not only in the brain but also in the liver as has been demonstrated in the parallel experiment in mice done in our laboratories.

1128 MANGANESE (Mn) EXPOSURE PROMOTES CELLULAR OVERLOAD OF IRON (Fe) IN CULTURED NEURONAL AND NEUROGLIAL CELLS IN VITRO.

Q Zhao, H Kim, and W Zheng. *Division of Environmental Health Sciences, School of Public Health, Columbia University, New York, NY, USA.*

Our recent studies indicate that Mn exposure potently inhibits aconitase, an enzyme possessing a [4Fe-4S] cubane cluster and regulating the expression of some critical proteins involved in cellular Fe regulation (Zheng, et al., Brain Res. 799:334, 1998). This study was performed to test the hypothesis that disruption in Fe regulatory processes by Mn may lead to an altered cellular Fe status in 3 major types of brain cells. The cultured astrocytes, oligodendrocytes or PC12 cells were exposed to Mn as $MnCl_2$ in culture medium. Cellular Fe uptake was determined by quantitation of residual ^{59}Fe radioactivity in cells following addition of 1.5-2.0 μM ^{59}Fe as $FeCl_3$ in culture medium. In astrocytes, Mn exposure greatly increased cellular ^{59}Fe uptake (5.3 fold at 100 μM, $p<0.0001$) as compared to the controls. The effect was dependent upon Mn concentrations within the range of 10-100 μM. While incubation of astrocytes with 50-250 μM MPP^+ or 10-100 μM Hg did not affect cellular Fe uptake, the treatment with 100-250 μM MPTP showed a significant decrease (-26-69%, $p<0.05$) in Fe uptake compared to controls. When the oligodendrocytes and PC12 cells were incubated with 100 μM Mn, the treatment raised cellular Fe by 3.2 fold ($p<0.0001$) and 2.7 fold ($p<0.026$) in oligodendrocytes and PC12 cells, respectively. Our results demonstrate that Mn, but not MPTP or MPP^+, promotes the cellular overload of Fe. The deleterious effect of Mn on cellular Fe status appears to occur in major cell types of the CNS, but the astrocytes seem to be more sensitive to Mn than other cell types tested. (Supported by Calderone Foundation and other private funds.)

1129 MANGANESE (Mn)-INDUCED NEUROTOXICITY: IN VIVO INTERACTION WITH IRON (Fe).

W Zheng[1,2], Q Zhao[1], H Kim[1], V Slavkovich[1], M Aschner[3] and J H Graziano[1,2]. [1]*Div of Env Health Sci, School of Public Health,* [2]*Dept of Pharmacol, College of Physicians and Surgeons, Columbia Univ, New York, NY;* [3]*Dept of Physiol/Pharmacol, Wake Forest Univ. School of Med, Winston-Salem, NC, USA.*

Our in vitro studies have shown that Mn exposure promotes cellular Fe overload in cultured neuronal and neuroglial cells (Zhao and Zheng). The current study was designed to investigate whether Mn alters Fe homeostasis in blood, CSF and brain. Groups of 8-10 rats received saline, Mn (36 mg/kg/wk, ip), Fe (250 mg/kg/wk, sc), or Mn (ip) plus Fe (sc) for 4 wks. Mn and Fe concentrations in tissues and body fluids were determined by AAS. While Mn injection alone caused a 32% decrease in plasma Fe ($p<0.01$) and no changes in plasma total iron binding capacity (TIBC), it increased CSF Fe by 3 fold ($p<0.01$) as compared to the controls. In rats treated with either Fe alone or Fe combined with Mn, both Fe and Mn levels in plasma and CSF were significantly increased. Combined exposure of Mn with Fe in rats greatly increased Mn concentration in striatum (4.5 fold), substantia nigra (6.2 fold), hippocampus (2.7 fold), frontal cortex (3.3 fold), and choroid plexus (8.3 fold); however, the same treatment raised Fe content selectively only in striatum (1.5 fold, $p<0.05$) and choroid plexus (2 fold, $p<0.05$). Northern blot analyses showed that none of the above dose regimens altered the expression of brain MT-I. In addition, we found that chronic Mn exposure appeared to increase the expression of glutamine synthetase by 34% ($p<0.05$) compared to controls. Our results indicate that Mn exposure seems likely to facilitate Fe transport from blood to CSF and increase Fe levels in selected brain regions. (Supported in part by NIEHS RO1 ES08146 and P20 ES06831.)

1130 MANGANESE TOXICITY IN CATECHOLAMINERGIC CELLS.

D Y Lewis, S G Mitchell, A H Stokes, S M Mockus, M Aschner, and K E Vrana. *Wake Forest University School of Medicine, Winston-Salem, NC, USA.*

Manganese (Mn) is an essential nutrient that, at excessive levels, produces extrapyramidal symptoms resembling those observed in patients with Parkinson's disease. Mn toxicity was tested in human neuroblastoma cells (SK-N-SH) and in a mouse catecholaminergic cell line (CATH.a). Mn was demonstrated to be more toxic (EC_{50} = 33 μM) towards the catecholamine producing CATH.a cells when compared to the non-catecholaminergic SK-N-SH cells (EC_{50} = 300 μM). This observation implicates catecholamines in the toxicant response. The Mn toxicity in the CATH.a cell line was augmented (EC_{50} = 1 μM) by pretreatment of the cells (36 hours) with an inhibitor of glutathione synthesis (1 mM L-BSO). Protection from Mn toxicity was observed with vitamin C (250 μM). The studies also evaluated the effect of Mn on tyrosine hydroxylase (TH), the rate limiting enzyme in catecholamine production. Exposure of cells to Mn produced an increase in the activity of TH (as normalized per cell). This effect was not mediated by the ability of Mn^{+2} to substitute for Fe^{+2} in the active site of TH due to the fact that addition of Mn^{+2} directly to the metal deficient enzyme did not restore activity. These results suggest that while toxic to catecholamine cells, Mn^{+2} has the potential to simultaneously upregulate biogenic amine biosynthesis.

1131 METHYLMERCURY ALTERS GLUTAMINE SYNTHETASE PROTEIN LEVELS IN NEONATAL RAT CORTICAL ASTROCYTE CULTURES.

J W Allen and M Aschner. *Department of Physiology and Pharmacology, Wake Forest University School of Medicine, Winston-Salem, NC, USA.*

Glutamine synthetase (GS, EC 6.3.1.2) is a glial specific enzyme localized largely in astrocytes. GS is responsible for detoxification of NH_4^+ in the brain via its ligation to glutamate, forming the non-excitotoxic amino acid glutamine. Inhibition of GS activity produces neurodegeneration likely due to increased levels of NH_4^+ and glutamate, decreased glutamine levels, or both. Previous in vitro studies suggest mercurials inhibit GS activity. Since methylmercury (MeHg) preferentially accumulates in astrocytes, we examined its effect on GS, as a potential mechanism for MeHg-induced neurotoxicity. Primary neonatal rat cortical astrocyte cultures (20-24 days in vitro) were treated with 0.5, 1, or 2 μM MeHg for 0 to 48 hours. Total cellular proteins were collected and immunoreactive GS protein levels were determined by Western analysis. MeHg initially decreased GS protein levels with the largest decrease (~ 50%) occurring at 12 hrs. By 24 hrs, protein levels had

nearly returned to baseline, and by 48 hrs GS protein levels had increased to ~ 50% above baseline. The initial decrease in GS protein levels may be related to MeHg-induced oxidative damage that renders it more susceptible to proteolytic degradation. The ability of astrocytes to increase GS protein levels at 48 hrs despite continued exposure to MeHg might be due to their capacity to increase intracellular buffering systems for MeHg or reactive oxygen species, or both. (Supported by ES07331.)

1132 TRANSFECTION OF ASTROCYTES WITH METALLOTHIONEIN-I INCREASES THEIR RESISTANCE TO METHYLMERCURY-INDUCED CYTOTOXICITY.

M Aschner, C P Yao, D R Conklin, and J W Allen. *Department of Physiology and Pharmacology, Wake Forest University School of Medicine, Winston-Salem, NC.*

Metallothionein-I (MT-I) was expressed in neonatal rat primary astrocyte cultures and an astrocytoma cell line by pGFAP-MT-I plasmid transfection under the control of the astrocyte-specific glial fibrillary acidic protein (GFAP) promoter. Following transient transfection of the pGFAP-MT-I plasmid, MT-I mRNA and MT-I protein levels were determined by northern blot and immunoprecipitation analyses, respectively. The ability of cells overexpressing MT-I to withstand acute methylmercury (MeHg) treatment was measured by the release of preloaded $Na_2{}^{51}CrO_4$, an indicator of membrane integrity. Transfection with the pGFAP-MT-I plasmid led to increased mRNA (2.5 fold in astrocytes and 7.4 fold in astrocytomas) and MT-I protein (2.4 fold in astrocytes and 4.0 fold in astrocytomas) levels compared with their respective controls. Increased expression of MT-I was associated with attenuated release of $Na_2{}^{51}CrO_4$ upon MeHg (5 μM) treatment. These results demonstrate that MT-I can be highly expressed both in primary astrocyte cultures and astrocytomas by pGFAP-MT-I plasmid transfection, and lend credence to the hypothesis that increased expression of MT-I affords protection against the cytotoxic effects of MeHg. Taken together, the data suggest that MT offer effective cellular adaptation to MeHg cytotoxicity.

1133 MEHG-INDUCED CHANGES IN MITOCHONDRIAL TRANSMEMBRANE POTENTIAL AND MITOCHONDRIAL MASS IN RAT EMBRYONIC CNS CELLS.

S Lu, S Kirchner, and E M Faustman. *University of Washington, Seattle, WA.*

Human and animal evidence suggests that the developing central nervous system is more sensitive to methylmercury (MeHg) exposure compared to adults. In previous studies we have shown MeHg (0-4 M, 0-24 hr) mediated gene induction of P21, Gadd 53 and mitochondrial cytochrome c oxidase subunit I (COX I) genes and cell cycle inhibition in rat embryonic CNS cells. Mitochondria are known to be a target for MeHg, and exposure can decrease both mitochondrial transmembrane potential ($\Delta\psi$) and intracellular ATP. Using confocal laser scanning microscopy, we examine changes in mitochondrial transmembrane potential and mitochondrial mass using the mitochodria-specific fluorochromes CMX-rosamine and MitoTracker Green, respectively, in MeHg exposed primary rat embryonic CNS cells. Cells were exposed to MeHg (0-2 μM) for either 8 hr or 24 hr. MeHg caused a dose-related decrease in $\Delta\psi$ over time and a dose-dependent increase in the mitochondrial mass over time. While the activity of COX did not change following MeHg exposure in this study, the expression of COX I is known to increase from previous studies. ND1, another mitochondrial gene was induced by exposure to MeHg for 24 hr, but no change was observed at 8 hr. Results suggest that MeHg decrease mitochondrial transmembrane potential and increase mitochondrial mass, which may be due to the increased mitochondrial number or swelling of mitochondria or both. (This research supported by US EPA grant R825358.)

1134 PROTECTIVE EFFECT OF CYCLOSPORIN A ON METHYLMERCURY (MeHg) -INDUCED CELL DEATH IN CEREBELLAR GRANULE CELLS.

B Maldonado, D M Autio, M S Marty and W D Atchison. *Dept. Pharm. Tox., Mich. State Univ., E. Lansing, MI.*

Cerebellar granule cells are particularly sensitive to degeneration following exposure to MeHg. MeHg alters Ca^{2+} homeostasis in granule cells resulting in increases of intracellular calcium ($[Ca^{2+}]_i$); MeHg-induced increases in $[Ca^{2+}]_i$ appear to contribute to granule cell mortality. Intracellular stores including mitochondria contribute to this increase in $[Ca^{2+}]_i$. Recent studies have shown that Cyclosporin A (CsA), an immunosuppressive cyclic endecapeptide which prevents the mitochondrial permeability transition, can delay the increase of $[Ca^{2+}]_i$ induced by MeHg in granule cells in culture. In the present study, we examined if CsA, at concentrations which prevent MeHg-induced elevations in $[Ca^{2+}]_i$ will protect cerebellar granule cells from MeHg-induced cell death. Granule cells were isolated from 7 day neonatal rats and cell viability was determined after 6-8 days *in vitro* using the Live/Dead Viability/Cytotoxicity Assay. Cells were exposed to MeHg concentrations of 0.2 μ M for 76 min, 0.5 μ M for 45 min, 1 μ M for 38 min and 2 μ M for 30 min. These MeHg exposure conditions induce characteristic $[Ca^{2+}]_i$ elevations in granule cells. At 30 min after MeHg exposure, cell viability remained unchanged; however, by 24 hrs after cessation of MeHg exposure, viability decreased to 78% in 0.2 μ M MeHg, 49% in 0.5 μ M MeHg, 16% in 1 μ M MeHg, and 9% in 2 μ M MeHg. In contrast, 10 min preincubation with 5.0 μ M CsA followed by MeHg exposure, protected granule cells from MeHg-induced cell mortality at 24 hr post-exposure at concentrations of 0.2 μ M and 0.5 μ M MeHg. Simultaneous incubation with CsA and MeHg produced the same protective effect. Control cells exposed to CsA for 10 min showed no immediate change in viability, but at 24 hr exhibited a decrease in cell viability at concentrations of 1.0 μ M and higher, suggesting that CsA itself can be cytotoxic. These results suggest that CsA may protect granule cells from MeHg-induced cell death by inhibiting the mitochondrial transition. (Supported by NIH grant ES03299.)

1135 EVIDENCE FOR INDUCTION OF THE MITOCHONDRIAL PERMABILITY TRANSITION PORE BY METHYLMERCURY (MeHg) IN RAT CEREBELLAR GRANULE CELLS.

T L Stringfellow and W D Atchison. *Dept. Pharm. and Tox., Mich. State Univ., E. Lansing, MI.*

The mitochondria permeability transition pore (MTP) is an inducible pore located on the inner mitochondrial membrane, which forms and opens under conditions of high matrix Ca^{2+} and mitochondrial membrane depolarization. MeHg causes release of intracellular Ca^{2+} stores followed by influx of extracellular Ca^{2+}, and mitochondrial depolarization reportedly results from MeHg exposure. Previous experiments demonstrated that the potent MTP inhibitor cyclosporin A (CsA) significantly delays the time-to-onset of both intracellular and extracellular Ca^{2+} phases of MeHg-induced increases in $[Ca^{2+}]_i$. Thus, we hypothesized that MeHg induces the MTP. We used single cell microfluorimetry to monitor changes in mitochondrial membrane potential (Ψ_m) of neonatal rat cerebellar granule cells in culture exposed to MeHg. Fluorescence from the potentiometric dye TMRE was measured continuously during a 10 min pretreatment with 5 μM CsA and a 45 min treatment with 0.5 μM MeHg. MeHg alone caused a significant, irreversible decrease in TMRE (tetramethylrhodamine ethyl ester) fluorescence, from 100% to 8± 2% in 45 min. Pretreatment with CsA reduced the amount of depolarization (to 43± 8% in 45 min) and delayed its time-to-onset. Use of an EGTA-containing buffer provided similar results for both the MeHg-alone and CsA-pretreated cells, indicating that the loss of mitochondrial membrane potential is not dependent on $Ca^{2+}{}_e$. These results suggest that mitochondria undergo a permeability transition in response to MeHg exposure, which is delayed but not prevented by exposure to CsA. (Supported by NIH grant ES03299.)

1136 EFFECTS OF METHYLMERCURY (MeHg) ON REGULATION OF INTRACELLULAR CALCIUM IN RAT CEREBELLAR NERVE TERMINALS.

S B K Stoughton and W D Atchison. *Dept. Pharm. Tox., Mich. State Univ., E. Lansing, MI.*

MeHg is a prominent environmental neurotoxicant with pronounced effects in the cerebellum, especially on granule cells. The effects of MeHg likely result from a variety of cellular actions; one mechanism may involve MeHg -induced increases of intracellular calcium concentration ($[Ca^{2+}]_i$) leading to Ca^{2+} -mediated cell death. The purpose of the present study was to examine the sensitivity of isolated nerve terminals (synaptosomes) of rat cerebellum to changes in $[Ca^{2+}]_i$ induced by MeHg. Cerebellar synaptosomes were isolated, loaded with the Ca^{2+} fluorophore fura-2, and fluorescence was monitored continuously using alternating excitation at 340 and 380 nm. The ratio of emitted fluorescence at 510 nm was calculated before and during exposure to MeHg (5-50μ M). MeHg caused a biphasic increase in fluorescence ratio- indicative of an elevation of $[Ca^{2+}]_i$. The first phase occurred within 10 sec of MeHg application and the second after 1 min. Removal of Ca^{2+} from the medium didn't affect the first phase, but completely ablated the second phase, indicating that the second phase arose from entry of extracellular Ca^{2+}. A significant increase in fluorescence ratio occurred at concentrations of MeHg $\geq$ 6.5μ M for both phases. In contrast, previous experiments using

cortical terminals showed that MeHg did not significantly affect $[Ca^{2+}]_i$ at concentrations < 25 μ M at 1 min. Thus, cerebellar nerve terminals appear to be more sensitive to the action of MeHg to disrupt Ca^{2+} regulation than are cortical terminals. Pretreatment with ω -conotoxin MVIIC (0.5 μ M) and ω -Aga toxin IVA (10 and 100nM), peptide toxins which block Q- and P-type Ca^{2+} channels respectively, caused decreases in both phases, suggesting that MeHg may enter the cell, in part through P- and/or Q- type Ca^{2+} channels. (Supported by NIH Grant ES03299.)

1137 EVALUATION OF SENSORY EVOKED POTENTIALS IN LONG EVANS RATS GESTATIONALLY EXPOSED TO MERCURY (Hg^0) VAPOR.

D W Herr[1], S M Chanda[2], J E Graff[1], O Karca[1], R P Beliles[3], and D L Morgan[2]. [1]*NHEERL/NTD, US EPA, RTP, NC, USA;* [2]*Laboratory of Toxicology, NIEHS, RTP, NC, USA;* [3]*NCEA, US EPA, Washington, DC.*

This study assessed sensory function following gestational exposure to mercury (Hg^0) vapor. Pregnant Long Evans dams were restrained and nose-only exposed to 0 (n = 12) or 4 mg/m³ Hg^0 vapor (n = 10) for 2 hr/day over gestational days 6 – 15. One male and one female offspring from each dam were allocated for electrophysiological evaluation of sensory function. At 19 - 23 weeks of age, the animals were surgically implanted with epidural screw electrodes. The following endpoints were quantified about 1 week after surgery: flash and pattern visual evoked potentials (0.08, 0.16, 0.32 cpd), brainstem auditory evoked potentials (rarefaction click, 4, 16, 64 kHz), cortical and cerebellar somatosensory evoked potentials, and ventral caudal tail nerve compound nerve action potentials and nerve conduction velocity. Three intensities were used for each stimulus condition. No significant treatment-related effects were indicated on the animal's body weight, colonic temperature, tail nerve temperature, nerve conduction velocity, cortical or cerebellar somatosensory potentials, flash evoked potentials, pattern evoked potentials, or brainstem auditory evoked responses. Although not highly statistically significant, there was an apparent slight decrease in amplitudes and increase in latencies of peaks of compound nerve action potentials in male animals after Hg^0 exposure. The data indicate that gestational exposure to 4 mg/m³ Hg^0 produced minimal changes in adult sensory electrophysiology. However, a small change in peripheral nerve function, of unknown biological significance, cannot be excluded.

1138 EFFECTS OF METHYLMERCURY CHLORIDE AND MERCURIC CHLORIDE ON NEURITE OUTGROWTH AND CELL VIABILITY IN PC-12 CELLS.

D K Parran[1], W R Mundy[2] and S Barone Jr[2]. *Curriculum in Toxicology, UNC, Chapel Hill, NC;* [2]*Neurotoxicology Division, US EPA, Research Triangle Park, NC.*

Rat pheochromocytoma (PC-12) cells differentiate to resemble sympathetic neurons upon exposure to nerve growth factor (NGF) making them a popular model for the study of neuronal development. We examined the effects CH_3HgCl or $HgCl_2$ on neurite outgrowth and cell viability using undifferentiated (unprimed) and differentiated (primed) PC-12 cells. When unprimed PC-12 cells are incubated with 50 ng/ml of NGF for 7 days (priming period), neurite growth was observed as early as 48 hours after exposure and increased throughout the priming period. Once primed, PC-12 cells can be replated and neurite outgrowth can be assessed relatively acutely (6-24 hours). At 24 hours, the EC_{50} for inhibition of neurite outgrowth in primed PC-12 cells in the presence of NGF for CH_3HgCl was approximately 0.02-0.03 μM, and approximately 0.1-0.3 μM for $HgCl_2$. In the absence of NGF, neurite outgrowth is low in controls, with little effect of CH_3HgCl or $HgCl_2$ noted. The mercurial compounds had opposite effects on neurite outgrowth in unprimed PC-12 cells as compared to primed PC-12 cells. At low concentrations (0.01-0.1 μM), both mercurial compounds appear to initiate neurite outgrowth in the presence or absence of NGF. In addition to neurite outgrowth, cell viability was assessed in parallel cultures. The EC_{50} for cytotoxicity of CH_3HgCl in both primed and unprimed PC-12 cells was approximately 1-3 uM. In the primed and unprimed PC-12 cells, the EC50 $HgCl_2$ was approximately 2-3 μM. These results show that cytotoxicity occurred at concentrations that were 10 fold higher than the EC_{50} for inhibition of neurite outgrowth, suggesting that the mercurial compounds may act specifically on the process of differentiation. (DKP was supported by NIEHS Training Grant T32ES07126.)

1139 LEAD ENHANCES NGF-INDUCED NEURITE OUTGROWTH IN PC12 CELLS VIA ENHANCED MAP KINASE ACTIVATION.

T M Williams[1], A M Ndifor[1], J T Neary[2], R R Reams[1]. [1]*Florida A&M University, College of Pharmacy and Pharmaceutical Sciences, Tallahassee, FL, USA;* [2]*Veterans Affairs Medical Center, Miami, FL, USA.* Sponsor: M Kolta.

Rat pheochromocytoma (PC12) cells were cultured for four to six days under the following conditions: in the presence of no toxins; various concentrations of lead acetate; nerve growth factor (NGF); and in the presence of lead acetate and NGF. Lead acetate enhanced NGF-induced neurite outgrowth in PC12 cells in a concentration dependent manner and promoted the formation of multiple neurites per cell. However, lead acetate alone did not cause neurite outgrowth in PC12 cells. Further studies showed a correlation between the effect of lead acetate on enhanced NGF-induced neurite outgrowth and enhanced NGF-induced mitogen activated protein (MAP) kinase activation. Lead acetate in the presence of NGF caused a significant concentration dependent increase in MAP kinase activation at 24 and 48 hour lead exposure times. The identity of the kinase being activated was confirmed to be MAP kinase by Western blot analysis. Thus, lead acetate can play a role in MAP kinase intracellular signaling initiated by NGF, and therefore cause amplified neurite outgrowth in PC12 cells. (This work was supported by The Department of Veterans Affairs and NIEHS Grant #5K14 ES00286-02.)

1140 LEAD ACETATE MODULATES THE *IN VITRO* PRODUCTION OF NITRIC OXIDE BY C6 GLIAL CELLS.

M A Mitchell, M Chen and A S Heiman. *Florida A&M University College of Pharmacy and Pharmaceutical Sciences, Tallahassee, FL, USA.*

The CNS neurotoxic effects of lead (Pb) are well documented, however, its molecular toxicity targets have not been clearly delineated. The present investigations were conducted to test the hypothesis that Pb exposure may perturb signal transduction systems leading to nitric oxide (NO) production by astroglial cells. C6 glioma cells were cultured in DMEM/no phenol red/2.5% fetal calf serum and stimulated with TNF-α (10 ng/ml) in combination with IL-1β (1 ng/ml), IFN-γ (100 U/ml) or LPS (1μg/ml). Generation of NO was quantified as the stable nitrite endproduct by the Griess reaction. C6 cells generated 12.3-13.8 nmol nitrite/10^6cells/24hr. Pretreatment with the nitric oxide synthase inhibitor Nω-nitro-L-arginine methyl ester (1-100μM) concentration-dependently inhibited NO production. Cells were then exposed to added lead acetate (100 nM-5 μM) for 3 hr and stimulated with the cytokine pairs for 24 hr. Pb concentration-dependently inhibited generation of NO up to 90% while no inhibition was noted in sodium acetate treated controls. In repeated experiments, calculated lead acetate IC_{50} (the concentration which inhibited NO generation by 50%) ranges were: 1.95-2.81 μM for TNFα + IL-1β, 3.55-4.6 μM for TNFα + IFN-γ and 1.64-2.41 μM for TNFα + LPS. The effects of Pb were not due to loss of cell viability or decreases in cell number. The central focus of ongoing investigations is identification of the molecular toxicity target(s) in these signal transduction pathways. Glial cells provide critical supportive and nutritive functions for neurons. Glial cells are a source of NO which is now recognized as a major messenger molecule in the CNS where it may function in neurotransmission, regulation of cerebral blood flow, and modulation of synaptic plasticity and sensory signaling. Perturbation of the NO generating pathways in the CNS may contribute to neurophysiologic changes noted following occupational or environmental exposure to Pb. (This research was supported in part by National Institutes of Health Grants RR08111 and RRO3020.)

1141 UPREGULATION OF TH MRNA EXPRESSION BY INORGANIC LEAD IN PC12 CELLS AND RAT LOCUS COERULEUS.

X Tian, H Pan, X Sun, and J B Suszkiw. *Dept. of Molecular & Cellular Physiology, University of Cincinnati, Cincinnati, OH.*

We have previously reported that inorganic lead (Pb^{2+}) causes an increase of tyrosine hydroxylase (TH) activity in the hippocampus of rat in vivo and in PC12 cells in vitro. In the present study we investigated the effects of Pb on TH mRNA expression in rat locus coeruleus and in PC12 cells as a model system. The results of competitive RT-PCR showed that TH mRNA level was increased by 152% in locus coeruleus of rat exposed to 0.2% lead acetate from gestational day 16 through postnatal day 21. Exposure of PC12 cells to 0.5 μ M Pb^{2+} for 2 hr increased TH mRNA level by 28%. Furthermore, in PC12 cells, the same Pb treatment resulted in 90% enhance-

ment of TH gene transcription rate and 180% increase of the expression of chloramphenicol acetyltransferase (CAT) reporter gene construct with the 5' flanking region of the TH promoter (bases –272 to +27). These results indicate that Pb^{2+}-induced increase in TH mRNA expression reflects, at least in part, the increase of gene transcriptional rate. The enhancement of the TH gene transcriptional rate may involve lead responsive element(s) in the proximal promoter region of 272 bases of TH gene. (This work was supported by NIEHS grants ES09516 and ES06365.)

1142 THE EFFECTS OF LOW LEVEL POSTWEANING LEAD EXPOSURE ON TYROSINE HYDROXYLASE.

D J O'Mara[1], A W Tank[2] and D A Cory-Slechta[1]. *Departments of [1]Environmental Medicine and [2]Pharmacology and Physiology, University of Rochester School of Medicine and Dentistry, Rochester, NY.*

Several recent studies from our lab and others suggest that one possible mechanisms for the detrimental effects of lead (Pb) on the CNS could be an alteration in dopaminergic (DA) systems. This study examined the effects of low level postweaning Pb exposure on tyrosine hydroxylase (TH), the rate limiting enzyme in the production of DA, in both the nigrostriatal and mesolimbic DA systems. Male Long Evans rats were exposed to 0, 100 or 500 ppm Pb acetate (n=8, 8, 8) in drinking water from 21 days of age until 171 days of age. These exposures produced mean blood lead levels of .44, 16.7 and 62.34 ug/ dl, respectively. Non-perfused brains were extracted and punches were taken to remove the SNc and VTA, while the NAcc and Str were extracted surgically. Due to the small amount of tissue, VTA samples were pooled (2 brains per sample) creating a VTA n=4 for each exposure. RNase protection assays were performed on the VTA and SNc samples to determine TH mRNA levels, while enzyme assays and western blotting were performed on the NAcc and Str samples to determine TH activity and TH protein levels. Pb exposure did not produce significant changes in either the SNc or VTA. However, there was an increase in TH activity in the NAcc with increasing Pb exposure (significance obtained between the 0 and 500 groups), while the Str showed no lead effect. There was a trend towards increasing amounts of TH protein with increasing Pb exposure, yet only in the Str were these changes significant (between the 0 and 500 ppm groups). These data suggests that while lead does not increase the amount of TH-RNA made by the dopaminergic cell bodies, it alters TH enzyme activity and protein levels in the dopamine nerve terminals, and may do so differently in the two dopamine systems. This could possibly be due to an increase in TH synthesis, a stabilizing effect on the TH protein, increased affinity for the biopterin cofactor or a combination of the three. ES07026, ES05017, ES02047.

1143 TIME COURSE AND REGIONAL SPECIFICTIY OF LEAD-INDUCED ALTERATIONS IN DOPAMINE CONTENT.

Y Gedeon and A L Jadhav. *College of Pharmacy & Health Sciences, Texas Southern University, Houston, TX, USA.*

Lead (Pb) is reported to produce differential, sometimes opposing effects on the mesocorticolimbic (nucleus accumbens (NA), frontal cortex (FC), and hippocampus (HIP)), and the nigrostriatal (striatum, brain stem and hypothalamus) dopamine (DA) metabolism (Kala and Jadhav 1994). This study sought to determine the time-dependent effects of Pb on the dopamine content of these systems during the postweaning period. Twenty-one day old male Long Evans rats exposed to 0 ppm (as sodium acetate in drinking water) and 50 ppm Pb (as lead acetate in drinking water) were sacrificed at 0, 30, 60 and 90 days. Blood lead analysis by atomic absorption spectrophotometry showed a significant difference between the control and lead-treated rats at each time point except at day 0, without any significant difference between day 30, 60, and 90, indicating that blood lead stabilizes to the Center for Disease Control and Prevention's threshold level for elevated lead burden for children by day 30 (10 μg/dl). The evaluation of tissue dopamine contents by high performance liquid chromatography indicated complex time- and region-specific changes in dopamine content: NA DA (% change from control) contents increased significantly in lead treated rats at day 30 and then decreased gradually at day 60 and 90; HIP DA contents increased at day 60 and at day 90; and FC DA contents showed insignificant decreases at day 30, 60 and 90. These data further support Pb's opposing effects within the mesocorticolimbic system and suggest time-dependent compensatory changes between NA and HIP. These results also demonstrate the critical need to explore the time course of effects of low lead exposure in greater detail. (Supported by ATSDR Cooperative Agreement # U50/ATU 398948.)

1144 INHIBITION OF PKC ACTIVITY IN RATS EXPOSED TO SUB CHRONIC LOW LEVEL LEAD (Pb).

G T Ramesh and A L Jadhav. *College of Pharmacy and Health Sciences, Texas Southern University, Houston, TX, USA.*

Our previous studies have demonstrated that low level exposure to Pb leads to specific changes in indices of operant behavior, i.e., fixed interval (FI) and fixed ratio (FR) in rats. Protein kinase C (PKC) is an important enzyme in mediating cellular transduction mechanisms and neurotransmitter release. Additionally, phosphorylation of brain proteins by PKC plays an important role in regulation of neuronal plasticity, a physiological basis of learning and memory. Under conditions which produced changes in operant behavior, we conducted studies to assess the effects of low level Pb exposure (50 ppm) for 90 days on PKC activity in various brain regions of male Long Evans rats. Results of these experiments indicate that significant region-specific Pb accumulation was associated with changes in PKC activity. These results indicate that Pb-PKC interactions may be important in learning deficits associated with low level Pb exposure. (Supported by ATSDR Cooperative Agreement # U50/ATU 398948.)

1145 ROLE OF PROTEIN KINASE C ACTIVATION IN LEAD ACETATE-INDUCED DNA SYNTHESIS IN 132 1N1 HUMAN ASTROCYTOMA CELLS.

H Lu, M Guizzetti, and L G Costa. *Department of Environmental Health, University of Washington, Seattle, WA.*

Lead is known to be a potent activator of protein kinase C (PKC) and the PKC signal transduction system may modulate the proliferation rate of gliomas. This study was undertaken to investigate the ability of lead to activate PKC and its downstream events in 132 1N1 human astrocytoma cells. Treatment with 50 μM lead acetate for 1 hour was able to induce PKCα translocation as evidenced by Western Blot analysis and enzyme activity assay, while PKCε was not affected. Lead treatment (1 μM to 100 μM for 24 hour), resulted in a concentration- and time-dependent increase in DNA synthesis up to 300% of basal level, as measured by ^{3}H-thymidine incorporation assay. No cytotoxicity was observed, as measured by LDH release assay. The effect of lead was blocked by two PKC inhibitors, bisindolylmaleimide and staurosporine, and also by down-regulation of PKC by a pretreatment with the phorbol ester PMA. Flow cytometric analysis using double staining with bromodeoxyuridine(Brdu)-quenchable Hoechst 33258 and ethidium bromide showed that treatment with lead or PMA stimulated the G_0/G_1 to S/G_2 phase transition resulting in increased percentage of cells in the S/G_2 phase (30% in treated group vs. 4% in control group). These results suggest that lead stimulates DNA synthesis and cell-cycle progression in human astrocytoma cells through a PKC-dependent mechanism. (Supported in part by grant ES07033.)

1146 LEAD AFFECTS EXPRESSION OF ZIFF268 IN RATS.

K Kim, G Goldstein, and J Bressler. *Kennedy-Krieger Institute, Baltimore, MD.*

Exposure to lead is associated with a significant impairment of cognitive function and a delay in behavioral development. However, the molecular and biochemical mechanism of lead toxicity is not clear. Transcriptional regulation of genes is one of the pivotal mechanisms of neuronal responses to many stimuli underlying neural plasticity. The immediate early response gene (IEG) zif268 encodes a zinc finger family transcription factor that has been shown to be a third messenger in neural plasticity. In our previous study, lead increased expression of IEGs including zif268, c-fos and c-jun in PC12 cells. Here, we investigated the effect of lead on expression of zif268 by in situ hybridization in brains of Long-Evans rats exposed at birth to 0.2% lead acetate in the drinking water. Exposure to lead resulted in higher levels of zif268 expression in the somatosensory cortex but not in the striatum, hippocampus, occipital cortex or cerebellum in 28-day old animals. Electroconvulsive seizure (ECS) was examined to study the effect of lead on the induction of zif268 mRNA expression. The expression of zif268 mRNA peaked within 30 min after ECS in nonexposed rats, dramatically declined at 1h, and returned to baseline levels within 4h. In lead-exposed rats, however, the levels of zif268 mRNA remained elevated in the dentate gyrus 1 h after ECS but declined to baseline levels at 4 h. This effect of lead was specific to the dentate gyrus since the time course of zif268mRNA decline did not change in other areas of brain, including the CA1, CA2, CA3 regions of the

hippocampus. Similar observations were made in 42-day old animals, and, in addition, ECS induced expression of zif268 in the cerebellum was also not affected by lead. These results suggest that exposure to lead interferes with the regulation of zif268 mRNA levels in specific areas of the brain.

1147 THE DNA-BINDING CHARACTERISTICS OF A SYNTHETIC APO-ZINC FINGER PEPTIDE VERSUS A rhSP1 PROTEIN IN THE PRESENCE OF VARIOUS DIVALENT METALS.

M Razmiafshari and N H Zawia. *Department of Pharmacology, Meharry Medical College, Nashville, TN, USA.*

The zinc finger motif belonging to the Cys_2-His_2 family provides structural framework for a number of critical proteins, which are essential for cellular function. This motif requires Zn(II) for its proper structural folding and activity. Perturbations in this domain either by metal competition or displacement could result in disruption of neurobiological functions, such as altered DNA-binding, changes in receptor function and channel properties. To determine whether these domains are potential targets for heavy metal perturbations, the DNA-binding activity of a rhSP1 protein and a synthetic apo-zinc finger peptide, of the type present in the transcription factor SP1, in the presence of several divalent metal ions, were analyzed using the electrophoretic mobility shift assay. Results indicate that metals with similar physiochemical configurations to Zn (Cd, Hg, and Pb) were able to complex with the apo-peptide and bind to their cognate DNA consensus sequence with high affinity and specificity. These same metals inhibited the DNA-binding activity of rhSP1 protein, which already contains the bound zinc, in a concentration-dependent manner. Both Pb(II) and Cd(II) were more detrimental to the DNA-binding of the intact rhSP1 than all the other metals tested. Class IIA metals such as calcium neither exhibited the proper peptide complexation nor did they bind DNA or interfere with rhSP1 DNA-binding ability. Therefore, we postulate that environmental heavy metals selectively modulate zinc finger proteins through structural alterations of their zinc finger motifs thus ultimately altering their function.

1148 Pb-INDUCED CHANGES IN SP1 FUNCTION INVOLVE PKC BUT NOT MAPK SIGNALING PATHWAYS.

D S Atkins and N H Zawia. *Dept. of Pharmacology, Meharry Medical College, Nashville, TN, USA.*

Cognitive deficits have been shown to result from developmental lead (Pb) exposure and may involve modulation of genes crucial for growth and differentiation. A link in these events may be the zinc-finger transcription factor Sp1 and the second messenger protein kinase C (PKC). Previous experiments from this lab have shown that Pb alters Sp1 DNA-binding and protein levels as well as PKC activity. Growth factor receptors can result in activation of PKC, thereby, initiating the mitogen-activated protein kinase (MAPK) cascade and resulting in phosphorylation of nuclear transcription factors associated with growth and differentiation. The objective of the following study was to relate previously observed changes in Sp1 with these signaling cascades and to determine their cellular location. Rat pups were exposed lactationally to Pb or control water from postnatal day 1-20 (0.2% Pb acetate in the drinking water of the dam). Animals were sacrificed at various postnatal time points, and their cerebella and whole corticies were dissected. Western blots were performed on cytosolic, nuclear and membrane protein extracts to determine changes in PKC and MAPK expression. Both nuclear PKC and MAPK showed an increasing developmental profile in the cerebellum and cortex, however only PKC patterns were modulated by Pb. No developmental patterns or effects of Pb were seen with either protein in cytosolic fractions. However, cerebellar membrane PKC protein developmental profiles were modulated by Pb. These data suggest that the effects of Pb on nuclear Sp1 involve PKC but not MAPK.

1149 Pb TOLERANCE IN C6 RAT GLIOMA CELLS.

Y Qian, Y Zheng and E Tiffany-Castiglioni. *Department of Veterinary Anatomy and Public Health, Texas A&M University, College Station, TX.*

Astroglia serve as a depot or filter for Pb in the brain. A number of observation in cell culture indicate that astroglia are capable of adaptive responses or tolerance to the presence of intracellular Pb, including minimal effects on proliferation and viability, recovery of transiently depleted intracellular glutathione levels and buffering of intracellular Ca and Pb. C6 rat glioma cells resemble rat astroglia in culture in that both cell types accumulate Pb intracellularly from the medium. As such, C6 cells are a model for Pb accumulation by the brain. In the present study we examined a possible molecular mechanism for tolerance. Exposure of C6 cells for one week to 1 μM Pb acetate resulted in the increased abundance of a protein with the following characteristics on two-dimensional acrylamide gels: 71 kD with pI of 5.6. This protein matches HSP78 and GRP78 by protein microsequencing. The levels of five other proteins ranging in size from 37-41 kD with pIs of 6.0-6.8 declined. In addition, we isolated a 71 kD protein from Pb-exposed C6 cells by the use of a Pb-affinity column. This protein was strongly bound to Pb and could not be eluted by 500 mM imidazole unless 50 mM EDTA was applied. The protein sequence is unknown and is under investigation. These observation extend our previous results that most of the Pb retained by C6 cells is associated with high molecular weight soluble components of the cytosol, rather than with smaller components, such as glutathione or metallothionein.

1150 SYNAPTOTAGMIN AND OTHER C2-DOMAIN PROTEINS BIND LEAD WITH HIGH AFFINITY.

C M L Bouton and J Pevsner. *Kennedy Krieger Institute and The Johns Hopkins University School of Medicine, Baltimore, MD, USA.* Sponsor: J Bressler.

Lead (Pb^{++}) has been shown to increase presynaptic neurotransmitter release from nerve terminals, and this action may cause its neurotoxicological effects during development. It has also been demonstrated that Pb^{++} potently activates protein kinase C (PKC), possibly by binding to its C2 regulatory domain that mediates calcium-dependent phospholipid binding. We hypothesized that Pb^{++} increases neurotransmitter release by activating synaptotagmin, a synaptic vesicle protein with two C2 domains that is required for synaptic vesicle exocytosis. We demonstrated that Pb^{++} promotes synaptotagmin binding to acidic phospholipids (EC_{50} ~7 nM free Pb^{++}), about 300-fold more potently than calcium (EC_{50} ~2 uM). Mutagenesis of a critical aspartate in synaptotagmin's C2A domain reduced both Pb^{++} and Ca^{++} binding to the protein. Pb^{++} (100 nM) partially protected endogenous synaptotagmin in rat brain extracts from tryptic cleavage in a manner similar to that of 10 uM Ca^{++}, further establishing that synaptotagmin is a high-affinity Pb^{++}-binding protein. We next investigated whether Pb^{++} interacts with C2 domain proteins in general. Pb^{++} promoted the binding of PKCα, synaptotagmin I, and synaptotagmin III C2A to phospholipids, but not the binding of rabphilin 3A, synaptotagmin III C2B, or Munc-13. Thus, Pb^{++} may bind and activate a subset of the dozens of proteins known to contain C2 domains, and its effects on synaptotagmin in particular may disrupt synaptic transmission during development.

1151 REGION-SPECIFIC EFFECTS OF Pb^{2+} EXPOSURE ON CENTRAL CHOLINERGIC AND CATECHOLAMINERGIC PATHWAYS.

H Bielarczyk, Y Morozov, M De, and J B Suszkiw. *Department of Molecular and Cellular Physiology, University of Cincinnati, College of Medicine, Cincinnati, OH.*

We previously reported that lead exposure of perinatal rats from E16 to PN21 caused a marked 20-40 % reduction in expression of ChAT activity in the septum and hippocampus and 50-90 % increase of TH activity in the hippocampus without alternations in the septal activity (Brain Res.1996). In this study the effects of Pb exposure on ChAT and TH activities were compared in different regions of the brain. The rats were maternally lead-exposed by giving 0.2 % lead acetate in drinking water to dams from one week before parturition through weaning at postnatal day 21 (PN21). Lead-exposure effected depression of ChAT activities in the septum (29%), hippocampus (24%), nucleus basalis of Meynert (27%), parietal cortex (37%), frontal cortex (21%), preoptic magnocellular nucleus (32%), striatum (24%), and spinal cord (14%), in contrast Pb had no influence on ChAT activities in the horizontal diagonal band, olfactory bulb, thalamus and cerebellum. Pb exposure resulted in increase of TH activity in the hippocampus (49%), substantia nigra (62%), striatum (18%), and locus coeruleus (137%) whereas TH activities in the septum, frontal and parietal cortices were not significantly altered. These results indicate that early developmental lead exposure decreases the ChAT activity in cholinergic areas Ch1, Ch2 and Ch4 but has slight or no effect on Ch3, Ch5, and Ch6. In contrast to its effect on ChAT activity, Pb increases activity of tyrosine hydroxylase in select catecholaminergic pathways i.e. locus coeruleus –hippocampus and substantia nigra-striatum. This suggest that Pb exposure can induce imbalance between cholinergic and catecholaminergic systems in the brain. (Supported by NIEHS grant # ES 06365.)

1152 LEAD NEUROTOXICITY IS ASSOCIATED WITH DNA FRAGMENTATION AND INCREASED BY GLUTAMATE.

J Loikkanen[1], J Naarala[2] and K Savolainen[1,3]. [1]*Department of Pharmacology and Toxicology, University of Kuopio, Kuopio, Finland;* [2]*Department of Environmental Sciences, University of Kuopio, Kuopio, Finland;* [3]*Finnish Institute of Occupational Health, Department of Occupational Hygiene and Toxicology, Helsinki, Finland.*

The role of glutamatergic neuronal stimulation, the production of reactive oxygen species (ROS) and DNA fragmentation in lead neurotoxicity was investigated in mouse hypothalamic GT1-7 cells. The cells were stimulated with 1 mM glutamate, 1 mM lead acetate (PbAc) and their combination for 3, 6, 12, 24, 48 or 72 hours in a cell incubator. The production of ROS and cell viability were measured at each time point in 48-well plates by using fluorescent probes, dichlorofluorescin diacetate and propidium iodide, respectively. DNA fragmentation was studied by isolating the fragmented DNA from cells cultured in 6-well plates. Isolated DNA was subjected to agarose gel electrophoresis in which typical DNA ladder formation is seen if DNA fragmentation had occurred. Glutamate alone increased ROS production compared to control during 72 hours. However, glutamate did not have a significant effect on cell viability, and did not induce DNA fragmentation at any timepoint. PbAc alone or together with glutamate did not increase ROS production during exposure time of 72 hours. Cytotoxicity of PbAc was seen at 24 hours after the beginning of exposure, thereafter neurotoxicity of PbAc was also amplified by glutamate. At this same, and at later time points, PbAc alone and together with glutamate induced DNA fragmentation. These data suggest that neurotoxic effects of lead are mediated through mechanisms other than ROS production, and that glutamatergic neuronal stimulation increases lead neurotoxicity. Because lead can mimic calcium in cellular processes, it seems possible that lead enters neuronal cells upon glutamate-induced excitation. Thus, glutamatergic receptor stimulation can be an important factor in augmented lead neurotoxicity. Moreover, lead-induced cell death may partially be mediated through apoptosis. (Supported by The Academy of Finland and University of Kuopio.)

1153 NMDAR-2A SUBUNIT PROTEIN EXPRESSION IS REDUCED IN THE DEVELOPING RAT HIPPOCAMPUS BY EXPOSURE TO Pb^{2+}.

T R Guilarte and M K Nihei. *Dept of Environ. Health Sci., The Johns Hopkins University SHPH, Baltimore, MD, USA.*

The *N*-methyl-D-aspartate receptor (NMDAR) has been identified as a principal target for lead (Pb^{2+})-induced neurotoxicity. Age-dependent changes in NMDAR subunit gene expression have been observed in the hippocampus of rats chronically exposed to Pb^{2+} during development (Guilarte and McGlothan, Brain Res 790:98, 1998). These changes were present at blood Pb^{2+} levels ranging from 20-60 µg/dl. In the present study, littermates were used to determine whether the changes found in gene expression were reflected in protein levels. NR1, NR2A, and NR2B subunit protein levels were measured in rat hippocampus and cortex at postnatal days (PND) 7, 14, 21, and 28 by Western blot and densitometric analyses. A treatment effect was apparent for NR2A subunit protein expression in the hippocampus ($F_{1,28}$=10.224, p<0.01). NR2A subunit protein was reduced by 40%, 19%, and 27% from control levels in PND14, 21, and 28 Pb^{2+}-exposed rats, respectively. Mean comparisons within age groups indicated that rats at PND14 exhibited the most significant reduction of NR2A ($F_{1,8}$=32.53, p<0.001). These data concur with our previous data finding reduced NR2A mRNA in hippocampal pyramidal and granule cells of Pb^{2+}-exposed rats. Pb^{2+}-exposure during development had no effect on NR1 or NR2B subunit protein expression in the hippocampus at any age. No effect was observed on any subunit in the cortex at any age. The developmental profile of the NMDAR-2A subunit protein in the hippocampus is specifically changed by chronic exposure to Pb^{2+}. These data suggest that the composition of subunits comprising hippocampal NMDAR may be altered in Pb^{2+}-exposed rats. (Supported by ES06189 to TRG and T32 ES07141 to MKN.)

1154 DEVELOPMENTAL Pb^{2+}-EXPOSURE CHANGES NMDAR1 SPLICE VARIANT mRNA IN THE RAT HIPPOCAMPUS.

J L McGlothan and T R Guilarte. *Dept of Environ. Health Sci., The Johns Hopkins University SHPH, Baltimore, MD, USA.*

N-methyl-D-aspartate receptors (NMDARs) serve important roles in synaptic plasticity and long-term potentiation, an experimental model of learning and memory. We investigated the effects of chronic Pb^{2+} exposure on the expression of NMDAR1 splice variants in the developing rat hippocampus. The oligonucleotide probes NR1-a, NR1-b, NR1-1, NR1-2, and NR1-4 have been described previously (Laurie and Seeburg, J. Neurosci. 14:3180-3194). Pb^{2+}-exposure resulted in a robust increase in NR1-a mRNA throughout the rat hippocampus at postnatal day (PND) 14 (p<0.05). The NR1-b mRNA was increased in the CA1, CA2 and CA3 regions at PND21 (p<0.05). NR1-2 mRNA was increased at PND21 in all regions of the hippocampus except the CA3 region. Notably, expression of NR1-4 mRNA was reduced in the CA3 region ($F_{2,12}$=4.62, p<0.05) and throughout the pyramidal cell layer ($F_{2,12}$=3.896, p<0.05), also at PND21. No differences were detected in NR1-1 mRNA variant expression. These data indicate that individual splice variants of the NMDAR are selectively affected by developmental Pb^{2+} exposure in the rat hippocampus. Alternative splicing of NR1 mRNA provides molecular diversity in NMDAR assemblies and result in combinations that exhibit different pharmacological and electrophysiological properties. Pb^{2+}-induced changes in NR1 splice variant mRNA may ultimately alter NMDAR function during development. These studies support the hypothesis that NMDAR and specific NR1 splice variants are important targets for Pb^{2+}-induced neurotoxicity. (Supported by ES06189 to TRG.)

1155 ENHANCEMENT OF THE INHIBITORY POTENCY OF ZINC (Zn^{+2}) FOR THE RAT NMDA RECEPTOR CHANNEL IN THE PRESENCE OF LEAD (Pb^{+2}).

S M Lasley[1], M C Green[1] and M E Gilbert[2]. [1]*Univ. of Illinois College of Medicine, Peoria, IL USA;* [2]*U. S. EPA, NHEERL, Research Triangle Park, NC, USA.*

The NMDA subtype of glutamate receptor is widely recognized to be important in synaptic plasticity and cognitive function. Consequently, the effect of Pb^{+2} on this receptor has been one focus of attempts to define the bases of exposure-induced cognitive impairments. This study examined the effects of acute exposure *in vitro* to concentrations of free Pb^{+2} and/or Zn^{+2} on NMDA receptor channel function. Tritonized cortical membranes were prepared from adult male non-exposed rats, and binding measured in 50 mM Tris-acetate (pH = 7.0) with ^{3}H-MK-801 in the presence of saturating concentrations of glutamate and glycine. The potency of Pb^{+2} to inhibit the receptor channel (IC_{50} 0.55 uM) was 2.3-fold greater than that of Zn^{+2} (IC_{50} 1.28 uM). Dissociation of MK-801 from its binding site exhibited two-component kinetics, and both components were significantly slowed in the presence of Pb^{+2} or Zn^{+2}. To determine if Pb^{+2} inhibited the receptor channel by binding to the Zn^{+2} modulatory site Zn^{+2} inhibition curves (10^{-8} – 10^{-4} M Zn^{+2}) of MK-801 binding were determined in the presence of constant concentrations of Pb^{+2}. In contrast to the rightward shift of the inhibition curve expected for a competitive interaction, increasing constant levels of Pb^{+2} produced a concentration-dependent downward shift of the Zn^{+2} inhibition curve, indicating a non-competitive inhibition by Pb^{+2} with respect to that of Zn^{+2}. Furthermore, Zn^{+2} IC_{50} values significantly decreased (1.28 uM to 0.54 uM) as a function of increasing Pb^{+2} concentration. Analogous results were obtained when Pb^{+2} inhibition curves (10^{-8} – $10^{-5.5}$ M Pb^{+2}) were determined in the presence of constant concentrations of multiple levels of Zn^{+2}. In contrast to acute Pb^{+2} exposure *in vitro* however, Scatchard analyses in hippocampal tissue from animals chronically exposed to Pb in drinking water reflected an increase of MK-801 binding sites that was significant in the 0.2% Pb group. These results indicate that: 1) Pb^{+2} and Zn^{+2} exert their inhibition on the NMDA receptor via independent binding sites; and 2) inhibition of the receptor channel may be one factor in the up-regulation of MK-801 sites found in chronically exposed animals. (Supported by ES06253, NRC, and US EPA.)

1156 EXPRESSION OF THE NMDAR1 mRNA AND ITS RELATIONSHIP TO SP1 DNA-BINDING IN THE RAT HIPPOCAMPUS FOLLOWING DEVELOPMENTAL LEAD EXPOSURE.

M J Brydie, Z Cao, J G Townsel, and N H Zawia. *Depts. of Pharmacology and Physiology, Meharry Medical College School, Nashville, TN.*

Learning incapabilities are known to be produced by lead exposure. The N-methyl-D-aspartate R1 subunit (NMDAR1), which plays a significant role in learning and memory, contains several Sp1 response elements in its promotor region. Sp1, a zinc finger protein, is a transcription factor essential for transcribing genes that are needed for cellular growth and differentiation. Evidence in our laboratory suggests that lead alters Sp1 DNA-binding. The goal of these experiments was to correlate the developmental profile of Sp1 DNA-binding and NMDAR1 mRNA expression in control and lead exposed

animals. Animals were exposed lactationally to 0.2% lead acetate placed in the drinking water of the dam, from birth to weaning. Control animals were given regular water. Pups were sacrificed on postnatal days (PND) 3, 5, 10, 15, 20, and 30 and their hippocampi were dissected and used for RT-PCR analysis. In control animals, the expression of the NMDAR1 mRNA was found to be low on PNDs 3 and 5 and gradually increased with the highest levels observed on PND 20 and 30. The NMDAR1 mRNA in lead-exposed animals peaked on PND 10 and 15 and was decreased by PND 30. These results are consistent with the pattern of Sp1 DNA-binding previously reported by us. These findings suggest that lead may alter NMDA receptor expression via modulation of the function of Sp1 thereby contributing to cognitive deficits.

1157 EFFECT OF LEAD (Pb) ON TRANSTHYRETIN (TTR) AND THYROXIN IN HUMAN CEREBROSPINAL FLUID (CSF).

O Cheung[2], Y M Lu[1], G Y Lu[1], and W Zheng[2]. [1]*Dept. of Neurosurgery, Hangzhou First Hospital, Hangzhou, PRC;* [2]*Div. of Environmental Health Sciences, Columbia University, New York, NY, USA.*

TTR, a major thyroid hormone transport protein in the CNS, is mainly manufactured by the choroid plexus (CP) in brain. Our previous animal studies suggest that the sequestration of Pb in the CP is associated with a decrease in CSF TTR. The major objective of this study was to determine whether the status of thyroid hormone (T4) in the CSF was altered both as a function of CSF-Pb and CSF-TTR in humans. Seventy-nine CSF samples were collected from randomly-selected patients who were requested for clinical diagnosis of CSF chemistry. The samples were analyzed by AAS for Pb, and by RIA for TTR and T4. Results showed that CSF concentrations of TTR ranged 0.77-8.15 μg/mg of CSF proteins (3.33±0.36 μg/mg, Mean±SE, n=79); T4 ranged 0.10-6.7 ng/mg (1.50±0.19SE ng/mg, n=79); and Pb ranged 0.05-3.84 μg/dl (0.53±0.09SE μg/dl, n=59 of those above the detection limit). The linear regression analysis revealed that CSF TTR was positively associated with CSF T4 ($r=0.34$, $p<0.005$), which strengthens the role of TTR in T4 transport in the CNS. The decline in CSF TTR, however, was inversely associated with the rise in CSF Pb ($r=-0.31$, $p<0.01$). We further observed an inverse correlation between CSF T4 and CSF Pb ($r=-0.28$, $p<0.05$). While there was an age-related reduction in CSF TTR, the changes in CSF T4 or Pb did not seem to be age-associated. The current human data support our earlier observation from the animal work that Pb exposure appears to alter TTR levels in CSF, and further suggest that the alteration in CSF TTR may result in a disrupted thyroid hormone status in CSF. (Supported by NIEHS RO1 ES08146.)

1158 INTEGRATING ENVIRONMENTAL ISSUES ACROSS SUBJECTS.

B D Steinberg, B Schlegel, D Shields, L Hemminger, A R Gotsch and L Weidner. *Environmental and Occupational Health Sciences Institute, Piscataway, NJ, USA.* Sponsor: M A Gallo.

From increased health risks to determining where children can safely play, environmental health issues are becoming a large part of children's everyday lives. It is appropriate and relevant to use these issues to teach basic science, math, language arts, social studies and health concepts in schools. ToxRAP™ teaches K-9 students how to evaluate environmental health problems utilizing content and skills from many subject matters. Students apply the ToxRAP™ framework, which draws upon the practice of industrial hygiene and the risk assessment model used by the US Environmental Protection Agency, to recognize, evaluate and, when necessary, control contaminants. Through age-appropriate, hands-on, investigative activities, students develop critical thinking, decision making and problem solving skills needed to address the complex environmental health issues of today and, more importantly, tomorrow. This award-winning multidisciplinary curriculum is divided into three modules and can be easily integrated across subjects. Pilot test results showed that students could readily transfer the ToxRAP™ framework to other environmental health concerns in their lives. The curriculum is indexed to the national science education standards and is being adopted in schools across the country through the ToxRAP™ Network. Curriculum development and dissemination were funded by the National Institute of Environmental Health Sciences.

1159 KIDNEYS AND METALS, AN INTERATIVE WEB RESOURCE FOR LEARNING TOXICOLOGY AND ENVIRONMENTAL HEALTH SCIENCE.

J K Norman and C A McQueen. *The Southwest Environmental Health Sciences Center, The University of Arizona, Tucson, AZ, USA.*

Chemicals & Human Health (CHH) is a web site designed to teach high school students basic principles of toxicology and research using actual experimental data. The newest CHH module, *Kidneys and Metals*, focuses on renal and metal toxicology. Research shows that students learn better when they are actively engaged in solving problems. The newest CHH module is an interactive problem set. Students are presented with problems and multiple-choice answers. Choosing the correct answer brings up information to reinforce student understanding of the concept. Choosing the incorrect answer brings up tutorials. These tutorials use different modes of presentation (text, illustrations, photographs, and animations) to help students understand the concepts and make the connections necessary for long term retention. Content includes kidney anatomy and function, membrane structure and transport, properties of metals, and mechanisms of metal toxicity. Several strategies are used to promote the new web site including the distribution of informational brochures and flyers and locating the CHH web site within another well known web resource, The Biology Project. During its initial six months, the CHH web site had over 10,000 user sessions indicating that the site is well utilized. It is anticipated that the addition of the *Kidneys and Metals* module will maintain or increase the usage of the web site. Future plans include the development of a set of data collection and interpretation activities to compliment the *Kidneys and Metals* module. Science education reform initiatives and the new national science standards call for hands-on science with a focus on problem-solving and inquiry. High school teachers can use these materials to help their students meet the new standards. (This project is supported by NIEHS Center grant ES 06694.)

1160 GENES, DISEASE AND THE ENVIRONMENT.

M O Dereski. *Institute of Chemical Toxicology; EHS Center for Molecular and Cellular Toxicology with Human Applications, Wayne State University, Detroit, MI, USA.*

With genetic polymorphisms expected to be associated with diseases such as cancer, heart disease and Alzheimer's, it should be stressed to the general public that a positive genetic test for a polymorphism, only implies that the person is at higher risk of developing the disease than is the general population, not that s/he is destined to develop that disease. A lesson plan is presented that introduces the concepts of polymorphisms to high school students and the interested lay person. Covered during the lesson are the molecular events leading up to a "change in function" protein and its associated cellular effects. One example utilized is Xeroderma pigmentosum (XP) as an autosomal recessive mutation in DNA repair genes causing unrepaired sections of DNA to persist which eventually lead to skin cancer. Also discussed are the ethical considerations of "Who should obtain information on an individual's genetic makeup?" A worker may prefer not to be overly exposed to occupationally hazardous agents if s/he had a predisposition to cancer or toxicity that may be caused by these agents. On the other hand an employer might like to know the genotype of its workers, in order to hire only those at low risk for toxicity or malignancy from exposure to particular agent(s) in the workplace. These and other topis are discussed through "hands on" activities and illustrated through patient case reports.

1161 THE SKYROCKETING IMPORTANCE OF RISK ASSESSMENT TRAINING.

V H Sublet, G Stoner, B Casto, and R Harris. *School of Medicine and Public Health, Ohio State University, Columbus, OH, USA.*

There has been an increase in the use of risk assessment in decision-making concerning the clean-up of environmentally contaminated sites, the protection of human health, and the future use of land at these sites. Subsequently, there has been an increase in the number of individuals entering the field of risk assessment who have had no formal training in this area. The concern for government regulators at the federal and state levels is that many of the personnel, currently, involved in doing health/risk assessments need further training to improve the quality of these evaluations and the data obtained. To help fulfill this need, a three-week course was implemented in 1997 at the School of Medicine and Public Health of the Ohio State University to pro-

vide risk assessors training in the areas of Environmental Health, Health/Risk Assessment, and Risk Management /Risk Communication. Attendees, came from multidisciplinary backgrounds ranging from engineering to ethics. Conclusions from the Overall Course Evaluation are that students ranked the Health/Risk Assessment segment as the most useful in their work, followed by Risk Management/Risk Communication and Environmental Health. Students, further ranked Site Investigation highest in a list of future courses, followed by Monte Carlo Analysis, Ecological Risk Assessment, PB-PK Modeling, and Hot Topics in Public Health. Also, students indicated that they liked case study presentations and tests that covered practical concepts. Evaluation of each segment of the course was also conducted. (This project was funded by Grant No. 97G003 from the Ohio Environmental Protection Agency.)

1162 HOW COPPER IONS SIGNAL TO THE TRANSCRIPTIONAL MACHINERY.

D J Thiele. *University of Michigan Medical School, Ann Arbor, MI, USA.*

The metal ion copper plays a dual role in biological systems. On one hand, copper plays an essential function in the active sites of a large number of critical cellular enzymes such as Cu, Zn superoxide dismutase, cytochrome oxidase, dopamine β-hydroxylase and lysyl oxidase. On the other hand, copper ions are potent toxins, through interactions with superoxide anions, resulting in the generation of hydroxyl radical resulting in damage to membranes, proteins and nucleic acids. Therefore, all cells must orchestrate the accumulation of copper for essential biochemical reactions, yet prevent the accumulation of free copper ions to cytoxic levels. My colleagues and I are interested in understanding the precise molecular mechanisms whereby cells maintain homeostatic control of copper ion levels through regulated transport, detoxification and through rapid transcriptional responses. Indeed, cells have exquisitely sensitive mechanisms for both sensing and responding to alterations in copper levels by directly signaling to the transcriptional machinery. Using yeast cells as a model eukaryotic organism, we have isolated genes encoding distinct copper sensing transcription factors that rapidly and potently activate the expression of copper detoxification genes in response to elevated copper levels. These rapid responses are achieve through the interdigitation of copper ion sensing and DNA binding domains in the copper metalloregulatory transcription factors, as well as through the use of specialized chromatin structures that poise metal induced genes in an accessible state. Furthermore, we have isolated genes encoding copper ion transporters and have identified transcription factors that activate expression of the copper transporter genes in response to copper starvation, but extinguish expression in the presence of high copper levels. The delicate balance that is required for maintaining sufficient levels of copper, while preventing copper toxicity, is dictated by the dynamic interplay between distinct copper ion sensing transcription factors and through the use of multiple layers of cellular regulation. These investigations lay the groundwork for understanding the molecular mechanisms by which mammals establish and maintain copper ion homeostasis.

1163 THE ROLE OF QUINONES IN TOXICOLOGY.

J L Bolton[1] and T J Monks[2]. [1]*Department of Medicinal Chemistry and Pharmacognosy, University of Illinois at Chicago, Chicago, IL, USA and* [2]*University of Texas at Austin, College of Pharmacy, Austin, TX, USA.*

Quinones represent a class of toxicological intermediate which can create a variety of hazardous effects in vivo including, acute cytotoxicity, immunotoxicity, and carcinogenesis. The mechanisms by which quinones cause these effects can be quite complex. Quinones are Michael acceptors and cellular damage can occur through alkylation of crucial cellular proteins and/or DNA. Alternatively, quinones are highly redox active molecules which can redox cycle with their semiquinone radicals leading to formation of reactive oxygen species (ROS) including superoxide, hydrogen peroxide, and ultimately the hydroxyl radical. Production of ROS can cause severe oxidative stress within cells through the formation of oxidized cellular macromolecules including lipids, proteins, and DNA. Formation of oxidatively damaged bases such as 8-hydroxydeoxyguanosine has been associated with aging and carcinogenesis. Further ROS can activate a number of signaling pathways including protein kinase C and RAS. This symposium will explore the varied cytotoxic effects of quinones using specific examples including quinones produced from benzene, polycyclic aromatic hydrocarbons, estrogens, and catecholamines. The numerous mechanisms of toxicity (i.e., alkylation versus oxidative stress) will be correlated with the known pathology of the parent compound(s).

1164 BENZENE QUINONES AND BONE MARROW TOXICITY AND CHEMOPREVENTION.

M A Trush. *Johns Hopkins University, Baltimore, MD, USA.*

Benzene is a widespread environmental pollutant. Exposure to benzene induces toxicity to various bone marrow cell populations which can be manifested as pancytopenia, aplastic anemia, leukemia and immunotoxicity. It is well established that metabolites originating in the liver may be further bioactivated to reactive intermediates within bone marrow target cell populations. Of particular interest is the conversion of hydroquinone (HQ) to p-benzoquinone (BQ) which is highly reactive toward SH-containing molecules. Treatment of cells with HQ results in: altered cytokine synthesis, cell division, cell differentiation and viability; the inhibition of DNA topoisomerase II; the induction of mitotic recombination, chromosomal translocations and aneuploidy, The bioreactivity of p-BQ within target cells is controlled by quinone reductase and glutathione, whose activity/content vary according to: the state of cell differentiation; bone marrow cell type; and strain/species. Accordingly, the induction of quinone reductase and glutathione serves as a basis for molecular intervention against benzene induced hematotoxicity. The focus of this symposium presentation will be to discuss the experimental evidence underpining the concepts described above.

1165 ortho-QUINONES AS ACTIVATED METABOLITES OF POLYCYCLIC AROMATIC HYDROCARBONS (PAH).

T M Penning. *Department of Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA, USA.* Sponsor: J L Bolton.

A novel pathway of PAH activation involves the formation of reactive and redox active o-quinones catalyzed by rat and human dihydrodiol dehydrogenase (DD) members of the aldo-keto reductase superfamily. In this pathway non-K-region trans-dihydrodiols (proximate carcinogens) are diverted from CYP1A1 and undergo enzymatic NADP+ dependent oxidation to yield the corresponding o-quinone. Using rat DD, human recombinant DD isoforms, rat hepatocytes, and stable-transfectants we have shown that (+)-trans-7,8-dihydroxy-7,8-dihydro-benzo[a]pyrene is converted to a catechol, 7,8-dihydroxy-benzo[a]pyrene, which is then autoxidized via an intermediate o-semiquinone to yield benzo[a]pyrene-7,8-dione. EPR and spectroscopic measurements showed that the autoxidation event is accompanied by the formation of reactive oxygen species (ROS) e.g., superoxide anion, hydrogen peroxide and hydroxyl radical. The PAH o-quinones generated are reactive Michael acceptors and can form stable and depurinating adducts with bases in DNA, and form thio-ether conjugates with L-cysteine, mercapturic acid and GSH. Covalent adducts are likely responsible for the frame-shift mutations that o-quinones cause in the Ames test. PAH o-quinones also undergo two electron (non-enzymatic) or one electron (enzymatic) reduction steps to establish futile redox-cycles in which ROS and o-semiquinone radicals are generated multiple times. Amplification of ROS leads to cytotoxicity (reduced cell viability and survival) and genotoxicity (DNA strand scission). Strand scission is dependent upon a Cu(II)/Cu(I) redox couple and hydroxyl radical. The release of malondialdehyde upon acid hydrolysis of quinone-treated DNA points to a Criegee rearrangement with the formation of base-propenals during the strand-scission event. Since ROS are the causative agents in radiation induced carcinogenesis and are generated by PAH o-quinones and catechol estrogens they may be the common mediators of the carcinogenic event. (Supported by NIH grant CA39504.)

1166 QUINONES FROM PREMARIN® ESTROGENS: ROLE IN ESTROGEN CARCINOGENESIS.

J L Bolton. *Department of Medicinal Chemistry and Pharmacognosy, University of Illinois at Chicago, Chicago, IL, USA.*

Endogenous estrogens as well as estrogens present in estrogen replacement formulations have been implicated in breast and endometrial cancers. The mechanism(s) of how estrogens cause these cancers remains both controversial and elusive. One mechanism could involve metabolic activation of these estrogens to o-quinones which then cause oxidation/alkylation of DNA. It has been shown that the catechol estrogens metabolites of estrone and 17β-estradiol can form DNA adducts *in vitro* and *in vivo*. The non-genotoxic 2-

hydroxycatechols seem to form mainly stable bulky adducts whereas the carcinogenic 4-hydroxylated metabolites primarily alkylate the N-7 position of guanine generating apurinic sites. The equine estrogens present in the popular estrogen replacement formulation Premarin® (Wyeth-Ayerst) can be metabolized to primarily 4-hydroxylated products. In contrast to the endogenous catechol estrogens, the 4-hydroxyequine estrogens autoxidize to semiquinone radicals and o-quinones without the need for oxidative enzyme catalysis. Both 4-hydroxyequilin and 4-hydroxyequilenin form the same highly unusual cyclic adducts with DNA. Several different types of lesions result including, bulky stable adducts with guanine and cytosine and apurinic sites resulting from adenine alkylation. Finally, 4-hydroxyequilenin in particular causes significant oxidative damage to guanine and adenine residues as well as damage to the phosphate/sugar backbone of DNA. These data suggest that DNA damage mediated by endogenous and/or exogenous catechol estrogens could contribute to the carcinogenic effects of estrogens in vivo. (Supported by CA73638-01.)

1167 QUINONE-THIOETHER MEDIATED TOXICITIES.

T J Monks and S S Lau. *Div. of Pharmacology & Toxicology, College of Pharmacy, Univ. of Texas at Austin, TX, USA.*

Conjugation of reactive electrophiles, such as quinones, with glutathione (GSH) is frequently associated with detoxication. However, quinol-GSH conjugates retain the ability to redox cycle, and the reactivity of the corresponding quinone-thioether often exceeds that of the parent quinone. Indeed, quinone-thioether-mediated DNA damage (including mutations [base substitutions/deletions] and single-strand breaks), growth arrest, cell transformation, and cell death (necrosis and apoptosis) are all linked to the generation of reactive oxygen species. Conjugation with GSH is usually efficiently coupled to the export of the conjugate from the cell, and limits the potential toxicity of quinol-GSH conjugates. In contrast, GSH conjugates are transported into cells via eiither the activity of an intact GSH transporter, or as the corresponding cysteinylglycine and cysteine conjugates following metabolism by γ -glutamyl transpeptidase (γ -GT) and dipeptidases. Cells that express either γ -GT or an intact GSH transporter will therefore be exposed to the potential toxic effects of these conjugates. Tissues susceptible to quinol-GSH conjugate induced toxicities share interesting physiological similarities. For example, γ -GT is frequently located in cells that separate the circulation from a second fluid filled compartment, such as occurs in the blood-urine (renal proximal tubule cells) and blood-brain (brain endothelial cells) barriers. Quinol-GSH conjugates are nephrotoxic, nephrocarcinogenic, and neurotoxic. In the latter case however, access to the brain appears to be mediated by an intact GSH transporter, and not by γ -GT. Similar physiological barriers exist within the body and may provide additional sites for the toxicity of these conjugates. (ES07359, ES 07247, CA58036, DA10832, GM 39338)

1168 QUINONE-THIOETHERS AND PARKINSON'S DISEASE.

G Dryhurst, X-M Shen, H Li, J H Han, L Gu, Z Yang, and F-C Cheng. *Department of Chemistry and Biochemistry, University of Oklahoma, Norman, OK, USA.* Sponsor: J L Bolton.

The characteristic motor symptoms of PD (tremor, rigidity, akinesia) are caused by the degeneration of nigrostriatal dopamine (DA) neurons. The pathological processes occur in the neuromelanin-pigmented cell bodies of these neurons in the substantia nigra pars compacta (SNc) and include a defect in mitochondrial respiration at the level of complex I and decreased α -ketoglutarate dehydrogenase. A massive loss of glutathione (GSH) is the earliest known change in the parkinsonian SNc that slightly precedes the complex I defect. Another change in the SNc of PD brains is increased activity of γ -glutamyl transpeptidase. Based on these observations and information drawn from studies of the dopaminergic neurotoxicity evoked by MPTP, methamphetamine and ischemia-reperfusion, a new mechanism will be discussed based on reactions between DA-o-quinone and cysteine. The intraneuronal reaction between DA-o-quinone and CySH is proposed to form cysteinyl conjugates of DA that are further easily oxidized to a number of dihydrobenzothiazines (DHBTs) and benzothiazines (BTs). These DHBTs/BTs include putative intraneuronal metabolites that can be accumulated by mitochondria and evoke irreversible inhibition of complex I and α -KGDH. These effects involve oxidation of DHBTs and BTs by a constituent of the inner mt membrane to give highly electrophilic intermediates that covalently bind to -SH residues of NADH-coenzyme Q1 reductase and α -KGDH thus evoking irreversible inhibition.

1169 BIOLOGIC MARKERS IN MOLECULAR EPIDEMIOLOGY: MEASURES OF EXPOSURE AND RISK FOR CANCER DEVELOPMENT.

R M Santella[1] and D G DeBord[2]. [1]*Columbia School of Public Health, New York, NY, USA and* [2]*National Institute for Occupational Safety and Health, Cincinnati, OH, USA.*

Although biomarkers have been used for sometime in epidemiology, recent advances in molecular biologic techniques have made it possible to detect biologic changes at low levels of exposure. Biomarkers can be used to identify exposures, effects of those exposures, and populations that may be at increased risk. Measurement of DNA adducts from polycyclic aromatic hydrocarbons, aflatoxin, and alkylating agents have been used to monitor exposure to these agents in smokers, workers, and those with environmental exposure. Lipid peroxidation produces high levels of malondialdehyde-DNA adducts which are highly mutagenic. Oxidative DNA damage is also present at high levels. Thus, DNA damage from endogenous sources may be an important factor in tumor development. Data on the relationship between DNA damage (or protein damage as a surrogate) and risk for cancer have demonstrated that these assays can predict development of disease in populations exposed to aflatoxin. Genetic susceptibility factors related to ability to metabolize carcinogens influence DNA damage levels and cancer risk. Biomarkers of effect measure mutations (HPRT or glycophorin A) or cytogenetic damage and are useful to help bridge the continuum of exposure to disease. Many of the biomarkers of exposure and early effects are reversible and can be used as tools to monitor reductions in workplace exposure or the efficacy of chemoprevention studies. The rapid expansion of large banks of stored blood samples will make possible nested case-control studies evaluating the relationship between biomarkers and disease risk and gene-environment interactions.

1170 THE RELATIVE CONTRIBUTION OF EXOGENOUS AND ENDOGENOUS EXPOSURES OF HUMANS TO CARCINOGENS AS REFLECTED BY DNA AND PROTEIN DAMAGE.

P B Farmer [1], Y Guichard[1], G D D Jones[2], E Martin[1], V I C Oreffo[1], R Singh[1], and D E G Shuker[1]. [1]*MRC Toxicology Unit and* [2]*CMHT, University of Leicester, Leicester, UK.*

DNA and protein adducts are now widely accepted as valid monitors of exposure to genotoxic compounds. In the case of hepatocellular carcinoma, biomarkers of exposure to aflatoxin B1 including DNA adducts proved to be highly predictive of tumour outcome in humans. Correlations between low dose exposures and DNA adduct formation in target organs have been observed for a number of carcinogens in experimental systems. However, in a recent study of N©nitrosodiethylamine in 3 inbred mice strains we showed that within strains there was a strong correlation between DNA adduct levels and tumour yield, whereas interstrain variation was less well predicted and may be determined by other susceptibility factors. Using the techniques of ^{32}P-postlabelling, immunoassay or mass spectrometry (MS) it is possible to detect DNA or protein damage (adducts) caused by genotoxic carcinogens in normal human tissues. In many cases the level of endogenously produced damage is comparable to, or greater than, that seen following exogenous exposures to carcinogens from for example occupational sources or tobacco smoking. Superior analytical methods are still required to improve the sensitivity of adduct detection for monitoring low level human exposures, and to identify the chemical nature of many of the DNA adducts, which is only indirectly achievable by the technique of ^{32}P-postlabelling. We have achieved greater selectivity and sensitivity of adduct detection in human tissues using accelerator MS (AMS), following for example administration of ^{14}C-tamoxifen (collaboration with K Turteltaub and R C Garner). We have also developed a ^{32}P-postlabelling method for the detection of phosphotriesters, which, because of their abundance and stability, may offer a further increase in sensitivity over standard postlabelling techniques for measuring adducts.

1171 APPROACHES TO THE ANALYSIS OF ENDOGENOUS DNA DAMAGE IN PEOPLE.

L J Marnett and J P Plastaras. *Department of Biochemistry, Center in Molecular Toxicology, and the Vanderbilt Cancer Center, Vanderbilt University School of Medicine, Nashville, TN, USA.*

Characterization of the sources of DNA damage in human beings is critical for identifying the causes of genetic diseases. A compendium of DNA damage products indicates that endogenous metabolic processes play a very significant role in genomic alteration. For example, malondialdehyde is a naturally occurring product of lipid peroxidation and prostaglandin biosynthesis that is mutagenic and carcinogenic. It reacts with DNA to form adducts to deoxyguanosine and deoxyadenosine. The major adduct to DNA is a pyrimidopurinone called M_1G. This adduct is highly mutagenic in E. coli and has been detected in liver, white blood cells, pancreas, and breast from healthy human beings at levels ranging from 1 - 120 per 10^8 nucleotides. Efforts are underway to develop high throughput methods for quantitation of MDA in population-based studies. Several different assays for M_1G have been described that are based on mass spectrometry, ^{32}P-postlabeling, or immunochemical techniques. Each technique offers advantages and disadvantages based on a combination of sensitivity and specificity. Recent advances in the application these techniques to the analysis of M_1G will be discussed as a prototype for the analysis of other endogenous DNA adducts.

1172 IMMUNOLOGIC METHODS FOR MEASURING DNA ADDUCTS: APPLICATIONS TO MOLECULAR EPIDEMIOLOGIC STUDIES.

R M Santella. *Division of Environmental Health Sciences, Columbia School of Public Health, New York, NY, USA.*

Measurement of carcinogen-DNA damage in humans can provide important information on individual exposure to various environmental, lifestyle, or occupational carcinogens. Polyclonal antisera and monoclonal antibodies recognizing specific types of DNA damage have high sensitivity and can easily analyze large numbers of samples. We are currently using an antiserum recognizing polycyclic aromatic hydrocarbon (PAH)-DNA in a competitive enzyme-linked immunosorbent assay (ELISA) to analyze lymphocyte DNA adducts in a breast cancer case-control study. The same antiserum is being used for immunoperoxidase staining of breast tissue sections to determine the correlation between target and surrogate tissue adduct levels. Investigation of the relationship between adducts and genotype for glutathione S-transferases M1 and P1 will help in understanding interindividual variation in DNA damage. Immuno-histochemical analysis of exfoliated oral and bladder cells for 4-aminobiphenyl (4-ABP)- and PAH-DNA and oxidative DNA damage (8-hydroxyguanosine) demonstrated elevated levels of damage in smokers compared to nonsmokers, suggesting these are good markers of exposure. Studies on the correlation between DNA damage and mutations in p53, a tumor suppressor gene, demonstrated an increased risk for mutant p53 in subjects with higher levels of aflatoxin B_1 or 4-ABP-DNA adducts, suggesting the importance of adducts in the etiology of cancer development. Finally, adduct measurements are also useful as intermediate biomarkers in intervention studies. For example, we recently completed an antioxidant vitamin intervention in smokers in which the endpoint is modulation of DNA damage in lymphocytes and exfoliated oral and bladder cells. Demonstration that an intervention can modulate a biomarker on the pathway to cancer development should simplify the testing of new chemopreventive agents.

1173 MOLECULAR MARKERS OF BIOLOGICAL EFFECT - USE AS MEASURES OF RETROSPECTIVE CUMULATIVE EXPOSURE AND AS PREDICTORS OF HUMAN HEALTH EFFECTS.

W L Bigbee. *Center for Environmental and Occupational Health and Toxicology, University of Pittsburgh, Pittsburgh, PA, USA.*

The tools provided by modern molecular biology and genetics, together with ever more sensitive and sophisticated analytical instrumentation, have allowed the development of powerful new markers of early biological effects relevant to the molecular etiology of human disease. These effect biomarkers, representing both cytogenetic and molecular genetic methods, have found useful application in recent molecular epidemiological studies both for assessing the biological impact of distant and/or cumulative exposures to chemical and physical agents as well as predicting, and molecularly characterizing, subsequent clinical disease. Examples from the contemporary literature will be used to illustrate these concepts and the current "cutting edge" of laboratory methods and molecular epidemiological study design. While these tools are presently best developed in cancer epidemiology, examples using other chronic disease endpoints and adverse reproductive effects will also be presented. Finally, the presentation will include a discussion of rapidly emerging techniques and scientific concepts that represent the next generation of biological markers that promise to offer increased sensitivity and specificity, early detection of preclinical disease, population screening for identification of susceptible groups, and assessment of individual risk of disease.

1174 LINKING BIOMARKERS OF BIOLOGICALLY EFFECTIVE DOSE AND EARLY BIOLOGIC EFFECT TO DISEASE RISK IN EPIDEMIOLOGIC STUDIES.

P A Schulte[1] and N Rothman[2]. [1]*NIOSH-Taft Labs, Cincinnati, OH;* [2]*Division of Cancer Epidemiology and Genetics, NCI, Bethesda, MD, USA.* Sponsor: R M Santella.

In order to understand the relevance of biomarkers of biologically effective dose and early biologic effects in a broad public health context, it is critical to understand the biomarker-disease relationship. Although preliminary work can be carried out for some biomarkers in case-control studies, the potential for disease bias will always raise a concern about results from these studies. As such, prospective cohort studies carried out on large, generally healthy populations are the optimal approach to study the relationship between biomarker levels and disease risk. In these studies, biologic samples are collected from a defined population and banked for later analysis. The cohort is followed forward in time; subjects who develop disease are identified, and premorbid biomarker levels in these cases are then compared with those in unaffected subjects. Often, a nested case-control approach is used. Samples from cases and only a sample of the controls are analyzed, which considerably reduces the laboratory requirements and costs. These studies allow calculation of the relative risk, which provides an estimate of the increased risk in disease for a given level of a biomarker, and the etiologic fraction, which estimates the proportion of disease reflected by the biomarker. The consistent results across several, small cohort studies showing a positive relationship between chromosomal aberration levels in peripheral lymphocytes and subsequent cancer incidence or mortality suggest that at least some biomarkers of early biologic effect will prove to be relevant for predicting cancer risk. There will soon be over a million subjects with blood samples banked in cohort studies in the U.S., Europe, and Asia. These studies will provide striking opportunities for the evaluation of the relationship between a wide range of biomarkers and disease risk over the coming years.

1175 TOXICOLOGY FOR KIDS: A HOW TO GUIDE FOR TOXICOLOGISTS.

G S Yost[1] and C A McQueen[2]. [1]*Department of Pharmacology and Toxicology, University of Utah, Salt Lake City, UT, USA and* [2]*Department of Pharmacology and Toxicology, University of Arizona, Tucson, AZ, USA.*

SOT has recognized the importance of education in the science of toxicology for students in grades K-12. While many members of SOT are interested in becoming involved in K-12 education, there is much uncertainty in what to do and how to do it. The Education Committee and its K-12 Subcommittee are committed to activities that will enhance the efforts of SOT members in their efforts. Thus, the K-12 Subcommittee has enlisted the help of several prominent scientists and educators to provide a program focused on the practical aspects of outreach programs with kids. The purpose of the workshop is to give SOT members the philosophical approaches and specific educational tools that are effective in classroom presentations. Specific hands-on demonstrations of proven techniques will be provided at the workshop.

1176 TOXICOLOGY CAN TURN KIDS ON TO SCIENCE.

N Biggart. Bonita *Vista High School, El Cajon, CA, USA.* Sponsor: G S Yost.

Toxicology is an excellent discipline with which to engage the interest of high school students because of two characteristics: it is relevant to students'

physical selves, a subject of intense interest; and secondly, it provides excellent opportunities for experimentation in the classroom. Toxicology can be included in cellular biology topics such as membrane transport, gene expression, and cancer. In addition, it is relevant to animal and human physiology as one can discuss toxicant damage in terms of tissues, organ systems, and the entire body. Finally, there are many simple toxicity experiments that can easily be performed in a classroom and that incorporate the concepts of variables, controls, assays, reproducibility, and experimental design. The inclusion of toxicology is appropriate for all aspects of biology from ecology to molecular genetics to physiology and even evolution. It is also appropriate in chemistry because toxicants are generally chemical compounds. Toxicology is an excellent way to discuss experimental design with students. Once teachers get some basic information and ideas, they can develop lots of plans.

1177 TOXICOLOGISTS SELLING SCIENCE IN THE CLASSROOM? LESSONS FROM MARKETING.

W T Klimecki. *Motorola Inc., Corporate Research Labs, Tempe, AZ, USA.*

Stripped to its bones, science education is a product in the marketplace. While this is a distasteful metaphor to some, excellent educational programs always share commonalties with excellent product marketing programs. Superior, long-term marketing programs have a good product (toxicology) which is sold by salespersons (teachers) who believe in the product, understand the product thoroughly, and successfully transfer their knowledge and enthusiasm in presentations which are tailored to their specific customers (students). These characteristics will be highlighted in this description of an outreach program at the University of Arizona, in which 5th and 6th grade students designed a project in which they collected drinking water samples weekly, analyzed the water for a variety of constituents, then statistically analyzed and presented the data. A primary goal of the program was to teach the students to use sound, scientific principles to evaluate the validity of scientific claims which are made or quoted by journalists. Drinking water analysis was chosen because it is a topic which receives frequent (often daily) coverage in the local media. For the students, drinking water quality is discussed at their dinner table; they feel it is relevant to their lives, and they found affirmation in reporting their data to their families. Students were required to collect one journalism media article weekly regarding water quality. By the end of the semester, the students became quite proficient at both identifying the critical issues and answers which were present in well substantiated scientific claims, as well as identifying their absence in poorly founded claims. The project was inexpensive, and was primarily dependent upon enthusiastic salesmanship and a collaborative, "let's try it!" spirit between academic scientists, public school teachers and administrators. (Project support: NIEHS Center Grant ES 06694.)

1178 EXPERIENCES OF AAAS IN K-12 SCIENCE, MATHEMATICS, AND TECHNOLOGY EDUCATION.

Y S George. *American Association for the Advancement of Science, New York, NY, USA.* Sponsor: G S Yost.

Since 1955, the American Association for the Advancement of Science (AAAS) has been involved in the development and implementation of science, mathematics, and technology (SMT) education programs in schools. In more recent years, AAAS has also implemented SMT programs in partnership with science museums and zoos, youth serving organizations, faith based organizations, public libraries, and businesses. Some initiatives have focused on attracting and retaining minorities, girls, and children with disabilities in the SMT education pipeline. Products developed include inquiry based SMT manuals and kits, science and mathematics benchmarks (AAAS Project 2061), children's radio show and cyber clubs, and other Internet products for teachers and parents. Thus, this presentation will highlight AAAS SMT initiatives, while focusing on lessons learned about presenting K-12 science to a diverse student population.

1179 OVERVIEW OF K-12 ENVIRONMENTAL HEALTH SCIENCE EDUCATION EFFORTS AT NIEHS.

A Dearry. *NIEHS, Research Triangle Park, NC, USA.* Sponsor: G S Yost.

A mandate in the 1990s is to reach out to students in grade school and high school to improve their science literacy. The NIEHS has thus established a priority to develop an environmental health sciences education program at the K-12 grade levels. The objective is to improve understanding of environmental health issues by all students and to expand career awareness for those interested in pursuing further education. The Institute has supported both material development and teacher training efforts. The former are designed to provide instructional materials which can be infused into existing curricula. Examples include science adventure stories, mini-magazines, teachers' guides, interactive CD-ROM software programs, student workbooks, board games, and videotapes. These materials address a variety of environmental health science topics, including toxicology, risk assessment, air pollution, global environmental problems, and career opportunities. In addition, the NIEHS seeks to enhance dissemination and effective implementation of materials pertaining to environmental health science. A necessary step in achieving this objective is the provision of teachers with requisite disciplinary and pedagogical skills. Hence, the Institute supports a series of teacher enhancement activities, which will ultimately enhance students' comprehension of and interest in environmental health sciences. A summary of these efforts and contact information will be provided.

1180 HANDS-ON DEMONSTRATIONS OF TOXICOLOGY MATERIALS.

G S Yost and C A McQueen. *Department of Pharmacology and Toxicology, University of Utah, Salt Lake City, UT, USA and Department of Pharmacology and Toxicology, University of Arizona, Tucson, AZ, USA.*

Examples of education materials for classroom presentations about toxicology will be presented at workstations around the room. The examples will include demonstrations, video tapes, and other media forms that have proven useful in science education and toxicology. Toxicologists from several of the NIEHS Centers will display materials that have been developed for a target population of K-12 students. There will be information on how to obtain these materials. Bibliographic resources will also be available. The materials will provide specific, hands-on examples of the most useful kinds of educational materials that can be employed by toxicologists in classroom settings.

1181 THE IMMUNOTOXICOLOGY OF NOVEL THERAPEUTICS.

R V House[1] and K L Hastings[2]. [1]*IIT Research Institute, Chicago, IL, USA;* [2] *US FDA, Rockville, MD.*

The discipline of immunotoxicology is predicated on the assumption that alterations in immune function resulting from xenobiotic exposure–whether stimulatory or inhibitory–are potentially deleterious. Although this assumption was suitable chemicals and "traditional" drugs, novel therapeutic agents being developed which will necessitate revision of how immunotoxicology is defined. At least three properties of these agents must be considered when assessing potential immunotoxicity. First, many novel therapeutics are proteins or polypeptides, and the use of xenogenetic proteins (or even native proteins with minor chemical alterations) may result in the development of neutralizing antibodies. Second, although the putative pharmacologic mechanism of action of many of these drugs is highly specific, unanticipated toxicities have become evident. Such toxicities may result from exaggerated pharmacological activity, non-targeted immunotoxicity, or unrelated effects on systems other than the immune system. This is confounded by the fact that the physicochemical properties and mechanism of action of these novel agents are so disparate; thus, it becomes difficult if not impossible to elucidate an overall pattern of toxic activity. Third, and perhaps most important, many of these agents are intended to therapeutically modulate the immune response. This last point is critical, since it is important to distinguish between the desired pharmacological activity and undesired side-affects.

1182 IMMUNOMODULATORY BIOLOGICS: DISTINGUISHING ACTIVITY FROM TOXICITY.

J L Bussiere. *Genentech, Inc., South San Francisco, CA, USA.*

Special issues with regards to immunotoxicity testing of new monoclonal antibody therapeutics must be considered when these molecules have known immunomodulatory activities. An important consideration for biotechnology compounds is the species specificity of the molecule. As is often the case for humanized antibodies, these compounds may by pharmacologically inactive in rodents. In addition, these proteins may be immunogenic in rodents,

and cause confounding findings in the rodent studies. Because of the pleiotrophic nature of many of the immunomodulators, non-target effects on the immune system must be investigated. However, immune responses in a 'normal' animal may be very different than during a 'disease' state. The difference in the immune system of the animal must also be considered when extrapolating risk to humans, i.e., not only in basic differences in immune function, but also differences in back-up systems, compensatory mechanisms, etc. Characterizing the risk/benefit of novel monoclonal antibodies must include separating the immunomodulatory activity from the immunotoxicity. It is important to distinguish between the pharmacological activity of the drug and toxicity that may be due to exaggerated pharmacology, due to non-targeted immunotoxicity, or due to cross-reactivity with non-target tissues.

1183 TOXICITY OF THERAPEUTIC CYTOKINES: FROM ANIMAL DATA TO CLINICAL ADVERSE EFFECTS.

J Descotes. *Lyon Poison Center and ISERM U98-X, Claude Bernard University, Lyon, France.*

Because cytokines exert pleiotropic effects, they have been proposed to treat a variety of pathological conditions. These pleiotropic effects affect primarily the immune system, but also physiological networks between the immune system, such as the CNS and endocrine glands, as well as other systems. Because (therapeutic) cytokines include a marked activation of the immune system, frequent and sometimes severe adverse effects have been described. Typical examples are the acute cytokine syndrome, autoimmune diseases such as thyroiditis and lupus erythematosus, and to some extent, allergic reactions to unrelated allergens and inhibition of hepatic drug metabolism. Due to their origin, cytokines were often, but erroneously considered safe, despite differences in dose levels and duration of exposure. Preclinical toxicity evaluation was then limited to a minimum, but most adverse effects observed in humans were later found to occur in laboratory animals as well. Thanks to the experience thus gained with available therapeutic cytokines, it should be possible to better define which safety endpoints should be included in the preclinical testing and clinical trials of novel therapeutic cytokines.

1184 MECHANISMS AND APPLICATIONS OF CpG DNA.

A M Krieg. *Veterans Affairs Medical Center and University of Iowa, Iowa City, IA, USA.* Sponsor: R V House.

The immune system has evolved the ability to distinguish prokaryotic and vertebrate DNAs because vertebrates have a relative lack of umethylated CpG dinucleotides in certain base contexts (CpG motifs). When B cells or monocytes detect DNA bearing CpG motifs, they rapidly proliferate and secrete immunoglobin (B cells) or secrete Th1-like cytokines especially IL-12 and IFN-(/ß (monocytic cells) resulting in NK deviation. CpG DNA requires cell uptake into an acidifier intracellular compartment. A cytoplasmic protein that specifically binds CpG DNA has been identified. CpG DNA triggers the activation of lymphocyte Jun kinase and NF(B within 7-15 minutes. Immune stimulation by CpG DNA promotes the generation of anitgen-specific immune responses in several ways. First, CpG DNA activation of B Cells synergizes with activation through the antigen receptor. Second, CpG DNA makes B cells resistant to activation-induced apoptosis. Third, B cells and other antigen presenting cells upregulate their expression of class II MHC and other constimulatory molecules. CpG DNA induces strong antibody and cell mediated immune responses to a variety of protein antigens (including tumor antigens) whether given intramuscularly, subcutaneously, intradermally, or through mucosal administration. In fact, CpG DNA is a stronger Th1-like adjuvant than Freud's complete, but causes no local or systemic toxicity at effective doses. CpG DNA is also an effective adjuvant for neonatal immunization and for immunization to polysaccharide antigens, and is required for effective DNA vaccination. As would be expected from the cytokines induced by CpG DNA, these immune responses are strongly Th1-like with a predominance of IgG2a antibodies and strong CTl responses. The Th1-like effect of CpG DNA reverses Th2 immune responses to allergens, preventing diseases in a mouse model of asthma. On the other hand, high loses of CpG DNA can also serve as a trigger for the sepis syndrome. These studies point to human therapeutic applications for CpG ODN.

1185 IMMUNOMODULATION BY THE PROTEASE SAQUINAVIR.

K L White, Jr.[1] and D R Germolec[2]. [1]*MVC/VCU Richmond, VA, USA and* [2]*NIEHS, RTP, NC, USA.*

Saquinavir mesylate is an HIV- protease inhibitor which is used in combination with nucleoside analogs in the treatment of HIV infection. As the target population receiving this drug may already be immunocompromised, it was important to establish that drug treatment would not further impair immune function. No alterations by standard toxicological parameters, including mean body weight or body weight change, organ weights and hematology profiles were observed in B6C3F1 mice treated with up to 1200 mg/kg Saquinavir for 28 days. Antigen-specific serum IgM antibody titers were significantly increased at the 600 mg/kg dose level, while splenis IgM antibody forming cell response against SRBCs was significantly increased at 1200 mg/kg. While low doses of saquinavir produced decreases in natural killer cell activity, preliminary studies suggest that the 1200 mg/kg dose potetiated NK cell responses. Although a significant increase in the number of CD3+ lymphocytes was observed at 1200 mg/kg dose, cell mediated immune functions, as measured by the cytotoxic T lymphocyte assay and the treatment. A significant increase in the number of immature these immunomodulatory effects could alter resistance to disease and neoplasia, we examined the effects of saquinavir in a bacterial challenge and lung tumor model. Treatment with saquinavir did not alter lung tumor burdens of B16F10 melanoma cells or modify numbers of moribund animals after challenge with Listeria monocytogenes. These data suggest that in addition to its entiretrovial activity, treatment with saquinavir may potentiate specific immunologic activity.

1186 TOXICITY OF THERAPEUTIC IMMUNOSUPPRESSANTS.

K L Hastings. *Division of Special Pathogens and Immunologic Drug Products, Center for Drug Evaluation and Research, US FDA, Rockville, MD, USA.*

Numerous immunosuppressant compounds have been developed in recent years for such purposes as prophylaxis of solid organ transplant rejection and treatment of chronic inflammatory diseases suspected to be autoimmune in nature. Cyclosporin and tacrolimus are probably the best known of these compounds: they appear to act via binding and inhibition of calcinerium, a molecule critical in T-cell activation. Clinical development of these potent compounds essentially involved determining systemic exposure levels that were effacious but did not result in complete devastation of the immune system. Other toxicities have been observed related to the use of these compounds that do not appear to de obviously related to their pharmacodynamic properties. Among these adverse effects are renal, neurological, gastrointestinal, cardiac, and pancreatic toxicity, the later being associated with a syndrome known as post-transplant diabetes mellitus (PTDM). The mechanisms of some of these toxicities have been elucidated and appear, at least in the case of PTDM, to be related to the pharmacological activity of the drugs. Other immunosuppressants, which act by mechanisms unrelated to cyclosporin, are also under development and have also demonstrated unique toxicites. These adverse effects are indicative of the interrelatedness of immune and non-immune functions.

1187 EVALUATION OF ADVERSE HEALTH EFFECTS FROM DOMESTIC METHYLPARATHION EXPOSURE.

R D Cox, R L Galli, J C Kolb, F R Carlton, and A M Houpt. *Section of Medical Toxicology, Department of Emergency Medicine, University of Mississippi Medical Center, Jackson, MS, USA.*

Methylparathion was used illegally as a domestic pesticide in over 2500 homes in Mississippi. The health impact of low-level chronic exposure to organophosphates is unknown. A prospective single-blinded study was undertaken to evaluate the presence of adverse health effects in residents of these homes. Using a structured history and physical examination, 353 residents were evaluated by four physicians. Each subject was rated as to the likelihood of having acute toxicity, chronic toxicity or past/subacute toxicity using a predefined set of criteria. No subjects were judged to have evidence of acute organophosphate toxicity at the time of examination. Three subjects were felt to have a high likelihood of having suffered a past episode

of organophosphate toxicity. All three episodes occurred within one month of the initial spraying and were associated with significant dermal and/or respiratory exposure. Symptoms involved gastrointestinal ailments that resolved within one week, and respiratory and neurologic problems that persisted up to 6 months. Forty-eight subjects were judged to possibly have had an episode of past acute or subacute toxicity. No relation was found between the likelihood of past/subacute toxicity and the concentration of methylparathion on home surface sampling or to urinary para-nitrophenol levels. A positive correlation was present between the presence of toxic symptomatology and time spent in the home. This study suggests that adverse health effects do occur from domestic methylparathion exposure. Surface sampling for methylparathion or urinary para-nitrophenol levels may not be sensitive predictors of potential toxicity.

1188 IMPACT OF DOMESTIC METHYLPARATHION EXPOSURE ON CHILDREN'S HEALTH.

J C Kolb, R D Cox, R L Galli, F R Carlton, and A M Houpt. *Section of Medical Toxicology, Department of Emergency Medicine, University of Mississippi Medical Center, Jackson, MS, USA.*

Methylparathion was used illegally as a domestic pesticide in over 2500 homes in Mississippi. The impact on children's health was of particular interest since children spend more time in the home and in contact with surfaces. The effect of methylparathion on the developing nervous system is unknown. Children living in these homes were evaluated by four physicians trained in Medical Toxicology. The Denver II Developmental Test Battery was administered to children under 7 years of age. Growth percentiles were measured for children less than 10 years of age. Using a structured history and physical examination, 153 children under 18 years, including 26 under 5 years were evaluated. Growth was below the 50th percentile in 1 child and below the 25th percentile in 3 (of 61). One child (of 50), who was born prematurely, tested as developmentally delayed. Eleven children were identified whose homes were sprayed during pregnancy, 39 prior to pregnancy and 12 within the first year of life. These children did not have a higher prevalence of health problems than other children in the study. Children under two years of age had a higher prevalence of GI problems than other children. No relationship was found between health problems reported by the parents or assessed by the physicians and home surface methylparathion levels or urinary paranitrophenol levels. Although children had early exposures to methylparathion, this study does not indicate delays in development or growth, or an increase in expected childhood illnesses.

1189 THE UTILITY OF PLASMA AND RBC CHOLINESTERASE MEASUREMENTS IN THE EVALUATION OF CHRONIC ORGANOPHOSPHATE TOXICITY.

R L Galli, R D Cox, J C Kolb, F R Carlton, and A M Houpt. *Section of Medical Toxicology, Department of Emergency Medicine, University of Mississippi Medical Center, Jackson, MS, USA.*

Plasma and RBC cholinesterase levels are usually depressed in the presence of acute organophosphate toxicity and are used as clinical markers. Their utility in the evaluation of chronic organophosphate exposure is unknown. A study was undertaken to evaluate the utility of cholinesterase levels in chronic low-level organophosphate exposure. Cholinesterase levels were obtained on 310 subjects who were being evaluated for adverse health effects resulting from domestic methylparathion exposure. Cholinesterase levels were determined colorimetrically using the reaction with propionylthiocholine. Analyses were performed on plasma and whole blood (total), and the RBC cholinesterase was calculated. Analyses performed on 51 control subjects showed significant variability, with coefficients of variation (CVs) of 13.3%, 24.3% and 13.3% for total, plasma and RBC respectively. A large variability was also found in the sample population, with CVs of 14.7%, 22.6% and 20.9%. Variability over time for the same subject was less: 6.8%, 6.2% and 10.1% (total, plasma, RBC). No correlation was found between the cholinesterase measurements and home surface methylparathion levels. No correlation was found between cholinesterase levels and the presence of toxic manifestations. No trends were observed of cholinesterase levels increasing over time after individuals were moved from their homes. This study suggests that there is too much inter-subject variability in cholinesterase levels to detect subtle health problems, or that the subtle health problems produced by chronic low-level organophosphate exposure are not associated with significant depression of cholinesterase activity.

1190 BLOOD CHOLINESTERASE FROM CALIFORNIA MIGRANT HOUSING CENTER RESIDENTS USING FINGER STICKS.

B W Wilson, J D Henderson, S A McCarthy, J E Billitti and S A McCurdy. *University of California, Davis, CA, USA.*

Blood cholinesterases are commonly used to monitor exposure to anticholinesterase chemicals. This objectives of this study were to compare venous draw and finger stick samples of acetylcholinesterase (AChE) of volunteers and to measure AChE from finger stick samples of adult residents of migrant housing centers in the Central Valley of California collected early and late in the spray season. Blood was collected after wiping the fingers thoroughly with alcohol, immediately hemolyzed with a phosphate/Triton X-100 buffer, frozen on dry ice and stored in an ultra-low temp freezer. Assays were conducted with a 96 well microplate reader using the Ellman assay at 410 nm run under optimal conditions. Mean AChE values from finger stick and venous blood draws from 13 laboratory volunteers averaged 14.6 ± 1.2 and 14.7 ± 1.2 nmol/min/mg Hb, respectively. Early season AChE levels from 891 subjects were similar, averaging 14.7 ± 2.6. Late season AChE levels from 510 subjects were 12.1 ± 3.5. Data analysis with regard to work history is in progress. The results to date show reproducible blood AChE levels can be obtained from finger stick samples if due care is taken in sampling, storage, and the conditions of the assay itself. (Supported in part by NIOSH R01 0403444-02, CA Department of Pesticide Regulation Contract 95-0190, and NIOSH (CDC U07/CCU906162-02) and NIEHS (ES05707) Center Grants.)

1191 EFFECTS OF A NOVEL ORGANOPHOSPHORUS INSECTICIDE ON DETOXIFYING ENZYMES OF RAT.

M Mahaboob[1], M K J Siddiqui[2], M F Rahman[1], and K Jamil[1]. [1]*Toxicology Unit, Indian Institute of Chemical Technology, Hyderabad, AP, India.* [2]*Analytical Toxicology Division, Industrial Toxicological Research Center, Lucknow, UP, India.* Sponsor: S Hussain.

The acute and subacute oral effects of 2-butenoic acid-3-(diethoxyphosphinothionyl)- methyl ester (RPR-V) on Phase-1 and Phase-II enzymes were studies in male albino wistar rats. Acute study (3 mg/kg) caused a reduction in cytochrome P-450) content in liver and lung and also brought depletion in reduced glutathione (GSH) content and inhibition in glutathione S-transferase (GST) activity. The sub-acute study at medium (0.066 mg/kg/d for 90 days) and (0.099 mg/kg/d for 90 days) doses caused time and dose specific decrease in Cyt. P-450, cytochrome b_5 (cyt. b_5), cytochrome P-450 reductase, GST and GSH content. Where as, the UDP-glucuronyl transferase (UDPGT) activity induced significantly in liver and kidneys. The withdrawal study (28 days post-treatment) revealed that changes produced were reversible. *In vivo* GSH and CDNB activation kinetics of GST demonstrated a mixed type of inhibition. *In vitro* GSH activation kinetics of GST and CDNB revealed a non-competitive and mixed type of inhibition respectively. The present studies indicated that this new phosphorothione insecticides was affecting the normal bio-transformation of xenobiotics.

1192 CHEMICAL MIXTURES: ANTAGONISTIC INTERACTIONS OF CHLORPYRIFOS AND METHYL MERCURY.

J A Steevens and W H Benson. *Environmental and Community Health Research/RIPS, Department of Pharmacology, The University of Mississippi, University, MS.*

The toxicodynamic interactions of chlorpyrifos and methyl mercury were evaluated utilizing an aquatic invertebrate animal model, *Hyalella azteca*. Binary combinations of chlorpyrifos and methyl mercury were assessed to elucidate the mechanism of interaction. Initial studies have demonstrated that chlorpyrifos and methyl mercury interacted additively with survival as an endpoint. Additionally, accumulation experiments demonstrate that exposure to chlorpyrifos (0.11 nM) significantly ($p < 0.05$) decreases the rate of accumulation and elimination of methyl mercury (42.4 nM). Specific activity of acetylcholinesterase was determined, *in vivo*, following exposure to chlorpyrifos (0.04, 0.14, and 0.27 nM) and methyl mercury (30, 190, and 440 nM) individually and in combination. Chlorpyrifos inhibited the activity of acetylcholinesterase at 0.14 and 0.27 nM, however, concurrent exposure to methyl mercury (190 nM) antagonized the enzyme inhibition. To further investigate the antagonistic interaction, the inhibition of acetylcholinesterase was assessed *in vitro* utilizing the bioactivated form of chlorpyrifos, chlorpyrifos-oxon, and methyl mercury. Chlorpyrifos-oxon inhibit-

ed acetylcholinesterase (IC_{50} = 118 nM), however, in combination methyl mercury failed to antagonize the inhibition. Results of the *in vitro* assessment of acetylcholinesterase activity demonstrates that methyl mercury does not antagonize chlorpyrifos at the acetylcholinesterase enzyme. Mechanisms responsible for the antagonistic interaction of methyl mercury and chlorpyrifos *in vivo*, potentially exist through alterations in accumulation due to chemical-chemical interactions prior to bioactivation of chlorpyrifos.

1193 DEVELOPMENTAL NEUROTOXICITY OF CHLORPYRIFOS: EFFECTS ON NUCLEAR TRANSCRIPTION FACTORS INVOLVED IN CELL DIFFERENTIATION.

T L Crumpton, F J Seidler and T A Slotkin. *Department of Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.*

Chlorpyrifos is a widely used organophosphate insecticide which is a suspected developmental neurotoxin. Although chlorpyrifos exerts some of its effects through cholinesterase inhibition via chlorpyrifos oxon, recent studies suggest additional, direct actions on developing neural cells. The current study explores effects of chlorpyrifos on nuclear transcription factors involved in cell differentiation using in vitro models in which formation of the oxon does not occur. HeLa nuclear extracts were incubated with the labeled consensus oligonucleotide for AP1 and Sp1 transcription factors in the presence of various chlorpyrifos concentrations. Chlorpyrifos altered the binding activity of AP1 but did not exert major effects on Sp1 DNA-binding activity. These results suggest that chlorpyrifos itself can modulate the DNA-binding activity of some nuclear transcription protein complexes. Next, chlorpyrifos was incubated with PC12 cells in either of two states: undifferentiated cells, and cells undergoing differentiation with nerve growth factor. Nuclear extracts again specific interference of transcription factor DNA-binding by chlorpyrifos. These results suggest that chlorpyrifos alters the activation of genes that are expressed during development, in part by interfering with the DNA-binding activity of transcription factors. Direct actions of chlorpyrifos on cell development reinforce the need for examination of safety independently of effects mediated by cholinesterase inhibition.

1194 EFFECTS OF NEONATAL CHLORPYRIFOS EXPOSURE ON THE DEVELOPMENT OF NEURONAL ACTIVITY.

K Dam, S J Garcia, F J Seidler and T A Slotkin. *Dept. of Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.*

After routine home application chlorpyrifos (cpf), infant and child exposures can exceed acceptable thresholds. We treated neonatal rats daily on postnatal days 1-4 (1 mg/kg, sc) or days 11-14 (5 mg/kg), treatments that evoked no overt signs of toxicity. Effects on the development of cholinergic neuronal function were assessed using choline acetyltransferase (ChAT) activity and hemicholinium-3 (HC-3) binding as indices of synaptic proliferation and synaptic activity, respectively. In the forebrain, early cpf treatment caused a decrease in ChAT without affecting HC-3 binding; late treatment decreased HC-3 binding without affecting ChAT. In the brainstem, early treatment had no effect on either parameter but late treatment decreased both ChAT and HC-3 binding. Effects of cpf were not limited to development of cholinergic synapses but also involved catecholamine pathways. For dopamine, either early or late cpf treatment evoked increased synaptic activity (transmitter turnover) in the forebrain and brainstem. For norepinephrine, early treatment increased activity only in the cerebellum, whereas late treatment increased activity in all brain regions. Our results suggest that cpf exposure during the postnatal period of synaptogenesis, elicits widespread disruption of the activity patterns of cholinergic and non-cholinergic pathways. As this is the period in which patterns of synaptic responsiveness and hence, behavior, are "programmed" by neural input, the period of developmental vulnerability to cpf is likely to extend into childhood.

1195 INCREASED SPONTANEOUS LIVER TUMOR SUSCEPTIBILITY IN CYTOCHROME P450 2B1 (CYP2B1) TRANSGENIC MICE.

L D Lehman-McKeeman, D Caudill, J D Vassallo and A S Fix. *Procter and Gamble Co., Cincinnati, OH.*

There is an empirical relationship between induction of CYP2B enzymes and liver tumor promotion in rodents, particularly mice. To better define the role of CYP2B induction in liver tumor development, transgenic mice (C57Bl/6N) were engineered to over-express CYP2B enzymes by microinjection of a fusion gene consisting of rat CYP2B1 cDNA under the regulatory control of the mouse metallothionein (MT) promoter. In the present study, spontaneous liver tumor rates were determined in three unique lines of transgenic mice and compared to non-transgenic (NT) controls. Mice were housed for 2 years under standard conditions, during which time, they received no chemical treatment. Liver tumors were detected at terminal necropsy by gross evaluation and histopathological exam. C57Bl/6 mice exhibit low spontaneous tumor rates, and no liver tumors were observed in NT mice (0/9 males; 0/12 females). In 2 transgenic lines that showed no hepatic expression of the transgene, a very low incidence of liver tumors was also observed (0/26 males; 1/22 females). MT-CYP2B1[3] transgenic mice express CYP2B1 mRNA and protein in liver, with constitutive CYP2B enzyme activity about 3-times higher than NT mice. These mice also show increased mortality rates, and to date, liver tumors (adenomas and carcinomas) have been observed in 3/11 males and 2/5 females. In total, liver tumors in NT and non-expressing transgenic mice were rare, with 1 liver tumor observed in 69 mice (1/34 females (3%); 0/35 males) at 2 years of age. In contrast, liver tumors have been seen in approximately 30% of the MT-CYP2B1[3] transgenic mice, thereby suggesting that sustained CYP2B enzyme activity increases liver tumor susceptibility in the resistant C57Bl/6 strain.

1196 RECENT RETROSPECTIVE AND PROSPECTIVE STUDIES IN THE TG.AC AND $P53^{+/-}$TRANSGENIC MOUSE LINES ON CHEMICALS COMPLETED IN THE TWO-YEAR NTP BIOASSAY.

J W Spalding[1], J E French[1], W Eastin[1], J Mahler[1], J Bucher[1], M Furedi-Machacek[2], F Connor[2], R R Tice[2], and R W Tennant[1]. [1]*NIEHS, Research Triangle Park NC;* [2]*Integrated Laboratory Services, Research Triangle Park, NC.*

The Tg.AC (zetaglobin/v-Ha-ras) and $p53^{+/-}$ heterozygous knockout transgenic mouse lines have been evaluated for their capability to detect and discriminate between chemical carcinogens and noncarcinogens. The Tg.AC line detects both genotoxic (GTC) and nongenotoxic(NGTC) carcinogens via topical application to the dorsal skin. Carcinogens induce skin papillomas, the reporter phenotype, that defines chemical activity. The $p53^{+/-}$ model detects GTC administered by various routes and a wide range of target organs respond to carcinogen induction. In a prospective study, eight nongenotoxic NTP chemicals, diethanolamine (DEA), oleic acid diethanolamine (OAD), lauric acid diethanolamine (LADA), coconut oil diethanolamine (COD), 1-chloro-2-propanol (CP), furfuryl alcohol (FA), pentachlorophenol (PCP) and pyridine (PY), were tested in both transgenic models before the 2-year bioassays were completed. PCP and LADA, two of the six chemicals that were identified as bioassay carcinogens, were active in Tg.AC mice, but as expected, none of the NGTC were detected in $p53^{+/-}$ mice. The bioassay NGTC that are primarily single sex/species carcinogens, especially those that specifically target mouse liver, are much less likely to be identified in the Tg.AC line than those that are genotoxic or nongenotoxic trans-species carcinogens. The fact that some liver specific nongenotoxic carcinogens (mirex, LADA, PCP) are active in Tg.AC mice and that others (N-methyloacrylamide, methylphenidate, triethanolamine, DEA) are not, suggests that these nongenotoxic mouse liver carcinogens induce tumors by different mechanisms. The correspondence of activity for human carcinogens in transgenic mice is very high. Benzene, cyclosporin A, diethylstilbestrol, melphalan, and 2,3,7,8-tetrachlorodibenzo-p-dioxin were all detected in Tg.AC mice and the two genotoxic carcinogens, benzene and melphalan, were active, as predicted, in the $p53^{+/-}$ model. These results support the premise that chemical evaluation in both transgenic lines will identify most trans-species carcinogens, which are likely to be of most concern in human risk assessment.

1197 ASSESSMENT OF A RAPID CANCER BIOASSAY USING THE *p53* DEFICIENT Tg.AC(v-Ha-*ras*) MOUSE MODEL.

J E French, G Lacks, G Moser, T L Goldsworthy, J W Spalding and R W Tennant. *NIEHS and ILS, RTP, NC, USA.*

Genetically altered mouse models for toxicology and carcinogenesis experiments may provide a mechanistic basis for understanding carcinogen induced neoplasia. We conducted rapid cancer bioassays (26 weeks exposure) in this mouse model using benzene (200 µL, 2× /wk; topical), p-cresidine (0.5%, oral, diet), and TPA (1.5 µg, 3× /wk, topical) for comparison to previously conducted cancer bioassays in either FVB/N-Tg.AC(v-Ha-*ras*) or heterozygous C57BL/6-*Trp53* mice. Mortality was greatest in p-cresidine treated mice due to rapid onset of urinary bladder masses. Mortality was also observed at lower levels in both untreated and treated dose groups due to the

rapid onset of sporadic tumors or treatment related tumors. Clinical observations indicated that both benzene and TPA induced papillomas with an expected incidence and multiplicity, but benzene mice developed more test site skin and other malignancies than TPA treated mice relative to the controls. p-Cresidine treated transgenic mice (but not the nontransgenic control FVB/N mice) rapidly developed urinary bladder masses (100% males and 70% females). p-Cresidine induced body weight depression was similar in both transgenic and nontransgenic mice. Overall, these results indicate that carcinogen induction of the v-Ha-ras transgene under p53 deficient conditions may allow a rapid detection of carcinogen induced tissue specific malignancy. Both *ras* and *p53* mutations are observed in many human cancers and a mechanistic understanding of the other critical genetic events occurring in these neoplasia may help in defining carcinogen specific mechanisms of cancer induction.

1198 ANALYSIS OF THE MUTANT FREQUENCY OF NONRESPONDER TG.AC MICE.

R E Cannon[1], D B Dunson[1], G Rao[1], D Kantz[2] and R W Tennant[1]. [1]*National Institutes of Environmental Health Sciences, Research Triangle Park, NC, USA;* [2]*Integrated Laboratory Systems, Research Triangle Park, NC, USA.*

The v-Ha-ras transgenic Tg.AC mouse model is under consideration by the National Toxicology Program (NTP) as an adjunct or alternative to the conventional two-year bioassay for the identification of chemical carcinogens. Tg.AC mice produce skin papillomas when topically treated with chemical carcinogens but fail to do so when treated with noncarcinogens. Molecular analyses indicate a 2000 base pair Bam HI fragment composed of two inverted transgene zeta globin promoters are essential for the induced phenotypic tumorigenic response. Genotypic analysis in conjunction with test mating to FVB/N mice indicate that the 2000 base pair inverted promoter region is subject to spontaneous deletion. Using the laws of Mendelian genetics a likelihood for any given genotype to occur at any given generation was derived. Applying these methods to the known genotypes of the 12 breeding pairs from the 25th generation a retrospective mutation probability was calculated. The probability that a Tg.AC responder allele "R" will spontaneously delete to a nonresponder allele " r " was estimated to be 1.59%. The observed mutation frequency determined from outcrossing responder Tg.AC mice to FVB/N was 1.476%. The methods from this study were used to determine the highest generation number, below which the proportion of nonresponder Tg.AC mice is acceptably small. This work provides valuable information for scientist involved in breeding and maintaining transgenic mouse lines in addition to the those involved in carcinogen identification studies employing Tg.AC mice.

1199 DEVELOPMENT OF NON-ISOTOPIC DNA RFLP ANALYSIS FOR IDENTIFICATION OF NON-RESPONDER Tg.AC MICE.

G J Moser[1], D C Kantz[1], G Lacks[1], R R Tice[1], T L Goldsworthy[1], G N Rao[2], R W Tennant[2], J W Spalding[2], and R Cannon[2]. [1]*ILS and* [2]*NIEHS, Research Triangle Park, NC.*

Tg.AC transgenic mouse models have been proposed as a short term in vivo alternative to the chronic bioassay to identify and characterize the mechanisms of action of carcinogens. When exposed to the tumor promoter, 12-0-tetradecanoyl-phorbol-1,3- acetate (TPA), Tg.AC mice responded with skin papillomas as a reporter phenotype. Recently, an increase in TPA-exposed non- responder (NR) Tg.AC mice has been identified. To characterize the NR phenotype, we calculated the incidence of Tg.AC mice with papillomas. Retrospectively, from 1991 to 1996 in 9 experiments, the incidence of papillomas in TPA-treated Tg.AC mice was consistently over 90%. In 1997, the incidence of papillomas precipitously dropped ranging from 44% to 65%. The NR phenotype as a function of Tg. AC genotype, TPA-dosing regiment, and generation number are now known. NR mice lack a 2.0 kb region found in responder mice. A 32P-based Southern blot assay allows for the identification of NR based on DNA band shift. We developed an analogous non-isotopic DNA Blot procedure. This methodology is accurate, sensitive, reproducible, requires less time and expense, and obviates the need for radioactivity. These data indicates that the NR phenotype first appeared in 1997 and can be genotypically identified by non- isotopic Southern analysis.

1200 TRANSFORMATION-ASSOCIATED RECOMBINATION CLONING TO EVALUATE LCR INVOLVEMENT IN TG.AC TRANSGENE EXPRESSION.

M C Humble[1,2], N Kouprina[2], V Larionov[2], R W Tennant[2], and R E Cannon[2]. [1]*Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA;* [2]*National Institute of Environmental Health Sciences, Research Triangle Park, NC, USA.* Sponsor: G L Erexson.

Genetically initiated Tg.AC transgenic mice carry a transgene consisting of an oncogenic v-Ha-ras coding region flanked 5' by a mouse zeta-globin promoter and 3' by an SV-40 polyadenylation sequence. Located proximal to the centromere on chromosome 11, the transgene is transcriptionally silent until activated by full thickness wounding, UV light, or chemical carcinogens. Expression of the transgene is an early event that drives cellular proliferation resulting in clonal expansion and tumor formation. Created on the FVB/N mouse, only one of five founder lines displayed the unique characteristics now associated with the Tg.AC mouse. To explore the possible presence of a Locus Control Region (LCR) responsible for transgene expression, a library of Yeast Artificial Chromosomes (YACs) were prepared by transformation-associated recombination (TAR) cloning. Isolated YACs contained the Tg.AC transgene and flanking mouse chromosome 11 up to 200kb 5' or 3' of the transgene. Following conversion of the YACs to Bacterial Artificial Chromosomes (BACs), each YAC/BAC was assayed for its ability to promote transcription of the transgene following transfection into an FVB/N carcinoma cell line. This data provides valuable insight into the requirement of a cis regulatory region in transgene expression.

1201 EVALUATION OF THE Tg.AC AND p53 (het) MOUSE AS POTENTIAL MODELS FOR CANCER TESTING OF PROTEIN MOLECULES AND PARTICULARLY GROWTH FACTORS.

J B Clarke, N Dybdal and A Cheng. *Genentech, Inc. South San Francisco, CA, USA.*

Three studies in both p53 (het) and Tg.ac mice were designed to address false positives caused by injection or an immune response to the protein, and the response to chronically administered growth factors. In study 1, animals received either no injection, saline, pH 5.5 vehicle or human albumin (1 mg/kg). In study 2 and 3, murine epidermal growth factor (mEGF) at 0.1, 1.0 or 10 μ g/kg or recombinant human insulin-like growth factor-1 (rhIGF-1) at 0.1, 1.0 or 10 mg/kg were administered respectively. The p53 mice used in study 1 were bred at Genentech Inc, remaining animals were from Taconic. In each study, treatments were administered 3 times per week, subcutaneously for 6 months, clinical pathology and hematology were performed prior to and at 3 and 6 months and animals were necropsied at 6 months for subsequent microscopic pathology. Blood samples were also drawn after 3 months to confirm exposure to the growth factors. All Tg.ac mice were tested retrospectively for the responder phenotype by Taconic. No apparent growth factor treatment-related gross lesions were observed. Unfortunately, injection and immune-related tumor formation in the Tg.ac model (study 1) could not be evaluated due to a 16% overall responder phenotype in this study. In study 2 and 3 the overall Tg.ac responder rate was 50% males/0% females and 83% male/ 91% female respectively. In studies 2 and 3,after 10 weeks, a small number of male Tg.ac mice developed small botryoid perineal masses, which did not appear to be treatment related. Also in studies 2 and 3, a few p53 mice developed subcutaneous masses consistent with areas of probable prior irritation at the injection site. In conclusion, neither model may be sensitive to an increased tumor risk as a result of chronic administration of either mEGF or rhIGF-1. Alternatively, this may indicate that chronic administration of growth factors is not associated with an increase in tumor risk, particularly since the Tg.ac model, which would be expected to respond to potential non-genotoxic carcinogens, was not responsive to either growth factor.

1202 SIX MONTH ORAL GAVAGE AND DIET CARCINOGENICITY STUDY WITH PHENOLPHTHALEIN IN THE HETEROZYGOUS P53+/- MOUSE.

S M Furst, K T Blanchard, P D Lilly, H E Holden, J H Stoltz, C Barthel and R E Stoll. *Dept. Toxicology and Safety Assessment, Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT, USA.*

Researchers have been investigating the use of the 6-month $p53^{+/-}$ transgenic mouse model as an alternative to a 2-year rodent carcinogenicity bioassay. In the current study, we evaluated the carcinogenic potential of phenolph-

thalein administered 26-weeks by gavage (800 and 2400 mg/kg/day) versus in the diet (2400 mg/kg/day) to heterozygous p53$^{+/-}$ mice. p-Cresidine was used as a positive control article and administered by oral gavage in corn oil at 400 mg/kg/day. Micronucleus analysis of peripheral blood smears and histopathological examination of the thymus was conducted on all animals. There was an unequivocal drug-induced incidence of thymic lymphoma in both male and female animals administered phenolphthalein by gavage or in the diet. There was a dose related increase in the incidence of thymic neoplasms and the highest incidence was observed when phenolphthalein was administered in the diet. Animals in the 800 mg/kg/day gavage group had 3/15 males and 5/15 females affected, and the 2400 mg/kg/day gavage group had 4/15 males and 8/15 females affected. Animals receiving phenolphthalein at 2400 mg/kg/day in the diet had the highest incidence of thymic lymphoma, with 12/15 males and 14/15 females affected. Micronucleus analysis indicated that phenolphthalein administered orally by gavage or diet produces elevation in the incidence of micronucleated polychromatic erythrocytes and in the ratio of PCE to NCE. This study clearly indicates that phenolphthalein rapidly induces thymic lymphomas in both male and female p53$^{+/-}$ mice irrespective of the mode of delivery (gavage versus diet).

1203 GENETIC ANALYSES OF PHENOLPHTHALEIN-INDUCED THYMIC LYMPHOMAS FROM P53+/- MICE.

J E Hulla[1], J E French[2], and J K Dunnick[2]. [1]*Department of Pharmacology and Toxicology, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND, USA;* [2]*National Institute of Environmental Health Sciences, Research Triangle Park, NC, USA.*

In p53 +/- mice on a C57Bl/6 background treated with 0, 200, 375, 750, 3000 or 12,000 ppm phenolphthalein (P9189), thymic lymphomas developed at a combined incidence of 0%, 5%, 5%, 25%, 100% and 95%, respectively. We compare genomic DNA isolated from 10 of these thymic lymphomas to DNA from 2 lymphomas that arose spontaneously and to surrounding normal tissue DNA. We use PCR to confirmed published *in situ* data and show that the wildtype p53 allele, present in both of the spontaneous tumors and each normal tissue, is absent from each of the 10 phenolphthalein-induced thymic tumors. We further establish that the p53 null allele is present in each of the tumors and normal tissues. We genotype over 70 simple sequence length polymorphism (SSLP) DNA loci using the tumor and normal DNAs as template for radiolabeled PCR. The amplicons are separated on acrylamide gels to compare sizes between normal- and tumor- derived amplicons. Only the results from chromosome 11 are remarkable. The sets of amplicons generated from 29 loci located on chromosomes other than chromosome 11 are consistent with the allelic homozygosity expected for the C57Bl/6 background and no tumor-specific size instability or deletions are detectable at these loci. In contrast, allelic heterozygosity is evident at 24 of 38 chromosome 11 loci surveyed. The size of each amplicon is consistent with alleles originating from either C57Bl/6 or 129 mouse strains. Most remarkable are findings that the phenolphthalein-induced thymic lymphomas show treatment-related patterns of loss of heterozygosity on chromosome 11. The data suggest treatment-related crossover and genetic recombination between chromosomes 11.

1204 CORRELATION BETWEEN SUSCEPTIBILITY TO CHEMICALLY INDUCED CARCINOGENESIS AND CELL PROLIFERATION IN THE EARLY STAGE IN HETEROZYGOUS P53 DEFICIENT MICE.

T Sukata[1,2], K Ozaki[1,2], S Yamamoto[2], S Uwagawa[1,2], H Wanibuchi[2], Y Okuno[1], and S Fukushima[2]. [1]*Environmental Health Science Laboratory, Sumitomo Chemical Co., Ltd., Konohana-ku, Osaka, Japan;* [2]*First Department of Pathology, Osaka City Univ., Abeno-ku, Osaka, Japan.*

We attempted to elucidate susceptibility to chemically induced carcinogenesis in heterozygous p53 deficient mice (p53(+/-) mice). Both p53(+/-) mice and the wild-type mice were given 0, 20, 40, 75 and 250ppm BBN in drinking water for 20 weeks. Frequency of transitional cell carcinoma and preneoplastic lesions in the urinary bladder of p53(+/-) mice was more elevated than in the wild-type mice, showing potent susceptibility to BBN-induced urinary bladder carcinogenesis. Subsequently, both mice were respectively given the following chemicals for 4 weeks; 75ppm BBN, 10ppm DMN or 0.1% DHPN in drinking water, or 25mg/ml DMBA dermal application once a week. P53 expression, or decrease of p53-dependent p21$^{waf1/cip1}$ mRNA and protein expression from the expression in the wild-type mice were observed in the all organs examined, that is, urinary bladder, liver, lung and skin in p53(+/-) mice. However, cell proliferation is accelerated only in the urinary bladder and skin. These data indicate that p53(+/-) mice show organ-specific acceleration of cell proliferation in the early stage, and the specificity has correlation to the susceptibility to chemically induced carcinogenesis.

1205 EVIDENCE FOR A CRITICAL PALINDROMIC ORIENTATION OF TRANSGENE PROMOTER SEQUENCE FOR TUMORIGENIC RESPONSIVENESS AMONG Tg.AC TRANSGENIC MICE.

K L Thompson[1], B A Rosenzweig[1], R Honchel[1], K T Blanchard[2], R E Stoll[2], and F D Sistare[1]. [1]*Center for Drug Evaluation & Research, FDA, Laurel, MD;* [2]*Boehringer Ingelheim Pharmaceuticals, Inc, Ridgefield, CT, USA.*

The Tg.AC transgenic mouse skin paint assay is being evaluated as a short-term carcinogenesis model as an alternate for one species in the conventional two-year bioassay for safety testing of pharmaceuticals. Tg.AC mice carry multiple copies of transgene consisting of a ζ-globin promoter fused to the v-Ha-*ras* structural gene with a terminal SV-40 polyA signal. We have noted previously that a subset (Weaver et al, 1998; Blanchard, et al 1998) of hemizygous Tg.AC mice were refractory to treatment with 12-O-tetradecanoylphorbol 13-acetate (TPA). We have also shown (Thompson et al, 1998) that all hemizygous Tg.AC mice screened contain about 40 copies of the transgene but that TPA-unresponsive mice had lost a 2 kb *Bam*HI fragment containing ζ-globin promoter sequence. Results from restriction enzyme digestion and S1 nuclease digestion experiments provide evidence that the 2 kb diagnostic *Bam*HI fragment is a palindromically oriented transgene sequence that has a propensity to form a cruciform structure. The cruciform structure appears to be both important for functional expression as well as a cause for the observed transgene instability. We also report examples of non-responders with only a small deletion in the 2 kb *Bam*HI fragment of ζ-globin promoter sequence. The locus of this short ζ-globin sequence, which is deleted asymmetrically and appears critical for regulated expression, has been identified. Systematic screening of Tg.AC breeder mice for the intact 2-kb diagnostic marker of phenotypic responsiveness is allowing Tg.AC mouse colonies to be culled of nonresponders so that the utility of this model for carcinogenicity testing can be fairly evaluated and evaluations of the carcinogenic potential of pharmaceuticals tested with this model can be made accurately. These findings provide incentive for improved transgenic mouse quality assurance monitoring. Furthermore, variants with small or large deletions of ζ-globin sequence are providing insight into the mechanisms by which Tg.AC mouse transgene expression may be regulated by carcinogens.

1206 ROLE OF TUMOR NECROSIS FACTOR α (TNFα) AND TNFα RECEPTOR 1 (TNFR1) IN SUPPRESSION OF HEPATOCYTE APOPTOSIS BY PEROXISOME PROLIFERATORS IN WILD TYPE AND PPAR$^{-/-}$ MICE.

R A Roberts, N H James, D West and P R Holden. *Zeneca Central Toxicology Laboratory, Alderley Park, Macclesfield, UK.* Sponsor: I Kimber.

Peroxisome proliferators (PPs) are a class of nongenotoxic rodent hepatocarcinogens that activate the peroxisome proliferator activated receptor α (PPARα) to cause increased hepatocyte DNA synthesis, peroxisome proliferation and liver enlargement. We have demonstrated previously that PPs suppress spontaneous rat and mouse hepatocyte apoptosis and that induced by the physiological negative regulator of liver growth, transforming growth factor β (TGFβ1). In addition, we have shown that tumor necrosis factor α (TNFα) is able to suppress apoptosis and induce S-phase in cultured mouse hepatocytes, mimicking the effects of PPs. Furthermore, the neutralisation of TNFα using anti-TNFα antibodies abrogated the suppression of apoptosis by the PP, nafenopin. Here, we show that neutralisation of one of the receptors for TNFα , TNFR1 (p55) abrogated the suppression of apoptosis and induction of S-phase by nafenopin. However, neutralisation of TNFR2 (p75) was without effect. In cultured hepatocytes isolated from the PPARα knock out mouse (PPARα -/-), PPs were no longer able to induce suppress apoptosis and induce DNA synthesis. Similarly, PPs were no longer able to induce peroxisome proliferation as measured by cyanide insensitive palmitoyl CoA oxidation (PCO). However, exogenous TNFα still was able to induce S-phase and suppress apoptosis in PPARα -/- hepatocytes, but was unable to induce PCO. Thus, TNFα , acting via TNFR1, appears to mediate PP-induced growth perturbation but not peroxisome proliferation. In addition, production or release of TNFα is downstream of PPARα activation. These data suggest a role for hepatic cytokines such as TNFα in nongenotoxic hepatocarcinogenesis.

1207 DIETHYLDITHIOCARBAMATE (DDC) INCREASES SENSITIVITY OF KUPFFER CELLS TO LIPOPOLYSACCHARIDE (LPS).

H Ishiyama, N C Hoglen and I G Sipes. *Department of Pharmacology and Toxicology, Center for Toxicology, The University of Arizona, Tucson, AZ.*

DDC, a chelator of copper and a potent inhibitor of superoxide dismutase, is widely used in agricultural, industry and clinical therapy. Previous studies have shown that DDC causes rat liver injury in rats and the pathogenesis of this injury involves, in part, activation of Kupffer cells (KCs). Moreover, we have found that DDC increased the sensitivity of KCs to LPS *in vitro*. To further investigate the role of KCs in the pathogenesis of DDC induced liver injury, KCs were isolated from male Sprague-Dawley rats by collagenase-protease perfusion and purified by centrifugal elutriation. Nitric oxide (NO) was estimated using a dichloro-fluorescin free base. Tumor necrosis factor (TNF)-α was determined by L929 cell bioassay. TNF-α and iNOS protein expressions as well as activated NF-κ B were detected by immunocytochemical analysis. Oxidative stress was detected by intracellular loading of dichlorofluorescin diacetate.

DDC (0-30 μ M) increased the secretion of NO and TNF-α by LPS-stimulated KCs in a concentration-dependent manner. DDC+LPS-treated KCs showed increases in iNOS and TNF-α immuno-reactivity as compared to that of LPS alone. The stimulatory effect of DDC was inhibited by H-7 (an inhibitor of protein kinase C) and N-acetyl-L-cysteine (an inhibitor of NF-κ B activation). DDC enhanced the nuclear translocation of activated NF-? B by LPS-stimulated KCs. There was no evidence of oxidative stress following either LPS or DDC+LPS exposure.

These findings demonstrate that DDC increases the sensitivity of KCs to LPS and suggest that DDC may affect signaling pathway upstream of protein kinase C. (Supported in part by NIEHS Center Grant ES 06694.)

1208 COORDINATE REGULATION OF INDUCIBLE NITRIC OXIDE SYNTHASE AND CYCLOXYGENASE-2 EXPRESSION IN HEPATIC MACROPHAGES DURING ACUTE ENDOTOXEMIA.

N Ahmad and D L Laskin. *Joint Grad. Program in Toxicology, Rutgers Univ., Piscataway, NJ.*

Nitric oxide (NO) is a cytotoxic mediator produced by activated macrophages via an inducible form of nitric oxide synthase (NOSII). NO has been implicated in the regulation of a number of enzymes involved in the inflammatory response. Of particular interest is cycloxygenase-2 (COX-2), an enzyme that oxidizes arachidonic acid leading to the formation of prostaglandins, prostacyclin and thromboxane A_2. Endotoxin is a bacterially derived product known to induce hepatic injury. This is associated with an infiltration of macrophages into the liver which release mediators such an NO and eicosanoids which are thought to contribute to endotoxin-induced tissue damage. In the present studies we analyzed mechanisms regulating production of these mediators in the liver during acute endotoxemia. To induce acute endotoxemia, rats were injected with Escherichia coli lipopolysaccharide (5 mg/kg, i.v.). Hepatic macrophages were isolated 3-48 hr later. We found that macrophages from control and endotoxin treated rats readily produced NO in response to inflammatory stimuli. Treatment of rats with endotoxin resulted in a time-dependent increase in NO production. This was correlated with increased NOSII expression by the cells as determined by Western blot analysis. Maximum NO production and NOSII protein were observed 3 hours after endotoxin treatment of rats. Following endotoxin administration, we also found that COX-2 expression in macrophages was increased. As observed with NOSII, maximal expression was observed 3 hours after endotoxin treatment of rats. To determine if NO is involved in the regulation of COX-2, we used aminoguanidine (AG), a relatively specific NOSII inhibitor. Treatment of macrophages with AG reduced NO production by the cells. In contrast, AG had no effect on NOSII or COX-2 expression by the macrophages. These data suggest that activation of both NOSII and COX-2 may be important in the pathophysiological response of hepatic macrophages to endotoxin. Moreover the activity of these oxidases appears to be regulated coordinately. (NIHGM34310, ES06897 and the Burroughs Wellcome Fund).

1209 POTENTIAL ROLES OF AP-1 AND NF-κB IN ITO CELLS DURING LIVER FIBROGENESIS.

D R Petersen, J Lee, and V Vasiliou. *Molecular Toxicology & Environmental Health Sciences, Department of Pharmaceutical Sciences, University of Colorado Health Sciences Center, Denver, CO.*

Exaggerated connective tissue accumulation occurs during hepatic fibrosis that is associated with a loss of functional hepatocytes. AP-1 is a key transcription factor which is involved in the positive and negative regulation of the interstitial collagenase (MMP-1) and α1-(1) procollagen gene expression, respectively. During liver injury NF-κB activates IL6 gene expression in Ito cells, which in turn stimulates NF-κB in hepatocytes and prevents them from apoptosis. We have investigated the AP-1 and NF-κB binding activities, by gel mobility shift assays, in Ito cell lines derived from normal (NFSC) or cirrhotic (CFSC) rat liver. We found constitutive AP-1 binding activity in NFSC, but not in CFSC cells. A different pattern of NF-κB binding was found in CFSC cells compared to that in NFSC cells, which is due to a non-phosphorylated protein complex. Our data indicate that changes in the AP-1 and NF-κB in Ito cells, during liver injury, may represent a mechanism by which cell injury stimulates collagen production, inhibits collagen degradation and causes apoptosis in hepatocytes. This chain of events is likely to potentiate the process of liver fibrosis. (Supported by NIH R01 AA09300.)

1210 EFFECT OF ENDOTOXIN PRETREATMENT ON OXIDATIVE STRESS, COLLAGEN AND CYTOKINE SECRETION OF HEPATIC STELLATE CELLS EXPOSED TO ETHANOL AND ACETALDEHYDE.

S C Quiroz[1], L Bucio[1], V Souza[1], I P Olivares[1], E González[1], E Hernández[1], F Vargas[2], D Kershenobich[2] and M C Gutiérrez Ruiz[1]. [1]*Dpto. Ciencias de la Salud, Universidad Autónoma Metropolitana, Mexico;* [2]*Dpto. Gastroenterología, INNSZ, Mexico.*

Endotoxins (LPS), are believed to play a major role in alcohol-induced liver injury. Plasma levels of LPS are increased after acute ingestion of ethanol and in patients with alcoholic liver disease. Alcohol also enhances oxidative stress in the liver which can either independently stimulate the release of cytokines or amplify the effect of LPS. The objective of the present study is to determine the effect of endotoxin pretreatment on the oxidative stress, collagen and cytokine secretion of rat stellate cells treated with ethanol (EtOH) and acetaldehyde (Ac). Media containing 1μ g/ml LPS were added to rat hepatic stellate cells (CFSC-2G) 24hs after seed, and replaced 48 hs later by media containing LPS+ EtOH (50 mM) or LPS + Ac (175 μ M). Measurements were done at least trice 24 hs later. Lipid peroxidation was measured as malondialdehyde production in the presence of thiobarbituric acid. Reduced glutathione was quantified by means of the Ellman reaction, and collagen secretion by the hidroxiproline micromethod. TNF-α , IL-1β , IL-6 and TGF-β_1 were determined in the media by ELISA using commercial kits (R&D). Lipid peroxidation damage did not increase as a result of endotoxin pretreatment. However, GSH content diminished 43% in EtOH and 83% in acetaldehyde endotoxin pretreatment.. LPS pretreated cells increased collagen secretion. Among cytokines, IL-6 presented sensible differences with endotoxin pretreatment . There were not found TNF-α or IL-1β secretion in any experimental condition. LPS pretreatment of rat hepatic stellate cells treated with EtOH and Ac increases oxidative stress and collagen secretion. These findings support a convergence of LPS damage, oxidative stress and cytokine pathways in the fibrogenic process. (Supported by grant from CONACYT # 400200-5-25175M.)

1211 THE ROLE OF NUCLEAR FACTOR-KAPPA B IN CARBON TETRACHLORIDE INDUCED LIVER INJURY.

H Chiu[1], L A Morio[1], D M Dambach[2], S K Durham[2], R Bravo[2], and D L Laskin[1]. [1]*Rutgers University, Piscataway, NJ;* [2]*Bristol-Myers Squibb Company, Piscataway, NJ.*

Carbon tetrachloride (CCl_4) is a well-characterized centrilobular hepatotoxicant. Recent studies have shown that the toxicity of CCl_4 is mediated, in part, by tumor necrosis factor-alpha (TNF-α), a macrophage derived inflammatory mediator. Thus following CCl_4 administration to mice there is a time-dependent induction of serum and hepatic TNF-α. Moreover, mice lacking the gene for TNF-α are protected from CCl_4 induced hepatotoxicity. The promoter region of the TNF-α gene contains binding sites for several different transcription factors including NF-κB. This transcription factor in composed of a family of proteins, including two homologous subunits: p50 and

p52. These bind to the p65 subunit to form an active p50/p65 or p52/p65 heterodimer. In the present studies we analyzed the role of NF-κB in liver injury induced by CCl_4 using knockout mice lacking the genes for the p50 or p52 subunits. Treatment of wild type control C57/BL6 mice with CCl_4 (0.3 ml/kg, i.p.) resulted in a time-dependent induction of centrilobular hepatic necrosis reaching a maximum at 24h. This was correlated with increased serum transaminase levels. CCl_4 was found to be significantly less effective in inducing hepatotoxicity in mice lacking the gene for the p50 NF-κB subunit. In contrast, knockout mice lacking the gene for the p50 subunit were not protected from CCl_4-induced liver injury. These data suggest the TNF-α induced signal transduction mediated by the p50 NF-κB subunit is an important regulator of CCl_4-induced liver injury (Supported by NIH GM34310 and Burroughs Wellcome Fund.)

1212 DIPHENYLENEIODONIUM, AN NADPH OXIDASE INHIBITOR, PREVENTS EARLY ALCOHOLIC LIVER INJURY BY CHRONIC INTRAGASTRIC ETHANOL EXPOSURE IN RATS.

H Kono, I Rusyn and R G Thurman. *Laboratory of Hepatobiology and Toxicology, Department of Pharmacology, University of North Carolina, Chapel Hill, NC, USA.*

Chronic ethanol administration enhances free radical formation in the liver. Reactive oxygen species could be involved in triggering liver injury due to alcohol by activation of transcription factors, such as nuclear factor κ B (NF-κ B), which regulate production of inflammatory cytokines by Kupffer cells. The purpose of this study was to determine whether NADPH oxidase is involved in early alcoholic liver injury. Male Wistar rats were fed a high-fat diet with or without ethanol (10-18 g/kg/day) continuously for up to 4 weeks using an intragastric enteral feeding protocol developed by Tsukamoto and French. Diphenyleneiodonium (DPI; 1 mg/kg/day) or vehicle (5% glucose, 0.2 ml/day) was administrated by subcutaneous injection for 4 weeks. DPI did not effect body weight or cyclic patterns of ethanol in urine. Mean urine ethanol concentrations were 251 ± 33 mg/dl and 262 ± 22 mg/dl in ethanol- and ethanol+DPI-treated groups, respectively. Ethanol treatment for 4 weeks caused about 4-fold increase in serum AST levels (253 ± 42 IU/L). DPI treatment blunted this increase significantly by about 55% (115 ± 15 IU/L). Ethanol treatment also caused severe fatty infiltration, inflammation, and mild focal necrosis in the liver after 4 weeks (pathology score: 7.2 ± 0.1). However, these pathological changes were blunted significantly by DPI (pathology score: 2.2 ± 0.3). Activation of NF-κ B was assessed with an electrophoretic mobility shift assay. After 4 weeks of ethanol treatment, NF-κ B activity in hepatic nuclear extracts was increased significantly nearly 2.5-fold over control. This increase was blunted significantly by DPI with values only 25% as high as ethanol alone. These results indicate that DPI prevents early alcoholic liver injury, most likely by inhibition of free radical formation by NADPH oxidase which prevents activation of NF-κ B.

1213 COMPARATIVE HEPATIC EFFECTS OF DIFFERENT LIPOPOLYSACCHARIDES FOLLOWING REPEATED DOSING IN RATS.

A Suganuma[1], S Motooka[1], S Hosokawa[2] and W D Kerns[1]. [1]*Eisai Research Institute of Boston, Inc., Andover, MA, USA;* [2]*Kawashima Drug Safety Research Department, Eisai Co., Ltd., Hashima-gun, Gifu, Japan.*

Lipopolysaccharide (LPS) is rapidly cleared by hepatic Kupffer cells and high doses induce the release of a variety of cytokines which result in hepatotoxicity and other systemic effects. The objective of this study was to compare the chronic effects of LPS from two bacterial strains, each with different LPS agonistic properties, on Kupffer cells to the Kupffer cell changes caused by beta-glucan. LPS from *E. coli* (ecLPS) and *Rhodobacter sphaeroides* (rsLPS) were given i.v. (0.6 and 6 mg/kg) to male SD rats (3/group) for 7 days. rsLPS and its lipid A are reported to elicit no cytokine synthesis from macrophages *in vitro* and to prevent LPS-dependent production of tumor necrosis factor. Beta-glucan (bGLU) was given i.v. (30 mg/kg) as a positive control. Control rats received 5% dextrose. Body weights, clinical pathology, and hepatic histology data were collected from each rat. Rats were killed on day 15. ecLPS (6 mg/kg) was lethal and caused hepatocellular necrosis and Kupffer cell vacuolation (KCV), with increased ALT, AST, ALP and GGT. ecLPS (0.6 mg/kg) caused only minimal KCV and inflammation; there were acute increases (day 2) in hepatic enzymes. rsLPS caused a dose-responsive increase in KCV associated with Kupffer cell hyperplasia/hypertrophy and inflammation, but no increases in liver enzymes were observed. bGLU hepatic lesions were manifest by florid granulomas which most likely originated from Kupffer cells; there were no increases in liver enzymes. Nonlethal doses of lipopolysaccharides, with differing agonistic properties, resulted in dramatically different Kupffer cell responses in this 15-day study. Because rsLPS is a very weak LPS agonist, higher doses resulted in greater Kupffer cell exposure resulting in a response that appears unique when compared to ecLPS in this study. It is possible that longer-term exposure to low doses of ecLPS could elicit similar responses as rsLPS. Neither ecLPS nor rsLPS caused granulomas similar to bGLU.

1214 ACUTE EXPOSURE TO DIMETHYLNITROSAMINE RESULTS IN ALTERED HEPATIC EXPRESSION OF CYTOKINE- AND APOPTOTIC-ASSOCIATED GENES.

T L Horn[1,2], A Bhattacharjee[2], L B Schook[1,2] and M S Rutherford[2]. [1]*Toxicology Graduate Program and* [2]*Department of Veterinary PathoBiology, University of Minnesota, St. Paul, MN.*

We have shown that following acute dimethylnitrosamine (DMN; 5.0 mg/kg) exposure, serum cytokine levels of tumor necrosis factor-α (TNFα), interleukin (IL)-1β and IL-6 increase. In addition, acute high dose DMN has been previously shown to result in apoptosis as measured by DNA laddering. However, the mechanism of apoptosis and pathway(s) involved have not been characterized. TNFα is a potent regulator of apoptosis, thus, mice deficient in both p55 and p75 TNF receptors (TNFR double knockout; DKO) were obtained. We examined the role of TNFα following acute high dose DMN (100 mg/kg) exposure on hepatic mRNA expression of proinflammatory cytokine, cytokine receptor and apoptotic genes. RNase protection assays showed that WT (TNFR intact) mice exposed to DMN had increased hepatic mRNA expression of TNFα and transforming growth factor (TGF)β 2. DMN also increased expression of the following cytokine receptors: IL-1RI, IL-1RII, TNFRp55, and TGFβ RII, whereas TNFRp75, IL-6Rα , and TGFβ RI remain unchanged. WT and DKO mice showed up-regulation of the apoptosis promoting genes, bax and Fas, and the anti-apoptosis gene bcl-X_L, while decreased expression of the apoptosis inhibiting gene, bcl-W. Another anti-apoptosis gene, bfl1, showed increased mRNA expression with DMN exposure in WT mice, but not in DKO mice suggesting TNFα signaling is capable of protective mechanisms during DMN-induced hepatotoxicity. In addition, histological evidence indicates that signaling through TNFRp55 is required during hepatic inflammatory responses as well as contributes to liver damage following acute DMN. Thus, our results show that acute high dose DMN alters the hepatic expression of different cytokines and their receptors as well as genes associated with apoptosis. (This work was supported by NIH Grant ES08395.)

1215 INCREASED SENSITIVITY OF TUMOR NECROSIS FACTOR-α (TNF-α) KNOCKOUT MICE TO ACETAMINOPHEN (AA) IS MEDIATED BY NITRIC OXIDE (NO).

D M Dambach[1], C R Gardner[1], H Chiu[1], M W Marino[2], S K Durham[3], and D L Laskin[1]. [1]*Joint Graduate Program in Toxicology, Rutgers University, Piscataway, NJ;* [2]*Memorial Sloan-Kettering Cancer Center, New York, NY;* [3]*Bristol-Myers Squibb Pharmaceutical Res. Inst., Princeton, NJ.*

TNF-α a macrophage-derived cytokine reported to contribute to chemical-induced tissue injury associated with inflammation. In the present studies, we used mice lacking the gene for TNF-α or the TNF-α p55 receptor to analyze the role of this cytokine in AA-induced hepatotoxicity. Mice were treated with 300 mg/kg AA, ip and sacrificed 1-12 hr later. In control animals treated with anti-TNF-α antibody, AA-induced hepatotoxicity was reduced. In contrast, TNF-α knockout mice exhibited significant increases in serum transaminase levels within 2 hr of AA treatment which corresponded to more severe liver injury and higher mortality rate when compared to wild type control (WT) mice. These data suggest that low levels of TNF-α may be hepatoprotective. NO is a cytotoxic agent known to be involved in AA-induced hepatotoxicity. Thus, following AA administration, inducible nitric oxide synthase (NOS II) expression and hepatocyte NO production are increased. Moreover pretreatment of animals with aminoguanidine, which blocks NOS II, abrogates AA-induced hepatotoxicity. To analyze the role of NO in the hypersensitivity of TNF-α knockout mice to AA, we measured levels of NOS II protein and mRNA in the liver. Although there were no differences in NOS II mRNA levels between TNF-α knockout and WT control mice, NOS II protein increased more rapidly in the TNF-α knockout mice as determined by immunohistochemistry and Western blot. In addition, aminoguanidine pretreatment reduced AA-induced tissue injury in TNF-α knockout mice. These data suggest that the hepatoprotective effects of TNF-α may involve negative regulation of NO production in the liver. 1216 CARDIOPULMONARY TOXICITY OF INSTILLED NICKEL, VANADIUM, AND IRON IN MONOCROTALINE-TREATED RATS.

M J Campen[1], K L Dreher[2], D L Costa[2], and W P Watkinson[2]. [1]*UNC School of Public Health/Curr. in Toxicology, Chapel Hill, NC;* [2]*PTB, ETD, NHEERL, USEPA, RTP, NC.*

Previous studies from this laboratory have demonstrated a biphasic *hypothermic response* to intratracheal instillation (IT) of residual oil fly ash (ROFA) particles in healthy and cardiopulmonary-compromised rats. This response consisted of both an acute (0–6 h post-IT) and delayed (12–72 h post-IT) hypothermia that was accompanied by bradycardia and an increased incidence of cardiac arrhythmias. Other studies using constituents of ROFA have implicated three transition metals, iron (Fe), nickel (Ni), and vanadium (V), as the primary mediators of ROFA-induced pulmonary inflammation. The present study examined the roles of these metals, both individually and in combination, in producing the hypothermic response and pulmonary inflammation in monocrotaline (MCT)-treated Sprague-Dawley rats (male, 60 d, n=4/group). Doses were chosen to match those of the individual metals contained within the highest dose of ROFA from the earlier studies, i.e., 105 μg $Fe_2(SO_4)_3$, 263 μg $NiSO_2$, and 245 μg VSO_4; control rats (n=4) received acidified saline vehicle (pH=2). Three weeks prior to metal IT, all rats were implanted with radiotelemeters capable of continuously monitoring ECG and core body temperature (T_{CO}). Two weeks pre-IT, MCT was injected (60 mg/kg, *ip*) to induce pulmonary vasculitis and hypertension. Bronchoalveolar lavage and lung tissue samples were collected 96 hours post-IT and assayed for inflammatory markers. Fe-treated rats showed no significant change in HR and T_{CO} from control animals. Rats dosed with V displayed an acute hypothermic response for the initial 4 hours post-IT (Δ_{max}=2.1°C↓ ; 60 bpm↓). Ni produced a delayed response from 18–72 h post-IT (Δ_{max}=2.4°C↓ ; 110 bpm↓). Lethalities (n=2) only occurred in the Ni-treated group. Cardiac arrhythmias were seen concurrently with hypothermic episodes in the V- and Ni-treated animals. These results suggest that these metals are important mediators of the toxic effects of ROFA, and that the biphasic aspect of the hypothermic response may result from combined effects of the individual metals.

1217 RESIDUAL OIL FLY ASH (ROFA) ENHANCES ALLERGIC AIRWAY RESPONSES TO HOUSE DUST MITE (HDM) VIA TH2 CYTOKINE UPREGULATION.

A L Lambert, W Dong, M J K Selgrade, and M I Gilmour. *Curriculum in Toxicology, University of North Carolina, Chapel Hill; NHEERL, US EPA, RTP, NC.*

Epidemiological studies have shown an association between elevated levels of particulate matter (PM) air pollution and increased morbidity, hospital visits, and use of medication in asthmatics. Residual oil fly ash (ROFA) is a product of combustion and a soluble particulate containing several transition metals including vanadium, nickel, and iron. We have previously shown that in a Brown Norway rat model of HDM–induced pulmonary allergy, animals exposed to ROFA prior to HDM sensitization had enhanced allergic pulmonary responses to HDM challenge compared to animals sensitized to HDM alone. In this study we examined TH2 cytokine levels in the bronchoalveolar lavage fluid (BALF), lung tissue, and lymph nodes of rats instilled via the trachea with 200 or 1000 μg ROFA 3 days prior to local sensitization with 10 μg HDM. Cytokine levels were assessed by ELISA assay of the BALF and lung homogenates at day 2 after sensitization, and at day 2 after challenge. Cytokines were also measured by semi–quantitative RT–PCR in the lung and bronchial lymph nodes at days 2 and 7 after sensitization and at day 2 after challenge. TNF–α, IL–6, and IL–10 were upregulated in the BALF and lung homogenates of ROFA+HDM–treated rats compared to HDM controls 2 days after challenge. IL–4 mRNA was upregulated in the lymph node 2 days after challenge, and TNF–αmRNA was upregulated 2 days after sensitization, and IL–10 and IL–5 mRNA were upregulated 7 days after sensitization in the lung tissue of the ROFA+HDM–treated group. These data suggest a mechanism for particulate–enhanced sensitization to allergens via increased expression of TH2 cytokines, and may explain the exacerbation of asthma following PM excursions. (This abstract does not reflect US EPA policy.)

1218 EXPOSURE TO DIESEL EXHAUST PARTICLES (DEP) COMPROMISED THE PULMONARY CLEARANCE *OF LISTERIA MONOCYTOGENES* IN RATS.

H-M Yang[1], J M Antonini[1], J Y C Ma[1], M W Barger[1] J K H Ma[2] and V Castranova[1]. [1]*HELD/NIOSH;* [2]*School of Pharmacy, WVU, Morgantown, WV.*

In this study, we tested the hypothesis that exposure to DEP may impair lung defense against *Listeria monocytogenes* infection. Male Sprague-Dawley rats were dosed with either 5 mg/kg of DEP or saline intratracheally for 3 days, then intratracheally instilled with ~ 5,000 *Listeria*/rat. At 3, 5 and 7 days post-*Listeria* instillation, the rats were killed; the left lobe of lungs and the spleen were excised; and the numbers of Listeria in the tissues were determined. The remaining lung underwent bronchoalveolar lavage. Nitric oxide (NO) was measured in AM-conditioned supernatant. All rats survived and no significant lung inflammation and injury were noted in these rats. The pattern of *Listeria* clearance from the lungs was different between DEP- and saline-pretreated rats. At 3 days post-*Listeria* exposure, the number of bacteria in the lungs of DEP-treated rats (~ 55,000 *Listeria*/left lobe) was lower than that of saline-treated rats (~ 110,000 *Listeria*/left lobe). In contrast, the number of *Listeria* in the lungs was significantly higher in the DEP-treated rats compared to the saline-treated rats at 5 and 7 days post-*Listeria* exposure (~ 17,000 *Listeria*/left lobe vs ~ 8,500 at 5 days; ~ 7,000 vs ~ 1,500 at 7 days). Exposure to DEP alone resulted in increased NO production by AM. However, the NO production among *Listeria*-infected rats was not different. These results show that DEP exposure compromises the pulmonary clearance of *Listeria* and increases the susceptibility of hosts to this infectious pathogen. This decreased *Listeria* clearance in rats after DEP exposure does not seem to be dependent on reactive nitrogen intermediates.

1219 ROLE OF ALVEOLAR MACROPHAGES (AM) IN PARTICLE-INDUCED INFLAMMATION: STUDIES IN AM-DEPLETED RATS.

J Finkelstein[1], A C P Elder[2], N Corson[2], R Gelein[2], C Johnston[1], P Mercer[2], G Oberdörster[2]. *University of Rochester Depts. of Pediatrics*[1] *and Environmental Medicine*[2]*, Rochester, NY, USA.*

Macrophages present in the lungs orchestrate many of the responses to inflammatory stimuli, such as particles, through release or induction of several proinflammatory molecules. We report here on a method of alveolar macrophage (AM) depletion in rats by exposure to liposome-encapsulated clodronate via intratracheal inhalation. Rats were anaesthetized with halothane, cannulated with a 14-gauge catheter, and attached to a rodent respirator system. Inspiratory pressure was set to 15 cm H_2O and a solenoid valve set the inspiratory phase to 1.5 sec and the expiratory phase to 0.5 sec. The liposomes containing clodronate were then delivered in aerosol form using a low-flow generator. In order to asses the role of AMs in response to inflammatory stimuli, one group of rats received 75 μ g crystalline SiO_2 by intratracheal instillation 3 days after liposome exposure. Twenty-four hrs after silica instillation, several indices of inflammation were assessed in bronchoalveolar lavage fluid. Rats exposed to liposomes had 80.5% fewer AMs as compared to rats exposed to saline-filled liposomes with no significant neutrophil (PMN) influx (0.7% of total cells in sham-exposed controls). Rats exposed to silica alone demonstrated significant lung inflammation (4.0 x 10^6 PMNs), while those exposed to silica after being depleted of AMs had less than half that number (1.7 x 10^6). We conclude that although AMs play a crucial role in orchestrating the response to particles, there may be other cell types such as epithelial cells which contribute to the particle-induced inflammatory cascade.

1220 PARTICULATE MATTER (PM) AS AN IMMUNOSUPPRESSIVE FACTOR THAT CAN EXACERBATE ONGOING PULMONARY INFECTIONS.

J T Zelikoff, C Nadziejko, K Fang, T Gordon, and M D Cohen. *New York University School of Medicine, New York, NY, USA.*

Infection, specifically pneumonia, contributes substantially to the increased mortality among elderly individuals following exposure to PM. Studies were performed to test the hypothesis that alterations in pulmonary immunologic mechanisms important for resistance against infectious pneumonia contribute to the observed increase in PM-induced mortality in the elderly. For these studies, the effects of inhaled concentrated ambient PM2.5 from New York City air upon rats infected with *Streptococcus pneumoniae* 48 hr prior to exposure were examined. The results indicated that a single 5 hr exposure to PM induced time-dependent increases in pulmonary bacterial burdens and numbers of circulating WBC, and decreases in levels of lavageable neu-

trophils/cytokines and bronchus-associated lymphoid tissue compared to that in infected air-exposed control rats. Moreover, exposure of infected rats to PM increased the extent of pneumonia-associated lung lesions, as well as the incidence of septicemia in rats for up to 18 hr following PM exposure. Taken together, these findings suggest that exposure of rats with fulminating *S. pneumoniae* infections to concentrations at or somewhat greater than the promulgated 24 hr NAAQS of 65 μg PM2.5/m3 can exacerbate the disease process and compromise host ability to adequately "handle" an ongoing pneumococcal infection. These changes, in turn, could possibly contribute to the increased incidence of pneumonia-related deaths observed in PM-exposed elderly populations. (Supported by HEI #94-03A.)

1221 RESIDUAL OIL FLY ASH (ROFA)-INDUCED PULMONARY INFLAMMATION AND MUCOUS CELL METAPLASIA IN RATS CORRELATES WITH LEACHABLE VANADIUM CONTENT.

J A Hotchkiss[1], J Carter[2], C B Bennett[1], K E Driscoll[2], and J R Harkema[1]. [1]*Michigan State University, East Lansing, MI, USA;* [2] *Procter & Gamble, Co., Miami Valley Labs, Cincinnati, OH, USA.*

Increases in particulate air pollution are linked with increased hospital admissions and emergency room visits for cardiopulmonary diseases. Intratracheal instillation of residual oil fly ash (ROFA), an emission source particulate, induces pulmonary inflammation, cytokine/chemokine expression, and airway epithelial injury. F344 rats were intratracheally instilled with 0, 50 or 200 μ g of ROFA containing high (ROFA6) or low (ROFA2) amounts of leachable Vanadium to examine the effect of this transition metal in ROFA-induced inflammation and mucous cell metaplasia. Rats were sacrificed 3 d and 7 d after instillation. Right lung lobes were lavaged and recovered fluids analyzed for inflammatory cells, LDH activity, and total protein content. RNA from right lung lobes was analyzed for MIP-2 and MCP-1 mRNA levels. The left lung was processed for light microscopy and morphometric quantitation of intraepithelial mucosubstances in pulmonary airways. Both ROFA2 and ROFA6 induced dose-dependent increases in recovered neutrophils and lymphocytes that were greatest 7 d after instillation. All ROFA6-instilled rats had significantly more neutrophils than ROFA2-instilled rats. Only ROFA6 induced an increase in LDH activity and total protein levels in lavaged fluids. Both ROFA6 and ROFA2 induced dose- and time-dependent increases in MCP-1 and MIP-2 mRNA levels. ROFA6, but not ROFA2, induced mucous cell metaplasia with significant increases in stored mucosubstances in the surface epithelium lining main axial pulmonary airways. These data suggest that ROFA-associated inflammation and mucous cell metaplasia is dependent on the amount of Vanadium associated with the particles and emphasizes the need to consider the chemical/physical characteristics of ambient air particulates when assessing potential pulmonary toxicity.

1222 RESIDUAL OIL ASHES WITH DIFFERING COMPOSITION ELICIT PRO-INFLAMMATORY CHEMOKINES IN THE LUNG AND HEART.

R W Clarke[1], E Al-Mutairi[1], J Love[1], T Rice[1], J M Antonini[2], J D Paulauskis[1], and J J Godleski[1]. [1]*Harvard School of Public Health, Boston, MA, USA;* [2]*HELD/NIOSH, Morgantown, WV, USA.*

Residual oil ash (ROA) is a significant environmental hazard and contributes to airborne particulate matter. In the present study, toxicity profiles for two ROAs differing in composition were examined. Residual oil ash 1 (ROA1) had a lower carbonaceous component and high vanadium content; ROA2 was rich in carbon and included high amounts of nickel and manganese. HYPOTHESIS: The greater presence of vanadium in ROA1 will result in more severe pulmonary injury. METHODS: Rats were lightly anesthetized and intratracheally instilled with 2.5 mg/kg ROA1 or ROA2 or PBS. Animals were sacrificed at 4, 24, and 48 hours (hr) post-instillation (PI). Bronchoalveolar lavage (BAL) was performed and BAL cells as well as lung and heart tissues were retained for RNA isolation and Northern analysis. RESULTS: Significant ROA-induced pulmonary inflammation was observed in BAL samples at all time points with neutrophil and eosinophil influx and increased biochemical markers of inflammation ($p < 0.05$). These changes were significantly more severe in the ROA1 group for several parameters, particularly at 4 hr. Macrophage inflammatory protein (MIP)-1α and MIP-2 mRNA levels were markedly increased in ROA-exposed BAL cells at 4 hr; expression was present but declining at later timepoints. Lung and cardiac tissue exhibited very low MIP-1α and -2 mRNA levels at 4 hr PI only. There was no difference in the level of mRNA expression of these chemokines between the two ROA groups. CONCLUSION: ROA1 appears to be a more toxic pro-inflammatory particle indicating that composition is an important determinant of pulmonary response. The presence of vanadium or lack of carbon content may play a role in this differing response. Secondly, these data indicate that ROA induces pulmonary inflammation by induction of pro-inflammatory chemokines. (Supported By: ES00002, ES08129, HL05947, and HL54958.)

1223 DISTRIBUTION OF RETAINED PARTICULATE MATERIAL IN RAT AND HUMAN LUNGS.

K J Nikula[1], V Vallyathan[2], F H Y Green[3], and F F Hahn[1]. [1]*Lovelace Respiratory Research Institute, NM, USA;* [2]*National Institute of Occupational Safety and Health, Morgantown, WV, USA;* [3]*University of Calgary, Calgary, Alberta, Canada.* Sponsor: J L Mauderly.

Rats and monkeys differ in patterns of particle retention in the lungs after identical exposures to diesel exhaust (DE) or coal dust at a single concentration (2 mg respirable material/m^3) resulting in moderate lung burdens. Here we extend the morphometric studies of particle retention to humans and examine the influence of exposure concentration on retention patterns in rats and humans. Histologic lung sections from a previous study in rats and from the National Coal Workers' Autopsy Study were examined morphometrically to estimate the volume percentage of particulate material in defined anatomic compartments. The rats had been exposed 7 h/day, 5 days/wk for 24 mo to DE at 0.35 (low), 3.5 (medium), or 7.0 (high) mg soot/m^3; the 24-mo soot lung burdens were 0.6, 12, and 21 mg, respectively. The human lungs sections were from 1) nonsmokers who did not work as miners, 2) nonsmoking coal miners who worked under the current standard of ≤ 2 mg dust/m^3 for 3 – 20 y (mean = 13 y), and 3) nonsmoking coal miners who worked under the former standard of < 10 mg dust/m^3 for 33 – 50 y (mean = 40 y). The volume percentage of the lung occupied by particulate material was 0.2, 1.6, and 3.7% in the low, medium, and high exposure concentration rats, respectively. The particulate material was predominately retained in macrophages in the alveolar and alveolar duct lumens, with 82, 81, and 85% of the material being in lumens and 18, 19, and 15% of the material being interstitial in the low, medium, and high exposure concentration rats, respectively. The volume percentage of the lung occupied by particulate material was 0.3, 1.8, and 10.3% in the non-miners, coal miners under the current standard, and coal miners under the former standard, respectively. Fifty-seven, 68, and 91% of the particulate material was interstitial, and the remainder was in lumens, in the non-miners, coal miners under the current standard, and coal miners under the former standard, respectively. These results show that chronically inhaled diesel soot is similarly retained predominately in lumens of rats over a wide range of exposure concentrations and resultant lung burdens. In non-miners and coal miners, chronically inhaled particulate material is retained primarily in the interstitium, and the percent of the material in the interstitium is related to dose (exposure concentration, years of exposure, and/or lung burden). (Research sponsored by the Assoc. of German Car Manufacturers (VDA).)

1224 RESPONSE TO ULTRAFINE AND FINE PARTICLES IN THE LPS-PRIMED LUNG.

G Oberdörster[1], A C P Elder[1], J Finkelstein[2], N Corson[1], R Gelein[1], and P Mercer[1]. *University of Rochester, Depts. of Environmental Medicine*[1] *and Pediatrics*[2]*, Rochester, NY, USA.*

Bacterial endotoxin (LPS) is an environmental contaminant and product of infection which has potent inflammatory and priming effects in organs such as the lung. Low levels of urban particles are associated with increased morbidity in susceptible populations. We hypothesize that ambient ultrafine particles are more effective than fine particles in causing adverse effects. To test this, we have compared the response of young (8 wks) and old (20 mos) F344 rats to two different sizes of TiO_2 both with and without prior exposure to LPS. Rats were exposed to LPS (0.02 μ g deposited for young rats; 0.01 μ g for old rats) via inhalation and then immediately to particles via intratracheal instillation (50 μ g ultrafine TiO_2 (~20 nm) or fine TiO_2 (~250 nm)). Animals were sacrificed 24 hrs after exposure and inflammatory parameters in bronchoalveolar lavage fluid were assessed. Priming with LPS resulted in a significantly greater PMN response in the lungs of particle-exposed rats as compared to LPS or particle exposure alone; this was true for both young and old rats. Additionally, the ultrafine particles produced greater inflammation by themselves and with LPS priming as compared to the fine particles. We conclude that inhaled LPS can act to prime the lung to subsequent particle exposure and that ultrafine TiO_2 has greater inflammatory potential than fine TiO_2.

Due to the ubiquitous nature of both endotoxin and low-toxicity dusts such as TiO_2, the interaction between the two shown here could aid in understanding the impact on health of such exposures in sensitized individuals.

1225 TISSUE INJURY INDUCED BY INHALED FINE PARTICULATE MATTER AND PEROXIDE IS ASSOCATED WITH ALTERED OXIDATIVE METABOLISM IN ALVEOLAR MACROPHAGES.

K A Hooper, T H Li, B Turpin and D L Laskin. *Environmental and Occupational Health Sciences Institute, Rutgers University and UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, USA.*

Inhalation of fine particulate matter (PM) has been positively correlated with mortality and morbidity in humans. The overall objective of our studies is to analyze the role of particle-associated peroxides in fine PM-induced toxicity. An aerosol consisting of ammonium sulfate (AS), a major component of fine PM in the eastern US, was used as a model. An aqueous solution of AS and hydrogen peroxide (H2O2) was atomized, conditioned to 85% relative humidity and introduced into a 6-port nose-only exposure chamber. The resulting aerosol contained 415 $\mu g/m^3$ AS with a particle number distribution that peaked at 0.3 μm in diameter, as measured by Lasair Optical particle sizer, and 17 ppb of gas-phase peroxide in equilibrium with the particle phase. Gas-phase and particle-phase peroxide concentrations were calculated using total peroxide concentration, Henry's law constant and aerosol water content. Sprague-Dawley rats were exposed to particle-free air or aerosols consisting of AS or AS plus H2O2 (17 ppb) (AS+H2O2) for 2 h. Rats were sacrificed 22 h post-exposure. We found that inhalation of AS aerosols had no effect the number, viability or composition of cells or lactate dehydrogenase (LDH) levels in bronchoalveolar lavage (BAL) fluid relative to air exposed rats. In contrast following inhalation of AS aerosols, an increase in serum LDH levels and BAL protein levels was observed and a decrease in superoxide anion production by alveolar macrophages. Whereas the presence of 17 ppb H2O2 in the aerosols caused no change in cell viability, cell composition or LDH levels in BAL relative to air and AS exposed rats, the effect of AS on superoxide anion production was reduced. These data suggest that components in fine PM may be important in the toxicity of these materials. (Supported by the Health Effects Institute and a National Research Service Award from the NIH).

1226 SPECIES DIFFERENCES IN THE PULMONARY RESPONSE TO PARTICLES.

J M Carter, B W Howard, M P Purdon, S M Curry, and K E Driscoll. *Procter & Gamble Company, Cincinnati, OH.*

A number of low solubility particles produce lung tumors in rats after chronic inhalation. These particles have not been shown to be genotoxic, indicating that the rat tumor response may result from a secondary, nongenotoxic mechanism. It has been hypothesized that the rat lung response to these particles may be due to the recruitment, activation, and subsequent release of damaging mediators by the inflammatory cells. Recent studies have suggested that hamsters and mice may be less sensitive to the inflammatory and tumorigenic effects of low solubility particles than rats. To investigate species differences in lung particle response, this study compared the effects on rats and hamsters to α quartz and carbon black. Briefly, rats and hamsters were intratracheally instilled with saline, 0.2, 2, or 20mg of α quartz or carbon black. Seven, 28, and 56 days after exposure bronchoalveolar lavage (BAL) was performed and the BAL fluid was characterized for cell number, type, LDH and total protein. Additionally, lung tissue was evaluated for the expression of various cytokines, as well as levels of metallothionein and glutathione. Both species showed dose related increases in neutrophils, LDH, and total protein after α quartz and carbon black exposure, however, the changes were significantly greater in the rat. Additionally, rats showed greater expression of several pro-inflammatory cytokines and lower levels of the anti-oxidants metallothionein and glutathione. These differences in cytokine expression and anti-oxidant production may contribute to the apparent species differences in tumor response.

1227 4-AMINOBIPHENYL (4ABP) HEMOGLOBIN (Hb) ADDUCTS IN MATERNAL SMOKERS: ROLE OF PASSIVE SMOKE EXPOSURE ON THE FETUS.

M P Ross[1] and S R Myers[2]. [1]*Dept. Pediatrics and* [2]*Dept. Pharmacology and Toxicology, Univ. Louisville, School of Medicine, Louisville, KY.*

Previous studies from this laboratory have focused on the qualitative and quantitative assessment of maternal:fetal exchange of a variety of tobacco smoke carcinogens including 4-aminobiphenyl, benzo(a)pyrene, and the tobacco specific nitrosamines NNN and NNK. In recent studies we have extended these observations into investigating the effect of "passive" smoke exposure on the *in utero* development of the fetus. In this study we examine the effect of "passive" exposure to tobacco smoke and the subsequent formation of both maternal and fetal hemoglobin adducts, specifically 4ABP adducts, resulting from this exposure. Women nonsmokers were enrolled in the study who were found to be exposed to passive smoke >8 hours/day either in the workplace or home environment. Upon admission for labor and delivery, maternal urine was obtained for cotinine assessment as well as maternal blood for Hb adduct determinations. Fetal bood was obtained via the umbilical vein for assessment of fetal exposures to tobacco smoke carcinogens. The results indicated that women exposed to passive smoke during pregnancy had significantly elevated levels of 4ABP ((maternal) 104.3 ± 26.5) and ((fetal) 46.2 pg/ gm Hb) adducted to both maternal and fetal Hb when compared to nonsmokers ((maternal) 34.6 ± 9.6; (fetal) 12.4 ± 5.9 pg/gm Hb). However, these values were found to be significantly lower than the maternal (375.2 ± 29.3) and fetal values (162.4.9 ± 31.5 pg/.gm Hb) of 4ABP adducts obtained in 1 - 2 pack per day smokers. These results demonstrate that exposure to "passive" cigarette smoke is a concern during pregnancy and the levels of Hb adduct detected as a result of passive smoke exposure warrant further investigations as to the health effects of in utero exposure to passive smoke

1228 REGIONAL DIFFERENCES IN HEMOGLOBIN ADDUCTS FROM AROMATIC AMINES IN CHILDREN.

E Richter[1], S Rösler[1], G Scherer[2], A Grübl[3], U Krämer[4] and H Behrendt[4]. [1]*Walther-Straub Institut für Pharmakologie und Toxikologie, Ludwig-Maximilians University, Munich;* [2]*Analytisch-biologisches Forschungslabor, Munich;* [3]*Kinderklinik und Poliklinik, Technische Universität, Munich;* [4]*KKG Umweltdermatologie und Allergologie GSF, Technische Universität, Munich, Germany.* Sponsor: R C Gupta.

The origin of hemoglobin (hb) adducts from aromatic amines in nonsmokers is largely unknown. Recently, the contribution of environmental tobacco smoke (ETS) exposure has been shown to be negligible (Falter et al., Biomarkers 3:35,1998). Regional differences relating to population and/or traffic density have been postulated to be of more importance. Therefore, hb adducts of 4-aminobiphenyl (4-ABP) as well as o-, m-, and p-toluidine were analysed in children from three different sized Bavarian cities, Munich (1.3 mill. inhabitants; N=34), Augsburg (0.25 mill. inhabitants; N=126) and Eichstätt (13,000 inhabitants; N= 65). ETS exposure was estimated from self-reported smoking of parents and other household members. Additionally, urinary cotinine was determined in Augsburg children. 4-ABP-hb adducts were significantly higher in children from Munich (31±6 pg/g hb, $p<0.001$) and Augsburg (27±17, $p<0.05$) compared to Eichstätt (21±12). In children from Augsburg and Munich, adducts from o-, m-, and p-toluidine were similar and 33-44% higher than in children from Eichstätt ($p<0.05$). 4-ABP and toluidine adducts were not influenced by ETS exposure. In children from Augsburg urinary cotinine highly significantly correlated with ETS exposure (Spearman rank correlation: r=0.69) but not with 4-ABP-hb adducts (r= 0.077) or adducts from o-, m-, and p-toluidines (r=-0.17, -0.18, -0.20). In children, hb adducts from aromatic amines are strongly influenced by regional differences whereas ETS is not an important source of these adducts.

1229 TOXICITY OF DEGRADABLE CHAFF COUNTERMEASURES.

C L Wilson. *Naval Health Research Center Detachment (Toxicology), Wright-Patterson Air Force Base, OH, USA.*

United States military aircraft and ships currently use aluminized glass chaff as a passive countermeasure for radar guided threats. Heightened concern for the health impact of deployed chaff on human and animal habitats has led to the development of an environmentally friendly, degradable chaff (EcoChaff(TM)). EcoChaff(TM) is an aluminum coated degradable vitreous

oxide (DVO(TM)) material. Aluminum, the principle toxic component of EcoChaff(TM), has been implicated in the etiology of at least one neurodegenerative disease, although data supporting this hypothesis are inconclusive. In an effort to assist in human health and ecological risk assessment of the geographical areas over which the new chaff will be deployed, current studies are evaluating the effects of human exposure to EcoChaff(TM). Preliminary analysis of sediment samples taken from the Naval Research Laboratory-Chesapeake Bay Detachment (NRL-CBD), an area over which aluminized chaff has been deployed for over twenty years, suggests that sediment bioavailable aluminum levels are not significantly different from background levels. Further studies will focus on the reactivity of the aluminum coating of EcoChaff(TM) under conditions which mimic the gastrointestinal (GI) tract environment using a physiologically-based extraction bioassay. Aluminum absorption by the GI tract and deposition in nervous tissue will also be monitored in *in vivo* experiments. (Funding Sponsor: Naval Air Warfare Center Aircraft Division, Patuxent River, MD.)

1230 MONITORING DEGRADATION OF POLYURETHANE FLEXIBLE FOAM IN A LANDFILL SIMULATOR.

C Bartlett, D Aul, M S Blough, M D'Andrea, J Hauck, A L Kennedy, E G Minkley and W E Brown. *Carnegie Mellon University, Pittsburgh, PA, USA.* Sponsor: M F Stock.

Polyurethane foams are found in many common products such as car seats and mattresses. Disposal of these materials has raised the question of the stability of the polyurethane in landfill environments and the potential for aromatic amine formation. For this study, a paper-based, recirculating, landfill simulator was used to monitor the fate of both fresh toluene diisocyanate-based flexible foam and cured auto shredder residue (ASR) under anaerobic, methanogenic conditions. Leachate taken at regular time intervals from the simulators was monitored specifically for the presence of toluene diamine (TDA) using GC/MS. Duplicate simulators were run for each experimental condition and monitored for 650 days. The flexible foam was added to the simulators at concentrations up to 9% (w/w) and TDA-spiked simulators were processed in parallel as positive controls. For the foam simulators, detectable levels of TDA were found in leachate with initial flow-through, reached a maximum after 26 days, and returned to below detectable levels (0.0001%) at 500 days. At maximum levels, an average of 0.001% of the flexible foam mass was measured in the leachate while no detectable TDA was found in simulators containing ASR. At a maximum point of elution, the average recovery from TDA spiked simulators was 3.5% of the TDA initially added to the simulator. These results indicate greater than 95% of the added TDA is bound in the simulator. No evidence of polyurethane foam degradation under landfill conditions was observed.

1231 TOTAL EXPOSURE AND BIOLOGICAL EFFECT ESTIMATES IN A TEXAS COMMUNITY NEAR FORMER URANIUM MINING AND MILLING WASTES.

M A McConnell, V M S Ramanujam, N Alcock, and W W Au. *Department of Preventive Medicine and Community Health, The University of Texas Medical Branch at Galveston, TX, USA.* Sponsor: M T Moslen.

Background: The northern section of Karnes County, Texas has been the site of uranium mining/milling since the early 1960s, producing serious concern in the local residents as to possible long-term health consequences. Experimental Design: We conducted a human health risk assessment on the local population utilizing molecular epidemiology and total exposure assessment strategies. Multiple pathways and routes of exposure to the local residents were considered and include soil, water, indoor dusts, indoor air, ambient air, and foodstuffs grown in the area. The long-lived radionuclide uranium-238 (^{238}U) and progeny, as well as lead isotopes were measured in order to evaluate the extent of contamination from mining/milling facilities. Thorium-232 (^{232}Th) was quantified simultaneously and served as a reference. Results: Concentrations of uranium in yard soil (n=98) of residents near mining/milling areas were higher in the surface (0.34-15.7 mg/kg) compared to subsurface (0.17-4.95 mg/kg) and higher than control soil surface (0.13-0.26 mg/kg) or subsurface (0.13-0.23 mg/kg). Distribution of ^{232}Th, indicated the increase in ^{238}U is anthropogenic. Water samples (n=8) from individual water wells indicate contamination into the local aquifer near a mining/milling facility. Indoor dust samples (n=27) revealed higher uranium concentrations in homes from the target area (27.1-570.3 μg/kg) compared to the control (9.1-80.1 μg/kg). Experimental gardens revealed bioaccumulation of uranium in vegetables proportional to soil concentration, resulting in higher concentrations of ^{238}U in vegetables from the target area. Total exposure evaluation indicates that the target population receives 5-times the individual total daily dose (TDD) of ^{238}U while the TDD of ^{232}Th was not significantly different, based on statistical distribution. Furthermore, cumulative individual dose (CID) of ^{238}U was up to 11-times higher in the target population compared to control. Analysis of 8-OHdG DNA adducts and chromosomal translocations by FISH analysis in lymphocytes of residents indicated no excessive damage in the target population compared to the control. Conclusion: Despite the documented uranium contamination, biomarkers of genetic damage did not indicate serious health threats. (Supported by NIH T32E507254.)

1232 NARCOSIS AND REACTIVITY: COMPARING TWO DIFFERENT MODES OF ACTION IN AQUATIC TOXICOLOGY.

J Hermens and A Freidig. *Research Institute for Toxicology, Utrecht University, Utrecht, The Netherlands.* Sponsor: M van den Berg.

In environmental risk assessment it is a challenge to correctly classify a chemical regarding its mode of action (MOA) with little or no mechanistic information. In the present work, we use a series of acrylates and methacrylates to illustrate a strategy to compare the importance of two MOAs and thereby identify the predominant cause of acute fish toxicity. Acrylates are known to be Michael acceptors and may therefore react with glutathione (GSH) causing GSH-depletion in vivo (reactive mechanism). On the other hand, acrylates may also act by a non-specific mechanism (narcosis). The following two, physiologically meaningful, parameters were calculated in order to estimate the contribution of these two mechanisms to the overall acute toxicity: (i) a lipid normalized body burden for narcosis and (ii) the potential degree of GSH depletion for reactive toxicity. The degree of GSH depletion is represented by the product of the reactivity towards GSH and the exposure concentration. This model was validated with four model compounds and an in vivo study. For both modes of action, a critical value was established.

1233 EFFECT OF ESTRADIOL AND CORTISOL ON Na^+K^+ATPASE AND FLAVIN-CONTAINING MONOOXYGENASE IN EURYHALINE FISH.

D Schlenk[1], B K Larsen[1], R Smith[1], L Peters[2], D R Livingstone[2], E Deane[3], and N Woo[3]. [1]*Environmental Toxicology Program/ECHR, University of Mississippi, MS, USA;* [2]*Plymouth Marine Laboratory, Plymouth, UK;* [3]*Department of Biology, Chinese University of Hong Kong, China.*

Euryhaline animals exposed to compounds bioactivated by FMO (i.e. aldicarb) are more susceptible to toxicity at higher salinity than fish residing in lower salinity. Previous studies in our laboratory have shown a direct relationship between flavin-containing monooxygenase (FMO) expression and osmotic pressure in several species of euryhaline fish. However, it is unclear how salinity regulates expression of FMO(s). Na^+K^+ATPase is also directly related to osmotic pressure and is regulated by a number of hormonal signals including 17-β estradiol (E2) and cortisol (CO). In order to determine the effect of these compounds on FMO expression, sexually immature Atlantic flounder (*Platichthys flesus*) received abdominal implants of 5 mg of E2 and CO and were maintained in ambient seawater for 18 days. Serum was sampled for hormone and osmolality measurments, and gill was sampled for Na^+K^+ATPase and FMO mRNA expression. Serum E2 levels were nearly 10-fold greater than untreated and sham-operated controls (n =4). Alpha subunit expression of gill Na^+K^+ATPase mRNA was significantly reduced ($p \leq 0.05$) by 75% when compared to controls. FMO activity (trimethylamine oxygenase) has also been shown to be reduced by E2 treatment. These data indicate that Na^+K^+ATPase and FMO are controled by similar hormonal signals and supports the hypothesis that FMO may play a role in cellular osmoregulation as well as xenobiotic biotransformation. (This work was supported by the Ray Lankester Investigatorship of the Marine Biological Association of the United Kingdom.)

1234 CHARACTERIZATION OF HYDROQUINONE AND CATECHOL FORMATION USING HEPATIC MICROSOMES FROM THREE SPECIES OF FISH.

R C Kolanczyk, L E Solem[1], P K Schmieder and J M McKim. *US EPA, (1NRC), NHEERL, Mid-Continent Ecology Division, Duluth, MN, USA.*

The in vitro metabolism of phenol at 11 °C has been studied using juvenile and immature adult rainbow (*Oncorhynchus mykiss*), immature adult brook (*Salvelinus fontinalis*), and immature adult lake trout (*Salvelinus namaycush*) hepatic microsomal preparations. Incubations were optimized for time, cofactor concentration, pH, and microsomal protein concentration. Formation of phase I ring- hydroxylation metabolites, i.e., hydroquinone and

catechol was quantified by the use of high performance liquid chromatography with dual channel electrochemical detection. Sample preparation and chromatographic conditions were optimized to achieve the separation and sensitivity required for the analysis of these very labile products. Metabolism of phenol over a range of substrate concentrations (1 to 150 mM) was quantified in an attempt to calculate the Michaelis-Menten kinetics constants K_m and V_{max}. Results indicate a difference in K_m values between species, with an apparent enzyme affinity for substrate greatest in rainbow trout, followed by brook trout, and less in lake trout. These experiments provide a means to quantify metabolic activation of xenobiotics in fish, to compare activation reactions across aquatic species, and to provide a basis for the prediction of metabolic pathways and rates in fish.

1235 EFFECT OF ß-NAPHTHOFLAVONE INDUCTION UPON 3,4,3',4', TETRACHLOROBIPHENYL BIOAVAILABILITY IN *IN SITU* PREPARATIONS OF CHANNEL CATFISH.

A M Doi[1], Z Lou[2], K M Kleinow[1], M O James[2], C S Venugopal[1] and E Holmes[1]. [1]*Department of Physiology, Pharmacology and Toxicology, School of Veterinary Medicine, LSU, Baton Rouge, LA, USA;* [2]*Department of Medicinal Chemistry, University of Florida, Gainesville, FL, USA.*

Fish are exposed to multiple agents in the diet, including persistent polychlorinated biphenyls and polycylic aromatic hydrocarbons-type P4501A inducers. These studies examined the relationship of intestinal induction with xenobiotic bioavailability. Systemic bioavailability of dietary [^{14}C]-3,4,3',4', tetrachlorobiphenyl (TCB) and intestinal metabolic abilities were evaluated using an *in situ* isolated perfused intestinal segment of the catfish. In addition to controls, catfish were preexposed *in vivo* for 10 days to dietary ß-naphthoflavone (BNF) at a low (10 mg/kg diet) or high dose (50 mg/kg diet). Upon BNF pretreatment, a [^{14}C]-TCB (60 µM) solution was administered via linoleic acid (10mM) micelles into isolated intestinal segment. Following a 60-min perfusion, the efferent blood, intestinal contents and mucosa were analyzed for [^{14}C] content. Assays of total P450 content and aryl hydrocarbon hydroxylase (AHH) and glutathione-S-transferase (GST) (1-chloro-2,4-dinitrobenzene, CDNB; ethacrynic acid, EA) activities were determined on mucosal subsamples. Dietary preexposure to BNF had no effect upon the systemic bioavailability of [^{14}C]-TCB, with controls showing blood values of 751 ± 263 pmol TCB/mL, while low and high dose BNF-treated animals exhibited 646 ± 80 and 612 ± 41 pmol TCB/mL. Similarly, BNF preexposure did not influence either [^{14}C]-TCB levels in the mucosal and postinfusate tissues, or P450 content and GST activity. AHH activity was significantly increased 9.2 and 12.5-fold after exposure to low and high doses of BNF. In conclusion, there was no correlation of intestinal monooxygenase induction by BNF with systemic TCB bioavailability. (Funded by NIEHS P42 E5 07375.)

1236 MULTIGENERATION REPRODUCTIVE EFFECTS OF DI-*N*-BUTYL PHTHALATE IN JAPANESE MEDAKA (*ORYZIAS LATIPES*).

P J Patyna, P E Thomas and K R Cooper. *Joint Graduate Program in Toxicology, Rutgers-The State University of New Jersey, Piscataway, NJ, USA.*

Japanese medaka, a freshwater teleost, was used to examine multigeneration reproductive effects of di-*n*-butyl phthalate (DBP). The endpoints included mortality, histopathologic changes, growth, gonadal-somatic index (GSI), sexual development, fecundity, embryonal development, vitellogenin induction and hepatic microsomal testosterone metabolism. The F_0 generation was first exposed as 14-day old larval fish. Exposure consisted of feeding DBP or 17 β-estradiol (E2) in dry flake food, at a daily ration 5 % body weight. There were seven treatment groups, with two replicates (n=20). The treatment groups included an ethanol control, 0.5, 5, 50 µg DBP/g flake food, and 0.05, 0.5, 5 µg E2/g flake food. The F_0 and F_1 generation were fed each treatment through sexual maturation. All E2 0.05 µg/g fish were phenotypic females, as confirmed histologically. No eggs were produced by E2-treated fish. DBP had no major effects in the F_0 generation. DBP at 50 µg/g decreased F_1 generation ovary weight, GSI, egg production, and in the F_1 generation males reduced testes weight and GSI. DBP at 50 µg/g caused an increase in microsomal protein levels, liver weight, and hepatic-somatic index in both F_1 generation males and females. Evaluation of F_1 and F_2 eggs from DBP-treated groups, showed normal embryonic development. The male to female ratios in all DBP groups were similar to the control. DBP caused reproductive toxicity in the second generation medaka offspring, following chronic dietary exposure, to environmentally relevant concentrations. (ES-22330, ES-29782, NJAES-01126)

1237 DIFFERENCES IN HEPATIC VITAMIN E CONCENTRATIONS IN THREE FISH SPECIES.

B R Sheedy and P K Schmieder. *USEPA, NHEERL, Mid-Continent Ecology Division, Duluth, MN, USA.* Sponsor: T R Henry.

Vitamin E (Vit E) or tocopherol is a lipid soluble vitamin with antioxidant properties. Various studies have shown increased susceptibility to oxidative stress when organisms have been raised on low Vit E diets. While there is a considerable amount known on the Vit E status in mammals, there is limited information on normal concentrations in aquatic organisms. Such information is necessary in making inferences as to the susceptibility of aquatic species to oxidative stress. Endogenous concentrations of Vit E were monitored in laboratory-reared male and female brook trout (BkT, 800-1400 g) (*Salvelinus fontinalis*), rainbow trout (RbT, 100-1000 g) (*Oncorhynchus mykiss*), and lake trout (LkT, 600-900 g) (*Salvelinus namaycush*) raised on similar diets. Specifically, Vit E was measured in whole liver homogenate and microsomes by HPLC with UV detection. Hepatic microsomal Vit E concentrations in male BkT and RbT tended to be higher than females when comparing fish of similar sizes ~800-1200 g, (BkT: 13 and 6 ug/g microsomal protein; RbT: 4.5 and 1.5 ug/g microsomal protein, respectively). Female RbT (500-900 g) had lower Vit E/g liver than male RbT (500-900 g). Additionally, concentrations of Vit E found in these females were similar to those found in younger, smaller female RbT (100-300 g). The male LkT had hepatic Vit E concentrations lower than males of the other species, but similar to those measured for female RbT. This study indicates hepatic Vit E may vary with sex and species despite similar diets. While previous studies indicated susceptibility to oxidative processes may be linked to lower dietary Vit E, this study raises the question of a possible inherent species specific susceptibility factor. Further testing is needed to verify the significance of Vit E differences among species.

1238 FISH HEPATIC ENZYMES IN A TROPICAL LAGOON FROM PUERTO RICO.

W F Ortiz[1], J. Ruiz[1], and B D Jimenez[2]. *University of Puerto Rico, Medical Sciences Campus, School of Public Health*[1], *School of Medicine*[2], *Center for Environmental and Toxicological Research, San Juan, PR.*

San Jose Lagoon is one of the most contaminated estuary environments in Puerto Rico. Contaminants measured in sediments show levels of PCB's (450 ug/kg), Chlordane (34.5ug/kg), Phalate Esters (16,000 ug/kg), PAH's (475 ug/kg), Lead (750 ug/kg) and Mercury (4.9 ug/kg). This Lagoon has been declared a National Estuary by the USEPA. A major clean up plan for the system is being established and remedial action will soon begin. In order to follow up with the effectiveness of the clean up operation, a hepatic enzyme biomarkers profile for the stripped moharra (Diapterus plumieri) has been obtained. Cytochrome P-450, cytochrome b5, NADH cytochrome b5 reductase, NADPH cytochrome P-450 reductase, cytosolic and microsomal Glutathione-S-Transferase (GST) together with Liver Somatic Index were examined from fish collected in five stations throughout the San Jose Lagoon and at a reference site in La Parguera, Puerto Rico. The induction of a specific isozyme, P-450IAI was determined by inmunoblot assay and other enzyme activities by spectrophotometric assays. Of all parameters measured, cytosolic and microsomal Glutathione-S-Transferase were found to be good enzyme indicators of pollution. An immunoblot of cytochrome P-450IAI showed induction of CYP1A1 in most of the fish from stations in the Lagoon. These results were compared to the reference site which showed no cross-reactivity with basal levels. Cytochrome P-450, NADH and NADPH reductases were also sensitive but not at the same level as cytosolic and microsomal GST. Some differences were observed between male and female fish. The liver somatic index was found to be considerably lower (1/2) at the control site than any of the experimental stations from San Jose Lagoon, this finding was statistically significant for all stations. This research serves as a baseline for future studies for the assessment of the remediation efforts of the San Juan Bay Estuary Program. The findings of this research may be useful for comparison of enzyme activities between temperate and tropical species.

1239 EFFECTS OF DIAZINON CONTAMINATINO IN *ICTALURUS PUNCTATUS*: BIOACCUMULATION AND TERATOGENIC MONITORING IN THE ECOLOGICAL FOOD CHAIN.

T Booker, L R Brown, III, and S W Chriss. *Southern University and A&M College, Baton Rouge, LA and Marasco-Newton Environmental Consultants and Laboratories, Washington, DC, USA.* Sponsor: F Dost.

Environmental contamination of organophosphates in the aquatic environments has reached epic portions since the late 1980s. Beginning in 1989 in the southern states of America, an unusually high record of organophosphate contamination was reported in the Mississippi River and surrounding areas. One OP in particular that was noticed in extremely high concentration levels was Diazinon. This OP is used as a basic insecticide/herbicide for controlling unwanted mosquitoes, weeds, and other annoying organisms and plants. However, recent biochemical evidence has shown that Diazinon has a strong tendency to induce high contamination levels in various aquatic animals, particular the members of *Ictalurus punctatus*-(known commonly as the Channel catfish). In 1997 it was reported that extremely high levels of this pesticide was found to exist in these species for a long period of time. In our study it was shown that Diazinon has a strong tendency to bioaccumulate in the tissues and muscle cells of these fish and thus induce teratogenic changes in fish morphology and structural development. It was also shown that exposure periods greater than 96-hrs tend to produce random movement behavior in these animals as well as increased dietary in-takes, thus inducing a severe increase in weight. It was also shown through CG/MS analysis that the lower fillet regions of these aquatic animals tended to have an extremely high concentration level of Diazinon before cooking (>45 ppms) and an even higher level after cooking ($90 \geq 101 \geq 117$ ppms) either through frying or boiling or stem cooking. Moreover, our study clearly shows that in cases where the pregnant female members of these aquatic animals were exposed to this contaminant for a period of six months or greater, the offsprings produced appeared to have four sets of fins, three eyes, or no development of fins or eyes as far as teeratogenic effects are revealed. In terms of the bioecological food-chain, male humans ingesting these contaminated fish over a three to twelve month period on a course of at least twice a day-(lunch and dinner) were known to develop extremely low sperm counts nd to have developed problems with nephritic stones appearing in the kidneys. In human females (18 to 51 yrs old) who absorbed an exceptionally high dietary in-take of these animals for a monthly period, exhibited severly painful urination problems as well as kidney infections.

1240 PHASE I AND II ENZYME AND ACTIVITY LEVELS IN THE GUMBOOT CHITON *CRYPTOCHITON STELLERI* FOLLOWING EXPOSURE TO A DIETARY BROMO-PHENOL, LANOSOL.

B C DeBusk[1], S S Chimote[1], J M Rimoldi[2], and D Schlenk[1]. [1]*Environmental Toxicology Research Program/ECHR, Department of Pharmacology,* [2]*Department of Medicinal Chemistry, School of Pharmacy, University of Mississippi, University, MS.*

The effects of diet and other non-anthropogenic effects on biochemical defenses and their relationship to susceptibility have been largely ignored in wildlife populations. Lanosol (1,2-dihydroxy, 3,4-dibromo-5-(hydroxymethyl)-benzene), found in the alga *Odonthalia dentata*, was administered to gumboot chitons (*Cryptochiton* stelleri) by oral gavage at 0, 1, 2.5, 5, or 10 mg/kg. *C. stelleri* feed on *O. dentata*, but it is avoided by other herbivores. After four days digestive gland microsomes were probed for expression of homologous isoforms of CYP1A, CYP3A, and CYP2 using a variety of anti-peptide, anti-trout (provided by D. Buhler) and commercial antibodies. No expression of CYP1A or CYP2-like proteins was observed. Expression of a CYP3A-like protein was increased by approximately 30% over control at 2.5, 5, and 10 mg/kg doses. Microsomal ethoxy-coumarin-*O*-deethylase activity was highly variable and did not change with dose. Estradiol hydroxylase activity showed an increasing trend with dose, while testosterone hydroxylase activity showed a decreasing trend with increasing dose. Antibodies raised against three mammalian glutathione-S-transferase (GST) families, α, μ, and π, (provided by E Gallagher) did not recognize any cytosolic protein from chitons. GST activity (CDNB conjugation) showed a decreasing trend with increasing lanosol dose. These results show that exposure to the brominated-phenol, lanosol, may alter expression and activity of some phase I and II biotransformation enzymes in chitons which may provide a selective dietary advantage for this species.

1241 TOXICITY STUDIES WITH POMACEA PALLUDOSA (APPLE SNAIL) AND CATHARANTHUS ROSEUS AXENIC PLANT ROOTS CONTAINING TRINITROTOLUENE.

E D Lykissa[1], S V Kala[1], C Prater[1], M Neely[1], J V Shanks[2], J B Hughes[2], and R F Turk[3]. [1]*Dept. of Pathology, Baylor College of Medicine, Houston, TX;* [2]*Dept. of Environmental Sciences and Engineering, Rice University, Houston, TX;* [3]*Center for Toxicology Services, Inc., Houston, TX.*

Trinitrotoluene (TNT) reduced (remediated) by the axenic plant roots of Catharanthus roseus and its potential toxicity to Pomacea palludosa (Apple snail), an aquatic mollusk indigenous to the Florida marshes, was studied extensively. These mollusks though they consumed quite readily the uncontaminated C. roseus axenic roots, they showed a definite aversion to the roots that had been grown in media containing various concentrations of TNT, ranging from 10-80 ppm. After the Apple snails were force fed these contaminated roots with TNT, they all succumbed within 48 hours to concentrations greater than 40 ppm. The smaller snails succumbed within 24 hours after ingesting these roots, while the larger (older) snails succumbed within 48 hours. Upon necropsy they all revealed an enlarged intestine with obvious large gas cysts. The livers of most mollusks also had necrotic lesions. Upon Gas Chromatographic chemical analyses of the contaminated axenic C. roseus roots we were able to clearly demonstrate the presence of 2-amino-4, 6-dinitrotoluene and 4-amino-2, 6-dinitrotoluene. The intestinal contents of the deceased snails similarly demonstrated the presence of the metabolites of reduced TNT, including a large concentration of phenols. We therefore have clearly demonstrated that though the axenic roots of Catharanthus roseus can absorb TNT after reducing it to monoaminated-dinitrotoluene, these metabolites are toxic to the Pomacea palludosa aquatic mollusk with a LD50 calculated value of 25 ppm.

1242 TOXICITY STUDIES WITH POMACEA PALLUDOSA (APPLE SNAIL) AND MYRIOPHYLUM AQUATICUM CONTAINING TRINITROTOLUENE.

E D Lykissa[1], J D Smith[1], C Prater[1], M Neely[1], J V Shanks[2], J B Hughes[2], and R F Turk[3]. [1]*Dept. of Pathology, Baylor College of Medicine, Houston, TX;* [2]*Dept. of Environmental Sciences and Engineering, Rice University, Houston, TX;* [3]*Center for Toxicology Services, Inc., Houston, TX.*

Trinitrotoluene (TNT) reduced (remediated) by Myriophyllum aquaticum and its potential toxicity to Pomacea palludosa (Apple snail), an aquatic mollusk indigenous to the Florida marshes, was studied extensively. These mollusks consumed quite readily the uncontaminated M. aquaticum plant, and they showed no aversion to the plants that had been grown in media containing various concentrations of TNT, ranging from 10-50 ppm. After the Apple snails were allowed to forage on plants containing 40 ppmTNT , they did not show any toxic effects in the period of 90 days. When compairing the acute toxic effects observed with the same animal model and the TNT containing axenic roots of Catharanthus roseus to the absence of any acute or chronic toxicity with TNT contaminated M. aquaticum plants, the great potential of this latter aquatic plant system for the removal and remediation of TNT from the water, is self evident. Liquid Chromatography coupled to electronspray negative ion atmospheric pressure ionization revealed monoaminated dinitrotoluene complexed with disaccharide and trisaccharide molecules. The necropsied mollusks revealed no significant pathologic findings, though the TNT was easily traceable in their intestinal contents. It should be noted that no TNT or any metabolite were detected in any of the other tissues of the apple snails.

1243 BIOENERGETIC EFFECTS OF LOW-DOSE CYANIDE ON HOMING PIGEONS (*COLUMBA LIVIA*):A MODEL FOR MIGRATORY BIRD STUDIES.

R D Cooper and C A Pritsos. *Department of Nutrition, Environmental Sciences and Health Program, University of Nevada, Reno, NV, USA.*

Modern gold mining techniques generate large quantities of cyanide-containing waste solutions which are released into the environment to form large ponds, some greater than 300 acres in size. These ponds are often used as watering sites by migratory birds and pose a potential danger to these birds. Our laboratory has shown that mallard ducks exposed to cyanide levels comparable to those found at many of these sites, and considered safe, had significantly reduced tissue ATP levels and significant biological damage. To assess how this non-acutely lethal biological damage might affect migratory birds at a population level, we treated homing pigeons with cyanide in order to determine the cyanide dosages resulting in comparable loss of tissue ATP in pigeons as observed in the mallard ducks. Tissue ATP levels were

determined by the luciferase-luciferin bioluminescence assay at 25° C. Using these homing pigeons and the previously determined cyanide dosages, we tested the impact of cyanide exposure on flight time. Pigeons were taken into the wild, given one of two dosages of sodium cyanide, and released. Individual bird return times were recorded by scanning their leg bands as they returned to the loft. The data show that flight times increase with increasing cyanide dosages, and with flight distance. These results suggest that this may be good model for assessing migratory bird exposure and toxicity to environmental pollutants. (These studies were funded by NIEHS grant 1P42ESO5951 and by USDA Hatch Grant NEV0720.)

1244 PHYTOTOXIC EFFECTS OF SHORT-TERM EXPOSURE TO RDX IN WILD/COVER PLANTS.

L E Winfield[1], C R Lee[1], K W Johnson[2] and D L Brandon[1]. [1]*US Army Corps of Engineers Waterways Experiment Station, Vicksburg, MS, USA;* [2]*AScl Corporation, McLean, VA, USA.* Sponsor: W H Benson.

Plants comprise most of the biomass in the biosphere and those growing on sites with RDS (hexahydro-1,3,5-trinitro-1,3,5-triazine) contaminated soil could be exposed to varying RDX concentrations. Limited information is available on the response(s) of terrestrial vascular plants to RDX exposure. Research conducted to date on the fate and effects of RDX in terrestrial vascular plants has focused on food crop plants. Short-term (5-10 days) phytotoxicity experiments were conducted using ten wild/cover plants to evaluate the effects of RDX exposure on early life stage growth and development (seed germination/seedling emergence, root and shoot length and morphological abnormalities). The experiments were conducted in two large walk-in growth chambers using a completely randomized experimental design. Chamber temperatures were either 23 or 26 +/- 2.0° C and the photo period was 14:10 (L:D). Treatments and controls (unamended or solvent) were replicated three times (ten seeds per replicate). Four grasses (rye, fescue, orchard grass, Kentucky blue grass), five legumes (red clover, white clover, lespedza, sanfroin, small burnett), and one forb (sunflower) were planted in a Grenada soil amended with graded concentrations (0 to 4000 ppm) of RDX (military grade). Plants were watered but not fertilized during the experiments. The Statistical Analysis System was used to perform statistical analyses. Phytotoxic effects were observed more frequently in dicots than in monocots. Sunflower plants were the most sensitive to RDX. Sunflower plants had significantly longer shoots (5.8 - 300ppm or shorter roots (500-4000 ppm) than control plants. Other phytotoxic effects observed included chlorosis, necrotic spots, malformed leaves or roots, and inappropriate pigmentation. Overall, phytotoxic effects were not as prevalent in most of the grass species.

1245 EFFECT OF MERCURY BODY BURDEN ON GENERAL AND REPRODUCITVE HEALTH OF LARGEMOUTH BASS (MICROPTERUS SALMOIDES) FROM THREE LAKES IN NEW JERSEY.

A S Friedmann[1], K Costain[2], D L MacLatchy[2], W Stansley[3], and E Washuta[3]. [1]*Ogden Environmental and Energy Services, Westford, MA, USA;* [2]*Centre for Coastal Studies and Aquaculture, University of New Brunswick, Saint John, NB, Canada;* [3]*State of New Jersey, Division of Fish, Game and Wildlife, Lebanon Fisheries Laboratory, Lebanon, NJ, USA.* Sponsor: B Magee.

The influence of mercury body burden, a ubiquitous metal in aquatic ecosytems, on the general and reproductive health of wild fish populations has not been well studied. Threfore, we determined serum androgen levels, body weight, length, condition factor, gonadosomatic and liversomatic indices, serum cortisol levels following stress, and intrarenal nuclear diameter in male largemouth bass (Micropterus salmoides) collected in April 1997 from three bodies of water in New Jersey: Assunpink Lake (containing low levels of mercury), Manasquan Reservoir (containing moderate levels of mercury), and Atlantic City Reservoir (containing high levels of mercury). The mean mercury content in fish from Assunpink Lake was 0.30 µg-Hg/g-bw, from Manasquan Reservoir 1.23 µg-Hg/g-bw, and from Atlantic City Reservoir 5.42 µg-Hg/g-bw. Inter-lake and intra-lake analyses indicated that mercury tissue concentrations were positively associated with 11-ketotestosterone serum concentrations and negatively associated with testosterone serum concentrations. While this relationship was statistically significant, a cause-effect relationship could not be established because other contaminants were not measured in the fish. Body weight, length, condition factor, and gonadosomatic and liversomatic indices were similar for all three lakes. In contrast to previous findings by others, mercury did not grossly impair adrenocortical function, indicated by intrarenal nuclear diameter and serum cortisol levels following stress. The findings of this study suggest that while elevated levels of mercury in fish potentially alter androgen profiles, they do not decrease other indicators of general and reproductive health.

1246 GENE EXPRESSION AS A POTENTIAL BIOMARKER OF INORGANIC MERCURY EXPOSURE IN TERRESTRIAL ECOSYSTEMS.

M R Garry, M Vredevoogd, E M Faustman. *Consortium for Risk Evaluation with Stakeholder Participation and Department of Environmental Health, University of Washington, Seattle, WA, USA.*

Biomarkers have shown tremendous benefit in human health risk assessment but their potential has not yet been fully evaluated in ecological settings. Studies with aquatic ecosystems suggest biomarkers can provide benefits in ecological evaluations as well, but few studies have examined terrestrial systems. This research is part of ongoing efforts to investigate the utility of molecular biomarkers in terrestrial ecotoxicology. The present study examines potential changes in gene expression of several stress response related genes (hsp70, metallothionein [MT], p21) in *Tenebrio molitor* beetles in response to inorganic mercury ($HgCl_2$) exposure. The study design was based on conditions found at Hanford Nuclear Reservations in order to allow laboratory developed biomarkers to be validated in the field, where conditions are more variable. Beetles were exposed to four different levels of $HgCl_2$ (0, 0.5, 5.0, and 50 ppm in "soil") for 12 days. RNA was extracted from each insect and analyzed by a Reverse Northern technique. No dose response patterns in gene expression were noted. Northerns were performed to validate the Reverse Northern findings, but no specific binding was noted, suggesting non-specific binding in the Reverse Northerns. In order to test a more specific probe, oligonucleotides were generated from high species homology regions of hsp70, MT, and p21 and Northern analyses were performed. In addition, a Northern was performed using a desiccation stress gene (DSP28) cloned from *Tenebrio molitor* as the probe. Results showed a dose response pattern with $HgCl_2$ exposure and expression of both DSP28 and the p21 oligonucleotide. Further experiments are underway to investigate alternative hsp70 and MT homology regions. The development of gene expression biomarkers could give subclinical and sensitive data at the both the species and ecosystem level. (Supported by USDOE DE-FC01-95EW55084 and NIEHS T32ESO-7032.)

1247 EFFECTS OF INORGANIC MERCURY AND ARSENIC CONTAMINATION ON *POECILIA RETICULATA* : HEALTH EFFECTS IN THE BIOECOLOGICAL FOOD-CHAIN.

L R Brown, III, S A Brown, and R H Miller. *Southern University and A&M College, Department Of Chemistry, Baton Rouge, LA, and EnvironTox LABS, Washington, DC, USA.* Sponsor: F Dost.

Bioaccumulation of inorganic mercury and arsenic in the basin and rivers along the Mississippi River stations between Baton Rouge and New Orleans is a serious environmental issue. For many years the Mississippi River was viewed as a large dumping bed for pesticides, metals, runoff debris and chemicals that were washed down from the northern and mid-sections of the United States. In 1996 a toxicological study revealed that a large concentration of inorganic mercury and arsenic was found at six industrial sampling stations in the Mississippi River between Baton Rouge and New Orleans. The concentration levels of mercury and arsenic found was reported as 0.67 ppbs (Hg) and .92 ppms (As). In our study we showed the effects that these high concentration levels of contaminants had on a species of aquatic animals known as *Poecilia retilculata*, commonly known as feeder fish. Inductively Coupled Plasma-Mass Spectrometer-(ICP/MS) analysis revealed that these aquatic animals had extremely high concentrations of mercury in their fillet tissues, stomach tissue, and liver regions. Additionally, it was revealed through ICP/MS analysis of the whole fish body over a twelve month period that a arsenic accumulation in the lower and upper fillet regions were extremely high-(1.00 ppms per fish examined). Also, the fish exposed to mercury developed severely boggling eyes in which the pupils had the appearance of white dot indicating a high concentration of mercury. Aquatic chemical analysis revealed that these animals have the ability to convert inorganic mercury into methyl mercury as to make absorption through the body cells and tissues easier. Analysis of *Macropterus salmoides*-(Smallmouth Bass)who consumed these contaminated fish revealed that these animals experienced a high concentration of mercury in their fillet and liver tissues.

1248 EFFECTS OF HIGH-LEVELS OF INORGANIC MERCURY ON *PROCAMBARUS CLARKII:* ECOLOGICAL AND HEALTH IMPLICATIONS FOR HUMAN CONSUMPTION.

S A J Brown, L R Brown, III, and R H Miller. *Department of Chemistry, Southern University and A&M College, Baton Rouge, LA, and Marasco-Newton Environmental Consultants and Laboratories, Washington DC, USA*. Sponsor: F Dost.

Recently high concentrations of mercury have been found in the area of Honey-Island Swamp, an are in the heart of Bay St. Louis, Mississippi. This area is of great economic importance to the crawfish industry in this region. Red crawfish beds are located throughout the Honey-Island Swamp. The effects of low to relatively high concentration levels of inorganic mercury on these aquatic animals has been astonishing. Through a series of biochemical reactions involving a process known as respiration, these and many other aquatic animals are able to convert inorganic mercury to methyl mercury as to make absorbtioninto the body more accessible.In our two year research study it was show that both male and female members of *Procambarus clarkii* have a string tendancy to absorb high concentrations of inorganic mercury and convert these inorganic levels to methyl mercury. It was also shown in our study through the use of ICP/MS-(Inductively Couples Plasma / Mass Spectrometer) that once absorbed into the bodies of these aquatic animals, the methyl mercury is then stored in the hepatic, tail, and fatty abdominal regions as absorbtion through these regions takes place. Severe abnormalities in the eye sizes of these aquatic animals as well as changes in their dietary in-takes were very noticable during this study. our study also showed that when females-(ages 18 through 45) ingest these contaminated animals over a six month to one year period on a semi-daily basis began experiencing trouble with their monthly menstrual cycles as well as problems with mild to excessive bleeding when their cycles commenced. For women who were past the age of 45 (>45), they experience excessive periods of sweating as well heat flashes on regular intervals after their dietary in-take was completed. These women also experience a marked increase in high-blood pressure as well as irritability from even the most insignificant of events. Additionally, it was shown that in the case of males (ages 17 through 51) ingesting large dosages of these contaminated animals on a normal dietary in-take for one-year they experienced severe headaches as well as urination problems. In some extreme cases where the male subjects ingested more than three pounds of these aquatic animals on a daily basis, they experience severe problems with vision and blurriness.

1249 HYPOXIA-LIKE EFFECTS OF NICKEL IN HUMAN CELLS.

K Salnikow, T Kluz and M Costa. *Nelson Institute of Environmental Medicine, New York University School of Medicine and NIEHS Center, New York, NY.*

Environmental or occupational exposure to nickel compounds represents a serious danger to human health. In searching for intracellular physiological pathways affected by nickel compounds we have cloned a new human gene Cap43, that was highly inducible by soluble and insoluble nickel compounds in human bronchoalveolar cells. The same gene was found to be highly induced by homocysteine in human endothelial cells. Further studies showed that nickel, but not homocysteine was able to universally induce expression of the mRNA for this gene in cells of different tissue origin. Here we report that the expression of Cap43 is greatly enhanced under hypoxic conditions with a time course similar to that observed following nickel exposure. In addition nickel induced the expression of another gene, glyceraldehyde 3-phosphate dehydrogenase, which was also induced by hypoxia. We conclude that nickel exposure causes a hypoxia-like stress in human cells. The molecular mechanisms involved in these effects of nickel are being addressed.

1250 A COMPARISON OF THE MOLECULAR CYTOTOXIC MECHANISMS OF COPPER AND CADMIUM.

J Pourahmad and P J O'Brien. *Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada*. Sponsor : D M Templeton.

The molecular cytotoxic mechanisms of hepatocyte cell lysis induced by $CuCl_2$ and $CdCl_2$ have been compared. "Reactive oxygen species" formation (dichlorofluorescin oxidation) increased much more rapidly with Cu than Cd likely because of redox cycling properties of Cu. Furthermore Cu but not Cd also rapidly oxidized hepatocyte GSH. A loss of mitochondrial membrane potential was an early event in the cytotoxic mechanism of both metals which along with cell lysis was prevented by SOD, catalase, desferal, dimethyl sulfoxide and antioxidants. This indicates that "reactive oxygen species" formation and lipid peroxidation were involved in the loss of mitochondrial membrane potential and cytotoxicity. Cu cytotoxicity was readily prevented by the endocytosis inhibitors methylamine, monensin, chloroquine and 3-methyladenine which suggests that cytotoxic Cu concentrations are stored in lysosomes and/or that ROS formed by the Cu caused a lysosomal leakage of digestive enzymes. Cd cytotoxicity was not affected by endocytosis inhibitors. Both metals induced apoptotic death signals as cell lysis was prevented by the cycloheximide (a protein synthesis inhibitor), actinomycin D or a tetrapeptide caspase protease inhibitor. This signalling may arise from a mitochondrial permeability transition (MPT) as cytotoxicity was prevented by the MPT inhibitors cyclosporin A, carnitine or trifluoperazine. In short, our results suggest that Cu and Cd induced cell lysis or necrosis shares common death signals initiated by mitochondrial or lysosomal injury with apoptosis but lacks the highly organized sequence of events that results in cell packaging required for apoptosis morphology.

1251 CADMIUM TOLERANCE IN PARASITE-SUSCEPTIBLE AND-RESISTANT STRAINS OF *BIOMPHALARIA GLABRATA*, AN INTERMEDIATE HOST FOR *SCHISTOSOMA MANSONI.*

C J Salice and G Roesijadi. *Univ. of MD, Chesapeake Biological Laboratory, Solomons, MD, USA.*

Biomphalaria glabrata is a tropical, freshwater snail that can act as an intermediate host for the trematode parasite that causes schistosomiasis. Different genetic strains of *B. glabrata* display both parasite susceptibility and resistance traits. Here, the relative cadmium tolerances in different life-history stages of parasite-susceptible NMRI and -resistant BS90 strains were examined in this species. Eggs, juveniles and adults were exposed to control and cadmium concentrations of 0.05 to 2.0 micromolar. Survival analysis showed that increasing cadmium concentration caused significant decreases in time-to-death in the three stages. Time-to-death was significantly shorter in all three stages of the parasite-resistant BS90 in comparison with the parasite-susceptible NMRI, indicating higher cadmium tolerance in the latter. To determine the relative sensitivity of the egg, juvenile, and adult stages, time-to-death was compared at 0.25 micromolar cadmium, which was common to all three. Stage significantly effected time-to-death, with the order of cadmium resistance as adult>juvenile>eggs. BS90 has a longer time-to-hatch than NMRI under normal conditions. Time-to-hatch in cadmium exposed eggs was increased in both strains but the effect was greater in BS90 as reflected in the significance of the interaction term (strain x cadmium). Percent hatch significantly decreased with increasing cadmium; BS90 was again more sensitive than NMRI. These results showed that cadmium tolerance was significantly effected by strain and life-history stage. The parasite-resistant strain was less cadmium tolerant than the parasite-susceptible strain. Use of this species for pollutant monitoring as proposed by others will need to consider this source of variability. Furthermore, the interaction of metal resistance and parasite susceptibility may have implications for human health since cadmium exposure favors the survival of the parasite-susceptible strain.

1252 PREVENTION OF MICROBIAL PROLIFERATION ON HEPA FILTRATION MATERIAL.

M S Connors[1], P J Kostyniak[1,2], and R F Giese[3]. [1]*Department of Pharmacology and Toxicology,* [2]*Department of Clinical Laboratory Sciences,* [3]*Department of Geology, State University of New York at Buffalo, Buffalo, NY, USA.*

Microbial growth in air handling systems can lead to exposure to bacteria, fungi, and viruses. Moisture retention gives rise to conditions favorable for microbial proliferation. Prevention of microbial growth would be beneficial. In prior studies adsorption of an antimicrobial to filters resulted in weak attachment of the agent to the filter surface. This attachment can be strengthened by first coating the HEPA (High Efficiency Particulate Air) filtration media with a colloid that binds tightly to the borosilicate glass fiber surface, followed by the binding of an antimicrobial agent to the colloid via cation exchange reactions. The ability of smectite clay to swell and form a gel-like colloid suspension in H2O allows for easy application to surfaces by a dipping process. Direct observation by scanning electronmicroscopy has shown that the clay does not obstruct the filter pores. Smectite clays have a net negative layer charge balanced by cations such as Na+ , Ca2+ , and Mg2+. Cation exchange reactions are used to bind the quaternary ammonium

antimicrobial compound, hexadecyltrimethyl ammonium (HDTMA), to the colloid on the filter surface. The colloid bound HDTMA had the same antimicrobial activity as the native HDTMA against *P. aeruginosa* in the Standard Plate Count assay. The antimicrobial activity of the treated HEPA filtration material was assessed using AATCC Method 100-1993 with *P. aeruginosa* as the test organism, and with an ATP luminescence assay. Both assays have confirmed the antimicrobial activity of the treated HEPA filters. Leachability of the HDTMA is prevented by the colloid pretreatment of the HEPA filter. This procedure can be utilized to impart antimicrobial activity to any surface that can be coated with clay or any other colloid possessing a significant cation exchange capacity. (This work was supported in part by grants from the Clay Minerals Society, the Western New York Safety Conference, and the University at Buffalo.)

1253 TOXICITY OF CHLOROACETIC ACID (MCA) IN RATS UNDER CONDITIONS OF TOXICOKINETIC STEADY-STATE APPEARS TO OCCUR ACCORDING TO HABER'S LAW OF INHALATION TOXICOLOGY.

K K Rozman[1,2] and S A Saghir[1]. [1]*Department of Pharmacology, Toxicology, and Therapeutics, University of Kansas Medical Center, Kansas City, KS;* [2]*Section of Environmental Toxicology, GSF-Institut für Toxikologie, Neuherberg, Germany.*

The rate of release of MCA was determined from surgically implanted mini-pumps. Three rats were implanted with ^{14}C-MCA filled mini-pumps. A 16-hr delay in the beginning of delivery of MCA was created by adding a polyethylene catheter (I.D., 0.76 mm; O.D., 1.22 mm) to the pump, which was filled with saline. The two liquids were separated by a small air bubble. Blood samples were collected from the tail vein at 0.25, 0.5, 1, 2, 4, and 8 hrs following the activation of the delivery of MCA from the mini-pumps. Radioactivity was determined in plasma. Results indicated constant release of MCA from the pumps. Subsequently a study was conducted to determine the time-to-effect of MCA in adult male Sprague-Dawley rats (160-175 g). Rats (5 animals per dose group) were injected with highly toxic loading doses (75, 100 and 125 mg/kg) of MCA followed by a maintenance dose delivered via the osmotic mini-pumps which were surgically implanted subcutaneously. After 16 hours of recovery from surgery, loading doses were administered into the tail vein. The beginning of delivery of MCA from the osmotic pumps was synchronized with the administration of the loading doses. Following the delivery of the loading doses, animals were closely monitored to determine the exact time-to-effect (coma, death). Preliminary results indicated that *dose x time = constant* is also valid for this highly water-soluble small molecule under conditions of toxicokinetic steady-state.

1254 METHYL-t-BUTYL ETHER (MTBE) EFFECTS ON PLASMA LUTEINIZING HORMONE (LH) IN GONADECTOMIZED MALE RATS.

B S Allgaier and A de Peyster. *Graduate School of Public Health, San Diego State University, San Diego, CA.*

MTBE, a widely used automotive fuel oxygenate, increased Leydig cell adenomas in male rats chronically exposed to high doses by inhalation (8000 ppm) or gavage (1000 mg/kg) but has had little or no activity in most genotoxicity tests conducted thus far. Several other recognized mechanisms of rodent Leydig cell chemical carcinogenesis ultimately involve chronic hyperstimulation of these testosterone-producing cells in the testes by LH from the anterior pituitary gland (Clegg et al., 1997). Like other ethers, MTBE causes CNS depression, and specific effects on the pituitary gland (weight changes, ACTH droplet accumulation in female mice) have also been reported with chronic high MTBE exposures. We report here results of studies on direct effects of MTBE on the hypothalamic-pituitary unit with respect to LH production and release using orchiectomized Sprague-Dawley rats with/without testosterone levels maintained by silastic implants containing testosterone propionate. No consistent or statistically significant differences between MTBE-exposed and vehicle control groups were found in mean plasma LH as measured by rat-specific RIAs 2-5 hr after and again 5 days after daily high MTBE gavage doses (800 mg/kg) sufficient to cause ataxia and sedation. We have previously observed reduced plasma testosterone levels in month-long MTBE studies using this dose administered to intact rats. These new findings do not support a mechanism involving a primary effect of MTBE on the hypothalamus and/or pituitary causing alteration of LH levels directly, although a more prolonged MTBE exposure period and more frequent LH sampling may be necessary to detect subtle cumulative effects.

1255 ACUTE TESTICULAR TOXICITY OF MTBE AND BREAKDOWN PRODUCTS IN LAB MICE.

J E Billitti, B C Faulkner and B W Wilson. *University of California, Davis, CA, USA.*

Concern for MTBE in drinking water prompted studies of its toxicity by University of California scientists. Our laboratory studied acute oral MTBE exposure and testicular function of male mice using a fecal testosterone ELISA biomarker from fecal ether-extracts. Testosterone baseline and human chorionic gonadotropin (hCG) stimulated levels were determined before, during and after exposure. Other parameters included animal and testis weights, end point serum testosterone, and histopathology of the testis by light microscopic examination of formalin fixed tissue sections. Groups of 5 mice were orally dosed with 0, 400, 1000 or 2000 mg/kg of MTBE in canola oil three times over a 5 day period. Three mice were dosed with cadmium (Cd), a known testicular toxicant, as a positive control. A final fecal testosterone sample was taken on day 7, blood sampled, and the testes removed. There was no change in unstimulated and hCG stimulated fecal testosterone at any treatment levels, nor were there any differences in end-point serum testosterone levels, body and testis weights between untreated and MTBE dosed animals. The only histological difference between control and 2000 mg/kg exposed animals was a small increase in gross disruption of tubules in the 2000 mg/kg group (6 ± 3%, mean ± SD, $p \leq 0.05$). Cd controls exhibited decreased testis weight, fecal and serum testosterone, and histopathological damage ($p \leq 0.05$). In addition to MTBE, we studied two UV/peroxidase breakdown products, tert-butyl alcohol and tert-butyl formate, in collaboration with Dr Thomas Young, UCD. Animals were run through a similar battery of tests as MTBE with little difference found between treated and untreated animals. These studies revealed no dramatic effects of high dose levels of MTBE or its major breakdown products on male hormone levels or testicular histology in mice. Whether chronic dosing would have elicited a response remains to be tested. (Supported by University of California Toxic Substances Research and Teaching Program; special funding by the State of California (SB521).)

1256 ALTERATIONS IN ENDOCRINE ACTIVITY IN MALE SPRAGUE-DAWLEY RATS FOLLOWING ORAL ADMINISTRATION OF METHYL *t*-BUTYL ETHER.

T M Williams, R C Cattley, and S J Borghoff. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA.*

Methyl *t*-butyl ether (MTBE) is an oxygenated fuel additive used to decrease carbon monoxide emissions during combustion. Both occupational and environmental exposures to MTBE are substantial due to its large production volume and widespread use. MTBE is a nongenotoxic carcinogen that induces Leydig cell tumors (LCT) in male rats. The mechanism of MTBE-induced LCTs is not known, however LCTs induced by other nongenotoxic chemicals has been associated with a disruption in the hypothalamus-pituitary-testicular (HPT) axis. The objective of this study was to determine if MTBE alters HPT feedback mechanisms in male rats. Nine week old male Sprague-Dawley rats were administered MTBE by gavage at 0, 250, 500, 1000, or 1500 mg/kg/day for 15 or 28 consecutive days and sacrificed one hour following the last dose. Treatment with MTBE for 15 or 28 days did not effect body weight, however high-dose (1500 mg/kg/day) animals exhibited clinical signs of toxicity throughout the study. Relative testis, adrenal gland, liver, and kidney weights were increased in the high-dose animals. No testicular lesions were observed at any dose level. Interstitial fluid testosterone was decreased at 1500 mg/kg/day in the group treated for 15 but not 28 days. Serum triiodothyronine was significantly decreased at 1000 and 1500 mg/kg/day and a dose-related decrease in serum luteinizing hormone was observed at 28 days. These results suggest that alterations in endocrine feedback signals due to MTBE are only apparent at high-dose levels.

1257 USE OF URINE AND PLASMA GH ASSAYS TO ASSESS THE GH SECRETION PATTERN IN MONKEYS AFTER DOSING WITH BIM 28041, A NEW PEPTIDIC hGRF RECEPTOR AGONIST.

J-J Legrand[1], C Pècheur[2], V Boulifard[1], B Keck[3] and F Garnier[3]. [1]*Institut Henri Beaufour, Les Ulis, France;* [2]*Chrysalis Preclinical Services Europe, L'Arbresle, France;* [3]*Ecole Nationale Vétérinaire de Lyon, France.*

Plasma and urinary Growth hormone (GH) levels were monitored in Cynomolgus monkeys treated for seven days with BIM 28041 [(hexenoyl trans 3)0 hGRF (1-29) NH2] in order to evaluate the efficacy and the safety

of this new peptidic human Growth Releasing Factor (hGRF) receptor agonist. Three groups of three monkeys each were treated with the vehicle or with the BIM 28041 either by daily subcutaneous injections or by continuous intravenous perfusion. GH was quantified by a radio-immunoassay in blood samples collected on days 1 and 7 at designated times and in urine samples collected from day 7 to day 8 during the last exposition period. In treated animals, GH plasma levels reached the high control levels corresponding to peak secretion values during all the exposure period. The urinary levels of GH indicated that the pituitary was only transiently stimulated after subcutaneous administration of the test compound, and that the continuous intravenous perfusion leaded to a continuous stimulation of the pituitary gland. No desensitization of the receptors nor exhaustion of the cells were observed through the administration period, and the amount of GH instantaneously released during the bursts of secretion was not increased above the physiological levels.

1258 PERSISTENT INCREASE IN ADRENAL OUTPUT WITHOUT CONCURRENT GONADAL ALTERATIONS IN MALE RATS THREE DAYS FOLLOWING ACUTE D,L-FENFLURAMINE EXPOSURE.

L L Morford[1], S L Inman-Wood[1], A E McCrea[2], C V Vorhees[1] and M T Williams[1]. [1]*Children's Hospital Research Foundation, Cincinnati, OH, USA;* [2]*Sinclair Community College, Dayton, OH, USA.*

We have demonstrated that acute d,l-fenfluramine (FEN) exposure has neurotoxic effects as evidenced by increased glial fibrillary acidic protein under hyperthermic conditions three days post-treatment. Previous research has shown that serotonergic agonists such as FEN can activate the hypothalamic-pituitary-adrenal (HPA) axis. In this study we examined the effect of FEN on HPA basal activity and gonadal output. Adult male Sprague-Dawley rats were administered 15 mg/kg FEN dissolved in saline every two hours for a total of four s.c. injections at either an ambient temperature of 21° C or 32° C. Control animals received saline at an ambient temperature of 32° C. Rectal temperatures were monitored on the day of dosing. As expected, the animals given FEN at 32 ° C exhibited hyperthermia as compared to the controls. Three days following the exposure period, trunk blood was collected immediately upon removal from the home cage. Corticosterone, aldosterone, and testosterone in plasma were analyzed in duplicate by RIA. Regardless of ambient temperature exposure, both FEN conditions had elevated corticosterone relative to controls. Aldosterone titers were only greater for the animals administered FEN at the higher ambient temperature. No effect was observed on the testosterone levels at this time period. These data suggest that the HPA axis shows increased responsivity following acute FEN exposure. Whether this increased activity is from a peripheral activation of the adrenal gland or a central elevation in hypothalamic or pituitary hormones remains to be determined. (Supported by NIH grants ES07051 and DA06733.)

1259 EFFECTS OF SHORT-TERM IN VIVO EXPOSURES TO POLYBROMINATED DIPHENYL ETHERS ON THYROID HORMONES AND HEPATIC ENZYME ACTIVITIES IN WEANLING RATS.

T Zhou[1], D G Ross[2], M J DeVito[2], and K M Crofton[3]. [1]*Curriculum in Toxicology, UNC, Chapel Hill, NC;* [2]*Experimental Toxicology and* [3]*Neurotoxicology Divisions, NHEERL, USEPA, RTP, NC, USA.*

Polybrominated diphenyl ethers (PBDEs), used as flame retardants, are ubiquitous environmental contaminants. Sharing similar structures as thyroid hormones, PBDEs act as endocrine disruptors via alterations in thyroid hormone homeostasis. We examined thyroid hormone concentrations and hepatic enzyme activity in weanling rats exposed to two commercial PBDE-mixtures, DE-71 (mostly tetra- and penta-bromodiphenyl ethers) and DE-79 (mostly octabromodiphenyl ether). Postnatal rats (PND 28) were orally administered various doses of DE-71 (0.3, 1, 3, 10, 30, 100 and 300 mg/kg/day) or DE-79 (0.3, 1, 3, 10, 30, 60 and 100 mg/kg/day) for four days. The rats were sacrificed on the 5th day, and serum and liver samples were analyzed for circulating thyroxine (T4), triiodothyronine (T3), or liver microsome ethoxy- and pentoxy-resorufin-O-deethylase (EROD and PROD) activities. Though the DE-71 treated groups did not exhibit significant changes in body weight, enlargement in liver as well as up to 20-30 folds induction in EROD (ED50= 11 mg/kg/day) and PROD (ED50= 8 mg/kg/day) were found . In comparison to controls, serum T4 levels in the DE-71 or DE-79 treated groups were dramatically reduced in a dose-dependent manner. Serum total T4 was decreased maximally about 80% in the highest dose, with an ED50 of approximately 21 mg/kg/day for DE-71 and DE-79. However, dose-related effects in serum T3 levels were less apparent; maximal reduction was 25% at the highest dose. There were no significant alterations in serum TSH levels for the DE-71 treated animals. TSH concentrations in animals treated with DE-79 were not examined. The present study demonstrates that commercial PBDE-mixtures interfere with the thyroid hormone system via Ah- and non-Ah-receptor activation. Non-PBDE impurities in the mixtures may be responsible for the EROD induction.

1260 THE RELATIVE CONTRIBUTIONS OF SYNTHESIS AND INACTIVATION TO THE LOWERING OF SERUM TESTOSTERONE LEVELS BY KETOCONAZOLE.

V S Wilson and G A LeBlanc. *North Carolina State University, Raleigh, NC, USA.*

At sufficiently high doses, the fungicide ketoconazole can significantly lower serum testosterone levels. This effect is generally attributed to the ability of ketoconazole to inhibit gonadal enzymes involved in testosterone synthesis. In an effort to identify potentially contributing mechanisms to this toxicity, the effects of the fungicide on adrenal and gonadal secretion and hepatic metabolism of androgen was evaluated. These studies were also used to substantiate our recent observation that the ratio of hepatic testosterone 6α:15α hydroxylase activities provides a superior indicator of the androgen status of CD-1 mice. Mice were orally administered dosages of ketoconazole (0 to 80 mg/kg) every 24 hours for 7 days. Four hours after the initial treatment, serum testosterone levels decreased and the hepatic 6α:15α hydroxylase ratio increased in a dose- dependent manner. This effect was accompanied by an overall decrease in the gonadal secretion and the hepatic biotransformation of testosterone. Twenty-three hours after the initial dosing, serum testosterone levels, gonadal testosterone secretion, and hepatic testosterone biotransformation had recovered. These parameters were also comparable to controls 7 days after treatment; although, adrenal secretion of androstenedione was suppressed in a dose-dependent manner. These results demonstrate the following. 1) The effects of ketoconazole on serum testosterone levels are transient. 2) Reductions in serum testosterone levels are due to decrease gonadal secretion of testosterone and not increased hepatic biotransformation. 3) The reduced secretion of androstenedione by the adrenal glands following ketoconazole treatment alone is not sufficient to decrease testosterone levels. 4) The hepatic 6α:15α hydroxylase ratio can serve as a biomarker of androgen deprivation even after short-term testosterone suppression.

1261 INTERACTIVE EFFECTS OF DDE, DIELDRIN AND METHOXYCHLOR ON HORMONE SYNTHESIS IN BASS GONADAL CULTURES.

C J Borgert[1,2], T S Gross[2,3], P D Guiney[4], and T G Osimitz[4]. [1]*Applied Pharmacology and Toxicology, Inc., Alachua, FL, USA;* [2]*Department of Physiological Sciences, University of Florida, College of Veterinary Medicine, Gainesville, FL, USA;* [3]*USGS BRD Caribbean Science Center, Gainesville, FL, USA;* [4]*S C Johnson & Son, Inc., Racine, WI, USA.*

A number of recent studies have reported that combinations of environmental contaminants exhibit greater than additive effects on endocrine-responsive tissues or biochemical systems (i.e. chemicals interact synergistically in producing effects). However, some of these studies have very low power to assess interactions because they only minimally characterized the dose-response curves of the individual agents or attempted to assess the effects of combinations of agents using only single dose ratios. We tested the hypothesis that p',p'-DDE, (DDE) dieldrin (DDL) and methoxychlor (MCL) interact to produce effects on hormone synthesis in gonadal tissue cultures harvested from female large mouth bass, a species whose reproductive fitness has relevance to ecosystem health in Florida. We characterized the concentration-response relationships of these agents on 11-ketotestosterone (T) and estradiol production over a 4-log concentration range. Combinations of the agents were tested at 0.01, 1, 100, and 10,000 ppb in the culture medium in a full-factorial, block treatment design. Gonadal tissue was harvested from female bass (2-3 years of age) during the peak reproductive season (February - April) to maximize steroidogenic activity and available gonadal mass, minced and incubated in culture medium with or without test agents for 48 hours. Duplicates of each treatment were performed in each of three experiments using gonadal tissue from a different female. Estradiol, testosterone, and 11-ketotestosterone were measured in aliquots of culture medium by validated RIA procedures. MCL alone produced a slight, dose-dependent decrease in testosterone. In the presence of increasing concentrations of DDL, MCL increased T production in a dose-dependent fashion. DDL alone had no effect on T production. Other main and interactive effects were not statistically significant.

1262 THE EFFECT OF BLEACHED KRAFT MILL EFFLUENT EXPOSURE ON THE METABOLIC ELIMINATION OF TESTOSTERONE AND THE PRODUCTION OF VITELLOGENIN IN THE FATHEAD MINNOW (*Pimephales promelas*).

L G Parks[1], D L Borton[2], W L Streblow[2], and G A LeBlanc[1]. [1]*North Carolina State University, Raleigh, NC, USA;* [2]*National Council for Air and Stream Improvement, New Bern, NC, USA.*

Recent studies have determined that certain bleached kraft mill effluents (BKME) reduce fecundity in fish but as yet, there is no known mechanism of action. In the present study, we evaluated whether estrogenicity, antiestrogenicity, or altered testosterone metabolic clearance associated with the BKME might contribute to this toxicity. Fathead minnows (*Pimephales promelas*) were exposed through one life-cycle to BKME. Immediately prior to spawning, a subset of these fish were evaluated for the metabolic clearance of testosterone. For the remaining fish, daily egg production was measured during 6 weeks of spawning and at the end of the study, blood plasma was assayed for the presence of vitellogenin (VTG). Egg production decreased significantly with increasing effluent concentration compared to control at 50 and 100% effluent with an IC25 calculated at 21% effluent. There was no significant decrease in VTG levels in females and no VTG was detected in males, indicating that this BKME is neither antiestrogenic or estrogenic, respectively. Testosterone was elimnated from the fathead minnow as a variety of hydroxylated and conjugated derivatives. The rate of elimination of six of these metabolites was significantly altered as compared to controls. Elimination rates of three of these metabolites significantly correlated with decreased egg production. These results demonstrate that the metabolic elimination of testosterone may contribute to the reproductive toxicity and may serve as a predictive biomarker of reproductive toxicity associated with BKME.

1263 INTERACTION OF POLYCYCLIC MUSKS WITH AMPHIBIAN AND FISH ESTROGEN RECEPTOR.

Y Chou and D R Dietrich. *Environmental Toxicology, University of Konstanz, Konstanz, Germany.*

Galaxolide (HHCB) (1,3,4,6,7,8-Hexahydro-4,6,6,7,8,8-hexamethylcyclopenta-(g)-2-benzopyran), Tonalide (AHTN) (7-acetyl-1,1,3,4,4,6-hexamethyltertraline) and Celestolide (ADBI) (4-acetyl-1,1-dimethyl-6-tert butylindane) are synthetic polycyclic musk fragrances. As the substitutes for natural musks, these compounds are widely used in detergents, perfumes and cosmetics. As a result of their inherent lipophilicity (Kow: 5.7 for AHTN, 5.9 for HHCB) and environmental persistence, these compounds have been detected in surface waters (ng-µg/l) and various tissues of aquatic organisms (mg/kg lipid). In view of this situation, the questions were asked whether these compounds have embryotoxic and teratogenic activity and if they could interact with the endocrine system of amphibians and fish. To address these questions, embryo-larvae of *X. laevis (X.l.)* and zebrafish (*D. rerio, D.r.*) were exposed to AHTN (0.09-1 mg/l; 0.09-2 mg/l, respectively) and HHCB (0.09-1 mg/l; 0.07-4 mg/l, respectively) for 96 h, using established assay procedures (ASTM, E1439-91, 1991, p.1-11; Dietrich et al., 1998, Toxicol. Sci. (42-1S), p259). In addition, the capability of these compounds to inhibit ^{3}H- estradiol binding to hepatic estrogen receptors of *X.l.* and rainbow trout (*O. mykiss, O.m.*), was investigated. 100% mortality occurred at the highest testing concentration for AHTN and HHCB in both species. *D.r.* embryos demonstrated a generalized ventro-dorsal curvature and tail flexure in the distal portion following exposure to AHTN or HHCB (EC_{50} = 0.2-0.3 mg/l). However no malformation was observed for AHTN and HHCB in *X.l* Estrogen receptors were prepared from both species using previously published methodology, the K_Ds determined for *X.l.* and *O.m.* were 30 nM and 3 nM, respectively. While no competitive inhibition was observed for ADBI in either species, a 1 mM concentration of AHTN inhibited E2 binding to the E-receptor in *X.l.* and *O.m.* by 40% and 30%, respectively, and 1 mM HHCB inhibited E2 binding by 40% and 20%, respectively.

1264 P-*TERT*-OCTYLPHENOL AND/OR VINCLOZOLIN INDUCED-INTERSEX IN DEVELOPING MEDAKA (*ORYZIAS LATIPES*).

C S Koger, S J Teh, and D E Hinton. *Department of Anatomy, Physiology, and Cell Biology, School of Veterinary Medicine, University of California, Davis, CA, USA.*

Endocrine-disrupting compounds may alter reproductive development. To study the effects of two environmentally relevant compounds, five replicates of stage 10 medaka (*Oryzias latipes*) embryos (N= 5 per replicate) were bath-exposed to 0 µg/L, 10 µg/L, 100 µg/L, 250 µg/L, 500 µg/L, 750 µg/L and 1000 µg/L of either the estrogenic surfactant, p-*tert*-octylphenol (OP), or the antiandrogenic fungicide, vinclozolin (*V*), and reared at 25°C until one day after hatch. In addition, exposure to a 50/50 mixture of both OP (500 µg/L) and *V* (500 µg/L) was performed. Ten fish per exposure and corresponding control groups were sampled at one month after initiation of the experiment. A significant increase in time to hatch was associated with exposure to10 µg/L, 100 µg/L, and 250 µg/L of *V*. Only the 100 µg/L OP group shown delayed hatch. Gross examinations under dissecting microscope revealed no signs of acute or developmental toxicity. Microscopic examination revealed eosinophilic protein droplets in kidneys of males and some females exposed to OP and *V* alone or as a mixture. There was no significant difference in sex-ratio between exposure or control groups. The most significant finding of this study was the presence of intersex gonads in medaka exposed to OP and *V* at concentrations of 250 g/L and higher. Intersex gonads were also seen in fish exposed to the 50/50 mixture of octylphenol and vinclozolin. The presence of intersex in a stable, sexually dimorphic species suggested an estrogenic or antiandrogenic effect of OP and *V* such that the male germ cells have been sexually reversed to female ova in affected individuals. Results from the three-month-old sampling will be reported. This study constitutes the first report of laboratory-induced intersex in fish exposed to vinclozolin.

1265 CYANAZINE (CYN) AFFECTS NOREPINEPHINE (NE) RELEASE IN PHEOCHROMOCYTOMA (PC12) CELLS.

P C Das[1] , W K McElroy[2] and R L Cooper[2]. [1]*Curr in Tox, UNC-CH, NC, USA;* [2]*Repro Tox Div, NHEERL, US EPA, RTP, NC, USA.* Sponsor: R J Kavlock.

We have previously found that the chlorotriazines i.e.Cyanazine, Simazine and Atrazine disrupt the ovulatory surge of luteinizing hormone in rats. Consistent with our hypothesis that this effect on pituitary hormone secretion is centrally mediated, we found that hypothalamic NE is decreased by these compounds. In the present study, we used PC12 cells to examine the possibility that the synthesis of NE is altered by a direct action of Cyanazine on dopamine-β hydroxylase (DBH). Cells were incubated in the presence of the CYN, the DBH inhibitor fusaric acid (FA), or the $GABA_A$ receptor agonist muscimol (MU). MU had no effect between 0.01 µM thru 10 µM, whereas FA blocked the release of NE at 10 µM to 250 µM following 6 h to 48 h exposure. NE release was significantly increased by 100 µM CYN, but NE concentration was either decreased or not different than respective controls at 400 & 800 µM. The increased NE release occurred from 12 h to 48 h of exposure with a maximum increase at 24 h. Intracellular DA was decreased by CYN in a dose-dependent fashion. These data suggest that CYN does alter the NE activity *in vitro* but the mechanism of action remains to be determined. (This abstract does not reflect U.S. EPA policy.)

1266 ENDOMETRIOSIS IN RHESUS MONKEYS IS ASSOCIATED WITH ALTERED LIVER CYTOCHROME P450 ENZYME ACTIVITY IN RELATION TO SERUM ESTRADIOL AND PROGESTERONE LEVELS, AND DIOXIN EXPOSURE.

D P Bofinger, L-H Chi, and J R Olson. *State University of New York at Buffalo, Buffalo, NY, USA.*

Endometriosis (EM) is a disease in which endometrial tissue is found outside of the uterus. Rier, et al. (FAT 21:433-441, 1993) showed a link between EM and exposure to dioxin (TCDD) (2,3,7,8-tetrachlorodibenzo-p-dioxin) in a surviving subgroup (17/24) of rhesus monkeys exposed to 0, 5, or 25 ppt TCDD/day in their feed from 1977-1982. In 1996, the 12 remaining monkeys were oophorectomized and cycled on hormones to mimic 2 menstrual cycles. They were sacrificed mid-way through the 2nd mid-secretory phase. Liver tissue, and serum estradiol (E_2), progesterone (P_4) levels were provided (Dr. Sherry Rier), and liver microsomes were used to measure CYP1A1 protein (western blotting), CYP1A1 activity (7-ethoxyresorufin-O-deethylase), and dimethylbenzanthracene (DMBA) metabolism (HPLC). Total DMBA metabolism increased with E_2 in monkeys without disease (-EM) (n=4) (R^2=0.94; p<0.03), but was unrelated to E_2 in monkeys with disease (+EM) (n=8). The trend was similar for P_4. The ratio of CYP1A1 activity: protein increased with P_4 (R^2=0.60; p<0.025) and P_4/E_2 (R^2=0.86; p=0.001) and decreased with E_2 in (+EM) monkeys, and was unrelated to P_4 or E_2 in (-EM) monkeys. EM alone resulted in decreased DMBA metabolism (p<0.0003) and E_2 (p<0.02). In (-) EM monkeys, TCDD exposure resulted

in decreased E_2 ($p<0.05$) and total DMBA metabolism ($p<0.01$), and in (+ EM) monkeys, exposure resulted in a decrease in E_2 with no effect on total DMBA metabolism. The results suggest that (-EM) and (+EM) monkeys show different profiles of cytochrome P450 activity in response to E_2, P_4 and TCDD (Sponsors: Fairleigh S. Dickinson, Jr. Fndn.; Endometriosis Assoc.; NIEHS #ES08539-01.)

1267 EFFECT OF DIETARILY ADMINISTERED ENDOCRINE ACTIVE AGENTS ON HEPATIC CYTOCHROME P450 (CYP450) AND ESTROGEN RECEPTOR ALPHA (ERα) EXPRESSION IN MALE AND FEMALE RATS.

E M Laurenzana[1], K B Delclos[1], C C Weis[1], L V Hardin[1], and R Newbold[2]. [1]*National Center for Toxicological Research, Jefferson, AR, USA;* [2]*NIEHS, Research Triangle Park, NC, USA.*

In addition to interacting with steroid receptors, endocrine active agents may act through other mechanisms. The objective of this study was to examine the effect of several endocrine active agents on hepatic CYP450 and ERα expression. Male and female rats were exposed to methoxychlor (MXC), genistein, or vinclozolin dietarily from gestational day 7 through postnatal day 50. Rats were sacrificed and liver microsomes and cytosolic fractions were prepared. CYP2C and CYP3A levels were determined by ELISA and Western blotting. Testosterone metabolism was also examined. Cytosolic ERα levels were determined by immunprecipitation followed by Western blotting. MXC decreased CYP2C expression in males at the highest dose (1000 ppm) with no effect on CYP3A. In male rats, genistein treatment resulted in an increase in CYP2C at 250 ppm and a decrease at 1250 ppm with no effect on CYP3A. No effects on CYP2C or CYP3A were observed in MXC or genistein treated female rats. Vinclozolin increased CYP3A expression in male rats with no effect on CYP2C. In female rats, vinclozolin increased CYP2C and CYP3A. Testosterone metabolism was altered by all compounds. Cytsolic ERα expression in the liver was also modified by all componds. MXC increased male ERα expression with no effect in females. Genistein decreased ERα expression in males and increased ERα in females. Vinclozolin increased ERα in female rats and had no effect in males. These studies suggest that endocrine active agents have differential effects on hepatic CYP450 and ERα in male and female rats. These changes could affect response to endogenous or exogenous hormones by altering metabolism and level of receptor available.

1268 ESTROGEN-MEDIATED TRANSACTIVATION VIA ESTROGEN RECEPTOR (ER)-Sp1 INTERACTIONS: COMPARISON OF WILD-TYPE AND MUTANT MOUSE ER.

K Kim[1], M G Parker[2] and S Safe[1]. [1] *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA;* [2]*Molecular Endocrinology Laboratory, ICRF, London, UK.*

Estrogen receptor (ER)-Sp1 protein complexes mediate hormone-induced transactivation of several genes through binding only GC-rich sites or composite elements containing both an estrogen responsive element half site ($ERE_{1/2}$) and GC-rich motifs [$ERE_{1/2}(N)_xGC$-rich]. The role of ER monomer or homodimer in ER/Sp1 action is unknown. This study utilizes wild-type and mutant mouse ER (MOR) expression plasmids in ER-negative MDA-MB-231 human breast cancer cells to further define functional ER-Sp1 interactions. MDA-MB-231 cells were transfected with constructs containing a consensus GC-rich (pSp1) or $ERE_{1/2}(N)_{23}GC$-rich [$pERE_{1/2}(N)_{23}Sp1$] oligonucleotide inserts linked to a bacterial chloramphenicol acetyltransferase (CAT) reporter gene; E2 did not induce CAT activity. However, in cells cotransfected with wild-type MOR and pSp1 or $pERE_{1/2}(N)_xSp1$, there was a 2.2- and 3.2-fold induction of CAT activity, respectively. Cotransfection with several MOR mutants including L511A, C241A/C244A, R507A, and progesterone receptor (PR) DNA binding domain were also investigated. E2-responsiveness were observed for L511A using both constructs; C241A/C244A was functional only with $pERE_{1/2}(N)_{23}Sp1$, and remaining plasmids were inactive with both pSp1 and $pERE_{1/2}(N)_{23}Sp1$. These results coupled with ongoing studies with ERE-containing constructs will define promoter-specific requirements for a functional ER and the role of ER as a monomer or homodimer. (NIH CA76636)

1269 THE APPLICATION OF GENOMICS ARRAY TECHNOLOGY TO UNDERSTANDING TOXIC MECHANISMS; A CASE STUDY USING CARBON TETRACHLORIDE.

W D Pennie, P R Holden, N James, A N Brooks, R A Roberts and I Kimber. *ZENECA Central Toxicology Laboratory, Cheshire, UK.*

We have examined the potential of genomics technology to examine the influence of carbon tetrachloride on hepatocyte gene expression. HepG2 (human hepatoma cell line) cells were exposed for 8 hours to either carbon tetrachloride (0.18% v/v) or to the vehicle (dimethyl formamide, 0.25% v/v) alone. RNA (polyA+) was then prepared and used as a template for first strand cDNA synthesis in the presence of radioactive nucleotide. These complex probes were individually hybridised to commercially available genomic arrays ("ATLAS", Clontech) and the resulting hybridisation patterns were visualised and quantitated using a Molecular Dynamics phosphorimager. Of the 580 genes on the array, approximately 40 genes showed differential transcriptional levels following normalisation of the signals to housekeeping genes (ubiquitin, Phospolipase A2, alpa tubulin, beta actin etc). These differentially regulated genes included putative onco/tumour suppressor genes (c-fms, mas, p55CDC, L-myc-2), stress response genes (STK2, RAB-6, P450), transcription factors (ASH-1, RAD-8) and growth factors (IL-8, Stem Cell Factor). This technique clearly represents an important tool in furthering our understanding of the mechanisms of carbon tetrachloride toxicity.

1270 GENE EXPRESSION PATTERNS AND OXIDANT DAMAGE.

S L Trasti[1,2], H R Brown[1], T R Fox[1], K T Morgan[1], G R Benavides[1], R D Tyler[1], B Gaskill[1] and C W Qualls[3]. [1]*GlaxoWellcome, Inc., RTP, NC;* [2]*North Carolina State University, Raleigh, NC;* [3]*Oklahoma State University, Stillwater, OK.*

Gene expression patterns have the potential to reveal mechanisms of chemically induced disease. To test this proposal, *in vitro* responses to 1,3,5-trinitrobenzene (TNB) were used. TNB induces testicular atrophy (rat), neural degeneration (rat), and methemoglobinemia (multiple spp), *in vivo*. The mechanisms responsible for these changes are not well understood, and may include superoxide generation. Changes in gene expression were determined in human HEP-G2 cells after 4 and 12 hrs exposure to 125 μ M TNB. Exposure to this concentration results in a minor reduction in cell viability at 4 hrs as assessed by the MTS assay and a distinct nitroblue tetrazolium reduction, consistent with superoxide generation. At 4 hrs, H&E stained cultures exhibit loss of cytoplasmic lipid droplets and decreased numbers of mitotic figures. At 12 hrs, there is reduced mitosis and individual cell death and at 24 hrs cultures show total cellular necrosis. Messenger RNA from 4 and 12 hr cultures was reverse transcribed to ^{33}P-labelled cDNA and hybridized to a high-density cDNA expression array (Atlas Human Array, Clontech, Palo Alto, CA) containing 588 genes. There were marked treatment-related changes, with both up and down regulation of specific genes, and clear differences between 4 and 12 hrs. At 4 hrs, several functional classes of genes were affected including early response (c-jun, FRA-1, ETR101), stress response (HSPs 40, 60 and 70), and DNA repair/synthesis (GADD 45, GADD 153). Similar changes were seen after 12 hrs, with significant differences including upregulation of the p21 gene, an important cell cycle inhibitor. These data indicate that a powerful oxidant induces transcriptional changes consistent with stress response, mitotic arrest and DNA repair. Studies of related compounds will be needed before a mechanism-specific pattern of gene expression can be defined.

1271 GENE EXPRESSION PATTERNS INDUCED IN HEP-G2 CELLS INDICATE THAT DNA DAMAGE MAY PLAY A MAJOR ROLE IN PARQUAT-INDUCED MITOTIC ARREST AND CELL DEATH.

G Benavides[1,5], T Fox[1], R Tyler[1], C Qualls[1,3], T Kepler[1,2], B Gaskill[1], S Trasti[1,2], C Merrill[1,2], L Crosby[1,4], R Reynolds[1,2], R Brown[1] and K Morgan[1]. [1]*GlaxoWellcome, Inc, RTP, NC;* [2]*North Carolina State University, Raleigh, NC;* [3]*Oklahoma State University, Stillwater, OK;* [4]*US EPA, RTP, NC;* [5]*Tech Specialists, Raleigh, NC.*

The mechanism of cell death induced by paraquat (PQ) in target tissues (lung, kidney and liver) remains to be determined. Patterns of gene expression, which may shed light on mechanisms of chemically-induced cell damage, were investigated in HEP-G2 cells exposed to 0 or 600 μ M PQ (EC_{50} for cytolethality) for 4, 12 or 24 hrs. Confluent HEP-G2 cultured on collagen coated 150 mm polystyrene dishes, containing a glass cover slip (for morphology studies) and 30 ml DMEM-10%FCS (depth 1.7 mm), were maintained at 37° C, 5% CO_2 for 48 hr, fresh medium for 24 hrs, and then PQ added in 3 ml DMEM. Following exposure to PQ, cover slips were fixed in absolute ethanol at -20° C, stained with H&E, and examined by light microscopy. Cells were lysed, poly A^+ RNA purified and reverse transcribed (^{33}P-dATP). ^{33}P-cDNA probe was hybridized to a 588 gene expression array (Atlas Human cDNA Expression Array, Clontech, Palo Alto, CA) and read

on a phosphorimager. Image intensities were determined and levels of up or down regulation estimated to yield expression patterns. H&E stained cover slips revealed PQ-induced loss of intracellular droplets, abnormal metaphase, absence of telophase stages of mitosis (control ~10/high power field) at 12 and 24 hrs, and scattered degenerating cells. Gene expression patterns included evidence of early response (↑ c-jun, ↑ fra-1), DNA damage and mitotic arrest (↑ GADD45, ↑ p21, ↓ cyclins, ↓ top2). Genes on the array expected to respond to oxidative stress (e.g. Cu/Zn SOD, GPx1, and GSH reductase) were unaffected, as were apoptosis associated genes (e.g. adenosine A1r, bcl-x, apo-1, caspases, p53). These observations are consistent with a significant role for DNA damage in PQ-induced cell death (Dusinska et al., Carcinogenesis, *19*,809-812) and mitotic arrest. (This publication may not necessarily reflect the views of the US EPA, and no official endorsement should be inferred.)

1272 THE USE OF GENOMICS TECHNOLOGY TO INVESTIGATE GENE EXPRESSION CHANGES INDUCED IN CULTURED CELLS IN THE PRESENCE OF XENOESTROGENS.

A N Brooks and W D Pennie. *Molecular Endocrinology and Neurobiology Group, ZENECA Central Toxicology Laboratory, Cheshire, UK.* Sponsor: I Kimber.

Recent research on mechanisms of estrogen action have highlighted complexities not being addressed by simplistic *in vitro* testing. We have developed a genomics array approach to investigate the transcriptional changes which occur in cultured human uterine cells on exposure to estrogens. cDNA "probes" from approximately 600 genes were prepared, PCR amplified and spotted on a nylon membrane to generate a "genomics" array. Human uterine cell lines (SK-UT 1) were then cultured in the presence or absence of estradiol before mRNA was prepared. The mRNA from control and estradiol treated (10^{-8} M, 4h and 24h) cells was then used in a first strand cDNA synthesis reaction to generate complex radiolabelled cDNA probes which in turn were individually hybridised to genomics arrays. The hybridisation patterns were then visualised and quantitated using a Molecular Dynamics phosphorimager. Comparison of the resultant patterns allowed the identification of changes in gene expression in control versus estradiol treated cells by normalising signal levels against background and housekeeping genes. We propose that this approach is a useful technique to investigate the changes in gene expression induced by exposure to xenoestrogens, and may facilitate the development of *in vitro* assays for estrogenicity.

1273 DEVELOPMENT OF A TOXICOLOGICAL GENE ARRAY AND QUANTITATIVE ASPECTS OF THIS MICROARRAY TECHNOLOGY.

M Bartosiewicz[1], M Trounstine[2], R Johnston[1], and A Buckpitt[1]. [1]*Department of Molecular Biosciences, School of Veterinary Medicine, University of California, Davis, CA;* [2]*Molecular Dynamics, Sunnyvale, CA, USA.*

DNA microarrays are high-density arrays of cDNA bound to a solid substrate. DNA arrays have proven to be a powerful system for monitoring the expression levels of thousands of genes simultaneously. Many genes are induced or repressed by toxicants and this pattern of gene expression can lead to a better understanding of underlying reactions of cells to injury as well as the processes associated with repair. Moreover, this approach is likely to yield new insights of the mechanism by which chemical toxicants interact. In this report, we describe efforts underway to examine the quantitative aspects of this microarray technology. In addition we describe the development of a "toxicology chip" that may be useful for detecting the response of mouse lung and liver to a variety of environmental toxicants including chemical mixtures. Additionally this chip may provide a mechanism for the rapid assessment of ecosystem health in relation to toxicants. Expression levels are being compared for several genes (i.e. *Cyp1a1, Cyp1a2*) using either standard Northern analysis or cDNA arrays. As expected, maximal upregulation of *Cyp1a1* in response to B-napthoflavone occurred at eight hours post treatment A dose response study is being conducted using B-napthoflavone to determine the sensitivity of the cDNA arrays as compared to Northern Blot Analysis. (Supported by NIEHS 04699 and TSR&TP.)

1274 TOXICOGENOMICS: TOXICANT IDENTIFICATION AND CLASSIFICATION USING cDNA MICROARRAY TECHNOLOGY.

E F Nuwaysir[1], A K Hayes[1], M Bittner[2], J Trent[2], J C Barrett[1], and C A Afshari[1]. [1]*Laboratory of Molecular Carcinogenesis, NIEHS, Research Triangle Park, NC;* [2]*Laboratory of Cancer Genetics, NHGRI, Bethesda, MD.*

We have developed a novel approach to the identification of potential toxicants and their putative mechanism of action. This approach utilizes cDNA microarrays to measure toxicant-induced gene expression profiles. In defined model systems, treatment with known agents such as polycyclic aromatic hydrocarbons, dioxins, peroxisome proliferators, estrogenic compounds, or oxidant stressors, can provide a gene expression "signature" on a microarray which represents the cellular response to these agents. These same systems can then be treated with unknown agents to determine if one or more of these standard signatures is elicited. The data derived from this approach is inherently mechanistic, and can be used to suggest a general mechanism of action for suspected toxicants. In addition, these studies may lend insight into the necessity for testing the agent in the more expensive, time-consuming traditional bioassays. We have designed and manufactured a "Toxicant Response Chip" (*ToxChip*) which contains approximately 2100 genes involved in cellular responses to toxic insult. Included on this microarray are cell cycle genes, oxidative stress genes, xenobiotic metabolizing enzymes, DNA replication and repair genes, hormone-responsive genes, and apoptotic cell death genes, as well as many others gene categories. In addition, we have attempted to include the entire complement of genes known to be responsive to *[Ah]*-receptor agonists and peroxisome proliferators. Our initial studies using this general approach have focused on the gene expression signature elicited by different types of oxidant stressors in human cell lines.

1275 USE OF A GENOMIC TECHNOLOGY FOR ASSESSMENT OF TOXICITY.

M J Cunningham[1], G Zweiger[1], M Furness[2], S Braxton[1], M Egerton[1], J Seilhamer[1] and D Bailey[2]. [1]*Incyte Pharmaceuticals, Inc., Palo Alto, CA, USA;* [2]*Incyte Europe, Ltd., Cambridge, UK.*

Analysis of differential gene expression on microarrays of key target tissues or cells may reduce the cost of toxicity testing required for the regulatory approval of new products. These assays may therefore allow higher throughput processing of compound candidates. In the present study, Sprague-Dawley rats were treated with three known hepatotoxins at doses known to cause toxicity: benzo(a)pyrene, clofibrate and acetaminophen. Compounds were administered i.p. and liver, brain, kidney, lung, spleen and pancreas were harvested at the following timepoints: 12 hr., Day 1, 3, 7, 14 and 28. Physical signs, liver/body weight ratios and serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) levels were monitored. Fluorescently-labeled cDNA made from RNA isolated from the tissues was used for hybridization onto a microarray containing primarily rat liver and kidney gene sequences. Different gene expression profiles were observed for each compound.

1276 QUANTITATIVE ANALYSIS OF GENE EXPRESSION ARRAY DATA FROM TCDD TREATED MOUSE HEPATOMA CELLS.

P M Saama[1], M R Fielden[2] and T R Zacharewski[2]. [1]*Dept. of Animal Science,* [2]*Dept. of Biochemistry and National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI, USA.*

cDNA array technology represents an efficient means to simultaneously analyze the expression of hundreds of genes. However, many current methodologies are not reproducible and appropriate quantitative analysis has not been described. Using a commercially available cDNA array, the effect of 100 nM 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) on gene expression in mouse Hepa 1c1c7 cells was examined. The hybridization signal intensities (HSI) from two replicate experiments were quantitated on a PhosphoImager. Results from conventional non-parametric methods of analysis and a more powerful parametric approach using a General Linear Model (GLM) were then compared. The non-parametric analysis of HSI data used global means of the background corrected HSI values to normalize each data point for direct comparison. Treatment-related effects on gene expression were then ranked by magnitude for each replicate. Rank correlation between replicates was 0.23 ($P<.05$) indicating poor reproducibility between experiments. Using a GLM, the variation in HSI was partitioned into treatment, replicate,

group, and interactions between them as classification effects and random effects of genes within group. The model was analyzed using the GLM procedure of SAS. Least Squares Means (LSM) for the genes within group were computed using Tukey adjustments. Genes were ranked according to the magnitude of the LSM. This model accounted for 94% of the variation in HSI. All of the effects in the model were significant (P<.0001). The two methods gave different rankings for the effects on gene expression. The probability of observing a treatment effect on each gene could not be calculated using the non-parametric analysis. However, the GLM approach provides a mechanism for hypothesis testing on target genes which is more consistent with the experimental design.

1277 DETERMINATION OF ACOX GENE EXPRESSION *IN VITRO* AND *IN VIVO* FOLLOWING TREATMENT WITH PEROXISOME PROLIFERATORS USING THE BRANCHED DNA TECHNIQUE.

L Gunawardhana, M A Heindel, R Jolly, R W Krasula, and R G Ulrich. *Abbott Laboratories, Abbott Park, IL, USA.*

Branched DNA (bDNA; Quantigene, Chiron) is a novel technique that facilitates the monitoring of gene expression in a microtiter plate format using non-radiolabeled probes specific for the target gene. To assess this technique for monitoring gene expression in cell cultures following drug exposure, isolated rat hepatocytes in primary culture were treated with subtoxic concentrations of bezafibrate (BZ, 0.5-250 μ M), clofibrate (CL, 10-250 μ M) and ibuprofen (IB, 10-100 μ M) for 6, 24 and 48 hours. All three drugs caused elevations in acyl-CoA oxidase (ACOX) gene expression with BZ being the most potent. BZ caused approximately 15-20 fold induction at 25 μ M and above. A microtiter plate assay was also developed to monitor ACOX enzyme activity in rat hepatocytes. In primary cultured hepatocytes, BZ caused 2-3 fold increase in ACOX enzyme activity at 100 μ M and above at 24 and 48 hours. To investigate the applicability of the bDNA technique for monitoring gene expression during *in vivo* studies, adult male Sprague-Dawley rats were treated with BZ (100 mg/kg/day) in 0.2% hydroxypropyl methylcellulose (HPMC) for 3 days by oral gavage. Liver homogenates from animals treated with BZ showed approximately 5 fold increase of ACOX gene expression over untreated animals. In contrast, ACOX gene expression in 0.2 % HPMC treated animals were similar to untreated controls. Moreover, for comparison GAPDH gene expression was also monitored in liver tissue from BZ treated animals. BZ had only a minimal effect on GAPDH gene expression (1.5 fold) compared to untreated rats. The *in vitro* data obtained through the bDNA technique for ACOX gene expression were similar to previously reported data obtained with the Cytostar assay. In conclusion, results presented here show that the bDNA technique would allow us to screen for changes in gene expression following exposure to drugs *in vitro* and *in vivo*.

1278 GENE EXPRESSION CHANGES AS A MARKER FOR CISPLATIN INDUCED APOPTOTIC CELL DEATH IN RAT AND HUMAN LIVER SLICES.

K Rose, K Dooling, A Pollack and A Vickers. *Novartis Institute for Biomedical Research, East Hanover, NJ.* Sponsor: D Lapadula.

Cisplatin is a DNA damaging agent that induces cell death through an apoptotic mechanism. Molecular and cellular indicators of apoptosis were measured in precision cut rat and human livers slices (8 mm in diameter and ~250 μm thick) exposed to cisplatin (0, 20 and 40 μM) for up to 18 hours. Molecular evidence for the initiation of apoptosis was apparent as early as 3 hours with a rise in p53 gene expression in the 40 μM cisplatin treated slices. Elevated expression levels of p53 continued, and was statistically significant, through the 6 hour time point. An increase in p53 protein (p53p) levels, a DNA binding transcriptional activator that is induced upon DNA damage, followed at 6 hours and reached a maximum 2 fold induction by 9 hours of treatment with 40 μM cisplatin. Activation of cellular growth arrest, as evidenced by the ~ 2.5 fold increase in levels of Gadd45 message, (9 - 12 hrs, 20 & 40 μM cisplatin) followed as part of the apoptotic cascade initiated by p53p induction. Genes regulating cell cycle progression (c-myc, c-fos) were also effected by cisplatin (20 & 40μM) treatment. Repression of c-myc expression (~50% at 40μM, & ~25% at 20μM by 12 hrs) preceded the elevation of Gadd45 expression. The early response gene c-fos exhibited a continual, dose dependent increase in expression throughout the time course in both cisplatin treated groups and was ~8 fold elevated over control by 18 hours in the 40 μM cisplatin treated slices. Genomic DNA degradation into 180-220 bp oligomers, a hallmark event in apoptosis, was detectable by 12 hours with 20 μM cisplatin. Liver slice viability, as measured by RNA stability and the leakage of LDH and α-GST proteins, was significantly decreased by 18 hr of culture, ~15% & ~30% in the 20 and 40 μM cisplatin treated groups, respectively. The results obtained in this study are consistent with the findings using immortalized cell lines, and demonstrate the apoptotic mechanism of cisplatin induced cell death in liver slices at both the cellular and molecular level.

1279 PHENOTYPIC AND GENOTYPIC VARIATION IN SERUM LIPID PARAMETERS IN CYNOMOLGUS MONKEYS.

D G Robertson, T S Gipson , W Tefera, S A Knight, J A Stevens, M R Bleavins, and F A de la Iglesia. *Department of Pathology and Experimental Toxicology, Parke-Davis Pharmaceutical Research, A Division of Warner Lambert Co., Ann Arbor, MI, USA.*

Non-human primates are a frequently used model in the development of novel therapeutic agents for the treatment of serum lipid disorders and atherosclerosis. A high level of homology occurs between human and cynomolgus monkey proteins involved in lipoproteins and lipoprotein metabolism, however, little is known about phenotypic and genotypic variation, with regard to serum lipid parameters, within cynomolgus populations. Serum cholesterol, triglycerides, HDL-C, HDL-C, VLDL-C, apo A1, apo B, and Lp(a) were measured in 222 feral cynomolgus monkeys (109 F, 113 M) from 2 different geographic sources, Vietnam (146) and Mauritius (76), and housed in 3 separate facilities: Ann Arbor, MI (69); Mississauga, Ontario (76); and Alice, Texas (77). PCR-RFLP methods were used to genotype polymorphic loci in Apo A-I, Apo B, Apo C-III, Lp(a), and Apo E genes. A number of statistically significant phenotypic differences were found. Most notably, serum Lp(a) and LDL levels in monkeys from Mauritius were 54% and 20% lower, respectively, and serum triglycerides were 25% higher than monkeys from Vietnam. All monkeys from Mauritius had the wild-type (CC) Apo B gene while, 17% of the Vietnamese monkeys had the heterozygous polymorph (CT). In addition, 10% of the Vietnamese monkeys had a novel polymorph. No other polymorphisms were noted, however, results indicate that the least common allele in humans appears to be the predominant allele in monkeys at one of the Apo A loci.

1280 PEROXISOME PROLIFERATOR-INDUCED SIGNALING PATHWAY CHARACTERIZATION USING NULL MOUSE MODELS AND cDNA ARRAYS.

J C Corton, A J Stauber, S P Anderson, L Q Fan, and R C Cattley. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA.*

Peroxisome proliferators (PP) induce alterations in homeostatic growth mechanisms in the livers of mice and rats resulting in increases in hepatocellular proliferation, decreases in apoptosis, and increases in hepatocellular adenomas and carcinomas. PP modulate hepatocyte growth through the activation of PP-activated receptor α (PPAR), the central mediator of PP actions in the liver. A tumor necrosis factor α (TNF)-dependent pathway has been hypothesized to contribute to PP-induced effects on hepatocyte growth. We further characterized and determined the importance of these pathways in hepatocyte growth modulation using mice which lacked functional genes for PPARα, TNF, or TNF receptor II (TNF RII). Mice were treated with WY-14,643 and assessed for changes in hepatocellular proliferation by BrdU labeling and mRNA levels using the Atlas blot (Clontech) or a cDNA array containing many known targets of PP-induced changes in gene expression. Wild-type and TNF RII-null mice exhibited indistinguishable increases in liver to body weight ratios and cell proliferation. Increases in liver to body weight ratios were abolished in TNF-null mice but WY-induced markers of peroxisome proliferation were unchanged. Thus hepatocyte growth could be uncoupled from peroxisome proliferation in this mouse model. Examination of gene expression after WY exposure demonstrated a number of genes involved in cell proliferation, apoptosis, and metabolism were altered in wild-type mice but not in PPAR-null mice. Metabolism genes included members of the glutathione-S-transferase family, whose proteins have been shown to be altered by PP in earlier studies. Our work demonstrates that PP modulate hepatocyte growth through PPAR- and TNF-dependent pathways and shows that null mouse models and cDNA arrays are a powerful combination to define signaling pathways important in tumor promotion and carcinogenesis.

1281 IDENTIFICATION OF GENES DIFFERENTIALLY EXPRESSED IN BENZO[A]PYRENE TREATED VASCULAR SMOOTH MUSCLE CELLS: IMPLICATIONS IN ATHEROGENESIS.

K P Lu and K S Ramos. *Department of Physiology and Pharmacology and Center for Environmental and Rural Health, Texas A&M University College Station, TX, USA.*

Uncontrolled proliferation of vascular smooth muscle cells (vSMCs) is a hallmark of the atherosclerotic process in both humans and experimental animals. In this context, we have previously shown that serial passage of vSMCs treated with low doses of benzo[a]pyrene (BaP) is associated with induction of highly proliferative, atherogenic phenotypes. To define the molecular basis of this response, differential display polymerase chain reaction (DD-PCR) has been used to identify early target genes in murine vascular SMCs following challenge with 3 uM BaP for 8 hr. A total of 170 differentially expressed cDNAs were excised, 111 of which were successfully re-amplified. Sixty four of these cDNAs have been successfully sequenced and examined for homology to known genes. Among 19 cDNAs abundant in control but not BaP-treated cells, the following genes have been identified: (1) Mus musculus mRNA with high homology to human Aac11 mRNA, a novel gene that inhibits apoptosis after growth factor withdrawal (four copies); (2) Mouse aldose reductase gene (four copies); (3) Mus musculus polypeptide GalNAc transferase-T1 (ppGaNTase-T1) (one copy); (4) Mus musculus Ccth mRNA for CCT eta subunit (chaperonin containing TCP-1) (one copy); and (5) Mouse mitochondrial genome (one copy). In contrast, of 45 cDNAs from BaP-treated cells, only one gene, mouse retrotransposon L1Md, was identified (five copies). The remaining 40 cDNAs did not exhibit homology to any known gene, but contained several human retrotransposon elements. Confirmation for differential expression of all matched cDNAs was successfully completed by Northern analysis. Of interest was the finding that a pattern characteristic of the mouse retrotransposon L1Md Northern signal was detected among the 40 unmatched cDNAs from BaP-treated cells. These results demonstrate that prominent changes in gene expression occur in vSMCs following acute BaP challenge, including the activation of retrotransposons and repression of an apoptosis inhibitor. These alterations may contribute to the genetic and epigenetic changes that set the stage for the early stages of chemical atherogenesis. (Supported in part by NIH grants ES 04849 and ES 09106.)

1282 CLONING AND CHARACTERIZATION OF GENES REGULATED BY QUINOL-THIOETHER MEDIATED OXIDATIVE STRESS IN HL-60 CELLS.

S Ramachandiran, S S Lau, and T J Monks. *Division of Pharmacology and Toxicology, College of Pharmacy, University of Texas at Austin, Austin, TX, USA.*

Glutathione conjugates of hydroquinone induce oxidative stress and apoptosis in cultured human promyelocytic leukemia (HL-60) cells. In order to understand the signal transduction pathways and the role of gene expression in this process, differential screening of cDNA libraries was performed. Two representative cDNA libraries (containing 1.5 x 10^6 clones each) were constructed in ZAP expression vectors using mRNA isolated from untreated HL-60 cells and HL-60 cells treated with 200 μM of 2,3,5 *tris*-(glutathion-S-yl)hydroquinone (TGHQ) for 30 min, 60 min and 120 min. Positive (TGHQ treated) and negative (untreated) cDNA probes with high specific activity (1-1.5x10^8 cpm/mg) were synthesised using superscript reverse transcriptase II. The size distribution of cDNA probes was 0.5-2.0 kb. Primary differential screening of clones from both untreated and TGHQ treated cDNA libraries has identified several clones which are regulated by TGHQ. Results of the screening show that TGHQ has both suppressive and inductive effects on gene expression. They also indicate that, at least in the initial 2 hrs after treatment, TGHQ has no effect on the expression of approximately 90% of genes, has a moderate effect on 5-10% of genes, and a dramatic effect on 0.5% of genes, suggesting that TGHQ modulates specific gene expression in HL-60 cells. The identity and expression pattern of some of these differentially regulated genes will assist in understanding the molecular mechanisms of action and toxicity of quinol-thioethers, and the regulation of the cellular stress response to these compounds.

1283 ZEBRAFISH TRANSCRIPTION FACTORS ACTIVATE POLLUTION-INDUCIBLE RESPONSE ELEMENTS AND DRIVE REPORTER GENE EXPRESSION.

M J Carvan III, W A Solis, and D W Nebert. *Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH, USA.*

Many classes of environmental pollutants are found at significant levels in the aquatic environment and, as a result, pose a threat to human health through consumption of contaminated fish and/or shellfish, as well as exposure in drinking water. Aromatic hydrocarbon, heavy metal, and potent electrophilic environmental pollutants alter cellular transcription via interaction with specific transcription factors that recognize specific DNA response elements (AHREs, MREs, EPREs, respectively) in the enhancer regions of certain genes. Zebrafish transcription factors from ZEM2S embryonic cell cultures are able to recognize these DNA response elements, as determined by electrophoretic mobility shift analysis. Transient transfection of ZEM2S cells with luciferase reporter constructs, in which expression is driven by these same response elements, imparts dose-dependent gene induction upon exposure to a variety of chemicals within each of these three classes of inducers. TCDD (2,3,7,8-tetrachlorodibenzo-*p*-dioxin), Cd^{++} (cadmium) and tBHQ (*tert*-butylhydroquinone) were used as model compounds for the induction of constructs containing AHRE, MRE and EPRE sequences, respectively. Maximal inducibilities were 13-fold for TCDD, 4-fold for Cd^{++}, and 9-fold for tBHQ. Inducible promoters of orthologous genes from several species are able to impart dose-dependent reporter gene activity to varying degrees and, surprisingly, the fish-derived promoters are not necessarily the most effective. Our data suggest that these reporter constructs might be useful for the generation of a transgenic environmental sentinel for biological monitoring. Such a sentinel will be capable of distinguishing specific classes of polluting chemicals within the complex mixtures found in the aquatic environment. (Supported in part by NIH Grants RO1 ES07058 and P30 ES06096.)

1284 TOXICOLOGY IN SILICO: IN SEARCH OF TARGET GENES FOR THE NUCLEAR ARYL HYDROCARBON RECEPTOR COMPLEX.

M R Fielden and T R Zacharewski. *Dept. of Biochemistry and National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI, USA.*

Upregulation of metabolic and detoxification enzymes by the nuclear aryl hydrocarbon receptor (AhR)/aryl hydrocarbon receptor nuclear translocator (Arnt) complex is dependent upon transcriptional activation through binding to upstream enhancers, termed dioxin response elements (DRE). This mechanism, however, does not reasonably explain the tissue-, sex- and species-specific toxicity of AhR agonists, such as 2,3,7,8-tetrachlorodibenzo-p-dioxin. Therefore, other potentially DRE-regulating genes were searched for in the Eukaryotic Promoter Database by searching for the core DRE sequence (5'-GCGTG-3'). An IUPAC search strategy revealed the existence of 1831 DREs in the 5' flanking region of 353 vertebrate, 104 invertebrate and 132 viral genes. Due to the functional importance of nucleotides flanking the core DRE sequence, we attempted to estimate the functionality of the extended DRE sequence string (5'-N7GCGTGN7-3') using MatInspector software. Each DRE sequence string was scored according to its relative similarity to a precompiled position weighted nucleotide distribution matrix derived from 25 selected AhR:Arnt binding sequences. Matrix similarity scoring of 10 bona fide DREs produced a cutoff score of 0.701, suggesting similarity scores above this value may be biologically functional. Matrix analysis of 1831 DREs resulted in 939 DREs in 423 promoters having scores above the cutoff value, which represent genes whose DREs have potential functionality. Subsequent ranking of DRE frequency and matrix similarity score prioritize these genes for subsequent experimental verification of DRE functionality. Due to the conserved nature of DRE binding, our results also suggest a role of the AhR:Arnt complex in viral gene regulation and the existence of ancestral AhR and Arnt orthologues in invertebrates, a hypothesis recently verified.

1285 ROLE OF THE ARYL HYDROCARBON RECEPTOR AND P450 METABOLISM IN THE REDOX REGULATION OF *c-Ha-ras* BY BENZO(A)PYRENE IN VASCULAR SMOOTH MUSCLE CELLS.

J K Kerzee and K S Ramos. *Department of Veterinary Physiology and Pharmacology & Center for Environmental and Rural Health, Texas A&M University, College Station, TX, USA.*

Previous studies in this laboratory have identified *c-Ha-ras* as a critical

molecular target of benzo(a)pyrene (BaP) in the dysregulation of vascular smooth muscle cell (vSMC) proliferation and differentiation. Acute challenge of vSMCs with BaP is associated with transcriptional activation of *c-Ha-ras*, a response mediated via electrophile responsive cis-acting elements (EpRE) within the promoter region of the gene. Because activation of EpREs involves aryl hydrocarbon receptor (AhR)-regulated events, we hypothesized that up-regulation of *c-Ha-ras* mRNA levels is mediated by oxidative metabolites of BaP that compromise redox regulation of the gene. To test this hypothesis, experiments were conducted to evaluate the inducibility of *c-Ha-ras* in vascular SMCs by oxidative metabolites of BaP and related products. BaP-3,6-quinone (0.3μM), a cytochrome P450 derived metabolite of BaP, and H_2O_2 (25 and 50μM), a by-product of oxidation and redox cycling, enhanced *c-Ha-ras* gene expression. Analysis of CyP1A1 and CyP1B1 mRNA levels in "wild type" vSMCs$^{+/+}$ and AhR "knock-out" vSMCs$^{-/-}$ by RT-PCR and Northern revealed constitutive expression of CyP1B1, but not CyP1A1, in both cell types. CyP1A1 and CyP1B1 were up-regulated in vSMCs$^{+/+}$, but not vSMCs$^{-/-}$, following BaP (3μM) challenge. Incubation with ellipticine (Ellip) or α-naphthoflavone (α-NF), inhibitors of P450 and weak ligands of the AhR, prior to BaP challenge interfered with *c-Ha-ras* up-regulation by BaP. These data implicate cellular metabolism of BaP by constitutively expressed CyP1B1 in the redox regulation of *c-Ha-ras* in vSMCs. (Supported by NIH Grant ES 04849 and ES 09106.)

1286 PROTEIN INTERACTIONS WITH THE ELECTROPHILE RESPONSE ELEMENT INDUCED BY BENZO(a)PYRENE AND RELATED OXIDANTS.

M T Holderman, K P Miller, and K S Ramos. *Department of Veterinary Physiology and Pharmacology and Center for Environmental and Rural Health, Texas A&M University, College Station, TX, USA.*

The toxicity and carcinogenicity of benzo(a)pyrene (BaP) may involve epigenetic events that culminate in the deregulation of gene expression. Previous investigations in this laborarory have demonstrated the involvement of a 5'-regulatory sequence within the c-Ha-ras promoter, termed the Electrophile Response Element (EpRE), that associates specifically with two vascular smooth muscle cell (vSMC) nuclear proteins of Mr 80 and 82 kDa. These protein/DNA associations are inducible by various reactive oxygen species (ROS) in different promoters and cell types, suggesting their participation in the regulation of genes harboring this element. More recently, our efforts have been directed at defining the nature of EpRE/protein(s) associations critical to gene regulation. Six EpRE-like oligonucleotide constructs were tested for their ability to bind EpRE binding proteins using electrophoretic mobility shift assays. The constructs were designed to evaluate the role of flanking sequences relative to the well-defined EpRE core region (5'RTGAYNNNGC3') in stabilizing protein/DNA interactions. Our results showed that a TMA box 5' to the core region, like that in the mouse GST-Ya ARE (5'TAATGGTGACAAAGCAACTT3'), is required for maximum binding. Consequently, the GST-Ya ARE sequence was used to construct a site-specific DNA-affinity column in order to isolate EpRE/ARE-associating proteins. Nuclear extracts from BaP-challenged vSMC were loaded directly onto the GST-Ya affinity column and four proteins of Mr 62, 60, 50, and 30 kDa were found to associate specifically. Cross-linking experiments with a BrdU-substituted GST-Ya oligonucleotide probe identified three specific complexes of Mr 80, 60, and 55 kDa. We conclude that the protein(s) specifically eluted by GST-Ya DNA affinity chromatography may participate in ROS-mediated deregulation of growth-related genes. (This work was supported by ES grants 048489 and E09106.)

1287 NEGATIVE REGULATION OF THE RAT GST-Ya GENE IN VASCULAR SMOOTH MUSCLE CELLS.

Y-H Chen and K S Ramos. *Department of Veterinary Physiology and Pharmacology & Center for Environmental and Rural Health, Texas A&M University, College Station, TX, USA.*

Previous studies in this laboratory have established that dysregulation of growth-related genes by benzo(a)pyrene (BaP) in vascular smooth muscle cell (vSMCs) involves functional interactions between electrophile and aryl hydrocarbon receptor (AhR) signaling. Our previous transfection studies have suggested that a negative regulatory mechanism may be operative within the rat GST-Ya promoter in both vSMCs and HepG2 cells. In the present study, electrophoretic mobility shift assays were conducted to define protein/DNA interactions which influence the ability of the electrophile response element (EpRE) to function as a negative regulatory sequence in vSMCs. Our results showed that the C/EBP and AP-1 consensus sequences, along with the NF-E2, CREB/ATF and AhR binding sites, compete to varying degrees with the proteins that interact with EpRE. In contrast, Ets and NF-kB sequences did not effectively compete with EpRE binding proteins. These data suggest that multiple proteins interact with the rat GST-Ya promoter to influence EpRE protein binding. Supershift experiments showed that C/EBP-beta, but not -alpha, bind to both EpRE and AhRE. This finding is consistent with the presence of C/EBP sites within those consensus sequences. Surpringly, the AhR was detected in the protein complex binding to the EpRE in the absence of an AhR binding site. These data suggest that C/EBP-beta and the AhR participate in the negative regulation of rat GST-Ya gene in vSMCs. (Supported in part by NIH Grant ES 04849 and ES 09106.)

1288 TYROSINE KINASE INHIBITORS ACTIVATE THE ANTIOXIDANT/ELECTROPHILE RESPONSIVE ELEMENT IN NEUROBLASTOMA CELLS.

J D Moehlenkamp, C A Waters and J A Johnson. *Dept. of Pharmacology, Toxicology and Therapeutics, Univ. of Kansas Medical Center, Kansas City, KS.*

NAD(P)H:quinone oxidoreductase (QR) detoxifies xenobiotics and inhibits free radical production by catalyzing the two-electron reduction of quinones and other hydrophobic compounds. The antioxidant/electrophile responsive element (ARE/EpRE) is located in the 5'-flanking region of the gene encoding QR. We hypothesize that tert-butyl-hydroquinone (tBHQ) activates the hQR-ARE/EpRE by inhibiting tryosine kinase activity. Human neuroblastoma (IMR-32) and human hepatoma (HepG2) cells were transiently transfected with a TATA-Inr minimal promoter luciferase reporter construct that contained a forty-one base pair DNA insert containing the ARE/EpRE from the hQR promoter. Treatment of IMR-32 cells with tBHQ (10μM) resulted in a 23-fold increase in hQR- ARE/EpRE luciferase expression. In contrast, tBHQ (200μM) had little effect on the hQR-ARE/EpRE-luciferase expression in HepG2 cells. β-Napthoflavone and the oxidants, hydrogen peroxide and tert-butylhydroperoxide, did not activate the hQR-ARE in the IMR-32 cells, suggesting that oxidative stress may not be involved in ARE/EpRE activation in these cells. Tyrphostin AG957, erbstatin analog and lavendustin A, share a common hydroquinone based structure with tBHQ. HQR-ARE/EpRE-luciferase expression, QR protein and QR activity were increased by treatment with these tyrosine kinase inhibitors, whereas lavendustin B, the inactive analog to lavendustin A, had no effect on QR in IMR-32 cells. These data suggest that tyrosine kinase inhibition is involved in ARE/EpRE activation by tBHQ in IMR-32 cells. (Supported by ES08089 and BWF New Investigator Award.)

1289 IDENTIFICATION OF ANTIOXIDANT/ELECTROPHILE RESPONSIVE ELEMENT (ARE/EpRE)-DRIVEN GENES IN HUMAN NEUROBLASTOMA CELLS.

N J Cherrington and J A Johnson. *Dept. of Pharmacology, Toxicology and Therapeutics, Univ. of Kansas Medical Center, Kansas City, KS, USA.*

Pretreatment of neuroblastoma cells with tert-butyl hydroquinone (tBHQ) has been shown to protect against glutamate-induced toxicity. This protection was correlated to increased NAD(P)H:quinone oxidoreductase (QR) activity. Recent studies have shown that QR is not solely responsible for blocking cytotoxicity since over expression of QR did not confer protection to the cells from dopamine induced toxicity. Hydrogen peroxide formation and increased oxidative stress is the mechanism of cell death for both glutamate and dopamine in these cells. We have postulated that a coordinate regulation of multiple genes rather than a single gene product is responsible for neuroprotection, and that this coordinate regulation is mediated via the ARE/EpRE. Few human genes have been shown to have functional ARE/EpREs. Our laboratory has demonstrated that IMR-32 human neuroblastoma cells are highly responsive to treatment with tBHQ resulting in robust transcriptional activation of the ARE/EpRE. Suppression subtractive hybridization has been performed on these cells using Clontech's PCR Select™. We have produced a differential cDNA library in which QR is ~ 10^7 more prevalent in the tBHQ treated population than in the control. Two other genes isolated from the differential library were tested and one was found to be differentially expressed. Sequencing of 48 random clones has produced 15 different known genes and 7 unknown sequences. Because many types of cell death may involve the formation of oxidants, coordinate regulation of genes identified as containing the ARE/EpRE may lead to a new strategy to combat neurodegenerative disease. (Supported by ES08089 and BWF New Investigator Award.)

1290 PI3-KINASE IS A CRITICAL ACTIVATOR OF THE ANTIOXIDANT/ELECTROPHILE RESPONSIVE ELEMENT.

J M Hanson, W A Chu, and J A Johnson. *Department of Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS, USA.*

There is evidence that phosphatidylinositol 3-kinase (PI 3- kinase) promotes cell survival both in cell culture and in primary neuronal cultures by providing antiapoptotic signals. Protein kinase B (Akt2), a downstream target of PI 3-kinase, has been shown to be a key serine/threonine kinase required for inhibition of apoptosis. The antioxidant/electrophile responsive element (ARE/EpRE) is an enhancer element located in the 5'-flanking region of many protective genes, including human NAD(P)H:quinone oxidoreductase (QR); however, the signal transduction cascade for the ARE/EpRE is yet undefined. The purpose of these studies was to determine if PI 3-kinase is involved in the upstream signaling cascade leading to ARE/EpRE activation. IMR-32 cells were transiently transfected with a TATA-Inr minimal promoter: luciferase reporter construct containing a 41 base pair ARE/EpRE insert from the hQR promoter. HQR-ARE/EpRE-luciferase expression was increased 22-fold by tert-butylhydroquinone (tBHQ) in these cells. Pretreatment (15 minutes) of the IMR-32 cells with an inhibitor of PI 3-kinase, LY294002, resulted in an 80% inhibition of the tBHQ-mediated activation. A corresponding inhibition was observed for the endogenous QR activity. These data suggest that PI 3-kinase is a critical component of the signaling pathway leading to ARE/EpRE activation in neuroblastoma cells. (Supported by NIEHS 08089 and BWF New Investigator In Toxicology Award.)

1291 DIFFERENTIAL INDUCTION OF THE ANTIOXIDANT/ ELECTROPHILE RESPONSIVE ELEMENT BY HEAVY METALS IN NEUROBLASTOMA CELLS.

M R Lobmeyer, J D Moehlenkamp and J A Johnson. *Dept. of Pharmacology, Toxicology and Therapeutics, Univ. of Kansas Medical Center, Kansas City, KS.*

NAD(P)H:quinone oxidoreductase (QR) detoxifies xenobiotics and inhibits free radical production by catalyzing the two-electron reduction of quinones and other hydrophobic compounds. The antioxidant/electrophile responsive element (ARE/EpRE) is located in the 5'-flanking region of the gene encoding human QR (hQR). The ARE/EpRE has been shown to be inducible by cadmium, zinc and arsenate in HepG2 cells. Induction of QR activity has been shown in a neuroblastoma cell line in response to cadmium, manganese and lanthanum treatment. The purpose of these studies was to evaluate the transcriptional activation of the hQR-ARE/EpRE in IMR-32 human neuroblastoma cells in response to treatment with a variety of heavy metals. IMR-32 cells were transiently transfected with a TATA-Inr minimal promoter luciferase reporter construct that contained a forty-one base pair DNA insert containing the ARE/EpRE from the hQR promoter. Dose-dependent increases in transcriptional activation were seen for cadmium (19.8-fold), mercury (14.1-fold), arsenite (5.7-fold), lead (5.3-fold), iron (5.4-fold), and cobalt (3.7-fold). Other metals including, zinc, manganese and copper caused a minimal activation of the ARE/EpRE-luciferase expression (<3-fold). In addition, cadmium and mercury were the most potent inducers of QR protein and QR activity. The mechanism by which cadmium and mercuric maximally activate the ARE/EpRE in these neuroblastoma cells remains to be determined. (Supported by ES08089 and BWF New Investigator Award.)

1292 CADMIUM-MEDIATED ACTIVATION OF THE METAL RESPONSE ELEMENT IN HUMAN NEUROBLASTOMA LACKING FUNCTIONAL METAL RESPONSE ELEMENT-BINDING TRANSCRIPTION FACTOR-1.

W A Chu[1], J D Moehlenkamp[1], D Bittel[2], G K Andrews[2] and J A Johnson[1]. *Depts. of [1]Pharmacology, Toxicology and Therapeutics and [2]Biochemistry and Molecular Biology, Univ. of Kansas Medical Center, Kansas City, KS.*

Metallothioneins (MTs) constitute a conserved family of cysteine-rich heavy metal binding proteins. MT-I and MT-II gene transcription is dramatically increased by heavy metals. Metal response elements (MREs) are essential for this induction, and these elements are present in multiple copies in the proximal promoters of mammalian MT genes. MTF-1 (MRE-binding transcription factor-1) binds specifically to MREs and transactivates MT gene expression in response to Zn, Cd and oxidative stress. Transcriptional activation of mouse mMT-I has been extensively studied in a variety of cell types, however there is little data on regulation of the mMT-I promoter in cells of neural origin. Thus, the purpose of this investigation was to determine if the mMT-I promoter is transcriptionally activated by metals and oxidative stress in IMR-32 human neuroblastoma cells. Cd activated a mMT-1 promoter (-150 bp) luciferase reporter 20- to 25-fold in transient transfections and Cd-mediated transcriptional activation of mMT-1 promoter was MRE-dependent. In contrast, tert-butylhydroquinone and Zn had little effect on luciferase expression. IMR-32 whole cell extracts from cells treated with Zn in vivo did not contain MRE binding activity detectable by gel shift assay and incubation of the IMR-32 extracts with Zn in vitro did not generate a MTF-1/MRE-s complex suggesting that IMR-32 cells lack functional MTF-1. Overexpression of mMTF-1 in transiently transfected IMR-32 cells regenerated a Zn-mediated induction of the MREd5-luciferase reporter without affecting Cd activation. Since no other transition metals tested activated the MRE, this effect appeared to be Cd-specific. These data demonstrate that, in IMR-32 human neuroblastoma cells, Zn and Cd can use independent mechanisms for activation of the mMT-I promoter and Cd-mediated MRE activation is independent of MTF-1 and Zn. (Supported by ES08089 and BWF New Investigator Award.)

1293 ESTROGEN CATECHOLS ACTIVATE THE ANTIOXIDANT/ELECTROPHILE RESPONSIVE ELEMENT IN IMR-32 HUMAN NEUROBLASTOMA CELLS.

J K Padgitt, J M Hanson, and J A Johnson. *Dept. of Pharmacology, Toxicology and Therapeutics, Univ. of Kansas Medical Center, Kansas City, KS, USA.*

It has been shown that estradiol and estrogen catechols protect neuronal cells from peroxide accumulation and glutamate-mediated toxicity. This protection required the presence of a 3'-hydroxy group on the A ring of estradiol and was independent of the estrogen receptor. Protection was attributed to the antioxidant properties of these estrogens. In addition, we hypothesize that the estrogen catechols can activate gene transcription through the ARE/EpRE. These studies were designed to determine if estradiol and its catechol metabolites activate the ARE/EpRE and ARE/EpRE-containing genes in IMR-32 human neuroblastoma cells. IMR-32 cells were transiently transfected with a TATA-Inr minimal promoter luciferase reporter construct that contained a forty-one base pair DNA insert containing the ARE/EpRE from the human NAD(P)H:quinone oxidoreductase (QR) promoter. Treatment of IMR-32 cells with 5 μM 2-hydroxyestradiol and 5 μM 4-hydroxyestradiol activated the QR-ARE/EpRE luciferase expression 6.0- and 6.8-fold, respectively, while no activation occurred with 5 μM estradiol. Correspondingly, 4-hydroxyestradiol increased endogenous QR activity 5.2-fold, however, 2-hydroxyestradiol had no effect on QR. As expected, estradiol did not increase endogenous QR activity. Thus, the neuroprotective effects of estrogens may not be due solely to their antioxidant properties, but may be a combination of these properties and increased ARE/EpRE-driven gene expression. (Supported by ES08089 and BWF New Investigator Award.)

1294 MOLECULAR GENETIC ANALYSIS OF HORMONE RECEPTOR GENES FROM THE JAPANESE MEDAKA (*ORYZIAS LATIPES*).

W C Colley and W H Benson. *Environmental and Community Health Research/RIPS, School of Pharmacy, The University of Mississippi, University, MS, USA.*

Reproductive dysfunction in humans and wildlife due to chemical exposure will invariably be the result of altered expression of those genes involved in normal reproductive physiology. Using the model teleost Japanese medaka we are investigating the effects of reproductive toxicants on the expression of several genes directly involved in piscine reproduction. These genes include the estrogen receptor (ER), the androgen receptor (AR), and the progesterone receptor (PR). We report the isolation of partial complimentary DNA clones for the AR and PR genes and the isolation of multiple cDNA clones for the ER which represent distinct messenger RNA isoforms derived from a single medaka ER gene. The medaka ER gene is expressed in a tissue-, sex-, and age-dependent manner. The medaka AR and PR cDNA's were cloned from male testis and female ovary, respectively, using RT-PCR with degenerate oligonucleotide primers based on conserved sequences within vertebrate AR and PR genes. The partial medaka AR cDNA clone encodes a putative AR peptide 87% identical to the region of human AR protein from amino acids 618 to 749. The partial medaka PR cDNA clone encodes a putative peptide which is 77% identical to the human PR (from amino acids 833 to 909) but is 96% identical to a reported cichlid (*Tilapia mossambica*) glucocorticorticoid receptor. Both the medaka AR and PR genes are differentially expressed in male and female liver and gonads.

1295 REGULATION OF MOUSE MAJOR URINARY PROTEIN mRNA LEVELS IN C57B6 MOUSE LIVER BY DI(2-ETHYL HEXYL) PHTHALATE AND FOOD RESTRICTION.

X Ye and S S Gill. *Environmental Toxicology Graduate Program, University of California, Riverside, CA.*

Mouse major urinary protein (MUP) mRNAs are the most abundant mRNAs in male mouse liver. MUP genes are transcriptionally regulated. Although the function of this group of genes has not been established, their abundance, tissue-specific expression, and developmental and multi-hormonal regulation suggest their biological importance. Di(2-ethylhexyl) phthalate (DEHP), a peroxisome proliferator and the most widely used plasticizer, can cause liver cancer in rodents. Food restriction, on the other hand, is proposed to slow down aging and reduce cancers. Using mRNA differential display, RNase protection assay, Northern analysis and quantitative RT-PCR, we found that the MUP mRNA levels in C57B6 mouse livers were down regulated by DEHP and food restriction. This suppression was both dose and time dependent. Mice fed 2% DEHP in the diet consumed 50-70% food of the control group; their liver MUP mRNA expression is almost completely shut down after 4 weeks of treatment. Although DEHP and food restriction have the same effect on the mouse liver MUP mRNA levels, DEHP caused liver hypertrophy, while food restriction significantly decreases the liver/body weight ratio. Since DEHP is proposed to regulate its target genes through the peroxisome proliferator activated receptor PPARα, and food restriction can activate PPARα through the hypothalamus-pituitary-adrenal axis, it is possible that PPARα is the convergence of the two pathways by which DEHP and food restriction regulate MUP gene expression. To elucidate the mechanisms involved, we are currently undertaking an analysis of the promoter of one MUP gene.

1296 EFFECT OF TRICHLOROETHYLENE AND CHLOROACETIC ACIDS ON THE METHYLATION OF THE GENES FOR *C-JUN* AND *C-MYC* IN LIVER AND TUMORS OF FEMALE B6C3F1 MICE.

L Tao, M Xie, R Ge, P M Kramer, and M A Pereira. *Medical College of Ohio, Toledo, OH, USA.*

Trichloroethylene (TCE) and its metabolites, dichloroacetic acid (DCA) and trichloroacetic acid (TCA) are environmental contaminants and hepatocarcinogens in female B6C3F1 mice. Their mechanism appears to be non-genotoxic involving increase in cell proliferation. DNA methylation controls in part the expression of genes involved in cell proliferation including the immediate-early protooncogenes, *c-jun* and *c-myc*. We have previously reported that mouse liver tumors initiated with methylnitrosourea and promoted by DCA or TCA are DNA hypomethyl-ated (Tao *et al.*, Toxicol Sci. 43, 139-144,1998). Therefore, we evaluated the effect of these contaminants on the methylation status of *c-jun* and *c-myc*. Female B6C3F1 mice were administered 3.2 gm/liter DCA or 4.0gm/liter TCA in their drinking water or 1,000 mg/kg TCE by oral gavage in corn oil for 11 days. DNA was isolated from the liver and the methylation status of c-*jun* promoter and c-*myc* exon II was determined using the Hpa II restriction enzyme (cuts DNA only when internal cytosine of CCGG sites is not methylated) and Southern blot analysis. Decreased methylation of CCGG sites in the *c-jun* promoter and *c-myc* exon II was observed in liver from animals exposed to TCE, DCA or TCA for 11 days. Furthermore, we report that the DCA and TCA promoted liver tumors including adenocarcinomas promoted by TCA from the study cited above also contain decreased levels of methylation of c-*jun* and c-*myc*. Thus, subchronic exposure to DCA, TCA and TCE appears to produce a decrease in the methylation of *c-jun* and *c-myc* that is maintained during promotion and progression to cancer. (Supported in part by US EPA Grant No. R 825384-01-0.)

1297 EFFECT OF TRICHLOROETHYLENE ON DNA METHYLATION AND THE EXPRESSION OF EARLY-INTERMEDIATE PROTOONCOGENES IN THE LIVER OF B6C3F1 MICE.

R Ge, L Tao, M Xie, P M Kramer, and M A Pereira. *Medical College of Ohio, Toledo, OH, USA.*

Trichloroethylene is a multimedia environmental pollution that is carcinogenic in mouse liver. The ability of trichloroethylene to modulate cell proliferation, DNA methylation and expression of immediate-early protooncogenes was evaluated. Female B6C3F1 mice were administered 1,000 mg/kg trichloroethylene by oral gavage and 5 days/week. The mice were euthanized after 1, 4, 11, 32 or 300 days of exposure. The liver/body weight ratio and the Proliferating Cell Nuclear Antigen (PCNA)-Labeling Index in the liver were increased by 4 days of treatment with trichloroethylene. The liver/body weight ratio but not the PCNA-Labeling Index remained increased by treatment of longer duration. DNA was isolated, hydrolyzed with perchloric acid and 5-methylcytosine and the four bases separated and quantified by HPLC. Total DNA methylation was expressed as the percentage of cytosine present as 5-methylcytosine in the DNA. The extent of 5-methylcytosine was decreased during the evaluated 4-32 days of trichloroethylene exposure. After a single dose of trichloroethylene, the expression of the mRNA of *c-jun* increased for 90 minutes and then decreased by 120 minutes; of *c-myc* continued to increase during the 120 minutes; and of *c-fos* was not detected. After 300 days of exposure, trichloroethylene still increased expression of the mRNA for c-*jun* and c-*myc*. Thus, while trichloroethylene only induced a transient increase in cell proliferation, it caused chronic DNA hypomethylation and increased expression of *c-jun* and *c-myc*. It is possible that these chronic effects of trichloroethylene could result in increase cell proliferation and promotion in initiated hepatocytes in contrast to the majority of cells. (Supported in part by US EPA Grant No. R 825384-01-0.)

1298 GENE EXPRESSION ANALYSES IN UROEPITHELIAL CELLS FROM AN ARSENATE EXPOSED WORKER POPULATION.

J W Yager[1], S C Kirchner[2,3], T J Kavanagh[2,3] and E M Faustman[2,3]. [1]*Electric Power Research Institute, Palo Alto, CA;* [2]*Department of Environmental Health and* [3]*Consortium for Risk Evaluation with Stakeholder Participation, Seattle, WA.*

Arsenate exposure is associated primarily with skin, lung, and bladder cancer in humans. The purpose of this study was to examine the feasability of using gene expression analyses as a biomarker of arsenate exposure by examining this endpoint in uroepithelial (UE) cells. Slovakia power plant workers can be exposed to relatively high airborne levels of arsenic during boiler cleaning processes resulting in urinary excretion of arsenic metabolites. UE cells were isolated from a small number of workers before they began the cleaning process and again after 5 days of exposure using a protocol developed for field lab conditions, and shipped to our laboratory for anlaysis. The cells were carried through RNA amplification and hybridized to reverse northern blots. Genes included for analysis were those involved in stress responses (HSPs 25,60,70 and metallothionein I and II); cell cycling (Cyc A ,Cyc B, p21, p53) and DNA damage (Gadd 45 and 153). Control genes included were actin, puc18 and G3PDH. Approximately 80% of the samples successfully amplified and hybridized with fold amplification ranging from 1.4 to 71. Expression levels for each gene have been determined. Analysis is being carried out to assess the magnitude of the association(s) between specific gene expression changes and exposure as estimated both by the concentration of arsenic metabolites in urine and by individual occupational breathing zone arsenic concentrations. (Supported by USDOE #DE-FC01-95EW 55084 and EPRI #WO3370-23.)

1299 NICKEL ENHANCES TELOMERIC SILENCING IN *Saccharomyces cerevisiae.*

L Broday, J Cai, W Peng and M Costa. *Nelson Institute of Environmental Medicine, NYU Medical Center, Tuxedo, NY, USA.*

Certain nickel compounds including crystalline nickel sulfide (NiS) and subsulfide (Ni_3S_2) are potent human and animal carcinogens. Nickel induced the inactivation of the *gpt* reporter gene in a transgenic *gpt+* Chinese hamster cell line (G12), which is located near an heterochromatic region, by chromatin condensation and DNA methylation processes. To determine if nickel can cause gene silencing independently of DNA methylation, based only on the induction of changes in chromatin structure, we measured its influence on the TPE (telomeric position effect) levels in the yeast *Saccharomyces cerevisiae*. We demonstrate that nickel chloride repressed a telomeric marker gene (URA3) and caused a stable epigenetic switch. This phenomenon is dependent on the number of cell doubling prior to selection and also on the distance of the marker gene from the end of the chromosome. The level of TPE induction increased linearly by elevation of nickel concentration. Magnesium inhibited this effect, but it did not silence the reporter gene by itself. The level of silencing was also assessed following treatment with other transition metals: cobalt, copper and cadmium. In the sublethal range, cobalt induced similar effects to nickel, while copper and cadmium did not change the basal level of gene suppression, suggesting that nickel and cobalt are active in gene silencing while copper and cadmium are not.

1300 MODULATION OF SULFUR MUSTARD STRESS GENE INDUCTION BY ANTI-INFLAMMATORY AGENTS.

J J Schlager and J H Clark. *Applied Pharmacology Branch, U.S. Army Medical Research Institute of Chemical Defense, APG, MD.*

Sulfur mustard (SM) exposure to human skin can produce delayed skin vesication by unknown mechanism(s). Recent studies have found that certain anti-inflammatory compounds have lessened or eliminated skin pathology occurring within the mouse ear 24 h after SM exposure. We were interested in the modulatory effects of three classes of anti-inflammatory compounds on specific stress gene responses produced by SM. Transformed HepG2 cells stably expressing chloramphenicol acetyl transferase (CAT) through a specific promoter or response element were used as model human cells for SM exposure (CAT Tox (L) Xenometrix, Boulder, CO). Cells were treated with 20mM indomethacin (INDO), 1mM dexamethasone (DEX) or 1mM olvanil (OV) for 1h prior to addition of 12.5 to 200μM SM. The medium mixture (100μL/96-plate well) was permitted to incubate at 37°C for 24h for CAT induction. Comparison of DEX treatment to SM alone showed a significant decrease in the activity of the promoter for 45kDa growth arrest and DNA damage protein (GADD45) and decreased activity of the response elements for the tumor suppressor gene p53 (p53RE), retinoic acid receptor (RARE) and cyclic AMP (CRE). INDO treatment decreased the promoters for 78kDa glucose regulated protein (GRP78) and GADD45 and decreased in the response elements for p53RE and CRE. OV treatment decreased metallothionein IIA, cytochrome P450 1AI, 153kDa growth arrest and DNA damage protein (GADD153), GADD45, and 70kDa heat shock protein (HSP70) promoters and decreased p53RE and CRE. OV produced a shift in nuclear factor kappa B requiring a higher SM concentration to produce a maximum response. These preliminary data suggest OV had the greatest effect to lower HD induced stress genes.

1301 ALDEHYDE DEHYDROGENASES: A GROWING GENE SUPERFAMILY.

T Ziegler and V Vasiliou. *Molecular Toxicology & Environmental Health Sciences, Department of Pharmaceutical Sciences, University of Colorado Health Sciences Center, Denver, CO.*

Aldehyde dehydrogenases (ALDHs) represent a superfamily of $NAD(P)^+$-dependent enzymes having similar primary structures that catalyze the oxidation of a wide spectrum of endogenous and exogenous aliphatic and aromatic aldehydes. Aldehydes are highly reactive molecules that are very important in numerous biologic and pharmacologic processes. Aldehyde-mediated effects vary from physiologic to cytotoxic, genotoxic, mutagenic and/or carcinogenic. The last five years, it has become evident that ALDHs represent a large superfamily. At the latest count, August 1988, a total of 164 ALDH cDNAs/genes have been described across various species including 4 in archaebacteria, 71 in bacteria, 18 in plants, 16 in fungi and 55 in animals. In addition, as of August 1998, a total of 2,330 ALDH-like expressed sequence tags (ESTs), or 0.13 % of the total EST database, have been generated by the Genome Projects including the Human. Evolutionary analysis of the eukaryotic ALDHs leads to the definition of 18 gene families and 37 subfamilies. The percent identities for two members of the same family and of the same subfamily are 40% and 60%, respectively. Of the 37 subfamilies, 13 and 4 have been mapped to the human genome and the mouse genome, respectively. This evolutionary-based scheme was used for the nomenclature system of the eukaryotic ALDHs. (Supported by NIH Grant EY11490 and NIAAA Training Grant 5T32AA07464.)

1302 THE CO-PLANAR PCB CONGENER 3,3',4,4',5-PEN TACHLOROBIPHENYL IS UTEROTROPIC IN PREPUBERTAL RATS.

R F Seegal[1,2] and K O Brosch[2]. [1]*Wadsworth Center, NYSDOH, Albany, NY;* [2]*School of Public Health, University at Albany, Albany, NY.*

Co-planar (CP) PCB congeners, inactive in *in-vitro* neural preparations and the adult animal, elevate brain dopamine (DA) concentrations in rats following developmental exposure (TAP, 146, 1997). To elucidate the mechanisms responsible for these elevations we have examined the potential estrogenic actions of ip administration of the CP PCB congener 3,3',4,4',5-pentachlorobiphenyl (PentaCB) on uterine wet weight (UWW) in prepubertal female rats. Rats were injected ip on postnatal days (PND) 21-23 with corn oil (vehicle control), 17ß-estradiol (E_2, 20 *ug*/kg, PND 22 and 23), PentaCB (64 to 400 *ug*/kg, PND 21 and 22) only or in combination with the estrogen receptor blocking agent (ICI 182,780, 0.5 mg/kg, PND 21-23) and were sacrificed on PND 24. Uteri were removed, cleaned of connective tissue and weighed in a blinded manner. Compared to control animals, E_2 increased UWW by approximately 250% while PentaCB increased UWW in a dose-dependent manner with a maximal response of 150% of vehicle control. Co-administration of ICI-182,780 with PentaCB reduced UWW to levels similar to vehicle control values. These results demonstrate that PentaCB or its metabolites increase UWW via the uterine estrogen receptor, although PentaCB is approximately two order of magnitude less potent than E_2. Thus, the elevations in brain DA seen in offspring following exposure of the dam to CP PCB congeners during pregnancy may, in part, be due to exposure of the fetal brain to estrogen-agonists. (Supported in part by NIH grant (ESO4913) to RFS.)

1303 STIMULATION OF [^{3}H]ARACHIDONIC ACID RELEASE IN RAT CEREBELLAR GRANULE NEURONS BY POLYCHLORINATED BIPHENYLS: STRUCTURE-ACTIVITY RELATIONSHIPS AND POSSIBLE MECHANISM(S).

E C Derr-Yellin and P R S Kodavanti. *Neurotox. Div., NHEERL/USEPA, Research Triangle Park, NC, USA.*

Previously, we have demonstrated significant stimulation of [^{3}H]arachi-donic acid (AA) release by Aroclor 1254 and the *ortho*-substituted 2,2'-dichlorobiphenyl -(DCB), but not by non-*ortho* substituted 4,4'-DCB. This [^{3}H]AA release seems to be mediated by activation of phospholipase A_2 (PLA_2). The objective of this study is to extend structure-activity rela-tionship (SAR) among polychlorinated biphenyl (PCB) congeners, their metabolites, and also to delineate the possible mechanism(s) by which 2,2'-DCB stimulated the release of [^{3}H]AA. Cerebellar granule cells at seven days in culture, obtained from 6-7 day old rat pups, were labeled with [^{3}H]AA for 16-20 h and exposed to pharmacological agents and/or PCBs. In agreement with previous results, other *ortho* PCBs such as 2,2',5,5'-tetrachlorobiphenyl (TeCB), 2,2',3,5',6-pentachlorobiphenyl (PeCB), and 2,2',4,4',5,5'-hexachlorobiphenyl (HCB) significantly stimu-lated [^{3}H]AA release at 10-30 μM while 3,3',4,4'-TeCB and 3,3',4,4',5-PeCB were not effective even at 50 μM. 2,2',4,5,5'-Pentachloro-4-biphe-nylol is as active as its parent compound, 2,2',4,4',5,5' HCB suggesting that hydroxy-metabolites of *ortho*-PCBs are equally active. As various types of PLA_2 exist in brain, we characterized the effects of 2,2'-DCB. Pretreatment with EGTA/AM, cell permeable Ca^{2+} chelator, only parti-ally blocked the response. Also, dantrolene (50 μM) and xestospongin C (10 μM), blockers of intracellular Ca^{2+} release from endoplasmic reticu-lum, partially reduced 2,2'-DCB-induced [^{3}H]AA release. 4-Bromo-phenacylbromide (1-30 μM) did not attenuate the 2,2'-DCB-stimulated [^{3}H]AA release, indicating that secretory PLA_2 is not the primary path-way. On the other hand, methyl arachidonyl fluorophosphonate (5 μM) completely inhibited [^{3}H]AA release suggesting the involvement of cytosolic PLA_2s. These results confirm our previous SAR data and [^{3}H]AA release caused by *ortho* PCBs might be due to activation of cytosolic PLA_2 that is Ca^{2+}-dependent as well as Ca^{2+}-independent.

1304 MATERNAL EXPOSURE TO AROCLOR 1254 IMPAIRS SPATIAL LEARNING AND MEMORY IN MALE OFFSPRING.

C S Roegge[1], J J Widholm[1], B W Seo[1], K M Crofton[2], and S L Schantz[1]. [1]*Neuroscience Prog. & Dept. of Vet. Biosciences, Univ. of Illinois, Urbana, IL;* [2]*NHEERL NTD, USEPA, RTP, NC.*

Developmental exposure to polychlorinated biphenyls (PCBs) has been associated with cognitive deficits in children. The current study examined the effects of gestational and lactational exposure to a commercial PCB mixture, Aroclor 1254 (A1254), on spatial learning and memory using the radial arm maze (RAM) and spatial discrimination-reversal learning (RL). Pregnant Long-Evans rats (10/dose) received 0 or 6 mg/kg A1254 (po in corn oil) from gestational day 6 to postnatal day 21. After they reached adulthood, one male and one female from each litter were tested on a working/reference memory task using a 12-arm RAM. Eight of the 12 arms were baited, with the pattern of baited arms remaining the same on every trial. Following RAM testing, the same animals were tested on a spatial discrimination-reversal learning (RL) task in standard 2-lever operant testing chambers. After a criterion of 85% correct on 2 consecutive days was achieved, five position reversals were given. Compared to controls, the A1254-exposed males made significantly more working memory errors (4.58 ± 0.19 and 5.45 ± 0.32 errors for control and A1254 males, respectively) and reference memory errors (3.88 ± 0.18 and 5.01 ± 0.40 errors for control and A1254 males, respectively) during acquisition of the RAM, and tended to take more trials to reach criterion on the first reversal of the spatial RL task.

In contrast, A1254-exposed females were not impaired relative to control females on either the RAM or spatial RL. These data suggest that perinatal exposure to A1254 may cause sex specific deficits in spatial learning and memory. (Supported by NIEHS ES07921 and EPA R825812.)

1305 COMPARATIVE EFFECTS OF POLYCHLORINATED BIPHENYLS ON NITRIC OXIDE SYNTHASES IN RAT BRAIN REGIONS DURING DEVELOPMENT.

R Sharma and P R S Kodavanti. *Neurotox. Div., NHEERL/USEPA, Research Triangle Park, NC, USA.*

Polychlorinated biphenyls (PCBs) have been reported to affect learning and memory during development. Also, PCBs have been shown to inhibit long-term potentiation (LTP)which is a physiological mechanism for synaptic plasticity and neuronal growth. Nitric oxide synthases (NOSs) mediate the production of nitric oxide, a neurotransmitter that has important role in LTP as well as learning and memory. The objective of this study is to unravel the molecular mechanism for the PCB effects on learning during development. We have compared the effects of *ortho* PCB, 2,2'-dichlorobiphenyl (-DCB) with that of non-*ortho* PCB, 4,4'-DCB on cytosolic and membrane NOSs from cerebellum, hypothalamus and hippocampus of PND 7, PND 21, and adult male Long-Evans rats. Among the three brain regions in adults, basal levels of cytosolic and membrane NOSs were highest in cerebellum and lowest in hippocampus. However, hypothalamus was more sensitive to 2,2'-DCB (IC_{50}s for cytosolic NOS; 15 μM for hypothalamus, 30 μM for cerebellum, > 50 μM for hippocampus). The membrane NOS of all three brain regions was inhibited to a maximum of only 15-20%. During development, the basal levels of cytosolic and membrane NOSs were low in all the brain regions of PND7 animals but increased several folds in PND 21 and adults. In all three brain regions, NOSs in PND7 animals (IC_{50}s = > 50 μM) were less sensitive to 2,2'-DCB than those of PND21 and adults (IC50s=15-30 μM). 4,4'-DCB did not have any effect on either cytosolic or membrane NOS of all brain regions of young and adult animals. These results indicate: (1) non-coplanar PCB was active but not the coplanar PCB; (2) cytosolic NOS was more abundant than membrane NOS in all brain regions; (3) age- and brain region-specific expression of NOSs and their differential sensitivity to 2,2'-DCB may play a role in the neurotoxic effects of PCBs during development (NRC SRA award to RS; This work does not necessarily reflect EPA policy).)

1306 NONCOPLANAR PCBS CAN DISCRIMINATE BETWEEN GENETIC ISOFORMS OF MICROSOMAL IMMUNOPHILIN/ Ca^{2+} CHANNEL COMPLEXES.

[1]I N Pessah, [2]L G Hansen, [1]T N Ta, [1]E Mai, and [1]P W Wong. [1]*Department of Molecular Biosciences, School of Veterinary Medicine, University of California, Davis, CA;* [2]*Veterinary Biosciences, University of Illinois, Urbana, IL.*

ortho-Substituted noncoplanar PCB congeners have been shown to interact with ryanodine-sensitive Ca^{2+} release channels (ryanodine receptors; RyR) localized within microsomal membranes and to alter cellular Ca^{2+} signaling. Both at the cellular and subcellular levels, the mechanism appears to require the integrity of a complex between the RyR channel protein and the major T-cell immunophilin FKBP12 (Wong *et al.*, 1999). Using the specific [^{3}H]ryanodine binding assay we have further examined the structure-activity relationship amongst 20 environmentally relevant noncoplanar PCBs toward two of the three genetic isoforms of RyR. A very stringent structural requirement was observed which revealed that three *ortho* chlorines were needed to produce full agonist activity towards both Ry1 and Ry2 isoforms. Significantly, Ry2, the major isoform in heart and brain, was found to be 2-5 fold more sensitive than Ry1 to PCB 41(2,3,4,2'; EC_{50}= 710 nM), PCB 132 (2,3,4,2',3',6'; EC_{50}= 370nM), PCB 138 (2,3,4,2',4',5'; EC_{50} =1.6 μ M), and PCB 170 (2,3,4,5,2',3', 4'; EC_{50}=745nM). By contrast, Ry1, the major form in skeletal muscle and the minor form in neurons, was significantly more sensitive to PCB 95 (2,3,6,2',5'; EC_{50}=350nM) and 149 (2,3,6,2',4',5'; EC_{50}=750nM) than Ry2. These data show that non-coplanar PCBs can discriminate between genetic isoforms of the major Ca^{2+} induced Ca^{2+} release channels found in excitable cells. (NIH ES05002 and ES05707)

1307 DOWN-REGULATION OF GLUCOCORTICOID RECEPTOR BY POLYCHLORINATED BIPHENYL (PCB) AROCLOR-1254 IN THE RAT.

B Ghosh[1], C Wood[2], R Hansen[3], M Nees[3], G Held[2], C Lau[2]. [1]*National Research Council;* [2]*RTD, NHEERL, US EPA, RTP, NC,* [3]*NCBA.* Sponsor: R J Kavlock.

Our laboratory has previously shown that PCB down-regulates type II glucocorticoid receptor (GR) in a variety of tissues in the rats at the level of transcription, leading to a reduction of GR protein. The current study examines the modes of action for PCB on GR regulation. Since Aroclor-1254 is known to induce hypothyroidism, we investigated whether the GR down-regulation was related to thyroid hormone deficiency. Sprague-Dawley rats were rendered hypothyroid with propylthiouracil (PTU,10 mg/L in drinking water) for 16 days and tissue GR levels were evaluated. Despite the profound reduction of circulating T_4 level in the PTU-treated rats, GR mRNA in hippocampus and pituitary were not significantly different from controls, indicating that the PCB-induced GR down-regulation was not mediated by hypo-thyroidism. To evaluate whether PCB might alter GR through feedback regulation of the HPA axis, Aroclor-1254 (24 mg/kg, *p.o.*) was given to rats for 16 days and serum corticosterone (CORT) and ACTH were measured. Aroclor-1254 decreased GR mRNA and protein but did not significantly alter the circulating CORT or ACTH, suggesting that PCB may exert a direct effect to regulate GR. To confirm this hypothesis, the effect of PCB on GR was examined in rat pituitary cell cultures. Cells were exposed to Aroclor-1254 (100 ppm) for 24 h while controls were treated with or without DMSO. DMSO did not alter cell viability or GR mRNA level. In contrast, Aroclor-1254 markedly reduced GR mRNA, by 45% compared to DMSO-control. Thus, these data suggest that Aroclor-1254 alters GR regulation by a direct mechanism. (This abstract does not reflect US EPA policy.)

1308 DIFFERENTIAL EFFECTS OF AROCLOR 1254 MIXTURES WITH TWO LOT NUMBERS: INTRACELLULAR CALCIUM BUFFERING AND PROTEIN KINASE C TRANSLOCATION IN RAT BRAIN.

P R S Kodavanti[1], N Kannan[2], N Yamashita[3],T R Ward[1], L S Birnbaum[4], and H A Tilson[1]. [1]*Neurotoxicology and* [4]*Experimental Toxicology Divisions, NHEERL/USEPA, Research Triangle Park, NC, USA;* [2]*Department of Marine Chemistry, University of Kiel, Kiel, Germany;* [3]*National Inst for Resources and Environment, Hydrospheric Environmental Protection Department, Tsukuba, Japan.*

Aroclor 1254 is a widely studied commercial polychlorinated biphenyl (PCB) mixture which, by definition, contains 54% chlorine by weight. Recent reports indicate substantial differences in the congener composi-tion among Aroclor lots and hence, their biological effects. The current study was designed to compare the effects of two lots of Aroclor 1254 (Lot #s 6024 and 124-191; AccuStandard). These two lots were analyzed for all 209 PCB congeners, dibenzofurans and any dioxins. For testing their biological activity, previously established techniques on intracell-ular Ca^{2+} buffering and protein kinase C (PKC) translocation were used. Results indicate that *ortho* and non-*ortho* congeners in these two lots varied in their percent contribution. Among all congeners, the percentage of non-*ortho* congeners (PCBs 77, 81, 126, and 169) were higher in Lot # 6024 (3.07% of total) versus Lot # 124-191 (0.02% of total). Dioxins were not detected in these two lots (<2 ppb). However, dibenzofurans were also higher in Lot # 6024 (38.7 ppm) versus Lot # 124-191 (11.3 ppm). When these two Aroclors were tested on Ca^{2+} buffering and PKC translocation, the effects were significantly different. While Lot # 124-191 was more potent on PKC translocation than Lot # 6024, the effects were almost similar on Ca^{2+} buffering. These effects could not be attributed to the differences in the percentage of non-*ortho* congeners or dibenzofurans, since they were inactive on these two parameters. However, these differential effects could be due to differences in the composition of *ortho*- congeners in these two mixtures. Because of these differential effects with different lot numbers, the composition of Aroclor mixtures used in investigations should be disclosed.

1309 DIFFERENTIAL EFFECTS OF AROCLOR 1254 WITH TWO LOT NUMBERS: HEPATIC ENZYME INDUCTION AND CIRCULATING THYROID HORMONE LEVELS.

D E Burgin[1], J J Diliberto[2], E C Derr-Yellin[3], L S Birnbaum[2], and P R S Kodavanti[3]. [1]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC, USA;* [2]*Experimental Toxicology and* [3]*Neurotoxicology Divisions, NHEERL/US EPA, Research Triangle Park, NC, USA.*

Toxicity studies with Aroclor 1254 mixtures have given different results.

Aroclor 1254 is defined by the weight percentage of chlorine. However, the polychlorinated biphenyl (PCB) congener composition varies from lot to lot. Two lots which have been used in toxicity studies, #124-191 and #6024 (AccuStandard), were analyzed for their congener composition. Lot #6024 has approximately ten times the dioxin toxic equivalents (TEQ) of Lot #124-191. The purpose of this study is to determine if the difference in the TEQ for the two lots explains the different responses seen on a weight basis. Male Long Evans rats (70 days old) were treated with 0 to 1000 mg/kg po of each lot. Hepatic EROD, MROD, PROD and serum T3/T4 concentrations were determined. On a weight basis, Lot #6024 led to greater responses for EROD, MROD, PROD and T3/T4. The differences in TEQ explained the values for EROD and MROD but did not account for the lower response of Lot #124-191 for PROD or T3/T4. The PROD effects are not due to dioxin-like congeners. The T3/T4 effects are due to multiple mechanisms. These results illustrate that the differences in the TEQ explains the differences in the dioxin-like effects, but the non-dioxin-like congeners cause other effects that are not associated with the Ah receptor. Thus, overall toxicity cannot be entirely predicted based on the TEQ values, and in the future it is vital that the lot number and congener composition are reported in studies conducted with Aroclor 1254. (This abstract does not necessarily represent EPA policy. DEB supported by NIEHS T32-ES07126 and EPA, CT902908.)

1310 PCB95 ALTERS METABOLISM IN PC12 CELLS WITHOUT DIRECTLY AFFECTING RESPIRATION IN ISOLATED RAT BRAIN MITOCHONDRIA.

P W Wong-Yim[1], E F Garcia[2] and I N Pessah[1]. [1]*Department of Molecular Biosciences, School of Veterinary Medicine,* [2]*Department of Neurobiology Physiology and Behavior, University of California, Davis, CA.*

Previously we reported that certain *ortho*-substituted PCB congeners, including PCB95, selectively alter Ca^{2+} signaling in rat pheochromocytoma cells (PC12) through an immunophilin-dependent ryanodine-sensitive pathway. We further investigated the effect of PCB95 on PC12 cells by using a pH-sensitive fluorescence dye (BCECF) and the photoimaging technique. PC12 cells loaded with BCECF were individually monitored for changes in cytosolic pH by measuring emission ratio at 530nm with excitation at 490nm/439nm. Fluorescence was calibrated by perfusing the cells with pH4 buffer followed by pH9 buffer. Perfusion of 5μ M PCB95 in the cell chamber which was shown to significantly mobilize Ca^{2+} from ryanodine-sensitive stores (Wong *et al.*, 1998), initiated intracellular acidification that coincided with altered Ca^{2+} signaling and persisted for >7min (at 7min, Δ pH = – 0.33± 0.04, n = 15 cells). Pre-incubation of cells with FK506 eliminated PCB95-induced acidification and Ca^{2+} transients. In order to further discriminate the mechanism by which PCB95 alters cellular metabolism, we measured the rate of O_2 consumption and coupling of mitochondria isolated from rat brain, using O_2 polarography. At all stages of respiration, the presence of PCB95 or PCB126 in the mixing chamber did not cause any significant changes in O_2 consumption rate. Moreover, calculation on ADP/O_2 ratio, in the presence of either PCB95 or PCB126, demonstrated a tight coupling of the isolated mitochondria. These results are consistent with a highly selective receptor mediated interaction between non-coplanar PCBs and microsomal FKBP12/RYR initiates alterations in neuronal cellular metabolism. (NIH ES05002 and ES05707)

1311 INTERACTION AMONG SIGNAL TRANSDUCTION PATHWAYS IN ACTIVATION OF RAT NEUTROPHILS BY POLYCHLORINATED BIPHENYLS.

J Olivero and P E Ganey. *Department of Pharmacology and Toxicology, Institute for Environmental Toxicology, Michigan State University, East Lansing, MI, USA.*

Stimulation of rat polymorphonuclear neutrophils (PMNs) by polychlorinated biphenyls (PCBs) requires a number of intracellular signals including increased intracellular free calcium, activation of phospholipase A_2 (PLA_2) and activation of tyrosine kinase. The sequence of activation of these pathways and their interdependence are unknown. The purpose of these studies was to examine the interaction among several pathways involved in activation of PMNs by PCBs. Isolated, rat PMNs were labeled with ^{3}H-arachidonic acid (^{3}H-AA), and activation of PLA_2 was determined from release of radioactivity into the medium. Exposure to the PCB mixture Aroclor 1242 induced release of ^{3}H-AA, and pretreatment with genistein, an inhibitor of tyrosine kinase, caused a small but significant decrease in this release. Daidzein, a genistein analog with no activity to inhibit tyrosine kinase, had no effect on ^{3}H-AA release. An inhibitor of mitogen-activated protein kinase (MAPK), SB203580 did not affect Aroclor-induced PLA_2 activity; however, PD98059, which inhibits MAPK kinase (MEK), decreased ^{3}H-AA release to about the same extent as genistein. Staurosporine, an inhibitor of PKC, did not inhibit PCB-induced release of ^{3}H-AA. To examine interaction between calcium signalling and PLA_2, the effects of TMB-8, a blocker of intracellular Ca^{2+} release, and two different calmodulin inhibitors, W7 and trifluoroperazine (TFP), were determined. Aroclor-induced release of ^{3}H-AA was inhibited by TMB-8 and by TFP but not by W7. Moreover, TFP by itself induced a release of ^{3}H-AA release, an increase in intracellular calcium and functional changes similar to Aroclor 1242. These results suggest that tyrosine phosphorylation and the MEK pathway, as well as release of intracellular calcium, play a role in PCB-induced activation of PLA_2. (Supported by ESO4911.)

1312 ALTERATIONS IN INTRACELLULAR FREE CALCIUM CONCENTRATION INDUCED BY POLYCHLORINATED BIPHENYLS IN RAT NEUTROPHILS.

P E Ganey, J Olivero, and A Mahajerin. *Department of Pharmacology and Toxicology, Institute for Environmental Toxicology, Michigan State University, East Lansing, MI, USA.*

Polychlorinated biphenyls (PCBs) stimulate polymorphonuclear neutrophils (PMNs) acting on different subcellular targets. The objective of this study was to characterize the effects of PCBs on Ca^{2+} homeostasis in rat PMNs. Aroclor 1242, a technical PCB mixture, induced a dose- and time-dependent increase in the concentration of intracellular free Ca^{2+} ($[Ca^{2+}]_i$) in Fura 2/AM-labeled PMNs. A significant increase in $[Ca^{2+}]_i$ was observed only after 4 min, reaching a plateau after 13-15 min. The effects of PCBs on $[Ca^{2+}]_i$ were structure-dependent: 2,4'-dichlorobiphenyl, an ortho-substituted congener, increased $[Ca^{2+}]_i$ with a similar time course as Aroclor 1242, whereas 3,3',4,4'-tetrachlorobiphenyl, a coplanar congener, was inactive. The dose-response curve for 2,4'-dichlorobiphenyl revealed a biphasic response in which increases in $[Ca^{2+}]_i$ were observed at 10-100 nM and 10 μM but not with 1 μM. The Aroclor 1242-induced increase in $[Ca^{2+}]_i$ was not dependent on extracellular Ca^{2+}, implicating an intracellular Ca^{2+} pool as the source released by PCBs. The PMN stimulus, fmlp, causes a rapid increase in $[Ca^{2+}]_i$ from inositol trisphosphate-sensitive pools, and this increase was abrogated by Aroclor 1242 in a time-dependent manner. These results suggested a shared intracellular calcium store for fmlp and Aroclor 1242. In summary, the PCB-induced increase in $[Ca^{2+}]_i$ in PMNs is dose-, time- and structure-dependent, and the Ca^{2+} pool released may be the same store as that released by fmlp (Supported by ESO4911.)

1313 CYTOTOXICITY AND AROMATASE (CYP19) ACTIVITY MODULATION BY ORGANOCHLORINES IN HUMAN PLACENTAL JEG-3 AND JAR CHORIOCARCINOMA CELLS.

R J Letcher[1], I van Holsteijn[1], R J Norstrom[2], Å Bergman[3], R Pieters[1] and M van den Berg[1]. [1]*Research Institute of Toxicology, Utrecht University, Utrecht, The Netherlands;* [2]*Environment Canada, Canadian Wildlife Service, Hull, Québec, Canada;* [3]*Department of Environmental Chemistry, Stockholm University, Stockholm, Sweden.*

The human placental JEG-3 and JAR choriocarcinoma cell lines have been used extensively as models for placental endocrine functions. These cell lines have been used to a limited extent to measure the effect of xenobiotics on the modulation of aromatase (CYP19) enzyme activity. Widely varying compound- and concentration-dependent (1.0 nM to 10 μ M) effects were observed for twenty-one, environmentally persistent organochlorine (OC) compounds and their hydroxyl (HO-) and methyl sulfonyl- ($MeSO_2$-) containing metabolites, on the cytotoxicity, cell proliferation and aromatase activity. In JEG-3 cells, polychlorinated biphenyl (PCB) 126 (3,3' ,4,4' ,5-Cl_5) and benzo[*a*]pyrene (B[*a*]P), PCB-52 (2,2' ,5,5' -Cl_4), and -70 (2,3' ,4' ,5-Cl_4), tris(4-chlorophenyl)methane (TCPMe), TCPMeOH, 3- and 4-$MeSO_2$-PCB metabolite compounds of PCB-52, -70, -87 (2,2' ,3' ,4' ,5-Cl_5) and -CB101 (2,2' ,4' ,5,5' -Cl_5), and the metabolite compound 4-OH-CB30 (2' ,4' ,6' -Cl_3), induced concomitant decreases in the aromatase activity, protein level and DNA content, and increases in the percent lactate dehydrogenase leakage at dosing concentrations as low as 1.0 nM . This similarity to 1,4-naphthaquinone indicated an OC-mediated modulation of cytotoxicity and cell proliferation, and therefore an indirect modulation of the aromatase activity. The effects were dependent on the cell density, and were largely negated by the presence of 10% fetal calf serum. Binding of the apoptotic cell-specific APO2.7, DNA fragmentation and trypan blue staining after OC treatment suggested an apoptotic mechanism of cytotoxicity. The JEG-3 and JAR cell lines are too unstable for use as *in vitro* biomarkers to evaluate the potential, xenobiotic-mediated modulation of aromatase activity. These cell

lines may prove useful for examining the capacity of xenobiotics to modulate placental toxicities.

1314 DIFFERENTIAL EFFECTS OF PCB CONGENERS ON RAT THYROID FUNCTION.

L A Martin and C D Klaassen. *Univ Kansas Med Ctr, Kansas City, KS.*

Circulating levels of thyroid hormones can be reduced by a number of compounds, including polychlorinated biphenyls (PCBs). Numerous studies have been conducted using mixtures of PCB congeners known as Aroclors, but little is known about the effects of individual congeners. The objective of this study was to determine the effects of PCB congeners on serum levels of thyroxine (T_4) and triiodothyronine (T_3). PCB congeners are commonly divided into three general categories. The "2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) type" are those congeners that have affinity for the aryl hydrocarbon receptor (AhR) and induce cytochrome P450 1A1 (CYP1A1); the "phenobarbital type" are those congeners that induce CYP2B1, and the "mixed type" are those cogeners capable of induction of both CYP1A1 and CYP2B1. Four PCB congeners were selected for use in this study: PCB 126, a "TCDD type", PCBs 95 and 99, which are "PB types", and PCB 118, a "mixed type". Arocolors 1242 and 1254 and TCDD were also evaluated. Each compound was administered at a minimum of four dose levels *via* gavage to male Sprague-Dawley rats for seven days. Blood was obtained *via* the retro orbital sinus on days -3, 3, and at necropsy on day 7. On day 7, serum T_4 levels were reduced to 5-10% of control values in rats administered Aroclor 1254 and PCBs 99 and 118. Reductions up to 50% of control values occurred for rats administered each of the remaining compounds. Serum T_3 levels were reduced to 30% of control values in rats administered Aroclor 1254. The remaining compounds caused only slight or no reductions in serum T_3. Results of this study suggest that PCB congeners may induce the majority of their effects on thyroid function *via* pathways not mediated by the AhR. (Supported by NIH grant ES-07079 and EPA Grant R826297.)

1315 ALTERATIONS OF STEROID HORMONE METABOLISM IN JUVENILE CD-1 MICE BY PCB153.

J S Gillette, R L Rose, and E Hodgson. *Department of Toxicology, North Carolina State University, Raleigh, NC.*

Several classes of xenobiotics, including the polychlorinated biphenyls (PCBs), are known to perturb the metabolism of steroid hormones by induction and/or repression of cytochrome P450 isozymes responsible for the hydroxylation of these compounds. Modulation by PCBs of CYP isoforms which hydroxylate testosterone has been investigated primarily in the rat. Less studied has been the effects of individual PCB congeners on steroid metabolism in the mouse, and the effects of these toxicants on estradiol as well as testosterone metabolism. In this study, juvenile (30 day old) male CD-1 mice were dosed with PCB 153 (a non-coplanar, phenobarbital-type P450 inducer) in their diet for 7 days at 5 mg/kg/day. This PCB congener was shown to be a potent inducer of Cyp2b-10 protein and a weak inducer of Cyp3a protein. PCB treatment induced the hydroxylase activity associated with the 2-hydroxy metabolite of estradiol, while concurrently repressing the 16-α estradiol hydroxylase. *In vitro* testosterone hydroxylation using hepatic microsomes from PCB treated mice revealed an increase in 6-α and 16-β hydroxylase activities. In addition, seminal vesicle weights of the PCB treated mice were significantly lower than those of control mice. Taken together, these data suggest effects of PCBs on steroid hormone metabolism in the mouse which are different from those published for the rat, and that altered metabolism of testosterone may have *in vivo* consequences. Continuing studies will determine the effects of PCB congeners which have differing P450 induction profiles on steroid metabolism and reproductive parameters in male and female mice.

1316 CATECHOL METABOLITES OF POLYCHLORINATED BIPHENYLS (PCBS) INHIBIT THE CATECHOL-O-METHYL TRANSFERASE-MEDIATED METABOLISM OF CATECHOL ESTROGENS.

C E Garner[1], L T Burka[1], A E Etheridge[2]; and H B Matthews[1]. [1]*NIEHS, Research Triangle Park, NC; and* [2]*RTI, Research Triangle Park, NC.*

The catechol metabolites of estradiol are potent signalling molecules and are hypothesized to be central to estrogen-linked carcinogenesis. Methylation by catechol-O-methyltransferase (COMT) is the principal means of catechol estrogen (CE) deactivation in the liver and other tissues. The present studies were conducted to determine the effects of PCBs and catechol PCB metabolites on the COMT-mediated catabolism of 4- and 2-hydroxyestradiol (4-OHE_2 and 2-OHE_2, respectively) in vitro and in vivo. Liver homogenates of female SD rats treated with Araclor 1254 for 21 days (5 mg/kg/day) showed a 30% and 40% reduction of COMT activity towards 2-OHE_2 and 4-OHE_2, respectively. Incubation of [^{3}H]-β-estradiol with these same liver homogenates, followed by HPLC analysis demonstrated an elevation of CEs and a nearly complete reduction in levels of methylated catechol estrogens. In classical enzyme kinetics studies, the catechol PCBs were demonstrated to be good substrates for COMT, with K_ms approximately equivalent to those of the CEs. Catechol PCBs were also mixed -type inhibitors of the O-methylation of CEs. The data suggest that PCBs significantly alter the metabolism of catechol estrogens in vivo and that this effect may be mediated by catechol PCB metabolites. Further, methyltransferase inhibition by PCB catechols may contribute to PCB-mediated endocrine effects and liver carcinogenesis.

1317 POLYCHLORINATED BIPHENYLS (PCBs) MEASURED IN A GRADE SCHOOL FOLLOWING A FLUORESCENT LIGHT BALLAST FAILURE.

M J Fedoruk and B D Kerger. *University of California, Irvine, CA, USA and Health Science Resource Integration, Inc., Tallahassee, FL, USA.*

A series of field investigations was performed following an incident in which a fluorescent light fixture failed resulting in overheating, leaking, and release of fumes from a PCB-containing ballast in a private elementary school that was built in 1961. Investigations performed shortly after removal of the failed ballast revealed trace levels of Aroclor 1254 (0.1 to 0.5 ug per 400 cm^2) in 16 of 19 rooms. No measurable airborne PCBs were observed using NIOSH Method 5503, although the detection limits were high ranging from 28,000-42,000 ng/m^3. Ballasts throughout the school were then removed and checked for PCB content and leakage. In total, 91 of 121 ballasts were identified as containing PCB fluids, 30 of the 91 PCB ballasts were leaky to some degree, and 11 of the 19 rooms in the school had at least one leaky PCB ballast. Following the incident, all PCB ballasts were replaced with non-PCB ballasts, and all accessible surfaces of the building and furniture were cleaned thoroughly with detergent and rinsed. Studies six months later using more sensitive sampling and analysis techniques (polyurethane foam, high volume sampler/EPA Method 8080; detection limit 0.5 ug/m^3) revealed the presence of airborne PCBs with patterns resembling Aroclors 1248 and 1254 at total PCB concentrations ranging from 170 to 368 ng/m^3. The source(s) of these airborne PCBs were not related to outdoor air or concurrent electrical equipment in the building. These findings appear to be consistent with other published reports examining the distribution and occurrence of PCBs in public buildings and homes with PCB-containing electrical equipment.

1318 90-DAY INHALATION TOXICITY OF 1,1-DIFLUORO-1,2,2-TRICHLOROETHANE (HCFC-122) IN RATS.

A J O'Neill, R J Baric, N E Everds, S R Frame, J C O'Connor, and W J Brock. *The DuPont Company, Haskell Laboratory for Toxicology and Industrial Medicine, Newark, DE.*

The toxicity of HCFC-122 was evaluated by exposing Crl:CD® (SD) BR male and female rats to 0, 25, 250, or 750 ppm for 90 days. Body weights and food consumption were measured weekly. Clinical pathology evaluations were conducted after 37 and 85 days on test. Morphological, hormonal, and hepatic biochemical evaluations were conducted after 90 days. Female rats exposed to 750 ppm had significantly lower mean body weights and body weight gains during the exposure period. Compound-related increases in liver weights were present in the 250 and 750 ppm groups. Microscopically, these liver weight changes were associated with minimal hepatocellular hypertrophy, centrilobular apoptosis, and increased pigment. Hypertrophy was typically characterized by minimal increases in cytoplasmic area and loss or decrease in the normal basophilic stippling of hepatocytes. In males, centrilobular hepatocytes often had clear granular swelling and, in some animals, variably-sized, clear vacuoles. Similar cytoplasmic granularity has been noted in association with peroxisome proliferation. The presence of apoptosis in the affected groups may represent a controlled mechanism to eliminate excess cells, rather than a manifestation of toxic injury to hepatocytes. Hepatic beta-oxidation rates were increased in all dose groups, with 219%, 375%, and 334% of control values at 25, 250, and 750 ppm, respectively. The no-observed-adverse-effect level (NOAEL) for 90 days inhalation exposure to HCFC-122 in male and female rats was not determined based on the hepatic biochemical results at 25 ppm.

1319 IN VITRO METABOLISM OF BETA-CHLOROPRENE.

M W Himmelstein, S C Carpenter, and R Valentine. *DuPont Haskell Laboratory for Toxicology and Industrial Medicine, Newark, DE, USA.*

Beta-chloroprene (2-chloro-1,3-butadiene, CD) is the monomer used in the production of polychloroprene (neoprene). The development of tumors in laboratory rodents exposed to CD by inhalation raises concern for humans potentially exposed during production and handling of this chemical. By analogy with compounds of similar structure (e.g., 1,3-butadiene, isoprene) metabolism of CD is probably a key determinant of toxicity. The purpose of the current study is to elucidate the metabolic fate of CD and determine if there are differences between rodents and humans with regard to the types and amounts of toxic metabolites formed. Liver microsomes from B6C3F1 mice and Fisher 344 rats were incubated at initial headspace concentrations of CD ranging from 10 to 200 ppm. CD in the vial headspace was quantitated by GC/FID, and its disappearance displayed saturable Michaelis-Menten behavior. The values for Vmax (nmol/min/mg protein) were 11.2 (rat) and 4.7 (mouse) with corresponding values for Km (uM in the aqueous medium) of 9.5 (rat) and 12.1 (mouse). The values for Vmax/Km (0.09 for rat and 0.38 for mice) indicated that mice were ~ 4 times faster at metabolizing CD than rats. Further experiments are underway to quantitate CD metabolism in human liver microsomes as well as identify the metabolites formed by each of the species. (Sponsored by the Scientific Oversights Committee of the International Institute of Synthetic Rubber Producers.)

1320 TOXICOKINETICS OF TRICHLOROETHYLENE (TCE) AND ITS METABOLITES IN THE BLOOD AND TISSUES OF RATS.

J V Bruckner and S Muralidhara. *Dept. Pharmaceutical and Biomedical Sciences, College of Pharmacy, Univ. of Georgia, Athens, GA, USA.*

TCE, a frequent contaminant of drinking water, is of concern as a potential human carcinogen. Current risk estimates are based upon results of chronic, high-dose cancer bioassays in rodents. Physiological models can be used to contrast target organ doses of toxic moieties in man and in rodents receiving the same administered dose. There are very few tissue time-course data, however, with which to construct models and to validate their predictions. The objective of this work was to clearly delineate the systemic disposition of TCE and its key metabolites. Male S-D rats were gavaged with 1, 5, 25, 50, 100 or 200 mg TCE/kg bw as an aqueous emulsion. Serial micro blood samples were taken via an indwelling arterial cannula. Other groups of rats were sacrificed periodically and tissues taken. Concentrations of TCE, trichloroethanol (TCEOH), trichloroacetic acid (TCA) and dichloroacetic acid (DCA) were analyzed by headspace gas chromatography, using a new esterification technique developed in the laboratory. TCE was rapidly absorbed and eliminated from the blood and tissues. TCEOH levels diminished quite rapidly, but TCA remained elevated in tissues for an extended period. Only trace amounts of DCA were seen at initial time-points. The toxicokinetics of the other TCE metabolites was dose-dependent. (Supported in part by DOE Grant #DE-FG01-912EW506.)

1321 MEASUREMENT OF TRICHLOROETHYLENE (TCE) AND ITS MAJOR METABOLITES IN BIOLOGICAL SAMPLES.

S Muralidhara and J Bruckner. *Department of Pharmaceutical and Biomedical Sciences, College of Pharmacy, Univ. of Georgia, Athens, GA, USA.*

A rapid and simple, yet sensitive method was developed for simultaneous measurement of TCE and its major metabolites (trichloroacetic acid (TCA): dichloroacetic acid (DCA); and trichloroethanol (TCEOH)) in blood and tissues. Most techniques used to date to quantify TCE and its polar metabolites are time-consuming and complex. Volatilization of TCE and instability of DCA have been problematic. The basic approach has been to derivative the polar metabolites, so they will volatize and can be analyzed by gas chromatography (GC). The method presented here involves transfer of 5-100 µl of blood or tissue homogenate to 20-ml vial containing 200 µl of esterizer (distilled water: conc sulfuric acid: methanol; 6:5:1; v:v:v). The vials are capped with PTFE-lined rubber septa, crimped tightly, vortexed and placed into a HS-101 headspace autosampler. They are heated for 30 min at 110°C, before being vented into a 10' x 1/8" stainless steel column packed with 10% OV-17 on a Supelco support. TCE, TCA, DCA and TCEOH are well resolved. The limit of detection for each compound is ~100 pg/l (ppt). This technique should be useful for toxicokinetic studies of TCE, in which large numbers of samples must be analyzed. (Supported in part by DOE Grant #DE-FG01-912EW506.)

1322 THE IMPACT OF EXPERIMENTAL UNCERTAINTY AND INTERINDIVIDUAL VARIABILITY ON *IN VITRO* TO *IN VIVO* EXTRAPOLATION FOR TRICHLOROETHYLENE METABOLISM IN HUMANS.

J Z Byczkowski[1] and J C Lipscomb[2]. [1]*TN & Associates, Inc., Cincinnati, OH;* [2]*U.S. EPA National Center for Environmental Assessment, Cincinnati, OH, USA.*

To examine the extent to which experimental uncertainty and human interindividual variability separately impacted the ability of physiologically based pharmacokinetic (PBPK) model to predict metabolism and blood concentration of trichloroethylene (TCE) in the human, two distinct modules were developed and fitted into a current PBPK model (*Risk Anal.* 13:71, 1993) for TCE. The Monte Carlo (MC) module sampled values from the range determined from the distribution of measured parameters, while the "drop-in" module was constructed to extrapolate *in vivo* metabolic rates from microsomal protein and hepatocyte recovery experiments and kinetic parameters (Km and Vmax) determined from *in vitro* experiments with human microsomes (*Toxicol. Appl. Pharmacol.* 142:311, 1997) and isolated human hepatocytes (*Toxicol. Appl. Pharmacol.* 152:XXX, 1998). The modified PBPK model was constructed to allow multiple PBPK simulations for various (within the range of experimentally determined standard deviations) headspace TCE concentrations, microsomal protein contents, partition coefficients hepatocytes/air, Vmax and Km in microsomes and hepatocytes, and the number of hepatocytes in the liver. Experimental uncertainties were estimated by repeated determinations of samples from the same individuals. The interindividual variability was determined by calculating the mean and standard deviation for the sample population. Our analyses have identified the measured parameters that contributed most to the overall uncertainty of the PBPK model output. This study demonstrates that the experimental errors from both *in vitro* systems added little to the uncertainty of the simulated values when compared with overwhelming and intrinsic differences in TCE metabolism as expressed in liver preparations from different human donors. (Partially supported by the Department of the Air Force Contract No. F41624-96-C-9010.)

1323 EXTENT AND TIMELINESS OF TISSUE REPAIR MODULATES THE DOSE-RELATED INCREASE IN TOXICITY OF CHLOROFORM.

M G Soni[1], S K Ramaiah[1], M M Mumtaz[2], H Clewell[3] and H M Mehendale[1]. [1]*Division of Toxicology, College of Pharmacy, Northeast Louisiana University Health Sciences Center, Monroe, LA;* [2]*ATSDR, Department of Health and Human Services, Atlanta, GA;* [3]*ICF Kaiser Engineers Inc., Ruston, LA.*

Under a cooperative agreement with ATSDR we are studying toxic effects of chemical mixtures. Earlier studies led us to hypothesize that the rate and extent of liver tissue repair response to a given dose of hepatotoxicants determines the end result of toxicity (death or recovery) regardless of the mechanisms by which injury is inflicted. To understand the effects of mixture we are studying the effects of model hepatotoxicants alone and in combination. Present studies were designed to test our hypothesis with chloroform, a well-known environmental pollutant. Male S-D rats were injected with a ten-fold dose range of chloroform (0.05, 0.125, 0.25 and 0.5 ml/kg or 74, 184, 368 and 736 mg/kg) and hepatotoxicity and tissue repair were studied during a time course of 0 to 96 hr. The highest dose (736 mg/kg) of chloroform led to 40% mortality by 72 hr. Liver injury as assessed by plasma alanine aminotransferase (ALT) elevation showed a dose-response over a ten-fold dose range. A significant and progressive increase in plasma ALT was observed in the highest dose (736 mg/kg) treated group after 24 hr. Tissue regeneration response as measured by [^{3}H]-thymidine incorporation into hepatocellular nuclear DNA peaked at 36 hr in rats treated with lower two doses of chloroform (74 and 184 mg/kg). Further increase in chloroform dose to 368 mg/kg resulted in an earlier increase in [^{3}H]-thymidine incorporation at 24 hr, which still peaked at 36 hr. However, with highest dose of chloroform (736 mg/kg), tissue repair was delayed and attenuated allowing for unrestrained progression of liver injury. These results support the concept that in addition to the magnitude of tissue repair response, the time at which this occurs is critical in restraining the progression of injury. Measuring tissue repair and injury as simultaneous biological responses to toxic agents might increase the usefulness of dose-response paradigms in predictive toxicology and risk assessment. (Supported by ATSDR Grant U61/ATU681482.)

1324 VEHICLE, VOLUME AND TIME DEPENDENT EFFECTS OF CHLOROFORM ($CHCl_3$) INDUCED HEPATOTOXICITY.

Y M Sey, A McDonald and J E Simmons. *NHEERL, U.S. EPA, RTP, NC.*

Digestible oils have been used frequently as vehicles for oral administration of volatile lipophilic chemicals. Previous results from our laboratory have shown that both the hepatotoxicity and nephrotoxicity of $CHCl_3$ were modulated by gavage vehicle with delivery in corn oil resulting in substantially greater toxicity than aqueous vehicle delivery. As a large gavage volume (10 ml/kg) was used in these studies, and gavage volume is also known to modulate toxicity, our objective in the present study was to examine the influence of vehicle at a lower gavage volume on the hepatotoxicity of Male F-344 rats (~70 days) received by oral gavage 0, 0.25, and 0.50 ml $CHCl_3$ /kg (N=6) in both corn oil and aqueous (10 % Alkamuls) based vehicles at a gavage volume of 5 ml/kg. Hepatotoxicity was assessed at 24, 48 and 72 hr post gavage. Little or no apparent change was evident in body and relative liver weight at any $CHCl_3$ dosage administered in either vehicle over 72 hr. Serum enzymes sorbitol dehydrogenase (SDH), and alanine (ALT) and aspartate (AST) aminotransferase showed that a dose–dependent increase in $CHCl_3$ hepatotoxicity occured following delivery in either vehicle. At the lower dosage, serum levels of AST, ALT and SDH were highest at 24 hr with recovery evident by 48 hr. In contrast, at the higher dosage, serum SDH, ALT and AST were similar at 24 and 48 hr with apparent recovery delayed until 72 hr. Statistically significant differences between oil and aqueous–based delivery of $CHCl_3$ were not detected at either $CHCl_3$ dose level at any time. This stands in contrast to the large differences seen in $CHCl_3$ toxicity between oil and aqueous vehicles at a large gavage volume. In conclusion, $CHCl_3$ toxicity observed in oil and aqueous vehicles appears to be modulated by gavage volume. (This abstract does not necessarily reflect EPA policy.)

1325 FURTHER REFINEMENT OF A PHYSIOLOGICALLY BASED PHARMACOKINETIC/PHARMACODYNAMIC MODEL FOR THE TOXICOLOGIC INTERACTION BETWEEN KEPONE AND CARBON TETRACHLORIDE.

R S H Yang, L Feng, and S A Benjamin. *Center for Environmental Toxicology and Technology, Department of Environmental Health, Colorado State University, Fort Collins, CO.*

The earlier PBPK/PD model for Kepone/CCl_4 interaction from our laboratory (El-Masri et al, 1996) was refined further by incorporating: (1) the liver zonal concept advanced by Andersen et al (1997); (2) the liver zonal distribution of P450 2E1 and P450 2B1/2, enzymes likely responsible for generating free radicals from CCl_4; (3) the concept of energy metabolism as related to hepatocellular regeneration (Soni et al, 1993); (4) the new categorization of liver histopathological changes resulting from studies in our own laboratory. The reason for these refinements is for a better capacity of predicting lethality as well as hepatocellular changes over a range of doses. In PBPK modeling, we simulated liver zonal bioactivation of CCl_4 mediated by cytochrome P-450 2E1 and P-450 2B1/2 with the incorporation of zonal expression and inductions of these P-450 isoenzymes. In PBPD modeling, the simulated liver dynamic process was composed of two stages: hepatocellular injury and hepatocellular regeneration. The construction of PBPD modeling was based on the liver histopathological study and PCNA study conducted in our lab. In histopathological study, hepatocytes were categorized as normal, injured, balloon changed and necrotic cells. In PCNA study, mitotic cell and G2 cell were counted as proliferative cells. This integrated PBPK/PD model can be used to predict liver histopathological change in rats treated with Kepone/CCl_4 at different doses of CCl_4. When coupled with Monte Carlo simulation, this model can be used to predict lethality. In Kepone/CCl_4 treated rats, at CCl_4 dose levels of 0.26, 0.52, 1.04 mmol/kg, mortality by 48 hours was 19.7%, 69.5%, 96.1% respectively in simulation involving 1,000 rats. In comparison, we observed 6.6%, 74.1%, 100% lethality from experiments in 9 to 27 rats. (Supported by NIEHS Superfund Basic Research Program Project P42 ES05949.)

1326 OLDER RATS ARE RESILIENT TO THE HEPATOTOXICITY OF CCl_4 AND CHLORDECONE + CCl_4.

H M Mehendale[1], S K Ramaiah[1], A Dalu[2] and M G Soni[1]. *Division of Toxicology, College of Pharmacy, Northeast Louisiana University Health Sciences Center, Monroe LA; [2]National Center for Toxicological Research, Jefferson, AR.*

While a considerable age-dependent variation in the incidence of chemical-induced hepatotoxicity is known, the reasons for this variation remain to be fully explored. The objective of the current studies was to investigate the effects of CCl_4 alone and chlordecone + CCl_4 in 24 month old rats. Male S-D adult (60 day) and aged (24 months) rats were challenged with 2.5 ml CCl_4/kg alone or were maintained on chlordecone (CD, 10 ppm) diet for 15 days and challenged with CCl_4 (100 μ l/kg, ip). In aged rats no mortality was observed at high dose of CCl_4 as against 30 % lethality in adult rats. Exposure to CD + CCl_4 resulted in 100 % mortality in adult rats, whereas, no mortality was observed in aged rats. Liver injury was assessed by plasma enzymes (ALT and SDH) and by histopathology at 0, 6, 24 and 48 h. In high dose treated rats comparable increase in plasma enzymes at 6 and 24 h was observed in both age groups. At 48 h a decline in plasma enzymes was noted in aged rats, whereas in adult rats these enzymes remained elevated. Both plasma enzymes showed a significant progressive elevation in adult rats exposed to CD + CCl_4. Interestingly, aged rats exposed to CD + CCl_4 showed marginal and transient increase in plasma enzymes. Histological studies supported the plasma enzyme observations. Hepatocellular regeneration as measured by [^{3}H]-thymidine incorporation into DNA was suppressed in adult rats. Interestingly, in aged rats undergoing either high dose CCl_4 toxicity or interactive toxicity, S-phase stimulation occurred early at 24 h. Further studies are needed to establish the role of tissue repair in aged rats in the protection against hepatotoxicity These initial studies suggest that the liver of aged rats has greater plasticity for repair after toxic injury, compared to adult rats. (Supported by Louisiana Board of Regents Support Fund.)

1327 ARSENIC STIMULATES BLADDER EPITHELIAL CELL PROLIFERATION.

P P Simeonova[1], J M Matheson[1], L Flood[1], M I Luster[1], W Toriumi[2], D Germolec[3]. [1]*NIOSH, Morgantown, WV;* [2]*Tanabe Seiyaku Co. Ltd., Saitama, Japan;* [3]*NIEHS, RTP, NC.*

Epidemiological studies have demonstrated a strong correlation between increased arsenic concentrations in drinking water and the incidence of bladder cancer in human. Additionally, it has been reported that dimethylarsinic, one of the metabolites of inorganic arsenicals, promotes nitrosamine - induced rat urinary bladder carcinogenesis. We have used in vivo and in vitro models to analyze the effect of inorganic arsenic (As3+) on bladder epithelial cells. Rats treated with arsenic in the drinking water (0.02%) had high levels in the urine of total arsenic represented by DMA, MMA and As3+, and demonstrated an increase in bladder epithelial cell proliferation in 4 weeks. The proliferative changes were documented by HE staining, PCNA immunostaining and electron microscopy. Consistent with the in vivo data, arsenic induced an increase in [3-H] thymidine incorporation in several bladder epithelial cell lines, a marker for DNA synthesis and cell proliferative response. Furthermore, arsenic stimulated the activation of transcription factors associated with modulation of the growth factor expression and control of the cell cycle of bladder epithelial cells, including AP-1. Taken together, these studies suggest that arsenic-induced bladder cancer may be associated with the ability of arsenic to directly stimulate bladder epithelial cell growth. Cell proliferation alone can provide an explanation of carcinogenesis. Arsenic can promote cell proliferation of previously initiated cells or the rapid cell proliferation can be prerequisite for increased mutational rate.

1328 PERTURBATION OF MOUSE LEYDIG CELL PROLIFERATION BY ESTROGENS.

J W DuMond Jr. and D Roy. *Department of Environmental Health Sciences, University of Alabama, Birmingham, AL, USA.*

Estrogen is a testicular carcinogen in animal models. Leydig cell tumors in human are estrogen secreting and/or estrogen sensitive. Recently, estrogenic chemicals have been implicated in the etiology of testicular cancer. The roles estrogenic chemicals play in the etiology of testicular cancer are not clear, as estrogens typically induce testicular atrophy in man when administered at pharmacological doses. In this study, we have conducted a cell proliferation

assay using the normalized mouse Leydig cell line, TM3. Cells were subcultured and plated for 24 hours prior to treatment, after which their growth medium was replaced with a non-hormone supplemented serum-free medium. Treatments consisted of DES (diethylstibestrol), 17β -estradiol, or 17α -estradiol in 1 of 7 (1*pg*-1μ g/ml) different concentrations, along with vehicle (ethanol) treatment of the controls. All treatments resulted in a bi-phasic stimulation of the cell proliferation. Results for DES ranged from 14.16%-248.23 % growth compared to controls assumed as 100%. Peak proliferation was noted at 72 hours with 1*pg*/ml and 100*ng*/ml DES treatments (186.87 and 248.23, respectively). Severe cytotoxicity was noted with 1μ g/ml DES treatment (14.16%). Results for 17β -estradiol ranged from 101.49-125.48% growth with peak values occurring at 1*pg*/ml and 100*ng*/ml. Results for 17α -estradiol ranged from 77.33-136.0% growth with peak values occurring at 1*pg*/ml and 100*ng*/ml. Cytotoxicity was noted for both 17β and 17α -estradiol at 1μ g/ml. These data presented here are both novel and intriguing, as an apparent tri-phasic response has been demonstrated. We conclude that the normalized mouse Leydig cell line TM3 can be both up and down regulated through estrogen exposure. Estrogen-increased cell proliferation may allow errors to occur during replication and this may be a factor responsible for estrogen-induced cancer.

1329 PROLIFERATIVE EFFECTS IN RESPIRATORY TISSUES OF THE SPRAGUE-DAWLEY RAT FOLLOWING STYRENE INHALATION EXPOSURE.

M T Sidel and R A Schatz. *Northeastern University Toxicology Program, Boston, MA, USA.*

Styrene is an industrial chemical widely used in the plastics industry. Styrene 7,8-oxide, the primary metabolite of styrene, is thought to be responsible for the carcinogenic and toxic effects associated with styrene exposure. Animal studies have shown that styrene is a respiratory toxicant and that styrene oxide causes proliferation in various tissues. The mechanism of carcinogenicity may therefore involve an increase in proliferation. The purpose of this study was to measure the levels of styrene oxide in lung, nasal mucosa and blood following a 50 ppm inhalation exposure and to determine if there was an increase in proliferating cell nuclear antigen (PCNA), a marker of proliferation, in these tissues immediately following, and 24 hours after exposure. Immediately following exposure, the level of styrene oxide in the blood was 20.9 ± 3.1 ng/g tissue while in the lung and nasal mucosa it was 62.8 ± 6.6 and 135.7 ± 18.7 ng/g tissue, respectively. There was no significant change in the level of PCNA in the lung at either time point following exposure. In the respiratory nasal mucosa, there was a significant increase in PCNA immediately following and 24 hours after exposure. In the olfactory nasal mucosa, there was a significant increase in PCNA immediately following exposure, but PCNA levels returned to control values 24 hours later. This indicates that, compared to the lung, the higher concentration of styrene oxide in the nasal mucosa may have a proliferative effect. Also, within the nasal mucosa, the olfactory and respiratory epithelia both proliferate following styrene exposure, but 24 hours after exposure proliferation is still occurring in the respiratory epithelia, while the olfactory epithelia has recovered.

1330 ALPHA ASSOCAITED DECRESAED P53 BYSTANDER EFFECTS AND ENHANCED CELLULAR PROLIFERATION IN HUMAN LUNG FIBROBLASTS.

R Iyer and B E Lehnert. *Los Alamos National Laboratory, Los Alamos, NM, USA.*

In our study, exposure of the cells to only 1 cGy of α particles resulted in markedly elevated levels in p53 and p21 protein levels, as seen by western blotting. However, based on our previous morphometric analyses, we estimate that ~7% of the cells in our study actually receive one or more nuclear hits by the α particles. We therefore investigated the possibility that a transmissible factor(s) may be induced by α particles that could contribute to the greater than expected p53 and p21Waf-1 elevations observed in the above experiment. We irradiated confluent HFL1 with 1 cGy of α particles and immediately and 4 hrs after irradiation we transferred their supernatants onto unirradiated HFL1. Four hrs later, we analyzed the cells for their p53 and p21Waf-1 contents by Western analysis. The supernatants from α -irradiated cells consistently caused *decreases* in the basal levels of p53 and p21Waf-1 in unirradiated cells, and more pronounced decreases in the cell cycle regulating proteins were obtained with supernatants that were harvested from cells at 4 hrs after exposure than immediately after exposure. Additionally, cells that have been treated with supernatants from α -irradiated cells show diminutions in p53 and p21Waf-1 protein elevations after subsequent exposure to α particles. Further experiments also indicated that cells preexposed to supernatants from a irradiated cells are compromised in their abilty to increase p53 levels on a subsequent exposure to α irradiation. We also describe new evidence that suggests exposure to low dose α particles can enhance cell proliferationas seen by clonogenecity assays. Such hyperproliferation likely is a step in the complex process that can culminate in bronchogenic carcinoma. Further, the decreased p53 bystander effect may have marked ramifications, such as, the transmittal of genomic defects to cell progeny due to checkpoint loss, replication of unrepaired DNA and, the failure of cells with excessive DNA damage to undergo p53-mediated apoptosis, and even, perhaps, a role in the yet to be explained phenomenon of genomic instability. (Funded by U.S.DOE.)

1331 A P53-INDEPENDENT METHYLMERCURY-INDUCED G_2/M ARREST.

M A C Mendoza, Y C Ou, S Hong and E M Faustman. *Department of Environmental Health, University of Washington, Seattle, WA, USA.*

We evaluated the role of p53 in the cell cycle inhibition induced by methylmercury (CH_3HgOH, 0-6 μM, 24 hrs) using wild type, heterozygous and p53-deficient mouse embryonic fibroblasts at passage 5 to 8. Following methylmercury exposure, cells were harvested and stained with 4', 6-diamidino-2-phenylindole (DAPI) to establish a DNA content-based cell cycle profile using a Coulter Elite flow cytometer. Consistent with a G_1-phase regulatory role for p53, untreated wild type cells accumulated in the G_1 phase at a greater fraction than p53-deficient cells. Methylmercury-exposed wild type cells showed a dose-dependent increase in the G_2/M phase population and a subsequent decrease in the percentage of cells in G_1, consistent with predicted effects of methylmercury on mitotic spindle function. In contrast, methylmercury-exposed p53-deficient cells demonstrated a decrease in the S phase cell fraction and increases in the hyperdiploid and sub-G_0 population suggesting heightened chromatid segregation errors and induction of apoptotic/necrotic cell death. The heterozygous cells exhibited an intermediate response to methylmercury. The results of the present study are consistent with earlier studies on p53-dependent G_1 arrest and methylmercury-induced mitotic spindle dysfunction, and suggest that the G_2/M phase inhibition after methylmercury exposure may be p53-independent. Further investigations on the fate of the growth-inhibited cells, expression of cell cycle control genes, and consequences on genetic stability will help understand the complex role of p53 in cell proliferation in the context of methylmercury toxicity. (This project is supported by USEPA R825358 and NIEHS P42ES-04696.)

1332 HUMAN MAMMARY EPITHELIAL CELLS EXHIBIT A DIFFERENTIAL p53-MEDIATED RESPONSE FOLLOWING EXPOSURE TO IONIZING OR UV RADIATION.

K M Meyer, S M Hess, and S A Leadon. *Curriculum in Toxicology and Department of Radiation Oncology, University of North Carolina, Chapel Hill, NC, USA.* Sponsor: J Swenberg.

The long term objective of our research is to provide a better understanding of how breast epithelial cells respond to DNA-damaging agents. The tumor suppressor protein, p53 plays a critical role as a transcriptional activator of downstream target genes involved in the cellular response to DNA damaging agents. We examined the cell cycle checkpoint response of human mammary epithelial cells (HMEC) and their isogenic fibroblast counterparts to ionizing (IR) and ultraviolet radiation (UV), two genotoxic agents whose DNA damage response pathways involve p53. Using flow cytometric analysis, we found that HMEC, which contain wild-type p53 sequence, do not exhibit a G1 arrest in response to IR (4 Gy), but show an intact G2 checkpoint. Western analyses were performed to examine the expression of p53 and its downstream target associated with G1 arrest, $p21^{WAF1}$. Supportive evidence obtained from these experiments revealed that there was neither an increase in p53 nor $p21^{WAF1}$ proteins in HMEC exposed to IR. In contrast, isogenic mammary fibroblasts arrest at the G1 checkpoint and induce the p53 and $p21^{WAF1}$ proteins following IR. By comparison, HMEC exposed to UV (5 J/m^2) displayed a cell cycle arrest and induced the expression of p53 and $p21^{WAF1}$. Our results show that the cellular response to DNA damage depends on both the type of damage introduced into the DNA and the specific cell type. Studies are currently underway to determine the phosphorylation status of p53 in HMEC after exposure to either IR or UV. In addition, we are performing luciferase assays to determine whether p53 in irradiated HMEC is in a transcriptionally active form. Thus, we are extending the initial investigations to experiments that will yield important mechanistic information about the p53-mediated response in irradiated HMEC.

1333 COORDINATE INHIBITION OF CELL CYCLE PROGRESSION AND TCDD ACTIVATION OF *CYP1A1* BY 12-0-TETRA- DECANOYLPHORBOL-13-ACETATE.

M Guo and J J Reiners, Jr. *Institute of Chemical Toxicology, Wayne State University, Detroit, MI, USA.*

The relationship between the effects of 12-0-tetradecanoyl-phorbol-13-acetate (TPA) on cell cycle progression and the transcriptional activation of *CYP1A1* by 2,3,7,8-tetrachlorodi- benzo-*p*-dioxin (TCDD) was examined in the human breast epithelial cell line MCF10A-Neo. Exposure of MCF10A-Neo cells to TPA induced a concentration-dependent (IC_{50} ~ 0.5 nM) G_1 arrest and inhibition of *CYP1A1/1B1* activation by TCDD. Both effects occurred rapidly but were transient and lasted less than 24 hr. The kinetics of cell cycle arrest/reentry paralleled the loss/recovery of responsiveness to TCDD. Cultures treated with TPA 24 hr prior to a second TPA challenge neither arrested nor lost their responsiveness to TCDD following the second TPA exposure. Within one hr of TPA treatment cultures produced a cytostatic conditioned media capable of partially suppressing *CYP1A1* activation by TCDD. Preabsorption of conditioned media with an antibody to TGF-β inhibited its cytostatic activity by ~50%. Addition of exogenous activated TGF-β duplicated the cytostatic and suppressive effects attributed to TGF-β in conditioned media. However, whereas direct treatment of cultures with anti-TGF-β prior to TPA addition inhibited the cytostatic activity of TPA by 50%, it did not inhibit suppression of *CYP1A1* activation. Thus, in MCF10A-Neo cells TPA activates protein kinase C-dependent processes which cause autocrine production of cytostatic cytokines (one of which is TGF-β) capable of weakly inhibiting TCDD activation of *CYP1A1*. TPA also activates a second non-related process which strongly inhibits *CYP1A1* activation by TCDD. (Research was supported by NIH grant CA34469.)

1334 BIOLOGICALLY-BASED DOSE-RESPONSE MODELING OF MULTISTAGE CARCINOGENESIS: DEVELOPMENT OF A MODIFIED MVK MODEL WITH EXPERIMENTAL DATA FROM SYRIAN HAMSTER EMBRYO (SHE) CELLS.

K H Liao[2], D L Gustafson[1], M H Fox[3], L S Chubb[1], K F Reardon[2] and R S H Yang[1]. *Center for Environmental Toxicology and Technology, Departments of [1]Environmental Health, [2]Chemical and Bioresource Engineering, and [3]Radiological Health Sciences, Colorado State University, Fort Collins, CO, USA.*

To further incorporate biologic information into quantitative cancer modeling, the two-stage MVK model has been modified for use with SHE cell neoplastic progression. There are four phenotypic stages included in this model, normal, immortal, anchorage-independent growth, and tumorigenic. Cells in each stage have distinct division, death and mutation rates, and mutation is assumed to occur during cell division. Model development and related experiments are focused on studying the abilities of lead, arsenic, chromium and a mixture of these three metals to induce progression of SHE cells from one phenotype to the next. The first phase of experimental work involved cytotoxicity studies and the exploration of methods for determining the division, death, and mutation rates. Toxicity of the three metals and the metal mixture has been assessed using the MTT assay. Results from cytotoxicity studies show that a mixture of the three metals are less-than-additive, suggesting some type of interaction at the level of cell killing. Cell division and death rates have been assessed using flow cytometric analysis for inclusion in the model. Cell division rates were measured using bromodeoxyuridine (BrdU) incorporation with propidium iodide staining, which allows for the calculation of potential doubling time, which is a cell cycling time that takes growth but not cell loss into account. Flow cytometry methods for measuring cell death in SHE cells is currently under development. Laboratory measurements of metal and metal mixture induced changes in key cell parameters are used to verify the development of this modified multi-stage carcinogenesis model. (This work was supported by ATSDR (Cooperative Agreement U61/ATU 881475) and NIEHS Superfund Basic Research Program (P42 ES05949).)

1335 CELL AUTONOMY AND THE RESPONSE OF THE HEPATOCYTE TO PARTIAL HEPATECTOMY.

T C Weglarz and E P Sandgren. *Dept. of Pathobiological Sciences, University of Wisconsin-Madison, WI, USA.*

The adult liver is a quiescent organ, but following 2/3 partial hepatectomy mature hepatocytes undergo DNA synthesis and cell division to replace lost parenchyma. This response depends initially upon cues external to the hepatocyte, namely the loss of liver mass, but proceeds to a stage at which DNA synthesis is initiated in the hepatocyte, a process that is intrinsic to the cell or cell autonomous. Exploring the stage at which control of hepatocyte proliferation switches from non-cell autonomous to cell autonomous was an objective of this study. uPA (urokinase-type plasminogen activator) transgenic mice were used to address this issue. Diseased liver of uPA transgenic mice was repopulated with hepatocytes of two different somatic genotypes, rat and mouse, which display different responses to 2/3 partial hepatectomy in the respective host species. In rats, peak DNA synthesis occurs around 24 hours post-hepatectomy. In mice, peak DNA synthesis is delayed approximately 12 hours, occurring around 36 hours post-hepatectomy. Immunodeficient transgenic uPA mice with chimeric livers composed of rat and mouse hepatocytes were subjected to 2/3 partial hepatectomy. At different times post-hepatectomy, BrdU was administered to mice one hour prior to sacrifice, and the number of rat and mouse hepatocytes undergoing DNA synthesis in the chimeric livers was quantitated and compared. In particular, we wished to determine whether peak DNA synthesis in rat hepatocytes follows the response of the rat donor species or the mouse host species. Our results suggest that donor rat hepatocytes initiate DNA synthesis earlier than endogenous mouse hepatocytes in the chimeric liver, and at the expected time for rat hepatocytes in a rat. That is, entry of hepatocytes into the S phase of the cell cycle appears to be regulated in a cell autonomous manner. This system of generating chimeric livers can also be used to study differences in metabolism and/or toxicity of chemical compounds between two different species.

1336 INHIBITED GROWTH OF HUMAN HT29 COLON CARCINOMA CELLS BY DETOXIFICATION ENZYME INDUCERS IS REVERSED BY N-ACETYL CYSTEINE.

R Y Odom[1], Y G Wirsiy[1], D P Jones[2], and W G Kirlin[1]. *[1]Morehouse School of Medicine, Atlanta, GA; [2]Emory University School of Medicine, Atlanta, GA.*

Differentiation of the human colon adenocarcinoma cell line HT29 with sodium butyrate (NaB) results in increased activity of the detoxification enzymes glutathione S-transferase (GST) and NAD(P)H:quinone reductase (N:QR). These events are also accompanied by a decrease in intracellular glutathione (GSH) concentrations and a shift to a more oxidized redox potential, as calculated from GSH and GSSG concentrations, using the Nernst equation. To determine whether compounds that induce GST and N:QR activity also affect carcinoma cell proliferation, HT29 cells were treated with 5 to 25 μM benzyl isothiocyanate (BIT) and 20 to100 μM dimethyl fumarate (DMF). In a concentration-dependent manner, BIT and DMF decreased thymidine incorporation to less than 25% of controls. These decreases in cell proliferation were reversible by pretreatment with 1 to 5 mM N-acetyl cysteine (NAC). In contrast, NaB-mediated decreases in cell proliferation to less than 25% of controls were not reversible by NAC. In fact, cell growth was further diminished by NAC, dose-dependently, to less than 5% of controls at 2.5 mM. These findings indicate that although BIT, DMF and NaB are capable of inibiting carcinoma cell proliferation and share a common property of detoxification enzyme induction, their effects on cell growth differ in their response to NAC. (Support: GM-028248, ES-09047.)

1337 THE ACTIVATED AH RECEPTOR (AHR) BINDS TO HYPOPHOSPHORYLATED RETINOBLASTOMA (RB) PROTEIN AND REINFORCES THE REPRESSION OF E2F-DEPENDENT EXPRESSION.

A Puga[1], S J Barnes[1], E S Knudsen[2], C Y Chang, A Maier[1] and B L Schumann[1]. *[1]Department of Environmental Health and [2]Department of Cell Biology, Neurobiology and Anatomy. University of Cincinnati Medical Center, Cincinnati, OH.*

Polyhalogenated aromatic hydrocarbons, of which 2,3,7,8-tetrachloro-*p*-dioxin (TCDD) is the prototype compound, elicit a variety of toxic, teratogenic, and carcinogenic responses in exposed animals and in humans. One of the most puzzling aspects of the biological impact of TCDD is that it causes a plethora of apparently unrelated effects, including craniofacial anomalies and hydronephrosis during rodent embryogenesis, and hepatic carcinoma and pulmonary and skin tumors in adult mice. TCDD also causes disturbances of lipid metabolism and has immunotoxic, reproductive and endocrine disruption effects, some of which appear to be present also in exposed humans. The effects of TCDD at the cellular level are just as diverse, and often contradictory, affecting cell cycle regulation differently in different cell lines. For example, TCDD induces keratinocyte proliferation and terminal differentiation, thymocyte apoptosis, and inhibition of the estrogen-dependent proliferation of human breast cancer cells. All the

effects of TCDD are mediated by the AHR, which prompted us to examine possible mechanisms that would connect the Ah receptor with cell cycle regulation. Using yeast two-hybrid assays, we find that AHR and RB can form heterodimers. To characterize the heterodimers we used in vitro pull-down techniques and found that both the LXCXE and the Q-rich AHR domains can form complexes with hypophosphorylated RB forms independently. Co-immunoprecipitation experiments with in vivo whole cell lysates show that AHR and RB coprecipitate using ether anti-AHR or anti-RB antibodies from lysates of TCDD-treated MCF-7 cells, but not from lysates of cells treated with DMSO vehicle. Using an E2F-dependent luciferase reporter, we find that ectopic expression of AHR and RB synergize to repress E2F-dependent expression. These results suggest that the Ah receptor may play a cell cycle regulatory role when cells are exposed to environmental toxicants. (Supported by NIH P30 ES06096 and R01 ES06273.)

1338 MECHANISM OF ESTROGEN-INDUCED E2F1 GENE EXPRESSION: ROLE OF ESTROGEN RECEPTOR/Sp1 INTERACTIONS WITH NF-YA.

W Wang and S Safe. *Department of Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX, USA.*

Treatment of MCF-7 human breast cancer cells with 10 nM 17β -estradiol (E2) induced E2F1 mRNA levels (3-fold) and immunoreactive protein (6-fold). Factors regulating basal and E2-inducible expression of E2F1 were investigated by transient transfection studies in MCF-7 human breast cancer cells using a series of deletion constructs ($pE2F1_{a-j}$) containing E2F1 gene promoter inserts linked to a luciferase (luc) reporter gene. Basal and inducible gene expression required a combination of one or more GC-rich sites (-169 to -116) and two downstream CCAAT elements (-122 to -54). Gel mobility shift assays using competitive oligonucleotides and transcription factor antibody supershift assays showed that Sp1 protein interacted with the GC-rich sites and NF-YA bound the CCAAT elements. $pE2F1_i$ (-146/-54) contains a single upstream GC-rich motif and two downstream CCAAT elements, and in transient transfection studies with wild-type $pE2F1_i$ and constructs with mutations in the GC-rich and CCAAT elements, only the wild-type plasmid was E2-responsive. Gel mobility shift analysis of proteins binding to the [^{32}P]-146/-54 oligonucleotide showed that ER protein enhanced Sp1 - DNA binding and Sp1 protein enhanced NF-YA - DNA interactions. This represents a unique complex ternary protein - DNA interaction required for E2-induced transactivation of E2F1. (Welch Foundation and NIH CA76636)

1339 DIETHYLSTILBESTROL (DES) INDUCES APOPTOSIS AND AFFECTS CELL CYCLE IN A MURINE THYMOCYTE-LIKE CELL LINE RL-3.

M D Laiosa, Z-W Lai, and A E Silverstone. *Dept. of Microbiology and Immunology, SUNY Health Science Center, Syracuse, NY, USA.*

It has previously been reported that DES, a synthetic nonsteroidal compound possessing estrogenic activity causes thymic atrophy both in exposed mice and in cultured fetal thymus organs. By using a murine thymocyte-like cell line RL-3 derived from a radiation-induced leukemia, we have further investigated the effects of DES in order to understand the mechanisms for thymic atrophy. RL-3 cells are $Thy1.2^+HSA^-CD45^+CD4^+CD8^+$, $CD3^{low}$, TCR^{low} and $c\text{-}kit^-CD44^-CD25^{hi}$. This cellular phenotype is similar to that of the majority of immature thymocytes in vivo. Exposure of the RL-3 cell line to between 20 and 40 μ M DES resulted in a significant reduction in cell number after 12 - 24 hours of culture. DES also affected cell cycle in RL-3 cells. After 6 - 12 hour of culture, the percentage as well as absolute number of cells in the G_2/M phase of cell cycle was increased. By using both the fluorescent TUNEL assay and electrophoresis of DNA, we also found that DES induced apoptosis. Although DES exposed RL-3 cultures did not manifest a significant difference in apoptosis for cells in S and G_2/M, there was a tendency to observe the increase of apoptosis in $G_{0/1}$ phase cells only after 12 hours but not at 6 hour exposure to DES. Analysis for apoptosis or cell cycle related gene expression by quantitative RT-PCR, showed that DES induced NOS mRNA in RL-3 cells after 6 - 12 hour of culture. DES also affected 14-3-3σ, p27, and bcl-2 gene expression. We did not find alterations of the expression of mRNAs for Fas, p21, p53, CDC2, CDK2a, CDK2L, CDK4, and cyclin A, D1, D2, D3 after DES exposure. (Supported by NIEHS grants ES07216 and ES04862.)

1340 INHIBITION OF THE MAPK PATHWAY BLOCKS QUINONE-THIOETHER MEDIATED CYTOTOXICITY, BUT NOT GROWTH ARREST, IN LLC-PK1 CELLS.

Q Huang, S S Lau and T J Monks. *Division of Pharmacology, College of Pharmacy, University of Texas at Austin, TX, USA.*

2-Br-*bis*-(glutathion-S-yl)hydroquinone (BBGHQ) is a potent nephrotoxicant causing severe necrosis of renal proximal tubules *in vivo*. In a renal tubular epithelial cell model (LLC-PK1), BBGHQ causes DNA damage, growth arrest, and cell death. We now report that BBGHQ causes a dose- and time-dependent S-phase delay in LLC-PK1 cells. This cell cycle delay appears to be mediated by p21/WAF1, the cyclin kinase inhibitor, since it is strongly induced by BBGHQ. The transcriptional activity of p53 is also increased by BBGHQ, indicating that p21-mediated growth arrest is probably p53-dependent. BBGHQ also rapidly (<15 min) activates the mitogen-activated protein kinase (MAPK) pathway as evidenced by increases in hyperphosphorylated extracellular signal-regulated protein kinases ERK1 and ERK2. Activation is maximal by 1 hr and remains elevated for at least 5 hr. Other subfamilies of MAPK, including c-Jun N-terminal kinases (JNK) and p38 kinase, are also stimulated by BBGHQ. However, the activation of both JNKs and p38 occurs later (2 hr) than ERK activation. Pretreatment of cells with inhibitors of ERKs or p38, PD98059 and SB202190, substantially attenuates BBGHQ induced cytotoxicity by 70% and 40% respectively. In contrast, PD98059 and SB202190 do not appear to block the cell cycle arrest in response to BBGHQ, even though both agents slightly decrease the induction of p21. Finally, both catalase and deferoxamine, which decrease the generation of reactive oxygen species, block the cytotoxicity and cell cycle arrest caused by BBGHQ, presumably because both block MAPK activation and p21 induction. In summary, the data suggest that in LLC-PK1 cells, BBGHQ causes cytotoxicity and growth arrest via independent pathways. Cytotoxicity is associated with induction of MAPKs, while growth arrest is associated with p53-dependent p21 induction. The relationship between these two pathways is being further investigated. (ES 07359)

1341 DECOUPLING OF BREVETOXIN'S FOUR DISTINCT PHYSIOLOGICAL EFFECTS ON VOLTAGE-GATED SODUIM CHANNELS BY SITE-DIRECTED TOXIN DERIVATIZATION.

D G Baden[1], K S Rein[2], and D J Adams[3]. [1]*NIEHS Marine and Freshwater Biomedical Sciences Center, University of Miami, Miami, FL, USA;* [2]*Florida International University, Miami, FL, USA;* [3]*University of Queensland, Brisbane, Australia.*

The polyether brevetoxins (PbTx) are a series of toxins produced by the marine dinoflagellate *Gymnodinium breve*. This dinoflagellate is the organism responsible for Florida's massive red tides, and also causes neurotoxic shellfish poisoning in humans and numerous epizootics of manatees, birds, fish, and other wildlife. The toxins are composed of a series of 10-11 ether rings exhibiting *trans/syn* orientation. All natural brevetoxins, and there are 10 different natural derivatives, induce four separate and distinguishable physiological effects when applied to voltage-gated sodium channels under patch clamp conditions: a shift of the activation potential to more negative values, a prolonging of mean open time, an inhibition of inactivation, and induction of subconductance states. Of 26 derivatives previously examined for their affinity at Site 5 associated with the voltage gated sodium channel, 3 have been subsequently found to differ in one or more of the above-identified physiological effects. 1-desoxy-PbTx-3 inhibits inactivation and shifts the activation potential to more negative values but has no effect on prolonging mean open time nor does it reveal subconductance states. Truncated-PbTx-3 (deficient in four sequential rings comprising a spacer region) only shifts the activation potential to more negative values. 2,3 dihydro-PbTx-3 possesses all four effects of native toxin, but reveals an additional 3 subconductance states for a total of 5 conductance states. These results assist in providing a molecular view of the portions of the brevetoxin molecule responsible for each of the four activities present in native toxin. The A-ring, or "head end" of the toxin appears involved in inhibiting inactivation, in promoting the visualization of subconductance states, and in prolonging mean open time. The mere act of binding causes the shift in activation potential and involves the H-K ring region distal from the activity region in the A-ring. Further, the length of the spacer region appears important in delivering toxin loci into environments within the channel to allow for full expression of toxin action.

1342 BREVETOXINS INDUCE A NEUROTOXIC RESPONSE IN CULTURED RAT CEREBELLAR GRANULE NEURONS THAT IS MEDIATED BY NMDA RECEPTORS.

F W Berman and T F Murray. *Dept. of Physiology and Pharmacology, College of Veterinary Medicine, Univ. of Georgia, Athens, GA, USA.* Sponsor: R P Sharma.

Brevetoxins (designated PbTx-1 to -10) are potent lipid-soluble polyether compounds which are known to bind to and modulate voltage-gated sodium channel activity. These toxins have been implicated in massive fish kills and human intoxications during 'red tide' blooms of the marine dinoflagellate *Ptychodiscus brevis*. To investigate whether brevetoxins produce direct CNS neurotoxic effects, cultured rat cerebellar granule neurons were exposed to brevetoxins in Locke's buffer for 2 hrs at 20° C. Neuronal injury was quantified by assaying lactate dehydrogenase activity in the exposure buffer and in conditioned growth media collected 22 hrs post-brevetoxin exposure. Brevetoxins produced acute neuronal injury and death in neurons with a rank order potency similar to their previously determined affinities for binding to recognition sites on the sodium channel. The neurotoxic response could be prevented by co-application of the sodium channel antagonist tetrodotoxin. Brevetoxin toxicity was also prevented by the co-application of the competitive and non-competitive N-methyl-D-aspartate (NMDA) receptor antagonists D-AP5 and dizocilpine, ketamine, dextromethorphan and dextrorphan, respectively. NMDA receptor antagonists afforded neuroprotection at potencies comparable to those measured previously for protection against glutamate-induced excitotoxic responses. These data indicate that brevetoxin-induced injury in cultured rat cerebellar granule neurons is mediated by NMDA receptors that are activated indirectly as a consequence of PbTx-induced sodium channel activation. (Supported by funds from the College of Veterinary Medicine, Univ. of Georgia.)

1343 OXIDIZED CEREBROSPINAL FLUID LIPOPROTEINS CAUSE MICROTUBULE DISRUPTION AND CYTOTOXICITY IN NEURO 2A CELLS.

M D Neely, L L Swift, K R Sidell, D G Graham and T J Montine. *Department of Pathology, Vanderbilt University Medical Center, Nashville, TN.*

Several neurotoxicants (among them heavy metals and organic solvents) cause changes in the prooxidant status of neurons. Reactive oxygen species have been postulated to be mediators of a "final common pathway" in several mechanisms of neurotoxicity. The nervous system, with its high oxygen consumption and enrichment of polyunsaturated fatty acids is particularly vulnerable to lipid peroxidation. Cerebrospinal fluid (CSF) lipoproteins are a likely vehicle for products of lipid peroxidation. However, little is known about the effect of oxidized CSF lipoproteins on neurons. We therefore oxidized human CSF lipoproteins and analyzed their effects on Neuro 2A cells. Oxidation of CSF lipoproteins resulted in covalent modifications of apolipoproteins E and AI and loss of polyunsaturated fatty acids, but caused no changes in the ultrastructure of the lipoproteins as analyzed by electron microscopy. We have previously shown that 4-hydroxynonenal, a major product of lipid peroxidation, causes microtubule disruption in Neuro 2A cells (Neely et al., 1998, Toxicologist:547a). Like 4-hydroxynonenal, oxidized CSF lipoprotein caused microtubule disruption in Neuro 2A cells within 1 hour of exposure. When the cells were exposed for longer periods, the oxidized lipoproteins eventually induced cell death. We conclude that oxidized CSF lipoproteins can cause microtubule disruption and neuronal cell death. The mechanism(s) for these effects are the focus of our investigation. (NIH grants AG00774 and ES02611, American Foundation for Aging Research.)

1344 γ-DIKETONE NEUROPATHY: I. QUALITATIVE NEUROPATHIC ASSESSMENT.

J H Fox[1], B S Jortner[1], E J Lehning[2], R M LoPachin[2], S K Perkins[1] and D Ward[1]. [1]*Laboratory for Neurotoxicity Studies, Virginia Tech, Blacksburg, VA;* [2]*Anesthesia Research, Albert Einstein College of Medicine, Bronx, NY.*

Exposure to 2,5-hexanedione (HD), the neurotoxic metabolite of n-hexane and other hexacarbons, causes a central-peripheral distal axonopathy characterized by axonal swelling and atrophy. To explore the spatiotemporal relationship of these morphologic changes to dosing rate and behavior, we conducted a comprehensive morphometric and molecular study of HD-induced peripheral neuropathy (see companion abstracts- Lehning et al., Chiu et al.). Rats were intoxicated at 3 daily dosing rates (175, 250 and 400 mg/kg/d) and were sacrificed at unaffected to severe behavioral end-points. Lumbar spinal nerves (5th), proximal and distal sciatic nerves and distal posterior tibial nerves were removed from perfused animals and were subjected to blinded qualitative morphologic evaluation. Also, swollen and atrophic axons were counted within selected nerve fields (x1000). All dosing rates produced axonal atrophy and swellings in peripheral nerve regions. However, swellings were very rare in the 400 mg/kg/d treatment group whereas, regardless of dosing rate, atrophied axons were abundant. For the 175 and 250 mg/kg/d groups, the incidence of atrophy increased as a linear function of distal distance along the nerve axis. Axonal swellings in these groups were initially present in tibial nerve (day 42) and then moved into sciatic regions as treatment continued. Axonal degeneration was not a prevalent feature of any HD dosing rate. In addition to these axonal changes, the 175 and 250 mg/kg/d groups displayed late-onset macrophage infiltration and bands of Bungner development. Results provide a basis for quantitative morphometric analyses and indicate that axonal atrophy is a significant component of HD neuropathy. Expression of swellings appears to be related to the length of neurotoxicant exposure. (Supported by NIEHS grant RO1 ES07912.)

1345 γ-DIKETONE NEUROPATHY: II. MORPHOMETRIC ANALYSES OF AXONAL ATROPHY AND SWELLING.

E J Lehning[1], B S Jortner[2], J H Fox[2], F C Chiu[1], and R M LoPachin[1]. [1]*Albert Einstein College of Medicine, Bronx, NY;* [2]*Virginia Tech, Blacksburg, VA.*

We hypothesized axonal atrophy is a consistent neuropathic feature of γ-diketone neuropathy which is manifest regardless of dose rate. In contrast, expression of axonal swelling is an epiphenomenon related to subchronic low-level exposure (LoPachin and Lehning, *NeuroToxicology 18:7-22, 1997*). To investigate this hypothesis, rats were exposed by gavage to 3 dosing rates (175, 250 or 400 mg/kg/d) of 2,5-hexanedione (HD) up to the endpoint of severe hindlimb weakness (99, 69 and 22 days, respectively). Throughout exposure, morphometric techniques were used to quantify axonal atrophy and swelling in 4 proximodistal locations of the sciatic nerve. Axonal atrophy was a prominent response to all HD dose rates. Atrophy initially manifested distally (tibial nerve) and spread proximally to lumbar spinal nerves with continued dosing. For all dose rates and nerve regions, atrophy was characterized by progressive decreases in size which culminated in a 50-67% loss in median axon area in the majority of myelinated axons. Significant changes in axonal shape also accompanied atrophy. The number and size of axonal swellings correlated inversely to dose rate but directly to length of exposure, i.e., as dose rate decreased and length of exposure increased, axonal swellings were larger and more frequent. Regardless, axonal swellings were very infrequent in nerves of rats exposed to 400 mg HD/kg/d (<0.5%) and never constituted >10% of the population of myelinated axons in all nerves of rats from the other dose rates. These results indicate expression of axonal swellings is rare and is dependent upon subchronic low-level exposure. Thus, swellings might not have mechanistic or functional importance. In contrast, axonal atrophy is a consistent and prominent neuropathic response to HD exposure which can manifest in the absence of axonal swelling. This suggests axonal atrophy is a relevant mechanistic component of γ-diketone neuropathy. Companion abstracts (Fox et al., Chiu et al.) present the effects of HD dose rate on qualitative neuropathology and neurofilament subunit content. (Supported by NIEHS Grant RO1 ES07912.)

1346 γ-DIKETONE NEUROPATHY: III. NEUROFILAMENT SUBUNIT CONTENT.

F C Chiu, R Malchie, D K He, E J Lehning and R M LoPachin. *Anesthesia Research, Albert Einstein College of Medicine, Bronx, NY.*

Quantitative morphometric analysis (see companion abstract; Lehning et al.) indicates axonal atrophy is a consistent component of γ-diketone peripheral neuropathy. To determine the molecular mechanism of atrophy, rats were exposed to 2,5-hexanedione (HD; 250 mg/kg /day) by oral gavage and development of neurotoxicity was assessed daily by gross behavioral indices. At endpoint, proximal sciatic and distal tibial nerve segments were removed, stripped of endoneurium and homogenized. Aliquots of nerve homogenates containing equal proteins were separated by electrophoresis, transferred to membranes and probed with monoclonal antibodies against neurofilament subunits (NF-L, NF-H) and β-tubulin. Immunoreactive bands were visualized and quantified in a densitometric scanner. Respective NF-L and NF-H contents in nerve regions from moderately affected, HD-treated rats were significantly reduced; i.e., in proximal sciatic, NF-L decreased to

50% of control, while in distal tibial nerve, NF-L content decreased to 34% of control. Smaller reductions were observed for NF-H in both peripheral nerve segments. Loss of neurofilament protein was generally greater in tibial than in proximal sciatic nerve. Decreased NF subunit content appears to be specific since no significant changes in β-tubulin were detected in nerve regions. Abnormal high MW NF-L and –H positive bands were not consistently observed. When present, these bands did not correlate with proximodistal reductions in native proteins. Thus, loss of NF subunits and inconsistent expression of high MW species do not support cross-linked proteins as a mechanistic feature of γ-diketone neuropathy. Moreover, reduced axonal NF content might underlie development of atrophy in HD-treated animals. (Supported by NIEHS grant RO1 ES07912.)

1347 ROLE OF CALCINEURIN AND IMMUNOPHILINS IN THE DECREASE OF BRAIN ENERGY METABOLISM CAUSED BY IMMUNOSUPPRESSANTS.

N Serkova[1], L Litt[2], T L James[3], R E Morris[4], L Z Benet[1] and U Christians[1]. *Depts. of [1]Biopharmaceutical Sciences, [2]Anesthesia, and [3]Pharmaceutical Chemistry, University of California at San Francisco, CA, and [4]Dept. of Cardiothoracic Surgery, Stanford University, CA, USA.* Sponsor: D E Johnson.

Neurotoxicity is one of the major side effects of the immunosuppressants cyclosporine (CsA) and tacrolimus (FK506) after organ transplantation. Recently we demonstrated that CsA- and FK506-induced reduction of high energy phosphate concentrations is the leading cause for *in vitro* toxicity in rat brain slices. Since binding to immunophilins and calcineurin is required for immunosuppressive activity of both drugs, it was our objective to study whether or not calcineurin and/ or immunophilins are involved in the reduction of high energy phosphate concentrations in brain. We used ^{31}P-MRS of perfused rat brain slices to evaluate the energy state during perfusion with immunosuppressants. CsA and FK506 led to significant decreases of high energy phosphates (phosphocreatine, PCr to -27± 4%; nucleoside triphosphates, NTP to -22± 6%; P<0.01; n=3) at concentrations as low as 500 μ g/L. Although calcineurin is not involved in its immunosuppressive mechanism of action, the new macrolide immunosuppressant sirolimus (rapamycin) also decreased brain energy metabolism (PCr:-17± 2% and NTP: -10± 5%; P<0.01; n=3). However, the sirolimus derivative SDZ RAD (40-O-(2-hydroxyethyl)-rapamycin) did not significantly affect high energy phosphate concentrations (PCr: +3± 6%; NTP: +3± 5%; n=3). Since SDZ RAD and sirolimus are both substrates of the same immunophilin, FKBP, our results suggest that immunophilins are not involved in the reduction of brain energy metabolism by sirolimus. We conclude that reduction of high energy phosphate concentrations in the brain caused by cyclosporine, tacrolimus and sirolimus involves a calcineurin- and immunophilin-independent pathway.

1348 GLUTATHIONE AND ANTIOXIDANTS PROTECT AGAINST THE *IN VITRO* TOXICITY OF METHYL IODIDE TO CEREBELLAR GRANULE CELLS.

M P Chamberlain[1], N C Sturgess[2], E A Lock[2], and C J Reed[1]. [1]*Liverpool John Moores University, Liverpool, UK;* [2]*Zeneca Central Toxicology Laboratory, Cheshire, UK.*

Methyl iodide (MeI) induces toxicity in several organs including the central nervous system. The aim of this work was to ascertain if glutathione (GSH) and certain antioxidants could afford neuroprotection. Primary cultures of rat cerebellar granule cells were prepared from post-natal day 8 rats and maintained in a serum free medium plus 25mM KCl for 8 days prior to exposure. Cells were exposed to MeI (0-10mM) for 5 min and cytotoxicity assessed over 48h using the Live/Dead assay (Molecular Probes). For the neuroprotection studies, cells were preincubated with L-buthionine sulphoximine (BSO, 0.5mM) or the isopropylester of GSH (IP-GSH, 1mM) for 1h prior to exposure to MeI for 5min at 1 or 2mM respectively, and then maintained in the presence or absence of the GSH modulating agent for 24h. Cells were also exposed to 1.6mM MeI for 5min in the presence of vitamin E (10μ M), butylated hydroxytoluene (25μ M) or desferrioxamine (1mM) and viability determined after culture for 24h in the presence of antioxidant. MeI produced a concentration dependant loss of cerebellar cell viability, with an EC_{50} of 1.6mM at 24h. BSO potentiated the toxicity of MeI, while IP-GSH and all three antioxidants afforded protection. These studies indicate that conjugation with GSH is a detoxification pathway and that GSH is neuroprotective. Conjugation with GSH results in depletion of this critical cellular antioxidant. Thus provision of additional GSH or exogenous antioxidants protects the cells from the ensuing oxidative stress.

1349 EFFECTS OF ACUTE IBOGAINE ADMINISTRATION ON THE PERFORMANCE OF COMPLEX OPERANT TASKS IN RATS.

Z Xu[2], A J Mayorga[1], C M Fogle[1], A Scallet[1], L W Chang[2], W Slikker[1], and M G Paule[1]. [1]*Division of Neurotoxicology, National Center for Toxicological Research / FDA, Jefferson, AR, USA;* [2]*Dept. of Pathology, University of Arkansas for the Medical Sciences, Little Rock, AR, USA.*

Ibogaine is a psychoactive compound that has been reported to ameliorate withdrawal symptoms in humans and to interrupt the addiction process. However, a 100 mg/kg i.p. dose has previously been shown to produce consistent neurodegeneration of cerebellar Purkinje cells in rats. In the present study, the behavioral effects of ibogaine were assessed using performance on a complex battery of food-reinforced operant tasks. One group of rats (n=6) performed a temporal response differentiation (TRD) task, which requires subjects to press and hold a lever in the depressed position for a 10-14 second "window." The second group of rats (n=6) performed a conditioned position responding (CPR) task to assess auditory, visual, and position discrimination. The TRD and CPR tasks were both paired with a progressive ratio (PR) task to assess aspects of motivation in the same test session. Administration of a single dose of 100 mg/kg ibogaine hydrochloride (i.p.) produced a statistically significant decrease in the number of reinforcers earned and accuracy in the TRD task, without significantly changing the overall rate of responding. This effect recovered one day after ibogaine administration. In the CPR task, ibogaine significantly decreased both the rate and the accuracy of responding. The effect on CPR accuracy recovered one day after ibogaine administration and the effect on response rate recovered after two days. The PR task was differentially sensitive to ibogaine administration depending on whether it was paired with TRD or CPR. These results demonstrate that certain acute behavioral effects of ibogaine are reversible, and suggest that further studies correlating the acute neurochemical and/or neuropathological effects of ibogaine administration with its behavioral effects are necessary.

1350 CYTOTOXICITY OF 2-HALOPROPIONIC ACIDS TO CEREBELLAR GRANULE CELLS IN CULTURE.

N C Sturgess, B E Birtwistle and E A Lock. *Zeneca Central Toxicology Laboratory, Cheshire, UK.*

Daily administration to rats of L-2-chloropropionic acid (L-2-CPA) 2-bromo- (2-BPA) and to a lesser extent 2-iodo- (2-IPA) but not 2-fluoro-propionic acid (2-FPA) produces selective cerebellar granule cell necrosis. Evidence suggests that the mechanism of neurotoxicity may involve cerebellar granule cell N-methyl-D-aspartate (NMDA) receptors as dizocilpine affords protection against L-2-CPA neurotoxicity *in vivo*. The aim of this study was to determine the toxicity of these 2-haloacids in primary cultures of rat cerebellar granule cells and whether the toxicity was NMDA receptor mediated. Primary cultures of rat cerebellar granule cells were prepared from post-natal day 8 rats and maintained in a serum free medium plus 25mM KCl for 8 days prior to exposure. Cells were continuously exposed to the 2-haloacids over 24, 48 or 72h and cytotoxicity assessed using the Live/Dead assay (Molecular Probes). All compounds produced a time and concentration dependant loss of cerebellar granule cell viability. With L-2-CPA the EC_{50} values were >10mM, 6.2 ± 1.1mM and 3.7 ± 0.8mM for 24, 48 and 72h respectively. Dizocilpine (3μ M) afforded complete protection at 24h but only partial protection at ≥ 3mM when exposure was for 48 or 72h. The EC_{50} for 2-BPA, 2-IPA and 2-FPA for 24h exposure were 0.5 ± 0.1mM, 0.3 ± 0.1mM and 1.7 ± 0.1mM respectively. The addition of dizocilpine with these analogues did not afford protection. These studies indicate that 2-halopropionic acids are toxic to rat cerebellar granule cells *in vitro*, and that the initial component of this toxicity with L-2-CPA occurs via an NMDA receptor dependant mechanism.

1351 PHARMACOLOGICAL MODULATION OF BEHAVIORAL CONVULSIONS INDUCED BY TRIMETHYLOLPROPANE PHOSPHATE (TMPP).

J Rossi III[1], G D Ritchie[2], S M McInturf[2], and A F Nordholm[1]. [1]*Naval Health Research Center Detachment-Toxicology and* [2]*Geo-Centers, Inc., Wright-Patterson AFB, OH, USA.* Sponsor: E A Smith.

TMPP {4-ethyl-1-phospha -2,6,7-trioxa-bicyclo-[2.2.2]- octane-1-oxide} is a potent bicyclophosphate convulsant in rats, hypothesized to act through binding to the picrotoxinin receptor site of the GABAA ionophore complex. Because TMPP can be produced through the partial pyrolysis of certain syn-

thetic lubricants or polyurethane foams, there is concern for accidental human exposure. Last year, we reported that the frequency and duration of EEG paroxysms induced in Fischer-344 rats by subconvulsive (0.20 mg/kg ip) administrations of TMPP could be effectively controlled with ethosuximide (ESM)+CGP 35348 > ESM > diazepam (DZP)+CGP 35348 > DZP > CGP 35348 > Phenobarbital (PB)+CGP 35348 > PB pretreatment. In the present study, young adult Fischer-344 rats were treated with PB (5-40 mg/kg), DZP (1-10 mg/kg), DNQX (5-20 mg/kg), scopolamine (SCOP; 1-5 mg/kg), tiagabine (TGB; 1-10 mg/kg) or MK-801 (0.5-3.0 mg/kg) 30 min prior to ip injection with a convulsive dose of TMPP (0.6 mg/kg). Rats were rated for convulsive activity for 2 hr post-injection. Time from TMPP injection to observation of subclinical seizures, generalized seizures and lethality, as well as frequency and duration of convulsive activity was rated for each pretreatment group. Convulsions were suppressed by DZP > PB > TGB > MK-801 > DNQX > SCOP.

1352 PAROXYSMAL DISCHARGES INDUCED BY TRIMETHYLOLPROPANE PHOSPHATE (TMPP) IN RAT HIPPOCAMPAL PYRAMIDAL CELLS.

J Lin[3], G D Ritchie[2], A F Nordholm[1], and J Rossi III[1]. [1]*Naval Health Research Center Detachment-Toxicology;* [2]*Geo-Centers, Inc.; and* [3]*ManTech Environmental Technology, Inc., Wright-Patterson AFB, OH, USA.* Sponsor: E A Smith.

The actions of TMPP, a potent convulsant, were tested on hippocampal CA1 pyrmaidal cells using intracellular electrophysiological methods *in vitro*. Eighty percent of neurons tested exhibited spontaneous activities (0.03-4.5 Hz). Bath applications of TMPP (0.1-100 *u*M) caused membrane hyperpolarization (7±2 mV, n=7) associated with an increase in input resistance (51±8%, n=7) in 41% (7 of 17) of neurons tested, and membrane depolarization (3.7±0.5 mV, n=5) associated with an increase in input resistance (18±3%, n=5) in 29% (5 of 17) of neurons tested. TMPP (0.1-100 *u*M) induced short epileptiform discharges followed by epileptiform burst afterdepolarizations in 59% (10 of 17) of neurons tested. TMPP (0.1-100 *u*M) also increased the spontaneous activities (101±23% increase, n=7) in 41% (7 of 17) of neurons tested and decreased spontaneous activities (56±8% decrease, n=9) in 53% (9 of 17) of neurons tested. The epileptiform bursts and increases in spontaneous activities induced by TMPP were blocked by muscimol (0.5-10 *u*M; n=4), a GABAA agonist, diazepam (0.5-10 *u*M), a GABAA-benzodiazepine receptor agonist (n=4), and baclofen (10 *u*M), a GABAB receptor agonist. Bath application of muscimol (0.5-10 *u*M; n=4), diazepam (0.5-10 *u*M; n=3), or baclofen (1-10 *u*M) abolished the spontaneous activities of CA1 neurons. TMPP (2-10 *u*M) reversed the actions of muscimol and diazepam but not baclofen. TMPP (0.1-100 *u*M) did not induce any changes in threshold, duration and amplitude of the action potentials (APs) evoked by direct depolarizing current injection but increased the latency to onset of the APs. (n=6). In summary, TMPP has excitatory and inhibitory actions on CA1 pyramidal cells. The actions of TMPP may be due to its interaction with GABAA-benzodiazepine receptors.

1353 IN VIVO ASSESSMENT OF PERIPHERAL BENZODIAZEPINE RECEPTOR LEVELS IN A BABOON BRAIN FOLLOWING PERMANENT CAROTID ARTERY OCCLUSION.

A C Kuhlmann[1], M K Nihei[1], V Villemagne[2], F Yokoi[2], R J Adams[3], D F Wong[2], R F Dannals[4] and T R Guilarte[1]. [1]*Dept. Environmental Health Sciences, School of Public Health;* [2]*Dept. Radiology,* [3]*Div. Comparative Medicine,* [4]*Div. Nuclear Medicine, School of Medicine, The Johns Hopkins University, Baltimore, MD, USA.*

Peripheral benzodiazepine receptors (PBR), normally found in low concentrations in the brain, are increased in response to ischemia, chemically induced neurotoxicity, and in some neurodegenerative diseases. The PBR response in baboon brain (*Papio anubis*) following permanent ligation of the left common carotid artery (LCCA) was characterized by positron emission tomography (PET). [^{15}O]-H_2O PET was used to estimate regional cerebral blood flow 22 days after LCCA occlusion. PBR levels were subsequently assessed by [^{11}C]-PK11195 PET. Reductions of blood flow were measured in left frontal (12.1%), parietal (12.8%) and occipital (18.7%) cortical areas compared to the contralateral, intact hemisphere. Despite the reduction in cerebral blood flow, [^{11}C]-PK11195 binding was increased by 1.2%, 11.5% and 7.9% in frontal, temporal and parietal regions, respectively. Eight days later, the animal was euthanized and the brain was rapidly removed and frozen. Coronal sections of the occipital lobe were processed for [^{3}H]-PK11195 autoradiography. Preliminary evidence suggest PBR levels are increased by as much as 114% in the dorsal occipital gray matter. Smaller or no change was observed in the ventral regions. This study indicates that [^{11}C]-PK11195 PET may be a useful tool for assessing the *in vivo* PBR response to neuronal damage. (Supported by NIEHS grant #ES07062 to TRG.)

1354 DEVELOPMENT OF IN VITRO SCREENING ASSAYS FOR POTENTIALLY NEUROTOXIC POLYCYCLIC AROMATIC HYDROCARBONS IN C6 RAT GLIOMA CELLS.

D Alexander, K C Donnelly and E Tiffany-Castiglioni. *Department of Veterinary Anatomy and Public Health, Texas A&M University, College Station, TX.*

The C6 rat glioma cell line has properties of a bipotential glial progenitor cell with both astroglial and oligodendroglial characteristics. As such, C6 cells are a model for glial toxicity in the developing brain. Very little is known about the potential neurotoxicity of polycyclic aromatic hydrocarbons (PAHs). In the present study we examined the effects of of three PAHs: benzo(a)pyrene, chrysene, and anthracene. Two assays were used to assess cytotoxicity: trypan blue dye exclusion and amino acid incorporation. C6 cells were treated for 4 and 7 days with 0.03 to 30 μM of each compound. With both assays and at all dosages of each compound, no significant effect was observed when compared to controls. The relative insensitivity of the above assays, even after prolonged exposure at high doses, indicates that cytotoxicity is an inadequate measure of potential PAH toxicity in glia. We have previously observed alterations in intracellular Ca^{2+} and translocation of protein kinase C as a result of exposure of C6 cells to low levels of halogenated aromatic hydrocarbons. Such assays may be more useful for the detection of potential neurotoxicants. (Supported by ATSDR #U61/ATU684505-01.)

1355 FIXED-INTERVAL PERFORMANCE FOLLOWING DEVELOPMENTAL EXPOSURE TO A1254, A COMMERCIAL POLYCHLORINATED BIPHENYL MIXTURE.

M M Taylor, K M Crofton, R C MacPhail. *Neurotoxicology Division, NHEERL, US EPA, Research Triangle Park, NC, USA.*

Lilienthal et al. (1990) reported that adult male rats, developmentally exposed to the commercial polychlorinated biphenyl (PCB) mixture (Clophen A30), displayed dose-dependent reductions in the post-reinforcement pause (PRP) and the index of curvature (IOC) on a fixed-interval 30-sec (FI 30-sec) schedule of food reinforcement. These results suggested that the temporal patterning of FI responding was disrupted by exposure to this PCB mixture. We tested whether a disruption in FI patterning could be achieved following perinatal exposure to another PCB mixture, Aroclor 1254 (A1254). Primiparous Long Evans rats were exposed to 0 or 6 mg/kg/day A1254 via oral gavage from Gestation Day 6 (GD6) through Postnatal Day 21 (PND21). At approximately PND90, male and female offspring (n=8/gender/treatment) were food deprived (85% free-feeding weight) and then trained to lever press for food reinforcers. Once the response was reliably emitted, a FI 30-sec schedule of reinforcement was introduced and remained in effect for 31 sessions. Under this schedule, reinforcement was available after 30 sec had elapsed since the previous reinforcement. There were no treatment-related effects on any aspect of FI 30-sec performance (IOC, PRP, or response rate). On the 32nd session the schedule requirement increased to FI 5-min for 69 additional sessions. For all animals, independent of treatment, there was a decrease in rate and IOC, and an increase in PRP, when the schedule was switched to FI 5-min. After approximately 30 sessions, the IOC gradually recovered to the asymptotic levels obtained under FI 30-sec, while responding persisted at a lower rate. These results, however, did not reveal a dose-related effect on any performance measure. These data are inconsistent with previous findings and suggest that A1254 may not affect fixed-interval performance in the same manner as did Clophen A30.

1356 PERFORMANCE ON A SPATIAL MEMORY TASK IN ADULT RATS FOLLOWING PERINATAL EXPOSURE TO AROCLOR 1254.

W R Mundy, B A Allen, E S Craft, M E Gilbert, P R S Kodavanti, K M Crofton. *Neurotoxicology Division, NHEERL, US EPA, RTP, NC, USA.*

Performance deficits in learning and memory tasks have been associated with PCB exposure in children and in animal models. The current work was designed to determine the effects in adult offspring of maternal exposure to Aroclor 1254 (A1254; Lot#124-191; AccuStandard), a commercial PCB

mixture that contains dibenzofuran contaminants. Primiparous rats (22-24/dose) received 0 (corn oil) or 6 mg/kg A1254 (po) from gestation day six through postnatal day 21 (PND21). We assessed one male and female per litter beginning approximately 90 days after birth on a reference memory task and a working memory task in a Morris-type water maze. Animals were tested in two blocks, approximately 6 months apart. Animals were first trained on a acquisition task where testing consisted of two trials per day for four weeks (5 days/week). Latency to reach the platform was the dependent variable. Following asymptotic performance in the fourth week, animals (first block only) were tested for five days on a repeated acquisition task; two trials per day, with the platform location changed every day (working memory). The latency difference between the two trials was used as the dependent variable. There were no treatment related effects on any dependent measures in reference or working memory tasks. These data suggest that maternal A1254 exposure does not affect spatial memory as assessed in the water maze.

1357 EFFECTS OF AROCLOR 1254 PRE-TREATMENT ON GABA INDUCED CHLORIDE INFLUX CULTURED CORTICAL NEURONS: A FLUORESCENCE IMAGING STUDY.

J R Inglefield and T J Shafer. *Neurotoxicology Division, NHEERL, USEPA, Research Triangle Park, NC.*

GABA receptors are modulated by many endogenous ligands, drugs, and chemicals including, pregnane steroids, hormones (e.g. T3 & T4), barbiturates, benzodiazepines, and chlorinated insecticides. Polychlorinated biphenyls (PCBs) are developmentally neurotoxic to humans and may act through a variety of mechanisms, including thyroid hormone level disruption, sex steroid mimicry, and Ca homeostasis impairment. We sought to determine whether PCBs may also interact at the GABA receptor by examining muscimol–induced [Cl changes in mature cortical neurons using fluorescence imaging. Rat P0 cortical neurons cultured for 5-19 days in vitro (DIV) on a feeder–layer of glia in DMEM containing 10% horse serum were loaded with the permeant form of a Cl sensitive dye, MEQ. Muscimol–induced Cl influx in cortical cultures underwent time dependent maturation. At DIV 5–6, muscimol (25 μ %ÀM) stimulated net Cl efflux from cells, whereas at DIV 7–14, muscimol stimulated Cl influx (equivalent to 6–8 mM net accumulation inside the cell following 1 min of continuous application). Mature responses exhibited classical GABA pharmacology, being dose–dependent (0–50 μ %M muscimol), potentiated by the neurosteroid allopregnanolone (50 nÿþM), and blocked by the non competitive antagonist, lindane (50 μ %ÀM). To begin to investigate whether PCBs interfere with GABA receptor function, Aroclor 1254 (Ultra Scientific; 20 μ %M in 3 mL 0.1% DMSO) was added to the cultures for 13.5 hr. Exposures of this concentration and duration did not result in overt cytotoxicity as assessed with propidium iodide staining. In functional studies from 7–8 DIV cells, muscimol–induced Cl influx in PCB–exposed cells was significantly ($P<0.05$) less than the response in control cells. In addition, the response frequency distribution of PCB–treated cultures was shifted to lower values. These results suggest that Aroclor 1254 interferes with GABA–stimulated Cl influx in cortical cells. Studies are underway to determine concentration– and time–responses as well as whether the receptor per se or intracellular chloride regulation (or both) is the target.

1358 DEVELOPMENTAL EXPOSURE TO AROCLOR 1254 PRODUCES A PERSISTENT DECREMENT IN THE MAGNITUDE OF LONG-TERM POTENTIATION IN THE DENTATE GYRUS *IN VIVO*.

M E Gilbert[1,2] and K M Crofton[2]. [1]*National Research Council,* [2]*Neurotoxicology Division, NHEERL, Neurotoxicology, US EPA, RTP, NC.*

Developmental exposure to polychlorinated biphenyls (PCBs) has been associated with cognitive deficits in children. A model of synaptic plasticity, long-term potentiation (LTP) is believed to represent memory at the synaptic level and has been extensively studied in the hippocampus. We examined the consequences of developmental exposure to a complex PCB mixture, Aroclor 1254 (A1254), on physiology and plasticity in the dentate gyrus of the adult rat *in vivo*. Pregnant dams were exposed to 6 mg/kg/day of A1254 from GD6 to PN21. This dosage of A1254 is associated with low-frequency hearing loss and reduced thyroid hormone concentrations in offspring during the early postnatal period. Between 5-7 months of age male offspring were anesthetized with urethane and stimulating and recording electrodes were placed in the perforant path and dentate gyrus. In the first experiment, input/output (I/O) functions were collected before and after a single series of high frequency (400 Hz) trains delivered at a moderate stimulus intensity (300 μA). The second experiment was performed on similarly exposed animals, but multiple train sets were delivered in an ascending series of train intensities (25-300 μA) to determine the effects of A1254 exposure on LTP threshold. Systematic A1254-induced alterations in baseline synaptic transmission as assessed by I/O functions were not observed in either experiment prior to the delivery of LTP-inducing trains. Posttrain I/O functions, however, revealed a reduced magnitude of LTP of the population spike (PS) in A1254-exposed animals relative to controls in both experiments. Effects on LTP of the EPSP slope were in the same direction but more variable and differences did not reach statistical significance. The mechanisms whereby this A1254 exposure leads to impairment in LTP are not known. However, disruption of the neurobiological processes that support hippocampal plasticity may contribute to the cognitive deficits observed following developmental exposure to A1254.

1359 THE EFFECTS OF DEVELOPMENTAL EXPOSURE TO POLYCHLORINATED BIPHENYLS ON D_1 AND D_2 DOPAMINE RECEPTORS IN JUVENILE AND ADULT RATS.

J A Guarisco, R I Carr, and J E Chambers. *Center for Environmental Health Sciences, College of Veterinary Medicine, Mississippi State University, Mississippi State, MS.*

Polychlorinated biphenyls (PCBs) are a class of halogenated aromatic hydrocarbons that have been shown to cause neurological dysfunction in humans and laboratory animals. PCBs have been shown to inhibit tyrosine hydroxylase and L-aromatic amino acid decarboxylase, two enzymes involved in the synthesis of dopamine. This inhibition may lead to a decrease in dopamine concentration. This project explores the possibility that dopamine receptors may up regulate in order to compensate for the postulated decrease in dopamine concentration. Pregnant Sprague-Dawley rats were administered 4mg/kg/day Arochlor 1254 in safflower oil p.o. beginning on gestation day 6 and ending on post-natal day 22. Pups from each group were sacrificed at post-natal days 15, 23, 31, or 70, and brains were removed and frozen for subsequent receptor analysis. B_{max} and K_d for D_1 and D_2 receptors were determined in membrane preparations from the corpus striatum for each group using ^{3}H-SCH 23390 and ^{3}H-spiperone, respectively. Receptor binding analysis indicated no apparent change in B_{max} and K_d values for ages 23, 31 and 70 days. However, there were differences in the age 15 day animals. A slight decrease was noted in the D_1 receptor B_{max1} but the K_d was unchanged. The D_2 receptor B_{max} and K_d values were both decreased. The treatment with PCBs did not appear to disrupt the pattern of receptor development, and did not appear to result in up regulation. (Supported by EPA R 825296.)

1360 SPONTANEOUS CATECHOLAMINE RELEASE AS MEASURED BY SINGLE CELL AMPEROMETRY: DISRUPTION BY TETRANDRINE AND 2, 2',4, 4'-TETRA CHLOROBIPHENYL.

Z Heck and H J Wiegand. *Medical Institute of Environmental Hygiene at the Heinrich-Heine-University, Duesseldorf, Germany.*

The plant alkaloid tetrandrine (TET) as well as the non-coplanar PCB-congener 2,2',4,4'-tetrachlorobiphenyl (2,4-TCB) increase spontaneous release of catecholamines from bovine chromaffin cell cultures (Wiegand et al., JPET, 1996; Messeri et. al, Arch. Toxicol.,1997). To quantify their effects on the single cell level we used amperometry of catecholamine quanta released spontaneously from single cells . We treated chromaffine cell cultures with both neurotoxicants by incubation with concentrations ranging from 10-100 μ M for time periods between 1 and 5 h. After the treatments the cells remained completely unstimulated and carbon-fibre microelectrodes measured the currents due to the oxidation of catecholamines spontaneously released from single cells as reviewed by Travis and Wightman (Annu. Rev. Biophys. Biomol. Struct.. 1998). Cells from untreated cultures served as controls. TET as well as 2,4-TCB increased the spontaneous catecholamine output by enhancing the frequency of spontaneously released catecholamine quanta from chromaffin cells in concentration ranges of 10-100 and 10-50 μ M, respectively. In addition the analysis of quantal signals revealed a statistically significant change of signal shape parameters which seemed to contribute to the catecholamine output. From these experiments we conclude that TET as well as 2,4-TCB disrupt neurohormonal release by interference with molecular mechanisms of the vesicular exocytotis. (This work is part of the thesis of Z H at the Heinrich-Heine-University Medical Faculty.)

1361 5-HYDROXYTRYPTOPHAN TOXICOSIS IN DOGS.

S M Gwaltney-Brant, J C Albretsen and S A Khan. ASPCA National Animal Poison Control Center, Urbana, IL.

5-Hydroxytryptophan (5-HTP) is a nutritional supplement that has gained popularity within the alternative medical community because of its reported ability to treat conditions such as depression, chronic headaches and insomnia in humans. 5-HTP apparently exerts its effects by increasing the levels of serotonin in the body. Serotonin is a central nervous system neurotransmitter, has a stimulatory effect on smooth muscle of the gastrointestinal tract, and is a promoter of platelet aggregation. The objective of this study was to describe the clinical syndrome, toxic doses, and treatment methods associated with accidental 5-HTP ingestion in dogs. Searches of the database at the ASPCA National Animal Poison Control Center identified 15 cases of accidental ingestion of 5-HTP by dogs. Dosages of 5-HTP ingested ranged from 2.5 mg/kg to 557 mg/kg, with 27 mg/kg being the lowest dose at which clinical signs occurred. Clinical signs developed in 13 dogs (86.7%), with the onset of signs ranging from 10 minutes to 2 hours post-ingestion. The most common clinical signs included diarrhea (33%), tremors (33%), seizures (33%), hyperthermia (33%), mydriasis (27%), and ataxia (20%). In all cases where follow-up data were available (10/15), the dogs fully recovered within 24 hours with supportive treatment including anticonvulsants, IV fluids, and thermoregulation. The clinical syndrome seen in these dogs shares similarities with "serotonin syndrome" described in humans following ingestion of tryptophan or monoamine oxidase inhibitors.

1362 AN EXAMINATION OF THE BIOCHEMICAL AND BEHAVIORAL EFFECTS OF MPTP IN TWO SNAKE SPECIES.

J G Temple[1], D B Miller[2], and G T Barthalmus[3]. [1]*Mary Washington College, Fredericksburg, VA;* [2]*NIOSH, Morgantown, WV;* [3]*North Carolina State University, Raleigh, NC.*

The synthetic neurotoxicant 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) induces a Parkinsonian-like syndrome in humans and non-human primates, and also causes similar movement disorders in rodents, fish, amphibians and lizards. In this study, the behavioral and biochemical effects of MPTP were assessed in the black ratsnake *Elaphe o. obsoleta* and the banded watersnake *Nerodia f. fasciata*. We report that MPTP induces in *E. o. obsoleta* a depletion of norepinephrine, dopamine and serotonin in fore, mid and hindbrain regions and also impedes righting ability. In *N. f. fasciata*, norepinephrine and dopamine were also depleted by MPTP in all three brain regions, but serotonin was only significantly reduced in the forebrain and righting ability was not affected. This study demonstrates a behavioral and biochemical sensitivity to MPTP in *E. o. obsoleta* that differs from that in *N. f. fasciata*. This novel reptilian model is beneficial for assessing central dopaminergic and serotonergic involvement in motor control in the lower vertebrates.

1363 ACUTE AND LONG-TERM EFFECTS OF MPP+ IN CELL LINES COEXPRESSING PLASMA MEMBRANE AND VESICULAR DOPAMINE TRANSPORTERS.

G W Miller[1], S E Stephans[2], J T Greenamyre[2], and A I Levey[2]. [1]*Division of Pharmacology and Toxicology, University of Texas, Austin ,TX;* [2]*Department of Neurology, Emory University, Atlanta, GA.*

The plasma membrane dopamine transporter (DAT) and the vesicular monoamine transporter (VMAT2) have been proposed to mediate the subcellular localization and ultimate toxicity of the active metabolite of MPTP, 1-methyl-4-phenylpyridinium (MPP^+). We have generated stable neuroblastoma cell lines (SK-N-MC) expressing either DAT or both DAT and VMAT2 to examine the effects of transporter expression on toxicity. Western blotting and immunofluorescence studies confirmed the expression of the transporter proteins. Basal levels of plasma membrane [^{3}H] dopamine uptake in either untransfected or VMAT2-expressing cell lines were 100 fmol/hr/10^6 cells and were unaffected by 10 μM nomifensine. Specific plasma membrane uptake was increased by 75-150 fold in cell lines expressing either DAT or DAT and VMAT2. Specific vesicular [^{3}H] dopamine uptake in digitonin-permeabilized VMAT2 cells was 500 fmol/hr/10^6 cells. Acute metabolic responses of these cell lines to MPP^+ were followed using a microphysiometer to measure proton excretion. Within 4 min. of application, MPP^+ (100 μM) caused a significant increase in proton excretion in DAT-expressing cells, which was attenuated by pretreatment DAT uptake inhibitors. The observed response was also attenuated in DAT/VMAT2 cells. Delayed toxicity was assessed by measuring the intercalation of the fluorescent probe, ethidium homodimer, into the DNA of dead cells. MPP^+ (10-500 μM) produced dose-dependent cell death in DAT-expressing cell lines during the 48 hr period after application. The rate of cell death (V_{max}) at an MPP^+ concentration of 10 μM was at least 40-fold higher than that in untransfected cells. In a cell line expressing DAT and VMAT2 (@ 500 μM) cell death was significantly attenuated compared to cells expressing DAT alone (V_{max} 110 and 240% of control). Together these data support the hypothesis that DAT acts as a gateway for MPP^+ entry into the cell and that intracellular compartmentalization of MPP^+ by VMAT2 can circumvent toxicity. (Supported by NIEHS 09248.)

1364 METHAMPHETAMINE NEUROTOXICITY : PROTECTIVE ROLE OF SELENIUM AND INVOLVEMENT OF S-ADENOSYLMETHIONINE.

S Z Imam[1], G D Newport[1], C K Wise[2], C A Cooney[2], L A Poirier[2], F Islam[3], W Slikker Jr.[1] and S F Ali[1]. [1]*Neurochemistry Laboratory, Division of Neurotoxicology;* [2]*Division of Molecular Epidemiology, National Center for Toxicological Research/FDA, Jefferson, AR, USA;* [3]*Neurotoxicology Laboratory, Department of Medical Elementology & Toxicology, Hamdard University, New Delhi, INDIA.*

Methamphetamine (METH) is a drug of abuse known to cause dopaminergic neurotoxicity in rodents, non-human primates and humans. The present study was designed to evaluate if METH-induced dopaminergic toxicity can be protected by pre- and post-treatment with an antioxidant, selenium (Se) and how it correlates with changes in S-adenosylmethionine (SAM). Adult female C57BL/J6 mice were dosed with Se (0.5 mg/kg) in drinking water. One week later, animals were treated with 4 X 10 mg/kg METH, i.p. Se treatment was continued for the next week before mice were sacrificed, trunk blood was collected and the brains were quickly removed and dissected into caudate nucleus (CN), frontal cortex (FC) and hippocampus (HIP) for neurochemical analyses. Concentrations of dopamine (DA), serotonin (5-HT) and their metabolites 3,4-dihydroxyphenylacetic acid (DOPAC), homovanillic acid (HVA), and 5-hydroxyindoleacetic acid (5-HIAA) were measured using HPLC/EC. SAM levels were measured in these brain regions as well as in blood using HPLC/PD. METH treatment produced a significant depletion of DA and its metabolites (DOPAC & HVA) and a significant increase in SAM in CN. Pretreatment with Se prevented the depletion of DA and its metabolites and increase in the SAM level in CN resulting from the METH treatment. In contrast, SAM level was decreased in the blood of animals treated either with METH or Se but in the case of animals treated with METH and supplemented with Se, blood SAM levels were equivalent to control. These data suggest that SAM is involved in the manifestations of METH neurotoxicity and Se has a possible protective role against METH-induced neurotoxicity.

1365 INTRASTRIATAL, INTRACORTICAL, AND INTRAHIPPO-CAMPAL ADMINISTRATION OF GLUTATHIONE AND N-ACETYLCYSTEINE CONJUGATES OF α-MEHTYLDOPAMINE PRODUCES SEROTONERGIC NEUROTOXICITY.

F Bai, S S Lau, and T J Monks. *Division of Pharmacology and Toxicology, College of Pharmacy, Univ. of Texas at Austin, TX, USA.*

The serotonergic neurotoxicity of 3,4-(±)-methylenedioxyamphet-amine (MDA) and 3,4-(±)-methylenedioxymethamphetamine (MDMA) is dependent upon the systemic generation of a neurotoxic metabolite(s), the identity of which remains unclear. α-Methyldopamine (α-MeDA) is a major metabolite of both MDA and MDMA, and following oxidation to the *ortho*-quinone undergoes conjugation with glutathione (GSH). The thioether conjugates of α-MeDA maintain the ability to redox cycle and generate reactive oxygen species. We now report that direct intrastriatal or intracortical administration of 5-(glutathion-S-yl)-α-MeDA (4 X 200 nmol, 4 X 400 nmol), 2,5-*bis*-(glutathion-S-yl)-α-MeDA (4 X 150 nmol, 4 X 300 nmol), and 5-(N-acetylcystein-S-yl)-α-MeDA (4 X 7 nmol, 4 X 20 nmol) causes significant decreases in striatal and cortical serotonin (5-HT) concentrations, 7 days following the last injection. Interestingly, intrastriatal injection of 5-(glutathion-S-yl)-α-MeDA or 2,5-*bis*-(glutathion-S-yl)-α-MeDA, but not 5-(N-acetylcystein-S-yl)-α-MeDA, causes decreases in 5-HT concentrations in the ipsilateral cortex. A similar pattern of changes is seen in the ipsilateral striatum, when the thioether conjugates of α-MeDA are injected into the cortex. Intrahippocampal injection of the thioether conjugates of α-MeDA also pro-

duces significant decreases in hippocampal 5-HT concentrations. The effects of the α-MeDA thioethers are confined to 5-HT nerve terminal fields, since no significant changes in monoamine neurotransmitter levels are detected in brain regions enriched in 5-HT cell bodies (midbrain/diencephalon/telencephalon and pons/medulla). In addition, the effects of the conjugates are selective to the serotonergic system, since no significant changes are seen in dopamine and norepinepherine concentrations. The results indicate that thioether conjugates of α-MeDA may contribute to the serotonergic neurotoxicity of MDA and MDMA. (DA 10832)

1366 REPEATED EXPOSURE RESULTS IN THE LOSS OF THE NEUROPROTECTIVE PROPERTIES OF RESTRAINT-INDUCED HYPOTHERMIA IN THE SUBSTITUTED AMPHETAMINE MODEL OF STRIATAL DOPAMINERGIC NEUROTOXICITY.

E A Johnson, J P O'Callaghan and D B Miller. *Chronic Stress and Neurotoxicology Lab, Toxicology & Molecular Biology Branch, CDC-NIOSH, Morgantown, WV, USA.*

Substituted amphetamines (SA) are well-characterized striatal dopaminergic (DA) neurotoxicants in mouse and restraint stress throughout the period of dosing prevents this neurotoxicity. The mechanism of this neuroprotection is unclear but appears linked to the ability of restraint to reduce SA-induced hyperthermia. We investigated whether with repeated exposure restraint remains neuro-protective. Female C57BL6J mice received 4 s.c. inj (0.2 mls every 2 hrs) of saline (SAL) or d-methylenedioxymethamphetamine (MDMA) at a dosage of 0 or 20 mg/kg, respectively on the 0, 1 (acute restraint) or 5th (repeated restraint) day of restraint (~8 hrs duration in plastic 50 ml centrifuge tubes) and rectal temperatures were monitored. On day 1-4 mice in the repeated restraint condition received SAL. Striatal tissue was collected at 72 hrs and levels of DA, its metabolites, tyrosine hydroxylase (TH) and GFAP (an astrocyte-localized protein known to increase in response to neural injury) were used to evaluate neurotoxicity. In concert with our previous findings MDMA induced hyperthermia and caused striatal dopaminergic neurotoxicity as indicated by significant depletions of DA and TH as well as elevations in GFAP; acute restraint blocked this hyperthermia and was neuroprotective. In repeatedly restrained mice significant core temperature reductions were observed on each of the first 4 days of restraint but not during MDMA administration on the final day. Neuroprotection was not observed in repeatedly restrained mice. These data suggest that hypothermia induced by restraint is a critical factor in the neuroprotective effects of this stressor. The molecular and cellular changes associated with acute and chronic restraint stress will be the focus of future work.

1367 EFFECTS OF MULTIPLE DOSES OF *l*-EPHEDRINE ON DOPAMINE, DIHYDROXYPHENYL ACETIC ACID AND 5-HYDROXYINDOLEACETIC ACID IN BRAIN MICRODIALYSATE AND BODY TEMPERATURE.

J Tor-Agbidye, W Slikker Jr., and J F Bowyer. *Division of Neurotoxicology National Center for Toxicological Research/FDA. Jefferson, AR.*

Extracellular dopamine levels and hyperthermia are important factors in the development of the neurotoxicity of substituted amphetamines. We reported earlier that multiple doses of 40 mg/kg *l*-ephedrine (*l*-E) given at 3 hr intervals failed to produce significant decreases in caudate/putamen (CPu) dopamine levels at 7 days. Lack of a robust 5-hyroxytryptamine release may be associated with the observation that *l*-E does not produce depletions in CPu dopamine (Tor-Agbidye *et al.* Soc. Neurosci. 1998). The aim of this study was to further explore the differences in the neurotoxic potential of *l*-E versus *d*-amphetamine. Male Sprague Dawley rats (4 months) were used. The effective *l*-E dose (4 X 25 mg/kg, i.p.) was determined (dose-range finding study) and given at 2 h intervals. We studied the effects of multiple doses of *l*-E on CPu extracellular dopamine, 5-hydroxyindoleacetic acid (5-HIIA), concentrations of ephedrine and its metabolite norephedrine, and temperature using *in vivo* microdialysis in conscious, freely moving rats. Microdialysis samples were collected at 20 min intervals for up to 10 h. Dopamine levels in the microdialysate reached a peak 1.3 h (ranging from 25 ± 7 to 55 ± 15 nM) after each dose of *l*-E. Dihydroxyphenylacetic acic (DOPAC) levels dropped after each injection of *l*-E (from 1921 ± 200 nM to 250 ± 36 nM) whereas 5-HIIA concentrations remained relatively constant through out the experimental period ranging from 383 ± 55 to 533 ± 94 nM. A significant increase in the microdialysate levels of *l*-E and norephedrine was observed within the period of the first three doses. The extracellular levels of *l*-E and norephedrine plateaued after the 3rd and 4th doses of drug. In summary, multiple doses of *l*-E produced peak dopamine and DOPAC concentrations that are similar to those observed after *d*-amphetamine challenges in our previous study. However, CPu dopamine levels were only decreased by 29 %. Perhaps factors in addition to extracellular dopamine levels and hyperthermia should be considered as candidates that contribute to the neurotoxic potential of amphetamine and substituted amphetamines. (Supported by the USFDA/NCTR and Oak Ridge Associated PostGraduate Research Fellowship, Oak Ridge, Tennessee.)

1368 COPPER SULFATE PRETREATMENT INHIBITS MPP -INDUCED STRIATAL LIPID PEROXIDATION (LPO) IN MICE.

M Alcaraz-Zubeldia and C Ríos. *Department of Neurochemistry, National Institute of Neurology and Neurosurgery, Mexico City, Mexico.*

1-methyl-4-phenylpyridinium (MPP+) is the major metabolite of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) a drug which induces parkinson-like damage in several animal species. It is now accepted that MPP+ is responsible for the neurotoxic effects of MPTP in dopaminergic nigrostriatal pathway. Our group previously reported that MPTP decreases copper content (50%) in *corpus striatum*, suggesting an important role of copper in dopaminergic neurotoxicity of MPTP. In this study, we evaluated the possible effect of copper sulfate pretreatment on MPP+-induced striatal lipid peroxidation. Adult male C57-Black mice (25-30g) were injected i.p. with either copper sulfate (2.5 mg/kg) or saline. After either 30 min or 24 h, mice were injected into their right lateral ventricle with MPP+ (20μg/3μl) and 2 hours later they were killed to measure striatal lipid peroxidation (LPO). Results showed an increase of 116% in striatal LPO in mice from the MPP+ group at 24 hours as compared with control group, while a non-significant increase of 32% in LPO levels of the copper plus MPP+ group versus control values was observed. In contrast, the $CuSO_4$ pretreatment 30 minutes before the microinjection with MPP^+ was not able to decrease MPP+-induced LPO. These results suggest that the mechanism involved in the MPP^+-induced LPO is inhibited by copper administration only after activation of delayed processes. This work has been supported by CONACyT Grant 26504-M.

1369 METALLOTHIONEIN-I AND -II KNOCK-OUT MICE ARE NOT MORE SENSITIVE THAN CONTROL MICE TO 1-METHYL-4-PHENYL-1,2,3,6-TETRAHYDROPYRIDINE NEUROTOXICITY.

P Rojas[1,2], S S M Habeebu[2], J Liu[2] and C D Klaassen[2]. [1]*National Institute of Neurology & Neurosurgery, México City, México;* [2]*Univ Kansas Med Ctr, Kansas City, KS, USA.*

Oxidative stress, resulting from either excess generation or reduced scavenging of free radicals, has been proposed to play a role in damaging striatal neurons in 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) neurotoxicity. Metallothionein (MT) has been proposed to be a scavenger of oxygen-derived free radicals. It is hypothesized that MT protects against oxidative damage of the central nervous system by free radicals. In the present study we used MT-I and -II knockout (MT-null) mice to determine whether the absence of MT protein alters MPTP neurotoxicity. Control and MT-null mice were treated with MPTP at doses of 30, 40 and 50 mg/kg, ip for 11 or 35 days. There was a time- and dose-dependent increase in lethality, but no difference was observed between MPTP-treated control and MT-null mice. Seven days after the last dose, brains were removed, and the dopamine (DA) and homovanillic acid (HVA) contents were analyzed in striatum and midbrain by HPLC. Striatal DA content in MPTP-treated control mice was reduced by 53%, 74% and 84% after 30, 40 and 50 mg MPTP/kg respectively. Similar decreases were observed in MT-null mice treated with MPTP. MT-null mice were not more sensitive than control mice to MPTP neurotoxicity. The data suggests that MT-I and -II proteins do not play a major role in protecting against MPTP neurotoxicity. (Supported in part by NIH Grant ES-01142.)

1370 METALLOTHIONEIN EXPRESSION AND RADIATION PROTECTION IN PRIMARY HUMAN CNS CULTURES.

L Cai, R R Hammond and M G Cherian. *Department of Pathology, University of Western Ontario, London, ON, Canada.*

Little is known about metallothionein (MT) synthesis in the human brain after exposure to ionizing radiation (IR) and the role of MT in IR-induced damage. In this study, MT protein synthesis and mRNA expression after exposure to IR were examined in human CNS cultures. The effects of pre-

induced MT by zinc (Zn) and cadmium (Cd) on IR-induced cytotoxity were also investigated. Primary human CNS cultures from fetal brain were grown as aggregates and monolayers, and were exposed to doses of 30-120 Gy γ - rays. Total MT proteins, and mRNA for MT-II and MT-III were measured by Cd-heme assay and by reverse transcription PCR. Cytotoxic effects of radiation on CNS cells were detected by LDH release and apoptotic cell death (ACD), using DNA gel electrophoresis and TUNEL techniques. Immunohistochemistry was used for staining of MT as well as astrocytic and neuronal markers. These results showed the induction of total MT protein and MT-II mRNA, but not MT-III mRNA, following exposure to IR. Exposure of human CNS cells to IR caused a marked increase in LDH release, ACD and cell loss evaluated by specific markers. All these effects could be ameliorated significantly after induction of MT synthesis with 5 μ M Cd or 100 μ M Zn. MT induction by Cd or Zn was confirmed by Cd heme assay and immunohistochemistry. In cultured mouse astrocytes, enhanced MT expression (by Cd) was associated with marked protection from IR-induced ACD. This suggests that the relative high resistance of astrocytes to IR (compared to that of neurons) may be due to an efficient MT induction mechanism. These results suggest that MT protein or MT-II mRNA is inducible in CNS cells by IR. Pre-induced MT can protect human CNS cells from IR-induced cytotoxic injury. Both findings are of importance in developing strategies to protect CNS tissue from oxidative damage. (Supported by funds from Medical Research Council of Canada.)

1371 EBSELEN (2PHENYL-1,2 BENZISOSELENAZOL-3-(2H) ONE) INDUCES HO-1 PROTEIN (HEME OXYGENASE-1) IN RAT HIPPOCAMPAL ASTROCYTES.

D Hardej and L D Trombetta. *College of Pharmacy, St. John's University, NY, NY, USA.*

Ebselen (2phenyl–1,2 benzisoselenazol-3(2H)-one) a seleno-organic compound, has been shown to have cytoprotective properties. This has been attributed to its ability to imitate the selenium dependent enzyme, glutathione peroxidase (GSH/Px). It has also been implicated in increasing intracellular glutathione (GSH). Ebselen has been shown to protect against ischemic injury and peroxidative damage in other cell types possibly by the induction of stress proteins. The presence of stress proteins has been used to demonstrate alterations in cellular activity which may result in cellular degeneration. The purpose of this experiment was to evaluate astrocytic viability after treatment with ebselen and to investigate the ability of ebselen to induce the expression of stress proteins in these cells. Rat hippocampal astrocytes grown in Dulbecco's modified Eagle's essential media were treated with 3,6,9,15 and 30μ M ebselen at subconfluency. Effects on cell viability were seen in treatment groups. A significant decrease in cell viability was seen at the highest dose. Treatment of astrocytes with 15μ M and 30μ M ebselen increased the expression of the stress protein HO-1 (heme oxygenase - 1) in a dose dependent manner as assessed by western blots. Induction of HO-1 is associated with oxidative damage resulting from heme, metals, hormones, sulfhydryl depleting agents and UV radiation. The expression of stress protein and decreased cell viability may indicate a toxic insult rather than initiating a cytoprotective effect as described in other cell types.

1372 ACUTE NEUROTOXIC EFFECTS OF INHALED TRICHLOROETHYLENE (TCE): LINKING APPLIED DOSE, ABSORBED DOSE (BLOOD), TARGET TISSUE DOSE (BRAIN), AND OUTCOME MEASURES.

W K Boyes[1], P J Bushnell[1], M V Evans[1], J E Simmons[1] and J H Raymer[2]. [1]*USEPA, Research Triangle Park, NC, USA;* [2]*Research Triangle Institute, Research Triangle Park, NC, USA.*

The ability to understand dose-response relationships is improved by considering sequentially the steps of applied dose, absorbed dose, target tissue dose, and adverse outcome. We have done this for acute changes in neurological function following TCE inhalation. A physiologically-based pharmacokinetic (PBPK) model was developed for *ad-lib* feed (350-450 g) and weight maintained (350 g) adult male Long-Evans rats. Rats were exposed by inhalation to TCE in concentrations of 0, 200, 500, 2,000, or 4,000 ppm. After durations ranging from 5-60 min, and up to 60 min after termination of exposure, rats were rapidly killed and blood, fat, liver and brain samples collected. Serial blood samples were collected from other rats with jugular vein cannulas during and after exposure. The concentration of TCE in tissues was measured using gas chromatography after solvent extraction, and compared with the predictions from the PBPK model. Blood [TCE] was higher in weight-maintained than ad-lib fed rats. Log_{10} [TCE] in blood showed a linear relationship to Log_{10} [TCE] in other tissues including brain (r^2 = 0.974). The [TCE] in brain at the time of recording accurately predicted TCE-induced reductions in the amplitude of pattern-elicited visual evoked potentials (PEP) (Boyes et al., SOT 1998), either during or after exposure. A declining exponential function fit the relationship between brain [TCE] and PEP amplitude ($r^2 = 0.908$). These results illustrate that the functional effects of many exposure scenarios can be understood in terms of target tissue dose. (This abstract does not necessarily reflect EPA policy.)

1373 ANILINE-INDUCED SPONGY CHANGE OF THE SPINAL WHITE MATTER IN RATS.

Y Okazaki[1], K Yamashita[1], M Sudo[1], M Tsuchitani[1], I Narama[2], R Yamaguchi[3], and S Tateyama[3]. [1]*Mitsubishi Chemical Safety Institute Ltd., Kashima, Ibaraki, Japan;* [2]*Setsunan Univ., Hirakata, Osaka, Japan;* [3]*Miyazaki Univ., Miyazaki, Japan.*

To investigate the potent neurotoxicity of aniline, two sets of 42 male rats, 4-week-old, were singly treated with 1000mg/kg of aniline or olive oil by gavage. Rats were sacrificed at 3, 7, 11, 14, 21, 29 and 59 days after dosing. Brain, spinal cords, trigeminal nerve, sciatic and tibial nerves, and gastrocnemius were perfused *in situ* with fixatives and then trimmed. Paraffin or plastic sections were made for light and electron microscopic evaluation. In aniline-treated rats, one was dead within 24 hours after dosing. Most of the remaining rats showed ataxic paraplegia, after a transient sign of cyanosis. The ataxic paraplegia resolved up to 19 days postdose. Spongy change of spinal white matter was seen in all aniline-treated rats which were sacrificed at 7 days postdose and thereafter. The lesion was most severe in the outer tracts of lateral and ventral columns. Macrophages infiltrated in some distended periaxonal space and hypertrophied astroglia were also observed at 11 to 29 days after dosing. Minimal axonal changes were seen only in the severe cases. The spinal roots and trigeminal nerve were also severely affected. Affected nerve fibers were sporadically found in the upper and lower tracts, including mesencephalon, pons, medulla oblongata, and sciatic and tibial nerves. Spongy change was corresponded to the distention and destruction of myelin sheath, essentially due to the splitting of intraperiod line in myelin sheath. No abnormalities were found in neuronal cells. At 59 days postdose, there was a significant improvement in all changes described above. The spongy change in the spinal white matter could be induced by a single oral dose of aniline in rats.

1374 DOES THE VULNERABLE PERIOD FOR DEVELOPMENTAL NEUROTOXICITY OF NICOTINE EXTEND INTO ADOLESCENCE?

J A Trauth, E C McCook, F J Seidler, and T A Slotkin. *Department of Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.*

Fetal nicotine exposure results in CNS cell loss, altered nicotinic cholinergic receptor (nAChR) expression, perturbed synaptic function, and elevated expression of genes putatively involved in apoptosis. In contrast, little work has been done on nicotine exposure during adolescence, despite the fact that most smokers begin their habit during that period. We administered nicotine continuously to adolescent rats using osmotic minipump implants, beginning on postnatal day (PN) 30 to PN47. In keeping with the effects of nicotine on nAChR in fetuses or adults, receptor expression was elevated in cerebral cortex and midbrain during and immediately after the end of the infusion period. However, in adolescent rats, unlike fetal rats, cortical receptor induction still remained prominent two weeks after discontinuing nicotine exposure. The effect was regionally-specific, as nAChR upregulation was shorter-lived in the midbrain. In contrast, fetal nicotine administration produced constitutive cortical protooncogene (c-fos) induction, whereas adolescent nicotine did not increase c-fos. Adolescent nicotine produced significant and persistent cell loss (decreased DNA) in the midbrain. We therefore suggest that the vulnerable period for adverse effects of nicotine on brain development extends into adolescence, when many behavioral and physiological patterns become consolidated. Supported by a grant from the Smokeless Tobacco Research Council.

1375 ESTABLISHMENT OF AN *IN VITRO* MODEL OF THE BLOOD-BRAIN BARRIER FOR DELINEATING THE TRANSPORT OF THIOETHER CONJUGATES INTO BRAIN.

F G Suleman, S S Lau and T J Monks. *Division of Pharmacology and Toxicology, College of Pharmacy, University of Texas, Austin,TX, USA.*

Systemic metabolism of 3,4-methylenedioxymetamphetamine (MDMA;

Ecstasy) and 3.4-methylenedioxyamphetamine (MDA) appears necessary to produce their serotonergic neurotoxicity, and thioether metabolites of α-methyldopamine (α-MeDA), a known metabolite of MDA and MDMA, may play a role in this toxicity. To assess mechanisms by which these metabolites gain access to the brain, we developed *in vitro* cultures of immortalised human cerebrovascular endothelial cells (IHCEC) as a model of the blood-brain barrier. Of five different extracellular matrices examined (collagen, fibronectin, gelatin, laminin, and Matrigelfi), gelatin gave the highest trans-endothelial cell electrical resistance (TEER; Ωcm2) and was used to coat filter inserts placed into larger wells for transport studies. The lumenal to basolateral transport of 5-(glutathion-*S*-yl)-α-MeDA (5-[GSyl]-α-MeDA; 100 μM) was monitored for 60 min, ~5% of 5-(GSyl)-α-MeDA was recovered intact in the basolateral compartment, whereas 78% of the substrate remained intact in the lumenal compartment. The residual 17% is likely metabolized by γ-glutamyl transpeptidase and dipeptidases since evidence of 5-(cystein-*S*-yl)-α-MeDA in both the lumenal and basolateral compartments was obtained by HPLC-coulometric electrode array analysis of the media. The barrier function of the IHCEC monolayers remains intact (no change in TEER) for the duration of the transport studies indicating maintenance of tight junctions. Transport of intact 5-(GSyl)-α-MeDA across the IHCEC monolayer is most likely due to the activity of an intact GSH transporter (DA 10832; Drug Metabolism, Merck & Co).

1376 THE CELLULAR NEUROTOXICITY TEST BATTERY USED IN THE ERGATT/CFN INTEGRATED TOXICITY TEST SCHEME (ECITTS).

A Forsby[1], M Nordin-Andersson[1], N Heldring[1] and J DeJongh[2]. [1]*Stockholm University, Dept. of Neurochemistry and Neurotoxicology, Stockholm, Sweden;* [2]*RITOX, Utrecht University, Utrecht, The Netherlands.* Sponsor: B Ekwall.

Neurotoxicity risk assessment is routinely based on animal studies. The availability of specific cellular test systems has made it possible to study the mechanisms of neurotoxic effects *in vitro*. This also offers economical and ethical advantages over large-scale *in vivo* studies. In the present study, the neurotoxicity of acrylamide, caffeine, diazepam, lindane, parathion and phenytoin was assessed in an *in vitro* test battery. The general cytotoxicity and neurite degeneration, as well as effects on intracellular Ca2+ homeostasis, protein synthesis, Ca2+ channel (VOCC) and acetylcholine receptor function, were investigated in human neuroblastoma (SH-SY5Y) cells after 72 hours exposure with the compounds. The most sensitive parameters were; neurite degeneration for acrylamide and parathion, VOCC function for caffeine, diazepam and lindane, and protein synthesis for phenytoin. The critical cellular neurotoxic concentration for each compound (i.e. lowest EC20 value) was integrated in a biokinetic model and the lowest effective *in vivo* doses (LOEDs) were estimated. The estimated LOEDs for acrylamide, caffeine and lindane correlated well with literature derived experimental LOEDs, implicating that the selected *in vitro* tests were appropriate for these compounds. However, the estimated LOEDs for diazepam, parathion and phenytoin were more than half a magnitude higher than the experimental LOEDs, possibly because no tests for benzodiazepine receptor function and choline esterase activity were included in the test battery. This result illustrates the importance of designing *in vitro* test batteries, in which endpoints, relevant for each class of compounds, are included.

1377 NOISE-INDUCED HEARING LOSS IN DIFFERENT CARBON MONOXIDE ENVIRONMENTS.

G Chen, M L McWilliams, and L D Fecter. *University of Oklahoma Health Science Center, Oklahoma City, OK.*

Intense noise, especially its high frequency components, may cause hearing loss (HL). The noise-induced-HL (NIHL) can be enhanced by simultaneous carbon monoxide (CO) exposure. Carbon monoxide exists in many environments. For example, pure cigarette smoking may cause an alveolar CO level of about 300 ppm. Therefore, it is important to know the lowest CO-level at which the CO interacts with intense noise and makes the noise-induced auditory impairment worse. In the present study, high-frequency octave-band noise (9.6-19.2 kHz, 100 dB_{Ln}) and CO-levels of 1200 ppm, 700 ppm, 500 ppm, 300 ppm and 0 ppm were applied. The hearing loss was determined by recording of CAP (compound action potential) from the round window, 4 weeks after exposure. The octave-band noise alone (0-ppm-CO) induced an approximate 30-dB permanent hearing loss in rats at frequencies higher than 10 kHz. CO alone did not induce any hearing losses, even at 30 minutes following the exposure. The combined exposure of the noise and 1200-ppm-CO, however, caused a much greater permanent hearing loss, especially in high frequency region. The HL-enhancement phenomenon by CO was obvious. The enhancement of the noise-induced hearing loss lessened gradually with CO-level. The hearing loss to the combined exposure with 300-ppm-CO was similar to that to the noise alone (0-ppm-CO). The lowest CO-level, which shows interaction with intense noise, must be between 300 ppm and 500 ppm. In human subjects the lowest CO-level, showing interaction with intense noise, might be lower than the data obtained in the rats. (Supported in part by NIOSH grant #03481 and NIH grant ES08082.)

1378 ACUTE DISRUPTION OF COCHLEAR POTENTIALS BY POTASSIUM CYANIDE.

W Tawackoli, and L D Fechter. *University of Oklahoma Health Science Center, Oklahoma City, OK.*

Cyanide is present in various environmental settings and is also an occupational hazard for firefighters. Effects and mechanisms of cyanide (CN) toxicity are unclear in hearing loss. In this study, adult male Long Evans hooded rats were used to examine the effects of potassium cyanide (KCN). Interactions with noise on cochlear potentials, namely, compound action potential (CAP) and cochlear microphonic (CM) were studied. Subjects were injected with KCN (7mg/kg, ip) and compared with controls (saline, ip). CAP sensitivity is dependent upon the function of inner hair cells and spiral ganglion cells. The CM is generated predominantly from outer hair cells. CAP and CM were recorded pre and post administration of KCN. Hearing levels at three frequencies (2 kHz, 12 kHz and 40 kHz) were tested. Blood cyanide levels were measured following KCN administration for a period of 30 min. A temporary threshold shift in both CAP and CM was observed for a period of 5 to 15 min. following KCN administration. Concurrent exposure to KCN and noise (110 dB, broad band) for 2 hours demonstrated no threshold shift in either CAP or CM. (Supported in part by NIOSH grant OH 03481 and NIEHS grant ES 08082.)

1379 EFFECTS OF EXPOSURE DURATION ON POTENTIATION OF NOISE INDUCED HEARING LOSS BY CARBON MONOXIDE.

D B Rao, G D Chen and L D Fechter. *University of Oklahoma Health Science Center, Oklahoma City, OK, USA.*

Noise induced hearing loss (NIHL) is still the most common occupational disease in the U.S. Concurrent noise exposures with chemical asphyxiants such as carbon monoxide (CO) is common in work environments of firefighters, automobile mechanics and tunnel-toll booth workers. Potentiation of NIHL following acute exposure to noise (102-103 dB, broad band) and CO (1500 ppm) has been demonstrated previously. It is well known that noise exposure of varying duration is related to exposure intensities. The equal energy principle states that an increase in exposure intensity is compensated for by a corresponding decrease (halving) in exposure duration. This study investigates whether or not the NIHL resulting from combined exposures complies with the equal energy principle. Adult male Long Evans hooded rats were acutely exposed to noise alone (100dB_{Ln}, 9.6-19.2 kHz), CO alone (1500 ppm), noise & CO, and air (controls). Duration of exposure varied between 2 and 8 hours. Auditory sensitivity was measured four weeks post-exposure. End points measured were electrophysiological, namely, compound action potential (CAP) and cochlear microphonic (CM). CAP is a measure of cochlear output generated at the inner hair cell-type I spiral ganglion synapse, and, CM is generated largely by the outer hair cell. These potentials were recorded in response to pure tones between 2 and 40 kHz. NIHL was found to comply with the principle of equal energy. However, hearing loss resulting from combined exposure did not follow a similar pattern. (This study is supported in part by NIOSH grant #03481 and NIEHS grant ES 08082.)

1380 SUBCHRONIC TOXICITY OF PILOCARPINE IN RATS.

S M Henwood[1], R F Marshall[2], T J Ryan[1], M J Palazzolo, and J R MacDonald[2]. [1]*Covance Laboratories Inc., Madison, WI, USA;* [2]*MGI Pharma, Inc., Minnetonka, MN, USA.*

Pilocarpine, a cholinergic parasympathetic agent with predominantly muscarinic action, is indicated as a treatment for symptoms of xerostomia in Sjogren's syndrome or head and neck cancer patients following radiation. A 90-day range-finding study was done to assess the toxicity, define an esti-

mated MTD, and assess the PK necessary to select doses for a carcinogenicity study. Male and female CD rats were assigned to 1 control group and 4 treated groups to assess toxicity (10/sex/group) and PK (61 animals /sex/group). Animals were dosed daily by oral gavage at 0 (control), 3, 9, 18, and 36 mg/kg/day; controls received the vehicle, reverse osmosis water. Detailed examinations, body weights, and food consumption were recorded weekly. Plasma pilocarpine levels were determined predose and at selected intervals through 180 minutes postdose on Day 1 and during Week 13. Toxicity animals were necropsied during Week 14; selected organs were weighed, and selected tissues were examined microscopically. Pilocarpine was rapidly absorbed and eliminated with no bioaccumulation during treatment. Clinical observations were consistent with the known muscarinic pharmacological activity, dose dependent, and persisted throughout treatment. Significant decreases in body weight, body weight gain, and food consumption were present for males given 9, 18, or 36 mg/kg. An MTD was identified in the range of 9 to 18 mg/kg for males and 18 mg/kg or below for females. In the absence of dose limiting pathological findings, doses of 3, 9, and 18 mg/kg for the carcinogenicity study were determined based on the relative ratios of AUC for rats and humans.

1381 ENHANCED ACUTE PULMONARY TOXICITY OF MERCURY VAPOR IN METALLOTHIONEIN-NULL MICE.

M Satoh[1], M Yoshida[2], A Shimada[3], A Yasutake[4], Y Sumi[2], C Tohyama[1]. [1]*Environmental Health Sciences Div., Natl. Inst. for Environmental Studies, Tsukuba, Japan,* [2]*Dept. of Chemistry, St Marianna Univ. School of Medicine, Kawasaki, Japan;* [3]*Dept. of Veterinary Pathology, Tottori Univ., Tottori, Japan and* [4]*Biochemistry Section, Natl. Inst. for Minamata Disease, Minamata, Japan.*

To elucidate the protective role of metallothionein (MT) in the acute toxicity of mercury vapor, we examined the sensitivity of MT-null transgenic mice, a kind gift from A. Choo, to the exposure to mercury vapor. Ten-week-old male MT-null mice and wild-type control mice (15 mice for each group) were exposed to mercury vapor at 6.6 to 7.5 mg/mm^3 for 4 h each day for 3 consecutive days. Blood, lung, liver and kidney were removed from each mouse under diethylether anesthesia at 24 h after the last exposure to mercury vapor. 67 % of MT-null mice died during this study whereas all of wild-type mice survived. In the lung of MT-null mice, marked morphological changes such as congestion, atelectasis and hemorrhages in the alveoli were observed following mercury vapor exposure. In contrast, the wild-type mice exposed to mercury vapor showed a lesser degree of pulmonary damage. In the liver and kidney of MT-null mice and wild-type mice, no histopathological changes were observed following exposure to mercury vapor. The present study indicates that MT-null mice were more sensitive to mercury vapor-induced pulmonary damage and lethality, and that MT in the lung plays a protective role against acute pulmonary toxicity caused by mercury vapor.

1382 REDOX REGULATION OF COPPER-METALLOTHIONEIN INTERACTIONS.

J P Fabisiak, V A Tyurin, Y Y Tyurina, G G Borisenko, A Korotaeva, B R Pitt, J S Lazo, and V E Kagan. *Depts. Environ. & Occup. Health and Pharmacology, Univ. of Pittsburgh, Pittsburgh, PA, USA.*

Metallothioneins (MTs) are cysteine-rich metal-binding proteins that exert cytoprotective effects during metal exposure and oxidative stress. The specific role of MTs in modulating Cu-dependent redox cycling remains unresolved. While MT is capable of binding up to 12 Cu^{1+} atoms/peptide, we hypothesize that oxidation of free thiols critical for metal binding can reduce MT/Cu interactions and potentiate Cu^{1+}-dependent redox cycling. We utilized a chemically-defined model system to study MT modulation of Cu-dependent redox cycling under physiologic reducing (Cu/ascorbate) and mild oxidizing (Cu/ascorbate + H_2O_2) conditions. In the presence of Cu and ascorbate, MT blocked Cu-dependent lipid oxidation and ascorbyl radical formation with a stoichiometry corresponding to Cu/MT ratios $\leq$ 12. In the presence of H_2O_2, the degree of protection by MT was less and biological oxidations and radical formation were inhibited only up to Cu/MT ratios of 6. Physical interaction of MT and Cu was measured by using low-temperature EPR of free Cu^{2+} in solution. The maximal amount of EPR-silent Cu^{1+} (presumably in complex with MT) corresponded to 12 molar equivalents of Cu/MT under reducing conditions, but only 9 in the presence of H_2O_2. Dithiodipyridine titration of reduced sulfhydryls on MT revealed a 50% decrease after H_2O_2 oxidation, which could be regenerated by the reducing agent, dihydrolipoic acid. H_2O_2 modulated the ability of MT to protect HL-60 cells from Cu-induced cell death in a manner that correlated with the ability of MT to mitigate Cu-redox cycling in cell-free systems. Thus, optimal binding of Cu to MT is achieved only under reducing conditions, however, a portion of this Cu appears releasable under oxidizing conditions. Release of free Cu from MT during oxidative stress could enhance the formation of reactive oxygen species and potentiate cellular damage. 1383 METALLOTHIOEIN ISOFORM GENE EXPRESSION IN HUMAN PROXIMAL TUBULE CELLS EXPOSED TO ZINC, COPPER, CADMIUM, MERCURY, SILVER, AND LEAD.

S H Garrett, S Somji, J H Todd, and D A Sens. *Department of Pathology, West Virginia University, Morgantown, WV.*

The organization of the human metallothionein (MT) gene family is more complex than the commonly utilized mouse and rat models, having a total of 10 functional and 7 non-functional isoforms. The objective of the study was to determine if the human MT expression is similar to or divergent from animal models. Human proximal tubule (HPT) cells were exposed to lethal and sublethal concentrations of Cd, Zn, Cu, Ag, Hg, and Pb, and the total MT protein content was determined. Large MT protein accumulations were evident in cells exposed to Cd, Zn, Cu, whereas no significant protein accumulation was found for the other metal exposures. In order to differentiate between the many MT isoforms, PCR primers were designed that would specifically amplify each individual mRNA isoform. MT-2A was expressed at the highest level; however, it was shown that the levels of mRNA did not increase significantly with metal treatments that induced total MT protein accumulation. This observation is different from results seen in mouse or the rat models. For the MT-1 isoforms, MT-1X and MT-1E were found to be major transcripts, whereas MT-1F and MT1A were found to be minor transcripts. The levels of mRNA for 1A and 1E were shown to increase significantly with metal treatments (Zn, Cd, Cu, but not Hg, Ag, or Pb) at concentrations that were toxic (MT-1A) and nontoxic (MT-1E).

1384 TRANSIENT NUCLEAR TRANSLOCATION OF METALLOTHIONEIN DURING MYOBLAST PROLIFERATION AND DIFFERENTIATION.

M D Apostolova and M G Cherian. *Department of Pathology, University of Western Ontario, London, Canada.*

Metallothionein (MT) may play a role in homeostasis of Zn and Cu and may have protective effects against heavy metal toxicity and active oxygen species. The requirement of Zn during G1/S phase transition of the cell cycle coincides with the cell cycle dependent expression of MT and its transient nuclear localization in certain proliferating cells. In order to investigate the changes in cellular localization of MT during proliferation and differentiation, two skeletal muscle cell lines were used: L6 and H9C2 myoblast. Both Insulin-like Growth Factor (IGF-I) and decrease in fetal bovine serum (FBS) to 1% stimulated the differentiation of myoblasts to myotubes within 8 days. MT was localized mainly in the cytoplasm in myoblasts but was translocated to the nucleus of newly formed myotubes during early differentiation. At later stage of differentiation, MT synthesis was decreased and was localized in the cytoplasm of myotubes. The changes in localization of MT were followed by immunofluorescence using a polyclonal MT-antibody and anti rabbit IgG labelled with FITC. In both cell lines, MT was localized in the nucleus at late G1/early S-phase after blocking cell growth with aphidicolin (an inhibitor of DNA polymerase-α) or deletion of the FBS. The slow progression of cell cycle leads to transfer of MT to the cytoplasm at the end of M-phase. Addition of rapamycin (serine/threonine p70 kinase inhibitor), PD98059 (an inhibitor of MAP kinase) or LY294092 (an inhibitor of PI3 kinase) blocked the translocation of MT in the nucleus of myoblast and myotubes. The results suggest that the increase of MT content and its translocation into the nucleus of myoblasts and myotubes during early differentiation may be due to a rapid mitogenic and myogenic response. It also suggests that various kinases and signal transduction cascades probably regulate these processes. (Supported by a grant from Medical Research Council of Canada.)

1385 ROLE OF METALLOTHIONEIN (MT) IN THE UPTAKE AND DISTRIBUTION OF ENVIRONMENTAL LEVELS OF CADMIUM IN MICE.

S S Rajan, A K Wilson and M H Bhattacharyya. *Argonne National Laboratory, Argonne, IL, USA.*

Humans are exposed to environmental cadmium via food. Metallothionein (MT), a small, inducible, cysteine-rich, metal-binding protein is believed to be at least partially responsible for the retention and correspondingly long half-life of Cd in tissues. The study presented here was aimed at exploring the role of MT in the uptake, transport and distribution of Cd administered intravenously and via gavage at doses that do not induce the biosynthesis of MT. The experiments were conducted on MT (I and II) knockout (MTKO) and MT normal (MTN) mice. The gavage experiments yielded results which were – 1. independent of MT status of the mice: (a) Cd was rapidly absorbed and retained by duodenum (% total dose – MTN: 34±9; MTKO: 38±10), (b) early deposition favored liver over kidney (4h liver/kidney Cd – MTN: 4.6±0.6; MTKO: 5.1±0.5), and (c) Cd transported across the GI tract amounted to only ~1% of the total dose; 2. MT-dependent: (a) Cd distributed throughout the body was 2-3X higher in MTKO than in MTN mice (% total dose – MTKO: 3.1±1.7; MTN: 0.6±0.2) and (b) absence of MT correlated with a significant increase in liver deposition after 8h following administration (% total dose – MTN: 0.3±0.03; MTKO: 0.9±0.1). The following features were independent of both route of exposure and MT status: (a) Cd was cleared from blood extremely rapidly (b) the remaining carcass (muscle, pelt, etc.) was a major deposition site for transported Cd and (c) liver deposition of Cd was consistently higher than that of kidney. Size-exclusion chromatography of plasma after gavage or iv administration revealed albumin to be the major Cd-binding entity in both MTN and MTKO mice. Diafiltration and metal-affinity chromatography of duodenal extracts from gavage-dosed mice indicated that most of the Cd retained in this tissue was associated with low molecular weight (<3 kda) chelators. Thus at basal MT levels and low doses (0.1 μg) of Cd, MT along with small chelators function to limit intestinal absorption and direct Cd away from the liver towards the kidney. (Supported by NIEHS grant ES07398.)

1386 SURGICAL CHOLESTASIS DOES NOT PRODUCE ZINC (Zn) MOBILISATION FROM PLASMA TO LIVER IN RATS.

E Brambila-Colombres, A Albores and J L Munoz-Sanchez. *Faculty of Chemistry, University of Puebla, Environmental Toxicology Section, Cinvestav and National School of Biological Sciences, IPN., Mexico.*

The mobilisation of Zn from plasma to the liver and the role of hepatic metallothionein (MT) and MT-I and MT-II isoforms during cholestasis were investigated. Bile duct was surgically ligated in adult male Wistar rats (200 g) and were sacrificed under deep anaesthesia (ether) at 3, 6, 9, 12, 16, 20 and 24 h. Controls received no surgical treatment. Livers were homogenised (sacarose 0.25M) and centrifuged. Zn (atomic absorption spectrometry) serum and liver supernatants, hepatic MT (cadmium saturation method) and MT-I and MT-II isoforms (ion exchange chromatography) were measured in liver supernatants. Cholestasis increased 1.5-fold hepatic Zn content (9 h) and correlated with MT increases (3.2-fold) but, MT-I and MT-II ratio and serum Zn content remained unchanged, suggesting that cholestasis do not promote a Zn plasma/liver mobilisation. Cholestasis results are in contrast with the post-surgical stress response where hepatic Zn increases correlate with serum Zn decreases and changes in the liver MT-I/MT-II ratio. These results suggest that the source of Zn in the post-surgical stress is plasma whereas in cholestasis might be the stagnated bile. Differences between post-surgical and cholestasis responses might be due, in the former, to the activation of hormonal and cytokine receptors in the vascular phase of the hepatocyte inducing MT-II and initiating Zn capture whereas, in the latter, passive mobilisation of Zn from bile to the hepatocyte may take place in addition to surgical stress changes.

1387 METAL PRETREATMENT INDUCES METALLOTHIONEIN AND ALTERS HORMONE RESPONSIVENESS IN MAMMALIAN CELLS.

J M DeMoor, O M Collins and J Koropatnick. *London Regional Cancer Centre, London, Ontario, Canada.*

Metallothioneins (MTs) are the major low molecular weight zinc-binding proteins in mammalian cells. It has been hypothesized that they play a role in the function of zinc-dependent signal transduction proteins and transcription factors. Glucocorticoids interact with a zinc-dependent glucocorticoid receptor (GR) to induce gene transcription via binding to the glucocorticoid response element (GRE). We studied, in a mouse mammary tumor cell line (2305), the ability of the synthetic glucocorticoid dexamethasone (DEX) to stimulate transcription of a chloramphenicol acetyl transferase (CAT) gene controlled by a GRE-containing mouse mammary tumor virus promoter. In cells pretreated with 20 to 100 μ M $ZnCl_2$, DEX-induced CAT activity correlated with zinc-induced MT levels. In contrast, pretreatment with 1 μM $CdCl_2$ significantly reduced CAT activity despite increased MT levels. This may reflect a direct effect of $CdCl_2$, or a functional difference between zinc-associated MT and cadmium-associated MT. Significantly more CAT activity was also observed in heat-shocked cells. Although heat shock alone (in the absence of DEX) did not induce MT protein, the possibility exists that both heat and zinc affect DEX-induced CAT activity through an MT-mediated mechanism. Changes in GR levels could not account for variations in CAT activity. These data indicate that hormonal signaling in mammalian cells can be altered by exposure to metal salts, and the effect is correlated with the level of MT and its associated metal ion. (Supported by the MRC of Canada.)

1388 METALLOTHIONEIN LEVELS IN HUMAN PERIPHERAL BLOOD LYMPHOCYTES: UTILITY IN ENVIRONMENTAL EXPOSURE ASSESSMENT.

E J Yurkow and C J DeCoste. *Environmental and Occupational Health sciences Institute, Rutgers University, Piscataway, NJ, USA.*

MT levels of human peripheral blood lymphocytes were determined using a MT-specific antibody and flow cytometry. Treatment of human whole blood *ex vivo* with $CdCl_2$ was found to induce a concentration- and time-dependent increase in lymphocyte MT levels at concentrations as low as 0.3 μM and within a 12 h period. Interestingly, differences were observed in the magnitude of cadmium-induced MT levels in the lymphocytes of six (6) human test subjects. Two members of the study population exhibited $CdCl_2$-induced cellular MT levels that were up to twofold greater than the lymphocytes of other human subjects. While the lymphocytes of most test subjects exhibited a symmetric (unimodal) distribution of cadmium-induced MT-specific fluorescence, the cells of two individuals displayed a heterogeneous (non-uniform) distribution of MT levels. Dual-parameter flow cytometric analysis using phenotype-specific antibodies indicated that variations in the responsiveness of subpopulations of lymphocytes to $CdCl_2$ was responsible for the heterogeneous distribution of MT-specific cellular fluorescence. T-helper (CD4-positive) and T-suppressor/cytotoxic (CD8-positive) lymphocytes expressed higher cellular levels of MT than other lymphocyte subpopulations (i.e., B-lymphocytes, natural killer cells). Our results suggest that MT protein levels of peripheral blood lymphocytes, as determined by this flow cytometric method, may be used to assess human exposure to toxic metals and characterize various quantitative/qualitative aspects of the response of individuals to cadmium and possibly to other types of environmental stresses.

1389 METALLOTHIONEIN AND INNATE ACTIVATION OF PRIMARY HUMAN AND MOUSE MONOCYTES.

S Dale[1], R K Zalups[2], and D J Koropatnick[1]. [1]*University of Western Ontario, London, ON, Canada;* [2]*Mercer University School of Medicine, Macon, GA, USA.*

Interactions with extracellular matrix may be important for the migration and location of immune cells in the tissue. In this study, we examined the adhesion of human intestinal mast cells to extracellular matrix proteins coated to plastic dishes. Mast cells were isolated from normal surgery tissue specimen and purified up to 99 % by positive selection using magnetic cell separation (MACSTM). 96-well plates were coated for 2 h at 37°C with 100 μl PBS containing 2 μg of different adhesion proteins. 5 x 103 mast cells/well were incubated for 90 min at 37°C in culture medium with or without addition of 100 ng/ml SCF. The dishes were washed three times and the quantity of adherent mast cells was determined by histamine measurement after cell lysis. Only few mast cells bound to collagen type I, III, IV, VI and XIV (3.0-8.1 %). Mast cells adhesion was more pronounced to laminin (12±6.7%) and to fibronectin (21.9±8.9%). Following stimulation with SCF mast cell adhesion increased from 8.1±6.2% to 16.0±8.8% on collagene type I, from 12±6.7% to 23.4±10.8% on laminin and from 21.9±8.9% to 44.7±17.3% on fibronectin. Independent of SCF stimulation, RT-PCR analysis revealed mRNA expression for ß1, ß3, a4 and a5-integrin receptor subunits. Conclusion: Human intestinal mast cells are able to adhere to fibronectin. SCF stimulates adhesion of mast cells to fibronectin and other matrix proteins about 2.5-fold.

1390 CARDIOVASCULAR SAFETY ASSESSMENT OF BMS-196854 (ONCOSTATIN M) IN CONSCIOUS CYNOMOLGUS MONKEYS.

M A Nedelman and C R Comereski. *Primedica Corporation, Worcester, MA, USA; Bristol-Myers Squibb, Department of Biologics Evaluation, Syracuse, NY, USA.*

BMS-196854 (Oncostatin M) is a pleiotropic cytokine that was examined for its potential use in acute inflammatory diseases. Two (one male and one female) conscious, biotelemetry-instrumented cynomolgus monkeys were used in this cardiovascular safety study. Arterial pressure (systolic, diastolic, and mean) and heart rate were monitored following a 30 μg/kg dose of BMS-196854 administered as a 60-minute infusion or by bolus intravenous injection. A similar dose volume of vehicle was administered as a 60-minute infusion or by bolus intravenous injection for control purposes. No significant effects on blood pressure were observed during or following the 60-minute intravenous infusion. Immediately following bolus injection, blood pressure declined by approximately 20-30% from pretreatment values and was associated with reflex tachycardia. The decline in pressure was effectively treated with either levophed or dobutamine. The cardiovascular effects of 30 μg/kg of BMS-196854 when administered by bolus intravenous injection did not occur when administered as a 60-minute infusion in cynomolgus monkeys. The results of this study supported intravenous infusion of BMS-196854 in Phase I trials in humans.

1391 APPLICATION OF THE INTEGRATED TELEMETRY SYSTEM FOR CARDIOVASCULAR ASSESSMENT OF PHARMACOTHERAPIES TO TREAT COCAINE ABUSE.

J H Ludens[1], P E Newton[1], N B Olivier[2], G J Schaefer[1], M P Smith[1], M H Wang[1] and J B Terrill[3]. [1] *MPI Research, Mattawan, MI;* [2]*Michigan State University, East Lansing, MI; and* [3]*National Institute on Drug Abuse, Rockville, MD.*

Potential pharmacotherapeutics for the treatment of cocaine addiction require an evaluation in the presence of cocaine to determine the likelihood of an adverse cardiovascular interaction. Adult male beagle dogs were instrumented with telemetric left ventricular and aortic pressure transducers, pulmonary artery flow probes and base-apex leads to provide measures of cocaine's major actions on hemodynamics, left ventricular function and electrocardiographics. Cocaine (0.3-3.0 mg/kg, i.v.) dose-dependently elevated mean arterial pressure, heart rate (HR), cardiac output, vascular resistance, left ventricular pressure, contractility and concomitantly increased myocardial oxygen demand while lengthening the P-R and QRS intervals. Additionally, the β_1-antagonist propanolol reduced resting HR and contractility and mitigated the tachycardiac and positive inotropic effects of cocaine. Comparison of these results with those obtained in sling-restrained animals demonstrate that the telemetered dog model provides an accurate depiction of the acute cardiovascular effects of cocaine, without the confounding effects of artificial restraint. (Supported by NIDA contract N01DA-6-8068.)

1392 FOUR-DAY CONTINUOUS INTRAVENOUS INFUSION TOXICITY STUDIES OF THE ENDOTHELIN ANTAGONIST CI-1020 IN BEAGLE DOGS AND CYNOMOLGUS MONKEYS.

N J Gragtmans[1], G E Macallum[1], M A Albassam[2], R M Walker[1], H Hallak[2], and S Haleen[2]. *Parke-Davis Pharmaceutical Research Division, Warner-Lambert Co.,* [1]*Mississauga, ON, Canada and* [2]*Ann Arbor, MI, USA.*

The butenolide CI-1020 is a potent and selective endothelin A receptor antagonist. As part of the preclinical toxicity program, CI-1020 was given for 4 days as a continuous intravenous infusion to beagle dogs at 0.144 to 480 mg/kg/day and to cynomolgus monkeys at 24 to 480 mg/kg/day. In dogs, emesis and miosis were observed at 24 to 480 mg/kg/day, aggressive and hyperreactive behavior at 72 to 240 mg/kg/day, tremors at 120 to 480 mg/kg/day, and hypoactivity at 240 to 480 mg/kg/day. All dogs at 480 mg/kg/day died on Day 2. In monkeys, emesis, hypoactivity, lordosis, and death occurred at 480 mg/kg/day. Decreases in hepatic microsomal cytochrome P450 and erythromycin N-demethylase occurred in dogs at 7.2 to 480 mg/kg/day and all CI-1020-treated monkeys. CI-1020 plasma concentrations increased disproportionately with dose in dogs and proportionately in monkeys. Plasma endothelin-1 concentrations increased 10 to 20 fold in dogs at 120 to 480 mg/kg/day and in monkeys at 480 mg/kg/day. Arteriopathy was observed in all dogs at 7.2 to 480 mg/kg/day, occurring primarily in coronary arteries, and characterized by focal or multifocal fibrinoid necrosis, hemorrhage, and mixed inflammatory cell infiltrate in the media and/or adventitia. A low incidence of arterial lesions was noted in other organs at 7.2 to 480 mg/kg/day. No pathologic findings were identified in monkeys. In conclusion, CI-1020 administered continuously for 4 days induced similar clinical signs and effects on hepatic microsomal enzymes and plasma endothelin-1 in dogs and monkeys. Arteriopathy was only observed in the dog.

1393 MATHEMATICAL CORRECTIONS FOR THE INVERSE RELATIONSHIP BETWEEN QT INTERVAL AND HEART RATE IN CONSCIOUS BEAGLE DOGS AND CYNOMOLGUS MONKEYS.

M M Cooper[1] and A S Bass[2]. [1]*Research Biostatistics and* [2]*Preclinical Toxicology-Safety Pharmacology, Pharmacia & Upjohn, Kalamazoo, MI.* Sponsor: T W Petry.

Pharmacodynamic prolongation of ventricular repolarization (QT Interval) has the potential liability of inducing polymorphic ventricular tachycardia (Torsades de Pointes), ventricular fibrillation and death. An inverse relationship exists between changes in heart rate and the QT interval which poses a dilemma for studying drugs that affect heart rate. Of the various mathematical formulae that have been proposed as a correction for this problem, 12 of these were evaluated in the present study. Twelve one and two parameter linear regression models were tested in the following manner. Electrocardiograms were collected using lead I, II, III, aVR, aVL, and aVF configurations from restrained, nontreated beagle dogs (n=872) and cynomolgus monkeys (n=235). There were a total of 1,808 and 470 QT - RR intervals pairs (dog and monkey, respectively) evaluated with each formula. The precision of each formula was tested using an Akike Information Criteria (AIC). Based on the results for the one and two parameter models, there are several formulae that would provide good precision for the corrected QT interval over a wide range of heart rates. These include $a \bullet RR^{(1/3)}$, $a \bullet RR^{(1/4)}$, $a \bullet \log RR$ and any of the 2 parameter models. However the one parameter models, would provide the most practical correction only requiring a single measurement.

1394 CARDIOTOXICITY OF NERIIFOLIN (NSC1243975) IN BEAGLE DOGS.

C R Hassler[1], R I Hamlin[2], N A Turner[1], K M Schweikart[3] and J B Tomaszewski[3]. [1]*Battelle, Columbus, OH, USA;* [2]*The Ohio State University, College of Veterinary Medicine, Columbus, OH, USA;* [3]*National Cancer Institute, Rockville, MD, USA.* Sponsor: A R Dahl.

Neriifolin, a cardiac glycoside, has demonstrated antitumor activity. Dose levels for the anticipated cardiac glycoside effects such as increased cardiac contractility and arrhythmic activity were not known. This study was designed to determine if cardiac effects were observed at effective antitumor concentrations via IV bolus and 24 hour infusion. Systemic and left ventricular pressures, heart rates and ECG's were collected via implanted radiotelemetry. Abnormal cardiac electrical activity was minimal at the 25 μ g/kg level and increased in severity in a dose related fashion. The abnormal electrical activity included a wide range of digitalis-like findings including PQ interval prolongation, 1st and 2nd degree heart block of the Mobitz type I, ventricular premature depolarizations and sustained tachycardia. The onset of delayed arrhythmic activity observed in the 50μ g/kg animals was unusual. Arrhythmic therapies alleviated, albeit to a minimal extent, arrhythmias that occurred shortly after dosing, suggesting an initial digitalis-like effect. Inability of these treatments to have an effect upon delayed arrhythmias suggests a nondigitalis-like mechanism. Hemodynamic alterations were subtle at the 50 μ g/kg dose and reached physiological significance at the 100 and 200 μ g/kg doses. Cardiac contractility was elevated for an extended period in animals dosed at 100 μ g/kg. The persistence of increased contractility was consistent with the known activity of some cardiac glycosides. A more impressive increase in contractility may be anticipated in a failing heart. Significant heart rate alterations were evident. The magnitude of the hemodynamic alterations appeared to be dose related. The 200 μ g/kg dose was lethal. There was no reduction in the toxicity of neriifolin delivered over 24-hours versus IV bolus infusion and therapeutic doses could not be administered without severe cardiotoxicity. (Sponsored by the National Cancer Institute, Contract NO1-CM-37834.)

1395 BOLUS INTRAVENOUS INJECTIONS OF PHOSPHOROTHIOATE OLIGODEOXYNUCLEOTIDES CAUSE SEVERE HYPOTENSION BY ACTING AS ALPHA-1 ADRENERGIC RECEPTOR ANTAGONISTS.

P L Iversen[1,3], K G Cornish[2], L J Iversen[1], J E Mata[1,3] and D B Bylund[1]. [1]*Dept. of Pharmacology, and* [2]*Dept. of Physiology, University of Nebraska Medical Center, Omaha, NE;* [3]*AVI BioPharma, Corvallis, OR.*

A phosphorothioate oligonucleotide (PS ODN) with sequence antisense to *c-myc* mRNA (5'-AACGTTGAGGGGCAT-3'; LR-3280) was injected into the right atrium of the heart of Rhesus monkeys as a 30-60 second bolus. A dose of 3.3 mg/kg into conscious monkeys produced no observable alterations in blood pressure while injection of 5.0 mg/kg produced profound hypotension with blood pressure as low as 27 mm Hg. Radioligand binding assays demonstrate LR-3280 competes with prazosin for the α_1 adrenergic receptor with an IC_{50} of 15μM which favors binding over serum albumin (IC_{50} = 54.7 μM). The LR-3280 concentrations required to inhibit vasoconstriction produced by epinephrine were estimated between 28 and 40 μM which is higher than free drug concentration of 27.4 μM produced by 3.3 mg/kg infusion. However, free drug concentration of 46.2 μM from 5.0 mg/kg of LR-3280 blocks sympathetic tone produced by epinephrine resulting in profound vasodilation followed by decreased cardiac output and blood pressure with increased heart rate. Hypotension was reversed by i.v. isotonic saline and prevented by admixing serum albumin to 5.0 mg/kg LR-3280 prior to injection confirming that free ODN concentration determines cardiovascular events. LR-3280 decreased *in vivo* response to phenylephrine suggesting a common adrenergic receptor site. Reducing the number of bases of the PS ODNs to 5 and 9 bases reduced the binding affinity *in vitro* and bolus infusion of 5.0 mg/kg of 9-mer no longer produced hypotension. In conclusion, the array of anionic charge is responsible for PS ODN induced hypotension following intravascular bolus injections.

1396 THE EFFECTS OF NANDROLONE ON MYOCARDIAL FUNCTION IN HAMSTERS: BIOINDICATORS OF TOXICITY.

S F Long[1] and E Puglielli[2]. [1]*Dept of Pharmaceutical Sciences, School of Pharmacy, Southwestern Oklahoma State University, Weatherford OK and* [2]*ChemAdvisor, Pittsburgh, PA.* Sponsor: C L Winek.

The anabolic-androgenic steroid class of drugs has been implicated in sudden myocardial death. This is supported by laboratory research demonstrating cardiovascular changes that could decrease cardiac health. The present research represents a portion of an on-going project to examine the effects of nandrolone decanoate (ND) on myocardial function. Golden Syrian hamsters (90 days old) were administered with 4 mg ND (100 mg/ml in sesame oil) subcutaneously once weekly for 24 weeks, during which time animals were weighed weekly and observed daily for gross adverse effects. Following the dosage period, subjects were anaesthetised with pentobarbitone (50 mg/Kg, intraperitoneally). Upon induction of anaesthesia, electrocardiograms (ECG) were obtained, using Chart 3.3.5 for MacLAB, for 2 min. Following ECG data collection and while the animal was anaesthetised, euthanasia by exsanguination (direct cardiac puncture) was performed. Blood was collected and subjected to centrifugation. The resultant serum was stored at -20°C for later analysis. The heart was then removed, ventricles dissected out, weighed, and homogenised. Following centrifugation of heart homogenate, the supernatant was collected and stored in glycerol at -20°C for analysis. Liver, kidneys, and testes were excised, weighed, and examined for gross abnormalities. Serum was used for the spectrophotometric analysis of creatine kinase activity, lactate dehydrogenase activity, and calcium. Ventricular homogenates were used for determination of creatine kinase activity. The results indicate that subjects dosed with ND exhibit less weight gain (20% increase in body weight) than controls (35%). Heart:body weight ratios were not significantly different between dosed (0.395±0.025) and control (0.36±0.02) subjects. However, testicular (1.38±0.245 vs. 2.95±0.276) weights were significantly lower in treated subjects. Kidney (1.24±0.032 vs. 0.79±0.017) and liver (5.34±0.243 vs. 4.06±0.0146) weights were significantly greater in treated subjects. There were no significant differences in serum or ventricular CK activity. However, serum calcium was significantly elevated in dosed subjects (4.47±0.512 vs. 2.137±0.149) as was serum LDH activity (317.8±41.7 vs. 112.4±17.2). Subsequent analysis of ECG data indicated no significant difference in PR intervals, QRS intervals, ST segments, nor in P, QRS, or T wave amplitudes. The data suggest that their is no direct toxic effect of ND on the myocardium of hamsters, as assessed by the parameters of this study. Therefore, if cardiovascular health is compromised by the anabolic steroid, it seems reasonable that it results from some indirect action which increases the risk of cardiovascular health, although further research is required to support this theory.

1397 COADMINISTRATION OF HERCEPTIN WITH ANTHRACYCLINE AND CYCLOPHOSPHAMIDE: NONCLINICAL INVESTIGATIONS INTO MECHANISM OF CARDIOTOXICITY.

W Leach, N Dybdal, J Fox, D Eppler, T Hotaling, and T Reynolds. *Genentech Inc., South San Francisco, CA.* Sponsor: J Bussiere.

HER2 (erbB2), a member of the human epidermal growth factor family of receptor tyrosine kinases, is overexpressed in 25-30% of primary breast cancers. Although cardiotoxicity is a known side-effect of anthracycline (A) + cyclophosphamide (C) administration, in Phase III clinical trials with Herceptin (recombinant humanized monoclonal anti-HER2, trastuzumab) an increased incidence of signs and symptoms of cardiac dysfunction was observed in some women receiving the combination of Herceptin + AC, compared with women receiving AC only. Cardiac dysfunction was not predicted by the nonclinical safety studies; there was no evidence of Herceptin binding to cardiac tissue, and there was no evidence of direct toxicity in chronic studies conducted in primates. In addition, nonclinical pharmacokinetic studies demonstrated that Herceptin did not impact the disposition of doxorubicin or the combination of doxorubicin + cyclophosphamide. To elucidate the possible role of Herceptin in the pathogenesis of cardiac dysfunction, HER2 expression was evaluated in endomyocardial biopsies (EMB) obtained from 3 patients enrolled in Herceptin Phase III clinical trials, and compared with archived heart tissue from cardiomyopathic and normal hearts. Evidence of HER2 gene expression was not detected by in situ hybridization (ISH) in normal heart but was detected in 2/3 of the EMB specimens and in the archived cardiomyopathic heart tissue. In contrast, there was no evidence of gene expression by ISH for neu (the rodent homolog of HER2) in a rat model of doxorubicin-induced cardiomyopathy. The use of animal models is limited by the species-specificity of Herceptin for human and primate HER2, thus a surrogate antibody was identified for use in a rat model of doxorubicin-induced cardiomyopathy. Based on the results of these studies, the role of Herceptin in the observed cardiotoxicity is still unknown.

1398 KINETICS OF CALCIUM IN SPONTANEOUS CARDIAC CALCIFICATION IN DBA/2 MICE.

N Maeda[1], K Fukuda[1], T Hosokawa[1], S Manabe[1], S Itagaki[2], and K Doi[2]. [1]*Lab. Anim. Sci. & Tox. Labs., Sankyo Company, Ltd., Tokyo, Japan;* [2]*The University of Tokyo, Tokyo, Japan.*

Two types of spontaneous cardiac calcification occurred in DBA/2 mice: massive myocardial calcification below the right ventricular epicardium and small focal calcification with no-specific location. Incidence of the former was found to be high at a relatively young (near 100% at 8 to 10 weeks). An ultrastructural study revealed that as an incipient event, electron-dense granular deposition occurred in mitochondria and myofibriller degeneration was concurrently observed. X-ray microanalysis demonstrated that such electron-dense granular deposits were a complex of calcium (Ca) and phosphorous. To investigate the kinetics of Ca in DBA/2 mice, uptake of ^{45}Ca in the cardiac tissue was measured in 4- to 8-week-old mice, and whole-body and heart autoradiograms (ARG) were made at 6 weeks of age. BALB/c (low incidence) and C57BL (zero incidence) mice were used for comparison. Corresponding with gross and histologic cardiac lesions, ^{45}Ca uptake in the cardiac tissue was higher in the right ventricle, and an extremely high level of ^{45}Ca uptake in the right ventricle was observed in 2 of 10 7-week-old DBA/2 mice. Quantification of tissue concentration of ^{45}Ca, using the whole-body ARG, revealed that uptake of ^{45}Ca was at similar level among 3 strains in tissues excluding right ventricle. On the heart ARG, 2 types of ^{45}Ca uptake, massive and focal as mentioned above, were also observed. These results and prophylactic efficacy of Ca antagonists reported by other researchers suggest that rapid Ca influx and resulting Ca overload in the cardiomyocytes might lead to degeneration and necrosis of them. Why massive myocardial calcification occurred below the right ventricular epicardium is still obscure.

1399 RAT CARDIOVASCULAR DYSFUNCTION PRIOR TO DEATH DURING EXPOSURE TO CONCENTRATED AMBIENT AIR PARTICLES.

E G Lovett[1], R W Clarke[1], R L Verrier[1], P Koutrakis[1], J Lawrence[1], J M Antonini[2], and J J Godleski[1]. [1]*Harvard School of Public Health, Boston, MA, USA;* [2]*HELD/NIOSH, Morgantown, WV, USA.*

Groups of 12 rats with or without monocrotaline treatment (MT)-induced pulmonary inflammation were exposed by inhalation to either filtered air (FA) or concentrated urban air particles (CAPs) for five hours per day on three consecutive days. Continuous electrocardiograms (EKGs) were recorded on three members of each group during exposures. CAPs concentrations were approximately 200, 600, and 150 μ g/m^3, respectively, on day 1, 2, and 3 of exposure. During the exposure period, one MT, FA-exposed (8.3 %) and three MT, CAPs-exposed (25%) animals expired. Continuous EKG was recorded on one of the MT rats which succumbed on the third day of CAPs exposure. Death occurred 90 minutes (min) into exposure and was preceded by an initially steady heart rate (HR) for 15 min followed by a linear reduction in HR from 340 to 290 beats per min over the next 60 min. Concomitant increases in PR interval, QRS duration, HR standard deviation, low frequency HR variability power, and low-to-high frequency ratio were observed. QT interval contemporaneously decreased accompanied by a decrease in T wave height, deepening of the S wave, and emergence of possible U waves. Numerous premature ventricular contractions and other dysrhythmias were noted prior to demise. To our knowledge, this is the first continuous recording of cardiac death apparently induced by inhalation of CAPs. A similar mode of death (bradycardia and dysrhythmia followed by asystole) was reported in MT animals instilled with residual oil fly-ash particles (Watkinson et al, *Tox Sci* 41:209). Canines exposed to CAPs in our laboratory have also exhibited HR slowing. Furthermore, analysis of human data obtained from implantable cardiac defibrillators has associated bradycardic events with $PM_{2.5}$ elevation. Cardiac conduction system dysfunction may be an important mechanism of death associated with fine particle exposure in the MT rat. (Supported By: ES00002, ES08129, HL05947, and HL54958.)

1400 ACUTE CARDIORESPIRATORY EFFECTS OF PYRIDOSTIGMINE BROMIDE AND N,N-DIETHYL-m-TOLUAMIDE (DEET) IN RATS.

L A Chaney, R W Rockhold, and A S Hume. *University of Mississippi Medical Center, Jackson, MS, USA.*

Acute co-administration of a reversible, peripherally acting cholinesterase inhibitor, pyridostigmine bromide (PB), and a personal insect repellent, N,N-diethyl-m-toluamide (DEET), resulted in potentiation of lethality. This study was designed to explore the mechanism(s) of that lethal interaction. Whole body plethysmography was used to measure respiratory activity in conscious freely-moving rats, while cardiovascular function was monitored simultaneously through an arterial catheter, following acute i.p. administration of PB (2 mg/kg) and/or DEET (300 or 500 mg/kg). PB (2 mg/kg) alone stimulated respiration and increased blood pressure. Arterial pH levels were decreased, while pO_2 and pCO_2 remained at control levels. Administration of DEET (300 mg/kg) alone increased tidal volume and reduced blood pressure. Blood gases and pH levels were unaltered. A higher dose of DEET (500 mg/kg) also decreased respiratory and heart rate. Co-administration of PB (2 mg/kg) and DEET (300 mg/kg) increased tidal volume, decreased arterial pH, and elevated pCO_2. Heart rate and blood pressure declined progressively after drug co-administration. Pretreatment with atropine methyl nitrate reduced the individual effects of PB or DEET, and significantly increased survival after co-exposure to both agents. While changes in respiratory function contributed to the lethal interaction, it was concluded that the primary cause of death was circulatory failure. The results are consistent with a hypothesis that DEET depresses central cardiorespiratory control mechanisms and sympathetic outflow. In addition, PB-induced accumulation of acetylcholine at peripheral cholinergic receptor sites resulted in bradycardia that is postulated to further reduce cardiac output, causing progressive circulatory shock. Pretreatment with atropine methyl nitrate protected against circulatory collapse by preventing PB-induced bradycardia.

1401 ACCELERATION OF ATHEROSCLEROTIC PLAQUE FORMATION IN Apo E$^{-/-}$ MICE BY EXPOSURE TO TOBACCO SMOKE.

C G Gairola[1] and A Daugherty[2]. *College of Pharmacy[1] and Medicine[2], University of Kentucky, Lexington, KY, USA.*

Epidemiological studies have implicated active and passive smoking with increased risk of cardiovascular diseases. The present study was performed to determine if exposure to sidestream cigarrette smoke (SSCS) influences the development of experimental atherosclerotic plaque formation in a rodent model. Female Apo E$^{-/-}$ mice (n=20), maintained on a high fat diet, were divided into two equal groups. One group was exposed to SSCS in a whole-body exposure chamber set at a particulate concentration of 22±5mg/m^3 for a total of 6 hrs each day, 5 days a week. The second group was exposed to filtered ambient air and served as control. Elevated levels of blood carboxyhemoglobin and pulmonary CYP 1A1 were used to ascertain effective exposure of animals to smoke. The animals were killed after 3 months of exposure and their serum and aorta were collected for analyses. Both groups exhibited high serum cholesterol and triglyceride concentrations but no differences between the control and smoke-exposed groups were noticed. Image analysis of entire intimal area of the aorta covered by grossly discernable lesions demonstrated a significant increase in the smoke-exposed group. In agreement with these data there were significant increases in the aortic content of free and esterified cholesterol following smoke exposure. These results clearly demonstrate an enhancing effect of tobacco smoke exposure on the development of lesions in an atherosclerosis susceptible mouse model. (Supported by KTRB 5-41110 and the Gill Heart Institute.)

1402 ALLYLAMINE AFFECTS GLUCOSE UPTAKE IN RAT VASCULAR SMOOTH MUSCLE CELLS.

S G Milton and Z Yousefipour. *College of Pharmacy and Health Sciences, Texas Southern University, Houston, TX.* Sponsor: M A Smith.

A streptozotocin diabetic rat model was used to investigate the effects of allylamine-induced atherosclerosis. Vascular smooth muscle cells (VSMC) from allylamine treated diabetic and non-diabetic rats were used to investigate deoxyglucose uptake as an insulin-sensitive response. VSMC from untreated animals exhibited a 1.8-fold increase over basal uptake. The observed effect appears to be mediated by specific glucose transporters as evidenced by inhibition of the effect in the presence of high glucose. Allylamine treatment inhibits both basal and insulin-stimulated uptake. In the absence of insulin approximately 33% inhibition was observed. This inhibition did not change significantly in the presence of insulin suggesting an alteration of insulin-sensitive response. However, cells remained sensitive to insulin effects following *in vitro* exposure of non-treated cells to 5μM allylamine during the course of the uptake. In VSMC from non-allylamine treated diabetic rats , basal and insulin-stimulated uptake were decreased by about 38% and 30%, respectively. Allylamine treatment does not decrease basal or insulin-stimulated uptake beyond the decrease attributed to the diabetic state. However, allylamine appears to exert an effect on glucose uptake in non-diabetic animals that is not insulin dependent. (Supported by NIH/NCRR RCMI Grant No. G12RR03045-11.)

1403 COLLAGEN AND ELASTIN DEPOSITION BY VASCULAR SMOOTH MUSCLE CELLS IN RESPONSE TO INHIBITION OF SEMICARBAZIDE-SENSITIVE AMINE OXIDASE.

S D Langford, M B Trent, and P J Boor. *Cardiovascular Toxicology Laboratory, University of Texas Medical Branch, Galveston, TX, USA.*

Aortic vascular smooth muscle cells (VSMC) have the highest tissue-specific activity of Semicarbazide-Sensitive Amine Oxidase (SSAO) - an amine oxidase who's physiological function is undefined. This cell type is also responsible for production of collagen and elastin within the mammalian aorta. Our laboratory has demonstrated that *in vivo* SSAO inhibition results in vasculotoxicity in developing rats exemplified by lesions of the medial elastin architecture. This study examines changes in collagen and elastin deposition by cultured rat VSMC exposed to natural and synthetic SSAO inhibitors. Collagen and elastin fractions were isolated from Rat VSMC cultures treated for 30 days with SSAO inhibitors. Semicarbazide ($1x10^{-6}$ M), benzylamine ($1x10^{-5}$ M), and (*E*)-2-phenyl-3-chloroallylamine (Marion Merrell Dow; $5x10^{-6}$ M) - which are relatively specific inhibitors of SSAO - substantially reduced the amount of mature elastin deposited by VSMC while only slightly affecting collagen deposition. $ -aminopropionitrile ($8x10^{-3}$ M) - an inhibitor of lysyl oxidase - predictably reduced insoluble col-

lagen deposition but also completely obviated mature elastin deposition. (*E*)-2-(3,4-dimethoxyphenyl)-3-fluoroallylamine (from $2.2x10^{-12}$ M to $2.2x10^{-9}$ M) - which exhibits affinity for both SSAO and lysyl oxidase - dramatically increased the amount of mature insoluble elastin deposited by VSMC. Altered elastin deposition caused by SSAO inhibition observed in this *in vitro* study strengthens the conclusion that *in vivo* aortic lesions caused by SSAO-inhibition are due to aberrations in elastin metabolism. (This work was funded in part by NIH HL-26189 to PJB and US EPA Fellowship U-915014-01-2 and NIEHS Toxicology Training Grant Fellowship T32ES07254 to SDL.)

1404 CYTOTOXICITY OF ERGINE TO BOVINE ENDOTHELIAL CELLS IN CULTURE.

A E Schultze and J W Oliver. *College of Veterinary Medicine. The University of Tennessee, Knoxville, TN, USA.*

Fescue toxicosis is a poorly defined syndrome of herbivores that consume tall fescue (*Festuca arundinacea* Schreb.) that is infected with an endophytic-fungus (*Neotyphodium coenophialum*). Ergot and pyrrolizidine alkaloid toxins produced by the endophyte-infected plants have been incriminated causally in the tall fescue related morbidity and mortality. Little is known regarding which of the toxins in tall fescue cause(s) the lesions in this syndrome. We examined the cytotoxicity of ergine, an ergot alkaloid of tall fescue, to vascular endothelial cells *in vitro*. Monolayers of confluent bovine endothelial cells received a single administration of ergine (10^{-5}, 10^{-7}, or 10^{-9} M), control vehicle or no treatment, and the media or lysates were examined at 2, 24, 72, and 120 hours after treatment. Administration of ergine as a single dose, repeated doses every 48 hours or repeated doses of ergine at the time of cell feeding caused no significant change in release of lactate dehydrogenase into the media, number of adherent cells or protein content of the monolayers. In contrast, monocrotaline pyrrole, a positive control in our experiments, caused delayed and progressive cytotoxicity to the endothelial cell monolayers. From these data we conclude that the ergot alkaloid, ergine, has little effect on bovine vascular endothelial cells *in vitro*. (Supported by USDA grant 97-35204-4814.)

1405 DISPLACEMENT OF ^{3}H-KETANSERIN IN THE HUMAN UMBILICAL ARTERY BY MIANSERIN, TYRAMINE, AND SEROTONIN.

T L Long[1], P J Rice[2], F R Jelovsek[3], and K E Ferslew[2]. [1]*Toxicology & Risk Assessment Section, Oak Ridge National Laboratory, Oak Ridge, TN;* [2]*Section of Toxicology, Dept. of Pharmacology and* [3]*Dept. of Obstetrics and Gynecology, East Tennessee State Univ., Johnson City, TN.*

We have demonstrated that cocaine produces toxicity in human umbilical arteries through inhibition of the presynaptic reuptake mechanism for norepinephrine and serotonin. Serotonin is a very potent constrictor of human umbilical arteries and norepinephrine and tyramine may produce vasoconstriction via serotonin receptors as well in this tissue. Tissue homogenates of umbilical arteries were used in competitive binding assays to determine displacement characteristics of unlabeled ketanserin, mianserin, serotonin, or tyramine (0.001 μ M - 100 μ M), and norepinephrine (10 μ M) using ^{3}H-ketanserin. The B_{max} of ^{3}H-ketanserin was 15 nmol/mg protein, and the K_D was 241 nM . ^{3}H-ketanserin was competitively displaced by mianserin, a serotonin$_2$ antagonist, with a K_D of 0.3 $\pm$ 0.1 μ M,. Serotonin competitively displaced ^{3}H-ketanserin at two sites with K_D values of 2.8 $\pm$ 1.9 nM and 2.7 $\pm$ 0.7 μ M. Tyramine was able to displace ^{3}H-ketanserin at two sites, with K_D values of 7.9 $\pm$ 7.8 nM and 36 $\pm$ 32 μ M, but norepinephrine was unable to displace ^{3}H-ketanserin, even at a concentration of 10 μ M. These results are paxadoxical to contractile studies where cocaine potentiation of norepinephrine was attenuated by ketanserin. The concentration-dependent displacement of ^{3}H-ketanserin by tyramine is a novel finding. The K_D for tyramine of 36 μ M is within the concentration range (10 - 100 μ M) which produced vasoconstriction. This provides evidence that tyramine is producing its contractile effects through a serotonin$_2$ receptor subtype. Based on the contractile responses to serotonin the functional site for serotonin has a K_D of 2.8 nM in human umbilical arteries.

1406 MENADIONE-INDUCED VASCULAR ENDOTHELIAL DYSFUNCTION AND ITS POSSIBLE SIGNIFICANCE.

J Y Lee, M Y Lee, S M Chung and J H Chung. *College of Pharmacy, Seoul National University, Seoul, Korea.*

Although many studies have shown that treatment of menadione leads to cytotoxicity to endothelial cells, investigations of menadione's effects on blood vessels are limited. Our previous studies have shown that menadione can indirectly provoke alteration in vasomotor tone through platelet cytotoxicity. To determine if menadione directly affects vascular function, menadione itself was added to the aortic rings with or without intact endothelium. Treatment of menadione directly resulted in contraction of aortic rings with endothelium, but did not cause any effect on aortic rings without endothelium. Menadione irreversibly inhibited the acetylcholine- and histamine-induced relaxation of aortic rings with endothelium in a time and dose-dependent manner. Menadione treatment potentiated phenylephrine-induced vasoconstriction in aortic rings with endothelium. Consistent with these *in vitro* results, when menadione was administrated intravenously to rats, blood pressure increased significantly in a dose-dependent manner. Furthermore, menadione infusion suppressed the blood pressure reduction induced by acetylcholine. By demonstrating that menadione caused *in vitro* endothelial dysfunction (i.e., decreased relaxation and increased vasoconstriction in the organ bath experiments) and confirming that these results were consistent with *in vivo* observations, we have provided evidence suggesting that a quinone such as menadione can alter vasomotor tone through endothelial dysfunction. Such dysfunction could possibly contribute to vascular diseases.

1407 MECHANISM FOR MENADIONE-INDUCED ENDOTHELIAL DYSFUNCTION.

J H Chung, J Y Lee, M Y Lee and S M Chung. *College of Pharmacy, Seoul National University, Seoul, Korea.*

Our previous study showed that menadione causes endothelial dysfunction which results in decreased relaxation and increased contraction of blood vessels. In other tissues, menadione exerts cytotoxicity by two mechanisms of action: 1) oxidative stress via redox cycling and 2) arylation. This investigation examined the role of these two mechanisms in menadione-induced endothelial dysfunction. Menadione increased superoxide anion generation in aortic rings in a dose-dependent manner. Superoxide dismutase treatment inhibited both menadione-induced superoxide anion production and menadione-reduced vascular relaxation, suggesting that oxidative stress was involved in these two effects. Menadione also inhibited relaxation induced by the NO donor, sodium nitroprusside, in a dose-dependent manner. Menadione resulted in a dose-dependent reduction of cGMP levels accumulated by acetylcholine. This effect was also blocked by superoxide dismutase, suggesting that superoxide generated by menadione could play a role in the inhibition of the nitric oxide pathway. Relaxation to acetylcholine was also inhibited by benzoquinone, suggesting that protein arylation by benzoquinone may also contribute to impairment of relaxation. These results suggest that menadione can cause endothelial dysfunction in blood vessels by the inhibition of the nitric oxide pathway via superoxide generation and that arylation activity may also be another important mechanism. Collectively, these results indicate that quinones such as menadione which have the ability to induce oxidative stress and arylation reactions can also cause endothelial dysfunction and ultimately, possibly contribute to vascular diseases.

1408 DEVELOPMENTAL VASCULOTOXICITY ASSOCIATED WITH INHIBITION OF SEMICARBAZIDE-SENSITIVE AMINE OXIDASES.

P J Boor, S D Langford, M B Trent, and A Balakumaran. *Cardiovascular Toxicology Laboratory, University of Texas Medical Branch, Galveston, TX, USA.*

The endogenous substrate(s) and physiological function(s) of semicarbazide-sensitive amine oxidases (SSAO), enzymes exhibiting highest activity in vascular smooth muscle cells of the mammalian aortic wall, remain undetermined. This study examines the pathophysiological effects to the aortic wall resulting from specific *in vivo* SSAO inhibition. Weanling Sprague-Dawley rats were treated acutely or chronically with either semicarbazide hydrochloride or the chloro- and fluoroallylamine derivatives MDL-72274 or MDL-72145 (Marion Merrell Dow). Treatment with these compounds produced acute (6 and 24 hr) and chronic (21 day) lowering of SSAO activity in aorta and lung with little effect on the activity of the vital matrix form-

ing enzyme - Lysyl oxidase in aortas of chronically treated animals. Chronic SSAO inhibition produced lesions consisting of striking disorganization of elastin architecture within the aortic media accompanied by degenerative medial changes and metaplastic changes in vascular smooth muscle cells. No significant differences in the total weight of dry, defatted aortic elastin and collagen components were observed between chronically SSAO inhibited and control animals. However, the amount of mature elastin was lowered and mature collagen was raised in the aortas of animals treated chronically with semicarbazide. Descending thoracic aortic rings isolated from chronically SSAO inhibited animals had larger cross sectional diameters (i.e., exhibited dilation) when compared to corresponding rings from control animals. This study demonstrates that developmental toxicity - characterized by striking vascular lesions and dilated thoracic aortas - can result from specific *in vivo* SSAO inhibition, suggesting a role for SSAO in connective tissue matrix development and maintenance, and specifically in the development of normal elastin. (Supported in part by NIH HL-26189 (PJB), NIEHS T32ES07254 (SDL, AB), and US EPA U-915014-01 (SDL).)

1409 THEOPHYLLINE INDUCES SPLANCHNIC ARTERIAL DAMAGE IN RATS.

E S Watson, D E Griswold, L W Schwartz and S J Newsholme. *SmithKline Beecham Pharmaceuticals, King of Prussia, PA, USA.*

The splanchnic vascular bed of the rat is susceptible to damage by vasodilating drugs, including phosphodiesterase (PDE) inhibitors. Theophylline, an extensively used PDE-inhibitor drug, has been well studied in animals with respect to its cardiotoxicity, but its vasotoxic potential to rats is not well characterized. Male Sprague-Dawley (S-D) rats (3/group) were given theophylline (100, 200 or 400 mg/kg) by oral gavage as a single dose or as 2-3 consecutive daily doses. Rats were killed 24 hr post-dose and splanchnic vascular beds evaluated histologically. Microscopic lesions (focal medial necrosis) were observed in splanchnic arteries of rats given single or repeated doses 3200 mg/kg. To measure pharmacological activity, male S-D rats (6/group) were given single doses of theophylline by oral gavage and challenged with bacterial lipopolysaccharide (LPS) administered intraperitoneally 90 min post-dose. Theophylline inhibited LPS-induced tumor necrosis factor alpha (TNFa) production (measured by sandwich ELISA in serum collected 90 min following LPS challenge) dose-dependently across the dose range evaluated (3.3-100 mg/kg) with a calculated ED50 of 31.9 mg/kg. The small dose multiple (~6x) between the vasotoxic dose and the pharmacological ED50 for theophylline illustrates remarkable sensitivity of the rat splanchnic vasculature to PDE inhibitor-mediated damage.

1410 AN ASSESSMENT OF THE ANTI-ANGIOGENIC POTENTIAL OF AE-941 IN THE CYNOMOLGUS MONKEY.

M Boyer[1], A Thibodeau[2], A J Lambert[1], P Batham[1], C Banks[1], and G Lulham[1]. [1]*ClinTrials BioResearch Ltd., Senneville, Québec, Canada;* [2]*Aeterna Laboratories, Ste-Foy, Québec, Canada.*

The purpose of the study was to evaluate the anti-angiogenic potential of AE-941 in-vivo in the Cynomolgus monkey using a cutaneous wound healing model. Four healthy Cynomolgus monkeys were allocated to one AE-941 treated group (n=2) and one control group (n=2). The animals were dosed by gavage with AE-941 (50 mg/kg/day) or saline for a period of 7 or 14 days. On the day prior to administration of the first treatment, full thickness cutaneous incisions were made in the interscapular region and sutured in order to allow healing by first intention. At the end of the treatment period, the animals were euthanized and whole body formalin perfusion was performed. The wound sites were collected and paraffin sections were stained with H&E, Masson's Trichrome and Factor VIII-Related Antigen for histopathological examination and morphometric analysis (blood vessel density, vessel wall area/tissue area and blood vessel diameter). The microscopic findings at the incision sites were consistent with healing by first intention in all monkeys and the subacute inflammatory process appeared to be slightly decreased in animals treated with AE-941. Morphometry indicated a decrease in vascular proliferation (blood vessel density) and vessel wall area/tissue area in treated animals when compared to the controls. An increase in the proportion of blood vessels with a diameter of < 10 μm was noted after 14 days of treatment when compared to the control animal and to animals euthanized on Day 8. Using this cutaneous wound healing model in the non-human primate, AE-941 demonstrated histopathological and morphometric changes consistent with an anti-angiogenic effect in-vivo. This model was considered an appropriate evaluation method that could be used concurrently on animals used for preclinical safety studies without impacting upon toxicological endpoints. This would not only minimize the use of animals but also demonstrate pharmacological activity in the species selected to evaluate the safety.

1411 THE CHALLENGES OF USING COMMON MECHANISMS OF TOXICITY IN CHEMICAL REGULATION.

J E Chambers and L P Sheets. *Mississippi State University, Mississippi State, MS, USA and Bayer Corporation, Stillwell, KS, USA.*

The 1996 Food Quality Protection Act (FQPA) has mandated that cumulative risk assessments be performed on pesticides acting through a common mechanism of toxicity. This strategy has not previously been used in pesticide regulation by the US Environmental Protection Agency (EPA). FQPA requires that new questions be asked to determine which pesticides act through a common mechanism of toxicity, and subsequently what methodology is appropriate for the new cumulative risk assessments. The FQPA©mandated time frame for reregistration of pesticides has created substantial pressure for the rapid development of new principles and procedures. Since these new principles and methods are without precedent in the risk assessment process for pesticides, there is considerable controversy regarding identification of cases when such cumulative risk assessments should be performed, and, if required, how they should be conducted. The roundtable panelists will present some common principles which can be used in judging whether toxicants act by a common mechanism of toxicity, and how these general principles were used to consider the anticholinesterase (organophosphate and carbamate) insecticides as a case study. The roundtable will also indicate the limitations and difficulties which arise by utilizing a restricted definition of mechanism of toxicity. Additionally, the roundtable will suggest possible methods which could be used to perform cumulative risk assessments on toxicants judged to act through a common mechanism of toxicity, and will indicate how the EPA is currently utilizing the common mechanism approach in its implementation of FQPA. The roundtable is designed to introduce a number of the controversies and pending questions associated with the common mechanism of toxicity issue.

1412 A PARTNERSHIP APPROACH TO THE EVALUATION OF ALTERNATIVE MODELS FOR CARCINOGENICITY TESTING.

D E Robinson and J S MacDonald. *International Life Sciences Institute, Washington, DC, USA and Schering-Plough Research Institute, Kenilworth, NJ, USA.*

The willingness of the agencies involved in the regulation of pharmaceuticals to accept data from newly proposed models of carcinogenicity testing (e.g. transgenic animals and the neonatal mouse model) has stimulated intense international interest in gaining experience and a greater understanding of the strengths and limitation of the specific models. The International Life Sciences Institute (ILSI) Health Environment Sciences Institute (HESI) is currently coordinating a collaborative research program to characterize the responsiveness of alternative models for carcinogenicity testing. Participating in this research effort are nearly 60 industrial, government and academic laboratories from the United States, Europe and Japan. The program involves the development of standardized protocols for variety of alternative assays and the use of prototype compounds selected on the basis of mechanistically meaningful carcinogenic activity or non-carcinogenicity in the rodent bioassay. In addition, collaborative research will be conducted in number of academic institutions to gain a greater understanding of the mechanistic basis for the responses of these new models, facilitating interpretation of the findings. Most of the studies are underway and results will be forthcoming throughout 1999. A workshop will be organized by ILSI in late 1999 to present the combined results of these studies. This roundtable will describe the scientific and regulatory basis for the collaborative research effort, and provide perspectives by some of the participating government, industry and academic scientists from the U.S., Europe and Japan on these models. Emphasis will be placed on the unique partnership that has been formed between these sectors to generate the necessary information to evaluate these models. The goal of the roundtable will be to stimulate discussion regarding the model the partnership provides for future cooperative activities aimed at evaluating new proposed approaches that may enhance toxicity assessments.

1413 ALIPHATIC ETHERS AS FUEL OXYGENATES: HEALTH EFFECTS AND REGULATORY ISSUES.

S J Borghoff and J M Benson. *Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA and Lovelace Respiratory Research Institute, Albuquerque, NM, USA.*

The Clean Air Act Amendments of 1990 require the use of oxygenated fuel in certain regions of the USA to reduce carbon monoxide emissions. Currently, the aliphatic ether most widely used to oxygenate gasoline is methyl tert-butyl ether (MTBE). However, other compounds of similar structure such as ethyl tert-butyl ether (ETBE) and tert-amyl methyl ether (TAME) are being used on a more limited basis. Because MTBE is added to gasoline at up to ~15% w/v, an enormous amount is being produced. People are potentially exposed to these compounds at low levels while refueling and driving automobiles (inhalation) and drinking contaminated water (ingestion). Complaints from the public along with chronic adverse effects of MTBE in rodents precipitated the need to further investigate the potential health effects of these ethers in people. An overview of the general toxicity (MTBE, ETBE, and TAME) and cancer (MTBE) studies carried out in rodents will be covered to emphasize the key human risk assessment issues associated with these chemicals. Results from human exposure studies will be presented and comparative studies on metabolic fate, and acute toxicity of these ethers in rodents and people will be included. Studies describing the potential modes of action by which MTBE induces tumors in chronic rodent studies will be described. Current risk assessment issues will be discussed and how the available information on these ethers is being used to carry out a more realistic risk assessment of the potential human health effects from exposure to these compounds.

1414 NEUROTOXIC, DEVELOPMENTAL AND TUMORIGENIC EFFECTS OF METHYL *tert*-BUTYL ETHER.

J Benson. *Lovelace Respiratory Research Institute, Albuquerque, NM, USA.*

Methyl tert-butyl ether (MTBE) is the predominant oxygenate currently used in oxyfuels and reformulated gasoline (RFG) to reduce carbon monoxide emissions from automobiles. The numbers of individuals living in metropolitan areas using oxyfuels is in excess of 120 million. Short-term effects reported by some individuals exposed to MTBE in gasoline include headache, eye irritation, burning sensation in the nose and throat, cough, dizziness/disorientation, and nausea. These symptoms have not been reproducibly duplicated in either community studies or studies involving controlled human exposures. There are no data on the long-term health effects associated with human exposure to MTBE. Adverse health effects in laboratory animals exposed to MTBE are generally only observed at high exposure levels. Acute, reversible neurotoxic effects have been observed in rats inhaling 800, but not 8000 ppm MTBE. Developmental effects have been observed in offspring of rats and mice exposed to 1300 ppm and 300 ppm, respectively. The no adverse effect level for developmental effects in these species was 300-400 ppm. Repeated exposure by ingestion or inhalation to high levels of MTBE have produced: 1) lymphomas and leukemias in female Sprague-Dawley (SD) rats ingesting 250 and 1000 mg MTBE/kg/day; 2) testicular interstitial cell neoplasms in SD rats ingesting 1000 mg/kg/day and F344/N rats inhaling 3000 and 8000 ppm MTBE; 3) renal tumors in male F344 rats inhaling 3000 and 8000 ppm; and liver tumors only in female CD-1 mice inhaling 8000 ppm MTBE. Tumor responses in rodents have all occurred at concentrations exceeding expected human exposure by orders of magnitude. Because of this, it is important to understand the mode of action for these responses in rodents and determine their relevance to assessing human risk from MTBE exposure.

1415 TOXICITY AND TOXICOKINETICS OF ALIPHATIC ETHERS- HUMAN VS RODENT STUDIES.

G Johanson[1,2] and A Nihlèn[1]. [1]*National Institute for Working Life, Solna, Sweden;* [2]*Department of Occupational and Environmental Medicine, Uppsala University Hospital, Sweden.*

Aliphatic ethers, mainly methyl and ethyl tertiary butyl ethers (MTBE, ETBE) and methyl tertiary amyl ether (TAME) are widely used as gasoline oxygenates in order to improve combustion and thereby reduce harmful emissions. Exposure in the low ppm to ppb range occurs mainly during manufacturing, distribution, filling, gas station attendance, and driving, and occasionally via polluted drinking water. Animal studies show that nearly 100% of the radioactivity is excreted within 24 h after administration of 14C-labelled ether, suggesting low potential for tissue binding. In man, the three parent ethers have similar inhalation toxicokinetic profiles, with substantial respiratory uptake and relatively rapid multiexponential postexposure decay, conistent with rapid partitioning between tissues and slight accumulation in adipose tissue. The decay in blood and urine of the metabolites t-butyl alcohol (TBA) and t-amyl alcohol (TAA) is much slower, with half times of about 10 h and 6 h, respectively. These metabolites may be suitable for biological monitoring of gasoline exposure. No evidence of saturation was seen at exposure levels up to 75 ppm in man and up to 300 ppm in rodents. CNS function, mucosal irritation, nasal inflammation and lung function have been studied after short-term exposure of a small number of male volunteers. No effects of MTBE were seen after 2h exposure at 50 ppm in one study, whereas another reported heaviness in the head and mild irritation after 3h at 75 ppm. Slight mucosal irritation and slightly impaired pulmonary function were seen in men exposed to 50 ppm ETBE for 2h. Similar symptoms have been associated with MTBE in epidemiological studies, with presumably markedly lower exposure levels raising the issue of sensitive subpopulations.

1416 BIOTRANSFORMATION OF METHYL *tert*-BUTYL ETHER IN HUMANS AND RATS.

W Dekant, A Amberg and E Rosner. *Department of Toxicology, University of Wurzburg, Wurzburg, Germany.*

Methyl tert-butyl ether (MTBE) is widely used as an additive to gasoline to increase oxygen content and reduce tail pipe emission of pollutants. Therefore, widespread human exposure may occur. To contribute to the characterization of potential adverse effects of MTBE, its biotransformation was compared in humans and rats after inhalation exposure. Human volunteers (3 males and 3 females) and rats (5 males and 5 females) were exposed to 4 and 40 ppm MTBE for 4 hours in dynamic exposure systems. Urine samples were collected for 72 h in 6 h intervals and blood samples were taken in regular intervals for 48 h in humans. In urine, the MTBE-metabolites tert-butanol, 2-methyl-1,2-butanol, 2-methyl-1,2-butane diol and 2-hydroxyisobutyric acid were quantified, MTBE and tert-butanol were determined in blood samples. After the end of the exposure period, blood concentrations of MTBE in rats (5.9 (1.8 (M) and humans (6.7 (1.6 (M) were similar after 40 ppm MTBE. MTBE was rapidly cleared from blood with a half life of 2.6 (0.94 in humans and 0.5(0.2 h in rats. The blood concentrations of tert-butanol were 21.8 (3.7 in humans and 36.7 (10.8 in rats after 40 ppm MTBE. Tert-butanol was also rapidly cleared from blood with half lives of 5.3 (2.1 h in humans and 0.4 (0.1 h in rats. In urine of both species, 2-hydroxyisobutyrate was recovered as major excretory product in urine. Both tert-butanol and 2-methyl-1,2-propane diol were minor metabolites. All metabolites of MTBE excreted with urine were also rapidly eliminated in both species. Elimination half lives for the different urine metabolites of MTBE were between 10 and 17 h in humans and 3.5 and 4.5h in rats. The obtained data indicate that MTBE-biotransformation and excretion is similar in rats and humans and MTBE and its metabolites are rapidly excreted in both species. Supported by the Health Effects Institute, agreement No. 96-3

1417 SPECIES-SPECIFIC TUMOR RESPONSES FOLLOWING EXPOSURE TO METHYL *tert*-BUTYL ETHER (MTBE): POTENTIAL MODES OF ACTION.

S J Borghoff[1], T M Williams[1], J Prescott-Mathews[2], G Moser[3], and T L Goldsworthy[3]. [1]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA;* [2]*Merck Research Laboratories, West Point, PA, USA;* [3]*Integrated Laboratory Systems, Research Triangle Park, NC, USA.*

MTBE is a gasoline additive used to decrease carbon monoxide emissions. In rats and humans, MTBE is metabolized to tert-butyl alcohol (TBA). MTBE and TBA are negative in genotoxicity assays and cause renal tumors in male rats following chronic exposure. Short-term inhalation exposure studies have shown that MTBE and TBA induce (2u-globulin nephropathy ((2u-N) and renal cell proliferation in male rats. These responses are associated with the development of renal tumors in male rats following chronic chemical exposure. The classification of both MTBE and TBA as chemicals that induce renal tumors mediated by (2u-N will have significant impact on the hazard identification of these chemicals. MTBE also caused liver tumors in chronically exposed female mice. MTBE increased liver weight and hepatic microsomal cytochrome P450 activity at 3 and 21 days and 16 wks without hepatotoxicity and transiently increased hepatocyte DNA synthesis at 3, but not 21 days or 16 wks. MTBE also produced endocrine modulations

suggestive of estrogen antagonism. These effects of MTBE were similar to those produced by unleaded gasoline (UG). However, unlike UG, MTBE lacked tumor promoting activity in DEN-initiated mice suggesting that MTBE produced liver tumors through a mechanism different from that of UG. The induction of Leydig cell tumors in male rats following exposure to nongenotoxic chemicals has been shown to be a consequence of the ability of a chemical to interfere with endocrine regulation. Information concerning the mode of action by which MTBE induces these tumors in rodents is necessary to evaluate if these responses are relevant in assessing human risk. (These studies were sponsored by the Oxygenated Fuels Association.)

1418 RISK ASSESSMENT OF ALIPHATIC ETHERS: CRITICAL ISSUES.

W H Farland and J M Davis. *National Center for Environmental Assessment, US EPA, Washington, DC, USA.*

The 1990 Clean Air Act Amendments require oxygenated fuels in certain areas of the U.S.A. with excessive levels of carbon monoxide or ozone. Methyl tert-butyl ether (MTBE) is the most widely used oxygenate and has also been used since the 1970s to enhance gasoline octane. The widespread use of oxygenates has led to increased interest in the fate and transport of, and the potential for human exposure to, these chemicals in air and water. Questions have also arisen about the possible risks to human health posed by oxygenated fuels or oxygenates alone. Although EPA has derived an inhalation reference concentration of 3 mg/m3 for noncancer effects of chronic MTBE exposure, the lack of an adequate data base has made it difficult to evaluate potential health risks related to other routes or durations of exposure to MTBE, particularly in drinking water. U. S. EPA's draft (1998)'Research Strategy for Oxygenates in Water' proposes that it may be possible to estimate oral toxicity risk using the inhalation toxicity data base on MTBE. Although pharmacokinetic modeling efforts would support this route-to-route extrapolation, to achieve credible results several issues have to be addressed related to species differences in the metabolism and toxicity of MTBE. Are the carcinogenic responses observed in rodent studies at relatively high concentrations relevant, qualitatively and/or quantitatively, to potential human carcinogenic responses? What are the modes of action underlying different carcinogenic effects in laboratory animals? Does the (2u-globulin protein account completely for the male rat kidney tumors? Do hormonal perturbations underlie male rat testicular, female mouse liver, and possibly other tumorigenic effects? If so, what are the implications for risk of other cancer and/or noncancer effects? What influence might organoleptic reactions have on exposure and effects? Answers to these and other questions will assist EPA in characterizing the potential health risks related to MTBE and other fuel oxygenates.

1419 THE ROLE OF DNA REPAIR IN MAINTENANCE OF GENOME STABILITY.

D L Springer and W M Baird. *Molecular Biosciences Department, Battelle Pacific Northwest National Laboratory, Richland, WA, USA and Environmental Health Sciences Center, Oregon State University, Corvallis, OR, USA.*

The ability of cells to repair damage to their DNA induced by xenobiotics is a critical factor in determining whether these agents induce mutations which can lead to diseases such as cancer. Recently there have been major advances in our understanding of the molecular processes of DNA repair. This symposium will describe some of the recent progress in determining the mechanism of repair of damaged DNA and the relationship between lesion removal and mutations. Structural studies of proteins involved in base excision repair, the process required to remove oxidative base damage and certain types of radiation-induced lesions, coupled with functional studies now provide an understanding of the molecular basis of this repair process. This understanding has been advanced by in vitro studies using DNA-histone substrates (i.e., chromatin complexes) that demonstrate the mechanisms by which DNA-protein interactions result in damage recognition and repair. Simultaneously, advanced PCR techniques have been developed to provide information on the location of damage within the genome, allowing measurements of damage removal at specific DNA bases, to determine how persistence of such adducts is related to the location of mutations in tumors. Recent availability of transgenic animals with specific repair gene knockouts are allowing the identification of critical genes involved in repair of different types of DNA damage. Thus, information from both molecular and structural biology approaches, coupled with sensitive analytical techniques, are providing the basis for improved risk assessments for DNA damaging agents by facilitating low dose extrapolation and interspecies comparisons.

1420 DNA REPAIR PATHWAYS AND ENVIRONMENTAL GENOMICS.

S H Wilson. *Laboratory of Structural Biology, Division of Intramural Research, National Institute of Environmental Health Sciences, Research Triangle Park, NC, USA.* Sponsor: D L Springer.

There is an extreme variability in mammalian cellular susceptibility upon exposure to genotoxic agents, such as DNA alkylating agents. In some cases, a genetic defect in a DNA repair gene renders a cell hypersensitive to a genotoxic agent, e.g., XPA and UV light, whereas in others the cells become tolerant to the agent, e.g., MSH2 and MNNG (N-Methyl-N'-Nitro-N-Nitrosoguanidine). While a host of genes that play a role in susceptibility to such environmental exposures have been identified, the genetic variations in these genes occurring in the human population have only recently been systematically studied and analyzed for functional implications. In the specific case of many DNA repair genes, a variation in the gene, thus eliminating function of the gene product, carries no apparent cellular phenotype by itself, e.g., mouse cell lines null for DNA polymerase (and 3-methyladenine DNA glycosylase. However, when such cells are exposed to an environmental challenge, such as a DNA methylating agent treatment, a hypersensitive phenotype is readily apparent. Such cellular phenotypes may be additive when associated with multiple variations and, therefore, elimination of more than one DNA repair pathway from the cell renders the cell extremely hypersensitive. Applications of these concepts in the field of environmentally related diseases will be discussed.

1421 REPAIR RATES OF DNA LESIONS ALONG THE p53 GENE: CORRELATION WITH SKIN AND LUNG TUMOR MUTATIONAL SPECTRA.

G P Holmquist. *City of Hope, Dept. Biology, Duarte, CA, USA.* Sponsor: D L Springer.

Repair rates for chemically identical adducts can vary up to thirty fold from one nucleotide position to the next. This variation appears primarily due to local DNA sequence context affecting how the repair machinery recognizes and excises DNA damage. The pattern of repair rate variation, as with the sequence context dependent pattern of DNA damage, is distinct for different mutagens and both the damage pattern and repair pattern contribute to a mutagen's mutational spectrum, the frequency distribution of transitions and transversions induced along a gene by that mutagen. The hot spots for mutation are the more readily damaged and more slowly repaired of the nucleotide positions. We treat human fibroblasts with various mutagens and, by ligation-mediated PCR, measure a mutagen's patterns of damage and repair rates. For skin and lung tumors respectively in humans, the patterns of p53 mutations are correlated with damage and repair rate patterns of UVB-induced cyclobutane dimers and BPDE-induced guanine adducts. For Aflatoxin B1-associated liver tumors, such correlations are absent.

1422 ROLE OF DNA/HISTONE INTERACTIONS IN DNA REPAIR.

D L Springer and V L Burnett. *Pacific Northwest National Laboratory, Richland, WA, USA.*

Within a cell DNA exists as a complex with proteins and is referred to as chromatin; repair enzymes must deal with damaged DNA in this context. The most basic functional unit of chromatin structure, the nucleosome, is composed of 146 bp of DNA wrapped around an octamer of histone proteins. We have evaluated DNA damage and repair using an in vitro model of 5S DNA reassembled into nucleosomes. Our results show that there is a generalized suppression of BPDE damage toward the center of the nucleosome relative to naked DNA and that the magnitude of the suppression is equally distributed at all adducted bases. Neither the translational positioning nor the rotational setting are altered by BPDE damage. Surprisingly, however BPDE damage increased the affinity of damaged DNA for the histone octamer relative to undamaged DNA, suggesting that damaged nucleosomal DNA may be more poorly repaired than naked DNA. Currently we are using highly efficient Xenopus oocyte nuclear extracts to determine the rate of lesion removal at specific sites along the 5S sequence of naked and nucleosomal samples. Using these procedures we are evaluating a number of variables associated with DNA histone interactions of chromatin to determine how

they contribute to DNA repair processes, the site specificity of lesion removal and ultimately mutations. (Supported by US DOE Contract DE-AC-76RLO 1830.)

1423 KNOWLEDGE OF MOLECULAR DOSIMETRY AND ENDOGENOUS DNA ADDUCTS CAN IMPROVE RISK ASSESSMENT AND MANAGEMENT.

J A Swenberg, S-Y Chiang, N Christova-Gueorguieva, A Ham, H Koc, D La, P-H Lin, E Morinello, J Nakamura, A Ranasinghe, M Rios-Blanco, I Roussyn, N Tretyakova, P Upton and K-Y Wu. *Dept of Environmental Sciences and Engineering and Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC, USA.*

The human genome is subjected to attack by a plethora of exogenous and endogenous electrophiles that can result in mutations if not repaired prior to DNA synthesis. Such mutations can result in initiation and progression of neoplasia. Recent developments in molecular biology and analytical chemistry are allowing new questions to be posed that critically evaluate the role of DNA adduct formation and repair. This talk will focus on the use of these highly specific and ultrasensitive tools to compare the amount of endogenous and exogenous adducts for such chemicals as ethylene and propylene oxide, vinyl chloride, butadiene, and oxidative stress inducers such as peroxisome proliferators and PCBs. Abasic sites occur in DNA as a result of incomplete DNA repair and depurination and also can result in mutations. By understanding dose-response relationships for this complex matrix of DNA damage, the scientific basis for risk assessment and management can be improved. (Supported in part by grants P42 ES5948, T32 ES7126 and F32 ES5779 from NIEHS and grants from the CMA and Health Effects Institute.)

1424 CHEMICAL MODIFIERS OF RESPONSE TO FOOD-BORNE MICROBIAL PATHOGENS.

R T Riley[1], J J Pestka[2], and R A Roth[2]. [1]*USDA-ARS, Athens, GA, USA and* [2]*Michigan State University, E. Lansing, MI, USA.*

Do chemicals contribute to increased human and animal health risks from exposure to food-borne microbial pathogens and their toxins? Chemicals can alter biological processes that are critical determinants in the host response to microbial pathogens and their products. Conversely, microbial pathogens induce inflammatory responses that can modify susceptibility to xenobiotics. Outbreaks of disease due to contamination of food and water with well-known and newly emerged microbial agents have been on the rise in developed countries. Characterization of the toxins produced by such pathogens and their role in tissue injury and disease progression is a challenging area of research. For example, the Shiga toxin family, produced by Shigella and E. coli 0157:H7, includes proteins that modify the host immune response and play key roles in the development of gastrointestinal and renal disease. In addition, bacterial endotoxin arising from translocation from the intestine into the circulation can interact with food-borne chemicals, leading to injury to liver and other tissues. For example, endotoxin can interact with mycotoxins to promote expression of proinflammatory cytokines and activation of apoptotic processes. Several recently discovered food contaminants can alter the expression of microbial pathogen/toxin receptors and adhesion sites. Food contaminants may also alter translocation of the toxins or the pathogen itself and can increase intestinal permeability, resulting in altered response to food-borne microbial pathogens/toxins. Thus, multiple interactions need be considered when assessing risk of food-related disease.

1425 EMERGING FOOD AND WATER-BORNE MICROBIAL DISEASES.

M A Smith and D L Holcomb. *University of Georgia, Athens, GA, USA.*

Food and water-borne illnesses in the US are common and result in an estimated 9000 deaths annually. The emergence of immunodeficient populations such as AIDS or transplant patients further increase the risk of such infections. Outbreaks of food or water-borne poisoning from pathogens such as E. coli 0157:H7, Shigella, Salmonella enteritidis, Campylobacter jejuni, Listeria monocytogenes, and Helicobacter pylori are of particular concern. While the basis for pathogenesis of these microbes is unclear, virulence can involve release of endotoxins and extracellular toxins as well as invasiveness mechanisms. Less is known about types of exposures and dose response relationships. Most food-borne pathogens are capable of inducing a response in the general population, however, the most susceptible populations for many pathogens are children, the elderly, and pregnant women. One understudied area is how chemicals and infectious microbes interact to heighten or reduce disease severity, though research is ongoing. In a classic example, hepatocellular carcinoma is more common in populations that consume large amounts of food contaminated with aflatoxin. Furthermore, individuals that test positive for the hepatitis B virus are a higher risk of developing hepatocellular carcinoma than uninfected individuals. Certainly, other pathogens and chemicals may show similar interactions. However, more information about the dose response, mechanism of action and types of exposures are needed to clarify these interactions.

1426 BIOCHEMICAL AND PHYSIOLOGICAL FACTORS THAT AFFECT PATHOGENESIS CAUSED BY SHIGA TOXIN-PRODUCING *ESCHERICHIA COLI.*

V L Tesh. *Texas A&M University Health Science Center, College Station, TX, USA.* Sponsor: R T Riley.

Although infections with Shiga toxin-producing E. coli are associated with the development of bloody diarrhea, infections with these bacteria are now also recognized as the most common cause of pediatric acute renal failure in many developed countries. The in vitro cytotoxic activity of Shiga toxins has been known for decades, but the precise mechanisms by which the toxins target renal microvascular endothelial cells for damage in vivo remain unknown. Recently, it has become clear that Shiga toxins interact with different cell types in vitro in fundamentally different ways. We hypothesize that the development of the extensive vascular lesions seen in patients with acute renal failure requires the differential interaction of Shiga toxins with multiple cell types. Finally, patients infected with Shiga toxin-producing E. coli are frequently endotoxemic due to damage to colonic epithelium. This presentation will focus on the interaction of Shiga toxins with immune cells and the contributions of Shiga toxins, bacterial endotoxins and the host immune response in the development of life-threatening systemic complications.

1427 BACTERIAL ENDOTOXIN INTERACTIONS WITH FOOD-BORNE CHEMICALS IN THE LIVER.

R A Roth. *Michigan State University, E. Lansing, MI, USA.*

Systemic exposure to small amounts of bacterial endotoxin is commonplace through processes such as infection and translocation from the intestine into the circulation. Such translocation can be enhanced by dietary factors such as alcohol consumption. Recent animal studies revealed an interaction between endotoxin and hepatotoxic, food-borne mycotoxins such as aflatoxin B1 or phytotoxins such as the pyrrolizidine alkaloid, monocrotaline. That is, pronounced liver injury occurs when modest exposure to endotoxin is combined with a subthreshold dose of an hepatotoxic chemical. The monocrotaline-endotoxin synergy does not appear to be due to enhanced bioactivation of the hepatotoxin, and it is not reproduced in cultured hepatocytes. Rather, the enhanced liver injury is likely related to the inflammagenic activity of endotoxin, which includes stimulation of inflammatory cells, release of soluble inflammatory mediators and an activated coagulation cascade. Endotoxin activates Kupffer cells in liver sinusoids, and this activation is critical to the liver injury that endotoxin alone causes at large doses. Kupffer cell destruction protects against the interactive effects of endotoxin with certain hepatotoxicants (eg, allyl alcohol) but is without influence on others (eg, monocrotaline). This and other results suggest that the specific inflammatory factors that are critical to endotoxin-induced enhancement of liver injury may differ among hepatotoxicants. Much remains to be learned about the interactions of endotoxin and other microbial products with food-borne chemicals, but such interactions should be considered for their potential to influence food-related disease.

1428 AMPLIFICATION OF ENDOTOXIN-MEDIATED CYTOKINE EXPRESSION AND LYMPHOCYTE APOPTOSIS BY TRICHOTHECENES: A PARADIGM FOR MICROBE-TOXICANT INTERACTIONS.

J J Pestka. *Michigan State University, East Lansing, MI, USA.*

There is increasing evidence that human exposure to endotoxin (lipopolysaccharide, LPS) from gram negative bacteria such as E. coli and Salmonella may increase the susceptibility of individuals to tissue injury by a variety of chemical agents. Trichothecene mycotoxins are frequent food and indoor air

contaminants that include some of the most potent protein synthesis inhibitors known. Concurrent exposure of mice to small doses of LPS and the trichothecene vomitoxin (VT) results in rapid and markedly elevated mRNA expression and serum concentrations of proinflammatory cytokines as well as prominent lymphocyte apoptosis as compared to mice receiving LPS or VT alone. Augmentation of transcription factor activity is one potential mechanism for cytokine superinduction by trichothecenes. For example, VT impairs synthesis of the negative regulatory protein ((B-(thereby increasing NF-(B activity. Other evidence suggests that trichothecenes increase cytokine mRNA stability thus favoring increased translation. Lymphocyte apoptosis following LPS and trichothecene co-exposure is likely to be mediated by elevated TNF-(expression and TNF-(mediated sequelae such as corticosterone and prostaglandin E2. In addition, trichothecenes can synergize with TNF-(or other apogenic signals to directly induce lymphocyte apoptosis thus further magnifying this response. Study of the interactions between LPS and trichothecenes will provide insight into the potential for increased sensitivity to chemical-mediated immune dysfunction among individuals exposed to gram negative bacteria or their inflammatory products.

1429 XENOBIOTIC-INDUCED ALTERATIONS IN GLYCOSPHINGOLIPID RECEPTORS, MICROBIAL TOXIN BINDING, ADHESION, AND TRANSLOCATION: POTENTIAL MODIFIERS OF DISEASE RESPONSE.

R T Riley[a], K A Voss[a], S Kumagai [b], Y Sugita-Konishi[b], and R P Sharma[c]. [a]*USDA-ARS, Athens, GA, USA;* [b]*National Institute of Infectious Diseases, Tokyo, Japan; and* [c]*University of Georgia, Athens, GA, USA.*

Several common food-borne xenobiotics have the potential to alter the expression of microbial pathogen/toxin receptors and adhesion sites in digestive epithelia and other target tissues. In addition, microbial toxin translocation and intestinal permeability can be modified by xenobiotics altering an organism's response to common food-borne pathogens. Fumonisins (FBs) are fungal toxins found in corn and corn products. Consumption of FB-contaminated corn can result in direct exposure of the digestive epithelia to FB concentrations which inhibit glycosphingolipid (GSL) biosynthesis by human intestinal and other epithelial cells. Thus, FBs and other food-borne inhibitors of GSL biosynthesis modify the expression of receptors and adhesions sites for microbial pathogens/toxins. For example, expression of the cholera toxin, Shiga-like-, and vero-toxin (VT) GSL receptors are decreased in epithelial cells exposed in vitro to FB1. Cholera toxin receptor expression is also altered in the tissue of rodents fed FBs. While expression of the VT receptor is decreased in vitro, VT translocation is increased by FB; suggesting FB alters regulatory processes that are independent of GSL expression. FBs and other fungal toxins, such as deoxynivalenol, have been shown to alter transepithelial permeability, in vitro. These and other studies indicate that food-borne toxin-induced alterations in pathogen/toxin adhesion, internalization, and translocation could significantly modify disease expression in response to common microbial pathogens such as Salmonella and E. coli.

1430 ENVIRONMENTAL JUSTICE: SOCIOECONOMIC INEQUITIES AND POPULATIONS AT RISK.

R Snyder. *Environmental and Occupational Health Sciences Institute and Rutgers University, Piscataway, NJ, USA.*

It has been recognized by minority groups across the nation that many of their communities contain potentially polluting industries which utilize chemicals or treat chemical wastes, develop natural resource, engage in developing or testing weapons, etc. The communities, sensing potential adverse impacts on their health, have appealed to the federal government for help and one response has been the Environmental Justice: Partnerships for Communication program established by NIEHS. The grant program supports studies aimed at determining whether the claims of impacts on health of the people in these communities can be substantiated via environmental health research. There are currently 12 research grants funded (approx. $3 million) by the NIEHS to perform community generated research, usually with the help of a university based research group, aimed at evaluating the impact of local industry on public health. The active participation of stakeholders in the development and performance of research provides new opportunities for interactions and mutual understanding between academics and neighborhood occupants. We will discuss research strategies, environmental contributions to asthma, health effects of PCB's, chemical exposure to migrant farm workers, and role of the community in developing research proposals. (Supported by ES07723.)

1431 THE COMPLEX INTERACTION OF POVERTY, POLLUTION, AND HEALTH STATUS.

K Olden. *National Institute of Environmental Health Sciences, Research Triangle Park, NC, USA.*

Several health surveys reveal that major disparities exist between the health status of the overall population of the U.S. and that of its socioeconomically disadvantaged groups. A recent county-by-county study of the U.S. population demonstrated that life expectancy was decreased by as much as 15 years in those communities experiencing the most severe poverty. While behavioral and lifestyle factors, nutrition, and access to health care services are important contributors to the increased morbidity and mortality among socioeconomically disadvantaged populations, environmental and occupational exposures, over which these individuals have little control, are likely to play a prominent role. Viewed from this perspective, the high morbidity and mortality among the poor might derive in part from the nation's social, economic, public health, and environmental policies. Indisputably a possible interaction of environmental pollution, poverty, and disease burden has gained greater prominence as a legitimate public health issue. Lead poisoning serves as a well-documented example of an association of poverty, pollution, and illness. What is now needed is data that more clearly establish a link between disproportionate exposure to environmental carcinogens and toxicants and a resulting disproportionate morbidity and mortality in the poor. The great need at this time is to conduct exposure assessment studies that define actual exposure levels, to investigate genetic and racial differences in susceptibility to these exposures, and to identify biomarkers of disease risk. Use of these three elements in future studies would bring a refinement in the data set that would be optimal in determining the boundaries of the environmental justice issue. The National Institute of Environmental Health Sciences has instituted several new projects to help achieve this data set. These include the Exposure Assessment Project, the Environmental Genome Project, and the Environmental Justice Grants.

1432 ENVIRONMENTAL JUSTICE AND HEALTH: OVERVIEW OF RESEARCH QUESTIONS, CONCEPTS AND METHODS.

S Wing. *Department of Epidemiology, School of Public Health, University of North Carolina, Chapel Hill, NC, USA.* Sponsor: R Snyder.

The environmental justice movement is challenging biomedical researchers to consider exposure assessment and environmental epidemiology within the context of community-based struggles against the inequitable distribution of hazardous exposures, and social inequalities in health. Research questions are being re-framed to reflect concerns about multiple exposures, multiple outcomes, susceptible sub-populations, and the socioeconomic consequences of disproportionate environmental burdens. Concepts of race and class, central to environmental justice research, are being re-cast as complex biosocial phenomena. Problems with exposure assessment and low statistical power in epidemiological studies have created a demand for geographical analysis using routine data sources, while community concerns have led to a demand for more sensitive assays and biomarkers, as well as for consideration of neuro-endocrine and central nervous system-mediated effects of chemical exposures. Poor access to medical care introduces ethical problems in research design but is also seen as an injustice that follows from socioeconomic and environmental disadvantage. Quantitative studies of the distribution of environmental pollution in North Carolina are used to illustrate the way that epidemiological research is responding to environmental justice concerns. Over 1,300 manufacturing facilities that report to the Environmental Protection Agency's Toxic Release Inventory, and approximately 2,500 confined hog feeding operations registered with the NC Division of Water Quality, are considered in relation to racial, economic and susceptibility characteristics of local communities. Methods of presentation of results reflect the importance of community needs for research findings that can be effectively communicated to a wide audience.

1433 EPIDEMIOLOGICAL & EXPOSURE ASSESSMENT STUDIES OF ASTHMA & LUNG DISEASE IN CHILDREN IN BORDER TOWNS.

M D Lebowitz[1], G Stephen[1], C McRill[1], and M K O'Rourke[1], T Flood[2], M Mack[2], C Rosales[2], L Ortega[2], I Tittelbaugh[3], Y Caruso[4], and [5]R Navarro. [1]*University of Arizona, Tucson, AZ;* [2]*Arizona Department of Health (ADHS);* [3]*Nogales School District, AZ;* [4]*Douglas School District, AZ;* [5]*Son. Sec. Salud Publica, Hermosillo, Son., Mexico; AZ-Son. Binat'l Councils.* Sponsor: R Snyder.

A series of epidemiological and exposure studies of lung diseases in school children & parents in relation to environmental contamination have been conducted in Arizona-Sonora border towns stemming from discussions with community-university-agency prevention partners; this is one of several joint efforts determined though open community communications, based on community health concerns. They have been designed & operated biculturally in full collaboration. Air pollution in Nogales, Son. exceeds US & Mexican standards for PM10, and are high in US border towns. Ozone & CO are also high in all the border towns. However, asthma prevalence rates (7-8%) in the 3 towns studied to date do not differ, but other chronic respiratory symptoms are higher in Nogales, Son., and in homes with tobacco smoking. Differences are also related to socio-economic-environmental inequities. Also, daily symptoms and peak flow relate to daily air pollutant & temperature levels. Community & school fora are being planned to discuss results and plan school & community-based prevention/intervention programs. Studies continue in other border towns. (This work supported by ADHS & ALA AZ grants.)

1434 INTEGRATING RESEARCH INTO THE COMMUNITY-HEALTH EFFECTS OF PCBs IN A NATIVE AMERICAN POPULATION.

D O Carpenter[1], K Cook[1,2], K Jock[2] and H Lickers[2]. [1]*University at Albany School of Public Health, Albany, NY, USA and* [2]*Mohawk Nation at Akwesasne, Hogensburg, NY, USA.* Sponsor: R Snyder.

The Mohawk Nation at Akwesasne lies in the shadow of three aluminum foundries which have contaminated local waters with PCBs and disrupted traditional life styles which depended on fishing as an occupation and food source. For the past ten years a university-community partnership has existed which attempts to determine the degree of PCB contamination in the community, what if any health effects have resulted from PCB exposure, educate community members on sources of exposure and work with the community on strategies and methods of cleanup. A major part of this partnership involves educating the scientists on the culture and values of this distinct community. Initial efforts were focused on determination of breast milk PCB levels, correlated with reported consumption of local fish. While a direct relation was observed prior to 1990, most women of reproductive age stopped eating local fish in response to fish advisories, and present levels are not above background. Considerable concern remains about cognitive, developmental and reproductive effects in children born during the time of PCB exposure, and disease in adults who were exposed for long periods of their life. Research attempting to evaluate these effects is ongoing. Other concerns relate to which diseases occur more commonly in this community than other populations, and this question is being pursued by analysis of clinic records of the Indian Health Service. In addition, through an Environmental Justice grant from NIEHS, a major program of community environmental health education, outreach and training has been implemented which has focused on making scientific information available to the community in a culturally relevant and understandable fashion.

1435 CHEMICAL EXPOSURE AMONG SEASONAL AND MIGRANT FARMWORKERS: COMMUNITY-BASED EPIDEMIOLOGY.

S A Quandt and T A Arcury. *Wake Forest University School of Medicine, Winston-Salem, NC, USA.* Sponsor: R Snyder.

Seasonal and migrant farm workers are at risk for exposure to agricultural chemicals that have short- and long-term health effects. Measuring this exposure, communicating the risk to farm workers and to farmers , and reducing exposure risk require social and cultural knowledge as well as toxicological and epidemiological data. This presentation uses data from ongoing research in North Carolina, which is designed to develop and test effective interventions to reduce farm worker exposure to workplace chemicals. We demonstrate the need to integrate methods from social science, epidemiology, and toxicology in a community participation framework to effectively address exposure issues for this population. In this project, community participation includes partnership with a community-based organization, an advisory committee of farm workers and farmers, and community forums. Formative research data show that the application of toxicological techniques to measure exposure is complicated by the local tobacco farming system with its numerous dispersed plots with individualized chemical application schedules. Data from in-depth interviews and focus groups with community members reveal belief systems that need to be incorporated into efforts to communicate risk. Many farmworkers do not believe they can be exposed unless they physically sense the wet chemicals. They consider exposure effects to be short-term, and know little of possible long-term consequences. Farmers do not believe that farmworkers are exposed to chemicals because the farmworkers do not mix or apply the chemicals. Using a community participation framework that involves both farm workers and farmers has provided access to data necessary for shaping an effective strategy for communicating risk information and potentially, reducing risk. (Funded by NIH grant ES08739.)

1436 DEVELOPMENT OF SUCCESSFUL COMMUNITY-BASED RESEARCH PROJECTS FROM A COMMUNITY PERSPECTIVE.

P M Shepard. *West Harlem Environmental Action, Inc., New York, NY, USA.* Sponsor: R Snyder.

The Environmental Justice Movement has illuminated the fact that people of color are disproportionately and excessively exposed to chemical and physical hazards in the environment. While there are egregious localized instances of environmental injustice, in aggregate, urban populations of color exposed to a multitude of hazards represent a sizable proportion of those who are affected by environmentally unjust policies and practices. To address the problem of environmental injustice, an effective public health approach must include a broad range of disciplines. The role of scientists, researchers, clinicians and community-based organizations is crucial to addressing health, environmental exposures, public communication, and priorities for research. Successful community-university partnerships are key to successful community-based research and interventions that are culturally sensitive and appropriate; ethical; address community concerns and priorities; provide educational components that can sustain the intervention; and provide for appropriate dissemination of findings to research participants and the community before submission to the media. This presentation will discuss these issues.

1437 REGULATION OF SUBCELLULAR LOCALIZATION OF THE ARYL HYDROCARBON RECEPTOR (AHR).

C A Richter[1], M Hannink[1], and D E Tillitt[2]. [1]*University of Missouri, Columbia, MO, USA;* [2]*Environmental and Contaminants Research Center, Columbia, MO, USA.* Sponsor: M S Denison.

The aryl hydrocarbon receptor (AhR) mediates the toxicity of dioxins and related compounds. In the absence of ligand, AhR is found in the cytosol. Binding of ligand activates AhR to relocalize to the nucleus, dimerize with its DNA-binding partner ARNT (aryl hydrocarbon receptor nuclear translocator), and bind dioxin-responsive enhancers (DREs) to stimulate or repress transcription of target genes. Although it has been well established that inactive AhR is cytosolic, little is known of how the localization of AhR is regulated. AhR contains both a nuclear localization signal (NLS) and a nuclear export signal (NES). In order to study the regulation of AhR localization, we transfected cos-1 cells with an expression vector containing myc-tagged full-length murine AhR. Transfected cells were treated with leptomycin B, a specific inhibitor of the nuclear export receptor CRM-1. In the absence of exogenous ligand, leptomycin B treatment caused a shift in AhR localization from cytosolic to nuclear. This result supports the hypothesis that AhR shuttles between the nucleus and cytosol independent of the presence of exogenous ligand, and that CRM-1 is required to maintain the cytosolic localization of unliganded AhR.

1438 OMEPRAZOLE AND RELATED BENZIMIDAZOLES ARE Ah RECEPTOR LIGANDS.

M S Denison, M G Winters, J L Lam and D M Phelan. *Department of Environmental Toxicology, University of California, Davis, CA.*

The Ah receptor (AhR) is a ligand-dependent transcription factor that mediates many of the biological and toxicological actions of 2,3,7,8-tetra-

chlorodibenzo-p-dioxin (TCDD) and related chemicals. Although several substituted benzimidazoles have been shown to be relatively potent inducers of CYP1A in human and rat hepatocytes, their inability to competitively bind to the AhR suggested that they mediated their effects via an AhR ligand-independent manner. Utilizing the CALUX (Chemically Activated LUciferase eXpression) cell bioassay (employing cell lines stably transfected with a TCDD/AhR-responsive firefly luciferase reporter gene) and an inducible AhR-dependent DNA binding (gel shift) assay, we have examine the ability of several benzimidazoles, including: omeprazole, (OMP) thiabendazole (TBD), albendazole (ALB) and others to activate the AhR signaling system. Although all three chemicals induced luciferase reporter gene activity in stably transfected rat hepatoma and guinea pig adenocarcinoma cells, only OMP induced in human hepatoma and all were inactive in mouse hepatoma cells. Gel shift analysis revealed that nuclear extracts from OMP-, TBD- or ALB-treated guinea pig adenocarcinoma cells contained activated AhR complexes. The ability of OMP, TBD and ALB to competitively inhibit the binding of [3H]TCDD to the guinea pig cytosolic AhR, clearly indicates that these chemicals are indeed AhR ligands. The somewhat greater inducing potency of these chemicals in intact cells, as compared to their potency *in vitro*, suggests that these chemicals may be converted within the cell to more potent activators. (Supported by the NIEHS (ES07685) and Superfund (ES04699).)

1439 ACQUIRED RESISTANCE TO TCDD-MEDIATED SUPPRESSION OF ESTROGEN-DEPENDENT MCF-7 TUMOR GROWTH.

J F Gierthy[1,2], J A Bennett[3], B C Spink[2], D C Spink[1,2], K F Arcaro[1,2] and D D Vakharia[2]. [1]*School of Public Health, State University of New York at Albany, Albany, NY;* [2]*Wadsworth Center, New York State Department of Health, Albany, NY,* [3]*Department of Surgery, Albany Medical College, Albany, NY.*

We previously reported that 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) transiently suppressed 17β-estradiol (E_2)-dependent growth of MCF-7 xenografts in immunosuppressed BDF_1 mice. To further elucidate this antiestrogenic action of TCDD we now report that the initial two week suppression of MCF-7 tumor growth by TCDD (5 μg/kg body weight) is coincident with expression, in the tumor, of the mRNA encoding the E_2 4-hydroxylase CYP1B1 (10 fold over untreated controls). This had declined 40-50% by the third week, at which time the tumor was growing. Levels of estrogen receptor and aryl hydrocarbon receptor mRNAs were essentially unchanged (80-100% and 110% of control respectively) and CYP1A1 mRNA remained low (30-100 fold less than CYP1B1). Three results suggest that host-mediated events underlie the loss of MCF-7 sensitivity to TCDD-mediated growth inhibition. (1) MCF-7 tumors that have become unresponsive to the growth inhibitory effects of TCDD are still E_2 dependent and TCDD sensitive when transplanted into naive mice. (2) MCF-7 tumor growth was not inhibited by TCDD when transplanted into mice that had been pre-treated with TCDD for two weeks. (3) Chemoresistance of MCF-7 tumors to TCDD was almost immediate when this tumor was transplanted into the highly TCDD-sensitive C57 strain, whereas in the less TCDD-sensitive DBA strain there was a two-week lag (similar to BDF_1) for induction of chemoresistance. These results are consistent with an inducible AhR-mediated mechanism of acquired resistance to TCDD, possibly involving hepatic sequestration of the xenobiotic. The results of these studies have temporal implications for TEF calculations as applied to risk assessment for chronic TCDD exposure. (ES03561)

1440 DIFFERENCES IN LOCALIZATION OF TCDD IN CENTRILOBULAR AND PERIPORTAL HEPATOCYTES GIVE INSIGHT INTO THE MECHANISM OF GENE EXPRESSION.

M J Santostefano[1], J Blanton[2], V M Richardson[2], S Alcasey[2], K O Lindros[3], and L S Birnbaum[2]. [1]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC, USA;* [2]*USEPA, NHEERL/ETD, RTP, NC, USA;* [3]*National Public Health Institute, Helsinki, Finland.*

Dose-response relationships for TCDD suggest a differential sensitivity of liver cell types to the induction of CYP1A1 and CYP1A2 and that the induction of CYP1A2 causes a sequestration of TCDD. Therefore, this study examined the dose-dependent effects of TCDD in unfractionated, centrilobular and periportal hepatocytes after acute exposure (3 days) of female Sprague-Dawley rats to a single oral dose of 0.01-10.0 μg [^{3}H]TCDD/kg. Whole hepatocytes were isolated by a collagenase perfusion technique; whereas centrilobular and periportal enriched-hepatocytes were isolated by a dual pulse digitonin-collagenase perfusion system. Examination of the isolated liver cells for alaninamino-transferase activity (ALT), a marker for periportal hepatocytes, showed a 3-fold elevation in ALT activity in periportal cells as compared to centrilobular cells, which was unaffected by dose of TCDD. A dose-dependent increase in localization of TCDD was accompanied by a dose-dependent increase in EROD and MROD activities in all liver cell populations. The centrilobular hepatocytes exhibited a 2.5 to 4.0-fold higher concentration of TCDD as compared to the periportal hepatocytes at doses up to 0.3 μg TCDD/kg. Centrilobular hepatocytes also exhibited an elevated MROD activity as compared to the periportal hepatocytes at doses up to 0.3 μg TCDD/kg. This is the first study to show that a dose-dependent difference in distribution of TCDD exists between centrilobular and periportal cells which may be due to regional differences in CYP1A2 induction resulting in a sequestration of TCDD in centrilobular hepatocytes at doses up to 0.3 μg TCDD/kg. (Abstract does not necessarily represent USEPA policy).

1441 TCDD AND DES INHIBIT FETAL THYMOCYTE DEVELOPMENT IN VITRO BY DISTINCTLY DIFFERENT MECHANISMS AS SHOWN BY STUDIES OF BCL-2 TRANSGENIC MICE.

Z-W Lai[1], N C Fiore[1], P J Hahn[2], T A Gasiewicz[3], and A E Silverstone[1]. [1]*Dept. of Microbiology and Immunology,* [2]*Dept of Radiation Oncology, SUNY Health Science Center, Syracuse, NY, USA;* [3]*Environmental Health Science Center, Dept. of Environmental Medicine, The University of Rochester School of Medicine, Rochester, NY, USA.*

Both 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and diethylstilbestrol (DES) induce thymic atrophy. Although similar effects have been observed on thymic stem cells the precise molecular mechanisms by which either agent induces thymic atrophy are still undetermined. In a previous study, we found that TCDD and DES inhibited C57BL/6 murine fetal thymocyte organ cultures (FTOC) at different stages of development. Now using a bcl-2 transgenic (TG) mouse model, we have further investigated the mechanisms of TCDD and DES on fetal thymocyte proliferation, differentiation, maturation and apoptosis. Thymocyte development in FTOCs was inhibited by either TCDD (10 nM) or DES (20 μM) in both bcl-2 TG+ mice and TG- littermates. However, the reduction of cell number induced by DES in bcl-2 TG+ mice was significantly less than the level of inhibition in TG- mice. On the other hand, there was no difference in the level of reduction from TCDD-exposed TG+ or TG- FTOC. While TCDD induced production of more mature CD8 cells in either strain, DES mainly yielded cells in the $CD4^-CD8^-$ (DN) stage in TG- mice. The anti-apoptotic bcl-2 transgene overcame some of the DES blocking of DN thymocyte development, allowing more cells to differentiate into CD4 single positive cells. Analysis of cell cycle showed that TCDD inhibited cell proliferation in the $G_{0/1}$ stage, whereas DES blocked cell cycle at the G_2/M phase. While TCDD did not induce apoptosis in FTOC, DES induced apoptosis in the TG- FTOC. These apoptotic cells were mainly in the DN subpopulation. This apoptosis could be prevented by the overexpression of bcl-2 in the TG+ mice. Taken together, our results demonstrate distinct mechanisms for thymic atrophy induced by TCDD and DES in vitro. (Supported by NIEHS grants ES07216, ES04862 and ES01247.)

1442 CELL PROLIFERATION IN THE LIVERS OF FEMALE RATS CHRONICALLY EXPOSED TO BOTH 2,3,7,8-TETRA CHLORODIBENZO-*P*-DIOXIN (TCDD) AND 17β-ESTRADIOL.

N J Walker[1], M E Wyde[1], S R Eldridge[2] and G W Lucier[1]. [1]*National Institute of Environmental Health Sciences, Research Triangle Park, NC, USA;* [2]*Pathology Associates International, Frederick, MD, USA.*

An understanding of the mechanism of hepatocarcinogenesis induced by TCDD will serve to reduce uncertainties in the risk assessment and setting of guidelines for human exposure to dioxin-like compounds. In chronic tumor promotion studies with dioxin, the dose-dependent increase in cell proliferation rates and formation of altered hepatic foci has been shown to be ovarian hormone-dependent. The aim of the present study was to test the hypothesis that estrogen is involved in the induction of cell proliferation by TCDD. DEN-initiated ovariectomized Sprague-Dawley female rats, treated with 100 ng TCDD/kg/day, were co-treated in the presence or absence of continuous 17β-estradiol administration for 20 or 30 weeks. Dose-dependent increases in serum 17β-estradiol levels and uterine weight were observed in estrogen-treated animals. Hepatic bromodeoxyuridine labeling indices in the liver were significantly lower in ovariectomized animals treated with TCDD after 30 weeks compared with intact TCDD-treated animals. Cell proliferation was significantly reduced, relative to control animals, in the livers of

animals exposed to either TCDD, 17β-estradiol, or TCDD and 17β-estradiol for 20 weeks and was significantly reduced by 17β-estradiol treatment, but not TCDD, after 30 weeks. There was no effect of supplemental estrogen treatment on cell proliferation in TCDD-treated ovariectomized rats. These data indicate that continuous treatment with 17β-estradiol alone cannot compensate for the effect of ovarian hormones on the induction of cell proliferation in TCDD-treated rats.

1443 CLARIFICATION OF DIFFERENTIAL TOXICITY OF TCDD TOWARD C-SRC KNOCKOUT AND WILD-TYPE MICE.

D Y Dunlap, M J Moreno-Aliaga, Z Wu, H Nagashima, D M Tessier, M E Hansen, and F Matsumura. *Department of Environmental Toxicology, University of California, Davis, CA, USA.*

Previously we have reported the results of our preliminary study on the toxic effects of TCDD *in vivo* in male c-src -/+ B6,129-src-tm1Sor mice. Two major deficiencies of the above study were: (a) the low number of individuals available at that time. (b) in some of the comparison tests, C57BL/6J mice were used as wild-type control mice. Since then we increased our laboratory breeding program and thereby the availability of -/+, -/-, and true littermate wild-type +/+ individuals as well as a genetically stable strain of B6,129 mice, B6,129-Fos-tm1Pa (c-src and c-fos +/+) mice. The results of *in vivo* toxicity tests, involving 8 to 15 mice per test group, showed that there are considerable variations expressed in toxicity within each group of c-src deficient mice, indicating that B6,129-Src-tm1Sor mice still harbor varying genetic backgrounds. Nevertheless, when a large enough number of individuals were tested, two toxic effects were found to be less expressed in src-deficient mice. They were: excess fatty deposits and mottled appearance of liver which were commonly observed in TCDD-treated wild type mice, but not in c-src deficient mice. The former trend was also confirmed by both liver lipid analysis and histological examinations of affected livers. On the other hand, src deficient mice showed consistently more severe cases of hepatomegaly as compared to wild type B6,129 mice. C57BL/6J mice cotreated with geldanamycin or quercetin, two known protein kinase inhibitors also showed the same differential responses of liver as toward TCDD as c-src knockout mice, the reduction of TCDD's toxicity in terms of the weights of pancreas and adipose tissues were less pronounced (statistically significant difference from those treated only with TCDD). Also, TCDD's effect to reduce bodyweight gain and thymus were less expressed in mice cotreated with these inhibitors. These tendencies however, were not statistically significant. (Supported by NIEHS ESO5233, ESO03575, and ESO05707.)

1444 THE EFFECTS OF TCDD ON THE ACTIVATION OF OVA-SPECIFIC DO11.10 TRANSGENIC T CELLS IN ADOPTIVELY-TRANSFERRED MICE.

D M Shepherd and N I Kerkvliet. *Department of Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR, USA.*

The activation of a naive CD4+ T lymphocyte is dependent on several key signals, primarily mediated by ligation of the antigen-specific T cell receptor and accessory molecules. Disruption of these signals may result in an inability to respond to a specific antigenic challenge. Previously, it has been shown that exposure to the environmental contaminant 2,3,7,8-tetrachlorodibenzo-*p* -dioxin (TCDD) suppresses the generation of T-dependent immunity, both humoral and cell-mediated. The mechanism of TCDD-induced immune suppression remains to be defined. We hypothesize that exposure to TCDD suppresses the activation of naive CD4+ T cells, and prevents their expansion and differentiation into effector T helper cells capable of driving T-dependent immune responses. To test this hypothesis, we adoptively-transferred DO11.10 transgenic T cells into syngeneic recipients allowing us to track the *in vivo* activation of naive, OVA-specific CD4+ T lymphocytes following exposure to antigen. Exposure of adoptively-transferred mice to TCDD (15 &g/kg) resulted in a 60-80% suppression of OVA-specific IgG1 and IgG2a antibodies without affecting production of anti-OVA IgM. TCDD did not alter the *in vivo* expansion or activation of OVA-specific CD4+ T cells as determined by flow cytometry, however, spleen cells from TCDD-treated mice produced reduced levels of T cell-derived cytokines following *in vitro* restimulation, suggesting defective differentiation of OVA-specific T cells. Production of IL-12, a cytokine produced by antigen-presenting cells (APC) which drives T cell differentiation, was also significantly suppressed in adoptively-transferred mice exposed to TCDD indicating defective activation of APC. Administration of recombinant IL-12 to TCDD-exposed mice elevated anti-OVA IgG2a titers to levels normally found in vehicle-treated OVA-immunized mice, yet had only partial or no effect on raising anti-OVA IgM and IgG1 titers, respectively. These data suggest that TCDD suppression of T cell-dependent humoral immunity is a consequence of dysfunctional APC-mediated differentiation of CD4+ T helper cells. Furthermore, these results highlight the potential of the DO11.10 adoptive transfer system to assess possible immunotoxic effects of other xenobiotics in an antigen-specific transgenic mouse model. (Supported by NIEHS grant ES003966.)

1445 VARIATION IN AH RECEPTOR EXPRESSION AND CYTOCHROME P450 INDUCIBILITY IN A DIOxiN-EXPOSED POPULATION.

S A Masten[1], J A Grassman[1], C R Miller[1], D L Spencer[1], D Jung[2], L Edler[3], L L Needham[4], and G W Lucier[1]. [1]*NIEHS, RTP, NC, USA;* [2]*University of Mainz, FRG;* [3]*German Cancer Research Center, Heidelberg, FRG;* [4]*CDC, Atlanta, GA, USA.*

Knowledge regarding both human individual variation in response to dioxin and susceptibility factors for dioxin-related adverse health effects should reduce uncertainty in human risk assessment for exposure to dioxin-like compounds. Utilizing a human peripheral blood mononuclear cell model, we evaluated dioxin exposure-response relationships in an exposed human population to identify factors that determine individual variation in biological response to dioxin. The present study examined aryl hydrocarbon receptor (AHR), aryl hydrocarbon receptor nuclear translocator (ARNT), cytochrome P4501A1 and 1B1 mRNA levels by quantitative RT-PCR, in resting and cultured peripheral blood lymphocytes from 104 individuals occupationally exposed to a wide range of TCDD and other dioxin-like compounds (plasma dioxin toxic equivalents [TEQ] up to 915 ppt lipid). In lymphocyte cultures from these individuals (n=85), there was a 20-fold, 22-fold and 14-fold range of *in vitro* TCDD-inducible CYP1A1 enzyme activity, CYP1A1 mRNA, and CYP1B1 mRNA levels, respectively. AHR and ARNT mRNA expression varied 27-fold and 20-fold, respectively, and AHR expression correlated weakly with some measures of individual CYP1 inducibility. There was no clear relationship between plasma dioxin TEQ and AHR, ARNT, or TCDD-inducible CYP1A1 or CYP1B1 expression. These results indicate there are individuals with a wide range of responsiveness to dioxin, related to AHR expression as well as other factors, and this may represent an altered sensitivity to the biological effects of dioxins.

1446 HUMAN DIOXIN EXPOSURE ASSESSMENT BASED ON BLOOD ANALYSES: EXPOSURE DIFFERENCES ATTRIBUTABLE TO GENDER, AGE, DIET, AND COUNTRY.

O Päpke[1] and A J Schecter[2]. [1]*ERGO Forschungsgesellschaft mbH, Hamburg, Germany;* [2]*State University of New York (SUNY) Binghamton, Binghamton NY, USA.*

Measurement of human blood dioxin concentration is currently used to estimate body burden and exposure in workers and the general public. We have found that exposure varies with age, gender, and country of residence, and also may vary with diet. Both congener patterns and exposure levels differ among countries. In pooled blood samples taken between 1988 and 1991, blood lipid TCDD toxic equivalent (TEQ) levels of dioxins and dibenzofurans were 42 pg/g in Germany and 41 pg/g in the USA. From relatively less industrialized central China and Hanoi, Vietnam, TEQ levels in pooled samples were 5 and 10 pg/g, respectively. Increasing levels of dioxins, dibenzofurans, and coplanar PCBs with increasing age were found in blood of 134 individuals in Germany in 1994. A similar age difference had been found earlier in central China for dioxins and dibenzofurans. TEQ levels for dioxins, dibenzofurans, and coplanar PCBs were 20% higher for women than for men in pooled blood samples collected in the USA in 1997. Mean blood lipid TEQ levels also were higher for individual German women than men tested in 1996. Almost all the human body burden of dioxins is from food ingestion, especially foods of animal origin. In blood taken in 1997 from one man and one woman who for approximately 3 decades had been vegans, strict vegetarians consuming no food of animal origin, total TEQ levels of dioxins, dibenzofurans, and coplanar PCBs were less than 1/3 that of the general population. Measurement of dioxins and dibenzofurans captures only a portion of the TEQ body burden. In individual analyses of blood lipids for dioxins, dibenzofurans and coplanar, mono-ortho, and di-ortho PCBs in fifty Michigan men in 1992, the PCBs accounted for most of mean total TEQ.

1447 EARLY RESULTS FROM A DIOXIN GENOME PROJECT.

R S Thomas[1], D R Rank[2], S Jovanovich[2], J B Hogenesch[1], G M Zastro[1], K M Carr[1], and C A Bradfield[1]. [1]*McArdle Laboratory for Cancer Research, University of Wisconsin Medical School, Madison, WI, USA;* [2]*Molecular Dynamics Inc., Sunnyvale, CA.*

In an attempt to better define the cellular and molecular mechanisms of toxicity for 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD), we have initiated a comprehensive survey of gene-expression alterations using an expressed sequence tag (EST) approach. This approach utilizes the partial sequencing and comparison of randomly selected clones from cDNA libraries derived from TCDD-treated and control groups. To generate the ESTs in our survey, cDNA libraries were constructed from the livers of male C57BL/6J mice treated i.p. with either 30 nmol/kg TCDD solubilized in a dioxane vehicle or the vehicle alone. Following treatment, animals were sacrificed after 48 hrs and the mRNA isolated from the liver of each mouse. Synthesis of cDNA was performed on mRNA samples pooled from the livers of three animals and the resulting transcripts were cloned unidirectionally into a plasmid vector. From each library, clones were randomly selected and sequenced from the 3' direction. ESTs were then assembled into clusters of overlapping sequences based on stringent assembly parameters and the identity of each cluster was established via BLAST searches against the GenBank database. Based on preliminary analysis of approximately 2,000 total clones, increases were observed in CYP1A2 ($p < 0.001$), aldolase B ($p = 0.1$), and CYP1A1 ($p = 0.1$) while a significant decrease was detected in mouse urinary protein (MUP) ($p < 0.001$). Other genes, such as albumin, maintained expression levels despite treatment ($p > 0.5$). In addition, preliminary results also show an increase in the number of unique transcripts in TCDD-treated animals as compared with controls which highlights the complex change in gene expression following TCDD treatment. Of these transcripts, nearly a dozen represent TCDD-inducible genes that have not yet been reported as upregulated by dioxin. The results will become increasingly informative as the number of clones sequenced continues to grow.

1448 DIOXIN INTAKE FROM FOOD IN THE UNITED STATES GENERAL POPULATION.

A J Schecter[1], P Cramer[2], K Boggess[2], J Olson[3], and A G Silver[1]. [1]*State University of New York (SUNY) Binghamton, Binghamton, NY, USA;* [2]*Midwest Research Institute, Kansas City, MO, USA;* [3]*S.U.N.Y. Buffalo, Buffalo, NY, USA.*

Almost all the burden of dioxins in humans is from food ingestion, especially from meat, fish, and dairy products. We recently conducted a nationwide food sampling to determine levels of dioxin-like chemicals in the US food supply and to calculate daily intake. Concentrations of dioxins and dibenzofurans, and also coplanar, mono ortho, and di-ortho PCBs were measured. Twelve separate analyses were conducted on pooled batches of foods from 110 samples purchased in 1995 in supermarkets in Atlanta GA, Binghamton NY, Chicago IL, Louisville KY, and San Diego CA. The food category with highest TCDD toxic equivalent (TEQ) pg/g, whole weight, was freshwater fish (1.7 pg/g); and the lowest was a simulated vegan (vegetarian) diet (0.08 pg/g). Based on our analyses and using USDA survey data on food consumption, we estimated mean daily intake of TEQ pg/kg BW for age 1-11 to be 5.44 pg/kg BW for males and 5.36 pg/kg BW for females; age 12-19, 3.07 for males and 2.35 for females; age 20-79, 2.24 for males and 2.00 for females, and age 80+, 1.71 for males and 2.04 for females. Mean daily intake of TEQ for US breast-fed infants - based on analyses of human milk collected in 1995 - was 37.6 pg/kg BW. "Acceptable daily intake" or "risk specific dose" in the US, in Europe, and recommended by WHO are 0.01 (US EPA dioxin draft document) or 1-10 pg/kg BW/day (WHO). For adults (age 20-79) PCDDs, PCDFs, and PCBs each contributed about 1/3 of dietary TEQ intake, when non-detects were calculated at 1/2 the level of detection. When calculated with non-detects = 0, mean daily intake for adults, age 20-79, was 0.80 pg/kg BW, with 60% of TEQ contributed by PCBs, 30% by PCDDs, and 10% by PCDFs.

1449 DECREASED INTRACELLULAR ZINC LEVELS ALTER MITOCHONDRIAL MEMBRANE FUNCTION AND INCREASE CASPASE-3 ACTIVITY IN HL-60 CELLS.

J Y Duffy[1], C M Miller[1], G L Rutschilling[1], G M Ridder[1], M S Clegg[2], C L Keen[2], and G P Daston[1]. [1]*Procter & Gamble Co., Cincinnati, OH, USA;* [2]*Department of Nutrition, University of California, Davis, CA, USA.*

Low levels of extracellular zinc (Zn) have previously been associated with the induction of apoptosis. The objective of this study was to assess the cellular responses to low intracellular Zn concentration in human premyelocytic leukemia cells (HL-60). Cells were grown in media (DMEM + 7.5% fetal calf serum) containing 0.5, 25, or 50 μ M Zn, then removed at indicated time points over 48 h for analysis by flow cytometry or fluorescence microscopy. Apoptotic cells were identified by their inability to retain rhodamine 123 (Rh123), a measure of the breakdown of mitochondrial membrane potential and an early indicator of apoptosis. Cells grown in 0.5 μ M Zn medium over 48 h exhibited a continuous decrease in intracellular Zn concentration as measured by the Zn-specific fluorophore, zinquin ($P<.01$). Zn levels were maintained in cells grown in 25 or 50 μ M Zn media. There was a decrease in Rh123 retention by the cells after 18 h in 0.5 μ M Zn media. However, the addition of 10 μ M Zn at or before 12 h of culture in 0.5 μ M Zn medium restored Rh123 retention to control levels. Caspase-3 activity, a recognized target for Zn inhibition, was four-fold higher in the cells cultured for 48 or 72 h in 0.5 μ M Zn compared to 24 h of culture in 0.5 μ M Zn or to cells cultured in 50 μ M Zn. In addition, cell cycle analysis of BrdU incorporation demonstrated a loss of cells in the S phase and an increase in the sub-G_0/G_1 peak when cells were cultured in 0.5 μ M Zn medium. These data indicated that decreasing intracellular Zn levels preceded alterations in mitochondrial membrane potential and the activation of the caspase cascade leading to apoptosis.

1450 APOPTOSIS IN CELLS LACKING MITOCHONDRIAL DNA.

J Cai, S Jiang, D C Wallace, and D P Jones. *Department of Biochemistry and Center of Molecular Medicine, Emory University School of Medicine, Atlanta, GA.*

Mitochondria play a central role in regulating apoptosis. Release of mitochondrial cytochrome *c* is an early and common signaling event after a variety of apoptotic stimuli. The loss of cytochrome *c* triggers superoxide production from mitochondria and contributes to the oxidation of the cellular thiol-disulfide redox state. In this study, we tested wthether depleting mitochondrial DNA would affect these signaling mechanisms during apoptosis. We found that cells lacking mitochondrial DNA (ρ0) could still undergo apoptosis similarly to control ρ+ cells in response to staurosporine, and the cytochrome *c* dependent caspase activation mechanism was well preserved. Release of cytochrome *c* was accompanied by the release of adenylate kinase, another mitochondrial intermembrane protein. Measurement of cellular GSH and GSSG contents showed that the thiol-disulfide redox status change, which was observed as a dramatic oxidation in ρ+ cells, was inhibited in ρ0 cells. Thus, the bio-energetic function of mitochondria can be separated from mitochondrial signaling of apoptosis and mitochondria are the principal source of the oxidative signal.

1451 STUDY OF APOPTOSIS IN THYMOCYTES OBTAINED FROM γ-GLUTAMYL TRANSPEPTIDASE (GGT) DEFICIENT KNOCKOUT MICE.

Y Will[1], R S Kaetzel[2], M Lieberman[3], and D J Reed[1]. [1]*Department of Biochemistry and Biophysics and* [2]*Toxicology Program, Oregon State University, Corvallis, OR, USA;* [3]*Department of Pathology, Baylor College of Medicine, Houston, TX, USA.*

Previous work from our laboratory has shown that a decrease in glutathione (GSH) can lead to cell damage and even cell death. We hypothesize that cellular GSH homeostasis depends on mitochondrial GSH. We have shown that in GGT-deficient mice cytosolic GSH as well as mitochondrial GSH is significantly decreased. In this study we investigated how this impairment in GSH homeostasis may relate to apoptosis. It is widely accepted that apoptosis is accompanied by a depletion of GSH. It has also been established that thymocytes treated with dexamethasone (DEX) undergo a step-wise dysregulation of mitochondrial function involving the mitochondrial permeability transition (MPT) leading to apoptosis. It's been known that MPT is influenced by thiol status. However, the question of how cytosolic and mitochondrial GSH relates to apoptosis remains complex and not very well understood. Mice were treated in vivo for 8 hours with DEX. Thymocytes

were isolated and subjected to flow cytometry to analyze dysregulation of mitochondrial function as it relates to apoptotic events. We determined mitochondrial membrane potential (DiOC6, JC-1), cardiolipin oxidation (NAO), changes in lipid packaging (MC540), cytosolic and mitochondrial calcium (calcium green-am, Rhod 2-am), glutathione (MCB), as well as early and late apoptotic cells (annexin V, 7-aaD) in thymic subpopulations. Our results show that GGT-deficient mice were significantly more susceptible to DEX treatment. We conclude that the observed decrease in mitochondrial GSH increased their susceptibility to MPT and apoptosis. Studies are currently underway to investigate if the GSH precursors, N-acetylcysteine and 2-oxo-4-thiazolidine-carboxylic acid, can reverse the observed susceptibility to apoptosis in the GGT-deficient knockout mice.

1452 MITOCHONDRIAL DEPOLARIZATION IS AN EARLY EVENT IN PHOTODYNAMIC THERAPY-INDUCED APOPTOSIS IN CHO CELLS.

A-L Nieminen[1], S R Rohr[1], K J Mann[2] and N L Oleinick[2]. *Departments of [1]Anatomy and [2]Radiation Oncology, School of Medicine, Case Western Reserve University, Cleveland, OH.*

Photodynamic therapy (PDT) is currently used as a promising cancer treatment against a variety of tumors. The mechanisms underlying PDT induced cell death remain unclear. In this study, we first examined the subcellular localization of the phthalocyanine photosensitizer Pc-4 in Chinese hamster ovary (CHO) cells. Cells were incubated with 200 nM Pc-4 for 2 h. Subsequently, red fluorescence of Pc-4 was imaged using confocal microscopy. Co-staining cells with MitoTracker Green demonstrated that Pc-4 was localized to mitochondria. To examine further the role of mitochondria in Pc-4 induced apoptosis, Pc-4-loaded CHO cells were co-loaded with MitoFluor Green, a mitochondrial memrane potential sensitive fluorophore. Radiation of Pc-4 with a red light (>600 nm; 1.53 kJ/m^2) caused mitochondrial depolarization after 10-30 min. Subsequently, caspase-3 became activated followed by apoptotic cell death. Cyclosporin A (1-10 μ M), a specific inhibitor of the mitochondrial permeability transition, prevented onset of apoptosis in a dose-dependent manner; 20 μ M cyclosporin A decreased apoptosis from 50% to 20% at 5 h. In conclusion, these results suggest that mitochondrial dysfunction induced by onset of the mitochondrial permeability transition is a critical event in the PDT-induced apoptotic death.

1453 MITOCHONDRIAL DEPOLARIZATION PRECEDES BAX TRANSLOCATION TO MITOCHONDRIA.

K M Heiskanen[1], P D Pichiule[1], M B Bhat[2], J J Ma[2] and A-L Nieminen[1]. *Departments of Anatomy, Physiology and Biophysics, School of Medicine, Case Western Reserve University, Cleveland, OH.*

Alteration of mitochondrial function plays a critical role in apoptosis. Previously, we showed that staurosporine induced mitochondrial depolarization, which is accompanied by cytochrome *c* release in pheochromocytoma (PC6) cells. Here, we studied changes of mitochondrial membrane potential in relation to insertion of pro-apoptotic protein Bax to mitochondria using confocal microscopy. We fused green fluorescent protein (GFP) to the amino terminus of Bax and transfected the GFP-Bax into PC6 cells. Transfected cells displayed a diffuse pattern of fluorescence indicating that Bax was initially localized to the cytosol. Cells were also loaded with TMRM, a mitochondrial membrane potential indicating fluorophore. To induce apoptosis, cells were treated with staurosporine (5 μ M). Mitochondrial membrane potential and Bax redistribution were monitored simultaneously in single living cells. Individual cells behaved asynchronously and lost their mitochondrial membrane potential and begun the process of Bax translocation at variable times. However, mitochondria depolarized before the translocation of Bax from the cytosol to mitochondria. Subsequently, cells began to die apoptosis. In conclusion, our results show that Bax insertion to the mitochondrial membrane occurs considerably later than mitochondrial depolarization and cytochrome *c* release in staurosporine-induced apoptosis.

1454 INDUCTION OF APOPTOSIS BY CYCLOSPORINE A IN RAT HEPATOCYTES.

S Grub, E Persohn, W E Trommer[1] and A Wolf. *Novartis Pharma AG, Experimental Toxicology, Basel, Switzerland; [1]University of Kaiserslautern, Germany.* Sponsor: A De Brugerolle de Fraissinette.

The role of cyclosporine A (CsA) during apoptosis has not been clarified yet and there is a lot of controversial information in the current literature. CsA acts as an inhibitor of apoptosis in some cellular systems, induction of programmed cell death has been observed in others. In rat hepatocytes and isolated mitochondrial fractions of the liver, CsA was very often used as a specific inhibitor of mitochondrial Ca^{2+} release and as a blocker of the mitochondrial permeability transition (MPT), both processes involved in the inhibition of apoptosis. Neither inhibition nor induction of apoptosis by CsA has been described in rat hepatocyte primary cultures. It was the purpose of the present study to characterize the effects of CsA on apoptosis at the morphological and biochemical level and to distinguish apoptosis from necrosis. Rat hepatocytes cultured for 4 or 20 h with CsA at concentrations of 0, 10, 25 and 50 μM were investigated for chromatin condensation, DNA fragmentation (TUNEL) and Annexin V reaction. Four hours after CsA treatment apoptosis increased dose-dependently without any enzyme leakage through the cytoplasmic membrane. In parallel the activity of the cysteine proteases caspase-3 (CPP 32) and caspase-6 (Mch 2) but not caspase-1 (ICE) were increased. The specific caspase inhibitors Ac-DEVD-CHO and Ac-VEID-CHO inhibited caspase activation and attenuated CsA-induced apoptosis. After 20 hours of CsA incubation apoptosis was further increased and accompanied by cytochrome c release into the cytosol. Necrosis appeared with typical leakage of cytosolic enzymes. Ultrastructural evaluations by TEM confirmed necrosis after 20 hour but not after 4 hours. The decreased mitochondrial membrane potential $\Delta \Psi_i$ and the increased cytosolic concentrations of $[Ca^{2+}]_i$, which were the result of extracellular uptake between 1-4 hours of incubation, might be regarded as early events triggering the cascade of apoptosis which results in proteolysis and DNA fragmentation. Our findings suggest that in rat hepatocyte cultures CsA specifically induces apoptosis at early time points, overlapping with necrosis after longer treatment.

1455 LEUKOTOXIN DIOL IS A POTENT AND SPECIFIC INDUCER OF THE MITOCHONDRIAL PERMEABILITY TRANSITION.

M F Sisemore[1], J C Yang[2], B D Hammock[1], and G A Cortopassi[2]. *[1]Entomology & Environmental Toxicology, [2]Molecular Biosciences, University of California at Davis, Davis, CA, USA.*

Leukotoxin (9,10-epoxyoctadec-12-enoate) is biosynthesized from linoleic acid by inflammatory cells upon activation and is converted by a biologically ubiquitous enzyme, epoxide hydrolase, to its toxic diol metabolite, leukotoxin diol. Leukotoxin has been proposed to be one of the causative agents involved in Acute Respiratory Distress Syndrome (ARDS), however, the mechanism of leukotoxin-induced cell death has not been characterized. We show for the first time, by spectrophotometric measurement of mitochondrial swelling, that leukotoxin diol, but not its epoxide precursor, is a potent and specific inducer of the mitochondrial permeability transition (MPT) and that cyclosporin A completely inhibits leukotoxin diol-induced MPT.

1456 SUBCHRONIC DOXORUBICIN ADMINISTRATION INCREASES MITOCHONDRIAL-MEDIATED CELL INJURY BY CALCIUM IONOPHORES.

S Zhou[1], L J Heller[2], J A Smith[2], and K B Wallace[1]. *[1]Department of Biochemistry & Molecular Biology and Toxicology Graduate Program; [2]Department of Medical and Molecular Physiology, University of Minnesota School of Medicine, Duluth, MN, USA.*

Recent research implicates interference with mitochondrial bioenergetics to be a critical factor responsible for the cardiomyopathy that limits the clinical efficacy of doxorubicin (DXR) antineoplastic therapy. We found that DXR interferes with mitochondrial calcium homeostasis and that cardiomyocytes isolated from rats treated subchronically with DXR are highly sensitive to calcium-induced cell killing. Since mitochondria play an important role in calcium signaling pathways, we questioned whether cardiomyocytes from DXR treated rats would express an exaggerated sensitivity to the cytotoxic response to agents that increase cytosolic calcium concentrations. Adult male Sprague-Dawley rats received 6 weekly (s.c.) injections of either 2 mg/kg doxorubicin or saline and were killed 7 days following the last injection. Cardiomyocytes were isolated and exposed in vitro to increasing concentrations of A23187. Cell killing was measured by trypan blue dye exclusion. Cytosolic calcium concentration was estimated fluorometrically with FURA-2AM and mitochondrial membrane potential was measured with TMRM. A23187 caused a dose-dependent increase in cytosolic calcium, depolarization of mitochondrial membranes and cell killing. There was no discernable difference in cytosolic calcium response to A23187 between cardiomyocytes from DXR and saline-treated rats. However, cells from DXR-treated rats were more susceptible to A23187-induced mitochondrial depolarization and cell killing. Cyclosporin A was not cytoprotective. The results

implicate a critical role for disruption of mitochondrial calcium homeostasis in the manifestation of doxorubicin cardiotoxicity. (Supported by NIH grant HL-58016.)

1457 ACETAMINOPHEN, AND ITS NONHEPATOTOXIC REGIOISOMER, INDUCE CELL DEATH BY ANOMALOUS APOPTOSIS *IN VIVO* AND *IN VITRO*.

R H Pierce[1], R P Tonge[2], W Chen[2], N Fausto[1], S D Nelson[2] & S A Bruschi[2]. *Departments of Pathology[1] and Medicinal Chemistry[2], University of Washington, Seattle, WA, USA.*

The biochemical events accompanying cell death by acetaminophen (*N*-acetyl-*p*-aminophenol, APAP), and its relatively nonhepatotoxic regioisomer *N*-acetyl-*m*-aminophenol (AMAP), are mostly unknown and have been examined using both *in vivo* and *in vitro* model systems. Hepatotoxic doses of APAP (600 mg/kg, i.p., $B6C3F_1$ mice) induced mitochondrial cytochrome *c* relocation and DNA fragmentation events normally associated with apoptosis. Although nucleosomal ladder formation was not evident for either compound, genomic DNA fragmentation (*ca.* 50 kb), a robust indicator of apoptotic nuclear changes, was detected using CHEF gel analysis. Surprisingly, effector caspase activation (caspase 3-mediated PARP, caspase 6-mediated lamin A or DEVDamc cleavage) was not observed with APAP treatment. AMAP treatment (600 mg/kg, i.p.), however, resulted in lamin A and atypical PARP cleavage despite no evidence of cytochrome *c* leakage. APAP bioactivation and resultant cell death in a differentiated, TGFα -transgenic, hepatocyte cell line (TAMH) was observed at concentrations, and over time frames, relevant to clinical overdose situations. Chromatin margination and 50 kb fragment formation *in vitro* confirmed the alterations to nuclear morphology found *in vivo*. Comparable AMAP-induced cytotoxicities were not observed in this cell line as expected from the *in vivo* hepatotoxicity of these compounds. The relative cytotoxic potency of APAP and AMAP was reflected in dose-related collapse of mitochondrial membrane potential which preceded loss of cellular reducing equivalents, as assessed by multiparameter flow cytometry. This contrasted with the sequence of events observed during apoptotic cell death induced by actinomycin D/TNF. In conclusion, APAP and AMAP-mediated cell death *in vivo* and *in vitro* does not resemble classical apoptosis but instead represents an atypical, possibly truncated, version of this form of cell death. (Supported by grants #CA74131 to NF, #GM25418 to SDN & #GM51916 to SB.)

1458 ROTENONE-INDUCED APOPTOSIS IN LIVER CELLS: INVOLVEMENT OF THE MITOCHONDRIAL MEMBRANE PERMEABILITY TRANSITION (MPT).

J S Isenberg and J E Klaunig. *Division of Toxicology, Department of Pharmacology & Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

Mitochondrial dysfunction, in particular the mitochondrial membrane permeability transition (MPT), has been implicated in the cascade of events involved in the execution of apoptosis. Fluorescent microscopy of Hoechst 33258-stained WB-F344 cells was utilized to examine the effect of rotenone, Atractyloside (Atr), and Cyclosporin A (CsA) on apoptosis. A time- and concentration-dependent increase in apoptosis was observed following treatment with Atr and rotenone (7.7 and 11.7 fold over control). CsA, an inhibitor of the MPT, was utilized to examine the role of the MPT in the induction of apoptosis by rotenone and Atr. When cotreated with 5.0 μM rotenone, 7.5 and 10.0 μM CsA inhibited rotenone induced apoptosis. A similar effect was observed following CsA cotreatment with Atr. To inhibit rotenone induced apoptosis, CsA exposure was necessary within 20 minutes of rotenone exposure. Examination of mitochondrial function by staining with the mitochondrial membrane potential ($\Delta \psi_m$)-selective fluorochrome, MitoTracker Red, demonstrated that rotenone (5.0 μM)- and Atr (5.0 μM)-induced a reduction of the $\Delta \Psi_m$ within 15 minutes and throughout the duration of the study (6 hours) to approximately 65% and 50% of control. However, cotreatment with concentrations of CsA that inhibited the rotenone- and Atr-induced apoptosis also prevented the rotenone- and Atr-induced reduction of the $\Delta \Psi_m$. The apoptogenic effect of rotenone and Atr thus appears to occur rapidly (within 20 minutes) and is irreversible once mitochondrial damage occurs. The inhibition of the rotenone and Atr induced apoptosis and mitochondrial dysfunction by CsA suggests that the MPT may be involved in the induction of apoptosis by rotenone.

1459 OXIDATIVE STRESS IS A MEDIATER OF DOPAMINE AND CYANIDE INDUCED NEURONAL APOPTOSIS.

D C Jones, P G Gunasekar, J L Borowitz and G E Isom. *Dept. of Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN, USA.*

Excessive exposure to dopamine (DA) produces degeneration of dopaminergic neurons. Since impaired mitochondrial metabolism might enhance DA toxicity, KCN was used to produce hypoxia, and alter mitochondrial function. Differentiated PC12 cells were exposed to DA, KCN, or a combination of the two. LDH assays indicated that both DA and KCN induced a dose and time dependent cell death and that their combination produced an additive cytotoxicity. Apoptotic death was both dose and time dependent for DA and KCN. DA/KCN produced an increase in apoptosis, indicating impaired mitochondrial function enhances DA cytotoxicity. In mechanistic studies, cells were pre-treated with a series of compounds and incubated with DA (300μ M) and/or KCN (100μ M) for 24 hours. Nomifensine, a DA re-uptake inhibitor, rescued nearly 50 % of the cells from DA and DA/KCN induced apoptosis. Pre-treatment with SOD (37 U/ml), catalase (500 U/ml), N-acetylcysteine (100μ M), or glutathione (100μ M) blocked both DA and KCN apoptosis indicating involvement of oxidative stress. Buthione sulfoximine, an inhibitor of glutathione synthesis, increased the apoptotic response. DA, KCN and DA/KCN produced a significant increase in intracellular ROS generation. The NOS inhibitor, L-NAME and uric acid, a peroxynitrate scavenger, blocked apoptosis and ROS production, supporting the involvement of NO. z-VAD, a caspase inhibitor, protected cells from apoptosis indicating activation of a cell death pathway. It is concluded that DA and KCN neurotoxicity involves ROS and NO mediated oxidative stress as an initiator of an apoptotic cascade. (Supported by NIH grant ES04140.)

1460 EFFECTS OF ATMOSPHERIC PARTICULATE MATTER ON BASAL AND BACTERIA-INDUCED DEGRANULATION OF HUMAN PERIPHERAL BLOOD LEUKOCYTES.

L A Zussman, B J Turpin, and E J Yurkow. *Environmental and Occupational Health Sciences Institute, Rutgers University, Piscataway, NJ, USA.*

The effects of three standard particulate materials (PM) (i.e., silica, diesel and urban) on the release of primary granules, secondary granules, and histamine from peripheral blood leukocytes were determined using whole blood assays. In these assays, fixed Staphylococcus aureus bacteria, a known inducer of degranulation and histamine secretion, were used as a positive control. Bacteria were found to induce the release of primary granules, as determined by the release of p-Nitrophenyl-N-acetyl-β -D-glucosaminidase and myeloperoxidase activity, secondary granules as determined by the release of lactoferrin, and histamine. Pretreatment of cells with either silica or diesel PM did not induce the release of any of the markers analyzed or dramatically alter the ability of bacteria to liberate these agents from the cells. Although urban PM did not affect the release of primary granules, this material caused release of lactoferrin from secondary granules. Urban PM was also found to be a potent inducer of histamine release. Fractionation studies revealed that soluble (aqueous) fractions and to a lesser extent, insoluble fractions of urban PM contained histamine releasing activity. The results indicate that simple assays of leukocyte degranulation and histamine release can be used to differentiate various types of PM. Furthermore, they demonstrate that both soluble and insoluble components of ambient PM can mediate leukocyte degranulation. The release of these bioactive components may be an important contributing factor to the adverse health effects associated with PM exposure.

1461 VANILLOID (CAPSAICIN) AND ACID SENSITIVE IRRITANT RECEPTORS UNDERLIE MOUSE STRAIN-SENSITIVITY TO PARTICULATE MATTER (PM).

B Veronesi [1], M Oortgiesen[2], S A Simon[2], S Madison[1], and S Gavett [1]. [1]*National Health and Environmental Effects Research Laboratories, U.S. Environmental Protection Agency, Research Triangle Park, NC and* [2]*Dept. Anesthesiology, Duke University Medical Center, Durham, NC, USA*

The causes of strain-species differences in response to chemically-induced inflammation remain unresolved. BALB/c and C57blk (B6) mice, exposed intratracheally to residual oil fly ash (ROFA, 3 mg/kg), were examined 24 hr later for signs of airway inflammation. BALB/c showed significantly higher numbers of neutrophiles and increased airway hyperresponsiveness to iv metacholine, whereas B6 mice showed no change in either endpoint. Dorsal

root ganglion (DRG) sensory neurons, which enervate the upper and lower airways, were cultured from BALB/c and B6 fetal mice. These cultures were exposed (4 hr) to ROFA (25-50 μg/ml), coal fly ash (25,50 mg/ml), capsaicin (1-3 μM) or acid (pH 5.0 and 6.5 for 15 min, then culture medium for 4 hr). In all instances, DRG neurons from BALB/c mice released significantly higher levels of the proinflammatory cytokine, IL-6 into their nutrient media compared to B6 mice. Finally, single cell recordings of intracellular calcium were taken from cultured DRG, loaded with the fluorescent calcium indicator dye Fluo-3 AM, in response to pH 6.5 and capsaicin (0.5 μM). These data indicated that significantly higher numbers of BALB/c neurons responded with increases in intracellular calcium compared to B6 neurons, but that qualitatively the responses (i.e., peak amplitudes) were equivalent between strains. Taken together these data suggest that irritant receptors (i.e., capsaicin, acid sensitive) located on sensory nerve fiber terminals subserve PM-induced airway inflammation and are quantitatively different in responsive and nonresponsive mouse strains. (This abstract does not reflect EPA policy.)

1462 PARTICULATE MATTER AND CHARGED SYNTHETIC POLYMER MICROSPHERE ANALOGUES ACTIVATE BRONCHIAL EPITHELIAL CELLS AND SENSORY NEURONS THROUGH CAPSAICIN AND ACID RECEPTORS.

S A Simon[1], M Oortgiesen[1], and B Veronesi[2]. [1]*Dept. Anesthesiology, Duke University Medical Center, Durham, NC;* [2]*US EPA, NHEERL, Research Triangle Park, NC, USA.*

Residual oil fly ash (ROFA), an industrial particulate pollutant, causes airway inflammation and hyperresponsiveness in rodents. Recent data showed that exposure of BEAS-2B bronchial epithelial cells to ROFA elicited inflammatory effects (e.g. increases in intracellular calcium, cytokine transcript and release), which were inhibited by capsazepine (CPZ), an antagonist of capsaicin receptors, and by amiloride, an antagonist of acid receptors (Veronesi et al., Toxicol. Appl. Pharmacol., *in press*). In this study, we examined whether physico-chemical characteristics of particles contributed to the inflammatory changes recorded in culture. Electrophoresis showed that 'field' ROFA particles carry a negative surface potential, as indicated by their zeta potential of -25 - -35 mV. Synthetic polymers microspheres (SPM) were synthesized, that resemble ROFA particles with 2-6 μm diameter and a zeta potential of -29 mV. The effects of ROFA and SPM were examined on BEAS-2B cells and sensory dorsal root ganglion (DRG) neurons. ROFA and SPM caused an immediate increase in intracellular calcium which was inhibited by CPZ and amiloride, respectively. In addition, exposure of BEAS-2B cells and DRG neurons to ROFA or SPM caused the release of IL-6, which was completely blocked by CPZ and partly blocked by amiloride. In both cell types capsaicin and pH 6.5 increased intracellular calcium and caused the release of IL-6 in a receptor-mediated fashion. These data suggest that the acidic environment associated with the negative zeta potential of the particles can activate capsaicin and acid receptors. We propose that activation of these irritant receptors triggers the subsequent release of inflammatory cytokines and neuropeptides which initiate and sustain neurogenic inflammation in the airways. (This abstract does not reflect EPA policy.)

1463 PHYSICOCHEMICAL COMPONENTS OF PARTICULATE MATTER CONTRIBUTE DIFFERENTIALLY TO INFLAMMATORY RESPONSES IN SENSORY NEURONS.

M Oortgiesen[1], S A Simon[1], and B Veronesi[2]. [1]*Dept. Anesthesiology, Duke University Medical Center, Durham, NC, USA;* [2]*US EPA, NHEERL, Research Triangle Park, NC, USA.*

Airborne particulate matter (PM) consists of complex aggregates of elemental and organic carbons, metals, sulfates and microbial contaminants. Its heterogeneous composition has complicated identifying the mechanism(s) which underlie the symptoms of airway inflammation. We examined the physicochemical characteristics of various urban and industrial PM in relation to their inflammatory effects in cultured sensory dorsal root ganglion neurons (DRG). The components of PM were separated by centrifugation and filtration, and characterized in terms of particle size, surface charge and pH in buffered solutions. The results show that most PM remain acidic in solution, even after multiple washings. The different PM contained particles of variable sizes, including ultrafine particles. The 'field' PM particles, their washed particle core and the ultrafine particles, obtained after 22 μm filtration, contained a variable surface charge as indicated by their zeta potentials. Exposure of DRG to PM caused a differential release of the proinflammatory cytokine IL-6 depending on the source and on the fraction of PM tested. Finally, pretreatment of DRG with antagonists of capsaicin receptors (i.e., capsazepine) or acid-sensitive receptors (i.e., amiloride or benzamil) inhibited the PM-induced IL-6 release in a differential manner. Collectively, these data support our hypothesis, that PM initiate inflammation by activation of capsaicin and acid-sensitive irritant receptors located on various airway target cells. In addition, the data indicate that soluble, acidic and charged particle components of PM contribute differentially to the inflammatory effects. (This abstract does not reflect EPA policy.)

1464 NUCLEAR FACTOR–KAPPA BETA (NF-KB) ACTIVITY IN RAT ALVEOLAR MACROPHAGES EXPOSED TO RESPIRABLE ORGANIC PARTICLES AND ANTIOXIDANTS.

D Ufferfilge[1], G N Cosma[1], H Gardner[2] and V Vallyathan[3]. [1]*Dept. Environmental Health, Colorado State University, Fort Collins, CO, USA;* [2]*US Army Center for Environmental Health Research, Fort Detrick, MD, USA;* [3]*NIOSH, Morgantown, WV, USA.*

Activation of the transcription factor NF-kB by respirable organic particles (ROP) facilitates oxidative damage in lung through increased expression of pro-inflammatory genes. In previous studies, we found that NF-kB in alveolar macrophages was activated maximally at 2 hours following <I>in vitro</I> treatments with ROP. Because of the recent interest in identifying oxygen radical pathways of NF-kB activation, we have investigated inhibitory effects by specific antioxidant agents. NR8383 rat alveolar macrophage cells were treated with ROP, with and without antioxidants, and analyzed for NF-kB activation employing the electrophoretic mobility shift assay (EMSA). Densitometry analysis of EMSA gels revealed the following reductions in NF-KB activation (reported as % of positive control). 200 units/ml superoxide dismutase reduced activation by 51%, whereas catalase had no inhibitory effect, strongly suggesting a primary role for the superoxide anion radical, but not hydrogen peroxide, in the activation of NF-kB in alveolar macrophages. Furthermore, only a 27% reduction in NF-kB activation was observed following cell treatments with 1 nM melatonin, an efficient scavenger of hydrogen peroxide. A series of vitamin E species, alpha-tocopherol succinate, vitamin E acetate, and Trolox, a vitamin E derivative, at 100 uM reduced NF-kB activation 63%, 33%, and 38%, respectively, clearly indicating that vitamin E analogs differ in their potencies of NF-kB inhibition. One uM pyrrolidinedithiocarbamate and 20 mM N-acetyl cysteine, which have effects on diverse oxygen free radical pathways, reduced NF-kB activation 54% and 66%, respectively, providing further support for a general role of reactive oxygen species in NF-kB activation. Ongoing studies are exploring the role of lipopolysaccharide receptors and calcium regulatory pathways on NF-kB activation in lung cells following exposure to particulate matter. (Support from NIOSH and USACEHR.)

1465 FREE RADICAL GENERATION BY WOOD SMOKE PARTICLES AND IN VITRO DNA DAMAGE.

S S Leonard[1], S Wang[1], X Shi[1], B S Jordan[2], V Castranova[1] and M A Dubick[2]. [1]*National Institute for Occupational Safety and Health, Morgantown, WV; and* [2]*US Army Institute of Surgical Research, San Antonio, TX.*

As a component of our investigations into the pathophysiology of smoke inhalation, the present study characterizes the free radicals generated by combustion of Western bark (fir and pine), using the technique of electron spin resonance (ESR) . Smoke was generated by heating the wood chips in a crucible furnace at a constant temperature of 400°C and an air flow of 6 L/min. Smoke was filtered through Whatman 1 filters or bubbled through saline over a 1 min period beginning at 0, 5, 10, 15 and 20 min after generation of the smoke. ESR analysis of the particles trapped by the filters revealed the generation of carbon-centered free radicals similar to those generated by coal or diesel particles. These radicals were observed at all time points and may be associated with the surface or the core of the particles. Addition of H_2O_2 generated hydroxyl radicals (•OH). There was no direct correlation between the generation of •OH and the level of carbon-centered free radicals. In aqueous media, wood smoke particles also generated •OH. Incubation of wood smoke particles with DNA, in vitro, caused DNA strand breaks as measured by gel electrophoresis. The H_2O_2 scavenger, catalase, the •OH scavenger, formate, and the iron chelator, deferoxamine, inhibited the DNA strand breaks, while H_2O_2 enhanced them. These data suggest that free radical reactions mediated by wood smoke particles may play an important role in the cellular injury associated with smoke inhalation.

1466 LUNG CELL INJURY INDUCED BY DIESEL EXHAUST PARTICLES (DEP) IN VIVO AND IN VITRO: EFFECTS OF OZONE (O_3) AS A CO-POLLUTANT.

M C Madden, L A Dailey, D M Reilly, and A J Ghio. *U.S. EPA, NHEERL, HSD, Research Triangle Park, NC, USA.*

DEP are a frequent, and sometimes major, constituent of ambient air particulate matter. DEP may contribute to the increased morbidity (e.g., increased pulmonary infections) and mortality associated with PM. These particles coexist in the ambient air with O_3 which may ozonize DEP to alter DEP chemical composition and subsequent toxicity. We examined the effects of DEP, and ozonized DEP, on pulmonary toxicity in vitro and in vivo. To generate ozonized particles, DEP were exposed to 0.1 ppm O_3 for 48 hr. For in vitro studies, cultures of human airway epithelial cells were initially exposed for 2 or 24 hr to HBSS (as control), unexposed DEP, ozonized DEP, or air-exposed DEP at $\leq$ 500 μg/ml. Viability among the treatment groups, assessed by LDH release, was not different from control at 2 and 24 hr. At 24 hr, an increase in prostaglandin E_2, an important immunoregulatory lipid, after melittin stimulation was observed for ozonized DEP-exposed cells, but not for other exposures. To examine the in vivo effects of unexposed DEP and ozonized DEP, 60 day old Sprague-Dawley rats were intratracheally instilled with 500 μg of particles and lungs lavaged 24 hr later. Rats instilled with ozonized DEP, but not DEP, had a significant increase in lavage protein (85% increase compared to control animals; $p<0.05$). Lavage neutrophils in both DEP and ozonized DEP treated rats increased similarly compared to saline-instilled controls. The data from these in vivo and in vitro studies suggest that ozonized DEP is more potent than unexposed DEP in inducing lung toxicity and injury. This change in the biological potency of DEP induced by O_3 exposure is likely due to ozonation of organic components. O_3 and DEP, and possibly other organic-rich particulate matter, may act together in the induction of increased human morbidity and mortality. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.)

1467 MOBILIZATION OF IRON FROM SIZE-FRACTIONED COAL FLY ASH IN HUMAN AIRWAY EPITHELIAL (A549) CELLS.

K R Smith[1], A E Aust[1], J M Veranth[2], A A Hu[2], J B Griffith[2], and J S Lighty[2]. [1]*Department of Chemistry and Biochemistry, Utah State University, Logan, UT, USA;* [2]*Chemical & Fuels Engineering, University of Utah, Salt Lake City, UT, USA.*

Coal fly ash (CFA), a contributor to particulate air pollution, contains as much as 15% iron by weight. Some of the pathological effects after inhalation may be due to reactive oxygen species produced by the redox cycling of iron. The objective of this study was to compare sized fractions of CFA and to determine whether iron could be mobilized in A549 cells and if this correlated with mobilization of iron by citrate *in vitro*. Fly ash samples produced by burning 3 types of coal were collected as fine (<2.5 μm), coarse (2.5-10 μm) or >10 μm size fractions. Iron was mobilized by 1 mM citrate from all 3 size fractions of all 3 coal types to levels as high as 56.7 nmol of Fe/mg of CFA after 24 h. With all 3 coal types, more iron was mobilized by citrate from the <2.5 μm fraction than from the fractions >2.5 μm. The mobilized iron was in the Fe(III) form and the amount mobilized had no relationship to the total iron present in the ash. A549 cells were treated with CFA and the amount of the iron storage protein, ferritin, was determined after 24 h as in indicator of intracellular iron mobilization. Ferritin levels were increased by as much as 11.9-fold with 20 μg coal fly ash/cm^2 cells. Higher ferritin levels were observed from treatment with the <2.5 μm than the >2.5 μm fly ash with 2 of the 3 types of coal studied. The amount of iron mobilized by citrate correlated with the amount of ferritin induced in A549 cells treated with CFA. The results of this study suggest that mobilization of iron in A549 cells was related to the size of the particles and the speciation of iron. These results support concerns by the EPA that particulate air pollution <2.5 μm is of greater importance for health concerns (Supported by a grant from HEI.)

1468 TOXICITY OF COBALT-CONTAINING DUST FOR RAT TYPE II PNEUMOCYTES AND ALVEOLAR MACROPHAGES.

G Roesems, P H Hoet, M Demedts, and B Nemery. *Laboratory of Pneumology, Unit of Toxicology, KU Leuven, Leuven, Belgium.*

Occupational exposure to cobalt-containing dust has been associated with the development of interstitial lung disease. Cobalt (Co) is used in many industrial applications, e.g. as a binder for tungsten carbide (WC) in hard metal (CoWC: 6%Co, 94%WC). We investigated the in vitro toxicity of different forms of Co for type II pneumocytes (AT-II) and alveolar macrophages (AM). Primary cultures of rat AT-II and AM were incubated for 24 hours in 24-well plates with Co metal, Co^{2+} ion or CoWC. In some experiments inserts were used to separate particles from cells and EDTA was used to chelate Co ions. As an index for cell toxicity, we determined mitochondrial activity using the MTT test. Co particles (5-25-100μg/well) caused a dose-dependent toxicity in AT-II (77-59-25% viability of control) and AM (93-72-58% viability of control). There was no change in toxicity when the particles were placed in an insert. The presence of EDTA decreased the toxicity of Co particles for AT-II, but not for AM. The presence of WC (i.e. CoWC) increased minimally the toxicity of Co for AT-II and definitely for AM, but only when the particles were in direct contact with the cells. EDTA was able to decrease the toxicity of CoWC for AT-II and AM. Medium in which 100μg Co particles had been placed in an insert for 24h (0-24h) was toxic for the AT-II and resulted in 15% viability compared to control cells. However, when the same (but now oxidized) particles were placed in fresh medium (24-48h), they caused much less toxicity (viability 71% of control). $CoCl_2$ (10^{-4}-$4x10^{-4}$-10^{-3}M) caused a dose-dependent toxicity in AT-II (79-69-42% viability of control) and AM (90-67-35% viability of control). Our results suggest that the toxicity of Co for AT-II is mainly due to the production of Co ions during the dissolution of the particles. For AM, the toxicity of Co is due in part to the Co ions and in part to the contact with the cells, especially in the presence of WC. These results suggest that Co causes toxicity via different mechanisms in AM and AT-II.

1469 TOXICITY TESTING OF AIRBORNE PARTICULATE EXTRACTS USING THE NEUTRAL RED BIOASSAYS WITH KERATINOCYTES AND BRONCHIOTREACHEAL CELLS.

D R Reyes,[1] L Maldonado-Baez,[2] O Rosario,[1] J F Rodriguez,[2] and B Jiménez[2]. [1]*University of Puerto Rico-Rio Piedras Campus, Department of Chemistry,* [2]*University of Puerto Rico-Medical Sciences Campus, Department of Biochemistry, San Juan, PR, USA*

Airborne particulate matter has been reported as one of principal causes of respiratory illnesses, acute bronchitis and asthmatic attacks in the world. Toxicity testing of particulate matter has been based mainly on traditional mutagenic assays determined by the widely used Salmonella/microsome bioassay. Normal human epidermal keratynocytes (NHEK) have been recently used in our laboratory to compare toxicities of adsorbed compounds to particulate matter. To establish stronger correlations between toxic effects and respiratory tract diseases, the Neutral Red Bioassay using normal human bronchial epithelial cells (NHBEC) were employed. Total suspended particles, less than 100μ m (TSP) and 10μ m (PM10) were processed using Soxhlet extraction methodology with solvents of different polarities (hexane, dichloromethane, acetone). A seasonal screening using both type of cells were performed in order to establish comparisons between cell types. Extracts of standard reference material (SRM 1649, urban dust) were tested using both types of cells as a reference point for comparison. The mutagenic activities of dichloromethane and polar extracts (acetone) from SRM 1649 have been reported to be relatively similar (20-23 revertants/μg) and was found to be 3-4 times higher than that of airborne particulates collected from a New Jersey site. The data proves evidence that moderately polar and polar fractions from SRM 1649 contain mutagenic organic material. Cytotoxic levels based on the neutral red uptake of bronchial cells exhibited a similar NR_{50} range for hexane extracts when compared to NHEK. The moderately polar and polar extracts from the same samples showed a wide difference among themselves for both type of cells. NR_{50} values ranged from 1 to 6 μg/mL (NHEK) and 6 to 43 μg/mL (NHBEC), for the SRM extracts. None of the control extracts from a reference site exhibited any detectable level of toxicity during the winter. Acetone extracts showed a broad difference in toxic effects when compared with NHEK and NHBEC. In summary, bronchial epithelial cells showed more sensitivity to extracts collected throughout the year at both sites.

1470 FURTHER CHARACTERIZATION OF THE IMMUNE RESPONSE TO ENZYME ALLERGENS IN THE BDF1 MOUSE USED IN THE MOUSE INTRANASAL TEST: LACK OF INFLUENCE OF SOURCE OF ANIMALS.

J S Parris, P A Horn, E D Clark, M K Robinson and K Sarlo. *The Procter & Gamble Co., Cincinnati, OH.*

The mouse intranasal (IN) test was developed as a method to assess the immunogenic potential of detergent enzymes. The BDF1 mouse was chosen based upon its robust IgG1 antibody response to certain enzymes and its

propensity to generate IgE antibody to protein antigens. Numerous detergent enzymes have been tested in this strain and the potency estimates match those obtained in the guinea pig intratracheal test which correlate with skin test res-ponses in occupationally exposed humans. Since the BDF1 is a hybrid of 2 inbred strains, the potential role the source of animals may have on the response to enzymes was tested. BDF1 mice obtained from 2 suppliers in the United States (US): Charles Rivers (CRL) and Taconic Farms (TF), 2 breeding sites from the same supplier in the US (CRL-MI, CRL-NC) and a third supplier (Harlan) in the United Kingdom (UK) received IN doses of enzyme in detergent matrix or saline vehicle on days 1, 3 and 10. Sera were collected on day 15 and IgG1 antibody titer to enzyme assessed by ELISA. The response to Alcalase in saline was similar in animals obtained from the 2 US suppliers: TF ED_{50} =2.24μ g, CRL ED_{50} =2.35-2.61μ g. The response to Alcalase in detergent was similar among the CRL US sourced animals: CRL-MI ED_{50} =0.25-0.39μ g, CRL-NC ED_{50} =0.25-0.34μ g. The response to the amylase Termamyl was also similar among the US CRL sourced animals: CRL-MI ED_{50} =0.042-0.091μ g, CRL-NC ED_{50} =0.056-0.087μ g. The response to Alcalase and Savinase was very similar between the US and UK sourced animals. The ED_{50} to Alcalase in UK animals was 0.37 μ g. The ED_{50}s to Savinase in US animals =0.25-0.38μ g and in UK animals = 0.32μ g. These data show that the IgG1 antibody response of BDF1 mice to different enzymes is consistent regardless of the source of animals.

1471 SENSITIZATION POTENTIAL OF A PIPERIDINYL CHLOROTRIAZINE DERIVATIVE IN A MURINE LOCAL LYMPH NODE ASSAY AND IG-E TEST.

C Mandervelt, H Xu, H Vanhooren, M Demedts, and B Nemery. *Laboratory of Pneumology, Unit of Toxicology, KU Leuven, Leuven, Belgium.*

A spectacular outbreak of occupational asthma in a polymer processing plant was found to be due to a novel UV-stabilizer, a piperidinyl chlorotriazine derivative (PCT; CAS # 52185-43-0). In this study we further investigated the sensitization potential of PCT using a local lymph node assay (LLNA), which has been proposed as a valid method to identify chemical sensitizers (Basketter *et al.*, Fd Chem Toxic, 32, 1994, 543-547). PCT [10 and 20 % (w/v) in dimethylformamide (DMF)] was tested in female BALB/c mice [n=3-7; 3 experiments]. During 3 consecutive days, 25 μl of PCT or vehicle were applied on the dorsum of both ears. On day 5, the mice were injected intravenously with 20 μCi [^{3}H]-thymidine. After 5 h, the auricular draining lymph nodes were excised and radioactivity was measured as an index of lymphocyte proliferation (Stimulation Index=SI). Our previously reported tests using low concentrations [0.05, 0.5, 2.0 % (w/v) in DMF] had been negative. However, after application of 10 % and 20 % solutions we found a significant increase in lymph node weight (1.3- and 1.5-fold, resp.) and cell proliferation (SI=2.7 and 3.2, resp.). We also used the mouse IgE test, which has been proposed to identify *respiratory* sensitizers (Dearman *et al.*, J Appl Toxicol, 12, 1992, 317-323). Female BALB/c mice [n=4-5] received 50 μl of PCT [10 or 20 % (w/v) in DMF] or vehicle on each shaved flank under occluded patch or 25 μl of the same solutions on the dorsum of both ears during 3 consecutive days. On day 8, 25 μl of the same solution diluted 1:1 with vehicle were applied to the dorsum of both ears. On day 15, serum IgE was determined using a sandwich ELISA. A significant increase in IgE was found for the 20 % group in both experiments (3- and 1.7-fold, resp.). We conclude that PCT is a respiratory sensitizer in mice when tested at high concentrations. This is in contrast with the very low concentrations of PCT that appear to have induced severe occupational asthma in humans.

1472 DETECTION OF SKIN SENSITIZERS IN THE LLNA: AN ANALYSIS BY CHEMICAL CLASS.

D A Basketter[1], L J Lea[1], G F Gerberick[2], C Ryan[2], R J Dearman[3], I Kimber[3], B L Carson[4], R R Tice[4], D W Sailstad[5], and W Stokes[6]. [1]*Unilever Safety and Environmental Assurance Centre, Sharnbrook, England;* [2]*Procter & Gamble, Cincinnati, OH, USA;* [3]*Zeneca Central Toxicology Laboratory, Macclesfield, England;* [4]*Integrated Laboratory Systems, Research Triangle Park, NC, USA;* [5]*US EPA, Research Triangle Park, NC, USA; and* [6]*NIEHS, Research Triangle Park, NC, USA.*

The murine local lymph node assay (LLNA) has been developed as a method for the prospective identification of chemicals with the potential to cause contact sensitization. As part of an extensive evaluation and validation program, the performance of the local lymph node assay with over 200 chemicals has been compared with results obtained using relevant guinea pig test methods and/or with available human data. In the investigations described here, we have compared LLNA with guinea pig test data according to the chemical class of test materials. An examination of 14 different chemical classes revealed a very high level of agreement. Differences between the LLNA and guinea pig test methods were seen only with the lactones and esters. Such differences are believed to have been exaggerated (in the case of esters) by the very small numbers of compounds tested, or due possibly (in the case of lactones) to species differences in response. For all other chemicals classes, the LLNA and guinea pig test methods yielded comparable results. Collectively these data provide additional evidence for the general utility of the LLNA as a routine method for the identification of skin sensitizing chemicals. (Supported by NIEHS under contract N01-ES-85424.)

1473 OXAZOLONE-INDUCED ALLERGIC SKIN INFLAMMATORY RESPONSE IS PREDOMINATED BY MIXED PATTERNS OF CYTOKINE PRODUCTION AND NEUTROPHIL INFILTRATION.

L Zhang and S S Tinkle. *CDC/NIOSH, Morgantown, WV.* Sponsor: M I Luster.

Allergic contact dermatitis (ACD) is traditionally classified as Type IV hypersensitivity. Previous studies employing local lymph node assay and *in vitro* organ and cell culture system documented an important role of Th1 cytokine production and CD4+ T cell in chemical-induced allergic contact dermatitis. However, a comprehensive *in situ* study of skin inflammatory response in terms of cytokine production and composition of infiltrating cells and its relation to the development of ACD largely remains absent. In this study, B6,129 mice were either sensitized with 0.5% oxazolone or control vehicle on abdominal skin and challenged five days later on ear. The dermal inflammatory response was evaluated by immunohistochemistry at 24, 48 or 72 hours post challenge. At 24 and 48 hours post challenge, the dermal cellular infiltrate consisted of CD4+ T cells, CD8+ T cells, mast cells, macrophages and neutrophils for animals sensitized with either vehicle or oxazolone. Interestingly, neutrophil were the predominant cell type. However, at 72 hours post challenge, while neutrophil are still the dominant infiltrating cells in the dermis, there is a significant increase in numbers of CD4+ T cells and CD8+ T cells in both groups. Among these inflammatory cells, large numbers of cells producing Th1 (IL-2, IFN-gamma), Th2 (IL-4, IL-10 and IL-13), and proinflammatory (IL-1beta and TNF-alpha) cytokines were consistently observed. Small numbers of infiltrating cells produced IL-12 or RANTES. Results of this study suggest that 1) both Th1 and Th2 cytokines, along with proinflammatory cytokines, are present in the inflammatory skin. 2) neutrophils are the dominant inflammatory cells. 3) chemical-induced allergic contact dermatitis may not be a traditional Type IV hypersensitivity response in terms of requirement for prior sensitization, pattern of cytokine production and type of inflammatory cells.

1474 LANGERHANS CELL MIGRATION INDUCED IN MICE BY SODIUM LAURYL SULFATE REQUIRES INTERLEUKIN 1α.

M Cumberbatch, R J Dearman and I Kimber. *Zeneca Central Toxicology Laboratory, Macclesfield, Cheshire, UK.*

Epicutaneous exposure of mice to skin sensitising chemicals induces the migration of Langerhans cells (LC) from the epidermis and their subsequent accumulation as immunostimulatory dendritic cells (DC) in lymph nodes draining the site of application. We have reported previously that this response is dependent upon receipt by LC of two epidermal cytokine signals; one provided by tumor necrosis factor α (TNF-α) and the other by interleukin 1β (IL-1β). Exposure of mice to the skin irritant sodium lauryl sulfate is also associated with the stimulation of LC migration, an event shown previously to be dependent upon TNF-α . Since SLS is thought not to induce in mice local IL-1β expression, we have investigated the contribution of IL-1α to SLS-induced LC migration. Systemic pretreatment of mice with a neutralising anti-IL-1β antibody was without effect on the accumulation of DC in draining lymph nodes measured 18 hours following topical exposure of mice to 10% SLS, under conditions where this antibody inhibited (by 75%) the response to the contact allergen oxazolone (Ox). Pretreatment of mice with a neutralising anti-IL-1α antibody, however, prevented completely both the reduction in epidermal MHC class II+ LC and the accumulation of DC in draining nodes and measured 4 hours and 18 hours, respectively, following exposure to SLS, but failed to inhibit Ox-induced responses. These data suggest that there may exist a differential requirement for IL-1α and IL-1β during irritant- and allergen- induced cutaneous responses with IL-1α substituting for IL-1β in the regulation of irritant-induced LC migration.

1475 EVALUATION OF DENDRITIC CELLS FOR IN VITRO DETECTION OF SENSITIZING CHEMICALS.

S Kerdine, H Lebrec, J Bertoglio and M Pallardy. *Immunotoxicology group, INSERM U461, Faculté de Pharmacie, Chatenay-Malabry, France.*

After application of haptens to the skin, Langerhans cells (LC) that are immature dendritic cells (DC) of the skin, secrete some cytokines and migrate to secondary lymphoid organs leading to activation of naive T cells. To assess which cytokines are produced by LC after an application of haptens, we have isolated $CD34^+$ hematopoietic progenitor cells from human cord blood through positive selection using anti-CD34 mAb and goat anti-mouse IgG coated microbeads. Isolation of $CD34^+$ cells was achieved using Minimacs separation column. After purification, $CD34^+$ cells were cultured with GM-CSF and h-TNF-α for 12 days in order to obtain Langerhans cells /dendritic cells. At day 12, surface marker analysis was performed using cytofluorometry. These LC/DC were positive for $CD1a^+$ (83%), CD83 (23%), B7-1 (40%) and ICAM-1 (80%). These cells showed a good uptake of antigens as measured using FITC-dextran and cytofluorometry. To assess the expression of cytokine mRNA after hapten stimulation, we added to LC/DC dinitrochlorobenzene (DNCB), a chemical agent known to induce cutaneous reactions. Results obtained using quantitative RT-PCR with a standard competitor DNA, showed that DNCB induced a three time fold increase in IL-1β mRNA expression as compared to controls. Maximal expression was obtained 15 min after the application of the hapten. These experiments showed that haptens can induce expression of IL-1β in cultured human dendritic cells. We are currently analyzing the expression of IL-12, MIP-1α and MIP-1β mRNAs in LC/DC after DNCB stimulation.

1476 EXAMINATION OF HUMAN PERIPHERAL BLOOD DERIVED DENDRITIC CELLS FOR USE AS ANTIGEN-PRESENTING CELLS IN AN *IN VITRO* LYMPHOCYTE PROLIFERATION ASSAY.

C A Ryan, B C Hulette and G F Gerberick. *The Procter & Gamble Company, Cincinnati, OH, USA.*

Dendritic cells (DC) are professional antigen presenting cells which are widely distributed in the body and are key for initiating T cell mediated immune responses. Methods for culturing human DCs from peripheral blood precursors have been developed by several laboratories. We were interested in examining DCs produced by these methods and evaluating their ability to present low molecular weight chemical haptens to sensitized T cells in an *in vitro* lymphocyte proliferation assay. Immature DCs (iDCs), were generated by culturing human peripheral blood mononuclear cells for 7 days in the presence of the cytokines Granulocyte-Macrophage Colony Stimulating Factor (GM-CSF) and Interleukin-4 (IL-4). When examined by flow cytometry, these cells were found to be MHC class II $HLA\text{-}DR^+$, $CD80^+$, $CD11b^+$, $CD45RO^+$ and $CD36^-$. iDCs were treated with the test allergen, dinitrobenzenesulfonic acid (DNBS), then cultured with 10^5 autologous T cells at several responder (T-cells) to stimulator (DCs) ratios (R:S). The cultures were incubated for four days, pulsed with ^{3}H-thymidine and harvested 18-20 hours later. T-cells cultured with DNBS haptenized iDCs at a 10:1 R:S demonstrated the greatest proliferation based on ^{3}H-thymidine incorporation compared with control cultures. Mature DCs (mDCs) were generated from iDCs by culturing them in the presence of GM-CSF, IL-4, TNF-α, IL-1β, IL-6 and PGE_2 for 2 additional days. These cells, in addition to being $HLA\text{-}DR^+$, $CD80^+$, were also found to be $CD83^+$. When mDCs haptenized with DNBS were used as antigen presenting cells, sensitized T cells demonstrated the greatest proliferation at an R:S of 50:1. Increased T cell proliferation above controls was also observed at an R:S ratio of 100:1. These initial results suggest that mDCs are better antigen presenting cells for chemical haptens.

1477 mRNA EXPRESSION BY CULTURED HUMAN BLOOD-DERIVED DENDRITIC CELLS: ASSOCIATION WITH SKIN SENSITIZATION POTENTIAL.

J S Pichowski[1], M Cumberbatch[1], R J Dearman[1], D A Basketter[2] and I Kimber[1]. [1]*Zeneca Central Toxicology Laboratory, Macclesfield, Cheshire, UK;* [2]*Unilever SEAC, Bedford, UK.*

Langerhans cells (LC) are a specialized form of dendritic cell found within the epidermis which are important for the development of contact sensitization and other cutaneous immune responses. The study of LC has been constrained by the fact that they represent only a minority population. However, methods have been developed recently that allow the expansion in culture of LC-like cells from precursors within a number of human tissues. Human peripheral blood mononuclear cells depleted of T and B lymphocytes by positive selection were cultured in the presence of interleukin-4 and granulocyte/macrophage-colony stimulating factor. After five days of culture, approximately 60% of cells displayed a LC-like phenotype, with characteristic dendritic morphology and cell surface expression of CD83, MHC class II and CD1a (determined by flow cytometry). The majority of the remaining cells was CD14+ monocytes/macrophages, while CD3+ T cells and CD19+ B cells represented minor populations. Cytokine expression was analyzed by semi-quantitative RT-PCR. In common with skin-derived LC, blood-derived DC expressed constitutively mRNA for interleukins (IL) -1β, IL-6 and IL-18. Following exposure of blood-derived DC to the chemical sensitizer 2,4-dinitrofluorobenzene (DNFB; 10.7pM) in 0.01% dimethyl sulfoxide (DMSO), IL-1β mRNA expression was up-regulated in cells derived from 2 out of 5 donors. Under the same conditions, 0.01% DMSO alone was without effect. The variation in IL-1β up-regulation may reflect subtle differences in culture conditions, particularly minor variations in cytokine concentration. These data suggest that with further optimisation, up-regulation of IL-1β mRNA expression by blood-derived DC might prove a useful marker of skin sensitizing activity.

1478 EVALUATION OF HUMAN IRRITANTS AND WEAK TO MODERATE SENSITIZERS USING A MODIFIED LLNA AND AN IRRITANCY/PHENOTYPING ASSAY.

J M Valosen[1], B B Hayes[1,2], M D Howell[1,3], T S Manetz[1,2], M R Woolhiser[1,2], and B J Meade[1]. [1]*National Institute for Occupational Safety and Health (NIOSH), Health Effects Laboratory Division, Morgantown, WV;* [2]*Virginia Commonwealth University, Richmond, VA;* [3]*West Virginia University, Morgantown, WV.*

One reported weakness of the murine Local Lymph Node Assay (LLNA) is its inability to differentiate weak sensitizers and strong irritants. In these studies, we evaluated a panel of irritants and weak to moderate sensitizers in a modified LLNA and an irritancy/phenotypic analysis assay. Compounds initially tested included p-xylenol, thiomerosal, formaldehyde, benzocaine, menthol, and phenol. The LLNA protocol was modified to include pre and post ear measurements as an indication of irritation. The irritancy/phenotypic analysis method also used ear swelling as an indication of irritancy but evaluated sensitization by an elevation of the %B220+ and/or %IgE+B220+ (IgE-mediated) draining lymph node cell populations. In both assays, female BALB/c mice were topically exposed on the ear pinnae for 4 consecutive days. Ear measurements were taken prior to exposure on day 1 and 24 hr after final exposure on day 5. For the LLNA, [^{3}H]-thymidine incorporation was measured on day 5 and for phenotypic analysis cell populations were examined on day 10. Consistent with the human literature, thiomerosal and formaldehyde were identified as irritants and sensitizers in both the modified LLNA and the irritancy/phenotypic assay. Additionally, the IgE+B220+ lymph node cell population was elevated in animals exposed to formaldehyde in agreement with reports of human contact urticaria following exposure to this compound. Phenol, a strong human irritant with a low sensitization index, was positive for irritation and sensitization in these assays. Benzocaine gave a false negative response for sensitization in both assays when tested at a 50% concentration in acetone. Although reported to be human irritants, menthol (50%), and p-xylenol (10%) were negative for both irritation and sensitization at the highest concentrations tested. (These studies were supported in part by the NIOSH/NIEHS interagency agreement # Y02ES10189.)

1479 USE OF THE MURINE LOCAL LYMPH NODE ASSAY TO ASSESS THE RELATIVE SKIN SENSITIZATION POTENCY OF TWO PROTEIN COUPLING REAGENTS.

J T Kozak[1], M Inlow[1], B D Naumann[2], T T Kawabata[2], and R V House[1]. [1]*IIT Research Institute, Chicago, IL and* [2]*Merck & Co., Inc., Whitehouse Station, NJ.*

The murine local lymph node assay (LLNA) was used to evaluate the contact allergenic potency of two protein coupling reagents, N,N-dicyclohexylcarbodiimide (DCC) and 1-ethyl-3-(3'-dimethylaminopropyl)-carbodiimide (EDC). Using a standard LLNA protocol, groups of five female CBA/J mice each were treated with concentrations ranging from 0.01, 0.03, 0.1, 0.3 and 1.0% DCC in isopropyl acetate and 0.1, 0.3, 1.0, 3.0 and 10% EDC in acetone/distilled water (1:1). Range-finding irritation studies employing clinical observations and ear thickness measurements were used to guide dose selection. Irritation was also monitored in the main studies. Draining auricular lymph nodes were evaluated in individual animals and a concurrent positive control (DNCB, 0.1%) was included. Separate groups of five animals each

were also included for vehicle and naive controls. Both DCC and EDC produced a clear dose-related increase in lymphocyte proliferation in draining auricular lymph nodes compared to vehicle controls and stimulation indices of ≥ 3 were obtained for all but the lowest concentrations tested for each compound. Therefore, the threshold for skin sensitization was between 0.01 and 0.03% for DCC and between 0.1 and 0.3% for EDC. DCC was equipotent to DNCB in this assay. The results of the study show that both DCC and EDC have the potential to induce contact hypersensitivity and the potency of DCC appears to be 10 times higher than EDC at equivalent concentrations. The guinea pig maximization test for these two compounds yielded parallel results.

1480 COMPARISON OF MURINE MODELS FOR THE IDENTIFICATION OF POTENTIAL CHEMICAL SENSITIZERS.

M D Howell[1,2], T S Manetz[1,3], and B J Meade[1]. [1]*National Institute for Occupational Safety and Health, Health Effects Laboratory Division, Morgantown, WV;* [2]*West Virginia University, Morgantown, WV;* [3]*Virginia Commonweath University, Richmond, VA.*

Efforts have been underway to develop a phenotypic analysis assay for the identification and differentiation of chemicals with the potential to induce irritation and IgE mediated and T cell mediated sensitization. The purpose of these studies was to compare results obtained with this assay to those obtained in the Mouse Ear Swelling Test (MEST) and the Local Lymph Node Assay (LLNA). The Irritancy/Phenotypic analysis assay utilizes the endpoints of ear swelling for irritation and the expression of B220 and IgE on the lymph node cells draining the site of chemical exposure as an indicator of sensitization. By measuring the increase in ear swelling, the MEST evaluates the elicitation response of previously sensitized mice following chemical challenge. A mouse ear swelling irritancy assay is used to determine the minimal irritating concentration of each chemical to be used as the challenge concentration in the MEST. The LLNA utilizes [^{3}H]-thymidine incorporation into draining lymph node cells as a measure of lymphocyte proliferation during the sensitization phase. Known human sensitizers, potassium dichromate (PDC) and 2,4-dinitrocholobenzene (DNCB), and the irritant methyl salicylate (MSC) were used for the dose response comparison studies. Female BALB/c mice were exposed topically to the chemicals following the protocol for each assay (four consecutive daily exposures for both the irritancy/phenotypic analysis and LLNA and three days of induction followed by a single challenge eight days post initial exposure for the MEST). DNCB was identified as a sensitizer in all three assays at concentrations as low as 0.25%. MSC tested negative at all concentrations in the MEST, LLNA, and phenotypic analysis assay. PDC tested positive as a sensitizer in the LLNA at concentrations as low as 0.25%, while it tested positive only at the 0.5% concentration at the 48 hr measurement of the MEST. Results obtained in these studies from the Irritancy/Phenotypic analysis assay were comparable to those for the MEST and LLNA. (These studies were supported in part by the NIOSH/NIEHS interagency agreement #Y02ES10189.)

1481 EFFECT OF VEHICLE ON POTENCY ASSESSMENT IN THE LOCAL LYMPH NODE ASSAY.

L J Lea[1], D A Basketter[1], R J Dearman[1] and I Kimber[2]. [1]*Unilever Safety and Environmental Assurance Centre, Sharnbrook, England and* [2]*Zeneca Central Toxicology Laboratory, Macclesfield, England.*

The murine local lymph node assay (LLNA) has been validated for the identification of skin sensitization hazards. Contact allergens are identified as a function of proliferative responses induced in draining lymph nodes and this provides the opportunity also of assessing relative potency by reference to dose response analyses. In the current investigations, the known skin sensitizer 1,4-dihydroquinone has been tested in 7 vehicle systems in each of two independent laboratories. The results from the two laboratories were almost identical. The dose response data from the pairs of LLNAs were interpolated using a statistical model to derive the estimated concentration of 1,4-hydroquinone necessary to cause a 3-fold stimulation of proliferation, the EC3 value. The vehicles and mean EC3 values obtained were as follows: methylethylketone 0.07%; acetone 0.08%; acetone/olive oil (80/20 $^{v}/_{v}$) 0.15%; dimethylformamide 0.22%; dimethylsulfoxide 0.4%; propylene glycol and acetone/saline (50/50 $^{v}/_{v}$) vehicles both yielded negative results. Thus the results demonstrate that the apparent potency of a contact allergen can depend critically on the vehicle in which it is presented. These data reveal that the vehicle in which a chemical is encountered in the skin can have a significant impact upon skin sensitization potency. The implication is that accurate assessment of risk to humans will require an appreciation of the likely condition of exposure.

1482 SEROPREVALENCE OF NATURAL RUBBER LATEX-SPECIFIC IgE ANTIBODY IN NON-HEALTHCARE WORKERS.

R E Biagini[1], D M Lewis [3], T A Bledsoe[3], B A MacKenzie[1], S A Robertson[1], and L E Pinkerton[2]. *DHHS/PHS/CDC/NIOSH,* [1]*DBBS;* [2]*DSHEFS, Cincinnati, OH and* [3]*DRDS, Morgantown, WV.*

Serological assays for latex (LAT)-specific IgE antibody are extensively used in the diagnosis of LAT allergy. We present the results of testing sera with two FDA 510K cleared, LAT IgE kits (CAP System and AlaSTAT Microplate [ALA]). Total IgE levels were also measured. The sera were obtained from 381 workers employed in numerous, non-healthcare industries over the last ten years and stored frozen . Twenty-six sera gave positive (pos) results using the ALA assay (6.82%), while 24 yielded pos results (6.30%), using the CAP assay (pos cutoff= ≥ 0.35 $kIU_{(A)}/L$). The assays agreed on the pos or negative (neg) status of 349 samples (91.6%). Discordant results (ALA pos, CAP neg) occurred in 17 sera (4.46%), while ALA neg, CAP pos results occurred in 15 sera (3.94%). Both assays agreed on the pos status of 9 sera (2.36%). The mean total IgE of all sera (N=374) was 144.19 ± 284.00 kU/L (± SD). There were no significant differences (P=NS) between the mean ALA and CAP assays' measurements of LAT antibodies for all 381 participants, yielding 0.28 ± 0.19 and 0.34 ± 0.59 $kIU_{(A)}/L$, respectively. CAP and ALA results were significantly correlated, (0.271, P<0.01). When sera with only pos LAT IgE antibodies were evaluated, CAP yielded significantly higher results than ALA (1.71 ± 1.93 (N=24) vs. 0.75 ± 0.55 $kIU_{(A)}/L$ (N=26), (P<0.05). Pearson correlation analyses of all sera indicated significant, albeit low, associations between total IgE levels and LAT specific IgE levels (ALA=0.117, P<0.05; CAP=0.411, P<0.01). These data indicate that both the CAP and ALA LAT specific antibody kits essentially agree on the seroprevalence of LAT IgE in non-healthcare workers (6.30% vs. 6.82%), respectively, and also agree with the seroprevalence (ALA, 6.4%) reported in 1000 blood donors (Ownby, 1996). The CAP assay gave significantly higher mean levels of LAT specific antibody in pos individuals than the ALA assay. However, both assays identify different individuals as being "pos", most probably since these assays detect different subsets of antibodies, presumably to different LAT allergen epitopes present in the kits.

1483 MURINE IMMUNE RESPONSES TO NATURAL RUBBER LATEX PROTEINS.

M R Woolhiser [1,2], A E Munson[1] and B J Meade[1]. [1]*National Institute for Occupational Safety and Health/Health Effects Laboratory Division, Morgantown, WV;* [2]*Medical College of Virginia Campus of VCU, Richmond, VA.*

It has been estimated that up to 17% of the 5.5 million U.S. health care workers (HCW) demonstrate IgE antibodies to natural rubber latex (NRL) products; an even higher prevalence of latex allergic spina bifida patients have been reported (as high as 70%). Furthermore, different allergen specific IgE profiles have been associated with HCW as compared to spina bifida patients. Although the exposure routes which elicit allergic responses are identifiable, the route(s) by which NRL sensitization occurs remains unclear. Our objective is to develop murine models representative of different routes of exposure to better understand latex sensitization and for testing intervention methodologies. Female BALB/c mice were treated for ~2 months subcutaneously (sc) or topically (abraded or intact skin sites) with latex proteins ranging from 1.5μg - 200μg per exposure. Following sc exposure, total IgE levels were elevated in a dose response fashion beginning at day 14 and peaked near 12,000ng/ml following 8 weekly injections of 200μg. Likewise, IgE levels were increased 9-fold after two weeks of daily applications to abraded skin sites using 150μg of latex protein diluted in acetone. Fifty μg applications to abraded skin sites also resulted in greater than a 4 fold elevation in total IgE by day 16 whereas intact skin exposure produced no increases until day 37. By day 53, total IgE concentrations following 50μg topical exposures were comparable between "abraded" and "intact" mice. Antigen specificity was demonstrated when *in vitro* stimulation of splenocytes (sc exposed mice) with 20μg/ml latex proteins caused a 500% increase in ^{3}H-thymidine uptake. Immunoblots identified IgE specific for all of the major latex allergens (Hev b1-7) following either sc or topical latex exposure. Functional, latex specific IgE was demonstrated in a murine Active Cutaneous Anaphylaxis assay within 5 minutes of intradermal latex protein challenge (~10μg) in the ear. These results indicate that BALB/c mice should serve as an acceptable model to study hypersensitivity to NRL. (This project is supported in part by NIOSH/NIEHS Interagency Agreement #Y02ES10189.)

1484 TYPE I HYPERSENSITIVITY TO LATEX AMONG GLOVE MANUFACTURING WORKERS IN MALAYSIA.

M Shahnaz[1], B A Nasuruddin[1], T Leakakos[2], V C C Lam[2], and W Truscott[2]. [1]*Institute for Medical Research, Kuala Lumpur, Malaysia;* [2]*Safeskin Corporation, Ipoh, Malaysia/San Diego, CA, USA.*

Previous studies indicate individuals in certain groups may have an increased risk for developing a latex allergy. This includes healthcare workers, rubber workers, atopic individuals, spina bifida patients and others who have undergone multiple surgical procedures. The study objective was to determine the extent of latex allergy in a Malaysian glove manufacturing facility where potential exposure to latex may be greater. Employee interviews and skin prick tests (SPT) were conducted. At least 16 allergens were used in the SPT including dust mites, grasses and latex. Sera was collected for measurement of latex-specific IgE antibodies. Airborne allergen concentrations, total proteins and antigenic proteins from the gloves in the production facility were determined. Results from 323 predominantly Banglideshi workers indicate a 2% incidence of latex sensitivity as determined by SPT. The mean age was 29.7 years and mean duration of exposure to rubber gloves was 5 years. The study has been expanded to include all nationalities employed at the manufacturing plant. Of those employees testing positive to latex, 80% were also positive to at least one other allergen, most typically dust mites, cockroach or watermelon. Airborne allergen concentrations ranged from 8–30,000 ng/m^3 which correlated with antigenic protein and total protein content of gloves sampled from different sites within the facility. The development of latex hypersensitivity does not appear to be increased in this population. These findings are comparable or lower than those reported in earlier studies conducted with glove factory workers.

1485 THE ROLE OF ENDOTOXIN IN THE DEVELOPMENT OF LATEX ALLERGY.

B A Olenchock, J M Valosen, and B J Meade. *National Institute for Occupational Safety and Health/Health Effects Laboratory Division, Morgantown, WV.* Sponsor: A E Munson.

Several investigators have hypothesized that endotoxin may act as an adjuvant, enhancing the development of an IgE response to natural rubber latex proteins following respiratory exposure. These studies were conducted to evaluate the role of endotoxin in the development of latex sensitization following two other relevant routes of exposure, topical and subcutaneous (sc). Groups of female BALB/c mice were exposed to 0, 5, 10 or 25μg of lipopolysaccharide (LPS) alone or in conjunction with 25μg of non-ammoniated latex (NAL). For topical studies mice were dosed 5 days a week to the shaven, derm-abraded, dorsal thorax. For sc studies animals were exposed once weekly by injection between the scapulae. Total IgE levels were monitored weekly and at the termination of the study; splenocyte proliferation assays were preformed and cytokine levels were quantified on *in vitro* splenocyte cultures. Following topical administration, animals simultaneously exposed to NAL and LPS (all doses) showed approximate 50% decreases in total IgE production as compared to animals exposed to NAL alone. Animals exposed sc to NAL and LPS demonstrated more dramatic decreases in IgE levels with values reaching less than 10% of the levels in mice exposed to NAL alone. A similar decrease in *in vitro* splenocyte proliferation was seen. A minimal effect on proliferation was seen following *in vitro* stimulation with NAL in splenocytes from animals topically sensitized to NAL in the presence of LPS. However, in animals sc sensitized to NAL in the presence of LPS an approximate 50% reduction in proliferation occurred. An increase in IL-2 levels were seen in splenocyte culture supernatants from these animals, which may hinder the class switch to IgE. Data from these studies suggest that the route of exposure to endotoxin may play a role in modulation of the IgE response to latex allergens. (These studies were supported in part by NIOSH/NIEHS interagency agreement Y02ES10189.)

1486 REDUCED PROINFLAMMATORY CYTOKINES IN FEED-RESTRICTED RATS EXPOSED TO HOUSE DUST MITE ANTIGEN.

W Dong[1], F W Kari[2], M J K Selgrade[1], and M I Gilmour[1]. [1]*Immunotoxicology Branch, US EPA, Research Triangle Park, NC;* [2]*Transgenic Carcinogenesis Group, NIEHS, Research Triangle Park, NC, USA.*

Feed restriction (FR) has been shown to reduce allergic responses to house dust mite (HDM) antigen in rats, which include less pulmonary inflammation, lower antigen-specific IgE in serum, and reduced antigen-specific lymphcyte proliferation in pulmonary lymph nodes. To understand the underlying mechanisms, both Th1/Th2 and proinflammatory cytokine expression was assessed in female Brown Norway rats fed either *ad libitum* (AL) or at feed intakes equal to 75% that of AL intake. Through an intratracheal instillation of HDM, rats were sensitized after 3 weeks of feed restriction then challenged 2 weeks later. Rats were euthanized and pulmonary lymph nodes collected 7 and 14 days after sensitization as well as 2 and 7 days after challenge. Although expression patterns of Th1/Th2 and proinflammatory cytokines were demonstrated in AL and FR rats exposured to HDM, no FR-related change was observed in IL-1β , IL-2, and IL-4 mRNA expression in pulmonary lymph nodes. However, IFN-γ expression level in FR rats was similar to that in AL rats prior to challenge and 2 days post challenge, it was higher in FR rats than that in AL rats 7 days after HDM challenge. While the expression of IL-6 and TNF-α was lower in FR rats than in AL rats 7 days after HDM sensitization, it elevated to the same levels as AL rats after HDM challenge. These data revealed Th1/Th2 and proinflammatory cytokine profiles in rats exposed to HDM antigen and indicated that dietary restriction reduced proinflammatory cytokine expression after sensitization. (This abstract does not necessarily reflect the views and policies of US EPA.)

1487 COMPARISON OF ALLERGIC RESPONSES TO HOUSE DUST MITE (HDM) AMONG LOCALLY AND SYSTEMICALLY SENSITIZED SUCKLING, WEANLING, AND ADULT BROWN NORWAY RATS.

L G Jimmerson[1,2], M I Gilmour[2], D W Winsett[2], and M J Selgrade[2]. [1]*North Carolina State University, Raleigh, NC, USA;* [2]*US EPA, NHEERL, ETD, Research Triangle Park, NC, USA.*

The model of HDM allergy in adult Brown Norway (BN) rats has been a useful tool for exploring the mechanisms of allergic disease and the impact of environmental pollutants on the development and expression of disease. Because the incidence of childhood asthma is increasing, it is necessary to adapt the HDM model to younger animals. In this study, allergic responses to Derf1, a purified HDM antigen, were compared among systemically and locally immunized 8-week-old adult, 3-week-old weanling, and 10-day-old suckling BN rats. Systemically immunized animals received subcutaneous injection of saline or 10μ g Derf1. Locally immunized animals received saline or a total of 10μ g Derf1 in 2 intratracheal (IT) instillations 48 hours apart. Twelve days after sensitization, rats were IT challenged with 10μ g Derf1. At 2,4, and 9 days post challenge, total IgE, antigen specific proliferation of lymph node and spleen cells, and pulmonary inflammation were measured. These data show that while local and systemic administration of antigen, without the use of adjuvant, caused allergic sensitization in adult and weanling animals, serum IgE levels were substantially higher in systemically immunized animals. Maximal pulmonary inflammation occurred at 2 days in adult rats, but was delayed until 4 days in weanlings. This immunization protocol was not sufficient to induce allergic sensitization in suckling rats. Future studies will investigate alternative immunization protocols, including multiple Derf1 instillations. (Funded by the NCSU/EPA Cooperative Training Program in Environmental Science Research, Training Agreement CT826512010 with North Carolina State University. This abstract does not reflect EPA policy.)

1488 A FLOW CYTOMETRIC METHOD TO SCREEN FOR BERYLLIUM SENSITIZATION.

A J Jabbour[1], J A Hill[1], R A Ponce[1], K B Ertell[1], T J Kavanagh[1], L S Newman[2], T K Takaro[1], and E M Faustman[1]. [1]*Consortium for Risk Evaluation with Stakeholder Participation, University of Washington, Seattle, WA, USA;* [2]*National Jewish Medical and Research Center, Denver, CO, USA.*

Human exposure to beryllium can result in chronic beryllium disease (CBD), an immune system-mediated disease resulting in loss of lung function, formation of granulomas, and fibrotic scarring. Medical monitoring relies on an assessment of beryllium sensitization based on the lymphocyte proliferation test (LPT), which currently measures ^{3}H-thymidine incorporation into DNA of beryllium-stimulated and -unstimulated peripheral blood lymphocytes (PBL). We present a flow cytometric assay that uses the quenching effect of bromodeoxyuridine on Hoechst 33258 DNA fluorescence to study the proliferative activity of PBL. This method allows the enumeration of cells in each G_1, S, and G_2/M phases of up to three successive cell cycles. PBLs were isolated from known CBD patients and normal controls and tested in culture for their response to either phytohemagglutinin P (PHA), tetanus, or beryllí-

um. PHA and tetanus caused similar increases in proliferation of cells from both CBD patients and normal controls. Increased cell proliferation to beryllium was only seen with blood cells from CBD patients but not normal controls. Beryllium elicited a positive proliferative response in cultured PBL that ranged from 4-6% at day 4 and 3-5% at day 6 of culture, respectively. Exogenous factors such as serum type and cytokines were tested with the goal of improving the sensitivity and specificity of the assay. Maximal proliferative response to beryllium was seen with 10% fetal bovine serum as compared to human AB serum or Nu serum. Interleukin 2 enhanced the survival of cultured cells but did not increase the total number of proliferating cells in response to beryllium. The proposed assay may prove useful in studying the etiology of CBD and for refining clinical assays currently used to identify beryllium-affected workers. (Supported by Department of Energy Cooperative Agreement #DE-FCO1-95EW55084).

1489 AN EVALUATION OF GUINEA PIG HYPERSENSITIVITY TESTS FOR ABILITY TO DETECT SYSTEMIC HYPERSENSITIVITY POTENTIAL OF DRUGS.

J L Weaver [1], D Staten [2], and K L Hastings[3]. [1]*Division of Applied Pharmacology Research;* [2]*Division of Antiviral Drug Products; and* [3]*Division of Special Pathogen and Immunologic Drug Products, Center for Drug Evaluation and Research, US Food and Drug Administration, Rockville, MD, USA.*

Guinea pig assays developed primarily to detect contact sensitizers have also been used to screen compounds for potential to produce systemic hypersensitivity. We examined the FDA Adverse Event Reporting System (AERS) and New Drug Application (NDA) reviews and found that 151 new molecular entities (NMEs) approved for marketing between 1993 - 1998 could be evaluated. Approximately 10% of adverse drug reports (ADRs) associated with these drugs appeared to be systemic hypersensitivity reactions. An analysis of NDA reviews demonstrated that guinea pig hypersensitivity assays had been conducted on 32% of the evaluable NMEs. Positive results in guinea pig assays had been reported for 18% of these drugs. Comparison of findings in guinea pig assays and ADRs indicates an approximate 20% probability that a positive result in any guinea pig assay would be predictive of clinical systemic hypersensitivity. Analysis of NMEs approved from 1978 - 1993 suggests that, in general, guinea pig assays were not predictive of systemic hypersensitivity reactions. It is unclear if potential sensitizers had been eliminated prior to marketing based on positive findings in guinea pig assays, but analysis of available data tends to suggest that this is not the case.

1490 TH1/TH2 PHENOTYPE OF HUMAN β-LACTAM SPECIFIC LYMPHOCYTES IN IMMEDIATE OR DELAYED HYPERSENSITIVITY REACTIONS.

H Lebrec[1], I Gaspard[1], N Bachot[1], M T Guinnepain[2], J Laurent[2], H Azouri-Tannous[3], S Kerdine[1], and M Pallardy[1]. [1]*INSERM U 461, Faculté de Pharmacie Paris Sud, France;* [2]*Hopital de l'Institut Pasteur, Paris, France;* [3]*Université Saint Joseph, Beyrouth, Lebanon.*

β-lactam antibiotics elicit CD4+ and CD8+ T cell-mediated immune responses that play a central role in allergic reactions. However, the involvement of a Th1- or a Th2-like differentiation remains unclear. We investigated the expression of IL-4 and IFN-γ mRNA by quantitative RT-PCR in patients-derived peripheral blood lymphocytes following specific *in vitro* stimulation. Samples were collected from a total of 12 patients with clinical manifestations of β-lactam immediate hypersensitivity (urticaria, angioedema, shock), 8 patients with delayed reactions (maculopapular rash, contact dermatitis), and 11 control subjects chronically treated with β-lactams and with no reported allergic reaction. PBMC were stimulated with either free antibiotics or antibiotic-HSA conjugates. The immediate type reactions were characterized by induction of IFN-γ mRNA only (6 out of 12), or induction of both IL-4 and IFN-γ (5 out of 12). Lymphocytes from one patient did not respond. IFN-γ mRNA was induced mainly following stimulation with conjugated drugs while IL-4 mRNA expression was mainly triggered by free drugs. Delayed-type reactions were characterized by induction of IFN-γ mRNA and a total lack of IL-4 response. Lymphocytes from control subjects never produced IL-4 and a more than twofold induction of IFN-γ mRNA was observed in only one case. These data show that delayed-type reactions are characterized by Th1-like responses and that immediate reactions are not linked to typical Th2-like responses.

1491 INTERLEUKIN-4 POTENTIATES IL-2-INDUCED HUMAN PENICILLIN-SPECIFIC CD4+ T CELLS PROLIFERATION THROUGH REGULATION OF CYCLIN-DEPENDENT KINASE INHIBITORS.

I Gaspard[1], D Blanchard[2], A Vazquez[2], M Pallardy[1], and H Lebrec[1]. [1]*INSERM U 461, Châtenay-Malabry, France;* [2]*INSERM U 131-IPSC, Clamart, France.*

β-lactam antibiotics are haptenic compounds known to induce hypersensitivity reactions. Clinically, penicillin-induced allergies include urticaria, angioedema, shock, and bullous skin eruptions. These toxic effects involve activation of CD4+ helper T lymphocytes and/or CD8+ T lymphocytes, as well as production of specific antibodies. We previously showed that interleukin-4 (IL-4) plays a dominant role in controlling Th1- or Th2-like primary immune response to the hapten penicillin G (PNG) in the mouse. The present work focuses on the effects of IL-4 on differentiation of human penicillin-specific T lymphocytes derived from allergic patients. Such lymphocytes proliferate in response to penicillin in the presence of irradiated autologous antigen-presenting cells (APCs: EBV-transformed B lymphocytes). This proliferation is MHC-restricted since no proliferation is induced with allogeneic APCs. Long-term culture of this cell population in the presence of IL-4 and IL-2 induces selection of a pure CD4+ population. The cell-cycle analysis of CD4+ penicillin-specific T lymphocytes showed that IL-4 increases IL-2-induced G1/S cell cycle transition. Cell cycle is in part regulated through an interplay between cyclins, serine/threonine cyclin-dependent protein kinases, and cyclin-dependent kinase inhibitors (CDKIs). We show that IL-4 decreases expression of CDKIs in human penicillin-specific T lymphocytes. These data underline the key role of IL-4 in regulation of drug-specific T cell responses.

1492 HUMORAL IMMUNE RESPONSE TO A SEVOFLURANE DEGRADATION PRODUCT IN THE GUINEA PIG FOLLOWING INHALATION EXPOSURE.

C K Begay, R C Lind, X H Zheng, and A J Gandolfi. *Department of Anesthesiology, University of Arizona, Tucson, AZ.*

Compound A (2-fluoromethoxy-1,1,3,3,3-pentafluoro-1-propene) is produced by reaction of the inhalation anesthetic, sevoflurane, with CO_2 absorbents. Compound A has been reported to directly react with protein. Since adduction of proteins can transform them into antigenic material, Compound A was assessed for its ability to produce a humoral immune response. Male outbred Hartley guinea pigs (500-600 g, N=7) were exposed via inhalation for 4 hr to a subtoxic level (100 ppm) of Compound A, 3 times, at 42 day intervals. Blood samples obtained at 2, 14, 28 and 40 days after each exposure were measured for ALT, creatinine, and urea nitrogen and for the presence of antibodies to trifluoroacetylated guinea pig albumin (TFA-GSA). All indicators of liver and kidney injury remained within normal range throughout the course of the study. A humoral immune response to TFA-GSA was observed following each exposure with a titer appearing by day 14 after exposure, peaking near day 28, and resolving to normal levels by day 40. The titer levels were approximately equivalent after each exposure and about one-third that previously seen in guinea pigs after multiple exposures to halothane. Compound A would appear to have the ability to form antigenic adducts during inhalation exposure. These findings are similar to those observed for halogenated inhalation anesthetics that have been linked to cases of immune-medicated idiosyncratic hepatitis and indicate that Compound A exposure may pose the same hazard. (Supported by Baxter Pharmaceutical Products Inc.)

1493 EVALUATION OF BENZO(A)PYRENE IN THE NZBWF1 MOUSE MODEL OF AUTOIMMUNITY.

C D Booker, G C Llewellyn, J W Parrett, and K L White, Jr. *Virginia Commonwealth University, Richmond, VA, USA.*

Potent immunosuppressive compounds such as cyclophosphamide and TCDD have been shown to enhance the immune response when administered at low doses. Benzo(a)pyrene (BaP) has been shown to act in a similar manner, enhancing the antibody forming cell response to sRBC at low dose levels. The objective of this study was to determine if exposure to BaP would exacerbate autoimmunity in genetically predisposed NZBWF1 mice. NZBWF1 mice spontaneously develop an autoimmune disease similar to systemic lupus erythematosus seen in humans. NZBWF1 mice (5 weeks of age at beginning of treatment) were dermally exposed to BaP (0.2, 2, 20 mg/kg) daily for thirty days. Vehicle mice were treated with an acetone: olive

oil mixture (9:1). No significant change in body weights or kidney and thymus weights was observed; however, animals treated with 20 mg/kg BaP had statistically significant increased liver (20%) and spleen (93%) weights. Using ELISA methodology, several autoimmune parameters were evaluated by detecting the presence of antibody to self and non-self antigens. When compared to vehicle mice, no difference in levels of serum IgG total antibodies or antibody titers to DNP-HSA, dsDNA, or laminin were observed in animals treated with BaP. While lower dose levels are currently under investigation, initial results indicate that dermal exposure to BaP for thirty days does not exacerbate autoimmunity in NZBWF1 mice. (Supported in part by NIEHS Contract ES55387 and Immunotoxicology Training Grant ES07087.)

1494 ACCELERATION OF AUTOIMMUNITY BY THREE CHLORINATED PESTICIDES WITH ESTROGENIC EFFECTS.

S M Roberts and J Schiffenbauer. *University of Florida, Gainesville, FL, USA.*

Systemic lupus erythematosus is an autoimmune disorder in which women are affected more frequently than men. Data from both human and animal studies support the findings that estrogens can have an adverse impact on the course of the autoimmune process. Considerable interest has focused on the possible environmental factors that may contribute to the development of autoimmune disorders in general, and lupus in particular. Recently, a wide array of common environmental contaminants has been shown to possess estrogenic effects. Specifically, environmental toxicants including DDT, chlordecone, and methoxychlor have been shown to have estrogenic effects in both in vitro and in vivo systems. However, the effects of these compounds on immune-mediated processes such as lupus have not been well studied. We examined the effects of these three agents on the course of an autoimmune disorder in mice using the (NZB x NZW)F1 (BWF1) mouse model of lupus. Each compound was tested at a dosing rate verified to produce estrogenic effects (uterine hypertrophy) in vivo. All three compounds were found to accelerate the course of lupus in ovariectomized BWF1 mice. Specifically, mice treated with DDT, chlordecone or methoxychlor developed an accelerated production of anti-dsDNA antibodies, an accelerated onset of renal disease, and an increased early mortality. The results suggest that chlorinated pesticides with estrogenic effects may pose a distinct risk to individuals with lupus and related autoimmune diseases. (Supported by ES 08551.)

1495 MULTIPLE IMMUNE FUNCTIONS IN RATS FED ECHINACEA.

J H Exon and E H South. *Department of Food Science and Toxicology, University of Idaho, Moscow, ID, USA.*

Echinacea purpurea (ECH) is found as the sole ingredient or in combination with other herbs in herbal products advertised as protective against colds and flu. Herbalist have traditionally recommended the use of the echinacea plant to stimulate immune system. Research using both human cells and rodent models suggest that this recommendation may be well founded. In our current study, two doses (50 and 250 mg/kg) of a liquid ECH preparation were fed to 6 wk old male rats. At the conclusion of the six week ECH feeding period the following immune functions were evaluated: 1) B cell-mediate antibody production; 2) T cell-mediated delayed-type hypersensitivity; 3) non-specific cell-mediated natural killer cell cytotoxicity. We found no significant difference between vehicle- and ECH-fed rats in the immune functions assayed. To address the possibility that tolerance to the immunostimulatory actions of ECH may occur over a 6 week feeding period, we examined antibody production in female and male rats fed ECH (250 mg/kg for 2 weeks) starting on the day of the first antigen injection. The rats were sacrificed and blood collected one week following the second antigen injection. We found no difference in antibody production between ECH- (6.2 ± 1.4) and vehicle- (6.8 ± 1.7) fed male rats, however, the female rats fed ECH exhibited a significant reduction (4.0 ± 1.2, $p < 0.01$) in antibody production compared to their vehicle control (9.0 ± 1.0). Our findings of no effect on immune function following 6 weeks of ECH feeding at doses that exceeded recommended human doses, no effect on antibody production in male rats, and a significant reduction in antibody production in female rats fed the high dose (250 mg/kg) of ECH for 2 weeks, fails to confirm the efficacy of commercially prepared echinacea as an immunostimulatory agent in our rat model.

1496 ORAL EXPOSURE TO BUTOXYACETIC ACID (BAA) DOES NOT MIMIC THE EFFECTS OF ITS PARENT COMPOUND, BUTOXYETHANOL (BE), ON SYSTEMIC IMMUNE RESPONSES.

P Singh, S Zhao and B L Blaylock. *Division of Toxicology, College of Pharmacy and Health Sciences, Northeast Louisisana University, Monroe, LA, USA.*

Immunomodulatory effects of glycol ethers have been studied in several rodent models. Previous studies in our lab indicated that 10-day oral dosing with 2-butoxyethanol (BE) enhances systemic immune responses in female BALB/c mice. The objective of this study was to determine whether oral dosing with BE's primary metabolite, butoxyacetic acid (BAA), would produce the same enhancement. Mice were given either 0, 50, 150 or 400 mg/kg/day BAA for 10 days by oral gavage and sacrificed 72 hours later for assessment of systemic immune parameters. We found no significant effects on lymphocyte blastogenesis in response to either B- or T-cell mitogens (lipopolysaccharide and concanavalin A, respectively). There were no significant effects on blastogenesis in the mixed lymphocyte response. We also observed no differences in natural killer cell activity or in cytotoxic T cell activity among any of the BAA doses when treatment groups were compared to the control group. Based on these findings, it appears that the immunoenhancement observed with oral BE administration is not due to the action of BAA.

1497 EFFECT OF CHEMICAL MODIFICATIONS ON A B CELL STIMULATORY OLIGONUCLEOTIDE.

K M Lemonidis, M V Templin, and R M Crooke. *Isis Pharmaceuticals, Carlsbad, CA, USA.*

Phosphorothioate oligodeoxynucleotides have been shown to induce a dose-dependent immune stimulation in rodents. The immunostimulatory effects are independent of the antisense target and unrelated to pharmacological activity. Stimulation has been observed with most phosphorothioates, but the levels of stimulation are highly variable due, in part, to sequence differences. Although palindromes (i.e. the CpG motif, unmethylated CpG dinucleotide flanked by two 5' purines and two 3' pyrimidines) play a critical role in the stimulatory effects of oligos, other sequence-related elements may also be involved. To better understand the influence of various structural and chemical modifications on immunostimulation, ISIS 12449 (5'ACC-GATAACGTTGCCGGT GACG 3'), a highly stimulatory phosphorothioate oligodeoxynuceotide, has been modified and its effects studied in a standard *in vitro* B cell stimulation assay using splenocytes from CD-1 mice. In general, stimulatory oligomers lose activity as their length is decreased. The stimulatory effects of ISIS 12449, and other oligomers, were also attenuated, respectively, by modifying the 2' position within the oligonucleotide with methoxy ethyl and the addition of 5-methyl cytosine. Combination of the modifications further decreased stimulation, but did not completely abrogate the effects. Alterations in the base positioning in relation to the CpG motif indicated that both base identity and position within the molecule also influenced biological effects. These data suggest that multiple factors contribute to the immunostimulatory effects of antisense oligonucleotides. Although, certain sequences may contain components that are highly stimulatory, immunostimulation may be ablated through chemical modifications.

1498 FUMONISIN ALTERS MACROPHAGE ACTIVATION AS MEASURED BY LUMINOL-DEPENDENT CHEMILUMINESCENCE.

S Conklin[1,2], K L Ponce[2], A J Cooley[2] and R D Schultz[1,2]. [1]*Environmental Toxicology Center;* [2]*Department of Pathobiological Sciences, School of Veterinary Medicine, University of Wisconsin-Madison, Madison, WI, USA.*

Fumonisin B1 (FB1) is a sphingosine analog mycotoxin purified from *Fusarium* species which contaminate corn and other crops worldwide. FB1 inhibits complex sphingolipid metabolism and causes a variety of animal diseases including hepatotoxicity, nephrotoxicity, equine leukoencephalomalacia and porcine pulmonary edema. In order to elucidate a possible cellular mechanism of fumonisin toxicity, an *in vitro* model was established using the murine macrophage RAW 264.7 cell line. Luminol-dependent chemiluminescence (LDCL), an *in vitro* technique to measure the oxidative burst in macrophages after phagocytosis, was used to characterize our previous observation that pretreatment with 10μM FB1 for 48 hours increased zymosan-stimulated LDCL of RAW 264.7 cells. Zymosan-stimulated LDCL enhancement by FB1 was dose-dependent, duration-dependent and reversible upon removal of FB1. In contrast to enhancement of zymosan-

stimulated LDCL, FB1 pretreated RAW 264.7 cells displayed a greatly reduced phorbol myristate acetate (PMA)-stimulated LDCL. This decrease was also FB1 dose- and duration-dependent. Differential RAW cell responses based on activating stimuli suggest that FB1 may alter cell signaling events by influencing secondary messengers or membrane integrity, perhaps via changes in cellular sphingolipid pools. To evaluate model validity, adherence-purified primary macrophages from mouse spleen cell suspensions and peritoneal washes were treated *in vitro* with 10 μM FB1. An increase in zymosan-stimulated LDCL was observed in these cells indicating the possibility that changes in macrophage function may occur during *in vivo* exposure to FB1. However, when female B6C3F1 mice were treated by gavage for 0, 3, 6, 9 or 12 days with 12 or 20 mg/kg/day FB1, no treatment-dependent alterations in zymosan-stimulated LDCL were observed.

1499 PARADOXICAL IMMUNOMODULATORY EFFECTS IN α-CD3/α-CD28-STIMULATED PRIMARY SPLENIC AND THYMIC T-LYMPHOCYTES FOLLOWING ACUTE TGF-β1 EXPOSURE *IN VITRO*.

S C McKarns and N E Kaminski. *Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI.*

Transforming growth factor-β1 (TGF-β1) is a 25 kDa hematopoietic cytokine which modulates a diverse array of biological activities including immune cell function. It has only recently been demonstrated that TGF-β1 elicits immunostimulatory effects, in addition to, the more thoroughly characterized immunosuppressive effects. Interleukin-2 (IL-2)/IL-2 receptor signaling, G1 to S-phase cell cycle transition, and lymphoid apoptosis have been proposed as putative mechanistic targets of TGF-β1-mediated immunomodulation in T-lymphocytes. The objective of the current studies was to characterize the concentration-dependent immunomodulatory effects of TGF-β1 on T-cell receptor-dependent immune cell function. Resting or α-CD3/α-CD28-stimulated primary B6C3F1 mouse splenic or thymic T-lymphocytes were incubated with TGF-β1 (0-10 ng/ml). Steady-state IL-2 mRNA expression, IL-2 protein secretion, and cell proliferation were quantified using qualitative RT-PCR, ELISA, and 3H-thymidine incorporation, respectively. IL-2 protein secretion was either enhanced or inhibited following low (0.0001 to 0.1 ng/ml) or high (10 ng/ml) concentration TGF-β1 exposure, respectively. Additionally, TGF-β1 impaired cell proliferation in a concentration-dependent manner (0.001 - 10 ng/ml). The stimulatory effect was dependent on the addition of TGF-β1 prior to, or at the time of, T-cell activation. In conclusion, we have identified several factors, including the concentration of TGF-β1, the mode of T-cell activation, and the temporal relationship between T-cell activation and TGF-β1 exposure which, at least in part, modulate whether TGF-β1 elicits an immune stimulatory or an immune suppressive response on T-lymphocytes following acute exposure. These data support the hypothesis that the *immunomodulatory* effects of TGF-β1 are regulated by multiple divergent molecular pathways. (This research was supported by NIEHS Grant P01 P42ES04911-08C.)

1500 EVALUATION OF TOXIC SHOCK SYNDROME-ASSOCIATED TOXIN CONTAMINATED TAMPONS IN A RABBIT MODEL.

S Y Wang, T Y Chang, Y J Chen, and C W Chen. *Development Center For Biotechnology, Taipei, Taiwan, R.O.C.* Sponsor: R A Renne.

Toxic shock syndrome (TSS) has gained concern because of its association with tampon use. The aim of this study was to develop an in vivo test system for detection of endotoxin (lipopolysaccharide; LPS) or toxic shock syndrome toxin-one (TSST-1) contaminated tampons. This study was designed to measure the febrile response in rabbits following intravenous injection of extracts of LPS or TSST-1 from contaminated tampons. LPS or TSST-1 were extracted from tampons contaminated with different concentrations(0, 250, 500, 1000 EU/ml) of each toxin. Rabbits were intravenously injected with these extracts, and body temperature was measured for 180 minutes following injection. The results of this study demonstrated that the i.v. administration of extracts of LPS or TSST-1 induced a febrile response in a dose-dependent pattern. Thirty minutes after injection, the temperature was increased up to 0.8-1.0°C in rabbits injected with 20 or 40 EU/kg LPS. The data also indicated the minimum pyrogenic threshold for rabbits was 5 EU/kg of LPS, which induced a minor temperature change (<0.2°C). At 180 minutes after injection of extracts from tampons contaminated with 50-200 EU of LPS, body temperature was increased 0.3-0.6°C. These data suggest that the pyrogen test in rabbits can be applied for the biological evaluation of toxic shock syndrome associated-toxin contaminated tampons or medical devices.

1501 SUBCHRONIC ORAL TOXICITY OF THIODIGLYCOL IN RATS.

R A Angerhofer, M W Michie, and G J Leach. *U S Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD, USA.*

Thiodiglycol, a hydrolysis product of sulfur mustard, has been shown to be present in the ground and surface water at several military installations. In order to establish toxicity standards for thiodiglycol to facilitate environmental remediation, a subchronic oral study was conducted in male and female Sprague-Dawley rats. Preliminary studies indicated that thiodiglycol had a relatively low toxicity by the oral route. Neat thiodiglycol was administered via gavage, five days per week, over a period of 90 days. Three groups of rats, consisting of 10 males and 10 females each, received test material at the rate of either 50, 500, or 5000 mg/kg/day. A fourth group served as a sham control. In addition to weekly measurement of individual body weight and food consumption, urine, blood and tissue samples were collected at or near study termination. Thiodiglycol was not lethal to rats nor did it produce visible signs of toxicity at dosage levels as high as 5000 mg/kg/day. The measurable signs of toxicity included decreased body weight gain, lower absolute body weight, increased urine output, lower urine pH, higher urine specific gravity, appearance of granular casts in the urine and increased kidney weights. These signs were found in both sexes at the 5000 mg/kg/day dosage level. Additionally, liver, testes and brain to body weight ratios were significantly higher than controls at 5000 mg/kg/day. In females at that dosage, adrenal to body weight ratios were higher than corresponding controls. The only effects noted at 500 mg/kg/day, and only for females, were lower urine pH and higher urine specific gravity. No compound-related histopathological changes were found. The NOAEL for subchronic oral exposure to thiodiglycol, as determined from this study, is 500 mg/kg/day.

1502 PRECLINICAL TOXICITY STUDIES OF THE PHOSPHO-DIESTERASE IV INHIBITOR CI-1018 IN RATS.

L A Dethloff, D G Pegg, and A L Metz. *Pathology and Experimental Toxicology, Parke-Davis Pharmaceutical Research, Warner-Lambert Co., Ann Arbor, MI.*

These studies were conducted to evaluate in rats the toxicity of the type IV phosphodiesterase inhibitor CI-1018 in support of clinical trials. Daily CI-1018 administration at 100, 300, and 1000 mg/kg for 2 weeks, caused dose-related gastrointestinal (GI) lesions and vasculitis in females at 300 mg/kg and in males at 1000 mg/kg. Vasculitis and GI inflammation were associated with significant morbidity, also greater in females, at 1000 mg/kg. Gender differences in sensitivity to CI-1018 correlated with approximately 2-fold greater plasma concentrations in females. In addition, epididymal edema and seminiferous tubular dilatation occurred at very low incidence at ≥ 100 mg/kg. Based upon these data, 13-week studies of CI-1018 in rats were conducted at doses of 30, 100, and 300 mg/kg. Despite systemic exposures comparable to those achieved in the previous 2-week study, as indicated by similar Cmax and AUC values, CI-1018 was well tolerated for 13 weeks at these doses and was without significant pathological change. Remarkably, gastrointestinal inflammation and vasculitis and epididymal effects were absent after 13 weeks of treatment suggesting possible accomodation to CI-1018. Additional studies demonstrated that doses up to 2000 mg/kg in males and 1000 mg/kg in females, with correspondingly greater systemic exposures, could be achieved by giving CI-1018 in the diet and escalating doses weekly over the first 4 weeks of treatment. In addition to previously noted target tissues, inflammation of the tarsal joint was identified at low incidence at these higher subchronic exposures to CI-1018.

1503 PRECLINICAL TOXICOLOGY PROFILE OF CI-1012 IN RATS.

D G Pegg, L A Dethloff, and K M Walsh. *Pathology and Experimental Toxicology, Parke-Davis Pharmaceutical Research, Warner-Lambert Co., Ann Arbor, MI.*

CI-1012 is a novel agent which induces zinc ejection from zinc fingers contained in the nucleocapsid p7 (NCp7) protein, a retroviral structural protein with multiple roles in early and late phases of the HIV-1 infection cycle. The objective of these studies was to characterize the toxicity of CI-1012 in rats in support of human clinical trials. CI-1012 given to rats by gavage at 100, 250, 500, and 1500 mg/kg for 2 weeks was associated with significant clinical signs of toxicity, body weight loss and deaths at 1500 mg/kg. Reductions

in red blood cell counts occurred at 1500 mg/kg and suppression of bone marrow hematopoiesis was evident at ≥ 250 mg/kg. Compensatory extramedullary hematopoiesis in spleen was observed at ≥ 100 mg/kg. Renal tubular degeneration occurred at 500 and 1500 mg/kg. Histiocytosis in spleen was observed at 1500 mg/kg and lymphadenopathy, dose-dependent incidence and severity, was present at all doses. Liver weight was increased without corresponding histopathological change. Histopathologic evidence of gastric irritation was present at ≥ 250 mg/kg. In chronic studies, CI-1012 was given to rats at 50, 100, and 500 mg/kg for up to 26 weeks. Gastric irritation occurred at ≥ 50 mg/kg and increases in liver and thyroid weight, both without histopathologic correlates were observed at 500 mg/kg and at ≥ 100 mg/kg, respectively. The data suggest that effects seen in 2-week studies at 500 mg/kg and below were relatively mild and non-progressive when CI-1012 is given chronically at these doses.

1504 SETTING INVENTORY LIMITS OF CHEMICALS FOR EMERGENCY PLANNING, HAZARD ASSESSMENT, OR SAFETY ANALYSIS.

D K Craig. *Westinghouse Safety Management Solutions, Inc., Aiken, SC, USA.*

Two different methods are in use for establishing the safety of facilities, processes, or operations involving hazardous chemicals. One sets inventory limits using Occupational Safety and Health Administration (OSHA) threshold quantity (TQ), Environmental Protection Agency (EPA) Clean Air Act Amendment threshold quantity (CAA-TQ), threshold planning quantity (TPQ) or reportable quantity (RQ), values published in the Federal Register. The second method uses toxicological consequence estimates at different receptor points (e.g., facility boundary, 100 m, site boundary) of concentration limits established for this purpose. These include such parameters as EPA acute exposure guidance level (AEGL), emergency response planning guideline (ERPG), and immediately dangerous to life or health (IDLH) values. These two methods were compared by estimating the potential downwind concentrations of all chemicals on the OSHA Process Safety Management regulation TQ list. EPA CAA-TQ, TPQ, and RQ, values were extracted for these chemicals. Only 50 of the 134 unique chemicals with TQs also have CAA-TQs, 60 have TPQs, and 72 have RQs. In general, CAA-TQs > TQs > TPQs > RQs, although there are exceptions. Only 7 of 60 TQs are less than TPQ values for that chemical. Conservative release fractions at 25 ° C and dispersion conditions were used to calculate potential airborne concentrations at 100 m downwind of the assumed release of TQ quantities of each chemical. These calculations were repeated for all chemicals on the TQ list that also had CAA-TQs, TPQs or RQs. These concentrations were compared with ERPG values wherever possible. Every TPQ to ERPG ratio was greater than unity. For RQs, only 3 of 23 RQ to ERPG-1, 5 of 30 RQ to ERPG-2, and 7 of 30 RQ to ERPG-3, ratios were less than unity. Most of the other RQ to ERPG ratios were one to three orders of magnitude > 1. These results demonstrate the undesirability of using regulatory quantities established for different purposes to include these chemicals in hazard assessments, or as inventory limits. It is recommended that concentration-limits established specifically for short-term acute exposures, such as AEGLs or ERPGs, be used in safety-related applications.

1505 TWO-WEEK CONTINUOUS INTRAVENOUS INFUSION OF PROBENECID IN DOGS.

L A Dostal[1], S C Groom[2], D A Manca[2], R M Walker[2], and N J Gragtmans[2]. *Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Co., [1]Ann Arbor, MI, USA, and [2]Mississauga, Ontario, Canada.*

Probenecid is a renal tubular transport-blocking agent used concurrently with other drugs to inhibit their renal secretion to decrease potential toxicity. In a range finding study, continuous IV infusion of 25 or 50 mg/kg/hr probenecid in male beagle dogs resulted in marked clinical signs (prostration, mydriasis, convulsions, tachypnea, miosis, emesis, spasms, hypoactivity) with plasma concentrations ≥ 408 μ g/mL within 21 hrs. In a subsequent 2-week study, 3 dogs/sex/group were infused with probenecid at 0, 2, 5, or 10 mg/kg/hr. Dogs were observed daily and changes in food consumption, body weight, hematology, serum biochemistry, and thyroid hormone levels were evaluated. Pathological examination was conducted. Plasma probenecid levels were measured on Days 1 and 14. Females had reduced food consumption at all doses. There was a non dose-dependent decrease (30% - 65%) in thyroxine (T_4) concentration from pretest to Day 14 in all probenecid groups. Triiodothyronine (T_3) was not affected. Mild thyroid follicular epithelial hypertrophy was noted in all probenecid groups with increased incidence at 10 mg/kg/hr with no changes in thyroid weight. Liver weights increased 16% and 24% in males at 5 and 10 mg/kg/hr, and 14%, 25%, and 40% in females at 2, 5, and 10 mg/kg/hr, respectively. Plasma probenecid levels generally increased with dose on Days 1 and 14, with means of 253 and 243 μ g/mL in males and females, respectively, at 10 mg/kg/hr on Day 1. However, Day 14 levels were approximately 35% lower than Day 1 levels. These results, and those from concurrent studies conducted in rats, suggest that the thyroid changes associated with continuous IV infusion of probenecid may be related to hepatic induction and increased elimination of T_4 with possible disturbances of the hypothalamic-pituitary-thyroid axis.

1506 SUB-ACUTE EFFECTS OF CONTINUOUS INTRAVENOUS INFUSION OF PROBENECID IN RATS FOR 2 WEEKS.

D A Manca[1], L E Lillie[1], R M Walker[1], S C Groom[1], N J Gragtmans[1], and L A Dostal[2]. *Parke-Davis Pharmaceutical Division, Warner-Lambert Co., [1]Mississauga, ON, Canada and [2]Ann Arbor, MI.*

Probenecid is a renal tubular transport blocking agent used as an adjunct with other drugs to inhibit their renal secretion. Its effects have not been evaluated following continuous intravenous infusion. In the present study, groups of 10 Wistar rats/sex were continuously infused for 2 weeks at 5, 10, and 20 mg/kg/hr through vascular access ports. Clinical examination, including changes in food consumption and body weight, were monitored throughout treatment, and clinical laboratory analysis, and pathological examination were conducted at termination. Plasma concentrations of probenecid were measured on Days 7 and 14. No changes were noted in animals given 5 mg/kg/hr. At 10 mg/kg/hr, changes were limited to decreases in circulating levels of thyroxin (T_4) (50%-65% less than concurrent controls). At 20 mg/kg/hr, a higher incidence of clinical signs was noted, consisting of chromodacryorrhea, hypoactivity, reduced or absent feces, and decreased food consumption and body weight gain. One female and 1 male were euthanatized in moribund condition on Days 4 and 11, respectively. Pathological changes noted at 20 mg/kg/hr included increased absolute and relative liver weights (17%-21%), and mild thyroid follicular cell hypertrophy in males. T_4 plasma concentrations decreased 70% in males and 49% in females, while triiodothyronine (T_3) decreased 18% in males. Plasma Probenecid concentrations increased more than dose-proportionally between 5 and 20 mg/kg/hr, and between Day 7 and Day 14. Concentrations at 5 mg/kg/hr were below the limit of quantification (10 μ g/mL), while at 10 mg/kg/hr they were within the intended therapeutic range of 30-150 μ g/mL. Higher concentrations were achieved at 20 mg/kg/hr (279-658 μ g/mL). These results, and those from concurrent studies conducted in dogs, suggest that thyroid changes induced by probenecid could be associated with disturbances of the hypothalamic-pituitary-thyroid axis consequent to increased hepatic clearance of T_4.

1507 TERFENADINE EVOKED PROLONGATION OF THE QTc INTERVAL IN ISOLATED PORCINE PURKINJE FIBRES - AN EXPERIMENTAL MODEL FOR THE ASSESSMENT OF ARRHYTHMOGENIC POTENTIAL IN MAN.

M Maginn, C M Algate, and D R Algate. *Huntingdon Life Sciences, Huntingdon, Cambs, England.* Sponsor: R J Harling.

Since the discovery that terfenadine, the non-sedative H_1-antihistamine produced a prolongation of the QTc interval, which can lead to the development of Torsades de Pointes in man , there has been a need for the development of an experimental model capable of predicting the arrhythmogenic effect of new non-cardiovascular medicinal products in man. The aim of this study was to investigate the electrophysiological effects of terfenadine using conventional microelectrode techniques in porcine cardiac Purkinje fibres. Each preparation was stimulated at a supramaximal voltage with a cycle length of 1000 ms and 1 ms duration. Increasing concentrations of terfenadine (10^{-6} M to 10^{-5} M) were administered to each preparation and, following a 30 minute incubation period, the maximum velocity of action potential upstroke (Vmax) and action potential duration (APD) were recorded. The results obtained showed that terfenadine (3 x 10^{-6} and 10^{-5} M) dose dependently increased action potential duration ($APD_{90,60,30}$). This reached significance at the highest dose of terfenadine ($p < 0.05$, n=10). Terfenadine had no significant effect on Vmax. In conclusion, these results support the usefulness of porcine cardiac Purkinje fibres in predicting the potential for QTc interval prolongation in man of new non-cardiovascular medicinal products.

1508 TOXICITY AND CARCINOGENICITY OF TACRINE IN B6C3F1 MICE.

R M Walker[1], L M King[1], S C Groom[1], C E Rothwell[2], D Welty[2], J Paulissen[2], and Z W Wojcinski[1]. *Parke-Davis Pharmaceutical Research Division, Warner-Lambert Co., [1]Mississauga, ON, Canada and [2]Ann Arbor, MI.*

Tacrine (1,2,3,4-tetrahydro-9-acridineamine hydrochloride; Cognex®) is a centrally active reversible acetylcholinesterase inhibitor approved for the treatment of Alzheimer's disease. The chronic toxicity and carcinogenicity of tacrine was characterized in B6C3F1 mice as part of the preclinical safety assessment. Tacrine was administered in diet at 100, 200, 300 or 400 mg/kg for 13-weeks and 50, 100, or 200 mg/kg for 104 weeks to groups of up to 60 male and 60 female mice. Controls received normal diet. Dosing at 400 mg/kg tacrine was terminated after 1 week due to severity of the clinical signs and at 300 mg/kg body weight loss was dose-limiting for the carcinogenicity study. In the 13-week study, body weight gain suppression occurred at all doses. Microscopic evaluation revealed minimal hepatocellular hypertrophy at all doses and single cell necrosis of centrilobular hepatocytes in males at 200 mg/kg and both sexes at 300 mg/kg. In the carcinogenicity study, tacrine reduced body weight gain at 100 and 200 mg/kg and increased mortality at 200 mg/kg. Survival did, however, exceed 50% in all groups at 104 weeks. Liver was a target organ both for tacrine-induced neoplastic and non-neoplastic changes. There was an increased incidence of foci of hepatocellular alteration and nuclear atypia at all doses. Incidence of single cell necrosis was also increased males at 50 and 200 mg/kg. Tumor analysis showed an increased incidence of hepatocellular adenoma and carcinoma at 100 and 200 mg/kg at which plasma concentrations exceeded 100 ng/mL or 3 times human therapeutic levels. Carcinoma was diagnosed in 5, 7, 14, and 20 males and 3, 2, 16, and 41 females in controls and at 50, 100 and 200 mg/kg, respectively. Adenoma occurred in 8, 5, 19 and 25 males and 4, 9, 18, and 45 females in controls and at 50, 100, and 200 mg/kg, respectively. The mechanism of tumor induction is unknown but may be related to the minimal hepatocellular cytotoxicity and/or genotoxicity in the highly susceptible B6C3F1 strain of mice.

1509 PANCREATIC ACINAR CELL TUMORS IN WISTAR RATS TREATED WITH TACRINE, A COGNITION ACTIVATOR FOR 104 WEEKS.

Z W Wojcinski[1], L E Lillie[1], N J Gragtmans[1], R Walker[1], D Welty[2], J Herman[2], and F A de la Iglesia[2]. *Parke-Davis Pharmaceutical Research Division, Warner-Lambert Co., [1]Mississauga, ON, Canada and [2]Ann Arbor, MI.*

Tacrine (1,2,3,4-tetrahydro-9-acridinamine, hydrochloride; Cognex®), a cognition activator approved for the treatment of Alzheimer disease, was evaluated in a 2-year carcinogenicity study in Wistar rats. Three groups of 60 Wistar albino rats per sex received tacrine in the diet at daily doses of 5, 10, and 15 mg/kg for 104 weeks. An additional group of 60 rats per sex received no drug and served as controls. Survival was adequate in all groups for evaluation of tumorigenicity. Body weight gain during the study was suppressed by 15% and 19% in males, and by 18% and 29% in females at 10 and 15 mg/kg, respectively, relative to controls. In general, morbidity and mortality were attributed to a spectrum of pathologic alterations that were unrelated to compound administration and were considered common age-related changes. Absolute pancreatic weights were increased in both sexes at the high dose. A statistically significant increased incidence of exocrine pancreatic (acinar cell) tumors was identified in treated males and females. These tumors in treated rats were observed within an unusually high background incidence of pancreatic exocrine tumors in concurrent controls. The incidence of pancreatic acinar cell adenoma was 31, 33, 35, and 43 for males and 1, 0, 7, and 6 for females in controls and at 5, 10, and 15 mg/kg, respectively. The incidence of pancreatic acinar cell carcinoma was 10, 9, 12, and 18 for males and 0, 2, 2, and 4 for females in controls and at 5, 10, and 15 mg/kg, respectively. There were no treatment-related increases in other tumour types. Biologically, malignant pancreatic exocrine tumors in the rat were considered of low grade because they were not invasive, rarely metastasized, were of late onset, and did not compromise survival. Further, tacrine-induced pancreatic exocrine neoplasia in the rat bears little histologic or biologic resemblance to pancreatic cancer in man which is primarily of ductal rather than acinar cell origin.

1510 SINGLE AND REPEAT DOSE DISPOSITION OF AG2034 IN LOW FOLATE MICE.

G J Stevens, A Lankford, R Grecko, and M Chen. *Agouron Pharmaceuticals, Inc., San Diego, CA, USA.*

The toxicity of GARFT inhibitors is often cumulative, and significantly enhanced under low folate conditions in mice. These effects may occur as a result of cellular accumulation of the inhibitors following polyglutamation. Studies were therefore initiated to determine the accumulation of the GARFT inhibitor, AG2034, in female C3H mice. Animals fed either a standard diet or a folate deficient diet for two weeks prior to a single intravenous administration of ^{14}C-AG2034 (20 mg/kg) were evaluated for drug elimination and tissue distribution. Elimination of ^{14}C-AG2034 at 24 hr was similar between standard fed (45% urine:25% feces) and low folate fed (38.7% urine:29.3% feces) mice. Tissue (liver, kidney, spleen and small intestine) radioactivity was determined over a 7 day period. Liver, kidney and intestine exhibited the greatest amount of radioactivity. In low folate animals, the tissue levels were 2-6 fold higher than the amount detected in standard fed animals. Seven days after treatment, 5.85 nmol Eq/g and 5.03 nmol Eq/g were detected in liver and kidney extracts from low folate animals while in standard fed animals levels were undetectable (<1.0 nmol Eq/g). To determine if accumulation would occur with repeat dosing, animals were treated with two intravenous doses of ^{14}C-AG2034 (5 mg/kg), seven days apart. Following the second dose, the amount of radioactivity was determined in liver, kidney and small intestine. The amount of total radiolabel observed in these tissues was similar to the single dose study. The data suggest under these conditions the tissues sequester a saturable level of intracellular drug and repeat dosing would only offer to sustain such levels. Therefore, in this animal model, while folate status appeared to play a significant role in AG2034 tissue sequestration, there was no evidence of tissue accumulation with repeat dosing.

1511 EFFECT OF BENZOYL PEROXIDE ON SOLAR-STIMULATED ULTRAVIOLET RADIATION-INDUCED SKIN TUMOR FORMATION IN SKH1Hhhh (hr/hr) ALBINO HAIRLESS MICE.

L C Totman[1], R M Parker[2], E J Winkelman[3], P D Forbes[2] and J F Nash[4]. *[1]Nonprescription Drug Manufacturers Association, Washington, DC; [2]Primedica, Horsham, PA; [3]SmithKline Beecham Consumer Healthcare, Parsippany, NJ; [4]Procter & Gamble, Cincinnati, OH.*

A photocarcinogenesis study was conducted with benzoyl peroxide at the request of the U.S. Food & Drug Administration. The study objective was to determine whether repeated, topical application of benzoyl peroxide suspended in carbopol gel enhanced solar-simulated radiation (SSR)-induced skin tumor formation in SKH1 (hr/hr) albino hairless mice. In this 12-month study, two groups of mice that received either 600 or 1200 RBU of SSR alone served as internal response calibrators for the study. Mice received benzoyl peroxide carbopol gel [0 (vehicle), 1, 15, or 50 mg/ml] applied to their back and sides before SSR (600 RBU) on Monday, Wednesday, and Friday, and after SSR on Tuesday and Thursday for 40 weeks, followed by a 12-week observation period with no treatment. The SSR received by all mice in the study was a tumorigenic dose. The time for tumors to appear (i.e., tumor latency) and the number of tumors per mouse (i.e., tumor yield) were determined at weekly intervals throughout the study. The benzoyl peroxide carbopol gels had no statistically significant dose-dependent effect on the appearance of SSR-induced skin tumor latency or yield in this study. Isolated values (i.e., sex-specific or treatment differences) that were statistically significant in multiple pairwise comparisons were small, not dose-dependent, and approximated the smallest change detectable in this test system. This study provides no clear evidence for enhancement by benzoyl peroxide carbopol gel of SSR-induced skin tumor formation in albino SKH1 (hr/hr) hairless mice. Thus, under the conditions of this rodent photocarcinogenicity study, benzoyl peroxide in a carbopol gel vehicle is not a photocarcinogenicity risk factor.

1512 PRECLINICAL SAFETY ASSESSMENT OF AG2034, AN INHIBITOR OF GLYCINAMIDE RIBONUCLEOTIDE FORMYLTRANSFERASE (GARFT), IN MICE AND DOGS.

M A Zorbas and A C Lankford. *Agouron Pharmaceuticals, Inc., San Diego, CA, USA.*

In support of the clinical evaluation of AG2034 for antitumor effects in humans, 5-day repeat dose intravenous (iv) toxicity studies were conducted in CD-1 mice and beagle dogs. Mice remained on study for 23 days follow-

ing the last dose and dogs remained on study for either one or 23 days after the last dose. In mice administered 1, 3, 10 or 30 mg/kg/day, deaths were observed between 8 and 11 days after the start of dosing at 30 mg/kg/day (5/10 males; 7/10 females) and 10 mg/kg/day (2/10 females). Moribund mice exhibited body weight loss, decreased food consumption, enteropathy of the small intestine, lymph node depletion, myeloid cell regeneration in the bone marrow. The NOEL in mice was 3 mg/kg/day. In dogs administered 0.05, 0.2 or 0.8 mg/kg/day, deaths were observed between 7 and 10 days after the start of dosing at 0.8 mg/kg/day (¾ males; ¾ females). Moribund animals exhibited general signs of deteriorating conditions along with emesis and unformed/watery stools, decrease in body weight and food consumption. Elevated RBC parameters, small and large intestine enteropathy (reversible after dosing cessation), decreased bone marrow cell and thymic lymphoid cell density and a decrease in peripheral lymphocytes were observed in the 0.8 mg/kg/day group. The NOEL was 0.2 mg/kg/day in dogs. Mean C_0 dog plasma levels of AG2034 on the first day of dosing were 0.046, 0.314 and 1.66 μg/mL, for 0.05, 0.2 and 0.8 mg/kg/day, respectively. The mean areas under the curve for 24 hours after dosing (AUC_{0-24}) were 0.180, 0.742 and 4.89 μg/mL-hr on the first day of dosing for 0.05, 0.2 and 0.8 mg/kg/day, respectively. The mean C0 and AUC values on day 5 were similar at each dose level in males and females.

1513 TOXICITY OF THE ANTIFOLATE, AG2034, IN LOW FOLATE MICE: EFFECT OF FOLINIC ACID RESCUE.

M Chen, M Zorbas and G J Stevens. *Agouron Pharmaceuticals, Inc., San Diego, CA, USA.*

AG2034 is a potent inhibitor of glycinamide ribonucleotide formyltransferase (GARFT) that exhibits antitumor activity in several mouse models. Previous studies with other GARFT inhibitors have shown that rodents are relatively insensitive to the toxicological effects of these antifolates primarily due to high folate levels. Studies were therefore initiated to evaluate the toxicity of AG2034 in animals maintained on a folate deficient diet. Female C3H mice were fed a folate deficient diet for two weeks prior to treatment with AG2034. The estimated LD_{50} in low folate animals following a single intravenous dose was approximately 20 mg/kg; 35-fold lower than the LD_{50} estimated in standard fed mice. In low folate animals the toxicity was delayed, with morbidity occurring 7 to 10 days after dosing. Clinical signs included diarrhea, decreased activity and significant loss of body weight. Hematological changes included significant decreases in hemoglobin, hematocrit, RBCs, and lymphocytes. There was a significant increase in spleen and liver weight. Histopathological evaluation of the intestine revealed dose-dependent enteropathy characterized by microvilli necrosis. In an effort to evaluate the potential rescue from these dose-limiting effects in low folate animals, a single dose of folinic acid (leucovorin) was administered intravenously three, six, or nine days after treatment with 20 mg/kg AG2034. Folinic acid reversed many of the toxicological effects induced by AG2034 with complete attenuation observed in animals treated three days after AG2034. At higher doses of AG2034 given alone (40 and 80 mg/kg), significant lethality occurred (4/6 and 5/6 respectively); however, in animals receiving folinic acid 3 days following AG2034, no deaths occurred in the 40 mg/kg group and only one animal treated at 80 mg/kg died. These data demonstrate a link between folate status and acute toxicity of AG2034 in female C3H mice, and indicate that intravenous folinic acid can attenuated AG2034-related adverse effects in low folate animals.

1514 MONITORING CELLULAR TOXICITY WITH AN INDUCED CALCIUM LOAD.

M K McMillian, L Li, P Cheung, W J Powers and M D Johnson. *R W Johnson Pharmaceutical Research Institute, Raritan, NJ, USA.*

An elevated cytosolic Ca^{2+} (Ca_i) concentration is frequently observed in cells exposed to toxic compounds. Healthy cells maintain the 10,000-fold Ca^{2+} gradient across the plasma membrane, while dying cells cannot. However, after some toxic treatments, severely compromised cells apparently can maintain their Ca_i near normal levels. In the present study we compared the effects of cisplatin and its relatively inactive isomer transplatin on Ca_i (as determined by fluo-3 fluorescence) in HepG2 cells. Published reports suggest an initial decrease in Ca_i after treatment with cisplatin (possibly due to release of free Pl^{2+} ions), followed within days by an increase in Ca_i, followed by cell death. We observed similar increases in Ca_i with higher concentrations of cisplatin (>1 μg/ml), but calibrating Ca_i in these experiments presumes similar loading of fluorescent dyes in healthy and damaged cells. A more sensitive indication of cell damage is observed by inducing a Ca_i load (e.g. by adding Ca^{2+} ionophores or dilute detergent). The cisplatin-damaged cells showed larger and/or more prolonged responses to this Ca^{2+} load than transplatin-treated or control cells. Conversely, one might expect healthy cells to respond better to phospholipase C-linked agonists which require intact phosphatidylinositol pools that may be depleted in damaged cells. As yet, we have not identified a suitable PLC-linked agonist for HepG2 cells to test this hypothesis. Monitoring the ability of cells to handle an induced Ca_i load may be useful for evaluating cellular toxicity during screening for new pharmaceutical lead compounds.

1515 A SUBCHRONIC (3-MONTH) TOXICITY STUDY OF ULTRANOX® XR-2677 IN THE RAT VIA ORAL GAVAGE ADMINISTRATION.

R C Mandella[1], S S Dimond[2], and R L Joiner[2]. [1]*Huntingdon Life Sciences, East Millstone, NJ, USA and* [2]*General Electric Company, Pittsfield, MA, USA.*

The objective of this study was to assess the potential subchronic toxicity of Ultranox® XR-2677 (CAS#161717-32-4), an organophosphite-based antioxidant/stabilizer used in the manufacture of polymers, when administered for 3 months via oral gavage to Sprague-Dawley CD® rats (20/sex/group) at doses of 0, 3, 12, 20, 30, 60, 90, or 270 mg/kg/day. Physical observations, body weight, and food consumption were examined on all animals at selected intervals during the treatment period. At study termination, hematology and clinical chemistry were performed on 10 animals/sex/group. All survivors were sacrificed, selected organs were weighed, and histopathological evaluation of tissues were conducted. Results revealed no treatment-related mortality, abnormal clinical signs of toxicity, or mean body weight changes in any treated group. There were no toxicologically significant changes in any clinical chemistry parameter at any dose. Hematology results showed dose-related increases in clotting parameters, prothrombin time (PT); and activated partial thromboplastin time (APPT) at doses of 30 mg/kg/day and higher. Following necropsy, there were statistically significant increases in absolute liver weight and liver/body weight ratios at doses of 12 mg/kg/day and higher. These increases correlated with microscopic evidence of centrilobular hypertrophy and were considered the result of a metabolic adaptation to the test material and not toxicologically significant. No other organ weight changes or histopathological findings were observed, with the exception of a statistically significant increase in absolute kidney weight at 90 and 270 mg/kg/day and edema and slight thickening of the forestomach mucosa in the high dose group only. In conclusion, based on the conditions of this study, a no observed adverse effect level (NOAEL) for Ultranox® XR-2677 when administered to rats via oral gavage for at least 3 months is 20 mg/kg/day.

1516 POLYCYSTIC KIDNEY DISEASE INDUCED IN F_1 SPRAGUE-DAWLEY RATS FED *PARA*-NONYLPHENOL IN A SOY-FREE CASEIN-CONTAINING DIET.

J R Latendresse[1], K B Delclos[1], C C Weis[1] and R R Newbold[2]. [1]*NCTR, Jefferson, AR, USA;* [2]*NIEHS, Research Triangle Park, NC, USA.*

para-Nonylphenol (NP; CAS # 84852-15-3), an alkylphenol with a 9 carbon olefin side chain, is widely used in the manufacture of nonionic surfactants, lubricant additives, polymer stabilizers, and antioxidants. NP has estrogenic activity. The NTP elected to assess its effects on reproduction in multigenerational studies due to its wide commercial use and putative endocrine effects in humans and wildlife. To avoid known estrogenic activity of isoflavones in soy, a soy-free casein-containing diet was used in a range finding study to determine the doses of NP to be further tested. NP was fed in the diet at 0, 5, 25, 200, 500, 1000 and 2000 ppm to F_0 dams beginning on gestation day 7. Exposure of the F_1 pups continued via the dams milk until postnatal day (PND) 21 and then by feed until sacrifice on PND 50 (N =15, all groups). Terminal body weights of both males and females in the 2000 ppm dose group were approximately 25% lower than the respective control body weights. Severe polycystic kidney disease (PKD) was present in 100% of the 2000 ppm-exposed male and female rats. At 1000 ppm, 100% of males and 93% of females had minimal to moderate PKD versus only minimal cysts in 47% male and 67% female controls. Incidence and severity in other dose groups were like controls. Previous studies of comparable duration to ours also administering 2000 ppm NP, but in soy-containing diets, reported either no or only mild PKD. We conclude that the renal toxicity of NP is highly dependent on the diet on which the animals are maintained.

1517 COMPARISON OF FIVE COGNITIVE TESTS USED IN RODENT DEVELOPMENTAL NEUROTOXICITY STUDIES AFTER PERINATAL PHENYTOIN AND METHIMAZOLE.

W P Weisenburger, C L Kozak, A R Hagler, and D S Chapin. *Pfizer Inc, Drug Safety Evaluation Dept., Groton, CT, USA.*

Tests of learning and memory are important in the assessment of potential developmental neurotoxicity for chemicals regulated by the USEPA and for the safety evaluation of new pharmaceuticals. Two critical issues for selection of tests for use in these studies are sensitivity and efficiency. There are few published studies comparing the sensitivity of the tests that are commonly used after perinatal exposures. The present study was designed to compare the sensitivity of 3 water mazes and 2 passive avoidance procedures using offspring of Sprague-Dawley dams (15/group) given sodium phenytoin in corn oil by gavage at 100 mg/kg on gestation day (GD) 6 through lactation day (LD) 21, methimazole in the drinking water at 0.1 mg/ml on GD17-LD10 or a vehicle control (corn oil) by gavage on GD6-LD21. When the offspring were young adults, they were assigned to one of five procedures: spatial M-maze (SM) - the escape ladder was always on the non-preferred side and the criterion was 5 consecutive errorless trials; visually-cued M-maze (VM) - 20 trials/day for 4 days with a light cue on the correct escape side; Cincinnati water maze (CWM) - 2 trials/day for 3 days in the forward path and 2 trials/day for 3 days in the reverse path; passive avoidance - with either one learning trial (OT) with shock or as many learning trials with shock as necessary (TTC) for the rat to avoid for 3 min. Both passive avoidance procedures had one retention trial one day later. An overall ranking of the sensitivities of the 3 tests that detected drug effects was: CWM>SM>OT. VM and TTC did not detect any deficits. The efficiencies of these procedures will be compared in terms of required resources, automation and data analysis.

1518 NINE- AND NINETY-DAY INHALATION TOXICITY STUDIES OF 4-VINYLCYCLO-HEXENE-1,2-EPOXIDE (VCMX).

J P Van Miller[1], T J Cawley[1] and G M Hoffman[2]. [1]*Union Carbide Corporation, Danbury, CT, USA;* [2]*Huntingdon Life Sciences, East Millstone, NJ, USA.*

VCMX is a primary metabolite of 4-vinylcyclohexene (VCH) but also has commercial value as a reactive diluent in UV curable coatings. VCH is an ovarian toxicant in mice but not rats via the active metabolite, VCH-diepoxide (VCD). VCMX is metabolized to VCD *in vitro* but competing detoxification pathways also exist (e.g. to VCH-1,2-diol). To determine potential toxicity of VCMX, 9- and 90-day vapor inhalation studies were conducted in CD-1® mice and Sprague Dawley rats. In the 9-day study, animals (5/sex) were exposed (whole-body) to target vapor concentrations of 0, 40, 200 or 400 ppm 6 hr/d for 9 d over 2 wk. The 400 ppm level was lethal to mice but not rats and only minimal exposure-related effects were observed at non-lethal exposure levels. A 9-day NOAEL of 200 ppm was established. No ovotoxicity was observed in either species although, based on published data, absorption of VCMX with metabolism to VCD could have resulted in follicular damage/loss. For the 90-day study, animals (10/sex) were exposed to target vapor concentrations of 0, 20, 80, 200 (mice) or 400 (rats) ppm 6 hr/d, 5 d/wk for 13 wk with 4 wk recovery groups (10/sex for high exposure levels and control). Measurements included body weight, food consumption, ophthalmology, clinical pathology, urinalysis, organ weights, gross and histopathology. Except for histopathological effects in the nasal epithelium, exposure-related findings were restricted to the high exposure groups and included: Rats - minimal signs of irritation and reduced body weight in males with recovery observed; Mice - death of 3 females, minimal signs of toxicity, reduced body weight in males, decreased ovary weights, and depletion of ovarian antral follicles with recovery limited to body weight. Concentration-related irritant changes in nasal epithelium were observed in some animals from all VCMX exposed groups without complete recovery in the high concentration group. Ovotoxicity occurred in mice, but not rats, only after long-term exposure (200 ppm) that was irritant and exceeded the maximum tolerated concentration based on mortality.

1519 EVALUATION OF THE ORAL SUBCHRONIC TOXICITY OF AHTN AND HHCB IN THE RAT.

A M Api and R A Ford. *Research Institute for Fragrance Materials, Inc., Hackensack, NJ, USA.*

7-Acetyl-1,1,3,4,4,6-hexamethyl-1,2,3,4-tetrahydronaphthalene (AHTN) and 1,3,4,6,7,8-Hexahydro-4,6,6,7,8,8-hexamethylcyclopenta-gamma-2-benzopyran (HHCB) are the two of the polycyclic musks commonly used in fragrances. AHTN and HHCB are widely used in a variety of fragrances that are in consumer products. Because of the widespread exposure to these materials, 90-day oral feeding studies, with 4-week recovery periods for selected rats, were conducted. The materials were added to the diet at levels calculated to result in daily doses of 1.5, 5, 15 or 50 mg/kg for AHTN and 5, 15, 50 or 150 mg/kg for HHCB. On completion of the treatment period, 3 males and 3 females from each of the high dose groups and controls were maintained for a treatment free period of 4 weeks. For AHTN, a slight reduction in red cell count, hemoglobin concentration and packed cell volume was seen in the high dose group. Also a reduction of plasma cholesterol, a higher A/G ratio, a slight reduction in total protein and a lower plasma glucose concentration was seen at the two higher doses. A dose dependent increase in liver weights with no associated histopathology was seen at the two higher doses in females only. A green coloration was observed in the livers, mesenteric lymph nodes and lachrymal glands at the high dose in males and females and in the lachrymal glands of 4 females given 15 mg/kg and in 1 female given 5 mg/kg. At the end of the treatment free period, the coloring was largely reversed but one male showed green colored lymph nodes and 2 females showed colored lachrymal glands. Microscopic examination of unstained sections of frozen livers under UV illumination did not reveal any florescence that might have been consistent with porphyrin accumulation. These findings were clearly related to administration of AHTN but were not accompanied by any histopathological changes. Additional research on the significance of the green discoloration is continuing. Based on these findings, a NOAEL of 15 mg/kg/day was concluded. For HHCB, there were no significant findings at any dose level; a NOAEL of 150 mg/kg/day was concluded.

1520 ONCE-DAILY DOSING DECREASES TOXICITY OF DAPTOMYCIN.

F B Oleson, Jr.[1], C L Berman[2], J B Kirkpatrick[3], K S Regan[3], J-J Lai[1], and F P Tally[1]. [1]*Cubist Pharmaceuticals, Inc., Cambridge, MA;* [2]*Consultant, Wayland, MA;* [3]*WIL Research Laboratories, Ashland, OH.*

Daptomycin is a novel lipopeptide antibiotic with potent bactericidal activity against gram-positive bacteria, including resistant strains. Skeletal muscle has been identified as the target organ of daptomycin toxicity. To investigate the potential effects of dose fractionation on toxicity, two studies were conducted in dogs comparing the effects of repeated intravenous administration once daily (q24h) versus every 8 hours (q8h). Muscle toxicity did not appear to be directly related to Cmax, since both serum CPK increases and the incidence of myopathy observed at 25 mg/kg q8h were greater than at 75 mg/kg q24h despite the lower Cmax. A 3 to 4- fold increase in peak CPK levels was observed when the dose interval was varied from q24h to q8h at a dose of either 5 mg/kg or 25 mg/kg. In contrast, no difference in CPK elevations was apparent when the dosing interval was held constant at 24 hours and the dose was varied from 25 to 75 mg/kg. Further, 5 mg/kg administered q24h caused no change in CPK, whereas a dose regimen of q8h was associated with a 3-fold increase in CPK at a comparable Cmax. Similarly, toxicity was not related primarily to AUC_{24h}, since the toxicity observed at 25 mg/kg q8h was greater than at 75 mg/kg q24h, at approximately the same AUC. The data suggest that dosing interval had a greater influence on toxicity than did dose itself. Once daily administration is hypothesized to allow greater time between doses (at non-toxic blood levels) for repair of subclinical muscle damage associated with daptomycin. Further, studies in animal efficacy models have demonstrated that effectiveness of daptomycin is optimized by once-daily dosing since Cmax was found to be the key PK parameter associated with eradication of infection (J Legget *et al.*, ICAAC abstract, 1987). These results suggest that once-daily dosing can minimize daptomycin muscle toxicity, while optimizing its antimicrobial efficacy.

1521 STRUCTURE-BASED ASSESSMENT OF OCULAR IRRITATION.

K Enslein and V K Gombar. *Health Designs, Inc. /OMG, Rochester, NY, USA.* Sponsor: J B Knaak.

There is a continuing need to assess the toxicity of new chemicals for environmental, industrial and consumer exposures. To partially fulfill this need, we have developed a quantitative structure-toxicity relationships (QSTR) model for the assessment of eye irritation. The model is based on 1453 compounds previously tested in the rabbit Draize eye irritation assay. The model permits the assessment of eye irritation potential for untested organic compounds. Chemicals in the model are parametrized by powerful electropolog-

ical state (E-State) descriptors, as contrasted to presence/absence of fragments. The model is composed of 5 chemical class-specific submodels. Each submodel, in turn, consists of 3 equations: given a query, the first determines whether the compound is (non-irritating or mild) vs. (moderate or severe). If it is in the first group, then the second equation can determine whether it is nonirritating or mild. If the compound falls into the second group, the third equation determines whether the irritation grade is moderate or severe. The equation-specific sensitivity of the 15 equations ranges between 80% and 100%, with the majority falling between 88% and 93%. Specificity ranges between 74% and 100%, with the bulk of the equations in the range of 86% to 94%.These equations are installed in the *TOPKAT* program, a system for toxicity assessment of organic compounds. *TOPKAT* provides for automatic check of the coverage of the query structure by the model, as well as determination whether the query falls within the Optimum Prediction Space (OPS) of the model, i.e., whether the model is applicable to the query compound.

1522 HISTOPATHOLOGICAL BACKGROUND LESIONS IN GÖTTINGEN MINIPIGS.

M Kolopp, B Vogel, R A Ettlin and A Cordier. *Novartis Pharma AG, Preclinical Safety, Basel, Switzerland.*

SPF Göttingen minipigs have been introduced in our laboratory four years ago as a non-rodent model for testing subchronic and chronic toxicities. The choice was based on the expectation that the similar physiology between pigs and humans would allow improved predictions in terms of safety assessment. A knowledge of the spontaneously occurring histopathological lesions is consequently essential for interpreting the drug-dependent lesions. Background lesions were evaluated in 50 male and in 50 female control minipigs from 2 to 4 weeks toxicity studies. At the end of the studies, minipigs were 4 to 8 months old and the mean body weight was around 10 kg. The full set of organs was examined. Background histopathological changes were mainly observed in adrenals, bone marrow, brain, epididymides, gall bladder, heart, kidneys, liver, lung, muscle, prostate, skin, testes, urinary bladder and vessels. The majority of these findings consisted in focal lymphoid/inflammatory cell infiltrates or small hematopoietic foci in various organs. Other findings, including lung granulomas, single vessel fibrinoid arteritis and/or periarteritis, testes tubular atrophy and bone marrow atrophy were observed in some animals. In addition, muscle myonecrosis and regeneration was described as a new finding for this strain of minipigs.

1523 MINIPIGS IN SAFETY ASSESSMENT OF A PHOSPHODIESTERASE TYPE IV INHIBITOR FOR THE TREATMENT OF INFLAMMATORY SKIN DISEASES.

B Vogel, M Kolopp, A de Brugerolle de Fraissinette, T Singer, R A Ettlin, J Birnbaum and A Cordier. *Novartis Pharma AG, Preclinical Safety, Basel, Switzerland.*

Minipigs have been considered to be a good model for dermal permeability and toxicity studies, due to their broad biological similarities to humans. Human and porcine skin are similar with regard to thickness and general morphology, epidermal cell turnover, orientation and distribution of vessels, and immunological reactivity. Therefore, PDI747, a selective type IV phosphodiesterase inhibitor with anti-inflammatory properties developed for the treatment of inflammatory skin diseases, was tested topically in Göttingen minipigs. After 2 weeks of dermal treatment, segmental vasculitis in small and medium sized vessels of the kidneys, stomach, small intestine and mesenteric lymph nodes was observed in animals of both sexes at 40 mg/kg/day with a mean $AUC_{(0\text{-}20h)}$ of approximately 10 ng.h/ml. Such lesions were not observed in minipigs after long term dermal treatment of PDI747 with similar AUC's. No cutaneous vascular lesions were observed at the application site. Finally, for the global safety assessment of PDI747, the vasculitis was of major importance taking into account that this lesion was also found in four other species (rat, dog, monkey and rabbit) and by three other routes of administration (oral, iv and inhalation).

1524 PRECLINICAL CONSIDERATIONS FOR THE DEVELOPMENT OF INTRAVITREAL DRUG PRODUCTS.

A Weir, W Chambers, C Chen, Z Chen, A Mukherjee, S Wilson, J Yang. *Division of Anti-inflammatory, Analgesic, and Ophthalmic Drug Products, Center for Drug Evaluation and Research, Food and Drug Administration, Rockville, MD, USA.*

The treatment of vitreal or retinal conditions may, in some cases, require intravitreal (ITV) administration of drug products. The pharmacokinetics, including bioavailability and ocular distribution, of ITV drugs should be defined early in the development process to assist in the design of nonclinical toxicology studies. ITV drugs should be evaluated in general toxicology, genetic toxicology, reproductive toxicology, and, if applicable, carcinogenicity studies. To fully define the toxicity profile of ITV drugs, general toxicology studies should be conducted using ITV and systemic (e.g., oral) routes. In each case, systemic toxicity should be assessed using standard measures (e.g., body weight, clinical pathology, histopathology). Toxicity at the ITV injection site should be assessed in 2 species, at least one with pigmented eyes. To support human trials during the investigational phase of drug development, the number of injections used in the nonclinical studies should at least equal the maximum number of human injections. For approval, the frequency/duration of treatment of animals should exceed the intended clinical use; however, given the intermittent nature of clinical treatment, the maximum frequency/duration of nonclinical studies will likely need to be decided on a case-by-case basis. ITV studies should be conducted with the clinical formulation and a formulation in which the concentration of drug substance exceeds that in the clinical formulation. The assessment of ocular toxicity following ITV injection should include slit lamp biomicroscopy, funduscopy, tonometry, electroretinography, and histopathology at appropriate times. Genotoxicity and *reproductive toxicity* should be assessed according to the ICH (International Conference on Harmonisation) Guidelines. However, pre- and postnatal development (Segment 3) and carcinogenicity studies may be waived unless there is significant systemic exposure or a cause for concern.

1525 EFFECT OF SINGLE SUBCUTANEOUS DOSES OF EXENDIN-4, AN ISOLATE FROM GILA MONSTER SALIVA, ON-CARDIOVASCULAR PERFORMANCE IN CYNOMOLGUS MONKEYS.

M Mistry[1], B Greenland[1], R A Hiles[2] and K S Prickett[2]. [1]*Oread, Inc., Farmington, CT, USA;* [2]*Amylin Pharmaceuticals, Inc., San Diego, CA, USA.*

Exendin-4 (CAS No. 141732-76-5) is a 39 amino acid peptide isolated from the saliva of *Heloderma suspectum, a* lizard commonly known as the Gila Monster. Exendin-4 is similar (53% amino acid identity) to mammalian glucagon-like peptide-1 (GLP-1) and lowers elevated plasma glucose (ED_{50} <0.1 μg/kg) in *db/db* mice. The purpose of the work reported here was to define the potential cardiovascular effects of chemically synthesized exendin-4 (AC2993) when administered subcutaneously (SC) to monkeys. Animals were surgically instrumented with radiotelemetry transmitters in the peritoneal cavity to measure blood pressure (systolic, diastolic and mean arterial), heart rate,-ECG (lead II configuration), body temperature and physical activity in freely moving conscious animals. Each of the 3 animals in the study received placebo on Day 1-followed by 30 μg AC2993/kg on Day 2; placebo on Day 3,4 and then 300 μg AC2993/kg on Day 5; placebo on Day 6,7, and then 1000 μg/kg AC2993 on Day 8. When compared to the results following the placebo dose given the day before the AC2993 dose, AC2993 at 30, 300 or 1000 μg/kg caused no changes in ECGs, arterial blood pressure and heart rate. At all dosage levels of AC2993, but in an apparent dose-level independent manner, depressions in spontaneous activity and body temperature were found. Activity depression reached a low plateau ~ 1 hr after dose administration and remained depressed for the next 3 hours when it returned to a level similar to that observed following placebo administration. The maximum temperature depression was ~0.6°C and occurred ~1 hr after dosing. The body temperature returned to pre-dose values ~4 hr after dose administration. AC2993 had no detectable effect on cardiovascular performance in the monkey at SC doses up to 1000 μg/kg.

1526 SUBCHRONIC TOXICITY AND TOICOKINETICS IN THE SPRAGUE-DAWLEY RAT OF EXENDIN-4, AND ISOLATE FROM GILA SALIVA.

J W Noveroske[1], D M Beaulieu[1], R A Hiles[2] and K S Prickett[2]. [1]*Oread, Inc. Farmington, CT, USA;* [2]*Amylin Pharmaceuticals, Inc., San Diego, CA, USA.*

Exendin-4 (CAS No. 141732-76-5) is a 39 amino acid peptide isolated from the saliva of *Heloderma suspectum, a* lizard commonly known as the Gila Monster. Exendin-4 is similar (53% amino acid identity) to mammalian glucagon-like peptide-1 (GLP-1) and lowers elevated plasma glucose (ED_{50} <0.1 μg/kg) in *db/db* mice. The purpose of the work reported here was to define the potential toxicological properties of chemically synthesized exendin-4 (AC2993) when administered subcutaneously (SC) to Sprague-Dawley rats in 28 consecutive daily doses. Preliminary studies had shown that it could be given as a single SC dose of 30,000 μg/kg without deaths. In the 28-day study, doses of 0, 10, 100 and 1000 μg/kg/d were used and each dose group consisted of 10 rats/sex. No deaths due to AC2993 occurred. Decreased food consumption and loss of body weight were observed in a dose-related manner at 100 and 1000 μg/kg/d. There were no AC2993-related changes in hematology and clinical chemistry values. There were no microscopic tissue changes in necropsy samples taken the day after the last dose. The concentration of AC2993 was determined in serial plasma samples collected after the first dose and 27th dose using an ELISA method with a lower limit of quantitation of 63 pg/mL. The systemic load of AC2993 increased with dose level (based on both C_{max} and AUC_{0-6}), but did not increase with number of doses (no changes between day 1 and day 27). The plateau near the C_{max} concentration was more extended with time as the dosage level increased. There was no indication of significant antibody formation. It was concluded that, based on the lack of pathological changes, 1000 μg/kg administered SC for 28 days does not exceed the maximum tolerated dose.

1527 SUBCHRONIC TOXICITY AND TOXICOKINETICS IN THE CYNOMOLGUS MONKEY OF EXENDIN-4, AN ISOLATE FROM GILA MONSTER SALIVA.

R A Hiles[1], K S Prickett[1] J W Noveroske[2] and L J Duggan[2]. [1]*Amylin Pharmaceuticals, Inc., San Diego, CA, USA;* [2]*Oread, Inc. Farmington, CT, USA.*

Exendin-4 (CAS No. 141732-76-5) is a 39 amino acid peptide isolated from the saliva of *Heloderma suspectum, a* lizard commonly known as the Gila Monster. The purpose of the work reported here was to define the potential toxicological properties of chemically synthesized exendin-4 (AC2993) when administered subcutaneously (SC) to Cynomolgus monkeys in 28 consecutive daily doses. Preliminary studies had shown that it could be given as a single SC dose of 5000 μg/kg without deaths. In the 28-day study, doses of 0, 10, 100 and 1000 μg/kg/d were used and each dose group consisted of 3 animals/sex. No deaths due to AC2993 occurred. Decreased food consumption and loss of body weight were observed in a dose-related manner at 100 and 1000 μg/kg/d. ECGs were normal for all animals. There were no AC2993-related changes in hematology and clinical chemistry values. There were no microscopic tissue changes in necropsy samples taken the day after the last dose. The concentration of AC2993 was determined in serial plasma samples collected after the first dose and the 27th dose using an ELISA method with a lower limit of quantitation of 63 pg/mL. The systemic load of AC2993 increased with dose level (based on both C_{max} and AUC_{0-12}), but did not increase with number of doses (no changes between day 1 and day 27). The plateau near the C_{max} concentration was more extended with time as the dosage level increased. There was no indication of significant antibody formation. It was concluded that, based on the lack of pathological changes, 1000 μg/kg administered SC for 28 days does not exceed the maximum tolerated dose.

1528 SAFETY ASSESSMENT OF COSMETIC INGREDIENTS AND COLOR ADDITIVES: EVALUATION OF A QUANTITATIVE STRUCTURE-TOXICITY RELATIONSHIP APPROACH FOR PREDICTING TOXICITY.

S R Milstein, J J Yourick, R L Bronaugh, W G Warner, D K Lowther, M B Meyers, A L Scher, and S J Bell. *Office of Cosmetics and Colors, Food and Drug Administration, Washington, DC.*

Cosmetic products and their constituent raw materials (except color additives) are not required to pass any FDA premarket approval process. Cosmetic ingredients and products, however, are expected to undergo adequate safety sub-stantiation prior to being offered for retail sale. Predictive quantitative structure-activity relationship (QSAR) toxicology prediction software is increasingly being considered by regulatory toxicologists as a supplemental tool for making an informed safety decision. We initiated a study designed to evaluate six of the toxicology endpoint prediction modules available in TOPKAT® (Health Designs, Inc. (HD_i), Rochester NY). For each module chemical evaluation set, we chose known toxicity data that met specific methodology testing criteria for TOPKAT. These chemicals must not have already been included in TOPKAT training sets. The rat oral LD50 module test resulted in a concordance of 90%. Developmental toxicity potential module predictions resulted in a specificity and sensitivity of 88 and 60%, respectively. The mutagenicity module predictions gave a specificity and sensitivity of 81 and 71%, respectively. Skin and eye irritation predictions resulted in specificities of 95 and 100%, respectively, and sensitivities of 22 and 78%, respectively. Not enough data could be identified (of sufficient quality and not already used by TOPKAT) to adequately test the carcinogenicity modules. This QSAR approach may serve as a valuable tool to aid in the safety evaluation of cosmetic ingredients and color additives.

1529 A NOVEL RISK ASSESSMENT/RISK MANAGEMENT OF CHILD EXPOSURE TO FIPRONIL GEL.

W C McCormick[1], D F Crawford[1] and S A Mobley[2]. [1]*The Clorox Company, Pleasanton, CA, USA;* [2]*TomenAgro, San Francisco, CA, USA.*
Sponsor: A K Reddy.

Hydramethylnon (HM) is an amidinohydrazone insecticide widely used by consumers and pest control operators (PCO) for the control of ants and cockroaches. Animal studies in several species have shown HM is a male reproductive toxicant. However, the mechanism as well as the exposure timeframe required to elicit adverse reproductive effects have not been well elucidated. Because of its widespread use of consumers to this insecticide, there is a concern about accidental dermal exposure to children and any possible testicular effects. To assess the potential hazard in household insecticides, a study was conducted to determine the effects of an acute exposure to young male rats. Since the dermal penetration rate of HM is relatively low (<1%), the material was administered by subcutaneous (sc) injection to assure that a higher systemic dose was achieved. Young male rats were given single sc injections of HM in an oil carrier at 100, 500, or 1,000 mg/kg of body weight. Daily clinical observations were conducted for 14 days. Clinical effects were limited to decreased body weight gain and decreased food consumption at 500 and 1,000 mg/kg. Animals were sacrificed 14 days post-exposure. Both gross and histopathological examinations revealed no apparent lesions in testes, epididymes or seminal vesicles at any dose. Relative testes to body weight ratios showed statistically significant increases only at 1,000 mg/kg dose. The study showed that single exposures even at high doses fail to elicit the testicular effects in young male rats.

1530 EFFECTS OF P-GLYCOPROTEIN (P-GP) INHIBITION WITH LY335979 ON PACLITAXEL PHARMACOKINETICS AND PHARMACODYNAMICS WHEN COADMINISTERED TO BEAGLE DOGS.

L L Truex, J L Zimmermann, J A Buben, and V R Reddy. *Lilly Research Laboratories, Eli Lilly and Company, Greenfield, IN, USA.*

LY335979 is a potent in vitro inhibitor (Ki = 59 nM) of P-gp (Dantzig et al. 1996) and is currently in development for treating human cancers demonstrating P-gp mediated drug resistance. LY335979 will be coadministered with various chemotherapeutic agents to enhance their efficacy. In a 1-month toxicity study, LY335979 was administered orally to dogs daily at doses of 2, 10, and 100 mg/kg. No important compound-related changes occurred in this study. The no-observed-adverse-effect level (NOAEL) was 100 mg LY335979/kg/day and plasma concentrations at this dose exceeded 80x the Ki for P-gp inhibition. In a subsequent study, LY335979 was given to dogs orally at doses of 10 or 100 mg/kg/day in combination with a single 4-hour continuous intravenous infusion of 60 mg paclitaxel/m^2, a dose of paclitaxel that produces moderate neutropenia. The pharmacokinetics of paclitaxel were unaffected by administration of LY335979. Decreased neutrophil, platelet, and reticulocyte counts occurred in dogs given paclitaxel alone and paclitaxel with LY335979. However, decreases in these parameters were of slightly greater magnitude when paclitaxel was given in combination with LY335979. Treatment-related lesions associated with paclitaxel administration included minimal enteropathy, slight or moderate hypospermatogenesis,

and myeloid prominence in the bone marrow. There were no histomorphologic changes to suggest an interaction or synergistic toxicity between paclitaxel and LY335979. In summary, LY335979 had no effect on paclitaxel pharmacokinetics. However, decreases in neutrophil, platelet, and reticulocyte counts were greater in dogs given both LY335979 and paclitaxel when compared to dogs given paclitaxel alone. These findings support the hypothesis that the inhibition of P-gp function in normal tissues can enhance the pharmacodynamic effects of an antineoplastic agent.

1531 SAFETY PROFILE OF THALIDOMIDE IN CD-1 MICE AND FISHER 344 RATS AFTER ORAL DOSING OVER 13 WEEKS.

M Morgan[1], S Teo[2], N Trigg[3], M Shaw[3], and S Thomas[2]. [1]*ROW Sciences, Gaithersburg, MD;* [2]*Celgene Corp., Warren, NJ;* [3]*Battelle, Columbus, OH.*

The safety profile of thalidomide was determined in CD-1 mice and F344 rats (10/sex/dose group) of both sexes after 13 weeks of oral dosing. Doses of 30, 300 and 3000 mg/kg were administered daily by oral gavage. Control animals were given 1% CMC. All animals were necropsied at the end of the study. There was no mortality in either species. In mice, thalidomide had no effect on body weight, food consumption, ophthalmic function or clinical chemistry and hematology. Oral absorption appeared to be saturable after prolonged dosing. A dose-dependent orange-red urine possibly caused by chromogenic urinary metabolites was observed. Hepatic centrilobular hypertrophy was seen in all treated males with the severity increasing with dose. Only the high dose females were affected. Liver weight was increased for the high dose mice of both sexes suggesting enzyme induction. In rats, thalidomide produced lower body weight in both sexes compared to control with a dose-response more evident in males (~ 20% decrease at 3000 mg/kg). Food consumption was also decreased in males. No treatment-related ophthalmic defects were observed. Functional observational battery tests indicated little to no persistent effects on autonomic, muscle tone/equilibrium, sensorimotor and CNS functions. At high dose, forelimb grip strength decreased for males at weeks 4, 8 and 13. Vertical motor activity increased for males at week 4 and both sexes at week 8. Drooping eyelids were observed for some males at high dose. There were some indications of mild anemia and leukopenia in males. Decreases in serum glucose, globulin and potassium and increase in globulin/albumin ratio was seen in some treated groups. A decrease in total and free T4 was more consistent in treated females than males. Gross thymus weight decreased in both sexes with no histological correlates compared to control. No treatment-related axonal degeneration of sural nerve fibers was present. No changes in histopathology were seen in distal lumbar spinal cord suggesting the absence of thalidomide-related peripheral neuropathy. In summary, some species differences in the safety profile of thalidomide were apparent after oral dosing for 13 weeks.

1532 TOXICOLOGY OF PLURONIC® F-68: A 14-DAY INTRAVENOUS TOXICITY STUDY IN HAN WISTAR RATS.

D H Melich[1], K Owen[2], R M Lightfoot[1], S A Selway[2], J S Allen[1]. [1]*Glaxo Wellcome Inc, Research Triangle Park, NC, USA;* [2]*Glaxo Wellcome plc, Ware, Hertfordshire, UK.*

Pluronic® F-68 (Poloxamer 188, Monolan), a surfactant that may be used to enhance the stability, absorption, and distribution of a chemical substance by micelle formation, is a possible vehicle for newly developing pharmaceuticals. The objective of this study was to determine the toxicological profile for Pluronic® F-68 in the Han Wistar rat after 14 consecutive days of intravenous treatment. Four male and four female Han Wistar rats per group were intravenously administered 0 (vehicle control), 100, 200, 400 or 750mg/kg/day of Pluronic F-68 dissolved in 0.9% sodium chloride using a dose volume of 5mL/kg for 14 consecutive days. Clinical observations, bodyweights, hematology and clinical chemistry measurements, organ weights and macroscopic and microscopic examinations (microscopic and electron microscopic examination at the 100 and 200mg/kg/day doses are currently ongoing) were performed on all animals. Treatment-related findings were noted at all doses and included a reduction in bodyweight gain (750mg/kg/day only), an increase in the lung weights (400 and 750mg/kg/day only) and kidney weights (100 and 200mg/kg/day males only and 400 and 750mg/kg/day both sexes), a dose-related increase in the accumulation of foamy macrophages in lung alveoli (400 and 750mg/kg/day), and vacuolation of the renal proximal tubules (all doses). Based on these data, the no-toxic-effect-dose was not determined and is less than 100mg/kg/day.

1533 COMPARATIVE INHALATION TOXICITY/ NEUROTOXICITY AND REPRODUCTIVE/ DEVELOPMENTAL TOXICITY OF THREE REFINERY STREAMS.

C A Schreiner, R J Breglia, D Burnett, C Lapin, P Podhasky, and R D White. *Petroleum Product Stewardship Council (PPSC), Washington, DC.*

A series of toxicity studies were performed on the gasoline blending streams, light alkylate naphtha (LAN), light catalytic cracked naphtha (LCCN) and light catalytic reformed naphtha (LCRN). Rats were exposed by inhalation to a distillate fraction of each stream which approximated the composition of the atmosphere to which humans are most likely exposed. Target concentrations were 750, 2500, 7500 ppm and exposure regimes varied with study design. Reproductive/ developmental screens were modifications of OECD Guideline 421. The 13 week subchronic toxicity study included a two week post-treatment recovery period and neurobehavioral tests consisting of motor activity and a functional observational battery, and neuropathology. Compositionally, the distillate fractions varied from 90+% isoparaffins in LAN to 60% olefins in LCCN and 58% isoparaffins and 9% aromatics in LCRN. No reproductive or developmental toxicity and no neurotoxicity were induced by any stream distillate. Systemic effects observed across all studies were increased liver weight at the high dose in both sexes without a microscopic correlate, and increased kidney weight in male rats. Increased kidney weights accompanied by increased hyaline droplet formation and alpha-2 μ-globulin accumulation in renal tubules are indicative of light hydrocarbon nephropathy (LHN), a species and sex specific toxic effect not relevant to toxicity in man. The occurrence of this event for distillates of similar composition but different proportions of specific chemical classes indicates that there are a broad range of capable of inducing LHN among the lower boiling range refinery streams. Thus, the no-observed-adverse-effects level (NOAEL) for neurotoxicity and developmental/reproductive toxicity for all three refinery stream distillates is ~7,500 ppm. Subchronic toxicity NOAEL ~2,500 ppm. (PPSC is Amoco, ARCO, BP Oil, Chevron, Mobil, Texaco and Unocal 76.)

1534 THE EFFECT OF O^6BENZYLGUANINE PRETREATMENT ON BCNU-INDUCED PULMONARY TOXICITY.

A C Smith[1], C J G Chang[2], R B Thompson[2], J E Tomaszewski[1], and J G Page[2]. [1]*National Cancer Institute, Bethesda, MD;* [2]*Southern Research Institute, Birmingham, AL.*

O^6Benzylguanine (O^6BG, NSC-637037) inhibits O^6-alkylguanine-DNA alkyltransferase, a DNA repair protein. The anticancer efficacy of BCNU (Carmustine; NSC-409962), an alkylating agent, was improved with O^6BG pretreatment in preclinical animal models. In addition, O^6BG pretreatment potentiated BCNU-induced myelotoxicity. In the current study, the effect of O^6BG pretreatment on BCNU-induced pulmonary toxicity was explored in male Fischer 344 rats. Rats were given 10 mg/kg/day of O^6BG alone or in combination with 0, 1, 3 or 5 mg/kg/day of BCNU on study days 1, 5 and 9. Administration of O^6BG and BCNU in combination produced more drug-related mortality than either drug alone. Drug-related mortality occurred in 6/10 and 9/10 rats in the 10 + 3 mg/kg/day (O^6BG + BCNU) and 10 + 5 mg/kg/day dose groups compared to 0/10 and 2/10 rats given 5 and 10 mg/kg/day BCNU alone. BCNU alone at doses up to 10 mg/kg/day produced mild myelotoxicity with no evidence of bone marrow lesions. In rats treated with O^6BG/BCNU, dose-related myelosuppression occurred beginning on day 12; at necropsy all the rats had moderate to severe bone marrow cellular depletion. BCNU alone at doses of 10 mg/kg/day produced chronic inflammation of the lung (considered to be an early indicator of pulmonary injury). However, the combination of O^6BG and BCNU did not produce either a higher incidence or greater severity of pulmonary toxicity. Unlike the effect of O^6BG pretreatment on BCNU-induced myelotoxicity, O^6BG pretreatment did not appear to potentiate BCNU-induced pulmonary toxicity in rats. (Contracts N01-CM-37835 and N01-CM-87100.)

1535 THE EFFECTS OF ORALLY ADMINISTERED CHOLESTAGEL AND LOVASTATIN IN BEAGLE DOGS.

T P O'Neill[1], R Rapoza[2], D P Rosenbaum[2], E Zimmer[1] and C B Spainhour[1]. [1]*Chrysalis Preclinical Services-North America, Olyphant, PA;* [2]*Geltex Pharmaceuticals, Waltham, MA.*

The purpose of this study was to evaluate cholesterol values in beagle dogs administered test articles orally via gelatin capsules once daily for fourteen

days. Five groups of five male dogs each were administered either Lovastatin (L) at 5 mg/kg, Cholestagel (C) at 1000 mg/kg or a combination of L (5mg/kg) and C (100, 300 or 1000 mg/kg). An additional group of five male dogs received empty gelatin capsules and served as the control group. Evaluations were made of mortality, clinical observations, body weights, food consumption, cholesterol and triglycerides. No mortality was observed throughout the study in any dose group. There were no clinical signs of toxicity observed during the course of the study for any dose group as well as no treatment-related effects on body weights, body weight changes or food consumption values. Statistically significantly lower serum cholesterol values were observed for the 1000 mg/kg C dose group and 5 mg/kg L - 1000 mg/kg C dose group on Days 8 and 14 of the study, when compared to the control group. Cholesterol values on days 8 and 14 were all decreased when compared to baseline readings for all treated groups with the largest decreases in the 1000 mg/kg C, 5 mg/kg L - 300 mg/kg C and 5 mg/kg L - 1000 mg/kg C dose groups. All cholesterol values returned to baselines values at the day 23 evaluation and remained at that level until the duration of the study. Statistically significantly lower triglyceride values were also observed in the 1000 mg/kg C dose group (Day 8) and 5 mg/kg L - 1000 mg/kg C dose group (Days 8 & 14), when compared to controls. Based upon the results of this study, C, when administered at 1000 mg/kg or in combination with 5 mg/kg L at doses of 300 and 1000 mg/kg, significantly reduced serum cholesterol in beagle dogs when administered once daily for fourteen days orally via gelatin capsules. Although not as significant a reduction, 5 mg/kg L and 5 mg/kg L 100 mg/kg C reduced cholesterol under the same regimen.

1536 AN ACUTE SAFETY AND TOLERANCE STUDY OF AN HERBAL CONTAINING DIETARY SUPPLEMENT PRODUCT.

E A Hyde[1], W E Bridson[2] and J P Wise[3]. [1]*Amway Corporation, Ada, MI, USA;* [2]*Covance Clinical Research Unit, Madison, WI, USA;* [3]*Madison Medical Center, Madison, WI, USA.* Sponsor: P Casterton.

In an effort to understand the potential impact of product misuse or abuse, we conducted a double-blind, placebo-controlled, dose escalation study on an herbal product combination. Nine female and 15 male normal healthy subjects were dosed 1x, 3x and 5x the recommended dosage levels of a product containing: Bilberry, Marigold, Acerola Cherry and Lemon Bioflavonoid extracts and Docosahexanoic acid. Safety evaluations, including physical and ophthalmologic examinations, 12-lead ECGs, vital signs and clinical laboratory evaluations (clinical chemistry [fasting], hematology and complete urinalysis) were performed prior to and at specified time points in the study. Adverse event information was collected throughout the study. The administration of this herbal product combination was well-tolerated and appeared to be safe at the dosages and length of administration studied. Further, none of the safety data were of a nature to preclude continuing exposure of additional individuals to this herbal product combination. This limited clinical evaluation exceeds current practices in the supplement industry. When combined with other risk assessment practices and safety surveillance programs, this type of detailed clinical evaluation provides the necessary verification of a low-safety risk with herbal combination products.

1537 AN EVALUATION OF THE POTENTIAL GENOTOXICITY OF DICHLORVOS (DDVP): FINAL REPORT OF THE EXPERT PANEL.

D Brusick[1], B K Bernard[2], J I Goodman[3], M Lotti[4], P Portoghese[5], B M Wagner[6], and C Weil[7]. [1]*Covance Labs, Vienna, VA, USA;* [2]*SRA Intl., Wash, DC, USA;* [3]*Mich St Univ., E. Lansing, MI, USA;* [4]*Univ. Degli Studi di Padova, Padova, Italy;* [5]*Univ. Minn., Minneapolis, MN, USA;* [6]*New York Univ., NY, NY, USA;* [7]*retired.*

An Expert Panel constituted for this purpose undertook a comprehensive evaluation of the potential genotoxicity of DDVP. The Panel of internationally known experts, using a weight-of-the-evidence approach (WOE), concluded: - DDVP should not be regarded as genotoxic *in vivo* due to a number of factors including: a) across six animals species studied (including man), DDVP favors phosphorylation over alkylation by at least 8 orders of magnitude, b) the absence of detectable alkylation of DNA *in vivo*, c) experimental data demonstrating that the metabolism of DDVP eliminates or significantly reduces the expression of genotoxicity, and d) the lack of usefulness of data generated through the use of extremely high doses and/or the IP injection route where anticipated exposure is by inhalation, and oral/dermal exposure. -DDVP is mutagenic *in vitro* but this is of minimal value in predicting either *in vivo* activity or potential risk to humans based upon what is known about DDVP metabolism and the biological activity of its metabolites. -There is no concern regarding a heritable effect of DDVP. -A WOE evaluation leads to the conclusion that a) DDVP is not genotoxic *in vivo*, b) it is an alkylating agent only at cellular concentrations that would be lethal, and c) the *in vivo* significance of the *in vitro* alkylating (DNA adduct forming) potential is biologically inconsequential for anticipated human exposures.

1538 THE MUTAGENICITY OF CAPTAN AND FOLPET.

E B Gordon. *Makhteshim-Agan of North America Inc., New York, NY, USA.*

Mutagenicity is central to the classification of chemical carcinogens. Rodent carcinogens that are also mutagenic are considered to have non-threshold mechanisms; thus, any exposure to humans is presumed to result in increased carcinogenic risk. On the other hand, compounds that are not mutagenic *in vivo* act through epigenetic mechanisms and are generally considered having thresholds. The outcome of risk characterizations using these two approaches is profoundly different. The U.S. Environmental Protection Agency currently classifies captan and folpet as "probable human carcinogens; B2" by citing, in part, their mutagenic activity. Captan and folpet have a common mechanism of toxicity with regard to tumor induction in the mouse duodenum. This involves increased crypt cell proliferation following villi damage. The mutagenicity of these two fungicides has been studied extensively. The accumulated data are generally consistent between captan and folpet and describe a pattern of activity predicted by and consistent with their chemical and physical properties. The degradation of these chloroalkylthio fungicides involves the reaction with thiol groups and the generation of thiophosgene. Thiophosgene is a reactive acylating agent that is believed to be responsible for a variety of mutagenic findings *in vitro*. Conversely, captan and folpet are not mutagenic *in vivo* since thiophosgene rapidly reacts with a variety of chemical species including those containing thiol (-SH) groups to form non-genotoxic moieties. Similarly, this deactivation mechanism can be reproduced *in vitro* by the addition of compounds containing -SH groups (e.g., S-9, cysteine, and glutathione). The rapid degradation of thiophosgene *in vivo* prevents the transit of this agent, generated in the gut lumen, to the DNA of duodenal crypt cells. The absence of *in vivo* mutagenicity is confirmed by a variety of assays. While it is difficult to "prove" the negative with regard to *in vivo* mutagenicity, the weight of evidence is clear: captan and folpet are not mutagenic in the intact animal.

1539 SURVIVAL CURVES FROM SPRAGUE DAWLEY RATS ON CARCINOGENICITY STUDIES.

C J Perry, S B Hornby and S J Barton. *Inveresk Research, Tranent, Scotland, UK.* Sponsor: A B Wilson.

Much concern was expressed during the late 1980's and early 1990's over the apparent decrease in survival performance of the Charles River strain of Sprague Dawley rat (CD® Rats; Crl: CD® BR) which was one of the most common strains for use on carcinogenicity studies. This resulted in Charles River rederiving their stock in the mid 1990's to produce the IGS International Genetic Standard Sprague Dawley rat ((IGS)CD® Rats; Crl: CD® BR) to overcome this problem. Inveresk Research in Scotland, obtaining rats from Charles River (UK) Ltd, did not experience any problem with survival but changed to the IGS strain in 1996. These first studies have now completed the in-life phase. No changes in the diet (low calorie maintenance, ca14% protein), caging (5 per cage) and environmental conditions were made over the period of the comparison. Presented is a comparison of a sample of some of the rat carcinogenicity studies conducted at Inveresk Research over a period from approximately 1992 to1998 which shows that there is essentially no difference in survival pattern of control rats between the two derivations. At ca 110 weeks old the survival was ca 50% in males and 40% in females. Other parameters routinely collected on this type of study, such as body weight profile, are also presented for comparison between the 2 different derivations of Sprague Dawley rat.

1540 USE OF ARTEMIS II, AN ON-LINE DATA CAPTURE AND REPORTING SOFTWARE, ON PRE-CLINICAL TOXICITY STUDIES.

C Parente[1], L J Kangas[1], M H Davies[2], P Batham[1], V Badalone-Johnston[1], C Banks[1], G Lulham[1]. [1]*ClinTrials BioResearch Ltd., Senneville, Quebec, Canada, and* [2]*Dupont Pharmaceuticals Co. Newark, DE.*

The purpose of this study was to demonstrate the reliability and efficiency of the Artemis II (AII) data capture software for preclinical toxicity studies at

these laboratories. To demonstrate the suitability of this software, AII was used in a GLP environment to capture the data generated on a three month daily oral (gavage) dosing study in rats with a one month recovery period. Dose volumes were calculated by AII based on the most recent body weight. Body weights (twice weekly), clinical observations (twice daily), ophthalmology, veterinary examination were directly captured on-line. Clinical chemistry and hematology data were also directly captured at analysis. AII was sufficiently flexible to allow for the selection of any activity and for the animal processing list to be defined by the user for each activity. The time and date each activity occurred was recorded and any edit was clearly indicated by an audit trial. This user friendly system allowed for efficient data collection, and all data capture by the system was immediately available for review by the Study Director and Sponsor. Functional access to AII was limited by a security system allowing different levels of accessibility to activities such as data entry or editing. Access to AII by the technical and scientific staff was authorized only upon training completion. This study demonstrated that the use of the AII on-line data capturing system facilitates the entry, processing and reporting of data in preclinical studies.

1541 EFFECTS OF DIETARY LEAD ACETATE ON PLASMA MELATONIN LEVELS IN CHICKS.

W E Donaldson[1], C H Hill[1], and R J Reiter[2]. [1]*North Carolina State University, Raleigh, NC, USA;* [2]*University of Texas Health Science Center, San Antonio, TX, USA.*

The administration of lead (Pb) to chicks results in increased levels of organ peroxides. Pb also provokes increased concentrations of reduced glutathione which presumably acts as part of a protective (antioxidant) mechanism against the actions of the peroxides. The hormone melatonin, like glutathione, also possesses strong antioxidant properties. Melatonin is produced by the pineal gland during the dark phase of the daily light/dark cycle. In the several experiments reported here, day-old chicks were exposed to various dietary Pb (as Pb acetate·$3H_2O$) levels ranging from 100 to 2000 ppm under conditions of continuous light (24L/0D) or of 12 h daily cycles of light and dark (12L/12D). The liver and brain levels of thiobarbituric acid-reactive substances (TBARS), an index of peroxide formation, were generally elevated by Pb. Supplementing the diet with ascorbic acid (an antioxidant vitamin not nutritionally required by chicks) or the antioxidant ethoxyquin prevented the elevation of TBARS by Pb. Exposure to 12L/12D resulted in a marked increase of plasma melatonin compared with 24L/0D. Pb consistently enhanced plasma melatonin concentrations in chicks exposed to 12L/12D but not in chicks exposed to 24L/0D. The melatonin effects were noted in chicks receiving a Pb dose as low as 100 ppm (non-growth inhibitory). Enhanced melatonin levels did not result in lower TBARS concentrations. This finding is similar to previous findings which showed that the elevated TBARS concentrations associated with Pb exposure occur despite elevated tissue levels of reduced glutathione. The results suggest that while dietary antioxidants can inhibit the production of Pb-induced TBARS, that TBARS production is unaffected by the concomitant Pb-induced increase of tissue antioxidants. Hsu (*J.Nutr.* **111**:26-33, 1981) suggested that the increase of tissue glutathione was a part of a compensatory response to ameliorate the effects of Pb-induced peroxides. The present data support that hypothesis and suggest further that, in animals exposed to diurnal light/dark cycles, melatonin may serve a similar function.

1542 EFFECTS OF SEX STEROID REPLACEMENT AND L-DOPA TREATMENT ON LEAD TOXICITY IN THE DEVELOPING RAT.

M J J Ronis, C Rector, T M Badger, W Hogue, J Aronson and C K Lumpkin Jr. *Department of Pediatrics, University of Arkansas for Medical Sciences and Arkansas Children's Hospital Research Institute, Little Rock, AR.*

The role of sex steroids and the GH/IGF_1 system in the pubertal effects of lead exposure were examined. Litters of rats (N = 5) were exposed to 2475 ppm lead acetate or acetic acid the drinking water beginning at gestational age 5 d. From age 30 -50 d, male and female offspring from each of the control litters were injected with saline; 7.5 mg/kg L-dopa, or fitted with minipumps delivering saline, offspring from each of the lead-exposed litters were injected with saline, L-dopa, or fitted minipumps delivering saline, 1.5 mg/kg/d testosterone; 3 mg/kg/d testosterone, 1.5 mg/kg/d DHT; 15 μg/kg/d E_2 or 45 μg/kg/d E_2. Vaginal opening was measured. Femur length was measured by X-ray, bone strength was measured by 3-point bending and plasma IGF_1 was measured by RIA. Lead exposure significantly reduced somatic and skeletal growth, bone strength and produced a pubertal delay of 4 days. L-dopa treatment produced significantly increased skeletal growth in control females ($p < 0.05$) and significantly increased bone strength in both sexes ($p < 0.05$). No effects of L-dopa were observed in lead-exposed animals. L-dopa treated, lead-exposed animals had lower plasma IGF_1, femur growth and bone strength than L-dopa treated controls ($p < 0.05$). Testosterone replacement had no effects on any of these parameters. Although DHT treatment restored plasma IGF_1 levels in lead-exposed male animals to control values no effects were observed on growth rates or bone strength. In lead-exposed female animals, estradiol replacement restored the timing of puberty but significantly further decreased somatic growth, IGF_1 and bone strength ($p < 0.05$). We conclude that lead-associated pubertal delay is a consequence of reduced sex steroid concentrations but that effects on growth and bone are either GH mediated or direct actions at skeletal targets. Supported in part by ES06684 (MJJR) and the Brooks Medical Research Fund (CKL).

1543 ESTIMATION OF CUMULATIVE LEAD RELEASES (LEAD FLUX) FROM THE MATERNAL SKELETON DURING PREGNANCY AND LACTATION.

M J Korsch[1], B L Gulson[2], J G Pounds[3], and P Mushak[4]. [1]*CSIRO, North Ryde NSW, Australia;* [2]*Graduate School of the Environment, Macquarie University, Sydney NSW, Australia;* [3]*Wayne State University, Detroit, MI, USA;* [4]*Pb Associates, Durham, NC, USA.*

Recent longitudinal studies with humans and non-human primates using high precision stable lead isotopes show that lead is mobilized from the maternal skeleton during pregnancy and the post-pregnancy period. We have now calculated the cumulative lead release (lead flux, μ g) mobilized from the skeleton during these periods by analysis of monthly blood lead samples (Pb-b) from recent immigrants to Australia. Results included a statistically significant inverse relationship (p 0.006) between the lead flux and the time of conception after the arrival of the subjects in Australia. Using area-under-the-curve approaches to determine the added lead inputs to blood during pregnancy and nursing, versus a baseline, the net monitored lead release to blood varied from 0.9 to 10.1 μ g/day, equivalent to 0.3 to 4.03 mg Pb. With group Pb-b concentrations usually less than 3 μ g/dl, the observed releases imply a high skeletal turnover, greater than 10%, and possibly greater than 30% in some subjects during pregnancy and the post-pregnancy period. These elevated rates in some subjects may partly arise from low daily calcium intakes, being one-half to two-thirds that of recommended daily requirements. The lead flux calculated from a cumulative approach was compared with other approaches: 1st order kinetics, bone turnover, bone x-ray fluorescence (XRF) measurements and the International Commission for Radiological Protection (ICRP) PB-PK model. Calculated lead releases and remaining bone Pb would likely not be detectable by current XRF methods.

1544 STRUCTURAL AND MATHEMATICAL MODEL OF THE REGULATION OF PROTEIN KINASE C BY LEAD AND CALCIUM.

S M Ksenzenko, M J McCabe, Jr. and J G Pounds. *Institute of Chemical Toxicol, Wayne State Univ, Detroit, MI, USA.*

Lead poisoning of the nervous, skeletal, renal, endocrine and reproductive systems is an important public health problem. Perturbations of the protein kinase C family is often identified as sensitive molecular targets for lead toxicity in affected organs systems. Pb^{2+} mimics Ca^{2+} in stimulating PKC translocation and in kinase activation in the absence of Ca^{2+}. To evaluate the interaction of Pb^{2+} and Ca^{2+} in more physiological conditions, we investigated the effects of Pb^{2+} on recombinant PKC α and β1 proteins in the presence of selected concentrations of Ca^{2+} using the PanVera assay for PKC activity. The computer program CHELATOR was used to define selected assay conditions of 0.05 to 1000 nM free Pb^{2+} in the presence and absence of 0.05 to 100 μM Ca^{2+}, buffered using ethylene glycol-bis(aminoethyl ether)-tetraacetic acid. We developed a structural and mathematical model for PKC activity in the presence of both Ca^{2+} and Pb^{2+} described by bi-substrate, bi-product, Ping-Pong kinetics involving ATP and the pseudosubstrate. In agreement with previous reports, our model demonstrates that very low levels of Pb^{2+} activate PKC α (K_a^{Ca2+} = 55.4±14.1 x10^{-9} M; K_a^{Pb2+} = 32.1±9.6 x10^{-12} M) and PKC β (K_a^{Ca2+}= 48.8±12.3 x10^{-9} M; K_a^{Pb2+} = 21.7±9.1 x10^{-12} M) activity in the presence of only one metal. However, under physiological conditions, when both metals are present, Pb^{2+} may either activate, inhibit, or have little effect on the enzymatic activity of PKCs depending on both the Pb^{2+} and Ca^{2+} concentrations. Our model assumes that Ca^{2+} and Pb^{2+} interact with PKC at multiple regulatory sites, and predicts that Pb^{2+} is a non-competitive inhibitor at high Pb^{2+} concentrations. Given

the spatial and temporal regulation of $[Ca^{2+}]_i$ and of PKCs the actions of Pb^{2+} on PKC activity is too complex to generalize. Supported by NIEHS ES04040.

1545 PKC DOES NOT MEDIATE THE EFFECTS OF LEAD ON THE VITAMIN D-DEPENEDNT PROCUDTION OF OSTEOCALCIN.

P Guity, R P Santini, M J McCabe, Jr. and J G Pounds. *Institute of Chemical Toxicology, Wayne State University, Detroit, MI.*

Lead toxicity decreases serum ostecalcin levels in children and vitamin D-dependent production of osteocalcin by osteoblast-like cells, ROS 17/2.8. It is often reported that activation of PKC is a sensitive mediator of the biological activity of Pb, and that PKC exerts a negative regulatory effect on vitamin D_3-dependent processes. The objective of our study was to characterize the role of PKC activation in mediating the actions of lead on vitamin D_3-dependent osteocalcin secretion. ROS 17/2.8 cells were pretreated with Pb for 24 hr and then stimulated with 0 or 100 pM 1,25-dihydroxyvitamin D_3 in the presence of Pb and pharmacological agents to inhibit or activate PKC activity. Lead treatment (5-20 μM for 24 hr) decreased the stimulating effects of vitamin D_3 on osteocalcin secretion. Inhibition of PKC activity by Gö6976, an inhibitor of both α and β isozymes, produced similar effects as lead on vitamin D_3-dependent osteocalcin secretion, while activation of PKC by tetra decanoyl phorbol ester (TPA) did not reverse this effect of lead. Similar data with other PKC inhibitors indicate that activation of PKC is not responsible for the actions of lead on osteocalcin. We also showed that 10 μM lead does not change the cellular or secreted activity of alkaline phosphatase, another vitamin D_3-dependent gene product in osteoblasts. Direct assay of PKC activity showed that 10 μM lead does not activate or inhibit the activity of PKC in ROS cells. Western blot analysis of cytosolic and particual fractions obtained from ROS cells indicated that lead does not translocate PKCα or β1 from cytosol to membrane. Therefore, it is concluded that PKC is not the mediator of actions of lead on decreasing the vitamin D_3-dependent osteocalcin secretion in ROS cells. Supported by NIH ES04040. Several studies suggest a negative controlling effect of PKC in the actions of vitamin D.

1546 CHRONIC LEAD INTOXICATION MAY CONTRIBUTE TO OSTEOPOROSIS.

J E Puzas[1], D A Cory-Slechta[2], R Rosier[1], R O'Keefe[1], J Cushing[1], and J G Pounds[3]. [1]*Depart. Orthopaedics;* [2]*Dept. Environmental Medicine, Univ. Rochester, Rochester, NY;* [3]*Institute of Chemical Toxicology, Wayne State Univ., Detroit, MI, USA.*

Over 90% of the body's burden of lead is found in bone. Sequestration of Pb in bone matrix may prevent damage to sensitive cells of the brain and kidney but may not protect bone cells. During menopause, skeletal Pb is mobilized to other organs with the greatest risk encumbered by peri-menopausal baby-boomers who were exposed to the high environmental lead levels of the 1950s and 1960s. Our goal was to determine the effects of Pb on bone cell activities *in vitro* and the contribution of Pb to osteopenia in animals *in vivo*. Osteoblasts and osteoclasts from neonatal rats were used to determine the dose-dependent effects of Pb on collagen synthesis, alkaline phosphatase activity, cell proliferation, resorption pit number and pit area. Male Long Evan rats were exposed to 0, 50, 150, 1000, or 2000 μg Pb acetate /ml drinking water for 8 or 15 mo. Blood and femur Pb was determined by AAS. Bone mineral mass, area, and density were measured using a Lunar DPX-L with 'small animal' software. Meta-analysis of all cellular functions revealed that osteoblasts are more sensitive to Pb than are osteoclasts. The in vivo studies found an inverse relationship between blood Pb and total bone mass and total bone area. Moreover, 12 to 20% of the treated animals were >2.0 SD below the control mean for all skeletal parameters. PbB levels were from 10 to 100 μg/dL in the Pb groups, within the range of environmental and occupational exposure respectively. Since lead affects osteoblast functions more than osteoclast activities, and decreases bone mass, a definable proportion of osteopenia and osteoporosis may result from chronic lead poisoning. Supported by NIEHS ES08121(JEP), ES01217, ES01247 (DCS) & ES04040 (JGP).

1547 CONTRIBUTION OF LEAD FROM FORMULA AND FOOD TO LEAD IN BLOOD AND URINE OF NEWLY-BORN INFANTS AND RELATIONSHIP TO SKELETAL MOBILIZATION.

B L Gulson[1], K J Mizon[1], N Patison[2], A J Law[2], M J Korsch[2], C W Jameson[3], K R Mahaffey[4], J Donnelly[5]. [1]*Graduate School of the Environment, Macquarie University, Sydney NSW, Australia;* [2]*CSIRO, North Ryde NSW, Australia;* [3]*NIEHS, Research Triangle Park, NC, USA;* [4]*U.S. EPA, Cincinnati, OH, USA;* [5]*CSIRO Information Sciences, Macquarie University, Sydney, Australia.* Sponsor: P Mushak.

We have estimated the contribution from formula and food to blood and urine lead in 8 newly born infants using changes in lead isotopic composition over a 6 months monitoring period. Lead concentrations in formula were generally low with a geometric mean of 1.8 μ g/kg (arithmetic median 1.99 ± 1.0) and a range from 0.36 to 4.3 μ g/kg (n=53). Lead concentrations in the baby food were up to 3 times that found in the formula with a geometric mean of 5.8 μ g/kg (arithmetic mean 6.7 ± 5.1) and a range from 1.4 to 27 μ g/kg (n=66). Differences in lead concentration between food and formula were statistically significant (p 0.003 two tailed test). The mean daily intake was 0.31 μ g Pb/kg body weight(bw)/day (geometric mean 0.25) and varied from 0.04 to 0.87 μ g Pb/kg bw/day. The contributions of infant diet to blood lead ranged from 24 to 82%, similar to those estimated for contribution of lead in breast milk to blood lead. However, multiple regression analyses showed that neither formula or food were significant predictors of urine isotopic composition or lead concentration for various time periods over the 6 months. The estimated excretion rate exceeded intake (geometric mean ratio of 2.7:1) except for two infants who had the highest daily intakes. As other sources such as air and dust contribute minimally to blood lead in these infants, we consider the increased excretion over intake and other evidence to reflect mobilization of infant skeletal lead arising from rapid bone turnover.

1548 THE USE OF LEAD STABLE ISOTOPES TO IDENTIFY HOUSEHOLD SOURCES OF LEAD EXPOSURE.

R H Gwiazda and D R Smith. *Environmental Toxicology, University of California, Santa Cruz, CA, USA.*

The variations in the natural distributions of lead isotopes provide a powerful tool to investigate the sources of lead in the environment. Lead released to the environment as a result of human activities had a different isotopic composition over time depending on the source ore from where it was extracted. In many houses built before 1978, lead incorporated in lead based paints has different isotopic compositions even within the same dwelling due to the use by different paint manufacturers of lead originated in different mines. In addition, soils have accumulated lead mainly from the dry deposition of lead particles derived from the combustion of leaded gasoline. This lead has also a distinct isotopic composition. We have investigated the sources of lead in children with elevated blood lead levels (PbB >15μg/dL) by determining the isotopic composition of lead in their blood and in the potential environmental and in-house sources of lead exposure. In children living in the same house throughout their life, the lead isotopic composition of the blood is a reflection of the current lead intake and therefore it provides a reliable indication of the source(s) of exposure. In cases where the child has moved at least 6 months before the sampling time, the blood lead isotopic composition diverts from the isotopic composition of current lead intakes because it also includes isotopically different lead released from the skeleton that had been incorporated during past exposures. While this approach relies on measurable differences between the lead isotopic compositions of blood and current intake (i.e., diet, dusts, etc.) to evaluate the sources of lead exposure to the child, it also provides a unique opportunity to determine the contribution of endogenous (skeletal) lead to blood in children. (Supported by the University of California Toxic Substances Research and Teaching Program).

1549 SYSTEMATIC EVALUATIONS OF PLASMA Pb LEVELS OVER TIME IN ENVIRONMENTALLY-Pb EXPOSED SUBJECTS.

C Seaton[1], M Hernandez-Avila[2], A Mercado[2], H Hu[3], and D Smith[1]. [1]*Environmental Toxicology, University of California, Santa Cruz, CA;* [2]*National Institute of Public Health, Cuernavaca, Morelos, Mexico;* [3]*Channing Laboratory, Harvard, Boston, MA.*

Recently, it has been suggested the lead (Pb) in plasma may be a more relevant indicator of biologically labile Pb than Pb in whole blood. Previous

reports of the relationship of plasma-Pb (P-Pb) to whole blood-Pb (WB-Pb) indicate a several-fold variability in the relative partitioning of Pb between whole blood and plasma for a given WB-Pb level. Studies investigating the variability of the P-Pb to WB-Pb relationship of individuals over time are needed to determine if the noted variability of this relationship is real or due to methodological differences. Here, we investigated the relationship between P-Pb and WB-Pb in repeatedly sampled environmentally exposed subjects over time. Two to five plasma and whole blood samples per subject (n=14 subjects) were collected over a one year duration for [Pb] and isotopic composition analyses by inductively coupled plasma - high resolution mass spectrometry using an ultraclean method developed in our laboratory (Smith et al., Am. J. Ind. Health, 33:430). Plasma samples were analyzed for iron and hemoglobin to evaluate hemolysis and resulting plasma contamination. In subjects sampled over a four week period (n=10 subjects, 4 samples each), P-Pb levels averaged 0.29 % (± 0.01% SE, range 0.17–0.46%) of WB-Pb levels (average 5.8± 0.3 μg/dL SE, range 3.3–9.7 μg/dL). Subjects sampled over a longer time period (2–4 samples, separated by at least 5 months, n=4 subjects) were similarly invariable, exhibiting average P-Pb levels of 0.27% (± 0.03% SE, range 0.17–0.52%) of WB-Pb levels (average 9.4± 0.78 μg/dL, range 5.4–13.8μg/dL). These data indicate the importance of proper sample collection and analyses methods, and that intra-subject variability in the P-Pb to WB-Pb relationship is substantially lower than previously reported. (Supported by NIEHS #ES0782).

1550 EFFECTS OF SUCCIMER ON THE DIURESIS OF ESSENTIAL METALS IN A PRIMATE MODEL OF CHILDHOOD Pb POISONING.

D Woolard[1], C Calacsan[1], M Luck[2], N Laughlin[2], and D Smith[1]. [1]*Environmental Toxicology, University of California, Santa Cruz, CA;* [2]*Harlow Primate Laboratory, University of Wisconsin, Madison, WI.*

Succimer (2,3-dimercaptosuccinic acid, DMSA) is a promising chelating agent used in the clinical management of lead (Pb) poisoning in children. While succimer exhibits high relative specificity for Pb, as a metal chelating agent it may also bind and effect the diuresis of other non-target essential metals. To address this, the urinary excretion of calcium (Ca), copper (Cu), cobalt (Co), iron (Fe), magnesium (Mg), manganese (Mn), nickel (Ni), phosphorus (P), and zinc (Zn) were evaluated in a juvenile primate model of childhood Pb poisoning. Twenty-two infant rhesus monkeys (*Macaca mulatta*) were exposed to Pb orally from birth to 1 year of age, then treated with placebo (n=11) or oral succimer (n=11) at a dose of 30 mg/kg BW/d for 5 days then 20 mg/kg BW/d for 14 days. Complete 24-hour urine samples were collected over the period T_{1d} - T_{5d} of treatment (6 days total), using acid-cleaned stainless steel metabolic cages and trace metal clean techniques. Sample collection blanks were similarly collected to evaluate sample contamination. Urine samples were analyzed for the above metals using a high resolution ICP-MS method developed in our laboratory. Five days of succimer treatment significantly increased the urinary excretion of Mn (by 77%) and Ca (by 63%) over controls ($P<0.05$, t-test). Excretion of Cu, Fe, Mg, Ni, and Zn also increased with succimer treatment (15 - 35%), but those increases did not reach significance ($0.2>P>0.06$). Succimer treatment had no measurable effect on the excretion of Co and P. By comparison, succimer increased the diuresis of Pb by 240% in these animals. These data may be qualified in some cases (e.g., Zn) due to possible urine contamination from monkey food — although this effect would likely diminish the observed differences between treatment groups. While the physiological significance of these data remain to be shown, they indicate that further study is warranted to evaluate the effects of prolonged succimer treatment on the excretion of essential metals. (Supported by NIEHS Grant #06918.)

1551 CHANGES IN BLOOD LEAD CONCENTRATION AND ISOTOPE RATIO IN SUCCESSIVE HUMAN PREGNANCIES.

W I Manton[1], C A Angle[2], and M J Inskip[3]. [1]*University of Texas at Dallas, Richardson, TX, USA;* [2]*University of Nebraska Medical Center, Omaha, NE, USA;* [3]*Environmental Health Directorate, Ottawa, ON, Canada.*

We measured the blood lead concentrations and the isotope ratios of blood and urine of two women living in Omaha from the first trimester of one pregnancy to 9 months after completion of a second. One was a 19 yr old primagravida who bottle fed both her infants; the other a 37 yr old breast feeder pregnant for the fourth time. During each pregnancy the blood lead concentrations showed a similar pattern, declining in the second trimester and increasing in the third, but in the second of the two pregnancies the changes and the overall blood lead concentrations were diminished. After delivery the blood lead of the bottle feeder remained elevated for 3 months, whereas that of the breast feeder continued to increase over the same period and remained elevated throughout lactation. We used seasonal variations in isotope ratio between pregnancies to infer the directions in which the isotope ratios of the cortical and trabecular bone of each woman lay. The decrease in blood lead concentration in mid-pregnancy is accompanied by a change in isotope ratio towards trabecular bone and the increase in late pregnancy by a change towards cortical bone, which in the case of both women reversed immediately after delivery. We conclude that: (1) the decline in blood lead in mid pregnancy is due more to a decrease in the flux of lead from cortical bone (an effect also observed in Cynomolgus monkeys) than to hemodilution; (2) the rise in late pregnancy results from increased resorption of cortical bone; (3) the post partum elevation of blood lead is in part due to the abrupt decrease in plasma volume (reflected in the hematocrit) that follows delivery; and (4) pregnancy strips lead from the skeleton, so that the blood lead of a multiparous woman decreases stepwise from pregnancy to pregnancy. The reason for the increase in blood lead during lactation is not clear because in our subject the isotope ratio patterns in the lactating and non-lactating states were indistinguishable.

1552 LEAD EXPOSURE IN CHILDREN FROM URBAN AREAS IN REGION LAGUNERA, MEXICO.

G G García-Vargas[1], M Rubio-Andrade[1], L M Del Razo-Jiménez[2], V Borja-Aburto[2], E Vera[2], and M E Cebrian[2]. [1]*Facultad de Medicina, UJED, Gomez Palacio, Dgo.* [2]*Seccion de Toxicología Ambiental, CINVESTAV-IPN, Mexico, D.F.*

The aim of this cross-sectional study was to assess lead exposure in children aged 6-9 years attending three primary schools. One of the schools is located ~500 m distant from a smelter complex which includes a lead refinery (high exposure group); the second is located ~ 900 m away from the complex and at the side of a heavy traffic road (medium exposure) in Torreón, Coahuila. The third school is located in Gómez Palacio, Durango, 5,000 m away from the smelter complex and distant from heavy vehicular traffic or industrial areas (low exposure group). Lead was measured in air, soil, dust and well water. Lead in blood (PbB) was determined in 394 children attending the above mentioned schools. Determinations were performed by atomic absorption spectrophotometry. Diet, socioeconomic status, hygienic habits and other variables were assessed by questionnaire. Average PbB (± SD) values were 8.7 ± 3.8 μ g/dL in the low exposure group, 22.4 ± 7.8 μ g/dL in the medium exposure and 28.8 ± 11.0 μ g/dL in children attending the school nearest to the lead refinery. The percentage of children having PbB ≥ 15 μ g/dL was 6.8%, 84.9% and 92.1%, respectively. In this order, the average Pb concentrations in air were 3.25 ± 2.59 μ g/m^3, 6.03 ± 2.07 μ g/m^3 and 8.16 ± 5.65 μ g/m^3. The range of Pb concentrations in soil and dust in playground areas in the medium and high exposure settings was 1,000 to 4,000 mg/kg. Pb values in drinking water were less than 6 μ g/L. Soil and dust ingestion and inhalation appear to be the main routes of exposure. Our results indicate that environmental contamination has resulted in an increased body burden of Pb, suggesting that children living in the vicinity of the smelter complex are at high risk of suffering the well known adverse effects of lead if exposure continues. Further studies are needed to evaluate the specific contributions of lead sources in the city and the presence of other metals in the environment.

1553 EQUILIBRIUM ADSORPTION OF LEAD IN WATER BY TRIOCTAHEDRAL SMECTITE CLAY.

C L Ake, K Mayura, H J Huebner, G R Bratton, and T D Phillips. *Faculty of Toxicology, Department of Veterinary Anatomy and Public Health, Texas A&M University, College Station, TX.*

Lead (a commonly occurring contaminant of drinking water) has been strongly implicated in the etiology of disease in man and animals. The main objectives of the present study were to screen representative silicoaluminates (both natural and chemically modified) for their ability to reduce Pb^{2+} levels in water. Among the various clays tested, a trioctahedral smectite (TOS) was shown to significantly adsorb Pb^{2+} at equilibrium. Aqueous solutions of $Pb(ClO_4)_2$ (20 μg/mL) were shaken with clay samples (100 μg/mL) for 24 hr, and the concentration of Pb^{2+} in solution was measured using an ion-selective electrode and validated by atomic absorption spectroscopy. Preliminary data indicated that TOS was able to adsorb 99.2% of Pb^{2+} from solution. Controls (i.e., quartz and activated carbon) exhibited 11.5% and 27.7% binding, respectively. Isotherm studies showed that Pb^{2+} adsorption followed a *Langmuir-Freundlich Model* with a maximum adsorption capac-

ity (Q_{max}) of 3.18 mol/Kg, a dissociation constant (K_d) of 7.64 x 10^5, and a Gibbs free energy (ΔG^o) of −33.58 KJ/mol. These results indicated a rapid initial adsorption of Pb^{2+} with a high affinity for clay surfaces. In other studies, adult Hydra attenuata were used to confirm the ability of TOS to adsorb lead in aqueous solution and to diminish the lethality of this toxic metal. A marked reduction in the toxicity of Pb^{2+} to hydra (50 fold) was observed in the presence of TOS and correlated well with equilibrium adsorption results with this clay. Work is ongoing to further characterize thermodynamic properties and to model the mechanism of adsorption of Pb^{2+} onto the surface of TOS. High affinity, high capacity adsorbents such as TOS may facilitate the field-practical detoxification of contaminated water via effective filtration and innactivation of Pb^{2+} and possibly other hazardous trace metals (Supported by NIH P42-ES04917).

1554 SOIL CLEANUP AND OTHER PREVENTION STRATEGIES FOR LEAD: WHAT DO WE KNOW ABOUT THEIR EFFECTIVENESS FOR REDUCING BLOOD LEAD LEVELS?

R E Grissom and A S Susten. *Agency for Toxic Substances and Disease Registry (ATSDR), Atlanta, GA, USA.*

Several approaches are currently being used to reduce or prevent exposure to lead in soil and indoor dust. Primary prevention activities prevent children and other susceptible populations from being exposed to lead in soil and indoor dust. These activities include identification and control of lead sources, public education, and education and training of health care professionals. Secondary prevention activities reduce blood lead levels after exposure has occurred and include blood lead screening and follow-up care. The relationships between blood lead levels and soil or indoor dust levels, and between blood lead levels and cleanup activities are difficult to evaluate. Several studies have attempted to address these issues; however, neither unequivocal quantitative nor qualitative associations have been identified. For example, cleanup actions have been associated with reduction, no change, or only a marginal change in blood lead levels. Factors that impede an understanding of the effectiveness of strategies that prevent exposure to lead or reduce blood lead levels include failure to identify or account for all sources of lead exposure and differences in protocols among studies including criteria for subject inclusion in the study, and seasonal and geographic differences. The effect of community outreach or changes in personal activities by community members prior to study initiation may also complicate our understanding of the effectiveness of prevention or cleanup activities. (*[1]The opinions expressed are those of the authors and do not necessarily reflect the opinions or policies of the ATSDR.)*

1555 PORPHYRIN PROFILES AND CHELATOR CHALLENGE RESPONSE AFTER METHYL MERCURY EXPOSURE IN VOLES.

K T Rummel[1], B M Adair[1], G P Cobb[1], J S Woods[2] and M J Hooper[1]. [1]*The Institute of Environmental and Human Health / Texas Tech University, Lubbock TX, USA;* [2]*University of Washington, Seattle, WA, USA.*

Porphyrins, precursors of heme, occur in characteristic profiles and are of interest in the kidney and urine as biomarkers of Hg exposure and effect. Increases occur primarily in 4-carboxylporphyrin (copro) in voles. Mercury chelation with 2,3-dimercaptopropane-1-sulfonate (DMPS), and subsequent measurement of urinary Hg and porphyrin profiles, more accurately approximate tissue burdens of Hg and their effects. Studies were carried out to determine a DMPS dose and the time and Hg dose dependence of the DMPS challenge in the prairie vole (Microtus ochrogaster). Voles received 1 ppm methyl mercury hydroxide in drinking water for four weeks after which they were challenged with saline, 0.01, 0.1 or 1.0 mmol/kg DMPS, ip. Urine was collected for 24 hours before and after the saline or DMPS injection. Kidney, urine and brain samples were analyzed for inorganic and organic mercury. Porphyrin profile analyses were carried out on kidneys and both urine samples. Mercury reached 1.4 ppm in the brain (92% organic mercury) and 15.5 ppm (94% organic) in the kidney. DMPS reduced brain Hg to 0.98, 1.3 and 1.1 ppm and kidney Hg to 7.1, 7.6 and 9.5 ppm in the high, medium and low DMPS treatments, respectively. Urinary Hg (24 hr. total) increased from 1.63 μg, initially, to 11.7, 8.04 and 3.47 μg in the high, medium and low DMPS treatments, respectively. Urinary Hg averaged ~65% organic in pre- and post-chelation samples. The proportion of mercury in the urine from renal depletion was 26, 36 and 63 percent for the high, medium and low dose, suggesting that higher DMPS doses better accessed non-renal tissues. Methyl mercury increased renal levels and urinary excretion of copro. DMPS decreased renal and urinary copro. These data support the utility of the combined porphyrin profile and DMPS chelation techniques, establish an appropriate DMPS dose, and demonstrate that brain mercury concentrations were not increased by DMPS administration in voles. (Funded by NIH ES04696.)

1556 DIAGNOSTIC USE OF 2,3-DIMERCAPTO-1-PROPANE SULFONATE (DMPS) TO ASSESS MERCURY EXPOSURE.

G M Bogdan[1], H V Aposhian[2], M M Aposhian[2], K M Hurlbut[1] and R C Dart[1]. [1]*Rocky Mountain Poison and Drug Center, Denver, CO, USA;* [2]*Department of Molecular and Cellular Biology, University of Arizona, Tucson, AZ, USA.*

Medical toxicologists use chelating agents as "provocative" or challenge tests to aid in diagnosis of patients with potential metal intoxication. A positive test is an increased amount of urinary metal excreted over a collection period per amount chelating agent administered. However, the interpretation of a challenge test is not well defined. We hypothesize that increased urinary mercury (Hg) excretion equal to or greater than 50 ug/6-hr after an oral DMPS challenge test indicates patients with a significant history of Hg exposure. To test this, we retrospectively examined urinary Hg excretion data of patients prospectively enrolled in four oral DMPS challenge test clinical trials. Study subjects consisted of dental professionals with or without a history of Hg exposure and controls (non-dental professionals with no Hg exposure history). A history of mercury exposure was defined as extensive use of Hg amalgams in dental practice or complaints self-attributed to Hg exposure. After a baseline urine collection, subjects ingested a single oral DMPS dose (300 mg) and urine was collected for 6 hours. A positive challenge test was defined as $\geq$ 50 ug Hg/6-hr urine. Eighty-nine subjects were enrolled: 47 dental professionals with no Hg exposure history, 19 dental professionals with Hg exposure history and 23 controls. Fourteen subjects had positive challenge tests and all had an extensive Hg exposure history. No subject with complaints self-attributed to Hg exposure had a positive test. The sensitivity of the oral DMPS challenge test was 100% with 93% specificity and a negative predictive value of 100%. We propose that an oral DMPS challenge test is accurate in confirming a significant history of Hg exposure and may have clinical utility in diagnosis of Hg intoxication.

1557 EFFECTS OF 2,3-DIMERCAPTO-1-PROPANE-SULFONATE (DMPS) ON TISSUE AND URINE MERCURY (Hg) AND PORPHYRIN LEVELS IN METHYL MERCURY-EXPOSED RATS.

S D Pingree, P L Simmonds and J S Woods. *Department of Environmental Health, University of Washington, Seattle, WA.*

Lead is known to be a potent activator of protein kinase C (PKC) and the PKC signal transduction system may modulate the proliferation rate of gliomas. This study was undertaken to investigate the ability of lead to activate PKC and its downstream events in 132 1N1 human astrocytoma cells. Treatment with 50 μM lead acetate for 1 hour was able to induce PKCα translocation as evidenced by Western Blot analysis and enzyme activity assay, while PKCε was not affected. Lead treatment (1 μM to 100 μM for 24 hour), resulted in a concentration- and time-dependent increase in DNA synthesis up to 300% of basal level, as measured by ^{3}H-thymidine incorporation assay. No cytotoxicity was observed, as measured by LDH release assay. The effect of lead was blocked by two PKC inhibitors, bisindolylmaleimide and staurosporine, and also by down-regulation of PKC by a pretreatment with the phorbol ester PMA. Flow cytometric analysis using double staining with bromodeoxyuridine(Brdu)-quenchable Hoechst 33258 and ethidium bromide showed that treatment with lead or PMA stimulated the G_0/G_1 to S/G_2 phase transition resulting in increased percentage of cells in the S/G_2 phase (30% in treated group vs. 4% in control group). These results suggest that lead stimulates DNA synthesis and cell-cycle progression in human astrocytoma cells through a PKC-dependent mechanism. (Supported in part by grant ES07033.)

1558 EFFECTS OF BILIARY LIGATION AND MODULATION OF GSH-STATUS ON THE RENAL AND HEPATIC DISPOSITION OF INORGANIC MERCURY IN RATS.

R K Zalups[1], D W Barfuss[2], and L H Lash[3]. [1]*Mercer University School of Medicine, Macon, GA, USA;* [2]*Georgia State University, Atlanta, GA, USA; and* [3]*Wayne State University School of Medicine, Detroit, MI, USA.*

The effects of biliary obstruction and modulation of glutathione (GSH)-status on the acute disposition of a low i.v. dose of inorganic mercury were studied in rats. Dispositional effects were studied in the kidneys, liver, small

and large intestines and blood one hour after the injection of 0.5 μmol/kg dose of mercuric chloride in control rats and rats pretreated with acivicin, buthionine sulfoximine (BSO) or diethylmaleate (DEM) that either underwent or did no undergo acute biliary ligation prior to the injection of mercury. Pretreatment with BSO or DEM was shown (in separate group of rats) to cause significant reductions in both the renal and hepatic concentrations of GSH, which is consistent with systemic depletion of GSH. Among the animals that did not undergo biliary ligation, pretreatment with BSO had no effect on the acute renal accumulation of mercury. By contrast, pretreatment with DEM or acivicin caused the renal accumulation of mercury to decrease. In general, the three chemical pretreatments used had varying effects on the disposition of inorganic mercury in the kidneys and liver. Interestingly, biliary ligation caused the net renal accumulation of mercury to decrease under all pretreatment conditions. By contrast, biliary ligation caused significant increases in the hepatic burden of mercury in all pretreatment groups except in the acivicin-pretreated animals. The additive effects of biliary ligation and chemical modulation of GSH-status on reducing the net renal accumulation of mercury indicate a likelihood of two independent mechanisms being involved in altering the renal disposition of mercury. Moreover, the data from the animals whose bile duct had been ligated indicate that at least some fraction of the renal accumulation of inorganic mercury in normal animals is linked mechanistically to the hepato-biliary (and enteric) systems.

1559 SELECTIVE ACTIVATION WITHIN THE MAPK PATHWAY BY HG(II).

K D Turney, A R Parrish, and A J Gandolfi. *Department of Pharmacology and Toxicology, University of Arizona, Tucson, AZ, USA.*

The kidneys are the primary target organ for the accumulation and toxicity of inorganic mercury. Studies have shown molecular alterations occur following a nephrotoxic insult, thus alterations in transcription factor binding and gene expression may be involved in the response of the kidney to metals. However, little is known about the molecular response of the kidney to environmentally relevant concentrations of Hg(II). Previous research in our laboratory utilizing rabbit renal cortical slices demonstrated that non-cytotoxic concentrations of Hg(II) (0-1000 nM), increased the DNA binding activity of the AP-1 transcription factor which correlated with a dose-dependent enhancement of c-jun gene expression. These results suggest a possible interference in the c-Jun NH_2-terminal protein kinase (JNK) pathway. Therefore the effects of Hg(II) on other components of this pathway were investigated. No changes were observed in the DNA binding activity of ATF2 and Elk-1, transcription factors involved in both the JNK and p38 pathways of MAP signal transduction. The specificity of Hg(II) for MAP signal transduction was also demonstrated by no changes of c-myc gene expression after exposure to Hg(II). The selectivity of alterations in molecular signaling suggests an acute response in signal transduction, specifically activation of the JNK pathway, in renal tissue following exposure to nanomolar concentrations of Hg(II). (NIH ES04940, NIEHS Training Grant T32 ES07091)

1560 INHIBITION OF NF-κ B-DNA BINDING BY MERCURIC ION (Hg^{2+}): EFFECTS OF THIOL VERSUS NON-THIOL REDUCTANTS ON Hg^{2+} INHIBITORY CAPACITY.

F J Dieguez-Acuña and J S Woods. *Department of Environmental Health, University of Washington, Seattle, WA.*

Hg^{2+}, a potent thiol inhibitor, prevents expression of nuclear factor κ B (NF-κ B) by mercaptide bond formation with a critical cysteine moiety (cys62) on the p50 subunit required for DNA binding. NF-κ B-DNA binding is typically measured in reaction mixtures in which dithiothreitol (DTT) or other thiol reductants are used to maintain cys62 in the reduced state. However, the presence of thiol reductants prevents accurate assessment of the [Hg^{2+}] required to prevent NF-κ B-DNA binding because of competitive mercaptide bond formation. In the present studies we evaluated the efficacy of tris(2-carboxyethyl)phosphine-HCl (TCEP), a non-thiol reducing agent which does not bind Hg^{2+}, on NF-κ B-DNA binding, using recombinant p50 protein and a ^{32}P-labeled κ B oligonucleotide. We also measured the minimal [Hg^{2+}] required to prevent this interaction in the presence of either reagent. DTT promoted NF-κ B-DNA binding in concentrations from 0.25 to 2.6 mM in binding reactions. However, in the presence of 0.25 mM DTT, inhibition of NF-κ B binding was seen only at [Hg^{2+}] > 100 μ M and results were highly variable. The inhibitory effects of Hg^{2+} in the presence of higher [DTT] were indeterminate. In contrast, TCEP promoted NF-κ B-DNA binding in a dose-related manner in concentrations from 0.25 to 6 mM. In the presence of even 6 mM TCEP, Hg^{2+} prevented NF-κ B-DNA binding at concentrations as low as 20 μ M in binding reactions. These findings support the use of TCEP as reductant in nuclear binding reaction assays. They also demonstrate inhibition of NF-κ B-DNA binding at [Hg^{2+}] comparable to those known to eicit toxicity in vivo. (Supported by NIH grant ES07033.)

1561 ACCUMULATION OF MERCURY AND ITS EFFECT ON ANTIOXIDANT ENZYMES IN BRAIN, LIVER, AND KIDNEYS OF MICE.

S Hussain, A Atkinson, A T Khan, S Thompson, O Clark, S Ali, and T Graham. *College of Veterinary Medicine, Nursing & Allied Health, Tuskegee University, Tuskegee, AL, USA.*

Mercury exhibits its toxicity by virtue of its interaction with proteins thereby inhibiting enzymes involved primarily in metabolism. Oxidative stress induced by various toxicants and pathological conditions in humans. Mercuric chloride ($HgCl_2$) happened to be one of the pro-oxidants that induces oxidative stress. The present study was undertaken to investigate whether oral doses of mercuric chloride alters the activities of antioxidant enzymes (catalase, superoxide dismutase, glutathione peroxidase, glutathione reductase) in different organs (liver, kidneys, and brain) of mice. The uptake of mercury shows that the kidneys accumulated the highest levels of mercury compare to brain and liver. The enzyme levels varied in mercury treated organs. A dose dependent increase of antioxidant enzymes occurred in the liver and kidneys. The increase in enzyme activities correlated with highest mercury accumulation in kidney and liver. Mercury is known to generate reactive oxygen species (ROS) *in vivo* and *in vitro*, therefore, it is likely that enzyme activities increased to scavenge ROS levels produced as a result of mercury accumulation. The increased antioxidant enzymes enhance the antioxidant potential of the organs to reduce oxidative stress.

1562 GENDER AND TISSUE SPECIFIC CHANGES IN GLUTATHIONE AND THE EXPRESSION OF THE CATALYTIC AND REGULATORY SUBUNIT OF GLUTAMATECYSTEINE LIGASE IN MICE EXPOSED TO METHYLMERCURY.

D Diaz, C C White, C M Krejsa and T J Kavanagh. *Department of Environmental Health, University of Washington, Seattle, WA.*

The toxicity of methylmercury is known to be influenced by gender and by glutathione status. Previous studies have shown that methylmercury can deplete glutathione in some tissues while increase the level of glutathione in others in a gender specific manner. Glutamylcysteine ligase (GLCL), the rate limiting enzyme in the synthesis of glutathione, is composed of two subunits: a large catalytic subunit (GLCLc) and a smaller regulatory subunit (GLCLr), and both of them are ubiquitously expressed in mammalian tissues. Previous studies have shown that MeHg exposure can result in the induction of GLCL at the RNA and protein level. We wished to determine the influence of methylmercury on the mRNA and protein levels of this enzyme, as well as enzyme activity, and glutathione levels in various tissues in male and female mice. C57Bl/6 mice were treated with one single dose of Methylmercury hydroxide (6mg/Kg) by intraperitoneal injection, and sacrificed 24 h later. Liver, kidney, small intestine and lung were collected and analyzed for glutathione content, GLCL mRNA and protein expression, and enzyme activity. Female mice had higher glutathione levels than males in the lung, but less in the small intestine. Male mice have higher levels of GLCLr mRNA in the kidney and lung (slightly), but lower in the liver, as well as lower levels of GLCLc mRNA in the small intestine, and lower levels of GLCLc protein in the lung. In response to MeHg treatment, male mice showed glutathione depletion, and GLClr mRNA induction in the liver. Female mice showed an increase in kidney and small intestine glutathione levels, induction of GLCLr mRNA in kidney and liver, and downregulation of GLCLc in the liver. There were no singnificant changes in protein levels with MeHg treatment. GLCL enzyme activity was increased in the liver in both sexes, as well as in the female small intestine. These results show diferential regulation of the catalytic and regulatory subunits of GLCL, at least at the transcriptional level, and marked sex differences in response to MeHg treatment.

1563 LUMINAL TRANSPORT OF DICYSTEINYLMERCURY ($(CYS)_2$-Hg) IN THE RABBIT PROXIMAL TUBULE.

V T Cannon[1], R K Zalups[2], and D B Barfuss[1]. [1]*Georgia State Univ., Atlanta, GA and* [2]*Mercer Univ., Sch. of Med., Macon, GA.*

Data from previous whole animal and isolated-perfused tubule experiments indicate that the lumen-to-cell transport of dicysteinylmercury ($(CYS)_2$-Hg) is via an amino acid transport mechanism. To extend these findings further we studied the luminal disappearance rate of $(CYS)_2$-Hg in isolated perfused S_2 segments of the rabbit proximal tubule. The control perfusion fluid was a balanced saline solution that contained 20μM Hg^{++} and 80μM cysteine. Replacing sodium ions with *N*-methyl-D-glucamine in both the bathing and perfusing solutions reduced the lumen-to-cell transport of $(CYS)_2$-Hg from 102 ± 4.2 to 65 ± 3.8 fmol min^{-1} mm^{-1}. To determine which amino acid transport system may be transporting $(CYS)_2$-Hg, competitive inhibition of $(CYS)_2$-Hg lumen-to-cell transport was examined by placing nine selected amino acids and two amino acid derivatives in the perfusion solution (at a concentration of 3 mM). The competitive inhibitors that had the greatest effect on the lumen-to-cell transport of $(CYS)_2$-Hg were *L*-serine, *L*-histidine, *L*-tryptophan, and 2-(-)-endoamino-bicycloheptane-2-carboxylic acid (BCH). These competitive inhibition experiments were performed in the presence and absence of sodium ions. The greatest inhibition of $(CYS)_2$-Hg transport was produced by the addition of *L*-histidine to the luminal fluid in a sodiun ion free environment, 102 ± 4.2 to 14.6 ± 1.4 fmol min^{-1} mm^{-1}. We conclude that $(CYS)_2$-Hg is primarily transported from the luminal fluid into the proximal epithelial cells by the sodium- dependent "ASC" and the sodium-independent "L" amino acid transport systems. We also conclude that $(CYS)_2$-Hg enters proximal tubular epithelial cells by a mechanism whereby this mercuric complex mimics the amino acid cystine at the site of the "ACS" and/or "L" amino acid transporters.

1564 EFFECTS OF ALUMINUM ON IMMUNE PARAMETERS IN ORALLY-EXPOSED HUMANS.

A Wicklund Glynn[1,2], A Thuvander[1], A Johannisson[3], A Gräske[1], I Gadhasson[1], and A Schütz[4]. [1]*The Swedish National Food Administration, Uppsala, Sweden;* [2]*Department of Environmental Toxicology, Uppsala University, Uppsala, Sweden;* [3]*Department of Pathology, The Swedish Agricultural University, Uppsala, Sweden;* [4]*Department of Occuptional and Environmental Medicine, Lund University, Lund, Sweden.* Sponsor: L B Willett.

Aluminum (Al) salts are used as adjuvants in vaccines, partly due to their immunostimulatory effects. Little is known about possible immune effects in humans during oral dosing of Al-containing pharmaceuticals. Eighteen healthy volunteers (mean age 42, 28-57 yrs) were divided into a test group (9 females, 4 males) and a control group (3 females, 2 males). Blood and urine were sampled twice during a base-line period of one month. During the following 42 days the subjects of the test group ingested 3x10 ml of antacid per day (Al-hydroxide, 59 mg Al/ml). Blood and urine were sampled on day 14, 28 and 42 in both groups. Al exposure resulted in a 20-fold increase in urine Al concentrations (base-line median: 20 μmol Al/mol creat.). The maximum Al concentration was reached already after 14 days of exposure. Nevertheless, there were no marked differences in immune parameters between Al-exposed and control groups. Both groups showed a time-dependent change in mitogen-stimulated lymphocyte proliferation, proportions of B-, T- and NK-cell populations, and immunoglobulin concentrations during the base-line and exposure periods. Therefore, seasonal changes in immune parameters may need to be considered in future immunological studies.

1565 CHANGES IN SOME ASPECTS OF CARBOHYDRATE METABOLISM IN HEPATO PANCREAS OF FRESHWATER CRAB, BARYTELPHUSA GUERINI EXPOSED TO CHROMIUM COMPOUNDS.

B Sridevi[1], P B Kishore[2], S Rajanna[3], B Rajanna[3],and S L N Reddy[3]. [1]*Osmania University, Hyderabad, India;* [2]*Primary Health Center, Khammam, India;* [3]*Department of Biology, Alcorn State University, Lorman, MS.* Sponsor: D Desaiah.

Trivalent and hexavalent chromium compounds are biologically important because of their existence in the environment in significant quantities. Though literature reveals heavy metal induced biochemical changes in various aquatic species, the information pertaining to biochemical toxicology of chromium in relation to crustaceans is very less. Therefore, the present study was designed to study the *in vivo* effects of tri and hexavalent chromium compounds on certain aspects of carbohydrate metabolism in the Hepatopancreas of crab, Barytelphusa guerini. Crabs were exposed to sublethal concentration (1/8 of LC-50 value) chromium chloride (15.6ppm) potassium dichromate (11.3ppm) representing tri and exavalent chromium forms for a period of 90 days. Following the exposure, glycogen, glucose, glycogen phosphorylases, lactate, pyruvate , succinic dehydrogenase (SDH), lactate dehydrogenase (LDH)and glucose-6-phophate dehydrogenase (G6PDH) were measured on 30, 60 and 90 days .Alterations in enzyme and metabolite levels exhibited tissue specific and time dependent variations. Impairment in SDH in the tissue suggests the animal's dependance on glycolytic mechanism for the energy demands.

1566 CHROMIUM DISPOSITION IN RATS FOLLOWING CHRONIC EXPOSURE TO HEXAVALENT Cr IN DRINKING WATER.

J E Sutherland[1], A Zhitkovich[2], T Kluz[1], and M Costa[1]. [1]*Dept. of Environmental Medicine, New York Univ. School of Medicine, New York, NY;* [2]*Dept. of Pathology, Brown Univ., Providence, RI, USA.*

Hexavalent Cr (VI) is more toxic than trivalent Cr (III) because it is actively transported across plasma membranes and is reduced via unstable reactive intermediates to Cr III. Intracellular Cr III is an important mediator of Cr VI carcinogenesis and toxicity. Although the U.S. EPA drinking water standard for Cr is 100 ppb, humans have sometimes been exposed to as much as 10 ppm Cr VI in drinking water from contaminated wells. The risks to these individuals are not well-understood because the digestive tract reduces some of the Cr VI to less bioavailable Cr III prior to absorption and the disposition of the remaining Cr VI has not been well-studied. We determined tissue Cr concentrations in rats after chronic ingestion of Cr VI in drinking water at concentrations relevant to human exposure levels. Adult male and female Fischer 344 rats (N=7 per treatment) consumed *ad libitum* 0, 0.5, 3, or 10 ppm Cr VI, as K_2CrO_4 in drinking water for 44 weeks. Renal Cr concentrations varied significantly with Cr VI exposure (ANOVA, $p \leq 0.0001$) and were significantly elevated in rats that drank 10 ppm Cr VI. Similarly, bone Cr concentrations varied significantly with Cr VI exposure (ANOVA, $p \leq 0.0001$) and were significantly elevated in rats that drank 10 ppm Cr VI. Hepatic Cr concentrations were not different among rats in different Cr VI treatment groups (ANOVA, $p \leq 0.07$). Brain and whole blood Cr concentrations were below detection limits (0.1 μ g Cr/g or ml) in all exposure groups. The Cr accumulation in bone and kidney in the rats given 10 ppm Cr VI may have resulted from absorption of a greater amount of Cr III and/or less effective clearance. However, Cr III is poorly absorbed therefore the increased tissue retention may also have resulted, in part, from increased absorption of Cr VI and its subsequent uptake from the systemic circulation.

1567 EVALUATION OF EFFECTS OF SUBCHRONIC EXPOSURE TO POTASSUIM DICHROMATE (Cr-VI) AND CHROMIC CHLORIDE (Cr-III) ON TESTICULAR HISTOPATHOLOGY AND SPERM PARAMETERS IN MICE.

H L Chen[1], M B Anderson[2], L B King[1], and W J George[1]. [1]*Department of Pharmacology;* [2]*Department of Anatomy, Tulane University Medical Center, New Orleans, LA, USA.*

Studies in the literature suggest that exposure to Cr-VI results in a reduced sperm count as well as a lower number of viable fetuses, fewer implantation sites, an increased number of resorptions and a greater number of dead fetuses (Elbetieha, 1997 and Zahid, 1990). The present study was conducted to characterize dose dependent accumulation of chromium in blood and testis as well as to determine whether histological changes occur following such exposure. Male Swiss albino mice were given drinking water containing Cr-VI (1000 ppm or 750 ppm) or Cr-III (2000 ppm) for twelve weeks. Previous studies demonstrated that the maximum tolerated dose for Cr-VI was in the range of 1000 ppm, whereas that for Cr-III was at least 2000 ppm. At the end of this study, total chromium concentrations in blood, testis, kidney, liver and spleen were monitored by atomic absorption spectrometry. Total chromium concentrations in whole blood were three-fold higher in the Cr-VI (1000 ppm) group [450 ± 80 ppb] and two-fold higher in the Cr-VI (750 ppm) group [295 ± 78 ppb] than in the Cr-III (2000 ppm) group [134 ± 48 ppb], respectively. Chromium concentrations in the testis following administration of Cr-VI (1000 ppm) and Cr-III (2000 ppm) were similar, whereas kidney concentrations in the Cr-VI (1000 ppm) group [2.27 ± 0.43 mg/g tissue] were two times that of the Cr-III (2000 ppm) group [1.19 ± 0.48 mg/g tissue]. Tissue histology and sperm parameters (sperm count, sperm motility, and sperm morphology) were also evaluated. Cr-III at 2000 ppm did not

affect sperm parameters whereas Cr-VI produced a significant reduction in epididymal sperm count to less than 40% of control, but produced no change in sperm motility or sperm morphology. No significant testicular histopathology was found with either Cr-VI or Cr-III. These studies indicate that Cr-VI may interfere with sperm production and/or viability.

1568 CHROMIUM(VI) INDUCES A HORMONE-INDEPENDENT ACTIVATION OF THE GLUCOCORTICOID RECEPTOR.

R C Kaltreider, A M Davis and J W Hamilton. *Dartmouth Medical School, Hanover, NH, USA.*

We previously reported that the genotoxic human lung carcinogen, chromium(VI), significantly and preferentially altered expression of the model inducible gene, phosphoenolpyruvate carboxykinase (PEPCK), in whole animal and cell culture systems following a single low dose which caused no overt toxicity. These effects were closely associated with chromium-induced DNA damage and repair. Chromium exposure was shown to paradoxically increase basal PEPCK expression while blocking the normal hormone induction of this gene by dexamethasone (Dex). Mutation of the GREs or their accessory factor binding sites within the PEPCK promoter abolished both hormone induction and chromium sensitivity of a luciferase transgene in stably transfected cell lines. We now report that non-cytotoxic doses of chromium can activate the glucocorticoid receptor (GR) and increase GRE-regulated gene expression in a hormone-independent manner. Chromium treatment of H4IIE rat hepatoma cells (20 μM, 0.5-4 hr) caused an increase in nuclear GR levels comparable to levels induced by Dex, and increased in vitro binding of nuclear extracts from treated cells to a glucocorticoid receptor (GR) recognition sequence (GRE). Chromium treatment increased expression of transiently transfected luciferase transgenes consisting of tandem GREs within a minimal promoter, but blocked the normal induction of these transgenes by Dex. Thus, the glucocorticoid receptor pathway appears to be one of the principal targets for the effects of chromium on PEPCK expression. We currently hypothesize that the effects of chromium(VI) on GR are a result of a direct allosteric mechanism rather than via the hormone binding site of GR. These results suggest that chromium(VI), and perhaps several other toxic metals such as arsenic, nickel and cadmium, may also be able to act as "endocrine disrupters" at low doses through a novel mechanism. (NIH-NIEHS ES07373)

1569 Ni(II) IN ALBINO VERSUS NORMALLY PIGMENTED *XENOPUS* EMBRYOS AFTER EXPOSURE TO 63NiCl2.

F W Sunderman Jr.[1], A Antonijczuk[1], A H Varghese[1], D Kotyzova[1], and H Tjalve[2]. [1]*Medical School, Univ of Connecticut, Farmington, CT, USA;* [2]*Veterinary Medicine Faculty, Swedish Univ of Agricultural Sciences, Uppsala, Sweden.*

The influence of pigmentation upon 63Ni(II) uptake and distribution was studied in *Xenopus laevis* embryos exposed to 63NiCl2 according to the FETAX (Frog Embryo Teratogenesis Assay: *Xenopus*) protocol. Ten groups of 60 embryos were tested, including progeny from 4 pairs of albino male and female adults and from 6 pairs of normally pigmented male and female adults. Twelve embryos in each group were exposed to 63NiCl2 (2.1 μmol/L) in FETAX medium during one of the following periods post-fertilization: 5-9 h, 9-29 h, 29-53 h, 53-77 h, and 77-101 h. The embryos were then rinsed, depurated for 4 h in non-radioactive FETAX medium, and either assayed for 63Ni content by liquid scintillation counting, or frozen on CO2-ice, embedded in carboxymethylcellulose, and examined by autoradiography. The progeny of albino adults exhibited varying degrees of albinism; some were totally apigmented; many showed sparse punctate deposits of melanin in the retina, skin, or gut wall. Following exposures to 63Ni(II) from 5-9 h, 9-29 h, or 29-53 h post-fertilization, the contents and distribution of 63Ni in albino embryos did not differ from the normally pigmented ones. Following exposure to 63Ni(II) from 53-77 h or 77-101 h post-fertilization, the 63Ni contents were significantly lower in the albino embryos, compared to the normally pigmented ones. For example, in albino embryos exposed from 77-101 h, 63Ni content averaged 8.7 (SD ± 2.5) pmol/embryo, versus 17.1 (SD ± 3.6) pmol/embryo in normally pigmented embryos ($p < 0.05$). After 63Ni(II) exposure from 53-77 h or 77-101 h, autoradiograms showed less radioactivity in the retina and gut wall of albino embryos, compared to the normally pigmented ones; low, evenly-distributed radioactivity was evident in most other tissues of the albino and normally pigmented embryos. These observations suggest that 63Ni-binding to melanin or its precursors may play an important role in nickel metabolism and toxicology. (Supported by NIH grant ES-05331 (NIEHS).)

1570 NICKEL ACCUMULATION IN RAT PRIMARY HEPATOCYTE CULTURES.

H Shimada[1], T Funakoshi[2], T Inoue[1], and S Kojima[1]. [1]*Department of Hygienic Chemistry, Faculty of Pharmaceutical Sciences, Kumamoto University, Kumamoto, Japan;* [2]*Kyushu University of Nursing and Social Welfare, Tamana, Japan.*

The present study was designed to clarify the mechanism of Ni uptake in primary cultures of rat hepatocytes. Exposure of the hepatocytes to Ni (2-50 uM; as NiCl2) for up to 6 h was not cytotoxic, as assessed by the tetrazolium-based dye (MTT) assay. Hepatocytes were treated with 10 uM NiCl2 in the absence or presence of calcium (Ca) and magnesium (Mg) (1 mM). Ni uptake was increased by 19% in medium lacking Mg or Ca and was increased by 37% in Ca- and Mg-free medium. The role of Ca channels on Ni uptake by the hepatocytes was investigated. Pretreatment with nicardipine or verapamil (200 uM), a potent inhibitor of Ca channels, decreased Ni uptake by 20%. This effect was only observed when the cells were incubated in the absence of Ca. Pretreatment with vasopressin (100 nM), a well known Ca channel agonist, significantly increased Ni uptake by the hepatocytes (24%). To determine the involvement of carrier-mediated processes on Ni uptake, the effect of temperature was also investigated. At 4C the Ni uptake was decreased by 20% compared to uptake at 37C. These results indicate that Ni uptake by the hepatocytes occurs, at least in part, through the Ca channel transport processes. Further study will be required to assess what other mechanisms are involved.

1571 INTRACELLULAR CLEARANCE OF NICKEL COMPOUNDS: AN IMPORTANT DETERMINANT OF CARCINOGENIC POTENTIAL.

G Lawrence[1], A Shipp[1], H Clewell[1], R Gentry[1], J Gearhart[2]. [1]*The K.S. Crump Group, Inc., ICF Kaiser, Ruston, LA;* [2]*Procter and Gamble, Cincinnati, OH.*

Inhalation exposure to nickel refinery dust, most of which was assumed to be nickel subsulfide, has been associated with the development of lung and nasal tumors in humans. Animal inhalation carcinogenicity studies indicate that nickel carbonyl and nickel subsulfide produce lung tumors in rats, but nickel oxide and nickel sulfate do not. The assumption has been made for some time that insoluble nickel compounds were human carcinogens, while soluble nickel compounds were not. However, evaluation of the pharmacokinetic data for nickel compounds strongly suggests that classification of these compounds based on their water solubility into soluble and insoluble species is unlikely to be predictive of carcinogenic potential. For example, the clearance of the highly potent nickel subsulfide form the lung is intermediate between the inactive soluble sulfate and insoluble oxide. Rather, both the residence time and mode of clearance, not only along the bronchial airways surface but also intracellularly, provides a more informative basis for predicting carcinogenic potential. Intracellular exposure provides a reasonable explanation for the carcinogenic differences in these three nickel compounds that may be applicable to other nickel species.

1572 TOXICITY OF DEPLETED URANIUM FRAGMENTS IN WISTAR RATS.

F F Hahn, R A Guilmette and M D Hoover. *Lovelace Respiratory Research Institute, Albuquerque, NM, USA.*

The objective of this study is to assess the carcinogenic risks associated with long-term exposure to depleted uranium (DU) shrapnel in wounds. The toxicity through 15 months after DU implantation in rats is reported here. The approach is to determine the carcinogenicity of foreign-body implants of fragments of DU (containing 0.75% titanium) in tissues relative to implants of a non-radioactive metal tantalum (Ta), as a negative control, and to injections of radioactive Thorotrast, a radiographic contrast media of thorium dioxide colloid, as a positive control. The test metals, in four squares (2.5 x 2.5 x 1.5 mm or 5.0n x 5.0 x 1.5 mm) or pellets (2.0 x 1.0 mm diam) were implanted in the quadriceps muscles of the thigh in male Wistar rats, 50 rats per group. The groups received a mass of DU metal that ranged from 0.119 to 2.79 g with a surface area that ranged from 31 to 320 mm^2 per rat. Body weight gains were significantly reduced in rats with the largest mass of DU. The type or amount of implanted material did not affect survival to 15 months. Radiographs of the implants showed marked corrosion on the surface of the DU fragments as early as 3 weeks after implantation. No surface changes were observed on the Ta controls. A fibrous capsule developed

around the implanted metals, but not the injected Thorotrast. The capsules were much thicker around the DU implants. These results indicate that DU, in sufficient dose, reduces weight gain and causes a local tissue reaction, but does not affect life span or carcinogenicity to 15 months after implantation in Wistar rats. The rats will be observed for another 9 months for evidence of neoplasia related to the implants. Research sponsored by the US Medical Research Development Command under MIPR No. KFM5529 with the US DOE, under cooperative agreement DE-FC04-96AL76406, in facilities fully accredited by the AAALAC.

1573 EFFECT OF 14 DAY ZINC CHLORIDE EXPOSURE ON TISSUE DISTRIBUTION OF ZINC IN RATS.

O Clark, A Khan, A Atkinson, T Graham, S Thompson, S Hussain, and S Ali. *CVMNAH, Tuskegee University, Tuskegee, AL, USA.*

Male and female Sprague Dawley rats were administered either 0.0, 60.0, 80.0, 120.0, or 160.0 mg/kg/day of zinc chloride via oral gavage to determine levels of zinc accumulation in different organs. Zn accumulation in the brain, liver, kidney, pancreas, spleen, thymus, ovary, uterus, epididymis, seminal vesicle and testis were analyzed by atomic absorption spectrophotometry. Body weight comparison and Zn accumulation were not made for the 120 mg/kg/day in males and 120 and 160 mg/kg/day in the females due to the high rate of mortality. Males had 3.60, 1.60 and 1.26% reductions in body weight gain in the 60.0, 80.0, and 160.0 mg/kg/day dose groups, while females had 1.0 and 0.2% reductions in the 60.0 and 80.0 mg/kg/day dose groups, respectively when compared to controls. In males, Zn accumulation in the pancreas and spleen at 160.0 mg/kg/day and in the liver at 80.0 and 160.0 mg/kg/day were significantly higher than the control. In females, Zn accumulation in the brain, kidney, spleen and ovary at 80.0 mg/kg/day were significantly higher than the control. Zn accumulation data showed a dose dependent increase in all organs of both sexes. (Supported by MHPF/ATSDR Cooperative Agreement # 5R51/ATR398004.)

1574 PRELIMINARY COMPARISON OF TWO SOIL METAL SURVEYS IN NEW ORLEANS.

H W Mielke, M K Smith and C R Gonzales. *Xavier University of Louisiana, New Orleans, LA, USA.*

This preliminary report evaluates similarities and differences of the quantity of Pb, Zn, Cd, Mn and Ni in soil in New Orleans between Survey I (1989-1991) and Survey II (1998-). In both surveys, three types of soil samples were collected in each census tract, streetside (9 samples) open space (3 samples) and foundation (3 samples). Streetside samples were collected from residential streets, at least one block away from the busiest road(s). All soil samples were collected from the top 2.5 cm by surface scrape. This preliminary report compares available data of Survey II (to date 55 or 19.2% of 286 census tracts) with data collected during Survey I from the same census tracts. All soil samples are air-dried, sieved (2 mm screen), shaker extracted 5:1 (volume to weight) with 1 mol L^{-1} nitric acid for 2 hours at room temperature, centrifuged (1000 x g for 15 min.), and filtered (Qualitative P4 Filter Paper). The extracts were analyzed for Pb, Zn, Cd, Mn, and Ni using Inductively Coupled Plasma Atomic Emission Spectroscopy (ICP-AES). The data are non-parametric and median results of the two surveys were analyzed for differences and similarities for Pb, Zn, Cd, Mn, and Ni using the Wilcoxon Signed Rank Test. Pb, Zn and Mn are not significantly different between Survey I and Survey II. This is expected because these metals are generally immobile and relatively stable in soils. There are significant reductions for Cd and Ni between Survey I and Survey II. The apparent reductions of both Cd and Ni suggest previous sources of these metals have curtailed and that Cd and Ni are mobilizing from urban soils. Further study is needed to evaluate these apparent changes. (Supported by ATSDR cooperative agreement # U50/ATU398948 to Xavier University.)

1575 EFFECT OF ORAL FRENOLICIN-B TREATMENT ON ESSENTIAL TRACE ELEMENTS IN MALE RATS: RELATIONSHIP TO PROLIFERATIVE LESIONS IN SELECTED TISSUES.

J D Bogden[1], S Han[1], F Kemp[1], R W Slauter[2], D Serota[2], N P Milner, A Davidovich[3], and D C Kossor[3]. [1]*University of Medicine & Dentistry of New Jersey, Newark, NJ;* [2]*MPI Research LLC, Mattawan, MI;* [3]*Roche Vitamins Inc., Nutley, NJ.*

Frenolicin-B (FB), a substituted 1,4-naphthoquinone antibiotic, produces inappetance and epithelial hyperplasia (EH) in the esophagus of rats; findings that also have been induced in rats by zinc (Zn) deficiency. FB also chelates divalent cations *in vitro*. The present studies were performed to determine if Zn and/or cation chelation is associated with FB-induced EH in the esophagus and selected tissues of male rats. Male Sprague-Dawley rats (*ca.* 250g; n=20/group) were fed diets containing either adequate (40ppm), deficient (<1ppm), or fortified (100ppm) Zn concentrations *ad libitum* for 28 days. Two groups (4 and 5) fed either Zn-adequate or Zn-fortified diets also were given 100 mg . $kg^{-1}.day^{-1}$ of FB in the diet, while groups 6 and 7 fed either Zn-adequate or Zn-fortified diets served as pair-fed controls. After 28 days of treatment, blood was collected for clinical chemistry and elemental analyses, rats were sacrificed and selected tissues from 10 rats/group were processed for either histopathological evaluation or elemental analyses. Compared to pair-fed controls, FB-treated rats had significantly lower mean body weight gains (67% and 74% of groups given Zn-adequate and Zn-fortified diets, respectively). FB treatment resulted in decreased hematocrit and hemoglobin concentrations, and decreased plasma activities of alkaline phosphatase (a Zn metalloenzyme). FB treatment also resulted in increases in platelet count and plasma cholesterol and phosphorus concentrations. Marginal and inconsistent FB-induced changes in plasma/tissue Zn, iron, magnesium and calcium were observed. However, mean copper (Cu) concentrations were significantly reduced in blood (30% of control) and all tissues evaluated except the kidney from FB-treated rats (10 to 64% of control). Although mean kidney Cu concentrations in FB-treated rats were comparable to control, a significant positive correlation was observed between kidney and plasma Cu; FB-induced increases in kidney weight with tubular proteinaceous deposits also were observed. FB treatment resulted in EH of the non-glandular stomach, but not the esophagus. Data suggest that FB selectively reduces circulating/storage Cu *in vivo*, possibly by the elimination of a FB-Cu chelate.

1576 EYE IRRITATION FROM CONSUMER PRODUCTS: COMPARISON OF HUMAN EXPERIENCE AND DRAIZE EYE TEST DATA.

J Martinez[1] and T Nusair[2]. [1]*The Clorox Services Company, Pleasanton, CA, USA;* [2]*Risk Assessment and Toxicology Services, Inc., Cincinnati, OH, USA.*

Eye irritancy data were reviewed for 12 household cleaning products. Human experience data captured by the American Association of Poison Control Centers' (AAPCC) Toxic Exposure Surveillance System (TESS) for the year 1996 were compared with the results of Draize eye irritation testing (0.1 ml; no rinsing). A mathematical model was employed and linear regression analysis was performed. An Outcome Index Factor (OIF) or weighted average of AAPCC TESS data was calculated for each product according to the equation: 7 (# of incidents x outcome)/(total # of ocular calls), where outcomes were assigned values of 0 for no effect, 1 for a minor effect, 5 for a moderate effect, or 10 for a major effect. The OIF was plotted against the Maximum Average Draize Score (MAS) for each product. There was poor correlation between the OIF and MAS (0.56), indicating that the 0.1 ml Draize test results generally overestimate the outcome of eye exposures. The results of this analysis are consistent with the findings of Freeberg et al (J Toxicol-Cut & Ocular Toxicol 1(3), 53-64 (1984).

1577 DISTRIBUTION OF LEAD (Pb) AND TRANSTHYRETIN (TTR) IN HUMAN EYE.

J W Eichenbaum[1] and W Zheng[2]. [1]*Dept. Ophthalmol, Mount Sinai Med Center, New York, NY;* [2]*Div. Env. Health Sci, School of Public Health and Dept. Pharmacol, College of Physicians and Surgeons, Columbia Univ, New York, NY, USA.*

The retinal pigment epithelium serves as a defensive barrier to the retina in the same way that the choroid plexus (CP) functions in the brain. Previous studies have shown that the CP sequesters Pb, which results in reduced production and secretion of TTR. This study was undertaken to examine whether Pb was accumulated within human ocular tissues and to learn about associated levels of TTR. Eight pairs of human eyes, aged 19-90, not suitable for corneal transplantation, were obtained from the NYC Eyebank within 24 hr of postmortem. The eyes were dissected to obtain aqueous, vitreous, retina, and choroid. The samples were stored at -80°C until the time of the assays. Pb and TTR concentrations in ocular tissues and liquids were determined by AAS, for Pb, and radioimmunoassay, for TTR. Our results showed that Pb accumulated in the retina at concentrations that were 166, 739, and 5 times higher than those in aqueous, vitreous, and choroid, respectively. Pb

disposition in ocular tissues or intraocular liquids, however, did not seem likely to be age-related. The average concentration of TTR in vitreous humor, 14.4 ± 5.1SE μg/ml, was twice as much as in aqueous humor, 7.0 ± 1.1SE μg/ml. We also found that TTR concentrations in retina were strongly associated with vitreous TTR levels (correlation coefficient = 0.9081, $p<0.005$), but not aqueous TTR levels. This preliminary study suggests that Pb accumulates in human ocular tissues and particularly in retina. The biochemical, physiological, and clinical implications of Pb disposition in human eyes are currently under investigation. (Supported in part by private funds and NIEHS ES08146.)

1578 ELECTRORETINOGRAM (ERG) RECORDING AND INTRAVITREAL INJECTIONS IN RABBITS AND MONKEYS.

M Vézina and G Washer. *ClinTrials BioResearch (CTBR) Ltd., Senneville (Montreal), Quebec, Canada.* Sponsor: G Lulham.

Background data for Dutch-belted rabbits and cynomolgus monkeys were obtained using an EPIC 2000 ERG recorder and a Grass flash stimulus with the background light off (scotopic conditions). Under anesthetic, following 30 minutes dark adaptation, rabbit eyes were tested independently (due to the lateral position of the eyes) and monkey eyes simultaneously. ERG protocol consisted of 4 tests: Blue filter (rod only response), red filter (rod and cone response), white (maximal response) and 30 Hz white flicker (cone only response). An average of 5 single flashes with 5 seconds between flashes comprised the blue, red and white tests. White flicker stimulus consisted of an average of five 5 second periods of white light stimulus at 30 Hz. Parameters measured from the waveforms were b-wave amplitude and latency. ERGs were recorded in untreated rabbits (n=63) and monkeys (n=22) and monthly or every other week for up to 32 weeks following single or multiple intravitreal injections of 50 μL of 0.9% NaCl or phosphate buffered saline. In untreated animals, only small differences between left and right eyes were apparent in mean results, though larger differences were occasionally observed for individual animals. Amplitude and latency in serial ERGs following single or multiple intravitreal injections generally remained consistent, with an occasional small transient decrease in b-wave amplitude shortly following intravitreal injection, which resolved by the subsequent dose/ERG measurement. The coefficient of variation (CV) for b-wave amplitude in untreated animals (a measure of individual variation) was approximately 20-30% within a given parameter. In treated animals, CV over time was 6 - 10% for single flash stimuli and 15-19% for flicker stimuli, sufficiently low to permit the onset of a retinal change to be ascertained. Thus combined with ophthalmology examinations, tonometry and histopathological examination, ERG recording is an important aid in the overall evaluation of changes in the retina.

1579 13-WEEK FEEDING STUDY WITH AN AROMATIC DIAMINE IN ALBINO RATS.

R Valentine, J W Sarver, S R Frame, and G S Elliott. *The DuPont Company, Haskell Laboratory for Toxicology and Industrial Medicine, Newark, DE, USA.*

Groups of 10 male and 20 female Crl:CD albino rats were fed diets containing 0, 100, 500, 1000, or 1500 ppm of 1,3-bis(4-aminophenoxy) benzene. Ten rats/sex/group were killed after 13 weeks of treatment and remaining groups of 10 female rats were killed after a 13-week recovery period. After 13 weeks, a slight anemia was seen in females at ≥ 500 ppm and in males at 1500 ppm; anemia was not found after a 1-mo recovery. Hepatic hypertrophy and eosinophilic foci were found in male and female rats at ≥ 1000 ppm. One of 10 males at 1500 ppm had a thyroid follicular cell carcinoma; this change was not accompanied by similar changes in any other treatment or recovery group rats, nor by proliferative changes such as hyperplasia or adenoma. In the eyes, retinal pigment epithelium hypertrophy, retinal photoreceptor degeneration/necrosis, and choriocapillaris atrophy were seen in females at ≥ 500 ppm and in males at ≥ 1000 ppm. Following 13 weeks of recovery, minimal hepatocellular eosinophilic foci were seen at ≥ 100 ppm. In addition, increased mitotic figures were detected in the liver of 1500 ppm females. Retinal injury, of comparatively greater severity than that noted after 13 weeks of exposure, was seen in females at 1000 and 1500 ppm. In mesenteric lymph nodes, macrophage aggregates (a common change in aged rats) were seen at all dose levels. The no-observed-adverse-effect level was 100 ppm based on the retinotoxicity observed in female rats at 500 ppm.

1580 SPONTANEOUS OCULAR FINDINGS IN THE COMMON MARMOSET (*Callithrix jacchus*).

O Loget, G Chevalier and R Forster. *CIT (Centre International de Toxicologie), Evreux, France.* Sponsor: R Glomot.

There is currently great interest in the use of common marmosets in toxicology and teratology. The present study was undertaken to provide background data on the normal pattern of ophthalmological findings in the marmoset. The examinations performed were those generally required for toxicity studies in non-rodent species. The following examinations were undertaken on a population of marmosets: the ocular reflexes (corneal, palpebral, direct and consensual pupillary reflexes) were evaluated. Macroscopic examination of the eye and adnexae was performed and more detailed examination was made using the head light source of the ophthalmoscope. After administration of a mydriatic, examinations were performed using a binocular indirect ophthalmoscope and a slit lamp biomicroscope. Sedation was required only for photography of the fundus, which was performed in a few instances. The reflexes were found to be normal in all animals. The principal ophthalmological findings were of developmental origin or of non determinate etiology and were: hyaloid artery remnants in the vitreous body, tigroid fundus, pupillary membrane remnants, posterior cortical pinpoint opacities and posterior capsular opacities of the lens. Other minor findings were observed at a lower incidence. The eye of the marmoset showed anatomical similarities with the human eye as regards the retina, the structure and curvature of the lens, and the holangiotic vascularisation of the fundus. These characteristics suggest that the eye of the marmoset will be a good experimental model for the identification of ocular adverse effects in general toxicology studies.

1581 EVALUATION OF CORNEAL DAMAGE USING CONFOCAL MICROSCOPY.

G L Rutschilling[1], D A Roberts[1], R Osborne[1], G M Ridder[1], B Roysam[2]. [1]*Procter & Gamble Company, Cincinnati, OH, USA;* [2]*Rensselaer Polytechnic Institute, Troy, NY, USA.* Sponsor: L D Lehman-McKeeman.

Area and depth of corneal injury have been shown to be diagnostic parameters for corneal response to surfactant-based substances *in vivo*. In the current work, an *ex vivo* method has been developed to examine damage to the cornea by surfactants and surfactant-based product formulations using confocal microscopy. Rabbit corneas, derived from commercial abattoir tissues, were exposed to test substances on the epithelial surface for up to 30 seconds. The corneas were washed, then incubated with fluorescent stains to differentiate live and dead cells and provide clear visualization of corneal cell damage by confocal microscopy. Several stain combinations were evaluated, including Calcein AM with Ethidium Homodimer-1 (C-AM/EthD-1), and Syto® 10 with Dead Red™ (Syto/DR). The C-AM/EthD-1 method results in live cells with green cytoplasm and dead cells with a red nucleus. The cytoplasmic staining also provides information about the size of the cell. Syto 10/Dead Red staining results in a field of fluorescent nuclei, live stained green and dead stained red. Confocal microscopy allowed determination of the distribution of cell damage in the corneas in three dimensions. The x, y, and z position of each nucleus and cell was calculated using image analysis, and mosaics were created of adjoining 3-D images. Using commercially available software (JMP), the x, y, and z data were plotted and evaluated for patterns of damage. Using prototype anionic and cationic surfactant-based formulations and ingredients, it was possible to distinguish substances and test conditions producing mild (epithelium alone), moderate (epithelium and stromal), and strong (full-thickness) damage to the corneas. It is proposed that the use of *ex vivo* rabbit corneas and quantitative confocal microscopy provide an alternative method to assess corneal responses that is linked directly to the *in vivo* mechanism of response (area and depth of injury).

1582 AN *IN VITRO* HUMAN CORNEAL MODEL FOR OCULAR IRRITANCY TESTING.

C M Griffith[1], J Xiong[1], M A Watsky[2] and R Osborne[3]. [1]*Univ. of Ottawa Eye Institute, Ottawa, Ontario, Canada;* [2]*Dept. of Physiology and Biophysics, Univ. of Tennessee Health Science Center, Memphis, TN, USA;* [3]*Procter & Gamble Company, Cincinnati, OH, USA.* Sponsor: L D Lehman-McKeeman.

The cornea is the major target of concern in the anterior segment of the eye following accidental exposures to chemicals or product formulations. The current work is focused on development of human corneal cultures as alter-

native models for assessment of corneal injuries. We have developed human corneal cells lines from the three main cell layers (epithelium, stroma and endothelium). These cell lines have been used in monolayer cultures to examine the effects of chemical irritants on mRNA expression of early response genes, cytokines and extracellular matrix molecules. We have also used the cell lines in combination with a mixture of native and/or chemically modified extracellular matrix molecules as scaffolding to reconstruct an artificial cornea *in vitro*. The reconstructed corneas contain the three cell layers (epithelium, stroma and endothelium) and resemble human eye bank corneas that have been maintained in tissue culture. Prototype chemical irritants have been applied to the epithelial surface of the reconstructed corneas to model *in vivo* exposures. The expression of early response genes, cytokines and extracellular matrix genes that are thought to have a role in the ocular irritancy response and in wound healing have been determined. Preliminary results indicate that there are differential patterns of gene expression with different chemicals. Experiments comparing responses to irritant chemicals in the monolayer cultures vs. the reconstructed corneas are in progress. The knowledge obtained to date is being used to further refine the reconstructed human corneas and their use as an alternative to animal tests for ocular irritancy. It is proposed that reconstructed human corneas will be a mechanistically sound model for the tissue and species of concern. Further, the base technology can be used to reconstruct other *in vitro* human tissues for toxicity testing.

1583 THE EPIOCULAR PREDICTION MODEL: A REPRODUCIBLE IN VITRO MEANS OF ASSESSING OCULAR IRRITANCY POTENTIAL.

M Klausner, H A Sennott, B Breyfogle, A Makwana, and J Kubilus. *MatTek Corporation, Ashland, MA, USA.*

The EpiOcular™ tissue model (OCL-200) is an organotypic model of the human corneal epithelium (HCE) cultured from normal human keratinocytes using serum free medium. Paraffin embedded, H & E stained histological cross-sections show the structure of EpiOcular closely parallels that of the HCE. During 1996 and 1997, 47 and 82 lots, respectively, of the OCL-200 model were produced and monitored using the MTT assay. The common surfactant, Triton X-100 (0.3%), was used as a positive control and the Effective Time-50 values (time of exposure after which viability is reduced to 50%, or ET-50) was determined for each lot of tissue. The ET-50 average of 24.9 ± 6.3 minutes (± 1 standard deviation) for 1996 (n=47 lots) was not statistically different ($p < 0.05$) than the 1997 average of 22.9 ± 4.7 minutes (n = 81 lots). Stability of the EpiOcular model for international shipment was probed using these standard quality control tests following packaging and storage of the tissue for 4 days; both positive and negative controls and histology of the tissue remained constant. Interlaboratory testing also confirmed the reproducibility of the tissue. Coefficients of variation (c.v.) for 3 materials tested in 3 laboratories were all below 10%. ET-50 values were measured for 19 water-soluble chemicals from the ECETOC database and 41 materials including final formulation shampoos, off-the-shelf cosmetic/personal care products, and surfactants. Draize data for these materials were correlated to ET-50 values and a prediction model was constructed: Draize = 4.735+101.65/(ET-50)^0.5 (correlation coefficient, r = 0.90). Thus, the EpiOcular tissue model is reproducible and appears to be an accurate *in vitro* means of predicting *in vivo* ocular irritancy.

1584 COMPARATIVE CYTOTOXICITY OF MITOMYCIN C AND 5-FLUOROURACIL IN IMMORTALIZED RABBIT CORNEAL ENDOTHELIAL CELLS.

C Yao, J Podval, J Kiehlbauch, D Edwards and J C Veltman. *Research Toxicology Department, Alcon Laboratories, Inc., Fort Worth, TX, USA.*

Mitomycin C (MMC) and 5-fluorouracil (5FU) are drugs currently used to stem cell proliferation following glaucoma filtration surgery. Their respective cytotoxic mechanisms on the corneal endothelium, however, differ. In *in vitro* experiments using immortalized rabbit corneal endothelial (RCEndo) cells, MMC elicited significant cytotoxicity (Neutral Red Uptake) after 1 h with 50 μg/ml and after 4h with 2 μg/ml. Higher doses of 5FU, 20 mg/ml after 1 h and 4 mg/ml after 4 h exposure were required to elicit significant cytotoxicity. Both drugs produce significant increases in protein carbonyl content, which suggest drug-induced oxidative insult. MMC produced a dose-dependent loss of GSH, a rise in GSSG and a reduction of the ratio of GSH/ GSSG. MMC reduced GSH S-TR by nearly 40% and GSH-PX by 28 % after 4 h of exposure but did not affect GSSG reductase activity. However after 4 h, 5FU produced a dose-dependent decrease in corneal endothelial cell GSH as well as increases in GSH-PX (4.2-fold, 20mg/ml) and GSSG Reductase (1.6-fold, 20 mg/ml) activities. DT-diaphorase was inhibited in a dose-dependent manner by MMC but was significantly increased by 5FU after 4 h. These data indicate that both drugs can induce oxidative-injury to corneal endothelial cells but that the differences in the toxic potency between 5FU and MMC may be due to effects on the glutathione redox cycle and DT-diaphorase in corneal endothelial cells.

1585 REVIEW OF THE LONG-TERM IN-HOUSE USE OF AN *IN VITRO* TEST BATTERY FOR PREDICTING SEVERE OCULAR IRRITANTS.

P A Botham and N A M Hadfield. *Zeneca Central Toxicology Laboratory, Macclesfield, Cheshire, UK.* Sponsor: I Kimber.

In 1994, we reported the development of an *in vitro* test battery for use within a stepwise approach to the assessment of ocular irritancy *in vivo* (Lewis *et al*, Tox *In Vitro*, 8, 865-6, 1994). The battery comprised a cytotoxicity assay using the K562 cell line followed by the isolated rabbit eye test. In contrast to the use of data from rabbit skin irritation tests, the *in vitro* battery was significantly more predictive; 83% of severe eye irritants were predicted compared to 23% by the use of *in vivo* skin irritation data; the battery was also highly specific (85%). This was based on more than 200 compounds, covering a wide range of chemical classes and formulations. This paper reports the extended use of this *in vitro* battery from 1991-1997. Using the same methods and prediction model, 1,136 compounds have now been assessed *in vitro*; 832 of these materials were also tested *in vivo* using CTL's approach of initial testing in one rabbit (using a "low volume" - 0.01ml/0.01g - following a prediction of severe irritant potential) with no further *in vivo* testing following a severe response. Correct predictions were made for 580 (70%) of these materials; sensitivity and specificity were both approximately 70%, with 19/65 confirmed severe eye irritants being under-predicted; the over-prediction rate was 233/767. Of the 19 false negatives, 14 were either surfactants or surfactant-containing pesticide formulations; however, many similar materials were correctly predicted or even over-predicted and no clear structure-activity relationship emerged from the analysis. Although this represents a reduction in performance of the battery compared to its initial use in CTL, it still allowed a reduction in the percentage of severe ocular irritants which were actually tested *in vivo* - only 2% (19/832) rather than 8% (65/832) - a significant refinement. In addition, many of the 304 compounds which did not proceed to *in vivo* testing were assessed *in vitro* to select the least irritating chemicals or formulations in a series, thus giving substantial reduction in animal use.

1586 CORRELATION OF THE BOVINE CORNEAL OPACITY AND PERMEABILITY (BCOP) ASSAY WITH THE RABBIT DRAIZE EYE IRRITATION ASSAY USING TRADITIONAL AND HISTOPATHOLOGICAL ENDPONTS.

F Heitfeld[1] and J W Harbell[2]. [1]*The Clorox Services Company, Pleasanton, CA, USA;* [2]*Institute for In Vitro Sciences, Inc., Gaithersburg, MD, USA.* Sponsor: A K Reddy.

The ability of the BCOP to predict the outcome of the Draize eye irritation assay was examined for laundry and home cleaning formulations. Based on screening experiments, the contact time of the products in the BCOP was reduced from 10 minutes to one minute to better differentiate between moderate and severe irritants. Two Draize parameters were used; the Maximum Average Draize Score and Days to Clear. These were compared to the standard BCOP score as well as the opacity and permeability scores. The best overall linear correlation (r=0.85) was between the calculated BCOP score and the maximum average Draize score. The second best correlation was between the BCOP opacity value and the maximum average Draize score (r=0.82). In addition to traditional BCOP endpoints, the corneas were also examined via histopathology. Injury severity was graded based on the structures of the cornea that were injured, their importance in recovery after eye injury and their depth in the cornea. Based on these factors, a "histopathology" score was assigned. These data were correlated versus the recovery time in the Draize eye irritation assay.

1587 HISTOPATHOLOGY ASSOCIATED WITH OPACITY AND PERMEABILITY CHANGES IN BOVINE CORNEAS IN VITRO.

J W Harbell[1], H A Raabe[1], M G Evans[2], and R D Curren[1]. [1]*Institute for In Vitro Sciences, Inc., Gaithersburg, MD, USA;* [2]*Pathology Associates International, Frederick, MD, USA.*

The Bovine Cornea Opacity and Permeability (BCOP) assay has been used

to evaluate the ocular irritation potential of a broad range of chemicals. However, the mechanisms by which opacity and permeability are induced are poorly understood and may well be different among chemical classes. We have used histopathological evaluation of corneas treated in the BCOP assay to obtain a concurrent assessment of the degree and depth of injury, and other qualitative tissue changes, associated with the in vitro opacity and permeability measurements. Corneas were fixed after completion of the fluorescein permeability step, bisected, embedded, sectioned, and stained with hematoxylin and eosin. Increased opacity readings were associated with two general types of damage, epithelial cell condensation (typical of acids and some organic solvents) and stromal swelling (typical of cationic surfactants and highly alkaline materials). If epithelial condensation was present, there was generally relatively low fluorescein permeability even when the epithelium was badly damaged. Stromal swelling, either microscopic (separation of the collagen fibrils progressing from the anterior to the posterior) or macroscopic (visible increases in overall cross sectional thickness), was usually accompanied by epithelial damage and increased permeability. In general, increased permeability reflected progressive damage to the epithelial cell layers, particularly the basal cell layer that accounts for the majority of the permeability barrier.

1588 A LONGITUDINAL ANALYSIS OF BENCHMARK AND CONTROL VALUES IN THE BCOP ASSAY.

D L Ippolito[1], P L Connolly[2], J E Swanson[1], P H Lloyd[2], H A Raabe[3], and C E Manderfield[1]. *SC Johnson & Son, Inc., [1]Racine, WI, USA and [2]Milton Park, Egham, England; [3]Institute for In Vitro Sciences, Inc., Gaithersburg, MD, USA.* Sponsor: R D Curren.

The Bovine Corneal Opacity and Permeability (BCOP) assay has been employed internationally to evaluate the ocular irritation potential of a wide range of test materials: surfactant-based formulations, organics, and fragrance materials. To evaluate the reproducibility of the assay over time, a longitudinal analysis of the scores from a concentrated fragrance benchmark and the assay positive control was made to ascertain possible changes over time. The benchmark was a moderately irritating complex fragrance mixture used as a comparative standard for evaluating prototype air fresheners. Ethanol exposures of ten minutes constituted an internal positive control for monitoring performance of the assay system. Over sixty benchmark values obtained in the assay over a five year period were plotted for both ten and thirty minute exposure times. The analysis showed that: 1) The assay was capable of significantly distinguishing a minor change in benchmark preparation ($p<0.001$); 2) A relocation of the testing laboratory led to no significant change in the studied values; 3) The degree of variance was significantly greater for the benchmark than for the positive control ($p<0.001$); and 4) The assay demonstrated internal consistency between exposure times for the benchmark ($r^2=0.75$). Studying the benchmark and control values over time in the BCOP Assay can be a valuable tool in monitoring variability and change in the assay system and testing environment.

1589 CORNEAL THICKNESS AS A MEASURE OF CORNEAL HYDRATION IN THE BOVINE CORNEAL OPACITY AND PERMEABILITY (BCOP) ASSAY.

P L Casterton[1] and J Swets[2]. *[1]Amway Corporation, Ada, MI, USA; [2]Calvin College, Grand Rapids, MI, USA.*

The Bovine Corneal Opacity and Permeability Assay (BCOP) currently employs measurements of those two parameters to assess eye irritation potential. The concept of corneal hydration was presented in a poster session at the 1998 SOT Annual Conference as a third possible measurement tool when using the BCOP. The purpose of this study was to determine whether corneal thickness correlates with measurements of corneal hydration. With good correlation, this key piece of information could be the trigger for development of a fast and accurate, yet practical, way to measure corneal thickness during routine BCOP procedures. All corneas were mounted in standard BCOP holders and incubated for one hour at 32°C in Eagle's Minimum Essential Medium (MEM). Following this equilibration period, irritant-treated corneas were dosed for 10 minutes with either acetone, 30% sodium lauryl sulfate (SLS), isopropyl alcohol (IPA) or 1% sodium hydroxide (NaOH) and incubated for an additional two hours in MEM. After incubation, the lower opacity corneas were dyed with methylene blue in MEM for 60 seconds to enable the thickness-measuring device to detect the corneal surface. Higher opacity corneas needed no such staining. Four 5mm punches were cut from each cornea and the thickness of each was measured at nine different sites using Smart Scope, manufactured by Optical Gauging Products, Inc., Rochester NY and its accompanying Master Mind Plus software. Thickness differences between treated and untreated corneas were detectable. Average thickness of corneas were 1) untreated = 0.9857mm 2) 30% SLS = 1.0225mm 3) IPA = 1.4158mm 4) acetone = 1.4731mm and 5) 1% NaOH = 1.7657mm. We conclude that measuring hydration via thickness has the practical potential to become part of the BCOP.

1590 AN INTERAGENCY EVALUATION OF THE MURINE LOCAL LYMPH NODE ASSAY (LLNA) IN THE REGULATORY PROCESS.

D M Sailstad[1], D G Hattan[2], R Hill[3] and W Stokes[4]. *[1]NHEERL, US EPA, Research Triangle Park, NC, USA; [2]CFSAN, US FDA, Washington, DC, USA; [3]OPPTS, US EPA, Washington, DC, USA; [4]ETP, NIEHS, Research Triangle Park, NC, USA.*

The LLNA, an alternative method to guinea pig (GP) tests for the identification of chemicals with potential to produce contact hypersensitivity, was the first test method to undergo independent peer review using the Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM) process. Although the LLNA has been extensively evaluated and reported in peer reviewed journals, it has not been accepted in the regulatory community as a stand-alone alternative to GP tests. Using validation and acceptance criteria recently developed by the Federal government, an expert peer panel conducted a comprehensive and rigorous review to reach consensus on the usefulness and limitations of the LLNA. The panel concluded that the LLNA was a satisfactory method for evaluating dermal sensitization and that it provided acceptable intra- and inter-laboratory repeatability and reproducibility. Furthermore, the LLNA exceeded the GP tests in method transferability, cost-effectiveness, reduced assay time, quantitative/objective endpoint and refinement of animal use. Based on this review, ICCVAM will make recommendations to relevant agencies concerning the usefulness and suitability of the LLNA. The LLNA review provided insight into the process that ICCVAM has established to evaluate new methods proposed for improved hazard identification and risk assessment with relevance to regulatory agencies. In addition to conserving resources, cost and time involved in the evaluation/acceptance process among agencies, the ICCVAM review process emphasizes the protection of human and environmental safety while attending to animal refinement, reduction and replacement. This organized and consistent approach may protect against premature acceptance of test methods and yet provide a mechanism to facilitate the adoption of scientifically valid and innovative alternatives. (This abstract does not reflect EPA, FDA or NIEHS policy.)

1591 TUMOR CLASSIFICATION FOR EVALUATION OF LONG-TERM RODENT BIOASSAYS.

I Linkov[1], A Shagiakhmetov[1], R Wilson[1,2], and G M Gray[2]. *[1]Department of Physics, Harvard University, Cambridge, MA, USA; [2]Harvard Center for Risk Analysis, Harvard School of Public Health, Boston, MA, USA.*

Evaluation of long-term rodent cancer bioassays requires analysis of many different organs, tissues and cell types. The manner in which tumor types and sites are combined for statistical analysis can have a significant influence on bioassay interpretation. In this study, we evaluate the influence of several alternative tumor classification schemes for the more than 4000 tumor types in the Cancer Bioassay Data System (CBDS) database of carcinogenesis test results on conclusions about carcinogenic or anticarcinogenic effects of specific chemicals. We compare our standard classification system, based on classification by tumor type, with an alternative classification system developed by Dr. Kenny S. Crump and colleagues. In addition, we test a classification system based on tumor sites, rather than types. We go so far as to evaluate all tumors as one classification, analyzing response by total tumors in control and treated groups. We compare the fraction of chemicals in the database classified as carcinogenic, or anticarcinogenic, under the different classification schemes. There are clear differences in the conclusions that would be drawn using the alternative classification systems. Of course, this would have significant influence on risk assessment and regulation. Often neglected in the past, formulation of tumor classification systems to most appropriately interpret the rodent bioassay will require cooperation of toxicologists, pathologists, and biostatisticians.

1592 MONONUCLEAR CELL LEUKEMIA (MNCL) IN F-344 RATS: IMPLICATIONS FOR HUMAN CANCER RISK ASSESSMENT OF PHTHALATES AND OTHER NONGENOTOXIC CHEMICALS.

D J Caldwell. *Exxon Biomedical Sciences, Inc., East Millstone, NJ, USA.*

The biological significance of F-344 rat MNCL for humans remains controversial and has confounded recent carcinogenicity studies of several chemicals, including dialkyl phthalate esters. Thus, a survey of the published literature was conducted to assess the occurrence of this finding in F-344 rats and to evaluate its potential significance to humans. MNCL occurs in untreated, aged F-344 rats at a high and variable rate, and is uncommon in most other rat strains. The background incidence of MNCL in F-344 rats has increased over time, which presents problems in retrospective data interpretation. MNCL has not been found in other mammalian species. No histologically comparable tumor is found in humans. Most leukemiogens are genotoxic and this is likely their mode of action. However, phthalates are not genotoxic as a class. Furthermore, in the case of phthalates, there is an apparent threshold dose that must be exceeded before MNCL is seen. The occurrence of a common tumor in the F-344 rat, which is not observed in other species, is an insufficient basis for determining that a chemical presents a carcinogenic hazard to humans. When these considerations are collectively evaluated, it can be concluded that a finding of increased MNCL in F-344 rats exposed for a lifetime to a particular chemical is not biologically relevant to humans, even when MNCL is observed at an increased incidence that is statistically significant. Thus, classification of a chemical as a carcinogen based on increased MNCL in F-344 rats is not scientifically supported. The increased incidence of MNCL observed in F-344 rats exposed to some alkyl phthalates is likely a strain-specific effect of little or no relevance for humans.

1593 CHRONIC BIOASSAYS FOR LIVER TUMORS IN $B6C3F_1$ MICE USING IDEALIZED WEIGHT CURVES PRODUCED BY CONTROLLED FEEDING.

J E Seng[1], E Horsley[1], W T Allaben[1] and J E A Leakey[1]. *National Center for Toxicological Research, Jefferson, AR.*

Use of dietary control (DC) to manipulate body growth in $B6C3F_1$ mice was used in an ongoing chronic bioassay. An idealized weight curve for male $B6C3F_1$ mice, which predicts a terminal background liver tumor incidence of 15%, was constructed and tested using a known mouse hepatocarcinogen. This approach successfully maintained cohorts of mice at weights approximating their idealized target weights throughout the two-year study. These mice exhibited less individual body weight variation than did their *ad libitum*-fed (AL) counterparts (e.g. BW ranged from 25-35g and 25-50g in the DC and AL groups respectively at 1 year of age). This was associated with a decreased variation in liver to body weight ratios, which allowed the demonstration of a statistically significant dose response to the test chemical in the DC, but not the AL test groups. The test chemical, in AL and DC diet groups, increased terminal liver tumor incidence but a statistical significant dose-response was observed only in the DC mice. Furthermore, this dose response positively correlated with markers of peroxisomal proliferation in the DC mice only. This increase in sensitivity did not appear to be due to diet effects on pharmacokinetics since there was no significant difference in the clearance (area under the curve) of the compound or its major metabolite between the DC and AL mice. Thus, DC not only improves terminal survival and decreases inter-assay variation, but can also increase assay sensitivity by decreasing intra-assay variation.

1594 RODENT CANCER BIOASSAYS COULD BE TERMINATED AT 18 MONTHS.

E Nestmann[1], A Monro[2], T Davies[3], B Lynch[1], and I Munro[1]. [1]*CanTox Inc., Consultants in Toxicology, Mississauga, ON, Canada;* [2]*Pfizer, Inc. Sandwich, UK;* [3] *Pfizer Inc., Central Research, Groton, CT, USA.*

One of the problems with the rodent cancer bioassay is that it produces "too many positive results" (about 50%). It is often difficult to decide which of these positive results poses a real cancer risk to humans. Clearly, fewer positive results would result from the use of lower dose levels or a shorter duration of study. We evaluated the carcinogenicity studies for chemicals reviewed in IARC Monographs Volumes 1 to 61 to determine the time to onset of treatment-related carcinogenicity (by clinical or pathological examination) and to assess the effect of using an 18 month study duration. Only study reports where chemicals were administered by the oral route, or by other routes not involving the production of site of administration tumors, were included. Several hundred study reports were reviewed on a total of 194 chemicals. Of these, 129 (66%) showed evidence of carcinogenicity in either rats or mice at or before 52 weeks, 48 (25%) between 52 and 80 weeks, and for only 17 (9%) was a study of longer than 80 weeks required to reveal a carcinogenic response. In this last group, most chemicals caused tumors of the liver, forestomach or endocrine organs. These tumors, depending upon the circumstances, have often been cited to be of limited relevance to humans. All of the Group 1 human carcinogens were found to be detected in studies of 15 months or shorter duration. The present analysis indicates that termination of bioassays at 18 months would not result in loss of information relevant to human cancer risk assessment. It would also improve survival and alleviate difficulties associated with the analysis of tumors within a background of age-related pathology.

1595 INTEGRATION OF CANCER AND NONCANCER RISK ASSESSMENT WITHIN A QUANTITATIVE FRAMEWORK OF UNCERTAINTY AND VARIABILITY.

P S Price and R E Keenan. *Ogden Environmental and Energy Service, Portland, ME.*

The current system for evaluating cancer and non-cancer risks used by regulatory agencies differ in their use of models, assumptions and produce different descriptions of risk. Toxicological criteria such as the Reference Dose (U.S. EPA), Minimal Risk Level (U.S. ATSDR), and Allowable Daily Dose (WHO) are establish using safety factors and estimate a dose associated with a minimal risk. The carcinogenic risks are evaluated using a linear dose response model that is intended to characterize the lower confidence limits of the true dose response and a model of interspecies extrapolation. The results of the two approaches differ with cancer risks being described in terms of a dose response slope and non-cancer in terms of a single toxicological criterion. However, both approaches must deal with the same issues including extrapolating to humans from animal results, high-dose to low-dose extrapolation, and management of uncertainty. We believe that both approaches can be placed into a single toxicological framework that describes dose response assessment as an attempt to characterize the lower confidence limit of the uncertainty in the human dose response. Under this framework, the non-cancer toxicological criteria are viewed as lower confidence limits estimates of zero or minimal risk level for compounds with non-zero thresholds. The dose response slope for a carcinogen is defined as the lower confidence limit of the dose response slope for a compound with non-threshold effects. This framework allows the comparison of the strengths and weaknesses of the various steps of the cancer and non-cancer assessment process. In addition, it provides an improved description of the uncertainty in current regulatory criteria.

1596 PCB TUMORIGENICITY IN RODENTS: HOW SHOULD IT BE MEASURED?

B A Mayes, K M Fish, J F Brown, Jr., and J B Silkworth. *General Electric Corporate Research and Development, Schenectady, NY, USA.*

In the past 30 years, several studies in rodents have been interpreted to suggest that PCBs are potentially carcinogenic for humans. More recently, the most comprehensive and detailed rat tumorigenicity study of PCBs ever conducted has been reported, and this study confirms the capacity of PCBs to increase the expression of liver tumors in Sprague-Dawley rats (described in Mayes *et al., Toxicol. Sci.* 41, 62-76, 1998). In 1996, using all available rodent carcinogenicity data (including data from the study cited above), the U.S. EPA reassessed the evidence for tumorigenicity and assigned revised (decreased) PCB cancer slope factors (q1*), based on hepatic tumorigenicity. In addition to hepatic tumors, the recently completed SD rat study allows for the numeration of the total tumor incidence across all sites, an important consideration for determining the true risk of cancer ascribable to PCBs. Total tumor counts, for all primary tumors (benign or malignant) at any site of origin, were determined during 24 months of exposure for the following dose groups: controls (0 ppm) and Aroclors 1016 (200 ppm), 1242 (100 ppm), 1254 (100 ppm) and 1260 (100 ppm). The average total number of tumors per rat for males was 1.35, 1.36, 0.92, 0.98 and 1.68, and for females was 1.83, 2.0, 2.02, 1.82 and 2.12, respectively. For males, decreases in total tumor incidence were identified for Aroclors 1242 ($p=0.024$) and 1254 ($p=0.054$) compared to control (Chi-square test). There were no statistically significant differences for females between any of the Aroclor-dosed groups and control. These data show that although there was an increased expression of hepatic tumors in rodents (especially females) chronically exposed to high doses of PCBs, the incidence of *total* tumors was not increased, and in

two instances, was actually decreased. Current risk assessment paradigms, by focusing on selected, isolated endpoints, can overestimate the actual total risk associated with PCB exposure. Therefore, a scientifically-based risk assessment should include evaluations for the overall incidence of tumors, in addition to counts at selected target organ sites.

1597 CENTRO DE INFORMACION TOXICOLOGICA: A RETROSPECTIVE STUDY OF NINE YEARS OF SERVICE.

O Torres-Alanís and L Garza-Ocañas. *Centro de Información Toxicológica (Centro Antivenenos), Departamento de Farmacología y Toxicología, Fac. de Medicina, Universidad Autónoma de Nuevo León, Col. Del Valle, Nuevo León, Mexico.* Sponsor: D Acosta.

The Toxicological Information Center was founded in 1989 and is situated in the Department of Pharmacology and Toxicology of the Medicine School of the Universidad Autónoma de Nuevo León. It has 24-h information service 7 days a week given to the general public and health professionals. The present is a report of calls received by the center during 9 years of activities. Our center had 9320 telephone calls (1989-1997 period), of which 61% were real intoxications and 39% were calls regarding toxicologic information about antidotes, adverse drug effects or asking for analysis. Sixty two percent of the calls came from hospital physicians and practitioners, 20% from general public and 18% from industries. Children were involved in 53% of the cases, adults in 47%. The children were mainly preschoolers (71%). Among adults, women were slightly more represented than men. Among the products involved, medicinal drug were the most important group(30%), household products and cleaning agents were second in frequency (20) followed by pesticides(15). Accidental was the predominant situation (78%) and the main route of exposure was oral (89%).

1598 RISK COMMUNICATION REGARDING DIOXIN EXPOSURES TO INFANTS FROM MOTHER'S MILK: KEY UNCERTAINTIES RELATING TO STEADY STATE MODELING ASSUMPTIONS.

B D Kerger[1], G E Corbett[2] and T L Copeland[2]. *Health Science Resource Integration, Inc. (HSRI), [1]Tallahassee, FL and [2]Orange, CA, USA.*

Accumulation of polychlorinated dibenzo-p-dioxins and dibenzofurans (PCDDs and PCDFs) in the adipose tissues and mother's milk of humans is an important risk communication issue. In regulatory risk assessments the breast-fed infant dose model by Smith and colleagues is typically used to evaluate the incremental dose from a specific industrial source. This model infers that long term body burdens of 2,3,7,8-PCDDs and PCDFs accumulate according to an exponential function until "steady state" is reached, i.e., until the daily dose absorbed equals the daily dose excreted. The underlying logic of this model is probably not clear to most risk assessors or risk managers, yet is important both for accurate dose estimation and risk communication. Our presentation illustrates the following key aspects: 1) plausible maternal exposure time and rate are key because steady state for TCDD is not likely reached until after 25 or more years of continuous exposure; 2) modeling TEq can be misleading because each dioxin and furan congener has different pharmacokinetics; 3) to understand the potential for infant toxicity, the infant's body burden vs. time profile is most important; and 4) the use of multiple upper bound parameters can greatly overstate the plausible dose attributable to the source(s) at issue. Use of conceptually similar steady state modeling for source-related dioxin accumulation in human foodstuffs further magnifies the likely overestimation of the plausible infant dose. We recommend that these significant uncertainties be explained in all risk assessments attempting to estimate breast-fed infant exposures to PCDDs/PCDFs and other chemicals.

1599 URANIUM HEALTH ADVISORY.

A T Bathija. *U.S.EPA, OW/OST, Washington, DC.* Sponsor: E V Ohanian.

Uranium (U) is a naturally occurring element that makes up about 2% of the earth's crust. Uranium is naturally released into the air and water through weathering of rocks. The principal isotopes of concern in drinking water are U-234 and U238. In 1991, EPA proposed a Maximum Contaminant Level Goal (MCLG) for U of zero based on emission of alpha radiation known to be carcinogenic in humans. EPA based the Maximum Contaminant Level (MCL) of 20 *ug* /L based on kidney effects seen in a 30-day rabbit study by Maynard and Hodge (1949). The kidney effects have been identified as the more sensitive end point of concern; the kidney effects are seen at very low levels of exposure to U. Also, carcinogenicity due to oral exposure to U has not been observed. The relative Source Contribution (RSC) used in the proposed MCL was 20%; EPA policy for water is to use a default factor of 20% RSC in the absence of specific data. Since the 1991 proposal, a new study has been published which has identified histopathological effects in rat kidneys (Gilman et al, 1998). In June of 1998, EPA sponsored a Uranium Issues Workshop (WS) to share research information and technical expertise on effects of U in drinking water. At the WS it was decided that the Gilman et al, 1998 study provided the most scientifically sound basis for risk assessment. Since the 1991 proposal, EPA has gathered data to show that the RSC from water is 77%. The details of the rat study and the procedure for deriving health-based levels and the new data to calculate the RSC will be presented. (The opinions expressed are those of the authors and do not reflect the Agency policy).

1600 IMPLICATIONS OF REGULATIONS IN THE CONTEXT OF CALIFORNIA'S PROPOSITION 65: IS IT REALLY NECESSARY TO LIMIT EXPOSURE TO BACKGROUND CONCENTRATIONS OF CHEMICALS?

D J Paustenbach, D B Mathur, and P J Sheehan. *McLaren/Hart-ChemRisk, Alameda, CA, USA.*

Under the Safe Drinking Water and Toxic Enforcement Act of 1986 (Proposition 65), Cal-EPA has developed a list of chemicals considered by the State to be carcinogens and/or reproductive/developmental toxicants. Cal-EPA has also established No Significant Risk Levels (NSRLs)-daily intakes that would result in one theoretical excess cancer in 100,000, for many of these chemicals. The NSRLs for N-nitrosodimethylamine (NDMA) and bis-diethylhexylphthalate (DEHP) are 0.04 and 80 μ g/day, respectively. In this study, we analyzed some major contributors to background exposures to these chemicals, and found backgrounds to range between 5-100 times the NSRLs. The criteria for NDMA are stringent for a chemical that is rare as an environmental contaminant, yet common in our diet. Cancer risks from consumption of two meals of bacon a week from adolescence to age 70, or consumption of 3 bottles of beer or malt whiskey drinks a week (NDMA concentration of 2.5 ppb) for 40 years are approximately 1/10,000. The estimated daily dietary intake of NDMA (1 μ g), may pose a cancer risk of approximately 1/1,000, and the total dietary dose of all nitrosamines is about 100 times the daily dose of NDMA. Further, lack of epidemiological data regarding excess cancers in humans associated with NDMA exposure suggests that it is unlikely that background exposures to NDMA, although significantly in excess of the NSRL, pose a genuine cancer risk. The DEHP NSRL is based on increased incidence of adenomas and carcinomas in the rat liver. Alternative analysis of the same animal data indicates the NSRL could be substantially higher, given the likely epigenetic mechanism of action, and still be health-protective. Given the stringent regulation of carcinogens by Cal-EPA, the risks from dietary and other background exposures are likely to be high relative to risks due to contaminated soil, water or other sources. We suggest that Cal-EPA and other regulatory agencies consider background concentrations while legislating and regulating chemicals. The recent EPA position on dioxin from incinerators using a Margin of Incremental Exposure Approach is a good starting point in this direction.

1601 RISK ASSESSMENT OF ATRAZINE, BENTAZON, DIBROMOCHLOROPROPANE, 1,2-DICHLOROPROPANE and 1,3-DICHLOROPROPENE FOR DETERMINATION OF CALIFORNIA PUBLIC HEALTH GOALS IN WATER.

R Tomar, D Rice, J Bankowska, J Polakoff, J Wisniewski, J Faust, M DiBartolomeis and A Fan. *California Environmental Protection Agency, Office of Environmental Health Hazard Assessment, Pesticide and Environmental Toxicology Section, Berkeley and Sacramento, CA.*

Derivation of proposed California Public Health Goals (PHGs) for atrazine, bentazon, dibromochloropropane (DBCP), 1,2-dichloropropane (1,2-DCP) and 1,3-dichloropropene (1,3-DCP) is described. Risk assessments on each pesticide estimated the concentrations in drinking water that would pose no significant health risk to individuals consuming the water daily over a lifetime. Critical studies were selected, and exposure scenarios, relative source contribution, and body weight were considered. The proposed PHGs are based on mammary tumors in rats for atrazine (0.15 ppb), reduced body weight, hematological changes and intestinal disturbances in dogs for bentazon (200 ppb), squamous cell carcinoma of the forestomach in mice for DBCP (1.7 ppt), hepatocellular adenoma and carcinoma in mice for 1,2-DCP (0.5 ppb), and bladder transitional cell carcinoma in mice for 1,3-DCP (0.2

ppb). The animal cancer potencies for atrazine, 1,2-DCP and 1,3-DCP were calculated by fitting the multistage model to the tumor incidence data and the lower 95% confidence limit on dose was used to estimate the 10% incidence. The cancer slope factors (CSFs) were calculated as $0.1/LED_{10}$. For DBCP, q1* was based on 95% upper confidence limit on the linear term (q1) calculated using the standard likelihood procedures. The PHG for bentazon was based on a non-cancer endpoint using the uncertainty factor approach.

1602 CALIFORNIA PUBLIC HEALTH GOALS FOR ENDRIN, HEPTACHLOR/HEPTACHLOR EPOXIDE, LINDANE, AND METHOXYCHLOR.

R Howd, J Brown, and L Jowa. *California Environmental Protection Agency, Berkeley and Sacramento, CA.*

The Office of Environmental Health Hazard Assessment conducted risk assessments to determine Public Health Goals (PHGs), based exclusively on public health considerations, for endrin, heptachlor/heptachlor epoxide, lindane, and methoxychlor. PHGs are concentrations of chemicals in water that are not expected to produce adverse effects in humans ingesting the water for a lifetime. In this process, published scientific studies as well as unpublished documents submitted for pesticide registration were reviewed. The rationale for the existing state and federal drinking water standards and current recommendations on risk assessment methods were also evaluated and considered. The proposed health-protective levels were peer reviewed and discussed in public workshops. The proposed PHG for endrin is 1.8 ppb based on convulsions and liver toxicity in dogs. The proposed PHGs for heptachlor and heptachlor epoxide are 0.008 and 0.006 ppb, respectively, based on mouse liver tumors. For lindane, the proposed PHG of 0.008 ppb is based on immunotoxicity in mice. The proposed PHG for methoxychlor of 30 ppb is based on reproductive system toxicity in female rats. Once adopted in December 31, 1998, the final PHG values are intended to guide California risk managers in establishing and interpreting state drinking water standards.

1603 CALIFORNIA PUBLIC HEALTH GOALS FOR CADMIUM, CHROMIUM, INORGANIC MERCURY AND THALLIUM.

L Jowa, D Morry, and J Polakoff. *California Environmental Protection Agency, Berkeley and Sacramento, CA.*

California Public Health Goals (PHGs) are concentrations of chemicals in water that are not expected to produce adverse effects in humans ingesting the water for a lifetime. The Office of Environmental Health Hazard Assessment conducted risk assessments to determine PHGs (based exclusively on public health considerations) for cadmium, chromium, inorganic mercury and thallium. In this process, current scientific literature was reviewed along with the documentation for the existing drinking water standards, and current recommendations on risk assessment methods were incorporated whenever applicable. The proposed health-protective levels were subjected to peer review and discussed in public workshops. The proposed PHG value for cadmium is 0.07 ppb based on renal tubular toxicity observed in an epidemiological study. Two PHG values were developed for chromium, 2000 ppm for trivalent chromium based on no effects seen in a chronic rat study, and 0.02 ppb for hexavalent chromium developed from evidence of carcinogenicity in female mice. For inorganic mercury, the proposed PHG of 1.2 ppb is based on renal pathology in a 6-month rat study. The proposed PHG for thallium of 0.02 ppb is based on lacrimation, exophthalmos, alopecia, and other changes to the coat and skin of rats. Once adopted in December 1998, the final PHG values are intended to guide California risk managers in establishing and interpreting state drinking water standards.

1604 CALIFORNIA PUBLIC HEALTH GOALS FOR 1,2-DICHLOROETHANE, 1,1-DICHLOROETHYLENE, HEXACHLOROCYCLOPENTADIENE, TOLUENE, 1,2,4-TRICHLOROBENZENE, AND TRICHLOROETHYLENE.

D Ting, J Brown, T Parker, J Polakoff, D Rice, and A Fan. *California Environmental Protection Agency, Office of Environmental Health Hazard Assessment, Berkeley and Sacramento, CA.*

The Office of Environmental Health Hazard Assessment conducted risk assessments to determine Public Health Goals (PHGs), based exclusively on public health considerations, for 1,2-dichloroethane, 1,1-dichloroethylene, hexachlorocyclopentadiene, toluene, 1,2,4-trichlorobenzene, and trichloroethylene. PHGs are concentrations of chemicals in water that are not expected to produce adverse health effects in humans using the water for drinking and other purposes for a lifetime. In this process, up-to-date scientific studies were critically reviewed and current risk assessment procedures were evaluated and applied. The proposed PHGs of 0.4 ppb for 1,2-dichloroethane and 0.8 ppb for trichloroethylene were based on cancers in rodents; they were developed considering the pharmacokinetic, metabolic, and other mechanistic data. The proposed PHGs for the other four chemicals were based on non-cancer endpoints in test animals; they were developed considering relative source contributions, exposure routes in addition to drinking water consumption, and interspecies as well as intraspecies variability. The proposed PHGs for 1,1-dichloroethylene, toluene, hexachlorocyclopentadiene, and 1,2,4-trichlorobenzene are 10, 150, 50, and 5 ppb, respectively. The proposed health-protective levels will be peer reviewed and discussed in public workshops. Once adopted on December 31, 1998, the final PHG values are intended to guide California risk managers in establishing and interpreting state drinking water standards.

1605 PRELIMINARY TOXICOLOGICAL EVALUATION OF POTENTIAL STAGE II DISINFECTION BY-PRODUCTS.

O Conerly. *USEPA, OST/OW, Washington, DC, USA.* Sponsor: C O Abernathy.

To control pathogens and prevent the spread of waterborne disease, water is treated with disinfectants. However, byproducts form when the disinfectant reacts with organic matter in water. Some disinfection byproducts have produced tumors or developmental effects in animals. In 1994, the Environmental Protection Agency (EPA) proposed regulations for a group of disinfectants and their byproducts (Stage I). These regulations are expected to be finalized by the end of 1998. The Stage I Disinfectant/Disinfection Byproducts Rule focused on total trihalomethanes, haloacetic acids and bromate. In preparation for Stage II, EPA collected toxicological data for thirteen other byproducts. Genotoxicity, systemic toxicity, carcinogenicity, mutagenicity, reproductive and developmental data were collected, analyzed and summarized for: acetaldehyde, bromoacetonitrile, bromochloroacetic acid, bromodichloroacetic acid, chlorate, cyanogen chloride, dibromoacetic acid, 1,1-dichloropropanone, glyoxal, hexachloropropanone, propanal and 1,1,1-trichloropropanone. There are data for positive genotox responses for 54% and data for 38% suggest potential for carcinogenicity. However, significant data gaps exist for the majority of the contaminants. (The opinions therein are those of the authors and do not necessarily reflect the opinions or policies of the EPA.)

1606 AMBIENT WATER QUALITY CRITERIA METHODOLOGY REVISIONS.

D R Borum, J Y Du, J M Donohue, Y M Patel, K G Sappington, R E Cantilli, C O Abernathy, W J Morrow, and S Gilbertson. *US EPA, Washington, DC.*

EPA published draft revisions to the Methodology for Deriving Ambient Water Quality Criteria (AWQC) for the Protection of Human Health pursuant to Clean Water Act requirements. States and Tribes may use the revised methodology to develop water quality standards. The revisions will substantially enhance science policy guidance for setting water quality criteria by incorporating scientific advances that have occurred during the past 18 years since the original guidance was published and, thus, increase the scientific defensibility of recommended criteria. It also provides more flexibility for decision-making at the State, Tribal and EPA Regional level. EPA is promoting greater involvement by States and Tribes in making risk assessment decisions and in adapting criteria to local conditions. The revisions recommend consideration of the Agency's guidance on assessing noncarcinogenic effects of chemicals, including integrating reproductive/developmental, immunotoxicity, and neurotoxicity data. EPA also recommends the use of quantitative dose-response modelling for RfD derivations. For cancer risk assessments, more sophisticated methods to comprehensively determine the likely mechanism that causes human carcinogenicity are recommended, consistent with EPA's 1996 proposed revised cancer guidelines. In the area of exposure assessment, the use of local studies on fish consumption is encouraged and EPA provides default values for the general population, recreational fishers and subsistence fishers. The methodology can also account for other sources of exposure when setting criteria to ensure that an individual's total exposure does not exceed a threshold level. The revisions also emphasize the use of bioaccumulation factors for estimating potential exposure to contaminants via the consumption of contaminated fish and shellfish, since they reflect the accumulation of chemicals by aquatic organisms from all surrounding media (water, food, sediment).

1607 PATHOGENICITY OF MAN-MADE VITREOUS FIBERS AFTER LONG-TERM INHALATION.

O Kamstrup[1], J M G Davis[2], A Ellehauge[1], E E McConnell[3], and J Chevalier[4]. [1]*Rockwool International A/S, Hedehusene, Denmark;* [2]*Institute of Occupational Medicine, Edinburgh, Scotland;* [3]*ToxPath, Inc., Raleigh, NC, USA;* [4]*Experimental Pathology Services, Muttenz, Switzerland.*

A summary is given of the pathology results after long-term inhalation in rats of a newly developed man-made vitreous fiber, MMVF 34 (HT stone wool), and the pathology results were compared with previously conducted long-term inhalation study with MMVF 21 (traditional stone wool). MMVF 34 is characterized by a relatively high content of aluminum, and a relatively low content of silica compared to MMVF 21. With regard to in-vitro dissolution rate measurements, MMVF 34 has a high dissolution rate at pH 4.5, and a relatively low dissolution rate at pH 7.5. Laboratory rats were exposed at one exposure level of 30 mg/m^3 by nose-only inhalation to a well-characterised fiber test atmosphere that had been selected to be largely rat respirable. The negative control group was filtered air. The exposure duration was 6 hours/day, 5 days/week for 104 weeks, with a subsequent non-exposure period lasting until approximately 20% survival in one of the groups. Interim sacrifices were performed at weeks 13, 26, 52, 78, and 104. Biopersistence was determined after 26, and 52 weeks exposure. Effectively the main protocol for the previously conducted chronic study with MMVF 21 was the same, except that there were three fiber exposure groups (3, 16, and 30 mg/ m^3). The incidence of proliferative lesions for the MMVF 34 fiber was comparable to the control group, which corresponds to the results from the long-term study with MMVF 21. However, MMVF 21 was more inflammatory than MMVF 34, and resulted in Wagner grade 4 fibrosis.

1608 EFFECTS OF 2-YEAR INHALATION EXPOSURE TO GLUTARALDEHYDE IN RATS AND MICE.

A P J M van Birgelen[1], B J Chou[2], R A Renne[2], S L Grumbein[2], J Roycroft[1], R Hailey[1], and J R Bucher[1]. [1]*NIEHS, Research Triangle Park, NC;* [2]*Battelle Northwest, Richland, WA.*

Whole-body inhalation toxicology and carcinogenicity studies were performed with the widely used fixative and cold-sterilant glutaraldehyde. Groups of 50 male and female F344/N rats and B6C3F1 mice were exposed to glutaraldehyde (rats: 0, 250, 500, and 750 ppb; mice: 0, 62.5, 125, and 250 ppb) for 6 hours/day, 5 days/week, and 104 weeks. Concentrations were based on results of 13-week studies. Survival of 500 and 750 ppb female rats was less than that of controls. Mean body weights of all exposed groups of male rats, 500 and 750 ppb female rats, and 250 ppb female mice were generally less than those of controls. No exposure-related neoplastic lesions were observed in either rats or mice. Exposure-related non-neoplastic lesions were limited to the nasal cavity and primarily to the most anterior region. In rats, hyperplasia and inflammation of the squamous epithelium; hyperplasia, goblet cell hyperplasia, inflammation, and squamous metaplasia of the respiratory epithelium; and hyaline degeneration of the olfactory epithelium were observed. In mice, the nasal lesions were quantitatively similar to those in rats. Squamous metaplasia of the respiratory epithelium was observed in both sexes of mice while female mice also had inflammation and hyaline degeneration of the respiratory epithelium. The toxicity of glutaraldehyde prevented the use of exposure concentrations compared to those which induced nasal cavity tumors with formaldehyde. However, exposure to glutaraldehyde resulted in considerable non-neoplastic lesions in the nose of rats and mice.

1609 HIGH DOSE EXPOSURE TO DINITROTOLUENE ASSOCIATED WITH CARCINOGENIC EFFECTS IN HUMANS?

T Bruening[1], C Chronz[1], R Thier[1], H M Bolt[1], H Vetter[2], and Y Ko[2]. [1]*Institute of Occupational Physiology at the University of Dortmund, Germany;* [2]*Medical Policlinic, University of Bonn, Germany.*

Dinitrotoluene (DNT) is suspected to be carcinogenic in humans. It is toxicologically closely related to aromatic amines, which may cause urothelial cancer. In order to investigate possible carcinogenic effects of technical DNT (t-DNT) we carried out a retrospective cohort study in miners with high exposure to explosives containing t-DNT. 14 kidney tumour cases and 6 urothelial tumour cases could be identified among 500 miners formerly exposed to t-DNT out of a total group of 3000 underground miners. A representative cohort of 183 workers with former occupational contact with t-DNT was interviewed and divided into 4 exposure categories. All identified tumour patients were genotyped by PCR of lymphocytic DNA regarding NAT2, GSTM1 and GSTT1. Genomic DNA of pathological tumour tissue was isolated and submitted to sequential analysis within the p53 gene (exon 5-8). The categorization of the 14 kidney tumour cases revealed no dose-dependent distribution over the 4 exposure categories, whereas the urothelial tumour cases were mainly found within the „high" and „very high" exposure categories. Genotyping of the tumour patients showed no remarkable distribution except for the urothelial tumour cases which were exclusively identified as „slow acetylators". Preliminary results of the p53 mutational analysis are a high mutation frequency (detection of missence mutations in all 6 urothelial cancer cases, among them 2 double mutations). Identified mutations were almost exclusively G>A transitions, which also have been reported in urothelial tumours from workers highly exposed to aromatic amines. Our findings corraborate the suspicion of a carcinogenic effect of t-DNT with regard to the human urothelium.

1610 MATHEMATICAL MODEL OF EFFECTS OF CARCINOMAS ON AIRFLOW PATTERNS IN THE LUNGS OF CHILDREN.

M Shearer[1], R A Segal[1], and T B Martonen[2]. [1]*North Carolina State University, Raleigh, NC, USA;* [2]*US EPA, ETD, NHEERL, Research Triangle Park, NC, USA.* Sponsor: D L Costa.

We investigated how tumors within lungs affect airflow patterns. In particular, we were interested in how tumor characteristics (i.e., sizes and locations) and ventilatory parameters (i.e., breathing rates and tidal volumes) influenced (1) bulk flow distribution within the lung and (2) localized velocity profiles within airways. We employed a computational fluid dynamics (CFD) package, FIDAP, to define flow conditions within lungs. Our model is based on the adult airway network proposed by Weibel, but scaled to be appropriate for a four-year-old child. Original physiologically realistic skewed velocity profiles were developed in our work. When a tumor was sufficiently developed (r/D > .4, where r=tumor radius and D=airway diameter), maldistribution of flow occurred (i.e., flow was directed away from the region containing the tumor). When the inspiratory flow rate was increased, these tumor effects were enhanced. At increased respiratory intensities, localized circulation currents developed downstream from the tumors. This work indicates that inhaled particle deposition is complicated by the existence of tumors but that the effects are systematic and predictable and therefore can be integrated into drug delivery protocols for the treatment of lung cancers. Disclaimer: This is an abstract of a proposed presentation and does not necessarily represent EPA policy. (Acknowledgements: RAS is funded by the NCSU/EPA Cooperative Training Program in Environmental Sciences Research, Training Agreement CT826512010 with NCSU.)

1611 CARCINOGENICITY OF INHALED BUTADIENE DIEPOXIDE.

R F Henderson, F F Hahn, M G Ménache, E B Barr, S A Belinksy, and J M Benson. *Lovelace Respiratory Research Institute, Albuquerque, NM, USA.*

The greater sensitivity of mice to 1,3-butadiene (BD) may result from mice metabolizing more of the BD to butadiene diepoxide (BDO_2) than rats. Female B6C3F$_1$ mice and Sprague-Dawley rats, 10-11 weeks old, 56/group, were exposed by inhalation to 0, 2.5, or 5.0 ppm BDO_2, 6 hrs/day, 5 days/wk for 6 wks to compare tumor incidence between mice and rats under identical exposure conditions. Previous studies in rodents indicated that blood levels would be ~100 and 200 pmole/g at the two exposure concentrations in the rat and twice those levels in the mouse. During the last week of exposure, the 5 ppm mice showed signs of labored breathing, and 4 died; the respiratory symptoms disappeared after exposures ended. Rats showed no clinical signs of toxicity during exposure, but developed labored breathing after the exposure leading to the death of 13 rats in 3 mos. At the end of the exposure, necrosis, inflammation, squamous metaplasia of the nasal mucosa, and atrophy of the turbinates were present in both species. Within 6 mos, necrosis and inflammation had subsided, but squamous metaplasia remained. In rats, squamous metaplasia extended beyond the areas of earlier inflammation with time. At the end of 18 mos, there was a dose-dependent increase in neoplasms of the nasal mucosa in the rat (0/47, 12/48, and 21/48 for the control, 2.5 ppm, and 5.0 ppm exposures, respectively), but not in the mice. Neoplastic lesions in the mice occurred in reproductive organs, lymph nodes, bone, liver, Harderian gland, and pancreas. Although there was a statistically significant increase in total neoplastic lesions as a function of dose (10/40,

7/42, and 16/36 for control, 2.5 ppm, and 5.0 ppm, respectively), there were no increases in any individual organ except the Harderian gland (0/44, 2/44, and 5/41). These findings indicate that BDO_2 is carcinogenic in the upper respiratory tract of rats. The lack of respiratory tract tumors in mice suggests that the site of formation of BDO_2 from BD is an important factor in the tumorogenicity of BDO_2 in mice. (Research supported by the Health Effects Institute, DE-FI04-95AL86988.)

1612 MOLECULAR DOSIMETRY OF N-7-GUANINE DNA ADDUCT FORMATION IN MICE AND RATS EXPOSED TO 1,3-BUTADIENE.

H Koc[1], N Y Tretyakova[1], V E Walker[2] and J A Swenberg[1]. [1]*Department of Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC and* [2]*New York State Department of Health, Albany, NY, USA.*

The molecular dosimetry of N-7 guanine adducts was studied in B6C3F1 mice and F344 rats exposed to 0, 20, 62.5, or 625 ppm of 1,3-butadiene (BD) for 4 weeks. The adducts, racemic and meso form of *N*-7-(2,3,4-trihydroxy-but-1-yl)-guanine (THB-Gua), *N*-7-(2-hydroxy-3-buten-1-yl)-guanine (EB-Gua I), *N*-7-(1-hydroxy-3-buten-2-yl)-guanine (EB-Gua II), were quantitated by LC/ESI+/MS/MS. THB-Gua adducts were more abundant (6-27 times) than the EB-Gua adducts in rats and mice. Liver, lung and kidney had similar numbers of adducts, with THB-Gua adducts (/10^6 guanine) of 6.3±1.2, 8.2, and 5.0±1.2 in mice exposed to 20 ppm BD and 5.5±1.1, 3.8±0.7 and 3.7±0.1 in rats, respectively. EB-Gua was 0.3, 0.8 and 0.4±0.2 in mice and 0.3, 0.5 and 0.3±0.2 in rats, respectively. THB-Gua was 15.4±1.2, 13.7±3.6 and 16.2±3.0 in mice exposed to 62.5 ppm BD and 13.7±3.3, 7.7±0.6 and 7.5±3.7 in rats. EB-Gua was 0.3±0.1, 0.5±0.3 and 0.6±0.2 in mice and 0.8±0.6, 0.3±0.2 and 0.5±0.1 in rats exposed to 62.5 ppm BD, respectively. Following exposure to 625 ppm BD, mice had 64.1±6.1, 59.1±8.2 and 62.5±13.9 THB-Gua, while rats had 11.8±6.6, 13.0±2.3 and 16.6±2.9, respectively. EB-Gua values in 625 ppm mice were 5.4±0.3, 3.6±0.5 and 3.7±0.6, while rats had 2.1±1.0, 2.1±0.5 and 2.9±0.7, respectively. EB-Gua adducts had a linear dose response relationship in both species, whereas THB-Gua adduct formation was supralinear. The THB-Gua data demonstrate that saturation of metabolic activation occured at 62.5 ppm in rats, while mice reached saturation at higher exposures. Assuming proportionality between tissue 3,4-epoxybutene and EG-Gua and between 1,2,3,4-diepoxybutane (DEB) and the fraction of THB-Gua adducts arising from DEB, we conclude that most of the THB-Gua adducts are formed by 1,2-epoxy-3,4-butanediol. This electrophilic metabolite has not been measured *in vivo*.

1613 ANALYSIS OF MUTATIONS IN *HPRT* cDNA OF SPLENIC T-LYMPHOCYTES FROM MICE EXPOSED BY INHALATION TO 1,3-BUTADIENE.

Q Meng[1], T Chen[2], R H Heflich[2], and V E Walker[1]. [1]*Wadsworth Center, New York State Department of Health, Albany, NY, USA;* [2]*National Center for Toxicological Research, Jefferson, AR, USA.*

Experiments were conducted to define mutations occurring in the *Hprt* gene of T-cells in female mice exposed for 4 weeks (6 hr/day, 5 days/week) to BD (625 ppm). In mice necropsied at 6 weeks post exposure, *Hprt* mutant frequencies (M/s) in exposed animals were 4.1-fold greater than control values. *Hprt* mutant colonies were expanded to ≥ 400,000 cells and analyzed by RT-PCR to produce *Hprt* cDNA for sequencing. To date, 47/52 *Hprt* mutant clones from BD-exposed mice were found to have mRNA by RT-PCR of β-actin. No *Hprt* cDNA was produced in 15 of these 47 mutants (32%), presumably due to whole gene deletions. The remaining mutations were base substitutions (12/47, 26%), internal exon deletions (10/47, 21%), frameshifts (9/47, 19%), and one complex mutation (2%). The base substitutions included 3 AT → CG transversions, 8 GC → AT transitions, and one GC → TA transversion. Additional mutants from control and BD-exposed mice are being analyzed; nonetheless, the M/ values suggest that about 75% of the mutations in exposed mice should be BD-induced. These preliminary data from BD-exposed mice suggest that the carcinogenicity of BD in the mouse may be more related to the production of large scale DNA damage than to the induction of point mutations. (Supported by Health Effects Institute and NIH grants.)

1614 LOSS OF DIFFERENTIATION IN THE PHENOTYPICALLY ALTERED PROGENY OF ALPHA-PARTICLE-EXPOSED NORMAL HUMAN BRONCHIAL EPITHELIAL CELLS.

C H Kennedy[1], J Tesfaigzi[2], and J F Lechner[3]. [1]*Biodynamics Institute & School of Veterinary Medicine, Louisiana State University, Baton Rouge, LA, USA;* [2]*Lovelace Respiratory Research Institute, Albuquerque, NM, USA;* [3]*Karmanos Cancer Institute, Wayne State University, Detroit, MI, USA.* Sponsor: V L Wilson.

Pulmonary deposition of alpha-particle-emitting radon daughters is estimated to account for 10% of all lung cancer deaths in the USA. However, the nature and timing of early (preneoplastic) genetic alterations in radon-associated lung cancer are still relatively uncertain. We have previously shown that exposure of normal human bronchial epithelial (NHBE) cells to fractionated doses of ^{238}Pu alpha-particles results in the formation of foci of phenotypically altered cells (PACs) (Kennedy et al. Carcinogenesis 17: 1671, 1996). Although these PAC cultures are not immortalized, they do exhibit an extended population-doubling potential relative to unexposed NHBE cells. The purpose of the current investigation was to determine if these PACs exhibit altered responsiveness to differentiation-inducing signals. Retinoic acid (RA)-deficiency induces squamous terminal differentiation in NHBE cells; therefore, we compared the effect of RA-deficiency on NHBE cells and PACs by measuring the expression of three genes involved in differentiation: bcl-2, p21 (WAF1/CIP1) and small proline-rich protein (SPR1). The results of Northern and Western analyses showed no significant difference between cell phenotypes with regard to expression of either bcl-2 or p21 in PACs. However, SPR1 mRNA and protein levels were significantly lower in the PACs relative to NHBE cells. These data suggest the following: 1) SPR1 expression is uncoupled from RA regulation in PACs; and 2) this uncoupling occurs via a mechanism that is independent of bcl-2 and p21 expression. Because altered control of differentiation is a hallmark of lung cancer cells, elucidation of the mechanism by which PACs fail to induce SPR1 following RA deprivation should provide insight into the early genetic changes that occur during the development of radon-associated lung cancer.

1615 THE EFFECT OF TRICHLOROETHYLENE CARCINOGENIC METABOLITES, TRICHLOROACETIC ACID (TCA) AND DICHLOROACETIC ACID (DCA), ON PEROXISOMAL ENZYME ACTIVITY AND DNA SYNTHESIS IN CULTURED HUMAN LIVER CELLS.

J L Everhart, D T Kurtz, and J M McMillan. *Department of Pharmacology, Medical University of South Carolina, Charleston, SC.*

Trichloroethylene (TCE), a common environmental contaminant, causes hepatocarcinoma in the $B6C3F_1$ mouse. The hepatic neoplasia is species and strain specific; the risk to humans is not yet defined. TCE and its metabolites, trichloroacetic acid (TCA) and dichloroacetic acid (DCA) are considered epigenetic carcinogens. Hepatic tumors are thought to arise directly as a result of excessive peroxisome-dependent active oxygen production or secondary to enhanced cell replication. We have previously demonstrated the peroxisome proliferative activity of TCA and DCA in mouse and rat hepatocytes in vitro. The current studies are aimed at isolating and characterizing human hepatocyte cultures, and subsequently studying the effects of TCA, DCA, and classic peroxisome proliferators such as clofibrate or WY-14,643, on peroxisomal function, DNA synthesis, and cell replication in human liver cell cultures. Both human primary and long-term cell cultures were characterized for liver-specific functions and used to study the potential of TCA and DCA to induce peroxisomal enzymes and modulate DNA synthesis/cell replication. For peroxisomal studies, cells were kept in serum-free medium and treated for 72 hours with either 0.5 mM clofibrate or 5 μM WY-14,643, 0.5-2 mM TCA, and 0.5-2 mM DCA. Peroxisome proliferation was assessed by measuring palmitoyl-CoA oxidation, selective staining for catalase activity, and Northern blot analysis of peroxisomal enzymes. Cultured human liver cells do not appear to be sensitive to clofibrate-, WY-14,643-, TCA-, or DCA-induced peroxisome proliferation. For DNA synthesis/cell replication studies, cells were kept in growth factor-free, serum-free medium for 24 hours before treatment with epidermal growth factor (EGF;positive control), 5 μM WY-14,643, 0.01-1 mM TCA, or 0.01-1 mM DCA. The cultured human liver cells did not display an increase in either ^{3}H-thymidine incorporation or cell number following treatment with WY-14,643, TCA, or DCA. The comparison of these human hepatocyte experiments to similar rodent hepatocyte studies can lead to a better assessment of the potential risk of TCE exposure in humans.

1616 IS PERCHLOROETHYLENE (PERC) A PROBABLE CARCINOGEN IN HUMANS?

L A Beyer[1], B D Beck[1], W E Maier[2]. [1]*Gradient Corporation, Cambridge, MA, USA;* [2]*Parke-Davis Pharmaceutical Research, Ann Arbor, MI, USA.*

Classification of perc as a probable human carcinogen by EPA is primarily based on positive findings in rats and mice in cancer bioassays. In human populations, positive findings have been inconsistent, even in populations receiving the highest exposures to perchloroethylene - drycleaners. To resolve this discrepancy, we evaluated species differences in type of cancer (*i.e.*, liver cancer in mice and kidney cancer in rats), and linked cancer site to species differences in perc metabolism. In mice, perc is metabolized to trichloroacetic acid, resulting in peroxisome proliferation, which in turn leads to hepatic cancer. Peroxisome proliferation is the result of a gene recently discovered to be specific to mice. In rats, peroxisome proliferation does not occur, so hepatic tumors are not observed in rats. In rats, metabolism of perc *via* the glutathione pathway results in byproducts that result in kidney cancer, an endpoint not observed in mice, which do not metabolize perc *via* the glutathione pathway. Humans, like mice, do not metabolize perc *via* a glutathione pathway, and unlike mice do not exhibit peroxisome proliferation. Therefore there is no metabolic basis for perc-induced cancer in humans. These findings are consistent with those observed in epidemiology studies in populations most exposed to perc (*e.g.*, drycleaners), which show inconsistent increases in certain types of cancers. However these cancers are known to be associated with confounders (*e.g.*, smoking, alcohol consumption, income), that could not be evaluated in the studies. Based on this analysis, we conclude that perc is not likely to be a human carcinogen.

1617 HEALTH RISK ASSESSMENT/CHARACTERIZATION OF THE DRINKING WATER DISINFECTION BYPRODUCT CHLOROFORM.

M L Dourson and L Haber. *Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH.*

Chloroform causes the development of cancer in several animal species by a mechanism that is believed to be non-linear in the low dose range, and a Margin of Exposure (MOE)-based dose of 0.02 mg/kg-day is proposed. Although chloroform will likely be carcinogenic to humans by all routes of exposure if a sufficient dose is administered, human data are insufficient to determine chloroform's potential carcinogenicity. Experimental animal studies are somewhat variable in both tumors evoked and magnitude of response. The principal studies for the determination of chloroform's tumorigenic effect and low dose extrapolation are NCI (1976) and EPA sponsored Jorgenson et al. (1985) in the Osborne-Mendel rats. Both linear and nonlinear approaches to the assessment of chloroform's cancer risk are presented, with emphasis on the nonlinear approach as being more relevant for chloroform, based on the substantial amount of data from oral and inhalation studies in rats and mice that cytotoxicity is necessary, although not sufficient, for chloroform carcinogenesis. For noncancer toxicity the use of the existing Reference Dose (RfD) of 0.01 mg/kg-day is proposed. This RfD is based on a Lowest-Observed-Adverse-Effect Level (LOAEL) for minimal liver injury of 15 mg/kg/day identified in a 7.5-year study in dogs (Heywood et. al., 1979). The critical study was of chronic duration, used a fairly large number of dogs, and measured multiple endpoints. Confidence in critical study is considered medium, and in its supporting database is considered medium to low. Overall confidence in the RfD is also considered medium to low, meaning that additional data may more likely change the value of the RfD when compared to a high confidence RfD.

1618 EXPOSURE OF JAPANESE MEDAKA (ORYZIAS LATIPES) EMBRYOS TO BENZENE, CHLOROFORM, AND BROMOFORM FOR ASSESSMENT OF CARCINOGENIC POTENTIAL.

W R Hartley[1], A Thiyagarajah[1], L K Teuschler[2], C Gennings[3], and C Cubbison[2]. [1]*Tulane University Medical Center, New Orleans, LA;* [2]*NCEA, U.S.EPA, Cincinnati, OH;* [3]*MCV, VCU, Richmond, VA.* Sponsor: J C Lipscomb.

Validation of *in vivo* short-term bioassays for screening chemicals such as disinfection by-products for carcinogenic potential using alternative species such as the medaka is needed for risk assessment. In this research, embryos in the 64 cell to early high blastula stage (critical period of embryogenesis) were exposed in groups in sealed vials for ten consecutive days to varying concentrations of benzene (0-150 mg/L), chloroform (0-100 mg/L) and bromoform (0-50 mg/l). After exposure, the embryos were washed in embryo rearing solution, grown-out for six months and one-year post hatch, and evaluated histologically. In the benzene study, at six months hepatic preneoplastic lesions included basophilic, eosinophilic, and clear cell foci. After one year the combined incidence of neoplasms in the liver (adenoma and cholangioma) increased with increasing concentration. There was one case of cholangioma in the controls. The one-year tumor incidence for benzene fit a linearized multistage model. In the chloroform studies, based on evaluation of 1/3 of the fish (20/60 per dose) at six-month, there were no neoplasms noted. Preneoplastic lesions included one case of clear cell foci in the highest exposure concentration. Non-neoplastic lesions in the liver included cysts. In the bromoform studies, based on evaluation of 1/3 of the fish (20/60 per dose) at six-months, one case of cholangioma was observed in the high concentration. Preneoplastic lesions including hepatic clear cell and altered foci were observed at 10 mg/L and 50 mg/L of bromoform. Non-neoplastic lesions observed in animals exposed to bromoform include hepatic cysts, spongiosis hepatis and cystic bile duct. Complete data on chloroform and bromoform exposed fish will be presented. These initial results indicate that a medaka embryo exposure method may be useful for efficient screening of chemicals for carcinogenic potential and other applications in risk assessment. (Abstract may not reflect U.S. EPA policy). (Funded in part by USEPA Cooperative Agreement.)

1619 THE INDUCTION OF ABERRANT CRYPT FOCI (ACF) IN THE COLONS OF RODENTS ADMINISTERED TRIHALOMETHANES (THMs) IN THE DRINKING WATER.

A B DeAngelo and M H George. *USEPA, NHEERL, Research Triangle Park, NC, USA.*

THMs administered by corn oil gavage increased cancer in various target organs of rodents. Among these, bromodichloromethane (BDCM) enhanced large bowel tumor incidence in both male and female F344 rats. Our recently completed 2-year bioassay for BDCM in the drinking water of male F344 rats failed to demonstrate large bowel tumor induction (manuscript in preparation). The objective of this study was to evaluate the ability of BDCM in the drinking water to induce ACF in the colons of male F344 rats and B6C3F1 mice. Chloroform (TCM), dibromochloromethane (DBCM), and bromoform (TBM) were also examined. Rats and mice (N=6) were given deionized water containing 0.25% emulphor and isomolar THM concentrations of 0.5 g/l TCM, 0.7 g/l BDCM, 0.9 g/l DBCM, and 1.1 g/l TBM for 13 weeks. Azoxymethane (AOM, 30 mg/kg ip) was the positive control; emulphor and deionized water served as controls. ACF incidences (percent) and number (foci/colon±SEM) in rat colons were: emulphor and water controls (0), AOM (100%; 41.3±14.3), TCM (17%; 0.2±0.2), BDCM (83%; 1.5±0.6), DBCM (50%; 1.2±0.7), and TBM (67%; 1.2±0.4). BDCM, DBCM, and TBM significantly ($p \leq 0.05$) increased ACF above the water and emulphor values. ACF (86-100%) occurred in the rectal 1/3 of the colon (segment 3). These studies demonstrate that brominated THMs given via drinking water induce ACF in the colon of rats though the preneoplastic lesions do not appear to progress to cancer at least in the case of BDCM. The effect of dietary fat and other promoting regimens are being investigated. No ACF in the mouse colon were observed for any of the THMs. (*This abstract does not necessarily reflect the opinion of the USEPA.*)

1620 AN EVALUATION OF THE POTENTIAL CARCINOGENICITY OF DICHLORVOS (DDVP): FINAL REPORT OF THE EXPERT PANEL.

B M Wagner[1], B K Bernard[2], S Cohen[3], C Weil[4], J I Goodman[5] and L McKinney[6]. [1]*New York Univ., NY, NY, USA;* [2]*SRA Intl. Inc., Wash., DC, USA;* [3]*Univ. Neb Med. Cntr, Omaha, NE, USA;* [4]*retired, Pittsburgh, PA, USA;* [5]*Mich. St. Univ., E. Lansing, MI, USA;* [6]*Armed Forces Institute of Pathology, Washington, DC, USA.*

An Expert Panel was convened to evaluate the results of the large database of cancer studies available on DDVP. The Panel included biochemical & genetic toxicologists, animal & human pathologists, molecular biologists, oncologists, and physicians. Using the weight-of-the evidence the Panel made the following conclusions: -The only endpoint currently given any consideration by regulatory agencies is monocellular leukemia (MCL) in the Fischer 344 rat. MCL is species-, strain- and in the case of DDVP, sex- specific. It is not an appropriate endpoint to estimate potential risk to humans. - The incidence of MCL (NTP, 1989) does not support a conclusion of carcinogenicity in part because 1) corn oil gavage was a confounder, 2) DDVP did not alter the relative severity of the disease, time-to-tumor latencies or percentage of rats surviving to study termination, 3) there was no dose-

response, 4) the results are not replicated in a very large number of carcinogenicity studies, 5) inhalation and/or drinking water are more appropriate routes than gavage for estimating human risk, and 6) the incidences are similar to normal background rates that are increasing over time. -Other potential carcinogenic endpoints provided neither substantive evidence of carcinogenicity in the rat or the mouse; nor were they useful for extrapolation to human risk. -DDVP is not a direct-acting, genotoxic carcinogen. -Based upon these data, the Panel concluded it is unlikely that DDVP poses a carcinogenic risk to humans.

1621 ALIETTE: AN EXAMPLE OF THE USE OF MECHANISTIC DATA IN THE CARCINOGENIC CLASSIFICATION.

G J Burin[1], R Hill[2] and W Phang[2]. [1]*Technology Sciences Group, Inc., Washington, DC;* [2]*OPPTS, US Environmental Protection Agency, Washington, DC.*

Aliette, a fungicide compound, was re-evaluated for carcinogenic potential by the Environmental Protection Agency's Office of Pesticide Programs Cancer Peer Review Committee taking into consideration mechanistic and other information bearing upon the relevance of the tumor findings in rodents to man. Aliette is not genotoxic and the primary urinary metabolite of aliette, monosodium phosphite, is not carcinogenic when administered in the diet to rats. Tumor induction is not observed at any site in mice. However, the induction of transitional cell urothelial tumors (papillomas and carcinomas) is observed in male rats after chronic dietary administration of aliette at a concentration of 30000/40000 ppm. Humans are not likely to be exposed to levels of the chemical that produce the urinary tract response that was determined to be a required precursor of the carcinogenicity. It also appears that the human bladder may be less sensitive than that of the rat to the carcinogenic stimulus. Anatomical, biochemical and physiological factors cause to male rat to be unusually sensitive to this form of tumor induction. The OPP Cancer Peer Review committee concluded that aliette is unlikely to pose a carcinogenic hazard to humans under the anticipated conditions of exposure. The conclusions of the EPA re-evaluation are consistent with the general approach to the use of mechanistic data that is proposed in the 1996 draft EPA Carcinogen Risk Assessment Guidelines and is exemplary of the use of the new guidelines.

1622 THE KEY RISK FACTORS IN DICHLOROMETHANE CARCINOGENICITY.

P J Sherratt[1], T Green[2] and J D Hayes[1]. [1]*Biomedical Research Centre, University of Dundee, Ninewells Hospital and Medical School, Dundee, Scotland, UK;* [2]*Zeneca Central Toxicology Laboratories, Macclesfield, England.* Sponsor: E Lock.

The inter-species differences in sensitivity to the carcinogenic effects of dichloromethane (DCM) has been a challenging issue to toxicologists for over a decade. Following exposure to DCM, there is an increase in liver and lung tumours in mice but not in rats or hamsters. The enzyme responsible for the activation of DCM is class Theta glutathione S-transferase T1-1 (T1). In this study the activity, expression levels and localisation of the mouse and human homologues were compared. Heterologously expressed native mouse and human T1 were purified and the activity towards DCM shown to be 1.8 fold higher with the mouse transferase. Immunoblotting of hepatic extracts using antibodies raised against human T1 demonstrated that mice express two orders of magnitude greater levels of T1 than humans. The tissue distribution of T1 in mice and humans was also compared. Interestingly, it was noted that the mouse kidney had similar levels of expression to the liver and lung, however this is not a DCM target organ. Immunohistochemical analysis demonsatrated that T1 is frequently present in the nuclei of certain mouse liver and lung cells but not in kidney cells. In comparison with human tissue a number of hepatocytes were observed that had the presence of T1 in the nucleus. In summary, humans express lower levels of an enzyme that has less activity towards DCM than the mouse. Nuclear localisation of the enzyme appears to be the major risk factor associated with DCM carcinogenicity. Since the human enzyme may be localised in the nucleus of certain cells, there is a finite carcinogenic risk associated with human exposure to DCM.

1623 THE EFFECTS OF AD LIBITUM (AL) OVERFEEDING AND MODERATE OR MARKED DIETARY RESTRICTION (DR) ON BODY WEIGHT, CARCASS COMPOSITION, CLINICAL PATHOLOGY, AND DEGENERATIVE LESIONS IN CD-1 MICE.

J B Coleman[1], K P Keenan[1], C L Baldwin[1], K A Soper[1], C-M Hoe[1], G Ballam[2], and R Dixit[1]. [1]*Merck Research Laboratories, Department of Safety Assessment, West Point, PA,* [2]*Purina Mills Inc., St. Louis, MO.*

Two 3-month studies were conducted with single-housed Charles River CD-1 mice (40/sex/group) to evaluate the effects of Purina (PMI) Rodent Chow (precision particles) fed AL or at moderate (70-75% of AL) or marked (50% of AL) DR to select appropriate measured feeding regimens for toxicity/carcinogenicity studies. As expected, body weight gain and body fat were proportional to food consumption. Average food intake and body weight were significantly different between and within most female and male groups. Food wastage was approximately 7-11% for each group. The mice in the marked DR group had transient paleness, tail tip necrosis, were cool to the touch, and had slight decreases in erythroid parameters and total leukocyte counts, compared to the AL and moderate DR groups. The marked DR group had lymphoid depletion in the thymus and hypoplastic ovaries and uteri that were not observed in the other groups. However, the lowest incidence of all other degenerative lesions was seen in the marked DR group, and the highest incidence and severity was seen in the AL group. No diet-related adverse changes in clinical signs, serum biochemical or hematologic parameters were observed in the moderate DR groups. The AL group had the highest hepatic oxidative stress (lipid peroxidative damage with low antioxidative capacity) which was significantly decreased by dietary restriction. The moderate (70-75% AL) DR groups did not have the adverse findings of the marked (50% AL) groups, but did have decreases in degenerative lesions seen in the AL groups. These data indicate that moderate DR (70-75% of AL) under single housing conditions is optimal for CD-1 mouse toxicity and carcinogenicity testing.

1624 CHRONIC TOXICITY OF N-METHYL-PYRROLIDONE (NMP) IN A TWO-YEAR FEEDING STUDY WITH RATS.

L A Malley[1], G S Elliott[1], T W Slone[1], G L Kennedy[1], R J Parod[2], T J McCarthy[2], J C Griffiths[2]. [1]*The DuPont Co., Haskell Laboratory for Toxicology and Industrial Medicine, Newark, DE, USA;* [2]*The NMP Producer's Group, Washington, DC, USA.*

The toxicity and potential oncogenicity of NMP was evaluated by administration of diets containing 0, 1600, 5000, or 15000 ppm NMP to Crl:CD®BR male and female rats for approximately 2 years. Body weights were determined weekly for the first 3 months, and every other week thereafter. Food consumption was determined at the time of weighing. At 12, 18, and 24 months, blood samples were collected for determination of leukocyte differential counts. A morphological evaluation was conducted at the end of the 2-year feeding period. NMP was not oncogenic in males or female at 15000 ppm or below. Decrements in body weight and weight gain occurred in 15000 ppm males and females, which correlated with decrements in food consumption and food efficiency. Survival was decreased in 15000 ppm males compared to control males due to an increased incidence of severe chronic progressive renal nephropathy. Although chronic progressive nephropathy is a common, age-related lesion in this rat strain, administration of NMP exacerbated the severity of the lesion in 15000 ppm males. There were no adverse test substance-related effects on clinical observations, ophthalmic observations, or differential leukocyte counts in males or females, or on female survival and tissue morphology at any dietary concentration. The NOEL was 5000 ppm for males and females.

1625 A 24-MONTH DIETARY CARCINOGENICITY AND TOXICITY STUDY OF MICROENCAPSULATED METHYL BROMIDE IN SD RATS.

J J W M Mertens[1], D A Banas[2], S A Lewis[3] and V J Piccirillo[4]. [1]*WIL Research Laboratories, Inc., Ashland, OH, USA;* [2]*Experimental Pathology Laboratories, Inc., Herndon, VA, USA,* [3]*Chemical Manufacturers Association, Arlington, VA, USA;* [4]*NPC, Incorporated, Sterling, VA, USA.*

Methyl bromide (MeBr), an important soil fumigant, has been studied extensively. However, there was no acceptable rodent chronic toxicity study using an oral route of exposure that does not involve bolus dosing. Thus, in the current dietary study microencapsulated MeBr was used. Test diets containing 0.5, 2.5, 50 and 250 ppm MeBr and control diets containing placebo

microcapsules or basal diet were offered daily. Each group consisted of 70 Crl:CDR(SD)BR rats/sex; 20 rats/sex/group were assigned to the chronic portion (sacrificed after 52 weeks) and 50 rats/sex/group were assigned to the carcinogenicity portion (sacrificed after 104 weeks). There were no adverse effects on survival (52%, 34%, 58% and 40%, 38%, 58% for basal diet, placebo, 250 ppm males and females, respectively), clinical condition, clinical pathology, and organ weights, nor were there any test article-related findings observed at the ophthalmic, macroscopic or microscopic examinations. Food consumption in the 250 ppm animals was decreased during the first 18 months, resulting in lower body weight gains relative to the start of the study of 10% and 13% for the males and of 9% and 15% for the females when compared to the diet control and placebo control groups, respectively. Thus, the no-observed-effect-level (NOEL) for systemic toxicity was 50 ppm. The low-observed-effect-level (LOEL) was 250 ppm. There was no treatment-related increase in tumor incidence in either sex; MeBr was not carcinogenic.

1626 ORAL BUCCAL AND TONGUE CARCINOGENESIS IN SENCAR MICE.

T Kim, D M Ramos, J A Regezi and R H Kramer. *Department of Stomatology and Anatomy, University of California, San Francisco, CA.*

Oral cancer is the most prevalent form of cancer in some regions of the world, but the mechanisms producing this lesion are not well established. In the present study, we developed a mouse model which should aid in understanding the development and progression of oral cancer. Female SENCAR mice were used to examine the carcinogenic effects of 7, 12-dimethylbenz[a]anthracene (DMBA) and 12-O-tetradecanoylphorbol-13-acetate (TPA) or 4-nitroquinoline-1-oxide (4NQO). One group of mice were initiated with 200 nmol DMBA followed by promotion with 5 nmol TPA. Another group (n=5) was treated with 0.5% 4NQO alone thrice weekly for 28 weeks. In the mice that were initiated with DMBA for one (n=6), two (n=12) or six (n=12) weeks and then promoted with TPA, an average of 0.5, 0.92 and 0.83 papillomas/mouse developed in the oral buccal mucosa, respectively, and the incidence of papillomas was 50% in all sub-groups. More than 50% of tumors produced with DMBA/TPA contained a c-Ha-ras A182 → T mutation. Similarly, 30% of mice initiated with DMBA for two or six weeks developed invasive oral squamous cell carcinoma (SCC), although none of the mice treated with DMBA for one week had SCC. In the mice that were initiated and promoted with 4NQO, an average of 0.6 papillomas/mouse developed in the tongue, and the incidence of papillomas was 60%. 67% of the tumors in these mice contained a c-Ha-ras A182 → T mutation. 4NQO produced a spectrum of lesions, ranging from papillomas with dysplasia to SCC. Collectively, DMBA/TPA and 4NQO reliably produced preneoplastic and malignant oral lesions. These results indicate that the SENCAR mice are a sensitive strain of mice useful for studies on the mechanism of oral carcinogenesis.

1627 DETECTION OF TUMOR PROMOTING ACTIVITY OF TWO COMBINATION PESTICICDES (CHLORPYRIPHOS 50% + CYPERMETHRIN 5% AND PROFENOS 40% + CYPERMETHRIN 4%) BY SHORT TERM *IN VIVO* BIOASSAY.

E Muralimohan, N Ramesh, K S Pillai, and P Balakrishnamurthy. *Department of Toxicology, FIPPAT, Padappai, India.*

It has been stated that upto 90% of cancers are attributable to environmental factors. The identification of the major environmental factors linked to human cancer is important for prevention and intervention efforts. Hence there is an urgent need to develop reliable and efficient screening systems for detecting potential carcinogens. Nurella-D, a combination of chlorpyrifos 50% and cypermethrin 5%, and Polytrene-C, a combination of Profenos 40% and Cypermethrin 4% were tested for its cancer promoting potential in wistar rats. Eight groups of rats (5/sex/group) were selected and to groups 1, 3, 5 and 7 diethyl nitrosamine (DEN) (200 mg/kg b.w. i.p) was administered on day-1. To groups 2, 4, 6 and 8 saline was administered (i.p). On day 14, 2-acetaminofluorine (2-AAF) (200 ppm i.p) was given to groups 3 and 4, Neurella-D (250 ppm) to groups 5 and 6 and polytrene-C to groups 7 and 8 in feed daily, for 7 weeks. Group 2 remained as vehicle control. On day 21, rats belonging to groups 1-8 were subjected 70% hepatectomy.At the end of week 9, blood was collected from the rats for estimating ALT, AST, GGT, AChE, protein and glucose, thereafter the animals were euthanised. Organs (liver and brain) were collected for biochemical (GGT in liver and AChE in brain) estimations and histopathology (liver and kidney). GGT showed significant increase in liver homogenate of group 3 and AChE showed significant inhibition in blood and brain of groups 5, 6, 7 and 8. Histopathological studies showed more number of altered hepatic foci in group 3 compared to other treated groups. The present study shows that the above combination pesticides are non carcinogenic.

1628 A NOVEL ELECTROPHORETIC PATTERN OF MICROSOMAL AND CYTOSOLIC POLYPEPTIDES FROM HEPATIC TUMORS IN RAINBOW TROUT.

M W Roomi. *Linus Pauling Institute, Oregon State University, Corvallis, OR, USA.*

There is compelling evidence to suggest that many of the major liver diseases including cancer are of environmental origin. Fish have been used as nonmammalian vertebrate surrogates for understanding mechanisms of human cancer and its prevention. In a recent study from this laboratory, it was demonstrated that hepatic tumor (HT) in rainbow trout (RT) are different from humans and rodents, in phase I and phase II drug metabolizing enzymes. This observation prompted us to study the elecrophoretic pattern in HT of microsome and cytosolic polypeptides by SDS-PAGE. Tumors were induced in male and female RT by dietary exposure of aflatoxin B_1. Liver and HT were excised from RT for the preparation of microsome and cytosol. HT of male and female RT microsomes showed a marked decrease in the mol. wt. of approximate 45-55 kDa, a cytochrome P-450 isozyme region. The male and female HT exhibited a similar pattern and so did the controls. This was further confirmed by estimating the total cytochrome P-450 content. Cytosolic polypeptide also showed a series of differences in HT. Most bands showed a decreased intensity. A prominent difference was the reduction in the polypeptide of mol. wt. 26 and 24 kDa, a glutathione s-transferase (GST) region. This was confirmed by determining GST activity using CDNB as a substrate. A consistent difference in all HT was a significant reduction in the amount of polypeptide of 14 kDa. In conclusion, HT of male and female RT showed a marked decrease in microsomal as well as cytosolic protein profile. The identification and expression of these proteins at the molecular level are under investigation. (Supported by The Linus Pauling Institute.)

1629 KINETICS OF ABERRANT CRYPT FOCI FORMATION IN MICE OF DIFFERING SUSCEPTIBILITY TO AZOXYMETHANE-INDUCED COLON TUMORIGENESIS.

A Papanikolaou, Q-S Wang, and D W Rosenberg. *University of Connecticut, Storrs, CT, USA.*

Aberrant crypt foci (ACF), putative preneoplastic lesions, are the earliest morphological change induced by the colon carcinogen, azoxymethane (AOM). Although inbred mice differ markedly in their susceptibility to AOM tumorigenesis, we have found that ACF develop in both resistant and sensitive mouse strains after AOM treatment. The purpose of this study was to evaluate the kinetics of ACF formation and regression in sensitive and resistant mice. SWR/J, A/J (both susceptible) and AKR/J (resistant) mice were treated with 10 mg/kg AOM or saline *i.p.* once a week for six weeks, and were sacrificed at 1, 2, 4, 6 and 9 weeks following the last injection. The number of ACF and adenomas was determined in distal colons. At one week following AOM administration, a comparable number of ACF was found in the SWR/J and AKR/J mice (5.9/cm colon vs. 4.8/cm; $p<0.05$). The A/J mice, however, developed a significantly greater number of ACF (10.6/cm; $p<0.05$) than the other strains, a finding that was consistent at each of the time points examined. At two weeks after treatment, the number of ACF was significantly higher in SWR/J than AKR/J mice(10.4/cm vs. 5.3/cm; $p<0.05$), but there was no significant difference between the two strains at each of the remaining time points. Adenomas were present as early as four weeks after AOM exposure in SWR/J and A/J mice and increased in frequency throughout the study in both strains. No adenomas developed in the AKR/J mice. Based on the presence of ACF and absence of adenomas in the resistant mice, our data suggest that the biological fate of ACF is governed in part by genetic background. (Supported by NIH Grant DK49805-01 and NIEHS Training Grant 1T32ES07163.)

1630 DIFFERENTIAL EXPRESSION OF p16INK4a IN AZOXYMETHANE-INDUCED MOUSE COLON TUMORIGENESIS.

Q-S Wang, A Papanikolaou, J Bu, and D W Rosenberg. *University of Connecticut, Storrs, CT, USA.*

Alterations in the p16INK4a gene have been implicated in the pathogenesis of a variety of human cancers and animal tumor models. We postulated that alterations in the expression of p16INK4a may also be involved in mouse

colon tumorigenesis induced by the chemical carcinogen, azoxymethane (AOM). In the present study, SWR/J mice were given AOM by i.p. injection at a dose of 10 mg/kg once a week for 8 weeks, and colon tissue and tumors were isolated 18 weeks later. The expression and localization of p16INK4a were examined by reverse transcription-polymerase chain reaction and immunohistochemical analyses. p16INK4a mRNA levels were low, and in some cases undetectable, in control colon tissue. However, colon tumors exhibited an 8-fold increase in p16INK4a mRNA level when compared with control colon tissue ($p<0.01$). While control colon epithelium was uniformly negative for p16INK4a immunoreactivity, p16INK4a immunoreactive cells were markedly increased in preneoplastic lesions and in adenomas isolated from AOM-treated mice. Immunohistochemical analysis also revealed a reciprocal relationship between p16INK4a and Rb protein expression. These findings suggest that alterations in the p16INK4a /Rb pathway may play an important role in AOM-induced mouse colon tumorigenesis. (Supported in part by NIH grant DK49805-01 and NIEHS Training Grant 1T32ES07163.)

1631 IDENTIFICATION OF A CANDIDATE UPREGULATED GENE IN TRANSFORMED C3H10T1/2 MOUSE EMBRYO CELL LINES INDUCED BY CARCINOGENIC NICKEL COMPOUNDS.

J Ramnath, A Verma, and J R Landolph. *Depts. of Mol. Microbiol. and Immunol., Pathol. and Mol. Pharm. and Toxicol., USC/Norris Com.prehensive Cancer Center, University of Southern California, School of Medicine and Pharmacy, Los Angeles, CA.*

Nickel compounds have been implicated in causing nasal and lung cancer in workers exposed to these compounds. Certain nickel compounds induce a variety of tumors in experimental animals and induce neoplastic transformation of cells in culture, and also have shown to cause chromosomal aberrations. Nevertheless, the exact mechanisms of nickel carcinogenesis are still unknown. Identification of the genes that are specifically expressed in nickel transformed cells but not in normal cells or genes that are expressed in normal cells but not in nickel transformed cells, is important for understanding the molecular basis of nickel carcinogenesis. We used the mRNA Differential Display to identify the mRNAs that are differentially expressed from normal and nickel transformed cell lines. Ten cDNA fragments that are differentially expressed were subcloned and sequenced. Subclones that are truly differentially expressed were identified by differential screening using composite cDNA probes. The expression of one cDNA fragment designated R3-2, is upregulated in nickel transformed cell lines compared to its expression in nontransformed 10T1/2 cells. Northern analysis of the fragment R3-2 showed a transcript size of 6.1 Kb. Sequence searches have revealed a very high sequence identity (93-98%) to calnexin gene. The isolation of this gene (fragment R3-2), that is upregulated in nickel transformed cell lines, will allow us to evaluate the functional consequences of this gene, to study its involvement in relation to tranformed phonotype.

1632 COMPARATIVE HEPATOCARCINOGENICITY OF HEXA CHLOROBENZENE, PENTACHLOROBENZENE, 1,2,4,5-TETRACHLOROBENZENE AND 1,4-DICHLOROBENZENE: APPLICATION OF A MEDIUM-TERM LIVER FOCUS BIOASSAY AND MOLECULAR AND CELLULAR INDICES.

D L Gustafson[1], R S Thomas[1], M E Long[1], S A Benjamin[2] and R S H Yang[1]. *Center for Environmental Toxicology & Technology, Departments of [1]Environmental Health and [2]Pathology, Colorado State University, Fort Collins, CO, USA.*

Due to the ubiquitous nature of chlorobenzene exposure in humans, a thorough understanding of potential adverse health effects induced by chlorobenzene exposure is needed. In the studies presented here, we measured the ability of 1,4-dichlorobenzene (DCB), 1,2,4,5-tetrachlorobenzene (TeCB), pentachlorobenzene (PeCB) and hexachlorobenzene (HCB) to promote glutathione s-transferase π (GSTP1-1) positive preneoplastic foci formation in rat liver following diethylnitrosamine (DEN) initiation. Within this same initiation/promotion study design, we also measured induction of CYP1A2, c-Jun, c-Fos ,and non-focal GST-P protein expression in liver. Liver reduced and oxidized glutathione (GSH) levels were also measured in response to chlorobenzene exposure. Results show that TeCB, PeCB and HCB all promote the formation of GST-P positive foci and that DCB does not. TeCB, PeCB and HCB treatment also led to perturbations in liver glutathione levels, whereas DCB does not. Induction of CYP1A2 was seen following treatment with TeCB, PeCB and HCB, and changes in c-Jun and c-Fos expression were consistent with GST-P expression. The results from these studies help elucidate the sequelae of chlorobenzene-induced preneoplastic foci promotion and applied to biologically-based modeling methodologies to predict the hepatocarcinogenicity of other chlorobenzene isomers. This work was supported by AFOSR (F49620-94-1-0304) and NIEHS Superfund Basic Research Program (P42 ES05949).

1633 ANTAGONISM OF HEPATIC PRENEOPLASTIC FOCI BY AN ARSENIC-CONTAINING CHEMICAL MIXTURE: ROLE OF APOPTOSIS.

W A Pott[1], S A Benjamin[2], and R S H Yang[1]. *Center for Environmental Toxicology & Technology, Departments of [1]Environmental Health and [2]Pathology, Colorado State University, Fort Collins, CO, USA.*

Previously, we reported the antagonistic effects of a 4-chemical mixture containing arsenic, 1,2-dichloroethane, vinyl chloride, and trichloroethylene on the development of rat pulmonary and hepatic preneoplastic/neoplastic lesions in a Multiple Organ Carcinogenicity Bioassay (Pott *et al.*, The Toxicologist 42(1-S):75, 1998). To determine if the antagonistic effects in the liver could be due to increased apoptosis and/or decreased proliferation of hepatocytes, we immunohistochemically evaluated hepatocellular apoptosis using the terminal deoxynucleotidyl transferase (TdT)-mediated dUTP-biotin nick end labeling (TUNEL) method. Apoptotic cells were evaluated in 10 random fields of each liver section (≥2000 total hepatocytes), and labeling index (LI) was expressed as the percentage of labeled nuclei. Compared to controls (LI=1.115±0.251), 4-chemical mixture treatment was associated with a significant decrease in the occurrence of hepatocellular apoptosis (LI=0.708±0.137, $p<0.01$). The decrease in apoptosis is contrary to what we anticipated and cannot account for the antagonistic effects of the 4-chemical mixture on the development of hepatic preneoplastic foci. Analysis of hepatocyte proliferation is currently underway. Co-localization of apoptotic and proliferating hepatocytes with preneoplastic hepatic foci is also planned. (This project is funded by the NCI (K08 CA72396-02), ATSDR (Cooperative Agreement No. U61/ATU881475), and NIEHS Superfund Basic Research Program (P42 ES05949).)

1634 DIETARY GLYCINE PREVENTS THE DEVELOPMENT OF LIVER TUMORS CAUSED BY THE PEROXISOME PROLIFERATOR WY-14,643.

R G Thurman[1], M L Rose[1], and R C Cattley[2]. [1]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC; and* [2]*CIIT, Research Triangle Park, NC, USA.*

Previous studies demonstrated that dietary glycine prevents elevated rates of cell proliferation following treatment with WY-14,643 (WY). Since increased cell replication is associated with the development of hepatic cancer caused by peroxisome proliferators, glycine may have anti-cancer properties. Therefore, experiments were designed to test the hypothesis that dietary glycine would inhibit the hepatocarcinogenic effect of WY. Male Fischer 344 rats were fed 4 different NIH 07-based diets: 5 % glycine; 5 % valine for N_2 balance (control); 0.1 % WY + 5 % valine (WY); 0.1 % WY + 5 % glycine (WY + glycine). Food consumption did not differ among the 4 groups, but WY-fed rats weighed 10 to 25 % less as expected. Serum glycine levels were elevated 4-5 fold by glycine-containing diets. After 22 weeks, livers from rats fed WY had a similar incidence and multiplicity of proliferative lesions (foci and adenomas) as those fed WY + glycine. Moreover, cell proliferation in the surrounding "normal" parenchyma (labeling index ≅ 4 %) and the foci (labeling index ≅ 50 %) did not differ between WY and WY + glycine-fed rats. However, after 52 weeks of dietary exposure to WY, glycine prevented formation of small (0-5 mm diameter) tumors by 23 % and inhibited the development of medium size (5-10 mm) tumors by 64 %. Moreover, glycine prevented the formation of the largest tumors (> 10 mm) nearly 80 %. Therefore, glycine did not inhibit early foci formation; however, it did significantly decrease tumors at 52 weeks, and the inhibitory effect of glycine was greater with increasing tumor size. These studies demonstrate that dietary glycine prevents the development of hepatocarcinoma caused by WY consistent with the idea that it may be an effective chemopreventive agent.

1635 DIETARY GLYCINE INHIBITS THE GROWTH OF B16 MELANOMA TUMORS IN MICE.

M L Rose[1], J Madren[2], H Bunzendahl[3], and R G Thurman[1,2]. *Curriculum in Toxicology[1], Departments of Pharmacology[2], and Surgery[3], University of North Carolina, Chapel Hill, NC, USA.*

Dietary glycine has been shown to blunt increases in cell proliferation which

are associated with tumor development. However, the effect of glycine on tumor growth *in vivo* is unknown. Therefore, these experiments were designed to test the hypothesis that dietary glycine would inhibit the growth of experimental tumors in mice. C57BL/6 mice were fed diets containing 5 % glycine or control diet (5 % casein for nitrogen balance) for 3 days prior to *s.c.* implantation of B16 tumor cells (7 x 10^5/mouse). Weight gain and food consumption did not differ between the control and glycine diet-fed mice for the 14 days of the study. As expected, tumor size, measured with digital calipers, increased rapidly in mice fed control diet. In mice fed glycine diet, however, tumor size was 50 to 75 % less, and at sacrifice on day 14, tumors from glycine-fed mice weighed about 65 % less than tumors from mice fed control diet. However, glycine (0.01mM – 10 mM) did not effect rates of growth of B16 cells *in vitro* consistent with the hypothesis that the mechanism of action of glycine was not via a direct action on cell growth. Moreover, tumor size and mitotic index of B16 tumors *in vivo* did not differ 2 days after implantation. All tumors were less than 2 mm diameter at this time and therefore were not dependent on vascular supply. After 14 days, tumors from mice fed dietary glycine had 70 % fewer arteries than those fed control diet ($p<0.05$). Further, glycine (0.01- 10 mM) inhibited the growth of endothelial cells *in vitro* in a dose-dependent manner (IC_{50} = 0.05 mM). These data are consistent with the hypothesis that dietary glycine prevents tumor growth *in vivo* via inhibition of angiogenesis by blocking proliferation of endothelial cells.

1636 TYROSINE AND PHENYLALANINE DEPRIVATION DECREASES B16BL6 MELANOMA CELL INVASION BY DECREASING PLASMINOGEN ACTIVATORS AND INCREASING PLASMINOGEN ACTIVATOR INHIBITOR-1.

B A Pelayo and G G Meadows. *Pharmacology and Toxicology Graduate Program and the Pharmaceutical Science Department, Washington State University, Pullman, WA, USA.*

The incidence of malignant melanoma is rapidly increasing in the United States. Once this cancer becomes invasive, it is very aggressive and can readily metastasize. Diet and nutritional factors are important to the development and progression of human cancers. We previously reported that B16BL6 melanoma cells isolated from mice fed a low tyrosine (Tyr) and phenylalanine (Phe) diet are less able to establish metastases when re-inoculated into mice fed a complete diet. Herein, we showed that invasion through Growth Factor Reduced Matrigel™ is significantly reduced by Phe (22%), Tyr (67%), or Tyr and Phe (76%) deprivation, respectively. Successful invasion requires destruction of basement membranes. Plasminogen activators (PAs) are enzymes necessary for local invasion of tumor cells. Zymographic analysis showed that Phe or Tyr deprivation and to a greater extent Tyr and Phe deprivation decreased urokinase PA and tissue PA activity. These results were verified by Western blot analysis. PA protein expression was decreased in melanoma cells cultured in Tyr- and Phe-free medium. PAs are regulated by plasminogen activator inhibitors (PAIs). Western blot analysis showed that Tyr and Phe deprivation increased PAI-1. Together, these data suggest that the decreased invasion observed in B16BL6 melanoma cells cultured in Phe-, Tyr-, or Tyr- and Phe-free medium is partially explained by decreased PAs and increased PAI-1. (Supported by NIH grants RO1 CA42465 and F31 CA70130 and AICR grant 97A158.)

1637 GENISTEIN STIMULATES GROWTH OF MALE HUMAN PANCREATIC TUMOR CELLS *IN VITRO*.

B D Lyn-Cook, G Hammons, Y Yan, E Blann, and F Kadlubar. *Division of Molecular Epidemiology, National Center for Toxicological Research, Jefferson, AR.* Sponsor: R W Hart.

Extensive research has focused on the anticarcinogenic effects of phytoestrogens. Genistein has been one of those most studied. A number of studies have shown growth inhibition of gastric cancer, prostate cancer, breast cancer, and lymphoma. Epidemiological studies have suggested this compound as a potential chemoprotective agent. However, our data in the present study suggest that this compound may have adverse effects on pancreatic cancer in males. This study demonstrated that genistein, at concentrations of 1 and 10 μ M, stimulated (>60%) the growth of human pancreatic adenocarcinoma cells *in vitro* from males and had no effect on pancreatic tumor cells from females. Equol, which is structurally similar to genistein, demonstrated inhibitory effects on the growth of female pancreatic tumor cells. Biochanin A also had inhibitory effects on tumor cells from females. This study further showed that genistein increased expression of K-*ras* in both male and female pancreatic tumor cells. Increased K-*ras* expression is associated with increased proliferation. Data in the present study also revealed that genistein upregulates the multidrug resistant gene, *mdr*-1, in pancreatic tumor cells from males. This study has shown gender differences in the response of pancreatic tumor cells to genistein. Because of the increased use of dietary supplements, including genistein, by consumers and non-regulation of these products by FDA, more studies are needed to ascertain their effects in humans under normal and cancerous conditions, as well as potential gender differences.

1638 DEVELOPMENTAL EXPOSURE TO GENISTEIN RESULTS IN LONG TERM ADVERSE EFFECTS.

E Padilla Banks[1], W N Jefferson[1], B C Bullock[2], and R R Newbold[1]. [1]*Laboratory of Toxicology, NIEHS, RTP, NC, USA;* [2]*Wake Forest Univ. School of Medicine, Winston-Salem, NC, USA.* Sponsor: M L Cunningham.

Exposure to synthetic estrogenic compounds results in permanent alterations in the reproductive tract if exposure occurs during critical stages of development. Reports from our lab have shown that perinatal exposure of mice to diethylstilbestrol (DES) results in impaired fertility, structural malformations and tumors in the genital tract. Thus, the developing reproductive tract appears to be exquisitely sensitive to perturbation by estrogenic compounds. The isoflavone genistein, which is found in soy products including soy-based infant formulas, is known to have estrogenic activity. The nutritional and pharmaceutical use of this compound has increased over the last few years because of its potential beneficial effects. We have investigated the possible risks posed by genistein if exposure occurs early in development. Mice were exposed to genistein (1-100 μ g/pup/day) on neonatal days 1-5. Early markers of estrogenicity including estrogen receptor alpha and beta expression were examined on day 5. Increases in uterine epithelial cell height and proliferation, and lactoferrin (LF) expression were demonstrated following neonatal genistein exposure similar to DES. Neonatally exposed genistein mice were allowed age to 18 mo. Lesions following genistein exposure include multi-oocyte follicles, uterine epithelial hyperplasia, and hypoplastic uteri. Many long-term effects observed after DES treatment, including uterine adenocarcinoma, were observed after developmental exposure to genistein. Similarities between DES and genistein point to the need for further mechanistic studies on phytoestrogens and their role in long-term effects following developmental exposure.

1639 EFFECTS OF NATURALLY-OCCURRING COUMARINS ON 7,12-DIMETHYLBENZ[A]ANTHRACENE DNA ADDUCT FORMATION IN SENCAR MOUSE EPIDERMIS.

H E Kleiner[1], A Uberecken[1], G W Ivie[2] and J DiGiovanni[1]. [1]*Department of Carcinogenesis, The University of Texas, M.D. Anderson Cancer Center, Science Park-Research Division, Smithville, TX, USA;* [2]*USDA, College Station, TX, USA.*

Coumarins are widely distributed in nature, present in citrus fruits, herbs, and vegetables, and represent an important part of the human diet. We have previously shown that naturally-occurring coumarins can inhibit P450 activity, block DNA adduct formation by 7,12-dimethylbenz[a]anthracene (DMBA), and inhibit skin tumor initiation in mice by this polycyclic aromatic hydrocarbon. Imperatorin, which preferentially inhibits pentoxyresorufin o-dealkylase activity, effectively blocks skin tumor initiation by DMBA whereas bergamottin, which preferentially inhibits ethoxyresorufin o-deethylase activity, does not. The current study was designed to determine the mechanistic basis for these differences. Female SENCAR mice were pretreated topically with coumarins or acetone (vehicle control) 5 min prior to topical treatment with 10 nmol [3H]DMBA. At 24 hr, epidermal DNA was isolated and DNA adducts determined using liquid scintillation spectroscopy. Adduct levels in mice that received no pretreatment were 4.5±0.6 (mean±SE, n=3) pmol/mg of DNA. Adduct levels (expressed as % control) in mice pretreated with coumarins (100, 400, 800 and 1600 nmol), were as follows: bergamottin, 124±37, 141±17, 70±29, and 67±23; imperatorin, 55±19, 42±15, 29±9, and 18±5; and isopimpinellin, 58±6, 45±9, 47±1, and 31±5, respectively. HPLC analysis of the above DNA hydrolysates revealed differences in the ratio of DNA adducts arising from syn-:anti-DMBA diol-epoxides.This ratio in control mice was 0.40±0.02. Pretreatment with the coumarins (100, 400, 800, and 1600 nmol) resulted in the following ratios: bergamottin, 0.71±0.08, 0.93±0.03, 0.94±0.06, and 0.98±0.08; imperatorin, 0.53±0.04, 0.65±0.03, 0.70±0.03, and 0.96±0.08; and isopimpinellin, 0.45±0.02, 0.49±0.02, 0.51±0.06, and 0.49±0.07, respectively. The differences in ability of specific coumarins to block DMBA DNA adduct formation and skin tumor initiation may be related to their specificity toward

inhibiting specific cytochrome(s) P450. Metabolism experiments in progress will specifically address this hypothesis. (ES06014)

1640 ANTIPROLIFERATIVE AND CYTOTOXIC EFFECTS OF XANTHOHUMOL IN HUMAN PROSTATE CANCER CELLS.

C L Miranda[1], J F Stevens[2], C Willard[3], S Bradford[3], Y-H Yang[1], M L Deinzer[2] and D R Buhler[1]. [1]*Department of Environmental & Molecular Toxicology;* [2]*Department of Chemistry;* [3]*Department of Biochemistry & Biophysics, Oregon State University, Corvallis, OR, USA.*

Xanthohumol (XN), the major prenylated flavonoid found in hops (Humulus lupulus), was examined for its potential chemopreventive activity for prostate cancer in humans. Out of 12 flavonoids from hops tested, XN was found to be most effective in inhibiting the growth of the human prostate cancer cell line, LNCaP. The antiproliferative activity of XN was accompanied by inhibition of DNA synthesis using the [3H]-thymidine incorporation assay, with IC50s of 5.1 and 3.8 μM, after 2 and 4 days of treatment, respectively. Xanthogalenol (XG), a flavonoid structurally similar to XN with an O-methyl substituent at 4' as compared to 6' in XN, was much less growth-inhibitory than XN in LNCaP cells. At 5 μM or greater, XN was cytotoxic as indicated by the tetrazolium dye (MTT) and trypan blue exclusion assays. Analysis by flow cytometry showed that XN, at 40 μM, caused apoptosis in LNCaP cells after 4 days of treatment. This concentration of XN also produced an increase in the number of cells in S phase with a decrease in cells at the G1 phase. The findings from these in vitro studies suggest that XN may potentially act as a chemopreventive agent for androgen-dependent prostate cancer in humans. However, further in vivo animal studies are needed to confirm this hypothesis. (Supported by the Hop Research Council and NIEHS grants no. ES00210 and ES03850).

1641 A *MU*-CLASS GLUTATHIONE S-TRANSFERASE (GST) IS RESPONSIBLE FOR HEPATIC CYTOSOLIC AFLATOXIN B1-8, 9- EPOXIDE (AFBO) CONJUGATING ACTIVITY IN THE NON-HUMAN PRIMATE *MACACA ASCICULARIS(MF).*

C- H Wang, T K Bammler, E J Kelly and D L Eaton. *Dept. of Environmental Health, University of Washington, Seattle, WA.*

Large species differences exist in sensitivity to aflatoxin B1 (AFB1)-induced liver cancer. Constitutive expression of certain forms of *alpha*-class GST are important determinants of resistance of rodents to AFB1-induced liver cancer. Mice are resistant to AFB-induced liver cancer because they express an *alpha*-class GST (mGSTA3-3) that has high activity towards AFBO. Rats do not constitutively express a GST with high AFBO activity and are sensitive to AFB1-induced hepatocarcinogenesis, but an inducible *alpha*-class GST (rGSTA5-5) can confer resistance in rats. In contrast to rodents, human hepatic *alpha*-class GST have little or no AFBO detoxifying activity. Recently, our lab has found that liver from the nonhuman primate *Mf*, has significant constitutive hepatic GST activity toward AFBO. Previous cDNA cloning from a *Mf* hepatic cDNA library identified three different *alpha*-class GST, but none had measurable AFBO activity. To determine which class of GST is (are) responsible for this activity, hepatic *Mf* GST were affinity purified, and individual proteins identified by reverse-phase HPLC and chromatofocusing. Specific *Mf* GST cDNAs were also cloned by RT-PCR. Western blot analysis of purified GST proteins revealed that the AFBO activity is due to *mu*-class GST. Two distinct *mu*-class *Mf* GST cDNAs were cloned- mfGSTM1 and mfGSTM2. cDNA-derived amino acid sequences revealed that mfGSTM1 shares 97% identity with hGSTM4 and mfGSTM2 shares 96% homology with hGSTM2. Activity analysis of cDNA-expressed proteins found that mfGSTM1-1 had no AFBO activity whereas mfGSTM2-2 had an AFBO activity of 333 pmol/min/mg, which could account for most or all of the hepatic cytosolic AFBO activity. Northern blot results demonstrated that mfGSTM2 is expressed in liver but not in lung and kidney. These results indicate that, unlike rodents, it is a *mu*-class GST that is responsible for the hepatic cytosolic GST activity toward AFBO in the nonhuman primate, *Mf*. (Supported by R01ES-05780, P30ES-07033 and P30RR00166.)

1642 THE ROLE OF DNA DOUBLE-STRAND BREAKS IN A NOVEL DNA REPAIR PROCESS.

N Whisnant-Hurst and S A Leadon. *Curriculum in Toxicology and Department of Radiation Oncology, University of North Carolina, Chapel Hill, NC, USA.*

DNA repair is vital for maintaining genomic stability. The role of DNA repair in assuring normal development and preventing carcinogenesis is demonstrated in individuals with DNA repair disorders such as xeroderma pigmentosum and Cockayne syndrome. We have discovered a novel, inducible DNA repair response in cells treated with ionizing radiation (IR) at the G1/S border of the cell cycle. This process differs from constitutive repair processes by producing very long repair patches (VLRP) of at least 150 nucleotides in addition to constitutive repair patches of 3-5 nucleotides. The aim of these studies is to examine the signal that induces VLRP and the proteins involved in their production. We examined whether VLRP are induced in response to a DNA lesion specific to IR. Cells were treated with agents that produce subsets of the damage induced by IR: hydrogen peroxide which produces predominately base modifications and single-strand breaks, or bleomycin which produces localized, multiple lesions, resulting in DNA double-strand breaks. The repair patch size was analyzed by alkaline cesium chloride density gradients. Treatment of cells at the G1/S border with hydrogen peroxide resulted in only short repair patches, while bleomycin treatment produced VLRP of 170 bases and constitutive short patches. Because the damage produced by bleomycin is concentrated in a manner similar to that produced by IR, our results indicate that the production of double-strand breaks, possibly as discrete clusters, may be the signal for the induced repair. These findings have led to an examination of the role of double-strand break repair proteins in the production of VLRP. We hypothesize that the ataxia telangiectasia (AT), DNA-dependent protein kinase, and XRCC4 gene products will be involved in the production of VLRP. Fibroblasts with mutant AT protein were synchronized to the G1/S border, treated with IR, and subjected to gradient analysis. The AT fibroblasts produced both VLRP of 170 nucleotides and constitutive repair patches. While this data does not support our hypothesis, it does not preclude a role for VLRP production in the repair of double-strand breaks. The components of the DNA-dependent protein kinase and XRCC4 gene product are currently under investigation. (Supported by NCI CA62059.)

1643 NEW CYCLIC ADDUCTS FORMED IN REACTIONS OF 2-CYANOETHYLENE OXIDE AND GLYCIDAMIDE WITH dA AND dC.

J J Solomon, B Zhu and W Winnik. *Department of Environmental Medicine, New York University School of Medicine, Tuxedo, NY, USA.* Sponsor: L C Chen.

We have previously demonstrated that several mutagenic and carcinogenic epoxides including ethylene oxide, propylene oxide, epichlorohydrin, glycidol and 2-cyanoethylene oxide (ANE, the mutagenic epoxide metabolite of acrylonitrile) react with dC and DNA under physiological conditions to form 3-hydroxyalkyl-dU (3-HA-dU) lesions which can be mutagenically bypassed during *in vitro* DNA replication. These lesions are formed following epoxide-induced hydroxyalkylation at N3 of dC and is followed by rapid hydrolytic deamination. This deamination is intramolecularly catalyzed by the sidechain hydroxyl group via the formation of a cyclic intermediate. During our investigations of the *in vitro* reactions of the mutagenic epoxide metabolite of acrylamide, (glycidamide, GA) with nucleosides, we found that in addition to the expected 3-HA-dU adduct with dC, relatively stable cyclic adducts were formed in reactions of GA with dC and dA. The cyclic adducts were spectroscopically characterized by UV and MS. These cyclic adducts can be hydrolyzed under physiological conditions to form adducts which are unstable and undergo deamination or Dimroth rearrangement to form 3-(2-hydroxy-2-carboxyethyl)-dU (3-HCE-dU) and N6-HCE-dA, the same adducts that form in the *in vitro* reactions of ANE with DNA (pH 7, 37oC, 3h). Mechanistic studies on the formation of these adducts will be presented. (Supported by grants from NIEHS (ES05694) and NIH Center grants ES00260 and CA16087.)

1644 IRON AND/OR AROCLOR 1254 DO NOT INDUCE MUTATIONS OF THE *CII* GENE OF LIVER DNA FROM LAMBDA/*LACI* C57BL/6 TRANSGENIC MICE.

A G Smith, B Clothier and R Davies. *MRC Toxicology Unit, Hodgkin Building, University of Leicester, Leicester, UK.*

Iron is a human hepatocarcinogen. ß2-Microglobulin gene and hemochromatosis gene knockout mice accumulate hepatocellular iron with postulated increase in liver carcinogenesis by an oxidative mechanism. Previously, we have shown massive synergistic interaction between iron overload and the polychlorinated biphenyl mixture Aroclor 1254 (AR) in C57BL/10ScSn mice leading to oxidative DNA damage and hepatocellular cancer. As one approach to study mutagenesis in this system, groups (n=4) of male lambda/*lacI* C57BL/6 transgenic mice were given iron-dextran (600mg/kg s.c.)

and some, after one week, AR in the diet (0.01 %) for 7 weeks. Hepatic ethoxyresorufin de-ethylase was determined as an estimate of CYP1A1 activity i.e. control 107 (&πλυσμν;25), iron 44 (&πλυσμν;9), AR 2714 (&πλυσμν;268), iron/AR 1418 (&πλυσμν;429) pmol/min/mg protein (&πλυσμν;SD). The lower levels of activity with iron have been observed before and may reflect increased CYP1A1 turnover. Western blotting confirmed the marked induction of both CYP1A1 and 1A2. No significant changes in mutational frequencies (MFs) of *lacI* were observed between the treatment groups. In an alternative assay, MFs of the *cII* gene of the lambda phage shuttle vector were determined i.e. control 8.0 &πλυσμν; 2.3, iron 10.5 &πλυσμν; 1.6, AR 8.2 &πλυσμν; 2.7, iron/AR 9.6 &πλυσμν; 2.4 per 10^5 plaques. In contrast, 14 days after 5 daily doses of N-nitrosodimethylamine as a positive control gave 24.9 &πλυσμν; 5.2. In conclusion, these studies show that oxidative processes with either iron overload alone or in combination with PCBs, do not induce simple point mutations and small insertions or deletions detected by this assay. However, other mutation processes such as homologous recombination require investigation.

1645 CYP1B1 SELECTIVELY MEDIATES BIOACTIVATION OF DIBENZO[A,L]PYRENE AND DIBENZO[A,L]PYRENE-11,12-DIHYDRODIOL IN PRIMARY HUMAN BREAST EPITHELIA.

M L Larsen[1], L A Schild[2], P R Hanlon[1], W M Baird[2], and C R Jefcoate[1]. [1]*University of Wisconsin, Environmental Toxicology Center, Madison, WI, USA;* [2]*Oregon State University, Environmental Health Sciences Center, Corvallis, OR, USA.*

Human primary breast epithelial cells [HBEC] convert the potent carcinogen, dibenzo(a,l)pyrene [DB[a,l]P], to dihydrodiol epoxides [DE] that modify adenine and guanine bases of DNA. Primary HBEC constitutively express cytochrome P450 [CYP], CYP1B1, which is induced by DB[a,l]P and by Ah-receptor [AhR] ligands, such as 3,4,5,3',4',5'-hexachlorobiphenyl [HCB] and 2,3,7,8-tetrachlorodibenzo-*p*-dioxin [TCDD]. Constitutive expression of CYP1A1 is absent in these cells. This study demonstrates that the formation of DB[a,l]P-DNA adducts in HBEC from three donors is consistent with metabolism by CYP1B1 rather than by CYP1A1. Relative distribution of adducts was constant, while the absolute level of adduct formation varied in proportion to the magnitude of CYP1B1 induction. The putative precursor, DB[a,l]P-11,12-dihydrodiol [DB[a,l]P-DH], produces syn- but not anti-DE adducts, which, however, form from DB[a,l]P [1.0 μM]. The magnitude of adduct formation following treatment with 0.1 μM DB[a,l]P [24 h] was 2- to 4 times lower than for 1.0 μM DB[a,l]P and showed a loss of syn-PAHDE adduct formation, consistent with exclusive metabolism through the DH. The bioactivation of DB[a,l]P-DH was highly induced by TCDD, while being extensively inhibited by HCB pretreatment. This is consistent with previous observations that HCB is a potent inhibitor of CYP1B1. This is consistent with previous observations that HCB is a potent inhibitor of CYP1B1. p53 was elevated approximately in proportion to adduct formation, was substantially increased two days after removal of DB[a,l]P or DB[a,l]P-DH, but declined five days later. p21 responded in parallel to p53, while also exhibiting independent regulation [high levels in confluent, untreated HBEC and a late response to DB[a,l]P and DB[a,l]P-DH]. DB[a,l]P and DB[a,l]P-DH each effected cell cycle arrest of HBEC in G2. (Supported by NIEHS 144EN46, NIH 144-FR43, and DOD DAMD17-94-J-4054.)

1646 7, 12-DIMETHYLBENZ[A]ANTHRACENE METABOLISM AND DNA ADDUCT FORMATION IN ISOLATED JAPANESE MEDAKA (*Oryzias latipes*) LIVER CELLS.

S C Stamm[1], D L Alexander[2], and M R Miller[1]. [1]*West Virginia University, Dept. of Biochemistry, Morgantown, WV, and* [2]*University of Wisconsin, Dept. of Pharmacology, Madison, WI.*

Some fish species are being used as supplemental animals for carcinogenicity studies; however, basic research is required to determine if mechanisms of carcinogenesis in these teleosts reflect the carcinogenic process in mammals. The object of this study was to compare 7, 12-dimethylbenz[a]anthracene (DMBA) metabolism and DNA adduct formation in liver cells from the teleost, Japanese medaka, with that in mouse embryo fibroblasts (MEF). Cells were isolated by enzymatic digestion and maintained in monolayer culture. Following exposure to DMBA, culture medium was removed and analyzed by high pressure liquid chromatography for phase I DMBA metabolites. The rate of formation of phase I metabolites was significantly lower in medaka liver cells (MLC) than in MEF. Differences in the types of phase I metabolites formed were also apparent: DMBA 3,4-dihydrodiol (important for mammalian carcinogenesis) was barely detectable in MLC, but was a significant metabolite in MEF; DMBA 5,6-diol and hydroxymethyl DMBA were major metabolites in MLC, but were minor metabolites in MEF. 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin pretreatment resulted in 5 to 6 fold increases in formation of total DMBA phase I metabolites in both types of cells. Furthermore, ^{3}H-DMBA-DNA adducts were formed at lower levels in MLC than in MEF, and C_{18} chromatography demonstrated the DNA-adducts formed in MLC were much more polar than most of the adducts formed in MEF. These findings indicate significant differences in DMBA metabolism and adduct formation between MLC and MEF. Although DMBA is a potent carcinogen in both mammalian and teleost systems, the mechanisms that bring about carcinogenesis may be quite different.

1647 ANALYSIS OF N-OH-NAABP INDUCED MUTATIONS AT THE HPRT GENE.

B Zayas, L F Zhang, S G Grant, P Keohavong and B W Day. *University of Pittsburgh, Pittsburgh, PA.*

Interaction of environmental chemicals with biological macromolecules can result in genotoxic and cytotoxic effects. 4-ABP, a human bladder carcinogen present in cigarette smoke, can be metabolized to N-OH-N-acetylaminobiphenyl (N-OH-AABP) a strong electrophile capable of reacting with DNA. In this study the mutational spectrum of N-OH-AABP exposed human lymphoblasts were analyzed using the HPRT gene as the target gene. Cultures of 2 x 10^8 TK6 cells were treated with N-OH-AABP, incubated for four days and treated with the HPRT selective agent 6-TG for two weeks. Control cultures (no treatment) were also exposed to 6-TG. DNA was then extracted for mutational spectra analysis of the HPRT exon 3, from both control and exposed cultures. HPRT sequences were separated from wild type sequences by denaturing gradient gel electrophoresis (DGGE). DGGE analysis of the HPRT exon 3 clearly indicated that exposure to N-OH-N-AABP can increase the level of induced mutations when compared to control cultures. Sequencing analysis showed the high specificity of the 4-ABP metabolite mutations induced. Background mutation detected both in control and exposed cultures were at base pair 197 with A to G transition. From the exposed mutants the detected changes were mainly G to T transversions (30%), followed by an insertion and repeat at position 178 (20%) and G to A transition (5%). In conclusion, all the mutations observed readily translated into structural changes that would alter or inactivate the HPRT enzyme.

1648 DETERMINATION OF RELATIVE GENOTOXICITIES OF SPECIFIC NICKEL COMPOUNDS IN SHORT-TERM *IN VITRO* ASSAYS USING 10T1/2 CELLS.

S Ohshima, A Verma, J Ramnath and J R Landolph. *Norris Comprehensive Cancer Center, Schools of Medicine and Pharmacy, University of Southern California, Los Angeles, CA.*

To evaluate carcinogenic potentials of specific nickel compounds, we conducted short-term in vitro assays for genotoxicity, cytotoxicity, and phagocytosis using C3H 10T1/2 clone 8 (10T1/2) mouse embryo cells. We studied six insoluble nickel compounds and two soluble nickel compounds. All insoluble nickel compounds were phagocytosed by 10T1/2 cells in the following order: NiO (black) > NiO (green) > Ni_3S_2 (INCO) > Ni_3S_2 (NTP) > Metallic Ni (<1 m Nm) > Metallic Ni (3-7 m 7m). All compounds caused cytotoxicity in the following order: Ni_3S_2 (INCO) = NiO (black) > Metallic Ni (<1 mIm) > NiO (green) > Ni_3S_2 (NTP) > $NiSO_4$ (Aldrich) > $NiSO_4$ (NTP) > Metallic Ni (3-7 m(m). Most of the compounds studied increased the micronuclei frequencies in the following order: Ni_3S_2 (INCO) ~ Ni_3S_2 (NTP) > NiO (black) ~ Metallic Ni (<1 m Mm) > $NiSO_4$ (Aldrich) ~ $NiSO_4$ (NTP) > Metallic Ni (3-7 m(m) > NiO (green). Ni_3S_2 (INCO), $NiSO_4$ (Aldrich) and Metallic Ni (<1 m(m) caused increases in chromosomal aberrations, while Metallic Ni (3-7 mrm) did not. All compounds studied caused morphological transformation, in the following order: NiO (green) > NiO (black) > Ni_3S_2 (NTP) > Ni_3S_2 (INCO) > $NiSO_4$ (Aldrich) = $NiSO_4$ (NTP). Our results for the genotoxicities of these nickel compounds were generally consistent with their carcinogenicity in animal studies. The efficiencies with which these nickel compounds induce morphological transformation in 10T1/2 cells broadly correlates with their carcinogenicity in animals. This transformation assay should be further validated with additional nickel compounds to determine its ability to predict the carcinogenicity of nickel compounds in general.

1649 STUDY ON METABOLISM OF ARSENIC AND FLUORIDE IN THE CHRONIC ARSENIC POISONING IN INNER MONGOLIA, CHINA.

H Yamauchi[1], T Yoshida[2], H Aikawa[2], T Sato[3], M Niwa[3], S Saito[1], M Aminaka[1], F Kayama[4] and K Yoshida[1]. [1]*Dept. of Preventive Medicine, St. Marianna University School of Medicine, Kawasaki, Japan;* [2]*Dept. of Environmental Health, Tokai University School of Medicine, Isehara, Japan;* [3]*Dept. of Hygiene, The Nippon Dental University, Tokyo, Japan;* [4]*Dept. of Hygiene, Jichi University School of Medicine, Tochigi, Japan.*

Chronic arsenic poisoning in China occurs as a result of arsenic as well as the mixture of arsenic(As) and fluoride(F) in well water. This studies on the metabolism of As and F in patients with chronic arsenic poisoning from Inner Mongolia, China. It is found a significant correlation between As and F in the well water. In some patients with chronic arsenic poisoning dental fluorosis was also observed patients with chronic arsenic poisoning. The mean urinary total As (iAs + metabolites) and F level in the 36 subjects was 2.39 ± 0.67 mg As/L and 2.1 ± 1.1 mg/L, respectively. There was a significantly higher concentration of inorganic arsenic(iAs), methylated arsenic and dimethylated arsenic in urine in the patients with chronic arsenic poisoning as compared to the control group. On the other hand, F concentrations were 2 times higher in the As group than control. Comparisons between male and female revealed higher concentrations of arsenicals and F in the urine of male patients with chronic arsenic poisoning in comparison to the female patients. The characteristic accumulation of iAs in the hair was confirmed in our study with a higher level found in the male patients versus the female patients. The level of F in the hair was 2 times the concentration found in controls. These data show no significant correlation between As and F concentrations in the hair. The cytotoxicty study using normal human liver cells exposed to As and F showed that fluoride reduced the cytotoxicty of arsenic. The importance of such data will be the focus of future studies.

1650 MONTE CARLO ANALYSIS OF INORGANIC ARSENIC EXPOSURE IN THE US.

D B Menzel[1], M B Dillencourt[1], D M Meacher[1], E Lee[1], L F Bic[1], R A Schoof[2], L J Yost[2], C H Farr[3] and D W Cragin[3]. [1]*University of California, Irvine, CA, USA;* [2]*Exponent, Bellevue, WA, USA;* [3]*Elf Atochem North America, Inc., Philadelphia, PA, USA.*

Daily inorganic arsenic (As_i) exposure of adults in the conterminous US from air, food, soil, and drinking water has been estimated. Existing databases of arsenic in air, soil, and drinking water were linked with data from a study of food commodities expected to account for at least 90% of the As_i in the US diet. A Monte Carlo simulation estimates that the range of daily As_i exposure (5th to 95th percentile) from the four exposure sources is 0.6 to 13.2 μg for women and 0.8 to 15.9 μg for men. The mean daily As_i exposure from the four sources is 5.2 μg for women and 6.3 μg for men. At the mean ratios, food and drinking water contributed most to the total daily As_i exposure. Food contributed 67.7% for women and 70.7% for men whereas drinking water contributed 28.8% for women and 26.4% for men. Contributions to the total daily As_i exposure by air and soil at the mean ratios are estimated to be negligible: air contributes 0.9% for women and 0.8% for men and soil contributes 2.7% for women and 2.0% for men. Variations in the mean daily exposure to As_i among the West, South, Midwest, and Northeast regions of the US appear to result primarily from differences in drinking water As_i levels. The results of simulation indicate that, for most adult Americans, the highest exposure to As_i comes from food and the next highest exposure comes from drinking water. The majority of adults in the US receive little exposure to As_i from air and soil.

1651 CONTROLLED ARSENATE EXPOSURES OF HUMAN SUBJECTS: KINETICS OF ELIMINATION.

E Lee and D B Menzel. *Department of Community and Environmental Medicine, University of California, Irvine, Irvine, CA, USA.*

The health effects of arsenic containing drinking water have been of concern because inorganic arsenic is a potential carcinogen or cancer promoter. Previously, we developed a physiologically based pharmacokinetic (PBPK) model of ingested, inhaled and injected arsenate (AsV); arsenite (AsIII), monomethylarsonic acid (MMA) and dimethylarsenic acid (DMA) using studies in mice. The PBPK model has been scaled to humans and the urinary elimination was optimized from literature values that are from foreign populations exposed at 5-10 times the US standard. To our knowledge this is first controlled human exposure study at the current EPA standard. To validate the model and to investigate the balance between inorganic arsenic and arsenic metabolites, five subjects (2 female; 3 male) were given a single dose of 100 μg sodium arsenate dissolved in deinoized water. A 24 hr pre-exposure and repeated individual urine samples were collected to 96 hr post exposure. Hydride generation and atomic absorption spectrometry quantified the urine arsenic. The pre-exposure values varied between 2.5-9.0 μg/L. The pattern of metabolites was essentially the same for all five subjects. The total arsenic processed to urine was about 55% of the dose. Clearance rates also varied between subjects. We conclude that diet has a major impact on the pre-exposure dose as reflected by diet recall. Methylation also varies as does clearance rates. Therefore, arsenic PBPK models should be optimized by the Monte Carlo method to account for population variations. (EL is supported by a Department of Education Graduate Assistance in Areas of National Need Program Grant. Supported by ARCO.)

1652 METABOLISM AND TOXICITY OF ARSENICALS IN PRIMARY RAT HEPATOCYTES.

M Styblo[1], M L Del Razo[2], and D J Thomas[3]. [1]*University of North Carolina, Chapel Hill, NC, USA;* [2]*National Polytechnic Institute, Mexico City, Mexico;* [3]*US EPA, HEERL, Research Triangle Park, NC, USA.*

The metabolism and toxicity of arsenite (iAs^{III}), arsenate (iAs^{V}) and trivalent and pentavalent methylated arsenicals have been examined in primary hepatocytes isolated from adult male Fischer 344 rats. The uptake and methylation of iAs^{III} by hepatocytes cultured in phosphate-rich medium was six to eight-fold greater than the uptake and methylation of iAs^{V}. At concentrations of 0.1 to 1 μ M, iAs^{III} was converted mainly to dimethylarsenic (DMAs). DMAs was quickly released from the cells. Little methylarsenic (MAs) was detected inside the cells. At 4 to 10 μ M iAs^{III}, the portion of MAs in cells increased and a significant amount of MAs was released into the medium. The total methylation yield increased in the range of 0.1 to 4 μ M iAs^{III}. At 10 to 20 μ M iAs^{III}, inhibition of methylation occurred and the DMAs/MAs ratio decreased dramatically. Metabolism of MAs also depended on valency of arsenic. Methylation of 1 μ M MAs^{V} yielded little DMAs; in contrast, more than 90% of 1 μ M MAs^{III} was converted to DMAs. The cytotoxicities of arsenicals were examined over a 24-hr incubation period using the MTT assay. Pentavalent arsenicals (iAs^{V}, MAs^{V}, and $DMAs^{V}$) were not toxic at concentrations up to 20 μ M. MAs^{III} and $DMAs^{III}$ were significantly more toxic (IC_{50} ~ 2.5 μ M) than iAs^{III} (IC_{50} > 5 μ M). Addition of 2.5 mM GSH into the culture did not change methylation yield from iAs but stimulated the release of MAs and DMAs from cells, decreasing the intracellular retention of arsenicals. GSH completely protected cells against toxicity of trivalent arsenicals. Simultaneous addition of 2 μ M sodium selenite reversibly inhibited methylation and increased retention of iAs^{III} in cells. Selenite potentiated the cytotoxicity of iAs^{III}, MAs^{III}, and $DMAs^{III}$ and interfered with the protective effect of GSH. These results indicate that the capacity for the methylation of arsenicals by primary rat hepatocytes is concentration dependent, influenced by the valency of the arsenical, and affected by the presence of GSH and selenite.

1653 ACTIVATION OF NF-κ B AND AP-1 BY SODIUM ARSENITE IN HUMAN KERATINOCYTES.

M Vargas and D B Menzel. *University of California, Irvine, CA, USA.*

Arsenic exposure is associated with a variety of human cancers. Although the mechanism of arsenic carcinogenesis remains elusive, inorganic arsenic has been suggested to act through epigenetic mechanisms such as interaction with intracellular signaling pathways. We examined the effect of arsenic on the transcription factors nuclear factor kappa b (NF-κB) and activator protein-1 (AP-1). We report here the time-course and concentration-response relationship for the activation of NF-κB and AP-1 by sodium arsenite in human keratinocytes. HaCaT cells were exposed to arsenite, whole cell extracts were prepared, and NF-κB and AP-1 activity were analyzed by the electrophoretic mobility shift assay. Activation of both NF-κB and AP-1 by arsenite occurred at concentrations as low as 0.1 μ M. Supershift analyses using polyclonal antibodies to various NF-κB and AP-1 subunits were performed to identify the proteins in the shifted complexes. The inducible form of AP-1 was found to be a heterodimer of c-Jun and c-Fos while the inducible form of NF-κB contained p50 but not p65. The involvement of reactive oxygen species in arsenic-induced activation of the studied transcription factors was also investigated by pretreatment of cells with the

antioxidants butylated hidroxyanisole (BHA), pyrrolidine dithiocarbamate (PDTC), and N-acetyl cysteine (NAC). BHA and PDTC inhibited arsenite-induced activation of NF-κB whereas NAC inhibited AP-1 activation. These studies suggest that arsenic activates these two signaling pathways by different mechanisms. MV holds a NIEHS Individual Predoctoral Fellowship.

1654 ARSENITE [As(III)] AND ARSENATE [As(V)] ENHANCE DNA BINDING OF THE AP-1 AND Elk-1 TRANSCRIPTION FACTORS AND c-jun AND c-fos GENE EXPRESSION IN PRECISION-CUT RENAL SLICES.

X-H Zheng, A R Parrish, K D Turney, H Younis, and A J Gandolfi. *Southwest Environmental Health Sciences Center, The University of Arizona, Tucson, AZ.*

Although arsenic is recognized as a nephrotoxicant, little is known about the molecular impact of low concentrations of various arsenic species on the kidney. Our previous studies have shown that nanomolar concentrations of arsenite [As(III)] or arsenate [As (V)] do not elicit overt cytotoxicity, but are associated with a concentration- and time-dependent induction of heat shock protein 32 (Hsp 32; heme oxygenase-1). Given that Hsp32 is regulated, in part, by the activator protein-1 (AP-1) transcription factor, we hypothesized that As(III) and As(V) would activate the MAPK pathway. Three transcription factors lie downstream of the stress-activated c-jun N-terminal kinase and p38 kinase: AP-1, ATF2 and Elk-1. Using electrophoretic mobility shift analysis, the impact of As(III) and As(V) on the DNA binding of these factors was investigated (0–1000 nM; 2-6 hr). Both species enhanced the DNA binding of AP-1 and Elk-1, but did not effect DNA binding of ATF2. Since expression of the early-immediate genes c-jun and c-fos are driven by AP-1 and Elk-1, respectively, expression of these genes was examined by RT-PCR. After 2 hr of exposure, 100 nM As(III) or As(V) enhanced c-jun gene expression 1.32±0.07 and 1.20±0.04 fold, respectively. c-fos gene expression was enhanced 1.44±0.12 and 1.78±0.16 fold by 100 nM As(III) and As(V), respectively, at 2 hr. These results demonstrate that both As(III) and As(V) elicit a specific activation of molecular signaling pathways in renal tissue at low concentrations. (Supported by NIH ES04940 and an SOT Colgate-Palmolive Fellowship.)

1655 MODEL FOR ARSENITE RELATED SKIN CARCINOGENESIS INVOLVING THE TUMOR SUPPRESSOR PROTEIN P53.

H K Hamadeh and D B Menzel. *Department of Community and Environmental Medicine, University of California Irvine, Irvine, CA, USA.*

The genetic toxicity of arsenic compounds has been rigorously evaluated and, based on the available data, arsenic and its metabolites do not seem to act as direct genotoxicants. Evidence is mounting that arsenic acts as a promoter rather than an initiator in carcinogenesis. This study reports a plausible mechanism by which arsenic could promote skin carcinogenesis with UV irradiation as an initiation step. The design of the experiment used the spontaneously immortalized keratinocyte cell line (HaCaT) which bears two UV-specific mutations on the *p53* gene as an *in vitro* model of an initiated cell. Keratinocytes were exposed to sodium arsenite (0, 1, 10, 100 nM) for 14 days. The exposure media were changed every day and cell samples were harvested every other day. We assayed p53 levels by Western blotting using chemiluminescence as the detection system. Cells viability was not affected throughout the study. p53 protein levels decreased in a dose-dependent manner after 7 to 9 days of exposure to arsenite. We conclude that arsenite treatment, after a latent period, either inhibits the activation or accelerates the degradation of the p53 protein. Decreased p53 protein levels might lead to a decrease in cell division arrest time thus increasing the probability of the cell to incur DNA damage that is left unrepaired, leading to excessive DNA mutations and ultimately carcinogenesis. (HH is supported by Department of Education Graduate Assistance in Areas of National Need Program Grant.)

1656 DISSIMILAR EFFECT OF ARSENIC ON CELL CYCLE KINETICS IN CONTROL AND RAS-TRANSFORMED C3H 10T1/2 FIBROBLASTS.

K J Trouba and R L Vorce. *Department of Pharmacology, University of Nebraska Medical Center, Omaha, NE.*

Arsenic is a human-specific carcinogen whose mechanism of action remains undefined. Results generated in this laboratory indicate that sodium arsenite sensitizes wild-type, but not ras-transformed C3H 10T1/2 fibroblasts to LPA and EGF-stimulated DNA synthesis as measured by tritiated thymidine incorporation. To further explore the effect of arsenic on these cell types, a study was designed to test the hypothesis that transient arsenite exposure differentially alters the distribution of wild-type and ras-transformed cells in S-phase of the cell cycle following mitogen exposure. To this end, serum-starved wild-type and ras-transformed fibroblasts were treated with 300 μM sodium arsenite for 1 hour. Eight hours post-arsenite cells were treated with sub-optimal concentrations of LPA or EGF, harvested at various time points following the addition of mitogen and subjected to cell cycle analysis using a fluorescence-activated cell sorter. The data indicate that arsenic pre-treatment increases the percentage of wild-type cells in S-phase of the cell cycle; conversely, the percentage of ras-transformed cells in S-phase is decreased by arsenic pre-treatment. Viability, as determined using neutral red incorporation, indicates that the effect observed in ras-transformed cells is not due to increased cellular toxicity. Taken together, these data suggest that transient sub-lethal arsenite exposure leads to changes in the distribution of wild-type and ras-transformed cells in S-phase of the cell cycle. Because cell proliferation is a key element in the promotion stage of carcinogenesis, the effect of arsenic on wild-type cells might prove to be an important etiologic factor in the development of arsenic-related cancers.

1657 ARSENITE-MEDIATED DECREASES IN INDUCTION OF CYPs IN CULTURED CHICK HEPTOCYTES: LACK OF A ROLE OF OXIDATIVE DAMAGE.

C Nichols[5], J Jacobs[1], D Marek[2], S Wood[4], P Sinclair[2,3,4] and J Sinclair[2,3,4]. *Depts. [1]Micro, [2]Biochem, [3]Pharmacol/Toxicol, Dartmouth Med. Sch., Hanover, NH; [4]VA Med. Ctr., White River Junction, VT; [5]Mount Holyoke College, S. Hadley, MA, USA.*

We have reported that arsenite decreased induction of CYP2H and CYP1A proteins in cultured chick hepatocytes by a mechanism not involving decreased availability of heme. Inductions of CYP2H1/2 and CYP1A4/5 proteins were dramatically decreased by arsenite . There was no decrease in the steady state levels of CYP2H mRNAs, however arsenite decreased the induction of CYP1A4 and CYP1A5 mRNAs. Concentrations of arsenite that decreased the induction of these CYPs (1 to 10 μM) caused no toxicity and no increased oxidative damage. Neither increasing GSH nor inclusion of antioxidants prevented the effects of arsenite to decrease induction of CYP. Treatment with inhibitors of MAP kinases themselves decreased the expression of CYP1A4/5 and, therefore, did not reverse the effects of arsenite. Inhibitors of phosphatases also did not reverse the effects of arsenite. The results suggest that the mechanism of arsenite-mediated decreases in CYP depends on the form of CYP expressed and is not solely due to oxidative damage. (This work was supported by NIEHS (ES07373) and the Dept. of Veterans Affairs.)

1658 ARSENIC-INDUCED PERTURBATION OF NEOPLASTIC RESPONSE IN MICE.

M P Waalkes[1], M Anver[2] and B A Diwan[2]. *[1]NCI at NIEHS, Research Triangle Park, NC, USA; [2]IRSP, SAIC Frederick, NCI-FCRDC, Frederick, MD, USA*

Arsenic is a known human carcinogen but animal evidence is equivocal. For instance, one older study indicates repeated iv arsenate injections might induce lymphomas in Swiss mice (58% incidence; Osswald and Goerttler, 1971), but was considered inadequate for critical evaluation of carcinogenic potential. Thus, we studied repeated arsenic injection and neoplastic response in mice also treated with barbital (BB), a multiorgan tumor promoter. Groups (n = 24-25) of male or female Swiss mice received sodium arsenate (As; 0.5 mg/kg, iv) or saline (control) once/week for 20 weeks and were observed for 96 weeks. Starting 2 weeks after As, BB (2500 ppm) was added to the drinking water and continued until the study ended. The groups were then: control, As, BB, As + BB. Differences in survival and body weights were unremarkable. In females BB + As reduced ($p < 0.05$) spontaneous lymphomas (control 20%; BB 4%; As 12%; As + BB 0%) but in males lymphoma incidence was unchanged. BB induced increases in hepatic proliferative lesions (HPL; foci of alteration + neoplasia) which were reduced by As in males (control 4%; BB 72%; As 4%; As + BB 40%) and females (control 4%; BB 54%; As 24%; As + BB 24%). HPL were elevated in females given As (24%) compared to control (4%). As did not alter the hepatocellular hypertrophy seen with BB. Staining for the tumor suppressor protein, *P53*, and *ras* oncogene protein, *P21*, showed no expression in HPL in BB or in As + BB treated mice. BB increased testicular interstitial cell hyperplasia (84%) over control (36%) but hyperplasia was reduced by As (As + BB 60%). These data indicate that As, while perhaps showing a weak neoplastic response in the female liver, generally suppressed BB induced

increases in proliferative lesions of the liver and testes and contributed to a suppression of spontaneous lymphoma. This potential for suppression of neoplastic response by As may complicate detection of a carcinogenic response.

1659 ORGAN SUSCEPTIBILITY FOR ARSINE TOXICITY IN SPRAGUE DAWLEY RATS.

F Ayala-Fierro and D E Carter. *Pharmacology and Toxicology, The Center for Toxicology, The University of Arizona, Tucson, AZ, USA.*

In animals and humans exposed to AsH_3, a severe lysis of erythrocytes occurs. Other organs such as liver and kidney are also susceptible to AsH_3 toxicity *in vivo*. AsH_3 is an important environmental health hazard to employees of industries, such as the semiconductor industry. We hypothesize that AsH_3 is metabolized to other arsenic species to produce toxicity and that this process is organ dependent. The arsenic species are arsenite [As(III)], and possibly metallic arsenic or arsenic dihydride. In this investigation we determined AsH_3 and As(III) toxicity in rat blood, liver and kidney, using heme release (Vis-Spectroscopy), LDH leakage (Sigma kit 228-20) and intracellular K^+ (flame photometry) as the toxic parameters. Rat blood was very susceptible to AsH_3 (0.5 mM) toxicity that produced 70% of total hemoglobin, 68% of total LDH and 75% of intracellular K^+, released after 1 hr treatment. As(III) was nontoxic to rat blood. The primary hepatocytes were susceptible for both arsenicals with a LC_{50} and LC_{95} of 10 μM and 100 μM, respectively (measured by % of total LDH released). In this system, K^+ dropped 75-80% after dosing with both compounds. In liver precision-cut slices AsH_3 treatment caused 50-75% decrease in intracellular K^+ above 10 μM AsH_3, but LDH was not significantly affected suggesting a K^+ pump as the target. As(III) produced a dose and time-dependent increase in % of total LDH release and reached 35, 45 and 50% at 2, 4 and 6 hrs, respectively, with 1 mM As(III). Intracellular K^+ dropped 50, 60 and 75% at the same time points and same concentrations. In the renal cortical primary epithelial cells, 1 mM AsH_3 was slightly toxic with 10 and 18% of total LDH and 1 and 25% of intracellular K^+ leakage at 3 and 5 hrs, respectively. 1 mM As(III) produced 25 and 63% of total LDH and 20 and 46% of intracellular K^+ leakage at the same time points. The rat kidney has factors that allow toxicity from these arsenicals to be distinguished and was chosen to further study arsine metabolism. We concluded that arsenical toxicity is organ dependent and that As(III) is not the sole metabolite from AsH_3 biotransformation *in vitro*. (Supported by NIEHS grant ES6644, the Flinn Foundation, and Superfund Basic Research Program.)

1660 THE ANION TRANSPORTER AND THE ACCUMULATION OF ARSENIC (As) IN ARSENATE (As^V)-EXPOSED RABBIT ERYTHROCYTES.

D J Thomas, L L Hall, J L Gundersen and K M Herbin-Davis. *NHEERL, US EPA, RTP, NC.*

The characteristics of accumulation of As by rabbit erythrocytes were examined using [$^{73}As^V$] arsenic acid in an *in vitro* system containing equal volumes of washed erythrocytes and Na, K gluconate/HEPES pH 7.5 buffer that did not contain Cl^-. In this system the accumulation of As by erythrocytes was both time and temperature dependent. Over the range of 0.05 to 5 μM As^V, the fractional accumulation of As in cells was proportional to the extracellular concentration of As^V. Addition of 35 to 140 mM Cl^- to the medium reduced the accumulation of As. Similarly, the addition of 4, 4' diiisothiocyanostilbene-2, 2' sulfonic acid which binds to the band 3 component of the anion transporter, reduced accumulation of As. The accumulation of As in cells incubated in Cl—free medium at pH 6 exceeded that found in cells incubated in Cl—free medium at pH 7.5. This difference in the accumulation of As is consistent with the favored transport by the anion transporter of the monovalent oxyanion, $H_2AsO_4^-$, which is the predominant species at pH 6, over the divalent oxyanion, $HAsO_4^{-2}$, which is the predominant species at pH 7.5. The molybdate oxyanion did not antagonize the accumulation of As. In summary, As^V transport by erythrocytes involves the anion transporter and may be modulated by other anionic species in plasma. (This abstract does not necessarily reflect EPA policy.)

1661 EFFECT OF SODIUM ARSENITE OF PORPHYRIN SYTHESIS AND HEME METABOLISM IN CULTURED CHICK HEPATOCYTES.

J Jacobs[1], D Marek[2], H Walton[2], P Sinclair[2,3,4] and J Sinclair[2,3,4]. [3]*VA Med. Ctr, WRJ, VT and Depts. of* [2]*Biochem,* [4]*Pharmacol/Toxicol and* [1]*Micro., Dartmouth Med. Sch., Hanover, NH.*

Arsenite has been reported to have multiple effects on heme turnover, inducing heme oxygenase, the rate-limiting enzyme in heme degradation, and increasing the urinary excretion of uroporphyrin and coproporphyrin, oxidation products of intermediates in heme synthesis. We had previously reported that 2.5 μM arsenite decreases the induction of several forms of CYP in cultured chick and rat hepatocytes. Here we report, in cultured chick hepatocytes, 1 to 25 μM arsenite did not increase uro- copro- or protoporphyrin accumulation from 5-aminolevulinic acid (ALA), indicating that the enzymes in the pathway between ALA synthase and protoporphyrinogen oxidase were unaffected by arsenite. 2.5 μM Arsenite had no effect on either the synthesis of heme from ALA or the drug-induction of ALA synthase, the rate-limiting enzyme in heme synthesis. Heme disappearance and biliverdin formation were not different in cultured chick hepatocyte treated simultaneously with arsenite and heme, or with heme alone. Our results indicate that doses of arsenite that induce heme oxygenase several-fold and cause decreases in inductions of CYP2H and CYP1A4/5 have little effect on porphyrin synthesis or heme metabolism. (Supported by NIEHS (ES07373) and the Dept. of Veterans Affairs.)

1662 A STUDY OF THE EFFECTS OF DIMETHYLARSINIC ACID ON THE LIGAND STATUS OF OXYHEMOGLOBIN IN RAT ERYTHROCYTES.

M A Peraza-Lopez and D E Carter. *Department of Pharmacology and Toxicology, The Center for Toxicology, University of Arizona, Tucson, AZ.*

Unlike other mammalian animal models, rats demonstrate significant accumulation of arsenic in blood over time. Studies have identified the arsenic compound to be dimethylarsinic acid (DMAsV). However, the actual binding site of DMAsV in the rat erythrocyte is not clear. Previous studies in our laboratory provide evidence that arsenic in erythrocytes is bound to hemoglobin. Possible binding sites are on the protein, porphyrin rings, or iron. This study examined the effect of DMAsV on rat hemoglobin. Studies were performed using both rat (Sprague Dawley) erythrocytes and isolated rat oxyhemoglobin (HbO_2). At concentrations ranging from 1 to 62.5 mM DMAsV, rat erythrocytes or hemoglobin solutions were dosed and incubated for up to 60 minutes at 37° C. Changes in HbO_2 in these preparations were examined from spectral changes between 450 nm and 750 nm. Spectra indicated that DMAsV was not altering the ligand state of HbO_2 since no spectral changes characteristic of other hemoglobin species were observed. Previous studies have shown that certain arsenic species cause hemolysis of erythrocytes. After spectral analysis, hemolysis of erythrocytes induced by DMAsV at concentrations up to 62.5 mM was also measured spectrophotometrically using Drabkin's reagent. No significant increase in hemolysis with respect to control preparations was observed (2-3% of total hemoglobin release in control preparations vs. 3-4% of total hemoglobin release in treatment preparations). From these results we can conclude that DMAsV does not alter the ligand state of HbO_2 or the oxidation state of iron in the heme groups of HbO_2 at these concentrations. Further studies are necessary to determine binding of DMAsV to the globin portion of hemoglobin. (Supported by NIH Grant ES6644, NIEHS Grant ES07091, and Center Grant P30 ES06694.)

1663 PHARMACOKINETIC AND PHARMACODYNAMIC STUDIES OF ARSENITE INDUCTION OF HEME OXYGENASE IN RATS.

K T Kitchin, L M Del Razo, J L Brown, W A Anderson, E M Kenyon and D J Thomas. *Environmental Carcinogenesis Division and Experimental Toxicology Division, NHEERL, U.S. Environmental Protection Agency, Research Triangle Park, NC.*

The identification of useful biomarkers of arsenic effects in both experimental animals and humans has been difficult. Arsenate and arsenite are good inducers of rat hepatic and renal heme oxygenase (HO); monomethylarsonic acid (MMA) and dimethylarsinic acid (DMA) are not effective HO inducers. Little oxidation of arsenite to arsenate occurs in vivo. Therefore, enzymatic induction of HO should theoretically be an excellent biomarker of biologically active arsenite concentration. Liver and kidney inorganic arsenic, MMA and DMA concentrations and HO enzyme activities were determined

2 to 144 hours after oral administration of 100 umoles/kg of sodium arsenite to adult female Sprague-Dawley rats. In rat liver the mean inorganic arsenic concentrations were 0.11, 2.15, 1.85, 1.86, 1.82, 0.68, 0.51, 0.20 and 0.10 ug/g at 0, 2, 4, 8, 16, 24, 48, 72 and 144 hours after arsenite administration, respectively. At these same time points, rat hepatic HO activities were 1.0, 10.8, 6.8, 16.3, 21.2, 5.2, 3.8, 0.8 and 0.5 times control HO values. At these time points 86, 46, 61, 66, 80, 89, 95, 97 and 98% of the total rat liver arsenic was present as DMA, an arsenite metabolite that does not induce HO. A hepatic concentration of 0.49 ug/g of additional inorganic arsenic was present before or at the time of HO enzyme induction. In rat kidney lower inorganic arsenic concentrations and less HO enzyme induction occurred after oral arsenite administration. This study links tissue dosimetry for arsenic with a biological effect (HO enzyme induction) in a pharmacokinetic and pharmacodynamic view of its action in two tissues that are targets for arsenic-induced carcinogenesis. (Disclaimer: This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.)

1664 DIMETHYLARSINIC ACID EFFECTS ON SIX BIOCHEMICAL PARAMETERS IN B6C3F1 MICE.

S Ahmad, W A Anderson and K T Kitchin. *Environmental Carcinogenesis Division, NHEERL, US Environmental Protection Agency, Research Triangle Park, NC.*

Historically, methylation of the inorganic forms of arsenic (arsenate or arsenite) was interpreted as a detoxification pathway; however, recent data from free radical, biochemical and carcinogenic studies of dimethylarsinic acid (DMA) suggest that methylation of arsenic may be a toxification pathway instead. DMA has tested positive as both a complete carcinogen (urinary bladder and fibrosarcomas) and as a promoter of carcinogenesis (lung, liver, kidney, urinary bladder and thyroid gland). Adult female B6C3F1 mice were given 720 mg/kg of DMA by gavage at one of three points - 2 hours before, 15 hours before, and both 21 and 4 hours before sacrifice. We determined the DNA damage, the reduced and oxidized glutathione (GSH, GSSG) content, cytochrome P-450 content, ornithine decarboxylase (ODC) activity and plasma alanine aminotransferase activity. Significant ($P < 0.05$) decreases (15 to 37%) in liver GSH and GSSG contents were observed in all exposures to DMA. This data suggests that DMA can lower cellular defenses against electrophiles and free radicals. DNA damaging and eventually carcinogenic effects may be mediated by GSH depletion and/or the enhancement of oxidative stress. A general trend toward a DMA-induced DNA damage was observed, particularly in the liver ($P < 0.1$, one tail), but no comparisons reached the $P < 0.05$ level of statistical significance. Pulmonary and hepatic ODC activities were reduced (19 to 59%) by prior DMA treatment. ODC is involved in cell proliferation. Overall, our DMA mouse results are quite different from our prior rat results. Rats and mice differ greatly in DMA pharmacokinetics, largely because of large binding of DMA to cysteine 125 on the β chain of rat hemoglobin. These biochemical studies show that mice are much less responsive to DMA than rats. (Disclaimer: This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.)

1665 TOUGHNESS OF SKIN IN ARSENIC EXPOSED MICE: ROLE OF GM-CSF AND TGFa.

T Yoshida[1], H Aikawa[1], H Yamauchi[2], K Sakabe[1], F Kayama[3], W Fujimoto[4], D R Germolec[5] and M I Luster[6]. [1]*Tokai Univ. School of Medicine,* [2]*Saint Marianna Medical College,* [3]*Jichii Medical College,* [4]*Okayama Univ. School of Medicine, Kanagawa, Japan and* [5]*NIEHS, NIH, RTP, NC, USA; and* [6]*NIOSH, Morgantown, WV, USA.*

Hyperkeratosis on the palms of the hand and soles of the feet are characteristics of arsenic (As) poisoning. However, toughness of skin has not been described as a manifestation of As poisoning. We previously reported that As induces GM-CSF and TGFa mRNA and protein production in human keratinocyte culture. In the present studies sodium arsenite was provided at 1 and 10mg/L to C57B/6n male and female mice via drinking water for 50 days. As concentrations were determined in hair and urine. Pieces of skin were excised from shaved ventral skin by scissors for histpathological and molecular analysis. Increase skin toughness dominantly in male was apparent in exposed groups when skin sections were prepared. Skin sections were prepared and stained for Haematoxilin and Eosin. GM-CSF in serum were measured by ELISA. RNA was extracted from skin and the expression of GM-CSF and TGFa mRNA were examined by RT-PCR. Although the epidermis appeared normal, the dermis in exposed animals showed moderate thickening of the collagen bundles. Seven of 12 exposed male mice and 4 of 12 female mice showed significantly thickened collagen bundles. GM-CSF in serum were elevated in 10mg/L, but not significantly. RNA expressions for GM-CSF and TGFa were enhanced moderately in exposed groups compared to controls. These results indicate that a number of changes occur in the skin of As-exposed mice, including thickening of collagen bundles and increased growth factor expression.

1666 PARTIAL PURIFICATION OF AN ARSENATE REDUCTASE FROM HUMAN LIVER AND CHARACTERIZATION OF ITS COFACTOR REQUIREMENTS.

T R Radabaugh[1] and H V Aposhian[2,3]. [1]*Committee on Genetics,* [2]*Dept. of Molecular and Cellular Biology,* [3]*Center for Toxicology, Univ. of Arizona, Tucson, AZ, USA.*

An arsenate reductase from human liver has been purified 200 fold using DEAE-Sephacel, Sephacryl S-200 HR, Activated Thiol Sepharose 4B and Reactive Brown 10. The starting liver cytosol reduced 860 pmoles arsenate/30 min/mg protein. The activity is associated with a heat labile protein which is greater than 30 kDa which required both a thiol and a heat stable cofactor less than 3 kDa in size. To determine the enzyme's thiol requirement, the ability of glutathione, thioredoxin and lipoic acid were tested to see if they would stimulate reduction of arsenate in the absence of other thiols. In the presence of enzyme, either glutathione or lipoic acid stimulated reduction but were less than 20 times as active as dithiothreitol in this respect. Thioredoxin did not stimulate activity. Mg^{+2}, Ca^{+2}, Cu^{+2}, Mn^{+2}, and Zn^{+2} did not stimulate enzyme activity. In addition, enzyme activity was not inhibited by the presence of 5 mM ethylenediamine tetraacetic acid. (Supported by Superfund Program NIEHS Grant #ES-04940 and NIEHS Center Grant #P30-ES-06694.)

1667 CHRONIC ARSENITE EXPOSURE INDUCES RESISTANCE TO ACUTE TOXICITY OF ARSENIC AND ITS METABOLITES AND CROSS TOLERANCE TO CADMIUM.

E H Romach[1] and M P Waalkes[2]. [1]*PAI, Durham, NC;* [2]*NCI at NIEHS, Research Triangle Park, NC, USA.*

Arsenic is a known human carcinogen. A previous study in our laboratory showed that chronic (>18 weeks), low dose (500 nM) exposure to arsenite induces malignant transformation in a rat liver epithelial cell line (TRL1215). This study sought to determine if the adverse effects of metals were altered in these transformed cells. Arsenite transformed cells (ATC) and untransformed cells (UTC) were exposed to arsenite, arsenate, monomethyl arsenate (MMA), dimethylarsenic acid (DMA) and cadmium for 24 hours and cell viability was determined. The LC_{50} for arsenite was 67 μM in ATC as compared to 26 μM in UTC. ATC were very tolerant to the acute toxic effects of arsenate (LC_{50} >500 μM) compared to UTC (LC_{50} 54 μM). After metallothionein (MT) induction with zinc (80 μM) pretreatment for 24 hours, UTC showed minimal changes in sensitivity to arsenite and arsenate (15% and 20% increase in LC_{50}, respectively) compared to ATC (155% and 826% increase in LC_{50}, respectively). Prior studies have shown that MT is hyperexpressible in ATC. DMA had a LC_{50} of 32 mM in ATC as compared to a LC_{50} of 7 mM in UTC. Differences in sensitivity to MMA were modest but significantly different between ATC (LC_{50} 68 mM) and UTC (LC_{50} 50 mM). Cellular accumulation of arsenic was 2.7-fold higher in UTC (9.5 ng/10^6cells) than in ATC (3.5 ng/10^6cells). Thus, UTC accumulate more arsenic than ATC and this may, in part, account for their increased sensitivity to acute arsenic toxicity. ATC also showed a cross tolerance to the toxic effects of cadmium. The LC_{50} of cadmium in ATC was 51% greater than that seen in UTC. The results of this study show that ATC are tolerant to the acute toxic effects of arsenite, arsenate, MMA, and DMA, and cross tolerant to cadmium. This tolerance may be based, at least in part, on reduced uptake of arsenicals.

1668 METALLOTHIONEIN-I/II NULL MICE ARE MORE SENSITIVE THAN CONTROLS TO CHRONIC ARSENIC TOXICITY.

J Liu[1], Y P Liu[2], and M P Waalkes[3]. [1]*PAI, Durham, NC;* [2]*Univ. Kansas Medical Center, Kansas City, KS;* [3]*NCI at NIEHS, Research Triangle Park, NC, USA.*

Metallothionein (MT) is low-molecular weight, sulfhydryl-rich, metal-binding protein. MT can protect against the toxicity of cadmium, mercury, and copper, but the role of MT in arsenic (As)-induced toxicity is less certain. To better define the ability of MT to modify As toxicity, metallothionein-I/II null (MT-null) and control mice were given repeated sc injections of As(III)

(10 and 30 μmol/kg) or As(V) (100 μmol/kg), 5 days/week, for 15 weeks. Repeated As injections increased hepatic and renal MT concentrations 3-6 fold in control but not in MT-null mice. Repeated As injections produced 2-10 fold elevation of serum interleukin-1, interleukin-6, and tumor necrosis factor-α. MT-null mice were more susceptible than controls to these elevations in serum cytokines. Repeated As injections decreased hepatic glutathione (GSH) by up to 40%, but GSH-peroxidase and GSH-reductase were minimally affected. MT-null mice and controls were similarly sensitive to the effect on GSH. Histologically, repeated As injections produce damage to liver (inflammation, focal necrosis and degeneration) and kidney (interstitial nephritis, tubular cell degeneration, and increases in kidney/body weight ratios). At the same dose levels, MT-null mice appeared to have more pathological lesions when compared to control mice. Thus, MT-null mice were more susceptible than controls to the toxicity of repeated As injections, suggesting that induction of MT could be one of the cellular mechanisms decreasing chronic As toxicity.

1669 CADMIUM AND ARSENIC INTERACTIONS IN CONTROL AND METALLOTHIONEIN-I/II NULL MICE.

Y-P Liu, J Liu, S S M Habeebu, and C D Klaassen. *Univ Kansas Med Ctr, Kansas City, KS.*

Cadmium (Cd) and arsenic (As) are toxic metals in the environment. People have the potential to be exposed to Cd and As as mixtures, but their interactions are not known. Metallothionein (MT) is a cystine-rich, metal-binding protein, that plays an important role in Cd detoxication, but the role of MT in As toxicity is less certain. To examine the role of MT in Cd and As interactions, control and MT-null mice were fed Cd in their diet (100 ppm), As (III) in drinking water (22.5 ppm), or Cd plus As for up to 4 months. Subsequent nephrotoxicity and hepatotoxicity were determined by morphological and biochemical techniques. At the doses used, chronic Cd exposure produced more renal and hepatic toxicity than did As, and the combination of Cd and As produced even more toxicity. In the mice receiving Cd plus As, proximal tubule degeneration, atrophy, glomerular swelling, and interstitial fibrosis were more severe than that produced by either metal given alone. Similarly, hepatic focal necrosis and granulomatous hepatitis were more severe in the mice that received Cd plus As. Furthermore, MT-null mice were not only more susceptible than controls to chronic Cd-induced toxicity, but also to chronic As toxicity. MT-null mice were especially sensitive to the combination of Cd- and As-induced injuries, as evidenced by decreased body weight, enzymuria, glucosuria and histopathology. In conclusion, this study indicates there is an interaction between Cd and As during long-term combined exposure, and demonstrates that MT protects against Cd- and As-induced toxicity. (Supported by NIH grants ES-01142, ES-06190 and ES-07079.)

1670 METALLOTHIONEIN-I/II NULL MICE ARE MORE SUSCEPTIBLE THAN CONTROLS TO CHRONIC ORAL CADMIUM-INDUCED TOXICITY.

C D Klaassen, Y-P Liu, J Liu, and S S M Habeebu. *Univ Kansas Med Center, Kansas City, KS.*

Chronic exposure to cadmium (Cd) via food is becoming a major concern for human health. We have previously shown that cellular metallothionein (MT), a small metal-binding protein rich in sulfhydryl groups, plays an important role in protecting against Cd toxicity produced by repeated sc injections. To determine whether MT protects against oral Cd toxicity following long-term exposure, MT-I/II null and control mice were fed Cd via drinking water (30, 100, and 300 ppm), or food (100 ppm) for up to 6 months. Chronic oral Cd exposure produced a dose-dependent accumulation of Cd in liver and kidney of control mice, reaching 50 μg/g tissue. In contrast, tissue Cd concentrations in MT-null mice were less than 8 μg/g tissue. In spite of the lower Cd concentrations in their liver and kidney, MT-null mice were more susceptible than controls to Cd-induced nephrotoxicity and hepatotoxicity. Cd exposure produced greater urinary excretion of gamma-glutamyltransferase in MT-null mice than in control mice, while urinary excretion of protein and glucose were minimally affected. Kidney and liver/body weight ratios were increased in a dose-dependent manner following oral Cd exposure, and again larger increases were seen in MT-null mice. In conclusion, this study demonstrates that MT-null mice are more susceptible than controls to oral Cd-induced toxicity, indicating the importance of cellular MT in decreasing Cd toxicity not only after sc injection, but also after oral exposure. (Supported by NIH grants ES-01142 and ES-07079.)

1671 REDUCED UPTAKE AND INCREASED EFFLUX OF CADMIUM IN CADMIUM-RESISTANT METALLOTHIONEIN NULL CELLS.

T Yanagiya[1], S Himeno[1], Y Kondo[2], and N Imura[1]. [1]*Kitasato University, Sch. of Pharmaceutical Sciences, Tokyo, Japan;* [2]*Nippon Medical School, Tokyo, Japan.*

Metallothionein (MT) is known to play a predominant role in the protection against Cd. To investigate other factors than MT involved in the detoxification of Cd, we utilized MT I and II null mouse embryonic cells transformed with simian virus 40 large T antigen. By exposure of these immortalized MT null cells to graded concentrations of Cd up to 10 μM, we established Cd-resistant MT null cell lines. Two clones of Cd-resistant MT null cells designated as Cd-rA7 and Cd-rB5 were characterized and compared with the parental MT null cell clone, P4. IC50 values of Cd for Cd-rA7 and Cd-rB5 were approximately ten times that of P4 as judged by MTT assay. No increase in glutathione concentration or enzyme activities of glutathione S-transferase, glutathione reductase, glutathione peroxidase, superoxide dismutase, and catalase was observed in Cd-rA7 and Cd-rB5 compared to P4. Interestingly, Cd-rA7 and Cd-rB5 showed no cross-resistance to other metals (Zn, Cu, Ni, Pb, Hg, As), cisplatin, H2O2 or 1-chloro-2,4-dinitrobenzene, suggesting that these cells had acquired Cd-specific resistance factor(s). We found that Cd accumulation after 24 h exposure to Cd in Cd-rA7 and Cd-rB5 was about 15 - 25% of that in P4, which might have resulted in the decreased sensitivity to Cd. To further investigate the mechanism underlying the reduced accumulation of Cd in Cd-rA7 and Cd-rB5, the uptake of trace amount of 109Cd-labeled CdCl2 was examined. A time-dependent increase in 109Cd concentration in each cell line was observed, but the rate of uptake in Cd-rA7 and Cd-rB5 was about 10% of that of P4. To measure the efflux of Cd, each cell line was exposed to 109Cd-labeled CdCl2 for 2 h, and then the medium was changed to Cd-free one. The 109Cd remaining in Cd-rA7 and Cd-rB5 dropped to about 50% during 60 min after the medium was changed, while less than 5% of 109Cd was released from P4. Thus, both the reduced rate of Cd uptake and the increased efflux of Cd from the cells may contribute to the decreased accumulation of Cd, and thereby the decreased sensitivity to Cd in Cd-rA7 and Cd-rB5.

1672 CYPROTERONE ACETATE, THE ANTIANDROGEN, INDUCES A NOVEL FORM OF CELLULAR TOLERANCE TO CADMIUM INVOLVING REDUCED CELLULAR ACCUMULATION.

M Takiguchi and M P Waalkes. *NCI at NIEHS, Research Triangle Park, NC, USA.*

Several reports indicate that some steroids, in particular sex steroid hormones, can modify cadmium toxicity. We recently reported that cyproterone acetate (CA), a synthetic steroidal antiandrogen that is closely related in structure to progesterone, affects cadmium toxicity in mice. In the present study, we investigated the influence of CA on cadmium toxicity in a rat liver epithelial cell line (TRL 1215) *in vitro*. TRL 1215 cells were exposed to various concentrations of CA (0, 1, 10, or 50 μM) for 24 h and subsequently exposed to cadmium (0, 50, or 100 μM; as $CdCl_2$) for an additional 24 h. CA pretreatment resulted in a decrease in the cellular sensitivity to cadmium as assessed by metabolic integrity. Additional study showed CA pretreatment provided protection against cadmium toxicity only when given more than 6 h prior to cadmium exposure. Cellular cadmium concentration was markedly reduced (60 %) in cells pretreated for 6 h or more with CA. In the presence of protein synthesis inhibitors, the protective effect of CA toward cadmium toxicity was abolished. CA alone modestly increased metallothionein (MT) levels (2.4-fold), while cadmium (50 μM) alone resulted in an 8.9-fold increase over control. However, cadmium-induced MT synthesis was markedly decreased by CA pretreatment. These data suggest that CA pretreatment provides protection against cadmium toxicity *in vitro* and indicate that this protection is due to a decreased accumulation of cadmium rather than through activation of MT synthesis. This decrease of cellular cadmium accumulation appears to be related to events that require protein synthesis and is an unusual form of tolerance in mammalian cells.

1673 DIFFERENTIAL INDUCTION OF METALLOTHIONEIN AND HEAT SHOCK PROTEIN 72 BY CADMIUM IN THE LIVERS OF THE MALE FISCHER-344 AND THE SPRAGUE DAWLEY RAT.

R K Kuester, M Waalkes, P L Goering, G Li, B Fisher, H Younis, and I G Sipes. *Department of Pharmacology and Toxicology, Center for Toxicology, The University of Arizona, Tucson, AZ.*

Liver injury by cadmium following acute exposure is well characterized. Previous work has shown that the Fischer-344 (F-344) rat is more sensitive to cadmium (Cd) toxicity than the Sprague Dawley (SD) rat. The primary detoxification of Cd is achieved by forming a complex with the metal binding protein, metallothionein (MT). In most cases, the rate of MT induction is paramount to protecting against cadmium toxicity. The *de novo* synthesis of stress or heat shock proteins (hsp) also occurs early after Cd administration. Hsp serve to maintain the structural integrity of proteins that have been damaged or denatured by toxic insults. The objective of this study was to determine if differential expression of MT and hsp plays a role in the sensitivity of two rat strains to Cd toxicity. F-344 and SD rats were challenged with cadmium chloride (3 mg/kg, i.v.) and the induction of hepatic MT and hsp was determined from 3 to 48 hr after treatment. Liver injury was assessed by plasma alanine aminotransferase (ALT) activity. Levels of MT in the liver were quantified by atomic absorption spectrophotometry. Liver samples were subjected to one-dimensional SDS-PAGE and the inducible form of hsp70 (hsp72) was identified using a specific monoclonal antibody. Administration of $CdCl_2$ resulted in a rapid increase in serum ALT activities within 3 hr in F-344 rats compared to SD rats (1241 U/L verses 226 U/L, respectively). ALT levels reached a maximum of 4100 U/L after 24 hr in the F-344 rat compared to 229 U/L in SD rats. The induction of MT occurred earlier in the livers of the SD rat (16 μg/g tissue verses 8 μg/g after 3 hr). Interestingly, enhanced hsp72 synthesis was observed in the SD rat liver by 3 hr but not in the F-344 liver until 6 hr after treatment. From these studies it appears that earlier synthesis of MT and hsp72 may contribute, at least in part, to the decreased sensitivity of the SD rat to Cd induced hepatotoxicity. (Supported by the NIEHS (ES-06694, ES-06095) and the Yuma Friends of AHSC.)

1674 ACTIVATION OF HEPATIC CASPASE-3 ACTIVITY FOLLOWING CADMIUM CHLORIDE ($CdCl_2$) TREATMENT IN MICE.

E B Harstad, D P Hartley, K L Kolaja, and C D Klaassen. *Univ Kansas Med Ctr, Kansas City, KS.*

Acute exposure to cadmium results in liver toxicity involving both apoptosis and necrosis. Recent advances in the study of cell death suggest that the biochemical mechanisms of apoptosis and necrosis may allow for a method to discern the importance of each death pathway. Caspase-3 is a highly conserved central mediator of the apoptotic program and is a widely accepted marker for apoptosis *in vitro*. Therefore this study was designed to determine whether acute cadmium exposure causes an increase in caspase-3 activity *in vivo*. A new method for the quantification of caspase-3 enzymatic activity in liver cytosolic extracts was developed and optimized. Serum alanine aminotransferase (ALT) was measured to assess liver necrosis. Male mice were treated with saline or 0.9, 1.8, 3.7, 5.5, 7.3 and 11 mg/kg $CdCl_2$ ip for 9 hours. Endotoxin (LPS)-treated mice (2 mg/kg ip for 9 hr) were employed as a positive control for apoptosis to verify this method of caspase-3 analysis. LPS-treatment caused a maximal increase in caspase-3 activity after 9 hours exposure with no increase in ALT. $CdCl_2$-treatment caused a 9 to 13-fold increase in caspase-3 activity with doses ranging from 0.9 mg/kg up to 5.5 mg/kg. However, at higher doses (7.3 and 11 mg/kg), caspase-3 activity was decreased 75% from control. $CdCl_2$-treatment caused an 4, 30, 70, and 100-fold increase in ALT at 3.7, 5.5, 7.3, and 11 mg/kg, respectively. These data demonstrate that caspase-3 is activated by doses of $CdCl_2$ which cause little or no necrosis *in vivo*. Only slight overlap between caspase-3 activity and ALT was observed, indicating that caspase-3 activity is not involved in $CdCl_2$-induced necrosis. Decreased caspase-3 activity may be due to direct inhibition of caspase-3. Inhibition of caspase-3 activity may prevent the completion of apoptosis, resulting in necrosis. (Supported by NIH grants ES-01142 and ES-07079.)

1675 CADMIUM BLOCKS APOPTOSIS INDUCED BY CHROMIUM, HYGROMYCIN B AND ACTINOMYCIN D: THE ROLE OF CASPASE-3 INHIBITION.

C Yuan[1], M B Kadiiska[2], R P Mason[2] and M P Waalkes[1]. [1]*NCI at NIEHS and* [2]*NIEHS, Research Triangle Park, NC, USA.*

Cadmium (Cd) and chromium (Cr) compounds are both human carcinogens. Cr(VI) is taken up into cells and reduced by cellular reductants (i.e., GSH) to Cr(III), a DNA damaging agent. Reactive oxygen species are produced during Cr reduction. A previous study in our laboratory found that Cd effectively inhibits Cr-induced apoptosis (J. Toxicol. Environ. Health, 54: 159, 1998). Inhibition of Cr-induced apoptosis by Cd may allow a larger proportion of genetically damaged cells to escape from apoptosis and become transformed. The present study was undertaken to define the molecular mechanisms of suppression of Cr-induced apoptosis by Cd in CHO cells. Cells were treated with either Cd (5-20 μM), Cr(VI) (350 μM) or Cd (5-20 μM) plus Cr(VI) (350 μM) for 3 hr. The cells were cultured in metal free media for 48 hr and DNA was extracted. Cd inhibited DNA fragmentation and reduced the number of apoptotic cells caused by Cr treatment. Electron spin resonance (ESR) was used to determine if the effect of Cd was due to an alteration of the cellular reduction of Cr(VI) to Cr(III). These data showed that Cd did not alter cellular Cr(VI) reduction as assessed by the levels of the intermediate, Cr(V). There was also no difference in cellular GSH levels between Cr-treated and Cd/Cr-treated cells. Thus, Cd suppression of Cr-induced apoptosis is not through an alteration in cellular Cr metabolism. Cd also inhibited apoptotic response to the non-metal agents, hygromycin B and actinomycin D. Additional study showed that Cd was very effective at inhibiting cellular caspase-3, a central mediator of apoptosis, with 10 μM Cd, which was otherwise non-toxic, resulting in ~ 40% inhibition. Our results indicate that Cd may have a generalized inhibitory effect on apoptosis possibly through caspase-3 inhibition. This inhibition of apoptosis by Cd may allow a greater portion of genetically damaged cells to survive, and has implications as a potential, non-genotoxic mechanism of Cd carcinogenesis.

1676 COMPARISON OF THE CYTOTOXIC EFFECTS OF CADMIUM (Cd^{2+}) IN S-180 AND S-180L CELLS.

P C Lamar, J P Johnsen and W C Prozialeck. *Department of Pharmacology, Midwestern University, Downers Grove, IL, USA.*

Recent findings from our laboratory have shown that Cd^{2+} can disrupt the tight junctions between epithelial cells by interacting with E-cadherin, a calcium-dependent cell adhesion molecule. In order to further explore the role of E-cadherin in the general cytotoxic response to Cd^{2+}, we have examined the effects of Cd^{2+} in a fibroblast-like mouse sarcoma cell line that does not express E-cadherin (S-180), and a modified strain of the cell line that has been transfected to express E-cadherin and exhibit an epithelial-like phenotype (S-180L). Depending on the particular experiment, the cells were grown in 6 well plastic tissue culture flasks or on glass coverslips in DMEM supplemented with 15% calf serum, and exposed to Cd^{2+} in serum-free medium. Cell viability was evaluated by the trypan blue dye exclusion assay, and E-cadherin was visualized by an indirect immunofluorescence procedure. In the E-cadherin-expressing S-180L cells, exposure to 200 - 400 μ M Cd^{2+} for 4-6 hours caused the cells to separate from each other without causing them to detach from the growing surface or killing them. This effect coincided with the loss of E-cadherin from the cell borders. In the S-180 cells, a similar exposure to Cd^{2+} caused the cells to change from an irregular, spindle shape to a round shape. With longer periods of exposure (ie., 8-24 hours), Cd^{2+} caused both cell lines to begin to die. However, the S-180L cells were significantly more resistant to the lethal effects of Cd^{2+} than were the S-180 cells. These results are consistent with the hypothesis that E-cadherin may be an early target for the junction-perturbing effects in epithelial cells. In addition, they indicate that the level of E-cadherin expression may influence the sensitivity of the cells to more severe toxic injury by Cd^{2+}. (Supported by NIH Grant R01 ES06478.)

1677 CADMIUM ACTIVATES ONCOGENE EXPRESSION IN HUMAN PROSTATE EPITHELIAL CELLS.

W E Achanzar[1], D Bello-Deocampo[2], M M Webber[2], and M P Waalkes[1]. [1]*NCI at NIEHS, Research Triangle Park, NC, USA;* [2]*Michigan State University, East Lansing, MI, USA.*

Cadmium is a toxic heavy metal classified by the International Agency for Research on Cancer as a human carcinogen. The prostate is a target site of

cadmium carcinogenesis in rats and possibly in humans. The carcinogenic mode of action for cadmium has not been elucidated, but the poor mutagenicity observed with this metal points toward an epigenetic mechanism. Thus, we are testing the hypothesis that cadmium exposure alters expression of genes involved in growth regulation of prostate epithelial cells. The present study examined the effects of cadmium exposure on gene expression in the normal human prostate epithelial cell line RWPE-1. This line is immortalized but not transformed, is androgen-responsive and represents an *in vitro* model of the suspected *in vivo* target cells of cadmium carcinogenesis. Treatment of RWPE-1 cultures with 10 μM cadmium chloride, which is not toxic to these cells, resulted in 2-fold increases in *c-myc* mRNA levels after 4 hours of exposure. By 6 hours after 10 μM cadmium, *c-myc* levels were decreasing and by 24 hours levels were back to control. In comparison, *c-jun* mRNA levels were increased 3-fold after 4 and 6 hours of cadmium exposure and 10-fold after 24 hours. Clear dose-dependent increases were observed between cadmium concentration and the levels of *c-myc* and *c-jun* mRNA. For instance, after 4 hours of cadmium treatment, *c-myc* levels were unchanged at 5 μM, 1.7-fold above control at 10 μM and 2.5-fold above control at 15 μM. A similar pattern was observed for the *c-jun* transcript. No changes in *c-fos* mRNA levels were observed after cadmium treatment. Taken together, our data show that cadmium can affect oncogene expression in a cell type analogous to potential target cells of carcinogenesis in humans.

1678 ACTIVATION OF CADMIUM UPTAKE BY CALMIDAZOLIUM DOES NOT REQUIRE CALMODULIN.

T Chakraborti, L Olivi, and J Bressler. *Kennedy-Krieger Institute, Baltimore, MD.*

In our investigation on cadmium (Cd) transport into Madin-Darby canine kidney (MDCK) cells, the role of calmodulin was investigated. This is because transporters, exchangers and pumps that could play a role in regulating the transport and efflux of Cd are activated by calmodulin. Whereas two calmodulin inhibitors, W-7 and trifluoroperazine, did not affect the uptake of ^{109}Cd, treatment with another calmodulin inhibitor, calmidazolium, resulted in a three-fold increase in the uptake of ^{109}Cd. These three inhibitors displayed a similar effect on the calmodulin-dependent regulation of calcium homeostasis suggesting that each interacted with calmodulin. Furthermore, treatment with an antisense oligonucleotide resulted in an almost complete loss of calmodulin but did not affect the uptake of ^{109}Cd. Calmidazolium was not a Cd ionophore since it did not stimulate the uptake of ^{109}Cd into liposomes. Calmidazolium-mediated uptake of ^{109}Cd was not affected by an activator of protein kinase C. Interestingly, copper but not several other metals including zinc, lead and nickel inhibited uptake of ^{109}Cd in cells treated with calmidazolium. Our results suggest that calmidazolium increases the uptake of Cd possibly by activating a unique transporter that does not require calmodulin.

1679 PROTEIN KINASE C REGULATES CADMIUM UPTAKE IN KIDNEY CELLS.

L Olivi, T Chakraborti, and J Bressler. *Kennedy-Kreiger Institute, Baltimore, MD.*

Heavy metals such as lead and cadmium (Cd) accumulate in the kidney, but the mechanism by which they are transported into kidney cells is unclear. Several mechanisms including anion exchange, calcium channels, and others that are not as well defined have been proposed. Madin-Darby canine kidney (MDCK) cells were used in this study to examine Cd transport since these cells express several transport mechanisms. For example, MDCK cells express anion exchanger 2 mRNA and display the anion exchange mechanism since the uptake of sulfate at acidic pH was largely blocked by inhibitors of anion exchange. Interestingly, conditions that stimulated anion exchange did not stimulate uptake of ^{109}Cd nor was the uptake of ^{109}Cd sensitive to drugs that inhibit anion exchange. Furthermore, ^{109}Cd uptake was not inhibited by drugs that block or activate calcium channels. ^{109}Cd uptake was increased in MDCK cells incubated overnight with the protein kinase C activator phorbol 12,13 dibutyrate (PDBu). The protein kinase C inhibitor GF 109203X blocked the effect of PDBu, and the increase in ^{109}Cd uptake was inhibited by the transcription inhibitor actinomycin D. The uptake of ^{109}Cd was inhibited by several metals including lead, copper and zinc, but not calcium. Our studies suggest that a metal transporter is under the control of protein kinase C.

1680 CADMIUM-INDUCED LUNG INJURY IN MICE: EVIDENCE FOR A SPECIFIC INCREASE IN EPITHELIAL PERMEABILITY.

W C Prozialeck[1], T S Pitt[1], K E Huncosky[1], P C Lamar[1], J N Kasimos[1] and R J Niewenhuis[2]. [1]*Midwestern University, Downers Grove, IL and* [2]*Philadelphia College of Osteopathic Medicine, Philadelphia, PA, USA.*

Although it is well known that respiratory exposure to Cd^{2+} results in pulmonary edema, inflammation and hemorrhaging, the specific mechanisms underlying these effects have yet to be elucidated. The recent findings from our laboratory showing that Cd^{2+} can disrupt the tight junctions between several types of epithelial cells in culture have lead us to examine the possibility that some of the pneumotoxic effects of Cd^{2+} might result from specific changes in the permeability of the tight junctions in capillary endothelial and alveolar epithelial cells. Male CF-1 mice were given either saline, or $CdCl_2$ (65 nmoles in 50 μ l saline) via intratracheal instillation. After 24 hours, the animals were euthanized, and their lungs were removed and either subjected to bronchoalveolar lavage or analyzed for histopathologic changes by light and electron microscopy. The results showed that Cd^{2+} caused an increase in lung weight and an increase in the erythrocyte and protein content of the lavage fluid. The microscopic analyses showed evidence of edema and capillary congestion but little evidence of injury to the alveolar epithelial cells or the capillary endothelial cells themselves. In addition, the samples from the Cd^{2+}-treated mice showed alterations in the pattern of distribution of E-cadherin, a Ca^{2+}-dependent cell adhesion molecule that is associated with the adhering junctions of epithelial cells. These findings suggest that the Cd^{2+}-induced pulmonary edema does not result from the death of the alveolar epithelial cells, but may be a consequence of an increase in the permeability of the E-cadherin-dependent junctions between the cells. (Supported by NIH Grant #R01 ES06478.)

1681 EFFECT OF ZINC AND ALBUMIN PRETREATMENT ON CADMIUM UPTAKE IN RAT HEPATOCYTES EXPOSED UNDER PHYSIOLOGICAL CONDITIONS.

N J DelRaso and J M Frazier. *Human Effectiveness Directorate, Air Force Research Laboratory, Wright-Patterson AFB, OH.*

A key factor in cadmium induced toxicity is uptake by the liver. Primary hepatocytes offer a useful tool for studying the uptake and toxicity of this heavy metal at the cellular level. However, differences in culture conditions, exposure conditions and exposure durations make it difficult to determine realistic dose-response relationships. The goal of this study was to investigate acute 1-h cadmium uptake kinetics and toxicity in healthy hepatocytes exposed under physiological conditions. Primary rat hepatocytes were exposed to cadmium concentrations ranging from 32 to 1,000 μM in buffer lacking or containing physiologic albumin levels (4%). In addition, hepatocytes pretreated with 100 μM zinc for 24 h were exposed to cadmium in buffer containing physiologic albumin. Cadmium toxicity in hepatocytes assessed 23 h following a 1 h exposure was observed to be significantly reduced by the presence of albumin in the exposure buffer and zinc pretreatment, respectively. The presence of albumin in the exposure buffer was also found to significantly decrease the rate of cadmium uptake when compared to exposure buffer lacking albumin. Pretreatment of hepatocytes with zinc did not effect the rate of cadmium uptake. It was observed that a rapid association of cadmium with the cell surface occurred over the first minute that was constant and sensitive to washing with buffer containing EGTA. A linear uptake rate was observed between 15 to 60 min of exposure that was insensitive to the presence of EGTA in the wash buffer. The results of this study indicated that hepatocyte culture and exposure conditions effect cadmium uptake kinetics and toxicity.

1682 EFFECTS OF ORAL CADMIUM ADMINISTRATION ON RENAL FUNCTION AND BONE METABOLISM IN MALE RATS.

H Ohta, S Asami , Y Seki, and H Yoshikawa. *Department of Occupational Health and Toxicology, School of Allied Health Sciences, Kitasato University, Sagamihara, Kanagawa, JAPAN.*

Male Wistar rats (6 weeks old) were given Cd (as CdCl2) at a dose of 0, 2, 5, 10, 20, 30 and 60 mgCd/kg/day by gastric tube daily for 6 consecutive days a week for 60 weeks. Animals were sacrificed at 0, 1, 3, 5, 10, 30, and 60 week after oral Cd administration. Cd concentration in the kidney, urinary excretion of enzymes (NAG,AAP,GST,ALP), the urinary excretion of Pyridinoline (Pyr) and Deoxypyridinolin (Dpyr) were determined. Bone mineral density of the femur was determined by microdensitometry (MD)

method, and the osteoid volume (%) was also determined by the Quantitative Image Analysis method. At low Cd administration groups of 2 and 5 mgCd/kg/day, the prominent renal dysfunction was not observed. On the other hand, in the high Cd dose groups of 20, 30 and 60 mgCd/kg/day, the renal proximal tubular dysfunction was observed, and the decreased bone mineral density was found at before and after the manifestation of renal dysfunction. Osteoid volume (%) in the femur was shown the lower level compared to that of control animal. The increased osteoid volume was not found in all animals except the case of 2 mgCd/kg group at the 5th week. The increased urinary excretion of Pyr, Dpyr and Ca was observed in the high Cd dose groups from the 3rd week after the Cd administration. It was suggested that the bone resorption is activated. These results suggest that the renal dysfunction, the decreased bone mineral density, and the decreased osteoid volume in the femur are resulted at different time corresponding to the Cd accumulation resulted by the different condition of Cd exposure. Dpyr and Ca was observed in the high Cd dose groups from the 3rd week after the Cd administration. It was suggested that the bone resorption is activated. These results suggest that the renal dysfunction, the decreased bone mineral density, and the decreased osteoid volume in the femur are resulted at different time corresponding to the Cd accumulation resulted by the different condition of Cd exposure. (This study is supported by the research grants from the Kitasato PRG B-10 and the Japanese EA.)

1683 ANTIOXIDANT POTENTIAL IN BLOOD OF WORKERS EXPOSED TO LEAD AND CADMIUM IN THEIR WORK-PLACE.

W Wasowicz, J Gromadzinska, and K Rydzynski. *The Nofer Institute of Occupational Medicine, Lodz, Poland.* Sponsor: E Dybing.

The aim of the study was to examine selenium (Se), zinc (Zn), copper (Cu) levels, and activities of antioxidant enzymes such as glutathione peroxidase (GSH-Px), superoxide dismutase (SOD), ceruloplasmin, total reactive antioxidant potential as well as thiobarbituric acid reactive substances (TBARS) in blood of workers exposed to lead (Pb) and cadmium (Cd). A group of 44 workers of a lead battery plant, and 21 workers of alkali battery plant (high cadmium levels) were examined. The reference group consisted of 52 persons from other industrial factories, medical staff, students with similar social background and living in the same area. It was found that both Se levels in plasma and GSH-Px activity in erythrocytes of workers exposed to high Cd concentrations (15.2± 7.7 μ g Cd/l whole blood), were significantly lower than in the reference group 50.0± 8.6 μ g/l and 63.0± 13.5 μ g/l ($p<0.0001$), and 15.3± 3.4 u/g Hb and 19.1± 4.1 u/g Hb ($p<0.0001$), respectively. No significant differences were found between other determined parameters. In the group of workers exposed to high lead concentration (504± 92 μ g Pb/l whole blood), lower activity of GSH-Px in erythrocytes and plasma was observed ($p<0.0001$) as compared to persons having no contact with lead. Concentrations of Zn and Cu in plasma of investigated workers were 0.82± 0.16 mg/l and 1.19± 0.17 mg/l and differed significantly from the reference group ($p<0.01$ and $p<0.05$, respectively). In the group of workers exposed to Pb lipid peroxidation measured as TBARS concentration in plasma was found to be increased by 43% (2.08± 1.18 μ mol/l and 1.45± 0.36 μ mol/l; respectively vs. controls; $p<0.0001$). The values of the other markers did not differ significantly from those found in the reference group. It is conclusion that antioxidative potential of the organism of people exposed to high concentrations of Pb and Cd at the work-place were lower than in workers of reference group not exposed to these heavy metals.

1684 PROTECTION AGAINST CHRONIC CADMIUM TOXICITY BY CALORIC RESTRICTION.

Z A Shaikh, S Jordan, and W Tang. *Department of Biomedical Sciences, University of Rhode Island, Kingston, RI, USA.*

Exposure to cadmium (Cd) can result in nephrotoxicity and osteotoxicity. Because Cd-induced nephrotoxicity involves oxidative stress and caloric restriction decreases oxidative stress, we examined whether reduced caloric intake will protect against nephrotoxicity. In addition, the protection against the osteotoxicity was also examined. Weanling male Sprague-Dawley rats were provided drinking water containing 100 mg Cd/l for up to 27 months. Because female rats drank more water/kg body weight than males, they were fed 100 mg Cd/l for 3 months, followed by 80 mg/l until 6.5 months, and 65 mg/l thereafter. Both males and females consumed a total of about 5 g Cd/kg body weight. After the first 3 months food was restricted to 20 g/day. The Cd-exposed females had a 23% reduction in their bone density during the 3 months of unrestricted food intake. No further reduction in bone density was noted during the dietary restriction period. Hepatic and renal Cd accumulation and corresponding MT levels were very similar in both sexes. The reported critical Cd concentration for nephrotoxicity was reached by 9 months. Renal MT levels were maximum at this time, and did not increase significantly despite a 1.5-fold increase in renal Cd concentration over the next 18 months. In spite of high renal Cd levels and lack of availability of sufficient MT, there was no sign of nephrotoxicity, as measured by urinary protein and glucose excretion. It is concluded that caloric restriction increases tolerance to both nephrotoxicity and osteotoxicity of Cd. (Supported by NIEHS grant # ES03187.)

1685 PROTECTION AGAINST CHRONIC CADMIUM TOXICITY BY GLYCINE.

W Tang and Z A Shaikh. *Department of Biomedical Sciences, University of Rhode Island, Kingston, RI, USA.*

A Japan drug containing glycine, glycyrrhizin, and cysteine (Stronger Neo-Minophagen C®) has been reported to protect against chronic Cd toxicity. The present study was conducted to evaluate which of the three constituents of this drug was the main antagonist for Cd toxicity and whether the mechanism of protection involved antioxidant action. Adult female Sprague-Dawley rats were injected sc with 5 μ mol $CdCl_2$/kg/day, 5 times/week, for 15 weeks. Under this dosing schedule the animals developed hepatotoxicity and renal toxicity by week 10. Starting from week 7 four groups of Cd-injected animals received co-treatments with either 10 mg glycyrrhizin/kg, 100 mg glycine/kg, 5 mg cysteine/kg, or with a mixture of all three compounds, 5 times/week. An additional Cd-treated group was co-treated with Vitamin E (100 mg/kg) as a positive control. Only those animals that received vitamin E, mixture, or glycine were protected against Cd-induced hepatotoxicity as well as nephrotoxicity. All three co-treatments decreased Cd-induced hepatic and renal lipid peroxidation. We conclude that the reported beneficial effects of Stronger Neo-Minophagen C® are due to glycine, which appears to protect against chronic Cd toxicity by reducing oxidative stress. (Supported by NIEHS grant # ES03187.)

1686 BIDIRECTIONAL TRANSPORT OF CADMIUM ACROSS APICAL MEMBRANE OF RENAL EPITHELIAL CELL LINES VIA H^+-ANTIPORTER AND INORGANIC ANION EXCHANGER.

T Endo, O Kimura, and M Sakata. *Health Sciences University of Hokkaido, Japan.*

The purpose of this study was to investigate whether Cd efflux across the apical membrane of renal epithelial cells is mediated via a H^+-antiportal system, and to confirm the re-uptake of Cd from the apical membrane via the inorganic anion exchanger. LLC-PK_1 and OK cell monolayers cultured on permeable membrane were incubated with 1 μM $CdCl_2$ added to the basolateral medium, and the basolateral-to-apical transport of Cd and the accumulation of Cd in the monolayers were measured. The Cd transport was increased by lowering the pH of the apical medium and was accompanied by a decrease in Cd accumulation. Coincubation with N'-methylnicotin- amide or cisplatin, typical and possible substrates of the H^+-antiportal systems, respectively, decreased the Cd transport and increased the Cd accumulation in a concentration-dependent manner. To confirm the re-uptake of Cd, LLC-PK_1 cell monolayers were pretreated with DIDS, a specific inhibitor of the inorganic anion exchanger, before incubation with $CdCl_2$. In separate experiment, $ZnCl_2$ (10 nM) or $NaHCO_3$ (2 mM) was added to the apical medium to inhibit and stimulate the re-uptake of Cd, respectively. Pretreatment with DIDS significantly increased the Cd transport and decreased the Cd accumulation in the apical medium at pH 7.4, but not at pH 5.5. The addition of $ZnCl_2$ significantly increased the Cd transport and decreased the Cd accumulation at pH 7.4, whereas the addition of $NaHCO_3$ significantly increased the Cd accumulation. These results suggest that the bidirectional transport of Cd across the apical membrane of renal epithelial cells occurs via the H^+-antiportal system (efflux) and the inorganic anion exchanger (influx), depending on the pH of the medium on the apical side.

1687 CADMIUM INDUCED BIO-ACCUMULATION IN THE SELECTED TISSUES OF A FRESHWATER TELEOST *OREOCHROMIS MOSSAMBICUS* (TILAPIA).

A U Rani. *Department of Zoology, S.V.University, Tirupati, A.P., INDIA.* Sponsor: S M Somani.

In recent years heavy metals discharged from industries are a major source of pollution which has become a threat to all forms of life. Among the myr-

iads of pollutants, cadmium(cd^{++}) is an ubiquitous, non-essential heavy metal which possesses high toxicity to both humans and aquatic organisms and it has the tendency to bio-accumulate (Ravera 1984, Usha Rani & Ramamurthy 1989). This uptake of heavy metal is mostly tissue specific and may even bio-magnify in the animals of higher trophic level. Freshwater fish *Oreochromis mossambicus* (Tilapia) were exposed to sublethal concentration (5 ppm) of Cadmium Chloride (Technical grade) for 1;15; and 30 days of long sojourn. The fish were fed daily with groundnut cake and all the physico- chemical conditions of the aquatic environment was maintained uniformly throughout the experimentation .Tissues like gill, liver, kidney, intestine and scales were isolated after each time interval and acid digested overnight in 3:2 nitric acid : perchloric acid mixture separately in air tight vials. This acid sediment mixture was ashed at 1200 °C and the left over residue was dissolved in 5ml of double distilled water. The Cadmium concentrations in all the above tissues were determined using the graphite furnace atomic absorption spectrophotometer. Results revealed accumulation of Cadmium in all the selected tissues with an exception of high tendency of accumulation in kidney (14.4 mg/l). Cadmium levels were least in intestine (0.92mg/l) and scales (0.7mg/l). Accumulation increased with increased time of exposure and kidney was found to be the specific site for Cadmium accumulation. This bio- accumulation studies can be used as indices of heavy metal pollution and are tools to identify tissue specificity of a particular heavy metal.

1688 CADMIUM INDUCED FREE RADICAL GENERATION AND LIPID PEROXIDATION IN THE KIDNEY AND GILLS OF FRESHWATER FISH,CLARIAS BATRACHUS.

D Desajah [1], T V D D Ramesh[2], S L N Reddy[3], B Rajanna[3] and S Rajanna[3]. [1]*Department of Neurology, University of Mississippi Medical Center, Jackson, MS;* [2]*Osmania University, Hyderabad, India;* [3]*Department of Biology, Alcorn State University, Lorman, MS.*

Cadmium , a non essential element is an important concern due to its accumulation in different organisms through food chains. Though cadmium induced biochemical and pathophysiological alterations are well documented, the mechanisms responsible for such changes are not clearly established. We have reported the free radical mediated lipid peroxidation during cadmium intoxication in brain and liver. The main causes for the pathophysiological manifestation is suspected to be the involvement of free radical generation. The present study is designed to study the cadium induced free radical generation leading to lipid peroxidation in the kidney and gill of a freshwater fish, Clarias batrachus, with a specific objective to find out tissue specific and time dependant variations in responses. Fishes were exposed to sublethal concentration (1/10 of LC-50 value i.e.1.2 ppm) of cadmium chloride for period of 30 days. Following cadmium exposure Xanthine Oxidase activity was measured at 1,7,15,and 30 days to assess the formation of free radicals such as superoxide anion. Further, free radicals were also measured by electron Spin Rosanance (ESR) studies. Malondialdehyde content of the tissues was also measured to quantify the amount of lipid peroxidation. The increased levels of free radical cearly reflected in the lipid peroxidation. The responses were found to be tissue specific and time dependent. The present result indicate that cadimium may cause toxicity in aquatic organisms through oxidative injury.

1689 DNA DAMAGE AND RECOVERY PRODUCED BY CD IN A HUMAN FETAL HEPATIC CELL LINE.

M C Gutiérrez-Ruiz, P López, E Hernández, I P Olivares, L Bucio and V Souza. *Dpto. Ciencias. De la Salud, DCBS, UAM-I, México, D.F.*

Cadmium (Cd) is one of the most important heavy metal environmental toxicants. It alters a wide variety of cellular and biochemical processes. The objective of this work was to study the subcellular distribution and DNA damage and recovery after acute and chronic $CdCl_2$ treatment in a human fetal hepatic cell line (WRL-68 cells). Cd subcellular distribution was 16% nuclear fraction, 23% mitochondrial fraction, 15% in microsomal and 46% in cytosolic fraction. DNA damage was determined by an alkaline microgel electrophoresis assay that detects DNA single-strand breaks and/or alkali-labile sites in individual cells. The mean migration length in control cells was 35.37 ± 1.43 μ m (8 % damaged nucleus), whereas cells treated with 0.005 μ M $CdCl_2$ during 3 hs (acute low dose) increased 86% (88% damaged nucleus). In the 0.01 μ M $CdCl_2$ treatment during the same time (acute high dose) increased 255% (92% damaged nucleus) and 0.005 μ M $CdCl_2$ treatment during 7 days (chronic treatment) increased it by only 65% (88% damaged nucleus). Lipoperoxidative damage expressed as malondialdehyde production per mg of protein was 15.7 ± 2.6 for control cells, and the Cd treated cells values were 20.2 ± 2.4 (acute low dose), 22.9 ± 2.2 (acute high dose) and 22.6 ± 2.1 (chronic treatment). To study the DNA damage recovery, cells were washed with 0.01 μ M meso-2,3-dimercaptosuccinic acid (DMSA), and fresh DMEM was added to cells. The percentage of damaged nucleus diminished after 90 min and DNA migration presented control values after 120 min. Cd treatment produced DNA single–strand breaks and the damage was greater in acute high dose treated cells. Lipid peroxidation values did not follow a direct correlation with DNA single-strand brakes. DNA damage recovery took 120 min after the metal was partially removed with DMSA.

1690 TISSUE DISTRIBUTION OF CADMIUM IN RATS TREATED ORALLY WITH CADMIUM FOR 8 MONTHS.

H Hiratsuka[1], S Satoh[2], M Satoh[3], M Nishijima[4], M Shibutani[5], K Mitsumori[5], and M Ando[5]. [1]*Mitsubishi Chemical Safety Inst. Ltd., Ibaraki, Japan;* [2]*Ina Research Inc., Nagano, Japan;* [3]*NIES, Ibaraki, Japan;* [4]*The Tokyo Metropolitan Res. Labo. of Public Health, Tokyo, Japan;* [5]*NIHS, Tokyo, Japan.* Sponsor: M Tsuchitani.

To investigate the distribution of cadmium (Cd) to various tissues after oral administration, female rats were given diets containing Cd (0.02, 0.04, 0.11, 1.1, 5, 20, and 40 ppm of Cd) for up to 8 months. At 1, 4, and 8 months after the commencement of Cd treatment, rats were administered a single dosage of ^{109}Cd, a tracer, of the matched amounts to Cd for the day (about 1.2 to 2400 μg Cd/kg BW). Then, they were necropsied 5 days later to determine the distribution of Cd to various tissues. In addition, Cd concentrations in the liver and kidneys and metallothionein (MT) in the liver, kidneys, intestinal mucosa, serum, and urine were determined. The distribution rates of Cd to the liver increased dose-dependently (40% at low doses to 60% at high doses), whereas those to the kidney decreased dose-dependently (20% at low doses to 10% at high doses). The Cd retention rates on 5 days after Cd administration (amounts of Cd in various tissues / amounts of Cd administered) ranged from 0.2 to 1.0% at any time points. The concentrations of Cd in the liver and kidneys and MT in the liver, kidney, serum, and urine at 4 and 8 months increased dose-dependently, whereas MT in the intestinal mucosa did not change markedly at any time points. These results suggested that the distribution of Cd to the liver and kidneys after oral administration were varied depending on the levels of Cd. The difference of the distribution pattern of Cd to the liver and kidney was thought to be due to difference in the form of the absorbed Cd, i.e., free ion or Cd-MT complex. However, it was not closely related to MT in the intestinal mucosa in this study.

1691 VALIDATION OF THE NAVY NEUROBEHAVIORAL TOXICITY ASSESSMENT BATTERY (NTAB).

S M McInturf[2], G D Ritchie[2], C Y Ademujohn[2], A F Nordholm[1], and J Rossi III[1]. [1]*Naval Health Research Center Detachment-Toxicology (NHRC/TD);* [2]*Geo-Centers, Inc., Wright-Patterson AFB, OH, USA.* Sponsor: E A Smith.

Since 1993, NHRC/TD has been involved in development of a comprehensive battery of animal-based tests for prediction of human performance decrements that may be a consequence of exposure to chemicals of military interest. The NTAB consists of nearly 20 tests that evaluate decrements in eight major neurobehavioral performance factors. The NTAB is currently being validated as a tool for human risk assessment through comparison of animal and human results on topographically-similar performance tests following administration of pharmacological compounds that are ethically-acceptable for human use. Pharmacologics used include: ethanol, d-amphetamine, diazepam, caffeine, and nicotine. To date, the Navy Roto-Wheel and forelimb grip strength tests have been evaluated for prediction of equilibrium, motor strength and endurance deficits; the Porsolt Forced Swim test for emotional depression; the operant Progressive Ratio/FR-5 test for motivational and motor performance deficits; the operant delayed spectral and geometric pattern delayed matching-to-sample tests for visual system and STM deficits; and the juvenile play behavior analysis test for changes in emotionality and socialization. Results of predictive validation studies are presented and compared to the existing human literature.

1692 BEHAVIORAL TOXICITY OF ETHANOL IN RATS.

E J Popke, S R Allen, C M Fogle, and M G Paule. *Division of Neurotoxicology, National Center for Toxicological Research, FDA, Jefferson, AR, USA.*

The adverse effects of ethanol on behavior and cognition are well documented but poorly understood. The present experiment sought to characterize the behavioral and cognitive effects of ethanol in 24 male Sprague-Dawley rats using tasks in the NCTR operant test battery. Tasks included: temporal response differentiation (TRD) to assess timing behavior; incremental repeated acquisition (IRA) to assess learning; conditioned position responding (CPR) to assess position discrimination; differential reinforcement of low rates (DRL) to assess timing and response inhibition; and progressive ratio (PR) to assess motivation. Task accuracy, percent task complete, and response rates were monitored for the TRD, IRA, CPR, and DRL tasks. Response rate was monitored for PR. Ethanol (0.0, 0.5, 1.0, 1.5, 2.0, and 3.0 g/kg) was suspended in water (40% v/v) and administered by orogastric gavage. Behavior testing began 15 minutes after ethanol administration. Ethanol reduced accuracy and percent task complete for the CPR, DRL, and TRD tasks. For CPR, this reduction was accompanied by a reduction in response rates. Ethanol also reduced response rates on the PR task. There were no effects of ethanol on the IRA task. Overall, the DRL and TRD tasks showed the greatest sensitivity to ethanol, followed by CPR, PR, and IRA. These data suggest that ethanol can impair performance on cognitive-behavioral tasks. Furthermore, because ethanol did not uniformly alter performance on all tasks presented, these data suggest that specific cognitive abilities are differentially sensitive to adverse effects of ethanol.

1693 NEUROBEHAVIORAL SCREENING OF CHILD AND ADULT BYSTANDERS EXPOSURE TO TOLUENE DIISOCYANATE APPLICATION.

R Singer. *Independent Practice, Santa Fe, NM, USA.*

Rationale: Toluene diisocyanate (TDI) is a well known respiratory sensitizer. Less widely reported are its potentially permanent neurotoxic properties. TDI is incorporated into sprayed urethane foam elastomeric coatings, such as roofing materials. Application to surfaces at occupied schools puts children and others (such as the sick and elderly) at risk, who may be more vulnerable to TDI toxicity than is the average male worker, for whom occupational standards have been promulgated. Scope: Over 500 gallons of roofing products containing .6% TDI at 135 degrees F was sprayed by workers in full protective gear over 27,000 sq. ft. of low-level roof of an occupied school building. Numerous students and teachers were exposed to the products and developed respiratory sensitivity symptoms. Assessment approach: A brief neurobehavioral screen (1 hour of testing) was administered to 10 subjects six years post-exposure with troubling respiratory symptoms (asthma, chronic bronchitis) associated with roofing materials containing TDI. The assessment included tests which have an established normative base and that are known to be sensitive to neurotoxicity, including the Benton Visual Retention test, subtests of the WAIS-III battery (Digit Symbol, Digit Span, and Block Design), a logical memory test, the Neurotoxicity Screening Survey, and tests for malingering and distortion. Summary of findings: Positive symptoms on the Neurotoxicity Screening Survey were found in 7/9, with 2/9 results borderline. Neurobehavioral test results (signs) were positive in 26/39 tests (67%), borderline in 5/39 (13%) and within normal limits in 8/39 (21%). All test results of malingering were negative. Conclusion: Findings are consistent with TDI neurotoxicity. Psychogenic causes are unlikely explanations of the illness in part due to negative malingering and distortion test results, positive cognitive deficits and duration of symptoms.

1694 A 13-WEEK NEUROTOXICITY STUDY OF PHENOL ADMINISTERED IN THE DRINKING WATER TO THE RAT.

P C Beyrouty[1], P A Tellier[1], S S Dimond[2], J H Butala[3], R L Joiner[2], B J Dunn[4], R Gingell[5], and J M Waechter[6]. [1]*ClinTrials BioResearch, Senneville, QC, Canada;* [2]*GE Plastics, Pittsfield, MA, USA;* [3]*Consultant to Aristech, Pittsburg, PA, USA;* [4]*Allied Signal, Morristown, NJ, USA;* [5]*Shell Chemical Company, Houston, TX, USA;* [6] *The Dow Chemical Company, Midland, MI, USA.*

Groups of 15 male and 15 female Sprague-Dawley (CD) rats were treated for 13 weeks, via the drinking water, with phenol at concentrations of 0, 200, 1000 or 5000 ppm. A 4-week recovery period followed the treatment phase. In-life evaluations included body weight, food consumption, water intake, clinical signs, as well as a functional observational battery (FOB) and motor activity test. At treatment termination, 5 rats/sex/group in the 0 and 5000 ppm groups underwent a neuropathological evaluation. At 5000 ppm, a lower body weight, reduced food and water consumption and abnormal clinical signs, including dehydrated appearance, were seen for many animals of both sexes. At this high dose, one female was euthanized early in the study due to poor condition. At 1000 ppm, decreased water intake and on occasion dehydrated appearance were seen. Marked improvements were noted for the 1000 and 5000 ppm groups immediately upon initiation of the recovery period. No effects were noted for any of these parameters at 200 ppm. The FOB did not reveal any findings of neurotoxicological significance at any concentration following treatment or recovery. Observations of altered motor activity (females only) were noted at 1000 and 5000 ppm, however, this finding was considered to be secondary to the reduction in water and/or food intake. No gross or histopathological lesions in nervous tissue attributed to treatment with phenol were noted. Based on these findings, the no observed effect level (NOEL) for neurotoxicity under the conditions of this study was 5000 ppm (corresponding to 308 and 360 mg phenol/kg body weight/day for males and females, respectively). (The Chemical Manufacturers Association Phenol Panel sponsored this study.)

1695 SUBCHRONIC TOXIC AND NEUROTOXIC EFFECTS OF ACPC (1-AMINOCYCLOPROPANE-1-CARBOXYLIC ACID) IN RATS.

C P Chengelis[1], C Elangbam[1], M Butt[2] and M Maccecchini[3]. [1]*WIL Research Laboratories, Inc., Ashland, OH;* [2]*Pathology Associates Int., Fredericksberg, MD;* [3]*Bearsden Bio, Inc., Aston, PA.*

ACPC a partial NMDA agonist, was evaluated in this 13-week study which also included a 13-week recovery period. Four of the groups (Groups 1-4, 20/sex/group) were used for toxicological assessment; the remaining four groups (Groups 5-8, 15/sex/group) were used for neurotoxicological and pharmacokinetic assessments. Dosage levels were 200, 600 and 1800 mg/kg/day administered daily by gavage. Clinical observations, body weight, feed consumption, clinical pathology, ophthalmology, gross necropsy, organ weights and standard histologic assessments were conducted on toxicology group animals. Functional observation battery, motor activity, neuropathology and pharmacokinetic assessments were conducted on the remaining groups. ACPC was rapidly absorbed in a dose proportional fashion and was generally cleared from the system within 24 hours. ACPC at 1800 mg/kg resulted in transient changes in the clinical condition of the animals (fine tremors one hour following dosing during the first few days of treatment), slight reductions in body weight gain and widely disseminated microscopic intramyelinic vacuolation of the brain (both white and grey matter) which was less severe after the recovery period. No neuro-behavioral deficit was identified by functional observation and motor activity assessment. Neuronal degeneration and necrosis typical of NMDA antagonists was not observed in perfused rats. At 600 mg/kg, ACPC related changes were limited to vacuolation in the brain in a limited number of animals and was not present after recovery. No signs of toxicity were observed at 200 mg/kg/day.

1696 SPATIAL LEARNING AND LTP CORRELATE WITH CHANGES IN HIPPOCAMPAL NMDAR-1 mRNA AND PROTEIN IN ADULT RATS EXPOSED TO Pb^{2+} DURING DEVELOPMENT.

M K Nihei[1], N L Desmond[2], J L McGlothan[1], A C Kuhlmann[1] and T R Guilarte[1]. [1]*Dept of Environ. Health Sci., The Johns Hopkins University SHPH, Baltimore, MD, USA and* [2]*Dept of Neurosurgery, University of Virginia, Charlottesville, VA, USA.*

N-methyl-D-aspartate receptor (NMDAR) activity is important for synaptic plasticity, in learning and memory, and during development. Lead (Pb^{2+}) neurotoxicity is known to impair both cognitive function in children, and long-term potentiation (LTP) in the rat hippocampus. Pb^{2+} is also a potent inhibitor of the NMDAR. This study examined relationships between spatial learning, LTP, and NMDAR gene and protein expression in adult, rat littermates exposed to Pb^{2+} during development. Spatial learning in the Morris water maze was impaired ($F_{2,25}$=5.77, p<0.05) in Pb^{2+}-exposed adult rats. *In vivo* LTP was induced unilaterally in the entorhinal cortex-dentate gyrus pathway of control and Pb^{2+}-exposed adult rats. Averaged over the 60 min post-conditioning period, the magnitude of LTP evoked in Pb^{2+}-exposed rats was significantly less ($F_{2,5}$=8.633, p<0.05) than in control rats. Rats exposed

to Pb^{2+} also exhibited reduced NMDAR-1 mRNA in both the granule ($F_{2,10}$=7.404, p<0.05) and pyramidal ($F_{2,10}$=6.602, p<0.05) cell layers of the hippocampus. NMDAR-1 protein was significantly reduced ($F_{2,9}$=6.826, p<0.05) in the hippocampus of Pb^{2+}-exposed adult rats. Together, these data suggest a relationship between both Pb^{2+}-induced impairment of spatial learning and Pb^{2+}-induced changes in synaptic plasticity, with molecular changes in the NMDAR-1 subunit. These findings support the hypothesis that the NMDAR is a principal target for Pb^{2+} neurotoxicity. (Supported by ES06189 to TRG and T32 ES07141 to MKN.)

1697 EFFECTS OF LEAD, MAGNESIUM AND ZINC MIXTURE ON SPATIAL MEMORY CAPABILITY AND NMDA-RECEPTOR SUBUNIT COMPOSITION IN F344 RATS.

H M Newman[1], K Magnusson[2], and R S H Yang[1]. [1]*Center for Environmental Toxicology and Technology, Department of Environmental Health and* [2]*Department of Anatomy & Neurobiology, Colorado State University, Fort Collins, CO.*

The N-methyl-D-aspartate (NMDA)-receptor complex (NR) is known to be involved in learning and memory processes. It undergoes changes in subunit composition early in life, affecting affinities for its ligands zinc (Zn) and magnesium (Mg). Presumably, lead (Pb) also binds to the Zn-binding site. Pb, Mg and Zn are common ground water contaminants, often occurring in combination. Goals of this study were to evaluate the effects of Pb, Mg and Zn individually and in combination: (1) on spatial learning and memory capabilities and (2) on the mRNA for the NR subunits. Male F344 rats (n=29) were gavaged once daily with Mg-, Zn- or Pb-acetate (individually or as a mixture) for 4 weeks, beginning on postnatal day 21. After 2 weeks of exposure, learning was tested daily using a water maze. Each animal was tested 3X per day for 12 days with a hidden platform, every 6th run being a probe trial. On day 13, their vision was tested using a visual cue on the platform. The behavioral data showed that all animals learned equally fast within 4 days, with no further improvement in performance thereafter. There were no significant group differences for swim speed, cumulative distance, runtime or pathlength, suggesting that short-term exposure to these metals in early post-weaning time does not result in immediate behavioral changes. Since it is possible that molecular changes indeed occurred but were not manifested behaviorally, we are currently analyzing amounts of mRNA for the different NR subunits in various brain regions using in situ hybridization. This study was supported by a number of small grants from Colorado State University.

1698 DEVELOPMENTAL LEAD (Pb) EXPOSURE FAILS TO DISRUPT SPATIAL LEARNING IN THE MORRIS WATER MAZE.

T E Samsam[1] and M E Gilbert[1,2]. [1]*NTD, NHEERL, US EPA, RTP, NC, USA;* [2]*Nat'l Res. Council, RTP, NC, USA.*

Long-term potentiation (LTP) is a plasticity model associated with the neurobiological mechanisms of memory. Chronic exposure to environmentally relevant Pb levels has previously been shown to impair hippocampal LTP. The present study examined the effects of developmental Pb exposure (0, 0.2%, 1.0%) on a spatial learning task. From GD16 to PND21 Long Evans rats were exposed to Pb through the drinking water of the pregnant dam and directly via their own water supply at weaning. Performance on an acquisition task and a working memory task was assessed in adult male offspring using the Morris water maze. Acquisition testing consisted of 2 trials/day for 14 days. Animals located a submerged platform positioned in a constant location throughout the task. There was no difference in rate of acquisition between Pb-exposed and control rats. Probe trials in which the platform was removed were implemented throughout the acquisition period and time spent in the correct quadrant of the test apparatus during the trials was assessed. The probe trials also failed to discriminate among groups. Following the acquisition phase animals were tested on a repeated acquisition task, 4 trials/day for 5 days in which the platform position remained constant across trials, but changed daily. Performance on this working memory task revealed no differences among the groups. Finally, the effects of the NMDA antagonist, MK801, on working memory were evaluated. MK801 (0, 0.05, 0.1 mg/kg, s.c.) was administered 20 minutes prior to the start of trial 1 with a minimum of 3 drug-free days interceding between each drug dose. A dose-dependent disruption in working memory was observed following MK801 but no differential effect of Pb on task performance was detected. These data fail to reveal an impairment in spatial learning following Pb exposure that produces deficits in hippocampal LTP. The findings are consistant with reports of intact spatial learning in similarly Pb-exposed animals using the radial arm maze (Driscoll et al., 1997) and reveal a dissociation in the Pb-induced deficits in spatial learning and hippocampal LTP.

1699 CHRONIC LEAD EXPOSURE ALTERS EXPLICIT MEMORY FUNCTION.

L L Driscoll , J J Wu, K J Zurich, & B J Strupp. *Dept. of Psychology & Div. of Nutritional Sci., Cornell Univ., Ithaca, NY.*

Despite increasing evidence that low-level lead (Pb) exposure impairs cognitive functioning, much remains to be learned about the specific processes affected and the underlying mechanism(s). Pb exposure has been shown to alter hippocampal electrophysiology (e.g., LTP) and neurochemistry. Because explicit memory depends on the hippocampus, Pb exposure would be expected to specifically impair this type of memory. However, there is no convincing evidence for this type of effect. One interpretation is that the neural changes are not of sufficient magnitude to be functionally significant. However, it is also possible that the paradigms used are not sufficiently sensitive to detect subtle impairments in explicit memory. To address this possibility, two previous studies in our lab examined the effect of chronic Pb exposure on explicit memory function, using a task that has been shown to be sensitive to manipulations that subtly alter hippocampal function. Both studies found that explicit memory function in the Pb-exposed animals was superior to controls, particularly at long retention intervals. The present study was designed to explore a wider range of exposures, to determine whether the putative memory modulatory effects of Pb manifest themselves as impairment at some BPb levels. Male Long-Evans rats were exposed to Pb chronically from birth, yielding mean BPb levels of <5, 35, & 70 μg/dl. Explicit memory was assessed in a radial arm maze with varying retention intervals (0, 4, & 8 hrs) imposed midway through the test session. Chronic Pb exposure significantly and specifically altered explicit memory function. A U-shaped dose-response curve was observed, with the low-dose group being significantly different from both controls and the higher-dose group; the latter groups did not differ. As in our previous 2 studies, the direction of the effect at the low dose was enhancement, rather than impairment, of explicit memory function. Possible underlying mechanisms will be presented as well as a regression analysis relating blood Pb level with memory function. (Supported by NIEHS ES07457, ES05950 and EPA U-915393-01-0.)

1700 ENDURING EFFECTS OF EARLY LEAD EXPOSURE: ASSESSMENT OF SUSTAINED ATTENTION, INHIBITORY CONTROL, AND INFORMATION PROCESSING SPEED.

B J Strupp, R M Morgan, and H Garavan. *Department of Psychology & Division of Nutritional Sciences, Cornell University, Ithaca, NY.*

Despite increasing evidence that early lead (Pb) exposure can produce lasting behavioral changes, much remains to be learned about the specific cognitive processes affected. One prominent theory is that Pb exposure produces a syndrome similar to attention deficit hyperactivity disorder (ADHD). Yet this theory is based primarily on behavioral observations in the classroom; few studies have included tasks specifically designed to assess sustained attention and inhibitory control, the hallmark areas of dysfunction in ADHD. The present study was designed to test these cognitive functions, using a rodent model of early childhood Pb exposure. Long-Evans dams received Pb acetate (300 or 600 ppm) during gestation and lactation, or lactation alone. Dams receiving sodium acetate served as the control. Pb exposure stopped at weaning on PND 30. Sixty adult offspring were tested on a series of automated tasks designed to assess visual sustained attention, inhibitory control, and speed of information processing. A deficit in sustained attention was observed in rats exposed to Pb during both gestation and lactation, or lactation alone. However, impairment was only observed on the most demanding of the four tasks, in which both the onset and duration of the visual cue varied randomly across trials. Tasks in which only cue onset varied did not reveal attentional dysfunction. Speed of information processing, a measure shown to correlate with IQ in humans, was not affected by early Pb exposure. The rate of premature responding, a measure of inhibitory control, did not yield consistent evidence of Pb-induced impairment. These findings provide one of the first demonstrations of an enduring effect of early Pb exposure on sustained attention. However, the relative lack of impairment in the area of inhibitory control argues against a clear ADHD-like profile. (Supported by NIEHS grants ES07457 & ES05950.)

1701 EVIDENCE FOR THE ROLE OF DOPAMINE D2 RECEPTORS IN MEDIATING ALTERATIONS IN FIXED INTERVAL PERFORMANCE BY LOW LEVEL LEAD (Pb) EXPOSURE.

O O Areola and A L Jadhav. *College of Pharmacy & Health Sciences, Texas Southern University, Houston, TX, USA.*

The aim of this study was to further investigate the contention that alterations in central dopaminergic mechanisms mediate the behavioral impairments reported with low level Pb exposure. Several studies have reported region-specific modulation of D2 receptor mechanisms and measures of FI (fixed interval) performance. 21-day-old male Long Evans rats were exposed to 0 or 50 ppm Pb acetate orally for 90 days. A FI-1min paradigm was imposed after 30 days of exposure and overall response rates (ORR) assessed over 30 sessions. Subsequently, each group was subdivided into two and treated with 0.01, 0.05, 1.0, 3.0 mg/kg i.p quinpirole (Q) or eticlopride (E) respectively. ORR were monitored for 5 sessions after each treatment. After the first few sessions, the Pb-treated group exhibited higher ORR. Quinpirole resulted in significantly ($p < 0.05$) decreased responding in the Pb group at all the doses except 0.01 mg/kg. Eticlopride did not alter ORR for both groups at the two lower doses, but at 1 mg/kg, ORR were higher for the control group. At 3 mg/kg, though there were temporal differences, ORR were higher for the control group. Although there were dose-dependent differences, quinpirole reversed the higher response rates of the Pb-exposed group and these changes were associated with alterations in extracellular dopamine. On the other hand, eticlopride did not alter changes in response rates and extracellular dopamine levels in Pb-treated rats. Taking together, these results showed that D2 receptor mechanisms can modulate changes in response rates that result from low level Pb exposure. (Supported by ATSDR Cooperative Agreement #U50/ATU 398948.)

1702 Pb EXPOSURE MODIFIES DOPAMINE (DA) ANTAGONISM OF BUT NOT BEHAVIORAL SENSITIZATION TO QUINPIROLE'S LOCOMOTOR ACTIVATING EFFECTS.

D E Pankevich, M R Bauter, B J Brockel and D A Cory-Slechta. *Department of Environmental Medicine, University of Rochester Medical School, Rochester, NY.*

Chronic Pb exposure alters mesolimbic (MES) dopamine (DA) function, suggesting that elevated Pb burden could serve as a risk factor for MES-associated behavioral dysfunctions, including schizophrenia, drug abuse and attention deficit disorder. This study sought to further understand mechanisms by which Pb alters MES DA function. Changes in motor activity following acute administration of the D2 agonist quinpirole (QUIN; 0.05-5.0 mg/kg), its blockade by the D2 antagonist eticlopride (0.05-0.20 mg/kg) or the D1 antagonist SCH23390 (0.02-0.04 mg/kg), and sensitization to repeated 1.0 mg/kg QUIN doses were examined in rats exposed chronically to 0, 100 or 500 ppm Pb acetate drinking water from weaning. QUIN dose-dependently increased motor activity but these effects were not impacted by Pb. Nor did Pb influence either the development or reversal of sensitization following repeated QUIN treatments. DA antagonism effects, however, differed by Pb exposure level. Both eticlopride and SCH23390 decreased QUIN-enhancement of motor activity. While D2 antagonist effects were potentiated by 100 ppm Pb (blood Pb = 17 ug/dl), 500 ppm Pb (blood Pb = 47 ug/dl) potentiated SCH23390 effects and altered its time course. These findings may provide a neurochemical analogue for biphasic behavioral manifestations of Pb; they also suggest a preferential or initial impact of low-level Pb on D2-mediated behavioral functions. A question to be pursued is the relationship of these findings to reported D1-D2 interactions. (ES05017, ES05903 and ES01247.)

1703 METHYLPHENIDATE (RITALIN) DOES NOT REVERSE THE EFFECTS OF LOW-LEVEL LEAD (Pb) EXPOSURE ON A WAITING FOR REWARD BEHAVIORAL PARADIGM.

B J Brockel and D A Cory-Slechta. *Department of Environmental Medicine, University of Rochester, Rochester, NY.*

Many of the effects of low-level lead (Pb) are similar to the symptoms of Attention Deficit Disorder (ADD). Children with ADD and those with elevated Pb levels are described as impulsive or having an inability to manage delays. Methylphenidate (ritalin) is commonly used to treat children diagnosed with ADD. This study compared acute and chronic methylphenidate effects in control and Pb exposed rats on a behavioral waiting task. Groups of 12 rats each were exposed chronically from weaning to levels of 0, 50, or 150 ppm Pb acetate in drinking water. After 40 days of exposure, rats were trained on a fixed ratio (FR) - wait behavioral baseline. A total of 50 responses (FR 50) on an operant lever produced a 45 mg food pellet. After earning an FR pellet, "free" pellets could be obtained until another lever response was emitted which reinitiated the FR component. "Free" pellets were delivered at increasing time intervals (i.e., 2 s, 4 s, 6 s, ...). Acute methylphenidate (0.0 - 16.0 mg/kg) treatment increased the number of responses per reinforcers in the 150 ppm group, suggesting that methylphenidate potentiated the effects of Pb. Chronic methylphenidate (4.0 mg/kg) increased FR resets, FR response rate, and responses per reinforcement and decreased mean longest wait times, with these effects not differentially altered by Pb exposure. These findings support previous results from this laboratory that the deficits produced by postweaning low-level Pb exposure is related to increased DA. (Supported by ES05727, ES05017, ES05903, ES01247.)

1704 EFFECTS OF CHRONIC LEAD EXPOSURE ON NEUROBEHAVIOURAL FUNCTION AND DOPAMINERGIC RECEPTORS IN RATS.

T Ma, H-H Chen, and I K Ho. *Department of Pharmacology and Toxicology, University of Mississippi Medical Center, Jackson, MS, USA.*

Effects of chronic Pb exposure on radial maze performance, locomotor activity, and dopaminergic receptors in rats were investigated. Rats were exposed pre- and post-natally from day 4 ± 1 post conception with 1000 ppm lead acetate (Pb) in their drinking water. This treatment continued after weaning and until post-natal day 84. No change in working error and reference error was found in the radial arm maze following Pb exposure, indicating no influence of Pb on spatial learning. However, Pb-treated rats took less time for the first 4-arm visits and for 4 baited arm visits in the radial maze, and also showed significantly higher locomotor activity in the open-field. The results reveal that Pb may induce hyperlocomotor activity in rats. Pb treatment did not affect the motor coordination, as observed in the rotarod test. Pb produced a decrease in [^{125}I]sulpiride binding to D2-receptors in the cerebral cortex, but not in the nucleus accumbens and caudate putamen. No effect of Pb exposure on [^{125}I]SCH-23982 binding to D1-receptors was found in all brain areas examined. This research suggests that Pb-induced changes in D2-receptor in the cerebral cortex may be related to increases in locomotor activity.

1705 EFFECTS OF SUCCIMER ON REGIONAL BRAIN Pb LEVELS IN PRIMATES.

J Cremin, Jr[1], M Luck[2], N Laughlin[2], and D R Smith[1]. [1]*Environmental Toxicology, University of California, Santa Cruz, CA, USA;* [2]*Harlow Primate Center, University of Wisconsin, Madison, WI, USA.*

While a number of studies have evaluated the efficacy of succimer (2,3-dimercaptosuccinic acid) for reducing brain Pb levels in rodent models, no data exist on the efficacy of this treatment for reducing brain Pb levels in primates. These data are necessary to better predict succimer's ability to ameliorate Pb-induced cognitive deficits in children, particularly since primates may metabolize succimer differently than rodents. The objectives of this study were to determine if succimer reduces brain Pb levels in a primate model, including those in brain regions associated with learning. Eleven adult male rhesus monkeys (*Macaca mulatta*) were orally exposed to Pb acetate via water for 5 weeks to achieve target blood Pb levels of 35 ug/dL. Prior to treatment, a pre-chelation biopsy of the pre-frontal cortex was collected (PRE-PFC). The next day Pb exposure ceased and the monkeys were randomly assigned to control (C, placebo, n=5) or succimer (n=6) groups. Succimer was given at 30 mg/kg BW/d for 5 days then 20 mg/kg BW/d for 14 days. The monkeys were then sacrificed and a post-chelation pre-frontal cortex biopsy (POST-PFC) collected and the frontal lobe (FL), hippocampus (H), and striatum (S) removed. Tissues were analyzed for Pb content using trace metal clean techniques and ICP-MS. Succimer treatment did not reduce brain Pb levels ($P>0.88$). However, cessation of Pb exposure reduced brain Pb in both treatment groups (PRE-PFC vs POST-PFC, $P = 0.006$). Regarding brain regions, Pb levels in the PFC were higher than the FL or H ($P<0.05$), while the S had the least Pb ($P<0.05$). Moreover, higher blood Pb levels during Pb exposure were associated with higher Pb in the H and S at sacrifice ($P<0.05$). These results indicate that 1) a standard clinical regimen of succimer is ineffective in reducing brain Pb levels, particularly when compared to the efficacy of eliminating Pb exposure, and 2) the accumulation of Pb in some brain regions is proportional to Pb exposure history. (Supported by NIEHS Grant #06918.)

1706 THE EFFECT OF CHRONIC DIETARY LEAD EXPOSURE ON GALACTOLIPID METABOLISM IN RATS.

W Deng and R D Poretz. *Rutgers University, New Brunswick, NJ, USA.* Sponsor: K R Cooper.

Lead exposure causes cognitive and behavioral deficits in children. We propose that a contributing mechanism for the neurological damage is that lead induces critically low levels of arylsulfatase A (ASA) at sensitive stages of nervous system development. Inadequate levels of ASA cause the accumulation of sulfatide and the demyelinating disease, metachromatic leukodystrophy. We hypothesize that the combined effects of a single nucleotide genetic polymorphism in human ASA which results in reduced levels of the enzyme, and lead concentrations which causes a decrease in the amount of ASA activity culminate in cellular enzymic activity below a critical threshold needed to maintain normal nervous system function. To examine the effect of lead on galactolipid metabolism, enzymes and galactolipids were studied in rat pups exposed to the metal *in utero* and subsequently through maternal milk from exposed mothers and water following weaning. Pups from control and exposed groups were sacrificed by decapitation at 1, 2, 3, 5 and 8 weeks of age. It was found that the specific enzyme levels of the relevant galactosyl and sulfotransferases and ASA were decreased by as much as 40-55% in whole brain homogenates of animals exposed to lead. Quantification of the various forms of brain galactosyl ceramide and sulfatide demonstrated the impact of lead as expected from the effect of the dietary metal on the enzymes. The results of these experiments and earlier studies with human fibroblast are consistent with the expectations of the hypothesis. (Financial support from NIH (R01-ES08373) and the March of Dimes Foundation is acknowledged.)

1707 BRAIN AND PLACENTAL LESIONS PRODUCED IN RAT FETUSES PRENATALLY EXPOSED TO LOW-LEVEL LEAD ACETATE.

J Villeda-Hernández[1], R Barroso-Moguel[1], M Méndez-Armenta[1] and C Ríos[2]. [2]*Lab Neuromorfología Celular & [2]Depto. de Neuroquímica. Instituto Nacional de Neurología y Neurocirugía, México.*

The effects of lead in the biological systems are well documented. In the central nervous system, lead toxicidad is more evident in the children than in adults and may produce either overt symptoms of acute encephalopathy such as ataxia, headache, convulsions and coma or lesser deficits including learning disorders and hiperactive behavior. During fetal development it is clear that lead crosses the placental barrier readily producing an increase in blood lead levels of fetus. The fetal blood lead levels correlate closely with that in the maternal blood. In this study the effect of prenatal lead administration was studied microscopically in the brain, placenta and umbilical cord of rat fetuses. Twenty-five pregnant Wistar rats were intoxicated with a lead solution of 32 ppm during 21 days through the drinking water. Control group rats received deionized water for the same period. Day of gestation was the day after mating and dosing began on this day. The rats were killed on gestation day 21 and fetuses were obtained for examination, the placenta and umbilical cord were collected too.The histopathological studies of the parietal-cortex, and hippocampus, showed shrunken, hiperchomatic cells and condensed nuclei with abnormal chromatin. The Purkinje cells of cerebellum were shrunken, vacuolar citoplasma and hiperchromatic nuclei, interstitial oedema in all regions studied. The placenta showed severe vascular congestion there are vacuolation citoplasmic, a lot of cells showed abnormal chromatin, Interstitial oedema . The umbilical cord showed hiperchromatic and shrunken cells with severe interstitial oedema. Results showed lead have a toxic effects in rat fetuses prenatally exposed to lead acetate.

1708 INFLUENCE OF SUBACUTE MANGANESE SULFATE ON THE NEUROBEHAVIOR OF FEMALE AND MALE RATS.

H L Komiskey, X F Chen, and D Sarpong. *College of Pharmacy, Xavier University of Louisiana, New Orleans, LA.*

The potential of manganese sulfate to produce neurotoxicity following two weeks of daily gavage was studied in male and female rats. The rats were gavaged with suspensions containing 0.1, 1.0, 10, 30, or 100, mg/kg manganese each day. The functional observational battery and motor activity measurements were used in an initial screen for neurotoxicity. Manganese sulfate only affected the forelimb grip strength and weight gain in male rats. The forelimb grip strength was significantly less in male rats gavaged with 1.0 mg/kg manganese, than those given 30 mg/kg. Male rats given 100 mg/kg manganese gained less weight, than the control rats. The doses of the metal salt did not alter any behavioral measurement in the female rat. The results from this initial neurotoxicity screen indicate the potential of excess manganese to elicit gender specific effects. This initial neurotoxicity screen found female rats less sensitive to any neurotoxic effect from manganese sulfate. In summary, two weeks of daily manganese gavage, at the above doses, produced a couple of toxic effects in only male rats. (Support by ATSDR grant U50/ATU398948.)

1709 THE EFFECTS OF METHYLMERCURY EXPOSURE ON VISUAL AND AUDITORY FUNCTIONS IN NONHUMAN PRIMATES.

T M Burbacher[1], K S Grant[1], S G Gilbert[2] and D C Rice[3]. [1]*University of Washington, Seattle, WA, USA;* [2]*Biosupport, Inc, Redmond, WA, USA;* [3]*Health Protection Branch, Ottawa, Ontario, Canada.*

The present study assessed visual and auditory functions in adult monkeys (*Macaca fascicularis*) exposed *in utero* to methylmercury (MeHg), a prevalent environmental pollutant. Maternal exposure of either 0, 50, 70, or 90 μg/kg/day of MeHg resulted in blood mercury levels at birth from 1.04 to 2.45 ppm for treated infants. There were 10, 9, 2 and 2 offspring produced, respectively. At approximately 15 years of age the monkeys were tested on a spatial visual contrast sensitivity task and an auditory pure tone detection task. For the vision test, a forced choice tracking procedure was utilized. The following spatial frequencies were assessed: 1, 4, 10, and 20 cycles per degree of visual angle. For the auditory test, a signal detection procedure was used. Frequencies of 125, 500, 1,000, 4,000, 10,000, 25,000, and 31,500 Hz were assessed. The results of these studies indicate that *in utero* exposure to MeHg has long-term effects on visual contrast sensitivity thresholds. Preliminary results from the auditory task suggest that auditory thresholds were not affected. Since previous studies have shown that pre- and postnatal or postnatal exposure to MeHg alone affects auditory thresholds, the results of this study point to the postnatal period as a possible critical window for MeHg induced auditory neurotoxicity. (Funded by Grant RO1 ES03745.)

1710 ACQUISITION OF A MULTIPLE DRH EXTINCTION SCHEDULE OF REINFORCEMENT IN RATS EXPOSED DURING DEVELOPMENT TO METHYLMERCURY.

E B Rasmussen and M C Newland. *Auburn University, Auburn, AL, USA.*

Female rats were exposed to 0, 0.5 or 6.4 ppm Hg as methylmercury in drinking water beginning at least 4 weeks before mating and ending on postnatal day 16. Brain Hg concentrations at birth in cohorts were 0.49 and 9.8 ppm for the two exposure groups. Female offspring were trained to lever press under Multiple Differential-Reinforcement of-High-Rate Extinction (MULT DRH-N:T EXT) schedules of reinforcement. Under the extinction schedule, lever-pressing had no scheduled consequences. Under the DRH-N:T schedule, a food pellet was delivered whenever N responses occur within T seconds. Two acquisition protocols were examined. First, the DRH parameter imposed in three successive sessions was 3:1, 5:2, and 9:4, values selected so that the same average inter-response time (*i.e.*, rate) was required by the schedules. Only ##, ##, and ## % of the control, low-dose, and high-dose rats met the DRH requirement during the third-session. Second, lever-repressing was re-established and the three schedules were imposed until behavior became stable, requiring at least 10 sessions. All but ### animals acquired the response. {A marginal/no effect of mercury was detected?}. This failed to replicate a similar experiment by Bornhausen (19**) showing effects of mercury on acquisition a Multiple DRH EXT schedule of reinforcement. (Supported by ES06466 from NIH.)

1711 EFFECTS OF MERCURY VAPOR AND GENDER ON SUSTAINED ATTENTION IN RATS.

P J Bushnell[1], T E Samsam[1], B K Padnos[1], D L Morgan[2], R P Beliles[3] and S Barone, Jr.[1]. [1]*Neurotoxicology Division, NHEERL, U.S. EPA, RTP, NC;* [2]*NIEHS, RTP, NC;* [3]*NCEA, U.S. EPA, Washington, DC.*

The developmental neurotoxicity of mercury vapor (Hg°) has been of concern to the general public, due to airborne sources of Hg° (e.g., combustion of medical waste and fossil fuels) and chronic exposure to dental amalgams containing Hg. Also, dental health professionals receive episodic exposure to Hg° in the workplace. To evaluate the potential developmental neurotoxicity of Hg°, adult female Long-Evans rats were exposed during pregnancy via inhalation to air or Hg° at 4 mg/m^3 for 2 hr/day from gestational day 6 – 15. Beginning at about 120 days of age, one male and one female offspring

(16 air, 16 Hg°) were trained to press a lever for food; they then learned a signal detection task for assessments of sustained attention. Two cohorts, each with n=8/sex/group, were trained: cohort 1 was trained with visual signals and cohort 2 with auditory signals. Rats trained with auditory signals acquired the leverpress response faster than did those with visual signals; however, acquisition of this response did not differ as a function of either Hg° exposure or sex. Hg° rats trained with visual signals learned the signal discrimination more quickly and to a higher level of accuracy than did controls; males also learned faster and to higher accuracy than did females. No differences were noted in acquisition of the auditory task due to either Hg° treatment or sex. These results do not indicate a strong need for concern regarding potential cognitive dysfunction resulting from gestational exposure to Hg°. (This abstract does not necessarily reflect EPA policy.)

1712 DIFFERENTIAL EFFECTS OF TRIMETHYLTIN ON TASKS RELATED TO TIME ESTIMATION AND APPETITIVE MOTIVATION IN RATS.

A J Mayorga, C M Fogle, and M G Paule. *Division of Neurotoxicology, National Center for Toxicological Research / FDA, Jefferson, AR, USA.*

The effects of the neurotoxic agent trimethyltin (TMT) were investigated in rats using two complex operant tasks designed to model aspects of time estimation and appetitive motivation. Subjects were trained to perform a temporal response differentiation (TRD) task in which they were required to depress and hold a lever for at least ten seconds but not more than fourteen seconds in order to receive a food reinforcer. To assess aspects of motivation in the same session, subjects performed a progressive ratio (PR) task where the number of required lever presses increased for each food reinforcer. Administration of a single dose of TMT chloride (8 mg/kg, i.p.) significantly decreased the number of reinforcers obtained (accuracy) in the TRD task by the sixth day after challenge without affecting the overall rate of responding in that task. The time course of the decrease in TRD accuracy was generally not correlated with a decrease in any parameter of the PR task. In addition, the decrease in TRD accuracy that occurred on the sixth day after TMT failed to recover in the six weeks after toxicant challenge. These results suggest that TMT may selectively affect timing behavior in rats at doses that do not similarly affect performance of operant tasks related to appetitive motivation. In addition, comparison with published neuropathology data suggests that the effect of TMT on TRD performance occurs prior to the time that neuronal cell death is maximal.

1713 METALS AND DISORDERS OF CELL ACCUMULATION: MODULATION OF APOPTOSIS AND CELL PROLIFERATION.

M P Waalkes[1] and M J McCabe[2]. [1]*NCI at NIEHS, Research Triangle Park, NC, USA and* [2]*Wayne State University, Institute of Chemical Toxicology, Detroit, MI, USA.*

As a class of agents, toxic metals are one of the highest priority concerns for human exposure. The carcinogenic potential of many metals or metalloids, like chromium and arsenic, is a major issue. Other metals, like lead and mercury, are potent neurotoxins and potential immunotoxins. Metals often have essential functions within the cell, including regulation of important events in gene regulation, cell proliferation and cell death by apoptosis. Apoptotic cell death, which is an ongoing normal event in the control of cell populations, can be induced by a variety of toxicants, including many toxic metals, resulting in the loss of the affected cells. What has often received less attention is the concept that apoptosis can be impaired by environmental agents, such as metals, and that hindered apoptosis can facilitate aberrant cell accumulation, which may be a critical step in the pathogenesis of malignancy or autoimmunity. Thus for many toxic metals disorders of cell accumulation may be a crucial event in their toxicity. For instance with lead there is evidence in model systems that apoptosis is a key factor in neurotoxicity. With arsenic cell cycle dysregulation, and altered DNA repair and apoptosis may be important early events in transformation. Similarly the carcinogenic potential of chromium may be based in aberrant apoptosis while disruption of normal apoptosis appears to be a key factor in mercury-induced autoimmunity. Understanding the mechanisms by which metals induce disorders of cell accumulation will be important in defining their toxic potentials in exposed populations.

1714 MITOCHONDRIA COORDINATE THE UPSTREAM AND DOWNSTREAM EVENTS IN LEAD-INDUCED RETINAL APOPTOSIS.

D A Fox, L He and A T Poblenz. *University of Houston, Houston, TX, USA.*

Selective retinal cell death occurs in man and animals following hypoxia-ischemia, excitotoxicity and lead exposure. This is associated with Ca2+ overload and its subsequent effects. To examine the mechanisms of lead-induced selective rod and bipolar cell apoptosis, we used in vivo (developmental) and ex vivo (isolated whole retina) lead exposure models. With both lead protocols, retinal: cGMP phosphodiesterase (PDE) - localized to only rod and bipolar cells - is decreased resulting in elevated [Ca] and [Pb]; respiration and mitochondrial ATP synthesis are decreased; mitochondrial cytochrome c is released; CPP-32 like caspase activity is increased; and high molecular weight (HMW) DNA fragmentation occurs. Chromatin condensation is seen in rods and bipolar cells during and following developmental lead exposure but only in rods following ex vivo lead exposure. The decrease in mitochondrial ATP synthesis, release of cytochrome c, activation of caspase and rod cell apoptosis (HMW fragmentation and chromatin condensation) are blocked by BAPTA, ruthenium red and/or cyclosporin A. However, only the activation of caspase and rod cell apoptosis are blocked by DEVD-FMK. These results suggest that lead-induced apoptosis in rod and bipolar cells: i) is triggered by Ca2+ and Pb2+ overload due to decreased cGMP PDE activity in these two cell types, ii) results from direct mitochondrial alterations that are upstream of DEVD-sensitive caspases and iii) is ultimately produced by the activation of downstream CPP32-like caspases. Thus, mitochondrial alterations appear to play a central and coordinating role during the effector phase of lead-induced rod and bipolar cell apoptosis. (Supported by NIH Grant ES03183.)

1715 ARSENIC-INDUCED DYSREGULATION OF CELL CYCLE AND DNA REPAIR GENE EXPRESSION.

J C States, D J Kaplan, J G Pounds, H G Sowder, J J Reiners, Jr., M J McCabe, Jr. and V J Lumetta. *Institute of Chemical Toxicology, Wayne State University, Detroit, MI, USA.*

Arsenic is a common contaminant of drinking water worldwide. Chronic ingestion of trivalent arsenic (arsenite) causes skin, liver and bladder cancer in humans but not in rodents. Arsenite disrupts microtubules and causes an M-phase delay and aneuploidy in normal, diploid human fibroblasts. In contrast, we have observed that 5 - 10 μ M arsenite induces anaphase arrest in SV40-transformed fibroblasts. A majority of anaphase arrested SV40-transformed fibroblasts die via an apoptotic process. Flow cytometry and single cell gel electrophoresis (Comet assay) confirmed the arsenic dose dependent accumulation of cells in G_2/M, loss of DNA, and DNA fragmentation. Spontaneously immortalized human breast epithelial cells (MCF10A) and keratinocytes (HaCaT), and human premyelocytic leukemia cells (U937, HL60) were comparable to SV40-transformed fibroblasts in their sensitivity to arsenite induced cell killing. The kinetics of arsenite killing of asynchronous cultures of immortalized cells directly correlated with population doubling times, consistent with the time needed to reach mitosis. No toxicity was observed in non-dividing confluent diploid fibroblasts (G_0/G_1 arrested) treated with 100 (μ M arsenite. Levels of the DNA damage recognition protein XPA decreased in an arsenite dose dependent manner. This result is consistent with reports of the inhibition of DNA repair by arsenite. These results suggest that arsenite toxicity is manifested by an apoptotic process dependent on cells being in mitosis. Furthermore, loss of cell cycle regulation as in immortalized cells in culture predisposes cells to arsenite induced apoptosis after anaphase arrest. (Supported by ES06639, RR12242, ES06460, WSU OVPPR.)

1716 MECHANISMS AND MODULATION OF CHROMIUM-INDUCED APOPTOSIS.

S R Patierno. *Department of Pharmacology, Molecular and Cellular Oncology Program, The George Washington University Medical Center, Washington, DC, USA.*

Certain chromium compounds are occupational respiratory carcinogens and are of growing environmental concern. These generally highly insoluble particulate forms of hexavalent chromium also cause respiratory mucosal irritation, ulceration and perforation. They cause tumor formation in animals and are genotoxic, mutagenic and transformagenic to cultured mammalian cells, but only at doses that evoke some cell death. We have utilized cellular, molecular, pharmacological and genetic approaches to study chromium tox-

icity and carcinogenesis using normal human respiratory fibroblasts and epithelial cells in culture, as a toxicologically relevant experimental system. We have studied the interaction of particulate chromium compounds with these cells with respect to particle internalization and micro environmental dissolution, using Cr-DNA adducts as an intracellular dosimeter of bioavailability. Structural DNA damage, especially DNA-Cr-DNA crosslinks, has been mechanistically related to functional damage in the form of replication arrest and altered transcription. Depending on the rate, magnitude and spectrum of genotoxicity and mitochondrial damage, and the nature of the affected signaling pathways, cells are fated to either terminal growth arrest or p53-dependent apoptosis. Cells which manage to resist or escape these two fates are predisposed to mutagenesis and neoplastic transformation. Agents which block end-stage apoptosis do not increase survival of replication-competent cells but agents which prevent the pre-apoptotic release of cytochrome c from the mitochondria, increase the survival of genetically damaged cells. Our goal is understanding the nexus between chromium genotoxicity, apoptosis and neoplasia. (Supported by NIEHS Grant ES05304.)

1717 MECHANISMS CONTRIBUTING TO SYSTEMIC AUTOIMMUNE DISEASE: MERCURY-INDUCED TYROSINE PHOSPHORYLATION AND DISRUPTION OF THE CD95/Fas APOPTOTIC DEATH PATHWAY.

M J McCabe, Jr. and A J Rosenspire. *Institute of Chemical Toxicology and Department of Biological Sciences, Wayne State University, Detroit, MI, USA.*

The CD95 apoptotic death pathway is a major regulatory mechanism for controlling the life span of activated lymphocytes. Defects in this pathway have been linked to autoimmunity. Inorganic mercury (Hg2+) induces a systemic autoimmune disease in genetically susceptible strains of rodents characterized by abnormal lymphoproliferation and accumulation of autoreactive lymphocytes. Additionally, epidemiological studies support a linkage between mercury exposure and autoimmunity. Inasmuch as many autoimmune diseases also are associated with abnormal lymphoproliferation and accumulation of autoreactive lymphocytes, we have studied the influences of Hg2+ on signaling pathways controlling cell growth and cell death. This talk will present evidence supporting the hypothesis that Hg2+modulates CD95 death pathway. Our experimental design employs human cell culture models to study the effects of Hg2+ on components of the CD95 death pathway and the epistasis of the effects of Hg2+ on this pathway. Non-toxic concentrations of Hg2+ significantly attenuate the concentration- and time-dependent response to anti-CD95 agonist. However, other apoptosis inducing stimuli such as ceramide and TNF are not attenuated by mercury, suggesting that the signaling component(s) targeted by Hg2+ is unique to the CD95 portion of the apoptotic death pathway. Inhibition of CD95-mediated apoptosis by Hg2+ was confirmed using several criteria including DNA fragmentation, nuclear condensation, phosphatidylserine externalization, and PARP degradation. Induction of caspase-3 autoproteolysis also is attenuated by Hg2+. Mercury does not interfere with the anti-CD95 agonist binding, nor does it down regulate the cell surface receptor density of CD95. Collectively, these data suggest that Hg2+, either directly or indirectly, interferes with CD95-mediated apoptosis by interacting with a signaling component downstream of the formation of the membrane proximal death inducing signaling complex (DISC) and upstream of caspase-3 activation. Additional studies are underway aimed at linking Hg-mediated activation of protein tyrosine kinases and the CD95 death pathway. The plausibility of such altered signaling mechanisms in the etiology of Hg-induced systemic autoimmune disease and the integration of these findings with the published literature concerning Hg-induced immunopathogenesis will be discussed.

1718 XENOBIOTIC EFFECTS ON CELL ADHESION MOLECULES AND EXTRACELLULAR MATRIX INTERACTIONS.

K T Shiverick and B L Allen-Hoffmann. *University of Florida, Gainesville, FL and University of Wisconsin, Madison, WI, USA.*

The extracellular matrix is composed of a variety of versatile proteins and polysaccharides that are secreted locally and assembled into an organized meshwork. The extracellular matrix plays an active and complex role in regulating the behavior of cells that contact it. Cell migration, gene expression, proliferation, shape, function, and cell death are all influenced by interaction with the extracellular matrix. Cells not only secrete extracellular matrix glycoproteins, but also bind to these molecules through specific cell surface receptors. Cell surface adhesion receptors that will be highlighted in the symposium include members of the integrin and cadherin superfamilies. CYP1A1 regulation in a variety of epithelial cell types is influenced by cadherin family members. Oxidative stress and polycyclic aromatic hydrocarbons disrupt cadherin/catenin complexes leading to decreased adhesion in hepatic and uterine models, respectively. Environmental contaminants such as asbestos impact on recruitment and adherence of neutrophils and macrophages in the lung. Remodeling of the extracellular matrix occurs during normal physiological processes such as embryonic development and wound healing in the adult. However, direct activation of tyrosine kinases and the matrix remodeling enzyme, urokinase, by asbestos may contribute to fiber-induced pathology in the lung. The effects of xenobiotics on extracellular matrix organization, signaling, and adhesion receptors will be discussed in this symposium designed to highlight this emerging area in toxicology. Each speaker will provide a unique perspective on xenobiotic perturbation of cell-cell and cell-matrix interactions.

1719 EXPRESSION OF ADHESION MOLECULSES AND PROTEASE ACTIVITY IN ENDOTHELIAL CELLS AND AIRWAY EPITHELIAL CELLS EXPOSED TO ASBESTOS.

A Barchowsky, R Roussel, and M Treadwell. *Department of Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH, USA.* Sponsor: K T Shiverick.

Inhalation of asbestos and certain particles causes recruitment of neutrophils and macrophages into the lung. Chronic activation of phagocyte extravasatio plays a central role in self-perpetuation and amplification of airway inflammation and fibrosis. The cellular and molecular events that lead to this activation are unclear, but appear to involve both direct effects of fibers on airway cells and indirect effects caused by altered cytokine balance in the lung. Cell culture experiments have demonstrated that asbestos directly activates endothelial cell tyrosine kinase activity, nuclear translocation oftranscription factors, and ICAM-1-dependent adherence of neutrophils. In addition these fibers caused the endothelial cells to undergo morphological changes that may result from increased expression of urokinase and its receptor, uPAR. These effects are not limited to the endothelial cells, since chrysotile asbestos also increased NF-kB activation and urokinase expression in human bronchial epithelial cells and in intact lungs. The relative contributions of fiber-induced effects on the different cell types in the lungs that contribute to cell invasion, inflammation, and fibrosis are unresolved. (Supported by HL 52738.)

1720 OXIDATIVE STRESS DISRUPTS THE E-CAD HERIN/CATENIN CELL ADHESION COMPLEX.

A R Parrish and A J Gandolfi. *Southwest Environmental Health Sciences Center, The University of Arizona, Tucson, AZ, USA.*

E-cadherin, the predominate mediator of cell-cell adhesion in epithelium, regulates adhesion via a Ca++-dependent, homophilic mechanism. β -catenin binds the cytoplasmic domain of E-cadherin and is in turn bound by α -catenin, which links the complex to the actin cytoskeleton. Given that E-cadherin is a morphogenic regulator and an invasion/motility suppressor, efforts have focused on the mechanism(s) which cause a loss of function. Interestingly, src family tyrosine kinases are activated by oxidative stress and stable over-expression of src is associated with enhanced phosphorylation of b-catenin and decreased adhesion. This lead to the hypothesis that chemically-induced oxidative stress disrupts the E-cadherin/catenin complex. Based on the maintenance of normal cell-cell interactions, precision-cut mouse liver slices were chosen as the in vitro system. Diamide (DA), a sulfhydryl depleting agent, and tert-butylhydroperoxide (tBHP), an initiator of radical formation, were chosen as model compounds. Initial incubations (6 hr) identified concentrations of DA (25-250 uM) and tBHP (5-50 uM) that were not associated with a significant alteration in protein expression of E-cadherin, b- or a-catenin. Oxidative stress was associated with activation of c-src (DA 200 & 250%; tBHP 340 & 400%) which correlated with tyrosine phosphorylation of b-catenin (DA 100 & 110%; tBHP 200 & 350%). This modification was associated with disruption of the protein interactions of adhesion complex, most notably a decrease in b-catenin:a-catenin interactions (DA 110 & 95%; tBHP 50 & 20%). In addition, oxidative stress induced a significant shift in the detergent solubility of b-catenin, another indication of functional disruption. Taken together, these results suggest that chemically-induced oxidative stress disrupts the E-cadherin/catenin complex and lend further support to the hypothesis that cell-cell and cell-matrix interactions are a molecular target of xenobiotics. (Supported by NIEHS Center

Grant (T30 ES06694), American Cancer Society Institutional Grant (IRG110T) and an SOT-Colgate Palmolive Fellowship.)

1721 BENZO(A)PYRENE-MEDIATED INHIBITION OF UTERO-PLACENTAL CELL INVASION AND EXPRESSION OF CELL ADHESION MOLECULES.

K T Shiverick, G D Charles and M A McGarry. *Department of Pharmacology and Therapeutics, University of Florida College of Medicine, Gainesville, FL, USA.*

The polyaromatic compounds benzo(a)pyrene (BaP) and 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) have been implicated in uterine disease and infertility. Our studies with human uterine endometrial and trophoblastic cell lines have found that BaP, but not TCDD, significantly inhibited cell proliferation and invasion of matrigel-coated membranes. Because cell invasion is a multifaceted process, the effects of BaP and TCDD were further examined on the processes of cell attachment to extracellular matrix vs expression of proteases necessary for matrix degradation. Human uterine endometrial adenocarcinoma cells pretreated with BaP showed minimal attachment to matrigel, whereas TCDD-exposed cells showed a high level of attachment comparable to control. No effect of either compound was observed on the fibrinolytic activity of the serine protease urokinase plasminogen activator, nor on matrix metalloprotease MMP-2 mRNA expression. Immunohistochemical analysis demonstrated that epidermal growth factor receptor (EGF-R) was detected primarily in plasma membranes in intercellular regions of adjacent cells. BaP, but not TCDD, resulted in markedly reduced staining intensity in the intercellular membrane regions without alteration in cytoplasmic staining intensity. Expression of E-cadherin protein, the predominant mediator of cell-cell adhesion in epithelial cells, was also decreased following BaP, but not TCDD, exposure. These data provide evidence that the differential effect of polycyclic compounds on EGF-R expression is a biomarker for altered uterine cell adhesion to the extracellular matrix and cell-cell interaction which may well involve modulation of the interaction of cadherin with the actin cytoskeleton. Evidence suggests that the the BaP-mediated dysregulation of cell adhesion may involve cellular stress relating to the formation of reactive metabolites. (Supported by NIEHS Superfund Grant 07375.)

1722 CELL ADHESION AND CYP1A1 EXPRESSION: WHAT'S THE CONNECTION?

B L Allen-Hoffmann and M A Weitzel. *Department of Pathology, Biotechnology Training Program and Environmental Toxicology Center, University of Wisconsin, Madison, WI, USA.*

Previous studies in our laboratory have shown that disruption of cell-cell and cell-substratum interactions in epithelial cells, but not fibroblasts, leads to a rapid induction of steady state CYP1A1 mRNA levels. In an effort to identify which adhesion receptors are involved in this process, we have employed methods which preferentially disrupt either cadherin mediated cell-cell interactions or integrin mediated cell-substratum interactions in epithelial cells. Normal human keratinocytes removed from substratum attachment as an epithelial sheet in which cell-cell contact is maintained do not show an increase in steady state CYP1A1 mRNA following a 6h treatment. In addition, reporter gene assays of Hepa 1c1c7 cells stably transfected with a luciferase gene downstream from part of the CYP1A1 promoter demonstrate that treatment of these cells with RGD-containing peptides to disrupt integrin mediated interactions does not lead to an increase in luciferase activity. Taken together, these results indicate that disruption of cell-substratum interactions may not be involved in the adhesion mediated induction of CYP1A1. To examine the role of cadherin-mediated interactions in this induction, we have disrupted cell-cell adhesion by decreasing the calcium concentration of the media to a level that is below the minimum required for cadherin function. Steady state levels of CYP1A1 mRNA increase in normal human keratinocytes following a shift from 0.66 mM Ca2+ media to 0.05 mM Ca2+ media. Concomitant with this induction, indirect imuno-fluorescent staining of the cells following a decrease in extra-cellular calcium shows that E cadherin is lost from the cell surface. These results imply that calcium-dependent cell-cell interactions may be involved in the induction of CYP1A1 following a loss of adhesion.

1723 CYTOKINES: BIOLOGY, GENE REGULATION, AND ROLE IN THE PATHOGENESIS OF LUNG DISEASE.

K E Driscoll[1] and D L Laskin[2]. [1]*Procter & Gamble Pharmaceuticals, Cincinnati, OH,* [2]*Rutgers University, Piscataway, NY, USA.*

Altered cytokine expression can contribute to changes in lung structure and function associated with inhalation of pneumotoxic chemical and biological agents. This symposium focuses on the role of cytokines in acute lung injury and the pathogenesis of lung diseases including: chronic airways disease; allergic asthma; and interstitial lung disease. Cytokines such as TNFα and interleukin (IL)-1 can initiate responses to inhaled agents, stimulationg a cascade of cytokine and cell:cell interactions which result in recruitment and activation of inflammatory and immunocompetent cells. Chemokines (e.g., IL-8, monocyte chemotactic protein 1) are TNFα and IL-1-inducible cytokines which play critical roles in recruitment of cells to sites of tissue injury. Recent studies suggest chemokines can influence expression of other cytokines (e.g., IL-4, IL-12) which drive a transition from Th1 to Th2 lymphocyte responses and contribute to chronicity of inflammation. In this respect, Th2 cells and their associated cytokines (e.g., IL-4, IL-5, IL-13) appear to play a role in the pathogenesis of asthma. IL-4 and IL-13 being critical in the regulation of IgE synthesis and IL-5 contributing to the recruitment and activation of eosinophils. Dysregulation of cytokine expression can be a key factor in remodeling of respiratory tract tissues after exposure to pneumotoxic agents. For example, altered expression of platelet-derived growth factor (PDGF) A and B, mitogens for mesenchymal cells, and transforming growth factor β 1 (TGFβ 1), which regulates expression of matrix proteins, plays a critical role in the pathogenesis of asbestosis and likely other interstitial lung diseases. Similarly, studies in transgenic models suggest overexpression of the IL-6 type cytokine, IL-11, can contribute to airway remodeling such as that seen in asthmatic lungs. Expression of genes coding for several inflammatory and immunoregulatory cytokines appears to be regulated, in part, by redox sensitive transcription factors such an NFkB and AP-1. Oxidant induction of cytokine gene transcription may represent a common mechanism whereby several environmental agents increase cytokine expression in the respiratory tract. Symposium presentations will discuss research at the molecular, cellular and whole animal levels relevant to the above concepts on cytokine function in normal health and disease.

1724 THE DYNAMIC INTERACTIONS BETWEEN CYTOKINES, CHEMOKINES, AND ADHESION MOLECULES DICTATES THE EVOLUTION OF CHRONIC DISEASE.

S L Kunkel. *Department of Pathology, The University of Michigan Medical School, Ann Arbor, MI, USA.* Sponsor: K E Driscoll.

Our current understanding of chronic inflammation would suggest that the recruitment of mononuclear cells from the lumen of a vessel into a localized area of inflammation is dependent upon the initiation and maintenance of leukocyte activation and chemotaxis. These responses are like dependent upon a cascade of events which must occur with some fidelity in order for the cells to successfully arrive at a site of inflammation. Initial phases of the activation/chemotactic responses are dependent upon a number of dynamic interactions, resulting in the expression of a variety of important inflammatory mediators. These mediators are involved in the transition from adherence to migration which allows the activated leukocytes to accumulate and pass through the endothelial cell and basement membrane barrier. Studies have now shown that chemokines are not only important in recruiting cells into an area of chronic inflammation, but they also appear to aid in dictating the evolution of particular types of chronic inflammation. For example, the monocyte chemoattractant protein-1 (MCP-1), which has been shown to be a potent chemotaxin for monocytes and lymphocytes, can also increase the expression of lymphocyte-derived interleukin-4 (IL-4) in response to antigen challenge and decrease the levels of macrophage-derived interleukin-12 (IL-12). This activity may facilitate the evolution, or switch, of a Th-2 response from a Th-1 response. In the context of chronic inflammation, the particular cytokine/chemokine phenotype that persists at an inflammatory site may play an important role in the development of long-term disease. This may be especially true in chronic inflammation where the continued cytokine expression pattern may predominate with characteristics of a Th-2 phenotype. Recent data supports the notion that this cytokine expression profile may be consistent with continued recruitment and activation of certain leukocyte subpopulations, fibroblast proliferation, and matrix deposition.

1725 THE ROLE OF TH2 CYTOKINES IN THE PATHOGENESIS OF ALLERGIC ASTHMA.

M Wills-Karp. *Johns Hopkins School of Hygiene and Public Health, Baltimore, MD, USA.* Sponsor: K E Driscoll.

Marked increases in the incidence, morbidity and mortality of allergic asthma have been reported over the last two decades, underscoring the need for a better understanding of the etiology of this disease. As a primary regulator of the inflammatory cascade, CD4+ T-lymphocytes have been implicated in the pathogenesis of this disease. Functional subsets of CD4+ T cells have been distinguished at both clonal and population levels by the unique profiles of cytokines that they produce. The differential presence of these cytokine phenotypes in a variety of allergic and infectious diseases of both mice and humans has provided both descriptive power and theoretical insight into disease pathogenesis. Th1 cells produce interleukin-2, TNF-β , and interferon gamma (IFN-γ), and are critical in the development of cell-mediated immunity. Th2 cells on the other hand produce IL-4, IL-5, IL-13, IL-6, and IL-10 and are important in humoral immune responses. A possible immunopathogenic role for the Th2 cells in asthma has been based on the role that these cytokines play in IgE synthesis and eosinophil regulation. In particular, IL-4 may be of critical importance in allergic inflammatory processes, as it is required for the differentiation an expansion of Th2 lymphocytes and inhibition of the development of Th1 lymphocytes, while both IL-4 and IL-13 regulate IgE syntheses. IL-5 is considered the primary regulator of eosinophil function. Experimental support for this hypothesis is provided by the fact that unique cytokine patterns (i.e. Th2) are expressed in T cells from asthmatic patients. Although considerable inferential evidence supports a role for these cytokines in allergic reactions, the exact mechanisms by which they induce the inflammatory and functional changes associated with allergic asthma are currently debated. Here we will discuss the data derived from both human and experimental animal studies (transgenic and knock-out) which have contributed to our current understanding of the mechanisms leading to the aberrant production of Th2 cytokines in allergic individuals and the mechanisms by which these cytokines induce allergic diseases.

1726 IL-6-TYPE CYTOKINES IN AIRWAYS DISEASE.

J A Elias. Yale *University, School of Medicine, New Haven, CT.* Sponsor: K E Driscoll.

The IL-6-type cytokine family includes IL-6, IL-11, LIF, oncostatin M and cardiotropin-1. IL-11 was initially described as an IL-6-like bioactivity and shown to regulate thrombopoiesis and hematologic recovery. Studies from our laboratory have demonstrated that: (1) IL-11 is produced by a variety of lung epithelial cells, fibroblasts and smooth muscle cells; (2) a variety of stimuli induce IL-11 elaboration by lung stromal cells including TGF-b1, respiratory syncytial virus, rhinovirus and parainfluenza virus type III and (3) TGF-b1 stimulation of stromal cell IL-11 elaboration is mediated, at least partly, via an AP-1-dependent transcriptional mechanism. To begin to address the effector functions of IL-11 in the lung, IL-11 was targeted to the murine lung using the Clara cell 10 kDa (CC10) promoter. These studies demonstrated that the prolonged overexpression of IL-11 caused: (a) enlarged alveoli; (b) peribronchiolar nodules composed of B cells, T cells and rare macrophages; (c) airway remodeling with subepithelial fibrosis and myocyte and myofibroblast hyperplasia. To determine which features of the CC10-IL-11 overexpression mice were development-dependent versus development-independent, an inducible lung-specific airway targeting system using the tetracycline transactivator was produced. When employed with IL-11, the following phenotypes were obtained: (a) short period of IL-11 expression during adulthood Ð no phenotype; (b) expression in utero-14 days of age Ð enlarged alveoli only; (c) expression in utero through 3 months of age Ð phenotype identical to CC10-IL-11 animals. These studies demonstrate that IL-11 is a stromal cell-derived cytokine which can cause development-dependent alveolar enlargement and development-independent peribronchiolar nodules and airway remodeling.

1727 EXPRESSION OF PDGF AND TFGβ1 AT SITES OF LUNG INJURY.

G Hoyle, A R Brody, D Brass, and J Liu. *Lung Biology Program, Department of Pathology, Tulane University Medical Center, New Orleans, LA, USA.* Sponsor: K E Driscoll.

Inhaled inorganic particles such as silica and asbestos damage the alveolar epithelium leading to the development of interstitial scarring. There is increasing evidence that certain peptide growth factors play a role in the fibroproliferative response that is the hallmark of the fibrogenic process. Thus, we have been studying expression of growth factors that could mediate disease development. Here, we present recent findings on two factors in rats and mice: platelet-derived growth factor (PDGF), A and B isoforms, and transforming growth factor beta1 (TGFβ1). PDGF is the most potent mecenchymal cell mitogen and TGFβ is a powerful inducer of extracellular matrix components. We have shown that during the five hrs. of a single exposure to chrysotile asbestos, both PDGF A and B as well as TFGβ 1 genes and cognate proteins were upregulated at sites of alveolar injury. In situ hybridization (ISH) and immunohistochemistry (IHC) showed that alveolar epithelial cells, interstitial fibroblasts and lung macrophages expressed the protein for at least two weeks post-exposure. Most interesting was our finding that mice with the receptors "knocked out" for tumor necrosis factor alpha (TNFα) were protected from the fibrogenic effects of inhaled asbestos. Since both PDGF and TGFβ1 expression was reduced in these mice, we postulate that TNFα acts as a key factor in controlling production of other molecules that mediate the fibroproliferative response to lung injury. (Supported by NIH Grants #ES06766 and HL60532.)

1728 CHEMICAL-INDUCED ACTIVATION OF NUCLEAR TRANSCRIPTION FACTORS AND THEIR REGULATION OF CYTOKINE SECRETION.

M L Luster. *National Institute for Occupational Safety and Health, Morgantown, WV, USA.*

Non-immune cells from a variety of organs, including the liver, lung and skin, when targeted by toxic agents, secrete pro-inflammatory cytokines and chemokines which participate in pathological as well as repair processes. In particular, tumor necrosis factor alpha (TNFα) and certain members of the neutrophil chemoattractant family of chemokines (CXC), including interleukin-8, play major roles in these responses. This presentation will describe several organ model systems for toxicity including asbestor-induced lung disease, arsenic-induced skin toxicity and heavy metal-medicated hepatotoxicity which demonstrate cytokine participation. In addition to describing the nature of these responses, the molecular events responsible will be detailed. A common pathway responsible for cytokine induction in all of these systems involves chemical-medicated, cellular oxidative stress, which, in turn, activates nuclear transcription factors, such as NF-kB, NF-IL-6 and AP-1. Unraveling the complex mechanism associated with these events may provide novel opportunities for intervention.

1729 CHARACTERIZATION OF THE METABOLIC CAPACITY OF SYRIAN HAMSTER EMBRYO (SHE) CELLS.

S B Stuard, G A Kerckaert, and L D Lehman-McKeeman. *The Procter & Gamble Company, Cincinnati, OH, USA.*

Syrian hamster embryo (SHE) cells are used in the SHE cell transformation assay to predict the carcinogenic potential of chemicals. Unlike other in vitro genetic toxicity assays, the SHE assay efficiently detects carcinogens that act via non-genotoxic mechanisms. In addition, procarcinogens that require metabolic activation to their carcinogenic form are detected by the assay even in the absence of an exogenous metabolic activation system, suggesting that SHE cells possess the ability to metabolize xenobiotics. However, while many of the molecular features of SHE cells have been well characterized, very little is known about the metabolic capacity of these cells. Since cytochromes P450 are the enzyme family primarily responsible for xenobiotic metabolism and procarcinogen activation, the goal of the present work was to characterize cytochrome P450 protein expression in SHE cells. SHE cells derived from several different Syrian hamster embryo isolates were cultured, harvested, sonicated, and microsomes isolated by differential centrifugation. Western blotting with enhanced chemiluminescent detection was used to evaluate SHE cell microsomes for the presence of a battery of cytochrome P450 (CYP) isozymes. The most abundant cytochrome P450

isozyme detected constitutively was CYP4A. In addition, CYP2E isozyme and cytochrome P450 reductase, a requisite cofactor for cytochrome P450 enzyme activity, were also detected constitutively. The following cytochrome P450 isozymes were not detected constitutively in SHE cells: CYP1A, CYP1B, CYP2A, CYP2B, CYP2C, and CYP3A. In SHE cells exposed to the procarcinogen benzo[a]pyrene at levels resulting in SHE cell transformation (5 mg/ml for 24 hours), CYP1A isozymes which metabolize this compound were induced significantly to detectable levels. Importantly, these results provide direct evidence of constitutive cytochrome P450 protein expression in SHE cells and demonstrate that SHE cells are capable of regulating expression of these proteins in response to xenobiotic exposure.

1730 ROLE OF METABOLISM IN ACRYLONITRILE (ACN) CARCINOGENICITY: STUDIES IN SYRIAN HAMSTER EMBRYO (SHE) CELLS.

J E Klaunig and L M Kamendulis. *Division of Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

Chronic oral exposure to ACN, a chemical used in the manufacture of plastics, rubber and acrylic fibers, results in brain, stomach and Zymbal gland tumors in rats. While the mode of action of ACN-induced carcinogenicity is unresolved, results from *in vivo* studies showed that ACN produced oxidative stress in the brains of ACN treated rats. Studies examining ACN metabolism have shown that one degradation pathway involves oxidative metabolism by cytochrome P450 to cyanoethylene oxide (CEO), a highly reactive epoxide metabolite. Further metabolism results in the liberation of cyanide (CN). In the present study, the SHE cell morphological transformation (MT) assay, which has been shown to be predictive of *in vivo* carcinogenicity, was utilized to determine whether ACN or ACN metabolites are involved in the transformation process. ACN treatment produced MT in a dose-dependent manner in SHE cells at concentrations of 75 μg/ml and below which was accompanied by increased 8-hydroxydeoxyguonosine (8OHdG) levels, an indicator of oxidative DNA damage. Blockage of CEO formation by 1-aminobenzotriazole, an inhibitor of cytochromes P450, prevented MT by ACN. Treatment of SHE cells with CN resulted in an increase in MT. These results indicate that ACN requires metabolism to produce SHE cell transformation and that CN formation may be contributory to the ACN-induced MT, suggesting a potential role for ACN metabolism in the induction of glial tumors in the rat.

1731 TAMOXIFEN INITIATION AND PHENOBARBITAL PROMOTION STUDIES IN LIVERS OF BIG BLUE™ TRANSGENIC F344 RATS.

J A Styles, R Davies, R E Edwards, E Martin and I N H White. *MRC Toxicology Unit, University of Leicester, Leicester, UK.* Sponsor: A G Smith.

Female F344 Big Blue™ transgenic rats were given tamoxifen (tam) (20mg/kg/day p.o.) or vehicle (tricaprylin) for 6 weeks. After 6 weeks some animals were sacrificed and the remaining animals were then given phenobarbital (PB) (0.1% w/v in water) or were untreated for up to 24 weeks. Groups of 4 animals were sacrificed at 2, 12 and 24 weeks after the commencement of PB treatment and the mutation frequencies (MF) in the livers determined. MF at 2 weeks: control 5.9 ± 0.3; control + PB 6.0 ± 0.3; tam 19.5 ± 2.9; tam + PB 19.8 ± 1.8. MF at 12 weeks: control 7.6 ± 2.4 ; control + PB 10.4 ± 1.2; tam 35.6 ± 4.0; tam + PB 34.8 ± 7.8. MF at 24 weeks: control 6.8 ± 2.7; control + PB 8.3 ± 2.0: tam 30.7 ± 0.7; tam + PB 31.9 ± 1.7. Liver weights in animals given phenobarbital or tamoxifen followed by phenobarbital showed a time-related increase compared with controls or animals given tamoxifen alone. After 2 weeks promotion liver cell proliferation, measured by PCNA expression, was significantly increased in both the phenobarbital-treated groups in comparison with concurrent controls and by 12 and 24 weeks labelling in both the phenobarbital-treated groups and the tamoxifen-initiated group were significantly elevated. compared with the concurrent control. There was a progressive increase in the number of GST-P expressing foci in the livers of rats initiated with tamoxifen with or without subsequent promotion with phenobarbital. The animals given phenobarbital alone showed no increase in foci. The results demonstrate that although phenobarbital is known to promote tamoxifen-initiated liver tumours in the rat it has no influence on the frequency of *lacI* mutations induced by tamoxifen but may select for oncogenic mutations.

1732 PHENOBARBITAL IS MUTAGENIC AND ALTERS THE MUTATION SPECTRUM (MS) OF lacI IN THE LIVER OF BIG BLUE® TRANSGENIC MICE.

B S Shane[1], D L Smith-Dunn[1], J G deBoer[2], B W Glickman[2] and M L Cunningham[3]. [1]*Institute for Environmental Studies, Louisiana State University, Baton Rouge, LA;* [2]*Centre for Environmental Health, University of Victoria, Victoria, BC, Canada;* [3]*Environmental Toxicology Program, NIEHS, Research Triangle Park, NC.*

Although phenobarbital (PHE) is a hepatocarcinogen in B6C3F1 mice, it is a weak mutagen in vitro and does not form DNA adducts. Thus, the mechanism by which PHE causes tumors may differ from that of mutagens which form DNA adducts. To investigate whether PHE causes mutations in vivo, B6C3F1 Big Blue® male transgenic mice harboring the lLIZ shuttle vector containing the lacI target gene were fed 2500 ppm PHE for 180 days. The mutant frequency (MF) of lacI in the liver of control mice, fed diet alone, was 5.02 ±2.4x10-5 and that in the PHE-fed mice was 6.88 ± 0.75x10-5, a significant increase ($p<0.05$). The mutation spectrum obtained from a random collection of mutants from each PHE-fed mouse was significantly different ($p<0.02$) from a spontaneously derived spectrum from control mice. In the PHE-fed mice, an increase in G:C>T:A and G:C>C:G transversions and a concomitant decrease in G:C>A:T transitions was obtained. It is postulated that the mutations found in the PHE-derived spectrum were due to oxidative damage following induction of CYP2B isozymes by chronic PHE feeding. Results from this study demonstrate that even though PHE is a weak mutagen in vitro, it is mutagenic in vivo in Big Blue® mice. The PHE-derived lacI spectrum was remarkedly similar ($p<0.8$) to that generated by oxazepam in vivo in Big Blue® mice. Oxazepam has similar pleiotropic properties to PHE, including its induction of CYP isozymes and thus, both these compounds could be tumorigenic through a similar mechanism. (Supported by CA72534-01.)

1733 SILICA-INDUCED MUTATIONS IN THE LUNGS OF BIG BLUE® RATS BUT NOT MICE.

A C P Elder[1], B Stripp[1], J Finkelstein[2], C Cox[3], N Corson[1], P Mercer[1], G Oberdörster[1]. *University of Rochester, Depts. of Environmental Medicine[1], Pediatrics[2], and Biostatistics[3], Rochester, NY, USA.*

Crystalline silica is a cytotoxic particle which causes lung inflammation in multiple species; however, tumor formation following inhalation exposure has only been demonstrated in the rat, suggesting possible species differences in sensitivity to silica-induced lung injury or repair. It would be desirable to directly assess species differences in genotoxicity within a single assay system. The Big Blue® *in vivo* mutagenesis system, which allows such an evaluation in both rats and mice, was utilized to examine silica-induced inflammation and fixed mutations. Big Blue® female B6C3F1 mice and F344 rats were exposed to the same dose of silica based on lung mass via instillation (500 μ g for mice; 2.5 mg for rats) and groups were sacrificed 2 weeks and 2 months after exposure. Significant inflammation was found in both species and at both time points as determined by the percentage of neutrophils (PMNs) in lavage fluid. The PMN response in rats, however, was greater than in mice at both 2 weeks and 2 months. There was a significant effect of exposure on mutant frequency of DNA isolated from rats ($F_{1,16} = 5.79, p = 0.029$) but not in mice; however, no significant differences between treatments were found within the time points alone. This data suggests that rats are more sensitive than mice to the inflammatory potential of silica, but that this assay system may not be as sensitive as others (e.g. Hprt mutations) in detecting mutations caused by indirect-acting genotoxic agents such as particles.

1734 USE OF A LACZ PLASMID-BASED TRANSGENIC MOUSE MODEL FOR THE DETECTION OF MUTATIONS INDUCED BY IONIZING RADIATION.

J A Kind[1], M E T I Boerrigter[2], R N Winn[1], C H Jagoe[3], and C E Dallas[1]. [1]*University of Georgia, Athens, GA;* [2]*Leven, Inc., Bogart, GA;* [3]*Savannah River Ecology Laboratory, Aiken, SC.*

Transgenic animal models are generally very efficient at detecting small size changes including DNA point mutations, but are relatively insensitive to clastogens, which are thought to cause predominantly large deletions. Recently, a transgenic mouse model, based on the pUR288 plasmid containing the *lacZ* reporter gene, was developed that is sensitive to a wide spectrum of mutations (Nature 377:657-659). The plasmid is purified from the rest of the genomic DNA by a restriction enzyme digestion and immunomagnetic affinity capture. Subsequently, the plasmids are circularized and

electrotransformed into electrocompetent *E.coli C* (*lacZ⁻ galE⁻*) host cells. A small portion of the transformed bacteria is used to determine the titer while the remainder is plated onto selective media containing phenyl-beta-galactoside, allowing only cells containing a mutated *lacZ* gene to form colonies. The spontaneous mutant frequency in spleen and brain DNA from these transgenic mice was approximately 5 x 10^{-5}. X-ray exposures over 3 Gy increased the mutant frequency in brain two to five-fold and spleen three to seven-fold, in a dose-dependent manner. The *lacZ* plasmid mouse model thus enabled comparisons of mutation frequencies between tissues, demonstrating differences in mutant frequencies in spleen and brain. It also detected a wide spectrum of mutations, and was potentially sensitive enough to elucidate dose-response relationships following exposure to ionizing radiation. (Supported by U.S. DOE DE-AC09-756R000 and the American Foundation for Pharmaceutical Education.)

1735 ASSESSMENT OF THE IN VIVO MUTAGENICITY OF ETHYLENE OXIDE IN THE BONE MARROW OF B6C3F1 *lacI* TRANSGENIC MICE FOLLOWING A CHRONIC INHALATION EXPOSURE.

L Recio[1], D J Abernethy[1], M Donner[2], L Pluta[1], and J Preston[1]. [1]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC;* [2]*Integrated Laboratory Systems, Research Triangle Park, NC, USA.*

Ethylene oxide (EO) is a direct acting somatic and germ cell mutagen. To assess the in vivo mutagenicity of EO in the bone marrow of B6C3F1 *lacI* transgenic mice, a chronic inhalation exposure of up to 48 weeks (wk) was conducted using exposure concentrations of 0, 25, 50, 100, or 200 ppm EO (6 h/day 5 days/wk). Animals were sacrificed at 12, 24, and 48 wk of exposure, and the *lacI* mutant frequency was determined in the bone marrow. Exposure to EO did not induce an elevated *lacI* mutant frequency at either the 12 or 24 wk time points. At 48 wk of EO exposure, an increased *lacI* mutant was not observed at either the 25, 50, or 100 ppm exposure levels. However, at 200 ppm EO for 48 wk, a significant increase (5-fold above background) in the *lacI* mutant frequency was observed. Preliminary DNA sequence analysis of *lacI* mutants isolated from the 48-wk 200-ppm exposure group indicated a specific increase in A:TmT:A transversions that was 10-fold above the background frequency of A:TmT:A transversions in age-matched controls. These data indicate that long-term exposure to EO (48 wk) is necessary for the induction of point mutations by EO detectable at *lacI* in the bone marrow of mice.

1736 TRANSGENE EXPRESSION IN LIVER AND KIDNEY OF TG.AC MICE FOLLOWING TISSUE INJURY.

D A Delker, B L Yano, and B B Gollapudi. *The Dow Chemical Company, Midland, MI, USA.*

The dermal Tg.AC transgenic mouse line is currently being used as a short-term alternative *in vivo* model for carcinogenicity screening of drugs and environmental chemicals. These mice carry multiple copies of an activated v-Ha-*ras* oncogene, making them susceptible to promotionally-induced tumorigenesis caused by carcinogen exposure or deep skin wounding. Transgene expression is associated with tumor development in these animals. To evaluate the usefulness of this model in predicting the carcinogenicity of chemicals by non-dermal routes of exposure, we characterized the pattern of transgene expression in naïve animals as well as mice treated by oral gavage with cytotoxic doses of chloroform. Hepatic BrdU labeling was increased 40-fold in females (240 mg/kg/day) and 20-fold in males (140 mg/kg/day) after 4 days of dosing with chloroform. An increase in renal BrdU labeling (7-fold) was observed only in male Tg.AC mice. After 3 weeks and 13 weeks of prolonged exposure to chloroform, there was a gradual reduction in the extent of regenerative proliferation in the liver and kidneys. Although chloroform did not induce v-Ha-*ras* expression either in the liver or the kidney, a constitutive amount of transgene message was evident in the kidneys of Tg.AC mice (n=30). This expression was not dependent on age, zygosity or the colony from which the mice were bred. V-Ha-*ras* transgene expression also correlated with the expression of GATA-3, a transcription factor that binds the zeta-globin promoter of the Tg.AC transgene. These studies suggest that tissue injury and regenerative cell proliferation *per se* are not sufficient for the induction of transgene expression in the liver and kidney of Tg.AC mice.

1737 DERMAL CARCINOGENICITY STUDIES IN HOMO- AND HEMIZYGOUS TRANSGENIC Tg.AC MICE WITH TPA: COMPARISON OF TRANSGENE EXPRESSION, GENOTYPE, AND PHENOTYPE.

P J Spencer[1], D A Delker[2] and B B Gollapudi[2]. [1]*University of Michigan, Toxicology Department, Ann Arbor, MI;* [2]*The Dow Chemical Company, Health and Environmental Research Laboratories, Midland, MI.*

The Tg.AC transgenic mouse is gaining support as a short-term alternative *in vivo* model for carcinogenicity screening of chemicals. These mice carry multiple copies of an activated v-Ha-ras oncogene making them susceptible to promotionally-induced skin tumorigenesis. It has been suggested that the responsiveness of these mice to papillomagenesis was dependent upon the zygosity of the transgene as well as other genetic rearrangements in the transgene. The objectives of the present investigation were (1) characterize the tumor responsiveness of homo- and hemizygous female Tg.AC mice (15 animals/group) to dermal treatment of TPA, a phorbol ester and tumor promoter (2.5 μ g/mouse, 3 days/week, 26 weeks), (2) correlate the tumor responsiveness with the genotype by presence of 2 kb band (Thompson *et al.*, Toxicol Pathol Vol.4, 1998), (3) examine transgene expression by RT-PCR, in various tissues of homo- and hemizygous mice, and (4) compare the pattern of transgene expression in individual animals responding to TPA treatments with that of the non-responders. No differences were observed either in the onset or magnitude of papilloma development between homo- and hemizygous mice following treatment with TPA; approximately a 50% response rate was observed for both genotypes. All mice developing papillomas were confirmed to have the responder genotype by Southern analysis. Expression of v-Ha-ras transgene was observed in several tissues of the Tg.AC mice. These tissues included kidney, spinal cord and hindbrain with the highest expression observed in the spinal cord for both responder and non-responder phenotypes. These data suggest that zygosity does not influence responsiveness to treatment with a tumor promoting agent in the Tg.AC mouse model. Furthermore, expression of the transgene is not altered in the non-responder phenotype despite the absence of the 2 kb band. Further characterization of the Tg.AC model currently underway in several laboratories will help establish it's future role in carcinogen identification.

1738 TRANSPONDER-INDUCED SARCOMA IN THE HETEROZYGOUS $p53^{+/-}$ MOUSE.

K T Blanchard, C Barthel, S M Furst, F D Pack, and R E Stoll. *Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT, USA.*

Heterozygous $p53^{+/-}$ transgenic mice are currently being studied as a potential short-term alternative model to the 2-year rodent carcinogenicity bioassay. During a 26-week study undertaken to assess the carcinogenicity of oxymetholone and *p*-cresidine in this mouse strain, masses were observed arising from the transponder site. Male and female $p53^{+/-}$ mice were individually housed and uniquely identified with subcutaneously implanted IMI™ radio signal transponders (BioMedic Data Systems, Inc., Seaford, DE). Upon study termination, all animals were subjected to a complete necropsy and histopathological analysis. Eighteen of the 177 animals on the study (10%) were microscopically diagnosed with sarcomas arising at the transponder site. Of these 18 animals, a total of 5 died prior to study termination between the 18th and 25th week of the study. Palpable masses were late developing but rapidly increased in size. The first detectable transponder site mass was identified in the 15th week and measured 12 mm x 8 mm x 6 mm. By the 25th week, this mass had attained a size of 55 mm x 39 mm x 35 mm. Transponder-associated neoplasms were characterized by undifferentiated sarcomas present at transponder sites in a number of animals in all study groups including controls. In addition, mesenchymal dysplasia was present in these study groups and was considered to be a prodromal change to the sarcomas. Light and scanning electron microscopic evaluation suggested that tumors arose from the mesenchymal tissue capsule surrounding the polypropylene component of the transponder. The mesenchymal changes appeared to begin at the barbed anchor, glass-polypropylene interface of the transponder and then later extended to completely surround the entire transponder in some instances. Capsule membrane endothelialization, inflammation, mesenchymal basophilia, dysplasia and sarcoma were all considered unequivocal responses to the transponder and were not obviously related to treatment with either oxymetholone or *p*-cresidine test substances.

1739 USE OF LASER CAPTURE MICRODISSECTION (LCM) TO DETECT HETEROGENEOUSLY DISTRIBUTED *p53* MUTATIONS WITHIN AFLATOXIN B_1 (AFB_1)-INDUCED MOUSE LUNG TUMORS.

A S Tam[1], J F Foley[2], T R Devereux[2], R R Maronpot[2], and T E Massey[1,3]. *Departments of [1]Pharmacology and Toxicology, and [3]Medicine, Queen's University, Kingston, ON, Canada; [2]National Institute of Environmental Health Sciences, Research Triangle Park, NC, USA.*

Inactivation of the *p53* tumor suppressor gene is one of the most frequent genetic alterations observed in human lung cancers. However, *p53* mutations are more rarely detected in chemically-induced mouse lung tumors. Seventy-one lung tumors from AFB_1-treated AC3F1 mice were examined for over-expression of p53 protein by immunohistochemical staining (IHS). Positive nuclear p53 staining was observed in 79% of the AFB_1-induced tumors, but the pattern was highly heterogeneous. Single strand conformation polymorphism (SSCP) analysis of the evolutionarily conserved regions of the *p53* gene (exons 5-8) from AFB_1-induced whole lung tumor DNA samples revealed banding patterns consistent with point mutations in 20 of 76 (26%) samples, with 85% of the mutations in exon 7 and 15% in exon 6. Direct sequence analysis identified apparent point mutations; however, bands representing the putative mutations appeared only weakly on autoradiograms. LCM of different regions of paraffin embedded AFB_1-induced tumor tissue sections, and subsequent SSCP analysis of exons 5-8, revealed banding patterns consistent with point mutations in 15 of 30 (50%) DNA samples. Direct sequencing of microdissected samples revealed clearly identifiable mutations at several different codons in exons 5-8. The results indicate that molecular analysis of laser capture microdissected lung tumor DNA can reveal the presence of *p53* mutations that are not detected by analysis of whole lung tumor DNA. (Supported by Medical Research Council of Canada Grant No. MT-10382.)

1740 RESPONSE OF THE TRANSGENIC P53+/- MOUSE 26-WEEK CARCINOGENICITY ASSAY TO CHLOROFORM.

B B Gollapudi, B L Yano, S J Day, V A Linscombe, K M Jackson and J S Bus. *Health and Environmental Research Laboratory, The Dow Chemical Company, Midland, MI.*

The transgenic $p53^{+/-}$ mouse model has been proposed as an alternative to the conventional 2-year bioassay for the detection of genotoxic carcinogens. However, the response of this model to well documented, MTD-induced epigenetic events (e.g., cytotoxicity and cell proliferation) has not been fully documented. In this study, the known non-genotoxic carcinogen chloroform, was given to $p53^{+/-}$ males at 0, 28, 90, or 140 mg/kg/day and females at 0, 24, 90, or 240 mg/kg/day via gavage in corn oil for 5 days/week for 13 (5/sex/dose) or 26 (15/sex/dose) weeks. $p53^{+/+}$ wild-type mice were also given 0, 140 (male) or 240 (female) mg chloroform/kg/day as above, to compare their sensitivity with that of $p53^{+/-}$mice. Standard toxicologic parameters were measured at 13 and 26 weeks; additionally, cell proliferation in the liver and kidneys was determined at 13 weeks using BrdU immunohistochemical methods. Administration of cytotoxic/MTD doses was confirmed by the observations of increased relative liver weights (30-40% at 26 weeks), degenerative hepatic lesions, and hepatocellular proliferation (10-fold in females at 13 weeks) at the high dose. Males also had decreased body weights (8%), renal tubular degeneration, and proliferation of renal tubular epithelial cells (approx. 2-fold at 13 weeks). There were no treatment-related increases in tumors of any tissue either in the transgenic or wild-type mice. Under the conditions of the study, cytotoxic/proliferative tissue injury *per se* was not sufficient to induce tumors in the $p53^{+/-}$ model following 26 weeks of dosing.

1741 CHARACTERIZATION OF THE *p53*-HETEROZYGOUS MOUSE: SPONTANEOUS PROLIFERATIVE LESIONS, ORGAN WEIGHTS, BODY WEIGHTS.

L L Lanning[1], M L Wenk[1], C E Bentley[1], E K LeGrand[2], T C Dailey[1]. [1]*MA Bioservices Inc., Rockville, MD, USA;* [2]*R.W. Johnson Pharmaceutical Research Institute, Raritan, NJ, USA.*

The aim of this cross-sectional study was to assess lead exposure in children aged 6-9 years attending three primary schools. One of the schools is located ~500 m distant from a smelter complex which includes a lead refinery (high exposure group); the second is located ~ 900 m away from the complex and at the side of a heavy traffic road (medium exposure) in Torreón, Coahuila. The third school is located in Gómez Palacio, Durango, 5,000 m away from the smelter complex and distant from heavy vehicular traffic or industrial areas (low exposure group). Lead was measured in air, soil, dust and well water. Lead in blood (PbB) was determined in 394 children attending the above mentioned schools. Determinations were performed by atomic absorption spectrophotometry. Diet, socioeconomic status, hygienic habits and other variables were assessed by questionnaire. Average PbB (± SD) values were 8.7 ± 3.8 μ g/dL in the low exposure group, 22.4 ± 7.8 μ g/dL in the medium exposure and 28.8 ± 11.0 μ g/dL in children attending the school nearest to the lead refinery. The percentage of children having PbB ≥ 15 μ g/dL was 6.8%, 84.9% and 92.1%, respectively. In this order, the average Pb concentrations in air were 3.25 ± 2.59 μ g/m^3, 6.03 ± 2.07 μ g/m^3 and 8.16 ± 5.65 μ g/m^3. The range of Pb concentrations in soil and dust in playground areas in the medium and high exposure settings was 1,000 to 4,000 mg/kg. Pb values in drinking water were less than 6 μ g/L. Soil and dust ingestion and inhalation appear to be the main routes of exposure. Our results indicate that environmental contamination has resulted in an increased body burden of Pb, suggesting that children living in the vicinity of the smelter complex are at high risk of suffering the well known adverse effects of lead if exposure continues. Further studies are needed to evaluate the specific contributions of lead sources in the city and the presence of other metals in the environment.

1742 EVALUATION OF THE GENOTOXICITY OF CHEMICALS CURRENTLY UNDERGOING IN VIVO CARCINOGENICITY TESTING USING THE p53 INDUCTION ASSAY.

P J Duerksen–Hughes, M D Kale, O Ozcan, J Yang and M Zaki. *Department of Biology, Georgia State University, Atlanta, GA, USA.* Sponsor: D Barfuss.

In vivo carcinogenicity testing is an expensive and time–consuming process, and as a result, only a relatively small fraction of new and existing chemicals can be tested in this manner. Therefore, the development and validation of alternative approaches is desirable. The Predictive Toxicology Evaluation 2 (PTE2) project, initiated in 1990, listed thirty chemicals currently undergoing in vivo toxicity testing. A number of laboratories have subjected this set of chemicals to analysis using a variety of alternative methods and on the basis of these results, predicted their carcinogenicity in the rodent models. We have previously developed a mammalian, in vitro assay for DNA damage based on the ability of cells to increase their level of p53 in response to DNA damage. Cultured cells are treated with several concentrations of the test substance, and at defined times following treatment, are harvested and lysed. The lysates are analyzed for p53 by Western blot and/or ELISA. An increase in cellular p53 following treatment is interpreted as evidence for DNA damage, and a lack of such an increase is interpreted as evidence of no significant DNA damage. To determine the ability of this p53–induction assay to predict carcinogenicity in rodents and to compare such results with those obtained using other alternate approaches, we subjected chemicals from the PTE2 list to analysis with this method. The results obtained from the p53 induction assay corresponded to those obtained with the Salmonella assay for most chemicals; however, there were a few differences.

1743 THE USE OF IN- SITU HYBRIDISATION FOR THE OPTIMISATION OF POLYMERASE CHAIN REACTION-IN SITU METHODOLOGIES IN FROZEN TISSUE.

A Lawrence , N Bullough, L McLoughlin and P R Ryle. *Huntingdon Life Sciences, Huntingdon, Cambs, England.* Sponsor: R J Harling.

In-situ polymerase chain reaction (IS-PCR) technique can be invaluable for localising specific DNA sequences in the safety evaluation of gene therapy products and xenotransplantation. Our initial attempt to validate IS-PCR using a low copy number gene was of limited success as appropriate controls for each stage of the complex PCR procedure were unavailable and the cause(s) of inconsistent results were difficult to identify. However the first major problem to be overcome was poor tissue morphology following PCR thermal cycling . In this presentation we describe the use of a high copy number porcine retro virus env gene as a model to optimise tissue sectioning and fixation in in-situ methods. The effect of thermal cycling on tissue morphology was also investigated. The initial investigation focused on tissue fixation, where twelve micron thick frozen sections of pig and human liver were fixed in acetone or buffered formalin. Formalin fixed sections gave superior in situ-hybridisation (ISH) staining (using FITC labelled oligonucleotide probe) and improved morphology compared to acetone fixation where high levels of background staining and poor morphology were seen. The effects of thermal cycling on tissue morphology and the ISH reaction were examined. The methodology involved thermal cycling with PCR buffer, porcine liver and testis sections, human liver was used as the nega-

tive control, followed by ISH technique using the oligonucleotide probe. The results showed that satisfactory morphology was achieved between zero and forty cycles. However, background staining increased significantly with those samples that had been subjected to thirty and forty cycles. In summary optimisation of the methodology for ISH depends on twelve micron thick sections and buffered formalin fixation of frozen tissues. Satisfactory morphology for ISH following PCR was observed up to thirty thermal cycles. This ISH approach can now act as a model system for the optimisation of PCR conditions in frozen tissues.

1744 SCREENING BY QXL-PCR AS A TOOL TO ASSESS GENOTOXICITY FROM AIRBORNE PARTICULATES.

A Molinelli, Y Rodríguez, B D Jiménez, and C L Cadilla. *Univ. of Puerto Rico, Sch. of Medicine; Dept. of Biochemistry and Ctr. for Environmental and Toxicological Research, San Juan, PR.*

This study assesses the genotoxic potential of airborne pollutants in the San Juan port area of Puerto Rico. Total suspended particles and PM-10 airborne extracts were obtained from filters placed at monitoring stations, and bioactivated using a chemically-induced rat liver microsomal cocktail. Known genotoxic agents were employed as positive controls for the two regions analyzed, a 17.7 kb fragment of the ß-globin gene and a 16.2 kb region of the mitochondrial DNA. Benzo[a]pyrene was employed as control agent for nuclear DNA damage, whereas H2O2 was used to evaluate the mitochondrial DNA region. Cultured human fibroblasts were exposed to different agents to assess DNA damage and repair. DNA was isolated, quantitated by fluorometry, and amplified by 32P-radioactively labeled QXL-PCR (Yakes, 1997). QXL-PCR is based on the inability of rTth DNA polymerase to elongate DNA fragments in presence of DNA lesions, leading to a reduction in amplification signal, which is proportional to the extent of damage suffered by the template. When performing a direct bioactivation of B[a]P using 0.5 mg/ml of hepatic microsomes, we observed a dose-dependent effect of DNA damage. The highest concentration of B[a]P induced the highest DNA repair response, both in the mitochondrial and the nuclear DNA. HPLC analysis of our B[a]P bioactivation cocktails demonstrated the presence of a polar B[a]P metabolite. H2O2 experiments also demonstrated dose-dependent DNA damage and repair, both in the mitochondrial and nuclear DNA. This damage was more persistent in the mitochondrial DNA. Genotoxicity of airborne extracts were more prominent in the PM-10 fractions. This technique is being optimized to monitor human exposure to genotoxic agents by analyzing human lymphocytes DNA from blood of both smokers and non-smokers as a preliminary test of this methodology.

1745 EVALUATION OF CYTOTOXICITY ASSAYS OF HUMAN EPIDERMAL KERATINOCYTES EXPOSED *IN VITRO* TO SULFUR MUSTARD.

C L Gross, S A Kelly, J Guzman, and W J Smith. *Drug Assessment and Pharmacology Divisions, United States Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.* Sponsor: T M Shih.

Sulfur mustard (HD) is a potent cytotoxic chemical agent. Reproducible analysis of HD cytotoxicity is a useful tool in screening candidate prophylactic and therapeutic (P/T) compounds as medical countermeasures against vesicant agents. Viability assessment of human lymphocytes (PBL) by flow cytometry of propidium iodide uptake has been a staple of the compound screening assays for years. Our laboratory has reported on problems associated with simple vital dye uptake as a measure of cytotoxicity in human keratinocytes (HEK) following *in vitro* exposure to HD. We have evaluated 6 different measures of cell viability for HEK exposed to HD *in vitro*. These are propidium iodide uptake (membrane integrity), viable cell number, calcein-AM (membrane integrity), alamar blue (mitochondrial metabolism), neutral red (lysosomal activity), MTS (mitochondrial dehydrogenase activity). The sensitivity of each assay to HD toxicity appears to be: viable cell number > calcein = alamar blue = PI uptake > MTS = neutral red. All of these assays can be performed by moderately trained laboratory personnel without the need for expensive flow cytometry instrumentation.

1746 AMNIOTIC FLUID AND MATERNAL/FETAL BLOOD COLLECTION IN LABORATORY MICE.

A Georgieva-Kotzeva, D E Rodwell, T Agajanova and M Tufa. *Huntingdon Life Sciences, East Millstone, NJ, USA.*

Researchers have become increasingly interested in quantifying the amount of test material crossing the placenta. The analysis of prenatal amniotic fluid and blood samples can provide this information. The method developed in this laboratory allows for determination of test substance levels in the amniotic fluid and in fetal/maternal blood in mice. The pregnant mouse, gestation day 17, is placed in a clear chamber for induction of anesthesia with isoflurane. The anesthetic (isoflurane) is driven through a vaporizer at a concentration of 4%-4.5% via the pressure from an oxygen tank set at 0.4 liters/min. Once the dam has reached a surgical plane of anesthesia, it is placed on a heating pad in a supine position. Anesthesia is maintained with isoflurane via a nose cone at an approximate concentration of 1%-1.5% and is adjusted as needed. The abdominal cavity is opened and the uterus is exposed. The fetuses are maintained in situ until the amniotic fluid is collected. Approximately 0.5 ml amniotic fluid per mouse litter can be obtained. The fetuses are removed sequentially from the uterus. Each fetus is placed on a heating pad, the thoracic cavity is opened and the great vessels anterior to the heart are exposed. The vessels are severed and a heparinized capillary tube is placed near the incision. After collection, the samples from each litter may be combined for analysis. Approximately 0.20 mL of pooled mouse fetal blood can be obtained. After all fetal samples are collected, a maternal blood sample is obtained from the vena cava. The dam may then be sacrificed by exsanguination while under anesthesia. This method allows for the maintenance of the maternal/fetal vascular supply and fetal viability during the procedure. We believe that the technique developed in the laboratory is advantageous and reliable based on the consistent results.

1747 ELISA-BASED OLIGONUCLEOTIDE LIGATION ASSAYS FOR THE DETECTION OF SINGLE NUCLEOTIDE POLYMORPHISMS (SNPs) IN BIOTRANSFORMATION ENZYMES.

F M Farin, S Quigley, Y Hitosis, C L Keener, J R Walker, and C J Omiecinski. *Center for Ecogenetics and Environmental Health, Dept. of Environmental Health, University of Washington, Seattle, WA, USA.*

High throughput genotyping methods are becoming more important for the timely completion of large-scale molecular epidemiologic studies. An ideal genotyping assay should be efficient, economical, automatable, and should yield consistent single-base pair discrimination. We have developed ELISA-based oligonucleotide ligation assays (OLAs) to detect specific SNPs in the cytochrome P450 (CYP) 1A1, CYP 2E1, CYP 2D6, microsomal epoxide hydrolase, NAD(P)H quinone oxidoreductase, glutathione S-transferase P1, and N-acetyl transferase 2 genes. These genotyping assays employ 96-well microtiter plates in a diallelic, single-well format. The OLA protocol is as follows: a specific region surrounding the SNP is PCR amplified from genomic DNA or a cell lysate and is incorporated as a template for an allele-specific ligation reaction using two adjacent oligonucleotides: a wild-type or variant specific reporter probe (labeled with digoxigenin or fluorescein) and a biotinylated anchor probe. The two allele-specific ligation oligomers are complementary to sequences nested within the PCR amplicon. Only probes that are perfectly complementary are ligated by a high-stringency thermal-cycled ligation step. Capture of the biotinylated anchor probe on immobilized streptavidin is followed by sequential analysis for the covalently-linked reporters using an ELISA. This procedure allows automated detection for the presence or absence of allelic variation in the PCR product thereby enhancing genotyping analytical capacity in a low cost format. (Supported by NIEHS Center ES-07033.)

1748 HORMONE DETERMINATIONS IN MACAQUES: VALIDATION OF A TESTOSTERONE ASSAY.

W Müller, F Vogel, and R Korte. *Covance Laboratories GmbH, Münster, Germany.* Sponsor: J C Norris.

Testosterone is a core parameter in reproduction toxicology and generally in reproduction research. Non-human primates are often the most appropriate model for this research due to their close relationship to man. As the number of assays for hormone determinations in animal species including primates is very limited, there is often no alternative other than using assays which have been developed for determinations in human samples. The implementation of such assays may be affected in an adverse manner by interferences of matrix differences between man and animal species and, in certain cases (but not regarding testosterone), differences in the molecular structure of the target hormone. The proper performance of an assay must therefore be demonstrated with respect to the target species. This validation procedure should follow national and international standards including the Good Laboratory Practice Regulations if acceptance by regulatory authori-

ties is aimed for. This poster outlines the validation procedures and the acceptance criteria for the routine use of the testosterone radioimmunoassay DSL-4100 from Diagnostic Systems Laboratories Deutschland GmbH for determinations in serum samples from macaques. Data are presented on intra- and inter-run accuracy (with one exception between 86.3% to 109.8%) and precision (between 2.2% and 15.9%), on stability (samples stable under the tested short- and long-term conditions), cross reactivity (less than indicated for human samples), parallelism (good parallelism within the examined range), sensitivity (not examined below 0.4 nmol/L) and robustness (no influences by staff or laboratory changes or by examination dates). The data confirm suitability of the assay for determinations in serum samples from macaques in the range of 0.4 to 86.7 nmol/L.

1749 ASSAYS FOR DNA DELETIONS DETECT CARCINOGENS.

R H Schiestl, R J Brennan, A Galli, J Aubrecht, R Rugo, W Yap and N Carls. *Department of Cancer Cell Biology, Harvard School of Public Health, Boston, MA.*

Genetic instability and deletions are involved in carcinogenesis. We have constructed and/or used assays (DEL assays) that select for DNA deletion events in yeast, human cells and in vivo in the mouse. DEL events in all three formats are inducible by a wide variety of carcinogens including carcinogens, such as benzene and PCBs, that are negative in many other short-term tests. Furthermore, the yeast DEL assay correctly differentiates between carcinogen-non carcinogen structural analogs. Of 62 chemicals of known carcinogenicity status the yeast DEL assay detects 85% correctly compared to the Salmonella assay that detects only 33% correctly. The DEL assays are currently used to determine dose response relations for carcinogens and to investigate the biological activity of these carcinogens. Mouse DEL assays may detect tissue specific effects and allow in vitro - in vivo comparisons. The yeast DEL assay is currently being further developed into a high throughput screening format and is currently used in governmental and industrial applications in attempts to identify the potential carcinogenic activity of chemicals. Further validation with 500 chemicals is ongoing. More widespread use of the DEL assays may reduce the number of experimental animals required, may lead to a higher accuracy in predicting the carcinogenic potential of chemicals and may give more mechanistic information about the biologic activity of carcinogens than current assays.

1750 ARE RIGOROUS STUDY METHODS REPORTED IN RESEARCH USING ANIMAL MODELS?

R C Dart, L Yip, K Heard, R E Hill, and G M Bogdan. *Rocky Mountain Poison and Drug Center, Denver, CO, USA.*

In 1996 the CONSORT statement was adopted by many medical journals to standardize the reporting of rigorous study methods, including randomization of subjects and blinding of investigators to the treatment of subjects. No such methodological requirements have been adopted for animal studies. We evaluated the reporting of study design in animal studies from four toxicology-oriented journals. Issues of the Journal of Toxicology-Clinical Toxicology (JTOX) from 1994 to 1997, Annals of Emergency Medicine (AEM) from 1994 to 1997, Veterinary and Human Toxicology (VHT) from 1996, and one month of Fundamental and Applied Toxicology (FAAT) from 1996 were reviewed. Using a standardized data collection form, three non-blinded investigators reviewed articles that studied a poison or drug effect using an animal model. Investigators assessed for reporting of the following data elements: use of a control group; randomization of animals to treatment groups; blinding of the investigator responsible for assessing study outcome; and age, weight, sex and species of the model. The model was considered adequately described if sex, species and age or weight were provided. Of the 83 articles reviewed, 58 (73%) reported adequate model descriptions, 76 (95%) use of control groups, 36 (45%) randomization of animals and 12 (15%) blinding of study outcome assessments. The use of controls and model descriptions were common in these journals, though blinding and randomization, considered crucial in human studies to distribute bias evenly, were not reported in a majority of studies. We advocate the adoption of randomization and blinding as standard practice in animal research until data demonstrates that these safeguards are not required.

1751 DEVELOPMENT AND UTILIZATION OF A PHARMACO/TOXICOKINETIC MODEL FOR EXTRA CELLULAR MATRIX PROTEINS USED IN THE TREATMENT OF PERIODONTAL DISEASE.

S E McPherson[1], B J Tucker[1], and A De Peyster[2]. [1]*Desmos Inc., San Diego, CA;* [2]*San Diego State University, San Diego, CA.*

Disease of the periodontium continues to be one of man's most widespread afflictions. Approximately 15% of the population in the United States suffers from this disease. Fibronectin was used as a surrogate ECM protein to develop a pharmaco/toxicokinetic model capable of assessing acute toxicity and bioavailability of I-125 radiolabeled ECM proteins administered I.V. or through a clinically relevant gingival flap procedure. The flap procedure consisted of resecting the gingival tissue from the mesial portion of the maxillary first molar, debriding the exposed root surface, administering fibronectin, and returning the flap to its original position. Chronically cannulated male rats were administered 5 μL of a 100 μg/mL (0.5 μg) into a gingival flap (n = 4) representative of the clinical route and dose received in human periodontal flap surgery therapy. The systemic bioavailability, urine clearance, through a bladder catheter, and tissue accumulation of the gingivally applied protein was compared to increasingly high systemic doses of fibronectin. Doses of 1, 10 and 100 μg (n = 4, 3 and 4 respectively) were administered I.V. Results showed no signs of acute toxicity, organ bioaccumulation or altering kinetics for the I.V. treated animals. A therapeutic ratio of greater than 2000 was demonstrated by comparing peak systemic doses of clinical dose to the highest systemic dose. Preferential binding to site of action, e.g.: tooth, gingiva and maxilla was also demonstrated in this model. The model was designed to evaluate the acute safety and true clinical exposure of ECM proteins in the periodontium. The model can be further utilized to address the pharmacokinetics of chemical entities where exposure in the periodontium occurs.

1752 ACUTE TOXIC CLASS METHODS: USE, PROPERTIES AND INTERNATIONAL HARMONIZATION.

W Diener and E Schlede. *Federal Institute for Health Protection of Consumers and Veterinary Medicine (BgVV), Berlin, Germany.* Sponsor: J Pauluhn.

The expected numbers of animals in acute toxicity testing is significantly reduced by the use of the Acute Toxic Class (ATC) Methods, on average 70% in comparison to the classical LD/LC50 tests. In March 1996 the oral ATC Method was adopted as an official OECD Test Guideline (No. 423). Thus, a worldwide use is possible. The oral ATC Method is as reliable as the oral LD50 Method with respect to classification and observation of clinical signs. Since 1996 in Germany the oral ATC Method has been used in 21% of all oral acute tests conducted for the notification procedure of new chemicals in the European Union. This Method is considered as an excellent alternative to the oral LD50 test which may be deleted in the near future by the OECD. For the inhalation and dermal routes of administration new guidelines based on the oral ATC Method were developed, which are also appropriate as alternatives to the respective LD/LC50 test methods. The ATC Methods (oral, inhalation, dermal) are also applicable in case that an international harmonization based on LD/LC50 as cut-off values is achieved. Nevertheless, all tests carried out before the completion of harmonization process can be used due to the specific procedure of the ATC Methods. In addition, modified test procedures can be easily applied with the harmonized cut-off values. Examples for the modified ATC Methods together with classification probabilities and expected numbers of used and dead animals are given according to the agreement on acute toxicity systems for all routes of administration at the 8th high level meeting of the OECD in September 1998.

1753 HUMANE END-POINTS IN ACUTE TOXICITY TESTING.

E Schlede, I Gerner and W Diener. *Federal Institute for Health Protection of Consumers and Veterinary Medicine (BgVV), Berlin, Germany.* Sponsor: J Pauluhn.

The reduction of severe pain and distress of test animals and avoidance of death as an end-point in acute toxicity testing should be feasible within the framework of the regulation of chemicals, drugs, pesticides etc. Examples for humane end-points with respect to acute toxicity testing are: -Theoretical considerations and in vitro tests prior to animal testing: Within a tiered testing strategy structure-activity (SAR) considerations and specific in vitro

tests can be used in order to predict severe acute toxic effects like skin corrosivity or eye damage. If severe effects can be predicted, animal testing should be avoided. - Prediction of local irritation/corrosion after a single contact: When no severe local irritant/corrosive properties of a substance can be predicted, Draize irritation tests using one single rabbit should be conducted. If corrosivity, severe corneal opacity or pannus are observed, the test can be terminated because these lesions do not resolve within an adequate observation time and thus, a reliable classification of local effects is possible. If a one-animal test does not demonstrate severe local effects, two further rabbits are used in order to rank local irritation according to international guidelines. - Clinical signs preceding death of test animals in oral toxicity testing: Neither a single nor a combination of clinical signs can be reliably associated with death. However, there are specific clinical signs that should be considered as „alert signs" for an impending death. These signs include all forms of convulsions followed by lateral position and tremor. Convulsions are almost non-existent in surviving animals (< 1%) in comparison to moribund animals (44%) and animals that die (28%). For example, only 10 out of 210 animals suffering from clonic convulsion survived. These data are based on the evaluations of clinical signs of 3942 rats that were used in the ring studies of the oral Acute Toxic Class Method.

1754 IN VITRO PERCUTANEOUS ABSORPTION STUDIES OF CONTAMINATED SOILS: HPLC DETECTION OF DERMALLY BIOAVAILABLE BENZO[A]PYRENE.

R Singh[1], A J Krueger[2], E H Weyand[1], and T A Roy[2]. [1]*College of Pharmacy, Rutgers, The State University of New Jersey, Piscataway, NJ, USA;* [2]*Petrotec Inc., Langhorne, PA, USA.*

A high performance liquid chromatography (HPLC) method has been developed to determine benzo[a]pyrene (BaP) in an aqueous (6%/Wt.) polyethylene glycol 20 oleyl ether surfactant (Volpo 20) receptor fluid used for *in vitro* percutaneous absorption studies. Previously, *in vitro* studies have estimated the dermal bioavailability of BaP and other carcinogenic polynuclear aromatic compounds (PAC) from contaminated soils by determining levels of (surrogate) ^{3}H-BaP in surfactant-modified receptor fluid. However, this method is disadvantageous as it may not accurately reflect the true bioavailability of endogenous PAC, which can be more tightly bound to soil than ^{3}H-BaP added to soil pre-(dermal) dosing. The present method is designed to detect endogenous BaP in surfactant-modified receptor fluid at the termination of *in vitro* percutaneous absorption experiments and thus allow a better estimate of the effect of soil aging on dermal bioavailability. This is a simple and fast method involving direct analysis of BaP without the need for radiotracers or tedious extraction procedures. The *in vitro* dermal studies are conducted in the usual manner and the receptor fluid analyzed by reverse-phase HPLC using fluorescence detection. The method shows good linearity in the range studied (10-400 picograms BaP in receptor fluid). The enhanced detection method for *in vitro* dermal bioavailability studies should improve the accuracy of experimentally determined environmentally acceptable endpoints for (contaminated) site risk assessment and remediation.

1755 EVALUATION OF BENZENE BIOMARKER S-PHENYLMER CAPTURIC ACID, A SENSITIVE BIOMARKER OF EXPOSURE.

A M Medeiros, D J Letinski, F T Whitman, D J Caldwell, and M G Bird. *Exxon Biomedical Sciences, Inc., East Millstone, NJ, USA.*

The American Conference of Governmental Industrial Hygienists (ACGIH) proposed S-phenylmercapturic acid (SPMA) as the biological exposure index (BEI) for benzene. We conducted an inhalation study in rats to evaluate the SPMA assay in a rodent model. This assay was developed by Van Sittert *et al.* (1993, 1995) in humans. Four Wistar rats per dose group were exposed for 8 hrs to 0, 0.5, 1.0 and 10 ppm benzene in individual metabolism cages. These cages served as the exposure chambers and facilitated the collection of urine. Chamber airflow and benzene concentrations were monitored continuously throughout the exposure and recorded every 60 minutes. Urine was collected at 8, 24 and 48 hrs after initial exposure. SPMA was analyzed using capillary gas chromatography with mass selective detection with a quantitation limit of 50 nM (24 ng/mL). S-benzylmercapturic acid (s-BMA; n-acetyl-s-benzyl-DL-cysteine) was used as the internal standard instead of deuterated SPMA. In addition to SPMA, phenol and creatinine were quantified in each sample. Exposure to 0.5, 1.0 and 10 ppm benzene resulted in mean SPMA concentrations (standard deviation) of 19.0 (2.3), 63.3 (10.1) and 1024.2 (380) μ g/g creatinine, respectively, at 8 hr time interval and 6.4 (2.6), 11.6 (5.3) and 79.2 (32.7) μ g/g creatinine, respectively, at the 24 hr interval. By 48 hrs after exposure, SPMA was detected only in the 10 ppm dose group with a mean concentration of 0.4 (0.2) μ g/g creatinine. SPMA was not detected in any of the control animals. Phenol concentrations in the urine were elevated only in the 10 ppm exposure group and only at the 8 hr time interval. These data confirm the sensitivity of the SPMA assay in the rat and validate SPMA as a suitable biomarker for low level benzene exposure.

1756 PRODUCTION OF ANTIBODIES TO METHADONE FOR TOXICOLOGICAL STUDY.

N Chikhi-Chorfi[1], C Pham-Huy[1], H Galons[2], J-M Warnet[1] and J-R Claude[1]. [1]*Laboratoire de Toxicologie,* [2]*Laboratoire de Chimie Organique, Faculté de Pharmacie, Université Paris V, Paris, France.*

A specific antibody to methadone (Mtd) was produced in rabbits by immunization with a conjugate of methadol - hemisuccinyl - bovine serum albumin. A hapten was first prepared by reduction of methadone with sodium borohydrure, then followed by esterification with succinic anhydride. The conjugation of hapten with albumin was achieved by the mixt anhydride method. Rabbits were immunized, and titres and specificity of antibodies were determined by ELISA using a conjugate of methadone - hemocyanin (KLH) as coating antigen. The antibodies obtained were tested with methadone, its major metabolite : 2-ethylidene, 1,5-dimethyl 3,3 diphénylpyrrolidine (EDDP) and other drugs and drugs of abuse. The antibody titers were 1:640,000. The detection sensitivity of methadone was10 ng/ml. The cross-reactivity with its EDDP metabolite was about 1.0% and with other drugs and drugs of abuse less than 0.01%. This specific antibody to methadone will be used for the development of an enzymatic method for the determination of methadone in biological fluids for maintenance treatment of opiate addicts and of an immunoaffinity chromatography method for the extraction of this compound especially in polypoisoning, intended to physico-chemical methods (HPLC, GC, MS).

1757 NEST BOX FOR EXCRETA COLLECTION FROM MOUSE DAMS THROUGH PARTURITION.

C A Blum[1], A K Wilson[2], and M H Bhattacharyya[3]. [1]*Oregon State University, Corvallis, OR, USA;* [2]*Benedictine University, Lisle, IL, USA;* [3]*Argonne National Laboratory, Argonne, IL, USA.*

Standard metabolism cages cannot be used to collect excreta from mouse dams through parturition and early lactation because newborn pups fall to the excreta collection area where the dam cannot reach them. A nest box that solves this problem was constructed from a rectangular polyethylene box with a removable lid and designed for placement inside a standard metabolism cage (patent filed). The nest box was tested in a metabolic study with pregnant mice, strain 129/SvJ (metallothionein-normal and metallothionein-knockout); nonpregnant mice without a nest box and pregnant mice in conventional plastic cages served as controls. Each mouse received two gavage doses of $^{109}CdCl_2$, one in late gestation and one in midlactation for dams, and at analogous time points for nonpregnant mice. Recovery of ^{109}Cd in excreta was determined for each dose. Dams urinated only outside the nest box and deposited <4% of their feces inside the box; all urine and the balance of feces were collected from the metabolism cage collection tray. In contrast, a nonpregnant test mouse with a nest box routinely deposited feces and urine both inside and outside the box. For dams, the percentage ^{109}Cd recovered after the first gavage — with nest box, collection through parturition (95±6%, mean+SE, n=5) was the same as after the second gavage — no nest box, collection during midlactation (95±6%, n=5). Results demonstrated that values for litter size, dam weight, pup weight, and pup survival were not significantly different from those obtained for mice in conventional plastic cages. The nest box provided a safe haven for mouse pups in the metabolism cage environment while allowing for quantitative excreta collection from mouse dams (and pups) through pregnancy, parturition, and the early postnatal period. With this box, drugs or toxic compounds that need testing in females can undergo continuous metabolic evaluation through parturition and early lactation in a metabolism cage setting. (Work supported by NIH grant ES07398.)

1758 EVALUATING THE CYTOTOXICITY OF 181 CHEMICALS TO HELA CELLS USING SAR EXPERT SYSTEM.

X Zhu [1], G Klopman[2], and H S Rosenkranz[1]. [1]*Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA, USA;* [2]*Department of Chemistry, Case Western Reserve University, Cleveland, OH, USA.*

Cellular toxicity (CelTox) is often used as a surrogate for other toxicological endpoints ranging from ocular irritation to systemic toxicity. In order to explore the validity of this assumption, we developed an SAR model of toxicity of chemicals towards cultured Hela cells. Based upon a database of 181 chemicals assayed for their growth-inhibiting activity after 24 hours of exposure, an SAR model based upon CASE/MultiCASE was developed. For chemicals external to the learning set, the model displayed a concordance between experimental and predicted results of 74% (Sensitivity: 0.75; Specificity: 0.72). This suggests that CelTox is a complex phenomenon reflecting a series of independent and/or sequential actions. Yet the SAR model is robust and the chemicals used to build the models are a good representation of the universe of chemicals. Moreover, it is to be expected that the predictivity of the model will improve as the number of chemicals included is increased. The structure overlap between SAR models can be taken as a measure of mechanistic similarity. There was significant, but not complete, structural overlap between CelTox and maximum tolerate dose (mice and rats), LD_{50} in rats, toxicity to fish, eye irritation and phenomena associated with electrophilicity (mutagenicity in *Salmonella;* allergic contact dermatitis). There was only minimal structural overlap between CelTox and α 2μ - induced nephrotoxicity or binding to the Ah receptor. These findings indicate that while CelTox can be used as a surrogate for other toxicological endpoints, this should be done as part of a battery of assays.

1759 A METHOD FOR QUANTITATION OF TISSUE VINCLOZOLIN AND METABOLITES USING A BENCHMATE® AUTOMATED SPE WITH GC-MS.

K L Cheever, K L Marlow, S R Skaggs, J C Clark, T W Turner, W J Moorman and D G DeBord. *NIOSH, Exp. Toxicol., Cincinnati, OH.*

Vinclozolin (*Vin*, CAS 50471-44-8), a dicarboximide fungicide, has been reported be an antagonist of androgen receptor binding in rats, effects that could result in decreased fertility, defects in reproductive organs or cancer. It is thought that *Vin* activation to the metabolites 2-[[(3,5-dichloro-phenyl)carbamoyl]oxy]-2-methyl-3-butanoic acid (*M1*, CAS 119209-27-7), 3',5'-dichloro-phenyl-2-hydroxy-2-methylbut-3-enanilide (*M2*, CAS 83792-61-4), and 3,5-dichlorobenzenamine (*M3*, CAS 626-43-7) could induce similar toxicity in workers. A potential biomonitoring method was developed to measure tissue levels and evaluated using Dutch Belted rabbits after exposure to *Vin*, either as a single dermal dose or multiple dermal doses. *Vin* (100 mg/kg) was applied to the skin in 100 µL DMSO. Plasma samples were taken at 0, 6, 8, 12, 24, and 48 hr after a single dose or weekly during multiple dose exposure. Skin from dermal application sites and testes were excised at termination, homogenized and filtered. A BenchMate® robotic workstation was used for automation of sample preparation. Bond Elute® 500 mg C8 SPE columns were conditioned with acetone, MeOH and H_2O pH 7. Samples were loaded onto columns, rinsed twice with H_2O. A fraction containing >96% of *Vin* and *Vin* metabolites was collected in 1.5-mL acetone, and reduced to 1 mL for GC-MS SIM analysis (Hewlett-Packard quadruple using a 12 m X 0.2 mm Ultra 1 column). Chromatographic standards *M1* and *M2* were synthesized by alkaline hydrolysis of *Vin* and isolated by HPLC. *Vin*, *M1*, *M2*, and *M3* were detected in both plasma and tissues, but animal variation was problematic. After a single application *Vin* plasma levels were highest at 6 hr whereas levels of *M1*, *M2*, and *M3* were highest at 12 hr. After 4 weeks of dosing *Vin* levels in plasma were 162.2 ng/mL — consistent with testes levels. *M2* was detected in the testes and skin levels of *Vin* were ~10 fold that of plasma. Thus, *Vin* and *Vin* metabolite internal exposure levels can be rapidly quantified in a single assay using an automated system.

1760 A FLUORESCENCE PLATE READER ASSAY FOR MONITORING THE SUSCEPTIBILITY OF BIOLOGICAL SAMPLES TO LIPID PEROXIDATION.

M A Tirmenstein, C A Pierce, T L Leraas and M W Fariss. *Department of Pharmaceutical Sciences, College of Pharmacy and Graduate Program in Pharmacology/Toxicology, Washington State University, Pullman, WA, USA.*

The susceptibility of biological samples to lipid peroxidation can be determined by exposing samples to a lipid peroxidation initiator and measuring the length of time prior to the onset of lipid peroxidation. Previous studies have shown that aldehydes generated by lipid peroxidation can react with amines to produce fluorescent products. We have utilized this principle to develop a fluorescence plate reader assay for measuring susceptibility to lipid peroxidation. In this assay, samples are placed in glycine/phosphate buffer and loaded into a 96 well plate. Lipid peroxidation initiators are added, and fluorescence is monitored over time at excitation and emission wavelengths of 360/430 nm. Samples were assayed for susceptibility to lipid peroxidation by both the thiobarbituric acid reactive substances assay and the fluorescence plate reader assay. We found good agreement between these two methods in assessing relative susceptibility to lipid peroxidation in liver microsomes and mitochondria. The fluorescence assay was also used to monitor lipid peroxidation in liposomes and rat liver homogenates. The addition of 4-hydroxy-2-nonenal but not malondialdehyde to glycine/phosphate buffer produced a fluorophore with similar excitation/emission maximums as liposomes peroxidized in glycine/phosphate buffer. Fluorescence was stable over an extended time period and could be induced by a variety of lipid peroxidation initiators. The fluorescence plate reader assay offers a rapid method for monitoring lipid peroxidation in a large number of samples. (This work was supported by NIEHS/NIH grant # R01ES 05452.)

1761 A RETROSPECTIVE ANALYSIS OF CLINICAL PATHOLOGY PARAMETERS IN DOMESTIC SWINE: A COMPARISON OF VALUES BEFORE AND AFTER JUGULAR VEIN CATHETERIZATION.

L I Mortin and C J Horvath. *Primedica Corporation, Dept. Experimental Medicine, Worcester, MA, USA.* Sponsor: H S Lilja.

Domestic swine are often utilized in preclinical safety and efficacy studies. We decided several years ago to surgically implant jugular catheters in domestic pigs to minimize stress and pain when multiple serial blood collections are required within a study. Animals arriving at our Test Facility are placed in quarantine for a minimum of seven days for observations (clinical and physical) and clinical pathology testing, including fecal samples for analysis of intestinal parasites and blood collection for analysis of hematology (red cells, white cells and platelets) and serum chemistry parameters. This blood collection requires tranquilization and/or physical restraint, and generally occurs 4-5 days after receipt of the animals into their new habitat. We compared the hematology and serum chemistry values obtained from this analysis with the same parameters from a sample collected in conscious, unrestrained pigs via a jugular catheter at least five days post-surgery. This analysis includes collation of clinical pathology data obtained from more than 200 castrated male and female Yorkshire pigs (*Suis sus*) approximately 2-3 months old. The pigs weighed between 25 and 40 kg at the post-surgical blood collection time point. Total white blood cell counts, moderately elevated at the quarantine blood collection, were decreased when collected via a jugular vein catheter. This was primarily due to a decrease in polymorphonuclear cells. In addition, there was often a small decrease in red blood cell values (total red cells, hematocrit, hemoglobin, MCV and MCH) post-surgically compared to values obtained from pigs without catheters. This retrospective analysis provides a set of baseline values for evaluation of treatments in future studies using domestic swine. (All animal studies at Primedica Corporation are conducted in compliance with USDA and NIH regulations, and reviewed by the Primedica Animal Care and Use Committee.)

1762 THE EFFECTS OF SODIUM NITRITE ON METHEMOGLOBIN FORMATION IN NONHUMAN PRIMATES.

G A Rockwood, M B Gold, A V Finger, K W Wyant and S I Baskin. *Divisions of Drug Assessment, Pharmacology, and Comparative Medicine, United States Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD, USA.*

Methemoglobin (MHb) formers are protective against cyanide (CN) toxicity in multiple species. Sodium nitrite-produced MHb was studied in nonhuman primates as part of an anti-CN pre/treatment development program. The time-course of sodium nitrite ($NaNO_2$)-produced MHb formation and changes in related hematological parameters were measured in six rhesus monkeys (*Macaca mullata*) (two females and four males with mean weights of 5.3 and 9.7 kg, respectively). A surgical plane of anesthesia was produced and maintained with tiletamine HCl/zolazepam HCl (3 mg/kg, IM) and inhalation of 0.5 - 2.0% isoflurane in oxygen, respectively. Arterial blood was collected serially from a centrally placed catheter and analyzed to determine the animals capacity to form MHb following increasing concentrations of intravenous administration of $NaNO_2$ (total cumulative dose per animal ranged from 16.0 - 20.0 mg/kg). Total hemoglobin, oxyhemoglobin, reduced

hemoglobin, saturated oxygen, oxygen content, sulfhemoglobin and MHb were measured with a OSM3 hemoximeter. Continuous body temperature was monitored by rectal probe. A dose-response relationship was developed for $NaNO_2$-produced MHb in the nonhuman primate, with maximum levels ranging from 8.6 - 15.5%. The data suggest that the relationship between the dose of $NaNO_2$ correlates well with the concentration of MHb formed, although differences across subjects were observed. This relationship lays the foundations for further study of MHb-forming anti-CN therapeutics in nonhuman primates.

1763 RAT ERYTHROCYTE ACETYLCHOLINESTERASE (AChE) MEASUREMENT USING A RADIOMETRIC METHOD.

L Huard and Y Deschamps. *ClinTrials BioResearch Ltd, Clinical Laboratories, Montreal, Quebec, Canada.* Sponsor: G Lulham.

The objective of this work was to evaluate the sensitivity and the reproducibility of a simple radiometric method for the measurement of rat erythrocyte acetylcholinesterase. The radiometric method is based on the extraction of ^{3}H-acetate generated by the action of AChE on ^{3}H- acetylcholine. The method published by Johnson and Russell was modified to include the following: a) pH of reactive medium set at 8.0; b) addition of a biological and a commercial control; c) preparation of an hemolysate from packed red blood cells. The following results were obtained: Intra-assay precision: 1.2% C.V. (n=10), Inter-assay precision 4.1% C.V. (5 runs), Linearity of dilution: coefficient of correlation = 0.9999 for a range of 152-787 nmoles/min/mL hemolysate, slope = 0.9896. Sensitivty was found to be 84.9 nmoles/min/mL. Physiological Range for 12-15 weeks old Sprague-Dawley rats was calculated as 673-940 nmoles/min/mL hemolysate. In conclusion, this method is considered to be very sensitive and reproducible for the measurement of rat erythrocyte acetylcholinesterase.

1764 THE DEVELOPMENT OF AN IN VITRO MODEL FOR URINARY TRACT CELLS FROM C57BL/6N MICE.

P L Bryant[1], L M Reid[2], E Diala[3], and B A Abbott[4]. [1]*Dept. Environmental Sciences and Engineering,* [2]*Dept. of Cell and Molecular Physiology and Program in Molecular Biology and Biotechnology,* [3]*ACT Core of the Center for Gastrointestinal and Biliary Disease Biology, UNC, Chapel Hill, NC;* [4]*RTD, NHEERL, US EPA, Research Triangle Park, NC, USA.*

2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) produces hydronephrosis by altering the proliferation of ureteric epithelial cells in the embryonic C57BL/6N mouse urinary tract. The mechanism appears to involve effects on growth factor regulation and in this study an *in vitro* model was developed to facilitate study of the role of growth factors in this response. Ureters were removed from the urinary tracts of gestational day (GD)18 fetuses. The ureters were minced and trypsinized and the digest was centrifuged to produce a cellular pellet. Single cells and small clusters were resuspended in medium and plated onto transwells (Millicell-CM inserts, Millipore Corporation, Marlborough, MA) coated with purified and defined extracellular matrix components. The basal medium with low calcium (Keratinocyte Growth Medium-2, Clonetics , San Diego, CA) was supplemented with trace elements, a complex mixture of lipids, a defined mixture of purified hormones and growth factors tailored for the epithelial cells. Fetal bovine serum was added at 2% for the first 48 hours and at 1% thereafter. The cultures were incubated at 37°C in a humidified atmosphere containing 5% CO_2 in air. These conditions permitted selective expansion of the ureteric epithelia relative to stromal cells by inhibiting differentiation and inducing growth of epithelial progenitor cells. These epithelial cultures were viable and functional for 21 days. This culture model will be important in further study of the TCDD-induced disruption of coordinated expression of epithelial growth factors that coordinates with excessive epithelial cell proliferation. Disclaimer: (This abstract does not necessarily reflect EPA policy.)

1765 A METHOD FOR SPECIFICALLY ASSAYING ACETYLCHOLIN-ESTERASE ACTIVITY IN PERIPHERAL TISSUES.

R S Marshall[1], T L Lassiter[1,2], and S Padilla[1]. [1]*Neurotoxicology Div., U.S. Environ. Protection Agency, RTP, NC;* [2]*UNC-Chapel Hill, Chapel Hill, NC.*

The total cholinesterase activity present in a given tissue consists of butyrylcholinesterase (BuChE) and acetylcholinesterase (AChE) activity. The Ellman *et al.* (1961) assay, routinely used to assay total cholinesterase activity, does not distinguish between BuChE and AChE activity. Furthermore, assay of a large number of samples often depends on automated instrumentation. The present group of experiments was designed to assess whether an automated instrument could be used to assay AChE in peripheral tissues. Plasma, lung, retina, brain, diaphragm, heart, and muscle were collected from adult, female Long-Evans rats. All subjects were perfused transcardially with saline. Following homogenization in 0.1 M Na phosphate buffer (pH 8) with 1% Triton X-100, the relatively specific BuChE inhibitor iso-OMPA (0.1 mM final concentration) was added to an aliquot of each sample. The samples with and without iso-OMPA were then assayed on an Hitachi 911 Automatic Analyzer and also a ThermoMax Microtiter Plate Reader. Using the plate reader, acetylthiocholine-hydrolyzing-activity and butyrylthiocholine-hydrolyzing-activity of all samples were assayed approx-imately 15 minutes after the addition of iso-OMPA. Acetylthiocholine hydrolysis was assayed using the 911 at three time points: 15, 60, and 120 minutes after the addition of iso-OMPA. The amount of acetylthiocholine hydrolysis assayed by the 911 at 15 minutes after addition of iso-OMPA was the same as the activity measured by the plate reader. One hour after addition of iso-OMPA, the AChE activity had not increased nor decreased more than 10% for any tissue. By 2 hours after the addition of iso-OMPA, however, AChE activity was decreased in most of the tissues. Taken in concert, the data indicate that addition of iso-OMPA to brain and peripheral tissues is a valid method for inhibiting BuChE activity (and therefore measuring only AChE activity)if assay is completed within one hour after the addition of iso-OMPA.

1766 COMPARISON OF DOG THYROID PROFILES AND MECHANISM OF ACTION IN AMITROLE, FOE 5043, KTU 3616 AND YRC 2388 REGULATORY STUDIES.

R D Jones, S G Lake, T F Hastings, B P Stuart and B D Becker. *Toxicology Department, Bayer Corporation, Stilwell, KS.*

Primary hypothyroidism due to chronic amitrole (0, 10, 500 and 1500 ppm) reflected inhibition of thyroid peroxidase. There was decreased T4, T3, TSH, increased cholesterol, globulin, AST; nonregenerative, normochromic anemia with reduction in muscle mass, and reduced R- and P-amplitudes. Thyroid weights were increased and heart weights were decreased. Micropathology revealed moderate/ severe diffuse thyroid follicular cell hyperplasia with capsular fibrosis, vascular dilatation, inflammation and thrombosis, with ectopic thyroid tissue near the aortic arch, minimal/slight hypertrophy with vacuolization in the pituitary. *Extrathyroidal clearance with metabolic abiotrophism* characterized chronic FOE 5043 treatment (0, 40, 800; 1600 ppm). There was decreased T3, T4 as ALP increased (0-180 days), then adaptation of T3, T4; regenerative anemia, hypercholestrolemia and ECG arrhythmias. Central neurologic deficits and QEEG became pronounced as T4 & T3 rebounded. Micropathology revealed a minimal/slight hepatocytomegaly and hepatocyte vacuolization; vacuolization of ciliary body epithelium and peripheral optic retina; minimal/moderate axonopathy in brain, spinal cord and sciatic nerve, with no thyroid microscopic findings. The *"Euthyroid Sick Syndrome"* characterized subchronic KTU 3616 (0, 100, 500, 5,000; 20,000 ppm). There was decreased T4 & T3, decreased T-Prot & Gluc, with cachexia, body weight loss (>30%), and decreased food consumption with mild anemia and decreased P-wave amplitudes. Micropathology revealed parenchymal atrophy of heart, muscle and/or kidney; depletion of thymic and bone marrow tissue; hepatopathy with protoporphyrin pigmentation and individual hepatocyte necrosis. The chronic YRC 2388 (0, 20, 40, 200 and 750 ppm) increased *extrathyroidal clearance via xenobiotic induction of T4-UDP-GT.* T3 and T4 were little changed, but Phase I, UDP-GT and ALP were increased. Cholesterol was decreased, but with no anemia or ECG changes. Micropathology revealed hepatocytomegaly and hyperplasia of gall bladder mucosa related to bile secretion/flow, but no thyroid abnormalities. We conclude that mechanistic work during chronic or subchronic studies benefits from concurrent measurement and time course data, which adds to data package integrity per FQPA.

1767 EVALUATION OF THE REPRODUCTIVE PARAMETERS IN RATS AFFECTED BY THE INTERACTIONS OF POLYCHLORINATED BIPHENYLS AND METHOXYCHLOR RESULTING FROM EXPOSURE DURING DEVELOPMENT.

D S Respess Jr[1], R L Carr [1],N M Cox[2], C P McCoy [1], A B Moore[2], and J E Chambers [1]. *Center for Environmental Health Sci,* [1]*Coll of Vet Med,* [2]*Dept of Animal and Dairy Science, Mississippi State University, Mississippi State, MS, USA.*

Reproductive toxicity has been linked to the disruption of the endocrine system. Polychlorinated biphenyls (PCBs) bioaccumulate in the food chain and are passed on to offspring, inducing their cytochromes P450. Methoxychlor

(MXC), a pesticide used as a substitute for DDT, has estrogenic properties. The objective of this study was to investigate whether basic reproductive parameters are altered by the gestational and lactational exposure to PCBs in combination with pre-weanling exposure to MXC. Female Sprague-Dawley rats were fed 4 mg/kg/day Aroclor 1254 from gestation day 6 until postpartum day 22. Pups (n= 745 total) were treated from postnatal days (PND) 10-14 with 0, 0.3, 3, or 300 mg/kg/day (IP) laboratory grade MXC in the vehicle safflower oil. Pups were sacrificed on PND 15, 23, 31, and 70. Day of vaginal opening, weight at vaginal opening, sacrifice weight (used as covariable where appropriate), and reproductive organ weights were determined. There was an interaction of PCBs by MXC on PND 15 ($P<0.003$) such that at 300 mg/kg/day MXC, control rats had greater ovarian weight (22 mg vs 11 mg) and greater uterine weight (38 mg vs 28 mg) than PCBs-treated rats. At PND 23, uterine weight was consistently suppressed by PCBs ($P<0.0004$). Testis weight was decreased at the highest dose of MXC at PND 15 and 31 ($P<0.0001$), but was increased by PCBs only on PND 23 ($P<0.015$). Day of vaginal opening ($P<0.0001$) was accelerated by 4 days and weight at vaginal opening ($P<0.0006$) was lowered by 25 g by the highest dose of MXC. PCBs appear to mitigate negative effects of the highest dose of MXC on ovarian and uterine weight, while positively affecting testis weight. (Supported by EPA R 825296.)

1768 DETECTION OF THE ANTIANDROGEN *p,p'*-DDE IN SPRAGUE-DAWLEY AND LONG-EVANS RATS USING A TIER I SCREENING BATTERY.

J C Cook, S R Frame, L G Davis, and J C O'Connor. *DuPont Haskell Laboratory, Newark, DE, USA.*

p,p'-DDE has been examined in a Tier I screening battery for detecting endocrine-active compounds (EACs). The Tier I battery that was used to examine *p,p'*-DDE consisted of a 15-day intact male *in vivo* battery and an *in vitro* yeast transactivation system (YTS). In addition, because other investigators have reported strain sensitivity differences with *p,p'*-DDE, Sprague-Dawley and Long-Evans rats were evaluated in Tier I. In the *in vivo* male battery using Sprague-Dawley rats, responses to *p,p'*-DDE included organ weight changes [increased relative liver and decreased absolute epididymis] and hormonal alterations [increased serum estradiol (E2) and decreased serum FSH and T_4]. Responses to *p,p'*-DDE in Long-Evans rats included organ weight changes [increased relative liver, absolute epididymis, relative accessory sex gland (ASG) unit, as well as the individual component weights of the ASG (prostate and seminal vesicles)], and hormonal alterations [increased serum testosterone (T), E2, dihydrotestosterone (DHT), thyroid stimulating hormone (TSH), and decreased T_4]. These data demonstrate that there are considerable strain sensitivity differences to *p,p'*-DDE exposure. The described *in vivo* male battery using Sprague-Dawley rats did not identify *p,p'*-DDE as an EAC. In contrast, the *in vivo* male battery using Long-Evans rats identified *p,p'*-DDE as an EAC. The pattern of responses suggest that *p,p'*-DDE is acting as an AR antagonist centrally, but not in the periphery, and that the increased ASG weights are a result of the increased serum T. In the YTS for the AR, *p,p'*-DDE had an EC_{50} value of 3.5×10^{-4} M; however, in the AR YTS competition assay, *p,p'*-DDE did not inhibit DHT binding to the AR. In summary, these data suggest that strain selection will affect the ability to detect certain weak EACs. However, a Tier I screening battery consisting of both *in vivo* and *in vitro* endpoints would reduce the chance that weak-acting compounds such as *p,p'*-DDE would not be identified as potential EACs. This example illustrates that a the proposed Tier I screening battery consisting of both *in vitro* and *in vivo* endpoints would detect *p,p'*-DDE as an EAC.

1769 EVALUATION OF A TIER I SCREENING BATTERY FOR DETECTING THE THYROID TOXICANTS PHENOBARBITAL AND PROPYLTHIOURACIL.

J C O'Connor, S R Frame, L G Davis, G T Makovec, and J C Cook. *DuPont Haskell Laboratory, Newark, DE, USA.*

Phenobarbital (PB; thyroid hormone excretion enhancer) and propylthiouracil (PTU; thyroid hormone synthesis inhibitor) have been examined in a Tier I screening battery for detecting endocrine-active compounds (EACs). In addition, several additional thyroid endpoints [serum rT_3 levels, thyroid weights, thyroid follicular cell proliferation, and hepatic UDP-glucuronyltransferase (UDP-GT) activity] have been evaluated for their ability to detect thyroid modulating effects at 7, 14, and 28 days of treatment using PB and PTU. The Tier I battery incorporates a 5-day ovariectomized female battery, a 15-day intact male battery, and an *in vitro* yeast transactivation system. In the female battery, PB increased relative liver weight and uterine epithelial cell height, and caused hormonal alterations (increased serum FSH , and decreased serum T_3 and T_4). In the male battery, PB administration increased relative liver weight and caused hormonal alteration (increased serum estradiol and TSH, and decreased serum prolactin, FSH, LH, T_3, and T_4). In the female battery, PTU caused hormonal alterations (increased serum TSH, and decreased T_3 and T_4). In the male battery, PTU administration decreased relative liver weight, caused thyroid gland hyperplasia, and caused hormonal alteration (increased serum TSH, and decreased serum T_3 and T_4). At all three timepoints in the thyroid timecourse experiment, PB induced UDP-GT activity and caused hormonal alterations [increased serum TSH (4-week timepoint only), and decreased serum rT_3, T_3, and T_4]. At all three timepoints, PTU increased absolute thyroid gland weight, caused hormonal alterations (increased serum TSH, and decreased serum T_3, and T_4), and increased thyroid follicular cell proliferation. Thyroid gland hyperplasia was evident in the PTU- but not in the PB-treated rats. It has been proposed that thyroid gland histopathology coupled with decreased serum T_4 levels be used as the criteria for identifying thyroid toxicants. However, using that criteria, weak thyroid toxicants like PB would not be detected using a study design of 28 days or less.

1770 EFFECTS OF DIETARY GENISTEIN ON REPRODUCTIVE DEVELOPMENT OF SPRAGUE-DAWLEY RATS.

M Casanova, L You, S Archibeque-Engle, and H Heck. *CIIT, Research Triangle Park, NC.*

Phytoestrogens such as genistein (GE) can affect sexual differ-entiation in rat pups when administered by gavage to their dams, but whether normal dietary levels of these compounds are suffi-cient to alter perinatal reproductive development is unknown. A modified NIH-07 open formula rodent ration was obtained in which casein and corn oil were substituted for soybean and alfal-fa meal and soy oil, respectively. In contrast to standard NIH-07, which contains about 0.016% GE, soy- and alfalfa-free diet (SAFD) had no detectable isoflavones. To determine whether dietary GE can affect sexual developmental end points, groups of six timed-pregnant SD rats were fed SAFD, SAFD + 0.02% GE (GE.02), SAFD + 0.1% GE (GE.1), or NIH-07 starting on gestation day (gd) 0. Body weights (BW) of dams or pups were monitored until postnatal day (pnd) 56. Birth weights of pups and BW gain of dams and pups were similar in animals consum-ing SAFD or NIH-07 but were slightly reduced in those fed GE.02 or GE.1. Anogenital distance/BW on pnd 1 was signifi-cantly higher in animals of both sexes ingesting GE.1 than in those fed SAFD. On pnd 21 a 2.5-fold higher uterus/BW was observed in animals ingesting GE.1 relative to the other three groups, all of which had similar weights. Vaginal opening was accelerated in animals ingesting GE.1 relative to the other three groups, all of which had similar values. The results suggest that dietary concentrations of GE = 0.02% do not induce marked effects on sexual development relative to a GE-free diet, but that effects can occur at a 5-fold higher level. Based on the above end points, it appears unlikely that the concentrations of genistein present in NIH-07 are sufficient to alter sexual development of rats in the perinatal period.

1771 A COMPREHENSIVE PROTOCOL FOR THE EVALUATION OF POTENTIAL ENDOCRINE DISRUPTING CHEMICALS.

R R Newbold[1] and K B Delclos[2]. [1]*NIEHS, Research Triangle Park, NC, USA;* [2] *NCTR, Jefferson, AR, USA.*

Exposure to endocrine modulating substances may occur from ambient environmental exposures, foods, food packaging materials, pharmaceuticals, and medical devices. An Interagency Agreement has been established between the NIEHS/NTP and FDA/NCTR to evaluate five compounds in a comprehensive protocol capable of assessing effects on multiple structural and functional endpoints expected to be sensitive to modulation of estrogenic or androgenic pathways. The compounds selected for study (genistein, methoxychlor, nonylphenol, ethinyl estradiol, and vinclozolin) include chemicals that have been demonstrated to have widely varying potencies as endocrine disrupting agents. The compounds are being administered to CD (Sprague-Dawley) rats in a natural diet modified to eliminate phytoestrogens contributed by soy and alfalfa. For short term dose range finding studies, exposure to 5 or 6 doses of test chemicals is conducted from gestation day 7 through postnatal day 50 to 77, depending on the specific endpoints to be evaluated. Developmental, neuroanatomical and neurochemical endpoints, organ weights and histopathology, sperm counts, blood chemistry, hematology, and evaluation of immune function and sexually dimorphic behaviors are included. The main study is a multigeneration design in which the F_0-F_4

generations are evaluated. A comprehensive assessment of reproductive effects, including determinations of cyclicity, ovarian follicle counts and staging, sperm motility and staging, will be included. Recovery from effects observed in earlier generations by withdrawal of exposure will be determined. Immunological, neurological, and behavioral effects of the test compounds will be evaluated in the main study if warranted. Evaluations of chronic effects resulting from multiple exposure windows are included for 2 compounds. This comprehensive protocol will thus address many of the central issues of concern related to exposure to endocrine disrupting chemicals.

1772 ASSESSMENT OF ESTROGEN AGONIST AND ANTAGONIST ACTIVITY USING A MODIFIED RAT UTEROTROPHIC ASSAY.

L A Albin, M L Kinnett, K B Flecke, A G E Wilson, W R Kelce and W F Heydens. *Monsanto Company, St. Louis, MO, USA.*

An increasing awareness of environmental chemicals and natural products with estrogen agonist activity has ignited research efforts to determine mechanistic links between xenoestrogen exposure and observed positive (therapeutic) and adverse health effects in animals and humans. As an increase in uterine weight in ovariectomized adult female rats following a 72 hour treatment period is generally considered to be the "gold standard" in vivo bioassay for estrogenicity, this assay was used to assess potential estrogen agonist effects of a chloroacetamide. We have also extended this assay to assess inhibition of 17β -estradiol induced increases in uterine weight (i.e., estrogen antagonism) using ovariectomized adult female rats injected with 17β -estradiol (40 μ g/kg/day). Here, adult ovariectomized female Crl:CD® (SD)BR rats (10 rats per group; 10 days post-surgery) received vehicle (corn oil) or 200 or 800 mg of the chloroacetamide/kg BW/day, with or without 17β -estradiol, daily by subscapular injection for 3 days. This chloroacetamide did not induce significant increases in uterine wet weight compared to vehicle controls and also did not inhibit the 7.7-fold increase in uterine wet weight induced by 17β -estradiol. The trophic effects of 17β -estradiol on uterine wet weight were not influenced by changes in body weight as body weights at necropsy were similar among all groups. These data suggest that this chloroacetamide does not exhibit estrogen agonist or antagonist activity using the above protocol. Future dose-response studies with lower dosage levels of 17β -estradiol and a positive anti-estrogen control will be completed to further examine the potential of this chloroacetamide to act as an anti-estrogen.

1773 HISTOLOGIC ANALYSIS OF THE TISSUE SPECIFIC ACTION OF THE XENO-ESTROGENS BISPHENOL A, p-tert-OCTYLPHENOL, o,p'-DDT AND THE PHYTOESTROGENS DAIDZEIN AND GENISTEIN.

P Diel[1], K Smolnikar[1], T Schulz[1], U Laudenbach[1], G Degen[2], C Schuhmacher[2], H Bolt[2], and H Michna[1]. [1]*Dep. Morphology and Tumor Research, DSHS, Cologne, Germany;* [2]*Institut für Arbeitsphysiologie, University of Dortmund, Germany.* Sponsor: E Bomhard.

Epidemiologic data suggest that phytoestrogens and xeno-estrogens may affect the endocrine system and may cause beneficial but also developmental, reproductive and oncological effects. For this reason we have analyzed the endocrine profile of xeno- and phytoestrogens in ovariectomized female DA/HAN rats. The animals were treated for 3 days p.o. with the xeno-estrogens bisphenol A (5, 50 and 200 mg/kg/day), p-tert-octylphenol (5, 50 and 200 mg/kg/day), o,p'-DDT (20, 100 and 500 mg/kg/day), daidzein (1, 10, 100 and 500 mg/kg/day), genistein (10, 50 and 100 mg/kg/day) and ethinylestradiol (100 μg/kg/day). A morphometric analysis of the uterus epithelia, mammary glands and the vaginal epithelia was performed. The uterus wet weight was dose-dependently stimulated after administration of DDT (100 and 500 mg/kg/day), genistein (50 and 100 mg/kg/day) and after administration of 200 mg/kg/day p-tert-octylphenol. A significant stimulation was detectable after administration of 200 mg/kg/day bisphenol A and 500 mg/kg/day daidzein. The thickness of the uterine epithelium was stimulated after administration of DDT and genistein. The stimulation of uterus weight after octylphenol administration correlates with a stimulation of the myometrium. Analysis of the vaginal epithelium revealed clear evidence for an estrogenic action of DDT and genistein. After administration of daidzein, octylphenol and bisphenol A a weak but significant effect of these compounds on the vaginal epithelium was visible. In the mammary glands estrogenic effects were detectable after administration of DDT and genistein. In summary, uterotrophic response and histologic analysis revealed clear evidence for an estrogenic action of DDT and genistein. The data also demonstrate an estrogenic action of octylphenol. Its mechanism of action, especially possible androgen like effects, is under further investigation. Only a weak estrogenic action of daidzein could be demonstrated. The potential estrogenic activity of bisphenol A at high doses will e investigated in further studies.

1774 EVALUATION OF THE EDSTAC FEMALE PUBERTAL ASSAY IN CD RATS USING 17β -ESTRADIOL, STEROID BIOSYNTHESIS INHIBITORS AND A THYROID INHIBITOR.

M S Marty, J W Crissman, and E W Carney. *Health and Environmental Research Laboratory, The Dow Chemical Company, Midland, MI, USA.*

The Endocrine Disrupter Screening and Testing Advisory Committee (EDSTAC) has designated the 20-d female pubertal assay as a Tier I screening test to detect potential endocrine disrupting (ED) chemicals. In two separate studies (S1 and S2), we began evaluating the ability of this assay to detect EDs acting through a variety of mechanisms. Weanling female rat pups were dosed for 20 d by gavage with vehicle (0.5% methocel) or the following test compounds (mg/kg/d): 17β -estradiol (E_2, 0.1, 2 or 4), ketoconazole (Keto, 24, 50 or 100), finasteride (Fin, 20), testolactone (TL, 220), fadrozole (Fad, 0.6, 1.2, or 6.0) or 6-propylthiouracil (PTU, 240). In vehicle-treated females, ages at pubertal onset, as evidenced by vaginal opening (VO), were 32.3 ± 1.6 d (S1) and 33.5 ± 1.8 d (S2). At 0.1 mg/kg E_2, age at VO was reduced slightly to 31.0 ± 1.6 d (S1), a reduction which was not statistically significant (α =0.05). However, at 2 or 4 mg/kg E_2, age at VO was maximally reduced to 28 d (S2). Keto, a broad spectrum steroid biosynthesis inhibitor, delayed VO, but this delay was statistically significant only at 100 mg/kg (39.7 ± 2.4 d). Fin, a 5α -reductase inhibitor, and TL, an aromatase inhibitor, had no effect on age at pubertal onset; however, Fad, a more specific aromatase inhibitor, significantly delayed VO. PTU, a thyroid inhibitor, significantly delayed VO to 34.2 ± 1.1 d (S1) and produced pronounced effects on thyroid weight, histology, and hormone levels. Thus, this assay failed to detect statistically significant differences in pubertal onset in rats receiving 0.1 mg/kg E_2, 24 or 50 mg/kg Keto, or 220 mg/kg TL, suggesting that VO is a relatively insensitive endpoint for assessing endocrine function; however, at higher doses, EDs operating through a variety of mechanisms can be detected. Considerable inter-animal variability suggests that even in the presence of EDs, intrinsic factors exert strong control over this endpoint.

1775 EVALUATION FOR ACTIVITY OF UTEROTROPHIC ASSAY USING OVRIECTOMIZED RATS TO DETECT ESTROGEN-LIKE COMPOUNDS.

T Yamada, K Miyata, T Sukata, H Sako, K Yoshioka, Y Kamita, T Seki, Y Okuno, and M Matsuo. *Environmental Health Science Laboratory, Sumitomo Chem. Co. Ltd., Osaka, Japan.*

In order to develop a short-term in vivo screening method for the detection of estrogen-like compounds, we evaluated the activity of a uterotrophic assay using ovariectomized (OVX) rats, based on the method of O'Connor et al. (Fundam.Appl.Toxicol. 33,182, 1996). The ability to identify 17_$B&B_(B-Estradiol (E2), a pure estrogen receptor agonist, was evaluated by comparing the responses to E2 between OVX and sham-operated rats. Female Crj:CD(SD)IGS rats (6 weeks old) were OVX or sham-operated 1 week before treatment, and then treated with E2 (0, 0.001, 0.05 mg/kg/day, ip) for 4 days. One day after the final treatment, endpoints including body weights, food consumption, organ weights, gross pathology, uterine histopathology, uterine epithelial cell height, and uterine stromal cell proliferation using BrdU labeling were determined. In OVX rats, responses to E2 included decreases in body weight gain and food consumption, as well as uterine enlargement in gross pathology, and increases in uterine weight, uterine epithelial cell height, and uterine stromal cell proliferation. The changes in uterotropic endpoints were observed even with the lowest E2 dose. On the other hand, examination of sham-operated rats did not reveal any of these responses, demonstrating that OVX rats are extremely sensitive for detecting E2-induced alterations. For further validation of this assay, methoxychor, a proestrogen, was tested. As previously described, methoxychor (95% purity) demonstrated relatively weak but apparent estrogenic activity in the current assay. These findings demonstrate that the current design of the uterotrophic assay is a useful short-term screening method for the detection of estrogen-like compounds.

1776 UTEROTROPHIC EFFECTS OF ADMINISTRATION OF COUMESTROL AND 17β -ESTRADIOL IN OVARIECTOMIZED SPRAGUE DAWLEY RATS.

D L Blanset, C M Kelly, C S Auletta, and H F Bolte. *Huntingdon Life Sciences, East Millstone, NJ, USA.*

Under the Food Quality Protection Act of 1996, the US EPA has been directed to develop and implement a testing program to screen chemicals for the potential to interfere with the function of estrogen and other hormones deemed appropriate by the agency. The uterotrophic assay utilizing rats has been proposed by the Endocrine Disruptor Screening and Testing Advisory Committee (EDSTAC) for inclusion in Tier 1 screening of chemicals for endocrine disruption. This particular study was conducted to assess the sensitivity of this assay in this laboratory. The uterotrophic responses of groups of 10 ovariectomized Charles River Sprague-Dawley rats to coumestrol and 17β -estradiol were assessed. The parameters evaluated included estrous cycling, uterine weight (wet and blotted), vaginal cornification, serum prolactin levels and serum estrogen levels. The administration of coumestrol in the diet at a concentration of 0.05% for 4 days resulted in the restoration of estrous cycling and an increase in uterine weights. The mean prolactin levels were increased in comparison to control animals (58 ng/mL vs 28 ng/mL) whereas estrogen levels were similar among the treated and control animals. Various dose levels of 17β -estradiol (1 to 50 μ g/kg/day) were administered by once daily, subcutaneous injection for 4 days to separate groups of animals. Doses up to 10 μ g/kg/day did not result in measurable estrogenic activity. The administration of 50 μ g/kg/day produced increases in uterine weight and restoration of estrous cycling. In the uterus, estrogenic activity was characterized by hypertrophy of the superficial epithelium covering the endometrium and an increase in the thickness and cornification of the stratified squamous epithelium covering the vaginal os of the cervix. Based on these results, coumestrol (0.05% in diet) and 17β -estradiol (50 μ g/kg/day, subcutaneously) can be used as positive control materials for this assay.

1777 UTEROTROPHIC ASSAY OF LOW AND HIGH ORAL GAVAGE DOSES OF 23 POLYSTYRENE MIGRATES USING IMMATURE WISTAR FEMALE RATS.

M S Christian[1], S Menges[2], J Hellwig[2], R Jäckh[2], P Klärner[2], R Klenz[2], R Eder[2], W E Volz[2], H W Schnell[2], D Leyendecker[2] and A Güntner[2]. [1]*Argus International, Horsham, PA, USA;* [2] *BASF Aktiengesellschaft, Ludwigshafen, Germany.*

This study was performed to address any concerns regarding styrene dimers and trimers potentially migrating from polystyrene containers into human food. Representative polystyrenes [9 general purpose (GPPS), 8 high impact (HIPS) and 6 expandable (EPS)] were eluted (50% ethanol) to obtain levels of dimers and trimers simulating human consumption of 0.5 or 5 kg of food (GPPS and HIPS samples) and of 0.5 or 3.15 kg of food (EPS samples), respectively. These two doses of polystyrene migrates were administered (oral gavage) to Wistar (Chbb:THOM-SPF) female rats (10 rats/ group) for 4 days, beginning at 22 ± 1 days of age (doses adjusted daily for body weights); absolute and relative (% body weight) uterine weights were determined at 26 ± 1 days of age. Untreated and vehicle (25% ethanol) controls, a positive control (diethylstilbestrol-dipropionate, DES-DP, 5 μg/kg/day), and low and high doses of 7 or 8 polystyrene oligomer migrates were tested in 3 blocks. DES-DP significantly increased absolute and relative uterine weights. No polystyrene oligomer migrate significantly increased absolute or relative uterine weights; thus, low and high doses of 23 polystyrene oligomer migrates were not estrogenic in the immature rat uterotrophic assay.

1778 PCBs EXHIBIT DIFFERENTIAL BINDING TO RECOMBINANT HUMAN α AND RAINBOW TROUT ESTROGEN RECEPTORS.

J B Matthews and T R Zacharewski. *Department of Biochemistry, Michigan State University, East Lansing, MI, USA.*

Although the function and activities of estrogen and the ER are conserved between species, the amino acid sequence of the regions involved in ligand binding (D, E and F domains) are poorly conserved. This suggests that species may exhibit different responses and sensitivities to non-traditional ligands and that one species may not be an appropriate surrogate to identify and predict responses in other species. In order to investigate potential species-specific sensitivities to non-traditional ER ligands, a comparative study was undertaken in which we examined the ability of 20 structurally distinct PCBs (IUPAC: 41, 51, 58, 60, 68, 78, 91, 99, 104, 112, 115, 126, 143, 153, 169, 173, 184, 188, 190, 193) at concentrations ranging from 10^{-9} to 10^{-5} M to compete with [^{3}H]-estradiol (E_2) for binding to bacterially expressed GST-human ERα DEF (GSThERαdef; amino acids 264-595) and GST-rainbow trout ER DEF (GSTrtERdef; amino acids 224-576) fusion proteins. Both fusion proteins were purified to greater than 90% and yields provided sufficient GSThERαdef and GSTrtERdef fusion protein for approximately 300 and 100 binding assays, respectively. The GSThERαdef and GSTrtERdef both exhibited high affinity for E_2 with dissociation constants (K_d) of 1.28 ± 0.10 nM and 2.14 ± 0.30 nM, respectively. Of the 20 PCBs tested, 184 (2,2',3,4,4',6,6'-hpCB; IC_{50}=0.51 μM), 104 (2,2',4,6,6'-pnCB; IC_{50}=0.83 μM) and 188 (2',3,4',5,6,6'-hpCB; IC_{50} = 1.3 μM) effectively competed with [^{3}H]E_2 for binding to the GSThERαdef fusion protein. Conversely, six PCBs competed with [^{3}H]E_2 for binding to the GSTrtERdef fusion protein: PCBs 184 (IC_{50} =0.92 μM), 104 (IC_{50}=1.8 μM), 188 (IC_{50}=3.8 μM), 51 (2,2',4,6'-tCB; IC_{50}=5.5 μM), 91 (2,2',4,4'6-pnCB IC_{50}=6.7 μM), 41 (2,2',3,4-tCB IC_{50}=9.5 μM). This data demonstrates that ERs from different species exhibit differential ligand preferences and affinities, and that the use of a single surrogate model may be unsuitable to predict estrogenic responses in all species.

1779 BIOCHEMICAL INDICES OF ENDOCRINE EFFECTS: AN *IN SITU* APPROACH TO ASSESS THE ESTROGENIC ACTIVITY OF MUNICIPAL WASTEWATER.

F Tilton, D Schlenk, and W H Benson. *Environmental and Community Health Research/RIPS, Department of Pharmacology, The University of Mississippi, University, MS, USA.*

A number of environmental chemicals possess estrogenic activity including chlorinated hydrocarbon pesticides and degradation products of high-use industrial surfactants. Included in this list are potent natural and synthetic estrogens which may find their way to the aquatic environment through municipal sewage effluent. In fish and wildlife, reproductive disorders resulting from exposure to environmental estrogens may include reductions in fertility and decreased viability, as well as alterations in hormone levels or adult sexual behaviors. The estrogenic activity associated with effluent from two municipal wastewater treatment plants (WWTP) was assessed in Fall 1996-97, Spring 1997, and Summer 1998. Fish were maintained at two sites within each WWTP; sites were located prior to pre-chlorination and within the post-chlorination stream. Male channel catfish (n=10; 200 to 300 g) were placed in cages at each experimental and reference site and exposed *in situ* for 21 days. Serum vitellogenin levels ranged seasonally from no detection to 4.8 fold above reference values at the WWTP. Hepatic ethoxyresorufin O deethylase (EROD) activity was elevated 2.2 to 4.1 fold above the reference and CYP1A content also varied from 1.4 to 10.1 fold above reference values. Tissue indices showed little to no change when compared to reference values. These data demonstrate estrogenic activity in WWTP effluent at levels sufficient to elicit a biological response that appears to be dependent on the WWTP design and seasonal changes in microbial populations within the WWTP.

1780 IN VITRO VITELLOGENIN PRODUCTION BY CARP (*CYPRINUS CARPIO*) HEPATOCYTES AS A TOOL FOR DETERMINING THE (anti-)ESTROGENIC ACTIVITY OF XENOBIOTICS.

J M W Smeets[1], T R Rankouhi[1], J Komen[2], K M Nichols[3], N E Kaminsky[3], J P Giesy[3] and M van den Berg[1]. [1]*Research Institute for Toxicology, Utrecht University, Utrecht, the Netherlands;* [2]*Agricultural University Wageningan, Wageningan, The Netherlands;* [3]*Michigan State University, East Lansing, MI.*

The yolk-protein vitellogenin (Vtg) is excreted by the liver of female, as well as male fish, in response to 17β -estradiol (E2) or other estrogenic compounds. Elevated levels of Vtg have been observed in the field, in male fish exposed to sewage effluents. In this study an in vitro system was developed, using isolated hepatocytes from a genetically defined strain of carp (Cyprinus carpio), in which Vtg-production could be measured by means of a competitive ELISA, after exposure to estrogenic compounds. A number of xenobiotics was tested for (anti-)estrogenic activity, both alone and in combination with E2. The estrogenic potencies of methoxychlor, op-DDT, bisphenol-A, 4-t-pentylphenol and chlordecone, were $1*10^{-3}$ to $1*10^{-4}$ when compared to E2. Dieldrin, β -endosulfan, op-DDE and toxaphene did not cause vitellogenesis at the concentrations tested. The synthetic estrogen DES had a relative potency of: 0.5. Because Vtg-production is an integrated result of (anti-)estrogenic activity, this assay system can detect estrogens and anti-estrogens working through different modes of action. Anti-estrogens tested include Tamoxifen and dioxin-like compounds. Carp hepatocytes were also shown to be very sensitive for the Ah-receptor mediated EROD induction. This assay is the

first of its kind in a fish-species other than rainbow trout. It can be performed in a 96-well plate format from the culturing of the cells to the ELISA-determination of Vtg, making the assay both rapid and convenient.

1781 USE OF A RAINBOW TROUT HEPATOMA CELL LINE (RTH-149) FOR SCREENING ESTROGENIC CHEMICALS: COMPARISON OF TRANSFECTION METHODS AND OPTIMIZATION OF REPORTER ACTIVATION.

M W Hornung[1], J J Korte[2], M A Tapper[2], C R Lambright[3], W R Kelce[4], P K Schmieder[2], L E Gray, Jr.[3] and G T Ankley[2]. [1]*National Research Council, US EPA, Duluth, MN, USA;* [2]*US EPA, NHEERL, MED, Duluth, MN, USA;* [3]*US EPA, NHEERL, RTD, Research Triangle Park, NC, USA;* [4]*Monsanto Company, St. Louis, MO, USA.*

A rainbow trout hepatoma cell line (RTH-149) was used to develop a screening protocol for potential estrogen disrupting chemicals in the environment. Transfection of a plasmid containing an estrogen-responsive luciferase reporter into the cells was used to determine the activation potential of these chemicals within the physiologically relevant temperature range for rainbow trout from 11 to 18°C. Multiple reagents for transfection including calcium phosphate, DEAE-dextran, and FuGENE™ 6 transfection reagent (Boehringer Mannheim) were used to optimize transfection efficiencies in this cell line. The FuGENE™ 6 reagent consistently produced higher responses compared to the other methods. To reduce the amount of background activity due to endogenous estrogen present in fetal calf serum and to avoid the growth inhibition, morphological changes and cell death produced in these cells when incubated in media with dextran-coated charcoal stripped serum, trout cells were weaned onto media containing 4% fetal bovine serum with serum components added. The estradiol concentration in this media was 0.015 - 0.06 nM as determined by RIA. This procedure provides a means of screening xenobiotic chemicals for estrogenic or anti-estrogenic activity in a model fish cell system under conditions in which cell viability is optimized.

1782 VITELLOGENIN INDUCTION IN TROUT LIVER SLICES EXPOSED TO 17-β-ESTRADIOL: A COMPARISON OF TWO INCUBATION METHODS.

P K Schmieder, M A Tapper, A Linnum, and R D Johnson. *USEPA, NHEERL Mid-Continent Ecology Division, Duluth, MN, USA.* Sponsor: T Henry.

The egg-yolk precursor protein vitellogenin (Vtg) is normally only produced in the liver of female rainbow trout (RBT). However, it's production can be induced in male RBT livers, upon exposure to estrogenic chemicals. An *in vitro* male RBT liver slice assay has been developed to detect Vtg protein induction in response to xenobiotics. Two methods of slice incubation are compared: 1) individual slices in media (11°C), in culture plate wells with continuous shaking (PL); or 2) individual slices on a titanium screen, in and out of media (11°C), in a scintillation vial, termed dynamic organ culture (DOC). Slices (200 μm X 8mm) were incubated in 1.7 mL modified L-15 media and exposed to 1.0 μM 17-β-estradiol for 72 h. Protein from media and slices were sampled at 24, 48, and 72 h. Western blot analysis, using a polyclonal antibody to Vtg, was used to detect appearance of Vtg protein. Maximum Vtg was seen at 72 h, with detectable protein at 24 and 48 h in slices and media following PL incubation. In contrast, slices incubated in DOC showed little detectable Vtg above background levels after 72 h. This difference was not attributable to protein adsorption onto vial or plate surfaces. Viability assays and histopathology did not reveal any striking differences between slices incubated in PL or DOC, yet production of Vtg was significantly impacted in DOC. An optimized method of RBT liver slice incubation, for detection of Vtg induction upon exposure to estrogenic chemicals, is presented.

1783 INDUCTION AND INHIBITION OF VITELLOGENIN PROTEIN SYNTHESIS IN RAINBOW TROUT LIVER SLICES UPON EXPOSURE TO ESTROGENS AND ANTI-ESTROGENS.

M A Tapper, A Linnum, M Pasha, J Korte, J Denny and P K Schmieder. *USEPA, NHEERL, Mid-Continent Ecology Division, Duluth, MN, USA.* Sponsor: T Henry.

The induction of vitellogenin (Vtg) in a male rainbow trout liver slice model was used to determine estrogenic effects of diethylstilbestrol (DES), 17β-estradiol (E2) and ICI-182,780. Liver slices, 200 μm x 8 mm, prepared from immature male rainbow trout (400-600 g) were incubated at 11°C, in L-15 media, using a culture plate incubation method. Slices were exposed for 72 h to 0.01, 0.1, 1.0, 10, 100, or 1000 nM E2 or DES in slice media. Vtg protein concentration in media samples was determined by Western blot analysis and ELISA. Relative concentration of Vtg mRNA in slices was determined by ribonuclease protection assay (RPA). Vtg mRNA was detectable 8 h after exposure to as little as 1 nM E2, with peak levels recorded at 24 h. Vtg protein was detectable 24 h after exposure to E2 or DES with protein production increasing through 72 h. DES appeared slightly more potent than E2 at inducing Vtg protein in male trout livers. Vtg protein was detected in the slice incubation media after exposure to as little as 0.1 nM DES, or 1 nM E2, with maximum Vtg induction reported for the highest concentration tested, 1000 nM. The ER antagonist ICI-182,780 only partially inhibited the ability of 1000 nM E2 to induce Vtg protein, but in a dose-dependent manner, up to a maximum inhibitory concentration of 1000 nM. These results indicate the estrogenic detection sensitivity of the mRNA (RPA) and protein (ELISA and Western) assays were similar. Detectable Vtg mRNA was seen at least 16 h earlier than measurable Vtg protein. This could potentially allow assay time to be shortened from 72 h to 24 h, and theoretically increase number of chemicals that could be tested for potential estrogenicity in this system. However, advantages gained in decreased assay length with RPA are countered by the disadvantage of relatively longer sample processing times with reduced sample capacity, when compared with protein endpoints.

1784 EFFECTS OF ENDOCRINE-DISRUPTING CHEMICALS (EDCs) ON LABORATORY-EXPOSED MALE JUVENILE SUMMER FLOUNDER.

L J Mills, R Gutjahr-Gobell, D Borsay, R Haebler, S M Baksi, S Jayaraman, R McKinney, R J Pruell, G Gardner, and G Zaroogian. *USEPA, NHEERL, Atlantic Ecology Division, Narragansett, RI.*

Effects of 17β -estradiol (+ control), *o,p'*-DDT, octylphenol and *p,p'*-DDE on hepatosomatic and gonadosomatic indices, plasma steroid hormone levels, vitellogenin induction, and gonadal development were evaluated in sexually immature, laboratory-raised summer flounder, *Paralichthys dentatus.* This study was conducted to determine which of the above indicators best reflected exposure to EDCs. Test chemical, dissolved in acetone and mixed with coconut oil, was injected into fish in a body sinus twice, two weeks apart. Estrogenic (*o,p'*-DDT; octylphenol) and anti-androgenic (*p,p'*-DDE) chemicals were evaluated alone and in combination (octylphenol plus *o,p'*-DDT or *p,p'*-DDE). Blood and tissues were sampled four, six and eight weeks after the first injection. Fish exposed to a combination of *o,p'*-DDT plus octylphenol were also sampled after 15 weeks. Chemical analysis of livers from fish treated with *o,p'*-DDT or *p,p'*-DDE confirmed significant concentrations of chemical eight weeks after the first injection; octylphenol was never detectable. In our experiments, reduced GSI and plasma testosterone levels were consistent indicators of treatment with estrogenic chemicals (*o,p'*-DDT; octylphenol). However, low GSI did not necessarily reflect changes in developmental stage of the gonads. Vitellogenin synthesis was not dependable as a diagnostic indicator of exposure to estrogenic chemicals. No indicators were found that would identify exposure to the anti-androgen *p,p'*-DDE.

1785 INHIBITION OF ECDYSONE-DEPENDENT GENE EXPRESSION BY PHYTOCHEMICALS.

E Oberdörster[1,2], M A Clay[2] and J A McLachlan[2]. [1]*Clemson University, Clemson, SC, USA;* [2]*Tulane/Xavier Center for Bioenvironmental Research, New Orleans, LA, USA.* Sponsor: G Oberdörster.

Many plant compounds are able to modulate growth and reproduction of herbivores by directly interacting with steroid hormone systems. In insects, several classes of chemicals, including the phytoestrogens, interfere with molting. We investigated whether the anti-ecdysone activity may be due to interaction with ecdysone-dependent gene regulation at the level of the Ecdysone Receptor (EcR) using a reporter-gene assay. Chinese Hamster Ovary cells, which stably express the *Drosophila* ecdysone receptor (VgEcR) and the heterodimeric partner, retinoic acid receptor (RXR), were transiently transfected with response element linked to β -galactosidase. Cells were dosed with one of 8 phytochemicals, either in the absence or presence of the potent EcR agonist, muristerone A. We tested the flavone-glycoside, rutin (delays molt in insects); the four flavones luteolin and quercetin (metabolites of rutin), and apigenin and chrysin; and three non-flavones, coumestrol and genistein (both estrogenic) and tomatine (alters molt in insects). None of the phytochemicals tested were ecdysone agonists. The flavones were able to significantly inhibit EcR-dependent gene transcription at 10 and 25 μ M concentrations. We suggest that the rutin effects on molting are most likely due

to the metabolites, luteolin or quercetin, while tomatine acts via a non-EcR pathway. Neither coumestrol nor genistein inhibited EcR-dependent gene transcription. In plants, flavones are signaling molecules and cause nitrogen-fixing bacteria to form root nodules. The bacterial NodD protein which regulates this symbiosis has two ligand-binding domains which are similar to that of human estrogen receptor (hERα). NodD, EcR and ER all interact with flavones, which may have evolutionary significance.

1786 APPLICATION OF THE CALUX BIOASSAY FOR DETECTION OF PHARMACOLOGICAL AGENTS WHICH ACTIVATE THE AH RECEPTOR SIGNALING SYSTEM.

D J Brown[1], S D Seidel[2], D Phelan[2], M S Denison[2] and G C Clark[1]. [1]*Xenobiotic Detection Systems Inc., Durham, NC, and* [2]*Department of Environmental Toxicology, University of California, Davis, CA.*

The Ah receptor (AhR) is a ligand dependent transcription factor that mediates the majority of the biochemical and toxicological effects of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD, dioxin) and related chemicals. Utilizing two recently developed AhR-based screening systems, the CALUX (Chemically Activated LUciferase eXpression) cell bioassay (employing cell lines stably transfected with a TCDD/AhR-responsive firefly luciferase reporter gene) and an inducible AhR-dependent DNA binding (gel shift) assay we have begun large scale screening of chemicals and chemical mixtures for their ability to activate the AhR signaling pathway. We have identified several pharmacologically-relevant chemicals including imidazoline receptor ligands (idazoxan, guanabenz and epinephrine) and benzimidazole drugs (omeprazole, albendazole and thiabendazole) which induced luciferase activity in several different CALUX cell lines. Although some of the imidazoline receptor ligands were also potent activators of AhR transformation and DNA binding in vitro, others were essentially inactive; all of the benzimidazoles were significantly less potent in the in vitro bioassay. These results, combined with those obtained using other chemicals reveal significant discrepancies between the ability of a chemical to activate the AhR in vitro and in intact cells. This clearly demonstrates the serious limitation of only using in vitro AhR-based bioassays in chemical screening approaches. (Supported by NIEHS (ES08372, ES07685, ES04699).)

1787 EFFECTS OF PHYTOCHEMICALS ON MCF-7 CELL GROWTH AND ESTROGEN RECEPTOR BINDING.

N E Hopkins[1], P L Scott[2], G Nikov[2], M Eshese[2], L Mosley[2] and W L Alworth[2]. [1]*Millsaps College, Jackson, MS, USA;* [2]*Tulane University, New Orleans, LA, USA.*

Recent attention has focused on the isoflavanoids in soya and the flavanoids in tea as possible mediators of carcinogenesis. In this study, we measured the binding properties of three isoflavanoid compounds found in soya- genistein, daidzein and coumestrol-, and two flavanoid compounds found in tea- catechin and epicatechin. The effects of these phytochemicals on the cell proliferation of estrogen-responsive MCF-7 breast cancer cells was also studied. Receptor binding to human estrogen receptor (ER) was measured with a Beacon 2000 fluorescence polarization system (PanVera, Inc, Madison, WI). Expressed, purified ER (PanVera, Inc, Madison, WI) was preincubated for 30 min with an optimal concentration of a fluorescent estrogen analog (EF, PanVera, Inc, Madison, WI) and then concentrations of the test compound (10^{-9} to 10^{-4} M) were added to the ER-EF complex. competitive binding of the phytochemicals was measured as a decrease in polarized fluorescence after 2 hrs. MCF-7 cell proliferation was determined by seeding 10^4 cells into 24 well plates and exposing the cells to varying concentrations of the test compounds in the presence and absence of estradiol for 5 days. On the sixth day, the cells were fixed and the effects on cell growth determined by measuring total protein in the cells as compared to the protein in cells incubated with an optimum concentration of estradiol or with vehicle alone. Genistein and coumestrol displaced EF from ER in the range of 10 μM while catechin and epicatechin displaced EF from ER in the range of 100 μM. Coumestrol stimulated MCF-7 cell growth at concentration ≥10 nM and genistein stimulated MCF-7 cell growth at concentration ≥100 nM, but both catechin and epicatechin strongly inhibited the growth of MCF-7 cells at all concentrations tested (10^{-10} M to 10^{-5} M). The effects of these phytochemicals on the growth of estrogen-responsive MCF-7 breast cancer cell, therefore, do not correlate with their competitive binding to the human ER.

1788 OPTIMAL pH AND SOLVENT CONCENTRATION FOR AN *IN VITRO*, HUMAN ESTROGEN RECEPTOR GENE TRANSACTIVATION ASSAY.

G D Charles[1], T R Zacharewski[2], C Gennings[3], J Clemons[2], B Gollapudi[1] and E W Carney[1]. [1]*The Dow Chemical Co., Midland, MI, USA;* [2]*Dept. of Biochemistry, Michigan State University, East Lansing, MI, USA;* [3]*Dept. of Biostatistics, Virginia Commonwealth U., Richmond, VA, USA.*

The estrogen receptor (ER) gene transactivation assay is currently being considered as a tool for large scale screening of materials from a wide range chemical classes (e.g., strong acids/bases). Therefore, the goal of this study was to determine optimal ranges for pH and solvent (dimethylsulfoxide; DMSO) concentration in this assay. MCF-7 cells were transfected with a chimeric Gal4-ER construct and a Gal4-regulated lucerifase reporter gene, then were exposed overnight to a range of 17β-estradiol (E2) concentrations (10^{-12} to 10^{-7} M), each tested at various pH levels (pH 6.8, 7.3, 7.5, 7.8, 8.0, 8.2, 8.8) or DMSO concentrations (0.1, 0.5, 1.0% v/v). At the end of incubation, the cells were lysed and the lysate assayed for luciferase activity. Maximal E2-induced reporter activity (25-40 fold relative to vehicle controls) occurred at pH 7.8, with a marked decrease in E2-induced activity at pH $\leq$ 7.5 or $\geq$ 8.0 (pH effect significant at $p<0.001$). E2-induced reporter activity tended be highest at a DMSO concentration of 0.1%, and lowest at 1.0% DMSO, while 0.5% DMSO produced somewhat variable responses across studies. These results show that pH is a critical variable in the conduct and interpretation of this ER reporter gene assay, and also suggest that DMSO concentration should not exceed 0.1% for optimal assay performance. (*Funded by The Chemical Manufacturers Association (Arlington, VA).*)

1789 USE OF A RECOMBINANT HUMAN BREAST CANCER CELL LINE, MVLN, TO SCREEN FOR ESTROGENIC ACTIVITY AMONG STRUCTURALLY-RELATED ALKYLPHENOLIC COMPOUNDS.

A L Blankenship[1,2], S A Villalobos[1], J P Giesy[1], and R Balcomb[3]. [1]*National Food Safety and Toxicology Center, Institute of Environmental Toxicology, Department of Zoology, Michigan State University and* [2]*ENTRIX, Inc., East Lansing, MI;* [3]*Ciba Specialty Chemicals Corp., Tarrytown, NY.*

Alkylphenolic compounds are used in great volumes, primarily in the manufacture of surfactants. Several of these compounds have been observed to possess weakly estrogenic activity. The purpose of the current study was to utilize the cell line, MVLN, which is a MCF-7 human breast cancer cell line that is stably transfected with a luciferase reporter under the transcriptional control of the estrogen receptor (ER) to determine relative estrogenic potencies for several alkylphenolic compounds compared to 17-β-estradiol (E_2) as a standard reference compound. Individual test compounds were tested for both their ability to produce a statistically significant response relative to the solvent control and their ability to elicit a full dose-response curve. Each test agent was tested in the absence of E_2 and in the presence of an EC_{50} concentration of E_2 (10 pM). The most potent test agent was tecnical nonylphenol (a mixture of ring and chain isomers) with a relative potency of 0.0001 compared to E_2. As expected, significant structure-activity relationships were observed. The number and position of substituents on the phenolic ring, length of carbon chain, and branched versus straight carbon chains were found to be important determinants of activity. A test agent with a straight carbon chain, 4-*n*-nonylphenol, was found to be inactive as an estrogen agonist up to 5 μM and was cytotoxic at greater concentrations. All of the alkylphenolic compounds that were tested, except technical nonylphenol, were either inactive as estrogen agonists or were weakly estrogenic. The MVLN cell line was found to be a useful screening assay that is sensitive and specific for estrogenic chemicals.

1790 SIMILARITIES BETWEEN ACETAMINOPHEN- AND ESTRADIOL-INDUCED PROLIFERATION OF CULTURED, ESTROGEN-RESPONSIVE BREAST CANCER CELLS.

E Harnagea-Theophilus[1] and M R Miller[2,3]. *West Virginia University, Departments of* [1]*Pharmacology & Toxicology and* [2]*Biochemistry, Morgantown, WV and* [3]*NIOSH, Morgantown, WV.*

Studies in this laboratory have shown that acetaminophen, a widely used analgesic/antipyretic, induces DNA synthesis and proliferation in estrogen-responsive (ER+) but not estrogen-nonresponsive (ER-) cultured, human breast cancer cells. Like estradiol, acetaminophen contains a *p*-phenol moiety; this moiety appears to influence estradiol- and xenoestrogen-induced ER+ cell proliferation. Thus, the first goal of this research was to determine

the importance of the *p*-phenol moiety in acetaminophen-induced proliferation. To this end, effects of *p*-, *m*-, and *o*-acetamidophenol on ER+ (MCF7 and T47D) cell proliferation and on % cells in S (DNA synthesis) phase of the cell cycle were determined. Therapeutic concentrations of *p*-acetamidophenol (~ 0.1 mM) significantly increased proliferation, and the relative order of potency was *p*- > *m*- > *o*-acetamidophenol. These data suggest the *p*-phenol moiety is important in both estradiol- and acetaminophen-induced ER+ cell proliferation. The second goal of this research was to establish if estrogen receptor pathways are involved in mediating the acetaminophen-induced proliferation of ER+ cells. Two antiestrogens (ICI 182,780 and 4-hydroxytamoxifen) were tested in 2 ER+ (MCF7, T47D) and 1 estrogen-nonresponsive, ER- (MDA-MB-231) cell lines. Effects of antiestrogens on acetaminophen-induced proliferation were assessed by flow cytometry (% S phase cells) and by cell counting. In MCF7 and T47D cells (but not in MDA-MB-231 cells), both antiestrogens inhibited proliferation induced by acetaminophen and by estradiol. These data also suggest that there are similarities between estradiol- and acetaminophen-induced proliferation. Furthermore, estrogen receptors may directly or indirectly mediate the acetaminophen-induced proliferation of ER+ cells.

1791 ROLE OF THE RAT SPLICE VARIANT OF ESTROGEN RECEPTOR BETA IN ESTROGEN SIGNALLING; IMPLICATIONS FOR ENDOCRINE DISRUPTION TESTING.

T C Aldridge, W D Pennie, and A N Brooks. *Molecular Endocrinology and Neurobiology Group, ZENECA Central Toxicology Laboratory, Cheshire, England.* Sponsor: I Kimber.

We have analysed the functional activity of an isoform of the estrogen receptor beta (ERβ) (found in rat and mouse) which has an 18 amino-acid insert in the ligand binding domain (ERβ2; ^{320}SSEDPHWHVAQMKSAAPR^{338}). The ERβ2 is capable of binding to the vitellogenin estrogen response element as demonstrated by electrophoretic mobility shift assays. The ability of ERβ2 to activate transcriptionally a reporter plasmid (consisting of a consensus vitellogenin ERE cloned upstream of a minimal SV40 promoter driving luciferase) when transiently transfected into Cos-1 cells was examined. The reporter in cells transfected with ERβ alone was activated in a dose-dependent manner by stimulation with estradiol-17β (10^{-12} - 10^{-6} M). In contrast, estradiol failed to activate the reporter in cells transfected with ERβ2 alone. Of all ligands tested to date, only the synthetic estrogen diethyl-stilbestrol (DES) was able consistently to activate ERβ2 in this assay. In addition, when cells were co-transfected with a constant amount of ERβ and increasing amounts of ERβ2 there was a significant decline in reporter activation by estradiol. Using *in situ* hybridization and RTPCR analyses, we have demonstrated expression of ERβ and ERβ2 in the rat prostate, ovary and pituitary while ERβ2 mRNA is not detectable in the αT3-1 rat pituitary gonadotrope specific cell line. These data provide evidence for an isoform of ERβ which may act as a negative regulator of ERβ function. The differences in relative abundance of these two receptors in different tissues, and the species specific nature of ERβ2 may play a role in determining species and tissue-specific responses to estrogenic substances.

1792 NEW DEVELOPMENTS IN A HAZARD IDENTIFICATION ALGORITHM FOR HORMONE RECEPTOR LIGANDS.

S P Bradbury[1], O G Mekenyan[2], and G T Ankley[1]. [1]*USEPA, NHEERL, Duluth, MN USA;* [2]*Bourgas University, Bougas, Bulgaria.*

Recently we described the Common REactivity PAttern (COREPA) technique to screen data sets of diverse structures for their ability to serve as ligands for steroid hormone receptors (Environ. Sci. Technol. 31:3702-3711). The approach identifies and quantifies similar global and local stereoelectronic characteristics associated with active ligands through a comparison of energetically-reasonable conformer distributions for selected descriptors. For each stereoelectronic descriptor selected, discrete conformer distributions from a training set of ligands are evaluated and parameter ranges common for conformers from all the chemicals in the training set identified. The use of discrete partitions of parameter ranges to define common reactivity patterns can, however, influence the outcome of the algorithm. To address this limitation, the method has been extended by approximating continuous conformer distributions as probability distributions. The COREPA-Continuous (COREPA-C) algorithm assesses the common reactivity pattern of biologically similar molecules in terms of a product of probability distributions, rather than a collection of common population ranges determined by examination of discrete partitions of a distribution. To illustrate the algorithm, common reactivity patterns based on interatomic distance and charge on heteroatoms were developed and evaluated using a set of 28 androgen receptor ligands. Using receptor binding affinity as the measure of biological activity, the algorithm successfully discriminated 'active' from 'non-active' ligands. Notable attributes of the COREPA-C algorithm include flexibility in establishing stereoelectronic descriptor criteria for identifying active and non-active compounds and the ability to quantify three-dimensional chemical similarity without the need to predetermine a toxicophore or align compounds(s) to a lead ligand.

1793 MOLECULAR MODELING SIMULATIONS OF RECEPTOR-LIGAND INTERACTIONS FOR ENVIRONMENTAL ESTROGENS.

T C Bishop[1,2] and T E Wiese[1,2]. [1]*Department of Environmental Health Sciences, Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, USA;* [2]*Division of Basic Pharmaceutical Sciences, Xavier University College of Pharmacy, New Orleans, LA, USA.*

Molecular modeling and molecular dynamics have been used to study the interaction of various environmental estrogens (EEs) with the human estrogen receptor α (hERα). EEs are endocrine disrupting chemicals (EDCs) that interfere with the normal function of ER in the effected tissues of exposed species. The modeling was based on the 3-D structure of the ligand binding domain of the hERα as recently determined by X-ray crystallographic studies from two different laboratories. The available structures include two of hERα with estradiol-17ß and one of hERα with the antiestrogen raloxifene. The purpose of this study was to develop an understanding of the possible ER binding modes of nonsteroidal environmental chemicals that are known to have the capacity to displace estradiol-17ß binding *in vitro*. Ligand-receptor docking studies were performed with the classic xenoestrogens DES, DDT isomers, methoxychlor, HPTE, chlordecone (kepone), t-octylphenol and bisphenol A. Each ligand-receptor model was subjected to a molecular dynamics annealing protocol and energy minimization to achieve a final binding conformation and orientation. The relative contribution of the van der Waals, electrostatic and hydrogen bonding energies to the total potential energy of each complex was determined and compared to reported *in vitro* binding affinities. An effort was also made to characterize ligand-receptor interactions that may be responsible for the relative differences in ER affinity among these xenoestrogens. These studies have resulted in the formulation of a ligand-receptor model which addresses the disparate binding capacities of various EDC's. Furthermore, these "virtual" receptor binding studies may also be of general utility as a component of endocrine disruptor screening and testing protocols.

1794 ENANTIOMER SELECTIVE ESTROGEN ACTIVITY OF o,p'-DDT AND o,p-DDD OPTICAL ISOMERS.

T E Wiese[1,2] and A W Garrison[3]. [1]*Department of Environmental Health Sciences, Tulane University School of Public Health and Tropical Medicine;* [2]*Division of Basic Pharmaceutical Sciences, Xavier University College of Pharmacy, New Orleans, LA, USA;* [3]*US EPA, NERL, Athens, GA, USA.*

Racemic mixtures of the chiral pesticides o,p'-DDT and o,p'-DDD have previously been described as endocrine disrtuping chemicals with estrogen activity. In this report, we account the estrogen activity of the individual enantiomers of o,p'-DDT and o,p'-DDD. Optically pure samples as well as racemic mixtures were evaluated for estrogen receptor (ER) binding and reporter gene activity in mammalian cells. Binding assays utilized recombinant ER and were performed at 20ûC using the PanVera fluorescence polarization method. Reporter gene assays employed MVLN cells which are MCF-7 human breast cancer cells containing ER that have been stably transfected with an estrogen responsive vit-Luc construct. All racemic mixtures and optically pure samples tested were found to have some capacity to bind the ER as well as induce MVLN reporter gene activity at concentrations up to 10 μM. It was also shown that the MVLN activity of each test compound was inhibited by the antiestrogen ICI-182,780. However, while both enantiomers and the racemic mixture of o,p'-DDD maintained minimal estrogen activity (EC_{50} from 3000nM to 10000 nM), the R or (-) enantiomer of o,p'-DDT displayed enhanced ER binding activity and was found be 25 times more potent in the MVLN assay than the S or (+) enantiomer (EC_{50} of 250 nM vs. 6500 nM respectively). This study highlights the importance of resolving the optical isomers of chiral compounds for both endocrine disruptor characterization studies as well as environmental monitoring. Furthermore, this study suggests that the enantiomer specificity of certain chiral compounds my be utilized to develop optically pure pesticides and other industrial chemicals with decreased endocrine activity.

1795 DOES FUNCTIONAL DISRUPTION OF P53 AND THE FAS SYSTEM HAVE EFFECTS ON MALE GERM CELL APOPTOSIS?

M E Embree and K Boekelheide. *Department of Pathology and Laboratory Medicine, Brown University, Providence, RI, USA.*

Mice with a targeted disruption of the p53 tumor suppressor gene were crossed with *gld* mice (deficient in Fas ligand) to produce mice deficient in both p53 and the Fas ligand. Several lines of evidence suggest that both p53 and the Fas system are important in regulating germ cell apoptosis in the rodent testis; the goal of developing a mouse deficient in both of these systems is to ascertain what the effects are on spermatogenesis and response to injury. The first aim of this study is to examine the effects of the double deficiency on the physiology of the testis, including spermatid counts, apoptotic germ cell assessment, gene expression and examination of the histology at timepoints between birth and 8 weeks. In the second aim, male mice will be exposed to injuries known to induce Fas system or p53-dependent responses such as mono(2-ethylhexyl)phthalate and γ-irradiation. The effects of these toxicants on the double deficient mice will be compared to similarly exposed p53 knockout mice, *gld* mutant mice and wild type controls. To obtain the double deficient mice, F1 heterozygote mice resulting from the initial p53 knockout and gld mouse cross were mated to produce 266 viable F2 offspring. The 8 possible genotypes were determined using a modified multiplex PCR technique, and double deficient male mice were produced at the expected frequency (9/144). Preliminary examination of testes of paired male siblings - wild type and double deficient - indicates an overall decrease in spermatogenesis: decreased testis weights, decreased seminiferous tubule diameters, and occasional retained elongate spermatids in stages IX and X. Given the viablility of the double deficient males and the preliminary data on the physiology of the testis of these mice, further characterization of spermatogenesis and response to injury in double deficient males will give more insight into the importance of the Fas system and p53 in male germ cell survival.

1796 ASSESSMENT OF TOXICANT-INDUCED MORPHOLGIC ALTERATIONS IN SERTOLI CELL-GERM CELL INTERACTIONS *IN VIVO*.

S L Fleming and K Boekelheide. *Department of Pathology and Laboratory Medicine, Brown University, Providence, RI, USA.*

Sertli cells are key in promoting and regulating spermatogenesis. Sertoli cells both structurally organize the seminiferous epithelium and secrete a number of factors which are essential to germ cell survival. Chronic exposure of rats to 2,5-hexanedione (2,5-HD), a metabolite of *n*-hexane, results in a testicular atrophy in which only Sertoli cells and immature germ cells remain. While *in vitro* data obtained in our laboratory have demonstrated that 2,5-HD stabilizes microtubules and interferes with kinesin-based transport, little is known about the mechanism by which 2,5-HD exposure elicits this injury, *in vivo*. This enhanced polymerization and stability of microtubules, and impaired microtubule-based transport has been proposed to underlie the progressive loss of germ cells following exposure to 2,5-HD. Intimate contact with germ cells is required for Sertoli cells to deliver nutrients and paracrine signals to germ cells, functions which are believed to be essential to their differentiation and survival. Because spermatogenesis is a highly dynamic process requiring extensive reorganization of Sertoli cell-germ cell junctions, compounds which stabilize microtubules may also impair the ability of Sertoli cells to remodel the cytoplasmic extentions surrounding germ cells, thereby impairing the ability to maintain spermatogenesis. To assess alterations in Sertoli cell-germ cell interactions following toxicant exposure, we have infected Sertoli cells *in vivo* with a replication-deficient adenovirus which expresses cytoplasmic green fluorescent protein (GFP). By confocal microscopy, we have obtained an exquisitely detailed, three-dimensional images of Sertoli cell-germ cell interactions, and can observe morphological alterations in Sertoli cells within intact seminiferous tubules. Using this tool, we plan to assess alterations in Sertoli cell-germ cell interactions following exposure to microtubule disrupting compounds colchicine, taxol and 2,5-HD.

1797 DELAYED LEUPROLIDE ADMINISTRATION RESCUES SPERMATOGENESIS IN 2,5-HEXANEDIONE-INDUCED TESTICULAR ATROPHY.

K Boekelheide , S J Hall, and H A Schoenfeld. *Dept. of Pathology and Laboratory Medicine, Brown University, Providence, RI, USA.*

2,5-Hexanedione (2,5-HD), a metabolite of the environmental toxicant n-hexane, produces irreversible testicular atrophy in rats, and therefore provides a useful model for studies of male infertility. Leuprolide, a gonatropin-releasing hormone agonist, reestablishes spermatogenesis after 2,5-hexadione-induced testicular atrophy when administered immediately after cessation of 2,5-hexanedione treatment. The current studies were undertaken to examine whether a delay in leuprolide administration may also affect recovery. 2,5-HD (1% v/v) was administered to Fisher rats in drinking water for 3.2 weeks. At week twelve, animals were divided into two groups, with one group receiving 3 s.c. injections of leuprolide (1.5 mg/animal; 24 days apart) and the other saline. Both groups were then allowed to recover for 12 weeks. Leuprolide treatment resulted in a significant recovery of 2,5-HD induced testicular atrophy_compared with their 2,5-HD treated controls, as determined by a significant 20% increase in testis weight, as well as histopathological analysis. Seminiferous tubules of rats exposed to 2,5-HD alone showed nearly complete (>95%) atrophy, however rats exposed to 2,5-HD and leuprolide showed a significant 20% recovery. This study indicates that administration of leuprolide can reestablish spermatogenesis when it is administered 3 months after the onset of atrophy. These findings may be of relevance to the clinical setting of male infertility, where intervention occurs long after exposure and the onset of atrophy .

1798 SEMEN QUALITY AND HUMAN MALE FERTILITY: A PROSPECTIVE STUDY WITH NORMAL COUPLES.

E D Clegg[1], S G Selevan[1], C C Brown[2] and M J Zinaman[3]. [1]*National Center for Environmental Assessment, U.S. EPA, Washington, DC, USA;* [2]*National Cancer Institute, Rockville, MD, USA;* [3]*Loyola University Medical Center, Maywood, IL, USA.*

A prospective study of 210 reproductive age couples was conducted to quantify relationships between semen parameters and human male fertility. Eligible couples without known risk factors for infertility, other than subsequently identified poor semen quality, were recruited. Each couple was followed for up to 12 complete menstrual cycles while they attempted to conceive. Semen quality measures were evaluated from multiple ejaculates per man with known abstinence intervals. For each cycle, the day of ovulation was predicted based on the preceding cycle, and the couple was advised to have intercourse on and bracketing that day (± 2 days). Pregnancy rate for the 12 cycle interval was 82%. Pregnancy rate was influenced significantly by parity and contraception status at study entry. Relationships between the semen quality measures and 12 cycle time to pregnancy were analyzed using Cox time to event regression analysis. Treating the variables as log-linear and adjusting for parity and contraception status, significant relationships with 12-cycle time to pregnancy (probability that relationship was not real) were found for sperm concentration (0.005), number of sperm (0.002), number of motile sperm (0.002), % normal sperm by strict criteria (0.0001) and number of normal sperm by strict criteria (<0.0001). In multivariate regression analyses, percent normal sperm by strict criteria and number of motile sperm were the most effective predictors after adjustment. These results demonstrate that several semen quality measures are predictive of human male fecundity. In addition, they provide information to allow prediction of the risk to men's fecundity from decrements in semen quality.

1799 DIFFERENTIAL SENSITIVITY OF RAT AND MOUSE TESTIS TO THE MICROTUBULE DISRUPTORS CARBENDAZIM AND COLCHICINE.

C Strandgaard[1], R A Hess[2], and M G Miller[1]. [1]*Dept. of Env. Tox., Univ. of CA Davis, Davis, CA;* [2]*Dept. of Vet. Biosciences, Univ. of Il, Urbana, IL.*

The alkaloid, colchicine (CLC) and the benzimidazole, carbendazim (CBZ) are well known testicular toxicants in the laboratory rat. The toxicity associated with these compounds is characterized by vacuolization, detachment, and sloughing of seminiferous epithelium via a mechanism involving microtubule disruption. The present study investigated the susceptibility of mouse testis to the effect of these cytoskeletal disruptors. Adult mice received CBZ (1000 mg/kg, po) or corn oil vehicle and were killed by CO2 inhalation 15, 30, 60, 120 min, and 6 and 24 hrs later. One testis from each animal was processed for histopathology and the other was snap frozen for HPLC determination of testicular CBZ levels. Adult rats receiving CBZ (250 mg/kg, po) and sacrificed 6 hrs later, served as positive controls and these animals exhibited histopathology characteristic of CBZ toxicity. However, mice administered CBZ at a dose level four times that required to cause a lesion in the rat, showed no indication of testicular damage. Immunocytochemical staining of alpha and beta tubulin in testis was carried out 6 hr after treatment, and no differences were observed between control and treated mice. The sensitivity of rat vs. mouse to damage after intra-testicular administra-

tion of CLC was investigated at dose levels of 117.6 ug/g testis and 5.3 ug/g testis for the mouse and 5.6 ug/g testis for the rat. Sloughing of the seminiferous epithelium was extensive for the high dose CLC in the mouse but did not occur at the lower (5.3 ug/g testis) dose. In contrast, 5.6 ug/g testis administered into rat testis caused severe testicular damage. These data indicate that mouse testis is more resistant than rat testis to the effect of microtubule disrupting agents. (Supported by NIH grant #ESO7832.)

1800 EPIDIDYMAL TOXICITY OF α-CHLOROHYDRIN: EFFECTS ON GLYCERALDEHYDE-3-PHOSPHATE DEHYDROGENASE ACTIVITY.

K B Jelks and M G Miller. *Department of Environmental Toxicology, University of California, Davis, CA, USA.*

α-Chlorohydrin (ACH) directly inhibits glyceraldehyde-3-phosphate dehydrogenase (G3PDH) in caudal sperm and is thought to impair sperm motility and thus fertilizing ability. Epididymal damage seen at high ACH doses can lead to permanent infertility. The present studies have investigated ACH epididymal toxicity in the rat and the effects of ACH on G3PDH activity. Onset of epididymal changes occurred rapidly within 6 hours of ACH administration (50 mg/kg, po). Early changes included epithelial vacuolization in the initial segment and increased tubular diameter with debris and few sperm cells in the initial segment lumen. The severity of the lesion increased with time and by 24 hours, no cellular structures lined the basement membrane of the initial segment. The possibility that ACH inhibited G3PDH in cell types other than spermatozoa was investigated by measuring G3PDH activity in multiple tissues 3, 6 and 24 hours following a single dose of ACH (50 mg/kg, po). G3PDH activity was decreased by 85% in sperm, 31% in kidney, 49% in liver and 35% in epididymis 3 hours after ACH. These remained low at 6 and 24 hours. G3PDH was immunolocalized within the initial segment and found associated with the microvilli and adluminal area. Smooth muscle surrounding the tubule throughout the epididymis also showed immunopositive stain. Overall, the effect of ACH on the initial segment of the epididymis occurs rapidly, within 6 hours. These data raise the possibility that G3PDH in initial segment cells may serve a specific function which when disrupted by ACH leads to toxicity.

1801 ESTERASE INHIBTION BY MOLINATE: ROLE IN TOXICITY.

B S Winder, W T Jewell and M G Miller. *Dept. of Environmental Toxicology, University of California, Davis, Davis, CA.*

Molinate, a thiocarbamate fungicide widely used on rice, has been shown to be a testicular toxicant in male rats. The ability of molinate to inhibit ester hydrolysis has been implicated in its toxicity. This study was designed to determine whether there is a dose and time dependent recovery of ester hydrolytic capacity in liver and testes microsomes following molinate exposure. In addition the ability of molinate to limit mobilization of cholesterol was examined. Testes and livers were collected from adult male rats previously exposed to single i.p. injections of molinate at 5, 50, 100 and 200 mg/kg in corn oil, 2 hours, 1, 2 and 7 days prior to sacrifice. Microsomes were prepared and assayed for nonspecific esterase (NSE) activity using alpha-naphthyl acetate as substrate. NSE activity in both liver and testes microsomes was markedly inhibited at all time points by the higher dose levels of molinate. The lower doses of 5 and 50 mg/kg also inhibited NSE activity in both tissues but recovery was complete by 2 days. NSE activity after 5 mg/kg was not reduced by more than 20% of control. The ability of the molinate-inhibited esterase to hydrolyze cholesterol esters was investigated using cholesteryl oleate as substrate. Addition of molinate to microsomal preparations markedly inhibited hydrolysis of the ester. These data indicate that molinate-induce inhibition of esterase activity is readily reversible especially at the lower dose levels. Moreover the esterase inhibited by molinate is capable of hydrolyzing cholesterol esters. The testicular toxicity of molinate may result from reduced availability of cholesterol required for testosterone biosynthesis. (Supported by the California Rice Growers Association.)

1802 PERCHLOROETHYLENE REDUCES RAT SPERM FERTILIZING POTENTIAL.

T Berger[1], C M Horner[1], K A Jelks[2], B S Winder[2] and M G Miller[2]. *Depts. of Animal Science[1] and Environmental Toxicology[2], University of California, Davis, CA, USA.*

Perchloroethylene exposure appears to reduce semen quality in dry cleaning workers. The objective of this study was to develop an animal model for perchloroethylene exposure. Mature male rats (100+ days of age) were exposed to perchloroethylene by inhalation (1 or 2 hours/day at 1700 ppm). Sperm were recovered after 2 or 3 weeks of exposure and evaluated for fertilizing potential in in vitro fertilization trials and subjected to motility assessment (Hobson Tracker). In an additional trial, male rats were exposed to perchlorethylene in drinking water (0.8% in 3% emulphor) or control (3% emulphor). In a third trial, young female rats (25 to 32 day) were exposed by inhalation to perchloroethylene for one week prior to oocyte recovery for in vitro fertilization. Sperm from male rats breathing perchloroethylene for two 1-hour periods/day for 3 weeks had reduced fertilizing potential (1.8 penetrated sperm/zona-free oocyte compared with 2.9 penetrated sperm/zona-free oocyte for sperm from control rats breathing room air in the same exposure chambers; $P < 0.05$). Testosterone levels were similar in exposed and control rats. Exposure to perchloroethylene in the drinking water also reduced sperm fertilizing potential (36.7% vs 51% fertilization of cumulus-intact oocytes, $P < 0.05$ and 4.4 vs 2.5 penetrated sperm/ zona-free oocyte, $P < 0.005$.) The kinematic parameter ALH (amplitude of lateral head displacement) was consistently affected by perchloroethylene exposure. Preliminary experiments suggest subtle histopathological changes in the efferent ducts consistent with the timing of initial exposure and gamete recovery. Oocytes from females inhaling perchloroethylene had reduced fertilizability (1.6 vs 2.5 penetrated sperm/zona-free oocyte). High exposures to perchloroethylene reduced gamete fertility and caused changes in rat sperm motility similar to those observed in man. Metabolic activation by cytochrome P4502E1 enzymes, particularly within the efferent ducts may be responsible for the observed changes. (Supported in part by EPA R825351 to TB and MGM.)

1803 DETECTION OF TOXICANT INDUCED CHANGES OF RAT SPERM MITOCHONDRIAL MEMBRANE POTENTIAL BY FLOW CYTOMETRY.

C G Gravance[1], M G Miller[1], T Berger[1] and D L Garner[2]. [1]*Environmental Toxicology, University of California, Davis, CA;* [2]*Veterinary Medicine, University of Nevada, Reno, NV.*

The mitochondria of the sperm midpiece provides energy for motility, hence any compound affecting this organelle may ultimately affect the motility of spermatozoa. The JC-1 fluorescent stain gives a green fluorescence when mitochondrial membrane potential is low and red-orange when the membrane potential is high. The present study has used flow cytometric analysis of JC-1 staining patterns of large numbers of sperm to detect toxicant induced alterations of sperm mitochondrial function. Spermatozoa were recovered from the cauda epididymides of rats by tubule puncture and allowed to swim out into Toyoda's Medium (TM). Sperm samples were diluted to 25×10^6 sperm/ml, and 200μ L aliquots were prepared. Samples were incubated for 10 min in the presence and absence of pentachlorophenol (PCP; 0.1μ M and 1.0μ M), a known uncoupler of mitochondrial oxidative phosphorylation, then labeled with JC-1 for mitochondrial function and SYTOX-Green for viability. Microscopic evaluation showed that the mitochondria of live, highly motile sperm stained bright orange, while the mitochondria of the live, non-motile sperm stained green. Mitochondria of an intermediate class of slightly and non-progressively motile sperm stained a faint orange-green. The heads of dead spermatozoa stained bright green. Flow cytometric analysis showed populations of sperm staining patterns similar to those viewed microscopically. The percentage of spermatozoa stained bright orange, faint orange and total orange (bright orange + faint orange) in the control samples of spermatozoa were significantly higher ($P<0.01$) than in the 1.0μ M and 0.1μ M PCP treated samples. Total orange staining was nearly 4-fold higher in control samples (92-100%) than in the 0.1μ M PCP samples (8-42%) and 10-fold higher than in 1.0μ M PCP samples (4-18%). A significant ($P< 0.05$) dose response effect was found between PCP treatments. These data indicate that sperm mitochondrial membrane potential is highly sensitive to the uncoupling effects of PCP and that JC-1 staining and flow cytometric analysis may be a sensitive assay for detecting the effects of toxicants on rat sperm function.

1804 ADHESION AND SIGNALING PROTEINS ASSOCIATED WITH INHIBITED SPERMIATION.

R N Wine and R E Chapin. *NTP/NIEHS, RTP, NC.*

Spermiation, the process by which late spermatids separate from the Sertoli cell, is disrupted by many / most testicular toxicants. In this study we used immunohistochemistry to identify some of the proteins associated with the

late spermatid-Sertoli junction. We confirmed the presence of tubulin, actin, and vinculin at the luminal edge, and report that paxillin is also present here (in both round spermatids and Sertoli cells). In other cell types, these proteins have been reported to colocalize with β -integrins. While numerous attempts to find β -integrins in the testis using immunohistochemistry and Western blots were unsuccessful, clear evidence was found for the presence in Sertoli cells of N-cadherin and it's associated intracellular proteins: β -catenin, pp120, pp60^{src}, and Csk. These proteins have been shown, in other cell types, to control cadherin adhesion. Cadherins bind homotypically; we found desmoglein (another cadherin) on late spermatids in a distribution pattern complementary to that of N-cadherin. In addition, N-cadherin and desmoglein were found around late spermatids retained by the epithelium after treatment with boric acid. From these data and previous literature reports, we propose a model wherein N-cadherin and desmoglein function in adhesion, and the Sertoli cell controls this adhesion through the intracellular proteins associated with N-cadherin. This model provides a framework for hypotheses of the steps involved in the complex process of spermiation in the rat testis, and its disruption by toxicants.

1805 A NEW METHOD FOR CHARACTERIZING THE MOTION OF SPERMATOZOA.

D B Dunson[1], C R Weinberg[1], S D Perreault[2] and R E Chapin[1]. [1]*NIEHS, Research Triangle Park, NC, USA;* [2]*US EPA, NHEERL, RTP, NC, USA.*

Proper characterization of the motion of spermatozoa is an important prerequisite for interpreting differences in sperm motility that might arise from exposure to toxicants. We set out to develop an alternative method for describing sperm motion, since existing methods do not adequately summarize the complexity of the movement pattern. Based on an exponential model that relates the curvilinear velocity to the tracking rate, we develop a statistic that indexes the predictability of the path for individual sperm. We summarize the path of each sperm using this and 2 other statistics: (1) the path displacement velocity; (2) linearity of movement. The proposed method is shown to outperform standard CASA measures in discriminating between normal and cooled sperm.

1806 RAT SPERM ACROSOMAL STAINING USING PEANUT AGGLUTININ LECTIN (FITC-PNA) LABELLING.

A M Cancel[1], R M Zucker[2], and S D Perreault[2]. [1]*Toxicology Program, UNC, Chapel Hill, NC, USA;* [2]*US EPA, RTP, NC, USA.*

The ability of spermatozoa to capacitate and undergo an acrosome reaction in vitro can be used as a test for sperm function in toxicology studies. Detection of the sperm acrosome in the rat, the animal of choice in toxicology studies, has been difficult because the acrosome is not visible by phase contrast microscopy. Several staining techniques, including labelling with fluoresceinated lectins which bind to specific carbohydrate groups in glycoproteins and glycolipids, have been used to differentiate between acrosome-intact and acrosome-reacted sperm. Fluorescein isothiocyanate-conjugated Arachis hypogea (peanut) agglutinin (FITC-PNA) has been used previously to detect the acrosome in several species. The aim of this work was to evaluate the use of FITC-PNA to detect the acrosome in rat sperm and to develop a fast, simple and reliable procedure to quantitate in vitro rat sperm capacitation and acrosome reaction. Spermatozoa were stained with FITC-PNA (50 μg/ml) using two different methods. In the first method, spermatozoa were washed in DPBS, air dried on a slide, followed by a 30 min fixation and permeabilization with cold- 95% ethanol, and staining with FITC-PNA for 30 min at 37 °C. Alternatively, sperm were fixed in 2% formaldehyde (2 h, 4 °C) followed by staining with FITC-PNA. Sperm nuclei were counterstained with the DNA fluorochrome Hoescht 33258. Confocal Laser Scanning Microscopy confirmed that FITC PNA stained the acrosomal region, with the fluorescence brightest along the dorsal crest and absent from the postacrosomal region. In contrast, when the acrosome was disrupted by sonication, the sperm did not stain with FITC-PNA. While the first method is better suited for long term storage, the alternate method provided a better image quality. Both methods offer a practical approach for detecting the rat acrosome reaction under in vitro capacitation conditions. (Disclaimer: This abstract does not necessarily reflect EPA policy).

1807 RELATIONSHIP BETWEEN DOSE AND EXPOSURE TIME ON INHIBITION OF SEA URCHIN SPERM MOTILITY BY $HgCl_2$ AND $CdCl_2$.

I Szabo[1], T A Shaffer[1], J S Tash[2,3], and K K Rozman[1,4]. [1]*Department of Pharmacology, Toxicology & Therapeutics;* [2]*Center for Reproductive Sciences;* [3]*Department of Molecular & Integrative Physiology, University of Kansas Medical Center, Kansas City, KS;* [4]*Section of Environmental Toxicology; GSF-Institut für Toxikologie, Neuherberg, Germany.*

Sperm of sea urchins (*Lytechinus pictus*) were collected after intracoelomic injection of 0.5M KCl in artificial sea water at pH=6.0. Under these conditions sperm are immotile and can be stored for several days at 4-5°C. Motility was restored by dilution with activation buffer (pH=8.0) for controls or with activation buffer containing the appropriate concentration of metal salts for toxicity studies yielding approximately 20-40 sperm per field in a motility chamber. Video-microscopy was carried out at room temperature using an inverted microscope connected to a video recorder. Motility was recorded on multiple viewing fields for 3 minutes. Quantitation of sperm motility was performed by collecting data from a minimum of 400 cells. Experiments were carried out in triplicate. Dose-response curves were established for $HgCl_2$ (0.1-2.5 μM) and $CdCl_2$ (1.0-10.0 μM) using 20 min exposure time. $HgCl_2$ and $CdCl_2$ inhibited motility of sea urchin sperm in a dose-dependent manner, with EC_{50}s of 0.91 μM and 2.2 μM, respectively. Dose-time-response relationships were determined under conditions of steady-state at 5, 10, 15 and 20 min with concentrations of 1.0, 1.5 and 2.0 μM for $HgCl_2$ and 2.5, 3.5 and 4.5 μM for $CdCl_2$. There was a linear relationship between exposure time and inhibition of motility at each concentration with $r^2>0.97$. Multiplying the dose (c) with exposure time (t) at EC_{50} yielded constants, 14.97 ± 1.03 μMA min (mean ± S.E., n=3) for $HgCl_2$ and 34.05 ± 2.30 μMA min (mean ± S.E., n=3) for $CdCl_2$. These findings support the notion of $c \times t = constant$ under near ideal conditions.

1808 SMOKING IS ASSOCIATED WITH SPERM ANEUPLOIDY AND LOWERED SEMINAL PLASMA ANTI-OXIDANT ACTIVITY.

R J Potts, C J Newbury, L J Notarianni, and T M Jefferies. *School of Pharmacy and Pharmacology, University of Bath, Bath, Avon, UK.*
Sponsor: E S Harpur.

Studies have shown that tobacco smoking is associated with reduced semen quality and oxidative damage to sperm DNA. Our objective was to determine if smoking increased the frequency of aneuploidy in human sperm and produced oxidative stress in seminal fluid. Sperm aneuploidy was assessed using multicolor fluorescence *in situ* hybridization (FISH) from semen samples donated by 20 non-smokers and 20 smokers (>15 cigarettes per day). Only fertile samples, as defined by World Health Organization criteria, from donors aged between 20-30 years, were used in the study. Aneuploidy was assessed on 10,000 cells per sample, using DNA probes specific for chromosomes Y and 1. Malondialdehyde (MDA), a product of lipid peroxidation that reacts with thiobarbituric acid to give an absorbing compound at 535 nm, was measured to indicate oxidative stress. Cells were separated from seminal plasma (SP) by centrifugation, allowing MDA concentrations to be determined in both spermatozoal and SP fractions. Total anti-oxidant activity was measured according to the ability of SP anti-oxidants to scavenge the radical cation $ABTS^+$, (2,2'-azinobis(3-ethylbenzothiazoline 6-sulfonate)), inhibiting its absorption at 734 nm. Smokers possessed significantly higher levels of sperm aneuploid for YY1 compared to non-smokers (0.13% and 0.08% respectively; $P<0.05$), although no difference was seen in the frequency of sperm aneuploid for Y1-1 (0.09% and 0.11% respectively; $P>0.05$). Total anti-oxidant activity was significantly lower in smokers' SP compared to that of non-smokers' (1232.22± 273.17 and 1514.49± 224.82 μmol/l respectively; $P<0.05$). MDA concentration was similar in both smokers' and non-smokers' SP (4.56± 0.34 and 5.24± 0.41 nmol/ml respectively; $P>0.05$) and spermatozoal fraction (0.53± 0.04 and 0.51± 0.08 nmol/ml respectively; $P>0.05$). The results indicate that smoking is associated with elevated levels of aneuploid sperm and reduced SP anti-oxidants.

1809 A PEROXYNITRITE GENERATOR MODULATES CALCIUM-MEDIATED RAT UTERINE CONTRACTILITY.

T C Clipson and R Loch-Caruso. *Dept.Environ. Ind. Hlth, The University of Michigan, Ann Arbor, MI, USA.*

Nitric oxide is important in maintaining vascular tone and uterine quiescence during pregnancy. Oxidative stress in the pregnant uterus may promote the

generation of superoxide anion and, subsequently, peroxynitrite. Using standard muscle baths, this study evaluated the possible role of Ca^{2+} in peroxynitrite-induced modulation of spontaneous oscillatory contractions of uterine segments isolated from gestation day 10 rats. Exposure to 3-morpholinosydnonimine (SIN-1), a compound that generates peroxynitrite, reduced contractile frequency in a concentration-dependent manner. After 40 min of exposure, frequencies were 77, 44 and 43% of controls for 0.5, 1 and 2 mM SIN-1, respectively. The voltage-dependent Ca^{2+} channel blocker nifedipine (20 nM) reduced contraction amplitude compared to controls, followed by complete abolishment of contractions within 10 min. Co-treatment of the uterine segments with 0.5 mM SIN-1 protected against nifedipine's abolishment of oscillatory contractions. Sustained contracture of uterine segments by 60 mM KCl, which stimulates voltage-dependent Ca^{2+} influx from the extracellular space, was attenuated by the SIN-1 and nifedipine treatments. Exposure of uterine segments to 5 μ M carbachol, which initiates Ca^{2+} release from $InsP_3$-sensitive intracellular stores, initially caused a sustained contracture followed by an increase in the frequency of uterine contractility as compared to the pre-treatment frequency. A 10-min pretreatment with 1 mM SIN-1 reduced the duration of the carbachol-induced sustained contracture by 50%. It is proposed that Ca^{2+} homeostasis is sensitive to oxidation by peroxynitrite and that Ca^{2+} channels are modulated by changes in cellular redox conditions.

1810 ACTIVATION OF PROTEIN KINASE C MEDIATES THE INHIBITORY EFFECT OF LINDANE ON SPONTANEOUS UTERINE OSCILLATORY CONTRACTION.

C T Wang and R Loch-Caruso. *Dept. Environmental and Industrial Health, University of Michigan, Ann Arbor, MI.*

The widely used agricultural insecticide lindane (γ-hexachlorocyclohexane) abolished spontaneous uterine oscillatory contractions in a concentration- and time-dependent manner. The present study tested the hypothesis that protein kinase C (PKC) mediates lindane-induced inhibition of uterine contraction. Isometric contractions were measured using standard muscle baths. Acute exposure to the PKC activators phorbol 12 myristate 13-acetate (PMA) (4-100 nM), 1-steroyl-2-arachidonoyl-*sn*-glycerol (1.55-15.5 μM) or 1-oleoyl-2-acetyl-*sn*-glycerol (25-250 μM) attenuated oscillatory contractions in concentration and time dependent manners. The negative control 4α-phorbol (10-250 nM) did not affect the pattern of contraction. Cumulative addition of RHC-80267 (1-150 μM), a diacylglycerol lipase inhibitior that blocks the catabolism of diacylglycerol, resulted in concentration-dependent decreases of contraction. The importance of PKC activation in inhibition of uterine contraction was further investigated by pretreating muscle strips with 50 nM PMA for 18 h, in order to deplete the tissue pool of PKC, prior to their exposure to 30 μM lindane. The PMA-pretreated strips were able to contract with greatly improved force and frequency in the presence of lindane compared to strips exposed to lindane alone. Because PKC-depleted tissues could slowly replenish their PKC pool, 50 nM of PMA was added into the bathing buffer. When PMA-pretreated strips were exposed to lindane in the continued presence of PMA, the strips maintained oscillatory contractions similar to controls. Using western blotting, the α, β, γ, δ, ε, and ζ isoforms of PKC were identified in the cytosol fraction of uterine smooth muscles isolated from midgestational rats. However, only the α, γ and ε isoforms were activated by 30 μM lindane, as indicated by translocation from the cytosol to the membrane. Inhibition of conventional PKC by Gö 6976 had no effect on lindane-mediated abolishment of contraction. However, Gö 7874, a PKC inhibitor which inhibits novel PKC and conventional PKC, partially reversed lindane's inhibition on uterine contraction. In conclusion, lindane-induced inhibition of spontaneous uterine oscillatory contraction is mediated by the activation of PKC, likely specific to novel PKC isoforms.

1811 DELTA-HEXACHLOROCYCLOHEXANE DISRUPTS THE ACTIONS OF UTEROTONINS IN VITRO.

S Goel and R Loch-Caruso. *Dept. Environ. & Indust. Health, University of Michigan, Ann Arbor, MI, USA.*

Oxytocin and prostaglandin $F_2\alpha$ ($PGF_2\alpha$) are key uterotonins that enhance the force of uterine contraction and determine the success of labor. This study examined the hypothesis that delta-hexachlorocyclohexane (δ-HCH) interferes with the actions of uterotonins to cause dysfunctional labor. To assess the changes in contraction, strips of uterine tissues from gestation day 10 rats were suspended in muscle baths and isometric contractions were recorded with a polygraph. After a period of equilibration, muscles were treated with δ-HCH for more than 6 hr. Exposure of uterine strips to 10, 20, 50 and 100 μM δ-HCH completely inhibited spontaneous oscillatory contractions in 64.0± 15.1, 23.3± 4.8, 16.8± 2.5 and 9.3± 1.9 min, respectively. Muscles treated continuously with ≤ 20 μM δ-HCH recovered partially within 215.0± 56.7 min, but higher doses of δ-HCH were cytotoxic. Delta-HCH (50 μM) significantly reduced the force of uterine contraction induced by 12 and 60 mM KCl, in a manner similar to that produced by 20 nM nifedipine, a voltage-sensitive calcium channel blocker. The inhibition of KCl response by δ-HCH was not due to its cytotoxic effects because the muscles recovered and developed spontaneous oscillatory contractions upon removal of δ-HCH. Pretreatment of muscles with 20 μM δ -HCH for 10 min inhibited the initial sustained and subsequent oscillatory uterine contractions induced by 8 nM oxytocin, 40 nM $PGF_2\alpha$ and 5 μM carbamoylchloride. Exposure of uterine strips to 100 μM α-tocopherol, an antioxidant, did not reverse the inhibitory effect of δ-HCH on uterotonin-induced responses, although it reversed δ-HCH-induced inhibition of spontaneous oscillatory uterine contractions. Our data suggest that δ-HCH interferes with response to uterotonins and therefore may cause improper uterine contractions resulting in delayed or dysfunctional labor.

1812 ALPHA-HEXACHLOROCYCLOHEXANE INHIBITS SPONTANEOUS AND OXYTOCIN-INDUCED UTERINE CONTRACTIONS.

N Goel and R Loch-Caruso. *Dept. Environ. & Indust. Health, University of Michigan, Ann Arbor, MI, USA.*

The alpha isomer constitutes 62% of the technical product of hexachlorocyclohexane (HCH) that is still used as an agricultural pesticide, and is a common environmental pollutant. Like other HCHs, α-isomer accumulates in adipose tissues, and may affect reproductive functions. The present study examined the hypothesis that α-HCH may interfere with labor by inhibiting spontaneous and agonist-induced uterine contractions. Using standard muscle baths, isometric contractions were recorded in longitudinal uterine strips from gestation day 10 rats *in vitro*. Exposure of uterine strips to 10, 50, 100 or 200 μM α-HCH induced a dose-dependent decrease in force of contraction, and completely abolished uterine contractions in 290± 11.1, 58.4± 8.8, 8.6± 1.4 and 4.5± 0.38 min. The muscles recovered and developed spontaneous oscillatory contractions in the continued presence of α-HCH, but the force and oscillatory activity of contractions were greatly reduced compared to basal uterine contractions. Furthermore, exposure of uterine strips to 20 μM α-HCH for 10 min inhibited the initial sustained and subsequent oscillatory contractions induced by 8 nM oxytocin. The duration of sustained contraction induced by oxytocin in the presence of α-HCH was 1.25± 0.25 min, which was significantly less compared to that with oxytocin alone (12.7± 2.98min). Pretreatment of the uterine strips with 100 μM α-tocopherol, an antioxidant, reduced α-HCH-induced inhibition of uterine contraction, but did not reduce the inhibitory effect of α-HCH on the oxytocin response. These data suggest that inhibition of uterine contraction is partially due to oxidative stress produced by α-HCH, but that the inhibition of oxytocin-induced uterine contraction involves a different mechanism. If these mechanisms are functional *in vivo*, then exposure to α-HCH may inhibit the effects of oxytocin, and cause dysfunctional labor without necessarily affecting the onset of labor.

1813 GAMMA GLUTAMATE CYSTEINE LIGASE (GlCl) ACTIVITY AND EXPRESSION DURING THE ESTROUS CYCLE IN THE RAT OVARY.

U Luderer, T J Kavanagh, C C White, and E M Faustman. *Department of Environmental Health, University of Washington, Seattle, WA, USA.*

Total glutathione (GSH) content of the rat ovary and *in vitro* release from perfused ovaries change during the estrous cycle, being highest on the day of estrus. Such changes may result in differential sensitivity of the ovary to toxicants during different cycle stages. However, little is known about the regulation of these changes. We hypothesized that changes in the activity and expression of the rate-limiting enzyme in GSH synthesis, GlCl (formerly known as gamma-glutamylcysteine synthetase), are responsible for the cyclic variation in GSH content. To test this hypothesis we measured GlCl activity and mRNA levels for the heavy chain, catalytic subunit of GlCl (HCGlCl) in normally cycling adult rats. The estrous cycles of female rats were monitored by vaginal cytology for at least two consecutive cycles prior to sacrifice on metestrus (MET), diestrus (DI), proestrus (PRO), or estrus (EST). Ovaries were snap frozen in liquid nitrogen and stored at -70 C. Ovarian GlCl activity was measured in the right ovaries by HPLC. RNA was extracted from the left ovaries and Northern blot analysis was performed using 32P-labelled cDNA probes to HCGlCl and to Cyclophillin, a house-

keeping gene which was used to normalize the densitometric data. Preliminary results comparing GlCl activity in ovaries from EST animals to that in MET, DI or PRO animals reveal a trend towards higher GlCl activity in estrous ovaries. In contrast, HCGlCl mRNA levels were constant from MET through PRO and then declined by about 25% on EST. In summary, the increase in ovarian GSH content on the day of estrus appears to be mediated by an increase in GlCl activity in the absence of increased expression of HCGlCl. Future studies will further investigate the regulation of GSH changes during the estrous cycle and the possible effects on ovarian sensitivity to toxicants. (Supported by NIEHS Center for Ecogenetics and Environmental Health (1 P30 ES07033-03) and by US EPA #R-825358-01-0 (to E.F.).)

1814 DIETARY GENISTEIN DOES NOT MAINTAIN SURGICALLY INDUCED ENDOMETRIOSIS IN RATS.

M S Cotroneo and C A Lamartiniere. *University of Alabama at Birmingham, Birmingham, AL, USA.*

Endometriosis is a disease in which uterine tissue proliferates in extrauterine sites. Exposure to chemicals with estrogenic activity via diet and environment has led to the investigation of potential links between these chemicals and endometriosis. Using a surgical model to simulate endometriosis, we explored the potential for the phytoestrogen, genistein, by injection and diet, to sustain endometriosis in rats. Uterine tissue was attached to intestinal mesentery of 8-week-old Sprague Dawley rats. After 3 weeks, the rats were ovariectomized and the implants measured. Following 3 weeks of daily injections (sc), the animals were necropsied and implants located. Injections of genistein (50 and 16.6 ug/g BW) or estrone (1 ug/rat) sustained the implants; genistein at 5.0 ug/g BW did not. Injection of the vehicle, dimethylsulfoxide (DMSO), did not support the implants. Using the same surgical protocol, we gave genistein via the diet (250 or 1000 mg genistein/kg AIN-76A diet); control rats were fed AIN-76A diet. Dietary genistein at either dose did not sustain the implants. To assess estrogenic actions of genistein in both the injection and dietary models, we measured uterine estrogen receptor alpha (ER) and progesterone receptor isoforms A and B (PR) by western blot. Rats injected with estrone or genistein (50 or 16.6 ug/g BW) had significantly reduced uterine ER, compared to DMSO treated animals, while 5.0 ug/g BW genistein did not. PR (B form) was significantly increased by estrone and genistein (50 ug/g BW). PR (A form) was significantly increased by genistein (16.6 and 5.0 ug/g BW). The dietary genistein treatments did not alter uterine ER or PR. These results suggest a critical role for ER modulation and genistein bioavailability in the maintenance of the implants.

1815 ROLE OF GLUTATHIONE IN UTERINE SECRETIONS DURING EARLY PREGNANCY.

J J Salmen and C S Gardiner. *Department of Biological Sciences, University of Northern Colorado, Greeley, CO, USA.*

In this study we examined the concentration of reduced glutathione (GSH) in reproductive tract fluid of mice during the first four days of pregnancy and the effects of blocking GSH synthesis with buthionine sulfoximine (BSO). Previous studies demonstrate that, while preimplantation embryos are unable to synthesize GSH de novo until the blastocyst stage, GSH is present in reproductive tract fluid and extracellular GSH protects preimplantation embryos in vitro. In this study we explore the hypothesis that GSH in reproductive tract fluid protects preimplantation embryos from glutathione-depleting toxicants in vivo. Reproductive tracts were removed from female mice and flushed with buffer. Subsequently, GSH in reproductive tract flushings was measured with flourescent HPLC. BSO was administered four times per day to female mice (4 mmol/kg/injection) from day 0 through day 4 of gestation (day 0 being the day of vaginal plug detection). The concentration of GSH in reproductive tract fluid on day 1 (d1) and day 2 were found to be significantly higher than day 0 and nonpregnant (np) (d1 33 nmol GSH/mg of protein, d2 31, d3 12, d0 4.0, np 9.9; $p< 0.05$). Furthermore, on day 0 there was a higher concentration of GSH in the oviduct than in the uterus, while on day 2 there was a higher concentration in the uterus (Ut) than in the oviduct (Ov) (Ovd0 13 nmol GSH/mg protein, Utd0 8.2, Ovd2 26, Utd2 73; $p<0.05$). Injection of mice with BSO caused a decrease in GSH concentration in reproductive tract fluid (control (C) np 77 nmol GSH/mg protein, BSOnp 3.0; Cd2 24 nmol total glutathione/mg protein, BSOd2 6.9; Cd3 26, BSOd3 1.8; $p<0.05$). Control mice also exhibited a larger percentage of embryos developing to the 2-cell stage in vivo (C 79%, BSO 66%, $p<0.05$). BSO mice exhibited more degenerated embryos (C 11%, BSO 25%, $p<0.05$). These data indicate that there is an increased concentration of GSH in reproductive tract fluid during the period of development when embryos are unable to synthesize GSH, that inhibition of GSH synthesis by BSO causes a decrease in the concentration of GSH in reproductive tract fluid, and that this inhibition has a detrimental effect on preimplantation embryos. In conclusion, these data support the hypothesis that GSH in reproductive tract fluid has a role in protection of the preimplantation embryo.

1816 DIFFERENTIAL EFFECTS OF ATRAZINE (ATR) ON SERUM LUTEINIZING HORMONE (LH) AND PROLACTIN (PRL) IN LONG-EVANS HOODED AND SPRAGUE DAWLEY RATS.

R L Cooper, T E Stoker, S R Mistich and W K McElroy. *Endo Br, Repro Tox Div, NHEERL, US EPA, RTP, NC, USA.* Sponsor: R J Kavlock.

The chlorotriazines (i.e., ATR, simazine and cyanazine) have been shown to disrupt the control of ovarian function, advance reproductive aging and lead to an early onset of mammary gland tumors in Sprague Dawley (SD) rats. We reported previously that these effects occur as a result of altered LH and PRL secretion. We also noted that at each dose tested, ATR disrupted estrous cycles in the Long Evans (LE) hooded rats to a greater extent than in SDs. Here, we examined the effect of ATR on LH and PRL secretion to determine the dose and duration of exposure required to disrupt pituitary hormone secretion in these two strains. LH and PRL surges were induced in ovariectomized females by implanting (sc) an estrogen-filled silastic capsule. Four different doses of ATR (50, 100, 200 & 300 mg/kg) were administered 21 (21X) or 3 (3X) days prior to or on the day (1X) of the surges. LH and PRL was suppressed in 1X LE rats at 300 mg/kg, but these measures were not affected in the SD rats. The surge of both hormones was reduced at each dose level in 3X LE rats, but again 3X SD LH and PRL were not affected. After 21 days of ATR pretreatment, however, the LH and prolactin in both strains were reduced similarly. These data demonstrate a clear strain difference in the onset of the effects of ATR on pituitary hormone secretion and suggest the LE female is more sensitive to the effects of this cholotriazine. *(This abstract does not reflect US EPA policy.)*

1817 OVULATORY BLOCKADE IN THE RAT BY LOCAL OVARIAN ADMINISTRATION OF SODIUM DIMETHYLDITHIOCARBAMATE: MECHANISM OF EFFECT RELATED TO TIME OF EXPOSURE DURING THE CYCLE.

J M Goldman and J M Hedge. *Repro Tox Div, NHEERL, US EPA, Research Triangle Pk, NC.* Sponsor: L E Gray.

When dosed systemically, the fungicide sodium dimethyldithiocarbamate (DMDC) can block ovulation in rats by interfering with hypothalamic activation of the luteinizing hormone surge. Local ovarian administration late on the afternoon of vaginal proestrus (pro) can also curtail oocyte release from exposed ovaries, while such dosing on diestrus 2 (di2) bilaterally blocked ovulation by suppressing the surge. In brain, the effect is likely due to a decrease in norepinephrine synthesis, but this does not appear true for ovarian exposures. Current experiments attempted to define the mechanisms underlying these local ovarian effects. Cycling Long-Evans rats were given DMDC (0 - 300 μmol/ovary) by unilateral intrabursal injection at 1900h on either pro or di2. Rats were then killed at various times, and serum samples obtained for estradiol (E2) or progesterone (P4) determinations. Groups of rats dosed on pro were also co-injected with prostaglandin F2α (PGF2α) or sodium nitroprusside (SNP). These females were then killed at 1200h on the following day and oviducts flushed for oocytes to explore whether ovarian DMDC could have affected either local prostaglandin or nitric oxide (NO) involvement in follicular rupture. In this regard, dithiocarbamates have been reported to inhibit NO synthase activity. The data showed that while the di2 exposures caused some small but statistically significant elevations in serum E2, a prompt 4-5 fold rise in P4 likely provided a down-regulatory feedback effect on the hypothalamus to block the surge. For the ovulatory suppression following pro DMDC injections, no effect was seen in response to graded PGF2α co-injections. However, co-administration of the NO donor SNP (5 μmol) & DMDC (200 μmol) was able to increase the percentage of ovulating ovaries from 25 to 66%, an effect marginally beyond statistical significance (p set at 0.05), but one that given the importance of NO in ovulatory process warrants further investigation as a potential target for the dithiocarbamates.

1818 CELLULAR AND MOLECULAR MECHANISMS OF ACTION OF THREE NOVEL ENVIRONMENTAL ANTIANDROGENS: TWO PHTHALATES AND LINURON.

C R Lambright[1], A K Hotchkiss[2] and L E Gray Jr.[1]. [1]*USEPA, NHEERL, Research Triangle Park, NC, USA;* [2]*NCSU/USEPA Cooperative Training Program, Raleigh, NC, USA.*

The antiandrogenic fungicide vinclozolin alters sex differentiation by competing with androgens for the androgen receptor (AR), inhibiting AR-DNA binding and altering androgen-dependent gene expression in vivo and in vitro. Several antiandrogens have been identified by their ability to induce reproductive malformations, but the mechanisms of action of these chemicals are unknown. We have developed a battery of in vitro and in vivo assays to determine if a chemical 1) is an AR ligand, 2) alters androgen-dependent gene expression in vitro or in vivo, 3) alters AR-DNA binding or 4) alters AR distribution of function in vivo. In this phase of the investigation, the potential AR-mediated action of linuron (L), a metabolite of L hydroxylinuron, dibutyl (DBP) and diethylhexyl (DEHP) phthalate and their metabolites monobutyl and monoethylhexyl phthalate were examined using competitive binding with rat AR and/or human AR (hAR) in COS cells, DHT-induced gene expression in transiently cotransfected CV-1 cells, gene expression in stably transfected CHO cells and AR-DNA binding in the promoter-interference assay. The phthalates did not bind hAR, inhibit (or stimulate) gene expression in CHO cells or inhibit AR-DNA binding in the promoter interference assay. At 10 μM, the highest dose tested, DEHP inhibited DHT-induced gene expression in CV-1 cells. As DEHP does not bind hAR, this effect may result from an interaction with cell specific coactivators or from altered cell function. Hydroxylinuron, and to a lesser degree linuron, competed with DHT for rat AR (EC_{50}=30 μM) and inhibited DHT-hAR induced gene expression in both the CV-1 (EC_{50}=0.2-0.5 μM) and CHO (EC_{50}=1-10 μM) cells, while in the COS cell, hydroxylinuron displayed hAR binding with an EC_{60} at 10 μM, the highest concentration. Although linuron, DBP and DEHP alter sexual differentiation their mechanisms of action appear to differ. (Disclaimer: These abstracts do not reflect USEPA policy.)

1819 8-METHOXYPSORALEN COMPROMISES OVARIAN FOLLICLE DEVELOPMENT IN WISTAR RATS.

M M Diawara, P B Hoyer, K J Chavez, and D E Williams. *Department of Biology, University of Southern Colorado, Pueblo, CO, USA.*

The psoralens are naturally occurring metabolites found in many crop plants, including common grocery fruits and vegetables. Synthetic forms of 5-methoxypsoralen (bergatpten) and 8-methoxypsoralen (xanthotoxin) are widely used in skin photochemotherapy. Our previous research documented for the first time that dietary bergapten and/or xanthotoxin reduced birthrate in female rats when males and females were exposed to these chemicals. Subsequent studies demonstrated that the two compounds, administered to female rats (mated to undosed males), significantly reduced levels of circulating blood estrogen, and the number of implantation sites, pups, and corpora lutea, compared with the control group, suggesting a direct effect on ovarian follicles. The present study was initiated to determine whether effects of xanthotoxin can be observed in ovarian follicles. Female Wistar rats were dosed daily (30 days) with vehicle control or xanthotoxin (30 mg/kg, p.o.). Ovaries were collected and prepared for histological evaluation. Antral follicle diameters (>600μm) were larger ($p<0.05$) in ovaries from xanthotoxin-dosed as compared with control rats. Additionally, the granulosa cell layer thickness, and granulosa cell layer:follicle diameter ratio were reduced ($p<0.05$) in dosed animals. This provides evidence that xanthotoxin compromises the granulosa cell population in large antral follicles, and is consistent with its observed reduction in circulating 17b-estradiol levels. (Supported by NIEHS/NIH #ES00288 (to MMD) and ADCRC #9808 (to PBH).)

1820 THE ARYL HYDROCARBON (AhR) RECEPTOR MAY BE INVOLVED IN THE DEVELOPMENT OF OVARIAN FOLLICLES.

J A Flaws[1], I K Loeffler[3], T-M Lin[3], R E Peterson[3], and A N Hirshfield[2]. [1]*Departments of Epidemiology and Preventive Medicine,* [2]*Anatomy and Neurobiology, University of Maryland School of Medicine, Baltimore, MD; and* [3]*School of Pharmacy and Environmental Toxicology Center, University of Wisconsin, Madison, WI.*

The AhR is believed to mediate the toxicity of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). However, the endogenous, physiological functions of the AhR signaling pathway are only beginning to be understood. The results reported here are part of a larger study by our group that examines the role of the AhR in the developing mammalian reproductive tract. Using AhR knockout mice and their wild-type littermates, we investigated the possibility that the AhR is important for the normal development of ovarian follicles. Ovaries were collected from knockout and wild-type mice on postnatal days 2-3, and complete serial sections were prepared for histological examination. Every tenth section was sampled to estimate the total number of primordial and primary follicles per ovary. Our results indicate that knockout ovaries contained about 65% more primordial follicles than wild-type ovaries (26,048 ± 1287 vs. 15,787 ± 2772; n = 3; p = 0.008). There was no significant difference between the number of primary follicles in ovaries from knockout and wild-type mice (n=3; p = 0.65). These data suggest that the AhR plays a role in the establishment of the primordial follicle pool, but not in the growth of primordial follicles to the primary stage by postnatal days 2-3. (Supported by the Heinz Family Foundation (JF), HD27194 (AH) and ES01332 (RP).)

1821 BIPHASIC EFFECTS OF OCTYLPHENOL ON TESTOSTERONE BIOSYNTHESIS BY CULTURED LEYDIG CELLS FROM NEONATAL RATS.

E P Murono, R Derk, J H deLen. *NIOSH, HELD, Morgantown, WV.* Sponsor: V Castranova.

Octylphenol (OP), a surfactant additive widely used in the manufacture of various detergents and other commercial products, has been reported to mimick the actions of estrogen in many cellular systems. In the present studies, the direct effects of OP on basal and human chorionic gonadotropin (hCG)-stimulated testosterone production by cultured Leydig cells from neonatal rats (6-7 days of age) were evaluated. Exposure of cultured cells to increasing concentrations of OP (1-2000 nM) and 10 mIU/ml hCG for 24 h caused a consistent biphasic pattern of testosterone response. Lower concentrations of OP enhanced testosterone levels (~10-70% above control), while higher OP concentrations (100-2000 nM) progressively decreased testosterone from peak levels to ~ 40-80% below control at the highest OP concentration. Interestingly, increasing concentrations of 17β-estradiol (1-1000 nM) were without effect on testosterone formation under the same conditions, and the biphasic pattern of testosterone biosynthesis elicited by increasing concentrations of OP and hCG was unaffected by concommitant treatment with 10 or 100 nM ICI 182,780, which is considered a pure estrogen antagonist. Therefore, these actions of OP do not appear to be mediated through the classic estrogen receptor α or β pathway. Because the biphasic pattern of testosterone biosynthesis was observed in response to exposure with increasing concentrations of OP and 0.1 mM 8-Br-cAMP, it appears that the main site(s) of action occurs following the generation of cAMP. In addition, because pretreatment of cells with increasing OP concentrations and hCG had no effect on the conversion of steroid precursors (1 μM each of 22 (R)-hydroxycholesterol, progesterone or androstenedione) to testosterone, it appears that the main actions of OP occur prior to the mitochondrial cholesterol side-chain cleavage step. Furthermore, because concommitant treatment of cells with antioxidants (α-tocopherol or butylated hydroxyanisole) did not alter the biphasic testosterone response pattern to increasing OP concentrations and hCG, it appears that OP is not acting as a pro-oxidant in producing these effects. It will be important to determine whether this dose-sensitive response to OP is observed *in vivo* and whether the maturational status of Leydig cells influences their sensitivity to OP and similar chemicals.

1822 OVOTOXIC SPECIES DIFFERENCES BETWEEN RATS AND MICE WITH 3-METHYLCHOLANTHRENE AND 7,12-DIMETHYLBENZ[A]ANTHRACENE.

S B Borman[1], P J Christian[1], I G Sipes[2], and P B Hoyer[1]. *Southwest Environmental Health Sciences Center, Departments of Physiology*[1] *and Pharmacology and Toxicology*[2]*, University of Arizona, Tucson, AZ, USA.*

Polycyclic aromatic hydrocarbons (PAH, contaminants in cigarette smoke) destroy ovarian follicles in laboratory animals, and are therefore the likely cause of early menopause in women smokers. The purpose of this study was to compare the ovotoxicity in rats and mice caused by repeated low dose exposure to PAHs, specifically 3-methylcholanthrene (3MC) and 7,12-dimethylbenz[a]anthracene (DMBA), because this more closely mimics human exposure. Ovaries were collected from female F344 rats and B6 mice following dosing for 15d with 3-MC and DMBA, and were prepared for histological counting of oocytes. 50% pre-antral follicle loss at 15d was seen with 0.15 mg/kg 3-MC in mouse primordial follicles, (152.7± 29 total folli-

cles counted, control; 68.6± 30.6 follicles, $p<0.05$, n=5), and in rat growing follicles (11.3± 1.2 follicles, control; 6.3± 0.75 follicles, $p<0.05$, n=4). 50% loss of primordial follicles was seen with 7 mg/kg DMBA in rats (167.0± 5.4 follicles, control; 82.0± 15.3 follicles), and with 0.35 mg/kg in mice (180.0± 47.0 follicles, control; 25.1± 11.0 follicles, $p<0.05$, n=6). Loss of primordial follicles caused by 3-MC and DMBA was greater ($p<0.05$) in mice than rats. Thus, primordial follicles in rats were most susceptible to DMBA and those in mice were most susceptible to 3-MC. Additionally, 3-MC (0.15 mg/kg) targeted primordial and primary follicles in mice, but growing follicles in rats. In using low-dose exposures we have demonstrated differential ovotoxicity targeting with these two PAHs. These observations suggest that 3-MC and DMBA produce ovotoxic effects by different mechanisms. (NIEHS Center grant ES06694, ADCRC 9809.)

1823 17β-ESTRADIOL RESCUES PRIMARY FOLLICLES FROM 4-VINYLCYCLOHEXENE DIEPOXIDE-INDUCED APOPTOSIS.

K E Thompson[1], I G Sipes[2], and P B Hoyer [1]. *Southwest Environmental Health Sciences Center, Departments of [1]Physiology and [2]Pharmacology and Toxicology, University of Arizona, Tucson, AZ, USA.*

Repeated dosing with 4-vinylcyclohexene diepoxide (VCD), a known occupational ovotoxicant, accelerates atresia via apoptosis in small preantral follicles in ovaries of rats and mice. The mechanism by which VCD alters follicular apoptosis is unknown, however this destruction is particularly apparent in immature animals. Physiologic atresia, a normal process in the ovary, slows as an animal enters puberty while 17β-estradiol (E_2) increases with the onset of cyclicity. The estrogen β receptor (ER) has recently been reported to be expressed in the granulosa cells of ovarian follicles, suggesting a role of E_2 in normal ovarian function; however the specific roles of this receptor in follicular development and cell fate are unknown. The hypothesis tested was that E_2 dosing of immature rats will rescue small follicles normally destroyed in VCD-induced apoptosis. Immature rats (d28) were dosed daily for 15 days with vehicle control (sesame oil), VCD (80 mg/kg, i.p.), or VCD and E_2 (0.1 mg/kg, s.c.). Ovaries were removed and either fixed, stained, and sectioned or dissociated for follicle isolation. RT-PCR of isolated fractions of small follicles (<100 μm) in both control and VCD treated animals demonstrated expression of mRNA encoding ERβ, but not ERα. The PCR product was confirmed as ERβ by oligonucleotide sequencing. Histologic evaluation of ovarian slices showed that VCD dosing caused a significant decrease in primary follicles ($p<0.05$, control=47.3 ± 1.76, VCD=29.25 ± 1.93 follicles in the total of every 40th section counted). However, concurrent VCD and E_2 dosing reversed the VCD-induced loss of primary follicles (VCD&E_2=49 ± 3.32). Physiologic dosing of E_2 given to immature animals appears to selectively protect primary follicles from VCD-induced apoptosis and suggests that VCD may interact with the ERβ receptor. (NIEHS Center grant ES-06694, Arizona Disease Control Research Commission.)

1824 TRANSPORT OF 2,4-D INTO THE SEMINAL FLUID OF DOGS.

D Bruce and L Ritter. *Canadian Network of Toxicology Centres, University of Guelph, Guelph, Ontario, Canada.*

Chemicals can be transported from the semen via the fluid or bound to sperm, to the gamete at fertilization, or to the developing embryo. However, little is known of the amount of toxicant that can be transmitted by the father into the environment of the conceptus, or the potential for adverse reproductive effects resulting from this exposure. Some epidemiology studies have suggested a possible association between male exposure to 2,4-D and adverse reproductive effects. In the present study, the possibility of 2,4-D entering the seminal fluid of dogs and binding to spermatozoa was assessed. Dogs were dermally exposed to 1, 10, or 20 mg 2,4-D/kg body weight. Seminal fluid was collected daily over 4 days as a split-ejaculate, separating the pre-sperm fraction from the sperm-rich and post-sperm fractions. 2,4-D was detected in both fractions indicating that it is secreted into the seminal fluid and is not merely an artifact of urine contamination. Of the applied dose, 0.0134% (±0.0113) was excreted in the seminal fluid over 96 hours irrespective of the amount applied. The percent of dose excreted in the urine increased as the dose decreased; 8.44%, 1.22% and 1.69% was excreted when the dose was 1,10 or 20 mg/kg respectively. The herbicide was detected in the seminal fluid and urine within 24 hours of dosing and was not detected in the seminal fluid after 120 hours but was still present in the urine. Statistically significant dose effects were observed in both media. Using radiolabelled 2,4-D *in vitro*, it was established that 2,4-D does not bind to spermatozoa.

1825 LACK OF EFFECTS OF NOSE-ONLY INHALATION EXPOSURE ON TESTICULAR TOXICITY IN MALE RATS.

S J Rothenberg, R M Parker, R G York, G E Dearlove, M M Martin, K H Denny, S D Lief and A M Hoberman. *Primedica Argus, Horsham, PA, USA.*

Reductions in testicular mass, sperm motility and mating frequency have been attributed to the stresses caused by confinement in nose-only exposure tubes. This study was designed to determine whether nose-only exposure of rats caused testicular toxicity following cooling of the exposure room and appropriate acclimation (The Toxicologist, Vol 15, 181, 1995). Twenty male rats were exposed nose-only for approximately two hours per day for 28 days prior to cohabitation and throughout a 14-day cohabitation period. To reduce thermal stress the exposure room temperature was maintained at 64° to 70°F and exposure tubes were cut to length so that not more than two inches of the tail-cooler was within the tube. Twenty control rats were housed in the same room as the exposed rats. End-points monitored were body weight, testicular weight, sperm count, sperm motility and histopathology of the testes, epididymides, prostate and seminal vesicles. The control rats gained weight more rapidly than the exposed rats. All the rats in both groups mated successfully, and testicular weights, normalized to body weight, were similar for both groups. There were no microscopic changes that could be correlated to an adverse effect on the reproductive tissues in the male rats placed in exposure tubes. Nose-only exposure for up to two hours per day for a total of 42 days did not cause adverse effects on the reproductive organs or performance of male rats.

1826 ASSESSMENT OF XANTHOTOXIN AS A REPRODUCTIVE TOXICANT IN MALE WISTAR RATS.

K J Chavez, M M Diawara, S L Sandoval, P B Hoyer, D E Williams, and K Boekelheide. *Department of Biology, University of Southern Colorado, Pueblo, CO, USA.*

The psoralens are plant metabolites found in common fruits and vegetables. The synthetic form of 8-methoxypsoralen (xanthotoxin) has been employed in combination with long-wave ultraviolet radiation, as a commercial drug since the 1940's for the treatment of psoriasis and other mitotic dermatoses. Although, an effective drug for skin photochemotherapy, xanthotoxin has been observed to cause lethal, mutagenic, and genotoxic effects in a wide variety of organisms. Previous studies revealed that xanthotoxin reduced birthrates in rats when both sexes were administered the drug. During subsequent studies, where dosed females were mated with undosed males, percent reduction in birthrate was less compared with when both males and females were treated. Thus, we hypothesized that the decrease in birthrate was due, in part, to direct effect of xanthotoxin on the male reproductive function. Male rats were dosed for 30 days with vehicle control or xanthotoxin (30mg/kg, p.o.). Animals were sacrificed and the seminal vesicles, testes, prostate gland, epipdidymis, and pituitary gland were collected and weighed. The study demonstrated that xanthotoxin significantly reduced the weights of the following organs when compared to the control; prostate, seminal vesicles and the epididymis (caput, cauda, and corpus) ($p<0.05$). The pituitary gland in the xanthotoxin-treated animals was also significantly reduced ($p<0.05$). This study provides evidence that xanthotoxin compromises normal physiological development in the male reproductive system. (Supported by NIEHS/NIH Grant ES-00288 to MMD.)

1827 (-)-FTC, AN OXATHIOLANE NUCLEOSIDE ANALOG FOR THE TREATMENT OF HIV AND HBV INFECTION, DID NOT PRODUCE ADVERSE EFFECTS ON REPRODUCTION AND DEVELOPMENT IN MICE.

T B Grizzle, F S Rousseau, J Delehanty, M R Almond, J P Walsh, J A Begley, and G M Szczech. *Triangle Pharmaceuticals, Inc., Durham, NC, USA.*

(-)-FTC is a nucleoside analog with potent activity against HIV-1 and HBV viruses, and is in Phase II/III clinical trials for treatment of HIV-1 infection in adults. The following GLP-compliant studies were conducted in CD-1® mice to characterize the potential reproductive and developmental toxicity of this candidate antiviral: 1) fertility and early embryonic development (Seg I); 2) teratology (Seg II); and 3) pre-and postnatal development with maternal evaluation (Seg III). Doses of 0, 250, 500, and 1000 mg/kg/day were tested in these experiments. There was no maternal or fetal toxicity (gestation-day 18) in a dose range-finding study in mice given (-)-FTC at doses of 0,

250, 500, and 1000 mg/kg/day. (-)-FTC had no effect on fertility, weights of reproductive organs, sperm motility or counts, and early embryonic development in the Seg I study. In the Seg II study, there were no treatment-related increases in gross, visceral, or skeletal abnormalities in mouse fetuses at any dose. Plasma concentrations of (-)-FTC in the Seg II study at 0.5 h post-dose on gestation-day 15 were proportional to dose; 50.8± 13, 88.1± 14, and 186± 14 μ g/mL (mean± standard deviation; n=5) for the 250, 500, and 1000 mg/kg/day doses, respectively. Parturition, lactation, and mothering, as well as pre-/postnatal development and fertility of the F_1 mice were not affected by (-)-FTC in the Seg III study. These favorable data support the further development of (-)-FTC for treatment of HIV-1, particularly in pregnant women and pediatric patients.

1828 THIRTEEN WEEK ORAL TOXICITY STUDY OF DIFLUOROMETHYLORNITHINE (DFMO) IN COMBINATION WITH TAMOXIFEN IN FEMALE RATS.

B S Levine[1], A P Brown[1], R L Morrissey[2], and J A Crowell[3]. [1]*Toxicology Research Laboratory, Univ. of Illinois at Chicago, Chicago, IL, USA;* [2]*Path. Assoc. Intl., Chicago, IL, USA;* [3]*Natl. Cancer Inst., Rockville, MD, USA.*

DFMO is an irreversible inhibitor of ornithine decarboxylase, the rate-limiting enzyme in the biosynthesis of polyamines, and inhibits tumorigenesis in animal models. Tamoxifen (TAM), a nonsteroidal antiestrogen, is used for treatment of estrogen receptor-positive breast carcinoma. Since these agents may be used for combination therapy, the toxicity of DFMO in combination with TAM was evaluated in female rats following thirteen weeks of daily administration by gavage. Dose levels in mg/kg/day were: 0 (vehicle control), 1000 DFMO, 0.25 TAM, 2.5 TAM, 0.25 TAM + 1000 DFMO and 2.5 TAM + 1000 DFMO. No mortalities occurred. DFMO produced dermal lesions consisting of scab formation and abrasions. Decreased body weight gains were produced by DFMO and TAM. Serum albumin, total protein, cholesterol and triglyceride levels were decreased in all drug-treated dose groups, with albumin and total protein decreased to the greatest extent in the combination dose groups. TAM increased numbers of red blood cells, whereas DFMO induced slight anemia. DFMO produced intestinal lesions consisting of necrosis of crypt epithelium and crypt microabscess that were enhanced by TAM co-administration. TAM induced lesions in the ovaries, fallopian tube, vagina, cervix and uterus, indicating inhibition of ovulation and reproductive cycle arrest in the proestrus stage. Co-administration of DFMO and TAM resulted in additive toxicity. (Supported by NCI Contract No. NO1-CN055144-MAO.)

1829 EFFECTS OF INORGANIC MERCURY ON THE REPRODUCTIVE PERFORMANCE OF C57/BL6 MICE.

A Khan, A Atkinson, T Graham, S Thompson, S Ali, and S Hussain. *CVMNAH, Tuskegee University, Tuskegee, AL, USA.*

The effects of inorganic mercury (Hgcl2) treatment on the reproductive performance of mice were evaluated. Males and females were dosed for 40 and 16 days prior to mating, respectively. Pairs of male and female mice were given 0.00, 0.25, 0.50, or 1.00 mg/kg/day of Hgcl2 via oral gavage. Males were continuously dosed throughout mating and the females were continuously dosed throughout mating, gestation and lactation. Fertility, litter size, and viability indices were calculated and analyzed. The fertility indices were 44, 16, 16, and 18% and the viability indices were 91, 96, 42, and 17% at 0.00, 0.25, 0.50, and 1.00 mg/kg/day, respectively. Mice exposed to Hgcl2 had significantly reduced fertility in all dose groups and in viability among the two higher dose groups when compared to the control. The mean numbers of pups per litter were 6.49, 7.25, 8.35 and 5.68 at 0.00, 0.25, 0.50, and 1.00 mg/kg/day dose groups, respectively. Exposure to Hgcl2 did not effect the litter size. However, the number of pups born alive was significantly lower in the treated groups when compared to control. These results provide evidence which suggests that Hgcl2 produced adverse effects on reproductive performance of mice (Supported by MHPF/ATSDR Cooperative Agreement # 5R51/ATR398004.)

1830 ZINC CHLORIDE DOSE RANGE FINDING REPRODUCTIVE STUDY IN RATS.

T Graham, A Khan, A Atkinson, O Clark, S Thompson, S Ali, and S Hussain. *CVMNAH, Tuskegee University, Tuskegee, AL.*

The purpose of this study is to conduct a reproductive dose range finding study by examining the effects of zinc chloride on reproductive organs of rats. Male and female Sprague Dawley rats (40-45 days old) were administered 0.0, 60.0, 80.0, 120.0, or 160.0 mg/kg/day of zinc chloride via oral gavage for 14 days. Body weights were recorded twice weekly. Twenty four hours following the final exposure, animals were scarified. Testis, epididymis, seminal vesicle, prostate, ovary and uterus were removed, weighed and prepared for routine light microscopic evaluation. The weights of the seminal vesicle and testis were significantly decreased at the 160.0 mg/kg/day dose. There were no significant changes in the weights of female reproductive organs. Histomorphologic evaluation of the male reproductive organs revealed giant cells in the lumens of epididymal ducts at all levels of zinc treatment, along with prostatic acinar atrophy at 60.0, 80.0, and 120.0 mg/kg/day dose groups. No lesions were seen in the reproductive tissues that were examined in females (Supported by MHPF/ATSDR Cooperative Agreement # 5R51/ATR398004.)

1831 HYDRAMETHYLNON EFFECTS ON MALE REPRODUCTION IN YOUNG ADULT RATS.

D F Crawford[1], W C McCormick[1] and S M Glaza[2]. [1]The Clorox Company, Pleasanton, CA, USA; [2]Covance Laboratories, Madison, WI, USA.
Sponsor: A K Reddy.

Hydramethylnon (HM) is an amidinohydrazone insecticide widely used by consumers and pest control operators (PCO) for the control of ants and cockroaches. Animal studies in several species have shown HM is a male reproductive toxicant. However, the mechanism as well as the exposure timeframe required to elicit adverse reproductive effects have not been well elucidated. Because of its widespread use of consumers to this insecticide, there is a concern about accidental dermal exposure to children and any possible testicular effects. To assess the potential hazard in household insecticides, a study was conducted to determine the effects of an acute exposure to young male rats. Since the dermal penetration rate of HM is relatively low (<1%), the material was administered by subcutaneous (sc) injection to assure that a higher systemic dose was achieved. Young male rats were given single sc injections of HM in an oil carrier at 100, 500, or 1,000 mg/kg of body weight. Daily clinical observations were conducted for 14 days. Clinical effects were limited to decreased body weight gain and decreased food consumption at 500 and 1,000 mg/kg. Animals were sacrificed 14 days post-exposure. Both gross and histopathological examinations revealed no apparent lesions in testes, epididymes or seminal vesicles at any dose. Relative testes to body weight ratios showed statistically significant increases only at 1,000 mg/kg dose. The study showed that single exposures even at high doses fail to elicit the testicular effects in young male rats.

1832 LACK OF EVIDENCE FOR EFFECTS OF DICOFOL ON REPRODUCTIVE HORMONE FUNCTION FOLLOWING DIETARY EXPOSURE IN RATS.

A M Hoberman[1], D L Shuey[2], J A Foss[1], R M Parker[1] and S S Hurt[2]. [1]*Argus Research Laboratories, Inc., Horsham, PA, USA;* [2]*Rohm and Haas Co., Spring House, PA, USA.*

Recently, the potential impact of environmental chemical exposure on reproduction and development via alteration of endocrine function has gained increasing attention, with particular emphasis on estrogenic and androgenic activities. Dicofol, a miticide, has been widely cited as an endocrine disruptor, due to its close structural similarity to DDT and DDE, which have known estrogenic and/or antiandrogenic activity. However, there is currently no direct evidence that dicofol alters reproductive hormone function. This study was designed to provide a comprehensive functional assessment of the effects of dicofol on reproduction and development in rats following dietary exposure at concentrations of 5, 25 or 125 ppm. This study was designed in accordance with draft EPA guidelines for reproductive toxicity studies which have been expanded to increase the sensitivity to altered reproductive hormone function. Parental animals were exposed to dicofol for 10 weeks, mated, offspring delivered, and offspring exposure continued to sexual maturation. Evaluation included, general toxicity, reproductive performance and fertility, estrus cycling, sperm analysis, age at puberty in offspring, organ weights and histopathology. Dicofol and its metabolite were detected in parental serum, neonatal tissues, milk and weanling serum, demonstrating exposure in parental animals, and gestational and lactational exposure of offspring. There were no effects of dicofol exposure on reproduction and fertility, or on survival or growth of offspring. There were no effects on estrus cycling or sperm parameters, or on age at vaginal patency, or preputial separation in female and male offspring, respectively. There were no treatment-

related effects on reproductive organ weights or histopathology at any dose. Liver weight was increased and histopathology of the liver was observed in both parental animals and offspring at 125 ppm. In conclusion, dicofol administration in the diet produced no functional effects indicative of reproductive endocrine disruption at doses which produced target organ toxicity.

1833 SPECIES-SPECIFIC NEPHROTOXICITY INDUCED BY GLUTATHIONE CONJUGATION OF EFAVIRENZ IN RATS.

R J Gerson, A E Mutlib, P C Meunier, P J Haley, L S Gan, H Chen, M H Davies, B Gemzik, D D Christ, D F Krahn, J A Markwalder, S P Seitz, G T Miwa and R T Robertson. *DuPont Pharmaceuticals Co., Newark, DE.*

Efavirenz (EFVZ), a potent non-nucleoside reverse transcriptase inhibitor for treatment of HIV infection, produced renal tubular epithelial cell necrosis in rats within 24 hours of a single oral dose ≥ 350 mg/kg. Nephrotoxicity was not observed in cynomolgus monkeys given EFVZ for ≤ 1 year at doses yielding plasma EFVZ concentrations higher than those producing nephrotoxicity in rats. A cysteinyl-glycine conjugate of an hydroxylated metabolite of EFVZ (CG-HEFVZ) was found in the urine, and the corresponding glutathione conjugate (GSH-HEFVZ) was found in the bile of EFVZ-treated rats. To investigate the potential nephrotoxicity of GSH-HEFVZ, it's formation or catabolism was inhibited in rats *in vivo* and the effect on EFVZ nephrotoxicity evaluated. Rats were given: 1) 700 mg/kg of EFVZ, 2) 700 mg/kg EFVZ 1 h after treatment with the GGT inhibitor acivicin (10 mg/kg iv), or 3) 700 mg/kg of deuterated EFVZ (d-EFVZ; specifically reducing formation of the hydroxylated metabolite of EFVZ, the obligate precursor to GSH-HEFVZ). Total urinary CG-HEFVZ was decreased by 63% in rats pretreated with acivicin and then given EFVZ versus rats given EFVZ alone. All rats (9/9) given EFVZ had renal lesions, whereas only 5 of 9 rats pretreated with acivicin had lesions. Similar decreases in nephrotoxicity and urinary CG-HEFVZ were observed in rats given d-EFVZ compared to rats given EFVZ. Results of this study provided compelling evidence that glutathione conjugation of EFVZ was directly involved in EFVZ-induced nephrotoxicity in rats. In contrast to rats, no CG- or GSH-HEFVZ is found in urine of EFVZ-treated cynomolgus monkeys or humans.

1834 FORMATION AND METABOLISM OF HYDROQUINONE GLUTATHIONE CONJUGATES IN EKER RATS.

M N Phan[1], T J Monks[1], C L Walker[2], and S S Lau[1]. [1]*Div.of Pharm./Toxicol, College of Pharmacy, Univ. of Texas at Austin, TX, and* [2]*UTMDACC, Science Park, Smithville, TX, USA.*

The Eker rat carries a germline mutation in the Tsc-2 tumor suppressor gene which predisposes these rats to the development of renal cell carcinoma. We have used the Eker rat to study the influence of genetic susceptibility on hydroquinone (HQ)-induced nephrocarcinogenesis. Although HQ generally tests negative in standard *in vitro* mutagenicity assays, glutathione (GSH) conjugates of HQ are potent nephrotoxicants in F344 and SD rats, implying a role for cytotoxicity in the carcinogenic response. To assess whether the Eker rat is a suitable model for HQ-induced nephrocarcinogenicity, we determined the metabolism and acute toxicity of HQ in this rat strain. LC-MS/MS and HPLC-EC analysis of bile (3 h) from Eker rats treated with HQ (0.45 μmol/kg, po) revealed the presence of 2-(GSyl)HQ (792 ± 277 μmol), 2,5-*bis*-(GSyl)HQ (86±31 μmol), 2,6-*bis*-(GSyl)HQ (22 ± 2 μmol) and 2,3,5-*tris*-(GSyl)HQ [TGHQ] (20 ± 4 μmol). In addition, dose dependent (TGHQ, 7.5 - 20 μmol/kg ip; HQ, 4.5 - 6.0 μmol/kg po) increases in BUN, and in the urinary excretion of alkaline phosphatase, γ-glutamyl transpeptidase (γ-GT), glucose, LDH and GST were observed 19 h post-injection. Renal γ-GT, cysteine conjugate N-acetyltransferase and N-acetylcysteine conjugate deacetylase activities were 1.2±0.3 μmol/mg/min, 3.24±0.19 and 0.71 ± 0.04 μmol/mg/min respectively. Thus, nephrotoxic HQ-GSH conjugates are formed from HQ in the Eker rat, and the activity of the enzymes involved in the processing of these conjugates are similar to those found in SD and F344 rats. The Eker rat is therefore an excellent animal model with which to examine mechanism(s) of HQ-GSH mediated nephrocarcinogenesis. (GM39338, ES07784)

1835 CHANGES IN TUMOR SUPPRESSOR GENE AND GROWTH FACTOR EXPRESSION DURING QUINOL-THIOETHER MEDIATED NEPHROCARCINOGENICITY IN EKER RATS.

H S Yoon[1], C L Walker[2], T J Monks[1] and S S Lau[1]. [1]*Div. of Pharm./Toxicol., College of Pharmacy, U. of Texas at Austin, TX; and* [2]*UTMDACC, Science Park, Smithville, TX, USA.*

Hydroquinone (HQ) is a rodent nephrocarcinogen that generally tests negative in standard mutagenicity assays. 2,3,5-*Tris*-(glutathion-*S*-yl)HQ (TGHQ) is a potent nephrocarcino-genic metabolite of HQ in the Eker rat. The Eker rat carries a germline mutation in the Tsc-2 tumor suppressor gene which predisposes these rats to the development of renal cell carcinoma. We now report that tumor formation in Eker rats exposed to HQ and TGHQ involves two events: the first being the inherited germline mutation of the Tsc-2 gene, and the second, induced by HQ and TGHQ, results in loss or mutation of the remaining normal allele of this gene. Loss of heterozygosity at the Tsc-2 locus, with subsequent loss in tuberin expression, the protein product of the Tsc-2 gene, occurs in tumors obtained from Eker rats treated with HQ (0.45 μmol/kg, 10 mo) or TGHQ (2.5 μmol/kg for 4 mo followed by 3.5 μmol/kg for 6 mo) suggesting that the Tsc-2 gene functions as an efficient tumor suppressor gene in normal renal tissue, and that HQ and TGHQ cause alterations in this gene. Tumor formation in TGHQ treated rats is preceded by the overexpression of transforming growth factor α (TGF-α) in preneoplastic lesions (obtained 4 mo after initiation of treatment) suggesting that TGF-α plays an important role in supporting tumor development during renal carcinogenesis. HQ and TGHQ were also capable of transforming isolated renal epithelial cells *in vitro*. Transformation frequency increased 6-20 fold and 1.8-4.0 fold in TGHQ and HQ treated cells, respectively. The data confirm that TGHQ is a nephrocarcinogenic metabolite of HQ and that loss of Tsc-2 gene function and overexpression of TGF-α play important roles in tumor development. (GM39338, ES07784, CA63613)

1836 DICHLOROETHYLENE INHIBITION OF ANION SECRETION IN MICROINJECTED HEPATOCYTE COUPLETS.

K A Mericle[1], A Mitchell[1], M T Moslen[1], D C Liebler[2], and S A Weinman[1]. [1]*Univ. of Texas Med. Branch, Galveston, TX, USA;* [2]*Univ.of Arizona, Tucson, AZ, USA.*

1,1-Dichloroethylene (DCE), a contaminant in drinking water, selectively produces liver injury including damage to bile canalicular membranes and defective hepatic secretion of organic anions. In order to determine the mechanisms of DCE-induced inhibition of transport, we used an isolated cell system to examine substrate specificity, reversal agents and the role of a specific DCE-glutathione conjugate. METHODS: Isolated hepatocyte couplets were prepared by collagenase-perfusion of rat liver. Secretion of fluorescent anions into dilated canalicular spaces was determined qualitatively by fluorescence microscopy and secretion rates were quantitated using serial confocal microscopy. Microinjection was performed by impalement of one cell of a couplet and pressure injecting through intracellular micropipets. RESULTS: DCE incubation (5 mM) of hepatocyte couplets inhibited carboxyfluorescein secretion (20% for DCE vs. 61% for control; $p<0.001$) but had no effect on fluorescent bile acid secretion (53% vs. 47%). Inhibition was not observed until 30 min and became maximal by 60 min. The DCE effect was not present in couplets pretreated with dibutyryl cAMP, known to recruit transport proteins to the canalicular membrane. The thiol reducing agent, dithiothreitol (2 mM) also completely prevented transport inhibition but did not reverse inhibition after DCE exposure. These results suggested that thiol-reactive intermediates may be involved. We started to test this hypothesis by simultaneously microinjecting the known DCE conjugate S-2-chloroacetylglutathione (CAG) and a fluorescent transport substrate intracellularly into hepatocyte couplets. CAG injection had no apparent immediate effect on secretion. CONCLUSIONS: Our data suggest that DCE-inhibition of hepatic transport is not simply the result of a rapidly produced glutathione conjugate serving as a direct inhibitor of a canalicular membrane transport protein. The slow onset of the effect, as well as prevention by cAMP suggests that a more delayed process, such as DCE-attenuated recruitment of transporters to the canalicular membrane may be involved. 1837 ROLE OF GLUTATHIONE IN THE BILIARY EXCRETION OF ARSENICAL DRUGS.

Z Gregus and Á Gyurasics. *Department of Pharmacology, University Medical School of Pécs, Pécs, Hungary.*

After administration of the inorganic sodium arsenite or arsenate to rats, the biliary excretion of arsenic (As) is rapid, is accompanied by the biliary output of large amounts of glutathione (GSH) and is completely arrested by the GSH depletor diethyl maleate (Gyurasics et al., Biochem. Pharmacol. 41: 937, 1991; 42: 465, 1991). We have studied the biliary excretion of trimelarsan (TMA) and melarsoprol (MAP) in rats in order to determine whether GSH is also involved in the hepatobiliary transport of these trivalent organic arsenicals that are used as therapeutic agents. After injection of either drug (100 μ mol/kg iv), as was rapidly excreted in bile (up to 1 μmol/kg/min, ~ 55% of dose/100 min). Concurrently, TMA and MAP increased the biliary output of GSH 2 and 5 fold, and lowered the hepatic GSH content by 24% and 27%, respectively. In TMA-injected rats, pretreatment with diethyl maleate or buthionine sulfoximine decreased the initial biliary excretion of As by 75% and 40%, respectively, whereas in MAP-injected rats these GSH depletors diminished As output by 45% and 20%. HPLC analysis of the bile collected after administration of TMA or MAP indicated the presence of the same GSH conjugate (purportedly melarsen-diglutathione) representing ~ 80% and ~ 45% of biliary metabolites, respectively. Some TMA was also excreted in the bile unchanged, whereas MAP appeared there also as two glucuronides amounting to ~ 50% of the biliary MAP metabolites. The GSH depletors virtually prevented the biliary excretion of TMA and MAP as the GSH conjugate, but did not diminish, or even increased, their excretion in other forms. These studies indicate that the biliary excretion of TMA and MAP (1) is significant in their disposition, (2) is partially dependent on the hepatic availability of GSH, as these arsenicals are excreted in part as a GSH conjugate, and (3) is concomitant with increased appearance of GSH in bile, probably originating from dissociation of the unstable GSH conjugate of these arsenicals. Thus, conjugation with GSH is important in the elimination of both TMA and MAP, however, glucuronidation is also involved in the fate of MAP.

1838 SUSPENSIONS OF FRESHLY ISOLATED RAT HEPATOCYTES GENERATE HIGH LEVELS OF NITRIC OXIDE.

F A Nicholls-Grzemski, M A Tirmenstein, and M W Fariss. *College of Pharmacy, Washington State University, Pullman, WA, USA.*

Nitric oxide (NO) is a reactive radical and intracellular/intercellular messenger. NO can induce numerous biochemical alterations in hepatocytes including inhibition of protein synthesis, mitochondrial respiration and CYP450 activities. In addition, NO can act as an antioxidant by scavenging reactive oxygen species and inhibiting lipid peroxidation. We investigated NO production in freshly isolated rat hepatocyte suspensions. Hepatocytes were isolated by standard collagenase perfusion techniques and incubated in modified Waymouths media at 37ûC for 6 hours. Extracellular nitrite levels (a breakdown product of NO) were measured by a fluorimetric assay. The level of extracellular nitrite remained at basal levels (<0.2 nmole/10^6 cells) for approx. 3 hours post-isolation, which was followed by a rapid increase in nitrite formation reaching 5 to 10 nmole/10^6 cells by 6 hours, constituting an up to 100-fold increase in nitrite level. The formation of nitrite was blocked by the nitric oxide synthase (NOS) inhibitors, N-methyl arginine or aminoguanidine. The nitrite burst was also inhibited by a nontoxic concentration of the protein synthesis inhibitor, cycloheximide. Collectively, these findings suggest that hepatocytes in suspension produce high levels of NO and that the inducible form of NOS may be involved. The NO production by hepatocyte suspensions was also inhibited by thiol depleting agents including diethylmaleate, ethylmethane sulphonate and N-ethylmaleimide, and the absence of extracellular calcium. In addition, antioxidants such as trolox and deferoxamine, were shown to both delay and attenuate nitrite production suggesting a relationship between the formation of reactive oxygen species and nitrite. These results provide the first evidence of marked NO production by rat hepatocyte suspensions that may have important implications for both mechanistic and metabolic studies conducted with this model system. (This work was supported by NIEHS/NIH grant # R01ES 05452.)

1839 MECHANISMS OF RESISTANCE TO OXIDATIVE STRESS INDUCED BY EXPOSURE TO NITRIC OXIDE.

L A Ridnour, P C Goswami, L Albee, C R Hunt, A Parsian, J Sim, and D R Spitz. *Section of Cancer Biology, Radiation Oncology Center, Washington University Medical School, St. Louis, MO.*

Pretreatment of mammalian cells with H2O2 has been shown to induce an oxidative stress response which enables cells to resist cytotoxicity associated with further challenge by higher levels of oxidants (J. Cell. Physiol. 131:364-373; Arch. Biochem. Biophys. 318:231-240). The hypothesis that nitric oxide (NO() is capable of inducing a similar response was tested. HA1 hamster fibroblasts were pretreated with media containing approximately 1.5 mM genuine NO(, or 2.5x10-13 moles/cell H2O2 as a positive control. When challenged with H2O2 8 to 48 hrs following pretreatment, both NO(- and H2O2-pretreated cells demonstrated resistance to H2O2-induced clonogenic inactivation when compared to N2 and sham treated controls. NO(induced resistance to oxidative stress appeared to be maximal between 8 and 24 hrs following pretreatment. The accumulation of c-fos and c-jun mRNA and immunoreactive protein also increased between 0 and 8 hrs following pretreatment. Inhibition of glutathione synthesis during the first 8 hrs of recovery following NO(-pretreatment inhibited the development of resistance to H2O2-mediated cytotoxicity. These data show that nitric oxide pretreatment induces resistance to subsequent challenge with H2O2-induced oxidative stress. Furthermore, these results suggest that nitric oxide exposure is capable of inducing an adaptive response to oxidative stress in mammalian cells and this adaptive response requires the presence of glutathione. (Supported by HL51469 and ESO578101.)

1840 1,2-DICHLOROBENZENE INDUCES OXIDATIVE STRESS IN HEPATOCYTES ISOLATED FROM FISCHER-344 AND SPRAGUE-DAWLEY RATS.

H S Younis, N C Hoglen, A R Parrish, R K Kuester and I G Sipes. *Dept. of Pharmacology/Toxicology, Center for Toxicology, College of Pharmacy, The University of Arizona, Tucson, AZ.*

1,2-Dichlorobenzene (1,2-DCB) is used as an industrial solvent and is present in the environment. Although 1,2-DCB is a potent hepatotoxicant in male rats, the Fischer-344 (F-344) rat is far more susceptible to liver injury than the Sprague-Dawley (SD) rat. Studies performed *in vivo* indicate that 1,2-DCB-induced hepatocellular oxidative stress, marked by increased glutathione disulfide (GSSG) production, is greater in F-344 rats than in SD rats. This difference in oxidative stress between the rat strains may explain their differential sensitivity to 1,2-DCB-meditated liver injury. The objective of this study was to determine if the differences in oxidative stress between F-344 and SD rats could be observed in vitro in primary cultured hepatocytes and if this oxidative event corresponds to differences in activating protein (AP-1) transcription factor activity. Hepatocytes were isolated from naive F-344 and SD rats and treated with 1,2-DCB (0-20 nmol, in vapor phase) for 0-13 hr prior to measuring lactate dehydrogenase (LDH) activity, the concentrations of glutathione (GSH) and GSSG, and AP-1 activity. Interestingly, the cytotoxicity of 1,2-DCB in isolated hepatocytes as determined by LDH leakage into media was similar for both F-344 (LC_{50} = 6.5 nmol) and SD (LC_{50} = 7.4 nmol) rats. In contrast, treatment of hepatocytes with 1,2-DCB altered the concentrations of GSH and GSSG only in cells isolated from F-344 rats, but not SD rats. In F-344 rat hepatocytes treated with 1,2-DCB (3.55 nmol) GSSG concentrations were maximally elevated (by 15%) at 1 hr, while GSH concentrations were reduced (to 78% of control) by 6.5 hr. Enhanced translocation of AP-1 into the nucleus was observed in hepatocytes of both rat strains 4 and 6 hr after 1,2-DCB (3.55, 7.1 and 12.43 nmol) treatment, providing a molecular marker of oxidative stress. These *in vitro* results correlate with previous *in vivo* data that show the oxidative stress that occurs within the hepatocyte following 1,2-DCB treatment is greater in the F-344 rat. 1841 ACRYLONITRILE-INDUCED OXIDATIVE STRESS IN NORMAL HUMAN ASTROCYTES.

S Jacob and A E Ahmed. *Department of Pathology, University of Texas Medical Branch, Galveston, TX.*

Previous studies in our laboratory and others have indicated that Acrylonitrile (VCN) induces acute and chronic neurotoxicity and brain tumor in animal microglial cells. Glutathione (GSH) depletion was suggest-

ed as the initiator of oxidative stress in VCN-induced neurotoxicity and immunotoxicity. Astrocytes possess 30% of total brain GSH and express various immunological characteristics including secretion of cytokines. We hypothesize that astrocytes could be a primary target cells for VCN effects in the brain. Therefore, the mechanism of VCN-induced neurotoxicity was studied by exposing proliferating NHA to various doses of VCN (100- 400μ M). Oxidative stress, secretion of TNF-α, damage to cell membrane and levels of endogenous antioxidants including GSH and cattalos were assessed. The results indicate: (1) a dose dependent increase (150-300% of control, P< 0.05) in the formation of reactive oxygen intermediates (ROI), (2) levels of promutagenic DNA lesion (8OHdG) were elevated at 400μ M of VCN to 275% of control, (3) depletion of GSH and increased GSSG levels (GSH/GSSG ratios in control and treated cells were 3.15 and 1.45 respectively), (4) catalase activity was increased (135% of control) at 100μ M VCN, while at 400μ M its levels were 60% of control (P< 0.05), (5) increased secretion of TNF-α at 400μ M VCN. (6) a dose dependent increase in LDH (160-220% of control) with corresponding decrease in cell viability. The current studies suggest that VCN-induces oxidative stress in astrocytes and depletion of GSH and catalase may further enhance VCN-induced microglial damage.

1842 ACRYLONITRILE INDUCES THE RELEASE OF TUMOR NECROSIS FACTOR-α (TNF-α), ALTERS GLUTATHIONE HOMEOSTASIS AND ACTIVATES OXIDATIVE STRESS IN MOUSE ALVEOLAR MACROPHAGES.

Y Moustafa[1], E El-Dinshary[2] and AE Ahmed[1]. [1]*Dept. of Pathology, University of TX Medical Branch, Galveston, TX; and* [2]*Dept. of Pharmacology, Faculty of Pharmacy, Suez Canal University, Suez, Egypt.*

Acrylonitrile (VCN), widely used monomer induces lung toxicity and cancer. The mechanism by which VCN induces its pulmonary toxicity was investigated using mouse alveolar macrophages (MAM). MAM were exposed to various concentrations of VCN (50-400μ M) for 4hr. The release of TNF-α was quantitated by ELISA and formation of reactive oxygen species (ROS) was determined flourometrically. Oxidative status of the macrophages was examined by measuring intracellular glutathione (GSH/GSSG) using standard redox cycling assay. The results indicate: (1) The viability was significantly ($p < 0.05$) decreased following exposure of MAM to various concentration of VCN (75% to 37% of control). (2) A concentration dependent increase in ROS formation ($p < 0.05$) and maximum levels of ROS (240% of control) were detected at 400μ M VCN. (3) An increase in extra-cellular TNF-α levels with only 400μ M VCN induced statistically significant ($p < 0.05$) increase (118% of control). (4) A concentration dependent decrease ($p < 0.05$) in reduced GSH (85% and 74% of control). (5) A significant ($p < 0.05$) increase in the formation of oxidized glutathione (GSSG) (197% of control) indicating that the cells are undergoing oxidative stress. The data provide evidence that the mechanism of VCN induced pulmonary toxicity could be mediated via activation of alveolar macrophage functions and depletion of the intracellular antioxidant, glutathione. ROS interact with membrane lipids or DNA causing oxidative cellular damage that may be lead to pulmonary toxicity or cancer.

1843 n-PROPYLTHIAZOLIDINE CARBOXYLIC ACID (PTCA) STIMULATION OF HEPATIC GLUTATHIONE (GSH) RECOVERY AFTER DEPLETION BY DIETHYLMALEATE (DEM) IN THE RAT.

C Srinivasan[1], T S Chen[1], H T Nagasawa[2], and W M Williams[1]. [1]*University of Louisville, Louisville, KY, USA;* [2]*VA Medical Center, Minneapolis, MN, USA.*

The ability of PTCA, a cysteine (Cys) precursor, to stimulate GSH recovery after depletion by DEM was investigated using the isolated perfused rat liver. DEM in corn oil (6 mmol/kg) was injected ip 30 min before the start of surgery. After perfusion for a 30-min equilibration period (time zero), PTCA was added to the recirculating fluid (100 ml). GSH and Cys in serial liver, bile, and blood samples were determined by HPLC with electrochemical detection. In livers from untreated rats (n=5-6), GSH and Cys concentrations were 4.7 &πλυσμν; 0.6 and 0.08 &πλυσμν; 0.06 μmol/g, respectively, at time zero and 3.9 &πλυσμν; 0.5 and 0.02 &πλυσμν; 0.02 μmol/g, respectively, at 4 h. Cumulative biliary excretion (4.5 h of perfusion) of GSH and Cys was 72 &πλυσμν; 20 and 28 &πλυσμν; 11 nmol/g, respectively. DEM pretreatment (n=3-5) significantly ($p<0.05$) decreased hepatic GSH concentration (to 0.4 &πλυσμν; 0.4 μmol/g at time zero and 2.1 &πλυσμν; 0.9 μmol/g at 4 h) and cumulative biliary GSH excretion (to 15 &πλυσμν; 4 nmol/g). In livers from DEM-pretreated animals, PTCA caused dose-related increases in hepatic sulfhydryl levels. At a PTCA dose of 1 mmol (n=5-7), hepatic Cys increased to 0.4 &πλυσμν; 0.1 μmol/g at 1 h ($p<0.05$), and then plateaued. Hepatic GSH increased continuously to 10 &πλυσμν; 1 μmol/g at 4 h ($p<0.05$). There were also significant increases in blood Cys at 4 h (from 0.001 &πλυσμν; 0.002 to 0.2 &πλυσμν; 0.05 μmol/ml) and cumulative biliary Cys excretion (to 149 &πλυσμν; 52 nmol/g). The results demonstrate that PTCA stimulates GSH recovery after depletion by DEM and suggest that the effect involves the release of Cys for GSH synthesis.

1844 GLUTATHIONE DEPLETION IN PRIMARY RAT HEPATOCYTES AS AN ADDITIVE EFFECT OF DIFFERENT TOXIC MECHANISMS.

A Freidig, M Hofhuis, I van Holsteijn and J Hermens. *Research Institute of Toxicology, Utrecht University, Utrecht, The Netherlands.* Sponsor: M van den Berg.

The toxicity of acrylic and methacrylic acid esters and structurally similar compounds is often thought to be related to the electrophilic chemical reactivity of their unsaturated carbon bond. Experimental reaction rates of these compounds towards glutathione show a clear distinction between the fast reacting acrylates and the slow reacting methacrylates. However, some slow reacting methacrylates show a very high toxicity. This implies that reactivity at the unsaturated carbons is not the only toxic mechanism. The present work tested an alternative toxic mechanism of these compounds: hydrolysis of the ester moiety. Glutathione depletion was used as an effect measurement for both mechanisms. Primary rat hepatocytes were exposed in air-tight culture flasks to acrylates or methacrylates for three hours. Lactate dehydrogenase(LDH) leakage, glutathione depletion in the cells and the release of malondialdehyde(MDA) and acetaldehyde into the medium were measured at the end of the exposure period. The results show that the alcohol moiety of the reactive esters can be liberated by hydrolysis. For allyl methacrylate, allyl alcohol will be formed, known to produce lipid peroxidation(LPO) in the liver. High MDA concentrations were indeed found in cells exposed to allyl methacrylate which indicates LPO. For allyl methacrylate, GSH depletion is paralleled by LDH leakage. For the chemically reactive acrylates, glutathione depletion was found to be a more sensitive parameter than LDH leakage. In mixture experiments with different acrylates and methacrylates, glutathione depletion was shown to be a concentration additive effect.

1845 EFFECT OF CHRONIC ACRYLONITRILE ADMINISTRATION ON GLUTATHIONE STATUS IN RATS.

T S Chen, D Corbett, J Li and F W Benz. *Department of Pharmacology and Toxicology, University of Louisville, Louisville, KY, USA.*

We found earlier that acrylonitrile (AN) produced a dose-dependent depletion of glutathione (GSH) and cysteine (Cys) in many tissues following acute administration (Toxicologist 36:80, 1997). Little is known about GSH status following chronic exposure. The aim of this study was to determine the effects of chronic AN treatment in rats. Male Sprague-Dawley rats were exposed to AN at 10, 50, and 100 ppm in drinking water for 7, 14, and 28 days. GSH, Cys, and glutathione disulfide (GSSG) concentrations in five tissues were measured by HPLC with electrochemical detection. AN-valine adduct formation in blood was also determined. AN produced dose-dependent increases in forestomach (FS) GSH concentration. At 50 and 100 ppm, GSH concentrations in FS increased to 148 and 182%, respectively, of untreated control values after 7 days of treatment. The elevated levels persisted up to day 28. No effect was found at 10 ppm. In glandular stomach, the only significant increase in GSH was found at 100 ppm. No changes in GSH levels were found in the other tissues studied (liver, kidney and heart). FS Cys levels were increased only in animals exposed to AN at 100 ppm for 28 days. AN had no effect on tissue GSSG concentrations. AN produced time- and dose-dependent increases in AN-valine adduct formation. It was concluded that chronic exposure to AN results in increases in GSH and Cys in selective tissues. (Supported by NIEHS P20 ES06832.)

1846 EFFECTS OF AN ACUTE ETHANOL ADMINISTRATION ON HEPATIC GLUTATHIONE IN RATS.

Y C Kim and D W Choi. *College of Pharmacy, Seoul National University, Seoul, Korea.*

Factors implicated in changes of the hepatic glutathione (GSH) concentration following an acute ethanol administration were examined in rats. Adult female rats treated with either ethanol (4 g/kg, po) or an isocaloric amount

of glucose were sacrificed at 0, 2.5, 6, 12, 16 or 24 hr following the treatment. At the dose of ethanol used the hepatic GSH concentration decreased rapidly after the ethanol intoxication with the maximum response being observed at t = 6 hr. The hepatic GSH concentration was increased gradually and finally rebounded when determined at 24 hr after the ethanol ingestion. An acute dose of ethanol did not induce a significant change in the hepatic GSSG concentration throughout the period. The activity of ?-glutamylcysteine synthetase (GCS), the rate limiting enzyme of GSH synthesis, and the cysteine concentration in the liver were also measured. The GCS activity was significantly inhibited at t = 2.5 hr after the treatment, but the hepatic cysteine concentration was not altered for 24 hr. The sinusoidal efflux of GSH from the liver was determined by subtracting the GSH concentration in blood of the prehepatic inferior vena cava from that of the posthepatic inferior vena cava. Acute ethanol administration induced a remarkable increase in GSH efflux from the liver at t = 2.5 hr. The results indicate that a transient decrease in GCS activity and an increase in GSH efflux from the liver may be responsible for the decrease in the hepatic GSH concentration observed in rats treated with ethanol acutely.

1847 GLUTATHIONE DEPLETION AND HEPATOTOXICITY FOLLOWING ADMINISTRATION OF HERBICIDE ALACHLOR.

B A Wetmore[1], R T Miller[2] and S A Meyer[1]. [1]*Department of Toxicology and* [2]*College of Veterinary Medicine, North Carolina State University, Raleigh, NC, USA.*

Alachlor (2-chloro-2',6'-diethyl-N-(methoxymethyl)-acetanilide) is a chloroacetanilide herbicide with hepatotoxic effects believed to be mediated through metabolic activation to a quinone imine. The model hepatotoxicant acetaminophen also acts through a quinone imine with resultant depletion of glutathione (GSH). To determine whether a similar mechanism is involved in the toxic effect of alachlor, we compared the dose-response for alachlor hepatotoxicity with modulation of hepatic GSH levels. Male Long-Evans rats (10 wks old) were exposed to alachlor at doses ranging from 126-600 mg/kg (ip in dimethyl sulfoxide) and sacrificed 2, 4, and 24h after administration. The lowest observed hepatotoxic effect level, as evidenced by histopathology (centrilobular hepatocyte vacuolation) and increased serum enzyme levels (alanine aminotransferase and sorbitol dehydrogenase) was 400 mg/kg, while lethality occurred at 600 mg/kg. At nonhepatotoxic doses of alachlor (≤ 200 mg/kg), determination of GSH as non-protein sulfhydryls showed a transient drop to 50% of control levels at 2h, a rebound to 80% at 4h and full recovery by 24h after administration. In contrast, GSH levels remained depressed by 40% at 24h after administration of a hepatotoxic dose (400 mg/kg). These results demonstrated that depletion of GSH occurred at all dose levels with alachlor exposure, but hepatotoxicity only resulted at doses high enough to sustain GSH depletion for 24h. Thus, alachlor hepatotoxicity parallels that of acetaminophen in that both require prolonged GSH depletion. (NIH ES00044, ES07046, and North Carolina ARS)

1848 MITOCHONDRIA-SPECIFIC EXPRESSION OF GLUTATHIONE REDUCTASE.

J P Katkin, X Xu, R S Geske, T Tamura, S E Welty, and C V Smith. *Dept. Pediatrics, Baylor College of Medicine, Houston, TX.*

Glutathione reductase (GR) regenerates glutathione (GSH) from glutathione disulfide (GSSG) in a process essential for function of GSH-dependent antioxidant systems. Chinese hamster ovary (CHO) cells stably transfected with the (human) hGR cDNA have increased resistance to oxidant-mediated cytotoxicity coincident with increased cytosolic GR activities. Modification of the hGR plasmid to include the mitochondrial targeting signal (MTS) for human MnSOD increased GR activities in mitochondrial and cytosolic fractions prepared and assayed by standard procedures, and imparted even greater resistance to oxidants. As the MTS-hGR construct retains the original hGR start codon 3' to the MTS, we tested the hypothesis that initiation of translation at the ATG in the hGR sequence could be responsible for the increased cytosolic GR activities observed in cells transfected with the MTS-hGR construct. We mutated the initial ATG of the hGR cDNA and transfected CHO cells with this construct, but still observed increases in GR activities in both cytosolic and mitochondrial fractions. When cells transfected with either the original or the mutated MTS-hGR construct were examined immunohistochemically using an anti-hGR antibody, GR appeared more specifically associated with the mitochondria than was apparent from the functional assays. Additional studies revealed that differential centrifugation after careful cell disruption using a triethanolamine-based procedure demonstrated highly selective increases in GR activities more compatible with the immunohistochemical findings. Neither assay revealed clear differences between cells transfected with the MTS-hGR and the mutated MTS-hGR constructs. Similar investigations of stably transformed CHO cells containing two intact ATG codons 5' to the MTS and GR coding sequences also indicated highly preferential expression of hGR in mitochondria. These results suggest that translation of MTS-hGR begins preferentially at the MTS start site and the resultant protein is directed to the mitochondria efficiently. The greater resistance to oxidant injury imparted to cells by increased mitochondrial expression of hGR is even more striking in view of the present data indicating that these cells have limited increases in cytosolic GR activities. (Supported by NIH GM44263 and U10 HL52637.)

1849 NRF-2, SMALL MAF PROTEINS AND AP-1 FAMILY MEMBERS REGULATE THE EXPRESSION OF THE γ -GLUTAMYLCYSTEINE SYNTHETASE (GCS) GENES VIA ELECTROPHILE RESPONSE ELEMENTS (EpRE).

A C Wild, H Moinova, J J Gipp and R T Mulcahy. *University of Wisconsin-Madison, Dept of Human Oncology, Madison, WI.* Sponsor: A Elfarra.

Basal as well as β -naphthoflavone- (β NF) and pyrrolidine dithiocarbamate-(PDTC) induced expression of the genes encoding the catalytic (GCS_h) and the regulatory (GCS_l) subunits of γ -glutamylcysteine synthetase (GCS) are regulated by EpREs. These EpREs contain internal AP-1 binding sites, are both adjacent to AP-1 or AP-1-like binding sites and share sequence similarities to TRE-like Maf Responsive Elements (T-MARE) and NF-E2 binding sites. We hypothesized that transcription factors including members of the AP-1 and small maf families, as well as the NF-E2-related proteins, Nrf1 and Nrf2, regulate the expression of the genes via binding to EpRE sequences. Electromobility supershift studies have identified proteins binding GCS_h/EpRE4 and GCS_l/EpRE1 present in nuclear extracts isolated from HepG2 cells. Both sequences are bound by proteins recognized by antibodies to Nrf2, JunD and small maf proteins. Northern analyses revealed increases in small maf mRNA transcripts following β NF and PDTC exposure. The timing of the increases in small maf mRNA levels preceded that of GCS_h and GCS_l induction following treatment with either agent. Transient transfection with an AP-1 dominant negative mutant (AFos) reduced constitutive expression (0.5X) and β NF-induced (0.4X) expression of GCS_l 5'-luciferase reporter constructs, but the effect on GCS_h 5'-luciferase reporter constructs was minimal (0.8X, for basal and β NF-induced expression). The dominant negative small maf mutant (DNmafK) significantly decreased basal expression and eliminated β NF inducibility of GCS_l 5'-luciferase reporters. These data provide evidence for the involvement of Nrf2, small maf factors and AP-1 family members in the regulation of GCS subunit genes via EpREs. (Supported by NIH CA57549.)

1850 CORRECT STRUCTURAL ORGANIZATION AND LOCATION OF THE HUMAN MICROSOMAL GLUTATHIONE TRANSFERASE GENE (MGST1): TRANSCRIPTIONAL UP-REGULATION IN RESPONSE TO OXIDATIVE STRESS.

M J Kelner[1], R D Bagnell[1], M A Montoya[1], L Forsberg[2], and R Morgenstern[2]. [1]*UCSD, San Diego, CA;* [2]*Karolisnka Institute, Stockhom, Sweden.*

The structure and regulation of the microsomal glutathione transferase gene (MGST1) is considerably more complex than originally perceived to be. We determined that the MGST1 gene is located in the 12p13.1-13.2 region and there are two alternative first exons. The region between these two first exons is not capable of directing transcription. Thus, there is one common promoter element capable of directing transcription, and RNA splicing occurs such that only one type of exon 1 is incorporated into each mRNA species with common downstream exons. MGST1 expression and regulation is therefore similar to other hepatic xenobiotic handling enzymes such as γ-glutamyl transferase and CYP19. The MGST1 gene was previously considered a "housekeeping" gene as non-oxidant inducers of cytosolic glutathione transferases had little affect on MGST1 activity. However, we discovered that the true MGST1 promoter region (region immediately upstream of the dominate first exon) is capable of transcriptionally responding to oxidative stress. In this respect, MGST1 is similar to glutathione peroxidases which also transcriptionally respond to oxidative stress. The discovery that MGST1 utilizes alternative splicing of the first exon eliminates the theoretical problem noted with the first description of MGST1 cDNA structure in which it appeared that high expression of MGST1 was in violation of the ribosomal

scanning model, due to the presence of an in-frame stop codon and an out-of-frame ATG codon upstream of the initiating ATG codon. The identification that the first exon originally noted is in fact a minor alternative first exon far downstream of the correct MGST1 promoter region and primary first exon eliminates this conundrum. The discovery that MGST1 can transcriptionally respond to oxidative stress is supportive of the idea that specific toxic compounds can activate or induce select enzymes to hasten their own demise. However, if the compound is a haloalkenes such as chlorotrifluoroethene, which after GSH-conjugate formation by MGST1 is converted to a nephrotoxin, the development of a pro-oxidant state may have adverse consequences for the organism.

1851 GROWTH RATE AND EFFECTS OF METHYL MERCURY ON SURVIVAL RATE AND MITOCHONDRIAL TRANSMEMBRANE POTENTIAL IN HEPA-1 CELLS OVEREXPRESSING GLUTAMATE-CYSTEINE LIGASE.

S Shi, S Lu, D Botta, and T J Kavanagh. *Department of Environmental Health, University of Washington, Seattle, WA, USA.*

GSH is important in defending against oxidative stress and heavy metal toxicants especially mercurials. MeHg can accumulate in mitochondria which results in decreased mitochondrial transmembrane potential (MTP). The rate limiting enzyme in GSH synthesis is glutamate-cysteine ligase (GLCL) which is composed of catalytic (GLCLc) and regulatory (GLCLr) subunits. We developed cells with metallothionein promoter-regulatable overexpression of either GLCLc alone, GLCLr alone or in combination to test the hypothesis that increased GSH synthetic ability can protect cells from oxidative stress and perturbations in MTP caused by MeHg exposure. Colony size distribution was evaluated as a measure of growth rate of these cells. In addition, colony forming efficiency was counted after four days of exposure to MeHg. After exposure to MeHg for 8 hours, GLCLc cells were stained with CMX-rosamine and MitoTracker Green mitochondrial stains and examined by confocal laser scanning microscopy. Cells overexpressing GLCLc were the most resistant to MeHg with or without induction by Zn^{++}. Cells overexpressing GLCLr became more resistant to MeHg when pretreated with Zn^{++} 20 hrs before the MeHg treatment. The growth rates of all GLCL-transfected cells are lower than control cells. With 25μ M Zn^{++}, the colony size of the control cells decreased while GLCL cells did not show much change. MeHg caused a dose-related decrease in mitochondrial transmembrane potential in cells transfected with the plasmid vector containing no insert. GLCLc cells were protected from this effect of MeHg. These results show that excess GSH suppresses growth rates but increased synthesis of GSH helps to protect cells from oxidative stress and perturbations of MTP caused by MeHg.

1852 EFFECT OF OVEREXPRESSION OF GLUTAMATE-CYSTEINE LIGASE ON TNF AND ACTINOMYCIN-D-INDUCED APOPTOSIS IN HEPA-1 MOUSE LIVER CELLS.

D Botta, C C White, C M Krejsa, R H Pierce, N Fausto, D L Eaton and T J Kavanagh. *Departments of Environmental Health and Pathology, and NIEHS Center for Ecogenetics and Environmental Health, University of Washington, Seattle, WA.*

Glutathione (GSH) has been shown to be important in free radical scavenging, cellular redox status and to influence the survival of cells to a wide variety of toxicants. The rate limiting enzyme in the synthesis of GSH is glutamate-cysteine ligase (GLCL), which is composed of catalytic (GLCLC) and regulatory (GLCLR) subunits. We have developed mouse liver (hepa-1) cell lines with increased expression of GLCLC, GLCLR, or the combination by transfecting the mouse cDNAs for these genes and selecting for cells that expressed the transgenes. Cells overexpressing the mRNA for the catalytic subunit alone have modest increases in GLCL activity, while cells overexpressing both subunits have large increases in GLCL activity. When cells overexpressing GLCLC+GLCLR are exposed to tumor necrosis factor TNFα in combination with actinomycin D, they exhibit decreased rates of apoptosis (as indicated by loss of redox potential and mitochondrial membrane potential) when compared to cells transfected with the plasmid vector alone. These cell lines should provide an interesting model to examine the influence of GSH in moderating toxicant induced necrosis and apoptosis. (This work was supported by NIH Grants ES04696, AG01571and ES07033.)

1853 REGULATION OF γ-GLUTAMYLCYSTEINE SYNTHETASE mRNA IN THE PREIMPLANTATION MOUSE EMBRYO.

S K Stover, G A Gushansky, and C S Gardiner. *Department of Biological Sciences, University of Northern Colorado, Greeley, CO.*

The present study examined the regulation of glutathione synthesis in the preimplantation mouse embryo in terms of γ-glutamlycysteine synthetase (GCS) expression. Previous studies indicate that glutathione concentration decreases 90% during the first four days of development, and the embryo only begins synthesizing glutathione de novo at the blastocyst stage. Consequently, the cleavage stage embryo may be very sensitive to glutathione-depleting toxicants and reactive oxygen species. GCS is the rate limiting enzyme for de novo glutathione synthesis, and its activity may be upregulated in response to toxicant exposure or oxidative stress. It is hypothesized that GCS mRNA is not normally expressed in the cleavage stage embryo, but its expression may be induced by lowering glutathione levels to blastocyst-like concentrations. To address this possibility, the pattern of GCS gene expression in both cleavage stage embryos and blastocysts was examined by use of the reverse transcriptase-polymerase chain reaction (RT-PCR). Transcripts for GCS were detected only at the blastocyst stage. Furthermore, while diethyl maleate (DEM; 65μM) exposure to deplete cellular glutathione also resulted in GCS transcript expression in blastocysts, cleavage stage embryos were not induced to upregulate expression of GCS. To compare GCS transcript expression with cellular glutathione concentration, embryos were incubated with monochlorobimane, a thiol-reactive probe that is converted to a fluorescent product when conjugated to glutathione. Fluorescence microscopy indicates that, while both cleavage stage embryos and blastocysts are depleted of glutathione by exposure to DEM, only those at the blastocyst stage are capable of glutathione recovery. These results suggest that gene expression necessary for glutathione synthesis in the blastocyst is not initiated in response to decreased glutathione concentration but may be regulated by a developmental program.

1854 DISTRIBUTION OF GLUTATHIONE, GLUTATHIONE REDUCTION, AND GLUTATHIONE SYNTHESIS CAPABILITIES IN THE TROPHECTODERM AND INNER CELL MASS OF THE PREIMPLANTATION MOUSE EMBRYO.

G A Gushansky, S K Stover , and C S Gardiner. *Department of Biological Sciences, University of Northern Colorado, Greeley, Co.*

This study examined reduced glutathione (GSH), glutathione reduction and GSH synthesis within inner cell mass (ICM) and trophectodermal (TE) cells of the mouse blastocyst. Previous studies indicate that cleavage stage embryos are unable to synthesis GSH *de novo* until the early blastocyst stage. Differentiation of the TE into a transporting epithelium is the first step in mammalian development, and redox status has been shown to be important in cellular differentiation. Redundant pretrophectodermal cells within the ICM are eliminated via apoptosis, whereas cells that continue development are believed to be protected via glutathione-dependent protective mechanisms. To begin to understand the role of redox status in differentiation of the blastocyst, we examined GSH recovery in ICM and TE cells after treatment with either diethyl maleate (DEM) (65 micromolar) or t-butyl hydroperoxide (tBH) (130 micromolar) and following 3.5 hours of recovery. Two-cell embryos and blastocysts were incubated with monochlorobimane, a thiol reactive probe that fluoresces after conjugation with GSH. Fluorescent microscopy with photography were then used to evaluate GSH concentration in cells of intact two cell and blastocyst stage embryos. In addition, Immnunosurgery was used to isolate ICMs, and GSH concentrations were quantified by flourescent HPLC. Both DEM and tBH depleted GSH from two-cell embryos. tBH-treated two-cell stage embryos were able to recover GSH, at times showing upregualtion of GSH concentrations. Two-cell stage embryos did not recover GSH after DEM treatment. Blastocysts depleted of GSH by both tBH and DEM demonstrated recovery. Both the cells of the ICM and TE recovered GSH after DEM or tBH. In summary, GSH concentrations, GSH reduction, and GSH synthesis capabilities did not differ between ICM and TE. In conclusion, this study does not support a role for GSH status in differentiation of the blastocyst.

1855 PURIFICATION, CHARACTERIZATION AND REGIONAL DISTRIBUTION OF GLUTATHIONE *S*-TRANSFERASE FROM CHANNEL CATFISH INTESTINE.

B Gadagbui and M O James. *Department of Medicinal Chemistry, University of Florida, Gainesville, FL, USA.*

Our laboratory is interested in understanding the role of the intestine in the first pass of biotransformation of lipophilic xenobiotics that are presented in the diet at very low, environmentally relevant concentrations in the aquatic environment. Studies of benzo[a]pyrene biotransformation in catfish intestine showed that glutathione conjugates were major metabolites. Our objectives were to isolate and characterize catfish intestinal GSTs, examine conjugation of BaP oxides by intestinal cytosol and purified GSTs, and investigate distribution of activity and anti-catfish GST π cross-reactive protein in segments of the intestine of catfish fed a semi-purified diet or a commercial chow for at least two weeks. Results indicate that the predominant catfish intestinal GST isolated (Mr 26,700) is closely related to the π -class enzymes. The enzyme had good activity for benzo[a]pyrene-4,5-oxide, benzo(a)pyrene-7,8-dihydrodiol-9,10-epoxide, ethacrynic acid, and 1-chloro-2,4-dinitrobenzene, but a low activity with 1,2-cichloro-4-nitrobenzene. GST activity and the percent protein cross-reacting with anti-catfish GST π showed a gradient from the proximal (highest) to the distal section in both diet groups. The cross-reacting protein was significantly higher in the proximal and medial segments in the chow-fed fish, except in the distal segment where it was higher in fish fed purified diet. These results confirm that catfish intestinal GSTs play an important role in the first pass metabolism of PAH oxides produced in the intestine from dietary PAHs and suggests they provide protection against other xenobiotics, the proximal intestine likely playing a greater role that the distal. Also, it is possible that components of the commercial chow affect the localized activity of GST and percent cross-reacting GST protein in intestine. (Supported by ES 05781.)

1856 CORRELATION OF INCREASED MORTALITY WITH THE SUPPRESSION OF RADIATION-INDUCEDIBLE EPOXIDE HYDROLASE (EH) AND GLUTATHIONE S-TRANSFERASE (GST) GENE EXPRESSION DEXAMETHASONE (DEX).

S G Kim and S Y Nam. *College of Pharmacy, Duksung Women's University, Seoul, Korea.*

The present study was designed to investigate the effects of DEX on the radiation-inducible expression of EH and rGST genes and on the vitamin C and E-induced radioprotective effects in association with the expression of the genes. Treatment of rats with a single dose of DEX (0.01-1 mg/kg, po) caused a dose-dependent decrease in the constitutive EH gene expression at 24 hr. The radiation-inducible EH mRNA level (3-fold increase after 3 Gy γ -irradiation) was decreased by 21%-88% by DEX at the doses of 0.1-1 mg/kg. Although DEX alone caused 2- to 5-fold increases in the hepatic rGSTA2 mRNA level, rats treated with DEX prior to 3 Gy irradiation exhibited 80%-93% suppression in the radiation-inducible mRNA level. The inducible rGSTA3 and rGSTA5 mRNAs were also significantly decreased by DEX. Vitamin C and/or E failed to enhance the radiation-inducible increases in hepatic EH and rGST mRNAs. Whereas rats exposed to 3 Gy irradiation with or without vitamin C treatment exhibited ~3-fold increases in the EH and rGSTA2/3/5 mRNA levels relative to untreated animals, DEX treatment resulted in 64%-96% decreases in the mRNA levels. The inducible rGSTM1/2 mRNA levels in the vitamin C/E-treated rats were ~50% suppressed by DEX. Although vitamin C and/or E treatment (200 mg/kg/d, po, 2d) improved the 30-day survival rates of the 8 Gy γ -irradiated mice from 39% up to 74%, the improved survival rate of γ -irradiated animals was reduced to 30% by DEX pretreatment. DEX caused no significant hematologic changes. These results demonstrate that: DEX substantially suppresses radiation-inducible EH, rGSTA and rGSTM expression; vitamins C/E exhibit radioprotective effects without enhancing radiation-inducible EH and GST gene expression; and inhibition of radiation-inducible EH and rGST gene expression in the vitamin-treated animals by DEX was highly correlated with reduction in the survival rate of γ -irradiated animals.

1857 EFFECTS OF SELECTED PCB CONGENERS ON DRUG- AND GLUTATHIONE- METABOLIZING ENZYMES IN THE RAT.

T P Twaroski, P Espandiari and L W Robertson. *University of Kentucky, Graduate Center for Toxicology, Lexington, KY, USA.*

Although Polychlorinated Biphenyls (PCBs) have been banned from production in many countries since the early 1970s, they persist in our environment and accumulate in target tissues, such as adipose and breast tissues. PCBs may induce drug-metabolism and may be substrates for the induced enzymes. Metabolism of PCBs may lead to oxidative events within the cell. The goal of this study was to determine the influence of PCBs on glutathione and glutathione related enzymes. Sprague Dawley rats were injected with 100 µmol/kg of PCBs 3, 12, 28, 77, or 153 IP, each day for four days. Rats were sacrificed on day four 3 hours after the final injection, and their livers were surgically removed, snap frozen in liquid nitrogen, and stored at –80°C. Microsomes and cytosols were prepared and EROD (1A1), MROD (1A2), PROD (2B1&2), glutathione transferase (GST), glutathione reductase (GR), and total glutathione were determined. Experimental data showed that both male and female rats, treated with PCB 77, which is a ligand for the Ah receptor, had increased hepatic P450 1A1 activity, increased GST activity as well as a decreased level of total glutathione. Rats treated with PCB 153, a PB-like inducer, showed significant increases in hepatic P450 2B activity and GST activity. GR activity was also significantly increased by PCB 77 & 153 treatments. Interestingly, male rats treated with PCB 28, a PCB that is retained in breast tissue and milk, showed a significant increase in P450 2B and GR activities but, not in GST activity. These data will be interpreted in the context of oxidative stress occurring after PCB exposure. (P42 ES 07380 and DAMD 17-96-1-6162)

1858 SUB-CHRONIC EXPOSURE OF THIODIGLYCOL ON HEPATIC-MIXED FUNCTION OXIDASE AND CYTOSOLIC GLUTATHIONE ANTIOXIDANT SYSTEM IN RATS.

J K Vodela[1], R A Angerhofer[2], M W Michie[2], G Reddy[2], and G J Leach[2]. [1]*Dynamac Corporation Environmental Services, Aberdeen Proving Ground, MD;* [2]*US Army Center for Health Promotion & Preventive Medicine, Aberdeen Proving Ground, MD.*

In compliance with the National Environmental Policy Act, the US Department of Defense prepared a programmatic environmental impact statement for the chemical stockpile disposal program. The US Army has proposed to neutralize sulfur mustard through a hydrolysis process to convert it to a biodegradable compound, known as thiodiglycol (2-2-thiodiethanol) (TD). Thiodiglycol has been detected as a contaminant of soil and water at certain Army installations. We studied the effect of TD on the hepatic-mixed function oxidase system and cytosolic glutathione antioxidant system in male and female rats . Liver samples were collected from Sprague-Dawley rats gavaged with neat TD (99.9% pure) at dose levels of 50, 500 and 5000 mg/kg/day for 90-days (5days/week). The exposure to TD for 90 days resulted in a significant decrease in glutathione (500 and 5000 mg/kg), glutathione S-transferase activity (in all dose groups), and glutathione peroxidase (5000 mg/kg). Decreased cytochrome b5 (500, 5000 mg/kg) and pentoxy resorufin O-dealkylase (PROD) activity (5000 mg/kg) were found in male rats but no significant differences were observed in any of these parameters in female rats. These results demonstrate the biochemical interaction of TD on the hepatic PROD and cytosolic glutathione antioxidant system in male rats. (Abstract does not reflect US Army policy.)

1859 A PREVALIDATION STUDY FOR THE ECVAM/CFN INTEGRATED TOXICITY TEST SCHEME (ECITTS) USING KINETIC SIMULATIONS AND IN VITRO TEST METHODS.

J DeJongh and B J Blaauboer. *Research Institute of Toxicology, Utrecht University, Utrecht, The Netherlands.* Sponsor: M VandenBerg.

The European Centre for Validation of Alternative Methods (ECVAM) and the Swedish Board for Laboratory Animals (CFN) have initiated a series of studies on the prediction of systemic toxicity of chemicals through integration of non-animal (e.g. in vitro) studies with kinetic models. For a prevalidation study, eight chemicals (benzene, toluene, acrylamide, lindane, parathion, caffeine, diazepam and phenytoin), having documented effects on the nervous system, were selected. Studies on general and specific aspects of neurotoxicity were performed on these chemicals using an in vitro neurotoxicity test battery. In addition, in vitro-derived data on biotransformation and body distribution were used for parameterisation of a kinetic models for each compound. From these models, target tissue (i.e. nervous system) concentrations could be simulated as a function of acute and/or (sub)chronic exposure. Thus, Lowest Observed Effect Doses (LOEDs) for acute and/or (sub)chronic exposure could be estimated for six of the eight compounds and were compared with experimental LOEDs. The discrepancy between estimated and experimental LOEDs ranged from approximately a factor two, for relatively nontoxic compounds (i.e. a high LOED), to a factor 10, for relatively toxic compounds (i.e. a low LOED). LOEDs for some compounds could only be established after additional consideration of in vitro test results

that were derived from the literature and were not reflected by the endpoints within the in vitro neurotoxicity test battery.

1860 COMPARISON OF ESTIMATED INDOOR AIR CHEMICAL CONCENTRATION RESULTS FROM FATE AND TRANSPORT MODELING VERSUS SURFACE FLUX MEASUREMENTS.

J E Ryer-Powder, E Morabito, E Smith, and J Dagdigian. *Waterstone Environmental, LLC, Fullerton, CA, USA.*

Exposures to chemicals can result from both direct (dermal or ingestion) or indirect (vapors from chemicals in groundwater) contact. Estimation of exposure concentrations for use in health risk assessments requires calculated or actual measurements. To estimate indoor air concentrations of chemicals due to vapors migrating upwards from chemicals in groundwater, one can use environmental fate and transport modeling or perform surface flux measurements. Environmental fate and transport modeling makes use of chemical- specific and site-specific data as well as default parameters to estimate first a vapor flux (using a vapor flux model) and then an indoor air concentration (using a box model). Surface flux measurements are directly used in a box model to estimate indoor air concentrations. In this assessment, we compared the results of using default parameters and chemical-specific parameters in a vapor flux model with the results of using surface flux measurements to estimate indoor air concentrations. At the site used for this case study, tetrachloroethylene was present in groundwater located 15 feet below ground surface. The Farmer et al. model was used to estimate flux at a point above contaminated groundwater. Surface flux measurements were taken at a point above which the groundwater concentration was measured. The modeled flux was 2 orders of magnitude less than the actual flux. This resulted in a 2 order of magnitude difference in estimated indoor air concentration and, subsequently, cancer risk. Uncertainties in the modeled flux include use of default parameters for total porosity and air-filled porosity. The results of this assessment demonstrate the importance of validation of models as well as the importance of use of more site-specific parameters in models.

1861 A HUMAN HEALTH AND ECOLOGICAL ASSESSMENT OF VOLATILE COMPONENTS OF PM10 EMISSIONS.

M J Wernke, J D Schell, R A Budinsky, R P DeMott, and H D Jones. *ATRA Occupational and Environmental Services, Inc., Tallahassee, FL, USA.*

Approval for the construction of a fiberglass manufacturing facility under the California Environmental Quality Act required an environmental impact report concerning human health and ecological effects of likely constituents of stack PM10 emissions. Specifically, PM10 components consisted of phenol, formaldehyde and various methylol phenols (MPs) compounds. There are currently no air standards for MPs or cured phenol-formaldehyde resins. An assessment of the hazard characteristics was developed for the following compounds: 2-MP, 4-MP, 2,6-diMP, 2,4,6-triMP, and cured phenol-formaldehyde resins. A threshold air concentration for mono- and diMP, based on potential dermal sensitization (assessed as the most sensitive endpoint), was estimated to be 3100 $\mu g/m^3$ of air. Modeled air concentrations of PM10 indicated likely levels of these compounds would not exceed 16 $\mu g/m^3$. We predicted the likely PM10 emissions would not represent a threat to human health. Information on the aquatic toxicity of MP compounds is extremely limited. A no-effect level for aquatic organisms was based on toxicological information generated from mono-substituted MPs. A no-effect level of 5 mg/l was derived for MP indicating the relatively low potency of this chemical. Modeled air concentrations were not predicted to yield a water concentration in excess of this threshold. Thus, the modeled air concentrations do not represent a threat to aquatic organisms. Based on this analysis, concentrations of these compounds released as constituents of PM10 from this planned facility are not expected to pose a significant threat to human health or the environment.

1863 CHARACTERIZATION OF AROMATIC CANDLE EMISSIONS AND ITS SIMILARITY TO DIESEL ENGINE EXHAUST.

J D Krause, N D Poor and R D Harbison. *Department of Environmental and Occupational Health, College of Public Health, University of South Florida, Tampa, FL, USA.*

At least fifty documented incidences of severe soot deposition in Florida residences, believed to be caused by aromatic candle emissions, have occurred since 1996. Concerns of occupant exposures and potential health impacts were raised. Submicron particulate has been recognized as carcinogenic in health assessments of diesel emissions. The estimated clearance time for these insoluble carbon particles from the human respiratory system is up to 1 year, providing adequate time for desorption of adsorbed organic compounds. Aromatic candle emissions resemble those of diesel engine exhaust in particle size and organic compounds, while their use in confined spaces may constitute a significant occupant exposure. An assessment of the emissions from aromatic candle usage was performed using a 45 liter stainless steel chamber with high air exchange rates to reduce losses to chamber surfaces. Exhaust was collected for analysis of particulate matter and gaseous emissions. Particulate and gaseous phase emission rates were calculated. To determine the quantity, and identification, of adsorbed compounds GC/MS and GC/FID analyses were performed. Initial characterization and quantification of particulate matter (PM) emissions revealed emission of particles ranging from 0.06 to 0.1 μm, determined by scanning electron microscopy (SEM), at rates up to 3.5 mg/min. Gas phase emissions contained compounds including benzene, 2-butanone, chloroform, carbon tetrachloride, xylenes, and other volatile and semivolatile compounds. This study determined that certain candles produce particulate and gaseous emissions similar to those of diesel engine exhaust, and when used indoors, can result in occupant exposures that may pose a significant risk. (Supported in part by NIOSH Grant T42/CCT412874.)

1864 HIERARCHICAL APPROACH TO PHYSIOLOGICALLY BASED PHARMACOKINETIC MODELS.

A S Collins[1,2], T B Kepler[2], and M Davidian[2]. [1]*Chemical Industry Institute of Toxicology, Research Triangle Park, NC, USA;* [2]*North Carolina State University, Raleigh, NC, USA.*

Historically, many physiologically based pharmacokinetic (PBPK) models have been analyzed through commercial simulation and optimization software such as SimuSolv®. During the optimization process, model parameters are adjusted to maximize the value of the objective function, the log likelihood function (LLF). Optimization of these PBPK models is usually based on repeated measurement data from multiple individuals. Under the normality assumption, the optimization method implemented in SimuSolv® is correct for data from a single individual when statistical inference is focused solely on that individual. When data from multiple individuals are pooled, however, a problem arises in using SimuSolv®. Used to derive the LLF, the error model in SimuSolv® is not appropriate because it confounds two sources of variation: intraindividual variability, which is variation among measurements within a given individual, and interindividual variability, which is random variation among individuals. If sources of variation are not taken into proper account, misleading estimates of the parameters and uncertainty in those estimates may result. These two variation components can be taken into appropriate account in a statistical hierarchical or staged model. We used the PBPK models for tert-amyl methyl ether (TAME) and tert-amyl alcohol (TAA) to contrast inference based on the incorrect error model implemented in SimuSolv® and inference based on a hierarchical model. To fit a hierarchical model, maximization of a more complex objective function than that found in SimuSolv® is required. SAS® software is very efficient in implementing hierarchical model fitting for PBPK models. With a hierarchical approach to current PBPK models, the model that most accurately accounts for variation can be developed, which will allow a more precise extrapolation to humans.

1865 ROUTE-TO-ROUTE EXTRAPOLATION WITH A PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) MODEL FOR CUMENE.

G L Foureman[1] and H J Clewell[2]. [1]*US EPA, NCEA-RTP, Research Triangle Park, NC, USA;* [2]*ICF Kaiser, Inc., Ruston, LA, USA.*

EPA's inhalation Reference Concentration (RfC) and oral Reference Dose (RfD) for cumene are both based on renal effects observed in separate studies where exposures were by the respective route. As some pharmacokinetic data are available, cumene toxicity could thus be examined for dosimetric route-to-route relationships. A PBPK model was developed in which the chemical-specific partition coefficients and metabolic parameters were estimated from structurally-related chemicals. The resulting model was used to convert the inhalation concentrations of the RfC study to equivalent oral doses based on the predicted area under the concentration curve for cumene metabolites in the blood. Estimates from this dose conversion, in mg/kg-day, are 78 (from 100 ppm inhalation), 408 (from 496 ppm inhalation) and 955

(from 1202 ppm inhalation) with the route-converted NOAEL (no observed adverse effect level) at 408 mg/kg-day. The effect levels and doses from the original oral study were the NOAEL at 154 and the LOAEL (lowest observed adverse effect level) at 462 mg/kg-day. The route-converted NOAEL was higher than the oral NOAEL, but less than the oral LOAEL, showing the relationship between the doses and effect levels across separate, independent studies. This exercise demonstrates that reasonable route-to-route extrapolations may be projected with PBPK models that utilize non-specific (but related) chemical parameters. However, chemical specific parameters would better validate the model and lessen the uncertainty of the model projections.

1866 RELATIVE BEHAVIORAL SENSITIVITY OF RATS AND HUMANS TO ACUTE TOLUENE EXPOSURE.

V A Benignus, P A Bushnell and W K Boyes. *US EPA, NHEERL, Research Triangle Park, NC, USA.*

The relative sensitivity of rats and humans can be empirically described by a cross-species map (CSM), a continuous function of human and animal dose pairs which produce equal effects in the two species. In previous work, literature on acute toluene exposure was used to fit dose-effect functions for behavioral data in rats and in humans. Effect magnitudes were transformed to percent-of-baseline to permit pooling data. Dose (arterial blood toluene) was estimated with a physiologically-based pharmacokinetic model. Two kinds of behavioral data in rats (avoidance and activity) and choice reaction time (CRT) in humans were analyzed. The rat and human dose-effect curves from the previous work were used here to estimate the CSM and the 95% confidence limits. A CSM was estimated for equating equal effect sizes for avoidance behavior in rats and CRT in humans. Another CSM was estimated for equating activity level in rats to CRT in humans. The CSM using rat avoidance behavior was an exponential function. From this CSM it was estimated that upper-range human doses were about 10% of equal-effect rat doses, but at ED-10, human doses were about 4% of ED-10 rat doses. The CSM for rat activity level and human CRT was nonlinear and slightly negatively accelerated. In contrast to avoidance, the ED-10 human dose was only about 33% of the equivalent rat dose. This means that activity level data produced the most sensitive index of effects in rats (almost as sensitive as humans). The CSM procedure is based on purely empirical data. Even behaviors that are not biologically or functionally similar can be numerically compared for sensitivity to toxicants. Such comparisons are useful for estimating relative sensitivity, but do not necessarily contribute to biological understanding. The CSM procedure is a precursor to empirical interspecies extrapolation for the frequent case where insufficient biological theory exists. This procedure estimates best for wide-dose-ranges in both species and gives dose confidence limits in the target species. (This is an abstract of a proposed presentation and does not reflect EPA policy.)

1867 HAZARD CHARACTERIZATION OF NONCANCER HEALTH EFFECTS OF BENZENE.

B R Sonawane and D Bayliss. *National Center for Environmental Assessment, U.S. Environmental Protection Agency, Washington, DC, USA.* Sponsor: J W Holder.

The U.S. EPA conducted a comprehensive review of the published literature on noncancer health effects of benzene to derive an inhalation reference concentration (RfC) and an oral reference dose (RfD). It was concluded that benzene exposure results in adverse noncancer health effects by all routes of exposure to test animal species. Hematotoxicity and immunotoxicity have been consistently reported to be the most critical noncancer effects both in limited studies in humans and experimental animals. The bone marrow is the most sensitive target organ for the expression of benzene hematotoxicity and immunotoxicity. The human occupational exposure epidemiological study of Rothman et al. (Am J. Ind. Med. 29:236, 1996) and the 28-day drinking water exposure study of Hsieh et al (Arch Environ. Toxico. 17:157, 1988) were considered to be the co-principal critical studies for derivation of the RfC and RfD. The Rothman et al (1996) showed significant reductions in absolute lymphocyte counts in Chinese factory workers exposed to a median 8-hr TWA concentration 7.6 ppm(24mg/m^3) and was identified as a lowest observed effect level (LOAEL). A LOAEL ($_{HEC}$) was adjusted for the occupational ventilation rate and for intermittent work week schedule for 24 hr exposure, 7 days/week to 8.6 mg/m^3. The adjusted LOAEL ($_{HEC}$) and 1000-fold uncertain factors (for lack of NOAEL, subchronic to chronic extrapolation and data deficiencies) were used to derive RfC of 9 E-3mg/m^3. The human chronic dose of ingested benzene considered to be without any appreciable risk (RfD) is 1E-3mg/kg-day and it is supported by and RfD value of 8 E-4 mg/kg-day, which is 1/10,000 of the LOAEL identified for hematological effects in subchronic drinking water study of Hseih et al (1988). The overall confidence in the RfC/RfD is medium. (The opinions expressed in this abstract are that of the authors and should not be constructed as the US EPA policy).

1868 CANCER RISK ASSESSMENT OF BENZENE.

D Bayliss, B Sonawane, L Valcovic and C Chen. *National Center for Environmental Assessment, U.S. Environmental Protection Agency, Washington, DC, USA.* Sponsor: C Kimmel.

Recently, we updated the EPA 1985 interim characterization of human carcinogenic risk of exposure to benzene. The study of pliofilm rubber workers (Rinsky et al (Am J Ind Med 2:217-245, 1981; N Engl J. Med 316: 1044-1050; 1987) continues to provide the basis for evaluation of human cancer risks from exposure to benzene. Benzene affects the hematopoietic system, especially, bone marrow cells in several different ways and the effects are produced by interactive action of multiple metabolites at DNA level. Both genotoxic and epigenetic effects, are critical components of the leukomogenic properties of benzene. However, data are not sufficient at this time to state precisely which of the various documented effects, genotoxic or otherwise, are critical ones for benzene induced leukomogenicity. Several risk estimates based on Rinsky's cohort have become available with individual risk estimates using various assumptions and/or models, with outcomes ranging more than six orders of magnitude. However, none of the approaches have a greater scientific validity than any other. The arguments in favor of benzene induced leukemia being nonlinear at low doses can be matched by opposing views as a most likely occurrence. There is not sufficient evidence currently to reject a linear dose-response curve for benzene in the low-dose region. Therefore, the EPA default approach of using a model with low-dose linearity is still recommended. Of the various approaches employing a linear assumption, the risk at 1 ppm exposure ranges from 7.1 x 10^{-3} to 2.5 x 10^{-2} within which any calculated risk estimate would have equal scientific validity. (The opinions expressed in this abstract are that of the authors and should not be constructed as the U.S. EPA policy).

1869 DETECTION OF THE DEPURINATING DNA ADDUCT, 7-(BENZO-[*A*]PYREN-6-YL)ADENINE (BP-6-N7A) IN HUMAN URINE: A NEW CLASS OF BIOMARKERS FOR CANCER RISK ASSESSMENT.

G P Casale[1], M Singhal[1], S Bhattacharya[1], E L Cavalieri[1], R RamaNathan[2], J Zhao[2], R Jankowiak[3], S I Rennard[4] and J L Mumford[5]. [1]*Eppley Institute for Research In Cancer, Omaha, NE, USA;* [2]*Mass Spectrometry Research Resource, Washington University, St. Louis, MO, USA;* [3]*Department of Chemistry, Iowa State University, Ames, IA, USA;* [4]*Internal Medicine-Pulmonary, University of Nebraska Medical Center, Omaha, NE, USA;* [5]*US EPA, Research Triangle Park, NC, USA.*

Exposures to complex mixtures, *e.g.*, cigarette and coal smoke, containing polycyclic aromatic compounds (PAC), are associated with increased incidences of lung cancers. Carcinogen-adducted DNA bases comprise the primary carcinogenic lesions which are transformed into gene mutations. Studies of stable PAC-DNA adducts indicate broad correlations with PAC exposures and large inter-individual variability. Recent studies have identified PAC-adducted purine bases which are rapidly and spontaneously released from the DNA. These have been termed "depurinating adducts". The goal of the present study was to determine whether BP-6-N7A, a depurinating DNA adduct of benzo[*a*]pyrene (BP), could be detected in the urine of individuals exposed to cigarette and coal smoke. Urine was collected from 5 smokers, 5 nonsmokers, 7 coal smoke-exposed women, and 7 non-exposed women. PAC exposure due to coal smoke was *ca.* 20 times that due to cigarette smoke. Each sample was extracted with a Sep-Pak cartridge eluted with an acetonitrile-water gradient. The extract was fractionated by reverse-phase high-pressure liquid chromatography, and the adduct fraction was analyzed by capillary electrophoresis inter-faced with fluorescence spectroscopy (CE/FS), and by liquid chromatography coupled with mass spectrometry (LC/MS). Analyses of the first 4 samples identified BP-6-N7A in the PAC-exposed individuals. The adduct was not detected in non-exposed individuals. Daily excretion of BP-6-N7A was 5 and 0.9 pmol, by LC/MS, and 14 and 0.7 pmol, by CE/FS, for coal and cigarette smoke exposure, respectively. This work has identified a new class of biomarkers for PAC-associated cancer risk assessment.

1870 INTERSPECIES DOSIMETRY OF FINE-MODE AEROSOLS.

C J Musante[1], R A Segal[2,3], and T B Martonen[2]. [1]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC, USA;* [2]*US EPA, ETD, NHEERL, Research Triangle Park, NC, USA;* [3]*North Carolina State University, Raleigh, NC, USA.* Sponsor: D L Costa.

Laboratory animals may be used as surrogates in inhalation exposure experiments to estimate the potential threat to human health of fugitive fine-mode aerosols derived from the combustion of fossil fuels (e.g., residual oil fly ash, ROFA). Interspecies dosimetry models may be used in a complementary manner with these animal experiments to: 1) aid in the determination of appropriate experimental conditions *a priori* which permit animal tests to simulate prescribed human exposures to air pollutants; and, 2) assist in the analysis and interpretation of laboratory data by providing a quantitative assessment of particle deposition in animals and humans. We have performed computer simulations to study factors affecting ROFA disposition within the lungs of humans and a selected surrogate (rat). In the animal tests CO_2 levels were regulated to simulate different degrees of respiratory intensity. A specific observation of this investigation is that the resting rat is a poor surrogate for the resting human. Moreover, the simulations suggest that the active rat, as described by the respiratory profile produced by a 4% CO_2 chamber atmosphere, is a suitable surrogate. (DISCLAIMER: This is an abstract of a proposed presentation and does not necessarily represent EPA policy. ACKNOWLEDGMENTS: C J Musante was funded by the EPA/UNC Toxicology Research Program, Training Agreement CT902908. R A Segal was funded by the NCSU/EPA Cooperative Training Program in Environmental Sciences Research, Training Agreement CT826512010.)

1871 CANCER AND NONCANCER ASSESSMENTS OF SOLUBLE NICKEL.

L T Haber[1], M L Dourson[1], J Zhao[1], L Erdreich[2], G Diamond[3], and R Ratney[4]. [1]*Toxicology Excellence for Risk Assessment, Cincinnati, OH;* [2]*Bailey Research Associates, New York, NY;* [3]*Syracuse Research Corporation, Syracuse, NY; and* [4]*Mabbett and Associates, Bedford, MA.*

A substantial body of occupational epidemiology data has associated exposure to mixtures of water-soluble and insoluble nickel compounds-with the development of lung and nasal cancer. However, due to coexposure to soluble and insoluble forms, and limitations in exposure measurements, the contribution of soluble nickel is difficult to determine. Soluble nickel was negative for tumorigenicity in an NTP inhalation bioassay, while there was some evidence for tumorigenicity in rats for insoluble nickel oxide, and there was clear evidence for tumorigenicity of insoluble nickel subsulfide in rats. Results of parenteral assays follow a similar pattern, but provide evidence of weak carcinogenicity of soluble nickel. The weight-of-evidence from the animal and epidemiology data, indicate that soluble nickel is not carcinogenic by itself, but appears to enhance the lung or nasal cancer risks associated with exposure to other forms of nickel. Therefore, the carcinogenic activity of insoluble nickel compounds should not be used to predict the carcinogenic potential of water-soluble nickel salts. A chronic oral RfD was derived based on decreased body weight and kidney effects in rats as the critical effects. A chronic inhalation RfC was derived based on a benchmark dose for fibrosis in male rats observed in an NTP bioassay. As part of an effort to foster cooperation between industry and government, this work was cosponsored by to the Metal Finishing Association of Southern California and the U.S. EPA. (Conclusions do not necessarily reflect the opinions or policies of U.S. EPA.)

1872 PREDICTIVITY OF PHARMACEUTICALS TOXICITY IN HUMANS FROM ANIMAL DATA.

H M Olson[1], G Betton[2], J Stritar[1] and D Robinson[3]. [1]*Pfizer Inc. Groton, CT, USA;* [2]*Zeneca Pharmaceuticals, Macclesfield, England;* [3]*ILSI-HESI, Washington, DC, USA.*

This investigation describes the procedure for compiling data and presents the results to-date from a multinational pharmaceutical company survey of the predictivity of the toxicity of pharmaceuticals in humans from animal data. The main aim of this project is to better understand the usefulness of animal studies to identify toxicity biomarkers for pharmaceutical-associated human toxicity (HT), and to identify opportunities to improve detection of HT. The strategy for developing the database for this survey resides in two sets of participant pharmaceutical company records: (1) significant HTs for therapeutics identified during clinical development, and (2) based on this data, the determination of whether animal toxicity studies did or did not identify biomarkers for the relevant HTs. A standardized tabular format was developed to collect information including: identification of therapeutic category, the type (organ system) of HT that was identified, and the duration of animal studies in which the corresponding toxicity was first identified or not observed. To-date the survey includes input from 7 pharmaceutical companies with data compiled from approximately 130 compounds with more than 160 human toxicity events reported. Interim results demonstrate the true positive prediction rate of animal models for human toxicity of 69% across therapeutic classes evaluated. The results support the predictive value for identifying HTs in non-clinical studies up to one month in duration. Study results from non-rodent (dog, primate) species have shown good potential to identify HTs from many therapeutic classes. The predictive value of toxicities from rodent studies bears further examination to determine if other factors (drug metabolism, toxicokinetics) play a significant role. While additional results are being included in updates, these survey results support the value of in vivo studies to predict for many significant HTs.

1873 PESTICIDE REGISTRATION: A NEW PARADIGM ON THE INCORPORATION OF MECHANISTIC CONSIDERATIONS WITHIN THE FRAMEWORK OF REQUIRED DESCRIPTIVE TESTING.

W R Christenson, B S Wahle, and C Croutch. *Bayer Corporation, Stilwell, KS.*

Within the context of conducting "guideline" testing to support registration of new chemical pesticides, mechanistic studies are typically performed after the emergence of some effect (usually tumors). Such an effect may lend itself to further clarification through testing of a mechanistic hypothesis that provides compelling evidence that the findings in the animal are not relevant to the human. However, despite the improved regulatory picture in terms of potentially achieving a more appropriate risk assessment, the fact remains that the chemical has often been linked to an undesirable outcome, such as tumors. Moreover, the mechanism work, which provided evidence to mitigate the guideline finding, was likely conducted at the same level of unrealistic exposure that in all probability promoted/contributed to the tumorigenic response seen in the original bioassay. With this brief introduction as background, we have developed a scheme or approach in which to merge the fundamental interests or requirements of the mechanistic study with the practical and time-driven characteristics that are fundamental to descriptive guideline testing. First, the approach focuses on developing a mechanistic "game plan" at the beginning of the product development process - not at the end. The key step is dose selection, which in turn is driven by the data from preliminary pilot studies, a toxicokinetic assessment, and a mechanistic screening study incorporating an endocrine focus (consistent with emphasis of FQPA). Currently, we are at different stages with respect to incorporating each of these components into the pesticidal development process. The toxicokinetic protocol is not a classic kinetic protocol (metabolites, plasma concentration etc.) but rather a dose and time-driven design intended to provide general evidence of the likelihood of a dose-related change in a given metabolic profile that can then be correlated to alterations in key endocrine endpoints. By combining the data obtained from each of these areas, one can initiate guideline studies at dose levels that in all probability are representative of the linear portion of the dose response curve. Furthermore, this approach facilitates the conduct of additional follow-up mechanistic work, employing a dosing regimen that is not only comparable to that selected for the guideline work but likewise positioned squarely in the linear segment of the dose response curve.

1874 APPROACH FOR ESTIMATING THE POTENTIAL AGGREGATE EXPOSURES TO ORGANOPHOSPHATES.

K E Van der Jagt[1], J H Driver[2], M D Pandian[2], and C Lunchick[3]. [1]*Jellinek, Schwartz & Connolly, Arlington, VA;* [2]*risksciences.com, L.L.C., Manassas, VA;* [3]*Rhone-Poulenc, Reasearch Triangle Park, Manassas, VA.*

The Food Quality Protection Act (FQPA) of 1996 requires a new approach for pesticide exposure and risk assessment. Instead of assessing potential risk by identifying dominant exposure routes for a single compound in a single source scenario, FQPA calls for the aggregation of exposure routes (i.e., dermal, inhalation and ingestion) from multiple sources, and adding the exposures of compounds that have a common mechanism of toxicology to estimate overall potential cumulative exposure and risk. Multiple sources

include diet, drinking water, and non-dietary residential (indoor and outdoor) sources. To address this task, a case study group focusing on organophosphates (OPs) was assembled. The case study group is working to prepare aggregate assessments for individual OPs and then to develop cumulative assessments for the group of OPs. The work of the non-dietary group will be presented. The non-dietary group began by identifying the product use patterns and associated exposure scenarios for a cluster of OPs. The group then considered the exposure potential of each scenario, and the plausible aggregation of the exposure scenarios for each compound. Basic algorithms quantifying exposure were established, and algorithm input parameters (including point estimates and distributions) were identified, characterized, and summarized for each exposure scenario. Non-proprietary exposure data were identified and categorized including mixer/loader/applicator, post-application, and use information. The model is flexible to permit the addition of proprietary data.. Standard operating procedures (SOPs) were developed for characterizing and summarizing the exposure data. The availability of data and information for age-specific activity patterns was reviewed: such information was then characterized and summarized. These efforts resulted in a screening-level residential exposure assessment model. This case study shows how spatial, temporal, and demographic data can be used to estimate potential exposure more precisely than point estimates.

1875 UNCERTAINTY ASSOCIATED WITH CARCINOGENIC POTENCY OF ETHYLENE DIBROMIDE.

R C Lee[1], L Swenson[2], B J Kelman[2]. [1]*Golder Associates Ltd., Calgary, AB, Canada;* [2]*GlobalTox, Inc., Seattle, WA, USA.*

Uncertainties associated with cancer potency values are often the result of model choice. An example is the cancer potency of ethylene dibromide (EDB, or 1,2-dibromoethane), which was formerly used as a pesticide and gasoline additive and is found in groundwater at some contaminated sites. Uncertainty associated with the carcinogenic potency of EDB is considerable. The U.S. Environmental Protection Agency (EPA) calculates a cancer slope factor (q*) of 85 per mg/kg× d (oral administration) using an unpublished model applied to a male rat gavage study conducted by the National Cancer Institute in 1978. A standard multistage model with a Weibull time-to-tumor component represents the most similar structure to the unpublished model. We were not able to reproduce the EPA value using the same data and assumptions listed in EPA documentation in the multistage and a number of other commonly-used linear (no threshold) cancer models. We calculate a maximum likelihood estimate (MLE) slope factor as 5 per mg/kg× d, and a 95% upper bound slope factor as 7 per mg/kg× d using the multistage model. MLE results from other models give a maximum value of approximately 40 per mg/kg× d, and a minimum of less than 1 mg/kg× d. Rather than select one model's results, we use weighted Monte Carlo sampling to estimate uncertainty distributions reflecting intra- and inter-model uncertainty in the EDB slope factor. Estimates of cancer risk, potential remediation levels, and remediation costs are directly dependent upon slope factor values. Therefore, careful assessment of cancer potency values and model uncertainty is important in the context of public safety and the costs of environmental remediation.

1876 COMPARISON OF A PROBABILISTIC APPROACH TO RISK ASSESSMENT BASED ON EMPIRICAL AND MODELED DATA.

J R Glowa[1], M A Bogdan[2], and R C MacPhail[3]. [1]*LSU Medical School, Shreveport, LA;* [2]*Stanford University School of Medicine, Stanford, CA;* [3]*Neurotoxicology Division, U.S. EPA, Research Triangle Park, NC.*

Perhaps the greatest uncertainty in human-health risk assessment lies in measuring individual differences in susceptibility. A method has been developed to quantify individual differences (Glowa et al., 1986) in laboratory animals, but the necessary baseline approach in experimental design is incompatible with most standard toxicity tests (e.g., developmental, chronic exposures). A modification was therefore created, based on randomization testing, to make the approach applicable to the more traditional types of toxicity data. Adult male Long Evans rats were used to establish dose-effect functions for two pesticides (triadimefon, carbaryl) and motor activity in each rat. For each pesticide, rats (N=36) were divided into 4 groups of 9, with group assignment determining the order of dosing. Triadimefon produced dose-related increases in motor activity and carbaryl produced dose-related decreases in activity. ED10s were determined by interpolation from each rat's dose-effect data, and then the group-mean and SD of ED10s were calculated. A similar analysis used randomization testing (with replacement) on the initial, group-defined (i.e., N=4x9) dose-effect functions, and the results were then compared to the empirical distributions of pesticide ED10s. Means and SDs of ED10s based on randomized testing closely matched those derived from the empirically determined distributions (for triadimefon: 12.1 and 1.3 mg/kg vs. 8.4 and 1.7 mg/kg, respectively; for carbaryl 2.5 and 1.8 mg/kg vs. 2.6 and 2.2 mg/kg, respectively). These results suggest randomization testing is a viable alternative to quantifying individual differences in chemical susceptibility in the absence of dose-effect data for individual subjects.

1877 EMPIRICAL vs. MECHANISTICALLY-BASED DOSE-RESPONSE MODELING OF ORGANOPHOSPHATE PESTICIDE TOXICITY.

L Fahey McGrath[1] and R Ponce[2]. [1]*UMDNJ-Robert Wood Johnson Medical School, EOHSI, Piscataway, NJ, USA;* [2]*University of Washington, Seattle, WA, USA.*

Dose-response assessment generally relies on empirical models. However, such models do not incorporate existing knowledge relating to mechanisms of toxicity. Biologically-based dose-response models have been proposed as a means to improve estimates of behavior outside the observed range of existing data. We explore the use of both empirical and biologically-based models as applied to dose-dependent acetylcholinesterase (AChE) inhibition by organophosphate pesticides (OPs). The mechanisms of organophosphate toxicity are well characterized and involve enzymatic interactions resulting in AChE inhibition. Thirteen data sets were used to examine the activity of seven OPs. Models used to fit the data included three empirical models (linear , power law and log-linear) and four models that have been developed based on the understanding of the mechanism of enzyme interactions and receptor theory (Sigmoid-Emax , Emax, modified Emax, and indirect response). Mean response (i.e. AchE inhibition) weighted by 1/SD were used to assess fit across all models and to estimate the dose at which 10% response is observed (ED_{10}). Dose-response model predictions are also evaluated at ED_{20}, and ED_{50}. Model fits were assessed using appropriate statistics including r^2, squared error, and uncertainty of parameter estimates. The best fits were provided by the various Emax-models and the Power Law function, consistent with the known mechanisms of OP activity. Estimates of ED_{10} using the Emax models and Power Law functions were generally lower, and in some cases more than an order of magnitude lower, than the study-derived LOAEL. This analysis demonstrates that model selection is critical when deriving benchmark dose estimates, and that using models based on described biologic processes can provide a credible rationale for dose-response assessment. (Work supported by the Consortium for Risk Evaluation with Stakeholder Participation (CRESP) through the Department of Energy, AI#DE-FC01-95EW55084 and the EPA/NIEHS Center for Child Environmental Health Risks Research R826886-01-0.)

1878 RELEVANCE OF DOG TOXICITY DATA FOR EVALUATING HUMAN HEALTH EFFECTS FROM EXPOSURE TO CHLORINATED PHENOXYACETIC ACID HERBICIDES AND RELATED ORGANIC ACIDS.

C Timchalk. *Battelle, Pacific Northwest Division, Richland, WA, USA.*

Compared to other species, the dog is particularly susceptible (lower NOEL) to the effects of chlorinated phenoxy herbicides such as 2,4-dichlorophenoxyacetic acid (2,4-D) and related organic acids. It is proposed that this sensitivity is due to a lower capacity to excrete organic acids that share common pharmacokinetic (PK) properties. These common properties include (1) extensive but reversible plasma protein binding; (2) high ionization of weak acids at physiological pH; (3) limited metabolism of the parent acid; and (4) urinary clearance involving saturable active secretion. To test this hypothesis the 2,4-D PK parameters, volume of distribution (V_d), renal clearance (Cl_r) and plasma half-life ($t_{1/2}$) were evaluated across species and the results compared to previously published data on 2,4,5-trichlorophenoxyacetic acid (2,4,5-T), triclopyr and 1-amino-cyclopropanecarboxylic acid (ACPC). Cross species comparisons were done by scaling the PK parameters utilizing an allometric approach based on the equation $Y=\alpha W\beta$. The variable parameter Y (V_d, Cl_r, $t_{1/2}$) was fit by log-linear regression, where body weight, and the allometric coefficient and exponent were represented by W, α and β , respectively. Comparisons of 2,4-D, V_d, Cl_r, and $t_{1/2}$ versus W for mice, rats, dogs, pigs, calves and humans were conducted. The V_d for 2,4-D was well described for all species ($V_d=0.12W^{1.11}$). Whereas, the relationship for Cl_r and $t_{1/2}$ versus W were well described by the equations $Cl_r=37W^{0.86}$ and $t_{1/2}=2.14W^{0.27}$ for all species, except the dog. The dog had a significantly slower Cl_r and longer $t_{1/2}$ relative to other species, including humans. The

results of this analysis are consistent with the allometric relationships observed with 2,4,5-T, triclopyr and ACPC in which the dog was an outlier, relative to other species. This PK evaluation of 2,4-D and related organic acids questions the relevance of using dog toxicity data for the extrapolation of human health risk. Based on the lack of a pharmacokinetic concordance between dogs and other mammalian species it is suggested that the dog is not a reasonable surrogate for humans.

1879 CHARACTERIZING NONCANCER RISKS ABOVE THE REFERENCE DOSE (RfD): CHLORDANE AND METHYL MERCURY AS EXAMPLES.

J A Stickney[1], H L Carlson-Lynch[1], P S Price[2], and M L Dourson[3]. [1]*ARCADIS Geraghty & Miller, Portland, ME, USA;* [2]*Ogden Environmental, Portland, ME, USA;* [3]*TERA, Cincinnati, OH, USA.*

Noncancer health risks above the RfD were characterized for methyl mercury (MeHg) and chlordane using a method that combines dose response modeling and Monte Carlo simulation of uncertainty factor (UF) distributions. The risks are based on the critical effect given in EPA's IRIS database. Dose response modeling was used to estimate the dose causing a 50% response (ED_{50}). Probability distributions were employed for each UF used by EPA in setting the RfD. A reference distribution (Swartout et al., 1998) was employed for UF values of ten and the square root of the values from the reference distribution were used for UFs of 3. The ED_{50} for chlordane was based on a study of liver toxicity in mice. Reference distributions were used for the interspecies and interindividual UFs and the square root of the reference distribution was used for the database UF. Dose response curves illustrate that at a dose 50 times greater than the RfD only 2% of individuals would be expected to respond (median) with 90% certainty that less than 10% would respond. The ED_{50} for MeHg was calculated from the neurodevelopmental data on exposed mother-child pairs from Iraq. Pharmacokinetic data was used to generate a distribution for human variability for MeHg (J. Swartout, pers. comm.) and the square root of the reference distribution was used for the database UF. The dose response curves were steeper for MeHg, with a 90% certainty that 4% of the population might respond at doses only 5 times the RfD. Risks above the RfD could not be calculated for PCBs, DDT, or dioxin due limitations in the dose response data. (EPA Co-Operative Agreement #CX825499-01 entitled "Comparative Dietary Risk.")

1880 COMPARATIVE DIETARY RISKS: BALANCING THE RISKS AND BENEFITS OF FISH CONSUMPTION.

P Anderson[1], D Cartledge[2], M Daviglus[3], M Dourson[4], B Knuth[5], E Murkin[6], J Patterson[4], J Sheeshka[6], J Stober[7], and J Unrine[4]. [1]*Ogden Environmental and Energy, Westford, MA, USA;* [2]*Prescott College, Prescott, AZ, USA;* [3]*Northwestern University, Chicago, IL, USA;* [4]*Toxicology Excellence for Risk Assessment, Cincinnati, OH, USA;* [5]*Cornell University, Ithaca, NY, USA;* [6]*University of Guelph, Guelph, ON, Canada;* [7]*U.S. EPA, Athens, GA, USA.*

Analyses of fish in water bodies throughout the United States have confirmed the presence of chemicals in fish. In many cases the concentrations of chemicals have been high enough to warrant the posting of fish consumption advisories. In virtually all cases, these advisories are based solely on the potential adverse effects posed by the chemicals in fish. Yet some recent publications have suggested that the health benefits of eating even contaminated fish may outweigh the potential risks caused the by the presence of contaminants. If contaminated fish also confer health benefits to people eating fish, then prior to setting of advisories, public health officials might estimate the magnitude of those benefits and consider altering advisories that are strictly risk-based. A framework for comparing the risks from chemical contamination of sport-caught fish to the reduction in the relative risk of several adverse health endpoints from eating fish is developed. The framework includes a simple method based on a four category severity scale and a novel approach to determine the risks from chemical exposures above the RfD in order to combine the health risks from cancer and non-cancer toxicity. A similar severity construct is used to compare these risks with the benefits of eating fish. The framework accommodates scales for perceived severity and cultural benefits, if desired. The framework is able to compare the risks and benefits of fish consumption over a wide range of fish consumption rates, illustrated with three case studies. People using the framework should be able to apply it to many contaminants at various concentrations. Data limitations, and assumptions used to develop the framework, are highlighted.

1881 RELATIVE DEVELOPMENTAL RISKS OF *FUSARIUM* MYCOTOXIN, DEXOYNIVALENOL (DON) and BENOMYL (BEN) IN WHEAT.

L R Hicks[1,2], D R Brown, R H Storch, and R J Bushway[2]. [1]*Maine Board of Pesticides Control, Augusta, ME, USA; University of Maine, Food Science Program, Orono, ME, USA.*

Since 1984, the wheat supply has had elevated DON levels from fungal infections which can be suppressed with BEN. DON and BEN are developmental toxins. As such, evaluation of the relative developmental risks is warranted. The dietary NOAELs for decreased pups body weights for DON, and BEN are 0.375 mg/kg/day in mice and 5 mg/kg/day in rat, respectively. Human exposure to DON was estimated from surveys of wheat grain and finished products. Mean DON concentration, 0.86 ppm, estimated from survey data and the tolerance level for BEN in grain, 0.2 ppm are used to estimate exposure. Presence of DON and BEN in wheat at these concentrations would not impact intake. A modified margin of exposure (modMOE) was developed using "*a*" kg (food) /kg (body weight) as the constant for wheat consumption. The modMOE for DON is 28/*a* and that for BEN is 1667/*a*. Comparative relative risks can be expressed as the ratio of BEN risks to DON risks (60). Treatment with BEN at the most efficacious time decreased DON levels to 34 % of controls, and decreased the comparative risk ratio to 27. The potential for fungicides to decrease mycotoxin residues is important in the evaluation of fungicides. This approach improves on current practices by including the expected reductions in risks from naturally occurring mycotoxins.

1882 ART MATERIALS (LHAMA) RISK ASSESSMENT FOR ACRYLIC STAINS.

C S Skinner, B L Rope and R E Sullivan. *BioScreen Testing Services, Inc., Torrance, CA, USA.*

An acute can chronic human health risk assessment was performed on an acrylic stain used as an art material according to the guidelines of the American Society for Testing and Materials (ASTM D-4236) to satisfy the Labeling of Hazardous Art Materials Act (LHAMA) requirements for art materials. Each ingredient in the product was identified by its CAS number and searches performed in the National Library of Medicine data bases. For pigments and dyes, the Color Index was used. Hazards for individual ingredients and the final product were evaluated by estimation of high-use hobbyist exposure rates for acute and chronic exposure and comparison made to acceptable intake levels. Exposure assessment for both brush and spray application was performed based on use rates for similar products and actual measurements of spray rates. Duration of exposure was assumed 6 years for the child and 30 years for adults. Acceptable Daily Intakes were derived from acute toxicity data using the EPA safety factor approach. Chronic exposure hazard was calculated using the EPA Human Health Evaluation Manual route specific equations for calculating chemical intakes. The product consisted of various acrylic polymers in aqueous solution with pigments. The oral ADI calculated from individual toxicities using a 100 fold safety factor to account for species and route differences, was 40 mg/kg or 13 ounces for a 10 kg child. The acute dermal hazard was below the 1.0 safety threshold but the acute hazard for inhalation was 2.9 for the child. Chronic hazard quotients for oral and dermal exposure were below the 1.0 threshold for dermal and oral exposure but 5.5 for inhalation by the child due to ammonia. Mild eye irritation was predicted based on Draize tests of ingredients. Sensitizers were identified among the acrylic monomers. Labeling for eye irritation and precautions for use by children were recommend.

1883 INTERIM ESTIMATES OF THE REFERENCE DOSE (RfD) FOR KEY BREAKDOWN PRODUCTS OF CHEMICAL AGENTS.

H T Bausum, G Reddy, and G J Leach. *U.S. Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD.*

There is a need to evaluate the health risks associated with chemical warfare (CW) agents and their degradative products. This need has been heightened by the present program of planned agent destruction. Provisional estimates of Reference Dose (RfD), for non-cancer toxicity, have been made for five key breakdown products for which toxicity data are either limited or lacking: thiodiglycol (TDG), methylphosphonic acid (MPA), ethyl methylphosphonic acid (EMPA), S-(2-diisopropyl amino) ethyl methylphosphonothioic acid (EA2192), and lewisite oxide/ 2-chlorovinyl arsonous acid. Three approaches were used for estimating RfD. (1) Experimental chronic or subchronic LOAEL or NOAEL, (2) LOAEL or NOAEL for a closely related compound,

and (3) An estimate of rat chronic LOAEL made using a commercially available computational toxicology system for Quantitative Structure Activity Relationships (QSAR). We used the TOPKAT ™ system (Health Designs, Inc., Rochester, NY). In all cases, calculation was based on the use of Uncertainty Factors (UF), adhering where possible to USEPA guidelines. Laboratory data suitable for RfD development were available only for TDG. For EA2192 and lewisite oxide/ 2-chlorovinyl arsonous acid, an experimental subchronic LOAEL for the chemical agent VX and an experimental NOAEL for lewisite were used, respectively. Similarly, for EMPA, a published LOAEL for isopropyl methylphosphonic acid (IMPA) was used. RfDs for TDG, MPA, and EMPA were developed using both actual data and TOPKAT estimates of the rat chronic LOAEL. The estimated RfDs for MPA, EMPA, EA2192, and lewisite oxide were 40, 28, 0.0006, and 0.1 :g/kg/day, respectively. For TDG, an RfD estimate is being developed based on recent 14-day and 90-day rat studies at this Center. These provisional values are intended for screening purposes and as an aid in cleanup decisions. (Abstract does not reflect U.S. Army policy.)

1884 IDENTIFICATION OF PERSISTENT AND TOXIC CHEMICAL WARFARE (CW) AGENT DEGRADATION PRODUCTS.

S S Talmage[1], N B Munro[1], A P Watson[1], J King[2], V Hauschild[2], and R A Young[1]. [1]*Oak Ridge National Laboratory, Oak Ridge, TN, USA;* [2]*U S Army, Aberdeen Proving Ground, MD, USA.*

The primary agents within the United States CW agent inventory include several vesicant or blister agents (sulfur mustards: H, HD, HT; nitrogen mustards: HN1, HN2, HN3; and the organic arsenical, lewisite: L), four nerve agents (VX, GA, GB, GD), and the blood agent, cyanogen chloride. With the occasional exception of the sulfur mustards, most of the CW agents are not persistent in the environment as they are subject to a variety of degradation mechanisms including hydrolysis and oxidation. The authors evaluated fate and toxicity data from field and laboratory studies as well as reports of storage container analyses at burial or unitary stockpile sites in order to identify degradation products that are highly persistent and/or exhibit high mammalian toxicity. The emphasis was on those potential degradation products resulting from agent contact with soil or water, especially from buried chemical weapons and wastes. The degradation products of primary interest include thiodiglycol for HD; lewisite oxide for lewisite; and *S*-(2-diisopropylaminoethyl) methylphosphonothioic acid (EA 2192), ethyl methylphosphonic acid, and methylphosphonic acid (MPA) for VX. Methylphosphonic acid is also a product of both GB and GD degradation. The GB contaminant diisopropyl methylphosphonate is of interest because of its environmental persistence; the closely related isopropyl methylphosphonic acid is a GB hydrolysis product that slowly hydrolyzes to MPA. Of these degradation products, only lewisite oxide and EA 2192 possess high mammalian toxicity.

1885 UPTAKE OF METALS AND POLYCYCLIC AROMATIC HYDROCRABONS FROM CONTAMINATED SEDIMENT INTO EDIBLE BLUE CRABS.

E J Hixson[1], D L Shelton[2], J D Frazier[3], and G White[3]. *CH2M Hill, Inc.,* [1]*Austin, TX;* [2]*Corvallis, OR;* [3]*Portland, OR.*

Estuarine areas of southeast Texas commonly provide habitat for a variety of species of commercial and recreational importance, including blue crabs (*Callinectus sapidus* Rathbun). Many of these areas provide drainage for a variety of municipal and industrial facilities, which may result in release of chemicals to surface water or sediment. Prior sampling of a drainage canal from which commercial fishing for crabs is known to occur adjacent to a refinery identified metals and polycyclic aromatic hydrocarbons (PAHs) in sediment at concentrations that might result in uptake by crabs to levels of concern for people who eat them. To confirm this, crabs of edible size were collected from the canal with emphasis on areas in which sediment concentrations were highest. Sediment samples were collected to determine the bioavailable fraction of the simultaneously extractable divalent metals (SEM; cadmium, copper, lead, nickel, zinc) by comparing the total molar concentration of SEM to the total concentration of acid volatile sulfide (AVS). Edible crab tissue (32 composite samples of 5 crabs each) was analyzed for PAHs and metals, and the 95 percent upper confidence limit of the mean concentration (95 UCL) of each analyte was compared to conservative risk-based values. None of the individual analyte concentrations or 95 UCLs exceeded the risk-based value. Results of the SEM/AVS determination indicated that the five divalent metals were not present in a bioavailable form; this finding was independently confirmed by the low concentrations of these metals in edible crab tissue.

1886 DEVELOPMENT OF FISH MODEL FOR ENVIRONMENTAL CANCER RISK ASSESSMENT; INTERRELATIONSHIP OF MUTATION, APOPTOSIS AND CANCER.

H I Kwak and M H Cho. *Laboratory of Toxicology, College of Veterinary Medicine, Seoul National University, Korea.*

We tried to develop fish model to get more information for the interrelationship of mutation, apoptosis and cancer, then eventually to use for environmental cancer risk assessment. Fish (medaka, *Oryzias latipes*) was investigated following a 28 day, 3 times /week pulse exposure to N-methyl-N'-nitro-N-nitrosoguanidine(MNNG). 5-week-old fishes were exposed to MNNG at concentrations of 0, 0.5, 1.0 mg/L and reared for 3, 5, 7 more months from the last day of exposure. Glutathione (GSH) and lactate dehydrogenase (LDH) levels from whole body samples were measured by spectrophotometer. GSH level was decreased while LDH level was increased in the samples of the higher dose groups and longer time groups. Mutational responses were detected by arbitrarily primed polymerase chain reaction (AP-PCR) fingerprinting method using whole body DNA samples as templetes and PBR primer. AP-PCR fingerprinting revealed dose- and time-dependent mutational changes by band density, loss and gain. A band from normal fish samples was disappeared after treatment of MNNG, then, the band disappeared was excised and sequenced. The band has 869 base pair-long sequence, however, there was no putative protein coding region based on analysis by Genbank. Flow cytometric analysis revealed that fishes from 3 and 5 month -reared group were under the severe apoptotic changes in the dose- and time-dependent manner, but those from 7 month-reared group were under less apoptotic, rather showed more necrotic and carcinogenic alterations. However, terminal deoxynucleotidyl transferase (TdT) assay showed that fish carrying tumor were still under the severe apoptotic cell changes. In deed, tumors were detected on the whole body sections from 4 individuals of 10 fishes and immunohistochemical analysis showed that tumor cells were actively proliferating. This study does not only show the interrelationship of mutation, apoptosis and cancer at a glance, but indicate that medaka can be used as a good fish model for environmental cancer risk assessment.

1887 HEALTH RISK ESTIMATES FOR "POLYBROMINATED DIPHENYL ETHERS" (PBDEs) ASSOCIATED WITH CONSUMPTION OF FISH AND HUMAN BREAST MILK.

M M Siesko[1], R R Fay[1], M L Hardy[2], J Biesemeier[3], R J Wenning[4], and C R Kirman[5]. [1]*McLaren/Hart, Inc., Lake Charles, LA, USA;* [2]*Albemarle Corporation, Baton Rouge, LA, USA;* [3]*Great Lakes Chemical Corporation, West Lafayette, IN, USA;* [4]*McLaren/Hart, Inc., Alameda, CA, USA;* [5]*McLaren/Hart, Inc., Cleveland, OH, USA.*

Recent reports in the scientific literature describe the detection of "polybrominated diphenyl ethers" (PBDEs) in human breast milk, human adipose tissue, fish, and marine mammals. Among the 209 possible congeners and three commercial PBDE products, the reports largely indicate the presence of 2,2',4,4'-tetrabromodiphenyl ether and, to lesser extent, tri- through hexa-brominated congeners. The most widely used PBDE, decabromodiphenyl ether (DPBDE), has not been detected in marine mammals, fish, or milk. Ultra-trace HRGC/HRMS analysis indicate levels of penta-, hexa-, and hepta- brominated congeners are generally below 0.1 ng/g in freshwater fish; substantially lower levels are reported in marine fish. Swedish studies report similar low levels in human breast milk and adipose tissue. However, little is understood about the source(s), the level of human exposure, or the toxicological significance of the different congeners found in the environment. Using the limited available exposure data and conservative assumptions in a risk assessment model, noncancer risks were calculated for the reasonably exposed and maximally exposed individual. Exposures to adults and infants through consumption of contaminated fish and breast milk were examined. For some congeners, references doses for noncancer effects were extrapolated from the available literature.

1888 HUMAN HEALTH RISKS OF ARSENIC IN MARINE ANIMALS AND REGULATORY APPROACHES.

T Zewdie and M S Hutcheson. *Massachusetts Department of Environmental Protection, Boston, MA, USA.*

High levels of arsenic are detected in marine animals. Despite the high concentration of arsenic in the edible portions of aquatic animals, no reports were found on the actual health effects of arsenic in people consuming large amounts of seafood. This may be because the arsenic found in marine animals exists in various methylated forms, which are not bioaccumulated and

have low toxcities. No legal limits exist for arsenic in fishery products in the U. S. However, the U.S. Environmental Protection Agency has calculated an ambient water quality criterion value of 0.140 μ g/L (inorganic arsenic) for waters containing edible aquatic animals representing a 1 x 10-6 incremental increase of cancer risk. This concentration of arsenic is lower than the average normal levels of arsenic (0.96 - 2 μ g/L) detected in marine waters. We used an alternative approach to determine the human health risk based on the actual inorganic arsenic concentration detected in seafood. Compiled data on the concentration of total arsenic in marine animals found in the world seas were used. The inorganic arsenic content in marine animals was estimated based on the reported average inorganic arsenic body burden ranging between 0.5 and <6 % of the total arsenic levels. These calculated inorganic arsenic levels were then used with estimates of average seafood ingestion rate (6.5 g/day) and apportioned total daily seafood consumption (44% fish, 44% crustaceans and 12% bivalves) to determine a lifetime average daily dose (LADD) of inorganic arsenic. The estimated excess lifetime cancer risk (ELCR) using the LADD and the inorganic arsenic slope factor (1.5 $mg/kg/day)^{-1}$ ranged between 1.5 $x10^{-6}$ and 1.2 x 10^{-6}. The results suggest that marine animals harvested from the world seas (containing up to 2 μ g/l arsenic) may pose minimal arsenic-related health hazards in the average consumer. Since data on arsenic speciation is abundant, it seems more appropriate to set limits to protect public health for arsenic in seafood based on the inorganic arsenic levels in marine organisms rather than using marine water arsenic concentrations.

1889 EXPOSURE FACTOR AND TOXICITY DATA FOR CALIFORNIA WILDLIFE: TRENDS, DATA GAPS AND SOURCES OF UNCERTAINTY FOR ECOLOGICAL RISK ASSESSMENTS.

J T Yamamoto, R M Donohoe and K E Ricker. *Office of Environmental Health Hazard Assessment, California Environmental Protection Agency, Sacramento, CA, USA.*

Evaluating wildlife exposure to toxicants in ecological risk assessments requires knowledge or estimation of a diverse array of species-specific information that includes various normalizing factors (e.g., body weight, metabolic rate), contact factors (e.g., ingestion rate, dietary composition), population dynamics (e.g., population density, fecundity) and seasonal activities. To meet this information need, a relational database containing such information for sixty-five California mammals, birds, reptiles and amphibians was created from the existing literature. Available toxicological data were also collected for these species to provide information relevant to interpretation of exposure data. A qualitative analysis was conducted to identify the relative abundance of various types of data for species and groups of species. Physiological exposure factors, except for body weight, were underrepresented compared to ecological factors (e.g., population dynamics) which tended to be well studied. Exposure factor information was limited for many species but data were most abundant for mammals, followed by birds and herpetiles. Wildlife toxicity data were considerably less abundant than exposure factors and were clustered within a few commonly studied species. Toxicity data on other, less "traditional", study species were available with data abundance greatest for birds, followed by mammals and herpetiles. Overall, this analysis may assist in the selection of "data-rich" receptors, as well as provide quick identification of exposure factor and toxicity information gaps that may be sources of uncertainty in ecological risk assessments.

1890 A MODEL FOR ASSESSING AIRBORNE EXPOSURES TO *LEGIONELLA* BACTERIA

B E Barry, J F Ludwig, and J F McCarthy. *Environmental Health & Engineering, Inc., Newton, MA.* Sponsor: D A Kaden.

Assessing exposures to airborne *Legionella* bacteria and the potential human health risks for developing disease depends on several factors. Factors considered for such exposure assessments should include not only the concentration of *Legionella* bacteria at the source, but also the characteristics of the pathway to potentially exposed individuals and how the original source concentration is modified by that pathway. We developed a model to estimate airborne concentrations of *Legionella* bacteria following release of an aerosol from a contaminated cooling tower in a hospital. Inhaling these bacteria may cause Legionnaires' disease, a serious pneumonia, or Pontiac fever, a less severe, flu-like illness. Several different exposure scenarios were developed to compare exposure estimates. The model incorporated a variety of factors affecting airborne concentrations of *Legionella* bacteria between the cooling tower source and exposed individuals. Variables affecting source concentrations included *Legionella* concentration in the cooling tower water, water flow and air flow rates in the tower, and the percentage of tower drift. Pathway variables affecting the aerosol concentration between the cooling tower and potentially exposed individuals included distance from the tower, wind conditions, moisture level in the air, and filters in the ventilation system. Evaluation of one exposure scenario determined that the time needed to inhale a dose of only one viable *Legionella* bacterium was 200,000 times longer for a hospital patient compared to a maintenance worker on the roof near the cooling tower. Development of an exposure assessment model that incorporates actual exposure parameters provides a useful tool for estimating health risks associated with exposures to *Legionella* bacteria.

1891 POLLUTANT-INDUCED IMMUNOSUPPRESSION AS A CAUSE OF DWINDLING AMPHIBIAN POPULATIONS.

L M Hudson[1], M Nagarkatti[2], D Linzey[3], J B Linzey[4], J Robertson[2], C Brecht[3], J Burroughs[5], J Bacons[6], and P S Nagarkatti[1]. [1]*Dept. of Biology,* [2]*Dept. of Biomedical Sciences, and* [5]*Dept. of Biochemistry, Virginia Tech, Blacksburg, VA, USA;* [3]*Wytheville Community College, Wytheville, VA;* [4]*New River Community College, Dublin, VA; and* [6]*Bermuda College, Paget, Bermuda.*

Recently, a decrease in the populations of marine toads (*Bufo marinus*) and whistling frogs (*Eleutherodactylus johnstonei* and *E. gossei*) has been noted on the island of Bermuda. In the current study, we investigated whether this decline was related to altered immune functions. During August 1998, a significant proportion (25%) of the toads exhibited deformities. Analysis of soil samples revealed presence of chlorinated pesticides and PCBs. Spleen cells from toads collected from more polluted areas exhibited a decrease in B cell proliferative response to lipopolysaccharide when compared to the responsiveness of B cells from toads collected from less polluted areas. In contrast, the T cell responsiveness to mitogens in these two groups was not significantly altered. Analysis of major parenchymatous organs in marine toads and whistling frogs showed alterations in hepatic and splenic morphology, indicative of exposure to toxicants. Together, the current study demonstrates that the immune functions of toads from contaminated sites of Bermuda are significantly altered, which may account for the decline in their population. (Supported in part by grants from NIH and EPA.)

1892 CANCER RISK ASSESSMENT OF METHYL T-BUTYL ETHER (MTBE) FOR CALIFORNIA DRINKING WATER.

A G Salmon, J P Brown, M S Sandy, Y Wang, and A M Fan. *Office of Environmental Health Hazard Assessment, California Environmental Protection Agency, Berkeley, CA.*

MTBE, an oxygenate in California's cleaner burning gasoline, has appeared in ground water and drinking water sources, primarily from leaks in underground fuel storage tanks. The California Local Drinking Water Protection Act of 1997 mandates the establishment of primary and secondary drinking water standards for MTBE. As part of this process OEHHA has developed a public health goal (PHG) for MTBE based solely on human health criteria. OEHHA evaluated the toxicity data on MTBE and concluded that the animal carcinogenicity data was an appropriate basis of the PHG. Carcinogenicity of MTBE has been observed in both sexes of the Sprague-Dawley rat in a lifetime gavage study, in male F344 rats in a 24-month inhalation study, and in male and female CD-1 mice in an 18-month inhalation study. The tumor types observed in rats were Leydig interstitial cell tumors, renal cell tumors and combined lymphoma/leukemia. Evaluation of genotoxicity and mechanistic data did not identify the modes of action for carcinogenicity at these sites; however the relevance to human cancer risk could not be discounted. A physiologically-based pharmacokinetic model was used to estimate an internal dose metric (AUC for unchanged MTBE) in the rat which allowed cross-route extrapolation (inhalation to oral equivalent). A polynomial curve was fit to the tumor incidence data and adjusted doses, and the 95% lower confidence limit on the dose for 10% incidence estimated for each site (LED_{10}). The cancer slope factors (CSFs) for the rat data were calculated as $0.1/LED_{10}$, yielding a geometric mean CSF of 1.8 x 10^{-3} $(mg/kg\text{-}d)^{-1}$.

1893 ENDCORINE DISRUPTOR KNOWLEDGE BASE (EKB).

W Tong[2], R Perkins[2], J Anson[1], W Branham[1], R Blair[1], B Hass[1], H Fang[1], L Shi[2], Y Chen[2], J Meehan[2], R Nossaman[2], W Welsh[3], D Sheehan[1]. [1]*FDA National Center for Toxicological Research (NCTR), Jefferson, AR;* [2]*R.O.W. Sciences, Jefferson, AR;* [3]*University of Missouri, St. Louis, MO, USA.*

The NCTR's Endocrine Disruptor Knowledge Base (EKB) is intended to assist in risk assessment and regulatory decisions for exogenous compounds that may alter responses and disrupt vertebrate endocrine systems. This integrated multidisciplinary program comprises three primary elements: 1) *in vitro* and *in vivo* experimentation 2) an Internet-based bibliography and bioactivity database; and, 3) computer-based predictive models. *In vitro* competitive binding assays have been done for about 100 active and 50 inactive compounds. The assays are for not only the estrogen receptor, but also Testosterone-Estradiol Binding Globulin and Alphafetoprotein, respectively, the human and rodent serum binding proteins that are major determinants of estrogen potency. The EKB provides a cross-linked database and bibliography that is searchable with an Internet browser. An ORACLE database is designed for *in vitro* and *in vivo* data, including complex assays such as the multi-generation protocols of the NIEHS-supported endocrine disruptor studies. The EKB will be made universally available via the Internet. Users will be able to obtain and contribute data, conduct data mining and structure search, share annotations among a defined audience such as for data peer review, and view or download data and chemical structure files. Thus, the EKB will provide an environment for virtual collaboration and knowledge mining facilitating identification of data gaps and research hypotheses, and development of QSAR, chemometric, and simulation predictive models. The overarching goal of our computational modeling efforts is to assess, develop and validate a broad spectrum of analytical tools for predicting a compound's endocrine disrupting potential at the mechanistic level. QSAR models include 3D Comparative Molecular Field Analysis, Hologram QSAR, as well as pharmacophoric models. Modeling is guided with structural diversity measures using descriptors selected with genetic algorithms. Classification models include unsupervised learning approaches such as Principal Components and Hierarchical Cluster Analysis, and supervised learning approaches with K Nearest Neighbor, SIMCA and neural networks.

1894 USING CLASS BASED ACTION LEVELS (CBAL) TO EVALUATE POTENTIAL CHEMICAL EXPOSURES IN DRINKING WATER.

M C Sanders, C J McLellan, C A Bradlee, F T Hammer, C I Cailipan, and L L Bestervelt. *NSF International, Ann Arbor, MI, USA.* Sponsor: M L Dourson.

NSF International is a not-for-profit group dedicated to the protection of public health and the environment through standards development and third-party certification of products impacting the quality of drinking water. In accordance with ANSI/NSF Standards 60 and 61, NSF international uses available chemical and toxicological data to establish chemical specific limits for drinking water. Often times however there is insufficient toxicological data available to establish a chemical specific Maximum Allowable Level (MAL), or chemicals are only tentatively identified by Gas Chromatography/Mass Spectrometry. For these evaluations, NSF International has established chemical Class Based Action Levels (CBAL). CBAL can be used to evaluate tentatively identified chemicals, as well as chemicals that do not have sufficient information to develop an MAL. A chemical class is defined by similarities in structure, functional group, and molecular weight. Prior to the establishment of CBAL, NSF created the Toxicology Evaluation Database (TED), which is a summary of toxicological information on over 780 chemicals. This database was constructed with relevant toxicological information available from sources such as the USEPA, Health Canada, NSF International, and various State and Federal Drinking Water Standards and Guidelines. In conjunction with OncoLogic® Structure Activity Program developed by EPA, the TED database was used to establish the various CBA> The use of this strategy is presented for the alkylated phenolic class.

1895 DEVELOPMENT OF AN AQUATIC TOXICITY DATABASE: CRITERIA FOR DETERMINING CRITICAL ENDPOINTS.

E L Puglielli, L M Milchak, J R DiPasquale, and T A Dobson. *ChemADVISOR, Inc., Pittsburgh, PA, USA.*

A database has been developed to provide a standardized resource of aquatic toxicity data for use in ecological risk assessment, environmental health and safety, and hazardous chemical evaluation. The dynamic list is comprised of data derived from a large amount of acute toxicity testing conducted on freshwater aquatic species for over 250 commonly used industrial chemicals. Data selection is in compliance with global harmonization efforts, based on information and guidelines established by the Toxic Substance Control Act (TSCA) and the Organization for Economic Cooperation and Development (OECD), as well as various reference texts. Entries in the database contain toxicity data from three species of fish, a representative invertebrate (*Daphnia magna*), a luminescent bacterium, and alga, where available. All entries in the database contain the test endpoint, the common name of the species of the aquatic organism, and experimental value. The entries also contain test parameters including age of test fish species, test method, and information on water conditions. The chosen parameters are considered to be the most commonly used and accepted to provide the most useful assessment of toxicity and to allow for comparisons between data sets. This data is particularly useful for incorporation into Material Safety Data Sheets (MSDS) in sections dealing with ecological information as recommended by ANSI Z400.1 and as measures of effect for assessment endpoints in ecological risk assessment.

1896 PEER REVIEW PROCESS FOR RISK ASSESSMENT DOCUMENTS AND METHODS.

J Patterson and M L Dourson. *Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH, USA.*

High quality human health risk values can be assured by independent peer review. Traditionally, governments have assessed the human health hazards of pollutants and derive risk values (e.g., RfCs, MRLs, slope factors, TDIs). Increasingly industry, states, consulting firms, trade groups and consortiums are estimating risk values and preparing supporting documentation. Toxicology Excellence for Risk Assessment (*TERA*) instituted a program in late 1996 to make independent peer review of risk values available. A balanced panel of scientists from government, industry, consulting, academia, and environmental groups is brought together for quarterly meetings. After approval, a risk value can be included on the International Toxicity Estimates for Risk (*ITER*) database (http://www.tera.org/iter) for use by other risk assessors world-wide. Participants have included Health Canada, the International Copper Association, ChemRisk, Dow AgroSciences and U.S. EPA. Summaries of discussions and results are made available on the Internet (http://www.tera.org/peer). Results include an acrylonitrile inhalation unit risk developed by *TERA* of 1.1E-2 per mg/cu.m, and a site-specific reference dose developed by ICF Kaiser International of 0.0003 to 0.001 mg/kg-day for people eating methylmercury contaminated fish. The latter risk value uses a PBPK model and Monte Carlo analysis, which results in a distribution of ingestion rates and the RfD. Both values were approved by expert panels and are now available on *ITER*. A hexavalent chromium RfC, developed by ChemRisk, and Telone II cancer and noncancer assessments, prepared by Dow AgroSciences, have also been approved by expert panels and will be loaded on *ITER* shortly.

1897 COMMUNICATING REGULATORY INFORMATION ABOUT ENVIRONMENTAL CONTAMINANTS TO THE PUBLIC.

M A Kamrin and J MacDonagh-Dumler. *Institute for Environmental Toxicology, Michigan State University, East Lansing, MI, USA.*

To contribute effectively as citizens and to make individual risk decisions, the public needs to have at least a rudimentary understanding of the different rules and regulations that govern environmental contaminants in different media; e.g., pesticides in foods. Although government agencies have made significant efforts to make information about regulations available, particularly on the WWW, it generally requires a great deal of time and effort to locate this information, even for those familiar with both the WWW and the way government functions. It is especially burdensome if a citizen wants to know regulations governing a pesticide in different media; e.g., drinking water and air. This requires visits to several WWW sites each requiring a different search strategy. To overcome this difficulty, we have summarized all of the critical federal laws and rules in lay language and put this information in one place on the WWW. In addition, these summaries are linked to the specific pages on government sites that provide regulatory values; e.g., MCLs in drinking water. Thus, this information is always current. Further, these pages are linked to information about the implementation of the regulations; e.g., lists of Superfund sites. The summaries are supplemented by

glossaries that provide definitions of terms that must be used to be accurate but which may not be familiar to the public. This WWW site is currently being expanded to include similar information relating to the rules and regulations in the states in the Great Lakes region. It is hoped that this will provide a model that can be used in other parts of the country.

1898 THE AIR TOXICS HOT SPOTS PROGRAM RISK ASSESSMENT GUIDELINES, PART II: TECHNICAL SUPPORT DOCUMENT FOR DESCRIBING AVAILABLE CANCER POTENCY FACTORS.

J D Budroe, M A Marty, J R Fowles, J B Faust, J Rabovsky, J F Collins, F J Mycroft and G V Alexeeff. *Office of Environmental Health Hazard Assessment, California Environmental Protection Agency, Berkeley, CA.*

A cancer unit risk and potency factor database for 120 compounds has been developed to facilitate cancer risk assessments performed in the state of California under the requirements of The Air Toxics "Hot Spots" Information Act of 1987 (AB2588). The compounds chosen are listed as Toxic Air Contaminants (TACs) by the California Air Resources Board (CARB). Unit risk and cancer potency factors for the compounds listed were obtained from the following sources in order of preference: TAC documents (CARB), Proposition 65 documents (Reproductive and Cancer Hazard Assessment Evaluation Section (RCHAS), Office of Environmental Health Hazard Assessment (OEHHA)), Integrated Risk Information System (IRIS) documents (Office of Health and Environmental Assessment, US EPA), Expedited Proposition 65 documents (RCHAS), and other OEHHA documents. A hierarchy of choice was developed for selecting cancer potency values available from multiple sources which gives preference to sources which 1) include external peer review and public comment procedures for publishing cancer potency values, and 2) use the most recent available data sets and scientific methodology. The database includes a summary of the key studies and methodology used to derive the cancer unit risk and potency factors for each compound listed. Changes from prior draft versions include 1) the addition of lead and lead compounds and diesel exhaust to the database; 2) adoption of new US EPA unit risk values for polychlorinated biphenyls (PCBs); 3) the addition of oral cancer potency factors where appropriate; 4) a discussion of how harmonization with the new draft US EPA cancer risk assessment guidelines will occur. This database has undergone external peer review (CARB Scientific Review Panel), public comments at workshops, and is accessible via the Internet. This Hot Spots database will facilitate Hot Spots cancer risk assessments performed in the state of California by providing a single, easily available source for cancer unit risk and potency factors.

1899 CLONING, HETEROLOGOUS EXPRESSION, AND CHARACTERIZATION OF HUMAN CYP2A13.

T Su, Q-Y Zhang, and X Ding. *Wadsworth Center, New York State Department of Health, School of Public Health, State University of New York at Albany, NY, USA.*

Three members of CYP2A subfamily, CYP2A6, CYP2A7, and CYP2A13, have been identified in humans. CYP2A6 is the major coumarin 7-hydroxylase and is involved in the metabolic activation of numerous procarcinogens, whereas CYP2A7 may be inactive. A cDNA for CYP2A13 has not been isolated; a putative coding sequence (CYP2A13*1) was previously deduced from *CYP2A13* gene sequence. It is not known whether CYP2A13 is functional or where it is expressed. In this study, the coding region of a CYP2A13 cDNA, named CYP2A13*2, was cloned from human nasal mucosa. Sequence alignment with CYP2A13*1 indicated that the two allelic variants share 98.6% amino acid sequence identity. Preliminary genotyping studies showed that CYP2A13*2 may be the predominant allele. CYP2A13*2 mRNA was detected by RNA-PCR in liver, in addition to nasal mucosa, and in a number of other extrahepatic tissues. Microsomal preparations from CYP2A13*2-expressing SF9 cells were active in a reconstituted system in metabolizing coumarin to 7-hydrxycoumarin, albeit with a lower activity than that of CYP2A6. In addition, CYP2A13*2 was also active in the metabolic activation of several xenobiotic compounds, such as hexamethylphosphoramide and N-nitrosomethylphenylamine. CYP2A13*2 may play important roles in xenobiotic toxicity in humans. (Supported in part by NIH grant ES-07462.)

1900 BIOTRANSFORMATION OF COUMARIN BY RODENT AND HUMAN CYTOCHROMES P450: METABOLIC BASIS OF TISSUE-SELECTIVE TOXICITY IN THE OLFACTORY MUCOSA OF RATS AND MICE.

X Zhuo, J Gu, Q-Y Zhang, D C Spink, L S Kaminsky, and X Ding. *Wadsworth Center, New York State Department of Health, School of Public Health, State University of New York at Albany, NY, USA.*

Coumarin was previously found to cause tissue-selective toxicity in the olfactory mucosa (OM) of rats and mice, with rats being the more sensitive species. The aim of this study was to explore the role of target tissue biotransformation in OM-selective toxicity and the metabolic basis of the species differences in coumarin toxicity. At least six coumarin metabolites were detected in OM microsomal reactions, with *o*-hydroxyphenylacetaldehyde (*o*-HPA) being the most abundant. The rates of metabolic activation of coumarin, as indicated by the formation of *o*-HPA, were comparable in OM microsomes of rats and mice, but were about 25- and 3-fold higher in OM than in liver microsomes of rats and mice, respectively. Thus, target tissue activation seems to play an important role in the tissue-selective toxicity, whereas differences in the rates of hepatic metabolism may be responsible for the species difference in olfactory toxicity. Purified, heterologously expressed mouse CYP2A5 and CYP2G1 produced 7-hydroxycoumarin and *o*-HPA as the predominant products, respectively. Kinetic analysis and immunoinhibition studies indicated that the OM-specific CYP2G1 plays the major role in metabolic activation of coumarin. Furthermore, of 13 human P450s examined, five were active in the metabolic activation of coumarin, suggesting a potential risk of coumarin toxicity in humans. (Supported in part by NIH grant ES-07462.)

1901 EXPRESSION OF BIOTRANSFORMATION ENZYMES IN HUMAN FETAL NASAL MUCOSA.

J Gu, T Su, Y Chen, Q-Y Zhang, and X Ding. *Wadsworth Center, New York State Department of Health, School of Public Health, State University of New York at Albany, NY, USA.*

High levels of P450 are present in the olfactory mucosa (OM) in mammalian animals and contribute to the known tissue-selective toxicity of numerous chemical compounds. Olfactory toxicity in perinatal period may have greater impact on behavior, growth, and development than in adults. To establish a molecular basis for determining the risk of developmental toxicity in OM, the expression of a number of P450 isoforms and other biotransformation enzymes was examined in hepatic and nasal microsomes prepared from aborted human fetus at gestational day 91-125 (G91-G125). The relative tissue levels of various biotransformation enzymes were determined on immunoblots. Expression of CYP2A, CYP2B6, CYP2J, NADPH-P450 reductase, and microsomal epoxide hydrolase was detected in both OM and liver at as early as G91. The level of expression in OM is lower than that in liver, except for the CYP2A-related protein, which was expressed in OM at much higher levels. OM expression of CYP2A6, CYP2A13, CYP2B6, and CYP2J2 mRNA was confirmed using RNA-PCR. The prenatal expression of biotransformation enzymes in human OM may have detrimental consequences upon transplacental exposure to xenobiotics. (Supported in part by NIH grant ES-07462.)

1902 THE EFFECT OF *o*-XYLENE INHALATION ON CYTOCHROME P450 ISOZYMES AND TOXICITY IN RAT LUNG AND NASAL MUCOSA.

L V Radzius and R A Schatz. *Northeastern University Toxicology Program, Boston, MA.*

The respiratory tract represents the initial site of contact for inhaled toxicants such as xylene. The lung and nasal mucosa receive the highest dose of inhaled xenobiotics and are known to have high mixed function oxidase capability. Exposure to *o*-xylene by inhalation (300 ppm for 6 hours) inhibited numerous cytochrome P450 isozymes in the lung and nasal mucosa. Pulmonary CYP2B1 activity, as measured by O-dealkylation of benzyloxyresorufin (BROD), and CYP2E1, as measured by NDMA demethylase activity, were inhibited, 50% and 13%, respectively, immediately following exposure to *o*-xylene. However, pulmonary CYP2B1 and CYP2E1 activity recovered to control values 24 hours following cessation of exposure. Pulmonary CYP4B1 activity, as measured by 2-aminofluorene N-hydroxylase activity, was inhibited by 59% immediately following exposure and remained inhibited (40%) 24 hours following cessation of exposure.

Isozymes of the nasal mucosa were also affected by exposure to *o*-xylene; CYP1A1 activity, as measured by O-dealkylation of ethoxyresorufin (EROD), as well as CYP2B1, CYP2E1, and CYP4B1 were inhibited by 69%, 44%, 40% and 49%, respectively. With the exception of CYP2B1 activity, none of these isozymes of the nasal mucosa recovered 24 hours following cessation of exposure. Although P450 isozymes in the respiratory tract were markedly affected by exposure to *o*-xylene, analysis of bronchoalveolar lavage fluid and nasal lavage fluid did not demonstrate evidence of cellular damage. Levels of gamma-glutamyl transferase (GGT), a membrane-bound enzyme, and lactate dehydrogenase (LDH), a cellular enzyme, were not significantly elevated in lavage fluid at either time point following *o*-xylene exposure. Therefore, a decrease in the metabolic capacity of the respiratory tract was not accompanied by overt toxicological changes at this site.

1903 METHYL-PARATHION (Me-PA) IS ACTIVATED IN RAT BRAIN HOMOGENATES BY CYTOCHROME P450 (CYP) 2B1.

G Ortega-Mantilla[1], A Sierra-Santoyo[1], J V Calderón-Salinas[2], J L Muñoz-Sánchez[3], M Manno[4] and A Albores[1]. [1]*Environmental Toxicology Section and* [2]*Departament of Biochemistry, Cinvestav-IPN, Mexico City, Mexico;* [3]*Department of Biochemistry, ENCB-IPN, Mexico City, Mexico; and* [4]*Institute of Occupational Medicine, University of Padua, Italy.*

The role of cytochrome P-450 on the activation of Me-PA, a widely used phosphorotioate pesticide and its inhibition by phenobarbital (PB), monoclonal anti-rat CYP antibodies and CO was studied in brain post-mitochondrial homogenates of adult male Wistar rats. The activation of Me-PA (20 – 160 nM) was monitored by the inhibition of acetylcholinesterase (AChE) using the hydrolysis of acetylthiocholine and colour development with 5,5'-dithio-bis-2-nitrobenzoate. As expected, Me-PA irreversibly inhibited the AChE activity (Vmax decreased 36%, whereas Km_{app} barely change). Previous bubbling with CO or addition of anti-2B1 antibodies totally prevented the inhibition of AChE by Me-PA, but anti-CYP 1A1 antibodies showed no effect. PB (80 μ M), which acts as a CYP 2B1 substrate, decreased 20% the inhibitory effect Me-PA (20 nM) on AChE. The protective effect of anti-2B1 antibodies and PB towards AChE inhibition by Me-PA indicates that CYP 2B1 is responsible for pesticide activation in the brain. However, Me-PA shows a higher affinity for CYP 2B1 than PB. (Supported by the European Commission: Biomed 2, BMH4-CT96-0184 and CONACyT and CNR, Mexican and Italian governments.)

1904 INDUCTION OF HEPATIC CYP2B1/2 FOLLOWING INHALATION EXPOSURE TO OCTAMETHYLCYCLOTE TRASILOXANE (D4): A DOSE RESPONSE STUDY.

P C Wilga[1], P A Jean[1], K P Plotzke[1], M E Andersen[2], D E Marshall[1], R H Gallavan[1], A L Quinn[1], R G Meeks[1], and J M McKim, Jr.[1]. [1]*Dow Corning Corporation, Health and Environmental Sciences, Midland, MI, USA;* [2]*ICF Kaiser, RTP, NC, USA.*

Exposure to D4 increases liver size and induces hepatic CYP2B1/2 enzymes in a manner similar to phenobarbital. The purpose of the present study was to characterize the pharmacodynamics of liver enlargement and hepatic CYP2B1/2 enzyme induction over a wide range of exposure concentrations. Female Fischer 344 rats were exposed to 0, 1, 7, 30, 70, 150, 300, 500, 700, and 900 ppm D4 via whole body inhalation 6 hr/day, for 5 days. Following exposure, liver was removed and microsomes were prepared. Liver-to-body weight ratios increased in an exposure- and liver concentration-dependent manner relative to controls. The response portion of the curve was linear with no apparent plateau. A maximum increase in liver weight of 24% over controls was achieved after exposure to 900 ppm D4. Hepatic CYP2B1/2 activity (as determined by PROD) increased in a D4 exposure- and liver concentration-dependent manner. Maximum activity occurred at 500 ppm D4, with decreasing activity between 500 and 900 ppm D4. Induction of CYP2B1/2 immunoreactive protein reached a plateau between 500 and 900 ppm D4. The lowest concentrations of D4 that resulted in significant liver enlargement and CYP2B1/2 induction were 150 and 7 ppm, respectively. These data indicate that the induction of hepatic CYP2B1/2 enzymes is an early biochemical response to D4 exposure in the rat and that a maximum response can be achieved following 5 days repeated inhalation exposure to 500 ppm D4. Supported in part by the Silicones Environmental Health and Safety Council.

1905 EVALUATION OF OCTAMETHYLCYCLOTETRASILOXANE (D4) AS A POTENTIAL INHIBITOR OF HUMAN HEPATIC CYTOCHROME P450 ENZYMES.

J M McKim, Jr[1]., A Madan[2], A Parkinson[2], P C Wilga[1], R H Gallavan[1], and R G Meeks[1]. [1]*Dow Corning Corporation, Health and Environmental Sciences, Midland, MI, USA;* [2]*XenoTech LLC, Kansas City, KS, USA.*

D4 is a low molecular weight (296 Da.) cyclic siloxane with industrial and consumer applications. Exposure to D4 increases liver size and induces hepatic CYP2B1/2 enzymes in a manner similar to phenobarbital. In addition, *in vivo* experiments with rats indicated that the enzymes induced by D4 are also involved with its metabolism. The purpose of the present study was to evaluate the ability of D4 to inhibit rat and human hepatic P450 enzymes *in vitro*. D4 inhibition of rat CYP2B1/2 activity in the presence of pentoxyresorufin (Km/2, Km, 2Km, and 4Km) was assessed by measuring the rate of dealkylation (PROD activity) with increasing D4 (0.095 to 2.4 μ M) concentrations. In these experiments D4 inhibited rat PROD activity in a concentration-dependent manner with a Ki value of approximately 0.11 μ M. To evaluate the ability of D4 to directly inhibit the major P450 enzymes in human liver, as well as determine the type of inhibition, microsomes from a pool of seven individuals were incubated with marker substrates at concentrations equal to Km/2, Km, 2Km and 4Km in the presence or absence of D4 (0.037 to 2.9 μ M). D4 appears to be a weak noncompetitive inhibitor of human CYP2B6 (Ki = 3.6 μ M), 2D6 (Ki=14 μ M) and 3A4/5 (Ki=11μ M) and a weak competitive inhibitor or CYP1A2 (Ki=12 μ M). Overall, these data indicate that D4 does not significantly inhibit the activity of the human CYP enzymes evaluated and therefore biologically relevant chemical-chemical interactions in humans would not be expected. Supported in part by the Silicones Environmental Health and Safety Council.

1906 SAR STUDIES OF CYP 2B INDUCTION IN PRIMARY CULTURED RAT HEPATOCYTES.

J M Silva, P Payette, J A Yergey and D A Nicoll-Griffith. Merck Frosst Centre for Therapeutic Research, Pointe-Claire-Dorval, Quebec, Canada. Sponsor: R Dixit.

Induction of cytochromes P450 (CYP) by drugs can lead to drug-drug interactions. Work in our laboratory has focused on the application of primary cultured hepatocytes to determine CYP induction potential of drug candidates in support of drug discovery. To further determine the usefulness of this model, a series of structurally related compounds from our COX-2 inhibitor program were evaluated for their ability to induce CYP 2B, in order to determine any structure activity relationship. Freshly isolated rat hepatocytes were cultured on Matrigel for 2 days to allow for culture adaptation followed by exposure (24 h) to test compounds. Cells were then harvested and CYP 2B analysis was performed by Western Blot using anti-rat CYP 2B1 antibodies. Nontreated cells as well as cells exposed to phenobarbital were used as negative and positive controls, respectively. Induction was defined as a percentage relative to positive control (phenobarbital treated cells). Results showed that CYP 2B inducibility by our model compound could be dramatically decreased by the simple modification of the R-group from an ethyl to a methyl or hydrogen moiety (from 80% to <5% CYP 2B induction). These studies clearly demonstrate that the use of such an *in vitro* cell model can significantly aid our ability to carry out SAR studies within a structurally related class of compounds.

1907 REVERSE TRANSCRIPTION-POLYMERASE CHAIN REACTION CHARACTERIZATION OF EXPRESSION OF CYP2B7 AND CYP2B8 (P450 hIIB2) mRNAs IN HUMAN LIVERS.

S Bai[1], A Parkinson[1,2], A Madan[2] and M Czerwinski[1]. [1]*Department of Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS;* [2]*Xenotech, LLC, Kansas City, KS, USA.*

The human CYP2B subfamily computes three mRNAs, namely CYP2B6, CYP2B7 and CYP2B8 (P450 hIIB2). In contrast to the already characterized, predominantly hepatic, expression of CYP2B6, our knowledge of the expression of CYP2B7 is limited, and the expression of CYP2B8 has not been evaluated at all. CYP2B7 mRNA has been found in lung, lung tumors, and bronchial epithelial cells. The mechanism of translation of CYP2B7 and CYP2B8 and the properties of the enzymes remain to be determined. We evaluated the extent of CYP2B7 and CYP2B8 mRNA expression in human livers. Detection of CYP2B7 mRNA was based RT-PCR amplification of a 578bp fragment of the mRNA. The CYP2B7 primers amplify the CYP2B6

mRNA as well, but the latter fragment is 704 bp long. The CYP2B8 forward primer hybridizes to a sequence unique to the CYP2B8. The detection of CYP2B8 mRNA is based on amplification of 480bp fragment. The RT-PCR analysis of 30 human livers was performed. Evidence for presence of trace amounts of CYP2B7 mRNA in human livers was found while strong bands representing CYP2B6 were also amplified. The expression of CYP2B8 was demonstrated in the majority of specimens analyzed. The data agree with lung-specific expression of CYP2B7. Expression of CYP2B8 mRNA in most human livers is a novel finding. Further studies are required to determine whether CYP2B8 mRNA encodes a functional enzyme. (Supported by NIH grant ES03765.)

1908 DIFFERENTIAL REGULATION OF THE CYP2B10 PHENOBARBITAL RESPONSIVE ENHANCER MODULE (PBREM) AND THE CYP2B1 PROMOTER IN HEPG2 CELLS.

P J Opdam[1], M Czerwinski[1] and A Parkinson[1,2]. [1]Department of Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS, USA; [2]Xenotech LLC, Kansas City, KS, USA.

Negishi and colleagues recently identified a 51 base pair phenobarbital-responsive enhancer module (PBREM) in the 5' -flanking region of the mouse *CYP2B10* gene (Honkakoski, P., *et al*; *Mol. Pharmacol.*, 53, 597, (1998)). This sequence significantly enhances reporter gene expression (~10-fold) in transfected mouse hepatocytes treated with either phenobarbital (PB) or 1,4-bis[2-(3,5-dichloropyridoyloxy)]benzene (TCPOBOP). A putative PBREM is found in the 5' regulatory region of the rat *CYP2B1* gene. This sequence shares 98% identity with the *CYP2B10* PBREM. We hypothesize that humfFan CYP2B genes contain similar regulatory sequences. The purpose of this study was to determine if the *CYP2B10* PBREM is activated in the human hepatoma-derived HepG2 cells. The PBREM and 3.9 kb of the CYP2B1 5' flanking region were subcloned into vectors with firefly luciferase (luc) as a reporter gene; pGL2-Promoter and pGL2-Basic, respectively. A CMV/β-galactosidase reporter was used as a control for transfection efficiency. Treatment of transfected HepG2 cells with either PB or TCPOBOP significantly activated the PBREM/luc construct (2-4 fold) but did not induce the expression of the CYP2B1/luc construct. These results suggest that HepG2 cells activate the PBREM in response to prototypical CYP2B inducers. Contrasting the response of PBREM/luc with that of CYP2B1/luc suggests the presence of one or more negative regulatory elements within the CYP2B1 promoter region. Further studies will address this hypothesis. (Supported by NIH grant ES03765)

1909 INSULIN-MEDIATED MODULATION OF CYTOCHROME P450 GENE INDUCTION PROFILES IN PRIMARY RAT HEPATOCYTE CULTURES.

J S Sidhu, and C J Omiecinski. *Dept. of Environmental Health, University of Washington, Seattle, WA, USA.*

In this investigation, we examined the effects of insulin on gene induction responsiveness in primary rat hepatocytes in light of recent studies which have questioned the role of this hormone in the maintenance of cytochrome P450 (CYP) gene expression. Cells were cultured for 72h either in the absence or presence of 1 μ M insulin and then exposed to increasing concentrations of phenobarbital (PB; 0.01-3.5 mM). Culturing in the absence of insulin produced 1.5-2-fold increases in the induction magnitude of CYP2B1 and CYP2B2 mRNA expression resulting from PB exposures, without altering the bell-shaped dose-response curve characteristic of this agent. However, for the CYP3A1 gene, insulin deprivation led to a pronounced shift in both the PB induction magnitude and dose-response relationships of the induction response, with higher levels of CYP3A1 expression resulting from exposures to lower concentrations of inducer. Insulin deprivation also reduced the time required for maximal induction of CYP2B1/2 and CYP3A1 gene expression. The insulin effects were not specific for PB induction, as insulin deprivation similarly enhanced both dexamethasone- and β -naphthoflavone-inducible CYP3A1 and CYP1A1 expression profiles, respectively. In contrast, the level of liver-specific albumin mRNA expression was considerably reduced in cells deprived of insulin. We conclude therefore, that insulin is an important regulator of inducible and liver specific gene expression in primary rat hepatocytes and that its concentration in media formulations should be more physiologically defined. (Supported by USPHS Grant GM 32281 and the Burroughs Wellcome Fund.)

1910 BONE MARROW STROMAL CELL EXPRESSION OF DMBA-METABOLIZING CYP1B1 IS REQUIRED FOR PRE-B CELL APOPTOSIS.

S M Heidel[1], C J Czuprynski[1], and C R Jefcoate[2]. [1]*Department of Pathobiological Sciences and* [2]*Department of Pharmacology, University of Wisconsin, Madison, WI.*

We hypothesize that the bone marrow toxicity of DMBA requires metabolism by CYP1B1. Previous studies in our laboratory have demonstrated that bone marrow stromal cells constitutively express high levels of CYP1B1 that metabolizes DMBA, and that the expression of CYP1B1 is not dependent on the AhR. To investigate the potential roles of CYP1B1 and the AhR in bone marrow toxicity, primary bone marrow stromal cell cultures were established from mice deficient or heterozygous for CYP1B1, and from mice deficient or heterozygous for the AhR. These primary bone marrow stromal cells were co-cultured with pre-B cells in the presence or absence of DMBA. Pre-B cells apoptosis was used as a measure of toxicity and was evaluated by TUNEL labeling and PARP cleavage methods. DMBA treatment resulted in a significant increase ($p<0.02$) in pre-B cell apoptosis when co-cultured with CYP1B1 heterozygous, AhR deficient, and AhR heterozygous bone marrow stromal cells. However, DMBA treatment did not result in pre-B cell apoptosis when co-cultured with CYP1B1 deficient bone marrow stromal cells. These findings suggest that CYP1B1, but not the AhR, is required for the bone marrow toxicity of DMBA.

1911 THE ARYL-HYDROCARBON RECEPTOR AND CYP1B1 ARE NEGATIVE REGULATORS OF ADIPOCYTE DIFFERENTIATION.

L G Ganem, D L Alexander and C R Jefcoate. *University of Wisconsin, Madison, WI, USA.*

Mouse embryo fibroblast (MEF) lines and primary embryo cells undergo differentiation to adipocytes when exposed to the appropriate hormonal stimulus. We have generated MEF lines derived from wild-type C57BL/6 mice (WT MEF) and from mice that are deficient in the aryl-hydrocarbon receptor (AhR(-/-)MEF). WT MEFs exhibit a typical cascade of adipogenesis that is blocked by TCDD in its early stages (first 48 hrs). TCDD treatment suppresses differentiation markers such as PPARγ and C/EBPα, G3PDH activity, and lipid accumulation. Subconfluent AhR(-/-)MEFs show enhanced lipid synthesis in standard medium. Given the appropriate stimulus, these cells also undergo adipogenesis that is completely resistant to TCDD. AhR(-/-)MEFs are also deficient in CYP1B1, the major xenobiotic metabolizing P450 found in fibroblasts that is under the control of the AhR. MEFs derived from CYP1B1-deficient mice (1B1(-/-)MEFs) show greatly enhanced spontaneous and induced adipogenesis. However, adipogenesis in these cells is sensitive to TCDD. Based on these results, we hypothesize that constitutively expressed CYP1B1 represses adipogenesis. AhR activation and the subsequent induction of CYP1B1 may further repress this pathway. However, AhR activation independent of CYP1B1 is sufficient to supress adipocyte differentiation. We propose that CYP1B1 activity determines the steady state level of an early lipophilic mediator of adipogenesis.

1912 LACK OF INVOLVEMENT OF cAMP AND PKA IN THE PHENOBARBITAL (PB) MEDIATED INDUCTION OF THE RAT CYTOCHROME P450 (CYP) CYP2B GENES IN PRIMARY HEPATOCYTE CULTURES.

N B Beck and C J Omiecinski. *Department of Environmental Health, University of Washington, Seattle, WA, USA.*

The effects of PB on the liver are quite diverse and include cellular hypertrophy, tumor promotion, perturbations of gap junctional intercellular communication, as well as gene induction. Previous research, from our laboratory and others, has focused recently on evaluating the signal transduction processes that regulate the inductive effects of PB on the CYP2B genes. These studies have examined the effects of diverse kinases, phosphatases, and cyclic adenosine monophosphate (cAMP) analogs on PB inducible CYP family members. The present studies were conducted to examine the potential role of second messenger pathways in the initial phases of induction, specifically addressing the effects of PB on the expression of intracellular cAMP levels and associated protein kinase A (PKA) activity. Using a highly differentiated primary rat hepatocyte system, cells were exposed to PB and examined for expression of intracellular cAMP and subsequent PKA activity. Cells were harvested at timepoints as early as 30 seconds and up to 48 hrs after treatment with PB. Intracellular cAMP was measured using a cAMP immunoassay and PKA activity was assessed by measuring transfer

of a labeled phosphate to a biotinylated Kemptide substrate. Although PB markedly induced CYP2B mRNA expression, there were no detectable increases in cAMP levels or PKA activity at any time following PB additions. These results demonstrate that the initial PB mediated induction of the CYP2B genes is not associated with cAMP dependent pathways or effects. (This work was supported by NIH grants GM32281 and ES07032, and the Burroughs Wellcome Fund.)

1913 REGULATION OF CYP1B1 TRANSCRIPTION IN MCF-7 AND HEPG2 CELLS.

S E Shehin and W F Greenlee. *University of Massachusetts Medical School, Worcester, MA, USA.*

Cytochrome P450 1B1 (CYP1B1) is expressed constitutively and is inducible by 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) in the human breast adenocarcinoma cell line MCF-7, but not in the human hepatoma cell line HepG2. Genomic DNA isolated from both cell lines was digested with the methylation-sensitive restriction enzyme isoschizomers *Msp*I and *Hpa*II and subjected to Southern analysis with a CYP1B1 *Xho*I fragment containing the region -1311 to +216 relative to the transcription start site. Although differences were observed in methylation patterns for the CYP1B1 gene from MCF-7 and HepG2 cells, treatment with the demethylating agent 5-azacytidine (10μM for six days) did not activate CYP1B1 mRNA expression in HepG2 cells. Treatment of HepG2 cells with the histone deacetylase inhibitor Trichostatin A (100 nM for 24h) also did not produce an increase in CYP1B1 mRNA. Analysis of DNA-protein interactions at the CYP1B1 minimal promoter region (-101 to +25) indicated no differences in protein binding patterns with nuclear extracts prepared from either MCF-7 or HepG2. Comparative analysis in MCF-7 and HepG2 cells of the constitutive expression of CYP1B1/luciferase reporter constructs containing a series of deletions in the 5' CYP1B1 enhancer region indicated the potential involvement of cell-specific *cis*-acting elements located within the region from -1336 to -911. Taken together, these findings indicate that the observed differences in CYP1B1 constitutive expression are not mediated by histone acetylation or DNA promoter/enhancer methylation. The results suggest that constitutive expression of CYP1B1 is controlled by the presence of negative regulatory factors, absence of positive regulatory factors, or both, acting in a cell-specific manner at a DNA element located at least 800 bp 5'-ward of the minimal promoter.

1914 USE OF THE YEAST 'ONE-HYBRID' APPROACH TO INVESTIGATE THE MOLECULAR MECHANISM OF TRANSCRIPTIONAL REGULATION BY PHENOBARBITONE.

J M Loughlin, T C Orton and J D Tugwood. *Safety of Medicines Group, Zeneca Pharmaceuticals, Macclesfield, Cheshire, U.K.*

Phenobarbitone (PB) is a potent inducer of CYP2B10 in mouse liver at the transcriptional level, and the gene regulatory elements that mediate this induction have been identified previously. The so-called Phenobarbitone-Responsive Enhancer Module (PBREM) is also present in the promoter regions of the rat PB-responsive CYP2B1 and 2B2 genes, and the PBREM sequences confer PB responsiveness on reporter genes in transient transfection assays using primary mouse hepatocytes. Our aim with these experiments was to obtain cDNA clones for the proteins that interact with the PBREM sequences, thereby improving our understanding of PB action at the molecular level. The yeast 'one-hybrid' system is designed to screen for DNA binding proteins, and is well suited to this situation where regulatory DNA sequences have been mapped but the interacting proteins have not been identified. Yeast 'reporter' strains were generated using three tandem of the PBREM sequences from the mouse CYP2B10 promoter, linked to the yeast HIS3 gene (to allow growth selection), and separately to the LacZ gene (to allow selection with X-Gal substrate). These reporter strains were screened with BALB/c mouse liver 'Activation Domain' (AD) libraries. Such libraries consist of plasmids containing cDNA fragments linked to a yeast transcription activator protein. Those cDNAs encoding proteins able to bind to CYP2B10 PBREM sequences will permit growth on medium lacking histidine, and/or produce blue colonies on exposure to X-Gal. To detect 'false positive' clones, yeast reporter strains have also been made using PBREM sequences from the closely related but PB-unresponsive CYP2B9 gene. The strategy is to screen for clones that are positive with the 2B10-based reporter strains, but negative with those containing 2B9 PBREM sequences. The results indicate that sequence-specific DNA binding proteins can indeed be identified in this way, and that this system represents a useful means of identifying factors involved in transcriptional regulation by toxic compounds.

1915 EFFECT OF PHENOBARBITAL ON SERUM ESTRADIOL LEVELS IN SPRAGUE DAWLEY RATS.

A L Quinn, R G Meeks and J M McKim Jr. *Dow Corning Corporation, Health and Environmental Sciences, Midland, MI.*

Phenobarbital (PB) is known to induce hepatic P450 enzymes, some of which are involved in the metabolism of 17β -estradiol (E_2). *In vitro* studies using high E_2 concentrations have suggested a role for the 2B1/2 enzymes in E_2 metabolism. The objective of this study was to evaluate the effect of phenobarbital (PB) on circulating levels of E_2 in female Sprague Dawley rats. A radioimmunoassay was utilized to monitor total E_2 levels at comparable stages of the estrous cycle. Microdialysis techniques were used to determine the percentage of total E_2 which existed as free hormone. Both techniques showed that PB treatment did not significantly decrease E_2, either as total hormone or alter the percentage that exists as free hormone. Follow up *in vitro* metabolism studies of estradiol by control and PB induced hepatic microsomes provided the following information: 1) The rate of disappearance of E_2 varies with substrate concentration, with the major PB inducible P450 enzymes, 2B1/2 appearing to have a role in E_2 metabolism only at concentrations that far exceed physiological levels (>500 nM). The induction of the 2B1/2 enzymes by PB was confirmed by PROD analysis, showing a >25 fold induction. 2.) Microsomes containing only recombinantly expressed rat CYP2B1 enzyme and reductase showed no metabolism of E_2 even at very high substrate concentration and high specific activity of radiolabeled E_2. 3.) CYP3A enzymes are involved in E_2 metabolism, however other P450 enzymes are capable of metabolizing E_2 as competition experiments with 100 fold excess of dexamethasone resulted in only a 50% reduction in the rate of metabolism. These *in vitro* metabolism studies illustrate the need for careful selection of substrate concentrations when *in vitro* experiments are used to predict *in vivo* events.

1916 MONO-SPECIFIC ANTIPEPTIDE ANTIBODY TO HUMAN CYP2B6.

D M Stresser and D Kupfer. *Department of Pharmacology and Molecular Toxicology, University of Massachusetts Medical Center, Worcester, MA, USA.*

To study the CYP2B6 contribution to methoxychlor metabolism within human liver microsomes and to initiate an investigation of CYP2B6 protein expression, we developed a highly sensitive polyclonal antibody targeted to a 20 residue CYP2B6 peptide. Though many immunological studies have described the absence or low expression CYP2B6 in human livers, in the present investigation we have found this not to be the case. Using our antibody, we immunoquantified CYP2B6 apoprotein expression in a panel of 28 livers and found concentrations ranging from 2 to 82 pmol/mg protein, with a mean value of 25 pmol/mg protein. Five livers (~18%) displayed relatively high levels of CYP2B6 (> 40 pmol/mg protein). There were no sex-related differences, though the highest level was observed in a one-week postpartum donor given several medications. A marked diminution in variability was found in individuals aged 56 or older (n = 12), but there were no age-related trends in mean CYP2B6 content. The antibody inhibited ortho-hydroxylation of methoxychlor catalyzed by cDNA-expressed CYP2B6 more than 90% but inhibited this reaction only 37% in human liver microsomes, indicating additional catalysis by other isoforms. We suggest that CYP2B6 represents a significant portion of total P450 in human liver. The exquisite sensitivity of our antibody (fmol quantities are easily detected on immunoblots) may explain our detection in 100% of livers versus the detection of CYP2B6 in a limited number of livers by certain other investigators.

1917 CONTRIBUTION OF CYTOCHROME P-450 2E1 AND P-450 2B1/2 TO THE HEPATOTOXICITY CAUSED BY KEPONE AND CARBON TETRACHLORIDE.

L Feng, S A Benjamin, and R S H Yang. *Center for Environmental Toxicology and Technology, Department of Environmental Health, Colorado State University, Ft. Collins, CO.*

The contribution of cytochrome P-450 isoenzymes P-450 2E1 and P-450 2B1/2 to hepatotoxicity induced by carbon tetrachloride (CCl_4) alone and Kepone/CCl_4 in combination was investigated in adult F344 male rats. Expression of P-450 2E1 and P-450 2B1/2 were evaluated in rats pretreated

with Kepone (single gavage dose at 16 mg/kg in corn oil, 8 days before sacrifice) by immunohistostaining and Western-blot. Hepatic damage was evaluated by histopathological examination in rats at 6 and 12 hr after the treatment of CCl_4 with or without the pretreatment of Kepone. In immunohistostaining study, we found that Kepone significantly induced P-450 2B1/2 in liver centrilobular and midzonal regions, however, it did not affect P-450 2E1 expression, which is mainly distributed in centrilobular region. Preliminary results from Western-blot studies suggested that Kepone could induce P-450 2B1/2 and did not have any significant effect on P-450 2E1. The above results can be used to explain the histopathological injury caused by CCl_4 alone and Kepone/CCl_4 interaction. In CCl_4 treated rats, liver histopathological change is mainly in centrilobular region, which is consistent with the centrilobular distribution of P-450 2E1, the dominant enzyme responsible for CCl_4 bioactivation in normal rats. In Kepone/CCl_4 treated rats, liver histopathological injury is throughout lobules with higher degree of injuries in centrilobular and midzonal regions. The induction of P-450 2B1/2 by Kepone in cetrilobular and midzonal regions might have caused the formation of free radicals from CCl_4 and contributed to the toxicity in these regions. We concluded that both P-450 2E1 and P-450 2B1/2 may play important roles in Kepone and CCl_4 interactive hepatotoxicity. (This study was supported by NIEHS Superfund Basic Research Program Project P42 ES05949.)

1918 INSULIN-MEDIATED DECREASE IN CYP2E1 EXPRESSION IN PRIMARY CULTURED RAT HEPATOCYTES: ROLE OF SRC KINASE AND PI3-KINASE.

K J Woodcroft and R F Novak. *Institute of Chemical Toxicology, Wayne State University, Detroit, MI, USA.*

We have previously demonstrated that insulin negatively regulates CYP2E1 mRNA and protein expression in primary cultured rat hepatocytes (Chem.-Biol. Interact., 1997, 107:75). In order to delineate the signalling pathways involved in the insulin-mediated decrease in CYP2E1, we have employed pharmacological inhibitors of various kinases involved in insulin-mediated signalling. Primary rat hepatocytes cultured in modified Chee's medium on Vitrogen substratum were maintained in the absence of insulin for 48 h. The addition of 1 nM, 10 nM or 1 μM insulin for 24 h resulted in a 65, 85, and >95% decrease in CYP2E1 mRNA levels, respectively, relative to untreated cells. Addition of the src kinase inhibitor geldanamycin (0.1 μM) 1 h prior to 1 nM, 10 nM or 1 μM insulin addition, diminished the insulin-mediated decline in CYP2E1 mRNA to 25, 70, and 85%, respectively. Addition of the phosphatidylinositol (PI)3-kinase inhibitor wortmannin (1-10 μM) 1 h prior to insulin addition also ameliorated the insulin-mediated decrease in CYP2E1. Wortmannin (10 μM) prior to 10 nM insulin addition maintained CYP2E1 mRNA levels at 75% of the level in untreated cells, whereas 10 nM insulin alone decreased CYP2E1 mRNA to 15% of the level in untreated cells. In contrast, the MAP kinase kinase inhibitor PD98059 (10-100 μM), and the p38 MAP kinase inhibitor SB202190 (1-100 μM), failed to affect the insulin-mediated decrease in CYP2E1 mRNA. Hence, the metabolic insulin signalling pathway involving Src kinase and PI3-kinase, and not the mitogenic pathway involving MAP kinases, is implicated in mediating the negative effect of insulin on CYP2E1 expression. (Supported by NIH Grant ES03656 and NIEHS Center Grant P30 ES0 6639.)

1919 GLUCOCORTICOID-MEDIATED EXPRESSION OF CYP2E1 AND CYP3A mRNA IN PRIMARY CULTURED RAT HEPATOCYTES.

M S Hafner, K J Woodcroft, and R F Novak. *Institute of Chemical Toxicology, Wayne State University, Detroit, MI.*

The effects of dexamethasone (Dex), on CYP2E1 and CYP3A expression was examined in primary cultured rat hepatocytes. Cells were plated on Vitrogen-coated 60 mm dishes and grown in modified Chee's medium (0.1 nM insulin and 0.1 μM Dex) for 18-22 h prior to glucocorticoid addition. Northern blot analysis revealed that hepatocytes treated with 0.1 nM to 10 μM Dex for 24 to 72 h gave a maximum induction of 20-fold (0.1 μM) for CYP2E1 mRNA levels, and 90-fold (10 μM) for CYP3A mRNA levels at 72 h. Furthermore, when Dex (0.1 μM) was incubated with the glucocorticoid receptor antagonist, RU486 from 1.0 nM to 10 μM for 48 h, CYP2E1 mRNA levels decreased by 80%, compared to a 2- to 3-fold stimulatory affect observed for CYP3A mRNA levels. Since gene expression can be influenced by mRNA stability, of which the latter is regulated (in part) by cytoplasmic mRNA binding proteins, constructs containing fragments of the CYP2E1 gene (coding sequence = 1.65 kb total) were cloned into appropriate vectors. Construct 2E1-R#3 (824-1648 bp, including the 3'UTR) was linearized and used to make 32P-labeled mRNA (*in vitro* transcription) that was incubated with cytosolic extracts of Dex-treated cells and 1 μg/μlRNase. Gel retardation assays revealed a band with increased intensity at 0.1 μM compared to 1.0 nM Dex treated hepatocytes. These data show that CYP2E1 and CYP3A are differentially induced by glucocorticoids and suggest that the Dex-mediated increase in CYP2E1 may be the result of mRNA stabilization. (Supported by grants ES03656 and EHS Center Grant ES06639.)

1920 COMPARISON OF CYP2E1 CONTENT IN LYMPHOCYTES OF ALCOHOLICS AND AMONG ETHNIC GROUPS.

J L Raucy, M Kearins, and S P Carpenter. *The Agouron Institute, La Jolla, CA, USA.*

Expression of the ethanol-inducible P450, CYP2E1 (2E1), in humans is influenced by several factors including xenobiotics and genetic polymorphisms. Monitoring 2E1 levels in individuals holds appeal because it may provide a means for risk assessment. We demonstrated that expression of 2E1 in lymphocytes reflected *in vivo* activity of the hepatic enzyme. The present investigation compares 2E1 content and metabolic parameters between alcoholics and non-alcoholics and among ethnic groups, including Native Americans (NA) and Hispanics (Hisp). In addition, previously described polymorphisms were examined. Individuals were administered the 2E1 substrate, chlorzoxazone (CZX) and lymphocytes isolated from whole blood samples. 2E1 protein and mRNA were measured in lymphocytes by western blotting or quantitative RT-PCR, respectively. Alcoholics exhibited elevated lymphocyte 2E1 mRNA (4-fold) and protein (2-fold) when compared to non-alcoholics. CZX clearance rates were 2.3-fold higher and AUC values were 2-fold lower in alcoholic individuals than in non-alcoholics. Furthermore, CZX clearance rates correlated ($r=0.40$, $p<0.005$, $n=52$) with 2E1 mRNA content of lymphocytes and mRNA further correlated ($r= 0.59$, $p<0.001$) with 2E1 protein content of white cells. The *Rsa*I + *Pst*I and *Dra*I polymorphisms were examined in the study participants, however the rare alleles were not identified. Nonetheless, 29% of NA and 13% of the Hisp were Type B (c1/c2) for the *Rsa*I + *Pst*I polymorphism. In contrast, Type B individuals were not identified in the Caucasian population. Interestingly, two Caucasians exhibited an unlinked *Rsa*I + *Pst*I allele, with the polymorphism occurring at the *Pst*I site. Individuals possessing the *Dra*I CD allele, included 22% of Hisp, 19% of NA and 8% of Caucasians. Results suggest that 2E1 mRNA in lymphocytes predicts corresponding protein levels and *in vivo* activity. Moreover, genotypic differences were observed among the two ethnic groups which differed from Caucasians. (Supported by DHHS grant AA08990.)

1921 THE ROLES OF CYTOCHROMES P450 2E1 AND 2B10 IN THE STEREOCHEMICAL BIACTIVATION OF 4-VINYLCYCLOHEXENE.

S M Fontaine, E Mash, and I G Sipes. *Department of Pharmacology and Toxicology, College of Pharmacy, The University of Arizona, Tucson, AZ, USA.*

4-Vinylcyclohexene (VCH), an intermediate in the production of rubber and styrene, is converted to toxic epoxides [1,2-vinylcyclohexene monoepoxide (1,2-VCHE), 7,8-vinylcyclohexene monoepoxide (7,8-VCHE), and, ultimately, vinylcyclohexene diepoxide (VCD)] by multiple isoforms of cytochrome P450. VCH has been shown to be ovotoxic in female $B6C3F_1$ mice, but not in female Fischer-344 rats. A crucial factor for the differences in toxicity can be attributed to a greater formation of the monoepoxides, and ultimately VCD, from VCH in the mice as compared to rats. Therefore, studies determining which cytochrome P450 isoforms are responsible for VCH bioactivation were performed to better explain the species-dependent toxicity. Hepatic microsomes isolated from mice treated with acetone (1% in drinking water for 5d) showed elevated levels of CYP2E1 and CYP2b10 as measured by densitometric analysis of blots. Following microsomal incubations, this treatment group demonstrated 2-fold increases in bioactivation of racemic VCH, (*R*)-VCH, and (*S*)-VCH to 1,2-VCHE as compared to controls. There was no increase in 7,8-VCHE formation. VCH pretreatment itself (7.5mmol/kg per day for 10d, ip) increased the formation of 1,2-VCHE (3-fold), 7,8-VCHE (2-fold), and VCD to detectable levels as compared to controls, all non-stereospecifically. Interestingly, VCH-induced microsomes showed approximately a 2-fold increase in CYP2b10 protein levels, but no increase in CYP2E1 levels. These data were supported by a lack of increase in aniline hydroxylase activity or p-nitrophenol activity (both CYP2E1 substrates) in VCH-induced microsomes as compared to control. Therefore, the increased epoxidation following repeated administration of VCH can be attributed to increased levels of CYP2b10 and not CYP2E1. (This research was supported in part by NIEHS (ES07091), Center Grant (ES06694) and Chemical Manufactures' Association.)

1922 VARIABLE CHANGES IN CYP2E1 ACTIVITY AFTER ENDOTOXIN ADMINISTRATION IN HUMANS.

S M Poloyac, R T Tosheva, S I Shedlofsky, and R A Blouin. *University of Kentucky College of Pharmacy and VA Medical Center, Lexington, KY, USA.*

Administration of E. coli lipopolysaccharide (LPS) has been shown to significantly reduce CYP2E1 protein and activity in the rat. To further investigate this phenomenon in humans, IV LPS (U.S. Standard Reference Endotoxin, CC-RE-Lot2) was administered to healthy volunteers for chlorzoxazone(CZN) pharmacokinetic and metabolite (6OHCZN) formation clearance analysis. Methods: Eight healthy nonsmoking male volunteers were enrolled in a balanced crossover design to evaluate the effect of endotoxin on the pharmacokinetics of chlorzoxazone. A 500mg oral dose of chlorzoxazone was given 1 hour following the final LPS or saline dose. Serum and urine CZN, 6OHCZN, and serum C-reactive protein (CRP) were quantified. In addition, serum protein binding of chlorzoxazone was determined via ultracentrifugation. Results: LPS administration produced a significant rise in temperature (3.1 ± 1.0 ° F), pulse (30 ± 9 bpm), and CRP (3.1 ± 0.8 mg/dL); thereby, demonstrating LPS induced an acute phase response. Endotoxin treatment failed to show a statistical change in CZN oral clearance (LPS; 4.2 ± 1.1 ml/min/kg vs. control; 4.1 ± 1.1 ml/min/kg) or formation clearance of 6OHCZN (LPS; 2.6 ± 1.1 ml/min/kg vs. control 2.5 ± 1.0 ml/min/kg). Upon closer inspection, intraindividual comparisons reveal 5 subjects which demonstrate an increase of 37 ± 30% in Clo and a 52 ± 41% increase in Clf. The remaining 3 subjects all demonstrate a reduction of 35 ± 3.5% in Clo and a 43 ± 30% decrease in Clf. Chlorzoxazone protein binding was not altered by endotoxin administration (LPS; 98.2 ± 0.6 vs. control 98.1 ± 0.4 %). Conclusions: Unlike the rat, humans demonstrate great interindividual response in 6OHCZN formation following endotoxin administration. This variability is not due to alterations in protein binding and is not well correlated with CRP alterations.

1923 CYTOCHROME P450 2E1 CONTENT OF ISCHEMIC LIVER IS MAINTAINED AT PRE-ISCHEMIC LEVELS BY DIMETHYL SULFOXIDE (DMSO).

J B Ulreich[1], J L Boles, M A Levy, R Roy, J J Whitehead, P W Johnson, K A Andreoni and P Z Nakazato. *Department of Surgery/Transplantation and [1]Center for Toxicology, The University of Arizona, Tucson, AZ, USA.*

Many potential transplant patients die waiting for organs. Using organs from non-heart-beating donors (NHBD) might reduce the current donor shortage. Warm ischemia in NHBD produces damage that can lead to graft failure in recipients post-transplantation. DMSO has several well-known biological activities that might prevent or reduce such damage. Male F344 rats were pre-treated with DMSO (2-6 ml/kg, IP) or saline (controls) and were made NHB for various periods. Organs were removed, cored, precision-cut and incubated *in vitro* for 4-96h. Potassium (K+) and lactate dehydrogenase (LDH) content determined viability of the tissue. Induction of heat shock proteins (HSP) was analyzed as they have been shown to increase in cells undergoing stress, heat or chemical damage. In another series, one lobe of the liver was clamped and, after an interval, reperfused. Animals were sacrificed or allowed to survive 24-48h. Microsomes were analyzed for CYP2E1 activity using the paranitrophenol hydroxylase assay. The K^+ and LDH content indicated that slice viability was significantly decreased in organs subjected to 15 minutes or more warm ischemia. Pretreatment with DMSO maintained tissue viability equal to control, non-ischemic organs. HSP were higher in the ischemic tissue compared to controls but were not induced in the DMSO treated group. CYP2E1 activity was maintained at non-ischemic levels in microsomes from rat livers pre-treated with DMSO and made ischemic for varying periods as well as in microsomes from rats given DMSO 24h post-ischemia. This suggests that DMSO pretreatment would prevent tissue damage in NHBD livers, thus providing additional organs suitable for transplantation. 1924 BENZENE INDUCES CYP 2E1 mRNA IN RAT PERIPHERAL LYMPHOCYTES.

E Gonzalez-Jasso[1], T Lopez[2], M Manno[3], A Albores[1] and A Ortega[2]. *[1]Environmental Toxicology Section and [2]Department of Genetics, Cinvestav-IPN, Mexico City, Mexico and [3]Institute of Occupational Medicine, University of Padova, Padova, Italy.*

Benzene is an environmental contaminant classified as a carcinogen which is activated mainly in the liver, by the cytochrome P450 monooxygenases, into reactive metabolites. Peripheral lymphocytes are very accessible cells which can be used for monitoring the exposure to xenobiotics. In the present study we investigated the expression of CYP 2E1 in lymphocytes of male rat intraperitoneally treated with benzene (5, 10, 15 mmoles/kg body weight), using the reverse transcriptase-polymerase chain reaction (RT-PCR). Fresh whole blood (about 8-10 mL collected from each rat) was mixed with Ficoll Hypaque and lymphocytes separated by centrifugation at 1000 Xg. Total RNA was extracted with TRIZOL Reagent and cDNA was obtained and amplified with specific rat CYP 2E1 primers. The resulting amplified product was electrophoresed through agarose gels and the expected 617 bp product was observed with Ethidium Bromide staining. Lymphocytes of benzene treated rats was higher expression of CYP 2E1 compared to controls. In addition, we used liver as a positive control, where also an increased expression of CYP 2E1 was detected in the treated animals. These results suggest that lymphocytes are suitable for monitoring the exposure to benzene and could be an adequate system to be used as a marker of effect *in vivo*. *Supported by the European Commission (Biomed-2 Contract N° BMH4-CT96-0184), CONACyT /CNR, Mexican and Italian governments.*

1925 EFFECTS OF LOW-DOSE CARBON TETRACHLORIDE EXPOSURE BY INHALATION OR DRINKING WATER ON CYTOCHROMES P450 2E1 AND 2B EXPRESSION.

R C Zangar[1], J M Benson[2], K J Nikula[2], V L Burnett[1], D L Springer[1]. *[1]Pacific Northwest National Laboratory, Richland, WA; [2]Lovelace Respiratory Research Institute, Albuquerque, NM.*

Rats, mice and hamsters were exposed to 0.5 and 5 ppm CCl_4 in drinking water for 1 and 4 weeks or by inhalation to 5, 20 or 100 ppm CCl_4 for 1 or 12 weeks. Effects on CYP2E1 and 2B protein levels and catalytic activities were examined. Hepatocellular necrosis and increased serum alanine amino transferase levels were observed in all species at 100 ppm and in mice at 20 ppm inhaled CCl_4. Microsomal protein content increased in rats exposed by inhalation for 1 week and in hamsters exposed by either route, but decreased in rats exposed by inhalation to 100 ppm CCl_4 for 12 weeks. CYP2E1-associated chlorzoxazone 6-hydroxylase (CHZ 6-OHase) was increased 16 and 23% in rats (but not mice or hamsters) exposed for 1 week to 0.5 and 5 ppm CCl_4, respectively, in the drinking water. In all species, inhaled CCl_4 at 100 ppm or, in some species, 20 ppm suppressed CHZ 6-OHase and two CYP2B-associated activities, benzyloxyresorufin and ethoxytrifluorocoumarin O-deethylase activities. Western blot analyses indicated that subtoxic doses of CCl_4 typically induced CYP2E1 and CYP2B apoprotein levels but that toxic doses generally decreased levels of these proteins. An exception was observed in the rats exposed by inhalation, where P450 apoprotein levels increased at doses that decreased catalytic activity. Overall, these results show that toxic doses of CCl_4 suppress CYP2E1 and 2B levels but that lower doses can stimulate microsomal proliferation and increase P450 apoprotein levels. The increase in apoprotein levels, however, is rarely associated with increased catalytic activity, presumably due to suicide inactivation by CCl_4. (Supported by US DOE contract DE-ACO6-76RLO 1830.)

1926 PULMONARY METABOLISM OF ETHYLBENZENE FOLLOWING EXPOSURE IN RATS.

D C Pedersen and R A Schatz. *Northeastern University Toxicology Program, Boston, MA.*

Previous studies have shown that exposure of Sprague Dawley rats to ethylbenzene vapor (300 ppm) for one or three days (six hours/day) results in a decline in the level of this compound in both blood and liver between the two exposure time points. *In vitro* rates of ethylbenzene metabolism in hepatic microsomes from ethylbenzene-exposed animals increase in this same time frame. In this study, levels of ethylbenzene in lung tissue were quantified and were also found to decrease, from 18.2 ug/g at one day of exposure to 9.4 ug/g at three days, a 48% decline. In contrast to the liver however, where the activity of cytochrome P450 (CYP P450) enzymes was found to increase

with exposure to ethylbenzene, activity of CYP P450 enzymes in the lung was reduced. Pulmonary CYP 2B1-associated benzyloxyresorufin dealkylase activity (BROD) was 40% of control values after one and three days exposure. However, CYP 2B1 protein levels did not similarly decline. CYP 4B1–associated 2-aminoflourene N-hydroxylase activity was 34% and 69% of control values at one and three days, respectively. CYP 2E1-associated N-nitrosodimethylamine demethylase (NDMA) activity was unchanged. *In vitro* rates of ethylbenzene metabolism were determined in pulmonary microsomes from control and treated animals. At a substrate concentration of 0.05 mM, the rate of 1-phenylethanol formation was 22.4± 1.5 pmol/min/mg protein in control microsomes. In tissues from animals exposed for one and three days, rates were significantly decreased compared to controls; 17.7± 1.1 and 13.6± 3 pmol/min/mg protein, respectively. The data indicate that hepatic metabolism of ethylbenzene dominates clearance of this compound following inhalation exposure, even in respiratory tissue.

1927 EFFECTS OF C-TERMINAL TRUNCATION ON THE TURNOVER AND FUNCTION OF CYTOCHROME P450 2E1.

J Y Huan and D R Koop. *Department of Physiology and Pharmacology, Oregon Health Sciences University, Portland, OR, USA.*

Cytochrome P450 2E1(CYP2E1) is an ethanol-inducible monooxygenase regulated posttranslationally. The C-terminal eight amino acids of CYP2E1 are completely conserved among species. In this study, the function of the conserved C-terminal region of rabbit CYP2E1 was studied by deleting nine amino acids (485-493) from the C-terminal end (CYP2E1CD). The steady state turnover of the mutant was determined by pulse-chase analysis and compared to wild type CYP2E1. The half-life of CYP2E1CD was 5.4 fold shorter than the full length enzyme (0.72 vs 3.9 h). 4-Methylpyrazole, a CYP2E1 ligand that normally stabilizes the enzyme and prevents degradation, did not alter the rapid turnover of CYP2E1CD. 1-Aminobenzotriazole, which inactivates P450 isozymes predominantly by N-alkylation of the heme and leads to formation of apoprotein, increased the half-life of the wild type enzyme but did not affect the half-life of CYP2E1CD. Wild type CYP2E1 is degraded predominantly by the proteasome pathway. Using selective inhibitors of lysosomal, Ca^{++}-dependent calpains and the proteasome proteolytic pathways, it appears that the C-terminal truncation did not alter the degradation pathway of the mutant. The mutant had no chlorzoxazone 6 hydroxylase activity and the reduced carbon monoxide complex was not detectable. These results suggest that the carboxyl terminus of CYP2E1 plays an important role in the turnover of this enzyme and may have a role in heme binding. (Supported by AA08608 and AA05462.)

1928 DEVELOPMENT OF A 96-WELL PLATE ASSAY FOR P4503A4 INHIBITION.

N Chauret, N Tremblay, R Lackman, J M Silva, J Marois, J Y Gauthier, J A Yergey and D A Nicoll-Griffith. *Merck Frosst Centre for Therapeutic Research, Kirkland, Quebec, Canada.* Sponsor: R Dixit.

The standard way to evaluate P4503A4 inhibition is to study the conversion of the specific P4503A4 probe testosterone to its 6ß-hydroxy metabolite in human liver microsomes, in the absence and presence of potential inhibitors. Quantification of the 6ß-hydroxy metabolite is achieved by HPLC resulting in a tedious and time-consuming assay. In order to increase the P450 inhibition assay throughput, efforts were made to find a P4503A4 probe that would produce a fluorescent metabolite. It was found that L-781,440, a COX-II inhibitor compound, was significantly metabolized in human microsomes to give the fluorescent compound L-788,706. Incubations conducted with Gentest Supersomes™ indicated that P4503A4 played a major role in the metabolism of L-781,440. Inhibition studies with specific P4501A1, 1A2, 2C8/9, 2C19, 2D6, and 2E1 chemical inhibitors did not suppress L-781,440 activity. However, troleandomycin, ketoconazole and nifedipine, three known P4503A4 inhibitors, completely abolished the formation of L-788,706. Also, there was also a good agreement between the formation of L-788,706 and formation of 6ß-hydroxytestosterone when L-781,440 and testosterone were incubated with various human liver microsome preparations. In order to use L-788,706 as a fluorescent P4503A4 marker in a 96-well plate format, it was important to remove the excess NADPH at the end of the incubation because the fluorescence of NADPH interferes with L-788,706 detection. This was achieved by adding oxidized glutathione and glutathione reductase to convert NADPH to $NADP^+$ which is not fluorescent. In this presentation, the optimization of the incubation conditions as well as the automation of the incubations in a 96-well plate with direct measurement of L-788,706 production will be described. Application of this new fluorescent HTS assay to test P4503A4 inhibitors will be presented.

1929 EFFECTS OF SOY PROTEIN ISOLATE ON EXPRESSION AND GLUCOCORTICOID-INDUCIBILITY OF CYP3A AND CYP2B ENZYMES IN MALE RAT LIVER.

T M Badger, M J J Ronis, W Lee, R Hakkak, J C Rowlands and S Shelnutt. *Arkansas Children's Nutrition Center, Arkansas Children's Hospital Research Institute and Department of Pediatrics, University of Arkansas for Medical Sciences, Little Rock, AR.*

The constitutive and glucocorticoid (dexamethasone; 50 mg/kg) inducible expression of hepatic cytochrome P450 enzymes in gene family CYP3A and CYP2B1 was studied in male Sprague-Dawley rats fed semi-purified diets (AIN93) where the protein source was casein (AIN) or changed to soy protein isolate (SPI). Dietary consumption of SPI resulted in significantly ($p<0.05$) increased constitutive expression of CYP3A1(CYP3A23) mRNA, CYP3A-apoprotein and testosterone 6b-hydroxylase and increased constitutive expression of CYP2B1 mRNA. Dietary consumption of SPI also resulted in significantly ($p<0.05$) increased expression of CYP3A1(CYP3A23) and CYP3A2 mRNA following dexamethasone induction. This was accompanied by significant ($p<0.05$) differences in CYP3A apoprotein expression and metabolism of CYP3A-substrates erythromycin, testosterone, ethylmorphine and corticosterone in dexamethasone-induced SPI-fed compared to AIN-fed animals. In contrast, diet and dexamethasone had no effect on expression of CYP3A9 or CYP3A18 mRNA or on the 6b-hydroxylation of the CYP3A18 substrate lithocholic acid. Dexamethasone induction of CYP 2B1 apoprotein and pentoxyresorufin O-depentylase activity was also increased in SPI-fed compared to AIN-fed animals. These results may partly explain the chemoprotective effects of soy consumption on tumorigenesis following exposure to dietary or environmental procarcinogens and suggest potential effects of soy consumption on metabolism and clearance of clinical medications. (Supported by USDA-ARS-Arkansas Children's Nutrition Center.)

1930 DIFFERENTIAL EFFECTS OF DEXAMETHASONE (DEX), PHENOBARBITAL (PB) AND CLOTRIMAZOLE (CLO) ON CYTOCHROME P450 (CYP) 3A AND MICROSOMAL EPOXIDE HYDROLASE (mEH) EXPRESSION IN MALE AND FEMALE RATS.

C Kim[1], S Y Chun[1], C K Kim[1], K Woodcroft[2], D A Putt[1], E S Roberts-Kirchhoff[1,3], S G Kim[4], R F Novak[2], and H Kim[1,2]. [1]*Detroit R&D, Inc., Detroit, MI;* [2]*Institute of Chemical Toxicology, Wayne State University, Detroit, MI;* [3]*University of Detroit Mercy, Detroit, MI;* [4]*Duksung Women's University, Seoul, Korea.*

CYP3A biotransforms numerous xenobiotics to epoxides which are further metabolized by mEH to their corresponding trans-dihydrodiols. This pathway detoxifies as well as activates procarcinogens to carcinogens. We have examined CYP3A and mEH protein levels in both male and female rats following treatment with DEX (10 mg/kg/day, i.p., 4 d), PB (100 mg/kg/day, i.p., 3 d) and CLO (80 mg/kg/day, i.p., 2 d). In untreated rats, CYP3A and mEH levels were lower in females than males. Following DEX treatment, CYP3A23 levels increased while mEH levels decreased in both sexes. Interestingly, CLO and PB treatment produced differing responses in males and females. In male rats, CLO and PB treatment resulted in comparable increases in CYP3A levels. In females, CYP3A increased ~20 fold following CLO treatment, but only one tenth of that increase was observed following PB treatment. The differential expression of CYP3A and mEH observed between untreated male and female rats, and male and female rats following CLO and PB treatment suggests that bioactivation of procarcinogens may be gender-dependent. (Supported by NIH grant N43 ES 81003 (H.K.) and ES 03656 (R.F.N.).)

1931 CHRONIC ETHANOL TREATMENT DIFFERENTIALLY AFFECTS THE EXPRESSION OF CYP3A ENZYMES IN THE LIVER OF MALE RATS.

J C Rowlands, R Hakkak, M J J Ronis, H W Strobel and T M Badger. *Department of Pediatrics, University of Arkansas for Medical Sciences and Arkansas Children's Hospital Research Institute, Little Rock, AR.*

The CYP3A subfamily is the most abundant of the human hepatic cytochromes. CYP3A isoforms mediate the biotransformation of many drugs, including a number of psychotropic, cardiac, analgesic, hormonal, immunosuppressant antineoplastic, and antihistaminic agents. We are studying diet/ethanol interactions using total enteral nutrition (TEN) for alcohol

delivery to adult male Sprague-Dawley rats in diets containing 16% protein, ethanol (> 12.5 g/kg), corn oil (25-45%) and high (21%) or low (1%) carbohydrate. Using this model we have reported that ethanol produced a decrease ($p<0.05$) in CYP3A activity (testosterone-6β-hydroxylation) and apoprotein levels (Western blot) and this effect was independent of the dietary carbohydrate content (Hakkak *et. al.*, Toxicological Sciences, 42:90, 1998). To further study the mechanism of this ethanol-induced inhibition of CYP3A, we have used specific antisense oligonucleotides against CYP3A1, CYP3A2 and CYP3A18 and a CYP3A9 cDNA to measure ethanol effects on CYP3A mRNA's using Northern blots. In all the animals studied, there was detectable mRNA for all the hepatic CYP3A enzymes with no differences in mRNA steady-state levels expressed for CYP3A1 and CYP3A18 in animals fed ethanol compared with animals fed control diets. In contrast, there was a large decrease (84%) in CYP3A2 mRNA in the animals fed ethanol versus control animals. Interestingly, in the livers of these same animals, ethanol in the low or high carbohydrate diets caused a 1.7 and 2.5 fold increase in CYP3A9 mRNA levels, respectively. These results indicate that the decrease in CYP3A activity and apoprotein levels reported earlier are most likely due to the ethanol-induced decrease in CYP3A2 mRNA levels. Moreover, ethanol differentially affects the expression of CYP3A gene family and this regulation can be modulated by dietary carbohydrate. (Supported in part by AA08645.)

1932 UNDERSTANDING P450 3A4 COOPERATIVITY: A ROLE FOR RESIDUE F304.

T L Domanski[1], G R Harlow[2] and J R Halpert[1]. [1]*University of Texas Medical Branch, Galveston, TX, USA;* [2]*Selectide, Tucson, AZ, USA.*

P450 3A4 is the most abundant cytochrome P450 in the liver, is responsible for the metabolism of endogenous and exogenous compounds of diverse structure, and exhibits both homotropic and heterotropic cooperativity. Our laboratory has successfully utilized molecular modeling to better understand structure-function relationships of cytochromes P450 and has applied this methodology to a rigorous study of P450 3A4 cooperativity. Using predictions from docked molecules of substrate and effector into the P450 3A4 active site, site-directed mutants were constructed and analyzed. Harlow and Halpert (PNAS 95, 6636-6641, 1998) demonstrated that mutant L211F/D214E displayed altered testosterone hydroxylase cooperativity, showing elevated rates of metabolite formation in the absence of effector and lower stimulation in the presence of effector when compared to P450 3A4. This presentation extends this work and analyzes a third residue, F304, which modeling studies also predicted to lie near a docked molecule of α-naphthoflavone. Mutant F304A, unlike L211 and D214, exhibited an altered ratio of the major progesterone metabolites in the absence and presence of α-naphthoflavone, without any change in the level of stimulation. F304W, however, displayed higher production of both metabolites in the absence of α-naphthoflavone, but lowered stimulation in its presence. The triple mutant, L211F/D214E/F304W, showed an even more dramatic loss of α-naphthoflavone stimulation. These results suggest that residue F304 may be positioned near both the substrate and effector binding pockets, while L211 and D214 appear to be involved exclusively in effector activity. (This work was supported by NIH grant GM54995 and NRSA GM19058.)

1933 INDUCTION OF CYP3A BY 24(S),25-EPOXYCHOLESTEROL IN PRIMARY CULTURED RAT HEPATOCYTES.

T A Kocarek[1], A B Reddy[1] and T A Spencer[2]. [1]*Institute of Chemical Toxicology, Wayne State University, Detroit, MI, USA;* [2]*Department of Chemistry, Dartmouth College, Hanover, NH, USA.*

Sterols modulate cholesterol homeostatic gene expression through diverse mechanisms involving sterol regulatory element binding proteins (SREBP) and LXR nuclear receptors. Several lines of evidence suggest that sterols may also modify hepatic cytochrome P450 expression. We examined the effects on P450 expression of treating primary cultured rat hepatocytes with either of two oxysterols, 25-hydroxycholesterol (a potent modulator of SREBP-regulated gene expression, but weak activator of LXR) or 24(S),25-epoxycholesterol (a potent activator of LXR). Treatment of 48 h-old rat hepatocyte cultures for 24 h with 25-hydroxycholesterol at doses of 3×10^{-5} M or higher produced slight elevations in CYP3A mRNA and immunoreactive protein levels. By contrast, treatment of hepatocyte cultures with 24(S),25-epoxycholesterol at doses of 10^{-5} M or higher produced marked dose-dependent elevations (up to ~50% of the increases observed with 10^{-5} M dexamethasone) of CYP3A mRNA and immunoreactive protein levels. CYP1A, CYP2B and CYP4A mRNA and immunoreactive protein levels were unaffected by sterol treatment. Treatment with 24(S),25-epoxycholesterol significantly elevated luciferase reporter gene expression in cultured rat hepatocytes transiently transfected with a plasmid containing a CYP3A23 gene fragment spanning bases -175 to +25 (containing both a DR4 and DR3 nuclear receptor motif) or bases -148 to +25 (containing the DR3 motif only), or containing four copies of the DR3 motif and driving reporter gene expression through the SV40 promoter. These results demonstrate that the naturally-occurring oxysterol 24(S),25-epoxycholesterol is an effective inducer of CYP3A expression, and suggest that activation of transcription through the DR3 motif represents one component of the regulatory mechanism. (Supported by NIH Grants HL50710 (TAK) and HL52069 (TAS) and NIEHS Center Grant ES06639.)

1934 REGULATION OF CYTOCHROME P450 ISOZYMES BY MIREX AND CHLORDECONE AND CLONING AND EXPRESSION OF CYP3A25 GENE IN *E.COLI.*

D Dai, R Bai, P Levi, R Rose, and E Hodgson. *Department of Toxicology, North Carolina State University, Raleigh, NC, USA.*

Mirex and chlordecone (kepone) were studied for regulation of cytochrome P450 (Cyp) isozymes 1a2, 2b10, 2e1 and 3a in mouse liver. Adult male and female CD-1mice were treated with either mirex or chlordecone at 20mg/kg/day for 3 days, respectively. Although mirex is structurally similar to chlordecone, these compounds exhibit different regulatory effects on P450 isozymes. Our results show that both mirex and chlordecone induce Cyp isozyme levels and catalytic activities, but there are gender differences, including increases in the ratio of liver weight to body weight, and Cyp content. *In vitro* enzyme activity assays indicate that mirex and chlordecone significantly increase pentoxyresorufin O-dealkylation (Cyp2b10) in either gender. Metabolism of methoxyresorufin O-dealkylation (Cyp1a2) was highly induced in males and slightly induced in females by either compound. No obvious induction was observed by the use of the p-nitrophenol hydroxylase assay (PNP) (Cyp2e1). Testosterone 6β –hydroxylase activity (Cyp3a) shows a different regulatory pattern: induction in females and inhibition in males. Immunoblotting results shows that both mirex and chlordecone induce males to a greater extent than females for isozymes Cyp1a2 and Cyp3a while females were induced more than males with respect to Cyp2b10. To further study Cyps, which are associated with sex hormone metabolism, a cDNA encoding a novel form of the Cyp3a subfamily, Cyp3a25, has been isolated from mouse liver. The sequence contained 2010 base pairs and encoded a protein of 503 amino acids. The amino acid identity with the murine Cyp3a13 and Cyp3a16 is 71% and 76%. To facilitate highly heterologous expression of Cyp3a25 in *E.coli,* the 8 amino acids in the N-terminus were modified. The expressed protein has a slight faster mobility than Cyp3a4 from human liver on SDS-PAGE. Cyp3a25 was expressed both in male and female mouse livers. Functional characterization of Cyp3a25 is currently being undertaken with use of testosterone, estradiol, and erythromycin.

1935 IMMUNOHISTOCHEMICAL LOCALIZATION OF CYTOCHROME P450 LMC5 (CYP3A27) IN RAINBOW TROUT G-I TRACT.

S-J Lee[1], K Fischer[2], O Hedstrom[2], A Sen[1], I Cok[1], B Schefke[1], J- L Wang-Buher[1], C M Miranda[1], and D R Buhler[1]. [1]*Department of Environmental and Molecular Toxicology and* [2]*College of Veterinary Medicine, Oregon State Univ., Corvallis, OR, USA.*

CYP3A27(LMC5), a cytochrome P450 3A subfamily member, is expressed in liver, intestine and other tissues. Immunohistochemical staining (IHS) procedures were used to investigate the location of its expression in the gastrointestinal tract in untreated male and female rainbow trout. Northern and Western blotting techniques were used to determine the transcriptional and translational expression of LMC5 in corresponding sections of intestine that were stained by the IHS procedure. Sections of esophagus, pyloric stomach, pyloric caeca, jejunum, and rectum were examined. Paraffin-embedded sections were incubated with rabbit polyclonal antibodies confirmed to be specific for trout LMC5 and detected by color substrate 3,3'-diaminobenzidine tetrahydrochloride in an avidin-biotin complex protocol. The greatest staining intensity was observed in the pyloric caeca and staining intensity decreased along the intestinal tract with little staining observed in rectum. The intensity of IHS for CYP3A27 was closely correlated with Western and Northern blot results. Western and Northern blot techniques showed the greatest expression in decreasing order as follows : pyloric caeca, jejunum, rectum, and pyloric stomach. Sex related differences in CYP3A27 expression were observed with higher expression in female G-I tract than male's

especially pyloric caeca in both Northern and Western blot results whereas higher amounts were found in male liver than female liver.

1936 ROLE OF CYTOCHROME P450 4B1 IN 1,3-BUTADIENE (BD) OXIDATION IN LUNG MICROSOMES OF HUMANS, RATS, AND RABBITS.

R J Krause[1], R M Philpot[2], and A A Elfarra[1]. [1]*Dept. of Comp. Biosci., Univ. of Wisconsin, Madison, WI and* [2]*NIEHS, RTP, NC, USA.*

Previously we have shown that 4B1 is the major cytochrome P450 isozyme involved in BD and butadiene monoxide (BMO) oxidations in the male mouse kidney. P450 4B1 also contributes to BD metabolism in male and female mouse lung microsomes. Since human exposure to BD in the petrochemical and synthetic rubber industries is mainly through inhalation, we examined the role of 4B1 in BD bioactivation with lung microsomes from the rat, rabbit and human. Inclusion of a polyclonal antibody prepared to rabbit lung 4B1 (2 mg IgG/mg protein) in BD incubations with male and female rat lung and male rabbit lung microsomes inhibited BMO formation by 73%, 81%, and 33% respectively. When the 4B1 antibody (2 mg IgG/mg protein) was included in BMO incubations with male rabbit lung microsomes, both meso- and (±)-diepoxybutane were inhibited by nearly 55%. Human lung microsomes did not catalyze BD oxidation; this may be due to low expression levels, different substrate selectivity, or inactivation of the P450s during isolation and storage of the human lung samples (brain dead and cadaver) since *p*-nitrophenol hydroxylase and 7-ethoxycoumarin deethylase activities were also not detectable. Immunoblotting showed that 4B1 was present in the lung microsomes of four human donors as well as in male and female rat and male rabbit lung microsomes. These results show that 4B1 is involved in BD bioactivation in the lungs of rats and rabbits and may contribute to BD activation in human lung. (Supported by NIH grant ES 06841.)

1937 THE STRUCTURE OF *CYP2F1*: A GENE THAT CODES FOR A HUMAN PULMONARY-SELECTIVE CYTOCHROME P450 ENZYME.

B A Carr and G S Yost. *Department of Pharmacology and Toxicology, University of Utah, Salt Lake City, UT.*

The selective bioactivation of a number of pneumotoxicants and pulmonary carcinogens is catalyzed by cytochrome P450s that are selectively expressed in lung cells. A human P450 gene *CYP2F1*, encodes a P450 capable of metabolizing several lung-selective toxicants. CYP2F1 expression is tissue-selective, showing the highest expression in the lung compared to the liver, kidney, and gastrointestinal tract. We hypothesize that expression of CYP2F1 is under *cis*-regulatory control and responds to specific activating factors that control the tissue-selective expression of CYP2F1 in lung cells. To determine the factors that regulate the expression of CYP2F1 in lung cells, it is necessary to identify the regulatory region of *CYP2F1*. Three cosmid clones containing the gene were previously identified (Hoffman et al., J Mol Evol 41: 894-900, 1995) from a human genomic library by Southern hybridization to *CYP2F1* cDNA. The cosmid clones have been restriction fragmented and probed with a 5' 298 bp fragment from *CYP2F1* cDNA to identify the 5'-most sequence. Sequencing to date has identified several intron/exon junctions of the *CYP2F1* gene but has not identified the transcriptional start site or TATA box. Further sequencing is required and will be performed on all three cosmid clones. This should permit the identification of the transcription start site and any *cis*-regulatory elements within the sequenced 5' region. Additional studies will attempt to characterize the *cis*-regulatory domains that control the tissue-selective expression of CYP2F1. These studies will use deletion analysis of the 5' flanking region with luciferase constructs, *in vitro* electrophoretic mobility shift assays, and DNase footprinting to analyze and identify *cis*-regulatory domains. These studies will provide novel information on the biochemical mechanisms of cytochrome P450 expression and the tissue-selective expression of CYP2F1 in lung cells. (Support provided by USPHS Grant #HL13645.)

1938 IMPORTANCE OF MURINE *cYP2F2* IN THE METABOLIC ACTIVATION OF NAPHTHALENE AND IN THE METABOLISM OF OTHER XENOBIOTICS.

M A Shultz[1], P V Choudary[2] and A R Buckpitt[1]. [1]*Department of Molecular Biosciences, School of Veterinary Medicine and* [2]*Department of Entomology, School of Agricultural and Environmental Sciences, University of California, Davis, CA, USA.*

Despite their substantially lower levels relative to the hepatic tissues, pulmonary cytochrome P450 monooxygenases play an important role in the metabolic activation of substrates that cause lung injury. The target- and species-selective toxicity of a number of pulmonary injurants has been attributed to distribution of enzyme and to the presence of enzymes with high k_{cat} in target airways of the susceptible species. However, experimental demonstration of these concepts and quantitative assessment of the contribution of individual P450 isoforms is lacking. This study was undertaken to characterize the catalytic activities of *Cyp2f2* with naphthalene, a murine Clara cell toxicant, as well as other xenobiotics that either undergo metabolic activation to cytotoxic intermediates or that are 'isoform-selective' substrates. *Cyp2f2* was generated using the baculovirus expression vector system. Recombinant *Cyp2f2* produced in Sf9 and Tn5 cells accounted for approximately 20% of total cellular protein. Incubations of Tn5 cell lysates, containing recombinant *Cyp2f2* with NADPH-cytochrome P450 reductase and NADPH, metabolized naphthalene with a high degree of stereoselectivity to the 1R,2S-naphthalene oxide (66:1 enantiomer ratio). The K_m and k_{cat} values along with the specificity constant for naphthalene metabolism by recombinant *Cyp2f2* were 4.7 μM, 118 min^{-1}, and $4.2x10^5$ $M^{-1}sec^{-1}$, respectively. The recombinant *Cyp2f2* also metabolized ethoxyresorufin, pentoxyresorufin, p-nitrophenol, 4-ipomeanol and 1-nitronaphthalene at easily detectable levels. These studies suggest that *Cyp2f2*: 1) plays a key role in the species- and cell-selective toxicity of naphthalene, and 2) efficiently metabolizes a number of other substrates, including some thought to be isoform-selective. (Supported by NIEHS 04699, 08408, 05711, 05707.)

1939 AN ADDITIONAL TEN-FOLD SAFETY FACTOR FOR CHILDREN: IS THIS NEEDED?

J A Reynolds. *Pfizer, Inc., Central Research Division, Groton, CT, USA.*

The Food Quality Protection Act of 1996 (FQPA) represents a major overhaul of pesticide regulations in the United States. A key section of the Act denotes that children exhibit an especially high susceptibility to pesticide-induced toxicity. This leads to a provision requiring the Environmental Protection Agency (EPA) to employ an additional 10-fold safety factor for infants and children. The EPA Administrator is, however, provided the option of using a different margin of safety if it can be shown that it will protect this subpopulation. In order to broaden access of children to essential medical treatments, the Food and Drug Administration Modernization Act of 1997 (FDAMA) provides incentives to pharmaceutical manufacturers who conduct acceptable studies in children with drugs identified by the FDA for which pediatric information would be beneficial. At the present time, following the establishment of safety in adults, safety in children is usually demonstrated by sequential clinical testing in children of decreasingly younger age groups. The FQPA's regulatory position that children are inherently more susceptible to the adverse effects of chemicals may carry over to pharmaceuticals (and other chemicals). This might engender alarm unnecessarily and discourage the proper use of pharmaceuticals in this age group. What factors should be considered in demonstrating the relative susceptibility or resistance of children to the potential adverse effects of pesticides or drugs? What is the basis for assuming that children exhibit an exceptionally high susceptibility to the potential adverse effects of chemicals? Should decisions be made on a case-by-case basis? What is the scientific basis for establishing pesticide exposure levels for children, bearing in mind that exposure does not equal dose? What is the scientific basis for establishing pharmaceutical dose levels in children?

1940 ENDOGENOUS ESTROGENS AS CARCINOGENS: METABOLIS ACTIVATION THROUGH OXIDATIVE METABOLISM.

J D Yager and D V Singh. *Division of Toxicological Sciences, Department of Environmental Health Sciences, Johns Hopkins School of Hygiene and Public Health, Baltimore, MD, USA and US Environmental Protection Agency, Washington, DC, USA.*

The major risk factors for human breast cancer include early age of menarche, late first full term pregnancy, nulliparity, late menopause, and to some degree, hormone replacement therapy. A common factor in all is prolonged and/or elevated estrogen exposure. The main mechanism proposed for estrogen carcinogenesis has been estrogen receptor-mediated, persistent cell proliferation associated with spontaneous replication errors. While estrogen-induced cell proliferation undoubtedly has a central role in the carcinogenic process, mounting evidence supports a hypothesis for a concomitant process in estrogen carcinogenesis involving indirect and direct genotoxicity originating from estrogen metabolites such as 16α -hydroxyestrone and the 4-hydroxy estradiol catechol. This symposium will address evidence in sup-

port of this hypothesis by summarizing the pathways of estrogen oxidative metabolism, addressing the formation of DNA damage caused by estrogen quinone metabolites and by reactive oxygen species arising from redox cycling processes supported by the estrogen catechols, and exploring evidence supporting a role for these metabolites in estrogen carcinogenesis. The symposium will include discussion of the possible effects of environmental chemical exposures on, and/or genetic polymorphisms in phase I and phase II metabolism of estrogens in breast cancer.

1941 GOOD DISRUPTERS, BAD DISRUPTERS.

H L Bradlow, D W Sepkovic, K Auborn and M P Osborne. *Strang Cancer Research Laboratory, NY, NY, USA; Long Island Jewish Hospital, Floral Park, NY, USA.* Sponsor: J D Yager.

A variety of molecules, dietary changes, and activities, can act to alter estrogen metabolism in opposing directions. Whether the results are protective or risk promoting depends on the metabolic responses which are induced. Compounds (e.g. I3C, EGCG) which increase 2-hydroxylation of estrogens appear to be protective against breast cancer and recurrent respiratory papillomatosis, while substances which increase 4 or 16(hydroxylation of estrogens (carcinogens, oncogenes, and viruses) appear to be risk promoting for breast or cervical cancer and recurrent respiratory papillomatosis. In many cases these act by inducing phase I enzymes capable of carrying out 2,4 or 16(-hydroxylation. More recently we have discovered that I3C, in addition to inducing 2-hydroxylation also markedly inhibits 4-hydroxylation. This shows that good disrupters can act both by enhancing a risk protecting pathway like 2-hydroxylation but also can decrease a risk increasing event like 4-hydroxylation. In addition to their effects on estrogen metabolism as a risk modulating event good disrupters also have direct effects on Er binding, cyclin activity, and apoptosis. Good disrupters can act to oppose the harmful effects of bad disrupters (e.g. reversing the decreased 2/16(metabolite ratio observed after carcinogen administration). Cancer risks from the environment may represent a balance between good disrupters causing favorable responses while bad disrupters cause opposite actions in terms of altering estrogen metabolism, apoptosis, cyclin action, etc. Increasing the role of good disrupters should be one of the goals of dietary and environmental studies in the coming years.

1942 XENOBIOTIC-INDUCED CATECHOL ESTROGEN FORMATION IN BREAST EPITHELIAL AND BREAST CANCER CELLS.

D C Spink. *Wadsworth Center, New York State Department of Health, Albany, NY, USA.*

Estrogens have long been associated with Carcinogenesis in the uterus and breast. In addition to cell-proliferative effects leading to tumor promotion, there is mounting evidence supporting a role for metabolic activation of steroidal estrogens by means of 4-hydroxylation in the initiation of carcinogenesis in experimental animals. In humans, elevated rates of estradiol 4-hydroxylation were observed in tumors of the breast and uterine myometrium. Our studies have focused on the regulation of estradiol 2- and 4-hydroxylation in human breast epithelial and breast cancer cells and the effects of xenobiotics on these activities. We found that exposure to Ah-receptor agonists including halogenated dibenzo-p-dioxins and dibenzofurans, polychlorinated biphenyls, and indolo {3,2-b} carbazole caused marked stimulation of both 2- and 4-hydrozylation in human breast cells. Ah-receptor-regulated estradiol 2- and 4-hydroxylases were identified as CYP1A1 and CYP1B1, respectively. Differential regulation of CYP1A1 and CYP1B1 in human breast cells was evident, as CYP1A1 inducibility was only observed in breast cell lines displaying epithelial morphology, whereas CYP1B1 inducibility was observed in cell lines displaying either epithelial or mesenchymal morphology. CYP1B1 expression and inducibility predominated over CYP1A1 in several estrogen receptor-negative cell lines representative of advanced breast cancer. Differential regulation of CYP1B1 and CYP1A1 was also observed in MCF-7 breast cancer cells in response to 12-O-tetradecanoylphrobol-13-acetate, as exposure to this compound augmented CYP1B1 but depressed CYP1A1 inducibility. These observed differences in CYP1B1 expression may reflect the same molecular mechanisms that give rise to the elevated rates of estradiol 4-hydroxylation observed in human breast tumors.

1943 FORMATION, ACTIVATION, AND DNA DAMAGE BY 4-HYDROXY-ESTROGENS.

J G Liehr. *Stehlin Foundation for Cancer Research, Houston, TX, USA.* Sponsor: J D Yager.

Estrogen-induced tumors in rodents such as in kidneys of hamsters, uteri of mice, and pituitaries of rats are used to study the mechanism of hormone-induced carcinogenesis. Increasing evidence suggests a tumor-initiating role by metabolic activation of estrogens in addition to hormonal responses mediated by receptors. For instance, an elevated 4-hydroxylation of estradiol was detected in organs of rodents (listed above) where estrogens induced tumors and also in normal and neoplastic human breast and uterus. In contrast, in human and rodent livers and other organs, 4-hydroxyestradiol is formed only as a minor by-product (15-20%) of total catecholestrogens. Both 2- and 4-hydroxyestradiol may undergo metabolic redox cycling between hydroquinone and quinone forms, a mechanism of free radical generation. Consistent with this argument, direct and indirect free radical-mediated DNA damage has been induced by estrogens in vitro and in vivo. These forms of DNA damage have been detected in organs of rodents treated with estradiol and in mammary DNA of breast cancer patients and include: 8-hydroxylation of guanine bases of DNA and DNA adducts formed by malonaldehyde, a decomposition product of free radical-induced lipid peroxides. Steroidal estrogens may be complete carcinogens and induce tumors in specific tissues capable of metabolic activation and of stimulating growth of cells depending on the receptor content. (Supported by the NIH, NCI (CA 63129).)

1944 DECREASED CATECHOL ESTROGEN PHASE II METABOLISM BY CATECHOL-O-METHYL TRANSFERASE (COMT) AS A RISK FACTOR FOR BREAST CANCER: MOLECULAR EPIDEMIOLOGIC AND EXPERIMENTAL EVIDENCE.

J D Yager and J A Lavigne. *Division of Toxicological Sciences, Department of Environmental Health Sciences, Johns Hopkins School of Hygiene and Public Health, Baltimore, MD, USA.*

Catechol metabolites of estrogens may contribute to the development of estrogen-induced cancers. Their inactivation is catalyzed by COMT which is polymorphic in the human population. We conducted a molecular epidemiology study to test the hypothesis that low activity COMT (COMTLL) may be a risk factor for human breast cancer using a PCR-based RFLP assay to determine COMT genotype in a cohort of 112 matched, nested case-control samples (Cancer Res., 57: 5493-5497, 1997). Postmenopausal COMTLL women had a greater than two-fold increased risk of developing breast cancer (OR=2.18, CI=0.93-5.11). The association of COMTLL with the development of postmenopausal breast cancer was stronger and statistically significant in those women with a body mass index >24.47. Combining COMTLL with either glutathione S-transferase (GST) M1 null or with GSTP1 intermediate/low activity genotypes, the risk for developing postmenopausal breast cancer was also significantly increased. These findings suggest that the allele encoding low activity COMT may be an important contributor to the postmenopausal development of breast cancer in certain women in this study population. Ongoing laboratory studies show that inhibition of COMT in human liver and breast epithelial cells causes an increase in cellular reactive oxygen species. However, a molecular epidemiology study in a different study cohort (Cancer Res., 58: 2107-2110, 1998) found that COMTLL was associated with an increased risk in premenopausal women and that the risk was greatest in the heaviest women. These differences will be addressed. (Supported by grants CA 70655, 36701, 77550 & ES 07141.)

1945 REACTIVE OXYGEN AND NITROGEN SPECIES: CELL ACTIVATION, INJURY, AND APOPTOSIS.

E M Postlethwait. *University of Texas Medical Branch, Galveston, TX, USA.*

Reactive oxygen species (ROS; eg., $O_2^{\cdot -}$, H_2O_2, Fe-O_2) and reactive nitrogen species (RNS; eg., ·NO, ·NO_2, $ONOO^-$) represent important effectors in numerous toxicologic processes. Within the lung, exposure to ROS and RNS can occur (i) from direct inhalation of gas phase contaminants (eg., O3, NO2), (ii) as a consequence of xenobiotic metabolism or direct biomolecule reactions (eg., paraquat, oxidant-induced peroxidation), (iii) inflammation, or (iv) due to toxicant-induced modulation of cellular processes (eg., disruption of mitochondrial function, upregulation of nitric oxide synthase). The

cellular interactions with ROS and RNS are, at best, complex with either suppression or upregulation of cellular processes potentially occurring. These reactive species not only initiate direct oxidation of macromolecules but also critically mediate cellular homeostasis via a diverse spectrum of mechanisms. In addition, their actions may not be homogeneous especially with respect to microanatomic and intracellular concentrations. Cell-specific susceptibility is likely a function of the balance among toxicant-induced ROS/RNS production, the sensitivity of cell control mechanisms to changes in ROS/RNS concentrations, and the extent of detoxification processes. The goal is to present a state-of-the-art perspective of how ROS/RNS are generated during toxic insult, paradoxical actions of oxidants and antioxidants, how ROS and RNS mechanistically influence cell signalling and control, and how the distribution of lung injury is uniquely governed by both airspace surface phenomenon and specificity of cellular metabolism. Discussions will include specific biochemical interactions, mechanisms which lead to alterations in gene expression and cell cycle control, lung surface reactions, and the intact lung.

1946 OXYGEN RADICAL-NITRIC OXIDE REACTIONS IN OXIDATIVE TISSUE INJURY.

B A Freeman. *Depts. of Anesthesiology and Biochemistry and Molecular Genetics, Center for Free Radical Biology, University of Alabama at Birmingham, Birmingham AL, USA.* Sponsor: E M Postlethwait.

Oxidation-reduction reactions induced by xenobiotics, impaired respiratory metabolism during cell injury and the tissue inflammatory reactions that occur in response to exposure to toxic substances all result in increased rates of tissue free radical (oxygen radical and nitric oxide) production. Nitric oxide (.NO) exerts potent actions in the regulation of cell function and tissue viability that extend far beyond the recognized ability of .NO to mediate signal transduction via activation of guanylate cyclase. Chemical reactions, cell culture/animal models and clinical studies have all revealed an ability of .NO to potently modulate oxygen radical reactions and pathologic processes associated with exposure to redox-active xenobiotics and inflammation. The focus of this presentation is to reveal the reactions of .NO with metalloproteins, reactive oxygen species and lipid radicals (LO. and LOO.) and discuss how they mediate the tissue-protective and injurious toxicological actions of .NO. Free radicals (such as .NO) and other oxidizing species have the capacity to directly mediate toxic reactions or initiate secondary deleterious reactions that become self-sustaining by regenerating propagating radicals. The best defenses against these events are to directly scavenge the initiating radical or to terminate the radicals that sustain propagation, via an integrated network of tissue antioxidant mechanisms. The products of .NO-oxidant reactions, NO2- (nitrite), ONOO- (peroxynitrite) and both LONO/LNO2 and LOONO/LONO2 adducts, are also reactive and can serve as mediators of inflammation and tissue injury. Through the catalytic actions of these labile secondary intermediates in tissues undergoing oxidative stress, .NO can lead to the formation of more stable nitrogen-containing adducts of aromatic amino acids in proteins (S-nitrosothiols, nitrotyrosine and nitrotryptophan), carbohydrates, purines and DNA. These nitrogen-containing products, many observed to be present in high concentrations in inflammatory and vascular diseases, serve as footprints for .NO-mediated events in tissue injury and display unique biological and signal transduction properties. Recent laboratory and clinical studies are also revealing that, under some circumstances, .NO can also play a central role in tissue antioxidant and anti-inflammatory defensive networks by serving as a terminator for propagating species formed during membrane and lipoprotein oxidation. The injurious versus tissue-protective roles of .NO seem to be determined by its concentration and the underlying extent of tissue oxidative stress. In summary, new understanding will be presented regarding the molecular mechanisms of .NO action and the critical mitigating factors that manifest the toxic qualities of .NO or alternatively, mediate its tissue-protective properties during oxidative stress.

1947 OXIDANT AND ANTIOXIDANT REGULATION OF CELLULAR SIGNALING.

H J Forman. *University of Southern California, Los Angeles, CA, USA.*

Signal transduction is a regulated sequence of biochemical steps through which a stimulant conveys a message resulting in a physiological response. There is increasing recognition that the effects of oxidative stress are not all mediated through damage of cellular constituents. Rather, reactive oxygen species can alter cell function by acting as, mimicking, or affecting the intermediates (second messengers) in signal transduction. Indeed, superoxide, hydrogen peroxide, and nitric oxide possess many of the essential characteristics of second messengers. Antioxidants therefore have the potential to counter or modulate the effects of oxidants and thereby modulate signal transduction. Examples in which oxidants have been shown to participate in signaling are the conversion of protein kinase C (α and β) to calcium- and phospholipid-independent activity and the activation of arachidonic acid metabolism. In much of "oxidative signal transduction" however, the actual redox reaction involved is not known and in many cases, participation of oxidants is only implied by the effects of compounds with antioxidant properties or correlation with changes in the "redox state." Nonetheless, oxidative activation does not necessarily require an imbalance in the "redox status" of the cell as recently shown for activation of NF-$_\kappa$B. Other recent investigation has suggested that the ras, p38-MAP kinas kB. Other recent investigation has suggested that the ras, p38-MAP kinase e, and sphingomyelinase pathways are activated by oxidative stress with the evidence provided through inhibition with N-acetylcyteine or other thiols. Thus, the importance of understanding the role of oxidants and antioxidants in cell signaling underlying normal physiology and pathophysiology is apparent. Nonetheless, the potential for action of agents, such as N-acetylcysteine and other "antioxidants" to act in a manner independent of their antioxidant capacity must also be considered.

1948 INDUCTION OF CELL SIGNALLING CASCADES AND TRANSCRIPTION FACTORS IMPORTANT IN CONTROL OF PROLIFERATION OR APOPTOSIS IN PULMONARY EPITHELIAL CELLS EXPOSED TO REACTIVE OXYGEN OR NITROGEN SPECIES.

Y M W Janssen and R P Soultanakis. *University of Vermont, Department of Pathology, Burlington, VT, USA.* Sponsor: E M Postlethwait.

Epithelial cells of the lung are exposed to reactive oxygen and nitrogen species (ROS and RNS, respectively) produced by cell types of the lung or as a result of inhalation of environmental oxidants. The functional responses of rat alveolar type II epithelial cells (RLE) to ROS/RNS are complex and include apoptosis, proliferation and the induction of inflammatory mediators. Exposure of RLE cells to H_2O_2 or NO causes dosage dependent increases in apoptosis or DNA synthesis which are preceded by the activation of extracellular signal regulated kinase (ERK) and c-jun-N-terminal kinase (JNK) members of the Mitogen Activated Protein Kinases (MAPKs) proteins and the induction of c-fos/ c-jun proteins which comprize the transcription factor, activator protein-1 (AP-1). Exposure of confluent cultures of RLE cells to peroxynitrite (ONOO-), or the ONOO- generator, 3-morpholino sydnonimine (SIN-1) causes a pronounced activation of JNK, but does not result in the induction of apoptosis, despite the formation of protein nitrotyrosine residues.These data suggest that tyrosine nitration per se is not important in the apoptotic response in our model system and that different reactive species elicit distinct phenotypic outcomes. Exposure of RLE cells to gas phase NO_2 (1-5 ppm) for 4 hrs also causes formation of nitrotyrosine residues and induces both ERK and JNK MAPKs in RLE cells. Following 24 hrs of exposure to NO_2, evidence of apoptosis is apparent in NO_2-exposed RLE cells. Localization of ERK and JNK MAPK in cells reveals that active JNK and c-jun are localized in cells in G2/M phases of the cell cycle whereas expression of ERK is found in apoptotic cells, suggesting that ERK and JNK may regulate cell cycle progression and apoptotic responses, respectively. The kinetics of generation of ROS/RNS, may dictate the extent and duration of ERK vs. JNK MAPK activation and the subsequent induction of apoptotic or proliferative responses in epithelial cells of the lung.

1949 GENERATION OF LUNG SURFACE SECONDARY REACTIVE SPECIES DURING INHALED OXIDANT EXPOSURE.

E M Postlethwait. *Pulmonary & Critical Care Medicine, University of Texas Medical Branch, Galveston, TX, USA.*

The airspace surfaces are covered by an aqueous epithelial lining fluid (ELF) that blankets all cells except airway macrophages and is the first compartment inhaled gases encounter. The ELF contains substrates (eg. antioxidants, lipids, proteins) that rapidly react with oxidants. Ozone (O_3) and nitrogen dioxide (NO_2) are ubiquitous oxidants that display high reactivity but limited aqueous solubility. Near interfacial reactions within the ELF maintain the driving force for the net uptake of both toxicants, limit diffusion of the solute gases, and produce reaction products. Thus, because most respiratory tract cells do directly contact the inspired oxidant, cellular oxidative stresses are most likely initiated by extracellular products. However, direct cellular reac-

tion with $\cdot NO_2$ may occur due to its formatain the driving force for the net uptake of both toxicants, limit diffusion of the solute gases, and produce reaction products. Thus, because most respiratory tract cells do directly contact the inspired oxidant, cellular oxidative stresses are most likely initiated by extracellular products. However, direct cellular reaction with $\cdot NO_2$ may occur due to its formation from other NOx (eg., $\cdot NO$, $ONOO^-$). Inhaled $\cdot NO_2$ preferentially reacts with ELF antioxidants to produce reactive oxygen species (ROS) which can initiate membrane oxidation. Although $\cdot NO_2$ reaction with ELF lipids is limited, unsaturated lipids may protect the underlying epithelial membranes by scavenging ROS and reducing antioxidant prooxidant activity. Conversely, reaction with ELF antioxidants appears to primarily quench inhaled O_3. Although O_3 reaction with ELF lipids is limited, lipid-derived bioactive species are produced which likely contribute to its cytotoxicity. The rates of ELF constituent turnover may not be sufficient to preclude exposure-induced concentration changes, especially in microanatomic regions of high deposition. The heterogenous nature of the ELF may account for response variations across individuals, species, and exposure time. Overall, the net extracellular production of bioactive species results from the flux of reduced substrates into the ELF, reaction with inhaled oxidants, and secondary reactions which either quench or produce other bioactive/toxic species. Consequently, ELF composition will directly influence oxidant dosimetry. Differences among various in vivo and in vitro models in terms of surface chemistry may impart substantial dissimilarities in the toxic species which cells encounter.

1950 3-D MAPPING OF OXIDANT-INDUCED TRACHEOBRONCHIAL EPITHELIAL CYTOTOXICITY.

C Plopper[1], E Postlethwait[2], J Joad[1], D Hyde[1] and L Van Winkle[1]. [1]*University of California, Davis, CA, USA and* [2]*University of Texas Medical Branch, Galveston, TX, USA.*

The cellular injury response of the respiratory system to reactive oxygen species, whether gases, such as ozone, or products of xenobiotic metabolism, such as naphthalene oxide, is focal, target phenotype-specific and microenvironment selective. To identify the mechanisms of injury within the numerous phenotypes of the respiratory system requires specific identification of the sites of cellular injury and a characterization of the individual cellular responses in relation to hallmarks of cell disintegration preceding death. A combination of airway microdissection to identify specific microenvironments within the respiratory system and cellular methods for determining loss of membrane integrity and the content of intracellular antioxidants, such as glutatione, are applied to lung samples which can then be used for high resolution histopathology and ultra-structural characterization of the status of cellular breakdown. Whole animals are exposed to toxic compounds and the lungs processed for multiple analysis using a series of fluorochromes to characterize membrane integrity (ethidium homodimer-1) and glutathione content (monochloro-bimane) followed by analysis using laser confocal scanning microscopy and quantitative epifluorescence. Density of membrane permeant cells and their distribution throughout the airway can be quantified by airway generation. Analysis of viable airway explants are used to map individual cell glutathione content on a site-selective basis. To date, this approach indicates that many markers of intracellular stress, including clearing of the cytoplasm, alterations in mitochondrial ultrastructure, rearrangement and dilation of endoplasmic reticulum, and formation of cytoplasmic blebbing, occur after intracellular glutatione has been depleted and prior to loss of plasma membrane integrity. The pattern of changes in membrane integrity varies by site and cell phenotype depending on the nature of the toxicant and the pattern of exposure.

1951 ENDOCRINE DISRUPTION AND NEUROTOXICITY: WHY TOXICOLOGISTS SHOULD BE CONCERNED ABOUT THE ACTIONS OF ESTROGENIC CHEMICALS IN THE CNS.

D B Miller[1] and S F Ali[2]. [1]*Toxicology & Molecular Biology Branch, Health Effects Laboratory Division, CDC/NIOSH, Morgantown, WV, USA and* [2]*Neurochemicstry Laboratory, Division of Neurotoxicology, NCTR/FDA, Jefferson, AR, USA.*

Susceptibility, whether acquired or innate, can dictate the biological response to a chemical and gender is one such susceptibility factor. Many toxicological responses have been examined in the context of gender and the recent concern regarding the "hormone-like" properties of certain man-made chemicals has focused interest on how estrogen and chemicals with estrogenic properties can influence toxicological endpoints. Reproductive endpoints, however, have been of primary concern and there has been little examination of neurotoxic endpoints in this context despite evidence that estrogen can have both neuroprotective as well as neurotoxic properties in the CNS. This workshop will present a general overview of estrogen and the mechanisms by which this hormone influences biological actions including a discussion of estrogen α and β receptor actions and how these actions impact toxicity. The remainder of the session will provide a more focused examination of estrogens' influences in the CNS and will examine its putative antioxidant actions, the role of receptor-mediated actions, direct membrane effects and neurosteroid properties in its neuroprotective actions. The influence of estrogenic chemicals on CNS injury utilizing well-established models of neurotoxic insult as well as their influence on brain structure in sexually-dimorphic areas of CNS will be examined. This workshop concerns endocrine disruption, estrogenic chemicals and injury processes. (Supported by CDC/NCTR.)

1952 BIOLOGICAL ACTIONS OF ESTROGEN: GENOMIC AND NON-GENOMIC MECHANISMS.

S C Laws. *Reproductive Toxicology Division, NHEERL, U.S. EPA, Research Triangle Park, NC, USA.* Sponsor: D B Miller.

Estrogen (E) plays a key role in male and female mammalian sexual development as well as adult reproductive behavior and function. Here we review the mechanisms through which E regulates the growth, differentiation and function of sex specific target tissues as well as the CNS, bone and cardiovascular systems. The classical genomic action of estrogen is mediated through its interaction with nuclear estrogen receptors (ERα and ERβ) upon which E induces conformational changes in the ER. E-ER complexes can then bind in dimer formation to the ER- response element (ERE) of specific target genes and facilitate gene transcription. Thus, E in conjunction with the ER acts as a tanscription factor by modulating mRNA and protein synthesis, with subsequent regulation of specific cellular and physiological functions. While E-mediated genomic responses generally require several hours to occur, short-term E-mediated responses (occurring within seconds) have been observed, suggesting alternative non genomic mechanisms of action. E-binding plasma membrane receptors and second messenger pathways may be mechanisms through which these rapid responses to E occur. Numerous reports suggest that environmental chemicals can interfere with E-mediated physiological responses by mimicking the actions of this steroid hormone by direct and indirect mechanisms. For example, phytoestrogens, industrial by products (alkylphenols), and pesticides (o,p'-DDT, methoxychlor, chlordecone) can bind to the ER and induce ER-mediated responses *in vivo*. Alternatively, lindane (γ -HCH, an organochlorine pesticide) and atrazine (a triazine herbicide) can interfere with E-induced effects without a direct interaction with the ER. (This abstract does not reflect U.S. EPA policy.)

1953 THE ROLE OF ESTROGENS IN SHAPING BRAIN STRUCTURE.

A C Scallet, J Meredith, C Bennett, R L Rountree, W Tong[1], C Weis, K B Delclos, and R Newbold[2]. *NCTR/FDA, Jefferson, AR, USA;* [1]*ROW Inc., Jefferson, AR, USA; and* [2]*NIEHS, Research Triangle Park, NC, USA.*

Prenatal and/or early postnatal exposures to estrogens have profound effects on the anatomy of the brain in the developing rodent fetus. Structural differences between adult male and female rats in hypothalamic cytoarchitecture as well as the functional expression of various mRNAs and their protein products have been reported. These "organizational" effects appear primarily mediated by brain estrogen receptors, which may be activated either directly by estrogenic chemicals or indirectly by androgens which are first converted to estrogens via cytochrome P450 aromatase. These "organizational" differences may be over-ridden by perinatal events, including exposure to endocrine disrupting chemicals, resulting in an adult hypothalamic structure and its associated functions that are incongruent with the original genetic sex of the animal. Sexually dimorphic hypothalamic nuclei within the medial preoptic area (MPO) and the bed nucleus of the stria terminalis (BNST), are most often considered the neuroanatomical targets of sexual differentiation in the CNS of rats. In humans it is uncertain which hypothalamic nuclei are comparable in terms of plasticity and function although the sexually dimorphic nucleus of the MPO, the BNST and the suprachiasmatic nuclei appear to be focal areas for the organizing effects of steroid hormones in both species. A scheme utilizing neuromorphometric (e.g., 3-D reconstruction methods) and neurochemical (e.g., ELISA measurement of estro-

gen receptors) approaches will be described that will be useful in assessing the impact of estrogenic compounds (e.g., phytoestrogens,) and other known or suspected endocrine disrupting chemicals on the development and function of these sexually dimorphic brain areas. (Supported by and Interagency Agreement between FDA & NIEHS.)

1954 NEUROPROTECTIVE ACTIONS OF ESTROGEN IMPLICATIONS FOR EXPOSURE TO ESTROGENIC CHEMICALS.

D B Miller[1], J P O'Callaghan[1], E A Johnson,[1] and S F Ali[2]. [1]*Toxicology & Molecular Biology Branch, Health Effects Laboratory Division, CDC/NIOSH, Morgantown, WV;* [2]*Neurochemistry Laboratory, Division of Neurotoxicology, NCTR/FDA, Jefferson, AR, USA.*

The recent focus on the hormone-like effects of many xenobiotics has led to a renewed interest in both the reproductive and nonreproductive actions of estrogen. Its protective or age-retardive actions are well established for multiple body systems including skin, bone and teeth, colon, blood vessels and heart. Clinical and epidemiological studies suggest neuroprotective properties in Parkinson's and Alzheimer's disease. *In vitro* and *in vivo* experimental data indicate estrogen may prevent the neuronal cell damage and necrosis observed following excitotoxic, metabolic and oxidative insult. Conversely, protracted estrogen exposure whether due to age or exogenous administration damages certain brain areas. Mechanisms mediating these protective or pathological actions may include activation of pathways or release of substances through specific intracellular receptor-mediated actions; direct, rapid, nongenomic effects at the cell membrane, at membrane receptor sites and ion channels or at cyclic AMP response elements; altered metabolic profile of critical brain enzymes; and alteration of neurotransmitter and neuropeptide transmitter mechanisms in brain. Utilization of transgenic technology has been useful in elucidating the mechanism of estrogen's protective effects in the vasculature and bone and should be useful in examining its CNS protective and pathological actions. Whether compounds with estrogen agonist, antagonist or mixed actions (e.g., tamoxifen, phytoestrogens, triphenylethylenes) can interfere with or mimic the neuroprotective or neuropathological actions of estrogen has received little scrutiny or debate. Tamoxifen can, however, block some but not all of the neuroprotective actions of 17α or β -estradiol *in vitro* and can modulate certain aspects of nigral striatal function including release of dopamine in response to stimulation and the response to dopaminergic neurotoxic insult. Actions of other estrogenic agents in these models is unknown. (Supported by CDC/NCTR.)

1955 NEUROPROTECTIVE ROLE OF ESTROGEN IN OXIDATIVE STRESS INDUCED NEURODEGENERATION: IMPLICATIONS FOR NEUROTOXIC INSULT.

S F Ali[1], and D B Miller[2]. [1]*Neurochemistry Laboratory, Division of Neurotoxicology, NCTR/FDA, Jefferson, AR, USA and* [2]*CDC/NIOSH, Morgantown, WV, USA.*

Certain neurodegenerative diseases like Parkinson's disease, affect more men than women and women with Alzheimer's disease receiving hormone replacement therapy show a lessened severity and slowed disease progression. Estrogen may have antioxidant properties as these diseases are linked to oxidative damage. *In vitro* studies utilizing neural tissue have shown that 17β -estradiol can decrease excitotoxic damage by directly inhibiting the NMDA receptor and limit the damage caused by β -amyloid peptides, a suspected etiological agent in Alzheimer's disease. In examining the striatal dopaminergic neurotoxicity of agents such as MPTP and methamphetamine (METH) that are suspected to cause neuronal injury by oxidative stress, greater dopaminergic neurotoxicity was noted in males. Evidence linking estrogen to this gender difference was provided by the finding that ovariectomized (OVX) mice, compared to mice receiving 17β -estradiol, displayed greater striatal damage in response to MPTP suggesting that estrogen has neuroprotective properties in this model of striatal dopaminergic neurotoxicity. Protection was not linked to alterations in metabolism or generation of the proximal toxicant although estrogen is known to affect metabolic processes. Similar neuroprotective effects of estrogen were found for METH-induced dopaminergic neurotoxicity and others have reported greater striatal damage in OVX female rats receiving 6-hydroxydopamine, another dopaminergic neurotoxicant suspected to damage tissue through a free radical/oxidative stress mechanism. Whether other estrogenic compounds, including tamoxifen, the triphenylethylenes, and the phytoestrogens, can mimic or disrupt the neuroprotective actions of estrogen has received limited examination or discussion. (Supported by NCTR/CDC.)

1956 COMPLEMENT ACTIVATION IN TRIMELLITIC ANHYDRIDE (TMA)-INDUCED PULMONARY HYPERSENSITIVITY IN THE GUINEA PIG.

C P Larsen and J F Regal. *Toxicology Graduate Program and Department of Pharmacology, University of Minnesota, Duluth, MN, USA.*

TMA is a small molecular weight compound known to cause hypersensitivity reactions in the lung, particularly occupational asthma. Actively sensitized guinea pigs challenged intratracheally with TMA conjugated to guinea pig serum albumin (TMA-GPSA) respond with an immediate bronchoconstriction and delayed eosinophil, neutrophil and mononuclear cell infiltration into the lungs and lung hemorrhage. These events are usually attributed to antigen interaction with mast cell antibody. However, our previous studies using Cobra venom factor to deplete complement indicated a role for the complement system in delayed cellular infiltration into the lungs and lung hemorrhage (Journal of Pharmacology and Experimental Therapeutics 273:793-801, 1995). Thus, we hypothesized that the complement anaphylatoxins C3a and C5a were the relevant products of complement system activation mediating the cellular infiltration and lung hemorrhage. The purpose of the present study was to determine if the complement system activation product C3a was produced in the bronchoalveolar lavage (BAL) fluid of actively sensitized guinea pigs in response to challenge with TMA-GPSA. Guinea pigs were sensitized intradermally with TMA in corn oil. Three weeks later animals were challenged by intratracheal instillation of either TMA-GPSA (n=33) or GPSA (n=28). Twenty-four hours after challenge, the guinea pigs were anesthetized with pentobarbital and the lungs lavaged with phosphate buffered saline. Complement activation product C3a was measured in the BAL fluid by Western blot and immunodetection. The quantity of C3a in the BAL fluid of TMA-GPSA challenged animals was significantly greater than that found in GPSA challenged guinea pigs ($p<0.01$). Our finding of increased C3a is consistent with a potential role for complement anaphylatoxins in TMA-induced cellular infiltration and lung hemorrhage. (Supported by NIH ES 07406.)

1957 ASSESSMENT OF RESPIRATORY SENSITIZING POTENTIAL OF ACID ANHYDRIDES BY CYTOKINE FINGERPRINTING.

E V Warbrick, R J Dearman and I Kimber. *Zeneca Central Toxicology Laboratory, Macclesfield, UK.*

We have demonstrated previously that contact allergens such as 2,4-dinitrochlorobenzene (DNCB) and respiratory allergens such as trimellitic anhydride (TMA) induce discrete type 1 and type 2 cytokine secretion patterns, respectively, following prolonged topical exposure of BALB/c strain mice. These observations have formed the basis of an approach to the identification of respiratory allergens known as 'cytokine fingerprinting'. We have now compared the patterns of cytokine production by TMA- and DNCB-activated draining lymph node cells (LNC) with those provoked by concurrent treatment with a number of additional acid anhydrides which have been implicated as potential occupational respiratory sensitizers. These comprised maleic anhydride, hexahydrophthalic anhydride and phthalic anhydride. Under immunogenic conditions of exposure, determined as a function of the induction of significant lymphocyte proliferation in draining nodes, all of the selected acid anhydrides stimulated a type 2 cytokine secretion phenotype. In each case interleukin 10 expression reached comparable levels to those provoked by the reference respiratory allergen TMA. Detectable mitogen-inducible interleukin 4 (IL-4) was also induced, although levels were generally much lower than those elicited by TMA. In contrast DNCB-activated LNC failed to produce detectable levels of these cytokines. Low expression of the type 1 cytokines interferon γ and interleukin 12 was observed in response to treatment with the acid anhydrides, compared with the substantial production of these cytokines by LNC cultured from DNCB-exposed mice. These data provide further confirmation that cytokine fingerprinting represents a robust and reliable approach for the identification of potential respiratory allergens.

1958 TRIMELLITIC ANHYDRIDE (TMA) HYPERSENSITIVITY IN MICE AFTER DERMAL EXPOSURE AND INTRATRACHEAL (IT) CHALLENGE.

E Boykin[1], M Ward[2], M J Selgrade[1], and D Sailstad[1]. [1]*Experimental Toxicology Division, US EPA, RTP, NC, USA;* [2]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC, USA.*

TMA causes Th2 related respiratory (RH) and Th1 related contact hypersensitivity (CH) responses. Elevated total serum IgE has been reported after

dermal exposure to TMA or other RH haptens, but not after exposure to exclusively contact sensitizing haptens, such as dinitrofluorobenzene (DNFB). Typically, Th1 and Th2 responses are thought to be mutually antagonistic. This makes the expression of both strong IgE and CH responses following TMA exposure perplexing. Our goal was to investigate the effect of additional TMA sensitizations and the IT challenge route on the Th1/Th2 responses. DNFB was used as the CH/Th1 control. We attempted to amplify the Th2 response and produce a comprehensive murine model of RH to small molecular weight chemicals. Mice were topically sensitized using a variety of exposure regimens. CH was assessed 4 days after final sensitization by the Mouse Ear Swelling Test. Results indicate that CH, following TMA sensitization, was significantly increased with repeated dermal applications, compared to a single sensitization protocol or DNFB exposure. Mice required at least 2 wks of dermal sensitization and an IT challenge to produce significant serum and bronchoalveolar lavage fluid (BALF) changes suggestive of a Th2 response (i.e. elevated total IgE, IL4). Other parameters indicated these TMA IT challenge doses cause non-specific inflammation. When challenge doses were reduced and the responses were examined, the indicators of RH were abrogated. These results may indicate that a slightly irritating IT dose of TMA is needed to induce the Th2 responses indicative of the respiratory sensitization. Of interest, was an increase in IFN-γ found in the BALF of TMA treated mice. This appears to be related to the Th1 component of the TMA response and may not be a result of lung irritation. Our aim is to evaluate alternative mouse exposure strategies and mechanisms involved in CH/RH (Th1/Th2 relationship) of low molecular weight compounds. (This abstract does not reflect EPA policy.)

1959 PHYSICOCHEMICAL CHARACTERISTICS THAT CONTRIBUTE TO THE SENSITIZING POTENCY OF ACID ANHYDRIDES.

J Lee, O T Macina, N B Sussman, and M H Karol. *Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA, USA.*

Acid anhydrides are small reactive industrial chemicals that have been associated with hypersensitivity disease of the lung. However, not all acid anhydrides have this biological activity. A study was undertaken to determine the relationship of anhydride structure with ability to induce immunologic lung hypersensitivity in animals. Anaphylactic antibody titer was used as a surrogate for hypersensitivity potency. A data base was constructed using physicochemical properties of the 15 acid anhydrides and the anhydride specific anaphylactic antibody titer in rats and guinea pigs. Nineteen parameters that represented transport, steric and electronic properties were evaluated. The single predictor that had the greatest statistical relationship with antibody titer was Hansen hydrogen bonding, with R^2 (adjusted) = 0.62, $p < 0.000$. The mathematical model indicates an inverse relationship, highest titers were associated with low hydrogen bonding. The best model that utilized two variables included HOMO and Hansen hydrogen bonding. Increased activity was associated with increased HOMO energy. This model had an R^2 (adjusted) of 0.72, $p < 0.05$. When tested for ability to predict the activity of 3,4,5,6 tetrahydrophthalic anhydride, an acid anhydride that had been deliberately excluded, the latter model accurately predicted the chemical to have minimal activity. These SAR model results indicate that for the pulmonary hypersensitivity of acid anhydrides, and increase in hydrophobicity and oxidation potential are important determinants of activity. (Supported by NIEHS #05651.)

1960 TOLUENE DIISOCYANATE-INDUCED SKIN HYPERSENSITIVITY REACTIONS IN GUINEA PIGS SENSITIZED BY INHALATION OF THE CHEMICAL.

K Ebino[1], H Kawakatsu[1], Y Shutoh[1], K Maita[1], R Lemus[2], and M H Karol[2]. [1]*Institute of Environmental Toxicology, Mitsukaido, Ibaraki, Japan;* [2]*Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA, USA.*

Toluene diisocyanate (TDI) is a known causative agent of occupational asthma. It is also a potent skin sensitizer in animals. It is uncertain if TDI can induce skin hypersensitivity reactions when exposure is via the inhalation route. The airways are the most likely exposure route of factory workers who are in contact with airborne TDI, and also exposed to TDI by skin contact. We attempted to develop a modified skin sensitization test. Seven week old female guinea pigs were exposed in a snout only exposure chamber to TDI mist for 4 hr at a concentration of 0.085 mg/L. TDI mist was generated using an atomizer. Two to 3 weeks later, the flank was exposed epicutaneously to 1% TDI dissolved in liquid paraffin for 6 hr using an occulusive patch. The skin sites were observed at 24 and 48 hr after removal of the patch. All of the 8 sensitized and challenged guinea pigs exhibited positive skin reactions (flare) at both time periods. By contrast, 8 non-sensitized and challenged control animals exhibited negative reactions at 24 hr. Two of the 8 control animals showed mild flare on the skin at 48 hr. These findings suggest that inhaled TDI has the potential to sensitize the skin of guinea pigs, and that skin hypersensitivity reactions may occur when TDI later contacts the skin.

1961 THE RELATIONSHIP BETWEEN TOTAL IgE AND ENVIRONMENTAL FACTORS.

V Piladang, R Lemus, N B Sussman, and M H Karol. *Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA, USA.*

A study was undertaken of environmental factors that may influence levels of total IgE in industrial workers. Factors considered were exposure to industrial chemicals, tobacco smoke, allergy to aeroallergens, and respiratory tract infections. From routine testing of industrial workers, total serum IgE was found to be elevated for a group located in South Carolina relative to a comparable group in Pennsylvania. Forty-four Pennsylvania (PA) workers exposed to toluene diisocyanate (TDI) and 19 workers from South Carolina (SC) exposed to cyanuric chloride (CyCl) were selected for detailed study. None of the workers reported industrial chemical exposure. Smoking status was determined by cotinine levels in serum. Total IgE in smokers was not statistically different from that in non-smokers. IgG antibodies was used to indicate previous respiratory tract infection. There was no statistically significant difference in total IgE levels of workers with previous respiratory tract infection compared to those without such infection. IgE antibodies to 10 aeroallergens were measured by RAST. Total IgE levels of SC workers who had numerous positive allergen RAST (9-10 allergen types) were higher than both PA and SC workers who had fewer positive RAST (0-8 allergen types). Exposure to industrial chemicals, tobacco smoke and previous respiratory tract infection did not contribute to high total IgE. Only allergy to a high number of aeroallergens correlated with high levels of total IgE. These results indicate that finding high total IgE in industrial workers may relate more to seasonal allergies rather than to chemicals in their industrial environment.

1962 ANALYSIS OF THE SPECIFICITY OF ANTIBODY DETECTION IN RELATION TO DIISOCYANATE ASTHMA.

S Gamaluddin[1], A L Kennedy[1], J-L Malo[2], and W E Brown[1]. [1]*Department of Biological Sciences, Carnegie Mellon University, Pittsburgh, PA, USA;* [2]*Hopital Du Sacre'-Coeur De Montreal, Canada.* Sponsor: M F Stock.

Numerous etiologies for diisocyanate-induced asthma have been proposed and evaluated including both immunologic and pharmacologic mechanisms. Despite the detection of specific antibodies (IgE and IgG) in the sera of some exposed workers, the results are not always consistent and often are not well correlated with disease. The question still remains as to what role, if any, IgE and/or IgG antibodies play in this disease process. The low signal found in ELISA for specific antibodies in workers exposed to toluene diisocyanate (TDI) necessitates methods that offer greater sensitivity without the loss of specificity. The present study began as an analysis for antibody responses in control population sera. Serum from thirty individuals with no known exposure to diisocyanate compounds were screened for specific IgG and IgG4 antibodies. Diisocyanate-human serum albumin (HSA) conjugates, a trimellitic anhydride-HSA conjugate, HSA and ragweed allergen were used as test antigens. Specific and nonspecific inhibition were performed to determine the specificity of any positive antigen recognition. Responses were corrected for total immunoglobulin concentration in the original serum sample. Several high responses (5/30) were detected in this control population and all but one of the five samples showed generalized antigen recognition that could not be specifically inhibited. These results suggest that within the general population, nonspecific reactions can compromise the specificity of diisocyanate antibody testing and indicate that further scrutiny of the responses may permit reclassification and the potential for more accurate diagnosis.

1963 ALBUMIN CONJUGATES OF HEXAMETHYLENE DIISOCYANATE AND HEXAMETHYLENE DIISOCYANATE-BIURET DETECT ANTIBODIES IN CAR PAINTERS.

R Lemus[1], A V Wisnewski[2], C A Redlich, and M H Karol[1]. [1]*Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA, USA;* [2]*Yale University School of Medicine, Occupational and Environmental Medicine Program and Pulmonary and Critical Care Section, New Haven, CT, USA.*

Car painting has been associated with occupational asthma. Isocyanates, in particular hexamethylene diisocyanate (HDI) , and its biuret (HDI-B), are frequently employed in this industry, and have been implicated as causative agents contributing to the disease. Based on previous experimental studies, we hypothesized that antibodies may be produced as a result of exposure to these isocyanates, and investigated the production of several classes of isocyanate-specific antibodies. Using ELISA and RAST, we examined the serum from 3 HDI asthmatic patients and 27 workers from three different car body shops and examined the incidence of antibodies to HDI and HDI-B. Several sera demonstrated antibodies to albumin conjugates of HDI and HDI-B. Titers were always greater with the latter reagent. Interestingly, IgG antibodies were detected in some workers and IgE antibodies in others. We also determined the ability of peripheral blood mononuclear cells from these subjects to proliferate in response to the same HDI conjugates using a ^{3}H-thymidine based assay. HDI conjugates induced proliferation in all HDI asthmatics and in approximately 20% of the other exposed workers. There was a good correlation between patients that displayed antibodies to HDI and those that showed lymphoproliferative responses. These results indicate that albumin conjugates of HDI and HDI-B can be used for biological monitoring of exposure through antibody determinations, and cell proliferative responses to isocyanates.

1964 INFLUENCE OF CARRAGEENAN ON ANTI-PROTEIN ANTIBODY ISOTYPE DISTRIBUTION.

R J Dearman[1], D A Basketter[2] and I Kimber[1]. [1]*Zeneca Central Toxicology Laboratory, Macclesfield, England;* [2]*Unilever Safety and Environmental Assurance Centre, Sharnbrook, England.*

The increased use of protein effect molecules has resulted in a growing interest in the evaluation of their allergenic potential. We have shown previously that intraperitoneal (ip) administration to BALB/c strain mice of the protein allergen ovalbumin (OVA) stimulates the production of both specific IgG and IgE antibody. Exposure under identical conditions to bovine serum albumin (BSA), which, by comparison, has weaker allergenic potential, elicits vigorous IgG, including IgG2a, antibody responses, but no, or only low titer, IgE antibody. We have now examined the influence of carrageenan, reportedly a specific IgE adjuvant, on the selectivity and sensitivity of antibody responses to these materials. Groups of BALB/c strain mice (n = 5) received a single ip injection of OVA or BSA (2, 0.2, or 0.02%) in the presence or absence of 250μg of carrageenan type V (iota). Serum samples were collected 28 days after exposure and analyzed for the presence of specific IgE, IgG, IgG1 and IgG2a antibody. In the absence of adjuvant there was a marked difference in the ability of OVA and BSA to provoke IgE antibody responses, with the former, but not the latter, inducing detectable IgE antibody at all doses tested. Co-administration of carrageenan resulted in more vigorous IgE responses to both materials, although exposure to OVA was associated with somewhat higher titers than was exposure to equivalent amounts of BSA. Treatment with adjuvant also enhanced IgG, IgG1 and IgG2a antibody responses to both proteins. These data suggest that carrageenan enhances both IgG and IgE antibody responses to proteins, lowering the concentration threshold at which antibody production is observed, but with a consequent loss in the selectivity of IgE antibody responses to proteins of differing allergenic potential.

1965 RESPIRATORY SENSITIZATION OF BALB/C MICE WITH THE BIOPESTICIDE.

M D W Ward[1], S L Madison[2], D M Sailstad[2], S H Gavett[2],and M J K Selgrade[2]. [1]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC;* [2]*NHEERL, US EPA, Research Triangle Park, NC.*

Metarhizium anisopliae, an entomopathogenic fungus licensed for indoor use, has previously been shown to elicit allergic responses in BALB/C mice intraperitoneally (IP) sensitized and intratracheally (IT) challenged with the soluble factors from a *M. anisopliae* crude antigen (MACA). In this study the IT route of sensitization is compared to the IP sensitization and to an IT vehicle control. The IT route consisted of 4 IT exposures of 10 μg MACA in 50 μl HBSS over a four-week period (vehicle controls received HBSS only). While the IP route consisted of IP sensitization with 25 μg MACA in 0.2 ml of 1.3% alhydrogel followed 14 days later with an IT challenge (10 μg MACA/50 μl HBSS). Mouse airway reactivity was assessed by methacholine challenge at 1 and 3 days following the last MACA IT challenge (DPIT). Additionally both serum and BAL fluid (BALF) samples were harvested at 1,3, and 8 DPIT. Significant increases in total BALF cellularity as well as macrophage, neutrophil, lymphocyte and eosinophils were seen in IT sensitized mice when compared to both IP and vehicle controls at 1 DPIT but only total cellularity and eosinophilia were still significant at 3 DPIT. BALF total protein and LDH levels for IT mice were significantly different from both IP and vehicle control mice at 1 DPIT. At 3 DPIT both IT and IP mice were elevated compared to vehicle controls but were near control levels by 8 DPIT. Only IP sensitized mice demonstrated elevated IL-4 levels. Airway reactivity (airway resistance and compliance) was significantly increased for IT mice. In summary we found that multiple IT exposures without adjuvant demonstrated elevated responses for most endpoints assessed at early time points and had resolved by 8 DPIT. (Supported by USEPA Cooperative Training Agreement (T-901915-02) with UNC-CH.) (This abstract does not reflect EPA policy.)

1966 IMMUNE RESPONSE TO ENZYMES IN THE MOUSE INTRANASAL TEST: STRAIN COMPARISON.

K Sarlo[1], J S Parris[1], P A Horn[1], E D Clark[1], M K Robinson[1], J A McCay[2], V L Peachee[2], J W Parrett, Jr.[2], and K L White, Jr.[2]. [1]*The Procter & Gamble Co., Cincinnati, OH and* [2]*ImmunoTox Inc., Richmond, VA.*

The mouse intranasal test (MINT) was developed to assess the immunogenic potential of detergent enzymes. Mice receive an IN dose of enzyme protein on days 1, 3 and 10 with serology on day 15. The BDF1 mouse (H-$2^{b/d}$), a cross of C57Bl/6 (H-2^b) x DBA/2 (H-2^d) has been used for most of the development work. Preliminary data in the CB6F1(H-$2^{b/d}$) a cross of C57Bl/6 x Balb/c (H-2^d) showed that this strain was similar to the BDF1 in its response to enzymes. These data also showed that the parental strains did not respond the same way as the F1 hybrids. To better understand the influence MHC background may have on immune responses to enzymes, 3 different enzymes were tested in the 3 parental strains and 2 hybrid strains. Enzymes are ranked as more, less or equipotent to the protease Alcalase. BDF1 mice rank enzymes the same as the guinea pig which in turn correlates with sensitization in occupationally exposed humans. The ranking is based upon the dose of enzyme needed to give ½ maximal IgG1 antibody response (ED50). Termamyl is more potent than Alcalase which is equipotent to Savinase. The H-2^d strains ranked the enzymes the same as the BDF1 but generated ED50's that were one order of magnitude greater than the BDF1 ED50's. The H-2^b strain did not rank the enzymes the same as BDF1 but the ED50's were similar to or lower than the BDF1 ED50's. Initial data show that all strains will make enzyme specific IgE antibody to high doses of enzyme with DBA/2 > Balb/c > C57Bl/6 in terms of the robustness of the response. Taken together, these data suggest the H-2^d background brings the robust IgE response and the ability to rank enzymes which correlates with human data. The H-2^b background brings sensitivity or responses to much lower doses of protein allergen. Therefore, the F1 hybrid is an appropriate strain for evaluating allergic responses to enzymes.

1967 DETECTION OF ALLERGIC INFLAMMATION AND ENZYME SPECIFIC IGE ANTIBODY IN THE MOUSE INTRANASAL TEST.

P A Horn, J S Parris, E D Clark, M K Robinson, A S Fix and K Sarlo. *The Procter & Gamble Co., Cincinnati, OH, USA.*

The BDF1 mouse has been used in the development of the mouse intra-nasal test (MINT) for the assessment of the immunogenic potential of enzymes. In this model, mice receive an intranasal (IN) dose of enzyme protein on days 1, 3 and 10 with serology on day 15. The IgG1 antibody (AB) response to several enzymes has been well characterized in this model. The goal of the present work was to begin characterizing allergic inflammation and IgE AB after IN exposure to enzyme allergen. Mice exposed to 1.6ug protease enzyme (Alcalase) on days 1, 3, and 10 did not produce enzyme specific IgE AB as detected by the rat passive cutaneous anaphylaxis test. However, mild subepithelial inflammatory infiltrates of eosinophils along with serocellular deposits (plugs) were seen in the nasal cavity of these animals 24 hours after

the last exposure to enzyme (day 11). The infiltrates and plugs were noted in the front, mid and pos-terior sections of the nasal cavity. Little inflammation and no plugs were observed in the nasal cavity of control animals. The eosinophilic infiltrates were less intense 5 days after the last exposure to enzyme. A 2 to 3-fold increase in blood eosinophils was also noted. Extension of the dosing protocol to exposure on days 1, 3, 10, 17 and 24 with serology on day 29 led to enzyme specific IgE production to 0.3 and 1.6ug Alcalase enzyme. In addition, IgE antibody was found in sera from mice dosed with 0.1 and 0.3ug amylase enzyme (Termamyl). Heat inactivation of these sera led to abrogation of the PCA response, confirming the presence of IgE antibody. These data show that enzyme allergen will generate a mild eosinophilic inflammatory response in the nose along with mild blood eosinophilia after 3 IN exposures and induce enzyme specific IgE antibody after 5 IN exposures to enzyme. The current MINT protocol is sufficient to induce mild allergic inflammation in the nose and a slight modification of the protocol will lead to development of allergen specific IgE antibody in the BDF1 mouse.

1968 STRAIN VARIATION IN THE IgG1 ANTIBODY RESPONSE TO PROTEINS ADMINISTERED INTRANASALLY IN THE MOUSE.

R W R Crevel, L Blaikie and D A Basketter. *Unilever Safety and Environmental Assurance Centre, Colworth House, Sharnbrook, Bedford, England.* Sponsor: I Kimber.

Proteins, including enzymes, have the potential to behave as respiratory allergens. Consequently guinea pig methods were developed to permit assessment of their respiratory allergenic potential relative to that of an appropriate reference. Recently, a murine model, the mouse intranasal test (MINT) has been proposed as a potential alternative. However, to be of value, the new method should give a rank order of relative potency for a range of proteins which correlates will with that found in guinea pig models and in human experience. Using the mouse strain recommended for the MINT, BDF1, in an extensive intralaboratory assessment the relative potency of several of the 8 proteins used was at variance with that expected from the historic data. Where genetic factors are important, as in the assessment of allergenicity, the rank order for a range of proteins in a particular inbred strain may not reflect that in humans. To examine whether these observations were a strain rather than a species dependent phenomenon, four proprietary enzymes of varying allergenic potency were selected and tested using the MINT protocol in BDF1, Balb/c, CBA/Ca and CB6F1 inbred strains, as well as in the outbred Swiss S strain. Additionally ovalbumin was tested in the BDF1 and Balb/c strains. The results clearly indicated that the relative potency of the proteins (rank order) was dependent on the mouse strain used and thus haplotype. When assessed against the standard reference enzyme, Alcalase (as used in historical models to establish occupational exposure guidelines), results from none of the mouse strains would have led to similar conclusions to those derived from existing models. Based on the presently available information, it is not possible to be certain that any mouse model reliant on the responsiveness of a particular strain (including the MINT) might not lead to an incorrect estimation of respiratory allergenic potency. It is concluded therefore that the MINT requires substantial further investigation if it is to be adopted as a model for the assessment of the relative allergenic potential of proteins.
