A subchronic nose-only inhalation study compared the effects of smoke from a cigarette consisting of 100% flue-cured tobacco cured by a direct-fired process to that of a cigarette consisting of 100% flue-cured tobacco cured by a heat exchanger process. The heat exchanger process applies indirect heat to the tobacco *via* a heat exchanger device. Sprague-Dawley male (M) and female (F) rats were exposed for 1 hour a day, 5 days per week, for 13 weeks to mainstream smoke at 0, 0.06, 0.20, or 0.80 mg/liter of air. Neither cigarette produced adverse changes in clinical signs, body and organ weights, serum chemistry, or hematology. Carboxyhemoglobin and serum nicotine increased with both cigarettes in an exposure-dependent manner. Smoke related histologic changes were nasal goblet cell hypertrophy, nasal chronic/active inflammation and epithelial hyperplasia, chronic/active inflammation of the larynx, squamous metaplasia and acute inflammation of the ventral larynx, tracheal epithelial hyperplasia and increased goblet cells, increased goblet cells of the lung, and increased non-pigmented and brown/gold pigmented lung macrophages. When histologic changes resulting from exposure to smoke from the two types of cigarettes were compared, the only observed difference was increased epithelial hyperplasia of the anterior nasal cavity in males in the high exposure group for the heat exchanger cigarette. Since only one difference was noted among all of the observed smoke related histologic changes, these findings indicate that the biological activity of smoke from cigarettes of flue-cured tobacco cured by a direct-fired or a heat exchanger curing process is not different under the conditions of the study.

955 CHRONIC EFFECTS OF INHALATION OF ROOM-AGED SIDESTREAM SMOKE AND DIESEL ENGINE EXHAUST IN THE RAT RESPIRATORY TRACT.

A. Teredesai, W. Stinn and H. J. Haussmann. *PRM, INBIFO GmbH, Cologne, Germany.*

Environmental tobacco smoke (ETS) and Diesel engine exhaust (DEE) are widespread environmental combustion aerosols found at similar concentrations. Similar relative risks for lung cancer have been reported for both. The purpose of this investigation was to determine the carcinogenic potency of room-aged sidestream smoke (RASS), as a surrogate for ETS, and DEE at toxicologically relevant concentrations that bear a realistic relationship to human exposure. Male and female Wistar rats were nose-only exposed to fresh air and to RASS and DEE at 3 and 10 mg/m^3 for 6 h/day, 7 d/week for 24 months followed by a 6-month postinhalation period. To increase the sensitivity for the detection of lung tumors, 0.5 mm step serial sections were utilized. The only findings in the nose, larynx, and trachea were hyperplasia and metaplasia. In the lung a few RASS-related non-neoplastic findings (goblet cell hyperplasia, pigmented alveolar macrophages) were observed. There was a dose-dependent increase in the severity of DEE-associated non-neoplastic changes, which comprised alveolar epithelium hyperplasia, bronchoalveolar metaplasia, squamous metaplasia, alveolar, interstitial and pleural particle-filled macrophages/particulate matter, chronic active inflammation, and septal fibrosis. The incidence of lung tumors (102 rats/group) in the RASS-exposed groups was 5% each (adenomas and one adenocarcinoma) and not statistically significantly different from sham (2%). In DEE-exposed groups lung tumors first appeared between 12 and 24 months. The incidence of tumors increased with dose (up to 50%) and comprised benign cystic tumors, adenomas, adenocarcinomas, and squamous cell carcinomas. This spectrum of neoplastic and non-neoplastic findings in rats exposed to DEE is consistent with the literature. No alveolar hyperplasia was seen at any time point in the RASS groups, which suggests that the tumors in the RASS groups were spontaneous in nature. INBIFO is a Philip Morris research laboratory.

956 NEUROKININ RECEPTOR-1 GENE EXPRESSION IN MICE SUBJECTED TO SIDESTREAM CIGARETTE SMOKE.

S. J. Wang, N. N. Sun and M. L. Witten. *Pediatrics, University of Arizona, Tucson, AZ.*

There are unmyelinated afferent nerves (C-fibers) that serve as an important sensory system in detecting the onset of pathophysiological changes in the lungs. To investigate whether the gene activation of neurokinin receptor-1 (NK-1) following sidestream cigarette smoke (SSCS) exposure, the elderly C57BL/6 mice were randomly assigned to 5 groups (10/group) in a study of the dose-effect relationship. The mice of each group were exposed to 0 (room air), 2, 4, 8, and 16 standard research cigarettes (1R4, University of Kentucky)/day, respectively, for 7 days through a nose-only exposure chamber (IN-Toxicology). The expression of NK-1 mRNA in the lung, heart, liver, kidney, and spleen tissues were detected by RT-PCR techniques and normalized against GAPDH expression. The mice subjected to lower SSCS exposure had a downregulation of NK-1 mRNA expression in heart, but an upregulation in liver and kidney when compared to control rats. However, less or more induction for the NK-1 gene was observed following the higher dosages of SSCS exposure when compared to the lower dose of SSCS exposure in these tissues. This finding suggests that there are the paracrine and/or autocrine signaling mechanisms through receptor-ligand interactions. No alteration of NK-1 gene expression was observed in the lungs and spleen tissues in this study. In conclusion, activation of NK-1 gene expression may contribute to passive cigarette smoke-induced lung responses, which may be of primary importance in shifting neurogenic inflammatory responses from their physiological protective/defensive functions to detrimental pathophysiological roles. (Supported by ADCRC No. 9925).

957 REVERSES OF β-CHEMOKINE RECEPTOR GENE EXPRESSION IN C57BL/6 MICE EXPOSED BY SIDESREAM CIGARETTE SMOKE.

N. N. Sun, S. Wang and M. L. Witten. *Pedatrics, University of Arizona, Tucson, AZ.*

Chemokines have recently been shown to play an important role in the activation and directional migration of inflammatory cells to sites of tissue injury. Their action requires the expression of their complementary chemokine receptors by their target

cells. However, the possible action of β-chemokine receptors (CCR) genes in the pathogenesis of environmental tobacco smoke has not been established. To examine if passive cigarette smoke can activate CCR gene expression, the lung, heart, liver, kidney, and spleen tissues were isolated from C57BL/6 mice, which are daily exposed to sidestream cigarette smoke (SSCS) from 0 (room air), 2, 4, 8, and 16 standard research cigarettes (1R4, University of Kentucky), respectively, for 7 days. The expression of CCR-1 to CCR-5 genes in these tissues were detected by RT multiplex PCR techniques and normalized against GAPDH expression. CCR-1 to CCR-5 mRNA levels of mice exposed to lower SSCS concentrations basically present a decreased trend in the lung, heart, and kidney tissues, but an increased trend in liver and spleen. However, significant reverses for these CCR gene expressions in heart and kidney tissues were observed following the higher dosages of SSCS exposure, suggesting there are the paracrine and/or autocrine signaling mechanisms through receptor-ligand interactions. The changes in CCR gene expressions in the tissue suggests the b-chemokine receptor and its ligand, such as Eotaxin-1, Eotaxin-2, Eotaxin-3, RANTES, MCP-2, 3, 4, and MIP-5, may play an important role in the recruitment of inflammatory cells following SSCS exposure. (Supported by ADCRC No. 9925).

957A OZONE TOXICITY IS ASSOCIATED WITH UPREGULATION OF PHOSPHATIDYLINOSITOL 3-KINASE (PI3K) AND PROTEIN KINASE B (PKB) IN LUNG MACROPHAGES. ROLE OF CAVEOLIN-1.

L. Fakhrzadeh, K. Lee, S. G. Rickatts, C. R. Gardner, V. S. Sunil, J. D. Laskin and D. L. Laskin. *Joint Graduate Program in Toxicology, Rutgers University and UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.*

Exposure of mice to toxic levels of ozone (O_3) causes type I epithelial cell damage and type II cell proliferation. This is associated with increased expression of inducible nitric oxide synthase (NOSII) and production of reactive nitrogen intermediates by alveolar macrophages (AM), which have been implicated in tissue injury. In the present studies we analyzed mechanisms regulating NOSII activity in AM after O_3. The promoter region of the NOSII gene is controlled by several transcription factors including NF-KB. O_3 inhalation (0.8 ppm, 3 h) caused a time-dependent induction of NF-KB nuclear binding activity in AM. The findings that AM isolated from knockout mice lacking the p50 subunit of NF-KB did not generate nitric oxide, and that the mice were protected from toxicity demonstrate that signaling through NF-KB is important in O_3 induced lung injury. Activation of NF-KB requires phosphorylation of IKB kinase, as well as NF-KB subunit proteins. O_3 inhalation resulted in a time dependent induction of phosphatidylinositol 3'-kinase (PI3K) and its downstream target Akt/protein kinase B (PKB) in AM. Moreover, treatment of the cells with the PI3K inhibitors, wortmanin and LY294002, blocked nitric oxide production. This was correlated with reduced NF-KB nuclear binding activity in the cells. PI3K activity is controlled by caveolins, a family of highly conserved integral membrane proteins. We found that caveolin-1 (Cav-1) was constitutively expressed in AM. O_3 exposure caused a marked reduction in Cav-1 in AM, which was evident immediately following exposure and persisted for 6 h. Changes in expression of Cav-1 were inversely correlated with expression of PI3K and PKB in AM. Taken together, these data suggest that Cav-1 may play a role in PI3K and PKB signaling and NF-KB activation leading to nitric oxide production following O_3 inhalation. Supported by NIH grants ES04738 and ES06897.

958 A METABONOMIC APPROACH TO STUDY THE ONSET OF NEUROTOXICITY USING 3-NITROPROPIONIC ACID, A MODEL FOR HUNTINGTON'S DISEASE.

B. C. Sweatman, A. D. Cann, J. N. Haselden and M. L. Anthony. *Safety Assessment, GlaxoSmithKline R & D, Ware, United Kingdom.* Sponsor: R. Tyler.

The model toxin 3-nitropropionic acid (3-NP) replicates, in animals, most of the pathological features, cognitive and motor dysfunctions that are observed in humans with Huntington's Disease [1]. We have used a metabonomic approach to study the onset of toxicity in male Sprague-Dawley rats (n=10 per group) following daily dosing with 3-NP (5, 7.5 mg/kg/day) over a 14 day period. Urine samples were collected throughout the study for NMR spectroscopic analysis and histological examinations were carried out on all animals at study termination. Rats treated with 3-NP exhibited weight loss, reduced food and water consumption and a degree of functional impairment. Although the animals exhibited symptoms ranging from ataxia to right hind-limb paralysis in all dose groups, histology failed to show the expected neuronal loss in brain tissue. Clinical findings were accompanied by mild to moderate decreases in urinary pH from 8hrs onwards. However, NMR analysis demonstrated a marked increase in the excretion of urinary succinate immediately post-dose until the end of the study. Multivariate statistical analysis using principal components analysis (PCA) confirmed an increase in succinate as the predominant biochemical change and demonstrated a Dose-Response relationship in the separation of 3-NP dosed animals from controls. The increase in urinary succinate excretion following administration of 3-NP has not been reported previously, but is consistent with the observation that 3-NP is an irreversible inhibitor of succinate dehydrogenase [2]. This result suggests a gross impairment of energy metabolism in the TCA cycle, which could be the cause of neuronal cell death. The observation of succinic aciduria in the absence of the expected brain pathology demonstrates the utility of NMR spectroscopy and the metabonomic approach as an adjunct to standard toxicological techniques, particularly during the onset of toxicity. 1. Acta Medica 43, 9–13 (2000) 2. Journal of Biological Chemistry 254, 5161-5167 (1979)

959 EFFECT OF DEXAMETHASONE ON THE METABONOMICS PROFILE ASSOCIATED WITH PHOSPHODIESTERASE (PDE) INHIBITOR-INDUCED MESENTERIC VASCULAR LESIONS IN RATS.

L. A. Dethloff, R. M. Slim, D. Robertson, M. D. Reily and M. Albassam. *Drug Safety Evaluation and Discovery Technologies, Pfizer Global Research and Development, Ann Arbor, MI.*

Metabonomics is a novel technology proposed as a predictive tool for screening novel compounds and for identification of biomarkers of toxicity in biological fluids. Utilizing this approach, we previously identified urinary spectral patterns in rat characteristic for vascular lesions induced by suprapharmacological doses of the type IV PDE inhibitor CI-1018. Whether the observed changes in metabonomics profile were related to the mechanism of toxicity or were instead a measure of the subsequent inflammatory response was uncertain. In the present study, dexamethasone (DEX) was used to examine the relationship between the inflammatory process and the metabonomics profile induced by CI-1018. Six female Wistar rats were given 5 daily doses of DEX (1 mg/kg IP), 4 daily doses of CI-1018 (750 mg/kg PO), or given a predose of DEX followed by 4 daily doses of DEX plus CI-1018. Twenty-four-hour urine samples were collected from each rat pretest and daily for the duration of the study for metabonomic analyses. All rats dosed with CI-1018 alone had marked mesenteric and/or mild hepatic vascular lesions characterized by medial necrosis, hemorrhage and/or edema accompanied by perivascular mixed inflammatory cell infiltrates. Minimal arteriopathy without concurrent inflammatory infiltration was noted in 5 of 6 rats given both dexamethasone and CI-1018. Principle component analysis performed on urine samples revealed an obvious pattern of separation between samples from control rats *versus* those from CI-1018-treated rats with marked lesions and rats given DEX plus CI-1018 with minimal lesions and no inflammatory cell infiltration. Pattern separation was not evident between the two CI-1018 treatment groups. The separation from controls, observed in rats with minimal lesions without inflammatory infiltrates, suggests that the observed shift in spectral pattern is independent of the inflammatory process associated with vascular injury induced by PDE inhibition.

960 HEPATIC OXIDATIVE STRESS RESPONSE TO LAZABEMIDE.

A. Paehler, F. Boess and R. Gasser. *Non-Clinical Drug Safety, Pharmaceuticals Division, F. Hoffmann-La Roche LTD, Basel, Switzerland.*

Tempium® (Lazabemide: Ro 19-6327) is a potent, highly selective and reversible inhibitor of MAO-B with clinical advantages over current therapies for the treatment of Alzheimer's disease. During the pre-clinical safety program an increase in rat liver enzymes with some similarity to clinical findings was observed. In a limited number of patients, transient increases in ALT and GGT and less frequently AST, have been recorded between weeks 6 to 12 of lazabemide treatment (100 mg bid). In one patient, however, plasma enzymes continued to increase after withdrawal of treatment but eventually declined to reference levels. Based upon this data and the pre-clinical findings the transient and reversible increase in liver-related enzymes appears to affect patients and experimental rats alike. Further investigative work was initiated to address the mechanism of this hepatic response. NMR analysis (metabonomics) of urine samples from rats treated with lazabemide (1500 mg/kg) indicated a decreased excretion of succinate, citrate and oxo-glutarate consistent with disruption of mitochondrial respiration (see presentation by U. Niederhauser et al.). As lazabemide is also a substrate for mitochondrial monoamine oxidase it was hypothesized that lazabemide induced hepatotoxicity is related to oxidative stress conditions likely due to a production of reactive products capable of mitochondrial function impairment. Treatment of rat hepatocytes in primary culture with 300 µM lazabemide did not lead to measurable cytotoxic effects. However, pre-treatment of cells with buthionine-sulfoximine and diethyl-maleate depleting reduced cellular glutathione and inhibiting its synthesis markedly increased cytotoxicity as assessed by the release of lactate dehydrogenase into the incubation medium. Thus, reduced glutathione seems to play an essential protective role against lazabemide-mediated cytotoxicity. Additional experiments aimed at detecting reactive species originating from lazabemide and its metabolism will be presented to clarify the role of oxidative stress response on mitochondrial function.

961 METABONOMICS STUDY INTO THE BIOCHEMICAL EFFECTS OF RO 19-6327 USING ^{1}H NMR SPECTROSCOPY AND PATTERN RECOGNITION ANALYSIS OF URINE SAMPLES.

U. B. Niederhauser[1], H. Senn[1], G. Schlotterbeck[1], M. Bollard[2], J. Lindon[2] and J. Nicholson[2]. [1]*Non-Clinical Drug Safety, F. Hoffmann - La Roche Ltd, Basel, Switzerland and* [2]*Biol. Chemistry, Biomedical Sciences Division, Imperial College, London, United Kingdom.* Sponsor: D. Robertson.

Tempium® (Lazabemide: Ro 19-6327) is a potent, highly-selective and reversible inhibitor of MAO-B with possible clinical advantages over current therapies for the treatment of Alzheimer's Disease. Results of toxicity studies showed that Ro 19-6327 induces in rats after repetitive oral doses of ≧ 700 mg/kg a mild transient increase in liver-enzymes (mostly ALT) and an increase in liver weight. A similar trend for an increase in liver-enzymes was observed in patients. To evaluate the technique and to gain further insight into the effects of Ro 19-6327, ^{1}NMR spectroscopy and metabonomics investigations have been performed using urine samples of Wistar rats. Two dose levels (single oral doses of 600 mg/kg and 2000 mg/kg) were given to assess the sensitivity of the metabonomics approach, and to evaluate if there are quantitative as well as qualitative changes in the toxicity profile. Ro19-6327 caused subtle biochemical perturbations in the urinary ^{1}H NMR spectra. The major changes in the urinary profiles were, beside the appearance of drug related resonances, severe reduction of citrate, 2-oxoglutarate and succinate. Depletion of these TCA cycle intermediates may be indicative of mitochondrial dysfunction. The subtle elevation of creatinine and taurine excretion may be associated with effects of Ro19-6327 on the liver. Little difference in the biochemical response of rats treated with 600 or 2000 mg/kg of Ro 19-6327 was observed. However, rats treated at the higher dose showed a more prolonged response. The effects were quickly reversible, with urinary profiles returning to normal by 3-4 days post-dose. Conclusion: Metabonomics may add valuable information to assess drug-induced effects. The results also confirm that Ro19-6327 exhibits low toxicity in the rat.

962 IMPROVED CLASSIFICATION OF HEPATIC TOXICITY BASED ON PATTERN RECOGNITION INVESTIGATION OF DIFFUSION-EDITED 1H NMR SPECTRA OF BLOOD SERUM.

B. M. Beckwith-Hall, E. Holmes, N. Thompson, J. C. Lindon and J. K. Nicholson. *Biological Chemistry, ICMS London University, South Kensington, London, United Kingdom.* Sponsor: D. Robertson.

Chemometric investigation of 1H NMR biofluid spectra taken from animals dosed with model toxins generates characteristic patterns of metabolic responses and enables the identification of biomarkers of toxic response and regeneration. Most of the studies to date have been conducted on urine, with limited investigations using blood plasma. In the current study we demonstrate new experimental methods for investigating toxin-induced changes in plasma profiles using ANIT (α-naphthylisothiocyanate, a model cholestatic agent). The use of conventional 1-dimensional 1H NMR spectra generates complex spectra with each biofluid requiring tailored NMR experiments and processing to optimize biological interpretation. Biofluids such as blood plasma or serum contain a wide range of macromolecules that generate a broad envelope of NMR signals, on which are superimposed sharper signals from lower mw metabolites and thus, key biomarker metabolite resonances can be obscured. ANIT was administered to male SD rats (@ 200 mg/kg p.o.) and plasma samples obtained prior to and at 48 h and 72 h post dosing. In order to simplify the subtle ANIT-induced changes in the lipoprotein profile of serum, diffusion-edited spectroscopy coupled with principal components analysis was used to focus on toxin-induced lipoprotein changes by minimizing the contribution of low mw molecules to the spectral profile. Using difusion edited spectra, marked changes to the plasma lipid profiles were detected and good separation of control and treated animals was effected. This study has demonstrated the potential of the application of chemometric analysis to diffusion edited 1H NMR spectra for probing lipoprotein metabolism disorders associated with toxic lesions.

963 NMR-BASED METABONOMIC STUDIES ON SALT TOXICITY IN ZEA MAYS: DECONVOLUTION OF PHYSIOLOGICAL AND TOXICOLOGICAL FACTORS.

C. L. Gavaghan[1], H. Antti[1], S. D. Hadfield[2], S. Hole[2], P. W. Howe[2], P. D. Stanley[2], J. K. Nicholson[1] and E. Holmes[1]. [1]*Biological Chemistry, ICMS London University, South Kensington, London, United Kingdom and* [2]*Syngenta, Jeallots Hill Research Station., Jeallots Hill, Bracknell,, Berkshire, United Kingdom.* Sponsor: D. Robertson.

High salinity, whether natural or induced by agricultural methods, is a widespread environmental stressor that can affect development and growth of plants. We have shown that application of NMR-based metabonomic technology can be used to characterise saline-induced stress effects in Zea Mays and to identify pertinent biomarkers. Interpretation of NMR-based metabonomic toxicity studies may be confounded by non-related physiological metabolic variation. Statistical experimental design was used to examine the relationship between metabolic differences arising from growth effects and salt toxicity. Maize plants were subjected to a continuous dosing of either 0, 50 and 150 mM saline solution and harvested after 2, 4 and 6 days (n=5 per class). 1H NMR spectroscopic analysis of the root and shoot extracts indicated differences in the metabolite spectral profiles relating to saline-induced stress. Clustering of control and treated classes based on inherent biochemical differences in the saline-treated plants was achieved *via* application of Principal Components Analysis to the spectral data. Analysis of the control and treated groups revealed clustering according to the time of harvesting, indicating differences in the metabolite profile resulting from growth effects. Partial Least Squares Analysis was employed to deconvolve the biochemical effects of growth and salt stress. Examination of the regression coefficients revealed important metabolic markers for saline toxicity including perturbed levels of malic acid, glucose, alanine, sucrose and glycinebetaine. This NMR-based metabonomic technology provided an efficient method for identifying stress effects in plants. Furthermore, statistically significant biomarkers for salt toxicity, growth differences and the interaction of these physiological factors were identified.

964 NUCLEAR MAGNETIC RESONANCE SPECTROSCOPIC AND PATTERN RECOGNITION STUDIES OF 3-NITROPROPIONIC ACID-INDUCED NEURONAL DAMAGE.

T. M. Tsang[1], J. Griffin[1], J. N. Haselden[2], M. L. Anthony[2], J. K. Nicholson[1] and E. Holmes[1]. [1]*Biological Chemistry, ICMS London University, South Kensington, London, United Kingdom and* [2]*Safety Assessment, GSK Pharmaceuticals, Ware, Herts, United Kingdom.* Sponsor: D. Robertson.

3-Nitropropionic acid (3NP) is a neurotoxin that produces lesions within the basal ganglia (particularly targetting the striatum) in rats and non-human primates with symptoms mimicking Huntington's Disease. 3NP is also an irreversible inhibitor of succinate dehydrogenase. Nuclear magnetic resonance (NMR) spectroscopy combined with pattern recognition (PR) analysis of biofluids and tissues offers a powerful approach to the investigation of the molecular consequences of toxin exposure. In this study magic angle spinning (MAS) NMR-PR methods have been applied to characterise the metabolic alterations in various neuronal regions caused by 14 days repeated exposure to 3NP (0, 5.0 and 7.5mg/kg i.p.) in the Sprague-Dawley rat. Selected brain regions were dissected and immediately snap frozen before analysis by 1D MAS-NMR. Principal components analysis (PCA) was used to show the biochemical variations induced by 3NP toxicity as a time-related trajectory plot. From the PCA eigenvector loadings, the discriminating regions of the NMR spectra, and thus the contributory endogenous metabolites were identified. Reductions in lactate, acetate, NAA, GABA and creatine levels were observed together with increases in succinate following systemic administration of this toxin. These studies show that MAS-NMR-PR offers a powerful contribution for the investigation of basic mechanisms of neurotoxicity.

965 COMPARISON OF THE TEMPORAL TOXICITY OF HYDRAZINE IN RAT AND MOUSE USING NMR-BASED METABONOMICS.

M. Bollard, T. Ebbels, H. Antti, H. Keun, O. Beckonert, E. Holmes, J. C. Lindon and J. K. Nicholson. *Biological Chemistry, ICMS London University, South Kensington, London, United Kingdom.* Sponsor: D. Robertson.

As part of our ongoing COnsortium for MEtabonomic Toxicology (COMET) designed to systematically investigate metabolic effects of drugs, 1H NMR spectroscopic and pattern recognition (PR)-based methods were used to investigate the biochemical responses to toxins in rat and mouse models. Principal components analysis (PCA) was used to evaluate the metabolic effect of hydrazine at 30 and 90 mg/kg in the rat and at 100 and 250 mg/kg in the mouse. Urine samples were collected from dosed and control animals at 10 time-points over an 8 day period and analysed by 600 MHz 1H NMR spectroscopy. Urinary biomarkers of hydrazine toxicity of the two species were determined from the PC loadings and included a number of endogenous metabolites which were common to both, including 2-aminoadipate, taurine, creatine and the TCA cycle intermediates. Metabolic trajectories were mapped in PC space using the mean spectra at each time point providing a means of monitoring the progression of and recovery from the toxic lesion. Due to the disparate magnitude of response shown in the two species, it was difficult to combine the two data sets in a single chemometric model. Thus, a hierarchical method was developed using multiple partial least squares (PLS) regression models which took account only of the direction of response in metabonomic space rather than magnitude. This enabled the time course of the responses to be compared in a meaningful way, showing that, although there were many similarities in

the effect of hydrazine dosing on endogenous metabolites, there were also subtle differences between the two species. Incorporation of these chemometric methods into automated NMR-based metabonomics will enable toxicological screening of biofluids from different species, thus aiding determination of the model species that best mimic the human.

966 A METABONOMIC INVESTIGATION OF THE BIOCHEMICAL EFFECTS OF ROSIGLITAZONE AND WY14643.

R. H. Barton[1], E. Holmes[1], J. K. Nicholson[1] and U. Sidelmann[2]. *[1]Biological Chemistry, ICMS London University, South Kensington, London, United Kingdom and [2]Drug metabolism, Novo Nordisk, Malov, Denmark.* Sponsor: D. Robertson.

The effects of diabetic treatment drugs Rosiglitazone and WY14643 were investigated by NMR-based metabonomic analysis using groups of healthy male Sprague-Dawley rats (n=10). 1H NMR spectra of plasma samples were obtained and data filtering and pattern recognition analysis applied to the spectra, in order to establish baseline reference effects of these drugs with particular emphasis on potential toxicological responses in non-disease state animals. Samples obtained after a low dose of Rosiglitazone administration were differentiated from the control group by increases in several metabolites including lipoproteins, triglycerides and glucose, whereas the intermediate group reversed this change and was most similar to the control group. The high dose group presented changes in the opposite metabolic direction to that of the low dose group, with lowered lipids and glucose levels. The WY14643 response also exhibited differential dose-related effects, initially at low dose showing increased lipids and decreased glucose signals. The intermediate-dose group showed an effective reversal of this pattern, and the high dose group was the closest to the control group, though marginally higher in glucose, choline and VLDL levels. This metabonomic evaluation of drug-response is aimed at allowing a better understanding and characterisation of the metabolic responses of diseased animals to these drug treatments, and in particular to identify potential biomarkers of toxic responses in the metabolism of healthy individuals

967 BUILDING NMR SPECTROSCOPIC METABONOMIC DATABASES OF XENOBIOTIC TOXICITY.

T. Ebbels, M. Bollard, H. Antti, H. Keun, O. Beckonert, E. Holmes, J. Lindon and J. Nicholson. *Biological Chemistry, Biomedical Sciences, Imperial College Faculty of Medicine, London, United Kingdom.*

The COnsortium for MEtabonomic Toxicology (COMET) project will construct a database of drug toxicity using ca. 100, 000 ^{1}H NMR spectra of biofluids from animals treated with model compounds. Mathematical models characterising the effects on endogenous metabolites will enable rapid toxicological screening of potential drug candidates and discovery of novel mechanisms and biomarkers for specific types of toxicity. To reveal any systematic differences between the 7 participating animal study centres, hydrazine was administered orally to rats at each site, in two dose groups (30 and 90 mg/kg). Urine samples were collected from dosed and control animals at 10 time-points over an 8 day period. At Imperial College, the urine was analysed by 600 MHz ^{1}H NMR spectroscopy and the spectra used to build statistical pattern recognition (PR) models based on principal component analysis (PCA) and partial least squares (PLS), describing both dose, time and between-Lab. related spectral signatures. The resulting 7 independent datasets showed a high degree of similarity, yet the metabonomic techniques could detect genuine low level biological differences between the laboratories. In addition, ^{1}H NMR spectra of plasma samples collected at 48 and 168 h post dose were analysed using PR. To further refine the information retrieval, PLS was used to model the relation between the NMR spectra and clinical chemistry of the plasma. This revealed co-variation between the NMR and clinical chemistry data, facilitating more detailed interpretation of the metabonomic variation. Finally, the reproducibility of metabonomic methodology was assessed by comparing spectra acquired at two different NMR facilities from alequots of the same urine samples. The two data sets showed close similarity, confirming the robustness of the technique. This work illustrates that metabonomic studies can obtain novel, reproducible information on the toxicity of model, and inevitably new compounds, across multiple laboratories with large numbers of samples.

968 MINIATURIZED NMR PROBEHEAD WITH INCREASED SENSITIVITY FOR PROFILING BIOFLUIDS AND METABOLITE IDENTIFICATION.

G. Schlotterbeck[1], A. Ross[1], H. Senn[1], D. Marek[2], T. Kuehn[2] and O. Schett[2]. *[1]PRBT-S, F. Hoffmann-La Roche, Basel, Switzerland and [2]Bruker Biospin AG, Fällanden, Switzerland.* Sponsor: D. Robertson.

Nuclear magnetic resonance (NMR) spectroscopy is one of the most powerful analytical tools to determine the structure of small molecules. It suffers, however, compared to other analytical techniques, from an inherent low sensitivity. Structural characterisation of mass- and volume limited samples are difficult with conventional NMR detectors, e.g.: bio-fluids (CSF, urine, plasma and synovial fluids), drug metabolites, fractionated peaks from micro-separation techniques and isolates of natural products. A new miniaturised 1mm NMR probe was built with a 100-fold smaller active sample volume than conventional NMR probeheads. The new probehead has an active volume of 2.5 µl. With this probe high resolution NMR was performed with hitherto unobtained mass sensitivity. The improvement in the signal to noise ratio by a factor of >4 compared to a conventional system lead to a reduction in measuring time of more than a factor of 16. Furthermore the favourable ratio of analyte to solvent lead to spectra with very low solvent background. NMR results are shown which illustrate the performance of the new probe for metabonomics investigations and metabolite identification. These include 1D 1H NMR spectra of rat urine, plasma and CSF, and 2D NMR experiments of mass limited samples.

969 APPLICATION OF METABONOMICS TO PHARMACEUTICAL DRUG DEVELOPMENT:EVALUATION OF PHENYLACETYLGLYCINE AS A POTENTIAL MARKER OF PHOSPHOLIPID ACCUMULATION.

M. L. Anthony, L. M. Keane, M. P. Hodson and J. N. Haselden. *Safety Assessment, GlaxoSmithKline Pharmaceuticals, Ware, Herts, United Kingdom.* Sponsor: R. Tyler.

Phospholipidosis (PLDS) can be caused by a range of agents in many animal species, including man [1]. PLDS is characterised by the accumulation of phospholipid-rich lamellated and crystalloid inclusions, identifiable only by transmission electron microscopy within a variety of cells [1, 2]. PLDS is a frequent finding in toxicology studies and, in order to miminise impact on drug development, there is a need to develop less labour-intensive and time-consuming methods for its detection. We have used nuclear magnetic resonance (NMR) spectroscopy to help to identify biochemical markers in urine collected from Sprague-Dawley rats following 7 days' repeated dosing with six structurally-related drug candidates (the cationic amphiphiles GSK-A to F) at 3 dose levels. All six compounds in the screen demonstrated morphological changes indicative of phospholipid accumulation in the mesenteric lymph node at the high dose level. Although a number of general housekeeping biochemicals were shown to change in urine by NMR, a feature common to all six drug candidates was a rise in the urinary levels of phenylacetylglycine (PAG). This observation supports previous reports that PAG may constitute a potential marker of PLDS [3, 4]. Significantly, PAG was also present in increased amounts in urine collected from rats dosed for 6 months with a structurally-unrelated drug candidate, GSK-G, that caused PLDS. In this case, PAG returned to control levels in urines collected from these animals after a 3 month off-dose period, mirroring a reversal of PLDS as detected by electron microscopy. This study highlights the utility of metabonomics technology in the monitoring of PLDS as part of novel chemical entity evaluation. Studies are ongoing to elucidate the origin of PAG and its biochemical significance. 1. Toxicologic Pathology 25, 53-60 (1997) 2. CRC Critical Reviews in Toxicology November, 185-217 (1975) 3. 970 APPLICATION OF METABONOMICS IN DRUG DESIGN: CAN METABONOMICS AND PHARMACOKINETICS (PK) STUDIES BE CONDUCTED SIMULATANEOUSLY IN THE SAME SET OF RATS?

Y. C. Wang[1], J. Fejzo[2], A. D. Heiser[1], J. R. Pocas[2], J. J. Spencer[1] and J. L. Moore[2]. *[1]Non-Clinical Drug Evaluation, Vertex Pharmaceuticals Incorporated, Cambridge, MA and [2]NMR, Vertex Pharmaceuticals Incorporated, Cambridge, MA.* Sponsor: E. Yau.

High-resolution ^{1}H-NMR spectroscopic analysis of biofluids is a powerful technique for investigating the response of organisms to xenobiotics. The ^{1}H-NMR spectral profiles of biofluids provide a unique temporal fingerprint of the metabolic state of an organism and information on the nature of xenobiotics to which an organism has been exposed. Metabonomics methods combine high resolution NMR of biofluids with pattern recognition techniques to determine the onset, duration, and localization of a toxic lesion in target organs. The feasibility of simultaneous metabonomics and PK studies in the same rats was assessed. Male Sprague-Dawley rats were divided into two experimental groups, without surgery (normal) or cannulated in the carotid artery (cannulated). Within each group, rats (n=6) received vehicle (control), methotrexate, or acetaminophen. Blank urine was collected on day 0. On day 1, treatments were delivered and the cannulated group was subjected to PK bleeding procedures. Urine was collected twice a day for 7 days. Urinary NMR spectra were acquired and data were analyzed with principal component analysis (PCA) and soft independent modeling of class analogy (SIMCA). Good clustering and good separation of clusters were observed in PCA map for all groups. When treated with xenobiotics, cannulated rats do not cluster the same as normal rats, indicating surgery had an impact on the response to xenobiotics treatment.

Loadings derived from SIMCA models indicate that there is no linear superposition of the effect of cannulation and the effect of xenobiotics exposure. These results suggest that simultaneous PK and metabonomics studies are feasible, which will provide information on both the systemic exposure and the effect of xenobiotics on the metabolic state of the rats. However, this requires a separate database for toxicity prediction built using cannulated rats.

971 COMPARISON OF NUCLEAR MAGNETIC RESONANCE (NMR) SPECTROSCOPY OF URINE AND CONVENTIONAL PATHOLOGY MEASUREMENTS IN PRECLINICAL SAFETY EVALUATION OF ALLYL ALCOHOL.

S. Goel, B. Bolon, R. Cattley, M. Cosenza, J. Sloan, C. Dipalma, I. Hayward, H. Davis and D. Smith. *Amgen, Inc., Thousand Oaks, CA.*

Detection of organ specific toxicity using nuclear magnetic resonance (NMR) spectroscopy of urine may be a novel method for evaluating toxicity of xenobiotics. This technique may allow for detection of toxicity below the doses that induces changes in standard pathology endpoints (e.g., serum chemistry and histopathology). The present study assessed this proposition using the model hepatotoxicant, allyl alcohol. Four Sprague-Dawley rats of each sex were orally gavaged with allyl alcohol at 0, 60, 120, or 240 mg/kg on Day 1 of the study. Survival permitting, two animals of each sex were necropsied on Days 3 and Day 5. Twenty-four hour urine samples were collected in metabolic cages prior to dosing and daily through Day 5. NMR spectra were acquired and the data subjected to principal component analysis (PCA). At necropsy, blood was taken for serum chemistry analysis, and selected organs were processed for microscopic evaluation. Allyl alcohol induced significant, dose-dependant increases in total bilirubin, blood urea nitrogen, release of hepatocellular enzymes (ALT, AST, LDH), and globulin as well as reducing serum albumin. The three most common histologic lesions were hepatocellular necrosis, forestomach ulceration, and granulocytic hyperplasia. NMR analysis of urine reliably separated samples from treated animals from those of control and pre-dose samples. The PCA of hematology and clinical chemistry showed similar pattern without time-dependent information. Allyl alcohol (60 mg/kg) increased urinary taurine levels on Day 1, with partial recovery by Day 5. The extent of NMR changes was correlated with the severity of hepatocellular necrosis. The NMR PCA revealed that inter-animal differences exceeded intra-animal differences. These data suggest two main roles for NMR spectroscopy in preclinical safety assessment: noninvasive metabonomic analysis of novel xenobiotic toxicity, and selection of metabolically homogenous animal population for *in vivo* studies.

972 EVALUATION OF METABONOMIC TECHNOLOGY FOR LIVER AND KIDNEY TOXICANTS IN MICE.

G. J. Stevens[1], J. Chambers[1], W. Evering[1] and A. Deese[2]. *[1]Drug Safety Evaluation, Pfizer Global R&D/Agouron Pharmaceuticals, San Diego, CA and [2]Analytical Research, Pfizer Global R&D/Agouron Pharmaceuticals, San Diego, CA.*

Metabonomic technology has been well characterized for the rat, however limited information is available for mice. The purpose of this study was to evaluate the utility of the mouse as a test system for early toxicology screening using metabonomics. Cisplatin (CP), 2-bromoethylamine (BEA), carbon tetrachloride (CCl_4), and p-aminophenol (PAP) were used as representative liver and kidney toxicants. Male B6C3F1 mice (4/dose group) were individually housed in metabolism cages and urine collected pre-test and every 24 hr period through Day 8. A low and high dose for each toxicant was selected to assess a Dose-Response effect. CP (10 and 25 mg/kg), BEA (100 and 30 mg/kg), CCl_4 (3000 and 2400 mg/kg) and PAP (100 and 300 mg/kg) were administered as single intraperitoneal or oral doses. Clinical chemistry and selected target organ histopathology was collected Day 2 and Day 8. High-resolution 1H-NMR spectra from urine were collected and data subjected to principle component analysis (PCA). A clear dose and time response was observed in the PCA analysis of the urine spectra with changes in agreement with clinical chemistry parameters in high-dose groups. In low-dose treated CP animals, PCA demonstrated effects at low doses which were not evident by clinical chemistry. PCA also demonstrated a time course of response, with early toxicity occurring followed by apparent recovery. These data demonstrate that the mouse is a viable test system for predictive toxicology screening using metabonomic technology.

973 APPLICATION OF NMR-BASED METABONOMIC TECHNOLOGY TO TOXICITY SCREENING; CHARACTERIZATION AND PREDICTION OF NEPHROTOXICITY.

J. T. Brindle, E. Holmes, J. K. Nicholson and J. Connelly. *Biological Chemistry, Imperial College, S. Kensington, United Kingdom.* Sponsor: D. Robertson.

NMR-based metabonomic technology was applied to the characterization of tissue and mechanism specific renal toxicity. Acute nephrotoxicity was induced in male SD rats using a single dose of one of the following; vancomycin, ifosfamide, lead acetate, maleic acid, sodium chromate and sodium fluoride. Proton NMR spectroscopic analysis was performed on urine samples obtained at timed intervals following dosing. Data reduction methods and multivariate statistical analyses were applied to the spectral data and separate mathematical models constructed to characterize the metabolic effects and biomarkers of each toxin. These models were combined to form a simple expert system for classifying nephrotoxicity. Extension of this preliminary expert system will be of obvious benefit for lead compound selection in the pharmaceutical industry.

974 MULTIVARIATE STATISTICAL PRE-TREATMENT OF NMR-BASED METABONOMIC DATA TO REMOVE INHERRANT PHYSIOLOGICAL VARIATION CONFOUNDING TOXICITY PATTERNS.

H. Antti, J. T. Brindle, J. Shockcor, E. Holmes and J. K. Nicholson. *Biological Chemistry, Imperial College, S. Kensington, United Kingdom.* Sponsor: D. Robertson.

Proton NMR-based metabonomics is a well-established technique used to analyze and interpret complex multiparametric metabolic data and has a wide number of applications in the development of pharmaceuticals. However, interpretation of biological data can be obscured by extraneous variation such as physiological variation or confounding toxicity related changes. Here we have shown the novel application of a data filtering method, orthogonal signal correction (OSC), to biofluid NMR data to minimize innate physiological variation and confounding toxicity patterns in two independent studies. The removal of this orthogonal variation exposed features of interest in the NMR data and facilitated biological interpretation and identification of biomarkers of toxicity. Furthermore, analysis of the orthogonal variation provided an explanation of the systematic spectral changes responsible for confounding the relevant toxicity patterns.

975 RENAL ORGANIC ANION TRANSORTER IS A MECHANISM FOR THE RENAL UPTAKE OF MERCURIC CONJUGATES OF CYSTEINLY HOMOLOGS.

A. G. Aslamkhan[1], Y. H. Han[1], J. B. Pritchard[1], D. W. Barfuss[2] and R. K. Zalups[3]. *[1]Pharmacolgy and Chemistry, NIEHS, Research Triangle Park, NC, [2]Biology, GA State Univ., Atlanta, GA and [3]Basic Medical Sciences, Mercer University School of Medicine, Macon, GA.*

The role of the human organic anion transporter subtype 1 (hOAT1) in the uptake of mercuric conjugates of cysteine (CYS), N-acetylcysteine (NAC) or GSH was studied in an MDCK cell-line stably transfected with the open reading frame sequence of the hOAT1 transporter. Uptake of p-aminohippurate (PAH), which is a high-affinity substrate for OAT1, by the transfected cells was 20 times greater than that in the non-transected cells. Mercuric conjugates, especially of CYS and NAC were significantly more toxic in hOAT1-transfected cells than in non-transfected cells as determine by a decrease in mitochondrial dehydrogenase activity (MTT conversion). This was particularly the case for the mercuric conjugate of NAC, which induced greater than 50% cellular death over 18 h at a concentration of 100 microM. The toxic effects of the mercuric conjugate of NAC was prevented by co-exposure to probenecid (a competitive inhibitor of OAT1) and partially prevented by co-exposure to PAH. Toxicity was also cis-inhibited by the OAT1 exchangeable dicarboxylates alpha-ketoglutarate, glutarate, and adipate. However, succinate, a non-exchangeable dicarboxylate, did not cis-inhibit induction of toxic effects. Compared with the toxicity induced by unbound mercuric ions, which occurred steadily over a 24-hour time period, no apparent toxic effects were detected with mercuric conjugates of NAC until ten hours of exposure had elapsed. Uptake studies confirmed a direct relationship between uptake of mercury and the toxic effects elicited. Probenecid, PAH and dicarboxylates competitively inhibited the uptake of mercuric conjugates of CYS or NAC. These findings are the first real line of mechanistic evidence showing that OAT1 transports mercuric conjugates CYS and NAC, which are species of mercury taken up *in vivo* and vitro by proximal tubular epithelial cells, which are the main targets of inorganic mercury in the kidneys.

976 INORGANIC MERCURY TOXICITY AND TRANSPORT IN DISTAL SEGMENTS OF THE RABBIT NEPHRON.

D. W. Barfuss[1] and R. K. Zalups[2]. *[1]Biology, Georgia State University, Atlanta, GA and [2]Division of Basic Medical Sciences, Mercer University School of Medicine, Macon, GA.*

Luminal transport and acute toxicity of inorganic mercury in selected segments of the distal region of the rabbit nephron were studied using the isolated perfused tubule technique. Segments studied were the cortical thick ascending limb (cTAL)

and the cortical collection duct (cCD). Both segments were relatively resistant to the toxic effects of luminal inorganic mercury (^{203}Hg, 9.3μM for the cCD and 20μM for cTAL) when compared to its acute toxic effects on the proximal tubule, which are prominent cellular uptake of vital dye, cellular swelling, marked luminal membrane blebbing and a great increase in the leakiness of the tight junctions. The cCD showed no acute toxic effects from luminal mercury while the cTAL was sensitive to the presences of the luminal inorganic mercury with some slight blebbing of the luminal membrane and an increase in the leakiness of the tight junctions, but there was no cellular swelling nor cellular uptake of the vital dye. The transport of luminal inorganic mercury was measured by its disappearance rate from the lumen (JD, fmol min^{-1} (mm tubular length)$^{-1}$), its appearance rate in the bath (JA, fmol min^{-1} (mm tubular length)$^{-1}$) and by cellular accumulation (fmol (mm tubular length)$^{-1}$). The JD was 33.5 ±2.8 and 81.6 ±9.5 for the cCD and cTAL respectively, while the JA was 9.3 ±2.1 and 70.0 ±17.4 for the cCD and cTAL respectively. The asymmetry of the JD and JA within each segment may be due to cellular uptake of the mercury, which was 1, 342± 347 and 1, 526 ±164 in the cCD and cTAL respectively. For both the cCD and cTAL, approximately 80% of the cellular accumulated mercury was associated with the tubular structure and 20% with the cytoplasm. We conclude that the cCD and the cTAL can transport inorganic mercury from the luminal fluid. A significant fraction of the accumulated mercury in the cell may be due to non-specific binding. Also, these segments are relatively resistant to the acute toxic effects of inorganic mercury.

977 MERCURIC ION (HG^{2+}) INCREASES THE SENSITIVITY OF KIDNEY CELLS TO APOPTOSIS BY INHIBITING NUCLEAR FACTOR-κB (NF-κB) ACTIVATION.

F. J. Dieguez-Acuna, P. L. Simmonds, M. E. Ellis, J. V. Kushleika and J. S. Woods. *Department of Environmental Health, University of Washington, Seattle, WA.*

NF-κB is a thiol-dependent transcriptional factor that promotes cell survival and protects from apoptotic stimuli. Recently, we reported (TAP 173:176-187, 2001) that Hg^{2+}, one of the strongest thiol-binding agents known, impairs NF-κB activation and transcriptional activity in normal rat kidney epithelial (NRK52E) cells at low concentrations (< 20 μM) by binding to specific reduced thiol moieties in the NF-κB activation pathway. Since NF-κB prevents apoptosis, we hypothesized that attenuation of NF-κB activation by Hg^{2+} may increase the sensitivity of kidney cells to apoptotic agents to which kidney cells are otherwise resistant because of their NF-κB activating capacity. In untreated cells, fewer than 5% were apoptotic when evaluated by DNA fragmentation (TUNEL) or flow cytometric DNA profile analyses. Hg^{2+} (5 μM) treatment for 24 hrs increased this proportion by 1.5- to 2-fold. Neither lipopolysaccharide (LPS) (1 μg/ml) nor tumor necrosis factor-α(TNF) (100 U/ml), potent inducers of NF-κB, altered the proportion of apoptotic cells, compared with untreated controls. However, when LPS or TNF were given following Hg^{2+} treatment (5 μM for 30 min.), the proportion of cells undergoing apoptosis at 22 hrs increased by 4- to 6-fold over that seen following LPS or TNF alone. In contrast, Hg^{2+} pretreatment did not increase the amount of apoptosis caused by apoptosis-inducers that do not activate NF-κB (staurosporine, Fas ligand). These findings support the view that Hg^{2+} enhances the sensitivity of kidney cells to apoptotic stimuli as a consequence of inhibition of NF-κB activity. Since apoptosis is known to play a key role in the pathogenesis of renal failure resulting from toxicant injury to proximal tubular cells, promotion of apoptosis *via* inhibition of NF-κB activity may define a novel molecular mechanism by which Hg^{2+} toxicity is initiated in kidney cells. Supported by ES04696 and ES07033 from the NIH.

978 DIFFERENTIAL SENSITIVITY TO CHEMICALLY INDUCED INJURY IN PRIMARY CULTURES OF RENAL EPITHELIAL CELLS FROM CONTROL AND UNINEPHRECTOMIZED RATS.

R. K. Zalups[1], D. A. Putt[2] and L. H. Lash[2]. [1]*Basic Medical Sciences, Mercer University Sch. Med., Macon, GA and* [2]*Pharmacology, Wayne State University Sch. Med., Detroit, MI.*

Primary cultures of renal proximal tubular (PT) and distal tubular (DT) cells from rats that had undergone uninephrectomy and compensatory renal growth (NPX) retain changes in morphology, enzyme and transport activities, and mitochondrial function that occur in kidneys of NPX rats. Acute cytotoxicity of tert-butyl hydroperoxide (tBH; 0.1, 0.5, 1, 5, 10 mM) was determined by measurement of lactate dehydrogenase (LDH) release in both freshly isolated and primary cultures of renal PT and DT cells from control and NPX rats. tBH-induced death of both cell types from NPX rats was greater than that in corresponding cells from control rats (net LDH release = 33.6% *vs.* 53.7% for PT cells from control and NPX; 10.8% *vs.* 62.1% for DT cells from control and NPX). tBH-induced malondialdehyde formation was 2- to 4-fold greater in PT and DT cells from NPX rats than in cells from control rats. Similarly, tBH and KCN (0.1-1 mM; a mitochondrial toxicant) both induced significantly greater cell death in confluent primary cultures of PT and DT cells from NPX rats than in corresponding cells from control rats. For inorganic Hg (5, 10, 50 μM), however, cytotoxic effects in cells from NPX rats were similar to those in corresponding cells from control rats at the two lower concentrations but were markedly higher at the highest concentration. Uptake of inorganic Hg (0.1, 1, 5 μM) across the brush-border and basolateral membranes of PT and DT cells grown on filter inserts was actually lower in cells from NPX rats at the two lower doses but was higher at the highest dose as compared to measurements in cells from control rats. These results indicate a general greater sensitivity of cells from NPX rats to chemical toxicants than cells from control rats. For inorganic Hg, however, more complex dose-response relationships exist between transport and toxicity. (Supported by NIEHS Grant ES05157, ES05980, and DK40725.)

979 IS MERCURY IN URINE INDICATIVE OF EXPOSURE TO LOW LEVELS OF MERCURY VAPOR?

J. S. Tsuji[1], P. R. Williams[1], M. R. Edwards[1], K. P. Avadhanam[2] and D. P. Paustenbach[2]. [1]*Exponent, Bellevue, WA and* [2]*Exponent, Menlo Park, CA.*

Exposure to elemental mercury has received increased attention as a result of ubiquitous use, improved analytical detection, and awareness of health effects. Although urinary mercury levels are considered the best predictor of mercury vapor exposures, a lack of relationship has been reported between airborne and urinary mercury levels at low air levels (i.e., <50 $μg/m^3$). We reviewed the literature on the correlation of mercury in air and urine to evaluated whether airborne mercury exposures at health-based action levels (e.g., 1 $μg/m^3$) are measurable in urine above background. A meta-analysis was conducted of ten studies reporting paired air and urine mercury data (149 samples total) and meeting specified criteria for data quality and sufficiency. The log-transformed dataset showed a strong correlation between mercury in air and in urine (r=0.77), although the relationship was best fit by a series of parallel lines with different intercepts for each study (R^2=0.81). Predicted ratios of air to urine mercury levels at 50 $μg/m^3$ air concentration ranged from 1:1 to 1:3. Toward the lower end of the dataset (i.e., 10 $μg/m^3$), predicted urinary mercury levels encompassed two distinct ranges: values on the order of 20 μg/L and 30–60 μg/L. Extrapolation to 1 $μg/m^3$ resulted in predicted urinary levels of 4–5 and 6–13 μg/L. Higher predicted urine mercury levels were associated with use of static area air samplers by some studies, rather than more accurate personal air samplers. Urinary mercury predictions based primarily on personal air samplers at 1 and 10 $μg/m^3$ are consistent with reported mean (4 μg/L) and upper-bound (20 μg/L) background levels, respectively. Thus, although mercury levels in air and urine are correlated below 50 $μg/m^3$, the impact of mercury in air below 10 $μg/m^3$ is likely indistinguishable from background urinary mercury levels.

980 MERCURIC CHLORIDE SUPPRESSES CYCLOOXYGENASE-2 EXPRESSION AND PROSTAGLANDIN PRODUCTION IN A HUMAN MONOCYTIC CELL LINE.

W. C. Glasgow and R. K. Zalups. *Basic Medical Sciences, Mercer University School of Medicine, Macon, GA.*

We examined the effects of a brief treatment of low-dose mercuric chloride on the activation of arachidonic acid metabolism in the human monocytic cell line THP-1. HPLC analyses revealed that LPS treatment stimulated induction of cyclooxygenase-2 expression and production of prostaglandin E2 (a major arachidonate metabolite)in these cells. Unstimulated THP-1 cells express the constitutive cyclooxygenase-1 isoform and a low level of cyclooxygenase-2, with a basal production of prostaglandin E2. THP-1 cells were pre-treated with 1 microM mercuric chloride for one hour, and then were incubated with LPS (1 microg/ml) for 4 hours. Cell viability was not affected by treatment with inorganic mercury, as assessed by trypan blue exclusion. Treatment with mercuric chloride suppressed both the basal level and LPS-stimulated expression of cyclooxygenase-2, as measured by Western-blot analysis. Correspondingly, EIA analysis revealed that both basal and LPS-stimulated prostaglandin E2 synthesis was attenuated by mercuric chloride treatment. We did not observe alteration of cyclooxygenase-1 expression. These results demonstrate an effect of mercury on attenuating the arachidonic acid pathway in activated monocytes/ macrophages. Modulation of this pathway by inorganic mercury suggests that part of the adverse effects of exposure to low levels of this metal may be suppression of inflammatory and immune responses.

981 EFFECTS OF METHYLMERCURY EXPOSURE ON THE IMMUNE AND NERVOUS SYSTEM RESPONSES OF CBA/J MICE TO A CHRONIC TOXOPLASMA GONDII INFECTION.

M. D. King, M. Ehrich and D. S. Lindsay. *Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA.*

Previous studies from our laboratory suggest that exposure to methyl mercury (MeHg) does not increase the susceptibility to acute toxoplasmosis in CBA/J mice. Therefore, we investigated endpoints associated with immunotoxicity and neuro-

toxicity in 6-week old, female CBA/J mice exposed to both MeHg and T. gondii during a chronic T. gondii infection. Mice were fed 25 T. gondii tissue cysts and dosed six weeks later with 20 mg/kg of MeHg. There were significant differences ($P < 0.05$) within the T cell subpopulation ratios as indicated by flow cytometric analysis. MeHg increased splenic CD8+ T cell subpopulations with or without a concurrent T. gondii infection, while the CD4+ T cell subpopulations were decreased ($P<0.05$). MeHg had no effect on the CD4+CD8+ T cell or non-T cell subpopulations. Groups without T. gondii infection showed a decrease in CD8+ T cells when compared to groups with the infection, while there was no difference in CD4+ T cells between infected or non-infected mice. There was a significant ($P<0.05$) increase in brain tissue cyst counts within the group exposed to both MeHg and T. gondii (16 ± 4, mean ± SE, n=7) *versus* T. gondii alone (4 ± 1, n=8). These data indicate that concurrent exposure to both MeHg and T. gondii has notable effects, especially on the immune system (Supported by NIH Grant F36GM20301).

982 DECREASED ARGINASE ACTIVITY AND LOSS OF MANGANESE CONTENT OF RAT LIVER BY METHYLMERCURY EXPOSURE *IN VIVO*.

M. Kikushima[1], Y. Kumagai[2], Z. L. Chen[3], Y. Ishii[2], M. Mori[4] and N. Shimojo[2]. *[1]Graduate School Doctoral Program in Medical Sciences, University of Tsukuba, Tsukuba, Ibaraki, Japan, [2]Department of Environmental Medicine, University of Tsukuba, Tsukuba, Ibaraki, Japan, [3]Masters Program in Environmental Sciences, University of Tsukuba, Tsukuba, Ibaraki, Japan and [4]Department of Molecular Genetics, Kumamoto University School of Medicine, Honjo, Kumamoto, Japan.*
Sponsor: A. Naganuma.

Alteration in arginase (ARI) which is an abundant manganese-binding protein in liver during methylmercuric chloride (MMC) exposure in vivo was examined because our previous study indicated that MMC administration caused a decrease in the mangaese-superoxide dismutase activity without affecting its gene expression and protein content. Subcutaneous administration of MMC (10 mg/kg/day) for 5 days to rats resulted in drastic decrease in the ARI activity (44% of control). Under the condition, hepatic manganese content did decline to 49% of control. Interestingly, there was a strong positive correlation ($r=0.72$, $P<0.01$) between hepatic ARI activities and hepatic manganese levels. Immunoblot analysis revealed that reduction of ARI activity caused by MMC was not due to that of the protein content. With purified ARI it was found that an thiol-modifying agent N-ethylmaleimide as well as MMC suppressed the enzyme activity, but this inhibitory effect of these chemicals reached plateau levels (20-30% of control), suggesting contribution of sulfhydryl modification to the decrease in ARI activity. This hypothesis was further supported by steady-attachment of ARI to an agarose gel conjugated with arylmercury and then dissociation of this protein from the affinity resin by 2-mercaptoethanol, but not NaCl, nonionic detergent and basic amino acid. These results suggest that covalent interaction of MMC with ARI through accessible cystein residues, presumably resulting in manganese release from the active center, appears to be, at least partially, associated with MMC-mediated reduction of ARI activity observed *in vivo*.

983 INORGANIC MERCURY SUPPRESSES NITRIC OXIDE PRODUCTION AND MODULATES CYTOKINE GENE EXPRESSION THROUGH NF-κB SIGNALING PATHWAY IN MURINE MACROPHAGE.

S. H. Kim, V. J. Johnson and R. P. Sharma. *Physiology and Pharmacology, The University of Georgia, Athens, GA.*

Mercury is a heavy metal known to adversely affect the immune system; however, little is known regarding molecular mechanisms. Previous studies showed that mercury potently inhibits nitric oxide (NO) production in pancreatic islet β-cells. Macrophages are major producers of NO and this signaling molecule is important in the generation and regulation of immune responses. Therefore, macrophages may be a target for mercury intoxication. The mechanisms involved in the regulation of NO by mercury remain unclear. We investigated the hypothesis that mercury inhibits NO production through a nuclear factor κB (NF-κB)-dependent mechanism. In this study J774A.1 cells, a murine macrophage cell line, were used to investigate the effects of low dose exposure to inorganic mercury (Hg) on the production of NO, TNFα, IL-6 and IL-1β. Cells were stimulated with Hg with or without LPS (30 ng/ml). Hg (5-20 μM) dose-dependently decreased the production of NO in LPS-stimulated cells. Concomitant decreases in the expression of inducible nitric oxide synthase (iNOS) mRNA and protein were observed. Treatment of J774A.1 cells with Hg alone did not affect the production of NO nor the expression of iNOS mRNA or protein. Interestingly, Hg stimulated the expression of TNFα mRNA and increased LPS-induced TNFα and IL-6 mRNA expression measured by reverse transcription-polymerase chain reaction. IL-1β mRNA expression was not affected by inorganic mercury. NF-κB controls the expression of many immune related genes including iNOS and pro-inflammatory cytokines. Exposure to Hg (20 μM) inhibited LPS-induced nuclear translocation of NF-κB as determined by western blot using anti-p65 antibody. Inhibition of NF-κB activity represents a likely mechanism for the inhibitory effects of Hg on NO production but fails to explain the stimulatory effects of this metal on cytokine gene expression. Other signaling pathways are currently under investigation, namely the effects of Hg on p38-mitogen activated protein kinase.

984 INORGANIC MERCURY (HGCL2) DECREASES ADIPOGENESIS AND CAUSES INSULIN RESISTANCE IN 3T3-L1 ADIPOCYTES.

E. A. Kircher and D. M. Barnes. *Animal Sciences; Molecular and Environmental Toxicology Center, University of Wisconsin - Madison, Madison, WI.*

Many aspects of the differentiation process of the 3T3-L1 preadipocyte fibroblast cell line have been determined and can be used as a model to study the effects of toxins on adipogenesis. Mercury (Hg) is a prevalent and mobile toxin in our environment that has been shown to increase the glucose uptake of mature adipocytes. In this report, we examine the effects of Hg on adipocyte differentiation and insulin responsiveness. 3T3-L1 fibroblasts were differentiated in the presence or absence of 1-10 μM Hg. The presence of Hg decreased the number of cells differentiating to adipocytes, decreased their lipid content, and decreased expression of PPARγ. Lipid content of cells differentiated in the presence of 5 or 10 μM Hg decreased by 22 and 21% respectively. Hg reduced the number of differentiated adipocytes by 14, 36 and 55% for 5, 10 and 20 μM Hg respectively. PPARγ expression decreased 60% in the presence of 5 and 10 μM Hg. Another physiological consequence of Hg exposure during differentiation was a reduction of insulin mediated glucose uptake. Cells differentiation in the presence of 1, 5, and 10 μM Hg decreased their insulin-mediated glucose uptake by 25, 57, and 62% respectively. These results show that low levels of Hg can disrupt adipocyte differentiation and alter their subsequent physiological responses to a hormonal stimulus.

985 MERCURY CONTAMINATION IN INTERNAL ORGANS OF CETACEANS MARKETED FOR HUMAN CONSUMPTION.

T. Endo[1], K. Haraguchi[2] and M. Sakata[1]. *[1]Pharmaceutical Sciences, Health Sciences University of Hokkaido, Ishikari-Tobetsu, Hokkaido,, Japan and [2]Daiichi College of Pharmaceutical Sciences, Minami-ku, Fukuoka, Japan.*

The internal organs such as liver, kidney, lung, and small intestine of toothed whales and dolphins have been traditionally eaten in the limited area of Japan. A mixture of these organs is sold as boiled products. We surveyed Hg contamination in the internal organs of cetaceans sold in Japanese market for human consumption. The averages with SD of total mercury (T-Hg) were 357 ± 520 (0.195-1980, n=27) ppm in liver, 40.5 ± 48.5 (7.85-95.1, n=15) ppm in kidney and 42.8 ± 43.8 (2.10-79.6, n=23) ppm in lung. The provisional limit of T-Hg in marine products set by Japanese Ministry of Health and Welfare is 0.4 ppm. The highest of T-Hg detected in the liver was about 5000 times higher than their limit, suggesting acute intoxication of Hg even by a single consumption. A high correlation was observed between T-Hg and Se concentrations; the molar ratio of T-Hg/Se in these organs was slightly higher than 1.0. Furthermore, a significant correlation was observed between Zn and Cu concentrations in liver and lung, suggesting the induction of metallothionein (MT). Probably, the formation of Hg-Se complex and the induction of MT should decrease the toxicity of Hg for cetaceans and allow tremendous accumulation of Hg in their livers. Supported by IFAW.

986 GADOLINIUM PRETREATMENT PREVENTS CADMIUM-INDUCED LIVER DAMAGE IN BOTH WILD-TYPE AND METALLOTHIONEIN-NULL MICE.

E. B. Harstad and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

The heavy metal cadmium (Cd) causes hepatotoxicity upon acute administration. Kupffer cells, the resident macrophages of the liver, have been implicated in the mechanism of Cd-induced hepatotoxicity, as suppressing Kupffer cells with gadolinium chloride ($GdCl_3$) prevents Cd-induced hepatotoxicity. However, $GdCl_3$ may also induce the Cd-binding protein, metallothionein (MT). Therefore, a study was conducted to determine whether $GdCl_3$ prevents Cd-induced hepatotoxicity *via* the induction of MT or depletion of Kupffer cells. First, hepatic MT and Kupffer cell counts were analyzed 24 h after administration of saline or 10, 30, or 60 mg $GdCl_3$/kg to wild-type (WT) mice. Second, WT and MT-null mice were pretreated with saline or 10, 30, or 60 mg $GdCl_3$/kg 24 h prior to a hepatotoxic dose of Cd (2.5 mg Cd/kg) to examine whether the hepatoprotective effects of

$GdCl_3$ are related to the observed induction of MT or Kupffer cell activation. Blood and livers were removed 16 h after Cd administration and analyzed for hepatotoxicity as well as MT and Kupffer cell content. $GdCl_3$ treatment alone induced MT in a dose-dependent manner and did not affect hepatic non-protein sulfhydryl content. Cd-induced hepatotoxicity was prevented in both WT and MT-null mice that were pretreated with 30 or 60 mg $GdCl_3$/kg, demonstrating that MT induction is not required for the hepatoprotective effects of $GdCl_3$. Hepatic Cd content was not decreased by $GdCl_3$, demonstrating that $GdCl_3$ did not alter Cd distribution to the liver. Furthermore, Kupffer cells were depleted at all doses of $GdCl_3$, whereas hepatoprotection was only observed at doses of 30 and 60 mg, but not 10 $GdCl_3$/kg. This did not conclusively rule out Kupffer cells in the mechanism of Cd-induced hepatotoxicity, but it does suggest that $GdCl_3$ exerts hepatoprotective effects on the liver in addition to depleting Kupffer cells. In summary, these data rule out MT induction and suggest a limited role for Kupffer cells as mechanisms of $GdCl_3$-induced protection from Cd-induced hepatotoxicity. (Supported by NIH grants ES-01142 and ES-07079)

987 MECHANISM OF RESISTANCE TO CADMIUM TOXICITY IN MALE WISTAR-IMAMICHI RATS.

H. Shimada[1], M. Nagano[2], A. Yasutake[2] and Y. Imamura[3]. *[1]Faculty of Education, Kumamoto University, Kumamoto, Japan, [2]National Institute for Minamata Disease, Kumamoto, Japan and [3]Faculty of Pharmaceutical Sciences, Kumamoto University, Kumamoto, Japan.*

It has been shown that the toxic effect of cadmium (Cd) can be varied with species, strain and sex in experimental animals. For these reasons, one of the key elements is thought to be metallothionein (MT) that plays a critical role in detoxification of Cd. However, the detailed mechanism for these variations of Cd toxicity remains to be elucidated. In the present study, we compared Cd-induced mortality in four strains of male rats. In the case of Fischer, Wistar and Sprague-Dawley strains, a single injection of 5 mg Cd/kg proved very toxic and induced 80~100% mortality within 2 days. On the other hand, in Wistar-Imamichi strain, the Cd treatment proved nonlethal during 7 days. Next, we attempted to analyze the inheritance pattern of Cd resistance, using resistant (Wistar-Imamichi) and sensitive (Fischer) inbred rats to the metal. The resistance to Cd toxicity was also observed in male rats of first filial (F1) generation (male Fischer x female Wistar-Imamichi). In order to establish whether the resistance to Cd toxicity in male Wistar-Imamichi rats is androgen-dependent, the effect of testectomy on Cd-induced mortality was examined. However, testectomy had no effect on the resistance to Cd toxicity in male Wistar-Imamichi rats, suggesting the resistance is independent of the regulation by androgens. Furthermore, we determined GSH and MT levels in several tissues of resistant (Wistar-Imamichi) and sensitive (Fischer) rats. Pronounced difference of GSH and MT levels in these two strains was not observed in the control or Cd-treated rats. Therefore, it is possible to assume that endogenous substance(s) other than GSH and MT is involved in the resistance to Cd toxicity found in male Wistar-Imamichi rats. Further studies are in progress to elucidate the mechanism of the resistance to Cd toxicity in male Wistar-Imamichi rats.

988 INDUCTION OF METALLOTHIONEIN BY CADMIUM IS ASSOCIATED WITH P53 AND APOPTOSIS IN HUMAN EPITHELIAL BREAST CANCER CELLS.

L. Fan and M. G. Cherian. *Pathology, University of Western Ontario, London, ON, Canada.*

Although the function of metallothionein (MT), a metal-binding protein, remains unclear, previous studies in human tumors and cellular differentiation have suggested a pro-apoptotic function. Since the tumor suppressor protein p53 plays an important role in apoptosis, the present study was undertaken to investigate any potential relationship between MT and p53 using human breast cancer epithelial cell lines differing in p53 and estrogen-receptor (ER) status. Cells were treated with 10 μM $CdCl_2$ for 24 h, and MT protein and mRNA levels were measured by ^{109}Cd-heme assay and RT-PCR. MCF7 cells (p53+, ER+) showed a much greater induction in MT protein and mRNA expression as compared to cell lines which are p53- and ER- or weakly positive for ER (ER±). MT localization was determined by immunohistochemical staining. Prior to Cd treatment, MCF7 and HCC1806 (p53-, ER-) cells both showed mainly cytoplasmic staining. Following treatment, MCF7 cells showed intense nuclear and cytoplasmic staining while HCC1806 cells showed staining in the cytoplasm and weak staining in the nucleus. The TUNEL technique was used to study Cd-induced apoptosis. It was found that 10-40 μM $CdCl_2$ treatments caused significant apoptosis in MCF7 cells, particularly at 6-8 and 48 h, but not in MDA-MB-231 cells (p53-, ER-). The data demonstrate that the induction of MT expression is higher in p53+ cells such as MCF7 than p53- epithelial cells. It also suggests that Cd-induced apoptosis may occur mainly in p53+ cells and could be a p53-dependent pathway. Since these cells can induce MT activity after exposure to Cd, this may explain the pro- and anti-apoptotic properties of Cd salts at different concentrations. Additional studies after transfection of p53 gene into p53- epithelial cells or inactivation of p53 gene in p53+ cells may explain the mechanisms involved in MT induction and changes in apoptosis. (Supported by grants from CIHR and NSERC)

989 CADMIUM INDUCED APOPTOSIS IN HUMAN PROXIMAL TUBULE CELLS AND ITS DERIVED CELL LINE, HK-2.

S. Somji, S. H. Garrett, M. A. Sens and D. A. Sens. *Urology, West Virginia University, Morgantown, WV.*

Cadmium (Cd^{+2}), a nephrotoxin can cause acute and chronic toxicity in man due to its slow accumulation in the proximal tubules of the kidney. Heavy metals have been known to cause cell death by necrosis or by apoptosis. The goal of this study was to determine if Cd^{+2}could induce apoptosis in the human proximal tubule (HPT) cells and its derived immortalized cell line, HK-2. For this purpose, HPT and HK-2 cells were exposed to lethal and sub-lethal concentrations of cadmium chloride for various time periods. Apoptosis was determined by observing the nuclear morphology with the nuclear binding dye, 4', 6-diamidino-2-phenylindole (DAPI), and internucleosomal DNA fragmentation. Continuous exposure of HPT cells to 27μM cadmium chloride for 12 to 60 hr caused cell death, with few cells showing the morphological changes typical for apoptosis and little DNA fragmentation. Exposure to 45μM cadmium chloride caused extensive cell death without any changes typical for apoptosis. HK-2 cells were more sensitive to Cd^{+2} and therefore lower doses of 4.5 and 9 μM Cd^{+2} were used which resulted in cell death with extensive chromatin condensation and DNA fragmentation. These results suggest that apoptosis is not the major mode of cell death elicited by Cd^{+2} in HPT cells and is concentration dependant, whereas HK-2 cells are more susceptible to death by apoptosis.

990 INDUCTION OF APOPTOSIS IN CELLS BY CADMIUM; QUANTITATIVE NEGATIVE CORRELATION BETWEEN BASAL OR INDUCED METALLOTHIONEIN CONCENTRATION AND APOPTOTIC RATE.

R. Shimoda[1,2], T. Nagamine[3], H. Takagi[2], M. Mori[2] and M. P. Waalkes[1]. *[1]NCI at NIEHS, Research Triangle Park, NC, [2]First Department of Internal Medicine, Gunma University, Maebashi, Japan and [3]Dept. of Health Science, Gunma University, Maebashi, Japan.*

Metallothionein (MT) often reduces the adverse effects of cadmium (Cd) but how it may alter Cd-induced apoptosis is unclear. Thus, the goal of this study was to define the role of MT in Cd-induced apoptosis using cell lines with widely varying sensitivity to Cd. Toxic effects of Cd on human hepatocellular carcinoma cell lines (HepG2 and PLC/PRF/5) were investigated and compared with Chang cells. These cells were cultured with 0, 5, 10, 20, 40, 80 and 120 μM of Cd for 3, 6, 12, and 24 h. Significant cytolethality was observed in HepG2 and PLC/PRF/5 cells in time-dependent and concentration-dependent manner with LC_{50} values of 24 μM and 13 μM, respectively. However, Chang cells were much less sensitive to Cd-induced cytotoxicity (LC_{50} = 64 μM). Apoptotic cell death occurring at cytolethal concentrations was demonstrated in all cell lines by DNA fragmentation with ELISA and confirmed with agarose gel electrophoresis. When MT was measured, there was a strong negative linear correlation between the rate of apoptosis induced by Cd in these cell lines and the basal levels of cellular MT concentration (r = - 0.996) or Cd-induced MT levels (r = - 0.975). Treating HepG2 cells with zinc (Zn) made the relatively sensitive HepG2 cell line resistant to Cd-induced apoptosis, likely due to Zn-induced MT. In fact, there was also a strong negative linear correlation (r = - 0.964) between the amount of Zn-induced MT in HepG2 cells and the rate of Cd-induced apoptosis. These findings revealed that Cd-induced apoptotic cell death in various cell lines was perturbed by basal or induced MT and a strong negative correlation exists between cellular MT content and the rate of apoptotic cell death induced by Cd.

991 CADMIUM INDUCES APOPTOSIS IN RAT KIDNEY PROXIMAL TUBULAR CELLS *VIA* THE MITOCHONDRIAL PATHWAY.

S. Ge and Z. A. Shaikh. *Biomedical Sciences, University of Rhode Island, Kingston, RI.*

Chronic cadmium (Cd) exposure causes renal proximal tubular cell damage and mitochondria appear to be the target organelle. The purpose of this study was to determine whether in these cells Cd-induced mitochondrial damage is responsible for apoptotic cell death. Normal rat kidney proximal tubular cells (NRK-52E) were exposed to 20 μM $CdCl_2$ for 5 h, followed by continuous culture in the absence of Cd for up to 12 h. Formation of reactive oxygen species was measured by hydrogen

peroxide accumulation and was found to be maximum 3 h after starting the Cd exposure. Cytochrome c release from the mitochondria to the cytosol peaked between 3 and 5 h. Caspase-3 activity was markedly elevated 12 h after stopping the Cd exposure and was higher in detached cells than in attached cells. Cytochrome c release was depressed upon inhibition of mitochondrial permeability transition with cyclosporin A along with the inhibition of phospholipase As_2 by aristocholic acid. The use of these inhibitors also decreased caspase-3 activity. Furthermore, both cytochrome c release and caspases-3 activity were depressed in cells over expressing Bcl-2. In conclusion, Cd-induced oxidative stress in rat kidney proximal tubular cell mitochondria appears to play a key role in apoptosis since generation of reactive oxygen species is followed by mitochondrial membrane permeability transition, cytochrome c release, and caspases-3 activation.

992 THE NITRIC OXIDE PRODRUG, V-PYRRO/NO, CONFERS RESISTANCE TO ARSENIC- AND CADMIUM-INDUCED CYTOTOXICITY AND APOPTOSIS IN CULTURED RAT LIVER CELLS.

W. Qu[1], R. Fuquay[1], L. K. Keefer[2] and M. P. Waalkes[1]. *[1]LCC, NCI at NIEHS, Research Triangle Park, NC and [2]LCC, NCI at Frederick, Frederick, MD.*

The liver is an important target tissue of both cadmium (Cd) and arsenic (As). The compound O2-vinyl 1-(pyrrolidin-1-yl)diazen-1-ium-1, 2 diolate (V-PYRRO/NO) is a liver-selective nitric oxide (NO) producing prodrug that is metabolized by hepatic P450 enzymes to release NO in hepatocytes. NO can compete for cellular binding sites with metals. Thus, we studied the effects of V-PYRRO/NO pretreatment on Cd (as $CdCl_2$) or As (as $NaAsO_2$) toxicity in cultured rat liver epithelial (TRL 1215) cells. Cells were pretreated with V-PYRRO/NO (at levels up to 1000 µM for up to 24 h) then exposed to Cd or As (for an additional 24 h) and cytotoxicity (by MTS assay) or apoptosis (by DNA fragmentation ELISA) was assessed. Cd was significantly less cytotoxic in V-PYRRO/NO (1000 µM) pretreated cells (LC_{50} = 6.1 ± 0.6 µM) compared to control cells (LC_{50} = 3.5 ± 0.4 µM). Likewise, the LC_{50} for As was 18.1 ± 1.4 µM in control cells and 27.3 ± 2.6 µM in V-PYRRO/NO pretreated cells. TRL 1215 cells acted upon the prodrug to release NO, producing nitrite levels (measured by Griess assay) in the extracellular media after 24 h of exposure to 500 or 1000 µM V-PYRRO/NO measured at 87.0 ± 4.2 and 324 ± 14.8 µM, respectively, compared to control levels of 7.70 ± 0.46 µM. Since both Cd and As are known to induce apoptosis, the effect of V-PYRRO/NO pretreatment on Cd- or As-induced apoptosis was studied. V-PYRRO/NO pretreatment (≥750 µM) markedly reduced apoptotic cell death induced by Cd (5 µM) or As (15 µM). Activation of the c-Jun N-terminal kinase (JNK) pathway can be critical to apoptotic cell death and pretreatment of cells with V-PYRRO/NO suppressed JNK activation after exposure to Cd or As. Thus, the prodrug, V-PYRRO/NO, protects against the adverse effects of Cd or As in rat liver cells in culture, including apoptosis and the concurrent activation of the JNK pathway, apparently through generation of NO. The role of NO in prevention of Cd or As toxicity deserves further study.

993 EFFECTS OF CADMIUM ON E-CADHERIN AND VE-CADHERIN/β-CATENIN MOUSE LUNG.

C. A. Pearson, P. C. Lamar and W. C. Prozialeck. *Pharmacology, Midwestern University, Downers Grove, IL.*

Although it is well established that respiratory exposure to Cd2+ results in pulmonary edema and fibrosis, the specific mechanisms underlying these effects remain unknown. Recently, we have obtained evidence suggesting that Cd2+ produces these effects by interfering with the normal function of the Ca2+-dependent cell adhesion molecules E-cadherin and VE-cadherin. These molecules serve as important structural components of adherens junctions in alveolar epithelial cells and vascular endothelial cells respectively. In addition, the intracellular domains of the cadherins are linked to β-catenin, which under certain circumstances can be released from the junctional complexes and act as a regulator of gene expression. The objective of the present study was to characterize the effects of Cd2+ on the localization of E-cadherin, VE-cadherin and β-catenin in relation to the development of acute pulmonary injury. Male CF-1 mice were given either saline or CdCl2 (65 nmoles) *via* intratracheal administration instillation. After 24 hours, the lungs were subjected to bronchoalveolar lavage or weighed and processed for the immunohistochemical analyses and for the evaluation of cell viability with ethidium homodimer. The results showed that Cd2+ caused an increase in lung weight and in the protein content of the lavage fluid. These effects were accompanied by a pronounced decrease in the amount of E-cadherin in the epithelial cells of the alveoli and small bronchioles and of VE-cadherin in the vascular endothelial cells. In addition, the pattern of β-catenin labeling changed from co-localization with the cadherins at the plasma membrane to diffuse labeling throughout the cytoplasm. Additionally, a thin band of β-catenin labeling was observed at the cell nuclei. Assessment of cell membrane integrity with ethidium homodimer showed no evidence of severe injury or death of the alveolar epithelial or vascular endothelial cells. These findings indicate that the E-cadherin and VE-cadherin/β-catenin complexes may be important early targets of Cd2+ toxicity in the lung. Supported by NIH Grant # r01 ES06478.

994 EFFECTS OF P-GLYCOPROTEIN INHIBITORS ON CADMIUM ACCUMULATION IN CULTURED EPITHELIAL CELLS, OK, LLC-PK_1 AND CACO-2.

O. Kimura, T. Endo and M. Sakata. *Pharmaceutical Science, Health Sciences University of Hokkaido, Ishikari-Tobetsu, Hokkaido, Japan.*

The effect of P-glycoprotein (P-gp) inhibitors on cadmium (Cd) accumulation in cultured epithelial cells, OK, LLC-PK_1 and Caco-2, was investigated. These cells were pre-incubated for 30 min with a typical P-gp inhibitor such as verapamil, diltiazem, nifedipine, vinblastine or cyclosporin A before the incubation with 1 µM $^{109}CdCl_2$ for 15 min. Pre-incubation with each P-gp inhibitor increased Cd accumulation markedly in OK and LLC-PK_1 cells and marginally in Caco-2 cells. Similarly, treatment of these cells with UIC2, a P-gp monoclonal antibody, increased Cd accumulation significantly in OK and LLC-PK_1 cells and marginally in Caco-2 cells. Thus, the pre-treatment of cells with P-gp inhibitor appears to increase Cd accumulation as a result of the inhibition of Cd efflux *via* P-gp. To confirm Cd efflux *via* P-gp, Cd accumulation in P-gp-overexpressed cells (LLC-GA5-COL150 cells) was compared with that in parental LLC-PK_1 cells. LLC-GA5-COL150 cells accumulated less Cd than did LLC-PK_1 cells, and the effects of the P-gp inhibitors and UIC2 on Cd accumulation were profoundly observed in LLC-GA5-COL150 cells. These results suggest that P-gp in OK, LLC-PK_1 and Caco-2 cells appears to act as an efflux pump of Cd, decreasing cellular Cd accumulation.

995 HEAT SHOCK RESPONSE IN THE HUMAN UROTHELIAL CELL LINE, UROtsa, EXPOSED TO CADMIUM AND ARSENITE.

D. A. Sens[1], M. R. Rossi[3], S. Somji[1], S. H. Garrett[1], J. Nath[3] and M. A. Sens[2]. *[1]Urology, West Virginia University, Morgantown, WV, [2]Pathology, West Virginia University, Morgantown, WV and [3]Genetics and Developmental Biology, West Virginia University, Morgantown, WV.*

The heat shock response of specific tissues to acute *versus* chronic exposure to toxic substances has not been addressed in the literature. We therefore wanted to determine if the heat shock response was a transient or persistent phenomena in UROtsa cells acutely and chronically exposed to chemical stress. UROsta cells are immortalized human urothelial cells that exhibit several features unique to normal urothelium. These cells were treated with sodium arsenite or cadmium chloride and mRNA and protein levels were detected by RT-PCR or western blots respectively. Acute exposure to 100 µM sodium arsenite or 53.4 µM cadmium chloride for 4 hours increased the levels of heat shock protein (hsp) 60, 70A, 70B and 70C mRNA and hsp 70 protein. There was no change in the level of hsp 27 mRNA and protein, and hsp 60 protein following acute exposure. Chronic exposure with 1, 5 or 9 µM sodium arsenite for 16 days had little effect on hsp 27, 60, 70A, 70B or 70 C mRNA levels, but hsp 70 protein was consistently present in cells treated with 5 and 9 µM sodium arsenite. Similarly, chronic exposure to various doses of cadmium chloride also demonstrated no obvious induction of hsp 27, 60, 70A or 70B genes. There was an increase in the levels of hsp 70C gene and hsp 70 protein in UROtsa cells chronically exposed to 5 and 9 µM cadmium, but the mRNA and protein levels decreased after 4 days with protein levels undetected after 7 days. These findings suggest that the heat shock response can be both transient and persistent, and that the duration of the response may be dependent upon the chemical treatment.

996 SIX-MONTH DRINKING WATER STUDY TO ESTABLISH A LOEL FOR CADMIUM TOXICITY.

G. Wang, M. H. Whittaker, M. Lipsky, X. Chen and B. A. Fowler. *Epidemiology and Preventive Medicine, The University of Maryland, Baltimore, MD.*

A lowest observed effect level (LOEL) associated with the oral ingestion of cadmium was investigated in a six-month drinking water study in rats. Male Sprague-Dawley rats were administered deionized drinking water containing 10, 25, and 50 ppm cadmium (as cadmium chloride) for durations of 30, 90, and 180 days. Signs of toxicity were evident at each timepoint, as evidenced by increased total urinary protein/24 hours and decreased body weight changes. At all three cadmium concentrations at days 90 and 180, urinary protein levels were greater than that of the control value. Among the three dose groups at days 30 and 180, body weight changes were decreased (65-85%) compared to control. Test animals adapted/compensated to the ingestion of cadmium over time for some parameters, and early increases in blood ALAD levels (156%-172% of control), and early decreases in

hematocrit (83-88% of control), urine production (15%-40% of control), and kidney ALAD (77% of control) were similar to control values within 180 days. Histopathological findings were unremarkable, other than increased inflammatory infiltrate between kidney tubules. This inflammation was observed at all timepoints and increased in severity with cadmium dose. At the 180-day timepoint, inflammation was most pronounced, and was characterized by an interstitial mononuclear cell infiltrate. A LOEL of 10 ppm was assigned and was based on decreases in hematocrit and urine volumes, increased proteinuria, and interstitial inflammation. This LOEL is currently being used in a metal/metalloid mixture study. [Supported by USEPA Star Grant R827161-01-0].

997 ANEMIA IN CHRONIC CADMIUM INTOXICATION IS INDUCED BY THE DESTRUCTION OF ERYTHROPOIETIN-PRODUCING CELLS IN KIDNEYS.

H. Horiguchi[1,2], E. Oguma[1,2] and F. Kayama[1,2]. [1]*Health Science, Jichi Medical School, Minamikawachi-machi, Japan and* [2]*CREST, JST, Kawaguchi, Japan.* Sponsor: T. Yoshida.

Long term exposure to cadmium (Cd) induces renal tubular dysfunction and anemia. The two symptoms are thought to be closely related with each other, because plasma levels of one of the major hematopoietic factors, erythropoietin (Epo), which is produced mainly from the interstitial tissues of kidneys, do not increase in response to the anemia in human patients and animals with chronic Cd intoxication. Thus it is suggested that Cd induces anemia through disturbance of Epo production by targeting Epo-producing cells in the renal interstitial tissues. In order to investigate the local relationship between Cd-target cells and Epo-producing cells in kidneys, we performed *in situ* hybridization using Epo cDNA probe as well as hematoxilin-eosin staining on the renal tissue specimens of rats which were injected with Cd for 8 months. Epo mRNA was expressed in renal tubular cells, but those cells were destroyed and the interstitial tissues were replaced by fibrosis in Cd-intoxicated rats. This result indicates that anemia with hypoproduction of Epo observed in chronic Cd intoxication is induced by the destruction of Epo-producing cells in kidneys, i.e. renal tubular cells.

998 INTESTINAL ABSORPTION OF CADMIUM IS ASSOCIATED WITH DIVALENT METAL TRANSPORTER 1 IN RATS.

J. D. Park[1,2], N. J. Cherrington[1] and C. D. Klaassen[1]. [1]*Pharmacology Toxicology & Therapeutics, University of Kansas Medical Center, Kansas City, KS and* [2]*Chung-Ang University, Seoul, South Korea.*

The intestinal absorption of cadmium (Cd) increases when body iron (Fe) stores are depleted. The depletion of Fe up-regulates the expression of Divalent Metal Transporter 1 (DMT1), which is located in the apical membrane of enterocytes lining the small intestine. DMT1 has been shown to transport Fe and other divalent metal ions *in vitro*. However, it is not known whether DMT1 mediates the intestinal absorption of Cd. To investigate DMT1 involvement in Cd absorption, rats were fed a diet for 4 weeks either deficient in Fe (FeD-diet, 2-6 mg Fe/kg) or supplemented with Fe (FeS-diet, 120 mg Fe/kg), followed by a single oral administration of $^{109}CdCl_2$. Body Fe status, hemoglobin, and tissue Cd concentration were determined 48 hr after Cd administration. Also, DMT1 mRNA levels were quantified in duodenum, kidney, and liver by the branched DNA signal amplification method. Animals fed the FeD-diet exhibited a reduced body weight gain, depletion of body Fe, and Fe deficiency anemia. Tissue Cd concentration was significantly higher in FeD-diet fed rats than in FeS-diet fed rats especially in the duodenum. The amount of Cd retained in the body was 10-fold higher in rats fed the FeD-diet than in FeS-diet fed rats. DMT1 mRNA was highly expressed in duodenum and was 15-fold higher in the FeD-diet group. The levels of DMT1 mRNA were significantly lower in kidney and liver than in duodenum, but were 30 and 40 percent higher, respectively, in rats fed the FeD-diet than in rats fed the FeS-diet. These findings suggest that functional DMT1 protein is likely up-regulated in small intestine at the mRNA level by body iron depletion and increases Cd uptake from the gastrointestinal tract with subsequent transfer of Cd to the circulation and other body tissues. Furthermore, the data from this study may indicate that DMT1 is a non-specific metal transporter, which can transport not only Fe, but probably the toxic metal Cd as well. (Supported by NIH grants ES-01142 and ES-07079)

999 SUBACUTE HEMATOLOGICAL RESPONSES OF THE YUCATAN SAILFIN MOLLY *(POECILIA VELIFERA)* EXPOSED TO CADMIUM CHLORIDE.

S. M. Rusnak[1], J. Fournie[2] and W. R. Hartley[1]. [1]*School of Public Health and Tropical Medicine, Tulane University Health Sciences Center, New Orleans, LA and* [2]*Gulf Ecology Division, NHEERL, USEPA, Gulf Breeze, FL.* Sponsor: C. Miller.

This study focuses on the subacute hematological responses of the Yucatan sailfin molly, *Poecilia velifera*, exposed to cadmium chloride. Previous studies in other teleosts and mammals have suggested that exposure to cadmium chloride results in a leucocytic response. Fish were exposed to nominal concentrations of 9, 5, 0.9, and 0.01 mg/L of cadmium chloride for seven days (n=100) in static exposure chambers. At the end of the exposure period, blood smears from surviving fish were taken *via* dorsal gill incision, fixed in methanol, and stained with Giemsa. Differential and total blood cell counts were determined and used to find the absolute blood cell count. Peripheral blood leucocytes, not previously characterized in this species of fish, were observed and described. Lymphocytes, large and small eosinophils, monocytes, and immature granulocytes were observed. Basophils and neutrophils were not observed in this species. Preliminary findings indicate a significant increase in the total leucocyte count as well as the absolute eosinophil count in fish exposed to cadmium chloride compared to the control group ($n < .02$). The potential use of the Yucatan sailfin molly as an environmental model for adverse hematological/immunological effects is discussed.

1000 ACTIVATION OF AP-1 DNA BINDING DURING MANGANESE TOXICITY IN PC-12 CELLS.

G. T. Ramesh[1], D. Ghosh[1] and P. G. Gunasekar[2]. [1]*Biology, Texas Southern University, Houston, TX and* [2]*Pharmacology & Toxicology, Wright State University, Dayton, OH.*

Occupational and environmental exposure to manganese (Mn2+) is an increasing problem. It manifests neuronal degeneration characterized by dyskinesia resembling Parkinson's disease. The study was performed to test the hypotheses whether exposure to Mn2+ alters cellular physiology through intracellular signaling mechanism associated toxicity in neuronal cell lines. Using rat catecholaminergic rich pheochromocytoma (PC12) cells, various concentrations of Mn2+ (0-100 muM) were exposed and then cell viability was assessed by MTT assay. Exposure of Mn2+ to PC12 cells reduced cell viability in a dose dependant manner compared to the controls. Since transcription factors have been shown to play an essential role in oxidative stress related toxicity, we measured changes in DNA binding activity of activator protein-1 (AP-1) by electrophoretic mobility shift assay (EMSA) following Mn2+ exposure in PC12 cells. Mn2+ (0.1-10 muM) produced eight-fold-activation of AP-1 DNA binding activity. This significant increase was seen within 60 min period after Mn2+ exposure. Besides activating AP-1, Mn2+ also activated N terminal c-jun kinase suggesting that a JNK pathway is involved, which may in turn activate AP-1 *via* c-jun phosphorylation. This study clearly suggests that induction of signaling factor AP-1 during Mn2+ exposure may have a significant cytotoxic effect on neuronal function. This work was supported by RCMI grant RR03045).

1001 MANGANESE OXIDATION STATE AND CELLULAR TOXICITY.

S. H. Reaney[1,2], C. Kwik-Uribe[2] and D. R. Smith[2]. [1]*Chemistry and Biochemistry, UCSC, Santa Cruz, CA and* [2]*Environmental Toxicology, UCSC, Santa Cruz, CA.*

BACKGROUND: Chronic elevated manganese (Mn) exposure has been associated with neurological disorders. The introduction of the anti-knock agent MMT to gasoline has lead to concern about the potential for increased Mn exposures and neurotoxicity. The combustion products of MMT may increase exposure to a mixture of Mn oxidation states (Mn(II), Mn(III) and Mn(IV)), which may possess different relative toxicity's. However, little reliable data exist on the biological handling of Mn(II) *versus* Mn(III) from environmental exposures, or on the relative toxicity of these oxidation states in biological systems. This lack of data is due in part to the challenges associated with evaluating Mn oxidation state *in vivo*. Therefore, the goal of this research was to elucidate the relative toxicity of Mn(II) and Mn(III) in a cell model. Total 8-isoprostanes were measured as a marker of cellular toxicity in a dopaminergic cell line(PC12). Cells were exposed to Mn(II) or Mn(III) *via* culture medium (0 - 250uM). The validity of the Mn(II) and Mn(III) exposures were verified by EPR spectroscopy and ICP-MS. Since addition of the pro-oxidant Mn(III) directly to the cell culture system can damage cells *via* processes that may not be relevant to effects on intra-cellular processes, Mn(II) and Mn(III) were added to medium and incubated prior to exposing the cells. Cells were exposed for 18 hours. Results show that 8-isoprostane levels were significantly (~5-fold) increased following 250uM Mn(III) exposure, relative to controls. Exposures to Mn(II) at these levels did not result in measurable increases in 8-isoprostanes. These results indicate that Mn(III) is more toxic to cells than Mn(II) *via* a mechanism that involves increased oxidative stress and lipid peroxidation.

1002 THE EFFECT OF MANGANESE EXPOSURE ON IRON HOMEOSTASIS IN CULTURED PC-12 CELLS.

C. L. Kwik-Uribe, S. H. Reaney and D. R. Smith. *Environmental Toxicology, University of CA, Santa Cruz, Santa Cruz, CA.*

Manganese (Mn) is a well-known neurotoxicant; however, its mechanism(s) of action remains elusive. We hypothesize that one factor contributing to Mn's neurotoxic effects is Mn-induced disruptions in intracellular iron (Fe) homeostasis as a

consequence of alterations to the post-transcriptional regulation of Fe responsive proteins. To investigate this hypothesis, undifferentiated PC-12 cells were cultured in 5% serum containing RPMI medium supplemented with 1-200 μM Mn as $MnCl_2$ for 24-72 hours. Intracellular Mn concentrations significantly increased over the culture period, reaching concentrations up to 50 times higher than that measured in control cells. This increase in intracellular Mn concentrations was correlated with changes in the intracellular Fe pool. In addition, the protein levels of the Fe-responsive proteins ferritin, transferrin receptor, and DMT-1 were also altered as a result of Mn exposure. The pattern in protein expression changes produced by exposure to Mn was similar to that observed for PC-12 cells cultured in the presence of the Fe-chelator, deferoxamine, our model for cellular Fe deficiency. These data demonstrate that Mn has the ability to disrupt not only the expression of Fe-responsive proteins, but also the intracellular availability of Fe, suggesting that Mn-induced changes in cellular Fe homeostasis may contribute to the neurotoxic effects of Mn.

1003 THE INFLUX OF MANGANESE, MANGANESE CITRATE AND MANGANESE TRANSFERRIN AT THE BLOOD-BRAIN BARRIER IS CARRIER-MEDIATED.

J. S. Crossgrove[1], D. D. Allen[2], B. B. Bukaveckas[1,3], S. S. Rhineheimer[1] and R. A. Yokel[1]. [1]*University of Kentucky, Lexington, KY,* [2]*Texas Tech University Health Sciences Center, Amarillo, TX and* [3]*University of Louisville, Louisville, KY.*

Manganese (Mn) is required for normal brain function, yet at high levels it can cause neurotoxicity. Regulation of entry into and exit from the brain plays a critical role in determining whether Mn is at a safe or toxic concentration. In serum, Mn exists as the hydrated ion, in complexes with small molecular weight ligands and bound to proteins. The speciation of Mn may influence the kinetics of its movement across the blood-brain barrier (BBB). This study examined the brain entry of Mn^{2+}, Mn citrate and Mn transferrin (Tf), which respectively represent the hydrated, complexed and protein-bound fractions of serum Mn. The influx rates of each Mn species were determined in adult male rats using the *in situ* brain perfusion technique. These values were compared to predicted rates of diffusion across the BBB, which were determined from their octanol/aqueous partitioning coefficients and molecular weights. Brain influx transfer coefficients (K_{in} values) were determined in nine brain regions and the lateral ventricular choroid plexus from four or five perfusion durations per Mn species. K_{in} values from the nine brain regions were 5-13, 3-51 and 2-13 x 10^{-5} ml/s/g for Mn^{2+}, Mn citrate and Mn Tf, respectively. The choroid plexus K_{in} values exceeded those for all brain regions by >10 fold for each Mn species. These results suggest carrier-mediated brain influx of Mn^{2+}, Mn citrate and Mn Tf when compared to their predicted diffusion rates (1.5, 1.7 and 2.8 x 10^{-5} ml/s/g, respectively). K_{in} values were independent of a flow rate, determined at 10 and 20 ml/min. ^{55}Mn citrate inhibited ^{54}Mn citrate uptake, and $^{55}Mn^{2+}$ inhibited $^{54}Mn^{2+}$ uptake. The greater influx transfer coefficients for Mn citrate than Mn^{2+} suggest separate influx mechanisms. These results suggest Mn citrate may be a major manganese species entering the brain. Supported by Health Effects Institute, Research Agreement #99-10.

1004 BRAIN REGIONAL INFLUX OF ^{59}Fe: EEFFECT OF *IN VIVO* MANGANESE (Mn) EXPOSURE.

R. Deane[1], B. Kong[2], J. R. Pilsner[2] and W. Zheng[2]. [1]*School of Chemistry & Life Sciences, University of Greenwish, London, United Kingdom and* [2]*School of Public Health, Columbia University, New York, NY.*

Our recent studies indicate that chronic Mn exposure is associated with an increased Fe concentration in the cerebrospinal fluid (CSF), possibly due to the action of Mn on Fe regulatory mechanisms at the blood-brain barrier (BBB) and/or the blood-CSF barrier (BCB). This study was performed to explore the relationship between Mn exposure and the influx of ^{59}Fe to various brain regions. Rat brains were infused with Ringer solution, containing traces of ^{59}Fe with or without transferrin (Tf), for 15 minutes at 37 °C *via* the common carotid arteries. Brain regions, e.g., frontal cortex (FC), striatum (ST), hippocampus (HP), brain stem (BS), cerebellum (CB), and choroid plexus (CP) were then dissected, cerebral vasculature removed by a capillary depletion method, and radioactivity assayed by a gamma counter. In control rats, addition of Tf to the perfusate greatly decreased ^{59}Fe influxes to CSF, FC, CB, and BS, while the influxes to CP, ST, and HP were apparently increased. In the absence of perfusate Tf, Mn exposure significantly augmented the influx of ^{59}Fe to the CP, but not affect the influx to the rest regions examined. In the presence of Tf, however, the influxes of ^{59}Fe to most brain regions were unexpectedly reduced in Mn-exposed animals, except for a 3-fold increase into the CSF compared to the controls. These data suggest that aside from a TfR dependent transport, the CP may possess a non-TfR mediated pathway for Fe influx. Elevated CSF ^{59}Fe following Mn exposure may result from a redistribution of ^{59}Fe from brain parenchyma to the CSF, which may be subsequently removed by the CP. 1005 MANGANESE (Mn) EXPOSURE ALTERS MITOCHONDRIAL MEMBRANE POTENTIAL IN HUMAN DOPAMINERGIC SH-SY5Y CELLS *IN VITRO.*

G. J. Li[1], C. Y. Zhou[2], J. Zhang[1], C. Zhang[2], H. Yang[1], C. L. Zhao[1], P. G. Li[1], Y. F. Deng[1], J. H. Chu[1] and W. Zheng[3]. Mn-induced cytotoxicity has been associated with mitochondrial disorders, including the inhibition of various enzymes in TCA cycle, disruption of electron transfer, and reduction in mitochondrial DNA (mtDNA). Since the electrical potential across the mitochondrial membrane reflects the integrity of mitochondrial function, we set out to test the hypothesis that Mn-initiated mitochondrial toxicity may ultimately lead to the alteration in mitochondrial membrane potential. Human dopaminergic SH-SY5Y cells were exposed to Mn as Mn chloride at the concentrations of 0.5-2 mM for 24 hr. The mitochondrial potential was determined by incubating the culture with Rhodamine 123, a mitochondrial specific dye, followed by Laser scanning confocal microtechnique (LCSM) analyses of fluorescence signal. Results showed that Mn treatment significantly decreased fluorescence signal by 26% as compared to controls, suggesting a diminished mitochondrial membrane potential after Mn treatment. The effects were Mn-concentration dependent and exposure-time related. Further study using flow cytometry revealed that Mn exposure increased the percentage of apoptotic cells to as high as 40% of controls. In addition, we found that Mn(III) appeared to be more cytotoxic than Mn(II) in induction of apoptosis at the concentration of 500 uM. These data confirmed that mitochondria may serve as the primary target for Mn cytotoxicity and that Mn-induced apoptosis may be a direct result of mitochondrial damage. (Support in part by National Natural Science Foundation of China Grant# 3000140 and Beijing Science Committee Grant# 9558102800).

1006 MANGANESE EXPOSURE INCREASES BLINK REFLEX EXCITABILITY IN SPRAGUE-DAWLEY RATS.

E. J. Schicatano[1], I. Kassem[3], C. Evinger[3] and P. M. Dey[2]. [1]*Dept of Psychology, Wilkes University, Wilkes-Barre, PA,* [2]*Neurotox and Experim Neuropath Lab, Dept of Pharmaceut Sci, Wilkes-Barre, PA and* [3]*Dept of Neurobiology, SUNY-Stony Brook, Stony Brook, NY.*

Manganese (Mn) exposure may result in manganism, a neuromotor disorder with symptoms similar to Parkinson's disease (PD) and dystonia. One of the hallmark symptoms of PD is hyperreflexia. In both humans with PD, and in an animal model of PD, the trigeminal blink reflex is hyperexcitable. In alert rodents and humans, electrical stimulation of the supraorbital branch of the trigeminal nerve elicits a blink reflex as measured by orbicularis oculi EMG activity (OOemg). Blink reflex excitability can be measured by comparing the magnitude of reflex blinks evoked by pairs of identical, blink-evoking stimuli with short interstimulus intervals (ISI). This behavioral assay is known as the paired stimulus paradigm (PSP). We investigated the effects of 4 wks of Mn exposure on the trigeminal blink reflex in rats using the PSP. Under general anesthesia, male Sprague-Dawley rats were implanted with electrodes unilaterally for chronic OOemg recording, and a nerve cuff for stimulation of the supraorbital branch of the trigeminal nerve. Within one wk of the surgery, pre-Mn data was collected. Rats then received a 4.8 mg/kg dose of Mn, i.p./3 days a wk for four wks. Control rats received i.p. saline injections. Blink reflex data was collected once/wk throughout these 4 wks. Rats were killed and their brains saved for morphological and biochemical analysis. Within one wk of Mn exposure, Mn-exposed rats demonstrated a two-threefold increase in blink reflex excitability at ISIs from 50-300 ms, compared to pre-Mn responses. These increases were observed throughout the four wk testing period. Correlation of behavioral data with morphological and biochemical changes in basal ganglia was also undertaken. These data indicate that the blink reflex becomes hyperexcitable following Mn exposure. Measurement of blink reflex excitability may be a sensitive tool in the study of Mn neurotoxicity. Supported by Wilkes University. Type 1 and 2 Research Grants.

1007 INFLUENCE OF SUBCHRONIC MANGANESE SULFATE ON BEHAVIOR OF FEMALE RATS.

H. L. Komiskey, M. Zhou, P. Mbawuike and D. Sarpong. *Pharm. Sci., Xavier University of Louisiana, New Orleans, LA.*

The potential of manganese sulfate to produce neurotoxicity following ninety days of daily gavage was studied in female rats. The rats were gavaged with suspensions containing 0.1, 1.0, 10, 30, or 100 mg/kg manganese or the vehicle each day. The functional observational battery, the step-down task, and the sequential, matching-to-sample task were used in an initial screen for neurotoxicity. At the above doses manganese sulfate did not significantly affect the behavioral of the rats in the functional observational battery. The rats gavaged with 100 mg/kg manganese did show

less motor activity during the hour in the figure-8 maze, relative to rats gavaged with the vehicle. The gavaged doses of the trace metal salt did not significantly alter the performance of the rats on the step-down task. On the sequential, matching-to-sample task, rats were trained to retain a specific sequence of events over intervals ranging from 0.25 to 5 seconds. The accuracy of responding by the female rats at 30 mg/kg manganese decreased at longer time intervals. In summary, the ability of manganese at 30 mg/kg to decrease accuracy of responding at longer time intervals indicates that the trace metal at 30 mg/kg is impairing working memory on the sequential, matching-to-sample task. (Support by ATSDR grant U50/ATU398948)

1008 TRIGEMINAL UPTAKE AND CLEARANCE OF INHALED MANGANESE CHLORIDE IN RATS.

J. L. Lewis[1], B. Tinner[1], G. Bench[2], W. Staines[3], E. Barr[4] and K. Divine[4]. *[1]Medicine, University of New Mexico, Albuquerque, NM, [2]CAMS, Lawrence Livermore National Laboratory, Livermore, CA, [3]Cellular and Molecular Medicine, University of Ottawa, Ottawa, ON, Canada and [4]Lovelace Respiratory Research Institute, Albuquerque, NM.*

Previously we have examined uptake and transport of inhaled manganese into the brain *via* the olfactory epithelium. We are now investigating the role of inhalation of environmental manganese in the development of Parkinson's disease. We have expanded our investigation of the transport pathways to include analysis of the trigeminal system. Proton Induced X-ray Emission (PIXE) is used to study the uptake, deposition, and clearance of soluble manganese chloride in the olfactory and trigeminal systems following nose-only inhalation exposures. Seventy Fisher 344 rats were exposed to manganese chloride, (2.2 ± .5 mg/m^3 of Mn, mass median aerodynamic diameter (MMAD) was 3.1 ± 1.4 microns). The OSHA ceiling Threshold Limit Value for Mn is 5 mg/m^3. Exposures were 6 hours/day for 10 days. Groups of rats (10 animals per group for dosed, 6 animals per group for control) were euthanized immediately (0), 7, 14, 30, 90, 180 and 360 days post-exposure. The brain, olfactory bulbs and trigeminal tissues are removed and cryosectioned into 10 micron thick sagittal sections. To date we have completed PIXE analysis of bilateral trigeminal tissues obtained from sacrifices at 0, 7, and 14 days. Mn dosed animals show statistically elevated levels of Mn in the trigeminal tissues at all three time points post exposure compared to vehicle controls. The maximum elevation seen in the 0 day animals decreases over successive time-points by a factor of 2, but has not reached background levels by the 14 day sacrifice. Identification of manganese within the trigeminal system raises the question of this pathway contributing to development of neurodegenerative diseases. This work is supported by NIEHS RO1-ES10766.

1009 RAT STRIATAL D-ASPARTATE UPTAKE IS REDUCED BY EXPOSURE TO MANGANESE.

D. S. Barber and M. N. Morales. *Physiological Sciences, University of Florida, Gainesville, FL.*

Excessive exposure to manganese can cause "manganism", a neurological disorder with extrapyramidal symptoms similar to Parkinson's Disease. The mechanism underlying manganese neurotoxicity is unknown and there is no effective treatment. The targets of manganese toxicity in the basal ganglia receive substantial glutamatergic input. Previous work has demonstrated excitotoxic lesions in the striatum, resulting from excessive stimulation of glutamate receptors, following manganese injection. This led us to hypothesize that manganese produces toxicity by altering glutamate neurotransmission in the basal ganglia. To test this hypothesis, male Sprague-Dawley rats were exposed to 1 or 10 mg of $MnCl_2.4H_20$/ml in drinking water for 60 days. Neurotransmitter uptake was determined in crude striatal synaptosomes prepared incubated at 37°C for 2.5 minutes. Uptake of D-aspartate, a nonmetabolizable glutamate analog, was reduced by 30% in rats exposed to 10 mg $MnCl_2$/ml, but was unchanged in those receiving 1 mg/ml. Dopamine and GABA uptake were not significantly altered by manganese exposure. The mechanism responsible for decreased aspartate uptake is unclear, but reduced cellular energy levels or transporter expression are likely mechanisms. The data suggest that manganese exposure causes neurotoxicity by decreasing excitatory amino acid uptake which may lead to excitotoxicity.

1010 PATHOLOGICAL CHANGES OF CHOROID PLEXUS FOLLOWING EXPOSURE TO LEAD AND CADMIUM IN RABBITS.

Z. F. Xu[1], X. F. Li[1], M. Y. Ma[1] and W. Zheng[2]. *[1]School of Public Health, China Medical University, Shenyang, China and [2]School of Public Health, Columbia University, New York, NY.*

Choroid plexus (CP) has been shown to sequester toxic metals such as lead (Pb) and cadmium (Cd). This study was performed to investigate morphological alterations in the CP following metal exposure. Rabbits received a single ip injection of 5, 25 and 50 mg Pb/kg or iv injection of 1, 2 and 4 mg Cd/kg. CP, cerebral cortex, CSF, and blood were collected at 4 and 24 h after dose administration for various assays and CP tissues fixed for pathological evaluation by light and electron microscopy. Concentrations of Pb and Cd were determined by AAS. Levels of glutathione (GSH) and total sulfhydryl (SH) groups were also assayed. Following exposure to Pb or Cd, the concentrations of both metals were significantly higher in the CP than those in the CSF, blood, and cerebral cortex. Under the light microscope, both metals caused vacuolation and granular degeneration in choroidal epithelia. By TEM, Pb treatment evidently altered morphology of the epithelial layer, characterized by increased numbers of lysosomes and swelling of mitochondria. Cd exposure produced abnormal choroidal convex luminal profiles, such as the loss in microvilli, increased cytoplasmic vacuolation, elevated numbers of lysosomes, dilated rough endoplasmic reticulum, and widened gaps between adjacent cells. While Pb injection increased GSH concentration in the CP, Cd exposure did not affect GSH status in the CP. The concentrations of total SH groups in tissues after Pb exposure were not different from those of controls. However, the total SH level of the CP in Cd-treated group was significantly lower than that of controls. These results suggest that sequestration of Pb or Cd in the CP can alter the morphology of the CP and that binding of toxic metals to GSH or tissue SH groups may underlie metal accumulation in this tissue. (Supported by National Natural Science Foundation of China Grant#39770642)

1011 INTERACTIONS BETWEEN TROPHOBLASTIC LEAD UPTAKE AND CALCIUM TRANSPORT MECHANISMS.

T. J. Evans[1], M. R. James-Kracke[2], S. B. Kleiboeker[1] and S. W. Casteel[1]. *[1]University of Missouri College of Veterinary Medicine, Columbia, MO and [2]University of Missouri Health Sciences Center, Columbia, MO.*

in utero exposure to lead (Pb) is associated with neurobehavioral abnormalities in children and laboratory animals. During pregnancy, mechanisms favoring divalent calcium (Ca^{2+}) uptake by the fetus enhance mobilization of maternal Pb^{2+} stores and maternal intestinal absorption of Pb^{2+}. Previously, a lack of adequate Pb^{2+}-specific measurement techniques has prevented real time assessment of hypothesized interactions between trophoblastic Pb^{2+} uptake and Ca^{2+} transport mechanisms. A novel method, which measures Pb^{2+}-induced indo-1 fluorescence quench (I-1FQ), was adapted for the assessment of Pb^{2+} uptake into undifferentiated and differentiated Rcho-1 trophoblastic cells. A factorial experimental design allowed detection of significant interactions between treatments known to affect cellular uptake of Ca^{2+}. Statistical analyses were performed using ANOVA, and 3 to 5 replicates of each treatment protocol were performed. Pb^{2+} uptake increased with time following the addition of higher concentrations of Pb^{2+} (10 μM *versus* 1 μM) and, to a much lesser degree, with lower Ca^{2+} in solution (100 μM *versus* 1 mM). Activation of capacitative Ca^{2+} entry by 10 μM thapsigargin enhanced Pb^{2+} uptake into Rcho-1 cells, and this mechanism of Pb^{2+} influx was inhibited by 10 μM La^{3+}. Incubation with the midportion of parathyroid hormone-related peptide (PTHrP), an endocrine stimulus for Ca^{2+} uptake by Rcho-1 cells, increased the uptake of Pb^{2+} into undifferentiated Rcho-1 cells. The lower relative rate of I-1FQ in differentiated, as compared to undifferentiated, Rcho-1 cells was unexpected. This observation could be explained by the binding of Pb^{2+} to differentiation-associated Ca^{2+}-binding proteins instead of to indo-1. Uptake of Pb^{2+} by Rcho-1 cells was affected by interactions between differentiation status and other treatments known to impact cellular uptake of Ca^{2+}. The hypothesized facilitation of trophoblastic Pb^{2+} uptake by Ca^{2+} transport mechanisms was supported by these results.

1012 BLOCKAGE OF COPPER RELEASE BY LEAD IN ASTROGLIA *VIA* TARGETING HEAVY METAL BINDING DOMAIN OF ATP7A.

Y. Qian, Y. Zheng and E. Tiffany-Castiglioni. *Veterinary Anatomy and Public Health, Texas A&M University, College Station, TX.*

Lead (Pb) is well known developmental neurotoxicant that may also be a risk factor for neurodegenerative disorders. Astroglia are the major site in brain for Pb accumulation. Astroglia are also the principal loci for other metals, such as copper (Cu) in Menkes disease, which offers a link for understanding some of the neurotoxic mechanisms of Pb. The central hypothesis of our work is that intracellular Pb exerts multiple neurotoxic effects by interfering with Cu transport and buffering mechanisms in astroglia. This hypothesis is based on compelling previous evidence from our laboratory that Cu accumulation in brain and in astroglial cultures is associated with Pb exposure, and that Cu efflux from C6 cells may be blocked by the binding of Pb to ATP7a (Menkes protein), a Cu-ATPase. We partially purified the heavy metal binding region (HMB) of ATP7a that was overexpressed in E. coli and showed that Pb has a stronger binding affinity than Cu for this construct. One molecule of HMB was found to chelate 11 Pb ions or 7 Cu ions, and Pb competitively bound HMB in the presence of Cu. These findings support the conclusion that Pb increases intracellular Cu levels in differentiated astroglia by blocking ex-

port *via* ATP7a. We also demonstrated the induction of several oxidative stress responses (induction of GRP78 and GRP94) in Pb-treated astroglia. The finding that oxidative stress occurred in Pb-exposed astroglia in culture, though Pb has no redox potential, indicates mediation by another ion, such as Cu.

1013 LEAD-INDUCED ALTERATIONS OF DOPAMINERGIC SIGNALING SYSTEMS IN PHEOCHROMOCYTOMA CELLS.

L. M. Gardiner and A. L. Jadhav. *College of Pharmacy, Texas Southern University, Houston, TX.*

Lead-induced alterations of the dopaminergic neurotransmitter system in specific brain regions appear to be closely associated with manifestations of behavioral changes. Moreover, alterations of the rate-limiting enzyme of the dopaminergic biosynthetic pathway, tyrosine hydroxylase (TH), have been associated with low-level lead exposure in various animal and cell models. However, the underlying biochemical and molecular events leading to these changes are obscure. Therefore, the objective of this study was to determine the effect of lead on the dopaminergic signaling system (i.e. Calcium Calmodulin dependent TH phosphorylation and activity) in pheochromocytoma (PC12) cells. PC12 cells are a particularly useful *in vitro* tool for this type of study because they synthesize, store and secrete appreciable amounts of dopamine. The results of this study revealed dose-dependent decreases of dopamine levels at .01, .05, .1, .5 and 1 μM lead exposure, followed by a dose-dependent increase to near control level at 10 μM lead exposure. CaMK II β protein expression exhibited significant increases from the control level at .05 and .5 μM of lead exposure, followed by significant decreases at 1 and 10 μM of lead exposure. There were overall decreases of tyrosine hydroxylase phosphorylation, and tyrosine hydroxylase activity with significant changes occurring at .5, 1, 5 and .05, 1, 5 μM lead exposures respectively. CaMK II activity exhibited biphasic changes with a significant increase at .05 and significant decreases at .5 and 1μM lead exposure. Further, this study revealed that 1μM lead decreased CaMK II β expression and inhibited CaMK II activity. The inhibition of CaMK II activity was associated with attenuated TH phosphorylation and TH activity, which subsequently lead to decreased dopamine levels. Hence, these findings suggest that lead-induced decreases in dopamine levels in PC12 cells may be due to its effects on the CaMK II dependent TH phosphorylation and TH activity. Supported by ATSDR, Cooperative Agreement #U50/ATU 398948 and NIEHS, Cooperative Agreement #ES 07290)

1014 ASSESSING THE ROLE OF THE DORSAL SUBICULUM/NUCLEUS ACCUMBENS PATHWAY IN PB-INDUCED CHANGES IN FIXED INTERVAL (FI) PERFORMANCE.

M. B. Virgolini and D. A. Cory-Slechta. *Environmental Medicine, University of Rochester, Rochester, NY.*

Previous studies from this laboratory have demonstrated that Pb-induced increases in FI response rates are related to dopaminergic/glutamatergic alterations in nucleus accumbens (NAc). NAc integrates dopaminergic input from ventral tegmental area with glutamatergic inputs from hippocampus (Hip) and prefrontal cortex (PFC), areas considered critical in the regulation of cognitive and motivational behaviors. An asymmetrical disconnection procedure was used to better delineate the circuits involved in regulating FI performance. Rats trained on a FI-1 minute schedule of food reward were bilaterally implanted with guide cannulae in NAc core and the dorsal subiculum (DSub) area of Hip. Lidocaine was microinfused unilaterally in NAc core and on the contralateral side of DSub (disconnection), temporary inactivating the circuit, while leaving operative glutamatergic circuits connecting VSub with PFC and PFC with NAc. Lidocaine disconnection decreased FI responses rates, but did not affect post-reinforcement pause time. To test whether preferential AMPAergic activation of the operative DSub to PFC to NAc circuit could reproduce Pb-induced increases in FI response rates, doses of MK 801 (1.0-5.0 mg) or AMPA (0.03-0.3 mg) were infused in the non-lidocaine side of DSub in conjunction with the disconnection. This procedure likewise lowered rather than increased FI response rates. Collectively, these findings suggest that DSub/NAc pathway could play a role in increased FI rates, since rates fall after inactivation of this circuit. But preferential AMPA receptor activation of the DSub to PFC to NAc pathway may not be the operative mechanism, since it did not reproduce increased FI rates. Supported by ES01247, ES05017 and ES05903.

1015 LEAD-INDUCED AGGRESSIVE BEHAVIOR IN ADULT MICE.

L. Y. Calvin, D. Hoover and E. K. Silbergeld. *Toxicology, University of Maryland at Baltimore, Baltimore, MD.*

Lead is a heavy metal hazardous to both children and adults. Lead has no biological benefit to the body and exposure to the body can produce a range of toxic effects, especially in the nervous system. While some epidemiological studies have associated lead exposure with aggressive behavior, there has been little research in animal models. Experimental research on aggression in rodents has utilized mostly qualitative descriptions of the behavior. No method for quantitatively measuring the amount of aggressive behavior has been reported. We have developed a method for quantitative assessment of aggression in mice, and we report on the effects of lead exposure on aggressive behavior. Adult female and male CD-1 mice were treated with 0.25% or 0.5% lead acetate for 3 or 5 weeks. They were paired by gender for behavioral testing with or without isolation. Behaviors were videotaped for 5 minutes and evaluated using a scoring system. The system was validated in studies of isolation-induced behavior and studies of haloperidol as an anti-aggressive agent. Our results revealed quantitative differences in aggressive behavior between male and female mice exposed to lead suggesting involvement of the hormonal system. These results permit future investigations on the mechanism(s)underlying lead-induced aggressive behavior, which may be an important public health impact of lead exposure. Supported by: A Ronald McNair Fellowship to Lynn Calvin as an undergraduate student at Coppin State College

1016 METHYLMERCURY IMPAIRS NEURONAL DIFFERENTIATION BY ALTERING NEUROTROPHIN SIGNALING.

D. K. Parran[1], S. Barone[2] and W. R. Mundy[2]. *[1]Curriculum in Toxicology, UNC-CH/USEPA, Chapel Hill, NC and [2]NHEERL/ORD, USEPA, Research Triangle Park, NC.*

In previous *in vivo* studies, we observed that developmental exposure to CH_3Hg can alter neocortical morphology and neurotrophin signaling. Using primed PC12 cells as a model system for neuronal differentiation, we examined the hypothesis that the developmental effects of CH_3Hg may result from inhibition of neurotrophin signaling through the Trk receptor. Stimulation of PC12 cells with nerve growth factor (NGF) for 24 hr resulted in robust neurite outgrowth, which was inhibited by CH_3Hg in a concentration-dependent manner (EC_{50}=0.03 μM). Whole cell binding assays using ^{125}I-NGF revealed a single binding site with Kd of ~1 nM. Exposure of PC12 cells to CH_3Hg (0.001 - 3 μM) had no effects on NGF binding. Following NGF binding, TrkA receptor autophosphorylation peaked at 2.5 min of NGF stimulation and was sustained up to 60 min. Concurrent exposure to CH_3Hg for 2.5 min resulted in a concentration-dependent decrease in TrkA autophosphorylation, which was significant at 0.1 μM CH_3Hg (~50%). To determine whether inhibition of TrkA activation affected downstream signaling, activation of MAP kinase (ERK1/2) and Protein Kinase C (PKC) were examined. Similar to TrkA, NGF-stimulation resulted in a time-dependent activation of ERK1/2, which peaks at 5 min and was sustained up to 60 min. Concurrent exposure to CH_3Hg for 2.5 min resulted in a concentration-dependent decrease in ERK1/2 activation, which was significant at 0.1 and 0.3 μM (~75%). While CH_3Hg inhibited PKC activity for several recombinant PKC isoforms (δ, ε, ζ) and in PC12 cell homogenates, there was no effect on NGF-stimulated PKC activity in whole cells. To correlate the neurochemical and morphological effects, PC12 cells were exposed to specific inhibitors of TrkA (K252A) and ERK1/2 (U0126) at concentrations selected to produce 50-75% inhibition. Both K252A and U0126 significantly inhibited components of neurite outgrowth. These data suggest that the inhibition of neurite outgrowth by CH_3Hg may be related to a disruption of the NGF signaling through the TrkA receptor.

1017 USE OF P53 GENETICALLY ENGINEERED PC12 CELLS FOR TESTING CHRONIC METHYLMERCURY NEUROTOXICITY.

C. Eskes[1], J. Gartlon[1], S. Stingele[1], D. Sladowski[2] and S. Coecke[1]. *[1]ECVAM, Institute for Health & Consumer Protection,, European Joint Research Center, Ispra (VA), Italy and [2]Department of Transplantology, Warsaw University School of Medicine, Warsaw, Poland.* Sponsor: E. Sabbioni.

Methylmercury is an environmental hazardous substance known to induce neurotoxic effects. Apoptosis is known to be one of the mechanisms by which methylmercury induces neural cell death. The expression of the p53 gene is often described to be implicated in the induction of apoptotic mediated cell death. A novel genetically engineered PC12 cell line was developed at ECVAM (Stingele *et al.*, 1999), which has a controlled expression of the p53 gene according to the media used. The present work was therefore undertaken to test whether p53 expression is implicated in chronic methylmercury toxicity. After application of NGF, to induce cell differentiation and acquisition of neuron-like characteristics, cells were subchronically treated for 10 days with 10^{-9} M to 10^{-6} M of methylmercury. Results were compared to previous experiments carried out on aggregating primary brain cell cultures. The use of this novel genetically engineered PC12 cell line in an integrated testing strategy for evaluating chronic neurotoxicity of xenobiotics is discussed. Stingele S., Coecke S., Nicotera P. & Balls M. (1999) EC Patent filed 27th of

August 1999 on Genetically engineered cell lines, and their uses, in particular for neurotoxicity testing, European Patent Office, Rijwijk, The Netherlands, Patent No. 99402139.2-2106/International No PCT/EP00/08223

1018 STIMULATION OF ARACHIDONIC ACID RELEASE BY METHYLMERCURY IN PRIMARY CULTURES OF ASTROCYTES AND NEURONS.

G. Shanker, L. A. Mutkus, K. H. Tan and M. Aschner. *Physiology and Pharmacology, Wake Forest University School of Medicine, Winston-Salem, NC.*

Cytosolic phospholipase A2 (cPLA2) stimulates the production of arachidonic acid (AA) from the sn-2 position of membrane phospholipids, the former serving as a precursor for the synthesis of prostaglandins. cPLA2 is upregulated in ischemia, epilepsy, and Alzheimer's disease, as well as by the excitotoxic neurotransmitter, glutamate. Glutamate uptake transporter inhibition is a known consequence of AA-mediated reactive oxygen species generation. There has been no systematic study examining the effect of methylmercury (MeHg) on astrocytic cPLA2 activation and AA release, or on the overall significance of this pathway to MeHg-induced neurotoxicity. In the present study, primary cultures of astrocytes and neurons were loaded overnight with [3H]-AA to label phospholipids. The effect of MeHg on the activation of cPLA2 was ascertained by measuring the release of radioactive fatty acid [3H]-AA from astrocytes or neurons over 120 minutes (at 1, 5, 10, 30, 60, 120 min). MeHg (5.0 μM) induced a significant ($p<0.05$) increase in AA release from astrocytes at 10, 30, 60, and 120 min. A significant increase in astrocytic AA release was observed with 2.5 μM MeHg only at the 120 min time point. No increase in neuronal AA release was noted at any time point upon treatment with 2.5 μM MeHg. MeHg (5 μM) induced a significant ($p<0.05$) increase in AA release at 5, 10, 30, 60, and 120 minutes. Consistent with these assays, studies demonstrate increased cPLA2 mRNA expression in astrocytes exposed for 6 hours to MeHg (5.0 and 10.0 μM). These results indicate that MeHg causes a dose- and time-dependent increase in the hydrolysis and release of AA *via* activation of cPLA2, lending credence to the hypothesis that its neurotoxicity is mediated, at least in part, by an excitotoxic mechanism. (Supported by PHS grant NIEHS 07331).

1019 MULTIPLE FACTORS CONTRIBUTE TO THE METHYLMERCURY (MEHG)-INDUCED EARLY STIMULATORY EFFECTS ON SPONTANEOUS SYNAPTIC CURRENTS OF PURKINJE CELLS IN CEREBELLAR SLICES OF RAT.

Y. Yuan and W. D. Atchison. *Pharmacology/Toxicology, Michigan State University, East Lansing, MI.*

Bath application of 20-100 μM methylmercury (MeHg) initially stimulates and then suppresses the frequency of spontaneous excitatory and inhibitory synaptic currents recorded from Purkinje cells in rat cerebellar slices using whole cell patch-clamp recording techniques. To determine whether the early stimulatory effect is the result of MeHg-induced elevation of intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$), which increases release of neurotransmitter, the effect of MeHg on the frequency of spontaneous synaptic currents were first examined in reduced extracellular Ca^{2+} concentration ($[Ca^{2+}]_o$). Reducing $[Ca^{2+}]_o$ from 2 to 0.5 mM did not significantly affect MeHg-induced early increases in the frequency of spontaneous synaptic currents, suggesting that Ca^{2+} influx is not a major contributor to the MeHg-induced early stimulatory effects. It is possible that increased release of Ca^{2+} from the intracellular stores is involved. To test this, ruthenium red (RR), an inhibitor of mitochodrial Ca^{2+} transport, was used to prevent the MeHg-induced release of transmitter. Preincubation of cerebellar slices with 20 μM RR diminished, but did not prevent MeHg-induced stimulatory effects on spontaneous synaptic responses. Preincubation of cerebellar slices with the membrane-permeable Ca^{2+} chelator BAPTA AM (40 μM) also failed to prevent MeHg-induced increases in spontaneous synaptic responses, suggesting that increased $[Ca^{2+}]_i$ is not the only factor contributing to the early stimulatory effects. Pretreatment of cerebellar slices with 40 μM TPEN, which chelates zinc but not MeHg, significantly reduced MeHg-induced increases in the frequency of spontaneous currents with larger amplitudes, but not those with smaller amplitudes, suggesting that the intracellular zinc may also play a role in MeHg-induced early stimulatory effects. Thus, multiple factors may be involved in the early stimulatory effects of MeHg on spontaneous synaptic currents in cerebellar Purkinje cells. Supported by NIH grant ES03299.

1020 METHYLMERCURY-INDUCED BLOCK OF VOLTAGE-GATED CA^{2+} CHANNELS IN ACUTELY ISOLATED CEREBELLAR PURKINJE NEURONS OF RAT.

S. Q. Peng, A. Z. Yao and W. D. Atchison. *Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI.*

Cerebellar granule cells are more susceptible to the toxicity of methylmercury (MeHg) than are Purkinje cells. Voltage-gated Ca^{2+} channels are a prominent target of MeHg. To determine if the presence of a unique type of Ca^{2+} channel, or a differential expression of Ca^{2+} channels, confers upon granule cells and Purkinje cells a differential sensitivity to MeHg, we examined the effects of MeHg on current of voltage-gated Ca^{2+} channels in acutely dissociated Purkinje neurons from 7-11 day-old rats, using whole-cell recording techniques. Ba^{2+} currents in Purkinje cells were blocked 18.9±2.4%, 27.0±3.6% and 56.4±1.7% by nimodipine (1.0 μM), ω-conotoxin-GVIA (1.0 μM) and ω-agatoxin-IVA (50 nM) after 3 min exposure, respectively. Exposure of Purkinje cells to MeHg (0.5-5 μM) reduced peak and end currents in both time- and concentration-dependent manner. At 0.5μM, the effect of MeHg was greater on the sustained current remaining at the end of a test pulse than on the peak current. MeHg accelerated the time course of inactivation of the current. At 1.0 and 5.0 μM, the degree of block by MeHg was approximately the same for both peak and sustained components of current. Whole cell currents were reduced in amplitude by 95% after 3 min exposure to 5.0 μM MeHg. The current-voltage relationship was not altered after 3 min exposure to MeHg. However, the steady-state inactivation relationship was shifted to more negative potentials. Wash with MeHg-free solution did not reverse effects of MeHg. Increasing the stimulation frequency from 0.1 Hz to 0.2 Hz did not accelerate the block of I_{Ba} by MeHg. Comparing these results with previous results from granule cells (Sirois and Atchison, Toxicol Appl Pharmacol, 167: 1-11, 2000), the sensitivity of Purkinje cell Ca^{2+} channels to MeHg was almost the same as that in granule cells. Thus, it is unlikely that the presence of a unique Ca^{2+} channel subtype or differential complement of Ca^{2+} channels renders granule cells more susceptible to neurotoxicity of MeHg. Supported by NIH grant ES03299.

1021 EFFECTS OF METHYLMERCURY EXPOSURE ON EXPRESSION OF EPHS AND EPHRINS IN EMBRYONAL CARCINOMA CELLS.

D. T. Wilson, K. R. Reuhl and R. Zhou. *JGPT and Neurotox Labs and Department Chem. Biol., Rutgers University, Piscataway, NJ.*

Repulsive interactions mediated by EPH receptors and ephrin ligands guide many morphogenetic processes, including the establishment of proper topographical mapping of various pathways within the CNS. Methylmercury (MeHg), a potent environmental neurotoxicant, induces morphological changes in the developing brain indicative of path-finding errors. The effects of MeHg on EPHs and ephrins were examined in P19 embryonal carcinoma (EC) cells and in neurons derived from P19 cells by retinoic acid induction. Undifferentiated EC cells and day 5 neurons were exposed to 0.5μM MeHg in the cell culture media. Following 24-hour exposure, total RNA was isolated from undifferentiated P19s or day 6 neurons and RNAse protection assays were performed. Levels of EPH and ephrin mRNA were evaluated using the RiboQuant RNAse protection assay system with receptor and ligand probe template sets. Undifferentiated EC cells expressed only ephrins-B2 and A5 and this expression was abolished by MeHg treatment. MeHg exposure also decreased expression of ephrins-B2 and A5 in day 6 neurons compared to control, while expression of ephrins-B3, B1, A6, A4, A3, and A1 remained unchanged. EPHs A1 and B3 were the only receptors detected in undifferentiated cells. EPHA1 expression was enhanced in MeHg treated cells while EPHB3 expression was decreased. EPHA1, A2, A3 and A4 expression was decreased in MeHg treated day 6 neurons *versus* control, while the remaining receptors appeared to be unaffected. These data suggest that selective perturbation of repulsive guidance molecules may play a role in the brain dysmorphogenesis caused by MeHg. (Supported by ES-05022 and 07148).

1022 THE EFFECT OF GESTATIONAL MERCURY VAPOR EXPOSURE ON RAT BRAIN α-SYNUCLEIN EXPRESSION.

J. E. Royland. *Neurotoxicology Div., NHEERL, USEPA, Research Triangle Park, SC.* Sponsor: S. Padilla.

Alpha-synuclein is a highly conserved protein that localizes to pre-synaptic terminals and is thought to play a role in neuronal plasticity. It is upregulated developmentally and continues to be expressed at high levels in the adult brain. Its presence in a number of neuronal (AD, PD, dementia with Lewy bodies) and glial (Multiple System Atrophy) pathologies has led to the naming of a class of specific neurodegenerative diseases known as synucleinopathies. Alpha-synuclein has been implicated in a number of possible neurodegenerative mechanisms ranging from oxidative stress to changes in neurotransmitter processing. In addition, the pesticides rotenone, dieldrin and paraquat have been reported to increase the rate of synuclein fibril formation *in vitro*, similar to those found in amyloid plaques of AD and Lewy bodies of PD. These factors make α-synuclein a likely participant in environmentally induced neurotoxicity. It is well accepted that exposure to methyl mercury chloride has critical consequences in the developing brain. Recently concern has been raised that exposure to mercury vapor may be similarly neurotoxic (Fredricksson et al., 1996). Pathological changes such as decreases in cortical layer widths, diminished cell size and number and the induction of gliosis (Barone et al.,

1998) as well as behavioral changes in somatosensory information processing have been reported. A study was designed to examine the consequences of gestational (GD 6-15) mercury vapor exposure (4 kg/m3) on neuroanatomical and neurochemical endpoints. Here we report on the consequences on α-synuclein protein expression 1 and 2 years post-dosing in cortical, striatal and cerebellar regions of the rat brain. Data do not support long-term changes in brain protein levels of α-synuclein after gestational mercury vapor exposure. However, this does not eliminate the possibility of early perturbations in the formation of synaptic connections that might result in long-term pathology. This abstract does not necessarily reflect USEPA policy.

1023 BEHAVIORAL EFFECTS OF EXPOSURE TO HG^{O} FROM DENTAL AMALGAM.

D. Echeverria[1], N. Heyer[1], A. C. Bittner[1], J. S. Woods[1], D. Rohlman[2] and K. Anger[2]. *[1]Center for Public Health Research Evaluation, Battelle, Seattle, WA and [2]CROET, Oregon Health Sciences, Portland, OR.*

Potential neurotoxicity from exposure to mercury vapor (Hg^{o})from dental amalgam fillings is a subject of public health debate. A urinary Hg (HgU) screen of 4, 750 dentists in Washington State yielded 2, 835 samples with a range of 0-59 and mean (sd) of 2.51 (3.01)μg/l HgU. Among 1, 488 eligible dentists, 200 dentists and 200 assistants were enrolled to be representative of Hg exposures in the population (DDS = 3.08 (2.00); DA = 1.96 (1.82) μg/l HgU). A repeated cross-sectional behavioral study was conducted six months apart at a study center. Sessions included an evaluation of symptoms (transient and persistent), mood, cognitive, motor, and peripheral nervous system function in relation to HgU, applying the Behavioral Evaluation for Epidemiology Studies (BEES) touch-screen test battery. Hold tests included Vocabulary, WRAT, and visual acuity. Nitrous oxide (mean ppm =1, 944 (1, 611) was measured in air. Multiple regression models found statistically significant ($p<.05$) effects were most pronounced for mood (Beck' Depression Index and the SCL90 (Beta =.38 and .20 respectively) and symptoms (Beta=.18), followed by motor function (Hand Steadiness (Beta=.19) and Finger Tapping (Beta=.18)). Selective adverse cognitive effects were found for Tracking and Trails A (both Beta =.18), Visual Reproductions and Symbol-digit (both Beta =.13), and Digit Span (Beta=.11). Visual Contrast, Smell, and Nerve Conduction Velocity (1/Lat mV) also achieved significance (all Beta =.14). No effects were found for Trails B, Pattern Recognition and Memory, Reaction Time, Vigilance, and Vibration Sensitivity. Models controlled for age, alcohol, medications, and glasses. Mean dental urinary Hg levels for the USA (~5.0 μg/l), Washington State (~3.0 μg/l), and the general population (~3-9 μg/l) are consistent with levels at which we have first observed significant CNS deficits (1-5 μg/l) justifying characterization of chronic exposure to determine a safe level.

1024 MITOCHONDRIAL MEDIATED APOPTOSIS IN A HUMAN NEUROBLASTOMA CELL LINE (SK-N-SH) BY THIMEROSAL: A PROAPOPTOTIC ROLE FOR NUCLEAR FACTOR KAPPA BINDING PROTEIN (NF κB).

K. K. Kiningham[1], M. P. Cole[1], J. C. Pendergrass[2] and D. K. St. Clair[1]. *[1]Graduate Center for Toxicology, University of Kentucky, Lexington, KY and [2]Affinity Labeling Technologies, Inc., Lexington, KY.*

The objective of this study was to examine the pathway of cell death in SK-N-SH cells by thimerosal, an ethylmercury containing preservative used in pharmaceutical preparations such as vaccines. Inorganic and organic mercurials cause apoptosis in cultured neurons; however, the signaling pathways resulting in programmed cell death have not been reported. SK-N-SH cells were exposed to thimerosal (0-10 μM) for 24 hours and then assayed by DNA fragmentation analysis. Cells treated with 5-10 μM thimerosal exhibited 250-300 bp nucleosomal fragments. To determine if the death pathway was mitochondrial mediated, JC-1 fluorescence, cytochrome c and apoptosis inducing factor (AIF) levels were analyzed. A significant decrease in JC-1 fluorescence was noted within 2 hours of treatment. Cytochrome c and AIF were shown to leak from the mitochondria in a dose dependent manner. Caspase 9 cleavage occured within 4 hours of treatment followed by caspase 3 activation. Within 12 hours poly(ADP)ribose polymerase, a downstream target of caspase 3 was cleaved to form 85 and 64 kDa proteolytic fragments. These results suggest a mitochondrial mediated apoptotic pathway in SK-N-SH cells upon thimerosal exposure. Reactive oxygen species (ROS) which contribute to mitochondrial mediated apoptosis increase upon mercurial exposure. A dose dependent increase in 4-hydroxy-2-nonenal adducted proteins was observed, indicative of ROS formation and lipid peroxidation. Sustained levels of the redox sensitive transcription factor, NF κB, was observed with 10 μM thimerosal. However, manganese superoxide dismutase, a NF κB target gene and antioxidant known to attenuate mitochondrial mediated apoptosis, was not induced suggesting a proapoptotic role for the transcription factor. In summary, this study identifies NF κB as a potential pharmacological target for intervention of thimerosal mediated neurotoxicity.

1025 THIMEROSAL INDUCES MICROTUBULE DEPOLYMERIZATION IN DEVELOPING NEURONS.

R. N. Grisham, S. S. Shah and K. R. Reuhl. *Pharm. and Toxicol., Rutgers University, Piscataway,, NJ.*

Thimerosal has been widely used in vaccines as an antiseptic and preservative. Recently, its use has come under scrutiny due to the potential neurotoxicity of its chief component, ethylmercury, but its exact mechanism of toxic action is unknown. Thimerosal acts as a sulfhydryl binding agent and increases intracellular calcium levels. Since the microtubule (MT) network is highly susceptible to perturbations by –SH agents and/or elevations of cytosolic calcium, disruption of MT-dependent functions may underlie the compound's toxicity. The effects of thimerosal and a known anti-MT agent, methylmercury (MeHg) on MTs of undifferentiated cells and neurons were compared using P19 embryonal carcinoma cells. EC cells differentiate into neurons following induction by retinoic acid (RA). EC cells and developing neurons were exposed to 0-4.5μM thimerosal or MeHg for 2-24 hrs, then fixed or allowed 22 hr recovery in control medium prior to staining with FITC-conjugated anti-α tubulin (clone DM1A) or neuron-specific βIII tubulin. MTs were examined by epifluorescence microscopy. Thimerosal induced robust disassembly of MTs in both undifferentiated cells and developing neurons. In EC cells, loss of MTs occurred at thimerosal concentrations as low as 0.1μM and MTs were completely lost at 1.5μM and above. In developing neurons, 1.5μM disassembled most perikaryal MTs and induced retraction of neuritic processes. At 2.5μM and above, MTs were completely absent and no neurites were observed. Both undifferentiated cells and developing neurons were less sensitive to MeHg-induced MT disassembly, with complete loss of MTs occurring at 2.5 and 3.5μM, respectively. Recovery of MTs in thimerosal-treated cells was incomplete even after 22 hrs and levels above 2.5μM appeared lethal to most cells. In contrast, substantial MT recovery was observed in MeHg cells up to 2.5μM. Data indicate that thimerosal is more toxic than MeHg to MTs in undifferentiated and neuronal cells. Effects on MTs may play a significant role in the toxicity of thimerosal. (Supported by NJ Governor's Council on Autism and ES 05022)

1026 RESPONSE OF EPENDYMAL STEM CELLS TO NEUROTOXIC DAMAGE.

B. C. Weig[1], M. W. McBurney[2], H. E. Lowndes[1] and K. R. Reuhl[1]. *[1]Pharmacology and Toxicology, Rutgers, The State University of New Jersey, Piscataway, NJ and [2]Ottawa Regional Cancer Center, Ottawa, ON, Canada.*

Numerous studies have confirmed the presence of neural stem cells capable of forming neurons within the adult brain. These cells have been isolated from several cortical regions, including hippocampus and the ependymal/subventricular zones. To test the hypothesis that neurotoxic injury may signal proliferation and migration of ependymal stem cell progeny as part of a repair response in the brain, C3H mice were unilaterally injected icv with the lipophilic fluorescent dye DiI and given the hippocampal neurotoxicant trimethyltin (TMT; 2.5 mg/kg, ip). Bromodeoxyuridine (BrdU) was administered daily (ip) to label proliferating cells. Brain sections from mice sacrificed 3, 7, and 14 days post-TMT were examined by fluorescence microscopy. DiI labeling appeared confined to ependymal cells and their progeny. At 7 days post-treatment, DiI-labeled cells were observed migrating from the subventricular zone toward the hippocampus and by day 14 DiI-tagged cells were observed within the inner hilus of the dentate gyrus. The ependymal lining adjacent to migrating DiI-labeled cells often exhibited "pitting" and decreased fluorescence implicating the ependymal layer as their point of origin. NeuN+/BrdU+ cells were visible in the dentate gyrus and subependymal zone 3 days after TMT treatment; however, at this time these cells were DiI-. A marked astroglial response consisting of GFAP+/BrdU- cells was seen in the hippocampus throughout the study. These results suggest two phases of neuronal replenishment occur following neurotoxic injury. The rapid first phase involves cells resident within the dentate while the second, slower phase involves activation and recruitment of cells originating in the ependymal layer. The relative contribution of the two phases to the final repair of damaged neural tissues remains to be determined. (ES-10153, ES-07148, ES-05022)

1027 INHIBITION OF NEURONAL OUTGROWTH IN HIPPOCAMPAL NEURONS IN CULTURE BY TRIMETHYLTIN.

H. A. Garcia[1], S. S. Lundback[1], S. R. Heidemann[2] and W. D. Atchison[1]. *[1]Department of Pharmacology/Toxicology, Michigan State University, East Lansing, MI and [2]Department of Physiology, Michigan State University, East Lansing, MI.*

Trimethyltin, (TMT) is an organotin neurotoxicant, which specifically affects pyramidal neurons in the hippocampus. The exact mechanism of toxicity of TMT is as yet unknown. The objective of this project was to examine the effect of TMT on

neural outgrowth, a developmental process, in hippocampal pyramidal cells in primary culture. Hippocampal neurons go through a highly stereotyped developmental sequence leading to outgrowth of axons. Stage 1 involves generalized motility, Stage 2 involves the outgrowth of short minor processes and Stage 3 involves the outgrowth of a long axon. Hippocampal cells isolated from 18 day old rat embryos were exposed *in vitro* for 24 hrs to 0.125μM, 0.25μM, 0.5μM, 1μM, or 2μM TMT, or TMT-free solutions as a control. TMT was subsequently removed, and photos of developing cells were taken at 24, 48 and 72 hrs after completing treatment. The number of cells in each stage was counted. TMT-free solutions did not compromise the outgrowth of hippocampal neurons at 24, 48 or 72 hours. By 72 hours, ~ 65% of the cells had progressed to Stage 3, and less than 20% remained in Stage 1. In contrast, TMT had a concentration-dependent action to suppress neuronal process outgrowth of hippocampal neurons. At low concentrations (0.125-0.5 μM) TMT moderately slowed the progression of neurons from stage 1 to subsequent stages. By 72 hrs, ~ 25-35% of the cells had progressed to Stage 3. However, at 1 and 2μM TMT, the slowing of growth progression was more prominent, and more long-lasting. Less than 25% of the cells progressed to Stage 3 under these conditions, and 40-50% of the cells remained in Stage 1. Thus acute exposure to TMT can affect the processes of neuronal growth and differentiation in hippocampal neurons in culture. Supported by NIH grant R03-ES10176.

1028 AUTOANTIBODIES TO NERVOUS SYSTEM PROTEINS FOLLOWING TRIMETHYL TIN (TMT) EXPOSURE: A COMPARISON OF ELISA AND WESTERN-BLOT ANALYSIS.

C. D. Clerval[1], B. Vivekanandan[1], A. P. De Feo[1,2], H. A. El-Fawal[1] and J. P. O'Callaghan[3]. [1]*Pharmacology and Toxicology Laboratory, Mercy College, Dobbs Ferry, NY,* [2]*Environmental Medicine, NYU Medical Center, Tuxedo, NY and* [3]*Molecular Neurotoxicology Laboratory, CDC-NIOSH, Morgantown, WV.*

Previous studies in both human and animals have demonstrated the presence of serum autoantibodies to neurotypic [e.g., neurofilament triplet (NF)] and gliotypic proteins [myelin basic protein (MBP) and glial fibrillary acidic protein (GFAP)] following exposure to some heavy metals, solvents, or pesticides. TMT has been used as a denervation tool to validate the enhanced expression of GFAP as a biomarker of astrogliosis resulting from neuronal damage and cell death. In particular, TMT targets hippocampal pyramidal neurons in CA3 and CA1. In the present study TMT was used to assess the detection of the serum polyclonal IgG responses against NFs, measured by ELISA, as a peripheral marker of neurotoxicity. Western-blots, using purified NF proteins, or hippocampal homogenates, were used to confirm ELISA. Male Long-Evans rats (45 days of age) were administered either TMT (8mg/kg; sc; n=16) or an equal volume of sterile 0.9% saline (n=16). At 3 weeks post-administration, serum was collected, and rats were sacrificed for the collection of brains. The polyclonal IgG response to NF68, NF160, and NF200, using ELISA, showed detectable titers of IgG autoantibodies to NFs in sera from TMT-exposed rats, only. Anti-NF68 titers were highest compared to NF160, or NF200. Immunostaining of Western-blots using HRP-conjugated anti-rat IgG confirmed the presence of antibodies, against purified proteins or hippocampal homogenates, in sera of rats exposed to TMT. This corresponded to the molecular weights of NF 68, NF160, and NF200. Immunoblot confirmed the use of the ELISA as a means of detecting the autoantibody response. This study suggests that the detection of autoantibodies to neurotypic proteins, using ELISA, may be used to indicate chemical neurotoxicity. (Supported by NIH HD36965 and USDE P217A990192).

1029 ZINC-INDUCED MODULATION OF CHOLINE TRANSPORT IN CULTURED CHOROID PLEXUS.

K. M. Kransler and A. R. Villalobos. *Environmental Medicine, University of Rochester, Rochester, NY.* Sponsor: M. McCabe, Jr..

Removal of choline from cerebrospinal fluid (CSF) by choroid plexus is a potentially critical regulatory point in central cholinergic homeostasis. Modulation of the transport pathway by chemical stress may alter choline availability in the CNS. We examined the potential effects of zinc on choline removal from CSF in primary cultures of neonatal rat choroid plexus epithelium. Cultures were exposed to 10 μM $ZnCl_2$ in serum-free medium for 1.5 h (37°C). After 0-12 h recovery in Zn-free medium/5% NuSerum ± severe heat shock (SHS, 45°C, 1 h) ventricular uptake of 10 μM 3H-choline ± 750 μM hemicholinium-3 was assayed in artificial CSF (30 min, 37°C). LDH release was assayed to evaluate cytotoxicity. HSP70 accumulation was analyzed by immunoblot and normalized to actin band intensity. To assess cytoskeleton integrity and general cell morphology, actin was probed with TRITC-labeled phalloidin and viewed by fluorescence microscopy. After Zn exposure choline uptake was comparable to that by untreated controls with LDH release increasing 12%. However, uptake was stimulated 15% after 1-h recovery. Stimulation persisted through 12-h recovery, at which time uptake was enhanced 50%. Thermotolerance of transport was also enhanced with recovery. Without Zn/recovery preconditioning, SHS increased LDH release <5% but reduced choline uptake 50%. However, after Zn exposure, SHS reduced uptake by only 25%. In cultures subjected to SHS after 1-6 h recovery, uptake was comparable to that by non-SHS controls. After 12-h recovery, SHS reduced uptake by 20%. Thus complete thermoprotection was transient. Zn exposure also induced HSP70 accumulation, with levels peaking 3-6 h post Zn exposure and declining thereafter. While overall cell morphology was maintained, Zn-exposure induced migration and localization of actin filaments to the cell periphery. These data suggest that zinc may induce latent stimulation and thermoprotection of choroid plexus removal of choline from CSF, possibly correlated with induction of HSP70 and the actin cytoskeletal reorganization. ES10439; NS39452

1030 TRANSPORT OF ZINC IN THE OLFACTORY PATHWAYS OF RATS.

E. Persson, J. Tallkvist, J. Henriksson and H. Tjälve. *Dept of Pharmacology and Toxicology, Swedish University of Agricultural Sciences, Uppsala, Sweden.* Sponsor: A. Oskarsson.

The olfactory route provides a pathway for metals to the brain, thus allowing them to circumvent the blood-brain barrier. In the present study zinc-65 was instilled intranasally in rats and the disposition of the metal in the olfactory system was examined. Autoradiography with tape-sections showed a transport of the metal to the terminals of the primary olfactory neurons in the glomeruli of the olfactory bulbs, followed by a passage across the synapses to the interior of the bulbs. Cell fractionations showed that the zinc in the olfactory epithelium and the olfactory bulbs was present both in the cytosol and in association with various particulate cell constituents. Gel filtrations of the cytosolic fractions on a Superdex 30 column showed that the zinc was eluted in the void volume (MW >10, 000 Da). Intranasal pretreatment of rats with cadmium, to induce metallothionein, did not affect the subcellular distribution of zinc. Our results show that zinc is transported along the olfactory pathway. The data indicate that during this process the metal is bound to both particulate cellular constituents and cytosolic components, the latter having a high molecular weight.

1031 ENVIRONMENTAL RISK FACTORS FOR ALZHEIMER'S DISEASE.

K. J. Ghosal, O. K. Siddiqi and N. H. Zawia. *Biomedical Sciences, URI, Kingston, RI.*

Alzheimer's disease (AD) is a progressive, neurodegenerative disorder, characterized, in part, by the extra-neuronal accumulation of beta-amyloid peptide. This peptide is a cleavage product of the amyloid precursor protein (APP). Aggregation of this peptide is suspected to lead to neuronal damage and cell loss. The factors that result in the aggregation of this peptide are not known, however, it is possible that exposure to environmental agents could promote such aggregation. Previous studies have alluded to the presence of Zn and potentially other metals in the amyloid plaques (Bush et al., JBC, 2000). In an attempt to identify environmental contributors to such a process, we screened a variety of metals and tested their ability to enhance beta-amyloid aggregation. Synthetic Abeta (1-40) peptide was obtained and used in an assay to determine its aggregation in the presence of a series of metals. The assay involved measuring Abeta aggregation by examining the fluorescence spectra that are produced at 482nm only when the aggregated peptide binds to the Thioflavin T probe. Initially the aggregation of the peptide was studied by varying the pH (pH 5-8) of the buffer. Subsequently, various metals were tested for their ability to enhance aggregation beyond that produced by pH alone. The metals studied were Zn, Pb, Mn, Ba. Pb and Mn promoted aggregation at pH 5-6, at a concentration of 10μM, while both Zn and Ba had minimal effects at this concentration. These preliminary results suggest that environmental metals may contribute to amyloidogenesis, however, further *in vivo* and *in vitro* studies are needed to confirm such an outcome.

1032 INHIBITION OF HUMAN SQUALENE MONOOXYGENASE BY SELENIUM COMPOUNDS.

N. Gupta and T. D. Porter. *Graduate Center for Toxicology, University of Kentucky, Lexington, KY.* Sponsor: M. Vore.

Excessive selenium exposure leads to a variety of toxicities in animals and in man. However, the chemical species of selenium and the molecular targets that mediate its toxicity are not well characterized. Methylated metabolites of tellurium, which is located directly below selenium on the Periodic Table, are potent inhibitors of squalene monooxygenase, the second enzyme in the committed pathway for cholesterol biosynthesis, and lead to a peripheral demyelinating neuropathy similar to that seen in selenosis. To evaluate the toxicity of selenium and its methylated metabolites, we

examined the ability of selenite and three methylselenium compounds, methylselenol, dimethylselenide, and trimethylselenonium iodide, to inhibit purified recombinant human squalene monooxygenase. Selenite proved to be the most potent inhibitor of this enzyme, with an IC_{50} value of 37 μM; methylselenol (95 μM) and dimethylselenide (680 μM) were less effective inhibitors, and inhibition by trimethylselenonium iodide was evident only at concentrations above 3 mM. The inhibition by methylselenol and selenite was slow and irreversible, but activity could be protected and restored by the addition of monothiols (glutathione, β-mercaptoethanol), indicating that the selenium compounds were reacting with sulfhydryl groups on the protein. Unexpectedly, the inhibition by selenite was significantly enhanced by dithiols (dimercaptopropanol, dithiothreitol), indicating that a more toxic species, possibly selenide, was formed in the presence of these dithiol reductants. These results raise the possibility that inhibition of squalene monooxygenase by selenite, selenide, and methylselenol may contribute to the neurotoxicity of selenium. Supported by a grant from the American Heart Association.

1033 INCREASED EXPRESSION OF PERIPHERAL BENZODIAZEPINE RECEPTORS IN THE MOUSE BRAIN FOLLOWING CUPRIZONE-INDUCED DEMYELINATION.

M. K. Chen and T. R. Guilarte. *Environmental Health Sciences, Johns Hopkins University, Baltimore, MD.*

The peripheral benzodiazepine receptor (PBR) has been used as a sensitive marker of gliosis and inflammation associated with neurotoxicity. Previous reports have suggested that PBR expression following brain injury is specific to areas expressing activated glial cells. Cuprizone, a copper chelator, has been used as a neurotoxicant to induce brain demyelination in mice. In the present study, we used this model in order to broaden the application of PBR as a biomarker of neurotoxicity, and to validate the relationship between PBR expression and glial cells. Adult male C57BL/6J mice were continuously fed a 0.2% (w/w) cuprizone-mixed powder diet and sacrificed at 2 and 4 weeks of treatment. [3H]-(R)-PK11195 autoradiography was performed to quantitatively measure PBR levels in anatomical regions. Increased expression of PBR was present in most white matter and in some gray matter regions of the cuprizone-exposed brain. Increased PBR levels were a function of the duration of cuprizone treatment. Consistent with previous studies on cuprizone neuropathology, significant ($p<0.05$) increases in PBR levels at 2 weeks of treatment were noted in hippocampus (117%), frontal cortex (114%), temporal cortex (106%), and entorhinal cortex (98%) relative to controls. A greater number of regions and higher levels of PBR binding ($p<0.01$) were measured at 4 weeks of treatment. These included: cerebellar peduncles (2907%), corpus collosum (2370%), intermediate white layer superior colliculus (1090%), globus pallidus (917%), thalamus (825%), cerebellar deep nuclei (475%), striatum (389%), hippocampus (256%), and different areas of the cerebral cortex (226-332%). Present studies are assessing the glial cell type contributing to the increased levels of PBR in this model of demyelination. These studies support the notion that PBR can be a useful marker to visualize and measure neuropathological changes in brain following treatments that result in demyelination. [Supported by grant # ES07062 to TRG]

1034 URANYL ACETATE-INDUCED SENSORIMOTOR DEFICIT AND INCREASED NITRIC OXIDE GENERATION IN THE CENTRAL NERVOUS SYSTEM OF RATS.

W. A. Khan[1], A. M. Dechkovskaia[1], L. B. Goldstein[2], D. U. Shah[1], S. L. Bullman[2] and M. B. Abou-Donia[1]. *[1]Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC and [2]Medicine (Neurology), Duke University Medical Center, Durham, NC.*

In the present studies, we investigated the effects of uranyl acetate as a surrogate for DU on sensorimotor behavior, generation of nitric oxide and the central cholinergic system of rats. Male Sprague-Dawley rats were treated with i.m injection of 0.1, and 1mg/kg uranyl acetate in water, daily for 7 days. The animals were maintained treatment free for an additional observation period of 30 days. On day 30 following the cessation of the treatment, the sensorimotor functions were evaluated using a battery of tests that included measurements of postural reflexes, limb placing, grip time, beam walking and incline plane performance. The levels of nitric oxide as marker for increased oxidative stress, and the integrity of the cholinergic as reflected in acetylcholinesterase activity and m2 muscarinic acetylcholine receptors ligand binding, in brain regions were determined. The data from behavioral observations showed that there was a dose-related deficit in incline plane performance. Both doses significantly reduced grip time. Similarly, both beam walk score and beam walk times were impaired at both doses as compared with the controls. A significant increase in nitric oxide was seen at 0.1 mg/kg dose in cortex and midbrain, whereas brainstem and cerebellum showed a decrease at both the doses. There was a significant increase in acetylcholinesterase activity in the cortex of the animals treated with1 mg/kg uranyl acetate, but not in other brain regions. Ligand binding densities for the m2 muscarinic receptor did not show any change. These results show that low-dose, multiple exposure to uranyl acetate, causes prolonged neurobehavioral deficits after the initial exposure has ceased, and suggest that exposure with uranium/DU to may cause long-term neurological deficits.

1035 MOLECULAR MECHANISMS OF CHEMICAL TERATOGENESIS.

P. G. Wells[1,2]. *[1]Faculty of Pharmacy, Univ. of Toronto, Toronto, ON, Canada and [2]Dept. of Pharmacology, Univ. of Toronto, Toronto, ON, Canada.*

Although over 50 years have passed since the thalidomide tragedy left thousands of infants born with severe malformations, only recently have a variety of biochemical and molecular biological approaches begun to reveal the underlying mechanisms and risk factors for chemical teratogenesis. This symposium provides a timely update of four approaches which, while diverse in technical repertoire and mechanistic thrust, all focus upon teratological mechanisms in the conceptus, providing both corroborating results and novel insights. First are the roles of reactive oxygen species-mediated signal transduction and oxidative macromolecular damage in teratogenesis, and the contributions of embryonic antioxidative enzymes and DNA repair in modulating teratologic risk. The second speaker focuses upon embryonic cellular thiols and redox-regulated developmental processes in sensitive and resistant species. The third approach investigates the teratological significance of alterations in gene expression and signal transduction pathways regulating conceptal cell cycle checkpoint activation, DNA repair and apoptosis. The last speaker focuses on the signaling pathways modulating apoptotic cell death in the developing embryo, and how their perturbation by xenobiotics may lead to teratogenesis.

1036 REACTIVE OXYGEN SPECIES (ROS) AND OXIDATIVE DAMAGE IN TERATOGENESIS.

P. G. Wells[1,2], J. T. Henderson[3], S. Kasapinovic[1], R. R. Laposa[1], T. Parman[1], M. J. Wiley[4] and L. M. Winn[1]. *[1]Faculty of Pharmacy, Univ. of Toronto, Toronto, ON, Canada, [2]Dept. of Pharmacology, Univ. of Toronto, Toronto, ON, Canada, [3]Samuel Lunenfeld Inst., Mt. Sinai Hosp., Toronto, ON, Canada and [4]Dept. of Surgery, Univ. of Toronto, Toronto, ON, Canada.*

Using xenobiotics (phenytoin, thalidomide, BENZO(A)PYRENE (B[a]P)) and gamma irradiation, we examined the teratologic relevance of embryonic bioactivation by prostaglandin H synthases (PHSs), ROS-mediated oxidative macromolecular target damage and signal transduction, and putative DNA repair in mouse, rat and rabbit models. The xenobiotics were bioactivated by purified PHS to free radical intermediates. PHS-2 expression was high in mouse embryos during organogenesis, xenobiotic embryopathy was reduced by PHS inhibitors and in PHS-1 and PHS-2 knockout mice. Xenobiotic bioactivation, DNA/protein oxidation and embryotoxicity occurred in embryo culture. *in vivo* embryonic DNA oxidation was reduced to baseline within 24 hr, indicating active DNA repair. Treatment with antioxidative enzymes increased embryonic antioxidative activity, blocked DNA oxidation and inhibited teratogenicity, as did free radical trapping agents and antioxidants. Thalidomide embryonic DNA damage occurred only in susceptible (rabbit) but not resistant (rodents) species. Hydroxyl radicals were formed *in vivo*, and teratogenicity increased either with mutant mice deficient in the antioxidative enzyme glucose-6-phosphate dehydrogenase, GSH depletion, or inhibition of GSH peroxidase or GSH reductase. Nitric oxide synthases (NOSs) likely contribute to ROS-mediated teratogenesis, since iNOS knockout mice were partially protected. Inhibition of Ras reduced embryotoxicity, implicating ROS-mediated signal transduction. DNA may be a teratologically important target for oxidative lesions, since Atm and p53 knockout mice were more susceptible to teratogenesis, in some cases independent of apoptosis. These studies suggest that embryonic processes regulating the balance of ROS signaling, oxidative DNA damage and repair may be important determinants of teratologic risk. (Support: CIHR)

1037 REDOX-SENSITIVE MISREGULATION OF LIMB OUTGROWTH BY THALIDOMIDE.

C. Harris[1], J. M. Hansen[1], E. W. Carney[3], S. G. Gong[2] and M. A. Philbert[1]. *[1]Toxicology Program, Department of Environmental Health Sci., Univ. of Michigan, Ann Arbor, MI, [2]Dept. of Orthodontics & Pediatric Dentistry, Univ. of Michigan, Ann Arbor, MI and [3]Health & Toxicology Research Laboratory, Dow Chemical Co., Midland, MI.*

The ability of thalidomide to become bioactivated and generate free radicals and/or reactive oxygen species has been shown in several developmental and disease models. Differences in the glutathione (GSH)/redox status and regulation in limb cells

from resistant (rat) and sensitive (rabbit) species suggest that redox regulation may be important in mechanisms of thalidomide-induced limb reduction defects. Exposure of whole animals, tissues and cultured limb cells show that the rabbit limb has lower overall levels of GSH and cysteine and cannot maintain a reducing nuclear redox environment when exposed to thalidomide. Limb outgrowth was regulated by NF-kB, a redox-sensitive transcription factor. No differences exist between sensitive and resistant species in terms of the ability of thalidomide to activate NF-kB in the cytosol and translocate it to the nucleus. The rabbit, however, is unable to maintain a reducing nuclear environment, not allowing NF-kB to bind its promoter and initiate limb outgrowth. Whole mount *in situ* hybridization of rabbit embryos exposed to thalidomide *in utero* with probes directed to fgf-10, twist and fgf-8 show that thalidomide blocks or attenuates the expression of these limb outgrowth genes as a result of the inability of NF-kB to bind its nuclear promoter. NF-kB-mediated gene expression and limb outgrowth is restored by the addition of phenylbutylnitrone, a free radical trap. These processes are not affected in the resistant rat. Our studies show how environmental factors and chemicals can interfere with endogenous gene expression to result in developmental disease and malformation. Selective redox-misregulation of gene expression may be a critical factor in the mechanisms of developmental abnormalities produced by thalidomide and other chemicals capable of eliciting oxidative stress. (Support: OVPR-University. of Michigan)

1038 HOW DOES THE CONCEPTUS RESPOND TO GENOTOXIC STRESS?

B. F. Hales and R. Vinson. *Dept. of Pharmacology & Therapeutics, McGill Univ., Montreal, PQ, Canada.*

Many teratogens, either directly or *via* reactive oxygen species, increase DNA damage in the conceptus. Mammalian cells have evolved complex genotoxic stress responses to detect DNA damage and maintain genomic integrity, including DNA repair, cell cycle arrest, and apoptosis. We hypothesize that the ability of the conceptus to respond to genotoxic stress is a determinant of the outcome of teratogen exposure. Our first goal was to elucidate the expression profile of DNA repair/stress response genes during organogenesis in the rat. Second, we determined the consequences of exposure to a DNA damaging teratogen, 4-hydroperoxycyclophosphamide (4-OOHCPA). Gestational day (GD)10-12 rat conceptuses were analysed with the aRNA technique. Transcripts for 17 nucleotide excision repair (NER) genes, the major mammalian DNA repair pathway, were expressed at low levels on GD10, except for XPD, XPE and PCNA. There were stage dependent increases in XPB expression in yolk sac and in hHR23B, XPB, XPE, ERCC1, and DNA polymerase epsilon expression in the embryo from GD10-12. Whereas 4-OOHCPA induced malformations, it did not affect NER transcript levels. Except for UNG, APNG, PMS1, and RAD54, genes in the base excision repair (BER), mismatch repair (MMR) and recombination repair (RCR) pathways were not detected or expressed at low levels on GD10. Interestingly, UNG transcripts (BER) increased from GD11-12 by over 400%. Unlike the NER genes, 4-OOHCPA down-regulated transcripts for most BER, MMR, and RCR genes in the embryo. The ATM stress-response pathway regulates cell cycle arrest after DNA damage. While in yolk sac ATM expression was constant from GD10-12, in the embryo ATM transcripts increased dramatically (~500% on GD12). 4-OOHCPA decreased ATM expression in the embryo but increased it in yolk sac. Thus, DNA repair and stress response gene expression in the conceptus is regulated in a pathway-, developmental stage- and tissue-specific manner. Understanding how the embryo responds to genotoxic stress will assist in the design of strategies to protect the conceptus from insult. (Support: CIHR & FCAR)

1039 APOPTOTIC SIGNALING PATHWAYS IN TERATOGENESIS.

P. E. Mirkes. *Dept. of Pediatrics, Univ. of Washington, Seattle, WA.*

Between 2 and 3% of all live-born infants have a major developmental defect identified at birth. Although the etiology of these birth defects is often unknown, environmental exposures are known to play a significant role. One of the early events in the pathogenesis leading to birth defects, induced by a wide variety of environmental agents, is cell death. The first part of my talk will describe our research showing that teratogens such as hyperthermia, cyclophosphamide, sodium arsenite, and staurosporine all induce an early episode of cell death in exposed day 9 mouse embryos. This cell death is apoptotic in nature and is characterized by the release of mitochondrial cytochrome c followed by activation of a caspase cascade. Thus, these 4 teratogens induce cell death by activating the intrinsic, mitochondrial apoptotic pathway. Teratogen-induced cell death is also selective, i.e., some cells in the embryo die while the majority of cells do not. For example, we have shown that cells of the developing CNS are particularly sensitive to teratogen-induced cell death whereas cells of the developing heart are completely resistant. The second part of my talk will present more recent data showing that this heart cell resistance is associated with a block in the mitochondrial apoptotic pathway. The final part of my talk will present a number of signaling pathways that have been shown to interact with the apoptotic pathway, such as the mitogen-activated protein kinase pathways, the NF-κB pathway, and the PI3-AKT pathway. (Research supported by grants ES 07026 and ES 08744 from the National Institutes of Environmental Health Sciences.)

1040 OLFACTORY TRANSPORT OF INHALED METALS: AN IMPORTANT ROUTE OF DELIVERY TO THE BRAIN.

D. C. Dorman[1] and J. R. Harkema[2]. *[1]CIIT Centers for Health Research, Research Triangle Park, NC and [2]Department of Food Safety and Toxicology, Michigan State University, East Lansing, MI.*

The olfactory system is unique in that it forms a direct interface between the air and the central nervous system (CNS). There is growing evidence that metals deposited within the nose can be absorbed at this site and then undergo transport along the olfactory nerve. The transport of metals within the olfactory nerve can result in direct delivery of inhaled metals to the brain. In some cases, direct olfactory transport is the dominant pathway by which an inhaled metal reaches the CNS. This symposium will discuss what is known about the neuronal transport of metals in the olfactory pathway and will include a discussion of the likely mechanisms by which transport occurs. This symposium will also cover clinical features of metal-induced nasal toxicity in humans and will discuss inter-species differences in nasal anatomy that may play a role in metal olfactory uptake and transport. One metal of special concern to be discussed in this symposium is manganese, a neurotoxic metal shown to be able to cross synapses in the olfactory bulb and migrate *via* secondary olfactory neurons to distant nuclei of the brain.

1041 COMPARATIVE NASAL STRUCTURE, FUNCTION AND TOXICOLOGY: RELEVANCE TO OLFACTORY TRANSPORT OF METALS.

J. R. Harkema. *Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI.*

In laboratory animals, several metals (e.g., Al, Cd, Mn, Ni, Zn) pass *via* olfactory neurons from the nasal airway lumen to distant sites in the brain. Exposure to metal-containing compounds (e.g., $NiSO_4$, $ZnSO_4$) may also cause marked toxicity of the olfactory mucosa. Differences in the nature and magnitude of metal-induced responses (physiologic or pathologic) of the olfactory mucosa to inhaled metals among mammalian species may be due to species-specific differences in nasal airway structure and function. The purpose of this introductory lecture is to provide a concise review of the similarities and differences in nasal anatomy, physiology, and toxicologic pathology among laboratory animals and humans, emphasizing important comparative aspects of the olfactory mucosa. Rodents are obligate-nose breathers and approximately half of their nasal lumens are lined by olfactory neuroepithelium with direct neuronal connections to the olfactory bulb. In contrast, primates are oronasal breathers with only a small amount of their nasal lumens lined by olfactory epithelium. These species differences along with differences in nasal airflow may translate into differences in intranasal deposition of inhaled metals and subsequent metal transport to the brain and/or olfactory toxicity. In addition, injury, adaptation and repair of the olfactory epithelium may markedly alter metal transport to the brain. Knowledge of comparative nasal structure, function and toxicity is essential for interpreting animal data and estimating the potential risks of nasal or neurological damage in humans exposed to inhaled metals.

1042 METAL TRANSPORT IN THE OLFACTORY SYSTEM.

H. Tjälve. *Pharmacol. & Toxicol., Swedish University of Agricultural Sci., Uppsala, Sweden.* Sponsor: D. Dorman.

We have examined the transport of several metals (manganese, cadmium, nickel, mercury, zinc and cobalt) in the olfactory system of rats and pike. Among these metals manganese has been found to have a unique capacity to be taken up *via* the olfactory pathway. Thus, following transport along the primary olfactory neurons to the olfactory bulbs, manganese continues *via* other neurons to all parts of the brain and even into the spinal cord. Studies with nickel, zinc and cobalt indicate that these metals slowly pass from primary to secondary olfactory neurons. Cadmium and mercury are transported along the primary olfactory neurons but appear unable to continue along secondary olfactory neurons. Studies in pike indicate that cadmium and manganese move along the primary olfactory neurons by fast axonal transport, whereas nickel moves by slow axonal transport. We assume that the metals will adhere to proteins or some other endogeneous neuronal con-

stituent(s) undergoing neuronal transport. Many metals have a strong affinity for SH-groups of proteins, which may render them prone not to leave the primary olfactory neurons, or to do so very slowly. Recent studies indicate that cadmium in rats and pike is transported along the olfactory neurons bound to metallothionein. Unlike many other metals manganese does not possess a high affinity for any endogeneous ligand, such as e.g. SH-groups, and may therefore move relatively easily between different tissue constituents within the olfactory system, as well as in the brain. We consider that the neurotoxicity seen at occupational inhalation of manganese-containing dusts or fumes may be due to an uptake of the metal into the brain *via* the olfactory pathway. We have recently shown that manganese taken up *via* the olfactory pathway in rats will affect astrocytes, indicating that these cells may be the primary targets of manganese in the CNS and that the adverse effects of the metal on neurons are secondary to impaired function of the astrocytes.

1043 OLFACTORY TRANSPORT OF INHALED MANGANESE.

D. C. Dorman. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Research efforts examining the dosimetry of inhaled manganese primarily focus on pulmonary deposition and subsequent hematogenous delivery of the metal to the central nervous system. Growing evidence suggests that nasal deposition and transport along the olfactory nerve represents a direct route by which manganese is delivered to the olfactory bulb and the telencephalon *via* transport in secondary olfactory neurons. Until recently, little was known regarding olfactory transport of manganese following inhalation exposure. We have conducted studies in rats using short-term (90-min) inhalation exposure to radiolabeled manganese aerosols ($54^{Mn}{}_{Cl2}$ or $54^{Mn}HP_{O4}$). These studies used an animal model in which one nostril was occluded thus preventing olfactory transport of manganese to one side of the rat brain. We found that the olfactory route contributes the majority (> 90%) of the 54^{Mn} found in the olfactory pathway of the brain following acute inhalation exposure. However, neither of these inhalation studies clearly demonstrated that olfactory uptake contributes significantly to increased striatal manganese concentrations. Results of 14-day inhalation studies in rats exposed to relatively soluble or insoluble manganese aerosols further demonstrate that manganese concentrations achieved in the olfactory bulb are significantly higher than that observed in either the striatum or cerebellum, lending credence to the direct olfactory transport theory. The relevance of these findings to human manganese inhalation exposure and the risks for neurotoxicity are not known and are complicated by interspecies differences in nasal and brain anatomy and physiology. In the rat, the olfactory bulb accounts for a relatively large portion of the central nervous system, and the nasal olfactory mucosa covers approximately 50% of the total nasal epithelium. These structures are proportionately smaller in humans, suggesting that this route of brain delivery may be less important in humans as compared to the rat. These differences likely predispose the rat, more so than humans, to olfactory deposition and potential olfactory transport of manganese.

1044 NASAL TOXICITY OF METALS IN HUMANS.

F. W. Sunderman, Jr[1]. [1]*Middlebury College, Middlebury, VT and* [2]*University of Vermont, Burlington, VT.*

Occupational exposures of workers to inhalation of certain metal dusts or aerosols can cause diverse forms of nasal toxicity, including loss of olfactory acuity, atrophy of the nasal mucosa, perforated nasal septum, or sinonasal cancer. Anosmia and hyposmia have been reported in workers exposed to Ni- or Cd-containing dusts in alkaline battery factories, nickel refineries, and cadmium industries. Anosmia has also developed in children following experimental nasal spraying with zinc sulfate solution. Ulcers of the nasal mucosa and perforated nasal septum have been reported in workers exposed to Cr(VI) in chromate production and chrome plating, or to As(III) in arsenic smelters. Cancers of the nose and nasal sinuses have been reported in workers exposed to Ni compounds in nickel refineries, cutlery factories, and alkaline battery manufacture, or to Cr(VI) in chromate production and chrome plating. In humans, the olfactory bulb contains an abundance of certain metals (Cd, Mn, Hg) compared to other regions of the brain, which is consistent with experimental evidence in animals that metals can enter the brain *via* the olfactory tract.

1045 INTRODUCTION: THE UNFILLED PROMISE OF BIOMARKERS.

H. Zenick. *National Health and Environmental Effects Research Laboratory, Office of Research and Development, USEPA, Research Triangle Park, NC.*

The 1983 NRC publication formalized human health risk assessment into a four-component process, namely, exposure assessment, hazard identification, dose-response assessment, and risk characterization. Since that report, research has focused on addressing scientific uncertainties within each of these components. Less emphasis has been given to research to strengthen the linkages between these elements to better understand the health risks associated with actual human exposures. The emergence and pursuit of biomarkers offered the promise of being able to measure signals and/or events that reflected more accurately the biology associated with exposure, effects, and susceptibility. However, much of this work remains disconnected rather than integrated. The cost of failing to conduct more integrative research can be illustrated by considering the recent CDC Human Exposure Report. In that report, blood and urine levels for 27 chemicals are presented; yet, save for lead and cotinine, the ability to interpret these values is quite limited (e.g., identify significant pathways and/or potential health risks). However, the report does provide a timely opportunity to reexamine the scientific issues and opportunities accompanying what will become an expanding, annual data base. This session will serve as a catalyst for such dialogue through a series of presentations to define the research needed to validate and translate such biomarker data. Following a review of the current and future scope and design of the CDC program, a case history will be presented that uses blood lead to demonstrate the attributes of a successful biomarker. The potential role of pharmacokinetic modeling to link exposure and effects biomarkers will be considered followed by an examination of the challenges to toxicology and epidemiology to provide the research and insights vital to interpreting biomarker data similar to that being generated by CDC. This abstract has been subjected to Agency for review and approval for publication.

1046 CDC'S BIOMONITORING PROGRAM: THE NATIONAL REPORT ON HUMAN EXPOSURE TO ENVIRONMENTAL CHEMICALS.

E. J. Sampson. *Division of Laboratory Sciences, Centers for Disease Control and Prevention, Atlanta, GA.* Sponsor: H. Zenick.

The Centers for Disease Control and Prevention (CDC) has established a National Report on Human Exposure to Environmental Chemicals that provides biomonitoring data from participants in the National Health and Nutrition Examination Survey (NHANES). In the Report, CDC measured 27 chemicals in blood and urine samples from this ongoing national survey of the United States population. The chemicals included metals (e.g., lead, cadmium, mercury, uranium), cotinine (a metabolite of nicotine), 6 organophospate pesticide metabolites, and 7 phthalate metabolites. Highlights of the Report show that blood lead levels among children have declined since the early 1990's and that there has been a major reduction in exposure of the US population to environmental tobacco smoke. In addition, the Report provides new data on children's and women's exposure to mercury and first time data on exposure in the general population to 24 chemicals. The Report will be updated each year with new data for the general population. For example, next year CDC will combine the 1999 survey data with new data from participants in NHANES 2000 to provide updated national estimates on the 27 chemicals. Plans are to expand the report with additional chemicals each year, eventually exceeding 100 chemicals measured on the population per year. Chemicals under consideration for future Reports include volatile organic compounds, carcinogenic polyaromatic hydrocarbons, dioxins, furans, polychlorinated biphenyls, carbamate pesticides, and organochlorine pesticides. Future additions to the Report will provide more detailed assessments of exposure levels among different population groups defined by sex, race/ethnicity, age, urban/rural residence, education, income and other characteristics.

1047 BLOOD LEAD LEVELS AS BIOMARKERS AND SURVEILLANCE INDICATORS.

E. K. Silbergeld. *Program on Human Health and the Environment, University of Maryland, Baltimore, MD.*

The National Health and Nutrition Examination Survey (NHANES) is a periodically conducted nationally representative surveillance of the US population. Its data on national blood lead levels in the US population have been among the most successful biomarkers for environmental health ever undertaken. In NHANES II (conducted from 1976 to 1980) the first national prevalence data on lead exposures revealed the extent of excess lead exposures and the socio-demographic determinants of environmental racism related to lead. These data were influential in the campaign to remove lead from gasoline, culminating with the 1990 amendments to the Clean Air Act. These data have also stimulated attempts at reducing sources of lead in housing and urban environments. The NHANES III (1991-1994) demonstrated the effectiveness of these policy interventions by showing significant reductions in blood lead levels among all subgroups of the US population (age, gender, ethnicity, income, and residence), but these data also showed the continued disparities in lead risks for US children under 6 years. NHANES data have also been used to generate important hypotheses on lead toxicity. Using NHANES data, studies have associated lead with decreased growth in stature, deficits in hearing, and increased blood

pressure. These data have also suggested a potential role for menopause in increasing blood lead. These blood lead data are powerful for two reasons: (1) the surveillance program is carefully designed for national relevance, and (2) toxicology allows us to draw inferences between the biomarker and health risks. Thus, well understood biomarkers collected in well designed studies can be extraordinarily useful in both research and public policy.

1048 BIOMARKERS AND PHARMACOKINETIC MODELING: THE KEY TO ESTABLISHING THE EXPOSURE-DOSE-EFFECTS LINKAGE.

M. L. Rigas[1], H. A. Barton[2] and M. S. Okino[1]. [1]*National Exposure Research Laboratory, USEPA, Las Vegas, NV and* [2]*NHEERL, USEPA, Research Triangle Park, NC.*

Measures of chemical in tissues, blood, or urine are useful to the extent that they can be related to health effects and because they are an integrated measure of absorbed dose following exposure. However, the direct relationship between biomonitoring data and pathway-specific exposures is more tenuous. Pharmacokinetic (PK)models are mathematical representations of, at minimum, absorption and clearance and can estimate internal dose based on multi-route exposure. The reverse calculation to extract a unique exposure profile based on biomonitoring data is not possible. PK models can provide useful information relating biomonitoring data to exposure using additional data such as those generated by human exposure field studies to aid in these estimates. There are several methods that use PK models and biomarker data to further understand the timing and magnitude of exposures. In one case, we have explored this relationship using the urinary metabolite of the organophosphate insecticide chlorpyrifos collected as part of a pesticide exposure study in children. To set bounds for the modeling, we assumed that the children received some constant low-level background exposure and were subjected to intermittent higher level exposure events as consequence of pesticide application in the home. Using a PK model and a mathematical algorithm to constrain possible exposures based on survey data of pesticide usage by the families, we calculated plausible exposure scenarios that would lead to the urinary biomonitoring results. It is also important to consider how the pharmacokinetic properties (e.g. elimination half life) of a compound are related to the certainty bounds of the exposure estimation from biomarker data. (The USEPA, through its Office of Research and Development, funded this research. The abstract has been subjected to Agency review and approved for publication.)

1049 IMPLICATIONS OF BIOMARKER DATA FOR THE FUTURE OF TOXICOLOGY AND RISK ASSESSMENT.

J. S. Bus. *Toxicology & Environmental Research & Consulting, The Dow Chemical Company, Midland, MI.*

The CDC's Annual Human Exposure Report will provide valuable exposure information impacting the future design and interpretation of toxicology studies, and also assure continued improvements in the integration of this toxicology and human exposure data into risk assessments. Data describing human body burdens of chemicals will be provide pivotal inputs to future dialog surrounding potential expansion and/or alteration of conventional toxicology testing protocols to more reasonably mirror real-world exposures (e.g., implications for use of traditionally-defined MTD's in toxicity hazard testing; design of mixture studies; etc.). However, the Annual Report would be of even greater value to the debate if it were expanded to include analyses of natural products. Such comparative perspectives (synthetic *vs.* natural) could significantly inform future directions of risk assessment, e.g., what represents appropriate Uncertainty Factors in Margin-of-Exposure based risk assessments. The Annual Report also will provide data critical for effective validation and refinement of human exposure models, improving their ability not only to more accurately estimate potential exposures resulting from manufacturing, distribution, and use of chemicals, but also to more effectively measure the efficacy of regulatory and/or product stewardship decisions. Despite the enormous potential of the Annual Report data to augment the future of toxicology and risk assessment, there must be concurrent emphasis that such biomonitoring data does not by itself indicate risk, i.e., it is the dose, not just the presence, that makes the poison.

1050 DRUG-INDUCED VASCULAR DISEASE: MARKERS OF INJURY.

W. D. Kerns[1] and L. W. Schwartz[2]. [1]*Pharma Consulting, Inc., Harvard, MA and* [2]*Safety Assessment, GlaxoSmithKline, King of Prussia, PA.*

Injury to vascular structures is a relatively common hazard identified in preclinical drug toxicity studies. The mechanism of action of novel compounds which cause vascular injury do not always fit accepted dogma that relates cardiovascular damage to marked hypotension and reflex tachycardia. Terminology, relative to classification of vascular lesions by pathologist and clinicians, also presents communication issues since the term vasculitis evokes differing images, mechanisms and consequences to scientists of differing backgrounds. Historically, studies in animals have not predicted the drug-induced vasculopathies observed in humans, nor have the drug-induced vascular lesions recognized in animals been associated with clinical consequences. Collectively, these issues culminate in confusion when attempting to predict potential hazards of new drugs in a clinical setting and emphasize the need for non-invasive markers that can be used preclinically and clinically to monitor for development of drug-induced vascular injury. The lack of markers for vascular injury has caught the attention of toxicologists, pathologists, vascular biologists, regulators and clinicians. This dilemma has prompted significant investigation, with novel approaches, to identify circulating markers predictive of damage to endothelial cells or cells of the vascular wall. Investigations have employed a spectrum of antibody-based, flow cytometric assessments or magnetic resonance spectroscopy-base technologies on various body fluids and tissues as well as traditional plasma-based evaluation of endothelial products. The purpose of this workshop will be to briefly discuss the possible approaches for detection of vascular injury, the terminology to facilitate common understanding and communications and to have in depth discussions of new markers, technical approaches and their promise for future application.

1051 PLASMA MARKERS OF VASCULAR INJURY: NEW TOOLS FOR THE TOXICOLOGIST AND CLINICAL PHARMACOLOGIST.

A. Blann. *City Hospital NHS Trust, Birmingham, United Kingdom.* Sponsor: W. Kerns.

Damage to the endothelium is thought to be important in the initial clinical stages of atherosclerosis and in the onset of several connective tissue diseases. Consequently, we have had the opportunity, in a clinical setting, to correlate changes in certain plasma markers with vascular disease and its progression. Among the plasma markers evaluated, reliable, sensitive, and specific markers of endothelial function in humans include von Willebrand factor, soluble E selectin and soluble thrombomodulin. Each represent different aspects of the physiology and cell biology of the vessel wall, the pathophysiology of the disease process and development of clinical events. Measurement of these markers by ELISA has helped provide essential contributions to our understanding of the development of cardiovascular disease as well as in risk factors (diabetes, hypertension, smoking) and in cancers and the diseases related to rheumatoid arthritis such as systemic sclerosis and systemic lupus erythematosus. For example, increased concentrations of some of these markers predict a poor prognosis such as myocardial infarction and stroke. Notably, von Willebrand factor can also be measured easily in rats, but its value as a possible marker for vascular damage is unknown. Therefore, as the markers have predictive power in helping identify those persons at risk for development or progression of disease, it seems possible that they may prove useful in studying vascular injury in cases of acute (aspirin) and chronic (heavy metals) poisoning. Following a brief review of endothelial cell biology, the predictive nature of various markers will be established from case studies in humans.

1052 USE OF METABONOMIC TECHNOLOGY TO NON-INVASIVELY ASSESS DRUG-INDUCED VASCULAR INJURY.

D. G. Robertson. *Drug Safety Evaluation, Pfizer Global Research & Development, Ann Arbor, MI.*

As a class, the vasculitides encompass a variety of preclinical and clinical conditions and are, in general, empirically defined and poorly understood because of the lack of specificity of associated signs and symptoms, the inaccessibility of target tissues for pathologic examination, and importantly, the absence of efficient non-invasive diagnostic tests. Metabonomics is a recently emerging approach that combines high-resolution nuclear magnetic resonance spectroscopy (NMR) of biofluids with pattern recognition technology to evaluate the metabolic status of an organism. The underlying principle of metabonomics, as with traditional biomarkers of disease, is that homeostatic alterations during disease processes or toxic insult may be reflected directly or indirectly in body fluids, and may ultimately leave biomolecular traces in urine. The advantage of metabonomics lies in its capacity to monitor simultaneously and non-invasively tremendous numbers of trace molecules. Metabonomic evaluation of urine collected from animals given model compounds has demonstrated the utility of this technology to detect changes induced by drugs that cause vascular injury. Appropriate discretion is advised as the technique is sensitive to unrelated pharmacologic and clinical effects that can complicate interpretation of the NMR spectra and the challenge remains to link specific changes with specific types of vascular injury. Nonetheless, the technology has shown significant promise for sensitively and selectively identifying animals with vascular injury by analysis of

urine samples. Apparent thresholds were tentatively identified and the ability to evaluate the complete temporal response has provided unique mechanistic insights into this troublesome lesion.

1053 PHOSPHODIESTERASE TYPE III INHIBITOR-INDUCED VASCULAR INJURY IN RATS: POTENTIAL BIOMARKERS OF VASCULAR DAMAGE.

F. D. Sistare. *Center for Drug Evaluation and Research, USFDA, Laurel, MD.*

A number of pharmacologic agents including dopaminergic agonists, reverse transcriptase inhibitors, phosphodiesterase inhibitors (PDEI's), and endothelin receptor antagonists induce, in a number of animal species, histopathologic evidence of vascular injury, a toxicity that has vexed both pharmaceutical developers and regulators. Consensus approaches are needed to establish the relevance or lack of relevance of such animal findings to humans. Uncertainty in drug development and regulatory decision-making could be reduced if specific signals heralding the earliest onset of events leading to vascular injury could be identified and monitored appropriately. Biomarkers that identify the onset of drug-induced vascular injury have not been established. We have treated several strains of rats with SK&F 95654, a PDEI III, and observed a spectrum of lesions in the mesenteric vascular bed with SHR being highly responsive and WKY fairly resistant. We have applied 2-d gel electrophoresis and SELDI to sera protein samples; screening antibodies, flow cytometry, and microarrays to circulating peripheral blood leukocyte samples; as well as metabonomics to urine samples from these studies, with the goal of identifying some parameter(s) that could serve as accessible biomarker(s). The data indicate that certain changes are consistently associated with drug-induced vascular injury. Defining the full practical utility of such potential biomarkers will require a careful assessment of the strength of their association with alterations in histopathology, including an assessment of drug sensitivity and specificity limitations using additional classes of agents across species.

1054 MECHANISTIC STUDIES OF PHOSPHODIESTERASE INHIBITOR INDUCED VASCULAR DAMAGE AND UTILITY OF CIRCULATING ENDOTHELIAL CELLS AS MARKERS OF VASCULAR INJURY.

H. C. Thomas. *Safety Assessment, GlaxoSmithKline, King of Prussia, PA.* Sponsor: L. Schwartz.

Studies of drug-induced vascular injury in animals have emphasized species differences, and vascular bed sensitivities to injury. Further, there are no widely accepted markers predictive of vascular injury in animals. Phosphodiesterase inhibitors are known to induce vascular injury in rats providing a useful model, but vascular injury is generally only recognized after necropsy and/or histologic examination. Differences in species susceptibility to drug-induced vascular damage has been correlated to differences in species pharmacologic responsiveness *in vitro*. Phosphodiesterase 4 (PDE4) inhibitors induce segmental mesenteric arterial lesions when administered to rats, but not rabbits or monkeys, even though exposure in rabbit and monkey were substantially higher than exposures associated with vascular injury in the rat. Vasorelaxant properties of a PDE4 inhibitor were compared in mesenteric arterial ring preparations from rats, monkeys and rabbits. The EC_{50} for relaxation was 18.0 μM in rats and > 100 μM in monkeys, and did not induce relaxation in rabbits. In addition, regional differences in the distribution of PDE4 isozymes have been explored to explain segmental distribution of mesenteric arterial lesions in rats. The PDE4 isozymes evaluated by confocal laser scanning microscopy were PDE4 A, B, C and D. Distribution differences in various isozymes apparently do not correlate with the segmental distribution of vascular injury. Quantitation of circulating endothelial cells may be a useful biomarker of vascular injury since numbers are known to increase after various physical, infectious and chemical insults to the vasculature. The usefulness of circulating endothelial cells as a potential biomarker for vascular injury in the rat has been evaluated using flow cytometric methodology. Results with selected drug-induced vascular insults will be summarized. In summary, continued investigation holds promise for further defining mechanisms of species and vascular bed sensitivities and to provide markers of vascular injury.

1055 EXAMPLES OF RODENT NONGENOTOXIC MECHANISMS OF NEOPLASIA: ARE THESE RELEVANT TO HUMAN RISK ASSESSMENT?

C. C. Capen[1] and J. C. Cook[2]. [1]*Department of Veterinary Biosciences, The Ohio State University, Columbus, OH and* [2]*Global Research & Development, Pfizer, Groton, CT.*

Numerous compounds (*e.g.*, agricultural products, commodity chemicals, and pharmaceutical agents) have been shown to induce neoplasia *via* nongenotoxic mechanisms when assessed for safety in two-year mouse and/or rat carcinogenicity studies. In many instances, the neoplasia has been attributed to disruption of normal physiology. When this disruption is sustained, a series of well-characterized changes occur in the target organ including hypertrophy, hyperplasia, and eventually neoplasia. The ovary (granulosa cell), pancreas (acinar cell), testis (Leydig cell), thyroid (follicular cell), and stomach (endocrine cell) were selected because sufficient investigative data exist to characterize the mode-of-action for several compounds. In addition, sufficient understanding and experience exist to provide context for their relevance to human risk assessment. Each speaker will describe the physiology of the target organ and provide examples of mode-of-action by which compounds disrupt physiologic function. A primary focus will be discussing the comparative differences of structure and function of these selected target organs between rodents and humans, as well as relating the findings to human endocrine disease states and epidemiology to assess whether these nongenotoxic mechanisms of neoplasia are relevant to human risk assessment.

1056 SECONDARY MECHANISMS IN THYROID CARCINOGENESIS.

R. M. McClain. *Robert Wood Johnson Medical School, UMDNJ, Piscataway, NJ.*

Numerous studies have reported that chronic treatment of rodents with goitrogenic compounds results in the development of tumors derived from thyroid follicular cells. Many goitrogenic xenobiotic chemicals increase the incidence of thyroid tumors in rodents by a direct effect on the thyroid gland to disrupt one of several steps in the biosynthesis, secretion, and metabolism of thyroid hormones. This includes (a) inhibition of the iodine trapping mechanism, (b) blockage of organic binding of iodine and coupling of iodothyronines to form thyroxine (T4) and triiodothyronine (T3), and (c) inhibition of thyroid hormone secretion by an effect on proteolysis of active hormone from the colloid. Another large group of goitrogenic chemicals disrupt thyroid hormone economy by increasing the peripheral metabolism of thyroid hormones through an induction of hepatic microsomal enzymes. This group includes CNS drugs, calcium channel blockers, steroids, retinoids, chlorinated hydrocarbons, polyhalogenated biphenyls, and enzymes inducers. Thyroid hormone economy also can be disrupted by xenobiotics that inhibit the 5'-monodeiodinase that converts T4 in peripheral sites to biologically active T3. Inhibition of this enzyme by iodine-containing compounds such as FD&C Red No. 3 lowers circulating T3 levels, which results in a compensatory increased secretion of thyroid stimulating hormone (TSH), follicular cell hypertrophy and hyperplasia, and an increased incidence of follicular cell tumors in rats. Physiologic perturbations alone, such as the feeding of an iodine-deficient diet, partial thyroidectomy, natural goitrogens in certain foods, and transplantation of TSH-secreting pituitary tumors in rodents also can disrupt thyroid hormone economy and, if sustained, increased the development of thyroid tumors in rats. A consistent finding with all of these goitrogens is the chronic hypersecretion of TSH which places the rodent thyroid gland at greater risk to develop tumors through a secondary (indirect) mechanism of thyroid oncogenesis associated with hormonal imbalances. The human thyroid is much less sensitive to this pathogenetic phenomenon than rodents.

1057 MECHANISMS OF HORMONE-MEDIATED CARCINOGENESIS OF THE OVARY.

C. C. Capen. *Department of Veterinary Biosciences, The Ohio State University, Columbus, OH.* Sponsor: J. Cook.

The objectives of this presentation are to: 1) discuss selected examples of non-genotoxic endocrine mechanisms of ovarian carcinogenesis in rodents, and 2) consider the relevance of rodent ovarian tumor development for human risk assessment. Factors that destroy or greatly diminish the number of ovarian follicles in rodents include senescence, genetic deletion of follicles, X-irradiation, a wide variety of marketed drugs and xenobiotic chemicals, transplantation of ovaries into the spleen, and early thymectomy with the development of autoantibodies to oocytes. All are known to diminish sex steroid hormone secretion by the ovary. Other mechanisms include xenobiotic chemicals that bind to the estrogen receptor in the hypothalamus, (*e.g.* selective estrogen receptor modulators such as Raloxifene), genetic deletion of the estrogen receptor (ER)-α (ER knockout mice), and transgenic mice expressing chimeric luteinizing hormone (LH)-β subunit. The resulting elevated circulating levels of gonadotrophins, especially (LH), due to disruption of negative feedback on the hypothalamus-pituitary axis promotes ovarian tumor development in rodents. For example, the long-term receptor-mediated stimulation of stromal (interstitial) cells by LH and indirectly the ovarian surface epithelium places the mouse ovary at increased risk for developing unique tubular (tubulo-stromal) adenomas. The formation of similar complex ovarian tumors in genetically sterile mice *not* exposed to exogenous chemicals and the prevention of tumor formation by estrogen administration or implantation of normal ovaries supports a secondary (hormonally mediated) mechanism of ovarian oncogenesis. The intense proliferation of ovarian surface epithelium and stromal cells with frequent development of complex

ovarian tumors in rodents as a response to sterility does not have a counterpart in the ovaries of women and is not a useful predictor for the development of ovarian neoplasia.

1058 RODENT LEYDIG CELL TUMORIGENESIS AND THE RELEVANCE TO HUMAN HEALTH.

J. C. Cook. *Global Research & Development, Pfizer, Groton, CT.* Sponsor: J. Cook.

Leydig cells (LCs) are the cells of the testis which have as their primary function the production of testosterone, and are a common target in rodent carcinogenicity bioassays. To date, 7 mechanisms for the chemical induction of Leydig cell tumors (LCTs) have been elucidated. Most of these mechanisms involve, ultimately, elevation in serum luteinizing hormone (LH). In contrast to the rat, LH does not appear to be a primary driver of LCTs in the mouse. In the mouse, estrogen receptor agonists/antagonists are the primary driver of LCTs, due to their direct mitogenic response at the LC. Hence, the induction of LCTs in mice does not appear to be relevant to humans due to the different responses at the hypothalamus, pituitary, and testis. However, pathways for regulation of the hypothalamo-pituitary-testis (HPT) axis of rats and humans are similar, such that compounds which either decrease testosterone or estradiol levels or their recognition will increase LH levels. Although, there are several lines of evidence which suggest that human LCs are quantitatively less sensitive than rats in their proliferative response to LH, and hence, in their sensitivity to chemically-induced LCTs. This evidence includes the following: (1) the human incidence of LCTs is much lower than in rodents; (2) several comparative differences exist between rat and human LCs which may contribute to the greater susceptibility of the rat to both spontaneous and xenobiotic-induced LCTs; (3) endocrine disease states in man underscore the marked comparative differences that exist between rats and man in the responsiveness of their LC's to proliferative stimuli; and, (4) several human epidemiology studies are available on a number of compounds that induce LCTs in rats which demonstrate no association between human exposure. This weight of evidence suggests that nongenotoxic compounds which induce LCTs in rats may have low relevance to humans because humans are quantitatively less sensitive than rats to the mitogenic effects of LH.

1059 NONGENOTOXIC MECHANISMS OF EXOCRINE PANCREATIC CARCINOGENESIS IN RODENTS AND THEIR RELEVANCE TO HUMAN HEALTH.

D. S. Longnecker. *Pathology, Dartmouth Medical School, Lebanon, NH.* Sponsor: J. Cook.

Spontaneously arising neoplasms in the exocrine pancreas of the rat are almost exclusively acinar cell tumors. Most genotoxic carcinogens that affect the pancreas induce acinar cell neoplasms that are histologically similar to spontaneous tumors. Several nongenotoxic dietary additives including trypsin inhibitors and peroxisome proliferators, as well as high fat diets, have increased the incidence of acinar cell neoplasms in the pancreas of rats. Most of these also promote the development of neoplasms in animals pretreated with genotoxic pancreatic carcinogens. It seems likely that the nongenotoxic dietary additives are promoting the growth of spontaneously-initiated clones of acinar cells which are manifest as focal hyperplasia in "control" rats. The mechanism of the promoting effect of high fat diets is not known, however promotion by trypsin inhibitors and cholestatic agents has been linked to an increase of cholecystokinin (CCK) secretion. CCK serves as a mediator of enyzyme secretion and as a trophic factor for the pancreas in rats. Injection of exogeneous CCK stimulates pancreatic growth (hyperplasia) and promotes carcinogenesis in carcinogen-treated animals. The feedback loop that stimulates excess CCK has been delineated and linked to intraluminal inhibition of trypsin activity or diminished bile secretion. In humans fewer than 1 per cent of pancreatic carcinomas are of acinar cell type and about 90 per cent have a ductal phenotype. Exocrine secretion is largely under neural control in humans, and it is uncertain that CCK is trophic for human pancreas. Some data suggest that human acinar cells express few receptors for CCK. These species differences raise a question as to the relevance of CCK-mediated promotion mechanisms in the human. Furthermore, there is no epidemiologic evidence linking ingestion of trypsin inhibitors to increased risk of pancreatic carcinoma.

1060 GASTRIC ENTEROCHROMAFFIN CELL-LIKE (ECL) CARCINOIDS IN RODENTS AND THEIR RELEVANCE TO HUMAN DISEASE.

I. Modlin, M. Kidd, K. Lye and T. Hinoue. *Surgery, Yale University School of Medicine, New Haven, CT.* Sponsor: J. Cook.

Clinically, gastric carcinoids develop as a component of atrophic gastritis or as part of the multiple neuroendocrine neoplasia (MEN)-1 syndrome (both types due to hypergastrinemia) or as sporadic lesions. Agents that cause hypergastrinemia and stimulate ECL cell proliferation have been investigated in a number of conventional models (rat, mouse) as well as the Mastomys and Japanese cotton rat. Pharmacological doses (100 x human levels) of H2 receptor antagonists or proton pump inhibitors result in ECL cell hyperplasia (8-10 wks) and eventually neoplasia (>2yrs) in rats, mice and cotton rats. A number of agents commonly found in the human diet (methyl eugenol), used as anti-lipidemic drugs (ciprofibrate) or in crop preservation (butachlor) are all tumorigenic and cause ECL cell carcinoids in rodents; effects due to gastric mucosal damage and hypergastrinemia. In contrast, in the Mastomys, the standard therapeutic doses of an acid suppressive agent result in ECL cell hyperplasia (6-8 wks) with tumor formation by 4 months. Tumor development in this rodent and in man share a number of common traits. Carcinoids may spontaneously develop over the life-time of both species. These tumors are somatostatin receptor type 2 (SSTR2) positive. Somatostatin (octreotide) therapy prior to acid perturbation inhibits tumor formation in this animal, while *in vitro* studies demonstrate that this may affect both ECL cell secretion as well as negatively regulate proliferation. Human and Mastomys tumors also share alterations in growth factors (TGF-alpha), in p53 (overexpressed) and in the menin gene (somatic mutations). One difference is in the ECL cell growth response to acid suppression; a doubling of ECL cell numbers is seen in humans, while neoplasia is most often seen in Mastomys. The underlying genomic alteration (s) is unknown. The substantial overlap in tumor pathophysiology between the Mastomys and the human suggest that this rodent may specifically be an important model for investigating nongenotoxic gastric carcinoid formation.

1061 AH RECEPTOR ACTIVATION REQUIRES INDUCTION OF MAP KINASE PATHWAYS BY TCDD.

Z. Tan, X. Chang, A. Puga and Y. Xia. *Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.*

TCDD is a widespread environmental contaminant that causes adverse toxic effects in animals and humans. Toxicity is mediated by activation of the cytosolic aryl hydrocarbon receptor (AHR), a ligand-activated transcription factor essential for TCDD-induced expression of several phase I and phase II drug metabolizing enzymes. TCDD also activates signal transduction pathways, but the molecular mechanisms by which these pathways may contribute to AHR activation and TCDD toxicity have yet to be defined. Here we report that TCDD induces in mouse hepatoma Hepa-1 cells the immediate activation of extracellular signal-regulated kinases (ERKs) and Jun N-terminal kinases (JNKs), two subgroups of the mitogen-activated protein kinase (MAPK) family involved in modulation of transcription factor activity and regulation of gene expression. Our results show that MAPK activation by TCDD is not mediated by the AHR, since it takes place in CV-1 cells and in *Ahr(-/-)* mouse embryonic fibroblasts, both of which lack AHR expression. Unlike treatment with serum factors or tumor promoters, TCDD-stimulated MAPK activities did not result in the transcriptional activation of ELK and c-JUN but was critical for the induction of AHR dependent gene transcription. Chemical compounds that inhibit ERK and JNK/p38 pathways and dominant-negative effectors of the ERK pathway suppressed induction by TCDD of AHR-dependent reporter gene expression. In addition, TCDD-induced CYP1A1 expression was also partially suppressed by inhibitors of the ERK or the JNK pathways. Inhibition of CYP1A1 induction was maximal when both pathways were blocked, suggesting that the ERK and the JNK pathway each make unique contributions to AHR activation. These results indicate that induction by AHR ligands of MAPK pathways is an important element in AHR activation of gene expression. *(Supported by NIH 2R01-ES6273 and 1R01-ES10807).*

1062 BRG-1 IS REQUIRED FOR CYTOCHROME P4501A1 TRANSCRIPTION MEDIATED BY THE ARYL HYDROCARBON RECEPTOR COMPLEX.

S. Wang and Q. Hankinson. *Pathology, UCLA, Los Angeles, CA.*

Chromatin remodeling is a key step in overcoming the nucleosomal repression of active transcription in eukaryotes. The mammalian SWI/SNF ATP-dependent chromatin-remodeling complexes contain multiple subunits. The major ATPase activities in these complexes are attributable to either BRG-1 or the related brahma(Brm) protein. The aryl hydrocarbon receptor (AHR), after binding xenobiotic ligands such as 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD), associates with the AHR nuclear translocator(ARNT), and the dimer activates transcription of several genes, including cytochrome P4501A1(CYP1A1). We show that introduction of BRG-1 into the BRG-1 and hBrm deficient SW13 and C33A human cell lines enhances expression from a transiently transfected AHR/ARNT- dependent reporter gene. We also demonstrate that replenishment of BRG-1 to SW13 cells restores endogenous cytochrome P4501A1 (CYP1A1) expression, whereas an ATPase deficient mutant of BRG-1 is unable to do so. Using CHIP (Chromatin Immunoprecipation), we demonstrate that BRG-1 associates with the enhancer region of the mouse CYP1A1 gene *in vivo* in a TCDD- and ARNT-dependent fashion, suggesting the specific recruitment of BRG1 by AHR/ARNT. Finally we demonstrate that the transcriptional activation domain of AHR interacts with

BRG-1. Together our studies reveal an essential involvement of BRG-1 in activating CYP1A1 gene transcription and implicate the importance of ATP-dependent chromatin remodeling activity in inducible gene expression mediated by AHR/ARNT.

1063 IDENTIFICATION OF HSP90 CHAPERONE COMPONENTS THAT REGULATE ARYL HYDROCARBON (DIOXIN) RECEPTOR SIGNALING.

C. A. Miller and M. B. Cox. *Environmental Health Sciences, Tulane University Health Sciences Center, New Orleans, LA.*

The chaperones are a family of highly conserved proteins that play numerous roles in cells. Among these roles, Hsp90 proteins and their co-factors are proposed to regulate the conformation and function of nuclear hormone receptors. Aryl hydrocarbon receptor is a transcription factor that is activated by xenobiotic ligands such as TCDD and requires interactions with Hsp90 proteins for proper function. We constructed a yeast model system that used transcriptional activation by the human aryl hydrocarbon receptor-Arnt protein complex as an endpoint to genetically assess which chaperones and co-chaperones regulate this signaling pathway. Most Hsp90 chaperones and co-chaperones are structurally and functionally conserved between yeast and humans, thus making this a relevant model system for these studies. Genetic evidence from strains lacking particular chaperone and co-chaperone genes indicates that the proteins Hsc82 (a homolog of human Hsp90), Sba1 (a homolog of human p23), and the tetratricopeptide repeat (TPR)-containing proteins Cpr7 and Cns1 have roles in the aryl hydrocarbon receptor signaling pathway. The absence of other Hsp90 and co-chaperone proteins (Hsp82, Cpr6, Ppt1) had no affect in this assay. Thus, specific chaperone and co-chaperone proteins participate in the aryl hydrocarbon receptor signaling pathway. We propose that the cellular levels and interactions of chaperones and co-chaperones may determine the response to TCDD and other compounds that act through the aryl hydrocarbon receptor. Our results suggest that interference with chaperone-aryl hydrocarbon receptor interactions might be used to mitigate the toxicity of TCDD and other compounds that act through the aryl hydrocarbon receptor pathway.

1064 IDENTIFICATION OF DOMAINS REQUIRED FOR ARYL HYDROCARBON RECEPTOR INTERACTION WITH THE RETINOBLASTOMA PROTEIN AND FOR REPRESSION OF E2F-DEPENDENT TRANSCRIPTION.

J. L. Marlowe, J. K. Kerzee, E. S. Knudsen and A. Puga. *Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.*

TCDD is a tumor promoter and carcinogen in rodents, and epidemiological evidence suggests that it causes certain cancers and cardiovascular disease in humans. Most effects of TCDD result from activation of the cytosolic aryl hydrocarbon receptor (AHR) to a transactivator of Phase I and II drug-metabolizing enzymes. AHR also binds the retinoblastoma protein (RB) and potentiates the RB-mediated active repression of E2F functions required for cell cycle progression. We used pull-down assays to identify AHR domains necessary for interaction with RB. Using AHR deletion mutants, we found that maximal binding of AHR to RB requires two AHR domains, the LXCXE cyclin D1-like motif in the B repeat, and a 100-amino acid region in the glutamine-rich transactivation domain. Pull-down assays with RB deletion mutants showed that full length AHR interacts with the large A/B pocket of RB, the region of interaction for all known LXCXE-binding proteins. In gel shift assays, truncated AHR proteins containing either domain displaced RB from an E2F-RB DNA-binding complex and shifted the mobility of E2F-DP1 complexes, suggesting that AHR may establish interactions with E2F that are independent of RB. We used AHR truncation mutants in transient transfection assays to determine the role of the various AHR domains in AHR-mediated repression of E2F-dependent transcription. These experiments confirmed that the LHCAE domain of AHR is required for this effect and showed that mutants lacking AHR transcriptional activity could still repress RB functions. Transfections in ARNT-negative C4 cells suggest that ARNT is not required for AHR-RB interaction *in vitro*, but is necessary for maximal repression of E2F-dependent transcription. These results suggest that AHR-dependent transcription is not involved in repression of E2F-mediated gene expression and that the AHR may exert a direct effect on E2F function independently of the formation of complexes with RB. *(Supported by NIH 2R01-ES06273)*

1065 ERK ACTIVATION BY GROWTH FACTORS OR EXPRESSION VECTORS RESTORES TCDD-SENSITIVITY IN UNRENEWED-SERUM ADIPOCYTE DIFFERENTIATION OF C3H10T1/2 CELLS.

P. R. Hanlon and C. J. Jefcoate. *Environmental Toxicology, University of Wisconsin, Madison, WI.*

C3H10T1/2 mouse embryo fibroblast cells differentiate into adipocytes when treated with insulin, dexamethasone, methylisobutylxanthine and the PPARγ ligand BRL49653 (IDM/BRL). In the presence of fresh fetal bovine serum (FBS), PPARγ expression and adipocyte differentiation are inhibited by 2, 3, 7, 8-tetrachloro-*p*-dioxin (TCDD). However, with unrenewed FBS adipocyte differentiation is TCDD-insensitive. Addition of Epidermal Growth Factor (EGF) had no affect on PPARγ expression or adipocyte differentiation in the absence of TCDD. However, in the presence of TCDD, EGF restored inhibition of adipocyte differentiation in a dose-dependent manner. On the other hand, Fibroblastic Growth Factor and Platelet Derived Growth Factor partially inhibited PPARγ expression and adipocyte differentiation in the absence of TCDD, and also restored TCDD-sensitivity in a dose-dependent manner. Addition of specific pharmacological inhibitors of growth factor receptors during serum stimulation showed that no single growth factor within FBS was responsible for TCDD-sensitivity. Pharmacological inhibitors of ERK activation show that the TCDD-mediated inhibition of adipocyte differentiation is dependent on ERK activation in a narrow time window. Addition of a MEK1 dominant positive vector to cells in unrenewed FBS also restored TCDD-sensitivity to the process of adipocyte differentiation. These data establish that factors from an ERK-activated pathway and a TCDD-activated pathway work synergistically to inhibit PPARγ expression and adipocyte differentiation.

1066 DISRUPTION OF NEPHROGENESIS BY BENZO(A)PYRENE, AN ARYL HYDROCARBON RECEPTOR LIGAND, INVOLVES INTERFERENCE WITH ALTERNATIVE SPLICING AND POST-TRANSCRIPTIONAL REGULATION OF THE WILMS' TUMOR SUPPRESSOR-1 GENE.

M. Falahatpisheh and K. S. Ramos. *Center for Environmental and Rural Health, Texas A&M University, College Station, TX.*

The aryl hydrocarbon receptor (Ahr) is a member of the large basic helix-loop-helix and PAS homology domain family of transcription factors. Members of this family are involved in the regulation of neurogenesis and myoblast differentiation. Unregulated activation of Ahr signaling is associated with hydronephrosis, but the mechanisms responsible for this response are unknown. The present studies were conducted to evaluate the influence of benzo(a)pyrene (BaP) on murine nephrogenesis *in vitro*. Embryonic kidneys were dissected from E11.5 mouse embryos and placed in humid culture chambers. Decreases rates of glomerulogenesis and deficits of cellular differentiation were observed in cultures challenged with 3 mM BaP for 4 days. BaP interfered with podocyte differentiation and formation of glomerular basement membranes. Ahr and Wilms' tumor suppressor (WT1) mRNAs were detected by *in situ* hybridization and reverse transcription polymerase chain reaction (RT-PCR) in differentiated, as well as BaP-treated metanephric cultures. Using specific primes for WT1 (±) KTS splice variants it was found that BaP induces the appearance of the (-) KTS splice variant, although total WT1 mRNA levels were unchanged by BaP treatment. Immunolocalization experiments showed a significant decrease in WT1 protein immunoreactivity in cultures challenged with BaP compared to control counterparts. Western analysis confirmed this finding and identified a unique WT1 isoform in metanephric cultures treated with BaP. Comparison of metanephric cultures from Ahr +/+ and Ahr -/- mice showed that Ahr is required for kidney development, as well as BaP-induced deficits in nephrogenesis. Collectively, these results indicate that activation of AhR signaling by BaP disrupts nephrogenesis *in vitro* by modulation of alternative splicing and post-transcriptional regulation of the WT1 gene. (This work was supported in part by NIH grants ES 04917 and ES 09106).

1067 AHR REPRESSOR: A THIRD MEMBER OF THE VERTEBRATE ARYL HYDROCARBON RECEPTOR (AHR) FAMILY.

S. I. Karchner[1], W. H. Powell[1,2], D. G. Franks[1] and M. E. Hahn[1]. *[1]Biology, Woods Hole Oceanographic Institution, Woods Hole, MA and [2]Biology, Kenyon College, Gambier, OH.*

The effects of 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) and related compounds occur *via* the AHR, a member of the bHLH-PAS protein superfamily. A single *AHR* gene has been identified in mammals, while many fish species, including the Atlantic killifish (*Fundulus heteroclitus*) possess two distinct *AHR* genes (*AHR1* and a novel form, *AHR2*). A bHLH-PAS protein closely related to AHR was recently identified in mouse and designated AHR repressor (AHRR) (Mimura et al., *Genes Dev* 1999). Mouse AHRR is induced by 3-methylcholanthrene and represses the transcriptional activity of the AHR. The sequence similarity between AHR and AHRR raised the possibility that AHRR is the mammalian ortholog of fish AHR2. To test this, we investigated the presence of an AHRR ortholog in *Fundulus* and identified a cDNA with high sequence identity to the mouse and human AHRRs. *Fundulus* AHRR encodes a 686 residue protein with a predicted

molecular mass of 75.2 kDa. Phylogenetic analysis shows that AHRRs (mammals and fish) form a third clade within the AHR family, along with AHR1 (mammals and fish) and AHR2 (fish only); these three vertebrate AHR-like genes descended from a single invertebrate AHR. Thus, mammalian AHRR is not the ortholog of fish AHR2. We show here that *in vitro*-expressed AHRR proteins from human, mouse, and *Fundulus* all fail to bind [^{3}H]TCDD or [^{3}H]-beta-naphthoflavone. In transient transfection experiments in COS-7 cells using a DRE-luciferase reporter gene, *Fundulus* AHRR had a concentration-dependent inhibitory effect on TCDD-dependent transactivation by both AHR1 and AHR2. *Fundulus* AHRR mRNA is widely expressed and is inducible by TCDD or PCBs. The *Fundulus* AHRR promoter contains three putative dioxin-response elements. Both AHR1 and AHR2 activated transcription of luciferase driven by the AHRR promoter, and AHRR could repress its own promoter. Thus, AHRR is an evolutionarily conserved, TCDD-inducible repressor of AHR1 and AHR2 function. [NIH Superfund ES07381 and NIH ES06272]

1068 GRIP1 ENHANCES AHR SIGNALING IN HEPA1C1C7 CELLS.

S. R. Rushing, C. L. Jones and M. S. Denison. *Environmental Toxicology, UC Davis, Davis, CA.*

Exposure to 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) and related compounds produces a variety of tissue and species specific toxic and biological effects, most of which are mediated *via* the aryl hydrocarbon receptor (AhR) signaling pathway. The AhR is a ligand-dependent transcription factor that regulates gene expression *via* its binding to the dioxin responsive element (DRE) as a heteromeric complex with the AhR nuclear translocator (ARNT) protein. The events necessary for transcriptional activation by the DNA-bound AhR complex remain to be elucidated. As part of our effort to identify nuclear factor(s) which can modulate the transcriptional activity of the AhR complex, we have examined the ability of the glucocorticoid receptor interacting protein 1 (GRIP1) cofactor to affect AhR/ARNT-dependent signal transduction. GRIP1, like the AhR and ARNT, contains a basic helix-loop-helix/PAS domain located near the N-terminus and two transcriptional activation domains, AD1 and AD2, near the C-terminus. Cotransfection of Hepa1c1c7 cells with a DRE-reporter construct and a GRIP1 expression plasmid results in a 5-8 fold increase in reporter activity over cotransfection with the empty parent vector alone. However, when these cells were cotransfected with a GRIP1 lacking AD1, reporter activity was not enhanced, suggesting a role for AD1 in the augmentation of AhR signaling. Co-immunoprecipitation and GST pull-down techniques revealed strong interactions between GRIP1 and the AhR in at least two regions. The addition of GRIP1 also enhanced AhR:ARNT:DNA complex formation as assessed by gel retardation analysis. These results demonstrate that GRIP1 acts as a coactivator of the nuclear AhR complex. Supported by NIEHS (ES07072, ES05707 and ES04699).

1069 CROSS-TALK BETWEEN THE ARYL HYDROCARBON RECEPTOR AND SIGNAL TRANSDUCTION PATHWAYS: A ROLE FOR NF-κB.

E. M. Khan and M. S. Denison. *Environmental Toxicology, University of California, Davis, CA.*

Activation of gene expression by 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) and related chemicals is mediated by the aryl hydrocarbon receptor (AhR), a ligand-dependent transcription factor. Previously, a role for protein kinase C (PKC) in AhR signal transduction was demonstrated, with PKC inhibition blocking AhR functionality and phorbol-12-myristate-13-acetate (PMA)-dependent PKC activation enhancing AhR-dependent gene expression. In the present study we have extended these analyses and demonstrate that the PMA enhancement of AhR signaling in mouse hepatoma (Hepa1c1c7) cells is dependent upon the AhR DNA-binding site and is transient, occurring within the first eight hours after PMA treatment. While the enhancing effect appears directly related to gene transcription, the inhibition of PKC is associated with decreases in nuclear AhR and gene expression. PMA is also a potent activator of nuclear factor-κB (NF-κB)-dependent reporter gene expression in these cells. Not only do three chemical inhibitors of NF-κB (pyrrolidinedithiocarbamate (PDTC), (E)-capsaicin (CAPS), and caffeic acid phenethyl ester (CAPE)) block PMA-induced expression from an NF-κB reporter gene, but they inhibit both normal and PMA-enhanced AhR-dependent gene expression. Although gel retardation analysis reveals that inhibition of PKC by chelerythrine chloride reduced AhR nuclear translocation, NF-κB inhibition by PDTC had no effect on nuclear AhR levels. These results demonstrate a role for both PKC and NF-κB in the regulation of AhR-dependent gene expression. (Supported by NIEHS grant ES07685)

1070 TNF-α TREATMENT SUPPRESSES CYP1A1 TRANSCRIPTION BY INHIBITING ACETYLATION OF HISTONE H4 AND PHOSPORYLATION OF THE C-TERMINAL DOMAIN OF RNA POLYMERASE II.

Y. Tian[1], A. B. Rabson[3], M. A. Gallo[2] and S. Ke[1]. *[1]Veterinary Physiology and Pharmacology, Texas A&M University, College Station, TX, [2]Environmental and Community Medicine, EOHSI-UMDNJ, Piscataway, NJ and [3]CABM/CINJ-UMDNJ, Piscataway, NJ.*

It has been known that TNF-α and lipopolysaccharide (LPS) suppress the gene expression of cytochromes P450 1A1(cyp1a1). In earlier studies, we demonstrated that activation of NF-KB is a critical event leading to the suppression of cyp1a1 gene expression, thus establishing a cross-interaction between the Ah receptor and NF-KB signal transduction pathways. In the present study, we demonstrated that Ah receptor/NF-KB interactions converges at level of transcription involving two steps of transcriptional regulation: (1) chromatin remodeling and (2) transcriptional elongation by RNA polymerase II (RNA Pol II). Specifically, using cyp1a1 transcription in Hepa1c1c7 cells as a model system, we demonstrated that dioxin treatment (10 nM, 2 hrs) causes significant histone H4 acetylation which is associated with chromatin remodeling activity. TNF treatment (5 ng/ml) markedly suppresses this histone acetylation activity, especially around the TATA box region, suggesting that NF-KB activation inhibits the histone H4 acetylation at cyp1a1 promoter. Furthermore, we demonstrated dioxin treatment causes phosphorylation of the C-terminal domain (CTD) of RNA PolI. The phosphorylation of RNA Pol II is a critical step of transcriptional elongation. TNF-α treatment significantly suppresses the dioxin-induced RNA Pol II phosphorylation, especially at serine 2 of YSPTSPS motif of the RNA Pol II CTD. These results established a mechanism for the inflammatory cytokin-induced inhibition of chytochrome P450 1A1, suggesting the involvement of chromatin remodeling and transcriptional elongation in the "cross-talk" between Ah receptor and NF-KB signaling pathways. Supported in part by NIEHS Grant ES09859 and NIEHS Center Grant ES05022.

1071 MECHANISM OF HORMONAL ACTIVATION OF EARLY GROWTH RESPONSE-1 (*egr-1*) IN BREAST CANCER CELLS.

C. C. Chen and S. H. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Egr-1 is induced by 17β-estradiol (E2) in estrogen receptor (ER)-positive MCF-7 breast cancer cells, and analysis of the *egr-1* gene promoter indicates that there are multiple *cis*-elements that could be activated by ER through genomic and non-genomic pathways. The E2-responsive -650 to +12 region of the promoter does not contain an estrogen response element (ERE), and direct binding of ER to the *egr-1* promoter has not been detected. 5'-Deletion analysis of the promoter showed that the -460 to -164 region of the promoter was essential for E2-responsiveness, and this sequence contains 3 serum response elements (SREs) and two Ets motifs. Identification of E2-responsive motifs was further investigated using a series of deletion constructs (pEgr-1f-i) containing the -460 to -283, -383 to -283, and -460 to -383 regions of the *egr-1* gene promoter, respectively. In transient transfection studies in MCF-7 cells, E2 induced reporter gene activity in cells transfected with pEgr-1f (-460 to -283) (7.5-fold), and only weak induction (< 2-fold) was observed in cells transfected with pEgr-1g (-383 to -283). The remaining constructs were not hormone-responsive suggesting that the upstream SRE was the major site of E2-induced transactivation. These results are similar to those recently reported for non-genomic activation of the proximal SRE in the c-*fos* gene by E2 and, in MCF-7 cells transfected with pEgr-1f, hormone-induced activation was blocked by the MAPK inhibitor PD98059. Current studies are focused on characterizing the SRE-binding transcription factors and the pathway for E2-dependent MAPK activation of Egr-1. (Supported by NIH ES09253 and ES09106)

1072 *IN VIVO* STRESS ACTIVATES JAK-STAT IN LIVER BUT NOT BRAIN.

D. B. Miller, S. A. Benkovic and J. P. O'Callaghan. *Toxicology & Molecular Biology, CDC/NIOSH, Morgantown, WV.*

The Janus kinase-signal transducers and activators of transciption (JAK-STAT) signaling pathways are believed to be crucial signalling pathways in the physiological changes induced by stress. Various stressors (e.g., UV) have been shown to activate the JAK-STAT pathway, *in vitro*, but only a few reports have examined the JAK-STAT pathway using stress models, *in vivo*. Here C57BL6/J female mice were exposed to restraint, vibration or cold stress. To preserve steady-state phosphorylation, the mice were killed by focused microwave irradiation. The activation state of STAT 3, 5 and 6 was assessed from blots of tissue homogenates probed with phospho state-specific antibodies as well as antibodies directed against the context-independent state of the various STATs to assess their total tissue levels. Quantification

was achieved by densitometry of bands generated by enhanced chemiluminescence. No changes in the activation (phosphorylation) state of any of the STATs were evident in brain; however, large increases in phosphoSTAT3 were evident in liver, with restraint and cold providing the largest magnitude changes (~ 300%). STAT3 levels did not change with any of the stressors. Restraint of adrenalectomized mice caused an even larger increase in phosphoSTAT3 (~ 500%). Immunohistochemical examination of STAT3 confirmed that restraint resulted in the nuclear location (i.e. activation) of STAT3, which was substantially greater in adrenalectomized mice. These data suggest that effects of physiological stressors are mediated through a STAT3 pathway that may involve the HPA axis and/or sympathetic nervous system.

1073 COSTS AND BENEFITS OF COMPLIANCE WITH ALTERNATIVE REMEDIATION STANDARDS AT HEXAVALENT CHROMIUM–CONTAMINATED SITES.

P. D. Williams and D. Proctor. *Exponent, Menlo Park, CA.*

The New Jersey Department of Environmental Protection (NJDEP) requires varying levels of soil remediation at hazardous waste sites depending on the pathway of exposure. For example, sites which contain hexavalent chromium [Cr(VI)] in soil, must comply with either uniform default or site-specific health-based standards for inhalation, dermal, and oral exposures. NJDEP currently relies on an "averaging" approach when evaluating the increased cancer risk from inhalation of suspended soil (i.e., the 95th percentile upper confidence limit of the mean concentration is not allowed to exceed the inhalation standard) and a "bright line" approach when evaluating allergic contact dermatitis (ACD), an acute effect, from dermal contact with Cr(VI) in soil or puddles (i.e., no single soil sample is allowed to exceed the dermal standard). NJDEP also relies on this latter "bright line" approach when evaluating the long-term non-cancer risks associated with incidental soil ingestion, although this is inconsistent with USEPA risk assessment guidelines. The current analysis evaluates whether the extra costs required to comply with NJDEP's approach are justified by the associated benefits. Cost estimates are based on average costs for site remediation and the difference in the volume of soil requiring treatment to meet the oral standard as either a "bright line" or an "average." Benefits are estimated as the expected change in health risk associated with NJDEP's approach, and assumptions about the population affected and value per fatal and nonfatal event averted. The results of the cost-benefit analysis indicate that NJDEP's approach for site remediation yields negative net benefits—i.e., estimated costs are about $100, 000 per site examined as compared to estimated benefits of about $100. Sensitivity analyses, which incorporate a range of possible costs and benefits, also suggest that NJDEP's approach is not cost-beneficial. These findings are important for evaluating the appropriateness and limitations of alternative approaches for complying with soil remediation standards.

1074 INVESTIGATION OF ASBESTOS IN CONSUMER PRODUCTS: CHILDREN'S PLAYSAND.

K. M. Hatlelid[1], D. Davis[1], A. M. Ristich[2], S. Smythe[2], O. S. Crankshaw[3], J. T. Ennis[3] and L. E. Saltzman[1]. [1]*U.S. Consumer Product Safety Commission, Bethesda, MD,* [2]*DataChem Laboratories, Cincinnati, OH and* [3]*RTI International, Research Triangle Park, NC.*

The US Consumer Product Safety Commission (CPSC) regulates 15, 000 types of consumer products, including products made with mined materials. Recently, CPSC staff obtained a convenience sample of six playsand products from three companies in five states. Under contract, two independent laboratories analyzed the sand by polarized light microscopy (PLM) and transmission electron microscopy (TEM) for the presence of asbestos fibers. The bulk of each sample was nonfibrous and consisted of quartz, with smaller amounts of rutile, sphene, zircon, horneblende, rock fragments, and opaque grains. Two samples from the same company contained chrysotile and tremolite asbestos (<0.001%). Fibers were small, about 1 µm long and 0.05-0.2 µm in diameter. Small chamber experiments were conducted to determine if asbestos fibers could be released into the air. Air filters were analyzed by TEM using the USEPA AHERA (Asbestos Hazard Emergency Response Act) protocol. Estimated asbestos fiber release from the two playsand samples was 210, 000-2.5 million fibers per minute. Airborne fibers had the same mineralogy and physical characteristics as fibers detected in the bulk samples. Thus, despite the relatively small proportion of asbestos structures in the sand, large numbers of fibers were released into the air during a simulated play activity. Indoor air modeling based on one hour of play in a daycare or classroom setting resulted in projected air concentrations of 0.03 to 0.35 fibers/mL. Although the staff concludes that the very short fibers detected in these samples are not a health concern, we will continue to monitor playsand and other mineral-containing consumer products for the presence of potentially hazardous asbestos fibers. (The opinions expressed by the authors do not necessarily represent the views of the Commission. This abstract is in the public domain and may be freely copied or reprinted.)

1075 DERMAL ABSORPTION OF PCBs IN RHESUS MONKEYS FROM SOIL CONTAMINATED WITH AROCLOR 1260.

B. A. Mayes[1], G. L. Brown[2], F. J. Mondello[1], K. W. Holtzclaw[3], S. B. Hamilton[3] and A. A. Ramsey[2]. [1]*GE Corp. Res. & Development, Schenectady, NY,* [2]*Huntingdon Life Sciences, East Millstone, NJ and* [3]*GE Company, Fairfield, NY.*

Dermal absorption is routinely evaluated as a potential pathway for absorption of contaminants when conducting human health risk assessments for Superfund sites. For PCB-contaminated soil, the US Environmental Protection Agency uses a dermal absorption factor of 14%, a factor derived from a 1993 study of the dermal absorption of Aroclors 1242 and 1254 from contaminated soil by Rhesus monkeys. In comparison to the 1993 study, the current study varied several parameters that can influence the dermal absorption of lipophilic hydrocarbons, including soil organic content, soil particle size, skin residence time and contaminant "aging" in the soil. The study consisted of four groups of four female Rhesus monkeys exposed to ^{14}C-radiolabeled Aroclor 1260. One group was exposed intravenously to PCBs in propylene glycol (100% absorption) and 3 groups were exposed dermally to PCB-spiked soil. Two dermal exposure groups were exposed for 12 or 24 hours, respectively, to PCBs that had been aged in soil. These groups exhibited percutaneous absorption of 3.43 ± 0.35% and 4.26 ± 0.52%, respectively, of the applied dose. The remaining dermal group was exposed for 24 hours to soil freshly spiked with PCBs and exhibited dermal absorption of 4.07 ± 0.46% of the applied dose. It has been reported that soil organic content is an important factor in modulating the percutaneous absorption of highly lipophilic compounds from soil. The soil used in the current study had an organic content of 5-6%, a value typical for US soil, and a value that contrasts sharply with the 0.9% soil organic content used in the 1993 study upon which the current 14% dermal absorption factor for PCBs is based. Therefore, the current dermal absorption factor used by EPA appears to substantially overestimate the fraction of PCBs available for absorption from soils with typical organics content.

1076 EPA'S INTEGRATED RISK INFORMATION SYSTEM (IRIS).

S. H. Rieth and A. L. Mills. *USEPA, Washington, DC.* Sponsor: D. Singh.

IRIS is an EPA database that contains consensus scientific positions on potential human health effects that may result from chronic exposure to chemical substances. IRIS assessments present summaries of qualitative and quantitative health effects information, including reference doses (RfDs) and reference concentrations (RfCs) for the noncarcinogenic effects of chemicals and cancer slope factors and unit risks. Quantitative assessments in IRIS are used extensively in combination with specific situational exposure assessment information to evaluate potential public health risks. The IRIS database currently contains assessments for over 500 chemical substances. Approximately 80 assessments are underway or will be initiated in FY 2002; these include assessments for chemicals new to IRIS and updates of existing summaries that provide new scientific information and application of more current risk assessment methodologies. The IRIS Program continues to explore ways to improve its assessments, the process by which the assessments are prepared, and the database itself. Two such initiatives are the re-engineering of the IRIS Web site and an IRIS "Needs Assessment." The Web site (www.epa.gov/iris) was redesigned to be a more user-friendly Web-enabled database, with extensive hyperlinks and search interfaces. Users can request a "QuickView" version, which provides essential values with links to full IRIS summary text and supporting documents. The Needs Assessment is intended to define the needs of the public and EPA program offices/regions for new and revised IRIS health assessments. Issues being examined include: what additional chemical substance assessments are needed; which assessments currently on IRIS are in greatest need of scientific update; what additional types of information would be of value (e.g., acute and subchronic values); and to what extent should EPA collaborate with external parties as a means of developing IRIS assessments. Input from this Needs Assessment will be used by EPA in developing the 2002-5 IRIS agenda and resource needs.

1077 EVALUATION OF NON-CARCINOGENIC EFFECTS OF SOLUBLE NICKEL SALTS.

A. T. Bathija[1] and L. Haber[2]. [1]*Office of Water, USEPA, Washington, DC and* [2]*TERA, Cincinnati, OH.*

A risk assessment for chronic toxicity of soluble nickel(reference dose; RfD) *via* oral exposure was prepared by USEPA in 1987 and is available on EPA's Integrated Risk Information System (IRIS). The RfD was based on a two year feeding study in rats given 0, 100, 1000 or 2500 ppm nickel in the diet (estimated as 0, 5, 50 and 125 mg/kg/day). No significant effects were reported at 100 ppm (5 mg Ni/kg/day). At 1000 ppm, body weight was significantly reduced in both sexes; at 1000 pm, females had significantly higher heart-to-body weight ratios and lower liver-to-body weight ratios than controls. The two year survival was poor, particularly in control

rats, both males and females (84% and 92% mortality, respectively), raising some concern about the interpretation of the results of this study. Using NOAEL of 5 mg/kg/day and an uncertainty factor of 300 (10 each for inter- and intra- species variability and 3 for lack of conclusive reproductive toxicity data) the RfD calculated was 0.002 mg/kg/day. A subchronic study conducted by American Biogenics Corporation, also found 5 mg/kg/day to be a NOAEL. Recently Springborn Laboratories completed a two generation reproductive study in which rats received 0, 1, 2.5, 5.0 or 10 mg/kg/day nickel sulfate hexahydrate (0, 0.22, 0.56, 1.12 or 2.22 mg Ni/kg/day) by gavage. Based on the absence of adverse effects on fertility/fecundity, fetal/neonatal survival and on developmental measures at any of the doses tested, the NOAEL identified in this study was 10 mg nickel sulfate hexahydrate/kg/day (2.2 mgNi/kg/day). Increased fetal loss was observed at higher doses in the range-finding study. Using this NOAEL and an uncertainty factor of 100 (10 each for inter- and intra-species variability) the RfD calculated is 0.022 mg/kg/day which is similar to the one currently on IRIS. The opinions expressed are those of the authors and do not reflect US-EPA policy.

1078 RE-EXAMINATION OF THE PROPOSED ARSENIC (AS) DRINKING WATER REGULATION.

C. O. Abernathy, J. Wiltse, R. Schoeny, J. Kempic, J. B. Bennett and A. Schulman. *Office of Water, USEPA, Washington, DC.*

In 2001, the EPA extended the effective date for the 1/22/01 As drinking water rule until 2/22/02. This enabled EPA to conduct an extensive review on the health effects of As and the cost/benefits of the rule. In addition, EPA asked the National Research Council(NRC) to consider health data published since its 1999 report entitled Arsenic in Drinking Water. The Agency also asked the National Drinking Water Advisory Council (NDWAC) to review EPA's cost calculations and the Science Advisory Board (SAB) to suggest methods to improve benefits analysis. The 2001 NRC panel concluded that recent data suggest that the +3 As metabolites might directly react with DNA and that the risks for bladder and lung cancer could be greater than the estimates in the earlier report. The NDWAC group reviewed the costing methodologies and assumptions underlying the system-size cost estimates as well as the aggregated national estimate of system costs of the As Rule. They also evaluated other costing approaches and critiques that may have an impact on the system costs. They were charged to determine whether there is adequate information to evaluate the basis for the alternate approaches or critiques and note where there is not adequate supporting information. For the benefits estimates, the SAB panel asked EPA to consider the latency after initial exposure and the lag between reduction of exposure to As and reduction of risk for bladder and lung cancer. EPA should also quantify the benefits from prevention of some additional diseases, eg. diabetes mellitus, ischemic heart disease, and skin cancer; increase its valuation of non-fatal diseases; and expand its uncertainty analysis. The Agency is weighing the risks of adverse health effects at different As exposures, the costs of treatments to meet the new As standard and the benefits from limiting As exposure in drinking water to concentrations of 3, 5, 10 or 20 µg As/L; EPA will use the balance among these three factors to set the new As Maximum Contaminant Level. [These opinions are the authors' and not necessarily those of the EPA]

1079 TESTING FOR THRESHOLDS AND CALCULATING THRESHOLD DOSES WITH NONLINEAR DOSE-RESPONSE RELATIONSHIPS IN BIOASSAYS FOR CARCINOGENICITY.

W. K. Lutz[1] and R. W. Lutz[2]. [1]*Toxicology, University of Wurzburg, Wurzburg, Germany and* [2]*Statistics, ETH, Zurich, Switzerland.*

Nonlinear dose-response relationships are often postulated to be thresholded, but definition, statistical criteria, or estimations of threshold doses (TD) are usually lacking. We propose a procedure to estimate TD, based on a linear extrapolation of the line between the response at the lowest-observed effect level LOEL and the no-observed-effect level NOEL to intersect with the dose axis. It is exemplified for bioassays for carcinogenicity with groups of 50 animals. The following data set was used: incidence 0/50 tumor-bearing animals (TBA) at dose 0; insignificant incidences of 1/50 to 5/50 TBA at dose 1; significant responses with 10, 15, or 20/50 TBA at dose 2. The assumption is that the observed sublinearity is a matter of chance only, in that the true incidence at dose 1 is higher than the observed incidence, while the true incidence at dose 2 is lower than the observed. True incidences were calculated by attributing a given percentile of a binomial distribution to the observed incidences. Symmetrical 80% confidence intervals were chosen, which results in a p=0.1*0.1=0.01. Linear extrapolation of the line that connects the true incidences at dose 1 and 2 resulted in the following dose levels at intersection with the dose axis: For 10/50 TBA at dose 2, incidence 1/50 at dose 1 resulted in an intersection at 0.11 dose units; for higher incidences at dose 1, the intersection was outside the threshold dose range of 0-1. For 15/50 at dose 2, incidences 1/50 and 2/50 at dose 1, but not higher, intersected at 0.60 and 0.30 dose units, respectively. For 20/50 at dose 2, thresholds were indicated for incidences up to 4/50, but not for 5/50 (TD's spanning from 0.75 to 0.17 dose units). In addition to the estimation of threshold doses (lower bounds), the procedure allows the estimation of a probability that the true incidences at dose 1 and 2 extrapolate linearly to the incidence in the controls. This could be regarded as a p-value for rejecting the null hypothesis of linearity, for an observed sublinearity.

1080 MULTIPLEX DETECTION OF CYTOKINES AND PHOSPHORYLATED PROTEIN KINASES *IN VIVO* AND *IN VITRO* USING THE BIO-PLEX PROTEIN ARRAY SYSTEM.

A. Zhang, Y. Song, I. Huang, K. Simonyi, D. Davis, E. Willis, E. Gerasimopoulos, M. Malit, P. Miranda, C. Etienne, J. Wong and Q. Nguyen. *Life Science Group, Bio-Rad Laboratories, Hercules, CA.*

Cytokines and kinases play pivotal roles in cell signaling events, mediating a wide range of physiological responses. Here we present data from the Bio-Plex protein array system demonstrating the sensitive, simultaneous quantitation of 8 cytokines in human or mouse sera, and in tissue culture media. We can quantify all 8 cytokines at a limit of detection less than 10pg/ml, and with inter- and intra-assay CV less than 10%. Using an 8-plex assay, a single 96-well plate can generate 786 concordant cytokine values from 12 µl of sample/well. We also demonstrate a multiplexed sandwich immunoassay that simultaneously measures phosphorylation levels of JNK, p38MAPK, Erk, Akt and IkBa in a single well of a 96-well plate. These high content, multiplexed assays are highly correlated with and as sensitive as ELISA and immunoblotting. All the assays are specific and exhibit no detectable cross-reactivity between antibodies. Most importantly, data obtained from multiplexed cytokine and phosphoprotein assays provide an invaluable profile of cellular response for drug discovery and development.

1081 BIOMARKERS IN HUMAN AND RAT- A PROTEOMICS APPROACH.

M. D. Kelly, S. J. Kennedy and L. R. Bandara. *Oxford GlycoSciences, Abingdon, United Kingdom.* Sponsor: D. Everret.

Proteomic technology has demonstrated the potential to increase the predictability of toxicology. Particularly *via* the discovery of biomarkers bridging between animals and man. A study conducted to investigate the effect of Gentamicin on the rat plasma proteome showed that although a large number of proteins displayed changes in expression, a smaller subset showed clear dose or time related changes. These included isoforms of complement components and apolipoprotein. The observed changes in the rat have been compared to protein expression changes in the plasma from Gentamicin treated humans. The studies were conducted as detailed in the table. The changes in protein expression in functionally similar groups of proteins in man and rat are compared in the time course following Gentamicin exposure.

Rat Study	
Doses (mg/kg/day)	0, 0.1, 1.0, 10.0, 40.0, 60.0
Group sizes and study design	Male animals only. 10 rats per treated group, 20 rats in control group. Dosed as above up to day 8, half of each treatment group were sacrificed and tissue and blood samples taken. Surviving animals were treatment free until day 22 and then sacrificed as before.
Blood samples taken	2, 3 and 8 days.
Clinical Chemistry parameters	BUN, creatinine.
Human Study	
Dose	80 mg (iv).
Regime	8 eligible subjects (male) were investigated. Four subjects were randomised to receive placebo (saline iv.) and the remaining 4 subjects received Gentamicin (80 mg iv.) on the first treatment period. On the second treatment period (14 days after the first) they received the alternative.
Blood samples taken	pre dose, 1, 2, 4, 8 12, 24 and 72 hours post dose.
Inulin	Inulin clearance was performed on the day of each admission and approximately 1-2 hours post dose.
Safety assessments	Vital signs, Physical examinations, Medical history updates, 12 Lead ECGs, Clinical Laboratory tests and adverse events were recorded regularly.

1082 RAPID METHOD FOR DETECTION AND IDENTIFICATION OF DIFFERENTIALLY EXPRESSED PROTEINS IN DRUG-TREATED CELLS.

T. T. Pham[1], S. Fu[1], W. Zhang[1], J. H. Lin[2] and S. Durham[2]. *[1]Ciphergen Biosystems, Fremont, CA and [2]Bristol-Myers Squibb Pharmaceutical Co, Princeton, NJ.* Sponsor: O. Flint.

Cell lines, in response to several drug treatments, regulate the amount of proteins expressed within the cell as well as the secreted proteins to the cell media. We have used a ProteinChip System and the Retentate Chromatography- Mass Spectrometry method (RC-MS) to monitor differentially expressed proteins in the cell media. Many proteins were detected to be up- or down- regulated when proteins in cell media were profiled using several chromatographic ProteinChip Arrays. Two low abundant, small protein biomarkers are subsequently purified for protein identification. Based on their binding characteristics to the arrays, we have quickly developed the protein enrichment and purification using micro spin columns together with a sensitive protein detection method by RC-MS assisted protein purification. We have identified these purified proteins at high confidence after tryptic digestion, peptide-mass mapping on the ProteinChip System and searching the publicly available protein databases. We show this technique as a new method to monitor the toxicological effect of drugs.

1083 IDENTIFICATION OF UBIQUITIN-CONJUGATED PROTEINS USING LC-MS TECHNIQUES: POTENTIAL MOLECULAR INDICATORS OF TOXIC INSULTS.

D. S. Kirkpatrick, K. V. Dale, D. C. Liebler and A. J. Gandolfi. *Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

Post-translational modification of proteins plays a key role in cellular stress responses and recovery from toxic insult. Ubiquitin, the protein modifier that targets proteins for proteosomal degradation, is now implicated in a number of proteosome-independent signaling processes. In order to study responses in the ubiquitin pathway following intoxication, a method has been developed to screen samples for ubiquitin conjugates. For this work, liquid-chromatography-mass-spectrometry (LC-MS) methods have been combined with newly developed search algorithms to study ubiquitin-conjugated Histone 2A/B. Insoluble fractions were prepared from HEK293 cells and separated by SDS-PAGE. Gel bands of molecular weight 22 kDa, known to contain ubiquitin-tagged Histone 2A and/or 2B, were excised and subjected to in-gel digestion with trypsin. MS-MS spectra were obtained from tryptic peptide mixtures on an LCQ-MS (ion trap). Peptide sequences matching both Histones 2A and 2B, as well as ubiquitin, were independently identified using SEQUEST and SALSA search algorithms to mine LCQ data files. Significant sequence coverage was obtained for Histone 2B (44%) and ubiquitin (34%), and to a lesser extent for Histone 2A (18%). Furthermore, the identification of one particular C-terminal ubiquitin peptide strongly suggests that certain peptides from ubiquitin-conjugated proteins carry a short polypeptide tag specifically identifying the modified residue. Thus far, MS-MS spectra have not yielded sequence coverage for peptides containing the lysine residue specifically modified by ubiquitin, probably because of complications arising from the modification that allow them to evade SEQUEST and SALSA detection. Despite this, Histones 2A and 2B have contributed significantly to our understanding of MS-MS fragmentation characteristics of ubiquitin-conjugated proteins and allowed us to search complex protein pools for molecular indicators of chemical intoxication. (Supported by NIH Grants ES 06694, ES 04940, ES 07091)

1084 IDENTIFICATION OF ORGANOPHOSPHATE INSECTICIDE TARGETS IN SH-SY5Y HUMAN NEUROBLASTOMA CELLS.

K. M. George[1,2], D. H. Williamson[2,3], C. R. Burgess[2], T. M. Voelker[3] and C. M. Thompson[1,2,3]. *[1]Center for Environmental Health Sciences, University of Montana, Missoula, MT, [2]Department of Pharmaceutical Sciences, University of Montana, Missoula, MT and [3]Department of Chemistry, University of Montana, Missoula, MT.*

Organophosphate (OP) insecticides increase agricultural production, but are considered highly toxic to humans and animals due to inhibition of acetylcholinesterase (AChE) resulting in cholinergic hyperstimulation. OP's have been implicated in many other pathological diseases, including Gulf War Syndrome, Parkinson's disease, cancers, and various immune dysfunctions. Other esterases, such as neurotoxic esterase, have been shown to be inhibited by OP, but it is likely that OP's interact with and modify the activity of other proteins. We have synthesized a biotinylated fluorophosphonate, FP-biotin, which shares common OP structural characteristics, but has a biotin group attached. Following covalent modification of the protein by FP-biotin, it is possible to visualize or isolate FP-biotin-bound proteins *via* avidin affinity. Our hypothesis is that OP compounds interact with neuronal cell proteins other than AChE. To test this hypothesis, we treated human neuroblastoma cells, SH-SY5Y, with varying concentrations of FP-biotin and tested for AChE inhibition and cell viability over time. Lysates were made of SH-SY5Y cells treated with FP-biotin and biotin-labeled proteins were purified using an avidin-affinity column prior to visualization by western immunobloting. Biotinylated proteins were digested with trypsin either in-solution or in-gel and analyzed by automated nanoLC-MS/MS. Accurate peptide mass fingerprinting combined with peptide fragment analysis was used to identify additional OP-protein conjugates. These experiments demonstrate that OP compounds bind proteins other than AChE in neuronal cells, and may identify complementary pathways to cholinergic hyperstimulation leading to pathology.

1085 UP AND DOWN REGULATION OF PHOSPHORYLATED HEPATIC PROTEINS FOLLOWING ADMINISTRATION OF THE PROTEIN PHOSPHATASE INHIBITOR, MICROCYSTIN-LR TO RATS.

L. D. Riggs, F. E. Regnier, C. R. Wilson and S. B. Hooser. *Chemistry and Veterinary Pathobiology, Purdue University, West Lafayette, IN.*

The field of proteomics is seeing an effort to utilize high throughput methods to quantify the degree in which cellular proteins change when exposed to disease, drugs, toxins, etc. Gallium(III) immobilized affinity chromatography can be used to select phosphorylated peptides. Affinity selected phosphopeptides can be analyzed by using phosphatase enzymes and mass spectrometry. Phosphopeptides are identified by comparing their mass/charge and sequence *via* MS/MS to databases. Quantification of the degree to which peptides and parent proteins are up- or down- regulated is achieved by derivatization with acetate. Control samples are labeled with acetate and experimental samples with trideuteroacetate. Control and experimental samples are mixed, affinity selected and resolved as above. Peptides appear in the mass spectrum as doublets separated by multiples of 3 mass units. The isotope ratio of non-changing proteins is approx. 1:1. Those that have a different ratio have undergone some regulatory change. Microcystin-LR (MCLR) is an inhibitor of protein phosphatases 1 and 2A. However, the change in phosphorylation state is only known for a few proteins which have been specifically identified. In this study, male rats were treated with microcystin-LR (500 ug/kg, ip) or saline. At 6h, they were necropsied. Liver sections were fixed or frozen. Microscopic liver necrosis was typical of MCLR. Frozen liver samples were homogenized, digested with trypsin, affinity-selected *via* gallium-IMAC, derivatized, and quantified *via* mass spec. Ga(III)-IMAC selection captured approximately 2800 phosphorylated peptides. MALDI-TOF mass spec of acetate-labeled peptides identified phosphoproteins which had undergone regulatory change. The majority were up regulated compared to controls, but some were down regulated or unchanged. This suggests that the regulation of protein activity *via* phosphorylation is complex with both increases and decreases in phosphorylation following inhibition of protein phosphatases.

1086 SELDI-TOF MASS SPECTROMETRY PROTEOMIC ANALYSIS OF PYRIDOSTIGMINE BROMIDE AND STRESS ON THE HP-AXIS.

S. Ropp[1], I. Bernatova[2], S. J. Paton[1], W. A. Price[1], M. Morris[1] and D. R. Cool[1]. *[1]Pharmacology & Toxicology, Wright State University, Dayton, OH and [2]Cardiovascular Physiology, Institute of Normal and Pathological Physiology, Bratislava, Slovakia.*

Pyridostigmine bromide (PB) is an acetycholinesterase (AChE) inhibitor used as a preemptive treatment against possible exposure to organophosphate nerve agents and as a treatment for myasthenia gravis. In order to analyze the effects of PB and stress on the hypothalamic-pituitary axis (HP-axis), SELDI-TOF mass spectrometry proteomic analysis was conducted on the hypothalamus in parallel with AChE activity assays. Two models were used; PB-treatment in which doses of 0, 0.5, 1, 2 and 3 mg/kg/day were administered using Alzet minipumps implanted subcutaneously in the mice for 7 days or 7 day chronic shaker stress. The hypothalamic AChE activity in the 7-day chronic stress model was unchanged when compared to controls. PB (5 mM) was able to inhibit 98% of this activity. In contrast, a significant dose-dependent decrease in hypothalamic AChE activity (>40% at the highest dose of 3 mg/kg/day) was observed in the chronically-treated PB model. Proteomic analysis of the same stress and PB-treated hypothalamic homogenates by SELDI-TOF MS showed significant and similar changes in the hypothalamic peptide/protein profiles for both stressed and PB-treated mice. Ratio analysis of the protein profiles indicated a decrease in peak intensity for large (>4000 d) and small (<4000 d) peptides. However, the decrease in intensity was greater for the larger proteins (2.0-7.5 vs small, 1.3-2.0), suggesting a buildup of the smaller peptides within the cells. Analysis of the posterior pituitary also showed a similar decrease in arg-vasopressin peptide in both stress and PB-treated mice. These results suggest that stress

and PB both affect the peptide protein profiles in the hypothalamus by changing either the protein expression or peptide processing and secretion patterns of the cells. Supported by DoD contract No.99214005.

1087 A PROTEOMIC APPROACH TO THE CHARACTERIZATION OF ARDS.

C. D. Mobarak[1], R. P. Baughman[2] and R. F. Henderson[1]. *[1]Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM and [2]University of Cinicinati, Cincinati, OH.*

Acute Respiratory Distress Syndrome (ARDS) is a severe lung dysfunction associated with a variety of catastrophic events. The condition is characterized by bilateral infiltrates of protein-rich fluid and large numbers of neutrophils. Because ARDS can be induced by multiple factors that produce similar pulmonary pathophysiologic changes, the mechanism likely involves a disturbance of basic homeostatic processes that protect and maintain normal lung permeability. Bronchoalveolar lavage fluid (BALF) contains a large number of proteins that comprise a source for testing and characterizing biochemical alterations associated with airway disease. Proteins that are regulated, modified, secreted or exudated in the airways during disease processes can provide vital mechanistic information, as well as identify novel treatment targets. Our Lab. uses proteomics techniques to identify proteins that are differentially expressed in ARDS by defining protein expression profiles (PEPs) in BALF. Human BALF samples from patients who have undergone bronchoscopy during the progression of their disease have been characterized using 2-DE gels, PDQuest software and Matrix-assisted laser desorption/ionization-time of flight-mass spectrometry. These human PEPs are being used to guide development of an ARDS animal model. Mouse was chosen for the animal model because its genome has the most complete sequence database available for protein identification. In mice we have compared control BALF to BALF from animals with trauma induced acute lung injury. In the trauma model BALF, the PDQuest software identified 30 protein spots that increase by at least 2-fold, 3 spots that decrease by 2-fold, and 14 spots not observed in control BALF. Glutathione-S-transferase and selenium binding protein are two of the up-regulated proteins. Correlation of human data with the mouse data will be used to validate this acute lung injury in mouse as an appropriate animal model of ARDS. Research supported by LRRI.

1088 PROTEIN EXPRESSION IN RAT TESTICULAR TISSUE FOLLOWING MULTIPLE EXPOSURE LEVELS OF JP-8 VAPORS FOR 91 DAYS.

G. B. Briggs[1], K. R. Still[1] and F. Witzmann[2]. *[1]Naval Health Research Center Detachment (Toxicology), WPAFB, OH, [2]Naval Health Research Center Detachment (Toxicology), WPAFB, OH and [3]University of Indiana, Indianapolis, IN.*

JP-8 jet fuel is being universally used by the US military. The Navy is primarily concerned about vapor exposures on ships. A 91-day inhalation exposure study was conducted in male Sprague-Dawley rats to evaluate reproductive system toxicity. Testicular tissue was harvested at the necropsy and prepared for proteomic evaluation. 2D electrophoresis and peptide mass fingerprinting procedures were used to generate protein expression profiles. More than 50 proteins were identified as being specific to the testes. These protein spots were excised robotically and identified by the MALDI-TOF-MS system. Increased relative protein abundance was observed in the low dose rats (250 mg/cubic meter). Declines in protein expression were observed in the high dose (1000mg/cubic meter). A total of 49 changes in protein expression differences were observed in the low dose group, 24 differences in protein expression were present in the mid dose group (500 mg/cubic meter), and 26 differences were observed in the high dose group. Specific proteins that showed increased abundance in the low dose group were generally associated with cell repair, and the proteins that demonstrated decreased abundance are generally associated with cell damage. These protein expression patterns may help to understand the mechanism of cellular changes in the testes that occur prior to functional and morphological evidence of male reproductive system functional defects. Proteomics data are being used to fill current reproductive toxicity data gaps in the risk assessment of JP-8 vapor. The information is being used to help formulate appropriate exposure levels for Navy personnel to JP-8.

1089 PROTEIN PROFILING OF RAT LIVER ORGANELLES AFTER SUBACUTE PHENOBARBITAL EXPOSURE:COMPARING PROTEOMICS AND CDNA MICROARRAY DATA.

M. E. Bruno[1], J. E. Hartis[1], S. E. Jayadev[2], K. T. Blanchard[2], R. E. Stoll[2], B. A. Wetmore[1], C. H. Borchers[3], M. J. Dial[3], K. B. Tomer[1], H. Hamadeh[1] and B. A. Merrick[1]. *[1]National Center for Toxicogenomics, NIEHS, Research Triangle Park, NC, [2]Biochemistry, UNC, Chapel Hill, NC and [3]Toxicology, Boehringer Ingelheim, Ridgefield, CT.* Sponsor: B. Merrick.

Abstract A primary focus of toxicogenomics concerns differential gene expression produced by chemical exposure that form expression signatures that can distinguish toxicant classes and actions. Protein expression was studied in male rat liver by proteomics after subacute exposure to the metabolic enzyme inducer, phenobarbital. Proteins were fractionated into mitochondria, endoplasmic reticulum (ER), cytosol and nuclei, separated by two-dimensional(2D) gel electrophoresis, quantitated by image analysis and identified by mass spectrometry. Over 60 proteins were identified throughout all fractions including the expected induction of cytochrome P450 and glutathione transferase subunits as confirmed by western blot. Several intermediary metabolic enzymes were affected by phenobarbital in cytosolic fractions, among them carbamoyl phosphate synthetase 1, 3 α hydroxysteroid dehydrogenase, arginosuccinate synthase and 10-formyltetrahydrofolate dehydrogenase. Changes observed in nuclear samples include downregulation of LBP-p40, hnRNPA3, hnRNP A2/B1 and hnRNP A1b as well as upregulation of hnRNP L. Results from Western analysis with an LPB40 specific rabbit polyclonal antibody were consistent with the 2D gel results previously observed. In addition, nine potentially new nuclear proteins were found by mass spectrometry not in public genomic databases. This study shows how proteomics might serve to establish protein signature profiles of chemical exposure in toxicogenomics studies and can also serve as an effective tool for gene discovery.

1090 IDENTIFICATION OF POTENTIAL *IN VITRO* ENDPOINTS FOR SKIN IRRITATION USING PROTEOMIC AND MICROARRAY ANALYSIS.

S. T. Fletcher[1], J. H. Fentem[1], D. A. Basketter[1], D. P. Kelsell[2], M. Philpott[2] and V. A. Baker[1]. *[1]SEAC, Unilever, Bedfordshire, United Kingdom and [2]Centre for Cutaneous Research, Queen Mary, University of London, United Kingdom.*

Understanding the mechanistic basis of the human skin irritation response is key to the development of relevant *in vitro* test systems for the predictive identification of skin irritation hazards. Recent progress in the development of proteomic and microarray technologies means that tools for the identification and investigation of important biochemical events in the processes of skin irritation are now available. This study was designed to identify proteins (and genes encoding proteins) which may be involved in the skin irritation response, following exposure of a reconstructed human skin model (EpiDerm™ (MatTek)) to the skin irritant sodium lauryl sulphate (SLS). EpiDerm™ cultures were treated in triplicate with a non-cytotoxic dose of SLS (0.1mg/ml, as determined by the MTT assay and histological examination) for 15min, 1h, 2h, 4h and 24h. Proteomics was performed using 2D-gel electrophoresis (Multiphor II and DALT system, (APB)) in combination with mass spectroscopy to investigate the protein expression profile and identify proteins of interest. In addition microarray analysis was performed using DermArray (Research Genetics) cDNA arrays covering 5000 genes of relevance to skin biology. 67 proteins of potential interest were selected and identified from a range of 2D-gels (1st dimension : pH 4-7, 4-5, 5-6, 6-9 and 6-11). Of the proteins selected, 35 were upregulated, 19 downregulated and the expression of 4 remained unchanged following exposure to SLS. Data indicated that post-translational modification occurred at an early time point (15 min) for calmodulin-like skin protein and involucrin following exposure of EpiDerm™ to SLS. Epithelial cell marker protein demonstrated post-translational modification after 1h exposure to SLS. These results demonstrate the differential regulation of a number of proteins in response to a known irritant, which could represent potential new *in vitro* markers of skin irritation.

1091 HALOACETIC ACIDS PERTURB PROTEIN PHOSPHORYLATION IN MOUSE EMBRYOS *IN VITRO*.

M. R. Blanton and E. S. Hunter. *Reproductive Toxicology Division, USEPA, Research Triangle Park, NC.* Sponsor: J. Rogers.

Haloacetic Acids (HAAs) formed during the disinfection process are present in drinking water. *in vitro* exposure of rodent conceptuses to these agents produces dysmorphology including craniofacial defects. Based on the effects of HAAs in adult tissues, we tested the hypothesis that exposure to HAAs perturbs signal transduction pathways. CD-1 mouse conceptuses (3-6 somites) were exposed to HAAs at concentrations that produce 100% dysmorphology [11mM dichloroacetate (DCA), 350μM dibromoacetate (DBA) or 300 μM bromochloroacetate (BCA)] in whole embryo culture. To determine if exposure to the HAAs perturbs protein kinase activity, embryos were radiolabelled with 33-P-phosphate in HAA-containing or control medium during 0-2, 4-6 or 22-24 hours of exposure. 2D gel electrophoresis was then performed and autoradiographs compared using Phoretix 2D Software (Nonlinear Dynamics). Both time and chemical changes in protein phosphorylation were observed. To further evaluate protein phosphorylation, Western analysis on 1D gels was conducted using a phospho-tyrosine antibody (PY-99: Santa Cruz Biotechnology). Two major phosphotyrosine containing proteins (122 and 183kDa) were found to be affected by HAA exposure. No changes were observed as early as 2 hours after treatment but an increase in the 122kDa protein was found 6 hours following DCA exposure. By 24 hour after culture both phospho-

proteins were increased in all three HAA treated groups with DCA producing the greatest effect. These changes indicate that the HAAs perturb signal transduction by altering the phosphorylation state of phospho-tyrosine proteins. Since pharmacological protein kinase inhibitors also produce dysmorphology, HAA-induced alteration of signal transduction may be responsible for altered differentiation and development. This abstract does not present EPA policy.

1092 LOCALIZATION OF IKB AND IKK SUBUNITS IN THE SMOOTH ENDOPLASMIC RETICULUM: ACUTE EFFECTS OF TCDD IN MALE AND FEMALE RAT LIVER.

B. A. Merrick, M. E. Bruno, N. J. Walker, J. M. Dial, J. E. Hartis, B. A. Wetmore, J. C. Barrett, K. B. Tomer and C. H. Borchers. *Toxicogenomics Center, NIEHS, Research Triangle Park, NC.*

Effects of acute 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) exposure upon protein expression in rat liver endoplasmic reticulum (ER) were determined by two-dimensional gel separation and mass spectrometry. Liver ER was prepared as microsomes from male and female Sprague-Dawley rats exposed for 72 hr to TCDD. TCDD induced cytochrome P450 enzymes, GST subunits, Hsp72 and Grp78. Mass spectrometry also revealed the presence of increased levels of IKB kinase beta (IKK-β) after dioxin treatment in males and females. This finding led us to search for other NF-κB binding proteins or kinases in ER and possible alterations by TCDD. Western blot for IKB family members in ER showed that IKB-β and IKB-γ were highly abundant in ER while IKB-α and IKB-ε proteins were barely detectable. TCDD induced hyperphosphorylated forms of IKB-β in both genders, but only the 85kd form of IKB-γ was present in females while males expressed an additional IKB-γ immunoreactive form at 115 kD. Although IKK-β was in ER of both genders, IKK-α was the most abundant IKK subunit and IKK-γ was not detectable. The effect of gender and TCDD treatment upon IKB and IKK family member expression was also examined in cytosol for critical comparison to the ER. In cytosol, all IKK subunits were expressed without substantial effect by TCDD. IKB-α, IKB-β, and IKB-ε, but not IKB-γ, were expressed in cytosol and were unaffected by TCDD. Hyperphosphorylated forms of IKB-β were observed in cytosol only in female (not male) rats but were not increased by TCDD as was the case in ER from females. Although NF-κB-p65 was readily found in male and female cytosol, it was not detectable in ER. IKK-α, β kinase activity, measured after immunoprecipitation from cytosol and solubilized ER, was unaffected by gender and treatment. These studies demonstrate a strength of proteomics in showing a unique distribution of NF-κB binding proteins and their kinases in liver ER as affected by gender and TCDD treatment.

1093 T-2 AND HT-2 TOXIN INDUCED APOPTOSIS IN HL-60 HUMAN PROMYELOCYTIC LEUKEMIA CELLS.

J. A. Holme, E. Morrison, J. T. Samuelsen, R. Wiger, M. Låg and M. Refsnes. *Environmental Medicine, National Institute of Public Health, N-0403 Oslo, Norway.* Sponsor: E. Dybing.

T-2 and HT-2 toxins belong to a group of mycotoxins, trichothecenes, which are widely encountered as natural contaminants. Exposure to such toxins may cause severe damage to the gastrointestinal mucosa and the immune system. In the present study the human promyelocytic cell line HL-60, was used to characterize the apoptotic effects of T-2 and its metabolite HT-2. Apoptotic cells were identified microscopically by chromatin condensation and nuclear fragmentation, by flow cytometric analysis and by DNA laddering. Apoptosis induced in the HL-60 cells following exposure to T-2 and HT-2 for 24 hours was concentration-dependent starting at 3.1 and 6.25 ng/ml, respectively. Little cytotoxicity (membrane damage) was observed even after exposure to concentrations (25-50 ng/ml) that induced 60-100 % of the cells to undergo apoptosis. Following exposure to 6.5 ng/ml an increased amount of apoptotic cells could be observed already after 4-6 hours. Whereas the absolute effects of toxin-induced apoptosis in the HL-60 cells seemed to vary somewhat during culturing and between different batches of cells, T-2 was more potent than HT-2. The apoptotic process could be almost completely blocked by the addition of z-VAD.fmk. In contrast, no or only minor effects were observed by the addition of DEVD.CHO, IETD.fmk and DEVD.fmk. As judged by Western blotting, no or only minor changes in bax and bcl-2 levels were observed, whereas PARP was totally degraded already 3 hours after toxin addition. Furthermore, the level of several procaspases (-3, -7, -8, -9, but not -12) were down regulated. Zn^{2+} and BAPTA-AM blocked the induction of apoptosis as judged by microscopic analysis and flowcytometry, as well as DNA fragmentation. The results suggest that T-2 and HT-2 both cause an increase in the level of Ca^{2+} thereby initiating a signal that activates several caspases resulting in chromosomal condensation, nuclear fragmentation, activation of DNA endonucleases and DNA laddering.

1094 ALTERATIONS IN EXPRESSION OF CYTOKINE NETWORK AND APOPTOSIS SIGNALING GENES IN MOUSE LIVER AFTER SUBACUTE FUMONISIN B_1 EXPOSURE.

N. Bhandari and R. P. Sharma. *Physiology and Pharmacology, University of Georgia, Athens, GA.*

Fumonisin B_1 (FB_1) is a naturally occurring mycotoxin produced primarily by *Fusarium verticillioides* and related fungi, which are common contaminants of corn throughout the world. FB_1 is a carcinogen and causative agent of several lethal animal diseases. Liver is the primary target organ in mice. Our previous studies showed altered expression of cytokines in mouse liver after FB_1 treatment. To further investigate the genes involved in the cytokine network and apoptosis signaling, male and female BALB/c mice (5/group) were injected subcutaneously with either saline or 2.25 mg/kg/day of FB_1 for 5 days. FB_1 treatment caused increased expression of tumor necrosis factor α (TNFα), interleukin (IL)-1α, IL-1β, IL-1 receptor antagonist (IL-1Ra), IL-6, IL-10, IL-12 p40, IL-18 and interferon γ (IFNγ) in male liver, with a similar increase in females except that IL-1β and IL-18 were unaltered. Control females showed higher basal levels of IL-1α, IL-1Ra, IL-10, IL-12 p40 and IFNγ as compared to males. Expression of TNF receptor 55 and TNF receptor associated death domain (TRADD) was increased, with no changes in Fas signaling molecules, Fas, Fas ligand, Fas associated death domain (FADD) and Fas-associated protein factor (FAF). Expression of c-Myc, B-Myc, Max and Mad oncogenic transcription factors and apoptotic genes, namely Bcl-2, Bax, Bad and caspase 3 was also increased after FB_1 treatment. FB_1 caused an activation of cytokine network in liver along with TNFα signaling pathways. FB_1-induced expression of TNFα, IL-1α, IL-1β, IL-6 and IFNγ could play a role in the observed liver toxicity, whereas increased expression of IL-1Ra and oncogenes could be responsible for the cancer promoting properties of FB_1.

1095 IMMUNOTOXIC EFFECTS OF ENDOSULFAN AND PERMETHRIN *VIA* THYMOCYTE APOPTOSIS.

J. J. Keenan[1], H. P. Misra[1], F. Adeshina[2] and H. Choudhury[2]. [1]*Biomedical Sciences & Pathobiology, Virginia Tech, Blacksburg, VA and* [2]*ORD, USEPA, Cincinnati, OH.*

Altered immune responses have been observed following occupational, inadvertent, or therapeutic exposure to xenobiotics. Many pesticides are known to cause immunotoxicity. Exposure to mixtures of pesticides, either concurrently or sequentially, may result in potentiating this effect mainly because one can effect the metabolism of the other. The objective of this study was to determine the effect the insecticides endosulfan, permethrin and their mixtures on C57BL/6 male mice thymocytes *in vitro*. Permethrin, is a broad-spectrum synthetic pyrethroid, is a widely used insecticide in agriculture and public health. Endosulfan is a highly toxic chlorinated hydrocarbon insecticide used worldwide. We examined the immunotoxic potential of these pesticides using a flow cytometric technique in combination with 7-Amino Actinomycin D (7AAD) to distinguish live, early apoptotic, and late apoptotic/necrotic cells. DNA ladder assay, hallmark of apoptosis, was also used to determine the occurrence of apoptosis. Both endosulfan and permethrin were found to cause significant apoptotic death of thymocytes in a dose- and time- dependent manner. Thus, permethrin at 50, 100 and 300 μ M was found to cause 5.49, 11.49 and 26.11% early apoptotic cell death, respectively. Endosulfan at 25, 50 and 250 μ M was found to cause 11.91, 15.72 and 68.01% early apoptotic cell death, respectively. For the mixture study, concentrations of 100 μ M permethrin and 50 μ M endosulfan was selected and that found to cause 27.09% apoptosis. Thus, these pesticides in mixture have an additive immunotoxic effect. No significant late apoptotic cells were found at these concentrations for either pesticide when exposed for 12 hours. DNA ladder assay confirmed the presence of DNA fragments. The results of this study suggest that the mixtures of endosulfan and permethrin have additive immunotoxic effects on C57BL/6 mice thymocytes.

1096 OXIDIZED PHOSPHATIDYLSERINE STIMULATES PHAGOCYTOSIS OF APOPTOTIC CELLS.

C. A. Smith[1], S. X. Liu[1], F. B. Serinkan[1], V. A. Tyurin[2] and V. E. Kagan[1]. [1]*Environmental & Occupational Health, University of Pittsburgh, Pittsburgh, PA and* [2]*Institute of Evolutionary Physiology and Biochemistry, Russian Academy of Science, St. Petersburg, Russian Federation.*

A critical event during programmed cell death or apoptosis is the acquisition of plasma membrane changes that allows phagocytes to recognize and engulf cells before they rupture. Externalization of phosphatidylserine (PS) has been considered a hallmark of apoptosis. Oxidative stress is an inherent part of the apoptotic program with an unkown specific function. We have previously found that apoptosis induced by oxidants and non-oxidants such as phorbol miristate acetate (PMA) and anti-Fas, was accompanied with PS oxidation and externalization in apoptotic cells. We hypothesize that PS oxidation plays important role in recognition and phagocytosis of apoptotic cells by macrophages. To test this hypothesis, 1-palmitoyl

(C16:0)-2-arachidonoyl (C20:4) PS was oxidized by incubation with 2, 2'-azo-bis-(amidinipropane) hydrochloride (AAPH) and incorporated into plasma membrane of HL-60 cells. By comparing phagocytosis of cells with PS and oxidized PS (PSox) by macrophage J774A.1 cell line, we found that PSox strongly enhanced engulfment of cells by macrophages. Another phospholipid, phosphatidylcholine (PC), when oxidized to the same extent as PS, had no effect on phagocytosis. Liposomes containing PSox inhibited phagocytosis of apoptotic HL-60 cells induced by tert-butyl hydroperoxide(tBuOOH)by macrophages more potent than those containing PS. Based on our experiments with different receptor-specific antibodies, uptake of cells with incorporated PSox was blocked 50% by mAb against both PS-R and Ox-LDL, and 40% by mAb against both CD36 and RGDS. This implies that CD36 and the lectin receptor might be responsible for recognition of PSox while the PS receptor and the scavenger receptor, CD-36, might be involved in recognition of PS. These results suggest that PS oxidation is likely to be a new signaling pathway for clearance of apoptotic cells by macrophages.

1097 VITAMIN E AND RECOGNITON/CLEARANCE OF APOPTOTIC JURKAT CELLS BY MACROPHAGES.

F. B. Serinkan, C. Smith, Y. Y. Tyurina and V. E. Kagan. *Enviromental and Occupational health, University of Pittsburgh, Pittsburgh, PA.*

Phagocytosis of apoptotic cells is important for effective clearance of dead cells without inflammatory reaction. PS externalization, a hallmark of apoptosis, is required for recognition of apoptotic cells by macrophages. Specific PS peroxidation has been documented during apoptosis and suggested to participate in PS-dependent signaling pathways. This implies that antioxidants may affect recognition of apoptotic cells by macrophages *via* inhibition of PS peroxidation. Apoptosis was induced by anti-Fas mAb in Jurkat cells after 48 h culturing with different concentration of alpha-tocopherol acetate (0.25-50μM). Intracellular vitamin E (VE) concentrations were measured by HPLC. PS oxidation was assessed by HPLC after metabolic-labeling of cells with oxidation-sensitive cis-parinaric acid. Apoptosis was assessed by nuclear morphology using Hoescht 33342 staining. For phagocytosis, we used J774A.1 murine macrophages cell line. Percentage of apoptotic cells was 7±1, 11±3, 33±2, 31± 1, 28±3, 35±3 in the control without any treatment, VE without anti-Fas mAb, anti-Fas mAb without VE, and 0.25, 2.5, 50 μM VE plus anti-Fas mAb, respectively. Percentage of phagocytosis-positive macrophages was 5±1, 5±2, 25±3, 34±4, 27±8, 29±4 in control without any treatment, VE without anti-Fas mAb, anti-Fas mAb without VE, and 0.25, 2.5, 50 μM VE plus anti-Fas mAb, respectively. These results show that VE treatment had no significant effect on phagocytosis of apoptotic Jurkat cells. Although PS externalization may be one of the final common pathways of apoptotic program that makes the cells recognizable by macrophages, peroxidation of PS can play a role as an important additional signal for one or more macrophage receptors. It is important to determine whether other lipid- and water-soluble antioxidants may affect phagocytosis of apoptotic cells *via* inhibition of PS peroxidation.

1098 HOW MUCH PHOSPHATIDYLSERINE (PS) IS ENOUGH FOR MACROPHAGES TO RECOGNIZE TARGET APOPTOTIC CELL?

G. G. Borisenko, T. Matsura, S. Liu, J. Jianfei, F. B. Serikan and V. E. Kagan. *Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

PS usually confined to the internal leaflet of plasma membrane (PM) is externalized on the cell surface during early apoptosis. Externalized PS (PSex) is required for effective phagocytosis and clearance of apoptotic cells by macrophages (MΦ). Others & we found in normal cells PS asymmetry is not absolute suggesting the amount of PS on cell surface is important for MΦ recognition of dead *vs.* live cells. Therefore, we developed a new sensitive method to quantify the amount of PSex. This method is based on the binding of annexin V conjugated with iron beads to PS. Because the beads have a strong iron EPR signal cells containing PSex can be labeled with annexin V-beads (AV-B) and assayed by EPR spectroscopy. We prepared Jurkat cells with known amounts of added PS on their surface by fusing them with PS-containing liposomes. EPR signal magnitude from AV-B labeled cells linearly depended on the amount of PSex. AV-B labeling was specific due to annexin-PS interaction as confirmed by low EPR signal magnitude from cells labeled with beads alone. We found that normal cells on average contains ~0.04 nmol of endogenous PSex/10^6 cells. To determine the level of PS sufficient for triggering phagocytosis, we prepared cells with different amounts of PSex. Phagocytosis percent as determined by fluorescence microscopy depended non-linearly on the level of PSex. In contrast to linear elevation of PSex, phagocytosis had a pronounced lag-phase at low amounts of PS and increased markedly, when PSex exceeded 0.2 nmol/10^6 cells. EPR signal from cells in which apoptosis was induced by camptothecine revealed that at least 1 and 4 nmol PS/10^6 cells were externalized after 1 and 4 h. Thus, MΦ have a sensitivity threshold for the amount of PS on the surface of target cells. Normal cells contain very low levels of PSex that dramatically increased during apoptosis providing reliable recognition of apoptotic cells by MΦ.

1099 ATTENUATION OF CD95-INDUCED T CELL APOPTOSIS BY INORGANIC MERCURY: COMPARISON BETWEEN THE EFFECTS OF MERCURY AND OTHER GROUP II METALS.

G. McCollum[1], A. J. Rosenspire[2] and M. J. McCabe[1]. [1]*Department of Environmental Medicine, University of Rochester, Rochester, NY and* [2]*Department of Biological Sciences, Wayne State University, Detroit, MI.*

Mercury (Hg), a metal implicated in systemic autoimmune disease, selectively dysregulates CD95-mediated apoptosis. Such dysregulation may be one mechanism that contributes to the accumulation of autoreactive lymphocytes. We have found that submicromolar Hg concentrations impair CD95 induced apoptosis in Type-I (HUT-78) and Type-II (Jurkat) T cell lines as well as in normal human activated $CD4^+$ T cells. Hg blocked the CD95-induced activation of caspase-8, caspases -3 and -7, as well as the association between CD95 and the signaling adaptor, Fas-associated protein with death domain. Multimerization of CD95 on the cell surface was not affected by Hg. Thus, the Hg sensitive step within the CD95 death pathway localizes to the death inducing signaling complex (DISC). Disruption of DISC formation and the downstream activation of caspases may be a mechanism whereby Hg contributes to autoreactivity. Although no clear linkages between other Group II metals (i.e., cadmium, zinc) and autoreactivity have been established, these metals have been shown to inhibit apoptosis in various cells. Thus, we compared the effects of Cd and Zn with Hg on CD95-induced apoptosis. Using Jurkat cells, the influences of Cd and Zn on CD95-mediated caspase-3 activation were investigated. Caspase-3 is an important effector of apoptosis, as many apoptotic inducers converge at its activation. Caspase-3 enzyme activity was assessed in CD95-agonist stimulated Jurkat cells exposed to Cd (0.05-5 μM)or Zn (5-500 μM). A dose-dependent inhibition of caspase-3 activity was noted for both Cd and Zn; however, unlike Hg we suspect that this caspase-3 inhibition is not selective for the CD95 pathway. Cd and Zn likely inhibit caspase-3 directly. As such, CD95-mediated apoptosis is not selectively inhibited by Cd and Zn inhibition, which may explain why there is limited evidence linking these metals with autoimmune disease. Supported by R21ES10351 and T32ES07026.

1100 BIOLUMINESCENT DETECTION OF P53 *IN VITRO* AND *IN VIVO* IN RESPONSE TO DNA DAMAGING AGENTS.

L. Esposito, P. Kwon, C. Yu, D. J. McMullen and L. C. Sambucetti. *Xenogen Corporation, Alameda, CA.* Sponsor: K. Steinmetz.

We have designed tumor cell-based models with the potential to detect apoptotic activity following exposure to genotoxic agents. p53, a known regulator of apoptotic activity in response to DNA damage, is frequently mutated, absent, or modulated in tumor cells. For this study, a luciferase reporter vector that contained p53-response elements upstream of a minimal TK promoter and the luciferase structural gene (p53RE-luc) was used to detect activation of p53 pathways by bioluminescence. Two human lung carcinoma cell lines, A549 cells (p53wt) and H1299 cells (p53-/-), were transfected with p53RE-luc, treated with doxorubicin or cisplatin. Luciferase activity was measured 24 and 48 hours post-treatment. In A549 cells, doxorubicin (0.01 to 0.30 μM) and cisplatin (0.30 μM to 30 μM) produced dose-related increases in luciferase activity when compared to vehicle-treated cells. As expected, luciferase activity was not induced in treated H1299 cells since these cells do not express p53. These results suggest that the observed response of A549 cells to genotoxic agents was mediated by p53. When H1299 and A549 cells were co-transfected with a p53-expression vector and p53RE-luc, p53 expression was dramatically induced in H1299 cells but not in A549 cells. These findings indicate that A549 cells, which are p53 competent, may modulate p53 activity by post-translational modifications. Western blot analysis showed increased phosphorylation of p53 at Ser15 following doxorubicin treatment. This modification has been associated with increased p53 activity. Athymic mice implanted with these bioluminescent reporter cell lines showed increased p53 activity within 6 hr after doxorubicin treatment, which was similar to the results obtained *in vitro*. These findings suggest that the p53RE-luc reporter may provide a rapid, *in vivo* assay that can be used to detect the activity of DNA damaging agents.

1101 SENSITIZATION OF DRUG-RESISTANT B-LYMPHOMA CELLS TO ARSENITE-INDUCED APOPTOSIS BY PHARMACOLOGICAL MANIPULATION OF MAP KINASE PATHWAYS.

D. E. Muscarella. *Microbiology and Immunology, Cornell University, Ithaca, NY.* Sponsor: S. Bloom.

Trivalent arsenic, or arsenite, is a potent inducer of mitogen-activated protein kinase (MAP) pathways, stress proteins, and apoptosis, and is clinically useful in the treatment of some hematopoietic malignancies. However, the signaling pathways

that regulate the induction of apoptosis by arsenite in hematopoietic cells are only partially known. I studied the activation of MAP kinases by sodium arsenite in a panel of B-cell lines derived from human Burkitt's lymphoma that show marked differences in their susceptibility to apoptosis induction, and investigated the hypothesis that treatments that effectively modulate MAP kinase activity can potentiate apoptosis induction in resistant cells. I found that the apoptosis-sensitive ST486 cell line differed from the apoptosis-resistant EW36 cell line, which over-expresses the Bcl-2 protein, with respect to the requirement for activation of the c-jun N-terminal kinase (JNK) pathway for apoptosis induction. Specifically, the sensitive cell line, ST486, underwent extensive arsenite-induced apoptosis at concentrations below 20 micromolar, which do not activate JNK. In contrast, JNK activation, which occurred only at higher concentrations of arsenite exposure, was required for apoptosis induction in the EW36 cell line. Furthermore, the EW36 cells were substantially sensitized to arsenite-induced apoptosis by exposure to prior, non-lethal hyperthermia. Moreover, pretreatment of EW36 cells with a pharmacological inhibitor of p38 MAP kinase also potentiated arsenite-induced apoptosis, and acted synergistically with hyperthermia to further sensitize these cells. Significantly, the experiments revealed that sensitization of EW36 cells is mediated by activation of the JNK pathway and that pharmacological inhibition of the p38 pathway acts synergistically with hyperthermia to overcome Bcl-2 mediated resistance to apoptosis by prolonging a transient period of JNK phosphorylation that occurs immediately after heat shock treatment. (Supported by NIEHS RO1 ES10815)

1102 FATTY ACID RELEASE AND OXIDATION AS FACTORS IN THE APOPTOSIS INDUCED BY LIPOXYGENASE INHIBITORS.

E. La and J. P. Kehrer. *Dept. of Pharmacology and Toxicology, College of Pharmacy, The University of Texas at Austin, Austin, TX.*

MK886, an inhibitor of 5-lipoxygenase activating protein (FLAP), and the general lipoxygenase (LOX) inhibitor nordihydroguaiaretic acid (NDGA), induce apoptosis by mechanisms independent of both lipoxygenase (*J. Biol. Chem.* **273:** 28163 (1998)) and FLAP (*Biochem. J.* **340:** 371 (1999)). FLAP can be considered a fatty acid binding protein (FABP), and we have hypothesized that MK886 can affect fatty acid binding at a number of FABP sites. Such an effect may increase intracellular levels of unbound fatty acids, particularly arachidonic acid (AA), and activate apoptosis signaling pathways either directly or following oxidation. In murine pro-B FL5.12 cells, MK886 (10 μM), baicalein (a LOX inhibitor) (50 μM) and NDGA (10 μM) significantly enhanced the release of [^{3}H]-AA within 2 h and induced apoptosis by 8 h. The presence of peroxides after treatment of FL5.12 cells with these agents was assessed by the ferrous oxidation-xylenol orange assay as well as by loading cells with carboxy-dichlorofluorescin and assessing its oxidation by flow cytometry. Peroxides were evident with both methods 1 h after treatment with MK886 or baicalein, but not NDGA. NDGA did, however, increase the production of glutathione disulfide. Isoprostane formation was measured as an additional index of lipid peroxidation. By both an ELISA and GC-MS assay, isoprostane levels were increased 3-fold 2 h, and 4-fold 4 h after MK886 or baicalein, but not after NDGA. The addition of AA (25-50 μM) directly to FL5.12 cells, induced apoptosis. In addition, pretreatment with PPARγ ligands (ciglitazone, 15δPGJ2, troglitazone) to increase PPAR (another type of fatty acid binding protein) enhanced the toxicity of MK886. These data support the hypothesis that fatty acids are released and oxidized species are generated in cells undergoing apoptosis in response to treatment with MK886, baicalein and NDGA. The time-course of formation of these species is consistent with their having a causal role in apoptosis. (Supported by NIH grant CA83701.)

1103 HUMAN MITOCHONDRIAL THIOREDOXIN (MTTRX) CONFERS RESISTANCE TO OXIDANT-INDUCED APOPTOSIS.

Y. Chen[1], J. Cai[2] and D. P. Jones[2]. [1]*Program of Biochemistry, Cell and Developmental Biology, Emory University, Atlanta, GA and* [2]*Department of Biochemistry, Emory University, Atlanta, GA.*

Oxidant damage to mitochondria is a central mechanism of apoptosis induced by many toxic chemicals. Thioredoxin family proteins share a conserved Cys-X-X-Cys motif at their active center and play important roles in control of cellular redox state and protection against oxidative damage. In addition to the well studied cytosolic and extracellular form (Trx1), a rat mitochondrial form of thioredoxin (mtTrx) has been reported. In this study, we cloned the human mtTrx gene based on available human genome sequencing data and performed localization and functional studies in 143B human osteosarcoma cells. The cloned gene has a putative mitochondrial localization signal (MLS) at its N-terminus. In stably transfected cell lines, mtTrx had a mitochondrial localization as measured by indirect immunostaining and confocal fluorescence microscopy. Subcellular fractionation studies showed that deletion of the MLS rendered it to be solely expressed in the cytosolic fraction. On SDS-PAGE, transfected mtTrx had the same apparent molecular weight as the MLS truncated form, indicating that the leader sequence is cleaved after being imported into mitochondria. Treatment with the oxidant tert-butylhydroperoxide (tBH) induced apoptosis in 143B cells. This oxidant-induced apoptosis was inhibited by overexpression of the full-length mtTrx in 143B cells but not in transfection controls. Thus, human mtTrx functions in protection against oxidant-induced apoptosis. (Supported by NIH grant ES 09047).

1104 OXIDATION AND EXTERNALIZATION OF PHOSPHATIDYLSERINE ON ACTIVATED NEUTROPHIL-LIKE CELLS: ROLE IN APOPTOSIS AND PHAGOCYTIC CLEARANCE.

A. Arroyo[1], M. Modrianský[2], F. B. Serinkan[1], R. I. Bello[3], T. Matsura[1], V. A. Tyurin[1], Y. Y. Tyurina[1] and V. E. Kagan[1]. [1]*Environmental & Occupational Health, University of Pittsburgh, Pittsburgh, PA,* [2]*Medical Chemistry & Biochemistry, Palacký University, Olomouc, Czech Republic and* [3]*Cell Biology, Physiology & Immunology, University of Córdoba, Córdoba, Spain.*

To prevent calamitous release of reactive oxygen species (ROS), macrophages remove excess activated neutrophils from an inflammatory site in a regulated way, through processes that ensure swift resolution of inflammation yet make provision for neutrophils to fulfill their microbicidal function. Clearance of activated neutrophils from inflamed areas is achieved *via* their apoptosis whose mechanisms are still poorly understood. In the present work, DMSO-differentiated HL-60 cells were used as a model to study NADPH oxidase-induced apoptosis pathways typical of neutrophils. Activation of NADPH oxidase by phorbol myristate acetate (PMA) caused oxidative stress shown by massive superoxide production and depletion of intracellular glutathione content. Importantly, among the major classes of phospholipids, preferential oxidation of phosphatidylserine (PS) occurred in cells upon PMA stimulation, along with its externalization on the cell surface. Furthermore, PMA stimulation of NADPH oxidase caused apoptosis as evidenced by chromatin condensation and nuclear and DNA fragmentation, and recognition and ingestion of stimulated cells by J774A.1 macrophages. Inhibition of NADPH oxidase by either diphenylene iodonium (DPI) or staurosporine or by scavenging of ROS by SOD/catalase inhibited expression of apoptotic biomarkers and prevented oxidation and externalization of PS. Furthermore, inhibition of NADPH oxidase-induced ROS production reduced recognition and phagocytosis by J774A.1 cells. We conclude that NADPH oxidase-induced oxidative stress in neutrophil-like cells triggers apoptosis and subsequent recognition and removal of apoptotic cells from inflammatory sites through pathways dependent on oxidation and externalization of PS.

1105 CYCLOPENTA POLYCYCLIC AROMATIC HYDROCARBONS INDUCE CYTOCHROME P450 1A1, ACCUMULATION OF CELLS IN S-PHASE AND APOPTOSIS IN MOUSE HEPATOMA (HEPA 1C1C7) CELLS.

A. Solhaug, M. Refsnes, M. Låg, P. E. Schwarze and J. A. Holme. *Environmental Medicene, National Institute of Public Health, Oslo, Norway.* Sponsor: E. Dybing.

Cyclopenta polycyclic aromatic hydrocarbons (CP-PAH) are formed by incomplete combustion of organic material. The CP-PAH cyclopenta(c, d)pyrene (CPP) has been detected in diesel and automobile exhaust at levels 5-20 times higher than the well known PAH benzo(a)pyrene (B(a)P). CPP has been found to be highly mutagenic in both bacterial and mammalian cells, and to induce tumors in mouse skin and lung. Two others CP-PAH, benz(j)aceanthrylene (B(j)A) and benz(l)aceanthrylene (B(l)A), have been shown to produce lung adenomas and to be potent skin tumor-initiating agents in mice with approximately the same activity as B(a)P. Hepa 1c1c7 cells constitute a powerful experimental system for studying the effects of PAH. Here we show that B(j)A was as potent as B(a)P to induce CYP1A1 in these cells as determined by Western blotting. With CPP only a small increase in the level of CYP1A1 was seen, furthermore CPP also caused an increase in CYP1A2. All the compounds resulted in accumulation of cells in the S-phase. At higher concentrations/later time points an increasing number of dead cells appeared. A major part of these cells was apoptotic judged by microscopy, flow cytometric analysis and DNA laddering. The addition of α-naphthoflavone, an inhibitor of CYP1A1, almost abolished the induced apoptosis and accumulation of cells in S-phase, whereas antioxidants had no or only minor effects. The caspase inhibitor z-VAD.fmk partially reduced the number of apotoptic cells. As judged by Western blotting, B(a)P and the CP-PAH increased the levels of p53 and bax, whereas a decreased level of bcl-2 was seen. Furthermore, the levels of several procaspases (-3, -7, -8) were down regulated. The mitogen-activated protein kinases (MAPKs) also seemed to be involved in the apoptotic process. Both the addition of SB202190 (an inhibitor of p38), and DP98059 (an inhibitor of ERK) reduced the apoptosis and accumulation of cells in S-phase.

1106 P38-MITOGEN-ACTIVATED-PROTEIN-KINASE-MEDIATED BAX TRANSLOCATION INITIATES CYTOCHROME C RELEASE IN CYANIDE-INDUCED APOPTOSIS.

Y. shou, J. L. Borowitz and G. E. Isom. *Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN.*

Cytochrome c release from mitochondria is a critical event in cyanide-induced apoptosis. To determine how cyanide treatment initiated cytochrome c release, we investigated endogenous Bax translocation in primary cultured cortical neurons. Under normal conditions, Bax resided mainly in cytoplasm. After 300 μM cyanide treatment for 1hr, Bax translocated specifically to the mitochondria as shown by immunocytochemical staining and western blotting analysis. Bax translocation preceded cytochrome c release from the mitochondria, which was initiated 3 hr after cyanide treatment. To determine that the translocation of Bax to mitochondria initiated cytochrome c release, double immunofluorescence labeling for both Bax and cytochrome c was used. This study showed that cytochrome c was released only in cells harboring Bax in mitochondria. In cells where Bax translocation did not occur, cytochrome c was still associated with mitochondria. P38 mitogen-activated protein (MAP) kinase was involved in regulating Bax translocation in cyanide-induced apoptosis. This kinase was activated 30 min after cyanide and its phosphorylation began to decrease 3 hr later. SB203580, a specific p38 MAP kinase inhibitor, blocked translocation of Bax to mitochondria. Inhibition of p38 MAP kinase by SB203580 blocked all downstream effects of Bax translocation including cytochrome c release, caspase activation and DNA fragmentation. These results demonstrated that Bax translocation was critical for cyanide-induced cytochrome c release and p38 MAP kinase was involved in regulating Bax translocation from the cytosol to mitochondria. (Supported by NIH grant 04140)

1107 APOPTOTIC EFFECT OF LINOLEIC ACID ON 15LO OVEREXPRESSING ENDOTHELIAL CELLS.

D. J. Millington Banks, J. R. Haskins, R. Maher and J. Cornicelli. *Drug Safety Evaluation, Pfizer, Ann Arbor, MI.*

The development of atherosclerosis is postulated to occur *via* endothelium alterations caused by unsaturated fatty acids and inflammatory cytokines. To test the hypothesis that 15-lipoxygenase (15-LO), a non-heme iron-containing enzyme, causes oxidant injury and apoptosis in endothelial cells the following experiment was conducted. ECV-304 (parental line) and ECV-LO cells (ECV-304 cells stably transfected with human 15-LO) were treated for up to 4 hr with 0, 50, 100, 200 μM linoleic acid (LA) and/or 7.5 μM NDGA, a non-specific inhibitor of lipoxygenase. Apoptosis was monitored by measuring changes in cellular status such as oxidative stress, intracellular calcium homeostasis, F-actin content, nuclear morphology, mitochondrial potential and c-Jun N-terminal kinase (JNK) activity. A 2-fold increase in oxidative stress occurred in ECV-LO compared to ECV-304 cells within 30 min of 200 μM LA. Nuclear fragmentation, decreased mitochondrial potential, and a significant decrease in F-actin content were seen within 15-60 min of 100 μM LA treatment in ECV-LO cells. Similarly, significant decreases in F-actin content and mitochondrial potential were seen in parental cells compared to control. However, these cells also had significant nuclear condensation within 30-60 min of treatment. Pretreatment of ECV-LO cells with NDGA inhibited nuclear fragmentation caused by 100 μM LA, but had no effect on observed decreases in mitochondrial potential or F-actin content. No effect on JNK activity was noted. Significant increases in intracellular calcium occurred in ECV-LO cells within 15 min of LA treatment. These results suggest that LA produces DNA fragmentation and oxidative stress in the endothelium as early as 15 min posttreatment. Mobilization of intracellular calcium may contribute to the apoptotic events observed in these cells.

1108 DMBA-INDUCED PRE-B CELL APOPTOSIS : INTRACELLULAR SIGNALING PATHWAYS.

H. Y. Ryu, J. J. Schlezinger, B. A. Jensen and D. H. Sherr. *Environmental Health, Boston University School of Medicine and Public Health, Boston, MA.*

The purpose of this study was to investigate intracellular signaling pathways of PAH-mediated, pre-B cell apoptosis and to compare these pathways to those activated in immature B cells. Apoptosis of immature WEHI-231 B cells induced by IgM crossing linking models deletion of autoreactive clones. Dexamethasone(Dex), which also induces B cell apoptosis, has been used to define apoptosis mechanisms in these cells. In both cases, WEHI-231 cell apoptosis is preceded by an increase in expression of $p27^{kip1}$ and $p21^{WAF1}$, growth arrest, NF-κB inactivation, and a reduction in NF-κB-regulated c-Myc expression. All of these changes play a causal role in WEHI-231 growth arrest and apoptosis. Previously, we demonstrated that prototypic PAHs, including DMBA, induce pre-B cell apoptosis in co-cultures of a pre-B cell line(BU-11) and cloned bone marrow stromal cells(BMS2). Similar to system employing immature WEHI-231 cells, DMBA treatment was shown herein to induce down-regulation of NF-κB activity, as assayed in EMSAs with oligonucleotide probes derived from the *c-myc* promoter, and c-Myc expression prior to pre-B cell death. However, unlike the WEHI-231 system, DMBA did not induce pre-B cell growth arrest and did not increase $p27^{kip1}$ or $p21^{WAF1}$ expression. Furthermore, Dex induced pre-B cell growth arrest and c-Myc down-regulation without down-regulating NF-κB or inducing apoptosis. These results indicate that: 1) pre-B cells and immature B cells can undergo apoptosis through distinct mechanisms which may or may not involve $p27^{kip1}$ or $p21^{WAF1}$, 2) growth arrest is not required for apoptosis in all B cell subsets(e.g. DMBA-treated pre-B cells), and 3) NF-κB and c-Myc down-regulation is common to apoptosis pathways activated in immature B cells by surface Ig cross-linking or Dex treatment and to apoptosis pathways initiated in pre-B cells by DMBA treatment. These results help define environmental chemical-induced apoptosis pathways and demonstrate the utility of these chemicals in dissecting apoptosis signaling pathways in normal B lymphocytes.

1109 REGULATION OF APOPTOSIS SENSITIVITY TO MITOCHONDRIAL TOXICANTS AND PESTICIDES BY BCL-2 PROTEIN AND MAP KINASES IN LYMPHOID CELL LINES.

S. E. Bloom and D. E. Muscarella. *Microbiology and Immunology, Cornell University, Ithaca, NY.*

The toxicity of environmental chemicals towards lymphoid cells appears to involve several components of the apoptotic machinery such as mitochondrial alterations, Bcl-2 proteins, and MAP kinase pathways. However, it remains to be determined how, and to what extent, each of these components influences cellular sensitivity or resistance to chemicals. The present study was designed to examine the relative contributions of Bcl-2 protein expression and MAP kinase signaling to the sensitivity of T-lineage lymphoid cells to chemicals targeting mitochondrial functions. The agents included the uncoupler carbonyl cyanide m-chlorophenylhydrazone (mClCCP) and the respiratory chain inhibitor rotenone (ROT). The herbicide alachlor was included in the study to ascertain whether Bcl-2 proteins may regulate its immunotoxic effects. A Jurkat wild-type (J-wt) cell line and a Jurkat Bcl-2 (J-bcl) stably transfected cell line were exposed for 24 and 48 hr to the three chemicals and assayed for the induction of apoptosis with the DNA-specific fluorochrome Hoechst 33342 and PARP cleavage. Immunoblotting analyses for MAP kinases and c-jun expression were performed at intervals from 2 to 8 hr. Alachlor, mClCCP, and ROT induced apoptosis extensively (50-60%) in J-wt cells but hardly in J-bcl cells. mClCCP failed to activate the p38 and JNK pathways. The constitutive levels of activated ERK (P-ERK) declined in a concentration-dependent manner and with similar kinetics in the two cell lines. ROT activated p38 similarly in the two cell lines, and P-ERK declined similarly with increasing concentration and duration. JNK was activated and c-jun expression preferentially induced in J-bcl cells from 2-8 hr. These results show a strong influence of Bcl-2 protein in the apoptotic resistance of T-lineage lymphoid cells to mitochondrial toxicants and pesticides. Bcl-2 related chemo-resistance is associated with prolonged expression of c-jun. Thus, multiple levels of regulation appear to underlie the chemo-sensitivity and resistance of particular T-lymphoid cell lineages.

1110 SPECIES DIFFERENCES IN THE METABOLISM AND TOXICITY OF 3-BUTENE-1, 2-DIOL.

C. L. Sprague and A. A. Elfarra. *Comparative Biosciences, University of Wisconsin-Madison, Madison, WI.*

3-Butene-1, 2-diol (BDD) is a urinary metabolite of 1, 3-butadiene (BD), a known rodent and human carcinogen. BDD is formed by cytochrome P450-mediated oxidation of BD to butadiene monoxide (BMO) and subsequent hydrolysis of BMO to BDD mediated by epoxide hydrolase. When male B6C3F1 mice were given BDD (250 mg/kg, ip) they excreted approximately 5% of the BDD dose into urine as BDD and its glucuronide and/or sulfate conjugates within 24 h after treatment. These results were confirmed in the present study, which also examined BDD metabolism and toxicity in male Sprague-Dawley rats which are considered less susceptible to BD-induced carcinogenicity in comparison with B6C3F1 mice. Surprisingly, the 250 mg/kg BDD dose was lethal in 2 of the 4 rats given BDD during the 24 h collection period; all of the rats given this BDD dose exhibited hemorrhagic signs. When rats were given a lower BDD dose (125 mg/kg, ip), they did not exhibit any toxicity and there were no alterations in their liver or kidney function tests. Trace amounts of 1-hydroxy-2-butanone, 2-ketobutyric acid, and propionic acid were detected in both mouse and rat urine. However, rats excreted significantly higher amounts of BDD and BDD conjugates in the urine than mice. Because the amounts of BDD and its glucuronide and/or sulfate conjugates recovered in rat urine did not decrease at the low BDD dose, the results suggest saturation of BDD elimination into rat urine at the high dose. Collectively, the results demonstrate significant species differences in the metabolism and toxicity of BDD. The results are also consistent with the previous identification of hydroxymethylvinyl ketone and

1-hydroxy-2-butanone as *in vitro* metabolites of BDD. (Supported by NIEHS grant ES06841. CLS was supported by an Institutional Chemistry-Biology Training grant from NIGMS).

1111 ENANTIOSELECTIVE METABOLISM AND INHIBITION OF GLUTAHIONE TRANSFERASE-ZETA BY BROMOCHLOROACETIC ACID.

S. R. Sylvestor[1], J. Kato-Weinstein[1] and J. R. Schultz[2]. [1]*Washington State University-Vancouver, Vancouver, WA and* [2]*Battelle PNL-MSL, Sequim, WA.*

Bromochloroacetic acid (BCA) is a chiral di-haloacetate (di-HAs) that may arise as a drinking water disinfection by-product. Chlorinated and brominated di-HAs are metabolized by glutathione transferase zeta (GSTZ1-1) to either form glyoxylate or cause suicide inactivation of the enzyme. To better understand the molecular events involved in (-), (+) BCA metabolism, we expressed and purified recombinant mouse GSTz and examined the metabolism and suicide substrate qualities of the separate enantiomers of BCA. We also studied the effect of in-vivo and *in vitro* exposure to (-) and (+) BCA on the GSTz activity in hepatic cytosol from male F344 rats. Experiments were also repeated in cytosol obtained from male rats previously treated with dichloroacetic acid to deplete GST-zeta activity. Results using purified GSTz and reduced glutathione as a co-factor indicated only (-) BCA produced glyoxylate. When the enzyme was preincubated with selected di-HAs and glutathione, dialyzed and then assayed with dichloroacetic acid (DCA), both (-)BCA and (+)BCA were found to inactivate the enzyme with similar potency. The inhibition of GSTz by BCA was also shown to be substantially greater than that observed with DCA. Results of cytosol experiments indicated that metabolism of (-)BCA was greatly reduced by modulating GSTz activity in contrast to (+) BCA which was unaffected. Drinking water exposure to (+) BCA concentrations as low as 1.4 mg/l were found to decrease GSTz activity in liver cytotsol. These results indicate (+) BCA is a potent mechanism based inhibitor of GSTz and its metabolism to glyoxylate is controlled by an additional GST isoenzyme as yet uncharacterized. Supported by EPA STAR grant R825954.

1112 ACRYLAMIDE: METABOLISM AND HEMOGLOBIN ADDUCTS FOLLOWING INTRAPERITONEAL, DERMAL, OR INHALATION EXPOSURE.

S. C. Sumner, C. C. Williams, R. Snyder, W. Krol and T. R. Fennell. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Occupational exposure to acrylamide (AM) *via* dermal contact or inhalation may occur during use as an intermediate in the production of polymers, or during the use of AM-containing grouting materials. In this study, AM-derived urinary metabolites and hemoglobin adducts were measured in rats and mice following inhalation exposure and in rats following intraperitoneal (ip) and dermal administration. No mortality occurred from a 6-hr exposure to 5.6 ppm AM-vapor. Rats exposed for 6 hr to 3 ppm [^{13}C /^{14}C]AM-vapor had a lower uptake (90 µmol [^{14}C]AM equiv /kg bw) than mice (245 µmol/kg bw). AM-derived ^{14}C was excreted in 24-hr urine and feces (42% of recovered ^{14}C in rats, 51% mice) or recovered in tissues (56% rats, 46% mice). Following dermal application of 162 mg/kg [^{14}C]AM for 6 hr, 22% of the applied dose was absorbed and distributed to the excreta (44%) or tissues (53%) by 24 hr. Following ip administration of [^{13}C]AM, 62% of the dose was excreted in 0-24-hr urine. In rats, metabolites derived from AM conjugation with glutathione (AM-GSH) accounted for 69% (ip), 52% (dermal), and 64% (inhalation) of the urinary metabolites. In mice, the AM-GSH pathway accounted for only 27% of the urinary metabolites. Remaining metabolites were derived from oxidation of AM to glycidamide (GA). Hemoglobin adducts of AM [*N*-(2-carbamoylethyl)valine, AAVal] and GA [*N*-(2-carbamoyl-2-hydroxyethyl)valine, GAVal] were analyzed by liquid chromatography mass spectrometry. AAVal in rats was 12900 ± 652 (ip), 6398 ± 2979 (dermal), and 1207 ± 127 fmol/mg globin (inhalation), while GAVal was 9031 ± 464 (ip), 10010 ± 3149 (dermal), and 1339 ± 206 fmol/mg globin (inhalation). In mice, AAVal was 1431 ± 509, and GAVal was 4853 ± 564 fmol/mg (inhalation). GAVal:AAVal ratios were 0.7 (i.p. rat), 1.56 (dermal rat), 1.3 (inhalation rat), and 3.4 (inhalation mouse). This study demonstrates marked species and route differences in the metabolism and internal dose (Hb-adducts) of AM and GA. [Funded by the Polyelectrolye Producers Group]

1113 BIOTRANSFORMATION OF 1, 1, 1, 3, 3-PENTAFLUOROPROPANE.

T. Bayer[1], W. Dekant[1], A. Amberg[1], G. F. Rusch[2] and M. W. Anders[3]. [1]*Department of Toxicology, University of Wuerzburg, Wuerzburg, Germany,* [2]*Honeywell, Morristown, NJ and* [3]*Department of Pharmacology and Physiology, University of Rochester, Rochester, NY.*

1, 1, 1, 3, 3-Pentafluoropropane (HFC-245fa) is developed as an alternative to replace chlorofluorocarbons. HFC-245fa has only low toxicity, the only toxic effect seen in rats after inhalation exposure to HFC-245fa in concentrations of up to 50 000 ppm for 90 days was an increased incidence of diffuse myocarditis. To elucidate the role of biotransformation in HFC-245fa toxicity, we studied its biotransformation in rats after inhalation and in rat and human liver microsomes. Rats (n = 5) were exposed to 50 000, 10 000, and 2 000 ppm HFC-245fa for 6 h, urine was collected for 72 h and metabolites excreted were identified by 19F-NMR and quantified by GC/MS. Trifluoroacetic acid and inorganic fluoride were identified as major urinary metabolites of HFC-245fa, 3, 3, 3-trifluoropropanoic acid and 1, 1, 1, 3, 3-pentafluoropropane-2-ol were minor metabolites. After inhalation exposure to 50 000 ppm HFC-245fa, a total of 3 929 ± 441 nmol of trifluoroacetic acid were recovered in urine in males and 3 054 ± 416 nmol in females; trifluoropropanoic acid in urine amounted to 79.3 ± 14.3 nmol in male and 9.1 ± 3.3 nmol in female rats. Extent of HFC-245fa biotransformation after inhalation of 10 000 ppm and 2 000 ppm was linearily dependent on exposure concentrations. In liver microsomes, HFC-245fa was transformed by a cytochrome P450 dependent reaction to trifluoroacetic acid and trifluoropropanoic acid. Rates of formation of trifluoroacetic acid were 99.2 ± 20.5 pmol/mg x min and of trifluoropropanoic acid were 17.5 ± 4.0 pmol/mg x min in rat liver microsomes. In human liver microsomes, rates of formation of trifluoroacetic acid ranged from 0 to 30.4 pmol/mg x min and rates of trifluoropropanoic acid ranged from 0.7 to 7.6 pmol/mg x min. The obtained results suggest that HFC-245fa is metabolized at very low rates *in vivo* and *in vitro*. The toxic effects of HFC-245fa may be due to the formation of the minor metabolite trifluoropropanoic acid, which is highly toxic in rats.

1114 TOXICOKINETICS OF BISPHENOL A IN HUMAN SUBJECTS.

W. Dekant, E. Lederer, N. Wolf, T. Colnot and W. Völkel. *Department of Toxicology, University of Wuerzburg, Wuerzburg, Germany.*

Bisphenol A is a widely used chemical and is a weak estrogen *in vitro* and in rats *in vivo*. In rats, bisphenol A is only slowly eliminated after oral administration due to enterohepatic circulation of metabolites. To characterize toxicokinetics of bisphenol A in humans, 3 male and 3 female human subjects were orally given 5 mg d16-bisphenol A. d16-Bisphenol A was used due to background concentrations of bisphenol A interfering with quantitation. Urine and blood concentrations of d16-bisphenol A and its glucuronide were determined by GC/MS and LC/MS-MS at different time points. The study was performed with informed consent by the human subjects and approved by the local institutional review board. Free d16-bisphenol A could not be detected in blood and urine samples after d16-bisphenol A administration; the administered dose was completely recovered in urine as d16-bisphenol A glucuronide within 24 h. Bisphenol A glucuronide was cleared by first-order kinetics from blood and with urine with half-lives of < 6 h, no gender differences were observed in maximum blood concentrations and in rates of excretion. The obtained data show that d16-bisphenol A is completely absorbed from the gastrointestinal tract in humans after giving low doses and subject to a complete first-pass metabolism to give d16-bisphenol A glucuronide which is rapidly excreted. The species differences in d16-bisphenol A excretion kinetics between humans and rats are most likely due to the different threshold for biliary elimination. Due to rapid biotransformation to the glucuronide, bioavailability of the weakly estrogenic bisphenol A is very low and accumulation in the human body is not expected due to rapid excretion. This work was supported by Umweltbundesamt, Berlin, Germany.

1115 EXPRESSION AND ACTIVITY OF A NOVEL MUTATION IN THE HUMAN FLAVIN-CONTAINING MONOOXYGENASE 3 GENE.

B. Furnes[1], J. Zhang[2], J. Cashman[2] and D. Schlenk[1]. [1]*Environmental Sciences, University of California, Riverside, Riverside, CA and* [2]*Human Biomolecular Research Institute, San Diego, CA.*

Flavin-containing monooxygenases are microsomal drug- and pesticide-metabolizing enzymes implicated in the NADPH-dependant oxidation of a variety of soft nucleophiles. The FMO family comprise 5 isoforms, each demonstrating ontologic, species- and tissue-specific regulation. The major human isoform, liver FMO3, catalyzes the N-oxidation of trimethylamine. Activity of FMO3 is deficient in patients diagnosed with the autosomal recessive human disorder trimethylaminuria. Trimethylaminuria patients excrete relatively large amounts of trimethylamine and results in a fish-like odor of the urine, sweat and breath. Hypertensive crises following consumption of tyramine-containing foods as well as clinical depression have also been observed in patients suffering from trimethylaminuria. As part of a larger effort to establish the frequency of polymorphisms in the FMO family of genes in African-Americans, a novel mutation in FMO3 was found. One individual expressing the mutation demonstrated phenotypic signs of trimethylaminuria, but another did not. The mutation is a GAT to CAT transition at codon 132, resulting in a change from aspartic acid to histidine. The 132 codon is in a region that is well

conserved within the human FMO family. We introduced the mutation into wild-type FMO3 using site-directed mutagenesis and expressed both wild-type and mutated FMO3 as maltose-binding fusion proteins using the pMAL-c2 plasmid and the bacterial JM109 strain. The proteins were purified on an amylose-resin column and the activity of the enzyme was investigated with regards to trimethylamine, 5-DPT (10-[(N, N-Dimethylamino)pentyl]-2-(trifluoromethyl) phenothiazine) and the prototypic FMO3 substrate methimazole. Preliminary activity data indicates that the D132H mutation renders the enzyme virtually inactive.

1116 ROLE OF HUMAN FLAVIN MONOOXYGENASES IN THE SULFOXIDATION OF ALDICARB.

D. Schlenk[1], J. R. Cashman[2], C. Yeung[3], X. Zhang[1] and A. E. Rettie[3]. *[1]Environmental Toxicology Program, University of California, Riverside, Riverside, CA, [2]Molecular Toxicology, Human Biomolecular Research Institute, San Diego, CA and [3]Medicinal Chemistry, University of Washington, Seattle, WA.*

Biotransformation of the carbamate insecticide, aldicarb, to aldicarb sulfoxide has been shown to significantly elevate its anticholinesterase activity. However, it is unclear what enzymes are responsible for this bioactivation. In this study, 51 human liver microsome samples were prepared and aldicarb sulfoxidation was examined *in vitro* under saturating substrate incubations (200 uM). NADPH-catalyzed sulfoxidation activities were extremely variable and observed in 13 of 51 samples with a mean value of 0.034 +/- 0.17 nmol/min/mg. Coincubation with 0.1% Lubrol to inhibit contributions of cytochrome P450 failed to alter activities (0.036 +/- 0.26 pmol/min/mg). Benzydamine N-oxidation was also examined and was 2.57 +/- 1.66 nmol/min/mg and observed in all samples. FMO3 content was determined in all samples and demonstrated a significant correlation with benzydamine N-oxidation (r2=0.41), but FMO3 did not correlate with aldicarb sulfoxidation. Incubations of aldicarb with 5 recombinant flavin-monooxygenase isoforms indicated catalysis by FMO1>>FMO3 with no activity detected from FMO2, FMO4 or FMO5. These results indicated limited hepatic biotransformation of aldicarb in human liver microsomes, but suggests other tissues may be more important such as fetal liver, the intestine or kidney which possess FMO1.

1117 PHARMACOKINETIC INTERACTIONS BETWEEN PYRIDOSTIGMINE BROMIDE (PB) AND PERMETHRIN IN RATS.

A. W. Abu-Qare, A. A. Abdel-Rahman and M. B. Abou-Donia. *Pharmacology and Cancer Biology, Duke University Medical center, Durham, NC.*

A single oral dose of 13 mg/kg of PB, and a single dermal dose of 1.3 mg/kg of permethrin, alone and in combinations were applied to male rats. Other animals received an intravenous dose of 1.3 mg/kg of PB or 1.3 mg/kg of permethrin. Five rats were sacrificed at: 0.5, 1, 2, 4, 8, 24, 48, and 72 h after dosing. In rats treated with a single agent, 0.5 and 72 h after dosing, the application site retained 95% and 12% of PB, and 62% and 4% of permethrin, respectively. PB was not detected in the brain. Plasma peak concentrations were detected within 2 h for PB (1, 326 ng/ml), and within 24 h for permethrin (193 ng/ml). Bioavailability of PB, and permethrin was 28%, and 52%, respectively. N-methyl-3-hydroxypyridinium bromide a metabolite of PB was detected in plasma after 2 hr. Permethrin metabolites m-phenoxybenzyl alcohol, and m-phenoxybenzoic acid were identified in plasma, liver and kidney 24 h after administration. In urine, PB and its metabolite N-methyl-3-hydroxypyridinium bromide were identified. Urine contained m-phenoxybenzyl alcohol and m-phenoxybenzoic acid following application of permethrin. A total 30% of urinary excretion of permethrin was in the form of glucuronide and sulfate conjugates. Time-plasma concentration curves for PB and permethrin were fitted into a two and one compartment pharmacokinetic model, with a terminal half-life of elimination of 3.2 h, and 32.6 h for PB, and permethrin, respectively. Following combined intervenous dose of PB and permethrin, PB significantly increased Cmax, AUCplasma, T1/2, and decreased concentration of urinary metabolites of permethrin by 40% and 32%, 10%, and 22% respectively. Also, Cmax, AUCplasma of permethrin was significantly increased (26%, 30%). The results show that PB significantly altered the pharmacokinetic profile of permethrin through interfering with its metabolism and excretion. This is could be due to competition for metabolism enzymes. This work was supported in part by the US army Medical Research and Materiel Command under Contract DAMD 17-99-1-9020.

1118 COMPARISON OF RATES OF GLUTATHIONE (GSH)-CONJUGATION OF TRIHALOMETHANES.

M. K. Ross[1] and R. A. Pegram[2]. *[1]Curriculum in Toxicology, UNC, Chapel Hill, NC and [2]ORD/NHEERL, USEPA, Research Triangle Park, NC.* Sponsor: M. Evans.

Investigation into the mutagenic potencies of trihalomethanes (THMs; a class of water disinfection-by-products), mediated by GSH S-transferase (GST) theta, have described an association between a THM's bacterial mutagenicity and its degree of bromination. Tested halomethanes ranked as follows in mutagenic potency: $ClCHBr_2 \approx CHBr_3 >> BrCHCl_2 \approx CH_2Cl_2$. $CHCl_3$ was not mutagenic at doses comparable to mutagenic doses of $BrCHCl_2$. To enable a mechanistic understanding of these effects, we have characterized GSH conjugation rates to compare this data with bacterial genotoxicity results. Several *in vitro* kinetic assays have been performed using THMs, CH_2Br_2 or CH_2Cl_2 and GST theta 1-1. Using a gas-phase equilibration technique, loss of parent compound from the head-space (determined by GC-ECD) did not reveal differences between enzymatic and non-enzymatic rates for each THM; nor were differences in conjugation rates found when different THMs were compared. Similarly, no apparent rate trends were observed among the THMs when formaldehyde (HCHO) production was measured by the Nash assay; in contrast, CH_2Br_2 produced significant amounts of HCHO at equivalent concentrations. A more sensitive coupled assay that indirectly measures HCHO formation resulted in detectable rates for the following THMs (units: nmol•min^{-1}•mg protein^{-1}•mM THM^{-1}): $BrCHCl_2$ (0.22), $ClCHBr_2$ (0.23), $CHCl_3$ (0.05), $CHBr_3$ (<0.05). HCHO does not appear to be responsible for the THM-mediated bacterial mutagenicity as rates of HCHO formation from $BrCHCl_2$ and $ClCHBr_2$ were not different, while the HCHO formation rate from CH_2Cl_2 was ~20-fold greater than for $BrCHCl_2$. That CH_2Cl_2 and $BrCHCl_2$ are equally potent in terms of mutagenicity, yet have significantly different rates of GSH conjugation and HCHO production, argues for existence of two separate pathways responsible for bacterial genotoxicity of di- and tri-halomethanes; suggesting THM-derived intermediates are more DNA-reactive and/or produce adducts that are more mutagenic. (Abstract does not reflect EPA policy).

1119 7H-BENZO[c]FLUORENE *IN VITRO* METABOLISM.

J. Maciejewski[1], E. H. Weyand[1], L. Landmesser[1], L. S. Goldstein[2], J. Q. Wang[3] and R. G. Harvey[3]. *[1]Pharmaceutical Chemistry, Rutgers University, Piscataway, NJ, [2]Environment Sector, Electric Power Research Institute, Palo Alto, CA and [3]Ben May Institute for Cancer Research, University of Chicago, Chicago, IL.*

BENZO(C)FLUORENE (B[c]F) is tumorigenic in lung when administered to A/J mice. The mechanism by which B[c]F induces lung tumors is currently unknown, however, it is likely that the formation of B[c]F:DNA adducts play an important role in lung tumor induction. This study evaluates the *in vitro* metabolism of B[c]F in order to better understand the ability of B[c]F to form DNA adducts. A standard *in vitro* metabolism system using Aroclor induced rat liver S9 was employed. Metabolites were isolated using exhaustive ethyl acetate extraction and subsequently analyzed by reverse phase HPLC equipped with UV detection. The effect of reaction time and B[c]F substrate concentration were also evaluated. The 7-hydroxyB[c]F, 3-hydroxyB[c]F, and the 3, 4-dihydrodiolB[c]F metabolites were synthesized and used to characterize the oxidation products observed with B[c]F. At least 7 oxidation products of B[c]F were detected within a 60 minute reaction time. The HPLC retention time of 7-hydroxy B[c]F corresponded to a predominant B[c]F oxidation product. When reaction times were increased to 160 min this metabolite peak was further converted to a more polar derivative. These results demonstrate that B[c]F is metabolized to a range of oxidation products *in vitro* and that the 7-hydroxy B[c]F metabolite can be further converted to a more polar derivative. These results, combined with recent DNA binding studies indicating that 7-hydroxy B[c]F is limited in its ability to form DNA adducts when applied to mouse skin. This suggests that the formation of 7-hydroxyB[c]F is a detoxification product of B[c]F. (This research was supported funds from EPRI.)

1120 MECHANISM(S) OF DIFFERENTIAL INHIBITION OF HEPATIC AND PANCREATIC FATTY ACID ETHYL ESTER SYNTHASE BY INHIBITORS OF BETA-ESTERASES.

B. S. Kaphalia[1] and G. S. Ansari[1]. *[1]Pathology, University of Texas Medical Branch, Galveston, TX and [2]Pathology, University of Texas Medical Branch, Galveston, TX.*

In previous studies, we reported that hepatic fatty acid ethyl ester synthase (FAEES) activity compared to pancreatic FAEES is inhibited by tri-o-tolylphosphate (TOTP), and that metabolism of TOTP is prerequisite for inhibition of FAEES as well as esterase activity. We also found that FAEES/esterase activity is associated with carboxylesterase (CE) in the liver and cholesterol esterase (ChE) in the pancreas. To further understand the interrelationship between hepatic and pancreatic FAEES, we synthesized two active metabolites of TOTP, 2-o-(cresyl)-4H-1;3;2-benzodioxaphosphoran-2-one (CBDP; cyclic saligenin phosphate) and di-o-tolyl-o-(alpha-hydroxy) tolylphosphate (hydroxylated-TOTP). Inhibitory effect of CBDP and hydroxylated-TOTP were studied using rat post nuclear (PN) fractions of hepatic and pancreatic homogenates, and commercially available porcine hepatic CE and pancreatic ChE. FAEES as well as esterase activity of hepatic PN fraction, and commercial CE and ChE was inhibited by CBDP and hydroxylated TOTP in a dose- dependent manner using 0.01, 0.1 and 1 mg/ml concentrations. No inhibition of the FAEES/esterase activity was observed in the pancreatic PN fraction after

exposure to either TOTP metabolites. Both the activities in the hepatic PN fraction and commercial CE and ChE preparations by TOTP metabolites were found irreversible. Although, the differential effect of the TOTP metabolites on hepatic and pancreatic FAEES/esterase activity is in agreement with the results of our earlier *in vivo* and *in vitro* studies, the anomaly of the differential effect on pancreatic FAEES/esterase activity in the PN fraction and commercial ChE preparation by either metabolite is not understood. Therefore, further studies are in progress on identification of covalent adducts of FAEES and metabolic products of CBDP and hydroxylated-TOTP.

1121 HEPATIC GLUTATHIONE (GSH) CONJUGATION OF COUMARIN 3, 4-EPOXIDE (CE) IN MICE, RATS AND HUMANS.

J. D. Vassallo[1], S. M. Curry[1], K. L. Flitter[1], S. W. Morrall[1], C. D. Eads[1] and L. D. Lehman-McKeeman[2]. [1]*CPS, The Procter & Gamble Co., Cincinnati, OH and* [2]*DuPont Pharmaceuticals, Newark, DE.*

CE, a reactive metabolite of coumarin, is thought to mediate coumarin-induced hepatotoxicity in rats. In the absence of GSH, CE spontaneously rearranges to *o*-hydroxyphenylacetaldehyde (*o*-HPA), which is also hepatotoxic. Metabolic activation to CE is highest in mice, a species that shows no evidence of hepatotoxicity, thereby suggesting that detoxification reactions are likely to determine species differences in liver toxicity. The purpose of the present work was to characterize hepatic GSH conjugation of CE in rats, mice and humans. The GSH conjugate (CE-SG), formed at the 3-position, was isolated and used as a standard in an HPLC assay to quantify CE-SG. Non-enzymatic GSH conjugation was observed, accounting for approximately 45 and 80% of total CE-SG formed in mouse and rat liver, respectively. Glutathione S-tranferase (GST)-catalyzed formation of CE-SG was observed in rat and mouse liver cytosols, with the Vmax for this reaction slightly higher in mice than rats (2.3 nmol/min/mg and 1.7 nmol/min/mg, respectively). Rat and human recombinant GST enzymes of the alpha and mu class catalyzed formation of CE-SG. The rat A1-3 and human A1-1 had the lowest Km values, while the highest activities were observed with the rat M2-2 and human M1-1. However, no GST-catalyzed formation of CE-SG was observed with human liver cytosols, suggesting that the formation of *o*-HPA is favored over CE-SG in humans. These results suggest that detoxification of CE by GSH conjugation is not the major determinant of species sensitivity to coumarin hepatotoxicity and implicates the detoxification of *o*-HPA as the critical detoxification pathway.

1122 INFLUENCE OF MATRIGEL-OVERLAY ON CONSTITUTIVE AND INDUCIBLE EXPRESSION OF 9 GENES ENCODING DRUG METABOLIZING ENZYMES IN PRIMARY HUMAN HEPATOCYTES.

K. Gross-Steinmeyer[1], P. L. Stapleton[1], J. H. Tracy[1], T. K. Bammler[1], S. C. Strom[2] and D. L. Eaton[1]. [1]*Environmental Health, University of Washington, Seattle, WA and* [2]*Pathology, University of Pittsburgh, Pittsburgh, PA.*

Previous studies have shown that rodent hepatocytes overlaid with matrigel maintain expression of drug metabolizing enzymes, and restore the *in vivo*-like induction response of cytochromes P450 (CYPs). However, whether matrigel provides similar advantages for xenobiotic metabolism studies in primary human hepatocytes is uncertain. Therefore, this study evaluated the influence of matrigel-overlay on the constitutive, phenobarbital (PB) and oltipraz (OPZ)-inducible gene expression in primary human hepatocytes. Hepatocytes were isolated from 5 viable human livers that were rejected for transplantation for various reasons. Hepatocytes were maintained in hormone-supplemented William's E medium on a rigid collagen substratum overlaid either with matrigel or culture media alone, and treated for 48 h with 0.5 and 2 mM PB and 10 and 50 uM OPZ. The mRNA levels of 4 CYPs (1A1, 1A2, 2B6, 3A4) and 5 glutathione S-transferases (GSTs; A1, A2, M1, P1, T1) were determined by real-time RT-PCR. Protein levels of selected enzymes were assessed by immunoblot and activity analyses. Following PB treatment, mRNA expression of CYP2B6, 3A4, GSTA1/2 was increased; OPZ induced mRNA levels of CYP1A2, 2B6, GSTA1/2. Our findings demonstrate further that, in the majority of cases, human hepatocytes overlaid with matrigel showed markedly higher constitutive and inducible gene expression relative to hepatocytes with no matrigel. Furthermore, the constitutive expression of most of the genes in hepatocytes overlaid with matrigel was similar to those in corresponding fresh liver tissue, and higher than hepatocytes with no matrigel. These results demonstrate that matrigel overlay facilitates the maintenance and induction of xenobiotic metabolizing enzymes in primary cultures of human isolated hepatocytes. (Supported by Hochschulsonderprogramm III (DAAD) and NIH grants R01 ES-05780 and P30 ES 07033)

1123 MODELING GENETIC POLYMORPHISMS OF ALCOHOL DEHYDROGENASE.

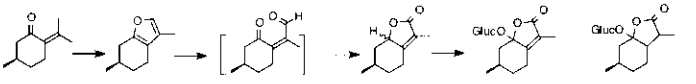
L. G. Sultatos[2], E. J. Flynn[1] and G. M. Pastino[2]. [1]*Pharmacology and Physiology, New Jersey Medical School, Newark, NJ and* [2]*Schering-Plough Res. Inst., Lafayette, NJ.*

The family of cytosolic enzymes known as alcohol dehydrogenase (EC 1.1.1.1) catalyze the reversible oxidation of ethanol to acetaldehyde, with corresponding reduction of NAD^+ to NADH. Alcohol dehydrogenase in humans exists as multiple forms, including class and isozyme multiplicity, as well as allelic variations within several different isozyme forms. In the current study continuous system models were constructed to simulate the activities of those forms of alcohol dehydrogenase that play a major role in the biotransformation of ethanol. Kinetic macroconstants reported in the literature were utilized to calculate microconstants descriptive of the Theorell-Chance mechanism for alcohol dehydrogenase homodimers. Models for the C1 and C2 homodimers, and the B1 homodimer included the previously reported negative cooperativity and substrate inhibition, respectively. Heterodimers were modeled as the sum of the activity of the respective monomers. All models indicated that under equilibrium conditions the reaction favored markedly the reduction of acetaldehyde to ethanol, as has been reported in the literature. In addition, comparisons of simulation output with published data indicated that the models accurately simulated the *in vitro* metabolism of ethanol by alcohol dehydrogenase. Interestingly, sensitivity analyses indicated that dissociation of NADH from alcohol dehydrogenase is not always the rate limiting step for the biotransformation of ethanol. These studies represent the first step in the investigation of how variability from genetic polymorphisms can be incorporated into biologically based models useful for risk assessment. (Supported by a grant from The American Chemistry Council).

1124 METABOLISM OF MENTHOFURAN IN F344 RATS.

L. C. Ferguson, E. H. Lebetkin and L. T. Burka. *NIEHS, Research Triangle Park, NC.*

Menthofuran is a major liver microsomal metabolite of pulegone, the chief component of pennyroyal oil. It has been detected in plasma of rats after i.p. administration of pulegone. Up to half of the pulegone hepatotoxicity has been estimated to arise from menthofuran. Menthofuran is further metabolized by liver microsomes to mintlactones through a reactive enonal that binds to proteins. However, previous metabolism studies on pulegone and menthofuran in rats did not report common urinary metabolites derived from this pathway. Recently, we have identified previously unknown phase II urinary metabolites of pulegone. In order to determine the pulegone metabolites derived from menthofuran, a study of ^{14}C-labeled menthofuran in F344 rats at a 60 mg/kg dose was conducted. Urine samples (24 h) were separated by HPLC equipped with a photodiode array detector and analyzed by MS. The urinary metabolite profile of menthofuran is complex. Two of the major metabolites were identified as 7a-hydroxy-3, 6-dimethyl-5, 6, 7, 7a-tetrahydro-2(4H)-benzofuranone (E3) and 7a-hydroxy-3, 6-dimethyl-3, 4, 5, 6, 7, 7a-tetrahydro-2-benzofuranone (G2) through comparison of their molecular weights, HPLC retention times, and UV absorption with those of the corresponding urinary metabolites of pulegone. Identification of common urinary metabolites from menthofuran and pulegone provides evidence for the *in vivo* metabolism of pulegone to menthofuran, then to mintlactones.



1125 *IN VITRO* METABOLISM OF CARBARYL BY HUMAN LIVER MICROSOMES AND HUMAN CYTOCHROME P450 ISOFORMS.

J. Tang, Y. Cao, R. L. Rose and E. Hodgson. *Department of Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC.*

Carbaryl is a widely used carbamate pesticide. Its effect as a pesticide results from anticholinesterase activity. The present study was designed to investigate the metabolic activity of human liver microsomes (HLM) and human cytochrome P450 (CYP) isoforms toward carbaryl *in vitro*. Carbaryl was incubated with HLM or a CYP isoform at 37°C for 15 min. The 3 major metabolites, i.e. 5-hydroxy carbaryl, 4 hydroxy carbaryl and carbaryl methylol, were analyzed by HPLC. The Km and Vmax for 5-hydroxy carbaryl in HLM were 351 μM and 0.04 nmol/mg protein/min, for 4-hydroxy carbaryl were 421 μM and 0.9 nmol/mg protein/min, for carbaryl methylol were 72 μM and 0.53 nmol/mg protein/min. Using the same experimental conditions, the Km and Vmax in rat liver microsomes were 96 μM and

0.6 nmol/mg protein/min for 5-hydroxy carbaryl, 111 μM and 2.3 nmol/mg protein/min for 4-hydroxy carbaryl, 37 μM and 2.6 nmol/mg protein/min for carbaryl methylol. Metabolic activity toward carbaryl was also investigated in 16 human CYP isoforms. Isoforms with the greatest ability to form 5-hydroxy carbaryl were CYP1A1, 1A2, and 3A4, while the 4-hydroxy carbaryl was formed predominately by CYP3A4, 1A1, and 2C9*1. The carbaryl methylol metabolite was primarily the result of metabolism by CYP2B6, although 1A2 and 2C19 were also involved. The information on CYP isoform activity could be used to estimate differential activity in the human population toward carbaryl and to understand the potential role of biotransformation in interactions of carbaryl with other pesticides or chemicals. (Supported by NCDA Environmental Trust Fund)

1126 INACTIVATION OF SEVERAL HUMAN GLUTATHIONE S-TRANSFERASE ISOFORMS BY METABOLITES OF ESTRADIOL.

E. A. Abel[1], T. K. Bammler[1], E. J. Kelly[2], D. H. Slone[1] and D. L. Eaton[1].
[1]*Department of Environmental Health, University of Washington, Seattle, WA and* [2]*Targeted Genetics Corp., Seattle, WA.*

A link has been established between lifetime dose of estrogen and risk of several human cancers such as breast and uterine cancer. In addition to estradiol's putative role as a tumor promoter through interaction with estrogen receptor, estradiol can be metabolized to redox active and/or mutagenic semiquinones and quinones. Furthermore, metabolites of equine estrogens (components of certain hormone replacement therapy preparations) have recently been shown to inhibit human glutathione S-transferases (hGSTs). The purpose of this study was to determine whether this inhibitory effect is unique to equine estrogens or whether it extends to estrogen metabolites found endogenously in humans. The quinone form of 2-hydroxy-17-β-estradiol was synthesized, and inhibition of hGST-mediated metabolism of 1-chloro-2, 4-dinitrobenzene was assessed. Bacterially expressed and purified recombinant hGSTA1-1, hGSTP1-1, hGSTM1-1 and hGSTM2-2 were utilized in this study. Inhibition of hGSTM1-1 and hGSTA1-1 occurred in a concentration-dependent manner with IC_{50}-values of approximately 250 nM and 350 nM, respectively. Interestingly, hGSTM2-2 was significantly less sensitive to inhibition, exhibiting an IC_{50}-value at least 1 order of magnitude greater than hGSTM1-1. hGSTP1-1 was moderately sensitive to inhibition with an approximate IC_{50}-value of 1.1 μM. Specific, spontaneously formed glutathione-conjugates of the estrogen quinone are likely responsible for a majority of the observed inhibition. These data suggest that endogenously-occurring metabolites of estradiol may modulate hGST functions such as toxicant biotransformation.

1127 HUMAN LUNG CELL CYTOSOLS CATALYZE THE BIOACTIVATION OF THE TOBACCO-SPECIFIC NITROSAMINE 4-(METHYLNITROSAMINO)-1-(3-PYRIDYL)-1-BUTANONE (NNK).

L. L. Bedard[1], G. B. Smith[1], K. R. Reid[2], D. Petsikas[2] and T. E. Massey[1].
[1]*Pharmacology and Toxicology, Queen's University, Kingston, ON, Canada and* [2]*Surgery, Queen's University, Kingston, ON, Canada.*

Bioactivation of the potent tobacco-specific carcinogen NNK involves α-carbon hydroxylation that could be catalyzed by cytochrome P450, hemoglobin (Hb), peroxidases and lipoxygenases (LOXs). We have previously observed NNK biotransformation in human lung cytosols incubated with [5-^{3}H]NNK, suggesting a role for Hb, LOXs and/or peroxidases. The objective of this study was to identify the enzyme system(s) responsible for NNK bioactivation in human lung cytosols. Lung cytosols (100 000 g supernatants) were prepared from six human lung specimens obtained during clinically indicated lobectomy. NNK bioactivation to keto acid, determined by reverse phase HPLC and radioflow detection, was observed in human lung cytosols incubated with 4.2 μM NNK (N=6). Keto acid formation in cytosols was inhibited by 37±23 % by 1-aminobenzotriazole (5.0 mM, N=5), a known P450 inhibitor. However, α-methylene hydroxylation was not inhibited by LOX inhibitor nordihydroguaiaretic acid (NDGA, 10 μM) (N=5). Arachidonic acid (AA, 100 μM) also inhibited NNK bioactivation to the keto acid by 22±5.0 % in the cytosols (N=4). Human lung cytosolic LOX was enriched by concanavalin A affinity chromatography. The two activities of LOX, dioxygenase and peroxidase, were quantified in LOX-enriched cytosols (N=6) using published assays and were inhibited by NDGA (10 μM). NNK bioactivation, in particular α-methylene hydroxylation, was not detectable in LOX-enriched cytosols (N=4), even in the presence of exogenous AA, as would be predicted if LOX is active in NNK metabolism. NNK metabolism by purified human myeloperoxidase was not detectable. However, α-methyl hydroxylation of NNK to keto alcohol was observed when NNK was incubated with horse radish peroxidase. These results suggest that NNK bioactivation in human lung cytosols is probably catalyzed by hemoglobin and that LOXs and myeloperoxidase are not involved in NNK metabolism (Supported by CIHR #10382).

1128 THIODIGLYCOL METABOLISM BY ALCOHOL DEHYDROGENASE USING NMR: TWO-STEP OXIDATION PRODUCES 2-HYDROXYETHYLTHIOACETIC ACID AND 2 MOLES OF NADH.

A. A. Brimfield[1], D. A. Sartori[1] and M. J. Novak[2]. [1]*Biochemical Pharmacology, USAMRICD, Aberdeen Proving Ground, MD and* [2]*Experimental Therapeutics, WRAIR, Silver Spring, MD.*

Sulfur mustard is a vesicant causing delayed injury to human skin. In aqueous medium mustard undergoes rearrangement and hydrolysis to form 2, 2'-bis hydroxyethyl sulfide (TDG), a dihydric alcohol. TDG is able to inhibit protein phosphatases in cytosolic preparations but not the pure enzymes. Therefore, we are investigating metabolic activation. We demonstrated the metabolism of the compound by alcohol dehydrogenases (ADH) from horse liver and human skin [Brimfield et al. 1998. J.Biochem. Molec. Toxicol. 12:361] and from cloned human ADH isoforms [Dudley, Brimfield and Winston. 2000. J. Biochem. Molec. Toxicol. 14:244] by monitoring NAD reduction using OD 340. That technique, however, provides little information about intermediates and products. Recent work with ADH using NMR showed the mechanism varies with increasing substrate chain length and that the mechanistic difference is transparent to spectrophotometry [Oppenheimer and Hennahan. 1993. Adv. Expt. Biol. Med.. 372: 407]. We used Oppenheimer's NMR technique to study the fate of TDG acted upon by horse liver ADH. Work was performed on a Varian 600 MHz NMR. Samples were prepared in 0.1 M $NaPO_4$, pH 7.5 containing 10% D_2O. Spectra were obtained at 37°C at 8 min intervals. The data showed the appearance of a singlet at 3.19 ppm from the methylene protons on carbon 2 of the acetate. Integration provided concentrations of the reactants which allowed us to evaluate kinetics and stoichiometry. The results indicate that TDG is oxidized to 2-hydroxyethylthioacetic acid by horse liver ADH *via* a two-step process in which TDG remains in the active site while two moles of NAD are sequentially reduced. There was no release of intermediate aldehyde as evidenced by the absence of a signal from an aldehydic proton at low field, nor was the monoacid a substrate. The structure was comfirmed by synthesis. Additional metabolism work awaits the availability of cloned human ADH isoforms.

1129 SPECIES VARIATION IN THE METABOLISM, BIOACTIVATION AND CYTOTOXICITY OF CARBARYL *IN VITRO*.

S. Madden, G. G. Kidd, B. D. Cameron, M. Phillips and R. J. Greenough.
Metabolism Chemistry, Inveresk Research, Tranent, United Kingdom.

Pesticides are, by their very nature, toxic. However, the metabolism of these chemicals to reactive metabolites may play a pivotal role in the pathogenesis of chemical toxicity. We have investigated the metabolism, bioactivation and cytotoxicity of carbaryl using human mononuclear leukocytes (MNLs) as targets for toxicity and hepatic microsomes from sheep, chickens and humans as the metabolite generating systems. MNLs, isolated from whole blood, were incubated with hepatic microsomes and [^{14}C]-Carbaryl (3-100μM) for 2h at 37°C in the presence and absence of cofactors. Following incubation stable metabolites were assessed by radio-HPLC-MS, protein-reactive metabolites assessed by exhaustive solvent extraction of the microsomal protein and cell death assessed by trypan blue exclusion. In the absence of NADPH, carbaryl was, in part, hydrolysed to yield 1-naphthol. Protein-reactive metabolite formation was low, however direct cytotoxicity to human MNLs was evident. In the presence of NADPH there was a significant increase in both the rate and routes of metabolism. The rank order of metabolite formation was chicken>sheep> man. The metabolite profile in all species was similar, with the exception that 1, 5 di-OH and 5, 6 di-OH naphthalene were produced by chicken microsomes only. Significant bioactivation of carbaryl was also evident, the rank order of protein reactive metabolite formation being sheep>man>chicken. Cytotoxicity was also increased in the presence of NADPH, with the rank order of cytotoxic metabolite formation being sheep>man>chicken. The introduction of the biologically ubiquitous cytoprotectant, reduced glutathione, decreased both the bioactivation and cytotoxicity, whilst the anti-oxidant, ascorbic acid, decreased the cytotoxicity. In conclusion, hepatic microsomal metabolism of carbaryl may enhance its bioactivation and cytotoxicity. Hepatic microsomes from sheep, chickens and humans, species that may become exposed to this chemical, have been shown to catalyse these biotransformations.

1130 *IN VITRO* METABOLISM OF DIETHYL TOLUAMIDE (DEET) BY HUMAN, MOUSE, AND RAT LIVER MICROSOMES, HUMAN CYTOCHROME P450 ISOFORMS, AND INTERACTION OF DEET WITH CHRLORPYRIFOS.

K. A. Usmani[1], R. L. Rose[1], J. A. Goldstein[2], W. G. Taylor[3], A. A. Brimfield[4] and E. Hodgson[1]. [1]*Department of Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC,* [2]*NIEHS, Research Triangle Park, NC,* [3]*Saskatoon Research Center, Saskatoon, SK, Canada and* [4]*USAMRICD, Aberdeen Proving Ground, MD.*

Metabolism of the insect repellent N, N-diethyl-m-toluamide (DEET) by pooled human liver microsomes (HLM), rat liver microsomes (RLM), and mouse liver microsomes (MLM) was investigated. DEET is metabolized by cytochrome P450s (CYP) leading to the production of a ring methyl oxidation product, N, N-diethyl-m-hydroxylmethylbenzamide (BALC) and an N-deethylated product, N-ethyl-m-toluamide (ET). Both the affinities and intrinsic clearance of HLM for ring hydroxylation are greater than those for N-deethylation. Pooled HLM show significantly lower affinities (Km) than RLM for metabolism of DEET to either of the primary metabolites (BALC and ET). Among 15 cDNA-expressed CYP enzymes examined, CYP1A2, 2B6, 2D6*1 (Val374), and 2E1 metabolized DEET to the BALC metabolite while CYP3A4, 3A5, 2A6, and 2C19 produced the ET metabolite. CYP2B6 is the principle cytochrome P450 involved in the metabolism of DEET to its major BALC metabolite while CYP2C19 had the greatest activity for the formation of the ET metabolite. Use of phenotyped HLM demonstrated that individuals with high levels of CYP2B6, 3A4, 2C19, and 2A6 have the greatest potential to metabolize DEET. Mice treated with DEET demonstrated induced levels of the CYP2B family, increased hydroxylation, and a 2.4 fold increase in the metabolism of chlorpyrifos to chlorpyrifos-oxon, a potent anticholinesterase. Preincubation of human CYP2B6 with chlorpyrifos completely inhibited the metabolism of DEET. (This research was supported by US Army Cooperative Agreement DAMD 17-00-2-0008)

1131 CHARACTERIZATION OF CATECHIN GLUCURONIDATION IN MICE.

H. Lu, C. Li, X. Meng, S. Sheng, B. Winnik, M. Lee and C. Yang. *Chemical Biology, Rutgers University, Piscataway, NJ.* Sponsor: K. Reuhl.

(–)-Epigallocatechin (EGC) and (–)-epigallocatechin gallate (EGCG) are major tea flavonoids with significant antioxidant and anticancer activities. After intestinal absorption, most of the EGC was in glucuronide form in the plasma. One O-glucuronide of EGC (M21), identified by LC/MS/MS, was predominantly found in human and mouse urine after ingestion of green tea. M21 was synthesized in preparative scale with mouse liver microsomes (MLM). Purified M21 and another EGC-O-glucuronide M16 were characterized by NMR as (–)-EGC-3'-O-ß-glucuronide and (–)-EGC-7-O-ß-glucuronide, respectively. M21 and M16 had very similar kinetics in regard to Km and Vmax although M21 was the predominant form of EGC glucuronides in mouse plasma and urine. The catalytic efficiency (Vmax/Km) of EGC glucuronidation by MLM was 0.74 and 0.65 for M16 and M21, respectively. The two major glucuronidation products of 4'-O-methyl-EGC, the major methylated EGC *in vivo*, had significantly different enzyme kinetics, indicating that the methylation of EGC affects its glucuronidation in site-dependent way. M21 was much more stable than EGC and M16 at pH 7.4. M21 was readily hydrolyzed by E. coli beta-glucuronidase and was weak substrate for hepatic beta-glucuronidase. Two major EGCG glucuronides (M37 and M40) formed by MLM and one major EGCG glucuronide M40 by mouse small intestine microsomes (MSIM) were identified by LC/MS/MS. The catalytic efficiency of EGCG glucuronidation by MLM was 0.18 and 0.35 for M37 and M40, respectively. Interestingly, The catalytic efficiency of EGCG glucuronidation by MSIM was 0.61 for M40, which is higher than that by MLM and close to that of EGC glucuronidation by MLM. After 0.6% green tea treatment for 16 days, the Vmax for M21 and M16 in MLM increased significantly whereas the Vmax for EGCG glucuronidation by MSIM decreased dramatically.

1132 *IN VITRO* DETERMINATION OF METABOLIC CONSTANTS FOR CHLOROFORM IN HUMAN MICROSOMES.

R. Tornero-Velez[1], J. W. Laskey[2], H. A. Barton[3], J. C. Lipscomb[4] and M. V. Evans[3]. [1]*DESE, UNC, Chapel Hill, NC,* [2]*SEE, Research Triangle Park, NC,* [3]*NHEERL, USEPA, Research Triangle Park, NC and* [4]*NCEA, USEPA, Cincinnati, OH.*

Chloroform ($CHCl_3$) is a member of the trihalomethane family of water disinfection by-products and is classified as a 2B carcinogen by IARC. Cytochrome P450 2E1 is responsible for most of the metabolic clearance of $CHCl_3$, resulting in the formation of phosgene, which is implicated in its toxicity. Because of the role of hepatic bioactivation in the toxic mechanism and the lack of kinetic parameters for $CHCl_3$ metabolism in human samples *in vitro*, this project was undertaken to examine human inter-individual variation in the metabolism of $CHCl_3$. Ten individual samples of microsomal protein (MSP) isolated from liver tissue from adult human organ donors were selected for analysis based on their representativeness of the CYP2E1 contents observed in the general sample (20 - 100 pmol CYP2E1/mg MSP). The vial equilibrium headspace technique was employed for determination of metabolic rate constants (kinetic parameters) for $CHCl_3$. Incubations at 37°C using each of the ten human hepatic MSP preparations individually were conducted at initial $CHCl_3$ concentrations of 0.4, 1.4, 9.4, and 38.6 ppm and the removal of $CHCl_3$ from the headspace was determined by gas-chromatography with electron capture detection. $CHCl_3$ removal demonstrated a time- and protein-dependent loss of $CHCl_3$ from headspace, which was dependent on the addition of cofactor. We observed substantial differences in the metabolism of $CHCl_3$ among samples derived from the ten organ donors, including significant correlation with hepatic 2E1content. In summary, this *in vitro* approach has proven useful in evaluating variance in human metabolism for chloroform and should be explored with other volatile organic compounds. Measures of variability in metabolism may be incorporated in physiologically-based pharmacokinetic (PBPK) models to reduce uncertainties in risk assessment. (This abstract does not reflect EPA policy).

1133 EFFECTS OF PREGNANCY AND DIET ON PULSATILE ETHANOL EXCRETION IN FEMALE RATS FED *VIA* TOTAL ENTERAL NUTRITION.

T. M. Badger, R. Hakkak, D. Irby, J. Sweeny, C. Mercado, M. Perry, C. Weatherford, S. Shelnutt and M. J. Ronis. *Pediatrics, Arkansas Children's Nutrition Center, University of Arkansas for Medical Sciences, Little Rock, AR.*

We have developed intragastric infusion systems in which ethanol (EtOH)-containing diets are fed as part of a system of total enteral nutrition (TEN). This allows complete control of ethanol and caloric intake. In this model, blood and urine ethanol fail to attain a steady-state, pulsing with a frequency of 6-7 days. Virgin female rats continuously infused 13 g/kg/d EtOH at a caloric intake of 160 $kcal/kg^{3/4}/d$ had mean peak urine EtOH concentrations (UECs) of 369 ± 25 mg/dl and an integrated area under the UEC profile of 2647 ± 164. In contrast, when the caloric intake was increased to 220 $kcal/kg^{3/4}/d$, using the same ethanol dose, the UEC peak was reduced to 200 ± 21 mg/dl ($P \leq 0.05$) and the integrated area reduced by over 50% to 1253 ± 264 ($P < 0.05$). When pregnant female rats were infused EtOH at the same dose at 220 $kcal/kg^{3/4}/d$, the optimal caloric intake to meet the nutritional requirements of pregnancy, peak UEC values were further reduced to 76 ± 8 mg/dl with an area of 309 ± 16 ($P \leq 0.05$ *vs.* 220 fed non–pregnant females). Subsequent experiments where pregnant rats were fed EtOH diets only at night, have demonstrated that a difference of 2 g/kg/d in EtOH intake was required to match UEC and blood EtOH concentrations in pregnant and non-pregnant rats. In pregnant females fed 160 $kcal/kg^{3/4}/d$ the UEC values were 325 ± 53 mg/dl (peak) and 1392 ± 283 (area). These values were significantly higher than those for the pregnant rats fed 220 kcal but lower than those for the virgin rats fed 160 kcal. These data suggest that diet and pregnancy both affect ethanol metabolism and clearance (Supported in part by AA08645 T.M.B. and AA12819 M.J.J.R.).

1134 *IN-VITRO* TO *EX-VIVO* EXTRAPOLATION OF INTRACELLULAR BSP METABOLISM PARAMETERS IN RAT LIVER.

B. Foy[1], J. M. Gearhart[2], A. Soto[2] and J. Frazier[3]. [1]*Physics, Wright State University, Dayton, OH,* [2]*Man Tech Environmental, AFRL/HEST Wright Patterson AFB, Dayton, OH and* [3]*Toxicology Division, AFRL/HEST Wright Patterson AFB, Dayton, OH.*

The primary purpose of a mathematical model of the kinetics of a toxin is to extrapolate to conditions/species where an experiment is impossible or undesirable. If the mathematical model is a detailed PBPK model, it is theoretically possible to obtain most or all parameters using in-vitro methods and a minimal number of whole animals. Here we report a study using both isolated perfused rat livers (the ex-vivo part) and S9 preparations from rat livers (the in-vitro part) to compare the intracellular metabolism of BSP. For the perfused rat livers, eight different combinations of perfusate BSA concentration, recirculating *vs.* one-pass perfusion, and initial BSP concentration were employed to enable estimates of membrane transport, and metabolism for both parent BSP and its glutathione conjugate (BSP-GSH). Extracellular protein binding parameters were taken from the literature. The S9 studies included not only metabolism studies to estimate Vmax and Km, but also protein binding studies to enable the proper extrapolation from S9 conditions to intracellular perfused liver conditions. Perfused liver study metabolism parameters

were estimated to be Vmax = 36.1 µmoles/h/liver and Km = 0.018 µM. The S9 study Vmax for whole liver was ~151 µmoles/h/liver and the apparent Km (before correcting for protein binding in S9) was 7.5 µM. Protein binding of BSP in S9 fit best with 2 binding sites, one site having a Bmax of (3.8 * scale-up factor, s9 to liver) mM and a Kd of 1.7 mM, and the second having a Bmax of (27.5 * scale-up factor) mM and Kd of 230 mM. Applying binding values to the S9 metabolism studies produced an estimated true Km of 0.015 mM (based on estimate of free BSP for total BSP of 7.5 mM and a scale-up factor of 200). This study shows promise for the process of using in-vitro experiments for ex-vivo or in-vivo models, and presents issues that must be considered for proper extrapolation.

1135 13 –WEEK DIETARY AND DEVELOPMENTAL TOXICITY STUDIES OF POLYDIMETHYLSILOXANES (PDMS) IN RATS AND RABBITS.

W. H. Siddiqui[1], M. B. Blee[2], E. C. Tompkins[3] and R. G. Meeks[1]. [1]*Dow Corning Corporation, Midland, MI,* [2]*Huntingdon Life Sciences, Eye, United Kingdom and* [3]*WIL Research Laboratories, Ashland, OH.*

Potential hazards of two PDMS fluids, 10 and 350 cSt were evaluated in studies which included 13-week dietary and developmental toxicity studies in rats and rabbits, respectively. In the dietary studies, 15 male and 15 female F-344 rats were fed Purina® certified chow mixed with the respective test articles at concentrations up to 5000 ppm for 13 weeks. In the developmental toxicity studies, the test articles were administered by dermal applications to 3 groups of 23 pregnant female New Zealand white rabbits from Day 6 to 19 after mating at dosages of 33, 300 and 1000 mg/kg/day. Test article administration in the feeding studies produced yellow matting at the anogenital region of males and females in the 5000 ppm group administered 10 cSt fluid, presumably as a result of anal leakage of the test article; increased mean food consumption that may be due the high concentration of the non-nutritive test article in the diet and dose related increases in the corneal opacities that may be associated with a local irritative effect of the test article in the eyes. In the developmental toxicity studies, one female in the control group aborted and one in each of the 33 and 1000 mg/kg/day groups of 10 cSt fluid had total litter resorptions. One female treated with 1000 mg/kg/day 350 cSt fluid aborted and one female in the control group had total litter resorptions. The incidence and distribution of these findings were not indicative of a test article effect. Litter parameters were considered to be unaffected and fetal examination revealed a number of abnormalities in both the control and treatment groups; however, none were considered to be attributable to treatment with PDMS fluids. Supported in part by Silicones Environmental, Health and Safety Council of North America.

1136 MULTIGENERATIONAL 5-AZA-2'-DEOXYCYTIDINE ABNORMAL DEVELOPMENT.

F. Cisneros and S. Branch. *Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC.*

Genomic imprinting plays a critical role in fetal growth and behavioral development, and it is regulated in part by methylation of cytosine in DNA. 5-aza-2'-deoxycytidine (d-AZA) is a potent inhibitor of DNA methylation thus controlling gene expression. Changes in methylation patterns can lead to heritable alterations in gene expression leading to abnormal growth and/or morphological development. It has been suggested that epigenetic defects in germline cells due to loss of methylation can be repaired by recombination at meiosis but that some are transmitted to offspring. The aim of this study was to determine if the DNA demethylating agent d-AZA would induce transmissible alterations in development. A multigenerational study was designed in which three generations were examined. At gestation day (GD) 10, pregnant mice were administered 1 mg/kg of d-AZA. Male and female treated offspring were mated avoiding consanguinity . In each generation, 50% of pregnant mice were killed and used for fetal necropsy and skeletal analysis while the other 50 % were allowed to give birth to produce the next generation. Leg and tail abnormalities, abnormal male mating behavior and retarded post natal body development, were observed in F1 d-AZA offspring. In the F2 generation, retarded female body development and cleft palate were observed. Also, there was abnormal development of the third ventricle of the brain. Presence of hydronephosis, reduced ossification of caudal vertebrae, supernumerary thoracic ribs, reduced ossification of the sternum and increased number of rib-sternum attachments were statistically different when compared to controls. In the F3 generation, nares malformations, cleft palate, reduced caudal vertebrae ossification, supernumerary thoracic ribs, and increased number of rib-sternum attachments were statistically significant in relation to controls. Our data suggest that altered methylation patterns (induced initially by d-AZA embryonic exposure) may be inherited by the offspring of exposed parents leading to altered imprinting and development

1137 CONTROL VAGINAL OPENING DATA FOR F1 GENERATION CRL SPRAGUE-DAWLEY ("GOLD STANDARD") RATS IN EPA DEVELOPMENTAL NEUROTOXICOLOGY, EPA MULTIGENERATION AND FDA PERI-POSTNATAL STUDIES.

A. M. Hoberman, M. S. Christian, E. Lewis and J. Barnett Jr. *Argus Research, A Division of CRL, Horsham, PA.*

Vaginal opening and balano-preputial separation are classically considered to be endocrine-mediated developmental endpoints indicative of sexual maturation in the rat that are generally independent of body weight. Because these events do not occur until after postnatal day 21, the usual day rat pups are weaned, the reported values are usually based on observations for 1 male and 1 female weanling rat per litter. Currently, there is considerable controversy regarding the adequacy of using one pup/sex/litter to represent the litter, because it has been shown for body weights and uterine weights that this practice can result in statistically significant differences reflecting random selection. However, historically, one/weanling rat/litter has been evaluated for these parameters in EPA-compliant Developmental Neurotoxicology and Multigeneration Studies, as well as in FDA-compliant Peri-Postnatal Studies. To identify whether evaluating additional animals was not only practical, but also provided improved data sets, we observed three rats/sex/litter in seven Developmental Neurotoxicology Studies and compared these individual and mean/litter data with that obtained in three Multigeneration Studies and seven Peri-Postnatal Studies. The results of these activities indicate: (1) The mean day of vaginal opening ranges from day 31.6 to day 34.0, based on 60 rats/group (3/litter, 7 Developmental Neurotoxicology Studies). (2) When 1 rat/litter (25/group; 7 Peri-Postnatal Studies) is evaluated, the mean day for vaginal opening ranged from 32.4 to 34.0. (3) Individual values varied remarkably among control animals, indicating that statistically significant differences may be associated with random selection of animals (individual values ranged from postnatal day 28 to 41). (4) Use of 3 rats/sex/litter improved the sensitivity of the assay. (5) There appeared to be a correlation between maternal age at GD 0 and age at vaginal membrane separation.

1138 VALIDATION OF THE MORRIS MAZE AS A TEST OF LEARNING AND MEMORY IN YOUNG RATS – SUITABILITY FOR DEVELOPMENTAL TOXICITY STUDIES.

S. D. Renaut, D. P. Myers and M. J. Collier. *Toxicology, Huntingdon Life Sciences, Huntingdon, United Kingdom.* Sponsor: C. Atterwill.

To assess the suitability of the Morris water maze as a test of learning and memory in young rats, performance of CD rats was assessed at 4 and 9 weeks of age after administration of Scopolamine. Groups of 10 male and 10 female rats were dosed by intraperitoneal injection with Scopolamine hydrobromide at 1.5 mg/kg/day on each of days 28-30 or 63-65 of age. Twenty minutes after each dose the rats were placed individually in the Morris water maze - a circular pool (0.9 m diameter days 28-30; 1.4 m diameter days 63-65) filled to a depth of 30 cm with water at approximately 29 °C made opaque using a non toxic opacifier. A similarly constituted Control group received saline vehicle. A platform was located at a fixed point in the pool, concealed below the surface of the water. Each animal received 3 trials on each of 3 consecutive days of testing. In each trial, the rat was placed in the water at the perimeter of the pool and allowed a maximum of 90 seconds to find the platform. The time to reach the platform and the number of pool sectors crossed were recorded. Treatment of rats with Scopolamine on both Days 28-30 and Days 63-65 of age resulted in a general impairment of performance in the water maze - for both sexes there were some statistically significant increases in mean trial times and mean number of sectors entered compared with the respective Controls. In contrast to Controls, which showed improved performance over the 3 days of testing, performance of treated males and females on Days 28-30 of age only improved between Days 2 and 3 of testing. At Days 63-65 of age, treated males showed improved performance over the 3 days of testing but females showed no improvement. These results demonstrate the suitability of the Morris water maze for assessing learning ability on regulatory developmental toxicity studies.

1139 THE USE OF THE MOUSE FOR EVALUATION OF PRENATAL DEVELOPMENTAL TOXICITY AND REPRODUCTION AND FERTILITY EFECTS.

M. E. Moxon and R. W. Lewis. *HAES, Syngenta CTL, Macclesfield, United Kingdom.* Sponsor: E. Lock.

In regulatory toxicology, the rat is the guideline preferred species for evaluation of prenatal developmental toxicity and for evaluation of reproduction and fertility effects. However, in some instances the rat may not be the most appropriate model i.e. when the rat is not the most relevant species for human health risk assessment. Within CTL, the mouse has been developed successfully as an alternative rodent

species for these evaluations. For evaluation of prenatal developmental toxicity, the technical challenges due to the change of species included control over the time of mating and hence control over the time of caesarean delivery. The purpose of this control was to optimise the size of the foetuses for evaluation and to avoid premature delivery of litters. Other challenges included the methodology for visceral examination of small foetuses by dissection under magnification, the preparation of double-stained skeletons and their subsequent examination. The test system is compliant with current OECD and EPA Guidelines. There were fewer technical challenges involved in using the mouse for evaluation of reproduction and fertility effects. Selection of the strain of mouse was an important factor particularly with respect to mating characteristics, i.e. the observation of a copulation plug needed to be a reliable indicator of successful mating, and litter size and pup survival needed to be adequate for continuation of the study over two generations and meaningful evaluation of the data. Currently, methodology is being developed to investigate oestrus cyclicity, examination of the post lactational ovary and sperm analysis to achieve compliance with the current OECD and EPA Guidelines.

1140 CONTROL PRIMORDIAL FOLLICLE COUNTS IN MULTIGENERATION STUDIES IN CRL SPRAGUE-DAWLEY ("GOLD STANDARD") RATS.

M. S. Christian[1] and W. R. Brown[2]. [1]*Argus Research, A Division of CRL, Horsham, PA and* [2]*Research Pathology Services, New Britain, PA.*

Ovarian primordial follicle (PF) count is an endpoint in the 1998 EPA multigen. PF counts are identified for ovaries from at least 10 F1 control and high group females, 5 sections/ovary. Means/ovary are determined and compared, lower group values are determined if statistically significant differences are present. Different counts and assay sensitivity are associated with age, number of animals, sections/ovary, section thickness, and criterion defining PF. Generally, 4 PF grades (1, 2, 3a, 3b) are counted (oocyte without surrounding granulosa cells to oocyte ringed by granulosa cells). These criteria were used in 3 multigeneration EPA- and GLP-compliant studies at our laboratories, using the same rat strain, procedures, definitions and evaluator. Variation existed in control PF counts between right and left ovaries of the same rat, mean values for individual ovaries and mean values/group. We have heard that our data differs from that of other groups. In toto, these findings indicate that intra- and inter-laboratory differences exist, and that as currently performed, this endpoint may not be sufficiently reproducible to be considered a pivotal endpoint for human risk assessment. In 2 of our 3 studies, mean and standard deviation control group values were based on 30 rats/group; in the 3rd study, values were based on 10/group. We confirmed age-related differences between P and F1 rats in 1 study (means/ovary: P rats = 9.29 ± 5.32 and 8.89 ± 3.48; F1 rats = 14.50 ± 6.12 and 16.07 ± 5.75). Mean values/ovary for F1 rats in the 3 studies for each ovary = 14.50 ± 6.12 and 16.07 ± 5.75, 13.96 ±7.44 and 13.41 ± 7.49, and 13.64 ± 8.36 and 12.66 ±8.42. Mean PF values/ovary ranged from 2.6 to 44.4. Mean PF of 2.6 = 1, 1, 1, 3 and 7 PF/5 sections; contralateral ovary mean PF = 7.0 (9, 10, 3, 2 and 11 PF/5 sections). Mean PF of 44.4 = 51, 75, 25, 54 and 17 PF/5 sections; the contralateral ovary mean PF = 26 (29, 27, 23, 27 and 24/5 sections). Individual values, criteria and artifact types will be shown.

1141 REPRODUCTIVE EFFECTS OF 1, 2, 3, 4-BUTANE-TETRACARBOXYLIC ACID (BTCA) IN SPRAGUE-DAWLEY RATS WHEN ASSESSED BY THE CONTINUOUS BREEDING PROTOCOL.

K. Layton[1], G. Wolfe[1], Y. Wang[1], J. Quance[2] and J. Bishop[3]. [1]*TherImmune Research Corporation, Gaithersburg, MD,* [2]*PAI, Frederick, MD and* [3]*NIEHS, Research Triangle Park, NC.*

BTCA was evaluated using the multigenerational Continuous Breeding paradigm to reveal potential reproductive toxicity in rats. Beginning on Study Day 1, BTCA was administered daily *via* oral gavage at doses of 0, 100, 250, 500 mg/kg/day to adult male and female rats (N=20). Mating pairs were allowed to produce three litters (F_{1a}, F_{1b}, and F_{1c}). Dosing of the F_1 generation (F_{1c} animals) was initiated on post-natal day (PND) 22. On PND 81±10, F_{1c} (N=20) animals were assigned to mating pairs and allowed to produce three litters (F_{2a}, F_{2b}, and F_{2c}). Endpoints evaluated included body weight, feed consumption, clinical signs, reproductive/litter parameters, sexual development and pathology. No changes were seen in the body weights or feed consumption of the F_0 animals. Decreases of 4-5% were seen in the body weights of the 500 mg/kg F_{1c} males during Week 2, and Weeks 12-16. Feed consumption was decreased during Week 12 for the 100 mg/kg F_{1c} males. Throughout the F_0 and F_1 generations, most reproductive parameters were unchanged in all dose groups compared to the controls with the exception of decreases in the pregnancy indices in the 500 mg/kg pairs compared to control during the second litter of each generation (F_{1b}; 13/17 compared to 20/20, F_{2b}; 16/20 compared to 20/20). Sperm parameters and vaginal cytology were unchanged in the F_0 and F_1 generations. The remaining reproductive changes were not considered to be treatment-related. The only microscopic lesion related to treatment was a renal lesion consisting of the presence of multinucleated giant cells, often centered around acicular crystalline material in both F_0 and, at a decreased incidence, F_1 generations. Excluding several incidental changes, BTCA produced no reproductive toxicity but did produce general toxicity at 250 and 500 mg/kg, as noted by the microscopic renal lesions seen in both the F_0 and F_1 generations. Based on the results of this study, BTCA would not be considered a reproductive toxicant.

1142 ANTIANDROGENIC EFFECTS OF A PHTHALATE COMBINATION ON *IN UTERO* MALE REPRODUCTIVE DEVELOPMENT IN THE SPRAGUE-DAWLEY RAT: ADDITIVITY OF RESPONSE?

P. M. Foster, K. J. Turner and N. J. Barlow. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Environmental antiandrogens constitute a class of chemicals that significantly affect reproductive development in laboratory animals. In the environment it is more likely that exposure will occur to multiple agents that may have similar or different mechanisms of antiandrogenicity. The objective of the present study was to examine the reproductive developmental effects on male rats exposed to two phthalates *in utero*, both as individual compounds and in combination. Dose levels were selected based on LOAELs for reproductive development obtained from previous dose-response studies. Pregnant Crl:CD(SD)BR rats, 10 per group, were treated by gavage with either corn oil vehicle, 100 mg/kg/day of di(n-butyl) phthalate (DBP) or di(2-ethylhexyl) phthalate (DEHP) or a combination of each phthalate at 100 mg/kg/day in combination (effectively 200 mg/kg/day of phthalate) on gestation days 12 to 21. On postnatal day (PND) 1 the anogenital distance (AGD) and male pup body weights were measured and each individual pup was uniquely identified with a footpad tattoo. On PND 13 the retained areolae were counted on each male pup. At necropsy on PND 90 the AGD was again measured and the rats were shaved to count permanent nipples. Organ weights were recorded for the testes, epididymides, prostate (dorsolateral and ventral) and seminal vesicles. On PND 1 the AGD was reduced significantly in the combination group while it did not differ from control for DBP or DEHP alone. Significantly increased numbers of areolae were retained on PND 13 in the males in the combination group but not in the other two phthalate groups. There were no consistent changes in organ weights and only a small number of reproductive tract lesions were seen in the phthalate-exposed animals. In line with default assumptions, the effect of prenatal exposure to a combination of two phthalates on AGD and nipple retention in male rats was additive in comparison with the effect of exposure to each phthalate alone.

1143 PERMANENT ALTERATION OF ANOGENITAL DISTANCE AND NIPPLE RETENTION IN MALE RATS EXPOSED TO DI(N-BUTYL) PHTHALATE *IN UTERO*.

N. J. Barlow, B. S. McIntyre and P. M. Foster. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Di(n-butyl) phthalate (DBP) has been shown to act as an antiandrogen when male rat fetuses are exposed during late gestation. Antiandrogenic effects noted include decreased anogenital distance (AGD) on postnatal day (PND) 1 and increased retention of areolae on PND 13. The objective of this study was to compare the AGD and areolae/nipple retention data obtained during the early postnatal period to those obtained in adulthood to determine if the changes were permanent. Pregnant Crl:CD(SD)BR rats, 10 per group, were treated by gavage with either corn oil vehicle or DBP at 100 and 500 mg/kg/day on gestation days (GD) 12 to 21. The AGD and male pup body weights were measured on PND 1 and retained areolae were counted on PND 13. These end points were also collected at necropsy on PND 180. Pups exposed to 500mg/kg/day exhibited a significant, 14%, decrease in AGD on PND 1. At necropsy these DBP-exposed offspring exhibited a significant, 10%, reduction in AGD. The reduction in AGD at PND 1 correlated with the reduction in AGD at PND 180 ($r^2 = 0.80$). Similar effects were seen in areolae/nipple retention with significantly increased numbers of retained areolae/nipples in the high dose group at both PND 13 and 180. Lesions in the male reproductive tract included atrophic testes accompanied by hypoplastic or malformed epididymides, malformed seminal vesicles and small prostates. The incidence of gross lesions in the reproductive tracts of control animals was ~2%, while at 100 and 500 mg/kg/day they were ~9 and 80%, respectively. These data demonstrate that decreased AGD and increased nipple retention following *in utero* DBP exposure are permanent effects with strong correlation between the data from the early postnatal period and adulthood. As the alterations in AGD and areola/nipple retention are permanent, there is support for the argument that these end points are malformations and should be incorporated routinely into standard testing protocols and considered in risk assessment.

1144 LACK OF DEVELOPMENTAL TOXICITY IN SD RATS WITH DI(2-ETHYLHEXYL)TEREPHTHALATE (DEHT, DOTP).

R. M. David[1], D. G. Stump[2] and K. R. Miller[3]. [1]*Eastman Kodak Company, Rochester, NY,* [2]*WIL Research Laboratories, Inc., Ashland, OH and* [3]*Eastman Chemical Company, Kingsport, TN.*

A developmental toxicity study was conducted in Sprague-Dawley rats with DEHT. Groups of 25 mated females were exposed to 0, 0.3, 0.6, and 1.0% DEHT in the diet beginning on Day 0 of gestation until termination on Day 20. Mean body weight and body weight changes were reduced for the 1.0% group. Net body weight and body weight change were significantly lower for the 1.0% group compared with controls. On Day 20, dams were euthanatized; the uterus was removed and weighed. The numbers of viable fetuses and early and late resorptions were counted. Each fetus was evaluated for external, visceral and skeletal anomalies. No effects on litter size or mean pup weight were observed. There were no differences in the percentages of viable fetuses or early or late resorptions. No visceral or skeletal effects were seen that could be attributed to treatment. The NOAEL for developmental toxicity was 1.0% in the diet. These data complement the information from Gray et al. (2000) which indicate that DEHT does not produce antiandrogenic-like effects, and the data from a 2-generation reproductive toxicity study indicating a lack of reproductive toxicity.

1145 EFFECTS OF *IN UTERO* FENITROTHION EXPOSURE ON ANDROGEN-DEPENDENT MALE RAT REPRODUCTIVE DEVELOPMENT: A DOSE-RESPONSE STUDY.

K. J. Turner, N. J. Barlow, M. F. Struve, D. G. Wallace, K. W. Gaido, D. C. Dorman and P. M. Foster. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Fenitrothion [O, O-dimethyl-O-(4-nitro-m-tolyl) phosphorothioate] is an organophosphate insecticide that is known to antagonize the androgen receptor. The objective of the present study was to evaluate the ability of fenitrothion to disrupt androgen-dependent sexual differentiation in the male rat. Pregnant Crl:CD(SD)BR rats were administered fenitrothion by gavage at 0, 5, 10, 15, 20, or 25 mg/kg/day (n=6-11/group) from gestation day (GD) 12 to 21. Maternal toxicity was observed in the dams treated with 20 and 25 mg fenitrothion/kg/day based on tremors and a significant decrease in body weight gain between GD 12 and 21. Embryo-fetal death was increased in the 20 and 25 mg/kg/day exposure groups as evidenced by a significant decrease in the proportion of pups born alive. *in utero* exposure to fenitrothion altered androgen-dependent sexual differentiation, confirming previous findings that fenitrothion is an androgen receptor antagonist *in vivo.* Anogenital distance (AGD) in the male offspring on postnatal day (PND) 1 was decreased relative to the control group by 8% ($p=0.06$) and 16% ($p<0.001$) in the 20 and 25mg/kg/day dose groups, respectively, with body weight as a covariate. Fenitrothion exposure significantly increased areola retention in male rats on PND 13 from 1.25 ±0.46 in the control group to 4.31 ±0.66 areolae per rat in the 25 mg/kg/day dose group (litter means ± SE). These alterations in AGD and areola retention were transient and not observed at sexual maturity (PND 100). Fenitrothion exposure did not induce a dose-responsive increase in the incidence of gross lesions of the male reproductive tract. Body weights and organ weights were unaltered in the adult male offspring. Fenitrothion exposure induced cholinergic stress in the dams and fetal mortality at the same dose level as that found to elicit the transient but significant effects on AGD and nipple retention in the male offspring.

1146 VALIDATION OF DEVELOPMENTAL NEUROTOXICITY ENDPOINTS IN RATS ADMINISTERED METHIMAZOLE IN DRINKING WATER.

G. J. Schaefer, M. D. Nemec, M. T. Herberth, J. A. Pitt, A. E. Radovsky and J. F. Knapp. *Neuroscience, WIL Research Laboratories, Inc., Ashland, OH.*

The purpose of this study was to validate procedures outlined in the USEPA OPPTS 870.6300 guideline for developmental neurotoxicity (DNT) studies. Pregnant Sprague-Dawley rats (N=25/group) were administered either 0, 10, 30 or 100 ppm methimazole (used to treat human hyperthyroidism) in drinking water from gestation day 6 through postnatal day (PND) 21. Endpoints evaluated in the dams included a modified functional observational battery (mFOB), body weights, and food and water consumption. In the pups, brain weights, qualitative neuropathology and quantitative brain morphometry were evaluated at PND 11, 22 and 72. Auditory startle, locomotor activity, learning and memory (Biel Maze) and mFOB were assessed in the offspring repeatedly throughout their development. During lactation, the dams in all three exposure groups weighed significantly less, and consumed less food and water than controls. Locomotor activity was reduced on PND 13 and increased on PND 21 for 30 and 100 ppm offspring relative to controls. Auditory startle response endpoints (Vmax, Tmax and Vave) were affected in the 30 and 100 ppm offspring at PND 20 and 60. Pup body weights were reduced from PND 1-70 for both sexes in all exposure groups relative to controls. Delayed sexual maturation (balanopreputial separation and vaginal patency) was readily apparent in all three exposure groups, except for vaginal patency at 10 ppm. In addition, on PND 11 and 22 both male and female offspring mean brain weights (100 ppm) were reduced relative to controls. Brain weights were reduced on PND 72 for 100 ppm male offspring only. No dam or offspring exposure-related deficits were noted in the mFOB at any time point. Qualitative neuropathology and quantitative morphometry at PND 11 (comparing immersion and perfusion fixation at PND 11), 22 and 72, along with learning and memory data, will be presented. The data analyzed thus far are being used to assess the appropriateness of methimazole as a positive control agent for DNT studies.

1147 REPRODUCTIVE EFFECTS OF DIETHYLHEXYLPHTHALATE (DEHP) IN SPRAGUE-DAWLEY RATS WHEN ASSESSED BY THE CONTINUOUS BREEDING PROTOCOL.

G. W. Wolfe[1], K. Layton[1], L. Nehrebeckyj[1], Y. Wang[1], R. Chapin[2], S. D. Rousselle[3] and J. Bishop[4]. [1]*TherImmune Research Corporation, Gaithersburg, MD,* [2]*DuPont Pharmaceuticals Company, Newark, DE,* [3]*PAI, Frederick, MD and* [4]*NIEHS, Research Triangle Park, NC.*

DEHP was evaluated using a multi-generational protocol in rats to assess potential reproductive effects over multiple generations. Beginning on Study Day 1, DEHP was administered *via* the diet at doses of 1.5 (control), 10, 30, 100, 300, 1000, 7500, and 10, 000 ppm to adult male and female rats (N=17). Each mating generation was allowed to produce three litters (F_{1a}, $_{1b}$, $_{1c}$, F_{2a}, $_{2b}$, $_{2c}$, F_{3a}, $_{3b}$, $_{3c}$). On PND 81 ± 10, animals from the third litter from each generation were assigned to mating pairs (N=17). Reductions were noted in mean body weight of animals receiving 7500 or 10, 000 ppm. Reproductive/litter effects including decreases in pregnancy indices for most generations; decreases in the no. of males per litter and the total no. of pups per litter; decreases in male and female pup weights at birth and during lactation; decreases in anogenital distance for male pups; and delay of sexual development parameters were noted at the top 2 dose groups. The 10, 000 ppm animals did not produce any F_2 generation animals. Outbreedings at 7500 and 10, 000 ppm of treated males with naive females revealed decreases in mating, pregnancy and fertility indices and decreases in the number of implantation sites. Sperm endpoints were decreased at 7500 ppm in all generations and at 10, 000 ppm in the F_0 and F_1 generations. Organ weight changes of the liver (increase), kidney (increase), and male accessory sex organs (decrease) occurred at 1, 000, 7500, and 10, 000 ppm. Treatment-related microscopic findings were noted at 7500 and 10, 000 ppm in the testes, epididymides, liver, adrenal, and kidney in all generations and in the liver at 1, 000 ppm in the F_1 and F_2 generations. DEHP is considered a reproductive toxicant at 7500 and 10, 000 ppm. There was no general or reproductive effects observed at dose levels at or below 1, 000 ppm except liver toxicity at 1, 000 ppm.

1148 DECREASE IN THE LITTER SIZE OBSERVED IN FEMALE RATS INTRAVENOUSLY GIVEN L-CYSTEINE.

M. Harada, K. Kishimoto, Y. Nakashima, Y. Kawaguchi and I. Hiraoka. *Naruto Research Institute, Otsuka Pharmaceutical Factory, Inc., Naruto Tokushima, Japan.* Sponsor: H. Inoue.

There are few reports on the reproductive and developmental toxicity of amino acids. We previously observed marked decrease in the litter size in female rats intravenously received a high dose of L-Cysteine (CySH) before mating. In the present study, we investigated the oocytes morphologically before and after mating to clarify the cause of the decrease in the litter size observed in the rats. SD rats, 11 weeks old, were intravenously infused CySH at a dose of 1000 mg/kg for more than 1 week before mating. The unfertilized oocytes (UO) collected from ampulla of uterine tubes and fertilized embryos (gestation day [GD] 1 and 2) collected from oviducts were examined morphologically by stereomicroscope. Morfometry was also performed for UO. The number of females in the CySH group from which UO could be collected was the same with that in the control group (non-treatment group), but the number of observed oocytes was a half of that in the control group. Moreover, zona pellucida (ZP)-lacking or partially ZP-lacking oocytes were observed in the CySH group. The morfometry of UO in the CySH showed similar diameter as compared with that in the control group, but ZP became thin. The number of female rats from which embryos were collected on GD 1 in the CySH group was similar to that in the control group, but the number collected on GD 2 was reduced to a half of that in the control group. The number of observed embryos in dams on GD 1 and GD 2 were decreased markedly in the CySH group, and most of them were degenerative embryos. It was observed in this study that a high dose of CySH induced the lacking or partially lacking of ZP or thinning of ZP in UO and embryos on GD 1 and GD 2. It is known that ZP plays an important role in

early embryogenesis. The oocytes, which were affected at ZP by CySH treatment, were degenerated. In conclusion, affected ZP was considered to contribute to the decrease in litter size.

1149 CONTROL PREPUTIAL SEPARATION DATA FOR F1 GENERATION CRL SPRAGUE-DAWLEY ("GOLD STANDARD") RATS IN EPA DEVELOPMENTAL NEUROTOXICOLGY, EPA MULTIGENERATION AND FDA PERI-POSTNATAL STUDIES.

E. Lewis, M. S. Christian, J. Barnett Jr and A. M. Hoberman. *Argus Research, A Division of CRL, Horsham, PA.*

Balano-preputial separation and vaginal opening are classically considered to be endocrine-mediated developmental endpoints indicative of sexual maturation in the rat that are generally independent of body weight. Because these endpoints do not occur until after postnatal day 21, the usual day rat pups are weaned, the values are generally based on observations for one male and one female weanling rat/litter. Currently, there is considerable controversy regarding the adequacy of using one weanling rat/sex/litter to represent the litter, because it has been shown, for body weight and uterine weights, that this practice can result in statistically significant differences reflecting random selection. However, historically, one rat/litter has been the number evaluated for these parameters in EPA-compliant Developmental Neurotoxicology and Multigeneration Studies, as well as in FDA-compliant Peri-Postnatal Studies. To identify whether evaluating additional animals was not only practical, but also provided improved data sets, we evaluated 3 rats/sex/litter in 7 Developmental Neurotoxicology Studies and compared these individual and mean/litter data with that obtained in 3 Multigeneration Studies and 7 Peri-Postnatal Studies. The results of these activities indicate: (1) The mean day of preputial separation ranged from days 45.2 to 48.4, based on 60 rats/group (3/litter, 7 Developmental Neurotoxicology Studies). (2) When 1 rat/litter (25/group; 7 Peri-Postnatal Studies) was evaluated, the mean day for vaginal opening ranged from 44.6 to 48.1. (3) Individual values varied remarkably among control animals, indicating that significant differences observed between studies may be associated with random selection of animals to be evaluated (individual values ranged from postnatal days 40 to 76). (4) Use of 3 rats/sex/litter improved the sensitivity of the assay. (5) There appeared to be a correlation between the age at sexual maturation and maternal age at GD 0.

1150 ROLES OF PROGESTERONE ON SUPPRESSION OF UTERINE DECIDUALIZATION AND IMPLANTATION FAILURE INDUCED BY DIPHENYLTIN DICHLORIDE (DPTCL) IN RATS.

M. Ema and E. Miyawaki. *Osaka Branch, National Institute of Health Sciences, Osaka, Japan.*

In our previous study, administration of DPTCl at 16.5 mg/kg and higher on days 0-3 of pregnancy was found to induce implantation failure in rats (Toxicol. Lett., 108, 17-25, 1999). In the present study, the effects of DPTCl on uterine function, as a cause of implantation failure, and the roles of progesterone in DPTCl-induced implantation failure were determined in rats. Female rats were given DPTCl by gastric intubation at 4.1, 8.3, 16.5, or 24.8 mg/kg on days 0-3 of pseudopregnancy and the decidual cell response was induced on day 4 of pseudopregnancy. The uterine weight on day 9 of pseudopregnancy served as an index of the uterine decidualization. A significant decrease in the uterine weight, which indicates suppression of the uterine decidualization, was detected at 16.5 and 24.8 mg/kg. The ovarian weight and number of corpora lutea in the DPTCl-treated groups were comparable to the controls. A significant decrease in the serum progesterone levels was found at 16.5 and 24.8 mg/kg. Hormonal regimen supported the decidual development in ovariectomized rats given DPTCl. The pregnancy rate and number of implantations in the groups given DPTCl at 16.5 and 24.8 mg/kg on days 0-3 of pregnancy in combination with progesterone on days 0-8 of pregnancy were higher than those in the groups given DPTCl alone. It could be concluded that implantation failure due to DPTCl is mediated *via* the suppression of uterine decidualization correlated with reductions in serum progesterone levels.

1151 HOMOLOGOUS RECOMBINATION AS A POTENTIAL MECHANISM FOR PHENYTOIN-INDUCED TERATOGENICITY.

P. M. Kim[1] and J. A. Nickoloff[2]. *[1]Dept. of Pharmacology & Toxicol. and School of Environment Studies, Queen's University, Kingston, ON, Canada and [2]Dept. Mol. Genet. & Microbiol., Univ. of New Mexico, Albuquerque, NM.*

Epilepsy treatment involves the use of anticonvulsants such as phenytoin (**PHY**). PHY is teratogenic in numerous species, but the mechanism by which it initiates teratogenicity remains to be elucidated. PHY can be enzymatically bioactivated to a reactive intermediate capable of damaging essential macromolecules including DNA. PHY can induce DNA double-strand breaks (**DSB**), which may be repaired through homologous recombination (**HR**). Increased DSB levels may induce hyper-recombination that can lead to deleterious genetic changes. We hypothesize that these changes, such as gene deletions, may be an important molecular mechanism for chemical-induced teratogenesis. We used a Chinese hamster ovary (**CHO**) cell line with a *neo* direct repeat recombination substrate (**CHO 3-6**). The 5' *neo* is driven by the dexamethasone (**DEX**)-inducible mouse mammary tumor virus promoter; the second *neo* lacks a promoter. HR frequencies were determined by counting the number of G418-resistant colonies per live cell, and recombinant products were analyzed by Southern blot to distinguish gene conversions without an associated crossover from deletions, which can occur by crossing over or single-strand annealing. CHO 3-6 cells were treated with PHY at 80, 240 and 800 μM for 4 or 24 hr, and the 24 hr experiments were performed in the presence or absence of DEX. We found that PHY enhances HR in a dose-dependent manner, and that PHY-induced HR is further enhanced by increased transcription of the 5' copy of *neo*. Of more than 10 HR products analyzed to date, all arose by gene conversion without associated crossover. These results are similar to HR stimulated by I-*Sce*I nuclease-induced DSBs, but contrast with the high rate of deletions seen with spontaneous and UV-induced HR. Thus, our data suggest that PHY-initiated DNA damage induced HR proceeds through a DSB intermediate, implicating HR as a potential mechanism for chemical-induced teratogenesis.

1152 STUDIES OF EMBRYOTOXIC EFFECTS OF BITUMEN-SALT MASSES (BSM) AND THEIR AQUEOUS EXTRACTS CONTAINING GB, GD, OR VX TWO-STAGE DESTRUCTION PRODUCTS.

A. S. Radilov, V. B. Popov, G. A. Protasova, L. V. Shabasheva and E. E. Ermolayeva. *Research Institute of Hygiene, Occupational Pathology and Human Ecology, St. Petersburg, Russian Federation.* Sponsor: L. Chaney.

In support of Cooperative Threat Reduction activities, the Research Institute of Hygiene, Occupational Pathology and Human Ecology in St. Petersburg, Russia participated in joint studies with the U. S. Army Center for Health Promotion and Preventive Medicine (USACHPPM) to investigate the potential reproductive effects of materials leached from the bituminous-salt mass (BSM) end-products of the Russian two-stage chemical agent destruction process. These studies were conducted to address concerns that materials leached from the BSMs could pose a health threat to receptors in the vicinity of future storage/disposal sites. Using aqueous leachates or oil extracts derived from Russian bitumen alone, or BSM containing demilitarized Russian manufactured sarin (GB), soman (GD) or VX, embryotoxicity was evaluated *in vitro* using pre- and post-implantation rodent embryos cultured in blood sera. Embryos were exposed either directly to aqueous extracts or indirectly by using serum obtained from donor animals that were exposed orally to oil suspensions of bitumen or the various BSMs for different durations. Developmental anomalies included dismorphogenesis, decreased cleavage rates, yolk sac edema, hemorrhages (pericardial sac, brain, allantois base) and decreased brain dimensions. Diluting extracts to 4% eliminated their embryotoxic action. In other studies, embryo/fetolethal effects were seen in embryos of pregnant rats orally exposed to aqueous extracts of bitumen, GB-, GD-, or VX-BSM (4, 20 or 100%) daily during gestational days 1-19. Embryos showed the highest sensitivity to BSM-VX aqueous extracts. In summary, BSM aqueous extracts possess weak embryotoxic properties that decrease proportional to decreasing concentrations. While all BSMs demonstrate a measure of embryotoxicity, BSM-VX is the most toxic for embryonic development.

1153 THE EFFECTS OF CONTINUOUS INTRAVENOUS SALINE INFUSION UPON CLINICAL PATHOLOGY PARAMETERS IN THE WEANLING ALBINO RAT.

L. S. Pouliot, S. N. Groom, J. McCartney and K. Robinson. *Toxicology, CTBR, Senneville, PQ, Canada.* Sponsor: G. Lulham.

The use of pharmaceuticals and biotechnology products to treat pediatrics requires that juvenile animal studies be considered prior to conducting clinical trials. The weanling rat represents a suitable model for testing infusion products since it allows for the use of the clinical dose route in the pre-clinical testing. In this study, animals were cannulated at Day 22 post partum using routine surgical procedures and thereafter infused continuously with physiological saline at rates up to 5 mL/kg/h up to 43 days post partum. Terminal blood sample were collected on Days 37 and 44 post partum from the abdominal aorta and analyzed for a standard panel of hematology and clinical biochemistry parameters. There were only minor effects upon clinical condition and a general lack of, or minimal, local tissue damage or inflammatory reaction seen pathologically at the infusion site in infused animals. Consequently, the clinical pathology data generated for these animals allowed for a direct evaluation of the potential changes associated with saline infusion. Although a slight reduction in white blood cell numbers was observed in infused animals *versus* age-matched historical controls, the values recorded for the infused weanlings

remained within our laboratory reference ranges for older (8 to 12 week old) rats. The differences between the remaining clinical pathology parameters of infused *versus* non-infused animals were minor in nature and likely represented biological variation. Consequently, it was concluded that continuous intravenous saline infusion did not adversely affect the clinical pathology of weanling rats thus confirming the suitability of this animal model for testing infusion products.

1154 CONTINUOUS INTRAVENOUS INFUSION IN THE WEANLING ALBINO RAT.

S. N. Groom, K. Robinson, G. Washer, H. Perras and M. Guimont. *Toxicology, CTBR, Senneville, PQ, Canada.* Sponsor: G. Lulham.

The use of pharmaceuticals and biotechnology products to treat pediatrics requires that juvenile animal studies be considered prior to clinical trials. The weanling rat represents a suitable model for infusion products since it allows for the use of the clinical dose route in the pre-clinical pediatric testing. For over a decade, our laboratory has conducted developmental/reproductive studies in rats and rabbits using the infusion route and recently applied our experience with infusion technology to weanling rats. Using aseptic techniques, 40 weanling rats were anesthetized and surgically implanted *via* the femoral vein with a medical-grade silicone-based catheter at 22 days of age. Animals were fitted with a jacket and tether infusion apparatus that was suitably scaled for their size and were infused with physiological saline *via* an in-line 0.µm filter, for 24 hours/day, up to 42 days of age. Dosimetry data for the infusion rates employed (2.5 and 5.0 mL/kg/h) confirmed animals received within ±10% of the nominal dose volume at each infusion rate over the course of the investigation. There were only minor effects upon clinical condition, body weight and clinical pathology parameters and these data are presented. The general lack of, or minimal, local tissue damage or inflammatory reaction seen pathologically at the infusion site suggests that the infusion interval could be extended beyond 42 days of age, if required. In conclusion, weanling rat infusion provides an appropriate animal model, to assess the safety and pharmacokinetics of infused drug products intended for pediatric use prior to initiation of clinical trials in human pediatric populations.

1155 AN ASSESSMENT OF THE USE OF DIMETHYL SULFOXIDE AS A SOLVENT FOR HYDROPHOBIC CHEMICALS IN A DROSOPHILA-BASED DEVELOPMENTAL TOXICITY PRESCREEN.

D. W. Lynch. *Biomonitoring & Health Assessment Br, NIOSH, Cincinnati, OH.*

Dimethyl sulfoxide (DMSO) is routinely used in toxicity testing to solubilize hydrophobic chemicals; however, the potential of DMSO to induce developmental toxicity in the Drosophila-based prescreen has not been well characterized. The purpose of this study was to investigate this toxicity and to determine a maximum concentration of DMSO which can be used. Three separate experiments were conducted with DMSO (CAS# 67-68-5; Sigma D-5879, 99.5%) at concentrations ranging from 0.05 - 150 µl/vial. Drosophila were exposed throughout development (egg through third instar larva) in culture vials to medium containing DMSO. A mated, untreated, Oregon-R wild-type female was added to each vial and allowed to oviposit for 20 hours, then removed. Emerging offspring were collected over 10 days, and examined microscopically (25x) for bent humeral bristles and wing blade notches; morphological defects shown to occur with an increased incidence in flies exposed to developmental toxicants. In each experiment, the incidence of the two defects at each concentration was compared to the concurrent controls using chi-square. Where replicate data were available at a given concentration, incidence data were also pooled and compared to the pooled controls. No flies emerged at concentrations greater than 50 µg/vial. In the first experiment the incidence of bent humeral bristles was significantly increased at 25 µl/vial, 64/246 ($p < 0.001$) and at 50 µl/vial, 2/2 ($p < 0.001$); in the second experiment bristle defects were increased only at 50 µl/vial, 5/8 ($p < 0.001$); in the third experiment bristle defects were increased at 1.0 µl/vial, 5/155 and 5.0 µl/vial 5/146 (both $p < 0.05$). These results indicate that higher concentrations of DMSO can increase the incidence of bristle defects in developing flies. However, based on the lack of a statistically significant increase in defects at lower concentrations in the pooled data across 3 experiments, the data suggest that DMSO at a concentration of 10 µl/vial can be used to evaluate hydrophobic chemicals in this assay.

1156 MODIFIED DAVIDSON'S FIXATIVE AS A REPLACEMENT FOR BOUIN'S SOLUTION USED FOR FETAL EVALUATION UTILIZING WILSON'S TECHNIQUE.

T. Agajanov, H. Jonassen, C. Lucacel, H. Gondek and D. E. Rodwell. *Fetal Pathology, Huntingdon Life Sciences, East Millstone, NJ.*

Near-term rat fetuses have been traditionally placed in Bouin's solution for fixation and decalcification. This allowed an adequate soft tissue evaluation following razor blade sectioning. While Bouin's solution produced good results, the contrast of the tissues could be improved. The picric acid component presents a health and safety hazard, and an environmental disposal problem. Davidson's fixative was modified at Huntingdon Life Sciences by H. Jonassen to be used as a replacement for Bouin's solution that is routinely used to fix reproductive organs, testes and epididymides. The modified Davidson fixative contains 14% of pure ethanol, 6.25% glacial acetic acid, 37.5% saturated formaldehyde and 42.25% distilled water. The fetuses are placed in a plastic jar containing modified Davidson's fixative for one week. After fixation, the fetuses are rinsed twice in tap water and stored in 70% Isopropyl Alcohol. The razor blade serial section technique described by Wilson is used to perform visceral evaluation. Superior contrast and enhanced definition of organs and vessels are achieved in the fetuses following fixation in Modified Davidson's fixative. Sections remained moist for an extended period of time during evaluation.

1157 INDUCTION OF STRESS PROTEINS BY ARSENIC COMPARED TO HYPERTHERMIA IN TISSUES OF THE AVIAN EMBRYO.

A. S. Schoen and S. E. Bloom. *Microbiology and Immunology, Cornell University, Ithaca, NY.*

Exposure of the early embryo to environmental insults may result in different developmental outcomes depending on target dose, developmental stage, and tissue specificity. The induction of stress proteins may be important indicators of exposure and may influence developmental toxicity. The present study was designed to evaluate the early avian embryo as a model system to study the induction of stress proteins by arsenic and hyperthermia in target tissues. The study compared the induction of the heat shock proteins Hsp24, Hsp70, as well as c-jun and its phosporylated form (P-c-jun) in the head and heart, which differ in stress resistance. K-strain chick embryos at 3 days of development were exposed to graded dosages of sodium arsenite (AS) or to heat shock (HS) of comparable embryo toxicity. Head and heart were harvested at 3, 6, and 10 hr post exposure to AS or HS. Then, stress protein induction was analyzed using immunoblotting analysis. Constitutive levels of Hsp70 and c-jun were similar in the 2 tissues, but constitutive P-c-jun expression was 7-fold higher and Hsp24 was 3-fold higher in the heart. Embryos treated with AS doses of 125, 200, and 250 ug/g demonstrated a dose-dependent increase in Hsp24, Hsp70, and P-c-jun by 10 hr with consistently and substantially higher expression in the heart. C-jun expression in response to AS was similar in the head and heart. AS compared to HS treatments were also evaluated for their capacity to induce stress responses. In the head, HS induced P-c-jun and Hsp24 at a 50-fold differential over comparable AS doses at 3 hr. Hsp70 induction by HS was also greater than AS by about 4-fold. Non-lethal HS treatments were effective at inducing Hsp24 and Hsp70, whereas comparable AS treatments failed to elicit significant responses in head and heart. Thus, profiles of differentially induced stress proteins may be useful as indicators of agent-specific exposures at the tissue level. Also, differential stress protein induction in the developing head and heart may contribute to regulating tissue sensitivity and overall developmental toxicity.

1158 POSTPARTUM DEVELOPMENTAL REFERENCE DATA FROM BEAGLE DOGS OVER FOUR DEFINED PEDIATRIC STAGES.

E. L. Padgett, C. P. Chengelis, K. K. Rhodes, D. L. Holbrook, M. C. Haas, J. L. Lehman, C. R. Bell and M. D. Nemec. *WIL Research Laboratories, Inc., Ashland, OH.*

The FDA Modernization Act of 1997 and the final FDA rule on April 1, 2001 require companies to address the safety and effectiveness of drugs and biologicals in pediatric patients. One way to address the presumed higher risk in children is to conduct safety evaluations during critical developmental stages using non-rodent animal models. However there is limited reference data available for non-rodent species. This study presents reference data for male and female Beagle dogs for defined developmental stages: term neonate (<3 weeks), infant/toddler (3-6 weeks), child (6-20 weeks) and adolescent (20-28 weeks). These data are derived from 7 to 10 Beagle litters whelped at WIL Research Laboratories, Inc.. The Beagle pups received no treatment over the course of gestational/postpartum development. Mean values and standard deviations are presented for endpoints collected over the course of the study. Parameters evaluated include growth patterns (body weight, height, length and torso circumference); developmental landmarks (incisor eruption, eye lid separation, balanopreputial separation, vaginal patency and testes descent); total body composition (lean vs non-lean tissue) and bone mineral endpoints (bone mineral density and bone mineral content); locomotor activity assessments; and standard clinical chemistry parameters (serum chemistry and hematology) are all presented to demonstrate patterns of change over the duration of Beagle development. The results of this study indicate that over the course of development predictive patterns of physiological changes can be measured and that these patterns can be associated with the defined pediatric developmental stages. Reference data of this kind will be essential for the design of non-rodent pediatric studies and in the in-

terpretation of findings for addressing the potential of pediatric risks from direct product exposure in regulatory toxicology studies employing non-rodent animal models.

1159 AN EVALUATION OF THE POTENTIAL OF TWO PEPTIDES, PRAMLINTIDE AND AC2993 (SYNTHETIC EXENDIN-4), TO CROSS THE HUMAN PLACENTAL BARRIER USING AN *EX VIVO* PERFUSION SYSTEM.

R. A. Hiles[1], R. E. Bawdon[2] and E. Petrella[1]. [1]*Preclinical Development, Amylin Pharmaceuticals, Inc., San Diego, CA and* [2]*Obstetrics and Gynecology, University of Texas, Southwestern Medical Center, Dallas, TX.*

Pramlintide (a 37-amino acid peptide) and AC2993 (synthetic exendin-4; a 39-amino acid peptide) are under development for treating patients with diabetes mellitus. Because of the chronic nature of diabetes and, thus its treatment, some patients will become pregnant while on therapy. Therefore, it is important to have knowledge of the potential for direct exposure of the developing fetus to these exogenous peptides. The use of human placentas obtained from full-term pregnancies in an *ex vivo* system allows this situation to be studied without the risk associated with an *in vivo* evaluation. The placental cotyledon selected for each perfusion (6 per peptide) met the acceptance criteria set by Challier[1]. Insulin (added as a control peptide known not to cross the placental barrier) and the study peptide were added to the maternal side of the perfusate and both the maternal and fetal sides were sampled over the 2-hour equilibrium perfusion period and assayed for insulin and the study peptide. Measured insulin on the maternal side of the perfusate remained elevated (~4, 000 µU/mL) while the concentration on the fetal remained low (~10 µU/mL). With mean pramlintide concentrations on the maternal side of 15, 000 to 43, 000 pg/mL, the concentrations on the fetal side ranged from 28 to 268 pg/mL (fetal-to-maternal ratio of 0.002 to 0.006). With mean AC2993 concentrations on the maternal side of 1, 200 to 2, 400 pg/mL, the concentrations on the fetal side ranged from 18 to 34 pg/mL (fetal-to-maternal ratio of 0.008 to 0.017). These results suggest that the potential for either pramlintide or AC2993 to cross the human placental barrier is very low. [1] Challier JC. Criteria for evaluating perfusion experiments and presentation of results. Contr. Gynec. Obstet. 1985; 13:32-9.

1160 INCIDENCE OF VARIATIONS AND MALFORMATIONS DURING FETAL DEVELOPMENT IN THE CYNOMOLGUS MONKEY.

G. Habermann, E. Buse, I. Osterburg, F. Vogel and R. Korte. *Covance Laboratories GmbH, Muenster, Germany.* Sponsor: R. House.

The cynomolgus monkey (Macaca fascicularis) is the predominant species for investigation of embryo-fetal development in the non-human. Given the current momentum of development of new biotechnology products and immunotherapeutics, it is obvious that the demand for developmental toxicity studies in this primate model will increase. In order to be able to distinguish between spontaneous and compound-induced developmental alterations, a comprehensive and reliable data base is mandatory. We therefore investigated 399 fetuses obtained at gestational day 100 and 63 fetuses obtained at gestational day 150 from control mothers. The parameter chosen for assessment was skeletal development. The ossified skeleton was stained with Alizarin red and the carcass was made translucent by preservation in glycerine. A highly graded evaluation scale for identifying even minimal variations was used. At day 100 minor variations were observed in nearly 90% of the fetuses, whereas malformations were encountered in seven fetuses only (1.7%). The most frequent variation was observed in the sternum followed by ribs, vertebral column and skull bones. At day 150 minor variations were also seen in the sternum and ribs at an incidence of 75%. However, malformations could not be detected. These data provide an exellent basis for the characterization of normal fetal development during developmental toxicity studies in the cynomolgus monkey model.

1161 EVALUATION OF TRICHLOROETHYLENE IN A RAT INHALATION DEVELOPMENTAL TOXICITY STUDY.

C. L. Zablotny[1], E. W. Carney[1] and P. H. Dugard[2]. [1]*The Dow Chemical Company, Midland, MI and* [2]*Halogenated Solvents Industry Alliance, Inc., Washington, DC.*

As part of a voluntary program to fill "priority data needs" identified by the US Agency for Toxic Substances and Disease Registry (ATSDR), an inhalation developmental toxicity study conforming to current global regulatory guidelines was conducted. Groups of twenty-seven time-mated, female CD rats were whole-body exposed to target concentrations of 0, 50, 150, and 600 ppm vaporized trichloroethylene (TCE) for six hours/day, seven days/week on days 6-20 of gestation in order to evaluate the maternal and developmental toxicity potential of this compound. The level of 600 ppm represents a limit dose defined in EPA guidelines for inhalation studies. In-life parameters evaluated for all groups included clinical observations, body weight, body weight gain, and feed consumption. On day 21 of gestation, all rats were euthanized and examined for gross pathologic alterations. Liver, kidneys, and gravid uterine weights were recorded, along with the number of corpora lutea, implantations, resorptions, and live/dead fetuses. All fetuses were weighed, sexed, and examined for external alterations. Visceral or skeletal examinations, each involving approximately one half of the fetuses, were conducted as designated. Visceral examinations included visualization of the internal structures of the heart. In addition, the internal structures of the head were examined by serial sectioning for one half of the fetuses. Dams exposed to 600 ppm TCE exhibited maternal toxicity as evidenced by significant decreases in body weight gain (22% less than the control group) on gestation days 6 through 9. There were no maternal effects at either 50 ppm or 150 ppm TCE and no indications of developmental toxicity (including teratogenicity) at any exposure level. Therefore, the no-observed-effect-concentration (NOEC) for maternal toxicity was 150 ppm, whereas the embryonal/fetal NOEC was 600 ppm. Funded by the Halogenated Solvents Industry Alliance, Inc..

1162 THE AFFECT OF FUMONINSIN B1 ON FOLATE TRANSPORT IN CELLS DERIVED FROM MURINE EMBRYOS THAT ARE SUSCEPTIBLE TO FB1-INDUCED NEURAL TUBE DEFECTS.

S. Heller, L. Gelineau-van Waes, J. R. Maddox, M. Solomon and G. D. Bennett. *Cell Biology and Anatomy, University of Nebraska Medical Center, Omaha, NE.*

Fumonisins are mycotoxins that are produced by *Fusarium moniliforme* (*F. verticillioides*) and are contaminants of grains, particularly corn. Their distribution is worldwide and there are at least 14 known fumonisins, of which fumonisin B1 is the most common. FB1 is associated with fatal toxicosis in horses and pigs and it causes hepatotoxicity in rodents. Several studies have linked FB1 to esophageal cancer and neural tube defects (NTDs) in humans. Of the few studies that have investigated the teratogenicity of FB1, most have found very little evidence that this mycotoxin causes any abnormalities other than a generalized embryotoxicity. However, recently we have demonstrated a strain difference to FB1-induced NTDs in two strains of mice, where the pregnant dams were acutely treated during the early stages of gestation. It has been demonstrated that FB1 can disrupt the transportation of folate into cultured cells. Additionally, folate deficiencies have been associated with NTDs in both humans and rodents. Therefore the current study was designed to determine whether FB1 could alter the transportation of folate into cultured primary embryonic cells derived from both susceptible and resistant strains of mice. Once established, primary cells were cultured for 2 days in folate free media during which time a group of cells were also exposed to 20 µg/ml of FB1. At the end of this culture period folate uptake was assayed, using [^{3}H]-folate, from 15 to 60 minutes. Preliminary results from these studies demonstrate that FB1 exposure lead to a decrease in folate uptake in the cells from the susceptible strain. In contrast, the cells from the resistant strain were unaffected by FB1. These differences in folate uptake may lead to a folate deficiency in susceptible embryos and may explain the teratogenic differences seen between these two strains of mice.

1163 *EX VIVO* HUMAN PLACENTAL PERFUSION SYSTEM IN THE ASSESSMENT OF TRANSPLACENTAL PASSAGE.

P. K. Myllynen[1], P. Pienimäki[1] and K. H. Vahakangas[1,2]. [1]*Department of Pharmacology and Toxicology, University of Oulu, Oulu, Finland and* [2]*Department of Pharmacology and Toxicology, University of Kuopio, Kuopio, Finland.* Sponsor: K. Savolainen.

Ethical considerations limit *in vivo* human studies of transplacental passage of drugs. Animal testing gives valuable information but the structure and functions of the placenta are species specific. Our aim is to clarify the usefulness of placental perfusion method as a part of pre-clinical risk assessment. Single human placental cotyledons were perfused for 2 hours. Modified Krebs-Ringer phosphate buffer with natriumbicarbonate, dextran and heparin was used as perfusion medium. In successful perfusions the leak from maternal to fetal side was less than 2 ml/h. Carbamazepine (5-carbamoyl-5H-dibenz-[b, f]azepine; CBZ), oxcarbazepine(10, 11-dihydro-10-oxo-5H-dibenz(b, f)-azepine-5-carboxamide; OCBZ) and lamotrigine (3, 5-diamino-6-[2, 3-dichlorophenyl]-1, 2, 4-triazine; LTG) were studied. Antipyrine, a non-ionized, non-metabolized and non-protein bound drug, was used as a reference substance. Drug concentrations were analyzed using high performance liquid chromatography. In addition, cord blood and maternal venous samples were collected from mothers using OCBZ, CBZ and LTG during pregnancy. All studied substrates crossed placenta rapidly, maternal and venous concentrations being equal at steady state. Equilibrium between maternal and fetal concentrations was reached earlier with CBZ, OCBZ and LTG than with antipyrine.

Although data achieved with placental perfusion method usually correlated well with available clinical data differences between *in vivo* and *ex vivo* situation were also noted. Perfusions indicated slight accumulation of 10-OH-CBZ in placental tissue but *in vivo* results indicated no accumulation. This may have been due to tissue oedema during perfusions. In conclusion, human placental perfusion system is a promising method but further studies are needed to validate the method for the assessment of fetal exposure.

1164 INTERLABORATORY STUDY OF THE PRIMARY ANTIBODY RESPONSE TO SHEEP RED BLOOD CELLS IN OUTBRED RODENTS.

S. E. Loveless[1], G. S. Ladics[1], C. Smith[1], M. P. Holsapple[2], M. R. Woolhiser[2], P. K. Anderson[2], K. L. White, Jr.[3], D. L. Musgrove[3], R. J. Smialowicz[4] and W. Williams[4]. *[1]DuPont Haskell Laboratory for Health and Environmental Sciences, Newark, DE, [2]Dow Chemical Co, Midland, MI, [3]Virginia Commonwealth University, Richmond, VA and [4]NHEERL, Research Triangle Park, NC.*

EPA guidelines currently provide a choice in evaluating immune system function in rats and mice using sheep red blood cells (sRBC) as the preferred antigen, namely, an antibody-forming cell (AFC) assay or a sRBC-specific serum IgM ELISA. The initial objectives of this interlaboratory study were for all four laboratories to use the same source of sRBC and determine 1) optimal sRBC concentration for immunization and 2) peak day of antibody response in female CD rats and CD1 mice. The primary objective was for each Lab. to determine which of the two methods was more sensitive in detecting suppression of the antibody response by cyclophosphamide (CP). Each Lab. determined optimal immunization concentrations for each assay and each species. Peak antibody response was day 4 for the AFC in mice or rats, whereas Day 5 was the peak day for the ELISA assay in mice and Day 6 for rats (sRBC injection was on Day 0). Rats were injected iv with sRBC followed by ip injections of 0, 0.3, 1, 3, 10 or 30 mg/kg/day CP. Statistically significant reductions in antibody response were first detected at 1 mg/kg/day (44% suppression, AFC/million splenocytes) and at 10 mg/kg (30-69% suppression by ELISA by 3 labs). Mice were injected iv with sRBC followed by ip injections of 0, 5, 10, 20, 40, or 60 mg/kg/day CP. Statistically significant reductions in the antibody response were detected at 5 mg/kg (36-64% suppression - AFC assay) by 3 labs and 10 mg/kg (55% suppression) by the remaining Lab.. Three labs detected suppression at 10 mg/kg (6-25% inhibition) using the ELISA. In conclusion, the rat ELISA detected significant suppression at the same (2 labs) or lower (1 Lab.) concentration compared to the PFC assay. In contrast, the mouse PFC assay detected suppression at a lower dose than the ELISA in 3 of 4 labs.

1165 THE RESPONSE OF C57Bl/6 MICE TO THE MOUSE INFLUENZA HOST RESISTANCE (MIHR) MODEL.

L. A. Cowan[1], G. R. Burleson[2], F. G. Burleson[2] and J. L. Bussiere[1]. *[1]Immunex Corp., Seattle, WA and [2]BRT-Burleson Research Technologies, Inc., Raleigh, NC.*

In safety testing of potential immune modulators, one of the major objectives is to determine if the compound has an immunosuppressive effect, resulting in an increased susceptibility to infectious disease. Since clearance of the influenza virus requires an intact functional immune system, incorporating cytokine production, antibody production and natural killer cell, macrophage, and cytotoxic T lymphocyte activity, the MIHR model allows an assessment of overall immunocompetence. Although the MIHR model is well characterized in BALB/c mice, there has been limited experience with this model in C57Bl/6 mice. The purpose of this study was to characterize the response of the C57Bl/6 mouse strain in the MIHR model, in order to establish baseline parameters that could be used to assess immune competence in specific knock-out mice on the C57Bl/6 background. Male and female C57Bl/6 mice, 6 - 8 weeks old were administered influenza virus (InV) intranasally [4 X 10^3 (lo InV) or 4 X 10^4 (hi InV) infectious particles], with or without daily oral dexamethasone (DEX) (Day -3 through Day 6 or Day 21) as a positive control. Viral burden in the lung homogenate and InV-specific IgG titers were determined at several time points postinfection. The 10 day survival rate in the C57BL/6 hi InV was 56.6% in males with 10 mg/kg/d DEX, 96.7% in male vehicle controls, 73.3% in females receiving 10 mg/kg/d DEX, and 96.7% in female vehicle controls. In a second study with female mice given 5 mg/kg/d DEX, there were 72% survivors in the hi InV group and 96% survivors in the lo InV group. With 1 mg/kg/d DEX, with hi InV, there were 96% survivors; vehicle control survival was 92-100%. Historical control BALB/c female mice receiving 20 mg/kg/day DEX or vehicle, had 100% 10 day survival. This study demonstrates in comparison to BALB/c mice, the C57Bl/6 strain is more susceptible to InV and DEX in the MIHR, and reinforces that establishing strain-specific characterization of the MIHR is critical for accurate assessment of an immunotoxic potential.

1166 COMPARITIVE ANALYSIS OF HUMAN, CYNOMOLGUS MONKEY AND COMMON MARMOSET PERIPHERAL BLOOD MONONUCLEAR CELLS BY FLOW CYTOMETRY.

M. G. Wing, D. F. Lanham, E. L. Hunter and J. M. Bidgood. *Experimental Biology, Huntingdon Life Sciences, Huntingdon, United Kingdom.* Sponsor: C. Atterwill.

Flow cytometry has become a recognised method to measure mononuclear cell numbers on samples taken from toxicology studies. For reasons of epitope expression and biopharmaceutical immunogenicity, non-human primates are often the toxicological species of choice. In the absence of reagents specific for non-human primates, commercially available cross-reactive anti-human monoclonal antibodies were evaluated in cynomologus monkeys and marmosets, using multiple colour analysis to improve the accuracy of immunophenotyping and reduce blood requirements. EDTA-blood was stained with cocktails of monoclonal antibodies then the human and cynomolgus samples lysed with TQ Prep (Beckman Coulter) or Pharmlyse (BD Pharmingen) for the marmoset samples. The non-human primate samples were analysed for total T lymphocyte (CD3+) and B lymphocyte (CD20+) numbers by flow cytometry using cell scatter to identify the lymphocyte population. T lymphocyte subset analysis was performed using a CD3 T-gate. The principle difference noted was the higher number of CD4 and CD8+ T lymphocytes and B lymphocytes in the cynomologus monkey which were 2-3 times higher than that seen in the marmoset and human samples. The cynomolgus monkey also had a higher proportion of peripheral blood B lymphocytes (~25%) compared to the common marmoset and man (~15%). In conclusion, 3-colour immunophenoptyping panels have been successfully used to analyse marmoset and cynomolgus monkey peripheral blood. Good similarity was noted between the human and non-human primate parameters, and in particular between the common marmoset and man.

1167 HUMORAL IMMUNE RESPONSE TO KEYHOLE LIMPET HAEMOCYANIN (KLH) IN THE CYNOMOLGUS MONKEY.

D. J. Spencer-Briggs, S. R. Wilkins, S. J. Crome and M. G. Wing. *Experimental Biology, Huntingdon Life Sciences, Huntingdon, United Kingdom.* Sponsor: C. Atterwill.

The safety assessment of immunomodulatory biopharmaceuticals require immunopharmacology/toxicity studies to be performed in a pharmacologically active species. Because species selection may have to take account of restricted epitope expression, ligand specificity and immunogenicity of human proteins, the non-human primate may be the most relevant species. Accordingly, the humoral immune response to the T-dependent antigen KLH was performed in the cynomolgus monkey to monitor specific antibody production. Groups of cynomolgus monkeys were immunised with KLH using 3 different protocols, then specific antibody to KLH was measured using a capture ELISA. In protocol 1, the animals received 2x100ug of KLH i.d. 43 days apart. Primary and secondary antibody responses were observed in all animals, however the variability in the response suggested that the dose of antigen or its formulation were not optimal. In protocol 2, the time between the two immunisations was reduced to 14 days to fit the procedure into a 4-week regulatory toxicology study. The animals received 2x100ug of KLH i.d. with the first dose formulated in Freund's incomplete adjuvant. This resulted in a robust and homogeneous antibody response, however the primary and secondary antibody responses were merged. In protocol 3 the animals received 2x1000ug KLH s.c. 14 days apart. Again the antibody response was homogeneous and robust, plus the primary response which typically plateaued by day 15, was distinguishable from the secondary response. In conclusion, protocol 3 offered the advantage of producing a homogeneous response without the need to use adjuvant and importantly allowed the primary and secondary responses to be monitored within a 4-week regulatory toxicology study design.

1168 ANALYSIS OF RAT IMMUNOTOXICOLOGY, HEAMATOLOGY AND CLINICAL CHEMISTRY PARAMETER VARIABILITY.

G. Healey, D. J. Lanham and M. G. Wing. *Experimental Biology, Huntingdon Life Sciences, Huntingdon, United Kingdom.* Sponsor: C. Atterwill.

Common methodologies are cited in regulatory guidelines for the immunotoxicity testing of pesticides, industrial chemicals, food additives and NCE's. These include immunophenotyping by flow cytometry, natural killer (NK) cell activity in a chromium release assay and specific antibody formation in a plaque forming cell (PFC) assay. Concerns have been raised over the variability seen in these assays and so immunotoxicology data were compared with clinical chemistry, haematology and organ weight data from a series of rat studies. Using data from control or unaf-

fected groups, the pooled within-group coefficient of variation (cv) was estimated using analysis of variance on logarithmically-transformed data. The cv's for the various endpoints in the two functional assays, PFC and NK, were quite high at 60-65%. For flow cytometry, however, the cv's for the various cell-types averaged around 40% for absolute counts and 20% for percentage counts. Whilst many chemistry parameters and the large organs have cv's below 20%, some enzymes, differential cell counts and small organs (endocrine and reproductive) have cv's between 30% and 70%.The higher cv seen with the PFC and NK assays *versus* flow cytometry is most likely due to the multiple sample processing steps and in the case of the PFC assay, immunisation of the animals. In conclusion, although the functional assay data was shown to have a high inter-study variability, this was not substantially different to some of the haematology and clinical chemistry parameters routinely measured on toxicology studies. The position for flow cytometry was even more favourable.

1169 IDENTIFICATION OF THE AGE AT WHICH IMMUNOTOXICOLOGICAL PARAMETERS CAN BE EVALUATED IN RATS.

R. A. Matulka[1] and R. J. Smialowicz[2]. [1]*Curriculum in Toxicology, UNC, Chapel Hill, NC and* [2]*ITB, ETD, USEPA, Research Triangle Park, NC.*

Development of the immune system begins early in gestation and continues to mature through puberty. Exposure to immunotoxic agents may occur at any point in development (i.e., prenatal, early post-natal, juvenile). Numerous immune function assays have been used to identify immunotoxicity in adult rats, however, these assays have not been adequately tested for application during early post-natal and/or juvenile immune system development. The objective of this study was to determine validity of utilizing adult immunotoxicological assays on juvenile Sprague-Dawley rats. Animals were tested for contact hypersensitivity (CHS) response to 2, 4-dinitro, 1-fluorobenzene (DNFB), delayed type hypersensitivity (DTH) responses to bovine serum albumin (BSA), and primary immune response, as demonstrated by increases in anti-sheep red blood cell (SRBC)-specific IgM. Sensitization or immunization was initiated at 3, 4.5 or 6 weeks of age. At 3 weeks of age both males and females demonstrated elevated CHS responses to DNFB, (i.e., 52.8% and 55.1% increase over naive controls, respectively). In contrast, DTH response was absent in males, and only minimally increased in females. Anti-SRBC IgM production, as determined by ELISA, averaged 4.3 and 7.9 µg/ml for males and females (adult concentrations average 30 µg/ml). At 4.5 weeks of age, the CHS response was 14% and 7% over control for females and males, respectively. IgM production averaged 15.3 µg/ml in males, and 10 µg/ml in females. DTH response increased 16% in males and 9% in females. At six weeks of age (i.e., the onset of puberty), IgM concentrations were 17.9 µg/ml in males, and 46.9 µg/ml in females. DTH response showed a 16% and 14% increase in males and females, respectively, and the CHS response in males and females increased 62% and 36%, respectively. These results indicate while the immune function responses employed produced measurable reactions in these three experimental procedures, the protocols must be refined for testing juvenile animals. (This abstract does not reflect EPA policy.)

1170 VALIDATION OF A METHOD TO DETERMINE RELATIVE PROPORTIONS OF ERYTHROID, MYELOID AND LYMPHOID PRECURSORS IN RAT BONE MARROW BY FLOW CYTOMETRY.

S. A. Kirk, G. Desilets, C. Provost and L. LeSauteur. *Toxicology, CTBR, Senneville, PQ, Canada.* Sponsor: G. Lulham.

To assess toxicity in the bone marrow, we have validated an assay to determine the proportions of myeloid, lymphoid and erythroid cells in rats using flow cytometry based on the method described by A Saad et al, "Differential Analysis of Rat Bone Marrow by Flow Cytometry" Comparative Haematology International (2000) 10:97-101. Bone marrow cells from rat femurs were stained with fluorochrome conjugated antibodies against CD71 and CD45. Cells were acquired using a flow cytometer and gated according to their expression of CD71 and CD45. Cells with a high level of CD71 expression were regarded as erythroid. A gate was placed around the remaining myeloid and lymphoid cells and these two populations were distinguished according to their side scatter properties. Cell proportions were calculated as a percentage of the total bone marrow population. Parameters examined in this validation were intra- and inter-assay precision, reference range and stability of fixed samples. Results for both the intra- and inter-assay precision produced CVs within the acceptance criteria of ¡Ü20%. Reference range results showed the proportion of erythroid cells ranged from 31.27 to 38.33% in males and 32.88 to 43.21% in females. Myeloid/lymphoid cell proportions varied between 32.83 and 42.30% for males and 27.67 to 41.31% for females. When a gate was set only on the myeloid/lymphoid population, the proportion of myeloid cells represented 45.36 to 53.88% in males and 44.11 to 52.25% in females. The proportion of lymphoid cells ranged from 40.42 to 50.35% for males and 44.21 and 50.21% in females. Results for stability were rejected as the isotype controls at 48 and 72 hours displayed a high level of fluorescence. Intra- and inter-assay precision met the acceptance criteria and the reference range for males and females was determined. Stability was not acceptable at 48 and 72 hours, therefore samples must be analyzed within 24 hours of staining.

1171 FURTHER INTERGRATION OF THE MOUSE LOCAL LYMPH NODE ASSAY.

M. R. Woolhiser, P. A. Anderson and M. P. Holsapple. *Toxicology & Environmental Research and Consulting, The Dow Chemical Company, Midland, MI.*

The LLNA has been extensively characterized and is now accepted as a "stand alone" to the traditional guinea pig models to assess the sensitization potential of chemicals. The goal of this investigation was to facilitate the continued integration of the LLNA. First, we have begun using an approach whereby a test material (TM) is evaluated for primary irritation in a pre-screen, range finding study. Briefly, at least six concentrations of TM are applied to the ears of mice for two days and ear swelling is determined 24 hrs later. Based upon measurable, detectable elevations in ear thickness, and reported increases in ear swelling for known irritants, we identify the concentration that produces 10% ear swelling as the minimal irritating concentration (MIC). The concentrations used in the subsequent LLNA are based on the MIC. The validity of this method is demonstrated with benzalkonium chloride (BC) and known irritants and sensitizers. Administration of the MIC for non-sensitizers produces a stimulation index (SI) near or less than 3.0, the standard threshold for a positive LLNA. Second, the standard LLNA protocol calls for a 5-hour pulse with ^{3}H-thymidine. This amount of time is not consistent with what is known about cellular proliferation or the uptake of radiolabel. A reduction in pulse time would reduce the time of the assay and introduce flexibility in the design. Initial studies with strong sensitizers (5% TMA and 1% DNCB) indicated no significant differences in absolute dpms after a 2-, 3- or 5-hour pulse. However, the absolute dpms in the vehicle groups were decreased at the earlier timepoints; this ultimately had an impact on SI values. This trend repeated when BC or the mild sensitizer, HCA, were evaluated and resulted in SI that were slightly greater at 2-hours than at 5-hours despite similar dpm values following TM exposure. These studies indicate that a shorter pulse is possible, thus providing flexibility in the conduct of the LLNA. These studies also highlight the importance of using both SI and absolute dpms for the interpretation of the LLNA.

1172 TRITIATED THYMIDINE INCORPORATION AS AN ENDPOINT IN THE POPLITEAL LYMPH NODE ASSAY.

C. Ruat[1], L. Faure[1], G. Choquet-Kastylevski[2] and J. Descotes[2]. [1]*MDS Pharma Services, L'Arbresle, France and* [2]*Poison Center & INSERM University of 503, Edouard Herriot Hospital, Lyon, France.*

The popliteal lymph node (PLN) assay is an investigational tool to predict drugs and chemicals that are likely to induce systemic autoimmune and immunogenic reactions in man. Typically, the endpoints used are lymph node weight and cellularity, but sensitivity is not considered optimal. In the present study, incorporation of tritiated thymidine was used. Groups of 8 Balb/c mice received 50 µl of 10, 20 or 40 mg/ml of streptozotocin, diphenylhydantoin, sulfamethoxa-zole, or metformin into one hind footpad. Two additional groups received either 20 mg/ml of imipramine or 50% ethanol. The same volume of the vehicle was injected into the other hind footpad. Seven days later they were sacrificed five hours after an intravenous injection of 20 µCi of tritiated methyl-thymidine. PLNs were weighed and the incorpo-ration of tritiated thymidine measured by liquid scintillation counting. PLN weight and thymidine incorporation were increased to a similar degree relative to the control limb with streptozotocin, diphenylhydantoin, imipramine and ethanol. No change was seen in either endpoint with sulfamethozaxole and metformin. Based on these results, the measurement of thymidine incorporation does not seem to enhance the sensitivity of the assay. In addition, it failed to identify either imipramine or ethanol as inducing a non-specific inflammatory response. Finally, the negative results obtained with sulfamethoxazole indicates that this assay will not readily detect immunogenic compounds.

1173 FURTHER EXAMINATION OF AN ALTERNATIVE VEHICLE FOR WATER SOLUBLE MATERIALS IN THE LOCAL LYMPH NODE ASSAY.

L. W. Cruse[1], C. A. Ryan[1], R. A. Skinner[2], R. J. Dearman[2], L. Kimber[2] and G. F. Gerberick[1]. [1]*The Procter & Gamble Company, Cincinnati, OH and* [2]*Syngenta CTL, Macclesfield, United Kingdom.*

Vehicle choice for the murine local lymph node assay (LLNA) is important and has been shown to influence the sensitization potential of haptens. Suggested vehicles include organic solvents and organic-aqueous mixtures. However, due to its poor

wetting qualities and high surface tension, water is not recommended so testing water soluble materials can be problematic. We previously identified a water-based vehicle that provided better skin wetting properties than water alone and assessed its performance in the LLNA relative to other solvents using two water soluble haptens, dinitrobenzene sulfonic acid and formaldehyde. This wetting vehicle, 1% aqueous Pluronic® L92 (L92) has been further examined using the metal salts potassium dichromate and nickel sulfate and its performance compared to dimethylsulfoxide (DMSO) and dimethylformamide (DMF). Estimates of the relative sensitizing potency in each vehicle were determined by calculation of EC3 values (the estimated concentration required to induce a threshold positive response). Potassium dichromate was positive in DMF, DMSO and 1%L92. The potency ranking was DMF ≅ DMSO > 1% L92 (EC3 values were 0.03%, 0.05% and 0.17%, respectively). Potassium dichromate in water was negative. Nickel sulfate induced threshold positive responses when formulated in DMSO and 1% L92 (stimulation indices of 3.1 and 3.0, respectively), whereas the maximal stimulation index recorded following application in DMF was 2.2. Based on the results of this study, we recommend either DMF or DMSO as the preferred vehicle for water soluble materials in the LLNA. However, if the chemical is not soluble in DMSO or DMF, or, if higher concentrations can be achieved in an aqueous vehicle, then 1% L92 provides a better alternative to water alone in terms of improved assay performance for hazard identification.

1174 USE OF A B CELL MARKER (B220) TO DISCRIMINATE BETWEEN ALLERGENS AND IRRITANTS IN THE LOCAL LYMPH NODE ASSAY (LLNA).

G. F. Gerberick[1], L. W. Cruse[1], C. A. Ryan[1], J. G. Chaney[1], R. A. Skinner[2], R. J. Dearman[2] and I. Kimber[2]. [1]*The Procter & Gamble Company, Cincinnati, OH and* [2]*Syngenta CTL, Macclesfield, United Kingdom.*

It has been shown that mice exposed to contact allergens show selective B cell activation in the draining lymph nodes (DLN) as seen by an increase in the % of B220$^+$ or IgG/IgM$^+$ cells. We have now examined whether measurement of % B220$^+$ cells could be used as an alternative endpoint for the LLNA to differentiate between allergenic responses and those few irritants which induce low level proliferation in the DLN. Mice were treated on the ears for 3 consecutive days with concentrations of allergens or irritants known to cause proliferation in DLN cells. The DLN were excised 72 h after the final treatment and the cells were prepared for B220 analysis by flow cytometry. The % B220$^+$ cells from test and vehicle treated mice were determined for 5 allergens and 4 irritants in multiple experiments (n=3 to 17). As expected, the % of B220$^+$ cells was increased with the allergens tested, whereas the % B220$^+$ cells was unaffected by irritant treatment. The % B220 values for each chemical treatment (41 allergen and 28 irritant observations) *versus* the % B220 value for the matched vehicle control were plotted and a classification tree model was developed to calculate a B220 test/vehicle ratio cutoff of 1.25 for discriminating between allergens and irritants. Using this ratio, 93% of the allergens and irritants were classified correctly. Moreover, the method was very reproducible, with the strong allergen 1-chloro-2, 4-dinitrobenzene classified correctly in 17 of 17 experiments and the weak allergen α-hexylcinnamicaldehyde classified correctly in 12 of 13 experiments. To evaluate the performance of this model ina second independent laboratory, 3 allergens and 2 irritants were tested. Each of the allergens and irritants were classified correctly using the B220 test/vehicle cutoff of 1.25. These data demonstrate that analysis of B220 expression on B cells may be useful in differentiating allergen and irritant responses in the DLN of chemically treated mice.

1175 PRE-VALIDATION STUDY FOR THE POPLITEAL LYMPH NODE ASSAY AS A TOOL TO PREDICT THE IMMUNOSENSITIZING CAPACITY OF (NON-) PHARMACEUTICALS.

S. Nierkens, L. Nieuwenhuijsen and R. Pieters. *Immunotoxicology, Institute for Risk Assessment Sciences, Utrecht, Netherlands.* Sponsor: M. van den Berg.

A large number of pharmaceutical drugs and non-pharmaceutical chemicals are known to cause systemic hypersensitivity and autoimmune-like clinical phenomena. The multifactorial pathogenesis of chemical-induced hypersensitivity is a major problem in developing models that allow recognition of the immunosensitizing potential of chemicals. To date no validated and generally applicable predictive immunotoxicological screening methods are included in traditional toxicity testing. The (reporter antigen-) popliteal lymph node assay (RA-PLNA) is regarded as a promising tool for this purpose as the RA-PLNA in particular is able to discriminate between compounds that act as adjuvant without stimulating specific T cell responses and chemicals that stimulate neo-antigen specific T cells. So far this assay has not been validated. We studied specific immune responses in the RA-PLNA and compared those with responses in the auricular lymph node (ALN) after s.c. injection of the drug together with the RA TNP-Ficoll into the ear (importantly s.c. injection between the ears did not elicit a TNP-specific response in the ALN). Responses showed similar proliferation of Th, Tc and B cells in the assays but the increase in dendritic cells was higher in the RA-PLNA. TNP-specific antibody responses were also more increased in the PLN than in the ALN. Clearly, results reveal that both assays, RA-PLNA and "RA-LLNA" are capable of identifying sensitizing chemicals (D-penicillamine, hydantoin, streptozotocin, ofloxacin), but that the RA-PLNA is more sensitive. Additionally, the narrow s.c. space in the ear requires injection of smaller volumes thus limiting the amount of chemical that can be injected. This also causes difficulties with injection of non- or poorly soluble chemicals and evidently affects reproducibility. Together, this study contributes to the validation of the RA-PLNA as a predictive test for immunosensitizing capacity of chemicals and indicates the advantage of footpad injection over ear injection.

1176 THE LOCAL LYMPH NODE ASSAY: CURRENT REGULATORY STATUS.

Z. Wright[1], D. A. Basketter[1], R. J. Dearman[2], C. A. Ryan[3], G. F. Gerberick[3], R. J. Fielder[4] and I. Kimber[2]. [1]*SEAC, Unilever Colworth Laboratory, Sharnbrook, United Kingdom,* [2]*Syngenta CTL, Macclesfield, United Kingdom,* [3]*Procter & Gamble, Miami Valley Laboratories, Cincinnati, OH and* [4]*Dept of Health, London, United Kingdom.*

The local lymph node assay (LLNA) is an alternative to guinea pig tests for identification of skin sensitising chemicals. In the standard LLNA protocol, CBA strain mice receive 3 consecutive daily topical applications of test substance (at 3 dose levels). Five days after the initiation of exposure, proliferative responses in lymph nodes draining the application site are measured by radiolabelled thymidine incorporation *in situ*. Chemicals which induce proliferative responses ^{3}3x those observed in concurrent vehicle treated control animals are considered to be skin sensitisers. The assay has been endorsed as a stand alone method for the determination of contact allergenic hazard by the FDA, the EPA and others following approval by the Interagency Co-ordinating Committee on the Validation of Alternative Methods (ICCVAM). The LLNA has also received formal approval from the European Centre for the Validation of Alternative Methods (ECVAM). Following these formal validations, the UK submitted the LLNA as an alternative method to the Organisation for Economic Co-operation and Development (OECD). The application has now been through redrafting and detailed discussion by the member states. It was approved by National Representatives in Paris on May 1st 2001 as OECD Guideline 429 and has been submitted to the Joint Meeting for final approval. Discussions are now underway concerning how to incorporate the LLNA into regulatory texts within the EU and within the Globally Harmonised System of toxicological testing.

1177 PREDICTION OF HUMAN SENSITISATION POTENCY USING LOCAL LYMPH NODE ASSAY EC3 VALUES.

D. A. Basketter[1], Z. Wright[1], N. J. Gilmour[1], C. A. Ryan[2], G. F. Gerberick[2], M. K. Robinson[2], R. J. Dearman[3] and I. Kimber[3]. [1]*SEAC, Unilever Colworth Laboratory, Sharnbrook, United Kingdom,* [2]*Procter & Gamble, Miami Valley Laboratories, Cincinnati, OH and* [3]*Syngenta CTL, Macclesfield, United Kingdom.*

Effective evaluation of skin sensitisation demands that potential contact allergens are identified and the risk of sensitisation amongst exposed populations assessed. Sensitisation hazard is not an all or nothing phenomenon; Dose-Response relationships can be discerned and thresholds identified for induction and elicitation of contact allergy. These parameters, under the heading of potency, are vital for risk assessment. The murine local lymph node assay (LLNA) is an accepted method for the identification of sensitisation hazards (a sensitiser is a chemical that induces a stimulation index 3 or more times that of the concurrent vehicle control). The LLNA has also been used to determine the potency of sensitisers, by derivation of an EC3 value, the estimated concentration of chemical required to induce a stimulation index of 3. Here we have compared potency assessments derived from LLNA data for 40 chemicals which have been classified as strong, moderate, weak, extremely weak or non-sensitisers on the basis of clinical information. The potency of each chemical was also independently classified, based on its LLNA EC3 value. The two sets of potency rankings were then compared. The potency ranking of the allergens was very similar using EC3 values or human clinical experience, with 36/40 being correctly classified by the LLNA. A good correlation existed across all of the potency classifications. Importantly the 21 chemicals evaluated and classified as sensitisers for humans and which would merit regulatory classification were categorised identically by the LLNA. This investigation demonstrates that the LLNA can provide quantitative estimates of relative skin sensitising potency which correlate well with human potency. The data support use of EC3 values for estimating skin sensitisation potency and the use of that information in the risk assessment process.

1178 RESTRAINT STRESS MODULATION OF EAR SWELLING IN ACD IS INDEPENDENT OF SENSITIZING DOSE OF CHEMICAL.

M. S. Flint, R. R. Salmen, K. Brumbaugh and S. S. Tinkle. *TMBB, NIOSH, Morgantown, WV.*

Stress plays an important role in numerous chronic health problems including modulation of immunologic diseases, however, the interaction between the stress response and the cutaneous immune response are incompletely understood. We have previously shown that acute stress suppresses the immune response in allergic contact dermatitis (ACD), and additional studies have shown a significant interaction between the concentration of chemical required for sensitization and for challenge in the development of ACD. We hypothesized that 2 hour restraint stress would change the sensitizing concentration of chemical required to elicit a full ear swelling response to chemical challenge. Male BALB/c mice were exposed on the back with increasing doses (0.05%-0.5%) of 2, 4 dinitrofluorobenzene (DNFB) on days 1 & 2 and challenged onto the ear with 0.1% DNFB on day 6. Mice were restrained for 2 hours prior to chemical application on day 1. We assessed ear swelling 24, 48 and 72 h post-challenge. Quantitative analysis of the data indicated that the ear swelling response to chemical challenge is dependent upon the sensitization concentration of DNFB and is dose-responsive. The curve shows a quadratic trend with 0.1% as a possible maximum dose for sensitization. Application of restraint stress did not alter the shape of this curve but significantly suppressed ear swelling at all concentrations of DNFB. These data suggest that restraint modulation of ACD is independent of the sensitizing dose of chemical.

1179 EXPRESSION OF TH2 CYTOKINES IS A GENERAL FEATURE OF MURINE CONTACT ALLERGY.

J. Streich, N. Runser, W. Suter and P. Ulrich. *Genetic and Experimental Toxicology, Novartis Pharma AG, Basel, Switzerland.* Sponsor: A. Wolf.

The cytokine response pattern following sensitisation (induction) and elicitation (challenge) of contact allergy in BALB/c mice with different chemicals (dinitrochlorobenzene, dinitrofluorobenzene, oxazolone, glutaraldehyde, formaldehyde, trimellitic anhydride, croton oil) was investigated. The results of our investigations showed that contact allergens induced both T helper (Th) 1 cytokines interleukin (IL) 2, interferon gamma (IFNg) and Th2 cytokines (IL-4, IL-10) at different stages during murine contact allergy. We also confirmed our previous findings that IL-4 and IL-10 release were up-regulated during the challenge phase regardless the contact allergen used, whereas the release of IFNg did not show a clear preference for being up- or down-regulated. In our hands, the increased expression of Th2 cytokines after challenge exposure to contact allergens appeared as a stable marker of secondary contact allergenic responses. Quantitative differences in the expression of IL-4 were observed between different contact allergens. The present results clearly indicate that skin sensitisers were able to elicit cytokine response patterns, which could not be related to a clear-cut Th1 or Th2 type of cytokine response. Furthermore, topical application of contact allergens produced different kinetics of cytokine secretion upon induction and challenge. In our hands, the co-expression of Th1 and Th2 type cytokines appeared as a universal consequence of dermal application of contact allergens to responsive mice. Our results also indicate that chemicals differ in their potency to induce the expression of these cytokines. Furthermore, the results do not support the view that different chemicals induce Th1 or Th2 cytokines in a mutually exclusive manner depending on their preference to induce either contact or respiratory allergy. The results are expected to renew the discussion about the usefulness of the Th1/Th2 paradigm in certain areas of immunotoxicology.

1180 THE USE OF CD54 AND CD86 EXPRESSION ON THE HUMAN THP-1 AND KG-1 CELL LINES TO PREDICT CONTACT SENSITIZERS.

Y. Yoshida, Y. Ito, H. Sakaguchi, M. Okuda and H. Suzuki. *Kao Corporation, Tochigi, Japan.* Sponsor: J. Avalos.

In regard to *in vitro* skin sensitization tests, dendritic cells (DCs) derived from human peripheral blood have been considered in the development of new tests. However, there are some problems with the use of human DCs in skin sensitization tests. These include availability of human blood, donor to donor variability and other problems. In the present study, we evaluated the use of two human cell lines, THP-1 (monocytic leukemia cell line) and KG-1 (acute myelogenous leukemia cell line) in developing a method to identify contact sensitizers. Naive cells were used in our studies after comparing the usefulness of cytokine-derived cells and naive cells. The expression of CD54 and CD86 on THP-1 and KG-1 cells was measured using flow cytometry after a 24-hour exposure to known allergens (e.g., DNCB, 2-MBT, $NiSO_4$) and non-allergens (e.g., SLS, methyl salicylate, DMSO). We found that only the allergens enhanced the expression of CD54 and/or CD86 significantly in a dose dependent manner. In particular, metal salts, such as $NiSO_4$ and $CoSO_4$, increased only the CD54 expression. Additionally, we examined the signaling pathways of DNCB in order to study the intracellular mechanisms involved in the activation of THP-1 by DNCB. Results obtained using Western blotting showed that the phosphorylation of p38 MAPK was increased after 30-minute exposure to DNCB. Furthermore, SB203580, a specific inhibitor of the p38 MAPK, inhibited the up-regulation of CD54 and CD86 upon stimulation with DNCB. These results suggested that the up-regulation of CD54 and CD86 was coupled to the phosphorylation of p38 MAPK. This method was further evaluated using more than 20 of our materials. The expression of CD54 and CD86 on THP-1 and KG-1 cells used for predicting the sensitization potential of these materials was compared to guinea pig test results. A higher accuracy was observed with THP-1 (>70%) than with KG-1 cells. These results suggest that *in vitro* sensitization tests using these cell lines, especially THP-1 cells are useful to predict various contact sensitizers.

1181 INTEGRATION OF THE PASSIVE CUTANEOUS ANAPHYLAXIS (PCA) ASSAY INTO STUDIES TO IDENTIFY POTENTIAL CHEMICAL ALLERGENS.

J. A. Hotchkiss, M. R. Woolhiser and M. P. Holsapple. *Toxicology & Environmental Research and Consulting, The Dow Chemical Company, Midland, MI.*

Establishing a predictive test to identify chemicals that may induce respiratory sensitization is a pressing need in safety assessment. Concerns over the introduction of novel protein allergens has resurrected an interest in the PCA assay to measure antigen-specific IgE. This study compared the ability of the PCA assay to identify known protein (ovalbumin; OVA) and chemical (trimellitic anhydride; TMA) respiratory sensitizers. Balb/C mice were systemically sensitized to OVA *via* two i.p. injections seven days apart with 5% OVA in PBS (or with PBS alone; control). Test serum was collected 21 and 28 days following initial exposure. Serial dilutions of test sera were injected i.d. into the ears of Balb/c mice or the shaved backs of Sprague-Dawley (SD) rats. OVA and Evan's blue dye were injected i.v. 48 h later. The lowest dilution producing a positive reaction (≥ 2 x 2 mm spot) was recorded. Both heterologous and homologous PCA assays indicated that Day 28 OVA serum had the highest titer. For the chemical allergens, A/J mice were treated topically with 25% TMA, 1% dinitrochlorobenzene (DNCB; dermal sensitizer) or acetone:olive oil (AOO; vehicle) on their shaved backs. Seven days later, 12.5% TMA, 0.5% DNCB, or AOO was topically applied to the ears. Serial dilutions of test sera, collected 7 days later, were injected into the ears of A/J mice or the shaved backs of SD rats. Four hours later, 12.5% TMA or 0.5% DNCB was topically applied at the injection sites and 0.5% Evan's Blue dye was injected i.v. Only mice injected with TMA sera and challenged with TMA displayed a positive PCA reaction. ELISA confirmed the presence of a modest increase of total IgE in the DNCB serum, a marked increase of total IgE in TMA serum and no elevation of IgE in AOO serum. The timing of serum injection, test chemical application, and assay endpoint must be optimized. These data suggest that the PCA assay may be used to identify elevations in specific IgE induced by chemicals which may induce respiratory sensitization.

1182 CYTOKINE PROFILING FOR CHEMICAL SENSITIZERS: EFFECT OF DOSE.

R. J. Smialowicz[1], L. M. Plitnick[2], S. E. Loveless[3], G. S. Ladics[3], M. P. Holsapple[4], D. M. Sailstad[1] and M. J. Selgrade[1]. *[1]NHEERL, USEPA, Research Triangle Park, NC, [2]Curr. in Toxicology, UNC, Chapel Hill, NC, [3]Haskell Laboratory, DuPont Co., Newark, DE and [4]Dow Chemical, Midland, MI.*

Chemicals encountered in both domestic and occupational settings may result in airway hypersensitivity (AHS). Because cytokine profiles generated during a T cell response are indicative of AHS (Th2) or contact hypersensitivity (CHS) (Th1), cytokine expression in draining lymph nodes (LN) has been used to identify chemicals with AHS potential. In this study, female BALB/c mice were sensitized twice on the flanks and challenged 3 times on the ears using the airway sensitizer trimellitic anhydride (TMA), or the contact sensitizer dinitrochlorobenzene (DNCB). Doses were varied during either: sensitization, challenge or both simultaneously. At various times following challenge, total mRNA was isolated from draining LN and analyzed by ribonuclease protection assay (RPA). When dose varied during sensitization only, TMA induced higher levels of the Th2 cytokines IL4, IL10 and IL13 than DNCB. However, no dose-dependent responses were observed with either chemical. DNCB did not induce Th1 cytokines at any dose tested. Variation of TMA dose during both sensitization and challenge also induced IL4, IL10 and IL13, and again showed no dose dependency. Dose only appeared to be a factor when TMA concentration was varied during challenge alone, suggesting the magnitude of the response depends upon the challenge phase. Thus, dose appears not to affect quantitative differences in Th2 responses between TMA and DNCB. These results suggest conventional cytokine profiling studies in which the same dose is

used for sensitization and challenge, allow the detection of differential cytokine responses regardless of chemical concentration. Lack of an IFN*gamma* response to DNCB may be due to the Th2-prone nature of the BALB/c mouse; therefore studies are currently underway to evaluate cytokine mRNA levels in Th1-prone C57BL/6 mice. (This abstract does not reflect EPA policy. This work was supported in part by The Dow Chemical Co. & DuPont Co.)

1183 CYTOKINE PROFILING FOR CHEMICAL SENSITIZERS USING THE RIBONUCLEASE PROTECTION ASSAY: DETERMINATION OF CYTOKINES GENERATED BY ISOCYANATES.

L. M. Plitnick[1], S. E. Loveless[2], G. S. Ladics[2], M. P. Holsapple[3], M. J. Selgrade[4], D. M. Sailstad[4] and R. J. Smialowicz[4]. *[1]Curriculum in Toxicology, UNC, Chapel Hill, NC, [2]Haskell Laboratory, DuPont Co., Newark, DE, [3]Dow Chemical, Midland, MI and [4]NHEERL, USEPA, Research Triangle Park, NC.*

Certain diisocyanates and acid anhydrides, which have been associated with occupational asthma, appear on the Hazardous Air Pollutant list (Clean Air Act 1990). Recent reports suggest that respiratory sensitizers may be identified based on their ability to induce a cytokine profile characteristic of a Th2 T cell response. Previous studies from this laboratory have shown that RNA message levels for the Th2 T cell cytokines IL4, IL10 and IL13 are elevated in response to the respiratory sensitizer trimellitic anhydride (TMA) and these increases may be detected by ribonuclease protection assay (RPA). In the current study, 4 additional chemicals (toluene diisocyanate (TDI), diphenylmethane-4, 4'-diisocyanate (MDI), dicyclohexylmethane-4, 4'-diisocyanate (HMDI) and isophorone diisocyanate (IPDI)) have been evaluated for their ability to induce Th2 cytokine mRNA expression. TDI and MDI are known respiratory sensitizers; however, there is conflicting data in the literature concerning the respiratory sensitizing potential of HMDI and IPDI. In the studies outlined here, female BALB/c mice were topically exposed to each of the isocyanates, and total mRNA was isolated from draining lymph nodes (LN) 14 days post challenge. RPA analysis showed that all 4 isocyanates tested induced cytokines characteristic of a Th2 T cell response (IL4, IL10 and IL13). These data support previous studies indicating that HMDI and IPDI are in fact respiratory sensitizers. (This abstract does not reflect EPA policy. This work was supported in part by The Dow Chemical Co. & DuPont Co.)

1184 AIRWAY RESPONSES AFTER SPECIFIC CHALLENGE OF RATS SENSITIZED *VIA* SKIN EXPOSURE TO TRIMELLITIC ANHYDRIDE (TMA).

X. D. Zhang, J. S. Fedan, D. M. Lewis and P. D. Siegel. *ASB, NIOSH, Morgantown, WV.*

TMA is a low-molecular-weight chemical that can induce production of specific IgE and occupational asthma in sensitized individuals. The respiratory tract is considered to be a major exposure route leading to immunological and airway sensitization, but the relationship between dermal exposure and subsequent airway responses to TMA is not known. Our previous work, using Brown Norway (BN) rats, demonstrated that topical skin exposure to dry TMA powder induces dose-dependent production of specific IgE. The present study investigated the airway responses to inhaled TMA of BN rats that have been sensitized dermally with TMA. Twenty mg of dry TMA powder was applied to the rat's back (clipped with scissors) on days 0, 7, 14 and 21, and occluded overnight with surgical tape. Rats were challenged by a 10 min, 40 mg/m3 TMA aerosol inhalation on day 35. Enhanced pause (Penh), an index of airway narrowing, was recorded overnight in a whole body plethysmography system. Compared to non-sensitized rats, the sensitized BN rats displayed both distinct early (EAR) and late airway responses (LAR), as noted by an increase in Penh after TMA inhalation. The EAR occurred immediately following the challenge and lasted approximately 0.5 to 1 hour. This was followed by 2 hours of normal breathing. The LAR began from 3 to 4 hours after challenge and the increase in Penh lasted up to 19 hours following exposure. This work and our previous studies demonstrate that dermal exposure to TMA powder can lead to both immunological sensitization and obstructive airway responses upon aerosol challenge. This BN rat model, with both EAR and LAR, may be valuable for further study of pathophysiological mechanisms of organic acid anhydride-induced asthma.

1185 CHEMICAL AND VEHICLE RESPONSES TO TRIMELLITIC ANHYDRIDE (TMA) AFTER INTRATRACHEAL (IT) CHALLENGE OF SENSITIZED MICE.

D. M. Sailstad, E. H. Boykin, M. D. Ward and M. J. Selgrade. *NHEERL, ORD, USEPA, Research Triangle Park, NC.*

Exposure to some low molecular weight (LMWT)chemicals has been known to produce respiratory hypersensitivity (RH), especially in occupational settings. Methods to predict the RH potential of new chemicals are needed by the regulatory community. While mouse models for RH to proteins are available, mouse models for LMWT chemicals have not been developed. Our goal was to assess the effect of IT-exposure of TMA (free or conjugated) in selected vehicles. We evaluated lung responses to the known respiratory sensitizer TMA by dermally sensitizing and IT challenging mice. The contact sensitizer, 2, 4-dinitrofluorobenzene (DNFB) was the negative control. Abdomens were exposed to 25% TMA for 2 consecutive days for 2 weeks. In week 3, TMA was applied to the ears. Two weeks later mice were IT-exposed to: TMA in Hanks' Balanced Salt Solution (TMA-HBSS), TMA in olive oil (TMA-O), mouse serum albumin-TMA conjugate in HBSS (MSA-TMA). Serum and bronchoalveolar lavage fluid (BALF) were collected before (D 0) and 1, 2, 3, and 7 D post IT (PIT). TMA-sensitized mice challenged with TMA-HBSS had an increase in BALF total IgE at D1and D2. Serum total IgE increased in TMA-HBSS and MSA-TMA IT groups as compared to controls. While DNFB-HBSS challenge did not increase in serum total IgE, an increase in the MSA-DNFB challenged group suggests that once conjugated to a protein, even "non-respiratory" sensitizers may stimulate IgE. Serum IgE increased in agent-oil and oil alone at D 7 PIT in non-sensitized groups only, indicating that oil IT alone can evoke an independent serum total IgE increase. Our results suggest that none of these methods for delivering TMA to the lung were entirely satisfactory. It is clear that attention is needed in the area of chemical structure, stability, solubility, chemical- vehicle compatibility and compatibility with the biological system in order to develop appropriate models for the evaluation of LMWT chemicals for RH potential. (This abstract does not reflect EPA policy.)

1186 CD11C/CD1A POSITIVE DENDRITIC CELLS FOR THE IDENTIFICATION OF CONTACT SENSITISERS.

N. J. Gilmour[1], D. A. Basketter[1], B. C. Hulette[2], C. A. Ryan[2] and G. F. Gerberick[2]. *[1]SEAC, Unilever Colworth Laboratory, Sharnbrook, United Kingdom and [2]Procter & Gamble, Miami Valley Laboratories, Cincinnati, OH.*

The use of human blood derived dendritic cell (DC) cultures has been examined as an *in vitro* alternative for the identification of contact sensitisers, although often with variable outcome and not always with evidence of specificity. Thus we aimed to derive a purified 'Langerhans cell (LC) like' DC population, a cell type more relevant for the identification of skin allergens. Pure populations of DC were isolated from human peripheral blood using BCDA-1 magnetic bead separation. The cells were cultured for 5 days in a combination of granulocyte-macrophage colony stimulating factor, interleukin-4 and transforming growth factor-b to generate LC-like cells. The cells generated were approx. 95% CD11c/CD1a positive, expressed HLA-DR but not CD86 or CD83 as determined by flow cytometry, demonstrated endocytic ability (FITC-dextran uptake), were weak stimulators of the mixed lymphocyte reaction and thus could be regarded to possess an 'immature' phenotype. Cells obtained by this method (from either human peripheral blood or leucopacs) were exposed to subtoxic doses of the potent contact sensitiser DNCB (2, 4-dinitrochlorobenzene). This resulted in elevated expression of HLA-DR (2-7 fold increase in mean fluorescence intensity [MFI]) and CD86 (15-20 fold increase in MFI) compared with control cells or those treated with subtoxic doses of the irritant sodium lauryl sulphate. Culture of blood derived CD11c+ dendritic cells thus may provide a population of Langerhans like cells for potential future *in vitro* approaches to the identification of skin sensitisers. Further investigation will determine whether this approach will provide a robust predictive model that stands up to future challenges of specificity and sensitivity.

1187 EVALUATION OF ANTIGEN SPECIFIC IgE RESPONSES IN C3H/HeJ MICE EXPOSED WEEKLY BY ORAL GAVAGE FOR SIX WEEKS WITH COW'S MILK PROTEIN AND CHOLERA TOXIN.

R. S. Scott, C. S. VanPelt and G. S. Ladics. *DuPont Co., Haskell Laboratory, Newark, DE.*

The objective of this study was to evaluate the antigen specific IgE Dose-Response in mice intragastrically exposed to cow's milk protein (CMP) and cholera toxin (CT) over a six-week period and to compare the responses to a cow's milk hypersensitivity model published by Li et al. (J Allergy Clin Immunol 103:206-214, 1999). Three-week-old female C3H/HeJ mice were sensitized by oral gavage to CMP plus CT and boosted 5 additional times at weekly intervals. Sera were collected at weekly intervals and the level of casein specific IgE measured by ELISA. Test groups (n=7 to 8) included naïve controls, 0.1 mg/g CMP + CT, 1 mg/g CMP + CT, 2 mg/g CMP + CT, 1 mg/g CMP without CT, and a CT only control. CT was administered at 0.3 µg/g. Casein specific IgE concentrations were determined by comparing individual or pooled serum samples to a mouse IgE anti-DNP standard curve. All analyses were performed in duplicate. As reported by Li et al., the maximal response occurred in the 1.0 mg/g CMP + CT group. However, differences in several measurements also occurred. We observed statistically significant differences in casein specific IgE levels between the 1.0 mg/g CMP + CT group and

the control groups by week 3 (Li et al. reported significant responses by week 6). Additionally, by weeks 4 through 6 casein specific responders were measured in all groups, including controls. The 1.0 mg/g CMP + CT group had the highest fraction of responders and the highest pooled casein specific IgE concentration. The number of responders and strength of response observed in the control groups illustrated that some animals within each group were generating significant IgE titers specific for casein. Following these unexpected results, we learned that the standard animal feed used in our facility contained a proprietary amount of casein as a dietary supplement. Our results generally support those reported by Li et al. and illustrate the need to strictly control the possible sources of protein exposure when conducting animal hypersensitivity models.

1188 NEGATIVE CONTROLS FOR PROTEIN ALLERGENICITY STUDIES.

M. D. Ward[1], M. E. Viana[2] and M. K. Selgrade[1]. [1]*NHEERL, USEPA, Research Triangle Park, NC and* [2]*College of Veterinary Medicine, North Carolina State University, Raleigh, NC.*

We have previously demonstrated immune and pulmonary responses typical of allergic responses in BALB/C mice exposed to fungal extracts of *Metarhizium anisopliae* crude antigen (MACA). MACA is composed of equal protein concentrations of the three component extracts from mycelium and conidia as well as inducible enzymes. Initial identification of the IgE inducing proteins by SDS-PAGE analysis suggested that the conidial extract does not contain allergenic proteins. In order to further explore the possibility of a non-allergenic extract we exposed BALB/C mice to 4 aspirations (ASP) of 10 µg of MACA, Conidia extract (Conidia), bovine serum albumin (BSA) (a weak or non-allergenic control) in 50 µl Hank's Balance Salt Solution (HBSS), or HBSS alone over a 4-week period. Serum and bronchoalveolar lavage fluid (BALF) were harvested before (D0), and at 1 (D1) and 3 (D3) days following the final ASP exposure. MACA exposed mice had elevated levels of both BALF total protein (D1 and D3) and lactate dehydrogenase (LDH) (D1). However, neither Conidia nor BSA exposed mice had increased levels of these non-specific parameters. BALF differential cells counts demonstrated that Conidia exposed mice had substantial increases in neutrophils, lymphocytes, and eosinophils compared to HBSS and BSA exposed animals. However, these increases represent low cell counts when compared to MACA exposed mice. Additionally, there was little or no increase in the levels of serum total IgE for either the Conidia or BSA exposed mice. These data suggest that the *M. anisopliae* conidia extract contains one or more proteins that cause mild inflammatory responses but would be classified as a weak or non-allergen. It appears that the conidia extract might be a useful negative control when assessing fungal extracts of unknown allergenicity in the mouse model. (Supported by NCSU/EPA Cooperative Training Agreement CT826512010.)(This abstract does not reflect EPA policy.)

1189 ANALYSIS OF PERIPHERAL BLOOD LYMPHOCYTE SUBSETS FROM COMMON MARMOSETS (*CALLITHRIX JACCHUS JACCHUS*) OF UK OR SWITZERLAND/JAPAN ORIGIN.

P. Kwanyuen, S. Witherspoon, L. Brown, N. Slocum and C. R. Waites. *Safety Assessment, GlaxoSmithKline, Research Triangle Park, NC.*

The common marmoset (*Callithrix jacchus jacchus*) represents a recent addition to the primate species employed in preclinical safety studies in North America. The variability of lymphocyte subsets between marmosets with different geographical origins is unknown. Source-related differences in lymphocyte subsets were investigated using immunophenotypic analysis of peripheral blood by flow cytometry to quantify differences between common marmosets of UK or Switzerland/Japan origin. Peripheral blood samples were collected from the conscious restrained marmoset *via* the femoral artery or vein into trisodium citrate from 8 and 10 native UK and Swiss/Japanese marmosets, respectively. Two-color assays were utilized for lymphocyte subset analysis to measure total T-cells, T-cytotoxic/suppressor cells, T-helper cells, NK cells and B-cells. The procedure involved staining whole blood with monoclonal antibodies conjugated to two fluorochromes: CD20-fluorecein isothiocyanate (FITC), CD-3-FITC, CD-8-phycoerythrin (PE), CD-2-PE, CD-4-PE and CD16-PE. The samples were analyzed on a Becton Dickinson FACSCalibur®, a flow cytometer equipped with a 480 nm argon laser. Preliminary results suggest there is no statistically significant difference in the percent of total T-cells, T-cytotoxic/suppressor cells, T-helper cells or B-cells between the UK and the Swiss/Japanese colonies. However, significant differences were detected between the NK cells(CD16+/CD3-) from the two colonies. Since immune modulators may potentiate the NK lymphocyte subset differences in the UK and Swiss/Japanese marmosets, consideration of animal source-related differences in biophysiologic measurements is critical to study design.

1190 DEVELOPMENT OF AN ALTERNATIVE TEST FOR PHOTOIRRITANTS: THE *IN OVO* PHOTOTOXICITY ASSAY (IOPA).

D. R. Cerven, E. J. Yurkow, L. R. Kendall, T. L. Fox, T. L. Ripper and G. L. DeGeorge. *MB Research Laboratories, Spinnerstown, PA.*

The potential phototoxicity of pharmaceuticals, consumer products and cosmetics are of increasing concern to regulatory agencies and the public. Preclinical phototoxicity studies are typically performed using large numbers of experimental animals. The 3T3 fibroblast phototoxicity assay has been validated by the EU, but this and other *in vitro* tests lack the complexity, metabolic capability and predictivity of animal models. We have devised an *In Ovo* Phototoxicity Assay based on the well-characterized chorioallantoic membrane(CAM) vascular assay, which uses the fertilized chicken egg as a test system. Groups of eggs were administered increasing concentrations of known irritants, non-irritants, and phototoxins, +/-5 J/cm^2 UVA irradiation. Eggs displaying vascular hemorrhage of the CAM, altered cell proliferation, or death of the embryo were scored as positive responses, and the percent positive eggs was plotted to determine the $EC_{50\text{-}UV}$ and EC_{50+UV} from the respective log-Dose-Response curves. The Photo-Irritancy Factor, (PIF = $EC_{50\text{-}UV}$ / EC_{50+UV}) was calculated and a PIF > 5 indicated a positive phototoxic response. Using this assay, the prototypical phototoxins 8-methoxypsoralen, promethazine, chlorpromazine, and 6-methylcoumarin were identified as phototoxic (8MOP; EC_{50+UV} = 0.0003 mg/ml > PMZ; 0.0017 mg/ml > CPZ; 0.082 mg/ml > 6-MC 0.44 mg/ml), whereas SLS, dinitrochlorobenzene, benzalkonium chloride, ethanol and mineral oil were negative. In addition, the IOPA correctly identified the metabolically-activated phototoxins nabumetone and 5-aminolevulinic acid, which are phototoxic *in vivo* (due to hepatic metabolism) but not when assessed *in vitro*. In these cases, up to an 18 hour pre-treatment time prior to UVA irradiation was necessary to allow for distribution and conversion to the phototoxic metabolite. In conclusion, we have developed an alternative phototoxicity assay that allows rapid, inexpensive and sensitive screening of chemicals, while retaining many advantages of animal models.

1191 ASSESSMENT OF OCULAR IRRITATION RANGES OF MARKET-LEADING COSMETIC AND PERSONAL-CARE PRODUCTS USING AN *IN VITRO* TISSUE EQUIVALENT.

N. E. McCain, R. R. Binetti, S. D. Gettings and B. C. Jones. *Cell Biology & in vitro Toxicology, Avon Products, Inc., Suffern, NY.*

The cosmetics and personal-care industry has focused considerable effort on the search for replacements for traditional animal-based safety tests. *in vitro* models have been found to be particularly useful for the assessment of eye irritation potential. We have used the MatTek EpiOcular® OCL-200 tissue model (composed of human epidermal keratinocytes that differentiate and form a stratified squamous epithelium similar to corneal tissue) to establish ranges of *in vitro* ocular irritation scores for several categories of cosmetic and personal-care products. A significant advantage of the EpiOcular model is that it can be used to discriminate between the irritation potential of extremely mild products (most cosmetic and personal care products are formulated for inherent mildness). Materials were topically applied to the EpiOcular tissue equivalents (167µL/cm^2). Surfactant-based products were tested at a concentration of 10% to simulate "rinse-off" exposures; all other products were tested without dilution. Materials were tested using either the standard (4 hours) or extended (≅20 hours) exposure protocol based on their expected irritation potential (ie consideration of formula composition, product type, etc.). Cellular viability was used as a marker for irritation potential and measured at various time points by a MTT metabolism colorimetric assay. MTT was quantitated spectrophotometrically at 570nm and an ET_{50} (time to 50% loss of viability) calculated for each product. A range of *in vitro* ocular ET_{50} scores was then determined for each product category. The results obtained from this study provide a reference database of *in vitro* ocular irritation scores for a cross-section of currently marketed cosmetic and personal-care products. Comparison of the ET_{50} for new formulations with the range of ET_{50} scores established for currently marketed products of similar type is a useful benchmark of anticipated consumer acceptability under conditions of actual use.

1192 THE APPLICATION OF BENCHMARKS FOR THE EVALUATION OF THE POTENTIAL OCULAR IRRITANCY OF AEROSOL FRAGRANCES.

N. Cuellar[1], J. C. Merrill[2], M. L. Clear[2], G. Mun[2] and J. W. Harbell[2]. [1]*S.C. Johnson & Son, Inc., Racine, WI and* [2]*Institute for in vitro Sciences, Inc., Gaithersburg, MD.*

Fragrances are complex mixtures used in many consumer products. In aerosol air care formulations, organic solvents, such as ethanol, are added to the final formulation as solubilizers, stabilizers, fillers, and fragrance delivery mechanisms. The current product development/safety program was established to preclude routine *in*

vivo ocular irritation testing and uses the Bovine Corneal Opacity and Permeability (BCOP) assay and reference formulations as "benchmarks" to calibrate the system and to establish acceptable ranges of irritancy potential. Abattoir-derived corneas were exposed to test materials for 3 or 10 minutes and opacity and permeability end points measured to calculate an *in vitro* score. These exposure times exceeded expected exposure times *in vivo* but were intended to increase separation among formulations. Negative (medium) and positive (100% ethanol) controls were tested concurrently with over 40 formulations (6 to 27% fragrance). The upper end benchmark induced an acceptable ocular response to a spray exposure *in vivo*. Ethanol alone produced an *in vitro* score of 52.4 ± 6.6 (10 minute exposure). The corneas showed surface coagulation of the squamous epithelium and marked nuclear swelling in the deeper epithelium. Changes in the upper stroma included moderate collagen matrix vacuolization (swelling) and keratocyte cytoplasmic eosinophilia. The addition of the fragrance component increased both parts of the *in vitro* score. The increase depended on the amount of fragrance (6 vs 27%) and the fragrance formulation itself. The upper end benchmark produced over double the *in vitro* score of ethanol alone. Histological changes were qualitatively similar but more pronounced. Acceptable new formulations would be expected to fall below the upper benchmark. These data show the need of using a formulation-specific benchmark to accurately assess ocular irritation in the *in vitro* BCOP assay, thus eliminating the need for *in vivo* testing for product evaluations.

1193 EXPLORATORY *IN VITRO* EYE IRRITATION STUDY OF MARKETED ALKALINE LIQUID LAUNDRY DETERGENTS BY BCOP ASSAY AND PH/RESERVE ALKALINITY (RA) PARAMETERS.

K. Cater[1], T. Nusair[2], J. Merrill[3] and J. Harbell[3]. [1]*The Dial Corporation, Scottsdale, AZ,* [2]*Risk Assessment & Toxicology Services, Cincinnati, OH and* [3]*IIVS, Gaithersburg, MD.*

An exploratory *in vitro* eye irritation study of 17 currently marketed alkaline liquid laundry (ALL) detergents was conducted to investigate the correlation between an *in vitro* biological endpoint and pH/RA ranges of ALL detergents. Currently marketed products can be considered "safe benchmarks", since they are produced by industry leaders and are assumed to have acceptable pH/RA characteristics. Based on performance in previous eye irritation studies with surfactants and the potential to measure depth of injury, the bovine corneal opacity and permeability (BCOP) assay was selected as an *in vitro* endpoint to evaluate biological effects. Based on preliminary studies, a 25% (w/v) aqueous dilution of each detergent was applied to the corneas for a 20-minute exposure period. The degree of epithelial damage is reflected in the increase in fluorescein permeability value. Permeability values (OD_{490}) for the 17 ALL detergents ranged from 0.278 to 2.193 reflecting a wide range in epithelial damage. The range of opacity scores was much lower (0.6 - 14.3) and showed little consistent change with the permeability values. Anionic/nonionic surfactant formulations often produce little *in vitro* opacity. The pH of each detergent dosing solution (25% w/v) was measured and ranged from 7.5 to 11.0. The RA (buffering capacity) was determined for a 1% (w/v) aqueous solution of each detergent titrated to a target pH of 9.5. Titration values ranged from 27.5 to 200 µmoles of NaOH or 10 to 120 µmoles of HCl. Neither pH nor RA values correlated with the epithelial damage as measured by permeability changes. These data suggest that characteristics of the formulation other than pH or RA are responsible for the epithelial damage produced in the BCOP. This BCOP protocol, using a 25% (w/v) aqueous dilution with a 20-minute exposure, the permeability endpoint (with histological confirmation) and benchmark formulations, shows promise for evaluating ALL detergents.

1194 USE OF HISTOLOGICAL EXAMINATION IN BOVINE CORNEAL OPACITY AND PERMEABILITY (BCOP) ASSAY FOR ASSESSING THE OCULAR IRRITATION POTENTIAL OF FRAGRANCED FORMULATIONS.

J. D. Burdick[1], J. C. Merrill[2], T. C. Spangler[2], G. O. Moyer[2] and J. W. Harbell[2]. [1]*Bath & Body Works, Reynoldsburg, OH and* [2]*Institute for in vitro Sciences, Inc., Gaithersburg, MD.*

Fragrances are complex mixtures containing numerous chemical compounds and are referred to generically in the context of consumer product formulations. Aside from the inherently complex contribution of fragrance to a formulation's ocular irritation potential, it is also difficult to elucidate the role of other components in the mixture. This study was undertaken to evaluate the use of histological analysis to identify ocular damage not detectable by BCOP alone. Formulations were grouped according to base and fragrance type/concentration and comparisons made between base-only and a series of fragranced formulations using the same base. Ocular irritation was measured using a standard BCOP assay with isolated corneas exposed to test material for 10 minutes, followed by opacity and permeability determination and histological analysis. Ethanol was used as a concurrent positive control. Within a series, BCOP scores varied significantly across fragrance type, ranging from 0.1 to 44.8, due mainly to changes in permeability. Histological analysis confirmed the relative degree of damage. For a given base, predicted irritation potential was dependent on the particular fragrance mixture. This study reinforces the need to determine the ocular irritation potential of formulations and not rely solely on component information. Understanding the nature and degree of ocular irritation potential to complex mixtures may help to improve the selection process for base and fragrance components of consumer products.

1195 THE RABBIT ENUCLEATED EYE TEST (REET) AS A SCREEN TO REDUCE THE USE OF ANIMALS IN WORKER SAFETY STUDIES.

E. J. Guerriero[1], C. W. Seaman[2], T. J. Sutton[2], G. L. Sprague[1], R. Guest[3] and A. Whittingham[3]. [1]*Corporate Environment, Health and Safety, GlaxoSmithKline, King of Prussia, PA,* [2]*Corporate Environment, Health and Safety, GlaxoSmithKline, Welwyn, United Kingdom and* [3]*SafePharm Laboratories, Ltd., Derby, United Kingdom.*

Identification of chemicals that cause eye irritation in the work place has traditionally used the Draize eye protocol. The REET, an *ex vivo* alternative, shows promise for predicting severe eye effects. Test material is placed onto enucleated eyes (animals euthanized for other purposes) in chambers perfused with warm saline and washed off after 10 seconds. Corneal opacity, thickness and fluorescein dye uptake are measured and corneal surface examined. Thirty materials (pharmaceuticals, intermediates, raw materials) were tested in both the Draize and REET. The Draize test identified 8/30 materials as severe with an additional 5 identified based on pH/dermal effects. Overall, 13/30 chemicals were classified severe and labeled with EU phrase R41 - Risk of Serious Damage to Eyes. REET evaluation suggested that a cutoff score for any one of these parameters appeared predictive of the Draize response: corneal opacity/area >/= 3; corneal swelling >/= 25; fluorescein dye uptake/area >/= 4 or observations of pitting, mottling or sloughing. The REET-positive criteria were met by 17/30 materials and included 13 labeled R41 (100%) with 4 false positives (1 moderate, 3 mild). Thirteen chemicals did not meet the REET criteria: 9 were minimal/mild eye irritants and 4 were moderates. In conclusion, using the REET assay with pre-assigned cutoffs appeared to identify severe eye irritants and provided data for hazard labeling. When used as a pre-screen for the Draize assay, the REET contributes to reducing the number of animals used to test for eye irritants.

1196 DEVELOPMENT OF AN IMMORTALIZED Z310 CHOROID PLEXUS CELL LINE FOR DRUG TRANSPORT AND TOXICOLOGICAL STUDY OF BLOOD-CSF BARRIER.

Q. Zhao[1] and W. Zheng[1,2]. [1]*Env. Health Sci., Columbia School of Public Health, New York, NY and* [2]*Pharmacology, Columbia College of Physicians & Surgeons, New York, NY.*

The blood-CSF barrier (BCB), located mainly in the epithelium of the choroid plexus, plays a wide range of roles in brain development, maturation, aging process, endocrine regulation, and pathogenesis of certain neurodegenerative diseases. To facilitate *in vitro* study of the BCB, we have used a gene transfection technique to immortalize murine choroidal epithelial cells. A viral plasmid (pSV3neo) was inserted into the host genome of primary choroidal epithelia by calcium phosphate precipitation. The transfected epithelial cells, i.e., Z310 cells, that survived from cytotoxic selection expressed SV40 large-T antigen throughout the life span, suggesting a successful gene transfection. The cells displayed typical polygonal epithelial morphology by light microscopy. Immunocytochemical studies of transfected cells demonstrate the presence of transthyretin (TTR), a thyroxine transport protein known to be exclusively produced by the choroidal epithelia. Western blot analyses further confirm the production and secretion of TTR by these cells. The mRNAs encoding transferrin receptor (TfR) were also identified by Northern blot analyses. The cells grow at a steady rate, currently in the 110th generation with a population doubling time of 20-22 h in the established culture. When Z310 cells were cultured onto a Trans-well apparatus, the cells formed an epithelial monolayer similar to primary choroidal cells, possessing distinctive features such as an uneven fluid level between inner and outer chambers and an electrical resistance approximately 150-200 ohm-cm^2. Moreover, the cells actively transported $[^{125}I]T_4$ across this monolayer. These results indicate that immortalized Z310 cells possess the characteristics of choroidal epithelia and may have the potential for toxicological research. (Supported by NIH/NIEHS RO1 ES08146)

1197 EVALUATION OF FETAL-RAT DORSAL ROOT GANGLIA (DRG) CULTURE SYSTEMS FOR ASSESSING CHEMOTHERAPY-INDUCED PERIPHERAL NEUROPATHIES.

R. E. Morgan, C. M. Zwickl, O. J. Trask and D. K. Monteith. *Investigative Toxicology, Lilly Research Labs, Greenfield, IN.*

A proposed mechanism for the induction of peripheral neuropathies involves effects on microtubule-dynamics, a process integral to neurite outgrowth (NG) and to the formation and maintenance of axon and dendrite terminals. For modeling nerve growth and arbor morphology, the sympathetic DRG isolated from fetal rodents can be cultured to promote NG. In this investigation, we evaluated fetal-rat, dissociated and whole-explant DRG culture systems using several oncolytics with distinct mechanisms of action including tubulin polymerization/depolymerization, DNA alkylation and topoisomerase inhibition. In the dissociated DRG model, cultures were prepared in 96-well plates and evaluated *via* fluorescence-labeling and automated image analysis (ArrayScan®). Whole-explants were prepared in multi-chambered slides and evaluated by light-microscopy and analyzed *via* Quantimet® image analysis. A viability assay was performed in each culture system to assess cytotoxicity. Both DRG models were employed to demonstrate concentration-dependent inhibition of NG in evaluation of: 1) compounds known to cause peripheral neuropathies in humans and 2) compounds not associated with neuropathic effects. In doing so, we showed that both test systems could be used to distinguish between specific and non-specific neuropathic agents by combining a viability assay with image analysis-techniques. The effects of various concentrations of nerve growth factor (NGF) were evaluated in both culture systems to demonstrate potential neuroprotection. In the whole-DRG model, we showed that elevated concentrations of NGF(>20 ng/mL) inhibited NG; as has been described previously. Interestingly, the dissociated-DRG culture system was relatively non-responsive to NGF concentrations between 2.9 and 900 ng/mL. Finally, we compared the relative merits of each culture system and the image analysis techniques carried out for both, and conclude that either system can be useful for evaluating compounds likely associated with peripheral neuropathy.

1198 EARLY ENDPOINTS FOR EVALUATING CADMIUM-INDUCED *IN VITRO* NEPHROTOXICITY.

A. Gennari, M. Boveri, J. Casado and P. Prieto. *JRC, IHCP, ECVAM, Ispra (VA), Italy.* Sponsor: E. Sabbioni.

Cadmium chloride ($CdCl_2$) is a potent nephrotoxin that causes damage to the proximal tubular epithelium. *in vivo*, it increases the permeability of epithelial surfaces, while *in vitro*, it acts on active trans-epithelial ion transport. The purpose of our research was to investigate the effects of $CdCl_2$ on a porcine renal proximal tubular epithelial cell line (LLC-PK1). In particular, we aimed to study damage to the epithelial barrier (by measuring trans-epithelial resistance [TER] and paracellular permeability [PCP]), and the molecular mechanisms underlying $CdCl_2$ toxicity (by measuring metallothioneins [Mts], heat shock proteins [HSPs], reactive oxygen species [ROS], and the induction of apoptosis). After exposure of the cells to different concentrations of $CdCl_2$, TER decreased, while PCP increased in a concentration-dependent and time-dependent manner, indicating a structural alteration of the junctional complex. At the molecular level, we observed an increase in protective proteins, such as Mts and HSP70, starting from exposure to 10 µM and 25 µM $CdCl_2$, respectively. Production of ROS at the mitochondrial level was also evident, indicating cellular oxidative stress. Treatment of the cells with higher concentrations of $CdCl_2$ (100 µM) revealed a clear induction of apoptotic cell death. Our data indicate that $CdCl_2$ nephrotoxicity can already be detected at rather low concentrations by measuring TER (damage at the barrier level) or Mts, HSPs, ROS production (damage at the cellular level), when cytotoxicity assays are unable to show any real damage. Therefore, these endpoints should prove to be very useful in studying xenobiotic- induced acute toxicity.

1199 CULTURES OF EXFOLIATED HUMAN UROTHELIAL AND RENAL TUBULAR CELLS.

J. Müller[1], A. Dörrenhaus[1], K. Golka[1], P. Jedrusik[1,2], H. Schulze[2] and W. Föllmann[1]. [1]*Institute of Occupational Physiology at the University of Dortmund, Dortmund, Germany and* [2]*Department of Urology, Städt. Kliniken Dortmund, Dortmund, Germany.*

Since tissues of the urinary tract or the renal tubule from surgery or transplant donors have very limited availability, a promising source for these cells is the urinary sediment. Midstream urine samples from 24 adults were concentrated to sediments by repeated centrifugation (100 x g, 5 min). To reduce urine concentration, sediments were washed twice with Ham's F12 culture medium. After resuspension in 0.5 ml culture medium, aliquots of 50-250 µl cell suspension were seeded onto collagen-coated 24-well plates. Cell culture was performed in a humidified incubator according to standard conditions. Vital cells started proliferation within 1 week after seeding and formed colonies of different morphology designated as type-1 or type-2 cell colonies. Most frequently, type-1 cell colonies occured which showed irregular colony contours and randomly arranged spindle-like cells. Subcultivation was possible up to 6 passages. Immunohistochemical staining for the epithelial marker cytokeratin-7 was positive. Staining for carbonic anhydrase was negative. Type-2 cell colonies which could be subdivided into two subgroups by morphological characteristics only occured occasionally. These colonies showed smooth-edged contours. A subcultivation was not possible. Cobblestone-like type-2 cells were able to form domes. These cells were positively stained for carbonic anhydrase, indicating a tubular origin. Primary cell cultures of exfoliated cells from urinary sediments can be used for *in vitro* studies in toxicological and clinical research.

1200 SUBACUTE CYTOTOXICITY TESTING WITH CULTURED HUMAN LUNG CELLS.

F. A. Barile, A. Yang and D. L. Cardona. *College of Pharmacy, Department of Pharmaceutical Sciences, St. John's University, Jamaica, NY.*

This study was designed to evaluate the potential of an *in vitro* cell culture method for its ability to determine subacute cytotoxicity and to compare the cytotoxic concentrations with rodent LD50s and clinical human toxicity data. Human fetal lung fibroblasts (HFL1) were incubated in the absence or presence of increasing concentrations of test chemicals for 72 hours, and cell proliferation was used as a marker for toxicity. Inhibitory concentrations were extrapolated from concentration-effect curves after linear regression analysis. Comparison of the cytotoxicity data from testing 50 chemicals, with available human lethal concentrations for the same chemicals, revealed that the 72-hour experimental IC50s are as accurate predictors of human toxicity as equivalent toxic blood concentrations derived from rodent LD50s. In addition, subacute 72-hour exposure of HFL1 cells more accurately predicts cytotoxicity than a 24-hour mitochondrial assay previously conducted in our Lab., although the experimental IC50 values were not statistically different in the two assays (table below of first 15 chemicals). It is anticipated that this procedure, together with a related battery of tests, may supplement or replace currently used animal protocols to screen chemicals for human risk assessment.

Number	Chemical Name	72-hour IC50s: Cell Proliferation Assay	24-hour IC50s: MTT Assay
1	paracetamol	4.25±.5	7.76±.84
2	acetylsalicylate	1.3±.1	3.02±.76
3	ferrous sulfate	0.6±.1	-
4	diazepam	.67±.12	.28±.05

1201 INHIBITION OF FATTY ACID ETHYL ESTER SYNTHASE ACTIVITY BY TRI-O-TOLYLPHOSPHATE METABOLITES IN HEPG2 CELLS.

K. A. Mericle, B. S. Kaphalia and G. A. Ansari. *Pathology, University of Texas Medical Branch, Galveston, TX.*

Fatty acid ethyl ester synthase (FAEES) is a family of enzymes that catalyzes the conjugation of alcohols and amines with fatty acids. Resultant conjugates are shown to be highly lipophilic, which can accumulate in target organs and cause toxicity. Previous studies from this laboratory have shown that FAEES purified from rat liver is structurally and functionally different from that of pancreas, and only hepatic FAEES activity is inhibited by tri-o-tolylphosphate (TOTP, a serine esterase inhibitor). Metabolism of TOTP is prerequisite for such inhibition. Therefore, two known metabolites of TOTP, 2-o-(cresyl)-4H-1:3:2-benzodioxaphosphoran-2-one (CBDP) and hydroxylated TOTP [di-o-tolyl-o-(α-hydroxy) tolylphosphate] were synthesized and their inhibitory effect on FAEES activity was investigated in HepG2 cells (human hepatoma cell line). HepG2 cells in culture were incubated with an equimolar concentration of 2.5 µM TOTP, CBDP or hydroxylated-TOTP

in ethanol at 37°C (a concentration causing 85% inhibition by CBDP in preliminary experiments). Cells treated with equivalent amount of ethanol served as control. Cells were harvested after 1 hour exposure, washed, scraped and homogenized. FAEES and p-nitrophenylacetate (PNPA) hydrolyzing (esterase) activities were measured. Inhibition of FAEES as well as esterase activities was found to be greatest in the cells treated with CBDP and hydroxylated-TOTP (~ 85 and 59%, respectively), followed by TOTP. The time course study performed at 0.25, 0.5, 1, 3 and 6 hours, demonstrated that inhibition by CBDP occurs in 15 minutes (earliest time point investigated). We conclude that the active metabolites of TOTP (CBDP and hydroxylated-TOTP) cause the inhibition of FAEES and esterase activities in HepG2 cells.

1202 MECHANISMS OF CERAMIDE-INDUCED APOPTOSIS IN A RAT HEPATOMA (H4IIE) CELL LINE.

J. F. Pregenzer, P. C. Wilga, D. K. Petrella, R. K. Patel and J. M. McKim, Jr.. *Investigative Toxicology, Pharmacia, Kalamazoo, MI.*

Ceramides are a group of sphingolipids that act as second messengers in the control of many biochemical functions including apoptosis. Tumor necrosis factor alpha (TNF) can increase the hydrolysis of sphingomyelin to form ceramide. Both ceramide and TNF have been shown to cause apoptosis *via* activation of caspases. Ceramide has also been shown to induce apoptosis *via* pathways independent of caspase activation. Thus, the precise signalling pathways activated by ceramide depend on the cell type. If TNF-mediated apoptosis is dependent on the formation of ceramide, then ceramide and TNF should produce similar effects *in vitro*. In the present study the biochemical pathways involved with ceramide-induced apoptosis were compared to those of TNF in a rat hepatoma (H4IIE) cell line. Cells were seeded into 96-well plates (10, 000/200 µL), allowed to equilibrate for 48 hr, and then exposed to C2-Ceramide (0, 0.1, 1, 5, 10, 50, 100, and 300 µM) or to TNF (0, 0.05, 0.5, 2.5, 5, 25, 75, and 150 ng/mL; specific activity = 1.0×10^9 U/mg) for 24 hr. Following the exposure period, changes in cell health were determined by monitoring mitochondrial function, membrane leakage, and cell proliferation. Oxidative stress was assessed by measuring changes in reduced glutathione (GSH) and membrane lipid peroxidation. Apoptosis was evaluated by caspase (3 and 9) activity and DNA fragmentation. TNF was cytotoxic above 5ng/mL, however, there were no significant changes in total GSH prior to cell death or in membrane lipid peroxidation as determined by 8-isoprostane. Exposure to TNF caused a marked increase in caspase 3 and 9 activities as well as DNA fragmentation, but did not increase lipid peroxidation. In contrast, ceramide had no effect on caspases 3 or 9, but did increase lipid peroxidation (10-300 µM ceramide). C2-ceramide also increased DNA fragmentation at the highest exposure (300 µM) and reduced mitochondrial function. These data suggest that in H4IIE cells apoptosis induced by TNF may occur through signalling pathways that are different from those induced by C2-Ceramide.

1203 HALOGENATED HYDROCARBON TOXICITY IN RAT PRIMARY HEPATOCYTES: INDUCTION OF OXIDATIVE STRESS AND DEVELOPMENT OF A NOVEL TOXICITY RANKING METHOD.

K. T. Geiss and J. M. Frazier. *Operational Toxicology Branch, AFRL/HEST, WPAFB, OH.*

Volatile halogenated aliphatic compounds are among those chemicals that can cause oxidative stress *in vitro* and *in vivo*. Here, we investigated the effects of 20 brominated and/or chlorinated one- or two-carbon molecules, including carbon tetrachloride, trichloroethylene and 1, 1, 1-trichloroethane. Following the use of a unique *in vitro* methodology to expose primary rat hepatocyte cells to these volatile chemicals, biological responses were assessed from separate exposures of rat primary hepatocytes to these halogenated aliphatics. Indicators of lipid peroxidation, reactive oxygen species, catalase enzyme activity, cellular thiol status, and cytotoxicity were measured. For this large group of chemicals, classification by multiple endpoints for oxidative stress in primary rat hepatocytes has not been shown previously. The toxicity values for these chemicals, such as the EC50s, ranged from 0.10 to 127.00 mM. We derived a novel composite toxicity index for purposes of ranking the potential toxicities of the chemicals. This scoring index had a potential range from 6 to 120, for ranking purposes. In this study, the composite scores ranged from 11 to 115. We also derived QSAR models to describe the relationships for these chemicals between their physico-chemical properties and their potential to cause oxidative stress *in vitro*. Our results show the ability to rank a group of chemicals, based on their *in vitro* toxicity values for multiple endpoints and the effectiveness of QSAR models in predicting relative toxicity ranking of chemicals. The impact of this approach provides a means of discerning the relative toxic potencies among a group of chemicals, which could be used in materials or drug development or identification of relative risk.

1204 RANKING GLITAZONE COMPOUNDS FOR HEPATOTOXIC POTENTIAL BY MONITORING STRESS-SPECIFIC ALTERNATIVE mRNA ISOFORMS: EVIDENCE AGAINST A GLITAZONE CLASS TOXICITY?

R. Einstein[1], G. Descotes[2], L. Delalonde[3] and F. Schweighoffer[3]. [1]*ExonHit Therapeutics Inc., Gaithersburg, MD,* [2]*Drug Safety Assessment, Servier, Paris, France and* [3]*ExonHit Therapeutics SA, Paris, France.*

A low incidence of severe unanticipated hepatotoxicity resulted in troglitazone (TRO) withdrawal. The ability of gene expression profiling in the Safe-Hit DNA macro-array, representing a library of 682 stress-specific p53-induced mRNA isoforms, to correctly rank for toxic potential three commercially available glitazone compounds was evaluated. Primary cultures of human hepatocytes from eight donors and the hepatocarcinoma line HepG2 were incubated for 16 hr with TRO, pioglitazone (PIO) or rosiglitazone (ROS) at concentrations ranging up to approximately 20 % cytotoxicity (MTT). The mRNA was isolated and used to probe the Safe-Hit macro-array. Up- or down-regulation of stress-specific mRNA isoforms by 2.5-fold relative to vehicle control cells was considered to represent gene deregulation, and a toxicity index corresponding to the total number of deregulated genes for that particular condition was calculated. TRO had the highest toxicity index in all cases and the difference was greater in the primary human hepatocytes than in HepG2. Toxicity indexes at the highest concentrations for TRO, PIO and ROS were 45, 11 and 7, respectively, in primary cultures of human hepatocytes and 33, 28 and 28, respectively, in HepG2 cells. The high toxicity index induced by TRO and the lower ones induced by PIO and ROS in human hepatocytes correlate with what is known about the clinical safety of these drugs and indicate that hepatotoxicity might not be a simple glitazone class-specific event. That the repertoire of deregulated genes differed between TRO on one side and PIO or ROS on the other further supports this idea. These results suggest that the monitoring of appropriately selected alternative splicing variants, such as those in the Safe-Hit library, may be a method of choice for *in vitro* detection of compounds that will induce rare severe liver toxicity, a phenomenon that historically has been difficult to predict.

1205 ANTIDIABETIC DRUGS IN THE THIAZOLIDINEDIONE CLASS REDUCE GLUTATHIONE LEVELS AND INCREASE LIPID PEROXIDATION IN AN *IN VITRO* MODEL.

J. M. McKim, Jr., P. C. Wilga, D. K. Petrella, J. F. Pregenzer, R. K. Patel, R. C. Steenwyk, M. P. Grillo and G. L. Cockerell. *Investigative Toxicology, Pharmacia, Kalamazoo, MI.*

Thiazolidinedione (TZD), troglitazone (TRO), pioglitazone (PIO), and rosiglitazone (ROS) are in the TZD class of oral hypoglycemic drugs used in the treatment of diabetes. TRO has been shown to produce idiosyncratic liver toxicity. The mechanisms underlying TRO hepatic toxicity remain unknown. Metabolism of TZD drugs involves ring opening and subsequent conjugation with GSH. TRO has been shown to reduce GSH and induce oxidative stress. Patients with type II diabetes have a significant reduction in tissue GSH. Moreover, the ability of a tissue to protect itself from oxidative stress is dependent on many factors including diet, age, and exposure to other medications. Thus, some diabetic individuals may be unable to adapt to compounds that produce oxidative stress by depleting GSH. The purpose of the present study was to evaluate the relative cytotoxic and oxidative stress potential of TZD, TRO, PIO, and ROS in an *in vitro* cell system. Rat hepatoma (H4IIE) cells were seeded into 96-well plates (10, 000/200 µL). Following a 48 hr equilibration period the cells were treated with compounds at concentrations of 0, 0.1, 1, 5, 10, 50, 100, and 300 µM for 24 hr. Cytotoxicity was evaluated by measuring membrane leakage, mitochondiral function, and cell number. Oxidative stress was assessed by measuring GSH and 8-isoprostane (8ISP). Markers of general toxicity were essentially unchanged at exposures below 100 µM. TZD and PIO reduced GSH and produced a concomitant increase in membrane lipid peroxidation. These changes were observed at low concentrations prior to changes in general cell health. TRO also reduced GSH levels, but only produced a modest increase in 8ISP at the highest exposure. ROS reduced GSH, but had no detectable effect on 8ISP. Thus, in terms of oxidative stress: TZD = PIO >TRO > ROS. These data suggest that the antioxidant status of individuals with diabetes may be a determining factor in how they respond to the TZD class of drugs.

1206 INCORPORATING LC/MS/MS IN DETERMINING CYTOCHROME P450 FORM-SPECIFIC ACTIVITY.

A. M. Walter[1], A. L. Roe[1], C. R. Dietsch[1], D. M. Bornes[1], C. M. Dunaway[2], T. Baker[2] and D. C. Ackley[1]. [1]*Drug Safety Assessment, P&G Pharmaceuticals, Mason, OH and* [2]*Research Analytical, P&G Pharmaceuticals, Mason, OH.*

The goal of drug discovery organizations is to increase the probability of compound success in clinical trials. Currently, the three main reasons for clinical failure are lack of efficacy, unexpected toxicity and poor drug metabolism/pharmacokinetics. New

methods and technologies are constantly being incorporated into drug discovery to screen new chemical entities (NCEs) with regards to these three areas, especially in the area of metabolism. Metabolism screening techniques rely upon various *in vitro* test systems, such as microsomes, S9, hepatocytes, etc. In order to use these systems, the native activity of the drug metabolizing enzymes, primarily the cytochrome P450s (CYP450), must be determined. CYP450 activity is also used to determine the inhibition potential of NCEs. Inhibition of the NCE metabolizing enzymes could result in elevated blood levels and greater likelihood of toxicity. In order to increase screening throughput, a faster method to evaluate CYP450 activity was developed. Previous methods required incubating a CYP450 marker substrate with the test system and determining metabolite production *via* HPLC/UV detection. A new analytical method was developed using LC/MS/MS to evaluate the production of metabolites for six CYP450 forms (1A1/2, 2C9, 2C19, 2D6, 3A4/5 and 4A11) following either multiple incubations or a single CYP450 "cocktail" incubation. The inhibition potential of SK-203580 and VX-745 (0 to 25 μM) was determined using individual CYP450-specific substrate incubations as well as "cocktail" incubations of CYP450 marker substrates in pooled human liver microsomes. Regardless of incubation method, SK-203580 inhibited the activity of CYPs 2C19 and 2D6, and VX-745 inhibited the activity of CYP2C19 but not CYP2D6. Individual incubations with either SK-203580 or VX-745 decreased CYP3A4/5 activity but "cocktail" incubations with either compound had no inhibition towards CYP3A4/5.

1207 A SENSITIVE METHOD TO DETECT METABOLIC TOXICITY IN A HOMOGENEOUS CELLULAR ASSAY.

L. E. Dike[1], R. D. Guarino[2], S. Parikh[1], H. Xia[1], C. Patten[1], P. Haaland[2] and C. L. Crespi[1]. [1]*R & D, BD Biosciences, Woburn, MA and* [2]*R&D, BD Technologies, Research Triangle Park, NC.*

A major concern in the pharmaceutical industry is the potential for metabolic toxicity of developmental compounds. However, existing assays are extremely cumbersome and time-consuming. Here, we present a cell-based, high throughput-screening assay that detects and differentiates between direct and indirect acting toxins. A B-lymphoblastoid cell line, MCL-5, was created expressing 5 human P450's known to be important in metabolic toxicity, CYP1A1, 1A2, 3A4, 2A6 and 2E1 and epoxide hydrolase. Direct and indirect toxicity was measured with the MCL-5 cells in comparison to its control cell line cH2 cells, using the BD Oxygen Biosensor System (OBS) as the method of detecting cell viability. Experiments were annotated and IC50's determined using the Multi-well Plate Manager (MPM) –ADMET software program. Data and the associated experiments were archived in MPMs' internal database for easy retrieval. The MCL-5 cells were shown to be significantly more sensitive to compounds that required metabolic activation for toxicity such as NNK, aflatoxin and benzopyrene (Table). The detection of toxicity for compounds such as acetaminophen required the inhibition of glutathione by 50uM buthionine sulfoximine (starred compounds*). Moreover, the metabolic toxicity of cyclophosphamide could be specifically inhibited by competitive inhibition of CYP2A6 by a non-toxic dose of coumarin. The OBS in combination with the MCL-5 and cH2 cell lines creates a simple, homogeneous, streamlined method for screening compounds for metabolic toxicity.

Test Substrate	cH2 cells	MCL-5 cells	Major P450's
Benzopyrene	IC50>20uM	1.6uM	1A1, 3A4, 1B1
Aflatoxin	IC50>0.2uM	0.0479uM	1A1, 3A4, 1A2
NNK	IC50>480uM	153.5uM	2A6, 2E1, 2D6
Acetaminophen*	2,900uM	1,200uM	2E1, 3A4, 1A2
PhIP	111.2uM	21.28uM	1A1
Methotrexate	0.021uM	0.023uM	Direct-Acting

1208 INDUCTION OF CYTOCHROME P450 2B6 AND 3A4 EXPRESSION BY PHENOBARBITAL AND CYCLOPHOSPHAMIDE IN CULTURED HUMAN LIVER SLICES.

H. Martin[1,2], J. P. Sarsat[1], I. de Waziers[2], C. Housset[3], P. Balladur[4], P. Beaune[2], V. Albaladejo[1] and C. Langrand[1]. [1]*Drug Safety Evaluation, Aventis-Pharma, Vitry-sur-Seine, France,* [2]*INSERM U490, Paris, France and* [3]*INSERM U402, Paris, France.* Sponsor: M. Bonnefoi.

Cytochrome P450 (CYP) inducibility is a major issue in drug development, as it reflects a potential risk of drug interaction. One promising *in vitro* model to predict CYP inducibility is cultured human liver slices. The region-specificity of CYP distribution, together with drug-induced histological changes, remain yet to be defined in this model. To address this issue, we tested the effects of cyclophosphamide (CPA) and of phenobarbital (PB) on CYP2B6, 3A4 and 2C9 expression. We report that basal CYP2B6 and 3A4 expression is higher in cultured human liver slices than in hepatocyte primary cultures. In addition, slices display the same region-specificity of CYP2B6 and 3A4 expression as intact liver. In-depth histological examination showed that morphological features are preserved in human liver slices. CYP2B6 and 3A4 mRNA, apoprotein and enzyme-related activities were induced by PB and by CPA. Their immunoreactivities were also increased, while their distribution was preserved on slice tissue sections. The cytoplasm took on a ground-glass aspect characteristic of smooth endoplasmic reticulum proliferation associated with microsomal enzyme induction. CYP2B6 and 3A4 induction was variable among slices prepared from different donors, although to a lesser extent than in hepatocyte monolayers. In conclusion, cultured human liver slices are an attractive alternative to hepatocyte culture for the prediction of human CYP isoenzyme induction by xenobiotics (Supported by EU Biotechnology Program, B104-CT97-2145).

1209 INDUCTION OF CYTOCHROME P450 (CYP) FORMS IN CULTURED PRECISION-CUT HUMAN LIVER SLICES.

B. G. Lake[1], R. J. Edwards[2], P. S. Watts[2], A. R. Boobis[2], J. M. Tredger[3], A. B. Renwick[1] and R. J. Price[1]. [1]*Molecular Sciences, TNO BIBRA International Ltd, Carshalton, United Kingdom,* [2]*Imperial College School of Medicine, London, United Kingdom and* [3]*Institute of Liver Studies, King's College Hospital School of Medicine, London, United Kingdom.*

In this study we have employed a panel of antipeptide antibodies to examine the induction of CYP forms in cultured human liver slices. Liver slices (diameter 10 mm, thickness around 250 μm) were prepared from samples of human liver (surplus to transplant requirements) with a Krumdieck tissue slicer and were cultured in Williams medium E containing 0.1 μM insulin, 0.1 μM dexamethasone (DEX), 2 mM L-glutamine, 50 μg/ml gentamicin and 2.5 μg/ml fungizone in a dynamic organ culture system in an atmosphere of 95%O_2/5%CO_2. Slices were cultured in control medium or medium containing either 0.05 mM β-naphthoflavone (BNF), 0.05 mM lansoprazole (LANS), 0.5 mM sodium phenobarbitone (NaPB), 0.05 mM rifampicin (RIF), 0.05 mM DEX or 0.05mM methylclofenapate (MCP) for 72hr. After culture, liver slice microsomal fractions were prepared for Western immunoblotting studies. CYP1A1 was not detectable in either control or CYP inducer treated liver slice microsomal fractions. Compared to control liver slice microsomal fractions, both BNF and LANS induced levels of CYP1A2 apoprotein. RIF induced levels of CYP2A6, CYP2B6, CYP2C19 and CYP3A4 apoproteins to 360, 1230, 305 and 440 % of control, respectively, whereas NaPB induced levels of CYP2B6 and CYP3A4 apoproteins to 980 and 255 % of control, respectively. While small effects were produced on levels of CYP2C8, CYP2C9 and CYP3A5 apoproteins, none of the CYP inducers studied had any significant effect on levels of CYP2D6, CYP2E1 and CYP4A11 apoproteins. These studies demonstrate the usefulness of liver slices for studying the induction of CYP forms in human liver. (Supported by EU BIOMED Contract No. BMH4-CT96-0254).

1210 OPTIMIZATION OF ORGAN SLICE LONGEVITY IN CULTURE TO LINK GENE EXPRESSION WITH ALTERED MORPHOLOGY.

M. J. Saulnier and A. E. Vickers. *Toxicology/Pathology, Novartis, E. Hanover, NJ.*

A procedure to maintain the morphology and function of rat liver slices up to 96 hours in culture has been developed. Slices cultured on titanium or teflon screen inserts lose their integrity at the contact point of the slice with the screen. This results in loss of tissue and normal architecture, which reduces the viability of the slice over time. Tissue quality and longevity is enhanced by organ perfusion and slicing in a preservation medium, and by culture improvements. The slices are morphologically healthy and metabolically active, synthesizing glycogen from the nutrients of the medium. The liver of Wistar rats (250-300 g) is perfused *via* the portal vein with heparinized University Wisconsin (UW) solution to cool and flush the organ of blood. The organ is cored (8 mm^3) and sliced (200 μm) in cold oxygenated UW solution using a Brendel/Vitron tissue slicer. The slices are loaded onto titanium-screen inserts covered with a mixed cellulose-ester filter, and cultured at 37°C, 85% O_2 and 5% CO_2 in a dynamic organ roller culture system in DMEM plus 5% FCS which is changed after 1 hour of incubation (T_0), and then every 24 hours. The filters maintain the viability and morphology of the slices by preventing cell necrosis and loss on contact with the screens (titanium or teflon). This was corroborated by the viability data. Slice ATP and GSH levels increased during culture until 48 hours, then stabilised. Morphological features of repair appeared after 48 hours and were characterised by the proliferation of stellate cells and neobiliary ducts. The

RNA extracted from the slices is suitable for genomic analysis. The extension of slice culture survival enhances the ability to investigate mechanisms of toxicity and to link genomics and proteomics to an altered morphology.

1211 MORPHOLOGICAL AND BIOCHEMICAL INTEGRITY OF HUMAN LIVER SLICES: EFFECTS OF OXYGEN TENSION.

V. Albaladejo[1], H. Martin[1], J. P. Sarsat[1], C. Housset[2], P. Balladur[2] and C. Langrand[1]. [1]*Drug Safety Evaluation, Aventis-Pharma, Vitry-sur-Seine, France and* [2]*INSERM U402, Paris, France.* Sponsor: M. Bonnefoi.

We tested the effects of low (20% O_2) and high (70% O_2) oxygen tension on the morphological and biochemical integrity of human liver slices incubated for up to 72 h in supplemented Williams' E medium in a dynamic rotating culture system. High oxygen tension was more effective than low oxygen tension for preserving morphological integrity in long-term culture (48-72 h). After 72 h of culture with 70% O_2, the lobular pattern was well preserved, and the survival of hepatocytes (approximately 80%) and other cell types was good. Immunohistochemical studies showed good preservation of the region-specific expression of CYP 2E1 and 3A4 isoenzymes for up to 72 h of incubation in 70% O_2. As compared to 20% O_2, the oxidized glutathione content and reactive oxygen species production were slightly increased in 70% O_2, suggesting that minimal oxidative stress occurred with the high oxygen tension. In conclusion, despite slight oxidative stress associated with high oxygen tension, 70% O_2 appeared more appropriate than 20% O_2 for preserving the morphological and biochemical integrity of human liver slices cultured in a dynamic organ culture system for up to 72 h. (Supported by EU Biotechnology Program, B104-CT97-2145).

1212 THE CYTOTOXICITY AND METABOLIC CHANGES INDUCED BY LEWISITE IN *IN VITRO* EXPOSED HUMAN LEUKOCYTES.

H. L. Meier. *BiochemPharm, USAMRICD, Aberdeen Providing Ground, MD.* Sponsor: S. Baskin.

To study the mechanism of vesication for the development of effective countermeasures, the cytotoxic and metabolic effects of the potent chemical warfare vesicant, lewisite (arsine, dichloro [2-chlorovinyl], L) were investigated in a human leukocyte model. Human leukocyte preparations were isolated by Percoll centrifugation and suspended at a final concentration of 10^6cells/ml in Tyrode's buffer with either buffer or L for various times. To determine the cytotoxicity of L at concentrations between $2x10^{-6}$ to $8x10^{-5}$ M, the cells were incubated for 1, 2, 4, 8, 12, 16, 18, and 22 hrs post-exposure before propidium iodide was added. The percent of viable cells was measured by using flow cytometry. The concentration-dependent cytotoxicity of L was detected as early as 1 hr post-exposure in the range of $1x10^{-5}$ to $6x10^{-5}$M. At the longer time intervals, cytotoxicity could be detected at lower concentrations of L. In the investigation of the effect of L on metabolism, exposures were conducted at various concentrations ranging from $6x10^{-7}$to $6x10^{-4}$ M. After exposures, the cells were harvested by centrifugation and their ATP levels were measured by the LKB-Wallac 1243-107 ATP Assay Kit in the LKB-Wallac 1250 Luminometer. Only leukocytes exposed to $6x10^{-4}$ M L demonstrated an initial decrease in ATP within 15 min after exposure. At 1 hr post-exposure, there was a concentration-dependent decrease in ATP. By 2 hrs post-exposure, the concentration-dependent decrease appears to be almost linear. The level of ATP then appears to plateau at all the concentrations of L studied from 4 to 24 hrs post-exposure. It appears that any assay designed to determine whether an antivesicant antidote directed against L is efficacious should be given during the first hr of post-exposure to block the effects on both viability and metabolism.

1213 DEVELOPMENT OF *IN VITRO* ANTIGENICITY STUDY EXPOSING TO TEST COMPOUNDS IN *IN VITRO* PRIMING CULTURE BY USING DENDRITIC CELLS (DC) INDUCED FROM BONE MARROW CELLS (BMC) IN MICE.

T. Inoue and I. Horii. *Preclinical Science, Nippon Roche Research Center, Kamakura, Japan.* Sponsor: R. Nagata.

In early stages of drug discovery, evaluations of toxicities are very important to reduce the attrition rate of the compounds in later stages of drug discovery and development. But, high throughput toxicity evaluation systems are not well established. In this paper, we investigated an *in vitro* antigenicity testing method by using mouse DC induced in *in vitro* culture system from BMC. BMC were isolated from mice and cultured with various cytokines (granulocyte macrophage-colony stimulating factor (GM-CSF) + interleukin-4, GM-CSF + tumor necrosis factor alpha, or GM-CSF + interleukin-6 + flt-3 ligand) for 6 days. The cell numbers were increased during the culture period, and cells having characteristics of DC (dendritic morphology, expression of DC markers; Ia, CD40, CD80 and CD86) were induced after 4-5 days of the culture. To confirm an antigen-presenting activity of the induced DC, the DC were exposed to positive reference compounds (antigens) in the culture system (a priming culture) for 1 day, and intraperitoneally injected in nontreated mice for 2-times in a 2 week interval. At 1 week after the last injection of primed DC, sera were isolated for the measurement of positive reference compound-specific antibodies, and splenocytes were isolated for an *in vitro* lymphocyte proliferation test (response to the antigens). High antibody titers were observed to bovine serum albumin (BSA), and positive antibodies were observed to dinitrobenzene sulfonic acid, sodium salt (DNBS) and trimellitic anhydride. Splenocyte proliferations were observed to BSA, DNBS and penicillin G. These results show that functional DC which have an antigen-presenting activity were induced by the culture of mouse BMC with the cytokines. These DC would be a candidate for antigen-presenting cells in *in vitro* antigenicity tests.

1214 RESPONSIVENESS OF MONKEY PLATELETS AGAINST THREE DIFFERENT AGGREGATION AGENTS.

K. Okasaki, Y. Mori, S. Nechev, D. LaFramboise, R. Coxen, B. Congdon, K. Fukuzaki and R. Nagata. *SNBL USA, Ltd., Everett, WA.*

This experiment was designed to compare non-human primate platelet aggregation using three aggregation agents. These data were also compared to human platelet aggregation with the same agents. Twelve male and five female cynomolgus monkeys and seven male human volunteers supplied platelet specimens. Maximum platelet aggregation rates (MPAR) in monkey platelets, after the addition of Adenosine Diphosphate (ADP; 5, 10 and 20 μM), Collagen (COL; 10μ/mL) and Epinephrine (EPI; 300 μM), were evaluated by gender and compared to human data. Lipoprotein levels of monkey plasma were analyzed by electrophoresis and compared to human electrophoresis data. Both monkey and human MPAR increased dramatically after the addition of COL, and 10 or 20 μM ADP. Monkey MPAR was slightly increased after a 5μM ADP addition. Monkey MPAR only showed a minimal response to an EPI addition in comparison to the human MPAR response. There was also no gender difference in monkey platelet aggregation induced with 20μM ADP, COL or EPI. It was previously reported that the MPAR response, after EPI treatment, was significantly less in cynomolgus monkey platelets as compared to human platelets (J.Med..Primatol.15, 1986). On the other hand, the influence of lipoproteins on platelet aggregation (Arteriosclerosis 3, 1983; Hemostasis 8, 1979; Prostaglandins Leukotrienes and Essential Fatty Acids 51, 1994) was also reported in humans. In this experiment, low-density lipoprotein (LDL) levels in monkeys were about two-fold lower than in humans. Different LDL levels between both species were considered as the possible cause of low sensitivity in monkey platelets against EPI. In conclusion, monkey platelets showed similar or different responsiveness against three aggregation agents when compared to humans.

1215 HEMOLYTIC POTENTIAL OF VEHICLES USED FOR RAPID *IN VIVO* SCREENING OF SMALL MOLECULES.

S. G. Sawant, S. Greene, M. E. Cosenza, S. Neervannan, A. Gore, A. Schultz, J. Jona, S. Goel and H. Davis. *Toxicology, Amgen Inc., Thousand Oaks, CA.*

Vehicles that are administered parenterally *in vivo* may be screened *in vitro* to determine the degree of hemolysis in erythrocytes and to evaluate the effect, if any, of varying vehicle concentrations on hemolysis. This study assessed the hemolytic properties of various vehicles used for rapid *in vivo* screening of small molecules when exposed to rat blood *in vitro*. All the test articles (Tween 80, ethanol, hydroxypropyl β cyclodextrin, polyethylene glycol 400, propylene glycol, poloxamer 188, dimethyl sulfoxide, dimethyl acetamide and multiple component vehicles) were diluted to the desired concentrations in phosphate buffered saline solution. Mixtures containing equal volume of blood and each vehicle dilutions were incubated under static conditions for 30 minutes at 37 ± 1°C. The tubes were centrifuged, and the supernatant harvested were observed visually for the appearance of red color and the optical densities were read at wavelength of 545 nm. A hemolytic index for each vehicle formulation was determined by comparing the optical density determined spectrophotometrically in the test article samples to the optical density under conditions of 0% and 100% hemolysis. There was a positive correlation between plasma color and optical density in all samples. Hemolysis was not seen at the following concentrations in these vehicles: Tween 80 ≦ 0.125%, Ethanol ≦ 5%, Hydroxypropyl β cyclodextrin ≦ 1%, Polyethylene glycol ≦ 2.5%, Propylene glycol ≦ 5%, Poloxamer 188 ≦ 0.5%, Dimethyl sulfoxide ≦ 5% and Dimethyl acetamide ≦ 7.5%. All the multiple component vehicles (25% Ethanol-5% Cremophor EL, 10% DMAC- 20% Ethanol, 10% DMAC-40% PG and 20% PG-20% PEG 400) induced hemolysis in rat blood. *in vivo* animal studies and *in vitro* cytotoxicity studies to understand the toxicity profiles of these commonly used vehicles are in progress.

1216 SELECTION OF REFERENCE CHEMICALS TO VALIDATE *IN VITRO* CYTOTOXICITY ASSAYS FOR ESTIMATING *IN VIVO* STARTING DOSES FOR ACUTE ORAL TOXICITY.

J. A. Strickland[1], M. W. Paris[1], R. R. Tice[1] and W. S. Stokes[2]. *[1]NICEATM, ILS, Research Triangle Park, NC and [2]NICEATM, NIEHS, Research Triangle Park, NC.*
Sponsor: J. Bucher.

The Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM) and NICEATM convened an international workshop in October 2000 to evaluate the validation status of *in vitro* methods for predicting acute systemic toxicity (see http://iccvam.niehs.nih.gov). As an interim step to developing and ultimately using *in vitro* cytotoxicity methods to accurately predict rodent oral LD50s for regulatory purposes, workshop participants recommended the use of *in vitro* methods to predict the *in vivo* LD50 starting dose in situations where other credible information was unavailable. It was conjectured that such an approach would further reduce the number of animals required for acute toxicity testing. In a joint effort with the USEPA, and in collaboration with the European Centre for the Validation of Alternative Methods (ECVAM), NICEATM is organizing a multi-laboratory study to validate the utility of two *in vitro* cytotoxicity tests for identifying the starting dose for *in vivo* acute toxicity tests. A major aspect of the study design was the selection of an appropriate number of test chemicals that represented 1) a wide range of toxicity, 2) the types of chemicals regulated by the various US regulatory agencies, and 3) those with human toxicity data and/or human exposure potential. Based on these criteria, a preliminary list of approximately 100 chemicals was compiled by mining several publicly available data sets. A priority list of 60 chemicals representing the 6 acute toxicity hazard classifications in the Globally Harmonized Scheme was created based on compatibility with the test systems, availability and quality of existing rodent oral LD50 data, human exposure data, commercial availability, ease of shipping, and availability of information on mechanism of action. Supported by NIEHS contract N01-ES-85424 with ILS, Inc.

1217 PRELIMINARY EVALUATION OF A CYTOTOXICITY MODEL FOR PREDICTING ACUTE ORAL TOXICITY TEST STARTING DOSES.

G. C. Mun[1], R. R. Ruppalt[2] and R. D. Curren[1]. *[1]Institute for in vitro Sciences, Inc., Gaithersburg, MD and [2]Bioreliance Corporation, Gaithersburg, MD.*

For almost fifty years *in vitro* cytotoxicity methods have been studied as predictors of acute lethality *in vivo*. Recently Halle has compiled a Registry of Cytotoxicity (RC) which compares the LD50 (in mmol/kg; rat or mouse) of 347 chemicals with an average *in vitro* IC50 (in mmol/l; various cell types). A graph of the RC shows reasonably good correlation between lethality *in vivo* and cytotoxicity *in vitro*; 73 % of the points lie within a +/- log 5 interval around the regression line. This has led Spielmann et al. to propose that, at a minimum, the results of *in vitro* basal cytotoxicity tests can be used to estimate the starting dose for *in vivo* LD50 tests. It has also been suggested that new cytotoxicity methods be first qualified for use in this scheme by testing them with RC chemicals having a range of toxicities and which fit closely to the RC regression line. To qualify, the new results should have a similar slope and lie within +/- log 5 of the RC regression line. We investigated whether two commonly used cytotoxicity tests (neutral red uptake in BALB/c 3T3 [3T3] and normal human keratinocytes [NHK]) would qualify under these conditions. Eleven chemicals from the RC whose *in vivo* LD50's ranged from ~0.1 mmol/kg to ~100 mmol/kg were chosen for evaluation. All chemicals were tested under code using a well-defined standard protocol. Cytotoxicity in the treated cells relative to that of control cells was determined after 24 hr (3T3) or 48 hr (NHK) exposure. When the resulting data were overlaid on the original RC graph, all new data points lay within a +/- log 5 interval around the RC regression line. The slopes of the regression lines for the new tests were 0.506 (3T3) and 0.498 (NHK) *versus* 0.625 for the RC. R2 values were 0.985 (3T3) and 0.936 (NHK). We conclude that the proposed qualification criteria are reasonable and that both of these candidate tests have met those criteria.

1218 TOXICITY TESTS USED ONLY AS SCREENS STILL NEED CAREFUL VALIDATION.

R. D. Curren[1], J. W. Harbell[1] and L. H. Bruner[2]. *[1]Institute for in vitro Sciences, Inc., Gaithersburg, MD and [2]The Gillette Company, Needham, MA.*

New toxicity tests, especially *in vitro* tests, are often used as screens; i.e. they are used to preliminarily divide a test set of chemicals into positive or negative subsets. One of two strategies can then be applied. Either 1) the negatives can be accepted as correct and the presumed positives evaluated in a second tier test, or 2) the positives can be accepted and the negatives evaluated in a second tier test. There has been a tendency to assume that validation does not have to be as stringent for a screen as it does for a stand-alone test because the screen is only a preliminary assessment. However, both approaches 1) and 2) above use screens to make some firm decisions; the first to classify a chemical as non-toxic and the second to classify the chemical as toxic. It is often thought that sensitivity (fraction of known positives correctly identified) is the most important criterion and that specificity (fraction of known negative materials correctly identified) has much less significance. It follows that sensitivity alone could be characterized by using predominately positive chemicals in a validation study. We present data to show that this reasoning can lead to major errors. In approach 1), choosing a tier I test with low specificity will result in a large number of false positive materials passing through to the more expensive or animal intensive tier two test, possibly negating the advantage of having two tiers. This is especially relevant when several mechanistically specific tests are combined into a tier I battery. In approach 2), a low specificity tier I test means that many useful chemicals may be discarded, without necessarily decreasing the prevalence of positives in the subset of negative chemicals identified by the screen. Finally we show that using predominantly positive test materials to validate a screen can result in a serious overestimation of the test's sensitivity. For any test to be useful as a screening test or as a stand-alone test, it must it must be both sensitive and specific for the endpoint of interest.

1219 THE SENSITIVITY AND SPECIFICITY OF A TOXICITY TEST ARE DEPENDENT ON THE DISTRIBUTION OF TOXIC CHEMICALS BEING EVALUATED.

L. H. Bruner[1], G. J. Carr[2], J. W. Harbell[3] and R. D. Curren[3]. *[1]Gillette Medical Evaluation Laboratory, The Gillette Company, Needham, MA, [2]Miami Valley Laboratories, The Procter & Gamble Company, Cincinnati, OH and [3]Institute for in vitro Sciences, Gaithersburg, MD.*

Often, the only measures of toxicity test performance provided after a validation study are the statistics sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and concordance. Sensitivity and specificity, which have been assumed to be independent of the chemical population being tested, are generally used as the primary indicators of test performance since NPV and PPV are commonly known to vary with changes in prevalence. The purpose of these studies was to test whether or not sensitivity and specificity are true constants. Monte Carlo simulations were used to generate four sets of data that fit a simple prediction model. The distribution of toxic chemicals was varied between four data sets evaluated in the study. The distribution of toxicity in two of the data sets was skewed such that either strongly or weakly toxic chemicals predominated. The toxicity of chemicals in the third data set was predominantly strongly and weakly toxic with few chemicals of intermediate toxicity. The fourth set contained chemicals predominantly of intermediate toxicity with relatively few strongly or weakly toxic chemicals. Cut-offs were set at different locations across the range of response and the performance statistics were calculated at each cutoff. The results showed that sensitivity and specificity, measured at identical cut-offs, were not constant across the data sets. We conclude that sensitivity and specificity should not be considered constant indicators of toxicity test performance and that more emphasis should be placed on the assessment of a toxicity test's positive and negative predictive value.

1220 RESULTS OF AN INTERAGENCY COORDINATING COMMITTEE ON THE VALIDATION OF ALTERNATIVE METHODS (ICCVAM) EXPERT PANEL EVALUATION OF THE VALIDATION STATUS OF THE FROG EMBRYO TERATOGENICITY ASSAY-XENOPUS (FETAX) FOR IDENTIFYING DEVELOPMENTAL TOXICANTS.

R. R. Tice[1], A. Auletta[2], G. Daston[3], E. Faustman[4] and W. S. Stokes[5]. *[1]NICEATM, ILS, Inc., Research Triangle Park, NC, [2]OPPT, USEPA, Washington, DC, [3]Procter & Gamble, Cincinnati, OH, [4]Univ. of Washington, Seattle, WA and [5]NICEATM, NIEHS, Research Triangle Park, NC.*

One of the most important aspects of a toxicity assessment is the determination of the potential of a chemical to affect fetal development. Traditional *in vivo* rodent methods for evaluating developmental toxicity potential are time-, resource-, and animal-intensive. To reduce animal use and expedite evaluation, alternative *in vitro* approaches for compound screening have been developed but few have undergone rigorous review. FETAX measures embryonic development of the South African clawed frog, Xenopus laevis and is a test for organogenesis, which is highly conserved across amphibians and mammals. In this assay, eggs hatch and develop into embryos during exposure to the test substance. After 96 hr of development, individual embryos are evaluated for mortality, malformations, and growth inhibition. In 1998, the USEPA requested that ICCVAM evaluate the validation status of FETAX, its potential regulatory usefulness, and the critical research, development, and validation efforts needed to improve it. An Expert Panel Meeting (May 2000) deliberated on these issues (http://iccvam.niehs.nih.gov) and concluded that the performance and reproducibility of FETAX was not adequate for regulatory applications and recommended that: 1) the FETAX protocol be modified to address specific limitations noted by the Panel, 2) the number of endpoints be expanded to improve assay performance for identifying developmental toxicants, 3) additional,

more robust decision criteria be developed, and 4) additional validation studies be conducted. In addition, the Panel recommended that validation criteria specific for developmental toxicity, and reliable and accurate comparative databases of animal and human developmental toxicants be developed.Supported by NIEHS contract N01-ES-85424 with ILS, Inc..

1221 MONOCLONAL ANTI-PHENCYCLIDINE (PCP) IgG PRODUCES LONG-TERM PROTECTION AGAINST ADVERSE EFFECTS OF PCP.

E. M. Laurenzana[1], S. F. Ali[2], W. B. Gentry[1] and S. M. Owens[1]. *[1]Dept. of Pharmacology and Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR and [2]Division of Neurotoxicology, National Center for Toxicological Research, Jefferson, AR.*

The purpose of this study was to determine if anti-PCP IgG protects against PCP-induced effects on locomotor activity, health and brain monoamine levels. Sprague-Dawley rats (2 groups, N=4) received 18 mg/kg/day of PCP continuously for 2 weeks *via* a subcutaneous osmotic minipump. Once PCP reached steady-state concentrations (<24 hr after implanting pump), baseline locomotor activity was determined. One group of rats then received a control saline treatment and the other group received a single dose of anti-PCP IgG, which was 0.3 times the molar equivalent amount of PCP in the body at steady-state. PCP-induced locomotor activity was determined immediately following the saline or IgG administration. The anti-PCP IgG caused a significant reduction in PCP-induced locomotor activity. Body weights were recorded for the entire 2 week experiment. Significant weight reductions were found in the rats receiving the saline. In stark contrast, anti-PCP IgG treated rats maintained their body weights and apparent good health. The rats were sacrificed 2 weeks after implanting SC pumps for determination of PCP concentrations in 7 brain regions, testis and serum. Anti-PCP IgG significantly decreased PCP concentrations in serum, testis and all brain regions, except the brainstem. Brain regions were also examined for brain monoamine levels by HPLC/EC. For these studies, a saline control group (N=4) that did not receive PCP was included. DOPAC levels were decreased in the frontal cortex of the PCP-saline group compared with the PCP-IgG group and saline control group. These results suggest that anti-PCP IgG can offer significant protective effects and improved health even in the presence of continuous high dose PCP that apparently saturates anti-PCP IgG binding capacity. (Supported by NIDA Grants DA7610 and K08 DA 339).

1222 RELATIONSHIP BETWEEN PARKINSONISM AND SERUM PROLACTIN LEVEL IN MPTP-TREATED COMMON MARMOSETS.

T. Kamenosono, B. Lee, Y. Mori, K. Okasaki, S. Meyer, K. Fukuzaki and R. Nagara. *SNBL USA, Ltd., Everett, WA.*

The main neural disorder in ParkinsonÅfs disease is degeneration of dopaminergic neurons in the substantia nigra. The MPTP-treated marmoset is an established model for ParkinsonÅfs disease, since MPTP produces motor deficits characteristic of those seen in patients with ParkinsonÅfs disease. Prolactin secretion is under tonic inhibitory control by dopamine (prolactin release-inhibiting factor). We examined the relationship between parkinsonism and serum prolactin level using MPTP-treated common marmosets. Male and female common marmosets (1.5-3 years old) were used for this study. Animals were treated 3 to 4 times with intravenous administration of MPTP (1.5-2.5 mg/kg) under ketamine anesthesia (with a 1 or 2 week interval between administrations). Immediately after MPTP treatment, the animals were immobile, with flexed hind quarters, postural tremors, and a loss of vocalization. Approximately 6 months after MPTP-treatment, in control (non-treatment) and MPTP-treated animals, spontaneous locomotor activities were measured by recordings on electromechanical counters (photocell sensor). Behaviors were observed by video recording to evaluate parkinsonian symptoms. Serum prolactin levels were analyzed using ELISA. The mean locomotor activity in all MPTP-treated animals was decreased compared with that in control animals. All MPTP-treated animals exhibited the characteristic parkinsonian symptoms such as slow and/or uncoordinated movements, however, there was individual difference in the degree of these symptoms. In the prolactin analysis, MPTP-treated animals showed higher prolactin levels compared to the control animals. The results of this study demonstrate that intravenous administration of MPTP produces motor deficits even 6 months after MPTP-treatment due to degeneration of dopaminergic neurons. This suggests that the increase in prolactin is induced by reduction of brain dopamine levels in the MPTP-treated common marmosets.

1223 CROTONONITRILE ISOMERS HAVE A DIFFERENT PROFILE OF NEUROTOXIC EFFECTS IN THE RAT.

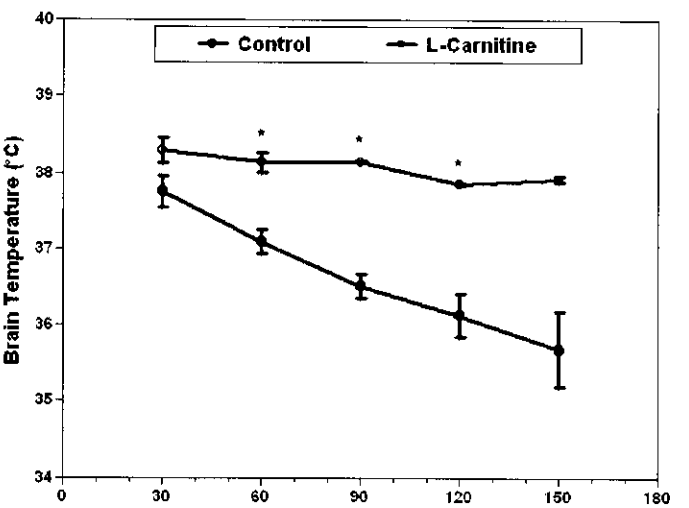
J. Llorens and E. Balbuena. *Dept. Ciencies Fisiologiques II, Universitat de Barcelona, L'Hospitalet de Llobregat, Spain.* Sponsor: K. Crofton.

IDPN (3, 3'-iminodipropionitrile) and allylnitrile have a number of common effects on the nervous and sensory systems of the rat, including degeneration of the vestibular and auditory hair cells, corneal opacification, and gliosis in the retina and olfactory bulb. Gliosis in other specific areas of the CNS has also been observed after IDPN. The vestibular toxicity of these nitriles results in a permanent behavioral syndrome. Crotononitrile (CRO), a mixture of *cis-* and *trans-* isomers, has been demonstrated to cause both this syndrome and vestibular hair cell degeneration. This study compared the effects of the two isomers of CRO, isolated to >93 % purity by fractionated distillation from the commercially available CRO mixture (approximately 60% *cis-* and 40 % *trans-*CRO). Adult male Long-Evans rats were administered for 3 days with vehicle control, *cis-*CRO (80, 100, 120 mg/kg per day) or *trans-*CRO (250 mg/kg per day) and the changes in corneal transparency and vestibular function were assessed. Surface preparations of the vestibular sensory epithelia and the organ of Corti were observed for hair cell loss by scanning electron microscopy. Concentrations in retina, olfactory bulbs, cerebellum, striatum and cingulate cortex of GFAP, a marker for reactive gliosis, were also determined. In a dose-dependent manner, *cis-*CRO increased the rating scores in behavioral tests of vestibular dysfunction, and caused corneal opacity, hair cell loss in both the vestibular epithelia and organ of Corti, and gliosis in retina, olfactory bulb and cortex but not in the cerebellum and striatum. This profile of neurotoxicity is similar to that shown by IDPN and allylnitrile. In contrast, *trans-*CRO did not cause vestibular dysfunction, hair cell loss or corneal opacity, although other neurotoxic actions, currently under investigation, were evident from the motor behavior of the treated animals. We conclude that the neurotoxic effects of nitriles depend on strict structural requirements; this suggest that they may act through their interaction with specific molecular targets.

1224 PRETREATMENT WITH L-CARNITINE PREVENTS HYPOTHERMIA INDUCED BY THE MITOCHONDRIAL INHIBITOR 3-NITROPROPIONIC ACID (3-NPA).

Z. K. Binienda[1], J. L. Summage[1], R. D. Skinner[2], R. L. Rountree[1] and W. Slikker, Jr.[1]. *[1]Neurotoxicology, FDA/NCTR, Jefferson, AR and [2]Anatomy, UAMS, Little Rock, AR.*

An environmental toxin, 3-NPA, can cause cellular energy deficits due to irreversible inhibition of a mitochondrial Complex II enzyme, succinate dehydrogenase (SDH). We have previously shown that exposure to 3-NPA and the resulting SDH inhibition were associated with a 2°C decrease in rectal temperature 3 hrs after dosing. While pretreatment with L-carnitine (an enhancer of free fatty acid beta oxidation) prior to 3-NPA administration, prevented the oxidative stress-associated increase in the activity of free radical-scavenging enzymes, it did not significantly prevent 3-NPA-induced SDH inhibition. Here, intracranial temperature was continuously measured near the cerebellum in adult male Sprague-Dawley rats injected with either 100 mg/kg, i.p. L-carnitine (LC) 60 min prior to 3-NPA (30 mg/kg, s.c.) or with 3-NPA alone. Rats were surgically implanted with temperature probes registering linear electrical responses to temperature change. Compared with baseline temperature, administration of 3-NPA alone was associated with a significant fall in temperature within 1 hr postinjection. Pretreatment with LC totally prevented this decrease ($p<0.05$). Data indicate that the neuroprotective effects mediated by the carnitines may result from the enhancement of energy production rather than direct or indirect interference with 3-NPA.



* indicates significant difference between L-Carnitine and Control at that time point.
Brain Temperature is average during 30 minute period

1225 NEUROTOXICITY PRODUCED BY DIBROMOACETIC ACID IN DRINKING WATER OF RATS.

P. M. Phillips[1], A. Levine[2], K. L. McDaniel[1], R. C. Sills[3] and V. C. Moser[1]. *[1]NTD/NHEERL/ORD, USEPA, Research Triangle Park, NC, [2]UNC, Chapel Hill, NC and [3]NTP, NIEHS, Research Triangle Park, NC.*

The Safe Drinking Water Act requires that EPA consider noncancer endpoints for the assessment of adverse human health effects of disinfection byproducts (DBPs). Dichloroacetic acid is a known human and animal neurotoxicant, but essentially no studies have evaluated the neurotoxic potential of the brominated analog, dibromoacetic acid (DBA). This study characterized the neurotoxicity of DBA during 6-month exposure in drinking water of rats, using a neurobehavioral test battery followed by perfusion fixation for neuropathological evaluation. Adolescent male and female Fischer 344 rats were administered DBA at 0, 0.2, 0.6, and 1.5 g/l, producing an average intake of about 0, 20, 72, and 161 mg/kg/day. In both sexes, weight gain was depressed in the high-dose group, but overall general health was not altered. Testing using a functional observational battery and motor activity took place before dosing began and at 1, 2, 4, and 6 months. DBA produced dose-related neuromuscular toxicity characterized by limb weakness, mild gait abnormalities, and hypotonia, as well as sensorimotor depression, with decreased responses to a tail pinch and click. Other signs of toxicity included decreased activity and chest clasping. The neurotoxicity did not appear progressive with continued exposure. The major neuropathological finding was degeneration of myelinated nerve fibers in spinal cord white matter (lateral and ventral areas) in the high-dose rats. In addition, small numbers of swollen, eosinophilic, and sometimes vacuolated neurites were observed in the spinal cord gray matter of mid- and high-dose rats. No treatment-related changes were seen in brain, eyes, peripheral nerves, or peripheral ganglia. Based on the neurobehavioral data, the LOEL from this study was 20 mg/kg/day (lowest dose tested). These studies demonstrate that neurotoxicity should be considered in the overall hazard evaluation of haloacetic acids. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

1226 EFFECTS OF EARLY POSTNATAL ESTRADIOL AND DIETHYLSTILBESTEROL EXPOSURE ON CINCINNATI WATER MAZE PERFORMANCE OF MALE AND FEMALE RATS.

R. L. Carr, J. C. Chambers, A. Kachroo and J. R. Richardson. *Center for Environmental Health Sciences, College of Veterinary Medicine, Mississippi State University, Mississippi State, MS.*

Estrogen plays an important role in the development of the brain. Thus, exposure of developing animals to chemicals which mimic the effects of estrogen could potentially disrupt normal development leading to alteration of function including behavior. These studies were designed to determine the effect of excessive stimulation of the estrogen receptors on cognitive function using the Cincinnati water maze. Intact male and female rats were orally administered 72 µg/kg 17β-estradiol (E_2) or 10 µg/kg diethylstilbesterol (DES) from postnatal day 1 (PND1) through PND14. On PND33, behavioral testing was initiated using Path A (2 trials per day for 5 days with a 2 hour intratrial period). Following a 2 days non-testing period, rats were retested using the reverse path (Path B) in similar fashion. Neonatal exposure to E_2 significantly reduced the number of errors made by female rats in Path A. Male rats treated with E_2 also made fewer errors than controls but it was not statistically significant. The latency of the E_2 treated rats to complete Path A was lower than controls but was not statistically significant. Neonatal exposure to DES resulted in an increased number of errors and longer latency in both male and female rats in Path A but these were not statistically significant with the exception of the longer latency to complete the maze by female DES rats. Neither E_2 or DES treatment produced any differences in Path B errors or latency in either sex. Statistical comparison between the two daily trials in Path A demonstrated that both male and female E_2 treated rats made significantly fewer errors on the second trial than the first while control rats performed similarly. This was not present in the DES treated rats. This suggests that E_2 treatment during development enhances short term memory. However, since DES did not produce similar results, it can be hypothesized that this enhancement may not be mediated through the traditional E_2 receptor.

1227 NEUROTOXICITY INDUCED BY REPEATED DOSES OF 2-(DIMETHYLAMINO)ETHYL METHACRYLATE IN RATS.

K. Yamashita, Y. Okazaki and M. Tsuchitani. *Mitsubishi Chemical Safety Institute Ltd., Ibaraki, Japan.*

To evaluate the neurotoxicity of 2-(dimethylamino)ethyl methacrylate, groups of 6 male SD rats were administered orally with 0 (corn oil), 500, or 1, 000 mg/kg for 6 consecutive weeks. The following items were conducted on all rats: the clinical observation (twice per day); the functional assessment (once or twice per week); the histopathological examination of the central and peripheral nervous tissues. The salivation was found in the 500 and 1, 000 mg/kg groups, and the tremor of the forelimbs and the clonic convulsion in the upper half of the body was found in the 1, 000 mg/kg group. The salivation was observed immediately after dosing and appeared from the second week. The tremor was a transient sign, occurring within 30 min after dosing, and it appeared from the fifth week. The clonic convulsion was observed at the sixth week, and its trigger was the stimulation as the handling. When an attack of convulsion began, the animals crouched, thrusting out their forelimbs. Vacuolation in the white matter of the spinal cord was found in all rats of the 1, 000mg/kg group. The lesions appeared symmetrically, and they were restricted in the dorsal spinocerebellar tracts. The affected nerve fibers comprised axonal fragmentation accompanying with myelin ballooning, disruption, and phagocytosis. It was considered that clonic convulsion was due to the nerve fiber degeneration in the dorsal spinocerebellar tracts of the spinal cord.

1228 AVOIDANCE RESPONDING AND MOTOR ACTIVITY IN EPH A5 KNOCKOUT MICE.

L. Michna[1], G. D. Yancopoulus[2], R. Zhou[3] and G. C. Wagner[4]. *[1]Toxicology, Rutgers University, Piscataway, NJ, [2]Regeneron Pharm, Tarrytown, NY, [3]Chemical Biology, Rutgers University, Piscataway, NJ and [4]Psychology, Rutgers University, Piscataway, NJ.*

The Eph receptor family has been implicated in the guidance of axons and formation of topographic projection maps. For example, the Eph A5 receptor is expresed in differentiated neurons of the hippocampus and striatum and is thought to be involved in the development of the septo-hippocampal and nigrostriatal pathways. Previous neurochemical analysis revealed that Eph A5 knockout mice have higher striatal dopamine and decreased accumbal dopamine compared to wildtypes. Presently, male and female Eph A5 receptor knockout and wildtype mice were evaluated in the active avoidance responding paradigm and horizontal motor activity test. In the two-way active avoidance paradigm, mice were given 20 trials/day for 30 days; each trial consisting of a 10 sec tone CS and a 10 sec, 0.5 mA footshock US with a criterion of 18 avoidances/day. In the motor activity test, horizontal activity was recorded after 10 min in an activity monitor following baseline, saline and cocaine HCl (0.3, 1, and 3 mg/kg). In the active avoidance paradigm, male Eph A5 knockouts reached criterion by day 16, while wildtypes only reached 50% by the end of 30 days. Also, female Eph A5 knockouts reached criterion by day 22 while female wildtypes only reached 33% at the end of 30 days. Both male and female Eph A5 knockouts were less active following saline and all doses of cocaine. As both male and female Eph A5 knockout mice show enhanced avoidance responding and decreased activity after cocaine, these results may indicate a role for Eph A5 in the regulation of dopamine-mediated motor response. (Supported by NIH ES07148)

1229 CONFIRMATION OF INTER-OBSERVER RELIABILITY IN THE CONDUCT OF FUNCTIONAL OBSERVATION BATTERY ASSESSMENTS.

K. Colahan, S. N. Groom, G. Washer and C. Gauthier. *Toxicology, CTBR, Senneville, PQ, Canada.* Sponsor: G. Lulham.

The Functional Observational Battery (FOB) of is widely accepted as a sensitive tool to screen for neurotoxicity. CTBR has extensive experience performing neurotoxicity testing in accordance with GLP and stringent guidelines of the USEPA and routinely conducts of inter-observer reliability (IOR's) studies to validate technical competence in the performance of FOB tests. With the advent of the ICH S7 Guideline, these capabilities have been applied to CNS safety pharmacology studies of pharmaceuticals. The current study was a recent IOR assessment of 4 technicians and employed 3positive reference compounds: amphetamine (AM), ethanol (ET) and carbaryl (CA). Since the technicians were not drawn from the pool of previously trained staff, the IOR was preceded by a two-week training session. The IOR therefore served to validate the consistency of observations between technicians but also served to evaluate the effectiveness of the training program. The technicians were able to detect the major neurotoxic endpoints expected for each of the positive control compounds including tremors and autonomic signs with CA, ataxia and gait abnormalities with ET and bizarre stereotypical behaviors with AM. Initial variability between the gradings were no longer evident by the end of the IOR assessment. Since all technicians were considered to be scoring with similar accuracy and precision, they were approved to perform FOB assessments in rats. In conclusion, the IOR performed by our laboratory provided reliable reproducible results and confirmed the effectiveness of the training program. IOR assessments provide laboratories with a means to assess the competence of their staff and Sponsors with a means to monitor the capabilities of laboratories in the performance of such tests. In order to further reduce the risk of inter-individual or temporal variability, it is critical to perform periodic IOR assessments on technical staff assigned to such studies and whenever possible ensure the same staff carry out the FOB for all occasions on a given study.

1230 DEVELOPMENT OF A MODEL FOR CHRONIC STRESS EXPOSURE IN MICE.

M. Dubovicky[1,2], I. Bernatova[1,3], M. Morris[1] and J. B. Lucot[1].
[1]*Pharmacology/Toxicology, Wright State University, School of Medicine, Dayton, OH,* [2]*Inst Exp Pharmacology, Slovak Academy of Sciences, Bratislava, Slovakia and* [3]*Inst Normal and Pathological Physiology, Slovak Academy of Sciences, Bratislava, Slovakia.*
Sponsor: P. Gunasekar.

Chronic stress contributes to physical and mental illness and may interact with chemical toxins. Our previous experiments demonstrated that acute stress potentiates neurotoxicity (Lucot, 1999). Thus, we conducted controlled scientific studies of the responses to stress preparatory to studying the interactions of stress and chemical toxins. We have developed a unique model of chronic emotional stress in mice based on intermittent shaker stress. Mice are kept in their home cages fixed to a cage rack mounted on the shaker power unit. Standard pellet diet and tap water are provided ad lib. Our experimental paradigm enables the study of the neuroendocrine, cardiovascular and behavioral responses to acute as well as chronic stress. Chronic stress did not have any unfavorable effect on the health of the mice. There was 10 % of loss in body weight. However, after discontinuation of chronic stress the mean values of body weight returned to the values of non-stressed controls. Neuroendocrine and cardiovascular assessment revealed significant increases in plasma corticosterone, blood pressure and heart rate in acutely and chronically stressed mice. Chronic emotional stress did not have any effect on total open field activity or on elevated plus maze behavior. However, emotional reactivity on the elevated plus maze as measured by defecation rate increased in the chronically stressed mice 7 days after stress. Unlike the chronic stress, acute stress resulted in significant decreases in locomotor activity in the open field test. Our results show that the chronic intermittent shaker stress provides an excellent model for stress exposure and for use in testing stress/chemical interactions. Supported by DoD, contract No. 99214005.

1231 ACUTE AND REPEATED RESTRAINT STRESS HAVE LITTLE INFLUENCE ON PYRIDOSTIGMINE TOXICITY.

X. Song[1], H. Tian[1], J. Bressler[2], S. Pruett[3] and C. Pope[1]. [1]*Physiol Sci, Oklahoma State Univ, Stillwater, OK,* [2]*Kennedy Krieger Institute, Baltimore, MD and* [3]*Cell Biol Anat, LSU Health Sciences Center, Shreveport, LA.*

Pyridostigmine bromide (PB), a quaternary, carbamate acetylcholinesterase inhibitor, has been used to protect soldiers from possible exposure to long-term inactivators of acetylcholinesterase, i.e., organophosphorus nerve agents. Some studies suggest that stress may alter BBB integrity and allow PB to enter the brain. We evaluated the effects of acute and repeated restraint stress on PB neurotoxicity. For acute restraint stress, rats were 1) restrained for 90 min and then given PB (30 mg/kg, po), 2) simultaneously restrained and given PB or 3) restrained for 3 hrs, given PB, and then restrained for another hour. In all cases, rats were evaluated for cholinergic toxicity (SLUD signs and involuntary movements) and sacrificed 1 hour after PB. Restraint stress (90 min) caused a significant increase in plasma corticosterone. Whole blood ChE was markedly inhibited (>80%) by PB whereas brain regional ChE activity (cortex, hippocampus, cerebellum) was only marginally affected (maximal 20% inhibition). PB-induced toxicity was not enhanced nor was brain ChE inhibition increased by any stress condition. BBB integrity assessed by the accumulation of horseradish peroxidase in brain regions following intracardiac tracer injection was not increased by prior stress. Rats were also exposed to daily stress (60 min) and concurrently treated with either saline or PB (3 or 10 mg/kg) for 14 days. PB-treated rats (both dosages) exhibited slight signs of cholinergic toxicity for the first 3 days of exposure after which tolerance developed. Repeated restraint, however, had little effect on functional signs of PB toxicity. Whole blood and diaphragm ChE were markedly reduced (57-84% and 74-83%, respectively) 1 hour after the last exposure but brain regional ChE activity showed minimal and inconsistent changes. The results suggest that acute and repeated restraint stress have little effect on PB toxicity or PB entry into the brain. (Supported by grant DAMD17-00-1-0070 from US Army).

1232 ADAPTIVE RESPONSE OF BLOOD-BRAIN BARRIER DISRUPTION AND INCREASED PERMEABILITY TO PYRIDOSTIGMINE BROMIDE (PB) BY REPEATED IMMOBILIZATION STRESS.

A. M. Shehata[1,2], A. W. Abu-Qare[1], T. V. Damodaran[1], W. A. Khan[1] and M. B. Abou-Donia[1]. [1]*Pharmacology and Cancer Biology, Duke University Medical center, Durham, NC and* [2]*Physiology, National Organization for Drug Control and Research, Cairo, Egypt.*

In the present study we investigated the effects of repeated immobilization stress in male Sprague-Dawley rats on the brain penetrability of PB and its effects on the brain regional acetylcholinesterase (AChE) activity. Animals were stressed by restraining in a Plexiglas tube for 15, 30, and 60 minutes, alone or following pretreatment with 15 daily oral dose of 1.3 mg/kg PB. Brain uptake of [3H]PB (100μCi/kg, oral) was used to assess the changes in the BBB permeability. Co-exposure of PB and stress resulted in significantly increased uptake of [3H]PB (~258, 170 and164% in midbrain, cortex and cerebellum, respectively at 30 minutes of stress) and ~256% increase in brainstem at 15 minutes of stress, as compared with exposure with PB alone. However, in all the brain regions, there was a decreasing trend in the uptake following co-exposure of PB and 60 minutes of stress. PB alone caused no significant change in AChE activity in brain regions, but significant inhibition in plasma BChE activity following treatment with PB alone. Cortex and midbrain AChE activity was maximally inhibited following 30 and 15 minutes of stress alone (~77 and 52%, respectively). Co-exposure to stress and PB resulted in significant inhibition in cortex, midbrain, spinal cord, cerebellum and plasma (~36-79% of control) at 30 minutes of stress whereas maximum inhibition (~56% of control) in the brainstem occurred at 15 minutes of stress. Co-exposure to PB and stress for 60 minutes resulted in reduction in the extent of inhibition of AChE activity. These results suggest that short-term stress could disrupt the BBB permeability to PB, whereas prolonged exposure to stress results in adaptive response. Supported, in part by the US army Medical Research and Materiel Command under contract #DAMD 17-99-1-9020.

1233 VALIDATION OF A CNS SAFETY PHARMACOLOGY BATTERY IN THE MOUSE.

S. Mason, G. Washer and C. Banks. *Toxicology, CTBR, Senneville, PQ, Canada.*
Sponsor: G. Lulham.

The ICH S7 Safety Pharmacology guidelines stipulate a core battery of tests that are required for assessment of effects on the central nervous system (CNS). In addition, follow-up studies may be required on a case-by-case basis for additional information. At CTBR, a GLP-compliant series of CNS studies (functional observational battery, locomotor activity, body temperature) have historically been performed in the albino rat. For greater flexibility, both core battery and extended follow-up studies were validated using the albino mouse. Initial studies comprised a modified Irwin Screen and evaluation of spontaneous locomotor activity and body temperature. Follow-up studies included assessment of forced locomotor activity, auditory startle response, barbiturate sleep time, acetic acid writhing and anti- and pro-convulsant assays with both chemical and electrical induction of convulsions. A range of common positive control compounds with well-documented effects in these studies were used to demonstrate the effectiveness and acceptability of the assays. 6 week old male Swiss Crl:CD-1®(ICR)BR mice were used in all tests. Positive control compounds were formulated in deionized water and were administered as a single oral gavage dose or intraperitoneal injection. Dose levels were based on published literature. Animals administered sedative or stimulant drugs and assessed for general behavioral responses, both spontaneous and forced motor activity or startle response all exhibited characteristic reactions. Extensions were seen for anesthesia time following co-administration of barbiturates and benzodiazepine or phenothiazine drugs, a reduction was seen in the number of writhes induced by acetic acid following both opioid and non-opioid analgesic administration, and escalation or diminution of the convulsive threshold was observed for both chemical and electrical induction of convulsions following alkaloid or chlordiazepoxide administration. All studies therefore met their pre-defined acceptance criteria and both the core battery and follow-up studies are considered validated for use at this laboratory.

1234 A FUNCTIONAL OBSERVATIONAL BATTERY (FOB) FOR USE IN DOG TOXICITY STUDIES: DEVELOPMENT AND VALIDATION.

S. C. Gad and S. D. Gad. *Gad Consulting Services, Cary, NC.*

The most commonly used nonrodent species in regulatory systemic toxicity and safety assessment studies has been and remains the dog, with the beagle being the standard breed employed. While a standardized FOB for use in rats (based on Gad, 1982) has been incorporated into rodent studies since the late 1980's, and some work has been previously conducted towards developing a similar screen in the dog (Haggerty, 1991), progress has been limited. Given both the differential metabolism and sensitivity of the dog compared to rodents, and the extreme desirability of having as complete a set of toxicity and/or functionality measures in the same species (to simplify and improve the accuracy of dose/response metrics), the need for such a validated methodology is clear. Study data from prior work establishes the susceptibility of dogs to a wide variety of neurotoxic agents, including 6-ANA, methanol, lasalocid, metronidazole, acrylamide, clinoquinol, organo tins, and mercury. Additionally, the dog is likewise well established as a sensitive model for a wide range of peripheral and central nervous system active pharmacologic agents, as required by recent regulatory requirements for safety pharmacology evaluations. A robust and yet sensitive noninvasive screening methodology for detecting and pro-

viding initial quantitation and characterization of such direct and indirect neurotoxic and neuropharmacologic effects has been developed. Additionally, an analysis and interpretation component which allows differentiation of neurotoxic from neuropharmacologic activities, has been developed and validated. Comparative species and strain differences in sensitivity to neuroactive agents are alos discussed, as well as means for integrating these measures into existing standard designs.

1235 CONTINUED USE OF A BEHAVIORAL TEST BATTERY TO ASSESS RHESUS MONKEY OFFSPRING EXPOSED TO COCAINE *IN-UTERO.*

P. Morris[1,2], M. P. Gillam[2] and M. G. Paule[2]. [1]*Pharmacology, Univrsity of North Texas, Fort Worth, TX and* [2]*NCTR, FDA, Jefferson, AR.*

In order to explore possible long-term effects of gestational cocaine (COC) exposure, pregnant rhesus monkeys were treated with COC chronically from about 1 month (mo) of gestation until term (either 0 (N=3), 0.3 (N=3), 1.0 (N=3), or escalating doses up to 8.5 (N=3) mg/kg (i.m.), 3 times/day, 5 days/week). Begining at 6 mo of age, the behavior of offspring (N=12) was monitored using an operant test battery with 4 food-reinforced tasks designed to model aspects of motivation, learning, color and position discrimination, short-term memory and attention. Between 6 and 18 mo of age, the acquisition of operant behaviors by juvenile offspring was not differentially affected by gestational COC exposure. Possible long-term effects of gestational COC exposure were examined further by measuring the sensitivity of acquired operant behaviors in young adult offspring to acute administration of SCH23390 (SCH: 0, 0.010, 0.030, 0.056, 0.100 or 0.175 mg/kg (i.v.)), quinpirol (QN: 0, 0.10, 0.30, 0.56, 0.75 or 1.00 mg/kg (i.m.)), or spiperone (SP: 0, 0.001, 0.003, 0.010 or 0.030 mg/kg (i.m.)). When assessed at 54 (SCH), 62 (QN), or 67 (SP) mo of age, the operant behavioral responses of offspring to acute challenges were not differentially affected by gestational COC exposure. It was concluded that gestational COC exposure had no significant effect on the subsequent acquisition of complex behaviors by offspring, or the sensitivity of those behaviors to pharmacological challenge with SCH, QN or SP. Supported by NIDA IAG #224-89-003

1236 NEUROLOGICAL ABNORMALITY IN WORKERS OF 1-BROMOPROPANE FACTORY.

G. Ichihara[1], W. Li[2], E. Shibata[3], X. Ding[2], M. Kamijima[1], H. Wang[1], Y. Liang[1], S. Peng[4], S. Itohara[1], Q. Fan[2], Y. Zhang[2], W. Zhong[2], X. Wu[2], W. M. Valentine[5] and Y. Takeuchi[1]. [1]*Nagoya University Graduate School of Medicine, Nagoya, Japan,* [2]*National Evaluating Centre for the Toxicology of Fertility Regulating Drugs, Shanghai, China,* [3]*Nagoya University School of Health Sciences, Nagoya, Japan,* [4]*Yixing Anti-epidemic and Health Station, Yixing, China and* [5]*Vanderbilt University Medical Center, Nashville, TN.*

It is been demonstrated that 1-bromopropane (1-BP), an alternative to ozone-depleting solvents, produces neurotoxicity and reproductive toxicity in rats. This study investigates the neurological effects of 1-BP in workers exposed to low concentrations of 1-BP. The survey examined 25 female workers at a 1-BP factory, 37.8Å}7.1 (Mean Å} S.D.) years old, and 27 female workers from a beer factory 35.8Å}5.8 years as controls. Individual time weighted average exposure levels of the workers in the 1-BP factory were estimated using individual passive sampler tubes to be 0.32-49.19 (median1.06) ppm. Neurobehavioral and electrophysiological assessments of nerve function were performed in both groups. Vibration sense deficits were detected in the feet of 17 exposed workers but not in any of the control subjects. Distal lantencies of the exposed workers were significantly longer than the controls, but the motor nerve conduction velocity of the tibial nerve did not show significant differences. Conduction velocities of the sural nerve and the F-wave of the tibial nerve were significantly decreased in the exposed workers relative to controls. Digit Symbol, Benton Visual Retention and Pursuit Aiming tests produced inferior values for the exposed group. In the Profile of Mood States testing, the exposed group exhibited lower scores than the control in Tension, Depression, Anger, Fatigue and Confusion. These findings suggest that exposure to 1-BP at levels below or around 50 ppm in the occupational setting may affect peripheral and central nervous system function.

1237 TOXICOKINETIC-TOXICODYNAMIC RELATIONSHIPS IN HUMAN MEPROBAMATE POISONINGS.

B. Mégrabane, F. J. Baud, S. W. Borron and C. Bismuth. *Intensive Care Unit, Lariboisière Hospital, Paris, France.*

The value of PK-PD relationships in clinical pharmacology is now well recognized. However, the potential interest of Toxicodynamic-Toxicokinetic (TK-TD) relationships in medical toxicology has been poorly investigated. The aim of this study was to correlate the depth of coma with plasma meprobamate (MB) concentrations. Materials and Methods : Plasma MB concentrations were measured using a colorimetric assay. The depth of coma was assessed using the Glasgow coma scale (GCS). Non-linear regression was used for modeling TK-TD relationships. Results : TK-TD relationships were studied in 7 acute MB poisonings. Three patients were previously treated with MB. Previous treatment was unknown in 2 patients. Mixed drug poisoning was noted in the 7 patients. The mean GCS at the time of hospital admission was 4 + 1, the mean plasma MB concentration was 1054 +/- 318 µmol/l. The mean plasma MB concentration associated with a GCS of 3 was 714.6 +/- 277.7 µmol/L (95% CIÜ: 546.8-882.4). The TK-TD relationship was well fitted with the sigmoidal Emax model. In the 7 patients, the mean Hill coefficient (m+/- SD) was 6.9 +/- 4.0 (95% CIÜ: 3.2-10.7), the mean C50 was 487.9 + 318.8 µmol/L (95% CI: 193.0-782.7). Two patients exhibited tolerance to the sedative effect of MB. In the 5 non-tolerant patients, the mean Hill coefficient (m+/-SD) was 8.0 + 4.4 (95% CIÜ: 2.5-13.4), the mean C50 was 315.8 +/- 148.9 µmol/L (95% CIÜ: 130.9-500.7). Discussion: A maximal toxic effect (GCS of 3) was associated with a wide range of plasma MB concentrations. During the course of MB poisoning, the relationship between the depth of coma and the corresponding plasma concentrations is of a sigmoidal shape. The high value of the Hill coefficient in non-tolerant patients showed that a small decrease in plasma MB concentrations near the C50 was associated with a dramatic improvement in their level of consciousness. In non-tolerant patients, the mean C50 was close to the upper limit of the therapeutic plasma concentration of MB given by our toxicological laboratory (< 200 µmol/l).

1238 EFFETS OF PEAK CONCENTRATIONS ON THE NEUROTOXICITY OF STYRENE IN VOLUNTEERS.

B. Ska, A. Vyskocil, R. Tardif, G. Carrier, R. Thuot and C. Viau. *Environmental and Occupational Health, Université de Montréal, Montréal, PQ, Canada.*

The manufacture of fibreglass reinforced plastic products may give rise to substantial peak exposures to styrene. Such exposure pattern needs further consideration in terms of styrene neurotoxicity. The aim of this study was to evaluate the neurotoxic effects of short-term peak exposures in volunteers, at levels respecting the Quebec occupational exposure limits (8-h-TWA of 213 mg/m^3 and 15-minutes average of 426 mg/m^3). The volunteers had not been previously exposed to styrene and they had no documented exposure to known neurotoxicants during the study. Forty volunteers were exposed to five exposure scenarios during 6 hours : a) stable exposure to 106 mg/m^3, b) variable exposure with a mean concentration of 106 mg/m^3 with four 15-minutes peaks mounting up to 213 mg/m^3, c) stable exposure to 213 mg/m^3, d) variable exposure with a mean concentration of 213 mg/m^3 and 4 peaks of 426 mg/m^3 and e) two stable exposures to 5 mg/m^3 (control). Before and after each exposure scenario, volunteers were submitted to a battery of sensory tests (visual and olfactory), neuropsychological tests (reaction time, attention, memory, psychomotricity), and self-evaluation questionnaires (mood and symptoms) in a test-retest design. The results show that the different exposure scenarios negatively influenced neither the performance to any test nor subjective signs and symptoms. Thus, the short-term exposure, below the Quebec occupational exposure limits does not induce neurotoxic effects evaluated using a battery of internationally recognized neurotoxic tests. Due caution must be exercised in extrapolation the current results to occupational exposure since only acute exposures were used and volunteers were at rest during exposure, which exposed them to lower doses than those experienced by physically active workers. This project was supported by IRSST, Quebec, Canada.

1239 BEHAVIOURAL EFFECTS OF PEAK EXPOSURE TO TOLUENE IN THE RAT.

J. H. Lammers, W. R. Pels Rijcken, V. J. Feron and J. van Asperen. *Target Organ Toxicology, TNO Nutrition and Food Research, Zeist, Netherlands.*

Occupational exposure limits of solvents are usually based on average exposure levels during the work shift. However, recent insights recognize that the effects of inhalatory exposure to solvents may not only depend on the total dose administered but also on the exposure scenario, e.g. exposure to fluctuating vs constant concentrations. In two inhalatory exposure studies, rats were exposed to constant toluene concentrations of 1333 or 2667 ppm or to fluctuating concentrations (cycles of 1.5 h each with peaks of 8000 ppm for 15 min or 30 min) for 7.5 hours. Rats received an overall similar total dose of 10000 or 20000 ppm-hours, respectively. Visual discrimination performance was tested prior to exposure, after the 7.5-h exposure period and one day post-exposure. The different exposure scenarios induced different changes in measures of response speed, stimulus control and disinhibition of responding, compared to air-exposed rats. Slowing of response was most pronounced when measured sometime after the end of a peak exposure, the effects on stimulus control and disinhibition of responding were most pronounced when measured immediately after a peak exposure or after a period of exposure to a constant concentration. In one study, spontaneous motor activity was measured continuously

for 72 h, from one day prior to one day after the exposure-day. Different effects were observed on motor activity depending on the exposure scenario. During peak exposure, increased activity was observed during exposure, with an even larger increase immediately after the end of a peak exposure. Behavioural effects appeared to be dependent on the exposure scenario. Comparison of behavioural data with toxicokinetic data showed that the concentration of toluene in the brain is not the only determinant of behavioural effects.

1240 PHYSIOLOGICALLY-BASED TOXICOKINETIC MODELLING OF PEAK EXPOSURE *VERSUS* CONSTANT EXPOSURE TO TOLUENE IN THE RAT.

J. van Asperen, W. R. Pels Rijcken, V. J. Feron and J. H. Lammers. *Explanatory Toxicology, TNO Nutrition and Food Research, Zeist, Netherlands.*

The health risks of inhalatory exposure to volatile organic solvents may not only depend on the total external dose, but also on the pattern of exposure. It has been suggested that exposure to regularly occurring peak concentrations (peak exposure) may have a stronger impact on the brain than constant exposure. Physiologically based toxicokinetic (PBTK) modelling may be a useful tool to assess the internal dose at target sites (e.g. the brain) as a result of various peak exposure scenario's compared to constant exposure. In two inhalatory exposure studies, toluene was selected as a model compound to evaluate whether PBTK-modelling can accurately predict the internal concentrations in the rat for different patterns of inhalatory exposure. The PBTK-model was constructed with parameters from literature. In order to validate the model, experimentally obtained data from groups of rats exposed to constant toluene concentrations of 1333 or 2667 ppm or to fluctuating concentrations (cycles of 1.5 h each with peaks of 8000 ppm for 15 min or 30 min) for 7.5 hours were used. Rats received an overall similar total dose of 10000 or 20000 ppm-hours, respectively. Toluene concentrations were determined in blood and brain at a number of time points during and after exposure. The experimental results showed relatively small differences in the kinetics of toluene between constant and peak exposure scenarios. The exposure scenario was found to have the most pronounced effect on the maximum concentrations of toluene in blood and brain. The predictions of the PBTK model corresponded well with the experimentally obtained data. The difference in the predicted area under the tissue concentration *versus* time curve (AUC) of toluene in blood and brain up to 24 hours after the start of exposure was very small between both types of exposure.

1241 ADOLESCENT NICOTINE ADMINISTRATION: EFFECTS ON SEROTONIN (5HT) RECEPTOR SYSTEMS.

Z. A. Xu[1,2], F. J. Seidler[1], W. Slikker[2] and T. A. Slotkin[1]. [1]*Pharmacology & Cancer Biology, Duke University Med. Ctr, Durham, NC and* [2]*Pharmacology & Toxicology, NCTR, Jefferson, AR.*

Adolescent smoking is highly associated with the subsequent development of depression, a condition related to disruption of 5HT function. We administered nicotine to adolescent rats on postnatal days (PN) 30-47, using an infusion paradigm that reproduces the plasma nicotine levels found in smokers, and examined 5HT receptors and related cell signaling during nicotine administration (PN45) and in the withdrawal period, concentrating on brain regions possessing major 5HT terminal projections. Adolescent nicotine treatment decreased 5HT2 receptor binding in the cerebral cortex, with a preferential effect on females. Reductions also were seen in the hippocampus across both genders, appearing during the withdrawal period and persisting for at least one month after discontinuing nicotine. In contrast, there were no significant changes in 5HT1A receptors. We also detected major changes in cell signaling pathways, exemplified by adenylyl cyclase (AC). Adolescent nicotine elicited significant induction of hippocampal AC, as assessed with the direct AC stimulant, forskolin. In addition, the ability of 5HT1A receptors to inhibit AC was enhanced during the withdrawal period, again with the effects restricted to females. Our results indicate that adolescent nicotine exposure influences the expression and function of postsynaptic 5HT receptors and their associated signal transduction cascades in brain regions associated with affective disorders, learning and memory. The gender selectivity seen here is consistent with prior work with markers of cell damage, and also with the higher incidence of depression in human females. Further studies of 5HT systems may provide a mechanistic link between adolescent nicotine exposure and affective disorders. (Supported by USPHS DA14247)

1242 EFFECT OF EPISODIC WEEKLY NICOTINE ADMINISTRATION ON REPEATED ACQUISITION IN RATS.

K. A. Jarema, J. D. Farmer and R. C. MacPhail. *Neurotoxicology, USEPA, Research Triangle Park, NC.*

Prior research (MacPhail et al., 2000) showed both tolerance and sensitization to nicotine's effects on the motor activity of rats when dosing occurred weekly. This experiment determined the generality of this finding to conditioned behavior. Adult male Long-Evans rats (N=18) were reinforced for emitting three-response sequences in standard operant chambers. Each daily session consisted of a multiple schedule with a new sequence to be learned (i.e., repeated acquisition) and a fixed sequence that was invariant (i.e., a performance control). Following extended training, all rats received a single dose (0.6 mg/kg) of nicotine, s.c., 5-min prior to testing. Rats were then divided, based on nicotine responses, into two groups that received either two additional injections of nicotine or saline vehicle at weekly intervals. All rats then received nicotine in the fourth week. Nicotine initially decreased response accuracy and reinforcement rate regardless of the sequence (fixed or varying). Tolerance developed to the effects of nicotine in rats dosed weekly. Substantial tolerance was also obtained in rats receiving nicotine three weeks after the first dose. No differences were obtained between the two groups during sessions when nicotine was not administered. These results suggest long-term behavioral changes in nicotine sensitivity following episodic acute nicotine administration. This abstract does not necessarily reflect USEPA policy.

1243 EFFECT OF WEIGHT MAINTENANCE AND ACTIVITY ON TISSUE LEVELS OF TRICHLOROETHYLENE IN MALE LONG-EVANS RATS.

J. E. Simmons[1], W. K. Boyes[1], M. V. Evans[1], J. H. Raymer[2], A. McDonald[1], Y. M. Sey[1] and P. J. Bushnell[1]. [1]*NHEERL/ORD, USEPA, Research Triangle Park, NC and* [2]*RTI, Research Triangle Park, NC.*

Trichloroethylene (TCE) is a common neurotoxic pollutant, contaminating air, water and food. Assessment of its risk to health will be aided by an exposure-dose-response model linking exposure to acute neurotoxicity. One test method for neurotoxicity being used to evaluate TCE neurotoxicity requires the use of weight-maintained animals actively working for rodent chow. Thus, part of our exposure-dose-response modeling effort is development of a physiologically-based pharmacokinetic model for TCE in weight-maintained rats. For this purpose, TCE concentrations were measured in the blood, brain, liver and fat of rats exposed by inhalation to 200 or 2000 ppm TCE for either 5, 20 or 60 min and rats exposed to TCE for 60 min and then to clean air for 60 min. Measurements were made in: weight-maintained (~350 g) rats actively performing a signal detection task during inhalation exposure to TCE; weight-maintained (~350 gm) rats exposed to TCE in the absence of task performance (sedentary); and, *ad libitum*-fed rats (~weight range, 350-450 gm) that were sedentary during exposure to TCE. The observed TCE tissue concentrations were not proportional to the external exposure concentrations as a 10-fold increase in external TCE concentration (200 to 2000 ppm) resulted in greater than 10-fold increases in tissue TCE levels. As expected, due to its lipophilic nature, the highest concentrations of TCE were observed in fat. At 200 and 2000 ppm TCE, the concentrations of TCE in blood, brain, liver and fat were higher in the active, weight-maintained rats than in either the sedentary, weight-maintained rats or the sedentary, *ad libitum*-fed rats. Thus, activity status (active vs sedentary) appeared to be a more important determinant of the pharmacokinetic behavior of TCE than weight status (*ad libitum*-fed vs weight-maintained). (This abstract may not reflect EPA policy.)

1244 EXPOSURE-DOSE-RESPONSE MODELING OF THE NEUROTOXIC EFFECTS OF ORGANIC SOLVENTS.

P. J. Bushnell[1], W. K. Boyes[1], J. E. Simmons[2], M. V. Evans[2], E. M. Kenyon[2], T. Leavens[3], W. M. Oshiro[1], T. E. Samsam[1], Q. T. Krantz[2], T. J. Shafer[1], V. E. Benignus[3] and T. L. Jackson[4]. [1]*Neurotoxicology Division, USEPA, Research Triangle Park, NC,* [2]*Experimental Toxicology Division, USEPA, Research Triangle Park, NC,* [3]*Human Studies Division, USEPA, Chapel Hill, NC and* [4]*Department of Mathematics, University of Michigan, Ann Arbor, MI.*

Risk assessments based on exposure to volatile organic compounds (VOCs) are hampered by the complexities of exposure scenarios, a lack of data regarding the mode of action of the VOCs, and uncertainties about extrapolating from animal data to human health risk. We are developing an approach to rationalize these assessments by (1) linking airborne exposure to internal dose *via* dosimetry modeling in rats; (2) investigating interactions of solvents with receptor systems in the CNS; and (3) comparing the relative sensitivities of rats and humans to the acute effects of VOCs. Physiologically-based pharmacokinetic (PBPK) models are being used to estimate the concentrations of VOCs in blood and brain of rats using a variety of exposure scenarios. Estimates of internal dose (concentrations of trichloroethylene or toluene in blood and brain) accurately predicted the effects of these VOCs on signal detection behavior and visual evoked potentials (VEPs). Mode of action studies are underway to identify critical neurochemical pathway(s) mediating the effects of toluene on signal detection behavior and VEPs, and to test the feasibility of *in vitro* tests of the acute neurotoxicity of VOCs. Parallel tests of signal detection in rats and humans inhaling toluene may yield a quantitative estimate of the relative sensitivities of the species, to facilitate extrapolation of toxicity in rats to the risk of adverse effects on human health. (This abstract does not necessarily reflect EPA policy.)

1245 A PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODEL FOR TOLUENE IN THE LONG-EVANS RAT: BODY COMPOSITION AND PHYSICAL ACTIVITY.

T. E. Samsam[1], W. M. Oshiro[1], T. L. Jackson[3], E. M. Kenyon[2], W. K. Boyes[1] and P. J. Bushnell[1]. [1]*Neurotoxicology Division, USEPA, Research Triangle Park, NC,* [2]*Experimental Toxicology Division, USEPA, Research Triangle Park, NC and* [3]*Dept. Mathematics, U. Michigan, Ann Arbor, MI.*

A physiologically-based pharmacokinetic (PBPK) model for inhaled toluene was developed for Long-Evans rats as a component of an exposure-dose-response (EDR) model for volatile organic compounds. The PBPK model was needed to link airborne toluene exposure to its concentration in blood and brain, the target organ for its neurotoxicity. The acute neurotoxicity of toluene was quantified in rats as impaired detection of visual signals and reduced visual evoked potentials (VEPs). The model required evaluation under test conditions for both of these endpoints, i.e., signal detection behavior is measured in weight-maintained, physically-active rats, whereas VEPs are measured in rats fed ad libitum and restrained during testing. Blood and brains were obtained from 64 sedentary rats, either weight-maintained (350 g) or fed ad libitum (400 - 500 g), after inhaling toluene at either 200 or 2000 ppm for 5, 20, or 60 min, or 60 min after a 60-min exposure to toluene (n = 4/gp). Weight maintenance had little effect on either predicted or observed concentrations of toluene. Effects of toluene on signal detection were not readily predicted by parameters of exposure, but were accurately predicted by concentrations of toluene in brain and blood estimated by the model. In contrast to the lack of effect of weight status, higher values of cardiac output and alveolar ventilation, expected as a result of physical activity, greatly increased the tissue concentrations of toluene predicted by the model. We are currently evaluating heart rate, obtained by telemetry from rats performing the signal detection task, as an index of activity-induced elevations of cardiac output and ventilation rate in the PBPK model. Adjusting these parameters for physical activity will improve the accuracy of the estimated concentrations of toluene necessary to impair signal detection. (This abstract does not necessarily reflect EPA policy.)

1246 EFFECTS OF TERBUTALINE (TER) ON BETA-ADRENOCEPTOR (BAR) SIGNALING IN THE DEVELOPING RAT: IMPLICATIONS FOR ADVERSE EFFECTS OF TOCOLYTIC THERAPY.

J. T. Auman, F. J. Seidler and T. A. Slotkin. *Pharmacology & Cancer Biology, Duke University Med. Ctr, Durham, NC.*

Preterm labor is commonly treated with B2AR agonists, like TER, that arrest uterine contractions, but that also enter the fetus. Ordinarily, tissues are protected from excessive BAR stimulation by desensitization and downregulation. The current study was undertaken to determine if these mechanisms also protect the developing fetus. We modeled late 2nd-3rd trimester human exposure by administering TER (10 mg/kg s.c.) to rats on postnatal days (PN) 2-5, a period prior to the development of peripheral sympathetic function, or on PN11-14, during the onset of sympathetic function. TER downregulated cardiac and hepatic BARs at both ages, with a greater effect in the liver. Despite the reduction in cardiac BARs, there was no desensitization of cell signaling mediated through adenylyl cyclase (AC). Using stimulants that operate at different loci in the AC cascade, we found that TER treatment on PN 2-5 did not desensitize any of the signaling proteins; treatment on PN11-14 actually increased activity of the G-proteins and AC itself, distal to the BAR. Similarly, in the liver, heterologous sensitization of AC signaling offset nearly all the BAR downregulation, so that BAR-mediated cAMP generation was maintained. Our results indicate that the developing organism does not display agonist-induced desensitization of the BAR/AC signaling pathway and can actually show sensitization in response to TER treatment. In light of the critical role played by cAMP in cell replication and differentiation, these unique responses may contribute to cardiac anomalies and alterations in glucose handling noted in infants whose mothers received tocolytic therapy. Finally, numerous environmental and hormonal factors converge on the generation of cAMP, so that sensitization of the AC pathway by tocolytics may render these individuals more vulnerable to developmental disruptors. (Supported by USPHS HD09713)

1247 ENHANCED SKIN CARCINOGENICITY IN PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR β-NULL MICE.

D. J. Kim[1], F. J. Gonzalez[2] and J. M. Peters[1]. [1]*Veterinary Science and Center for Molecular Toxicology and Carcinogenesis, Pennsylvania State University, University Park, PA and* [2]*Laboratory of Metabolism, NCI, Bethesda, MD.*

The peroxisome proliferator activated-receptor-β (PPARβ) shows high levels of expression in the skin, although the role of this receptor in skin function is uncertain. Interestingly, the epidermal hyperplastic response induced by the tumor promoter 12-O-tetradecanoylphorbol-13-acetate (TPA) is greatly increased in PPARβ-null mice. This suggests that PPARβ functions to attenuate epidermal cell proliferation in response to TPA. In this study, PPARβ-null and wild-type mice were subjected to the two-stage chemical carcinogenesis bioassay to elucidate a functional role of PPARβ in skin cancer. PPARβ-null mice were more sensitive to TPA than wild-type controls as evidenced by differences in skin morphology after two-three topical applications of TPA. This phenotype continued for the duration of the six month experiment. The formation of papillomas in PPARβ-null mice was greatly accelerated compared to wild-type mice and the percentage of PPARβ-null mice that developed papillomas was significantly greater than wild-type controls. After 24 weeks of TPA application, the average number and size of papillomas in PPARβ-null mice was greater than in wild-type controls. These results suggest that PPARβ attenuates cell proliferation. In the absence of a functional PPARβ, skin tumor formation and growth are greatly enhanced in this two-stage chemical carcinogenesis model, which suggests that activation of this receptor could inhibit skin cancer. Additionally, these data suggests that humans with a polymorphism or mutation in PPARβ gene may be at increased risk for developing skin cancer. (Supported by RO1 CA89607, J.M.P)

1248 MOLECULAR AND BIOCHEMICAL ALTERATIONS IN PEROXISOME PROLIFERATOR- ACTIVATED RECEPTOR-β (PPARβ) NULL MOUSE SKIN IN RESPONSE TO 12-O-TETRADECANOYLPHORBOL-13-ACETATE (TPA).

F. S. Harman[1], S. Yim[2], D. J. Kim[1], F. J. Gonzalez[2] and J. M. Peters[1]. [1]*Veterinary Science and Center for Molecular Toxicology and Carcinogenesis, Pennsylvania State University, University Park, PA and* [2]*Laboratory of Metabolism, NCI, Bethesda, MD.*

The biological roles of PPARβ remain largely unknown. The use of the PPARβ-null mouse model should greatly advance our understanding of how this receptor functions in target tissues. Recent evidence suggests a role for PPARβ in epithelial cells. In the absence of PPARβ, epidermal hyperplasia is greatly enhanced in response to TPA suggesting that PPARβ may function to attenuate cell proliferation. Potential PPARβ target genes that could regulate the cell cycle have not been identified. Using microarray analysis, several genes were identified that are likely regulated by PPARβ. Northern Blot analysis confirmed that expression of these genes in response to TPA is mediated by PPARβ. The specific role of these target genes in epithelial cell cycle control is currently under investigation. In addition to molecular alterations, biochemical changes in intracellular phosphorylation events were also examined since this type of regulation is a common mechanism found in replicating cells. Significant differences in phosphorylated proteins were found between wild-type and PPARβ-null mouse skin in response to TPA. Specifically, cytosolic levels of phosphorylated mitogen-activated protein kinase kinase (MAPKK) and several protein kinase C (PKC) isoforms were approximately 2-fold higher in null mouse skin treated with TPA compared to wild-type controls. Additionally, western blot analysis revealed that the translocation of PKC from the cytosol to the particulate fraction is markedly different between TPA-treated PPARβ-null and wild-type skin. Combined, these results suggest that PPARβ regulates epidermal target gene expression that ultimately leads to modulation of phosphorylation events, which in turn regulate cell cycle progression. (Supported by RO1 CA89607, J.M.P.)

1249 DIFFERENTIAL EFFECTS OF 3'-METHOXY-4'-NITROFLAVONE (3'M4'NF) ON INDUCTION OF LUCIFERASE AND CYP1A1 IN RECOMBINANT MOUSE HEPATOMA CELLS.

J. Zhou and T. A. Gasiewicz. *Toxicology, University of Rochester, Rochester, NY.*

Aryl hydrocarbon receptor (AhR) is a transcription factor belonging to the bHLH-PAS gene superfamily. Ligand-free receptor resides in cytosol as a complex associated with several other proteins. Upon ligand activation, the receptor undergoes a series of transformation process that involve translocation to the nucleus, association with AhR translocation partner (Arnt), and interaction with dioxin responsive element (DRE), leading to the enhancement of gene expression such as *CYP1A1*. Cell lines stably transfected with AhR-responsive, mouse *CYP1A1* DRE-driven luciferase (*2DLuc*) are sensitive bioassay systems for the study of AhR signaling mechanisms and determining the presence of dioxin-like environmental contaminants. Although studies have shown that TCDD induces *2DLuc* and *CYP1A1* in a similar pattern, there is little information about the induction of these two genes by structurally different AhR ligands. It is possible that dissimilar ligands may elicit a different AhR conformation, which may lead to distinct expression profiles between *2DLuc* and *CYP1A1* (or other genes). To test the hypothesis, the recombinant cells were treated with 3'M4'NF. The induction of *CYP1A1* or *2DLuc* was examined by three different endpoints: mRNA transcription, protein expression and enzyme activity. The studies demonstrated that 3'M4'NF produces a differential effect on the induction of reporter gene and *CYP1A1*. 3'M4'NF has no or little activity in enhancing the expression of *2DLuc* by itself but is able to antagonize TCDD-induced reporter gene induction completely, an indicative of 'pure' antagonist. In contrast, it promoted the *CYP1A1* expression in a dose-dependent manner, an indicative of partial agonist. The results presented herein provide us further insights and qualifications for the use of reporter genes to study the AhR signaling pathway. (Supported by NIH grant ES09702 and Center grant ES01247)

1250 2D GEL ELECTROPHORESIS, MUTATION ANALYSIS, AND SEQUENCE/STRUCTURE-BASED PHOSPHORYLATION PREDICTION OF ARYL HYDROCARBON RECEPTOR (AhR) TYROSINE RESIDUES SUGGEST PHOSPHORYLATION AT TYROSINE 9.

G. D. Minsavage, D. Vorojeikina and T. A. Gasiewicz. *Toxicology Training Program, Department of Environmental Medicine, University of Rochester School of Medicine and Dentistry, Rochester, NY.*

The AhR is a ligand-activated member of the bHLH transcription factor family. Xenobiotics such as TCDD bind to the AhR to mediate pleiotropic toxicities. For the AhR, a phosphoprotein with demonstrated charge heterogeneity, DNA binding is a critical step necessary to modulate target genes that mediate TCDD toxicity. We previously reported that treatment of a purified AhR/Arnt complex with tyrosine (Y) phosphatases or mutation of AhR Y9 to phenylalanine (AhRY9F) abrogates DNA binding *in vitro*. We hypothesized that utilization of computational analysis together with 2D gel electrophoresis (2-DE) of AhR Y mutants would correlate AhR charge heterogeneity with predicted Y phosphorylation and indicate a possible role for AhR Y9 phosphorylation in DNA binding. An N-terminal truncated mutant (AhR1-399) was shown to retain DNA binding potential *in vitro*. Point mutations of each of the twelve N-terminal Y residues indicated that only the Y9 mutant abrogates DNA binding, suggesting a specific functional role for this conserved amino acid. Computational sequence and structure-based prediction analysis indicated that Y9 also maintains conserved phosphorylation potential across all species sequenced. To corroborate this potential, *in vitro* translated AhR WT and point mutants were analyzed by 2-DE. These data indicate more basic isoforms for AhRY9F and other sites with a high predicted phosphorylation potential (AhRY372F) while sites with low predicted phosphorylation potential (AhRY365F) have isoforms similar to AhR WT. These data suggest consistency between charge heterogeneity and the predicted phosphorylation potential of AhR Y residues and putative phosphorylation at AhR Y9. This, along with previous data, strongly suggests that Y9 phosphorylation plays a role in AhR DNA binding. (Supported by NIH Grant ES02515, Training Grant ES07026, and Center Grant ES01247.)

1251 COMPREHENSIVE ANALYSIS OF GENE EXPRESSION IN HEPATOMA CELLS EXPOSED TO THE PEROXISOME PROLIFERATOR WY, 14, 643: EVIDENCE OF AN AUTOREGULATORY PATHWAY.

K. A. Burns[1], D. Kreder[2], B. Belda[1], C. Nugent[1], M. Taylor[2] and J. Vanden Heuvel[1]. *[1]Center for Molecular Toxicology and Carcinogenesis, Penn State University, University Park, PA and [2]Roche Bioscience, Toxicology and Neurobiology Units, Palo Alto, CA.*

Peroxisome proliferator-activated receptors (PPARs) are ligand-activated transcription factors belonging to the nuclear receptor family. PPARs are activated by a large group of chemicals that include industrial pollutants which are called peroxisome proliferators (PPs). PPs are believed to cause cancer in rodents by altering gene expression and affecting the phenotype of the target cell. Examination of gene expression microarrays from rat hepatoma cells treated with the PP Wy14, 643 showed the expected increase in mRNA for fatty acid catabolism genes including acyl-CoA oxidase, fatty acid binding protein and cytochrome P450 4A1. A wide variety of lipid metabolism, cell cycle and growth regulatory genes were also observed to be PP-responsive. The expression microarray experiments also revealed a variety of protein kinases, phosphatases, and signaling molecules as being PP-responsive. Several of these proteins have been shown to affect PPARα activity as well as being key players in the cell cycle. For example, members of the MAPK, JAK/STAT and PKA pathways were affected by PPs at the mRNA, protein and activity level. Inhibition of these kinase cascades results in an alteration in PPARα activity. In addition, we tested the hypothesis that PP's ability to regulate kinase cascades may affect the phosphorylation of important cell cycle regulators. Of particular interest is Retinoblastoma (Rb). Following treatment with PPs, an increase in Rb phosphorylation at serines 807 and 811 is observed. We are studying the mechanism by which this important protein is being affected by PPs. The data from this study can also be used to speculate on other kinase pathways that affect this nuclear receptor and also heighten awareness of the importance of cross-talk between PPAR and growth factor signaling. (Funded by NIH ES07799 and DK49009).

1252 EFFECTS OF CYTOSOLIC CONVERSION OF ESTRONE TO ESTRADIOL ON RAINBOW TROUT ER BINDING AFFINITY.

M. A. Tapper[1], R. Kolanczyk[1], J. Denny[1], T. Henry[2] and P. Schmieder[1]. *[1]USEPA, Mid-Continent Ecology Division, Duluth, MN and [2]USEPA, NHEERL, Experimental Toxicology Division, Research Triangle Park, NC.*

The relative binding affinity (RBA) for estrone (E1) to the rainbow trout (*Oncorhynchus mykiss*) estrogen receptor (rtER) was measured as part of a larger effort to determine chemical structural features predictive of chemical estrogenicity in fish. Estrone RBA was found to vary considerably (14 to 68%) among cytosolic preparation more than expected due to experimental variability. The cytosolic concentrations of E1 after 20h incubation at 4°C (binding assay conditions) was subsequently found to vary from 32 to 85% of the original E1 concentration, raising concerns over possible differences in hydroxysteroid dehydrogenase levels in individual fish. In mammals, 17β-hydroxysteroid dehydrogenases (HSD) are responsible for the interconversion of estrogens and androgens to and from active and inactive forms. HSD 1 has been identified as the primary enzyme responsible for the conversion of E1 to 17β-estradiol (E2). Mammalian HSD 1, localized in ovary and placenta, is present at low levels in mammalian livers. Little is known about HSD activity in fish but likely a HSD 1-like enzyme in liver cytosol preparations converts E1 to E2. Depending on the cytosol used, 15 to 68% of the initial E1 was converted to E2. No conversion was detected in water or cytosol buffer under the same conditions. A positive correlation was noted between increasing cytosolic E2 levels and RBA presumably attributable to the interaction of E2 with the rtER. A similar variation in E1 to E2 conversion (48 to 71% E2) was observed when lake trout (*Salvelinus namaycush*) liver cytosols were exposed under the same conditions. Therefore it appears that measurable HSD-like activity in fish cytosolic preparations can readily alter steroid concentrations, and alter apparent RBA measurements, and that the RBA of rtER for E1 is closer to 14% than 68%. *This abstract does not necessarily reflect EPA policy*

1253 CHARACTERIZATION OF ARYL HYDROCARBON SIGNALING PROTEINS FROM *XENOPUS LAEVIS*.

C. A. Beck, J. J. DePowell and W. H. Powell. *Biology, Kenyon College, Gambier, OH.* Sponsor: M. Hahn.

Embryos of the African clawed frog, *Xenopus laevis*, are used in FETAX (frog embryo teratogenesis assay-Xenopus) to assess developmental toxicity of chemicals. Halogenated aromatic hydrocarbons, including 2, 3, 7, 8 tetrachlorodibenzo-*p*-dioxin (TCDD), can be potent developmental toxicants. However, several frog species are relatively resistant to TCDD toxicity. Although assessments of TCDD toxicity in X. laevis vary, some reports suggest that this species may also be relatively insensitive. In other vertebrates, TCDD toxicity is mediated by the aryl hydrocarbon receptor (AHR), a ligand-activated transcription factor, and by ARNT (aryl hydrocarbon receptor nuclear translocator), the dimeric partner of AHR. To investigate the mechanisms of TCDD sensitivity and resistance in X. laevis, we have isolated cDNA sequences encoding AHR and ARNT from 96 hour embryos. X. laevis resembles many fish in the expression of two distinct AHR genes. However, phylogenetic analysis demonstrates that both X. laevis AHRs are orthologs of mammalian AHR1; neither resembles the AHR2 genes common to fish. The two proteins, AHR1α (836 aa; 94.1 kDa) and AHR1β (833 aa; 93.4 kDa), share 86% amino acid identity, suggesting that they evolved rather recently, perhaps coincident with the tetraploidization of the Xenopus genome approximately 30 mya. X. laevis represents the first species in which multiple AHR1 genes have been observed. Analysis of the single X. laevis ARNT sequence detected revealed that it is an ARNT2 ortholog. ARNT2 is widely expressed in certain fish, but is restricted to kidney and CNS in mammals. Since sequencing multiple X. laevis ARNT clones detected only ARNT2, we suggest that it is the predominant ortholog expressed at this life stage. FETAX is used as a model for predicting the developmental toxicity of materials to other vertebrates. An understanding of the molecular mechanisms underlying sensitivity differences to halogenated aromatic hydrocarbons should contribute to the development of FETAX as a model for developmental toxicity of samples containing these compounds. [NIH: ES11130]

1254 COMPARATIVE STUDY OF HUMAN AND MOUSE AH RECEPTOR FUNCTION USING CHIMERIC RECEPTORS.

P. Ramadoss and G. H. Perdew. *Graduate Program in Biochemistry, Microbiology and Molecular Biology and Department of Veterinary Sciences and the Center for Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, University Park, PA.*

The aryl hydrocarbon receptor (AhR) is a ligand induced transcription factor that exists in the cytoplasm complexed with hsp90 and XAP2. The most widely studied AhR ligand is TCDD. The intra- and inter-species differences in sensitivity to TCDD may occur as a result of differences in receptor structure. Sequence variations in the mouse and human receptors resulting in quantitatively different responses to TCDD are of importance since rodent models are used in *in vivo* toxicity studies. Two chimeras of human and mouse AhR were generated in order to study functional differences due to the low homology in the C-terminal half of the AhR. A unique BamH1 restriction site in both receptors at amino acid residue 424 was used to remove and exchange the C-terminal halves of the receptors. Constructs expressing both FLAG- and yellow fluorescent protein-tagged chimeras were generated. Cellular localization studies in COS-1 cells showed that mouse

AhR (mAhR) is predominantly nuclear, whereas human AhR (hAhR) is cytoplasmic. The mouse-human chimera (MH, murine N-terminus) is cytoplasmic and the human-mouse chimera (HM, human N-terminus) is predominantly nuclear. Co-expression of XAP2 does not affect the localization of hAhR and MH, but causes re-localization of mAhR to the cytoplasm. Interestingly, HM is also unaffected by co-expression of XAP2. All receptors showed ligand induced translocation to the nucleus. Immunoprecipitation of the receptors and western blot analysis demonstrated that each receptor was capable of binding co-expressed XAP2 and endogenous hsp90. Experiments showed that all receptors could induce transcription of a dioxin responsive element (DRE) driven reporter construct and they appear to have similar activity at a saturating ligand concentration. These studies suggest that the C-terminal half of the AhR may influence biochemical properties of the N-terminal half. This study is funded by NIEHS 04869.

1255 DIOXIN ALTERS PROLIFERATION, DIFFERENTIATION AND SENESCENCE IN KERATINOCYTES.

S. Ray. *Dept. of Molecular and Biomedical Pharmacology, University of Kentucky Medical Center, Lexington, KY.* Sponsor: H. Swanson.

TCDD (2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin), a prototype of the polyaromatic hydrocarbons, elicits a variety of toxic, teratogenic and carcinogenic responses in both animals and humans. Many effects of TCDD are mediated by the aryl hydrocarbon receptor (AHR), a bHLH/PAS transcription factor. Ligand activation of AHR alters both cellular proliferation and differentiation of keratinocytes, but the signaling pathways involved in these processes are poorly understood. The objective of this study was to delineate the mechanisms involved in dioxin's tumor promoting activities using normal human keratinocytes (NHK). Using western blot analysis of involucrin and filaggrin expression, markers that are expressed at different stages of differentiation, we have shown that TCDD decreases differentiation of NHKs. This result is supported by flow cytometric analysis, which show that TCDD decreases the number of differentiating keratinocytes while increasing the number of non-differentiating keratinocytes. On performing cell cycle analysis using propidium iodide, we found that treatment with TCDD increases in the number of cells in S-phase and decreases the cells in G1/G0 phase of the cell cycle. By riboprobe protection assay we found that the decrease in differentiation is accompanied by a significant decrease in the expression of $p16^{INK4a}$, p53, Rb, $p27^{KIP1}$ and p14/p15. Some of these results were also verified by western blot analysis. $p16^{INK4a}$ is a cyclin dependent kinase inhibitor that regulates the G1 to S progression and increases both differentiation and senescence. To determine the effect of TCDD on senescence we performed senescence-associated β-galactosidase staining and found that TCDD causes a decrease in senescence of keratinocytes. These results suggest that TCDD may act as a tumor promoter by inhibiting both differentiation and senescence *via* a decrease in the expression levels of $p16^{INK4a}$. Overall these results suggest that the tumor-promoting activities of TCDD is in part mediated by down regulation of these important cell cycle regulatory proteins.

1256 GENERATION OF TEMPERATURE-SENSITIVE LIVER CELL LINES FROM PPARα-DEFICIENT AND WILD-TYPE CB6 MICE.

J. P. Gray, E. S. Tien, J. M. Peters and J. P. Vanden Heuvel. *Center for Molecular Toxicology, Pennsylvania State University, University Park, PA.*

Several novel cell lines were generated from the neonatal liver cells of either wild-type (wt) or PPARα-deficient (null) CB6 mice using a temperature sensitive SV40 virus. These cells are passaged at the virus's permissive temperature (34°C) and gene expression experiments are performed at the non-permissive (37°C) temperature. The wt and null cell lines express equivalent concentrations of albumin as well as acyl-CoA oxidase (ACO) and fatty acid binding protein (FABP) mRNA, indicating the retention of liver-specific genes. PPARα presence or absence in the wild type or PPARα-null lines was confirmed by genotype PCR as well as western blotting. The cell lines also retain the ability to appropriately respond to peroxisome proliferators whereby Wy-14, 643 (50mM) treatment for 6 hours failed to induce ACO in the null cells, but significantly increased expression in wt cells. Cell cycle analysis also confirms a defect in the response of PPARα-deficient cells to Wy-14, 643 treatment. These lines will help us to investigate the mechanistic aspects of PPARα-dependent signaling in response to peroxisome-proliferator treatment and effectively recapitulates what has been observed *in vivo* in the mouse models. (Funded by NIH ES07799 and DK49009).

1257 THE EFFECTS OF GREEN TEA EXTRACTS AND INDIVIDUAL TEA CATECHINS ON AhR FUNCTION.

C. M. Palermo[1], J. I. Martin Hernando[2], A. S. Kende[2] and T. A. Gasiewicz[1]. *[1]Environmental Medicine, University of Rochester, Rochester, NY and [2]Chemistry, University of Rochester, Rochester, NY.*

Previous investigations have implicated green tea as affording protection against polycyclic aromatic hydrocarbon induced cancers in animal models of chemical carcinogenesis. In an effort to understand the mechanism and compound/s responsible for this protection, the effects of green tea extracts (GTE) and individual catechins on the function of the aryl hydrocarbon receptor (AhR) were determined. Green tea (GT) was organically extracted and subsequently fractionated by TLC. The chemical composition of these fractions, as well as a commercially available GTE, were determined by NMR. All GT fractions inhibited tetrachlorodibenzo-*p*-dioxin (TCDD)-induced transcription of a dioxin-responsive element (DRE)-dependent luciferase reporter in stably transfected mouse hepatoma cells in a concentration dependent manner. The most potent of the fractions was then examined for its ability to compete with TCDD for binding to the AhR, and to inhibit TCDD-elicited binding of the AhR to DRE's *in vitro*. From these studies, it was shown that GTE blocked TCDD-induced binding of the AhR to DNA. However, it did not compete directly with TCDD for binding to the receptor. To determine the green tea component/s responsible for the observed effects, individual catechins were tested in these systems at concentrations comparable to those within the GT fractions. Of the catechins tested, epigallocatechingallate (EGCG) followed by epigallocatechin were the most potent antagonists of TCDD induced luciferase, having IC_{50} values of 60uM and 100uM respectively. Subsequent analysis of EGCG's mechanism of action revealed that as seen with GTE, EGCG was capable of inhibiting TCDD induced DRE binding but did not compete with TCDD for binding to the AhR. This data suggests that individual catechins are capable of altering AhR transcriptional activity and that these compounds may function through a mechanism unlike typical AhR antagonists.(Supported in part by NIH grant ES09702, Training Grant ES07026, and Center Grant ES01247)

1258 STRIKING VARIABILITY IN THE STRUCTURES OF ARNT AND ARNT2 IN THE RAT.

M. Korkalainen[1,2], J. Tuomisto[1,2] and R. Pohjanvirta[1,3,4]. *[1]Department of Environmental Health, National Public Health Institute, Kuopio, Finland, [2]Department of Public Health and General Practice, University of Kuopio, Kuopio, Finland, [3]Department of Food and Environmental Hygiene, Faculty of Veterinary Medicine, University of Helsinki, Helsinki, Finland and [4]National Veterinary and Food Research Institute, Kuopio Department, Kuopio, Finland.*

The biological and toxic effects of dioxins are largely mediated by the aryl hydrocarbon receptor (AHR). The AHR functions as a ligand-activated transcription factor binding DNA as a heterodimeric complex with a structurally related bHLH/PAS protein, the AHR nuclear translocator (ARNT) or its homologue in the brain, ARNT2. We recently discovered 3 splice variants of AHR in an extremely TCDD-resistant rat strain, Han/Wistar (Kuopio), which appear to account for its resistance. In ARNT protein, so far only one splice variant (deletion of exon 5) has been described in the literature. To find out whether structural deviations of ARNT could be related to TCDD sensitivity, we cloned hepatic ARNT and hypothalamic ARNT2 cDNAs by blunt-end cloning after RT-PCR from untreated H/W and TCDD-sensitive Long-Evans (Turku AB) rats. To our surprise, we recorded several different products of alternative splicing of ARNT mRNA: in addition to exon 5, deletions occurred at 3' end of exon 6 (NTs 354-494) and at 5' end of exon 11 (NTs 964-978). A small insertion (CAG) was detected at the 5'end of exon 20. Interindividual variation transpired in the number of GCA repeats at the 5' end of exon 16. In the case of ARNT2, an insertion of 31 NTs appeared at NT 2128. Importantly, this insertion contained a premature stop codon resulting in a truncated protein at the C-terminus, with potentially a repressor-type function. All other variants represented in-frame changes, but at least the two largest deletions are likely to seriously impair protein function. There were no major differences between the two rat strains in relative expression levels of the variants as assessed by semi-quantitative RT-PCR implying that they do not contribute to strain-specific sensitivity to TCDD.

1259 THE ARYL HYDROCARBON RECEPTOR (AHR) HOMOLOGUE OF THE SOFTSHELL CLAM (*MYA ARENARIA*) DOES NOT BIND PROTOTYPICAL AHR LIGANDS TCDD OR BNF.

R. A. Butler[1], M. L. Kelley[1,2], W. H. Powell[3,4], M. E. Hahn[3] and R. J. Van Beneden[1]. *[1]University of Maine, Orono, ME, [2]University of Texas, Austin, TX, [3]Woods Hole Oceanographic Institute, Woods Hole, MA and [4]Kenyon College, Gambier, OH.*

The aryl hydrocarbon receptor (AHR) mediates various toxic effects of aromatic hydrocarbon compounds, including 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD). Some populations of softshell clams (*Mya arenaria*) have historically exhibited a high prevalence of gonadal neoplasia. Although the etiology of these germinomas is unknown, their incidence has been correlated with environmental herbicide (TCDD-contaminated) usage. One hypothesis proposes an AHR-mediated pathway of tumorigenesis. To investigate this, a clam AHR homologue (cDNA) was cloned. Amino acid alignments indicate domains characteristic of vertebrate AHRs. Despite these structural similarities, binding analyses using *in vitro*-expressed clam AHR or clam cytosolic proteins showed that this AHR homologue

binds neither [^{3}H]TCDD nor [^{3}H]B-naphthoflavone (BNF). However, preliminary studies indicate the *in vitro*-expressed clam AHR does exhibit sequence-specific interactions with a mammalian xenobiotic response element (XRE) in the absence of exogenous ligand. *in vitro*-expressed *D. melanogaster* and *C. elegans* AHR homologues also lack specific binding to [^{3}H]TCDD and [^{3}H]BNF. The lack of specific binding to these prototypical AHR ligands appears to be a property shared by known invertebrate AHR homologues, distinguishing them from vertebrate AHRs. Comparative studies of phylogenetically diverse organisms may help identify an endogenous ligand(s) and the physiological role(s) for this protein.

1260 HORMONAL ACTIVATION OF LACTATE DEHYDROGENASE GENE EXPRESSION IN BREAST CANCER CELLS.

X. Li and S. H. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

In previous studies, we identified the -92 to -37 region of the lactate dehydrogenase (LDH) gene promoter as estrogen (E2)-responsive in transient transfection studies in MCF-7 human breast cancer cells. This promoter sequence contains a cAMP response element (CRE) and nuclear extracts from MCF-7 cells bound [^{32}P]-58/-36 (CRE-sequence from LDH promoter) in gel mobility shift assays to form a broad retarded band which was decreased in intensity after competition with an unlabeled consensus CRE oligonucleotide. The retarded band was supershifted after incubation of nuclear extracts with antibodies that bound ATF-1 and CREB. Constitutively active protein kinase A and an inducer of cAMP (cholera toxin) induced reporter gene activity in breast cancer cells transfected with the E2-responsive pLDH1 construct (contains the -58 to +9 LDH gene promoter insert) confirming that cAMP-PKA induction also activates the CRE. Hormonal activation of pLDH1 and related constructs was also inhibited by cotransfection with KREB, a dominant negative form of CREB. Activation of CREB and ATF-1 by E2 through non-genomic pathways was confirmed in studies showing that 10 nM E2 caused a 7- and 27-fold induction of reporter gene activity MCF-7 cells transfected with GAL4-ATF1 and GAL4-CREB fusion proteins and a construct containing five tandem GAL4 response elements. Thus, LDH upregulation by E2 is due to non-genomic activation of the cAMP-PKA pathway. (Supported by NIH ES09253 and ES09106)

1261 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) INDUCES PLASMINOGEN ACTIVATOR INHIBITOR-1 THROUGH AN ARYL HYDROCARBON RECEPTOR-MEDIATED PATHWAY IN A MOUSE HEPATOMA CELL LINE.

D. S. Son[1] and K. K. Rozman[1,2]. [1]*Pharmacology, Toxicology & Therapeutics, University of Kansas Medical Center, Kansas City, KS and* [2]*Section of Environmental Toxicology, GSF-Institut fur Toxikologie, Neuherberg, Germany.*

2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD), an ubiquitous environmental pollutant, elicits a variety of toxicities and is a well-known carcinogen. TCDD alters the expression of many genes including CYP1A1/2, CYP1B1, glutathione S-transferase Ya, aldehyde-3-dehydrogenase, NAD(P)H:quinone oxidoreductase, TGF-alpha, TGF-beta, plasminogen activator inhibitor-2 and interleukin-1beta. The present study investigated the effect of TCDD on plasminogen activator inhibitor-1 (PAI-1) in a mouse hepatoma cell line (Hepa1c1c7). Based on Western and Northern blots, TCDD induced dose- (0, 0.1, 1 & 10 nM) and time- (0, 3, 6, 12, 24 & 48 h) dependently PAI-1 in Hepa1c1c7 cells. However, TCDD did not induce PAI-1 in the aryl hydrocarbon receptor (AhR) and AhR nuclear translocator (Arnt)-deficient mutants derived from Hepa1c1c7 cells, indicating a functional role of the AhR-Arnt complex in this effect. Transfection with PAI-1 promoter resulted in increased PAI-1 promoter activity in Hepa1c1c7 cells treated with TCDD, but no such effect occurred in the AhR or Arnt-deficient cell lines, implying involvement of the AhR and Arnt proteins. In addition, alpha-naphthoflavone and phenanthroline, two AhR antagonists, blocked the enhancing effect of TCDD on PAI-1 promoter-coupled luciferase activity in Hepa1c1c7 cells. The results revealed that the induction of PAI-1 by TCDD occurs in the same dose range as other known TCDD-induced AhR-mediated signal transductions, implicating PAI-1 as the most recently found gene induced by TCDD.

1262 HYPOXIA INDUCES PROTEASOME-DEPENDENT DEGRADATION OF ESTROGEN RECEPTOR αA (ERα) IN HUMAN BREAST CANCER CELLS.

M. Stoner and S. H. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Cell growth under hypoxic conditions induces a cascade of responses linked to changes in enzymes responsible for metabolic adaptation for growth and survival under low oxygen conditions. Hypoxic conditions in tumors can lead to a more clinically aggressive phenotype and, therefore, we have investigated the effects of reduced oxygen levels on key regulatory genes/proteins in estrogen receptor α (ERα)-positive ZR-75 human breast cancer cells. ZR-75 cells were maintained in an atmosphere of 21% (normoxia) or 1% (hypoxia) oxygen or grown in the presence of 0-500 μM cobaltous chloride to approximate hypoxic conditions. Western blot analysis of whole cell lysates from ZR-75 cells grown under normoxia or hypoxia for up to 24 hr showed that levels of several nuclear transcription factors, including Sp1, Sp3, hypoxia inducible factor 1β (HIF1β or Arnt) and the aryl hydrocarbon receptor (AhR), were relatively unchanged. In contrast, HIF1α protein was not detected under normotic conditions, but accumulated to very high levels between 3 - 24 hr after exposure of cells to 500 μM cobaltous chloride or 1% O_2 treatment. This increase in HIF1α was due to inhibition of proteosome-dependent degradation of HIF1α under normoxic conditions. In contrast, growth of ZR-75 cells in 500 μM cobaltous chloride or 1% oxygen resulted in > 70% degradation of ERα protein and, in time course studies, this response was observed after growth for > 3 hr in hypoxic conditions. Treatment with the proteasome inhibitor MG132 did not affect levels of ERα protein in cells maintained in 21% oxygen, whereas hypoxia-induced degradation of ERα protein was reversed by the proteasome inhibitor. The role of estrogens and antiestrogens on ERα protein and hormone-induced transactivation is complex and dependent, in part, on "optimal" expression of ERα protein. (Supported by NIH ES04176 and ES09106)

1263 NOVEL MECHANISM OF TCDD TOXICITY: SEQUESTRATION OF ARNT FROM AN ENDOGENOUS ROLE IN P53 GENE INDUCTION.

M. S. Hoagland, J. Yang and H. I. Swanson. *Molecular and Biomedical Pharmacology, University of Kentucky, Lexington, KY.*

Most of the toxic and carcinogenic actions of 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD), a ubiquitous environmental contaminant, are mediated by its ability to bind and activate the aryl hydrocarbon receptor (AhR). The physiological effects of TCDD exposure include altered drug metabolism, disruption of endocrine signaling, and tissue-specific alteration of cellular processes including proliferation, differentiation, and apoptosis. Indeed, AhR directly mediates the gene induction of several xenobiotic-metabolizing enzymes *via* ineracting with its DNA binding partner, ARNT; however, the mechanisms by which AhR mediates many of the TCDD effects is poorly understood. One mechanism by which the AhR may mediate TCDD toxicity includes the sequestering of ARNT from an endogenous role. ARNT is a promiscuous nuclear transcription factor that not only homodimerizes but also dimerizes to transcription factors of the hypoxia signaling pathway (HIF-1a) and neurogenesis (Sim). To investigate the putative role of ARNT in modulating other signaling pathways, we performed transient transfection assays using a reporter gene regulated by the P53 promoter and c-myc and ARNT expression plasmids. In addition to our discovery that ARNT is able to enhance c-myc induction of the P53 gene, we have also discovered that this occurs independent of DNA binding by ARNT. In another approach, we have analyzed endogenous P53 mRNA levels within stably transformed MCF7 cells that over-express ARNT, c-myc or both. Our data indicates that TCDD toxicity may be mediated by activation of AhR, which sequester ARNT, impairs the induction of P53, and accelerates cell cycle progression and/or inhibits apoptosis.

1264 INTERACTION OF AH RECEPTOR WITH PHENOLIC ANTIOXIDANT SIGNAL TRANSDUCTION.

Q. Ma[1], K. L. Kinneer[1], H. Burdette[1] and M. Denison[2]. [1]*HELD/TMBB, CDC/NIOSH, Morgantown, WV and* [2]*Dept. of Environmental Toxicology, University of California, Davis, CA.*

The aryl hydrocarbon receptor (AhR) mediates a spectrum of adaptive and toxic responses to the environmental contaminant TCDD and related halogenated aromatic hydrocarbons. AhR may also play a role(s) in development, growth, and differentiation of tissues in the absence of an exogenous ligand. The broad range of TCDD toxicity and AhR function suggest that the mechanism of AhR action involves multiple signaling mechanisms. In this study, we examined the interaction of AhR with phenolic antioxidant signal transduction, which involves oxidative signaling. Phenolic antioxidants, such as tert-butylhydroquinone (tBHQ), hydroquinone (HQ), or catechol, induce the expression of CYP1A1 in mouse hepa1c1c7 cells; the induction is enhanced by inhibition of protein synthesis by cycloheximide (CHX) (termed superinduction). Induction by the antioxidants is both concentration and time-dependent. Furthermore, the induction and superinduction require AhR and Arnt, as they are absent in AhR or Arnt defective variant cells, and are mediated through the DRE-containing enhancer of CYP1A1, as they are reconstituted in a CYP1A1 enhancer-luciferase reporter expression system. These findings demonstrate that phenolic antioxidants can activate AhR-mediated gene transcription and suggest interaction of AhR with antioxidant mediated oxidative signaling.

1265 TRANS-ACTIVATION OF PPARα AND PPARγ BY PHTHALATE MONOESTERS.

C. H. Hurst and D. J. Waxman. *Biology, Boston University, Boston, MA.*

Phthalate esters are widely used as plasticizers in the manufacture of products made of polyvinyl chloride and can be found in a variety of industrial products, including fixatives, detergents, and solvents. Rodent hepatocarcinogenesis, in part linked to the activation of peroxisome proliferator activated receptor-α (PPAR), has been reported for mono-2-ethylhexyl phthalate (MEHP). Recent studies demonstrate substantial human urinary levels of several other phthalate monoesters, including monobenzyl phthalate (MBzP) and monobutyl phthalate (MBuP), raising the question of whether significant PPAR activation, and perhaps adverse health effects, accompanies environmental or occupational exposure to these agents. The responsiveness of mouse and human PPARα and PPARγ to activation by phthalate monoesters (0-300 μM) was therefore investigated by transient transfection using COS-1 cells. Treatment with MBzP or MBuP for 24 hr increased mouse PPARα transcriptional activity by 3 to 3.5-fold. The activation of human PPAR was somewhat weaker, suggesting a species-dependence of PPARα activation by these chemicals. Mouse PPARγ transcriptional activity was increased 2-3-fold by MBzP and MBuP, while the activation of human PPARγ was again weaker. The activation of PPARα by MBzP and MBuP was confirmed using PPARα-stably transfected FAO liver cells, where the endogenous PPARα target genes acyl-CoA oxidase and 3-ketoacyl-CoA thiolase were induced by both phthalate monoesters in a PPARα-dependent manner. We conclude that MBzP and MBuP are environmental chemical activators of PPARα and PPARγ, and perhaps may contribute to phthalate toxicity. Further study is required to characterize the effects of these phthalate monoesters on PPAR target genes *in vivo* and to evaluate their potential for adverse human health effects. [Supported in part by NIH/NIEHS grants F32 ES11105 (CHH), ES07381 (DJW), and Superfund Basic Research Center at Boston University].

1266 TIMING OF TCDD TREATMENT WITH RESPECT TO HORMONAL STIMULATION DICTATES MAPK SENSITIVITY OF THE AHR BLOCK ON ADIPOGENESIS.

M. A. Cimafranca[1] and C. R. Jefcoate[2]. *[1]Mol & Env Toxicology, University of Wisconsin, Madison, WI and [2]Pharmacology, University of Wisconsin, Madison, WI.*

The mouse embryo fibroblast cell line C3H10T1/2 is a multipotential cell population that will differentiate into various cell types under the appropriate conditions. 10T1/2 cells will undergo adipogenesis if treated with insulin, dexamethsone, methylisobutylxanthine, and the PPAR*gamma* ligand BRL49653 (IDM/BRL). The extent of adipogenesis is measured by the expression of the key adipogenic transcription factor PPAR*gamma* and the number of mature adipocytes at day 8. We use the *gamma*1-isoform of PPAR (PPAR*gamma*1)expression as a marker of the commitment phase of adipogenesis. We have previously shown that if cells are challenged with TCDD 48hrs prior to adipogenic stimulation, there is a block on adipogenesis that is completely dependent on extracellular signal-regulated kinase (ERK) activation for 6-16hrs after IDM/BRL stimulation. The use of either of the MEK inhibitors PD98059 or UO126 reversed the TCDD-mediated inhibition when added 6-16hrs after IDM/BRL, thus demonstrating there is an ERK sensitive component of the TCDD mediated inhibition. Here we show that adding TCDD substantially after IDM/BRL treatment gives increased PPAR*gamma*1 suppression and loss of adipogenesis. The addition of TCD 6-12hrs after IDM/BRL yields an 80% reduction of PPAR*gamma*1 expression, which again is fully reversed by subsequent addition of MEK inhibitors. Here we define the timing of MEK activation that is necessary for this late suppresion of PPAR*gamma*1 expression by TCDD *via* AhR and the mechanism of cross-talk between the two pathways.

1267 REGULATION OF THE HUMAN *UGT1A1* GENE BY THE NUCLEAR PREGNANE X RECEPTOR.

M. Yueh[1], E. G. Schuetz[2], W. Xie[3], R. M. Evans[3] and R. H. Tukey[1]. *[1]Dept. of Chem & Biochem and Pharmacology, UCSD, La Jolla, CA, [2]Dept of Pharmaceutical Sciences, St. Jude Children's Research Hospital, Memphis, TN and [3]The Salk Institute for Biological Studies, La Jolla, CA.*

The UDP-glucuronosyltransferase, *UGT1A1*, controls the detoxification of bilirubin and plays a role in geno-protection against carcinogens such as N-hydroxy 2-amino-1-methyl-6-phenylimidazo[4, 5-b]pyridine. Nuclear orphan receptors have recently been shown to regulate metabolic pathways in response to chemical and hormone exposure by alteration in gene statement patterns of drug-metabolic enzymes. Here, we demonstrate that *UGT1A1* was inducible by a number of compounds known to be Pregnane X receptor (PXR) ligands. HepG2 cells that over-express the human PXR confirm that rifampicin and dexamethasone induce *UGT1A1* gene statement as demonstrated by enhanced mRNA levels as well as catalytic activities. To examine the molecular interactions that control PXR-medicated *UGT1A1* statement, the *UGT1A1* responsive elements were identified and cloned into reporter plasmids. A 230-bp responsive fragment, localized approximately ¡V3.5 kb upstream of the transcriptional start site, was required for PXR-mediated induction as examined in transfection experiments. In addition, a constitutively active PXR statement plasmid called VP16-hPXR stimulated enhancer-dependent reporter gene activity, producing a 10-fold induction of luciferase activity, thus confirming that the PXR-distal *UGT1A1* responsive sequence interaction is functional. Taken together, these observations demonstrate a regulatory mechanism for *UGT1A1* induction that is dependent upon nuclear receptor PXR. The induction of *UGT1A1* through PXR may provide a defensive mechanism against the toxicity of endogenous and foreign chemicals. (Supported in part by USPHS grant GM49135).

1268 LIGAND-INDEPENDENT PHYSIOLOGICAL MECHANISMS FOR AHR ACTIVATION.

Y. C. Cho. *Pharmacology, University of Wisconsin, Madison, WI.* Sponsor: C. Jefcoate.

The aryl hydrocarbon receptor is a ligand-activated basic helix-loop-helix (bHLH)/Per-Arnt-Sim domain transcription factor. Although the mechanism of AhR activation by xenobiotics is well understood, activation of AhR in the absence of exoligand remains unclear. Here we have demonstrated an alternate regulatory mechanism of AhR activation in the absence of exogenous ligand in both suspended and monolayer cells using mouse embryonic fibroblast (MEF) cell lines which contain integrated mouse Cyp1B1 promoter constructs linked to luciferase reporters responding to AhR activation. First, the AhR activity was increased in methylcellulose-suspended fibroblasts as effectively as by TCDD in confluent monolayer. Second, overlay of monolayer fibroblasts with methylcellulose substantially increased AhR activity while retaining adhesion. Suspension stimulated AhR activity was completely insensitive to an antagonist, a-naphthoflavone (aNF) indicating that activation is not due to a constitutive ligand. Suspension activation was selectively inhibited by Ro 32-8220, a PKC inhibitor and activated by LiCl, a GSK-3b inhibitor. We project that these inhibitors target the suspenson activation of AhR. Several specific cellular inhibitors affect each process similarly (Thapsigargin, MG132, and geldanamycin). These data characterize a ligand-independent physiological process for AhR activation.

1269 GENETIC EVIDENCE THAT THE P23 CO-CHAPERONE REGULATES HUMAN DIOXIN RECEPTOR SIGNALING IN A YEAST MODEL SYSTEM.

M. B. Cox and C. A. Miller. *Environmental Health Sciences, Tulane University Health Sciences Center, New Orleans, LA.*

The dioxin (or aryl hydrocarbon) receptor is a nuclear receptor that binds toxic ligands (e.g., TCDD) and it requires the action of Hsp90 and cofactors for proper function. The dioxin receptor exists in a cytoplasmic complex which contains a dimer of Hsp90, other co-chaperone proteins, and p23 prior to ligand exposure. Whether p23 has a role in dioxin receptor signaling is not known. *in vitro* studies suggest that the p23 co-chaperone protein enhances the stability of dioxin receptor-Hsp90 complexes following ligand binding. This stabilization may involve p23's ATP-dependent interaction with the nucleotide-binding site of Hsp90. We used a yeast genetic model system that expressed functional human dioxin receptor and Arnt proteins to test whether p23 affects dioxin receptor signaling. Deletion of the SBA1 gene (the yeast p23 homolog) reduced ligand-mediated dioxin receptor signaling in a reporter gene assay and reduced ligand potency by approximately five-fold. Signaling and ligand potency were restored to wild type levels when SBA1 was expressed in this strain. More importantly, human p23 effectively substituted for yeast p23 in this assay. To further investigate the role of p23 in dioxin receptor signaling, we used a temperature sensitive Hsp90 mutant strain with a severe dioxin receptor signaling defect both at the permissive and non-permissive temperatures. The mutation in this hsp90 strain maps to the ATP/p23 binding pocket, suggesting that the dioxin receptor signaling defect and temperature sensitivity may be due to impaired p23-Hsp90 interactions. In support of this hypothesis, we found that SBA1 or human p23 overexpression suppressed temperature sensitivity and the dioxin receptor signaling defect in this mutant. These results provide the first genetic evidence that p23 modulates dioxin receptor signaling and suggest that p23 levels may be a determinant of ligand-mediated toxicity by TCDD and related compounds.

1270 FUNCTIONAL ANALYSIS OF AH RECEPTORS CONTAINING MUTATIONS WITHIN THE NUCLEAR LOCALIZATION SIGNAL (NLS).

Z. Song and R. S. Pollenz. *Biology, University of South Florida, Tampa, FL.*

The nuclear localization signal (NLS) of the Ah receptor (AHR) spans amino acids 12-39 and overlaps the basic region that is involved in DNA binding. Studies were initiated to evaluate the importance of the NLS in AHR localization, AHR degradation, and AHR-mediated gene induction. Stable cell lines were generated in the

Hepa-1 cell line that expressed 1) wild type AHR (wtAHR), 2) AHR containing a K to A substitution at amino acid 13 (NLS-1) and 3) AHR containing an R to A substitution at amino acid 12 and a K to A substitution at amino acid 13 (NLS-2). Expression of NLS-1 or NLS-2 *in vitro* revealed that both proteins could bind to DNA in a TCDD-dependant manner to the same level as wtAHR. Immunohistochemical analysis of the NLS-1 and NLS-2 stable cell lines showed that the mutated AHRs were predominantly cytoplasmic and did not translocate to the nucleus in the presence of TCDD. However, the staining intensity of the NLS-1 and NLS-2 became reduced following exposure to TCDD for 4-16 hours. These results were confirmed by Western blot analysis of various AHR mutants and showed that NLS-1 was reduced by 60-80% following 16hr TCDD exposure while NLS-2 was reduced by approximately 50% after 16hr TCDD exposure. Interestingly, while neither NLS-1 nor NLS-2 could be detected in the nucleus, cells expressing these proteins exhibited TCDD-mediated *CYP1A1* induction that was 10-20% of that observed in cells expressing wtAHR or in the wild type Hepa-1 line. Thus, these results support the hypothesis that AHR can be proteolytically degraded within the cytoplasmic compartment, but also suggest that the NLS-1 and NLS-2 mutations are not absolute in blocking nuclear localization. Supported by ES10991.

1271 ANALYSIS OF RAINBOW TROUT AH RECEPTOR ISOFORMS (RTAHR2) IN CELL CULTURE REVEALS CONSERVATION OF FUNCTION.

K. Marks-Sojka[1], B. Necela[1] and R. S. Pollenz[2]. [1]*Biochemistry, Medical University of South Carolina, Charleston, SC and* [2]*Biology, University of South Florida, Tampa, FL.*

Two distinct aryl hydrocarbon receptor (AHR) cDNAs have been isolated from rainbow trout. These proteins termed rtAHR2 α and rtAHR2β are 97% identical at the amino acid level but are reported to have distinct functions with regard to AHR-mediated gene regulation when expressed in COS cells. To evaluate this hypothesis, these proteins were functionally evaluated *in vitro* and in the Chinese hamster lung cell line, E36. To facilitate the ability to detect and measure the expression of these proteins, both rtAHR2 isoforms were tagged with the FLAG peptide on the carboxy-terminus. When the rtAHR2 proteins were expressed *in vitro* and then incubated with 2, 3, 7, 8-tetrachlorodibezo-*p*-diozin (TCDD) in the presence of either mammalian or rainbow trout ARNT, they failed to form functional complexes that could associate with xenobiotic response elements (XRE) in a ligand-dependant manner. Use of different temperatures, protein concentrations or extracts from trout cells did not affect the negative results. In contrast, both proteins exhibited positive function on AHR-mediated signaling when expressed in E36 cells. Both rtAHR2 isoforms showed a cytoplasmic distribution in the unliganded state and could drive expression of a reporter gene under control of the trout *CYP1A3* promoter. Although both proteins could induce reporter gene activity to the same magnitude, the EC_{50} values of the two isoforms for TCDD differed by an order of magnitude with the rtAHR2β isoform less responsive to TCDD. When function of the rtAHR2 isoforms were tested in the context of the dominant negative $rtARNT_a$ isoform, TCDD-mediated induction of reporter gene activity was significantly reduced compared to when $rtARNT_b$ was utilized. Thus, both rtAHR2 isoforms appear to exhibit positive function in AHR-mediated signaling suggesting conservation. Supported by ES 08890.

1272 A SINGLE AMINO ACID DIFFERENCE UNDERLIES THE DIFFERENTIAL TRANSACTIVATION ACTIVITIES OF THE RAINBOW TROUT ARYL HYDROCARBON RECEPTORS (RTAHR2α AND RTAHR2β).

E. A. Andreasen[1], R. L. Tanguay[3], W. Heideman[1,2] and R. E. Peterson[1,2]. [1]*Environmental Toxicology Center, University of Wisconsin, Madison, WI,* [2]*School of Pharmacy, University of Wisconsin, Madison, WI and* [3]*Pharmaceutical Sciences, University of Colorado Health Sciences Center, Denver, CO.*

Two rainbow trout aryl hydrocarbon receptor cDNAs (rtAhR2α and rtAhR2β) were recently isolated and characterized. The predicted amino sequences share 98% amino acid identity yet their functional properties differ. Both rtAhR2α and rtAhR2β bind 2, 3, 7, 8 tetrachlorodibenzo-*p*-dioxin (TCDD), dimerize with rainbow trout ARNTb (rtARNTb), and recognize dioxin response elements *in vitro*. However, in a transient transfection assay in COS-7 cells the proteins show differential activity towards a reporter driven by the rainbow trout cyp1a promoter. In response to 10 nM TCDD, cells co-transfected with rtARNTb and rtAhR2α showed an 8.6-fold increase in luciferase activity whereas cells co-transfected with rtARNTb and rtAhR2β showed only a 1.5-fold increase. Our objective was to determine which of the amino acid substitutions are responsible for the differences in rtAhR2α and rtAhR2β transactivation activity. Chimeric rtAhRs were constructed by switching sequences between the two rtAhR2s and an N-terminal region was responsible for the differential transactivation activity of the proteins. To determine the specific residues underlying the differential activity we utilized site-directed mutagenesis to convert certain rtAhR2β amino acids to those found in rtAhR2α. When amino acid 111 in rtAhR2β, located just N-terminal to the PAS domain, was changed from lysine to glutamate, transactivation activity of the altered rtAhR2β was similar to that of rtAhR2α. When substitutions are made in the zebrafish and human AhRs at this residue, activity is similarly altered indicating that this amino acid is essential for the structure and function of the aryl hydrocarbon receptors.

1273 DO DIFFERENCES IN THE DEER MOUSE AH RECEPTOR LIGAND BINDING DOMAIN EXPLAIN WHY DDE IS A CYP1A1 INDUCER IN THIS SPECIES?

R. L. Dickerson, D. Settachan and L. T. Frame. *Pharmacology, Texas Tech University Health Sciences Center, Lubbock, TX.*

Previously, we reported that DDE exposure in the deer mouse induces ethoxyresorufin-deethylase activity and that this activity is neutralized by rat anti-CYP1A1 antibody but not rat anti-CYP2B antibody. This was accompanied by an increase in CYP1A1 message as determined by RT-PCR. In contrast, exposure of laboratory rat and mouse to DDT or DDE results in CYP2B induction, a phenomena not observed in the deer mouse, a New World species. Induction of CYP1A1 by environmental chemicals predominantly involves binding of the compound to the Ah receptor, resulting in its activation, dimerization with ARNT, and binding of the complex to dioxin response elements in the 5' flanking region of the CYP1A1 gene. DDE has been shown to bind with the murine Ah receptor. One hypothesis for the ability of DDE to induce CYP1A1 in the deer mouse is that the deer mouse Ah receptor differs significantly in the ligand binding domain from laboratory mouse. To test this hypothesis, we isolated mRNA from deer mouse liver, produced Ah receptor and ARNT cDNA by RT-PCR, and sequenced the resulting clones. The most significant difference in the Ah receptor was in position 236 in which the deer mouse has a valine and the house mouse a methionine. Other differences were in position 306 (valine to isoleucine), 317 (lysine to argenine), 329 (methionine to isoleucine) and 331 (tyrosine to histidine). The deer mouse Ah receptor binding domain also differed from the rat in positions 236, 306, 316, and 331. We are currently in the process of determining the effect of each of these substitutions on xenobiotic binding.

1274 MOUSE HEPATOCYTE RESPONSE TO PEROXISOME PROLIFERATORS: DEPENDENCY ON HEPATIC NONPARENCHYMAL CELLS AND PEROXISOME PROLIFERATOR ACTIVATED RECEPTOR α (PPARα).

K. Hedley, N. H. James, S. C. Hasmall, K. Olsen and R. A. Roberts. *HAES Research, Syngenta CTL, Macclesfield, United Kingdom.*

Peroxisome proliferators (PPs) are rodent nongenotoxic hepatocarcinogens that induce peroxisome proliferation and DNA synthesis, and suppress apoptosis in rodent hepatocytes. PPs act through the PP activated receptor α (PPARα). Tumour necrosis factor α (TNFα) and hepatic nonparenchymal cells (NPCs), the major source of TNF α in the liver, have also been implicated in mediating the rodent hepatic response to PPs. We have used an established *in vitro* model to investigate the interaction between PPARα and NPCs in regulating the response to PPs. Using normal hepatocyte cultures containing around 20% NPCs, the PP nafenopin (50μM) induced DNA synthesis and suppressed TGFβ1 -induced apoptosis. However, when the NPCs were removed by differential centrifugation, nafenopin did not induce DNA synthesis nor suppress apoptosis in the pure hepatocytes. Reconstitution of the normal hepatocyte cultures by mixing together the pure hepatocytes and the previously separated NPCs in the same proportions as the original cell preparation (17.7 + 8.7% NPCs) restored these responses to nafenopin. Interestingly, nafenopin was still able to induce β-oxidation in the pure hepatocyte cultures, consistent with NPCs being required for PP-induced growth but not for peroxisome proliferation. Next, we evaluated the role of PPARα in the hepatocyte dependency upon NPCs. Interestingly, NPCs isolated from PPARα null mice, like those isolated from the wild type NPCs, restored the hepatocyte response to nafenopin. However, as expected, PPARα null hepatocytes remained non-responsive to PPs, irrespective of the genotype of the added NPCs. These data support a role for NPCs in facilitating a response of hepatocytes to PPs that is ultimately dependent on the presence of PPARα in the hepatocyte.

1275 DOWNREGULATION OF LACTOFERRIN BY PPARα LIGANDS ASSOCIATED WITH THE RODENT HEPATOCARCINOGENICITY OF PEROXISOME PROLIFERATORS.

S. C. Hasmall, I. Kimber, G. Orphanides, N. H. James, W. D. Pennie, K. Hedley, A. R. Soames and R. A. Roberts. *HAES Research, Syngenta CTL, Macclesfield, United Kingdom.*

In rats and mice, peroxisome proliferators (PPs) cause liver cancer, associated with suppression of apoptosis and increased hepatocyte replication. PPARα (PP activated receptor α) is a ligand-activated transcription factor that mediates the growth

and tumorigenic responses to PPs *via* mechanisms that remain to be identified. Using microarray gene expression profiling we detected a 3 to 7-fold down-regulation of murine hepatic lactoferrin (LF) in response to the PP, diethylhexylphthalate (DEHP; 1150mg/Kg). LF is an iron binding glycoprotein implicated in cancer and in regulating inflammatory responses, possibly *via* tumor necrosis factor α (TNFα). Northern blot analyses using a human LF probe confirmed down-regulation of LF mRNA by DEHP. LF has been reported to repress TNFα levels suggesting that LF down-regulation by PPs may permit TNFα levels to rise, enhancing hepatocyte survival and proliferation. To address this, we asked if LF down-regulation could drive the perturbation of hepatocyte growth by PPs. *in vitro*, MEHP (the principal metabolite of DEHP and proximal PP), the PP nafenopin (50μM) or exogenous TNFα (5000U/ml) induced hepatocyte proliferation and suppressed apoptosis. LF (200μM) blocked the growth but not the peroxisome proliferation response to MEHP and nafenopin but could not block the growth response to TNFα. These data suggested a role for LF in the growth response to PPARα ligands. However, sequence similarities raised the possibility that the DEHP-regulated mRNA could be transferrin, a related gene previously shown to contain a PP response element (PPRE). Immunocytochemistry using specific anti-LF and anti-TF antibodies demonstrated that both LF and TF are expressed in murine liver and furthermore, both were downregulated by DEHP in both wild type and PPARα null mouse liver. These data suggest that the regulation of iron binding proteins by PPARα ligands plays a role in PP-mediated liver growth, but not in peroxisome proliferation.

1276 HEPATIC EFFECTS OF PPARδ ARE DISTINCT FROM PPARα

E. H. Romach, J. L. Shenk, R. J. Ott, T. M. Willson and R. T. Miller. *Safty Assessment, GlaxoSmithKline, Research Triangle Park, NC.*

The PPAR receptor family includes three receptor subtypes PPARα, PPARγ, and PPARδ, which are all members of the steroid/thyroid/retinoid nuclear receptor superfamily of transcription factors. PPARα is abundant in rodent liver and plays a role in regulation of fatty acid metabolism. PPARδ is moderately expressed in most tissues including liver, but its biological function is unclear. PPARδ agonists have been reported to lower lipids in animal models; however, it is not known if this effect is distinct from activation of PPARα. We used a potent and selective PPARδ agonist (GW501516) to compare the effects of activation of PPARδ to those induced with PPARα agonists (GW7647 and fenofibrate). In *in vitro* assays, high concentrations of GW501516 cross-react with PPARα receptors. Four days of oral administration of low and medium doses of GW501516 to Wistar Han rats did not cause peroxisome proliferation (PP), but PP occurred in rats that received a high dose. We hypothesized that induction of PP induced by GW501516 in rodents was due to activation of PPARα consistent with liver levels of GW501516 at the high dose. Gene expression analyses support this hypothesis in that peroxisomal bifunctional enzyme mRNA levels were increased in only the rats that received the high dose of GW501516 and in rats that received both PPARα agonists. Serum triglycerides decreased in all treated groups with the largest changes occurring in rats that received the high dose of GW501516 and both PPARα agonists. Lipid lowering was seen at doses below those that resulted in the induction of PP. Increase in liver weight was seen only in rats given the high dose of fenofibrate; although, a dose related increase of hypertrophy and granular eosinophilia was seen in the livers from GW501516- and fenofibrate-treated rats. Results suggest that PP caused by GW501516 results from activation of PPARα and that the effects of GW501516 on lipid lowering are independent of the induction of PP.

1277 PEROXISOME PROLIFERATOR ACTIVATED RECEPTOR ALPHA IS ESSENTIAL FOR LIVER REGENERATION FOLLOWING PARTIAL HEPATECTOMY.

M. D. Wheeler, O. M. Smutney, I. Rusyn and R. G. Thurman. *Pharmacology, University of North Carolina, Chapel Hill, NC.*

Liver regeneration following partial hepatectomy involves several signaling mechanims including activation of the small GTPases Ras and RhoA 1, 2 in response to mitogens 3, leading to DNA synthesis and cell proliferation. Peroxisome proliferator activated receptor alpha (PPARa) regulates the expression of several key enzymes in isoprenoid synthesis 4, 5, key events for membrane-association of Ras and RhoA. Thus, the role of PPARa in cell proliferation was tested. Peak DNA synthesis 42 hours after partial hepatectomy was reduced by ~ 60% in PPAR*alpha* deficient mice compared to wild-type mice, despite increases in TNF*alpha* and IL-1 in both groups. After partial hepatectomy, PPAR*alpha* regulated genes, farnesyl pyrophosphate synthase and HMG-CoA synthase, were significantly increased in wild-type but not in PPAR*alpha*-/- mice. Also, under these conditions, membrane-association of Ras and RhoA was high in wild-type mice but was nearly absent in PPAR*alpha*-/- mice. Concomitantly, Ras and RhoA were elevated in the cytosol in PPAR*alpha*-/- mice. Deletion of PPAR*alpha* blunted the degradation of cell cycle inhibitors p21waf and p27kip1, prevented activation of cdk2 and cdk4, and blunted phosphorylation of Rb protein. These results support the hypothesis that PPAR*alpha* is necessary for cell cycle progression in regenerating mouse liver *via* mechanisms involving Ras and RhoA.

1278 THE COMMON MARMOSET (CALLITHRIX JACCHUS) IN DRUG SAFETY STUDIES.

O. M. Loget. *Non-Clinical Drug Safety, F. Hoffmann-La Roche, Basel, Switzerland.* Sponsor: M. Stephan-Gueldner.

Callitrichids are not adapted to captivity, except common marmosets, for which a database is now available in toxicology, allowing regulatory submission. Animals of defined health status, age and history are available since purpose-bred colonies are established. We have defined background data on clinical pathology, electrocardiology, ophthalmology and histopathology facilitating interpretation of toxicology studies. Marmosets are the smallest non-rodents used in toxicology and have therefore reduced dietary and particularly substance requirements. They can thus be employed early in the drug development process. Their small size was not always an advantage because of limited amounts of blood which can be taken on studies, and because of difficulties in performing some examinations (e.g. ophthalmology). Blood analysis is now more easily possible with microtechniques, except for toxicokinetics. In this case satellite animals are recommended in order to not jeopardize results. The eye is small, deep-seated and eyelids are difficult to maintain open, making fundus photographs difficult, but possible for experienced ophthalmologists. Marmosets are not yet used routinely in reproductive toxicology, although presenting several advantages: rapid maturation, short pregnancy, and multiple births. The main disadvantage consisted of the absence of external signs of the ovarian cycle preventing to detect gestation early enough without repeated blood withdrawals. Timing of ovulation and pregnancy can however be determined by monitoring urinary or fecal hormones. In addition, similarity to simian primates suggests that the marmoset should be a good experimental model, suitable for teratological investigations. Several reproductive biology studies have been performed. Unfortunately, a large database is not yet available for reproductive toxicology studies. If the use of the marmoset could be more often envisaged, for example to possibly replace the cynomolgus monkey in reproductive toxicology, a larger database could be built and, as a consequence, this species would be more easily accepted as an alternative.

1279 A COMPARISON OF SELECTED LABORATORY INVESTIGATION PARAMETERS IN CYNOMOLGUS MONKEYS FROM MAURITIUS AND CHINA.

L. A. Powell and S. J. Crome. *Toxicology, Huntingdon Life Sciences, Huntingdon, United Kingdom.* Sponsor: C. Atterwill.

The limited availability of primates for pre-clinical safety evaluation studies is a continuing issue. Huntingdon Life Sciences has accumulated background data from animals supplied from Mauritius over many years, but more recently other sources have been investigated. Yunnan in China has been identified as a suitable source and a number of projects have been completed with these animals. The purpose of this review is to compare results for the parameters normally investigated in the laboratory investigations conducted during pre-clinical toxicity tests; haematology, blood chemistry and urinalysis from the two sources. While review of blood chemistry and urinalysis data from animals from the two sources indicated few clear consistent differences in any of the standard parameters included in safety evaluation studies, there were some marked differences seen in the haematology parameters. This was most apparent in erythrocyte values. The potential for differences in haemoglobin parameters in cynomolgus monkeys from different sources is a possible confounding factor in the interpretation of the results of toxicological studies. It is concluded that the source of cynomolgus monkeys must be taken into account in the interpretation of haematological data and in fact, ideally, cynomolgus monkeys from the same source should be used throughout a programme of work on the same compound.

1280 EFFECTS OF A SINGLE INTRAMUSCULAR INJECTION OF KETAMINE IN CYNOMOLGUS MONKEYS.

N. A. Sharpe, N. Collins, S. A. Barat, R. Price, K. S. Dunham, R. E. Morrissey and J. S. MacDonald. *Toxicology, Schering-Plough Research Institute, Lafayette, NJ.*

Ketamine is frequently used to produce temporary chemical restraint in primates for procedures performed during toxicology studies. The cynomolgus monkey is a common species used on these studies. However, limited information is available on the acute effects of ketamine administration on the various parameters evaluated during toxicology studies. Effects of ketamine administration on parameters typically evaluated on these studies could confound the interpretation of the data.

Thus, the effects of ketamine were evaluated in cynomolgus monkeys. Following IM administration of 10 mg/kg of ketamine or 0.9% saline, monkeys were evaluated for clinical effects including onset and recovery from sedation as well as food intake. Clinical pathology parameters including hematology, coagulation, platelet aggregation, serum chemistry and urinalysis/urine chemistry were also determined at multiple time points. Sedation occurred within 2 to 4 min following ketamine administration and lasted 20 to 33 min. Clinical effects of ataxia, hypoactivity and sitting posture were present up to 2 hrs post-administration. Monkeys were fully recovered by 4 hrs post-administration. Food intake was decreased on the day of ketamine administration. There were no ketamine-related effects on hematology, coagulation and platelet aggregation parameters measured at 10 min, 24 hrs and 4 and 9 days post-administration. A minimal decrease in serum potassium concentrations (3.2-3.9 mEq/L *vs.* pretest values of 3.8-5.2 mEq/L) occurred in all ketamine administered monkeys at 10 min post-administration. Urine pH was minimally to mildly lower (6.0-7.5 *vs.* pretest values of 8.5) 24 hrs post-administration compared to control. These data indicate that a 10 mg/kg dose of ketamine is suitable for temporary chemical restraint of cynomolgus monkeys. However, evaluation of clinical pathology endpoints should be initiated no earlier than 24 hrs post-ketamine administration based on the minimal limited changes that occurred within 24 hrs of ketamine administration.

1281 INFRARED THERMOMETRY FOR REMOTE BODY TEMPERATURE MEASUREMENT IN THE CYNOMOLGUS MONKEY.

J. Henken, P. Nowak, U. Zuehlke, W. Mueller, R. Vogel, R. Korte and G. Weinbauer. *Covance Laboratories GmbH, Muenster, Germany.* Sponsor: R. House.

Rectal thermometry is commonly used in toxicity studies for the determination of body temperature in nonhuman primates. This approach necessitates capture and handling of the animal. We, therefore, investigated the suitability of remote infrared thermometry for suface body temperature measurement in an established nonhuman primate toxicology model, the Cynomolgus monkey (Macaca fascicularis).Rectal (Gerathermâplus) and infrared (Raynger RMX4PD, Raytek) determinations were performed in eight male and female animals. Infrared measurements were conducted on caged animals and were recorded for the forehead and, among male animals, also for the testis. For all animals, data were collected for both techniques twice daily (8 am and 12 am) on 9 occasions at least one day apart.Baseline body temperature by the rectal approach in male and female animals was 38.7±0.5 °C. Forehead temperature was 31.0±0.8 °C in male and female animals. Testis surface temperature was 33.5±0.7 °C and was similar at 8 am and 12 am. Results obtained for male and female animals were comparable for both techniques. Also, the data measured were nearly identical for the 9 occasions and the two timpoints during the day.Our observations suggest that infrared temperature assessment is not suitable for determination of core body temperature. However, infrared measurements were surprisingly stable over daytime and over several days. Hence, the infrared approach is suitable for monitoring body temperature *via* surface temperature without the need of capture and handling of experimental animals.

1282 CIRCADIAN RHYTHM OF ACTH AND SERUM CORTISOL IN CONSCIOUS MONKEYS USING AN AUTOMATIC SAMPLING METHOD.

R. Nagata, A. Akune, N. Horai and G. Kito. *Shin Nippon Biomedical Laboratories (SNBL), Ltd., Kagoshima, Japan.*

In animals, severe stress from restraint for blood sampling can cause marked changes in biological parameters such as hormone levels. In this study, ACTH and serum cortisol levels were measured in blood sampled from conscious, unrestrained monkeys using an automatic blood sampling apparatus, to determine if the sampling method affected circadian variations. Methods: Eight male cynomolgus monkeys (BW 4 - 6 kg) were used. A polyurethane catheter for blood sampling was aseptically inserted into the femoral vein under anesthesia, and connected to a fluid swivel by a stainless tether. The swivel was connected to an automatic blood sampling apparatus by a polyurethane tube. Blood (1.5 ml) was automatically drawn every four hours and stored in a chamber (4°C). Samples were assayed for ACTH and serum cortisol levels by radioimmunoassay. Results and conclusion: Blood was sampled starting at three weeks after surgery for catheter insertion, ACTH and serum cortisol showed stable values from four weeks after surgery. ACTH levels were 13 - 18 pg/ml (daytime) and 7 - 10 pg/ml (nighttime) from four weeks after surgery, while serum cortisol levels were approximately 30 µg/ml (daytime) and 10 - 20 µg/ml (nighttime). Circadian rhythms were observed in both ACTH and serum cortisol levels, with high values during the day and low values at night. Furthermore, serum cortisol levels increased markedly according to the load of ACTH (5 µg/kg). These results demonstrate that the measurement of stable and exact ACTH and serum cortisol concentrations in monkeys is possible using an automatic blood sampling apparatus.

1283 A MODEL OF CISPLATIN-INDUCED RENAL IMPAIRMENT IN THE CYNOMOLGUS MONKEY.

B. J. Mounho[1], J. Bussiere[2], S. Ortega[1] and J. Kapeghian[3]. [1]*Toxicology, Genentech, Inc., South San Francisco, CA,* [2]*Immunex, Corp, Seattle, WA and* [3]*Sierra Biomedical, Sparks, NV.*

Preclinical toxicity studies for human protein drug candidates are generally conducted in normal, healthy non-human primates, which may not be representative of the target patient population. Many individuals in the target patient population may have a compromised organ system due to the existing disease-state or previous drug exposure, such as chemotherapy. While the drug candidate alone may not induce a particular toxicity, it could potentially exacerbate a pre-existing injury. For this reason, a non-human primate model of renal impairment can be a valuable tool to evaluate potential exacerbation of pre-existing renal injury by the drug candidate. This study was conducted to establish a model of mild renal-impairment in the cynomolgus monkey using clinically relevant doses of the highly nephrotoxic chemotherapeutic agent cisplatin. Adult male monkeys were administered 35 or 58 mg/m^2 cisplatin on Days 1 and 22 *via* intravenous infusion, and all animals were evaluated for changes in clinical signs, body weight, and clinical pathology indices. In order to characterize the time course of cisplatin-induced nephrotoxicity, serum chemistry parameters were evaluated at various timepoints throughout the study and two animals from each dose group were euthanized on Days 7, 21, and 42 for microscopic analysis of kidney tissue. Mild elevations in serum BUN and creatinine levels were observed in 1/6 animals in the low-dose group, whereas moderate to marked elevations were noted 3/6 animals in the high-dose group. While renal tubular necrosis ranging from minimal to marked was noted in individual animals in both dose groups at all timepoints, the incidence and severity of the renal injury was greater in the high-dose group. This study demonstrates that administration of clinically relevant doses of cisplatin results in renal toxicity in the monkey and that the nephrotoxic effects of cisplatin vary within each dose level, with a higher incidence and more severe changes occurring at the higher dose.

1284 THE USE OF THE MINI-PIG IN BIOMEDICAL RESEARCH.

R. J. Harling. *Scantox A/S, Lille Skensved, Denmark.*

The popularity of the mini-pig in pharmacokinetic and safety evaluation studies has increased rapidly over recent years. A better appreciation of the similarities between man and the mini-pig together with increased concerns over the use of nonhuman primates are two of the principal reasons for this increase. To ensure that other researchers are aware of the potential advantages of this species presentation of background information is essential. Summary data relating to frequently measured variables including electrocardiography, clinical pathology and organ weights will be presented. The use of the mini-pig in the development of dermal products, and in the investigation of reproduction toxicity will be illustrated with data from completed studies. In addition, a number of disease models have been developed to specifically address the use of the mini-pig in Parkinson's disease, atherosclerosis and diabetes research. Data from completed studies showing the induction of symptoms of Parkinson's disease following the adminstration of 1-methyl-4-phenyl-1, 2, 3, 6-tetrahydropyridine (MPTP) and the successful use of this species in this type of research will be described.

1285 A CROSSOVER DESIGN FOR TELEMETRIC CARDIOVASCULAR ASSESSMENT IN UNRESTRAINED CONSCIOUS DOGS.

F. Goldfain-Blanc, N. Lhote, J. P. Belet, P. Desbois, M. Lupart and G. Descotes. *Drug Safety Assessment, Groupe de Recherche Servier, Orléans, France.*

Telemetry studies are part of the cardiovascular assessment of drugs, but their design has still to be optimized for appropriate analysis of repeated measurements, repeated dosings, compound comparison over successive dosing periods, in a limited number of subjects, and residual influence of treatments (carryover). In a crossover study, six beagle dogs were surgically implanted with a pressure sensor in the femoral artery for continuous recording of blood pressure (BP) and heart rate (HR), and two subcutaneous electrodes for lead II-electrocardiograms. The dogs were randomly allocated to 6 sequences each of three 5-day dosing periods with placebo, erythromycin (100 mg/kg/d sc) or sotalol (320 mg/dog/d po), the dosing periods being separated by one-week washout periods. The six sequences differed according to the six possible combinations. Evaluations included systolic and diastolic BP, HR and rhythm, PR and QT intervals and QRS complex duration. The QT interval was also adjusted for HR changes according to Bazett or Fredericia formula or using control values as a covariate. A specific statistical analysis was applied to the mini-

mum and maximum values, derived variables such as the mean daily sums ("area under the curve") and the slope and the intercept of QT=f(HR). Carryover effects and time-related effects (i.e., differences between dosing days and between dosing periods) were evaluated. Sotalol statistically significantly decreased HR and BP and significantly prolonged QT and QTc. Erythromycin resulted in increased HR, likely secondary to the local inflammatory reaction, which precluded detection of QT prolongation. The test system was stable over time. The few carryover effects suggest that washout periods have to be adjusted according to the kinetics of the compounds. This design with a limited number of animals and repeated dosing to allow detection of time-related effects and comparison of compounds is considered suitable for the nonclinical cardiovascular assessment of drugs.

1286 DEVELOPMENT AND VALIDATION OF A CANINE FUNCTIONAL OBSERVATIONAL BATTERY (FOB) FOR USE IN TOXICITY STUDIES.

J. A. Wasielewski, J. C. White, P. E. Newton, R. J. Briscoe and T. J. Baird. *Pharmacology, MPI Research, Mattawan, MI.*

Systematic observational evaluations for potential test article related acute and chronic neurofunctional effects are often standard components of general toxicity studies conducted on newly-developed pharmacologic and chemical entities, such as food additives, therapeutic drugs, and industrial/agricultural agents. The beagle dog is a frequently employed non-rodent species in regulatory toxicology studies, and in a considerable amount of discovery/efficacy work. However, the vast majority of standardized neurobehavioral evaluations are performed in rodents (Irwin, 1968; Gad, 1982), and progress towards a validated FOB in canines (i.e., Haggerty, 1991) has been slow. Prior investigations have established the susceptibility of dogs, like rodents, to a variety of neurotoxic agents. Still more literature establishes the dog as a sensitive model for detecting and characterizing the adverse neurofunctional effects of pharmaceuticals. The need for, and utility of, a robust and yet sensitive screening methodology for detecting and providing initial characterization of such neurotoxic and neurofunctional effects is clear, and has now been developed and validated in the beagle dog. Initial validation of this 39-item FOB was performed using four common pharmacologic positive control compounds: haliperidol (3.0 mg/kg, s.c.), ethanol (2.0 g/kg, p.o.), pilocarpine (2.0 mg/kg, s.c.) and amphetamine (2.0 mg/kg, s.c.). Results indicate that this observational battery is sensitive to the known acute pharmacological effects of these agents. Additional work is planned to further establish the capacity of this FOB to detect and characterize neurobehavioral pathology associated with chronic exposure to known neurotoxicants.

1287 PERFORMANCE VALIDATION AND DEMONSTRATION OF THE SENSITIVITY TO DETECT DRUG INDUCED ALTERATIONS USING A LOCOMOTOR ACTIVITY SYSTEM FOR LARGE ANIMALS.

C. P. Chengelis, E. L. Padgett, K. K. Rhodes, R. Frey, M. L. Simons, G. J. Schaefer and M. D. Nemec. *WIL Research Laboratories, Inc., Ashland, OH.*

Neurotoxicity regulatory guidelines require that automated systems which quantify activity be evaluated to ensure the reliability of operation across devices and that the system be able to detect chemically induced changes in experimental endpoints. This study was designed to evaluate the performance and sensitivity of a system (Hamilton-Kinder MotorMonitor Activity System) to measure locomotor activity in large animals. The performance validation consisted of eight sessions for each of four enclosures; two each day; one in the am and one in the pm for four consecutive days. At random intervals throughout the 1-hour session a remote control was used to steer an object in each enclosure. The total rest time of each performance session for the object was calculated manually and compared to the total rest time recorded by the system software. To demonstrate the sensitivity of the system to detect drug-induced changes in motor activity, 12 adult male Beagles were used in a Latin Square design in which each animal served as its own saline control and received first d-amphetamine (0.1, 0.3 and 1 mg/kg i.m.) and then chlorpromazine (1, 3 and 10 mg/kg i.m.) during the course of the study. Basic movements (fine + ambulatory counts) were recorded in each 60-minute test session which consisted of twelve 5-minute epochs. The results for the performance evaluation indicated a mean difference of < 2 seconds between the manual and software calculated total rest times for each enclosure over four consecutive days, which met the acceptance criteria of ± 5 seconds. Administration of d-amphetamine resulted in detectable dose-related increases of 50%, 66% and 79% in basic movements above control values, while chlorpromazine induced detectable dose-dependent decreases of 25%, 53% and 70% below controls for basic movements. These results demonstrate that the performance of this activity system is reliable and can detect chemically induced changes in locomotor activity for Beagles.

1288 CONFIRMATION OF BLOOD IN FECES USING HEMATEST® REAGENT TABLETS: COMPARATIVE EVALUATION WITH CANINES, NON-HUMAN-PRIMATES, AND RATS.

Z. Adams, K. Andrew, T. Geary, C. Ziemba, M. Oquendo, A. Atwood, M. Maddix, N. R. Vansell and E. R. Kirchner. *Regulatory Toxicology, Wyeth-Ayerst Research, Chazy, NY.*

Hematest® Reagent Tablets, marketed for the detection of occult blood in human feces, have been used to confirm the presence of blood in laboratory animal fecal material. Discrepancy between visual observation and assay results forced into question the utility of the test in laboratory animals. The purpose of this study was to determine whether Hematest® Reagent Tablets provide useful information for confirming the presence of blood in laboratory animal feces. Fecal observations were recorded from 5 canines and non-human primates (NHP) per sex and from 5 cages of rats per sex (2 per cage) for 10 days. Four random samples per animal or cage were tested per day with the Hematest® Reagent Tablets. All fecal samples were visually observed for the presence of red pigment and those containing red pigment were tested in lieu of a random sample. Of the 396 canine samples collected, approximately 4% were visually noted to contain red pigment; 71% of those samples observed with red pigment tested positive for blood in feces. Of the total number of samples observed with or without red pigment, 60% tested positive for the presence of blood with Hematest® tablets. In NHP, 8% of all fecal samples observed contained red pigment, of which 91% subsequently tested positive for blood in feces. Hematest® results were positive in 46% of the total NHP fecal samples collected. In rats, no samples observed during the 10 days were visually noted to contain red pigment, however, 89% of all fecal samples collected tested positive for occult blood. These findings indicate that in the species examined and manner used, Hematest® Reagent Tablet assay results do not agree with the observations of red pigment (or lack thereof) in feces. Because of the high incidence of positive results in naïve animals, the test may be inappropriate and misleading when used in laboratory animals to confirm a visual observation of red pigment as blood in feces.

1289 FECAL BILE ACID EXCRETION AND PROFILE IN THE BEAGLE DOG CHARACTERIZATION ACCORDING TO SEX AND AGE.

C. E. Wilker, S. S. Morton, K. M. Stanfield, B. T. Keller and E. T. Blomme. *Global Toxicology, Pharmacia, Skokie, IL.* Sponsor: M. Schlosser.

Beagle dogs are commonly used as a nonclinical model for the safety assessment of industrial chemicals, pesticides and human pharmaceuticals. In general each laboratory maintains a historical data base for routine parameters including hematology and clinical chemistry values. However, similar data are limited or not available for non-routine tests such as fecal bile acid (FBA) excretion and profile. Thus, as a reference, FBA excretion and profile were determined in male and female beagle dogs at ages ranging from 6 to 18 months. Feces were collected over a 48-hour period and were processed and evaluated enzymatically for the concentrations of 3α-hydroxy bile acids (which account for approximately 85% of total fecal bile acids in dogs). These samples were further analyzed by LC/MS to provide concentrations of specific α-hydroxy bile acids -cholic acid (cholic), deoxycholic acid (deoxy), chenodeoxycholic acid (cheno), and lithocholic acid (litho). The results obtained are presented in the table below. Fecal bile acid excretion decreased with age in males. Deoxycholic acid was the predominate bile acid in feces. There were no major changes in the proportions of the major α-hydroxy bile acids between sexes and among the different age groups. However, the ratio of Deoxycholic:Cholic acid was greater in females than males indicating greater intestinal bacterial dehydroxylation in females.

MALE					
Age (months)	**Fecal Bile Acids (μmoles/kg/day)**	**Cholic * (%)**	**Deoxy* (%)**	**Cheno* (%)**	**Litho* (%)**
6	45.0	5.6	76	2.4	15.9
12	30.8	9.6	75.1	2.3	13.0
18	19.9	7.6	73.5	2.2	16.7
FEMALE					
6	40.3	6.5	84.8	1.6	13.8
12	36.7	9.7	78.3	1.7	10.2
18	29.0	4.5	81.3	1.3	12.9
*The proportion or percentage of each of the bile acids was calculated by dividing the concentration of each bile acid by the total concentration of the four bile acids examined					

1290 A COMPARISON OF FECAL BILE ACID EXCRETIONS IN CD, WISTAR, LONG EVANS, HSD:SD, AND F344 FEMALE RATS.

C. M. Salamon, C. E. Wilker, K. M. Stanfield and E. A. Blomme. *Regulatory Toxicology, Pharmacia Corporation, Skokie, IL.* Sponsor: M. Schlosser.

Rodent suppliers maintain and publish hematology and clinical chemistry values for routine parameters. However, similar data are not available for non-routine tests such as fecal bile acid (FBA) excretion. Therefore, to provide this information for reference, and to compare strain variations, fecal bile acid concentrations were determined for five different strains of female rats: Crl:CD®(SD)IGS BR and Crl:(WI)BR (Charles River, Portage, MI), Crl;(LE)BR, (Charles River, Rawleigh, NC), and Hsd:SD and F344/NHsd (Harlan Sprague-Dawley, Indianapolis, IN). The age of the females ranged from 8 to 11 weeks. Feces were collected over a 72-hour period and were processed and evaluated enzymatically for the concentrations of 3α-hydroxy bile acids (which account for approximately 70% of total fecal bile acids). These samples were further analyzed by HPLC to determine the concentrations of specific bile acids: cholic acid (cholic), deoxycholic acid (deoxy), chenodeoxycholic acid (cheno), and lithocholic acid (litho). The results obtained are presented in the table below. Fecal bile acid excretions ranged from 67.9 µmol/kg/day for the HSD rats to 104.6 µmol/kg/day for the F344 rats. F344 rats had higher concentrations of deoxycholic acid than the other strains. In general, concentrations of cholic acid and lithocholic acid were similar among the strains. Chenodeoxycholic acid was usually present at concentrations below the level of sensitivity of the assay. Concentrations are presented in µmol/kg/day

Strain	FBA	Cholic	Deoxy	Cheno	Litho
CD	91.1	0.867	3.804	0	2.237
WI	67.9	0.404	2.797	0	2.515
LE	97.1	2.087	4.293	0.354	3.917
HSD	76..6	0.282	3.366	0.010	2.003

1291 A COMPARISON OF THE IN-LIFE PARAMETERS AND TUMOUR DATA FROM TEN GANG-HOUSED DIETARY TUMORIGENICITY STUDIES USING THE SPRAGUE-DAWLEY INTERNATIONAL GENETIC STANDARD OR HAN WISTAR STRAINS OF RAT.

W. N. Hooks and S. M. Harling. *Toxicology/Pathology, Huntingdon Life Sciences, Huntingdon, United Kingdom.* Sponsor: C. Atterwill.

The in-life and tumour data were reviewed from the control groups of ten gang-housed dietary tumorigenicity studies completed over 1994 to 1999. Five studies using the Sprague-Dawley International Genetic Standard rat (SD IGS) from Charles River, UK were compared with five studies using the Han Wistar rat from Bioresearch Laboratories, Switzerland. Low protein maintenance diet was used in these studies. The comparisons have shown that the percentage mortality at 2 years for the Han Wistar rat studies (18% in males and 26% in females) was considerably lower than that of the SD IGS rat studies (57% in males and 66% in females). The bodyweight and food consumption data obtained for the Han Wistar rat were also considerably lower in comparison with the SD IGS rat. The most prevalent tumours in both groups were pituitary adenoma in both sexes and mammary tumours in females (also the major pathological factors contributory to death). However, the incidence of these tumours was lower in the Han Wistar rat group in both sexes. Other notable differences between the groups were a higher incidence of subcutaneous fibroma and adrenal phaeochromocytoma in SD IGS male rats and lymph node haemangioma in Han Wistar male rats. In conclusion, the Han Wistar rat has a satisfactory tumour profile and, when compared with the SD IGS rat, a high survival rate. Additionally, on the basis of regulatory requirements to reach 2 years with an adequate number of survivors the Han Wistar rat would be a suitable strain to use without recourse to diet optimisation methods.

1292 EVALUATION OF SELECTED PSYCHOACTIVE DRUGS IN THE RAT USING A MODIFIED IRWIN TEST.

P. R. Atterson[1], J. J. Mitchell[2], J. A. Lord[2], F. E. Munro[2] and L. Patmore[2]. [1]*Department of Safety Pharmacology, Quintiles Inc., Kansas City, MO and* [2]*Department of Pharmacology, Quintiles Ltd., Edinburgh, United Kingdom.* Sponsor: R. Long.

The characterization of the general pharmacology of drugs by observational techniques in mice is a widely-used approach in the pharmaceutical industry to profile the properties of newly-synthesized agents and to evaluate their safety prior to clinical testing. A systematic study to characterize the effects of some selected psychoactive drugs has been carried out in the rat using a modification of the original Irwin procedure. Groups of 6 male Sprague-Dawley rats were orally dosed with vehicle (1% methylcellulose), chlorpromazine (10-50 mg/kg), amphetamine (2-10 mg/kg), diazepam (10-50 mg/kg) or morphine (10-50 mg/kg). Each rat was then systematically evaluated using a procedure in which previously-defined parameters were scored (0-8) according to their intensity. Parameters already present were scored "4" with potentiation or depression scored higher (4-8) or lower (4-0), respectively. Rats dosed with chlorpromazine showed catalepsy, decreased alertness, decreased sensory responses, hypothermia and ptosis. Rats dosed with amphetamine displayed behavioural arousal with increased locomotor activity, restlessness, increased sensory responses, piloerection and stereotyped behaviour. Rats dosed with diazepam displayed behavioural passivity with mild catalepsy, decreased alertness, decreased grooming, some decrease in sensory responses with some impairment of the righting reflex. Rats dosed with morphine displayed increased alertness, increased grooming and increased locomotor activity, exopthalmos, decreased response to pain and compulsive licking. The general observations were consistent with varying levels of depression or stimulation of the central nervous system together with specific and characteristic signs for the drugs tested and it is concluded that observational testing in the rat using a modified Irwin procedure provides a means of discriminating drugs on the basis of changes in behaviour and identifying their safety.

1293 APPLICATION OF UNRESTRAINED WHOLE BODY BIAS FLOW PLETHYSMOGRAPHY TO MEASURE RESPIRATORY PARAMETERS IN THE CONSCIOUS RAT.

S. M. Jordan, C. Davies, A. Murphy and C. N. Williams. *Pharmacology, Huntingdon Life Sciences, Alconbury, United Kingdom.* Sponsor: C. Atterwill.

It is essential that potential undesirable effects on the respiratory system, of new pharmaceutical, veterinary or agricultural products, are properly evaluated prior to exposure to humans. In this context, the revised ICH Guidelines on Safety Pharmacology Studies for Human Pharmaceuticals (S7A) identify assessment of *in vivo* effects on the respiratory system, as part of the Safety Pharmacology core battery. To meet the S7A guidelines and as part of our safety pharmacology R&D programme, the Department of Pharmacology has developed procedures for the measurement of a number of respiratory parameters in conscious, freely moving rats. The equipment (Buxco Electronics) comprises whole body plethysmographs connected to a data acquisition computer enabling real time analysis (using Biosystem XA software). This allows the determination of a number of respiratory parameters including respiration rate, tidal volume and minute volume. Preliminary baseline studies showed that there were no statistically significant differences in respiratory parameters between Sprague-Dawley and Wistar rats, sex or time of day of recording although not surprisingly, there was evidence of habituation with repeated or prolonged exposure. To demonstrate ability of the system to detect drug effects on respiratory parameters, studies were conducted using morphine sulphate and theophylline, administered as single dosages either by oral gavage or intravenous injection, to male and female Wistar rats. As expected, relative to vehicle-treated animals, morphine depressed respiration whereas theophylline increased respiration rate with consequential increases in minute volume. These drug results confirm the ability of whole body plethysmography to detect potential side effects of substances on the respiratory system in freely moving rats. The methodology ideally meets the ICH guidelines for an *in vivo* core safety pharmacology study using conscious animals under the preferred conditions of nonrestraint.

1294 IV LOCAL TOLERANCE STUDIES: HOW TO REDUCE THE NUMBER OF ANIMALS?

U. Mentzel and O. M. Loget. *Non-Clinical Drug Safety, F. Hoffmann-La Roche, Basel, Switzerland.* Sponsor: M. Stephan-Gueldner.

For oral compounds (iv bioavailability study in man) local tolerance is usually assessed in rat. For iv compounds, general toxicology studies can be used to assess this. For compounds infused in non-clinical trials *via* central veins, local tolerance may have to be assessed in a peripheral vein: first choice again is rat. Due to too long study duration and small size of rodent veins, other species could be preferred. Generally no bolus injections are performed but slow injections, or short or continuous infusions. Centrally a vena cava is used for continuous infusion. The anterior one should be avoided for local tolerance, because it is difficult to be sure that the tip of catheter was in vein and not in heart. Different injection sites can be used superficially. For rats the tail vein is appropriate. For rabbits and minipigs a marginal ear vein is generally used. Other superficial injection sites could be used to check the risk of misdosing. Several concentrations may have to be tested and placebo and ideally saline control groups should be added. The total number of animals can thus be quite high. Especially if several veins have to be used, several necropsy occasions are scheduled and/or further groups have to be added, taking into considera-

tion first findings (with first tested concentrations). We propose different ways to reduce this number. 1/ Several veins from the same animal (e.g., one central and four superficial veins on different days) could be used, allowing evaluation of local tolerance at different times after treatment. 2/ Animals implanted and dosed in different weeks (however needed for continuously infused animals, e.g., one week per concentration), allowing easier and better concentration selection and avoiding useless concentrations. 3/ Some investigations could be performed during pilot escalating dose studies (e.g., on different days before necropsy): visual evaluation and grading of the external aspect of the superficial injection sites, and echography or MRI of superficial as well as central vessels.

1295 A PRIMARY SKIN IRRITATION STUDY OF ELECTROTRANSPORT SYSTEMS ON HAIRLESS GUINEA PIGS AND RABBITS.

A. E. Chester and P. Quigley. *NonClinical R&D, ALZA, Mountain View, CA.*

The objective of this study was to evaluate the potential degree of dermal inflammation produced by three different E-TRANS® (placebo) systems containing cetylpyridinium chloride (CPC)(0.08% or 0.2%) in the cathode hydrogel and one of two adhesives to adhere the systems to the skin. Each system had an anode and cathode. All of the systems had the same anode hydrogel formulation. Systems were applied to the intact dorsal skin of 12 hairless guinea pigs (1 or 2 systems/guinea pig) and 6 New Zealand White (NZW) rabbits (3 systems/rabbit). The total wearing time was approximately 13.3 hours. The direct current density was approximately 71.4 $\mu A/cm^2$ (based on a hydrogel area of 1.4 cm^2 and a total current of approximately 100 microamps) at both the anode and cathode. Application sites were scored for erythema and eschar formation and edema (modified Draize method) 0.5, 24, and 48 hours after system removal, and Primary Irritation Indexes were calculated. No treatment-related changes occurred in body weights or clinical conditions. No mortality occurred. The Primary Irritation Indices are presented below. Histopathology results supported the mild irritation observed. In conclusion, the cathode hydrogels containing 0.08% or 0.2% CPC were mild irritants in guinea pigs and rabbits. The anode hydrogel was a mild irritant in guinea pigs and a non-to mild irritant in rabbits.

	Hairless Guinea Pig		NZW Rabbit	
Cathode Formulation	Anode	Cathode	Anode	Cathode
0.08% CPC/Adhesive 1	1.3 (mild; n=5)	1.6 (mild; n=5)	0.0 (none; n=6)	1.4 (mild; n=6)
0.2% CPC/Adhesive 1	0.9 (mild; n=6)	2.0 (mild; n=6)	0.3 (none to negligible; n=3)	1.8 (mild; n=3)
0.2%CPC/Adhesive 2	1.3 (mild; n=6)	2.0 (mild; n=6)	0.6 (mild; n=4)	1.6 (mild; n=4)

1296 ASSESSMENT OF RETINAL DEGENERATION IN OUTBRED ALBINO MICE.

L. M. Serfilippi[1], D. R. Pallman[1], M. M. Gruebbel[2], T. J. Kern[3] and C. B. Spainhour[1]. *[1]Calvert Preclinical Services, Inc., Olyphant, PA, [2]EPL, Herndon, VA and [3]Cornell University, Ithaca, NY.*

Complete evaluations of a drug's safety necessarily include an ophthalmic assessment. Various stocks of mice are typically used in nonclinical safety studies. However, despite the genetic diversity that breeders attempt to maintain in outbred populations, certain genetic constitutions develop that provide sensitivities of which both breeders and toxicologists are unaware. Increased sensitivity to light in a laboratory animal can confound the interpretation of ophthalmic data generated from a particular study. Retinal degeneration (RD) was observed to occur in outbred albino mice (HsdICR.CD1). Such a pathologic manifestation has been reported to be associated with an autosomal recessive gene rd, retinal degeneration. In an effort to evaluate the genetic basis for the observation of RD in HsdICR.CD1 mice, a study was conducted comparing the light sensitivity of the following stocks/strains of mice: Hsd:ICR(CD-1); Hsd:NSA(CF-1); HsdWin:CFW-1; Crl:CD-1(ICR)BR; Crl:CF-1BR; Crl:CFW(SW)BR; Tac:Icr:Ha(ICR); Tac(SW); FVB/NCrlBR; and C57BL/6J-$Tyr^{c-2J/+}$. FVB/NCrlBR was used as a positive control since it has been established that these animals carry an rd gene. C57BL/6J-$Tyr^{c-2J/+}$ was used as a negative control since these animals have been reported to be resistant to retinal degeneration. Mice were observed over a twelve-week period of time. Average room and in-cage illumination were determined. Hematology and serum clinical chemistry revealed no abnormal findings. Histopathologic evaluation revealed clear differences. Affected stocks/strains did not exhibit sex-related differences, except for Hsd:ICR(CD-1) mice, in which retinal atrophy was almost twice as common in males as females. Incidences of retinal atrophy for the various stock/strains were: Hsd:ICR(CD-1) (43.3%); Crl:CF-1BR (3.0%); Crl:CFW(SW)BR (98.3%); Tac:Icr:Ha(ICR) (75%); Tac(SW) (80%); and FVB/NCrlBR (100%). No retinal atrophy was observed in the following strains: Hsd:NSA(CF-1); HsdWin:CFW-1; Crl:CD-1(ICR)BR; and C57BL/6J-$Tyr^{c-2J/+}$.

1297 BIOPHOTONIC IMAGING IN HO-LUC TRANSGENIC MICE: REAL-TIME DEMONSTRATION OF GENDER SPECIFIC CHLOROFORM INDUCED RENAL TOXICITY.

L. R. Weir, E. Schenk, J. Meakin, R. Driver, K. Rush, F. McClure, J. Fuller, M. York and A. M. Lynch. *Safety Assessment, GlaxoSmithKline, Welwyn, United Kingdom.* Sponsor: P. Trennery.

The metabolism of luciferin in mice transgenic for luciferase (HO-luc) produces light that may be detected *'trans-vivo'* by an intensified CCD camera (biophotonics). Thus the generation of transgenic promoter-luciferase animals for genes regulated by specific toxic processes, coupled with real-time evaluation of site-specific gene expression may provide novel, non-invasive *in vivo* biomarkers which are predictive of developing toxicity. As part of a programme to evaluate the potential of biophotonics for predictive toxicology we have conducted a series of studies in HO-luc mice, transgenic for the murine heme oxygenase-1 promoter (Xenogen, CA, USA). Chloroform induced renal toxicity shows a marked gender difference in mice, with males being much more sensitive than females due to the expression of CYP2E1 in male mouse kidney. CYP2E1 mediated oxidative metabolism converts chloroform to phosgene and results in covalent binding to proteins and depletion of glutathione. However, when female mice are pre-treated with testosterone the expression of renal CYP2E1 removes the gender difference and the kidneys become susceptible to chloroform toxicity. As part of the evaluation of HO-luc Tg mice, male and female animals were treated with chloroform (200 mg/kg, p.o., daily for 5 days) and imaged 2 and 6 hours after dosing. During a two-day washout period, female animals were treated daily with testosterone prior to repeat administration of chloroform for a further 5 days. Comparison of the *in vivo* response of the luciferase reporter with markers of toxicity measured *ex vivo* (differential gene expression of antioxidant system response genes, clinical chemistry and pathology) confirms the gender specific difference in chloroform renal toxicity in HO-luc Tg mice, and correlates with the expression of the endogenous HO-1 gene. These studies demonstrate the capacity of biophotonics for real-time site-specific gene expression, which may be predictive of developing toxicity.

1298 INTERPRETING TOXICITY STUDIES; RECOGNISING EFFECTS AND DIFFERENTIATING BETWEEN ADVERSE AND NON-ADVERSE EFFECTS.

R. W. Lewis[1], R. Billington[2], E. Debruyne[3], A. Gamer[4], B. Lang[5], J. van Miller[6] and F. Carpanini[7]. *[1]Health Assessment, Syngenta CTL, Macclesfield, United Kingdom, [2]Agroscience, Dow Agroscience, Oxford, United Kingdom, [3]Toxicology, Aventis Crop Protection, Sophia Antipolis, France, [4]Toxicology, BASF AG, Ludwigshaven, Germany, [5]HSA, Syngenta AG, Basel, Switzerland, [6]TRS Services Inc, Charlottesville, VA and [7]ECETOC, Brussels, Belgium.*

It is difficult to find criteria that can be used to guide consistent interpretation of toxicity studies. A two step process is outlined to address this issue. Differences from control values are initially evaluated in order to decide if they are treatment related or if they are chance deviations. In the second step, only those differences judged to be effects are further evaluated in order to discriminate between those that are adverse and those that are not. In differentiating an effect from a chance finding, criteria used to aid evaluation are: Dose-Response, consideration of spurious measurements, the precision of the measurement under evaluation, ranges of natural variation and the overall biological plausibility of the observation. In discriminating between the adverse and the non-adverse effect it is important to consider: whether the effect is an adaptive response, whether it is transient, the magnitude of the effect, its association with effects in other related endpoints, whether it is a precursor to a more significant effect, whether it has an effect on the overall function of the organism, whether it is a specific effect on an organ or organ system or secondary to general toxicity or whether the effect is a predictable consequence of the experimental model. In interpreting complex studies it is recognised that a weight of the evidence approach, combining the criteria outlined above to reach an overall judgement, is the optimal way of applying the process. It is believed that the use of such a scheme will help to improve the consistency of study interpretation that is the foundation of hazard identification and risk assessment.

1299 APPLICATION OF *IN SILICO* APPROACHES TO TOXICITY PREDICTION.

A. C. White, R. A. Mueller and A. G. Wilson. *Preclinical Development, Pharmacia Corporation, St. Louis, MO.*

In recent years there has been an increasing requirement for the early selection of lead drug candidates as a way to improve the efficiency of the drug discovery process. This has led to the emergence of highthroughput screening assays for

ADME and toxicity prediction. A rapidly developing adjunct to this approach for drug discovery is the use of computer based (*in silico*) prediction tools. In this presentation we will describe the results of a validation study of over 2400 structures analyzed by predictive systems (TOPKAT, DEREK, CASETOX) and compare their accuracy to predict toxicity for a series of proprietary and commercial molecules. Statistical analysis of the results showed the accuracy of individual programs for novel structures to be in the range of 65-75%. When we used the predictive systems in combination the accuracy increased to greater than 90%. We have developed a decision tree approach to support the use of these programs for decision-making that will also be discussed.

1300 SAFETY EVALUATION OF PHENOL AND *M*-CRESOL AS INACTIVE INGREDIENTS IN SUBCUTANEOUS DOSAGE FORMULATIONS.

G. H. Goodfellow[1], E. Cheng[1] and J. M. Daniels[1,2]. [1]*Pharmaceutical & Healthcare Group, Cantox Health Sciences International, Mississauga, ON, Canada and* [2]*Pharmaceutical & Healthcare Group, Cantox Health Sciences International, Bridgewater, NJ.*

Phenol and *m*-cresol exhibit a wide range of overlapping commercial applications as demonstrated by their usage in the pharmaceutical, chemical, and agricultural industries. In pharmaceutical applications, their primary functional role is the antimicrobrial preservation of drugs formulated for intramuscular, intradermal, and subcutaneous injections. Extensive use of these compounds in approved subcutaneous dosage forms is well documented in the US Food and Drug Administration's *Inactive Ingredients Guide* at levels up to 0.5% for phenol and 0.31% for *m*-cresol. In order to understand more fully any potential risks associated with the use of these compounds, the comparative safety of phenol and *m*-cresol was investigated. In acute subcutaneous toxicity studies performed in mice, rats, guinea pigs, and rabbits, the LD_{50} values for phenol and *m*-cresol were comparable and in excess of 300 mg/kg. Similar toxicological profiles (reduced water consumption, body weight loss, and nephropathy) were observed in 90-day rodent toxicity studies. In F344 rats treated with 0 to 780 mg/kg/day phenol in drinking water for 90 days, the lowest-observed-adverse-effect level (LOAEL), based on decreased water intake and body weight gain, was 780 mg/kg/day. A LOAEL, also based on weight gain reduction, was observed at 150 mg/kg/day in Sprague-Dawley rats administered *m*-cresol (0 to 450 mg/kg/day) by oral gavage for 90 days. It is concluded that the use of either of these compounds in subcutaneous dosage formulations is strongly supported by the similarity of the results in available animal data, and preference for one agent over the other should be based upon other considerations.

1301 A 3-MONTH DIETARY TOXICITY STUDY IN RATS WITH POLYVINYL ALCOHOL.

C. M. Kelly[1] and C. C. DeMerlis[2]. [1]*Huntingdon Life Sciences, East Millstone, NJ and* [2]*Colorcon, West Point, PA.*

Polyvinyl Alcohol (PVA) is a water-soluble synthetic polymer prepared from the polymerization of vinyl acetate and the subsequent partial hydrolysis of polyvinyl acetate. PVA is used as a polymer for film coating pharmaceutical and dietary supplement tablets where moisture barrier/protection properties are required. A special grade of PVA was used in this study that is produced to meet global pharmaceutical standards using good manufacturing practices (GMP's). The PVA grade is characterized by compendial and proprietary specifications. The impurities are strictly monitored by process controls, stringent specifications and analytical methods developed by the manufacturer. The potential systemic and neurotoxicity of PVA was assessed when fed in the diet to Sprague-Dawley rats (20/sex/group) for 90 days at dose levels of 2000, 3500 and 5000 mg/kg/day. Control rats received untreated standard laboratory diet. Assessments included clinical observations, ophthalmology, body weight and food consumption, hematology, coagulation, clinical chemistry, urinalyses and motor activity and functional observational battery evaluations. After 3 months of treatment, selected organs were weighed, and complete macroscopic as well as histopathological and neuropathological evaluations were conducted. The only test article-related finding observed during the study was unformed stool with brown/black anogenital staining in rats fed 3500 and 5000 mg/kg/day. This finding was attributed to the high levels of test article being consumed and subsequently excreted in the stool. It was not accompanied by changes seen macroscopically or microscopically in these rats. No test article-related changes were seen in mortality, ophthalmology, bodyweight and food consumption data, hematology, clinical chemistry, urinalysis data, functional observational assessments, motor activity, organ weight data and macroscopic and microscopic examinations. Dietary concentrations of 2000, 3500 and 5000 mg/kg/day of PVA to Sprague-Dawley rats for up to 90 days did not result in any adverse, toxicological effects.

1302 13-WEEK GAVAGE TOXICITY STUDY OF 5-(HYDROXYMETHYL)-2-FURFURAL (HMF) USING F344 RATS AND B6C3F1 MICE.

M. Hejtmancik[1], J. D. Johnson[1], S. W. Graves[1], A. W. Singer[1], M. R. Ryan[1], R. Irwin[2], R. Chhabra[2] and M. Vallant[2]. [1]*Toxicology, Battelle, Columbus, OH and* [2]*National Toxicology Program, NIEHS, Research Triangle Park, NC.*

HMF, a furan compound formed during the thermal decomposition of hexose sugars and carbohydrates, is ubiquitous in the human diet and a contaminant of parenteral solutions of glucose and fructose sterilized by heating or autoclaving. F344/N rats and B6C3F1 mice (10 animals/sex/group) were given HMF by gavage at doses of 47 (mice only), 94, 188, 375, 750, or 1500 (rats only) mg/kg, 5 days/week for 13 weeks. Controls received the vehicle only (deionized water). Survival decreased for the 1500 mg/kg group male (9/10) and female (7/10) rats. Group mean body weight decreased 14 percent (relative to control) for the male 750 mg/kg group mice. Rat urine volume increased (1500 mg/kg) and urine creatinine decreased (≧375 mg/kg, m; ≧750 mg/kg, f). There were no HMF-related changes in clinical observations and clinical pathology. Mouse kidney weights decreased and microscopic findings were limited to large clear cytoplasmic vacuoles in the proximal tubular epithelial cells (≧188 mg/kg, m). Gross and microscopic findings were similar to control for the rats. (Supported by Contract No. N01-ES-15320.)

1303 ACUTE AND CHRONIC TOXICITY OF BITUMEN-SALT MASS END-PRODUCTS FROM THE DESTRUCTION OF RUSSIAN SARIN, SOMAN AND VX.

V. G. Zoryan, E. I. Malochkina, O. A. Khodakovskaya and A. S. Pushkin. *The State Scientific and Research Institute of Organic Chemistry and Technology (GosNIIOKhT), Moscow, Russian Federation.* Sponsor: L. Chaney.

In support of Cooperative Threat Reduction, the Russian Federation (RF) (GosNIIOKhT) participated in joint studies with the U. S. Army Center for Health Promotion and Preventive Medicine (USACHPPM) to investigate the toxicity of materials leached from bituminous salt masses (BSM) containing by-products from a chemical demilitarization process developed by the RF. These studies determined hazard categories for the BSMs and evaluated the effects of long-term exposure to leachates from the BSMs in animals. Acute oral toxicity values (LD50) were determined in rodents for the components of BSM resulting from the destruction of Russian sarin (GB), soman (GD) and VX. Inhalation studies in rats evaluated the toxicity of volatile components resulting from heating (up to 130 °C) the BSMs, a process similar to that involved in the second phase of BSM production. Chronic toxicity was also investigated over six months in rats. Using a leaching process developed by GosNIIOKhT, aqueous leachate solutions were produced from bitumen alone, or GB-, GD- or VX-BSM. For each leachate, five groups of animals were dosed orally five days per week. Three groups were administered leachate at concentrations of 100%, 20% or 4%. Two other groups served as controls and were exposed to either leachate derived from bitumen alone, or ground water. Various physiological, biochemical and hematological indices as well as histopathology were evaluated. Results indicated no adverse effects in rats following inhalation of volatile components or chronic oral exposure to leachates from GB-, GD- or VX-BSM. Data from these experiments placed each BSM into a low hazardous toxicity category (Category IV), according to RF standards. The data is supported by toxicity studies conducted by USACHPPM.

1304 NINETY-DAY SUBCHRONIC ORAL TOXICITY OF AQUEOUS LEACHATES DERIVED FROM BITUMINOUS-SALT MASSES CONTAINING REACTION BY-PRODUCTS FROM THE NEUTRALIZATION OF U. S. OR RUSSIAN NERVE AGENTS.

L. A. Chaney, M. W. Michie, W. C. McCain, M. S. Johnson, R. A. Angerhofer, G. D. Young and R. E. Baumgartner. *Directorate of Toxicology, U.S. Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground - Edgewood Area, MD.*

In support of Cooperative Threat Reduction activities, the U. S. Army Center for Health Promotion and Preventive Medicine (USACHPPM) participated in joint studies with the Russian Federation (RF) to evaluate the subchronic oral toxicity of materials leached from the bituminous-salt mass (BSM) end-products of a chemical demilitarization technology developed by the RF. Subchronic oral toxicity studies were conducted by USACHPPM to address concerns that materials leached from the BSMs could pose a potential health threat to receptors in the vicinity of future storage/disposal sites in Russia. Aqueous leachate materials derived from Russian bitumen alone, BSM containing demilitarized U. S. manufactured sarin (GB), or Russian manufactured GB, soman (GD) or VX were prepared using a toxicity characterization leaching procedure (TCLP) and administered by gavage to adult male and female rats for 90 days. Dosage levels of leachate were set at 0, 4, 20, and 100%

of the test material, and were administered at 10 ml/kg body weight. Data included measurements of body weight, food consumption, serum chemistry, hematology, urinalysis, organ weights, histopathology, and immunotoxicology parameters. The results indicated that aqueous leachate materials derived from US GB-BSM, or RF GB-BSM, GD-BSM or VX-BSM caused no significant adverse health effects when administered subchronically to rats for the given test periods. This data supports and enhances the findings of additional joint toxicology studies conducted in Russia.

1305 GENOTOXICITY AND 90-DAY/DEVELOPMENTAL TOXICITY STUDIES ON AN EXPLOSIVE FORMULATION.

D. E. Dodd[1], S. Sharma[2] and G. M. Hoffman[3]. *[1]AFRL/HEST, ManTech Environmental, Dayton, OH, [2]ManTech Environmental, Research Triangle Park, NC and [3]Huntingdon Life Sciences, East Millstone, NJ.*

Composition B Replacement 12 (PAX-21) is a new explosive formulation that is being considered for replacement of the current explosive, Composition B (Comp B). PAX-21 differs from Comp B because it contains new components, such as 2, 4-dinitroanisole (DNA) and ammonium perchlorate (AP). Genotoxicity and 90-day/developmental toxicity studies were performed to evaluate potential toxic effects of PAX-21. PAX-21, Comp B, and DNA were mutagenic to bacteria (Ames assay). However, these substances were not mutagenic in Chinese Hamster Ovary cells (AS52/XPRT assay) and did not induce micronuclei in the Swiss CD-1 mouse polychromatic erythrocyte system. Mortality resulted in rats exposed for two weeks (6 hr/d, 5d/wk) to aerosol concentrations of DNA (the most volatile component of PAX-21)≧ 545 mg/m^3. Mild signs of toxicity and non-specific minimal metaplasia of laryngeal epithelium were observed at 165 mg/m^3. Rats were dosed (gastric intubation) with 0 (control), 15, 30, or 90 mg/kg-d PAX-21 for 90 days and monitored for general toxicity, including histopathology, neurotoxicity and blood methemoglobin measurements. Partial mortality was observed at 90 mg/kg-d, liver and thyroid weight alterations with slight (adaptive) heptaocellular hypertrophy at 30 mg/kg-d, and no observable adverse effects at 15 mg/kg-d (NOAEL). In a prenatal developmental toxicity study, rats were dosed (gastric intubation) with 0, 15, 30, or 60 mg/kg-d PAX-21 on gestation days 6-19. Mortality was observed at 60 mg/kg-d, maternal signs of toxicity and slight fetal body weight alterations at 30 mg/kg-d, and a NOAEL at 15 mg/kg-d. Results from these studies were used to propose an occupational exposure level of 0.35 mg/m^3 for PAX-21. (Supported by US Army Product Manager for Mortars in collaboration with US Air Force AFRL/HEST)

1306 APPLICATION OF TOXICOLOGY IN THE DEVELOPMENT OF ENVIRONMENTALLY-FRIENDLY ELECTRONIC COUNTERMEASURES.

D. P. Arfsten[1], C. L. Wilson[1], K. R. Still[1] and B. J. Spargo[2]. *[1]Naval Health Research Center Toxicology Detachment, WPAFB, OH and [2]Naval Research Laboratory, Washington, DC.*

Millions of thin, aluminum-coated fiberglass dipoles (i.e., "chaff"), ranging from 0.8 –7.5 cm in length, can be deployed by military aircraft and vehicles to confuse enemy radar. Chaff is stored onboard vehicles in small cartridges that consist of a piston, 0.5-1.5 million chaff fibers, a cartridge body, an endcap, and either a pyrotechnic charge or spring-loaded release mechanism that forces the piston through the cartridge body resulting in the liberation of the endcap and chaff dipoles. The accumulation of discarded styrene piston and endcaps in the environment from chaff training missions is a concern of the Department of Defense and other governmental agencies. The US Navy has embarked on a program to develop degradable chaff cartridges, pistons, and endcaps by the 2003 fiscal year. Five biodegradable materials are being considered for use. Degradability and environmental toxicity tests are helping to select the most suitable construction materials. Relative degradability of the materials is being evaluated by measuring total organic carbon (TOC) released by the materials over time in deionized water. Environmental toxicity testing of the biodegradation products from the five materials is being conducted in 2 terrestrial plant species and 7 species of aquatic organisms. Biodegradation products from each of the five biomaterials under consideration did not inhibit seed germination or affect shoot growth of Brassica rappa or Lepidium sativum significantly. Biodegredation products from 3 of the biopolymers were found to be toxic to aquatic organisms with LC50s ranging from 0.6 – 14.7 mg/l TOC. Information gained from these studies will be used for making decisions on which (if any) of the polymers will be suitable for the construction of biodegradable chaff cartridges, pistons, and endcaps. Tensile strength, ease of casting, production waste stream, and overall cost of manufacture are factors that also need to be considered.

1307 QUANTITATIVE DETERMINATION OF PETROLEUM HYDROCARBONS IN INDOOR AIR: AN ON-SITE TOOL FOR RISK ASSESSMENT.

J. F. Thingelstad and D. C. Tilotta. *Chemistry, University of North Dakota, Grand Forks, ND.* Sponsor: S. Pyle.

Many homes in the United States are heated with #2 fuel oil. In northern climates, fuel oil storage tanks are often kept in basements to avoid gelling during the winter months. During catastrophic flooding events, these tanks may rupture and release their contents. The spilled fuel oil then absorbs into the building materials (e.g. wood and concrete) and subsequently desorbs into the indoor air over time. Methods for on-site, quantitative determination of petroleum hydrocarbons in air were explored. Currently accepted methodologies (e.g. USEPA standard methods) require that air samples, regardless of sampling method, be transported to an off-site laboratory for analysis. During this transport, the possibility of analyte loss is introduced, and inaccuracies may arise in the obtained results. Accurate measurement of the concentration of airborne pollutants is essential for the determination of the health risk to individuals. On-site analyses not only reduce the risk of analyte loss, the results are also immediately available, and appropriate actions (i.e. removal of individuals present) may be taken with little or no delay. Portable Gas Chromatography (GC) equipped with an adsorbent resin (Tenax GR) trap was used for direct air sampling and chromatographic separation of gasoline, diesel fuel, aviation gas and #2 fuel oil. Analyses were also carried out with a hand-held Photoionization Detector (PID), which were compared to the GC results. The GC method showed comparable response factors for all test fuels, whereas the PID showed an increased response factor for gasoline. Both methods were linear over the tested range of concentrations, with good to fair reproducibility. A study of aging #2 fuel oil over a period of two weeks showed a fairly smooth drop of in response using GC methods, and somewhat erratic response with the PID.

1308 EVALUATION OF POTENTIAL HEALTH EFFECTS FROM INHALATION EXPOSURE TO MYCOTOXINS IN INDOOR OFFICE AND RESIDENTIAL ENVIRONMENTS.

B. J. Kelman, C. A. Robbins and L. J. Swenson. *GlobalTox, Redmond, WA.*

There have been numerous claims of human toxicity from molds in indoor office and residential environments. None of these claims include a quantitative analysis of exposure. To determine an upper limit of exposure to mycotoxins in office and residential environments, we created a simple inhalation exposure model based upon concentrations of representative mycotoxins in mold spores. The model uses: 1) the amount of mycotoxin per spore as reported in peer-reviewed literature, 2) the greatest concentration of spores which, in our experience, could credibly be present in continuously occupied space, 3) 100% retention of inhaled particles, 4) and 24 hour/day exposure duration. The maximum modeled exposures of some mycotoxins potentially found in molds that may grow indoors are: fumitremorgen A, 5.4 x 10^{-7} mg/kg; satratoxin H, 1.6 x 10^{-7} mg/kg; and trichoverrols, 5.6 x 10^{-8} mg/kg. These exposures are 10^4 – 10^6 less than reported lowest adverse effects levels in appropriate in vivo systems. Analogous assumptions can be used to establish a maximum modeled exposure of some better-studied and more toxic mycotoxins (not reported in offices or residences) to serve as a point of comparison. If molds produced the following mycotoxins in offices or residential environments, modeled exposures for aflatoxin B_1, ochratoxin A, and T-2 toxin would be 1.2 x 10^{-6} mg/kg, 1.0 x 10^{-4} mg/kg, and 9.1 x 10^{-5} mg/kg, respectively. For aflatoxin B_1 and ochratoxin A, the modeled exposures are at least two orders of magnitude below those considered safe by the USFDA for the most sensitive human population (children) by ingestion and by WHO for the most sensitive species by ingestion, respectively. For T-2 toxin, the modeled exposure for 24 hours is approximately 10^{-4} less than the estimated human acute oral LD_{50}. Ingestion data were used because quantitative inhalation data are not currently available. It appears that even when using extremely conservative estimates, it is nearly impossible to inhale sufficient mycotoxin in office and residential environments to produce meaningful toxic effects.

1309 EVALUATION OF THE SUBCHRONIC TOXICITY AND ONE GENERATION REPRODUCTIVE EFFECTS OF A FLUOROALKYLETHYL URETHANE POLYMER.

G. T. Makovec, D. A. Delker, E. Mylchreest and J. C. Stadler. *General Toxicology, DuPont Haskell Laboratory for Health and Environmental Sciences, Newark, DE.*

A fluoroalkylethyl urethane polymer, used as a carpet protectant, was evaluated for its oral subchronic toxicity and reproductive effects when administered to male and female rats by gavage at dosages of 0, 50, 250, or 1000 mg/kg/day. No compound-related mortality occurred in the study. No adverse clinical signs of toxicity or neurobehavior changes were observed in male or female rats in any dose group. Hepatocellular hypertrophy was observed after 90 days of dosing in male rats at all

dose levels. Nasal olfactory epithelium degeneration/necrosis was observed in male and female rats at all dose levels and inflammation of the olfactory epithelium in male rats dosed with 250 and 1000 mg/kg/day. Thyroid hypertrophy was seen in male and female rats in the 250 and 1000 mg/kg/day dose groups. After a 90-day recovery, hepatocellular hypertrophy was still present in male rats in the 250 and 1000 mg/kg/day dose groups. Nasal epithelial lesions were absent and evidence of reversibility of thyroid effects was observed after the recovery period. No test substance-related effects on reproductive parameters were observed. However, mean thyroid organ weight was significantly lower in the 250 and 1000 mg/kg/day dose groups in the F1 generation. There were no histopathological changes in the thyroid of the F1 generation rats. Due to the presence of nasal lesions, a no-observed-adverse-effect-level (NOEL) could not be determined for the subchronic toxicity evaluation. For reproductive assessments a NOEL of 50 mg/kg/day was determined based on decreased thyroid weights observed in both male and female F1 adults. It could not be determined whether the nasal lesions observed are due to systemic toxicity or local toxicity as a result of gavage dosing. Based on the other systemic effects observed at 250 mg/kg/day and above, the potential risk of human health effects from exposure to this product is very low.

1310 EVALUATION OF THE SUBCHRONIC TOXICITY AND ONE GENERATION REPRODUCTIVE EFFECTS OF A FLUOROALKYLETHANOL MIXTURE.

E. Mylchreest, J. C. Stadler, G. T. Makovec, N. E. Everds and G. S. Ladics.
DuPont Haskell Laboratory for Health and Environmental Sciences, Newark, DE.

The objective of this study was to evaluate the subchronic and reproductive toxicity of a fluoroalkylethanol mixture which is employed as an intermediate in the production of other fluoroorganic compounds utilized as protectants and surfactants. Test material was administered by gavage at dosages of 0, 25, 100, or 250 mg/kg/day. No test substance-related mortality or neurotoxicity occurred in the study. Body weights and/or nutritional parameters were significantly reduced at 100 and 250 mg/kg/day but similar to control after recovery. Broken and absent teeth were observed at 250 mg/kg/day. Microscopic tooth lesions (ameloblast degeneration/disorganization) occurred at 100 and 250 mg/kg/day and persisted after recovery. Plasma and urine fluoride levels were elevated in a dose-dependent manner. Decreased red cell mass parameters occurred at 250 mg/kg/day and persisted after 36 days of recovery. The 100 and 250 mg/kg/day groups had increased ($p < 0.05$) liver weights which persisted in the high dose after recovery and correlated with microscopic hepatocellular hypertrophy in males and females (250 mg/kg/day subchronic animals only). Hepatic β-oxidation was increased in a dose-dependent manner and persisted after recovery at 250 mg/kg/day. Increased kidney weights occurred at 25 (females only), 100 and 250 mg/kg/day which persisted in the high dose after recovery and correlated with microscopic tubular hypertrophy (males only). Thyroid follicular hypertrophy was present at 100 and 250 mg/kg/day but was not present after recovery. The test material contains 2% residual iodides. Litter size at birth and pup weights during lactation were reduced at ≥ 100 mg/kg/day. No other reproductive parameter was affected. There were no adverse effects observed for either subchronic or reproductive toxicity in animals dosed with 25 mg/kg/day. A wide margin of safety exists between potential human exposure levels and the doses which result in adverse effects.

1311 DIAMMONIUM PHOSPHATE EMPLOYED AS A CIGARETTE INGREDIENT: 13-WEEK CIGARETTE SMOKE INHALATION STUDY IN THE RAT.

M. Misra[1], J. D. Heck[1], C. L. Gaworski[1,2], N. Rajendran[3] and R. L. Morrissey[4].
[1]Lorillard Company, Greensboro, NC, [2]Philip Morris USA, Richmond, VA, [3]IIT Research Institute, Chicago, IL and [4]Pathology Associates, Chicago, IL.

Diammonium phosphate, $(NH_4)_2HPO_4$ [DAP], is employed as an ingredient in some cigarette tobacco blend components to enhance their organoleptic qualities through reaction with sugars to produce desirable flavoring compounds. The biological responses of male and female Fischer-344 rats exposed nose-only to smoke from filtered control cigarettes were compared to those of rats similarly exposed for 13 weeks to the smoke of test cigarettes containing DAP added directly to the tobacco blend or to a blend component in a manner resembling that employed in contemporary cigarette manufacturing. Test cigarettes contained DAP at five target levels of addition ranging from 882 to 10, 882 ppm in the final tobacco blend. Exposures of 350 mg/m^3 mainstream cigarette smoke were conducted for 1 hr/day, 5 days/week for 13 weeks. The cigarettes' smoke particulate and vapor phase nicotine yields were unaffected by any of the DAP additions. All smoke-exposed groups exhibited similar reductions in body weight gain and increases in blood carboxyhemoglobin, serum nicotine and cotinine relative to the sham control. Smoke-associated changes in respiratory rates and volume, clinical chemistry/hematology, organ weights, gross necropsy findings, and respiratory tract histopathology did not differ substantially among all smoke-exposed groups. All smoke-exposed groups exhibited a similarly reduced incidence and severity of respiratory tract histopathologic findings after a 6-week recovery period following the smoke exposure period. It is concluded that the addition of DAP to experimental cigarettes at levels resembling or exceeding those reportedly employed in contemporary cigarette manufacture does not significantly affect a variety of indices of smoke inhalation exposure or effect in this subchronic rat model.

1312 SAFETY ASSESSMENT OF HIGH FRUCTOSE CORN SYRUP (HFCS) AS AN INGREDIENT ADDED TO CIGARETTE TOBACCO.

M. S. Stavanja, P. H. Ayres, D. R. Meckley, E. A. Bombick, D. W. Bombick, M. F. Borgerding and J. E. Swauger. *R. J. Reynolds Tobacco Company, Winston-Salem, NC.*

Cigarette design has evolved over a century, with many new technologies introduced in the last several decades. Modifications to cigarette designs have historically involved the incorporation of new ingredients, papers, filters, and tobacco processes. The majority of ingredients are used to enhance aroma and flavor. Others are used to facilitate tobacco processing, facilitate cigarette manufacturing, and preserve moisture levels in the finished cigarette. RJRT has developed a tiered testing strategy to evaluate the potential for new ingredients, tobacco processes, and technological developments to increase or reduce the biological activity of cigarette smoke or cigarette smoke condensates (CSC). The core of RJRT's product stewardship program is comparative testing, typically including chemical and biological components. This comparative approach characteristically relies on the comparison of data from a test cigarette, incorporating the change, as compared to data from an appropriate control. As part of the ongoing stewardship efforts, cigarettes produced with high fructose corn syrup (HFCS), as added tobacco casing material, were subjected to an extensive evaluation. Principal components of this evaluation were an analysis of selected mainstream smoke constituent yields, an Ames assay in Salmonella typhimurium strains (TA98 and TA100), a sister chromatid exchange (SCE) assay in Chinese hamster ovary (CHO) cells and a neutral red cytotoxicity assay in CHO cells, a 30-week dermal tumor-promotion evaluation of cigarette smoke condensate in SENCAR mice, and a 90-day inhalation study of cigarette smoke in Sprague-Dawley rats. The results from these studies demonstrate that the addition of HFCS as an alternate tobacco casing material, up to an inclusion level of 3% dry weight in the final blend, did not produce a differential response in smoke chemistry or biological activity when compared to CSC or mainstream cigarette smoke from control cigarettes without added HFCS.

1313 CALAMUS:REASSESSMENT OF CARCINOGENICITY.

S. H. Humphreys, P. N. Dua, W. Franke-Carroll and P. M. Bolger. *Risk Assessment, USFDA, Washington, DC.*

The flavoring agents, Calamus acorus and its constituents, were considered carcinogens because of reported association of ingestion in feeding and gavage studies and intestinal (mesenchymal) cancers in the 1960's. Recent introduction of Calamus in dietary supplements again raises questions of potential hazards of ingesting Calamus. Osborne-Mendel rats were dosed with oil of calamus or *beta* ascarone, an alkylbenzene component of the oil, and not the plant itself. Often neither the species of Calamus was recorded or the level of ascarone, which ranges from 0 to 96% of the oil, depending on the cultivar and season, with the oil constituting up to 10% of the plant. Extant internal FDA reports reveal flaws in experimentation and interpretation. Absence of complete protocols, small numbers of rats used in the experiments, respiratory disease, poor survival, inadequate sampling of tissues for microscopic examination, and inadequate tissue preservation preclude definitive interpretation. Cardiac and hepatic lesions with chronic passive hyperaemia, growth depression, and mortality were reported in 18-week studies and most of the dose-response relationship claimed in 2-year carcinogenicity studies were in rats dosed well above the 18-week LD50. Examination of archived slides revealed pleomorphic, mesenchymal tumors, some similar to fibrous histiocytomas, a spontaneously occurring tumor type in Osborne-Mendel rats. Bias in over reporting tumors in experimental animals may explain why a positive control in one set of experiments was negative in another set. Other studies of carcinogenesis in mice after intraperitoneal injection of *beta* ascarone in 1987 and in 1999 described palpable hepatomas; but no histologic confirmation was made. The only known effect in humans is protracted emesis after ingestion of a whole rhizome. The relevance of these studies to occasional human oral ingestion of *beta* ascarone in the parts per billion range used for flavoring is equivocal. Available evidence is inadequate to establish the carcinogenic potential of Calamus acorus and its constituents.

1314 PEROXIDE DEGRADATION KINETICS DURING USE OF CREST WHITESTRIPS.

L. B. Patel, G. L. Walden, M. M. Kaminsky, R. E. Bailey and D. A. McMillan. *Central Product Safety, Procter & Gamble, Mason, OH.* Sponsor: D. McMillan.

Oral cavity and systemic exposure to peroxide are important measures of tooth whitening safety. This clinical trial evaluated the hydrogen peroxide (HP) degradation kinetics of 6.0% HP Crest Whitestrips (CWS) on the device, tooth and in saliva during use of this polyethylene strip-based tooth bleaching system. This was a single center, cross-over, 12 subject trial where only maxillary teeth were treated. Device, tooth, and saliva peroxide concentrations were determined at four time points: 5, 10, 30, and 60 minutes. The median peroxide concentrations on the strips at 0, 5, 10, 30, and 60 minutes wearing time were 6.1, 3.8, 3.4, 2.6 and 1.4%. The median peroxide concentrations on teeth at 5, 10, 30, and 60 minutes of strip wearing time were 4.0, 3.1, 3.0 and 1.7%. The median peroxide concentrations in saliva were 0.017, 0.004, 0.006 and 0.002% at 5, 10, 30 and 60 minutes. The concentration of peroxide on teeth was not significantly different from device. The HP concentration in saliva was significantly different from both device and teeth ($p<0.0001$ using a single ranked test). A comparison was made to a previous study with 5.3% HP CWS, 10% Opalescence (10% carbamide peroxide tooth whitening tray system, ~3.3% HP) and 20% Opalescence (20% carbamide peroxide, ~6.6% HP). Dose-Response relationships were observed for the device and teeth data with the 5.3% and the 6.0% HP CWS, as well as with the 10% and 20% Opalescence products. Overall, median salivary HP concentrations were less than 0.02% for any product at any time point measured. This clinical research confirms the safety of CWS by demonstrating the minimal systemic exposure and rapid degradation of HP during use.

1315 FROM EPIDEMIOLOGY TO THE GENE: MECHANISMS BY WHICH PARTICULATE MATTER INDUCES CARDIOVASCULAR EFFECTS.

R. B. Devlin and K. L. Dreher. *NHEERL, EPA, Research Triangle Park, NC.*

Much attention is currently focused on understanding the pathophysiological basis for the observed linkage between ambient air PM exposure and acute mortality. Although there are indications that PM may directly or indirectly affect the cardiovascular system, the biological mechanisms for most of these associations are unknown. A significant effort in PM health effects research has turned towards examining the toxicological mechanisms that underlie PM systemic effects. Recent epidemiology, clinical, and toxicology studies suggest that PM can induce changes in the autonomic control of the heart as well as alter blood components involved in the acute phase response, clotting and coagulation. This symposium will draw on recent cutting edge approaches that investigate PM effects of the cardiovascular system and will integrate information from panel, controlled human exposure, animal and *in vitro* studies. The first two presentations will describe how PM induces changes in heart rhythm and blood components involved in inflammation, the acute phase response, clotting, and coagulation. The next two presentations will describe changes in the cardiovascular system of animals exposed to PM, and will contrast these results with changes found in humans. The final presentation will explore *in vivo* and *in vitro* cardiac molecular effects produced by combustion PM

1316 CHANGES IN CARDIAC BIOMARKERS ASSOCIATED WITH AMBIENT PARTICLES.

A. Peters[1,2], A. Ibald-Mulli[1,2], R. Ruckerl[1,2], G. Wolke[1,2], M. Pitz[1,2], W. Koenig[3], V. Marder[4], W. Zareba[4] and E. Wichmann[1,2]. *[1]Institute of Epidemiology, GSF, Neuherberg, Germany, [2]Ludwig-Maximilians University, Munich, Germany, [3]University of Ulm, Ulm, Germany and [4]Department of Medicine, University of Rochester School of Medicine, Rochester, NY.* Sponsor: R. Devlin.

Ambient particles have been associated with exacerbation of cardiovascular disease. However, the biological mechanisms leading from the deposition of ambient particles to acute coronary disease are still to be elucidated. A panel of 58 patients with coronary artery disease has been studied in Erfurt, Germany during the winter of 2000/2001. The goal of the study is to quantify the role of fine and ultrafine particles in elicitation of an acute phase response and changes of the autonomous nervous system function. Repeated clinical examinations were conducted including EKG recording, blood pressure measurements and blood sampling. Ambient particles were characterised by a laser spectrometer and a differential mobility analyser proving particle number concentrations in the size range between 10 nm and 2.5 µm. Multivariate regression models using generalized linear models will be used to quantify the associations between physiological markers such as CRP protein or heart rate variability and ambient particle concentrations in different size ranges adjusting for time trend, metrological variables and viral infections. 683 examinations have been conducted over a half year period, which were more than 95% of the scheduled examinations. EKG readings and blood samples are currently being analysed. The contribution of the study to elucidate the biological mechanisms responsible for the observed health effects of ambient particles within a potentially susceptible subgroup of the general population will be discussed.

1317 CARDIOVASCULAR CHANGES IN YOUNG AND ELDERLY HUMANS EXPOSED TO CONCENTRATED AMBIENT AIR PARTICLES (CAPS).

R. B. Devlin[1], W. E. Cascio[2], H. Kehrl[1] and A. J. Ghio[1]. *[1]NHEERL, EPA, Research Triangle Park, NC and [2]Department of Medicine, University of North Carolina, Chapel Hill, NC.*

Epidemiology studies have shown an association between ambient air particles (PM) and mortality related to cardiovascular causes. In addition, recent panel studies have shown associations between PM and decreased heart rate variability in elderly people with cardiovascular disease. Panel studies have also shown associations between PM and changes in blood factors involved in viscosity and coagulation. The purpose of this study was to determine if exposure of young and elderly volunteers to moderate levels of PM under controlled conditions results in decreased heart rate variability and increased blood factors involved in coagulation. Twenty healthy young volunteers (aged 18 - 35) and 20 healthy elderly volunteers (aged 65 - 80) were exposed to concentrated Chapel Hill ambient air particles (CAPS) for two hours. Heart rate variability was determined before, immediately after, and 24 hrs after exposure. Decreases were observed in both time and frequency domain immediately following CAPS exposure in the elderly, but not young, subjects. No changes were apparent in either group 24 hours following exposure to CAPS. Both young and elderly subjects had increased blood factors involved in coagulation 24 hours after CAPS exposure. These data confirm and extend findings reported in panel studies and suggest a possible mechanism by which PM may cause increased cardiovascular mortality. This abstract of a proposed presentation does not necessarily reflect EPA policy.

1318 EFFECTS OF EXPOSURE TO PARTICULATE AIR POLLUTANTS IN ANIMALS WITH CARDIOVASCULAR DISEASE.

C. Nadziejko, T. Gordon and L. C. Chen. *Environmental Medicine, NYU School of Medicine, Tuxedo, NY.*

We have examined the effects of particulate air pollutants (PM) in normal rats and rats with cardiovascular disease to determine whether PM can cause adverse effects in cardiac function in the absence of exacerbation of respiratory disease. Normal young rats, old rats (18 months old), and spontaneously hypertensive rats (SHR) were implanted with either EKG transmitters or blood pressure transmitters. A single 4-6 hr exposure to concentrated ambient PM (CAP) caused a significant change in heart rate in young, old and SHR rats that was not associated with a change in body temperature. No significant change in heart rate was seen in rats exposed to 25 ppm Co., 1 ppm NO2 (SHR rats) or 1 ppm SO2 (young and old rats). Exposure of old and young rats to ultrafine carbon (generated by pyrolysis of acetylene) caused changes in heart rate that were similar to that seen with exposure to CAP. The time course and duration of heart rate change was independent of particulate exposure concentration or particle size (CAP or ultrafine carbon). In young rats, heart rate changes occurred within about 6 hours after exposure and lasted for about 24 hrs but in old rats the onset of heart rate changes lagged about 24 hrs after exposure and was shorter in duration. The old rats were found to have significantly more spontaneous arrhythmias than young rats. Exposure to CAP (but not ultrafine carbon or SO2) significantly increased the frequency of sinus arrhythmias in the old rats. These results suggest that adverse cardiac effects can occur following exposure to PM in rats with underlying cardiac disease without co-existing respiratory disease. Supported in part by EPA R827351

1319 CARDIOPULMONARY CHANGES IN PIGS EXPOSED TO RESIDUAL OIL FLY ASH (ROFA).

W. E. Cascio[2], T. Johnson[2], A. J. Ghio[1], T. Huang[1], D. L. Costa[1], P. A. Bromberg[2] and R. B. Devlin[1]. *[1]NHEERL, USEPA, Research Triangle Park, NC and [2]Department of Medicine, University of North Carolina, Chapel Hill, NC.*

Changes in cardiopulmonary function may contribute to mortality associated with ambient particulate matter (PM). In this study young pigs weighing 30 kg were mechanically ventilated and exposed to 2 mg/kg body weight nebulized ROFA suspended in saline, or to saline alone. Supplemental oxygen was used to maintain O_2 saturation >90%. Changes in heart rate; aortic, central venous, and pulmonary artery pressure; cardiac activation and recovery intervals (ARIs) - an index of cardiac

repolarization - were assessed over a 4 hr period. At that time bronchoalveolar lavage was performed on the cardiac lobe and portions of the lung and heart were removed for immunohistochemical analysis. ROFA-exposed pigs had a 8.3 fold increase in BAL PMNs and a 2.4 fold increase in BAL protein compared with pigs exposed to saline. There was a 4.8 mm Hg increase in pulmonary artery systolic pressure following ROFA exposure compared with a 2.3 mm Hg decrease after saline exposure. In ROFA-exposed pigs, heart rate increased by 19 bpm and ARIs decreased, compared to saline-exposed animals. In this pig model, ROFA increases lung injury and inflammation, pulmonary hypertension, and affects cardiac impulse formation and repolarization. This abstract does not necessarily reflect EPA policy.

1320 BIOAVAILABLE CONSTITUENTS MEDIATE CARDIAC MOLECULAR EFFECTS OF PULMONARY DEPOSITED FUEL OIL COMBUSTION PARTICLES.

K. Dreher[1], R. Jaskot[1], J. Richards[1] and T. Knuckles[2]. [1]*USEPA, Research Triangle Park, NC and* [2]*North Carolina State University, Raleigh, NC.*

Environmental health effects studies have shown the ability of particulate air pollution to affect cardiac autonomic control. The mechanism(s) by which particulate air pollution alters cardiac physiology are unknown. It is also not known what cardiac molecular effects, if any, may relate to specific combustion particles present within the fine fraction of particulate air pollution. This study examines the ability of fuel oil combustion particles, residual oil fly ash (ROFA), deposited in the lung to induce cardiac molecular effects and determines the mechanism(s) by which these effects arise. Gene expression profiling detected an increase in mRNA levels for several cytokines and matrix metalloproteinases within hearts recovered from ROFA-instilled rats at 1 - 6h and 24h post-exposure. Protein profiling detected an increase in the total phosphotyrosine protein content and the activation of several protein kinases in hearts recovered from ROFA exposed rats as early as 0.25 - 1h post-exposure, indicating a rapid alteration in cardiac intracellular signaling homeostasis. Pulmonary exposure to ROFA did not increase plasma levels of IL-1beta, TNFalpha, IL-10 or endothelin-1. Elevated plasma vanadium (V) content was observed in ROFA-exposed rats as early as 15 min post-exposure which remained elevated up to 6h post-exposure before decreasing towards control saline levels by 24h post-exposure. Exposure of cardiac fibroblast/myocyte co-cultures to a particle free ROFA leachate produced similar molecular responses as observed *in vivo*. These results demonstrated the ability of ROFA to produce cardiac molecular effects that were temporally correlated with plasma V content. These effects occurred rapidly and prior to the development of pulmonary inflammation, and could be replicated *in vitro*. These findings suggest that bioavailable metal constituents are responsible for the cardiac molecular effects following *in vivo* or *in vitro* exposure to fuel oil combustion particles.

1321 TRANSCRIPTIONAL INVOLVEMENT IN NEUROTOXICITY.

N. H. Zawia. *Biomedical Sciences, University of Rhode Island, Kingston, RI.*

It has become more apparent that exposure to various chemicals and environmental hazards elicits changes in the expression of a variety of genes. The study of gene expression and transcriptional regulation is an important aspect of understanding the mechanisms associated with neurotoxicity. The availability of whole genome sequences and the development of new tools to identify and monitor transcriptional activity have accelerated the rate of discovery. This has led to the identification of new genes and the ability to monitor the activity of multiple genes that act in concert in response to a stimulus. This symposium will deal with recent advances related to the elucidation of genes expression associated with the neurotoxic response as well as deciphering of signal transduction/transcription coupling that is altered following exposure to neurotoxic agents.

1322 THE SP FAMILY OF TRANSCRIPTION FACTORS MEDIATE METAL-INDUCED CHANGES OF GENE EXPRESSION.

N. H. Zawia. *Biomedical Sciences, URI, Kingston, RI.*

Sp1 is a transcription factor which contains a zinc finger motif and whose activity is modulated both *in vivo* and *in vitro* by heavy metals such as Pb, Hg, and Cd. Some of the genes under Sp1 control include ornithine decarboxylase, myelin basic protein, proteolipid protein, NMDAR1 subunit, and metallothionein. It has now become apparent that Sp1 belongs to a family of proteins whose members include Sp2, Sp3, Sp4. All the Sp factors recognize the same DNA element. While the role of Sp2 is unknown, Sp3 is suspected of being a negative modulator of transcription and Sp4 exhibits tissue specificity for the brain. The interactions of Sp1 with cell cycle regulatory proteins, including p53, retinoblastoma protein, and cyclins is consistent with its developmental role. Furthermore, Sp1 has been shown to play a critical role during the differentiation of oligodendrocytes in the human brain. This presentation will discuss metal-induced changes in the activity and structure of this transcription factor family. Specific focus will be placed on the different roles of the various members of the Sp family in the regulation of gene expression.

1323 GENE EXPRESSION AND CELL-SIGNALING EVENTS ASSOCIATED WITH TOXICANT-INDUCED GLIOSIS.

J. P. O'Callaghan[1], K. Sriram[1], M. I. Luster[1] and D. M. Felschow[2]. [1]*Molecular Neurotoxicology, CDC-NIOSH, Mogantown, WV and* [2]*Ciphergen Biosystems, Fremont, CA.*

Astrogliosis represents a sensitive and early response of the nervous system to all types of neurotoxic injuries. The generality of the glial reaction, despite the target selectivity of specific neurotoxic insults, implies that there are common "signals" underlying this cellular response. The discovery and characterization of such signals would, therefore, broaden our understanding of molecular mechanisms underlying diverse neurotoxic responses and lead to early "predictors" of neurotoxic outcomes. We present evidence for candidate genes and signaling pathways underlying the glial response to neuronal damage resulting from exposure to the dopaminergic neurotoxicant, MPTP. In our model, a single 12.5 mg/kg dose of MPTP to the C57 Bl6/J mouse results in a 50% decline in dopamine and TH protein. The accompanying astrogliosis, as assessed by immunoassay of GFAP, begins at 12 hrs and peaks at 48 hrs post dosing. Striatal homogenates prepared from mice sacrificed by focused microwave irradiation to preserve steady-state phosphorylation revealed activation of the JAK-STAT pathway in the earliest phase of MPTP-induced gliosis. This effect was not observed in non-target regions and was completely reversed by neuroprotection with nomifensine. These results were indicative of effects specific to the neurotoxic condition and implicated potential upstream effectors in the JAK/MAP kinase modules, such as cytokines and trophic factors acting through the gp130/Ras pathways. Gene array analysis revealed enhanced expression of TNF-α mRNA and the Ciphergen Protein Chips®platform of SELDI-TOF/MS analysis revealed a striatal-specific induction of 18 kD proteins consistent with induction of TNF-α. TNF-α receptor deficient mice showed complete neuroprotection against the neurotoxic effects of MPTP. Together these data show that a gene- protein- and phospho-specific antibody "arrays" can reveal novel mechanisms potentially underlying the glial response to neurotoxic insult.

1324 GENE EXPRESSION PATTERNS IN LEAD NEUROTOXICITY.

T. R. Guilarte. *Environmental Health Sciences, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Human studies and animal models have clearly demonstrated the impact of developmental lead (Pb) exposure on behavior and cognitive function. Experimental animals exposed to environmentally relevant levels of Pb express deficits in tests of spatial learning and in synaptic plasticity such as long-term potentiation (LTP). The hippocampus is a brain structure essential for both of these processes and its known to be affected by Pb exposure. We have been interested in understanding the molecular basis associated with these deficits and have identified changes in the expression of specific subunits of the NMDA receptor in the hippocampus of Pb exposed rats. This presentation will discuss Pb-induced changes in the expression of selective genes associated with NMDA receptor-dependent signal transduction and calcium homeostasis. [Supported by NIEHS grant ES06189]

1325 INDUCTION OF TRANSCRIPTION FACTORS IN NEURONS THAT SURVIVE NEUROTOXICITY.

K. R. Pennypacker. *Pharmacology, USF, Tampa, FL.*

We report that levels of Fos-related antigen-2 (FRA-2) are elevated long-term in several models of chemical-induced brain injury as well as after ischemia suggesting that this protein is involved in enhancing the transcription of genes related to the process of regeneration and repair. Trimethyltin, which causes degeneration of neurons primarily in the hippocampus and other limbic regions, results in a 5-fold induction of FRA-2 immunoreactivity in neurons in the pyramidal and dentate layers of the hippocampus starting at seven days post treatment and persisting for 60 days. Ischemic insult caused by middle cerebral artery occlusion results in an increase in FRA-2 expression the hippocampus ipsilateral to the ischemic lesion at 6 hours

after reperfusion. By one day, the increased expression is found in the neuronal layers of both hippocampi and its elevated expression lasts for at least 21 days. Methamphetamine and methylenedioxymethamphetamine, agents which cause degeneration of dopaminergic nerve terminals in the striatum of the mouse, cause an increase in FRA-2 immunoreactivity which begins at three days post-treatment and returns to basal levels by day 5 and 15, respectively. Treatment with 1-methyl-4-phenyl-1, 2, 3, 6-tetrahydropyridine caused elevated levels of FRA-2 in the mouse striatum at three days post-treatment. This abbreviated timecourse of FRA-2 induction in terminal degeneration is consistent with less severe insult (terminal damage) relative to trimethyltin and ischemia (cell death) but induction occurs during the period of regeneration and repair in both models. Thus, FRA-2 is induced in models of both cell death and terminal degeneration suggesting this transcription factor may serve as a universal signal transduction molecule involved in the regulation of genes related to regeneration and repair in the central nervous system. Work supported by AHA Nat. 9930072N and NIH NS39141-01A2.

1326 NUCLEAR FACTOR KAPPAB ACTIVATION PROMOTES SURVIVAL OF MOUSE HIPPOCAMPAL CELLS AFTER ACUTE TRIMETHYLTIN EXPOSURE.

C. A. Kassed and K. R. Pennypacker. *Pharmacology and Therapeutics, University of South Florida, Tampa, FL.*

Members of the nuclear factor-kappaB (NF-$_{\kappa}$B) family of transcription factors play essential roles in diverse physiological processes including cell growth, differentiation, and development. A variety of external stimuli including pathogens, stress, and pharmacological agents can activate NF-$_{\kappa}$B. However, the role of this transcription factor as a neurodegenerative or survival-promoting response to brain injury remains an area of dissension. To address this controversy, we have established transgenic mouse models of neurodegeneration using trimethyltin, the well-characterized neurotoxicant with exquisite limbic selectively. Neurodegeneration is exacerbated in the hippocampi of mice lacking the p50 subunit of NF-$_{\kappa}$B. Activation of this transcription factor in response to an acute, systemic injection of TMT is shown in mice carrying a $_{\kappa}$B-dependent *lacZ* ($_{\beta}$-galactosidase) reporter gene. Granule cells of the murine dentate gyrus subregion are particularly vulnerable to TMT toxicity, but neurons expressing activated NF-$_{\kappa}$B, identified by $_{\beta}$-galactosidase reporter activity, survived the injury seven days after treatment. Additionally, Fluoro-Jade, the histochemical marker of degenerating neurons, does not label cells immunoreactive for $_{\beta}$-galactosidase. These results further support a role for NF-$_{\kappa}$B transcription factor in neuronal survival. This work was supported by grants from American Heart Association National 9930072N and National Institutes of Health NS39141-01A2

1327 APPLICATION OF GENOMICS FOR MECHANISM BASED RISK ASSESSMENT.

R. D. Tyler and D. E. Robinson. *ILSI Health & Environmental Sciences Institute, Washington, DC.*

Recent advances in genomic and proteomic research, coupled with the availability of novel tools and methods with which to analyze the products of altered gene expression, have provided new insights into mechanisms of toxicity evoked by xenobiotics. While these advances promise to revolutionize our ability to characterize hazard, one of the short-term needs is to establish a body of publicly available knowledge to serve as a foundation for applying the data generated by these new methods to risk assessment. The ILSI Health and Environmental Sciences Institute is providing a scientific forum to facilitate further development and advances in genomics and proteomics methodologies toward the goal of increasing the utility of gene expression data for mechanism-based risk assessment. A collaborative research effort has been undertaken to help establish appropriate experimental methodologies for measuring alterations in gene expression and to relate genomic and proteomic expression data to toxic endpoints characterized by established methods under standardized conditions. Through this collaboration, data are being generated in government, industry and research laboratories on a series of prototype compounds across a broad range of available microarray platforms. This workshop will present the outcome of the initial phase of this project which has focused on nephrotoxicity, hepatotoxicity, and genotoxicity as important endpoints for the risk assessment of many chemicals. Presenters will discuss the issues associated with drawing correlations between patterns of gene expression with key biological parameters for these endpoints, insights gained into the mechanism of action of the compounds studied, the influence of specific experimental conditions on data variability and reproducibility, and other issues associated with interpretation and future application of data from these types of studies for risk assessment.

1328 FUTURE DIRECTIONS FOR SCIENTIFIC VALIDATION AND APPLICATION OF GENOMICS APPROACHES IN RISK ASSESSMENT.

W. D. Pennie. *Syngenta CTL, Macclesfield, United Kingdom.* Sponsor: R. Tyler.

The ILSI Health and Environmental Sciences Institute is providing a scientific forum to facilitate further development and advances in genomics and proteomics methodologies toward the goal of increasing the utility of gene expression data for mechanism-based hazard identification and possibly risk assessment. One of the short-term goals of this endeavour is to establish a body of publicly available knowledge to serve as a foundation for assisting in the generation, interpretation and application of data generated by these new methods. To this end, a collaborative research effort has been undertaken to help establish appropriate methodologies for measuring alterations in gene expression by developing and applying standard protocols across multiple technical platforms. The initial phase of this project has focused on nephrotoxicity, hepatotoxicity, and genotoxicity as important endpoints for the risk assessment of many chemicals. The successful completion of these initial studies has raised important technical issues relating to microarray applications including experimental design, sources of variability, gene annotation, analysis methods and the sharing and comparison of results from different technical platforms. To facilitate the sharing of multi-platform results, the ILSI subcommittee has developed short-term microarray data exchange and storage formats, which allow simplistic comparisons between multiple datasets. It is clear that the most likely value from these approaches will be obtained when they are applied in concert with more "traditional" measurements of toxicant action such as well-characterized biochemical or histopathological markers or endpoints. In addition the successful interpretation of changes in global patterns of gene expression will be greatly facilitated by the availability of an appropriately curated and carefully annotated public domain database of gene expression data with simultaneous recording of appropriate phenotypic markers related to the effects of chemical exposure. Ongoing effort and challenges in these areas will be presented.

1329 GENOMIC AND PROTEOMIC ANALYSIS OF ACUTE AND SUBCHRONIC NEPHROTOXICITY.

T. A. Bertram. *Drug Safety, Pfizer, Groton, CT.*

Pharmaceutical agents account for about 40% of clinically relevant acute renal failures/nephrotoxicity accounts for up to 6% of regulatory actions related to target organ toxicity. Nephrotoxicity is associated with 4 basic mechanisms. These mechanism are active on the Glomerulus; Tubules/collecting ducts; &/or Interstitium. The Nephrotoxicity group of ILSI's Genomics Subcommittee tested dose-/time-response relationships of 3 agents in SD rats: Gentimycin; Cisplatin; & Puromycin. 4 genomic platforms were used to evaluate mRNA expression. Common sources of variation in genomic analysis included: inter-laboratory in-life studies, inter-laboratory m-RNA array analysis, inter-animal & intra-array effects. Genes were found to be regulated in treated animals at all times. Microarray analysis demonstrated temporal/dose-response for genes functioning in cellular injury, molecular repair, intercellular signaling, cellular proliferation, apoptosis, inflammation, fibrosis, electrolyte transport & acute phase response. Classical gene markers for glomerular injury (vimentin), proximal convuluted tubular damage (gamma glutamyl transpeptidase), collecting duct toxicity (Na-H exchanger), & interstitial damage (KIM-1) were identified using microarray technology. Patterns of gene responses for known toxic mechanisms & functional categories were consistent with what is known about the mechanism of nephrotoxicity. Potential applications from genomic & proteomic studies of nephrotoxicity include early candidate selection & prioritization, animal model development, elucidation of mechanisms for tissue injury & response, and interspecies extrapolations.

1330 GENE EXPRESSION MONITORING USING MICROARRAYS AS AN APPROACH FOR ASSESSING HEPATIC TOXICITY.

R. G. Ulrich. *Abbott Laboratories, Abbott Park, IL.* Sponsor: R. Tyler.

Hepatic toxicity is the most common adverse effect leading to label warnings, use restrictions and market withdrawals for pharmaceuticals. Traditional experimental approaches can reveal dose-dependent toxicity in animal models but rarely indicate toxic mechanism and are equivocal predictors for human responses. Microarrays and related tools have shown promise for the rapid identification of toxic mechanism and may have utility in more precisely predicting human responses. To be useful for risk assessment these tools must be challenged for reliability and inter-laboratory reproducibility of results. Towards this, the hepatotoxicity working group of the ILSI Genomics Subcommittee is evaluating responses in rats to two hepatotoxins using a standard experimental protocol. Clofibrate (25 and 250 mg/kg/d) and methapyrilene (10 and 100 mg/kg/d) were administered by oral gavage for 1, 3 and

7 days. Studies for both compounds were conducted in two different laboratories, and traditional toxicity parameters were consistent with reported effects. RNA samples from liver were distributed for examination in 16 different laboratories using six different platforms and at least three different data analytical approaches. Gene expression results for both compounds show sufficient agreement between laboratories and across platforms to show promise for this new approach to toxicity evaluation. In most cases expression of known marker genes for these compounds was observed. Discrepancies for specific genes are largely due to differences in platforms (gene representation, annotation and specific sequences) and approach to data analysis rather than biological or inter-laboratory variability. This consortium effort provides an unprecedented opportunity to evaluate and compare biological, genomic and toxicological parameters across different laboratories and different analytical platforms. Though improvements are needed in annotation and in data analysis tools, it is clear that monitoring gene expression changes has value for identifying and assessing hepatic toxicity.

1331 ASSESSMENT OF THE UTILITY OF DNA MICROARRAYS AS A PRACTICAL TOOL FOR CHARACTERIZING GENOTOXICITY.

R. K. Newton. *Investigative Toxicology, Eli Lilly, Greenfield, IN.* Sponsor: D. Robinson.

Genetic damage elicits a variety of stress-related signals that alter expression of genes associated with numerous biological pathways. It has been proposed that patterns of gene expression changes may be characteristic of specific classes of genotoxic compounds and can be used to classify agents with different mechanisms of action. DNA microarray platforms provide a promising technology to assess these changes. To test the hypothesis that gene expression patterns can be correlated with mechanisms of action of genotoxicants, the ILSI Genomics Subcommittee has investigated the gene expression profiles of several direct-acting genotoxins in two different cell lines (mouse lymphoma and human TK6 cells). This multi-laboratory collaboration has afforded the opportunity to assess several factors of inter-laboratory variability associated with various aspects of the technology. Two time points were examined: 1) cells were treated for 4 hr and immediately harvested for RNA isolation, or 2) cells were treated for 4 hr and allowed to recover for 20 hr (24 hr time point) before being harvested. At least two concentration levels were chosen with one inducing 70-80% cytotoxicity with a robust induction of genotoxicity (determined by either a TK gene mutation assay or a micronucleus assay) or one inducing limited cytotoxicity with a 2-4 fold genotoxic response. Overall, the data indicates that modest changes in gene expression (<3-fold) were common in the *in vitro* studies, and levels of test compound that produce low cytotoxicity appear to induce relatively few gene changes. Interpretation of the data is influenced by the filter criteria used to define a response. At present, it is uncertain that these modest changes represent key biological responses to damage in these cell lines or if other mechanisms apply. To fully utilize information from these studies, it will be critical to analyze data in a manner that identifies critical genes in biological pathways involved in a genotoxic response and to distinguish small, but real changes from background noise.

1332 USING MICROARRAY TECHNOLOGY IN SAFETY EVALUATION: WHERE DO WE GO FROM HERE?

L. L. Stevens, D. E. Watson and T. P. Ryan. *Toxicology and Drug Disposition, Lilly Research Laboratories, Indianapolis, IN.*

Expression profiling by microarray analysis significantly contributes to many areas of Toxicology including biomarker development and mechanistic studies. However, the promise represented by microarray analysis must be balanced against the significant challenges that exist at all levels of the technology. For example, the quality of the data must be consistent from chip to chip and Lab. to Lab.. In addition, for public data to be widely disseminated, hardware and software systems must manage and deliver complex data sets from many sources and platforms to multiple users *via* internet links. Additional complexity occurs in interpreting results. One must know the function of a gene to interpret the biological significance of a change in expression. Thus, functional annotation of genes is a significant hurdle for the field since correct assignment increases the likelihood that changes in gene expression will yield useful biological information. Unfortunately, much of the transcriptome is not annotated nor has function been assigned to many novel genes. In addition, nomenclature often does not reflect function. These problems represent significant challenges if we are to develop databases into which many users can deposit data and from which useful biological information can be extracted. Nonetheless, reference sets of expression profiles developed around defined SARs do offer insights into mechanism, suggesting that databases of gene expression information have applications in risk assessment. The ILSI effort on microarray technology highlights the promise and problems inherent to microarray technology. Continued effort will contribute to international databases and provide a benchmark for standardizing microarray technology within the industry.

1333 APPROACHES TO THE ASSESSMENT OF FOOD ALLERGENICITY.

G. S. Ladics[1] and W. Dong[2]. [1]*DuPont Co., Haskell Laboratory, Newark, DE and* [2]*USFDA, Washington, DC.*

Food allergy is an important health issue with the prevalence of IgE antibody-mediated food allergies among adults being approximately 2% and nearly 5% in children. There is a need to assess the safety of foods deriving from genetically modified (GM) crops, including the allergenic potential of novel gene products. In January 2001, a Joint FAO/WHO Consultation developed a revised decision tree for the evaluation of the allergenic potential of GM foods. In addition to indirect measurements of allergenic activity (amino acid sequence homology and structural similarity to known human allergens, together with resistance to pepsin digestion), the new hierarchical approach now recommends confirmation using serological screening (i.e., using targeted evaluation of the reactivity of novel proteins with IgE antibody from sensitized subjects) and relevant immunological assays. Presently, there are no *in vitro* or animal models that have been validated for the identification or characterization of potential protein allergens. This Workshop will gather researchers working on various strategies for assessing protein allergenicity to describe the current state of knowledge and progress that has been made in the development and evaluation of appropriate testing strategies and to identify critical issues that must now be addressed. *in vitro* models of digestibility, bioinformatics, and risk assessment in the context of food allergy prevention and management clinically will be discussed. Both rodent and non-rodent models for the measurement of allergenic potential of GM foods will also be reviewed.

1334 ALLERGY ASSESSMENT OF GENETICALLY MODIFIED (GM) FOODS: WHAT ARE THE ISSUES?

M. P. Holsapple. *TERC, Dow Chemical Company, Midland, MI.*

Prior to marketing, GM products are required to be evaluated for their safety, including the potential for allergenicity. The process by which allergy assessment is conducted has evolved under the guidance of a variety of expert scientific bodies, and the key steps in the current decision tree include the following: Is the source of the gene allergenic? (addresses the history of exposure and safety of the source of the gene); Is the amino acid sequence similar to any known allergen? (addresses the potential for broad homology of the protein to known allergens; search for 8 or more contiguous amino acids); Is the protein stable to pepsin digestion? (addresses the potential for absorption through the stomach). To date, approximately 70 GM products have been assessed for safety and approved for food use in at least one country by regulatory authorities. While the current decision tree has been successfully applied, there are scientific issues requiring additional clarification including the following: the need to standardize the amino acid sequence analysis; the uncertainty about whether IgE epitopes are missed by the current search criteria; the need to standardize the pepsin digestion assay; the need for scientific consensus on what to do with stable proteins; the need for scientific consensus regarding the usefulness of broad serum screens; the need for more research to validate predictive animal models. The FAO/WHO 2001 report addressed many of these issues and made recommendations that could provide additional reassurance of allergenicity assessment. However, some of these recommendations cannot presently be integrated because of the unavailability of validated methods. Any change in the current methodology should include a development plan with clearly defined goals and criteria. The FAO/WHO 2001 decision tree does not allow for a GM food to be devoid of allergenic risk - the best scenario is a low probablility of allergenicity, which introduces a degree of uncertainty. Any safety assessment approach should enable its practioners to make clear, consistent decisions based on sound scientific evaluations.

1335 FACTORS RELEVANT TO THE ALLERGY ASSESSMENT OF FOODS DERIVED FROM BIOTECH CROPS.

J. D. Astwood, R. E. Goodman and E. A. Rice. *Product Safety Center, Monsanto Company, St. Louis, MO.* Sponsor: W. Dong.

Protection of food allergic subjects from unwelcome exposures to the proteins which cause their clinical symptoms represents a major public health priority for plant biotechnology. Successful methodologies for identification of established al-

lergens have been utilized since the introduction of the first biotech crops in the early 1990's. Recent progress in the understanding of both the natural history of food allergy and the characteristics which define food and other allergens has lead to new insights into the potential predictive value of *in vitro* tools with a view towards preventing the development of new food allergies. The most advanced of these tools include 1) the adaptation of bioinformatics techniques; and 2) the refinement of two factors which influence protein exposures *via* foods: stability to digestion and protein levels. The positive and negative predictive values of these factors alone and in combination will be discussed. In addition, emerging trends in the characterization of food and other allergens, especially allergens responsible for Oral Allergy Syndrome (OAS), will be reviewed with a view to enhancing the risk assessment approach for foods derived from biotech crops.

1336 ANIMAL MODELS FOR THE IDENTIFICATION OF PROTEIN ALLERGENIC POTENTIAL: THE BALB/C MOUSE.

I. Kimber and R. J. Dearman. *Research, Syngenta Central Toxicology Laboratory, Cheshire, United Kingdom.*

Food allergy is an important and common health issue, and there is consequently a need to identify and characterize the sensitizing potential of novel food proteins. One strategy we have adopted is to measure allergenic activity as a function of the ability of proteins to provoke antibody (IgG and IgE) responses in BALB/c mice; a strain that is known to favour adaptive immune responses of the quality required for allergic sensitization. Emphasis has focused to date on an examination of humoral immune responses induced following systemic exposure of mice (by intraperitonal [ip] administration) to the test material. Under these conditions it has been found that proteins known to be associated with food allergy in humans (including for instance peanut proteins and ovalbumin) elicit both specific IgG and IgE antibody responses, measured using enzyme-linked immunosorbent and passive cutaneous anaphylaxis assays, respectively. In contrast, other proteins derived from foods believed to exhibit little or no allergenic potential (such as for instance an extract of potato proteins), although immunogenic in BALB/c mice (measured as a function of IgG antibody production) either failed to induce IgE responses at all, or were associated with only low grade IgE production. In comparative analyses, exposure of BALB/c mice to proteins by gavage was found to be less sensitive and discriminatory. Experience to date indicates that the inherent sensitizing potential of novel food proteins can be evaluated (identified and ranked) on the basis of antibody responses stimulated by parenteral exposure of BALB/c strain mice.

1337 DETERMINATION OF PROTEIN ALLERGENICITY: STUDIES IN A BROWN NORWAY RAT FOOD ALLERGY MODEL.

L. M. Knippels[1], J. D. Astwood[2], A. H. Penninks[1] and R. E. Goodman[2]. *[1]Experimental Immunology, TNO Nutrition and Food Research, Zeist, Netherlands and [2]Monsanto Company, St. Louis, MO.* Sponsor: W. Dong.

There is a need to identify and characterize the potential allergenic activity of novel proteins introduced into genetically engineered crops. Although structural and physico-chemical approaches have been described, including comparison of sequence and structure to known allergens, determination of the stability to digestion with pepsin, stability with heat, and the presence of glycans or disulfide bonds; none of these directly measure the ability of proteins to cause allergic sensitization. For that reason there has been a growing interest in the development of suitable predictive animal models. Although several animal models are under development, none of these models have been widely tested with a variety of allergenic and non-allergenic proteins. In our rat food allergy model, we expose young Brown Norway (BN) rats (high IgE responder strain) to food proteins by daily gavage dosing for 42 days without the use of adjuvants. The animals develop specific IgE responses against known food allergens. After an oral challenge in previously sensitized animals, increased gut permeability, drop in blood pressure, drop in breathing frequency, and increased release of Rat Mast Cell Protease II *in vivo* was observed. In recent studies with the BN rat food allergy model the animals were sensitized to common strong and a non-allergenic protein to study the potential allergenicity of food proteins. Sensitizations were attempted orally both with and without the use of the oral adjuvant Cholera Toxin (CT) and parenterally with the use of alum as an adjuvant. The results indicate that at day 42 the immune responses in the BN rat can distinguish between strong and non-allergenic proteins. Although none of the proteins induced 100% of the animals to respond after oral exposure there was a difference in response observed between the proteins as measured by either antigen and isotype specific ELISA and by PCA.

1338 NON-RODENT ANIMAL MODELS FOR ASSESSING PROTEIN ALLERGENICITY.

R. M. Helm. *Pediatrics Allergy/Immunology, University of Arkansas for Medical Sciences, Arkansas Children's Hospital Research Institute, Little Rock, AR.* Sponsor: G. Ladics.

In veterinary medicine, skin and gastrointestinal reactions to foods are commonly diagnosed in domestic animals such as pigs, calves, and dogs. An inbred Spaniel/Basenji colony with a genetic predisposition, significant history and cutaneous signs consistent with food-induced allergic dermatitis has been selected to study food-induced IgE-mediated allergy. Newborn pups, subcutaneously sensitized with allergens in alum and vaccinated with attenuated distemper-hepatitis vaccine respond with allergen-specific IgE, skin test reactivity, and histologic features that mimic human food allergy. A significant contribution of this model is that it mimics a proposed mechanism in children representing viral infections and a protein "bystander" antigen response. Young pigs experience allergic reactions to legume proteins and represent a naturally occurring food allergy model for studying food sensitization and gut-immune mediated disorders resembling human food allergic diseases. The pig mimics the human digestive and gut immunologic functions, including nutritional requirements, a transient porosity of the immature gut to dietary proteins, the distribution and maturation of intestinal enzymes, and the enteric absorption of antibodies. Neonatal piglets sensitized by either an intraperitoneal or intragastric administration of peanut allergens in the presence of adjuvant followed by intragastric challenge with peanut meal provokes emesis, skin rashes, lethargy and respiratory distress. These two non-rodent animal models demonstrate skin test reactivity when challenged with the relevant allergen, show pronounced mucosal swelling and persistent erythema following endoscopic analysis of food challenges that is similar to that of human subjects undergoing diagnosis for food allergy. Continued efforts in these non-rodent animal models will provide valuable insight into the mechanisms of IgE-mediated allergic disease and be able to assist in the prediction of the relative allergenicity of novel proteins.

1339 EXPRESSION PATTERNS OF ORTHOLOGOUS SEQUENCES IN MOUSE AND HUMAN.

R. S. Thomas, S. G. Penn, D. K. Hanzel, T. Hu, W. Chen, M. Shannon, Y. Ji, B. S. Love, Y. Gu, D. A. Jenkins, A. P. Chung, S. Dozier, M. L. Lewis and D. R. Rank. *Aeomica Inc., Sunnyvale, CA.*

The comparison of two genomes provides insight into the function and organization of the shared genes. A genome wide comparison of available human (95%) and mouse (15%) sequence was performed to identify putative orthologous genes. Approximately, 95, 000 conserved elements were identified that were greater than 100 bp and 62% of these regions contained an open reading frame. The mean identity of the conserved elements was 87.2 ± 4.2% which is consistent with previously described orthologous transcripts between both human and mouse. A subset of 2, 000 putative orthologous elements were spotted on tandem microarrays (one human and one mouse) and used to evaluate conservation of expression patterns between organisms. Across a panel of 9 tissues, gene expression between mice and humans was largely conserved with 92% expressed with less than 6-fold difference between organisms and 74% expressed with less than 3-fold different. Of the genes expressed with greater than 10-fold difference, the majority were genes of unknown function (42%), followed by signal transduction (24%), metabolism (12%), and cytoskeletal (10%). Although this study extends the comparison between mouse and man from the genome to the transcriptome, it highlights the potential differences between these two species and provides an approach for evaluating cross-species extrapolation issues in toxicology at the molecular level. Preliminary experiments show similar transcriptional responses to phorbol esters between human HepG2 and mouse Hepa1 cells. Additional experiments are underway to compare human and mouse transcriptional responses to a variety of chemical treatments. We propose that such orthologous arrays will be useful for evaluating animal models for relevance to both human disease and toxicology.

1340 INTERSPECIES COMPARISON OF HEPATOTOXIC STRESS RESPONSE USING MICROARRAYS OF ORTHOLOG CDNA FRAGMENTS.

A. Bosio[1], B. Gerstmayer[1], S. Tomiuk[1], K. Hofmann[1], F. Hübel[1], K. Buss[1] and J. Borlak[2]. *[1]MEMOREC Stoffel GmbH, Cologne, Germany and [2]Centre for Drug Research and Medical Biotechnology, Fraunhofer Institute ITA, Hannover, Germany.* Sponsor: H. Muhle.

The rat is extensively used in toxicological studies, partly, because the degree of evolutionary divergence is low enough to allow a cross-referencing to human and rat responses with respect to toxicological endpoints. Therefore, cross referencing molecular transcriptome data from studies with rat and human probes has many important applications. We have investigated the expression pattern of 1007 orthologues genes that code for detoxification, cell proliferation, tumor development,

heat shock response, signal transduction, apoptosis and cell cycle regulation after treatment of primary human and rat hepatocytes with a set of toxic compounds, e.g. Aroclor 1254. cDNAs were assigned into gene families and a suitable subsequence was selected fulfilling a variety of quality parameters. First the sequence architecture was verified by cross-species comparison. The second step included the masking of repetitive elements as well as vector sequences and the region beyond the first possible polyadenylation signal. After analysis of putative alternative splice events and the removal of ambiguous regions, the remaining sequence was used for similarity searches. Finally, a fragment was generated by RT-PCR using gene specific primers from the part of the sequence that has no apparent risk for cross-hybridization with other closely related genes and is sufficiently well conserved between human and rat to allow amplification of fragments from the same region of a given gene from both species. These cDNA fragments from human and rat were used to produce species specific microarrays and probed with human and rat hepatocytes respectively, which have been treated under the same conditions. An interspecies correlation of orthologe genes with respect to their transcriptional regulation is presented. Our results have various implications concerning the predictive power of toxicology studies using primary rat hepatocytes.

1341 HEPATIC GENE EXPRESSION PROFILES IN MICE TREATED WITH LPS: COMPARISON OF WHOLE LIVER AND LASER CAPTURE MICRODISSECTED HEPATOCYTES.

M. Lawton, J. Jeffries-Griffor, N. Barrezueta, D. Potter, J. Brees and J. Loy. *Drug Safety Evaluation, Pfizer Inc., Groton, CT.*

We investigated the feasibility of using laser capture microdissected (LCM) material for Affymetrix gene expression profiling (GEP). Approximately 12, 500 cells were dissected from randomly selected areas of sectioned lipopolysaccharide (LPS) or saline-treated mouse livers. Total RNA extracted from these cells was found to be intact and of good quality when analyzed with the Agilent Technologies 2100 Bioanalyzer. A modification of published procedures was used to label 50 ng of RNA from the 12, 500 LCM cells. For comparison to the LCM samples, total RNA was also extracted from intact liver and either labeled directly according to the standard Affymetrix protocol (10 ug) or diluted (50 ng) and labeled with the modified protocol. All samples were hybridized to Affymetrix murine U74A GeneChips and analyzed by a variety of statistical methods. Multidimensional scaling analysis revealed more similarity among samples analyzed using the modified amplification protocol compared to the standard protocol. This is most likely due to the 3' bias that is introduced in the amplified samples from the random hexamers and oligo-dT priming used in the second round of cDNA synthesis. Importantly, however, when control and LPS-treated samples were compared for differential gene expression profiles, the patterns in both the unamplified (i.e. undiluted liver RNA) and amplified (i.e. diluted liver and LCM liver RNA) samples were remarkably similar. In all samples genes encoding several acute-phase and other LPS-responsive proteins were up-regulated, and numerous cytochromes P450 were down-regulated. Additional results comparing profiles generated from 500 cells and from hepatocytes isolated from centrilobular and periportal regions control and LPS-treated livers will also be discussed. The conservation of differential gene expression profiles generated from small amounts of RNA demonstrates that this approach should have broad applicability to the investigation of molecular mechanisms of toxicity and disease.

1342 THE USE OF cDNA MICROARRAYS FOR ASSESSING HEPATOTOXICITY - AN INTER LABORATORY ASSESSMENT.

V. A. Baker[1], H. M. Harries[1], C. M. Duggan[1], R. Brown[2], H. Ni[2], J. D. Parry[3] and A. T. De Souza[3]. *[1]SEAC, Unilever, Bedfordshire, United Kingdom, [2]GlaxoSmithKline R&D, Research Triangle Park, NC and [3]GlaxoSmithKline R&D, Ware, United Kingdom.* Sponsor: D. Basketter.

cDNA microarray technology has the potential to have a significant impact on our ability to identify toxic hazards by the identification of mechanistically-relevant markers of toxicity. First however, an assessment of the reproducibility of the data generated must be undertaken. As part of the Hepatotoxicity Working Group of the ILSI/HESI Genomics Subcommittee, the biological response in rats to the model hepatotoxin clofibrate, was investigated. Animals were treated with high (250mg/kg/day) and low (25mg/kg/day) doses of clofibrate by oral gavage for a period of 1, 3 and 7 days. Following sacrifice, livers were removed for histopathological assessment and total RNA (pooled) prepared for distribution to participating laboratories for analysis. This presentation focuses on gene expression data obtained using Atlas™ Rat Toxicology II arrays (Clontech). Samples were processed on triplicate arrays using ^{33}P labelled cDNA probes. Probed arrays were exposed to X-ray film or phosphor screens and images captured and analysed using AtlasImage™2.0 software. Further statistical analysis of the data was performed by each laboratory. In general, there was a good degree of concordance between the gene expression profiles generated at each site. Expected changes in gene involved in fatty acid metabolism (e.g. acyl CoA oxidase, hydroxyacyl CoA dehydrogenase, 3-ketoacyl CoA thiolase A/B), cell proliferation (e.g. topoisomerase II-α) and metabolism (CYP4A1) were observed. Real Time PCR was used to confirm modulations for selected genes. Although some discrepancies in microarray data between the two laboratories were observed, they appear largely due to different approaches to image and data analysis. In conclusion, toxicogenomics has the potential to provide new and refined approaches to hazard identification and safety evaluation based on the identification of biologically relevant markers of toxicity.

1343 GENE EXPRESSION RESPONSES OF PRIMARY HEPATOCYTES TO VARIOUS HEPATOTOXINS.

R. Dunn[1], A. Kalkuhl[2], A. Field[1], M. Derbel[1], T. Woodruff[1], R. Bader[2] and T. Singer[2]. *[1]Phase-I Molecular Toxicology, Santa Fe, NM and [2]Pre-Clinical Drug Safety, Boehringer-Ingelheim Pharmaceuticals, Biberach, Germany.*

Pharmaceutical companies are aggressively evaluating screening systems to shorten the time required to identify leads and simultaneously eliminate poor drug candidates. To this end, both *in vitro* cell culture systems and gene expression profiling are being widely used. Immortalized cell lines, while useful in certain situations, have not yielded the breadth of toxicological information required to aid decision making for lead optimization. Primary hepatocytes are currently being evaluated for use in toxicity screening. As a first step for determining the utility of expression profiling in primary hepatocytes, experiments were designed around "paradigm" compounds that elicit well-understood toxicities *in vivo*. Primary rat hepatocytes were exposed to various hepatotoxins including allyl alcohol (AA), isoniazid (ISO), methotrexate (MTX), phenobarbital (PB), tacrine (TAC), Trovan (TRO), and valproic acid (VPA). Cells were exposed to each compound for multiple dose and exposure times in order to put the gene expression responses into perspective. AA had only modest effects on gene expression possibly due to induction of aldehyde dehydrogenase that detoxifies acrolein, the toxic metabolite of AA. ISO did not have consistent effects on gene expression and alterations were modest. MTX induced genes indicative of an oxidant response such as catalase and glutathione synthetase. PB was nearly without effect in these studies. TAC induced expression of glutathione synthetase in addition to genes involved in reducing oxidative stress. TRO induced several genes of unrelated function and the responses were highly dependent on exposure time. VPA induced several genes including those linked to peroxisome proliferation in a dose- and time-dependent manner. VPA treatment of rats *in vivo* is linked to peroxisome proliferation. Thus, hepatotoxin gene expression profiles derived from treatment of primary rat hepatocytes can provide insight into toxic mechanism.

1344 PREDICTIVE MODELING OF HEPATOTOXICANTS USING MICROARRAYS AND A LINEAR DISCRIMINANT MODELING APPROACH.

A. L. Castle, M. W. Porter, M. Elashoff, K. R. Johnson, H. W. Sun, M. S. Orr, C. G. Chang and D. L. Mendrick. *Toxicology, Gene Logic, Inc., Gaithersburg, MD.*

In order to increase speed and depth of toxicological screening we have established a toxicogenomic database, ToxExpress™, that can be used to accurately predict and help classify potential toxicants using gene expression changes. Using the Affymetrix GeneChip® RGU_34 series microarray, we have collected expression information from over 1, 000 rat liver samples for greater than 26, 000 microarray elements per sample. Rats were treated with known hepatotoxicants that exert pathologies such as necrosis, steatosis, cholestasis, and hepatitis along with appropriate controls. In general, samples from rats treated with vehicle, pharmacologic, or toxic doses of each compound were collected at three or more time points. Over 500 general marker elements and more than 1, 000 compound/class-specific markers were found to be predictive based on discriminative ability and determined to be significant using randomization procedures. Predictive models were built using linear discriminant analysis (LDA). Preliminary results show successful predictions of toxicity using the markers determined to be discriminative, as well as for subsets of these markers. In addition, more specific classification of toxic compounds was achieved with compound- and class-specific markers. We are continuing efforts to validate our liver models, expand them into other organ systems and cell types, and investigate the mechanisms of action of marker genes.

1345 PREDICTING TOXICITY IN TWO DISTINCT SECTIONS OF THE KIDNEY *VIA* MICROARRAY ANALYSIS.

M. S. Orr, M. Elashoff, A. L. Castle, K. R. Johnson, M. W. Porter, H. W. Sun, C. G. Chang and D. L. Mendrick. *Toxicology, Gene Logic, Inc., Gaithersburg, MD.*

In the toxicogenomics field, many debates have centered on whether injury to a specific area of the kidney can be detected by gene expression profiling of the entire organ. The feasibility of detecting toxicity in the kidney was evaluated by exposing

Sprague-Dawley rats for 6 hrs, 24 hrs, and 7 days to multiple doses of either puromycin aminonucleoside (PAN), which induces glomerular injury, or cisplatin, which produces proximal tubular injury. Clinical chemistry and histopathologic examination indicated clear evidence of overt toxicity only after 7 days of exposure unlike the 6 and 24 hour time points that failed to exhibit any signs of damage. The kidneys from all time points and doses were analyzed by the Affymetrix RGU_34 GeneChip®. A subgroup of genes selected from statistically significant expression differences induced by PAN-treated rats from both the 6 and 24 hour times were used to develop a predictive model, as we were interested in determining if acute expression changes can predict late events. The model was tested against itself as well as against the cisplatin-treated samples in order to determine if it could predict the samples as toxic or non-toxic. The results indicate that the PAN model was accurate in predicting itself. More importantly, the PAN model was accurate in predicting the cisplatin-exposed samples, providing evidence that expression profiling can be used in predictive toxicology studies even if a complex tissue is analyzed and the damage occurs in a specific area of the organ. Gene expression alterations are present before overt toxicity is observed by classical parameters of toxicity. This suggests that expression profiling is a more sensitive measure of toxicity that is capable of predicting the manifestations of a toxic phenotype much earlier than classical techniques.

1346 GENE EXPRESSION IN SPLEENS OF RATS DOSED WITH ESTRADIOL, HYDROXYUREA, OR TAMOXIFEN.

G. M. Farris. *Database, PHASE-1 Molecular Toxicology, Santa Fe, NM.*

The differential gene expression in spleens of rats dosed with immunotoxicants were evaluated to determine patterns related to tissue damage and mechanisms of toxicity. Rats received an intraperitoneal injection of estradiol, hydroxyurea or tamoxifen at two concentrations and then tissues were collected at 6, 24 and 72 hours later. Estradiol and tamoxifen induced lymphocyte necrosis in spleen follicles at 72 hours and hydroxyurea induced mild lymphocyte hyperplasia. RNA from spleen, liver, and kidney samples were hybridized on the PHASE-1 700-gene rat toxicology array. Comparison of hydroxyurea-induced gene expression in the spleen at 72 h demonstrated a strong similarity with estradiol gene response after 6 h. The stimulation of corticosterone production by hydroxyurea as described in the literature could be inducing this spleen response. Our evaluation of gene expression includes comparisons with other steroids including dexamethasone and prednisone and comparisons in spleen, liver, and kidney. Differential gene expression can provide information about mechanisms of toxicity with a simple screening protocol when a gene expression database including traditional toxicology data is used for comparisons.

1347 EVALUATION OF TUMOR-PROMOTING ACTIVITY BY GENE EXPRESSION PROFILING.

J. Scheel[1], C. K. Behrens[1], T. Storck[1], M. C. von Brevern[1], E. Jacob[2], M. Haushalter[1] and A. Bach[1]. [1]*Toxicology Dept, BASF-LYNX Bioscience AG, Heidelberg, Germany and* [2]*GVT, BASF AG, Ludwigshafen, Germany.* Sponsor: M. Battalora.

The number of potential leads pharmaceutical companies obtain has increased steeply in the last years due to advances in combinatorial chemistry and high throughput screening. We therefore develop our predictive toxicology platform that will help pharmaceutical companies to focus as early as possible on the most promising candidates by excluding potentially harmful lead compounds. Carcinogenic activity may be a knock-out criterion for a drug. While genotoxic activity can be detected in short-term assays (eg Ames test), the detection of carcinogenicity by tumor promoting compounds represents a real bottleneck since long-term animal studies are necessary. Using our broad gene expression profiling technology platform we have analyzed liver samples of rats fed with a panel of tumor promotors of different mode of action-classes (eg Phenobarbital, WY14, 643, Ethinylestradiol) and compounds with cytotoxic activity (Furan, CCl_4). The two pairs of 2, 4- and 2, 6-diamino- and dinitrotoluenes that have or do not have tumor promoting activity, respectively, were also included in our analysis. We have conducted our experiments in two phases. In phase 1 we identified marker genes (regulated in response to a certain compound class) using Massive Parallel Signature Sequencing (MPSS), Restriction-Mediated Differential Display (RMDD) and "discovery" DNA arrays. These marker genes were added to our TOXaminer DNA array containing several hundred cDNA fragments of toxicology-relevant genes. In phase 2 all samples were analyzed on this "grown" TOXaminer array. With our analysis we identified many genes known but also around 200 genes not known to be regulated by these substances. Using hierarchical clustering and principal component analysis we could group compounds according to their mode of action. Thus, our study shows that gene expression changes induced by a certain chemical is characteristic of that chemical and that compounds with similar mode of action induce similar gene expression changes.

1348 CROSS COMPOUND PREDICTIONS USING GENE EXPRESSION PROFILES FROM ACETAMINOPHEN OR CARBON TETRACHLORIDE, TWO STRUCTURALLY DISTINCT LIVER TOXICANTS.

D. L. Mendrick[1], M. Flashoff[1], A. L. Castle[1], K. R. Johnson[1], M. W. Porter[1], H. W. Sun[1], C. G. Chang[1], M. S. Orr[1] and M. P. Carver[2]. [1]*Toxicology, Gene Logic, Inc., Gaithersburg, MD and* [2]*DSM, Wyeth, Andover, MA.*

It is essential to develop tools to rapidly determine if new chemical entities (NCEs) have the potential to elicit a toxic response in critical organs such as the liver or kidney. In order to address this need, Gene Logic has developed the ToxExpress™ reference database as a pre-clinical tool for ranking NCEs. Two classical liver toxicants, acetaminophen (APAP) and carbon tetrachloride (CCl_4), were studied to determine if gene expression differences, measured by the Affymetrix RGU_34 GeneChip®, induced by a drug could predict toxicity in samples exposed to a solvent such as CCl_4. In this study, Sprague-Dawley rats were treated with either APAP or CCl_4 and liver samples were collected from multiple time points with replicate numbers of at least three. Elevations of ALT levels and signs of necrosis by histopathological examination confirmed that both APAP and CCl_4 induced liver damage at 24 hrs. A statistically significant subgroup of genes was selected from the gene expression alterations induced by the APAP-treated rats at 3, 6 and 24 hr time points. These genes were used to develop a predictive model. The model was tested against itself as well as CCl_4 in order to determine the capacity of the model to predict samples as toxic or non-toxic. The APAP model was accurate in predicting itself and all the 3, 6, 24, and 48 hr CCl_4-treated samples correctly. Interestingly, the 1 hr and 72 hr CCl_4-exposed samples were predicted as non-toxic. These samples failed to show evidence of necrosis and steatosis, and 72 hr samples displayed features of fibrosis and regeneration. This study provides evidence that predictions between structurally distinct toxicants are feasible.

1349 DOSE-RESPONSE BEHAVIOR OF ANDROGENIC AND ANTIANDROGENIC CHEMICALS: IMPLICATIONS FOR LOW-DOSE EXTRAPOLATION AND CUMULATIVE TOXICITY.

L. E. Gray, C. J. Wolf, J. Furr, M. G. Price, C. Lambright, V. S. Wilson and J. Ostby. *EB, USEPA, Research Triangle Park, NC.*

Concern has arisen regarding the shape of the Dose-Response curves in the low dose range for EDCs. Although it is generally assumed that noncancer effects, including those induced by EDCs, display a threshold, several scientists have questioned the validity of this assumption. In regards to cumulative risk, it is generally assumed that dose-additivity prevails for chemicals that act *via* a common mechanism of action. A TEF (Toxic Equivalent Factor) approach for mixtures is valid if the dose-response curves for all the chemicals are parallel. This presentation will examine the dose-response behavior of several androgenic and antiandrogenic chemicals. *in vitro*, antiandrogenic chemicals like hydroxyflutamide and M2, a vinclozolin metabolite, display antiandrogenic activity at low concentrations and AR agonist activity at high concentrations. U- or inverted U-shaped Dose-Response curves have been described *in vivo* for AR agonists. In addition, many AR-mediated *in vivo* and *in vitro* effects do not display obvious thresholds. Furthermore, the dose-response curves for the antiandrogenic developmental effects produced by vinclozolin (V) administration reveals that the responses to this AR antagonist do not display a common shape or ED50. When V and procymidone (P, an AR antagonist) are coadministered, the effects all appear dose-additive, suggesting that a single TEF could be used to assess cumulative toxicity. While cumulative developmental effects also were observed with coadministration of P and an inhibitor of fetal testosterone synthesis (di-n-butyl phthalate), it is evident that single TEF will not suffice because the relative potencies of these two chemicals varies from tissue to tissue. Our data indicate that cumulative adverse effects can be observed after coadministration of chemicals that affect the differentiation of the reproductive tract, regardless of the mechanism of action. Disclaimer: This is an abstract of a proposed presentation and does not necessarily reflect USEPA policy.

1350 EVALUATION OF THE 15-DAY INTACT MALE ASSAY: CAPABILITY TO DETECT THE ANTI-ANDROGEN FLUTAMIDE.

M. S. Marty, K. E. Stebbins and E. W. Carney. *Toxicology & Environmental Research, The Dow Chemical Company, Midland, MI.*

The Endocrine Disrupter Screening and Testing Advisory Committee (EDSTAC) recommended that the 15-day intact male assay be evaluated as a possible alternate Tier I screening assay to detect endocrine–active compounds (EACs). While many EACs have been tested in this assay, studies to address interlaboratory variation and route of exposure are warranted. To this end, male CD rats (n=15/group) were exposed to the anti-androgen flutamide (0, 0.5, 1, 10 or 50 mg/kg/day) by gavage for

15 days, then euthanized 2 hours after the final dose. Reproductive organ, accessory sex gland and thyroid weights were measured to detect endocrine effects. At 50 mg/kg/day, flutamide significantly reduced terminal body weight by 9% and increased relative liver weight by 17%. At both 10 and 50 mg/kg/day, there was a dose-dependent decrease in several organ weights, including 16 and 27% decreases in absolute epididymal weights, 21 and 48% decreases in relative prostate weights, and 27 and 61% decreases in relative seminal vesicle weights. The body weight decreases exhibited by the high dose animals were not sufficient to account for these organ weight changes. The decreases in these organ weights were similar in magnitude to previous results with the intact male assay (O'Connor et al., 1998), wherein 20 mg/kg/day flutamide given intraperitoneally decreased epididymal, prostate and seminal vesicles weights by 22, 44 and 55%, respectively. Testes and thyroid weights were not altered in either study. These data show that the 15-day intact male assay can reproducibly detect the endocrine activity of flutamide across different laboratories and routes of exposure.

1351 HERSHBERGER ASSAY: DOSE-RESPONSE AND COMPARISON OF TISSUE RESPONSES TO ANDROGENS GIVEN ORALLY AND SUBCUTANEOUSLY.

C. Sloan[1], K. Vick[1], P. A. Fail[1] and R. A. Becker[2]. [1]*Research Triangle Institute, Research Triangle Park, NC and* [2]*American Chemistry Council, Arlington, VA.*

Three experiments (Exp.) tested effects of androgen agonists testosterone propionate (TP) and methyl testosterone (MT) on male sex accessory tissues. The protocols were adapted from the OECD program for validation of the rodent Hershberger Assay. TP (s.c.; Exp 1) at doses of 0.1, 0.2, 0.4, 0.8, and 1.6 mg/kg/day (n = 6/group) or MT by gavage (p. o.) at doses of 0.1, 5, 10, 25 and 50 mg/kg/day (n = 6/group; Exp 2) was administered once daily for 10 days to 8-week old Sprague-Dawley rats (castrated postnatal day (pnd) 42-43, treated pnd 60-69). Exp. 3 evaluated the androgen antagonist flutamide (FT; 1, 5 or 10 mg/kg/day) in combination with MT (5 or 10 mg/kg/day). FT was administered p.o. first (ca. 8am) and MT was given p.o. ca. 4 hours later. Vehicle dosed controls were included in all studies. Rats were euthanized 24 hours after the final dose. The liver, glans penis (GP), ventral prostate (VP) (both fresh and fixed), seminal vesicles plus coagulating glands with contents (SVCG), Cowper's glands (CG), and levator ani and bulbo-cavernosus muscles (LABC) were weighed to the nearest 0.1 mg. TP produced distinct dose-responses in these tissues: (dose level to produce maximum tissue weight: wt.): GP at 0.4 mg/kg/day; VP and CG at 0.8 mg/kg/day; LABC at 1.6 mg/kg/day; and SVCG response was linear over the dose range. Responses (fold increase in tissue wt. compared to control) at TP 1.6 mg/kg/day ranged from ca. 2 to 25 in the order GP<LABC<CG<VP<SVCG. MT p.o. was somewhat less potent (shallower dose responses): fold increase in tissue wt. compared to control at MT 50 mg/kg/day ranged from ca. 1.6 to 10.6 in the order GP<LABC<CG<SVCG<VP, and Coefficients of Variance of tissue wt. ranged from 2 to 51, GP<LABC<SVCG, CG<VP. Agonist activity of MT was reduced by combined treatment with FT. No major differences in Dose-Response curves were seen between VP fresh or fixed. This comparison of assay performance by the relevant oral route to the s.c. route supports additional validation by both routes.

1353 DETECTION OF ENDOCRINE EFFECTS: AN ENHANCED OECD TEST GUIDELINE 407: STUDY WITH TAMOXIFEN.

F. Chuzel, G. Espuna, E. Barale-Thomas, C. Pallen and R. Bar. *Experimental Toxicology, Aventis CropScience, Sophia-Antipolis, France.* Sponsor: N. Carmichael.

As part of a global OECD exercise, an enhanced version of the OECD TG 407 (28-day rat toxicity study) is being evaluated to detect endocrine disrupters. A range of different molecules acting *via* different modes of action are included in this exercise, the effects of a nonsteroidal antiestrogen (tamoxifen) in male and female rats are reported here. Wistar rats were administered tamoxifen by gavage at 0, 5, 30 and 200 µg/kg/day for at least 28 days. Endocrine-related parameters included in the study were: necropsy of females in dioestrus only; assessment of sperm parameters (number, motility and morphology); determination of plasma hormone levels (T4, T3, TSH, LH, testosterone and estradiol). Significant decreases in body weight gain were observed in high dose males and females. Males treated at 200 and 30 µg/kg/day showed decreased secretion in prostate and seminal vesicles without apparent effects on sperm parameters. In females, tamoxifen induced interstitial gland hypertrophy in the ovaries, diffuse epithelial and glandular hyperplasia/hypertrophy in the uterus, and diffuse mucoid metaplasia in the vagina at 200 and 30 µg/kg/day. In addition, acinar atrophy of mammary glands were noted in both males and females at 200 and 30 µg/kg/day. No apparent effects were detected on thyroid hormone levels. These results support that a potent antiestrogen can be detected in the enhanced version of the OECD TG 407mainly through histopathological examination. (supported by EMSG and OECD)

1354 DETECTION OF ENDOCRINE EFFECTS: AN ENHANCED OECD TEST GUIDELINE 407; STUDY WITH METHYLTESTOSTERONE.

G. Espuna, F. Chuzel, G. Pohlmeyer Esch, C. Pallen and R. Bars. *Experimental Toxicology, Aventis CropScience, Sophia-Antipolis, France.* Sponsor: N. Carmichael.

As part of a global OECD exercise, an enhanced version of the OECD TG 407 (28-day rat toxicity study) is being evaluated for detection of endocrine disrupters. A range of different molecules acting *via* different modes of action are included in the exercise; the effects of an androgen agonist (methyltestosterone) in male and female rats are reported here. Wistar rats were administered methyltestosterone by gavage at 0, 10, 40 or 200 mg/kg/day in males and 0, 10, 100 or 600 mg/kg/day in females for at least 28 days. Endocrine-related parameters included in the study were : necropsy of females in dioestrus only; assessment of sperm parameters (number, motility and morphology); determination of plasma hormone levels (T4, T3, TSH, LH, testosterone and estradiol). A significant decrease in body weight gain (BWG) was observed in high dose males whereas all female treated groups showed a marked increase in BWG. Males at 40 and 200 mg/kg/day showed decreased testis weights and a low number of Leydig cells with diffuse degeneration of germinal epithelium associated with an alteration in the sperm parameters. In addition, prostate weights were increased in high dose males only. Females at 100 and 600 mg/kg/day showed gonadal atrophy (interstitial cells atrophy, follicular atresia) with epithelium hyperplasia of the uterus and vagina. Histopathological findings in both males and females were also observed in the liver, thyroid, adrenals, mammary glands and kidneys. Hormonal measurements showed increased TSH and decreased LH plasma levels in both sexes. These results support that a potent androgen can be detected in the enhanced version of the OECD TG 407. (Supported by EMSG and OECD)

1355 ASSESSMENT OF A FATHEAD MINNOW REPRODUCTION ASSAY FOR IDENTIFYING ENDOCRINE-DISRUPTING CHEMICALS WITH DIVERSE MODES OF ACTION.

J. J. Korte, M. W. Hornung, K. M. Jensen, M. D. Kahl, E. A. Makynen and G. T. Ankley. *USEPA, Duluth, MN.*

The USEPA has developed a short-term reproduction test with the fathead minnow to identify potential endocrine disrupting chemicals (EDCs). The assay is initiated by collecting baseline spawning data from reproductively-active adult fathead minnows for 21 d, followed by a 21 d exposure to sublethal concentrations of test material. Measurements are made of fecundity, fertility, hatch success, secondary sex characteristics, gonadal condition (e.g., histopathology), plasma vitellogenin, and plasma sex steroids (estradiol, testosterone, and 11-ketotestosterone). To evaluate performance of the assay, we have conducted tests with several chemicals representative of major modes of action of concern from an EDC perspective. Chemicals tested have included: methoxychlor (metabolites are estrogen receptor agonists); ZM 189, 154 (estrogen receptor antagonist); methyltestosterone and trenbolone (androgen receptor agonists); flutamide and vinclozolin (androgen receptor antagonists); and fadrozole (cytochrome P450 aromatase [CYP19] inhibitor). Reductions in fecundity were clearly evident in exposures to methoxychlor, methyltestosterone, trenbolone, flutamide and fadrozole. These reproductive effects were accompanied by changes in other parameters reflective of the expected mode of action. For example, in the fadrozole test, estradiol and vitellogenin levels were decreased in females, as would be predicted if CYP19 was inhibited. Likewise exposure to the androgen receptor agonists caused masculinization in females, while estrogenic chemicals produced feminization (e.g., vitellogenin production) in males. This assessment of the test method shows the utility of the assay to provide guidance in identifying diverse modes of action of potential EDCs. *This abstract does not necessarily reflect EPA policy.*

1356 DEVELOPMENT OF AN AMPHIBIAN-BASED ASSAY TO SCREEN FOR CHEMICAL EFFECTS ON THE THYROID AXIS.

S. J. Degitz, K. M. Flynn, G. W. Holcombe, J. J. Korte, P. A. Kosian and J. H. Tietge. *Mid-Continent Ecology, USEPA, NHEERL, Duluth, MN.* Sponsor: S. Bradbury.

In response to the initial EDSTAC recommendations, research was conducted on the development of a *Xenopus laevis* based tail resorption assay for evaluating thyroid axis disruption. The results of these initial experiments highlighted key limitations associated with relying on tail resorption as a measure of anti/thyroid activity. The most critical being that the tail tissue of tadpoles in metamorphic climax are insensitive to perturbation by agonists and antagonist. To begin to improve on the initial proposal we have conducted experiment comparing the sensitivity of pre-metamorphic (stage 51) and pro-metamorphic (stage 54) tadpoles to the model

thyroid axis antagonists methimazole (control, 6.25, 12.5, 25, 50, 100 mg/L) and 6-propylthiouracil (control, 1.25, 2.5, 5, 10, and 20 mg/L). Tadpoles were exposed for a 2 wk. period, and developmental stage, thyroid size, and thyroid histology were examined at 1 and 2 wks after exposure. Methimazole treatment resulted in a dose dependent inhibition of metamorphosis at both developmental stages within one week, while 6-propylthiouracil treatment resulted in metamorphic inhibition in stage 51 tadpoles within one week and of both stages within two weeks. Further, both compounds caused dose dependent changes in thyroid gland morphology. These changes were characterized as reduced colloid, glandular hypertrophy, and cellular hyperplasia. Treatment failed to affect growth, even in tadpoles which experienced significant metamorphic inhibition. As determined from these endpoints, there were only minor differences in sensitivity observed among the 2 stages examined. These results indicate that tadpoles in the early stages of metamorphosis are sensitive to thyroid axis inhibition and that development of a short term, diagnostic amphibian-based thyroid screening assay shows considerable promise. *This abstract does not necessarily reflect EPA policy*

1357 INTERPRETING THYROID TOXICITY FOR RISK ASSESSMENT.

R. T. Zoeller. *Biology, University of Massachusetts, Amherst, MA.*

Thyroid hormone is essential for normal brain development. A large number of chemicals, of both natural and synthetic origin, are known to affect thyroid function. Therefore, it is important to characterize the effects of specific chemicals on the ability of thyroid hormone to exert its action(s) during brain development. However, the present strategy for testing thyroid toxicity in rodent models employs end points of thyroid function only – chemicals are not tested for their ability to interfere with thyroid hormone action. This strategy is valid if and only if chemicals interfere with thyroid hormone action exclusively by affecting thyroid function, or that measurable changes in thyroid function are always associated with changes in thyroid hormone action. Considering that the consequences of thyroid hormone deficits during development are not remediable, and that thyroid hormone action is quite pleiotropic, end points of thyroid hormone action must be recruited into studies to be used for risk assessment. However, these measures must be identified and validated.

1358 EVALUATION OF A CANNULATION MODEL AND ISOFLURANE ANAESTHESIA FOR BLOOD SAMPLING IN THE RAT: EFFECTS ON SERUM PROLACTIN AND CORTICOSTERONE.

J. L. Verbeeck, P. Vinken, R. De Coster, B. Verstynen, A. Lampo, T. Jansen, L. Lammens and W. Coussement. *Toxicology and Pathology, Janssen Research Foundation, Beerse, Belgium.* Sponsor: W. Powers.

The purpose of this study was to validate two different techniques for blood sampling in female Wistar Hannover rats, i.e. by permanent cannulation of the vena femoralis and by orbital puncture after isoflurane anaesthesia. To this purpose the effects of stress caused by the two techniques on two stress-sensitive hormones were measured, i.e. prolactin and corticosterone. Decapitation was used as a reference technique as it is believed to have minimal effects on these hormones. It is regarded by the American Veterinary Medical Association as an acceptable technique when properly performed (2000 report). Blood was sampled in all rats 7 days after surgery of the cannulated animals over a period of 4 hours at 4 timepoints. Repeated blood sampling was performed in ten rats while with the two other techniques six animals were used on each timepoint. No in-life technical problems were encountered with any of these techniques although in cannulated animals the amount of blood that can be sampled is limited and sometimes insufficient. Both isoflurane anaesthesia and cannulation induced higher prolactin levels than decapitation and isoflurane anaesthesia induced higher prolactin levels than cannulation. Isoflurane anaesthesia and decapitation were comparable when corticosterone levels were measured. Cannulation induced higher corticosterone levels than both other techniques. Cannulation and isoflurane anaesthesia are technically feasible but have the potential to induce alterations in the levels of one or both hormones. Decapitation does not alter the levels of prolactin and corticosterone. Cannulation offers the possibility of repeated blood sampling in the same animal which reduces the inter-animal variability which can be useful for e.g. pharmacokinetic studies and PK/PD studies.

1359 NADPH OXIDASE *VERSUS* MITOCHONDRIAL OXIDANT STRESS IN ACETAMINOPHEN TOXICITY.

L. P. James[1,2], S. S. McCullough[1,2], T. R. Knight[2], H. W. Jaeschke[2] and J. A. Hinson[2]. [1]*Pediatrics, UAMS, Little Rock, AR and* [2]*Pharmacology, UAMS, Little Rock, AR.* Sponsor: J. Hinson.

Previous studies have demonstrated that nitrotyrosine (NT) adducts in proteins are formed in the centrilobular regions of the livers of mice dosed with acetaminophen (APAP). NT is formed by peroxynitrite, a species produced by the very rapid reaction of superoxide and nitric oxide. Previous studies indicated that pretreatment of mice or rats with macrophage inactivators resulted in decreased toxicity and NT formation. The initial site of nitration was hepatic sinusoids. These data suggested a role for activated Kupffer cells in peroxynitrite formation. In the present study, we investigated the importance of superoxide generated by NADPH oxidase (present in Kupffer cells and neutrophils) in the development of APAP hepatotoxicity. APAP toxicity was compared in genetically engineered (knock out, KO) mice deficient in the gene encoding gp91phox, a large critical subunit of NADPH oxidase, and C57BL/6J (wild type, WT) mice. Intracellular sources of superoxide (ie., mitochondria) were evaluated by measurement of glutathione disulfide (GSSG) in hepatic mitochondria of KO and WT mice. No significant differences were found between KO and WT mice in hepatotoxicity. Liver glutathione was depleted by > 88% at 1 hour in both KO and WT mice. The mitochondrial GSSG-to-GSH was increased by 6 fold at 1 hour and by 7 fold at 2 hours in both KO and WT mice. Immunohistochemical analyses indicated a centrilobular distribution of APAP protein adducts and NT in both groups of mice. Sinusoidal staining for APAP and NT was present at 1 hour and subsequently hepatocyte staining for APAP and NT was observed in both groups of mice. These data indicate that superoxide from NADPH oxidase does not significantly contribute to peroxynitrite formation in APAP toxicity. However, peroxynitrite formation in sinusoidal endothelial cells and mitochondrial oxidant stress are important early events in acetaminophen toxicity.

1360 MEMBRANE ASSOCIATION OF MURINE GSTA4-4, A GLUTATHIONE TRANSFERASE THAT ACTS ON LIPID PEROXIDATION PRODUCTS.

S. P. Singh[1], A. Janecki[2], S. K. Srivastava[3], S. Awasthi[4], Y. C. Awasthi[3], S. J. Xia[1] and P. Zimniak[1]. [1]*Univ. of Arkansas for Medical Sciences, Little Rock, AR,* [2]*Univ. of Texas Medical School, Houston, TX,* [3]*Univ. of Texas Medical Branch, Galveston, TX and* [4]*Univ. of Texas at Arlington, Arlington, TX.*

Reactive oxygen species (ROS) react with proteins, nucleic acids, and lipids. The latter process produces lipid hydroperoxides and electrophilic α, β-unsaturated aldehydes including 4-hydroxynonenal (4-HNE). The conjugation of 4-HNE with glutathione is catalyzed by specialized alpha-class GSTs exemplified by murine mGSTA4-4. The crystal structure of mGSTA4-4 reveals the presence of two highly exposed lysine residues (K115, one per subunit). Position 115 is occupied by acidic residues in most other alpha-class GSTs. We hypothesized that the positive charges of K115 residues in mGSTA4-4 may interact with negative charges on membranes. This could "dock" the enzyme to membranes, *i.e.*, the site of generation of its substrates (lipid peroxidation products). Therefore, we examined the intracellular localization of mGSTA4-4 in hepatocytes of normal mouse liver and in transfected HepG2 cells by fluorescence microscopy and digital deconvolution. mGSTA4-4 was found to be predominantly localized at or near the plasma membrane in transfected HepG2 cells, as well as in hepatocytes where it is expressed endogenously. *in vitro*, mGSTA4-4 associated with liposomes, and this interaction was potentiated when the liposomes contained phosphatidylserine. Mutating lysine-115 to glutamic acid resulted both in a loss of the plasma membrane targeting of mGSTA4-4 and in a significant reduction of its binding to liposomes *in vitro*. These data suggest that lysine-115 is critically important for the membrane association of mGSTA4-4, most likely by entering into an electrostatic interaction with negatively charged phospholipid headgroups, including phosphatidylserine. Membrane association of mGSTA4-4 may facilitate the transfer of lipid peroxidation products from the membrane to the active sites of the enzyme.

1361 GENERATION AND CHARACTERIZATION OF A KNOCKOUT MOUSE LACKING GSTA4-4, A GLUTATHIONE TRANSFERASE THAT METABOLIZES LIPID PEROXIDATION PRODUCTS.

M. R. Engle[1], J. D. Ceci[2], Y. C. Awasthi[2] and P. Zimniak[1]. [1]*University of Arkansas for Medical Sciences, Little Rock, AR and* [2]*University of Texas Medical Branch, Galveston, TX.*

Lipid peroxidation products have signaling functions and, at higher concentrations, are toxic and may trigger cell death. The compounds are metabolized predominantly by glutathione S-transferases exemplified by mGSTA4-4, an enzyme highly efficient in glutathione conjugation of 4-hydroxyalkenals, and possessing glutathione peroxidase activity toward phospholipid hydroperoxides. Metabolism of lipid peroxidation products may thus have a dual role: signal termination and detoxification. To determine the physiological implications of these processes, we generated a mGSTA4-4 knockout mouse by homologous recombination. The mouse is viable, although preliminary observations on a limited number of available animals suggest lower fertility. Northern and Western blotting confirmed the

absence of *mGSTA4* mRNA and mGSTA4-4 protein in tissues of mice homozygous for the gene disruption. However, residual 4-HNE-conjugating activity was measurable, indicating the presence, and perhaps compensatory upregulation, of alternative enzymes catalyzing that reaction. The activity was 22% of wild-type in lung, 42% in liver, and 35% in brain. Because of the significantly lower capacity for 4-HNE metabolism, the knockout mouse will be a useful experimental model for the elucidation of toxic effects of lipid peroxidation products.

1362 CYTOPROTECTION FOLLOWING THE INDUCTION OF ENDOPLASMIC RETICULUM STRESS PROTEINS IS CELL TYPE AND TOXIN DEPENDENT.

K. J. Bedard, N. MacDonald, J. Collins and A. E. Cribb. *Anatomy and Physiology, Atlantic Veterinary College, Charlottetown, PE, Canada.* Sponsor: J. Uetrecht.

Recent evidence suggests that induction of endoplasmic reticulum (ER) stress proteins increases cellular tolerance to agents which cause cytotoxicity through either oxidative stress or covalent binding. Previous work has been done primarily in kidney and neuronal cell types. To determine if protection against cytotoxic agents following the induction of endoplasmic reticulum (ER) stress proteins is a phenomenon that can be generalized across cell types, we assessed the protective effect of an ER stress response in a human hepatocyte cell line (HepG2), a rat hepatocyte cell line (H4IIE), a porcine kidney cell line (LLC-PK1), and a human lymphocyte cell line (K562). The ER stress response was induced by pretreatment with the glycosolation inhibitor, tunicamycin. Induction of the ER stress proteins GRP78, GRP94 and protein disulfide isomerase (PDI) was assessed by immunoblotting. In all cells, at least two of the ER stress proteins were induced, although the pattern varied between cell types. Tolerance to 3 hour challenges with the alkylating agent iodoacetamide (IDAM), the oxidative stressor *tert*-butylhydrogenperoxide (TBHP), the redox cyling agent menadione, or a 2 hour challenge with the reactive intermediate of acetaminophen NAPQI was assessed by the MTT assay 24 hours after addition of the toxin. In LLC-PK1 cells, the dose of toxin resulting in 50% survival increased for IDAM (505% ± 115%) and TBHP (168% ± 58 %) as previously reported, and for menadione (117% ± 9.0%) and NAPQI (205% ± 45%). However, in the hepatocyte and lymphocyte cell lines, increased tolerance was observed only in the HepG2 cells, where after ER stress, cells were more tolerant only to IDAM, exhibiting an 69% ± 8.8% increase in the TD50 after tunicamycin treatment. Induction of ER stress proteins in H4IIE cells and K562 cells did not alter susceptibility to any toxins tested in those cells. Our results indicate that protection afforded by the induction of an ER stress response is dependent on the cell type and toxin.

1363 ENGINEERING OF A BINARY TRANSGENIC MOUSE BROADLY EXPRESSING FPG FOR TESTING THE PATHOLOGICAL ROLE OF OXIDATIVE DNA DAMAGE.

D. Huang[1], J. T. Henderson[2] and P. G. Wells[1,3]. *[1]Faculty of Pharmacy, Univ. of Toronto, Toronto, ON, Canada, [2]Samuel Lunenfeld Research Inst., Mt. Sinai Hospital, Toronto, ON, Canada and [3]Dept. of Pharmacology, Univ. of Toronto, Toronto, ON, Canada.*

Reactive oxygen species (ROS) are formed endogenously, enhanced by some xenobiotics, and are believed to promote a number of pathologic processes. ROS enhance the formation of 8-oxoguanine (8-oxo-G), a promutagenic oxidative DNA lesion that undergoes base excision repair in mammals *via* oxoguanine glycosylase (OGG1). OGG1's bacterial counterpart is formamidopyrimidine DNA glycosylase (fpg). FPG exhibits an 80-fold higher activity and a broader substrate specificity compared to OGG1. To determine the role that oxidative DNA damage and repair plays in ROS-mediated toxicity, we engineered tetracycline-regulable transgenic mice that broadly expressed fpg during development. To optimize tet-regulated expression in these mice, trans-activator (beta-actin /CMV-IE promoter / tTA) and operator (TetO/fpg) constructs were simultaneously introduced into murine embryonic stem (ES) cells. The resulting ES clones were selected for those with optimal performance characteristics, which were used to construct murine lines. To more easily detect fpg *in vivo*, a FLAG epitope was fused in-frame with our fpg cDNA. In addition, TetO /beta-Geo was introduced into some ES cell clones to allow for lac-Z and neomycin detection in affected cells. Prior to the introduction into ES cells, constructs were tested in HEK 293 cells. In these cells carboxy-terminal FLAG-tagged fpg was correctly localized to the cell nucleus, although it exhibited lower repair activity (~50%) compared to our wild-type fpg clones. Co-transfection of actin/tTA strongly activated expression of both TetO/fpg-FLAG and TetO/beta-Geo as determined by Western blotting and lacZ cell staining. Transgene expression was abolished when cells were cultured in the presence of doxycycline. We are currently assessing the ROS response of our ES cell clones in response to various xenobiotic agents (Support: Canadian Institutes of Health Research).

1364 MUTATION OF THE TSC-2 GENE IN EKER RATS IS ASSOCIATED WITH REDUCED EXPRESSION OF 8-OXOGUANINE-DNA GLYSOSYLASE (OGG-1) AND A LACK OF INDUCIBILITY DURING OXIDATIVE STRESS.

S. L. Habib, H. S. Yoon, T. J. Monks and S. S. Lau. *Center for Molecular and Cellular Toxicology, University of Texas at Austin, Austin, TX.*

Treatment of either wild type (Tsc-$2^{+/+}$) Eker rats, or those carrying the mutant Tsc-2 allele (Tsc-$2^{EK/+}$) with 2, 3, 5-tris-(glutathion-S-yl)hydroquinone (TGHQ; 2.5 µmol/kg, i.p. for 4, 8 or 16 wks), a potent nephrotoxic metabolite of HQ, causes cell necrosis and proliferation within the outer stripe of the outer medulla (OSOM) in both groups of rats. However renal cell carcinomas only arise in the OSOM of the mutant Tsc-$2^{EK/+}$ strain. These findings provide compelling evidence that cell proliferation per se is not sufficient for tumor development. TGHQ can redox cycle and generate reactive oxygen species, and the mutation spectra induced by TGHQ following treatment and replication of the supF gene in both human AD293 cells and Eschericha coli MBL50 cells is consistent with that reported for OH•-induced mutations. 8-Oxo-deoxyguanosine (8-oxodG) is not only a measure of oxidative stress, but is a potentially mutagenic lesion. TGHQ (2.5 µmol/kg, i.p.; 5X/wk for 4, 8, 16 wks) increased 8-oxodG 2 fold within the OSOM of both rat strains at 4 wks. While elevated 8-oxodG levels were sustained in Tsc-$2^{EK/+}$ rats, they returned to baseline levels in Tsc-$2^{+/+}$ rats at 16 wks. Interestingly, although OGG-1 expression in Tsc-$2^{+/+}$ rats increased significantly during treatment with TGHQ, no such induction occurred in Tsc-$2^{EK/+}$ rats. Furthermore, the constitutive expression of OGG-1 was 3 fold lower in Tsc-$2^{EK/+}$ compared to Tsc-$2^{+/+}$ rats. These results suggest that mutation of the Tsc-2 gene is coupled to the suppression of constitutive OGG-1 expression and interferes with the ability to up-regulate this gene following oxidative stress. Moreover, the high basal and inducible OGG-1 levels in the wild-type Eker rats likely provide for a more efficient removal of oxidative DNA damage in these rats, thereby limiting tumor development. The basis for the lack of OGG-1 induction in Tsc-$2^{EK/+}$ rats is unknown and is currently being investigated. (GM39338, ES07784).

1365 COVALENT MODIFICATION OF PEPTIDES BY 4-HYDROXYNONENAL AND 4-OXONONENAL.

J. A. Doorn[1] and D. R. Petersen[2]. *[1]Pharmacology, University of Colorado Health Sciences Center, Denver, CO and [2]Pharmaceutical Sciences, University of Colorado Health Sciences Center, Denver, CO.*

Previous work has demonstrated that the α, β-unsaturated aldehydes 4-hydroxynonenal (4HNE) and 4-oxononenal (4ONE) are generated during lipid peroxidation. Recent evidence has implicated that covalent modification of proteins by 4HNE may play a role in some pathophysiological processes. Currently, the reactivity of 4ONE toward proteins is unknown. The purpose of this study was to identify residues that react with these α, β-unsaturated aldehydes, characterize the covalent adduct(s) formed, and measure the kinetics of adduction. Model peptides containing one or more nucleophilic residues (i.e. Cys, Met, Lys, Arg, and His) were reacted with a 20-fold excess of 4HNE and 4ONE at pH 7.4 and 37 °C. Control and treated peptides were analyzed using matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF-MS), and post-source decay (PSD) analysis was used to confirm the presence of a peptide adduct and identify the residue modified. Bimolecular rate constants for the reaction of glutathione (GSH) with 4HNE and 4ONE were measured. Peaks with mass corresponding to the peptide with a Michael adduct were observed in the mass spectra of model peptides containing either Cys, His, or Lys that had been treated with 4HNE. In contrast, peaks with mass corresponding to the peptide with a Michael adduct were observed in the mass spectra of model peptides containing either Cys, His, Lys or Arg that had been treated with 4ONE. The rate constants for the reaction of GSH with 4HNE and 4ONE were found to be 1.33 and 145 $M^{-1}s^{-1}$, respectively, indicating a >100-fold difference in potency for GSH modification between these two compounds. The results demonstrate that both 4HNE and 4ONE react with nucleophilic peptide residues to form covalent adducts but with contrasting specificity and a remarkable difference in potency for GSH conjugation. (Supported by grants NIH/NIAAA R01AA09300, NIH/NIEHS R01ES09410 and PHS 5T32AA07464-25.)

1366 OLTIPRAZ AND TERT-BUTYLHYDROQUINONE DO NOT INDUCE GLUTATHIONE S-TRANSFERASE IN A COMPLETELY IDENTICAL MANNER.

J. G. Lamb and M. R. Franklin. *Department of Pharmacology and Toxicology, University of Utah, Salt Lake City, UT.*

Both oltipraz [4-methyl-5-(2-pyrazinyl)-3H-1, 2-dithiole-3-thione] and tert-butylhydroquinone (tBHQ) induce a similar range of drug metabolizing enzymes, a range that does not include most cytochrome P450s. Among the most prominent

responding enzymes is glutathione S-transferase (GST) and in the rat, the GSTA2 form has been the most studied. After transiently transfecting a luciferase reporter construct consisting of an ARE enhancer and a HNF1 binding region (-872 to -582) and the minimal promoter region (-164 to +1) of rGSTA2 into rat hepatoma cells (H4IIE), luciferase activity was induced to an order of magnitude greater extent by 500mM tBHQ than by 500mM oltipraz. With a reporter construct containing the XRE enhancer and HNF1 binding regions (-1110 to -812), and the minimal promoter region, luciferase activity was induced to a much lesser extent, but again tBHQ induced more than oltipraz (6-fold). With a reporter construct containing a large portion of the proximal 5' flanking region of the GSTA2 gene (-1651 to +1), tBHQ induced to a 20-fold greater extent than oltipraz and in a slightly more robust manner than with the ARE/HNF1-only containing construct. All of these luciferase responses contrasted with the induction of the rGSTA2 mRNA in H4IIE cells which was only slightly better induced (1.5-fold) by tBHQ compared to oltipraz. (In intact animals, the oltipraz response was far greater in magnitude than the response to tBHQ). rGSTA2 mRNA responses to both agents were similarly (completely) inhibited by 1 uM actinomycin D co-treatment. With cycloheximide, (1uM), the slightly smaller oltipraz response was completely inhibited but with tBHQ, some induction remained. Thus, despite many characteristics in common, oltipraz appears capable of up-regulating drug metabolizing enzymes in a manner different from tBHQ, and by mechanisms outside of XRE and ARE enhancers.

1367 INCREASED HEPATOTOXICITY OF ACETAMINOPHEN IN TUMOR NECROSIS FACTOR ALPHA (TNFα) R1 (P55) KNOCKOUT MICE IS ASSOCIATED WITH DECREASED ACTIVATOR PROTEIN-1 (AP-1) ACTIVATION.

H. Chiu, C. R. Gardner, S. G. Ricketts, J. D. Laskin and D. L. Laskin. *Joint Graduate Program in Toxicology, Rutgers University and UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.*

Tumor necrosis factor alpha (TNFα) is a macrophage-derived proinflammatory cytokine implicated in the hepatotoxicity of acetaminophen. In the present studies, we examined possible mechanisms mediating the actions of TNFα. Treatment of wild type control mice with acetaminophen (300 mg/kg, i.p.) resulted in a time-dependent induction of centrilobular hepatic necrosis and increased serum transaminase levels, which reached a maximum after 18 hours. Knockout mice lacking TNFR1 (p55) were found to be significantly more sensitive to acetaminophen than wild type mice, as determined histologically and by increases in serum transaminases. This was correlated with decreased levels of the antioxidants, superoxide dismutase and heme oxygenase, when compared to wild type mice. To determine if signaling pathways regulating the production of antioxidants were altered in TNFR1 knockout mice, we analyzed hepatic levels of c-Jun N-amino terminal kinases (JNKs) and its downstream target, AP-1. Western blot analysis revealed that administration of acetaminophen to wild type mice resulted in a time-dependent activation of JNK, which was evident within 3 hours. Nuclear binding activity of the transcription factor, AP-1, measured by gel shift assays, was also increased. These responses were significantly reduced in mice lacking TNFR1. These data suggest that TNFR1 plays an important role in the activation of JNK and AP-1, as well as in increases in antioxidants during acetaminophen-induced hepatotoxicity. Supported by NIH GM34310 and ES06897.

1368 INDUCIBLE NITRIC OXIDE SYNTHASE KNOCK-OUT (iNOS(-/-)) MICE EXHIBIT INCREASED OXIDATIVE STRESS INJURY IN RESPONSE TO ADRIAMYCIN (ADR)-INDUCED CARDIOTOXICITY.

M. P. Cole[1], T. D. Oberley[2], S. M. Lin[1], K. K. Kiningham[1] and D. K. St. Clair[1]. *[1]Graduate Centers for Toxicology and Nutritional Sciences, Univ. of KY, Lexington, KY and [2]Dept. of Pathology, Univ. of WI, Madison, WI.*

ADR is a chemotherapeutic agent known to cause dose-related cardiotoxicity. Heart injury associated with ADR treatment involves the generation of free radicals, such as superoxide. Increases in superoxide in the presence of reactive metals leads to generation of the injurious hydroxyl radical. Alternatively, superoxide can react with nitric oxide (NO) forming peroxynitrite. Therefore, the levels of NO can alter the fate of superoxide radicals *in vivo*. Here we investigate the role of NO *in vivo* in ADR-induced cardiotoxicity using an iNOS(-/-) mouse model. Electron microscopy demonstrates that 5 days following one intraperitoneal injection of ADR (20 mg/kg), iNOS(-/-) mice exhibit cytoplasmic swelling and degradation of mitochondria as compared to wildtype (iNOS(+/+)) mice. Tissue damage, assessed by creatine phosphokinase, lactate dehydrogenase, and cardiac troponin serum levels, is increased in iNOS(-/-) mice as compared to iNOS(+/+) mice, supporting the pathological findings. Antioxidant enzymes such as superoxide dismutase, catalase, and glutathione peroxidase are increased to a larger degree in iNOS(+/+) mice than iNOS(-/-) mice following ADR, indicating a compromise in their ability to illicit an adaptive response to ADR-induced oxidative injury. The oxidized to reduced glutathione ratio increases in iNOS(-/-) mice treated with ADR and an increase in 4-hydroxynonenal (4-HNE) adducts is observed 24 hours following treatment, further verifying an increase in oxidative stress in the knock-out model. Time course studies indicate an increase in nitrotyrosine prior to the increase in 4-HNE in iNOS(+/+) mice, but not in iNOS(-/-) mice. Endothelial NOS protein levels are unchanged following treatment with ADR in both iNOS(-/-) and wildtype mice. These findings suggest that ADR-induced NO production is an early cardioprotective event associated with adaptation to oxidative stress.

1369 OXIDATIVE STRESS CAUSES THE FORMATION OF TWO DISULFIDES IN HUMAN THIOREDOXIN.

W. H. Watson, J. Pohl, O. Stuchlik and D. P. Jones. *Biochemistry, Emory University, Atlanta, GA.*

Thioredoxin (Trx) is a small protein that restores disulfide bonds in proteins to the reduced form following oxidative stress. Trx contains two essential active site cysteines that cycle between the dithiol and disulfide forms as Trx reduces target proteins. Human Trx contains three additional cysteines, the functions of which are unclear. The purpose of the present study was to determine the redox state of human Trx under defined redox conditions *in vitro* and before and after oxidative stress within cells. Purified Trx was reduced with DTT or oxidized with diamide or hydrogen peroxide, derivatized with iodoacetic acid which carboxymethylated thiols but not disulfides, and separated by non-reducing, non-denaturing polyacrylamide gel electrophoresis. MALDI-TOF mass spectrometry of tryptic digests of individual gel bands demonstrated unequivocally the locations of carboxymethylated cysteines and disulfide bonds. Human Trx treated with dithiothreitol contained no disulfides. Trx treated with diamide or hydrogen peroxide contained two disulfide bonds: one between Cys32 and Cys35 (the active site cysteines), and one between Cys62 and Cys69. To define the midpoint potentials, Trx was equilibrated in glutathione redox buffers. The midpoint potential for the formation of the active site disulfide, determined by plotting the ratio of the oxidized and reduced forms of Trx against the potential of the redox buffer, was -230 mV. The second disulfide bond formed only under more oxidizing conditions, with a midpoint potential of about -150 mV. Within cells, the redox state of Trx was -280 mV, and the two-disulfide form of Trx was not detected. However, Trx was rapidly oxidized to the two-disulfide form upon exposure of the cells to t-butylhydroperoxide. Thus, human Trx contains a second dithiol that undergoes oxidation during oxidative stress. The function of this non-active site disulfide is unknown, but its position near the interface region suggests that it may regulate redox-dependent interactions with other proteins.

1370 INVOLVEMENT OF THE ELECTROPHILE RESPONSIVE ELEMENT (EPRE) IN THE ACTIVATION OF HEPATIC STELLATE CELLS DURING FIBROGENESIS.

L. Qamar, A. Pappa, D. Petersen and V. Vasiliou. *Department of Pharmaceutical Sciences, University of Colorado Health Sciences Center, Denver, CO.*

Hepatic stellate cells (HSC) produce the type I collagen in normal and cirrhotic liver. During liver fibrogenesis HSC undergo an activation process that includes increased proliferation and synthesis of extracellular matrix proteins, along with a phenotypic transformation to myofibrotic-like cells. Activated HSC contribute to chronic hepatic inflammation, which ultimately leads to cirrhosis. We have found a 20-fold increase of NAD(P)H: quinone oxidoreductase 1 (NQO1) enzymatic activity and protein levels in a HSC line derived from cirrhotic (CFSC) rat liver compared to that of normal (NFSC) rat liver. This NQO1 up-regulation appears to be responsible for the increased resistance of the CFSC line cells to menadione cytotoxicity. Gel mobility shift assays and functional analysis using transient transfection experiments suggest the involvement of the Electrophile Responsive Element (EPRE) in the up-regulation of the NQO1 gene expression in CFSC cells. In conclusion, the EPRE-signaling pathway, which regulates several antioxidant genes, may play a major role in the resistance of HSC against oxidative stress that occurs during hepatic fibrogenesis. This EPRE-mediated resistance may be part of the HSC activation process, which takes place during liver injury. [Supported by NIH R01 AA11885 & R01 AA09300-05].

1371 OLIGONUCLEOTIDE MICROARRAY ANALYSIS REVEALS AN ANTIOXIDANT RESPONSIVE ELEMENT-DRIVEN GENE SET INVOLVED IN CONFERRING PROTECTION FROM AN OXIDATIVE STRESS-INDUCED APOPTOSIS IN IMR-32 HUMAN NEUROBLASTOMA CELLS.

J. Li, J. M. Lee and J. A. Johnson. *UW School of Pharmacy, Madison, WI.* Sponsor: J. Johnson.

The current study was aimed to investigate whether and how tert-butylhydroquinone (tBHQ) prevents hydrogen peroxide-induced apoptosis in neuroblastoma cells. Hydrogen peroxide at a final concentration of 200 μM induced IMR-32 cells

to undergo apoptosis with morphological changes such as condensed and fragmented nuclei (TUNEL assay), increased caspase-3 activation, and poly ADP-ribose polymerase cleavage. In cytotoxicity assays and TUNEL assays, tBHQ pretreatment (10 μM) attenuated hydrogen peroxide-induced cell death and the number of TUNEL-positive cells, respectively. We hypothesize that tBHQ-mediated activation of the antioxidant response element (ARE) is critical for generating the protective response. Our laboratory has recently shown that a selective inhibitor of phosphatidylinositol 3-kinase (PI3-kinase), LY294002, blocks ARE activation by tBHQ. Addition of LY294002 30 min prior to tBHQ treatment completely reversed the protective effect of tBHQ. Oligonucleotide microarrays were used to analyze the gene expression profile associated with tBHQ treatment in the absence and presence of LY294002. 63 genes showed transcriptional upregulation by tBHQ. RT-PCR for selected genes also confirmed the gene expression pattern. Many of these genes function to combat oxidative stress and increase the cells detoxification potential through increased production of NADPH, glutathione (reduced form), and ATP. Some examples are NAD(P)H:quinone oxidoreductase, gamma-glutamylcysteine ligase regulatory subunit, thioredoxin reductase, glutathione reductase, and cytosolic malic enzymes. Inhibition of PI3- kinase significantly blocked the enhanced expression of 49 of the 63 genes induced by tBHQ. These are the first data to show the gene set involved in conferring protection from an oxidative stress-induced apoptosis and imply that the PI3-kinase-Nrf2-ARE pathway is critical in mediating protection from oxidative stress in human neuroblastoma cells.

1372 IS THERE A RELATIONSHIP BETWEEN URINARY AND LEUKOCYTE 8-HYDROXYDEOXYGUANOSINE IN HUMANS?

M. Toraason, P. Mathias, A. Ruder, M. A. Butler, L. Taylor, C. Forrester, E. Krieg and D. G. DeBord. *NIOSH, Ciincinnati OH, OH.*

8-Hydoxydeoxyguanosine (8-OHdG) is typically measured in DNA of white blood cells (WBCs) or in urine. Urine measurement is believed to provide an index of oxidative DNA damage repair. WBCs are considered a surrogate for target tissues. These markers are used almost interchangeably to assess the adverse effects of a variety of environmental factors. Only a few of the hundreds of studies assessing 8-OHdG as a biomarker of oxidative DNA damage in humans, have measured 8-OHdG in both urine and WBC DNA. Two recent studies reported non-significant inverse associations between urinary excretion of 8-OHdG and WBC DNA 8-OHdG. We examined this relationship in male roofers with (n=26) or without (n=12) exposure to polycyclic aromatic compounds and female dry cleaners and launderers with (N=18) or without (N=20) exposure to perchloroethylene. For males, urine and blood were obtained pre-shift at the start and post-shift at the end of a work week. For females, urine was obtained pre- and post-shift mid-work week, and blood was obtained once pre-shift mid-work week. 8-OHdG was measured by HPLC-ECD. Linear models were used to look for relationships between leukocyte DNA and urine levels of 8-OHdG. Terms for gender, exposure, smoking, and race were included. Interaction terms were also included to see if the relationship between blood and urine levels varied by these terms. The models were also used to estimate and test individual slopes. For the model comparing pre-shift urine with pre-shift blood, no main effects or interactions were statistically significant, but a significant inverse association (b = -0.1231, p = 0.0336) was noted for the individual sub-group of female controls. For the model comparing pre-shift blood with post shift urine no main effects or interactions or individual slopes were statistically significant. For the model comparing post-shift blood to post shift urine, the smoking interaction was significant (p = 0.0314). Results demonstrate a limited association between leukocyte DNA 8-OHdG and urinary excretion of 8-OHdG

1373 EFFECTIVE FACTORS ON URINARY 1-HYROXYPYRENE IN A KOREAN POPULATION.

M. Yang[1], S. Lee S[1], D. Kang[1], H. Shin[3], S. Kim[2] and J. Jang[2]. [1]*Preventive Medicine, Seoul National University, Seoul, South Korea and* [2]*Preventive Medicine, Ajou University, Suwon, South Korea.*

Urinary 1-hyroxypyrene (1-OHP) has been used as a biomarker for exposure to environmental carcinogenic polycyclic aromatic hydrocarbons (PAHs). For proper biological monitoring of the PAH exposure, associated factors with 1-OHP bioproduction should be clarified. In this study, we investigated effects of lifestyle, environmental factors, and genetic polymorphisms of metabolic enzymes, i.g., GSTM1, GSTT1, CYP1A1, and CYP1B1 on urinary 1-OHP levels in 700 Korean population (male, 65 % ; female, 35 % ; mean-age, 36 yrs, std, 10.79 yrs) who were not occupationally exposed to PAHs. Using questionnaire, we obtained information of cigarette smoking, indoor heating-system, housing-environment, consumption of well-done meat, vegetables, yogurts, coffee, alcohol, etc. We analyzed urinary 1-OHP and cotinine, a biomarker of smoking, by HPLC. To determine genotypes of the enzymes, we used PCR-RFLP and single base extension methods. As results, urinary 1-OHP was detected in 76 % of the subjects (range, 0.1-3.8 ug/L). In the Korean population, CYP1B1 codon 48 and 119 polymorphism were completely linked and CYP1B1 codon 48 polymorphism was associated with codon 432 polymorphism ($p < 0.05$). Urinary 1-OHP was correlated with urinary cotinine level, number of cigarette smoked before sampling, yogurts consumption, and GSTT1 polymorphism (Spearman Rank correlation, $p < 0.05$). However, polymorphisms of GSTM1, CYP1A1, and CYP1B1 were not associated with urinary 1-OHP levels. After multiple regression analysis, urinary 1-OHP was associated with only number of cigarette smoked before sampling ($p < 0.05$). In conclusion, recent cigarette smoking affects urinary 1-OHP compared to any other environmental, food- or genetic factors.

1374 NEUROPATHY TARGET ESTERASE (NTE) IN WHOLE BLOOD: BIOMARKER FOR EXPOSURE TO NEUROPATHIC ORGANOPHOSPHORUS COMPOUNDS (OPS).

G. F. Makhaeva[1], I.. V. Sigolaeva[2], L. V. Zhuravleva[1], A. V. Eremenko[2], I. N. Kurochkin[2], R. J. Richardson[3] and V. V. Malygin[1]. [1]*Institute of Physiologically Active Compounds Russian Academy of Science, Chernogolovka, Russian Federation,* [2]*Center of Molecular Diagnostics and Therapy, Moscow, Russian Federation and* [3]*Toxicology Program, Michigan University, IL.*

NTE is the target protein for neuropathic OPs that cause OP-induced delayed neurotoxicity (OPIDN). The inhibition/aging of brain NTE within hours of exposure predicts the potential for the development of OPIDN in susceptible animal models. Lymphocyte NTE has also found limited use as a biomarker of human exposure to neuropathic OPs. Recently, we developed a highly sensitive biosensor for NTE assay using a tyrosinase carbon-paste electrode to detect phenol produced by the hydrolysis of the substrate, phenyl valerate. The biosensor enabled NTE to be assayed in whole human and hen blood, whereas the usual colorimetric assay is impossible. NTE activity in hen and human blood was found to be 0.10 ± 0.03 and 0.19 ± 0.02 nmol/min x mg of protein, respectively. Mipafox I_{50} values for hen and human blood NTE were found to be 4.22 ± 0.12 and 6.27 ± 0.43 μM, respectively. To study the possibility of using blood NTE inhibition as a biochemical marker of neuropathic OPs exposure, NTE inhibition in brain and lymphocytes as well in brain and blood was studied 24 hr after dosing hens with the neuropathic OP, O, O-dipropyldichlorvinyl phosphate. Brain, lymphocyte and blood NTE were inhibited in a dose-responsive manner. There were strong correlations of NTE inhibition between brain and lymphocyte, brain and blood, and lymphocyte and blood. Taking into account the small sample volume required, simplicity of sample preparation, rapid analysis time, stability of samples after freezing, and strong correlation of NTE inhibition between blood and brain, our biosensor NTE assay for whole blood shows promise, not only as a biomarker of human exposure to neuropathic OP compounds, but as a predictor of OPIDN and an adjunct to its early diagnosis. Supported by ISTC, Project 1055.2.

1375 CHOLINESTERASE ACTIVITY IN MICE CHRONICALLY EXPOSED TO PYRIDOSTIGMINE BROMIDE.

R. D. Grubbs, W. A. Price, B. S. Mauck, I. Bernatova, S. J. Paton, D. R. Cool, J. B. Lucot and M. Morris. *Pharmacology & Toxicology, Wright State University, Dayton, OH.*

Pyridostigmine bromide (PB), given to soldiers during the Persian Gulf War as a prophylactic against potential nerve gas attack, is now thought to be a possible causative agent of the symptoms of Gulf War Syndrome. We have developed a murine model to test the effect of chronic exposure to PB on cholinesterase (ChE) activity in the blood and the brain. C57B/J mice were surgically implanted with osmotic mini-pumps to deliver a steady dose of PB over 7 days. ChE activity was determined by a modified version of the colorimetric assay of Ellman, et al. Total ChE activity was measured in diluted whole blood and brain homogenate samples. Blood acetylcholinesterase (AChE) activity was determined by inhibiting butyrylcholinesterase (BChE) with iso-OMPA (tetraisopropylpyrophosphoramide). BChE activity was then calculated by subtracting AChE activity from total ChE activity. Following 7 days of exposure to PB, reductions of blood ChE activity of 27%, 42%, and 55% were seen in the 3, 6 and 10 mg/kg/D dosage groups, respectively, when compared to pretreatment levels. The decrease in blood ChE activity, due primarily to a drop in AChE activity, indicated that the osmotic mini-pump delivery system was functioning properly. We found no change in CHE activity in sham-implanted control animals. Interestingly, while analysis of prefrontal cortex showed no significant change in AChE activity after exposure to PB, we observed a dose-dependent decrease in AChE activity (48% at 3 mg/kg) in the hypothalami of PB treated mice (see Ropp, et al. abstract, this meeting). We are currently evaluating ChE activity in other brain regions of these animals and other mice exposed to both chronic stress and PB. Our findings indicate that chronic exposure to PB pro-

duces a dose-dependent decrease in blood and hypothalamic cholinesterase activity possibly contributing to symptoms of Gulf War Syndrome. This research is funded by DoD contract DAMD17-00-C-0020.

1376 EVALUATION OF OXIDATIVE PROCESSES IN T LYMPHOCYTE PROLIFERATION AND DEATH WITH CYTOCHROME P450 INHIBITORS AND HIGH-SPEED, CAPILLARY GC/TOFMS MEASUREMENT OF VOLATILE COMPOUNDS.

S. J. Pernecky, F. Ebisu, V. Venkatachalam, V. Bhaskara, H. Jayatilake and H. L. Holmes. *Chemistry, Eastern Michigan University, Ypsilanti, MI.*

A murine T cell hybridoma (2B4.11) was used to investigate how oxidative processes contribute to cell proliferation and to cell death induced by various agents. Inhibitors of the oxygen-activating enzyme cytochrome P450 attenuated cell death caused by calcium ionophore or T cell receptor ligand, but not dexamethasone, at concentrations that did not cause cell death. These results suggest that the P450 monooxygenase system plays a role in some pathways that signal T cell death. In view of the role of cytochrome P450 and other pro-oxidant enzymes in lipid peroxidation, methodology was developed to identify and measure biomarkers of lipid peroxidation in T cells. Malondialdehyde, as judged by the spectrophotometric measurement of the thiobarbituric acid complex, was produced in T cells during proliferation, was enhanced in the presence of 1 mM dexamethasone, and was inhibited in the presence of 20 μM ascorbate. To monitor the volatile products of lipid peroxidation, petri dishes containing T cell hybridoma cells were incubated at 37 °C in a closed chamber equipped with a fan to disperse volatile products of cellular metabolism. The head-space gas was passed through a membrane (provided by Restek) to exclude water and was then collected and concentrated over a five-min period at –90 °C by a trap cooled by liquid nitrogen. Firing of the trap was achieved at 170 °C by application of a 90-volt current. Using this novel method, hexanal was easily identified by GC/TOFMS above the 10 mL of about 0.5×10^6 T cells/mL in RPMI 1640/10% fetal bovine serum. The simultaneous characterization of volatile products in a continuous assay provides a non-invasive approach to examining the kinetics of formation of volatile lipid peroxidation products formed during oxidative stress induced by pro-oxidant systems such as cytochrome P450. [Supported by Research Excellence Fund/Graduate School Research Support Fund (EMU) and NSF Grant DBI-9987063].

1377 CAN SERUM CALMODULIN BE USED AS A BIOLOGICAL MARKER IN CHRONIC LEAD EXPOSURE?

X. D. Wu, X. Ding and W. Li. *National Evaluation Center for the Toxicology of Fertility Regulating Drugs, Shanghai, China.* Sponsor: A. Faqi.

We have evaluated whether serum calmodulin (CaM) can be used as a biological marker in chronic lead exposure. Thirty-six workers exposed to lead from a storage battery factory were selected as exposed group and twenty-six non-lead exposed workers were selected as control group. Confounding factors such as age, length of service, marriage and bad habits were carefully considered in the evaluation. Blood CaM, blood lead, calcium, magnesium, copper and zinc were determined from both lead and non-exposed workers and all data were analyzed using SAS software. The blood CaM was reduced in workers with high blood lead levels. At blood lead level higher or equal to 40 ug/dl; the blood CaM in exposed group was found to be (35.18 ± 6.92 ug/dl), which was significantly lower when compared to the control group (76.54 ± 10.35 ug/dl, $p<0.05$). Age, length of exposure, marriage status and bad habits had no effect on blood CaM levels ($p>0.05$). The correlation analysis results showed that blood lead and blood calcium was correlated to blood CaM levels ($p<0.05$), while blood magnesium, copper and zinc had no significant correlation with CaM ($p>0.05$). The results indicated that reduction of blood CaM in lead-exposed workers was accompanied by the increased blood lead. The concentration of 40 ug /dl might be considered as the biological threshold for blood lead, which coincided with the current diagnostic standard for blood lead in China. The results of the present study are promising and may indicate a role of CaM as a biological marker. However, further study with increased number of lead exposed individuals will be required before CaM could be suggested as a biological marker for chronic lead exposure.

1378 SIMULTANEOUS DETERMINATION OF N-7-HYDROXYETHYLGUANINE, O^6-HYDROXYETHYLGUANINE AND N-3-HYDROXYETHYLADENINE WITH LC/MS/MS.

H. U. Käfferlein and T. R. Fennell. *CIIT Centers for Health Research, Research Triangle Park, NC.*

N-7-hydroxyethylguanine (7-HEG) has been previously described as the major DNA adduct *in vivo* after exposure to ethylene oxide (EO), with analysis by gas chromatography/mass spectrometry (GC/MS) or high performance liquid chromatography (HPLC) with fluorescence or electrochemical detection. Here we present a method for the determination of 7-HEG by HPLC and tandem mass spectrometry (LC/MS/MS). In addition, the method is also capable of analysis of O^6-hydroxyethylguanine (6-HEG) and N-3-hydroxyethyladenine (3-HEA) in one analytical run. For this purpose, DNA was isolated from mouse liver tissue by chloroform/phenol extraction. DNA samples were fortified with the adducts mentioned above. Subsequently, a neutral thermal hydrolysis was carried out. Separation of adducts from oligonucleotides was achieved by centrifugation of the hydrolysate using microconcentration filters. After injection and separation of the adducts employing a novel stationary phase (silica-bonded polyamide) for HPLC, the adducts were quantified by the use of their isotopically-labeled analogs N-7- and O^6-hydroxyethyl-[^{13}C-8, ^{15}N-7, 9]guanine (7-HEG* and 6-HEG*), and N-3-hydroxyethyl-[^{13}C-8, ^{15}N-6, 9]adenine (3-HEA*). Multiple reaction monitoring (MRM) was carried out to detect the fragments [M-44] for the analytes and their labeled internal standards. The limits of detection for the method were determined to be between 2.6 and 2.8 fmol on column depending on the particular adduct. The LC/MS/MS method presented here has advantageous over the previously published GC/MS methods, since derivatization of adducts could be omitted and all three major adducts of EO can be analyzed in one single analytical run.

1379 ELECTROSPRAY IONIZATION TANDEM MASS SPECTROMETRY (ESI-MS/MS) ANALYSIS OF 1-BROMOPROPANE MERCAPTURIC ACID METABOLITES IN URINE.

K. L. Cheever, K. L. Marlow, D. E. Stinson, A. W. Teass and D. G. DeBord. *Molecular and Genetic Monitoring, NIOSH, Cincinnati, OH.*

1-Bromopropane (1-BP, CAS 106-95-5), an alternative solvent to chlorofluorocarbons, has been reported to cause reproductive and neurotoxicity in male rats. The related 2-bromopropane has been shown to cause similar toxicity in rats and amenorrhea, oligozoospermia, and anemia in workers. Activation to reactive intermediates may be important. Metabolism of 1-BP is complex, including debromination, CYP2E1 oxidation and glutathione S-conjugation. The formation of 3-bromopropionic acid and n-propanol as well as of S-n-propyl-glutathione, S-n-propyl-L-cysteine and the mercapturic acids N-acetyl-S-(n-propyl)-L-cysteine (M1), N-acetyl-S-(n-propyl)-L-cysteine-S-oxide (M2), N-acetyl-S-(2-carboxyethyl)-L-cysteine (M3), and N-acetyl-S-(3-hydroxy-n-propyl)-L-cysteine (M4). A potential biomonitoring method was developed to measure urinary levels of M1, M2, M3 and M4. Standards and a stable isotope-labeled analog of M1 as internal standard were synthesized using the general procedure of van Bladern et al. (1980). Samples mixed with internal standard were loaded onto Bond Elute C18 SPE columns. A fraction containing >90% of 1-BP metabolites was eluted with acetone for analysis by HPLC ESI-MS/MS on a 150X2 mm Phenomenex Aqua C18 column using a 10-min H2O:MeOH (1% acetic acid) linear gradient at 300 μL/min. The ESI-MS/MS operated in the positive ion mode to detect protonated M1, M2, M3 and M4 and used Selected Reaction Monitoring of major transition products. Urine samples fortified with standards were mixed with 10 μg/mL internal standard and evaluated for recovery, limits of detection and limits of quantitation. Calibration of M1, M2, M3 and M4 was linear from 30 - 10000 ng/mL ($r2>0.99$). Sample preparation and analysis appears to offer significant advantages over typical derivatization that would be required for GC-MS analysis of these compounds. Thus, 1-BP internal exposure levels for various exposure situations can be rapidly determined by analysis of these metabolites in a single assay using selective sample preparation.

1380 IMMUNOLOGICAL DETECTION OF HEXAMETHYLENE DIISOCYANATE ADDUCTS IN SERA FROM AUTOBODY SHOP WORKERS.

R. Lemus, L. Lukinskeine and M. H. Karol. *Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

Hexamethylene diisocyanate (HDI), a potent irritant and allergen, is widely used in the manufacture of polyurethanes for paints and coatings. Detection of HDI is problematic since diisocyanates are difficult to characterize, measure and control. Biomarkers would be of great benefit for early detection of exposure to prevent possible chronic adverse health effects. We have previously reported development of a sensitive and specific immunoassay for detection of HDI adducts on proteins. Microtiter plates coated with rabbit IgG from anti-HDI-keyhole limpet hemocyanin antiserum are used to capture HDI-adducted proteins. The immunoassay has a sensitivity of 95 nmol HDI adduct. To evaluate the potential use of the immunoassay to detect recent HDI exposure, sera were collected from six autobody shop workers who are exposed to HDI in paints. Serum samples were obtained from three of these workers periodically during one workday, and from the remaining three workers only at 24 hr after the start of the workday. Sera were also obtained from control non-exposed individuals. HDI adducts were detected using

peroxidase-labeled sheep anti-human albumin, followed by substrate. No HDI adducts were detected in any of the samples from control individuals nor in samples taken at the start of the workday. However, in one worker 99 nmol HDI adduct was detected at 4 hr, and 423 nmol was detected at 24 hr. HDI adducts were detected in sera from three of the individuals at 24 hr. Concentrations ranged from 104- 426 nmol adduct. These results indicate that this immunoassay has appropriate sensitivity to detect recent HDI exposure and can be applied for human biomonitoring of HDI in the workplace. Supported by NIEHS #05651.

1381 ACETAMINOPHEN PROTEIN ADDUCTS IN MOUSE LIVER AND SERUM AND HUMAN SERUM AFTER HEPATOTOXIC DOSES OF ACETAMINOPHEN DETECTED BY HIGH-PERFORMANCE LIQUID CHROMATOGRAPHY WITH ELECTROCHEMICAL DETECTION.

K. L. Muldrew, L. P. James, L. Coop, S. S. McCullough, H. P. Hendrickson, P. R. Mayeux and J. A. Hinson. *Pharmacology and Toxicology and Pediatrics, Univ Arkansas Med. Sci, Little Rock, AR.*

Acetaminophen-induced hepatotoxicity has been attributed to covalent binding of the reactive metabolite N-acetyl-*p*-benzoquinone imine to cysteine groups on proteins as an acetaminophen-cysteine conjugate. We report a high-performance liquid chromatography with electrochemical detection (HPLC-ECD) assay for the conjugate with increased sensitivity compared to previous methods. Previous methods to quantitate the protein-bound conjugate have used a competitive immunoassay, or radiolabeled acetaminophen. With HPLC-ECD, the protein samples are dialyzed then digested with protease. The acetaminophen-cysteine conjugate is then quantified by HPLC-ECD utilizing tyrosine as an internal reference. Acetaminophen protein adducts were detected in liver and serum as early as 15 min after hepatotoxic dosing of acetaminophen to mice. Adducts were also detected in the serum of acetaminophen overdose patients. Analysis of human serum samples for the acetaminophen-cysteine conjugate revealed a positive correlation between acetaminophen-cysteine conjugate concentration and serum aspartate aminotransferase (AST) and alanine aminotransferase (ALT) activities, and time to treatment with the antidote, N-acetylcysteine. Adducts were detected in the serum of patients even with relatively mild liver injury, as measured by AST and ALT. This assay may be useful in the diagnostic evaluation of patients with hepatotoxicity of an indeterminate etiology, for which acetaminophen toxicity is suspect.

1382 AN LC-ESI-MS/MS ASSAY FOR THE QUANTITATION OF CROTONALDEHYDE-DERIVED EXOCYCLIC 1, N^2-PROPANODEOXYGUANOSINE ADDUCTS.

M. D. Stout, A. L. Ham, H. Koc, R. Sangaiah and J. A. Swenberg. *Curriculum in Toxicology and Departments of Environmental Sciences and Engineering, and Pathology and Laboratory Medicine, University of North Carolina, Chapel Hill, NC.*

Crotonaldehyde is a genotoxic and carcinogenic α, β-unsaturated aldehyde. Endogenous formation of crotonaldehyde presumably occurs through lipid peroxidation. Crotonaldehyde is a proposed metabolite of butadiene and is also ubiquitous in our environment due to automobile exhaust and industrial processes. Upon reaction with DNA, crotonaldehyde forms, among several other classes of DNA adducts, a pair of diastereomeric exocyclic 1, N^2-propanodeoxyguanosine adducts. These propano adducts are present in two cell systems in which crotonaldehyde is mutagenic. The ubiquity and mutagenicity of crotonaldehyde point to a need for the development of biomarkers for the assessment of crotonaldehyde exposure and risk. A sensitive and specific adduct quantitation method employing mass spectrometry would permit measurements of adducts at low doses and comparisons between endogenous and exogenous adducts. To this end, we have initiated development of an LC-ESI-MS/MS assay to quantitate crotonaldehyde-derived exocyclic 1, N^2-propanodeoxyguanosine adducts (C-dGuo 1&2). Both analyte and [4, 5, 6, 8-$^{13}C_4$]-labeled internal standards for C-dGuo 1&2 have been synthesized and characterized by HPLC, UV, full-scan MS, and NMR. The first analyte standard to elute during HPLC has been analyzed by LC-ESI-MS/MS (SRM 338→222) to determine preliminary conditions for quantitation of these adducts and to determine their sensitivity to LC-ESI-MS/MS. LC-ESI-MS/MS has proven to be an extraordinarily sensitive means of detecting these adducts, as 750 amol (10^{-18}mol) injections of the analyte standard yielded signal to noise ratios of up to 114. Method development is continuing with more extensive LC-ESI-MS/MS work to optimize the detection of C-dGuo 1&2 in DNA samples, and to determine a cleanup procedure for enrichment of C-dGuo 1&2 in DNA samples. Following the completion of method development, we will quantitate C-dGuo 1&2 in a variety of DNA samples.

1383 EFFECT OF CYP2E1 GENOTYPE ON ACRYLONITRILE HEMOGLOBIN ADDUCTS.

T. R. Fennell[1], R. W. Snyder[1], W. Krol[1], B. Chanas[2], F. Gonzalez[3], B. I. Ghanayem[2] and S. C. Sumner[1]. *[1]CIIT Centers for Health Research, Research Triangle Park, NC, [2]NIEHS, Research Triangle Park, NC and [3]NCI, Bethesda, MD.*

Acrylonitrile (ACN) is metabolized by two pathways: conjugation with glutathione, and oxidation to cyanoethylene oxide catalyzed by CYP2E1. Measurement of ACN metabolites indicated an absence of oxidation to cyanoethylene oxide in CYP2E1-null mice [Sumner et al., Chem. Res. Toxicol. 12: 1110-1116, (1999)]. Hemoglobin adducts provide a long-term measure of the internal dose of a reactive chemical. ACN reacts with hemoglobin to form a number of adducts, including *N*-(2-cyanoethyl)valine (CEVal). We have developed a new method for analysis of CEVal using LC-MS/MS. After a modified Edman degradation with phenylisothiocyanate as derivatizing agent, the resulting adducted valine phenylthiohydantoin derivative was isolated by solid phase extraction, and chromatographed by reverse phase HPLC. Elution was monitored by selected reaction monitoring on a PE Sciex API 3000 triple quadrupole mass spectrometer. The method can measure adducts from natural abundance and isotope labeled ACN. To investigate the impact of the CYP2E1 genotype on ACN internal dose, [1, 2, 3-^{13}C] ACN (20 mg/kg) was administered to wild type and CYP2E1-null mice, and blood was collected for CEVal analysis. In the wild type mice, CEVal levels were approximately 3 fold lower than in the CYP2E1-null mice (1487 ± 728 fmol/mg globin *vs.* 4863 ± 911 fmol/mg globin). These data indicate that, in the absence of CYP2E1 and the capability to oxidize ACN, the internal dose of acrylonitrile in the CYP2E1-null mice increased to greater than 3 times the levels in wild type mice.

1384 ESTIMATING POPULATION MEANS FOR THE DISTRIBUTIONS OF POLYCHLORINATED BIPHENYL CONGENERS IN CENSORED DATA SETS.

J. L. Helferich[1], K. T. Halvorsen[2] and P. J. Kostyniak[1]. *[1]J.L. Helferich, University at Buffalo, Buffalo, NY and [2]K. Halvorsen, Smith College, Northampton, MA.*

Samples of milk from 99 lactating women were analyzed for 69 PCB congeners, DDE, Mirex, and hexachlorobenzene (HCB) (Kostyniak et al. Environmental Research 80:S166-174, 1999). Eight PCB congeners and one pesticide (DDE) were found in amounts above the limit of detection (LOD) in all 99 women. The remaining PCB congeners and pesticides were found in some, but not all, of the women. Values below the LOD are treated as censored data. Several methods have been suggested in the literature for estimating the mean and standard deviation of the population of concentrations for censored data sets. In the present study we examine the performance of five methods: substitution of the LOD or half the LOD (LOD/2), the maximum likelihood estimator (MLE), the restricted maximum likelihood estimator (RML) and a linear regression analysis (LR). We compare the estimators' performance in the eight PCBs and in DDE for which there is a complete data. The mean and standard deviation are calculated for each congener of the full data set. Censored data sets were created from the complete data set by dropping the smallest 10, 20, 30, 40, 50, 60, 70, 80, and 90 percent of the data. The methods were then compared for each degree of censoring, using the percent error as a measure of the bias of the estimates of the mean, and the ratio of the observed to estimated variance in the population as a measure of the relative efficiency of the estimator. The RML, MLE and LR gave estimates of the mean within 7% of the actual value for all levels of censoring. Although we could not statistically distinguish between the RML, MLE and LR, all three methods performed significantly better than substitution of the LOD or LOD/2. In conclusion the RML, MLE and LR are more useful than substitution of the LOD or the LOD/2 to estimate the population mean PCB congener concentration in censored data sets.

1385 SECULAR CHANGE OF BIOLOGICAL MONITORING MEASUREMENTS IN JAPAN.

T. Kawamoto, M. Ichiba, M. Ueki, M. Hosokawa, S. Kanemura and S. Kageyama. *Environmental Health, University of Occupational and Environmental Health, Kitakyushu, Japan.*

Partial amendments to the Japanese Ordinance on the Prevention of Lead Poisoning and the Japanese Ordinance of the Prevention of Organic Solvent Poisoning were made in 1989. As results, the measurement of lead in blood and urinary delta-aminolevulinic acid (ALA) became indispensable items of the occupational health examination for workers who handle lead. Also, the measurement of urinary metabolites of workers who handle eight kinds of organic solvents became mandatory. In order to support the national-wide biological monitoring program in Japan, seven major laboratories meet regularly to improve quality control and collect the measurement results after the enforcement of the amended ordinances. The annual number of measurements was about 100, 000 for lead in blood and ALA in urine, and about 500, 000 for the metabolites of the organic solvents, however, the total number of the subjects has slightly decreased for the last 10 years. The number of urine with high ALA concentration decreased drastically during the

10 years. The reasons seem to be not only the improvement of working environment but also the alteration of analytical methods from colormetric one to HPLC. The number of urine with high concentration of the metabolites also has decreased during the 10 years except hippuric acid. It can be concluded that occupational exposure to lead or the organic solvents has been decreased after the commencement of the national-wide biological monitoring.

1386 CHANGES OF URINARY AND BLOOD PORPHYRINS DURING PROLONGED EXPOSURE AND POST EXPOSURE TO PCBs, PB OR DIAZINON IN RATS.

S. H. Jeong, J. H. Cho and O. K. Kim. *Veterinary Drugs Toxicology Division, National Veterinary Reasearch & Quarantine Service, Anyang, South Korea.* Sponsor: J. Chung.

Porphyrins are intermediates in the biosynthesis of heme. The porphyrin pattern in excreta or tissues has been introduced as a useful biomarker for hazardous xenobiotics. In this study, we evaluated and compared the urinary and blood porphyrin profiles by treatment of PCBs (Aroclor1254), Pb or diazinon in rats. PCBs (10, 50, and 100 mg/kg bw), Pb(62.5, 250 and 1, 000 ppm) and diazinon(10, 30 and 90 mg/kg bw) were administered to SD male rats *via* gavage (PCBs and diazinon) or *via* drinking water (Pb) daily for 5 weeks. The highest dose of each chemical was selected as LD10. Uro, copro and protoporphyrin in urine and blood collected every week for 5 weeks of exposure and 5 weeks of post exposure were quantitated with fluorospectrometer. No clinical signs were observed by Pb and diazinon, while icterus and 15% lethality were induced by 100mg/kg PCBs. Three of urinary porphyrins and blood protoporphyrin were increased gradually and dose responsively in progress of PCBs exposure time and then urinary coproporphyrin came to peak at 5 weeks of exposure, urinary uroporphyrin and blood protoporphyrin at 2 weeks after withdrawal and urinary protoporphyrin at 3 weeks after withdrawal. They were continued to be higher than control until 5 weeks after PCBs withdrawal. By the treatment of Pb, the increase of urinary porphyrins and blood protoporphyrin was induced more quickly than PCBs. That is, urinary porphyrins were increased rapidly, came to peak at 2 weeks of exposure and returned to normal levels as soon as withdrawal and blood protoporphyrin began to increase from 1 week, peaked at 5 weeks of treatment and continued to be higher than control during withdrawal period. In diazinon case, urinary and blood porphyrins were not so much sensitively affected as PCBs and Pb, just showing weak increase of urinary coproporphyrin. These results demonstrate that urinary and blood porphyrin profiles confer characteristic biomarkers and useful tools for exposure assessment of PCBs, Pb and diazinon.

1387 PLATINUM LEVELS IN NASAL LAVAGE ARE NOT RELATED TO TRAFFIC DENSITY BUT TO NASAL INFLAMMATION.

P. J. Borm[1], D. Polat[1], J. Begerow[2], M. Turfeld[2], A. Becker[1] and R. P. Schins[1]. *[1]Particle Toxicology, Institut für Umweltmedizinische Forschung (IUF), Düsseldorf, Germany and [2]Analytical Chemistry, Medizinisches Institut für Umwelthygiene, Düsseldorf, Germany.* Sponsor: P. Kodavanti.

Platinum (Pt) is a well-known constituent of particles emitted by autocatalysts. To evaluate Pt as a potential marker for traffic related particle exposure, we investigated Pt content along with non-traffic related metals (Cr, V) in coarse and fine particulate matter (PM) sampled in 4 areas with different traffic density as well as in nasal lavage fluid (NALF) of 63 children living in these areas. Pt, Cr and V content of coarse and fine PM were not significantly different between different sites, although CO emmission as a validated traffic marker during the sampling interval was clearly different (ANOVA, $P < 0.05$). In addition, concentrations of these metals in nasal lavage of children living in these locations were not significantly different. However, a significant correlation between Pt levels in NALF and total number of cells or interleukin-8 as markers for inflammatory status of the nose was found. No relationship was present between inflammation and Cr and V levels in nasal lavage.We suggest that Pt is a marker for traffic-related PM that are able to induce inflammation in the upper respiratory tract.

1388 USE OF DNA ARRAYS TO MONITOR GENE EXPRESSION IN BLOOD AND UTERUS FROM LONG-EVANS RATS FOLLOWING 17-BETA-ESTRADIOL EXPOSURE - A NEW APPROACH TO BIOMONITORING ENDOCRINE DISRUPTING CHEMICALS USING SURROGATE TISSUES.

J. C. Rockett, R. J. Kavlock, C. Lambright, L. G. Parks, J. E. Schmid, V. S. Wilson and D. J. Dix. *Reproductive Toxicology Division, USEPA, Research Triangle Park, NC.*

Evidence exists that environmental xenobiotics are disrupting the endocrine systems of certain wildlife species, resulting in developmental abnormalities and reproductive impairment. Although the relationship between human disease and exposure to such endocrine disrupting chemicals (EDCs) is unknown, it is believed that EDCs present a potential threat to public health. Gene expression analysis offers the ability to identify preclinical effects of exposure to EDCs and provide mechanistic data useful for risk assessments, and could ultimately provide a vehicle for developing early diagnostic and preventative measures in at-risk populations or individuals. Since apparently healthy human reproductive organs cannot be sampled directly, a method to utilize more accessible tissues must be developed. We propose that gene expression changes in accessible tissues such as blood will often reflect those in inaccessible tissues, thus offering a convenient biomonitoring method for providing insight into the effects of environmental toxicants on target tissues. In this pilot study, gene expression changes in peripheral blood lymphocytes (PBLs) were compared with those in the uteri of adult rats to identify genes that were altered in both tissues following estradiol treatment. Ovariectomized rats were treated with either 17-beta-estradiol or vector control for three days. Uteri and PBLs were harvested, and total RNA extracted and hybridized to Clontech Atlas rat 1.2i arrays. A number of genes were found to demonstrate a similar degree of expression change that was treatment-, but not tissue-specific, demonstrating that accessible tissues such as PBLs can act as surrogate tissues for observing gene expression changes in inaccessible target tissues.

1389 PLATELET MAO-B ACTIVITY AS A STATE MARKER OF ALCOHOLISM.

L. Manzo[1,2], C. Gandini[1], A. F. Castoldi[1], G. Randine[1] and T. Coccini[1]. *[1]Toxicology Division, Maugeri Foundation, Pavia, Italy and [2]Dept. of Internal Medicine, University of Pavia, Pavia, Italy.*

This study evaluated time-related changes in platelet monoamine oxidase B (MAO) activity in a homogeneous Italian cohort of alcoholic-dependent subjects (n = 98) during early abstinence and the effect of potential confounding factors, such as gender and smoking status, on the temporal trend of this enzyme activity. While still under the influence of ethanol (time point T1) mean MAO activity in alcoholics was 6.4 ± 3.1 nmol/mg protein/hr. This returned within the control range (9.9 ± 0.9 nmol/mg protein/hr) after 8 days of withdrawal (T2), and remained stable thereafter (T3 and T4: 15 and 22 days of abstinence, respectively). Alcohol intake cessation was confirmed by serum %carbohydrate-deficient transferrin (CDT), which was pathologically above the reference limits (6%) at T1 (7.8 ± 3.3%), decreased to 6.6 ± 2.1% at T2 and reached physiological values at T3 and T4. In cirrhotic alcoholics %CDT did not decrease over time, while MAO activity was comparable to that of abstinent noncirrhotic alcoholics. The mean values of other liver function tests were elevated at the first evaluation (GGT, serum gamma-glutamyltransferase: 641 ± 894 U/l; AST, aspartate aminotransferase: 119 ± 70 U/l; ALT, alanine aminotransferase: 86 ± 56 U/l), decreased during hospitalization but remained above the reference values at the patient's dismissal (GGT: 231 ± 487 U/l; AST: 39 ± 34 U/l; ALT: 47 ± 37 U/l). MCV (mean corpuscular volume) values were elevated at admission and remained so during hospitalization. Neither gender nor tobacco smoking affected the temporal pattern of MAO activity during early withdrawal. MAO-B can be regarded as a state-marker of alcohol consumption. The temporal pattern of its activity may be used for the diagnostic assessment of alcoholism and early abstinence, regardless of gender and smoking status. (Supported by grant QLRT-2001-00186 from the European Commission).

1390 CYTOCHROME OXIDASE ACTIVITY AND CHOLINERGIC MUSCARINIC RECEPTOR BINDING AS PERIPHERAL MARKERS OF CARBON MONOXIDE NEUROTOXICITY.

T. Coccini[1], A. F. Castoldi[1], C. Gandini[1], G. Randine[1] and L. Manzo[1,2]. *[1]Toxicology Division, Maugeri Foundation, Pavia, Italy and [2]Dept. of Internal Medicine, University of Pavia, Pavia, Italy.*

Carbon monoxide (CO), a widely spread neurotoxicant, has been shown to alter cytochrome oxidase C (COX) activity and cholinergic parameters in the brain of acutely exposed rodents. A decrease in COX activity has also been observed in the lymphocytes of acutely poisoned humans. In this study we investigated the early and delayed effects of *in vivo* CO exposure on cholinergic muscarinic receptor (MR) binding and COX activity in the rat brain and whether CO-induced central changes would be reflected by similar alterations in peripheral lymphocytes. Male Wistar rats were exposed by inhalation to 500 ppm CO for 6 hr/day, 5 days/wk for 4 wks. One and 7 days after the end of the treatment, no changes were detected in 3H-QNB binding to MR in the cerebral cortex, cerebellum and hippocampus (control values, mean ± SD, were for cerebral cortex, cerebellum and hippocampus 171 ± 45, 77 ± 7 and 245 ± 53 fmol/mg protein, respectively) as well as in the lymphocytes (24 ± 19 fmol/million cells). Similarly ineffective was repeated CO exposure towards brain (124 ± 25 nmol/min/mg protein) and lymphocyte (26 ± 9 nmol/min/mg protein) COX activity at the same time points. Acute CO inhalation (2400 ppm, 1 hr) did not modify central and peripheral COX activity and MR

binding 1 hr, 1 day, 3 and 7 days after treatment. Studies on other possible CO targets (such as cGMP) are in progress in order to identify valuable peripheral biomarkers of central effect (Supported by grant QLK4-CT99-01356 from the European Commission).

1391 SENSITIVE EARLY INDICATORS OF HEPATIC AND KIDNEY DAMAGE IN WORKERS EXPOSED TO JET FUEL(JP-8).

J. E. Snawder, M. A. Butler, J. C. Clark, E. A. Knecht and E. F. Krieg. *Biological Monitoring Laboratory Section, NIOSH, Cincinnati, OH.*

Jet Propellant type 8 (JP-8)is used for all US military operations. Because of the widespread exposure and concern for potential health effects, three hundred twenty-four US Air Force (USAF) active duty personnel participated in a study at six USAF bases between April and September, 2000. Animal & human studies suggest that exposure to fuels and solvents can adversely effect the liver and kidney. Glutathione transferase (GST) isoenzymes possess specific patterns of distribution in organs and are released to biological fluids in response to toxic insult. ELISA techniques can be used to measure those GSTs associated with liver and kidney damage. Pre- and post-shift serum and urine samples were collected from USAF personnel and commercial GST assays were used to measure alpha GST in serum (marker for liver damage) and alpha and pi GST in urine which are associated with proximal and distal tubule damage, respectively. Exposed workers were tank-entry personnel with at least nine months of persistent exposure to jet fuel; the unexposed group were USAF personnel with no significant exposure to fuels or solvents. Levels of serum hepatic alpha-GST, and urinary nephritic alpha- and pi-GST in the study subjects fell within the normal range for healthy subjects. No differences were observed indicative of liver or kidney damage attributable to any of the exposure, lifestyle and other demographic variables examined. Creatinine, used to normalize urinary GSTs was elevated in post-shift samples from the highest exposure category. This study group represents a very healthy segment of the population. Sensitive measures for liver and kidney damage did not detect any adverse effects in this study group. Evidence of elevated creatinine in the mean post-shift samples of the high exposure category was seen. However, while these values are within normal clinical ranges, they are consistent with concentrated urine indicative of mild dehydration.

1392 A BIOLOGICAL LIMIT VALUE (BLV) FOR OCCUPATIONAL EXPOSURE TO PERFLUOROOCTANOATE.

R. Roy, G. Olsen, P. Lieder, J. Mandel and J. Butenhoff. *Medical Department, 3M Company, St. Paul, MN.*

A biological limit value (BLV) of 5 ppm for perfluorooctanoate (PFOA) in the serum of workers has been established by 3M. Ammonium PFOA (APFO) is a polymerization aid used in fluoropolymer production. The 3M BLV represents the best scientifically-based estimate of a concentration of PFOA in a biological fluid (serum) that, if present, even on a chronic basis, is not expected to correlate with a risk of adverse health effects in workers. Serum levels above the 5 ppm BLV do not necessarily imply a health risk. A significant body of toxicological, epidemiological, and medical surveillance information is available for PFOA and APFO to support a BLV of 5 ppm PFOA in serum. The results of toxicology studies indicate that the major target organ of APFO is the liver. Oral administration of APFO to monkeys at 3 and 10 mg/kg/d for six months resulted in mean serum concentrations of approximately 50 and 70 ppm, respectively, and was associated with increases in both absolute liver weight and liver-to-body weight ratios without gross or histopathological abnormalities or changes in clinical chemistries. Approximately 90 percent of 3M workers exposed to APFO have had serum PFOA levels below 10 ppm. Investigators have not observed any exposure-related clinical hepatic toxicity or hormonal changes in these workers. The repeated analyses, to date, provide reasonable assurance that workers with serum PFOA levels below 10 ppm do not experience exposure-related clinical hepatotoxicity; however, there have been too few employees with serum PFOA concentrations above 10 ppm to draw statistically-significant conclusions regarding a lack of clinical hepatotoxic effects with serum PFOA levels at or above 10 ppm.

1393 DIFFERENT RESPONSES IN THE PATTERN OF EXPRESSION OF P53 CHALLENGED WITH ARSENIC.

P. Ostrosky[1], C. Acuña[1], D. Menéndez[1], M. Sordo[1], C. Trejo[2], L. A. Herrera[1,2], A. Dueñas[1,2] and A. M. Salazar[1]. [1]*Genomic Medicine and Environmental Toxicology, Instituto de Investigaciones Biomedicas, UNAM, Mexico D.F., Mexico and* [2]*Division de Investigacion Basica, Instituto Nacional de Cancerologia, Mexico D.F., Mexico.*
Sponsor: M. Cebrián.

Different pattern of expression of the p53 protein were observed when lymphocyte cultures were challenged with arsenic. To evaluate the reproducibility of this effect we determined the presence of p53 in blood samples from 22 healthy individuals, using 4 different treatment conditions: (1) non-stimulated lymphocytes (Go); (2) lymphocytes stimulated with phytohemagglutinin during 48h (Control); (3) stimulated lymphocytes treated with arsenic(As); or (4) with actinomycin-D (AcD) during the last 24h. Proteins were obtained at the end of culture, and measured by immunoblot. Data show three different patterns of p53 expression : I) 16 individuals had bands in As and AcD treated cultures but not in Go; II) 4 individuals in addition to the previous pattern, showed a band in Go; III) 2 donors did not show any p53 response. No relation of these expression-pattern differences with cell proliferation could be established. Since we have found a higher frequency of polymorphisms in the intron 1 (Bgl II P53) among breast cancer patients, we analyzed the p53 expression in females with and without polymorphism. No relationship among both parameters was found. The expression of p53 in lymphocyte cultures could be of relevance in the understanding of individual susceptibility to xenobiotics and might have a great potential as a biomarker.

1394 BIOMARKER CHARACTERIZATION OF ASPHALT FUME EXPOSURE.

J. J. Wang, D. M. Lewis, B. Law, D. G. Frazer, S. Stone, T. Goldsmith, A. Mosley, J. Simpson and P. D. Siegel. *HELD, CDC/NIOSH, Morgantown, WV.*

Each year more than 60 million tones of asphalt are produced and used worldwide. It has been estimated that approximately two million workers were employed and potentially exposed to asphalt. Health concern from exposure to asphalt is related to its content of hazardous chemicals, such as polycyclic aromatic hydrocarbons (PAHs). The development of a biomarker to provide an assessment of the integrated external exposure following uptake by living system through inhalation is valuable for this kind of complex mixture exposure. Many PAHs are metabolized to hydroxyl-PAHs and excreted in urine; therefore, urinary hydroxyl-PAH was used as a biomarker for asphalt fume exposure in this study. Female Sprague-Dawley rats and B6C3F1 mice were exposed to asphalt fume in a whole body inhalation chamber for 5 or 10 days (3.5 hrs/day, 71-97 mg/m ^{3}). Clean air chamber animals were used as controls. The test asphalt was the type used by paving industry throughout the Midwestern United States. The fume was generated under simulated road paving conditions. Urine sample preparation for the analysis of hydroxyl-PAHs metabolites included enzymatic digestion, solid phase extraction, and isotope dilution GC/MS and microflow LC-Q-TOF MS detections. Four priorities PAH metabolites, including, 1-hydroxypyrene, 9-phenanthrenol, 1-chrysenol, and 2-naphthalenol were identified and determined in urine. Isotope-dilution has proved to be useful for quantification of those metabolites. Preliminary results indicated that urinary PAH metabolite could be a sensitive biomarker following asphalt fume exposure. The method developed in this study has potential application to monitor of PAHs from occupational mixture exposure.

1395 BIOMARKERS OF OXIDATIVE STRESS STUDY: ARE OXIDATION PRODUCTS OF LIPIDS MARKERS IN CCL4 POISONING?

M. B. Kadiiska, B. C. Gladen, D. B. Baird, D. R. Germolec, L. Graham, C. E. Parker, K. B. Tomer, R. P. Mason and J. C. Barrett. *NIEHS/NIH, Research Triangle Park, NC.*

Oxidation products of lipids in plasma and urine of rats were measured as part of a comprehensive, multilaboratory validation study searching for non-invasive biomarkers of oxidative stress. This is the second report of the nationwide Biomarkers of Oxidative Stress Study (BOSS). The time (2, 7, and 16 h) and dose (120 and 1200 mg/kg ip)-dependent effects of CCl4 on concentrations of lipid hydroperoxides, TBARS, malondialdehyde (MDA) and isoprostanes were investigated with different techniques. Plasma concentrations of MDA and isoprostanes (measured by GC/MS) and urinary concentrations of isoprostanes (measured with an immunoassay) were increased in CCl4 treated rats in a time- and dose-dependent manner. All other products were not changed by CCl4 or showed only high-dose and/or single time point effects. It is concluded that measurements of MDA and isoprostanes concentrations in plasma and urinary isoprostanes are promising candidates for general biomarkers of oxidative stress. 1396 URINARY BISPHENOL A GLUCURONIDE AS A BIOMARKER FOR BISPHENOL A EXPOSURE.

A. Matsumoto, N. Kunugita, K. Kitagawa, R. Suenaga, T. Isse, T. Oyama and T. Kawamoto. *Environmental Health, University of Occupational and Environmental Health, Kitakyusyu, Japan.*

The estrogenic effects of bisphenol A (BPA) have been reported in E-screen assay and in *vivo* studies of rodents, however, the exposure levels and health effects of BPA in humans are still unknown. We assessed the BPA exposure by the measurement of urinary BPA-glucuronide. University students and workers who handled BPA diglycidyl ether (DGEBPA) were evaluated in the present study. There urinary BPA levels were measured using a HPLC with fluorescence detector. BPA-glucuronide concentration was calculated by the subtraction of BPA measurement without β-glucuronidase treatment from BPA measurement with β-glucuronidase treatment. The method developed for urinary BPA determination shows a linear calibration, and good recovery rates and reproducibility. The urinary BPA levels of the students in 1992 were significantly higher than those of 1999, and BPA levels in the students who habitually drink more coffee and tea tend to be higher than those of students who drink less. The urinary BPA levels of BPADGE-workers were significantly higher than those of the control workers. It is thought that the high levels of urinary BPA of the students in 1992 were caused by drinking BPA dissolved from inside-wall coating of coffee and tea cans. However, our recent BPA exposure seems to be very low because the inside coatings had been changed. Although the workers who handle BPADGE have a risk of BPA exposure, their exposure levels were almost same as those of the university students in 1992.

1397 RAPID GENOTYPE METHODS TO DISTINGUISH SINGLE NUCLEOTIDE POLYMORPHISMS WITHIN THE HUMAN NAT1 AND NAT2 GENES.

M. A. Doll and D. W. Hein. *Pharmacology and Toxicology, University of Louisville, Louisville, KY.*

N-acetyltransferase 1 (NAT1) and 2 (NAT2) catalyze the activation and deactivation of aromatic amine drugs and carcinogens. Genetic polymorphisms in NAT1 and NAT2 have been associated with the incidence of cancers related to exposures to aromatic and heterocyclic amines found in cooked foods, cigarette smoke, and the environment. We designed facile *NAT1* and *NAT2* genotyping methods that distinguish among the most frequent and/or functional nucleotide polymorphisms in the *NAT1* and *NAT2* coding regions and *NAT1* 3*acute*-untranslated region (UTR). The single nucleotide polymorphisms detected in NAT1 are: C97T (R33Stop), C190T (R64W), G445A (V149I), C559T (R187Stop), G560A (R187Q), A752T (D251V), T1088A (3*acute-*UTR), C1095A (3*acute*-UTR). All NAT1 alleles (*NAT1*3, NAT1*4, NAT1*10, NAT1*11A, NAT1*11B, NAT1*14A, NAT1*14B, NAT1*15, NAT1*17, NAT1*19, NAT1*22*) except very rare ones are detected by this method. The single nucleotide polymorphisms detected in the *NAT2* genotyping method are: G191A (R64Q), C282T (silent), T341C (I114T), C481T (silent), G590A (R197Q), A803G (K268R), G857A (G286T). This method can detect all except very rare human *NAT2* alleles including *NAT2*4, NAT2*5A, NAT2*5B, NAT2*5C, NAT2*5D, NAT2*5E, NAT2*6A, NAT2*6B, NAT2*6C, NAT2*7A, NAT2*7B, NAT2*11, NAT2*12A, NAT2*12B, NAT2*12C, NAT2*13, NAT2*14A, NAT2*14B, NAT2*14C, NAT2*14D, NAT2*14E, NAT2*14F and NAT2*14G.* These genotyping methods do not require post-PCR processing or the use of radioactivity, and therefore are very suitable for high-throughput applications. Partially support by USPHS grant CA-34627 from the National Cancer Institute

1398 COMPARING THE EFFECTS OF ALTEPLASE (TPA), TENECTEPLASE (TNK-TPA) AND RETEPLASE (RPA) ON HEMOSTATIC PARAMETERS IN A RABBIT MODEL OF PROLONGED INFUSION.

A. S. Cheng[1], K. P. McKeever[1], C. P. Semba[2], C. J. Refino[3], G. DeGuzman[3], D. L. Combs[4], R. C. Dere[5], W. J. Leach[1], J. Klein[1] and C. A. O'Neill[1]. *[1]Safety Assessment, Genentech, Inc., South San Francisco, CA, [2]Cardiovascular Medicine, Genentech, Inc., South San Francisco, CA, [3]Cardiovascular Research, Genentech, Inc., South San Francisco, CA, [4]Clin/Exp Pharmacology, Genentech, Inc., South San Francisco, CA and [5]Bioanalytical R&D, Genentech, Inc., South San Francisco, CA.*

Urokinase unavailability has led clinicians to use other thrombolytics for catheter-directed thrombolysis (CDT) in treating acute limb ischemia and deep vein thrombosis. Despite the widespread clinical use of thrombolytics, there is no preclinical safety data evaluating the effects of these agents on coagulation parameters when administered using CDT. This study evaluated the effect of tPA, TNK-tPA, or rPA on hemostatic parameters using a rabbit model and infusion techniques similar to clinical practice. tPA, TNK-tPA, or rPA were infused (IV) at doses corresponding to 0, 0.5, 1.0, 2.0, and 10 (mg/hr, t-PA, TNK; U/hr, r-PA) in a 70 kg human. Arterial blood samples were collected at 0, 0.5, 1, 2, 3, and 4 hours for coagulation parameters (PT, aPTT, fibrinogen, plasminogen and alpha2-antiplasmin). A dose related change in PT and systemic fibrinogen was exhibited with all thrombolytics; however, rPA had a greater increase in PT and greater depletion of systemic fibrinogen than tPA or TNK-tPA. tPA exhibited reduced alpha2-antiplasmin depletion (>65% of baseline at all doses) compared to TNK-tPA (20% of baseline with 0.143 mg/kg TNK-tPA) and rPA (0, 40 and 50% of baseline with 0.143, 0.029 and 0.014 U/kg rPA, respectively). Plasminogen levels exhibited similar dose related changes. This data indicates significantly less alteration of systemic hemostasis parameters using highly fibrin-specific agents, tPA and TNK-tPA, compared to rPA. Consequently, tPA and TNK-tPA may provide a better safety profile with less systemic fibrinolysis when used for peripheral vascular applications; further comparative studies are warranted.

1399 EARLY EFFECT OF PHOSPHODIESTERASE (PDE) IV INHIBITION ON LEUKOCYTE-ENDOTHELIAL CELL INTERACTION: FUNCTIONAL RELEVANCE OF ENHANCED EXPRESSION OF INTEGRINS AND ADHESION MOLECULES TO EXPERIMENTAL VASCULITIS IN RATS.

R. M. Slim, A. Becker, M. Albassam and L. A. Dethloff. *Drug Safety Evaluation, Pfizer Global Research and Development, Ann Arbor, MI.*

PDE inhibitors have been shown to cause vasculitis in nonclinical toxicology studies, typically in rats. Vasculitis, such as that induced by the type IV PDE inhibitor CI-1018 is characterized by medial necrosis with perivascular mixed inflammatory cell infiltrates. Underlying mechanisms associated with initiation of the vascular inflammatory process are poorly understood. In the present studies we investigated the ability of CI-1018 to modulate early events of leukocyte-endothelial cell interactions, leukocyte surface expression of betta2-integrins, and gene regulation of the corresponding endothelial counter ligand intercellular adhesion molecule-1 (ICAM-1). Leukocyte adhesion and rolling activity were studied in female Wistar rats by intravital microscopy (IVM) between 1.5 and 4 hours following a single oral dose of CI-1018 at 750 mg/kg. IVM revealed an increase in the number of adherent and rolling leukocytes in mesenteric postcapillary venules. In a separate experiment, flow cytometric analysis showed that neutrophil surface integrin expression was upregulated 4 hours after a single dose (CD11a and CD11b) and 72 hours after 3 daily doses (CD11a, CD11b and CD18) of CI-1018, respectively. RT-PCR analyses revealed a rapid upregulation of ICAM-1 mRNA that occurred within 4 hours of a single dose with CI-1018. Using an *in vitro* leukocyte-endothelial adhesion assay, significantly more neutrophils from CI-1018-treated rats adhered to TNF-alpha-activated cultures of rat endothelial cells compared to neutrophils from controls. Blockade with anti-CD18 antibody significantly decreased neutrophil adhesion to the endothelial cell monolayer. These results suggest that CI-1018 induces early leukocyte adhesion which is mediated, at least in part, by betta2-integrins and the endothelial ligand ICAM-1. These events likely have functional relevance to the pathogenesis of PDE IV inhibitor-induced vascular inflammation in rats.

1400 EXPRESSION OF ENDOTHELIAL AND INDUCIBLE NITRIC OXIDE SYNTHASE AND FORMATION OF PEROXYNITRITE-MODIFIED PROTEINS IN PHOSPHODIESTERASE (PDE) INHIBITOR-INDUCED VASCULITIS IN RATS.

Y. Song, R. M. Slim, M. Albassam and L. A. Dethloff. *Drug Safety Evaluation, Pfizer Global Research and Development, Ann Arbor, MI.*

The type IV PDE inhibitor CI-1018 has been shown to cause vascular lesions in nonclinical toxicology studies, typically in rats. It has been proposed that excessive release of nitric oxide by inducible nitric oxide synthase (iNOS) and subsequent formation of highly reactive peroxynitrite plays a role in tissue damage in PDE inhibitor-induced vascular injury. This study was conducted to determine the putative cellular source of iNOS, to identify the distribution of nitrotyrosine residues as a measure of peroxynitrite production, and to evaluate their association with vascular injury induced by CI-1018. Four groups of female Wistar rats were given doses of vehicle or CI-1018 at 750 mg/kg daily by gavage for up to 3 days. One group of CI-1018-treated rats was sacrificed at 24 hours after each dose. Endothelial nitric

oxide synthase (eNOS), iNOS and nitrotyrosine were evaluated by immunohistochemistry in paraffin sections of mesenteric artery. Arteries showed intense iNOS immunostaining of endothelial cells in rats that received the full course of 3 daily doses of CI-1018 and only in sections that showed mild to marked vascular injury. eNOS was evident in endothelial cells without differences in staining intensity between control and CI-1018-treated groups. Nitrotyrosine-positive cells were detected only on reactive oxygen species-producing inflammatory cells, distinct from iNOS-producing endothelial cells. Nitrotyrosine-postitive staining was present exclusively in inflammatory cells at 72 hours, coinciding with the peak in iNOS expression in mesenteric artery. It is concluded that PDE IV inhibitor-induced vascular injury in rats is associated temporally with the induction of iNOS in endothelial cells and with production of peroxynitrite by inflammatory cell infiltrates, but direct evidence of peroxynitrite-mediated vascular injury remains to be demonstrated.

1401 EFFECTS OF VARIOUS COMPOUNDS ON ACTION POTENTIAL PARAMETERS IN ISOLATED DOG PURKINJE FIBERS.

J. R. McCullough, G. P. Thomas, B. R. Klatt and C. B. Spainhour. *Calvert Preclinical Services, Inc., Olyphant, PA.*

The QT interval on the electrocardiogram is the time from the onset of ventricular depolarization (the Q wave) to completion of repolarization (the end of the T wave) in the axis of the lead chosen for measurement. The QT interval is of special interest in view of potential therapeutic agents that can influence the duration of the interval and the known association between QT prolongation and the potential for malignant ventricular arrhythmias. As part of preclinical safety assessment packages, both *in vitro* and *in vivo* systems can be used to demonstrate effects of chemicals on electrophysiological and electrocardiographic parameters. *in vitro* Purkinje fiber preparations from a variety of laboratory species are considered to be suitable experimental models provided that the major ionic currents underlying the investigated cardiac action potential do not differ substantially from those encountered in human cardiac tissues. In this study, the effects of various compounds on action potential parameters were determined in isolated canine cardiac Purkinje fibers using intracellular microelectrodes. Action potential parameters measured were disatolic membrane potential, maximum rate of depolarization of action potential upstroke, overshoot action potential, action potential amplitude and action potential duration at 30, 50 and 90% repolarization. Reference standards of dl-sotalol and l-phenylephrine were observed to prolong action potential duration, while lidocaine was found to shorten action potential duration. Lidocaine shortened action potential duration at all concentrations and frequencies tested. Interestingly, the effects of the l-phenylephrine standard on action potentials were found to be time-dependent and biphasic. Low concentrations of phenylephrine rapidly prolonged action potential duration, but the maximum extent of this prolongation was not maintained throughout the 30 min exposure period. The standard dl-sotalol was observed to prolong action potential duration in a

1402 PRE-CLINICAL ASSESSMENT OF CARDIOTOXICITY AND IN COMMON MARMOSETS.

K. Kuwano[1], R. Nagata[1], S. Nagayama[1], T. Hamada[1], T. Kamenosono[1], K. Fukuzaki[2] and G. Kito[1]. *[1]Shin Nippon Biomedical Laboratories (SNBL), Ltd., Kagoshima, Japan and [2]SNBL USA, Ltd., Everett, WA.*

Appropriate species selection for safety pharmacology and drug toxicity testing is essential for the development of novel pharmaceuticals for human use. The purpose of this study was to obtain information on both the cardiovascular system in conscious common marmosets using a telemetry system, and the characteristics of marmoset ventricular myocytes through measurement by the patch-clamp method. experiment: Male and female marmosets (1-3 years old) were used. The heart was removed and perfused with Ca -free Tyrode solution containing collagenase through the coronary artery, using a Langendorff perfusion system. The ventricles were cut into pieces and dispersed with a pipette in order to isolate ventricular myocytes. Action potential (AP) and ion current of ventricular myocytes were measured by the patch-clamp method. experiment: Male marmosets (1-3 years old) were used. In conscious, unrestrained marmosets, ECG (similar to CM-V5 in Holter recording), heart rate and blood pressure were continually measured by a telemetry system. In the experiment, astemizole prolonged APD (AP duration at 90% repolarization) of ventricular myocytes. E4031, an inhibitor of I (rapid phase of K current in AP) also prolonged APD90. In the experiment, astemizole at 30 mg/kg (p.o.) or 3 mg/kg (i.v.) was shown to induce QT interval prolongation, resulting in torsades de pointes-like ventricular tachycardia. In conclusion, the assessment demonstrated the scientific value of the marmoset as a predictor of adverse effects in humans.

1403 INDUCTION OF ANTIOXIDANTS BY 3H-1, 2-DITHIOLE-3-THIONE IN CARDIOVASCULAR CELLS AFFORDS PROTECTION AGAINST OXIDATIVE CELL INJURY.

Y. Li[1], Z. Cao[1] and M. Trush[2]. *[1]Department of Pharmaceutical Sciences, St. John's University College of Pharmacy, Jamaica, NY and [2]Division of Toxicological Sciences, Johns Hopkins University School of Public Health, Baltimore, MD.*

Considerable evidence suggests that reactive oxygen species (ROS) are critically involved in the pathogenesis of cardiovascular diseases, particularly atherosclerosis. Consistent with this concept, consumption of antioxidants, such as vitamin E, has been shown to be causally related to a decreased incidence of atherosclerosis. However, whether induction of endogenous cellular antioxidants by chemicals (drugs) also affords protection against oxidative cardiovascular injury has not been extensively investigated. In this study, using rat aortic A10 cells as an *in vitro* system we have characterized the induction of cellular antioxidants by the antioxidant-inducing agent, 3H-1, 2-dithiole-3-thione (D3T) and the protective effects against ROS-mediated injury in cardiovascular cells. Incubation of A10 cells with D3T for 24 hours resulted in a significant dose-dependent induction of a battery of cellular antioxidants, including reduced glutathione (GSH), GSH peroxidase, glutathione reductase, catalase, and superoxide dismutase. To further examine the protective effects of the induced endogenous antioxidants against oxidative cell injury, A10 cells were pretreated with D3T and then exposed to xanthine oxidase (XO) plus xanthine, a system that produces superoxide and hydrogen peroxide. We observed that D3T pretreatment of A10 cells led to significant protection against XO/xanthine-induced cytotoxicity as determined by 3-[4, 5-dimethylthiazol-2-yl]-2, 5-diphenyltetrazolium bromide (MTT) reduction and morphological changes. Taken together, this study demonstrates that a number of endogenous antioxidants in vascular smooth muscle cells can be induced by exposure to D3T, and that this chemical induction of cellular antioxidants is accompanied by markedly increased resistance to ROS-mediated cardiovascular cell injury.

1404 CHARACTERIZATION OF CELLULAR GLUTATHIONE AND GLUTATHIONE S-TRANSFERASE, AND THEIR INDUCIBILITY BY 3H-1, 2-DITHIOLE-3-THIONE IN RAT AORTIC SMOOTH MUSCLE A10 CELLS: PROTECTION AGAINST REACTIVE ALDEHYDE-INDUCED TOXICITY.

Z. Cao[1], M. Trush[2] and Y. Li[1]. *[1]Department of Pharmaceutical Sciences, St. John's University College of Pharmacy, Jamaica, NY and [2]Division of Toxicological Sciences, The Johns Hopkins University School of Public Health, Baltimore, MD.*

There is increasing evidence that aldehydes generated endogenously during the degradation process of biological molecules are involved in the pathogenesis of cardiovascular diseases, such as atherosclerosis. Because glutathione (GSH) and GSH S-transferase (GST) are a major cellular defense against the toxic effects of reactive aldehydes, in this study we have characterized the inducibility of GSH and GST by 3H-1, 2-dithiole-3-thione (D3T) and their protective effects against acrolein and 4-hydroxy-2-nonenal (4-HNE)-induced toxicity in rat aortic smooth muscle A10 cells. Incubation of A10 cells with micromolar concentrations of D3T resulted in a concentration- and time-dependent induction of both GSH and GST. Furthermore, the levels of GSH and GST remained higher than basal levels 72 hours after removal of D3T from the culture media. To examine the protective effects of D3T-induced GSH and GST against reactive aldehyde-mediated toxicity, A10 cells were pretreated with D3T and then exposed to acrolein or 4-HNE. Pretreatment of A10 cells with D3T resulted in a marked decrease of acrolein or 4-HNE-induced toxicity as determined by MTT reduction assay and morphological changes. To further demonstrate the involvement of GSH and GST in protecting against acrolein and 4-HNE-induced toxicity, buthionine sulfoximine (BSO) and sulfasalazine were used to inhibit cellular GSH biosynthesis and GST activity, respectively. Either depletion of cellular GSH by BSO or inhibition of cellular GST by sulfasalazine led to a marked potentiation of acrolein or 4-HNE-induced toxicity in A10 cells. Taken together, our results demonstrate that both GSH and GST in aortic smooth muscle cells can be induced by D3T, and that this increased cellular defense affords protection against reactive aldehyde-induced cardiovascular cell injury.

1405 THE FORMATION OF PEROXYNITRITE AND INDUCTION OF THE INFLAMMATORY MEDIATOR, CYCLOOXYGENASE-2, ARE IMPORTANT FACTORS IN ARSENIC-RELATED CARDIOVASCULAR DISEASE.

M. Bunderson and H. D. Beall. *The Department of Pharmaceutical Sciences, University of Montana, Missoula, MT.*

There is substantial epidemiological evidence linking arsenic-contaminated drinking water with an increased risk of cardiovascular disease. This includes decreased cardiac function as well as peripheral vascular diseases and atherosclerosis. The

mechanisms behind these phenomena are largely unknown. The purpose of this study was to determine whether arsenic could contribute to the chronic inflammatory and oxidative stress symptoms characteristic of atherosclerosis. In endothelial cells treated with sodium arsenite, we saw a significant increase in peroxynitrite, an oxidant formed from nitric oxide and superoxide that is also capable of nitrating protein tyrosine residues. This follows the pathology seen in atherosclerotic plaques in which the observed increase in nitrotyrosine residues is believed to be due to the presence of peroxynitrite. Peroxynitrite formation was confirmed by western blotting of a COX-2 immunoprecipitation probed with a nitrotyrosine antibody. There was increased nitration of the COX-2 protein in arsenic treated cells compared to controls. The COX-2 protein itself was also up-regulated in response to arsenic exposure, indicating an increase in the inflammatory response in endothelial cells. This was supported by an increase in the synthesis of PGE2 following exposure to arsenic. The results of this study suggest an increase in reactive species, particularly peroxynitrite, in endothelial cells exposed to arsenic. Furthermore, induction of important inflammatory mediators such as the COX-2 enzyme may exacerbate the inflammatory state typical of atherosclerosis.

1406 METALLOTHIONEIN PROTECTION AGAINST CADMIUM INDUCED CARDIOTOXICITY IN MICE.

L. Elsherif and Y. J. Kang. *Pharmacology and Toxicology, University of Louisville, Louisville, KY.*

Cadmium (Cd) is a heavy metal environmental pollutant linked to the development of cardiovascular diseases. In murine models of Cd exposure, the effects of Cd are manifested by significant increase in blood pressure as well as heart morphological alterations. The sensitivity of the heart to Cd could be due to the low level of a thiol-rich, metal-binding protein, metallothionein (MT), in the tissue. The present study was thus undertaken to test the hypothesis that elevation of MT in the heart makes this organ resistant to Cd toxicity. A cardiac-specific MT-overexpressing transgenic (MT-TG) mouse model was used and cardiotoxicity was analyzed by evaluating performance of left ventricle and heart morphological changes. MT-TG mice and non-TG controls were treated with $CdCl_2$ (6 mg/kg) for 48 hrs. This treatment lead to a significant decrease in heart rate, maximum left ventricle pressure, and the first derivative of intraventricular pressure (dP/dt). On the other hand the duration of contraction and relaxation and the time constant (Tau) were prolonged. These changes were more pronounced in non-TG than in MT-TG animals. In addition, an increase in contractility caused by isoproterenol (Iso) administration in Cd-treated non-TG animals was more pronounced in comparison to saline treated animals; whereas, Cd-treated MT-TG animals responded in a similar manner to control. The direct effect of MT on Cd toxicity in cardiomyocytes, the contractile units of the heart was determined using primary neonatal mouse cardiomyocyte cultures. An MTT assay was performed for the assessment of cell viability; treatment with 0.1 μM Cd for 1 hr lead to a 65% decrease in non-TG cells whereas this dose lead to only a 50% decrease in viability in MT-TG cardiomyocytes. Results of this study demonstrate that elevation of MT in transgenic animals protects against Cd-induced cardiotoxicity manifested by functional alterations; furthermore cardiotoxicity most likely occurred in cardiomyocytes as demonstrated by the results obtained from cell cultures.

1407 MYOCARDIAL PROTECTION BY METALLOTHIONEIN FROM ISCHEMIA/REPERFUSION INJURY.

Y. Li and Y. J. Kang. *Medicine, Pharmacology and Toxicology, Louisville, KY.*

Ischemia-reperfusion causes depressed myocardial function and associated deleterious morphological alterations that lead to heart failure. Metallothionein (MT) has been shown to provide cardioprotection against a variety of insults. This study was undertaken to test the hypothesis that MT also protects the heart form injury induced by ischemia/reperfusion. An open-chest coronary artery occlusion and reperfusion procedure to produce ischemia/reperfusion-induced left ventricle infarction was used. A total of 40 male MT-overexpressing transgenic and wild type mice were divided into 4 groups. The mice were subjected to 30 min of anterior descending coronary occlusion followed by a reperfusion for 24 hours. A sham surgery was applied to control groups. The MT concentrations in transgenic mouse hearts were ~10 fold higher than that in wild type controls. Myocardial infarction was significantly inhibited in the MT transgenic mice. The infarct sizes averaged 35% of the region at risk in transgenic and 61% in wild mice respectively. This inhibition correlated with the suppressed cardiac morphological and functional alterations, as determined by Hematoxylin-Eosin staining and heart function performance. In additon, ischemia-reperfusion-induced reactive oxygen species generation and lipid peroxidation were significantly inhibited in the transgenic myocardium. These results thus demonstrate that MT plays an important role in protection of the heart from ischemic/reperfusion injury. This cardioprotective effect of MT correlates with its antioxidant action. (Supported in part by NIH grants HL63760 and HL 59225)

1408 THE CORRECTION OF QT INTERVAL IN CONSCIOUS AND ANAESTHETISED BEAGLE DOGS USING DIFFERENT FORMULAE.

S. W. Dean, G. Mesiti, F. Mattei and J. Brightwell. *Research Toxicology Centre, Pomezia, Italy.*

During the last decade some non-cardiovascular drugs already on the market were revised for clinical use on the basis of possible prolongation of QT interval, a pro-arrhythmic event which can degenerate into a fatal ventricular arrhythmia (torsade de pointes). Therefore, starting from 1997, QT assessment for human medicinal products has attracted the attention of regulatory authorities. During *in vivo* pre-clinical studies, QT interval could be assessed directly from recorded electrocardiograms in conscious or in anaesthetised dogs. Nevertheless, the correction factors for heart rate are critical for an accurate and well understood QT interval assessment and the literature suggests that the best formulae to correct QT in dog are those with a minimal correlation with the heart rate. Our laboratory introduced the correction of QT interval as a standard method in pre-clinical dog studies using several different formulae for correction. The electrocardiograms were obtained from 142 (71 males and 71 females) untreated conscious dogs, 24 - 30 weeks old, held in right lateral recumbency. The six main leads (I, II, III, aVF, aVL, aVR) were recorded synchronously and QT intervals were measured from II standard limb leads. We investigated the QT-RR relation in conscious and anaesthetised Beagle dogs by individual analysis of the QT and preceding RR intervals. QTi mean values were 171.8 ms in males and 171.3 ms in females with a range from 140 to 209 ms. The heart rates of both sexes ranged from 73 to 209 beats/min and the RR interval from 287 to 820 ms. QTc were calculated using the Bazett's square root formula, the Fridericia's cubic root formula and the Kovacs' inverted root formula. Results from these studies to address a potential for QT interval prolongation contributed to the design and interpretation of early clinical investigations. The investigation of the potential of pharmaceuticals to prolong the QT interval should be an integral part of pre-clinical safety assessment studies.

1409 A COMPARATIVE HISTOPATHOLOGIC AND METABONOMIC EVALUATION OF VASCULITIS INDUCED BY SK&F 95654, A PHOSPHODIESTERASE III INHIBITOR, IN SPONTANEOUSLY HYPERTENSIVE (SHR) AND NORMOTENSIVE WISTAR-KYOTO (WKY) RATS.

J. Zhang[1], E. H. Herman[1], D. G. Robertson[2], A. Knapton[1], D. Chadwick[1] and F. D. Sistare[1]. *[1]Center for Drug Evaluation and Research, FDA, Laurel, MD and [2]Ann Arbor Laboratories, Pfizer, Inc., Ann Arbor, MI.*

The present study was initiated to compare the vascular toxicity of SK&F 95654 (SKF) between SHR and WKY. Adult male rats were euthanized 24 h after a single s.c. injection of 100 or 200 mg/kg SKF. SKF caused small vessel vasculitis (with arterial hemorrhage and necrosis) of the mesentery, renal (tubular hyaline droplets, protein casts, glomerular vacuolization), cardiac (necrosis, inflammation, edema), and hepatic (degeneration, inflammation) lesions. Lesions were assessed semiquantitatively microscopically on a scale of 0-5 (cardiac and vascular) or 0-3 (hepatic and renal). Mean scores of vascular lesions were higher in SHR (4.4 and 5.0 given 200 or 100 mg/kg, respectively) than in WKY (0.7 and 0.8 at the same doses). Following dosing with SKF both mast cell prevalence and the percentage of mast cells undergoing degranulation in sections of mesentery increased more significantly in SHR than in WKY. On the other hand, renal lesion scores of 2-3 were seen only in WKY treated with either dose of SKF. Renal pathology correlated with serum elevations in BUN, creatinine, and GGT seen only in WKY. In both strains significant cardiac and hepatic lesions were seen. Cardiac lesion scores of 4-5 were seen in SHR given 200 mg/kg (10/10) or 100 mg/kg (4/6) compared to (2/6) WKY given the high dose of SKF. Hepatic lesion scores of 2-3 were more frequent in WKY, but without changes in serum ALT, AST, or bilirubin. Metabonomic analyses of urine collected by cystocentesis revealed alterations in NMR spectral patterns that segregated by treatment and by the sharply different pathologies produced in the two strains. These results indicate that the differences in SKF-induced toxicities between SHR and WKY are providing mechanistic insight as well as strategies for identifying and evaluating biomarkers associated with drug-induced vasculitis.

1410 POLYCYCLIC AROMATIC HYDROCARBONS WITH BAY-LIKE STRUCTURES INHIBITED GAP JUNCTIONAL INTERCELLULAR COMMUNICATION IN NEONATAL RAT CARDIOMYOCYTES AND CAUSED ASYNCHRONOUS BEATING.

B. L. Upham[1], J. M. Davis[2], J. E. Trosko[1] and K. A. Schwartz[1]. *[1]Pediatrics & Human Development and National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI and [2]Human Medicine, Michigan State University, East Lansing, MI.*

Cigarette smoke has been implicated in causing or contributing to many human pathologies including cancer and cardiovascular disease. Polycyclic aromatic hydrocarbons (PAHs) are one class of compounds in this complex mixture of combusted

by-products of tobacco that has been extensively studied. Although the most abundant PAHs in cigarette smoke are methylated anthracenes and phenanthrenes, the toxicity of these compounds has not been extensively studied. Recently, several published reports showed that methyl- or chloro-anthracenes, which possess a bay-like structure, induces a release of arachidonic acid, inhibits gap junctional intercellular communication (GJIC), and activates mitogen activated protein kinases in a pleuripotent rat liver epithelial stem cell line. Anthracenes with no bay-like structures were inactive. These biological effects are all molecular events associated with the promotional phases of cancer. In the present study, we demonstrated that anthracenes with bay-like structures inhibited GJIC in primary cultures of cardiac myocytes from neonatal rats, whereas the anthracene lacking a bay-like structure had no affect on GJIC. This inhibition of GJIC directly correlated with the induction of asynchronous beating, illustrating the importance of GJIC in the metabolic coordination of synchronous contraction of cardiac myocytes. These results indicate that a prominent component of cigarette smoke, namely methylantracenes with distinct structural configurations, could be a potential etiological agent contributing to cardiac dysfunction.

1411 VASCULAR SMOOTH MUSCLE CELL PROLIFERATION FOLLOWING CHRONIC, INTERMITTENT EXPOSURE TO 4, 4'-METHYLENEDIANILINE.

T. R. Dugas[1], B. C. Jones[1], R. C. Mifflin[2], V. Santa Cruz[2], P. J. Boor[2] and M. K. Kanz[2]. *[1]Dept. of Pharmacology, LSU Health Sciences Center, Shreveport, LA and [2]Dept. of Pathology, University of Texas Medical Branch, Galveston, TX.*

Since 1900, more Americans die annually from cardiovascular diseases (CVD) than from any other disease, and since 1984, more women die from CVD than men. Ironically, few environmental toxicants have been evaluated for their capacities to mediate these diseases. We recently discovered that in female rats weekly, low-dose exposure to 4, 4'-methylenedianiline (DAPM), a compound used in the production of polyurethane, results in vascular medial hyperplasia in both the liver and lung. In addition, treatment of vascular smooth muscle cells (VSMC) in culture with micromolar amounts of DAPM results in VSMC proliferation. Relevant to this newly revealed toxicity, Kautiainen et al. (1998) have suggested that the majority of DAPM metabolite bound to protein in the blood is formed through metabolism by extrahepatic peroxidase enzymes. Peroxidase enzymes metabolize aromatic amines like DAPM to their corresponding imines, which are reactive intermediates capable of binding to DNA and protein. To evaluate whether peroxidase enzymes in VSMC are involved in DAPM-induced VSMC proliferation, we treated VSMC in culture with 0-50 μM DAPM and analyzed the cells for peroxidase activity and the presence of cyclooxygenase-2 (COX-2) protein. Western analysis revealed that VSMC express COX-2, and DAPM treatment increased peroxidase activity 12h after exposure. DAPM or its metabolites thus appear to upregulate the expression of COX-2. Finally, VSMC proliferation was attenuated when cells were simultaneously treated with N-acetylcysteine, a non-protein thiol capable of reacting with electrophilic intermediates, thus competing for their reaction with endogenous molecules and possibly preventing cell damage. The totality of the data presented here suggest that VSMC themselves are capable of metabolizing DAPM to reactive intermediates. (Supported by F32 ES 05892-01.)

1412 TIME COURSE OF PYRIDOSTIGMINE BROMIDE TREATMENT ON BLOOD PRESSURE AND ACETYLCHOLINESTERASE ACTIVITY IN MICE.

I. Bernatova[1,2], W. A. Price[1], R. D. Grubbs[1] and M. Morris[1]. *[1]Pharmacology and Toxicology, Wright State University School of Medicine, Dayton, OH and [2]Cardiovascular Physiology, Institute of Normal and Pathological Physiology, Slovak Academy of Sciences, Bratislava, Slovakia.*

Pyridostigmine bromide (PB) is used primarily for treatment of myasthenia gravis and for prophylactic protection against oranophosphorus nerve poisoning. PB acts by reversible inhibition of acelylcholinesterase (AChE) which is involved in the metabolism of ACh and thus in regulation of neuromuscular and autonomic function. However, there is a little information on the effect of PB on cardiovascular (CV) function. Experiments were performed to determine the time course of the effect of PB on plasma AChE and blood pressure (BP) and heart rate (HR) in conscious mice. The experiment used C57 male mice with chronic carotid arterial catheters for CV measurements and collection of blood samples. PB was administered sc using osmotic minipumps at doses of 1 and 3 mg/kg/day for 7 days. The controls were sham-operated with minipumps filled with saline. BP and HR (sampling rate 85 Hz) were measured for 24 hr on day 0 and days 3 and 7 after minipump insertion. Sequential blood samples (25 ul) for AChE determination were collected on the same days. Mean BP of the control group was 108±5 and 103±4 mm Hg during the dark and light period, respectively. HR was 499± 62 and 478±63 beats/min during the dark and light period, respectively. PB treatment had no effect on BP and HR. Basal AChE activity was 0.44±0.18 umol/min/ml. PB treatment (1 mg/kg/day) had no influence on AChE activity. However, 3 mg/kg/day of PB decreased significantly AChE activity on day 7 by 84±16%. In conclusion, chronic low dose PB exposure in mice decreased AChE activity but had no effect on BP and HR. Supported by DoD contract No.99214005.

1413 TELEMETRY MONITORING OF CARDIOVASCULAR FUNCTION IN CONSCIOUS MALE CYNOMOLGUS MONKEYS AFTER ORAL TERFENADINE OR ASTEMIZOLE.

T. W. Beck, T. Kamenosono, D. Aissat, G. Kito, S. Meyer, K. Fukuzaki and R. Nagata. *SNBL USA Ltd., Everett, WA.*

A primate telemetry system was evaluated for its utility in detecting QT prolongation, cardiac arrhythmias or other physiological changes after terfenadine or astemizole. Data collection and analysis was done with an Open-A.R.T./Ponemah (Data Sciences International/Gould Instruments) system. A telemetry transmitter designed to monitor blood pressure (BP), core temperature (Temp) and ECG was surgically implanted in each of three male cynomolgus monkeys. The animals were allowed four weeks recovery. Treatments were administered orally (5 mL/kg) at one-week intervals. The dosing sequence was: Control vehicle (0.05% methylcellulose), three doses of terfenadine (30, 100 and 300 mg/kg body weight), control vehicle, three doses of astemizole (10, 30 and 100 mg/kg body weight) and a final control vehicle. Continuous data recording began 2 hours before dosing (0700) and ended 24 hours after dosing (0900 the next day). Animals were recorded on videotape over the same time period (infrared light at night) for subsequent behavior analysis. All parameters were evaluated at half hour intervals before dosing and hourly after dosing. The data files were analyzed for BP, heart rate, QT interval and Temp. QTc (Bazett's) increased after treatment in one of three terfenadine and all three astemizole animals. The QT prolongation was readily detected with the hourly sampling protocol. Five Torsades de pointes (TDP) polymorphic ventricular arrhythmia episodes were detected between 3 and 6 hours after the high astemizole dose in one animal. TDP events were of very short duration (2–4 second) and required continuous monitoring for detection. No other treatment related changes were seen. Heart rate and Temp exhibited consistent diurnal variation during all treatments. In conclusion, the telemetry system and protocol used in this study, successfully detected QT prolongation plus TDP after astemizole and QT prolongation after terfenadine. Continuous recording was needed to insure detection of intermittent polymorphic ventricular arrhythmias.

1414 PREVENTION OF DIABETIC CARDIOMYOPATHY BY METALLOTHIONEIN THROUGH SUPPRESSION OF HYPERGLYCEMIA-INDUCED OXIDATIVE STRESS AND CELL DEATH.

L. Cai, W. Li, X. Sun, Y. Li and Y. J. Kang. *Medicine, University of Louisville, Louisville, KY.*

Diabetic cardiomyopathy is related directly to hyperglycemia; however, proper treatment strategies are unavailable since its cellular and molecular mechanism is unclear. The present study was undertaken to test the hypothesis that hyperglycemia-induced myocardial injury is mediated by oxidative stress and metallothionein (MT), a potent antioxidant, suppress diabetic cardiomyopathy. A cardiac-specific, MT-overexpressing, transgenic mouse model (MT-TG) and non-transgenic controls (WT) were treated with streptozotocin (STZ). About 70 % of the mice treated with STZ-developed diabetes as determined by whole-blood glucose levels. There were no differences in hyperglycemia, body-weight gain, or serum lipid peroxide levels between MT-TG and WT diabetic mice. However, serum creatine phosphokinase activity, a biomarker of myocardial injury, was markedly increased in WT diabetic mice. Correspondingly, myocardial pathological changes as examined by light and electron microscopy and functional alterations as determined by a heart performance analysis were found in WT diabetic mice. Importantly, these diabetic myocardial injuries were all suppressed in MT-TG diabetic mice. In addition, high levels of glucose caused directly lipoprotein and bovine serum albumin (BSA) oxidation, measured by TBARS and Western blotting. High levels of glucose also caused cell death, detected by TUNEL and diapi staining, in cultured cardiac cells. The cell death was associated with accumulation of reactive oxygen species and activation of mitochondrial cytochrome c release-mediated caspase-3 pathway. These results demonstrate that MT prevents diabetic cardiomyopathy, likely through inhibition of cardiac cell death caused by hyperglycemia-derived oxidative stress. (Supported by NIH, AHA and U of L School of Medicine)

1415 DIFFERENTIAL EFFECTS OF LOW AND HIGH CONCENTRATIONS OF QUINIDINE TO INDUCE TORSADE DE POINTES ARRHYTHMIAS: ROLE OF LATE SODIUM AND DELAYED RECTIFIER CURRENTS.

G. P. Thomas[1], C. B. Spainhour[1] and C. Antzelevitch[2]. [1]*Calvert Preclinical Services, Inc., Olyphant, PA and* [2]*Masonic Medical Research Laboratory, Utica, NY.*

It is well-known that Torsade de Pointes arrhythmias develop with low, but not high, plasma levels of quinidine. Previous studies have suggested that this may be due to the ability of the drug to amplify transmural dispersion of repolarization (TDR) and thus create a vulnerable window at low concentrations of the drug. Low levels of quinidine were shown to dramatically increase TDR, secondary to a preferential prolongation of the action potential duration (APD) of the mid myocardial (M) cell. Selective block of rapid delayed rectifier current (I_{Kr}) was shown to mediate this action. This study is designed to elucidate the ionic basis for the differential arrhythmogenic effects of low and high concentrations of quinidine. M cells have a smaller slow delayed rectifier current (I_{Ks}) but a larger late sodium current (I_{Na}) compared to epicardial or endocardial cells. We hypothesized that inhibition of I_{Ks} and late I_{Na} underlies the uniform prolongation of APD and the reduction in TDR caused by higher concentrations of quinidine. I_{Ks} was measured using whole cell patch clamp techniques and defined as the chromanol 293B-sensitive tail current elicited by repolarization to 0 mV after a 3 sec step to 40 mV. 5 *micro*|M quinidine did not affect I_{Ks} (1.57 ± 3.7 % inhibition), but 10-25 *micro*|M significantly inhibited the current (79.4 ± 5.9 % inhibition at 25 *micro*|M). Late I_{Na}, (the sustained TTX-sensitive current at the end of a 300 msec depolarizing pulse to 0 mV from -130 mV) was measured using the perforated patch technique. Quinidine (10 and 25 *micro*|M), significantly inhibited late I_{Na}, while lower concentrations were devoid of any effect. In addition to the selective I_{Kr} block observed with low concentrations of quinidine, high levels inhibit I_{Ks} and late I_{Na}. Simultaneous block of all three currents is likely responsible for the homogeneous prolongation of transmural APD and lower arrhythmogenicity of higher levels of the drug.

1416 DOXORUBICIN CARDIOTOXICITY IN SPONTANEOUSLY HYPERTENSIVE RATS.

C. I. Nduaka[1], E. Fryar[2], R. A. Jolly[1], D. L. Weddle[1] and R. G. Ulrich[1]. [1]*Drug Safety Evaluation, Abbott Laboratories, Abbott Park, IL and* [2]*Pharmacology, Howard University, Washington, DC.* Sponsor: C. Nduaka.

Doxorubicin (DOX) is an anthracycline used in the treatment of cancer. Clinical use of DOX has resulted in well documented dose-limiting cardiotoxicity. Using spontaneously hypertensive rats (SHR), we investigated gene expression changes associated with DOX cardiotoxicity in heart, liver and blood. DOX was administered to rats by intravenous injection for up to 2 weeks at a dosage of 1 mg/kg/day, resulting in a cumulative dosage of 1, 3 to 6 mg/kg. Toxicities were evaluated by clinical observation, clinical pathology, light microscopy, and ultrastructural pathology. Dose dependent increase in cTnT levels indicated DOX-induced cardiomyopathy in all treatment groups. This was later confirmed by small multifocal lesions of necrosis observed in all treated groups. Overall 10 genes were regulated in heart, 20 in liver and over 90 in blood. With the exception of a few genes there were few points of overlap in gene expression between treatment groups within a given tissue or between tissues. 12- lipoxygenase was one of these genes and was increased 17 fold in heart, 9 fold in liver and 3 fold in blood in high dose rats. 12-lipoxygenase has been previously implicated for its function in cardiac repair processes and may serve as a marker for DOX-induced cardiotoxicity. Many other genes of interest were regulated in blood after DOX treatment including catalase, transferrin receptor, BCLx, LECAM-1 and others. Further studies are ongoing investigating whether functional correlates ascribed to these transcriptional events correlate with cTnT levels and histopathological changes observed in DOX treated rats. In addition these ongoing studies would help confirm these gene changes and determine their pharmacological or toxicological relevance.

1417 RECRUITMENT OF NUCLEAR RECEPTOR COREGULATORS BY THE PEROXISOME PROLIFERATOR ACTIVATED RECEPTOR α

E. S. Tien and J. P. Vanden Heuvel. *Veterinary Science, Center for Molecular Toxicology and Carcinogenesis, Penn State University, University Park, PA.*

The peroxisome proliferator activated receptor α (PPARα) is a member of the nuclear receptor family and regulates genes that are involved in the metabolism of fatty acids in response to peroxisome proliferaters (PPs). Coregulators are a class of proteins whose main function is to enhance or repress the transactivation of genes that are regulated by receptors such as PPARα. In these studies, we examined the nuclear protein p35srj, the RNA coregulator SRA and the PPAR binding protein (PBP). SRA and p35srj were both able to enhance transcriptional activity of PPARα and can be classified as coactivators of PPARα. PBP is a known coactivator for PPARα, leading to enhanced activation of a PP reporter gene. Activation of PPARα by conjugated linoleic acid (CLA) in the presence of PBP leads to enhanced activation of a PP responsive gene to a greater extent than Wy-14, 643. This suggests greater recruitment of PBP to the transcription complex upon activation with CLA. The possibility that coregulator recruitment to nuclear receptor transcription complexes may be ligand specific is being examined.

1418 SELECTIVE DRINKING FOR ALCOHOL PREFERENCE IS PRESENTED ON ACETALDEHYDE DEHYDROGENASE 2 (*ALDH2*) GENE TARGETING MICE.

T. Isse[1], K. Kitagawa[2], A. Matsumoto[1], T. Oyama[1], A. Yoshida[3], T. Kawamoto[1], K. Nakayama[4] and K. Nakayama[4]. [1]*Environmental Health, University of Occupational and Environmental Health, Kitakyushu, Japan.* [2]*First Department of Biochemistry, School of Medicine, Hamamatsu Medical University, Shizuoka, Japan,* [3]*Beckman Research Institute of the City of Hope, Duarte, CA and* [4]*Department of Molecular and Cellular Biology, Medical Institute of Bioregulation, Fukuoka, Japan.*

Aldehyde dehydrogenase 2 (ALDH2) plays a major role in the detoxification of aldehyde. A diminished enzyme activity due to mutation of the *ALDH2* gene is associated with high alcohol sensitivity and a low tolerance in humans. The genomic background distinguishing an alcohol preference and avoidance of various inbred mouse strains are not clear. And there is no animal model for human *ALDH2* alleles. We genearated *Aldh2* mutant C57BL/6 mice by the targeting knockout, and Aldh2 activity was null in the mitchondrial fractions of the liver of the *Aldh2* -/- mice (K Kitagawa et al. 2000). The mice showed selective drinking for alcohol as like a human *ALDH2* genotype. The *Aldh2* -/- mice consumed only one-third the volume of ethanol solution compared to oridinal *Aldh2* +/+ mice. No significant difference were observed in the body weight and food intake between the two strains during the experiment. The *Aldh2* +/+ and *Aldh2* -/- C57BL/6 mice own same genetic background except *Aldh2*. Therefore, the present study demonstrates a clear effect of *Aldh2* genotype on alcohol preference.

1419 *IN VIVO* QUANTIFICATION OF SEX-SPECIFIC HEME OXYGENASE-LUCIFERASE (HO-LUC) TRANSGENE EXPRESSION FOLLOWING CHLOROFORM-INDUCED TOXICITY IN MICE.

D. J. McMullen, K. L. Steinmetz, W. A. Zhang, S. E. Malstrom and L. C. Sambucetti. *Xenogen Corporation, Alameda, CA.*

Heme oxygenase-1 (HO) is a key enzyme in the conversion of heme to bilirubin and may be involved in some cellular anti-oxidative responses. The HO gene has been previously shown to be up-regulated very quickly after treatment with chemicals or other inducers of oxidative stress. FVB mice transgenic for the luciferase gene under transcriptional control of the HO promoter (HO-luc) have been shown to express the HO-luc transgene similarly to the endogenous HO gene following the administration of HO-inducing compounds. *in vivo* tissue-specific expression of HO-luc can be visualized using a low-light imaging system (IVIS ™) after i.p. injection of luciferin. The HO-luc mouse has previously been shown to express luciferase in response to cadmium chloride, a potent HO inducer. In this study, the sex-specific differences in HO-luc expression following chloroform treatment were explored. Male and female HO-luc mice were treated with 100, 200 and 250 mg/kg chloroform either orally or i.p. Male mice showed renal expression of HO-luc whereas female mice did not. Female mice that had been pretreated with testosterone for 3 days prior to chloroform treatment showed HO-luc expression similar to males. This expression pattern was reversed in the same female mice dosed with chloroform 7 days after testosterone depletion. Pathology confirmed the tissue-specific toxicity of chloroform. These findings suggest an androgen-mediated pathway involved in sex-specific chloroform toxicity.

1420 EXPOSURE TO LEAD INCREASES THE ACTIVITY OF SP1-DRIVEN SV40 PROMOTER IN TRANSFECTED PC12 CELLS IN A CONCENTRATION-DEPENDENT MANNER.

V. Balasubramanyam, W. Wei and N. H. Zawia. *Biomedical Sciences, URI, Kingston, RI.*

Transcription factors organize and orchestrate differential gene expression, a phenomenon that allows cells to obtain different recipes from the same inherent genome. Zinc finger proteins (ZFP), a class of transcription factors; require Zn for their structural and functional integrity. Hence, ZFPs are susceptible to coexisting heavy metals such as lead (Pb). Sp1, a member of the ZFP family, has been shown to be a cellular target and mediator for Pb-induced anomalies in the regulation of gene expression. Sp1 is a component of a transcriptional complex that is involved in

the regulation of a variety of genes responsible for differentiation and development. It has been shown that Pb modulates Sp1-DNA binding both *in vivo* and *in vitro*. In order to understand the mechanisms involved in Pb-induced interferences at the transcriptional level, we transfected PC12 cells with the vector pGL3 (Promega), which contains a SV40 promoter recognized by Sp1, and a luciferase reporter gene. Twenty-four hours post-transfection, cells were exposed to four concentrations of Pb acetate (0.01uM to 10uM) and nerve growth factor (NGF 50ng/mL). Luciferase activity was measured at 48 hour, post-exposure. NGF increased the activity of the SV40 promoter consistent with its ability to elevate Sp1 DNA-binding as evidenced by the EMSA studies. Very similar to the growth signal NGF, Pb exposure resulted in a consistent increase in SV40 promoter activity that was observed in a concentration-dependent manner. Pb (0.01uM and 0.1uM) resulted in a modest increase when compared to 1uM and 10uM, which resulted in up to a two-fold increase. To confirm the involvement of Sp1 in the activation of the SV40 promoter, we blocked the Sp1 mRNA by co-transfecting with Sp1 antisense oligonucleotides. The activity of SV40 was reduced following such treatment. These data suggest that both NGF and Pb can modulate the function of Sp1-driven transcriptional constructs and gene expression may be perturbed during development through interference with the transcription factor Sp1.

1421 DIFFERENTIAL EFFECTS OF 17β-ESTRADIOL ON VASCULAR ENDOTHELIAL GROWTH FACTOR RECEPTOR EXPRESSION IN ENDOMETRIAL AND BREAST CANCER CELLS LINES.

K. Higgins, M. Stoner and S. H. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Vascular endothelial growth factor receptor (VEGFRII) plays a key role in VEGF-induced angiogenesis. This study investigated the effects of E2 on transcriptional activation of reporter gene (luciferase) activity in HEC1A cells transfected with the following constructs containing VEGFRII gene promoter inserts: -716 to +268 (pVEGFR-A); -225 to +268 (pVEGFR-B); -95 to +268 (pVEGFR-C). In HEC1A cells cotransfected with pVEGFR-A and 250 ng of human estrogen receptor α (hERα) expression plasmid, E2 decreased luciferase activity by 50%, and similar results were observed after transfection with pVEGFR-B and pVEGFR-C. E2-mediated downregulation was also observed in MCF-7 human breast cancer cells, but not in ZR-75 breast cancer cells where E2 induced luciferase activity. Further deletion of the VEGFRII gene promoter indicates a region from -60 to -37 that is important for E2-mediated downregulation in MCF-7 cells and E2-mediated upregulation in ZR-75 cells. This region contains two Sp1 sites and mutation of either site alone or both sites results in the loss of the E2-mediated responses in both cell types. E2-mediated activation and downregulation of reporter gene activity in ZR-75 and HEC1A/MCF-7 cells, respectively, was reversed after cotreatment with the antiestrogen ICI 182, 780. When HEC1A and MCF-7 cells were cotransfected with pVEGFR-C and HE11, a DNA binding domain (DBD) deletion mutant of ERα, E2-dependent downregulation of this promoter was not observed. This indicated that E2-mediated downregulation of pVEGFR-C in HEC1A and MCF-7 cells is dependent on the ERα DBD. In contrast, HE11 was functional for hormone-mediated induction in ZR-75 cells. Current studies are focused on identifying *cis*-acting promoter elements and *trans*-acting factors required for cell-specific modulation of VEGFRII expression. (Supported by NIH CA76636 and ES09106)

1422 MECHANISM OF HORMONAL REGULATION OF *cad* GENE EXPRESSION IN BREAST CANCER CELLS.

S. Khan, M. Wormke and S. H. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

The multifunctional *cad* gene (carbamoyl phosphate synthase, aspartate transcarbamylase, dihydroorotose) regulates pyrimidine nucleotide biosynthesis and is induced by 17β-estradiol (E2) and insulin-like growth factor 1 in estrogen receptor (ER)-positive MCF-7 and ZR-75 breast cancer cells. E2 induced reporter gene activity in MCF-7 and ZR-75 cells transfected with pCAD1 which contains a -90 to +115 *cad* gene promoter insert. This region of the promoter contains two upstream GC-rich motifs that bind Sp proteins and two downstream E-boxes that are important targets in some cells for binding mitogen-induced c-*myc*. In MCF-7 cells transfected with pCAD1, E2 induced reporter gene activity in cells cotransfected with wild-type ERα, ER-11C (DNA binding domain deletion) and ER-TAF1 (D538N, E542Q and D545N mutations that inactivate activation function 2) but not ERβ or ERα mutants that delete N-terminal or C-terminal activation functions 1 or 2, respectively. Moreover, in MCF-7 cells transfected with pCAD1 and a construct expressing a dominant negative form of Sp1 protein, there was complete inhibition of E2-induced transactivation. Deletion analysis of the *cad* gene promoter showed that only the GC-rich and not the E-boxes were required for E2-responsiveness in MCF-7 cells. In contrast, similar studies in ZR-75 cells demonstrated that both GC-rich and E-box motifs were independently E2-responsive indicating significant cell context-dependent differences in hormonal regulation of *cad* even among ER-positive breast cancer cells. The indirect antiestrogen 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin blocks hormone activation of *cad* in both cell lines and the mechanism of this response is being investigated. (Supported by NIH CA64081, ES04176 and ES09106)

1423 MECHANISM OF ESTROGEN RECEPTOR α/Sp1-MEDIATED ACTIVATION OF ESTROGEN-RESPONSIVE GC-RICH PROMOTERS.

K. Kim[1], N. Thu[1], B. Saville[2], I. Samudio[1] and S. H. Safe[1]. [1]*Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX and* [2]*Biochemistry & Biophysics, Texas A&M University, College Station, TX.*

Estrogen receptor α (ERα)/Sp1 activates GC-rich gene promoters in MCF-7 or MDA-MB-231 breast cancer cells, and this response is dependent on activation function 1 (AF1) of ERα. This study investigates contributions of the DNA binding domain (DBD) and AF2 and also promoter context on ERα/Sp1 action in breast cancer cells. In transient transfection studies, wild-type human (hERα) and mouse ERα activated GC-rich constructs containing three tandem Sp1 binding sites ($pSp1_3$) or estrogen-responsive GC-rich promoter inserts from the adenosine deaminase (pADA) or retinoic acid receptor α1 (pRARα1) genes. The pattern of activation was similar for all three promoters in MCF-7 and MDA-MB-231 cells, and binding of hERα and Sp1 to the endogenous adenosine deaminase and retinoic acid receptor α1 gene promoters was observed in chromatin immunoprecipitation assays. The relative contributions of the DBD and AF2 regions of ERα on ERα/Sp1-mediated transactivation were determined using human and mouse ERα constructs containing critical deletions (zinc fingers 1 or 2) and mutations (AF2:D538A, E542A and D545A). The results indicate that the DBD of hERα was not required for estrogen-dependent activation of hERα but was essential for antiestrogen-responsiveness. Results obtained with AF2 mutants and competition with nuclear receptor box (LXXLL) peptides from Grip1 indicate that AF2 of ERα was not essential for ERα/Sp1 action, and prototypical AF2-interacting coactivators did not enhance the activity. Thus, the mechanism of ERα/Sp1-mediated gene expression is uniquely AF1-dependent and differs significantly from the classical ERα activation of an estrogen-responsive element promoter or ERα/AP1 modulation of AP1-dependent promoters/genes. (Supported by NIH CA76636 and ES09106)

1424 SARIN CAUSES DIFFERENTIAL ALTERATION OF MRNAS CODING FOR GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP), VIMENTIN AND ALPHA TUBULIN IN THE CENTRAL NERVOUS SYSTEM OF RATS.

T. V. Damodaran, A. A. Abdel-Rahman, M. A. Bilska, A. A. Mecklai and M. B. Abou-Donia. *Pharmacology and Cancer Biology, Duke University Medical center, Durham, NC.*

We studied the effect of a single (50 μg/kg, im) dose of sarin (0.5XLD 50) on the expression of the cytoskeletal genes, GFAP, vimentin (astroglial markers), and alpha tubulin (mostly neuronal) in the central nervous system (CNS) of male rats which were sacrificed at different time points, i.e., 1, and 2 hrs, as well as, 1, 3 and 7 days post-treatment. Northern data collected indicate differential / spatial / temporal regulation of all three transcript levels. Both GFAP and vimentin were induced at 1 hr in all tissues except for brainstem. Overexpressed transcript levels of GFAP and vimentin remained high in more sensitive regions like brainstem and midbrain, while other regions like cortex, cerebellum and spinal cord showed more downward trend for either or both GFAP and vimentin at 7 days. Observed changes in these transcript levels may indicate injury-response and recovery of astroglia. The immediate induction levels of the alpha tubulin transcripts ranged from small (127% in cortex) to high (151% midbrain) except the brain stem, where there was no induction until day one. The levels, however, showed time-dependent increase and reached peak values (246%) at 7 days in the brainstem. The cerebellum showed a great degree of fluctuations in alpha tubulin transcript levels after immediate induction while the cortex showed more or less the same moderately induced levels for the major part of the time course. Immediate induction and variable persistence of these transcripts in sarin-treated CNS suggest that sarin-induced neurotoxicity is in part mediated by the altered expression of cytoskeletal genes. Furthermore, our data indicate that although sarin induces acute toxicity by disrupting the cholinergic system, the development and persistence of long-term neurological deficits may depend on other pathways in the CNS. Supported in part by US .Army Medical Research and Materiel Command under contract DAMD 17-98-C-8027.

1425 VITAMIN D-INTERACTING PROTEIN 150 (DRIP 150) AS A COACTIVATOR OF ESTROGEN RECEPTOR α (ERα)- AND ERα/Sp1-MEDIATED TRANSACTIVATION IN ZR-75 CELLS.

J. E. Lee and S. H. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Vitamin D interacting protein 150 (DRIP 150) is a member of a family of nuclear proteins that interact with a variety of transcription factors and nuclear receptors including estrogen receptor α (ERα). The effects of DRIP 150 as a coactivator of ERα- and ERα/Sp1-mediated transactivation was investigated in ZR-75 breast cancer cells transfected with constructs containing multiple copies of estrogen response elements (ERE) ($pERE_3$) or GC-rich ($pSp1_3$) motifs. In transient transfection studies, DRIP 150 induced a maximal 10- and 4-fold enhancement of estrogen-dependent activation of $pERE_3$ and $pSp1_3$, respectively. The domains of ERα required for DRIP 150-mediated coactivation of ERα and ERα/Sp1 were investigated by cotransfection of inhibitory polypeptides the competitively interact with activation function (AF1) (pAF1) or AF2 (pNR-box). The results showed that ERα/Sp1-mediated transactivation was primarily AF1-dependent, whereas DRIP 150 coactivation involved AF2 of ERα. The following deletion mutants of DRIP 150 have also been generated and these include: DRIP 150m1 (deletion of aa 1145-1454), DRIP 150m2 (deletion of aa 789-1454), and DRIP 150m3 (deletion of aa 325-1454). The results of coactivation of ERα/Sp1 with wild-type and deletion mutants of DRIP 150 indicate that amino acids 789-1145 are required for activity. Current studies are further defining the minimum sequences within DRIP 150 that are necessary for coactivation of ERα/Sp1- and ER-mediated transactivation. (Supported by NIH CA76636 and ES09106)

1426 PROTEIN INHIBITOR OF STAT-1 (PIAS) AS COACTIVATORS OF ESTROGEN-INDUCED GENE EXPRESSION IN BREAST CANCER CELLS.

W. R. Lee, B. Saville, H. Felix and S. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

The zinc finger region of the androgen receptor has been used as bait to investigate interacting proteins that may subsequently play a role in modulating gene expression. Research in this laboratory has demonstrated that one of these interacting proteins (SNURF) coactivates estrogen receptor α (ERα)- and ERα/Sp1-mediated transactivation in breast cancer cells transfected with constructs containing estrogen response elements ($pERE_3$) and GC-rich ($pSp1_3$) promoter inserts. Protein inhibitor of activated STAT-1 (PIAS) has also been identified as an androgen receptor interacting protein (ARIP) that binds the DNA binding domain, and we have investigated the activity of PIAS proteins as coactivators of ERα and ERα/Sp1 in breast cancer cells. E2 induces reporter gene activity in ZR-75 cells transfected with $pERE_3$ and in cells cotransfected with 5 - 300 ng rat ARIP3 (homologous to human PIASxα), there was a > 3-fold coactivation using 50 ng ARIP3 expression plasmid, and significant coactivation was observed using up to 300 ng ARIP3. In contrast, ARIP3 coactivated ERα/Sp1-mediated transactivation only 1.7-fold in ZR-75 cells over a smaller range of expression plasmid concentration (5 - 50 ng). In parallel studies, the coactivator activities of human PIAS1 and PIAS3 were also investigated in ZR-75 cells transfected with $pSp1_3$. The results showed that PIAS1 was inactive as a coactivator, whereas PIAS3 caused a 2.4-fold enhancement of ERα/Sp1-mediated activation of $pSp1_3$. Current studies are focused on the mechanisms of PIAS proteins as coactivators of ERα and ERα/Sp1 and domain-specific physical and functional interactions of ERα and Sp1 with PIAS proteins. (Supported by NIH CA76636 and ES09106)

1427 TYROSINE AND SERINE-THREONINE KINASE INHIBITORS BLOCK SODIUM ARSENITE INDUCED DISRUPTION OF THE ACTIN CYTOSKELETON AND FOCAL ADHESIONS.

T. Suramana[1], J. M. Murray[2], K. Hu[3], T. Posayanonda[1], N. Nuntharatanapong[1], R. Sindhuphak[4], N. Dusitsin[4] and P. Sinhaseni[1,4]. *[1]Department of Pharmacology, Faculty of Pharmaceutical Sciences, Chulalongkorn University, Bangkok, Thailand, [2]Department of Cell and Developmental Biology, University of Pennsylvania School of Medicine, Philadelphia, PA, [3]Department of Biology, University of Pennsylvania, Philadelphia, PA and [4]The Institute of Health Research, Chulalongkorn University, Bangkok, Thailand.*

Arsenic is a human carcinogen, but the diverse acute physiological effects caused by arsenic are likely due to the activation of various signaling pathways rather than genotoxicity. We used immuno-fluorescence microscopy to study the effects of 0.25-25 micromolar sodium arsenite on the actin cytoskeleton, focal adhesions, and mitochondrial localization in mouse fibroblasts. At 0.25 micromolar, short-term effects of sodium arsenite were minimal, but at higher concentrations we noted loss of F-actin and vinculin and a concomitant change in cell morphology, from flat and well-spread to rounded and loosely attached. At 25 micromolar, sodium arsenite caused a severe loss of F-actin and vinculin and most cells detached from the substrate. Signaling by tyrosine and serine-threonine phosphorylation play important roles in regulation of the actin cytoskeleton and focal adhesion formation. Co-treatment with the tyrosine kinase inhibitor genistein or the serine-threonine kinase inhibitor staurosporine completely blocked these toxic effects of sodium arsenite. Studies currently underway will identify the specific members of these kinase families that appear to mediate the toxic effects of sodium arsenite.

1428 COCAINE INDUCES A DOSE DEPENDENT ALTERATION IN THE EXPRESSION IMMEDIATE EARLY GENES *C-FOS* AND SP-1 AND IN NUCLEAR FACTOR NF-Kß IN PC12 CELLS.

H. M. Duhart, S. Z. Imam, J. T. Skinner, W. Skikker Jr. and S. F. Ali. *Neurotoxicology, NCTR, Jefferson, AR.*

Cocaine is a widely used drug of abuse and psychostimulant which acts on the central nervous system by blocking the dopamine re-uptake sites. PC12 cells, a rat pheochromocytoma clonal line, which in the presence of nerve growth factor (NGF), multiply and differentiate into competent neurons that can synthesize, store and secrete the neurotransmitter dopamine (DA). In the present study, we evaluated the effect of increasing doses of cocaine on the expression of immediate early genes (IEGs), *c-fos* and SP-1 and a closely related nuclear factor, NF-Kß 24 h after the exposure to cocaine (50, 100, 250, 500, 1000, 2500 µM) in NGF-differentiated PC12 cells. Cocaine (50-500 µM) resulted in significant induction of the expression of *c-fos*, SP-1 and NF-Kß. However, higher concentrations of cocaine (1000 & 2500 µM) resulted in the down-regulation of these expressions after 24 h. We also evaluated the effect of increasing doses of cocaine on dopamine. A significant dose-dependent decrease in the concentration of dopamine was observed 24 h after the exposure of PC12 cells to cocaine. Therefore in the present study, we reported that cocaine has both upstream and downstream regulatory actions on some IEGs and nuclear factors which is independent of its action on the dopaminergic system. Further studies are underway to explore more mechanistic details.

1429 INDUCTION OF *p53* GENE EXPRESSION IN MCF-7 BREAST CANCER CELLS BY 17β-ESTRADIOL IS MEDIATED BY CALMODULIN KINASE IV-DEPENDENT ACTIVATION OF AN NF-κB/CTF-1 COMPLEX.

C. Qin[1], T. Nguyen[1], J. Stewart[1], I. Samudio[1], R. B. Burghardt[2] and S. H. Safe[1]. *[1]Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX and [2]Veterinary Anatomy & Public Health, Texas A&M University, College Station, TX.*

Initial studies in this laboratory showed that 17β-estradiol (E2) induced tumor suppressor gene *p53* mRNA and protein levels in MCF-7 human breast cancer cells. Analysis of the *p53* gene promoter identified a minimal E2-responsive region (-106 to -30) that binds multiple transcription factors, but only motifs that bind CTF-1 and NF-κB are required for hormone-induced activation of p53-10 (contains a -106 to -30 *p53* gene promoter insert). The p65 subunit of NF-κB was identified in both nuclear and cytosolic fractions of untreated MCF-7 cells, and induction of *p53* by E2 was inhibited by the IκB super repressor and precursor-derived inhibitor containing the C-terminal region of p105, the precursor of p50. Although nuclear p65 is required for hormonal activation of *p53*, formation of nuclear NF-κB complex was essentially E2-independent. We therefore investigated direct activation of *p65* in MCF-7 cells in transient transfection studies using p53-10 and a chimeric protein containing the C-terminal 30 amino acids of *p65* (pM-p65c2) fused to the yeast GAL4 protein DNA binding domain. Results of studies using selective kinase inhibitors showed that only KN-93, an inhibitor of calmodulin kinase IV (CaMKIV), blocked hormone activation of p53-10 or pM-p65c2, and inhibition was also observed with ethylene glycol tetraacetate-AM, a cell permeable chelator of divalent calcium ions. In addition, constitutively active CaMKIV also activated pM-p65c2 in MCF-7 cells. Our results demonstrate that *p53* is upregulated by E2 in MCF-7 cells through direct kinase-dependent activation of *p65* and cooperative p65-CTF-1 interactions. (Supported by NIH ES09255 and ES09106)

1430 ANALYSIS OF ESTROGEN RECEPTOR α (ERα) AND Sp1 PROTEIN INTERACTIONS WITH PROMOTERS OF ESTROGEN RESPONSIVE GENES IN BREAST CANCER CELLS BY CHROMATIN IMMUNOPRECIPITATION.

I. Samudio and S. H. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Studies in this laboratory have identified GC-rich elements in the promoters of the cathepsin D (CD), retinoic acid receptor α1 (RARα1), and adenosine deaminase (ADA) genes that bind estrogen receptor α (ERα)/Sp1 *in vitro* and are required for

estrogen (E2)-induced transactivation. Interactions of ERα, Sp1 and other nuclear transcription factors with specific E2-responsive regions of the CD, RARα1 and ADA gene promoters were investigated by the chromatin immunoprecipitation (ChIP) assay. Briefly, MCF-7 human breast cancer cells were treated with 10 nM E2 for 30, 60, 90 or 120 min; formaldehyde was then added to crosslink proteins and DNA, isolated nuclei were obtained and sonicated for 45-60 sec to obtain chromatin with appropriate fragment length (500-1000 bp). ERα and Sp1 antibodies were used to immunoprecipitate chromatin associated with these proteins and, after removal of the crosslinks and extensive purification, DNA from immunoprecipitated fractions was analyzed by PCR with primers to detect E2-responsive regions of the CD (-246/+17), RARα1 (-187/-10) and ADA (-148/+51) gene promoters. PCR analysis demonstrated that both ERα and Sp1 proteins occupied the CD gene promoter for at least two hours after treatment with E2 and, in contrast to previous reports, cyclic occupation of the promoter by these proteins was not detected. Using a similar approach, we also observed occupation of the ADA and RARα1 gene promoters for up to 120 min by both Sp1 and ERα proteins; however, there was some variability in ERα-promoter interactions that was dependent on the antibody used in the immunoprecipitation step. Current studies are refining this technique, extending the time-course studies, and determining interactions of other coactivator proteins with these gene promoters. (Supported by NIH CA76636 and ES09106).

1431 COOPERATIVE COACTIVATION OF ESTROGEN RECEPTOR α IN ZR-75 HUMAN BREAST CANCER CELLS BY SNURF AND TATA-BINDING PROTEIN.

B. Saville[1], M. Wormke[2], M. Stoner[2], I. Samudio[2] and S. H. Safe[2]. [1]*Biochemistry & Biophysics, Texas A&M University, College Station, TX and* [2]*Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

SNURF is a small RING finger protein that binds the zinc finger region (ZFR) of steroid hormone receptors and enhances Sp1- and androgen receptor-mediated transcription in COS and CV-1 cells. In this study, we show that SNURF coactivates both wild-type estrogen receptor α (ERα) (4-fold) and HE19 [ERα deletion of activation function 1 (AF1)] (10-fold)-mediated activation of an estrogen responsive element (ERE) promoter in ZR-75 cells. In mammalian two-hybrid assays conducted in ZR-75 cells, SNURF interactions with ER were estrogen (E2)-dependent and not observed with the antiestrogen ICI 182, 780. ERα interacted with multiple regions of SNURF; SNURF interactions with ERα were dependent on the helix 12 of AF2, since D538N, E542Q and D545N mutations in the region abrogated both SNURF-ERα binding and coactivation. Moreover, peptide fusion proteins that inhibit interactions between helix 12 of ERα with LXXLL box-containing proteins also blocked ERα coactivation by SNURF, suggesting that confactors that interact with helix 12 are required for coactivation by SNURF. However, cotransfection of SNURF with prototypical steroid receptor coactivators 1, 2 and 3 that contain LXXLL box motifs did not enhance E2-responsiveness, whereas TATA binding protein (TBP) cooperatively coactivated ERα-mediated transactivation. The results are consistent with a unique model for cooperative coactivation of ERα that requires ligand binding, repositioning of helix 12, recruitment of TBP, and interaction with SNURF. (Supported by NIH CA76636 and ES01906)

1432 *IN VIVO* ANALYSIS OF ESTROGEN-INDUCED CYCLIN D1 EXPRESSION UTILIZING *IN SITU* HYBRIDIZATION AND CHROMATIN IMMUNOPRECIPITATION (ChIP) ASSAYS IN A MURINE MODEL.

K. B. Walker, I. Samudio and S. H. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Cyclin D1 (CD1) is an important protein in the normal development of the reproductive tract and mammary glands and in the development of mammary carcinogenesis. 17β-Estradiol (E2) induces CD1 expression in estrogen receptor (ER)-positive human breast cancer cells; the promoter elements involved are cell context-dependent. For example, a GC-rich Sp1-binding site, activated by ERα/Sp1 complexes, is functional in ZR-75 but not in MCF-7 cells. Utilizing the mouse uterus model, we compared a time course for CD1 mRNA expression in the uterus of wild-type and estrogen receptor α knockout (ERKO) mice treated with E2. In wild-type mice, CD1 mRNA levels were induced by E2 in the luminal epithelium of E2-treated mice after 6 hr; however, in ERKO mice, the staining of CD1 mRNA was comparable in the E2-treated and control mice at 6 hr. Thus, ERα is necessary for the induction of CD1 by E2 in the mouse uterus. Furthermore, to confirm the interaction of ERα with both the murine and human CD1 gene promoters *in vivo*, we adapted the ChIP assay for analysis of freshly collected murine tissue and xenografts of human breast cancer cells in mice. Cells were isolated, lysed by hypotonic bursting, and isolated nuclei were obtained and sonicated to obtain chromatin with appropriate fragment length (500-1000 bp). ERα and Sp1 antibodies were used to immunoprecipitate chromatin associated with these proteins, and the chromatin was analyzed by PCR with primers to detect E2-responsive regions of the human CD1 (-204/-103) and the murine CD1 (-156/+7) gene promoters. Using this technique, we have shown that Sp1 is bound to the CD1 promoter in mouse uterine cells and ERα is bound to the CD1 promoter in brain and liver cells. The ChIP assay will be utilized along with *in situ* hybridization analysis of other E2-responsive genes in the mouse to determine the presence of ERα, Sp1, and other transcription factors on their respective promoters. (Supported by NIH CA70636 and ES09106)

1433 VITAMIN D INTERACTING PROTEIN 205 (DRIP 205) AS A COACTIVATOR OF ESTROGEN RECEPTOR α/Sp1-MEDIATED TRANSACTIVATION.

Q. Wu[1] and S. H. Safe[2]. [1]*Biochemistry & Biophysics, Texas A&M University, College Station, TX and* [2]*Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Several independent studies have identified vitamin D interacting protein 205 (DRIP 205) as one of a family of mediator complex proteins that associate with transcription factors and hormone receptors. DRIP 205 coactivates 17β-estradiol (E2)-induced gene expression in ZR-75 and other breast cancer cell lines transfected with wild-type estrogen receptor α (ERα) and constructs containing estrogen response elements ($pERE_3$) or GC-rich motifs ($pSp1_3$) that bind ERα/Sp1. Ten nM E2 alone induced reporter gene activity in ZR-75 cells transfected with $pSp1_3$ and wild-type ERα (HE11) (a DNA binding domain deletion mutant) or hER-TAF1 [point mutations inactivating activation function 2 (AF2)]. Cotransfection with DRIP 205 coactivated wild-type/mutant ERα 3.8-, 2.7- and 1.7-fold, respectively. DRIP 205 contains 1566 amino acids including two nuclear receptor (NR)-boxes containing LXXLL motifs (within the aa 528 - 714 sequence) that interact with helix 12 in the AF2 domain of ERα. Plasmids expressing aa 1 - 714 (DRIP 205m1), aa 516 - 1566 (DRIP 205m2), and aa 528-714 (DRIP 205m3) were prepared by PCR. The coactivator activity of mutant DRIP 205 expression plasmids was investigated in ZR-75 cells transfected with $pSp1_3$ and ERα. Both N-terminal (DRIP 205m2) and C-terminal (DRIP 205m1) deletion mutants of DRIP 205 coactivated ERα/Sp1-mediated transactivation 3.6- and 2.0-fold, respectively, whereas DRIP 205m3 was inactive. Current studies are focused on delineating specific domains of DRIP 205 required for coactivation of ERα/Sp1. (Supported by NIH CA76636 and ES09106)

1434 THE UTILITY OF LARGE-SCALE INSERTIONAL MUTAGENESIS (GENE TRAP) SCREENS TO IDENTIFY AND DISRUPT NOVEL GENES INDUCED BY TCDD IN MOUSE EMBRYONIC STEM(ES)CELLS.

C. J. Broccardo, C. T. French, G. K. DeKrey, M. E. Legare, R. E. Billings and W. H. Hanneman. *Department of Environmental Health and Radiological Sciences, Colorado State University, Fort Collins, CO.*

Polychlorinated dibenzo–*p*–dioxins (PCDDs) are industrial compounds or by–products which have been identified in extracts from diverse environmental matrices including fish, wildlife and humans. PCDDs are complex mixtures of congeners with a limited number being ubiquitous in environmental samples. Recently, PCDDs have been the focus of extensive toxicological studies and serious public debate. As a result of this, 2, 3, 7, 8–tetrachlorodibenzo–*p*–dioxin (TCDD) has been identified as the most toxic congener in the PCDD family and has been shown to elicit numerous adverse responses in animals including neoplasia, immunosuppression, hepatotoxicity, neurotoxicity, reproductive toxicity, and teratogenesis. While TCDDs physiological effects are well known in animals, the overall risk that TCDD poses to humans is unclear. Moreover, outside of the "classical dioxin-inducible gene battery" little is known about the complex molecular actions of TCDD, which are likely to be associated with many observed physiological effects. To address this issue, we have developed an experimental strategy that simultaneously identifies TCDD-inducible genes, mutates them, tags them with a reporter molecule, and enables the production of knockout animals carrying the induced mutations. This process has been termed "gene-trapping." The power of this technology is the ability to discover novel genes responsive to a particular chemical, rather than testing the responsiveness of a known gene. Within the scope of this research, we have conducted the molecular and functional characterization of the role of these genes in cells and animals. To date, 26 TCDD-sensitive genes have been identified out of approximately 2000 mutated genes; 12 of those genes have been sequenced. The generation of a knockout mouse for one identified gene is currently in progress.

1435 TRAPPING GENES ASSOCIATED WITH TOBACCO USE.

A. F. Flint, C. T. French, C. J. Broccardo, G. K. DeKrey, M. E. Legare, R. E. Billings and W. H. Hanneman. *Department of Environmental Health and Radiological Sciences, Colorado State University, Fort Collins, CO.*

Data from epidemiological studies have strongly linked the development of squamous cell carcinomas of the upper aerodigestive tract to consumption of tobacco, particularly when combined with alcohol. The exact mechanisms leading from to-

bacco use to disease are not well understood, but for tumorigenesis those mechanisms are surely genetic. Understanding how carcinogens induce tumor formation ultimately relies on identifying and characterizing the genes that are targeted for mutation and/or dysregulation by those carcinogens. To this end, many mutations have been found in cancer cells from tobacco users, but not all mutations have been associated with specific genes. Thus, the goal of this project is to identify, mutate and characterize those genes. This goal is part of the long-term objective of understanding the genetic mechanisms underlying the development of cancer. To address this goal we have deployed a gene-trapping strategy to identify tobacco-sensitive genes. Briefly, mouse embryonic stem (ES) cells are transfected with a promoterless reporter gene construct. Successful transfection of an ES cell will knockout an endogenous gene, but the reporter gene will be active and under the control of the endogenous promoter. Large numbers of unique gene-trapped ES cell clones are then screened in the presence or absence of cigarette smoke condensate (CSC), and altered reporter gene expression is identified and recorded. The reporter gene itself is then used as the starting point for sequencing of the endogenous genes. Sequences are then compared to those in the GenBank database to identify novel genes as well as previously known genes that were unknown to be altered/dysregulated by tobacco. In addition, mutant ES cells created as described above can be used to generate knockout mice. Those mice, in turn, will then be studied to understand the role of each gene relative to the development of cancer and disease.

1436 PREGNANE X RECEPTOR MEDIATES THE INDUCTION OF RAT ORGANIC ANION TRANSPORTING POLYPEPTIDE 2 BY PREGNENOLONE-16 ALPHA-CARBONITRILE.

G. L. Guo, J. L. Staudinger and C. D. Klaassen. *Pharmacology, Toxicology, and Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

The rat organic anion transporting polypeptide 2 (oatp2; Slc21a5) is a hepatic sinusoidal transporter that mediates the uptake of a variety of structurally diverse compounds, and has a very high affinity for cardiac glycosides. Treatment of rats with pregnenolone-16 alpha-carbonitrile (PCN), a potent ligand for the rodent pregnane X receptor (PXR), significantly enhances the transcription of the oatp2 gene leading to subsequent increases in hepatic oatp2 mRNA and protein levels. In an effort to understand the molecular mechanism of oatp2 induction by PCN treatment, approximately 8700 bp of the 5' flanking region of the rat oatp2 gene were linked to the luciferase reporter gene and used in transient transfection assays in H4IIE cells. PCN treatment induced the expression of the reporter gene in a dose-dependent manner. A total of four potential PXR response elements (PXRREs) were identified in the 5' flanking region of the rat oatp2 gene. One element (DR3-1) is located approximately -5000 bp with three more (DR3-2, DR3-3, DR3-4) clustered at about -8000 bp upstream of the predicted transcription start site. Results gathered from Electrophoretic Mobility Shift Assays showed that the PXR-RXRalpha heterodimer directly binds to the DR3-2 with the highest affinity, followed by to the DR3-4 and DR3-1, but only to the DR3-3 weakly or not at all. Furthermore, a series of partial deletions of the 5' flanking region of the rat oatp2 gene illustrated that both the proximal and distal cluster of PXRREs are required for maximal induction of rat oatp2 by PCN. In conclusion, these data elucidate the molecular mechanism by which PCN treatment induces rat oatp2 gene expression. In addition, this study identifies rat oatp2 as a direct PXR-targeted gene and further supports the hypothesis that activation of PXR affects a network of genes that is involved in either metabolism or transport of drugs, steroids, and bile acids. (Supported by NIH grant ES-09649 and ES-07079)

1437 ENDOCRINE REGULATION OF RAT ORGANIC ANION TRANSPORTER 2 (OAT2) mRNA EXPRESSION IN KIDNEY.

S. C. Buist, N. J. Cherrington and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

Initially, rat Oat2 was described as a liver-specific transporter. However, recent data indicate gender divergent expression of Oat2 in which male levels are highest in liver while female levels are highest in kidney. Furthermore, in kidney there was a female-predominant pattern of Oat2 evident after the onset of sexual maturity. Therefore, the goal of this study was to investigate endocrine involvement in the elevation of Oat2 mRNA levels in female as compared to male kidney. Sex steroid influence was determined by comparing Oat2 mRNA levels in kidneys of castrated and ovariectomized rats to those of intact control rats. Additionally, endocrine effects were studied in hypophysectomized (HX) rats randomly placed in one of the following four treatment groups: 1) testosterone (daily); 2) estrogen (daily); 3) male-pattern growth hormone (two injections per day to simulate pulsatile secretion); or 4) female-pattern growth hormone (continuous infusion *via* mini-osmotic pumps). Hormones were administered subcutaneously for 5 days. Renal Oat2 mRNA levels were measured by branched DNA signal amplification. Levels of Oat2 mRNA were 10-fold higher in control female kidneys as compared to control male kidneys. Interestingly, gonadectomy did not affect male or female Oat2 mRNA levels, but HX did decrease renal Oat2 levels in females by 90%, resulting in Oat2 mRNA levels in kidney of HX females equivalent to those in kidneys of control male rats. Neither testosterone nor estrogen administration altered Oat2 mRNA levels in kidneys of HX rats. Likewise, male-pattern growth hormone replacement did not increase Oat2 mRNA levels in kidneys of HX males or HX females. However, continuous infusion of rat growth hormone, which mimics female-pattern secretion, did increase renal Oat2 mRNA levels in both HX male and HX female rats. Therefore, these data demonstrate that the gender difference in Oat2 mRNA levels in kidney is not the result of sex steroid influences, but rather a function of female-pattern growth hormone secretion. (Supported by NIH grants ES-09716 and ES-07079)

1438 TISSUE EXPRESSION OF THE RAT UDP-GLUCURONOSYLTRANSFERASE SUPERFAMILY.

M. K. Shelby, N. C. Cherrington, N. R. Vansell and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

UDP-Glucuronosyltransferases (UGTs) are a superfamily of phase II drug metabolizing enzymes that catalyze the conjugation of glucuronic acid to a broad spectrum of endobiotic and xenobiotic substrates. The rat UGTs have been divided into two gene families, UGT1 and UGT2, which include at least 14 enzymes. The complete tissue expression of rat UGTs has not been thoroughly examined, but could provide further indication of individual UGT functions. The aim of this study was to quantitatively determine the mRNA levels of rat UGT1 and UGT2 families in various tissues using the branched DNA signal amplification method. UGT1A1 was present at high levels in all tissues examined except lung. UGT1A2 was detected primarily in small intestine. UGT1A5 was detected primarily in liver at low levels. UGT1A6 was present predominantly in kidney and gastrointestinal (GI) tract, whereas UGT1A7 was detected in the GI tract and at low levels in lung. UGT2A1 was detected at high levels only in nasal epithelium. UGT2B1 was detected only in liver. UGT2B3 and 2B6 were detected mainly in liver, whereas 2B8 was detected in stomach, duodenum, and kidney at low levels. UGT2B12 was primarily localized in liver and kidney, with lower levels in duodenum. Finally, UGT1A3, 1A8, and 2B2 were difficult to detect. In summary, the UGTs present in liver include UGT1A1, which was present at high levels, and 2B1, 2B3, 2B6, 2B12, 1A5, and 1A6, which were present at low levels. In both small and large intestine UGT1A1, 1A6, and 1A7 were present at high levels, but 1A2, 2B8, and 2B12 were present in small intestine at low levels. UGT1A1 and 1A6 were present at high levels in kidney, in which lower levels of 2B12 and 2B8 were detected. UGT1A1, 1A6, 1A7, and 2B12 were present at low levels in lung. Only UGT1A1 was present at high levels in brain, with 1A6, 2B3, and 2B12 at low levels. The tissue specific expression of UGTs may be responsible for the tissue specific detoxification or activation of UGT substrates and thus suggests a possible role in target organ toxicity. (Supported by NIH grants ES-09716 and ES-07079)

1439 LIPOPOLYSACCHARIDE-MEDIATED REGULATION OF HEPATIC TRANSPORTER mRNA LEVELS IN RATS.

N. J. Cherrington, A. L. Slitt, N. Li and C. D. Klaassen. *Pharmacology Toxicology & Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

The major function of hepatic transporters is to move a wide range of organic substances across the sinusoidal and canalicular membranes. During extrahepatic cholestasis, some hepatic transporters that are involved in the normal vectoral flow of organic substances from blood to bile, such as Ntcp and Mrp2, are known to be dramatically down-regulated, while other transporters such as Mrp3 are up-regulated. Unlike models of extrahepatic cholestasis where alterations in transporter expression are in response to the accumulation of bile constituents in the hepatocyte, lipopolysaccharide (LPS) may directly alter transporter expression leading to cholestasis characterized by impaired bile flow. The aim of this study was to quantitatively determine the effect of LPS on the mRNA levels of hepatic transporters in Sprague-Dawley rats and whether dexamethasone pretreatment could modulate the LPS-mediated changes in hepatic transporter mRNA levels. Sixteen h after LPS (4 mg/kg) administration, the branched DNA signal amplification assay revealed that hepatic mRNA levels of Mrp2, Mrp6, Mdr1a, Oatp1, Oatp2, Lst, Ntcp, Bsep, Oct1, and Oat3 were dramatically decreased, but Mrp5, Mdr2, and Oat2 levels remained unchanged. In contrast, LPS administration increased mRNA levels of Mrp1, Mrp3, and Mdr1b. A 1 h pretreatment with dexamethasone (10 mg/kg) significantly diminished the reduction of Mdr1a, Oatp1, Oatp2, Oct1, and Ntcp mRNA following LPS administration, but had little or no effect on the decrease of Mrp2, Mrp6, Lst, Bsep, and Oat3 levels. Dexamethasone also blocked the LPS-mediated increase in Mrp1, Mrp3, and Mdr1b mRNA. The dexamethasone abatement of both LPS-mediated suppression and induction of transporters indicates

that these responses may be mediated through similar pathways. Moreover, the prevention of LPS-mediated effects by dexamethasone pretreatment on some, but not all transporters underscores the complex nature of hepatic transporter regulation. (Supported by NIH grants ES-09716, ES-09649, and ES-07079)

1440 DOWN-REGULATION OF LIVER-SPECIFIC TRANSPORTER (Lst OR Oatp4) BY LIPOPOLYSACCHARIDE THROUGH TOLL-LIKE RECEPTOR 4 (TLR4).

N. Li, S. Choudhuri, N. J. Cherrington and C. D. Klaassen. *Pharmacology, Toxicology, and Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

Lipopolysaccharide (LPS) is a component in the outer membrane of Gram-negative bacteria. LPS stimulates the immune system and causes a dramatic systemic reaction known as sepsis, which can cause cholestasis in humans and rodents and is associated with the down-regulation of the liver-specific transporter (Lst or Oatp4) and other transporters in rat liver. Biological action of LPS is thought to be mediated by toll-like receptor 4 (TLR4). The purpose of this study was to determine (1) whether LPS treatment decreases the levels of Lst mRNA in mice and (2) whether TLR4 plays a role in the LPS-mediated decrease of Lst expression. To address this hypothesis, C3H/HeJ mice were used because they are LPS-hyporesponsive due to a missense mutation (P712H) in TLR4. LPS-responsive C3H/OuJ mice were used as controls. Both C3H/HeJ and C3H/OuJ mice (25-30 g) were injected with a single, nonlethal dose of 5 mg/kg LPS ip in saline. Livers were excised at various time points: 0, 1.5, 3, 6, 12, 16, 24, and 48 h after treatment, and the levels of Lst mRNA were analyzed by the branched DNA signal amplification assay. In control C3H/OuJ mice, LPS treatment decreased Lst mRNA levels rapidly in a time-dependent fashion, reaching the minimal level (about 80% decrease) at 12 h following treatment, and returning to normal levels over the following 36 h. In the TLR4 mutant mice (C3H/HeJ), the decrease in Lst mRNA levels was much less pronounced (about 40% decrease) than that observed in the controls (C3H/OuJ). A complete ablation of the response to LPS was not expected in the TLR4 mutant mice (C3H/HeJ), because these mice are hyporesponsive but not unresponsive to LPS. These data support the hypothesis that the LPS-mediated decrease in the expression of Lst is through TLR4. (Supported by NIH grant ES-09649)

1441 TISSUE DISTRIBUTION AND REGULATION OF THE MULTI-DRUG RESISTANCE PROTEINS 5 AND 6.

J. M. Maher, N. J. Cherrington and C. D. Klaassen. *Pharmacology, Toxicology, and Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

Multidrug Resistance Proteins (Mrps) are a class of ATP-dependent transporters distinguished by their ability to confer resistance to anti-cancer drugs. Two of the newest family members, Mrp5 and Mrp6, were only recently cloned and have not been well characterized. The purpose of this study was to determine the tissue distribution of Mrp5 and 6, and to ascertain whether hepatic mRNA levels of the transporters were altered by cholestasis or administration of microsomal enzyme inducers. Mrp5 and 6 mRNA levels were quantified using the branched DNA signal amplification method. Transporter mRNA levels were examined in Sprague-Dawley rats for both Mrp5 and Mrp6 in various tissues. Additionally, microsomal enzyme inducers representing six different transcriptional activation mechanisms were utilized to determine effects on Mrp5 and 6 mRNA levels. In a subsequent study, bile-duct ligation was used to model cholestasis, and the transcriptional regulation of Mrp5 and 6 was subsequently examined. Mrp5 mRNA levels were detected predominantly in the adrenal gland, followed by cerebral cortex, cerebellum, and stomach. Expression of Mrp5 in the adrenal gland was substantially higher than that present in other tissues. In contrast, Mrp6 tissue expression was more ubiquitous, but expression was highest in intestinal tissue, liver, and kidney. Mrp5 mRNA expression was minimal in the liver, and neither treatment with microsomal enzyme inducers nor bile duct ligation altered mRNA levels. Mrp6, while present in liver, also showed little alteration by these treatment conditions. In conclusion, Mrp5 is most highly expressed in the adrenal gland, while Mrp6 is mainly expressed in excretory organs (liver, intestine, and kidney), suggesting markedly different functions. Additionally, the hepatic mRNA levels of Mrp5 or Mrp6 are not altered in response to challenges such as bile duct ligation or microsomal enzyme induction. (Supported by NIH grants ES-09716 and ES-07079)

1442 SIGNAL TRANSDUCTION PATTERNS IN VARIOUS MOUSE IMMUNE SURVEILLANCE CELLS AFTER XENOBIOTIC STIMULATION.

K. A. Singh, G. F. Gerberick, B. C. Hulette, K. E. Driscoll, C. A. Ryan and J. M. Carter. *Central Product Safety, Procter & Gamble, Cincinnati, OH.*

With the exception of stem cells, as a general rule cells are specialized to perform a primary function or limited set of functions unique to its type or subset. Immune cells, as a subset, have functions that are distinguished by the role that particular cell plays in the inflammatory process. A determining factor of this role is based, in part, on the mediators (or endpoints) released from a cell, which regulate the inflammatory response. The activation and release of these endpoints are controlled by complex intracellular signaling mechanisms. A single signaling molecule, such as LPS or PMA, can activate a variety of endpoints (genetic changes occurring at the termination of a signal transduction cascade) in different subsets of immune cells. Multiple signal transduction pathways can be activated to create unique patterns of activation (signature response), which may or may not to be toxicant and cell specific. In order to determine the specificity of this response, alveolar macrophages, spleen dendritic cells, and PMN's (various surveillance cells important in the inflammatory process) were isolated from mice and stimulated with either LPS or PMA. Genomic array analysis of cells stimulated with either LPS or PMA revealed a unique expression profile for signal transduction pathways for each toxicant that was common to all cell types, though endpoints varied considerably among the cell types. These data suggest that intracellular "signature responses" can occur which are unique to the inducing toxicant or class of toxicants, but common to all cells or subset of cells. These "signature responses" can be utilized to develop a mechanistic understanding of toxicity and exploited to develop rapid, cost effective *in vitro* assays. Understanding mechanisms of intracellular signal transduction can lead to improved *in vitro* screening assays which ultimately reduce animal usage and provide less expensive assays for screening potential toxicants.

1443 ALTERNATIVE PROCESSING OF THE HUMAN *FMO6* TRANSCRIPT.

K. A. Hopp and R. N. Hines. *Pediatrics, Medical College of Wisconsin, Milwaukee, WI.*

The flavin-containing monooxygenases (FMO) are important for the metabolic disposition of a wide variety of environmental toxicants and therapeutics. There is evidence for five distinct mammalian flavin-containing monooxygenases (FMO1-5) each exhibiting a highly regulated tissue-, developmental, and species-specific expression pattern. A sixth *FMO* gene sequence is found within the *FMO* cluster on the long arm of human chromosome 1. Although this gene exhibits the expected 48-55% sequence identity with FMO1, FMO2, FMO4 and FMO5, it is unusual in that it shares 70% sequence identity with FMO3. Sequence analysis revealed the presence of the conserved NADPH and FAD binding elements typical of this gene family and predicted normal splicing to yield a 1, 649 base plus transcript encoding a 539 amino acid protein. However there has been no evidence of FMO6 expression or demonstration of specific enzyme activity. In this study, RNA was isolated from human liver and the FM06 cDNA was amplified by nested RT-PCR. Products were separated by agarose gel electrophoresis and visualized by ethidium bromide staining. Individual amplification products were purified and sequenced using the PCR primers. The expected cDNA amplification products were not observed in any of the samples. Rather, truncated versions were seen in the range of 1, 100 to 1, 400 bases. Examination of the DNA sequence revealed splice variants which either eliminated or shortened some of the expected exons. Comparison to *FMO3* revealed sequence changes at each of the alternative splice sites conforming to consensus splice donor or splice acceptor sites. Open reading frame analysis of these variant transcripts indicated a loss of competency to encode full length functional enzyme and suggests that FMO6 activity is not present in hepatic tissue and that this gene represents a pseudogene. Further studies will examine *FMO6* splicing scenarios in other tissues. (Supported in part by PHS Grant No. CA53106).

1444 p, p'-DICHLORODIPHENYL DICHLOROETHYLENE (p, p'-DDE) INHIBITS THE ANDROGEN-INDUCED ANTIPROLIFERATIVE RESPONSE IN CAMA-1 CELLS.

P. Ayotte and C. Larochelle. *Public Health Research Unit CHUQ-CHUL, Laval University, Beauport, PQ, Canada.*

We recently reported that p, p'-DDE, the main metabolite of p, p'-DDT and a potent anti-androgen, was associated with tumor aggressiveness in women diagnosed with breast cancer (Cancer Epidemiol. Biomarkers Prev. 2000; **9**: 161-6). Since androgens are known to inhibit the growth of breast cancer cells, we tested the hypothesis that p, p'-DDE might block this antiproliferative response in the estrogen-responsive CAMA-1 human breast cancer cell line that expresses the androgen receptor. CAMA-1 cell proliferation was determined by seeding 2 x 10^4 cells into 24 well plates and exposing the cells to various concentrations of 17-bestradiol (E2), dihydrotestosterone (DHT) or p, p'-DDE for 12 days. Cells were then fixed with methanol and the effect on cell growth was determined by measuring DNA in the cells by fluorometry, following the addition of DABA. The maximum proliferative response was observed with 0.1 nM E2. DHT added alone to the cell medium did not increase cell proliferation, but 0.1 and 1 nM DHT reduced the proliferative response induced by 0.1 nM E2 by 30% and 50%, respectively. p, p'-DDE had no effect by itself on CAMA-1 cell growth. However, in combination with 0.1 nM E2 and 0.1 nM DHT, increasing concentrations of p, p'-DDE in the incubation

medium (0.1–1 μM) partially restored the proliferative response induced by E2. These results add biological plausibility to our previous epidemiological observations linking p, p'-DDE and breast cancer aggressiveness.

1445 MECHANISM OF P53 ELEVATION BY BUTADIENE DIEPOXIDE IN HUMAN FIBROBLASTS.

P. M. Muganda, S. Y. Seemanapalli and M. Starks. *Biological Sciences, Southern University, Baton Rouge, LA.* Sponsor: E. Spencer.

The environmental chemical butadiene is prevalent in petrochemical industrial areas, and is a known mutagen and suspected human carcinogen. The molecular mechanisms of butadiene toxicity, however, are not yet well understood, though the cellular effects of this compound are mediated through its metabolites. Since the tumor suppressor p53 protein responds to cellular stress, and mediates cellular responses to environmental stress and DNA damage, we investigated whether p53 levels were affected in human embryonic lung fibroblasts exposed to butadiene diepoxide, the most genotoxic metabolite of butadiene. We found that under experimental conditions where glyceraldehyde-3-phosphate dehydrogenase (G3PDH) levels remain unchanged after western blot analysis, butadiene diepoxide was effective in elevating p53 levels in exposed fibroblasts at concentrations as low as 1 micromolar. Levels of p53 were elevated 10 fold at 1 micromolar butadiene epoxide concentration, and continued to increase as the concentration of butadiene diepoxide increased. Levels of p53 were maximal when butadiene diepoxide concentrations of 200 micromolar were utilized, and at this point p53 levels were elevated approximately 40 fold as compared to control fibroblasts. Further investigation by pulse chase analysis revealed that p53 stability was mainly responsible for the elevated p53 levels in butadiene diepoxide exposed fibroblasts. Our data also revealed that levels of acetylated p53 at lysine 382 increased in correlation to the elevated p53 levels in butadiene diepoxide exposed cells. Since p53 acetylation has been found to be important in stabilizing and regulating p53 function in response to genotoxic stress in other systems, our results suggest that p53 acetylation at lysine 382 may play a similar role in human fibroblasts exposed to butadiene diepoxide.

1446 TUMOR FORMATION IN MICE BY STYRENE: INDUCTION OF CELL PROLIFERATION IN THE LUNG BY STYRENE METABOLITES.

R. Landseidel, W. Kaufmann, W. Mellert and H. D. Hoffmann. *Department of Product Safety, BASF, Ludwigshafen, Germany.* Sponsor: R. Bahnemann.

Styrene is a high production volume chemical (approx. $2x10^7$ tons/year) used as a monomer for plastic productions. Mice develop lung tumors when exposed chronically to styrene. The relevance of these findings for humans is under investigation. Epidemiological data provide no evidence for a carcinogenic potential in humans. Styrene is metabolised to styreneoxide. This electrophilic metabolite is assumed to cause genotoxicity and consequently lung tumors in mice. Research on the metabolism, kinetics and genotoxic effects of styreneoxide in mice and rats did not disclose a clear-cut model for tumor formation depending predominantly on styreneoxide. Thus styreneoxide cannot be seen as the only ultimate toxicant. Recent mechanistic studies demonstrated that the induction of cell proliferation in the lungs of mice is a major cause of tumor formation by styrene rather than a genotoxic effect. We tested styrene and five of its metabolites (α-phenylethanol, β-phenylethanol, phenylacetaldehyde, acetophenone, phenylacetic acid) for induction of cell proliferation in the lungs of CD-1 mice and Fisher rats. Test substances were administered i.p. The cell proliferation in the lungs was quantified by the S-phase response (BrdU labelling index). It was determined 24 and 72 hours post application in large and medium bronchi, terminal bronchi and alveoli. Highest increases of cell proliferation were observed in the alveoli of mice treated with β-phenylethanol, phenylacetaldehyde and phenylacetic acid, with the aldehyde causing the most pronounced effect. This was observed 24 and 72 hours post application. Interestingly the oxidation at the β-carbon of styrene is an important pathway in mice, but not in rats. This metabolism leads to phenylacetaldehyde and phenylacetic acid, the most potent inducer of cell proliferation in this study. A considerable contribution of these metabolites to the tumor formation by styrene exposure would explain the differences between mice and rats and may provide a better basis for the assessment of risks in humans.

1447 FUNCTIONAL CHARACTERIZATION OF C190T POLYMORPHISM IN HUMAN N-ACETYLTRANSFERASE 2 (NAT2) GENE.

Y. Zhu, M. A. Doll and D. W. Hein. *Pharmacology and Toxicology, University of Louisville, Louisville, KY.*

N-acetyltransferase 2 (NAT2) is an important phase II enzyme, which catalyzes N-acetylation (detoxification) and O-acetylation (activation) of many drugs and environmental carcinogens. Genetic polymorphisms in the NAT2 gene have been associated with differential susceptibility to cancers and drug toxicity from these compounds. Single nucleotide polymorphisms (SNPs) have been identified in the human NAT2 coding region. Their effects on NAT2 expression, stability, and catalytic activity have been investigated in our laboratory. A new allele *NAT2*19* recently was identified. This variant allele possessing the C190T (R64W) SNP was cloned and expressed in yeast (*Schizosaccharomyces pombe*). Substantial reduction in expression of NAT2 immunoreactive protein and protein stability were observed for *NAT2*19* (half-life=2.71 min) when compared with the reference rapid acetylator allele *NAT2*4* (half-life=36.4 min). No significant differences in mRNA expression or transformation efficiency were observed following Northern and Southern blotting. The enzymatic activities for N-acetylation of two arylamine carcinogens (2-aminofluorene, 4-aminobiphenyl), and a sulfonamide drug (sulfamethazine) were over 100-fold lower for NAT2 19 compared to reference NAT 4. In addition, activity for O-acetylation of the heterocyclic amine carcinogen 2-amino-1-methyl-6-phenylimidazo [4, 5-b] pyridine was 24-fold lower. The results show that *NAT2*19* encodes slow acetylator phenotype for both N- and O-acetylation. Our findings define more clearly the effects of individual SNPs on human NAT2 expression, stability and catalytic activity. This work is partially supported by USPHS grant CA34627 from the National Cancer Institute.

1448 A NOVEL REGULATORY MECHANISM FOR TYROSINE HYDROXYLASE.

R. R. Vaillancourt and N. A. Sachs. *Department of Pharmacology & Toxicology, University of Arizona College of Pharmacy, Tucson, AZ.*

Tyrosine Hydroxylase (TH) is regulated by the reversible phosphorylation of serines 8, 19, 31 and 40. The physiological significance of phosphorylation of the serines remains enigmatic, as pan phosphorylation is not obligatory for catecholamine biosynthesis. The purpose of our study was to characterize the physiological relevance of the heterogeneous phosphorylation of TH by identifying novel interacting proteins. Serine 19 is arguably unique due to its requirement of 14-3-3 binding after phosphorylation for optimal enzyme activity, although it has been suggested that phosphorylated serine 40 also binds 14-3-3. 14-3-3 proteins are prevalent in mammalian brain and isoforms of 14-3-3 serve diverse functions including the regulation of intracellular signal transduction cascades by serving as a scaffold between proteins. To characterize proteins that interact with TH after phosphorylation on serine 19, this amino acid was mutated to alanine (THS19A), since it was reported that a serine to alanine mutation promotes a stable interaction between proteins. For the identification of proteins that interact with TH, THS19A was used as the bait in the yeast two-hybrid system and two cDNA clones were identified, consisting of amino acids 147-262 of mouse-derived PITSLRE. PITSLRE is a serine/threonine kinase and characterization of the corresponding human cDNA, in the form of a GST fusion protein, encoding amino acids 1-373 of a splice variant of the a isoform of human PITSLRE demonstrates an interaction between TH and GST-PITSLRE (1-373). Additionally, *in vitro* transcribed and translated TH interacts with full-length FLAG-PITSLRE immunoprecipitated from COS-7 cells. TH does not serve as a substrate for PITSLRE in an *in vitro* kinase assay. However, PITSLRE prevents the interaction between TH and 14-3-3 in HEK 293 cells through a mechanism, which remains to be characterized. It appears that PITSLRE may serve as a negative regulator of TH activity and therefore, possibly catecholamine biosynthesis.

1449 IDENTIFICATION THROUGH GENE EXPRESSION OF A TOXIC RESPONSE IN THE RAT FOR A COMPOUND THAT EXHIBITS OVERT TOXICITY IN HUMANS, BUT NOT IN RATS.

M. W. Porter, M. Elashoff, K. R. Johnson, A. L. Castle, M. S. Orr, H. W. Sun, C. G. Chang and D. L. Mendrick. *Toxicology, Gene Logic, Inc., Gaithersburg, MD.*

The classical measures of toxic response have been found to be insensitive to certain known hepatotoxicants, such as those that cause damage in humans, but whose effects are not detectable within the mammalian species used in pre-clinical trials. The implementation of a more sensitive measure of the toxic response to identify this type of compound is needed to assess accurately the potential toxicity of compounds in humans. For a variety of reasons, gene expression measurements from animal models may provide the means necessary to determine the eventual toxic response observed in humans. Tacrine is one such compound where an overt hepatotoxic response is observed in humans, but not in pre-clinical animal models. To identify the genes that characterize a response in the absence of overt hepatotoxicity, tacrine was administered to Sprague-Dawley male rats and liver tissue was isolated at various time points post-exposure. Using the Affymetrix RGU_34 GeneChip® set as a platform for measurement of gene expression levels, we have identified rat genes that are strong indicators of a toxic response for tacrine, but not the vehicle-treated controls. In addition, these genes have been previously shown to be good collective indicators of toxicity using samples extracted from rats treated

with known hepatotoxicants including acetaminophen (APAP), carbon tetrachloride (CCl_4), diclofenac sodium, and alpha-naphthylisothiocyanate (ANIT). These results may indicate that marker genes in the liver detected by administration of known toxicants are more sensitive for detection of the toxic response than classical methods. This expression information can also be used to identify toxic compounds that would otherwise be missed as part of the pre-clinical testing process.

1450 CHROMIUM-INDUCED CHANGES IN GENE EXPRESSION IN HEPG2 CELLS, AND IN WINTER FLOUNDER AND MICE LIVER USING MACRO- AND MICROARRAYS.

W. S. Baldwin[1], L. J. Bain[1], J. A. Roling[1], E. Buzhardt[2] and L. M. Chapman[1]. *[1]Biological Sciences, University of Texas at El Paso, El Paso, TX and [2]Biology, Anderson College, Anderson, SC.*

Chromium is the dominant toxicant found at several Superfund sites around the United States, including sites in Odessa, TX and a estuarine sites in Maine and South Carolina. However, chromium's effects are not well understood. Therefore, we have attempted to characterize the effects of Cr(III) and Cr(VI) on gene expression in HepG2 cells, as well as male winter flounder *(Pseudopleurinectes americana)*, and male CD-1 mice. HepG2 cells were exposed to Cr(VI), as chromium oxide and Cr(III), as chromium chloride hexahydrate to determine their toxicity. Cr(VI) caused death of 80% of the HepG2 cells at 1μM, while Cr(III) did not cause cell death, but significantly decreased growth at 100μM. Therefore, cells were treated with 20μM Cr(III), RNA was extracted and an array was incubated and analyzed. Several genes showed altered expression due to Cr(III), including α-1 antichymotrypsin, cathepsin D, and C-1. RT-PCR was performed to confirm differential expression of several of these genes. Additionally, mice and winter flounder were examined as *in vivo* models. Winter Flounder was injected with Cr(III) and Cr(VI) at 400 and 25μg/kg, respectively, and euthanized 24 hours later. mRNA was extracted from liver and subtractive hybridization was performed to enhance the production of differentially expressed clones, that were amplified by PCR and used to produce macroarrays. The macroarrays will be used to confirm differential expression, and clones demonstrating altered expression will be sequenced. Additionally, mice were treated with Cr(III) in the water for 14 days at 1000 and 2000 ppm, which approximates 7.5-15mg/kg/day. Superoxide dismutase was increased in treated mice, suggesting Cr(III) caused oxidative stress. Microarrays will also be performed on mRNA extracted from mouse livers to determine if similar genes are induced in mice, humans and winter flounder by Cr(III).

1451 DEVELOPMENT OF A NOVEL METHOD FOR ANALYSIS OF TRANSCRIPTIONAL CHANGES IN TRANSITIONAL EPITHELIUM FROM URINARY BLADDERS OF RATS EXPOSED TO DRINKING WATER DISINFECTION BY-PRODUCTS.

D. C. Wolf and S. D. Hester. *Environmental Carcinogenesis Division, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

Epidemiologic studies in human populations drinking disinfected water have consistently shown an increase in the risk of urinary bladder cancer. Increased incidence of transitional cell carcinoma of the urinary bladder is associated with consumption of chlorinated surface waters. The transitional cell epithelium is therefore the target for chemically-induced toxicity and carcinogenicity in the urinary bladder. After chronic treatment to MX alone or a mixture of DBP's, transitional epithelial cells had marked anisokaryosis and megalokaryocytes associated with focal hyperplasia. To detect and analyze biologic events which contribute to transitional cell carcinoma, we developed a method by which only the target cell population was removed from the urinary bladder of male rats and the RNA isolated for transcriptional analysis using the Clontech™ Rat Atlas 1.2. Twelve male Long-Evans rats, 4 per group, were exposed to a mixture of potassium bromate, MX, chloroform, and bromodichloromethane administered in drinking water in a mixture of low doses of 0.02, 0.005, 0.4 and 0.07 g/L, or as a mixture of high doses of 0.4, 0.07, 1.8 and 0.7 g/L, respectively. In the present study, animals were exposed to deionized water or the mixture solutions for 3 weeks, then euthanized and necropsied. At necropsy the urinary bladder was instilled with 500 microliters of Trizol™ reagent, set for 7 minutes, then flushed to remove the lining cells. The amount of total RNA extracted per bladder after *in situ* Trizol treatment ranged from 12 to 363 micrograms. Total RNA was used to perform the cDNA array analysis which was then verified using real-time PCR, (TaqMan™). Ths method will allow study of the biology of the transitional epithelium of the urinary bladder and detection of altered gene expression for improved understanding and defining of biologically relevant responses to urinary bladder carcinogens. This abstract does not reflect EPA policy.

1452 ALTERATIONS IN GLOBAL GENE EXPRESSION INDUCED BY AFLATOXIN B_1 IN YEAST EXPRESSING HUMAN CYTOCHROME P450 1A2.

Y. Guo[1,2], L. Jing[2], H. Xie[2], E. J. Kelly[1], K. Gross-Steinmeyer[1], T. K. Bammler[1], H. Zarbl[2] and D. L. Eaton[1,2]. *[1]Environmental Health, University of Washington, Seattle, WA and [2]Fred Hutchinson Cancer Research Center, Seattle, WA.*

Aflatoxin B1 (AFB) is a human hepatotoxin and hepatocarcinogen produced by the mold *Aspergillus flavus*. In human, AFB is bioactivated by cytochrome P450 (CYP) enzymes, mostly CYP1A2, to genotoxic epoxide which forms N^7-guanine DNA adducts. To characterize the transcriptional responses to AFB genotoxic insult, *S. cerevisiae* strain YHE2, engineered to express human CYP1A2 or vector, was grown to a density of 5 X 10^6 cells/ml and exposed to AFB (10, 25, 50, 100 μM) or vehicle control (DMSO) for 2 or 4 hours in ura(-) medium at 30°C. AFB did not result in significant cell death at 2 hr, determined by colony forming ability, but did induce dose and time-related increases in mitotic recombination measured by *Trp* reversion assay. No cell death or mitotic recombination was observed in the vector expressing strain. cDNA was synthesized from total RNA isolated from treated and control CYP1A2-expressing cells using oligo $d(T)_{15}$ primers and aminoallyl-dUTP, which was then chemically coupled with Cy5 or Cy3 fluorescent dye, respectively. The labeled cDNA pools were admixed and hybridized to a yeast microarray spotted with 6, 246 cDNAs, representing the entire yeast genome. Approximately 200 transcripts were changed by at least two-fold with respect to time and/or dose, which included stress response, protein degradation, DNA replication, RNA synthesis and cell cycle regulation genes, as well as approximately 60% with unknown identity and/or function. Expression of 12 genes increased consistently in a time and/or dose-dependent fashion. Decreased expression was observed for about 30 genes at all conditions except the highest dose (100 μM), at which over 150 genes decreased. Cluster analysis suggested a role for the recombination-mediated DNA repair mechanism, as Rad51 and ribonucleotide reductase genes (RNR1, RNR2, RNR3, RNR4) were co-upregulated in a dose- and time-dependent manner. (Supported by NIH grants ES07033 and ES05780).

1453 ALTERED LIVER GENE EXPRESSION AND POST-TRANSLATIONAL PROTEIN MODIFICATIONS IN RESPONSE TO LETHAL OR NON-LETHAL *LISTERIA MONOCYTOGENES* INFECTION IN FEMALE BALB/C MICE.

C. E. Frantz[1], H. He[1], L. Rausch[1], N. Kirsten[1], D. Fairchild[1], E. Riccio[1], Y. Freund[1], T. Hunter[2], J. Panucci[2], E. M. Bradbury[2], X. Chen[2], J. C. Mirsalis[1] and C. Litterst[3]. *[1]SRI, Menlo Park, CA, [2]LANL, Los Alamos, NM and [3]NIAID, Bethseda, MD.*

Infection of mice with *L.monocytogenes* (*LM*) is widely-used to study host response to intracellular bacterial pathogens and to examine immunotoxic effects of therapeutics. *LM* is also a food-borne pathogen and is thought to act in part by modifying host cell signal transduction and utilization of the host's actin-based cytoskeleton. While this model is well studied, effects on murine gene expression remain largely unknown. The objective of this study was to determine if infection induced differential gene expression or protein modification in the liver, a primary target organ. Mice received by i.v. route either vehicle, $1x10^3$ (non-lethal), or $5x10^4$ CFU *LM* (lethal) and were sacrificed 1, 2, 4, and 14 days later. Levels of RNA were measured with Affymetrix Genechip® arrays. Differentially phosphorylated proteins were identified using gel separation and MALDI-TOF. Infectious burden, clinical and histopathology confirmed infection and showed significant effects in the high dose group. Multiple genes were found to be differentially expressed in a reproducible and dose-related manner. Classes of genes altered included immune-function genes (lymphocyte antigen 6 complex, macrophage expressed gene 1), genes associated with liver toxicity (Ntcp, hypoxia inducible factor1, HSP 70), and genes involved in cell signaling (EGF-R, IGFBP-4, IGFR-2). In addition, using data analysis and modeling tools we have identified a preliminary set of genes that may be useful in assessing if an infection with *LM* will be lethal or non-lethal. Protein analyses indicate that, γ-actin, ATP-synthase β-chain and CDC5 kinase regulatory subunit1 undergo differential tyrosine phosphorylation. These results indicate large-scale differences in gene expression and patterns as well as in protein modification in livers of exposed mice. Supported in part by NIAID Contract N01-AI-05417

1454 TRANSPLACENTAL EXPOSURE TO ESTROGENS INDUCES A DISTINCTIVE GENE EXPRESSION PROFILE IN THE FETAL UTERUS OF THE RAT.

J. M. Naciff, M. L. Jump, S. M. Torontali, G. J. Carr, J. P. Tiesman, G. J. Overmann and G. P. Daston. *Miami Valley Laboratories, Procter & Gamble, Cincinnati, OH.*

In order to understand the molecular events associated with the estrogenicity of different chemicals, we have used microarray technology to determine whether there is a common set of genes which expression profile could be traced to estrogenic com-

pounds exposure during organogenesis and development. Changes in patterns of gene expression were determined in the developing uterus and ovaries of Sprague-Dawley rats on gestational day (GD) 20, exposed to different doses (s.c.) of 17 α-ethynyl estradiol (0.5, 1, and 10 μg EE/kg/day); bisphenol A (5, 50, and 400 mg BPA/kg/day) and genistein (0.1, 10 and 100 mg/kg/day) from GD11 to GD20. Gene expression was evaluated using high density oligonucleotide arrays. A dose-dependent analysis of the gene expression profile revealed that each estrogenic compound induces a distinctive transcript profile, reflecting their estrogenicity as well as their molecular mechanism of action. Of the ~7000 annotated rat genes and 1740 ESTs, analyzed in this study, there were 366, 398 and 344 genes whose expression level shows some evidence of treatment effect (up or down regulated) by EE, BPA and genistein, respectively, relative to the vehicle control. From those genes, the expression of 66 was consistently and significantly regulated in the same direction, although at different magnitudes, by the three estrogenic compounds. Among the genes regulated by estrogens there are some that have been described in the literature including intestinal calcium-binding protein, progesterone receptor, 11-β-hydroxylsteroid dehydrogenase type 2, interleukin 4 receptor, and insulin-like growth factor 1. However, most of the genes responsive to estrogen exposure had not been previously identified. These data demonstrate that transplacental exposure to estrogens changes the gene expression profile of estrogen-sensitive tissues, and that the uniqueness of these transcript profiles could be a valuable tool to determine the estrogenicity of different compounds.

1455 EFFECTS OF GESTATIONAL AND LACTATIONAL EXPOSURE TO DIETHYLSTILBESTROL ON TESTICULAR GENE EXPRESSION USING cDNA MICROARRAYS AND REAL-TIME PCR.

M. R. Fielden[1], R. G. Halgren[1], C. J. Fong[1], K. Chou[2] and T. R. Zacharewski[1]. *[1]Department of Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI and [2]Department of Animal Science, Michigan State University, East Lansing, MI.*

To explore the molecular events underlying the adverse effects on sperm quality following developmental exposure to estrogenic chemicals, we have constructed cDNA microarrays to examine testicular gene expression in B6D2F1 offspring of mice exposed by gavage to 10 μg/kg diethylstilbestrol (DES) from gestational day 12 to postnatal day 21. Replicate gene expression profiles were examined in male offspring at 3, 15 and 45 weeks of age to determine if the effects on gene expression paralleled the long term decreases in testis weight, sperm count, and sperm fertilizing ability, as previously described. A mouse cDNA microarray containing approximately 1948 genes was constructed and used to compare testicular gene expression in the offspring of DES-exposed mice to that of vehicle-exposed mice. An independent reference design coupled with paired t-tests was used to identify genes significantly ($p<0.05$) altered in expression by DES. Based on adjusted p values, there was only one gene significantly altered at 3 weeks of age (a component of the 20S proteasome). At 15 weeks of age, there were 46 genes significantly altered in expression. There were no significant changes at 45 weeks of age. Raw p values and functional annotation were used to prioritize the selection of genes for verification. Using real-time PCR, both age and dose-dependent changes in gene expression were examined. There was a significant decrease in the expression of ER alpha mRNA at 3 weeks of age ($p<0.01$), while mRNA expression was below the limits of detection in 15 and 45 week old mice. Other genes selected for verification include inhibin, the orphan receptor TR2, and Xmr, a component of the synaptonemal complex. These results suggest that the adverse effects on sperm fertilizing ability may be due to altered expression of ER alpha, and possibly other genes, in the testis.

1456 THE EFFECT OF GLUTATHIONE DEPLETION ON GENE EXPRESSION IN HEPG2 CELLS.

A. T. White[1], F. J. Elcock[2,1] and J. K. Chipman[1]. *[1]School of Biosciences, University of Birmingham, Birmingham, United Kingdom and [2]GlaxoSmithkline, Welwyn, United Kingdom.* Sponsor: T. Hammond.

Glutathione is known to play a critical role in the control of cellular homeostasis through reductive and anti-oxidant action and through the regulation of specific intracellular cell signalling. We wished to determine the influence of glutathione depletion on the expression of a range of stress-response genes in cultured human HepG2 cells. Following treatment of cells with buthionine sulphoximine (1.0mM) for 6 and 24h, the concentration of reduced glutathione (GSH) was depleted to 60 ± 3.1 and 17 ± 1.5 % of control values respectively (n = 5). There was no associated increase in oxidised glutathione or evidence of cytotoxicity as measured by intracellular ATP concentrations and lactate dehydrogenase leakage. Differentially expressed genes were identified by suppressive subtractive hybridisation (SSH) and through the use of "Phase 1" human microarrays customised for toxicity detection. A wide range of genes known to be responsive to oxidative stress showed no change in expression under these conditions. However, consistent increases (1.5 - 2.8 fold with correlation coefficients > 0.95 in the microarray analyses) in sub-sets of genes (approximately 50)were indicative of apparent adaptive responses. A total of 26 genes were also down-regulated following microarray analysis. These include transferrin and UDP glucuronosyltransferase 2B. In particular, induced genes included c-jun in accord with previous reports of AP1 activation by GSH depletion. There was an increase in glutathione peroxidase and ubiquitin (by SSH) that may reflect adaptation. Eleven cytochrome P450 (CYP) forms were also over expressed which suggests an inter-relationship between control of GSH homeostasis and CYP regulation.

1457 MICROVESICULAR STEATOSIS INDUCED BY SHORT CHAIN CARBOXYLIC ACID ANALOGS: EVALUATION OF GENE EXPRESSION AND CORRELATION TO MITOCHONDRIAL TOXICITY.

R. Jolly, J. Waring, M. Helgren, D. Morfitt, C. Nduaka, L. Loberg, L. Gallenberg and R. Ulrich. *Drug Safety Evaluation, Abbott Laboratories, Abbott Park, IL.*

Hepatotoxicity characterized by microvesicular steatosis features abnormal accumulation of numerous small cytoplasmic lipid droplets in hepatocytes. Fulminant or progressive cases may lead to liver failure and death. Experimentally, short-chain fatty acids are known to induce hepatocellular microvesicular steatosis. The precise mechanism(s) whereby short-chain fatty acids induce microvesicular steatosis are unknown, although there is evidence implicating disruption of mitochondrial function. The identification of gene changes that correlate with microvesicular steatosis concomitant with biochemical indices would provide a better understanding of how the toxicity occurs. To this end, a series of short chain fatty acids including valproic acid (VPA), cyclopropane carboxylic acid (CPCA), 4-pentenoic acid (4PE), pivalic acid (PIV), butyric acid (BTR) and propionic acid (PRO) were tested *in vitro* for their ability to inhibit mitochondrial beta oxidation and *in vivo* for 1, 3 and 7 days to evaluate their ability to induce microvesicular steatosis in rats. VPA, CPCA and PIV resulted in microvesicular steatosis 1-3 days post treatment while PRO and BTR did not. In agreement with this finding these compounds inhibited mitochondrial beta-oxidation in a dose dependent manner *in vitro* and caused a reduction in mitochondrial respiration, whereas no inhibition was evident with PRO or BTR. Gene expression results showed a regulation in genes involved in beta-oxidation, including thiolase, acyl-coa hydrolase and cytochrome P450 2C11, as well as other genes not previously associated with microvesicular steatosis. Overall, these results support altered hepatic mitochondrial function as a causative mechanism of the toxicity induced by short-chain fatty acids and provide potential markers for this toxicity.

1458 CONCORDANCE OF DEGREE OF RENAL INJURY WITH GENE EXPRESSION IN INDIVIDUAL ANIMALS TREATED WITH THE NEPHROTOXICANT CISPLATIN.

K. L. Thompson[1], M. L. Mirsky[2] and F. D. Sistare[1]. *[1]CDER, USFDA, Laurel, MD and [2]Drug Safety Evaluation, Pfizer, Inc., Groton, CT.*

As part of a coordinated evaluation of the application of genomic methodologies to mechanism-based risk assessment, the Nephrotoxicity subteam of the ILSI Genomics and Proteomics Subcommittee examined the relationship between traditional toxicologic endpoints and gene expression responses to prototypic nephrotoxic drugs in Sprague-Dawley rats. As part of one study, 5 male rats received a single ip injection of 5 mg/kg cisplatin. Six days later, the animals were sacrificed, standard serum chemistry and urinalysis parameters were measured, and the kidneys were processed for histopathology and RNA. Gene expression profiles were evaluated with the 700 gene Phase-1 Rat(CT) microarray on samples from individual animals, pooled controls, and pooled treated animals. 3 of the 5 animals had moderate tubular necrosis and regeneration, and highly elevated serum levels of BUN and creatinine. One animal had mild tubular necrosis and regeneration, and no evidence of kidney injury was observed in a fifth rat. Both of these latter animals had normal BUN and creatinine levels. The gene expression induction profiles were highly correlative among the 3 animals that had the same degree of renal damage and altered serum chemistry, and with the pooled sample from treated rats. In a subset of genes, there was concordance between the magnitude of the induction and the type and extent of tubular injury seen. The observed gene induction profile was highly concordant with results from pooled animals in an earlier, independent study using the same dose of cisplatin. Genes significantly up-regulated in animals with evidence of renal toxicity included damage-inducible genes like GADD153, clusterin, and cyclin G. Renal tubular markers like OAT3, HNF4, and EGF were

significantly down-regulated in these animals. The observed patterns of gene induction in this study were consistent with known mechanisms of cisplatin nephrotoxicity, highly reproducible, and reflective of the extent of damage observed in histopathologic analysis.

1459 TEMPORAL EXPRESSION PATTERNS OF GENES IN THE UTERI OF IMMATURE, OVARIECTOMIZED MICE TREATED WITH ETHYNYL ESTRADIOL.

K. C. Fertuck[1], J. Eckel[2], C. Gennings[2] and T. R. Zacharewski[1]. *[1]Department of Biochemistry & Molecular Biology, National Food Safety & Toxicology Center, and Institute of Environmental Toxicology, Michigan State University, East Lansing, MI and [2]Department of Biostatistics, Virginia Commonwealth University, Richmond, VA.*

Estrogens are classically defined as compounds that are capable of inducing a trophic effect on the uterus. This physiological change has been linked to alterations in the expression of estrogen-responsive genes, but the cascade of molecular events remains unknown. In the present study, the effects of ethynyl estradiol (EE), a synthetic estrogen, on global gene expression in then uterus were examined in immature, ovariectomized C57BL/6 mice. Mice were gavaged with 0.1mg/kg EE or vehicle, and uteri harvested at 0, 2, 8, 12, or 24 hr. Overall, while no differences in uterine weight were found between treatment groups (p=0.296) from 0 to 24 hrs, changes in global gene expression levels were observed during this period. Mu11KsubA Affymetrix GeneChips were used to assess relative expression levels of over 6000 genes in uterine tissue of two animals from each treatment and time-matched vehicle treated (control) group. Data were then screened using standardized t scores to identify gene expression changes outside the normal range of variation for the control group. Treated values were standardized using i) a global control mean and standard deviation assuming no time effect among the control observations, or ii) the average and standard deviation of the time-matched control values. These methods were found to give different results, with the time-matched control approach resulting in the identification of fewer active genes. Large t scores were interpreted to indicate active gene responses. Overall the 24 hr time point had the largest t scores as determined by average ranks and summary statistics over time. The nature of the changes over time was characterized using a parametric model based on the general shape of the time-effect relationship.

1460 EVALUATION OF DIFFERENTIAL GENE EXPRESSION IN THE SPLEENS OF RATS AT SEVERAL TIMEPOINTS AFTER INJECTION OF CYCLOPHOSPHAMIDE.

Y. Ng-Smith, K. W. Tiegler, J. T. Gonzales and G. M. Farris. *Database, PHASE-1 Molecular Tocicology, Inc., Santa Fe, NM.*

The toxicity of drugs and chemicals is dynamic with overlapping stages of drug metabolism, direct and indirect cellular damage, and repair. Recognizing this complexity in the toxicity response, Phase-1 evaluates gene expression by sacrificing rats at 6, 24 and 72 hours after a single intraperitoneal injection of a compound at two concentrations. For this study Sprague-Dawley rats were dosed with several immunotoxicants. Cyclophosphamide dosed at 25 and 100mg/kg induced lymphoid depletion in the spleen at 72 hours. The spleen of each rat was harvested and total RNA was isolated for transcription to cDNA with dual cy-3, cy-5 labeling and hybridized on the PHASE-1 rat 700 gene toxicology array. The gene expression levels were compared across time points and across doses. The differential gene expression with cyclophosphamide was also compared with other immunotoxicants. The ability to detect toxicity by determining differential gene expression improves the process of evaluating toxicity in pre-clinical studies with rats

1461 THEOPHYLLIN INDUCED DIFFERENTIAL GENE EXPRESSION IN THE HEART.

D. P. McGinn, G. M. Farris and C. L. Reynolds. *PHASE-1 Molecular Toxicology, Santa Fe, NM.*

Gene expression data generated using PHASE-1's comprehensive toxicological, 700-gene micro array was evaluated in order to compare gene expression profiles for different cardiac toxicants. Labeled cDNA was produced by reverse transcription of mRNA isolated from tissue harvested at 6, 24, and 72 hours after rats received a single intraperitoneal injection of a cardiac toxicant at two concentrations. This cDNA was then hybridized onto arrays composed of genes empirically determined to be toxicologically relevant. The gene expression showed correlations between theophyllin (cyclic phosphodiesterase inhibitor) dosed at 25 and 100 mg/kg, and other cardiac toxicants, including nifedipine (calcium channel blocker) dosed at 30 and 120 mg/kg. The data corresponded to the histologic evidence of myocardial degeneration and inflammation observed at 72 hours and to the compound's mechanism of toxicity. This study demonstrates how microarray technology used at PHASE-1 can be a powerful toxicological tool.

1462 SEXUAL DIMORPHISM OF HEPATIC GENES EXPRESSED IN HEXACHLOROBENZENE (HCB)-TREATED RATS.

B. Alt, M. Charbonneau and D. G. Cyr. *Human Health Research Centre, INRS-Institut Armand Frappier, Pointe Claire, PQ, Canada.*

HCB is an epigenetic carcinogen that predisposes females to the formation of liver tumours. Short-term exposure (5 days) to HCB promotes, with greater efficiency in females than in males, rat liver tumours induced by DEN injection 95 days following the last treatment. The objective of this study was to determine gender-specific differences in hepatic gene expression and their relationship to tumour promotion. To address this objective four experimental groups of rats were used: 1. vehicle-exposed males (control); 2. vehicle-exposed females (controls); 3. HCB-treated males; 4. HCB-treated females. Rats were administered corn oil (vehicle) or HCB (100 mg/kg) by gavage for 5 consecutive days and sampled on day 50 of the experiment. Cellular mRNA was isolated from the liver of each rat (n=4/group) and used to screen an Atlas array 1.2 II (Clontech) containing 1176 genes. Results indicate that in control male rat liver, 137 genes could be detected using this array, with 94% of expressed hepatic genes being common to each individual. In the female livers, 186 genes were expressed and 82% of these were common to each individual. These results indicate that, of the genes screened, there are 26% more genes expressed in female livers than in males and that there is more variability in the expression of these genes between individual females than between males. In HCB-treated males, there were 161 genes expressed, i.e. an 18% increase in the number of genes expressed as compared to controls, but only 71% of these were expressed in all four males. In HCB-treated females, 153 genes were expressed, i.e. an 18% decrease in the number of genes expressed as compared to controls, and 83% of these were found in each individual female. Male *versus* female differential comparisons of HCB-modulated genes will be discussed in relation to gene clusters that may be responsible for the gender-specific response in liver tumour promotion. (Supported by TSRI, Health Canada)

1463 QUANTITATIVE PROFILE OF TESTICULAR GENE EXPRESSION PATTERNS IN MICE EXPOSED TO DIETHYLSTILBESTROL DURING GESTATION AND LACTATION .

P. Saama[1], M. Fielden[2,3], J. Han[1], S. M. Samy[2], T. Zacharewski[2,3] and K. Chou[1,3]. *[1]Animal Science, Michigan State Univerity, E. Lansing, MI, [2]Biochemistry & Molecular Biology, Michigan State Univerity, E. Lansing, MI and [3]Institute for Environmental Toxicology, Michigan State Univerity, E. Lansing, MI.*

Previously, we have reported decreases in sperm fertilizing ability in male offspring exposed to diethylstilbestrol (DES) during gestation and lactation. In this study, a mouse cDNA microarray containing approximately 1948 genes was used to profile the testicular gene expression of the offspring. Pregnant C57BL/6 female mice bred with DBA/2 males were gavaged with 10 ug of DES/kg of B.W/day from gestational day 12 to postnatal day 21. The construction of cDNA microarray and gene expression identified by computing t-statistics and P-values have been reported in a separate presentation. In this report, the fluorescence measurements were analyzed using two interconnected mixed models, a ¡°normalization" model and a ¡°gene¡± model. The normalization model accounted for experiment-wide systematic effects that could bias inferences made on the data from individual genes. The residuals from this model represent ¡°normalized¡± values, and were the input for the gene model. The gene model was fitted separately to the normalized data for each gene, allowing inferences to be made using separate estimates of variability. Differences between Least Squares Means for treatment groups were estimated using Scheffe adjustments. At 15 weeks of age, the expression of 20 genes in the exposed males were four times or higher of the levels in the controls. Additional 39 genes were expressed at least twice of that in the controls. Among the genes which expression was suppressed, 31 genes were expressed less than one fourth of that in the controls and another 31 were expressed at less than half of the control levels. Over expression of prolactin receptor, serine/threonine kinase 10, and tyrosine phosphatase and under expression of prostaglandin E receptor 1 are among the several prominent changes observed in the testes of DES exposed offspring.

1464 IDENTIFICATION OF DIFFERENTIAL EFFECTS OF BENZO(A)PYRENE AND 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN ON GENE EXPRESSION IN HUMAN PLACENTAL JEG-3 CELLS USING CELL CYCLE AND DNA MICROARRAY ANALYSES.

T. A. Medrano, J. T. Schwanke, E. A. Ablordeppey and K. T. Shiverick. *Pharmacology & Therapeutics, University of Florida, Gainesville, FL.*

Maternal cigarette smoking disrupts placental growth and function, and the aryl hydrocarbon compound benzo(a)pyrene (BaP), a major toxicant in cigarette smoke, has been shown to inhibit proliferation and growth factor expression in cul-

tured human placental cells and JEG-3 choriocarcinoma cells. This study further investigated the effects of BaP on cell cycle and gene expression in JEG-3 cells in comparison with 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD), the reference ligand for the aryl hydrocarbon receptor (AhR), and benzo(e)pyrene (BeP), a weak ligand for the AhR. JEG-3 cells treated with 10 uM BaP for 48 hours showed a 75% decrease in [3H]thymidine incorporation, whereas 10 nM TCDD had no effect. Flow cytometry analysis showed that BaP induced a G2M cell cycle arrest, while TCDD and 50 uM BeP had no effect on cell cycle phase distribution. Cell cycle regulatory proteins were analyzed by Western immunoblot and immunohistochemistry. BaP markedly induced expression of nuclear p21 protein, a major inhibitor of cyclin-dependent kinases. Although BaP had no effect on total cellular p53 levels, phosphorylation of p53 at serine 15 was markedly increased. In contrast, neither TCDD nor BeP had any effect on the expression of p21 or p53 phosphorylation. Lastly, a human cancer cDNA microarray was used to evaluate changes in gene expression induced by treatment with BaP and TCDD. Data were analyzed using Atlas Image, Cluster and Treeview programs. BaP down-regulated 7 genes, while 3 were up-regulated. In comparison, TCDD was found to down-regulate 9 genes, while 1 was up-regulated. Of these, BaP and TCDD had similar effects on only 3 genes. In summary, although BaP and TCDD are both ligands for the Ah receptor, only BaP produces G2/M cell cycle arrest with induction of p21 and p53 serine phosphorylation that is characterized by a unique pattern of gene expression in JEG-3 cells. (Supported by NIH ES07375)

1465 DIFFERENTIALLY EXPRESSED SEQUENCES IN THE MUMMICHOG AS A RESULT OF ANTHRACENE EXPOSURE.

J. S. Peterson and L. J. Bain. *Dept. of Biology, University of Texas at El Paso, El Paso, TX.*

Approximately 40% of all USEPA Superfund sites have some sort of polycyclic aromatic hydrocarbon (PAH) contamination. Many of these sites are scheduled for remediation and tools are needed to assess whether efforts have been successful. Knowledge of the induction or suppression of specific genes as a result of exposure may be useful in understanding the mechanisms of PAH toxicity. We are attempting to generate a fingerprint of exposure to the PAH anthracene using the differential-display reverse transcription polymerase chain reaction (DD RT-PCR) technique. This technique has produced a series of cDNA fragments that will be used in constructing a microarray specific to anthracene. We then compare these fragments that have been detected to sequences of known genes in order to identify possible physiological consequences of exposure to anthracene. Mummichogs (*Fundulus heteroclitus*) are a non-migratory estuarine fish used to model exposure because they have contact with contaminated sediments over the full course of their lifetime. The fish were subjected to 7-day static renewal tests using environmentally relevant concentrations of 0 ppb, 27 ppb, 50 ppb, and 80 ppb of anthracene. The fish were euthanized, livers were removed, and total RNA was extracted. The mRNA was reverse transcribed into cDNA, amplified by rationally designed primers and run on a differential display gel. Sixteen cDNA fragments that represented differentially expressed mRNA sequences were isolated, amplified, and sequenced. The GENBANK database was searched to compare these mummichog sequences to gene sequences of known function. Three sequences thus far have shown similarity to known genes—CYP2N2 in the mummichog, insulin-like growth factor I in the Japanese flounder (*Paralichthys olivaceus*), and trypsinogen in both the Atlantic cod (*Gadus morhua*) and the Maori cod (*Paranotothenia magellanica*). Future work will relate the up- or down-regulation of these genes to the physiological impacts of anthracene exposure.

1466 THE LONG-TERM EFFECTS OF NEONATAL EXPOSURE TO ENDOCRINE DISRUPTORS ON TESTICULAR GENE EXPRESSION IN MICE.

M. Komiyama[1], T. Adachi[1,2] and C. Mori[1,2]. [1]*Department of Bioenvironmental Medicine, Graduate School of Medicine, Chiba University, Chiba, Japan and* [2]*Core Research for Evolutional Science and Technology, Japan Science and Technology Corporation, Kawaguchi, Japan.* Sponsor: A. Puga.

In order to evaluate the feasibility of cDNA microarrays for the risk assessment of endocrine disruptors (EDs), alteration of gene expression profiles was analyzed in adult mouse testes after neonatal exposure to diethylstilbestrol (DES), bisphenol A (BPA) or genistein (Gen), using cDNA microarrays. Analysis with Mouse GEM I revealed that expression levels of 34, 38 and 12 genes were changed in testes of DES-, Gen- and BPA-treated 12-week-old mice, respectively. Gene expression profiles were very similar between DES- and Gen-treated mice, but that of BPA-treated mice was quite different. These results suggest that gene expression profiles might be feasible for grouping of EDs in terms of their effects. Further, it is suggested that mechanisms of BPA action may be different from those of DES and Gen, although they are all estrogen-like compounds. Next, we investigated transition of the expression profiles in testes of DES-treated mice during 4-12 weeks of age using in-house cDNA microarrays. Many of genes affected by DES were up- or down-regulated at restricted periods, but some genes were continuously up-regulated or shifted from down-regulated state to up-regulated state. These results suggest that the transition patterns may represent the gene expression cascades that were affected by EDs. Moreover, the gene that was up-regulated continuously in the long term might be a candidate for the biomarker indicating that the exposure of individuals to EDs occurred at some sensitive period. We propose that cDNA microarray is a useful tool, which provides us a bird's eye view of global effects of EDs on the gene expression.

1467 EFFECTS OF DIETARY EXPOSURE TO GENISTEIN AND METHOXYCHLOR ON THE GENE EXPRESSION PROFILE OF THE MAMMARY GLAND IN MALE RATS.

E. J. Bartolucci and L. You. *Systems Biology, CIIT Centers for Health Research, Research Triangle Park, NC.*

Our previous study has shown that the isoflavone genistein (GE) altered the toxicological effect of the pesticide methoxychlor (MXC) on the growth pattern of mammary glands in male rats. The objective of this study was to determine the gene expression profile in the mammary glands of GE- and MXC-treated male rats. Sprague-Dawley rats were fed a soy- and alfalfa-free diet containing GE (800 ppm) and MXC (800 ppm), either alone or in combination throughout pregnancy and lactation. Dietary exposure of the offspring was continued until postnatal day 90, when the pups were killed. Total RNA was isolated from one inguinal mammary gland of each non-littermate (n = 3). Radiolabeled cDNA was generated using Clontech CDS primer labeling and hybridized to Clontech Rat 1.2 arrays (with 1, 176 gene probes). Phosphoimager-detected radio signals were background-adjusted (Atlas Image, Clontech) and analyzed for gene expression patterns (GeneSpring, Silicon Genetics). Both the GE and MXC treatments altered the gene expression profile of the mammary glands. More genes were affected (at least three-fold up- or down-regulation) in the treated groups than in the control group when data values were normalized to the 50th percentile of all the measurements and then to each gene itself. The combination of GE and MXC showed a more prominent effect than either compound alone. Some subsets of genes were only affected in the GE group, only in the MXC group, and only in the combination group (47, 47, and 172 genes, respectively), while 78 genes were affected in all treatment groups. The general pattern of the changes is in close agreement with treatment effects observed at the morphological and biochemical levels. While the toxicological significance of such changes in gene profiles is not yet clear, we expect that further analysis of the data will help guide our research on elucidation of the pathways leading to the GE- and MXC-induced mammary gland effects.

1468 THE USE OF DNA MICROARRAY TECHNOLOGY TO ANALYZE THE EFFECT OF 3, 4-DICHLOROPROPIONANILIDE (DCPA) ON HUMAN T LYMPHOCYTES.

K. M. Brundage[1], R. Schafer[1], C. A. Afshari[2] and J. B. Barnett[1]. [1]*Micro., Immuno. and Cell Bio., West Virginia University, Morgantown, WV and* [2]*Microarray Center, NIEHS, Research Triangle Park, NC.*

DCPA or propanil is the active ingredient in post-emergence herbicides such as WHAM! EZ®and is used extensively in the cultivation of rice. Previous work in our laboratory using both an *in vivo* mouse model and an *in vitro* exposure model has demonstrated that DCPA inhibits several important immune system functions including both T-independent and T-dependent antibody responses, cytokine production and natural killer (NK) cell function. Additional studies using the human T lymphoma cell line Jurkat have demonstrated that exposure to 100 µM DCPA decreased the secretion of IL-2. The decrease in IL-2 production is due in part to a decrease in the DNA binding activity of the transcription factors AP-1, NFAT and NF-kB. To understand the overall effect DCPA has on human T lymphocytes DNA microarray technology was employed. Jurkat cells were stimulated with PMA and the calcium ionophore A23187 and exposed to 100 µM propanil or ethanol (vehicle control). The experiment was designed to address three questions: 1) what are the initial or early (15 and 30 m) effects of DCPA exposure? 2) What are the downstream (2 and 8 h) effects? 3) What are the long-term (24 and 36 h) effects? Using the ToxChip created by the NIEHS Microarray Center, we analyzed the mRNA expression patterns of approximately 2000 genes. Results from two independent experiments demonstrated that 92 genes or 4.6% of the genes analyzed were affected by DCPA exposure in each experiment. Some of the effected genes included transcription factors, cell cycle control genes, kinases, transcription/translation genes and phosphatases. Consistent with our previous data, many of the genes whose mRNA expression was decreased in DCPA treated cell are known to be regulated by at least one of the three transcription factors AP-1, NFAT and NF-κB which have decreased DNA binding activity in DCPA treated cells. Supported by NIEHS ES07512

1469 MICROARRAY ANALYSIS OF GLOBAL GENE REGULATION BY TUMOR NECROSIS FACTOR ALPHA.

B. Y. Chin, K. K. Wong and B. D. Thrall. *Molecular Biosciences, Pacific Northwest National Laboratory, Richland, WA.*

Tumor necrosis factor alpha (TNF-α) is an important cytokine with pleitropic effects on cellular functions. TNF-α can mediate cellular responses either in a paracrine or autocrine manner by activating the signaling pathways involved in the expression of appropriate genes. It is well documented in the scientific literature that under certain *in vitro* conditions, TNF-α can quickly and markedly induce the expression of early response genes. In order to investigate the rapid effects of TNF-α we exposed a macrophage cell line, RAW 264.7 cells, for 1 hour to exogenous TNF-α. In two identical experiments we identified 147 cDNAs that were consistently induced > 2 fold. Many of the induced genes fell into 3 categories: cytokine and immune function (TNF-α, macrophage colony stimulating factor, small inducible cytokine A2, immunoresponsive gene 1, IL-15 receptor, CD 48 antigen, TNF α-stimulated ABC protein); cell signaling and transcriptional regulators (p38δ, zinc finger like protein 36 (*zpf36*), c-myc oncogene, toll like receptor 2, guanidine nucleotide binding protein alpha, serum-inducible kinase, fos-like antigen 2), and lipid metabolism (very long fatty acyl coA synthetase and cytochrome p450A10). Interestingly, amongst the 147 consensus genes induced by TNF-α, the most highly induced were TNF-α itself (25 fold) and *zpf36* (12 fold). *Zpf36* is a transcriptional factor known to modify the stability of TNF-α mRNA. Overall, the genes induced are consistent with a known physiological role of TNF-α in amplifying the immunomodulatory response. Currently, studies are ongoing to better understand and tease out the specific TNF-α signaling pathways involved in autocrine regulation of macrophage function.

1470 IDENTIFICATION AND CHARACTERIZATION OF GENES RESPONSIVE TO PERFLUOROOCTANE SULFONIC ACID EXPOSURE USING DIFFERENTIAL DISPLAY AND GENE CHIPS.

W. Y. Hu[1], P. D. Jones[1], J. P. Giesy[1], C. Lau[2] and R. G. Hanson[2]. *[1]National Food Safety and Toxicology, Michigan State University, East Lansing, MI and [2]USEPA, Research Triangle Park, NC.* Sponsor: R. Roth.

Differential display, first introduced by Liang and Pardee (1992), is a useful method to identify differences in gene expression at the whole genome level. Affymetrix rat genome U34A chip, containing ~8000 full-length annotated genes and EST clusters, has been proven to be a powerful tool in toxicology studies using rat as model system. Perfluorooctane sulfonic acid (PFOS) is the end metabolite of a number of perfluorinated fatty acids analogues extensively used in industrial materials and commercial applications. Few studies have been conducted on this novel compound, and its mechanism of action still remains unclear. In the current study, the restriction fragment differential display (RFDD-PCR) a modified version of the original method and Affymetrix gene chips were used to identify alterations in gene expression levels due to PFOS exposure *in vitro* and *in vivo*. H4IIE rat liver hepatoma cells were treated with solvent control, PFOS at 2ppm and 50ppm in medium for 96hrs. SD rats were oral gavaged with vehicle or PFOS at 5mg/kg/day for either 3 days or 3 weeks. RNA samples were extracted from cells and rat livers and prepared for subsequent analysis. Following the RFDD-PCR procedure, 90 bands on sequencing gel were identified as different among treatment groups. All these candidate genes were sub-cloned and sequenced. Gene chip analysis was conducted by hybridizing U34A chips with experimental samples, and analyzed using microarray suite software and data mining tools. Genes that were differentially expressed in response to PFOS exposure can be clustered as genes coding for fatty acid metabolizing enzymes, nuclear binding factors, and proteins involved in signal transduction pathways. Consistent results were obtained from replicates in gene chips, however, expression profiles *in vitro* and *in vivo* showed only limited similarity.

1471 THE HYPOXIA INDUCIBLE FACTOR, HIF1α, IS CRITICAL TO METAL INDUCED TOXICITY.

A. Vengellur[1,2] and J. J. LaPres[1,2]. *[1]Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI and [2]National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI.* Sponsor: J. Trosko.

Metal induced toxicity is one of the most important environmental health issues facing humans. Metals, such as nickel, cobalt, lead and cadmium are known or suspected carcinogens. The mechanism of action for the toxicity of these metals remains largely unknown. The process has been linked to a number of factors, including, stress proteins, reactive oxygen species, DNA methylation and others. To identify target genes for metal induced toxicity we utilized DNA microarrays representing approximately 9000 human genes. Hep3B cells were treated with nickel (100 μM), cobalt (100 μM) or hypoxia (1% O_2) for 24 hours. Hypoxia treatments lead to significant expression changes in 61 genes. These genes included known hypoxia regulated genes (e. g. vascular endothelial growth factor and adrenomedullin) and several new hypoxia regulated targets (e.g. Ras suppressor protein and the WSB-1 signaling protein). Greater then 50% of these hypoxia regulated genes were also regulated by nickel and/or cobalt. The overlap between these expression profiles suggests a common signaling system. The most likely target for this central mediator is the hypoxia inducible factors (HIFs). To test the hypothesis mouse embryonic fibroblast (MEFs) from wild type (wt) and Hif1α null (Hif1α-/-) animals were prepared. These two cell types were treated with various concentrations of cobalt and their growth properties were analyzed. In wt MEFs, cobalt exposure (100 μM $CoCl_2$) displayed significant toxicity. Growth rates were decreased by 95% when compared to the untreated controls. The Hif1a-/- MEFs, however, showed little if any toxicity at this concentration. To find the potential targets of the metal induced toxicity cDNA microarray assays were performed in parallel cultures of the wild type and null MEFs. Preliminary results suggest that a subset of genes is differentially regulated in the wt cells. These results suggest that HIF1α plays an important role in metal induced toxicity.

1472 GENECHIP MICROARRAY ANALYSIS PROVIDES INSIGHT INTO THE DISRUPTIVE EFFECTS OF 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD) ON UROGENITAL SINUS (UGS) AND PROSTATE DEVELOPMENT.

T. M. Lin, U. Simanainen and R. E. Peterson. *School of Pharmacy, Univ. of Wisconsin, Madison, WI.*

Mouse prostate development starts as projections (buds) of UGS basal epithelial cells into the surrounding mesenchyme on Gestation Day (GD) 16. *in utero* TCDD exposure blocks ontogenesis of ventral buds, reduces dorsolateral bud number, and delays anterior and dorsolateral bud formation. To investigate the mechanism by which TCDD disrupts UGS development, we examined gene expression in the UGS. Pregnant C57Bl/6J mice were given 5 μg TCDD/kg or vehicle on GD 13. On GD 16, UGSs from male fetuses were separated into ventral and dorsal mesenchyme and epithelium. Total RNA preparations were pooled to make one composite sample per tissue and treatment group. Probes were generated and hybridized onto Affymetrix Murine Genome U74A and U74Av2 arrays. Using Microarray Suite software, 195 genes were identified whose steady state mRNA levels were altered by TCDD in at least one region of the UGS. Forty-three are ESTs without known function. Forty-one genes belong to cytoskeleton and extracellular matrix families. Cell adhesion molecules involved in skin development were also altered, suggesting a major disruption of UGS epithelial development/organization. Twenty-nine altered genes (neural-specific intracellular structure, neural crest markers, and neuropeptides) are associated with neural development. TCDD-AhR target genes were also activated. Five transcription factor genes were altered, of which HNF-3 and capsulin are involved in prostate development. Only 7 altered genes belong to growth factor signaling pathways, of which only TGFβ is known to be important to prostate development. Growth factors may not be important at this early stage of UGS development, or spatial distribution may be more important than amount. Preliminary results from real time LightCycler RT-PCR support the GeneChip results. These findings enhance our understanding of TCDD disruption of fetal UGS development and suggest new research directions, e.g. neural crest cell distribution and function. (NIH Grant ES01332 and Fulbright Grant)

1473 DIFFERENTIATION BETWEEN SENSITIZERS AND IRRITANTS IN THE LOCAL LYMPH NODE ASSAY BY GLOBAL EXPRESSION PROFILING.

P. M. Collier[1], G. F. Hollis[1], T. C. Burn[1], B. D. Carl[1], W. R. Foster[1], R. M. Huber[1], C. Smith[2], C. M. Glatt[2] and G. S. Ladics[2]. *[1]DuPont Pharmaceuticals Co., Newark, DE and [2]DuPont Co., Haskell Laboratory, Newark, DE.*

The objective of this study was to use the local lymph node assay (LLNA) in conjunction with high density DNA microarrays to 1) evaluate expression profiling as a technique to discriminate between structurally diverse sensitizers and irritants; and 2) identify potential transcript biomarkers specific for each compound class. Expression profiling was performed on auricular lymph node RNA isolated from female CBA/J mice (n=8/group) dosed with either 4:1 acetone/olive oil (vehicle control) or one of four sensitizers (0.25% dinitrochlorobenzene, DNCB; 0.05% oxazolone, OX; 25% trimellitic anhydride, TMA; 1% toluene diisocyanate, TDI) or one of four irritants (25% chlorobenzene, CB; 5% phenol, PH; 20% benzoic acid, BA; 0.5%, 1%, or 2% benzalkonium chloride, BAC) according to the standard LLNA protocol. All experiments were performed using 12, 000-gene Affymetrix arrays. Two-dimensional agglomerative cluster analysis revealed a statistically significant similarity in the expression profiles of sensitizer-treated animals ($R^2 > 0.6$; $P < 0.01$). Irritant profiles clustered together in an unrelated group with no correlation to the sensitizer cluster ($R^2 < 0$). Evaluation of sensitizer-specific sig-

natures revealed a strong induction of multiple cell cycle and inflammatory response transcripts that are unaltered by irritant treatment. These clusters of potential biomarkers effectively confirm proliferation-based scoring of sensitizers in the LLNA. Expression profiling performed on higher doses of BAC that typically score positive in the LLNA revealed a similar induction of many of these same cell cycle and inflammatory-response transcripts, providing a molecular basis for high-dose irritant scoring in the LLNA. These results illustrate the utility of query-able expression profile databases for compound classification, and revealed several candidate biomarkers that may serve as sensitive endpoints for the LLNA.

1474 DNA ARRAY ANALYSIS OF GENE EXPRESSION ALTERATIONS UNDERLYING SENSITIZATION USING THE LOCAL LYMPH NODE ASSAY AS A MODEL.

C. M. Glatt, C. Smith, C. S. VanPelt and G. S. Ladics. *The DuPont Company, Newark, DE.*

The objective of this study was to identify the underlying and distinctive genetic mechanisms of dermal and respiratory sensitization using the local lymph node assay (LLNA) and DNA array technology. We have previously shown that there are temporally dependent alterations in gene expression in mouse auricular lymph nodes at days 1, 3, and 6 of dosing with a known dermal sensitizer, 1-chloro-2, 4-dinitrobenzene (DNCB). The current study was designed to 1) examine early gene expression changes following exposure to DNCB, as well as a known respiratory sensitizer, trimellitic anhydride (TMA); and 2) identify markers to discriminate between dermal and respiratory sensitization. Female CBA/J mice were dosed with either 4:1 acetone:olive oil (AOO) vehicle-control, 0.25% DNCB, or 25% TMA. Groups of vehicle-control (n=8), DNCB-treated (n=8), and TMA-treated (n=8) mice were sacrificed and auricular lymph nodes (AULS) were removed and pooled within each group 1, 4, 12, and 24 hours following a single dose of either DNCB or TMA. An additional group of naive (n=9) mice were sacrificed and AULS were removed and pooled at the 24-hour time point. Total RNA was isolated and cDNA was prepared and radiolabeled using gene-specific primers to probe a murine cDNA expression array (Atlas™ Mouse 1.2 Array; Clontech Labs, Inc.). Of the arrayed genes, DNCB-induced changes in expression levels were detected in approximately 0.8%, 0.3%, 3.4%, and 0.2%, and TMA-induced changes were detected in 1.2%, 1.1%, 3.1%, and 1.8% at 1, 4, 12, and 24 hours, respectively. Unrelated gene expression signatures between DNCB and TMA were revealed. These data demonstrate the differential and temporally dependent gene regulation that occurs following the topical application of a known dermal or respiratory sensitizer. Additionally, these data illustrate the utility of expression profile databases to distinguish dermal from respiratory sensitizers that are traditionally indistinguishable in the LLNA.

1475 cDNA MICROARRAY ANALYSIS OF GENE EXPRESSION DURING CHEMICAL INDUCED NEPHROCARCINOGENICITY IN THE EKER RAT.

S. K. Patel, T. J. Monks and S. S. Lau. *Center for Molecular and Cellular Toxicology, University of Texas at Austin, Austin, TX.*

The Eker rat, derived from the Long-Evans strain, provides an excellent model for studying renal carcinogenesis. A germ-line insertion in the tuberous sclerosis (*Tsc-2*) tumor suppressor gene, predisposes these rats to the development of spontaneous or chemical induced tumors. Hydroquinone (HQ) is a rodent carcinogen and a possible human carcinogen. 2, 3, 5-*tris*-(glutathion-*S*-yl)hydroquinone (TGHQ) has been implicated as a reactive metabolite that contributes to HQ-mediated nephrocarcinogenicity. The mechanisms of HQ-mediated renal carcinogenesis remain unknown. TGHQ-treated rats develop numerous toxic proximal tubular dysplasias that represent early transformation within tubules, and adenomas are seen to arise from these lesions. cDNA microarrays were used to examine aberrant gene expression associated with TGHQ-induced transformation in tumor tissue derived from the kidneys of Eker rats treated with TGHQ. The expression of 38 genes were altered by three-fold or greater in tumor tissue compared to normal kidney tissue. Furthermore, the levels of a number of genes, identified using cDNA microarrays, were validated by semi-quantitative RT-PCR. The differentially expressed genes are involved in cell cycle regulation (cyclin-dependent kinase 4), signal transduction (extracellular regulated kinase 2), stress response (glutathione-S-transferases), tissue remodeling (urokinase-type plasminogen activator) and energy production (cytochrome c oxidase), and likely contribute to tumor development in the Eker rat. Importantly, the annexin I gene, implicated in signal transduction, was highly induced at both the mRNA and protein levels in tumor tissue. In addition, toxic tubular dysplasias obtained by laser capture microdissection of kidneys from Eker rats treated chronically (10 months) with TGHQ also show high mRNA levels of annexin I (6-fold over control). These results suggest that annexin I gene likely plays an important role during the early stages of TGHQ-mediated nephrocarcinogenicity in the Eker rat. (GM 39338, ES 07784).

1476 NBS1 CANCER-SUSCEPTIBILITY GENE INFLUENCES GENE EXPRESSION FOLLOWING DNA DAMAGE.

R. P. Amin[1,2], C. L. Innes[2], A. N. Heinloth[2], K. G. Flores[2], S. O. Sieber[2], P. R. Bushel[1] and R. S. Paules[1,2]. *[1]NIEHS Microarray Center, NIEHS, Research Triangle Park, NC and [2]Laboratory of Environmental Carcinogenesis and Mutagenesis, NIEHS, Research Triangle Park, NC.*

The contribution of defects in cellular response to DNA damage and development of disease, particularly cancer, in patients with genetic susceptibilities is poorly understood. Nijmegen Breakage Syndrome (NBS), a chromosome instability disorder, is associated with hypersensitivity to ionizing radiation and predisposition to cancer. Nibrin, the gene product of NBS1, complexes with Rad50/MRE11 and co-localizes with BRCA1 to regions of damaged DNA, suggesting a role in normal DNA damage recognition/repair processes. We hypothesize that nibrin is important in pathways regulating cell cycle checkpoints in response to DNA damage downstream of, but complementary to, ATM-dependent signaling. We investigated cell cycle checkpoint responses and gene expression changes in mortal diploid fibroblasts in response to ionizing radiation (1.5 to 5 Gy), comparing nibrin-deficient (NBS-/-) and wild type (WT) cells. Three assays were used: (i) flow cytometric analysis of BrdU incorporation in DNA synthesis to investigate G1/S checkpoint response, (ii) fluorescence-based DAPI staining to quantitate mitotic cells, a measure of G2/M checkpoint response, and (iii) gene expression profiling, to elucidate molecular pathways involved in checkpoint responses that are defective in NBS. We observe a mitotic delay defect in NBS-/- cells following exposure to low doses of gamma irradiation, indicating a role for NBS1 in the G2/M checkpoint. In contrast, at higher doses (5 Gy), NBS-/- cells induce a G2/M checkpoint delay. This suggests an important role for nibrin in checkpoint responses and repair at low levels of DNA damage, but at higher levels the activation of compensatory pathways leads to a stronger checkpoint delay. Preliminary comparison of responses to radiation induced damage in WT and NBS-/- cells, using cDNA microarray analysis, revealed nibrin-dependent transcripitional patterns that may be correlated with defects in cell cycle checkpoints and DNA repair.

1477 APPLICATION OF TOXICOGENOMICS TO DRUG DISCOVERY AND DEVELOPMENT: EFFECT OF A KINASE INHIBITOR ON GENE EXPRESSION IN RAT NASAL TISSUE.

Z. Jayyosi, M. Wojke, M. Gallagher, J. Dwyer, M. Pino, L. Geiger and P. Rao. *Drug Safety Evaluation, Aventis Pharmaceuticals, Bridgewater, NJ.*

Kinase inhibitors are important therapeutic targets. Because of the large number of intracellular kinases, specificity of a selected kinase inhibitor is crucial for its pharmacological action as well as its potential toxicity. Within a class of kinase inhibitors, toxicity may be similar, but not likely identical. Compound X is a kinase inhibitor that was being developed for treatment of asthma. In a 5-Day oral toxicity study in rats, compound X was shown to produce nasal epithelial toxicity. The aim of this work is two fold: 1- Examine the use of toxicogenomics to evaluate alteration in gene expressions in the nasal tissue as a function of treatment with an attempt to elucidate the mechanism(s) of toxicity. 2- Determine the overall utility of toxicogenomics in drug discovery and development. Male rats were dosed with Compound X at 0, 100 and 1000 mg/kg/day for 1 or 5 days. Histopathologic evaluation confirmed target organs. Toxicogenomic analyses utilized the rat RgU34A chip(Affymetrix). Treatment-related nasal epithelial degeneration and inflammation in the transitional, respiratory and olfactory mucosa was detected in some rats in the high dose group after 1 or 5 days of treatment. Principal component analysis of individual rats showed that the affected rats were clustered separately. Specific genes involved in inflammation, cell proliferation, apoptosis and cell injury were up regulated while genes involved in neuronal transport and signaling, and drug metabolizing enzymes were down-regulated. The alteration in gene expression patterns correlated with treatment-related histopathologic changes.

1478 CHARACTERIZATION OF THE MOLECULAR MECHANISMS UNDERLYING THE HEPATOCARCINOGENESIS INDUCED BY THE NONGENOTOXIC CARCINOGENS, PEROXISOME PROLIFERATORS, IN THE RAT.

C. Michel, J. P. Marchandeau, M. Flor, D. Leroy, J. C. Gautier and E. Boitier. *Aventis Pharma, Drug Safety Evaluation, Vitry sur Seine, France.* Sponsor: M. Bonnefoi.

Peroxisome proliferators (PP), a diverse group of nongenotoxic compounds, cause cell proliferation, apoptosis suppression and peroxisome proliferation through the activation of the peroxisome proliferator-activated receptor alpha (PPAR-alpha). This cascade of events is believed to contribute to formation of liver tumors in rodents. The aim of this study is to evaluate and characterize the molecular mechanisms of the carcinogenesis induced by these compounds and to determine whether

a specific gene expression pattern could be elucidated in rat liver for the compound class of PP. Compounds included in this study were the hypolipidemic compounds Clofibrate (25 and 250 mg/kg), Fenofibrate (10 and 100 mg/kg), and WY-14643 (25 and 250 mg/kg). They were administered twice a day to Sprague-Dawley rats for up to 1 and 5 days. In addition to PP, Phenobarbital (PB, 12 and 120 mg/kg) was also tested in this study as a nongenotoxic hepatocarcinogen acting through a mechanism different from PPAR-alpha activation. Hepatic gene expression profiles were generated using Affymetrix microarrays. Gene expression fold-changes after PP or PB treatment were estimated using a powerful in-house-developed software, GECKO2. The transcriptional mapping of the liver was compared with classical toxic end-points such as histopathological evaluation. Preliminary histopathological results indicated a moderate increase in mitotic figures (evocative of an increase in cell proliferation) and mild centrolobular hypertrophy (most likely due to peroxisome proliferation) only with the high dose of WY-14643 after a 5 day-treatment. PB induced a mild hypertrophy (proliferation of endoplasmic reticulum) at the highest dose after 5 days. Initial gene expression analysis clearly revealed distinct molecular patterns between PP and PB. These data should provide mechanistic information on early marker genes whose modulation of expression would indicate the carcinogenic potential of PP.

1479 GP3: GENEPIX POST-PROCESSING SCRIPT FOR AUTOMATED ANALYSIS OF RAW TOXICOGENOMIC MICROARRAY DATA.

E. Dere, M. R. Fielden, R. G. Halgren and T. R. Zacharewski. *Department of Biochemistry & Molecular Biology; Institute for Environmental Toxicology; National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI.*

Toxicogenomic studies generate vast amounts of data that require processing prior to clustering and other analyses. We describe a script to automate the post-processing of raw microarray data captured with GenePix, a widely used commercial microarray image analysis application. The script, written in Perl, filters outlying signal intensities, performs background corrections and normalizes signal intensities between the Cy3 and Cy5 channels. Signal intensities are filtered to ensure they exceed a defined signal threshold of detection while also falling below the saturation level of the microarray scanner. After filtering, valid signals undergo local background correction prior to subsequent normalization. Systematic and experimental biases between the two fluor-labeled cDNA populations being compared in a two-color fluorescence-based cDNA microarray assay can result in inaccurate quantitation of relative differences in gene expression. To minimize this affect, signal intensities for each fluor are adjusted to normalize the gene expression distribution in log2 space. By doing so, signal intensities across the entire microarray can be expressed as a percentage thereby minimizing systematic biases in fluor incorporation and intensity characteristics and differences in RNA quality and sample handling. The script can operate in batch mode to process data in a high-throughput manner. Other features include abilities to override default parameters of the script through a command line interface. Filtered and normalized values are appended to the GenePix results file. In addition, averages and standard deviations of replicate spots are calculated and provided in a summary file. Therefore this script automates the high-throughput post-processing of raw toxicogenomic microarray data generated by GenePix and minimizes human error introduced with repetitive manual adjustments.

1480 DEVELOPMENT OF A RELATIONAL TOXICOGENOMICS DATABASE FOR THE PREDICTION OF CHEMICAL TOXICITY.

P. C. Boutros[1,2,3], L. D. Burgoon[2,3,4] and T. R. Zacharewski[1,2,3]. *[1]Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI, [2]Institute for Environmental Toxicology, Michigan State University, East Lansing, MI, [3]National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI and [4]Pharmacology and Toxicology, Michigan State University, East Lansing, MI.*

Toxicogenomic studies generate vast amounts of data that require proper storage in order to facilitate data handling and analysis. The inability to relate changes in global gene expression to specific genes, their function, and other information further complicates data analysis and interpretation. To automate these essential functions, dbZach, a database operating under the Oracle relational database management system has been built. dbZach provides a core database that handles all aspects of our multi-species toxicogenomic/microarray investigations including: 1) storage of important cDNA/EST clone information, such as sequence, 2) frequent, automated updates of gene annotation information, 3) microarray data storage, 4) physical mapping data for each microarray utilized and constructed within the Lab.. Currently, dbZach is comprised of four main subsystems: 1) the Clones Subsystem, 2) the Microarray Subsystem, 3) the Gene Function Subsystem, and 4) the Lookup Subsystem. The subsystems interrelate to find data within a dataset, and define relationships between tables. Querying dbZach for information regarding mTZ2.0, our mouse microarray, reveals the availability of 2, 288 cDNAs/ESTs representing 1, 948 unique genes. Ninety-five percent of the available cDNAs/ESTs can be assigned to a specific cluster with the average cluster represented by 1.25 clones. Less than 1% of the genes on our murine microarray, mTZ2.0, are represented by more than 3 clones. As part of our effort to develop a transcript profile database predictive of chemical toxicity, future planned developments for dbZach include compliance with MIAME standards for microarray experiments, statistical analysis functionality, and comparisons of global gene expression data stored within dbZach.

1481 UTILIZATION OF SUBTRACTIVE HYBRIDIZATION AND MACROARRAYS TO DETERMINE ALTERED GENE EXPRESSION IN PYRENE EXPOSED MUMMICHOG *(FUNDULUS HETEROCLITUS).*

J. A. Roling, N. L. Maples, L. J. Bain and W. S. Baldwin. *Biological Sciences, University of Texas at El Paso, El Paso, TX.*

Mummichogs are ideal for monitoring the sublethal effects of pollutants in estuarine environments along the east coast because of their small home range. Estuaries, due to their proximity to humans are susceptible to anthropogenic stress from numerous sources, such as polycylic aromatic hydrocarbons (PAHs), including pyrene. Therefore, mummichogs were exposed in the laboratory to several concentrations of pyrene at 0, 10, 20, 35, and 50 ppb in 7-day static renewal exposures and alterations in gene expression in liver was examined. Previous work in our laboratory has demonstrated that pyrene induces XIR retrotransposon and P450 1A RNA levels. Subtractive hybridization was performed on mRNA from the pyrene exposed mummichog to enhance the production of differentially expressed transcripts and to find novel biomarkers of PAH exposure in mummichog. The transcripts were cloned and 96-gene macroarrays were produced. Control and treated mummichog liver cDNA was then incubated onto the blots and changes in gene expression were measured. Genes demonstrating differential expression due to pyrene will be sequenced and presented at SOT.

1482 DEVELOPMENT OF MICROARRAYS AS A TOOL FOR DISCOVERING ENVIRONMENTAL EXPOSURE INDICATORS.

A. L. Miracle[1], D. L. Lattier[1], R. Flick[1], D. Versteeg[2] and G. Toth[1]. *[1]NERL, USEPA, Cincinnati, OH and [2]Proctor & Gamble, Cincinnati, OH.* Sponsor: K. Rao.

Toxicogenomics is research that can be applied to identification of differential gene expression in wildlife and predict effects of environmental stressors. We are developing a multiple stressor exposure model using fathead minnow (Pimephales promelas) cDNAs in a microarray platform. A two-pronged approach has been developed to examine specific gene expression and to identify patterns over a portion of the expressed genome through the use of subtractive libraries. In order to start synthesis of a fathead minnow specific gene chip for array analysis, homologs of specific genes were identified in P. promelas using degenerate PCR primers based on conserved homology across mammalian and non-mammalian taxa. Categories of genes include DNA repair genes, receptor and non-receptor kinase genes, transcription factors, and genes involved in apoptotic cascades such as caspases. Initially, single exposure-specific microarrays were employed using subtractive cDNA clones to identify gene patterns for single-exposure analysis. Multiple exposures can also be assessed at the microarray level to gain a better understanding of relative bioavailability of environmental stressors present in mixtures. Thus, the use of microarray technology to examine gene expression is a powerful tool in understanding the impacts of environmental exposures.

1483 NCBI-BASED ANNOTATION AND CROSS–COMPARISON OF MICROARRAY CHIP FEATURES.

W. B. Mattes[1], S. D. Pettit[2], R. D. Tyler[4], W. E. Pennie[3] and D. E. Robinson[2]. *[1]Investigative Toxicology, Pharmacia, Kalamazoo, MI, [2]Health and Environmental Sciences Institute, ILSI, Washington, DC, [3]Investigative Toxicology, Syngenta, Macclesfield, United Kingdom and [4]Safety Assessment, GlaxoSmithKline, Research Triangle Park, NC.*

Transcript profiling (TxP) uses genomic technologies such as microarrays to measure the response of hundreds to thousands of transcripts to various environmental perturbations. These studies are carried out to determine not only the response of certain genes, but also overall patterns of gene expression. A toxicological mechanism may be inferred from the response of a particular transcript, or from the pro-

file of the responses for hundreds of genes. However, comparison of data from different laboratories is complicated not only by the nature of the different microarray technologies used, but also by the inconsistent annotation used by different platforms to describe the sequences queried. As a tool for the multi-laboratory genomics research program coordinated by the ILSI Health and Environmental Sciences Institute, we developed a system using custom Perl programs and data from the NCBI (National Center for Biotechnology Information). The accession number for a sequence queried by a microarray element is used to obtain cross-referenced information from UniGene (a system for grouping GenBank sequences into gene-oriented clusters) and/or LocusLink (curated descriptive information about genes). The UniGene and LocusLink ID s provide a means to determine if sequence elements on the same or different platforms monitor the same gene, and provide a source of consistent annotation. Thus, of the 20, 151 "genes" on the Affymetrix U34 Rat Genome GeneChip®, 1806 are shared in common with the 5902 "genes" on the Incyte RatGem 3 microarray. Likewise, the U34 GeneChip has 232 "genes' in common with Phase-1 Toxicology's 250 "gene" microarray. While cross-referencing elements based on accession number alone is not precise, this system does provide a rapid method for determining some similarities and a means for updating annotation on a regular basis.

1485 STUDIES ON THE MECHANISM OF ACTIVATION OF 7H-BENZO[c]FLUORENE.

B. Parimo[1], E. H. Weyand[1], I. G. Goldstein[2], J. Q. Wang[3] and R. G. Harvey[3]. *[1]Pharmaceutical Chemistry, Rutgers University, Piscataway, NJ, [2]Environment Sector, Electric Power Research Institute, Palo Alto, CA and [3]Ben May Institute for Cancer Research, University of Chicago, Chicago, IL.*

BENZO(C)FLUORENE (B[c]F) induces lung tumors in A/J mice when administered by ip injection or in the diet. B[c]F is responsible for a major DNA adduct in lung of mice exposed to a variety of coal tar materials. This study evaluates the DNA adducting properties of B[c]F metabolites in order to better understand the mechanism by which B[c]F induces lung tumors. B[c]F, 7-hydroxy B[c]F, 3-hydroxy B[c]F, or 3, 4-dihydrodiol B[c]F were synthesized and evaluated for their ability to form DNA adducts in skin and lung of mice following topical administration. B[c]F or a metabolite was applied to the shaved backs of female CD1 mice at 1.0 and 4.0 umol dose levels. Skin and lung tissue were collected 24 hr after dosing and DNA was evaluated using 32P-postlabeling analysis. DNA adduct formation was detected in skin and lung of mice treated with B[c]F. These DNA adduct maps were similar to those observed in lung when B[c]F is administered to mice in the diet. The 3, 4-dihydrodiol metabolite of B[c]F formed adducts that were similar to the pattern observed with B[c]F. The total level of lung DNA adducts observed with the 3, 4-dihydrodiol metabolite was considerably greater then that observed with B[c]F. These results suggest that B[c]F metabolic activation likely involves the formation of the 3, 4-dihydrodiol metabolite, which could be further converted to a dihydrodiol epoxide metabolite. These results are consistent with the known activation pathway of other more extensively study carcinogenic polycyclic aromatic hydrocarbons. (This research was supported by funds from EPRI.)

1486 ^{32}P-POSTLABELING OF PHOTOCHEMICALLY BOUND DNA ADDUCTS.

A. M. Jeffrey[1], J. D. Duan[1], D. Seide[2], H. G. Enzmann[2], E. von Keutz[2] and G. M. Williams[1]. *[1]Dept. Pathology, New York Medical College, Valhalla, NY and [2]Institute of Toxicology, Bayer AG, Wuppertal, Germany.*

Many compounds can be photoactivated to genotoxic products. We have investigated three photoactive compounds by ^{32}P-postlabeling for DNA adducts: BAY y3118, an experimental fluoroquinolone antibiotic, chlorpromazine (CPZ) an antiemetic and antipsychotic and 4, 5', 8-trimethylpsoralen (TMP) a compound related to 8-methoxypsoralen used in the PUVA treatment of psoriasis. BAY y3118 has not been investigated for DNA adduct formation, although it is photochemically mutagenic (*Arch. Toxicol.*, **74**, 555, 2000), while CPZ is known to form DNA adducts *in vitro* (*Chem. Biol. Interact.*, **51**, 273, 1984) and TMP has been previously demonstrated by ^{32}P-postlabeling to form adducts in HeLa cells (*Carcinogenesis*, **15**, 89, 1994) in the presence of UV light. All three compounds were photoactivated by 345 nm UVA light in the presence of calf thymus DNA and the DNA purified by ethanol precipitation. Photoactivation of BAY y3118 yielded DNA that exhibited substantial fluorescence (Ex 350 nm, Em 450 nm). Such modification did not occur when BAY y3118 was irradiated prior to mixing with the DNA suggesting the formation of a short lived species during the photochemical reaction. Using ^{14}C-BAY y3118, photoactivation resulted in radioactivity bound to DNA corresponding to about 70 adducts in 10^6 normal nucleotides. Oxygen was not required since, under anaerobic conditions, the fluorescence associated with the purified DNA was even higher. Postlabeling of these DNA samples either directly, using nuclease P_1 or column (Water Oasis HLB) enrichment of the samples showed DNA adducts were formed with CPZ but not with the other two chemicals. TMP, however, was positive by the specific approach developed for it which involves digestion to di-2'-deoxyribonucleoside monophosphates (*Carcinogenesis*, **15**, 89, 1994), but even using these conditions, BAY y3118 was negative. Thus, although successful with CPZ and TMP, we have not detected DNA adducts by ^{32}P-postlabeling with BAY y3118. (Supported by NCI Grant RO1-CA86056)

1487 APURINIC/APYRIMIDINIC (AP) SITES, INTERMEDIATES IN BASE EXCISION REPAIR, ARE NOT INCREASED BY ETHYLENE OXIDE INHALATION IN RATS.

S. Asakura, J. Nakamura and L. A. Swenberg. *Environmental Sciences and Engineering, UNC-Chapel Hill, Chapel Hill, NC.*

Ethylene oxide (EO) is an important industrial chemical and gaseous sterilant that is mutagenic and carcinogenic in rodents. N7-(2-hydroxyethyl) guanine (HEG) represents 90% of the DNA adducts induced by EO. While not promutagenic itself, HEG could cause mutations through the formation of apurinic (AP) sites, which are promutagenic lesions. We developed a sensitive assay to detect AP sites in genomic DNA, which can quantitate <1 AP site/10^6 nucleotides. A newly established AP site cleavage assay can further characterize three kinds of AP sites (3'-nicked, 5'-nicked and intact). The present study was conducted to quantitate the number of AP sites in brain, liver, lung and spleen in male rats exposed by inhalation to 0 and 100 ppm EO (a concentration with positive results in HPRT mutation and 2-year carcinogenicity studies) for up to 4 weeks. Furthermore, the AP sites in spleen, a target organ for mutation and carcinogenicity studies, were characterized using the cleavage assay in male rats exposed to a single 6 hour or 4 weeks of exposure. The number of AP sites in each organ of control and EO exposed rats were shown in Table 1. No significant differences in the number of AP sites were observed between 0 and 100 ppm EO. AP site analysis of spleen using the cleavage assay showed that the majority of AP sites were 3'-nicked AP sites in both control and EO exposed rats. No significant differences were observed between control and exposed rats. These data suggest that AP sites induced following EO are efficiently repaired and that AP sites are not likely to be the primary mechanism for mutations and carcinogenesis induced by EO. Table 1 Number of AP sites (per 10^6 nucleotides, n=8, mean ± S.D.) in DNA of rats exposed by inhalation to 0 and 100ppm EO.

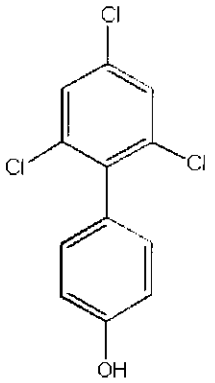
Groups	Brain	Liver	Lung	Spleen
Control (0 ppm)	6.3±1.85	6.1±0.71	9.6±1.41	7.7±1.95
EO exposed (100 ppm)	7.6±3.39	6.5±1.08	7.5±1.42	8.6±1.44

1488 ESTROGENIC PHENOL AND CATECHOL METABOLITES OF PCBs DOWN REGULATE CATECHOL-O-METHYLTRANSFERASE.

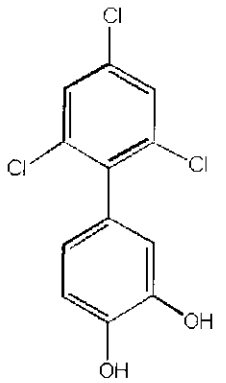
C. E. Garner[2,1], F. Zhe-hui[3], D. Ramsden[4], H. B. Matthews[2], L. T. Burka[2] and S. L. Ho[3]. *[1]DSE&M, Schering-Plough Research Institute, Lafayette, NJ, [2]Lab. of Pharmacology and Chemistry, NIEHS, Research Triangle Park, NC, [3]Div. of Neurology, University of Hong Kong, Hong Kong, Hong Kong and [4]Dept. of Medicine, University of Birmingham, Birmingham, United Kingdom.*

PCB mixtures induce liver tumors in female rats and this effect may be due altered estrogen metabolism. This laboratory has demonstrated that metabolites of PCBs are potent inhibitors of COMT and may contribute to reduced clearance of genotoxic catechol estrogens (CEs). Liver S9 of female SD rats treated with carcinogenic doses of Aroclor 1254 for 21 days (10 mg/kg/day) showed ca. 40% reduction of COMT activity towards CEs. We hypothesize that estrogenic PCB metabolites may contribute to reduced COMT activities *via* the estrogen receptor, which has been demonstrated to regulate COMT. The xenoestrogens, 2, 4, 6-trichloro-4-biphenylol and 2, 4, 6-trichloro-3', 4'-biphenyldiol were incubated in human MCF-7 cells expressing the ER and COMT for 48 hours and expression of COMT determined. Western blot analysis showed that COMT protein levels were reduced in a concentration dependent manner by both metabolites. Additionally RT-PCR analysis showed a concentration dependent reduction of COMT RNA, suggesting that the PCB metabolites reduced COMT expression at the transcriptional level. The above suggests that COMT levels may be reduced *via* interaction between PCB metabolites and the ER. The above information, coupled with our prior work, supports the hypothesis that PCB metabolites may contribute to PCB-mediated

carcinogenesis through reduced clearance of endogenous and xenobiotic catechols by reducing both catechol O-methyl transferase levels and activities.



2,4,6-trichloro-4-biphenylol



2,4,6-trichloro-3',4'-biphenyldiol

1489 FUNCTIONAL CHARACTERIZATION OF N-ACETYLTRANSFERASE 1 (NAT1) AND 2 (NAT2) IN MAMMARY PRIMARY CELL CULTURES FROM RAPID AND SLOW ACETYLATOR SYRIAN HAMSTER CONGENIC AT NAT2.

G. H. Xiao, E A. Jefferson and D. W. Hein. *Pharmacology and Toxicology, University of Louisville, Louisville, KY.*

Aromatic and heterocyclic amine carcinogens present in the diet and in cigarette smoke induce breast tumors in rodents. N-acetyltransferase-1 (NAT1) and N-acetyltransferase-2 (NAT2) are important in the metabolism of these carcinogens. Human epidemiological studies suggest that genetic polymorphisms in NAT1 and/or NAT2 predispose to breast cancer in women exposed to these carcinogens. We hypothesized that NAT1- and NAT2-catalyzed activation and/or deactivation of these carcinogens within the breast may effect breast cancer risk. Our laboratory constructed a rapid and slow acetylator Syrian hamster model congenic at the NAT2 locus that we used to investigate NAT1 and NAT2 expression in mammary primary cell cultures. p-Aminobenzoic acid (PABA), and 4-aminobiphenyl N-acetyltransferase and N-hydroxy-2-amino-1-methyl-6-phenylimidazo[4, 5-b] pyridine O-acetyltransferase activities were significantly ($p<0.05$) higher in mammary cell cultures from rapid than from slow acetylator hamsters. Sulfamethazine (an NAT1-selective substrate) N-acetyltransferase activity was low and did not differ between rapid and slow acetylators. NAT1 and NAT2-specific mRNA were quantitated by real-time polymerase chain reaction. Levels of NAT1 and NAT2 mRNA were similar, but NAT2 mRNA was higher in rapid than in slow acetylators. Hamster mammary cells cultured in the medium supplemented with PABA for 24h showed a significant decrease (50-70%) in NAT2 activity. The loss of activity was concentration-dependent (EC50 4 *micro*M) and selective because PABA treatment showed no effect on NAT1 activity. The loss of NAT2 activity was associated with reduction in the amount of NAT2 but not NAT1 mRNA. These studies clearly show NAT1- and NAT2 -catalyzed acetylation of aromatic and heterocyclic amine carcinogens in mammary cell cultures modified by substrate regulation of NAT2 expression. Partially supported by USPHS grant CA-34627 from the National Cancer Institute.

1490 N-ACETYLTRANSFERASE 2 PHENOTYPE IN PAINTERS WITH UROTHELIAL BLADDER CANCER AND NON-DISEASED COLLEAGUES.

K. Golka, W. Weistenhöfer, P. Jedrusik, F. Geller, M. Blaszkewicz and H. M. Bolt. *Institute of Occupationally Physiology at the University of Dortmund, Dortmund, Germany.*

Aim: This study was designed to evaluate the impact of N-acetyltransferase 2 (NAT2, substrate: aromatic amines) on bladder cancer in painters. Background: Until the beginning of the 60s, painters in Germany have used, among others, azo dyes based on carcinogenic aromatic amines. Materials and Methods: Sixteen painters, from different areas in Germany suffering from transitional cell carcinoma of the bladder, and 26 healthy painters from the same areas and at the same age (± 5 years) as controls, were investigated. All painters were phenotyped for NAT2 by the molar ratio of two caffeine metabolites in urine, determined by a HPLC method. All painters were asked for the period of work as a painter and for their life-time smoking habits. Results: Exposure against paints (colorants) started in 1950 in cases (SD 9.3) and controls (SD 9.6). Fourteen cases and 23 controls had been exposed to paints before 1960. Age at first exposure against paints was 15.5 years (SD 5.3) in cases and 16.3 years (SD 4.9)in controls. Cases had worked 31.1 years (SD 15.0), and controls had worked 44.8 years (SD 7.2) as a painter. Four cases and 7 controls were non-smokers. In the present study, 88% of 16 diseased painters and 65% of 26 non-diseased painters were of the "slow" acetylation phenotype. Conclusions: The results suggest that the "slow" acetylation status is an individual risk factor for bladder cancer in persons occupationally exposed to amounts of carcinogenic aromatic amines released from water-soluble azo dyes.

1490A N-ACETYLTRANSFERASE-1 AND -2 GENOTYPES AND PROSTATE CANCER.

D. W. Hein[1], M. A. Leff[1], N. Ishibe[2], R. Sinha[3], J. Berlot[4], J. Frame[4], H. A. Frazier[4], M. A. Doll[1], M. C. Weinrich[5] and N. E. Caporaso[2]. *[1]Pharmacology and Toxicology, University of Louisville, Louisville, KY, [2]Genetic Epidemiology Branch, NCI, Bethesda, MD, [3]Nutritional Epidemiology Branch, NCI, Bethesda, MD, [4]National Navy Medical Center, Bethesda, MD and [5]Medicine, University of Louisville School of Medicine, Louisville, KY.*

N-acetyltransferase-1 (NAT1) and N-acetyltransferase-2 (NAT2) are important in the bioactivation and deactivation of aromatic and heterocyclic amine carcinogens that induce prostate tumors in the rat. We investigated the association of genetic polymorphisms in *NAT1* and *NAT2*, alone and in combination, with human prostate cancer. Incident prostate cancer cases and controls in a hospital-based case-control study were frequency-matched for age, race, and referral pattern. Slow acetylator *NAT2* genotype exhibited borderline association with prostate cancer (OR, 1.75; 95% CI, 0.86-3.54), but the association was greater for individuals homozygous for *NAT2* alleles (*NAT2*5*) with lowest NAT2 catalytic activity (OR, 2.43; 95%CI, 0.96-6.12; P = 0.08). In contrast, individuals possessing the putative rapid acetylator *NAT1* genotype (one or more *NAT1*10* allele) were over-represented in prostate cancer (OR, 2.17; 95% CI, 1.08-4.33; P= 0.03). Combinations of *NAT1*10* with *NAT2* slow genotypes (OR, 5.08; 95% CI, 1.56-16.5; P= 0.008) or with *NAT2* very slow acetylator (homozgyous *NAT2*5*) genotype (OR, 7.50; 95% CI, 1.55-15.4; P = 0.016) further increased prostate cancer risk. The results of this pilot study suggest increased susceptibility to prostate cancer in combinations of *NAT1*10* and the slowest *NAT2* genotypes, but needs to be investigated further in larger cohorts and in other ethnic populations. Partially supported by USPHS grant CA34627 from the National Cancer Institute.

1491 THE PRESENCE OF DIMETHYLARSINOUS ACID (DMA^{III}) IN THE URINE OF RATS TREATED WITH DIMETHYLARSINIC ACID (DMA).

S. M. Cohen[1], L. L. Arnold[1], M. Cano[1], X. Lu[2] and X. C. Le[2]. *[1]Univ. of Nebraska Med. Ctr., Omaha, NE and [2]Univ. of Alberta, Edmonton, AB, Canada.*

DMA is carcinogenic to the rat urinary bladder when administered in the diet or drinking water. At a dietary dose of 100 ppm, it produces cytotoxicity within six hours and increased proliferation (hyperplasia) by seven days of administration. 2, 3-Dimercaptopropane-1-sulfonic acid (DMPS) reacts with trivalent forms of arsenic and has been used in the treatment of arsenic poisoning. When DMPS is co-administered with DMA the cytotoxicity and regenerative hyperplasia of the urothelium are inhibited. Analyses of arsenicals in 24-hr urine specimens showed high concentrations of DMA and trimethylarsine oxide (TMAO) in the DMA-treated group. DMA levels increased and TMAO levels decreased in the group co-administered DMA and DMPS. The presence of TMAO suggests the formation of the intermediate trivalent metabolite, DMA^{III} since DMA must be in the trivalent state prior to methylation to TMAO. We hypothesize that formation of the reactive intermediate, DMA^{III}, is involved in the induction of the urothelial cytotoxicity found in DMA-treated rats. To evaluate this possibility, groups of 10 female 5-week old Fischer F344 rats were fed either DMA, DMA plus DMPS, or the control diet. Fresh void urines were collected from the rats approximately 24 hr after treatment began and again during week 10 of the study. DMA^{III} was found in the urine of DMA and DMA plus DMPS-treated rats at approximately micromolar concentrations (24 hr:DMA-1.4±0.3; DMA+DMPS-0.9±0.2; wk 10:DMA-5.0±1.2; DMA+DMPS-3.0±0.2). Using rat (MYP3) and human (1T1) cells, we further evaluated the cytotoxicity of various forms of arsenic. Sodium arsenite, monomethylarsonous acid (MMA^{III}) and DMA^{III} were cytotoxic at 0.4-5 μM concentrations, whereas MMA, DMA, and TMAO were cytotoxic at millimolar concentrations. Since the urinary DMA^{III} from the rats fed 100 ppm DMA is present at micromolar concentrations, these results suggest that DMA^{III} produced *in vivo* may be responsible for the toxic effects in the rat urinary bladder after dietary administration of DMA.

1492 PREDICTION OF THE CARCINOGENESIS OF FUMONISIN B_1 IN MALE AND FEMALE F344/N/NCTR RATS FROM URINARY AND TISSUE SPHINGOLIPID CHANGES.

P. C. Howard[1], L. H. Couch[1], K. A. Voss[2], R. J. Lorentzen[3] and T. J. Bucci[4]. *[1]Biochemical Toxicology, NCTR, USFDA, Jefferson, AR, [2]Agriculture Research Service, USDA, Athens, GA, [3]CFSAN, USFDA, Washington, DC and [4]Pathology Associates International, Charles River Company, Jefferson, AR.*

Fumonisin B_1 (FB1) is a mycotoxin that has been detected world-wide as a result of growth of *Fusarium* species in corn. FB1 was carcinogenic in a two-year feeding study inducing renal tubule tumors in male F344/N/NCTR rats at 50 and 150 ppm, but was not carcinogenic at the highest dose (100 ppm) in females. FB1 inhibits *de novo* sphingolipid synthesis through inhibition of ceramide synthase, resulting in increased tissue levels of sphinganine (Sa). This increase has been used as a biomarker of exposure. Urinary sphingoid bases were determined in the feeding study after 6, 10, 14, and 26 weeks, and tissue levels of sphingoid bases were determined at the interim sacrifices and in some cases at 2-years. Urinary Sa was increased in the males at 15, 50, and 150 ppm, and in the females at 50 and 100 ppm. Urine Sa/sphingosine (Sa/So) ratios were likewise consistently increased in the males at 15, 50, and 150 ppm, and in the females at 50 and 100 ppm. Kidney Sa and Sa/So were elevated in the males at 15, 50, and 150 ppm, and in the females consistently only at 50 and 100 ppm. Liver Sa/So ratios were only elevated at the interim sacrifices in the female rats at 100 ppm. These results demonstrate that induction of tumors in the kidney but not in the liver of male rats correlates with Sa and Sa/So ratios in these tissues. These results also show a correlation between the renal tubule carcinogenicity of FB1 and the extent of accumulation of Sa in the male rat urine and kidney; however, since Sa levels were also increased in the female urine and kidneys in the absence of carcinogenicity, the Sa biomarker may not be predictive of tumorigenic outcome in the kidney.

1493 THE EFFECT OF ETHANOL IN THE PROLIFERATION OF BOTH ESTROGEN SENSITIVE LEYDIG CELLS AND ESTROGEN RECEPTOR POSITIVE MCF-7 CELLS.

J. W. DuMond, A. Sharga and D. Roy. *EHS, UAB, Marbury, AL.*

Excess alcohol consumption has been identified as a risk factor for breast and other hormonal cancers. Now alcohol is considered as a co-carcinogen. The mechanism for increased of hormonal cancers is not known. Recently it has been reported that ethanol induces proliferation of MCF-7 cells and increases estrogen receptor expression. While the mechanism for these effects are not known, they seem to support epidemiological evidence that link alcohol consumption with an increased risk of breast cancer. In this study we have examined the influence of low and high concentrations of ethanol on testicular Leydig cells and MCF-7 cells. We examined the effect of ten different concentrations of ethanol on the proliferation of TM3 Leydig and MCF7 cells. We report for the first time that exposure of cells to a low dose of ethanol (1 ml/ml) produce significant increase in cell growth, and the doses of ethanol greater then 5 ml/ml produced inhibition of cell growth. Exposure of Leydig cells to ethanol in combination with tamoxifen failed to significantly lower the ethanol-mediated proliferation. It appears that alcohol may be playing a role in hormonal carcinogenesis presumably through influencing signaling pathways involved in the regulation of cell cycle.

1494 INHIBITION OF ESTROGEN RECEPTOR NEGATIVE BREAST CANCER CELL GROWTH BY SELECTIVE ARYL HYDROCARBON RECEPTOR MODULATORS.

L. Kotha, A. McDougal and S. H. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Aryl hydrocarbon receptor (AhR) agonists induce inhibitory AhR-estrogen receptor α (ERα) crosstalk in breast cancer which is accompanied by inhibition of cell cycle progression *in vitro* and tumor growth in rodent models. Growth of ER-negative MDA-MB-468 breast cancer cells is also inhibited by AhR agonists and in Balb/c athymic nude mice bearing MDA-MB-468 cell xenografts, the selective AhR modulators (SAhRMs) 6-methyl-1, 3, 8-trichlorodibenzofuran (MCDF) and diindolylmethane (DIM) inhibited mammary tumor growth. We have further investigated the Ah-responsiveness of several other ER-negative breast cancer cell lines and the growth inhibitory effects of MCDF, DIM and related SAhRMs. Cell lines were initially screened for induction of CYP1A1-dependent ethoxyresorufin *O*-deethylase (EROD) activity after treatment with 10 nM TCDD for 24 hr. The results showed that EROD activity was significant induced by TCDD in HCC-38, MDA-MB-453, MDA-MB-157, and MDA-MB-435 cells, whereas no induction was observed in BT-20 cells. In parallel studies, the effects of TCDD, MCDF and DIM on proliferation of the four ER-negative breast cancer cell lines were also investigated. TCDD and the SAhRMs inhibited growth of the four ER-negative breast cancer cell lines. For example, the IC_{50} values for inhibition of MDA-MB-157 cell growth using 2.5% serum were ≤ 1 nM TCDD, 100-1000 nM DIM and 10-100 nM MCDF. The IC_{50} values for these compounds varied among the cell lines and was also dependent on percent serum used. Current studies are focused on the AhR-mediated mechanisms of cell growth inhibition. (Supported by NIH CA64081, ES04176 and ES09106)

1495 EFFECT OF CHRONIC HEXACHLOROBENZENE (HCB) EXPOSURE ON TELOMERASE ACTIVITY IN HUMAN MAMMARY EPITHELIAL CELLS.

R. Audet, M. A. Poirier, G. Lassonde and M. Charbonneau. *Human Health Research Center, INRS-Institut Armand-Frappier, Université du Québec, Montreal, PQ, Canada.*

HCB is a widespread environmental contaminant virtually present in 100% of North American women. Epidemiological studies suggested that a higher HCB level could be a risk factor for breast cancer. HCB has been shown to increase the phosphorylation of the EGF receptor family, such as *neu*, in human mammary epithelial cells. Such epigenetic alterations can promote the appearance of cells with a procarcinogenic phenotype. Normally absent in somatic cells, telomerase is induced in most tumour cells enabling them to divide indefinitely and become immortal. In order to evaluate the potential of HCB to cause epigenetic changes akin to a procarcinogenic phenotype, cultures of a non-tumorigenic human mammary epithelial cell line, MCF10-A, were chronically exposed to 20 µM HCB (0.1% in DMSO) or to DMSO alone. Cells were grown in DMEM supplemented medium with 20 ng/ml EGF, 10 mg/ml insulin, 5% horse serum, and telomerase activity was measured using the telomeric repeat amplification protocol at specific passages. Cell proliferation was assessed throughout the experiment by calculating the population doubling time. Following approximately 25 passages of continuous exposure to HCB, a marked increase in telomerase activity was observed; these cells were proliferating at a 2-fold higher rate. When these cultures were subsequently maintained with DMSO alone, telomerase activity remained higher than in the continuously DMSO-treated cells; the increased cell proliferation also remained higher. The latter observations imply that HCB-induced epigenetic changes are long lasting. Increased telomerase activity is a very widespread phenotype of tumorigenic cells. Overall, results show that a major mechanism enabling mammary epithelial cells to become immortal is activated by continuous HCB exposure. This work supports the contention that environmental contaminants can be a risk factor in breast cancer development.(Supported by the Toxic Substances Research Initiative and the Pgrm of Research in Environment Etiology of Cancer).

1496 EFFECTS OF ORGANOCHLORINES ON c-erbB-2 (*neu*) SIGNALING PATHWAY IN HUMAN MAMMARY EPITHELIAL CELLS.

S. Girard, M. A. Poirier and M. Charbonneau. *Human Health Research Center, INRS-Institut Armand-Frappier, Université du Québec, Montreal, PQ, Canada.*

Environmental factors such as chemical exposure to contaminants, dietary habits and lifestyle could have an important role in breast cancer development (BCD). Organochlorines are lipophilic contaminants distributed in breast tissue, however their role in BCD is debated. *Neu* is an oncoprotein belonging to the epidermal growth factor receptor (EGFR) family which correlates with poor prognosis for breast cancer patients. In human mammary epithelial cells organochlorines could perturb receptor signaling pathways, such as that linked to the *neu* receptor overexpressed in several breast cancers. This research aims to assess the *in vitro* effect of an environmental mixture (Mix), made of 3 PCBs, 7 polychlorinated dibenzofurans (PCDFs) and 6 polychlorinated dibenzodioxins (PCDDs) found in human breast milk, on constitutive and phosphorylated *neu* levels in a non tumorigenic human mammary epithelial cell line (MCF-10A). Cells, grown in DMEM medium supplemented with 20 ng/ml EGF, 10 µg/ml insulin, 5% horse serum, were exposed to the Mix for 10 and 30 min, then were collected with lyzing buffer for Western Blot analyses; expression (erbB-2/HER-2 antibody) and activation (phospho-erbB-2/HER-2 antibody) of *neu* were measured. Data were expressed as the ratio between phospho-*neu* over *neu* using actin levels for normalization. Mix caused a 2- to 4-fold increase of the phospho-*neu*/*neu* ratio at both time points. In another series of experiments, a long term treatment (more than 25 passages) with hexachlorobenzene (HCB), an important environmental contaminant, also caused a 2-fold increase in the ratio. Overall, these observations show that environmental contaminants cause an overactivation of a key tyrosine kinase receptor frequently overexpressed in breast cancer tissue. Downstream events may involve overactivation of proteins, such as Akt and ILK. This work brings biological plausibility to the involvement of environmental contaminants in BCD. (Supported by the Toxic Substances Research Initiative, Health Canada)

1497 EFFECT OF 2, 2', 4, 4', 5, 5'-HEXACHLOROBIPHENYL (PCB-153) ON HEPATOCYTE PROLIFERATION IN MICE DEFICIENT IN THE P50 SUBUNIT OF NF-κB.

Z. Lu, E. Y. Lee, L. W. Robertson, B. T. Spear and H. P. Glauert. *Graduate Center for Nutritional Sciences, University of Kentucky, Lexington, KY.*

Polychlorinated biphenyls (PCBs) are a group of synthetic chemicals that induce and promote liver tumors in rodents. Our previous studies showed activation of the hepatic transcription factor NF-κB in rats treated with PCBs and an increase in hepatocyte proliferation that is correlated with the NF-κB activation. In this study, the effect of NF-κB activation on hepatocyte proliferation after PCB administration was analyzed in male B6129 mice and mice deficient in the p50 subunit of NF-κB. In a 2-day study, mice received a single i.p. injection of corn oil or PCB-153 (300 μmol/kg) and were euthanized after 48 hours. In a 21-day study, mice received six i.p. injections of corn oil or PCB-153 (100 μmol/kg) and were euthanized 4 days after last injection. Nuclear NF-κB DNA binding activity, measured by electrophoretic mobility shift assay, was present in control wild type mice and increased with PCB-153 in the 2-day study. NF-κB DNA binding activity was less in the p50-/- mice and did not increase with PCB-153. Hepatocyte proliferation was measured in these mice by the 5-bromo-2'-deoxyuridine (BrdU) labeling index. Control wild type mice had the same level of cell proliferation as the control p50-/- mice. Cell proliferation increased in the wild type mice treated with PCB-153 in both studies. PCB-153 did not change the cell proliferation in the p50-/- mice in the 2-day study, but the p50-/- mice had a slight increase in cell proliferation after 21 days. These data indicate that NF-κB is involved in the proliferative changes in response to PCB-153. (Supported by P42 ES 07380)

1498 EFFECTS OF VITAMIN E ON NF-κB DOWNSTREAM EVENTS IN P50-/- MICE TREATED WITH THE PEROXISOME PROLIFERATOR, CIPROFIBRATE.

K. G. Calfee-Mason, E. Y. Lee, H. P. Glauert and B. T. Spear. *Nutritional Sciences, University of Kentucky, Lexington, KY.*

Peroxisome proliferators (PPs) are a diverse class of chemicals, including some hypolipidemic drugs and plasticizers, which cause a dramatic increase in the size and number of hepatic peroxisomes in rodents and eventually lead to hepatic tumors. The pathway to tumorigenesis by PPs has not been delineated, but oxidative stress is believed to alter signal transduction pathways thereby leading to cell growth disturbances. Nuclear factor-κB (NF-κB) is a transcription factor activated by reactive oxygen and is involved in cell proliferation and apoptosis. We previously found that the peroxisome proliferator ciprofibrate (CIP) activates NF-κB and that dietary vitamin E is effective in decreasing CIP-induced NF-κB DNA binding. We hypothesized that increased dietary vitamin E reduces CIP-induced oxidative stress and cell proliferation by reducing the activation of NF-κB in mice. Sixteen B6129 female mice and twenty homozygous NF-κB1 deficient mice (p50-/-) were fed a purified diet containing 10 or 250 ppm vitamin E (α-tocopherol acetate) for 28 days. At that time, half of the wild-type and half of the p50-/- mice were placed on the same diet with 0.01% CIP for 10 days. Nuclear extracts were prepared from the livers and the NF-κB DNA binding activity was determined using electrophoretic mobility shift assays. Hepatocyte proliferation was determined immunohistochemically by measuring the 5-bromo-2'-deoxyuridine (BrdU) labeling index. In the wild-type mice, CIP-treatment increased the p65:p50 NF-κB activity and increased cell proliferation, yet neither endpoint was significantly altered by dietary vitamin E levels. In contrast, the p50-/- mice had lower NF-κB activation and higher basal levels of cell proliferation and lower GSH/GSSG. The p50-/- mice fed higher dietary vitamin E and treated with CIP had 60% lower cell proliferation in comparison to the group fed low vitamin E. Thus, the effects of vitamin E on cell growth parameters are not solely through decreased NF-κB activation.

1499 EFFECT OF KUPFFER CELL ACTIVATION ON LIVER FOCAL LESION GROWTH.

P. J. Klein, L. M. Kamendulis and J. E. Klaunig. *Pharmacology and Toxicology, Indiana University, Indianapolis, IN.*

The induction of hepatocellular neoplasia in rodents is a multistep process involving a series of cellular modifications. While most studies have focused on the hepatocyte as the target cell, recently a role for other liver cell types, specifically the Kupffer cell, have been suggested to participate in the carcinogenesis process. The purpose of the present study was to investigate the effect of Kupffer cell activation on preneoplastic focal lesion growth in liver. Hepatocellular foci were induced in F344 male rats using diethylnitrosamine. Following focal lesion formation, selected rats were treated with bacterial lipopolysaccharide (0.25 mg/kg I.P. weekly). Rats were sampled after 7 and 28 days of treatment, and livers were examined for DNA synthesis, apoptosis, and mitosis in normal and focal liver lesions. In addition, the relative area and number of hepatic focal lesions was quantified using stereologic methods in H and E and glutathione S-transferase (GST-P) stained histologic sections. Lipopolysaccharide treatment caused a significant increase in GST-P positively stained foci area as compared to control. In addition, a 2-fold increase in relative focal lesion volume (GST-P and H and E) were seen in lipopolysaccharide treated rat liver compared to control. This increase appeared to be mainly localized to eosinophillic foci. While lipopolysaccharide produced an increase in focal lesion size no increase in the number of focal lesions was seen. Lipopolysaccharide treatment also produced an increase in DNA synthesis in both normal liver and focal lesions, although the increase was markedly greater in focal hepatocytes. From these results, it appears that Kupffer cell activation by lipopolysaccharide functions at the promotion stage of the multistage carcinogenesis process.

1500 MECHANISMS OF BUTOXYETHANOL CARCINOGENESIS IN THE RAT AND MOUSE.

A. M. Siesky, L. M. Kamendulis, Y. Xu and J. E. Klaunig. *Pharmacology and Toxicology, Indiana University, Indianapolis, IN.*

Butoxyethanol induces an increase in liver tumors (hemangiosarcomas) following chronic treatment in the mouse but not in the rat. Concomitant with tumor development is the induction of hemolysis and an increase in hemosiderin deposition in the liver. Previous studies by our group have shown an increase in oxidative damage in mouse liver following butoxyethanol treatment. These observations have led to our proposal that butoxyethanol induces tumors indirectly through activation of Kupffer cells (*via* iron loading) that in turn produces reactive oxygen species as well as the release of cytokines resulting in induction of cell proliferation in the target cells. The present studies examined whether butoxyethanol induced oxidative stress and altered cell growth in the susceptible species (B6C3F1 mouse) and in the nonsuceptible species (F344 rat) following treatment with 0, 225, 450 and 900 mg/kg butoxyethanol for 7, 14, 28, and 90 days. Butoxyethanol produced a bi-phasic response in the mouse. Butoxyethanol (450 and 900 mg/kg) resulted in an increase in oxidative damage in DNA (OH8DG) and lipid (malonaldehyde) at both the 7 and 90 day treatment points. Hepatic vitamin E levels were also decreased at these time points. DNA synthesis was increased in liver endothelial cells at 7 days while DNA synthesis in hepatocytes was only increased at 90 days. No increases in oxidative damage or DNA synthesis were seen in the rat at any dose or time point examined. No changes in apoptosis or mitosis were observed in the liver of either species at any dose or time point. In summary butoxyethanol caused an increase in oxidative damage and DNA synthesis in the mouse (susceptible species) in cell types that correspond to the observed tumors, while no changes were seen in the rat (non-sensitive species). These results support our proposal that butoxyethanol-induced neoplasia occurs through the induction of oxidative stress resulting in an increase in DNA synthesis in the target cell types in the mouse liver.

1501 MECHANISMS OF MACROPHAGE ACTIVATION BY PEROXISOME PROLIFERATORS.

O. M. Smutney, X. Li, M. D. Wheeler and R. G. Thurman. *Curriculum in Toxicology, Department of Pharmacology, Department of Nutrition, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Although the peroxisome proliferator receptor α(PPARα), localized exclusively in hepatocytes, is required for peroxisome proliferator-induced cell proliferation, evidence has accumulated that Kupffer cell-derived oxidants and mitogenic cytokines are also required in this mechanism. However, it is unknown how peroxisome proliferators activate Kupffer cells. Since circulating Wy-14, 643 is almost exclusively bound to albumin *in vivo*, it was hypothesized that Wy-14, 643 is recognized by macrophage scavenger receptors which function physiologically to recognize modified lipoproteins and albumin. Indeed, the data presented here show that Wy-14, 643 bound to albumin leads to a significant but transient increase in intracellular calcium in a murine macrophage cell line (RAW 264.7 cells); this effect was nearly completely prevented by preincubation with the scavenger receptor inhibitor polyinosinic acid. Interestingly, Wy-14, 643 also lead to a rapid increase in ERK1/2 expression suggesting a role for the MAP kinase pathway in addition to calcium-dependent signaling in mediating macrophage activation in response to peroxisome proliferators. Collectively, these data begin to address for the first time how peroxisome proliferators initially activate Kupffer cells to ultimately result in oxidant and mitogenic cytokine production.

1502 *IN UTERO* ORIGINS OF CANCER IN p53 KNOCKOUT MICE: MATERNAL DIETARY VITAMIN E, FETAL OXIDATIVE DNA DAMAGE AND POSTNATAL CARCINOGENESIS.

C. S. Chen[1] and P. G. Wells[1,2]. [1]*Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada and* [2]*Dept. of Pharmacology, University of Toronto, Toronto, ON, Canada.*

Reactive oxygen species (ROS), including hydroxyl radicals, can oxidatively damage cellular macromolecules such as lipids, proteins and DNA. ROS-mediated oxidative stress and macromolecular damage have been implicated in cancer initiation

and promotion, and the embryo has limited protective antioxidative mechanisms, leaving it at potentially greater risk. We have previously shown that maternal supplementation with the antioxidant vitamin E (VE) alters levels of endogenous embryonic DNA oxidation. Here, to determine whether cancer can have *in utero* origins, we examined the effect of maternal dietary VE (dl-α-tocopherol-acetate) supplementation on spontaneous postnatal tumorigenesis, using high-dose VE and the cancer-prone p53 knockout mouse model. Virgin heterozygous (+/-) p53-deficient females were placed on either a normal or 10% [w/w] VE-supplemented diet for 4 weeks and mated with +/- p53-deficient males. VE supplementation was stopped on the day of birth. The offspring were p53-genotyped and observed for spontaneous tumor development. Compared to offspring from dams supplemented with control diet, *in utero* exposure to VE enhanced spontaneous tumor formation in both +/- and -/- p53-deficient offspring. At 40 weeks of age, VE-exposed -/- p53 pups had less than half the survival rate of -/- p53 control offspring (22% *vs.* 49%) ($p<0.02$). Among +/- p53 offspring, 78% of the VE offspring were still alive at 40 weeks of age, compared to 92% in the control group ($p<0.04$). This tumorigenic enhancement is consistent with a study in CD-1 mice in which high-dose VE failed to reduce endogenous fetal DNA oxidation, and shows that high-dose VE can exacerbate rather than block some ROS-mediated pathologies. These preliminary results indicate that some cancers originate *in utero* and can be substantially modified by altering embryonic redox status, suggesting novel carcinogenic mechanisms and potential therapeutic strategies. (Support: NCIC; CIHR)

1503 PUTATIVE COLON CANCER RISK FACTORS SPECIFICALLY INDUCE DAMAGE OF *P53* IN PRIMARY HUMAN COLON CELLS.

A. Schäferhenrich[1], W. Sendt[2], J. Scheele[2] and B. L. Pool-Zobel[1]. [1]*Institute for Nutrition, Friedrich Schiller University of Jena, Jena, Germany and* [2]*Department of Surgery, Friedrich Schiller University of Jena, Jena, Germany.* Sponsor: D. Schrenk.

Introduction: Colon cancers are strongly linked to dietary factors. Although it has been possible to identify whole foods as increasing risks it awaits clarification which individual compounds are involved at the molecular level. One group of candidates includes α, β-unsaturated aldehydes (products of lipid peroxidation) and reactive oxygen species (result from oxidative stress). Both are elevated in tissues and body fluids during unfavourable diets. **Aim:** It is of high interest to experimentally assess their potency for inducing cancer-relevant endpoints in colon cells, and thus to obtain more evidence for their relative impacts during colon carcinogenesis. For this we have developed a novel application utilising fluorescense *in situ* hybridisation of isolated DNA ("comet" structures, single cell microgelelectrophoresis) with *p53* specific probes (Comet FISH). **Methods:** Human epithelial colon cells were isolated from surgical tissue by enzyme digestion. Test compounds were trans-2-hexenal (400-1600μM) and H_2O_2 (18.75-150μM). Global DNA damage was determined with the alkaline comet assay and specific breakage of *p53* with Comet FISH. **Results:** Both compounds induced DNA damage in primary human colon cells. Increased global DNA damage is associated with a higher probability of *p53* breakage. The highest doses induced similar degrees of damage with similar staining patterns for *p53* migration. **Conclusions:** The results clearly show that trans-2-hexenal and H_2O_2 induce genetic damage in primary human colon cells. Moreover, for the first time it has been shown that they induce specific genetic damage in *p53*. The novel and relevant method of Comet FISH is now being developed to compare *p53* breakage with damage in *APC* and *K-ras*. The approach of measuring genotoxic impact in the cancer relevant genes of human colon cells offers new unique possibilities to study potential risk factors and learn more on the aetiology of colon cancer.

1504 MODULATION OF BENZO(A)PYRENE-INDUCED P53 BY ACROLEIN.

S. S. Biswal[2], T. Maxwell[1] and J. P. Kehrer[1]. [1]*Dept. of Pharmacology and Toxicology, College of Pharmacy, The University of Texas at Austin, Austin, TX and* [2]*Div. Toxicological Sciences, Department Environmental Health Sciences, Bloomberg School of Public Health, Johns Hopkins Univ., Baltimore, MD.*

Acrolein, a highly electrophilic α, β-unsaturated aldehyde, is by far the most reactive amongst the aldehydes present in smoke. Levels of acrolein in ambient air are estimated at 0.04 to 0.08 ppm, although it is found at up to 90 ppm in cigarette smoke. Subchronic-inhalation animal studies have reported physiological effects at 0.4 ppm. The relative contribution of acrolein to complex mixture toxicity of smoke at the molecular level remains unknown. Our past work with exposure of human type II (A549) lung cells to acrolein has shown that it inhibits the redox sensitive transcription factors NF-κB and AP-1. We have extended this to study the ability of acrolein to modulate the effect of benzo(a)pyrene (BaP) on p53 protein. The hypothesis being investigated is that a thiol imbalance induced by acrolein can alter the activity of p53 protein induced by BaP. Exposure of A549 cells to 1 μM BaP for 48 h strongly activated the expression of p53 as seen by western blotting, and its DNA binding as shown by electrophoretic mobility shift assay. Treatment of A549 cells with a non lethal dose of acrolein alone (50 fmol/cell for 0.5 h) depleted 80% of total cellular glutathione but did not alter p53 protein levels. When BaP-treated cells (48 h) were exposed to acrolein for 0.5 h there was no effect on BaP-induced p53 protein levels, but a 90% inhibition in the DNA binding of p53 activated by BaP. Using a p53 dual luciferase reporter assay, acrolein caused an 83% decrease in the p53 activity induced by BaP (1 μM for 24 h post transfection). The downstream consequence of inhibiting p53 activity with acrolein is being investigated. Results from this study suggest that acrolein can alter p53 DNA binding and function which may play an important role in lung cancer attributed to cigarette smoke carcinogens such as BaP. (This work was supported by the Maryland Cigarette Restitution fund, NIEHS Center grant ES03819 and RO1 ES09791.)

1505 FOMESAFEN: A MURINE HEPATOCARCINOGEN THAT ACTS *VIA* PPARα TO SUPPRESS APOPTOSIS AND INDUCE CELL AND PEROXISOME PROLIFERATION.

G. J. Moffat, N. H. James, S. C. Lloyd and R. A. Roberts. *Syngenta CTL, Alderley Park, United Kingdom.*

Fomesafen is a herbicide that increased liver tumor incidence in male and female CD-1 mice when administered in the diet at 100 and 1000 ppm. Previous studies indicated that fomesafen belongs to the peroxisome proliferator (PP) class of non-genotoxic hepatocarcinogens. In rodent liver, PPs activate the peroxisome proliferator activated receptor α (PPARα) causing peroxisome proliferation, suppression of apoptosis and cell proliferation, ultimately leading to tumors. In contrast, human liver is refractory to the adverse effects of PPs. To confirm that fomesafen belongs to the PP class of non-genotoxic hepatocarcinogens, fomesafen was administered to CD-1 mice for 28 days. Fomesafen at 100 or 1000ppm increased mean relative liver weight in male and female mice (1.4- and 1.8-fold and 1.1- and 1.6-fold, respectively, relative to control), and caused a marked induction of hepatic peroxisomal volume in both male and female mice (8.2- and 12.0-fold and 9.4- and 12.5-fold, respectively, relative to control). To assess the ability of fomesafen to regulate cell proliferation and apoptosis, and to assess the role played by PPARα, hepatocytes isolated from control and PPARα null mice were used for *in vitro* investigations. In wild type mouse hepatocytes, fomesafen (250μM) caused peroxisome proliferation, increased the rate of cell proliferation (from 7.6±0.7% to 12.0±1.5% of cells in S-phase) and decreased the rate of apoptosis (from 1.4±0.3% to 0.7±0.1% of hepatocytes). In contrast, PPARα null mice hepatocytes were refractory to the effects of fomesafen on peroxisome proliferation, cell proliferation and apoptosis. Since human liver is resistant to the effects of PPs, the response of human hepatocytes to fomesafen was investigated *in vitro*. Human hepatocytes were refractory to the effects of fomesafen on peroxisome proliferation, cell proliferation and apoptosis. These data demonstrate that fomesafen belongs to the PP class of rodent specific hepatocarcinogens that induce tumors *via* a mode of action that is not relevant for man.

1506 INHIBITION OF APOPTOSIS IN RAT HEPATOCYTES BY 'NON-DIOXIN-LIKE' POLYCHLORINATED BIPHENYLS.

H. J. Schmitz, B. Wagner, S. Bohnenberger and D. Schrenk. *Food Chemistry and Environmental Toxicology, University of Kaiserslautern, Kaiserslautern, Germany.*

Polychlorinated biphenyls (PCBs) lead to a variety of biological effects in experimental models. Among other adverse effects in humans, an increased incidence of liver cancer was observed under high exposure to PCBs. In contrast to 'dioxin-like' PCBs, 'non-dioxin-like' PCBs are inactive or almost inactive as aryl hydrocarbon receptor (AhR) agonists. Although they do not share structural properties with phenobarbital (PB) certain 'non-dioxin-like' PCBs show induction of PB-inducible drug-metabolizing enzymes. Like TCDD and PB, several PCBs are tumor promoters in rat liver. Since the inhibition of apoptosis in pre-neoplastic foci has been demonstrated for the liver tumor promoters TCDD and PB, it may also play a central role in the mechanism of tumor promotion by PCBs. Nevertheless, no data concerning an anti-apoptotic effect of tumor-promoting PCBs in pre-neoplastic rat liver are available. This study investigates the possible relationship between 'PB-type' induction of CYP isozymes and the effect on UV-initiated apoptosis in cultured rat hepatocytes after treatment with 'non-dioxin-like' PCBs. For this purpose, hepatocytes from rat liver were cultured using the collagen sandwich technique and apoptosis was initiated by irradiation with UV light. Addition of the PCBs IUPAC numbers 28, 101 and 187, and of PB 30 min after irradiation, suppressed the UV-induced increase in apoptosis in a concentration-dependent manner, following the rank order of PCB 28 > PCB 101 = PB > PCB 187 for apoptosis-suppressing potencies. PB and all PCBs tested also led to a concentration-dependent induction of CYP2B1/2B2 activity following the rank order PCB 187 > PCB 28 > PCB 101 > PB for inducing potencies. For the first time, our results demonstrate the suppression of UV-initiated apoptosis in rat hepatocytes by 'non-dioxin-like' PCBs.

Furthermore, both the inhibition of apoptosis and the 'PB-type' induction of CYP activity show distinct concentration-response relationships, indicating different signaling pathways for both effects.

1507 ROLE OF CHOLINE DEPLETION IN DIETHANOLAMINE INDUCED DNA SYNTHESIS IN MOUSE HEPATOCYTES.

L. M. Kamendulis, D. J. Smith and J. E. Klaunig. *Pharmacology and Toxicology, Indiana University, Indianapolis, IN.*

Diethanolamine increased the incidence and multiplicity of liver tumors in the mouse but not in the rat following chronic dermal exposure. While the mechanism(s) for tumor induction is not readily evident, diethanolamine inhibits cellular choline uptake. Choline deficiency is known to produce tumors in rodents, therefore, one might postulate that diethanolamine, through depletion of choline, may result in the development of tumors in the mouse. The present studies examined the effect of diethanolamine and choline depletion on DNA synthesis in primary cultured mouse hepatocytes. Mouse hepatocytes were cultured with 0 – 500 mg/ml diethanolamine for 24 hours and DNA synthesis measured immunohistochemically, based on BrdU incorporation into DNA. In mouse hepatocytes DNA synthesis was increased following treatment with 10 mg/ml diethanolamine and higher and ranged from 1.8- to 3.2-fold over control. Incubation of mouse hepatocytes in medium containing reduced choline concentrations (1/10 to 1/100 of normal medium; 0.898 mg/L to 0.0898 *vs.* 8.98 mg/L) for 24 hours resulted in an increase in DNA synthesis (1.4- to 2.4-fold over control); whereas incubation of cells in medium containing 10-fold higher choline concentration produced a 50% reduction in DNA synthesis from control. These results showing that reduction of cellular choline results in an increase in DNA synthesis suggest that the DNA synthesis seen following diethanolamine treatment may be a result of cellular choline depletion and may contribute to diethanolamine carcinogenicity.

1508 ENDOTHELIAL-CELL KINETICS IN RAT MODEL OF RIDDELLIINE-INDUCED HEMANGIOSARCOMA.

C. R. Moomaw[1], P. C. Chan[4], J. F. Foley[1], R. R. Maronpot[1], S. Peddada[2], C. A. Cummings[3], S. Eldridge[3] and A. Nyska[1]. *[1]Laboratory Experimental Pathology, NIEHS, Research Triangle Park, NC, [2]Biostatistics Branch, NIEHS, Research Triangle Park, NC, [3]Pathology Associates, Durham, NC and [4]Environmental Toxicology Program, NIEHS, Research Triangle Park, NC.* Sponsor: R. Maranpot.

Riddelliine is a naturally occurring pyrrolizidine alkaloid nominated by the FDA for carcinogenicity testing because of its economic impact on the livestock industry and the potential for human exposure. In NTP 2-year studies with riddelliine administered by gavage, high incidences of hemangioma and hemangiosarcoma were induced in the liver of rats and mice. In an effort to understand the pathogenesis of hemangiosarcoma, the capacity of riddelliine to damage endothelial cells and induce endothelial-cell proliferation was tested. 42 male Fisher rats received riddelliine (0, 1, and 2.5 mg/kg/day) by gavage for up to 6 weeks. 7 animals/group were sacrificed after 8 consecutive daily doses, and the remainder was sacrificed after 30 doses. By light microscopy, non-parenchymal-cell hypertrophy and karyomegaly were noted in the high-dose livers of the terminal sacrifice. That these cells were immunopositive for Factor VIII suggested them to be endothelial. A slight trend of increase in apoptosis (TUNEL method) was noted in the liver of the high-dose animals of the interim sacrifice. A significant increase in non-parencymal-cell proliferation (BrdU method) was noted in the liver of animals of the interim and terminal sacrifices. A significant increase in parencymal-cell proliferation was noted in the liver of the interim-sacrificed, while an opposite effect was noted in the terminally sacrificed. Electron microscopic evaluation indicated treatment-related damage as well as hyperplasia of non-parenchymal cells. The data suggest that the endothelial cells are specifically damaged by riddelliine. This event may lead to endothelial-cell proliferation, perhaps of the regenerative type. Possible growth factors involved in the proliferation of the endothelial cells are currently being investigated.

1509 15-DEOXY-¡â^{12,14}-PROSTAGLANDIN J_2, A LIGAND OF PEROXISOME PROLIFERATOR-ACTIVATED RECEPTER-¥ã INDUCED APOPTOSIS THROUGH G2/M PHASE ARREST IN NEUROBLASTOMA CELLS.

K. S. Park[1], E. J. Kim[1], J. H. Oh[1], C. W. Song[1], H. K. Jung[1], K. H. Yang[1], S. Y. Chung[1], Y. Y. Sheen[2] and J. T. Hong[3]. *[1]Department of General Toxicology, Natl. Inst. Toxicol. Res., Seoul, South Korea, [2]College of Pharmacy, Ewha Womans Univ., Seoul, South Korea and [3]College of Pharmacy, Chungbuk National Univ., Chongju, South Korea.*

15-Deoxy-¥Ä15-Deoxy-¥Ä^{12,14}-prostaglandin J_2 (15-deoxy-PGJ_2), a peroxisome proliferator-activated receptor (PPAR-¥ã) ligand, has been shown to stimulate differentiation and induced apoptosis in several cancer cells including breast, prostate and lung cancer cells. In this study, we examined whether 15-deoxy-PGJ_2 could inhibit cell growth through induction of apoptosis in neuroblastoma cells (SK-N-MC and SK-N-SH). We also investigated the expression of (anti-) apoptosis-related genes and activation of transcription factors. 15-Deoxy-PGJ_2 inhibited neuroblastoma cells growth and induced apoptosis in a dose (2-16 ¥M) and time-dependent manner. Consistent with the induction of apotosis, 15-deoxy-PGJ_2 reduced the expression of anti-apoptotic Bcl-2 but increased the expression of pro-apoptotic Bax, caspase 3 and caspase 9. Flow cytometric analysis showed that these cells were arrested in G2/M phase after 15-deoxy-PGJ_2 treatment. Furthermore, 15-deoxy-PGJ_2 significantly increased the expression of cyclin B1, but decreased the expression of cdk4, cyclin D1, cdk2 and cdc2. It was also found that PPAR-¥ã was expressed by 15-deoxy-PGJ_2 in these cells. Taken together, these results suggest that 15-deoxy-PGJ_2 may be a candidate for a preventive or a therapeutic agent for neuroblastoma.

1510 INHIBITION OF ULTRAVIOLET B-MEDIATED ACTIVATION OF NUCLEAR FACTOR KB BY GREEN TEA CONSTITUENT (-)-EPIGALLOCATECHIN-3-GALLATE IN CULTURED HUMAN EPIDERMAL KERATINOCYTES.

F. Afaq, V. M. Adhami, N. Ahmad and H. Mukhtar. *Dermatology, Case Western Reserve University, Cleveland, OH.*

Ultraviolet (UV)-B radiation to mammalian skin results in oxidative stress *via* an increased generation of reactive oxygen intermediates (ROIs). ROIs are known to cause a variety of adverse effects including cancer. Nuclear factor kappa B (NF-kB), a redox sensitive transcriptional factor, plays an important role in regulating the expression of various genes that participate in many physiological processes such as inflammation, apoptosis, and cellular proliferation. Green tea polyphenol (-)-epigallocatechin-3-gallate (EGCG) has been shown to possess photochemopreventive properties. Because, NF-kB has been implicated in UV response, we investigated its involvement in photochemopreventive effects of EGCG. In dose- and time- dependent studies, we evaluated the effect of EGCG on the phosphorylation and degradation of IkB alpha and activation of IKK alpha and NF-kB following UVB irradiation of normal human epidermal keratinocytes (NHEK). Immunoblot analysis demonstrated that the treatment of NHEK with EGCG (10-40 micro M) for 24 hrs before UVB (40 mJ/cm2) exposure dose-dependently inhibited UVB-mediated degradation and phosphorylation of IkB alpha and activation of IKK alpha protein expression. Employing immunoblot analysis and enzyme linked immunosorbent assay, we found that EGCG inhibits the UVB-mediated activation of NF-kB/p65 in the nucleus. In time-dependent study we observed that EGCG (10 micro M) inhibits degradation and phosphorylation of IkB alpha and activation of IKK alpha and NF-kB/p65 at 1, 2, 3, 6, 12 hrs post UVB-exposure. We next examined the effect of UVB on upstream targets of NF-kB. Following UVB exposure, the expression of RANK (receptor activator of NF-kB) and NIK (NF-kB-inducing kinase) proteins remained unaltered suggesting that RANK and NIK are not involved in UVB-mediated activation of NF-kB. These results provide molecular basis for the photochemopreventive effect of EGCG and suggest that green tea may be a useful agent against UVB-induced effect in human skin.

1511 MODULATION OF TRANSFORMED AND NORMAL SYRIAN HAMSTER EMBRYO (SHE) CELL GROWTH BY COMPONENTS OF GREEN AND BLACK TEA.

Y. Xu, Z. Jiao and J. E. Klaunig. *Pharmacology and Toxicology, Indiana University, Indianapolis, IN.*

The field of chemoprevention has seen increased interest in the last decade. While a number of chemicals have been shown to delay or prevent the cancer process, less is known about the mechanisms by which chemopreventive agents function in this regard. Chemicals can inhibit a tumorigenic growth by function directly on preneoplastic, initiated cells or indirectly on normal cells surrounding them. Using beno(a)pyrene (BP) induced transformed SHE cells and untreated, normal SHE cells, we studied the effects of a component of green tea, EGCG, and of black tea, tea pigment, on the growth and death of preneoplastic and normal SHE cells. Following treatment both EGCG and tea pigment increased the clonal growth rate of normal SHE cells in a dose dependent manner. In contrast, a decrease of clonal growth of the BP transformed cells was observed. Further investigation, showed that the decreased clonal growth of the BP induced preneoplastic SHE cells was through an increase in cell death (apoptosis). These data suggest a selective effect on cell growth and death of the tea components on the preneoplastic and normal SHE cells. This effect was dose responsive in both cell types. No difference was seen at low doses of the components and at high doses, the tea components decreased the growth of both normal and preneoplastic cells. In addition, an increase in DNA damage (using COMET analysis) was seen at high doses of the tea components in both cell types suggesting a risk to promote the growth of transformed cells. These dose-related modifications growth regulation of the tea components in gene expres-

sion of cell proliferation and apoptosis pathways was also examined. These results show a selective effect of tea components on growth in normal and preneoplastic cells that is dose dependent.

1512 INDUCTION OF QUINONE REDUCTASE ACTIVITY IN HEPA 1C1C7 CELLS AND IN FISHER 344 RATS BY BROCCOLI DEPENDS ON SULFORAPHANE BUT NOT ON GLUCORAPHANIN CONTENT.

A. S. Keck and E. H. Jeffery. *Division of Nutrition, Champaign-Urbana, IL.*

Glucosinolates (GS) and their bioactive hydrolysis products such as sulforaphane (SF) upregulates detoxification enzymes and are suggested to be responsible for the chemopreventative effects of cruciferous vegetables. Broccoli (brassica oleracea L., Italica) is the primary source of GS in the American diet. We previously analyzed >50 broccoli varieties and found that the total GS content and individual GS species varied greatly depending on variety. In this study nine broccoli varieties were tested for their ability to increase quinone reductase (QR) activity, a biomarker for anti-carcinogenesis, in mouse hepatoma (Hepa 1c1c7) cells. The objective was to study whether QR activity correlates with total amount of GS, the specific GS glucoraphanin (GP, precursor to SF) or any of the hydrolysis products such as SF. 130, 000 cells/well were plated in 12 well plates 24 h prior to exposure to aqueous extracts of 100, 500 or 1000 mug freeze-dried broccoli/ml medium, for 24 h. The increase of QR activity was dose-dependent and significant differences in QR inducibility among the broccoli varieties were detected: Peto #7 > Ma191 = Peto #15 > Packman = Majestic = Brigadier> VI-158 = EV 6-1. QR inducibility did not correlate with total GS or GP, but did correlate significantly ($p<0.01$) with SF content of the extracts. Two broccoli varieties, Packman and Majestic, were fed to male Fisher 344 rats for 5 days (20% of diet). As in cell culture, hepatic QR induction reflected relative SF levels, but not total GS or GP levels. Results indicate that SF is primarily responsible for increases of QR activity both *in vitro* and *in vivo* and that different broccoli varieties may provide differing chemopreventative potency. Supported by USDA grant # 99-35503-7010

1513 *IN VITRO* TWO-STAGE MORPHOLOGICAL TRANSFORMATION OF SYRIAN HAMSTER EMBRYO (SHE) CELL.

H. Zhang, H. D. Borman and B. C. Myhr. *Genetic and Molecular Toxicology, Covance Laboratories Inc., Vienna, VA.*

Cell transformation systems have been used for many years to study the mechanisms of carcinogenesis *in vitro* and to detect the carcinogenic potential of chemicals. Cell transformation to a malignant state is a multistage process, and in SHE cells the first stage is characterized by a morphological transformation (MT). MT may itself be susceptible to a generalized two-stage process of initiation and promotion, as that occurs *in vivo*. Although two-stage transformation models have been demonstrated in several cell transformation systems and exploratory work has been performed with SHE cells, a well-defined method for detecting initiating/promoting activity in SHE cell cultures has not been developed. The initial results of a program to establish an *in vitro* two-stage SHE cell morphological transformation assay system are reported. BaP and TPA were used as an initiator and promoter, respectively. A preliminary study was conducted to determine subtransforming doses of BaP and TPA. No significant increases in the frequency of MT were observed in SHE cell cultures treated with BaP for 24 hours at < 334 ng/mL. Treatment with TPA for 7 days at < 1 ng/mL also did not induce significant increases in the MT frequency. When SHE cell cultures were treated with 334 ng/mL BaP for 24 hours, followed by TPA at 1 ng/mL for 6 days, a MT frequency of 2.18% was observed, compared to 0.63% by BaP treatment alone and 0.56% by TPA alone. Thus, a synergistic effect appeared to occur between the two subtransforming treatments. Similarly, a synergistic effect on MT was also observed in SHE cell cultures treated with BaP at a transforming dose of 5 µg/mL for 24 hour, followed by a subtransforming dose of TPA (1 ng/mL) for 6 days. The MT frequency induced by the sequential treatment was 2.98%, with a frequency of 1.79% for BaP alone and 0.29% for TPA alone. These initial data suggest that a two-stage morphological transformation model can be established using cultured SHE cells and studies designed to fully characterize this model system are in progress.

1514 DEVELOPMENT OF TUMOR PROMOTER TESTING MODEL WITH TRANSFECTED CELL LINES HARBORING C-HA-RASV12G.

T. Wu and M. Yin. *Protein Engineering, Beijing institute of Biotechonlogy, Beijing 100071, China.* Sponsor: M. Yin.

Chemicals can be identified as tumor promoters by their ability to induce tumor in promotion process. To develop a rapid tumor promoter testing system, human mutant c-Ha-rasV12G gene was introduced into human embryo lung fibroblast line WI 38 and human bronchial epithelial cell line BEAS-2B by electroporation. Transfectants were selected with G418 at different concentrations. A series of G418-resistant (G418r) monocolonies from transfected cells were isolated. Following exposure to different concentrations of phorbol-12-Myristate-13 Acetaet(PMA), phenotypes of neoplastic transformation of G418r cells were studied. According to our data, G418r WI 38 cells underwent neoplastic transformation by PMA treatment. Relative coefficiency was 0.9972. No obvious changes were found in untransfected cells. Results about BEAS-2B cells showed: (1) On untransfected cells, when the concentration of PMA was below 100nM, there was no evident growth inhibitory and promoting tumor effects. PMA at concentration over 100nM could induce squamous differentiation ($p<0.05$);(2) Contrastly, G418r cells could be promoted by PMA at concentration below 500nM($P<0.05$), and the treatment of 100nM of PMA for 24h might be mitogenic best. When the concentration of PMA reached 1uM, there would be growth arrest; (3) PMA could endow G418r cells with proliferation reaction induced by fetal bovine serum conditionally. Initiated cells are resistant to terminal differentiation effects of some tumor promoters. Thus, with the development of neoplastic transformation, the resistance to terminal differentiation induced by promoter increases until the promoter becomes mitogenic. The irreversible cessation of division of human epithelial cells expressing a mutant ras oncogene could be induced by PMA at high concentration(>1uM), and the promoting action of PMA may be mainly mediated *via* the activation PKC pathway. Collectively, the two transfected cell lines provide powerful and convenient models for detecting potential tumor promoters and research on mechanism of promotion tumor process.

1515 THE ABSENCE OF FASL ENHANCES THE DEVELOPMENT OF TUMORS AND REDUCES LIFE EXPECTANCY OF P53+/- MICE.

M. Embree-Ku and K. Boekelheide. *Pathology and Laboratory Medicine, Brown University, Providence, RI.*

In the multi-step process of tumor development, several genetic and epigenetic events occur to transform cells from normal to malignant. Although p53 is one of the most commonly mutated genes in a wide variety of tumors, how other genes interact with p53 to transform cells is only just beginning to be understood. To study the effects of the interaction of the Fas system with p53 in tumor progression and development, mice with a targeted disruption of the p53 tumor supressor gene and deficient in Fas ligand were evaluated. Organ weights, life expectancy, and tumor and tissue histology were assessed. Although the absence of FasL had no effect on life expectancy of homozygous p53-deficient mice, the absence of a functional FasL had a profound effect on the life expectancy of p53 heterozygous mice, reducing the median time to death from 12.1 months to 9.6 months. Additionally, the tumor spectrum in p53 heterozygous mice shifted from predominantly sarcomas (63%) when FasL was present to a large number of lymphomas (76%) in FasL-/-p53+/- mice. The reduction in life span and increased incidence of lymphoma in FasL-/-p53+/- mice suggests that these mice could be used in carcinogenicity testing, particularly in understanding the mechanisms of compounds that induce lymphomas. Future studies will examine the possibility of using FasL-/-p53+/- mice as an alternative model in carcinogenicity assessment.

1516 EVALUATION OF THE Tg.AC TRANSGENIC MOUSE FOR PREDICTING THE PHOTOCARCINOGENIC POTENTIAL OF PHARMACEUTICALS: DOSE-RESPONSE OF Tg.AC MICE TO SOLAR-SIMULATED LIGHT.

R. Honchel[1], J. Zhang[1], C. S. Trempus[2], S. A. Miller[1], G. N. Rao[2] and E. D. Sistare[1]. *[1]CDER, FDA, Laurel, MD and [2]NIEHS, NIH, Research Triangle Park, NC.*

Tg.AC mice [FVB/N-Tg(v-Ha-ras)] have been shown to develop large numbers of papillomas within 26 weeks in response to dermal application of certain carcinogens. This propensity to develop skin tumors may make Tg.AC mice an ideal alternative short-term model for photocarcinogenicity testing. Since UV light alone is a carcinogen, our first objective was to determine the threshold levels of solar simulated light (SSL) that are tumorigenic to Tg.AC mice. The acute minimal erythemal dose (Med.) was determined in FVB/N mice (the parental strain). Groups of 7 male and female Tg.AC mice were then exposed to a fraction of the Med. of SSL (0, 0.1, 0.2, 0.3, 0.4, or 0.6 Med.). A similar SSL dose-response study was performed on FVB/N mice to confirm an enhanced tumorigenic response in Tg.AC mice. Mice were exposed 5 days per week for 26 weeks, then observed for an additional 12 weeks with no SSL exposure. No significant papilloma incidence was observed with any group after 26 weeks of treatment with SSL or after 12 additional weeks of observation. Most Tg.AC mice that received the higher SSL doses developed large nonpapilloma skin tumors (4/6 male and 5/5 female in 0.6 Med. group vs 0/4 male and 0/6 female in no SSL group), but only during the 12 week post SSL dosing period of the study. In FVB/N mice, only the female 0.6 Med. group (2/7) developed skin tumors (both nonpapilloma) during the final week (week 38). Unlike typical carcinogen-induced tumors in Tg.AC mice, *in situ* hybridization indicated, surprisingly, that the transgene was not expressed in these UV-induced tumors and immunohistochemical analysis revealed that all tumors were positive for p53 expression. The absence of skin tumors in all SSL treatment groups at 26 weeks indicates

that Tg.AC mice are not highly sensitive to chronic suberythemal SSL exposure and that the "background" incidence will be low when evaluating the Tg.AC mouse response to photocarcinogens in future studies.

1517 COMPARISON OF THE SKH1 AND K6/ODC MOUSE STRAINS FOR SENSITIVITY TO PHOTOCARCINOGENESIS.

Y. Chen and T. G. O'Brien. *ODC Mouse Group, Drexel Hill, PA.*

As a result of overexpression of the enzyme ornithine decarboxylase (ODC) in skin, the K6/ODC transgenic mouse is exquisitively sensitive to tumor induction by a wide variety of genotoxic chemicals. In order to determine this model's sensitivity to UV-induced carcinogenesis, K6/ODC mice and the widely used photcarcinogenesis model, SKH1, were subjected to a side-by-side comparison experiment. Groups of mice were exposed to 4 dose levels of primarily UV B radiation from the same bank of Q-Panel lamps on the same days of the week. Mice were irradiated three times a week for 24 weeks. The highest dose (100 mJ/cm^2 3 times per week) corresponded to a weekly dose of 5 minimal erythema doses (MEDs). At the highest dose, K6/ODC and SKH1 mice developed an equivalent tumor incidence (75%) and multiplicity (1.3 tumors/ mouse). At progressively lower doses, however, K6/ODC mice developed more tumors than SKH1. At 60 mJ/cm^2 thrice weekly, the tumor incidence was 45% *vs.* 15% and multiplicity was 0.45 *vs.* 0.15 for K6/ODC and SKH1 mice, respectively. At the two lowest doses (30 and 15 mJ/cm^2 thrice weekly), SKH1 mice developed no tumors while K6/ODC mice had 5 tumors in these dose groups. There were no tumors in unirradiated control groups of either strain. The majority of the tumors were squamous papillomas in both strains, but some squamous cell carcinomas were also present. These results demonstrate the utility of the K6/ODC model for photocarcinogenesis studies, especially at low doses and relatively short exposure periods. Because of it's high sensitivity to both genotoxic chemicals and UV irradiation, the K6/ODC mouse may be uniquely suited for certain applications, such as studies of the interaction of environmental chemicals and UV. (Supported by SBIR grant R43 CA 76901 from NCI, NIH, DHHS)

1518 HISTOPATHOLOGIC EVALUATION OF CLARA CELL-DERIVED LUNG TUMOR PROGRESSION IN A TRANSGENIC MOUSE MODEL.

S. M. Hicks[1], C. L. Lewis[1], J. D. Vassallo[1], L. O. Whiteley[1], A. S. Fix[1] and L. D. Lehman-McKeeman[2]. [1]*The Procter & Gamble Company, Cincinnati, OH and* [2]*DuPont Pharmaceuticals, Newark, DE.*

The purpose of the present work was to characterize the histomorphological progression and phenotype of Clara cell-derived lung tumors in a transgenic mouse. In this model, the Clara cell secretory protein (CC10) promoter was used to direct expression of the SV40 large T antigen (SV40TAg) to Clara cells. These mice developed lung tumors within 3 months. Early lesions observed at 1 month included terminal bronchioli lined by hyperplastic intensely basophilic cuboidal epithelial cells, which were disorganized and formed small papillary projections. Bronchiolar epithelium was also extending into adjacent alveoli. In larger airways there were multifocal segments of basophilic disorganized cuboidal epithelium interspersed between segments of normal ciliated epithelium. At this time, CC10 expression was markedly reduced as determined by Western blotting and immunohistochemistry. Lung lesions advanced with time, and at 2 months there was a more prominent extension of proliferating epithelium into alveoli. Solid masses of cuboidal cells were forming in terminal bronchioli and papillary lesions were present in medium to larger bronchioles. By 3 months, solid tumor masses were starting to compress adjacent alveoli and there were focal areas of disorganized small anaplastic cells. At 4 months, tumor size increased with obvious compression of adjacent alveoli and there was evidence of pleural fibrosis and pleural lymphatic invasion. This transgenic mouse model, characterized by extensive bronchiolar hyperplasia which progresses rapidly to tumor formation, provides new insight into changes associated with Clara cell transformation and differentiation. The model also demonstrates the early loss of CC10 expression in Clara cell-derived tumors.

1519 DOXYCYCLINE (DOX)-REGULATED, LUNG-SPECIFIC EXPRESSION OF MUTANT HUMAN Ki-*ras* IN BITRANSGENIC MICE: ALTERATIONS IN LUNG MORPHOLOGY.

H. M. Smith[1], J. W. Tichelaar[2], M. C. Mizesko[1], S. T. Dance[1], J. Everitt[3], J. A. Whitsett[2] and M. S. Miller[1]. [1]*Wake Forest University School of Medicine, Winston-Salem, NC,* [2]*Children's Hospital Research Foundation, Cincinnati, OH and* [3]*CIIT, Research Triangle Park, NC.*

Mutation in Ki-*ras* is a critical and early event in the development of lung adenocarcinomas in both humans and animal tumor models. Development of transgenic mice that possess constitutively active Ki-*ras* has been attempted but was unsuccessful because expression of the transgene resulted in embryonic lethality. We have thus developed a bitransgenic mouse model that allows for the regulation of Ki-*ras* expression in a lung-specific and DOX-inducible manner. A CYS^{12} mutant allele of the human Ki-*ras* gene was linked to a tetracycline (tet)-inducible promoter and then used to establish a line of transgenic mice with this construct. These mice, which do not express the Ki-*ras* gene, were then crossed with a second trangenic line containing the reverse tet activator (rtTA) expressed constitutively from either the SPC or CC10 lung-specific promoters. Induction of the Ki-*ras* transgene was detected by RT-PCR in bitransgenic mice following 1 week of DOX exposure. DOX-treated bitransgenic mice exhibited hyperplastic lung foci after only 12 days of DOX-treatment. By 5 weeks of treatment, extensive epithelial hyperplasia of the alveolar region of the lung tissue could be seen. Lung morphology in untreated bitrangenic mice or either of the DOX-treated single transgenic or control mice was normal. The hyperplasia noted in the lungs is consistent with preneoplastic lesions observed in chemically-induced mouse lung tissues that precede the onset of frank neoplasia. These results demonstrate that the bitransgenic mouse model will provide an important new research tool that will allow us to determine the role of Ki-*ras* mutations in lung tumorigenesis. This will have important implications for future research on the etiology, genetics, prevention, and development of novel therapies for lung cancer.

1520 REPLACEMENT OF PARTIAL HEPATECTOMY WITH FASTING/REFEEDING OR THE USE OF NEONATAL ANIMALS IN THE RESISTANT HEPATOCYTE MODEL.

P. Espandiari, H. P. Glauert and L. W. Robertson. *Toxicology, University of Kentucky, Lexington, KY.*

In rat liver several models have been developed to study multistage carcinogenesis, including the Solt-Farber resistant hepatocyte model. In this model initiation consists of either a necrogenic dose of a hepatocarcinogen or a non-necrogenic dose in conjunction with partial hepatectomy. As an alternative to partial hepatectomy, we investigated two different procedures: fasting/refeeding or the use of one-day-old neonates. The experimental design consisted of four groups: 1) control; 2) fasted for 4 days, then refed; 3) partial hepatectomy; 4) neonates. Groups 1-3 were injected p.o. with diethylnitrosamine (DEN) (100mg/kg) 24 hrs after refeeding or partial hepatectomy. Group 4 was treated with the same dose of DEN at one day of age. All initiation animals were treated with selection agents, 3 daily doses of 2-acetylaminofluorene (2-AAF), followed by a single dose of carbon tetrachloride(2ml/kg) followed by 3 additional daily treatments of 2-AAF. Rats were killed two weeks after the last treatment. Most of the rats in the partial hepatectomy and fasting/refeeding groups developed visible nodules. All three experimental groups developed significantly more gamma-glutamyl transpeptidase (GGT)- positive foci per cu cm of liver tissue than in the control group. In the fasting/refeeding group, the size and the volume % of GGT- positive foci in liver tissues were higher compared to rats subjected to partial hepatectomy. Furthermore, the number of GGT-positive foci in neonates was higher compared to the partial hepatectomy group. We conclude that both fasting/refeeding and the use of neonatal rats can replace partial hepatectomy as a method of initiation in the Solt-Farber method since both of these methods appear to be less stressful to the animals and equally sensitive. (Supported by ES 07380)

1521 ALTERED LEVELS OF PITITUARY AND SEX HORMONES IN MEXICAN AGRICULTURAL WORKERS EXPOSED TO ORGANOPHOSPHATE PESTICIDES.

R. Recio[1,2], M. E. Cebrián[1], G. Ocampo-Gómez[3], J. Morán-Martínez[2], V. H. Borja-Aburto[3] and A. Gómez-Muñoz[1]. [1]*Toxicología, Cinvestav-IPN, Mexico,* [2]*CIB, UAC, Torreón, Coah., Mexico and* [3]*CENSA, DGSA, Mexico.*

Many pesticides are considered endocrine disruptors due to their capacity to block or activate steroid hormone receptors and/or to affect reproductive hormone levels in experimental models. However, information regarding organophosphate pesticide (OP) exposure and their effects on humans is limited. The objective of this study was to evaluate the relationships between pituitary and sex hormone levels and OP exposure. A longitudinal study was conducted in an agricultural community located in north Mexico where OP were the most widely sold and used pesticides. Hormone levels were measured according to WHO. OP exposure was evaluated by measuring urinary levels of six dialkyl phosphates and phosphorothioates and by an exposure index constructed on the basis of frequency and intensity of OP exposure. FSH serum levels were negatively associated with OP metabolites DMTP and DMDTP. FSH levels were also significantly decreased in the most exposed group. LH serum levels were also negatively associated with DMTP and DMDTP. Marginal decreases in prolactin levels were also observed. Regarding sexual hormones, significant increases in estradiol serum levels were observed in the periods of higher exposure and they were positively associated with DMP and DETP urinary concentrations. Testosterone levels increased during the period of highest exposure and were positively associated with DMTP concentrations. Our results strongly suggest that high OP exposure alters the homeostatic relationships between the pi-

tuitary and the testes. Further studies are needed to determine the specific targets responsible for the effects here reported. (Partially supported by CONACyT (Grant No. 28403-M), WHO (Grant No. 96349) and by The Advanced Training Program of The Border XXI Initiative.

1522 NEUROBEHAVIORAL EVALUATION OF RESIDUAL EFFECTS OF LOW-LEVEL BYSTANDER ORGANOPHOSPHATE PESTICIDE EXPOSURE.

R. Singer. *Independent practice, Santa Fe, NM.*

Organophosphate pesticides (OP's) may cause neurotoxicity at low-levels of exposure. Subject: A female, 42 years old, high school graduate, farmer, working in a hay field, wearing shorts and a swim suit top, without respiratory protection was exposed to Thimet and possibly Lorsban applied to a downwind neighboring field in 6/98, with re-exposure by working in the adjacent field 6-8 times over the next 3 days. The evening of the exposure, she experienced headache, nausea, vomiting, leg pain, diarrhea, chest tightness, dizziness, blurred vision, and weakness in legs and arms - symptoms of OP poisoning - with continuing vertigo, nausea, pain etc.. Later and persistent symptoms included memory loss, sleep disorder, fatigue, irritability, and impaired executive function. ACHE testing was inconclusive. Assessment: Included comprehensive neurobehavioral toxicity evaluations, 2 years post-exposure, with an extensive interview and testing, and record review (educational, medical, letters of reference). Findings: Prior IQ was at the 80%tile. The Neurotoxicity Screening Survey showed results consistent with those of patients diagnosed with neurotoxicity. Current Full-scale IQ had declined to the 47%tile, with Processing Speed (a factor very sensitive to global neurotoxicity) at the 8%tile. Additional deficits were seen in detecting visual figure-ground relationships - 36%tile; Selective Reminding Test (measures learning) <1%tile; Stroop Color and Word Test (evaluates mental flexibility) 31%tile; Visual Search and Attention Test 23%tile; logical memory <1%tile; with moderate anxiety and moderate-severe depression. Distortion was below the level of detection. Malingering was ruled out by 5 separate tests. Personality testing using the NEO Personality Inventory found no personality disorders that could contribute to the findings. Record review found no competing explanations of her illness. Conclusion: Relatively low-level organophosphate exposure can cause neurotoxicity, revealed by neurobehavioral evaluation, lasting many years after exposure.

1523 AN APPROACH FOR SCREENING CHOLINESTERASE INHIBITORS IN DRINKING WATER.

K. R. Rogers[1], N. N. Mishra[1] and A. M. Mahfouz[2]. [1]*ORD/NERL, USEPA, Las Vegas, NV and* [2]*OW/OST, USEPA, Washington, DC.* Sponsor: J. Du.

Under the 1996 amended Safe Drinking Water Act (SDWA), a Contaminant Candidates List (CCL) has been compiled in 1998 (FR 63:40). Several Cholinesterase (ChE) inhibitors were identified in this list, some are organophosphates and others are carbamates. Prior to 1996, ChE inhibitors in drinking water were regulated individually and monitored by using conventional analytical methods to detect the presence and concentration of individual contaminants. Because of specific advances in analytical chemistry and the need for cumulative risk assessment of chemicals that have a common mechanism of toxicity, we developed an approach for initially screening for the presence of ChE inhibitors in drinking water. This approach is based on the use of a Microwell Plate Assay kit. In this method, Acetyl Cholinesterase (AChE) was stabilized in a gelatin film to determine low levels of pesticide contaminants in drinking water that inhibit ChE activity. The remarkable properties of the dry immobilized ChE preparation include its stability to prolonged storage at room temperature as well as its stability to short term elevated temperatures (60 degrees C). The enzyme could be maintained in dry gel form for 365 days at room temperature without substantial loss of activity. Several procedures were evaluated to oxidize less potent organothionophosphate (P=S) compounds to their more inhibitory oxon forms. Inhibition profiles were run for six commonly used carbamate insecticides (and some of their metabolites) and eight organophosphate insecticides using this assay. IC_{50} and IC_{20} values were determined for purified water and several drinking water matrices. Results using this assay were also compared to a commercially available test kit. This method may be successfully used for screening drinking water ChE inhibitors individually or in mixture. The opinions expressed are those of the authors and do not necessarily reflect USEPA policy.

1524 ACETYLCHOLINESTERASE INHIBITION: PREDICTION USING THREE-DIMENSIONAL QUANTITATIVE STRUCTURE-ACTIVITY RELATIONSHIPS.

W. Slikker, Jr.[1], S. N. Rao[2], A. Mehl[2] and J. El Yazal[1]. [1]*Neurotoxicology, National Center for Toxicological Research/USFDA, Jefferson, AR and* [2]*Molecular Simulations Inc., San Diego, CA.*

Organophosphorus pesticides are known to produce their biological effects through the inhibition of a number of esterases, including acetylcholinesterase (AChE), the enzyme responsible for the degradation of the neurotransmitter acetylcholine. The combined use of conformational analysis and three dimensional (3D), quantitative structure-activity relationship (QSAR) methods were used to rationalize the inhibitory potencies of a series of organosphorus pesticides against AChE. The CATALYST program was used to identify the structural features in the group of eight inhibitors whose IC_{50} values ranged from 0.34 nM to 1.2 µM. The 3-D pharmacophore models were characterized by at least one hydrogen bond acceptor site and 2-3 hydrophobic sites and demonstrated good correlation (r^2=0.994) between the predicted and experimental IC_{50} values. This approach can be used to screen databases of organophosphorous and other chemicals for their neurotoxic potential *via* the inhibition of AChE.

1525 ASSESSING THE IMPACT OF HUMAN PON1 POLYMORPHISMS: SENSITIVITY AND MONTE CARLO ANALYSES USING A PHYSIOLOGICALLY BASED PHARMACOKINETIC/PHARMACODYNAMIC (PBPK/PD) MODEL FOR CHLORPYRIFOS.

C. Timchalk, A. Kousba and T. S. Poet. *Battelle, Pacific Northwest Division, Richland, WA.*

A PBPK/PD model was developed for chlorpyrifos (CPF) and the active metabolite CPF-oxon. Susceptibility to organophosphate (OP) insecticides is associated with variation in pharmacokinetic/ pharmacodynamic response. A genetic polymorphism in the PON1 (arylesterase) detoxification of OPs results in the expression of a range of PON1 enzyme activities within humans. The objective was to identify sensitive parameters that influence the model output, and to investigate the impact of human PON1 status on CPF-oxon brain concentration over a range (5 µg/kg - 5 mg/kg) of CPF doses. The model was used for parameter sensitivity analysis, and Monte Carlo simulations for PON1 activity utilizing the human PON1 polymorphic distributions. Based on the sensitivity coefficients (SC), the model was sensitive to the following parameters: CPF-oxon plasma protein-binding, liver partitioning, liver PON1 metabolism, plasma butyrylcholinesterase (BuChE) and blood flow to the liver and brain. In addition, the SC for plasma protein binding, PON1, and BuChE demonstrated a clear dose-dependency. The model simulations suggest a dose-dependent non-linear increase in the brain CPF-oxon AUC, at doses >0.5 mg/kg, which is a function of both dose and PON1 activity. In contrast, at low environmentally relevant doses (~5 µg/kg) the model is relatively insensitive to the variability in PON1 activity. The results suggest that other esterase detoxification pathways may adequately compensate for lower PON1 activity; hence an increased sensitivity to low PON1 is not observable until non-target esterases have been appreciably depleted. This response is consistent with simulations that show an increased sensitivity to PON1 status at doses that significantly deplete plasma BuChE activity in humans (>90% inhibited). This study illustrates the utility of PBPK/PD modeling for determining the overall impact of parameter uncertainty and variability on risk assessment predictions for OP insecticides. (Supported by EPA grant R828608)

1526 EFFECTS OF DIETARY CHLORPYRIFOS ON PERIPHERAL TISSUE *VERSUS* BRAIN AND RBC ACETYLCHOLINESTERASE ACTIVITY IN DOGS.

J. P. Maurissen[1], B. R. Marable[1], P. C. Baker[1], K. E. Stebbins[1], R. Billington[3] and J. L. Mattsson[2]. [1]*The Dow Chemical Company, Midland, MI,* [2]*Dow AgroSciences, Indianapolis, IN and* [3]*Dow AgroSciences, Wantage, United Kingdom.*

Chlorpyrifos (CPF) is a widely-used broad-spectrum insecticide. At the request of the United Kingdom's Advisory Committee on Pesticides, a 6-week dog study was conducted to examine the effects of dietary exposure to CPF on peripheral tissue (left atrium, nodose ganglia, diaphragm, and quadriceps muscle) acetylcholinesterase (AChE) activity as compared to AChE in brain and red blood cells (RBC). Six-month old Beagle dogs (n = 4/sex/dose) were given 0, 0.5, 1.0, or 2.0 mg/kg/day CPF in their diets. AChE was assayed using acetylthiocholine in the presence of the butyrylcholinesterase inhibitor iso-OMPA (0.1 mM). AChE activities were compared using Dunnett's test (alpha = 0.05). RBC AChE showed a slight (~10%) but statistically significant decrease in the mid- and high-dose groups after 1 day of exposure to CPF. RBC AChE was inhibited at all dose levels after one week, reaching a steady-state of inhibition within three weeks of exposure. After 6 weeks of treatment at 2.0 mg/kg/day, a small difference in brain AChE (~7% inhibition; males and females combined) may represent a true treatment effect but was not statistically significant and was not considered adverse (<20% inhibition). Peripheral tissue AChE activity was corrected for connective tissue content as AChE activity in diaphragm, quadriceps, and nodose ganglia was inversely-correlated with the amount of connective tissue in the sample (r^2 < 0.49). No statistically significant differences in peripheral tissue AChE were found. However, the left atrium AChE activity in high-dose males was about 25% lower than controls, and may represent a true treatment effect despite a comparable but opposite effect in females, which indicated random variability. We conclude that RBC AChE is more

sensitive than peripheral tissue or brain to inhibition by CPF. The acute RBC NOAEL was 2.0 mg/kg and the repeated-dose NOAEL for brain and peripheral tissue was at least 1.0 mg/kg/day.

1527 METHODS TO EVALUATE PERIPHERAL TISSUE ACETYLCHOLINESTERASE ACTIVITY IN DOGS TREATED WITH CHLORPYRIFOS.

B. R. Marable[1], P. C. Baker[1], K. E. Stebbins[1], J. P. Maurissen[1], J. L. Mattsson[2], R. Billington[3] and S. R. Mortensen[2]. [1]*The Dow Chemical Company, Midland, MI,* [2]*Dow AgroSciences, Indianapolis, IN and* [3]*Dow Agrosciences, Wanton, United Kingdom.*

Total cholinesterase activity (ChE), as measured by reaction with acetylthiocholine (ASCh), is often used as an estimate of acetylcholinesterase activity (AChE) in animals treated with anticholinesterases. Measurements of ChE may overestimate the potential effects of anticholinesterases on AChE by ignoring the contribution of tissue butyrylcholinesterase (BuChE), for which ASCh is also a substrate. Moreover, the relative content of AChE and BuChE in peripheral tissues is not fully understood in many species, including dogs. Therefore, methods were optimized to measure tissue AChE activity in dogs treated with the anticholinesterase chlorpyrifos (CPF). ChE activity was evaluated in the RBC, brain, nodose ganglion, left atrium, left ventricle, diaphragm muscle, and quadriceps muscle of male Beagle dogs (8-9 months old). Dogs (3/dose level) were treated with CPF at 0, 0.3, 0.6 or 1.2 mg/kg/day in their diets for 4 weeks. ChE and BuChE were measured by reaction with ASCh or butyrylthiocholine, respectively. AChE activity was isolated from ChE using iso-OMPA, a specific inhibitor of BuChE. Brain ChE activity was largely (92%) composed of AChE. The percent of ASCh activity attributed to AChE in peripheral tissues ranged from 40% (left ventricle) to 87% (nodose ganglion). Overall, RBC AChE and tissue BuChE were inhibited at all dose levels. There was no apparent inhibition of brain or peripheral tissue AChE (ASCh with iso-OMPA). Small differences in tissue ChE (ASCh without iso-OMPA) were attributed to inhibition of BuChE. We conclude that RBC AChE is more sensitive than brain or peripheral tissue AChE, and that the importance of considering the contribution of BuChE when assessing AChE activity cannot be overstated.

1528 *IN VIVO* DETOXICATION OF ORGANOPHOSPHATES BY HEPATIC AND SERUM ESTERASES.

T. A. Couch[1], H. W. Chambers[2] and J. E. Chambers[1]. [1]*Coll Vet. Med, Mississippi State University, Miss State, MS and* [2]*Dept of Entomology, Mississippi State University, Miss State, MS.*

The protective effect(s) were studied of hepatic and serum A-esterases (AEST), which catalytically hydrolyze organophosphate (OP) oxons, and carboxylesterases (CaE), which stoichiometrically degrade OP's, for brain cholinesterase (ChE) during *in vivo* exposures to chlorpyrifos-oxon (CPO) and paraoxon (PO) at postnatal days (PND) 3 and 80. Rats were injected ip with either corn oil or the specific CaE inhibitor, bis-(4-nitrophenyl) phenylphosphonate (BNPP), followed by injections of CPO or PO. OP dosages were as follows for PND3 and 80, respectively: CPO (0.5 and 15 mg/kg), and PO (0.1 and 1.5 mg/kg). At PND3, brain ChE activity was inhibited 76% and 81%, in male rats exposed to BNPP followed by exposure to CPO or PO, as compared to 44 and 17% for CPO or PO treatment only, respectively. At PND3, activities were similar for males and females. At PND80, ChE inhibition was 84% and 95% in males exposed to BNPP-CPO or BNPP-PO, respectively. However, activity was similar to corn oil control levels for PO exposure, but was 50% inhibited after CPO exposure. For PND80 females, brain ChE inhibition was 88% and >90%, in rats exposed to BNPP-CPO and BNPP-PO, respectively, and 57% and 70% inhibited for CPO or PO exposures. The protective effect of CaE can be shown in the difference between ChE activities in the presence and absence of CaE. To speculate on AEST protection *in vivo*, and using *in vitro* inhibition data, it is possible to calculate the effective OP concentration required for the observed % inhibition *in vivo*, and to compare this to the dosage (in micromoles/kg) administered to BNPP-treated animals. For PND3 males, these calculated values [in ratios of nM/(micromoles/kg)] were 4.9 for PO and 5.9 for CPO. For PND80 males, which have much higher AEST levels, the values were 3.6 for PO and 0.28 for CPO. These data suggest that AEST are more important for CPO hydrolysis, whereas CaE are more effective in detoxication of both CPO and PO. (Supported by NIH F31 ES05752).

1529 INHIBITION OF PARAOXONASE (PON1) BY HEAVY METALS.

T. B. Cole[1], W. F. Li[2], R. J. Richter[1], C. E. Furlong[1] and L. G. Costa[2]. [1]*Genetics and Medicine, Medical Genetics, University of Washington, Seattle, WA and* [2]*Environmental Health, University of Washington, Seattle, WA.*

Paraoxonase (PON1) is a serum enzyme that hydrolyzes multiple substrates, including oxidized lipids, lactones, and organophosphorus (OP) compounds such as the nerve agents sarin and soman and the oxon forms of the insecticides parathion, diazinon, and chlorpyrifos. PON1 activity is determined in part by the Q192R coding region polymorphism, which affects its catalytic activity, and in part by differences in PON1 expression levels, which can vary as much as 13-fold among individuals of the same genotype. Because PON1 plays an important role in protecting against environmentally-induced disease, as well as atherosclerosis, we sought to determine the effects of heavy metals on PON1 activity and expression. In an *in vitro* assay of PON1 activity, cadmium, mercury, zinc, and iron, at levels less than 1 μM, inhibited the activity of purified human PON1 by more than 90%. Inhibition by iron, but not the other metals, was specific to the $PON1_{192R}$ isoform, with less striking effects on $PON1_{192Q}$. Despite this robust inhibition of PON1 activity by heavy metals *in vitro*, chronic exposure of mice to cadmium chloride (up to 0.5 mg/kg daily for two weeks, resulting in blood cadmium levels as high as 1 μM) did not decrease serum PON1 activity significantly. Similarly, chronic exposure of mice to methylmercury hydroxide (up to 7.5 mg/kg daily for two weeks) did not decrease PON1 activity significantly in either serum or liver microsomes. We conclude that environmental exposure to either cadmium or methylmercury is not likely to affect PON1 activity. Metal-binding proteins in the blood seem to be sufficient to protect PON1 against inhibition by these metals. Supported in part by ES 04696, ES 07033.

1530 DEVELOPMENT OF AN *IN VITRO* ASSAY WHICH MAY IDENTIFY WHICH ORGANOPHOSPHORUS PESTICIDES ARE MORE TOXIC TO THE YOUNG.

S. Padilla[1], H. J. Sung[2], P. Phillips[1], L. Jackson[3] and V. Moser[1]. [1]*Neurotoxicology Division, USEPA, Research Triangle Park, NC,* [2]*Pesticide Safety Division, National Institute of Agricultural Science and Technology, Rural Devel. Admin., Suwon, South Korea and* [3]*Univ. of NC, Chapel Hill, NC.*

Some, but not all, organophosphorus pesticides are more acutely toxic to the young as compared to adults. We have developed an *in vitro* assay which measures the detoxification potential (*via* carboxylesterase and A-esterases) of tissues. Previous results using this *in vitro* assay correlated with the marked *in vivo* sensitivity of the young to chlorpyrifos, and also correlated with the equal sensitivity of the young and adult to methamidophos (Padilla *et al.*, Neurotoxicology, 2000). We have now extended these observations to two other pesticides that have already been shown in the literature to be more toxic to the young: paraoxon and malathion. In our *in vitro* assay, liver and plasma from 7-day old rats were much less effacacious than adult tissues at detoxification of the active metabolites of these two pesticides-a pattern that correlates with the *in vivo* sensitivity of the young to those two pesticides. Using our *in vitro* assay we also tested the active metabolite of diazinon, diazoxon, and again found that young liver or plasma possessed much less detoxification capability than adult tissues. From these results, we predicted that young animals would be more sensitive to diazinon, which, in fact, was the case: when postnatal day (PND)17 or adult rats were given a dosage of 75 mg/kg diazinon, adult brain cholinesterase (ChE)actvity was only inhibited 38%, while brain ChE in the PND 17 animals showed much more inhibiton (75%). Furthermore, higher doses (200-500 mg/kg) were lethal to PND17 rats, but adults only showed signs of toxicity. We conclude that our *in vitro* test may prove to be a useful, quick convenient method for predicting *in vivo* age-related sensitivity to organphosphorus pesticides. *This abstract does not reflect EPA policy.*

1531 LACK OF SEX DIFFERENCES IN ACETYLCHOLINESTERASE INHIBITION IN NEONATAL RAT FOREBRAIN FOLLOWING ACUTE AND REPEATED ORAL EXPOSURE TO CHLORPYRIFOS.

A. M. Betancourt and R. L. Carr. *Center for Environmental Health Sciences, College of Veterinary Medicine, Mississippi State University, Mississippi State, MS.*

Chlorpyrifos (CPS), one of the most widely used organophosphorus insecticides in the USA, exerts its toxicity through the inhibition of acetylcholinesterase (AChE). Multiple studies have reported a marked susceptibility of young animals to the toxic effects of CPS compared to adult animals, which has evoked increased concerns about its safety. The literature has reported significant sex differences in the inhibition of AChE following acute exposure to CPS in neonatal rats. In this study, postnatal day 1 (PND1) male and female rat pups were acutely exposed by oral gavage to 1.5 or 3.0 mg/kg CPS. AChE activity was determined in the forebrain at various times following exposure to determine the time of peak inhibition of AChE to identify any possible differences between sexes. Following 1.5 mg/kg CPS, peak inhibition (57-59%) occurred at 12 hours with minor recovery of activity by 24 hours (47-50%). Following 3.0 mg/kg, peak inhibition (87%) occurred at 3-4 hours with little recovery by 12 hours but significant recovery by 24 hours (51-56%). Time to peak inhibition and inhibition levels were very similar for both males and females suggesting that following an acute oral exposure, male and female neonates respond similarly. In addition, male and female rat pups were repeatedly exposed from PND1-PND6 by oral gavage to these dosages of CPS. The re-

duction of forebrain AChE activity was similar between males and females on PND 4, 7, and 12 with inhibition levels of 25-29%, 31-33%, and 12-13% for 1.5 mg/kg CPS and 41-46%, 44-48%, and 18% for 3.0 mg/kg, respectively. These data suggest that following repeated CPS exposure, male and female rat pups also respond similarly.

1532 AGE- AND TIME-DEPENDENT EFFECTS OF EQUITOXIC DOSAGES OF PARATHION OR CHLORPYRIFOS ON HIGH AFFINITY CHOLINE UPTAKE IN RAT CORTEX AND STRIATUM.

K. J. Olivier and C. N. Pope. *Dept Physiological Sciences, Oklahoma State University, Stillwater, OK.*

High affinity choline uptake (HACU) in brain is altered in adult rats after exposure to some organophosphorus (OP) toxicants. Immature rats are more sensitive than adults to the toxicity of OP insecticides parathion and chlorpyrifos, but little is known regarding age-related effects on HACU. AChE and HACU in cortex and striatum of neonatal (7 days), juvenile (21 days) and adult (90 days) rats (n=8-15/treatment group) were evaluated at 4, 24 or 96 hr after equitoxic exposures to parathion (LD10 = 0.8, 1.5 and 6.6 mg/kg, po) or chlorpyrifos (LD10 = 15, 47 and 136 mg/kg, po). HACU was studied by incubation of synaptosomes with [3H]choline and subsequent separation of incorporated and unincorporated label by rapid filtration. Parathion elicited relatively similar levels of peak ChE inhibition in all age groups (64-82% at 4 hrs after dosing). Chlorpyrifos also elicited similar age-related reductions in ChE activity (81-91%), but peak inhibition was earlier in neonates and juveniles (4 hrs) than in adults (24 hrs). HACU was increased after parathion exposure, with maximal increases occurring at 4 hrs after exposure in neonatal striatum (52%), juvenile cortex (19%) and striatum (23%), and at 96 hrs after treatment in adult cortex (41%) and striatum (36%). In contrast, HACU was generally reduced by chlorpyrifos, with maximum reduction at 4 hrs after dosing in neonates (43%), 24 hrs in juveniles (22%) and 96 hrs in adults (18%). Interestingly, HACU was increased (15%) in neonatal striatum at 96 hrs after chlorpyrifos. Increased uptake of choline could lead to higher acetylcholine synthesis and amplification of the toxic consequences of parathion-induced acetylcholinesterase inhibition. Alternatively, a reduction in HACU following chlorpyrifos could potentially limit the amount of ACh released into the synapse and thereby reduce cholinergic toxicity. Changes in HACU may contribute to OP toxicant-selective and age-related toxicity following AChE inhibition by these two insecticides. (Supported by STAR grant GR825811 from USEPA).

1533 COMPARATIVE TOXICITY OF ORAL CHLORPYRIFOS EXPOSURES IN ADULT AND AGED RATS.

S. Karanth, K. Olivier and C. N. Pope. *Physiological Sciences, Oklahoma State University, Stillwater, OK.*

Chlorpyrifos (CPF) is a widely used organophosphorus insecticide that elicits toxicity through inhibition of acetylcholinesterase. A number of studies have reported that CPF is more toxic to immature animals and that aged rats (15 and 24 months of age) are not differentially sensitive to subcutaneously administered CPF. We evaluated the relative sensitivity in adult (3 months) and aged (15 months) rats to oral CPF exposures. Adult (3 months of age) and aged (15 months of age) Sprague-Dawley rats (n=5) were challenged with an effective but sublethal dosage (LD1) previously determined in adult rats (i.e., 80 mg/kg, po in peanut oil). Adult rats showed no signs of functional toxicity while aged rats exhibited moderate to severe signs (principally autonomic) and 2/5 lethality. Additional groups (n = 5) were treated daily with CPF (0, 1, 3 or 10 mg/kg, po) for 14 days and sacrificed for neurochemical measurements 4 hrs after the final dosing. None of the adult or aged rats exhibited functional signs of toxicity throughout the dosing period. Blood cholinesterase inhibition was greater in aged rats (71%) than in adults (55%) at 1 mg/kg/day group. Diaphragm ChE was significantly increased (16-25%) in adult rats at 1 and 3 mg/kg/day while in aged rats there was a dose-related reduction in activity (15-66%). In frontal cortex, ChE inhibition was significantly greater in aged rats (81%) compared to adults (39%) at 3 mg/kg/day, whereas at 10 mg/kg/day, ChE inhibition was similar in both groups (86-92%). These results suggest that aged rats may be more sensitive than adults to both acute and repeated oral CPF exposure. (Supported by grant ES09119 from NIEHS).

1534 CHRONIC DIETARY EXPOSURE WITH INTERMITTENT SPIKE DOSES OF CHLORPYRIFOS FAILS TO ALTER FLASH- OR PATTERN REVERSAL-EVOKED POTENTIALS IN RATS.

D. W. Herr, J. E. Graff, R. S. Marshall and D. L. Hunter. *Neurotoxicology, USEPA, Research Triangle Park, NC.*

Human exposure to pesticides is often characterized by chronic low level exposure with intermittent spiked higher exposures. Visual disturbances are often reported following exposure to xenobiotics, and cholinesterase-inhibiting compounds have been reported to alter visual function. This study examined the effects of chronic (1 year) dietary exposure (0, 1, or 5 mg/kg/day) to chlorpyrifos in male Long Evans rats (100-110 days old at study initiation). These doses were chosen to produce minimal and approximately 50% inhibition of brain cholinesterase activity, respectively. In addition to dietary exposure, half of the animals received an oral bolus of 45 mg/kg chlorpyrifos (in corn oil) every other month (n = 16-18 rats/treatment). Subjects were weight maintained at 350g throughout the study. After the final spiked exposure, the animals were allowed to recover for about 2.5 months, so only irreversible effects would be examined. Subjects were surgically implanted with screw electrodes over the visual cortex and allowed to recover for one week. Unanesthetized animals were placed in a restrainer and presented with vertical bar stimuli (square wave spatial and temporal modulation) of 0.06, 0.13, and 0.26 cpd visual angle, at contrast levels of 15, 30, and 60 percent contrast. Reversal rate was 0.49 Hz, and a mean illuminance of 50 lux was maintained between stimuli. After pattern testing, the animals were presented with a 10 μs flash stimulus at 11, 39, and 148 lux-s, with an ambient illumination of 15 lux. Dietary exposure to chlorpyrifos (alone or in combination with oral spike doses) did not produce changes in either flash- or pattern reversal-evoked potentials. The evoked potentials did show the expected intensity and spatial frequency dependent changes, showing that the animal's responses were under stimulus control. Thus, chronic exposure to chlorpyrifos did not appear to alter visual responses at the level of the cortex in adult animals. *This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.*

1535 PATTERN OF CHOLINESTERASE INHIBITION IN ADULT, MALE RATS CHRONICALLY EXPOSED TO DIETARY CHLORPYRIFOS.

R. S. Marshall, D. L. Hunter and S. Padilla. *Neurotoxicology Division, USEPA, Research Triangle Park, NC.*

Very little is known about the effects of chronic exposure to relatively low levels of anticholinesterase insecticides or how the effects of chronic exposure compare to higher, intermittent exposure of the same compound for the same duration. To that end, we exposed adult male rats to the anticholinesterase insecticide, chlorpyrifos (CPF)for one year at three levels of dietary exposure: 0, 1, or 5 mg/kg/day. In addition, those groups also received a bolus dosage of CPF (*i.e.*, "spiked" animals; 60 mg/kg initially and 45 mg/kg thereafter) in corn oil every two months; therefore, there were 6 dosage groups, n=5/group. Animal tissues were taken for analysis during dosing (at 6 or 12 months) and also 3 months after dosing ceased (*i.e.* "recovery" animals). Tissues analyzed were retina, whole blood and components, diaphragm, and central nervous system (pons). In general, the groups receiving dietary CPF exposure only showed substantial cholinesterase (ChE) inhibition (80%) in the blood at 1 mg/kg/day and no inhibition in retina, pons, or diaphragm; the higher dosage (5 mg/kg) produced more blood inhibition and approximately 50% or less ChE inhibition in the other tissues. One day after receiving the oral, spike dose, all three feeding (*i.e.*, 0, 1 or 5 mg/kg/day) groups showed more than 70% inhibition in each tissue. In the dietary exposure groups (unspiked), the ChE inhibition at 6 months was, in general, not different from the inhibition at 12 months, indicating that a steady state had been reached prior to 6 months. Three months after CPF dosing ended, ChE levels had returned to control levels in all groups. These data indicate that although chronic feeding with or without intermittent spiked dosages with CPF produces substantial ChE inhibition in a dose- and tissue-related manner, ChE activity recovers to normal within 3 months after dosing is ceased. *This abstract does not reflect EPA policy.*

1536 NEUROBEHAVIORAL EVALUATION OF RATS EXPOSED TO CHLORPYRIFOS *VIA* CHRONIC DIETARY AND REPEATED HIGH-LEVEL SPIKE EXPOSURE.

V. C. Moser, P. M. Phillips, K. L. McDaniel, R. S. Marshall, D. L. Hunter and S. Padilla. *NTD/NHEERL/ORD, USEPA, Research Triangle Park, NC.*

This study aimed to model long-term subtoxic human exposure to an organophosphorus pesticide, chlorpyrifos (CPF), and to examine the influence of that exposure on the response to intermittent high-dose acute challenges. Adult Long-Evans male rats were maintained at 350g body weight by limited access to CPF-laced food pellets to produce an intake of 0, 1, or 5 mg/kg/day (n=40/feed group). During the year-long exposure, half of the rats in each feed group received bi-monthly challenges (spikes) of CPF, and the other half received vehicle. Rats were periodically tested, using a neurobehavioral screening battery and motor activity, to evaluate the magnitude of the acute response (spike days) as well as recovery and ongoing chronic effects (non-spike days). In non-spiked rats, the lower feed level produced blood but no brain cholinesterase inhibition, whereas the higher feed level produced about 50% brain cholinesterase inhibition. Effects of the spikes differed as a function of dietary level for several endpoints (*e.g.*, tremor, lacrimation), and in

general, the high-dose feed groups showed greater effects of the spike doses. In the intervening months, neurobehavioral differences among treatment groups were influenced more by the spike administration than by the level of CPF in the feed. Thus, chronic and intermittent CPF exposure produced long-lasting neurobehavioral changes and altered the response to acute challenges. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

1537 CHOLINERGIC CHANGES AND NEUROBEHAVIORAL DEFICITS FOLLOWING CO-EXPOSURE WITH CHLORPYRIFOS AND NICOTINE IN RATS.

A. M. Dechkovskaia, A. A. Abdel-Rahman, L. B. Goldstein, D. U. Shah, S. L. Bullman, W. A. Khan and M. B. Abou-Donia. *Pharmacology and Cancer Biology, Duke University Medical center, Durham, NC.*

Approximately 20% of the US population is directly exposed to nicotine *via* direct smoking of tobacco. Many more are exposed indirectly through environmental tobacco smoke. In addition to exposure to nicotine, many of the same individuals are exposed to environmental neurotoxic chemicals such as the organophosphorus pesticide, chlorpyrifos. In the present study, we evaluated the cholinergic system in the central nervous system and neurobehavioral performance following combined exposure with low doses of nicotine and chlorpyrifos. Male Sprague-Dawley rats (250-300 g) were treated daily with nicotine (0.1mg/kg, s.c., in normal saline) or chlorpyrifos (1.0 mg/kg, dermal, in ethanol) or a combination of nicotine and chlorpyrifos for 30 days. Control animals were treated with saline and ethanol. On day 30 sensorimotor functions were evaluated using a battery of tests that included measurements of postural reflexes, limb placing, grip time, beam walking and incline plane performance. The data from behavioral observations showed that there was a significantly exacerbated deficit in incline plane performance, beam-walk score and beam-walk time following combined exposure than exposure with each chemical alone. A significant increase in nAChR ligand binding was observed in brainstem and cortex following exposure with nicotine or chlorpyrifos that was further augmented with combined exposure, while mAChR showed only a modest increase in binding in the cortex. A decrease in cerebellar and an increase in midbrain AChE was observed following combined exposure whereas exposure to nicotine or chrorpyrifos alone did not show any significant change brain regional AChE activity. These data suggest that combined exposure with physiologically relevant doses and route of nicotine and chlorpyrifos may cause additive neurobehavioral deficit and differential changes in the cholinergic system. Supported, in part by an EPA grant # R829399-01-0

1538 PROTECTION AGAINST PARATHION TOXICITY BY SINGLE OR REPEATED ADMINSTRATION OF PHYSOSTIGMINE IN RATS.

Y. C. Kim, S. Y. Kim and M. G. Lee. *Pharmacy, Seoul National University, Seoul, South Korea.*

The protective effects of physostigmine against the toxicity of parathion were examined in male Sprague-Dawley rats. Physostigmine (100 or 1, 000 μg/kg, ip) injected 30 min before decreased the inhibition of acetylcholinesterase (AChE) activities in brain, lung and blood induced by parathion (2 mg/kg, ip). Physostigmine pretreatment did not affect the total hepatic microsomal cytochrome P450 (CYP) or cytochrome b_5 contents. There was no change in p-nitrophenol hydroxylase, p-nitroanisole demethylase or aminopyrine N-demethylase activities in liver of physostigmine-pretreated rats. However, erythromycin N-demethylase activity, a selective CYP3A marker, was significantly inhibited by the carbamate in a dose-dependent manner. Physostigmine also decreased erythromycin N-demethylase activity in brain. Physostigmine did not alter carboxylesterase or paraoxonase activity, indicating that detoxication of parathion was not affected by this carbamate. The pharmacokinetic parameters of parathion (3 mg/kg, iv) were determined after a single dose of physostigmine. In physostigmine-pretreated rats, the area under the curve (AUC) of parathion was significantly greater; clearance (Cl) was lower than control rats. Physostigmine (100 or 1, 000 μg/kg/day, ip) was repeatedly administered to rats for 7 consecutive days. When parathion was given to rats 4 or 24 hr after the final dose of the carbamate, the brain AChE inhibition was reduced significantly. Repeated administration of physostigmine did not affect erythromycin N-demethylase activity or the pharmacokinetic parameters of parathion. However, there was a significant decrease in specific [^{3}H] QNB binding in striatum and hippocampus. Scatchard analysis revealed a significant decrease in Bmax without a change in Kd. The results suggest that the inhibition of CYP3A plays an important role in the decrease of parathion toxicity provided by an acute dose of physostigmine, but changes in characteristics of muscarinic receptor could account for the protection against parathion toxicity in rats treated with this carbamate repeatedly.

1539 RELATIVE INHIBITORY POTENCIES OF CHLORPYRIFOS OXON AND CHLORPYRIFOS METHYL OXON FOR HEN BRAIN MICROSOMAL ACETYLCHOLINESTERASE (ACHE) AND NEUROPATHY TARGET ESTERASE (NTE).

T. J. Kropp and R. J. Richardson. *Toxicology Program, The University of Michigan, Ann Arbor, MI.*

The relative inhibitory potency (RIP) of an organophosphorus (OP) inhibitor against ACHE *versus* NTE may be defined as the ratio, [k_i (ACHE)/k_i (NTE)], where k_i is the bimolecular rate constant of inhibition for a given inhibitor against each enzyme. RIP values > 1 correlate with the inability of OP inhibitors or their parent compounds to produce OP compound-induced delayed neurotoxicity (OPIDN) at doses below the LD50. Chlorpyrifos oxon (CPO) has a RIP value >>1 for enzymes from hen brain homogenate, and the parent compound, chlorpyrifos (CPS), cannot produce OPIDN in hens at sublethal doses. The present study was carried out to test the hypothesis that the methyl homologue of CPO, chlorpyrifos methyl oxon (CPMO), also has a RIP value >>1. Hen brain microsomes were used as the enzyme source and k_i values ($X \pm$ SE) were determined at 37°C for ACHE and NTE (n = 3 and 4 separate experiments, respectively). The k_i values for CPO against ACHE and NTE were 17.8 ± 0.3 and 0.0994 ± 0.0049 μM^{-1} min^{-1}, respectively, yielding a RIP value of 179 ± 9. The k_i values for CPMO against ACHE and NTE were 10.9 ± 0.1 and 0.0582 ± 0.0013 μM^{-1} min^{-1}, respectively, yielding a RIP value of 187 ± 4. The results demonstrate that the RIP values for CPO and CPMO are comparable and both are >>1, suggesting that neither parent compound, CPS nor chlorpyrifos methyl, could produce OPIDN at sublethal doses. (Supported in part by a contract from Dow AgroSciences).

1540 IMMUNOLOGIC DETECTION & AFFINITY SELECTION OF ORGANOPHOSPHATE-ACETYLCHOLINESTERASE ADDUCTS USING ACTIVE SITE SPECIFIC ANTIBODIES.

L. E. Sandoval[1], K. M. George[1,2], D. H. Williamson[1,3] and C. M. Thompson[1,2,3]. [1]*Dept. of Pharmaceutical Science, University of Montana, Missoula, MT,* [2]*Center for Environmental Health Sciences, University of Montana, Missoula, MT and* [3]*Dept. of Chemistry, University of Montana, Missoula, MT.*

Organophosphate (OP) insecticides are rapidly absorbed to quickly infiltrate blood and nervous tissue, resulting in covalent inactivation of acetylcholinesterase (AChE). Exposure to OP compounds, therefore, is expected to correlate with formation of an OP-conjugate as determined by measurement of total erythrocyte and serum ChE activity. This method is both limited by population variation in total ChE levels and the inability to identify the responsible OP compound. It is our hypothesis that OP-AChE conjugates can be reliably detected by antibodies raised specifically against an active site sequence in both its native and phosphorylated states. Such antibodies would be capable of quantifying OP-modified cholinesterase and capable of identifying the OP compound. We have prepared antibodies specific to the active site sequence of mammalian AChE in both its native and phosphorylated states. Western Blots were employed to examine binding of a panel of antibodies against the native and OP-modified enzyme. Antibodies raised against the active site domain of AChE recognize the untreated enzyme but fail to bind to AChE covalently modified by OP's. In contrast, antibodies raised against the phosphorylated active site bind to POCl3 treated AChE (formation of phosphoserine) but do not bind AChE or AChE inactivated by a phosphoester group. To confirm selectivity of the custom antibodies, samples of treated and untreated AChE were trypsinized and resultant peptides isolated by affinity chromatography using the active site antibodies. Peptide samples were further separated by capillary liquid chromatography and sequenced by mass spectrometry. Using a combination of immunologic techniques, synthetic chemistry and mass spectrometry this presentation outlines methods to detect, identify and differentiate OP-AChE adducts.

1541 AUTOANTIBODY DETECTION USING ELISA AND WESTERN BLOT IN DELAYED NEUROPATHY INDUCED BY ORGANOPHOSPHATES (OP).

B. Vivekanandan[1], C. D. Clerval[1], A. P. De Feo[1,2] and H. A. El-Fawal[1]. [1]*Pharmacology and Toxicology Laboratory, Mercy College, Dobbs Ferry, NY and* [2]*Environmental Medicine, NYU Medical Center, Tuxedo, NY.* Sponsor: J. O'Callaghan.

Earlier studies demonstrated the attenuating effects of calcium channel blockers, and calpain inhibitors on the development of OP-induced delayed neuropathy (OPIDN) in hens. This modifying effect was evidently due to the attenuation of the calcium-dependent protease calpain's activity in brain and nerves. Selective calpain inhibitors I (CaI) and II (CaII) were used to modify the development of OPIDN following a single dose of phenyl saligenin phosphate (PSP, 3 mg/kg, im,

n=8). CaI (n=8) and CaII (5 mg/kg, im, n=7) were administered immediately before PSP and 24h after PSP. Functional impairment, evaluated by measurement of stride width and length, was greatest in hens treated with PSP only. The amelioration of the degree of OPIDN development by CaI and CaII was confirmed by assay for serum autoantibodies to neurofilaments (NFs), using ELISA and by gel electrophoresis. SDS gels of purified proteins and whole brain homogenates were used for immunoblot, and the protein bands visualized using HRP-conjugated goat anti-chicken IgG following addition of serum dilutions. Autoantibodies to NFs were detected as early as 6 days post-PSP exposure and predominated in hens not receiving calpain inhibitors. SDS gels showed bands with greater immunostaining at 60, 160, and 200 kD for serum from hens treated with PSP only. Anti-NF detection was consistent with the neurodegenerative effects of some OPs. The results confirm earlier studies of autoantibody detection against nervous system proteins in sera of humans and animals exposed to neuropathy-inducing OPs. This data also confirms the possible involvement of calpains in the development of OPIDN, and suggests that calpain inhibitors can modify OPIDN. The detection of serum autoantibodies against nervous system proteins, using ELISA, may be useful in monitoring the development of neuropathy. (Supported by NIH HD35965 and USDE P217A990192).

1542 ORGANOPHOSPHATE PESTICIDES DIFFERENTIALLY ALTER AXONAL AND DENDRITIC GROWTH IN CULTURED SYMPATHETIC NEURONS.

P. J. Lein[1], A. S. Howard[1], R. A. Schuh[1], R. Bucelli[2] and D. A. Jett[1]. *[1]Environmental Health Sciences, Johns Hopkins University, Baltimore, MD and [2]Biology, Canisius College, Buffalo, NY.*

There is increasing evidence that cognitive and behavioral problems may be linked to perinatal exposure to environmental chemicals, such as organophosphate pesticides (OPs), however, the mechanism(s) by which OPs cause these changes in neuronal function have yet to be determined. We used primary cultures of sympathetic neurons to investigate the possibility that OPs interfere with morphogenic events critical to establishing neuronal connectivity, specifically axonal and dendritic outgrowth. When grown in serum-free medium in the absence of glial cells, sympathetic neurons extend a single axon and no dendrites. In contrast, neurons grown in the presence of either glial cells or bone morphogenetic proteins (BMPs) extend multiple dendrites. Neurons grown under these various conditions were exposed to chlorpyrifos (CPF, 0.01 uM to 10 uM) or its oxon metabolite, CPFO (0.01 nM to 10 nM) for 24 or 72 hr then immunostained for either axon- or dendrite-selective antigens. Axonal and dendritic growth were quantified using Metamorph image analysis software. A 24-hr exposure to either CPF or CPFO causes a significant inhibition of axonal outgrowth in sympathetic neurons even at the lowest concentrations tested. In contrast, a 72-hr exposure to the same concentration range of these OPs weakly induces dendritic growth in the absence of BMPs, and enhances dendritic growth observed in the presence of BMPs. These effects on axonal and dendritic growth occur in the absence of effects on cell viability or acetylcholinesterase enzymatic activity, which indicates that OPs may exert specific and differential effects on axonal and dendritic growth. These data support the hypothesis that OPs disrupt patterns of neuronal connectivity in the developing brain.

1543 REMEDIATION OF ORGANOPHOSPHORUS NEUROTOXICITY IN SY5Y NEUROBLASTOMA CELLS BY ORGANOPHOSPHORUS HYDROLASE (OPH).

T. M. Cho, J. R. Wild, K. C. Donnelly and E. Tiffany-Castiglioni. *Veterinary Anatomy and Public Health, Texas A&M University, College Station, TX.*

In a previous study, model organophosphorus insecticides (OPs) produced anti-acetylcholinesterase activity, and mipafox and paraoxon modified the expression of the proteins associated with the neuronal cytoskeleton in human SY5Y neuroblastoma cells. The patterns of protein modification were different between mipafox and paraoxon. Numerous approaches have been studied to degrade OP compounds and remediate their toxicity. In the current study, biodegradation of model OP compounds and its efficiency to prevent or reduce neurotoxicity of the compounds were tested with SY5Y cells. OPs preincubated with organophosphorus hydrolase (OPH) did not inhibit acetylcholinesterase (AChE) and neuropathy target esterase (NTE) in SY5Y cells as potently as did buffer-treated OPs. The anti-AChE activity of paraoxon (maximum 3 μM) and anti-NTE activity of mipafox (250 μM) in SY5Y cells were completely prevented by degradation with OPH. Mipafox (40 μM) produced significant modifications in expression of MAP2ab and NF200 proteins in SY5Y cells, while equimolar paraoxon did not. The reaction of NGF-differentiating SY5Y cells to mipafox on protein modulation was dependent on the stage of differentiation at which the OP compound was applied. Neurofilament 200 protein in SY5Y cells exposed to the OPH-treated mipafox containing about 4 μM of mipafox remained after biodegradation was downregulated when given during the early stages of cell differentiation, but upregulated when given at a late stage. Biodegradation of mipafox with OPH significantly reduced neurotoxicological stress on the modulation of these neuroskeletal protein biomarkers. These results support the conclusion that OPH can be used to biodegrade OPs and remediate their neurotoxic effects *in vitro*.

1544 EFFECTS OF NEUROPATHY-INDUCING ORGANOPHOSPHORUS (OP) COMPOUNDS ON MITOCHRONDRIAL ATP PRODUCTION IN PRIMARY DORSAL ROOT GANGLIA CELL CULTURES.

C. Massicotte, C. J. van der Schyf, B. S. Jortner and M. Ehrich. *Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA.*

Cultures of dorsal root ganglia (DRG) can achieve neuronal maturation with axons. They have not, however, previously been used to investigate metabolic events that occur following exposure to neuropathy-inducing organophosphorus (OP) esters. Recent studies in other systems demonstrated *in vivo* alterations of ATP concentrations and changes in mitochondrial transmembrane potential following exposure to neuropathy-inducing OP compounds, suggesting that mitochondrial dysfunction occurs. We report an investigation using chick embryo DRG cultures to evaluate effects on the mitochondrial respiratory chain associated with exposure to these toxicants. This approach uses an *in vitro* neuronal system from the animal species (chicken) that provides the USEPA-approved animal model for OP-induced delayed neuropathy (OPIDN). DRG were obtained from 9-10 day old chick embryos, and grown for 14 days in minimal essential media (MEM) supplemented with bovine and human placental sera and growth factors. Cultures were then treated with 1 uM phenylsaligenin phosphate (PSP), mipafox, paraoxon, or the DMSO vehicle. Mipafox and PSP readily elicit OPIDN in hens; paraoxon does not. *in situ* evaluation of ATP production measured by bioluminescence assay in neurons treated with PSP and mipafox, but not paraoxon, showed significantly ($p<0.05$) decreased ATP concentrations. Values (in pmol/cell, mean ± SEM, n=6) were 307 ± 8 in control cultures, and 271 ± 18, 179 ± 5 and 256 ± 14 in paraoxon, PSP, and mipafox-treated cells, respectively. This low energy state was present in several levels of the mitochondrial respiratory chain, including complexes I, III and IV, although complex I was the most severely affected (<40% of control following mipafox and PSP treatments, $p<0.05$; paraoxon had a nonsignificant effect). We conclude that mitochondria are a primary target for neuropathy-inducing OP compounds, resulting in depletion in ATP concentrations.

1545 PHENYL SALIGENIN PHOSPHATE INDUCED SPINAL CORD GENE EXPRESSION CHANGES IN ADULT *GALLUS GALLUS*.

J. Fox, M. Ehrich, S. P. Hancock and B. S. Jortner. *Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA.*

Adult hens (*Gallus gallus*) exposed to a single dose of phenyl saligenin phosphate (PSP) develop delayed onset central-peripheral distal axonopathy. Mechanisms of this axonopathy are thought to be initiated by inhibition and aging of the carboxylesterase called neurotoxic esterase (NTE). However, events subsequent to NTE inhibition/aging and onset of neurologic deficits 7-10 days later are poorly understood. We hypothesized that spinal cord gene expression changes occur in this clinically silent period in PSP treated hens, but not in hens treated with the vehicle (dimethyl sulfoxide, DMSO), or phenylmethyl sulfonyl fluoride (PMSF), a compound that results in NTE inhibition without aging and does not result in axonopathy. Spinal cord mRNA transcript expression was evaluated 24 hours after a single im dose of PSP (2 mg/kg), PMSF (90 mg/kg) and DMSO by a cDNA screening approach (targeted display) and Northern analysis on select cytoskeletal genes (vimentin, neurofilament-M, alpha-tubulin). A time course was subsequently undertaken on those genes that showed altered expression at 24 hours. Alpha-tubulin transcript was increased 38% at 12 hours ($p=0.0125$); while at 48 hours PSP and PMSF treated birds had 28% and 42% decreased transcript ($p=0.0576$ and 0.0062, respectively). Two differential expressed genes were identified by targeted display in PSP treated hens. Both showed small (20-30%) but highly significant ($p<0.01$) expression changes at 12 hours. One gene is unidentified, the other is 82% homologous to the human gene KIAA1307. Current work is focusing on identifying the cell/neuronal types that are modulating the expression of these genes.

1546 ORGANOPHOSPHORUS COMPOUND-INDUCED DELAYED NEUROTOXICITY (OPIDN) IN WHITE LEGHORN HENS AS ASSESSED BY HEMATOXYLIN/EOSIN AND FLUORO-JADE STAINING.

K. Carlson, B. S. Jortner and M. Ehrich. *Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA.*

Organophosphorus compounds may induce a delayed neuropathy (OPIDN) having one of two patterns, namely Types I and II OPIDN (Abou-Donia and Lapadula, 1990). In this study we evaluated the distribution and extent of lesions of

OPIDN in White Leghorn hens as determined by staining of brain and spinal cord with hematoxylin and eosin (H&E) and a Fluoro-Jade, fluorescent stain for degenerating neurons and their processes. Hens were injected with single dosages of the Type I neurotoxicant phenyl saligenin phosphate (PSP, 2.5 mg/kg im), the Type II neurotoxicant triphenyl phosphite (TPPi, 500 mg/kg sc), or the vehicle dimethyl sulfoxide (DMSO, 0.5 ml/kg, im or sc). They were evaluated daily for clinical signs of neural dysfunction and sacrificed after one, two, and three weeks. PSP- and TPPi-injected hens displayed progressive neurological dysfunction beginning about one week post-administration. The brain and lumbar levels of spinal cord were prepared for microscopic study, as noted above. Samples of the nerve to the biventer cervicis muscle were also prepared for light microscopic examination. H&E stained sections from PSP-dosed hens revealed degenerating myelinated fibers in regions such as long spinal cord and medullary tracts. TPPi-dosed hens had these along with neuronal necrosis in spinal, brainstem and deep cerebellar regions. Staining with Fluoro-Jade revealed more profound and extensive time-dependent PSP- and TPPi-induced degeneration of nerve fibers, terminals, and cell bodies (for TPPi) in spinal, brainstem and cerebellar regions. Both compounds elicited peripheral nerve axonopathy progressing to Wallerian-like degeneration of a similar (severe) intensity. This study demonstrates the utility of Fluoro-Jade staining to reveal the extent of neuronal degeneration in OPIDN, and the presence of a peripheral neuropathy in the Type II form.

1547 A QUANTITATIVE HISTOCHEMISTRY TECHNIQUE FOR MEASURING REGIONAL DISTRIBUTION OF ACETYLCHOLINESTERASE AND BUTYRYCHOLINESTERASE IN THE BRAIN USING DIGITAL SCANNING DENSITOMETRY.

T. Ma, Z. Cai, S. E. Wellman and I. K. Ho. *Pharmacology & Toxicology, University of Mississippi Medical Center, Jackson, MS.*

Studies of brain acetylcholinesterase (AChE) are traditionally based on biochemical assays, immunoreactivity, and histochemistry. Conventional histochemistry yields rich morphological data from tissue sections but yields quantitative results only with great difficulty. Several histochemical methods developed in recent years, including microdensitometry, microphotometry and video-based histochemistry, are effective in quantitative and detailed study of AChE in tissue sections. However, they are usually time-consuming. As we report here, we adapted digital scanning densitometry to quantitate AChE histochemical staining in brain sections. The AChE and butyrylcholinesterase (BuChE), as measured by the method, were heterogeneously distributed throughout the brain, results that are consistent with those obtained by biochemical methods. The staining intensity is dependent on section thickness, substrate concentration, and reaction time. The cholinesterase inhibitor methyl paraoxon significantly decreased AChE staining intensity. Furthermore, data acquired from densitometry are similar to those obtained by video-based microscopy or by spectrophotometry. The advantage of the densitometric measurements compared to other quantitative histochemical methods is that it is very rapid, while collecting data that are equivalent in quality. Because the digital scanning densitometers provide high quality and sensitive imaging, wide dynamic ranges, and convenient image analysis software, they are very useful tools in quantitative histochemistry.

1548 MONITORING BLOOD ACETYLCHOLINESTERASE ACTIVITIES IN RATS GIVEN MULTIPLE DOSES OF ORGANOPHOSPHORUS COMPOUNDS.

M. Ehrich, K. Furhman, L. Correll, S. Hancock, L. Flory and B. S. Jortner. *Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA.*

Acetylcholinesterase (AChE) inhibitions in whole blood and brain were used to examine interactions of organophosphorus (OP) compounds in adult male Long-Evans rats given chlorpyrifos (60 mg/kg sc) followed in one week by oral tri-ortho-tolyl phosphate (TOTP, 75, 150 or 300 mg/kg) every other day for 2 weeks before sacrifice. AChE inhibition was monitored in blood 48 hr after dosing with chlorpyrifos, 5 days after initiating TOTP treatment, and on the day of sacrifice. At sacrifice, AChE activities in hippocampus, cortex, basal forebrain and caudate putamen of rats given only chlorpyrifos were 45% ± 5 (mean ± SE, n = 6), 33% ± 5, 43% ± 7, and 39% ± 7 of control, respectively. AChE activities in these brain regions after treatment with chlorpyrifos + 300 mg/kg TOTP were 23% ± 5, 18% ± 2, 25% ± 5, and 18% ± 2, respectively. AChE activities after chlorpyrifos + 300 mg/kg TOTP were in the range of 11 - 18% of control in brain regions from rats drinking corticosterone-treated water (400 ug/ml) beginning 1 week before chlorpyrifos administration. Chlorpyrifos caused blood AChE activities to drop to 45% ± 2 of control 48 hr after dosing with activity remaining this depressed at the time of the second bleeding, but returning to 85% ± 12 of control (considerably higher than in any brain regions) at time of sacrifice. Following chlorpyrifos and 5 days and 2 weeks of 300 mg/kg TOTP, blood AChE activities were 41% ± 11 and 31% ± 7 of control, respectively. Lower doses of TOTP caused less AChE inhibitions in both blood and brain. Corticosterone in drinking water did not alter blood AChE activities. Therefore, blood AChE activities provided dose-response data, although activities were significantly higher than in brain of rats given one OP compound (chlorpyrifos) weeks earlier. (Supported by DAMD 17-99-1-9489. This abstract does not necessarily reflect the position or policy of the US Government.)

1549 BEHAVIORAL CHANGES IN RATS GIVEN TRI-ORTHO-TOLYL PHOSPHATE (TOTP) AFTER CHLORPYRIFOS AND CORTICOSTERONE: LACK OF DOSE-RELATED CORRELATION WITH EFFECTS ON GLUTATHIONE PEROXIDASE, SUPEROXIDE DISMUTASE AND GFAP.

L. Correll, L. Flory, J. Hinckley, S. Hancock, D. Ward, M. Ehrich and B. S. Jortner. *Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA.*

Motor activity, a Functional Observational Battery (FOB), and passive avoidance were used to evaluate rats given tri-ortho-tolyl phosphate (TOTP) 75, 150 or 300 mg/kg po every other day for 2 weeks, beginning 1 week after a single administration of chlorpyrifos (60 mg/kg sc). In addition, half of the rats in each group were given corticosterone (400 ug/ml) in drinking water beginning 7 days before administration of chlorpyrifos. The behavioral endpoints were measured the day before dosing with chlorpyrifos, and 2 and 3 weeks later. Chlorpyrifos administration resulted in decreased beam breaks (an indicator of motor activity) in the presence and absence of corticosterone (p=0.007). TOTP decreased ambulation after 2 weeks of dosing. Chlorpyrifos exaggerated effects on motor activity and on limb grip strength caused by corticosterone treatment alone. No treatment affected passive avoidance. Biochemical studies at terminal sacrifice revealed that neither corticosterone, TOTP or chlorpyrifos had effects on glutathione peroxidase (GPx) or superoxide dismutase (SOD) activities in the cerebral cortex or hippocampus. Glial fibrillary acidic protein (GFAP) was elevated by all treatments (corticosterone, TOTP, chlorpryfos) in cerebral cortex, but effects were not dependent on dose of TOTP. These results indicate that each treatment had effects on behavior, but they were not dependent on alteration of enzymes indicative of oxidative stress (GPx, SOD). GFAP, however, appeared useful for identification of rats exposed either to corticosterone or organophosphates. (Supported by DAMD 17-99-1-9489. This abstract does not necessarily reflect the position or policy of the US Government.)

1550 THE ORGANOPHOSPHORUS NEUROTOXICANT TRIORTHOTOLYL PHOSPHATE CAUSES LIVER DYSFUNCTION IN RATS.

K. Zimmerman, M. Ehrich and B. S. Jortner. *Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA.*

The interactions of stress and exposure to neurotoxic chemicals are a matter of considerable interest in toxicology. In a study designed to evaluate these, young adult male Long-Evans rats were administered the following (alone or in various combinations): 400 ug/ml corticosterone in the drinking water (the stress model) from days 1-63;60 mg/kg sc chlorpyrifos on days 7 and 42; tri-otho-tolyl phosphate (TOTP, 75, 150 or 300 mg/kg) by gavage every other day from days 14-26 and 49-61. This portion of the study evaluated clinical chemistry and hematologic findings in the blood collected at sacrifice (day 63). Corticosterone exposure alone or in combination with chlorpyrifos produced no significant variation of analytes. However, a significant alteration in cholesterol concentration (mean 114 mg/dL compared to 85 mg/dL in controls, p = 0.017) occurred with TOTP exposure at 150 mg/kg. Exposure to TOTP at 300 mg/kg produced alterations in cholesterol (mean 125 mg/dL, p = 0.003) and alanine aminotransferase (ALT) activity (mean 142 U/L compared to 52 U/L in controls, p = 0.041). TOTP at 75 and 150 mg/kg combined with corticosterone and chlorpyrifos individually or in combination produced significant alterations in cholesterol concentrations (mean range 127 - 171 mg/dL, p = 0.028 - 0.056). In addition, TOTP at 300 mg/kg, combined as described above, resulted in alteration in albumin concentration (mean 2.8 g/dL p = 0.055), albumin globulin ratio (mean 0.073, p = 0.055), urea nitrogen concentration (mean 13.3 mg/dL, p = 0.001), cholesterol (mean 131 mg/dL, p = 0.030), and ALT activity (mean 153 U/l, p = 0.032). Therefore, multiple administration of TOTP to Long Evans male rats at doses of 75 mg/kg and greater appears to alter hepatocellular membrane permeability and cholesterol metabolism, and TOTP at 300 mg/kg resulted in reduced hepatic function. (Supported by DAMD 17-99-1-9489. This abstract does not necessarily reflect the position or policy of the US Government.)

1551 LOW-LEVEL SOMAN EXPOSURE LEADS TO SYNAPTIC DAMAGE IN THE HIPPOCAMPUS AND POTENTIATES NEURONAL VULNERABILITY.

S. Munirathinam and B. A. Bahr. *Dept. of Pharmaceutical Sciences and the Neurosciences Program, University of Connecticut, Storrs, CT.*

Hippocampal slice cultures were used to examine the action of the organophosphate agent soman (GD). Soman is known to inhibit acetylcholinesterase, causing accumulation of ACh, but it also appears to increase glutamate release to promote seizure-related damage. In the present study, the effects of low concentrations of soman on hippocampal tissue were assessed over an extended series of exposures. Single application was used to induce a period of toxicity until agent hydrolysis, and this was repeated daily for one week. No evidence of degeneration was found after the first day of treatment, however, dose-dependent declines in pre- and post-synaptic proteins occurred after a week. The decline in synaptophysin was evident at the 100-nM dose of soman, and further reduction was found at 20 μM (ANOVA: p=0.001, F=9.7). Synaptophysin was reduced throughout the hippocampus, especially in dendritic fields of CA1 and in the molecular layer of the dentate gyrus. Synaptic toxicity appears first since overt cellular pathology was not visible in the three subfields. The decline in the postsynaptic GluR1 subunit was only evident at the 20-μM soman dose ($p<0.001$, F=11.8). Soman also elicited a pronounced increase ($p<0.01$) in spectrin breakdown mediated by calpain, a protease known to cause neurodegeneration in response to glutamate-induced excitotoxicity. Interestingly, while no degeneration was found after the first day of soman treatment, pathogenic changes did occur when the soman insult was combined with a trimethyltin (TMT) insult - TMT is known to cause seizures and hippocampal damage. A 1-h TMT exposure did not cause appreciable synaptic deterioration or spectrin breakdown in control slices, however, robust levels of degeneration were evident when such a TMT insult was followed by a single application of soman. Thus, low-level soman exposure causes synaptic damage in the hippocampus and potentiates vulnerability to other types of toxic insults. Supported by US Army Med.. Res. grant DAMD17-99-C9090, and NIH grant 1R43NS38404-01.

1552 ACUTE EXPOSURE TO SARIN INCREASES BLOOD-BRAIN BARRIER (BBB) PERMEABILITY AND INDUCES NEUROPATHOLOGICAL CHANGES IN THE RAT BRAIN.

M. B. Abou-Donia, A. A. Abdel-Rahman and A. K. Shetty. *Pharmacology and Cancer Biology and Neurosurgery, Duke University Medical Center and VA Medical Center, Durham, NC.*

We evaluated the early changes in the adult brain of male Sprague-Dawley rats following single i.m injection of 1, 0.5, 0.1, and 0.01xLD50 of sarin. Twenty four h after treatment, both sarin-and vehicle-treated control animals were processed for: 1) BBB permeability, 2) brain acetylcholiesterase (AChE) and plasma butyrylcholinesterase (BChE) activity, 3) brain m2 muscarinic acetylcholine receptor (m2 mAChR) ligand binding, and 4) histopathological examination of brain. Animals treated with 1 and 0.5 x LD50 exhibited a significant inhibition of BChE activity, while 1 x LD50 caused a significant inhibition of AChE in the cerebrum, brainstem, midbrain, and cerebellum. Ligand binding to m2 mAChR was decreased in cerebrum and showed a significant increase in brainstem. Analysis of [3H]hexamethonium iodide uptake demonstrated a significant increase in BBB permeability in animals treated with1 x LD50. The LD50 dose caused significant decrease in the expression of BBB protein, a diffuse neuronal cell death and a decrease in MAP-2 positive elements within the cerebral cortex and hippocampus, and degeneration of Purkinje cells in the cerebellum. Animals treated with 0.5, 0.1, or 0.01 x LD50 did not exhibit the above changes expect in the cerebellum, where animals treated with 0.5 x LD50 showed Purkinje neuron loss. Thus, the early brain damage after acute exposure to sarin induces significant injury in many regions of the adult brain by 24 h after exposure. The early neuropathological changes observed after a single 1x LD50 sarin could lead to a profound long-term neurodegeneration in many regions of the brain, and neurobehavioral abnormalities. Supported, in part by the US Army Medical Research and Materiel Command under contract DAMD 17-98-C-8027.

1553 LOW-LEVEL SARIN VAPOR EXPOSURE IN RATS: EFFECT OF EXPOSURE CONCENTRATION AND TIME ON PUPIL SIZE.

R. J. Mioduszewski[1], J. A. Manthei[1], R. A. Way[1], D. C. Burnett[1], B. P. Gaviola[1], W. T. Muse[1], S. A. Thomson[1], D. R. Sommerville[1], R. B. Crosier[1], C. L. Crouse[2], K. L. Matson[2] and D. A. McCaskey[2]. [1]*Operational Toxicology, US Army Chemical Biological Center, Aberdeen Proving Ground, MD and* [2]*GeoCenters, Inc., Abingdon, MD.*

Sarin (GB) vapor exposure is associated with both systemic and local toxic effects occurring primarily *via* inhalation and ocular routes, respectively. The objective of this study was to develop a model for predicting dose-response effects (miosis) of GB vapor concentration as a function of exposure duration. Groups of male and female rats (Sprague-Dawley) were exposed to one of a series of GB vapor concentrations for a single duration (10, 60 or 240 minutes), in a whole-body dynamic chamber. Separate effective concentrations for miosis (defined as a post-exposure pupil diameter 50% or less of the pre-exposure pupil diameter) in 50% of the exposed population (EC50) and corresponding dose-response slopes were determined for each exposure duration by the Bliss probit method. In addition, blood esterase activities (acetylcholinesterase, butyrylcholinesterase and carboxylesterase) were measured before and after each exposure. Pupil constriction was the only clinical sign noted, given the GB vapor exposure conditions used in this study. Overall, female rats were more sensitive than male rats to GB vapor-induced miosis. Linear regression analysis was used to derive a model of low-level GB vapor-induced pupil diameter changes in the rat as a function of exposure concentration and time. Contrary to that predicted by Haber's Rule, ECT50 values increased with exposure duration (i.e., the CT for 50% of the exposed population to show miosis was not constant over time). Blood esterase activities were not significantly inhibited by the low-level exposures of GB vapor used in this study.

1554 CHARACTERIZATION OF A *S*-HEXAHYDRO-1*H*-AZEPINE-1-CARBONYL ADDUCT PRODUCED BY MOLINATE ON RAT HEMOGLOBIN β2 AND β3 CHAINS *IN VIVO*.

L. J. Zimmerman, H. S. Valentine, K. Amarnath and W. M. Valentine. *Pathology, Vanderbilt University, Nashville, TN.* Sponsor: W. Valentine.

Molinate is a thiocarbamate herbicide used in the rice industry for over 25 years and has been shown to produce testicular toxicity in male rats. It is has been proposed that bioactivation of molinate *via* sulfoxidation to form the sulfoxide and sulfone metabolites capable of protein binding, may be involved in molinate-induced toxicity. Based on previous *in vitro* studies, carbamylation of an active site serine residue in Hydrolase A has been proposed to be the mechanism responsible for the observed testicular toxicity. The experiments presented here utilize hemoglobin to characterize covalent protein modifications produced *in vivo* by molinate in rats dosed intraperitoneally as a function of exposure duration. Examination of globin from molinate-treated rats by HPLC demonstrated a new peak in the isolated samples that when collected and analyzed using MALDI-TOF MS, revealed a 126 Da increase in mass relative to the native β3 chain. Digestion of the globin using Glu-C and analysis by MALDI-TOF MS revealed two modified peptide fragments at *m/z* 2743 and 4985 consistent with a 126 Da increase to peptide fragments [122-146] and [102-146] in the unmodified β2 and β3 chains of globin. Selected reaction monitoring LC/MS/MS was used to detect the presence of *S*-hexahydro-1*H*-azepine-1-carbonyl cysteine (HHAC-Cys) in the globin hydrolysates isolated from the molinate-treated rats and to confirm the structure of the modification. These experiments demonstrate the ability of molinate to covalently modify proteins *in vivo* in a dose dependent manner *via* carbamylation at Cys-125, similar to the modification produced by disulfiram and *N, N*-diethyldithiocarbamate. The ability of molinate to covalently modify cysteine residues provides a potential mechanism to account for enzyme inhibition following molinate exposure and suggests that enzymes with cysteine residues in their active site may be inhibited by molinate. These results may also extend to other structually related pesticides.

1555 GLUTATHIONE DEPLETION IN RAT PRIMARY HEPATOCYTES AND LIVER BY N-METHYLDITHIOCARBAMATE (NMDC) AND N, N-DIMETHYLDTHIOCARBAMATE (DMDC).

R. W. Thompson and W. M. Valentine. *Pathology, Vanderbilt University Medical Center, Nashville, TN.*

Several decomposition and metabolic pathways are shared by the commercially used monoalkyl and dialkyl dithiocarbamates that can alter intracellular thiol status. This investigation examines the role of glutathione in the cytotoxicity of dithiocarbamates and investigates the primary mechanisms responsible for glutathione depletion by NMDC and DMDC in cultured primary hepatocytes and perfused rat liver. Because monoalkyl dithiocarbamates can acylate intracellular thiols *via* generation of an isothiocyanate (ITC) intermediate, the contribution of ITC to the cytotoxicity of NMDC was also determined. Viability was assessed in hepatocyte cultures by LDH release while reduced, oxidized and S-methylthiocarbamoyl glutathione (GSMITC) levels were determined using HPLC and LC/MS/MS in both cultured hepatocytes and bile samples. The cytotoxicity for both NMDC and DMDC was inversely correlated with intracellular levels of GSH. Although hepatocytes exposed to either NMDC or DMDC had diminished intracellular levels of GSH, DMDC appeared to oxidize GSH to GSSG whereas NMDC exposure resulted in generation of GSMITC. In bile samples, GSMITC was also detected

within 5 minutes of infusion of NMDC into the liver, however GSSG was not elevated upon DMDC exposure. These results demonstrate that distinct processes involved in lowering glutathione levels in hepatocytes following incubation with NMDC or DMDC. For the monoalkyl dithiocarbamate generation of the reactive ITC followed by acylation of cellular thiols appears to play a significant role. The rapid appearance of GSMITC in bile samples from NMDC infused livers indicate that enzymatic systems may be involved. In contrast, dialkyl dithiocarbamates altered intracellular thiol status in cultured hepatocytes by oxidation of GSH but a similar observation was not obtained in the perfused liver experiments. It is anticipated that the results obtained for these two dithiocarbamates may be applicable to other monoalkyl and dialkyl dithiocarbamates.

1556 ETHYLENE-*BIS*-DITHIOCARBAMATES CAN INHIBIT ISOLATED BRAIN AND LIVER MITOCHONDRIA.

V. A. Fitsanakis[1,2], V. Amarnath[3] and T. J. Montine[1,2,3]. *[1]Center for Molecular Neuroscience, Vanderbilt University, Nashville, TN, [2]Center for Molecular Toxicology, Vanderbilt University, Nashville, TN and [3]Pathology, Vanderbilt University, Nashville, TN.*

Dithiocarbamate (DTC) pesticides, such as maneb (manganese ethylene-*bis*-dithiocarbamate (EBDTC)), have been reported in the literature to cause parkinsonian symptoms in certain individuals. Recent data from other labs have also demonstrated that mice treated with maneb show neurodegeneration, which is specific to the striatum. Our hypothesis is that maneb can initiate this neurodegeneration through the production of reactive oxygen species. One mechanism by which maneb could facilitate the formation of free radicals is through inhibition of mitochondrial respiration. Brain and liver mitochondria, isolated from C57 Bl/6 male mice, were treated with various concentrations of DTC compounds in oxygen consumption chambers equipped with oxygen sensing electrodes. Two classes of DTCs, EBDTC and diethyldithiocarbamate (DEDC), were used in order to determine the relative importance of the organic or metal constituent in inhibiting respiration. Maneb, zineb (Zn(EBDTC)), (NH_4)EBDTC, and $Mn(DEDC)_2$ were all shown to inhibit mitochondria in the nmol / mg protein range when glutamate / malate was used as a substrate for complex I. Furthermore, brain mitochondria were more severely inhibited than liver mitochondria, suggesting a mechanism for brain selectivity. The potency of compounds for brain mitochondria was $Mn(DEDC)_2$ > EBDTC > maneb ≈ zineb. For liver mitochondria the potency was zineb > $Mn(DEDC)_2$ > EBDTC > maneb. This data suggests that, for mitochondrial inhibition, the organic moiety plays a more significant role than the metal in reducing mitochondrial respiration.

1557 MANEB AND PARAQUAT EFFECTS ON ANTIOXIDANT SYSTEMS IN PC12 CELLS.

D. Lee, D. A. Cory-Slechta and L. A. Opanashuk. *Environmental Medicine, University of Rochester, Rochester, NY.*

Environmental chemical exposures are potential risk factors for Parkinson's disease (PD). Recently, combined paraquat (PQ) and maneb (MB) exposure were shown to produce synergistic effects in the nigrostriatal dopamine system *in vivo*. Although PQ is a redox cycling compound, the mechanisms by which MB or combined agrichemical exposures produce neurotoxicity are unresolved. In this study, PC12 cells were used as a model to assess the effects of MB and evaluate mechanisms of neurotoxicity following combined agrichemical exposure. Cultures were exposed to various concentrations of MB, PQ and combined PQ+MB for 6-48 h then assayed for cell viability by measuring lactate dehydrogenase (LDH) release into the culture media. LDH levels did not differ between control and treated cells until 48 hours, where there was a slight concentration-dependent elevation in both the MB and combined treatment groups. To assess intracellular redox status, total glutathione (GSH) was enzymatically measured following treatments. Total intracellular GSH increased between 6h and 24h following MB treatment, with maximal levels reaching 225% of control. By 48h, GSH levels remained elevated in cells treated with the highest concentration of MB alone. In combined MB+PQ treatment groups, GSH levels declined by 30% in the lower dose combination groups after 24 hours, compared to MB treatment alone. Higher dose combinations resulted in a more robust elevation of intracellular GSH, which increased with treatment duration. To further evaluate antioxidant defense systems, CuZn- and Mn-SOD protein levels were monitored by immunoblot analysis. At 6 hours, CuZn SOD levels were elevated following treatment with both low and high dose combinations compared to MB alone. SOD expression was increased after 24h by MB and PQ treatments alone. However, SOD levels declined below control in both dose combination groups. These findings suggest that interactions between MB and PQ disrupt cellular antioxidant defense systems, ultimately resulting in altered cellular homeostasis and function. Supported by NIH ES10791 and ES01247.

1558 GENDER DIFFERENCES ASSOCIATED WITH DEVELOPMENTAL AND ADULT EXPOSURE TO PARAQUAT AND MANEB.

M. Thiruchelvam, E. K. Richfield, B. M. Goodman and D. A. Cory-Slechta. *Department of Environmental Medicine, University of Rochester School of Medicine & Dentistry, Rochester, NY.*

Parkinsons disease (PD), an aging neurological disorder, for unknown reasons is more prevalent in males than females. While the etiology of PD remains unclear, environmental factors are strongly implicated. We have previously demonstrated that combined exposure to paraquat (PQ) and maneb (MB) produces an early irreversible PD phenotype, including potentiated reductions in locomotor activity and loss of nigrostriatal dopamine neurons in adult male mice. To determine whether gender effects are observed with this model, male and female C57BL/6 mice were exposed developmentally to saline, 0.3 mg/kg PQ, 1 mg/kg MB or PQ+MB from postnatal (PN) day 5-19. A subset of these mice was re-challenged as adults (AD) with saline, 10 mg/kg PQ, 30 mg/kg MB or PQ+MB. A separate group was exposed only as adults. PN exposure to PQ+MB decreased locomotor activity similarly in males and females at 6 weeks of age. By 6 months of age, PQ+MB treated males showed a progressive decrease in activity compared to 6 weeks of age, whereas the females showed a progressive recovery, with activity levels returning to control levels at this time-point. Consistent with this, PN only exposure significantly decreased striatal DA, DOPAC and HVA levels in males and females exposed to PQ alone and PQ+MB, with greater decreases observed in males. PN + AD exposure significantly decreased striatal DA, DOPAC and HVA in all male treatment groups to a greater extent compared to PN alone exposure. In contrast, DA and metabolite levels in PN + AD females treated with PQ and MB alone and in combination were not significantly reduced. The males showed a significantly greater decrease compared to the females. Further, females exhibited full recovery, but males only partial recovery of locomotor activity following AD only exposure to PQ+MB. These data suggest protective mechanism(s) in females that may be provided by estrogen, which has repeatedly been demonstrated to be a neuroprotective agent against dopaminergic neurotoxicants.

1559 FIXED RATIO (FR) SCHEDULE-CONTROLLED BEHAVIOR IN RATS FOLLOWING EXPOSURES TO PARAQUAT AND MANEB.

M. R. Bauter, D. A. Cory-Slechta, M. J. Thiruchelvam, B. M. Goodman and S. Y. Stevens. *Environmental Medicine, University of Rochester School of Medicine and Dentistry, Rochester, NY.*

Previous studies have shown that combined exposure to paraquat (PQ) and maneb (MB) produce potentiated, selective and irreversible neurotoxicity to the nigrostriatal dopamine (DA) system in C57BL/6 mice. This includes sustained reductions in locomotor activity, loss of DA and of DA neurons in the substantia nigra and serves as a model of early environmental Parkinsonism (PD). To determine the species generality of these effects, and attempt to develop a comparable rat model of PD, male Long Evans rats were trained to lever press for food reinforcement on a FR schedule. Reductions in response rates on FR schedules have been related to DA loss in the nigrostriatal DA system as induced by the neurotoxicant 6-OHDA. Thus, it was utilized here as a means of preclinical detection of DA loss. The FR requirement was increased to an FR 40 and continued until a stable baseline was attained. Rats were then treated twice a week for 3 weeks with saline, 10mg/kg PQ, 30mg/kg MB, or PQ+MB for a total of 5 doses. PQ and MB administered alone produced marginal decreases in overall response rates (OR) and run rates (RR) compared to control on the FR schedule. Administration of combined PQ+MB resulted in decreases in both measures that appeared to increase in magnitude with successive doses. For 24 hr post-dosing, OR and RR in the PQ or MB alone groups had fully recovered to control levels, whereas rates in the combined PQ+MB showed residual reductions and only returned to control levels 48 hr post-dosing. This 24 hr post-dosing reduction in FR rates in the PQ+MB group also seemed to increase with successive treatments. Rats are known to be resistant to MPTP, the commonly used neurotoxicant model of PD. Unlike MPTP, however, PQ+MB seem to exert greater effects in the rat than were observed in mice where total regimens of 12 injections using these same doses of PQ+MB were administered without any signs of overt toxicity. 1560 PARAQUAT TOXICITY IS NOT MEDIATED BY THE DOPAMINE TRANSPORTER.

Y. Quan and G. W. Miller. *Division of Toxicology and Pharmacology, University of Texas at Austin, Austin, TX.*

Parkinson's disease is characterized by the loss of nigrostriatal dopaminergic neurons and the resultant loss of dopamine input to the striatum is thought to cause the clinical symptoms. Pesticide exposure is considered to be a risk factor for

Parkinson's disease. The herbicide paraquat has been suggested as a candidate environmental agricultural chemical risk factor due to its structural similarity to 1-methyl-4-phenylpridinium ion (MPP+), the active component of dopaminergic neurontoxin 1-methyl-4-phenyl-1, 2, 3, 6-tetrahydropyridine (MPTP). In addition, mice treated with combined paraquat and maneb exhibit the toxicity in the nigrostiatal dopamine system. Our Lab. had generated an inducible system for dopamine transporter (DAT) in SK-N-MC neuroblastoma cell line. Using this system, we have already shown that MPP+ toxicity corresponded with DAT expression. To determine the role of DAT in paraquat neuron toxicity, we tested the effect of paraquat in the DAT-mediated dopamine uptake. Only the 10mM paraquat partially inhibited the dopamine uptake (~20%). Furthermore we treated the inducible DAT cell line with serial concentrations of paraquat (0, 0.05, 0.1, 0.2, 0.25, 0.5, 0.75, 1 mM). The toxicity corresponded with the concentration of paraquat (the cell viability was from 90%-26%), but was independent of the DAT expression level while the MPP+ toxicity corresponded to the DAT expression level. These findings indicate that while paraquat and MPP+ have similar chemical structures, paraquat is not transported by DAT. Future studies should be aimed at identifying the mechanism by which paraquat targets the dopamine neuron. (Supported by NIH ES-09248, ES-07784, and NS-37031)

1561 MODULATION OF MURINE STRIATAL DOPAMINE TRANSPORTER EXPRESSION BY THE PYRETHROID INSECTICIDE PERMETHRIN.

J. S. Gillette and J. R. Bloomquist. *Entomology, Virginia Polytechnic and State University, Blacksburg, VA.*

The pyrethroid insecticide permethrin may play a role in the development of Parkinson's disease as a consequence of Gulf War Syndrome. Previous work in our laboratory has shown that an i.p. dose of 1.5 mg/kg permethrin in the C57BL/6 mouse causes a significant increase in striatal dopamine uptake to 125% of control values. Recently, we have dosed C57 mice with either 0.8 or 1.5 mg/kg permethrin (3 i.p. injections over 2 weeks). To assess reversibility of effects on striatal dopamine transporter (DAT), a portion of the mice were sacrificed on the day following the last dose (t=0), while a second group was sacrificed 2 weeks post last treatment (t=2), and a third group 4 weeks post last treatment (t=4). At t=0, DAT protein as assayed by Western blotting was increased 119% and 107% in the 0.8 and 1.5 mg/kg group, respectively, over that of control mice. DAT binding was analyzed by incubating the ligand [^{3}H]GBR 12935 with striatal synaptosomes from control and treated mice. [^{3}H]GBR 12935 binding was increased 156% and 118% in mice treated with 0.8 and 1.5 mg/kg permethrin, respectively. Preliminary evidence suggests that this effect is persistent, since DAT protein was likewise elevated in the t=2 group of mice. Due to its effects on mouse DAT, the ability of permethrin to synergize the effects of the neurotoxin MPTP was ascertained. MPTP (30 mg/kg) was administered to C57BL/6 mice on day 1 of the treatments, followed the next day by administration of various doses of permethrin from 0.8 mg/kg to 200 mg/kg. Striatal dopamine and its metabolite, DOPAC, were determined by HPLC-ECD. Only the highest dose of permethrin (200 mg/kg) in combination with MPTP was able to deplete dopamine significantly greater than MPTP alone. However, DOPAC titers were significantly elevated at doses above 50 mg/kg permethrin, suggesting an increase in dopamine turnover. Taken together, these data suggest that insecticides such as permethrin may have subtle effects on the dopaminergic system, and may be involved in the etiology of Parkinson's disease.

1562 DECREASE OF DOPAMINE LEVELS AFTER PYRETHROID TREATMENT.

A. Anadon, M. A. Martinez, M. Martinez, M. J. Diaz, M. T. Frejo, V. J. Castellano, M. E. Morales and M. R. Martinez-Larranaga. *Toxicology & Pharmacology, Complutense University, Madrid, Spain.*

Cyfluthrin and Cyhalothrin, Type II pyretroid insecticides, are used topically for the control of ectoparasites. Cyfluthrin and Cyhalothrin when injected peripherally to rat produced a severe syndrome characterized by tremor, salivation and choreoathetosis. Because of toxicological data are needed to further define the use safety of these insecticides, the objective of the present study was to investigate neurochemical effects following the administration of Cyfluthrin (14 mg/kg/day, orally for 6 days) or Cyhalothrin (8 mg/kg/day, orally, for 6 days) in male Wistar rats (n =6/group). Animals were sacrificed 24 hours following pyrethroid administration and their brains were rapidly removed. The frontal cortex, midbrain and striatum were dissected and analyzed for content of dopamine (DA) and its metabolites dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA) using a HPLC method with electrochemical detection. A dopamine depleting effect was produced by these pyrethroids. Cyfluthrin decreased DA, DOPAC and HVA levels in frontal cortex (29%, P<0.01; 48%, P<0.001and 20%, P<0.05), midbrain (22%, P<0.05; 23%, P<0.01and 33%, P<0.01) and striatum (23%, P<0.05; 21%, P<0.05 and 29%, P<0.001) respect to corn oil controls. Similarly, Cyhalothrin decreased DA, DOPAC and HVA levels in frontal cortex (64%, P<0.01; 30%, P<0.01and 14%), midbrain (19%, P<0.05; 31%, P<0.01and 13%) and striatum (28%, P<0.05; 3% and 39%, P<0.001) respect to corn oil controls. These findings indicate that a lower activity of dopaminergic system exists in the action of Cyfluthrin and Cyhalothrin. This work has been supported by projects No. PB9701236, (DIGICYT), No. 08.8/0002/98 (CAM) & No. 99/0936 (FIS), Spain.

1563 NEURON DEGERNERATION INDUCED BY SUBCHRONIC APPLICATION OF N, N-DIETHYL M-TOLUAMIDE (DEET) AND PERMETHRIN, ALONE AND IN COMBINATION TO RATS.

A. A. Abdel-Rahman, A. K. Shetty and M. B. Abou-Donia. *Pharmacology and Cancer Biology and Neurosurgery, Duke University Medical Center and VA Medical Center, Durham, NC.*

Histopathological alterations in the brain of adult male rats were evaluated following a daily dermal dose of DEET (40 mg/kg in 70% ethanol) or permethrin (0.13 mg/kg in 70% ethanol) or a combination of the two for 60 days. Control rats received a daily dermal dose of 70% ethanol for 60 days. Animals were perfused and brains were processed for morphological and histopathological analyses following the above regimen. In animals receiving either DEET or Permethrin, degenerating (eosinophilic) neurons were diffusely observed in distinct regions of the motor and somatosensory cortex, the hippocampus, and the cerebellum. In contrast, dying neurons were infrequent in animals receiving both DEET and Permethrin. The density of surviving neurons in cerebral cortex, hippocampus and cerebellar Purkinje cell layer of these animals, however, was dramatically less than control animals, suggesting that in animals receiving both DEET and permethrin neuronal cell death occurred earlier than animals receiving either DEET or permethrin alone. Analysis of glial fibrillary acidic protein immunoreactivity revealed significant hypertrophy of astrocytes in all three treated groups with maximal changes in rats receiving both DEET and permethrin. Further, surviving neurons in the latter group exhibited abnormal dendrites. Thus, sub-chronic dermal application of DEET and permethrin either alone or in combination leads to diffuse neuronal cell death in cerebral cortex, hippocampus and cerebellum of the adult brain; the neurotoxic effect is more pronounced when DEET and permethrin are applied together. Collectively, the above alterations can lead to many physiological, pharmacological and behavioral abnormalities, particularly motor and sensory deficits and learning and memory dysfunction. Supported in part by the US Army Medical Research and Materiel Command under Contract DAMD 17-99-1-9020.

1564 MECHANISMS OF PYRETHROID NEUROTOXICITY: IMPLICATIONS FOR CUMULATIVE RISK ASSESSMENT.

D. M. Soderlund[1] and L. P. Sheets[2]. [1]*Entomology, Cornell University, Geneva, NY and* [2]*Bayer Corportation, Stilwell, KS.*

The Food Quality Protection Act (FQPA) of 1996 requires the USEPA to consider the cumulative effects of exposure to pesticides having a "common mechanism of toxicity." This presentation reviews published and proprietary data on the neurotoxicity and mechanisms of toxic action of pyrethroid insecticides in mammals as pertains to this statute. The principal effects of pyrethroids in mammals are various signs of excitatory neurotoxicity. Historically, pyrethroids were grouped into two subclasses (Type I and Type II), based on chemical structure and the associated syndrome of intoxication (T (tremor) or CS (choreoathetosis with salivation). However, this classification system is inadequate for identification of common toxic effects. In particular, it does not reflect the diversity of toxic signs evident following oral administration of the various pyrethroids. With respect to mechanisms of toxicity in mammals, pyrethroids act *in vitro* on a variety of putative biochemical and physiological target sites that merit consideration as sites of toxic action. Voltage-sensitive sodium channels, the sites of insecticidal action, are also important target sites in mammals. However, unlike insects, mammals have many sodium channel isoforms that vary in their biophysical and pharmacological properties, including their sensitivity to various pyrethroids. Pyrethroids also act on some isoforms of voltage-sensitive calcium and chloride channels and these may contribute to toxicity. Effects on peripheral-type benzodiazepine receptors are unlikely to be a principal cause of pyrethroid intoxication but may contribute to convulsions caused by actions at other target sites. Other putative target sites that have been identified *in vitro* do not appear to play a major role in pyrethroid intoxication. The diverse toxic and pharmacologic effects of pyrethroids suggest that simple additivity models, based on combined actions at a single target, are not appropriate to assess cumulative risk.

1565 AN HPLC METHOD FOR THE DETERMINATION OF MAJOR PERMETHRIN METABOLITES AND PERMETHRIN METABOLISM IN HUMAN LIVER.

J. Choi, R. L. Rose and E. Hodgson. *Department of Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC.* Sponsor: E. Hodgson.

An efficient high performance liquid chromatography (HPLC) method was developed to separate and quantitate two permethrin isomers and three major metabolic products (phenoxybenzyl alcohol, phenoxybenzoic acid and phenoxybenzaldehyde), which were produced in studies of *in vitro* human metabolism using human liver fractions. Two hundred and thirty nanometers was found to be the most sensitive detection wavelength for permethrin isomers and metabolites among 4 previously used wavelengths (210, 230, 254 and 270 nm). Detection limits at 230 nm were 12 nM for phenoxybenzoic acid and 24 nM for all other compounds. A gradient elution using two solvents was used with the initial mobile phase condition of 50 % of solvent B (100 % water adjusted to pH 1.7 with phosphoric acid) and 50 % of solvent A (90 % acetonitrile and 10 % water, v/v). A pH of less than 2 was required for solvent B to fully protonate and separate an ionizable metabolite, phenoxybenzoic acid. Retention times were 3.7, 4.1, 5.9, 10.2 and 10.5 minutes for phenoxybenzyl alcohol, phenoxybenzoic acid, phenozybenzaldehyde, trans-permethrin and cis-permethrin, respectively. When trans-permethrin was incubated with human liver fractions, phenoxybenzyl alcohol and phenoxybenzoic acid were the major products. Trans-permethrin incubation with 12 individual human cytochrome P450 isozymes did not produce any significant amounts of metabolites. Addition of NAD^+ to human liver microsomal fraction significantly increased the production of phenoxybenzoic acid with a minimum amount of phenoxybenzyl alcohol detected. An incubation of phenoxybenzyl alcohol and phenoxybenzaldehyde metabolism with horse liver alcohol dehydrogenase and yeast aldehyde dehydrogenase resulted in significant levels of phenoxybenzaldehyde and phenoxybenzoic acid formation respectively. These results suggested that permethrin hydrolysis products in human liver may be further metabolized by NAD^+ requiring alcohol and aldehyde dehydrogenases without cytochrome P450 involvement.

1566 INDUCTION OF CYTOCHROME P4501A1/2 AND P4504A1 ACTIVITIES BY PYRETHROIDS.

M. R. Martinez-Larranaga, M. J. Diaz, M. A. Martinez, M. Martinez, M. T. Frejo, V. J. Castellano, R. Fernandez and A. Anadon. *Toxicology and Pharmacology, Complutense University, Madrid, Spain.*

The objective of the present study was to investigate the effects of repeated exposure to Cyfluthrin or Cyhalothrin, Type II pyretroid insecticides, on hepatic mixed function oxidase activities in male Wistar rats following oral administration. Animals were treated with Cyfluthrin (20 mg/kg/day orally for 6 days) or cyhalothrin (8 mg/kg/day orally for 6 days); control animals received orally corn oil. Pyrethroid-treated and control animals were sacrificed 24 hours after the last administration and livers were removed. The livers were individually homogenized and microsomal pellets were prepared and stored at –80°C for enzyme determinations. O-demethylation of metoxyresorufin (MROD) and O-deethylation of ethoxyresorufin (EROD) were determined from appearance of resorufin measured fluorimetrically. Finally 11- and 12-hydroxylations of lauric acid were also determined on the microsomal fraction by a HPLC method with radiochemical detection. **Effects of pyrethroids on rat hepatic mixed function oxidase system:** Results are significantly different from the control value at *P<0.05, **P<0.01, or ***P<0.001 These findings may prove a valuable contribution for risk assessment of these insecticides. This work has been supported by projects No. PB9701236, (DIGICYT), No. 08.8/0002/98 (CAM) & No. 99/0936 (FIS), Spain.

1567 COMPARISON OF DIETARY AND ORAL GAVAGE ADMINISTRATION OF BIFENTHRIN IN DEVELOPMENTAL TOXICITY STUDIES IN SPRAGUE-DAWLEY RATS.

J. D. McCarty, C. Freeman and B. A. Watt. *Toxicology, FMC Corporation, Princeton, NJ.* Sponsor: J. McCarty.

Bifenthrin, a synthetic pyrethroid insecticide/miticide, was tested in two developmental toxicity studies in Sprague-Dawley rats. Bifenthrin was administered at 5 ml/kg/day *via* gavage to groups of 25 rats as a solution in corn oil at dosages of 0, 0.5, 1.0 and 2.0 mg/kg/day on days 6 through 15 of gestation. Intermittent tremors were seen among animals receiving 2.0 mg/kg between days 10 and 19 of the study. There were no treatment-related effects observed on body weight gains, food consumption, pregnancy, number of implantations, resorptions, litter size, external or internal anomalies (c-sections on day 20). There were no effects at 1.0 mg/kg or below. In the second study, bifenthrin was administered in the diet at dose levels of 0, 30, 90 and 200 ppm on days 6-20 of gestation. Treatment-related clinical signs included tremors, hypersensitivity to sound, piloerection and splayed hindlimbs at 200 ppm. Significant reductions in maternal body weights and gains, adjusted maternal body weights and food consumption were noted at 200 ppm. At c-section on day 20, there were no significant differences in number of implants, pre-implantation loss, litter-size, the percentage of live and dead fetuses, percentage of early and late resorptions, fetal body weights and fetal sex ratios or fetal or litter incidence of external, visceral or skeletal findings. The No Observed Effect Level was 90 ppm (7.4 mg/kg/day), based on clinical signs at 200 ppm (16.3 mg/kg/day). The use of corn oil as a vehicle allows for dosing using oral gavage and measurement of the dose each animal receives, however, it results in delivery of a bolus dose into the stomach in an unrealistic vehicle. Administration of bifenthrin in the diet more closely approximates the route of exposure for the human population exposed to small amounts of bifenthrin in their diet.

1568 PESTICIDE TOXICITY IN THYMOCYTES IS RELATED TO OXIDATIVE STRESS.

S. Olgun and H. P. Misra. *Biomedical Sciences and Pathobiology, VA Tech College of Veterinary Medicine, Blacksburg, VA.*

Pesticides are widely used in the environment, and exposure to multiple pesticides is very likely, either concurrently or sequentially, over one's lifetime. We have found that selected pesticides lindane (L; an organochlorine), malathion (M; an organophosphate), and permethrin (P; a pyrethroid) are cytotoxic to murine (C57Bl/6) thymocytes in both concentration- and time- dependent manner, *in vitro*. Based on minimum cytotoxicity ($\leq LC_{30}$ with individual pesticides), the following concentrations were chosen: 50 µM L, 75 µM M, 150 µM P, 50 µM L + 75 µM M mixture, and 50 µM L + 150 µM P mixture. These concentrations of pesticide caused 16.6, 21.5, 29.0, 59.8 and 53.3 % cell death (examined by 7 aminoactinomycin-D assay), respectively. To investigate the role of oxidative stress in causing cytotoxicity, we monitored both the pro- and anti-oxidant status of cells. The generation of hydrogen peroxide (H_2O_2), an indicator of pro-oxidant status of cells, was monitored by CM-H_2 DCFDA assay. Exposure to above concentrations of pesticides for 15 min augmented the H_2O_2 production in cells (L 37.2, M 39.2, P 40.5, L+M mix 52.4 and L+P mix 50.6 % over control). The effects of above concentrations of pesticide exposure to the cells for 12 hr on activities of catalase (CAT), superoxide dismutase (SOD), glutathione peroxidase (GSH-Px) and glutathione reductase (GSH-Rx) enzymes were studied to evaluate the antioxidant status of cells. The activity of CAT was not significantly altered by these treatments. SOD levels were not altered by individual pesticide exposure, but mixtures of pesticides caused increase in SOD levels (Units/mg; L 29.1, M 29.4, P 28.0, L+M mix 37.5, L+P mix 41.1). GSH-Px and GSH-Rx levels were not affected with individual pesticide exposures, but significantly reduced with pesticides mixtures (GSH-Px Units/mg: 30.9, 28.7, 32.8, 23.2, 21.8; GSH-Rx Units/mg: L 33.9, M 36.1, P 36.6, LM mix 25.7, LP mix 26.1). These results indicate that lindane, malathion and permethrin exposure cause immunotoxicity, at least in part, *via* oxidative stress.

1569 TOXICOLOGICAL ASSESSMENT OF THE OXANILIC ACID METABOLITE OF ALACHLOR.

J. M. Kronenberg, W. F. Heydens and J. L. Honegger. *Monsanto Company, St. Louis, MO.*

Alachlor is a selective herbicide used on corn and other crops. The *tert*-amide oxanilic acid metabolite of alachlor (alachlor OXA) is an environmental degradate that is formed in soil by microbial action and is occasionally detected in ground and surface water. Thus, a number of toxicological studies were conducted with alachlor OXA in order to evaluate the potential human or ecological effects that may be associated with this metabolite. These included acute and subchronic studies in rats, a battery of *in vitro* and *in vivo* genotoxicity studies, and acute studies in fish, aquatic invertebrates, earthworms and algae. These studies demonstrated that alachlor OXA is relatively non-toxic to all species tested. No mortality occurred in rats following a single oral dose of 5000 mg/kg. The No-Observed-Effect-Levels (NOELs) in 28-day and 90-day rat feeding studies were 10, 000 ppm (approximately 792 mg/kg/day) and 13, 000 ppm (approximately 922 mg/kg/day)(highest level tested), respectively. No evidence of genotoxicity was observed in Ames, mouse lymphoma, *in vitro* chromosomal aberration or mouse micronucleus assays. Alachlor OXA was also practically non-toxic in acute studies with several aquatic and terrestrial organisms. No mortality was observed in rainbow trout (*Oncorhynchus mykiss*), *Daphnia magna* or earthworms (*Eisenia foetida*) at the high-

est concentrations tested (100, 95 and 1000 ppm, respectively). The EC_{50} values in *Selenastrum capricornutum* and *Navicula pelliculosa* were greater than 100 ppm. Thus, these results demonstrate that the acute and subchronic toxicity of alachlor OXA is substantially less than that of parent alachlor, and indicate that the very low levels of alachlor OXA which are sometimes found in ground and surface water will not pose a significant risk to human health or the environment.

1570 HEPATIC RESPONSES TO CHLOROACETANILIDE HERBICIDE α-CHLORINE DISPLACEMENT DISTINGUISHED BY INDUCTION WITH BOTH ALACHLOR AND METOLACHLOR.

S. R. Miranda[1], S. R. Dalton[2], B. A. Wetmore[3] and S. A. Meyer[1]. [1]*Toxicology, Univ. of Louisiana at Monroe, Monroe, LA,* [2]*Univ. of Nebraska Medical Ctr., Omaha, NE and* [3]*National Ctr. for Toxicogenomics, NIEHS, Research Triangle Park, NC.*

Previous studies indicate that acute hepatotoxicity of alachlor [2-chloro-2', 6'-diethyl-*N*-(methoxymethyl)-acetanilide; > 400mg = 1.85 mmol/kg] to male Long-Evans rats is associated with sustained depletion of reduced glutathione (GSH). However, comparable GSH loss occurs with metolachlor [2-chloro-*N*-(2-ethyl-6-methylphenyl)-*N*-(2-methoxy-1-methylethyl)acetamide; ≦ 2.6 mmol/kg] in the absence of acute hepatotoxicity (Dalton et al., *Toxicol. Sciences.* 60:54, 2001). Unlike alachlor, metolachlor is not metabolized to quinoneimine, but both chloroacetanilides contain an acetyl α-chlorine group. In the present studies, neither alachlor nor metolachlor induced oxidative damage, assessed as thiobarbituric acid-reactive malondialdehyde of liver samples (prepared with antioxidant BHT). Glutathione-*S*-transferase activity (GST), with chlorodinitrobenzene as substrate, showed statistically significant dose-dependent increases 24 hr after exposure to both alachlor and metolachlor, which immunoblot analysis indicated was not due to an increase in oxidant-induced isoform α or μ. Collectively, these data suggest that alachlor-induced GSH loss results from conjugation of the α-chlorine group by nucleophilic substitution and is insufficient to cause oxidant-mediated hepatotoxicity. Additional comparative studies using enzymatic and immunoblot analyses of cytochrome P450s indicated that alachlor and metolachlor (0.5 mmol/kg, 4 daily doses) induced CYP2B1/2 to a similar extent, but neither induced CYP1A1, 1A2 or 3A1. In conclusion, sustained GSH depletion and induction of GST and CYP2B1/2 by metolachlor, but in the absence of hepatotoxicity, indicate that these responses are related to adaptation to chloroacetanilide exposure. Further, they suggest that alachlor hepatotoxicity can be attributed to a structural group other than the acetyl α-chlorine. (support: NIH ES07046 & University. La-Monroe Coll. Pharmacy)

1571 EFFECTS OF CARBARYL ON THE MOTOR ACTIVITY OF SPONTANEOUSLY HYPERTENSIVE (SHR) AND NORMOTENSIVE (WKY) RATS.

R. C. MacPhail, J. D. Farmer, K. A. Jarema, L. C. Jackson and S. Padilla. *Neurotoxicology, USEPA, Research Triangle Park, NC.*

SHR rats have been widely used to investigate the etiology and mechanisms of hypertension. Recent evidence suggests SHR rats have an increased sensitivity to cholinesterase inhibitors. In an effort to develop animal models of susceptibility for use in risk assessment, this experiment compared the effects of the carbamate pesticide carbaryl on the motor activity of SHR and WKY rats. Adult male rats of each strain (N=18) were tested daily during 30-min sessions in a photocell device that separately recorded horizontal and vertical activity. Once activity levels stabilized, carbaryl (5-100 mg/kg) was administered p.o. in corn oil, once weekly, 60-min presession to all rats. Baseline motor activity was consistently higher in SHR than in WKY rats; SHR rats also showed no habituation of activity across initial test sessions, in contrast to the WKY rats. Carbaryl produced dose-related decreases in horizontal and vertical activity in SHR rats. Over the same dose range, carbaryl decreased vertical activity but had no effect on the horizontal activity of WKY rats. Determination of cholin-esterase activity in blood showed that activity was higher in SHR than WKY rats after vehicle, but carbaryl (15 mg/kg) produced a comparable degree of inhibition in both strains. Our behavioral results indicate that SHR rats are sensitive to carbaryl and WKY rats are remarkably insensitive to this pesticide. This abstract does not necessarily reflect USEPA policy.

1572 EXPOSURE TO THE TRIAZOLE FUNGICIDE TRIADIMEFON CAN PRODUCE BOTH INDUCTION AND EXPRESSION OF BEHAVIORAL SENSITIZATION.

R. Reeves, M. Thiruchelvam and D. A. Cory-Slechta. *Department of Environmental Medicine, University of Rochester School of Medicine, Rochester, NY.*

Triadimefon (TDF), a triazole fungicide widely used on fruit and grain crops, increases both locomotor and stereotypical activity in rodents. TDF, like cocaine, blocks reuptake of dopamine (DA), leading to increased extracellular DA levels in the CNS. A recent study in this laboratory, in which mice were administered 24 doses of 50 mg/kg TDF (TDF50) over 12 weeks, found a progressive increase in vertical and ambulatory activity suggesting its ability to result in behavioral sensitization, a process thought to be associated with relapse to drug abuse and addiction. The current study hypothesized that TDF itself, as a psychostimulant, could both induce behavioral sensitization, i.e., the progressive increase in the locomotor response to psychostimulants, as well as lead to the expression of sensitization, the heightened locomotor activity response following re-challenge after withdrawal. Towards this end, C57BL/6 mice were dosed with 50 (TDF50) or 75 mg/kg TDF (TDF75) or with saline ip, twice a week for a total of 14 doses and locomotor activity measured. Re-challenge doses of saline and of TDF were given after a 2 week and 2 month withdrawal period. Vertical activity showed the greatest sensitivity to TDF and was increased across the dosing period. At the 2 week re-challenge, TDF75, but not TDF50, further increased vertical activity to levels higher than those exhibited during dosing. The 2 month TDF re-challenge did not reveal sensitization, possibly due to progressive neurotoxicity which may dampen neurochemical sensitization. This study reveals for the first time that TDF exposure can produce both the induction and expression of behavioral sensitization, a phenomenon commonly associated with dopaminergic and glutamatergic neurochemical changes. TDF exposure could therefore serve as a risk factor for disturbances in behavioral functions mediated by these neurochemical systems. Supported by ES10791, ES01247, and ES007026

1574 COMPARATIVE *IN VITRO* AND EX-VIVO STUDIES ON PROPANIL MYELOTOXICITY.

M. Mattachini[1], L. Manzo[1,2], T. Coccini[1], L. Gribaldo[3] and A. F. Castoldi[1]. [1]*Toxicology Division, Maugeri Foundation, Pavia, Italy,* [2]*Dept. of Internal Medicine, University of Pavia, Pavia, Italy and* [3]*ECVAM, EC Joint Research Centre, Ispra Varese, Italy.*

3', 4'-Dichloropropionanilide (propanil) has been shown to possess methemoglobinemic activity in both animals and humans possibly through its metabolites 3, 4-dichloroaniline (DCA) and N-hydroxy 3, 4-DCA. Propanil also exerts immunotoxic and myelotoxic effects in experimental models. The aims of this study were (i) to compare *in vitro* the myelotoxic effects of propanil and its metabolite DCA on mouse bone marrow (BM) precursors by means of colony forming unit (CFU) assays of the myeloid - granulocyte and macrophage - lineage (CFU-GM), the erythroid lineage (CFU-E) and the less mature burst-forming unit erythroid (BFU-E); (ii) to compare the *in vitro* data with those obtained in ex-vivo experiments performed on BM cells isolated from mice exposed acutely to propanil *in vivo*. In the vitro assays, propanil and DCA concentration-dependently reduced the number of erythroid colonies. Propanil IC50s were 69 ± 12 and 18 ± 11 microM in the CFU-E and BFU-E assays, respectively, while those of DCA were 26 ± 7 and 13 ± 5 microM, respectively. Propanil and DCA were equally potent inhibitors of CFU-GM colony formation *in vitro* (IC50 = 170 microM). *in vivo* exposure to a single dose of propanil (0, 50, 100 and 200 mg/kg i.p.) caused a dose-dependent decrease of CFU-E, BFU-E and CFU-GM progenitors 7 days post-exposure. Compared to controls, 100 and 200 mg/kg propanil reduced CFU-E colony formation by approximately 40 and 50%, respectively, and BFU-E by 24 and 38%, respectively. CFU-GM colony formation was also inhibited to a similar degree. Peripheral blood parameters were not affected by any dose of propanil 1 week after injection. In summary, propanil elicits myelotoxic effects both *in vitro* and *in vivo*. The higher potency of DCA toward the BFU-E cells compared to that of propanil suggests a role for propanil metabolites in its toxicity.

1575 CLODINAFOP IS A PEROXISOME PROLIFERATOR IN THE MOUSE LIVER.

E. W. Weber[1], B. Lang[1], F. Waechter[1], L. Stevens[2] and C. F. Trendelenburg[1]. [1]*Syngenta Crop Protection, Basel, Switzerland and* [2]*Syngenta Crop Protection, Greensboro, NC.*

Clodinafop-propargyl (CLF) induced hepatocellular neoplasms at high doses in male mice. In the absence of any mutagenic activity, the induction of liver tumors was considered to be due to a non-genotoxic mechanism. Increased liver weight and hepatocellular hypertrophy was observed in subchronic studies, suggesting an induction of liver enzymes and a mitogenic response. Two studies with male mice were initiated comprising biochemical liver parameters (cytochrome P450 monooxygenases and peroxisomal fatty acid oxidation) and bromodeoxyuridine-based cell proliferation analysis (treatment periods up to 28 days). Major treatment-related biochemical alterations comprised an induction of cytochrome P450 isoenzymes of gene subfamily Cyp4a as indicated by a strong increase in immunochemically detectable Cyp4a proteins and by associated lauric acid 12-hydroxylase activity. Peroxisomal fatty acid oxidation activity was markedly increased. Cell proliferation analysis revealed a strong but transient stimulation of hepatocellular proliferation, accompanied by hepatocellular hypertrophy. In addition, morphometry

of hepatocellular peroxisomes revealed an increase in number and percent area of these organelles. These data identify CLF as a strong peroxisome proliferator with mitogenic and enzyme inducing activity in the mouse liver. Therefore, the carcinogenic response observed with CLF in the mouse liver is inappropriate for extrapolation to humans.

1576 ASSESSMENT OF THE POTENTIAL INTERACTION OF ^{14}C-THIAMETHOXAM WITH HUMAN P-GLYCOPROTEIN.

J. T. Stevens[1,3], L. G. Fox[2] and R. C. Peffer[1]. [1]*Syngenta Crop Protection, Inc., Greensboro, NC,* [2]*GENTEST Corporation, Woborn, MA and* [3]*Wake Forest University, Winston-Salem, NC.*

P-glycoprotein (PGP, encoded by mdr1) is a member of the ABC transporter superfamily and is expressed in endothelial cells of the capillary bed in the brain, intestine, liver, kidney and other tissues. PGP serves as a barrier to keep toxins out of these tissues by actively pumping chemicals that bind to PGP across the cell membrane and out of the cytoplasm. Numerous insecticides have been demonstrated to interact with human PGP [Bain et al., 1997, *EHP*, 105: 812-818]. In order to evaluate the potential of the new insecticide, thiamethoxam to interact with PGP, two experiments were performed in control and human PGP-expressing LLC-PK1 cells derived from the human kidney. The first, a time-dependence experiment with ^{14}C-thiamethoxam, was performed to determine the apparent permeability(P_{app}) and bidirectional transport of thiamethoxam in the control and polarized cell monolayers. The P_{app}(7.4 - 8.5 x 10^{-6} cm/sec for a time cource of 15 to 120 minutes) in the control cell (clone A) monolayers is consistent with a membrane-permeable substance. The polarization ratio ($P_{app\ B\ to\ A}/P_{app\ A\ to\ B}$) in the human PGP-expressing LLC-PK1 cells (clone 15B-J) was essentially equal to that in the control cells, at each timepoint measured. In contrast, the 15B-J polarization ratio with digoxin (the positive control for PGP transport) was higher than the control cell ratio, demonstrating that digoxin was transported. The mass balance analysis at 120 minutes resulted with a % recovery of 98±1. The results demonstrated that thiamethoxam was not transported by PGP. The second experiment (PGP-inhibition) determined that the PGP-facilitated transport of digoxin was not inhibited by co-incubated thiamethoxam, as was evident by the consistent digoxin polarization ratios measured over the thiamethoxam concentration range of 0 to 100 µM whereas, ketoconazole inhibited the digoxin transport. The results of the study clearly demonstrated that thiamethoxam is not a substrate or inhibitor of human PGP-mediated efflux.

1577 BLOCK OF COCKROACH NEURON SODIUM CHANNELS BY INDOXACARB INSECTICIDE.

X. Zhao, T. Ikeda, J. Z. Yeh and T. Narahashi. *Molecular Pharmacology and Biological Chemistry, Northwestern University Medical School, Chicago, IL.*

Indoxacarb is a newly developed insecticide with high insecticidal activity and low toxicity to nontarget organisms. Our previous study has shown that indoxacarb at 1 ~10 µM is less potent than its metabolite, DCJW, to block voltage-gated sodium channels in mammalian neurons. However, our knowledge of the mechanism of action of indoxacarb on insect sodium channels is very limited. The present study was undertaken to investigate the actions of indoxacarb and DCJW on tetrodotoxin-sensitive (TTX-S) sodium channels in cockroach thorathic ganglion neurons by the whole-cell patch clamp technique. DCJW at 0.1 ~ 1.0 µM slowly and irreversibly blocked TTX-S sodium channels. At -100 mV membrane holding potential, 100 nM DCJW reduced the peak amplitude of sodium current by 75.7 ± 12.1% (n = 6). Indoxacarb was less potent than DCJW. No changes in sodium channel activation kinetics was observed after application of indoxacarb or DCJW. Sodium channels of cockroach neurons undergo two kinetically distinct types of inactivation, fast inactivation and slow inactivation. DCJW at 100 nM shifted the half-maximum fast inactivation potential ($Vh_{0.5}$) to -72.1 ± 1.6 mV (n = 6) from the control value of -64.0 ± 4.0 mV (n = 6, $p < 0.01$) and shifted the $Vh_{0.5}$ of slow inactivation to -97.1 ± 3.4 mV from the control of -87.3 ± 3.2 mV (n = 3, $p < 0.05$). The voltage-gated potassium channel was not affected by indoxacarb or DCJW. These results suggest that the insect sodium channels are more sensitive to indoxacarb and DCJW than the mammalian sodium channels providing the basis for high insecticidal activity and low mammalian toxicity. Supported by NIH grant NS14143.

1578 INSECTICIDAL ACTIVITY OF ESSENTIAL OILS: OCTOPAMINERGIC SITES OF ACTION.

E. E. Enan. *Biochemistry, School of Medicine, Vanderbilt University, Nashville, TN.*

A study was conducted to determine the insecticidal activity and mechanism of action of three essential oils (eugenol, a-terpineol and cinnamic alcohol) and an equal part mixture (3-blend) against American cockroaches (Periplaneta americana). To address species differences in response to treatment with the test oils, Carpenter ants (Camponotus pennsylvanicus De Geer), and German cockroaches (Blattella germanica) were included in this study. Exposed American cockroaches demonstrated hyperactivity followed by hyperextension of the legs and abdomen, then fast knockdown or quick immobilization followed by death. Ants and German cockroaches showed fast immobilization/knockdown followed by mortality. The 1:1:1 mixture (3-blend) was substantially effective against all test insects. One of the most remarkable observations was the increased frequency of heartbeats of American cockroaches in response to topical application of test oils. The changes in the pattern of cAMP level was biphasic. A significant increase in the cAMP level was found in response to 1 nmole/ml of eugenol, or 3-blend or 10 nmole/ml of a-terpineol. At higher concentrations a significant decrease in cAMP level was found. Blockage of octopamine receptors binding sites was also illustrated at lower concentrations of the test chemicals as judged by the decreased binding activity of 3H-octopamine to its receptors. In conclusion: 1- test oils are neuro-insecticides and their insecticidal activity is species-dependent, 2- a synergistic effect of the three oils was found when they were equally mixed (3-blend), and 3- octpaminergic system mediates the insecticidal activity of eugenol, a-terpienol and the 3-blend.

1579 DOSE CONVERSIONS BETWEEN UNITS OF MG/KG AND MG/M^2 FOR CYTOTOXIC ANTICANCER AGENTS: A CASE STUDY REGARDING THE IMPORTANCE OF CONSISTENT ESTIMATIONS OF BODY SURFACE AREA.

V. Lee-Brotherton[1], M. Luksic[1], V. Tai[1], P. Tam[2], R. Oshanek[2], B. Lynch[1], J. Manley[1], G. Goodfellow[1] and J. Daniels[1]. [1]*Cantox Health Sciences International, Mississauga, ON, Canada and* [2]*Inex Pharmaceuticals Corporation, Vancouver, BC, Canada.*

The toxicity of cytotoxic anticancer drugs correlates more closely with body surface area (BSA) than with body weight (BW). Thus, it is standard practice to administer and compare such drugs on the basis of BSA. To interconvert between units of mg/kg and mg/m^2, it is necessary to know either BSA or BW. Accurate values for BW are easy to obtain. In contrast, BSA is difficult to measure, and, therefore, is usually calculated from a known BW. The relationship between BW and BSA is described by the formula $BSA(m^2) = b \times [BW(kg)]^{2/3}$, where b is a species-specific constant derived from empirical data. In practice, the values for b vary between laboratories (*e.g.*, values for b for the mouse have been found to vary from 0.090 to 0.096). Confusion and miscommunication can occur as a result of the use of different species-specific constants. For example, difficulties have arisen during the dose selection process for a novel cytotoxic anticancer agent with a steep dose-response curve. In this case, if different investigators use b values as varied as 0.099, 0.101, and 0.111, then animal BSA values for a 10 kg dog will vary by up to 12% (0.4631, 0.4724, and 0.5192 m^2, respectively). Also, although quantities of the anticancer drug are calculated from a target dose set in units of mg/m^2, the amounts of the drug given to the 10 kg dog will likewise vary, depending on the choice of b (0.926, 0.945, and 1.038 mg, respectively, for a 2 mg/m^2 dose). The use of a single set of species-specific constants by all investigators is proposed, as it would be beneficial in removing confusion from discussions of study designs and results. Such a proposal has an even more immediate benefit in the case of compounds with very steep dose-response curves, where even small variations in dosing can profoundly influence the results obtained and their interpretation.

1580 FOUR WEEK ORAL TOXICITY STUDY OF THE CANCER CHEMOPREVENTIVE AGENT RESVERATROL IN RATS.

P. J. Korytko[1], R. L. Morrissey[2], V. Hebbar[3], G. Shen[3], T. Kong[3], J. A. Crowell[4] and B. S. Levine[1]. [1]*Toxicology Research Laboratory, University of IL at Chicago, Chicago, IL,* [2]*Pathology Associates, Chicago, IL,* [3]*Rutgers University, Piscataway, NJ and* [4]*NCI, Rockville, MD.*

Resveratrol, a naturally occurring compound derived from grapes, inhibits cellular events associated with tumor initiation, promotion, and progression, and is being developed as a cancer chemopreventive agent. The present study examined the toxicity of resveratrol following 28 days of daily gavage administration to four groups of 20 rats/sex. Dose levels were 0, 300, 1000, and 3000 mg/kg/day, based on a two week pilot study. Oral administration of 3000 mg/kg/day resulted in nephrotoxicity observed as elevated serum BUN and creatinine levels, increased kidney weights, and gross and microscopic renal lesions. Dehydration at this dose was supported by reduced body weight gains (secondary to dec. food intake) and hyperalbuminemia. Additional clinical signs in high dose animals included labored breathing, hunched posture, decreased activity, rough coat, diarrhea, soft stool, and red material around the nose. Leukocytosis occurred in males, whereas anemia in females and possibly in males in the 3000 mg/kg/day dose group may have been a direct effect on RBCs (Inc.. total bilirubin), or secondary to renal injury (dec. erythropoietin synthesis). Increased serum ALT, ALKP and possibly total bilirubin indicated mild liver toxicity in the high dose group, but these changes were not supported histologically. At

this dose, liver QR, GST, UGT, and 2E1 were elevated, whereas 1A1 was slightly reduced. Effects seen at 1000 mg/kg/day included dehydration, labored breathing, reduced body weight gains and increased WBC count (males only). Dose-related plasma resveratrol levels in week 4 were relatively low given the high dose levels. On the basis of the present investigation, the no observed adverse effect level was 300 mg/kg/day. (Supported by NCI Contract No. NO1-CN-95132).

1581 PHARMACOKINETICS AND TISSUE DISTRIBUTION OF THE PROSTATE CANCER CHEMOPREVENTIVE AGENT LYCOPENE IN MALE BEAGLE DOGS.

B. S. Levine[1], P. J. Korytko[1], M. Stacewicz-Sapuntzakis[2], K. A. Rodvold[3], P. E. Bowen[2] and J. A. Crowell[4]. [1]*Toxicology Research Laboratory, Univ. of IL at Chicago, Chicago, IL,* [2]*Human Nutrition, Univ. of IL at Chicago, Chicago, IL,* [3]*Pharmacy Practice, Univ. of IL at Chicago, Chicago, IL and* [4]*NCI, Rockville, MD.*

Lycopene, the predominant carotenoid in tomatoes and tomato products, has been associated with a decrease in prostate cancer risk. The present study was conducted to determine the pharmacokinetics and tissue distribution of lycopene in male dogs following 28 days of oral administration. Pilot studies examined the pharmacokinetics of lycopene following single doses of 10, 30 and 50 mg/kg, and 30 and 50 mg/kg/day for 4 consecutive days. The results indicated that the elimination half-life after a single dose of 10 to 50 mg/kg was about 36 hours, whereas the elimination half-life was somewhat shorter after four daily doses. In addition, peak plasma lycopene levels were similar following either 30 or 50 mg/kg/day for four days. Based on those results, 30 mg/kg/day was selected for the main study. An oral dose of 30 mg/kg/day administered to six dogs for 28 days resulted in steady-state plasma concentrations between 400 and 700 ng/mL 96 hours after the first dose. Mean apparent clearance, volume of distribution, and elimination half-life were 2.29 L/hr/kg, 96 L/kg, and 30.5 hours, respectively. Three dogs each were sacrificed one or five days after the last dose on day 29 and tissues were collected for lycopene analysis. Lycopene concentrations were highest in liver, adrenals, spleen, lymph node, and GI tract (in that order). Mean liver lycopene levels were 35 ug/g one day and 49 ug/g five days after cessation of treatment. Prostate lycopene levels were fairly low, with mean values less than 0.13 ug/g five days after dosing ceased (< 0.4% of liver levels). The long plasma elimination half-life was consistent with greater lycopene levels in tissues five days compared to one day following cessation of treatment. (Supported by NCI Contract No. NO1-CN-95055).

1582 DIETARY FOLATE DEPLETION IN BEAGLE DOGS: IS THYMIDYLATE SYNTHASE INHIBITOR TOXICITY INCREASED?

D. B. Colagiovanni[1], C. Ruaux[2], D. A. Williams[2], D. J. Meyer[1], R. Bendele[1] and F. C. Richardson[1]. [1]*Life Sciences, Gilead Sciences, Inc., Boulder, CO and* [2]*Texas Agriculture Experiment Station, Texas A & M University, College Station, TX.*

The objective of the study was to determine if dietary folic acid depletion in beagle dogs altered the toxicity of the thymidylate synthase inhibitor (TSI), GS7904L (GW1843U89), currently under clinical development as an oncolytic. Classically, human cancer patients are deficient in nutrients, including Vitamins A and C and folic acid. An association has been made between patient's homocysteine status (a reflection of intracelullar folic acid)and enhancement of TSI toxicity. In previous studies with GS7904L, severe toxicity was observed in dogs treated with 2-3 mg/kg (40 – 60 mg/m2) as a single intravenous administration. To assess if GS7904L toxicity may be exacerbated in association with folic acid deficiency, a model was established to mimic this condition in beagle dogs. Two groups of young, female beagle dogs were fed either a standard certified diet or a diet deficient in folic acid (Teklad TD069) for 21 or 72 days. Both diets were equally palatable. Samples were collected over the timecourse of the study for serum folate, plasma homocysteine and whole blood hematology analyses. Clinical observations and body weights were recorded daily. All dogs were administered 1 mg/kg (20 mg/m2) GS7904L by bolus IV administration on either day 14 or day 66 of the study. At the time of drug administration, the serum folate levels were reduced 25 or 50% from baseline concentrations. Mild hematologic changes to white blood cell counts were noted in both the dogs fed the folate deficient and normal diets and no clinical toxicity was seen in any dog. These findings show that, in the dog under the conditions tested, dietary folic acid depletion did not increase GS7904L toxicity.

1583 EVALUATION OF THE ACUTE TOXICITY OF LIPOSOME-ENCAPSULATED VINCRISTINE SULFATE.

P. Tam[1], R. Oshanek[1], C. Flowers[1], V. Lee-Brotherton[2], M. Luksic[2], V. Tai[3] and J. Daniels[2]. [1]*Inex Pharmaceuticals Corporation, Vancouver, BC, Canada,* [2]*Cantox Health Sciences International, Mississauga, ON, Canada and* [3]*Cantox Health Sciences International, Vancouver, BC, Canada.*

Vincristine Sulfate Liposomes Injection (VSLI) utilizes sphingomyelin/cholesterol liposomes (55:45) as a systemic drug delivery vehicle for the treatment of neoplastic disease. In this presentation, the acute toxicity of VSLI was evaluated in Sprague-Dawley rats and beagle dogs. Rats (5/sex/dose) were administered single iv doses of 1.1 to 4.7 mg/m^2; dogs (1/sex/dose) were administered doses of 0.6 to 2.0 mg/m^2. Free VCR, empty liposomes, and saline groups were included in each study. In rats, VSLI was associated with dose-dependent body weight (BW) loss, myelosuppression, and testicular atrophy. There was no mortality among rats. Dogs treated with VSLI also showed dose-dependent BW loss and myelosuppression. Gastrointestinal toxicity was observed in both dogs administered VCR (1.1 mg/m^2; graded minimal in male, slight in female), in the male given VSLI at 1.1 mg/m^2 (minimal), and in animals given ≥1.6 mg/m^2 VSLI (minimal to slight). The only mortality was the male dog administered high-dose VSLI (2.0 mg/m^2). At 1.1 mg/m^2, BW loss in the free VCR dogs was 7% (male) and 22% (female) greater than in the VSLI-treated animals. The effects of equivalent doses of free VCR and VSLI on myelosuppression were comparable in rats (doses of 2.9 mg/m^2) and in dogs (doses of 1.1 mg/m^2) in terms of time of onset, severity, and duration. Free VCR and VSLI (1.1 mg/m^2) induced similar increases in aspartate aminotransferase levels in dogs, suggestive of muscle injury in the absence of increases in other aminotransferase levels. These data suggest that dogs may be more sensitive than rats to the toxic effects of VCR, whether free or liposomal, and that there are no new, unexpected acute toxicities observed for VSLI when compared to free VCR.

1584 A SINGLE DOSE INTRAVENOUS TOXICITY STUDY OF A LYMPHOTOXIN BETA RECEPTOR AGONIST ANTIBODY IN THE CYNOMOLOGUS MONKEY.

M. T. Cooper[1], L. Bernier[2] and J. D. Green[1]. [1]*Preclinical Development, Biogen, Cambridge, MA and* [2]*Covance Laboratories, Vienna, VA.*

LTBR mAb, a murine antibody with agonist activity toward the lymphotoxin beta receptor (LTBR), is currently being developed as a treatment for LTBR-expressing solid tumors. Agonism of the LTBR leads to cytokine release and death or differentiation of some neoplasms. A single intravenous injection of LTBR mAb in male cynomolgus monkeys at a dose level of 0.2 or 2.0 mg/kg had no effect on the study parameters. There were no abnormal clinical observations noted immediately following dose administration or over the subsequent 7- to 21-day observation period. Body weight changes and body temperatures recorded were within normal variations for cynomolgus monkeys. LTBR mAb had no effect on the delayed hypersensitivity (DTH) response or keyhole limpet hemocyanin (KLH) evaluations, as comparable variations were seen in all groups. The hematology, coagulation results, differential leukocyte counts, cellular morphology, and clinical chemistry parameters were unremarkable and similar among all groups on days 8 and 22. Serum concentrations of LTBR mAb at 2 hours post-dose were below the limit of quantitation in animals treated with 0.2 mg/kg LTBR mAb and were 41-52 µg/mL in animals treated with 2.0 mg/kg LTBR mAb. Antibodies to LTBR mAb were detected by day 8 in all LTBR mAb-treated animals. Findings noted at necropsy or identified during histopathologic examination were those known to occur as spontaneous changes in cynomolgus monkeys or associated with administration of Incomplete Freund's Adjuvant (used for DTH immunization). LTBR mAb administration did not alter the incidence or character of these findings. Based on the results of this study, a single intravenous administration of 2.0 mg/kg LTBR mAb was well tolerated.

1585 SAFETY OF A RIBOZYME TARGETING HER2 RECEPTOR mRNA (HERZYME ™) IN CD-1 MICE AND CYNOMOLGUS MONKEYS FOLLOWING DAILY BOLUS SUBCUTANEOUS INJECTIONS FOR 29 DAYS.

J. A. Sandberg[1], T. E. Jackson[1], E. A. Caputo[2], E. L. Padgett[3] and P. A. Lee[1]. [1]*Ribozyme Pharmaceuticals, Inc., Boulder, CO,* [2]*Sierra Biomedical, Inc., Sparks, NV and* [3]*Wil Research Laboratories, Inc, Ashland, OH.*

A ribozyme (HERZYME) targeting the mRNA of the human epidermal growth factor receptor-2 (HER2) has been developed. Two toxicity studies were performed in CD-1 mice and cynomolgus monkeys. Animals received daily subcutaneous (SC) injections for 29 days of HERZYME (30, 100 or 300 mg/m^2/day). In CD-1 mice, HERZYME was well tolerated with no effects on clinical chemistry, hematology, viability, clinical observations, body weights, food consumption or gross pathology. HERZYME-related increases in liver weights were seen in mid- and high-dose females that resolved in the recovery groups. Cytoplasmic basophilia of renal cortical tubules and Bowman's capsule epithelial cells in the kidneys was observed for all HERZYME-treated groups and resolved in all but the high-dose group at recovery. In monkeys, there were no effects of HERZYME treatment on body weight, urinalysis, heart rate, blood pressure, ECG, clinical chemistry, clinical hematology or coagulation parameters. HERZYME-related changes in organ weights were: decreased thymus weights and slightly increased kidney weights in all treatment groups. The former was associated with microscopic findings of thymic atrophy and resolved completely in recovery animals. Accumulation of basophilic

granules in renal tubular epithelium and minimal to mild renal tubular degeneration was seen in most HERZYME-treated animals. Renal changes resolved in all males but persisted in one high-dose female. Kupffer cell hypertrophy and cytoplasmic basophilia was were observed in varying degrees in all HERZYME-treated animals. These changes had resolved in all but the high-dose animals. There were minimal injection site reactions in all HERZYME-treated monkeys that resolved in females and had partially resolved in males at recovery. In summary, daily SC administration of HERZYME for 29 days at doses up to 300 mg/m^2/day was well tolerated in mice and monkeys.

1586 28-DAY ORAL TOXICITY STUDY OF *Se*-METHYLSELENOCYSTEINE IN RATS.

W. D. Johnson[1], R. R. McKinstry[1], C. Ip[2], R. L. Morrissey[3], J. A. Crowell[4] and D. L. McCormick[1]. [1]*IIT Research Institute, Chicago, IL,* [2]*Roswell Park Memorial Institute, Buffalo, NY,* [3]*Pathology Associates International, Chicago, IL and* [4]*National Cancer Institute, Bethesda, MD.*

Se-Methylselenocysteine (MSC) is an organoselenium compound being developed for use in breast cancer chemoprevention. The present study was conducted to characterize the toxicity of subchronic oral administration of MSC in rats. CD rats (20/sex/group) received daily oral (gavage) administration of MSC at doses of 0, 0.5, 1.0, or 2.0 mg/kg body weight/day [target selenium doses of 0, 0.2, 0.4, or 0.8 mg/kg/day] for 28 consecutive days. Toxicology endpoints evaluated included body weight, food consumption, clinical observations, clinical chemistry, hematology, coagulation, ophthalmology, organ weights, gross pathology, and microscopic pathology. MSC induced a dose-related suppression of food consumption and body weight gain in both sexes; suppression of body weight gain was greater in females than in males. Administration of MSC at 2.0 mg/kg/day induced mild anemia and modest elevations in ALP, AST, ALT, and GGT in female rats; these changes were not seen in female rats receiving lower doses of MSC, nor in male rats at any dose level studied. At termination, dose-related hepatomegaly was present in both sexes. Dose-limiting histopathologic findings in male rats receiving MSC at 2.0 mg/kg/day included hepatocellular degeneration and arrested spermatogenesis; these changes were not observed in rats exposed to lower doses of MSC. Dose-limiting hepatocellular degeneration and atrophy of corpora lutea were present in female rats receiving MSC at doses of 2.0 and 1.0 mg/kg/day; hepatocellular degeneration of minimal severity was present in female rats receiving MSC at 0.5 mg/kg/day. These data suggest that the No Adverse Effect Level [NOAEL] for 28-day oral administration of MSC in male rats is 1.0 mg/kg/day. The NOAEL for 28-day oral administration of MSC in female rats is < 0.5 mg/kg/day. [Supported by contract N01-CN-05130 from the National Cancer Institute.]

1587 A 3 MONTH TOXICITY AND TOXICOKINETIC STUDY OF BAY 36-1677 (AN IL-4 SELECTIVE AGONIST) IN CYNOMOLGUS MONKEYS.

G. Prawdzik[1], M. Horner[2], P. Lappin[2], L. Neyer[1], E. Cheung[1], P. Lum[1], M. Boes[1], A. Fleser[1] and T. Reynolds[1]. [1]*Preclinical Development Dept., Bayer Corportation, Center for Biotechnolgy Research, Berkeley, CA and* [2]*Sierra Biomedical, a Division of Charles River Laboratories, Inc., Sparks, NV.*

BAY 36-1677 is a recombinant interleukin-4 selective agonist, a mutein of human IL-4 that selectively stimulates T and B cells with minimal endothelial cell activation. The purpose of this study was to evaluate the potential toxicity and toxicokinetics of BAY 36-1677 when administered daily (0-30 mcg/kg) or thrice weekly (100 mcg/kg) by subcutaneous (SC) injection to cynomolgus monkeys (6-8/sex/group) for 3 months. There were no BAY 36-1677-related adverse effects on clinical observations, food consumption, body weights, clinical chemistry, coagulation, urinalysis, blood pressure, heart rate, and electrocardiograms. Dose-dependent BAY 36-1677-associated effects consisted of increased white blood cell counts primarily attributed to lymphocytes. Flow cytometry analysis demonstrated increased B cells, T helper and T suppressor cells in most BAY 36-1677-treated animals. Microscopic evaluation revealed hypercellularity in the spleen and bone marrow, and increased periportal lymphoid cell infiltrates and leukocytic foci in the hepatic parenchyma. Injection sites showed cellular infiltrates in the subcutaneous tissue, perivascular dermatitis, and subcutaneous edema. Dose-related BAY 36-1677-specific antibodies were present at 2 months in all BAY 36-1677-treated animals. The antibody response was neutralizing with respect to BAY 36-1677 activity. Toxicokinetic data demonstrated that exposure was approximately proportional to the dose level and changes in toxicokinetics by 3 months correlated with the formation of antibodies. In conclusion, BAY 36-1677 was well tolerated in male and female cynomolgus monkeys with evidence of pharmacologic activity and no apparent signs of systemic toxicity, when administered daily up to 30 mcg/kg or three times weekly at 100 mcg/kg for a period of 3 months.

1588 A 13-WEEK TOXICITY STUDY OF BAY 16-9996 (AN IL-4 RECEPTOR ANTAGONIST) IN MALE AND FEMALE RHESUS MONKEYS WITH A 4-WEEK RECOVERY PERIOD.

C. Ji[1], M. Horner[2], J. Newgren[1], E. Cheung[1], E. Burmeister-Betz[1], M. Boes[1], L. Neyer[1], S. Rousselle[3] and T. Reynolds[1]. [1]*Preclincal Development Department, Bayer Corporation, Center for Biotechnology Research, Berkeley, CA,* [2]*Sierra Biomedical, A Division of Charles River Laboratories, Inc, Sparks, NV and* [3]*Pathology Associates, A Charles River Company, Frederick, MD.*

BAY 16-9996 is a recombinant human interleukin-4 receptor antagonist being developed for the treatment of severe asthma. It is designed to compete with endogeneous IL-4 for the binding of the IL-4 receptor, resulting in a switch from a Th2 cytokine secretion profile to a Th1 cytokine profile. To support ongoing clinical development, BAY 16-9996 was administered to male and female rhesus monkeys by subcutaneous (SC) injection every other day for 13 weeks followed by a 4-week recovery period at doses of 0, 0.3, 1.0 and 3.0 mg/kg (4-6/sex/group). BAY 16-9996 produced no apparent toxicity. There were no changes in clinical observations, food consumption, body weights, serum chemistry, hematology, coagulation, urinalysis, blood pressure, heart rate, body temperature, respiration, ophthalmic, or electrocardiographic parameters. BAY 16-9996-related findings were limited to injection site reactions: minimal to moderate perivascular infiltrates of mononuclear cells, and hemorrhage and fibrosis, which were largely reversible at the end of the recovery period. A dose dependent increase in the incidence of BAY 16-9996-specific antibodies was observed at three weeks post initiation of treatment. The magnitude of antibody response correlated with an increase in circulating levels of BAY 16-9996. In summary, BAY 16-9996 was well tolerated in male and female rhesus monkeys with no signs of systemic toxicity, when administered by SC injection every other day, at doses of up to 3.0 mg/kg for 13 weeks.

1589 3-MONTH INHALATION TOXICITY STUDY WITH sIL-4R IN CYNOMOLGUS MONKEYS.

L. L. Carlock[1], A. I. Morgan[2], A. Richards[2] and J. L. Bussiere[1]. [1]*Immunex Corp., Seattle, WA and* [2]*Inveresk Research Group, Tranent, United Kingdom.*

Immune function and general health were evaluated in cynomolgus monkeys administered human sIL-4R receptor *via* inhalation exposure (closed face mask system) or intravenous (IV) injection twice weekly for 12 weeks with a 12-week recovery period. Study animals were divided into four groups: placebo inhalation, low dose inhalation (0.1 mg/kg), high dose inhalation (1 mg/kg), or IV (0.2 mg/kg). Animals were evaluated for effects on clinical signs, body weights, ophthalmoscopy, hematology, clinical chemistry, urinalysis, pharmacokinetics and antibody response to the drug. Cellular immune function was assessed using delayed-type hypersensitivity (DTH) testing. Humoral immune function was assessed by measuring antibody response to keyhole limpet haemocyanin (KLH). Lymphocyte subpopulation analysis (CD3, CD4, CD8, CD14, CD20, CD56, and CD69) was conducted using flow cytometry of whole blood. All animals were subjected to a detailed necropsy, histological and immunohistochemical evaluations. There were no clinical signs, ophthalmoscopic findings or differences in body weight that could be attributed to administration of sIL-4R. Clinical pathology evaluation revealed no discernable treatment-related effects. Immune function was not affected by treatment with sIL-4R as assessed by DTH, antibody response to KLH, or by lymphocyte subset analysis. Antibody response was seen in 90% of animals receiving drug by inhalation; 20% of animals receiving drug IV. Exposure levels decreased with time in the inhalation-treated groups, most likely due to antibody development. Exposure levels were maintained in the IV-treated group. Terminal investigations did not reveal an effect of sIL-4R administration. Immunohistochemistry evaluations of lymphoid tissues revealed no differences in T and B lymphocyte populations. In conclusion, there was no evidence of systemic effects or evidence of alteration in immune function in animals administered human sIL-4R either by inhalation or IV for 12 weeks.

1590 DIFFERENTIAL SENSITIVITY OF 4 SPECIES TO OBSTRUCTIVE NEPHROPATHY PRODUCED BY AMDOXOVIR, A NUCLEOSIDE ANALOG WITH POTENT ANTIVIRAL ACTIVITY AGAINST HIV.

L. C. Trost, M. Brosnan-Cook, F. Rousseau, L. H. Wang and G. M. Szczech. *Triangle Pharmaceuticals, Inc., Durham, NC.*

1-β-D-2, 6-diaminopurine dioxolane (Amdoxovir, DAPD) is in Phase I/II clinical trials for treatment of HIV. Amdoxovir is rapidly absorbed after oral dosing and deaminated by adenosine deaminase to yield dioxolane guanosine (DXG), the active anti-HIV agent. One-month toxicology studies in mice and marmosets supported an IND. Amdoxovir produced obstructive nephropathy at doses ≧ 90 mg/kg in mice and 120 mg/kg in marmosets. One-month studies were also con-

ducted in rats and cynomolgus monkeys which were selected for chronic studies because, like humans, they produce more dilute urine. In rats, amdoxovir produced obstructive nephropathy at doses ≧ 400 mg/kg. In cynomolgus monkeys, a dose of 1200 mg/kg produced only minimal histopathologic alterations in the kidney. In chronic studies, obstructive nephropathy and sequellae was the only significant finding, occurring at doses ≧ 100 mg/kg in rats and 400 mg/kg in monkeys. The nephropathy was characterized by tubular dilatation, presence of crystalline material in tubular lumens, and degeneration, necrosis and regeneration of groups of tubules mainly in the cortex. There were no glomerular or vascular lesions. Both amdoxovir and DXG have limited solubility in aqueous media. Because the kidney is the major organ of elimination, it is hypothesized that amdoxovir or DXG precipitate in kidney tubules as urine is concentrated. In summary, similarly characterized obstructive nephropathy was observed in subchronic studies of amdoxovir in 4 species and in chronic studies in 2 species. However, while renal tubular obstruction occurred at lower doses in small, water-conserving mice and marmosets, higher doses were required to produce obstruction in less water-conserving rats and cynomolgus monkeys. Based on water conservation levels, it is anticipated that the dose level (per kg basis) causing obstructive nephropathy in humans will be similar to that in cynomolgus monkeys. Thus, at doses selected for clinical trials, the risk of obstructive nephropathy appears low.

1591 PHARMACOKINETIC DISPOSITION IN ARTHROPATHY OF JUVENILE DOGS INDUCED BY A QUINOLONE ANTIMICROBIAL AGENT.

K. Yabe[1,2], K. Yoshida[1], S. Nishida[1], M. Sekiguchi[1], T. Sugawara[1], K. Furuhama[1], M. Goryo[2] and K. Okada[2]. [1]*Tokyo R&D Center, Daiichi Pharmaceutical Co., Ltd., Edogawa-ku, Japan and* [2]*Department of Veterinary Pathology, Iwate University, Morioka, Japan.*

Quinolone antimicrobial agents including ofloxacin induce arthropathy in juvenile animals, but not in adult animals. To examine the age-specific difference in susceptibility to ofloxacin arthropathy, its pharmacokinetic disposition and early pathological change in the articular cartilages were compared between male juvenile (3-month-old) and adult (18-month-old) dogs. Ofloxacin was orally administered at 5, 10 or 20 mg/kg/day to these dogs for 8 consecutive days, and serum and cartilage drug concentrations were periodically analyzed by HPLC. Serum Cmax and AUC0-24h, and drug concentrations in the cartilage of juvenile dogs were increased in a dose dependent manner. At 20 mg/kg/day, the drug disposition of juvenile dogs was equal to or lower than those of adult dogs. Macroscopically, arthropathy characterized by fluid-filled vesicles in the articular surface was observed only in the juvenile dogs receiving 10 and 20 mg/kg/day, but not 5 mg/kg/day. Microscopically, the juvenile dogs showed cavity formation with unmasked collagen fibers in the middle zone of the articular cartilage and numerous degenerative or necrotic chondrocytes around the cavity on day 2, followed by appearance of chondrocytes clusters on day 8. Meanwhile, the adult dogs represent the thin and zonal different cartilage layer, in which the typical tidemark was observed, suggesting that the existence of the mature articular cartilage tissue may related to protective action on arthropathy. Based on these results, high susceptibility to arthroptahy in juvenile dogs can not be explained only by drug disposition to the articular cartilage. The interaction between ofloxacin and immature cartilages on cell cycles and matrix synthesis may be important for pathogenesis of arthropathy.

1592 REPEAT-DOSE TOXICITY STUDIES IN RATS WITH TWO SUSTAINED RELEASE FORMULATIONS OF LY307161, A PROTEASE-RESISTANT GLP-1 ANALOG.

R. A. Byrd and K. F. Mace. *Toxicology and Drug Disposition, Eli Lilly and Company, Greenfield, IN.* Sponsor: P. Sausen.

LY307161 is a protease-resistant analog of Glucagon-Like Peptide 1 (GLP-1) that is under development for treatment of Type 2 diabetes. Two sustained release formulations of LY307161, designated NDP-1 or NDP-2, were evaluated in separate 1-month rat studies. F344 rats (8-12/sex/group) were given daily subcutaneous doses of 0, 1, 4, or 20 mg/kg. GLP-1 pharmacodynamic effects observed with NDP-1 included decreases in body weight (↓5-16%), food consumption (↓6-16%), and triglycerides (↓9-44%) at all doses. No target organ toxicity was identified with NDP-1. Toxicologically important findings with NDP-1 were limited to injection site reactions in the 4- and 20-mg/kg groups characterized by swelling, minimal-to-marked granulomatous inflammation, and correlative changes in clinical pathology consistent with the inflammation. Injection site reactions in the 1-mg/kg group were of lesser incidence and magnitude, were not associated with clinical pathology changes, and were not clinically apparent. On Day 29, $AUC_{0\text{-}24hr}$ values for the 1-, 4-, and 20-mg/kg groups were 232, 843, and 2649 ng•hr/mL, respectively. With NDP-2, GLP-1 pharmacodynamic effects also included decreases in body weight (↓7-14%), food consumption (↓7-18%), and triglycerides (↓17-39%); no target organ toxicity was identified with NDP-2. Injection site reactions with NDP-2 occurred only in the 4- and 20-mg/kg groups without clinical pathology changes, and the severity of the reactions, characterized as minimal-to-moderate, was reduced relative to NDP-1. Plasma exposure with NDP-2 was higher relative to NDP-1; the $AUC_{0\text{-}24hr}$ values on Day 33 for the 1-, 4-, and 20 mg/kg groups were 380, 1247, and 4424 ng•hr/mL, respectively. In conclusion, NDP-2 exhibited improvements in local tolerability and bioavailability relative to NDP-1 in rats. The NOEL for target organ toxicity with either LY307161 formulation was 20 mg/kg. Plasma exposure (AUC) at the NOEL was 284- to 449-fold the maximum anticipated human exposure thus demonstrating an adequate Margin of Safety.

1593 REPEAT-DOSE TOXICITY STUDIES IN DOGS WITH TWO SUSTAINED RELEASE FORMULATIONS OF LY307161, A PROTEASE-RESISTANT GLP-1 ANALOG.

K. F. Mace and R. A. Byrd. *Toxicology and Drug Disposition, Eli Lilly and Company, Greenfield, IN.* Sponsor: P. Sausen.

LY307161 is a protease-resistant analog of Glucagon-Like Peptide 1 (GLP-1) that is under development for treatment of Type 2 diabetes. Two sustained release formulations of LY307161, designated NDP-1 or NDP-2, were evaluated in separate 1-month dog studies. Beagle dogs (3/sex/group) were given daily subcutaneous doses of 0, 0.2, 0.8, or 3 mg/kg. GLP-1 pharmacodynamic effects observed with NDP-1 included vomiting, decreased body weight (↓1-7%), and decreased qualitative food consumption at all doses. No target organ toxicity was identified with NDP-1. Toxicologically important findings in the 0.8- and 3-mg/kg groups were limited to injection site reactions characterized by swelling, moderate-to-marked pyogranulomatous inflammation, and correlative changes in clinical pathology consistent with the inflammation. Injection site reactions in the 0.2-mg/kg group were of lesser magnitude, were not associated with important clinical pathology changes, and were not clinically apparent. On Day 29, $AUC_{0\text{-}24hr}$ values for the 0.2-, 0.8-, and 3-mg/kg groups were 71, 210, and 620 ng•hr/mL. With NDP-2, GLP-1 pharmacodynamic effects also included vomiting, decreased body weight (↓3-9%), and food consumption (↓1-23%) at all doses; no target organ toxicity was identified with NDP-2. Toxicologically important findings were again limited to injection site reactions at all NDP-2 doses, but the severity of the reactions, characterized as minimal-to-moderate pyogranulomatous inflammation, was reduced relative to the NDP-1 formulation. Correlative clinical pathology changes were also diminished relative to NDP-1. On Day 28, $AUC_{0\text{-}24hr}$ values for the 0.2-, 0.8-, and 3-mg/kg groups were 52, 137, and 349 ng•hr/mL. In conclusion, LY307161 NDP-2 exhibited an improved local tolerability profile in dogs. The NOEL for target organ toxicity with either LY307161 formulation was 3 mg/kg. Plasma exposure (AUC) at the NOEL was 35- to 63-fold the maximum anticipated human exposure thus demonstrating an adequate Margin of Safety.

1594 HEPATIC PEROXISOMAL PROLIFERATION AND MICROSOMAL ENZYME INDUCTION BY THE LIPID-REGULATING AGENT CI-1027 IN RODENT AND NONRODENT.

R. M. Walker[1], L. M. King[1], E. J. McGuire[2], D. Manca[1] and L. Radulovic[2]. [1]*Drug Safety Evaluation, Pfizer Global Research & Development, Mississauga, ON, Canada and* [2]*Drug Safety Evaluation, Pfizer Global Research & Development, Ann Arbor, MI.*

CI-1027 (6, 6'-oxybis[2, 2-dimethyl-4-hexanoic acid]-Ca) is a dicarboxylic acid lipid-regulating agent in experimental models of dyslipidemia. Hepatic peroxisome proliferation and microsomal enzyme induction were evaluated after oral CI-1027 administration for 2 weeks in beagle dogs, 4 weeks in Wistar rats and cynomolgus monkeys, and 13 weeks in B6C3F1 mice. Peroxisomal enzyme activity markers were carnitine acetyltransferase, acyl CoA oxidase, β-oxidation, and catalase, and microsomal enzyme activity markers included lauric acid hydroxylase, an activity marker for CYP4A1, and UDP glucuronyl transferase (GT). No hepatic changes occurred in dogs given doses up to 1000 mg/kg. In monkeys, liver weight increased at 300 mg/kg, but was unchanged at 10 to 100 mg/kg. However, there was no pattern of enzyme changes indicative of peroxisomal proliferation or microsomal enzyme induction in monkeys. In rats at all doses, 30 to 750 mg/kg, liver weight increased up to ~100% and peroxisomal enzyme activities up to 6-fold. Lauric acid hydroxylase increased up to 11-fold at all doses in rats and GT activity increased up to 1.5-fold at 100 to 750 mg/kg. Increased CYP4A concentrations were confirmed with an ELISA. In mice, liver weight increased up to 25%, peroxisomal enzyme activities increased 48% to 4.7-fold, and microsomal lauric acid hydoxylase increased 3- to 10-fold at all doses (500, 1000, and 2000 mg/kg). Peroxisome proliferation was confirmed by ultrastructural evaluation. Toxicokinetic profiles revealed that CI-1027 exposures were less than dose-proportional in all species. It is concluded that CI-1027 is similar to related compounds that induce hepatic peroxisome proliferation and microsomal enzyme induction in rats and mice, but not in nonrodent species.

1595 PRECLINICAL SAFETY EVALUATION OF THE LIPID-REGULATING CANDIDATE CI-1027 IN CYNOMOLGUS MONKEYS AFTER 4 AND 26 WEEKS OF ORAL DOSING.

D. Manca[1], E. J. McGuire[1], M. Albassam[2] and R. J. Walker[1]. [1]*Drug Safety Evaluation, Pfizer Global Research & Development, Mississauga, ON, Canada and* [2]*Drug Safety Evaluation, Pfizer Global Research & Development, Ann Arbor, MI.*

The sub-acute and chronic effects of CI-1027 (6, 6'-oxybis[2, 2-dimethyl-4-hexanoic acid]-Ca), a peroxisome proliferator in rodents, were investigated in male and female cynomolgus monkeys receiving 10, 30, 100, or 300 mg/kg daily by gavage for 4 weeks, or 10, 30, or 100 mg/kg for 26 weeks. In the 4-week study, 1 male and 2 females at 300 mg/kg were euthanized moribund during Week 3 or 4. Clinical laboratory changes consisted of decreased RBC count/hematocrit/ hemoglobin in females at 100 and 300 mg/kg (10% to 27% from pretest), and increased APTT (41% to 72%) and PT (14%) in males at 100 and 300 mg/kg. Pathological changes included increased relative liver weight at 300 mg/kg (58% to 93%), hepatocellular hypertrophy and/or hepatocellular fatty change, and decreased fine vacuolation of the adrenocortical zona fasciculata at 100 and 300 mg/kg. There was no hepatic microsomal or peroxisomal enzyme induction, indicating absence of peroxisome proliferation. In the 26-week study, RBC count/hematocrit/hemoglobin were 11% to 18% lower in males and females at 100 mg/kg. Slight decreases in mean corpuscular volume (7.1%) and mean corpuscular hemoglobin (9.2%) were also noted in males at 100 mg/kg. Increase in absolute (32% to 34%) and relative (46% to 49%,) liver weight and relative kidney weight (33% to 45.6%) were noted in males and females receiving 100 mg/kg. Microscopic findings consisted of a dose-related increase in the relative incidence and severity of lipid vacuolation in the liver of all males and females receiving 30 and 100 mg/kg. Lipid vacuolation was also noted in the kidneys of 2 animals at 30 mg/kg, and all animals at 100 mg/kg. CI-1027 appears to act similar to other peroxisome proliferators in primates.

1596 TOXICOKINETIC-TOXICODYNAMIC RELATIONSHIPS IN HUMAN PHENOBARBITAL POISONINGS.

B. Mégarbane, F. J. Baud, S. W. Borron and C. Bismuth. *Intensive Care Unit, Lariboisière Hospital, Paris, France.*

The value of PK-PD relationships in clinical pharmacology is now well recognized. However, the potential interest of Toxicodynamic-Toxicokinetic (TK-TD) relationships in medical toxicology has been poorly investigated. The aim of this study was to correlate the depth of coma with plasma phenobarbital (PB) concentrations. Materials and Methods: Plasma PB concentrations were measured using an enzymatic assay. The depth of coma was assessed using the Glasgow coma scale (GCS). Non-linear regression was used for modeling TK-TD relationships. Results : TK-TD relationships were studied in 6 acute PB poisonings. Two patients were previously treated with PB. Previous treatment was unknown in 2 patients. Mixed drug poisoning was noted in 2 patients. The GCS at the time of hospital admission was 3 in the 6 patients, the mean plasma PB concentration was 710.5 +/- 281.9 µmol/l (range: 360 – 1030). The TK-TD relationship was well fitted with the sigmoidal Emax model. In the 6 patients, the mean Hill coefficient (m+ SD) was 6.0 +/- 1.9 and the mean C50 was 289.7 +/- 97.1 µmol/l (range: 170 – 440). Discussion: A maximal toxic effect (GCS of 3) was associated with a wide range of plasma PB concentrations. During the course of PB poisoning, the relationship between the depth of coma and the corresponding plasma PB oncentration is of a sigmoidal shape. The high value of the Hill coefficient showed that a small decrease in plasma PB concentrations near the C50 was associated with a dramatic improvement in their level of consciousness. In the 6 patients, the mean C50 was approximately equal to 3-fold the upper limit of the therapeutic plasma concentration of PB given by our toxicological laboratory (< 100 µmol/l).

1597 CLINICAL SYNDROME ASSOCIATED WITH ALPRAZOLAM INGESTION IN DOGS: 238 REPORTS (JANUARY 1998-AUGUST 2001).

T. A. Wismer, J. A. Richardson and J. C. Albretsen. *ASPCA-Animal Poison Control Center, Urbana, IL.*

Alprazolam is a benzodiazepine that is used as an anti-anxiety agent. Alprazolam acts at the limbic, thalamic, and hypothalamic level of the CNS and has anxiolytic, sedative, hypnotic, skeletal muscle relaxant, and anticonvulsant properties. A retrospective study was conducted of alprazolam ingestion in dogs that were reported to the ASPCA Animal Poison Control Center between January 1998 to August 2000. Data analysis included amount ingested, clinical effects, and time of onset of signs. Two hundred and thirty-eight cases of suspected alprazolam toxicoses in dogs (ranging in age from 11 weeks to 13.5 years) were evaluated. Approximate ingested dosages ranged from 0.01 to 5.55 mg/kg. Of the two hundred and thirty-eight cases of suspected toxicosis, there were 108 males (45%) and 113 females (47%.) Gender information was not available in 17 dogs (7%.) Incidence of clinical signs reported included: ataxia/disorientation (68 %, 161 cases), depression (34%, 83 cases), hyperactivity (13%, 30 cases), vomiting (8%, 19 cases), weakness (7%, 18 cases), tremors (5 %, 13 cases), and vocalization (4%, 10 cases.) Other signs reported included tachycardia, tachypnea, hypothermia, diarrhea, and increased salivation. In 38% of cases, clinical signs developed within 10 – 30 minutes. Treatment of overdoses would include standard decontamination procedures, such as emesis and activated charcoal. Flumazenil is a specific benzodiazepine antagonist and could be used to treat dogs with severe CNS depression.

1598 ATTENUATION OF HEPATIC FIBROSIS OBSERVED WITH A "GUTLESS" ADENOVIRAL VECTOR.

L. M. King[1], J. E. Markovits[2] and R. M. Lyons[1]. [1]*Genetic Therapy, Inc., Gaithersburg, MD and* [2]*Novartis Pharmaceuticals, East Hanover, NJ.*

Adenoviral vectors are being explored as potential therapeutic agents, although clinical utility has been limited due to the adverse effects seen in liver following intravenous injection. In previous studies, we demonstrated in male monkeys and CD-1 mice that an early generation adenoviral vector caused hepatocellular apoptosis and activation of hepatic stellate cells with subsequent fibrosis. In this study, in order to determine if viral gene expression contributes to hepatic toxicity, male and female CD-1 mice were injected with 6×10^{11} (low dose), 3×10^{12} (mid dose) or 1.5×10^{13} (high dose) viral particles/kg of either an early generation vector (Av3Null) or a "gutless" vector with all viral genes removed (AGVNull). Serum IL-6 levels were measured during the first week after dosing. Selected clinical pathology parameters were evaluated on days 2, 8, 15, 29, 43, and 57. Histopathology was evaluated at day 8 and 57. Dramatic increases (200 fold) in serum IL-6 levels were seen in high dose mice 6 hours after receiving either vector. Significant elevations in serum liver enzymes were seen in high dose mice with either vector on day 2, with a decrease in platelets observed in these animals at day 4. Values returned to normal by the termination of the study. Morphological changes were present following treatment with either vector and included hepatocellular apoptosis, extramedullary hematopoiesis, activation of stellate cells and increased extracellular matrix production. Hepatic fibrosis (as measured by sirius red index) in both sexes was not significantly different from controls following treatment with the gutless vector, but significant differences were seen in Av3Null-treated animals. In summary, liver changes produced by the gutless vector were less severe than those due to Av3Null. Since serum liver enzyme measurements did not reveal these vector-induced hepatic changes, studies are currently underway to determine if serum collagen and alpha-GST levels can be used as markers for early detection of hepatic injury and fibrosis.

1599 BIODISTRIBUTION STUDIES AS PART OF THE PRECLINICAL TOXICOLOGICAL ASSESSMENT OF CANARYPOX GENE TRANSFER VECTORS.

M. Christ[1], L. Bonnet[1], F. Roche[1], J. C. Golfier[1], E. Duperray[1], F. Fievet-groyne[2] and F. Verdier[2]. [1]*MDS Pharma Services, Lyon, France and* [2]*Aventis Pasteur, Marcy L'etoile, France.*

One critical point in the non-clinical safety evaluation of gene transfer products is the evaluation of the distribution of the exogenous genetic material after administration. Therefore, biodistribution studies are requested by the authorities in the early development phases. The goals of vector biodistribution studies are: (1) to assess possible dissemination of the vector to the germ-line cells with the potential risk of transmission to the offspring and (2) to assess dissemination to non-target tissues, providing information about the potential target organs for toxicity, which helps with the design and conduct of toxicology studies. As part of a toxicology study, we evaluated the biodistribution of the canarypox virus DNA, ALVAC(2)-gp100 mod vaccine, by nested qualitative PCR in Cynomolgus monkey tissues following repeated administrations by the intranodal or subcutaneous route. Forty days after the last ALVAC injection, ALVAC(2)-gp 100 mod DNA sequences were found by PCR in the injected inguinal lymph node in 4 out of 4 intranodal-injected animals, and in the right axillary lymph node (draining the last injection site) in one out of 4 subcutaneous-injected animals. There were no positive PCR results in any other organs, including gonads. These results complete those from a generic study in the rat with an « empty » ALVAC vector (no inserted gene) administered by 3 different routes (intravenous, subcutaneous and intramuscular). This generic study included several sacrifice time points and employed a quantitative PCR method. This strategy, employing an extensive analysis of the vector itself without any inserted genes together with PCR data on the candidate product as part of the pivotal toxicology study, not only complies with both US and European requirements but also represents the most rational approach in terms of cost and analysis.

1600 LYSOSOMAL-STORAGE DISORDER INDUCED BY ELMIRON IN RATS AND MICE.

A. Nyska[1], J. B. Nold[2], J. D. Johnson[3] and K. Abdo[4]. [1]*Laboratory Experimental Pathology, NIEHS, Research Triangle Park, NC,* [2]*Pathology Associates, Durham, NC,* [3]*Battelle Columbus Laboratories, Columbus, OH and* [4]*Environmental Toxicology Program, NIEHS, Research Triangle Park, NC.*

Elmiron, a highly sulfated, semi-synthetic pentose polysaccharide with properties similar to heparin, is used for the treatment of interstitial cystitis. Thirteen-week gavage studies were conducted by administering the drug in deionized water to F344/N rats and B6C3F1 mice once daily, 5 days per week for up to 13 consecutive weeks, at doses of 0, 63, 125, 250, 500, and 1000 mg/kg body weight. No significant drug-related effects were observed in body weight, survival, and clinical and gross necropsy results. Significant organ weight increases were seen in the liver, lung, and spleen of both species and the kidney of rats, mainly in groups treated with 250 mg/kg/day and above. Hematological analysis indicated increases for both species in the white blood cell and lymphocyte counts. Sites of toxicity identified histopathologically were the rectum, liver, mesenteric and mandibular lymph nodes (both species), spleen (mice only), and lungs and kidneys (rats only). Lesions consisted mainly of infiltration into multiple tissues of vacuolated histiocytes; histochemical investigation indicated the presence of neutral and acidic mucins and lipidic material within the vacuoles. Transmission electron microscopy identified these vacuoles as lysosomal structures that exhibited a variety of contents. On the basis of our findings, we propose that Elmiron was absorbed through the focally disrupted rectal mucosa, accumulated in the lamina propria, phagocytized, and then transported *via* the lymphatics and blood to the various organ sites manifesting histiocytic infiltration. The cytoplasmic membrane-bound structures within macrophages are lysosomes containing membranous material of cellular origin and, perhaps, remnants of the phagocytized test material, Elmiron.

1601 A FRACTURE HEALING STUDY OF PRINOMASTAT™ IN THE SKELETALLY MATURE SPRAGUE-DAWLEY RAT.

A. M. Leyshon[1], S. Y. Smith[1], L. Chouinard[1], B. Dube[1] and G. J. Stevens[2]. [1]*Toxicology, CTBR, Senneville, PQ, Canada and* [2]*Pfizer Global R&D / Agouron, La Jolla, CA.*

This study was designed to investigate the effect of prinomastat (a matrix metalloproteinase inhibitor) on fracture healing in the rat, during twice daily oral administration at dose levels of 20, 100 and 250 mg/kg/day for a minimum of 3 or 6 consecutive weeks, commencing the day following surgical induction of a closed femoral fracture with intramedullary pinning. Selected endpoints (histopathology, biomechanical testing, *ex vivo* peripheral quantitative computed tomography (pQCT) and *ex vivo* dual energy X-ray absorptiometry (DXA) provided an assessment of effects on the reparative and modelling/remodelling phases of the healing process. Surgery involved a parapatellar incision into the joint capsule of anesthetized rats, lateral retraction of the patellar ligament and insertion of an intramedullary Kirshner wire into the femur such that knee joint mobility was unaffected. Following wound closure, a closed transverse fracture of the femoral diaphysis was created using a blunt guillotine driven by a dropped weight. Radiographs were taken following surgery. Minimal comminution and angulation of the intramedullary pin was permitted. Prinomastat was well tolerated, with no adverse toxicological effects, although a reduction in body weight gain was noted. Treatment resulted in reduced biomechanical strength associated with reduced callus formation, evidenced by a reduction in callus area and mineral content as determined by DXA and/or pQCT. Histopathological data suggested prinomastat delayed callus formation/remodelling in rats with an experimentally induced closed fracture. These data suggest that prinomastat delays fracture healing in rats, as evidenced by a reduced callus and biomechanical properties at Week 3 and by persistent soft callus at Week 6, however, prinomastat does not completely inhibit the healing process.

1602 POSTPRANDIAL SERUM CALCIUM IS A SURROGATE MARKER FOR CHANGES IN INTESTINAL CALCIUM ABSORPTION INDUCED BY THE VITAMIN D ANALOG RO 65-2299 IN THE DOG.

T. Pfister, M. Bopst and H. Urwyler. *Nonclinical Drug Safety; General Toxicology, F. Hoffmann La-Roche, Basel, Switzerland.* Sponsor: M. Stephan-Guelder.

Calcium-related toxicity, typical for the class of vitamin D (VitD) analogs, is characterized by increased intestinal calcium (Ca) absorption accompanied by increased renal Ca excretion and at an advanced stage of disturbed Ca homeostasis, hypercalcemia. While urinary Ca and serum Ca concentrations can be easily measured by standard methods, quantification of intestinal Ca absorption requires specialized methods not normally applied in routine studies. In toxicity studies with the VitD analog Ro 65-2299, we established a simple indirect method to identify changes in intestinal Ca absorption in the dog. The animals were adapted to a defined amount of feed given during one hour period in the morning. Ro 65-2299 was administered daily by the oral route during this hour. After at least 5 days treatment, blood was collected before and at 6-8 time points within 6-7 hours after dosing. We demonstrated a dose-dependent effect on the increase in serum Ca concentration during the first few hours after feeding. This was well correlated with Ca-related toxicity observed in subchronic 4-week and 13-week toxicity studies. At non-toxic doses up to 100 mg/kg/day, the postprandial serum Ca concentrations did not exceed the normal range of 2.4-3.0 mmol/l. At 200 mg/kg/day the postprandial Ca level rose slightly above the normal range in some animals but returned to normal before the next day feeding. The 200 mg/kg/day caused only a transient hypercalciuria only after 5 to 8 weeks of treatment. At higher doses (300 and 400 mg/kg/day over 5 days; 250 mg/kg/day over 4 weeks) postprandial calcium levels markedly exceeded the normal range, which corresponded with severe hypercaliuria and hypercalcemia. In conclusion, the time-concentration profile of serum Ca after feeding under defined conditions is considered a surrogate marker for changes in intestinal Ca absorption, due to treatment with VitD analogs.

1603 ABSENCE OF TOXICOLOGICAL EFFECTS FROM THE IMMUNOLOGICAL ADJUVANT MONOPHOSPHORYL LIPID A (MPL®).

P. Baldrick[1], D. Richardson[2], G. Elliott[3] and A. W. Wheeler[2]. [1]*Covance Laboratories Ltd, Harrogate, United Kingdom,* [2]*Allergy Therapeutics Ltd, Worthing, United Kingdom and* [3]*Corixa Corporation, Hamilton, MT.*

The addition of the immunostimulatory adjuvant monophosphoryl lipid A (MPL®), a detoxified bacterial lipopolysaccharide, to a range of conventional vaccine (eg malaria, herpes, hepatitis) and allergy vaccine (eg grass pollen) materials is the subject of ongoing clinical trials. However despite this use, there are no robust published data on the nonclinical safety assessment of MPL®. Thus a series of preclinical studies have been performed with the material to examine for potential toxicological safety issues. An intravenous cardiovascular/respiratory function assessment in anaesthetized dog (at up to 100 µg/kg/day) showed no adverse effects. Repeat dose subcutaneous or intravenous investigations in the rat (for up to 4 weeks and at up to 2500 µg/kg/day), rabbit (once weekly for 8 weeks at up to 200 µg/kg/occasion) and dog (for up to 2 weeks and at up to 1200 µg/kg/day) showed no unexplained study findings. Expected immunostimulatory effects and/or signs of toxicity associated with over-stimulation of the immune system (notably increase spleen and white cell activity) were seen in the rat and dog. Embryo-fetal and peri-post natal subcutaneous reproduction toxicity studies in rat and rabbit (at up to 100 µg/kg/day) showed no adverse effects. Genotoxicity studies (Ames test and chromosome aberration assay) were negative. Overall, the lack of findings of toxicological concern support the hypothesis that MPL® is a safe adjuvant for human use.

1604 SB-242235: ORAL MALE FERTILITY STUDY IN RATS.

H. M. Solomon, P. J. Wier, M. K. Ziejewski, T. V. Toscano and T. S. Sellers. *Safety Assessment, GlaxoSmithKline Pharmaceuticals, King of Prussia, PA.*

SB-242235 is a selective p38 protein kinase inhibitor which suppresses pro-inflammatory cytokine biosynthesis. The purpose of this study was to evaluate the potential effects of SB-242235 when administered orally by gavage to male rats, on mating, fertility and gonadal function. Male Sprague-Dawley rats (25/group) were treated with 1% methylcellulose or 3, 10 or 100 mg/kg/day of SB-242235 for 85 to 89 days. On days 15 to 22 and on days 71 to 78, the males were cohabited with untreated, virgin female (F0) rats. Mated females were killed on day 20 postcoitus. Drug-related mortality (1 of 25 males) and clinical signs (salivation, stereotypic, kneading behavior) were evident at 100 mg/kg/day. Overall, body weight gain for males was reduced (13%, 19%, 46%, at 3, 10, 100 mg/kg/day, respectively) as was food consumption (up to 8%, 22% at 10, 100 mg/kg/day, respectively). There was no effect on pregnancy following mating on days 15 to 22, but pregnancy rate was significantly decreased *vs.* controls (4% *vs.* 96%) for males given 100 mg/kg/day and mated on days 71 to 78. At 100 mg/kg/day, decreases were evident in weights of the epididymides (left epididymis, intact (22%), right caput and corpus (10%) and right cauda epididymis (36%), and ventral prostate (34%), number of spermatids/gram testis (25%) and sperm/gram cauda epididymis (52%). There was a decrease (83%, control vs 7%, 100 mg/kg/day) in the percentage of motile sperm. In conclusion, SB-242235 produced mortality at 100 mg/kg/day and overt toxicity at all doses. Reproductive toxicity was demonstrated by reduced organ weights (epididymides and ventral prostate), impaired gonadal function (reduced spermatogenesis and sperm motility) and infertility (reduced number of litters sired) among males given 100 mg/kg/day for 10 weeks.

1605 CYCLOSPORIN AND RITONAVIR ARE POTENT P-GP INHIBITORS *IN VITRO*.

J. S. Moffit, R. J. Mireles, J. J. Xu and D. E. Amacher. *DSE/CEG, Pfizer, Groton, CT.*

In humans the multidrug resistance (MDR-1) gene codes p-glycoprotein (P-gp). As an ATP-dependent export pump, P-gp is involved in the transport of hydrophobic, neutral or cationic xenobiotics in a variety of tissues. In addition, the sister of P-glycoprotein (SPGP) is the major canalicular bile salt export pump of mammalian liver. Certain drugs, as for example, cyclosporine (CSA), have been shown to inhibit both P-gp and SPGP, which can result in an impairment of bile flow (cholestasis). Protein trafficking from Golgi to the apical plasma membrane is an important step in the maturation of P-gp. In this study, we compared chrysin, ritonavir, progesterone, prazosin, estradiol-17beta-glucoronide, CSA, and wortmannin, as inhibitors of P-gp in two cell lines based on competition with the efflux of a fluorescent P-gp probe, calcein. The inhibition of P-gp efflux function was investigated following drug treatment in a cell-based assay. The assay compared Madin-Darby canine kidney (MDCK) cells and MDCK cells over-expressing the transfected human MDR1 gene. In the absence of transport inhibition, it has previously been shown that intracellular retention of calcein is high in MDCK cells but low in the MDR1 cells. As a result, we observed inhibition of P-gp efflux function (i.e., increased intracellular calcein fluorescence) by CSA and ritonavir. Our results provide a mechanism for clinically observed effects of CSA and ritonavir.

1606 MISOPROSTOL HAS POTENT *IN VITRO* TUMORICIDAL ACTIVITY THAT IS INDEPENDENT OF ITS PROSTANOID ACTIVITY.

P. F. Wright[1], D. M. Cheah[1] and D. R. Haynes[2]. [1]*Key Center for Toxicology, RMIT-University, Melbourne, Australia and* [2]*Dept Pathology, University of Adelaide, Adelaide, Australia.* Sponsor: P. Di Marco.

Misoprostol (MP) was originally developed as a synthetic prostaglandin (PG) agonist for treating gastric ulcers caused by non-steroidal anti-inflammatory drugs. As part of our research program on the immunomodulatory effects of prostanoid compounds, we investigated the effects of MP on the growth and viability of immune-related tumour cell lines. Mouse leukaemia P388 cells were exposed *in vitro* to MP over 48 hours, and tumouricidal activity was measured by changes in cell number and viability (*via* trypan blue exclusion). MP was potently tumouricidal to P388 leukaemia cells, with a 50% inhibitory concentration (IC_{50}) of 100 nM - exhibiting a similar dose-response curve as that reported for MP's immunosuppression of mouse thymocyte proliferation [1]. In contrast, PGE_2 (the mammalian PGE form and PG receptor agonist) and dibutyryl cyclic AMP (a stable membrane-permeable analog of the intracellular PG messenger, cAMP), had minimal effects on P388 cells, even when used at >0.1 mM, which is orders of magnitude greater than the IC_{50} values for their immunosuppressive effects [1]. Furthermore, MP was equally cytotoxic to the adriamycin-resistant sub-line of P388 (P388/ADR), and was generally more toxic to immune-related tumour cell lines, with the following order of potency: P388 = P388/ADR > mouse T-lymphoma (Yac-1) > mouse mastocytoma (P815) > mouse fibrosarcoma (WEHI-164). This study indicates that MP is potently cytotoxic to leukaemia cells, in a manner that is independent of both its prostanoid activity and the mechanisms involved with tumour resistance to adriamycin. These findings have important implications for the potential use of MP as a selective chemotherapy of immune-related tumours. [1] D R Haynes, M W Whitehouse and B Vernon-Roberts (1992) Immunology, 76: 251-257.

1607 AN INTEGRATED APPROACH TO HAZARD EVALUATION FOR WORKER SAFETY ASSESSMENT OF PHARMACEUTICALS AND SYNTHETIC INTERMEDIATES.

M. J. Olson[1], C. W. Seaman[2] and F. J. Guerriero[3]. [1]*GlaxoSmithKline, Research Triangle Park, NC,* [2]*GlaxoSmithKline, Welwyn, Herts., United Kingdom and* [3]*GlaxoSmithKline, King of Prussia, PA.*

Workplaces in the pharmaceutical industry are unique — hazards may be posed both by synthetic chemistry intermediates and the biologically active substances (drugs) created as products. Effective occupational health programs in the pharma industry rely on substance hazard profiles. These are used to identify appropriate containment and protective strategies and are created/updated to support the process of drug development. However, hazard characterization is constrained by cost containment efforts, ethical considerations in use of laboratory animals, and recognition of high rates of attrition of substances in development. We have developed an animal-sparing, tiered approach for hazard characterization of drugs and intermediates aligned with the development cycle. An initial tier includes physical-chemical characterization (pH/partition coefficient), computerized QSAR (DEREK), *ex vivo* assays assessing skin and eye irritant potential (transcutaneous electrical resistance (TER) and rabbit enucleated eye (REET) tests), high-throughput mutagenicity assays (SOS*umu*, HTFT, COMET) and *in vitro* cytotoxicity tests (predicting acute lethality). Screening of pharmaceuticals occurs earlier in the development cycle than that for intermediates, accounting for changes in the identity of intermediates as syntheses are scaled up for manufacture. A second tier of evaluation includes the local lymph node assay (LLNA) and conventional assays for genetic toxicity (Ames, L5178Ytk+/-). The initial *in silico, in vitro,* and *ex vivo* screens aid by eliminating substances causing positive results from subsequent *in vivo* evaluation for acute oral toxicity, dermal/ocular irritation, dermal sensitization, and potential target organ toxicity (final tier). Benefits of this approach include support for data-based judgments regarding substance hazards and required labeling at appropriate points in development, and the inherent potential for minimizing extensive *in vivo* testing.

1608 NEUROTOXICOLOGY OF BLOOD-BRAIN BARRIER AND BLOOD-CSF BARRIER: STRUCTURAL AND FUNCTIONAL CONCERNS.

W. Zheng[1] and M. Aschner[2]. [1]*Environmental Health Sciences, Columbia University, New York, NY and* [2]*Physiology & Pharmacology, Wake Forest University, Winston-Salem, NC.*

To enter the brain parenchyma chemicals have to cross the brain barrier systems that safeguard the milieu of the central nervous system (CNS). The barrier that separates the systemic circulation from the brainÕs interstitial fluid is defined as the blood-brain barrier (BBB), while the one that separates the systemic circulation from the cerebrospinal fluid (CSF) is named blood-CSF barrier (BCB). Though ubiquitous, certain areas of the brain, referred to as the circumventricular areas are void of the restrictive properties that characterize the BBB. Research in the past decade suggests that beyond the well-defined role as ÒgateÓkeepersÓ, the brain barriers actively participate in brain ontogenesis and development, neuroendocrine regulation, drug efflux and metabolism, aging processes, chemical-induced neurotoxicities, and the etiology of a number of neurodegenerative diseases. For example, the interaction of manganese (Mn) with iron (Fe) metabolism at brain barrier interfaces alters the cerebral homeostasis of Fe, which may contribute to Mn-induced neurodegenerative disorder. Exposure to organophosphate insecticides impairs the BBB, leading to neurotoxic consequences. Metabolism and/or efflux of drugs and endogenous molecules at the barriers are not only critical for an effective drug therapy, but also essential in preventing CNS side effects. Cumulative evidence also suggests that the BBB, by partaking in the development of cerebral amyloidosis, plays an important role in the etiology of Alzheimer's disease. Thus, the investigation of transport, metabolism, and molecular interaction at the brain barrier systems has become a new focus in neurotoxicological research. This symposium will provide comprehensive reviews of the cutting edge research in this area, will discuss the use of new technologies in brain barrier studies, and will explore the brain barriers as the new frontier in drug development, toxicity evaluation, and neurodegenerative disorder research.

1609 BRAIN BARRIERS TOWARDS ORGANIC CHEMICALS: DRUG EFFLUX, BIOTRANSFORMATION AND MULTIDRUG RESISTANCE.

J. F. Ghersi-Egea, N. Strazielle and M. F. Belin. *INSERM U433, Faculté de Médecine RTH Laennec, Lyon, France.* Sponsor: W. Zheng.

The maintenance of brain homeostasis is achieved by 1) the specific properties of the blood-brain interfaces which control the exchange processes between the blood and the brain, i.e., the cerebral capillaries, the choroid plexuses (CPs), and the meningeal arachnoid; and 2) a unique cerebrospinal fluid (CSF) circulatory system in the central nervous system (CNS). These specific brain features protect the brain from exposure to different blood-borne drugs and toxins, and regulate the cerebral clearance of neurotoxicants. The tight junctions that seal both the endothelial cells of the parenchymal capillaries and the choroidal epithelial cells restrict the entry of polar compounds in the CNS. Brain efflux mediated by transporters such as the P-glycoprotein at the blood-brain barrier and members of the oatp(organic anion-tranporting polypeptide) and OAT(organic anion transport) families at the CP epithelium, also limits the cerebral bioavailability of various lipophilic, amphipathic or anionic compounds. Several drug metabolizing and antioxidant enzymes are present at both the blood-brain and blood-CSF barriers. In particular, CP appear to be a main site of detoxification in the brain. The use of an *in vitro* cellular model of this blood-CSF interface allows to demonstrate the existence of an effective metabolic barrier toward neurotoxins at the choroid plexus. This conceptual metabolic barrier is dependent upon the intracellular level of cofactors, such as glutathione, and results from active conjugation processes coupled to a polarized basolateral (i.e., blood-facing) efflux of the conjugated metabolites *via* a multidrug-resistance-

associated efflux pump. Reactive compounds, however, can also be generated at these interfaces by metabolic activation, a process that could lead to a disruption of brain homeostasis, should the antioxidant capacity of the interfaces be overflown.

1610 BLOOD-BRAIN BARRIER TRANSPORT OF METALS: IMPLICATIONS IN CNS HOMEOSTASIS OF ESSENTIAL AND NONESSENTIAL METALS.

M. Aschner. *Physiology and Pharmacology, Wake Forest University School of Medicine, Winston-Salem, NC.*

This lecture will highlight the transport of various metals (e.g. manganese and mercury) across the blood-brain barrier (BBB). It will emphasize the mechanisms of transport and address the means of both essential (manganese) and nonessential (mercury) metal transport by the BBB, *via* the mechanisms of ionic (iron) and molecular (methionine) mimicry, respectively. An important process in the toxicologic outcome of exposure to metals is their transport from plasma into the brain across the capillary endothelial cells that comprise the BBB. In order to cross this barrier, metal complexes must be either highly lipid soluble, or possess affinity for specific carrier-mediated transport systems within the endothelial cell plasma membrane. Little is known about manganese and mercury transport. The objectives of this lecture are, therefore, to identify the transport mechanism(s) of mercury and manganese, under the assumption that increased rate of metals transport across the BBB is reflected in elevated CNS concentrations and by inference increased neurotoxicity. Emphasis will be directed at experimental results derived from both *in vivo* and *in vitro* studies, as well as elaborating on the advantages and disadvantages of current methodologies for the assessment of transport kinetics of these metals, such as tissue culture techniques and *in vivo* microdialysis. (Supported by Public Health Service grant ES07331 and ES10563)

1611 INTERACTIONS BETWEEN TOXICANTS AND TIGHT BARRIERS.

L. P. Bressler[1], D. I. Bannon[1,2], L. B. Olivi[1] and J. Cheong[1,2]. [1]*Neurology, Kennedy Krieger Institute, Baltimore, MD and* [2]*Environmental Health Sciences, Johns Hopkins University, Baltimore, MD.*

Tight barriers such as those formed by epithelial and brain endothelial cells prevent the passage of large molecules or those carrying charges from entering brain, thus providing protection for neural cells against xenobiotics. Nonetheless, toxicants are capable of passing through barriers. Some toxicants have been shown to increase nonspecific permeability by compromising the integrity of the blood brain barrier (BBB). A class of transporters that mediate uptake of metals, for example Pb, are the anion exchangers (AE). Because AE is highly expressed by choroid epithelium, it may explain why lead (Pb) is readily taken into the choroid plexus. However, physiological and anatomical studies have suggested that AE are unlikely involved in the transport of Pb through the intestinal barrier and the BBB. Instead, the major intestinal iron transporter, i.e., divalent metal transporter 1 (DMT1) which has been shown to transport a broad range of metals, may be involved. Overexpression of DMT1 in yeast by results in an increased uptake of Pb, whereas knockdown of DMT1 in intestinal epithelial cells results in a decreased uptake of Cd, suggesting that DMT1 mediates the transport of Pb and Cd. Interestingly, DMT1 requires H+ for its function and thus is not likely to be involved in the transport of Pb from the blood across the BBB. Pb at higher concentrations does not require a transporter because it induces a breakdown in the BBB. Organophosphate insecticides also increase permeability of toxicants by inducing a similar breakdown in the BBB. In summary, tight barriers express specific transporters for nutrients that can also transport toxic metals. Additionally, toxicants can increase permeability by compromising the integrity of the tight barriers.

1612 CONTRIBUTIONS OF BRAIN BARRIERS IN NEURODEGENERATIVE DISORDERS AND CHEMICAL-INDUCED NEUROTOXICITIES.

W. Zheng. *Environmental Health Sciences, Columbia University, New York, NY.*

Normal neurological function relies on the delicate chemical balance among neurons, neuroglia and their associated synaptic connections. The damaging effect of a chemical to the barriers can contribute substantially to chemical-induced neurotoxicity. Mechanistically, some chemicals directly disrupt barrier structure and increase its permeability, perturbing the chemical milieu and allowing for unregulated materials to come into contact with brain parenchyma. Other chemicals may not directly alter the morphology of the barriers, but rather impair barriers' regulatory function, bringing about neurotoxicity due to disordered cerebral homeostasis. Furthermore, certain chemicals prior to their entrance to the cerebral compartment are bio-activated or bio-deactivated by metabolizing enzymes present in brain barriers. Recent evidence also suggests that the structural and functional integrity of brain barriers is important in the etiology of Alzheimer's disease. The aging of the cerebral vascular structure, the ability of barriers to transport extracerebral beta-amyloid, and the production of beta-amyloid solubilizing macromolecules by the barriers, are amongst the possible contributive factors under considerable scrutiny, although the role of chemical exposure in disordered barriers of Alzheimer's remains poorly understood. In addition, the dysfunction in iron regulation at brain barriers caused by manganese (Mn) exposure has been suggested to underlie a Mn-induced Parkinsonism-like syndrome. This lecture examines the current understanding of the role of brain barriers in CNS disorders by focusing on chemical-induced neurotoxicity. The perspectives for future research needs will also be discussed.

1613 NIEHS SYMPOSIUM: ENVIRONMENTAL INFLUENCES ON CHILDHOOD ASTHMA.

K. M. Olden. *NIEHS, Research Triangle Park, NC.*

Childhood asthma is the subject of the symposium. This disease was chosen because of the strong link to environmental exposures, the gene-environment interactions, and because it represents an example of how basic research can be translated into intervention and prevention programs. In addition, childhood asthma is a chronic lung disorder of enormous public health importance that disproportionately affects minorities and persons of lower socioeconomic status. It is the most frequent cause of pediatric emergency room use and hospital admissions and is the leading cause of school absences. Despite improvements in diagnosis and management, and an increased understanding of the epidemiology, immunology, and biology of the disease, asthma prevalence, morbidity, and mortality have progressively increased over the past 15 years. To reduce the incidence of childhood asthma a multidisciplinary approach to the research effort is necessary. This symposium will include presentations that span research in epidemiology, molecular mechanisms, gene-environment interactions, environmental agents related to the disease, and intervention and prevention of childhood asthma.

1614 ENVIRONMENTAL INFLUENCES ON CHILDHOOD ASTHMA.

F. D. Martinez. *Arizona Respiratory Center, University of Arizona, Tucson, AZ.* Sponsor: K. Olden.

Significant advances have been made during the last ten years in our understanding of the environmental factors that may protect against or predispose to the development of asthma. The finding that most cases of asthma begin during the first years of life has focused the attention of many researchers to the factors that may influence the risk for asthma in these early years of development. The study of risk factors for asthma is complicated by the heterogeneous nature of the disease. Recurrent airway obstruction is the final common pathway for at least three different syndromes, which co-exist during infancy and childhood. "Transient infant wheezing" is confined to the first 2-3 years of life and is benign in course and mainly associated with maternal smoking during pregnancy. "Non-atopic wheezing" is a typical disease of infants and toddlers but may also persist up to the school years. It is characterized by attacks by wheezing mainly associated with wintertime infections. "Atopic asthma" is less frequent during the early years but becomes the most prevalent form of asthma by early adolescence. It is associated with chronic symptomatology, deficits in lung function, and persistence of symptoms into the adult years. It now appears that, whereas early microbial burden is a risk factor for transient infant wheezing and non-atopic asthma, several studies have shown that such burden is a protective factor against the development of atopic asthma. The mechanisms by which microbial burden in early life protects against the development of atopic asthma are beginning to be understood. Exposure to external "danger" signals that interact with the innate immune system may be necessary for the development of a mature, balanced immune response that may last for a lifetime. Lack of such microbial burden at crucial times at the development of the immune system may select certain forms of immune responsiveness that are associated with allergic sensitization, airway hyperresponsiveness, and chronic asthma systems in susceptible individuals.

1615 ENVIRONMENTAL AGENTS RELATED TO CHILDHOOD ASTHMA.

D. Zeldin. *NIEHS, Research Triangle Park, NC.* Sponsor: K. Olden.

Prior studies indicate that exposure to a variety of indoor allergens, such as those that derive from house dust mites and cockroaches, are important risk factors for the development of allergy and asthma in children. Moreover, recent studies indicate that bacterial endotoxin may be an important environmental factor in asthma

pathogenesis and that exposure to both allergens and endotoxin may cause a more severe inflammatory response than exposure to either stimulus alone. The National Allergen Survey, a descriptive study of allergen types/levels and endotoxin in floor and bedding dust in the nation's housing, is the first study to provide estimates of allergen and endotoxin exposure in the entire US population. The survey was conducted between 1998-1999 using a population-based, multi-stage area probability design which has yielded a sample that is representative of diverse geographic regions, socioeconomic groups and housing types. It encompasses 831 homes in 75 primary sampling units located throughout the country. The major endpoints are measurements of dust mite (Der f 1, Der p 1), cockroach (Bla g 1), cat (Fel d 1), dog (Can f 1), rodent (Mus m 1, Rat n 1) and fungal (Alternaria) allergen levels, and endotoxin in dust samples collected from an array of sites in the surveyed homes. This presentation will: (a) provide a brief overview of previous studies which demonstrate a relationship between indoor allergen/endotoxin exposure and asthma/allergy; (b) review preliminary data from the National Allergen Survey which provide current estimates of indoor allergen/endotoxin exposure in the US housing stock; and (c) discuss regional, socioeconomic, and housing factors that influence indoor allergen/endotoxin exposure.

1616 CELLULAR AND MOLECULAR MECHANISMS OF ASTHMA PATHOGENESIS.

M. Wills-Karp. *Division of Immunobiology, Childrens Hospital Medical Center, Cincinnati, OH.* Sponsor: D. Brown.

Asthma is characterized by variable airflow obstruction, airway hyperresponsiveness and airway inflammation. The inflammatory response in the asthmatic lung is characterized by infiltration of the airway wall with mast cells, lymphocytes and eosinophils. Although asthma is multifactorial in origin, recent advances suggest that asthma is an immune disease with a prominent role for T lymphocytes in the pathogenesis. As such, CD4+ T cells producing a Th2 pattern of cytokines (IL-4, IL-13, IL-5) have been hypothesized to play a pivotal role in the pathogenesis of this disease. The paradigmatic Th2 cytokines, IL-4 and IL-5, had been thought to be the primary regulators of the allergic response. However, recent studies from my group have shown that IL-13 is likely the central mediator of the effector phase of allergic responses. Specifically, we showed that blockade of IL-13 at the time of antigen challenge in antigen sensitized mice *via* administration of a sIL-13Rα2-Ig which only binds IL-13, ablated antigen induced AHR. Furthermore, delivery of the recombinant cytokine to the lungs of naive animals reproduced the entire allergic phenotype (i.e. AHR, eosinophilia, mucus hyperplasia). A role for IL-13 in human asthma has been suggested by the demonstration that IL-13 mRNA and protein levels are elevated in the lungs of asthmatics as compared to normal individuals. Although the exact mechanisms by which IL-13 induces AHR are currently not known, IL-13 has effects on a number of effector cells thought to be important in asthma including mast cells, B cells, eosinophils, airway epithelial cells, and smooth muscle cells. Grunig et al, 1998 have shown that T and B cells are not necessary for IL-13-induced AHR. Recent findings from my laboratory suggest that IL-5 and eosinophils are also not necessary for the effects of IL-13 on airway reactivity. As IL-13 receptors are expressed on airway smooth muscle cells, IL-13 may have direct effects on airway smooth muscle contractile function. Determination of the exact mechanisms by which IL-13 induces airway hyperresponsiveness awaits further studies.

1617 GENE-ENVIRONMENT INTERACTIONS IN CHILDHOOD ASTHMA.

S. Kleeberger. *Environmental Health Sciences, Johns Hopkins University, School of Public Health, Baltimore, MD.*

The prevalence of asthma morbidity and mortality has increased in industrialized countries at an alarmingly high rate for the last 20 years. The rates are disproportionately high in urban environments and in children, but the causes are unknown. It has become increasingly clear that genetic background is an important determinant. Inheritance patterns of asthma indicate that it is a complex quantitative disease. The complexity stems partly from the number of subphenotypes that characterize the disease, including airways hyperresponsiveness, inflammation, and allergic status. For each subphenotype, there may be a gene or set of genes that confer susceptibility or predisposition, and these genes interact to produce the asthma phenotype(s). Genome-wide searches for linkages of asthma subphenotypes have revealed a number of quantitative trait loci, each of which has potential candidate genes for the phenotype in question. Further, family and population studies have identified linkage of specific phenotypes with candidate genes. However, genetic background alone cannot account for the increasing asthma prevalence. The expression of the disease or its subphenotypes is likely dependent on environmental factors. That is, the relative risk of asthma for a specific gene or combination of genes may be a function of the frequency of exposure to the environmental agent, the strength of interaction between the genotype and the agent, and the specificity of the environmental effect with respect to the genotype. Potentially important environmental exposures for asthma include indoor air pollutants (NO2, tobacco smoke), outdoor air pollutants (ozone, PM2.5 and ultrafine, NO2, and SO2), and allergens such as house dust mite, cockroach, pollen, and cat dander. Assessment of exposure to these agents is critical to evaluating respective risk for each relative to specific genotypes. Understanding the interaction of environmental and genetic factors will lead to improved evaluation of risk of a specific genotype(s) for a given environmental exposure, and a potential means for intervention and prevention.

1618 A COMMUNITY-BASED PARTICIPATORY RESEARCH APPROACH TO REDUCING ENVIRONMENTAL TRIGGERS TO CHILDHOOD ASTHMA IN DETROIT.

B. A. Israel, E. A. Parker, T. Robbins, T. Keeler and T. Dvonch. *Health Behavior and Health Education, University of Michigan, Ann Arbor, MI.* Sponsor: K. Olden.

The Michigan Center for the Environment and Children's Health (MCECH), is one of the NIEHS/EPA, Centers for Children's Environmental Health and Disease Prevention. MCECH's research projects focus on: 1) determining the effects of allergen-induced local, excessive production of chemokines on the respiratory system; 2) assessing the separate and possible interaction effects of outdoor and indoor air quality on exacerbation of asthma in children; and 3) household and neighborhood level interventions focusing on reduction of environmental triggers for asthma among children in the southwest and east side of Detroit. The latter two projects have been combined to form Community Action Against Asthma (CAAA). A unique feature of the CAAA project is the use of a community-based participatory research approach. CAAA's household intervention employs Community Environmental Specialists (CES) who visit the homes of intervention participants using an individualized plan that has been developed jointly with the caregiver. This plan draws upon data such as, the results of the child's allergy skin-test, a household dust sample, the caregiver's responses on a baseline survey, and a household environmental assessment tool. Through this plan, the CES's are able to tailor the activities in their visit (e.g., education on asthma and indoor environmental triggers and social support); supplies (e.g., vacuum cleaners, mattress covers, cleaning supplies); integrated pest management services; and referrals to social service/health agencies to emphasize those changes likely to impact the child's asthma symptoms.

1619 IS THERE REPRODUCTIVE RISK ASSOCIATED WITH EXPOSURE TO DISINFECTION BY-PRODUCTS OF DRINKING WATER?

G. R. Klinefelter. *Reproductive Toxicology Division, USEPA, Research Triangle Park, NC.*

The Safe Drinking Water Act requires the US Environmental Protection Agency to establish national drinking water standards that protect the health of the 250 million people who get their drinking water from public water systems. Today there is considerable interest on the part of Stakeholders (i.e. Congress, water industry, environmental groups) in the potential adverse reproductive and developmental outcomes associated with exposure to chemical by-products formed during the process of drinking water disinfection. During summer 2002 the Federal Advisory Committee will cast its final decision on the existing Stage 2 DBP rule which sets the maximum contaminant level goal for by-products in finished drinking water. Toxicology data demonstrate that sensitive reproductive and developmental endpoints are perturbed by specific disinfection by-products (DBPs). Epidemiology data suggest an association between elevated DBPs and adverse reproductive outcomes such as spontaneous abortion, still birth, and developmental anomalies. While there are still insufficient epidemiology data to substantiate causality, the toxicologic data provide some degree of biological plausibility. Of particular interest are emerging toxicology data which: establish the potential for DBPs to adversely affect the developing reproductive system, indicate that animals with a longer period of reproductive development are more sensitive to DBP-induced effects, and identify novel biomarkers applicable to epidemiology. In addition, proteomic data provided from both developmental and reproductive studies might aid in the elucidation of the mode of action of the haloacids. However, both the toxicology as well as the epidemiology data suffer from weaknesses which make formal risk assessment difficult. Moreover, one of the most perplexing issues surrounding the risk assessment process of DBPs is the requisite cost-benefit analysis, and it is for this reason that Stakeholders are undergoing intensive debate.

1620 REPRODUCTIVE AND DEVELOPMENTAL EFFECTS ASSOCIATED WITH HUMAN EXPOSURES TO DISINFECTION BY-PRODUCTS.

J. S. Reif. *Department of Environmental Health, Colorado State University, Fort Collins, CO.* Sponsor: G. Klinefelter.

While chlorination, the primary method of disinfecting municipal water in North America, is pivotal to protect the public from water borne infectious agents, the numerous byproducts formed during disinfection (DBPs)are now considerd a poten-

tial health risk. The chemical mixture of DBPs include trihalomethanes, haloacetic acids, and haloacetonitriles/aldehydes. Reproductive endpoints are important potential outcomes of DBP exposure for several reasons: (1) due to the ubiquitous nature of the exposure, small increases in relative risk will have a significant public health impact; (2) the fetus and reproductive system are sensitive to environmental toxicants; and, (3) they can be effectively studied because the interval between exposure and outcome is short. The epidemiologic database evaluating this relationship remains sparse. To date, there have been 18 studies published; 9 relied on reported quarterly concentrations of THMs in water supplies serving the subjects' community as the exposure metric. The remainder used a qualitative exposure assessment to examine associations between water source or method of disinfection and risk of adverse reproductive outcome. Several studies found weak associations between exposure to DBPs and adverse reproductive outcomes including spontaneous abortion, stillbirth, low birth weight, intrauterine growth retardation, somatic parameters and developmental anomalies (e.g. heart, oral cleft and central nervous system malformations). Recent studies suggest that the brominated DBPs may be more hazardous. However, the findings are inconsistent and the epidemiologic evidence is insufficient to infer a causal relationship. Additional laboratory and human studies are needed before this issue can be resolved. Future human studies should incorporate improved methods of exposure assessment to reduce misclassification, focus on specific byproducts, especially the brominated species of the trihalomethanes and haloacetic acids, and include additional outcomes such as fertility, fecundity and potential effects on semen markers.

1621 DEVELOPMENTAL CONSEQUENCES OF EXPOSURE TO DISINFECTION BY-PRODUCTS IN ANIMAL MODELS.

E. S. Hunter. *Reproductive Toxicology Division, USEPA, Research Triangle Park, NC.* Sponsor: G. Klinefelter.

Disinfection by-products (DBPs) have been associated with a variety of adverse developmental outcomes in epidemiology studies including cardiac defects, neural tube defects, still births, and spontaneous abortions. In toxicology studies, the trihalomethanes (THMs) do not produce high rates of dysmorphogenesis, but selected THMs do cause pregnancy loss, i.e. full-litter resorptions (FLR) in rats. Serum luteinizing hormone (LH) is diminished when bromodichloromethane (BDCM) is administered to Fischer 344 rats during the LH-dependent period of pregnancy maintenance suggesting that perturbation of the endocrine axis may be responsible for FLR. The possibility that BDCM compromises LH responsivity is also being explored as this has more relevance to human pregnancy maintenance. Among the haloacetic acid (HA) class of DBPs, trichloroacetate (TCA) and dichloroacetate (DCA) each induce heart, eye and kidney defects in rats. Dibromoacetate (DBA) produces small/absent kidneys in mice, eye defects in rats and skeletal abnormalities in both species. Bromochloroacetate (BCA) exposure results in decreased fetal implants and live fetuses. In the rat, BCA reduced day 6 pup weights, and DBA induced pre-and postnatal loss and reduced pup weight on PND 1 and 6. When compared in mouse whole embryo culture (WEC) the relative potency of the HAs are BCA>DBA>DCA. Dose additivity of DCA, DBA and BCA was observed in rat WEC. Haloacetonitriles, another class of DBPs, induce FLR [dichloroacetonitrile {DCAN) and trichloroacetonitrile {TCAN)], decrease birth weight [chloroacetonitrile, DCAN, TCAN, bromochloroacetonitrile BCAN), dibromoacetonitrile (DBAN)], decreased postnatal weight gain (DCAN, BCAN, DBAN) and increased postnatal mortality (DCAN, TCAN). While most DBPs produce effects on development and neonatal growth, many are only effective at doses that produce maternal toxicity. *in vitro,* embryos show induction of cell death with little concurrent effect on the cell cycle. Mechanistic studies are focused on HA-induced alteration in signal transduction pathways.

1622 REPRODUCTIVE TOXICITY IN THE MALE RAT FOLLOWING EXPOSURES TO DISUBSTITUTED HALOACETIC ACIDS.

G. R. Klinefelter. *Reproductive Toxicology Division, USEPA, Research Triangle Park, NC.*

Over the past decade many studies have demonstrated that disubstituted haloacetic acids present in drinking water as a result of disinfection produce adverse reproductive consequences in the male rat. Equimolar exposure to these haloacids over 14 days alters spermatogenesis in a manner which would indicate alterations in sperm quality, and indeed, fertility of cauda epididymal sperm is significantly compromised. The reduction in fertility is associated with diminutions in proteins in detergent extracts of sperm. One protein, SP22, is highly correlated with resultant fertilty. Based on emerging data generated in humans using anti-SP22 antibodies, future drinking water epidemiology studies may incorporate an assessment this biomarker. It is interesting that when haloacid exposures span the duration of spermatogenesis (i.e. 70 days), Sertoli-cell only seminiferous tubules manifest, even 6 months after cessation of exposure. This exacerbation rather than recovery may be significant in species in which spermatogenesis is less efficient (e.g. humans). Evidence that the magnitude of effects increase with duration of exposure has also been provided by assessments of the developing reproductive system. It is now clear that the duration of exposure rather than the window of exposure accounts for significant delays in preputial separation. Again, implications are a concern for species with a longer period of reproductive develoment. Spermatogenesis, fertility (including mating ability), and puberty are each hormone dependent processes. That these processes are altered significantly by haloacids indicates endocrine disruption. Indeed, recent data suggest that these chemicals inhibit steroidogenesis. Attempts to identify the mode of action within the seminiferous tubule indicate several specific cytosolic proteins which are diminished by both *in vivo* and *in vitro* exposures. These proteins await identification. Elucidation of the time and concentration response of these proteins may help point the way to mode of haloacid-induced spermatogenic disruption.

1623 THE RABBIT MAY REPRESENT A BETTER ANIMAL MODEL FOR DETERMINING REPRODUCTIVE RISK ASSOCIATED WITH DBPS.

D. N.R. Veeramachaneni. *Animal Reproduction and Biotechnology Laboratory, Colorado State University, Fort Collins, CO.*

Rabbits have a long quiescent period of reproductive development before puberty mimicking human development better than rodents. Moreover, longitudinal evaluations of endocrine profiles, sexual capacity, and semen quality are feasible in rabbits. These considerations suggest that the rabbit may be a more relevant animal model in evaluating human reproductive health risk. For the study of dibromoacetic acid (DBA), male and female rabbits were exposed to *via* drinking water from gestation day 15 through puberty (0, 1, 5, and 50 mg/kg). Six ejaculates (one every third day) were collected and sexual capacity and seminal quality were determined. Two untreated females were artificially inseminated with a known number of sperm from each experimental male and pregnancy outcome determined. Males in the DBA groups showed reduced sexual interest and ejaculation failures. Rabbits in the 50 mg group that completed ejaculation took more attempts (1.5 *vs.* 1 in control) and longer time (30 *vs.* 15 sec) to achieve ejaculation; two had no sperm in their ejaculates at least once. The conception rates for male rabbits in 0, 1, 5, and 50 mg groups were 85, 55, 65 and 55%, respectively. The individual conception rates of each of the treated groups were significantly lower than that of the control group. Male rats exposed similarly had reduced fertility at >50 mg/kg. Female rabbits in the DBA groups had reduced populations of primordial follicles; numbers were significantly lower in both the 5 and 50 mg/kg groups. Female mice exposed similarly to DBA, were found to have no differences in the populations of ovarian follicles. That sexual function, seminal quality (reflected by lowered fertility even at 1 mg/kg), and primordial follicle populations were more sensitive in rabbits compared to mice and rats, may reflect longer exposure during reproductive development in the rabbit. Thus, the rabbit may be a more useful model for human reproductive health risk assessment than rodents, particularly when cumulative risk is indicated and lowered low effects are anticipated.

1624 DO AVAILABLE TOXICOLOGY DATA ON DBPS IMPACT OUR ABILITY TO ASSESS HUMAN REPRODUCTIVE RISK ?

R. W. Tyl. *Center for Life Sciences & Technology, Research Triangle Institute, Research Triangle Park, NC.*

The strengths of the recent animal data set are the sensitivity of the endpoints, the characterization of the DBP(s) employed, and the use of exposure during sensitive life stages. There is some concordance of outcomes from the *in vitro* to *in vivo* animal studies, and from *in vivo* animal studies to some epidemiologic studies. The weaknesses of the animal studies are often relevance of the route of administration, exposure levels, exposures to single DBPs rather than mixtures, risks of false positives/negatives (especially in *in vitro* work), and limited gestational exposure duration and endpoints. Epidemiology studies employ large populations and methods to correct for confounders, but there is limited, and nonconcurrent characterization of the DBPs (are surrogates such as TTHMs [total trihalomethanes] or HAAs [haloacetic acids] useful?) in the drinking water, varying and divergent results, bias, confounding, misclassification, and intrinsic variability in drinking water profiles and human populations. Formal risk assessment requires data which satisfy strict criteria (not yet met for the most part). Identified data gaps are being filled with improved developmental and reproductive toxicity studies in animals and mechanistically driven studies with well characterized, standardized drinking water, and more sophisticated evaluation of reproductive and developmental endpoints. Epidemiologic studies must concurrently better characterize the drinking water (at

the faucet), better ascertain reproductive outcomes, and control for confounders, etc. All of these studies are expensive, labor intensive, difficult, and of long duration. We must address the costs *versus* the human health benefits of such efforts. Is it reasonable to generate data which may/may not result in the reduction of MCLGs (maximum contaminant level goals) if cost savings resulting from possible human health benefit can not be determined ? In other words, does the benefit (if any) offset the cost both with respect to research and treatment plant MCLG reduction ? There is a hazard; is there sufficient risk?

1625 NON-CLINICAL TESTING OF PHARMACEUTICALS FOR PEDIATRIC USE.

J. L. Schardein[2] and L. A. Dostal[1]. [1]*Drug Safety Evaluation, Pfizer Global Research & Development, Ann Arbor, MI and* [2]*Consultant, Chelsea, MI.*

Since the issuance of the Pediatric Final Rule by the FDA in 1998, the importance of adequate testing for the safety and efficacy of pharmaceutical products in children has become clear. The Pediatric Rule defines what products require testing, when pediatric studies are needed (with waiver and referral provisions), and expected interactions with the FDA. The FDA Guidance for Industry for compliance with the Pediatric Rule is expected to provide further clarification of the expectations of the Rule. To support clinical studies of new pharmaceuticals in children, preclinical safety studies must be conducted. Many organ systems (eg., central nervous system, pulmonary, reproductive, immune, etc.) continue to develop postnatally, sometimes until adulthood, and develop at different rates in different species. Since standard reproductive and developmental toxicity studies as described by ICH guidelines do not cover direct exposure of offspring during the postnatal and peripubertal periods, special juvenile toxicity studies may be necessary. Depending upon the target organ system of particular concern, different periods of postnatal exposure, and different animal species, may be most appropriate. When designing juvenile toxicity studies, many practical considerations must be taken into account, such as feasibility of dosing, sampling procedures, and development of new methodologies for assessment of targets in young animals. Finally, the FDA's experiences in reviewing study designs and results of juvenile toxicity studies will provide insight into the future designs and conduct of these studies.

1626 UNDERSTANDING THE PEDIATRIC RULE: AN INDUSTRY PERSPECTIVE.

L. A. Dostal. *Drug Safety Evaluation, Pfizer Global Research & Development, Ann Arbor, MI.*

The Pediatric Rule was issued as a regulation effective April 1, 1999 and requires the sponsor of an NDA or marketed product to provide information on the efficacy and safety of the drug product in children. This presentation will describe the requirements of the Rule as it applies to new active ingredients or dosage forms that are used in a large number of pediatric patients, where there is a potential for significant improvement in treatment, or where there is no current therapy available for children. If the sponsor believes that none of these conditions apply, they may request a waiver of the studies, or a deferral of the pediatric assessment until after the NDA is submitted. Often the design of a pediatric plan is complicated by the development of a suitable pediatric formulation and issues of safety of dosing infants and children with new chemicals that are not already demonstrated to be safe and effective in adults. This presentation will cover various strategies and questions that could be considered in the design of an acceptable Pediatric Plan to address the Pediatric Rule.

1627 SPECIES DIFFERENCES IN POSTNATAL DEVELOPMENT OF TARGET ORGAN SYSTEMS.

T. Zoetis. *Milestone Biomedical Associates, Frederick, MD.*

Animal studies have been used to investigate the response of immature systems for many years. Developmental toxicity studies have traditionally focused on the prenatal period of growth and maturation. Studies using juvenile animals are currently being designed to investigate developmental issues that occur postnatally in humans. Importantly, not all target organ systems develop during the same timeframe with reference to the time of birth for different species. Selecting the appropriate species and timing of dosing are critical to the success of postnatal developmental studies. A consideration in making this selection is the timeframe in which exposure is expected during the development and maturation of the given test species compared to humans. Differences in timing of growth and maturation between species can be considered using microscopic evaluation for cellular proliferation and differentiation, as in the case of postnatally developing alveoli, or by other methods appropriate for assessing organ functional capacity, as in the postnatally developing nervous system. In some cases, the immature systems of children can render the toxicity of a chemical to be lower than that occurring in the adult due to differences in metabolism. On the other hand, children may lack the ability to detoxify a chemical resulting in a higher level of toxicity when compared to adults. Organ systems that undergo major postnatal development or maturation include nervous, skeletal, renal, pulmonary, and reproductive. Examples of drugs that behave differently in adult (mature) and pediatric (immature) organ systems will be presented to illustrate the effects of differences between species and the timing of maturation in the study of postnatal development.

1628 PRACTICAL CONSIDERATIONS IN THE EXPERIMENTAL DESIGN OF JUVENILE ANIMAL STUDIES.

M. E. Hurtt. *Drug Safety Evaluation, Pfizer Global Research and Development, Groton, CT.*

The design of juvenile animal toxicology studies to support pediatric clinical trials is usually dependant on the identification of target organ toxicity in adult toxicology studies, the understanding of species differences in postnatal development of those target organs, as well as the clinical indication(s) and target population of the drug. The scientific question that the study is intended to address is a significant determinant of the design. Selecting the appropriate species is a critical component of the design of juvenile animal studies. In addition, a number of dose considerations are important including route, volume, selection, duration/period and vehicle. Other study design issues will be addressed such as need for pilot studies, pharmacokinetic/toxicokinetic considerations, animal handling, and identification and distribution of animals to dose groups. Specific examples of study designs will be presented to illustrate the importance of these issues in the design of juvenile animal studies.

1629 FDA EXPERIENCE WITH NONCLINICAL DATA SUBMITTED TO SUPPORT DRUG TRIALS IN PEDIATRIC PATIENTS.

K. L. Hastings. *Division of Special Pathogen and Immunologic Drug Products, Center for Drug Evaluation and Research, USFDA, Rockville, MD.* Sponsor: K. Hastings.

Pediatric patients may be more susceptible to certain drug toxicities compared to adults, possibly because organ systems could be more vulnerable to insult during development than when fully developed. There are a number of examples of increased susceptibility to drug toxicity in pediatric patients compared to adults. There are also examples of unique toxicities seen in this population that have not been observed in adults. The Center for Drug Evaluation and Research has received reports of nonclinical toxicology studies submitted to support the safety of clinical drug trials in infants and children: analysis of some of these data sets supports the idea that there can be adverse effects in pediatric patients which might not have been anticipated based on studies in relatively mature animals or adult humans. These observations indicate that nonclinical toxicology studies in immature animals might be valuable in determining the safety of clinical trials in pediatric subjects. Nonclinical toxicology studies have varied in design and the potential implications of these variations will be discussed with respect to pediatric risk issues.

1630 RECENT DIOXIN CONTAMINATION FROM AGENT ORANGE IN RESIDENTS OF A SOUTHERN VIETNAM CITY.

A. Schecter[1], L. C. Dai[2], O. Päpke[3], M. Pavuk[1], J. Prange[4], J. D. Constable[5], M. Matsueda[6] and V. Duc Thao[7]. [1]*University of Texas-Houston School of Public Health, Dallas, TX,* [2]*Vietnam Red Cross, Hanoi, Viet Nam,* [3]*ERGO Laboratory, Hamburg, Germany,* [4]*National Research Center for Environmental Toxicology, Griffith University, Brisbane, Australia,* [5]*Harvard Medical School, Massachusetts General Hospital, Boston, MD,* [6]*Ehime University, Matsuyama City, Japan and* [7]*Institute for Environmental Science and Technology, Hanoi University, Hanoi, Viet Nam.*

Marked elevation of dioxin associated with the herbicide Agent Orange was recently found in most blood samples from Vietnamese living in Bien Hoa, a large city in southern Vietnam near Ho Chi Min City. This city is located near an airbase used for Agent Orange spray missions between 1962 and 1970. A spill of Agent Orange occurred at this airbase over 30 years prior to blood collection in 1999. Blood samples were collected, frozen and sent to a World Health Organization-certified dioxin laboratory for congener-specific analysis as part of a Vietnam Red Cross project. Dioxin congener that contaminated Agent Orange, 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD), was elevated in the blood of 40 out of 42 (95%)

Bien Hoa residents. Median TCDD level was 67 parts per trillion (ppt) (Range 2.4 to 413 ppt). A comparison sample from over100 residents of Hanoi where Agent Orange was not used, had blood TCDD levels of 2 ppt. TCDD contamination was also found in some nearby soil and sediment samples. Persons new to this region and children born after Agent Orange spraying ended also had elevated TCDD levels. This TCDD uptake was recent and occurred decades after spraying ended. We hypothesize that a major route of current and past exposures is from the movement of dioxin from soil into river sediment, then into fish, and from fish consumption into people.

1631 SERUM TCDD LEVELS AND THYROID EFFECTS AMONG US AIR FORCE VETERANS.

M. Pavuk[1], A. Schecter[1] and F. Akhtar[2]. [1]*University of Texas Houston School of Public Health in Dallas, Dallas, TX and* [2]*SpecPro Inc., Austin, TX.*

We assessed potential health effects of 2, 3, 7, 8-tetrachlorodibenzodioxin (TCDD) on thyroid function in US Air Force veterans involved in aerial spraying of herbicide Agent Orange during the Vietnam War from 1962 to 1971 (Operation Ranch Hand). We examined associations between serum TCDD level with levels of thyroxin (T4), thyroid stimulating hormone (TSH), triiodothyronin percent uptake (T3% uptake), free thyroxin index (FTI), as well as with incidence of thyroid diseases. Data were available for 1009 Ranch Hands and 1429 comparison veterans categorized into four exposure groups – Comparison, Background, Low and High. We found consistently elevated levels of TSH in the High exposure group of Ranch Hand over all five medical examinations. We also observed statistically significant dose-response relationship between TSH and TCDD levels in 1982, 1985, 1987, and 1992. The High group of Ranch Hands had also a higher risk of having abnormally high TSH levels over all five exams, with 1997 results approaching statistical significance. Overall, the incidence of thyroid diseases was not increased in Ranch Hand veterans. These findings suggest that in the highest exposure group of Ranch Hand veterans, TCDD may affect thyroid hormone metabolism and function.

1632 SEQUENCE VARIATION AND PHYLOGENETIC HISTORY OF THE *MURINE AH* LOCUS.

D. R. Rank[1], S. G. Penn[1], K. Holden[1], C. A. Bradfield[2] and R. S. Thomas[1]. [1]*Aeomica Inc., Sunnyvale, CA and* [2]*McArdle Cancer Research Laboratory, University of Wisconsin, Madison, WI.*

The *Ah* locus encodes for the aryl hydrocarbon receptor (AHR) which plays an important toxicological and developmental role. Sequence variation at this locus was studied in 13 different mouse lines that included 8 laboratory strains, 2 *Mus musculus* subspecies, and 3 additional *Mus* species. The data presented represents the largest study of sequence variation across multiple mouse lines at a single locus (≈15.9 kb/mouse line). A total of 2, 213 polymorphisms were identified and used to estimate the polymorphism rates and characteristics at this locus. Among all mice, the average frequency of polymorphisms in the intronic regions was 20.3 SNPs/kb and the average exonic frequency was 14.1 SNPs/kb. Between laboratory strains, the average intronic and exonic frequencies dropped to 5.4 and 2.9 SNPs/kb, respectively. By comparison, polymorphism frequencies were significantly higher at this locus than those observed in whole genome scans. There were 111 non-synonymous polymorphisms that resulted in 42 different amino acid changes, of which only 10 amino acid changes have been previously identified. Based on the nucleotide sequence, the phylogenetic history of the gene showed mice from the Ah^{b2} and Ah^{d} alleles in separate branches while mice from the Ah^{b1} and Ah^{b3} alleles exhibited a more complex history. Evolutionarily, the AHR protein as a whole appears to be under purifying selective pressure (K_a:K_s ratio = 0.237). Despite significant functional constraint in the basic-helix-loop-helix and PAS domains, ligand binding is not constrained to the high affinity allele, which further supports the role of the AHR in development and its importance beyond the adaptive response to environmental toxicants.

1633 TCDD AND THE BIOLOGICAL CLOCK.

L. T. Frame[1], W. Li[1], D. Settachan[1], J. D. Miller[2], P. Patel[1] and R. L. Dickerson[1]. [1]*Pharmacology, Texas Tech Health Sciences Center, Lubbock, TX and* [2]*Cell and Neurobiology, Keck School of Medicine of USC, Los Angeles, CA.*

Sleep disturbances and other neurological disorders are associated with occupational exposure to 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD, or dioxin). These problems may persist for years after exposure, significantly affecting quality of life. We hypothesize that TCDD causes permanent circadian rhythm disturbances, which can be modeled in rodents. Using an infrared beam detection system, we monitored deer mouse locomotor activity continuously in the dark for several weeks. We found that TCDD doses as low as 10 ng/kg (gavage, in corn oil) caused persistent phase-shifts of intrinsic locomotor rhythm. However, the timing of the dose and the concentration were critical. The magnitude of the phase-shift was greatest when the dose was administered by gavage (in corn oil) during the subjective night. Doses in the ng/kg range or less were associated with hyperactivity, while doses in the ug/kg range were associated with more severe pathological and biochemical changes, including weight loss, disheveled appearance, paw edema, and death after several weeks to months. Interestingly, this syndrome resembles rodent models of chronic sleep deprivation, as described in the scientific literature. Using immunohistochemistry and Western blot techniques, we characterized critical protein expression patterns within the suprachiasmatic nucleus (SCN) of the hypothalamus, where the master circadian pacemaker resides in mammals. Maximal diurnal expression of the clock-associated protein, mPER1, was delayed 6 hours by TCDD exposure during the dark cycle. Light and the endogenous pacemaker normally regulate the transcription of c-FOS, an immediate-early gene. However, with TCDD, expression of c-FOS protein was significantly increased in the SCN throughout the light/dark cycle. Entrainment of circadian rhythms to environmental chemicals represents a mechanism by which organisms may lose synchrony with their normal environment.

1634 EFFECTS OF TCDD ON RAT MOLAR DEVELOPMENT: THE CRITICAL TIME WINDOW.

H. Kattainen[1,2], J. Tuomisto[1,2] and M. Viluksela[1]. [1]*Department of Environmental Health, National Public Health Institute, Kuopio, Finland and* [2]*University of Kuopio, Kuopio, Finland.*

Dental defects, especially disturbances in tooth development, are sensitive endpoints of dioxin-induced toxicity in both humans and animals. In rats TCDD exposure results in dental defects ranging from pulpal perforation in incisors to complete block of third molar development. We determined the critical time window for the effect of TCDD on rat molar development in a TCDD-sensitive rat line. Dams were exposed to a single oral dose of 1 µg/kg TCDD on gestation day (GD) 11, 13 or 19, or on postnatal day (PND) 0, 2 or 4. In a cross-fostering study dams were exposed on GD15 and the pups from each exposed dam were transferred to a non-exposed dam and vice versa immediately after delivery. Pups were killed at the age of 40 days, the eruption status of the third molar observed by stereomicroscopy, and the presence of the molars confirmed by radiography. Highest frequency of missing molars was observed in pups exposed both *in utero* and *via* lactation, and only the development of third molars was blocked. Frequency of missing molars was the higher the earlier the dam was exposed: 64%, 50% and 26% of third molars were missing in offspring of dams exposed on GD11, 13 and 19, respectively. In the cross-fostering study, 13% of third molars were missing in pups exposed only *in utero* and no more than 1% of molars were missing in pups exposed only *via* lactation. TCDD exposure time-dependently retarded the eruption of third molars, whereas the eruption of incisors and opening of the eyes was accelerated. The results indicate that the critical time window of molar development comes to the end right after parturition. However, continued exposure during lactation may further amplify the response. It is possible that TCDD affects incisors and molars *via* different mechanisms. 1635 SUSCEPTIBILITY LOCI FOR PORPHYRIA AND LIVER INJURY IN THE INTERACTION OF TCDD WITH IRON IN MICE.

A. G. Smith, S. W. Robinson, B. Clothier, R. A. Akhtar, A. Yang, I. Latour, C. van IJperen and M. F. Festing. *Toxicology Unit, Medical Research Council, Leicester, United Kingdom.*

Among the actions of the 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) is the induction of hepatic porphyria. This is similar to the most common disease of this type in humans, sporadic porphyria cutanea tarda (PCT). Evidence is consistent with the action of TCDD being mediated through binding to the aryl hydrocarbon receptor with different *Ahr* alleles in mouse strains apparently accounting for differential downstream gene expression and susceptibility. However, studies of TCDD-induced porphyria and liver injury evidence indicate that there must be interactions with other susceptibility genes, perhaps associated with iron metabolism. We performed a quantitative trait locus (QTL) analysis of an F_2 cross (204 individuals) between susceptible C57BL/6J (Ahr^{b-1}allele) and the highly resistant DBA/2 (Ahr^{d}allele) strains after treatment with TCDD and iron. Genome-wide scans of crosses were performed using polymerase chain reaction amplification of microsatellite DNA markers. To determine the location of susceptibility genes, the extreme phenotype cohorts for hepatic porphyria, plasma ALT and AST together with thymus size (48 each) were initially genotyped for 44 markers spread across the genome at an average of about 20 cM apart. After assessment by principle component analysis, all mice were genotyped with 6-9 markers on candidate chromosomes. For porphyria we found QTLs on chromosomes 11 and 14 in addition to

the *Ahr* gene (chromosome 12). SWR mice are syngenic for the *Ahr*^{b}allele with the DBA/2 strain but are susceptible to porphyria after elevation of hepatic iron. Analysis of SWRxD2 F_2 mice (242) treated with iron and TCDD showed a QTL on chromosome 11, as well as finding others on chromosomes 1 and 9, for both porphyria and plasma ALT as a measure of liver injury. These findings show, for the first time, the location of genes other than *Ahr* that modulate the hepatic porphyria and injury caused by TCDD in mice. Orthologous loci may contribute to the pathogenesis of human sporadic PCT.

1636 POSTNATAL DEVELOPMENT OF RESISTANCE TO ACUTE LETHALITY OF TCDD IN TWO TCDD-RESISTANT RAT STRAINS.

J. T. Tuomisto[1], U. Simanainen[1], M. Viluksela[1], R. Pohjanvirta[1,2] and J. Tuomisto[1]. [1]*Department of Environmental Health, National Public Health Institute, Kuopio, Finland and* [2]*National Food and Veterinary Research Institute, Helsinki, Finland.*

The exceptional resistance to acute lethality of 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) is related to a point mutation in the transactivation domain of the Ah receptor (AhR) in adult Han/Wistar (Kuopio) (H/W) rats. However, during fetal period H/W rats seem to be sensitive to at least teratogenic effects of TCDD. This study investigated the time window where resistance develops. HW rats, line A rats (a new line with the H/W-type mutated AhR), and line B rats (line with a normal AhR but moderately resistant due to an unidentified gene) were exposed to a single i.p. dose 2 - 56 days after birth (8 - 21 rats per group, occasionally 4 rats). H/W and line A rats received 1000 ug/kg; male and female B rats received 200 and 100 ug/kg, respectively. The LD50 doses of these strains/lines are >10000, >10000, 830, and 410 ug/kg, respectively. HW rats were sensitive (25 - 65 % died within 42 days) if the dose was given on postnatal days (PND) 5 - 9, but were resistant thereafter (0 - 33 % mortality). Line A rats were sensitive on PND 2 (47 - 57 % mortality) but resistant after PND 5 (0- 6 % mortality). Line B rats were very sensitive on PND 5 - 14 (all died) but developed resistance before PND 28 (no rats died if exposed after PND 28). The results show that H/W rats are sensitive to TCDD immediately after birth but develop the exceptional TCDD resistance to acute lethality within the first two weeks after birth. The moderate resistance of line B rats develops approximately at the time of weaning. It seems likely that within this time window there is a change in one or more AhR-mediated toxic pathways. Studies on this temporal change might bring forth new understanding on the mechanisms of action of AhR.

1637 *AHR(-/-)* AND *CYP1A2(-/-)* KNOCKOUT MICE ARE PROTECTED FROM TCDD-STIMULATED INCREASES IN REACTIVE OXYGEN FROM LIVER MITOCHONDRIA.

A. P. Senft, T. P. Dalton, R. J. Hutchinson, J. K. Kerzee, D. W. Nebert, M. B. Genter and H. G. Shertzer. *Center for Environmental Genetics and Department of Environmental Health, University of Cincinnati, Cincinnati, OH.*

TCDD (2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin) causes oxidative stress (OS) in liver and extrahepatic tissues. We have previously shown that TCDD increases mitochondrial respiration-dependent reactive oxygen (RO) production, an important component of TCDD-induced OS. We herein examined the dependence of mitochondrial RO on the aromatic hydrocarbon receptor (AHR) or cytochrome P450 1A2 (CYP1A2), proteins critical for TCDD-induced hepatotoxicity. Congenic female *Ahr(+/+)*, *Ahr(-/-)*, *Cyp1a2(+/+)*, and *Cyp1a2(-/-)* mice were treated with TCDD (15 µg/kg, i.p.) or corn oil vehicle on 3 consecutive days; liver mitochondria were examined 1 week following the first treatment. Whereas TCDD elevated succinate-stimulated mitochondrial H_2O_2 production in the *Ahr(+/+)* and *Cyp1a2(+/+)* mice, this increase did not occur in mitochondria from *Ahr(-/-)* or *Cyp1a2(-/-)* mice. Interestingly, while constitutive levels of H_2O_2 production from the *Ahr(-/-)* mitochondria were only 25% of that observed in *Ahr(+/+)* mitochondria, there was no difference between *Cyp1a2(+/+)* and *Cyp1a2(-/-)* mitochondria. Mitochondrial aconitase, an enzyme inactivated by superoxide, was decreased 44% by TCDD in the *Ahr(+/+)* and *Cyp1a2(+/+)* mice but not in the *Ahr(-/-)* or *Cyp1a2(-/-)* mice. TCDD treatment increased mitochondrial glutathione levels in the *Ahr(+/+)*, *Cyp1a2(+/+)* and *Cyp1a2(-/-)* mice, but not in the *Ahr(-/-) mice.* These results suggest that the AHR controls the expression of genes involved in the TCDD-induced mitochondrial RO production and that one of these genes is *Cyp1a2*. These results may be related to our observation, using Western immunoblot analysis, that shows TCDD causes the accumulation of CYP1A1 and CYP1A2 proteins in liver mitochondria. The mechanism by which CYP1 family members cause mitochondrial OS may be of fundamental importance to TCDD-induced toxicity. *Supported by NIH grants P30 ES06096, R01 ES10133, ES08147, and T32 ES07250.*

1638 TCDD-INDUCED GENE EXPRESSION PROFILE SUGGESTS THE INVOLVEMENT OF DEATH-RECEPTOR PATHWAY LEADING TO INDUCTION OF APOPTOSIS IN THE THYMUS.

A. Zeytun[1], R. J. Mckallip[1], M. Fisher[2], M. Nagarkatti[1] and P. S. Nagarkatti[2]. [1]*Microbiology and Immunology, MCV/VCU, Richmond, VA and* [2]*Pharmacology and Toxicology, MCV/VCU, Richmond, VA.*

Previous studies from our laboratory demonstrated that TCDD triggers apoptosis in thymocytes. Recently, two major apoptotic pathways in mammalian cells have been described. In the first pathway known as the death-receptor pathway, members including Fas (CD95) and TNF receptor I are activated. The second, mitochondrial pathway is triggered primarily through the activation of pro-apoptotic members of the Bcl-2 family. In the current study, we used cDNA arrays to detect the apoptotic pathway initiated by TCDD. To this end, C57BL/6 mice were injected with 0.1-50 µg/kg body weight of TCDD and 1 or 3 days later, thymus and liver were analyzed for a wide range of apoptotic genes. In the thymus, 23 out of 37 genes involved in apoptosis were up-regulated by TCDD by a factor of 2 or more. In contrast, in the liver, only 16 out of 37 apoptotic genes were up-regulated. In the thymus, several genes belonging to the death- receptor pathway were up-regulated including FasL, caspase-8, casper, CRADD, RIP, DAXX, TNF, TRAF, Trail and TRIP following TCDD treatment. In contrast, the expression of anti-apoptotic members of Bcl-2 family including Bcl-xL and Bcl-2 and proapoptotic members such as Bad and Bax were not significantly up-regulated. In the spleen, 20 out of 22 apoptotic genes screened were up-regulated following TCDD treatment. The induction of caspases was seen at all doses of TCDD tested. Together, the current study suggests that TCDD-treatment induces the death-receptor rather than the mitochondrial pathway in the sensitive organs to induce apoptosis (Supported in part by grants from NIH: ES09098 and HL58641).

1639 ROLE OF AH RECEPTOR IN TCDD-INDUCED APOPTOSIS IN THE THYMUS.

I. A. Camacho, M. Nagarkatti and P. S. Nagarkatti. *Virginia Commonwealth University, Richmond, VA.*

It is well established that 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) is a potent suppressor of the immune system. Exposure to TCDD has been associated with marked thymic atrophy. Despite extensive studies, the mechanistic aspects of TCDD immunotoxicity in the thymus are unclear. Many reports suggest that the immunotoxic effects of TCDD are regulated by the aryl hydrocarbon receptor (AhR). Previous studies from our laboratory have demonstrated that TCDD induces apoptosis in thymocytes. In the current study we tested the hypothesis that TCDD-induced apoptosis in thymocytes is regulated by the AhR. To test this hypothesis, alterations in the expression of various surface molecules in the thymus were measured as a predictable biomarker of apoptosis, as previously reported. To this end, C57BL/6 (Ah-high responder) and DBA/2 (Ah-low responder) mice were injected with 5 µg/kg TCDD (i.p.). Five days later, thymocytes were analyzed for phenotypic alterations using flow cytometry. At this dose, thymic atrophy was observed in TCDD-treated C57BL/6 but not DBA/2 mice when compared to the control mice. Consistent with our earlier reports, thymocytes from TCDD-treated C57BL/6 mice showed an increase in the density of expression of CD3 and CD44, and a decrease in the density of expression of CD4, CD8 and J11d markers, when compared to the vehicle-treated control group. These phenotypic alterations were associated with thymocytes undergoing apoptosis. Interestingly, thymocytes from TCDD-treated DBA/2 mice did not exhibit any phenotypic changes characteristic of apoptotic thymocytes. The thymocytes of C57BL/6 wild-type mice when examined using pathway-specific cDNA microarray showed marked up-regulation in several genes involved in apoptosis. In contrast, AhR knockout mice showed no significant up-regulation in apoptotic genes. Together, these data suggest that TCDD triggers apoptosis in the thymus by an AhR-dependent mechanism. (Supported in part by grants from NIH: ES09098, F31ES11562-01 and HL58641).

1640 COMPARATIVE GENE EXPRESSION RESPONSES IN RATS FOLLOWING ACUTE AND CHRONIC EXPOSURE TO 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD).

N. J. Walker[1], R. P. Amin[2], C. R. Miller[1] and R. S. Paules[2]. [1]*Environmental Toxicology Program, NIEHS, Research Triangle Park, NC and* [2]*NIEHS Microarray Center, NIEHS, Research Triangle Park, NC.*

While humans are exposed to both persistent and non-persistent aromatic hydrocarbon receptor (AHR) ligands, it is believed that the sustained activation of the AHR response pathway by poorly metabolized ligands such as dioxins may be a key event in the development of associated adverse health effects such as cancer. The present study compares the *in vivo* response following acute or chronic exposure to

2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD), a potent AHR ligand, in the livers of Sprague-Dawley rats. Animals were treated weekly by oral gavage with either: 700 ng TCDD/kg/week for 13 weeks, corn oil for 12 weeks followed by a single dose of 1ug TCDD/kg, or corn oil for 13 weeks; and killed 3 days after the final dose. Replicate pairwise two-color fluorescence cDNA microarray analyses were carried out using total RNA from each exposed group and pooled RNA from time-matched vehicle-treated controls. Initial analyses confirmed the induction of CYP1A1 and CYP1A2 after both chronic and acute exposure, and identified numerous known and unknown expressed sequence tags (ESTs) as being significantly altered, based on the observed fluorescence ratio distributions. To validate similar levels of AHR activation in the different exposure groups, levels of CYP1 RNAs were quantified in total RNA isolated from the livers of these animals using quantitative real-time RT-PCR. While expression of CYP1A1 and CYP1A2 was similar between both chronic and acute exposure, consistent with the expected similar liver levels of TCDD, expression of CYP1B1 RNA was significantly higher after chronic exposure compared with acute exposure. These data together indicate that chronic exposure can lead to differences in gene expression responses compared to single exposures and may provide further insights into comparative mechanisms of action/toxicity of persistent *versus* non-persistent AHR ligands.

1641 DYSREGULATION OF AHR, ARNT AND CYP1A1 CNS DEVELOPMENTAL EXPRESSION PROFILES AND EFFECTS ON BENZO(A)PYRENE METABOLISM IN F1 GENERATION PUPS FOLLOWING SUBACUTE INHALATION EXPOSURE OF TIMED PREGNANT DAMS.

T. Nayyar, A. Ramesh, J. Wu, M. Greenwood and D. B. Hood. *Pharmacology and Toxicology, Meharry Medical College, Nashville, TN.*

Very few studies have focused on mechanistically based dose-related neurotoxicity at the molecular level with respect to development of the central nervous system in F1 generation pups. To fill this important data gap and to highlight possible mechanistic pathways, a study was undertaken to determine the bioavailable dose as well as transcriptional changes of Ah Receptor (AhR), aryl hydrocarbon nuclear translocator (ARNT), and CYP1A1 associated with the transplacental disposition of Benzo(a)pyrene [B(a)P] metabolites in F1 generation pups. In this developmental range-finding study, laparotomy on GD 8 was performed on timed-pregnant rats followed by dosing *via* nose-only exposure for four hours a day for ten days (GD 11- GD 20) to three concentrations of a B(a)P : carbon black aerosol (0.025, 0.075 and 0.1 mg/m3). Bioavailability studies in F1 generaton pups revealed a dose-dependent increase in total B(a)P metabolites in brain tissue. Analysis of the qualitative distribution of metabolites in brain tissue indicated a predominance of the 7, 8; 9, 10-diols during the first postnatal week. The expression of the AhR, ARNT, and CYP1A1 was analyzed from the cerebrocortical, cerebellar, and hippocampal brain regions by using semiquantitative RT-PCR and Western Blotting to determine the temporal developmental expression profile from PND 0 through PND 30. The RT-PCR results, using β-actin as the internal standard demonstrate that inhaled B(a)P significantly downregulates AhR, and CYP1A1 in cerebrocortical, cerebellar and hippocampal tissue during the first postnatal week when the regulatory synergism between neuronalglial interactions is essential for programmed growth and differentiation. (Supported by U50NS41071, G12RRO3032, ES 00287, and GM 008037 to DBH).

1642 MIDGESTATIONAL, SUBACUTE, MIXED TCDD/ B(A)P EXPOSURE: EFFECTS ON F1 GENERATION PUPS IN RADIAL ARM MAZE PERFORMANCE AND TEMPORAL EXPRESSION OF DEVELOPMENTAL CNS NEONATAL MARKERS II.

W. Zhang, T. Nayyar, J. Wu, S. Johnson, M. Greenwood and D. B. Hood. *Pharmacology and Toxicology, Meharry Medical College, Nashville, TN.*

In order to test the hypothesis that mixed TCDD/B(a)P exposure to timed pregnant dams deleteriously affects cognition in F1 generation offspring, the following study was conducted. Laparotomy on GD 8 was performed on four groups of timed-pregnant rats including unexposed control, corn oil-dioxin, B(a)P: carbon black aerosol, and dioxin-B(a)P: carbon black aerosol. A dose of 700 ng/kg of dioxin was given by gavage on GD 14 to timed-pregnant dams followed by dosing *via* nose-only exposure for four hours a day for four days (GD 14 through 17) to 0.1 mg/m3 B(a)P : carbon black aerosol. On PND 40, three animals from each litter were tested on a working/reference memory task using an 8- arm, Radial Arm Maze (RAM). All arms were baited during shaping and testing. Compared to control males, the time required (latency) to locate a food pellet in the female mixed exposure group significantly increased by a factor of two by session 8. In contrast, male mixed exposure litter mate latency times were indistinguishable from control males after session 8. RT-RCR and western blot analysis from cerebrocortical extracts for AhR from PND 0 through PND 30 revealed a downregulation of AhR in the mixed exposure group as compared to controls. Brain nuclear extracts from F1 pups were analyzed by EMSA on PND 0 through PND 30. Premature Sp1-DNA binding was observed on PND 5 in the mixed exposure group as compared to the control group. The results suggest that mixed TCDD/B(a)P exposure causes: 1) modulation of the developmental expression profile of transcription factors involved in growth and differentiation in the developing CNS . A probable consequence of this modulation is to dysregulate the timetable of cellular development and growth in the CNS such that the phenotypic expression is 2) a significant reduction in spatial learning and memory. (Supported by U50NS41071, G12 RRO 3032, ES 00287, and GM 008037 to DBH).

1643 MIDGESTATIONAL, SUBACUTE, MIXED TCDD/ B(A)P EXPOSURE : EFFECTS ON F1 GENERATION LONG-TERM POTENTIATION AND TEMPORAL EXPRESSION OF DEVELOPMENTAL CNS NEONATAL MARKERS I.

D. B. Hood, J. Wu, T. Nayyar, D. Wormley, M. Greenwood and S. Chirwa. *Pharmacology and Toxicology, Meharry Medical College, Nashville, TN.*

The purpose of this study was to access the effects of mixed TCDD/B(a)P exposure to timed pregnant dams on the cellular basis of learning and memory in F1 generation offspring. Laparotomy on GD 8 was performed on four groups of timed-pregnant rats including unexposed control, corn oil-dioxin, B(a)P: carbon black aerosol, and dioxin-B(a)P: carbon black aerosol. A dose of 700 ng/kg of dioxin was given by gavage on GD 14 to timed-pregnant dams followed by dosing *via* nose-only exposure for four hours a day for four days (GD 14 through 17) to 0.1 mg/m3 B(a)P : carbon black aerosol. A significant ($p<0.05$) reduction in the birth index was observed in the dioxin-B(a)P: carbon black aerosol exposed group. There were no significant differences relative to controls in liver and/or brain to body weight ratios. Electrophysiological studies in the dentate gyrus revealed a significant dimunition in I/O curves and in long term potentiation in the mixed exposure group relative to controls. RT-PCR developmental expression profiles for AhR as well as western blot analysis from PND 0 through PND 30 revealed downregulation of AhR in the mixed exposure group as compared to controls in cerebrocortical extracts. Brain nuclear extracts from F1 pups were analyzed by EMSA on PND 0 through PND 30. Premature Sp1-DNA binding was observed on PND 5 in the mixed exposure group as compared to the control group. In conclusion, the mixed TCDD/B(a)P exposure was shown to 1) modulate the developmental expression profile of transcription factors involved in growth and differentiation in the developing CNS and 2) cause a significant reduction in a persistent synaptic enhancement induced by high frequency stimulation of afferents which has been suggested to be an important component of the cellular basis of forms of learning and memory. (Supported by U50NS41071, G12 RRO 3032, ES 00287, and GM 008037 to DBH).

1644 MODULATION OF SELECTED APOPTOSIS-RELATED GENES DURING RETINOIC ACID-INDUCED DIFFERENTIATION IN MURINE EMBRYONIC STEM CELLS.

S. A. Sarkar and R. P. Sharma. *Physiology and Pharmacology, The University of Georgia, Athens, GA.*

Apoptosis plays an important role during embryonic development. Apoptotic cell death is executed by caspases and can be regulated by Bcl-2 family of genes. Selected apoptosis-related genes of the Bcl-2 family; pro-apoptotic Bax and Bad, anti-apoptotic Bcl-2 were investigated by ribonuclease protection assay (RPA) during differentiation of murine embryonic stem cells (ES), mediated by all-*trans*-retinoic acid (RA). The mRNA expression of caspase 3, caspase 6 and certain proinflammatory cytokines were also investigated simultaneously. The ES cells mimic *in vivo* differentiation and provide an excellent alternative method to study differentiation and apoptosis. The ES cells were grown on mitotically inactivated fibroblast feeder layers in Dulbecco's modified Eagle's medium supplemented with retinol free 15% Knock-Out Serum Replacement, leukemia inhibitory factor (LIF) and β-mercaptoethanol. Differentiation was initiated in the absence of feeder layers and LIF. Ribonuclease analysis revealed increased expression of Bax, Bad and no effect on Bcl-2 mRNA in RA-treated cells compared to the vehicle-treated cells. Increased mRNA expression of caspase 3 and caspase 6 in RA-exposed ES cells suggested that caspases played an important role in RA-mediated apoptosis during ES differentiation. Increased expression of TNFα and macrophage migration inhibitory factor (MIF) was noted in RA-treated cells on day 14 as compared to vehicle-treated cells. Increased expression of interferon gamma inducing factor (IGIF/IL-18) in RA-treated cells on day 14 and 17 did not translate to increased INFγ expression. Expression of other proinflammatory cytokines was detected at only at background levels. Results suggested that RA-mediated apoptosis during differentiation of ES cells involves caspase 3, caspase 6, Bad and Bax. Our data is consistent with the biochemical process of apoptosis since there is relative lack of other proinflammatory cytokines except TNFα, IGIF/IL-18 and MIF in RA-treated cells, whose function during ES differentiation is speculatory.

1645 MATERNAL IMMUNE STIMULATION REDUCES URETHANE-INDUCED CLEFT PALATE AND ALTERS MATERNAL SPLENIC AND FETAL PALATE GENE EXPRESSION.

S. D. Holladay, L. V. Sharova, R. M. Gogal and A. A. Sharov. *Biomedical Sciences, Virginia Tech, Blacksburg, VA.* Sponsor: S. Holladay.

Maternal immune stimulation by diverse techniques, prior to conception or during gestation, has been shown to be effective in reducing chemical-induced birth defects in mice. Morphologic lesions that are reduced include cleft palate and associated craniofacial defects, digit and limb defects, tail malformations, and neural tube defect, caused by chemical agents TCDD, urethane, methylnitrosourea, cyclophosphamide, or valproic acid. Limited information is available regarding mechanisms by which such immune stimulation reduced fetal dysmorphogenesis. In the present studies, immune stimulation in urethane-treated pregnant mice increased splenic leukocyte number, including T helper and cytotoxic/suppressor cells, B cells and macrophages. An array consisting of 151 genes was used to study genes in these leukocytes that control cell cycle and apoptosis, cytokine/interleukin production, and signal transduction and transcription regulatory factors important in development. As might be expected, maternal immune stimulation up-regulated expression of leukocyte genes involved in cell proliferation and cytokine production. Interestingly, expression of genes in the fetal palate, including bcl2a, b, pkCa and p53 was restored to control levels by maternal immune stimulation. Possible relationships between maternal immune stimulation and altered maternal and fetal gene expression, and reduced urethane-induced cleft palate, remain to be investigated.

1646 EFFECTS OF PHORBOL 12-MYRISTATE 13-ACETATE (PMA) TREATMENT ON MORPHOLOGY AND GENE EXPRESSION OF *XENOPUS* EMBRYOS.

M. T. Murray[1], D. J. Kaplan[1], L. J. Syu[1], R. F. Novak[2] and H. Kim[1,2]. *[1]Detroit R&D, Inc., Detroit, MI and [2]NIEHS Center, Wayne State University, Detroit, MI.*

Effects of PMA treatment on morphology and gene expression were studied using embryos of *Xenopus laevis* at stages 8 (blastula) and 15 (neurula). *Xenopus* embryos were obtained by induction of ovulation followed by *in vitro* fertilization. Embryos at stage 8 were obtained after incubation of the fertilized embryos at 23°C for 5 hours. PMA (100 ng/ml) or DMSO (0.01%, solvent used to dissolve PMA) was added to the embryos 2 hr after fertilization. Whereas embryos without PMA treatment progressed to blastula stage, PMA-treated embryos remained in a pre-blastula stage, suggesting that PMA treatment impaired differentiation. Embryos at stage 15 were obtained after incubation of the fertilized embryos at 18°C for 30 hours. PMA or DMSO was added to the embryos 21 hr after fertilization. Whereas embryos without PMA treatment showed typical morphology of neurula, PMA-treated embryos were in a pre-neurula stage. Embryos treated with 4 alpha-PMA, a stereoisomer of PMA that is ineffective at activating protein kinase C, showed typical neurual morphology. Embryos at stages 8 and 15 treated with PMA or DMSO were harvested and mRNA was isolated. The mRNA (3-5 µg) was reverse-transcribed with oligo$(dT)_{18\text{-}22}$ primer and dNTPs mixed with Cy3-dUTP (DMSO control) or Cy5-dUTP (PMA-treated). The Cy3- and Cy5-incorporated probes were mixed and microarray analyses were carried out using a glass chip printed with PCR products of *Xenopus* expressed sequence tag (EST) clones (duplicate of ~1, 100 genes). Microarray analyses of stage 8 and 15 embryos showed that PMA altered the gene expression profile differently in the two embryonic stages. These results suggested that, whereas cell differentiation was blocked after treatment of *Xenopus* embryos with PMA at both pre-blastula and pre-neurula stages, the PMA-responsive gene expression profiles were developmentally stage-specific. Sponsored by the NIEHS SBIR contract N43-ES-15462 & the NIEHS Center grant P30 ES06639.

1647 TEMPORAL CHANGES IN THE EXPRESSION OF TRANSCRIPTION FACTORS IN THE DEVELOPING LEAD-EXPOSED HIPPOCAMPUS AS DETERMINED BY MACROARRAY ANALYSIS.

S. A. Bakheet and N. H. Zawia. *Biomedical Sciences, URI, Kingston, RI.*

The exposure to lead (Pb) may alter developmental gene expression and brain development through selective effects on the transcriptional machinery. In this study macroarray analysis was used in an attempt to identify transcription factors that are involved in the response to Pb-exposure. Rat pups were exposed to Pb-acetate (0.2 %) from birth to weaning *via* lactating dams. On various postnatal days the hippocampi of control and lead-exposed pups were examined by macroarray analysis for changes in the developmental profiles of approximately 30 transcription factors, belonging to known transcription factor families. A number of transcription factors appear to be altered following lead exposure and have distinctive temporal patterns of expression. The most prominent changes were exhibited by the Sp and Oct families. Expression of Sp1 and Sp2 peaked on PND 5 and was diminished by PND 15 in Pb-exposed animals. By contrast, elevated Oct-1 & Oct-2 expression was sustained in these animals during the same period. These two transcription families appear to play a critical role in mediating Pb-induced disturbances in developmental gene expression. While the involvement of Sp transcription factors in the response to Pb exposure has been previously shown, the changes in Oct-1 and Oct-2 expression identify a novel target for Pb. Future work will focus on determining changes in Oct-1 and Oct-2 protein levels and DNA-binding and the role of the Oct family of transcriptions factors in the neurotoxic effects of Pb.

1648 2, 3, 7, 8-TETRACHORODIBENZO-*p*-DIOXIN (TCDD) REDUCES CARDIAC HYPOXIA AND VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF) EXPRESSION IN THE CHICK EMBRYO.

A. L. Sanchez, I. D. Ivnitski and M. K. Walker. *College of Pharmacy, University of New Mexico, Albuquerque, NM.*

We have shown that TCDD inhibits coronary angiogenesis in the chick embryo. During normal embryo development cardiac hypoxia stimulates the expression of VEGF in the heart, which then stimulates coronary angiogenesis to occur. We tested the hypothesis that TCDD inhibits hypoxia-stimulated VEGF mRNA expression in the chick embryo heart. To estimate levels of cardiac hypoxia, we used a hypoxia-sensing drug, EF5, that is metabolically reduced by an oxygen-inhibitable nitroreductase. When tissues are hypoxic, more EF5 is reduced to a reactive intermediate which then binds to cellular macromolecules. Bound EF5 was visualized using a Cy-3-conjugated antibody. VEGF mRNA expression was assessed by *in situ* hybridization. To confirm EF5 binding and VEGF mRNA expression correlated with cardiac hypoxia, chick embryos on day 9 were incubated for 24 hr at 20% O_2 (normoxic) or 15% of O_2 (hypoxic). Hearts from the hypoxic embryos showed increased EF5 binding and VEGF mRNA expression, which localized primarily to the trabeculae, compared to hearts from normoxic embryos. To test the effect of TCDD on cardiac hypoxia and VEGF expression, fertile chicken eggs were injected with 5 ml corn oil (control) or 0.3 pmol TCDD/g in 5 ml corn oil prior to incubation. On day 10 semiquantitative analysis of EF5 staining showed a significantly decreased level of hypoxia in hearts from TCDD-treated embryos as compare to controls. Similarly, qualitative analysis showed that TCDD-treatment decreased VEGF mRNA expression in the cardiac trabeculae as compare to controls. We conclude that TCDD may inhibit coronary angiogenesis by down-regulating hypoxia-induced VEGF mRNA expression. Supported by NIH grant ES-09804.

1649 ANALYSIS OF GENE EXPRESSION PROFILES IN DIFFERENTIATING MURINE EMBRYONIC STEM CELLS.

C. Schleger, B. Viertel and T. Singer. *Non-clinical Drug Safety, Boehringer Ingelheim Pharma KG, Biberach, Germany.*

Pluripotent embryonic stem (ES) cells of the mouse are able to differentiate *in vitro* into a variety of different cell types. In the embryonic stem cell test (EST), an *in vitro* assay for the determination of the teratogenic potential of compounds, ES cells of the mouse (cell-line D3) are investigated for their preserved potency to differentiate into contracting cardiomyocytes following compound exposure. The inhibitory effect of a compound on differentiation is compared with its cytotoxicity on ES cells and on differentiated mouse 3T3 fibroblasts. To improve the EST, molecular endpoints of differentiation were examined for their potential to predict the embryotoxic potential of a compound. Gene expression of the ES cells was measured at different time points after initiation of differentiation using oligonucleotide microarrays (Affymetrix). The effect of the strongly embryotoxic compounds 5-fluorouracil and all-trans retinoic acid, the weakly embryotoxic diphenylhydantoin and dexamethasone as well as the non embryotoxic penicillin and ascorbic acid were investigated in comparison with untreated controls. Among the genes showing the strongest up-regulation in untreated cells between day 7 and day 10 of differentiation compared to undifferentiated ES cells, several genes coding for cardiac specific proteins could be found. This included atrial/fetal and ventricular myosin light chain 1, myosin light chain 2, alpha and beta cardiac myosin heavy chain and cardiac troponins. Also, up-regulation of further cell-type specific genes like hematopoietic, endothelial or neuronal genes could be seen. 5-fluorouracil and all-trans retinoic acid as well as diphenylhydantoin led to a down-regulation of the relative expression of cardiac specific genes, while dexamethasone induced an up-regulation of cardiac genes. Penicillin and ascorbic acid did not significantly affect the relative expression of cardiac genes. In conclusion, gene expression represents a effective endpoint to study compound induced changes in cardiac differentiation. The implementation in the EST will be evaluated.

1650 DEVELOPMENTAL EXPOSURE TO POLYCHLORINATED BIPHENYLS EXERTS THYROID HORMONE-LIKE EFFECTS ON THE EXPRESSION OF THYROID HORMONE-RESPONSIVE GENES IN THE FETAL RAT BRAIN.

K. J. Gauger, C. T. Herzig and R. T. Zoeller. *Biology, University of Massachusetts, Amherst, MA.*

Background exposure to polychlorinated biphenyls (PCBs) during fetal development is associated with lower IQ and attention deficit in humans and clear neural defects in experimental animals. These effects may be caused by interfering with thyroid hormone signaling in as much as PCBs reduce serum thyroid hormone. However, the structure of some individual PCB congeners is reminiscent of that of thyroid hormone and some authors propose that PCBs may interact directly with the thyroid hormone receptor. Therefore, we initiated a study to determine whether maternal exposure to PCBs has an effect on specific thyroid hormone-responsive genes in the fetal rat brain, including RC3/Neurogranin, Neuroendocrine-Specific Protein A (NSP-A), and Oct-1. NSP-C, which is not affected by maternal thyroid status, was used as a negative control. Using *in situ* hybridization, we have found that PCBs increase the expression of RC3/Neurogranin and do not affect NSP-C expression. The remaining analyses are forthcoming. These studies are the first to address the effect of PCBs on thyroid hormone action in the fetal rat brain, an important question considering that all humans are contaminated with measurable levels of PCBs. Moreover, they justify a concerted effort to test whether individual PCB congeners can bind to the thyroid hormone receptor and transactivate gene expression. Supported by ES10026.

1651 EFFECTS OF SINGLE COMPONENTS (HYPERTHERMIA & BORIC ACID)AND MIXTURES ON MID-ORGANOGENESIS STAGE RAT EMBRYOS USING MICROARRAY ANALYSIS.

W. A. Harrouk[1], M. B. Rosen[2], S. E. Fenton[2], J. E. Schmid[2], G. L. Kimmel[3] and C. A. Kimmel[3]. *[1]DLS/CDRH, USFDA, Rockville, MD, [2]NHEERL, RTD, DBB, USEPA, Research Triangle Park, NC and [3]NCEA, ORD, USEPA, Washington, DC.*

The goal of this project is to examine the interaction of two developmental toxicants, hyperthermia and boric acid (BA), and their effects on the gene expression profile of mid-organogenesis rat embryos following maternal *in vivo* exposure. When administered singly on gestational day (GD) 10 in the rat, both agents cause similar developmental toxicity profiles (malformed/reduced numbers of thoracic vertebrae & ribs). When used in combination, the interaction of BA (oral dosing, 500 mg/kg) and hyperthermia (41C & 42C, rectal temp maintained for 5 min) was synergistic as manifested by an increased prevalence of sternal, thoracic, lumbar and sacral defects, and reduced numbers of presacral vertebrae. These effects seem to target newly developed somites or the presomitic mesoderm at the time of exposure. We have shown that adverse morphological, biochemical and molecular alterations occur as early as 1-3 hr post exposure. Here, we have used the microarray approach to map the gene expression profile in embryonic tissues containing the somitic region isolated 3 hrs after *in vivo* exposure to BA, 41 or 42C. Briefly, 33P labeled cDNA was synthesized from total embryonic RNA by reverse transcription. Labeled cDNAs were then hybridized to Atlas Rat Toxicology 1.2 arraysTM and exposures were recorded using an FX phosphorimager. The relative expression of each gene was determined using Atlas ImageTM software. Preliminary normalized data focusing on sets of genes belonging to DNA damage & repair, apoptosis, heat shock and cell signaling pathways indicate upregulated expression following 42C and even greater with BA+ 42C exposure but not 41C or BA+ 41C, suggestive of a synergistic mechanism of action in the high dose combination. Long term efforts are to build predictive models for risk assessment for single and combined exposures. Supported by a fellowship to WAH by ORISE. This abstract does not necessarily reflect EPA or FDA policies.

1652 MATERNAL THYROID HORMONE INCREASES THE EXPRESSION OF GENES THAT AFFECT GLIAL DETERMINATION IN THE EARLY CORTEX.

R. Bansal, C. A. Herzig, E. A. Iannacone and R. T. Zoeller. *Biology, University of Massachusetts, Amherst, MA.*

Thyroid hormone (TH) is well known to play essential roles in brain development in both humans and animals. However, the specific developmental events affected by thyroid hormone are poorly understood. As a result, risk assessment is not based on specific end points of thyroid hormone action, often making the assignment of adverse effects difficult. To identify specific end points of TH action in the fetal brain, we have begun to examine members of the Notch signaling pathway, which transduces cell-cell contact information on decisions of cell fate during cortical development. The target genes of the pathway are the basic Helix-Loop-Helix (bHLH) genes Hairy Enhancer of Split homologues 1 and 5 (HES-1, HES-5), which encode transcriptional repressors thought to antagonize proneural bHLH genes and favor gliogenesis in the cortex. To test whether TH of maternal origin affects Notch signaling in the fetus, we treated pregnant rats (n=36) in one of 6 ways: 1) Untreated 2) propylthiouracil (PTU) + Saline 3) PTU + one of two doses of T4 24 hours prior to sacrifice 4) PTU + one of two doses of T4, 48 hours prior to sacrifice. The doses of T4 were calibrated to restore maternal blood concentrations to within the normal range, or to be 10-fold higher. Animals were sacrificed on gestational day 16 when the fetal cortex is actively producing both neurons and glia. Semi-quantitative *in situ* hybridization revealed that PTU decreased HES1 expression and T4 restored or increased HES 1 expression in a specific region within the fetal cortex. We conclude that thyroid hormone affects the Notch signaling pathway in the fetal cortex. Independently, we have found that TH does not affect neuronal proliferation of the early cortex; therefore, we are pursuing the hypothesis that TH increases the formation of glia at the expense of neurogenesis. Funded in part by ES10026.

1653 INTERSPECIES DIFFERENCES IN BBDR MODEL INPUT PARAMETERS AND THEIR IMPLICATION FOR MODELING TUMOR INCIDENCE.

T. A. Lewandowski[1], C. S. Wells[2] and L. R. Rhomberg[2]. *[1]Gradient Corporation, Mercer Island, WA and [2]Gradient Corporation, Cambridge, MA.*

The utility of biologically-based Dose-Response (BBDR) models for predicting cancer risks in humans could be increased if we understood how model parameters scale across species and what these scaling relationships indicate about species-specific cancer risks. Yet parameter selection is often treated as trivial relative to statistical aspects of model formulation. We are identifying species-specific values from the literature for the initial cell number and rates of cell birth, death and mutation in both normal and initiated cells. Such data are difficult to obtain because they are rarely the focus of published studies or abstracts and must be gleaned from control data. Collection of cell cycle kinetic and cell number data for several tissues of interest has revealed varied patterns in cross-species scaling. For example, while hepatocyte number increases in a ratio of 1:3:850 among mice, rats and humans, thyroid follicular cell number increases in a ratio of 1:20:4500. Hepatocyte number scales linearly with organ weight but follicular cell number deviates from linearity due to structural differences in the rodent and human thyroid. Backround levels of cell proliferation and apoptosis are similar among the three species, with greater differences between tissues than between species. A review of spontaneous mutation frequencies indicates that, across all three species, mutation frequencies for all tissues except lymphocytes generally range from 1×10^{-5} to 8×10^{-5} per cell. Thus, most of the key parameters in a Moolgavkar-type carcinogenesis model appear to be similar across species. We are now developing a modeling approach in which these similarities in input parameters, species lifetime differences, and the background tumor incidence rates in rodent and human populations can be considered in a coherent manner. Other factors, such as different rates of DNA repair may also be included in the modeling. This work is supported by funding from the American Chemistry Council.

1654 APPLYING THE B6C3F1 MICE GROWTH MODEL USING WEIGHT DATA FROM A NTP BIOASSAY STUDY: ASSESSING DOSE-RESPONSE EFFECTS OF P-NITROBENZOIC ACID.

J. T. Walker[1] and O. A. Walker[2]. *[1]National Center for Environmental Assessment, USEPA, Washington, DC and [2]JTW Research Institute, Upper Marlboro, MD.*
Sponsor: D. Singh.

Biologically based Dose-Response (BBDR) models are being used increasingly by regulatory agencies for predicting biological risks in terms of the dose level of a particular chemical. The primary purpose of the dose-response model is to provide a descriptive summary of experimental data as function of dose. For BBDR models that are based on growth, empirical models establishing relationships between body weights and age in growing animals are needed. In this paper, we applied our newly developed B6C3F1 mice growth model in assessing the dose-response effects of p-nitrobenzoic acid on the growth curves and parameters of mice that were involved in a NTP bioassay study. Individual growth curves of these animals exposed to 0, 1250, 2500, or 5000 ppm of p-nitrobenzoic acid were fitted by the model using a nonlinear least squares technique. Our main objective was to determine if the chemical caused dose-dependent changes in the mean values of the model's parameters. Standard linear regression techniques were used to determine if the parameter

values varied with dose. The results showed that most of the parameters demonstrated a significant dose-response trend; some increased with dose, while others decreased. Some showed no significant changes, however. These results are preliminary, but important, for three primary reasons. First, they show evidence which suggests that low chronic levels of p-nitrobenzoic acid cause dose-dependent changes in the growth parameters of living mice. Second, although the model is purely empirical, it is a potentially useful tool for analyzing B6C3F1 mice weight growth data from NTP bioassay studies. Third, because the parameters of the model represent biological indices of growth, they can be used for BBDR modeling purposes. 1655 PROBABILISTIC FRAMEWORK FOR NON-CANCER RISK ASSESSMENTS.

M. Pelekis, M. J. Nicolich and J. Gauthier. *Toxicology & Environmental Sciences Division, ExxonMobil Biomedical Sciences, Inc., Annandale, NJ.*

Non-cancer human health risk assessments use point values to develop risk estimates and thus impart a deterministic character to risk, which by definition is a probability phenomenon. The objective of the present work was to develop a probabilistic framework that eliminates the deficiencies of point values and to estimate non-cancer risk across the population without the use of uncertainty factors. Probability distribution functions (PDFs) were incorporated within a physiological modeling framework to account for the propagation of uncertainty/variability in exposure, kinetics and dynamics of volatile organic compounds. The integrated physiological-based toxicokinetic-toxicodynamic model for the dichloromethane(DCM)-induced carboxyhemoglobinemia in humans was used to illustrate the proposed probabilistic framework. The mechanistic parameters were represented by: (1) PDFs which provided both the value of the parameters and their frequency of occurrence and (2) the correlations among the parameters to characterize the inter-relationships among the parameters. Ambient exposure concentration was linked to dose absorbed by PDFs that described the variability of DCM exposure (indoors, outdoors, exposure frequency, exposure duration, exposure time) and population characteristics such as gender, age, and inhalation rates at different activity levels. The median and 95% confidence interval of carboxyhemoglobin (HBCO) in blood after a lifetime of continuous exposure were estimated. The distribution of risk (i.e., HBCO) in the population was thereby determined by taking into account the combined effects of the multiple sources of uncertainty/variability encountered in the exposure-tissue dose-tissue response continuum without the use of uncertainty factors. This approach provides an alternative to the default methodology. It shows that application of probability into non-cancer risk assessments can reduce uncertainties when establishing exposure limits for specific compounds and provide better assurance that established limits are adequately protective.

1656 A BIOLOGICALLY-BASED DYNAMIC MODEL FOR PREDICTING THE DISPOSITION OF FORMALDEHYDE AND ITS METABOLITES IN ANIMALS.

M. Bouchard, R. C. Brunet, P. O. Droz and G. Carrier. *Environmental and Occupational Health, Chair of Toxicological Risk Assessment for Human Health, Université de Montréal, Montreal, PQ, Canada.*

A multi-compartment biologically-based dynamic model was developed to describe the time evolution of formaldehyde biodisposition in animals (rats, mice and rabbits) following different formaldehyde exposure scenarios. A model previously developed to describe the biodisposition of methanol and its metabolites in animals and humans (Bouchard et al., 2001) was used as a framework for the development of this model since methanol is metabolized mainly to formaldehyde in the animal and human body. In the model, a certain fraction of formaldehyde is readily oxidized to formate, a major fraction of which is rapidly converted to CO_2 and exhaled. The rest of formaldehyde is converted to unobserved by-products which are represented by a compartment with slow elimination. The dynamic of inter-compartment exchanges was described mathematically by a mass balance differential equation system. Parameters were estimated from metabolite time profiles published in the literature following either methanol or formaldehyde exposure. Data were available over longer periods of time after exposure to formaldehyde than was the case following methanol exposure. These data showed that time profiles of CO_2 exhalation in rats, mice and rabbits followed a bi-exponential pattern after formaldehyde exposure that was not apparent from previously published data on methanol exposure. The model reproduces these patterns by introducing a slow elimination route of unobserved formaldehyde by-products through metabolism to CO_2 and exhalation, in addition to the more rapid elimination from the formate body burden.

1657 REACTION NETWORK MODELING: A NEW MODELING APPROACH FOR BENZO(A)PYRENE BIOLOGICAL PATHWAYS.

K. H. Liao[1,2], W. Wei[3], M. T. Klein[3], K. F. Reardon[2] and R. S. Yang[1]. *[1]Quantitative and Computational Toxicology Group, Center for Environmental Toxicology and Technology, Colorado State University, Fort Collins, CO, [2]Department of Chemical Engineering, Colorado State University, Fort Collins, CO and [3]Department of Chemical and Biochemical Engineering, Rutgers, The State University of New Jersey, Piscataway, NJ.*

A new modeling approach, BioMOL (Biological application of Molecular Oriented Lumping), has been used to simulate the metabolic pathways of xenobiotics in a biological system. By setting the reaction rules, the reaction network is generated automatically at the molecular level. Graph theory is used to convert chemical structures and reaction rules into computer code. The atomic connectivity of the molecule is represented by the bond-electron matrix. The reaction matrix is a compact representation of bond formation and breakage caused by a chemical reaction. BENZO(A)PYRENE was used to build the first model by BioMOL since it is a human carcinogen as well as an ubiquitous environmental pollutant. Its metabolic pathway has been extensively studied and a great deal of information is available in the biomedical literature. The reaction rules used in this model include epoxidation of double bonds, hydrolyation of epoxide, NIH shift of arene oxide to phenol, oxidation of phenol to quinone, glucuronidation, sulfation, and glutathione conjugation. The rate constants are estimated based on the reaction family concept and Quantitative Structure Reactivity Correlations (QSRCs). The reactivity indexes, which are converted to rate constants by QSRCs, can be calculated by BioMOL-integrated semi-empirical quantum chemistry software. Candidate reactivity indexes include heat of reaction, π-electron density, and bond order. Key parameters were determined in a normal human epidermal keratinocyte cell culture system and used to verify the model built by BioMOL. This approach will be a promising tool for complex biological processes involved in chemical and chemical mixture toxicology. This work was supported by NIEHS Grant # R01 ES09655.

1658 NEW DEVELOPMENTS IN THREE-DIMENSIONAL MODELING OF THE RESPIRATORY TRACT.

R. A. Corley[1], H. E. Trease[1], K. R. Minard[1], D. R. Rommereim[1], J. S. Kimbell[2], C. G. Plopper[3] and C. Timchalk[1]. *[1]Pacific Northwest National Laboratory, Richland, WA, [2]CIIT Centers for Health Research, Research Triangle Park, NC and [3]University of California, Davis, CA.*

Advances in computer hardware, software and imaging technologies have enabled the rapid development of three-dimensional (3D) models of the lungs and nasal passages of the rat and human. Magnetic resonance (NMR) techniques were developed to image nasal and lung airways of rats at 50-μm resolution. The level of detail achieved by NMR (terminal bronchioles) is comparable to lung cast measurements but the geometry is obtained at far greater speed and accuracy. Semi-automated methods were used to translate imaging data from NMR, confocal microscopy and other formats (e.g. lung casts) into 3D mesh structures. Together, these approaches reduced the development time for initial 3D meshes, which will facilitate the processing of multiple rats. Subsequent mesh refinement time (artifact removal) is highly dependent upon the quality of the source imaging data. In addition to reconstructing airway surfaces, the models are being extended to include details captured by NMR of tissue structures and boundaries governing lung expansion/contraction (e.g. lobes, diaphragm, heart, etc). Confocal microscopic images of smooth muscles lining terminal airways of normal and asthmatic monkey lungs were also reconstructed into 3D meshes and merged with airway surface meshes. More robust airway structures will facilitate future modeling of particulate clearance, gas/vapor exchange or linkage with dynamic response models. The 3D models will form the basis for computational fluid dynamics modeling of inhalation, exhalation and deposition of particulate matter. The model can be manipulated to simulate the impact of altered lung structure or function to improve dosimetry predictions in normal *vs.* potentially sensitive individuals. Confirmation of the ability of the models to predict dosimetry at this level of detail will require new techniques for measuring airflows and particulate deposition in discrete regions of the respiratory tract.

1659 A PHYSIOLOGICALLY BASED PHARMACOKINETIC/PHARMACODYNAMIC MODEL FOR THE INSECTICIDE PARATHION IN THE RAT.

A. A. Kousba and L. G. Sultatos. *Pharmacology and Physiology, New Jersey Medical School, Newark, NJ.*

A physiologically based pharmacokinetic/pharmacodynamic model was constructed for the insecticide parathion. Tissue/blood partition coefficients were determined by equilibrium dialysis, while metabolic constants were obtained from

previously published studies. Detoxification pathways included enzymatic pathways mediated by cytochromes P450 and A-esterase, as well as non-enzymatic pathways involving butyrylcholinesterase and carboxylesterase. The pharmacodynamic model describing the interaction of paraoxon with acetylcholinesterase included phosphorylation of the active site, as well as a peripheral binding site, that when occupied by paraoxon, reduced the appki for phosphorylation of the active site by paraoxon. The apparent Ki (appki) for paraoxon when the peripheral site was unoccupied, determined experimentally, was 0.90 $pM^{-1}h^{-1}$, while the same constant when the peripheral site was occupied by paraoxon was 0.00000125 $pM^{-1}h^{-1}$. Other significant events included in the pharmacodynamic model were reactivation of inhibited enzyme, aging, and normal synthesis and degradation of enzyme. Comparison of the simulation output with data from various publications involving different routes of administration of parathion and paraoxon in the rat, indicated that the model accurately simulated the pharmacokinetic disposition of parathion and paraoxon, and accurately simulated the degree of acetylcholinesterase inhibition in brain, diaphragm and blood, as well as butyrylcholinesterase and carboxylesterase inhibition in liver, blood, and heart/lungs following exposure to parathion or paraoxon.

1660 BIOLOGICALLY BASED MODELING OF CHLOROFORM CYTOLETHALITY AND REGENERATIVE CELLULAR PROLIFERATION.

Y. Tan[1], B. E. Butterworth[2] and R. B. Conolly[1]. [1]*Center for Computational Biology and Extrapolation Modeling, CIIT Centers for Health Research, Research Triangle Park, NC and* [2]*Butterworth Consulting, Raleigh, NC.*

The cytolethality of chloroform occurs when the rate of generation of toxic metabolites exceeds the capacity of cellular protective mechanisms. In this study, a PBPK model for chloroform was extended to include cytolethality and regenerative cellular proliferation (RCP). This allowed calculation of a simulated labeling index (LI) that was compared with LI data from chloroform-exposed B6C3F1 mice and F344 rats. Key challenges in developing the model were (1) identifying the optimal form of the function linking chloroform metabolism to cytolethality and (2) defining a mechanism controlling the rate and extent of RCP. Possible forms of the linking function include (a) the rate of metabolism, (b) the AUC for the rate of metabolism over some interval, (c) the rate of metabolism ≥ a minimum rate, and (d) the AUC for the rate of metabolism ≥ a minimum rate over some interval. The actual biological mechanism of RCP is only partially understood, but involves growth factors and signaling pathways. In the interests of model parsimony, a simplified signaling submodel was developed. In this submodel, liver cells secrete a signal into blood and normal liver size is associated with a specific blood level of signal. As cytolethality reduces the number of cells, the level of signal falls. The difference between the control and exposed levels of signal is used as a driving force to increase the rate of cell division. This is an efficient means of simulating the LI data. Simulations with rate of metabolism and the AUC for rate of metabolism signaling submodels did not accurately describe the LI data, and the more complex submodels are being evaluated. This work will increase our understanding of the quantitative relationship between chloroform pharmacokinetics and cytolethality and support biologically based modeling of the dose-response for chloroform-induced cytolethality in humans.

1661 A COMPUTER DOCKING STUDY OF THE BINDING OF POLYCYCLIC AROMATIC HYDROCARBONS AND THEIR METABOLITES TO THE LIGAND BINDING DOMAIN OF THE ESTROGEN RECEPTOR.

J. R. Rabinowitz[1], S. B. Little[1] and K. W. Brown[2]. [1]*Environmental Carcinogenesis Division, USEPA, Research Triangle Park, NC and* [2]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC.* Sponsor: M. Gilmour.

Polycyclic aromatic hydrocarbons (PAH) are a class of ubiquitous, anthropogenic chemicals found in the environment. In the present study, we use computational methods to evaluate their potential estrogenicity and the contribution chemicals in this class make to environmental estrogenicity. Classical docking methods, Dock and Affinity, are used to evaluate the potential binding affinity of chemicals in this class and their metabolites to the published crystal structures of the ligand binding domain of the estrogen receptor. These methods, with a molecular mechanics interaction energy scoring function, were able to place estradiol within an RMSD of 0.4 Å from its binding position determined by x-ray crystallography. The scores obtained in this manner show wide variation for the PAHs and their metabolites. They depend on PAH type and the three dimensional structure of the metabolites. For example, (-)-anti-benzo[c]phenanthrene diolepoxide is a much better binder in this model than the (+) enantiomer. A few dominant modes of binding have been identified and will be presented. These results will be compared to the results for known binders. Semi-empirical quantum mechanical methods were also used to compute the interaction energy of the most stable structures obtained from the classical computer docking experiments. These quantum mechanical calculations provide a quantitative description of the interaction between the ligand and the receptor and contain elements that are omitted from the classical scoring function. The comparison of these results demonstrates the importance of the nonclassical interaction terms for molecules that have pi electron systems. (This work does not necessarily reflect EPA policy. K. W. Brown was funded by EPA/UNC Toxicology Research Program Training Agreement CT902908 and CT827206.)

1662 THE EFFECTS OF ATRAZINE ON THE ABILITY OF ESTRADIOL TO BIND TO ESTROGEN RECEPTOR IN THE HYPOTHALAMUS.

T. S. McMullin[1], A. H. Nagahara[2], R. J. Handa[2] and M. E. Andersen[1]. [1]*Environmental Health, Colorado State University, Fort Collins, CO and* [2]*Anatomy and Neurobiology, Colorado State University, Fort Collins, CO.*

Atrazine (ATRA), a chloro-triazine herbicide, is widely applied throughout the United States. At high doses, it suppresses the preovulatory luteinizing hormone (LH) surge in female rats. Although the site of action is the hypothalamus, the mechanism is unknown. Estradiol (E2) acts on hypothalamic neurons to initiate the LH surge. Chloro-triazines have weak anti-estrogenic effects in some assays. Our studies determined if ATRA's anti - estrogenic properties are responsible for the diminished LH surge in female rats. We verified this by an *in vitro* ER competition binding study with ATRA and 3H-E2. ATRA (0-750uM) caused a dose-dependent decrease in E2 binding to ER, independent of pre-incubation. Decreased responsiveness of the hypothalamus to E2, caused by ATRA, could interfere with the E2 - mediated positive feedback required for the LH surge. To test this, the following *in vivo* studies were performed: (1) we confirmed the ability of ATRA to blunt the LH surge in ovariectomized, E2 - primed female rats. At 300 mg/kg/day for 5 days, it significantly suppressed the surge. The remaining studies used this treatment regimen. (2) Using in - situ hybridization, we assessed changes in progesterone receptor (PR) mRNA expression following *in vivo* exposure to ATRA. PR mRNA is upregulated in response to activation of ER - E2 complex in the nucleus. If ATRA decreased ability to bind ER, PR mRNA would not be increased. ATRA treatment caused no change in PR mRNA expression in various hypothalamic regions compared to control. (3) An *in vivo* ER nuclear exchange assay determined changes of occupied hypothalamic ER after ATRA and estrogen treatment. ATRA had no effect on the ability of ER to bind E2. Therefore, despite evidence of anti-estrogenicity, this property of ATRA is unlikely to be involved in suppression of the LH surge. This research was funded by Superfund Grant (5 P42 ES05949).

1662A A SHORT-TERM DOSING MODEL FOR DETECTING THE EFFECTS OF ENVIRONMENTAL CONTAMINANTS ON THYROID HORMONES IN THE RAT: EFFECTS OF PESTICIDES.

J. M. Hedge[1], D. G. Ross[2], M. J. DeVito[2] and K. M. Crofton[1]. [1]*Neurotoxicology Division, USEPA, Research Triangle Park, NC and* [2]*Experimental Toxicology Division, USEPA, Research Triangle Park, NC.*

Recently, a short-term rat dosing model has been developed to examine the effects of environmental mixtures on thyroid homeostasis (TH). Prototypic chemicals such as dioxins, polychlorinated biphenyls and polybrominated diphenyl ethers have been tested and shown to adversely impact both neurological development and TH, primarily by up regulating catabolism of thyroid hormones by liver enzymes. Current efforts examined the effects of select pesticides in this model. Female Long Evans rats (28 days old) were orally dosed for four consecutive days with the dithiocarbamate fungicide mancozeb (MAN) or the herbicide pronamide (PRO) (0, 3.9, 7.8, 15.6, 31.25, 62.5, 125, 250, 500, 1000 mg/kg/day), or the dithiocarbamate fungicide thiram (THI) (0, 6.25, 12.5, 25, 50, 100, 200, 400, 800 mg/kg/day). Serum and liver samples were collected 24 hrs after the last dose. Triiodothyronine (T3) and thyroxine (T4) were measured *via* radioimmunoassays. Hepatic ethoxy-resorufin-O-deethylase (EROD), pentoxy-resorufin-O-deethylase (PROD), and uridinediphosphate-glucuronsyltransferase (UDPGT), were determined in hepatic microsomal fractions. Liver-to-body weight ratios (LBR) increased for PRO at doses >125 mg/kg/day. MAN at >500 mg/kg/day, and THI at >400 mg/kg/day. PRO, MAN and THI all produced similar dose-related decreases in T4, with estimated ED50s of approximately 250 mg/kg/day. Potencies for decreases in T3 were THI > PRO > MAN. Maximal suppression of T3 and T4 was ~50% and 80% at the highest doses, respectively. Neither MAN or THI caused changes in EROD or PROD. These data suggest that this rodent dosing model is sensitive to short-term pertubations in thyroid hormones caused by these pesticides. This abstract does not necessarily reflect the policy of the USEPA.

1663 17β-ESTRADIOL- AND 4-HYDROXYTAMOXIFEN-INDUCED TRANSACTIVATION IN BREAST AND ENDOMETRIAL CANCER CELLS IS DEPENDENT ON ER-SUBTYPE, CELL AND PROMOTER CONTEXT.

E. Castro-Rivera and S. H. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

The pattern of transcriptional activation by 17β-estradiol (E2) and 4-hydroxytamoxifen (4-OHT) was determined in ZR-75 and MDA-MB-231 breast, ECC1 and HEC1A endometrial and HepG2 liver cancer cell lines cotransfected with E2-responsive constructs and wild-type estrogen receptor α (ER-WT) or ERβ (ERβ-WT) or variant forms of ERα expressing activation function 1 (AF1; ER-AF1) or AF2 (ER-AF2). The E2-responsive constructs contained promoter inserts from the human complement C3 (pC3-luc), human cathepsin D (pCD-CAT) and rat creatine kinase B (pCKB-CAT) genes. Minimal ERβ-dependent transactivation (<2.5-fold induction) was observed for E2 only in ECC1 and MDA-MB-231 cells transfected with pCKB-CAT or pC3-luc, whereas 4-OHT was inactive as an ERβ agonist for all promoters in the four cell lines. The pattern of E2- or 4-OHT-activated gene expression and their interactions were highly complex and dependent on cell and promoter context and form of cotransfected ERα. For example, E2 did not activate pCD in HepG2 cells transfected with wild-type or variant ERα, whereas E2 activated reporter gene activity in the four endometrial/breast cancer cell lines transfected with ER-WT and pCD, pCKB or pC3. However, hormone activation of these constructs by ER-AF1 or ER-AF2 was highly variable among the different cell lines and even in the same cell line transfected with the three E2-responsive constructs. Similar variability was observed for 4-OHT suggesting that transcriptional activation by E2 and 4-OHT induces recruitment of different transcription factor complexes that are dependent not only on the cell type but also the gene promoter. (Supported by NIH ES04917 and ES09106)

1664 EVALUATION OF POTENTIAL ESTROGENIC PROPERTIES OF OCTAMETHYLCYCLOTETRASILOXANE (D4) USING THE MCF-7 CELL LINE.

A. L. Quinn, L. S. Meeker, J. M. McKim, Jr, R. H. Gallavan, R. G. Meeks and K. P. Plotzke. *Dow Corning Corporation, Midland, MI.*

The objective of this research was to evaluate the potential estrogenic properties of octamethylcyclotetrasiloxane (D4). Using an *in vitro* estrogen responsive reporter gene system followed by Northern blot analysis, D4, estradiol (E2), and diethylstilbestrol were evaluated using the MCF-7 human cell line. Treatment with D4 for 24 hours at an applied dose of 0.1 - 10μM resulted in a dose-dependent increase in pS2 expression. As expected, all of the positive control compounds resulted in dose-dependent increase in mRNA expression. Linear regression analyses indicated that D4 was 74, 009 times less potent than E2 with the compounds showing equivalent efficacy at the highest dose. Maximal mRNA expression was seen between 6 and 24 hours, although exposure at shorter times resulted in increasing levels of mRNA. The loss of D4 in the medium was monitored and there was a rapid loss of compound, which reached a plateau around 12 hours with less than 10% remaining. The potential for D4 to act as an anti-estrogen was evaluated comparing the E2 Dose-Response curve with and without co-incubation with 1.0 μM D4. This regression analysis resulted in parallel slopes with statistically indistinguishable y-intercepts, indicating that the D4 is not reducing the potency of E2 under these conditions. Preliminary receptor binding studies were carried out to examine the binding of D4 to ER-α and ER-β. Studies indicate that the D4 can weakly compete for the estrogen receptor, both ER-α and ER-β. D4 did not reduce E2 binding beyond 70% of the control value even at D4 concentrations of 250μM. This data suggests that D4 can elicit an estrogenic effect that is dose-dependent with no significant anti-estrogenic activity. Binding data indicate that the effect is mediated through the estrogen receptor. Supported in part by Silicones Environmental, Health and Safety Council of North America.

1665 CELL CONTEXT-DEPENDENT DIFFERENCES IN THE MECHANISM OF ESTROGEN REGULATION OF E2F1 IN BREAST CANCER CELLS.

S. Ngwenya[1] and S. H. Safe[2]. [1]*Biochemistry & Biophysics, Texas A&M University, College Station, TX and* [2]*Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

E2F1 is a member of the E2F family of transcription factors which plays an important role in cell cycle progression and cell proliferation. E2F1 is induced by 17β-estradiol (E2) in breast cancer cells and contributes to hormone-induced proliferation of estrogen receptor (ER)-positive cell lines. Mutation and deletion analysis of the E2-responsive -146 to -54 or -169 to -54 regions of the E2F1 gene promoter using transient transfection assays demonstrates that hormone-induced transactivation in MCF-7 cells requires at least one of three GC-rich sites (-169 to -111) that bind ERα/Sp1 and cooperatively interacts with two downstream CCAAT motifs (-122 to -54) that bind NFYA. Transient transfection of E2-responsive constructs pE2F1a (-169 to -54) or pE2F1b (-146 to -54) containing E2F1 gene promoter inserts are induced ≥ 3.5-fold in both ER-positive MCF-7 and ZR-75 cells. Gel mobility assays of nuclear extracts from both cell lines gave comparable patterns of retarded bands and confirm that Sp and NFY proteins bind upstream (^{32}P-169/-111) and downstream (^{32}P-122/-54) oligonucleotides, respectively. Deletion analysis of the E2F1 promoter in ZR-75 cells using pE2F1c and pE2F1d (containing -169 to -111 and -122 to -54 E2F1 promoter inserts) showed that E2 induced a 2.5- and 3.5-fold increase in reporter gene activity, whereas these constructs were inactive in MCF-7 cells. These results demonstrate that E2F1 is differentially regulated by cooperative ERα/Sp1-NFYA interactions in MCF-7 cells and by independent ERα/Sp1 and ERα activation of CCAAT binding proteins in ZR-75 cells. Current studies are investigating the novel genomic/non-genomic pathways associated with hormonal activation through CCAAT motifs. (Supported by NIH ES04176 and ES09106)

1666 ESTROGENIC RESPONSES TO GENISTEIN IN JAPANESE MEDAKA (*ORYZIAS LATIPES*).

L. Zhang[1], I. A. Khan[2] and C. M. Foran[3,1]. [1]*Department of Pharmacology, The University of Mississippi, University, MS,* [2]*Department of Pharmacognosy, The University of Mississippi, University, MS and* [3]*Department of Biology, West Virginia University, Morgantown, WV.* Sponsor: K. Willett.

Although the phytoestrogen genistein has been determined to be weakly estrogenic, the change in endocrine function associated with genistein exposure is not necessarily expected to mirror the physiological changes following exposure to endogenous estrogens. Because of the potential for genistein to compete with 17-β-estradiol at the receptor, some estrogenic responses might be diminished in the presence of genistein. Thus, this study was designed to determine the estrogenic effect of the phytoestrogen genistein on endocrine physiology in adult Japanese medaka (*Oryzias latipes*) relative to 17-β-estradiol. Adult animals of both sexes were exposed to 75ng/fish, 750ng/fish, and 30μg/fish (average fish weight was 0.26g/fish) of genistein by i. p. injection. A positive control group was similarly treated with 300ng/fish of 17-β-estradiol, while a negative control group received a vehicle only (corn oil) injection. Several assays were used to determine the extent and type of changes in the endocrine system of treated animals. Vitellogenin, while induced by estradiol, was not increased in the liver of individuals treated with genistein. Genistein treatment at higher doses increased the estradiol production by ovaries more than estradiol treatment. In males, genistein treatment resulted in decreased testosterone production from *ex vivo* testis and a comparable reduction in circulating testosterone level. The changes in endocrine physiology in medaka in response to genistein are similar to that of estradiol. However, some endpoints are more sensitive to estradiol treatment (vitellogenin) while others are more sensitive to genistein (male testosterone and female ovarian estrogenesis). Future studies with dietary supplements will build on these results, which will serve as a basis for testing individual components of plant extracts for estrogenic activity.

1667 DIFFERENTIAL EXPRESSION OF THREE ESTROGEN RECEPTOR ISOYPES DURING LARGEMOUTH BASS *(MICROPTERUS SALMOIDES)* REPRODUCTION AND FOLLOWING EXPOSURE TO NONYLPHENOL.

T. L. Sabo-Attwood, M. S. Nelson, J. J. Upp and N. D. Denslow. *Pharmacology and Therapeutics, Molecular Genetics and Microbiology, and Biochemistry and Molecular Biology, University of Florida, Gainesville, FL.*

Discovery of multiple estrogen receptor (ER) isotypes raises questions regarding their role in gene regulation by endogenous estradiol and xenoestrogens. Here we report the discovery of three ER isotypes in largemouth bass (LMB), ERα, ERβ, and ERγ. Using real-time quantitative PCR we have determined that these isotypes are differentially expressed in brain, pituitary, gonad, and liver tissues in vitellogenic females. For example, ERα and ERβ are more highly expressed than ERγ in the liver. However, ERγ expression is greater than both of the other ER isotypes in gonadal tissue. This differential tissue distribution pattern suggests they play very different roles during the reproductive process. To begin to understand their roles in reproduction we measured the expression pattern of each ER in adult female LMB during normal oocyte development. Liver tissue was collected at approximately two-week intervals from October through June. Expression of each ER and vitellogenin (VTG) mRNA were quantitated using real-time PCR. We also measured plasma VTG protein levels by direct ELISA. Results show that each ER isotype displays a distinct pattern of expression. There is an apparent correlation between ERα and VTG mRNA and VTG protein levels. ERβ however, appears to be down regulated during peak vitellogenesis. ERγ expression remain fairly constant throughout reproduction suggesting it plays a minimal role in gene regulation in the liver. To

determine if nonylphenol (NP) treatment induced similar expression profiles of the ERs we injected adult male LMB with 50 mg/kg or 500 mg/kg, and sampled tissues after 48 hours. Both NP treatments increased the production of plasma VTG and ERα mRNA in a dose dependent manner. The results from the NP injection are similar to the results of the seasonal study, and both suggest that ERα plays a greater role in the regulation of VTG.

1668 THE ESTROGENIC PROPERTIES OF 3, 3'-DIINDOLYLMETHANE (DIM) ARE DEPENDENT UPON CYTOCHROME P450 (CYP) METABOLISM.

S. C. Thompson[1], A. D. Shilling[2] and D. E. Williams[1]. [1]*Environmental and Molecular Toxicology and The Linus Pauling Institute, Oregon State University, Corvallis, OR and* [2]*Department of Drug Safety and Metabolism, Wyeth-Ayerst Research, Collegeville, PA.*

Indole-3-carbinol (I3C) is a glucosinolate hydrolysis product from cruciferous vegetables that has been found to have chemoprotective effects in several animal models. However, I3C given long-term postinitation promotes liver carcinogenesis in trout and rat models, but inhibits hepatic tumors in mice similar to the actions of 17β-estradiol (E2). A major acid condensation product of I3C, DIM, is estrogenic in precision trout liver slices and accounts for the majority of the estrogenicity of I3C in trout *in vivo*. This evidence, along with the species selectivity of I3C as a hepatic tumor modulator, suggests an estrogenic mechanism of action for hepatocarcinogenesis. In this study, we demonstrate that DIM requires CYP-dependent metabolism to the active estrogen. Trout liver slices were incubated with 0.2% DMSO, 100 nM E2 or 20 μM DIM. CYP metabolism was inhibited in these slices with 20 μM SKF 525-A (SKF) or ketoconazole (KC). Vitellogenin (VTG) induction in E2-treated slices was not affected by either CYP inhibitor whereas VTG induction by DIM was significantly decreased 79% and 86% in slices treated with KC and SKF, respectively ($p < 0.05$). These data further support the importance of estrogenic mechanisms in tumor modulation by I3C and suggest that species differences in hepatic tumor promotion are due to the CYP-specific metabolism of DIM to estrogenic metabolites. Supported by PHS grants ES03850 and ES07060 from the NIH.

1669 THE REGULATION OF THE STEROIDOGENIC ACUTE REGULATORY PROTEIN (STAR PROTEIN) IN LARGEMOUTH BASS (MICROPTERUS SALMOIDES).

R. J. Kocerha, T. L. Sabo-Attwood, J. J. Upp, M. S. Nelson and N. D. Denslow. *Biochemistry, University of Florida, Gainesville, FL.*

The Steroidogenic Acute Regulatory Protein (StAR) transports cholesterol across the mitochondrial membrane, making cholesterol available to be metabolized into steroid hormones. Some environmental contaminants have been found to alter the levels of steroid hormones, which could occur through targeting the expression of the StAR Protein. We obtained gonad samples of largemouth bass (LMB) at two week intervals throughout a year to determine the normal mRNA levels of the StAR Protein and it's correlation with steroid hormone levels. Total RNA was isolated from gonads and mRNA levels of StAR were then quantitated using real-time PCR with Taqman technology. Primers for the real-time PCR assay were designed from a partial, 345 base pair sequence of the LMB StAR Protein previously cloned in our Lab.. The levels of StAR in LMB go from an average of 0.2 pg StAR mRNA/ug of total RNA during the quiescent period in the fall to a peak of 7.3 pg StAR mRNA/ug of RNA during the primary reproductive season. The expression pattern of StAR correlates with the expression pattern of 17-beta-estradiol, as would be expected since it is the rate limiting step in steroid synthesis. Establishing the normal levels of StAR in LMB during the reproductive season will set baseline parameters for studying the effects of environmental contaminants on StAR expression. It has been shown already that several contaminants, including herbicides and insecticides, decrease the expression of the StAR Protein in mammalian cell lines (Walsh et al, 2000, Environ Health Perspectives, 108(8):769). Fish exposed to contaminants from paper mills have been extensively shown to exhibit decreased steroid levels, possibly through alteration of StAR expression. LMB is an excellent model for studying the effects of contaminants on the regulation of the StAR Protein

1670 4-NONYLPHENOL ALTERS STEROID HORMONE METABOLISM IN THE LIVER OF FVB MICE.

R. Acevedo[1], R. Robinson[2], S. Cox[2] and W. S. Baldwin[1]. [1]*Biological Sciences, University of Texas at El Paso, El Paso, TX and* [2]*Biology, Anderson College, Anderson, SC.*

4-Nonylphenol (4-NP) is an endocrine disrupting chemical that enhances proliferation of MCF-7 breast cancer cells due to its affinity for the estrogen receptor. Recent data also indicates that 4-NP binds to the PXR receptor (Masuyama et al., 2000), therefore it has the potential to alter CYP 3A family member expression. These P450s are important in the inactivation and 6β-hydroxylation of testosterone. Because PXR receptor activation appears to alter xenobiotic and steroid metabolism, we hypothesized that 4-NP may alter steroid hydroxylation and possibly steroid conjugation. This may be important in activating 4-NP's own elimination or the elimination of other chemicals; however, it is also possible that 4-NP may alter steroid hormone metabolism in ways that are not beneficial to the organism. Female FVB mice were treated for seven days with 0, 25, 50, and 75mg/kg/day 4-NP in honey, and then euthanized. Livers were excised, microsomes and cytosol prepared and then both estradiol and testosterone glucuronidation, sulfation and hydroxylation was examined. 4-NP significantly increased estradiol sulfotransferase activity 50% at 75mg/kg/day 4-NP and in a dose-dependent fashion, but 4-NP did not increase estradiol or testosterone glucuronyltransferase activity. 4-NP did signficantly inhibit both estradiol and testosterone glucuronyltransferase activity *in vitro*. We are currently investigating 4-NP's actions on estradiol and testosterone hydroxylase activity, and those results will be presented. These alterations in steroid conjugation may effect clearance of steroids from exposed tissues, and thus increase the potential of 4-NP to promote steroidogenic cancers.

1671 STIMULATION OF THE THYROID GLAND WITH THYROTROPIN RELEASING HORMONE IN THE RAT: VALIDATION OF THE MEASUREMENT OF THYROID STIMULATING HORMONE.

J. Verbeeck, P. Vinken, R. De Coster, B. Verstynen, A. Lampo, T. Jansen, L. Lammens and W. Coussement. *Toxicology and Pathology, Janssen Research Foundation, Beerse, Belgium.* Sponsor: W. Powers.

The purpose of this study was to validate the measurement of serum Thyroid Stimulating Hormone (TSH) with a rat specific radioimmunoassay (Amersham, UK) after stimulation with commercial Thyrotropin Releasing Hormone ((TRH UCB® (Protirelin)). T3 (triiodothyronin) and T4 (thyroxine) were measured as well. TRH stimulates the release of TSH by the anterior pituitary which regulates the secretion of the thyroid hormones. Commercial TRH is used for diagnostic purposes in the TRH-test in humans. TRH was given as a single IV injection to 3 groups of five male and female rats each at a dose of 2.5 micrograms/kg body weight. Rats of a fourth, control, group were not injected. Blood was sampled *via* the orbital venous plexus 15 minutes after stimulation in the first group, after 30 minutes in the second and after 60 minutes in the third. Stimulation of each group (and sampling in the controls) was done on three different occasions with 7 days between to check reproducibility. The final blood sampling was done at terminal kill of the animals (pentobarbitone anaesthesia) *via* the carotid artery. Increase in TSH levels reflected the expected biological response after stimulation of the pituitary gland by exogenous TRH. Approximately 15 and 30 minutes after stimulation, an increase in TSH levels occurred in male and female rats. This increase was no longer statistically significant 60 minutes after stimulation in males. In females, TSH levels were comparable or lower than the control group after 60 minutes. Both in male and female rats, stimulation of the pituitary gland with TRH resulted in increased T3 levels at 30 and/or 60 minutes after TRH administration. T4 levels remained unchanged. The stimulation model tested was reproducible in time. Stimulation with commercial TRH can be used to test the integrity of the hypothalamic-pituitary-thyroidal axis in the rat or as an aid in validation of measurement of hormones related to this system.

1672 PERCHLORATE INDUCED THYROID HORMONAL CHANGES IN PREGNANT RATS AND FETUSES.

L. Narayanan[1], K. O. Yu[2], D. R. Mattie[2] and J. W. Fisher[3]. [1]*Geo-centers, Inc, Wright Patterson Air Force Base, OH,* [2]*AFRL/HEST, Wright Patterson Air Force Base, OH and* [3]*The University of Georgia, Athens, GA.*

The production and storage of ammonium perchlorate (AP) has resulted in the contamination of soil, ground, and drinking water in a number of states. The perchlorate ion interferes with iodide uptake in the thyroid, resulting in reduced thyroidal hormone synthesis. In rodents, this leads to lower triiodothyronine (T_3) and thyroxine (T_4) levels in the blood, and the activation of thyroid stimulating hormone (TSH). A time-course kinetic study with perchlorate was conducted to examine perchlorate kinetics and corresponding hormone changes in pregnant rats. Pregnant rats (n=8) were administered perchlorate at a concentration of either 0 or 0.1 mg/kg *via* tail vein on gestation day 20 (GD20) and sacrificed at 1, 4, 8, 12, 24 and 48h post dosing. Maternal and fetal serum perchlorate concentrations, determined at all time points, reached their maximum at 4 hours after perchlorate exposure. Serum perchlorate concentrations were undetectable at 24 and 48h post dosing in the dams, where as in the fetuses they were undetectable at 8, 12, 24 and 48h post dosing. Serum levels of TSH, T_3 and T_4 were measured in both the dams and fetuses. In the 0.1-mg/kg-dose group serum TSH levels were increased significantly ($p<0.05$) at 4h and 8h post dosing in both the dams and fetuses. Serum thyroid

hormones decreased significantly ($p<0.01$) at 4h post dosing in the 0.1 mg/kg perchlorate dose group in both the dams and fetuses. Maternal and fetal serum TSH levels at 0.1 mg/kg perchlorate dose in the 8h post dosing groups were 5.47 ± 0.34 and 6.06 ± 0.45 ng/mL as compared to maternal and fetal serum TSH levels of 4.60 ± 0.38 and 5.11 ± 0.49 ng/mL in the control groups at GD20. Fetal Serum T_4 levels were significantly decreased at 4h, 8h and 12h post dosing in the 0.1 mg/kg dose group. Assessment of serum perchlorate and thyroid hormone levels serves as the most sensitive end point to understand perchlorate effects during gestation and provide data to develop a pharmacodynamic model for perchlorate in rodents.

1673 EXPRESSION PROFILE IN LIVER, PITUITARY, AND THYROID FROM PHENOBARBITAL TREATED RATS.

B. A. Jessen, M. J. Chambers and G. J. Stevens. *Drug Safety Evaluation, Pfizer Global Research and Development/Agouron Pharmaceuticals, Inc., La Jolla, CA.*

Phenobarbital is a microsomal enzyme inducer that causes thyroid follicular cell hyperplasia and tumors in rats, presumably by increasing the clearance of thyroxine (T4) and triidothryonin (T3) leading to a compensatory increase in serum thyroid-stimulating hormone. Increased clearance of T3 and T4 is due in part to induction of UDP-glucuronosyl transferase (UGT). The induction by phenobarbital in the liver is well documented, however its effects in the thyroid and pituitary have not been reported. Through the use of DNA arrays, the effect of phenobarbital (100 mg/kg/day) on the expression of 8, 740 genes in the liver, thyroid, and pituitary of male rats treated for 14 days was measured. Several xenobiotic metabolizing enzymes, including the CYP 2B and 3A family, as well as UGTs were induced in all three tissues. Specifically, CYP3A1 was induced 3.4, 15, and 14.4-fold, CYP3A3 was induced 2.4, 11.9, and 18.7-fold, CYP2B2 was induced 51.2, 6.7, and 21.4, CYP2B19 was induced 9.8, 27, and 37.3-fold, and UGT2B was induced 4.4, 4.5, and 19.5-fold in rat liver, pituitary, and thyroid, respectively. These findings imply that thyroid hormone metabolism in extrahepatic tissues could contribute to the mechanism of phenobarbital induced tumors in the rat by reducing hormone levels at the site of hormone regulation.

1674 SHORT-TERM EXPOSURE TO AN ENVIRONMENTAL MIXTURE OF PHAHS: DOSE-ADDITIVE EFFECTS ON SERUM THYROXINE.

K. M. Crofton[1], R. W. Setzer[2], J. M. Hedge[1], D. G. Ross[2] and M. J. DeVito[2]. *[1]Neurotoxicology Division MD-74B, USEPA, Research Triangle Park, NC and [2]Experimental Toxicology Division, USEPA, Research Triangle Park, NC.*

Endocrine disruption from environmental contaminants has been linked to a broad spectrum of adverse outcomes. An additional concern about endocrine disrupting xenobiotics is the potential for additive or synergistic effects of mixtures. A short-term dosing model to examine the effects of environmental mixtures on thyroid homeostasis (TH) has been developed. Prototypic chemicals such as dioxins, polychlorinated biphenyls and polybrominated diphenyl ethers have been shown to alter thyroid hormone homeostasis in this model primarily by up regulating hepatic catabolism of thyroid hormones. Current efforts are testing the hypothesis that the effects of mixtures of these chemicals on thyroxine (T4) concentrations can be predicted by dose-additivity theory. The current study used 28 day-old female Long-Evans rats, orally dosed with varying concentrations of 18 different PHAHs (2 dioxins, 4 dibenzofurans, and 12 PCBs, including dioxin-like and non-dioxin-like PCBs) for four consecutive days. Serum samples were collected 24 hours after the last dose. Serum total T4 was measured *via* radioimmunoassay. Extensive (7-9 doses/chemical) dose-response functions were statistically modeled to determine ED50s using the Hill equation. A mixture was custom synthesized with the ratio of chemicals based on environmental concentrations (e.g., relative to TCDD: TCDF-1.5x, PCB126-50x; PCB153-30, 000x). Serial dilutions of this mixture were tested in the 4-day dosing assay. Predicted outcome, based on the assumption of dose-additivity, was tested using statistical dose-response modeling. Preliminary analyses of results suggest that the effects of the mixture on serum total T4 can be predicted by dose-additivity. There was no evidence of synergism or antagonism. Future work will expand the mixture to include chemicals from diverse classes of thyroid disruptors such as TH synthesis inhibitors. *This abstract does not necessarily reflect the policy of the USEPA.*

1675 DDE PARTIALLY RESTORES ANDROGEN-REPRESSED TRANSCRIPTIONAL ACTIVITY OF THE CONSTITUTIVELY ACTIVE RECEPTOR (CAR).

M. E. Wyde[1], A. Ueda[2], M. Negishi[2] and L. You[1]. *[1]CIIT Centers for Health Research, Research Triangle Park, NC and [2]NIEHS, Research Triangle Park, NC.*

The constitutively active receptor (CAR) is an orphan nuclear receptor that primarily regulates the transcriptional induction of cytochrome P450 (CYP) 2B but also cross-regulates the CYP 3A gene. Steroid hormones are CAR ligands and affect CAR-mediated regulation of CYP 3A and 2B expression. CYP 3A and 2B are involved in the metabolism of steroid hormones. Xenobiotics have also been demonstrated to activate or repress CAR-mediated transcriptional regulation of enzyme expression. Alterations in CAR-regulated CYP 3A and 2B expression may lead to enhanced steroid catabolism and alterations in endocrine function. The aim of this current study was to test the hypothesis that the antiandrogen 1, 1-dichloro-2, 2-bis(p-chlorophenyl)ethylene (p, p-DDE, or DDE) affects androgen-induced repression of CAR transcriptional activation. Activation of CAR in response to chemical exposure was determined in cultured HepG2 cells that were cotransfected with mouse CAR expression plasmid, a control vector (pRL-SV40), and the luciferase reporter gene construct containing the CAR nuclear receptor binding site NR1. CAR activation was lower in cells treated with testosterone and other androgens than in cells treated with vehicle alone. No significant effect was observed in CAR activation following exposure to DDE alone at concentrations ranging from 0.01 to 50 μM. However, transcriptional activation of CAR was partially restored by DDE in cells treated with androgens. These data indicate that DDE mitigates androgen-induced repression of CAR transcriptional activation and suggest involvement of CAR in the antiandrogenic effects of DDE.

1676 INTERACTION OF TRENBOLONE, A POTENTIAL FEEDLOT EFFLUENT CONTAMINANT, WITH HUMAN AND RAINBOW TROUT ANDROGEN RECEPTORS (AR) *IN VITRO* AND *IN VIVO* ANDROGENIC EFFECTS IN THE RAT.

V. S. Wilson[1], C. Lambright[1], J. Ostby[1], E. M. Wilson[2], M. Cardon[1], P. Hartig[1], L. J. Guillette[3] and L. E. Gray,Jr[1]. *[1]RTD, USEPA, ORD, NHEERL, Research Triangle Park, NC, [2]UNC, Chapel Hill, NC and [3]UFL, Gainsville, FL.*

Concern has arisen regarding the presence and presistence of trenbolone in the environment. Trenbolone acetate is an anabolic steroid used to promote growth in cattle. It is hydrolyzed to the active compound, 17 beta-trenbolone, which is one of the primary metabolites then excreted by cattle. Both reproductive alterations in fish living in waters receiving feed-lot effluent and *in vitro* androgenic activity in feedlot effluent samples have been reported . In the current study, the potency of 17 beta-trenbolone was examined both *in vitro* and in an *in vivo* screening assay for androgenic activity. In COS cell binding assays using transfection of rainbow trout or human AR, trenbolone competed equally well for [3H]R1881 binding to either AR with relative binding affinities of 4.0 % and 3.4%, respectively, *versus* 100% for R1881. Trenbolone was also tested for its ability to activate androgen dependent transcription at concentrations ranging from 1 pM to 10 mM in MDA-kb2 cells with endogenous human AR and a stably transfected androgen responsive luciferase reporter. Trenbolone was a full AR agonist in these cells producing a Dose-Response curve similar to that of dihydrotestosterone. Futhermore, agonist activity was inhibited by the AR antagonist, hydroxyflutamide. Trenbolone was also a potent AR agonist in the N/C terminal interaction assay performed in HeLa cells, an assay that is highly specific for androgens. When examined *in vivo* in the Hershberger assay, trenbolone displayed selective AR mediated (SARM) activity, affecting some androgen-dependent tissues in rats more than others suggesting that 5 alpha reduction inactivated the parent compound. In summary, trenbolone is a potent SARM. Further studies are needed to determine if trenbolone is present in feed-lot effluent and to characterize the ability of this chemical to alter vertebrate reproduction and development.

1677 POST-TRANSCRIPTIONAL EVENTS ARE INVOLVED IN CYPROHEPTADINE INDUCED INHIBITION OF PREPROINSULIN SYNTHESIS IN RINm5F CELLS.

B. S. Hawkins and L. J. Fischer. *Department of Pharmacology and Toxicology and Institute for Environmental Toxicology, Michigan State University, East Lansing, MI.*

Previous studies have demonstrated that the antihistaminic, antiserotonergic drug cyproheptadine (CPH) inhibits insulin synthesis in RINm5F cells without an alteration in preproinsulin mRNA (PPImRNA) levels. This suggests that the compound is acting *via* one or more post-transcriptional mechanisms to inhibit the synthesis of insulin. A critical step in secretory protein synthesis is the translocation of the ribosome-associated nascent chain from the cytosolic compartment, where protein synthesis begins, into the lumen of the endoplasmic reticulum (ER) where translation continues. Using a subcellular fractionation technique followed by real-time RT-PCR, the percentage of PPImRNA in various stages of ribosome association was examined. Control cells showed 62.7 ± 2.0% of PPImRNA in ER-bound form and 31.6 ± 3.4% in translationally-initiated free cytosolic form while a two hour treatment with 10μM CPH altered these distributions to 38.7 ± 3.9% and 52.9 ± 4.9% respectively. CPH also induced an increase in the percentage of translationally-uninitiated free PPImRNA. This CPH induced dislocation of PPImRNA from ER-bound form to free cytosolic forms was found to be concentration dependent, evident within thirty minutes, and reversible upon removal of the compound. Also,

the ability of CPH to induce PPImRNA dislocation was found to be chemical structure specific as the CPH analog 4-diphenylmethylpiperidine, active in inhibition of insulin synthesis, elicited similar PPImRNA dislocation while the CPH analog 2-diphenylmethylpiperidine, inactive in inhibition of insulin synthesis, did not. Overall, these data provide evidence supporting an effect of CPH on PPImRNA translation. CPH may act to inhibit insulin synthesis by altering one or more of the processes involved in the initiation or elongation stages of translation or in the binding of ribosomes to the ER.

1678 AROMATASE INHIBITION BY AZOLE DRUGS: ASSESSING PREGNANCY RISKS.

S. D. Turner[1], L. Kragie[2], T. Ho[1], C. L. Crespi[1] and D. M. Stresser[1]. *[1]BD Biosciences, Woburn, MA and [2]Endocrine Health Foundation Ltd., Silver Spring, MD.*

Human aromatase (CYP19) converts C_{19} androgens to aromatic C_{18} estrogenic steroids that are important for pregnancy maintenance and also in regulating uterine contractions in late pregancy. Inhibitors of this enzyme are associated with fetal loss in non-human primates. We tested a panel of azole antifungals which may be administered to pregnant women for their potential to inhibit aromatase using the fluorometric substrate dibenzylfluorescein and cDNA-expressed CYP19. Potency varied by several orders of magnitude. For example, metronidazole was consistently inactive as an inhibitor at concentrations up to 100 μM whereas ketaconazole and miconazole returned IC_{50} values of 1.5 μM and 0.04 μM, respectively. Typical plasma levels of some azole drugs (e.g. miconazole) following oral or topical administration are at or above these IC_{50} values. These data suggest that some azole compounds may disrupt estrogen production in pregnancy and may affect pregnancy outcome.

1679 EFFECTS ON AROMATASE ACTIVITY IN MAMMALIAN CELL LINES AFTER EXPOSURE TO VARIOUS PESTICIDES.

M. Heneweer, J. T. Sanderson and M. VandenBerg. *Institute for Risk Assessment Sciences (IRAS), Universiteit Utrecht, Utrecht, Netherlands.*

Imidacloprid, carbendazim, epoxiconazol and atrazine are widely used pesticides in Europe and the USA. These compounds contain a triazine, imidazole or triazole ring and previous research suggests that these molecular structures are, at least partly, responsible for interaction with aromatase (CYP19). Interference with the aromatase enzyme can cause an alteration in steroidogenesis, leading to an enhanced or impaired conversion of androgens to estrogens. We used the rat Leydig tumor cell line R2C to assess the effects on aromatase activity after a 24h exposure to these pesticides. Concentrations ranged from 0.3 to 100 mM. Aromatase activity, with a K_M value of 25 nM for androstenedione, was measured using a ^3H_2O-release assay. Cytotoxic effects of the pesticides were assessed by performing an MTT test for cell viability. Exposure of R2C cells to imidacloprid resulted in a 1, 5 fold induction of aromatase activity at concentrations > 30 mM, while no effect on cell viability was observed up to 100 mM. Epoxiconazol and carbendazim showed an inhibitory effect on aromatase activity at concentrations > 3 mM and > 10 mM, respectively. Both pesticides caused a decrease in cell viability at concentrations > 100 mM. Atrazine did not affect aromatase activity nor cell viability in R2C cells, whereas it was shown to cause induction of aromatase activity in the human adrenocortical carcinoma cell line NCI-H295R. These results suggest different mechanisms of action concerning regulation of aromatase activity within the different cell systems. It is concluded that these commonly used pesticides have the potential to interfere with steroidogenesis and could possibly be endocrine disruptors in the *in vivo* situation. Further research on effects of these pesticides and on their mechanism of action concerning regulation of aromatase activity within the NCI-H295R cell line and the rat Leydig carcinoma cell line LC-540 is in progress.

1680 PUBERTAL DEVELOPMENT IN FEMALE WISTAR RATS FOLLOWING EXPOSURE TO PROPAZINE AND ATRAZINE METABOLITES, DIAMINO-S-CHLOROTRIAZINE AND HYDROXYATRAZINE.

S. C. Laws, J. M. Ferrell, T. E. Stoker and R. L. Cooper. *RTD, NHEERL, USEPA, Research Triangle Park, NC.* Sponsor: R. Kavlock.

We have shown that the chorotriazine herbicide, atrazine (ATR), delays the onset of pubertal development in female rats. ATR and its by-products of microbial degradation are present in soil and groundwater. Since current maximum contaminant levels are set only for ATR, it is important to determine whether or not these metabolites can alter pubertal development and possibly pose a cumulative exposure hazard. Here, we have evaluated the effects of two ATR metabolites, diamino-s-chlorotriazine (DACT) and hydroxyatrazine (OH-ATR), and a structurally similar chlorotriazine, propazine (PRO), on female pubertal development. Rats were gavaged from postnatal day (PND) 22 through PND41 with DACT (16.5, 33.7, 67.5, 135 mg/kg), OH-ATR (22.8, 45.7, 91.4, 183 mg/kg), or PRO (26.5, 53, 107, 213 mg/kg). The dose range for each chemical was selected as the molar equivalent of ATR (25, 50, 100, 200 mg/kg). Females were monitored daily for vaginal opening (VO) and killed on PND 41. DACT delayed VO by 3.1, 4.5, and 7.1 days compared to controls (32.7 ± 1.8 days of age) after doses of 33.7, 67.5 and 135 mg/kg, respectively. The NOAEL for DACT (16.5 mg/kg) was identical to the equimolar NOAEL for ATR (25 mg/kg). Body weight (BW) on PND41 was reduced only by the high dose of DACT (7.1% reduction) indicating that growth was not associated with delayed VO. Also, the BW on the day of VO was increased by 33.7, 67.5 and 135 mg/kg DACT. PRO (107 or 213 mg/kg) delayed VO by 4 days, but did not alter BW on PND41. In contrast, the dechlorinated metabolite, OH-ATR, did not significantly delay the age at VO, suggesting that the presence of the chlorine group may be necessary for activity. Together, these data demonstrate that PRO and DACT can delay the onset of puberty in the female rat at doses equimolar to that of ATR, and suggest that environmental exposure to multiple chlorotriazines and metabolites may pose a cumulative hazard. *This abstract does not reflect USEPA policy.*

1681 EFFECT OF AN ACUTE EXPOSURE TO MOLINATE ON OVULATION IN THE RAT.

T. E. Stoker, D. Guidici, S. Jeffay, S. D. Perreault and R. L. Cooper. *RTD, USEPA, Research Triangle Park, NC.* Sponsor: R. Kavlock.

Molinate, a thiocarbamate herbicide used on rice, has been shown to impair fertility in the male rat. In a two-generation study, molinate exposure to female rats resulted in decreased litter size and ovarian abnormalities. However, published data is lacking on the effects of acute exposure to molinate in the female. Based on reported esterase inhibition by molinate and our previous observations with related dithiocarbamates, we hypothesized that a single exposure to molinate during the critical window for the neural trigger of ovulation on proestrus would alter the timing of ovulation. Cycling females gavaged with 0, 25 or 50 mg/kg molinate at 1300h on proestrus were examined for ovulation and oocyte number 24 or 48h later. All controls ovulated at 24h. Molinate at 25 mg/kg delayed ovulation for 24h in 43% of the rats, while 50 mg/kg delayed ovulation in 85%. The number of ova present in the delayed females was unaltered. To examine LH secretion, ovariectomized (OVX) rats were implanted with physiological levels of estradiol (E2) and the induced LH secretion determined by tail bleeds at 0, 2, 4 or 6h after a single oral dose at 1300h. 25 mg/kg molinate caused a significant suppression of the LH in 67% of the rats (4h mean = 0.566 ± 0.1 ng/ml vs 3.560 ± 0.7 ng/ml in controls). 50 mg/kg molinate suppressed the LH surge in 83.3 % of the rats (4h mean = 0.347 ± 0.1 ng/ml). In another study, OVX/E2 rats were killed at 0, 1, 3 and 6h after similar dosing. 50 mg/kg suppressed the LH surge in 75% of the rats, while 25 mg/kg suppressed the LH surge in 63%. These results indicate that molinate is able to delay ovulation by suppressing the LH surge on the day of proestrus and that the brain and/or pituitary are target sites for this pesticide. These effects may explain in part the effects observed in previously published chronic studies with molinate in the female rat. Because delayed ovulation can result in altered pregnancy outcome and reduced litter size, it will be important to determine the precise CNS/pituitary mechanism involved in this effect. This abstract does not reflect USEPA policy.

1682 EFFECTS OF OCTAMETHYLCYCLOTETRASILOXANE (D4) AND PHENOBARBITAL (PB) ON LH SURGE AND OVULATION IN SPRAGUE-DAWLEY (SD) RATS.

A. Dalu, R. H. Gallavan, L. S. Meeker, A. L. Quinn, P. A. Jean, J. W. Crissman, R. G. Meeks and K. P. Plotzke. *Health and Environmental Sciences, Dow Corning Corporation, Midland, MI.*

This study was conducted to assess the potential mechanism of previously observed reproductive effects of D4 in SD rats. Cannulated SD rats were exposed to 0, 700, or 900 ppm D4 vapor for 3 days (6 hr/day) from diestrus day-1 through the day of proestrus. A different set of rats received saline or PB (40 mg/kg, i.p.) on the day of proestrus at 1:45 p.m. Blood for the analysis of LH was collected with autologous replacement on the day of proestrus at 2, 4, 6, 8, and 10 p.m. Trunk blood was collected on the day of estrus at 8 a.m. for the evaluation of plasma estradiol (E2) levels in D4- and PB-treated rats. Ova were counted in wet mounts of fresh oviducts. The ovaries were routinely fixed and processed for light microscopy. D4 exposure increased the percentage of rats with attenuated LH surge at 4, 6, and 8 p.m. in 900 ppm group, and at 6 p.m. in 700 ppm group relative to controls. Similarly, the LH surge in PB-treated rats was suppressed at all time points. In D4-treated rats, E2 levels on the day of estrus were higher both in 700 (22.2 ± 4 pg/mL) and 900 ppm (21.1 ± 1.8 pg/mL) groups relative to controls (7.8 ± 1.4 pg/mL, $p < 0.05$). Plasma E2 levels in PB group were also higher (12.1 ± 2.7 pg/mL *vs.* 6.8 ± 2.1 pg/mL in controls), but not statistically significant. D4 and PB both significantly decreased

the percentage of rats that ovulated. Among ovulators, they had little effect on the number of ova produced. Rats that failed to ovulate had numerous mature follicles and lacked basophilic (new) corpora lutea as evidenced by histopathology. Control and treated rats that failed to ovulate had similar hormonal and ovarian morphology profiles; conversely, control and treated rats that ovulated normally were also similar. These results indicate that D4 and PB have similar suppressive effects on LH and ovulation. Supported in part by Silicones Environmental, Health, and Safety Council of North America.

1683 THE EFFECT OF MELATONIN AGAINST RADIATION INDUCED DAMAGE IN ALBINO RATS.

H. M. Abdel Ghafar, W. Z. Atta, M. E. Ramadan, S. El-ghazaly and M. A. Abdel Kawi. *Pharmacology and Phyiology, New Jersey Medical School, Newark, NJ.* Sponsor: L. Sultatos.

Melatonin is a hormone produced by the pineal gland and has been shown to have radioprotective properties. The objective of this study was to determine the potential radioprotective effects of melatonin. Adult albino rats were treated with an oral dose of 250 mg/kg melatonin one hour before exposure to whole-body gamma radiation of a single dose 8 Gy (Lethal dose LD50/30). The animals were observed for mortality over a period of 30 days following irradiation. A second group was treated with an oral dose of 250 mg/kg melatonin one hour before exposure to whole-body gamma radiation of single dose 6 Gy (Sublethal dose). Two days post irradiation animals were sacrificed and the following were analyzed: histopathology, lipid peroxidation, bone marrow, blood cytology and biochemical studies. A third group was treated oral doses of 250 mg/kg melatonin one hour before exposure to whole-body gamma radiation of multiple doses of 1 Gy per week for 6 weeks (Fractionated doses). Two days post last irradiation animals were sacrificed and the same analysis performed. The data obtained in this study suggest that melatonin at a dose as high as 250 mg/kg is non-toxic, and that high doses of melatonin are effective in protection of rats from effects of lethal, sublethal and fractionated doses of whole-body irradiation.

1684 PLACENTAL RESPONSES TO BUTADIENE DIEPOXIDE TREATMENT IN PREGNANT RATS.

F. Spencer, E. Nixon and L. Chi. *Biology, Southern University, Baton Rouge, LA.*

Butadiene diepoxide(BDE)is a metabolite of 1, 3-butadiene that is reproductively toxic in rats and mice and is utilized in synthetic rubber production. In rats specifically, since BDE-induced reductions in ovarian weights and follicular growth may result in impaired uterine function *via* steroid regulation, the purpose of the study was to clarify biochemical and physiological responses to post-implantation BDE exposure (gestation days 5-8). Gestation in female Sprague-Dawley rats 220-250g, maintained under 12L:12D and 20+2oC, was initiated by cohabitation between a fertile male and proestrous female rats. Rats (n=6/group) were treated with 5 daily 0900-1000h intraperitoneal doses of BDE 0, 0.25, 0.30, 0.35 or 0.40 mmol/kg in sesame oil. The dosing volume was 2.5ml in sesame oil/kg body weight. Animals were sacrificed on gestation day 9 or 12 0900-1000h, the period of placentation and early fetal development, for retrieval of uterine tissues. Placentae were scraped away from the adjacent uteri. This procedure was followed by bioassay determinations placental PACAP mRNA expression by RT-PCR, placental MMP-9 activity by substrate zymography and serum progesterone levels by RIA; and by developmental evaluations of implantation sites, deaths/resorptions and corpora lutea. The results analyzed by Student's t test, showed that in pregnant BDE-treated rats, there were dose-linked reductions in placental PACAP mRNA $p<0.001$, placental MMP-9 activity ($p<0.001$) and in the number of dead or resorbed fetuses $p<0.001$. These reductions were similar when measured on either gestation day 9 or 12. Declines in implantation sites and corpora luteal levels were more consistent under gestation day 12 than at day 9. However, fetal mortality was drastically increased overall by 100% on gestation day 12 compared to a general increase of 55% on gestation day 9. The data suggest that the pervasive anti-placental biochemical and developmental actions of post-implantation BDE treatment in pregnant rats were apparently more critical as fetal development progressed from gestation day 9 to day 12. Supported by NIEHS/ARCH Research Grant ES 10018-02

1685 INDUCTION OF VITELLOGENIN IN RESPONSE TO GENISTEIN FROM A SOY BASED DIET IN CHANNEL CATFISH.

E. C. Meek and J. E. Chambers. *Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS.*

Genistein, 4', 5, 7-trihydroxyisoflavone, is a phytoestrogen contained in soy. Soy is a major component of many commercial catfish feeds. Genistein may induce the hepatic production of the egg yolk protein, vitellogenin, normally induced by endogenous estrogen. Channel catfish were fed a specialized diet containing casein as the protein source, and not containing soy, for 18 days to allow dissipation of genistein from the tissues. Channel catfish were injected ip once with .02mg/g 17 β-estradiol, as a positive control, and serum was collected. Vitellogenin was precipitated using N, N-dimethylformamide from serum of catfish treated with .02mg/g 17 β-estradiol. Total protein in the precipitate was determined using the BCA protein assay. Vitellogenin was identified using Western blot and quantified using ELISA with a vitellogenin specific monoclonal antibody. Catfish were gavaged once with 0.2mg/g, 1.0mg/g, or 2.0mg/g body wt. genistein. Serum and liver samples were taken for analysis. A dose-response curve for vitellogenin synthesis was generated from catfish gavaged with genistein. A second group was gavaged with 0.2mg/g or 2.0mg/g genistein to determine the dissipation of genistein in the liver and the effect of genistein on vitellogenin synthesis over time. A third group was placed on a soy-based diet. Levels of genistein in the liver were determined by HPLC. The fish that were gavaged with genistein or placed back on a soy diet showed an increase in genistein in the liver. Soy fed catfish had vitellogenin levels in their serum greater than casein fed catfish. The results suggest that the phytoestrogens present in commercial soy-based catfish food can bind the hepatic estrogen receptor and induce the synthesis of vitellogenin. 1686 COMPARISON OF DERMAL AND INHALATION EXPOSURES TO JP-8 JET FUEL.

P. J. Robinson and J. N. McDougal. *ManTech-GeoCenters Joint Venture, AFRL/HEST, Dayton, OH.*

JP-8 is a kerosene based fuel consisting of a complex mixture of hundreds of components from a number of hydrocarbon classes, including straight chain alkanes, branched chain alkanes, cycloalkanes, diaromatics and napthalenes. Occupational exposure to JP-8 occurs *via* both the inhalation (aerosol and vapor) and dermal routes. It is thus necessary to extend accepted standards (such as the OEL) for permissible levels of JP-8 and other similar materials in ambient air to the dermal exposure route. This can be done by comparing the absorbed doses *via* each exposure route. The dermally absorbed dose can be estimated from the exposed concentration c_{skin}, the exposure time, exposed surface area A and the dermal penetration coefficient K_p. This latter parameter can be estimated from the physico-chemical properties of the chemical (such as its molecular weight and octanol-water partition coefficient). For inhalation exposure, the absorbed dose depends on the concentration c_{air} in the ambient air, the alveolar ventilation rate Q_a, and the fraction f of the material inhaled that is actually absorbed. Assuming f is 100% often leads to a non-conservative and misleading under-assessment of the relative importance of the dermal route. A more realistic estimate of f can be made from the blood-air partition coefficient P_b (which can be measured or estimated from physico-chemical properties), together with its concentration c_b in the alveolar blood. This latter can be estimated, in turn, by means of a PBPK model. However, in most cases, development of such a model is expensive and time-consuming and so is not practical. Nonetheless, useful estimates of c_b can be made under specific limiting conditions of systemic elimination and metabolism. This leads to useful upper and lower limits on the ratio R of skin to lung absorption rates that depend on c_{air} and c_{skin}, as well as K_p, P_b, A, Q_a, and cardiac output Q_c. These limits can be used to assess the relative importance of the dermal and inhalation routes under specific exposure scenarios, as well as to compare dermal exposures with inhalation exposure standards.

1687 FETAL HORMONAL CONDITION IS AFFECTED BY PHYTOESTROGEN TRANSFERRED FROM MOTHER.

K. Sakurai[1], E. Todaka[1], H. Miyakawa[2], M. Uzuki[2], H. Osada[3], Y. Ikezuki[4], O. Tsutsumi[4,5] and C. Mori[6,5]. *[1]Department of Environmental Medical Science (SRL), Graduate School of Medicine, Chiba University, Chiba, Japan, [2]SRL Inc., Tokyo, Japan, [3]Department of Obstetrics and Gynecology, Chiba University Hospital, Chiba, Japan, [4]Department of Obstetrics & Gynecology, Faculty of Medicine University of Tokyo, Tokyo, Japan, [5]Core Research for Evolutional Science and Technology (CREST), Kawaguchi, Japan and [6]Department of Bioenvironmental Medicine, Graduate School of Medicine, Chiba University, Chiba, Japan.* Sponsor: B. Beck.

Phytoestrogens are estrogen-like chemicals. Phytoestrogens are suggested to contribute to prevention of chronic diseases. But one concern is that exposure to phytoestrogens may pose a developmental hazard to infants and fetuses. To study whether the exposure to phytoestrogens had any influences on human fetuses, we investigated feto-maternal relationship between the serum concentrations of phytoestrogens and relationship between phytoestrogens and hormonal condition of fetuses. Serum samples were obtained from 20 mothers and umbilical cord of their babies. Informed consent was required from each subject. This study was agreed on by the ethics committee of Chiba University School of Medicine. Serum phytoestrogen concentrations were determined by liquid-chromatography/tandem-mass

spectrometry. Data were expressed as mean (mean-SD to mean+SD) calculated with the log transferred concentrations, then converted to their original scale. In cord serum, mean genistein concentration was 63.1 (30.6-130.0) ng/ml, mean daidzein concentration was 6.8 (2.7-17.5) ng/ml. Equol was detected in only seven samples. We detected that the concentrations of genistein and daidzein were significantly higher in cord serum than in maternal serum. In cord serum, genistein concentration was negatively correlated to SHBG concentration. These data suggested that the phytoestrogen affected the hormonal condition of human fetuses and the response to the phytoestrogen of the fetuses was different from the adults.

1688 THE VALUE OF LACTIC ACIDOSIS IN THE ASSESSMENT OF THE SEVERITY OF ACUTE CYANIDE POISONING.

F. J. Baud, B. Mégarbane, S. W. Borron and C. Bismuth. *Intensive Care Unit, Lariboisière Hospital, Paris, France.*

Introduction: In pure cyanide poisonings, the correlation between plasma lactate concentrations and the corresponding blood cyanide concentrations has not been addressed. Thus, we tested the hypothesis that the repeated measurement of plasma lactate concentrations could have a confirmatory value in acute pure cyanide poisonings. Materials and Methods: We reviewed the charts of the 11 patients admitted to our toxicological intensive care unit between 1988 and 2000 who had exposures to cyanide. Victims of smoke inhalation were excluded from this study. Ten patients had pre-treatment blood sampling for cyanide and plasma lactate. Nine patients had repeated blood sampling. Treatment included supportive care and hydroxocobalamin + sodium thiosulfate. Blood cyanide and plasma lactate concentrations were measured by a colorimetric assay using microdiffusion and an enzymatic method (Nal: 9 to 18 mg/l), respectively. Results: Before antidotal treatment, the median plasma lactate concentration was 168 mg/dL, the median blood cyanide concentration was 4.2 mg/L. Using Spearman test, there was a significant correlation between plasma lactate and blood cyanide concentrations ($r = 0.74$, $p = 0.017$). Before antidotal treatment, plasma lactate concentration correlated positively with anion gap and inversely with systolic blood pressure, spontaneous respiratory rate, and arterial pH. Blood cyanide concentrations correlated inversely with systolic blood pressure and arterial pH and positively with anion gap and blood glucose concentration. During the course of cyanide poisonings, a plasma lactate concentration > 72 mg/d/L (8 mmol/L) was sensitive (94%) and moderately specific (70%) for a toxic blood cyanide concentration (> 1.0 mg/L). The specificity was substantially improved in patients not receiving catecholamines (85%). Conclusions: The immediate and serial measurement of plasma lactate concentrations is useful in assessing the severity of cyanide poisoning.

1689 CONSEQUENCES OF BRIEF EXPOSURE TO HIGH-CONCENTRATION CARBON MONOXIDE IN AWAKE RATS.

Z. Gu, A. J. Januszkiewicz and M. A. Mayorga. *Respiratory Research, Walter Reed Army Institute of Research, Silver Spring, MD.* Sponsor: N. Elsayed.

Exposure to high concentration carbon monoxide (CO) is of concern in military operations. Experimentally, the harmful consequences of a brief exposure to high concentration CO have been poorly described. This study investigated the development of acute CO poisoning in awake male Sprague-Dawley rats (220-380g). Animals were randomly grouped and exposed to either 1000, 3000, 6000, 10000, 12000 or 24000 ppm CO in a continuous air/gas dynamic exposure chamber for five minutes. Respiration was recorded prior to and during exposures. Mixed blood carboxyhemoglobin (COHb) and pH were measured before and after exposure. Compared to the pre-exposure control, at the end of exposure in the 10000, 12000, and 24000 ppm groups, breath rate was significantly decreased by 64%, 47%, and 18%, respectively. Tidal volume was significantly increased by 121, 137, and 142%, and minute ventilation volume was significantly decreased by 77, 64, and 26%, respectively. Blood COHb was elevated to 60.1, 63.4, and 69.3%, and blood pH was reduced to 7.43± 0.09, 7.25± 0.05, and 7.13± 0.04, respectively. The mortality was 1/12 in the 12000 ppm group and 4/12 in the 24000 ppm group. Deaths occurred in the fifth minute of exposure. Breath rate was < 27% of the control, pH < 6.87, and COHb > 80% in animals that died during exposure. There were no significant changes in respiratory parameters and pH, and no deaths, in rats exposed to CO at concentrations under 6000 ppm, although COHb was elevated to 14.5, 29.7, and 54.3% in the 1000, 3000, 6000 ppm groups, respectively. These results suggested that brief exposure to CO at concentrations under 10000 ppm may cause minor to moderate health risk. However, exposure to CO at concentrations greater than 10000 ppm for a period of time as short as five minutes will change breathing patterns which may result in acute respiratory failure, acidemia, and even death.

1690 AN OUTBREAK OF HEPATITIS AS A RESULT OF OCCUPATIONAL EXPOSURE TO SOLVENTS IN A HAZARDOUS WASTE FUEL BLENDING FACILITY.

R. C. Chen[1], P. H. Jenkins[2], C. A. Riely[2], T. C. Payne[2], K. C. Johnson[2], J. E. Bailey[2], G. L. Hensley[3], C. L. Powers[4], M. A. Thomas[5], J. W. Morrison[4], L. F. Stafford[5], N. C. La Chapelle[5] and A. S. Craig[1]. [1]*Tennessee Department of Health, Nashville, TN,* [2]*UT-Memphis, Memphis, TN,* [3]*Tennessee Department of Labor and Workforce Development, Nashville, TN,* [4]*Tennessee Department of Environment and Conservation, Nashville, TN and* [5]*Memphis-Shelby County Health Department, Memphis, TN.*

This is a multi-disciplinary investigation of an outbreak of hepatitis. The methods include environmental and occupational health investigations, epidemiological survey, clinical examination, liver function tests, liver biopsy, serological tests for hepatitis A, B, and C, and serum infrared and/or mass spectrometry. Of the 91 workers tested, 44% exhibited symptoms of hepatitis consistent with exposure to chlorinated solvents. These symptoms include nausea, vomiting, abdominal pain, diarrhea, headache, dizziness, fever, and weight loss. Alanine aminotransferase (ALT) levels higher than 1.5 times normal were regarded as case. Among the cases 15% tested positive for hepatitis B or C. A total of 92% of the cases worked in the tower where the fire and clean up occurred. All maintenance workers participating in repair and clean-up had elevated ALT. The liver biopsy of the worker with the highest ALT (8, 000 IU) indicated diffuse hepatitis with acidophilic bodies and microvesicular fat on oil red O stain. Among the workers not normally working in the tower, only 10% were cases. After comparing the medical history, test results, primary work locations, job descriptions, onset of symptoms, usage of PPE among the workers, and other health and safety measures, it is concluded that the outbreak of hepatitis probably resulted from exposure to solvents during the post-fire cleanup. The identification of chloro/fluorocarbons by serum infrared spectroscopy in one case, and the presence of fluorinated compounds in the fire retardant surfactant suggests that chloro/fluorocarbons may have been liberated leading to inhalation exposure as a result of heat from the fire.

1691 COMPARATIVE OCCUPATIONAL EXPOSURES TO FORMALDEHYDE RELEASED FROM INHALED WOOD DUSTS *VERSUS* THAT IN GASEOUS FORM.

N. H. Gosselin[1], R. C. Brunet[2] and G. Carrier[1]. [1]*Santé environnementale et santé au travail, Université de Montréal, Montréal, PQ, Canada and* [2]*Mathématiques et Statistique, Université de Montréal, Montréal, PQ, Canada.*

Particle boards and other wood boards are usually made with formaldehyde-based resins. Wood workers are thus exposed to formaldehyde in gaseous form as well as from airborne dust once it enters their respiratory tract. These workers remain exposed to formaldehyde released from the dust still present in their upper respiratory tract, even after their work shift. In assessing the risk associated with formaldehyde exposure, one needs to consider the relative importance of these two sources of exposure. This study proposes a kinetic model to estimate the exposure to formaldehyde released from dust and compares it to exposure from the gaseous form. Model parameters are determined using data from published studies which estimate amounts of dust deposited in different regions of the respiratory tract, their residence time according to particle sizes and the rate of formaldehyde released from wood product dust once in the tract. The model predicts the amount of formaldehyde absorbed by the respiratory tract upon its release from wood product dust for various exposure scenarios. Based on a daily work shift of 8 hr, it is found that, for a dust concentration in air of 5 mg/m^3 and a formaldehyde concentration of 9 µg/mg of dust, the amount of absorbed formaldehyde released from wood dust is approximately 1/100 of the amount absorbed from the gaseous form at a concentration level of 0.38 mg/m^3 (0.3 ppm). Considering that the formaldehyde concentration in wood dust used above is much higher than usually observed and that dust and gaseous form formaldehyde concentrations used are of the order of the recommended threshold limit values, the simulations show that the formaldehyde exposure from wood dust is comparatively negligible.

1692 ASSESSMENT OF TOLUENE AND ETHYL ACETATE EXPOSURE FROM WEARING A COSTUME MASK BONDED WITH CONTACT CEMENT.

M. J. Fedoruk[1] and B. D. Kerger[2]. [1]*Center for Occupational & Environmental Health, University of California, Irvine, Irvine, CA and* [2]*Health Science Resource Integration, Inc., Tallahassee, FL.*

A series of experiments was performed to assess the solvent evaporation rates and relevant exposure concentrations for primary solvents (toluene and ethyl acetate) emitted from a contact cement used to bond foam surfaces within a costume mask (a furry bear head)that is worn by theatrical dancers. Four coats of the contact cement were applied to each of four 3 by 3 inch areas on both foam components of

the mask (the fitted helmet and the mask structural foam); each coat was allowed to dry for 10 minutes before bonding (joining the cement-coated foam surfaces). Solvent concentrations were measured within the mask under undisturbed (static) conditions at 2, 4, 8, 16, and 20 hours after bonding. Each sample was collected as a one-minute grab sample using 1 liter Summa canisters, and analyzed by EPA Method TO-14. An exponential loss pattern was observed for both toluene and ethyl acetate concentrations inside the mask. Ethyl acetate levels diminished quickly and were nondetectable (< 1 ppm) at 8 hours, while toluene levels diminished quickly but were stable at 11 to 14 ppm when measured at 8, 16 and 20 hours after bonding. Personal toluene exposure was simulated at 21 hours after bonding by fitting the mask on an adult-size mannequin equipped with a breathing zone sampling port in a convection chamber at 37 C. Toluene exposure concentrations in the breathing zone ranged from 1.7 to 2.9 ppm when measured at 0, 5, 10, 15 and 20 minutes after donning the mask, and a level of 7 ppm was observed at 30 minutes. These studies illustrate that the majority of solvents in contact cement were evaporated from the costume mask under static conditions within 4 to 8 hours after bonding, that residual toluene levels after that time are relatively low, and that donning the mask displaces most of the residual toluene. Toluene exposures at 1 to 7 ppm are well below occupational exposure limits and adverse effect levels in humans.

1693 AMMONIA EXPOSURE AND DOSE-RESPONSE ASSESSMENT FOR HOUSEHOLD CLEANING USES.

B. D. Kerger[1] and M. J. Fedoruk[2]. [1]*Health Science Resource Integration, Inc., Tallahassee, FL and* [2]*Center for Occupational & Environmental Health, University of California - Irvine, Irvine, CA.*

There is scant information pertaining to airborne ammonia exposures from common household use of ammonia-containing floor/tile cleaners and spray-on glass cleaners. We assessed instantaneous and event-specific time-weighted average (TWA) exposures to airborne ammonia during mixing and use (cleaning with a soaked sponge) of a typical household floor/tile cleaner containing 5% ammonium hydroxide. One cup of the ammonia cleaner was mixed with two gallons of hot water to make the washing solution, as per the label directions. Airborne ammonia sampling was conducted while the tile walls and floors within three different size bathrooms in a residence were washed. We also assessed exposures during use of a spray-on glass cleaner containing 1 to 3% ammonium hydroxide, while washing several large windows in a small office setting. In each case, TWA ammonia was assessed using a breathing zone personal sampling pump equipped with a silica gel tube and analyzed by NIOSH Method 6015. Simultaneous measurements were recorded each minute with a breathing zone probe from a Draeger PAC III monitor with electrochemical cell detector. Peak ammonia levels ranged from 16 to 28 ppm and short-term TWA concentrations ranged from 9.4 to 13 ppm during mixing and cleaning in each the three bathrooms. Ammonia exposures while using spray-on window cleaners were below reliable detection limits (monitor < 3 ppm; TWA < 1.3 ppm). Brief, moderate exposure levels for airborne ammonia can occur during standard bathroom cleaning uses, i.e., averaging 11 ppm. Peak ammonia concentrations were above the 8-hour TWA occupational exposure limit (OEL) of 25 ppm. Use of the concentrate or less dilute cleaning solutions could result in ammonia exposures exceeding the OEL ceiling limit of 50 ppm, and could cause moderate eye, nose and throat irritation and respiratory symptoms in sensitive individuals. Thus, ammonia-containing cleaner products should contain clear warnings to avoid use of undiluted concentrates.

1694 EXPOSURE OF CHILDREN AND ADULTS TO TRANSFERABLE RESIDUES OF CHLORPYRIFOS FROM DOGS TREATED WITH FLEA CONTROL COLLARS.

J. S. Boone, J. Tyler and J. E. Chambers. *Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS.*

Twenty-four households were chosen that included a pet dog and a child between the ages of 3 and 12 years. These family units were used to determine the levels of insecticide that could be transferred by a flea control collar from a pet dog and any increased amounts of chlorpyrifos metabolites in the urine of one child and one adult in the household. Commercially available flea control collars containing the organophosphate insecticide chlorpyrifos (8%, 2.54g) were applied to dogs as per package directions. Transferable residues were quantified by petting the dog in 3 areas (back, neck, neck with collar) with cotton gloves for 5 min and analyzed by GC/ECD. The averaged transferable residues of the insecticide chlorpyrifos were highest from rubbing directly over the collar (168-454 µg), less from the fur of the neck under the collar (49-252 µg), and lowest from the fur of the back distant from the collar (3-14 µg). The urinary metabolite 3, 5, 6-trichloro-2-pyridinol (TCP) was quantified in first morning void samples using a magnetic particle/antibody assay. The urine of both adults and children obtained before the collar was placed on the dog showed measurable levels of TCP, presumably because of the numerous approved agricultural and residential uses of chlorpyrifos. Ranges of urinary TCP levels in the adults and children prior to placement of the flea collar on the pet dog were 1.1-35.0 and 1.9-22.4 ng/ml, respectively. There were no statistically significant increases in urinary TCP in either the adults or the children of the study at any time point up to 4 months after the application of the collar. The range of levels in the adults and children after application of the flea collar to the dogs were 1.4-52.0 ng/ml and 1.2-52.4 ng/ml, respectively. These results suggest that the insecticide residues obtained from the routine use of a flea collar did not contribute significantly higher levels of exposure to the people in contact with pet dogs. (Supported by EPA R 825170).

1695 MEASURING AND ASSESSING THE RISK OF CHEMICAL EMISSIONS FROM CONSUMER PRODUCTS; SUMMARY STUDY OF OFFICE PRINTERS.

D. R. Cortes, M. S. Black and A. G. Worthan. *Air Quality Sciences, Marietta, GA.* Sponsor: K. Willett.

Good product stewardship as well as regulatory and non-regulatory programs necessitates knowledge of high and low-level chemical emissions from consumer products, and understanding their risks to users. This requires a complete IAQ exposure effects assessment that includes multiple components. This study summarizes the results of the assessment of over 100 office printers. Testing was conducted under environmentally controlled chamber conditions with parameters appropriate for the intended use of the product. A sensitive sampling and analysis method with a specialized chromatographic and mass spectral indoor air library was used to properly identify all emissions. Because accurate emission rates are needed to predict consumer exposures for comparison to specifications set by government and private organizations, product-specific emission profiles were fit to appropriate mathematical models. The predicted user exposure concentrations were then compared to multiple databases containing information on inhalation health risks and irritation/odor potentials of all of the chemicals identified in the product emissions. The most common emissions from laser printers were styrene, xylene, and ethylbenzene, while the most common emissions from plotters were acetic acid, benzyl alcohol, and nonanal. These types of compounds are fairly typical in the indoor environment, and the exposure levels contributed by these emissions are low relative to normal indoor levels. However, the compound list is different when examined in terms of highest average emissions. For laser printers they are butyldigol (emission rate = 11, 305 µg/hr), cyclohexane (6, 055 µg/hr), and 2, 2, 4, 4-tetramethylpentane (3, 500 µg/hr), while for plotters they are 2-propanol (19, 500 µg/hr), ethanol (8, 000 µg/hr), and 1, 3-dichloro-2-propanol (3, 800 µg/hr). Exposure concentrations of these and hundreds other chemical emissions were calculated based on a typical use scenario, and then compared to multiple databases to determine health risk, discomfort levels, sensory irritation, and odor perception.

1696 ESTIMATION OF DIETARY INTAKE OF INORGANIC ARSENIC IN CHILDREN.

L. J. Yost[1], R. S. Schoof[2] and M. R. Garry[1]. [1]*Exponent, Bellevue, WA,* [2]*Gradient Corporation, Bellevue, WA and* [3]*Exponent, Bellevue, WA.*

Arsenic is a natural component of our environment, and is ubiquitous in soils and in the diet. Accurate dietary intake estimates for inorganic arsenic are needed to establish background levels of exposure for children. Previous investigations have estimated dietary intake in adults in the USA ranging from 1 to 20 µg/day with an average of 3.2 µg/day, based on a comprehensive market basket survey in which 40 commodities anticipated to provide at least 90 percent of dietary inorganic arsenic intake were analyzed for inorganic arsenic content (Schoof et al. 1999a, b). Four samples of each commodity were collected. Total arsenic was analyzed using an NaOH digestion and inductively coupled plasma-mass spectrometry. Separate aliquots were analyzed for arsenic species using an HCl digestion and hydride atomic absorption spectroscopy (Schoof et al. 1999a). In addition, intake in the USA was previously estimated using a more limited number of foods analyzed for inorganic arsenic (Yost et al. 1998), to derive average estimates of 9.4 µg/day in children and 12.7 µg/day for adults. This paper estimates average dietary intake in children using the more robust dataset for inorganic arsenic and the total arsenic dietary intake estimates compiled by FDA. Dietary intake in young children is highly influenced by intake from dairy products, due to the fraction of the diet comprised by dairy products, which contain a relatively high proportion of inorganic arsenic (49%) (Yost et al. 1999, Schoof et al. 1999a). Application of total arsenic intake data from FDA for the years 1982 to 1991, with recent inorganic arsenic percentages resulted in an estimate of average dietary inorganic arsenic intake for children (ages six months to two years) of 6.7 µg/day. Because inorganic arsenic in the diet is naturally occurring and exposure unavoidable, this intake estimate provides a useful context in risk management of arsenic exposure.

1697 RISK CHARACTERIZATION USING DIFFERENT ASSUMPTIONS REGARDING SPECIATED ARSENIC IN FISH AND SHELLFISH.

R. Lorenzana[1], D. Davoli[1], A. Johnson[2] and H. Choudhury[3]. [1]*Region 10, USEPA, Seattle, WA,* [2]*Environmental Assessment, Washington Department of Ecology, Olympia, WA and* [3]*ORD-NCEA, USEPA, Cincinnati, WA.*

When only total arsenic tissue concentrations are available, assumptions are required regarding concentrations of speciated arsenic in fish and shellfish. Using consumption data from the Pacific Northwest, this work demonstrates the effect of different assumptions using tissue data for total arsenic in fish and shellfish recently collected for freshwater and saltwater species in the same area. The results of a worldwide literature search provide the basis for initial assumptions. Additionally, assumptions based on a small amount of speciated arsenic data from the Pacific Northwest are included. Total arsenic concentrations are higher in saltwater fish then in freshwater fish. However, the percentage of inorganic arsenic (As_{inorg}) is higher in freshwater fish than in saltwater fish. Based on sparse information, it appears that lower trophic-level fish tend to have higher percentage As_{inorg}. Total arsenic concentrations tend to be higher in shellfish than in finfish, with a great deal of species variability. The percentage of As_{inorg} in shellfish is higher than in finfish, as is the percentage of another toxic arsenical species, dimethylarsinic acid. Uptake of arsenic in an arsenic-contaminated system appears to be a complex process, and no generalizable trends were observed in the data. In an evaluation that assesses risks from multiple contaminants in the same animal species, the impact of the percent As_{inorg} depends on the overall contaminant concentration present in the species. The importance of the amount of As_{inorg} in animal tissues increases as overall contaminant concentrations decrease. While having speciated arsenical data is preferable in all situations, it is most critical when total contaminant concentrations are suspected to be low. Use of speciated arsenic data facilitates risk management decisions by avoiding risk characterizations in which As_{inorg}, based on assumptions rather than measurements, predominates the risk.

1698 ESTIMATION OF INORGANIC ARSENIC INTAKE FROM FISH: MARKET BASKET *VS.* RECREATIONAL CATCHES.

R. A. Schoof[1] and L. J. Yost[2]. [1]*Gradient Corporation, Mercer Island, WA and* [2]*Exponent, Bellevue, WA.*

Seafood contributes the greatest fraction of total As to the diet; however, the majority of the As in fish is composed of complex organic arsenicals. The contribution of fish to dietary intake of the more toxic inorganic As (As_i) is pertinent both for assessing background As exposures and for assessing the contribution of As in recreationally caught fish to As exposures from surface water. Due to the expense and difficulty of analyzing As_i concentrations in fish, most available fish data are for total As (As_{tot}) only. Dietary intake estimates for Asin fish are frequently made by assuming that a certain fraction of the As_{tot} reported in the fish is As_i. For example, NRC (1999) assumed that 10 % of seafood As is inorganic. Limited data has been available to support such assumptions, but several recent studies suggest that the NRC (1999) assumption may be too high. Schoof, *et al.* (1999) report data for saltwater finfish, canned tuna, shrimp and freshwater fish purchased at markets. From these data the fraction of As_i *vs.* As_{tot} may be estimated. Whereas 2-8 % of freshwater fish As is inorganic, <0.1 to 0.6 % of the marine food As is inorganic. The As_i in all of these samples was very low, so the variation in fractional inorganic content is almost solely due to variations in the amount of As_{tot} reported. Buchet. et al. (1994) reported somewhat higher As_i content in marine fish, ranging from 0.4 to 3 %. Since most seafood intake in typical diets is from marine sources, these and other recent studies suggest that the NRC assumption is an overestimate, and that As_i is closer to 1 % of As_{tot} in seafood. New data also allow estimates of fractional As_i in wild freshwater fish. EVS (2000) report As_{tot} and As_i for fish caught in the Willamette River in Oregon. No As was detected in pike minnow, while the fraction of As_{tot} that was As_i averaged 5 %, 4% and 13 % in bass, carp and sucker, respectively. The implications of these findings for risk assessment of As in fish in surface water and the derivation of ambient water quality criteria for As will be explored.

1699 DOSE RECONSTRUCTION OF BENZENE EXPOSURE FOR PLIOFILM COHORT (1936-1976) USING MONTE CARLO TECHNIQUES.

P. Williams and D. Paustenbach. *Exponent, Menlo Park, CA.*

Regulatory standards or guidelines for occupational exposure to benzene are based predominantly on studies of workers. The cohort of rubber hydrochloride (Pliofilm) workers, in particular, serves as the primary basis for the OSHA Permissible Exposure Limit (PEL) and ACGIH Threshold Limit Value (TLV). Previous assessments of this cohort by Rinsky (1981), Crump and Allen (1984), and Paustenbach et al. (1992) have relied on varying assumptions about workplace practices and processes over time, as well as different exposure data and assumptions, thereby yielding significantly different estimates of benzene dose for certain job categories. Given the inherent limitations and uncertainties involved in estimating historic exposures for this cohort, a "distributional" rather than a "point estimate" approach should be more informative for this cohort. In this paper, we re-evaluate the Pliofilm data using Monte Carlo techniques and discuss the impacts of various exposure parameters on estimated doses. A key objective of this work is to address criticisms that previous exposure parameter values were either too high or too low. Estimated benzene doses are reported as equivalent 8-hour time-weighted averages for more than ten job categories from 1936 to 1965 (Akron I and II facilities) and 1940 to 1976 (St. Mary's facility). The key sources of uncertainty addressed in the analysis include characterization of benzene air concentrations (background and peak), uptake of benzene from dermal exposures, engineering controls over time, extended work hours and plant shut down in early years, accuracy of monitoring devices, and effectiveness of personal protective equipment. Sensitivity analyses are used to illustrate areas of uncertainty that have the greatest impact on estimated benzene dose. The results of this analysis provide a more thorough and defensible characterization of benzene exposures among the Pliofilm cohort than those previously reported. These results may also be used, in conjunction with the available mortality data, to provide a more refined assessment of benzene's chronic toxicity in humans.

1700 RATE OF HEXAVALENT CHROMIUM REDUCTION BY HUMAN GASTRIC FLUID.

D. M. Proctor[1], S. M. Hays[2], M. V. Ruby[2], S. Liu[2], A. Sjong[2], M. Goodman[3] and D. J. Paustenbach[3]. [1]*Exponent, Irvine, CA,* [2]*Exponent, Boulder, CO and* [3]*Exponent, Menlo Park, CA.*

Hexavalent chromium [Cr(VI)] is reduced to the essentially non-toxic trivalent state [Cr(III)] in the human stomach. This study investigates the rate of Cr(VI) reduction under a variety of simulated gastric conditions, and in real human gastric juice collected from fasting volunteers. The rate of Cr(VI) reduction in simulated gastric fluid was measured at pH values from 1.5 to 4.5, at starting Cr(VI) concentrations ranging from 100 to 400 ppb, in diluted stomach fluid (10-fold), following ingestion of Rolaids®, and in the presence of food. Stomach conditions were simulated by preparing an aqueous mixture of the primary components of gastric fluid (pepsin, mucine, gastric lipase, gastric amylase, etc.), acidifying with HCl, and providing continuous stirring and heating to approximately 37°C. All experiments were conducted for 60 minutes, with Cr(VI) measured using a Hach AccuVac ChromaVer3 instant test kit. The findings of these studies are: 1) real human stomach fluid has a 10-fold greater capacity to reduce Cr(VI) than simulated stomach fluid; 2) within the first 2 to 5 minutes, 0.3 to 1 mg Cr(VI)/L is reduced in real stomach fluid collected under fasting conditions; 3) increasing gastric pH from 1.5 to 4.5 reduces the rate and extent of Cr(VI) reduction by at least one-third; 4) the amount and rate of Cr(VI) reduced is constant regardless of the starting Cr(VI) concentration, which suggests that these results may be extrapolated to lower concentrations of Cr(VI) in drinking water; 5) antacids dramatically increase the pH of the stomach (from pH 1.5 to 8.2) but appear to have little effect on the Cr(VI) reduction rate or capacity as compared to reduction at pH 4.5; and 6) the presence of food substantially increases Cr(VI) reduction in simulated stomach fluid, with 10 mg/L reduced within the first 4 minutes. These results suggest that ingested Cr(VI), at the federal MCL of 100 ppb, would exist in the stomach, even under fasting conditions, for less than 1 minute before being reduced entirely to Cr(III).

1701 EXACERBATION OF UROPORPHYRIA DEVELOPMENT IN MICE HOMOZYGOUS FOR GENETIC DISRUPTION AT THE HEMOCHROMATOSIS (HFE) GENE.

M. R. Franklin[1], J. D. Phillips[2] and J. P. Kushner[2]. [1]*Department of Pharmacology and Toxicology, University of Utah, Salt Lake City, UT and* [2]*Division of Hematology, Department of Medicine, University of Utah, Salt Lake City, UT.*

Two recently developed strains of genetically modified mice have made it possible to study the contribution of mutations at the hemochromatosis (Hfe) and uroporphyrinogen decarboxylase (URO-D) genes to porphyric susceptibility. Homozygosity for the null mutation of the URO-D gene (URO-D-/-) was lethal. Homozygosity for the null mutation of the Hfe gene caused high levels of iron to accumulate in the liver; heterozygosity was without effect. Neither URO-D nor Hfe gene disruption alone was sufficient to cause the development of uroporphyria. We have investigated polyhalogenated aromatic hydrocarbon-induced uroporphyria in male and female mice bearing either or both these genetic variables. In mice heterozygous for a null mutation at the URO-D gene, mild uroporphyria develops 21 days after a single dose of Aroclor 1254, a polychlorinated biphenyl mixture. The presence of high hepatic iron-load from a disruption of the hemochromatosis gene in addition exacerbates the porphyric response. The hepatic porphyrin

levels were higher in female mice. Mice genetically normal at the uroporphyrinogen decarboxylase gene locus do not develop uroporphyria with Aroclor 1254 administration and high iron concentrations in the liver due to disruption of the hemochromatosis gene were without effect. Elevated hepatic porphyrin concentrations, were always accompanied by depressed uroporphyrinogen decarboxylase activity determined in subsequently isolated cytosol, and upon heat denaturation of that cytosol, the presence of a factor that inhibits recombinant human uroporphyrinogen decarboxylase enzyme. Overall, hepatic siderosis from Hfe gene disruption in mouse models of porphyria cutanea tarda was insufficient to cause uroporphyria, but exacerbated its development in mice made susceptible through genetic depression of constitutive URO-D activity.

1702 DISRUPTION BY ORTHO-SUBSTITUTED POLYCHLORINATED BIPHENYLS OF SPONTANEOUS CATECHOLAMINE RELEASE FROM BOVINE CHROMAFFIN CELLS.

H. J. Wiegand. *Med. Inst. Env. Hyg., Heinrich-Heine-University, Duesseldorf, Germany.*

Ortho-substituted non-coplanar polychlorinated biphenyl congeners have been shown to perturbate neurohormonal release mechanisms in a variety of different cells. In dissociated cultures of chromaffin cells from the bovine adrenal medulla 2, 2', 4, 4'-tetrachlorobiphenyl (PCB47) has been shown to enhance the amount of catecholamines spontaneously released from chromaffin cell cultures as measured by high precision liquid chromatography (HPLC) of the culture supernatants. To further elucidate the mechanisms by which ortho-substituted polychlorinated biphenyls could have increased spontaneous release of catecholamines from chromaffin cells single cell carbon fibre microelectrode amperometry was performed in chromaffin cell cultures. These were exposed to PCB47 solubilized in cell culture medium using 0.1% DMSO for 5 h whereas culture medium with 0.1% DMSO added served as control. Carbon fibre microelectrodes amperometry was used to measure the currents due to oxidation of spontaneously released catecholamine quanta. 5 h exposure of chromaffin cells to PCB47 increased the half width, decay time, and frequency of catecholamine current spikes released spontaneously. Latrunculin B, a marine sponge toxin known to depolarize actin filaments and applied in a concentration of 5 µm had a similar action on catecholamine release. However after pretreatment of chromaffin cells using PCB47 Latrunculin B was uneffective to increase the amount of catecholamine release from chromaffin cells as measured by HPLC of the culture medium. The same was true if Cytochalasin D, another well known depolymerizer of actin filaments, was used. From these experiments it is suggested that PCB47 as well as Latrunculin B and Cytochalasin D may interact at a common target side to disrupt the spontaneous release of catecholamines from chromaffin cells. This target side seems to be the actin filament network which exists in the submembraneous area of chromaffin cells regulating the access of chromaffin granula to their membraneous release sites. (Supported by DFG, Germany)

1703 GLUCURONIDATION OF HYDROXYLATED POLYCHLORINATED BIPHENYLS.

N. M. Tampal, H. J. Lehmler, P. E. Espandiari and L. W. Robertson. *Toxicology, University of Kentucky, Lexington, KY.*

Polychlorinated biphenyls (PCBs) are metabolized to hydroxylated compounds. While many of these metabolites are further converted to either the glucuronic acid or sulfate conjugates by phase II enzymes, which facilitates their excretion, some hydroxylated PCBs persist in the body, reflecting their inability to be conjugated. A possible role of uridine diphosphate glucuronosyl transferase (UDPGT) in the elimination of hydroxylated metabolites of PCBs was investigated. Glucuronidation studies of some PCB metabolites, including ones which are eliminated with relative ease and also ones which are reported to be retained in blood, were carried out. Liver microsomes, prepared from male Wistar rats treated by intraperitoneal injections of phenobarbital for 3 days (400 µmol/kg/day), were used as the source of UDPGT. Enzyme kinetics (V_{max} and K_m) were determined for each of the metabolites. The enzyme efficiency towards glucuronidation (K_{cat}/K_m)was found to be dependent on the structure of the metabolites. Substitution of chlorine atoms on the non-hydroxylated ring greatly lowered the V_{max} of the enzyme, with substitution in the meta- and para- positions being least favorable for enzyme activity. Steric hindrance around the hydroxyl group by chlorines on adjacent carbon atoms did not play a major role. Also, no apparent correlation between the calculated dihedral angle (planarity) and enzyme activity was determined ($r^2 < 0.5$) however, a weak correlation for the surface area of the molecule and partition coefficient was observed ($r^2 \geq 0.5$). (Supported by P42 ES 07380).

1704 ENZYMATIC OXIDATION OF PCB METABOLITES INCREASES INTRACELLULAR OXIDATIVE STRESS.

A. Srinivasan, P. Espandiari, L. W. Robertson and G. Ludewig. *Graduate Center for Toxicology, Univ. of Kentucky, Lexington, KY.*

Polychlorinated biphenyls (PCBs) are highly persistent environmental contaminants. In rodents PCBs are complete carcinogens. Questions remain concerning the mechanism(s) of PCB carcinogenesis. PCBs are metabolized to mono- and dihydroxylated compounds. *in vitro* the dihydroxylated compounds are further metabolized either slowly by autooxidation or rapidly in the presence of enzymes like peroxidases or prostaglandin synthase to quinones, accompanied by the generation of reactive oxygen species (ROS). In this study, we wanted to evaluate the effect of enzymatic oxidation of PCB metabolites in cells in culture in terms of ROS production. Three human cell lines with different metabolic activities were chosen for this analysis: the leukemia cell line HL-60 (high in myeloperoxidase), the breast cancer cell line MCF-7 (high in prostaglandin synthases) and the lymphoma cell line Jurkat (low levels of either enzyme). We used the hydroquinone and para-quinone of 4-chlorobiphenyl (4ClPh-HQ and 4ClPh-pQ, respectively) as test compounds. Intracellular ROS production was determined using dichlorofluorescein-diacetate (DCFH-DA) that is converted by cellular esterases to DCFH and further in the presence of ROS to the fluorescent DCF, which can be detected by fluorometry, flow cytometry or confocal microscopy. Propidium iodide was used to measure viability. 4ClPh-pQ caused a dose-dependent increase in fluorescence in all three cell lines at sub-lethal concentrations. With 4ClPh-HQ, however, treatment of MCF-7 and HL-60 cells produced an increase in intracellular fluorescence while it had no effect on Jurkat cells. Cells were mostly viable in all treatments with the exception of HL-60 cells in the presence of ≧10 mM 4ClPh-pQ. These results show that PCB quinones can produce intracellular oxidative stress in any cell type. On the other hand, the conversion of PCB-hydroquinone to quinone and hence ROS production occurs at a higher rate only in cell types with high amounts of peroxidases or prostaglandin synthase (Supported by ES 07380).

1705 EFFECT OF PCB 77 ON TOTAL SELENIUM AND SELENIUM-DEPENDENT GLUTATHIONE PEROXIDASE IN RAT LIVER TISSUES.

D. N. Stemm, T. P. Twaroski, P. Espandiari and L. W. Robertson. *Graduate Center for Toxicology, University of Kentucky, Lexington, KY.*

Selenium (Se) provides defense against oxidative damage and is a critical component of several proteins including glutathione peroxidase (SeGPx), a cellular antioxidant enzyme. Persistent inducers of cytochrome P450, such as the polychlorinated biphenyls (PCBs), may generate reactive oxygen species and are associated with oxidative stress. Among the PCB congeners, PCB 77 (3, 3', 4, 4'- tetrachlorobiphenyl) is an aryl hydrocarbon receptor (AhR) agonist, and an efficacious inducer of cytochome P450. The effect of PCB 77 on hepatic total Se and SeGPx activity in male and female rats was investigated. We administered PCB 77 dissolved in corn oil (300µg/kg i.p. bolus dose) to male and female Sprague-Dawley rats fed with unrefined rat chow. The animals were sacrificed at different time points after dosing: 6 hours, 12 hours and 1, 4, 7, 14 and 21 days. Cytochrome P450 1A1 was induced in all treated animals. Hepatic total Se levels was decreased in the 4 to 21 days treatment groups of female rats. In contrast, there is no marked reduction in the treated male rats. Hepatic, cytosolic Se-GPx activity was also diminished in the 4 to 21 days time points for both male and female with the 3 week time point reduced by 6 times. However, the female SeGPx activity was markedly higher than the male in all time points except for the 12 hour time point. A study of GPx activity in vehicle (corn oil-treated) rats found that GPx activity in the liver were higher in female than male rats. This indicates that female rats may be more sensitive to PCB 77 effects on Se. Gender also appears to influence PCB 77's associated effects on the SeGPx enzymatic activity. (Supported by ES 07380)

1706 DNA ADDUCT FORMATION BY POLYCHLORINATED BIPHENYLS: CROSS-SPECIES COMPARISON OF MICROSOMAL BIOACTIVATION SYSTEMS AND ADDUCTION BY SYNTHETIC QUINOID METABOLITES.

D. Pereg[1,3], L. W. Robertson[1] and R. C. Gupta[1,2]. [1]*Graduate Center for Toxicology, University of Kentucky, Lexington, KY,* [2]*Preventive Medicine and Environmental Health, University of Kentucky, Lexington, KY and* [3]*Health and Environment Unit, Laval University Medical Research Center, Ste-Foy, PQ, Canada.*

PCBs are ubiquitous environmental contaminants. They are complete carcinogens in rodents and DNA adduction by PCBs was reported. The current study was designed to compare DNA adducts formed after bioactivation of PCBs with rat, mouse and human hepatic microsomes, and to investigate the role of quinoid PCB metabolites in DNA adduction. Eight congeners ranging from mono- to hexachlo-

rinated biphenyls were tested. Metabolites obtained through microsomal bioactivation as well as synthetic quinoid metabolites of 4-chlorobiphenyl were incubated with calf-thymus DNA. The resulting adducts were analyzed by ^{32}P-postlabelling. Adducts were formed only with mono- di- and trichlorinated congeners. Similar adduct patterns were observed with 2-chlorobiphenyl activated with microsomes from all species, while 4-chlorobiphenyl, 3, 4-dichlorobiphenyl and 3, 4, 5-trichlorobiphenyl showed similar adduct patterns in two out of the three systems. 4, 4'-dichlorobiphenyl showed different adduct patterns in all systems. High levels of DNA adduct were formed by the most oxidized quinoid metabolite [2-(4'-chlorophenyl)-1, 4-benzoquinone] and lower levels by the reduced form [2-(4'-chlorophenyl)-1, 4-hydroquinone]. When adducts formed by synthetic quinoid metabolites were compared with those derived from microsomal activation of 4-chlorobiphenyl by co-chromatography, one adduct co-migrated in three different chromatography systems. This study demonstrates that rodents and human hepatic enzymes metabolize lower chlorinated biphenyl congeners to reactive intermediates that form DNA adducts *in vitro* and shows that the *para*-quinone metabolites of PCBs are involved in direct DNA adduction in microsomal systems. (Supported by P42 ES 07380)

1707 THE EFFECTS OF PURIFIED *VS.* UNREFINED DIETS ON LIPID PEROXIDATION AND ANTIOXIDANT ENZYMES IN TESTES OF PCB-153-TREATED RATS.

Z. A. Fadhel[1], N. Stafine[2], H. P. Glauert[2], L. W. Robertson[2] and G. Ludewig[2]. [1]*University of Petra, Amman, Jordan and* [2]*University of Kentucky, Lexington, KY.*

The testes are known to be highly sensitive to a number of physical stresses. Among others, reactive oxygen species (ROS) have been shown to impair testicular function. Previous observations led us to postulate that different diets may influence oxidative stress levels in the testes. In this study we compared the effects of purified *vs.* unrefined diets on 1) the production of thiobarbituric acid-reactive substances (TBARS) in the testes as an indicator of oxidative stress, and 2) the activities of antioxidant enzymes in the testes. Thirty-six male Spraque-Dawley rats were fed a purified diet (similar to the AIN-93M diet) or an unrefined diet (Teklad Global 18% Protein Rodent Diet) for 3 weeks. Six animals per diet then received a single IP injection of 2, 2', 4, 4', 5, 5'-hexachlorobiphenyl (PCB-153, 300 µmol/kg), while six other animals per diet received no injection (control) or the vehicle only (corn oil). All animals were euthanized 2 days after treatment, the testes were excised, and subcellular fractions were prepared by differential centrifugation. The results indicate that feeding a purified diet to rats produced a significant decline in TBARS in testes cytosols in control and vehicle groups, and in animals treated with PCB-153, compared to animals on unrefined diets. No reduction in TBARS was seen in testes homogenates. Catalase activity in testes was increased in control groups receiving purified diet compared to unrefined diet, but not in PCB-treated groups. Glutathione transferase activity gave mixed results and total glutathione peroxidase activity was unchanged. This study shows that purified diets may lower oxidative stress in rat testes and that catalase activity may be partially responsible for this decrease. Further studies are needed to identify those dietary components responsible for these phenomena (Supported by NIH ES07380 and EPA GOK20395).

1708 DOES AN ENVIRONMENTAL PCB/PCDF MIXTURE ENHANCE ULTRAVIOLET RADIATION-INDUCED SKIN CANCER?

K. Imsilp, C. K. Morrow, L. G. Hansen and R. B. Cope. *Veterinary Biosciences, University of Illinois, Urbana, IL.*

The incidence of non-melanoma skin cancer (NMSC) has been increasing significantly. Chemical carcinogens synergistically interact with solar ultraviolet radiation (UVR) in non-melanoma skin cancer development. PCBs/PCDFs are ubiquitous environmental contaminants and potential epithelial carcinogens that bioaccumulate in skin. Our objective was to examine the interaction between an environmentally relevant chemical mixture and UVR on skin carcinogenesis. Our aim was to test the hypothesis that living in a PCB/PCDF contaminated area would enhance UVR-induced skin carcinogenesis in the CRL:SKH-hrBr hairless mouse model of human NMSC. Four groups of mice were placed on either PCB/PCDF contaminated soil collected from an old electric landfill in Illinois or control soil for weeks 1-11. Mice were weighed weekly. Two weeks after the beginning of the experiment, 2/4 groups of mice, 1 on treated and 1 on control soil bedding, were exposed to UVR 5 days/week. Mice exposed to the chlorinated aromatic contaminated soil were significantly ($p<0.001$) heavier than those exposed to control soil. At week 18, papillomas were only present in the chemical mixture treated groups. Regardless of UV exposure, the tumor incidence and multiplicity were significantly ($p<0.001$) greater in the UVR/contaminated soil treated group compared with the no UVR/contaminated soil treated group. Based on the preliminary results, a synergistic interaction between contaminated soil and UVR on skin carcinogenesis is likely. Therefore, environmental exposure to chemical carcinogens could possibly be an important factor that enhances the incidence of NMSC.

1709 EFFECTS OF POLYCHLORINATED BIPHENYLS AND 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN ON PROLIFERATION AND CELL CYCLE REGULATION IN HUMAN PLACENTAL TROPHOBLASTIC JEG-3 CELLS.

E. A. Ablordeppey, T. A. Medrano and K. T. Shiverick. *Pharmacology & Therapeutics, University of Florida, Gainesville, FL.*

The environmental contaminants polychlorinated biphenyls (PCBs), dioxin and polyaromatic hydrocarbons have been linked to infertility and low birth weight in animals and humans. This study used the JEG-3 human placental trophoblastic cell line to investigate potential growth inhibitory effects of prototype organochlorines in relation to aryl hydrocarbon receptor (AhR) mediated induction of cytochrome P450 1A1. Cells were treated respectively with the AhR ligands 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD), BENZO(A)PYRENE (B[a]P) and 3, 3', 4, 4'-tetraCB (TCB) in comparison with 2, 2', 4, 4', 5, 5'-hexaCB (HCB), which is not an AhR ligand. Following five-day treatment in the presence of 10% serum, [3H] thymidine incorporation was significantly decreased by 50 uM TCB, 50 uM HCB and 10 uM B[a]P, respectively, whereas 10 nM TCDD had no effect. Flow cytometry analysis of cell cycle phase distribution, however, showed no significant effects on the cell cycle distribution of cells treated with TCB, HCB or TCDD, whereas B[a]P treatment clearly produced a G2M arrest. Western immunoblot analysis showed no effect of TCB, HCB or TCDD on expression of the cell cycle inhibitory proteins p21 and p53. In contrast, B[a]P treatment strongly induced expression of p21 and, while total p53 levels were unchanged, serine-15 phosphorylation of p53 was markedly increased. The induction of CYP1A1 protein was seen only with TCDD and B[a]P, however, and not with either PCB congener. In conclusion, both HCB and TCB congeners significantly altered proliferation in the absence of cell cycle changes or CYP1A1 induction. In comparison, B[a]P-mediated growth inhibition was characterized by G2M cell cycle arrest and induction of p21WAF1 protein and p53 phosphorylation, which is a pattern reported for DNA damaging agents. Thus, data indicate that the TCB and HCB compounds decrease proliferation through an AhR-independent mechanism in JEG-3 cells. (Supported by NIH ES07375)

1711 CAUSATION ANALYSIS EXPOSES CRITICAL WEAKNESSES IN PURPORTED LINK BETWEEN PCBs AND NEURODEVELOPMENTAL DEFICITS.

J. B. Silkworth[1], J. E. Bernier[2], J. Borak[3] and D. Palumbo[4]. [1]*GE Corp. Res. & Devel., Schenectady, NY,* [2]*State University of New York, Albany, NY,* [3]*Yale School of Medicine, New Haven, CT and* [4]*Univ. of Rochester, Rochester, NY.*

Causation analysis was applied to 24 epidemiology studies that sought an association between maternal PCB exposure and neurodevelopmental effects in 2, 573 children in 6 international cohorts. Our analysis judged: strength of association; consistency; evidence of a dose-response relationship; specificity of effect; biological plausibility; and temporality. Across the epidemiology studies, 5 analytical approaches were used to measure PCBs in 8 biologic media, resulting in more than 60 PCB metrics (including statistically generated composites) to assess exposure. Neurodevelopmental status was evaluated from birth to 11 years by means of 16 different tests assessing over 200 abilities. Of over 2, 200 comparisons between various exposure metrics and neurodevelopmental outcome measures, the number of statistically significant findings was fewer than expected by chance alone. All children were reported to be within normal ranges of performance. Performance of more highly PCB-exposed breast-fed children was not diminished, but was positively correlated with duration of breast-feeding. Some negative correlations reported between neurodevelopment and PCBs were equally attributable to lead or mercury. The findings were generally inconsistent and lacked specificity, credible evidence of a dose-response, or any assurance of a temporally correct relationship. Although the authors reported associations between PCB exposure and neurodevelopmental effects, our analysis found no support for that view. Those purported findings were more likely due to imprecise and inconsistent exposure measurements, poor measures of effect, uncorrected multiple comparisons and other improper statistical methods, and inadequate control for confounders and covariates. Thus, although there is biologic plausibility, a causal association between this ascribed cause (PCBs) and this purported effect (impaired neurodevelopment) is without empirical support.

1713 APPLICATION OF QSARs TO PREDICT TRANSFORMATIONS OF POLYHALOGENATED ALIPHATIC COMPOUNDS (PHAs) IN HOMOGENEOUS AND HETEROGENEOUS SYSTEMS.

R. Venkatapathy and J. A. Perlinger. *CEE, Michigan Tech University, Houghton, MI.* Sponsor: C. Moudgal.

Under anaerobic reducing environments, PHAs may undergo reductive dehalogenation reactions, yielding products that may be less or more toxic than the parent compounds. The toxicity of the parent compounds and their dehalogenated products depend on their concentration in the environment, which in turn depends on

the kinetics of the dehalogenation reaction. Quantitative Structure Activity Relationships (QSARs) were developed to predict rates of transformation of PHAs in nine homogeneous and heterogeneous model systems obtained from literature. The model systems are representative of engineered and natural environments where PHAs are reduced either in the aqueous phase or at the surface of metals, oxides or hydroxides. The descriptors for predicting rates depended on the rate-limiting step in the compounds' reactions with reductants. Statistical techniques such as regression, factor and cluster analyses were used to examine rate-limiting steps, which are due to diffusion, sorption or dissociative electron-transfer (DET) in the transformation of PHAs in various studies. Descriptors that were chosen to describe DET were calculated using quantum chemistry, while diffusion and sorption of reactants and products to/from the surface were described using physical-chemical properties of the PHAs. Results from QSARs for homogeneous systems indicate that the rate-limiting step is dissociative one-electron transfer. Statistical analysis results indicate that in heterogeneous systems, the transformation of methanes is limited by electron transfer. The results also indicate that transformation of ethenes is limited by mass transfer, while ethanes are limited by both mass and electron transfer. Experiments were carried out for three new compounds to verify the QSARs for two different homogeneous systems. The difference between measured and predicted rate constants was within the uncertainty limits at 95% confidence, thereby demonstrating the predictive ability of QSARs for transformation of PHAs in homogeneous systems.

1714 PREVENTION BY CHLOROFORM AND METHIONINE OF DICHLOROACETIC ACID AND TRICHLOROACETIC ACID-INDUCED HYPOMETHYLATION OF GENES AND OF THE CHLOROACETIC ACIDS PROMOTION OF LIVER AND KIDNEY TUMORS IN MICE.

P. M. Kramer, L. Tao, P. B. Conran, M. Edelbrock and M. A. Pereira. *Pathology, Medical College of Ohio, Toledo, OH.*

Chloroform, dichloroacetic acid (DCA) and trichloroacetic acid (TCA) are mouse liver carcinogens. The effect of chloroform and methionine on DCA and TCA-induced hypomethylation of genes was determined. B6C3F1 mice were administered chloroform (0, 400, 800 and 1, 600 mg/l) in their drinking water and 500 mg/kg DCA or TCA daily by gavage. DCA, TCA and to a much lesser extent chloroform caused hypomethylation the c-myc and IGF-II genes. Co-administering chloroform prevented only DCA and not TCA-induced hypomethylation of the genes. Methionine at 0, 4, 000 or 8, 000 mg/kg diet was administered to B6C3F1 mice with 0, 3.5 gm/l DCA or 4.0 gm/l TCA administered in the drinking water. Methionine prevented both DCA and TCA-induced hypomethylation of the genes. The relationship of hypomethylation of genes to tumor development was tested in female and male B6C3F1 mice initiated on day 15 of age with N-methyl-N-nitrosourea. At 5 weeks of age, the mice started to receive in their drinking water DCA (3.2 gm/l) or TCA (4.0 gm/l). The mice also received chloroform at 0, 800 or 1, 600 mg/l in their drinking water or methionine at 0, 4, 000 and 8, 000 mg/kg in their diet. Chloroform prevented DCA, but not TCA promotion of liver foci and tumors. In male mice, TCA promoted kidney tumors while DCA promoted kidney tumors only when co-administered with chloroform. Hence, chloroform prevented only DCA and not TCA hypomethylation of the c-myc and IGF-II genes and promotion of liver tumors. Thus the ability to prevent hypomethylation of the genes was associated with the ability to prevent tumor promotion supporting the involvement of hypomethylation with tumor promotion.

1715 KINETIC AND MECHANISTIC STUDIES ON THE HYDROLYSIS OF HALOGENATED ETHYLENE OXIDES.

T. Yoshioka and F. P. Guengerich. *Biochemistry and Center in Molecular Toxicology, Vanderbilt University, Nashville, TN.*

Chlorinated ethylenes, e.g. trichloroethylene (TCE) and tetrachloroethylene (PCE) have been shown to be toxic and carcinogenic. P450-catalyzed biotransformation of these compounds to electrophilic ethylene oxides, followed by rearrangements of the oxides to acylating intermediates, are thought to be related to their toxicities. TCE oxide has been shown to generate adducts with lysine and proteins. In order to elucidate the inherent reactivity of these oxides, comparative kinetic studies on the hydrolysis and rearrangement were performed by using TCE oxide, tribromoethylene (TBE) oxide, and PCE oxide. These oxides decomposed in a MOPS/KOH buffer with first-order kinetics, TBE oxide being the most reactive. TCE and TBE oxides gave similar decomposed products of dichloroacetic acid (dibromoacetic acid in the case of TBE oxide), formic acid, glyoxylic acid and carbon monoxide, with different ratios. Dibromoacetic acid was the major product of TBE oxide, consistent with formation of a bromonium ion intermediate to give the acid through an intramolecular rearrangement. PCE oxide yielded trichloroacetic acid in a very low yield under the same conditions. In phosphate buffer, the oxide gave oxalyl phosphate and oxalic acid as well as trichloroacetic acid. These results indicate that PCE oxide decomposes through two pathways; one is an intramolecular chlorine migration to give trichloroacetic acid and the other is a hydrolysis of the oxide to give oxalyl chloride which is known to react to give the phosphate. The phosphate decomposed gradually to oxalic acid with first-order kinetics. Differences of reactivity in the decomposition reactions of these oxides may affect their reaction with intracellular nucleophilic molecules and both the pattern and extent of the adduct formation. (Supported in part by USPHS R01 ES10546 and P30 ES00267)

1716 MASS SPECTROMETRY STUDIES OF OLIGONUCLEOTIDES CROSS-LINKED TO ALKYLGUANINE TRANSFERASE *VIA* ETHYLENE DIBROMIDE.

K. M. Williams[1], L. Liu[2], A. E. Pegg[2] and F. P. Guengerich[1]. *[1]Department of Biochemistry, Vanderbilt University School of Medicine, Nashville, TN and [2]Department of Cellular and Molecular Physiology, Pennsylvania State University College of Medicine, Hershey, PA.*

O^6-Alkylguanine transferase (AGT) is a DNA repair protein that normally removes alkyl groups from the O6 atom of guanine or the O4 atom of thymine, with Cys145 as the acceptor site for the alkyl group. However, AGT expression leads to increased cytotoxicity and mutagenicity of ethylene dibromide in *Escherichia coli* cells that lack endogenous AGT activity (Abril et al. *Mol. Carcinog.* **12**, 110-117, 1995; Liu et. al. *Mutat. Res.* **452**, 1-10, 2000). Ethylene dibromide or 2-bromoethanol was incubated with AGT in the presence or absence of oligonucleotides, and trypsin-digested samples were characterized by matrix-assisted laser desorption ionization (MALDI) and electrospray ionization mass spectrometry (MS). In the absence of oligonucleotides, both ethylene dibromide and 2-bromoethanol react with AGT to form an $-SCH_2CH_2OH$ adduct at Cys145; ethylene dibromide apparently forms this adduct *via* an episulfonium ion that reacts with water in the absence of other nucleophiles. When ethylene dibromide was added to AGT in the presence of a G-containing oligo and then subjected to trysin digestion, MALDI indicated that Cys145 was cross-linked to a G base. This result suggests that the episulfonium ion reacts with guanine at the N7 position, resulting in neutral thermal hydrolysis of the base during the trypsin digestion. Thus, the mutagenicity increase of ethylene dibromide in the presence of AGT may be due at least in part to the formation of abasic sites from guanine residues. Crosslinking of AGT to T was also observed with oligonucleotides. The contributions of the G and T modifications to mutation is under investigation. These findings provide an example of a DNA repair protein acting to increase the genotoxicity of a chemical. (Supported in past by USPHS R35 CA44353, R01 E10546, P30 ES00267, T32 ES07028)

1717 THE INFLUENCE OF ADVANCED AGE ON THE TIME COURSE OF THE HEPATIC TOXICITY OF BROMODICHLOROMETHANE.

A. McDonald, Y. M. Sey and J. E. Simmons. *NHEERL/ORD, USEPA, Research Triangle Park, NC.*

Chemical disinfection, by chlorination or by ozonation followed by either chlorine or chloramine, of water containing organic matter results in the production of a variety of halogenated byproducts, which includes trihalomethanes (THMs) such as bromodichloromethane (BDCM). Exposure to BDCM is virtually ubiquitous across all segments of the US population, including the aged. The present study evaluated the influence of advanced age on the time course of BDCM-induced hepatic toxicity. Young (~90 day old) and aged (22-24 months old) male F-344 rats were administered 0, 0.5, 1.0 or 2.0 mmol BDCM/kg by gavage in an aqueous vehicle (10% Alkamuls at a gavage volume of 5 ml/kg at ~ 3 p.m.). Hepatotoxicity was assessed, in separate experiments, at either 24 hr or 48 hr after dosing, by determination of the serum activities of sorbitol dehydrogenase (SDH) and alanine (ALT) and aspartate (AST) aminotransferases. The hepatotoxicity of BDCM was dose-dependent in both young and old rats. Based on these serum indicators, the hepatotoxic response to BDCM was dependent on age, with greater toxicity observed in the aged rats. At both 24 and 48 hr, the differences between young and aged rats were most apparent at the highest dosage (2.0 mmol/kg). At 2.0 mmol/kg, little or no recovery was apparent between 24 and 48 hr. These results are in contrast to results previously obtained (Lilly et al., 1997, McDonald et al, 2001) with chloroform, another THM ubiquitous in chlorinated or chloraminated water, where recovery was apparent in both young and aged rats between 24 and 48 hr and consistent with BDCM results in young rats (Lilly et al., 1997). In conclusion, these data suggest that advanced age alters the hepatic response to BDCM, indicating that the aged may be a susceptible subpopulation for THMs. (Abstract may not reflect EPA policy.)

1718 SENSITIVE METHODS FOR THE DETECTION OF TRACE LEVELS OF TRICHLOROETHYLENE (TCE) IN RAT PLASMA.

A. M. Dixon, S. D. Brown, S. M. Muralidhara, J. V. Bruckner and M. G. Bartlett. *Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA.*

TCE is a widely used solvent and metal degreasing agent that is frequently found in US drinking water supplies in trace levels (i.e. a few ppb to pptr). Current cancer and noncancer risk assessments of the chemical predict that exposure to even minute amounts of TCE may be associated with risks to humans. Due to a lack of analytical sensitivity, it has not yet been possible to conduct experiments to evaluate the validity of some key assumptions in the risk assessments. Two analytical methods were developed for this purpose and compared to one another. The first is a more traditional gas chromatography (GC) liquid-liquid extraction (LLE) method, while the second uses the relatively new technology of solid phase microextraction (SPME). With SPME, a fiber is inserted into the headspace of a sample vial to allow TCE to adsorb onto the fiber. The fiber is then placed into the injection liner of the GC where TCE is desorbed. SPME has the advantage of simpler, more rapid sample preparation. High resolution GC/MS was used for the analysis of plasma samples by both methods. For each technique, 100 uL of plasma were spiked with 100 uL of an aqueous TCE solution (1-10, 000 ng/mL). With LLE, 100-200 uL of diethyl ether were added to each sample. These samples were then centrifuged before analysis. Samples run by SPME were transferred to vials where the SPME fiber was inserted for 1 min, then removed and inserted into the GC for analysis. The limit of detection (LOD) was found to be 1 ng/mL (ppb) for both methods. This is an improvement over the LOD of 25 ng/mL for the GC headspace method currently in place in our laboratory. With the increased analytical sensitivity, trace level studies involving first-pass metabolism of TCE and interaction of TCE with inducers/inhibitors of metabolism are now possible. (Supported in part by DOE Grant # DE FC02 98CH10902 and ATSDR contract # 68164).

1719 PRESENCE AND ACTIVATION OF THE ARYL HYDROCARBON RECEPTOR IN NEURONAL VASCULAR ENDOTHELIUM.

C. R. Filbrandt and T. A. Gasiewicz. *Environmental Medicine, University of Rochester, Rochester, NY.*

The aryl hydrocarbon receptor (AhR) is a member of the bHLH-PAS family of transcriptional regulatory proteins known functionally as a modulator of xenobiotic toxicity. Many of the mechanisms involved in AhR activation and the transcriptional events following ligand binding have been well characterized, but not all tissue-specific targets or functional consequences have been defined. Although the brain is a target for AhR mediated toxicity, consequences localized regions, such as the cerebral vascular endothelium are unknown. Receptor activation and subsequent CYP1A1 upregulation could compromise integrity and function of the neuronal endothelium and therefore, the blood-brain barrier. The purpose of these studies was to examine the presence and activity of AhR in brain endothelium. Receptor mRNA and protein were found regionally throughout the brain of adult C57BL/6 mice. Relative quantitation by real-time RT-PCR indicated receptor mRNA within the cerebellum > cortex and stratum > thalamus and hypothalamus. Furthermore, the receptor was also detected in total RNA and protein isolated from primary cortical endothelial cultures. Although its abundance is nearly ten-fold less in the whole cortex and endothelial cell culture than in liver, exposure to 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD), induced upregulation of CYP1A1 transcription. We hypothesize that receptor activation and downstream gene transcriptional upregulation in these cells may have functional consequences in terms of oxidative stress and barrier permeability. If these consequences occur *in vivo*, they could play a significant role in the potentiation of vascular injury that may underlie the development of various neurodegenerative diseases. (Supported by NIH grant ES09430, Training Grant ES07026, and Center Grant ES01247)

1720 KERATINOCYTE INTERLEUKIN-1β EXPRESSION IS MEDIATED BY THE ARYL HYDROCARBON RECEPTOR.

D. V. Henley[1], C. J. Bellone[2], D. A. Williams[1] and M. F. Ruh[1]. *[1]Pharm/Phys Science, Saint Louis University, St. Louis, MO and [2]Molec Micro & Immunology, Saint Louis University, St. Louis, MO.*

Halogenated aromatic hydrocarbons represent a wide variety of environmental contaminants. Human exposure to 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD), the most potent member of the halogenated aromatic hydrocarbon family, produces several adverse health effects, including chloracne, a skin rash characterized by epidermal hyperkeratinization and inflammation. The proinflammatory cytokine interleukin-1β (IL-1β) has previously been suggested to play a role in the pathology of chloracne. TCDD elicits its effects by binding to the aryl hydrocarbon receptor (AhR) and forming an AhR heterodimeric nuclear complex. To test the hypothesis that the IL-1β gene is regulated by an AhR-mediated mechanism, differentiating SCC-12 and HaCaT human keratinocytes were treated with TCDD or vehicle. Western blot analyses were performed to determine the effect of TCDD on IL-1β protein expression in these keratinocytes. Time and dose dependent increases in prointerleukin-1β (pIL-1β) were seen in both SCC-12 and HaCaT cells following TCDD treatment when compared to vehicle controls. Northern blot analyses were performed to ascertain the effect of TCDD on IL-1β steady state mRNA levels. TCDD treatment resulted in dose and time dependent increases in IL-1β mRNA in both SCC-12 and HaCaT cells when compared to vehicle controls. Increases in CYP1A1 mRNA, a gene known to be transcriptionally activated by TCDD in cells undergoing terminal differentiation, paralleled increases in IL-1β mRNA with respect to time in both cell lines. Both cell lines were treated with TCDD in the presence and absence of α-naphthoflavone, an AhR antagonist, to determine if the TCDD-mediated increases in IL-1βprotein and steady state mRNA were AhR-dependent. Western blot and Northern blot analyses revealed that the AhR antagonist attenuated TCDD-mediated increases in IL-1β. These results confirm that the AhR regulates TCDD-mediated increases in IL-1β gene expression in differentiating keratinocytes. (Supported, in part, by NIH ES05968).

1721 DIOXIN TOXICITY: LARGE-SCALE GENE EXPRESSION IN A RESISTANT RAT MODEL.

M. A. Franc[1], R. Pohjanvirta[2,3], J. Tuomisto[3] and A. B. Okey[1]. *[1]Dept of Pharmacology, Univ of Toronto, Toronto, ON, Canada, [2]Veterinary Medicine, Univ of Helsinki, Helsinki, Finland and [3]National Public Health Institute, Kuopio, Finland.*

2, 3, 7, 8-Tetrachlorodibenzo-*p*-dioxin (TCDD) is exceptionally toxic and also alters expression of a wide spectrum of genes in cell culture and *in vivo via* the AH receptor (AHR). Dysregulated gene expression probably triggers toxicity but the dioxin-regulated genes that are key to lethality and other toxicities remain ill-defined. We are using gene expression arrays to identify and to compare TCDD-responsive genes in rat strains that differ dramatically in their sensitivity to TCDD lethality and in their AHR structure: Long Evans *Turku AB* (LE) [LD_{50} ~ 10 μg/kg] and Han/Wistar *Kuopio* (H/W) [LD_{50} > 9600 μg/kg]. Our postulate is that genes whose expression is altered by TCDD in sensitive LE rats but not in resistant H/W rats are the genes most likely to be relevant to lethality. Rats were given a single TCDD dose of 50 μg/kg intragastrically. Liver was removed after 24 hours and RNA was reverse-transcribed and labeled with ^{32}P prior to hybridization to Clontech Atlas 1.2 rat arrays. Of 1185 genes on the array, TCDD caused 6% (67 genes) to change in expression (1.5-fold, up or down) in the LE rat and 8% (90 genes) in the H/W. Of these, only 33 were genes common to both strains. Genes well-established as being responsive to dioxins (*CYP1A1, CYP1A2, CYP1B1, GST-Ya*) were upregulated in both LE and H/W strains, establishing the validity of this array for detection of responses to TCDD. In addition to altered expression of these "positive control" genes, the experiments revealed altered expression of several novel genes not previously reported to be affected by TCDD. Additional rat strains & lines now are being studied with the Clontech array and with a glass microarray from the Ontario Cancer Institute (>15, 000 unique cDNA sequences) to establish a hierarchy of genes whose TCDD-responsiveness consistently differs between dioxin-sensitive *versus* dioxin-resistant rats to identify candidate genes that are most likely to be involved in dioxin lethality.

1722 LOW *IN VITRO* HEMATOPOIETIC TOXICITY OF TENOFOVIR RELATIVE TO OTHER NRTIS: COMPARISON OF RAPID THROUGHPUT CELISA AND COLONY ASSAY DATA.

D. E. Greenwalt[1], T. Cihlar[2], J. Szabo[1] and M. Hitchcock[2]. *[1]R&D, BioWhittaker, Walkersville, MD and [2]Gilead, Foster City, CA.* Sponsor: G. Dearlove.

Nucleoside reverse transcriptase inhibitor (NRTI)-containing regimens have been demonstrated to produce various hematological disorders. In comparison with untreated control groups, anemia and/or neutropenia have been detected at a higher rate in HIV patients treated with ZDV (Richman et al., 1987), d4T (Browne et al., 1993), or ddC (Yarchoan et al., 1988). Tenofovir is an acyclic nucleotide analog with potent *in vitro* and *in vivo* antiretroviral activity. Its lipophilic prodrug, tenofovir disoproxil fumarate, is currently in late stage clinical development as a novel oral agent for treatment of HIV infection. The present study was designed to help define the *in vitro* toxicity profile of tenofovir and other NRTIs by assessing their cytotoxic effects in human hematopoietic progenitor cells. Two different *in vitro* toxicity assays were used: the clonogenic "colony assay" and the 96-well filter plate-based CELISA. Human $CD34^+$ progenitor cells were isolated from two individual

donors, treated with lineage-specific growth factors to induce myeloid and erythroid differentiation and exposed to NRTIs for 10 days. Lineage-specific differentiation was determined by use of the CELISA platform technology utilizing lineage-specific fluorescent antibody-based immunoassays and colony counting assays. The tested NRTIs displayed a range of toxicities with IC_{50} values ranging from >200μM to <60nM. The relative toxicities of the NRTIs were ddC > ZDV > d4T > 3TC ≅ tenofovir. ZDV and d4T had a >10-fold increased myelotoxicity in one donor relative to the second and exhibited marked lineage-specific toxicities, the erythroid lineage being the more sensitive in each case. The CELISA data correlated with colony assay data in all cases. We conclude that lead optimization of NRTIs and other drugs can be greatly accelerated through use of the rapid-throughput CELISA assay of *in vitro* cell differentiation.

1723 THE ROLE OF REACTIVE OXYGEN SPECIES IN MEDIATING THE ACTIVITY OF THE C-MYB ONCOGENE.

L. M. Winn[1] and S. A. Ness[2]. [1]*Pharmacology and Toxicology, Queen's University, Kingston, ON, Canada and* [2]*Molecular Genetics and Microbiology, University of New Mexico Health Sciences Center, Albuquerque, NM.*

The incidence of childhood leukemias has increased 20% over the last two decades. Exposure to several drugs and environmental toxicants has been proposed to be a primary cause for this increase. Mutated or overexpressed versions of the *c-myb* oncogene are believed to play a pivotal role in the development of a variety of leukemias and other tumours. The *c-myb* gene encodes a highly conserved 78 kDa transcription factor that has been implicated in a diverse set of biological processes, including the regulation of cell proliferation, differentiation and apoptosis. While the structure of the c-Myb protein and the regulation of *c-myb* gene expression have been studied in great detail, little is known about the upstream activators that regulate c-Myb protein activity. Furthermore, nothing is known about the effects of xenobiotic exposure on c-Myb activity. The toxicity of many xenobiotics is mediated by xenobiotic bioactivation to a reactive free radical intermediate, which if not detoxified may initiate the formation of reactive oxygen species (ROS). We hypothesize that exposure to xenobiotics that lead to increased ROS mediate leukemogenesis by disrupting crucial cell signalling pathways involving the *c-myb* oncogene. To evaluate this hypothesis, quail QT6 cells were transfected with a Myb-responsive luciferase reporter plasmid derived from the chicken *mim-1* promoter, along with control vector DNA or a plasmid expressing c-Myb. The following day cells were serum starved for 24 hr and then exposed to 400 μM H_2O_2 for 5 minutes. Luciferase activities were then measured in cell lysates to evaluate c-Myb activity. Results of these studies showed that cells exposed to H_2O_2 had significantly increased c-Myb activity compared to cells exposed to the vehicle control and support the hypothesis that ROS mediate the transcriptional activity of this oncogene. The hypothesis that xenobiotic-induced ROS production leads to aberrant c-Myb signalling is currently being investigated.

1724 SIMULTANEOUS DETERMINATION OF SIX URINARY PORPHYRINS IN THE UNTREATED BEAGLE DOG USING LIQUID CHROMATOGRAPHY - TANDEM MASS SPECTROMETRY.

T. P. O'Neill[1], W. Bu[1], C. P. Chengelis[1], N. Myers[1], J. D. McCarty[2], P. L. Stetson[1] and D. Sved[1]. [1]*Toxicology, WIL Research Laboratories, Ashland, OH and* [2]*Toxicology, FMC Corporation, Princeton, NJ.*

Porphyrin is converted to heme through a series of enzymatic steps. Deficiencies in these enzymes can lead to porphyria, which can have specific toxicological consequences. Evaluation of porphyrins in urine can be useful in the recognition of these toxicological sequelae. A liquid chromatographic-tandem mass spectrometric (HPLC-MS-MS) method without sample pretreatment was developed and validated for determination of urinary porphyrins. The acidified urine sample was directly injected for HPLC/MS/MS analysis using a reverse-phase column with gradient elution, and ESI positive ion detection and quantitation. The mass spectrometer was operated in the multi-reaction monitoring (MRM) mode and six porphyrins (mesoporphyrin, coproporphyrin, 5-carboxyporphyrin, 6-carboxyporphyrin, 7-carboxyporphyrin and uroporphyrin) were detected with excellent sensitivity and selectivity. Values obtained in the untreated beagle dog corresponded to not present, 0.1361, 0.0196, below lower limit of quantification, 0.0328 and 0.0624 nmol/mL respectively, which are within expected normal values. The lower limit of quantitation was 0.014 nmol/mL for each porphyrin, and a good linear response for calibration standards ranging from 0.01 to 1.0 nmol/mL for each porphyrin was demonstrated. This method can be used for determining the effects of chemicals and pharmaceuticals on urinary porphyrin excretion profiles in preclinical animal studies and in the investigation or diagnosis of porphyria in clinical studies.

1725 *IN VIVO* DISTRIBUTION AND TOXICITY OF THE NOVEL COPPER-BASED ANTICANCER COMPOUND: CASIOPEINA II.

A. E. Vizcaya-Ruiz[1,3], A. Rivero-Müller[1], J. James[1], L. Ruiz-Ramirez[2] and M. Dobrota[1]. [1]*SBS, University of Surrey, Guildford, United Kingdom,* [2]*Facultad de Química, UNAM, México, D.F., Mexico and* [3]*Toxicología, CINVESTAV-IPN, México, D.F., Mexico.* Sponsor: M. Cebrián.

The *in vivo* fate and toxicity of the novel copper-based anticancer agent, casiopeina II [Cu(4, 7-dimethyl-1, 10-phenanthroline)(glycine) NO_3], was studied. Casiopeinas are a family of square planar copper-coordinated complexes that have shown promising anticancer activity. The phenanthroline ligand of CII was tritium labeled to follow the distribution of the two components of the complex. After a single iv administration of ^{3}H-casiopeina II (CII) (5mg/kg dose) in the rat the complex was rapidly distributed to tissues (liver and kidney), the ^{3}H-phenathroline was excreted *via* urine and feces whilst the copper appeared to be predominantly retained with a small amount being excreted *via* feces. Differences in tissue copper retention and ^{3}H-phenanthroline elimination suggest an *in vivo* dissociation of the complex. The major toxic effect attributed to CII administration was an hemolytic anemia (reduced hemoglobin concentration, red blood cell count and packed cell volume as well as leukocytosis and neutrophilia) observed 12 hours and 5 days after administration, attributed to a direct erythrocyte oxidative damage. Increased reticulocyte levels and presence of normoblasts in peripheral blood 5 days post-administration indicated an effective erythropoietic response and tendency towards recovery at 15 days. Increase in spleen weight was attributed to an increased uptake of damaged erythrocytes by the reticuloendothelial system. Erytropoietin pretreatment before CII administration reduced the hematological effects. In conclusion data from copper and ^{3}H distribution and excretion suggests that CII complex is readily dissociated *in vivo*, which could give rise to the acute toxic effect in erythrocytes due to the generation of free radicals and oxidative stress from the reduction of Cu(II) to Cu(I). Improving the stability of the complex *in vivo* could increase its biological activity and thus its anticancer potential.

1726 SINUSOIDAL ENDOTHELIAL CELL INJURY DURING HEPATOTOXICITY FROM MONOCROTALINE AND BACTERIAL LIPOPOLYSACCHARIDE COEXPOSURE.

S. B. Yee, B. L. Copple, P. E. Ganey and R. A. Roth. *Pharmacology and Toxicology, National Food Safety and Toxicology Center, and the Institute for Environmental Toxicology, Michigan State University, East Lansing, MI.*

A previous study demonstrated that a nontoxic dose of bacterial lipopolysaccharide (LPS) given 4 hours after a small dose of monocrotaline (MCT) resulted in synergistic hepatotoxicity within 12 to 18 hours after MCT administration. Histopathologic analysis revealed centrilobular and midzonal lesions characteristic of those associated with larger toxic doses of MCT and LPS, respectively. Moreover, within these lesions there was pronounced hemorrhage, loss of sinusoidal architecture, and the loss of central vein intima, suggesting a vascular component to the injury. It has been postulated that injury to sinusoidal endothelial cells (SECs) creates microcirculatory disturbances that contribute to hepatic parenchymal cell injury. To begin to explore this hypothesis, the association of SEC injury with hepatic parenchymal cell injury was evaluated. At 18 hours, a significant increase in plasma hyaluronic acid (HA), a biomarker of SEC injury, was observed in animals cotreated with MCT/LPS. This increase in SEC injury was confirmed through immunohistochemistry with a rat endothelial cell antibody (RECA-1). Morphometric analysis revealed a decrease in RECA-1 staining intensity (i.e., a loss of SECs) in livers of rats treated with MCT/LPS. The decreased staining occurred in both centrilobular and midzonal regions of the liver lobule. A significant increase in liver hemoglobin, a biomarker of hemorrhage, was also observed at 18 hours in cotreated animals, further suggesting circulatory and vascular disturbances. Finally, SEC injury developed before the onset of hemorrhage and parenchymal cell injury, an observation consistent with the hypothesis that SEC injury plays a causal role in this model of liver injury. *Supported by NIH Grant ES 04139.*

1727 NAPROXEN SODIUM NEPHROTOXICITY: INTERSPECIES DIFFERENCES.

P. B. Senese[1], D. A. Baron[2], K. M. Stanfield[1] and K. N. Khan[1]. [1]*Global Toxicology, Pharmacia, Skokie, IL and* [2]*Toxicology, Takeda, Lincolnshire, IL.* Sponsor: M. Schlosser.

Cyclooxygenase (COX) exists in two isoforms, COX-1 and COX-2. Constitutive COX-2 is found in the macula densa (MD) and thick ascending limb of the loop of Henle in rodents and dogs, and is absent at these sites in normal adult humans and monkeys. This difference in COX expression may be responsible for the contrasting nephrotoxicity profiles of NSAIDs in these species. We compared the toxicity profile of naproxen sodium (a non-selective COX inhibitor) in dogs and monkeys.

Beagle dogs and cynomolgus monkeys were given naproxen sodium orally for six weeks at dosages up to 10 and 150 mg/kg/day. The dogs exhibited a 5-fold increase in BUN and a 1.1-fold increase in creatinine suggesting pre-renal azotemia. Kidneys exhibited tubular atrophy and fibrosis in the outer cortex of 4/6 dogs and renal papillary necrosis in 3/6 dogs. The lesions correlated with increases in BUN. In contrast, monkeys exhibited a less pronounced increase in BUN (2.7-fold) and did not develop renal papillary necrosis or cortical tubular atrophy and fibrosis; however, obstructive nephropathy, presumably due to drug accumulation in the renal tubules, was observed. Monkeys also exhibited an increase in creatinine (3.6-fold) which was likely secondary to the obstructive nephropathy. These data suggest that dogs are more sensitive to NSAID-related nephrotoxicity in comparison to monkeys. The renal changes in dogs appear to be secondary to regional hypoxia/ischemia and implicate an effect of naproxen sodium on renal hemodynamics. The MD plays an important role in renin angiotensin system; thus, co-localization of high levels of COX-2 at this site in dogs suggest an important role of COX-2-mediated prostaglandins in normal renal physiology in dogs. The role of COX-2 on renal hemodynamics in the normal monkey appears to be less significant. This study demonstrates that a differential renal response to NSAID administration among species can be explained by the interspecies variation of renal COX-2 expression and its species specific role in normal kidney function.

1728 NEUTROPHIL APOPTOSIS AND THE RESOLUTION OF PULMONARY INFLAMMATION.

A. J. Wiethoff, K. L. Reed, T. R. Webb and D. B. Warheit. *DuPont Haskell Laboratory for Health and Environmental Sciences, Newark, DE.*

The apoptosis, or programmed cell death, of neutrophils and their subsequent engulfment by macrophages is important in the resolution of pulmonary inflammation. Previous studies showed a correlation between inflammation and apoptosis in silica-exposed rats. However, in titanium dioxide (TiO2) exposed rats, only a slight apoptotic potential was seen at very high doses even in the presence of measurable levels of inflammation. The goal of the current study is to further investigate the mechanism of apoptosis and its correlation to the inflammatory process due to amorphous and crystalline silica, LPS and TiO2 exposure. Rats were instilled with TiO2, Zeofree 80 (amorphous) or Min-U-Sil (crystalline silica) at both 1 and 5 mg/kg. A group of rats were also instilled with 6 mg LPS. Bronchoalevolar lavage fluid and tissue were collected at 12, 24, 48 and 168 hours after instillation. Only the amorphous silica instilled animals displayed measurable apoptosis (detected by ELISA) at 1 mg/kg with the highest level at 24 hours post instillation. At 5mg/kg, apoptosis was highest at 12 hours for amorphous silica, and at 24 hours for the other substances tested. By 168 hours, only crystalline silica instilled animals had any measurable response. Pulmonary inflammation, as evidenced by neutrophil influx correlated with the apoptotic measurements. cDNA array technology was employed on lung tissue from sham, Zeofree 80, Min-U-Sil and LPS animals and expression of several genes related to apoptosis were upregulated. These studies confirmed that TiO2 exposure causes low levels of inflammation and apoptosis. Amorphous silica and LPS produce a strong, but transient inflammatory response while instillation of crystalline silica results in sustained pulmonary inflammation and measurable apoptosis after a week.

1729 COMPARISON OF LOW DOSES OF AGED AND FRESHLY FRACTURED SILICA ON PULMONARY INFLAMMATION AND DAMAGE IN THE RAT.

D. W. Porter, M. Barger, V. A. Robinson, S. Leonard, D. Landsittel and V. Castranova. *HELD, NIOSH, Morgantown, WV.*

Most previous studies of silica toxicity have used relatively high doses of silica. In this study, rats received by intratracheal instillation either vehicle, aged or freshly fractured silica at a dose of either 5 ug per rat once a week for 12 weeks (total dose of 60 ug) or 20 ug per rat once a week for 12 weeks (total dose of 240 ug). One week after the last exposure, bronchoalveolar lavage (BAL) was conducted and pulmonary inflammation, alveolar macrophage (AM) activation and pulmonary damage were examined. Specifically, pulmonary inflammation was assessed by BAL polymorphonuclear leukocyte (PMN) yields, AM chemiluminescence was measured as an indicator of AM activation, and first acellular BAL fluid lactate dehydrogenase activity and serum albumin concentration were determined as markers of pulmonary damage. For rats exposed to a total of 60 ug silica, both aged and freshly fractured silica increased PMN yield and AM chemiluminescence above control to a similar degree, but no evidence of pulmonary damage was detected. For rats exposed to 240 ug silica, aged or freshly fractured silica increased PMN yield and AM chemiluminescence above control. However, total and NO-dependent AM chemiluminescence was greater for rats exposed to freshly fractured silica compared to aged silica. Exposure to 240 ug aged or freshly fractured silica also resulted in pulmonary damage, but the extent of this damage did not differ between the two types of silica. The results suggest that exposure to silica levels far lower than those previously examined can cause pulmonary inflammation and damage. In addition, exposure to freshly fractured silica causes greater generation of reactive oxygen and nitrogen species from AMs (measured as total and NO-dependent AM chemiluminescence) in comparison to aged silica, but there is an apparent threshold below which this difference does not occur.

1730 INCREASED IL-6 AND IL-8 EXPRESSION IN HUMAN AIRWAY EPITHELIAL CELLS EXPOSED TO CARBON ULTRAFINE PARTICLES.

R. Silbajoris[1], A. G. Lenz[2], L. Jaspers[3] and J. M. Samet[1]. *[1]NHEERL, ORD, USEPA, Research Triangle Park, NC, [2]GSF-Institute for Inhalation Biology, Neuherberg, Germany and [3]CEMLB, UNC-CH, Chapel Hill, NC.*

Ultrafine particles are a potentially toxic constituent of particulate matter (PM) and may contribute to the health effects of ambient PM. Exposure to extracts or components of PM has been shown to evoke inflammatory responses in cultured normal human airway epithelial cells (NHBE). One of these responses is the expression of pro-inflammatory proteins such as IL-6 and IL-8. The aim of the present study was to characterize the effect of ultrafine elemental carbon particle (EC) exposure on IL-6 and IL-8 expression in NHBE. Particles were generated by spark discharge and had a diameter of 75 nm and a surface area of 750 m^2/g. Cells were exposed to 0 to 66 ug/ml of EC for 2 to 30 hr and levels of IL-6 and IL-8 mRNA and protein were measured using real-time fluorescent PCR and ELISA, respectively. After 2 hr of exposure to 33 or 66 ug/ml EC, there were minimal increases in IL-6 and IL-8 mRNA when compared to untreated controls. However, a 24 hr exposure to 33 ug/ml EC showed 9-fold and 12-fold increases in IL-6 and IL-8 mRNA, respectively. Doubling the amount of EC to 66 ug/ml resulted in a 10-fold increase in IL-6 mRNA and a 20-fold increase in IL-8 mRNA. To minimize underestimation of IL-6 and IL-8 protein release caused by non-specific protein binding to EC, a pulsed exposure protocol was used. After exposing NHBE to media with 33 or 66 ug/ml EC for 8 hr to initiate mRNA induction, media was changed so that protein release would take place in media without EC. When compared to controls, this regimen resulted in 5-fold elevations in IL-6 and IL-8 release by NHBE that were exposed to EC for 24 hr. These data show that carbon ultrafine particle exposure induces inflammatory mediator expression, suggesting a contributing mechanism for the health effects of ambient PM inhalation. Further studies will be required to identify the mechanism of IL-8 expression induced by exposure to EC. **This abstract of a proposed presentation does not necessarily reflect EPA policy.**

1731 RESPONSIVENESS OF ALVEOLAR MACROPHAGES FROM INOS KNOCKOUT OR WILD TYPE MICE TO AN *IN VITRO* LPS OR SILICA EXPOSURE.

P. C. Zeidler, V. A. Robinson and V. Castranova. *NIOSH, Morgantown, WV.*

The role of nitric oxide (NO) in pulmonary disease has been controversial with both anti-inflammatory (scavenging radicals and inhibiting NF-κB activation) and pro-inflammatory (forming highly reactive peroxynitrite and augmenting NF-κB activation by inflammatory agents) actions reported. Therefore, a project has been initiated to determine whether deletion of the iNOS gene in the C57BL/6J mouse alters the pulmonary response to lipopolysaccharide (LPS) or silica. The objective of the initial phase of this study was to determine the responsiveness of alveolar macrophages (AM's), harvested from naive wild type (WT) or iNOS knockout (KO) mice, to an *in vitro* LPS or silica exposure. Primary AM's were obtained by bronchoalveolar lavage from age and weight matched iNOS KO and WT mice. The cells were treated with IFN-γ (50 U/ml), IFN-γ (50 U/ml) plus LPS (1μg/ml), LPS (0.01 -100 μg/ml), or silica (25 - 250 μg/ml). Inflammatory parameters included: NO, tumor necrosis factor-α (TNF-α) and macrophage inflammatory protein-2 (MIP-2) production, and intracellular generation of hydrogen peroxide and superoxide. Data show a significant increase in NO production upon exposure to IFN-γ +/- LPS in the WT but not iNOS KO AM's. NO production by KO or WT AM's was not increased by *in vitro* exposure to LPS or silica alone. LPS, but not silica, induced TNF-α and MIP-2 production with the KO AM's being more responsive than WT. Basal intracellular production of hydrogen peroxide and superoxide was significantly greater in KO compared to WT AM's. In addition, LPS (10 μg/ml) or silica (100 μg/ml) stimulated intracellular oxidant production was lower in KO AM's. In conclusion, when compared to WT AM's, iNOS KO AM's exhibit a decreased ability to generate reactive oxygen species in response to LPS or silica. However, iNOS KO AM's exhibit enhanced inflammatory cytokine and chemokine production in response to LPS.

1732 EFFECTS OF OIL COMBUSTION EMISSION EXPOSURE ON ACUTE LUNG INJURY AND SUSCEPTIBILITY TO INFECTION IN MICE.

M. Daniels[1], Q. T. Krantz[1], D. L. Costa[1], W. P. Linak[2], C. A. Miller[2], C. King[3] and M. I. Gilmour[1]. *[1]NHEERL, USEPA, Research Triangle Park, NC, [2]NRMRL, USEPA, Research Triangle Park, NC and [3]Arcadis Corp, Research Triangle Park, NC.*

It has been suggested that the increased morbidity and mortality associated with exposure to airborne particulates (PM) is related to materials derived from combustion sources such as gasoline, diesel, oil, wood and coal. The purpose of this project

was to develop a system that allows for the generation of primary combustion particles followed by controlled dilution and conditioning, and subsequent whole-animal inhalation exposure. In these pilot studies a heavy oil # 5 was burned in a residual oil combustor previously shown to produce approximately 150 mg/m3 of PM. The particles were then passed through a 2.2 μM cyclone and diluted with clean ambient air. The resulting PM was then directed to a Hinners animal exposure chamber equipped for continuous monitoring of O_2, Co., CO_2, NO_x, SO_2, as well as total particle concentrations. Mean PM 2.5 concentrations ranged between 2 and 3 mg/m-3 with 40-50 ppm SO_2 and 20-30 ppm NO_x. Balb/C and CD1 mice were exposed to the combustion atmosphere for 4 hrs and immediately and 24 hr later assessed for acute lung injury (both strains) and susceptibility to Streptococcus zooepidemicus infection (CD1 strain). Exposure to the emission atmosphere caused a significant increase in neutrophils and lactate dehydrogenase (LDH) in bronchoalveolar lavage (BAL) of both strains of mice but did not affect levels of protein. Mortality to infection was low in all animals and was not affected by the emission exposure. We conclude that this acute exposure caused mild pulmonary injury and inflammation in a similar fashion to other oxidant pollutants but did not affect host defenses to streptococcal infection. Future studies will determine the relative contribution of gases *versus* particles on these inflammatory responses, and will test whether animals with other forms of cardio-pulmonary disease are further compromised by such exposures. This abstract does not necessarily reflect EPA policy.

1733 COMPARISON OF SINGLE AND MULTIPLE EXPOSURES OF CONCENTRATED AIR PARTICLE (CAPS)ON PATHOPHYSIOLOGIC RESPONSES IN HEALTHY RATS.

M. I. Gilmour, M. Daniels, J. Lehmann, L. Walsh, D. W. Winsett, K. L. Dreher, G. Hatch, U. P. Kodavanti and D. L. Costa. *NHEERL, USEPA, Research Triangle Park, NC.*

Several studies have reported that exposure to CAPS from various cities causes pulmonary inflammation in rats. The purpose of this study was to determine whether CAPS from the Research Triangle Park area could cause similar effects, and to compare responses between single and multiple CAPS exposures. Using a 4 stage Harvard concentrator system which concentrated particles 80-fold, male Sprague-Dawley rats were exposed to CAPS for 4 hours, 3 times a week for 5 weeks. During the last 2 exposures (chamber concentrations of 0.57 and 1.7 mg/m3 respectively), additional groups of animals were exposed to CAPS or clean air and their acute pulmonary inflammatory responses (18 hr post-exposure)were compared to animals which had been exposed for the entire 5 week period. After 2 and 4 weeks of exposure, animals monitored with a Buxco plethysmograph system showed a small exposure-related decline in enhanced pause values, suggesting an alteration in ventilatory function. At necropsy, no changes were apparent in bronchoalveolar lavage levels of protein and LDH. The higher CAPS concentration however, caused an increase in pulmonary alveolar macrophage and neutrophils. This effect seemed to be driven by the last exposure as animals exposed 14 times to CAPS prior to this exposure did not have significantly greater responses. Further, exposure to the lower concentration had no effect indicating either; a Dose-Response effect, or changes in the physico-chemical makeup of the PM over the last 2 exposures. Other significant differences included a decrease in lung ascorbate levels following acute exposure to the higher CAPS concentration, and an acute, transient increase in plasma fibrinogen levels. The data show that acute CAPS exposure causes a dose-dependent pulmonary infiltration of cells, depletion of anti-oxidants, and increased potential for systemic coagulation. These effects did not appear to be worsened with multiple exposures. This abstract does not reflect EPA policy

1734 PARTICULATE 1->3-β-GLUCAN IS THE MORE POTENT FORM FOR INDUCING PULMONARY INFLAMMATION IN RATS.

S. Young, V. A. Robinson, M. Barger, D. G. Frazer and V. Castranova. *Health Effect Laboratory Division, NIOSH, Morgantown, WV.*

1->3-β-Glucans, derived from the inner cell wall of yeasts and fungi, are commonly found in indoor air dust samples and have been implicated in organic dust toxic syndrome. In a previous study, we reported that 1->3-β-glucan (zymosan A) induced acute pulmonary inflammation in rats. The present study investigates which form of 1->3-β-glucans, particulate or soluble, is more potent in inducing pulmonary inflammation. Zymosan A was suspended with 0.25 N NaOH for 30 min, neutralized, dialyzed for 2 days against deionized water, and particulate and soluble fractions collected. Male Sprague-Dawley rats were exposed *via* intratracheal instillation to NaOH-soluble or NaOH-insoluble zymosan A (1.8 mg/ml, 0.26 ml). At 18 hrs post-exposure, various indicators of pulmonary response were monitored, including indicators of lung damage, such as serum albumin concentration and lactate dehydrogenase activity in acellular bronchoalveolar lavage fluid. Inflammation was characterized by an increase in lavageable polymorphonuclear leukocytes (PMN), pulmonary irritation (breathing frequency increase) and oxidant production (nitric oxide and chemiluminescence (CL)). Exposure to the particulate fraction of NaOH-treated zymosan caused a significant increase in all these indicators. In contrast, rats exposed to the NaOH-soluble fraction did not show significant increase for most of these indicators except for albumin, PMN and CL. However, these increases were significantly smaller than with exposure to NaOH-insoluble zymosan. Therefore, the results demonstrate that particulate zymosan A is more potent in inducing pulmonary inflammation and damage in rats than the soluble form of this β-glucan.

1735 VANADIUM-INDUCED PULMONARY INFLAMMATION AND APOPTOSIS IN MICE.

L. Wang[1], D. Medan[2], C. Huang[3], X. Shi[1], R. R. Mercer[1], L. Millecchia[1], V. Castranova[1] and Y. Rojanasakul[2]. *[1]PPRB, NIOSH, Morgantown, WV, [2]School of Pharmacy, West Virginia University, Morgantown, WV and [3]School of Medicine, New York University, New York city, NY.*

Pulmonary exposure to vanadium and vanadium-containing compounds is associated with acute pulmonary inflammation, characterized by a rapid influx of polymorphonuclear neutrophils with a peak response at 6 h and resolution by 3 d. Sodium metavanadate [V (V)] can induce cell apoptosis *in vitro*, but little is known about relationship of V (V) and lung cell apoptosis *in vivo*. We hypothesized that vanadium may induce lung cell apoptosis through reactive oxygen species (ROS) *in vivo* and neutrophil apoptosis is involved in the resolution of vanadium-induced lung inflammation. To test this hypothesis, mice were treated with V (V) or saline control, and the bronchoalveolar lavage (BAL) cells were examined at various times for short-lived free radicals by electron spin resonance (ESR) and for apoptosis using terminal deoxyribonucleotidyl transferase-mediated nick end labeling (TUNEL). Control mouse BAL cells showed no significant free radical activity and only resident alveolar macrophages in the BAL fluids with no evidence of apoptosis. In contrast, V (V) induced a greater level of free radicals and caused apoptosis of BAL cells which are predominantly neutrophils. Catalase blocked both free radical generation and apoptosis induced by V (V). The number of apoptotic cells gradually increased and reached a maximal level by 24 h where it subsequently declined. After 24 h when the vanadium-induced lung inflammation was in the resolution phase, we observed an increased influx of macrophages and their engulfment of apoptotic bodies in the BAL fluid. At 72 h when the total number of neutrophils fell to the baseline level, remnants of apoptotic bodies could still be seen in the cytoplasm of macrophages. We conclude that (1): ROS, like H_2O_2, are one of causes of apoptosis induced by vanadium; (2): apoptosis of neutrophils and clearance by macrophages is an important mechanism in the resolution of vanadium-induced lung inflammation.

1736 SYMPATHETIC NERVOUS SYSTEM PLAYS A MAJOR ROLE IN ACUTE COLD/RESTRAINT STRESS INHIBITION OF HOST RESISTANCE TO *LISTERIA MONOCYTOGENES*.

L. Cao, N. M. Filipov and D. A. Lawrence. *Toxicology, Wadsworth Center, Albany, NY.*

Multiple studies have demonstrated that both glucocorticoids and norepinephrine (NE) can modulate immune responses *in vitro* and *in vivo*, and it is well known that the sympathetic nervous system innervates both primary and secondary lymphoid organs. Here, we show that acute cold/restraint stress (ACRS) significantly lowers host resistance to *Listeria monocytogenes* (*LM*) in BALB/c mice, and the involvement of stress hormones corticosterone (CORT) and NE is evaluated. CORT and NE were investigated by pretreating mice with the CORT synthesis inhibitor metyrapone and the chemical sympathectomy drug 6-hydroxydopamine (6-OHDA), respectively. *LM* burdens were determined 3 days post-infection. 6-OHDA significantly decreased the *LM* burden in both control and stressed animals. 6-OHDA also completely blocked the stress effects observed in spleens while only partially affecting the liver. The 6-OHDA-uptake inhibitor desipramine confirmed that peripheral sympathetic adrenergic nerves and NE depletion and not the nonspecific 6-OHDA toxicity were responsible for the enhanced host defense. In contrast, metyrapone-treated animals had further decreased host resistance to *LM* after ACRS. The results suggest that the peripheral sympathetic nervous system (SNS) postganglionic neurotransmitter NE plays a major role in *LM* host resistance, but there are significant tissue-dependent effects after ACRS, while CORT provides a potential protective effect after ACRS. Altogether, stress hormones play important roles in stress-modulated host resistance and NE is a major hormone involved in ACRS-induced suppression of host resistance in the spleen but not the liver. (Supported by NYSDOH and NIEHS ES15-3506A).

1737 *ASPERGILLUS VERSICOLOR* ISOLATED FROM INDOOR AIR OF A MOISTURE-DAMAGED BUILDING PROVOKED ACUTE INFLAMMATION IN MOUSE LUNGS.

J. Jussila[1], H. Komulainen[1], K. Huttunen[3], M. Roponen[3], A. Hyvärinen[1], V. M. Kosma[2], J. Pelkonen[3,4] and M. R. Hirvonen[1]. Sponsor: M. Viluksela.

Moisture related microbial growth in buildings is associated with respiratory symptoms and inflammatory reactions. *Aspergillus versicolor* is a mycotoxin producing fungus detected in the air and materials of water-damaged buildings. We investigated the dose-response and time course of the effects induced by the spores of *A. versicolor*, isolated originally from indoor air of a moisture-damaged building, after a single intratracheal dose instilled into NIH/S mouse lungs. In dose-response study ($1x10^5$, $1x10^6$, $5x10^6$, $1x10^7$ and $5x10^7$ spores) lungs were lavaged at 24 hours, and in time course study ($5x10^6$ spores) at time points 6 h, 24 h, 3 d, 7 d, 14 d, 21 d and 28 d. The concentrations of the cytokines (tumor necrosis factor alpha (TNFα) and interleukin (IL)-6) in bronchoalveolar lavage fluid (BALF) were measured by ELISA method, total cell number was counted by the Trypan blue exclusion method, and cell differentials were determined from cytospin plates. The spores caused dose- and time dependent increase in both TNFα and IL-6 concentrations. Both cytokines peaked at 6 h, and the responses were over by 3 days. The number of neutrophils peaked at 24 h, and practically leveled off by 3 days. Macrophages peaked at 3 and lymphocytes at 7 days. Lymphocyte response was transient, but macrophages remained at a slightly higher level until the end of the study. Our results suggest that *A. versicolor*, isolated from a moldy building, is able to cause an acute inflammation in mouse lungs. (Supported by the SYTTY Programme, Academy of Finland.)

1738 CYCLOOXYGENASE-2 INHIBITION DOES NOT AFFECT MONONUCLEAR PHAGOCYTE FUNCTION.

W. J. Komocsar[1], A. Crosbie[1], J. Stapleton[1], K. McGehee[1], K. Kowalkowski[1], V. L. Peachee[2], K. L. White, Jr.[2], K. N. Khan[1] and S. M. Furst[1]. [1]*G.D. Searle & Co., Skokie, IL and* [2]*ImmunoTox, Inc., Richmond, VA.*

Two isoforms of cyclooxygenase (COX), COX-1 and COX-2, catalyze the production of prostaglandins (PGs) involved in various physiologic and pathophysiologic processes. COX-2 is the only isoform induced at the site of inflammation and is responsible for the generation of pro-inflammatory PGs. It is not known whether inhibition of COX-2 at the site of inflammation will affect primary inflammatory cell functions. Therefore, a series of *in vitro* and *in vivo* studies were conducted to evaluate the functional capacity of mononuclear phagocytes following treatment with a selective COX-2 inhibitor (SC-58236) and a non-selective COX inhibitor (naproxen sodium). The *in vitro* studies evaluated the effects of these drugs (1, 10, or 100μM) on the capacity of rat peritoneal macrophages to phagocytose opsonized *S. aureus* coated bioparticles. Cytochalasin B, a microfilament disruptor, was used as a positive control. The *in vivo* study evaluated the functional activity of tissue-specific macrophages by monitoring the clearance of ^{51}Cr-labeled sheep erythrocytes (sRBC). Female B6C3F1 mice were treated orally for 3 days with vehicle or 3, 10, and 30 mg/kg SC-58236 or naproxen sodium. Maleic vinyl ether was used as positive control. Peripheral blood clearance of labeled sRBC was monitored for 60 minutes, then the animals were sacrificed, exsanguinated, and liver, kidney, spleen, lungs, thymus, skin, intestine and kidneys were removed and analyzed for radioactivity. The *in vitro* data showed no effect at any concentration with SC-58236 and a statistically significant inhibition of phagocytosis at all naproxen sodium concentrations tested. The *in vivo* study showed no effect of SC-58236 or naproxen sodium on phagocytic indices (organ weights, %uptake or total counts/mg tissue). Collectively, these data indicate that COX-2 is not involved in the phagocytic function of macrophages and that its inhibition at the site of inflammation does not affect the primary phagocytic activity of inflammatory cells.

1739 PERIPHERAL BENZODIAZEPINE RECEPTOR (PBR) EXPRESSION AS A MARKER OF LIPOPOLYSACCHARIDE (LPS)-INDUCED INFLAMMATION.

M. J. Hardwick, M. K. Chen, K. Baidoo and T. R. Guilarte. *Environmental Health Sciences, Johns Hopkins University, Baltimore, MD.*

Inflammatory diseases afflict millions of people each year. The ability to visualize the immune response with compounds targeted to immune cells will enhance our understanding and diagnosis of inflammatory disease. PBR is present in neutrophils and monocytes, as well as in microglia, the macrophages of the brain. Specific PBR ligands have been used to visualize brain tumors and inflammation using non-invasive imaging techniques such as positron emission tomography. To further develop the use of PBR as a non-invasive marker of inflammation, we used LPS as a model of inflammation in mice. Mice were injected with 0, 10, or 30mg/kg LPS. Two days later, mice were injected with the PBR specific radioligand 123I-(R)-PK11195. Static planar images revealed increased radioactivity in the chests of both 10 and 30mg/kg LPS animals (48±13% and 161±24%, respectively) above control levels. Immediately after the scan, animals were sacrificed and various organs harvested. In the heart, gamma counting revealed significant increases in radioactivity for both 10 and 30mg/kg LPS above controls (86±30% and 232±31%, respectively; $p<0.05$). In the lungs and spleen, only the 30mg/kg LPS mice were significantly increased above control levels (191±51% and 272±70%, respectively-$p<0.05$). To determine the specificity of the PBR response, 30mg/kg LPS mice were treated with excess non-radioactive (R)-PK11195 30 minutes prior to tracer injection. Static planar images revealed that activity in the chest of blocked animals was lower than in 30mg/kg animals (decreased 31±5%, $p=0.013$). Gamma counting revealed that specific tracer activity in the blocked animals was decreased in the lungs (39±7%; $p=0.023$) and spleen (54±6%; $p=0.012$). These data show that LPS induces specific increases in PBR ligand binding in the lungs and spleen. Further, this study indicates that PBR expression is a promising non-invasive marker for imaging inflammatory responses. [supported by grant # ES07062 to TRG]

1740 CRISTOBALITE AND αQUARTZ SILICA ACTIVATES NF-κB-DEPENDENT GENE TRANSCRIPTION IN MOUSE MACROPHAGES.

S. Mowbray[1], C. Giardina[2], J. J. Helble[3] and A. K. Hubbard[1]. [1]*Pharmaceutical Sciences, University of Connecticut, Storrs, CT,* [2]*Molecular & Cell Biology, University of Connecticut, Storrs, CT and* [3]*Chemical Engineering, University of Connecticut, Storrs, CT.*

Exposure *in vitro* of mouse macrophages to inorganic particles increases expression of several inflammatory cytokines whose promoter regions contain binding sites for specific transcription factors. Past studies by others have demonstrated the ability of crystalline silica particles to induce transactivation of the transcription factor, NF-κB (Rojanasakul et al; Mol Cell Biochem 200:119, 1999). However, few studies have evaluated particle characteristics responsible for this effect. To investigate if two forms of crystalline silica, αquartz and cristobalite, or amorphous silica (all ~1um) could activate NF-κB dependent gene transcription in mouse macrophages, RAW264.7 cells were transiently transfected (DEAE/chloroquine) with an NF-κB luciferase construct. The following day, cells were exposed to increasing concentrations of particle (6, 12 or 25 ug/cm^2) for 8 or 24 hrs. Both αquartz and cristobalite increased gene transcription by approximately 2 fold with a maximal activation at 25 ug/cm^2 for 8 hrs. Activation was specific for crystalline silica since exposure of cells to amorphous silica did not activate NF-κB dependent gene transcription. These data suggest that particle characteristics may influence transcription factor activity altering cytokine expression and eventual cell activation. (Funded by ES NIH09433).

1741 INHIBITION OF TNFα PROMOTER/ENHANCER ACTIVITY BY PHENOLIC ANTIOXIDANTS.

K. L. Kinneer[1], J. Ye[2] and Q. Ma[1]. [1]*HELD/TMBB, CDC/NIOSH, Morgantown, WV and* [2]*Pennington Biomedical Research Center, Louisiana State University, Baton Rouge, LA.*

Exposure to occupational chemicals often elicits inflammatory responses, resulting in tissue damage and disease. The cytokine Tumor necrosis factor alpha (TNFα) is an important mediator in the early stages of inflammation and plays an essential role in many inflammatory diseases. Certain phenolic antioxidants exhibit anti-inflammatory activity and thereby protect against chemical toxicity. The mechanism of anti-inflammation by the antioxidants is largely unclear. In a previously study, we demonstrated that phenolic antioxidants block signal-induced TNFα protein and mRNA production in macrophage cells. In this study, we further investigate the molecular mechanism of this inhibition by analyzing the effect of the antioxidants on the promoter/enhancer activity of TNFα. We used a stable reporter cell line that expresses luciferase under the control of TNFα promoter/enhancer for measuring TNFα gene transcription. The data reveal that bacterial endotoxin LPS induces luciferase production and tert-butylhydroquinone (tBHQ), a prototype of phenolic antioxidants, blocks this induction in the cell. The inhibition is both time- and dose-dependent. Inhibition of LPS-induced transcription of TNFα by diphenols (hydroquinone, HQ; catechol, and resorcinol) correlates with their capacity to undergo redox cycling. Furthermore, tBHQ and HQ blocked LPS-induced H_2O_2 generation within the cell, while resorcinol did not. Treatment with N-acetyl-cysteine, a general ROS inhibitor, blocks LPS-induced luciferase expression similarly. Taken together, these findings demonstrate phenolic antioxidants inhibit TNFα gene transcription and implicate redox cycling in the inhibition.

1742 EFFECTS OF INHALED CARBON BLACK PARTICLE OVERLOAD ON CYTOKINE, OXIDANT, AND MUTATIONAL RESPONSE IN THE LUNG: A SPECIES COMPARISON.

J. M. Carter[1], G. Oberdorster[2], A. C. Elder[2], K. A. Singh[1] and K. E. Driscoll[1]. [1]*Central Product Safety, Procter & Gamble, Cincinnati, OH and* [2]*Environmental Medicine, University of Rochester, Rochester, NY.*

Increased levels of adenomas and carcinomas in the rat lung have been associated with chronic inhalation to poorly soluble low toxicity particles at levels that cause persistent, marked inflammation. This response appears to be unique to the rat species and has not been observed in mice, or hamsters. Substantial evidence indicates this species specific lung tumor response is from a secondary, non-genotoxic, inflammatory mechanism. The recruitment of neutrophils during the inflammatory response and their subsequent release of oxidants from these cells have been demonstrated to play an important role in the pathogenesis of lung tumors. To investigate mechanisms underlying species specific lung inflammation and its persistence, female Fisher 344 rats and B6C3F1 mice were exposed to air, 1, 7 and 50mg/m3 of carbon black for 13 weeks. Serial sacrifices were performed immediately, 3 months and 11 months post exposure. Bronchoalveolar lavage (BAL) was performed and characterized for cell number, type, oxidant and antioxidant levels. *ex vivo* mutational analysis of inflammatory cells was evaluated by co-incubating with a lung epithelial cell line (RLE). Additionally, lung tissue was evaluated for gene expression and enzyme activity of various pro- and anti- inflammatory mediators. There was a dose and time related effect with all the parameters evaluated for both species. Rats showed a greater propensity for generating a pro-inflammatory response while mice demonstrated an increased anti-inflammatory response. These differences in the pro- and anti-inflammatory response may contribute to the apparent species differences in tumor response. Sponsored by the International Carbon Black Association.

1743 COMPARATIVE DOSE-RELATED EFFECTS IN THE LUNGS OF RATS AND MICE FOLLOWING CARBON BLACK INHALATION.

A. Elder[1], N. Corson[1], R. Gelein[1], P. Mercer[1], K. Nguyen[1], J. Finkelstein[2], J. Harkema[3], K. Driscoll[4] and G. Oberdorster[1]. [1]*Environmental Medicine, University of Rochester, Rochester, NY,* [2]*Pediatrics, University of Rochester, Rochester, NY,* [3]*Michigan State University, East Lansing, MI and* [4]*Proctor and Gamble Company, Cincinnati, OH.*

High concentrations of inhaled carbon black (CB) induce overload-associated lung tumors in rats, but not mice or hamsters. The specificity of this response is not related to direct genotoxicity of CB particles, but may be related to species-dependent activation and progression of inflammatory and proliferative processes. In order to examine particle dose-related inflammation, responses to inhaled CB (1, 7, 50 mg/m^3, 13 wks) in the post-exposure phase have been compared in female F-344 rats and B6C3F1 mice. At the end of exposure, mice had retained more CB per gram of lung in terms of particle surface area than rats; however, clearance was slower in rats such that the CB burden in the high-dose group was higher than in mice 11 months post-exposure. Throughout the post-exposure phase, CB-induced increases in lung weights were comparable in rats and mice. For the low- and mid-dose groups, increases in total lavageable cells were also comparable in the two species; however, the total cell increases after high-dose CB in rats was greater and more prolonged. Lavage neutrophils increased in both species in response to mid- and high-dose CB; however, the response to the highest dose was ~3-10 times greater in rats than in mice. Increases in biochemical indices of inflammation were comparable in rats and mice at the two lower doses, but higher in rats at the highest dose. The results suggest that the lowest exposure dose of 1 mg/m^3 CB did not have any adverse effects in either species. In addition, rats appear to have greater and more prolonged inflammation in response to high-dose CB as well as retain CB longer. Funded by the International Carbon Black Association.

1744 INVESTIGATIONS ON THE INFLAMMATORY AND GENOTOXIC LUNG EFFECTS OF TWO TYPES OF ULTRAFINE TITANIUM DIOXIDE - UNTREATED AND SURFACE TREATED.

B. Rehn[1], F. Seiler[1], J. Bruch[1] and M. Maier[2]. [1]*Institute of Hygiene and Occupational Medicine, University of Essen Medical School, Essen, Germany and* [2]*Aerosil & Silanes, Degussa AG, Hanau-Wolfgang, Germany.* Sponsor: J. Barter.

TiO2 is considered to be toxicologically inert, at least under non-overload conditions. There is discussion about enhanced toxicity of ultrafine particles, independent of the particle chemistry. Therefore, we investigated inflammatory and genotoxic lung effects of two types of ultrafine TiO2 at low doses relevant for working environments. Female Wistar rats were exposed by instillation to a single dose of 0.15, 0.3, 0.6, and 1.2 mg of ultrafine TiO2 (P25, untreated) or ultrafine TiO2 (T805, surface treated) particles suspended in 0.2 ml of physiological saline containing 0.25 % lecithin. As controls, animals were instilled with the vehicle only or with a single dose of 0.6 mg quarz DQ12. 3, 21, and 90 days after exposure, 10 rats per group were sacrificed. In 5 animals bronchoalveolar lavage was performed and inflammatory parameters (cells, protein, TNF-alpha, fibronectin, surfactant phospholipids) were measured. The other animals' lungs were inflated with freezing medium, removed and stored in liquid nitrogen. For immunohistochemical staining, 8 µm frozen sections of the left lobe were cut and stored at -80°C. The sections were used for detection of 8-oxoguanine by a polyclonal antibody. Using a secondary fluorescence labelled antibody, 8-oxoguanine was quantified by image analysis. In the quarz exposed animals, a strong progression in lung inflammatory response was observed. 90 days after exposure, a slight but not significant increase in the amount of 8-oxoguanine in the DNA of lung cells was detected. In contrast, animals exposed to both types of TiO2 showed no signs of inflammation 90 days after exposure. The level of 8-oxoguanine as a marker of DNA damage was comparable to vehicle control, even in the highest dose. The results indicate the inert type of both titanium dioxides because neither any inflammatory nor genotoxic effects could be observed in the hygienic relevant range of doses.

1745 INFLAMMATORY TRANSCRIPT AND PROTEIN PRODUCTION BY CULTURED HUMAN KERATINOCYTES FOLLOWING SULFUR MUSTARD (SM) EXPOSURE.

J. J. Schlager, H. R. Benjamin, K. Ali, A. D. Dodds, C. M. Hofmann, K. L. McGary, B. A. Yentzer, C. S. Phillips, C. R. Braue, J. E. Sistrunk, J. H. Clark, E. G. Midboe and J. F. Dillman. *Applied Pharmacology, USAMRICD, Aberdeen Proving Ground, MD.*

Human skin exposure to SM occurs initially without pain; however, over time, SM produces a painful burn with the loss of adherence of the basal keratinocyte layer to the dermis, which progresses to form large coalescing fluid-filled blisters. The primary changes occurring within the epidermal basal keratinocyte layer producing this loss of attachment are not known. However, in human skin, a strong delayed inflammation response occurs, which we believe enhances blister formation and tissue damage. We were interested in defining the specific inflammation transcript and protein changes produced by cultured human epidermal keratinocytes (HEK) following SM exposure. To focus these studies, we initially probed cDNA blots and produced subtraction libraries with cDNA generated from polyA transcripts isolated at various times (0.5, 1, 2, 4, 8 and 16 hr) after HEK exposure to SM. HEK exposure for these studies was performed either at 25 µM SM, an estimated subvesicating skin exposure, or at 200 µM, a vesicating exposure of SM. Using both techniques, we identified interleukin-8 (IL-8) as the predominant pro-inflammatory transcript up regulated in response to 200 µM SM. Transcripts also found using cDNA arrays were macrophage inflammatory protein-2α (MIP-α) and tumor necrosis factor-α (TNF-α). None of these transcripts was increased at the 25 µM SM exposure. Real-time PCR studies using an exposure range of 12.5-200 µM SM have identified transcript and protein increases in IL-8, TNF-α and MIP-α as early as 1-2 hrs for dose 100 and 200 µM, and the transcripts increase dramatically over time to 8 hr. Studies by ELISA showed parallel findings for protein production. These inflammatory transcript and protein data correlate well to doses estimated to blister skin and define the specific proteins that may be participating in the inflammatory events produced by HEK in exposed skin.

1746 FOUR WEEK INHALATION TOXICITY STUDY WITH NYLON RFP IN RATS.

D. B. Warheit, K. L. Reed, T. Webb and G. L. Kennedy. *DuPont Haskell Laboratory for Health and Environmental Sciences, Newark, DE.*

Groups of male rats were exposed, nose-only to aerosols of Nylon RFP (respirable-sized fiber-shaped particulates) for 4 weeks at concentrations of 0, 4, 15 and 57 f/cc (ratio of RFP: particles 1:10-20). The mean gravimetric counts were 0.6 (low), 2.7 (mid)and 19.6 (high level) mg/m3. The samples containing Nylon RFPs were prepared using flock rotary cutters. Subsequently, the lungs of sham and Nylon-exposed rats were assessed at 24 hrs, 1 week, and 1, 3, 6 and 12 months postexposure (pe) using bronchoalveolar lavage (BAL) and/or lung tissue analyses. Results showed that retained mean lung burdens at 24 hrs pe were 1.8E+07 RFP (high level) 3.4E+06 RFP (mid level) and 4.8E+05 RFP (low level). Mean lengths and diameters of the Nylon aerosol were 9.8 and 1.6 um, respectively. Six months pe, the retained lung burdens were 8.9E+05 RFP(high), 1.9E+05 RFP (mid), and 1.7E+05 RFP/lung (low level). There were no significant increases in lung weights or indications of pulmonary inflammation/cell proliferation in Nylon-exposed animals compared to controls - based on BAL cell differentials, BAL fluid analyses, BrdU cell proliferation (airway and parenchymal) and chemotaxis activity. Greater than 90% of the alveolar macrophages recovered by BAL (high level) contained Nylon RFP or

nonfibrous particulates within their cytoplasm. Interim histopathological analyses have thusfar (thru 6 months pe)revealed no adverse lower pulmonary or upper respiratory effects. These results indicate that 4-week inhalation exposures in rats to concentrations as high as 57 f/cc Nylon RFP produced no significant adverse pulmonary effects. (Study funded by the American Fiber Manufacturers Association).

1747 REMOVAL OF SOLUBLE METALS FROM RESIDUAL OIL FLY ASH BY CHELEX PROTECTED RATS FROM INCREASES IN MORTALITY AND LUNG INJURY AFTER INFECTION.

J. R. Roberts[1], M. D. Taylor[1], A. B. Lewis[2] and J. M. Antonini[1]. [1]*NIOSH, Morgantown, WV and* [2]*WVU, Morgantown, WV.*

Inhalation of residual oil fly ash (ROFA) impairs lung defense in susceptible populations. Bioavailability of soluble transition metals appears to play a key role in compromised lung defense caused by ROFA exposure. We evaluated the effect of soluble metals on lung defense in animals pre-exposed to ROFA followed by pulmonary challenge with a bacterial pathogen. ROFA was collected from Boston Edison, Co., Everett, MA, suspended in saline, incubated for 24 hr at 37°C, and separated into soluble (ROFA-Sol) and insoluble (ROFA-Insol) fractions. A portion of ROFA-Sol was treated with the metal-binding resin, Chelex, for 24 hr at 37°C. Sprague-Dawley rats were intratracheally dosed at day 0 with 1.0 mg/100 g body wt of ROFA-Insol, ROFA-Sol, saline, saline + Chelex, or ROFA-Sol + Chelex. At day 3, $5x10^5$ *Listeria monocytogenes* were intratracheally instilled into rats from each treatment group. At days 6, 8 and 10, left lungs were removed, homogenized, cultured, and colony forming units (CFUs) were counted to assess bacterial clearance. Treatment with ROFA-Sol before infection led to a marked increase in lung injury at all time points after inoculation, and a 50% increase in mortality in comparison to saline control rats. Treatment with ROFA-Insol, saline + Chelex, and ROFA-Sol + Chelex caused no significant increases in lung damage and mortality when compared to control. On day 6, a 34-fold increase in the number of bacterial CFUs was observed for the ROFA-Sol group when compared with saline control. By day 10, the ROFA-Sol group had 3693 times more lung CFUs than saline control, indicating its inability to effectively respond to the infection. None of the other groups had significant impairments in bacterial clearance. In summary, exposure to ROFA-Sol suppressed the lung response to infection. Upon removal of soluble metals from ROFA, there was no alteration in lung defense mechanisms. Soluble metals present in ROFA may play a key role in increased susceptibility to pulmonary infection in exposed populations.

1748 GENERATION OF METAL-INDUCED REACTIVE OXYGEN SPECIES BY RESIDUAL OIL FLY ASH.

J. M. Antonini[1], A. B. Lewis[2], J. R. Roberts[1], S. S. Leonard[1], X. Shi[1] and M. D. Taylor[1]. [1]*NIOSH, Morgantown, WV and* [2]*West Virginia University, Morgantown, WV.*

Inhalation of residual oil fly ash (ROFA) increases pulmonary morbidity in exposed workers. We examined the role of reactive oxygen species (ROS) in ROFA-induced lung injury. ROFA was collected from Boston Edison Co., Everett, MA. ROFA (ROFA-total) was suspended in saline, incubated for 24 hr at 37°C, centrifuged, and separated into soluble (ROFA-sol) and insoluble (ROFA-insol) fractions. The generation of ROS from the ROFA samples was measured by electron spin resonance (ESR). Sprague-Dawley rats were intratracheally instilled with saline, ROFA-total, ROFA-sol, or ROFA-insol (1 mg/100 g body weight). Lung tissue and bronchoalveolar lavage cells were harvested at 4, 24, and 72 hr after instillation. Chemiluminescence (CL) of recovered cells was measured as an index of ROS production, and tissue lipid peroxidation was assayed to assess oxidative injury. Using a spin trap (DMPO), hydroxyl radicals were detected in the ROFA-total sample. Significantly more hydroxyl radicals were measured in ROFA-sol as compared to ROFA-insol. Superoxide anion and hydrogen peroxide were implicated in the production of the hydroxyl radicals. After treatment with the metal chelator, desferrioxamine, the production of hydroxyl radical was greatly diminished. None of the ROFA samples had an effect on CL or lipid peroxidation at 4 hr. Treatment with ROFA-total and ROFA-insol caused significant increases ($p<0.05$) in both CL (at 24 hr) and lipid peroxidation (at 24 and 72 hr) when compared to control. ROFA-sol significantly reduced ($p<0.05$) CL production at 72 hr after treatment and had no effect on lipid peroxidation at any time point. In summary, ROFA, particularly its soluble fraction, generated a metal-dependent hydroxyl radical as measured by cell-free ESR. However, cellular oxidant production and tissue injury were observed mostly with the ROFA-total and ROFA-insol particulate forms. ROS generated by ROFA-sol as measured by ESR appear not to play a major role in the lung injury caused after ROFA exposure.

1749 REMODELING IN HUMAN LUNG IN RELATION TO PARTICLE AND METAL CONTENT.

J. E. Gallagher[1], J. Inmon[1], S. Schlaegle[2], A. Levine[2], T. Rogers[3], J. Scott[1], F. Green[4], M. Schenker[5] and K. Pinkerton[5]. [1]*Human Studies Div., NHEERL USEPA, Research Triangle Park, NC,* [2]*Chem., RJ Lee Group, Monroeville, PA,* [3]*NCSU, Raleigh, NC,* [4]*Path/Chem., U.of Calgary, Calgary, AB, Canada and* [5]*Epid./Prevent.Med., U.of Cal., Davis, CA.*

Little data exists about particle/metal burden in human lung and associated health effects. Remodeling of the terminal and respiratory bronchioles occurs at sites of particle deposition.We extend these findings providing data on particle and metal content in relation to indicators of effect classified by standard diagnostic criteria for 1)chronic bronchitis 2)asthma 3)mineral dust disease and 4)smoking-related disease.Lung autopsies(non-respiratory related deaths)were examined from 40 males from the Central Valley of California.Scanning electron microscopy was used to determine particle dose(No.particles/mg tissue) and inductively coupled plasma emission spectrometry for metal analysis.Lung samples with and without indicators of effect were compared.Significant($p<0.05$)fold increases in no. of particles was observed for indicators of mineral dust disease; (4.0X);lymph node fibrosis; (2.0X) smoking related disease (2.2X). No. of particles were (1.6X) lower in asthmatic lung samples. Regardless of disease state, >90% of the 24, 000 particles analyzed were <2.5 microns, 70% <1.0 and 42% <0.5. Ti, V and Mn were significantly $p<.05$ elevated in mineral dust disease and lymph node fibrosis. Consistent with tobacco contaminants, significant fold increases were shown for Ni(2.9X), Cr(3.6X), and Cd(4.6X)in smoking-related disease lung samples.Elevated metals were not observed in asthmatic lung tissue. Determining fate/dose of particulates in humans is essential for predicting health effects and elucidating the mechanisms of particle induced lung injury.Our data support the association between particle exposure and increased risk of lung disease.Microdisection, histology, evaluation of tissue changes and measurements of internal particle/metal burden provide a means toward establishing dose levels and anatomical sites in human lung required to produce adverse health outcomes.

1750 CARBONYL CONTENT OF DIESEL EXHAUST FROM TWO SOURCES AND POSSIBLE IMPLICATIONS FOR CELL RESPONSES.

J. G. Stonehuerner, L. A. Dailey and M. C. Madden. *Human Studies Division, USEPA, Chapel Hill, NC.*

Diesel exhaust is known to cause health effects including lung inflammation and altered immunological parameters. The diesel exhausts used in our studies were collected into ice-cooled PBS from a diesel engine running at idle speed (DE2A) or at full load (DE5A). Previous work has shown that DE5A causes more cytotoxicity and greater increases in levels of inflammatory mediators in cultured human airway epithelial cells than DE2A. Some carbonyls are cytotoxic to epithelial cells and increase inflammatory mediator production. We therefore examined whether the carbonyl content of the exhausts were involved in the epithelial cell responses to diesel exhaust exposure. A method was developed for simultaneous determination of C_2 to C_{12} aldehydes by HPLC/MS. Diesel exhausts were derivatized with 2, 4-dinitrophenylhydrazine and derivatives isolated by hexane extraction and evaporation under nitrogen. Using quantitation of the peak at 365 nm in the UV/VIS spectra as an indication of the total concentration of carbonyl compounds in the reconstituted extracts, DE2A was found to contain a >10X higher level of total carbonyl compounds than DE5A, indicating an inverse correlation between toxicity and total carbonyl content. Reconstituted extracts were injected into an HPLC/MS with a C18 column using ESI negative ion detection with selective ion monitoring. HPLC/MS results were consistent with the UV/VIS result in that levels of polar aldehydes with retention times (R_T) similar to C_2 to C_4 averaged ~10X higher concentration in DE2A than in DE5A. However, DE5A contained higher levels of aldehydes of intermediate polarity with R_T similar to C_7 to C_{10} than did DE2A. These data suggest that diesel-derived carbonyls of intermediate polarity may be important in epithelial cell-mediated responses. These observations underscore the importance of sensitive and selective analytical methods such as HPLC/MS in linking components of complex mixtures to biological effects. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

1751 DIFFERENTIAL PERSISTENCE OF ALVEOLITIS AND EPITHELIAL PROLIFERATION IN THE LUNGS OF RATS AND MICE EXPOSED TO CARBON BLACK.

M. Ambo[1], J. R. Harkema[1], J. K. Golding[1], A. C. Elder[2], K. E. Driscoll[3] and G. Oberdorster[2]. [1]*Michigan State University, East Lansing, MI,* [2]*University of Rochester, Rochester, NY and* [3]*Procter & Gamble Pharmaceuticals, Mason, OH.*

Rats, but not mice, chronically exposed to high levels of airborne carbon black particles (Cb) or other low toxicity particles develop lung tumors in association with chronic alveolar inflammation and epithelial proliferation. The purpose of the present study was to determine the postexposure persistence of alveolitis and type II cell

proliferation in the lungs of rats and mice similarly exposed to Cb. Female F344 rats and B6C3F1 mice were exposed by inhalation to three concentrations of Cb (1, 7, 50 mg/m3) for 6 h/day, 5 days/wk, for 13 wk. Rodents were sacrificed one day or 13 wk postexposure (PE). The left lung lobe of each animal was processed for light microscopy. Numeric cell densities of alveolar type II cells and neutrophils were determined using image analysis and standard morphometric techniques. Compared to air-exposed controls (0 mg/m3 Cb), rats exposed to Cb had a dose-dependent increase in numeric cell densities of neutrophils (alveolitis) and alveolar type II cells (epithelial hyperplasia). Cb-induced type II cell proliferation persisted throughout 13 wk PE only in the lungs of rats that were exposed to 50 mg/m3 Cb. In contrast, no or minimal Cb-induced alveolitis was evident in Cb-exposed mice at one day or 13 wk postexposure. A minimal increase in the number of alveolar type II cells was evident only in mice exposed to 50 mg/m3 Cb and sacrificed 13 wk PE. These results indicate that rats, but not mice, chronically exposed to high airborne concentrations of Cb develop severe and persistent alveolitis and epithelial proliferation for at least 13 wk PE. No persistent lung lesions were observed in mice or rats exposed to 1 mg/m3 Cb. (Research sponsored by the International Carbon Black Association)

1752 PARTICLE NUMBER AND SURFACE CHARGE PREDICT THE BIOLOGICAL ACTIVATION OF HUMAN BRONCHIAL EPITHELIAL CELLS EXPOSED TO PARTICULATE MATTER.

B. Veronesi[1], G. Wei[1], W. Bernt[2] and M. Oortgiesen[3]. *[1]NHEERL, USEPA, Research Triangle Park, NC, [2]PCL, Novato, CA and [3]Cato, Research Triangle Park, NC.*

Exposure to particulate matter (PM) produces a uniform degree of mortality in exposed populations, in spite of its diverse sources. This suggests a common mechanism of action to explain its initial toxicity. The present study relates certain physicochemical characteristics (i.e., size, number, surface charge, acidity) of PM particles to their biological activation (i.e., increases in intracellular calcium, $[Ca^{2+}]_i$, IL-6 release) in human, immortalized, tracheal bronchial epithelial cells (BEAS-2B). Urban ambient, volcanic, occupational and industrial PM were examined in suspension and after being passed through a 0.22 μm pore size, cellulose-acetate filter. The size, number and surface charge (i.e., zeta potential) of PM suspensions and their microfiltrates were measured using ZetaPALs technology. Linear regression analysis correlated the IL-6 release caused by field PM and their microfiltrates with their physicochemical characteristics. Of all of these, the surface charge (i.e., zeta potential) of particles in the suspended and microfiltrate fractions strongly correlated with the IL-6 released of their respective exposures. Similarly, the counts of microfiltrate particles also significantly correlated with IL-6 release associated with these fractions. To test whether the surface charge alone could stimulate cytokine release, polystyrene beads (SPM) of low and moderate zeta potentials were obtained. Exposing cells to 12-60 $\mu g/cm^2$ concentration of SPM produced IL-6 release similar to PM which was sensitive to CPZ exposure, an antagonist of the VR1 irritant receptor. RT-PCR indicated that the charged BEADS activated the acid sensitive, VR1 receptor of the BEAS-2B cells. Together, these data suggest that the surface charge of particles can stimulate a measurable biological response in human respiratory target cells. (This abstract has been reviewed by NHEERL but does not necessarily reflect EPA policy).

1753 A TYPICAL PATH MODEL OF TRACHEOBRONCHIAL CLEARANCE OF INHALED PARTICLES IN RATS.

E. C. Kimmel, J. E. Reboulet and R. L. Carpenter. *Naval Health Research Center Toxicology Detachment, WPAFB, OH.*

A typical path model of tracheobronchial (TB) particle clearance was developed using previously reported deposition model airway anatomy (Kimmel et al, 1998, Carpenter and Kimmel, 1999). Particle transport velocities for a typical airway in each generation were extrapolated from mean tracheal mucous transport velocities (TMV) using allometric equations describing the relationships between TMV and airway surface area, diameter, and length. Published interspecies allometric equations were modified to use theoretical (dimensional) exponents, indicating a greater degree of sameness, for intraspecies extrapolations. Multi-component clearance rate equations describing a typical clearance path from each generation of airways were developed. Consideration was given to conservation of mucous flow between airways. Overall TB region clearance was calculated by applying these clearance rate equations to the predicted fraction of aerosol particles deposited in corresponding airways generations. Predicted short-term clearance half-lives were 4.45, 6.42, and 20.97 hrs for aerosols in which theoretical deposition was 100, 80, and 50 % distributed evenly throughout the TB region. Although these initial predictions were in general agreement (within 15%) with published data they systematically overpredicted clearance. Adjustments of model clearance velocities for airway size dependent differences in mucous thickness and density and comprehensive comparison of model predictions with published data will be presented.

1754 THE EFFECT OF SIZE FRACTIONATED PARTICULATE MATTER ON HUMAN AIRWAY EPITHELIAL CELLS *IN VITRO*.

L. A. Dailey[1], C. Sioutas[2], J. M. Soukup[1], S. Becker[1] and R. B. Devlin[1]. *[1]NHEERL, USEPA, Research Triangle Park, NC and [2]Civil and Environmental Engineering, USC, Los Angeles, CA.*

Epidemiologic studies have demonstrated a compelling causal relationship between episodes of high concentrations of particulate matter (PM) and adverse health effects to the human respiratory and cardiovascular system, as evidenced by increased hospitalizations and mortality. Many factors have been implicated in the toxicity of PM, including particle size, number and constituents. Advances in technology now allow researchers to simultaneously collect, concentrate, and size fractionate coarse, fine, and ultrafine ambient air particulates. We have collected Chapel Hill ambient air PM in the following size ranges: coarse (CS) 2.5-10 micron, fine (FN) 0.1- 2.5 micron, and ultrafine (UF) <0.1 micron and examined their effects on human primary airway epithelial cells *in vitro* . Cells were exposed to 25, 100, and 250 ug/ml doses of each PM fraction for 2 and 24 hours. LDH and the inflammatory cytokine IL-8 were measured. Preliminary studies show that all three fractions elicit a dose-dependent response at 24 hours. When airway epithelial cells were exposed to different PM fractions on an equal mass basis, CS and UF fractions appeared to induce a larger cytokine response than FN particles. At 250 ug/ml, the highest dose examined, cells exposed to CS PM had approximately 4.3 fold greater IL-8 production than untreated cells; cells exposed to UF had 3.7 fold increased IL-8, while cells exposed to FN PM had 2.5 fold increased IL-8 compared to untreated cells. Similarily, human alveolar macrophages exposed 18 hours to 10 ug/ml CS and FN PM showed a far greater IL-6 cytokine production in response to coarse PM than fine PM (81.2 vs 7.8 fold increases compared to control). These studies suggest that coarse PM particles can induce increased inflammatory mediators in important lung cell types. [This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.]

1755 cDNA MICROARRAY ANALYSIS OF GENE EXPRESSION IN RAT ALVEOLAR MACROPHAGES IN RESPONSE TO ORGANIC EXTRACT OF DIESEL EXHAUST PARTICLES.

E. Koike[1,3], S. Hirano[2] and T. Kobayashi[3]. *[1]Department of Medicine, University of Tsukuba, Tsukuba, Japan, [2]Research Center for Environmental Risk, National Institute for Environmental Studies, Tsukuba, Japan and [3]Environmental Health Sciences Division, National Institute for Environmental Studies, Tsukuba, Japan.*

Diesel exhaust particles (Department) induce pulmonary diseases including asthma and chronic bronchitis. The comprehensive evaluation has been required to know the effects of air pollutants including Department on the lung diseases. Alveolar macrophages (AM) encounter and phagocytose Department in the alveolar space and their biological responses are implicated in Department-induced pulmonary diseases. Therefore, we investigated the gene expression in rat AM after exposure to Department extract using a cDNA microarray. AM were prepared from male Sprague-Dawley rats (8-10 w) by bronchoalveolar lavage. The Department extract was prepared using dichloromethane. AM were pre-cultured for 20 h and exposed to 10 μg/ml Department extract for 6 h. Total RNA was extracted from AM using TRIZOL. cDNA probe synthesis and cDNA microanalysis were carried out using an Atlas Pure Total RNA Labeling System and Atlas Rat Toxicology Array II (CLONTECH) that includes 450 rat cDNAs. The results were further confirmed by northern blot analysis. Transcriptions of 6 genes on the cDNA microarray were significantly elevated by exposure to Department extract. These were heme oxygenase (HO) 1 and 2, thioredoxin peroxidase 2 (TDPX-2), glutathione S-transferase P subunit (GST-P), NAD(P)H dehydrogenase, and proliferating cell nuclear antigen (PCNA). The antioxidative enzymes such as HO, TDPX-2, GST-P, and NAD(P)H dehydrogenase may play a role in the pulmonary defense against oxidative stress caused by Department. PCNA may have contributed to the repair of the DNA damage and cell proliferation. Our results suggest that cDNA microarray analysis provides useful information to investigate the biological response to pulmonary toxicants.

1756 EFFECT OF EXTRACT OF PARTICULATE MATTER UNDER 2.5μM (PM2.5) AND DIESEL EXHAUST PARTICULATE (DEPARTMENT) ON RESPIRATORY AND CARDIAC FUNCTION IN SPONTANEOUSLY HYPERTENTION RATS.

M. K. Iijima[1], R. Maruyama[2] and T. Kobayashi[3]. *[1]Department of Medicine, Tsukuba University, Tsukuba, Japan, [2]School of Nursing, Miyagi University, Miyagi, Japan and [3]Environmental Health Sciences Division, National Institute for Environmental Studies, Tsukuba, Japan.* Sponsor: S. Hirano.

Epidemiological studies have shown the association between the morbidity and mortality of populations with preexisting cardiopulmonary disease and concentration of PM2.5. The present study was designed to clarify the effect of instillation of

PM2.5 on respiratory and cardiac function in rats with hereditary systemic hypertension. Male spontaneously hypertensive (SH) rats and Wistar/kyoto (WKY) rats, control strain, (11-12weeks old, 8/group) were used. Rats were operated to insert electrode subcutaneously. One week after, they were anesthetized with halothane, and were instilled intratrachealy with PM2.5 extract or Department extract (3mg/kg) in DMSO-PBS solution. Pulmonary function and electrocardiogram were measured at 3h before, 3h and 24h after instillation. R-R interval, power spectra of low frequency (LF) and high frequency (HF) were analyzed from electrocardiogram. LF/HF ratio and HF contents are indices of sympathetic and parasympathetic nervous activities, respectively. Lung resistance increased in SH and WKY rats administrated with PM2.5 or Department extract. In SH rats administrated with PM2.5, R-R interval extended, HF increased, but LF/HF didnÕt change. In WKY rats administrated with PM2.5, HF tended to increase, but R-R interval and LF/HF didnÕt change. Department, however, R-R interval, HF and LF/HF were not changed by Department in both SH and WKY rats. In conclusion, PM2.5 decreased heart rate and increased parasympathetic nervous activity in SH rats. Our results suggest that populations preexisting hypertension might be susceptible to PM2.5.

1757 LONG-TERM CARCINOGENICITY STUDY OF MAN MADE FIBERS BY INTRAPERITONEAL ROUTE IN RATS.

J. Richard[1], R. Forster[1], M. Attia[1], H. G. Grimm[2] and A. de Reydellet[3]. [1]*CIT, Evreux, France,* [2]*Consultant, Braunschweig, Germany and* [3]*St. Gobain, Paris, France.*

The assessment of carcinogenicity of Man Made Fibers (MMF) in rats by the intraperitoneal (i.p.) route has been proposed as an alternative to inhalation studies, which may offer greater sensitivity. We have evaluated the carcinogenic potential of five vitreous MMF using this approach; MMF were administered as 2 to 20 weekly i.p. injections to groups of 51 female Wistar rats in a 123 week study. Crocidolite was used as a reference carcinogenic fiber. The tested fibers (designated M, O, P, V and B) were administered at 2 or 3 dose-levels up to 5 x 10^9 fibers, corresponding to an injected mass up to 400 - 700 mg. Crocidolite was given at dose-levels up to 1 x 10^9 fibers (up to 5 mg). The tested fibers did not produce notable adverse effects on the basis of mortality, clinical signs and body weight, except at the highest dose-level. All the fibers produced non-specific fibrous adhesions between abdominal organs, with dose-related severity; this finding was sometimes associated with chronic peritonitis or hepatocellular necrosis. Interestingly, the incidence of mesotheliomas permitted discrimination between the various fibers: - fibers M and O did not induce any mesothelioma at dose-levels up to 5 x 10^9 fibers; - fibers P and V induced mesothelioma in 16% and 28% of animals respectively at 5 x 10^9 fibers; - fiber B, for which previously published data was also available, induced mesothelioma in 18% of animals; - 90% of the crocidolite-treated animals displayed mesotheliomas at 1 x 10^9 fibers. No fiber-related tumor other than mesothelioma was observed. In conclusion, long-term bioassay in rats with i.p. injection was found to be a suitable and sensitive model which permitted discrimination of the carcinogenic potential of MMF with similar solubility or biopersistence.

1758 *IN VITRO* ASSAY OF THE BIOLOGICAL ACTIVITY OF AMBIENT $PM_{2.5}$ COLLECTED BY A HIGH FREQUENCY AEROSOL SAMPLER.

R. J. Mitkus[1], M. O. Falconer[1], J. L. Powell[1], J. M. Ondov[2] and K. S. Squibb[1]. [1]*Epidemiology and Preventive Medicine, University of Maryland, Baltimore, MD and* [2]*Chemistry and Biochemistry, University of Maryland, College Park, MD.*

Epidemiological evidence suggests that health effects associated with air particulate matter (PM) correlate closely with the $PM_{2.5}$ fraction, which is a highly complex, variable mixture of inorganic ions, elemental carbon, organic carbon compounds, trace elements and water. Local sources in urban environments contribute greatly to the composition of $PM_{2.5}$, thus studies of the specific components within this fraction that contribute to health effects are needed to develop effective control strategies. With this aim, an *in vitro* assay using A549 airway epithelial cells was developed to test the biological activity of $PM_{2.5}$ samples collected over time intervals as short as 1 hr with a recently developed high frequency semi-continuous aerosol sampler (SEAS) (Kidwell, C B and Ondov, J M, Development and Evaluation of a Prototype System for Collecting Sub-Hourly Ambient Aerosol for Chemical Analysis, Aerosol Science Technology 35: 596-601, 2001). Exposure of cells for 24 hr to a SEAS sample collected over a 24 hr period in College Park, MD produced no cytotoxicity (as measured by lactate dehydrogenase release) but particle concentrations from 12.5 to 100 µg/ml induced the release of IL8 in a dose dependent manner. Samples collected hourly at the same location differed over 10 fold in their ability to stimulate IL8 release, which ranged from 22 to 420 pg/ml of media. Cell responses to SEAS samples at 100 ug/ml were similar to those observed using NIST 1648 standard urban particulate matter at 200 µg/ml and 0.3 mM ZnCl2 exposures. Correlation of results of this assay with elemental analysis data for SEAS samples will aid in identifying the role played by trace elements in the toxicity of urban $PM_{2.5}$. *Supported by the Baltimore Supersite Program grant R82806301 and NIEHS Training Grant T32ES07263.*

1759 EFFECTS OF INSTILLED RESIDUAL OIL FLY ASH (ROFA) ON INDICES OF CARDIAC, PULMONARY, AND THERMOREGULATORY FUNCTION IN SPONTANEOUSLY HYPERTENSIVE (SH) RATS.

L. B. Wichers[1], J. P. Nolan[2], U. P. Kodavanti[2], M. C. Schladweiler[2], R. Hauser[3], D. W. Winsett[2], D. L. Costa[2] and W. P. Watkinson[2]. [1]*SPH, UNC, Chapel Hill, NC,* [2]*ORD/NHEERL/ETD/PTB, USEPA, Research Triangle Park, NC and* [3]*SPH, Harvard, Cambridge, MA.*

Epidemiological studies have linked increased levels of ambient particulate matter (PM) with increased morbidity and mortality, noting higher correlations in persons with cardiopulmonary disease. To investigate this phenomenon, we examined the effects of ROFA (a model emission PM) in SH rats (a susceptible disease model). Rats were implanted with radiotelemeters capable of monitoring electrocardiogram (ECG), heart rate (HR), and core temperature (T_{co}). Animals were divided into four groups and exposed *via* intratracheal instillation (IT) to suspensions of ROFA (0.0, 0.25, 1.0, 2.5 mg) in acidified saline vehicle. Telemetered rats were monitored continuously for 96h post-IT and ventilatory function was examined (Buxco Electronics) for 6h/day on postexposure days 1 - 4. At 24h and 96h post-IT, subsets of rats underwent bronchoalveolar lavage (BAL) and the BAL fluid was examined for biochemical indices of pulmonary damage and inflammation. The IT exposures to vehicle and low dose ROFA caused no changes in T_{co}, while mid and high dose ROFA induced substantial decreases (1.2–2.6°C). ROFA-induced decreases in HR (30–120 bpm) did not return to control levels until 24h post-IT (low dose) or 72h post-IT (mid and high dose). ECG abnormalities (rhythm disturbances, premature ventricular contractions) were observed primarily in the high dose group. Adverse changes in BAL indices mirrored the dose-related changes in physiological parameters, yielding increases in protein, albumin, and LDH (24h post-IT>96h post-IT). These studies demonstrate substantial deficits in cardiopulmonary function in SH rats after IT exposure to ROFA PM, along with significant increases in BAL indices of pulmonary injury. Toxicity appears to be greater than that reported previously in healthy rats and comparable to that observed in other compromised rodent models. (Abstract does not represent USEPA policy.)

1760 *IN VITRO* EFFECTS OF PARTICULATE MATTER ON AIRWAY EPITHELIAL CELLS ISOLATED FROM CONCENTRATED AIR PARTICLES-EXPOSED SPONTANEOUS HYPERTENSIVE RATS.

I. Pagan, U. Kodavanti, P. Evansky, D. L. Costa and J. A. Dye. *NHEERL, USEPA, Research Triangle Park, NC.*

Spontaneously hypertensive (SH) rats, a strain with the genetic tendency to develop pulmonary and cardiac disease, are being used as a model to study the health effects of particulate matter (PM). In the present studies male SH rats were subjected to multiple exposures (12 exposures, over a 6 week period, 4 hr/day,) of either filtered air (control), or concentrated air particles (CAPS) from the Research Triangle Park (RTP), NC. Then, primary rat tracheal epithelial (RTE) cell cultures were established from both control and CAPS-exposed rats using an air-liquid interface system. After reaching confluency and maturity, cells were exposed to saline control, or to RTP-PM (PM 1.7-3.7, collected in bulk using a high volume sampler) at either 3.5 or 35 ug/ cm2 of culture area. Toxicity and cell injury were evaluated by lactate dehydrogenase (LDH) released and albumin translocation (index of increased solute permeability). Cell metabolism changes were evaluated by measuring intracellular glutathione (GSH) and ATP levels. RTE cell exposure to RTP-PM did not induce significant changes in LDH released by RTE cells. However, exposure of RTE cells to RTP-PM at 35 ug/ cm2 induced a mild increase in apical albumin levels that was greater in cells originating from CAPS-exposed rats than in cells from control air-exposed rats. RTP-PM exposures also induced decreases in GSH levels in cells originated from either air- or CAPS- exposed SH rats. RTP-PM exposures induced increases in ATP levels in RTE cells from either air or CAPS-exposed SH rats. Alterations of cellular metabolism by CAPS could contribute to the enhanced responses of cardiopulmonary compromised animals to the effects of ambient air pollutants, however more studies are needed to elucidate the extent of these differences. (The contents of this abstract do not necessarily reflect the views and policies of the USEPA).

1761 HEALTH EFFECTS OF CONCENTRATED CALIFORNIA PARTICULATE MATTER IN RATS.

K. R. Smith[1], S. Kim[2], J. J. Recendez[1], C. Sioutas[2] and K. E. Pinkerton[1]. [1]*ITEH, University of California, Davis, CA and* [2]*Civil Engineering, University of Southern California, Los Angeles, CA.*

Epidemiological studies have shown that airborne particulate matter (PM) with an aerodynamic diameter less than 10 microns is associated with increased pulmonary disease. However, particles less than 2.5 microns are thought to elicit the greatest

toxicity. PM is a complex mixture of organic and inorganic compounds, but the properties responsible for its effects on the respiratory system remain unknown. During the fall and winter of 2000-01 adult Sprague-Dawley rats were exposed in Fresno, CA to filtered air or combined ultrafine and fine fractions of PM enhanced approximately 20-fold over ambient levels in 6 separate experiments. Exposures were for 4 hours per day for 3 consecutive days. PM was concentrated while preserving chemical composition, size distribution and surface morphology. PM mass and particle numbers were measured continuously during exposure. Chemical analysis of the concentrated PM was conducted for each study. The mean mass concentration of particles ranged from 200 to 900 micrograms/cubic meter. PM was enriched primarily with nitrate, organic and elemental carbon, and metals. Bronchoalveolar lavage (BAL) was performed on each group of rats following exposure. Viability, total cells, and numbers of macrophages, neutrophils and lymphocytes in the BAL was determined. Viability of BAL cells from rats exposed to concentrated PM was significantly decreased during 4 of 6 weeks, compared to rats exposed to filtered air ($P<0.05$). Total BAL cells were increased during 1 week of the 6-week study, while macrophages increased during 1 week and neutrophils during 2 weeks. The decreased cell viability in PM-exposed rats is indicative of cell membrane damage, possibly through oxidative stress catalyzed by transition metals. The increased neutrophils in PM-exposed rats indicates a mild inflammatory response. These observations suggest that exposure to enhanced concentrations of ambient particles in Fresno, CA is associated with significant effects in the lungs of healthy adult rats.

1762 EVALUATION OF TOXICITY BY OIL FLY-ASHES IN RAT ALVEOLAR EPITHELIAL CELLS: ROLE OF FENTON DRIVEN OH-RADICAL GENERATION AND PARTICLE FRACTION.

P. Borm[1], T. Shi[1], U. P. Kodavanti[2] and R. P. Schins[1]. [1]*Particle Toxicology, Institut für Umweltmedizinische Forschung (IUF), Düsseldorf, Germany and* [2]*Pulmonary Toxicology Branch, NHEERL, USEPA, Research Triangle Park, NC.* Sponsor: P. Kodavanti.

Leachable transition metals are considered to be important mediators in the biological effects of ambient particulate matter (PM) and model particles such as oil-fly ashes (OFA). We determined metal driven Fenton activity in 10 OFA in the presence of hydrogen peroxide using electron spin resonance (EPR) and a suitable spin-trap (DMPO) and their ability to induce 8-hydroxydeguanosine (8-OH-dG) in nude DNA using immunodotblot. In addition, the toxicity of the OFA suspensions and supernatants was determined in a rat alveolar type II cell line using leaching of LDH (membrane damage) or conversion of MTT (mitochondrial function). Suspensions of OFA were consistently more toxic than their filtrates obtained by centrifugation and 0.1 µm filtration. Correlations between both cytotoxicity assays were seen using OFA suspensions ($r=0.862$) but not for the filtrates. The DMPO-OH generation of filtrates in water did correlate well with the cytoxicity assessed by MTT conversion of the filtrate ($r=0.820$) and the formation of 8-OHdG ($r=0.57$). Together these findings suggest that the different fractions of OFA exert cytotoxicity through different mechanisms. This is supported by different effects of filtrate and suspensions on 8-OHdG formation and DNA unwinding. The watersoluble Fenton-active fraction seems to affect mitochondrial competence (MTT), while the membranolytic effects seem to be determined by the total suspensions.(This abstract does not reflect USEPA policy).

1763 COMPARISON OF ASBESTOS FIBER CONTENT IN LUNGS OF CANCER PATIENTS WITH NORMAL KOREAN SUBJECTS WITH NO KNOWN OCCUPATIONAL ASBESTOS EXPOSURE HISTORY.

I. Yu[1], K. Sakai[3], N. Hisanaga[4], H. Chang[2], Y. Lee[2], I. Kwon[6], J. Park[5] and H. Chung[1]. [1]*Center for Occupational Toxicology, Korea Occupatioanl Safety & Health Research Institute, Daejeon, South Korea,* [2]*Dept.of Pathology, Kosin University, Busan, South Korea,* [3]*Nagoya City Public Health Institute, Nagoya, Japan,* [4]*National Institute of Industrial Health, Kawasaki, Japan,* [5]*Dept. of Preventive Medicine, Chung-Ang University, Seoul, South Korea and* [6]*National Institue of Scientific Invdstigation, Busan, South Korea.*

To evaluate the effect of environmental asbestos exposure on inducing lung cancer, pulmonary fiber contents of both asbestos and non-asbestos types were evaluated in 36 normal Korean subjects and 37 lung cancer patients with no known occupational history of asbestos exposure. Pulmonary fiber contents were analyzed by transmission electron microscopy with energy dispersive X-ray analysis after using the low temperature ashing procedure. Chrysotile fiber was the major fiber type found in the lungs of Korean subjects. Asbestos fiber concentrations found in the lungs of normal 25 males and 11 females were 0.23 x 106 fibers/g of dry lungs and 0.15 x 106 fibers/g of dry lung tissue, respectively. Asbestos concentrations found in the lungs of cancer patients were 0.16 x 106 fibers/g of dry lungs for 31 males and 0.45 x 106 fibers/g of dry lungs for 6 females. There was no statistical difference in pulmonary asbestos content between normal and lung cancer patients.

1764 YOU CAN'T DILUTE FRESH COMBUSTION EMISSIONS WITHOUT ALTERING THEIR COMPOSITION.

J. D. McDonald. *Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM.* Sponsor: J. Mauderly.

Recent research has shown that the dilution level can affect the both the particle size distribution and composition of diesel exhaust. This may be important in inhalation toxicology because lung deposition patterns may differ with changes in particle size distribution, and changes in chemistry can lead to non-linear dilutions of all constituents of combustion material such as diesel exhaust. Data reported here were generated during a diesel exhaust inhalation toxicology study conducted at Lovelace Respiratory Research Institute under the auspices of the National Environmental Respiratory Center (NERC). As part of this research, the size distribution and chemical composition of particulate material was investigated at four different dilutions of exhaust. Dilutions with scrubbed ambient air were set to achieve diesel particulate concentrations of 30, 100, 300, and 1000 microgram per cubic meter. Particle size distribution, including number count and mass distribution, were characterized at all exposure levels along with the chemical composition of the particulate material. Particle mass distribution centered at approximately 150nm for all exposure levels, but number distribution was different at all levels, with the highest dilution levels (lowest mass) producing higher amounts of particles in the "nanoparticle" range (<100nm). Particle composition was found to change most at the more concentrated levels, with chemical interactions between nitrogen oxides and ammonia producing higher relative levels of ammonium nitrate/ammonium sulfate particles at low dilution levels. Research conducted by the National Environmental Respiratory Center (NERC) with support from multiple government and industry sponsors, including the USEPA. This abstract is not intended to represent the views or policies of any NERC sponsor

1765 EFFECT OF ULTRAFINE CARBON BLACK EXPOSURE ON RESPIRATORY SYNCYTIAL VIRUS INFECTION IN MICE.

A. L. Lambert, M. P. DeLorme, F. S. Trasti, J. B. Mangum and J. I. Everitt. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Epidemiological studies have indicated that exposure to elevated levels of ultrafine (UF) particulate matter exacerbates a variety of pulmonary diseases, including asthma, bronchitis, and viral infections. Respiratory syncytial virus (RSV) is the most important etiological agent in respiratory diseases of infancy, is the major cause of bronchiolitis and pneumonia in infants under 1 year of age, and may lead to the development of asthma in childhood. RSV also contributes to the development of pneumonia in the elderly and the immunocompromised. To ascertain whether particle exposure modulates the immune response to RSV, we developed a BALB/c mouse model of RSV infection that mimics the pathophysiological and immunological features of RSV disease in humans. For the study, 8 week-old female BALB/c mice were instilled *via* the trachea with either 40 µg UF carbon black (CB) particles or saline vehicle. The following day, mice were instilled with either 10^6 pfu RSV or uninfected media. End points were examined 1, 2, 4, 7, and 10 days after RSV infection. Airways hyperresponsiveness and total IgE in the serum were increased in RSV-infected animals compared to controls and were unaltered by CB exposure. RSV antigen titers in the bronchoalveolar lavage fluid (BALF) and lung homogenates were reduced in RSV+CB-treated mice relative to RSV alone. On days 1 and 2 of infection, TNF-αprotein was reduced in the BALF of RSV+CB mice; on day 4, there was a significant reduction in BALF lymphocyte numbers, which correlated with a reduction in IFN-γprotein in the BALF of RSV+CB mice compared with RSV alone. Ribonuclease protection assays of lung tissue showed reductions in RANTES, eotaxin, MCP-1, MIP-1α, MIP-1β, and IFN-γand increases in IL-6, IL-10, and IL-15 message in RSV+CB mice compared to RSV alone. These data indicate that preexposure to CB particles may stimulate alveolar macrophages and the pulmonary immune response to RSV infection, leading to accelerated viral clearance and less severe disease.

1766 ROLE OF ASSOCIATED TRANSITION METALS IN THE IMMUNOTOXICITY OF INHALED PARTICULATE AIR POLLUTION.

J. T. Zelikoff, K. Schrmerhorn, G. Chee, C. Prophete, M. D. Cohen and R. B. Schlesinger. *Environmental Medicine, New York University School of Medicine, Tuxedo, NY.*

Epidemiological studies demonstrate that pneumonia contributes to increased mortality among individuals following exposure to particulate matter (PM). This suggests that PM acts as an immunosuppressant that undermines normal lung immu-

nity. A 5h inhalation exposure of bacterially-infected rats to concentrated ambient $PM_{2.5}$ from NYC air, altered immune function and exacerbated infection. *S. pneumoniae*-infected rats exposed to PM 48h following bacterial instillation had increased: bacterial burdens; circulating WBC; bacteria-associated lung lesions; and, bacteremia compared to controls. PM exposure also decreased lavageable PMN, cytokines, and BALT. While these results provide a basis for the epidemiological findings, the identity of constituents responsible for the worsening pneumonia remains unclear. To address this, studies were performed to correlate physiochemical attributes of ambient $PM_{2.5}$ with *in vivo* immunotoxicity. Previously-infected or uninfected rats were exposed (nose-only) to soluble forms of Fe, Cu, Mn, or Ni. At designated timepoints, uninfected rats were sacrificed, their lungs either lavaged for levels of cytokines, markers of lung damage, and oxyradicals, or fixed for histology. Blood cell profiles and B- and T-cell proliferation were also examined. In studies employing infected hosts, lungs were assessed for bacterial clearance and analyzed for extent/severity of infection. Results demonstrated that while exposure to Mn and Ni at ~90μg/m^3 had no effect on immunity, inhalation of Fe altered immune function in uninfected hosts and reduced pulmonary bacterial clearance in infected rats. Fe-induced changes in bacterial burdens correlated with elevated blood PMN and increased amounts of pneumococcal-associated lung lesions. Studies demonstrate that exposure to ambient PM worsens the outcome of an ongoing pulmonary infection, and that associated Fe may play a role in this immunotoxicity. EPA R827351 and HEI 95-14.

1767 CORRELATED PULMONARY AND SYSTEMIC EFFECTS IN SPONTANEOUSLY HYPERTENSIVE RATS FOLLOWING ACUTE EXPOSURES TO CONCENTRATED AMBIENT PARTICLES (CAPS).

M. C. Schladweiler, A. D. Ledbetter, L. Walsh, E. Lappi, H. Hilliard, M. J. Gilmour, D. L. Costa, J. Norwood, K. Crissman, G. E. Hatch, J. H. Richards and U. P. Kodavanti. *Pulmonary Toxicology Branch, USEPA, Research Triangle Park, NC.*

The increase in plasma fibrinogen, a risk factor for cardiovascular disease (CVD), has recently been associated with exposures to particulate air pollution (PM) in humans. We have shown a similar pattern of fibrinogen increases in rats exposed to emission PM. The purpose of this study was to ascertain the consistency of the plasma fibrinogen increase following acute CAPS exposures, and its relationship to lung injury in a rat model of CVD. Male Spontaneously Hypertensive (SH) rats (13 wks) were exposed whole body to filtered air (n=4-7) or CAPS (n=5-9) from local air, 4 h/d x 1 d (6 replicates) or 2 d (2 replicates). The estimated daily CAPS concentrations ranged from 700-1800 μg/m3. To assess injury, bronchoalveolar lavage fluid (BALF) protein, n-acetylglucosaminidase, inflammatory cells and antioxidants (BALF and lung), as well as plasma fibrinogen were analyzed either immediately or 20 h following final exposure. A small increase in plasma fibrinogen was apparent after each 2 d exposure, and in five out of six 1 d exposures. BALF neutrophils and lung cell injury parameteres did not indicate a consistent exposure-related pattern of response. However, the lung glutathione and ascorbate content decreased after both 2 day exposures, with a smaller decrease after 1 d exposure. The degree of change in lung injury and systemic parameters following the 2 d exposures appeared to be concentration-dependent, however, the fibrinogen increases noted in the 1 d exposure groups did not relate to CAPS concentration. The chemical composition of filters and meteorological data in relation to animal responses are being evaluated. This study demonstrates that acute CAPS exposure may produce antioxidant decreases in the lung and systemic increases in plasma fibrinogen in a rat model of human CVD. (This abstract does not reflect USEPA policy).

1768 EXPRESSION AND NUCLEAR TRANSLOCATION OF NF-E2 RELATED FACTOR (NRF2) IN HEPATIC STELLATE CELLS.

J. F. Reichard and D. R. Petersen. *Toxicology, University of Colorado Health Sciences Center, Denver, CO.*

Increased intracellular levels of reactive oxygen intermediates, or oxidative stress, can result from exposure to alcohol, iron or chlorinated hydrocarbons and is causally associated with hepatic fibrosis. During oxidative stress electrophilic intermediates, including 4-hydroxynonenal (4-HNE), are generated and *in vitro* purportedly stimulate hepatic stellate cells (HSC) to transdifferentiate from a quiescent to an activated phenotype. It is this activated phenotype that is responsible for the production of the excessive extracellular matrix characteristic of fibrosis. However, it remains unclear whether HSC activation is modulated directly by peroxidative intermediates *in vivo*, or through other cell signaling pathways. The objective of the present study is to investigate the role of oxidative stress in HSC activation. Recent studies have demonstrated that the bZIP transcription factor Nrf2 is crucial for antioxidant response element (ARE)-mediated gene transcription of phase II metabolizing enzymes. Electrophilic agents trigger the release Nrf2 from its cytoplasmic anchor protein (Keap1) allowing Nrf2 to translocate into the nucleus and activate ARE-dependent genes. In this investigation we have isolated and identified HSC for the purpose of studying oxidative stress induced HSC activation in rat liver following 4 weeks carbon tetrachloride (CCL4) treatment. In treated animals it is shown that HSC become activated and proliferate throughout the liver forming intralobular bands. These bands of activated stellate cells are further demonstrated to colocalize with bridging bands of fiberous tissue. Utilizing both freshly isolated and primary culture HSC we demonstrated that HSC express the Nrf2 transcription factor. Functional activity of Nrf2 was confirmed in cultured HSC suggesting its usefulness as a sensor system for oxidative stress *in vivo*. The studies presented here provide a foundation to clarify the role of oxidative stress in hepatic stellate cell activation *in vivo*. (Supported by NIH/NIAAH-09300 and F31 NIH/AA05578-01.)

1769 NITRIC OXIDE GENERATION BY CULTURED RAT HEPATOCYTES DURING SIMULATED ISCHEMIA.

J. Kim and J. J. Lemasters. *Department of Cell & Developmental Biology, University of North Carolina, Chapel Hill, NC.*

BACKGROUND: Nitric oxide (NO) is an important regulator of biological functions that has also been linked to cellular injury. NO can be generated during ischemia/reperfusion, but mechanisms of NO formation in ischemic hepatocytes are not known. The **AIM** of this study was to investigate the effect of ischemia on the generation of NO in hepatocytes. **METHODS:** Rat hepatocytes were cultured overnight and loaded with 10 μM DAF-FM diacetate, an NO specific fluorescent probe, for 30 minutes at 37°C in Krebs-Ringer-HEPES (KRH) buffer at pH 7.4. After washing three times with cold KRH, hepatocytes were further incubated for 15 minutes at 37°C to complete deesterification. The cells in warm KRH were then incubated in air (normoxic) or argon (ischemic) at either pH 6.2 or at pH 7.4 for up to 4 h. Changes in green DAF-FM fluorescence were monitored in a fluorescence plate reader. In other experiments, 5 mM arginine, 1 mM of the NO synthase inhibitor N-nitro-arginine methyl ester hydrochloride (L-NAME), or 100 μM of the NO donor S-nitroso-N-acetylpenicillamine (SNAP) was included in the incubation medium. Confocal images of DAF-FM fluorescence were collected with a Zeiss LSM 410 microscope. **RESULTS:** NO formation, as revealed by DAF-FM fluorescence, increased during anoxia at pH 6.2 but not at pH 7.4. NO production during 4 h anoxia at pH 6.2 was about 10-fold greater than during 4 h of normoxia at pH 6.2. Incubation of hepatocytes with arginine or L-NAME did not increase or decrease NO formation during ischemia, although SNAP rapidly enhanced DAF-FM fluorescence both in normoxic and ischemic cells at either pH. Confocal imaging confirmed a dramatic increase of intracellular DAF-FM fluorescence during ischemia but not during normoxia. **CONCLUSION:** Anoxia to hepatocytes under acidotic conditions enhanced NO formation. The oxygen-independent mechanism by which NO is formed during ischemia appears not to involve nitric oxide synthase. The contribution of NO formation to ischemic hepatocellular injury remains to be determined.

1770 TRANSLATIONAL REGULATION OF RAT HEPATIC MRP2.

M. Vore, T. Hoffman and J. Cao. *Graduate Center for Toxicology, University of Kentucky, Lexington, KY.*

Mrp2 mediates the biliary excretion of glutathione, glucuronide and sulfate conjugates. Hepatic expression of Mrp2 protein is decreased in pregnant (P) rats but is increased in rats treated with pregnenolone-16α-carbonitrile (PCN), eventhough expression of Mrp2 mRNA is unchanged. We examined hepatic expression of Mrp2 protein (Western analysis), mRNA (Northern analysis) and the polysomal distribution of Mrp2 mRNA in female control (C) and P (19 - 20 d) rats, and in rats treated with corn oil (CO) or PCN (75 mg/kg/d, 2d, ip). Polyribosomes (polysomes) were separated from single ribosomes (monosomes, M) by differential sedimentation through a continuous sucrose gradient (20-75%), followed by Northern analysis of Mpr2 mRNA purified from 24 individual fractions (0.5 ml) of the sucrose gradient. Results are expressed as "% of total Mrp2 mRNA" in the bottom (I; 1-7), middle (II; 8-14) and top (III; 15-21) of the gradient and the M (22-24) fractions and show Mean ± SE where n = 3-5; *, $p < 0.05$ in C vs P or CO vs PCN, t- test. RESULTS. Mrp2 protein was decreased by 50% (*) in P vs C and increased two-fold (*) in PCN vs CO; mRNA was unchanged. In polysomal distribution analysis (Table), C Mrp2 mRNA was uniformly distributed throughout the gradient. In P, Mrp2 mRNA shifted from I, containing the heavier polysomes, to II and III, relative to C. In PCN, Mrp2 mRNA in I was increased two-fold relative to Co., reflecting a shift from II and III. CONCLUSIONS. The decreased enrichment of Mrp2 mRNA in the denser polysomal fractions in P is consistent with a decrease in protein synthesis and decreased Mrp2 protein expression while increased association of Mrp2 mRNA with the fraction most actively engaged in protein synthesis is consistent with increased Mrp2 protein expression in PCN. These

data indicate that in P and PCN rats, hepatic Mrp2 expression is translationally regulated.

1771 STRUCTURAL DETERMINANTS OF PERFLUOROOCTYL-DERIVATIVE-MEDIATED INDUCTION OF THE MITOCHONDRIAL PERMEABILITY TRANSITION.

T. M. O'Brien and K. B. Wallace. *Biochemistry and Molecular Biology, University of Minnesota, Duluth, MN.*

Perfluorooctanoate (PFOA), perfluorooctanesulfonate (PFOS), and substituted perfluorooctanesulfonamides are commercial compounds widely used as water and stain repellents, fire retardants, and anti-corrosion agents among many other applications. We recently showed that these compounds disrupt mitochondrial bioenergetics in one of three ways: by stimulating proton conductance to uncouple mitochondrial respiration, as inducers of the mitochondrial permeability transition (MPT), or by causing the nonspecific increase in ion permeability across the mitochondrial membranes. The purpose of this investigation was to screen several members of this class of compounds, PFOA, PFOS, perfluorooctanesulfonamide (FOSA), perfluorooctanesulfonamidoacetare (FOSAA), N-ethylperfluorooctanesulfonamide (N-Et-FOSA), 2-(N-ethylperfluorooctanesulfonamido)ethyl alcohol (N-Et-FOSE), and N-ethylperfluorooctanesulfonamidoacetate (N-Et-FOSAA) to reveal a common structural characteristic responsible for induction of the mitochondrial permeability transition. Each compound was added at concentrations previously shown to alter mitochondrial respiration to a reaction medium containing glutamate/malate energized rat liver mitochondria. Mitochondrial swelling was monitored spectrophotometrically. PFOS, FOSA, N-Et-FOSA and N-Et-FOSE did not induce swelling at any concentration. In contrast, the carboxylated compounds PFOA, FOSAA, and N-ET-FOSAA induced calcium-dependent, cyclosporin A inhibited mitochondrial swelling. The fully substituted amide N-Et-FOSAA is the most potent inducer of the MPT, followed by FOSAA, then PFOA. The results indicate that the primary determinant of induction of the MPT is the carboxylic group, and that it is the induction of the MPT that is responsible for the observed interference with mitochondrial respiration by these carboxylated fluorochemicals. (This work as supported by a grant from the 3M Company).

1772 THE IMPACT OF PERFLUOROOCTYL DERIVATIVES ON PEROXISOME PROLIFERATION AND MITOCHONDRIAL BIOGENESIS.

J. M. Berthiaume and K. B. Wallace. *Biochemistry and Mol. Biology, University of Minnesota, Duluth, MN.*

Perfluorooctanesulfonate (PFOS), perfluorooctanoate (PFOA) and related sulfonamido derivatives have drawn recent attention due to their broad industrial application, environmental persistence, and detection in biological samples. Despite their chemical stability, these compounds induce peroxisome proliferation characterized in part by the upregulation of enzymes of fatty acid β-oxidation. Several of these fluorochemical derivatives interfere with mitochondrial bioenergetics *in vitro* and PFOA is capable of stimulating both peroxisomal and mitochondrial proliferation *in vivo*. The purpose of this investigation was to determine whether stimulation of mitochondrial biogenesis is a general characteristic associated with proliferation of peroxisomal bodies in liver. PFOS and N-ethyl perfluorooctanesulfamido ethanol (N-EtFOSE) were investigated as potential peroxisome proliferators using PFOA as a positive control. PFOA, PFOS, or N-EtFOSE was administered *via* a single IP injection at 100mg/kg to adult male rats and measurements were made 3 days later. Parameters chosen to assess peroxisome proliferation were; stimulation of lauroyl CoA oxidase activity, reduction of serum cholesterol, and hepatomegaly. Mitochondrial biogenesis was assessed on the basis of cytochrome oxidase activity, cytochrome content, and mitochondrial DNA copy number (mtDNA). In this model, PFOS and PFOA shared similar peroxisome proliferative activity, whereas N-EtFOSE did not induce peroxisome proliferation. Mitochondrial parameters were altered only in the PFOA group where mtDNA was increased and cytochrome c oxidase activity was decreased in liver tissue. None of the compounds tested affected cytochrome content. These results demonstrate that acute treatment with PFOS or PFOA causes hepatic peroxisome proliferation in rats. However, induction of mitochondrial biogenesis appears to be a characteristic of PFOA and not an effect associated with the peroxisome proliferative response in general. (Supported by the 3M Company.)

1773 INDUCTION OF HEMEOXYGENASE-1 (HO-1) PROTECTS AGAINST TNF-INDUCED APOPTOSIS AND NEUTROPHIL-MEDIATED NECROSIS IN THE LIVER.

R. B. Dorman[1], J. Mayes[1], M. L. Bajt[1], A. Farhood[2] and H. Jaeschke[1].

HO-1 is a stress-response enzyme, which can protect against oxidative tissue injury. We previously demonstrated the critical role of reactive oxygen in the model of galactosamine/endotoxin-induced apoptosis and neutrophil-mediated liver cell necrosis (Hepatology 29: 443-450, 1999). To investigate a potential protective role of HO-1, C3Heb/FeJ mice were pretreated with 5 or 15 mg/kg Cobalt-protoporphorin IX (CoPP). This treatment dose-dependently induced HO-1 in nonparenchymal cells and in hepatocytes as assessed by immunohistochemistry and Western blotting of isolated cell fractions. Injection of 700 mg/kg galactosamine and 0.1 mg/kg endotoxin (G/E) caused hepatocellular apoptosis as indicated by a 10-fold increase of caspase-3 activity and procaspase-3 processing at 6 h. Large numbers of neutrophils were present in sinusoids and postsinusoidal venules at that time. Following transmigration, these neutrophils caused additional cell injury as indicated by high levels of ALT (3720 ± 920 U/L) and necrosis (40-50%) at 7 h. Both doses of CoPP signifcantly attenuated the increase in plasma ALT levels (5 mg/kg: 244 ± 120 U/L; 15 mg/kg: 51 ± 14 U/L) and necrosis (10%) but had no effect on hepatic neutrophil sequestration in either vascular bed. Caspase-3 activity was reduced by 40% and 90% with the low and high dose of CoPP, respectively. Additional treatment with the HO-1 inhibitor Sn-PP restored the sensitivity to G/E-mediated injury. Cell injury after injection of 700 mg/kg galactosamine/7 μg/kg murine TNF-α was also attenuated with HO-1 induction. CONCLUSION: Induction of HO-1 in nonparenchymal cells and in hepatocytes with CoPP dose-dependently protected against TNF-mediated apoptotic cell death and subsequent neutrophil-induced injury to hepatocytes. The mechanism may involve the increased formation of endogenous antioxidants by HO-1.

1774 ACETAMINOPHEN TOXICITY AND APOPTOTIC SIGNALING PATHWAYS IN THE LIVER.

T. R. Knight and H. Jaeschke. *Pharmacology and Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR.*

Recently, it has been shown that a moderately toxic dose of acetaminophen (AAP) interrupts the signaling pathway of Fas receptor-mediated apoptosis (Toxicol Appl Pharmacol 156: 179-186, 1999). The aim of our study was to investigate the mechanism of this effect. Male C3Heb/FeJ mice received a single dose of AAP (300 mg/kg i.p) and/or anti-Fas antibody Jo-2 (0.6 mg/kg, iv). Some animals were treated with allopurinol (100 mg/kg, po) 18 and 1 h before AAP injection. RESULTS: After 90 min of Jo-2 treatment, there was processing of BID and procaspase-3 and a significant increase in liver caspase-3 activity, which is consistent with apoptotic cell death. Treatment with AAP 2.5 h before Jo-2 prevented the increase in hepatic caspase-3 activities and the processing of both BID and procaspase-3. When administered alone, AAP did not cause processing of BID or procaspase-3 but caused significant liver injury. AAP metabolism resulted in a substantial depletion of tissue and mitochondrial glutathione (GSH). However, the mitochondrial GSSG levels increased from 3-5% of total glutathione in controls to 15-25% 1 - 4 h after AAP indicating a significant oxidant stress. Pretreatment with allopurinol prevented the mitochondrial oxidant stress and liver injury due to AAP toxicity but had no effect on Jo-mediated apoptosis. Consequently, allopurinol restored hepatocyte sensitivity to Fas receptor signaling in AAP-treated animals. Evaluation of DNA fragmentation with the TUNEL assay showed staining of midzonal (Jo-2) or centrilobular hepatocytes (AAP). Treatment with AAP eliminated staining of midzonal hepatocytes after Jo-2 injection. Allopurinol restored TUNEL staining of midzonal and prevented staining of centrilobular hepatocytes after combined Jo-2 and AAP administration. CONCLUSION: Metabolic activation of AAP causes mitochondrial dysfunction, which is responsible for disruption of Fas receptor-mediated intracellular signaling. These data suggest that maintaining mitochondrial integrity is critical for the execution of receptor-mediated apoptotic cell death pathways in hepatocytes.

1775 MECHANISMS OF PROGRESSION AND REGRESSION OF ACUTE LIVER INJURY.

Toxicant-initiated liver injury progresses to liver failure unless newly divided cells obtund progressing injury. To test the hypothesis that progression of injury occurs due to destructive action of cytoplasmic and lysosomal degradative enzymes (death proteins) released from dying cells, the role of calpain, a Ca^{2+}-activated cytoplasmic

protease was evaluated. A specific calpain inhibitor, N-CBZ-VAL-PHE- methyl ester (CBZ, 60 mg/kg, in DMSO), administered ip 1 h after a lethal dose of CCl_4 (3 ml/kg, in corn oil, ip) protected 75% of male S-D rats. Liver injury measured by ALT was 6-fold lower in the rats receiving CBZ. Calpain leakage from dying cells was confirmed by immunohistochemistry in liver sections at 0 to 150 h after CCl_4 injection (2 ml/kg, in corn oil, ip). Calpain appeared in the perinecrotic intercellular spaces at 3 h after CCl_4 and increased up to 48 h spearheading progression of injury. In the CCl_4 + CBZ treated group, calpain leakage and liver injury were strikingly lower. Plasma calpain activity after CCl_4 treatment mirrored the intercellular leakage and progression of injury, while it was lower in the inhibitor treated group mirroring lower injury. Breakdown of α- fodrin, a cytoskeletal protein, and specific calpain substrate, analyzed in liver samples by Western blot, increased at 12 and 48 h after CCl_4 treatment. Normal rat hepatocytes incubated with calpain and 1.3 mM free Ca^{2+} confirmed that calpain can induce cell death. In contrast, dividing cells remain unaffected by destructive action of death proteins due to higher expression of endogenous inhibitors. Immunohistochemically, expression of calpastatin, the endogenous inhibitor of calpain, was found to be increasing in dividing cells. These data indicate that calpain released from dying cells destroys cellular cytoskeleton, inducing cell death and progression of liver injury, while higher expression of calpastatin in newly divided cells resists its action and thereby regresses injury.

1776 INDUCTION OF RAT LIVER MULTIDRUG RESISTANCE PROTEIN 3 (MRP3) EXPRESSION FOLLOWING TREATMENT WITH CARBON TETRACHLORIDE (CCl4) AND ACETAMINOPHEN (APAP).

G. E. Hennig[1], H. E. Whiteley[1], A. L. Slitt[3], N. J. Cherrington[3], C. D. Klaassen[3] and J. E. Manautou[2]. [1]*Pathobiology, University of Connecticut, Storrs, CT,* [2]*Pharmaceutical Sciences, University of Connecticut, Storrs, CT and* [3]*University of Kansas Medical Center, Kansas City, KS.*

Chemically-induced compensatory hepatocellular proliferation results in enhanced protection against subsequent toxicant challenge. Induction of liver plasma membrane ATP-dependent transporters may be one of several mechanisms by which proliferating hepatocytes acquire enhanced resistance to cytotoxicity. The multidrug resistance associated proteins are one family of these transport proteins for organic anions. Within this family, Mrp3 is known to be inducible. Therefore, the relative abundance of Mrp3 mRNA transcripts was measured using branched DNA signal amplification. Male Wistar rats received either 900 mg APAP/kg i.p. or 26 µl CCl4/kg i.p. and control rats received vehicle only. Liver samples were collected at 6, 24, 48, and 72 hours after treatment and processed for histopathologic analysis and isolation of poly A+ RNA. CCl4 produced 10-40% liver necrosis in the 6, 24, and 48 hr samples and 0-<10% necrosis in the 72 hr samples. APAP produced 10-40% necrosis at 24 hr, 0-40% at 48 hr, and 0->50% in the 72 hr samples. Mrp3 mRNA expression was significantly increased at 6, 24, and 48 hours following CCl4 administration and at 72 hours after APAP administration. In conclusion, induction of Mrp3 during compensatory hepatocellular proliferation may be important to the enhanced resistance to chemical -induced cytotoxicity in this model. (Supported by NIH grant ES10093).

1777 PROTECTION AGAINST ACETAMINOPHEN HEPATOTOXICITY BY CLOFIBRATE PRETREATMENT : EFFECT OF CATALASE INHIBITION.

C. Chen[1], G. E. Hennig[2], H. E. Whiteley[2] and J. E. Manautou[1]. [1]*Pharmaceutical Sciences, University of Connecticut, Storrs, CT and* [2]*Pathobiology, University of Connecticut, Storrs, CT.*

Mice pretreated with the peroxisome proliferator clofibrate (CFB) are highly resistant to acetaminophen (APAP)-induced hepatotoxicity. The objective of the present study was to investigate whether the increase in hepatic catalase activity after CFB pretreatment plays a role in the hepatoprotection. An irreversible catalase inhibitor, 3-amino-1, 2, 4-triazole (3-AT), was used to modulate enzyme activity. Hepatic catalase activity in mice pretreated with CFB (500 mg/kg, i.p. for 10 days) was significantly inhibited by 3-AT (either 0.1 or 0.5 g /kg, i.p.). In addition, the lower dose of 3-AT (0.1 g /kg) had little effects on biliary and urinary excretion of APAP and its metabolites, which suggests that APAP metabolism was not affected by this dose of 3-AT. In toxicity studies, the mortality rate of corn oil-pretreated mice challenged with APAP (800 mg/kg, p.o.) was significantly increased by 3-AT (0.1 g /kg, i.p.) given one h before APAP. As expected, CFB pretreatment conferred full protection against APAP-induced hepatotoxicity. The same 3-AT treatment, however, did not abolish the hepatoprotection in CFB-pretreated mice, despite the marked inhibition of hepatic catalase activity. These results indicate that elevated catalase activity in mice exposed to CFB does not appear to mediate the hepatoprotection. Our findings also provide additional support for the role of reactive oxygen species in APAP-induced hepatotoxicity. (Supported by NIH grant ES10093).

1778 ORGANIC ANION-INDUCED CHOLESTASIS PROTECTS FROM ACETAMINOPHEN (APAP) HEPATOTOXICITY IN MALE CD-1 MICE.

V. M. Silva[1], C. Chen[1], G. E. Hennig[2] and J. E. Manautou[1]. [1]*Pharmaceutical Sciences, University of Connecticut, Storrs, CT and* [2]*Pathobiology, University of Connecticut, Storrs, CT.*

Previous studies showed that administration of the non-metabolizable organic anion indocyanine green (ICG) immediately prior to a toxic dose of APAP reduces liver injury 24 hours after challenge. ICG produces dose dependent decreases in bile flow (cholestasis) in mice and rats. Studies performed in rats suggest that cholestasis can play a role in this protection. Therefore, this study was conducted to determine if the cholestatic properties of this and other model organic anions is relevant to the protection against APAP liver injury previously observed in mice receiving ICG. For this purpose, overnight fasted male CD-1 mice were dosed i.v. with the cholestatic dyes: bromcresol green (BCG, 30umol/kg) and rose bengal (RB, 60 umol/kg) immediately prior APAP challenge (500mg/kg, i.p.). Other groups of mice received the non-cholestatic dyes dibromosulphthalein (DBSP, 150umol/kg) and amaranth (AM, 300umol/kg) prior to APAP. Controls were given vehicle only. Liver toxicity was assessed 24 hrs later. Hepatocellular necrosis was evident at 24 hrs in control mice receiving APAP, as determined by sorbitol dehydrogenase activity and histopathology. Pretreatment with the cholestatic dyes BCG and RB decreased the severity of hepatocellular necrosis induced by APAP. However, the administration of the non-cholestatic dyes DBSP and AM did not alter APAP-induced liver damage. APAP-induced glutathione depletion was not altered by pretreatment with any of these dyes. Since cholestatic dyes were able to protect from APAP-induced liver damage while non-cholestatic dyes did not, these data indicate that cholestasis is a contributing factor to the changes in susceptibility to APAP hepatotoxicity produced by some of these cholephilic dyes. (Supported by NIH grant ES10093).

1779 MECHANISMS OF METALLOTHIONEIN PROTECTION AGAINST ALCOHOLIC HEPATOTOXICITY: CRITICAL ROLE OF ZINC.

Z. Zhou, X. Sun, J. C. Lambert, J. T. Saari and Y. J. Kang. *Medicine, University of Louisville, Louisville, KY.*

Metallothionein (MT) is a low molecular weight, cysteine rich (20 cysteinyl residues among 61 amino acids) protein. MT plays an important role in cellular zinc homeostasis. Our previous studies using MT-overexpressing transgenic mice demonstrated that MT is a potent cytoprotective agent against alcoholic liver injury. The present study was undertaken to determine (1) whether MT provides protection against alcoholic liver injury through zinc, and (2) whether zinc prevents alcoholic hepatotoxicity through its antioxidant property. An unique MT-knockout (MT-KO) mouse model was used. MT-KO mice along with their wild-type 129/Sv mice were assigned into four groups: control, ethanol-only, zinc-only and zinc-ethanol. Ethanol was administrated by gavage at a dosage of 5g/kg every 12 h for 3 doses, and zinc sulfate was injected by i.p. at a dosage of 5 mg zinc/kg/day for three days before ethanol treatment. Hepatic MT and zinc concentrations, liver pathological changes and oxidative stress were determined. MT-KO mice showed undetectable hepatic MT content and lower zinc concentration than wild-type mice. Zinc treatment significantly elevated hepatic MT as well as zinc concentrations in wild-type mice and only hepatic zinc concentrations in MT-KO mice. Under light and electron microscopes, pathological changes were observed in the livers treated with ethanol, while the cellular injury was much severer in the MT-KO mice. However, this acute alcoholic hepatotoxicity was significantly inhibited by zinc in both MT-KO and wild-type mice. Furthermore, ethanol treatment decreased hepatic reduced glutathione concentration and increased hepatic lipid peroxidation, though wild-type mice showed less lipid peroxidation than MT-KO mice. This hepatic oxidative stress was abrogated by zinc pretreatment in both MT-KO and wild-type mice. These results thus demonstrate that zinc plays a critical role in MT protection against alcoholic liver injury through its antioxidant action.

1780 METALLOTHIONEIN-NULL MICE ARE SENSITIVE TO ENDOTOXIN/D-GALACTOSAMINE-INDUCED HEPATOTOXICITY.

T. Kimura[1], N. Itoh[2], M. Takehara[2], I. Oguro[2], J. Ishizaki[2], T. Nakanishi[2], M. Isobe[1] and K. Tanaka[2]. [1]*Department of Toxicology, Faculty of Pharmaceutical Sciences, Setsunan University, Osaka, Japan and* [2]*Department of Toxicology, Graduate School of Pharmaceutical Sciences, Osaka University, Osaka, Japan.* Sponsor: M. Cherian.

Metallothionein (MT) is induced during acute-phase. It is thought to regulate zinc and copper homeostasis, detoxify heavy metals and scavenge free radicals. However, the specific function of MT in the acute-phase response remains to be elucidated.

We examined whether MT acts as a protective factor or not. Mice treated with endotoxin (LPS)/D-galactosamine (GalN) selectively develop hepatic failure. We found that MT-null mice were more sensitive to LPS/GalN-induced lethality than wild-type mice. The increase of serum TNF-α, a vital mediator, in MT-null mice was similar to wild-type mice. To investigate whether intracellular MT can directly inhibit TNF-induced hepatocyte death, we compared sensitivity to TNF/actinomycinD (ActD)- and TNF/Ad5IκB, an inhibitor of IκB degradation, - induced cytotoxicity. The degree of cytotoxicity caused by TNF/ActD and TNF/Ad5IκB in primary hepatocytes from wild- type mice was similar to MT-null mice. Hepatocyte apoptosis precedes liver injury in mice administered with LPS/GalN. Hepatic apoptosis caused by LPS/GalN was detected only in MT-null mice under our experimental conditions. The induction of hepatic α_1-acid glycoprotein (AGP) mRNA in the response to LPS/GalN was decreased in MT-null mice compared to that in wild type mice. The acute-phase protein AGP has been demonstrated to protect mice from LPS/GalN-induced hepatic apoptosis and hepatotoxicity. These results suggest that MT might have the potential to prevent LPS/GalN-induced hepatotoxicity, at least, through the enhancement of AGP induction.

1781 CASPASE ACTIVATION AND CYTOCHROME C RELEASE IN RAT LIVER FOLLOWING TREATMENT WITH GALACTOSAMINE.

J. McMillan. *Pharmacology, Med. University of S. Carolina, Charleston, SC.*

Galactosamine is a well-known model hepatotoxin. The hepatic lesion described by Keppler et al. in 1968 is a scattered focal hepatic necrosis. Recent reports have demonstrated that galactosamine also induces hepatocyte apoptosis when given to rats or mice. In the present studies we wished to determine which cell signaling pathways might contribute to the development of hepatocyte apoptosis following galactosamine treatment in rats. Studies by Stachlewitz et al. (1999) suggested that galactosamine-induced hepatocyte apoptosis may be mediated in part through activation of Kupffer cells and their production of TNFα. To distinguish between TNFα-mediated and non-TNFα mediated apoptosis pathways, we determined the activation of caspases 8 and 9 and the release of cytochrome c from the mitochondria. Caspase activities were assessed in liver cytosolic fractions at various times (1-12 hours) following galactosamine treatment of rats. Activation of caspases 8 and 9 was determined by cleavage of the substrates IET-pNA or LEHD-pNA, respectively. Our data suggest that caspase 8 activation occurs within 1 hour following galactosamine treatment. Caspase 9 activation was not observed until 6 hours following galactosamine treatment. At the peak time of apoptosis, 12 hours after treatment, cytochrome c release from mitochondria was clearly detected in livers of rats treated with galactosamine. Cytochrome c was not detected in the cytosolic fraction of livers from control rats. These data suggest that following galactosamine treatment, the TNFα-mediated apoptosis pathway (caspase 8 activation) may be activated in hepatocytes initially, followed by activation of the mitochondrial apoptosis pathway (cytochrome c release and caspase 9 activation). A thorough determination of the timecourse of caspase activations and cytochrome c release will confirm the importance and contributions of the TNFα-mediated pathway *versus* cytotoxic damage to the development of galactosamine-induced hepatocyte apoptosis.

1782 BACTERIAL LIPOPOLYSACCHARIDE EXPOSURE ALTERS AFLATOXIN B_1 HEPATOTOXICITY: BENCHMARK DOSE ANALYSIS FOR MARKERS OF LIVER INJURY.

J. P. Luyendyk, K. C. Shores, P. E. Ganey and R. A. Roth. *Department of Pharmacology and Toxicology, National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI.*

Aflatoxin B_1 (AFB_1) is a toxin produced by fungi that causes both acute hepatotoxicity and hepatocellular carcinoma in humans and experimental animals. Epidemiological studies have shown that individuals exposed to AFB_1 who have concurrent hepatitis B infection, a disease characterized by chronic inflammation, are at greater risk of developing liver carcinoma. Previous work from this laboratory demonstrated that a small, noninjurious dose of bacterial lipopolysaccharide (LPS) augments the hepatotoxicity of AFB_1 through activation of inflammatory cells resulting in the production of soluble inflammatory mediators. This study was conducted to examine the effect of a noninjurious dose of LPS on the dose-response relationship for AFB_1-induced liver injury. Male, Sprague-Dawley rats (250-350g) were treated with AFB_1 (0.1 mg/kg-6.3 mg/kg ip) and 4 hours later with *E. coli* LPS (7.4×10^6EU/kg, iv). Twenty-four hours after AFB_1 administration, hepatic parenchymal cell injury was determined from elevations in serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) activities. Injury to intrahepatic bile ducts was evaluated from increased serum γ-glutamyl transferase and alkaline phosphatase activities. Based on benchmark dose (BMD) analysis, the AFB_1 BMD for parenchymal cell injury was decreased 10-fold by LPS cotreatment, whereas AFB_1 BMDs for bile duct injury were decreased nearly 20-fold. Overall, the data suggest that concurrent inflammation renders the liver considerably more sensitive to the hepatotoxic effects of AFB_1. (Research supported by NIH grant ES04139)

1783 MECHANISMS OF POTENTIATION OF CARBON TETRACHLORIDE HEPATOTOXICITY AND LETHALITY IN TYPE II (NIDDM) DIABETIC RATS.

S. P. Sawant[1], P. B. Limaye[1], K. Shankar[1], T. J. Bucci[2] and H. M. Mehendale[1]. [1]*Toxicology, The University of Louisiana at Monroe, Monroe, LA and* [2]*Pathology Associates International, NCTR, Jefferson, AR.*

The objective of this study was to develop a refined animal model of Type II diabetes and investigate the effect of CCl_4 hepatotoxicity in Type II diabetic rats. Diabetes was induced in male Sprague-Dawley rats (100-124 g) maintained on high fat diet (20% fat, 24% protein, 54% carbohydrate) for 24 days. On day 14, streptozotocin (STZ, 45 mg/kg, ip, in citrate buffer) was injected. Appropriate controls i.e. high fat diet, normal diet and normal diet + STZ were maintained. On day 24, Type II diabetes was confirmed by hyperglycemia (600 ± 13 mg/dl) and normoinsulinemia before use in experiments. An ordinarily nonlethal dose of CCl_4 (2 ml/kg, ip, 1:1 in corn oil) yielded 100% mortality in Type II diabetic rats. A time course study of 0 to 96 h was conducted after CCl_4 challenge. In the diabetic rats, liver injury increased as assessed by plasma ALT, AST and histopathology. Liver function, measured by plasma bilirubin, was markedly decreased at 24 h. Liver glycogen measured as an indicator of hepatic energy status declined. Death resulted due to hepatic failure as indicated by hyperammonemia and hypoglycemia between 24 to 48 h. Hepatic microsomal CYP 2E1 measured by Western blot analysis was induced in Type II diabetic rats, about 40% above controls. Tissue repair, assessed by ^{3}H-thymidine incorporation and proliferating cell nuclear antigen assay (PCNA), was inhibited. In the non-diabetic rats liver injury peaked at 48 h but timely and robust tissue repair resulted in recovery. In diabetic rats this dose resulted in liver injury that peaked at 24 h and insufficient tissue repair led to progression of injury and animal death. In summary, CCl_4 hepatotoxicity is potentiated due to a combination of higher bioactivation following induction of CYP 2E1 and compromised tissue repair in Type II diabetic rats. These findings suggest that just as Type I diabetes, Type II diabetes also is a predisposition factor for CCl_4 hepatotoxicity.

1784 PROTECTIVE MECHANISMS AGAINST ACETAMINOPHEN TOXICITY IN DIABETIC MICE: ROLE OF PPAR-α ACTIVATION.

K. Shankar[1], V. S. Vaidya[1], J. E. Manautou[2], M. J. Ronis[3], T. J. Bucci[4], J. C. Corton[5] and H. M. Mehendale[1]. [1]*Department of Toxicology, The University of Louisiana at Monroe, Monroe, LA,* [2]*Department of Pharmaceutical Sciences, University of Connecticut, Storrs, CT,* [3]*Arkansas Children's Hospital Research Institute, Little Rock, AR,* [4]*Pathology Associates Inc., NCTR, Jefferson, AR and* [5]*CIIT Centers for Health, Research Triangle Park, NC.*

Our recent work has demonstrated diabetic mice to exhibit significantly less liver injury and mortality together with augmented compensatory tissue repair after challenge with acetaminophen (APAP). Diabetes causes activation of PPAR-α just as peroxisome proliferators, and both protect against APAP toxicity. The present work examines the mechanistic role of PPAR-α activation in diabetes as a hepatoprotective mechanism against lethal APAP challenge. PPAR-$\alpha^{-/-}$ mice made diabetic by streptozotocin (150 mg/kg, ip, citrate buffer) did not show CYP4A induction (a marker of PPAR-α activation), unlike wild-type (WT) diabetic phenotypes which showed considerable CYP4A induction. On treatment with APAP (600 mg/kg, ip in basic saline, a LD_{100} dose in WT non-diabetic mice), WT-diabetic mice showed only 30% mortality and 50% less liver injury measured by ALT and histopathology. In contrast, diabetic-PPAR-$\alpha^{-/-}$ mice did not exhibit any protection against APAP toxicity suggesting the importance of PPAR-α in diabetes-induced protection. S-phase DNA synthesis and PCNA histochemical staining after injury showed earlier and robust tissue repair in WT-diabetic mice, but not in the PPAR-$\alpha^{-/-}$diabetic mice. The upregulation of compensatory tissue repair in the diabetic mice appears to be mediated *via* PPAR-α activation. Although hepatic CYP2E1 and 1A2, which are involved in APAP bioactivation, were lower in the WT-diabetic mice, covalent binding of APAP was unchanged. Western analysis of APAP bound to 58, 56 and 44 KDa acetaminophen binding proteins was similar among diabetic and non-diabetic mice. Here we report PPAR-α activation and upregulated liver tissue repair as primary mechanisms of protection against APAP toxicity in diabetes.

1785 UPREGULATED SIGNAL TRANSDUCTION ENHANCES LIVER TISSUE REPAIR UPON TOXIC CHALLENGE IN CALORIC RESTRICTED RATS.

U. M. Apte[1], P. B. Limaye[1], M. Z. Chen[1], T. J. Bucci[2], A. Warbritton[2] and H. M. Mehendale[1]. [1]*Department of Toxicology, College of Pharmacy, The University of Louisiana at Monroe, Monroe, LA and* [2]*Pathology Associates Inc., NCTR, Jefferson, AR.*

We have previously reported that moderately caloric or diet restricted (DR) rats are protected from lethal hepatotoxic challenge of thioacetamide [600 mg/kg TA; 90% lethality in Ad libitum (AL) vs 30% in DR rats] due to timely and robust compen-

satory liver tissue repair response. This study was designed to investigate the role of various signal transduction pathways in the stimulation of higher liver regeneration in the DR rats over a time course of 0 to 72 h after TA administration. Pro-inflammatory cytokines TNF-α and IL-6 were estimated in plasma by ELISA and in liver by either RT-PCR analysis or immunohistochemistry. Although, no significant difference in plasma TNF-α levels was observed between AL and DR, slightly higher TNF-α mRNA was found in the livers of DR rats at 48 and 72 h after TA injection. Plasma IL-6 was significantly higher in DR, which peaked at 48 h (6-fold higher than in AL). IL-6 in liver measured by immunohistochemical analysis was consistent with these results. TNFR-I and IL-6 R mRNA did not change in AL or DR at any time after TA administration. Expression of growth factors TGF-α and HGF was studied by immunohistochemical analysis in livers of AL and DR rats after TA administration. DR rats exhibited higher and consistent expression of both TGF-α and HGF during the phase of active mitogenesis while expression in AL rats was decreased and diminished. Western blot analysis of EGFR (TGF-α receptor) indicated that DR rats have initial higher EGFR protein levels which remained consistently higher until 48 h. Similar higher c-met (HGF receptor) protein was observed in DR rats at 48 h. Taken together, these data indicate that the higher liver tissue repair is stimulated in DR rats by timely expression of the pro-mitogenic factors leading to subsequent upregulation of the signal transduction pathways involved in liver regeneration. (Supported by ES-09870)

1786 HIGHER EXPRESSION OF TNF-α AND IL-6 IN LIVER OF DIET RESTRICTED RATS AFTER THIOACETAMIDE-INDUCED LIVER INJURY.

M. Z. Chen, U. M. Apte, P. B. Limaye and H. M. Mehendale. *Department of Toxicology, College of Pharmacy, The University of Louisiana at Monroe, Monroe, LA.*

Previous studies in our laboratory have shown that moderate diet restriction (DR, 35% for 21 days) protects male Sprague-Dawley rats from lethal dose of thioacetamide (TA). The protection in DR rats is due to enhanced liver tissue repair. Studies indicate that proinflammatory cytokines, TNF-α, IL-6 and their receptors, may play an important role in stimulating quiescent liver cells to proliferate. The present studies were designed to investigate TNF-α/TNFR1 and IL-6/IL-6R expression in TA poisoned rats over a time course of 0 to 72h after injecting TA. AL and DR rats received an ordinarily lethal dose of TA (600 mg/kg in saline, ip). Liver injury was measured by ALT, AST and histopathology, and tissue repair was measured by ^{3}H-thymidine incorporation and PCNA. Plasma TNF-α and IL-6 were assayed by ELISA. Expression of mRNA in the liver was detected by semi-quantitative RT-PCR. The data indicate that TNF-α in plasma and its mRNA in liver tissue increase in both DR and AL groups after TA administration. There was no significant difference in plasma TNF-α in DR and AL rats at any time point. DR rats had significantly higher TNF-α mRNA in liver at 24 to 72h as compared to AL rats. IL-6 in plasma and its mRNA in liver also increased after TA administration. DR rats had 6-fold higher plasma IL-6 at 48h coincidental with higher IL-6 mRNA in the liver. Immunohistochemical analysis of IL-6 in liver indicated localization mainly in sinusoidal endothelial cells, suggesting that these may be the source of IL-6. In both AL and DR rats, TNFR1 and IL-6R mRNA expression was similar over the time course. Because expression of TNFR1 and IL-6R was unchanged, upregulation of pro-mitogenic signaling is achieved by up-regulated TNF-α and IL-6 in DR rats compared with AL rats. These results indicate that higher expression of TNF-α and IL-6 may play an important role in higher tissue repair in DR rats upon liver injury induced by TA. (Supported by ES-09870)

1787 EFFECTS OF TICLOPIDINE, AN ANTIPLATELET AGENT, ON RAT MODELS OF HYPERBILIRUBINEMIA.

T. Nishiya, M. Shibao, K. Mori, H. Satoh, Y. Takahashi, M. Shibano, M. Sekiguchi, F. Fujii and K. Furuhama. *Drug Safety Research Laboratory, Daiichi Pharmaceutical Co., Ltd., Tokyo, Japan.*

Ticlopidine, an anitplatelet agent, has been reported to cause cholestatic hepatitis in patients with rare cases. To approach the mechanism underlying the event, we investigated effects of ticlopidine on hepatic function and morphology of Eisai hyperbilirubinuria rats (EHBR), Sprague-Dawley rats (SDR), as an original strain of EHBR, and bile duct ligated rats. Repeated oral administration of ticlopidine (100 and 300 mg/kg/day for 7 consecutive days) remarkably raised serum bilirubin level only in EHBR from day 2. On day 7, the bilirubin level was 5-8 times higher (control 1.37 mg/dL vs 7.41-11.24 mg/dL) than that of the vehicle control. This change was accompanied by slight elevations in serum bile acid, cholesterol and phospholipid levels without increased serum transaminase activities. Histopathologically, no hepatic necrosis and cholestasis were enhanced. In SDR and bile duct ligated rats, deterioration was neither functionally nor morphologically observed. To elucidate the mechanism of ticlopidine-enhanced hyperbilirubinemia in EHBR, the effects on bile flow and, bilirubin and bile acid excretion into the bile were investigated. Ticlopidine did not affect these parameters, suggesting that impairment of biliary excretion did not relate to the enhanced serum bilirubin level. In the analysis of hepatic transporters mRNA levels involved in bilirubin and bile acid transport by a real time PCR, a significant increase in rat multidrug resistance-associated protein 3 (Mrp3) mRNA level as a transporter for excretion from the liver into peripheral blood was noted. Messenger RNA level of heme oxygenase-1, a rate-limiting enzyme in the catabolism of heme to bilirubin, was also elevated compared to the vehicle control ($P<0.05$ by StudentÅfs t test), whereas this phenomenon was not seen in SDR. These results provide the possibility that the facilitation of bilirubin formation and transport from the liver into peripheral blood through Mrp3 may contribute to ticlopidine-enhanced hyperbilirubinemia in EHBR.

1788 QUANTIFICATION OF HEPATOCYTE PROLIFERATION AND APOPTOSIS FOLLOWING ILEAL RESECTION IN RATS.

R. Duan, M. Gralinski, C. Wilker, B. Keller and E. Blomme. *Global Toxicology, Pharmacia, Skokie, IL.* Sponsor: M. Schlosser.

Bile acids regulate the expression of various molecules involved in cholesterol and lipid metabolism by binding the nuclear receptor FXR and activating FXR-mediated transcription. Evidence also suggests that bile acids may regulate the proliferation of hepatocytes. To investigate the role of bile acids on hepatocyte proliferation and apoptosis *in vivo*, we used a rat model of ileal resection to reduce the ileal bile acid transporter (IBAT)-mediated enterohepatic recirculation of bile acids. Rats were sacrificed 2, 4, and 13 weeks following ileal resection. Cholesterol 7alpha-hydroxylase (Cyp7a) activity and fecal bile acid concentrations were determined to demonstrate the decrease in ileal bile acid reabsorption. Proliferating and apoptotic hepatocytes were detected by immunohistochemistry using PCNA as a marker of cell proliferation and activated caspase-3 as a marker of apoptosis. The proliferation and apoptotic rates were quantified using computer-assisted image analysis. Our results demonstrated a slight decrease in liver weights and significant increases in Cyp7a activity and fecal bile acid concentrations following ileal resection. In addition, a moderate, but significant decrease in hepatocyte proliferation was observed 2 and 4 weeks after surgery, while no differences in the apoptotic rate among groups were detected at any time points. In conclusion, inhibition of ileal bile acid reabsorption through surgical ileal resection is associated with slight decreases in the rate of hepatocyte proliferation and slightly decreased liver weight, suggesting that physiologic concentrations of bile acids may regulate hepatocyte proliferation *in vivo*.

1789 INTERACTIONS OF COMBINED BILE ACIDS ON HEPATOCYTE VIABILITY: CYTOPROTECTION OR SYNERGISM.

A. P. Rolo[1], C. M. Palmeira[1] and K. B. Wallace[2]. [1]*Zoology, Center for Neurosciences and Cell Biology of Coimbra, Coimbra, Portugal and* [2]*Biochemistry & Molecular Biology, University of Minnesota, Duluth, MN.*

Cholestasis results from hepatocyte dysfunction due to the accumulation of bile acids in the cell, many of which are known to be cytotoxic. Recent evidence suggests that through competing reactions nontoxic bile acids might afford cytoprotection against cholestasis. In this work, we compare the relative cytotoxicity of bile acids based on a dose- and time-dependent study. To better elucidate the controversy related to the therapeutic use of ursodeoxycholate (UDCA) in cholestatic patients, we also evaluated the effects of bile acid combinations. Viability of Wistar rat hepatocytes in primary culture was measured by LDH leakage after 12 and 24 hr exposure of cells to the various bile acids. All unconjugated bile acids caused a dose-dependent decrease in cell viability. The tauro- and glyco-conjugates of chenodeoxycholate (CDCA) and UDCA were all less toxic than the corresponding unconjugated form. Although relatively non-toxic, UDCA caused synergistic cell killing by lithocholate (LCA), CDCA, glyco-CDCA (GCDC) and tauro-CDCA (TCDC). Glycoursodeoxycholate decreased the toxicity of GCDC but potentiated the toxicity of unconjugated CDCA and LCA. The tauro-conjugate of UDCA had no significative effect. These data suggest that at cholestatic relevant concentrations, bile acid-induced cell death is dependent on the degree of lipophilicity and conjugative status of individual bile acids. However, these results indicate that the reported improvement of biochemical parameters in cholestatic patients treated with UDCA is not due to a direct effect of UDCA on hepatocyte viability. Therefore, any therapeutic effect of UDCA must be secondary to an altered membrane transport or nonparenchymal cell function.

1790 EFFECTS OF BETAINE ON HEPATIC FIBROSIS INDUCED BY NITROSODIMETHYLAMINE IN RATS.

S. K. Kim, Y. S. Jung and Y. C. Kim. *Pharmacy, Seoul National University, Seoul, South Korea.*

Effects of betaine intake on hepatic fibrogenesis were examined in adult male SD rats treated with nitrosodimethylamine (DMN; 10 μl/kg/day, ip) 3 days a week for 4 weeks. From two weeks prior to initiation of DMN treatment until sacrifice rats

were provided with drinking water containing 1 % betaine. DMN treatment at this dosage regimen resulted in hepatic fibrosis as determined by changes in hepatic 4-hydroxyproline contents and serum biochemical parameters, such as alanine aminotransferase, aspartate aminotransferase, total bilirubin and plasma protein contents. Hepatic microsomal enzyme activities were also reduced in rats treated with DMN. Betaine intake significantly decreased the changes induced by DMN, which was further supported by the results of histopathological examination of rat liver. DMN treatment also elevated hepatic concentration of malondialdehyde measured by HPLC analysis, which was completely blocked by betaine. In liver of rats treated with DMN, S-adenosylmethionine level was decreased but cysteine, taurine, glutathione disulfide and homocysteine levels were all increased. Consistent changes in the activities of critical enzymes involved in the transsulfuration pathway were also observed. Betaine intake inhibited all the changes in the metabolic intermediates/products and enzyme activities induced by DMN. It is suggested that antifibrotic activity of betaine could be associated with its potential for maintaining homeostasis of hepatic sulfur-containing amino acid metabolism.

1791 ENDOTHELIAL CELL INJURY AND FIBRIN DEPOSITION IN RAT LIVER AFTER MONOCROTALINE EXPOSURE.

B. L. Copple, P. E. Ganey and R. A. Roth. *Pharmacology and Toxicology, Michigan State University, East Lansing, MI.*

Monocrotaline (MCT) is a pyrrolizidine alkaloid plant toxin that produces hepatotoxicity in people and animals. Human exposure to MCT occurs through consumption of contaminated grains and herbal medicines. Intraperitoneal injection of 300 mg/kg MCT into rats produced time-dependent hepatic parenchymal cell (HPC) toxicity beginning 12 hours after treatment. To determine the development of damage to sinusoidal endothelial cells (SECs) in the liver, SEC injury was quantified using immunohistochemical staining and by increased plasma hyaluronic acid concentration. MCT produced extensive SEC injury that was restricted to centrilobular regions by 8 hours after treatment. To determine if damage to SECs in the liver stimulated activation of the coagulation system, fibrin deposition was quantified in the liver using immunohistochemistry. Extensive fibrin deposition occurred in the liver after MCT treatment and was restricted to centrilobular regions. Fibrin deposition occurred simultaneously with SEC damage and before HPC injury. Accordingly, the hypothesis was tested that activation of the coagulation system is required for MCT-induced liver injury. Treatment of rats with anticoagulant heparin significantly prevented MCT-induced fibrin deposition in the liver and HPC injury. By contrast, heparin did not prevent MCT-induced damage to SECs. These results suggest that activation of the coagulation system is required for MCT-induced HPC injury but not SEC injury in the liver. (Supported by NIH grants ES04139 and DK50728.)

1792 PROGRESSIVE HEPATOTOXICITY DUE TO A THIAZOLIDINEDIONE CONTAINING ANALOGUE OF N-(3, 5-DICHLOROPHENYL)SUCCINIMIDE (NDPS) IN FISCHER 344 RATS.

E. L. Kennedy, P. J. Harvison and R. Tchao. *Dept. of Pharmaceutical Sciences, Univ. of the Sciences in Phila., Philadelphia, PA.*

3-(3', 5'-dichlorophenyl)thiazolidine-2, 4-dione (DCPT) is an analogue of the nephrotoxic agricultural fungicide, N-(3, 5-dichlorophenyl)succinimide (NDPS). The target organ for toxicity changed from kidney to liver when the succinimide ring of NDPS was replaced by the thiazolidinedione (TZD) ring of DCPT. To further investigate DCPT-induced toxicity a time course study was conducted. Male, Fischer 344 rats were administered DCPT (0.6 mmol/kg, i.p. in corn oil), and kidney and liver function were assessed at 24, 72, and 96 hours post-dosing. DCPT treatment produced marked and persistent diuresis. Ketonuria was seen up to day 2 of the experiment. A sharp increase in urine glucose levels was observed from day 1 to day 2. However, by day 4 urine glucose values returned to day 0 levels. Also, body weight, and water and food consumption decreased on day 1, but were elevated above day 0 values by day 2 and beyond. Kidney and liver weights were not elevated throughout the experiment, however alanine aminotransferase (ALT) levels were increased at 24 hours (380.00 ± 63.77), compared to 72 (25.75 ± 4.80) and 96 (25.25 ± 3.33) hours post-dosing. The histological data support these toxicological findings because there was a focal infiltration of neutrophils from the vasculature into the surrounding tissue 24 hours post-dosing. At 72 and 96 hours the neutrophils were absent, however diffuse damage was seen throughout the liver. The results suggest that DCPT has diuretic, ketonuric and glucosuric activity. Furthermore, DCPT appears to produce progressive hepatotoxicity in rats. Since liver damage was reported in patients taking troglitazone and other TZD-containing insulin sensitizers, DCPT may be a useful model compound for studying the toxicity of these drugs. However, the role of the TZD ring in DCPT-induced hepatotoxicity requires further investigation.

1793 LACK OF SEX DIFFERENCES IN ALCOHOL-INDUCED LIVER DAMAGE IN RATS FED LOW CARBOHYDRATE DIETS.

M. J. Ronis[1], T. M. Badger[1], R. Hakkak[1], S. Korourian[2], E. Albano[3], M. Ingelman-Sundberg[4] and K. O. Lindros[5]. *[1]Pediatrics, University of Arkansas for Medical Sciences, Little Rock, AR, [2]Pathology, University of Arkansas for Medical Sciences, Little Rock, AR, [3]Medical Sciences, University A Avogadro of East Piedmont, Novara, Italy, [4]Molecular Toxicology, Karolinska Institute, Stockholm, Sweden and [5]National Public Health Institute, Helsinki, Finland.*

It has been reported that female rats are significantly more susceptible to alcohol-induced liver damage (ALD) than males, in a model of ALD which utilizes intragastric feeding (Iimuro et al. Am. J. Physiol. 272:G1186-94, 1997). This has been linked to estrogen-associated increases in Kupffer cell expression of the CD14 endotoxin receptor. We have attempted to replicate these data using two different models of ALD, one involving intragastric feeding of ethanol as part of total enteral nutrition (TEN) and one involving the use of a low carbohydrate liquid diet. Both of these models have previously been shown to produce ALD, but do not result in statistically significant increases in plasma endotoxin. Groups of N = 8 to 10 male and female Sprague-Dawley rats, 300 g were placed on the TEN system or the liquid diets for 42 to 60 days. Blinded pathological evaluation of liver samples was performed. In both models, ethanol treatment at 12 to 13 g/kg/d produced statistically significant liver hyperplasia accompanied by increases in plasma ALT, steatosis, inflammation and necrosis and induction of CYP2E1 ($P \leq 0.05$). However, in neither model, were females significantly more damaged than males. Total pathology score: TEN EtOH males 10 ± 0.6 and females 8.7 ± 0.6; liquid diet model EtOH males 7.7 ± 0.7 and females 8.1 ± 0.5. Thus, our data do not support the previous conclusion that female rats have a greater susceptibility to ethanol-induced hepatotoxicity than males. Supported in part by R21 AA12031 (T.M.B).

1794 EFFECTS OF THE DIETARY ANTIOXIDANTS BUTYLATED HYDROXYTOLUENE (BHT) AND N-ACETYL CYSTEINE (NAC) ON ALCOHOL-INDUCED LIVER DAMAGE IN A RAT MODEL UTILIZING TOTAL ENTERAL NUTRITION.

R. Hakkak[1,3], M. J. Ronis[1,3], S. Korourian[2], T. Fletcher[1,3], M. Ferguson[1,3], M. Perry[1,3], S. Sharp[1,3], M. Reeves[1,3], R. Prior[3] and T. M. Badger[1,3]. *[1]Pediatrics, University of Arkansas for Medical Sciences, Little Rock, AR, [2]Pathology, University of Arkansas for Medical Sciences, Little Rock, AR and [3]Arkansas Children's Nutrition Center, Little Rock, AR.*

We have developed a total enteral nutrition (TEN) model to study alcohol-induced liver damage (ALD). It has been suggested that development of ALD is dependent upon free radical formation as the result of CYP2E1-dependent metabolism of ethanol and unsaturated fatty acids. In this study we examined the protective effects of two different antioxidants – the free radical scavenger BHT and the glutathione precursor NAC. Six groups of N = 8-10 Sprague-Dawley rats (300 g)were used. Groups were placed on TEN, TEN + BHT (150 mg/kg/d), TEN + NAC (4.2 g/kg/d), EtOH, EtOH + BHT and EtOH + NAC for 45 d. NAC treatment significantly increased total anti-oxidant capacity of liver cytosol in TEN controls using the ORAC assay ($P \leq 0.05$). Ethanol treatment reduced ORAC values significantly in both the EtOH and EtOH + NAC groups ($P \leq 0.05$) but the values for the EtOH + NAC group were insignificantly different from TEN controls showing that NAC consumption significantly protected the liver from oxidative stress produced by EtOH. In contrast BHT treatment reduced ORAC values in control animals but EtOH treatment had no further effect. Whereas CYP2E1 apoprotein was induced 14-fold in EtOH and EtOH + NAC groups, it was only induced 5-fold in the EtOH + BHT group. Significantly elevated liver weight, plasma ALT ($P \leq 0.05$) and typical pathology associated with ALD (steatosis, inflammation and necrosis) were observed in all three groups of ethanol-treated rats and neither treatment provided significant protection against ethanol-associated liver damage. These data cast doubt upon the roles of CYP2E1 and free radicals in development of ALD. Supported in part by AA08645 (T.M.B).

1795 POTENTIATION OF ALLYL ALCOHOL HEPATOTOXICITY BY ENDOTOXIN REQUIRES ACTIVATION OF THE COAGULATION SYSTEM.

S. Kinser, R. A. Roth and P. E. Ganey. *Pharmacology and Toxicology, Michigan State University, E. Lansing, MI.*

Noninjurious doses of bacterial endotoxin (LPS) potentiate allyl alcohol-induced liver damage in rats. This enhanced injury could not be replicated in the isolated, buffer-perfused liver and was attenuated *in vivo* by heparin, suggesting that the coagulation system is required for the response. Inasmuch as heparin has effects other than anticoagulation, rats were dosed with warfarin (20 mg/kg, p.o.) or its vehicle

42 and 18 hours before LPS ($1.2x10^6$ EU/kg, i.v.). Rats were then treated two hours after LPS with allyl alcohol (30 mg/kg, i.p.). Like heparin, warfarin attenuated the increase in serum ALT activity of rats treated with LPS/allyl alcohol, suggesting that the coagulation system contributes to hepatic damage in this model. Thrombin is a component of the coagulation cascade that is inhibited by both heparin and warfarin. To assess the specific role of thrombin in the injury, livers were isolated from rats treated 2 hours earlier with LPS ($1.2x10^6$ EU/kg, i.v.) or sterile saline and were perfused with buffer containing thrombin (70 units/liver) or vehicle and various concentrations of allyl alcohol. Thrombin did not increase the sensitivity of the livers to allyl alcohol. This result suggests that thrombin does not contribute to hepatic damage through activation of receptors in the liver. Allyl alcohol-induced toxicity was greater in isolated, perfused livers from LPS-pretreated compared to vehicle-pretreated rats, indicating that some change occurs within the first 2 hours after LPS exposure to increase the sensitivity of the liver to allyl alcohol. This change may be related to accumulation of neutrophils and other blood components in the liver. In summary, LPS augments the hepatotoxicity of allyl alcohol through a mechanism involving the coagulation cascade, and the role of thrombin may be dependent on other blood components (supported by ES08789).

1796 ACTIVATION OF PROTEIN KINASE C δIN ALLYL ALCOHOL-INDUCED TOXICITY IN RAT HEPATOCYTES.

J. F. Maddox, N. Tesheva, R. A. Roth and P. E. Ganey. *Pharmacology and Toxicology, Michigan State University, East Lansing, MI.*

Allyl alcohol (AA)-induced toxicity in hepatocytes is well established, though the specific mechanism by which AA leads to cell death is not known. Several downstream effects of AA have been linked to cell killing, including protein sulfhydryl loss and lipid peroxidation. However, early events in the process have not been identified. The purpose of these studies was to examine whether specific signal transduction pathways could be associated with AA toxicity in hepatocytes. Rat hepatocytes were isolated, adhered to tissue culture dishes and used for experiments within 3 hours of plating. Inhibitors of various signal transduction pathways were added to cells prior to AA addition, and alanine aminotransferase (ALT) release was measured as an indicator of hepatocyte injury/death. Inhibition or augmentation of cAMP/protein kinase (PK) A by Rp-cAMPS or IBMX, respectively, had no effect on AA-induced cell death. H-7, an inhibitor of PKA, PKC and PKG, partially inhibited cell killing by AA. Whereas, chelerythrine chloride, a panspecific PKC inhibitor, almost completely abrogated AA cytotoxicity. Use of selective inhibitors of PKC isoforms showed no effect on cell killing by HBDDE, a PKC αand β inhibitor, or by bisindolylamide I, an inhibitor of PKC α, β, and ε. In contrast, rottlerin, a PKC δ inhibitor, blocked hepatocellular killing by AA. Experiments with chelerythrine chloride and rottlerin were repeated using acrolein instead of AA to test whether the PKC inhibitors were preventing the bioactivation of AA to acrolein, and results again showed marked inhibition of ALT release by chelerythrine chloride and rottlerin. Upon activation, PKC δ is phosphorylated and translocates from the cytosol to cell membranes. Western blotting and immunohistochemistry techniques revealed phosphorylation and translocation of PKC δ to hepatocyte membranes by AA within 30 minutes. Together, these results indicate that activation of PKC δ is a critical early event in initiating hepatocyte injury and death by AA. (Supported by NIEHS 08789)

1797 *IN VITRO* METABOLISM OF DIETHYLENE GLYCOL MONOETHYL ETHER (DEGEE) AND ETHYLENE GLYCOL MONOETHYL ETHER (EGEE) BY RAT AND HUMAN HEPATOCYTES.

S. E. LeValley, L. Sharp, E. Hegwer and C. E. Green. *Metabolism and Pharmacokinetics, SRI International, Menlo Park, CA.*

Ethylene glycol monoethyl ether (EGEE) is converted to a toxic metabolite, ethyoxyacetic acid (EAA). Diethylene glycol monoethyl ether (DEGEE) is similar structurally to EGEE but its metabolism is not known. The objective of this study was to compare the *in vitro* metabolism of DEGEE and EGEE by rat and human hepatocytes to determine whether DEGEE is likely to be converted to toxic metabolites *in vivo*. Rat and human hepatocytes were isolated and suspensions were incubated with 15, 150, and 1500 μM ^{14}C-DEGEE or 150 μM ^{14}C-EGEE. Aliquots of the incubations were removed up to 4 hr and were analyzed by HPLC with radiochemical detection. At the end of the 4 hr incubation period, over 88% of the radioactivity was associated with DEGEE in rat hepatocyte incubations with 150 and 1500 μM ^{14}C-DEGEE and 70% of the radioactivity was ^{14}C-DEGEE in cells incubated with the lowest concentration (15 μM ^{14}C-DEGEE). The rest of the radioactivity was in small, unidentified peaks. Rat hepatocytes converted ^{14}C-EGEE (150 μM) into ethylene glycol (9.65%)and EAA (52.18%). Human hepatocytes did not metabolize ^{14}C-DEGEE to a significant extent; approximately 98 to 99% of the radioactivity remained unchanged. EGEE was readily metabolized by human hepatocytes to ethylene glycol (7.66% and 25.37% for 2 specimens) and EAA (17.57% and 69.50%). In summary, EGEE was readily metabolized by both rat and human hepatocytes to EAA and ethylene glycol, and the rat liver cells metabolized EGEE at a higher rate than human liver cells, in agreement with previously published *in vitro* metabolism data (Green et al., Occup. Hyg., **2**, 67-75, 1996). In contrast, DEGEE was slowly metabolized by rat hepatocytes to several different unidentified metabolite peaks that accounted for as much as 17% of the total radioactivity. Human hepatocytes did not metabolize DEGEE significantly. No EAA or EGEE was formed from DEGEE by either rat or human hepatocytes.

1798 SPECIES COMPARISON OF VITAMIN K1 2, 3-EPOXIDE REDUCTASE ACTIVITY.

C. R. Wilson[1], J. M. Sauer[2], G. P. Carlson[1], R. Wallin[3] and S. B. Hooser[1]. *[1]Purdue University, West Lafayette, IN, [2]Eli Lilly & Company, Indianapolis, IN and [3]Wake Forest University, Winston-Salem, NC.*

In the hepatic vitamin K cycle, vitamin K1 2, 3-epoxide reductase is the microsomal enzyme responsible for catalyzing the reduction of vitamin K1 2, 3-epoxide (VKO) to vitamin K1 hydroquinone (VKH2). VKH2 is a required cofactor for posttranslational carboxylation of proteins carried out by the carboxylase. This modification is essential for synthesis of biologically active factors II (prothrombin), VII, IX, and X, and proteins C, S, and Z of the blood coagulation system. To expand our understanding of hepatic vitamin K metabolism and function across species, a comparative study of vitamin K1 2, 3-epoxide reductase (VKOR) activity was conducted. Using an *in vitro* assay for VKOR activity, the enzyme kinetic constants Km and Vmax have been determined using bovine (n = 5), canine (n = 5), human (n = 1), murine (n = 5), ovine (n = 5), porcine (n = 5), and rat (n = 5) hepatic microsomes. Microsomal incubations contained 1 ml of microsomes (3 mg protein/ml), the substrate VKO (1 uM - 100 uM), and 2 mM dithiothreitol (reducing agent). Using HPLC/PDA to measure reduced metabolites of VKO formed at each concentration of epoxide, the kinetic constants Km and Vmax were assessed for each species. Tukey's test for multiple comparisons revealed statistically significant species differences ($p<0.0001$) in the Km and Vmax of the enzyme for the epoxide. The greatest statistically significant difference in the Km was observed between murine and rat microsomes, 3.99 ± 0.78 and 10.51 ± 1.66 uM vitamin K1 2, 3-epoxide respectively. Ovine and porcine microsomes had the largest statistically significant difference in the maximum reaction velocity (Vmax) of the enzyme, 1.62 ± 0.07 and 5.23 ± 0.28 umoles vitamin K1 quinone/mg protein/minute respectively. Since VKOR has been shown to be the rate-limiting step in the carboxylation system (Dr. Wallin, personal communication), the data suggest that the posttranslational capacity of the system to produce vitamin K-dependent proteins differs between species.

1799 DIFFERENTIAL ESTRADIOL (E2) AND DIMETHYLBENZANTHRACENE (DMBA) METABOLISM BY MONKEY LIVER MICROSOMES IN RELATION TO TCDD EXPOSURE AND ENDOMETRIOSIS (EM).

D. P. Bofinger, L. H. Chi, S. R. James, D. E. Shubert and J. R. Olson. *State University of New York at Buffalo, Buffalo, NY.*

Recently, Rier, et al.(2000) showed that serum E2 levels decreased ($p<0.02$) with TCDD (2, 3, 7, 8- tetrachlorodibenzo-*p*-dioxin) exposure (0 vs 5+25 ppt in diet)in rhesus monkeys (ovariectomized; E2/progesterone replacement) with and without EM. This study examined whether this could be explained by increased liver E2 metabolism, since TCDD induces liver cytochrome P450 enzymes (CYPs) that metabolize E2. DMBA metabolism was also investigated since it is metabolized by similar CYPs. E2 and DMBA metabolism were compared using liver microsomes from the monkeys studied by Rier. Inconsistent with the serum E2 levels, the rate of E2 utilization and the production of E2 metabolites by liver microsomes was generally unaffected by TCDD exposure, except for estriol (E3)production which showed a decrease ($p=0.01$) with TCDD dose. Instead, E2 metabolism was more affected by EM status with decreased production of 2OH-E2 ($p=0.004$), 4OH-E2 ($p=0.003$), and E3($p=0.05$) in monkeys with EM. In animals without EM, the DMBA utilized ($p=0.008$) and the production of the 5, 6-($p=0.04$), 8, 9-($p=0.04$), and 3, 4-($p=0.03$) diols correlated with 2OH-E2 production, and the formation of the 3, 4-($p=0.04$) and 10, 11-($p=0.02$) diols correlated with 4OH-E2 production. In animals with EM, 10, 11-diol formation correlated with estrone production ($p=0.02$), as well as with CYP1A1 (ethoxyresorufin-O-deethylase) activity ($p=0.005$) and protein ($p=0.007$). In this group, decreased serum E2 levels weakly correlated ($p=0.05$) with increased rates of E2 utilization and generally related to increased CYP1A1 (not seen in disease-free animals). The results of this study suggest that the decreased serum E2 levels observed in TCDD-exposed rhesus monkeys with and without EM do not result from a TCDD-induced increase in liver E2 metabolism, but suggest that E2 and DMBA metabolism are differentially altered with disease status (supported by Endometriosis Association, Farleigh Dickinson Foundation, and NIEHS grant ES08539-01).

1800 PROTEIN EXPRESSION CHANGES IN THE RAT LIVER AFTER 90-DAY JP-8 EXPOSURE.

A. J. Bobb, G. B. Briggs, C. L. Wilson and K. R. Still. *Naval Health Research Center Detachment (Toxicology), Wright Patterson AFB, OH.* Sponsor: R. Carpenter.

The military jet fuel JP-8 and its commercial counterpart, Jet A, are used worldwide, causing exposure to liquid fuel, aerosol, and vapor. While most studies have found little toxicity from acute exposure, long-term effects are not well studied. Sprague-Dawley rats were exposed to 250, 500, or 1000 mg/m3 JP-8 vapor for 6 hours per day, 7 days/week for 90 days. Livers were removed, homogenized and fractionated into crude nuclear, microsomal, plasma membrane, and cytosol fractions. Proteins were examined by SDS-PAGE analysis and immunoblotting for cytochrome P450 isozymes, apoptosis-related proteins, oncogenes, and other protein factors, and distinct changes in the expression of specific proteins identified. Proteomic data available from the same exposure groups allows a balanced interpretation of the changes in protein expression in the rat liver.

1801 MORPHOLOGICAL CELL TRANSFORMATION OF C3H10T½frac18½CL8 MOUSE EMBRYO CELLS BY THE K-REGION DIHYDRODIOL OF BENZO[*A*]PYRENE OCCURS IN COINCIDENCE WITH DNA DAMAGE BUT WITHOUT THE FORMATION OF DETECTABLE STABLE COVALENT DNA ADDUCTS.

S. Nesnow, C. Davis, G. B. Nelson, G. Lambert, W. T. Padgett, M. Pimentel, A. H. Tennant, A. D. Kligerman and J. A. Ross. *Environmental Carcinogenesis Division, USEPA/ORD/NHEERL, Research Triangle Park, NC.* Sponsor: L. King.

Benzo[*a*]pyrene (B[*a*]P) is the most thoroughly studied polycyclic aromatic hydrocarbon (PAH). Many mechanisms have been suggested to explain its carcinogenic activity, yet many questions still remain. K-region diols of PAHs are common metabolites and have been thought to be detoxification products. Here, we present evidence that the K-region diol of B[*a*]P, B[*a*]P-4, 5-diol, induced morphological cell transformation (MCT) in C3H10T½frac18½Cl8 mouse embryo fibroblasts (C3H10T½frac18½ cells). This diol also induced DNA damage in these cells but did not form stable covalent DNA adducts. B[*a*]P-4, 5-diol and B[*a*]P induced MCT in C3H10T½frac18½ cells as significant numbers of Type II and Type III foci were produced over a concentration range of 1.8-10.5 μM for B[*a*]P-4, 5-diol, and 2.1-8.1 μM for B[*a*]P. The dose-response curves for B[*a*]P-4, 5-diol and B[*a*]P were the same. Both B[*a*]P-4, 5-diol (8 and 10 μM) and B[*a*]P (1, 4, 8, 10 μM)induced DNA damage as determined by the comet assay after 1 hr of treatment without significant concurrent cytotoxicity. Furthermore, the distributions of comet tail contents were altered in the B[*a*]P-4, 5-diol and B[*a*]P treatment groups compared to the controls. DNA adduct patterns in C3H10T½frac18½ cells were examined after PAH treatment using ^{32}P-postlabeling techniques and TLC elution systems designed for polar adducts. While B[*a*]P treatment produced one major DNA adduct identified as B[*a*]P-DE-dGuo, no stable covalent DNA adducts were detected in the DNA of B[*a*]P-4, 5-diol-treated cells. In summary, this study provides evidence for the DNA damaging and MCT activities of the K-region diol of B[*a*]P in the absence of covalent stable DNA adducts. In concert with the reported MCT activities of K-region diols of other PAHs, these data suggest a new mechanism/pathway for the bioactivation of PAHs. This abstract does not reflect EPA policy

1802 A ROLE FOR HEAT SHOCK PROTEIN 90 (HSP90) IN INTRACELLULAR TRAFFICKING OF BENZO(A)PYRENE (BP) IN RAINBOW TROUT LIVER.

L. R. Curtis[1], T. Musafia[1], C. Doneanu[1,2] and D. Barofsky[1,2]. *[1]EMT, Oregon State University, Corvallis, OR and [2]Chemistry, Oregon State University, Corvallis, OR.*

Feeding rainbow trout 0.3 to 0.4 mg/kg/day of dieldrin for 9 to 12 weeks markedly alters the disposition of a subsequent dose of radiolabeled dieldrin and benzo(a)pyrene. After a single challenge dose of 10 umol/kg of [^{14}C]dieldrin or [^{14}C]BP the concentrations of their equivalents in bile increase 2 to 5-fold and 3 to 12-fold in visceral fat of dieldrin fed over control fish. This phenomenon can be partially explained by an increase in binding capacity and intracellular trafficking of [^{3}H]BP, rather than by microsomal metabolism. Size exclusion chromatography on Sephacryl S-300 HR of hepatic cytosol of control and dieldrin fed fish, separates a putative [^{3}H]BP binding protein aggregate that is greater than 300 kD. One component of this aggregate has been identified as HSP90 by electrospray ionozation mass spectroscopy. We propose that this aggregate traffics BP to sites of metabolism or secretion in hepatocytes. In low dose *in vivo* experiments, intracellular trafficking may be a rate limiting step for hepatic disposition of lipophilic xenobiotics.

1803 DMBA INDUCED APOPTOSIS IN MURINE preB CELLS IS DEPENDENT ON ACTIVATION OF CASPASE-8.

T. J. Page[1,2], S. A. O'Brien[1], C. R. Jefcoate[2,3] and C. J. Czuprynski[1,2]. *[1]Pathobiological Sciences, Univ. of Wisconsin, Madison, WI, [2]NIEHS Center for Developmental and Molecular Toxicology, Univ. of Wisconsin, Madison, WI and [3]Pharmacology, Univ. of Wisconsin, Madison, WI.*

Polycyclic aromatic hydrocarbons (PAHs) are known to be both carcinogenic and immunotoxic. We have demonstrated that DMBA, a prototypic PAH, causes apoptosis in a murine preB cell line (70Z/3) cocultured with a bone marrow stromal cell line (BMS2). We have also observed that *in vivo* treatment of C57Bl/6 mice with DMBA (50mg/kg) results in marked hypocellularity in the bone marrow. The aim of this study was to identify the specific apoptotic pathways activated by DMBA *in vitro* and *in vivo*. We observed caspase-8 cleavage in 70Z/3 cells following treatment with DMBA *in vitro*. Apoptosis was blocked by ZVAD-fmk and ZIETD-fmk, which are pan-caspase and caspase-8 specific inhibitors, respectively. Although a caspase-9 specific inhibitor (ZLEHD-fmk) failed to block cleavage of caspase-8, caspase-9 activation was blocked by the addition of the caspase-8 specific inhibitor (ZIETD-fmk). These results suggest that caspase-8 activation is upstream of caspase-9 activation in preB cells undergoing apoptosis as a result of exposure to stromal cell and DMBA metabolites. Typically, caspase-8 is activated in response to binding of death receptors by their cognate ligands. DMBA induced apoptosis was not blocked by the addition of a neutralizing mAb to FasL, indicating that the Fas/FasL system was not responsible for caspase-8 activation in our system. We have detected up-regulation of Protein Kinase R (PKR) a double stranded RNA dependent kinase that is capable of death receptor independent activation of caspase-8 in response to DMBA treatment. Caspase-8 activation has also been detected in the bone marrow of mice treated *in vivo* with DMBA, which may explain in part the hypocellularity that occurs in the bone marrow. By comparing our *in vitro* and *in vivo* systems we hope to better understand how caspase activation might lead to leukocyte apoptosis and the immunotoxic effects of DMBA.

1804 POLYCYCLIC AROMATIC HYDROCARBON MIXTURES: ASSESSMENT OF HUMAN HEALTH RISKS AND RESEARCH NEEDS.

L. Flowers. *USEPA/NCEA, Washington, DC.* Sponsor: D. Singh.

The Integrated Risk Information System (IRIS) Program has initiated a health assessment for chronic environmental exposure to polycyclic aromatic hydrocarbon (PAH) mixtures. Current health assessments and guidance that are used by EPA for estimating risks from exposure to PAH mixtures were developed in the early 1990s and include: 1) IRIS health assessments for 15 individual PAH; and 2) Provisional Guidance for Quantitative Risk Assessment of PAH (1993) which provides relative potency factors (RPF) for seven PAH identified as probable human carcinogens using BENZO(A)PYRENE (B[a]P) as a standard. Risk assessment of PAH mixtures has been hindered by a lack of information on the composition of mixtures, the toxicity of specific mixtures, the components that contribute most to toxicity, and the interactions and differences in mode of action of toxicity between components. This information is critical for the evaluation of risks for specific mixtures and the use of surrogates to estimate risk. More recent studies have emerged which, at least in part, address these issues; but the studies also point to data gaps and additional research needs. The status of the health assessment for PAH mixtures and a compilation of the identified research needs is presented which includes the following as exemplary data gaps: 1) oral and inhalation toxicity of various PAH mixtures and inhalation toxicity of B[a]P using standard chronic bioassays is lacking; 2) the use of B[a]P as a standard for assessing the toxicity of PAH mixtures is now questioned, but animal bioassays for potential surrogates (e.g., "supercarcinogens") and comparative *in vitro* studies of these PAH with other known components of PAH mixtures are minimal; and 3) although recent studies have provided more data regarding interactive effects among PAH, they are limited in scope with regards to PAH mixtures as a whole and the quantitative aspects have not been elucidated. (The opinions expressed are those of the author and should not be construed as EPA policy).

1805 POLYCHLORINATED BIPHENYLS-INDUCED APOPTOSIS OF MURINE SPLEEN CELLS IS ARYL HYDROCARBON RECEPTOR-INDEPENDENT BUT CASPASES-DEPENDENT.

Y. J. Jeon[1], S. H. Lee[2], J. Suh[3], Y. J. Na[3] and H. M. Kim[2]. *[1]Pharmacology, Chosun University School of Medicine, Kwangju, South Korea, [2]Korea Research Insitute of Bioscience and Biotechnology, Taejon, South Korea and [3]Biological Sciences, Korea Advanced Institute of Science and Technology, Taejon, South Korea.*

Polychlorinated biphenyls (PCBs) are ubiquitous environmental contaminants, and many of the toxic effects including immunotoxicity are mediated by the activation of aryl hydrocarbon receptor (AhR). We previously reported that Aroclor 1254, one

of the most widely used PCB mixtures, increased DNA fragmentation in mouse spleen cells, assuming that apoptosis was correlated with the immunotoxicity of PCB (Yoo et al., 1997). In the present study we investigated the mechanism by which PCB induces apoptosis and the involvement of AhR in PCB-mediated apoptosis in mouse spleen cells. Aroclor 1254 induced DNA fragmentation without AhR activation, and the apoptosis was not affected by a-NF, a well-known antagonist of AhR. PCB congeners (PCB 47, 52, 128, and 153) that have little affinity for AhR induced DNA fragmentation, whereas congeners (PCB 77, 126, and 169) that have high affinity for AhR did not induce the fragmentation. Di-ortho form of PCB congener (PCB 153) and Aroclor 1254 induced DNA fragmentation in spleen cells of both AhR knockout mice (AhR-/-) and Ah low-responsive mice (DBA/2), whereas non-ortho form of PCB congener (PCB 126) did not induce the DNA fragmentation. In light of these findings, it is clear that AhR is not involved in the PCB-mediated apoptosis. PCB 153 significantly increased caspase-3 activity in both spleen cells and human leukemia (HL-60) cells. Z-VAD-fmk, general inhibitor of caspases, prevented the PCB-induced DNA fragmentation. Based on our findings, the most likely mechanism that can account for this biological effect involves the induction of caspase-dependent apoptotic cell death..

1806 EFFECTS ON PROLIFERATION, DIFFERENTIATION, AND GENE EXPRESSION OF BENZO(A)PYRENE, ARSENIC, AND CALCIUM ON NORMAL HUMAN EPIDERMAL KERATINOCYTES.

D. S. Perez, R. S. Yang and J. A. Campain. *Center for Environmental Toxicology & Technology, Environmental Health, Colorado State University, Fort Collins, CO.*

We are interested in developing accurate risk assessment strategies for environmentally relevant chemical mixtures. To this end, normal human epidermal keratinocytes (NHEK) were chosen as an *in vitro* model for measuring the carcinogenic potential of petroleum-based hydrocarbons. Our initial studies examined the effects of BENZO(A)PYRENE (BaP), on proliferation and differentiation in NHEK; perturbations in these cellular processes have been strongly linked to carcinogenesis in keratinocytes. We have demonstrated that BaP inhibits terminal differentiation in NHEK, as measured by cornified envelope (CE) formation, by up to 5.8-fold in control cells and 1.8-fold in calcium (Ca) induced cells. In comparison, arsenic (As), a known inhibitor of this process, decreased CE formation by approximately 20-fold in control cells and 3.2-fold in Ca induced NHEK. We are interested in delineating the effects of BaP on both terminal growth arrest and subsequent expression of protein markers of keratinocyte differentiation. To this end, flow cytometric analysis is being used to measure cell-cycle distribution in BaP- and As-treated *versus* control populations and populations undergoing Ca-stimulated differentiation. BaP at 2μM has been shown to increase proliferation rates by 1.5-fold. In contrast, As at 1μM inhibited proliferation 1.6-fold; similar growth arrest is observed (1.4-fold) in NHEK treated with 2mM Ca. Our findings suggest that, although both BaP and As inhibit CE production in NHEK, different mechanisms may be involved. Current studies will attempt to identify, through microarray analysis, molecular markers involved in the observed chemical effects. Our aim is to correlate alterations in these molecular markers with the transformation process in NHEK, and to develop predictive capabilities for risk assessment of petroleum-based hydrocarbon mixtures. This research was supported by NIEHS Grant # RO1 ES09655 & Minority Supplement # RO1 ES09655-01S1.

1807 SUPPRESSION OF OVARIAN FUNCTION BY INHALED BENZO(A)PYRENE.

A. E. Archibong[1], F. Inyang[2], A. Ramesh[2], M. Greenwood[2], P. Kopsombut[2], M. Niaz[2], D. B. Hood[2], A. M. Nyanda[2], J. Cross[1] and L. Huddleston[1]. *[1]Obstetrics & Gynecology, Meharry Medical College, Nashville, TN and [2]Pharmacology, Meharry Medical College, Nashville, TN.*

This study was conducted to evaluate the effect of BaP on ovarian function. Adult female Fisher-344 rats were randomly assigned to a treatment and a control group per exposure regimen. Two treatment regimens utilized in this study, consisted of subacute exposure of rats *via* inhalation to 0.05 or 0.1mg m^3 of BaP:carbon black aerosol, four hours a day for 10 days. From the fourth day of exposure, animals in the control (unexposed) and treatment groups were synchronized with subcutaneous progesterone (P_4) injections (1 mg P_4/animal/day for 4 days). Folliculogenesis was induced in these animals with intra-peritoneal (IP) injection of 15 IU of equine gonadotropin (EG) about 24 hours after the last P_4 injection [day 7 of BaP treatment]. Ovulatory response was subsequently induced at 48 hours post EG by an IP injection of 15 IU of human chorionic gonadotropins [hCG; day 9 of BaP treatment]. Twenty four hours post cessation of exposure of animals to BaP, all animals in the study were sacrificed, ovaries excised and weighed and number of ovulation points per animal determined by counting the total number of corpora lutea on both ovaries. All rats responded identically to the synchronization and folliculogenesis/ovulation induction protocol. Both regimens of BaP supressed ovulation rates ($P<0.05$) compared with controls (0.05 mg BaP/m^3, 11.0 ± 2.4 vs 24.4 ± 1.6; 0.1mg BaP/m^3, 18.7 ± 1.5 vs control, 29.0 ± 1.3) The percentage suppression of ovulation rate by BaP was exposure concentration-dependent ($P<0.05$). However, regardless of BaP-exposure concentration, ovarian weights were unaffected. These data suggest that (a) BaP perturbs the ability of fixed exogenous gonadotropins to adequately initiate folliculogenesis and ovulation and (b) BaP probably acts to reduce ovulatory response to gonadotropins *via* a reduction in follicular steroidogenesis (Supported by MHPF/ATSDR grant U50/ATU398948).

1808 ROLE OF BENZO(A)PYRENE (BAP) METABOLISM IN LUTEOTROPIC ACTIVITY AND FETAL SURVIVAL OF TIMED-PREGNANT RATS EXPOSED TO BAP: CARBON BLACK AEROSOL.

A. Ramesh[1], F. Inyang[1], A. E. Archibong[2], M. Greenwood[1], T. Nayyar[1], D. B. Hood[1], P. Kopsombut[1] and A. M. Nyanda[1]. *[1]Pharmacology, Meharry Medical College, Nashville, TN and [2]Obstetrics & Gynecology, Meharry Medical College, Nashville, TN.*

This study was undertaken to assess the effect of BaP metabolites on luteal maintenance and fetal survival in timed-pregnant Fisher 344 rats. Treatment consisted of subacute nose-only inhalation exposure of rats to 25, 75, and 100 μg/m^3 of BaP: carbon black aerosol, for 4 hours a day for 10 days, beginning on day 10 of gestation. Control animals were either sham exposed to carbon black (CB) or unexposed (UNC). Blood samples were collected on days 15, 17, and 20 of gestation *via* ocular puncture for plasma. Number of pups per litter was determined postpartum. Luteotropic factor in plasma samples was determined by measuring prolactin (PRL) levels by RIA. Metabolite levels in plasma and tissue samples from pregnant rats, and pups (postnatal day 1) were measured and identified by reverse phase HPLC coupled with fluorescence detection. Fetal survival declined ($P<0.05$) in a concentration-dependent manner as a result of exposure of rats to BaP (25μg/m^3 73%; 75 μg/m^3 38%; 100 μg/m^3 31%) compared with CB (77%) and UNC (86%). Plasma PRL concentrations in BaP treated rats showed a concentration-dependent decline relative to controls. The metabolite levels in plasma, uterine tissues, and pups were also exposure concentration-dependent. These results indicate a significant correlation ($P<0.05$) between plasma, tissue metabolite levels of mothers and fetal survival, and also between plasma metabolite and PRL levels. Further, these results strongly suggest that the exposure concentration-dependent disposition of inhaled BaP metabolites, especially the trans-7, 8-dihydrodiol contributed to a suppression in luteotropic activity and reduced embryonic survival (Supported by MHPF/ATSDR grant U50/ATU398948, NIH grant G12RRO3032, SCOR project 2SO6GMO8037-28, and RCMI project RR/AI 0303271).

1809 DIFFERENTIAL EFFECTS OF POLYCHLORINATED BIPHENYLS (PCBs) ON EXPRESSION OF HEPATIC ANION TRANSPORTERS Oatp2 AND Oatp3 AND MULTIDRUG RESISTANCE PROTEIN 2 (Mrp2) IN RATS.

L. A. Martin[1], M. A. Gallo[1], K. R. Reuhl[1] and C. D. Klaassen[2]. *[1]JGPT, Rutgers University and UMDNJ, Piscataway, NJ and [2]University of Kansas Medical Center, Kansas City, KS.*

Transfer of thyroxine (T_4) across plasma membranes is accomplished, in part, *via* transport proteins. Two proteins possibly involved in this process are organic anion transporting polypeptides Oatp2 and Oatp3. Additionally, Mrp2, a member of the superfamily of ATP binding cassette transporters, is implicated in the excretion of T_4-glucuronide (T_4-G) into bile. The purpose of this study was to determine whether PCBs, which markedly reduce serum T_4, might do so by enhancing the hepatic uptake of T_4, and subsequent excretion into bile, *via* increases in the expression of these proteins. Male rats were administered Aroclor 1254 or Aroclor 1242 for 7 consecutive days and 24 hrs after the last dose, [^{125}I]-T_4 was administered iv. At 1, 3, 5, 10, 15 and 30 min post-injection, blood and liver were sampled. The [^{125}I]-T_4 present in serum and liver was quantified by gamma spectrometry, and transporter protein levels in liver were determined by western-blot analysis. Within one min post-injection, Aroclor 1254 produced a 56% decrease in serum [^{125}I]-T_4 and Aroclor 1242 a 30% reduction within 3 min, as compared to controls. At the one min time point, Aroclor 1254 and Aroclor 1242 produced a 105% and a 54% increase, respectively, in the uptake of [^{125}I]-T_4 into liver, as compared to the control value. Oatp2 protein levels were suppressed 87% by Aroclor 1254, compared to the control, but Aroclor 1242 had no significant effect on Oatp2. No significant changes in Oatp3 protein levels were observed. In contrast, Aroclor 1254 and Aroclor 1242 produced significant increases in Mrp2 protein levels of 108% and 92%, respectively, relative to control. These data suggest that the increase in hepatic uptake of T_4 in rats exposed to PCBs cannot be explained by upregulation of Oatp2 and Oatp3. However, upregulation of Mrp2 may contribute to increased biliary excretion of T_4-G. (Supported by NIH grants ES-07148, ES-05022 and ES-08156)

1810 MODULATION OF ACUTE NEUROBEHAVIORAL TOXICITY OF BENZO(A)PYRENE BY METABOLISM, ANTIOXIDANT ENZYMES, AND NEUROCHEMICAL PARAMETERS IN F-344 RATS.

C. R. Saunders[1], S. Mukherjee[2], S. K. Das[2], A. Ramesh[1] and D. C. Shockley[1]. *[1]Pharmacology, Meharry Medical College, Nashville, TN and [2]Biochemistry, Meharry Medical College, Nashville, TN.*

The objective of this study is to understand the effects of Benzo(a)pyrene (BaP) on perturbation of nervous system by correlating behavioral changes with metabolism, antioxidant enzyme activities, and neurochemical parameters in selected brain regions. The neurobehavioral effect of single oral doses (12.5-200 mg/kg) of BaP on motor activity and the functional observational battery (FOB) were studied in male F-344 rats. Immediately after dosing, animals were returned to Digiscan activity cages and monitored for locomotor activities, beginning at 1800 hrs at 2 hrs and for a total of 12 hrs for five consecutive days. The FOB was conducted at 2, 6, 12, 24, 48, 72 and 96 hrs post BaP treatment. Benzo(a)pyrene parent compound and metabolites in plasma and brain tissues were measured by reverse phase HPLC. The effects of BaP on dopamine levels in the striatum were examined at 24 and 48 hrs post treatment by HPLC. Concentrations of antioxidant enzymes [catalase, superoxide dismutase (SOD), and glutathione peroxidase] were determined at 6 and 96 hrs in both the striatum and hippocampus of BaP exposed rats. Locomotor activity was suppressed on day 2 with recovery to control levels by day 3 in treated rats. Behavioral effects reached a maximum at 6 hrs in all FOB test measures but were reversible after 72 hrs in all dose groups. Bioavailability data suggest a strong link between BaP metabolism and the onset and duration of behavioral effects. A dose-dependent decrease in striatal dopamine content was noticed in treated rats. Benzo(a)pyrene produced a 30-50% and 12-25% upregulation of SOD at 6 and 96 hrs post treatment respectively. These findings suggest BaP cause acute neurobehavioral toxicity and modulation of striatal dopamine levels. Furthermore, the alteration of free radical status may contribute to BaP- caused neurotoxicity (Supported by MHPF/ATSDR U50ATU398948, NHLBI T32-HL07809, US Army DAMD-17-99-1-9550 and NIH 2506-GM-08037).

1811 REPRODUCTIVE PERFORMANCE OF TWO GENERATIONS OF RATS EXPOSED TO LOW LEVELS OF TECHNICAL CHLORDANE.

M. M. Mansour[1], V. E. St. Omer[1], B. C. Datiri[1], K. M. Mizinga[2], E. O. Abdulla[1], H. O. Goyal[3], F. O. Johnson[1], R. D. Mosha[3] and K. Ali[1]. *[1]Biomedical Sciences, Tuskegee University, Tuskegee, AL, [2]Pharmacology, University of Health Sciences, Kansas City, MO and [3]Veterinary Physiology, Sokoine University of Agriculture, Sokoine, Tanzania.* Sponsor: R. Dalvi.

Technical chlordane is a persistent organochlorine mixture of four main isomers (heptachlor, cis-chlordane, trans-chlordane, and trans-nonachlor). The effects of chlordane at environmental levels on reproductive performance of humans and other mammals are relatively unknown. Sprague-Dawley rats (F0, F1 & F2) were used in a two-generation study to evaluate technical chlordane effects on fertility index, pregnancy outcome, indices of puberty, reproductive organs weight and morphology, vaginal cytology and testicular parameters. Chlordane doses were 0.0, 0.125, 0.250 & 1.0 mg/kg body weight/day. Results of the first of two replicates indicated that, chlordane delayed ($P<0.05$) the ontogeny of vaginal opening in F1 females, but time to first estrus was unaffected; in contrast, F2 generation manifested no effect in time of vaginal opening, but time to first estrus was delayed at 1.0 mg/kg level. Estrus cyclicity was not affected. Time of preputial separation was advanced in F1 males at 0.125 mg/kg/day. Relative to the control, mating index was decreased in F1 chlordane treated groups, but not in F0. There was no treatment effect on total litter weight, litter size and sex ratio in both F1 and F2 generations. At necropsy, chlordane increased uterine weight in F0 dams at 0.125 mg/kg level and reduced testicular weight of F2 males at 0.250 mg/kg level. Measurement of the semeniferous tubules revealed an increase in its diameter and epithelial height of F1 & F2 chlordane treated groups. Sperm cells motility, velocity, morphology and concentration as well as plasma testosterone levels were unaffected. These results indicated that low levels of technical chlordane disrupted the normal morphology and physiology of the reproductive organs. (Supported by: MHPF/ATSDR-#U50/ATU3922660008)

1812 REPRODUCTIVE TOXICITY ASSESSMENT OF CHRONIC ORAL ADMINISTRATION OF FLUTAMIDE IN MALE RATS.

A. S. Faqi[1], D. Land[1], W. D. Johnson[1], R. L. Morrissey[2] and D. L. McCormick[1]. *[1]IIT Research Institute, Chicago, IL and [2]Pathology Associates International, Chicago, IL.*

Flutamide [2-methyl-*N*-(4-nitro-3-[trifluoromethyl]phenyl)propanamide] is a non-steroidal antiandrogen used as a therapeutic agent for prostate cancer. We have recently demonstrated that chronic dietary administration of flutamide also inhibits prostate carcinogenesis in a rat model. The present study was performed to determine the effects of a chemopreventive flutamide regimen on male reproductive parameters. Groups of 10 male Wistar-Unilever rats (9 - 10 weeks of age) were fed a basal chow diet or basal diet supplemented with flutamide (25 or 100 mg/kg diet) for $\geq$ 12 months. In comparison to dietary controls, rats exposed to flutamide demonstrated significant reductions in mean testes and epididymis weights. A non-monotonic dose-response was seen: testicular atrophy was present in 10/10 rats in the low dose flutamide group, but only in 4/10 rats in the high dose group. Similarly, although both doses of flutamide reduced spermatid number and daily sperm production, the low dose had quantitatively greater effects. Epididymal smears obtained from flutamide-treated rats demonstrated relatively few sperm; greater reductions in epididymal sperm count were seen at the low flutamide dose than at the high dose. Percent abnormal sperm (kinky tail, absence of head) was increased only in samples obtained from rats receiving the low dose of flutamide; percent abnormal sperm in the high dose group was comparable to that in dietary controls. Testicular histopathology in flutamide-treated rats demonstrated small seminiferous tubules populated primarily by spermatogonia and spermatocytes; relatively few spermatids were present. These data suggest that flutamide doses that confer significant protection against prostate cancer induction are likely to have significant adverse effects on male fertility. Decisions regarding the possible use of flutamide in prostate cancer prevention must include considerations of the impact of this agent on sexual potency.

1813 TRANSGENIC RATS AS A MODEL FOR THE INVESTIGATION OF ESTROGENIC EFFECTS.

G. Schönfelder, H. Bohnemeier, C. Labouvie, M. Neumerkel, I. Chahoud and M. Paul. *of Clinical Pharmacology and Toxicology, Benjamin Franklin Medical Center, FU Berlin, Berlin, Germany.* Sponsor: R. Stahlmann.

Endocrine disruptors are environmental chemical which may disrupt reproductive development.The ability xenooestrogens to bind to the estrogen receptor (ER) has been used as a definition of estrogenicity.Data suggest that endocrine disruptive effects are due to the interaction of the xenoestrogen with ER that regulate gene expression.Estrogenic chemicals typically bind the ER, the ER-ligand complex interacts with estrogen response elements (ERE), and transcription factors are recruited to the ER-ligand/ERE complex, resulting in enhanced gene expression.Receptor/ligand binding causes changes in gene expression leading to altered function of endocrine-regulated physiological systems.The inital screening methods used to detect estrogenic/anti-estrogenic activity are combinations of ER binding activity and transcriptional cellular assay systems *in vitro*.The interpretation of these data in the context of the *in vivo* situation can be difficult.The purpose of our study was to establish a transgenic animal approach, which allows to investigate transcriptional changes with functional alterations in the same animal.For this purpose, we investigated ERE-containing promotor-reporter usage *in vitro*.Reporter assays revealed dose-dependent response curves after treatment of the MCF-7 cells with a series of 17beta–estradiol and Bisphenol A concentrations. After *in vitro* testings, we established different transgenic rat strains on a Sprague-Dawley background using a pS2 promoter-construct.Mating of the founder generation with wild type Sprague-Dawley rats revealed transgenic positive rats.RT-PCR analysis of mRNA revealed reporter-gene expression in different organs (e.g. uterus) of untreated rats from different transgenic strains postnataly.Here we established a transgenic ERE-reporter rat as a model for testing estrogenicity of endocrine disruptors *in vivo*.Using this transgenic rat strain we have the posibillity to study the effects estrogens and xenooestrogens on endocrine-regulated physiological systems.

1814 IDENTIFICATION OF A CONSUMER PRODUCT ADDITIVE THAT INHIBITS OVIDUCTAL FUNCTIONING IN PICOMOLAR DOSES.

K. Riveles and P. Talbot. *Cell Biology and Neuroscience, University of California, Riverside, CA.*

Our past studies have shown that chemicals in cigarette smoke inhibit oviductal functioning *in vivo* and *in vitro* (Magers, Reprod Toxicol 1995, 9:513; Knoll, Reprod Toxicol 1998, 12:57). The purposes of this study were to identify the individual toxicants in cigarette smoke solutions made from 2R1 research brand cigarettes (University of Kentucky) that inhibit oocyte pickup rate, ciliary beat frequency, and infundibular smooth muscle contraction, and to determine their effective doses. Solid phase extraction and gas chromatography-mass spectrometry (GC-MS) were used to identify individual chemicals in the mainstream and sidestream cigarette smoke solutions. Pyridine derivatives were the most abundant class of compounds identified by GC-MS. Commercially available pyridines were purchased, assayed for purity, and tested in dose-response studies on the oviduct using an *in vitro* bioassay. The no observable adverse effect level (NOAEL) and lowest observable adverse effect level (LOAEL) were determined for each pyridine compound using the oocyte pickup rate, ciliary beat frequency, and infundibular mus-

cle contraction assays. 2-ethylpyridine, 2-methylpyridine, and 3-ethylpyridine were inhibitory at picomolar concentrations in all assays. In the 2R1 cigarettes, 3-ethylpyridine was found in smoke, but not in unburned cigarettes. 3-ethylpyridine is one of 599 chemicals added to commercial cigarettes to enhance flavor(http:\www.rjrt.com/TI/Pages/Ticig_ingred_Summary.asp). Two commercial cigarette brands were analyzed and significant amounts of 3-ethylpyridine were found in the unburned tobacco as well as in the mainstream and sidestream smoke. 3-ethylpyridine is also used as an additive in candy, ice cream, meat, and baked goods and is on the Flavor and Extract Manufacturers' Association's GRAS "generally regarded as safe" list, and the FDA's EAFUS (everything added to food in the United States) list. This work shows that very low doses of 3-ethylpyridine significantly inhibit proper oviductal functioning.

1815 LACK OF REPRODUCTIVE TOXICITY IN A 2-GENERATION STUDY OF DI(2-ETHYLHEXYL)TEREPHTHALATE (DEHT, DOTP) IN RATS.

W. D. Faber[1], D. G. Stump[2], R. M. David[3] and K. R. Miller[4]. [1]*Willem Faber Toxicology Consulting, Victor, NY,* [2]*WIL Research Laboratories, Ashland, OH,* [3]*Eastman Kodak Company, Rochester, NY and* [4]*Eastman Chemical Company, Kingsport, TN.*

A two-generation reproductive toxicity study of DEHT was conducted in which groups of 30 male and 30 female Sprague-Dawley rats were exposed to 0, 0.3, 0.6, or 1.0% DEHT in the diet. The F0 animals received the diets for at least 70 days prior to mating and until termination of the generation; the F1 generation received diets beginning on PND 22. All females were allowed to deliver and rear their pups to weaning (lactation day 21). Mean maternal body weights and body weight gains were reduced for F0 and F1 females in the 1.0% group throughout gestation. Mean maternal body weights were also reduced for the F0 and F1 females in this group throughout lactation. Overt toxicity and mortality were seen in the 1.0% F0 and F1 groups. Increases in absolute (F0 females) and mean relative (to body weight) liver weights (females in both generations) were observed for the 0.6 and 1.0% groups. No test article-related microscopic findings were observed in any of the tissues examined for either sex in either generation. Reproductive parameters (fertility, mating, days between pairing and coitus, gestation, parturition, and estrous cycling) were unaffected by treatment at any dose level during the F0 and F1 generations. Mean litter sizes, numbers of pups born, percentages of males per litter at birth and postnatal survival were unaffected by parental treatment at all concentrations. F1 and F2 offspring weights in the 0.6 and 1.0% groups were reduced throughout the pre-weaning period for the F1 generation and beginning on PND 4 and 7 for the F2 generation in the 0.6 and 1.0% groups, respectively. The NOAEL for reproductive toxicity was considered to be 1.0%. The NOAELs for parental toxicity and neonatal toxicity were considered to be 0.3%. These data complement the information from Gray et al. (2000) that indicate that DEHT does not produce antiandrogenic effects.

1816 EFFECTS OF PRENATAL TESTOSTERONE PROPIONATE AND VINCLOZOLIN ON PERINATAL AND INFANTILE DEVELOPMENT OF MALE AND FEMALE RATS.

C. J. Wolf[1,2], J. Furr[1], G. A. LeBlanc[2] and L. E. Gray[1]. [1]*RTD, USEPA, Research Triangle Park, NC and* [2]*Environmental and Molecular Toxicology, NCSU, Raleigh, NC.*

Prenatal exposure to both androgenic and antiandrogenic chemicals can adversely effect pregnancy and growth of offspring, but have opposite effects on sexual development. We conducted a study to determine whether an antiandrogenic chemical, vinclozolin (V), and an androgenic chemical, testosterone propionate (TP), in combination or alone, have similar or opposing effects on perinatal health and reproductive development. Sprague-Dawley rat dams were dosed on gestational day (GD) 14 (GD 1 = day of plug) to GD 19 with either corn oil (vehicle, orally), V (200 mg/kg, orally), TP (1 mg/rat, sc injection), or V+TP. Weight gain in dams through the dosing period was reduced by V (35.4 g, $p < 0.05$ *vs.* 53.1 g in controls) and by TP (28.1 g; $p < 0.005$) but was further reduced by V+TP (21.9 g, $p < 0.0005$). Live litter size on postnatal day (PND) 2 was reduced by V+T only (5.6, $p < 0.001$ vs 13.8 in controls), although mean number of uterine implantation sites was not affected. Anogenital distance (AGD) in females on PND 2 was increased from control values (1.73mm) by TP (2.51mm; $p < 0.0001$) and restored by co-administration of V (1.62). AGD in males was reduced from control values (4.04 mm) by V (2.18; $p < 0.0001$), but this reduction was not antagonized by co-administration of TP (2.07mm). Number of areolas on PND 14 in females was reduced from control values (12.05) by TP (3.69; $p < 0.0001$) and fully restored by V. Areolas were induced by V in males and co-administration of TP partially attenuated the prominence of the areolas (score = 23, scored by prominence on a scale of 1 - 36 per pup; $p < 0.0001$) compared to those in the V group (score = 30). We conclude that V and TP are additive in maternal and pup health, V attenuates the androgenic effects of TP on AGD and areolas in the female rat offspring, but the dose of TP used here does not fully attenuate the antiandrogenic effects of V on AGD and areolas in male rat offspring. This abstract does not necessarily reflect USEPA policy.

1817 DIBROMOACETIC ACID (DBA) ALTERATIONS IN OVARIAN STEROIDOGENESIS: SITE(S) OF IMPACT ON PROGESTERONE (P4) SECRETION.

J. M. Goldman and A. S. Murr. *Endocrinol Br, Repro Toxicology Div, USEPA, Research Triangle Park, NC.* Sponsor: A. Cummings.

Chlorination of public drinking water is among the most successful of treatments to combat disease. However, various generated byproducts have been linked to certain types of cancer & reproductive alterations in test animals. Haloacetic acids are a major class of these byproducts, & at least 2, DBA & dichloroacetic acid, are reported to alter sperm production and gonadal hormone activity in male rats. In females, DBA (90 & 270 mg/kg, po) disrupted cyclicity, an effect possibly related to a fall in P4 secretion (seen *in vitro*). To explore this further, 26d Sprague-Dawley rats given 15IU of pregnant mare serum gonadotropin were killed 48h later. Preovulatory ovarian follicles from 12-13 rats (per incubation) were removed & pooled. They were paired in oxygenated Medium 199 (M199, 37°C) with added BSA, HEPES & gentamicin sulfate within Teflon® vials under 1 of the following conditions: M199, DBA (50 µg/ml), hCG (100 IU/ml), or DBA+hCG (all pH-adjusted to 7.4). The DBA concentration reflected a mean 5h circulating value after a dose (270 mg/kg, po) that reliably disrupted cyclicity. Samples were taken at 4, 8, 12 & 24h. As before, 50 µg/ml lowered non-stimulated (NS) & hCG-stimulated (STIM) P4 release, an effect mirrored by the follcular P4 content at 24h. Estradiol release was unchanged. No effects on NS or STIM P4 release were seen following inclusion of pregnenolone (Pregn, 1 µg/ml), indicating tissue viability & Pregn conversion to P4 were not affected. Addition of 22(R)-hydroxycholesterol (22R-HC, 20µM) (circumventing intramitochondrial cholesterol transport by steroidogenic acute regulatory protein [StAR]) showed no difference in NS P4 release between DBA & non-DBA controls, implicating an effect on StAR in P4 suppression. Whether the alteration in cyclicity is linked to a decrease in P4 is uncertain. However, the P4 antagonist RU486 will cause such disruptions in cyclicity, suggesting that an effect on P4 secretion may at least partially contribute to the observed alteration in cyclicity. (This abstract does not reflect EPA policy.)

1818 *IN UTERO* EXPOSURE TO ATRAZINE INDUCES DELAYED PUBERTY OF LONG EVANS RATS: DAM-MEDIATED EFFECTS IN FEMALES.

J. L. Rayner[1] and S. E. Fenton[2]. [1]*DESE, School of Public Health, University of North Carolina, Chapel Hill, NC and* [2]*Reproductive Toxicology Division, USEPA, NHEERL, ORD, Research Triangle Park, NC.*

Exposure of Wistar dams to the common herbicide atrazine (ATR) on postnatal days (PND)1-4, will delay vaginal opening (VO) in the offspring, without reduced body weight (BW). We evaluated the effect of gestational ATR on puberty induction and compared whether effects were strictly dam-mediated or a direct effect on the pups. Time pregnant Long Evans rats (N=20/group) were gavaged gestational days (GD) 15-19 with 100 mg ATR/kg or methylcellulose (controls, C). BW of the ATR dams on GD19 was significantly reduced (346±7g), when compared to control dams (396±7g). On PND1, half litters were cross-fostered, creating 4 treatment groups; C-C, C-ATR, ATR-C, and ATR-ATR (milk-birth source, respectively). BW was compared on PND4, PND22, day of VO or preputial separation (PPS), and PND60 (female) or PND120 (male). A significant delay in VO was observed in females fostered to ATR-treated dams (Mean±SE, N>30 pups each group); C-C 33.7±0.4d, C-ATR 33.3±0.4d, ATR-C 35.4±0.6d, and ATR-ATR 37.1±0.5d. BW was significantly reduced at PND4 (N>35 pups in each group) in ATR-ATR animals *vs.* C-C (9%) or C-ATR (9%), but was not different between those dose groups at weaning or PND60. Although VO was delayed by ATR, the BW at VO of ATR-ATR (146.8±4.4) and ATR-C offspring (140.0±4.4) was greater than C-C (130.6±2.8). Male pups exposed to ATR *in utero* (N>18/dose group) displayed delayed PPS whether they suckled from an ATR (43.8±0.5d, ATR-ATR) or control dam (42.5±0.4, ATR-C). However, PPS was similar between C-ATR(41.5±0.4) and C-C (41.3±0.3). The ATR-ATR and ATR-C males were reduced in BW 9% and 6%, respectively, from that of C-C at PPS. Our data suggests that the delay in VO in offspring exposed to ATR *in utero* is mediated *via* the dam, and does not appear to be caused by decreased BW. Whether these effects are the result of a hormonal or lactational alteration requires further investigation. *(This abstract has been reviewed in accordance with USEPA policy and approved for publication)*

1819 ABBREVIATED ONE-GENERATION STUDY OF DIETARY BISPHENOL A (BPA) IN CD-1® MICE.

R. L. Joiner[4], C. B. Myers[1], M. C. Marr[1], A. F. Gilliam[1], T. Y. Chang[1], J. C. Seely[2], B. F. Thomas[1], G. D. Stropp[3] and R. W. Tyl[1]. [1]*Research Triangle Institute, Research Triangle Park, NC,* [2]*Experimental Pathology Laboratories, Inc., Research Triangle Park, NC,* [3]*Toxicology, Bayer AG, Wuppertal, Germany and* [4]*Global Toxicology, General Electric Company, Pittsfield, MA.*

This study duplicated the species/strain, route, and top 2 dietary BPA concentrations (5000 and 10, 000 ppm) employed in a previous RACB study (Reel et al., 1985), but with shorter duration, one breeding, and enhanced evaluation of parental systemic/reproductive toxicity to provide the context for previously reported F1 offspring effects at these doses. F0 mice (20/sex/group) were exposed ad lib to BPA for 2-wk prebreed; 1-wk mating (F0 males necropsied after mating; 3-wk total exposure); and ca. 3-wk gestation. F0 dams and F1 litters were necropsied at parturition (pnd 0). Parental systemic toxicity was present at both BPA doses: increased liver and kidney weights (WT) in both sexes; for F0 dams: reduced body weights (BW), weight gain, and feed efficiency during pregnancy; prolonged gestation (no effects on precoital interval or ovarian or uterine WT); histopathology in liver (dose-related hepatocellular hypertrophy) and kidneys (dose-related tubular epithelial degeneration, necrosis and regeneration); elevated serum BUN at 10, 000 ppm; and reduced serum Na, K, and Cl at 5000 ppm (consistent with renal toxicity). F1 offspring toxicity was observed only at 10, 000 ppm: slightly reduced total and live pups/litter, with no effects on pre-/postimplantation loss or pup BW. This study resulted in comparable daily BPA intakes (for both sexes and doses) and confirmed litter size effects at 10, 000 ppm by Reel. It also demonstrated parental systemic toxicity at both doses. Our data support the interpretation of litter size effects at 10, 000 ppm as caused by the compromised status of dams (after 5-6 wks total exposure), while the lesser systemic toxicity at 5000 ppm did not cause litter size effects. F1 litter size effects at 5000 ppm were observed by Reel only for 4th-5th litters after much longer exposure duration (>90 days).

1820 ALTERATIONS IN THE RAT ESTROUS CYCLE BY DIBROMOACETIC ACID (DBA): RELATIONSHIP TO A SUPPRESSION IN ESTRADIOL (E2) METABOLISM?

A. S. Murr and J. M. Goldman. *Endocrinol. Br., RTD, NHEERL, USEPA, Research Triangle Park, NC.* Sponsor: A. Cummings.

Of the large variety of chemicals formed by chlorination of public drinking water, a number are suspected to cause reproductive alterations in humans and test animals. Members of one class, the haloacetic acids (of which DBA is a member) have been reported to alter rat sperm production & gonadal hormonal activity at elevated doses. In females, DBA was found to induce a persistent alteration in estrous cyclicity, something found in the present study using 14d exposures (0-270 mg/kg, po). Body wts were unaffected. While a fall in progesterone (seen *in vitro*) could impact cyclicity, it may be that E2 levels are also altered. *in vitro* data did not show shifts in ovarian E2 release, but an impact on E2 metabolism could affect blood levels. Consequently, cycling female rats were treated (po) daily for 2 wks with DBA (0, 30, 90, 270 mg/kg in water, pH adj. to 6.8). After 8d (during which cycles continued), females were ovariectomized & 3d thereafter implanted with estradiol capsules (OVX-E2). Daily tail nick blood was then taken for 3d. Non-E2 capsules were also implanted & blood taken (0 & 270 mg/kg DBA). Additional OVX-E2 rats (270 mg/kg) received phenobarbital (PB, 0.1% in drinking H_2O) for 4d before sampling to stimulate E2 metabolism. After capsule implantation, an initial serum E2 rise then fell over the next 2d. By 72h, DBA caused a dose-related increase in E2 that at the highest dose was approx. 2 1/2-fold above controls. PB reduced DBA-elevated E2 levels. Data suggest that alterations in cyclicity seen following DBA exposures could be at least partially due to a suppression in hepatic E2 metabolism. The rise in E2 is reversible & speaks against suicide inhibition of the relevant P450 activity. The data indicate that DBA given at these doses over 2 wks acts as an endocrine disrupting chemical. While it is conceivable that lower doses over more extended periods could have similar effects on reproductive functioning, such studies remain to be conducted. (This abstract does not reflect EPA policy.)

1821 EFFECTS OF METHOXYCHLOR (M) OR ITS ACTIVE METABOLITE, 2, 2-BIS (P-HYDROXYPHENYL)-1, 1, 1-TRICHLOROETHANE (HPTE), ON TESTOSTERONE (T) FORMATION BY CULTURED ADULT RAT LEYDIG CELLS (LC).

E. P. Murono and R. C. Derk. *Pathology and Physiology Research Branch, CDC/NIOSH, Morgantown, WV.* Sponsor: V. Castranova.

M is a pesticide developed as a replacement for dichlorodiphenyltrichloroethane (DDT). Its active metabolite is reported to be HPTE. Both M and HPTE have been shown to exhibit weak estrogenic or antiandrogenic activities in various *in vivo* or *in vitro* testing protocols. In the present studies, we examined the direct effects of M or HPTE on T biosynthesis by cultured LC from young adult rats. Increasing concentrations of M or HPTE (1-1000 nM) caused a progressive decline in both basal and 10 mIU/ml human chorionic gonadotropin (hCG)- or 1 mM 8-Br-cAMP-stimulated T following exposure for 4 or 24 h, beginning at 100 or 500 nM, although the declines with HPTE generally were greater. To localize the site(s) of action of HPTE, LC were exposed to HPTE (1-1000 nM) alone for 24 h, then fresh media containing steroid precursors of T were added to follow the ability of exposed cells to convert these substrates to T over 4 h. The conversion of 0.01 mM pregnenolone, progesterone, or androstenedione to T was unaffected by prior exposure to HPTE; however, there was a progressive decline in the conversion of 0.01 mM 22(R)-hydroxycholesterol to T, suggesting that among the enzymes involved in the conversion of cholesterol to T, P450 cholesterol side-cleavage activity is inhibited by HPTE. The concomitant inclusion of the pure estrogen antagonist, ICI 182, 780, did not alter the inhibitive effects of HPTE, suggesting that the actions of HPTE are not mediated by binding to estrogen receptor alpha or beta. Also of interest, the addition of the native estrogen, 17beta-estradiol, or the antiandrogens, cyproterone acetate (1-1000 nM) or hydroxyflutamide (1-1000 nM), had no effect on basal or hCG-stimulated T following exposure for 24 h, suggesting that the actions of HPTE are not due to its estrogenic or antiandrogenic properties.

1822 EXPRESSION OF BIOTRANSFORMATION ENZYMES IN OVARIAN INTERSTITIAL CELLS: EFFECT OF DOSING WITH 4-VINYLCYCLOHEXENE AND ITS DIEPOXIDE METABOLITE IN MICE.

E. A. Cannady[1], P. J. Christian[2], L. P. Mayer[2], C. A. Dyer[3], I. G. Sipes[1] and P. B. Hoyer[2]. [1]*Pharmacology/Toxicology, University of Arizona, Tucson, AZ,* [2]*Physiology, University of Arizona, Tucson, AZ and* [3]*Biological Sciences, Northern Arizona University, Flagstaff, AZ.*

Our laboratory is investigating the role of ovarian metabolism in 4-vinylcyclohexene-induced ovotoxicity in mice. This study was designed to evaluate the effect of repeated dosing with the ovotoxicants 4-vinylcyclohexene (VCH) and its diepoxide metabolite (VCD) on expression of several biotransformation enzymes in the ovarian interstitium, whose function is poorly understood. Female B6C3F$_1$ mice (d28) were dosed daily (15d) with vehicle (Con), VCH (800 mg/kg) or VCD (80 mg/kg). Ovaries were removed and fixed for immunohistochemistry, or isolated into interstitial cells. We evaluated the effects of VCH/VCD dosing on mRNA expression and protein distribution of cyp 2e1, cyp 2a4/5, and microsomal epoxide hydrolase (mEH) using realtime PCR or confocal microscopy, respectively. Luteinizing hormone receptor was used as a marker for confocal visualization of interstitial cells. mRNA encoding *cyp* 2e1, *cyp* 2a4/5, and *mEH* was present in interstitial cells from control mice. However, after repeated dosing, expression was significantly decreased only for *mEH* (60±37% of Con, VCH, $p<0.05$), compared to control. Intense immunostaining for cyp 2e1, cyp 2a4/5, and mEH proteins was seen in interstitial cells from control mice. VCH dosing decreased staining intensity for cyp 2e1 (19±2.4% of Con VCH, $p<0.05$), while increasing staining intensity (39±5.1% above Con VCH, $p<0.05$) for cyp 2a4/5, compared to control. Although not significant, there was a downward trend in staining intensity for mEH, (20±10.3% of Con VCH, 32±19.3% of Con VCD) compared to control. Taken together, mRNA and protein for several biotransformation enzymes were investigated in ovarian interstitial cells. Their expression was affected by repeated dosing with VCH/VCD. Thus, these cells may play an important role in the ovarian metabolism of xenobiotics. (ES08979, ES06694, ES07019)

1823 EFFECT OF BLOCKADE OF GLUTATHIONE (GSH) SYNTHESIS ON OVARIAN FOLLICULAR ATRESIA.

U. Luderer. *Center for Occupational and Environmental Health, University of California, Irvine, CA.*

The mammalian ovary contains a finite complement of oocytes, most of which are destined to undergo the apoptotic process of degeneration termed follicular atresia. Our previous work has shown that healthy, growing follicles, but not atretic follicles, express high levels of the modulatory subunit of glutamate cysteine ligase (GCL), the rate limiting enzyme in the synthesis of the antioxidant tripeptide GSH (Luderer et al, 2000, Toxicol Sciences:54:257). Depletion of cellular GSH causes apoptosis in many cell types; however, the effect of GSH depletion on ovarian follicular atresia has not been investigated. To test the hypothesis that GSH depletion causes increased follicular atresia, cycling adult rats were treated with i.p. injections of 5mmol/kg buthionine sulfoximine (BSO), a specific inhibitor of GCL, in saline or with saline alone at 0700 and 1900h on proestrus (n=2, saline; n=3, BSO) or estrus (n=3 saline; n=4, BSO), and sacrificed at 0700h the next day. One ovary was homogenized for total GSH assay using the Tietze method. The other ovary was cryosectioned and subjected to terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling (TUNEL) using the Cell Death Detection Kit (Roche

Molecular Biochemicals, Mannheim, Germany) to detect apoptotic cells and counterstained with hematoxylin. Follicles were also scored for atresia using histological criteria. Logistic regression analysis was used to examine the effect of BSO treatment on atresia while adjusting for estrous cycle stage and follicle type. Ovarian GSH concentrations in BSO-treated animals were 50% lower than in saline treated animals. BSO treatment was associated with a statistically significant increase in follicular atresia as determined by histological criteria and a non-significant increase in follicles containing apoptotic cells by TUNEL. Estrous cycle stage and follicle type were also significantly associated with atresia, with antral follicles from metestrous ovaries most likely to be atretic. These results suggest that ovarian GSH plays a role in preventing follicular atresia.

1824 COMPARISON OF THE EFFECTS OF MT-1E AND MT-3 OVEREXPRESSION ON GROWTH INHIBITION AND CHEMOTHERAPEUTIC DRUG RESISTANCE IN THE PROSTATE CANCER CELL LINE, PC-3.

S. H. Garrett[1], R. Dutta[1], D. A. Sens[1], S. Somji[1] and M. A. Sens[2]. [1]*Urology, West Virginia University, Morgantown, WV and* [2]*Pathology, West Virginia University, Morgantown, WV.*

The third isoform of metallothionein (MT-3) has been shown to be overexpressed in prostate cancers and PIN lesions. The expression of MT-3 is highly variable but appears to correlate to the type and grade of the tumor. The expression of MT-3 in prostate cancer was modeled by stably transfecting the commonly utilized prostate tumor cell line, PC-3 with MT-3. Previously it was shown that this caused an inhibition of cell growth and an increased resistance to the chemotherapeutic drugs, vinblastin, etoposide, mitoxantrone, cisplatin, and paclitaxel as assess by the colony formation assay. The PC-3 cell line was also stably transfected with another commonly expressed MT isoform in the prostate that is not expressed in this cell line, MT-1E, to see if the above effects are specific to MT-3 or a general feature of all metallothioneins. Five MT-1E expressing clones were picked for further analysis and the level of the MT1/2 protein was found to be increased from 0.98±0.1 to 5.81±0.14 ng MT/μg protein as assessed by immuno-dot blot analysis. The MT-1E expressing clones had similar resistance profiles to the above chemotherapeutic drugs as the MT-3 expressing clones, but did not show any change in the growth rate of the cells. The mean doubling time the MT-1E expressing clones was 39.2±3.8 hr compared to 34.6±1.9 hr for the blank vector controls whereas the MT-3 transfected clones had a mean doubling time of 63.4±2.2 hr. These data indicate that the effect of MT-3 on cell growth is a unique feature of the MT-3 isoform probably facilitated by the unique sequence in the beta domain of the protein whereas the effect on the resistance to chemotherapeutic drugs is a common characteristic of the MT isoform family.

1825 TIME-COURSE ALTERATIONS IN CDK FAMILY GENES IN GERM CELL APOPTOSIS INDUCED BY 2-BROMOPROPANE (2-BP) IN RAT.

X. Z. Yu, R. S. Wang, Y. Ogawa and N. Hisanaga. *National Institute of Industrial Health, Kawasaki, Japan.*

Epidemiological surveys and animal experimental studies suggested that exposure to 2-BP could develop reproductive and hematopoietic disorders both in human and experimental animals. In our previous studies, we confirmed that 2-BP exposure results in apoptotic death of testicular germ cells and this process involves the Bcl-2 family genes and the Fas signaling system. In this study, we further explored the roles of cyclin dependent kinase (CDK) family genes in the development of male germ cells degeneration. Sixty-four rats were divided into eight groups, and percutaneously injected with a dose of 1350 mg/kg of 2-BP for 1 to 5 days. The rats were time-serially euthanized at 6 h after1, 2, 3, 5 doses, and 2 or 7 days after final treatments. Histological examination, TUNEL staining of DNA fragments, and Western blotting analysis of CDK family proteins (Cyclin E, CDK 2, CDK 4, Cyclin D1), and the expression of proliferation cell nuclear antigen (PCNA) were conducted. Two dayÅfs treatment resulted in selective apoptotic death of spermatogonia. The TUNEL staining analysis showed 2-BP treatment resulted in two distinct stages of morphological changes, namely the immediate effects on spermatogonia, and secondary apoptosis in spermatocytes 9 days after treatment. The expression of PCNA, a marker of proliferating cells, slightly decreased during 2-BP treatment, and it decreased significantly 9 days after treatment. CDK 2 decreased slightly during 2-BP treatment, and significantly by the day 2 or 9 after treatment, while CDK 4 significantly increased after 2-BP exposure, however, it decreased by the day 9 after exposure. Cyclin D decreased markedly during 2-BP treatment, and 2 or 9 days after treatment. Cyclin E reduced after first injection of 2-BP, and then increased a little during the second, third days injection, and then decreased again 2 or 9 days after treatment. The present study suggested that cyclin D might be involved in the apoptotic death of spermatogonia, while other CDKs might be involved in the secondary degeneration of spermatocytes.

1826 CHARACTERIZATION OF A RAT *IN VITRO* OVARIAN CULTURE SYSTEM TO STUDY THE OVARIAN TOXICANT 4-VINYLCYCLOHEXENE DIEPOXIDE.

P. J. Devine[1], I. G. Sipes[2,3] and P. B. Hoyer[1]. [1]*Physiology, University of Arizona, Tucson, AZ,* [2]*Pharmacology and Toxicology, University of Arizona, Tucson, AZ and* [3]*Center for Toxicology, University of Arizona, Tucson, AZ.*

The heterogeneity of the mammalian ovary can cause complications for mechanistic studies involving ovarian toxicity. Repeated daily dosing of rats with the occupational chemical 4-vinylcyclohexene diepoxide (VCD) causes depletion of small preantral (primordial and small primary) ovarian follicles. These targeted populations are difficult to study due to their small size and random distribution throughout the ovary. Therefore, a rat ovarian culture system was developed and its susceptibility to VCD was assessed. Ovaries from 4-day old Fischer 344 rats were collected, laid onto membranes floating on defined medium, and covered with a drop of medium. Medium was replaced every two days. Ovaries were then prepared for histologic examination after 15 days (15d). Follicles were classified and counted in every 6th section. Initial follicle populations in ovaries consisted of primordial (80%) and small primary (20%) follicles, whereas somewhat more developed populations were present after 15d of culture (66% primordial, 32% small primary, 2% large primary, few secondary). Rat ovaries in culture for 15d were sensitive to VCD in a concentration-dependent manner. 10μM VCD had no significant effects ($p>0.05$), whereas primordial and small primary follicle populations were reduced after culturing 15d with 30μM VCD relative to controls (by 99% and 80%, respectively; $p<0.01$). To verify susceptibility of noenatal rats to VCD, rats (d4-19 of age) were dosed daily with VCD (80 mg/kg) for 15d. This resulted in a depletion of primordial (by 80%, $p<0.01$) and small primary follicles (by 70%, $p<0.05$). These results demonstrate that ovaries from neonatal rats are sensitive to VCD in culture. Because of the similarity of VCD's targets *in vitro* and *in vivo*, this system will be useful for future studies into the mechanism of action of VCD-induced ovarian follicle loss that has been well-characterized *in vivo* in rats. (ES06694, ES08979)

1827 NONYLPHENOL AND ATRAZINE INDUCE INVERSE EFFECTS ON MAMMARY GLAND DEVELOPMENT IN FEMALE RATS EXPOSED *IN UTERO*.

H. J. Moon[1], S. Y. Han[1], C. C. Davis[2] and S. E. Fenton[2]. [1]*Department of Toxicology, Korea FDA, NITR, Seoul, South Korea and* [2]*Reproductive Toxicology Division, NHEERL, USEPA, Durham, NC.*

These experiments tested whether exposure to 4-nonylphenol (NP) or atrazine (ATR) during fetal mammary bud outgrowth alters mammary gland (MG) development in adult female offspring. Time pregnant Long Evans rats (N=7-8/treatment) were gavaged with NP (10 or 100 mg/kg), ATR (100 mg/kg), or corn oil on gestation days (GD) 15-19. MGs from female pups were removed and prepared as whole mounts or histological sections on postnatal days (PND) 4, 22, 33 and 41. Delayed MG development was detected on PND4 in ATR pups, and persisted through PND41(stunted epithelial progression through the fat pad, fewer primary and lateral branches). High dose NP pups had advanced lobular development of their MG by PND22 (in contrast, in controls at PND41). Low dose NP glands were not morphologically different from controls. Immunohistochemical comparisons of mammary sections from PND 41 demonstrated low levels of estrogen receptor (ER) staining in control gland stroma and epithelium, and was visibly increased in tissue of pups exposed to NP and ATR. ATR also elevated ER in the stroma surrounding the terminal end buds (TEB). Progesterone receptor (PR) staining was visibly decreased in the epithelium of NP100 glands *vs.* control glands. However, PR was present at high levels in epithelium of NP10 glands and was even more prominent in ATR-exposed ductal epithelium and fat cell nuclei. PR was expressed in TEB of all rats, but was undetectable in the TEB cap cell layer. Prolactin staining was elevated *vs.* control levels only in glands containing lobule areas (NP-exposed). These qualitative evaluations suggest that the environmental contaminants, NP and ATR, have opposite effects on MG development following gestational exposure. These exposures during a critical period of epithelial outgrowth altered levels of mammary PR and prolactin, which may contribute to the differences in mammary morphology at PND41. (This abstract has been reviewed in accordance with USEPA policy and approved for publication)

1828 ACTIVATION OF MITOGEN-ACTIVATED PROTEIN KINASES AND AP-1 TRANSCRIPTION FACTOR IN OVOTOXICITY INDUCED BY 4-VINYLCYCLOHEXENE DIEPOXIDE IN RATS.

X. Hu[1], J. A. Flaws[3], I. G. Sipes[2] and P. B. Hoyer[1,2]. [1]*Physiology, University of Arizona, Tucson, AZ,* [2]*Pharmacology, University of Arizona, Tucson, AZ and* [3]*Epidemiology/Preventive Medicine, University of Maryland, Baltimore, MD.*

Previous studies indicated that ovotoxicity induced in rats by 4-vinylcyclohexene diepoxide(VCD) is *via* acceleration of the normal rate of atresia. Mitogen-activated

protein kinases are thought to play a pivotal role in transmitting transmembrane signals required for cell proliferation or death. This study was designed to investigate whether the MAPK signaling pathways were involved in VCD-induced ovotoxicity. Female F344 rats were dosed daily with VCD (80 mg/kg, i.p.) for 1 day (1d, ovotoxicity has not been initiated), 10 days (10d; early signs of impending follicular destruction with no follicle loss) or 15 days (15d; significant follicle loss underway). 4 h following the final dose, ovaries and livers were collected. Ovarian small pre-antral follicles (25-100 μm) were isolated, and sub-cellular fractions were prepared. Activities of MAPKs, including extracellular signal-regulated kinase (ERK), c-Jun N-terminal protein kinase (JNK), and p38 kinase, were determined in cytosolic fractions. Activator protein 1 (AP-1) DNA-binding activity was determined in nuclear fractions. The data obtained from ovarian small pre-antral follicles are summarized in the following table (* $p<0.05$; ** $p<0.01$ compared with control). VCD did not affect any these measurements in liver. Taken together, these data support that the acceleration of atresia is associated with the activation of JNK and p38 kinases and reduced AP-1 DNA binding activity after VCD-induced follicle destruction is underway. This kinase activation or inactivation may be crucial in mediating the normal rate of *atresia* in small pre-antral follicles. (ES09246; ES06694; HD38955).

1829 STRAIN COMPARISON OF ENDOCRINE RESPONSE IN RATS TO BROMODICHLOROMETHANE (BDCM) DURING PREGNANCY.

S. R. Bielmeier[1], D. S. Best[2] and M. G. Narotsky[2]. [1]*Curriculum in Toxicology, Univ. of North Carolina, Chapel Hill, NC and* [2]*Reproductive Toxicology Division, NHEERL, USEPA, Research Triangle Park, NC.* Sponsor: A. Cummings.

Previously, we reported that BDCM, a drinking water disinfection by-product, causes pregnancy loss, i.e. full-litter resorption (FLR) in F344 rats when treated during the luteinizing hormone (LH)-dependent period. We also found that Sprague-Dawley (SD) rats were unaffected at even higher doses. Here, we examined the effects of BDCM on serum progesterone and LH levels during pregnancy in both strains. BDCM, in 10% emulphor, was dosed by gavage on gestational days (GD) 6-10 (plug day = GD 0) at 75 mg/kg/d in the F344 rat, and 100 or 200 mg/kg/d in the SD rat. Blood samples were collected from the lateral tail vein once daily on GD 6-11; serum progesterone and LH were measured using DELFIA®. The rats were allowed to deliver and pups were examined postnatally. FLR was confirmed by staining uterine resorption sites with 10% ammonium sulfide. Unlike the F344 rats, the SD rats maintained their litters and progesterone levels; although, similar to the F344 rats, they did display decreased LH levels. F344 rats had an 88% (7/8) incidence of FLR at 75 mg/kg/d, whereas SD rats had 0% (0/10, 0/9) incidences at both 100 and 200 mg/kg/d. BDCM-treated F344 dams with FLR had reduced progesterone and LH levels on GD 10; mean ± SE LH levels were 0.07 ± 0.04 *vs.* 0.15 ± 0.02 ng/ml for controls. In contrast, the SD rats treated at 200 mg/kg/d did not show a decrease in serum progesterone levels on GD10; however, serum LH levels were significantly decreased from controls (0.24 ± 0.06 *vs.* 0.49 ± 0.06 ng/ml). Importantly, control serum LH values were significantly higher in SD than F344 rats ($p<0.0001$). Thus, these dramatic strain differences in baseline LH levels and susceptibility to BDCM-induced pregnancy loss exemplify the importance of strain as a consideration when assessing reproductive toxicity. [Funded by the EPA/UNC Toxicology Research Program, Training Agreement CT827206 Curriculum in Toxicology, UNC-Chapel Hill. This abstract does not necessarily reflect EPA policy.]

1830 A STUDY TO EVALUATE THE EFFECTS OF LEPTIN ADMINISTERED SUBCUTANEOUSLY DURING CRITICAL PHASES OF GESTATION IN MICE.

J. Nokleby[1], W. Davis[1], M. Nemec[2] and M. E. Cosenza[1]. [1]*Toxicology, Amgen Inc., Thousand Oaks, CA and* [2]*WIL Research Laboratories, Ashland, OH.*

Leptin is a protein hormone, produced by adipose tissue, involved in the regulation of body fat. Recombinant r-metHuLeptin (Leptin) administered to normal animals results in rapid loss of body weight primarily due to body fat reduction. Previous studies with Leptin administration continuing into late gestation resulted in reduced postnatal pup survival. The objective of this study was to evaluate if the effects of Leptin previously noted are related to a critical phase of fetal development. For this study, Leptin, 10 mg/kg/day, was administered daily on Gestation Days (GD) 6-15, 15-18, or 6-18. Clinical observations, body weights, and food consumption were recorded at appropriate intervals. Laparohysterectomies were done on GD 18 for one subset of females from each treatment regimen. Another subset was allowed to deliver and rear the offspring to Lactation Day 21. Increased incidences of prolonged gestation and/or dystocia and increase in length of gestation were noted in the groups that were administered Leptin GD 6–18 or 15–18. Body weight reductions typical of Leptin administration were noted in all Leptin-treated groups. Food consumption was reduced GD 15-18 for females treated during that period. Changes in clinical chemistry parameters were typical of previous studies conducted with Leptin. At laparohysterectomies, no changes in intrauterine growth and survival were noted and there were no treatment-related external malformation or variations observed in the fetuses. Mean live litter size and postnatal pup survival were reduced in the groups that were administered Leptin GD 6–18 or 15–18. Mean pup body weights were reduced in the groups that were administered Leptin GD 6–18. The effects of Leptin administration were considered to be most prevalent when the dams were treated late in gestation (GD 15–18), confounding the process of parturition and resulting in higher mortality rate in the F1 pups and decrements in postnatal growth.

1831 TISSUE- AND STRAIN-SPECIFC EXPRESSION OF MULTIDRUG RESISTANCE PROTEIN 1 (MRP1) IN INBRED MOUSE STRAINS.

M. Z. Dieter[1], N. J. Cherrington[2] and L. D. Lehman-McKeeman[3]. [1]*Procter & Gamble, Cincinnati, OH,* [2]*University of Kansas Medical Center, Kansas City, KS and* [3]*Dupont Pharmaceuticals, Newark, DE.*

MRP1 is a member of the ATP-binding cassette (ABC) superfamily of membrane-spanning transporter proteins. These proteins catalyze the ATP-dependent export of many hydrophobic compounds and products of Phase II metabolism, including steroid hormone conjugates, across cellular membranes, and are implicated in the acquired resistance of tumors to chemotherapeutic agents. The purpose of this work was to compare constitutive expression levels of MRP1 in five commonly used strains of female laboratory mice. MRP1 protein was detected in tissue membranes by Western blot analysis. In all strains of mice examined, the highest expression of MRP1 was observed in the reproductive tract, particularly the ovary and fallopian tube. Marked strain differences were noted in the uterus as expression was highest in 129Sv ∽ C57BL/6 > CD-1 > B6C3F1 ∽ FVB. Strain differences were also noted in skeletal muscle and kidney; in muscle, levels of MRP1 were highest in B6C3F1 ∽ FVB ∽ CD-1 > C57BL/6 > 129Sv, whereas, in kidney, MRP1 levels were highest in C57BL/6 ∽ 129Sv > CD-1 > B6C3F1 ∽ FVB. Examination of MRP1 mRNA in tissues of B6C3F1 mice using branched DNA methods revealed that mRNA levels are not consistent with protein expression, as mRNA levels in ovary were not markedly different from other tissues. These results suggest that the regulation of MRP1 expression in mice is: (1) highly complex; (2) under the control of several factors that may be functionally polymorphic among mouse strains and (3) may contribute to phenotypic differences in xenobiotic metabolism and distribution. In addition, the abundance of MRP1 in the ovary coupled with its ability to transport conjugates of estrogen and other steroids, suggest an important role for this protein in the reproductive tract and implicates it in mechanisms of reproductive toxicology.

1832 EFFECTS ON THE GONADAL DEVELOPMENT OF MEDAKA (*ORYZIAS LATIPES*) EXPOSED AS EMBRYOS TO BROMODICHLOROMETHANE .

A. Thiyagarajah[1], S. Parker[2], C. Gennings[2], L. E. Teuschler[3], O. Conerly[4] and W. R. Hartley[1]. [1]*Environmental Health Sciences (SL29), Tulane University Health Sciences Center, New Orleans, LA,* [2]*Medical College of Virginia, VCU, Richmond, VA,* [3]*NCEA, USEPA, Cincinnati, OH and* [4]*Office of Water, USEPA, Washington, DC.* Sponsor: C. Miller.

The purpose of this study is to determine the toxic effects of bromodichloromethane (BDCM) on the developing gonad of medaka. BDCM is one of the trihalomethanes, a disinfection by-product found in the drinking water with developmental/reproductive toxicity concerns expressed in epidemiological studies. Medaka embryos at early high blastula stage were exposed to 10 or 25 mg/L BDCM for 10 days, and transferred to contaminant-free embryo rearing medium until hatched. Upon hatching, medaka fry were grown-out in spring water for 6 and 12 months. Two controls (embryo-rearing solution and DMSO carrier) were used. Fish were sampled at 6 and 12-month post-exposure and processed for histological evaluation. The evaluated endpoints, indicative of endocrine disruption or other reproductive toxicities were: hermaphroditism; immature gonads; ectopic gonads; male:female ratio, and other pathology. Hermaphroditism was not observed. There were two cases of ectopic gonads (10 mg/L BDCM and DMSO exposure groups) in the female medaka, but none in male medaka. The male: female ratios were skewed towards males suggesting possible androgenic or anti-estrogenic effects

of BDCM. Exposure to BDCM resulted in a dose-dependent increase in the proportion of males. Immature testis and ovaries, found in all concentrations including controls, are under evaluation. Other pathologic observations were granulomas and cystic ovaries, and granulomas in the testis with no apparent differences between exposed and control groups. The medaka embryo exposure protocol is useful for screening for endocrine disruption/reproductive toxicity. (Abstract may not reflect USEPA policy. The opinions expressed in this abstract are those of the authors and not necessarily those of EPA. Funded in part by USEPA and DOD Cooperative Agreement)

1833 OVEREXPRESSION OF INSULIN-LIKE GROWTH FACTOR (IGF)-I WITH IGF-I RECEPTOR SIGNALING AND MITOGEN-ACTIVATED PROTEIN KINASE (MAPK) ACTIVATION IN HUMAN UTERINE LEIOMYOMAS.

H. He, H. X. Nie, A. B. Moore, R. G. Richards and D. Dixon. *LEP, NIEHS, Research Triangle Park, NC.*

Uterine leiomyomas (fibroids) are benign tumors that are clinically apparent in up to 25-30% of women over 30 years of age in the USA. Although the cause of fibroids remains unknown, research in our laboratory suggests that the cell signaling pathways activated by the IGF-I peptide may be important in tumor growth during the proliferative phase of the menstrual cycle. IGF-I can bind with either IGF-I receptor (IGF-IR) or insulin receptor (IR) and both IGF-IR and IR signaling pathways can ultimately lead to mitogen-activated protein kinase (MAPK) activation and DNA transcription, or phosphatidylinositol 3-kinase activation and possibly cell survival. In this study, we examined leiomyoma and normal myometrial tissue from premenopausal women. IGF-I, IGF-IRβ, IR, and phospho-p44/42 MAPK were immunolocalized in tissue samples. Activation of the IGF-IR signaling pathway was assessed by identifying phosphorylated sites on the IGF-IRβ subunit and phosphorylation of the p44/42 active sites of the downstream effector MAPK using Western blot analysis. We found that IGF-I was increased and concentrated in fibrous stromal regions and smooth muscle cells of leiomyomas. However, in myometrial samples, staining was mostly perivascular in localization and minimal. Both leiomyoma and myometrial samples expressed IGF-IRβ; however, greater phosphorylation of IGF-IRβ was observed in the tumors compared to myometrium. IR was only minimally present in both leiomyomas and myometrial samples, and therefore most likely not a major signaling pathway utilized by IGF-I in these tumors. The downstream effector protein MAPK was expressed more intensely in the nuclei of leiomyoma cells than in the smooth muscle cells of the myometrium. These data show that the IGF-I peptide is overexpressed in uterine leiomyomas compared to myometrium, and that the IGF-IR signaling pathway and activation of MAPK may be important in the growth of uterine leiomyomas.

1834 EFFECTS OF POLYVINYL ALCOHOL ADMINISTERED IN THE DIET TO RATS ON FERTILITY, EARLY EMBRYONIC DEVELOPMENT, GROWTH AND DEVELOPMENT.

D. E. Rodwell[1], C. M. Kelly[1] and C. C. DeMerlis[2]. [1]*Huntingdon Life Sciences, East Millstone, NJ and* [2]*Colorcon, West Point, PA.*

Polyvinyl Alcohol (PVA) is a water soluble synthetic polymer prepared from the polymerization of vinyl acetate and the subsequent partial hydrolysis of polyvinyl acetate. PVA is used as a polymer for film coating pharmaceutical and dietary supplement tablets where moisture barrier/protection properties are required. PVA was administered in the diet to rats (26/sex/group) at treatment levels of 0, 2000, 3500 and 5000 mg/kg/day for 2 generations. The study design assessed gonadal function, estrous cycle, mating behavior, conception, gestation, parturition, lactation, weaning, and growth and development of F_1 and F_2 offspring. Parental rats were treated for 70 days prior to mating, throughout mating, gestation and lactation until sacrifice. Clinical observations, body weights and feed consumption were routinely recorded. Dietary concentrations were adjusted for each sex to provide the intended mg/kg/day PVA levels on a weekly basis except during gestation and lactation. Pups were weighed routinely and weaned at 21 days of age prior to selection for the next generation. Unformed stool was noted predominately at the 3500 and 5000 mg/kg/day levels in P_0 and F_1 parental animals. This finding was attributed to the high levels of PVA being fed and subsequently excreted in the stool. Slight decreases in the mean body weights of P_0 males were noted at 2000 and 5000 mg/kg/day. Feed consumption was elevated at the 3500 and 5000 mg/kg/day treatment levels in both generations but not during either lactation period. These increases generally were observed in a dose-related manner (grams/kg/day), as a result of the large amount of PVA being consumed to maintain the caloric intake necessary for normal growth. There were no effects of PVA on P_0 or F_1 male or female reproductive performance or pup survival, growth, organ weights, and macroscopic or microscopic observations at dietary concentrations of 2000, 3500 and 5000 mg/kg/day.

1835 METABOLIZING ENZYMES IN THE RAT EPIDIDYMIS AND EFFERENT DUCTS: POTENTIAL ROLE IN MALE REPRODUCTIVE TOXICITY.

S. B. DuTeaux, D. E. DeGroot and M. G. Miller. *Environmental Toxicology, University of California, Davis, CA.*

The presence of metabolizing enzymes in the epididymis and efferent ducts may indicate that these structures are potential toxicologic targets *via* metabolic activation. Previously, we proposed that the epididymis may be toxicologically analogous to the kidney. Our studies have focused on identifying and localizing enzymes involved in nephrotoxic responses, such as cytochrome P4502E1, soluble epoxide hydrolase, and cysteine conjugate β-lyase (β-lyase). We immunolocalized P4502E1 in the efferent ducts, and confirmed those findings with Western blotting and enzyme activity assays. Likewise, soluble epoxide hydrolase was localized in the efferent ducts, epididymis, and epididymal sperm. Our most recent studies provide evidence for the presence of β-lyase in the excurrent duct system. Using immersion-fixed frozen embedded tissues from untreated rats, β-lyase was immunolocalized in 10μm sections probed with anti-rat β-lyase (gift of James L. Stevens) and AlexaFluor488 conjugated IgG (Molecular Probes). Preliminary fluorescent imaging indicated a clearly visible, diffuse signal in the efferent ducts when compared to kidney controls. The caput, corpus, and cauda epididymis were slightly reactive, while the initial segment was devoid of any antibody reactivity. To confirm these findings, kidney and excurrent duct proteins were separated on a 10% SDS gel, affixed to nitrocellulose, and probed with the same antibody. Preliminary immunoblot data indicated the presence of strongly reacting band (~55kDa) in kidney cytosol and mitochondria. A similar-sized band was present in epididymal and efferent duct cytosolic fractions, as well as in the efferent duct S9 pellet. These bands were not present in similar membranes immunoblotted without antibody. Overall, our data indicate that enzymes associated with nephrotoxicity are concentrated to a higher degree in the efferent ducts than in the epididymis. Such findings suggest that the proximal excurrent ducts are a potential target for compounds typically considered nephrotoxicants, such as chlorinated solvents.

1836 IN-LIFE EFFECTS OF DAILY CHLORDANE EXPOSURE AT ENVIRONMENTAL LEVELS IN F0 RATS AND THEIR NEONATES.

B. C. Datiri[1], V. E. St. Omer[1], K. M. Mizinga[2], M. M. Mansour[1], E. O. Abdalla[1] and F. O. Johnson[1]. [1]*Biomedical Sciences, Tuskegee University, Tuskegee, AL and* [2]*Pharmacology, University of Health Sciences, Kansas City, MO.* Sponsor: R. Dalvi.

This in-life study of FO-rats and their neonates was a part of Replicate II of a multigenerational investigation to evaluate the effects of technical chlordane. Chlordane, a formerly used pesticide and currently an ATSDR priority-listed hazardous substance, is a bioaccumulative and persistent organochlorine pollutant in the environment. The in-life pregnancy and neonatal effects in humans and other mammals exposed to environmental levels of chlordane used in this study are unknown. Sprague-Dawley FO-rats were gavage-fed daily with chlordane at 0.0, 0.125, 0.25 and 1.0 mg/kg body weight. In-life measurements included body weight, feed intake, mating index, gestation length and weight, parturition index, litter size and weight, pup mortality at birth, sex ratio and ano-genital distance. Chlordane treatment did not affect parental body weight and feed intake, mating index, gestation length and weight, parturition index, litter size and weight, and pup mortality at birth. However, on postnatal day one (PND1) chlordane treatment increased ($P<0.05$) male/female ratio of live pups at the 0.125 mg/kg and ano-genital distance of the male neonates at the 0.125 and 0.25 mg/kg dosed groups. The data indicated that chlordane treatment in this study elicited androgenic effects *in utero* and hence, chlordane may put humans at risk as an endocrine disruptor. (Supported by MHPF/ATSDR - #U50/ATU3922660008)

1837 THE EFFECTS OF TETRATHIOMOLYBDATE (TTM, NSC-714598) AND COPPER SUPPLEMENTATION ON FERTILITY AND EARLY EMBRYONIC DEVELOPMENT IN RATS.

A. V. Lyubimov[1], J. D. Smith[2], S. Rousselle[2], M. D. Merceica[2], J. E. Tomaszewski[3], A. C. Smith[3] and B. S. Levine[1]. [1]*University of Illinois at Chicago, Chicago, IL,* [2]*Pathology Associates, Frederick, MD and* [3]*NCI, Bethesda, MD.*

Based on its unique anti-copper action, TTM is being studied as an antiangiogenic agent and is currently in Phase II clinical trials for cancer therapy. The purpose of the present study was to evaluate the toxicity of TTM and the protection of copper supplementation on the reproductive capability of male and female CD® rats. Doses of 0, 1, 4, 12 mg/kg/day (0, 6, 24, 72 mg/m^2/day) and 12 mg/kg/day with copper supplementation (110 mg/kg of diet) were given orally by daily gavage to male rats for at least 59 days and to pregnant female rats for about 30 days, including 29 and 15 days, respectively, of dosing prior to cohabitation. There were no

drug-related toxic effects on the estrous cycle or reproductive indices, or maternal toxicity in any female rat. Therefore, the no observed effect level (NOEL) for female reproductive toxicity was at least 12 mg/kg/day (72 mg/m^2/day). Male rats given 12 mg/kg/day showed significant decreases in body weight gains and food consumption and drug-related anemia developed primarily toward the end of the study. Serum ceruloplasmin levels were dose-dependently decreased in all drug-treated male rats. At 12 mg/kg/day, rats in the copper supplemented dose group had serum ceruloplasmin levels 16 times higher than the nonsupplemented dose group. TTM given at doses of 12 mg/kg/day resulted in reduced epididymal weights, sperm counts, and sperm motility as well as sperm morphologic abnormalities including excessive sperm fragmentation and histopathologic changes in testis and epididymis. None of these drug-related effects occurred in the 1 and 4 mg/kg/day dose groups. Copper supplementation prevented the adverse sperm effects produced by 12 mg/kg/day of TTM. Therefore, the NOEL for male reproductive toxicity was 4 mg/kg/day (24 mg/m^2/day). (Supported by NCI Contract No. NO1-CM-87103.)

1838 ENHANCED MITOCHONDRIAL TESTICULAR ANTIOXIDANT CAPACITY IN GOTO-KAKIZAKI (GK) DIABETIC RATS: ROLE OF COENZYME Q.

C. M. Palmeira[1], D. L. Santos[2], R. Seiça[3], A. J. Moreno[1] and M. S. Santos[1]. *[1]Zoology, Center for Neurosciences and Cell Biology of Coimbra, Coimbra, Portugal, [2]Biology, University of Trás os Montes e Alto Douro, Vila Real, Portugal and [3]Faculty of Medicine, University of Coimbra, Coimbra, Portugal.*

Since diabetes mellitus is associated with impairment of testicular function, ultimately leading to reduced fertility, this study was conducted to evaluate the existence of a cause-effect relationship between increased oxidative stress in diabetes and reduced mitochondrial antioxidant capacity. The susceptibility to oxidative stress and antioxidant capacity (in terms of glutathione, coenzyme Q and vitamin E content) of testis mitochondrial preparations isolated from Goto-Kakizaki non-insulin dependent diabetic rats and from Wistar control rats, 1 year of age, were evaluated. It was found that Goto-Kakizaki mitochondrial preparations showed a lower susceptibility to lipid peroxidation induced by ADP/Fe2+, as evaluated by oxygen consumption and reactive oxygen species generation. The decreased susceptibility to oxidative stress in diabetic rats was associated with an increase in mitochondrial glutathione and coenzyme Q9 contents, while vitamin E was not changed. These results demonstrate a higher antioxidant capacity in diabetic GK rats, that we suggest is an adaptive response of testis mitochondria to the increased oxidative damage in diabetes mellitus.

1839 THE ARYL HYDROCARBON RECEPTOR (AhR) MAY REGULATE GROWTH, BUT NOT APOPTOSIS OF ANTRAL OVARIAN FOLLICLES.

J. C. Benedict[1], T. M. Lin[2], R. E. Peterson[2] and J. A. Flaws[1]. *[1]Program in Toxicology, University of Maryland, Baltimore, MD and [2]School of Pharmacy, University of Wisconsin, Madison, WI.*

The AhR mediates the toxicity of chemicals such as 2, 3, 7, 8 tetrachlorodibenzo-*p*-dioxin. Although little is known about the physiological role of the AhR, our previous work indicates that the AhR may alter the number of antral follicles in the ovary. Mice deficient in the AhR (AhRKO) have 54% fewer antral follicles than wild-type (WT) mice in postnatal (PN) life. The mechanism by which the AhR influences the numbers of antral follicles is not understood. It is possible that the AhR may regulate the number of antral follicles by increasing the rate of growth of immature follicles to the antral stage or by decreasing the rate of death of antral follicles. Thus, the purpose of this study was to test the hypothesis that follicles from AhRKO mice have decreased follicular growth and/or increased apoptosis compared to WT mice. AhRKO and WT (PN 28-35) mice (both on a C57Bl/6J background) were primed with pregnant mare serum gonadotropin to induce growth of immature follicles to the antral stage. After 48 hours, antral follicles were isolated from each ovary and subjected to measurements of follicular size. Additional follicles were cultured in serum free medium to induce apoptosis and then subjected to 3' end labeling to measure the amount of apoptosis. The results indicate that antral follicles from WT mice were significantly larger than antral follicles from AhRKO mice (WT = 211 ± 10 mm; AhRKO = 182 ± 6 mm; $n = 6$, $p \leq 0.02$). In contrast, antral follicles from AhRKO mice and WT mice contained similar amounts of apoptotic DNA after isolation from the ovary (AhRKO = 4619.8 ± 741.6 cpm; WT = 7843 ± 4511 cpm; $n = 3$, $p \geq 0.5$). They also contained similar amounts of apoptotic DNA after being cultured in serum free medium overnight (AhRKO = 96, 811 ± 62, 640 cpm; WT = 73, 043 ± 28, 346 cpm; $n = 3$, $p \geq 0.7$). These data suggest that the AhR may regulate the growth, but not apoptosis of antral ovarian follicles in the mouse. Supported by HD 38955 (JAF) and ES01332 (REP).

1840 EFFECTS OF 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD) ON SERUM INHIBIN CONCENTRATIONS AND INHIBIN IMMUNOSTAINING DURING FOLLICULAR DEVELOPMENT IN SPRAGUE-DAWLEY RATS.

Physiol, Univ. of Kansas Med. Ctr., Kansas City, KS, [2]Center for Reprod. Sci., Univ. of Kansas Med. Ctr., Kansas City, KS, [3]Dept. of Obstet. and Gynecol., Univ. of Kansas Med. Ctr., Kansas City, KS, [4]Dept. of Pharmacology Toxicol. Exp. Ther., Univ. of Kansas Med. Ctr., Kansas City, KS, [5]Dept. of Anat. Cell Biol., Univ. of Kansas Med. Ctr., Kansas City, KS, [6]Section Environment Toxicol, GSF-Institut fur Toxicologie, Neuherberg, Germany and [7]Lab. Vet. Physiol., Tokyo University Agricultural Technol., Fuchu, Tokyo, Japan.*

Intact and hypophysectomized immature rats were pretreated with TCDD (0 or 32 µg/kg p.o.) and sacrificed throughout synchronized follicular development (0, 12, 24, 48 and 72 hours after equine chorionic gonadotropin, eCG). TCDD administration to intact rats resulted in a premature elevation of serum FSH and LH by 12 hours post-eCG. In intact rats pretreated with TCDD, the intensity of ovarian immunoreactivity for inhibin and the number of ovarian follicles staining for inhibin in midsaggital ovarian sections were decreased at the time of eCG administration (24 hours post-TCDD) in comparison to controls. However, this decreased ovarian staining for inhibin was not associated with alterations in serum inhibin concentrations. Serum inhibin was suppressed in comparison to intact controls only at 24 hours post-eCG (48 hours post-TCDD) in intact rats that received TCDD. Hypophysectomized animals exhibited no effect of TCDD on serum inhibin at any timepoint. In summary, TCDD reduced serum concentrations of inhibin after the premature increases in FSH and LH suggesting that inhibin is not causally related to the initial elevation of FSH following exposure to TCDD in this model.

1841 EFFECTS OF INDOLE-3-CARBINOL AND TAMOXIFEN ON OVULATION AND ITS HORMONAL REGULATION - COMPARISON TO 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD).

X. Gao[1,2], B. K. Petroff[1,2], O. Oluola[2], K. K. Rozman[4,5] and P. F. Terranova[1,2,3]. *[1]Dept. of Mol. Int. Physiol., Univ. of Kansas Med. Ctr., Kansas City, KS, [2]Center for Reprod. Sci., Univ. of Kansas Med. Ctr., Kansas City, KS, [3]Dept. of Obstet. Gynecol., Univ. of Kansas Med. Ctr., Kansas City, KS, [4]Dept. of Pharmacology Toxicol. Therap., Univ. of Kansas Med. Ctr., Kansas City, KS and [5]Section of Environment Toxicol., GSF-Institut fur Toxikologie, Neuherberg, Germany.*

Immature Sprague-dawley rats received daily doses of indole-3-carbinol (I3C, 0-1.5g/kg/day), diindolymethane (DIM, 0-400mg/kg/day), tamoxifen (TAM, 0-0.5mg/kg/day) or vehicle. Follicular development was induced by equine chorionic gonadotropin (eCG, 5 IU) one day after the initial dose. In a hormone replacement study, human chorionic gonadotropin (hCG, 10 IU s.c., 48h post eCG) was used to mimic a normal preovulatoy LH surge following treatment with either I3C or TAM. Blood and ovaries were collected thoughout follicular development and the number of ova shed was measured on the morning following normal ovulation (72 h post eCG). I3C but not TAM reduced body weight gain at higher doses after 4 days of dosing. Ovarian weight gain and ovulation were inhibited by both I3C and TAM in a dose-dependent fashion. During the preovulatory period, I3C and TAM blocked normal LH and FSH surges and supressed serum P4 profoundly without changing circulating levels of E2. After the time of expected ovulation, serum E2 was increased in rats receiving I3C or tamoxifen, whereas serum P4 was decreased dose dependently. DIM exerted no significant effects on any of the endpoints studied even at the highest dose. hCG restored ovarian weight gain and ovulation in TAM-treated rats. However, hCG only partially reversed the blockage of ovulation by I3C, although ovarian weight gain was restored to normal. In summary, I3C seems to block ovulation by mechanism(s) similar to TCDD (at both ovarian and hypothalamic levels), whereas TAM appears to alter ovulation primarily *via* effects at the hypothalamic-pituitary axis.

1842 MULTI-GENERATION REPRODUCTION TOXICITY STUDY OF 3, 3', 4, 4'-TETRACHLOROAZOBENZENE ADMINISTERED TO SPRAGUE-DAWLEY RATS BY ORAL GAVAGE.

M. Hooth[1], G. Wolfe[2], R. Patel[2], J. Quance[3], B. Davis[1], B. Collins[1], J. Blake[4], M. Vallant[1] and J. Bishop[1]. *[1]NIEHS, Research Triangle Park, NC, [2]TherImmune Research Corporation, Gaithersburg, MD, [3]PAI, Frederick, MD and [4]RTI, Research Triangle Park, NC.*

3, 3', 4, 4'-Tetrachloroazobenzene (TCAB) is generated as a by-product during the manufacture or environmental degradation of 3, 4-dichloroaniline and its herbicidal derivatives. TCAB was tested for reproductive toxicity in Sprague-Dawley rats

using the NTP Reproductive Assay by Continuous Breeding protocol. F_0 males and females (20/sex/group) were administered TCAB by corn oil gavage at concentrations of 0, 1, 3, and 10 mg/kg/day. Mating pairs produced 3 F_1 litters/pair and the 3rd litter was reared to adulthood. F_1 weanlings were exposed to TCAB at the same concentrations as their F_0 parents and on postnatal day 81± 10, 20 pairs of F_1 adults/dose were mated to produce 3 F_2 litters/pair. Parental observations included body weight, feed consumption, organ weights, and gross and microscopic pathology. Litter observations included number of live pups/litter and live pup weight. F_0 parental body weights were decreased minimally during the study. There were significant reductions in the number of live F_1 pups/litter in all dose groups. Mean body weight was decreased significantly in F_1 parents treated with 10 mg/kg. The number of live F_2 pups/litter was significantly reduced at 3 and 10 mg/kg and live pup weight was decreased at 10 mg/kg. A crossover mating was conducted with the F_0 parents to determine which sex was affected by TCAB treatment. Treated F_0 males and females from the control and 10 mg/kg groups were paired with naïve males and females for 7 days. The reproductive data for the treated males was comparable to the controls. When treated females were cohabited with naïve males, the number of live males/litter was decreased by 53%. There was no effect on the number of primordial follicles in the ovaries of F_0 females treated with 10 mg/kg TCAB relative to controls suggesting that *in utero* developmental toxicity was responsible for the reductions in litter size.

1843 EFFECTS OF GESTATIONAL AND LACTATIONAL EXPOSURE TO GENISTEIN ON SPERM QUALITY AND TESTICULAR GENE EXPRESSION IN MICE.

S. M. Samy[1], M. R. Fielden[1], K. Chou[2] and T. R. Zacharewski[1]. [1]*Department of Biochemistry and Molecular Biology, National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI and* [2]*Department of Animal Science, Michigan State University, East Lansing, MI.*

The objective of this study was to examine the effects of gestational and lactational exposure to phytoestrogen genistein on sperm quality, *in vitro* sperm fertilizing ability and testicular gene expression. Pregnant mice were gavaged with 0.1, 0.5, 2.5 or 10 mg/kg genistein in corn oil from gestational day (GD) 12 to postnatal day (PND) 21. Anogenital distance (AGD) of male offspring was recorded on PND 7 and PND 21. On PND 21, 105 and 315, body weight and testis weight were recorded. On PND 105 and 315, sperm count and sperm fertilizing ability of F1 males were assessed *in vitro*. Testicular gene expression was examined using a custom mouse cDNA microarray representing 2689 cDNA. Testicular RNA from mice in the 10 mg/kg dose group on PND 21 and 105 was compared to that from corresponding control mice. Testis weight was slightly increased in the 10 mg/kg group at PND 105 and 315 but not significantly ($p>0.05$). AGD was decreased on PND 21 in the 10 mg/kg dose group ($p<0.05$). No effect on sperm motility or sperm count was observed. *in vitro* fertilizing ability was significantly increased on both PND 105 (18.7%, $p<0.001$) and PND 315 (17.7%, $p<0.001$) in the 10 mg/kg group, but it was decreased by 8.5% on PND 105 in the 0.5 mg/kg dose group ($p<0.05$). The percent of fragmented eggs was decreased significantly on PND 105 in the 0.1, 2.5 and 10 mg/kg dose groups ($p<0.001$) and slightly increased on PND 315 10 mg/kg dose group. The percentage of one-cell fertilized eggs was significantly decreased on PND 315 in the 0.5, 2.5 and 10 mg/kg dose groups ($p<0.001$). Microarray data were analyzed using paired t-tests to identify differentially expressed genes. Five genes were under-expressed on PND 105, but there were no changes on PND 21. This study suggests that exposure to genistein in early development increases sperm fertilizing ability in adult mice.

1844 NITROBENZENE-INDUCED TESTICULAR GERM CELL APOPTOSIS IN YOUNG AND ADULT FASL-DEFICIENT (*GLD*) MICE.

A. Nañez and J. H. Richburg. *College of Pharmacy, The University of Texas at Austin, Austin, TX.*

Apoptosis of testicular germ cells (GCs) is essential for functional spermatogenesis. We have previously shown that the Fas/CD95 signaling system is important for triggering GC apoptosis in four-week old male C57/bl6J (C57) mice testes after MEHP (mono-2-ethylhexyl phthalate, 1g/kg p.o.)-induced Sertoli cell injury. However, in B6Smn.C3H-Fasl-*gld* (*gld*) mice, that express a nonfunctional form of Fas Ligand, a profound reduction in MEHP-induced GC apoptosis was observed as compared to C57 mice. To test if Fas-mediated GC apoptosis is a common signaling event after Sertoli cell injury, we evaluated the Sertoli cell toxicant, nitrobenzene (NB). Four-week old C57 and *gld* male mice were dosed with NB (600mg/kg p.o.) and testes were collected at 0, 16, 20, 24 hours. Apoptosis was quantified by determining the percentage of seminiferous tubules that contain >3 TUNEL positive germ cells. Vehicle (corn oil) treated 4 week-old C57 and *gld* mice exhibited less than 10% germ cell apoptosis. After NB exposure, both C57 and *gld* mice showed variable (10-65%) increases in GC apoptosis, with a trend for larger increases in the C57 mice at 16 h, whereas similar increases occurred in the testes of *gld* mice at the later (20 & 24h) time points. Eight-week old C57 and *gld* male mice were dosed with NB (800mg/kg p.o.) and testes were collected at 0, 3, 6, 12, 24 hours. Vehicle-treated C57 and *gld* mice both showed ~4% apoptosis. As opposed to the young mice, the levels of GC apoptosis remained at control levels for 3, 6, and 12 hours post NB exposure. However, a large increase in GC apoptosis (C57: 50.36 ± 3.11%; *gld*: 66.10 ±2.18%, mean ± SD) occurred after 24 hour after NB treatment. Taken together, these findings suggest that a FasL-independent signaling mechanism may be responsible for NB-induced germ cell apoptosis in both young and adult C57 and *gld* mice. (Supported by RO1ES09145, NSF's LSAMP, and UT Co-op Society).

1845 EFFECTS OF GESTATIONAL AND LACTATIONAL EXPOSURE TO GENISTEIN ON OVULATION AND EGG FERTILIZING ABILITY IN MICE .

J. Han[1], M. Fielden[2,3], S. M. Samy[2], P. M. Saama[1], T. Zacharewski[2,3] and K. Chou[1,3]. [1]*Animal Science, Michigan State University, East Lansing, MI,* [2]*Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI and* [3]*Institute for Environmental Toxicology, Michigan State University, East Lansing, MI.*

Genistein (GEN) is an isoflavonold phytoestrogen in soybeans. Our previous study demonstrated that gestational and lactational exposure to diethylstilbestrol decreases the number of eggs produced in superovulated mature female mice, without affecting egg-fertilizing ability. The objective of the study was to examine the effect of gestational and lactational exposure to GEN on ovulation and egg fertilizing ability in female offspring. Pregnant C57BL/6 mice (F-0) bred with DBA/2 male were gavaged with 0, 0.1, 0.5, 2.5, or 10 mg GEN/kg of body weight/day in 0.1 ml corn oil from gestational day 12 to postnatal day (PND) 21. No significant effects on fecundity ($P>.1$) or 4- and 21-day pup survival were observed. An increase in litter size in the 0.5 mg treatment group was observed ($P<.05$). There were no effects on sex ratio, litter weight, or average birth weight of pups among treatment groups ($P>.05$). AGD of the female offspring (F-1) in 2.5 mg and 10 mg treatment groups were longer than that in the controls ($P<.05$). In 3-6 week old F-1 females, the number of eggs ovulated was not different among treatment groups, In 8-11 week old females, a trend of decrease in the number of eggs ovulated was observed in the 0.5 mg treatment group ($P=.09$). Fertilizing ability of eggs from 3-6 week old females in the 0.1mg/kg treatment group was significantly lower than that of controls ($P<.05$), but no effect on the eggs from the 8-11 week old females was observed. Results from this study suggest that exposure to low dose of GEN during gestation and lactation decreases fertilizing ability of eggs from pre-pubertal F-1 females, while high doses of GEN exposure increase the number of non-viable eggs in the mature F-1 females. (This work is supported, in part, by EPA, R827-420-01-0.)

1846 METHOXYCHLOR MAY DAMAGE THE MURINE OVARY AND VAGINA.

C. Borgeest[1], L. P. Mayer[2], P. B. Hoyer[2] and J. A. Flaws[1,3]. [1]*Program in Toxicology, University of Maryland, Baltimore, MD,* [2]*Department of Physiology, University of Arizona, Tucson, AZ and* [3]*Department of Epidemiology and Preventive Medicine, University of Maryland, Baltimore, MD.*

Methoxychlor (MXC) is an organochlorine pesticide that is currently used to protect agricultural products from insects. Although this chemical is a suspected reproductive toxicant, its effects on the ovary and vagina are not well understood. Thus, the purpose of this study was to test whether MXC induces ovarian atresia and vaginal keratinization by direct action on the ovary and vagina or by indirect action involving the disruption of hormone levels. To test this hypothesis, adult CD-1 mice were dosed with sesame oil (control) or MXC (8, 16, 32 mg/kg/d) for 10 or 20 days. Estrous cyclicity and vaginal keratinization were evaluated daily *via* vaginal lavage. After dosing, ovaries were collected for histological evaluation of follicular atresia and blood was collected for measurement of follicle-stimulating hormone (FSH) levels and estradiol (E_2) levels. The results indicate that MXC disrupted estrous cyclicity (controls = 33% abnormal cycles, n=27; 8mg/kg MXC = 56% abnormal cycles, n=16; 16 and 32mg/kg MXC = 60% abnormal cycles; n=10 for each dose) and induced vaginal keratinization. In addition, MXC increased the amount of follicular atresia compared to controls (controls = 52.9% ± 3.6 atretic follicles, n=9; 32mg/kg MXC = 71.8% ± 1.5 atretic follicles, n=4; $p < 0.05$). MXC did not alter hormone levels at any dose. After 10 days of dosing, FSH levels were 4.6 ± 0.8ng/ml in controls and 3.4 ± 0.3ng/ml in mice treated with 32mg/kg MXC ($p\geq0.5$; n=3). E_2 levels were 148.9 ± 27.3pg/ml in controls and 121 ± 14.7pg/ml in mice treated with 32mg/kg MXC ($p\geq0.8$; n=3). These data suggest that MXC disrupts estrous cyclicity, induces vaginal keratinization, and causes follicular atresia by a direct action on the ovary and vagina and not by an indirect action involving FSH and E_2. Supported by HD 38995, T32-ES07263, and the Women's Health Research Group at the University of Maryland.

1847 NITRIC OXIDE DECREASES UTERINE CONTRACTILITY BY BLOCKING THE CLOSURE OF ATP-DEPENDENT POTASSIUM CHANNELS.

T. Clipson, T. J. Miller, M. A. Philbert and R. Loch-Caruso. *Environmental Health Sciences, The University of Michigan, Ann Arbor, MI.*

Both nitric oxide and ATP-dependent potassium channel activators decrease uterine tone and inhibit spontaneous rat and human myometrial contractions during pregnancy. We tested the hypothesis that nitric oxide hyperpolarizes myometrial cells, cultured from gestation day 20 rats, by opening ATP-dependent potassium channels. Functional activity of ATP-dependent potassium channels was measured by evaluating changes in membrane potential using the bis-oxonol dye DiBAC4(3) and confocal microscopy. As indicated by a reduction in fluorescence intensity from pretreatment, ATP-dependent potassium channel opener pinacidil (1 μM) hyperpolarized myometrial cells and increased significantly their membrane potential compared with solvent controls. Glibenclamide (5 μM), an ATP-dependent potassium channel blocker, caused a significant depolarization, indicated by increased fluorescence, followed by hyperpolarization. Pretreatment with the nitric oxide donating compound spermine NONOate (25 μM) inhibited the observed depolarization and augmented the hyperpolarization state caused by glibenclamide. Carboxy-PTIO, a nitric oxide scavenger, prevented the inhibitory effects of spermine NONOate on the glibenclamide-induced hyperpolarization. A role for ATP-dependent potassium channels in nitric oxide's effects on contraction frequency is suggested by the observation that treatment of uterine strips with glibenclamide blocked relaxation by spermine NONOate. Previous findings support an inhibitory function for oxidative stress. Collectively, these data suggest an equilibrium between oxidative stress and nitric oxide in the maintenance of potassium channels and uterine tone.

1848 HUMAN TISSUE MODEL FOR VAGINAL IRRITATION STUDIES.

M. Klausner[1], J. Kubilus[1], C. L. Cannon[1], J. E. Sheasgreen[1] and E. C. Lonardo[2]. *[1]R & D, MatTek Corporation, Ashland, MA and [2]Medical Affairs, Johnson & Johnson, Personal Products Company, Skillman, NJ.*

Recently, a tissue culture based model of the vaginal epithelium has been developed. Normal, human ectocervico-vaginal (ECV) epithelial cells were induced to form a three-dimensional tissue using specially formulated serum free medium. The *in vitro* tissue reproduces many of the histological, ultrastructural, and protein expression properties of native tissue, including inter-digitation of cells, glycogen production, and cytokeratin expression. Initial experiments investigated the use of this tissue model and the MTT tissue viability assay for predicting ECV irritation. Vaginal anti-fungal products, contraceptives and lubricants were exposed to the tissue model and the exposure time which causes a 50% reduction in tissue viability (ET-50) was determined. The ET-50s were compared to rabbit vaginal irritation scores for 7 products which are currently marketed or in clinical trials. Using an ET-50 cutoff of 9.0 hrs, the products could be successfully categorized into minimal or mild irritation classes. Based on these results and the problems associated with obtaining and the handling of human vaginal tissue, it is anticipated that the tissue model will be very useful in assisting product development scientists in developing safe, efficacious products.

1849 EFFECTS OF DIETARY ETHINYL ESTRADIOL (EE2) ON THE MAMMARY GLAND OF MALE CD (SPRAGUE-DAWLEY) RATS.

J. R. Latendresse[1], C. Weis[2], R. R. Newbold[3] and K. B. Delclos[2]. *[1]PAI, Jefferson, AR, [2]NCTR, Jefferson, AR and [3]NIEHS, Research Triangle Park, NC.*

Previous dose range-finding experiments had indicated that EE2 and the soy phytoestrogen genistein induced hyperplasia in pubertal (PND 50) male mammary glands and that this was among the most sensitive indicators of activity of these compounds. The present study was designed as an adjunct to a subsequent multigeneration bioassay to determine if this effect was reproducible, required continuous dosing, and persisted into adulthood. The parental generation received a soy- and alfalfa-free diet containing 0, 2, 10, or 50 ppb EE2 starting 28 days prior to mating. Dosing continued throughout pregnancy and lactation. F_1 pups were fed the same diet as their parents until sacrifice. One male from each of 18 litters was sacrificed at PND 50 and another at PND 90. F_2 pups were removed from dose at weaning (PND21) and sacrificed according to the same schedule as the F_1 pups. Mammary glands were removed, fixed in 10% NBF, and processed for microscopic evaluation. Hyperplasia of the mammary gland in the F_1 rats was evident at PND 50 and PND 90. Mostly mammary ducts were affected at PND 50 (control 2/18, 2 ppb 4/18, 10 ppb 6/18, 50 ppb 14/18), while both ducts and alveoli were hyperplastic in dose dependent-manner at PND 90. In the F_2 generation, there was still a trend of ductal hyperplasia at PND 50 (control 3/18, 2 ppb 4/18, 10 ppb 6/18, 50 ppb 7/17), but by PND 90 treatment groups were similar to control. We conclude that hyperplasia of mammary gland in male rats is a sensitive indicator of estrogenic activity of EE2, and perhaps other estrogens, but appears to require continuous exposure.

1850 EFFECT OF DIETARY ETHINYL ESTRADIOL (EE2) ON SERUM TESTOSTERONE, PROSTATE WEIGHT, AND ESTROGEN RECEPTORS (ER) IN CD (SPRAGUE-DAWLEY) RATS.

B. Blaydes[1], C. Bryant[1], R. R. Newbold[2] and K. B. Delclos[1]. *[1]NCTR, Jefferson, AR and [2]NIEHS, Research Triangle Park, NC.*

Estrogen treatment of neonatal rodents has been shown to induce permanent effects on the prostate, but the dose levels at which such permanent effects can be elicited have sparked controversy in recent years. Recently, subclinical doses of EE2 have been reported to effect the reproductive tract in male mice (Thayer et al., Human Reprod., 16, 988, 2001). In a dose range-finding study with dietary EE2 in Sprague-Dawley rats, we had found a marginally increased dorsolateral prostate weight in animals sacrificed at PND 50 in the intermediate dose range (5 ppb, approximately 1 μg/kg body weight/day). The results reported here were obtained in a subsequent multigeneration study using doses of 0, 2, 10, and 50 ppb EE2 administered in a soy- and alfalfa-free diet. Dosing was begun for the parental generation 28 days prior to mating and was continued throughout pregnancy and lactation. F_1 pups were fed the same diet as their parents continuously. One male from each of 18 litters was sacrificed at PND 50 and another at PND 90. F_2 pups were removed from dose at weaning (PND21) and sacrificed according to the same schedule as the F_1 pups. Serum testosterone levels were significantly depressed in PND 50 animals of the F_1 (10 and 50 ppb) and F_2 (50 ppb) generations. However, no significant effects on ventral or dorsolateral prostate weights were observed in F_1 or F_2 animals at PND 50 or PND 90. Prostates from 12 animals per treatment group were analyzed by Western blot for levels of ERs α and β. Subtle treatment-related changes, not greater than 2-fold, were observed in both prostate lobes, with the most pronounced change being a decreased level of ERα in the PND 90 ventral prostate. These results indicate that while low doses of EE2 have demonstrable effects on serum testosterone and prostatic estrogen receptors in the male Sprague-Dawley rat, the effect on testosterone appears to be transient and prostate weight is not a robust indicator of these effects under the experimental conditions used here.

1851 EFFECTS OF EXPOSURE TO VINCLOZOLIN ADMINISTERED IN A SOY- AND ALFALFA-FREE DIET ON MALE AND FEMALE CD (SPRAGUE-DAWLEY) RATS.

C. Weis[1], J. R. Latendresse[2], T. J. Bucci[2], R. R. Newbold[3] and K. B. Delclos[1]. *[1]NCTR, Jefferson, AR, [2]PAI, Jefferson, AR and [3]NIEHS, Research Triangle Park, NC.*

Developmental exposure of male pups to the fungicide vinclozolin induces a spectrum of effects that parallel those of the androgen receptor antagonist flutamide. There is a discrepancy in the doses at which some of these effects have been observed (Gray et al., Toxicol. Ind. Health, 15: 48, 1999; Hellwig et al., Reg. Toxicol. Pharmacology, 32: 42, 2000). Our laboratory is conducting a series of studies of endocrine active compounds, including vinclozolin, administered in a soy- and alfalfa-free diet that has low and carefully monitored levels of the phytoestrogens genistein and daidzein. In the present study, the compound was administered at dose levels of 0, 2, 10, 50, 150, 300, and 750 ppm to dams from gestation day 7 through delivery and lactation. Pups (5 litters, standardized to 4 per sex) were continued on the same dosed feed as their parents until sacrifice at PND 50. Ingested doses ranged from approximately 0.2 – 85 mg/kg body weight/day Gestational duration, total and live pups per litter, litter sex ratios, and birth weight were not significantly affected, nor were body weight and food intake for dams or pups. Anogenital distance was decreased only in male pups at the highest dose. Preputial separation was delayed, seminal vesicle/coagulating gland weight decreased, and female liver weight increased at 150 ppm and above. Atrophy of the seminal vesicles was noted microscopically only at 750 ppm. In the 10 ppm dose group (approximately 1 mg/kg/day), vaginal opening was significantly delayed and absolute dorsolateral prostate and epididymal weights were increased. When analyzed with body weight as a covariate, the epididymal weight was also elevated at 10 ppm and dorsolateral prostate weight showed a significant quadratic dose trend. These latter results are unexpected and require replication. If replicated, further investigation would be required to explain these effects since they are not consistent with the known antiandrogenic action of vinclozolin.

1852 GENETIC SUSCEPTIBILITY TO INHALED POLLUTANTS.

I. Jaspers[1] and T. Gordon[2]. [1]*CEMLB, University of North Carolina at Chapel Hill, Chapel Hill, NC and* [2]*Environmental Medicine, New York University, Tuxedo, NY.*

A person's susceptibility to inhaled pollutants is invariably multi-factorial, depending on the individual's age, gender, socioeconomic and ethnic background, and many other variables. However, there is increasing interest in understanding the susceptibility or resistance of individuals to environmental agents based on genetic differences. It is important to understand how genetic polymorphisms in the general population affect responses to environmental agents in order to correctly interpret inter-individual differences in toxicological studies and to ultimately improve risk assessment and environmental policies. This symposium will present current technologies and experimental approaches to identify potential genetic loci regulating susceptibility to inhaled pollutants. The symposium will present evidence from human familial inheritance studies and linkage analysis from inbred mouse strains on the susceptibility to environmental lung diseases induced by inhalation of particles or gases. In addition, the presentations will address state-of-the-art technology, such as novel high-throughput single nucleotide polymorphisms (SNP)-based genotyping method, which could greatly accelerate the identification of potential susceptibility genes. The presenters will demonstrate that inter-individual differences in responses often observed in toxicological studies may be strongly linked to genetic determinants.

1853 HUMAN STUDIES IN GENETIC SUSCEPTIBILITY.

S. R. Kleeberger. *Environmental Health Sciences, Johns Hopkins University, Baltimore, MD.*

Inter-individual variation in human responses to air pollutants suggests that some subpopulations are at increased risk to the detrimental effects of pollutant exposure. Extrinsic factors such as previous exposure and nutritional status may influence individual susceptibility. Intrinsic (host) factors that determine susceptibility include age, gender, and pre-existing disease (e.g. asthma), and it is becoming increasingly clear that genetic background also contributes to individual susceptibility. Environmental exposures and genetic factors associated with disease risk interact in a complex fashion that varies from one population to another. The relationships between the genetic background and disease risk and severity is often evaluated through traditional family-based linkage studies and positional cloning techniques. However, it is becoming increasingly clear that case-control studies based on association of disease or disease subphenotypes with candidate genes may have certain advantages over family pedigree studies for complex disease phenotypes. This is based in part on continued development of quantitative analysis and the discovery and availability of simple sequence repeats (SSRs) and single-nucleotide polymorphisms (SNPs). Linkage analyses with genetically standardized animal models also provide a useful tool to identify genetic determinants of host responses to environmental pollutants. Comparative mapping between the human and mouse genomes will yield candidate susceptibility genes that may be tested by association studies in human subjects. The combined human studies and mouse modeling likely will provide important insight to understanding genetic factors that contribute to differential susceptibility to pollutants in human populations. Support: HL57142, R826724, ES09606, and P30 ES00002

1854 ANIMAL STUDIES IN GENETIC SUSCEPTIBILITY.

T. Gordon. *Environmental Medicine, NYU School of Medicine, Tuxedo, NY.*

The contribution of genetic background to a biological process may be more easily determined and partitioned from environmental influence in the inbred mouse than in more heterogeneous species such as humans. The controlled standardized inbreeding of mice has led to genetic homogeneity that cannot be found or duplicated in human populations, making the inbred mouse an important source for genetic modeling of human diseases. Linkage relationships of homologous loci from human and mouse indicate that highly significant homology in gene order and chromosomal structure have been maintained since the evolutionary divergence of the human and mouse. Therefore, identification of the chromosomal location of a susceptibility gene in the mouse provides the basis for potentially localizing a homologous gene in the human. Recently, web-based tools have greatly enhanced searches for inter-strain homology (http://www.ncbi.nlm.nih.gov/HomoloGene/). The considerable resources and energy applied to the mapping of the mouse genome as an integral component of the Human Genome Project emphasize the importance of this murine model for human diseases. It is anticipated that, because the numbers of genes mapped in the human and mouse genomes are increasing almost exponentially with the advent of modern molecular genetic techniques, there will be similar increases in homologous association of disease genes in the two species.

1855 FROM MOUSE TO MAN: ACCELERATING DISCOVERY OF GENETIC SUSCEPTIBILITY LOCI FOR HUMAN DISEASE.

G. Peltz. *Inflammatory Disease Unit, Roche Bioscience, Palo Alto, CA.* Sponsor: T. Gordon.

The integrated use of a novel SNP-based genotyping method and gene expression analysis using high-density oligonucleotide microarrays has markedly increased the rate at which complex biological processes can be analyzed. Application of these technologies to murine experimental models of human inflammatory disease has enabled genetic susceptibility loci to be rapidly identified. As one example, a genetic locus regulating susceptibility to experimental allergic asthma in an experimental murine genetic model was identified using this approach. The identified murine susceptibility genes provide insight into pathways regulating human inflammatory disease susceptibility. We have also developed a SNP database and software that enable chromosomal regions regulating complex traits in mice to be computationally predicted. Several examples as to how the computational prediction program has been used to identify chromosomal regions regulating complex traits in mice will be presented. The correlation of computationally predicted regions and experimentally verified regions will be assessed.

1856 USING THE HUMAN GENOME PROJECT TO UNDERSTAND HUMAN VARIABILITY IN RESPONSE TO POLLUTANTS.

D. W. Nebert. *U Cinci Med. Center, Cincinnati, OH.*

Some human diseases are predominantly monogenic, but most diseases—including lung toxicity or cancer are polygenic (the combinatorial result of two, and usually more than a dozen or hundred, genes) and multifactorial (affected by epistasis and environmental factors). A polymorphism denotes the presence of two or more subgroups in any species population. Ford in the 1940s and Harris in 1980 stated that a polymorphism exists when the "commonest identifiable allele has a frequency of $\leq$=0.99 .." Polymorphic and rare variants have frequencies of $\geq$=0.01 and <0.01, respectively. Considering Hardy-Weinberg distribution ($p + q = 1.0$; $p^2 + 2pq + q^2 = 1$), q = the sum of the variant allele frequencies. If q = 0.01, the percentage of individuals homozygous for an autosomal recessive trait would be 0.0001% (1 in 10,000). All genes are polymorphic to varying degrees. Single-nucleotide polymorphism (SNP) consortia have compiled a map of 1-2 million SNPs, 85% of which are located within 5 kb of the nearest exon, but only 24 individuals of several ethnic backgrounds have been examined so far. In just the most recent generation of humans on this planet, every site at which mutations are compatible with life has been mutated an average of 240 times. Similar rates of mutation have occurred in every previous Homo generation. Classic neutral theory of population genetics allows us to infer from this rate that, by analyzing 99% of the most ethnically diverse 192 haplotype genomes on this planet, we will asymptotically approach 11 million ($q \geq 0.01$) SNPs; the number of rare SNPs will of course be much greater.On average, about 4-10 coding SNPs exist per gene, and 40-60% of these are expected to alter the gene's function. This computes to ~9.5 million SNPs (85% of 11 million) in the 5' and 3' flanks plus introns of the ~31, 000 genes, plus all cSNPs, which will make up 40-80 haplotypes per gene—with wide variation on a gene-by-gene basis. Ultimately, our knowledge of haplotype patterns of probably several hundred genes will be able to predict one's risk of lung toxicity or cancer caused by a particular inhaled pollutant.

1857 MITOCHONDRIAL TOXICITY PRODUCED BY ANTIVIRALS; MODELS AND MECHANISMS.

G. Szczech[1] and A. Nieminen[2]. [1]*Triangle Pharmaceuticals, Durham, NC and* [2]*Case Western Reserve University, Cleveland, OH.*

The need for new treatments for serious viral infections, especially with HIV(Human Immunodeficiency Virus), HBV(Hepatitis B Virus), and HCV(Hepatitis C Virus), is urgent. Unfortunately, mitochondrial toxicity has impaired the development of nucleoside analogs, easily the most successful approach to treatment to date. The intracellular location of mitochondria, heritable defects, unique method of replication and susceptibility to effects on both electron transport and the oxidation of fatty acids combine to provide toxicologists with a formidable challenge. Pathophysiological implications of mitochondrial function include DNA that is unique to mitochondria (mtDNA), maternal inheritance of this special DNA, and regulation of intramitochondrial Ca^{2+} ions critical for normal function. Importantly, mitochondria control both the life and death of cells. The biogenesis of mitochondria is particularly dependent upon γ polymerase. Therefore chemicals, in particular nucleoside analogs, that inhibit or are a substrate for this enzyme can produce mitochondrial toxicity. This Symposium will link topics given above with the best understood but unfortunately fatal toxicity produced by the D

enantiomer of a pyrimidine nucleoside known as fialuridine. *in vitro* and *in vivo* experiments will compare and contrast effects on mitochondria produced by nucleside analogs and correlate these data with toxicity. Finally, research to develop novel molecular toxicological assays, including quantitative real-time PCR, will show how these techniques, coupled with data on uptake and phosphorylation of nucleoside analogs, can be used to predict the potential for mitochondrial toxicity. In addition to furthering our understanding of this enigmatic toxicity, this research will improve risk-benefit assessments and help to decrease this major impairment to the development of new antivirals.

1858 PATHOPHYSIOLOGICAL IMPLICATIONS OF MITOCHONDRIAL FUNCTION.

A. Nieminen. *Case Western Reserve University, Cleveland, OH.*

Compared to other organelles of the cell mitochondria are unique in that they contain their own DNA. mtDNA encodes genes for several subunits of complexes I, III, IV, and V and genes for ribosomal proteins and tRNA. mtDNA is maternally inherited so that new sequence variants are transmitted along maternal lineages without the benefit of recombination with male mtDNA. Mutations in mtDNA often result in deficiencies in the respiratory chain causing defects in heart, skeletal muscle, and nervous system function. Toxic chemicals have long been known to disrupt mitochondrial metabolism and lead to cellular injury, but the mechanisms causing the injury are turning out to be more complex than expected. Mitochondria are normally a source of reactive oxygen species generation but enhanced generation of free radicals ultimately results in mitochondrial dysfunction. This can be due to direct damage to the mitochondrial respiratory components or enhanced inner membrane permeabilization, an event occurring during the mitochondrial permeability transition (MPT). The MPT initiates mitochondrial swelling, which ruptures the mitochondrial outer membrane, causes release of cytochrome *c* into the cytosol from the mitochondrial intermembrane space, and signals apoptosis. Mitochondrial ion regulation, such as free Ca^{2+}, is tightly regulated by Ca^{2+} uptake and release mechanisms across the membranes. Mitochondrial free Ca^{2+} levels may fluctuate to regulate mitochondrial ATP generation. Several pathophysiological conditions, however, can disrupt mitochondrial Ca^{2+} homeostasis, resulting in mitochondrial Ca^{2+} loading. Excess mitochondrial Ca^{2+} dissipates the membrane potential and can precipitate the MPT, causing bioenergetic failure and ultimately cell death. Thus, mitochondria are critical organelles both in the life and death of cells.

1859 INHIBITION OR PERTURBATION OF MITOCHONDRIA DNA SYNTHESIS BY ANTIVIRAL β-D-DIDEOXY-NUCLEOSIDE ANALOGS COULD BE ONE OF THE KEY MECHANISMS RESPONSIBLE FOR THEIR TOXICITY.

Y. Cheng. *Yale University, New Haven, CT.* Sponsor: G. Szczech.

β-D-dideoxy-nucleoside analogs are class of compounds having anti-cancer and anti-viral activity. The major limiting toxicity encountered is manifested in proliferating tissues. Several β-D-dideoxy-nucleoside analogs were found to have anti-HIV activity and were used on a long-term basis for the treatment of patients with AIDS. At a clinically relevant dose, those compounds exerted toxicity at non-proliferating tissues after a period of time of usage. One of the mechanisms responsible for their delayed toxicity in non-proliferating tissue is that depletion of mitochondrial DNA (mt-DNA) no longer supports mt function in tissues that were toxified. Those compounds exert their action on mt-DNA through DNA polymerase γ by terminating mt-DNA elongation, which is needed for mt-DNA replication or repair. However, the delayed toxicity is reversible due to mt-exonuclease by removing the analogs from the mt-DNA terminal once the treatment is terminated. In contrast, the delayed toxicity of nucleoside analogs such as FIAC or FMAU, which could be internalized into mt-DNA through the action of DNA polymerase γ and affect mt-DNA synthesis as well as transcription, is irreversible since mt does not have the mechanism to remove the internal incorporated nucleoside analog. For the treatment of viral diseases, an ideal nucleoside analog only acts on viral DNA synthesis apparatus but not nuclear or mt-DNA synthesis of uninfected cells. In the process of looking for such analogs, L(-)SddC was discovered to have potent anti-HBV and HIV activity by several laboratories including mine but does not have potent activity as other anti-HIV β-D-dideoxy-nucleoside analogs against mt-DNA synthesis. The lack of action is due to the lack of uptake of the active metabolite in mt although the DNA polymerase γ could still utilize L(-)SddC-TP as a substrate resulting in DNA chain termination. A summary of our work and understanding in terms of the mechanism of those anti-HIV and anti-HBV nucleoside analogs in affecting mt-DNA synthesis will be presented.

1860 MITOCHONDRIAL TOXICITY OF FIAU AND OTHER ANTIVIRAL NUCLEOSIDE ANALOGS: MECHANISMS AND METHODS OF EVALUATION.

J. M. Colacino. *Infectious Diseases Research, Lilly Research Labs, Indianapolis, IN.* Sponsor: G. Szczech.

FIAU is a thymidine nucleoside analog (NA) with antiviral activity against hepatitis B virus (HBV) *in vitro* and in animal models of infection. Initially, FIAU demonstrated clinical promise for the treatment of chronic HBV infection but in further clinical trials, long term administration of FIAU resulted in fatal multiorgan toxicity with a delayed onset characterized by refractory lactic acidosis. The clinical manifestations were consistent with mitochondrial dysfunction. FIAU was demonstrated to have effects on mitochondrial function in a number of experiments including evaluation of mitochondrial (mt) DNA replication and production of lactic acid in cells treated with FIAU; measurement of incorporation of FIAU into mtDNA; interaction of FIAU-TP with cellular DNA polymerase gamma which replicates mtDNA; and EM examination of mitochondrial morphology in cells treated with FIAU. FIAU was orally administered to woodchucks uninfected or chronically infected with woodchuck hepatitis virus in an effort to simulate the clinical trials. Whereas no adverse events were observed in animals that received clinically relevant doses of FIAU for 28 days, animals that received FIAU for 12 weeks died or were euthanized 78 to 111 days after initiation of treatment. Among other toxicities, these animals demonstrated hepatic insufficiency, lactic acidosis, and hepatic steatosis in the final stages of FIAU toxicity. These findings were similar to those seen in humans treated orally with FIAU and are consistent with a deleterious effect on mitochondrial function. Some NAs that are used for the treatment of AIDS can cause a delayed toxicity the symptoms of which include myopathy, peripheral neuropathy, deafness, pancreatitis, hepatocellular failure, and lactic acidosis. These symptoms are consistent with mitochondrial dysfunction and might be mediated through interactions of the NA-triphosphate with DNA polymerase gamma. The experience with FIAU underscores the need for a systematic evaluation of the effects of antiviral nucleoside analogs on mitochondrial function.

1861 MECHANISMS OF ANTIVIRAL NUCLEOSIDE ANALOGUE-INDUCED MITOCHONDRIAL TOXICITY.

O. P. Flint and S. K. Durham. *Discovery Safety Optimization, Bristol-Myers Squibb, Princeton, NJ.*

Chronic treatment with nucleoside analogues (NRTIs) used in treatment of HIV and HBV has been linked to lactic acidosis, hepatotoxicity, myopathy, pancreatitis, peripheral neuropathy and lipodystrophy. A common mechanism of mitochondrial toxicity has been proposed. Mitochondria each contain 2 - 3 DNA strands (mtDNA) with thirteen genes encoding enzymes in the electron transport chain. mtDNA replication is independent of nuclear replication but requires DNA polymerase γ (DNA pol γ), an enzyme encoded by nuclear DNA. DNA pol γ binds and inserts endogenous nucleoside triphosphates into the growing DNA strand, but also binds many NRTIs. Most NRTIs are chain terminators of mtDNA replication, but some (e.g. fialuridine) are incorporated into mtDNA. Impaired cell function or cell death follows the gradual depletion of mtDNA to between 15 and 20% of normal cell content. In some cases there is a correlation between inhibition of DNA pol γ and toxicity *in vivo*. Zalcitabine (ddC), for example, is the most potent inhibitor of DNA pol γ and also the most potent inducer of peripheral neuropathy. This correlation does not always hold. Both ddC and d4T (stavudine) are more potent inhibitors of DNA pol γ than AZT (zidovudine), but only AZT has been associated with clinical signs of myopathy, and evidence of mitochondrial damage in muscle cells in experimental studies in rodents. In our own laboratory, we have shown that NRTI inhibition of adipogenesis precedes depletion of adipocyte mtDNA *in vitro*, indicating that mitochondrial toxicity may not explain lipodystrophy associated with highly active antiretroviral therapy (HAART) for HIV. This presentation will review the evidence for mitochondrial toxicity as an explanatory mechanism for all adverse side effects of NRTI treatment.

1862 NOVEL MOLECULAR TOXICOLOGICAL ASSAYS FOR ANTIVIRAL AGENTS.

L. Stuyver. *Pharmasset, Tucker, GA.* Sponsor: G. Szezech.

One of the most preferred targets for the development of the drugs viral infections has been the nucleic acid synthetic machinery. Nucleoside analogs are phosphorylated intracellularly to their triphosphates and can either incorporate into viral nucleic acids or inhibit the viral polymerases. For a compound to be considered selec-

tive and potentially useful for drug development, it must preferentially target viral polymerases and minimally affect cellular polymerases. The search for potent and non-toxic compounds requires expertise in sophisticated toxicological assays that can reduce the risk of potential problems in humans treated chronically with antiviral agents at relevant and effective concentrations. Stereospecific nucleosides that target the polymerase are versatile molecules with well-established biochemical activation mechanisms and pharmacology. They continue to provide a rich source of anti-HIV and HBV agents, although other classes of compounds are beginning to emerge. Some of these new molecules have the desired selectivity and potency *in vitro* and in animal models, as well as a unique resistance profile. Our laboratory has used cellular assays as well as enzyme assays to determine the effect of nucleosides on mitochondrial function and morphology. Using quantitative real-time PCR (Q-RT-PCR) coupled with cellular drug uptake and phosphorylation assays, the relative toxicity of new nucleoside analogs can be determined reproducibly and rapidly. These novel molecular toxicological assays will further aid in designing improved treatment protocols. The attendees of this symposium will gain a better understanding of the opportunities and challenges in anti-HIV and HBV drug discovery, and the systematic approach for developing new safe compounds for Phase 1 clinical trials.

1863 SAFETY ASSESSMENT OF FOODS DERIVED FROM BIOTECH FOOD CROPS - INTRODUCTORY REMARKS.

G. A. Burdock. *Burdock Group, Vero Beach, FL.*

The current "generation" of toxicologists is faced with the challenge of ensuring the safety of biotechnologically produced foods and food ingredients. Food holds a position of inviolability in our culture because of the involuntary nature of its consumption and the pleasure with which fulfill our nutritional needs. This cultural demand for the absolute purity of food is reflected in literal interpretations of the Delaney clause with no room for *de minimus* considerations. This demand for absolute purity is under assault with seeds of doubt about the integrity and thoroughness of the vetting process for safety of biotechnologically produced substances and has given rise to generalized fears, as exemplified by the Precautionary Principle. This workshop examines key concepts for safety evaluation of biotechnologically produced foods and includes a look at some critical lessons gained from safety evaluation of irradiated food, a strikingly similar problem. What is accomplished within the next 24 months, in terms of safety evaluation of biotechnologically produced food, will profoundly affect the nature and abundance of the food supply for the next three generations of the world's population.

1864 COMPLEXITY OF TOXICOLOGICAL STUDIES OF IRRADIATED FOODS.

A. Brynjolfsson. *Applied Radiation Industries, Wayland, MA.* Sponsor: G. Burdock.

The Surgeon General of the US Army initiated preliminary studies on safety of some irradiated foods in 1948, and short-term studies of 54 foods in 1954, followed by long-term multi-generation animal feeding studies of 21 foods. December 1953 President Eisenhower in an address before the United Nations urged international cooperation and acceptance of the "Atoms for Peace Program". This led to the first International Conference on Peaceful Uses of Atomic Energy. Many countries became then involved in studies of irradiated foods' wholesomeness. Finally, in the 80's and 90's irradiated foods became generally recognized as wholesome. Food is important in international trade and its safety requires worldwide acceptance, open scientific cooperation and exchange of information across the globe. Not only the Health Authorities of each country must accept the results, but also United Nations' WHO and FAO, as well as the Codex Alimentarius, and WTO. We must assure ourselves scientifically that no harmful effects could go undetected, and we must also reassure the public. The word irradiation leads to many misconceptions and dispelling suspicion of harmful effect becomes very difficult. When the evaluation of the data shows that the test group is doing better than the control, the test-group is considered normal or showing no detrimental effect. However, if the control group does better than the test-group, the test-group is suspect. Multi-generation studies can multiply the probability for the test-group to become suspect. These variations may be completely unrelated to the diets. Detailed qualitative and quantitative analyses of all the chemical changes in foods when irradiated, and realization that these changes are similar to those normally occurring in foods when stored and processed by conventional methods, as well as feeding concentrates of the radiolytic products to animals in smaller studies were important in proving beyond reasonable doubt that irradiated foods are safe and wholesome. In all this, openness and international scientific cooperation is important as food and food processing requires international acceptance.

1865 OECD/FAO SUBSTANTIAL EQUIVALENCE FRAMEWORK FOR WHOLE FOOD SAFETY ASSESSMENT.

I. C. Munro. *CANTOX Health Sciences International, Mississauga, ON, Canada.*

OECD/FAO has developed the concept of "substantial equivalence" to assess the safety of foods derived from biotech food crops. This concept involves the comparison of key nutrient/antinutrient composition between biotech crop varieties and existing varieties from which they were derived. Many thousands of compositional comparisons are made for crops grown across multiple geographies and over 2 or more growing seasons. Extensive data bases are being developed to establish the normal range of composition in existing commercial crop varieties. If the composition of food derived from the biotech crops is "substantially equivalent" to existing varieties, then the safety assessment focuses on the defined difference between the new and existing varieties, e.g. the trait(s) introduced by genetic engineering (introduced protein). Several biotech crops, such as herbicide resistant corn, canola, soybeans, and cotton, as well as insect protected corn and cotton, have undergone this assessment and have been shown to be substantially equivalent to commercial crop varieties. If existing varieties of a crop are being improved to increase nutrient levels (e.g. increased levels of essential amino acids, or fatty acids) through genetic engineering, then the new crop variety is by definition "non - substantially equivalent" to existing crop varieties. Strategies for assessing the safety of nutritionally improved "non-substantially equivalent" crop varieties are similar to those described above and would include a nutritional/safety assessment of intended changes in composition of the crop.

1866 SAFETY ASSESSMENT OF PROTEINS INTRODUCED INTO FOOD CROPS.

S. L. Taylor. *Food Science & Technology, University of Nebraska, Lincoln, NE.*

The safety assessment of protein products of genes introduced into food crops is multifaceted. The most important food safety concern is to assess the allergenic potential of the introduced protein. This includes comparing the amino acid sequence of the introduced protein to data bases of known protein food allergens to confirm that the protein is not related to known allergens. The levels of accumulation of the introduced protein in food parts of the plant and assessment of its potential digestibility are key learnings. Known protein allergens tend to be present at abundant levels in the food and are generally resistant to digestion by proteases in the GI tract. The mode of action of the introduced protein should be known, e.g. if it is an enzyme, what are its substrates and the catalytic products. The amino acid sequence of the introduced protein needs to be compared to data bases for known toxic/antinutrient proteins to confirm the absence of similarity of the introduced protein to known toxicants. Since known protein toxicants often act through acute mechanisms to cause toxicity when ingested, the potential acute toxicity of the introduced protein can be tested by administration by gavage at high dosages to rodents.

1867 ROLE OF COMPOSITIONAL ANALYSES AND SUB-CHRONIC TOXICITY STUDIES IN THE EVALUATION OF SUBSTANTIAL EQUIVALENCE OF BIOTECH FOOD CROPS.

W. P. Ridley, B. G. Hammond and J. D. Astwood. *Product Safety Center, Monsanto Company, St. Louis, MO.*

Extensive compositional analyses including nutrients, anti-nutrients and secondary metabolites are conducted to evaluate the nutritional status of food crops produced through biotechnology. The results of these compositional evaluations are compared with the results obtained for parental control varieties and conventional commercial varieties in order to examine the placement of the biotech food crop within the natural variability seen for an individual biochemical component. This extensive biochemical sampling, although directed towards nutritional parameters, also assesses unexpected effects due to either the expression or the insertion of the introduced genes. To further assess the potential for an unintended or unexpected effect, food crops produced through biotechnology may be incorporated into the diets for sub-chronic toxicity studies in rats. Various toxicological endpoints are evaluated in rats including body weight gain, hematology, clinical chemistry, urine chemistry, organ weights at necropsy and, gross and microscopic pathology. The food and feed safety assessment of Roundup Ready® corn (GA21) included both compositional and toxicological studies. Compositional analysis results showed that, except for a few minor differences that are unlikely to be of biological significance, the grain and forage of GA21 corn were comparable to that of the control corn line and to conventional corn (Sidhu et al, *J. Agricultural Food Chem*, **2000**, 48, 2305-2312). Similar results were obtained for the toxicological endpoints - the magnitude of the significant differences was small and the values were within historical limits. These data taken together demonstrate that Roundup Ready® corn is as safe and nutritious as conventional corn for food and feed use.

1868 THE USE OF ANIMAL FEEDING STUDIES TO CONFIRM THE SAFETY/WHOLESOMENESS OF NEW CROP VARIETIES.

B. Glen. *Federation of Animal Science Societies, Bethesda, MD.* Sponsor: G. Burdock.

The US regulatory review process for new crop varieties is accomplished jointly by three federal agencies through a science-based, integrated and multi-disciplinary approach. To date, more than 50 crops produced through biotechnology have been approved for commercialization and these have been substantially equivalent to conventional counterparts for nutrient content and known toxicants. For crops approved to date, feeding studies using livestock have not been required as part of the regulatory process. Further, the US Food and Drug Administration considers the consumption of DNA to be "Generally Regarded as Safe." Nevertheless, to reassure the users of these crops that the food/feed is safe, numerous research studies have been undertaken in various farm animal species around the world. Many new crop varieties that are herbicide tolerant or insect protected (eg corn, soy, canola, cotton) have been fed to chickens, beef and dairy cattle, swine, sheep and fish in universities around the world using commercial feeding conditions. Findings from over 30 independently conducted studies have indicated no differences for nutrient composition, digestibilities, and animal performance when livestock were fed feedstuffs from conventional and biotech crops. Furthermore, in independent studies conducted to determine whether transgenic DNA and proteins can be detected in animal products, no transgenic plant-source DNA and proteins have been found in milk, meat, and eggs.

1869 TRANSGENIC MODELS IN REPRODUCTIVE TOXICOLOGY: APPLICATIONS IN MECHANISTIC AND APPLIED RESEARCH.

D. L. Shuey[1] and B. D. Abbott[2]. [1]*DuPont Pharmaceuticals Co., Newark, DE and* [2]*Reproductive Toxicology Division (MD67), USEPA, Research Triangle Park, NC.*

The development of transgenic models has proven to be an invaluable tool for dissection of critical pathways in embryo-fetal development and reproduction. Phenotypic characterization of such models have helped to define critical roles for specific genes and molecules in pattern formation, differentiation and function. Only recently have such models been applied to toxicological investigations. This workshop explores the application of transgenic models in mechanistic and applied toxicological research. Comparison of phenotypes resulting from gene inactivation with patterns of toxicity can provide insight regarding the mechanisms through which agents/compounds act. The models can also be used to directly test hypotheses regarding the roles of specific genes and pathways in the toxic response by administering the test agent(s) to knockout animals. Although the workshop will focus on investigations in developmental and reproductive toxicology, these models also have value in drug development and evaluation of pharmacologic action in non-reproductive tissues/organs. Such an application will be discussed in which a transgenic model was used to evaluate and develop candidate compounds based on specific mechanistic responses. This workshop will present current applications of transgenic models in toxicology and stimulate discussions of future applications in both mechanistic and applied research.

1870 TRANSGENIC MOUSE MODELS FOR GENE - NUTRITION INTERACTIONS DURING EMBRYONIC DEVELOPMENT.

J. M. Salbaum[1], R. H. Finnell[2,1] and C. Kappen[1]. [1]*Center for Human Molecular Genetics, University of Nebraska Medical Center, Omaha, NE and* [2]*Institute for Biosciences and Technology, Texas A&M University System Health Science Center, Houston, TX.*

Congenital abnormalities associated with maternal diabetes include neural tube defects, cardiovascular malformations, and caudal regression/sacral agenesis, and are referred to as diabetic embryopathy. We found such defects can be phenocopied in Isl-1-transgenic mice. Isl-1 is essential for differentiation of motor neurons in the spinal cord and proper pancreatic development. This functional spectrum is similar to that of the HLXB9 gene, which is linked to human sacral agenesis (Currarino Syndrome). The parallel developmental phenotypes of HLXB9 mutations in humans and Isl-1 misexpression in mice imply that transcription factors from one cellular pathway can cause comparable pathogenesis in the developing embryo. These phenotypes are not a general property of homeobox transcription factors: classical Hox genes induce different phenotypes that may be modulated by nutrition. We have initiated a genome-wide search for genes regulated by Isl-1 to understand the mechanistic aspects how de-regulated Isl-1 expression can cause developmental defects. Using transgenic mice as tools for gene discovery and gene classification, we have identified target genes on mouse chromosome 9. We have now started to analyze regulatory elements in this gene cluster *in vivo*. Nature and location of these control elements suggest that Isl-1 is one part of a complex regulatory pattern. We submit that de-regulation of Isl-1 expression could be responsible for congenital defects found in human diabetic embryopathy, suggesting that metabolic factors contribute to the control of Isl-1 expression. To test this hypothesis, we have developed a method to screen large genomic regions for the presence of regulatory elements *in vitro* and *in vivo*. The identification of such elements will provide information on upstream factors that regulate Isl-1 expression and the influence of metabolic status on gene expression in diabetic embryopathy.

1871 EPIDERMAL GROWTH FACTOR RECEPTOR PATHWAY IN DEVELOPMENTAL TOXICITY: KNOCKOUT MODELS IN MECHANISTIC TOXICOLOGY RESEARCH.

B. D. Abbott and A. R. Buckalew. *Reproductive Toxicology Division, USEPA, Research Triangle Park, NC.*

Epidermal growth factor (EGF) and related factors regulate proliferation and differentiation of cells in many tissues and represent important signal transduction pathways in embryo/fetal development. The EGF receptor (EGFR) has six ligands (including EGF and transforming growth factor-alpha, TGF-alpha) with tissue-specific expression patterns. This pathway appears to be involved in the induction of cleft palate and hydronephrosis following exposure to 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD). TCDD exposure *in utero* alters proliferation of palatal and urinary tract epithelial cells and is associated with disrupted expression of EGFR, EGF and/or TGF-alpha. Transgenic knockout (KO) mice which do not express EGF, TGF-alpha or either growth factor (EGF+TGF) offer an interesting model for inquiry regarding the role of these peptides in mediating toxicity. Teratogenic responses in EGF KO, TGF KO, and EGF+TGF KO mice were evaluated following gestational exposure to TCDD. The tissue-specific dose-response profiles indicated that expression of EGF, TGF-alpha or both influenced the incidence and severity of teratogenic responses. For cleft palate, the absence of EGF muted the response, suggesting an EGF-mediated effect. In the urinary tract, the absence of EGF increased responsiveness and this may be related to effects of TCDD on the expression of TGF-alpha in ureteric epithelial cells. These transgenic models provide a means to discriminate the sensitivity of target tissues based on the role of specific ligand(s) in mediating the toxic response. Thus, transgenic models can help evaluate multiple components of complex, interactive pathways, such as those for signal transduction, and can provide important insight into mechanisms of toxicity. This abstract does not necessarily reflect EPA policy.

1872 HYPOTHESIS TESTING IN MALE REPRODUCTIVE TOXICOLOGY USING MUTANT MICE.

K. Boekelheide[1], M. E. Embree[1], H. A. Schoenfeld[1], R. J. Rasoulpour[1] and D. A. Gray[2]. [1]*Brown University, Providence, RI and* [2]*Ottawa Regional Cancer Centre, Ottawa, ON, Canada.*

Several different mutant mouse models have been used to test mechanisms by which male reproductive toxicants trigger germ cell apoptosis. The Fas system is a paracrine pro-apoptotic signaling pathway; in the testis, Fas ligand (FasL) is expressed by Sertoli cells and induces apoptosis of germ cells expressing Fas receptor. p53 is a transcription factor which modulates the expression of bcl-2 family members, Fas receptor, and other elements of the apoptotic machinery. To examine the possible interactions between the Fas system and p53, germ cell apoptosis was measured in deficient mice exposed to a germ cell toxicant (radiation) or a Sertoli cell toxicant (mono-(2-ethylhexyl)phthalate, MEHP). Double deficient mice lacking both FasL and p53 and p53 knockout mice were highly resistant to radiation-induced germ cell apoptosis, while FasL deficient mice were as sensitive as wild type mice to this injury. In contrast, upon exposure to MEHP, all of the deficient strains were protected compared to wild type. These results indicate that the apoptotic response to radiation is p53-dependent and FasL-independent while the apoptotic response to MEHP is at least partially dependent on both FasL and p53. A second set of experiments evaluated testicular injury in transgenic mice expressing both a normal endogenous ubiquitin and a dominant negative mutant human ubiquitin that prevents poly-ubiquitination and thus frustrates the processing of abnormal and short-lived proteins involved in signal transduction. When these transgenic mice were made cryptorchid, their testes were more sensitive to this heat-induced injury than wild type controls. These results identify the processing of abnormal and short-lived proteins as an important mechanism underlying the response to injury in the testis, and suggest that impaired activation of polyubiquitination-dependent

signal transduction pathways, such as the anti-apoptotic transcription factor NF-kB, could play a role in the increased sensitivity of the mutant ubiquitin mouse testis.

1873 USE OF GENE KNOCKOUTS TO ESTABLISH A MOLECULAR FRAMEWORK FOR TOXICANT-INDUCED OOCYTE APOPTOSIS IN MURINE AND HUMAN OVARIES.

J. L. Tilly. *Vincent Center for Reproductive Biology, Department of OB/GYN, Massachusetts General Hospital/Harvard Medical School, Boston, MA.* Sponsor: D. Shuey.

For many years my Lab. has studied the role of programmed cell death (PCD) or apoptosis in normal and pathological depletion of germ cells from the ovaries (Dev Biol 1999 217:1-13). A powerful approach to understanding how chemicals kill oocytes has been to examine the impact of "knocking out" PCD regulatory genes, including those encoding signaling molecules (acid sphingomyelinase or ASMase), integrators (Bcl-2 family members) and executioners (caspases), on toxicant-induced oocyte apoptosis in mice (Mol Endocrinol 2001 15:845-853). The evolutionary conservation of the findings is then tested by exposing human ovarian tissue grafted in immunodeficient mice to the same insult and evaluating human oocyte responses. Two examples of our work with gene knockouts in female reprotoxicology will be discussed. The first example describes our efforts to elucidate the intracellular mechanisms by which the widely-used anticancer drug, doxorubicin, activates oocyte apoptosis. These studies have shown that ASMase-generated ceramide, the pro-apoptotic Bcl-2 family member Bax, and the PCD executioner enzyme caspase-2 are needed for oocytes to die in response to this toxicant (Nature Med. 1997 3:1228-1232; Genes Dev 1998 12:1304-1314; Nature Med. 2000 6:1109-1114). The second example concerns the identification of PCD-related genomic targets for the aromatic hydrocarbon receptor (AHR) in oocytes that are required for the ovotoxic effects of polycyclic aromatic hydrocarbons (PAHs). A novel intracellular signaling pathway involving AHR-driven transcription of the gene encoding Bax in oocytes will be discussed in detail, along with results from parallel studies of human oocyte responses to PAH using a human ovarian xenograft model (Nature Genet 2001 28:in press). Collectively, these studies using gene knockout technologies have identified functionally important biochemical and genetic pathways in oocytes that, when perturbed by xenobiotics, trigger female germ cell death *via* apoptosis (supported by NIH R01-ES08430).

1874 THE USE OF KNOCKOUT MICE TO DISSOCIATE INDUCTION OF THE HEPATIC MICROSOMAL MIXED-FUNCTION OXIDASE (MFO) SYSTEM FROM INHIBITION OF THE 5-LIPOXYGENASE (5-LO) ENZYME.

W. P. Beierschmitt[1], J. D. McNeish[1], R. J. Griffiths[1], A. Nagahisa[2], M. Nakane[2], S. J. Schomaker[1] and D. E. Amacher[1]. *[1]Pfizer Global Research and Development, Groton, CT and [2]Pfizer Global Research and Development, Taketoyo, Japan.*

Leukotrienes (LTs) are biologically active metabolites of arachidonic acid (AA) that function in normal and pathophysiologic conditions. The initial step in LT biosynthesis is the ezymatic conversion of AA to LTA_4 by 5-LO. Initially developed to understand the role of LTs in inflammatory conditions, we tested 5-LO -/- mice in the collagen-induced arthritis assay. Since this assay is most effectively established in DBA/1 inbred mice, we developed a congenic strain of 5-LO -/- mice for phenotypic analysis by consecutive backcrossing for 10 generations onto the DBA/1 genetic background. This effort demonstrated that 5-LO deficient mice had reduced inflammatory responses in the collagen-induced arthritis assay. Since LTs have also been implicated in asthma, a variety of anti-LT therapies have been tested for efficacy in treating the disease. We found in preclinical testing that the 5-LO inhibitors zileuton (Abbott), CJ-11, 802 (Pfizer) and ZD2138 (Zeneca) all induce the hepatic microsomal MFO system of rodents. Since these three agents are structurally dissimilar, we hypothesized that MFO induction by 5-LO inhibitors could be pharmacologically-mediated. To test this hypothesis, male wild-type and 5-LO -/- mice were administered either CJ-11, 802 (200 mg/kg/day) or vehicle by oral gavage for 14 consecutive days. At necropsy, various indices of MFO induction (e.g. liver weight, cytochrome P450 content, and cytochrome c reductase) were measured and all were increased similarly in the treated wild-type and 5-LO -/- mice compared to corresponding controls. These results indicate that induction of the hepatic microsomal MFO system in rodents by 5-LO inhibitors is not related to altered LT status.
